Python Module Index 381

Index 383
Various parts of schemes were implemented by Volker Braun, David Joyner, David Kohel, Andrey Novoseltsev, and William Stein.

AUTHORS:

• David Kohel (2006-01-03): initial version
• William Stein (2006-01-05)
• William Stein (2006-01-20)
• Andrey Novoseltsev (2010-09-24): update due to addition of toric varieties.

• Scheme: A scheme whose datatype might not be defined in terms of algebraic equations: e.g. the Jacobian of a curve may be represented by means of a Scheme.

• AlgebraicScheme: A scheme defined by means of polynomial equations, which may be reducible or defined over a ring other than a field. In particular, the defining ideal need not be a radical ideal, and an algebraic scheme may be defined over Spec(R).

• AmbientSpaces: Most effective models of algebraic scheme will be defined not by generic gluings, but by embeddings in some fixed ambient space.

• AffineSpace: Affine spaces and their affine subschemes form the most important universal objects from which algebraic schemes are built. The affine spaces form universal objects in the sense that a morphism is uniquely determined by the images of its coordinate functions and any such images determine a well-defined morphism. By default affine spaces will embed in some ordinary projective space, unless it is created as an affine patch of another object.

• ProjectiveSpace: Projective spaces are the most natural ambient spaces for most projective objects. They are locally universal objects.

• ProjectiveSpace_ordinary (not implemented) The ordinary projective spaces have the standard weights [1, ..., 1] on their coefficients.

• ProjectiveSpace_weighted (not implemented) A special subtype for non-standard weights.

• ToricVariety: Toric varieties are (partial) compactifications of algebraic tori \((\mathbb{C}^*)^n\) compatible with torus action. Affine and projective spaces are examples of toric varieties, but it is not envisioned that these special cases should inherit from ToricVariety.

• AlgebraicScheme_subscheme_affine: An algebraic scheme defined by means of an embedding in a fixed ambient affine space.

• AlgebraicScheme_subscheme_projective: An algebraic scheme defined by means of an embedding in a fixed ambient projective space.
• **QuasiAffineScheme (not yet implemented):** An open subset $U = X \setminus Z$ of a closed subset $X$ of affine space; note that this is mathematically a quasi-projective scheme, but its ambient space is an affine space and its points are represented by affine rather than projective points.

**Note:** AlgebraicScheme_quasi is implemented, as a base class for this.

• **QuasiProjectiveScheme (not yet implemented):** An open subset of a closed subset of projective space; this datatype stores the defining polynomial, polynomials, or ideal defining the projective closure $X$ plus the closed subscheme $Z$ of $X$ whose complement $U = X \setminus Z$ is the quasi-projective scheme.

**Note:** The quasi-affine and quasi-projective datatype lets one create schemes like the multiplicative group scheme $\mathbb{G}_m = \mathbb{A}^1 \setminus \{(0)\}$ and the non-affine scheme $\mathbb{A}^2 \setminus \{(0,0)\}$. The latter is not affine and is not of the form $\text{Spec}(R)$.

1.1 **TODO List**

• **PointSets and points over a ring:** For algebraic schemes $X/S$ and $T/S$ over $S$, one can form the point set $X(T)$ of morphisms from $T \to X$ over $S$.

```
sage: PP.<X,Y,Z> = ProjectiveSpace(2, QQ)
sage: PP
Projective Space of dimension 2 over Rational Field
```

The first line is an abuse of language – returning the generators of the coordinate ring by `gens()`.

A projective space object in the category of schemes is a locally free object – the images of the generator functions `locally` determine a point. Over a field, one can choose one of the standard affine patches by the condition that a coordinate function $X_i \neq 0$

```
sage: PP(QQ)
Set of rational points of Projective Space
of dimension 2 over Rational Field
sage: PP(QQ)([-2,3,5])
(-2/5 : 3/5 : 1)
```

Over a ring, this is not true, e.g. even over an integral domain which is not a PID, there may be no single affine patch which covers a point.

```
sage: R.<x> = ZZ[]
sage: S.<t> = R.quo(x^2+5)
sage: P.<X,Y,Z> = ProjectiveSpace(2, S)
sage: P(S)
Set of rational points of Projective Space
of dimension 2 over Univariate Quotient Polynomial Ring in t over Integer Ring with modulus x^2 + 5
```

In order to represent the projective point $(2 : 1 + t) = (1 - t : 3)$ we note that the first representative is not well-defined at the prime $pp = (2, 1+t)$ and the second element is not well-defined at the prime $qq = (1-t,3)$, but that $pp + qq = (1)$, so globally the pair of coordinate representatives is well-defined.

```
sage: P( [2, 1+t] )
(2 : t + l : 1)
```
In fact, we need a test \( R.\text{ideal}([2,1+t]) == R.\text{ideal}([1]) \) in order to make this meaningful.
AUTHORS:

\begin{verbatim}
class sage.schemes.generic.scheme.AffineScheme(R, S=None, category=None)
Bases:    sage.structure.unique_representation.UniqueRepresentation, sage.schemes.generic.scheme.Scheme

Class for general affine schemes.

See also:

For affine spaces over a base ring and subschemes thereof, see \texttt{sage.schemes.generic.algebraic_scheme.AffineSpace}.

Element
    alias of \texttt{sage.schemes.generic.point.SchemeTopologicalPoint_prime_ideal}

base_extend(R)

Extend the base ring/scheme.

INPUT:
    \begin{itemize}
      \item \texttt{R} – an affine scheme or a commutative ring
    \end{itemize}

EXAMPLES:

\begin{verbatim}
sage: Spec_ZZ = Spec(ZZ); Spec_ZZ
Spectrum of Integer Ring
sage: Spec_ZZ.base_extend(QQ)
Spectrum of Rational Field

sage: Spec(ZZ['x']).base_extend(Spec(QQ))
Spectrum of Univariate Polynomial Ring in x over Rational Field
\end{verbatim}

coordinate_ring()

Return the underlying ring of this scheme.

OUTPUT:

A commutative ring.

EXAMPLES:

\end{verbatim}
```
sage: Spec(QQ).coordinate_ring()
Rational Field
sage: Spec(PolynomialRing(QQ, 3, 'x')).coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
```

**dimension()**

Return the absolute dimension of this scheme.

**OUTPUT:**

Integer.

**EXAMPLES:**

```
sage: S = Spec(ZZ)
sage: S.dimension_absolute()
1
sage: S.dimension()
1
```

**dimension_absolute()**

Return the absolute dimension of this scheme.

**OUTPUT:**

Integer.

**EXAMPLES:**

```
sage: S = Spec(ZZ)
sage: S.dimension_absolute()
1
sage: S.dimension()
1
```

**dimension_relative()**

Return the relative dimension of this scheme over its base.

**OUTPUT:**

Integer.

**EXAMPLES:**

```
sage: S = Spec(ZZ)
sage: S.dimension_relative()
0
```

**hom(x, Y=None)**

Return the scheme morphism from `self` to `Y` defined by `x`.

**INPUT:**

- `x` – anything that determines a scheme morphism; if `x` is a scheme, try to determine a natural map to `x`
- `Y` – the codomain scheme (optional); if `Y` is not given, try to determine `Y` from context
- `check` – boolean (optional, default: True); whether to check the defining data for consistency

**OUTPUT:**

The scheme morphism from `self` to `Y` defined by `x`. 

---

**Chapter 2. Schemes**
EXAMPLES:

We construct the inclusion from $\text{Spec}(\mathbb{Q})$ into $\text{Spec}(\mathbb{Z})$ induced by the inclusion from $\mathbb{Z}$ into $\mathbb{Q}$:

```python
sage: X = Spec(QQ)
sage: X.hom(ZZ.hom(QQ))
Affine Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Integer Ring
  Defn: Natural morphism:
        From: Integer Ring
        To:   Rational Field
```

```python
sage: X.hom(ZZ.hom(QQ))
```

A scheme is in the category of all schemes over its base:

```python
sage: ProjectiveSpace(4, QQ).category()
Category of schemes over Rational Field
```

There is a special and unique $\text{Spec}(\mathbb{Z})$ that is the default base scheme:

```python
sage: Spec(ZZ).base_scheme() is Spec(QQ).base_scheme()
True
```

**base_extend**($Y$)

Extend the base of the scheme.

Derived classes must override this method.

EXAMPLES:

```python
sage: from sage.schemes.generic.scheme import Scheme
sage: X = Scheme(ZZ)
sage: X.base_scheme()
```

(continues on next page)
sage: X.base_extend(QQ)
Traceback (most recent call last):
... 
NotImplementedError

base_morphism()
Return the structure morphism from self to its base scheme.

OUTPUT:
A scheme morphism.

EXAMPLES:

sage: A = AffineSpace(4, QQ)
sage: A.base_morphism()
Scheme morphism:
   From: Affine Space of dimension 4 over Rational Field
   To:   Spectrum of Rational Field
   Defn: Structure map

sage: X = Spec(QQ)
sage: X.base_morphism()
Scheme morphism:
   From: Spectrum of Rational Field
   To:   Spectrum of Integer Ring
   Defn: Structure map

base_ring()
Return the base ring of the scheme self.

OUTPUT:
A commutative ring.

EXAMPLES:

sage: A = AffineSpace(4, QQ)
sage: A.base_ring()
Rational Field

sage: X = Spec(QQ)
sage: X.base_ring()
Integer Ring

base_scheme()
Return the base scheme.

OUTPUT:
A scheme.

EXAMPLES:

sage: A = AffineSpace(4, QQ)
sage: A.base_scheme()
Spectrum of Rational Field

sage: X = Spec(QQ)
coordinate_ring()
Return the coordinate ring.

OUTPUT:
The global coordinate ring of this scheme, if defined. Otherwise raise a `ValueError`.

EXAMPLES:

```sage
R.<x, y> = QQ[]
I = (x^2 - y^2) + R
X = Spec(R.quotient(I))
X.coordinate_ring()
```

count_points(n)
Count points over finite fields.

INPUT:
- n – integer.

OUTPUT:
An integer. The number of points over $F_q, \ldots, F_{q^n}$ on a scheme over a finite field $F_q$.

EXAMPLES:

```sage
P.<x> = PolynomialRing(GF(3))
C = HyperellipticCurve(x^3+x^2+1)
C.count_points(4)
```

```sage
P.<x,y,z> = ProjectiveSpace(GF(4,'t'), 2)
X = P.subscheme([y^2- x^3 - z^3])
X.count_points(2)
```

dimension()
Return the absolute dimension of this scheme.

OUTPUT:
Integer.

EXAMPLES:

```sage
R.<x, y> = QQ[]
I = (x^2 - y^2) + R
X = Spec(R.quotient(I))
X.dimension_absolute()
Traceback (most recent call last):
...
NotImplementedError
```
**hom** *(x, Y=None, check=True)*

Return the scheme morphism from `self` to `Y` defined by `x`.

**INPUT:**

- `x` – anything that determines a scheme morphism; if `x` is a scheme, try to determine a natural map to `x`
- `Y` – the codomain scheme (optional); if `Y` is not given, try to determine `Y` from context
- `check` – boolean (optional, default: `True`); whether to check the defining data for consistency

**OUTPUT:**

The scheme morphism from `self` to `Y` defined by `x`.

**EXAMPLES:**
```python
sage: P = ProjectiveSpace(ZZ, 3)
sage: P.hom(Spec(ZZ))
Scheme morphism:
  From: Projective Space of dimension 3 over Integer Ring
  To:  Spectrum of Integer Ring
  Defn: Structure map

identity_morphism()
Return the identity morphism.

OUTPUT:
The identity morphism of the scheme self.

EXAMPLES:
```
sage: X = Spec(QQ)
sage: X.identity_morphism()
Scheme endomorphism of Spectrum of Rational Field
  Defn: Identity map

point (v, check=True)
Create a point.

INPUT:
- v – anything that defines a point
- check – boolean (optional, default: True); whether to check the defining data for consistency

OUTPUT:
A point of the scheme.

EXAMPLES:
```
sage: A2 = AffineSpace(QQ, 2)
sage: A2.point([4, 5])
(4, 5)
sage: R.<t> = PolynomialRing(QQ)
sage: E = EllipticCurve([t + 1, t, t, 0, 0])
sage: E.point([0, 0])
(0 : 0 : 1)
```

point_homset (S=None)
Return the set of S-valued points of this scheme.

INPUT:
- S – a commutative ring.

OUTPUT:
The set of morphisms $\text{Spec}(S) \circ X$.

EXAMPLES:
```
sage: P = ProjectiveSpace(ZZ, 3)
sage: P.point_homset(ZZ)
Set of rational points of Projective Space of dimension 3 over Integer Ring
sage: P.point_homset(QQ)
```
(continues on next page)
Set of rational points of Projective Space of dimension 3 over Rational Field
```
sage: P.point_homset(GF(11))
```
Set of rational points of Projective Space of dimension 3 over Finite Field of size 11

**point_set** (*S=None*)
Return the set of *S*-valued points of this scheme.

**INPUT:**
- *S* – a commutative ring.

**OUTPUT:**
The set of morphisms *Spec(S)oX*.

**EXAMPLES:**
```
sage: P = ProjectiveSpace(ZZ, 3)
sage: P.point_homset(ZZ)
Set of rational points of Projective Space of dimension 3 over Integer Ring

sage: P.point_homset(QQ)
Set of rational points of Projective Space of dimension 3 over Rational Field

sage: P.point_homset(GF(11))
Set of rational points of Projective Space of dimension 3 over Finite Field of size 11
```

**structure_morphism()**
Return the structure morphism from *self* to its base scheme.

**OUTPUT:**
A scheme morphism.

**EXAMPLES:**
```
sage: A = AffineSpace(4, QQ)
sage: A.base_morphism()
Scheme morphism:
  From: Affine Space of dimension 4 over Rational Field
  To:   Spectrum of Rational Field
  Defn: Structure map

sage: X = Spec(QQ)
sage: X.base_morphism()
Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Integer Ring
  Defn: Structure map
```

**union** (*X*)
Return the disjoint union of the schemes *self* and *X*.

**EXAMPLES:**
```
sage: S = Spec(QQ)
sage: X = AffineSpace(1, QQ)
sage: S.union(X)
Traceback (most recent call last):
```

... 
NotImplementedError

**zeta_function()**
Compute the zeta function of a generic scheme.
Derived classes should override this method.
OUTPUT: rational function in one variable.
EXAMPLES:

```sage
sage: P.<x,y,z> = ProjectiveSpace(GF(4,'t'), 2)
sage: X = P.subscheme([y^2*z - x^3 - z^3])
sage: X.zeta_function()
Traceback (most recent call last):
... 
NotImplementedError
```

**zeta_series***(n, t)**
Return the zeta series.
Compute a power series approximation to the zeta function of a scheme over a finite field.
INPUT:

- n – the number of terms of the power series to compute
- t – the variable which the series should be returned

OUTPUT:
A power series approximating the zeta function of self

EXAMPLES:

```sage
sage: P.<x> = PolynomialRing(GF(3))
sage: C = HyperellipticCurve(x^3+x^2+1)
sage: R.<t> = PowerSeriesRing(Integers())
sage: C.zeta_series(4,t)
1 + 6*t + 24*t^2 + 78*t^3 + 240*t^4 + O(t^5)
```

If the scheme has a method `zeta_function`, this is used to provide the required approximation. Otherwise this function depends on `count_points`, which is only defined for prime order fields for general schemes. Nonetheless, since trac ticket #15108 and trac ticket #15148, it supports hyperelliptic curves over non-prime fields:

```sage
sage: C.base_extend(GF(9,'a')).zeta_series(4,t)
1 + 12*t + 120*t^2 + 1092*t^3 + 9840*t^4 + O(t^5)
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(GF(4,'t'), 2)
sage: X = P.subscheme([y^2*z - x^3 - z^3])
sage: R.<t> = PowerSeriesRing(Integers())
sage: X.zeta_series(2,t)
1 + 5*t + 21*t^2 + O(t^3)
```

**sage.schemes.generic.scheme.is_AffineScheme***(x)**
Return True if x is an affine scheme.
EXEMPLARY:

```
sage: from sage.schemes.generic.scheme import is_AffineScheme
sage: is_AffineScheme(5)
False
sage: E = Spec(QQ)
sage: is_AffineScheme(E)
True
```

```
sage.schemes.generic.scheme.is_Scheme(x)
Test whether x is a scheme.

INPUT:
• x – anything.

OUTPUT:
Boolean. Whether x derives from Scheme.

EXEMPLARY:

```
sage: from sage.schemes.generic.scheme import is_Scheme
sage: is_Scheme(5)
False
sage: X = Spec(QQ)
sage: is_Scheme(X)
True
```
AUTHORS:

- William Stein (2006): initial implementation
- Peter Bruin (2014): rewrite Spec as a functor

```
sage.schemes.generic.spec.Spec(R, S=None)
```

Apply the Spec functor to $R$.

**INPUT:**

- $R$ – either a commutative ring or a ring homomorphism
- $S$ – a commutative ring (optional), the base ring

**OUTPUT:**

- `AffineScheme` – the affine scheme $\text{Spec}(R)$

**EXAMPLES:**

```
sage: Spec(QQ)
Spectrum of Rational Field
sage: Spec(PolynomialRing(QQ, 'x'))
Spectrum of Univariate Polynomial Ring in x over Rational Field
sage: Spec(PolynomialRing(QQ, 'x', 3))
Spectrum of Multivariate Polynomial Ring in x0, x1, x2 over Rational Field
sage: X = Spec(PolynomialRing(GF(49, 'a'), 3, 'x')); X
Spectrum of Multivariate Polynomial Ring in x0, x1, x2 over Finite Field in a of size 7^2
sage: TestSuite(X).run()
```

Applying `Spec` twice to the same ring gives identical output (see trac ticket #17008):

```
sage: A = Spec(ZZ); B = Spec(ZZ)
sage: A.is(B)
True
```

A `TypeError` is raised if the input is not a commutative ring:

```
sage: Spec(5)
Traceback (most recent call last):
...
TypeError: x (=5) is not in Category of commutative rings
sage: Spec(FreeAlgebra(QQ,2, 'x'))
Traceback (most recent call last):
...
```
class sage.schemes.generic.spec.SpecFunctor(base_ring=None)

Bases: sage.categories.functor.Functor, sage.structure.unique_representation.UniqueRepresentation

The Spec functor.
SCHEME OBTAINED BY GLUING TWO OTHER SCHEMES

```python
class sage.schemes.generic.glue.GluedScheme(f, g, check=True)
    Bases: sage.schemes.generic.scheme.Scheme
    INPUT:
    • f - open immersion from a scheme U to a scheme X
    • g - open immersion from U to a scheme Y
    OUTPUT: The scheme obtained by gluing X and Y along the open set U.

Note: Checking that f and g are open immersions is not implemented.

gluing_maps()
```
class sage.schemes.generic.point.SchemePoint(S, parent=None)
Bases: sage.structure.element.Element

Base class for points on a scheme, either topological or defined by a morphism.
scheme()
Return the scheme on which self is a point.

EXAMPLES:

```python
sage: from sage.schemes.generic.point import SchemePoint
sage: S = Spec(ZZ)
sage: P = SchemePoint(S)
sage: P.scheme()
Spectrum of Integer Ring
```

class sage.schemes.generic.point.SchemeRationalPoint(f)
Bases: sage.schemes.generic.point.SchemePoint

INPUT:

• $f$ - a morphism of schemes

morphism()

class sage.schemes.generic.point.SchemeTopologicalPoint(S)
Bases: sage.schemes.generic.point.SchemePoint

Base class for topological points on schemes.

class sage.schemes.generic.point.SchemeTopologicalPoint_affine_open(u, x)
Bases: sage.schemes.generic.point.SchemeTopologicalPoint

INPUT:

• $u$ – morphism with domain an affine scheme $U$
• $x$ – topological point on $U$

affine_open()
Return the affine open subset $U$.

embedding_of_affine_open()
Return the embedding from the affine open subset $U$ into this scheme.

point_on_affine()
Return the scheme point on the affine open $U$. 
class sage.schemes.generic.point.SchemeTopologicalPoint_prime_ideal(S, P, check=False)

Bases: sage.schemes.generic.point.SchemeTopologicalPoint

INPUT:

- S – an affine scheme
- P – a prime ideal of the coordinate ring of S, or anything that can be converted into such an ideal

prime_ideal()

Return the prime ideal that defines this scheme point.

EXAMPLES:

```python
sage: from sage.schemes.generic.point import SchemeTopologicalPoint_prime_ideal
sage: P2.<x, y, z> = ProjectiveSpace(2, QQ)
sage: pt = SchemeTopologicalPoint_prime_ideal(P2, y*z-x^2)
sage: pt.prime_ideal()
Ideal (-x^2 + y*z) of Multivariate Polynomial Ring in x, y, z over Rational Field
```

sage.schemes.generic.point.is_SchemeRationalPoint(x)
sage.schemes.generic.point.is_SchemeTopologicalPoint(x)
class sage.schemes.generic.ambient_space.AmbientSpace(n, R=Integer Ring)

Bases: sage.schemes.generic.scheme.Scheme

Base class for ambient spaces over a ring.

INPUT:

• n - dimension
• R - ring

ambient_space()

Return the ambient space of the scheme self, in this case self itself.

EXAMPLES:

sage: P = ProjectiveSpace(4, ZZ)
sage: P.ambient_space() is P
True
sage: A = AffineSpace(2, GF(3))
sage: A.ambient_space()
Affine Space of dimension 2 over Finite Field of size 3

base_extend(R)

Return the natural extension of self over R.

INPUT:

• R – a commutative ring, such that there is a natural map from the base ring of self to R.

OUTPUT:

• an ambient space over R of the same structure as self.

Note: A ValueError is raised if there is no such natural map. If you need to drop this condition, use self.change_ring(R).

EXAMPLES:

sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: PQ = P.base_extend(QQ); PQ
Projective Space of dimension 2 over Rational Field
sage: PQ.base_extend(GF(5))
Traceback (most recent call last):
...
ValueError: no natural map from the base ring (=Rational Field) to R (=Finite Field of size 5)!

change_ring(R)
Return an ambient space over ring $R$ and otherwise the same as self.

INPUT:
• $R$ – commutative ring

OUTPUT:
• ambient space over $R$

Note: There is no need to have any relation between $R$ and the base ring of self, if you want to have such a relation, use self.base_extend(R) instead.

defining_polynomials()
Return the defining polynomials of the scheme self. Since self is an ambient space, this is an empty list.

EXAMPLES:

sage: ProjectiveSpace(2, QQ).defining_polynomials()
()  
sage: AffineSpace(0, ZZ).defining_polynomials()
()

dimension()
Return the absolute dimension of this scheme.

EXAMPLES:

sage: A2Q = AffineSpace(2, QQ)  
sage: A2Q.dimension_absolute()  
2  
sage: A2Q.dimension()  
2  
sage: A2Z = AffineSpace(2, ZZ)  
sage: A2Z.dimension_absolute()  
3  
sage: A2Z.dimension()  
3

dimension_absolute()
Return the absolute dimension of this scheme.

EXAMPLES:

sage: A2Q = AffineSpace(2, QQ)  
sage: A2Q.dimension_absolute()  
2  
sage: A2Q.dimension()  
2  
sage: A2Z = AffineSpace(2, ZZ)  
sage: A2Z.dimension_absolute()  
3  
sage: A2Z.dimension()  
3
**dimension_relative()**
Return the relative dimension of this scheme over its base.

**EXAMPLES:**
```python
sage: A2Q = AffineSpace(2, QQ)
sage: A2Q.dimension_relative()
2
sage: A2Z = AffineSpace(2, ZZ)
sage: A2Z.dimension_relative()
2
```

**gen(n=0)**
Return the \(n\)-th generator of the coordinate ring of the scheme self.

**EXAMPLES:**
```python
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: P.gen(1)
y
```

**gens()**
Return the generators of the coordinate ring of the scheme self.

**EXAMPLES:**
```python
sage: AffineSpace(0, QQ).gens()
()sage: P.<x, y, z> = ProjectiveSpace(2, GF(5))
sage: P.gens()
(x, y, z)
```

**is_projective()**
Return whether this ambient space is projective \(n\)-space.

**EXAMPLES:**
```python
sage: AffineSpace(3, QQ).is_projective()
False
sage: ProjectiveSpace(3, QQ).is_projective()
True
```

**ngens()**
Return the number of generators of the coordinate ring of the scheme self.

**EXAMPLES:**
```python
sage: AffineSpace(0, QQ).ngens()
0
sage: ProjectiveSpace(50, ZZ).ngens()
51
```

sage.schemes.generic.ambient_space.is_AmbientSpace(x)
Return True if \(x\) is an ambient space.

**EXAMPLES:**
from sage.schemes.generic.ambient_space import is_AmbientSpace
is_AmbientSpace(ProjectiveSpace(3, ZZ))
True
is_AmbientSpace(AffineSpace(2, QQ))
True
P.<x, y, z> = ProjectiveSpace(2, ZZ)
is_AmbientSpace(P.subscheme([x+y+z]))
False
An algebraic scheme is defined by a set of polynomials in some suitable affine or projective coordinates. Possible ambient spaces are

- Affine spaces (AffineSpace),
- Projective spaces (ProjectiveSpace), or
- Toric varieties (ToricVariety).

Note that while projective spaces are of course toric varieties themselves, they are implemented differently in Sage due to efficiency considerations. You still can create a projective space as a toric variety if you wish.

In the following, we call the corresponding subschemes affine algebraic schemes, projective algebraic schemes, or toric algebraic schemes. In the future other ambient spaces, perhaps by means of gluing relations, may be introduced.

Generally, polynomials $p_0, p_1, \ldots, p_n$ define an ideal $I = \langle p_0, p_1, \ldots, p_n \rangle$. In the projective and toric case, the polynomials (and, therefore, the ideal) must be homogeneous. The associated subscheme $V(I)$ of the ambient space is, roughly speaking, the subset of the ambient space on which all polynomials vanish simultaneously.

**Warning:** You should not construct algebraic scheme objects directly. Instead, use `.subscheme()` methods of ambient spaces. See below for examples.

**EXAMPLES:**

We first construct the ambient space, here the affine space $\mathbb{A}^2$:

```python
sage: A2 = AffineSpace(2, QQ, 'x, y')
sage: A2.coordinate_ring().inject_variables()
Defining x, y
```

Now we can write polynomial equations in the variables $x$ and $y$. For example, one equation cuts out a curve (a one-dimensional subscheme):

```python
sage: V = A2.subscheme([x^2+y^2-1]); V
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x^2 + y^2 - 1
sage: V.dimension()
1
```

Here is a more complicated example in a projective space:
```
sage: P3 = ProjectiveSpace(3, QQ, 'x')
sage: P3.inject_variables()
Defining x0, x1, x2, x3
sage: Q = matrix([[x0, x1, x2], [x1, x2, x3]]).minors(2); Q
[-x1^2 + x0*x2, -x1*x2 + x0*x3, -x2^2 + x1*x3]
sage: twisted_cubic = P3.subscheme(Q)
sage: twisted_cubic
Closed subscheme of Projective Space of dimension 3
over Rational Field defined by:
-x1^2 + x0*x2,
-x1*x2 + x0*x3,
-x2^2 + x1*x3
sage: twisted_cubic.dimension()
1
```

Note that there are 3 equations in the 3-dimensional ambient space, yet the subscheme is 1-dimensional. One can show that it is not possible to eliminate any of the equations, that is, the twisted cubic is not a complete intersection of two polynomial equations.

Let us look at one affine patch, for example the one where $x_0 = 1$

```
sage: patch = twisted_cubic.affine_patch(0)
sage: patch
Closed subscheme of Affine Space of dimension 3
over Rational Field defined by:
-x1^2 + x2,
-x1*x2 + x3,
-x2^2 + x1*x3
sage: patch.embedding_morphism()
Scheme morphism:
From: Closed subscheme of Affine Space of dimension 3
over Rational Field defined by:
-x1^2 + x2,
-x1*x2 + x3,
-x2^2 + x1*x3
To:  Closed subscheme of Projective Space of dimension 3
over Rational Field defined by:
x1^2 - x0*x2,
x1*x2 - x0*x3,
x2^2 - x1*x3
Defn: Defined on coordinates by sending (x1, x2, x3) to
(1 : x1 : x2 : x3)
```

AUTHORS:

- Volker Braun (2010-12-24): documentation of schemes and refactoring. Added coordinate neighborhoods and is_smooth()
- Ben Hutz (2014): subschemes of Cartesian products of projective space
- Ben Hutz (2017): split subschemes types into respective folders

```python
class sage.schemes.generic.algebraic_scheme.AlgebraicScheme(A)
    Bases: sage.schemes.generic.scheme.Scheme
```
An algebraic scheme presented as a subscheme in an ambient space.

This is the base class for all algebraic schemes, that is, schemes defined by equations in affine, projective, or toric ambient spaces.

**ambient_space()**

Return the ambient space of this algebraic scheme.

**EXAMPLES:**

```python
sage: A.<x, y> = AffineSpace(2, GF(5))
sage: S = A.subscheme([])
sage: S.ambient_space()
Affine Space of dimension 2 over Finite Field of size 5
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x-y, x-z])
sage: S.ambient_space() is P
True
```

**coordinate_ring()**

Return the coordinate ring of this algebraic scheme. The result is cached.

**OUTPUT:**

The coordinate ring. Usually a polynomial ring, or a quotient thereof.

**EXAMPLES:**

```python
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x-y, x-z])
sage: S.coordinate_ring()
Quotient of Multivariate Polynomial Ring in x, y, z over Integer Ring by the ideal (x - y, x - z)
```

**embedding_center()**

Return the distinguished point, if there is any.

If the scheme \( Y \) was constructed as a neighbourhood of a point \( p \in X \), then \( \text{embedding_morphism()} \) returns a local isomorphism \( f : Y \to X \) around the preimage point \( f^{-1}(p) \). The latter is returned by \( \text{embedding_center()} \).

**OUTPUT:**

A point of \( self \). Raises \( AttributeError \) if there is no distinguished point, depending on how \( self \) was constructed.

**EXAMPLES:**

```python
sage: P3.<w,x,y,z> = ProjectiveSpace(QQ,3)
sage: X = P3.subscheme( (w^2-x^2)*(y^2-z^2) )
sage: p = [1,-1,3,4]
sage: nbhd = X.neighborhood(p); nbhd
Closed subscheme of Affine Space of dimension 3 over Rational Field defined by:

\[-w^2*y^2 + x^2*y^2 + 6*w^2*y - 6*x^2*y + 2*w*y^2 + 2*x*y^2 - 7*w^2 + 7*x^2 + 12*w*y + 12*x*y - 14*w - 14*x\]
sage: nbhd.embedding_center()
(0, 0, 0)
sage: nbhd.embedding_morphism()(nbhd.embedding_center())
(1/4 : -1/4 : 3/4 : 1)
```

(continues on next page)
sage: nbhd.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 3 over Rational Field
  \[\begin{align*}
  w^2+y^2 - x^2+2y + 6w^2+y - 6x^2+y + 2w+y^2 + \\
  2x^2+y^2 - 7w^2 + 7x^2 + 12w+y + 12x^2+y - 14w - 14x
\end{align*}\]
  To: Closed subscheme of Projective Space of dimension 3 over Rational Field
  \[\begin{align*}
  w^2+y^2 - x^2+y^2 - w^2z^2 + x^2z^2 + x^2z^2
\end{align*}\]
Defn: Defined on coordinates by sending (w, x, y) to
\[(w + 1 : x - 1 : y + 3 : 4)\]

**embedding_morphism()**

Return the default embedding morphism of self.

If the scheme \(Y\) was constructed as a neighbourhood of a point \(p \in X\), then `embedding_morphism()` returns a local isomorphism \(f: Y \to X\) around the preimage point \(f^{-1}(p)\). The latter is returned by `embedding_center()`.

If the algebraic scheme \(Y\) was not constructed as a neighbourhood of a point, then the embedding in its `ambient_space()` is returned.

**OUTPUT:**

A scheme morphism whose `domain()` is self.

- By default, it is the tautological embedding into its own ambient space `ambient_space()`.
- If the algebraic scheme (which itself is a subscheme of an auxiliary `ambient_space()`) was constructed as a patch or neighborhood of a point then the embedding is the embedding into the original scheme.
- A `NotImplementedError` is raised if the construction of the embedding morphism is not implemented yet.

**EXAMPLES:**

```python
sage: A2.<x,y> = AffineSpace(QQ, 2)
sage: C = A2.subscheme(x^2+y^2-1)
sage: C.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 2 over Rational Field
  \[\begin{align*}
  x^2 + y^2 - 1
\end{align*}\]
  To: Affine Space of dimension 2 over Rational Field
  Defn: Defined on coordinates by sending (x, y) to
  \[(x, y)\]

sage: P1xP1.<x,y,u,v> = toric_varieties.P1xP1()
sage: P1 = P1xP1.subscheme(x-y)
sage: P1.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of 2-d CPR-Fano toric variety covered by 4 affine patches defined by:
  \[x - y\]
  To: 2-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined on coordinates by sending [x : y : u : v] to
  [y : y : u : v]
```

So far, the embedding was just in the own ambient space. Now a bit more interesting examples:
```python
sage: P2.<x,y,z> = ProjectiveSpace(QQ,2)
sage: X = P2.subscheme((x^2-y^2)*z)
sage: p = (1,1,0)
sage: nbhd = X.neighborhood(p)
sage: nbhd
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
-y^2*z - 2*y*z

Note that \(p = (1,0,0)\) is a singular point of \(X\). So the neighborhood of \(p\) is not just affine space. The neighborhood() method returns a presentation of the neighborhood as a subscheme of an auxiliary 2-dimensional affine space:

```python
sage: nbhd.ambient_space()
Affine Space of dimension 2 over Rational Field
```

But its `embedding_morphism()` is not into this auxiliary affine space, but the original subscheme \(X\):

```python
sage: nbhd.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  \(-y^2*z - 2*y*z\)
  To:  Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  \(x^2*z - y^2*z\)
  Defn: Defined on coordinates by sending \((y, z)\) to
  \((1 : y + 1 : z)\)
```

A couple more examples:

```python
sage: patch1 = P1xP1.affine_patch(1)
sage: patch1
2-d affine toric variety
sage: patch1.embedding_morphism()
Scheme morphism:
  From: 2-d affine toric variety
  To:  2-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined on coordinates by sending \([y : u]\) to
  \([1 : y : u : 1]\)
sage: subpatch = P1.affine_patch(1)
sage: subpatch
Closed subscheme of 2-d affine toric variety defined by:
  \(-y + 1\)
sage: subpatch.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of 2-d affine toric variety defined by:
  \(-y + 1\)
  To:  Closed subscheme of 2-d CPR-Fano toric variety covered by 4 affine patches defined by:
  \(x - y\)
  Defn: Defined on coordinates by sending \([y : u]\) to
  \([1 : y : u : 1]\)
```

`is_projective()`

Return True if self is presented as a subscheme of an ambient projective space.

OUTPUT:
Boolean.

EXAMPLES:

```
sage: PP.<x,y,z,w> = ProjectiveSpace(3, QQ)
sage: f = x^3 + y^3 + z^3 + w^3
sage: R = f.parent()
sage: I = [f] + [f.derivative(zz) for zz in PP.gens()]
sage: V = PP.subscheme(I)
sage: V.is_projective()
True
sage: AA.<x,y,z,w> = AffineSpace(4, QQ)
sage: V = AA.subscheme(I)
sage: V.is_projective()
False
```

Note that toric varieties are implemented differently than projective spaces. This is why this method returns False for toric varieties:

```
sage: PP.<x,y,z,w> = toric_varieties.P(3)
sage: V = PP.subscheme(x^3 + y^3 + z^3 + w^3)
sage: V.is_projective()
False
```

ngens ()

Return the number of generators of the ambient space of this algebraic scheme.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, GF(5))
sage: S = A.subscheme([])
sage: S.ngens()
2
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x-y, x-z])
sage: P.ngens()
3
```

class sage.schemes.generic.algebraic_scheme.AlgebraicScheme_quasi(X, Y)

Bases: sage.schemes.generic.algebraic_scheme.AlgebraicScheme

The quasi-affine or quasi-projective scheme \( X - Y \), where \( X \) and \( Y \) are both closed subschemes of a common ambient affine or projective space.

**Warning:** You should not create objects of this class directly. The preferred method to construct such subschemes is to use `complement()` method of algebraic schemes.

**OUTPUT:**

An instance of `AlgebraicScheme_quasi`.

**EXAMPLES:**

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([])
sage: T = P.subscheme([x-y])
sage: T.complement(S)
```

(continues on next page)
Quasi-projective subscheme $X - Y$ of Projective Space of dimension 2 over Integer Ring, where $X$ is defined by:
(no polynomials)
and $Y$ is defined by:
$x - y$

$X()$
Return the scheme $X$ such that self is represented as $X - Y$.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([])
sage: T = P.subscheme([x-y])
sage: U = T.complement(S)
sage: U.X() is S
True
```

$Y()$
Return the scheme $Y$ such that self is represented as $X - Y$.

EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([])
sage: T = P.subscheme([x-y])
sage: U = T.complement(S)
sage: U.Y() is T
True
```

`rational_points(**kwds)`
Return the set of rational points on this algebraic scheme over the field $F$.

INPUT:

kwds:
- `bound` - integer (optional, default=0). The bound for the coordinates for subschemes with dimension at least 1.
- `F` - field (optional, default=base ring). The field to compute the rational points over.

EXAMPLES:

```
sage: A.<x, y> = AffineSpace(2, GF(7))
sage: S = A.subscheme([x^2-y])
sage: T = A.subscheme([x-y])
sage: U = T.complement(S)
sage: U.rational_points()
[(2, 4), (3, 2), (4, 2), (5, 4), (6, 1)]
sage: U.rational_points(F=GF(7^2, 'b'))
[(2, 4), (3, 2), (4, 2), (5, 4), (6, 1), (b, b + 4), (b + 1, 3*b + 5), (b + 2, 5*b + 1),
(b + 3, 6), (b + 4, 2*b + 6), (b + 5, 4*b + 1), (b + 6, 6*b + 5), (2*b, 4*b + 2),
(2*b + 1, b + 3), (2*b + 2, 5*b + 6), (2*b + 3, 2*b + 4), (2*b + 4, 6*b + 4),
(2*b + 5, 3*b + 6), (2*b + 6, 3), (3*b, 2*b + 1), (3*b + 1, b + 2), (3*b + 2, 5),
(3*b + 3, 6*b + 3), (3*b + 4, 5*b + 3), (3*b + 5, 4*b + 5), (3*b + 6, 3*b + 2), ...
```

(continues on next page)
class sage.schemes.generic.algebraic_scheme.AlgebraicScheme_subscheme(A, polynomials)

Bases: sage.schemes.generic.algebraic_scheme.AlgebraicScheme

An algebraic scheme presented as a closed subscheme is defined by explicit polynomial equations. This is as opposed to a general scheme, which could, e.g., be the Neron model of some object, and for which we do not want to give explicit equations.

INPUT:

- A - ambient space (e.g. affine or projective \( n \)-space)
- polynomials - single polynomial, ideal or iterable of defining polynomials; in any case polynomials must belong to the coordinate ring of the ambient space and define valid polynomial functions (e.g. they should be homogeneous in the case of a projective space)

OUTPUT:

- algebraic scheme

EXAMPLES:

```
sage: from sage.schemes.generic.algebraic_scheme import AlgebraicScheme_subscheme
sage: P.<x, y, z> = ProjectiveSpace(2, QQ)
sage: P.subscheme([x^2-y*z])
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x^2 - y*z
sage: AlgebraicScheme_subscheme(P, [x^2-y*z])
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x^2 - y*z
```

Jacobian()

Return the Jacobian ideal.

This is the ideal generated by

- the \( d \times d \) minors of the Jacobian matrix, where \( d \) is the \texttt{codimension()} of the algebraic scheme, and
- the defining polynomials of the algebraic scheme. Note that some authors do not include these in the definition of the Jacobian ideal. An example of a reference that does include the defining equations is \cite{LazarsfeldJacobian}.

OUTPUT:

An ideal in the coordinate ring of the ambient space.

REFERENCES:
EXAMPLES:

```python
sage: P3.<w,x,y,z> = ProjectiveSpace(3, QQ)
sage: twisted_cubic = P3.subscheme(matrix([[w, x, y],[x, y, z]]).minors(2))
sage: twisted_cubic.Jacobian()
Ideal (-x^2 + w*y, -x*y + w*z, -y^2 + x*z, x*z, -2*w*z, w*y, 3*w*y, -2*w*x, w^2, y*z, -2*x*z, w*z, 3*x*z, -2*w*z, w*y) of Multivariate Polynomial Ring in w, x, y, z over Rational Field
sage: twisted_cubic.defining_ideal()
Ideal (-x^2 + w*y, -x*y + w*z, -y^2 + x*z) of Multivariate Polynomial Ring in w, x, y, z over Rational Field

This example addresses ticket trac ticket #20512:

```python
sage: X = P3.subscheme([])
sage: X.Jacobian() == P3.coordinate_ring().unit_ideal()
True
```

```
Jacobian_matrix()
Return the matrix $\frac{\partial f}{\partial x_j}$ of (formal) partial derivatives.

OUTPUT:
A matrix of polynomials.

EXAMPLES:

```python
sage: P3.<w,x,y,z> = ProjectiveSpace(3, QQ)
sage: twisted_cubic = P3.subscheme(matrix([[w, x, y],[x, y, z]]).minors(2))
sage: twisted_cubic.Jacobian_matrix()
[ y -2*x w 0]
[ z -y -x w]
[ 0 z -2*y x]

This example addresses ticket trac ticket #20512:

```python
sage: X = P3.subscheme([])
sage: X.Jacobian_matrix().base_ring() == P3.coordinate_ring()
True
```

```
base_extend(R)
Return the base change to the ring $R$ of this scheme.

EXAMPLES:

```python
sage: P.<x, y, z> = ProjectiveSpace(2, GF(11))
sage: S = P.subscheme([x^2-y*z])
sage: S.base_extend(GF(11^2, 'b'))
Closed subscheme of Projective Space of dimension 2 over Finite Field in b of size 11^2 defined by: x^2 - y*z
sage: S.base_extend(ZZ)
Traceback (most recent call last):
  ... ValueError: no natural map from the base ring (=Finite Field of size 11) to R (=Integer Ring)!
```

```
change_ring(R)
Returns a new algebraic subscheme which is this subscheme coerced to $R$.
```
INPUT:

- \( R \) – ring or morphism.

OUTPUT:

- A new algebraic subscheme which is this subscheme coerced to \( R \).

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
```

```python
sage: X = P.subscheme([3*x^2-y^2])
```

```python
sage: H = Hom(X,X)
```

```python
sage: X.change_ring(GF(3))
```

Closed subscheme of Projective Space of dimension 1 over Finite Field of size 3 defined by:

\[-y^2\]

```
sage: K.<w> = QuadraticField(2)
sage: R.<z> = K[]
sage: L.<v> = K.extension(z^3-5)
sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: X = P.subscheme(x - w*y)
sage: X.change_ring(L)
```

Closed subscheme of Projective Space of dimension 1 over Number Field in \( v \) with defining polynomial \( z^3 - 5 \) over its base field defined by:

\[x + (-w)*y\]

```
sage: K.<w> = QuadraticField(2)
sage: R.<z> = K[]
sage: L.<v> = K.extension(z^3-5)
sage: P.<x,y,z> = AffineSpace(L,3)
sage: X = P.subscheme([x-w*y, z^2-v*x])
sage: emb = L.embeddings(QQbar)
sage: X.change_ring(emb[0])
```

Closed subscheme of Affine Space of dimension 3 over Algebraic Field defined by:

\[x + (-1.414213562373095? + 0.?e-16*I)*y, z^2 + (0.8549879733383485? + 1.48088260982365?*I)*x\]

```
sage: K.<w> = QuadraticField(-3)
sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: X = P.subscheme(x-w*y)
sage: X.change_ring(CC)
```

Closed subscheme of Projective Space of dimension 1 over Complex Field

(continues on next page)
with 53 bits of precision defined by:
\[ x + (-1.73205080756888*I) \cdot y \]

```
sage: K.<w> = QuadraticField(3)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: X = P.subscheme(x-w*y)
sage: X.change_ring(RR)
Closed subscheme of Projective Space of dimension 1 over Real Field
with 53 bits of precision defined by:
\[ x - 1.73205080756888*y \]
```

```
sage: K.<v> = CyclotomicField(7)
sage: O = K.maximal_order()
sage: P.<x,y> = ProjectiveSpace(O, 1)
sage: X = P.subscheme([x^2+O(v)*y^2])
sage: X.change_ring(CC)
Closed subscheme of Projective Space of dimension 1 over Complex Field
with 53 bits of precision defined by:
\[ x^2 + (0.623489801858734 + 0.781831482468030*I) \cdot y^2 \]
```

```
sage: R.<x> = QQ[]
sage: f = x^6-2
sage: L.<b> = NumberField(f, embedding=f.roots(CC)[2][0])
sage: A.<x,y> = AffineSpace(L, 2)
sage: H = Hom(A,A)
sage: X = A.subscheme([b*x^2, y^2])
sage: X.change_ring(CC)
Closed subscheme of Affine Space of dimension 2 over Complex Field
with 53 bits of precision defined by:
\[ (-0.561231024154687 - 0.972080648619833*I) \cdot x^2, y^2 \]
```

**codimension()**

Return the codimension of the algebraic subscheme.

**OUTPUT:**

Integer.

**EXAMPLES:**

```
sage: PP.<x,y,z,w,v> = ProjectiveSpace(4,QQ)
sage: V = PP.subscheme(x*y)
sage: V.codimension()
1
sage: V.dimension()
3
```

**complement**(other=None)

Return the scheme-theoretic complement other - self, where self and other are both closed algebraic subschemes of the same ambient space.

If other is unspecified, it is taken to be the ambient space of self.
EXAMPLES:

```python
sage: A.<x, y, z> = AffineSpace(3, ZZ)
sage: X = A.subscheme([x+y-z])
sage: Y = A.subscheme([x-y+z])
sage: Y.complement(X)
Quasi-affine subscheme X - Y of Affine Space of
dimension 3 over Integer Ring, where X is defined by:
  x + y - z
and Y is defined by:
  x - y + z
sage: Y.complement()
Quasi-affine subscheme X - Y of Affine Space of
dimension 3 over Integer Ring, where X is defined by:
  (no polynomials)
and Y is defined by:
  x - y + z
sage: P.<x, y, z> = ProjectiveSpace(2, QQ)
sage: X = P.subscheme([x^2+y^2+z^2])
sage: Y = P.subscheme([x*y+y*z+z*x])
sage: Y.complement(X)
Quasi-projective subscheme X - Y of Projective Space of
dimension 2 over Rational Field, where X is defined by:
  x^2 + y^2 + z^2
and Y is defined by:
  x*y + x*z + y*z
sage: Y.complement(P)
Quasi-projective subscheme X - Y of Projective Space of
dimension 2 over Rational Field, where X is defined by:
  (no polynomials)
and Y is defined by:
  x*y + x*z + y*z
```

```python
defining_ideal()
Return the ideal that defines this scheme as a subscheme of its ambient space.

OUTPUT:
An ideal in the coordinate ring of the ambient space.

EXAMPLES:

```python
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x^2-y*z, x^3+z^3])
sage: S.defining_ideal()
Ideal (x^2 - y*z, x^3 + z^3) of Multivariate Polynomial Ring in x, y, z over Integer Ring
```

```python
defining_polynomials()
Return the polynomials that define this scheme as a subscheme of its ambient space.

OUTPUT:
A tuple of polynomials in the coordinate ring of the ambient space.

EXAMPLES:

```python
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: S = P.subscheme([x^2-y*z, x^3+z^3])
```
intersection(\texttt{other})

Return the scheme-theoretic intersection of \texttt{self} and \texttt{other} in their common ambient space.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: A.<x, y> = AffineSpace(2, ZZ)
sage: X = A.subscheme([x^2-y])
sage: Y = A.subscheme([y])
sage: X.intersection(Y)
Closed subscheme of Affine Space of dimension 2 over Integer Ring defined by:
    x^2 - y,
y
\end{verbatim}

irreducible_components()

Return the irreducible components of this algebraic scheme, as subschemes of the same ambient space.

\textbf{OUTPUT:}

an immutable sequence of irreducible subschemes of the ambient space of this scheme

The components are cached.

\textbf{EXAMPLES:}

We define what is clearly a union of four hypersurfaces in \(\mathbb{P}^4\) over \(\mathbb{Q}\), then find the irreducible components:

\begin{verbatim}
sage: PP.<x,y,z,w,v> = ProjectiveSpace(4,QQ)
sage: V = PP.subscheme( (x^2 - y^2 - z^2)*(w^5 - 2*v^2*z^3)* w * (v^3 - x^2*z) )
sage: V.irreducible_components()
[Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
    w,
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
    x^2 - y^2 - z^2,
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
    x^2*z - v^3,
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
    w^5 - 2*z^3*v^2]
\end{verbatim}

We verify that the irrelevant ideal isn’t accidently returned (see trac ticket #6920):

\begin{verbatim}
sage: PP.<x,y,z,w> = ProjectiveSpace(3,QQ)
sage: I = [f] + [f.derivative(zz) for zz in PP.gens()]
sage: V = PP.subscheme(I)
sage: V.irreducible_components()
[ ]
\end{verbatim}
The same polynomial as above defines a scheme with a nontrivial irreducible component in affine space (instead of the empty scheme as above):

```
sage: AA.<x,y,z,w> = AffineSpace(4,QQ)
sage: V = AA.subscheme(I)
sage: V.irreducible_components()
[Closed subscheme of Affine Space of dimension 4 over Rational Field defined by:
  w, z, y, x]
```

**is_irreducible()**

Return whether this subscheme is or is not irreducible.

OUTPUT: Boolean.

EXAMPLES:

```
sage: K = QuadraticField(-3)
sage: P.<x,y,z,w,t,u> = ProjectiveSpace(K, 5)
sage: X = P.subscheme([x*y - z^2 - K.0*t^2, t*w*x + y*z^2 - u^3])
sage: X.is_irreducible()
True
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: X = P.subscheme([(y + x - z)^2])
sage: X.is_irreducible()
False
sage: A.<x,y,z,w> = AffineSpace(GF(17), 4)
sage: X = A.subscheme([x*y*z^2 - x*y*z*w - z*w^2 + w^3, x^3*y*z*w - x*y^3*z - x^2*y*z*w - x^2*w^3 + y^2*w^2 + x*w^3])
sage: X.is_irreducible()
False
```

**normalize_defining_polynomials()**

Function to normalize the coefficients of defining polynomials of given subscheme.

Normalization as in removing denominator from all the coefficients, and then removing any common factor between the coefficients. It takes LCM of denominators and then removes common factor among coefficients, if any.

EXAMPLES:

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: S = A.subscheme([2*x^2 + 4*x*y, 1/8*x + 1/3*y])
sage: S.normalize_defining_polynomials()
sage: S.defining_polynomials()
(x^2 + 2*x*y, 3*x + 8*y)
```

**rational_points(**kwds)**

Return the rational points on the algebraic subscheme.

For a dimension 0 subscheme, if the base ring is a numerical field such as the ComplexField the results
If the polynomials defining the subscheme are defined over a number field, you will get better results calling rational points with $F$ defined as the numerical field and the base ring as the field of definition. If the base ring is a number field, the embedding into $F$ must be known.

In the case of numerically approximated points, the points are returned over as points of the ambient space.

**INPUT:**

```
kwds:
  • bound - integer (optional, default=0). The bound for the coordinates for subschemes with dimension at least 1.
  • prec - integer (optional, default=53). The precision to use to compute the elements of bounded height for number fields.
  • F - field (optional, default=base ring). The field to compute the rational points over.
  • point_tolerance - positive real number (optional, default=10^(-10)). For numerically inexact fields, two points are considered the same if their coordinates are within tolerance.
  • zero_tolerance - positive real number (optional, default=10^(-10)). For numerically inexact fields, points are on the subscheme if they satisfy the equations to within tolerance.
  • tolerance - a rational number in (0,1] used in doyle-krumm algorithm
```

**OUTPUT:** list of points in subscheme or ambient space

**Warning:** For numerically inexact fields such as ComplexField or RealField the list of points returned is very likely to be incomplete at best.

**EXAMPLES:**

Enumerate over a projective scheme over a number field:

```
sage: u = QQ['u'].0
sage: K.<v> = NumberField(u^2 + 3)
sage: A.<x,y> = ProjectiveSpace(K,1)
sage: X=A.subscheme(x^2 - y^2)
sage: X.rational_points(bound=3)
[(-1 : 1), (1 : 1)]
```

One can enumerate points up to a given bound on a projective scheme over the rationals:

```
sage: E = EllipticCurve('37a')
sage: E.rational_points(bound=8)
[(-1 : -1 : 1), (-1 : 0 : 1), (0 : -1 : 1), (0 : 0 : 1), (0 : 1 : 0), (1/4 : -5/8 : 1),
(1/4 : -3/8 : 1), (1 : -1 : 1), (1 : 0 : 1), (2 : -3 : 1), (2 : 2 : 1)]
```

For a small finite field, the complete set of points can be enumerated.

```
sage: Etilde = E.base_extend(GF(3))
sage: Etilde.rational_points()
[(0 : 0 : 1), (0 : 1 : 0), (0 : 2 : 1), (1 : 0 : 1),
(1 : 2 : 1), (2 : 0 : 1), (2 : 2 : 1)]
```

The class of hyperelliptic curves does not (yet) support desingularization of the places at infinity into two points:
sage: FF = FiniteField(7)
sage: P.<x> = PolynomialRing(FiniteField(7))
sage: C = HyperellipticCurve(x^8+x+1)
sage: C.rational_points()
[(0 : 1 : 0), (0 : 1 : 1), (0 : 6 : 1), (2 : 0 : 1),
 (4 : 0 : 1), (6 : 1 : 1), (6 : 6 : 1)]

sage: K.<v> = QuadraticField(-3)
sage: P.<x,y,z> = ProjectiveSpace(K, 2)
sage: X = P.subscheme([x^2 - v^2*x*z, y*x-v*z^2])
sage: X.rational_points(F=CC)
[(-3.00000000000000 : -0.577350269189626*I : 1.00000000000000),
 (0.000000000000000 : 1.00000000000000 : 0.000000000000000)]

sage: K.<v> = QuadraticField(3)
sage: A.<x,y> = AffineSpace(K, 2)
sage: X = A.subscheme([x^2 - v^2*y, y*x-v])
sage: X.rational_points(F=RR)
[(1.73205080756888, 1.00000000000000)]

Todo: Implement Stoll’s model in weighted projective space to resolve singularities and find two points (1 : 1 : 0) and (-1 : 1 : 0) at infinity.

reduce()
Return the corresponding reduced algebraic space associated to this scheme.

EXAMPLES: First we construct the union of a doubled and tripled line in the affine plane over Q

sage: A.<x,y> = AffineSpace(2, QQ)
sage: X = A.subscheme([(x-1)^2*(x-y)^3]); X
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
x^5 - 3*x^4*y + 3*x^3*y^2 - x^2*y^3 - 2*x^4 + 6*x^3*y - 6*x^2*y^2 + 2*x*y^3 + x^3 - 3*x^2*y + 3*x*y^2 - y^3
sage: X.dimension()
1

Then we compute the corresponding reduced scheme:

sage: Y = X.reduce(); Y
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
x^2 - x*y - x + y

Finally, we verify that the reduced scheme Y is the union of those two lines:

sage: L1 = A.subscheme([x-1]); L1
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
x - 1
sage: L2 = A.subscheme([x-y]); L2
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
x - y
sage: W = L1.union(L2); W
# taken in ambient space

(continues on next page)
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
   \( x^2 - x*y - x + y \)
sage: Y == W
True

**specialization** *(D=None, phi=None)*

Specialization of this subscheme.

Given a family of maps defined over a polynomial ring. A specialization is a particular member of that family. The specialization can be specified either by a dictionary or a `SpecializationMorphism`.

**INPUT:**

- `D` – dictionary (optional)
- `phi` – `SpecializationMorphism` (optional)

**OUTPUT:** `SchemeMorphism_polynomial`

**EXAMPLES:**

```
sage: R.<c> = PolynomialRing(QQ)
sage: P.<x,y> = ProjectiveSpace(R, 1)
sage: X = P.subscheme([x^2 + c*y^2])
sage: X.specialization(dict({c:2}))
Closed subscheme of Projective Space of dimension 1 over Rational Field defined by:
   x^2 + 2*y^2
```

```
sage: R.<c> = PolynomialRing(QQ)
sage: S.<a,b> = R[]
sage: P.<x,y,z> = AffineSpace(S,3)
sage: X = P.subscheme([x^2+a*c*y^2 - b*z^2])
sage: from sage.rings.polynomial.flatten import SpecializationMorphism
sage: phi = SpecializationMorphism(P.coordinate_ring(),dict({c:2,a:1}))
sage: X.specialization(phi)
Closed subscheme of Affine Space of dimension 3 over Univariate Polynomial Ring in b over Rational Field defined by:
   x^2 + 2*y^2 + (-b)*z^2
```

**union**(other)

Return the scheme-theoretic union of self and other in their common ambient space.

**EXAMPLES:** We construct the union of a line and a tripled-point on the line.

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: I = ideal([x,y])^3
sage: P = A.subscheme(I)
sage: L = A.subscheme([y-1])
sage: S = L.union(P); S
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
   y^4 - y^3,
   x*y^3 - x*y^2,
   x^2*y^2 - x^2*y,
   x^3*y - x^3
sage: S.dimension()
(continues on next page)
```

(continues from previous page)
We can also use the notation “+” for the union:

```python
sage: A.subscheme([x]) + A.subscheme([y^2 - (x^3+1)])
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x^4 - x*y^2 + x
```

Saving and loading:

```python
sage: loads(S.dumps()) == S
True
```

### weil_restriction()

Compute the Weil restriction of this variety over some extension field. If the field is a finite field, then this computes the Weil restriction to the prime subfield.

A Weil restriction of scalars - denoted $\text{Res}_{L/k}$ - is a functor which, for any finite extension of fields $L/k$ and any algebraic variety $X$ over $L$, produces another corresponding variety $\text{Res}_{L/k}(X)$, defined over $k$. It is useful for reducing questions about varieties over large fields to questions about more complicated varieties over smaller fields.

This function does not compute this Weil restriction directly but computes on generating sets of polynomial ideals:

Let $d$ be the degree of the field extension $L/k$, let $a$ a generator of $L/k$ and $p$ the minimal polynomial of $L/k$. Denote this ideal by $I$.

Specifically, this function first maps each variable $x$ to its representation over $k$: $\sum_{i=0}^{d-1} a^i x_i$. Then each generator of $I$ is evaluated over these representations and reduced modulo the minimal polynomial $p$. The result is interpreted as a univariate polynomial in $a$ and its coefficients are the new generators of the returned ideal.

If the input and the output ideals are radical, this is equivalent to the statement about algebraic varieties above.

**OUTPUT:** Affine subscheme - the Weil restriction of self.

**EXAMPLES:**

```python
sage: R.<x> = QQ[]
sage: K.<w> = NumberField(x^5-2)
sage: R.<x> = K[]
sage: L.<v> = K.extension(x^2+1)
sage: A.<x,y> = AffineSpace(L,2)
sage: X = A.subscheme([y^2-L(w)*x^3-v])
sage: X.weil_restriction()
Closed subscheme of Affine Space of dimension 4 over Number Field in w with defining polynomial x^5 - 2 defined by:
  (-w)*z0^3 + (3*w)*z0*z1^2 + z2^2 - z3^2,
  (-3*w)*z0^2*z1 + (w)*z1^3 + 2*z2*z3 - 1
```
sage: X.weil_restriction().ambient_space() is A.weil_restriction()
True

sage: A.<x,y,z> = AffineSpace(GF(5^2,'t'),3)
sage: X = A.subscheme([y^2-x*z, z^2+2*y])
sage: X.weil_restriction()
Closed subscheme of Affine Space of dimension 6 over Finite Field of size 5 defined by:
  z2^2 - 2*z3^2 - z0*z4 + 2*z1*z5,
  2*z2*z3 + z3^2 - z1*z4 - z0*z5 - z1*z5,
  z4^2 - 2*z5^2 + 2*z2,
  2*z4*z5 + z5^2 + 2*z3

sage.schemes.generic.algebraic_scheme.is_AlgebraicScheme(x)
Test whether x is an algebraic scheme.

INPUT:
- x – anything.

OUTPUT:
Boolean. Whether x is an algebraic scheme, that is, a subscheme of an ambient space over a ring defined by polynomial equations.

EXAMPLES:

sage: A2 = AffineSpace(2, QQ, 'x, y')
sage: A2.coordinate_ring().inject_variables()
Defining x, y
sage: V = A2.subscheme([x^2+y^2]); V
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
  x^2 + y^2
sage: from sage.schemes.generic.algebraic_scheme import is_AlgebraicScheme
sage: is_AlgebraicScheme(V)
True

Affine space is itself not an algebraic scheme, though the closed subscheme defined by no equations is:

sage: from sage.schemes.generic.algebraic_scheme import is_AlgebraicScheme
sage: is_AlgebraicScheme(AffineSpace(10, QQ))
False
sage: V = AffineSpace(10, QQ).subscheme([[]]); V
Closed subscheme of Affine Space of dimension 10 over Rational Field defined by:
  (no polynomials)
sage: is_AlgebraicScheme(V)
True

We create a more complicated closed subscheme:

sage: A,x = AffineSpace(10, QQ).objgens()
sage: X = A.subscheme([sum(x)]); X
Closed subscheme of Affine Space of dimension 10 over Rational Field defined by:
  x0 + x1 + x2 + x3 + x4 + x5 + x6 + x7 + x8 + x9
sage: is_AlgebraicScheme(X)
True
\begin{verbatim}
sage: is_AlgebraicScheme(QQ)
False
sage: S = Spec(QQ)
\textbf{sage: } \text{is\_AlgebraicScheme}(S)
False
\end{verbatim}
CHAPTER

HYPERSURFACES IN AFFINE AND PROJECTIVE SPACE

AUTHORS:

- William Stein <wstein@gmail.com> (2005-12-08)
- David Kohel <kohel@maths.usyd.edu.au> (2005-12-08)
- Alex Ghitza <aghitza@alum.mit.edu> (2009-04-17)

```python
class sage.schemes.generic.hypersurface.AffineHypersurface (poly, ambient=None)
Bases: sage.schemes.affine.affine_subscheme.AlgebraicScheme_subscheme_affine

The affine hypersurface defined by the given polynomial.

EXAMPLES:

```sage```
A.<x, y, z> = AffineSpace(ZZ, 3)
AffineHypersurface(x*y-z^3, A)
```
Affine hypersurface defined by -z^3 + x*y in Affine Space of dimension 3 over Integer Ring

```sage```
A.<x, y, z> = QQ[]
AffineHypersurface(x*y-z^3)
```
Affine hypersurface defined by -z^3 + x*y in Affine Space of dimension 3 over Rational Field

defining_polynomial ()
Return the polynomial equation that cuts out this affine hypersurface.

EXAMPLES:

```sage```
R.<x, y, z> = ZZ[]
H = AffineHypersurface(x*z+y^2)
H.defining_polynomial()
y^2 + x*z
```

class sage.schemes.generic.hypersurface.ProjectiveHypersurface (poly, ambient=None)
Bases: sage.schemes.projective.projective_subscheme.AlgebraicScheme_subscheme_projective

The projective hypersurface defined by the given polynomial.

EXAMPLES:

```sage```
P.<x, y, z> = ProjectiveSpace(ZZ, 2)
ProjectiveHypersurface(x-y, P)
```
Projective hypersurface defined by x - y in Projective Space of dimension 2 over Integer Ring
sage: R.<x, y, z> = QQ[]  
sage: ProjectiveHypersurface(x-y)  
Projective hypersurface defined by $x - y$ in Projective Space of dimension 2 over $\mathbb{Q}$

**defining_polynomial()**

Return the polynomial equation that cuts out this projective hypersurface.

EXAMPLES:

```
sage: R.<x, y, z> = ZZ[]  
sage: H = ProjectiveHypersurface(x*z+y^2)  
sage: H.defining_polynomial()  
y^2 + x*z
```

`sage.schemes.generic.hypersurface.is_Hypersurface(self)`

Return True if self is a hypersurface, i.e. an object of the type ProjectiveHypersurface or AffineHypersurface.

EXAMPLES:

```
sage: from sage.schemes.generic.hypersurface import is_Hypersurface  
sage: R.<x, y, z> = ZZ[]  
sage: H = ProjectiveHypersurface(x*z+y^2)  
sage: is_Hypersurface(H)  
True

sage: H = AffineHypersurface(x*z+y^2)  
sage: is_Hypersurface(H)  
True

sage: H = ProjectiveSpace(QQ, 5)  
sage: is_Hypersurface(H)  
False
```
For schemes $X$ and $Y$, this module implements the set of morphisms $\text{Hom}(X, Y)$. This is done by \texttt{SchemeHomset\_generic}.

As a special case, the Hom-sets can also represent the points of a scheme. Recall that the $K$-rational points of a scheme $X$ over $k$ can be identified with the set of morphisms $\text{Spec}(K) \rightarrow X$. In Sage the rational points are implemented by such scheme morphisms. This is done by \texttt{SchemeHomset\_points} and its subclasses.

**Note:** You should not create the Hom-sets manually. Instead, use the \texttt{\texttt{Hom}} method that is inherited by all schemes.

**AUTHORS:**

- Volker Braun (2011-08-11): significant improvement and refactoring.
- Ben Hutz (June 2012): added support for projective ring

```python
class sage.schemes.generic.homset.SchemeHomsetFactory
    Bases: sage.structure.factory.UniqueFactory

Factory for Hom-sets of schemes.
```

**EXAMPLES:**

```python
sage: A2 = AffineSpace(QQ,2)
sage: A3 = AffineSpace(QQ,3)
sage: Hom = A3.Hom(A2)
```

The Hom-sets are uniquely determined by domain and codomain:

```python
sage: Hom is copy(Hom)
True
sage: Hom is A3.Hom(A2)
True
```

The Hom-sets are identical if the domains and codomains are identical:

```python
sage: loads(Hom.dumps()) is Hom
True
sage: A3_iso = AffineSpace(QQ,3)
sage: A3_iso is A3
True
sage: Hom_iso = A3_iso.Hom(A2)
sage: Hom_iso is Hom
True
```
create_key_and_extra_args(X, Y, category=None, base=Integer Ring, check=True, as_point_homset=False)

Create a key that uniquely determines the Hom-set.

INPUT:

- X – a scheme. The domain of the morphisms.
- Y – a scheme. The codomain of the morphisms.
- category – a category for the Hom-sets (default: schemes over given base).
- base – a scheme or a ring. The base scheme of domain and codomain schemes. If a ring is specified, the spectrum of that ring will be used as base scheme.
- check – boolean (default: True).

EXAMPLES:

```sage
A2 = AffineSpace(QQ,2)
A3 = AffineSpace(QQ,3)
A3.Hom(A2)  # indirect doctest
Set of morphisms
From: Affine Space of dimension 3 over Rational Field
To: Affine Space of dimension 2 over Rational Field
sage: from sage.schemes.generic.homset import SchemeHomsetFactory
sage: SHOMfactory = SchemeHomsetFactory('test')
sage: key, extra = SHOMfactory.create_key_and_extra_args(A3,A2,check=False)
sage: key
(..., ..., Category of schemes over Integer Ring, False)
sage: extra
{'X': Affine Space of dimension 3 over Rational Field,
 'Y': Affine Space of dimension 2 over Rational Field,
 'base_ring': Integer Ring,
 'check': False}
```

create_object(version, key, **extra_args)

Create a SchemeHomset_generic.

INPUT:

- key – a key created by create_key_and_extra_args().
- extra_args – a dictionary of extra keyword arguments.

EXAMPLES:

```sage
A2 = AffineSpace(QQ,2)
A3 = AffineSpace(QQ,3)
A3.Hom(A2) is A3.Hom(A2)  # indirect doctest
True
sage: from sage.schemes.generic.homset import SchemeHomsetFactory
sage: SHOMfactory = SchemeHomsetFactory('test')
sage: SHOMfactory.create_object(0, [id(A3), id(A2), A3.category(), False],
....: check=True, X=A3, Y=A2, base_ring=QQ)
Set of morphisms
From: Affine Space of dimension 3 over Rational Field
To: Affine Space of dimension 2 over Rational Field
```
class sage.schemes.generic.homset.SchemeHomset_generic(X, Y, category=None, check=True, base=None)

Bases: sage.categories.homset.HomsetWithBase

The base class for Hom-sets of schemes.

INPUT:

• X – a scheme. The domain of the Hom-set.
• Y – a scheme. The codomain of the Hom-set.
• category – a category (optional). The category of the Hom-set.
• check – boolean (optional, default=True). Whether to check the defining data for consistency.

EXAMPLES:

sage: from sage.schemes.generic.homset import SchemeHomset_generic
sage: A2 = AffineSpace(QQ,2)
sage: Hom = SchemeHomset_generic(A2, A2); Hom
Set of morphisms
From: Affine Space of dimension 2 over Rational Field
To: Affine Space of dimension 2 over Rational Field
sage: Hom.category()
Category of endsets of schemes over Rational Field

natural_map()

Return a natural map in the Hom space.

OUTPUT:

A SchemeMorphism if there is a natural map from domain to codomain. Otherwise, a
NotImplementedError is raised.

EXAMPLES:

sage: A = AffineSpace(4, QQ)
sage: A.structure_morphism()  # indirect doctest
Scheme morphism:
From: Affine Space of dimension 4 over Rational Field
To: Spectrum of Rational Field
Defn: Structure map

class sage.schemes.generic.homset.SchemeHomset_points(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.generic.homset.SchemeHomset_generic

Set of rational points of the scheme.

Recall that the \( K \)-rational points of a scheme \( X \) over \( k \) can be identified with the set of morphisms \( \text{Spec}(K) \circ X \). In Sage, the rational points are implemented by such scheme morphisms.

If a scheme has a finite number of points, then the homset is supposed to implement the Python iterator interface. See SchemeHomset_points_toric_field for example.

INPUT:

See SchemeHomset_generic.

EXAMPLES:
sage: from sage.schemes.generic.homset import SchemeHomset_points
sage: SchemeHomset_points(Spec(QQ), AffineSpace(ZZ,2))
Set of rational points of Affine Space of dimension 2 over Rational Field

cardinality()
Return the number of points.

OUTPUT:
An integer or infinity.

EXAMPLES:

sage: toric_varieties.P2().point_set().cardinality()
+Infinity
sage: P2 = toric_varieties.P2(base_ring=GF(3))
sage: P2.point_set().cardinality()
13

extended_codomain()
Return the codomain with extended base, if necessary.

OUTPUT:
The codomain scheme, with its base ring extended to the codomain. That is, the codomain is of the form $\text{Spec}(R)$ and the base ring of the domain is extended to $R$.

EXAMPLES:

sage: P2 = ProjectiveSpace(QQ,2)
sage: K.<a> = NumberField(x^2 + x - (3^3-3))
sage: K_points = P2(K); K_points
Set of rational points of Projective Space of dimension 2 over Number Field in a with defining polynomial $x^2 + x - 24$

sage: K_points.codomain()
Projective Space of dimension 2 over Rational Field
sage: K_points.extended_codomain()
Projective Space of dimension 2 over Number Field in a with
defining polynomial $x^2 + x - 24$

list()
Return a tuple containing all points.

OUTPUT:
A tuple containing all points of the toric variety.

EXAMPLES:

sage: P1 = toric_varieties.P1(base_ring=GF(3))
sage: P1.point_set().list()
([0 : 1], [1 : 0], [1 : 1], [1 : 2])

value_ring()
Return $R$ for a point Hom-set $X(\text{Spec}(R))$.

OUTPUT:
A commutative ring.

EXAMPLES:

```python
sage: P2 = ProjectiveSpace(ZZ,2)
sage: P2(QQ).value_ring()
Rational Field
```

```python
sage.schemes.generic.homset.is_SchemeHomset(H)
Test whether $H$ is a scheme Hom-set.

EXAMPLES:

```python
sage: f = Spec(QQ).identity_morphism(); f
Scheme endomorphism of Spectrum of Rational Field
  Defn: Identity map
sage: from sage.schemes.generic.homset import is_SchemeHomset
sage: is_SchemeHomset(f)
False
sage: is_SchemeHomset(f.parent())
True
sage: is_SchemeHomset('a string')
False
```
Note: You should never create the morphisms directly. Instead, use the \texttt{hom()} and \texttt{Hom()} methods that are inherited by all schemes.

If you want to extend the Sage library with some new kind of scheme, your new class (say, \texttt{myscheme}) should provide a method

- \texttt{myscheme._morphism(*args, **kwds)} returning a morphism between two schemes in your category, usually defined via polynomials. Your morphism class should derive from \texttt{SchemeMorphism_polynomial}. These morphisms will usually be elements of the Hom-set \texttt{SchemeHomset_generic}.

Optionally, you can also provide a special Hom-set class for your subcategory of schemes. If you want to do this, you should also provide a method

- \texttt{myscheme._homset(*args, **kwds)} returning a Hom-set, which must be an element of a derived class of \texttt{SchemeHomset_generic}. If your new Hom-set class does not use \texttt{myscheme._morphism} then you do not have to provide it.

Note that points on schemes are morphisms $\text{Spec}(K) \to X$, too. But we typically use a different notation, so they are implemented in a different derived class. For this, you should implement a method

- \texttt{myscheme._point(*args, **kwds)} returning a point, that is, a morphism $\text{Spec}(K) \to X$. Your point class should derive from \texttt{SchemeMorphism_point}.

Optionally, you can also provide a special Hom-set for the points, for example the point Hom-set can provide a method to enumerate all points. If you want to do this, you should also provide a method

- \texttt{myscheme._point_homset(*args, **kwds)} returning the \texttt{homset} of points. The Hom-sets of points are implemented in classes named \texttt{SchemeHomset_points_...}. If your new Hom-set class does not use \texttt{myscheme._point} then you do not have to provide it.

AUTHORS:

- David Kohel, William Stein
- William Stein (2006-02-11): fixed bug where P(0,0,0) was allowed as a projective point.
- Volker Braun (2011-08-08): Renamed classes, more documentation, misc cleanups.
- Ben Hutz (June 2012): added support for projective ring
- Simon King (2013-10): copy the changes of \texttt{Morphism} that have been introduced in trac ticket #14711.

\begin{class}
\texttt{sage.schemes.generic.morphism.SchemeMorphism} (parent, codomain=None)
\end{class}
Bases: \texttt{sage.structure.element.Element}
Base class for scheme morphisms
INPUT:

- parent – the parent of the morphism.

Todo: For historical reasons, SchemeMorphism copies code from Map rather than inheriting from it. Proper inheritance should be used instead. See trac ticket #14711.

EXAMPLES:

```
sage: X = Spec(ZZ)
sage: Hom = X.Hom(X)
sage: from sage.schemes.generic.morphism import SchemeMorphism
sage: f = SchemeMorphism(Hom)
sage: type(f)
<class 'sage.schemes.generic.morphism.SchemeMorphism'>
```

category()
Return the category of the Hom-set.

OUTPUT:
A category.

EXAMPLES:

```
sage: A2 = AffineSpace(QQ,2)
sage: A2.structure_morphism().category()
Category of homsets of schemes
```

category_for()
Return the category which this morphism belongs to.

EXAMPLES:

```
sage: A2 = AffineSpace(QQ,2)
sage: A2.structure_morphism().category_for()
Category of schemes
```

glue_along_domains(other)
Glue two morphism

INPUT:

- other – a scheme morphism with the same domain.

OUTPUT:

Assuming that self and other are open immersions with the same domain, return scheme obtained by gluing along the images.

EXAMPLES:

We construct a scheme isomorphic to the projective line over Spec(Q) by gluing two copies of \( \mathbb{A}^1 \) minus a point:

```
sage: R.<x,y> = PolynomialRing(QQ, 2)
sage: S.<xbar, ybar> = R.quotient(x*y - 1)
sage: Rx = PolynomialRing(QQ, 'x')
sage: ll = Rx.hom([xbar])
sage: Ry = PolynomialRing(QQ, 'y')
```
Now \( f_1 \) and \( f_2 \) have the same domain, which is a \( \mathbb{A}^1 \) minus a point. We glue along the domain:

\[
\begin{align*}
sage: & \quad P1 = f1.glue_along_domains(f2) \\
sage: & \quad a, b = P1.gluing_maps()
\end{align*}
\]

\( a \) and \( b \) are Affine Scheme morphisms:

\[
\begin{align*}
\text{a:} & \quad \text{Affine Scheme morphism:} \\
& \text{From: Spectrum of Quotient of Multivariate Polynomial Ring in x, y over Rational Field} \\
& \text{To: Spectrum of Univariate Polynomial Ring in x over Rational Field} \\
& \text{Defn: Ring morphism:} \\
& \quad \text{From: Univariate Polynomial Ring in x over Rational Field} \\
& \quad \text{To: Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x*y - 1)} \\
& \quad \text{Defn: x |--> xbar}
\end{align*}
\]

\[
\begin{align*}
\text{b:} & \quad \text{Affine Scheme morphism:} \\
& \text{From: Spectrum of Quotient of Multivariate Polynomial Ring in x, y over Rational Field} \\
& \text{To: Spectrum of Univariate Polynomial Ring in y over Rational Field} \\
& \text{Defn: Ring morphism:} \\
& \quad \text{From: Univariate Polynomial Ring in y over Rational Field} \\
& \text{To: Quotient of Multivariate Polynomial Ring in x, y over Rational Field by the ideal (x*y - 1)} \\
& \quad \text{Defn: y |--> ybar}
\end{align*}
\]

**is_endomorphism()**

Return wether the morphism is an endomorphism.

**OUTPUT:**

Boolean. Whether the domain and codomain are identical.

**EXAMPLES:**

\[
\begin{align*}
sage: & \quad X = AffineSpace(QQ,2) \\
sage: & \quad X.structure_morphism().is_endomorphism() \\
& \quad \text{False} \\
sage: & \quad X.identity_morphism().is_endomorphism() \\
& \quad \text{True}
\end{align*}
\]

**class** `sage.schemes.generic.morphism.SchemeMorphism_id(X)`

**Bases:** `sage.schemes.generic.morphism.SchemeMorphism`

Return the identity morphism from \( X \) to itself.

**INPUT:**
• $X$ – the scheme.

**EXAMPLES:**

```python
sage: X = Spec(ZZ)
sage: X.identity_morphism()  # indirect doctest
Scheme endomorphism of Spectrum of Integer Ring
  Defn: Identity map
```

```python
class sage.schemes.generic.morphism.SchemeMorphism_point(parent, codomain=None)

Bases: sage.schemes.generic.morphism.SchemeMorphism

Base class for rational points on schemes.

Recall that the $K$-rational points of a scheme $X$ over $k$ can be identified with the set of morphisms $Spec(K)oX$. In Sage, the rational points are implemented by such scheme morphisms.

**EXAMPLES:**

```python
sage: from sage.schemes.generic.morphism import SchemeMorphism
sage: f = SchemeMorphism(Spec(ZZ).Hom(Spec(ZZ)))
sage: type(f)
<class 'sage.schemes.generic.morphism.SchemeMorphism'>
```

```python
change_ring(R, check=True)

Returns a new **SchemeMorphism_point** which is this point coerced to `R`.

If check is true, then the initialization checks are performed.

**INPUT:**

• $R$ – ring or morphism.

**kwds:**

• *check* – Boolean

**OUTPUT:** **SchemeMorphism_point**

**EXAMPLES:**

```python
class sage.schemes.generic.morphism.SchemeMorphism_point

sage: P.<x,y,z> = ProjectiveSpace(ZZ, 2)
sage: X = P.subscheme(x^2-y^2)
sage: X(23,23,1).change_ring(GF(13))
(10 : 10 : 1)
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: P(-2/3,1).change_ring(CC)
(-0.666666666666667 : 1.00000000000000)
sage: P.<x,y> = ProjectiveSpace(ZZ,1)
sage: P(152,113).change_ring(Zp(5))
(2 + 5^2 + 5^3 + O(5^20) : 3 + 2*5 + 4*5^2 + O(5^20))
sage: K.<v> = QuadraticField(-7)
sage: O = K.maximal_order()
sage: P.<x,y> = ProjectiveSpace(O, 1)
sage: H = End(P)
sage: F = H([x^2+O(v)*y^2, y^2])
sage: F.change_ring(K).change_ring(K.embeddings(QQbar)[0])
```

(continues on next page)
Scheme endomorphism of Projective Space of dimension 1 over Algebraic Field
Defn: Defined on coordinates by sending (x : y) to
(x^2 + (-2.645751311064591?*I)*y^2 : y^2)

sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^2-x+1)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: Q = P([a+1,1])

sage: emb = K.embeddings(QQbar)
sage: Q.change_ring(emb[0])
(1.5000000000000000? - 0.866025403784439?*I : 1)
sage: Q.change_ring(emb[1])
(1.5000000000000000? + 0.866025403784439?*I : 1)

sage: K.<v> = QuadraticField(2)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: Q = P([v,1])
sage: Q.change_ring(K.embeddings(QQbar)[0])
(-1.414213562373095? : 1)

sage: R.<x> = QQ[]
sage: f = x^6-2
sage: L.<b> = NumberField(f, embedding=f.roots(QQbar)[1][0])
sage: A.<x,y> = AffineSpace(L,2)
sage: P = A([b,1])
sage: P.change_ring(QQbar)
(1.122462048309373?, 1)

scheme()
Return the scheme whose point is represented.

OUTPUT:
A scheme.

EXAMPLES:

sage: A = AffineSpace(2, QQ)
sage: a = A(1,2)
sage: a.scheme()
Affine Space of dimension 2 over Rational Field

specialization(D=None, phi=None, ambient=None)
Specialization of this point.
Given a family of points defined over a polynomial ring. A specialization is a particular member of that family. The specialization can be specified either by a dictionary or a SpecializationMorphism.

INPUT:
• D – dictionary (optional)
• phi – SpecializationMorphism (optional)
• ambient – ambient space of specialized point (optional)

OUTPUT: SchemeMorphism_polynomial

EXAMPLES:
class sage.schemes.generic.morphism.SchemeMorphism_polynomial(parent, polys, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism

A morphism of schemes determined by polynomials that define what the morphism does on points in the ambient space.

INPUT:

- parent – Hom-set whose domain and codomain are affine or projective schemes.
- polys – a list/tuple/iterable of polynomials defining the scheme morphism.
- check – boolean (optional, default:True). Whether to check the input for consistency.

EXAMPLES:
An example involving the affine plane:

```python
sage: R.<x,y> = QQ[]
sage: A2 = AffineSpace(R)
sage: H = A2.Hom(A2)
sage: f = H([x-y, x*y])
sage: f([0,1])
(-1, 0)
```

An example involving the projective line:

```python
sage: R.<x,y> = QQ[]
sage: P1 = ProjectiveSpace(R)
sage: H = P1.Hom(P1)
sage: f = H([x^2+y^2, x*y])
sage: f([0,1])
(1 : 0)
```

Some checks are performed to make sure the given polynomials define a morphism:

```python
sage: f = H([exp(x),exp(y)])
Traceback (most recent call last):
  ...  TypeError: polys (=[e^x, e^y]) must be elements of
  Multivariate Polynomial Ring in x, y over Rational Field
```

`base_ring()`

Return the base ring of `self`, that is, the ring over which the coefficients of `self` is given as polynomials.

**OUTPUT:**

- ring

**EXAMPLES:**

```python
sage: P.<x,y>=ProjectiveSpace(QQ,1)
sage: H=Hom(P,P)
sage: f=H([3/5*x^2, 6*y^2])
sage: f.base_ring()
Rational Field
```

```python
sage: R.<t>=PolynomialRing(ZZ,1)
sage: P.<x,y>=ProjectiveSpace(R,1)
sage: H=Hom(P,P)
sage: f=H([3*x^2, y^2])
sage: f.base_ring()
Multivariate Polynomial Ring in t over Integer Ring
```

`change_ring(R, check=True)`

Returns a new `SchemeMorphism_polynomial` which is this map coerced to `R`.

If `check` is `True`, then the initialization checks are performed.

**INPUT:**

- `R` – ring or morphism.
- `check` – Boolean

**OUTPUT:**
A new SchemeMorphism_polynomial which is this map coerced to $R$.

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(ZZ, 1)
sage: H = Hom(P,P)
sage: f = H([3*x^2, y^2])
sage: f.change_ring(GF(3))
Traceback (most recent call last):
  ... ValueError: polys (=[0, y^2]) must be of the same degree
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: H = Hom(P,P)
sage: f = H([5/2*x^3 + 3*x*y^2-y^3, 3*z^3 + y*x^2, x^3-z^3])
sage: f.change_ring(GF(3))
Scheme endomorphism of Projective Space of dimension 2 over Finite Field of size 3
  Defn: Defined on coordinates by sending (x : y : z) to
        (x^3 - y^3 : x^2*y : x^3 - z^3)
```

```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: X = P.subscheme([5*x^2 - y^2])
sage: H = Hom(X,X)
sage: f = H([x, y])
sage: f.change_ring(GF(3))
Scheme endomorphism of Closed subscheme of Projective Space of dimension 1 over Finite Field of size 3 defined by:
-\x^2 + \y^2
  Defn: Defined on coordinates by sending (\x : \y) to
        (\x : \y)
```

Check that trac ticket #16834 is fixed:

```python
sage: A.<x,y,z> = AffineSpace(RR, 3)
sage: h = Hom(A,A)
sage: f = h([x^2+1.5, y^3, z^5-2.0])
sage: f.change_ring(CC)
Scheme endomorphism of Affine Space of dimension 3 over Complex Field with 53 bits of precision
  Defn: Defined on coordinates by sending (x, y, z) to
        (x^2 + 1.50000000000000, y^3, z^5 - 2.00000000000000)
```

```python
sage: A.<x,y> = ProjectiveSpace(ZZ, 1)
sage: B.<u,v> = AffineSpace(QQ, 2)
sage: h = Hom(A,B)
sage: f = h([x^2, y^2])
sage: f.change_ring(QQ)
Scheme morphism:
  From: Projective Space of dimension 1 over Rational Field
  To:   Affine Space of dimension 2 over Rational Field
  Defn: Defined on coordinates by sending (x : y) to
        (x^2, y^2)
```

```python
sage: A.<x,y> = AffineSpace(QQ,2)
sage: H = Hom(A,A)
sage: f = H([3*x^2/y, y^2/x])
```

(continues on next page)
sage: f.change_ring(RR)
Scheme endomorphism of Affine Space of dimension 2 over Real Field with
53 bits of precision
Defn: Defined on coordinates by sending (x, y) to
(3.000000000000000000000000000000*x^2/y, y^2/x)

sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^3-x+1)
sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: H = End(P)
sage: f = H([x^2 + a*x*y + a^2*y^2, y^2])
sage: emb = K.embeddings(QQbar)
sage: f.change_ring(emb[0])
Scheme endomorphism of Projective Space of dimension 1 over Algebraic
Field
Defn: Defined on coordinates by sending (x : y) to
(x^2 + (-1.324717957244746?)x*y + 1.754877666246693?*y^2 : y^2)
sage: f.change_ring(emb[1])
Scheme endomorphism of Projective Space of dimension 1 over Algebraic
Field
Defn: Defined on coordinates by sending (x : y) to
(x^2 + (0.6623589786223730? - 0.5622795120623013(?)*I)*x*y +

sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: X = P.subscheme(x-y)
sage: H = End(X)
sage: f = H([6*x^2+2*x*y+16*y^2, -w*x^2-4*x*y-4*y^2])
sage: f.change_ring(QQbar)
Scheme endomorphism of Closed subscheme of Projective Space of dimension
1 over Algebraic Field defined by:
x - y
Defn: Defined on coordinates by sending (x : y) to
(6*x^2 + 2*x*y + 16*y^2 : 1.414213562373095?*x^2 + (-4)*x*y + (-4)*y^2
-2)

sage: R.<x> = QQ[]
sage: f = x^6-2
sage: L.<b> = NumberField(f, embedding=f.roots(QQbar)[1][0])
sage: A.<x,y> = AffineSpace(L,2)
sage: H = Hom(A, A)
sage: F = H([b*x/y, 1+y])
sage: F.change_ring(QQbar)
Scheme endomorphism of Affine Space of dimension 2 over Algebraic Field
  Defn: Defined on coordinates by sending (x, y) to
        (1.122462048309373?*x/y, y + 1)

sage: K.<a> = QuadraticField(-1)
sage: A.<x,y> = AffineSpace(K, 2)
sage: H = End(A)
sage: phi = H([x/y, y])
sage: emb = K.embeddings(QQbar)[0]
sage: phi.change_ring(emb)
Scheme endomorphism of Affine Space of dimension 2 over Algebraic Field
  Defn: Defined on coordinates by sending (x, y) to
        (x/y, y)

coordinate_ring()
  Returns the coordinate ring of the ambient projective space the multivariable polynomial ring over the base ring

OUTPUT:
  • ring

EXAMPLES:

sage: P.<x,y>=ProjectiveSpace(QQ,1)
sage: H=Hom(P,P)
sage: f=H([3/5*x^2,6*y^2])
sage: f.coordinate_ring()
Multivariate Polynomial Ring in x, y over Rational Field

sage: R.<t>=PolynomialRing(ZZ,1)
sage: P.<x,y>=ProjectiveSpace(R,1)
sage: H=Hom(P,P)
sage: f=H([3*x^2,y^2])
sage: f.coordinate_ring()
Multivariate Polynomial Ring in x, y over Multivariate Polynomial Ring in t over Integer Ring

defining_polynomials()
  Return the defining polynomials.

OUTPUT:
  An immutable sequence of polynomials that defines this scheme morphism.

EXAMPLES:

sage: R.<x,y> = QQ[]
sage: A.<x,y> = AffineSpace(R)
sage: H = A.Hom(A)
sage: H([x^3+y, 1-x-y]).defining_polynomials()
(x^3 + y, -x - y + 1)

specialization(D=None, phi=None, homset=None)
  Specialization of this map.

Given a family of maps defined over a polynomial ring. A specialization is a particular member of that family. The specialization can be specified either by a dictionary or a SpecializationMorphism.
INPUT:

- \( D \) – dictionary (optional)
- \( \phi \) – SpecializationMorphism (optional)
- \( \text{homset} \) – homset of specialized map (optional)

OUTPUT: \texttt{SchemeMorphism\_polynomial}

EXAMPLES:

```python
sage: R.<c> = PolynomialRing(QQ)
sage: P.<x,y> = ProjectiveSpace(R, 1)
sage: H = End(P)
sage: f = H([x^2 + c*y^2, y^2])
sage: f.specialization({c:1})
Scheme endomorphism of Projective Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending (x : y) to
(x^2 + y^2 : y^2)
```

```python
sage: R.<a,b> = PolynomialRing(QQ)
sage: P.<x,y> = ProjectiveSpace(R, 1)
sage: H = End(P)
sage: f = H([x^3 + a*x*y^2 + b*y^3, y^3])
sage: from sage.rings.polynomial.flatten import SpecializationMorphism
sage: phi = SpecializationMorphism(P.coordinate_ring(), dict({a:2,b:-1}))
sage: F = f.specialization(phi=phi); F
Scheme endomorphism of Projective Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending (x : y) to
(x^3 + 2*x*y^2 - y^3 : y^3)
```

```python
sage: R.<c> = PolynomialRing(QQ)
sage: P.<x,y> = ProjectiveSpace(R, 1)
sage: X = P.subscheme([x - c*y])
sage: H = End(X)
sage: f = H([x^2, c*y^2])
sage: f.specialization({c:2})
Scheme endomorphism of Closed subscheme of Projective Space of dimension 1 over Rational Field defined by:
\(-x + 2*y\)
Defn: Defined on coordinates by sending (x : y) to
(x^2 : 2*y^2)
```

```python
sage: R.<c> = QQ[]
sage: P.<x,y> = ProjectiveSpace(R,1)
sage: f = DynamicalSystem_projective([x^2 + c*y^2, y^2], domain=P)
sage: F = f.dynatomic_polynomial(3)
sage: g = F.specialization({c:1}); g
x^6 + x^5*y + 4*x^4*y^2 + 3*x^3*y^3 + 7*x^2*y^4 + 4*x*y^5 + 5*y^6
sage: g == f.specialization({c:1}).dynatomic_polynomial(3)
True
```
class sage.schemes.generic.morphism.SchemeMorphism_spec(parent, phi, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism

Morphism of spectra of rings

INPUT:

- parent – Hom-set whose domain and codomain are affine schemes.
- phi – a ring morphism with matching domain and codomain.
- check – boolean (optional, default:True). Whether to check the input for consistency.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: phi = R.hom([QQ(7)]); phi
Ring morphism:
  From: Univariate Polynomial Ring in x over Rational Field
  To:   Rational Field
  Defn: x |--> 7

sage: X = Spec(QQ); Y = Spec(R)
sage: f = X.hom(phi); f
Affine Scheme morphism:
  From: Spectrum of Rational Field
  To:   Spectrum of Univariate Polynomial Ring in x over Rational Field
  Defn: Ring morphism:
        From: Univariate Polynomial Ring in x over Rational Field
        To:   Rational Field
        Defn: x |--> 7

sage: f.ring_homomorphism()
Ring morphism:
  From: Univariate Polynomial Ring in x over Rational Field
  To:   Rational Field
  Defn: x |--> 7
```

ring_homomorphism()

Return the underlying ring homomorphism.

OUTPUT:

A ring homomorphism.

EXAMPLES:

```
sage: R.<x> = PolynomialRing(QQ)
sage: phi = R.hom([QQ(7)])
sage: X = Spec(QQ); Y = Spec(R)
sage: f = X.hom(phi)
sage: f.ring_homomorphism()
Ring morphism:
  From: Univariate Polynomial Ring in x over Rational Field
  To:   Rational Field
  Defn: x |--> 7
```

class sage.schemes.generic.morphism.SchemeMorphism_structure_map(parent, codomain=None)

Bases: sage.schemes.generic.morphism.SchemeMorphism

The structure morphism
INPUT:

• parent – Hom-set with codomain equal to the base scheme of the domain.

EXAMPLES:

```python
sage: Spec(ZZ).structure_morphism()  # indirect doctest
Scheme endomorphism of Spectrum of Integer Ring
  Defn: Structure map
```

```python
sage.schemes.generic.morphism.is_SchemeMorphism(f)
```
Test whether f is a scheme morphism.

INPUT:

• f – anything.

OUTPUT:

Boolean. Return True if f is a scheme morphism or a point on an elliptic curve.

EXAMPLES:

```python
sage: A.<x,y> = AffineSpace(QQ,2); H = A.Hom(A)
sage: f = H([y,x^2+y]); f
Scheme endomorphism of Affine Space of dimension 2 over Rational Field
  Defn: Defined on coordinates by sending (x, y) to
         (y, x^2 + y)
sage: from sage.schemes.generic.morphism import is_SchemeMorphism
sage: is_SchemeMorphism(f)
True
```
DIVISORS ON SCHEMES

AUTHORS:

- William Stein
- David Kohel
- David Joyner

EXAMPLES:

```python
sage: x,y,z = ProjectiveSpace(2, GF(5), names='x,y,z').gens()
sage: C = Curve(y^2*z^7 - x^9 - x*z^8)
sage: pts = C.rational_points(); pts
[(0 : 0 : 1), (0 : 1 : 0), (2 : 2 : 1), (2 : 3 : 1), (3 : 1 : 1), (3 : 4 : 1)]
sage: D1 = C.divisor(pts[0])*3
sage: D2 = C.divisor(pts[1])
sage: D3 = 10*C.divisor(pts[5])
sage: D = D1 - D2 + D3; D
3*(x, y) - (x, z) + 10*(x + 2*z, y + z)
sage: D[1][0] -1
sage: D[1][1]
Ideal (x, z) of Multivariate Polynomial Ring in x, y, z over Finite Field of size 5
```

```python
sage.schemes.generic.divisor.CurvePointToIdeal(C, P)

Return the vanishing ideal of a point on a curve.

EXAMPLES:

```python
sage: x,y = AffineSpace(2, QQ, names='xy').gens()
sage: C = Curve(y^2 - x^9 - x)
sage: from sage.schemes.generic.divisor import CurvePointToIdeal
sage: CurvePointToIdeal(C, (0,0))
Ideal (x, y) of Multivariate Polynomial Ring in x, y over Rational Field
```

```python
class sage.schemes.generic.divisor.Divisor_curve(v, parent=None, check=True, reduce=True)

Bases: sage.schemes.generic.divisor.Divisor_generic

For any curve $C$, use $C$.divisor($v$) to construct a divisor on $C$. Here $v$ can be either

- a rational point on $C$
```
• a list of rational points
• a list of 2-tuples \((c, P)\), where \(c\) is an integer and \(P\) is a rational point.

TODO: Divisors shouldn’t be restricted to rational points. The problem is that the divisor group is the formal sum of the group of points on the curve, and there’s no implemented notion of point on \(E/K\) that has coordinates in \(L\). This is what should be implemented, by adding an appropriate class to \texttt{schemes/generic/morphism.py}.

EXAMPLES:

```python
sage: E = EllipticCurve([0, 0, 1, -1, 0])
sage: P = E(0,0)
sage: 10*P
(161/16 : -2065/64 : 1)
sage: D = E.divisor(P)
sage: D
(x, y)
sage: 10*D
10*(x, y)
sage: E.divisor([P, P])
2*(x, y)
sage: E.divisor([(3,P), (-4,5*P)])
3*(x, y) - 4*(x - 1/4*z, y + 5/8*z)
```

\texttt{coefficient\(\)} \(P\)

Return the coefficient of a given point \(P\) in this divisor.

EXAMPLES:

```python
sage: x,y = AffineSpace(2, GF(5), names='xy').gens()
sage: C = Curve(y^2 - x^9 - x)
sage: pts = C.rational_points(); pts
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: D = C.divisor(pts[0])
sage: D.coefficient(pts[0])
1
sage: D = C.divisor([[(3,pts[0]), (-1,pts[1])]])
D
3*(x, y) - 4*(x - 1/4*z, y + 5/8*z)
sage: D.coefficient(pts[0])
3
sage: D.coefficient(pts[1])
-1
```

\texttt{support\(\)}

Return the support of this divisor, which is the set of points that occur in this divisor with nonzero coefficients.

EXAMPLES:

```python
sage: x,y = AffineSpace(2, GF(5), names='xy').gens()
sage: C = Curve(y^2 - x^9 - x)
sage: pts = C.rational_points(); pts
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: D = C.divisor_group()([(3,pts[0]), (-1,pts[1])])); D
3*(x, y) - 4*(x - 1/4*z, y + 5/8*z)
sage: D.support()
[(0, 0), (2, 2)]
```
class sage.schemes.generic.divisor.Divisor_generic(v, parent, check=True, reduce=True)

Bases: sage.structure.formal_sum.FormalSum

A Divisor.

scheme()

Return the scheme that this divisor is on.

EXAMPLES:

sage: A.<x, y> = AffineSpace(2, GF(5))
sage: C = Curve(y^2 - x^9 - x)
sage: pts = C.rational_points(); pts
[(0, 0), (2, 2), (2, 3), (3, 1), (3, 4)]
sage: D = C.divisor(pts[0])*3 - C.divisor(pts[1]); D
3*(x, y) - (x - 2, y - 2)
sage: D.scheme()
Affine Plane Curve over Finite Field of size 5 defined by -x^9 + y^2 - x

sage.schemes.generic.divisor.is_Divisor(x)

Test whether x is an instance of Divisor_generic

INPUT:

• x – anything.

OUTPUT:

True or False.

EXAMPLES:

sage: from sage.schemes.generic.divisor import is_Divisor
sage: x,y = AffineSpace(2, GF(5), names='xy').gens()
sage: C = Curve(y^2 - x^9 - x)
sage: is_Divisor( C.divisor([]) )
True
sage: is_Divisor("Ceci n'est pas un diviseur")
False
AUTHORS:

- David Kohel (2006): Initial version

```
sage.schemes.generic.divisor_group.DivisorGroup(scheme, base_ring=None)
```

Return the group of divisors on the scheme.

**INPUT:**

- `scheme` – a scheme.
- `base_ring` – usually either \( \mathbb{Z} \) (default) or \( \mathbb{Q} \). The coefficient ring of the divisors. Not to be confused with the base ring of the scheme!

**OUTPUT:**

An instance of `DivisorGroup_generic`.

**EXAMPLES:**

```
sage: from sage.schemes.generic.divisor_group import DivisorGroup
sage: DivisorGroup(Spec(ZZ))
Group of ZZ-Divisors on Spectrum of Integer Ring
sage: DivisorGroup(Spec(ZZ), base_ring=QQ)
Group of QQ-Divisors on Spectrum of Integer Ring
```

```
class sage.schemes.generic.divisor_group.DivisorGroup_curve(scheme, base_ring)
```

Bases: `sage.schemes.generic.divisor_group.DivisorGroup_generic`

Special case of the group of divisors on a curve.

```
class sage.schemes.generic.divisor_group.DivisorGroup_generic(scheme, base_ring)
```

Bases: `sage.structure.formal_sum/FormalSums`

The divisor group on a variety.

```
base_extend(R)
```

**EXAMPLES:**

```
sage: from sage.schemes.generic.divisor_group import DivisorGroup
sage: DivisorGroup(Spec(ZZ),ZZ).base_extend(QQ)
Group of QQ-Divisors on Spectrum of Integer Ring
sage: DivisorGroup(Spec(ZZ),ZZ).base_extend(GF(7))
Group of (Finite Field of size 7)-Divisors on Spectrum of Integer Ring
```

Divisor groups are unique:
sage: A.<x, y> = AffineSpace(2, CC)
sage: C = Curve(y^2 - x^9 - x)
sage: DivisorGroup(C, ZZ).base_extend(QQ) is DivisorGroup(C, QQ)
True

scheme()
Return the scheme supporting the divisors.

EXAMPLES:

sage: from sage.schemes.generic.divisor_group import DivisorGroup
sage: Div = DivisorGroup(Spec(ZZ))  # indirect test
sage: Div.scheme()
Spectrum of Integer Ring

sage.schemes.generic.divisor_group.is_DivisorGroup(x)
Return whether \( x \) is a \texttt{DivisorGroup\_generic}.

INPUT:

• \( x \) – anything.

OUTPUT:

True or False.

EXAMPLES:

sage: from sage.schemes.generic.divisor_group import is_DivisorGroup, DivisorGroup
sage: Div = DivisorGroup(Spec(ZZ), base_ring=QQ)
sage: is_DivisorGroup(Div)
True
sage: is_DivisorGroup('not a divisor')
False
13.1 Affine $n$ space over a ring

Return affine space of dimension $n$ over the ring $R$.

EXAMPLES:

The dimension and ring can be given in either order:

```
sage: AffineSpace(3, QQ, 'x')
Affine Space of dimension 3 over Rational Field

sage: AffineSpace(5, QQ, 'x')
Affine Space of dimension 5 over Rational Field

sage: A = AffineSpace(2, QQ, names='XY'); A
Affine Space of dimension 2 over Rational Field

sage: A.coordinate_ring()
Multivariate Polynomial Ring in X, Y over Rational Field
```

Use the divide operator for base extension:

```
sage: AffineSpace(5, names='x')/GF(17)
Affine Space of dimension 5 over Finite Field of size 17
```

The default base ring is $\mathbb{Z}$:

```
sage: AffineSpace(5, names='x')
Affine Space of dimension 5 over Integer Ring
```

There is also an affine space associated to each polynomial ring:

```
sage: R = GF(7)['x, y, z']
sage: A = AffineSpace(R); A
Affine Space of dimension 3 over Finite Field of size 7

sage: A.coordinate_ring() is R
True
```

class `sage.schemes.affine.affine_space.AffineSpace_field`($n$, $R$, names, ambient_projective_space=None, default_embedding_index=None)

Bases: `sage.schemes.affine.affine_space.AffineSpace_generic`
curve ($F$)

Return a curve defined by $F$ in this affine space.

**INPUT:**

- $F$ – a polynomial, or a list or tuple of polynomials in the coordinate ring of this affine space.

**EXAMPLES:**

```
sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: A.curve([y - x^4, z - y^5])
Affine Curve over Rational Field defined by -x^4 + y, -y^5 + z
```

points_of_bounded_height (**kwds**)

Returns an iterator of the points in this affine space of absolute height of at most the given bound.

Bound check is strict for the rational field. Requires this space to be affine space over a number field. Uses the Doyle-Krumm algorithm 4 (algorithm 5 for imaginary quadratic) for computing algebraic numbers up to a given height [Doyle-Krumm].

The algorithm requires floating point arithmetic, so the user is allowed to specify the precision for such calculations. Additionally, due to floating point issues, points slightly larger than the bound may be returned. This can be controlled by lowering the tolerance.

**INPUT:**

kwds:

- `bound` - a real number
- `tolerance` - a rational number in (0,1] used in doyle-krumm algorithm-4
- `precision` - the precision to use for computing the elements of bounded height of number fields

**OUTPUT:**

- an iterator of points in self

**EXAMPLES:**

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: list(A.points_of_bounded_height(bound=3))
[(0, 0), (1, 0), (-1, 0), (1/2, 0), (-1/2, 0), (2, 0), (-2, 0), (0, 1),
 (1, 1), (-1, 1), (1/2, 1), (-1/2, 1), (2, 1), (-2, 1), (0, -1), (1, -1),
 (-1, -1), (1/2, -1), (-1/2, -1), (2, -1), (-2, -1), (0, 1/2), (1, 1/2),
 (-1, 1/2), (1/2, 1/2), (-1/2, 1/2), (2, 1/2), (-2, 1/2), (0, -1/2), (1, -1/2),
 (-1, -1/2), (1/2, -1/2), (-1/2, -1/2), (2, -1/2), (-2, -1/2), (0, 2), (1, 2),
 (-1, 2), (1/2, 2), (-1/2, 2), (2, 2), (-2, 2), (0, -2), (1, -2), (-1, -2),
 (1/2, -2), (-1/2, -2)]
sage: u = QQ['u'].0
sage: A.<x,y> = AffineSpace(NumberField(u^2 - 2, 'v'), 2)
sage: len(list(A.points_of_bounded_height(bound=2, tolerance=0.1)))
529
```

weil_restriction()

Compute the Weil restriction of this affine space over some extension field.

If the field is a finite field, then this computes the Weil restriction to the prime subfield.

**OUTPUT:** Affine space of dimension $d$ * self.dimension_relative() over the base field of self.base_ring().
EXAMPLES:

```python
sage: R.<x> = QQ[]
sage: K.<w> = NumberField(x^5-2)
sage: AK.<x,y> = AffineSpace(K, 2)
sage: AK.weil_restriction()
Affine Space of dimension 10 over Rational Field
sage: R.<x> = K[]
sage: L.<v> = K.extension(x^2+1)
sage: AL.<x,y> = AffineSpace(L, 2)
sage: AL.weil_restriction()
Affine Space of dimension 4 over Number Field in w with defining polynomial x^5 - 2
```

```python
class sage.schemes.affine.affine_space.AffineSpace_finite_field(n, R, names, ambient_projective_space, default_embedding_index):
    Bases: sage.schemes.affine.affine_space.AffineSpace_field
class sage.schemes.affine.affine_space.AffineSpace_generic(n, R, names, ambient_projective_space, default_embedding_index):
    Bases: sage.schemes.generic.ambient_space.AmbientSpace, sage.schemes.generic.scheme.AffineScheme
```

Affine space of dimension $n$ over the ring $R$.

EXAMPLES:

```python
sage: X.<x,y,z> = AffineSpace(3, QQ)
sage: X.base_scheme()
Spectrum of Rational Field
sage: X.base_ring()
Rational Field
sage: X.category()
Category of schemes over Rational Field
sage: X.structure_morphism()
Scheme morphism:
  From: Affine Space of dimension 3 over Rational Field
  To:   Spectrum of Rational Field
  Defn: Structure map
```

Loading and saving:

```python
sage: loads(X.dumps()) == X
True
```

We create several other examples of affine spaces:

```python
sage: AffineSpace(5, UnivariatePolynomialRing(QQ, 'z'), 'Z')
Affine Space of dimension 5 over Univariate Polynomial Ring in z over Rational Field
sage: AffineSpace(RealField(), 3, 'Z')
Affine Space of dimension 3 over Real Field with 53 bits of precision
```

(continues on next page)
sage: AffineSpace(Qp(7), 2, 'x')
Affine Space of dimension 2 over 7-adic Field with capped relative precision 20

Even 0-dimensional affine spaces are supported:

sage: AffineSpace(0)
Affine Space of dimension 0 over Integer Ring

**change_ring** $(R)$

Return an affine space over ring $R$ and otherwise the same as this space.

**INPUT:**

- $R$ – commutative ring or morphism.

**OUTPUT:**

- affine space over $R$.

**Note:** There is no need to have any relation between $R$ and the base ring of this space, if you want to have such a relation, use `self.base_extend(R)` instead.

**EXAMPLES:**

sage: A.<x,y,z> = AffineSpace(3, ZZ)
sage: AQ = A.change_ring(QQ); AQ
Affine Space of dimension 3 over Rational Field
sage: AQ.change_ring(GF(5))
Affine Space of dimension 3 over Finite Field of size 5

sage: K.<w> = QuadraticField(5)
sage: A = AffineSpace(K,2,'t')
sage: A.change_ring(K.embeddings(CC)[1])
Affine Space of dimension 2 over Complex Field with 53 bits of precision

**chebyshev_polynomial** $(n, kind='first')$

Generates an endomorphism of this affine line by a Chebyshev polynomial.

Chebyshev polynomials are a sequence of recursively defined orthogonal polynomials. Chebyshev of the first kind are defined as $T_0(x) = 1$, $T_1(x) = x$, and $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$. Chebyshev of the second kind are defined as $U_0(x) = 1$, $U_1(x) = 2x$, and $U_{n+1}(x) = 2xU_n(x) - U_{n-1}(x)$.

**INPUT:**

- $n$ – a non-negative integer.

**OUTPUT:** `DynamicalSystem_affine`

**EXAMPLES:**

sage: A.<x> = AffineSpace(QQ, 1)
sage: A.chebyshev_polynomial(5, 'first')
Dynamical System of Affine Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending $(x)$ to $(16*x^5 - 20*x^3 + 5*x)$
```
sage: A.<x> = AffineSpace(QQ, 1)
sage: A.chebyshev_polynomial(3, 'second')
Dynamical System of Affine Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending (x) to
(8*x^3 - 4*x)
```

```
sage: A.<x> = AffineSpace(QQ, 1)
sage: A.chebyshev_polynomial(3, 2)
Traceback (most recent call last):
...  
ValueError: keyword 'kind' must have a value of either 'first' or 'second'
```

```
sage: A.<x> = AffineSpace(QQ, 1)
sage: A.chebyshev_polynomial(-4, 'second')
Traceback (most recent call last):
...  
ValueError: first parameter 'n' must be a non-negative integer
```

```
sage: A = AffineSpace(QQ, 2, 'x')
sage: A.chebyshev_polynomial(2)
Traceback (most recent call last):
...  
TypeError: affine space must be of dimension 1
```

**coordinate_ring()**

Return the coordinate ring of this scheme, if defined.

**EXAMPLES:**

```
sage: R = AffineSpace(2, GF(9,'alpha'), 'z').coordinate_ring(); R
Multivariate Polynomial Ring in z0, z1 over Finite Field in alpha of size 3^2
sage: AffineSpace(3, R, 'x').coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2 over Multivariate Polynomial Ring in z0, z1 over Finite Field in alpha of size 3^2
```

**ngens()**

Return the number of generators of self, i.e. the number of variables in the coordinate ring of self.

**EXAMPLES:**

```
sage: AffineSpace(3, QQ).ngens()
3
sage: AffineSpace(7, ZZ).ngens()
7
```

**projective_embedding**(i=None, PP=None)

Returns a morphism from this space into an ambient projective space of the same dimension.

**INPUT:**

- i – integer (default: dimension of self = last coordinate) determines which projective embedding to compute. The embedding is that which has a 1 in the i-th coordinate, numbered from 0.
- PP – (default: None) ambient projective space, i.e., codomain of morphism; this is constructed if it is not given.

**EXAMPLES:**

```
13.1. Affine \(n\) space over a ring

77
```
sage: AA = AffineSpace(2, QQ, 'x')
sage: pi = AA.projective_embedding(0); pi
Scheme morphism:
   From: Affine Space of dimension 2 over Rational Field
   To: Projective Space of dimension 2 over Rational Field
   Defn: Defined on coordinates by sending (x0, x1) to
          (1 : x0 : x1)
sage: z = AA(3, 4)
sage: pi(z)
(1/4 : 3/4 : 1)
sage: pi(AA(0,2))
(1/2 : 0 : 1)
sage: pi = AA.projective_embedding(1); pi
Scheme morphism:
   From: Affine Space of dimension 2 over Rational Field
   To: Projective Space of dimension 2 over Rational Field
   Defn: Defined on coordinates by sending (x0, x1) to
          (x0 : 1 : x1)
sage: pi(z)
(3/4 : 1/4 : 1)
sage: pi = AA.projective_embedding(2)
sage: pi(z)
(3 : 4 : 1)

sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: A.projective_embedding(2).codomain().affine_patch(2) == A
True

rational_points (F=None)
Return the list of F-rational points on the affine space self, where F is a given finite field, or the base ring of self.

EXAMPLES:

sage: A = AffineSpace(1, GF(3))
sage: A.rational_points()
[(0), (1), (2)]
sage: A.rational_points(GF(3^2, 'b'))
[(0), (b), (b + 1), (2*b + 1), (2), (2*b), (2*b + 2), (b + 2), (1)]
sage: AffineSpace(2, ZZ).rational_points(GF(2))
[(0, 0), (1, 0), (0, 1), (1, 1)]

subscheme (X, **kwds)
Return the closed subscheme defined by X.

INPUT:

• X - a list or tuple of equations.

EXAMPLES:

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: X = A.subscheme([x, y^2, x*y^2]); X
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
 x,
(continues on next page)
**13.2 Morphisms on affine varieties**

A morphism of schemes determined by rational functions that define what the morphism does on points in the ambient affine space.

**AUTHORS:**
- David Kohel, William Stein
- Volker Braun (2011-08-08): Renamed classes, more documentation, misc cleanups.
- Ben Hutz (2013-03) iteration functionality and new directory structure for affine/projective
class sage.schemes.affine.affine_morphism.SchemeMorphism_polynomial_affine_space (parent, polys, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism_polynomial

A morphism of schemes determined by rational functions.

EXAMPLES:

```python
sage: RA.<x,y> = QQ[]
sage: A2 = AffineSpace(RA)
sage: RP.<u,v,w> = QQ[]
sage: P2 = ProjectiveSpace(RP)
sage: H = A2.Hom(P2)
sage: f = H([x, y, 1])
sage: f

Scheme morphism:
From: Affine Space of dimension 2 over Rational Field
To: Projective Space of dimension 2 over Rational Field
Defn: Defined on coordinates by sending (x, y) to
(x : y : 1)
```

as_dynamical_system ()
Return this endomorphism as a DynamicalSystem_affine.

OUTPUT:

- DynamicalSystem_affine

EXAMPLES:

```python
sage: A.<x,y,z> = AffineSpace(ZZ, 3)
sage: H = End(A)
sage: f = H([x^2, y^2, z^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.affine_ds.DynamicalSystem_affine'>

sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: H = End(A)
sage: f = H([x^2-y^2, y^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.affine_ds.DynamicalSystem_affine'>

sage: A.<x> = AffineSpace(GF(5), 1)
sage: H = End(A)
sage: f = H([x^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.affine_ds.DynamicalSystem_affine_finite_field'>

sage: P.<x,y> = AffineSpace(RR, 2)
sage: f = DynamicalSystem([x^2 + y^2, y^2], P)
sage: g = f.as_dynamical_system()
sage: g is f
True
```

dynatomic_polynomial (period)
Return the dynatomic polynomial.

EXAMPLES:
Sage: A.<x> = AffineSpace(QQ, 1)
Sage: H = End(A)
Sage: f = H([x^2-10/9])
Sage: f.dynatomic_polynomial([2, 1])
doctest:warning
...
531441*x^4 - 649539*x^2 - 524880

global_height (prec=\text{None})

Returns the maximum of the heights of the coefficients in any of the coordinate functions of the affine morphism.

INPUT:

- \text{prec} – desired floating point precision (default: default RealField precision).

OUTPUT: A real number.

EXAMPLES:

Sage: A.<x> = AffineSpace(QQ, 1)
Sage: H = Hom(A, A)
Sage: f = H([1/1331*x^2 + 4000]);
Sage: f.global_height()
8.29404964010203

Sage: R.<x> = PolynomialRing(QQ)
Sage: k.<w> = NumberField(x^2 + 5)
Sage: A.<x,y> = AffineSpace(k, 2)
Sage: H = Hom(A, A)
Sage: f = H([13*w*x^2 + 4*y, 1/w*y^2]);
Sage: f.global_height(prec=100)
3.3696683136785869233538671082

Sage: A.<x> = AffineSpace(ZZ, 1)
Sage: H = Hom(A, A)
Sage: f = H([7*x^2 + 1513]);
Sage: f.global_height()
7.32184971378836

homogenize (n)

Return the homogenization of this map.

If it’s domain is a subscheme, the domain of the homogenized map is the projective embedding of the domain. The domain and codomain can be homogenized at different coordinates: \text{n[0]} for the domain and \text{n[1]} for the codomain.

INPUT:

- \text{n} – a tuple of nonnegative integers. If \text{n} is an integer, then the two values of the tuple are assumed to be the same.

OUTPUT:

- \text{SchemeMorphism_polynomial_projective_space}.

EXAMPLES:
sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: H = Hom(A, A)
sage: f = H([(x^2-2)/x^5, y^2])
sage: f.homogenize(2)
Scheme endomorphism of Projective Space of dimension 2 over Integer Ring
  Defn: Defined on coordinates by sending (x0 : x1 : x2) to
  (x0^2*x2^5 - 2*x2^7 : x0^5*x1^2 : x0^5*x2^2)

sage: A.<x,y> = AffineSpace(CC, 2)
sage: H = Hom(A, A)
sage: f = H([(x^2-2)/(x*y), y^2-x])
sage: f.homogenize((2, 0))
Scheme endomorphism of Projective Space of dimension 2 over Complex Field with 53 bits of precision
  Defn: Defined on coordinates by sending (x0 : x1 : x2) to
  (x0*x1*x2^2 : x0^2*x2^2 + (-2.00000000000000)*x2^4 : x0*x1^3 - x0^2*x1*x2)

sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: X = A.subscheme([x-y^2])

jacobian()

Return the Jacobian matrix of partial derivative of this map.

The \( (i, j) \) entry of the Jacobian matrix is the partial derivative \( \text{diff}(\text{functions}[i], \text{variables}[j]) \).

OUTPUT:

- matrix with coordinates in the coordinate ring of the map.

EXAMPLES:

sage: A.<z> = AffineSpace(QQ, 1)
sage: H = End(A)
sage: f = H([z^2 - 3/4])

(continues on next page)
sage: f.jacobian()
[2*z]

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: H = End(A)
sage: f = H([x^3 - 25*x + 12*y, 5*y^2*x - 53*y + 24])
sage: f.jacobian()
[ 3*x^2 - 25  12]
[ 5*y^2 10*x*y - 53]

sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: H = End(A)
sage: f = H([(x^2 - x*y)/(1+y), (5+y)/(2+x)])
sage: f.jacobian()
[ (2*x - y)/(y + 1) (-x^2 - x)/(y^2 + 2*y + 1)]
[ (-y - 5)/(x^2 + 4*x + 4) 1/(x + 2)]

multiplier(P, n, check=True)
Return the multiplier of the point.

EXAMPLES:

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: H = End(A)
sage: f = H([(x^2, y^2)])
sage: f.multiplier(A([1, 1]), 1)
doctest:warning
...
[2 0]
[0 2]

nth_iterate(P, n)
Return the nth iterate of the point.

EXAMPLES:

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: H = End(A)
sage: f = H([(x-2*y^2)/x, 3*x*y])
sage: f.nth_iterate(A(9, 3), 3)
doctest:warning
...
(-104975/13123, -9566667)

nth_iterate_map(n)
Return the symbolic nth iterate.

EXAMPLES:

sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: H = End(A)
sage: f = H([(x^2-2)/(2*y), y^2-3*x])
sage: f.nth_iterate_map(2)
doctest:warning
...
Dynamical System of Affine Space of dimension 2 over Integer Ring
Defn: Defined on coordinates by sending \((x, y)\) to
\[
\frac{(x^4 - 4x^2 - 8y^2 + 4)}{(8y^4 - 24xy^2 + 2)}, \quad \frac{(2y^5 - 12xy^3 + 18x^2y - 3x^2 + 6)}{(2y)}
\]

\textbf{orbit} \((P, n)\)
Return the orbit of the point.

\textbf{EXAMPLES:}

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: H = End(A)
sage: f = H([\{(x-2*y^2)/x, 3*x*y\}])
sage: f.orbit(A(9, 3), 3)
doctest:warning ...
[[9, 3], (-1, 81), (13123, -243), (-104975/13123, -9566667)]
```

\textbf{class} \texttt{sage.schemes.affine.affine_morphism.SchemeMorphism_polynomial_affine_space_field}(\texttt{parent}, \texttt{polys}, \texttt{check})

\textbf{Bases:} \texttt{sage.schemes.affine.affine_morphism.SchemeMorphism_polynomial_affine_space}

\textbf{weil_restriction}()
Compute the Weil restriction of this morphism over some extension field.

If the field is a finite field, then this computes the Weil restriction to the prime subfield.

A Weil restriction of scalars - denoted \(\text{Res}_{L/k}\) - is a functor which, for any finite extension of fields \(L/k\) and any algebraic variety \(X\) over \(L\), produces another corresponding variety \(\text{Res}_{L/k}(X)\), defined over \(k\). It is useful for reducing questions about varieties over large fields to questions about more complicated varieties over smaller fields. Since it is a functor it also applied to morphisms. In particular, the functor applied to a morphism gives the equivalent morphism from the Weil restriction of the domain to the Weil restriction of the codomain.

\textbf{OUTPUT:} Scheme morphism on the Weil restrictions of the domain and codomain of the map.

\textbf{EXAMPLES:}

```
sage: K.<v> = QuadraticField(5)
sage: A.<x,y> = AffineSpace(K, 2)
sage: H = End(A)
sage: f = H([\{x^2-y^2, y^2\}])
sage: f.weil_restriction()

Scheme morphism: From: Affine Space of dimension 4 over Rational Field To: Affine Space of dimension 4 over Rational Field
Defn: Defined on coordinates by sending (z0, z1, z2, z3) to
-\(z0^2 + 5*z1^2 - z2^2 - 5*z3^2, 2*z0*z1 - 2*z2*z3, z2^2 + 5*z3^2, \rightarrow 2*z2*z3)\)
```

```
sage: K.<v> = QuadraticField(5)
sage: PS.<x,y> = AffineSpace(K, 2)
sage: H = Hom(PS, PS)
sage: f = H([\{x, y\}])
sage: F = f.weil_restriction()
sage: P = PS(2, 1)
sage: Q = P.weil_restriction()
sage: f(P).weil_restriction() == F(Q)
True
```
class sage.schemes.affine.affine_morphism.SchemeMorphism_polynomial_affine_space_finite_field(
    parent, polys, check=True)
Bases: sage.schemes.affine.affine_morphism.SchemeMorphism_polynomial_affine_space_field
cyclegraph()
    Return the directed graph of the map.
    EXAMPLES:
    sage: A.<x,y> = AffineSpace(GF(5), 2)
    sage: H = End(A)
    sage: f = H([x^2-y, x*y+1])
    sage: f.cyclegraph()
    doctest:warning...
    Looped digraph on 25 vertices

orbit_structure(P)
    Return the tail and period of the point.
    EXAMPLES:
    sage: A.<x,y> = AffineSpace(GF(13), 2)
    sage: H = End(A)
    sage: f = H([x^2 - 1, y^2])
    sage: f.orbit_structure(A(2, 3))
    doctest:warning...
    [1, 6]

13.3 Points on affine varieties

Scheme morphism for points on affine varieties.

AUTHORS:

• David Kohel, William Stein
• Volker Braun (2011-08-08): Renamed classes, more documentation, misc cleanups.
• Ben Hutz (2013)

class sage.schemes.affine.affine_point.SchemeMorphism_point_affine(X, v, check=True)
Bases: sage.schemes.generic.morphism.SchemeMorphism_point

A rational point on an affine scheme.

INPUT:

• X – a subscheme of an ambient affine space over a ring R.
• v – a list/tuple/iterable of coordinates in R.
• check – boolean (optional, default:True). Whether to check the input for consistency.

EXAMPLES:
```
sage: A = AffineSpace(2, QQ)
sage: A(1, 2)
(1, 2)
```

**global_height** *(prec=None)*

Returns the logarithmic height of the point.

**INPUT:**

- **prec** – desired floating point precision (default: default RealField precision).

**OUTPUT:**

- a real number.

**EXAMPLES:**

```
sage: P.<x,y> = AffineSpace(QQ, 2)
sage: Q = P(41, 1/12)
sage: Q.global_height()
3.71357206670431
```

```
sage: P = AffineSpace(ZZ, 4, 'x')
sage: Q = P(3, 17, -51, 5)
sage: Q.global_height()
3.93182563272433
```

```
sage: R.<x> = PolynomialRing(QQ)
sage: k.<w> = NumberField(x^2+5)
sage: A = AffineSpace(k, 2, 'z')
sage: A([3, 5*w+1]).global_height(prec=100)
2.4181409534757389986565376694
```

**Todo:** P-adic heights.

```
homogenize(n)
```

Return the homogenization of the point at the \(n\)th coordinate.

**INPUT:**

- **n** – integer between 0 and dimension of the map, inclusive.

**OUTPUT:**

- A point in the projectivization of the codomain of the map.

**EXAMPLES:**

```
sage: A.<x,y> = AffineSpace(ZZ, 2)
sage: Q = A(2, 3)
sage: Q.homogenize(2).dehomogenize(2) == Q
True
```

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: Q = A(2, 3)
sage: P = A(0, 1)
```

(continues on next page)
sage: Q.homogenize(2).codomain() == P.homogenize(2).codomain()
True

nth_iterate \((f, n)\)

Returns the point \(f^n(self)\)

**INPUT:**

- \(f\) – a SchemeMorphism_polynomial with self in f.domain().
- \(n\) – a positive integer.

**OUTPUT:**

- a point in f.codomain().

**EXAMPLES:**

```python
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: H = Hom(A, A)
sage: f = H([(x-2*y^2)/x, 3*x*y])
sage: A(9,3).nth_iterate(f, 3)
doctest:warning...
(-104975/13123, -9566667)
```

orbit \((f, N)\)

Returns the orbit of the point by \(f\).

If \(n\) is an integer it returns \([self, f(self), \ldots, f^n(self)]\).

If \(n\) is a list or tuple \(n = [m, k]\) it returns \([f^m(self), \ldots, f^k(self)]\).

**INPUT:**

- \(f\) – a SchemeMorphism_polynomial with the point in f.domain().
- \(N\) – a non-negative integer or list or tuple of two non-negative integers.

**OUTPUT:**

- a list of points in f.codomain().

**EXAMPLES:**

```python
sage: A.<x,y>=AffineSpace(QQ, 2)
sage: H = Hom(A, A)
sage: f = H([(x-2*y^2)/x, 3*x*y])
sage: A(9,3).orbit(f, 3)
doctest:warning...
[(9, 3), (-1, 81), (13123, -243), (-104975/13123, -9566667)]
```

class sage.schemes.affine.affine_point.SchemeMorphism_point_affine_field(X, v, check=True)

**Bases:** sage.schemes.affine.affine_point.SchemeMorphism_point_affine

** intersection_multiplicity \((X)\)**

Return the intersection multiplicity of the codomain of this point and \(X\) at this point.

This uses the intersection_multiplicity implementations for projective/affine subschemes. This point must be a point on an affine subscheme.
INPUT:

- $X$ – a subscheme in the same ambient space as that of the codomain of this point.

OUTPUT: Integer.

EXAMPLES:

```python
sage: A.<x,y> = AffineSpace(GF(17), 2)
sage: X = A.subscheme([y^2 - x^3 + 2*x^2 - x])
sage: Y = A.subscheme([y - 2*x + 2])
sage: Q1 = Y([1,0])
sage: Q1.intersection_multiplicity(X)
2
sage: Q2 = X([4,6])
sage: Q2.intersection_multiplicity(Y)
1
```

```python
sage: A.<x,y,z,w> = AffineSpace(QQ, 4)
sage: X = A.subscheme([x^2 - y*z^2, z - 2*w^2])
sage: Q = A([2,1,2,-1])
sage: Q.intersection_multiplicity(X)
Traceback (most recent call last):
  ...TypeError: this point must be a point on an affine subscheme
```

`multiplicity()`

Return the multiplicity of this point on its codomain.

Uses the subscheme multiplicity implementation. This point must be a point on an affine subscheme.

OUTPUT: an integer.

EXAMPLES:

```python
sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: X = A.subscheme([y^2 - x^7*z])
sage: Q1 = X([1,1,1])
sage: Q1.multiplicity()
1
sage: Q2 = X([0,0,2])
sage: Q2.multiplicity()
2
```

`weil_restriction()`

Compute the Weil restriction of this point over some extension field.

If the field is a finite field, then this computes the Weil restriction to the prime subfield.

A Weil restriction of scalars - denoted $\text{Res}_{L/k}$ - is a functor which, for any finite extension of fields $L/k$ and any algebraic variety $X$ over $L$, produces another corresponding variety $\text{Res}_{L/k}(X)$, defined over $k$. It is useful for reducing questions about varieties over large fields to questions about more complicated varieties over smaller fields. This functor applied to a point gives the equivalent point on the Weil restriction of its codomain.

OUTPUT: Scheme point on the Weil restriction of the codomain of this point.

EXAMPLES:
sage: A.<x,y,z> = AffineSpace(GF(5^3, 't'), 3)
sage: X = A.subscheme([y^2-x*z, z^2+y])
sage: Y = X.weil_restriction()
sage: P = X([1, -1, 1])
sage: Q = P.weil_restriction(); Q
(1, 0, 0, 4, 0, 0, 1, 0, 0)
sage: Q.codomain() == Y
True

sage: R.<x> = QQ[]
sage: K.<w> = NumberField(x^5-2)
sage: R.<x> = K[]
sage: L.<v> = K.extension(x^2+w)
sage: A.<x,y> = AffineSpace(L, 2)
sage: P = A([w^3-v, 1+w+w*v])
sage: P.weil_restriction()
(w^3, -1, w + 1, w)

class sage.schemes.affine.affine_point.SchemeMorphism_point_affine_finite_field(X, v, check=True)

Bases: sage.schemes.affine.affine_point.SchemeMorphism_point_affine_field

orbit_structure(f)
This function returns the pair \([m, n]\) where \(m\) is the preperiod and \(n\) is the period of the point by \(f\).

Every point is preperiodic over a finite field.

INPUT:

- \(f\) – a SchemeMorphism_polynomial with the point in \(f\).domain().

OUTPUT:

- a list \([m, n]\) of integers.

EXAMPLES:

sage: P.<x,y,z> = AffineSpace(GF(5), 3)
sage: f = DynamicalSystem_affine([x^2 + y^2, y^2, z^2 + y*z], domain=P)
sage: f.orbit_structure(P(1, 1, 1))
[0, 6]

sage: P.<x,y,z> = AffineSpace(GF(7), 3)
sage: X = P.subscheme(x^2 - y^2)
sage: f = DynamicalSystem_affine([x^2, y^2, z^2], domain=X)
sage: f.orbit_structure(X(1, 1, 2))
[0, 2]

sage: P.<x,y> = AffineSpace(GF(13), 2)
sage: f = DynamicalSystem_affine([x^2 - y^2, y^2], domain=P)
sage: P(3, 4).orbit_structure(f)
doctest:warning
...  
[2, 6]

sage: P.<x,y> = AffineSpace(GF(13), 2)
sage: H = End(P)
13.4 Subschemes of affine space

AUTHORS:

• David Kohel (2005): initial version.
• Ben Hutz (2013): affine subschemes

class sage.schemes.affine.affine_subscheme.AlgebraicScheme_subscheme_affine(A, polynomials, embedding_center=None, embedding_codomain=None, embedding_images=None)

Bases: sage.schemes.generic.algebraic_scheme.AlgebraicScheme_subscheme

Construct an algebraic subscheme of affine space.

Warning: You should not create objects of this class directly. The preferred method to construct such subschemes is to use subscheme() method of affine space.

INPUT:

• A – ambient affine space
• polynomials – single polynomial, ideal or iterable of defining polynomials.

EXAMPLES:

sage: A3.<x, y, z> = AffineSpace(QQ, 3)
sage: A3.subscheme([x^2-y*z])
Closed subscheme of Affine Space of dimension 3 over Rational Field defined by:
  x^2 - y*z

dimension()

Return the dimension of the affine algebraic subscheme.

OUTPUT: Integer.
EXAMPLES:

```
sage: A.<x,y> = AffineSpace(2, QQ)
sage: A.subscheme([]).dimension()
2
sage: A.subscheme([x]).dimension()
1
sage: A.subscheme([x^5]).dimension()
1
sage: A.subscheme([x^2 + y^2 - 1]).dimension()
1
sage: A.subscheme([x*(x-1), y*(y-1)]).dimension()
0
```

Something less obvious:

```
sage: A.<x,y,z,w> = AffineSpace(4, QQ)
sage: X = A.subscheme([x^2, x^2*y^2 + z^2, z^2 - w^2, 10*x^2 + w^2 - z^2])
sage: X
Closed subscheme of Affine Space of dimension 4 over Rational Field defined by:
    x^2, x^2*y^2 + z^2, z^2 - w^2, 10*x^2 - z^2 + w^2
sage: X.dimension()
1
```

**intersection_multiplicity** *(X, P)*

Return the intersection multiplicity of this subscheme and the subscheme X at the point P.

The intersection of this subscheme with X must be proper, that is codim(*self* ∩ X) = codim(*self*) + codim(X), and must also be finite. We use Serre’s Tor formula to compute the intersection multiplicity. If I, J are the defining ideals of self, X, respectively, then this is

\[\sum_{i=0}^{\infty} (-1)^i \text{length}(\text{Tor}_i^{O_{A, p}}(O_{A, p}/I, O_{A, p}/J))\]

where A is the affine ambient space of these subschemes.

**INPUT:**

- X – subscheme in the same ambient space as this subscheme.
- P – a point in the intersection of this subscheme with X.

**OUTPUT:** An integer.

**EXAMPLES:**

```
sage: A.<x,y> = AffineSpace(QQ, 2)
sage: C = Curve([y^2 - x^3 - x^2], A)
sage: D = Curve([y^2 + x^3], A)
sage: Q = A([0,0])
sage: C.intersection_multiplicity(D, Q)
4
```

```
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^6 - 3*a^5 + 5*a^4 - 5*a^3 + 5*a^2 - 3*a + 1)
sage: A.<x,y,z,w> = AffineSpace(K, 4)
sage: X = A.subscheme([x*y, y*z + 7, w^3 - x^3])
sage: Y = A.subscheme([x - z^3 + z + 1])
sage: Q = A([0, -7*b^5 + 21*b^4 - 28*b^3 + 21*b^2 - 21*b + 14, -b^5 + 2*b^4 - _, -3*b^3 \]
```

(continues on next page)
+ 2*b^2 - 2*b, 0])
sage: X.intersection_multiplicity(Y, Q)
3

sage: A.<x,y,z> = AffineSpace(QQ, 3)
sage: X = A.subscheme([z^2 - 1])
sage: Y = A.subscheme([z - 1, y - x^2])
sage: Q = A([1,1,1])
sage: X.intersection_multiplicity(Y, Q)
Traceback (most recent call last):
...
TypeError: the intersection of this subscheme and (=Closed subscheme of Affine Space of dimension 3 over Rational Field defined by: z - 1, -x^2 + y) must be proper and finite

sage: A.<x,y,z,w,t> = AffineSpace(QQ, 5)
sage: X = A.subscheme([x*y, t^2*w, w^3*z])
sage: Y = A.subscheme([y*w + z])
sage: Q = A([0,0,0,0,0])
sage: X.intersection_multiplicity(Y, Q)
Traceback (most recent call last):
...
TypeError: the intersection of this subscheme and (=Closed subscheme of Affine Space of dimension 5 over Rational Field defined by: y*w + z) must be proper and finite

is_smooth(point=None)

Test whether the algebraic subscheme is smooth.

INPUT:

• point – A point or None (default). The point to test smoothness at.

OUTPUT:

Boolean. If no point was specified, returns whether the algebraic subscheme is smooth everywhere. Otherwise, smoothness at the specified point is tested.

EXAMPLES:

sage: A2.<x,y> = AffineSpace(2,QQ)
sage: cuspidal_curve = A2.subscheme([y^2-x^3])
sage: cuspidal_curve
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
-x^3 + y^2
sage: smooth_point = cuspidal_curve.point([1,1])
sage: smooth_point in cuspidal_curve
True
sage: singular_point = cuspidal_curve.point([0,0])
sage: singular_point in cuspidal_curve
True
sage: cuspidal_curve.is_smooth(smooth_point)
True
sage: cuspidal_curve.is_smooth(singular_point)
False
sage: cuspidal_curve.is_smooth()  # default point None
False
**multiplicity** (*P*)

Return the multiplicity of *P* on this subscheme.

This is computed as the multiplicity of the local ring of this subscheme corresponding to *P*. This subscheme must be defined over a field. An error is raised if *P* is not a point on this subscheme.

**INPUT:**
- *P* – a point on this subscheme.

**OUTPUT:**
An integer.

**EXAMPLES:**

```sage
sage: A.<x,y,z,w> = AffineSpace(QQ, 4)
sage: X = A.subscheme([x*y - x^7, w - 2*z])
sage: Q1 = A([1,1/3,3,6])
sage: X.multiplicity(Q1)
1
sage: Q2 = A([0,0,0,0])
sage: X.multiplicity(Q2)
2
```

**projective_closure** (*i=None, PP=None*)

Return the projective closure of this affine subscheme.

**INPUT:**
- *i* – (default: None) determines the embedding to use to compute the projective closure of this affine subscheme. The embedding used is the one which has a 1 in the i-th coordinate, numbered from 0.
- *PP* – (default: None) ambient projective space, i.e., ambient space of codomain of morphism; this is constructed if it is not given.

**OUTPUT:**
- a projective subscheme.

**EXAMPLES:**

```sage
sage: A.<x,y,z,w,v> = AffineSpace(GF(23), 5)
sage: C = A.curve([x^8 - y, y^7 - z, z^3 - 1, w^5 - v^3])
sage: Q = A([22,1,1,0,0])
sage: C.multiplicity(Q)
3
```

(continues on next page)
\texttt{sage: X.projective_closure()}
Closed subscheme of Projective Space of dimension 4 over Rational Field
defined by:
\begin{align*}
x_0^2 & - x_1 x_4, \\
x_0 x_1 & - x_2 x_4, \\
x_1^2 & - x_3 x_4, \\
x_0 x_2 & - x_3 x_4, \\
x_1 x_2 & - x_0 x_3, \\
x_2^2 & - x_1 x_3
\end{align*}

\texttt{sage: A.<x,y,z> = AffineSpace(QQ, 3)}
\texttt{sage: P.<a,b,c,d> = ProjectiveSpace(QQ, 3)}
\texttt{sage: X = A.subscheme([z - x^2 - y^2])}
\texttt{sage: X.projective_closure(1, P).ambient_space() == P}
\texttt{True}

\textbf{projective_embedding} \texttt{(i=None, PP=None)}

Returns a morphism from this affine scheme into an ambient projective space of the same dimension.

The codomain of this morphism is the projective closure of this affine scheme in \texttt{PP}, if given, or otherwise in a new projective space that is constructed.

\textbf{INPUT:}

\begin{itemize}
\item \texttt{i} \ – integer (default: dimension of self = last coordinate) determines which projective embedding to compute. The embedding is that which has a 1 in the \textit{i}-th coordinate, numbered from 0.
\item \texttt{PP} \ – (default: None) ambient projective space, i.e., ambient space of codomain of morphism; this is constructed if it is not given.
\end{itemize}

\textbf{EXAMPLES:}

\texttt{sage: A.<x, y, z> = AffineSpace(3, ZZ)}
\texttt{sage: S = A.subscheme([x*y-z])}
\texttt{sage: S.projective_embedding()}
Scheme morphism:
\begin{itemize}
\item\textbf{From:} Closed subscheme of Affine Space of dimension 3 over Integer Ring
\item\textbf{Defined by:} \quad \begin{align*}
x y - z
\end{align*}
\item\textbf{To:} Closed subscheme of Projective Space of dimension 3 over Integer Ring
\item\textbf{Defined by:} \quad \begin{align*}
x_0 x_1 - x_2 x_3
\end{align*}
\item\textbf{Defn:} Defined on coordinates by sending \texttt{(x, y, z)} to \\
\texttt{(x : y : z : 1)}
\end{itemize}

\texttt{sage: A.<x, y, z> = AffineSpace(3, ZZ)}
\texttt{sage: P = ProjectiveSpace(3,ZZ,'u')} 
\texttt{sage: S = A.subscheme([x^2-y*z])} 
\texttt{sage: S.projective_embedding(1,P)}
Scheme morphism:
\begin{itemize}
\item\textbf{From:} Closed subscheme of Affine Space of dimension 3 over Integer Ring defined by:
\item \texttt{x^2 - y*z}
\item\textbf{To:} Closed subscheme of Projective Space of dimension 3 over Integer Ring defined by:
\item \texttt{u_0^2 - u_2 u_3}
\item\textbf{Defn:} Defined on coordinates by sending \texttt{(x, y, z)} to \\
\texttt{(x : 1 : y : z)}
When taking a closed subscheme of an affine space with a projective embedding, the subscheme inherits the embedding:

```python
sage: A.<u,v> = AffineSpace(2, QQ, default_embedding_index=1)
sage: X = A.subscheme(u - v)
sage: X.projective_embedding()
Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 2 over Rational Field
  Defined by:
    u - v
  To:  Closed subscheme of Projective Space of dimension 2 over Rational Field
  Defined by:
    x0 - x2
Defn: Defined on coordinates by sending (u, v) to
  (u : 1 : v)
sage: phi = X.projective_embedding()
sage: psi = A.projective_embedding()
sage: phi(X(2, 2)) == psi(A(X(2, 2)))
True
```

### 13.5 Enumeration of rational points on affine schemes

Naive algorithms for enumerating rational points over \( \mathbb{Q} \) or finite fields over for general schemes.

**Warning:** Incorrect results and infinite loops may occur if using a wrong function.

(For instance using an affine function for a projective scheme or a finite field function for a scheme defined over an infinite field.)

**EXAMPLES:**

Affine, over \( \mathbb{Q} \):

```python
sage: from sage.schemes.affine.affine_rational_point import enum_affine_rational_field
sage: A.<x,y,z> = AffineSpace(3, QQ)
sage: S = A.subscheme([2*x-3*y])
sage: enum_affine_rational_field(S, 2)
```
Affine over a finite field:

```python
sage: from sage.schemes.affine.affine_rational_point import enum_affine_finite_field
sage: A.<w,x,y,z> = AffineSpace(4, GF(2))
sage: enum_affine_finite_field(A(GF(2)))
[(0, 0, 0, 0), (0, 0, 0, 1), (0, 0, 1, 0), (0, 0, 1, 1), (0, 1, 0, 0),
 (0, 1, 0, 1), (0, 1, 1, 0), (0, 1, 1, 1), (1, 0, 0, 0), (1, 0, 0, 1),
 (1, 0, 1, 0), (1, 0, 1, 1), (1, 1, 0, 0), (1, 1, 0, 1), (1, 1, 1, 0),
 (1, 1, 1, 1)]
```

- John Cremona and Charlie Turner <charlotteturner@gmail.com> (06-2010): improvements to clarity and documentation.

`sage.schemes.affine.affine_rational_point.enum_affine_finite_field(X)`

Enumerates affine points on scheme $X$ defined over a finite field.

**INPUT:**

- $X$ - a scheme defined over a finite field or a set of abstract rational points of such a scheme.

**OUTPUT:**

- a list containing the affine points of $X$ over the finite field, sorted.

**EXAMPLES:**

```python
sage: F = GF(7)
sage: A.<w,x,y,z> = AffineSpace(4, F)
sage: C = A.subscheme([w^2+x+4, y*z*x-6, z*y+w*x])
sage: from sage.schemes.affine.affine_rational_point import enum_affine_finite_field
sage: enum_affine_finite_field(C(F))
[
]
sage: C = A.subscheme([w^2+x+4, y*z*x-6])
sage: enum_affine_finite_field(C(F))
[(0, 3, 1, 2), (0, 3, 2, 1), (0, 3, 3, 3), (0, 3, 4, 4), (0, 3, 5, 6),
 (0, 3, 6, 5), (1, 2, 1, 3), (1, 2, 2, 5), (1, 2, 3, 1), (1, 2, 4, 6),
 (1, 2, 5, 2), (1, 2, 6, 4), (2, 6, 1, 1), (2, 6, 2, 4), (2, 6, 3, 5),
 (2, 6, 4, 2), (2, 6, 5, 3), (2, 6, 6, 6), (3, 1, 1, 6), (3, 1, 2, 3),
 (3, 1, 3, 2), (3, 1, 4, 5), (3, 1, 5, 4), (3, 1, 6, 1), (4, 1, 1, 6),
 (4, 1, 2, 3), (4, 1, 3, 2), (4, 1, 4, 5), (4, 1, 5, 4), (4, 1, 6, 1),
 (5, 6, 1, 1), (5, 6, 2, 4), (5, 6, 3, 5), (5, 6, 4, 2), (5, 6, 5, 3),
 (5, 6, 6, 6), (6, 2, 1, 3), (6, 2, 2, 5), (6, 2, 3, 1), (6, 2, 4, 6),
 (6, 2, 5, 2), (6, 2, 6, 4)]
```

**ALGORITHM:**

13.5. Enumeration of rational points on affine schemes
Checks all points in affine space to see if they lie on \( X \).

**Warning:** If \( X \) is defined over an infinite field, this code will not finish!

AUTHORS:

- John Cremona and Charlie Turner (06-2010)

```python
sage.schemes.affine.affine_rational_point.enum_affine_number_field(X, **kwds)
```

Enumerates affine points on scheme \( X \) defined over a number field. Simply checks all of the points of absolute height up to \( B \) and adds those that are on the scheme to the list.

This algorithm computes 2 lists: \( L \) containing elements \( x \) in \( K \) such that \( H_k(x) \leq B \), and a list \( L' \) containing elements \( x \) in \( K \) that, due to floating point issues, may be slightly larger then the bound. This can be controlled by lowering the tolerance.

**ALGORITHM:**

This is an implementation of the revised algorithm (Algorithm 4) in [Doyle-Krumm]. Algorithm 5 is used for imaginary quadratic fields.

**INPUT:**

\textit{kwds}:

- \textit{bound} - a real number
- \textit{tolerance} - a rational number in (0,1] used in doyle-krumm algorithm-4
- \textit{precision} - the precision to use for computing the elements of bounded height of number fields.

**OUTPUT:**

- a list containing the affine points of \( X \) of absolute height up to \( B \), sorted.

**EXAMPLES:**

```python
sage: from sage.schemes.affine.affine_rational_point import enum_affine_number_field
sage: u = QQ['u'].0
sage: K = NumberField(u^2 + 2, 'v')
sage: A.<x,y,z> = AffineSpace(K, 3)
sage: X = A.subscheme([y^2 - x])
sage: enum_affine_number_field(X(K), bound=2**0.5)
[(0, 0, -1), (0, 0, -\sqrt{2}), (0, 0, -\sqrt{1/2}*v), (0, 0, 0), (0, 0, \sqrt{1/2}*v), (0, 0, v), (0, 0, \sqrt{2}), (1, -1, -1), (1, -1, -\sqrt{2}), (1, -1, -\sqrt{1/2}*v), (1, -1, 0), (1, -1, \sqrt{1/2}*v), (1, -1, v), (1, -1, \sqrt{2}), (1, 1, -1), (1, 1, -\sqrt{2}), (1, 1, -\sqrt{1/2}*v), (1, 1, 0), (1, 1, \sqrt{1/2}*v), (1, 1, v), (1, 1, \sqrt{2})]
```

```python
sage: u = QQ['u'].0
sage: K = NumberField(u^2 + 3, 'v')
```

(continues on next page)
sage.schemes.affine.affine_rational_point.enum_affine_rational_field(X, B)
Enumerates affine rational points on scheme X up to bound B.

INPUT:
• X - a scheme or set of abstract rational points of a scheme.
• B - a positive integer bound.

OUTPUT:
• a list containing the affine points of X of height up to B, sorted.

EXAMPLES:

sage: A.<x,y,z> = AffineSpace(3, QQ)
sage: from sage.schemes.affine.affine_rational_point import enum_affine_rational_field
sage: enum_affine_rational_field(A(QQ), 1)
[(-1, -1, -1), (-1, -1, 0), (-1, -1, 1), (-1, 0, -1), (-1, 0, 0), (-1, 0, 1),
(-1, 1, -1), (-1, 1, 0), (-1, 1, 1), (0, -1, -1), (0, -1, 0), (0, -1, 1),
(0, 0, -1), (0, 0, 0), (0, 0, 1), (0, 1, -1), (0, 1, 0), (0, 1, 1), (1, -1, -1),
(1, -1, 0), (1, -1, 1), (1, 0, -1), (1, 0, 0), (1, 0, 1), (1, 1, -1), (1, 1, 0),
(1, 1, 1)]

sage: A.<w,x,y,z> = AffineSpace(4, QQ)
sage: S = A.subscheme([x^2-y*z+1, w^3+z+y^2])
sage: enum_affine_rational_field(S(QQ), 1)
[(0, 0, -1, -1)]
sage: enum_affine_rational_field(S(QQ), 2)
[(0, 0, -1, -1), (1, -1, -1, -2), (1, 1, -1, -2)]

sage: A.<x,y> = AffineSpace(2, QQ)
sage: C = Curve(x^2+y-x)
sage: enum_affine_rational_field(C, 10) # long time (3 s)
[(-2, -6), (-1, -2), (-2/3, -10/9), (-1/2, -3/4), (-1/3, -4/9),
(0, 0), (1/3, 2/9), (1/2, 1/4), (2/3, 2/9), (1, 0),
(4/3, -4/9), (3/2, -3/4), (5/3, -10/9), (2, -2), (3, -6)]

• Charlie Turner (06-2010): small adjustments.
• Raman Raghukul 2018: updated.

13.6 Set of homomorphisms between two affine schemes

For schemes X and Y, this module implements the set of morphisms \( \text{Hom}(X, Y) \). This is done by SchemeHomset_generic.
As a special case, the Hom-sets can also represent the points of a scheme. Recall that the $K$-rational points of a scheme $X$ over $k$ can be identified with the set of morphisms $\text{Spec}(K) \to X$. In Sage the rational points are implemented by such scheme morphisms. This is done by SchemeHomset_points and its subclasses.

**Note:** You should not create the Hom-sets manually. Instead, use the Hom() method that is inherited by all schemes.

**AUTHORS:**
- Ben Hutz (2018): add numerical point support

```python
class sage.schemes.affine.affine_homset.SchemeHomset_points_affine(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.generic.homset.SchemeHomset_points

Set of rational points of an affine variety.

INPUT:

See SchemeHomset_generic.

EXAMPLES:

```python
sage: from sage.schemes.affine.affine_homset import SchemeHomset_points_affine
sage: SchemeHomset_points_affine(Spec(QQ), AffineSpace(ZZ,2))
Set of rational points of Affine Space of dimension 2 over Rational Field
```

```python
numerical_points(F=None, **kwds)
```

Return some or all numerical approximations of rational points of an affine scheme.

This is for dimension 0 subschemes only and the points are determined through a groebner calculation over the base ring and then numerically approximating the roots of the resulting polynomials. If the base ring is a number field, the embedding into $F$ must be known.

INPUT:

F - numerical ring

kwds:

- zero_tolerance - positive real number (optional, default=10^(-10)). For numerically inexact fields, points are on the subscheme if they satisfy the equations to within tolerance.

OUTPUT: A list of points in the ambient space.

**Warning:** For numerically inexact fields the list of points returned may contain repeated or be missing points due to tolerance.

**EXAMPLES:**

```python
sage: K.<v> = QuadraticField(3)
sage: A.<x,y> = AffineSpace(K, 2)
sage: X = A.subscheme([x^3 - v^2*y, y - v*x^2 + 3])
sage: L = X(K).numerical_points(F=RR); L # abs tol 1e-14
```
\begin{verbatim}
[(1.57693558184861, 1.30713548084184),
 (4.80659931965815, 37.0162574656220)]
sage: L[0].codomain()
Affine Space of dimension 2 over Real Field with 53 bits of precision

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: X = A.subscheme([y^2 - x^2 - 3*x, x^2 - 10*y])
sage: len(X(QQ).numerical_points(F=ComplexField(100)))
4

sage: A.<x1, x2> = AffineSpace(QQ, 2)
sage: E = A.subscheme([30*x1^100 + 1000*x2^2 + 2000*x1*x2 + 1, x1 + x2])
sage: len(E(A.base_ring()).numerical_points(F=CDF, zero_tolerance=1e-9))
100

sage: A.<x,y> = AffineSpace(QQ, 2)
sage: X = A.subscheme([y^2 - x^2 - 3*x, x^2 - 10*y])
sage: X(QQ).numerical_points(F=CC, zero_tolerance=-1)
Traceback (most recent call last):
  ... ValueError: tolerance must be positive
\end{verbatim}

\section*{points (**kwds**)}

Return some or all rational points of an affine scheme.

For dimension 0 subschemes points are determined through a groebner basis calculation. For schemes or
subschemes with dimension greater than 1 points are determined through enumeration up to the specified
bound.

Over a finite field, all points are returned. Over an infinite field, all points satisfying the bound are returned.
For a zero-dimensional subscheme, all points are returned regardless of whether the field is infinite or not.

For number fields, this uses the Doyle-Krumm algorithm 4 (algorithm 5 for imaginary quadratic) for
computing algebraic numbers up to a given height \cite{Doyle-Krumm}.

The algorithm requires floating point arithmetic, so the user is allowed to specify the precision for such cal-
culations. Additionally, due to floating point issues, points slightly larger than the bound may be returned.
This can be controlled by lowering the tolerance.

\textbf{INPUT:}

\textbf{kwds:}

- \texttt{bound} - real number (optional, default: 0). The bound for the height of the coordinates. Only used
  for subschemes with dimension at least 1.

- \texttt{zero_tolerance} - positive real number (optional, default=10^(-10)). For numerically inexact
  fields, points are on the subscheme if they satisfy the equations to within tolerance.

- \texttt{tolerance} - a rational number in (0,1] used in doyle-krumm algorithm-4 for enumeration over
  number fields.

- \texttt{precision} - the precision to use for computing the elements of bounded height of number fields.

\textbf{OUTPUT:}

- a list of rational points of a affine scheme

13.6. Set of homomorphisms between two affine schemes \hfill 101
**Warning:** For numerically inexact fields such as ComplexField or RealField the list of points returned is very likely to be incomplete. It may also contain repeated points due to tolerance.

EXAMPLES: The bug reported at #11526 is fixed:

```sage
def example(x, y):
    A = AffineSpace(ZZ, 2)
    F = GF(3)
    A(F).points()

    A.<x, y> = ZZ
    I = A.ideal(x^2 - y^2 - 1)
    V = AffineSpace(ZZ, 2)
    X = V.subscheme(I)
    M = X(ZZ)
    M.points(bound=1)

    u = QQ['u'].0
    K.<v> = NumberField(u^2 + 3)
    A.<x, y> = AffineSpace(K, 2)
    len(A(K).points(bound=2))

    A(<x, y> = AffineSpace(2), 2)
    E = A.subscheme([x^2 + y^2 - 1, y^2 - x^3 + x^2 + x - 1])
    E(A.base_ring()).points()

    A.<x1, x2> = AffineSpace(CDF, 2)
    E = A.subscheme([x1^2 + x2^2 + x1*x2, x1 + x2])
    E(A.base_ring()).points()
```

Bases: `sage.schemes.generic.homset.SchemeHomset_generic`

Set of rational points of an affine variety.

INPUT:
See SchemeHomset_generic.

EXAMPLES:

```
sage: from sage.schemes.affine.affine_homset import SchemeHomset_points_spec
sage: SchemeHomset_points_spec(Spec(QQ), Spec(QQ))
Set of rational points of Spectrum of Rational Field
```
14.1 Projective $n$ space over a ring

EXAMPLES:

We construct projective space over various rings of various dimensions.

The simplest projective space:

\[ \text{sage: ProjectiveSpace(0)} \]
Projective Space of dimension 0 over Integer Ring

A slightly bigger projective space over $\mathbb{Q}$:

\[ \text{sage: X = ProjectiveSpace(1000, QQ); X} \]
Projective Space of dimension 1000 over Rational Field

\[ \text{sage: X.dimension()} \]
1000

We can use “over” notation to create projective spaces over various base rings.

\[ \text{sage: X = ProjectiveSpace(5)/QQ; X} \]
Projective Space of dimension 5 over Rational Field

\[ \text{sage: X/CC} \]
Projective Space of dimension 5 over Complex Field with 53 bits of precision

The third argument specifies the printing names of the generators of the homogenous coordinate ring. Using the method \texttt{objgens() you can obtain both the space and the generators as ready to use variables.}

\[ \text{sage: P2, vars = ProjectiveSpace(10, QQ, 't').objgens()} \]
\[ \text{sage: vars} \]
(t0, t1, t2, t3, t4, t5, t6, t7, t8, t9, t10)

You can alternatively use the special syntax with < and >.

\[ \text{sage: P2.<x,y,z> = ProjectiveSpace(2, QQ)} \]
\[ \text{sage: P2} \]
Projective Space of dimension 2 over Rational Field

\[ \text{sage: P2.coordinate_ring()} \]
Multivariate Polynomial Ring in x, y, z over Rational Field

The first of the three lines above is just equivalent to the two lines:

\[ \text{sage: P2 = ProjectiveSpace(2, QQ, 'xyz')} \]
\[ \text{sage: x,y,z = P2.gens()} \]
For example, we use $x, y, z$ to define the intersection of two lines.

```python
sage: V = P2.subscheme([x+y+z, x+y-z]); V
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
  x + y + z,
  x + y - z
sage: V.dimension()
0
```

AUTHORS:

- Ben Hutz: (June 2012): support for rings
- Ben Hutz (9/2014): added support for Cartesian products
- Rebecca Lauren Miller (March 2016): added point_transformation_matrix

```
sage.schemes.projective.projective_space.ProjectiveSpace(n, R=None, names='x')
Return projective space of dimension $n$ over the ring $R$.

EXAMPLES: The dimension and ring can be given in either order.
```
```python
sage: ProjectiveSpace(3, QQ)
Projective Space of dimension 3 over Rational Field
sage: ProjectiveSpace(5, QQ)
Projective Space of dimension 5 over Rational Field
sage: P = ProjectiveSpace(2, QQ, names='XYZ'); P
Projective Space of dimension 2 over Rational Field
sage: P.coordinate_ring()
Multivariate Polynomial Ring in X, Y, Z over Rational Field
```

The divide operator does base extension.

```python
sage: ProjectiveSpace(5)/GF(17)
Projective Space of dimension 5 over Finite Field of size 17
```

The default base ring is $\mathbb{Z}$.

```python
sage: ProjectiveSpace(5)
Projective Space of dimension 5 over Integer Ring
```

There is also an projective space associated each polynomial ring.

```python
sage: R = GF(7)['x,y,z']
sage: P = ProjectiveSpace(R); P
Projective Space of dimension 2 over Finite Field of size 7
sage: P.coordinate_ring()
Multivariate Polynomial Ring in x, y, z over Finite Field of size 7
sage: P.coordinate_ring() is R
True
```

```python
sage: ProjectiveSpace(3, Zp(5), 'y')
Projective Space of dimension 3 over 5-adic Ring with capped relative precision 20
```

```python
sage: ProjectiveSpace(2, QQ, 'x,y,z')
Projective Space of dimension 2 over Rational Field
```
```python
sage: R.<x> = QQ[]
sage: ProjectiveSpace(R)
Projective Space of dimension 0 over Rational Field
```

Projective spaces are not cached, i.e., there can be several with the same base ring and dimension (to facilitate gluing constructions).

```python
sage: R.<x> = QQ[]
sage: ProjectiveSpace(R)
Projective Space of dimension 0 over Rational Field
```

### class sage.schemes.projective.projective_space.ProjectiveSpace_field

```
Bases: sage.schemes.projective.projective_space.ProjectiveSpace_ring
```

### curve(F)

Return a curve defined by F in this projective space.

**INPUT:**

- F – a polynomial, or a list or tuple of polynomials in the coordinate ring of this projective space.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: P.curve([y^2 - x*z])
Projective Plane Curve over Rational Field defined by y^2 - x*z
```

### point_transformation_matrix(points_source, points_target)

Returns a unique element of PGL that transforms one set of points to another.

Given a projective space of degree n and a set of n+2 source points and a set of n+2 target points in the same projective space, such that no n+1 points of each set are linearly dependent finds the unique element of PGL that translates the source points to the target points.

**Warning**: will not work over precision fields

**INPUT:**

- points_source - points in source projective space.
- points_target - points in target projective space.

**OUTPUT**: Transformation matrix - element of PGL.

**EXAMPLES:**

```python
sage: P1.<a,b,c>=ProjectiveSpace(QQ, 2)
sage: points_source=[P1([1,4,1]),P1([1,2,2]),P1([3,5,1]),P1([1,-1,1])]  
sage: points_target=[P1([5,-2,7]),P1([3,-2,3]),P1([6,-5,9]), P1([3,6,7])]
sage: m = P1.point_transformation_matrix(points_source, points_target); m
[ -13/59 -128/59 -25/59]
[538/177 8/59 26/177]
[ -45/59 -196/59 1]
```

(continues on next page)
sage: [P.list(m*vector(list(points_source[i]))) == points_target[i] for i in range(4)]
[True, True, True, True]

sage: P.<a,b> = ProjectiveSpace(GF(13),1)
sage: points_source = [P([-6,7]), P([1,4]), P([3,2])]
sage: points_target = [P([-1,2]), P([0,2]), P([-1,6])]
sage: P.point_transformation_matrix(points_source, points_target)
[10 4]
[10 1]

sage: P.<a,b> = ProjectiveSpace(QQ,1)
sage: points_source = [P([-6,-4]), P([1,4]), P([3,2])]
sage: points_target = [P([-1,2]), P([0,2]), P([-2,4])]
sage: P.point_transformation_matrix(points_source, points_target)
Traceback (most recent call last):
  ...
ValueError: source points not independent

sage: P.<a,b> = ProjectiveSpace(QQ,1)
sage: points_source = [P([-6,-1]), P([1,4]), P([3,2])]

ValueError: target points not in self

points_of_bounded_height(**kwds)
Returns an iterator of the points in self of absolute height of at most the given bound.

Bound check is strict for the rational field. Requires self to be projective space over a number field. Uses
the Doyle-Krumm algorithm 4 (algorithm 5 for imaginary quadratic) for computing algebraic numbers up
to a given height [Doyle-Krumm].

The algorithm requires floating point arithmetic, so the user is allowed to specify the precision for such cal-
culations. Additionally, due to floating point issues, points slightly larger than the bound may be returned.
This can be controlled by lowering the tolerance.

INPUT:
kwds:
  • bound - a real number
  • tolerance - a rational number in (0,1] used in doyle-krumm algorithm-4
  • precision - the precision to use for computing the elements of bounded height of number fields.

OUTPUT:
  • an iterator of points in this space

EXAMPLES:

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: sorted(list(P.points_of_bounded_height(bound=5)))
[(0 : 1), (1 : -5), (1 : -4), (1 : -3), (1 : -2), (1 : -1), (1 : 0),
 (1 : 1), (1 : 2), (1 : 3), (1 : 4), (1 : 5), (2 : -5), (2 : -3),
 (2 : -1), (2 : 1), (2 : 3), (2 : 5), (3 : -5), (3 : -4), (3 : -2),
 (3 : -1), (3 : 1), (3 : 2), (3 : 4), (3 : 5), (4 : -5), (4 : -3),
 (4 : -1), (4 : 1), (4 : 3), (4 : 5), (5 : -4), (5 : -3), (5 : -2),
 (5 : -1), (5 : 1), (5 : 2), (5 : 3), (5 : 4)]

sage: u = QQ['u'].0
sage: P.<x,y,z> = ProjectiveSpace(NumberField(u^2 - 2, 'v'), 2)
sage: len(list(P.points_of_bounded_height(bound=1.5, tolerance=0.1)))
57

subscheme_from_Chow_form(Ch, dim)
Returns the subscheme defined by the Chow equations associated to the Chow form Ch.

These equations define the subscheme set-theoretically, but only for smooth subschemes and hypersurfaces
do they define the subscheme as a scheme.

ALGORITHM:
The Chow form is a polynomial in the Plucker coordinates. The Plucker coordinates are the bracket
polynomials. We first re-write the Chow form in terms of the dual Plucker coordinates. Then we expand...
$Ch(span(p, L))$ for a generic point $p$ and a generic linear subspace $L$. The coefficients as polynomials in the coordinates of $p$ are the equations defining the subscheme. [DalbecSturmfels].

**INPUT:**

- $Ch$ - a homogeneous polynomial.
- $dim$ - the dimension of the associated scheme.

**OUTPUT:** a projective subscheme.

**EXAMPLES:**

```python
sage: P = ProjectiveSpace(QQ, 4, 'z')
sage: R.<x0,x1,x2,x3,x4> = PolynomialRing(QQ)
sage: H = x1^2 + x2^2 + 5*x3*x4
sage: P.subscheme_from_Chow_form(H,3)
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
-5*z0*z1 + z2^2 + z3^2
```

```python
sage: P = ProjectiveSpace(QQ, 3, 'z')
sage: R.<x0,x1,x2,x3,x4,x5> = PolynomialRing(QQ)
sage: H = x1-x2-x3+x5+2*x0
sage: P.subscheme_from_Chow_form(H, 1)
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
-z1 + z3,
z0 + z2 + z3,
-z1 - 2*z3,
-z0 - z1 + 2*z2
```

```python
sage: P.<x0,x1,x2,x3> = ProjectiveSpace(GF(7), 3)
sage: X = P.subscheme([x3^2+x1*x2,x2-x0])
sage: Ch = X.Chow_form();Ch
t0^2 - 2*t0*t3 + t3^2 - t2*t4 - t4*t5
sage: Y = P.subscheme_from_Chow_form(Ch, 1); Y
Closed subscheme of Projective Space of dimension 3 over Finite Field of size 7 defined by:
x1*x2 + x3^2,
-x0*x2 + x2^2,
-x0*x1 - x1*x2 - 2*x3^2,
x0^2 - x0*x2,
x0*x1 + x3^2,
-2*x0*x3 + 2*x2*x3,
2*x0*x3 - 2*x2*x3,
x0^2 - 2*x0*x2 + x2^2
```

```python
sage: I = Y.defining_ideal()
sage: I.saturation(I.ring().ideal(list(I.ring().gens())))[0]
Ideal (x0 - x2, x1*x2 + x3^2) of Multivariate Polynomial Ring in x0, x1, x2, x3 over Finite Field of size 7
```

class sage.schemes.projective.projective_space.ProjectiveSpace_finite_field(n, $R=\text{Integer Ring}$, $names=\text{None}$)

**Bases:** sage.schemes.projective.projective_space.ProjectiveSpace_field

**rational_points** ($F=\text{None}$)

Return the list of $F$-rational points on this projective space, where $F$ is a given finite field, or the base ring.
of this space.

EXAMPLES:

```python
sage: P = ProjectiveSpace(1, GF(3))
sage: P.rational_points()
[(0 : 1), (1 : 1), (2 : 1), (1 : 0)]
sage: P.rational_points(GF(3^2, 'b'))
[(0 : 1), (b : 1), (b + 1 : 1), (2*b + 1 : 1), (2 : 1), (2*b : 1), (2*b + 2 : 1),
 (1 : 1), (1 : 0)]
```

```python
rational_points_dictionary()
Return dictionary of points.

OUTPUT:

• dictionary

EXAMPLES:

```python
sage: P1 = ProjectiveSpace(GF(7),1,'x')
sage: P1.rational_points_dictionary()
```

```python
class sage.schemes.projective.projective_space.ProjectiveSpace_rational_field(n, R=Integer Ring, names=None)

Bases: sage.schemes.projective.projective_space.ProjectiveSpace_field

rational_points (bound=0)

Returns the projective points \((x_0 : \cdots : x_n)\) over \(\mathbb{Q}\) with \(|x_i| \leq \text{bound}\).

ALGORITHM:

The very simple algorithm works as follows: every point \((x_0 : \cdots : x_n)\) in projective space has a unique largest index \(i\) for which \(x_i\) is not zero. The algorithm then iterates downward on this index. We normalize by choosing \(x_i\) positive. Then, the points \(x_0, \ldots, x_{i-1}\) are the points of affine \(i\)-space that are relatively prime to \(x_i\). We access these by using the Tuples method.

INPUT:

• bound - integer.

EXAMPLES:

```python
sage: PP = ProjectiveSpace(0, QQ)
sage: PP.rational_points(1)
[(1)]
sage: PP = ProjectiveSpace(1, QQ)
sage: PP.rational_points(1)
[(1)]
sage: PP = ProjectiveSpace(2, QQ)
sage: PP.rational_points(2)
[(-2 : 1), (-1 : 1), (0 : 1), (1 : 1), (2 : 1), (-1/2 : 1), (1/2 : 1),
 (-1 : 1)]
sage: PP = ProjectiveSpace(2, QQ)
```

(continues on next page)
AUTHORS:

• Benjamin Antieau (2008-01-12)

class sage.schemes.projective.projective_space.ProjectiveSpace_ring(n, R=Integer Ring, names=None): sage.structure.unique_representation.UniqueRepresentation, sage.schemes.generic.ambient_space.AmbientSpace

Projective space of dimension $n$ over the ring $R$.

EXAMPLES:

```
sage: X.<x,y,z,w> = ProjectiveSpace(3, QQ)
sage: X.base_scheme()
Spectrum of Rational Field
sage: X.base_ring()
Rational Field
sage: X.structure_morphism()
Scheme morphism:
    From: Projective Space of dimension 3 over Rational Field
    To: Spectrum of Rational Field
    Defn: Structure map
dsage: X.coordinate_ring()
Multivariate Polynomial Ring in x, y, z, w over Rational Field
```

Loading and saving:

```
sage: loads(X.dumps()) == X
True
sage: P = ProjectiveSpace(ZZ, 1, 'x')
sage: loads(P.dumps()) is P
True
```

Equality and hashing:

```
sage: ProjectiveSpace(QQ, 3, 'a') == ProjectiveSpace(ZZ, 3, 'a')
False
sage: ProjectiveSpace(ZZ, 1, 'a') == ProjectiveSpace(ZZ, 0, 'a')
False
sage: ProjectiveSpace(ZZ, 2, 'a') == AffineSpace(ZZ, 2, 'a')
```

(continues on next page)
False

```
sage: ProjectiveSpace(QQ, 3, 'a') != ProjectiveSpace(ZZ, 3, 'a')
True
sage: ProjectiveSpace(ZZ, 1, 'a') != ProjectiveSpace(ZZ, 0, 'a')
True
sage: ProjectiveSpace(ZZ, 2, 'a') != AffineSpace(ZZ, 2, 'a')
True
```

```
sage: hash(ProjectiveSpace(QQ, 3, 'a')) == hash(ProjectiveSpace(ZZ, 3, 'a'))
False
sage: hash(ProjectiveSpace(ZZ, 1, 'a')) == hash(ProjectiveSpace(ZZ, 0, 'a'))
False
sage: hash(ProjectiveSpace(ZZ, 2, 'a')) == hash(AffineSpace(ZZ, 2, 'a'))
False
```

**Lattes_map** \((E, m)\)

Given an elliptic curve \(E\) and an integer \(m\) return the Lattes map associated to multiplication by \(m\).

In other words, the rational map on the quotient \(E/\{±1\} \cong \mathbb{P}^1\) associated to \([m] : E \to E\).

**INPUT:**
- \(E\) – an elliptic curve.
- \(m\) – an integer.

**OUTPUT:** a dynamical system on this projective space.

**Examples:**

```
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: E = EllipticCurve(QQ,[-1, 0])
sage: P.Lattes_map(E, 2)
Dynamical System of Projective Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending (x : y) to
       (1/4*x^4 + 1/2*x^2*y^2 + 1/4*y^4 : x^3*y - x*y^3)
```

**affine_patch** \((i, AA=None)\)

Return the \(i\)th affine patch of this projective space.

This is an ambient affine space \(A^n_R\), where \(R\) is the base ring of self, whose “projective embedding” map is 1 in the \(i\)th factor.

**INPUT:**
- \(i\) – integer between 0 and dimension of self, inclusive.
- \(AA\) – (default: None) ambient affine space, this is constructed if it is not given.

**OUTPUT:**
- An ambient affine space with fixed projective_embedding map.

**EXAMPLES:**

```
sage: PP = ProjectiveSpace(5) / QQ
sage: AA = PP.affine_patch(2)
sage: AA
Affine Space of dimension 5 over Rational Field
sage: AA.projective_embedding()
```

(continues on next page)
Scheme morphism:
From: Affine Space of dimension 5 over Rational Field
To: Projective Space of dimension 5 over Rational Field
Defn: Defined on coordinates by sending (x0, x1, x3, x4, x5) to
(x0 : x1 : l : x3 : x4 : x5)
sage: AA.projective_embedding(0)
Scheme morphism:
From: Affine Space of dimension 5 over Rational Field
To: Projective Space of dimension 5 over Rational Field
Defn: Defined on coordinates by sending (x0, x1, x3, x4, x5) to
(1 : x0 : x1 : x3 : x4 : x5)
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: P.affine_patch(0).projective_embedding(0).codomain() == P
True
cartesian_product (other)
Return the Cartesian product of this projective space and other.

INPUT:
• other - A projective space with the same base ring as this space.

OUTPUT:
• A Cartesian product of projective spaces.

EXAMPLES:
sage: P1 = ProjectiveSpace(QQ, 1, 'x')
sage: P2 = ProjectiveSpace(QQ, 2, 'y')
sage: PP = P1.cartesian_product(P2); PP
Product of projective spaces P^1 x P^2 over Rational Field
sage: PP.gens()
(x0, x1, y0, y1, y2)

change_ring (R)
Return a projective space over ring R.

INPUT:
• R – commutative ring or morphism.

OUTPUT:
• projective space over R.

Note: There is no need to have any relation between R and the base ring of this space, if you want to have such a relation, use self.base_extend(R) instead.

EXAMPLES:
sage: P.<x, y, z> = ProjectiveSpace(2, ZZ)
sage: PQ = P.change_ring(QQ); PQ
Projective Space of dimension 2 over Rational Field
sage: PQ.change_ring(GF(5))
Projective Space of dimension 2 over Finite Field of size 5
sage: K.<w> = QuadraticField(2)
sage: P = ProjectiveSpace(K,2,'t')
sage: P.change_ring(K.embeddings(QQbar)[0])
Projective Space of dimension 2 over Algebraic Field

chebyshev_polynomial (n, kind='first')
Generates an endomorphism of this projective line by a Chebyshev polynomial.

Chebyshev polynomials are a sequence of recursively defined orthogonal polynomials. Chebyshev of the
first kind are defined as $T_0(x) = 1$, $T_1(x) = x$, and $T_{n+1}(x) = 2xT_n(x) - T_{n-1}(x)$. Chebyshev of the
second kind are defined as $U_0(x) = 1$, $U_1(x) = 2x$, and $U_{n+1}(x) = 2xU_n(x) - U_{n-1}(x)$.

INPUT:

• n – a non-negative integer.

• kind – first or second specifying which kind of chebyshev the user would like to generate. Defaults to first.

OUTPUT: DynamicalSystem_projective

EXAMPLES:

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: P.chebyshev_polynomial(5, 'first')
Dynamical System of Projective Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending (x : y) to
(16*x^5 - 20*x^3*y^2 + 5*x*y^4 : y^5)

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: P.chebyshev_polynomial(3, 'second')
Dynamical System of Projective Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending (x : y) to
(8*x^3 - 4*x*y^2 : y^3)

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: P.chebyshev_polynomial(3, 2)
Traceback (most recent call last):
  ... ValueError: keyword 'kind' must have a value of either 'first' or 'second'

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: P.chebyshev_polynomial(-4, 'second')
Traceback (most recent call last):
  ... ValueError: first parameter 'n' must be a non-negative integer

sage: P = ProjectiveSpace(QQ, 2, 'x')
sage: P.chebyshev_polynomial(2)
Traceback (most recent call last):
  ... TypeError: projective space must be of dimension 1

coordinate_ring ()
Return the coordinate ring of this scheme.

EXAMPLES:
```python
sage: ProjectiveSpace(3, GF(19^2, 'alpha'), 'abcd').coordinate_ring()
Multivariate Polynomial Ring in a, b, c, d over Finite Field in alpha of size
˓→19^2
```

```python
sage: ProjectiveSpace(3).coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2, x3 over Integer Ring
```

```python
sage: ProjectiveSpace(2, QQ, ['alpha', 'beta', 'gamma']).coordinate_ring()
Multivariate Polynomial Ring in alpha, beta, gamma over Rational Field
```

**is_projective()**

Return that this ambient space is projective \( n \)-space.

**EXAMPLES:**

```python
sage: ProjectiveSpace(3, QQ).is_projective()
True
```

**ngens()**

Return the number of generators of this projective space.

This is the number of variables in the coordinate ring of self.

**EXAMPLES:**

```python
sage: ProjectiveSpace(3, QQ).ngens()
4
sage: ProjectiveSpace(7, ZZ).ngens()
8
```

**point**

Create a point on this projective space.

**INPUT:**

- \( v \) – anything that defines a point
- \( \text{check} \) – boolean (optional, default: True); whether to check the defining data for consistency

**OUTPUT:** A point of this projective space.

**EXAMPLES:**

```python
sage: P2 = ProjectiveSpace(QQ, 2)
sage: P2.point([4,5])
(4 : 5 : 1)
sage: P = ProjectiveSpace(QQ, 1)
sage: P.point(infinity)
(1 : 0)
sage: P = ProjectiveSpace(QQ, 2)
sage: P.point(infinity)
Traceback (most recent call last):
  ...
ValueError: +Infinity not well defined in dimension > 1
```
```python
sage: P = ProjectiveSpace(ZZ, 2)
sage: P.point([infinity])
Traceback (most recent call last):
...
ValueError: [+Infinity] not well defined in dimension > 1
```

**subscheme** \((X)\)
Return the closed subscheme defined by \(X\).

**INPUT:**
- \(X\) - a list or tuple of equations.

**EXAMPLES:**
```python
sage: A.<x,y,z> = ProjectiveSpace(2, QQ)
sage: X = A.subscheme([x*z^2, y^2*z, x*y^2]); X
Closed subscheme of Projective Space of dimension 2 over Rational Field
˓→ defined by:
x*z^2,
y^2*z,
x*y^2
sage: X.defining_polynomials ()
(x*z^2, y^2*z, x*y^2)
sage: I = X.defining_ideal(); I
Ideal (x*z^2, y^2*z, x*y^2) of Multivariate Polynomial Ring in x, y, z over Rational Field
sage: I.groebner_basis()
[x*y^2, y^2*z, x*z^2]
sage: X.dimension ()
0
sage: X.base_ring ()
Rational Field
sage: X.base_scheme ()
Spectrum of Rational Field
sage: X.structure_morphism ()
Scheme morphism:
  From: Closed subscheme of Projective Space of dimension 2 over Rational Field
  ˓→ defined by:
x*z^2,
y^2*z,
x*y^2
  To:   Spectrum of Rational Field
  Defn: Structure map
```

**veronese_embedding** \((d, CS=None, order='lex')\)
Return the degree \(d\) Veronese embedding from this projective space.

**INPUT:**
- \(d\) – a positive integer.
- \(CS\) – a projective ambient space to embed into. If this projective space has dimension \(N\), the dimension of \(CS\) must be \(\binom{N+d}{d} - 1\). This is constructed if not specified. Default: None.

14.1. Projective \(n\) space over a ring 117
• **order** – a monomial order to use to arrange the monomials defining the embedding. The monomials will be arranged from greatest to least with respect to this order. Default: 'lex'.

**OUTPUT:**

• a scheme morphism from this projective space to CS.

**EXAMPLES:**

```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: vd = P.veronese_embedding(4, order='invlex')
sage: vd
Scheme morphism:
  From: Projective Space of dimension 1 over Rational Field
  To:    Projective Space of dimension 4 over Rational Field
  Defn: Defined on coordinates by sending (x : y) to
         (y^4 : x*y^3 : x^2*y^2 : x^3*y : x^4)
```

**Veronese surface:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: Q.<q,r,s,t,u,v> = ProjectiveSpace(QQ, 5)
sage: vd = P.veronese_embedding(2, Q)
sage: vd
Scheme morphism:
  From: Projective Space of dimension 2 over Rational Field
  To:    Projective Space of dimension 5 over Rational Field
  Defn: Defined on coordinates by sending (x : y : z) to
         (x^2 : x*y : x*z : y^2 : y*z : z^2)
```

```python
sage: vd(P.subscheme([]))
Closed subscheme of Projective Space of dimension 5 over Rational Field
  defined by:
    -u^2 + t*v,
    -s*u + r*v,
    -s*t + r*u,
    -s^2 + q*v,
    -r*s + q*u,
    -r^2 + q*t
```

**sage.schemes.projective.projective_space.is_ProjectiveSpace(x)**

Return True if x is a projective space.

In other words, if x is an ambient space \( \mathbb{P}^n_R \), where \( R \) is a ring and \( n \geq 0 \) is an integer.

**EXAMPLES:**

```python
sage: from sage.schemes.projective.projective_space import is_ProjectiveSpace
sage: is_ProjectiveSpace(ProjectiveSpace(5, names='x'))
True
sage: is_ProjectiveSpace(ProjectiveSpace(5, GF(9,'alpha'), names='x'))
True
sage: is_ProjectiveSpace(Spec(ZZ))
False
```

# 14.2 Morphisms on projective varieties

A morphism of schemes determined by rational functions that define what the morphism does on points in the ambient projective space.
AUTHORS:

- David Kohel, William Stein
- William Stein (2006-02-11): fixed bug where P(0,0,0) was allowed as a projective point.
- Volker Braun (2011-08-08): Renamed classes, more documentation, misc cleanups.
- Ben Hutz (2013-03) iteration functionality and new directory structure for affine/projective, height functionality
- Brian Stout, Ben Hutz (Nov 2013) - added minimal model functionality
- Dillon Rose (2014-01): Speed enhancements
- Ben Hutz (2015-11): iteration of subschemes

```python
class sage.schemes.projective.projective_morphism.SchemeMorphism_polynomial_projective_space:

Bases: sage.schemes.generic.morphism.SchemeMorphism_polynomial

A morphism of schemes determined by rational functions that define what the morphism does on points in the ambient projective space.

EXAMPLES:

```python
sage: R.<x,y> = QQ[]
sage: P1 = ProjectiveSpace(R)
sage: H = P1.Hom(P1)
sage: H([y,2*x])
Scheme endomorphism of Projective Space of dimension 1 over Rational Field
  Defn: Defined on coordinates by sending (x : y) to
         (y : 2*x)
```

An example of a morphism between projective plane curves (see trac ticket #10297):

```python
sage: P2.<x,y,z> = ProjectiveSpace(QQ,2)
sage: f = x^3+y^3+60*z^3
sage: g = y^2*z-(x^3 - 6400*z^3/3)
sage: C = Curve(f)
sage: E = Curve(g)
sage: xbar,ybar,zbar = C.coordinate_ring().gens()
sage: H = C.Hom(E)
sage: H([zbar,xbar-ybar,-(xbar+ybar)/80])
Scheme morphism:
  From: Projective Plane Curve over Rational Field defined by x^3 + y^3 + 60*z^3
  To:  Projective Plane Curve over Rational Field defined by -x^3 + y^2*z + 6400/3*z^3
  Defn: Defined on coordinates by sending (x : y : z) to
         (z : x - y : -1/80*x - 1/80*y)
```

A more complicated example:

```python
sage: P2.<x,y,z> = ProjectiveSpace(2, QQ)
sage: P1 = P2.subscheme(x-y)
sage: H12 = P1.Hom(P2)
sage: H12([x^2, x*z, z^2])
Scheme morphism:
  From: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
         x - y
  To:  Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
         z^2 - x*z - x^2
```

(continues on next page)
To: Projective Space of dimension 2 over Rational Field
Defn: Defined on coordinates by sending (x : y : z) to
(x^2 : x*z : z^2)

We illustrate some error checking:

```sage
sage: R.<x,y> = QQ[
...
    sage: H = P1.Hom(P1)
    sage: f = H([x-y, x*y])
    Traceback (most recent call last):
    ... ValueError: polys (= [x - y, x*y]) must be of the same degree
sage: H([x-1, x*y+x])
    Traceback (most recent call last):
    ... ValueError: polys (= [x - 1, x*y + x]) must be homogeneous
sage: H([exp(x), exp(y)])
    Traceback (most recent call last):
    ... TypeError: polys (= [e^x, e^y]) must be elements of Multivariate Polynomial Ring in x, y over Rational Field
```

We can also compute the forward image of subschemes through elimination. In particular, let \(X = V(h_1, \ldots, h_t)\) and define the ideal \(I = (h_1, \ldots, h_t, y_0 - f_0(\bar{x}), \ldots, y_n - f_n(\bar{x}))\). Then the elimination ideal \(I_{n+1} = I \cap K[y_0, \ldots, y_n]\) is a homogeneous ideal and \(f(X) = V(I_{n+1})\):

```sage
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
    sage: H = End(P)
    sage: f = H([(x-2*y)^2, (x-2*z)^2, x^2])
    sage: X = P.subscheme(y-z)
    sage: f(f(f(X)))
    Closed subscheme of Projective Space of dimension 2 over Rational Field
    defined by:
        y - z
```

```sage
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
    sage: H = End(P)
    sage: f = H([(x-2*y)^2, (x-2*z)^2, x^2])
    sage: f(P.subscheme([x,y,z]))
    Closed subscheme of Projective Space of dimension 3 over Rational Field
    defined by:
        w,
        y,
        x
```

**as_dynamical_system()**

Return this endomorphism as a `DynamicalSystem_projective`.

**OUTPUT:**

- `DynamicalSystem_projective`

**EXAMPLES:**
sage: P.<x,y,z> = ProjectiveSpace(ZZ, 2)
sage: H = End(P)
sage: f = H([x^2, y^2, z^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.projective_ds.DynamicalSystem_→projective'>

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2-y^2, y^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.projective_ds.DynamicalSystem_→projective_field'>

sage: P.<x,y> = ProjectiveSpace(GF(5), 1)
sage: H = End(P)
sage: f = H([x^2, y^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.projective_ds.DynamicalSystem_→projective_finite_field'>

sage: P.<x,y> = ProjectiveSpace(RR, 1)
sage: f = DynamicalSystem([x^2 + y^2, y^2], P)
sage: g = f.as_dynamical_system()
sage: g is f
True

automorphism_group(**kwds)
Return the automorphism group.

EXAMPLES:

sage: R.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(R)
sage: f = H([x^2-y^2, x*y])
sage: f.automorphism_group(return_functions=True)
doctest:warning
...
[x, -x]

canonical_height (P, **kwds)
Return the canonical height of the point.

EXAMPLES:

sage: P.<x,y> = ProjectiveSpace(ZZ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, 2*x*y]);
sage: f.canonical_height(P.point([5,4]), error_bound=0.001)
doctest:warning
...
2.1970553519503404898926835324

conjugate (M)
Return the conjugate of this map.

EXAMPLES:
sage: P.<x,y> = ProjectiveSpace(ZZ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, y^2])
sage: f.conjugate(matrix([[1,2], [0,1]]))
doctest:warning
...
Dynamical System of Projective Space of dimension 1 over Integer Ring
Defn: Defined on coordinates by sending (x : y) to
    (x^2 + 4*x*y + 3*y^2 : y^2)

critical_height (**kwds)
Return the critical height.

EXAMPLES:

sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^3+7*y^3, 11*y^3])
sage: f.critical_height()
doctest:warning
...
1.1989273321156851418802151128

critical_point_portrait (check=True, embedding=None)
Return the directed graph of critical point portrait.

EXAMPLES:

sage: R.<z> = QQ[]
sage: K.<v> = NumberField(z^6 + 2*z^5 + 2*z^4 + 2*z^3 + z^2 + 1)
sage: PS.<x,y> = ProjectiveSpace(K,1)
sage: H = End(PS)
sage: f = H([x^2+v*y^2, y^2])
sage: f.critical_point_portrait(check=False, embedding=K.
   \rightarrow \text{embeddings}(QQbar)[0])
doctest:warning
...
Looped digraph on 6 vertices

critical_points (R=None)
Return the critical points.

Examples:

sage: setVerbose(None)
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^3-2*x*y^2 + 2*y^3, y^3])
sage: f.critical_points()
doctest:warning
...
[(1 : 0)]

critical_subscheme ()
Return the critical subscheme.

Examples:
```python
sage: set_verbose(None)
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^3-2*x*y^2 + 2*y^3, y^3])
sage: f.critical_subscheme()
doctest:warning
...  
Closed subscheme of Projective Space of dimension 1 over Rational Field
defined by:
9*x^2*y^2 - 6*y^4
```

degree ()
Return the degree of this map.

The degree is defined as the degree of the homogeneous polynomials that are the coordinates of this map.

OUTPUT:
- A positive integer

EXAMPLES:
```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([x^2+y^2, y^2])
sage: f.degree()
2

sage: P.<x,y,z> = ProjectiveSpace(CC,2)
sage: H = Hom(P,P)
sage: f = H([x^3+y^3, y^2*z, z*x*y])
sage: f.degree()
3

sage: R.<t> = PolynomialRing(QQ)
sage: P.<x,y,z> = ProjectiveSpace(R,2)
sage: H = Hom(P,P)
sage: f = H([x^2+t*y^2, (2-t)*y^2, z^2])
sage: f.degree()
2

sage: P.<x,y,z> = ProjectiveSpace(ZZ,2)
sage: X = P.subscheme(x^2-y^2)
sage: H = Hom(X,X)
sage: f = H([x^2, y^2, z^2])
sage: f.degree()
2
```

degree_sequence (iterates=2)
Return the sequence of degrees of iterates.

EXAMPLES:
```python
sage: P2.<X,Y,Z> = ProjectiveSpace(QQ, 2)
sage: H = End(P2)
sage: f = H([Z^2, X+Y, Y^2])
sage: f.degree_sequence(15)
doctest:warning
... (continues on next page)
```

14.2. Morphisms on projective varieties

123
dehomogenize \((n)\)

Returns the standard dehomogenization at the \(n[0]\) coordinate for the domain and the \(n[1]\) coordinate for the codomain.

Note that the new function is defined over the fraction field of the base ring of this map.

**INPUT:**

- \(n\) – a tuple of nonnegative integers. If \(n\) is an integer, then the two values of \(n\) are assumed to be the same.

**OUTPUT:**

- SchemeMorphism_polynomial_affine_space.

**EXAMPLES:**

```sage
sage: P.<x,y> = ProjectiveSpace(ZZ,1)
sage: H = Hom(P,P)
sage: f = H([x^2+y^2, y^2])
sage: f.dehomogenize(0)
Scheme endomorphism of Affine Space of dimension 1 over Integer Ring
  Defn: Defined on coordinates by sending (y) to
  \((y^2/(y^2 + 1))\)
```

```sage
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([x^2-y^2, y^2])
sage: f.dehomogenize((0,1))
Scheme morphism:
  From: Affine Space of dimension 1 over Rational Field
  To:   Affine Space of dimension 1 over Rational Field
  Defined on coordinates by sending (y) to
  \((-y^2 + 1)/y^2)\)
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: H = Hom(P,P)
sage: f = H([x^2+y^2, y^2-z^2, 2*z^2])
sage: f.dehomogenize(2)
Scheme endomorphism of Affine Space of dimension 2 over Rational Field
  Defined on coordinates by sending (x, y) to
  \((1/2*x^2 + 1/2*y^2, 1/2*y^2 - 1/2)\)
```

```sage
sage: R.<t> = PolynomialRing(QQ)
sage: P.<x,y,z> = ProjectiveSpace(FractionField(R),2)
sage: H = Hom(P,P)
sage: f = H([x^2+t*y^2, t*y^2-z^2, t*z^2])
sage: f.dehomogenize(2)
Scheme endomorphism of Affine Space of dimension 2 over Fraction Field
  of Univariate Polynomial Ring in t over Rational Field
  Defined on coordinates by sending (x, y) to
  \((1/t*x^2 + y^2, y^2 - 1/t)\)
```
sage: P.<x,y,z> = ProjectiveSpace(ZZ,2)
sage: X = P.subscheme(x^2-y^2)
sage: H = Hom(X,X)
sage: f = H([x^2, y^2, x*z])
Scheme endomorphism of Closed subscheme of Affine Space of dimension 2 over Integer Ring defined by:
\[ x^2 - y^2 \]
Defn: Defined on coordinates by sending (x, y) to 
(\frac{x}{y^2}, \frac{x}{y^2})
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2 - 2*x*y, y^2])
sage: f.dehomogenize(0).homogenize(0) == f
True
sage: K.<w> = QuadraticField(3)
sage: O = K.ring_of_integers()
sage: P.<x,y> = ProjectiveSpace(O,1)
sage: H = End(P)
sage: f = H([x^2 - O(w)*y^2, y^2])
sage: f.dehomogenize(1)
Scheme endomorphism of Affine Space of dimension 1 over Maximal Order in Number Field in w with defining polynomial \( x^2 - 3 \)
Defn: Defined on coordinates by sending (x) to 
(\frac{x^2 - 3}{w})

dynamical_degree \( (N=3, prec=53) \)
Return the dynamical degree.

EXAMPLES:

```sage
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2 + (x*y), y^2])
sage: f.dynamical_degree()
doctest:warning
...
2.00000000000000
```

dynatomic_polynomial \( (period) \)
Return the dynatomic polynomial.

EXAMPLES:

```sage
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2 + y^2, y^2])
sage: f.dynatomic_polynomial(2)
doctest:warning
...
x^2 + x*y + 2*y^2
```

global_height \( (prec=None) \)
Returns the maximum of the absolute logarithmic heights of the coefficients in any of the coordinate functions of this map.

14.2. Morphisms on projective varieties
INPUT:
- `prec` – desired floating point precision (default: default RealField precision).

OUTPUT:
- a real number.

EXAMPLES:
```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([1/1331*x^2+1/4000*y^2, 210*x*y]);
sage: f.global_height()
8.29404964010203
This function does not automatically normalize:
sage: P.<x,y,z> = ProjectiveSpace(ZZ,2)
sage: H = Hom(P,P)
sage: f = H([4*x^2+100*y^2, 210*x*y, 10000*z^2]);
sage: f.global_height()
9.21034037197618
sage: f.normalize_coordinates()
sage: f.global_height()
8.51719319141624
```

```python
sage: R.<z> = PolynomialRing(QQ)
sage: K.<w> = NumberField(z^2-2)
sage: O = K.maximal_order()
sage: P.<x,y> = ProjectiveSpace(O,1)
sage: H = Hom(P,P)
sage: f = H([2*x^2 + 3*O(w)*y^2, O(w)*y^2])
sage: f.global_height()
1.44518587894808
```

```python
sage: P.<x,y> = ProjectiveSpace(QQbar,1)
sage: P.<u,v,w> = ProjectiveSpace(QQbar,2)
sage: H = Hom(P,P2)
sage: f = H([x^2 + QQbar(I)*x*y + 3*y^2, y^2, QQbar(sqrt(5))*x*y])
sage: f.global_height()
1.0986128866811
```

`green_function(P, v, **kwds)`
Return the value of the Green’s function at the point.

```
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, x*y]);
sage: Q = P(5,1)
sage: f.green_function(Q, 0, N=30)
doctest:warning
...
1.6460930159932946233759277576
```

`height_difference_bound(prec=None)`
Return the bound on the difference of the height and canonical height.
EXAMPLES:

```sage
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, x+y])
sage: f.height_difference_bound()
doctest:warning...
1.38629436111989
```

**is_PGL_minimal** *(prime_list=None)*

Return whether the representation is PGL minimal.

EXAMPLES:

```sage
sage: PS.<X,Y> = ProjectiveSpace(QQ,1)
sage: H = End(PS)
sage: f = H([X^2+3*Y^2, X*Y])
sage: f.is_PGL_minimal()
doctest:warning...
True
```

**is_morphism()**

returns `True` if this map is a morphism.

The map is a morphism if and only if the ideal generated by the defining polynomials is the unit ideal (no common zeros of the defining polynomials).

**OUTPUT:**

- Boolean

EXAMPLES:

```sage
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([x^2+y^2, y^2])
sage: f.is_morphism()
True
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(RR,2)
sage: H = Hom(P,P)
sage: f = H([x-z-y+z, x^2-y^2, z^2])
sage: f.is_morphism()
False
```

```sage
sage: R.<t> = PolynomialRing(GF(5))
sage: P.<x,y,z> = ProjectiveSpace(R,2)
sage: H = Hom(P,P)
sage: f = H([x+z-t*y^2, x^2-y^2, t*z^2])
sage: f.is_morphism()
True
```

Map that is not morphism on projective space, but is over a subscheme:

```sage
sage: P.<x,y,z> = ProjectiveSpace(RR,2)
sage: X = P.subscheme([x*y + y*z])
sage: H = Hom(X,X)
```

(continues on next page)
\begin{verbatim}
  sage: f = H([x*z-y*z, x^2-y^2, z^2])
  sage: f.is_morphism()
  True

is_postcritically_finite (err=0.01, embedding=None)
Return whether the map is postcritically finite.
Examples:
  sage: P.<x,y> = ProjectiveSpace(QQ,1)
  sage: H = Hom(P,P)
  sage: f = H([x^2 - y^2, y^2])
  sage: f.is_postcritically_finite()
  doctest:warning...
  True

local_height (v, prec=None)
Returns the maximum of the local height of the coefficients in any of the coordinate functions of this map.

INPUT:
  • v – a prime or prime ideal of the base ring.
  • prec – desired floating point precision (default: default RealField precision).

OUTPUT:
  • a real number.

EXAMPLES:
  sage: P.<x,y> = ProjectiveSpace(QQ,1)
  sage: H = Hom(P,P)
  sage: f = H([1/1331*x^2 + 1/4000*y^2, 210*x*y]);
  sage: f.local_height(1331)
  7.19368581839511
  This function does not automatically normalize:
  sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
  sage: H = Hom(P,P)
  sage: f = H([4*x^2+3/100*y^2, 8/210*x*y, 1/10000*z^2]);
  sage: f.local_height(2)
  2.77258872223978
  sage: f.normalize_coordinates()
  sage: f.local_height(2)
  0.000000000000000

  sage: R.<z> = PolynomialRing(QQ)
  sage: K.<w> = NumberField(z^2 - 2)
  sage: P.<x,y> = ProjectiveSpace(K,1)
  sage: H = Hom(P,P)
  sage: f = H([2*x^2 + w/3*y^2, 1/w*y^2])
  sage: f.local_height(K.ideal(3))
  1.09861228866811

local_height_arch (i, prec=None)
Returns the maximum of the local height at the \(i\)-th infinite place of the coefficients in any of the coordinate
\end{verbatim}
functions of this map.

INPUT:

• \( i \) – an integer.

• \( \text{prec} \) – desired floating point precision (default: default RealField precision).

OUTPUT:

• a real number.

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([[1/1331*x^2+1/4000*y^2, 210*x*y]]);
sage: f.local_height_arch(0)
5.34710753071747
```

```python
sage: R.<z> = PolynomialRing(QQ)
sage: K.<w> = NumberField(z^2-2)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: H = Hom(P,P)
sage: f = H([[2*x^2 + w/3*y^2, 1/w*y^2]])
sage: f.local_height_arch(1)
0.6931471805599453094172321214582
```

minimal_model \((\text{return\_transformation=False, prime\_list=None})\)

Return the minimal model.

EXAMPLES:

```python
sage: PS.<X,Y> = ProjectiveSpace(QQ,1)
sage: H = End(PS)
sage: f = H([X^2+3*Y^2, X*Y])
sage: f.minimal_model(return_transformation=True)
doctest:warning...
```

```python
{Dynamical System of Projective Space of dimension 1 over Rational Field
  Defn: Defined on coordinates by sending (X : Y) to
    (X^2 + 3*Y^2 : X*Y),
  [1 0]
  [0 1])
```

multiplier \((P, n, \text{check}=True)\)

Return the multiplier at the point.

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: H = End(P)
sage: f = H([[x^2,y^2, 4*z^2]]);
sage: Q = P.point([4,4,1], False);
sage: f.multiplier(Q,1)
doctest:warning
```

(continues on next page)
multiplier_spectra\((n,\ formal=False,\ embedding=None,\ type='point')\)
Computes the formal \(n\) multiplier spectra of this map.

This is the set of multipliers of the periodic points of formal period \(n\) included with the appropriate multiplicity. User can also specify to compute the \(n\) multiplier spectra instead which includes the multipliers of all periodic points of period \(n\). The map must be defined over projective space of dimension 1 over a number field.

The parameter type determines if the multipliers are computed one per cycle (with multiplicity) or one per point (with multiplicity). Note that in the cycle case, a map with a cycle which collapses into multiple smaller cycles will have more multipliers than one that does not.

INPUT:

- \(n\) - a positive integer, the period.
- \(\text{formal}\) - a Boolean. True specifies to find the formal \(n\) multiplier spectra of this map. False specifies to find the \(n\) multiplier spectra of this map. Default: False.
- \(\text{embedding}\) - embedding of the base field into \(\mathbb{Q}\).
- \(\text{type}\) - string - either point or cycle depending on whether you compute one multiplier per point or one per cycle. Default: point.

OUTPUT:

- a list of \(\mathbb{Q}\) elements.

EXAMPLES:

```
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([4608*x^10 - 2910096*x^9*y + 325988068*x^8*y^2 + 31825198932*x^7*y^3 + 4139806626613*x^6*y^4 - 44439736715486*x^5*y^5 + 15344764859590852*x^4*y^6 - 150049940203963800*y^10, 4608*y^10])
sage: f.multiplier_spectra(1)
doctest:warning...
[0, -7198147681176255644585/256, 848446157556848459363/19683, -332378196286026872172253135/35184372088832, 529278480109921/256, -4290991994494936653/2097152, 1061953534167447403/19683, -3086380435599991/9, 82911372672808161930567/8192, -119820502365680843999, -3553497751559301575157261317/8192]
```

normalize_coordinates()
Scales by 1/gcd of the coordinate functions.
Also, scales to clear any denominators from the coefficients. This is done in place.

OUTPUT:

- None.

EXAMPLES:
```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([5/4*x^3, 5*x*y^2])
sage: f.normalize_coordinates(); f
Scheme endomorphism of Projective Space of dimension 1 over Rational Field
   Defn: Defined on coordinates by sending (x : y) to
         (x^2 : 4*y^2)

sage: P.<x,y,z> = ProjectiveSpace(GF(7),2)
sage: X = P.subscheme(x^2-y^2)
sage: H = Hom(X,X)
sage: f = H([x^3+x*y^2, x*y^2, x*z^2])
sage: f.normalize_coordinates(); f
Scheme endomorphism of Closed subscheme of Projective Space of dimension 2 over Finite Field of size 7 defined by:
   x^2 - y^2
   Defn: Defined on coordinates by sending (x : y : z) to
         (2*y^2 : y^2 : z^2)

sage: R.<a,b> = QQ[]
sage: P.<x,y,z> = ProjectiveSpace(R, 2)
sage: H = End(P)
sage: f = H([a*(x*z+y^2)*x^2, a*b*(x*z+y^2)*y^2, a*(x*z+y^2)*z^2])
sage: f.normalize_coordinates(); f
Scheme endomorphism of Projective Space of dimension 2 over Multivariate Polynomial Ring in a, b over Rational Field
   Defn: Defined on coordinates by sending (x : y : z) to
         (x^2 : b*y^2 : z^2)
```

**Note:** gcd raises an error if the base_ring does not support gcds.

### nth_iterate \((P, n, **kwds)\)
Return the nth iterate of the point.

**EXAMPLES:**

```python
sage: P.<x,y> = ProjectiveSpace(ZZ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, y^2])
sage: Q = P(1,1)
sage: f.nth_iterate(Q,4)
doctest:warning
...
(32768 : 32768)
```

### nth_iterate_map \((n, normalize=False)\)
Return the nth iterate of the map.

**EXAMPLES:**

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, y^2])
sage: f.nth_iterate_map(2)
(continues on next page)
```
Dynamical System of Projective Space of dimension 1 over Rational Field
Defn: Defined on coordinates by sending \((x : y)\) to
\((x^4 + 2x^2y^2 + 2y^4 : y^4)\)

**orbit** \((P, N, **kwds)\)
Return the orbit of the point.

**EXAMPLES:**

```sage
sage: P.<x,y,z> = ProjectiveSpace(ZZ,2)
sage: H = End(P)
sage: f = H([x^2+y^2, y^2-z^2, 2*z^2])
sage: f.orbit(P(1,2,1), 3)
doctest:warning ...
[(1 : 2 : 1), (5 : 3 : 2), (34 : 5 : 8), (1181 : -39 : 128)]
```

**periodic_points** \((n, minimal=True, R=None, algorithm='variety', return_scheme=False)\)
Return the periodic points.

**EXAMPLES:**

```sage
sage: set_verbose(None)
sage: P.<x,y> = ProjectiveSpace(QQbar,1)
sage: H = End(P)
sage: f = H([x^2-x*y+y^2, x^2-y^2+x*y])
sage: f.periodic_points(1)
doctest:warning ...
[(-0.500000000000000? - 0.866025403784439?*I : 1), (-0.500000000000000? + 0.
˓→866025403784439?*I : 1), (1 : 1)]
```

**possible_periods** (**kwds)\)
Return the possible periods of a rational periodic point.

**EXAMPLES:**

```sage
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([1/3*x^2+1/2*y^2, y^2])
sage: f.possible_periods(ncpus=1)
doctest:warning ...
[1, 3]
```

**primes_of_bad_reduction** (**check=True**)\)
Return the primes of bad reduction.

**EXAMPLES:**

```sage
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([1/3*x^2+1/2*y^2, y^2])
```
sage: f.primes_of_bad_reduction()
doctest:warning
...
[2, 3]

reduced_form (prec=300, return_conjugation=True, error_limit=1e-06)
Return the reduced form of the map.

EXAMPLES:

sage: PS.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(PS)
sage: f = H([x^3, 10794303*x^3 + 146526*x^2*y + 663*x*y^2 + y^3])
sage: f.reduced_form()
doctest:warning
...
(Dynamical System of Projective Space of dimension 1 over Rational Field
 Defn: Defined on coordinates by sending (x : y) to
    (x^3 + 3*x*y^2 : y^3),

    [ 0 -1]
    [ 1 221]

resultant (normalize=False)
Computes the resultant of the defining polynomials of this dynamical system.
If normalize is True, then first normalize the coordinate functions with
normalize_coordinates(). Map must be an endomorphism

INPUT:
  • normalize – Boolean (optional - default: False).

OUTPUT: an element of the base ring of this map.

EXAMPLES:

sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2+y^2, 6*y^2])
sage: f.resultant()
doctest:warning
...
36

sage: P2.<x,y,z> = ProjectiveSpace(QQ,2)
sage: P1.<u,v> = ProjectiveSpace(QQ,1)
sage: H = Hom(P2,P1)
sage: f = H([x,y])
sage: f.resultant()
Traceback (most recent call last):
...
ValueError: must be an endomorphism

scale_by (t)
Scales each coordinate by a factor of t.
A TypeError occurs if the point is not in the coordinate ring of the parent after scaling.

INPUT:

- t – a ring element.

OUTPUT:

- None.

EXAMPLES:

```python
sage: A.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(A,A)
sage: f = H([x^3-2*x*y^2,x^2*y])
sage: f.scale_by(1/x)
sage: f
Scheme endomorphism of Projective Space of dimension 1 over Rational Field
  Defn: Defined on coordinates by sending (x : y) to
        (x^2 - 2*y^2 : x*y)
```

```python
sage: R.<t> = PolynomialRing(QQ)
sage: P.<x,y> = ProjectiveSpace(R,1)
sage: H = Hom(P,P)
sage: f = H([3/5*x^2,6*y^2])
sage: f.scale_by(5/3*t); f
Scheme endomorphism of Projective Space of dimension 1 over Univariate Polynomial Ring in t over Rational Field
  Defn: Defined on coordinates by sending (x : y) to
        (t*x^2 : 10*t*y^2)
```

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(7),2)
sage: X = P.subscheme(x^2-y^2)
sage: H = Hom(X,X)
sage: f = H([x^2,y^2,z^2])
sage: f.scale_by(x-y); f
Scheme endomorphism of Closed subscheme of Projective Space of dimension 2 over Finite Field of size 7 defined by:
        x^2 - y^2
  Defn: Defined on coordinates by sending (x : y : z) to
        (x*y^2 - y^3 : x*y^2 - y^3 : x*z^2 - y*z^2)
```

**sigma_invariants**(\(n,\ text{formal=False, embedding=None, type='point'}\))

Computes the values of the elementary symmetric polynomials of the \(n\) multiplier spectra of this dynamical system.

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([512*x^5 - 378128*x^4*y + 76594292*x^3*y^2 - 4570550136*x^2*y^3 - 2630045017*x*y^4 + 28193217129*y^5, 512*y^5])
sage: f.sigma_invariants(1)
doctest:warning
...

```

(continues on next page)
wronskian_ideal()

Returns the ideal generated by the critical point locus.

This is the vanishing of the maximal minors of the Jacobian matrix. Not implemented for subvarieties.

OUTPUT: an ideal in the coordinate ring of the domain of this map.

EXAMPLES:

```python
sage: R.<x> = PolynomialRing(QQ)
sage: K.<w> = NumberField(x^2+11)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: H = End(P)
sage: f = H([x^2-w*y^2, w*y^2])
sage: f.wronskian_ideal()
Ideal ((4*w)*x*y) of Multivariate Polynomial Ring in x, y over Number Field in w with defining polynomial x^2 + 11
```

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: P2.<u,v,t> = ProjectiveSpace(K,2)
sage: H = Hom(P,P2)
sage: f = H([76*x^2 - 180*x*y + 45*y^2 + 14*x*z + 45*y*z - 90*z^2, 67*x^2 - 180*x*y - 157*x*z + 90*y*z, -10*x^2 - 157*x*z + 90*y*z, -90*z^2])
sage: sorted(f.all_rational_preimages([P(-9,-4,1)]))
[(-9 : -4 : 1), (0 : -1 : 1), (0 : 0 : 1), (0 : 1 : 1), (0 : 4 : 1), (1 : 0 : 1), (1 : 1 : 1), (1 : 2 : 1), (1 : 3 : 1)]
```
A non-periodic example

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2 + y^2, 2*x*y])
sage: sorted(f.all_rational_preimages([P(17,15)]))
[(1/3 : 1), (3/5 : 1), (5/3 : 1), (3 : 1)]
```

A number field example.

```python
sage: z = QQ['z'].0
sage: K.<w> = NumberField(z^3 + (z^2)/4 - (41/16)*z + 23/64);
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: H = End(P)
sage: f = H([16*x^2 - 29*y^2, 16*y^2])
sage: f.all_rational_preimages([P(16*w^2 - 29,16)])
[(-w^2 + 21/16 : 1),
 (w : 1),
 (w + 1/2 : 1),
 (w^2 + w - 33/16 : 1),
 (-w^2 - w + 25/16 : 1),
 (w^2 - 21/16 : 1),
 (-w^2 - w + 33/16 : 1),
 (-w : 1),
 (-w - 1/2 : 1),
 (-w^2 + 29/16 : 1),
 (w^2 - 29/16 : 1),
 (w^2 + w - 25/16 : 1)]
```

```python
sage: K.<w> = QuadraticField(3)
sage: P.<u,v> = ProjectiveSpace(K,1)
sage: H = End(P)
sage: f = H([u^2+v^2, v^2])
sage: f.all_rational_preimages(P(4))
[(-w : 1), (w : 1)]
```

`conjugating_set(other)`

Return the set of PGL element that conjugate this map to `other`.

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(GF(7),1)
sage: H = End(P)
sage: D6 = H([y^2, x^2])
sage: D6.conjugating_set(D6)
doctest:warning
...
[
 [1 0] [0 1] [0 2] [4 0] [2 0] [0 4]
 [0 1], [1 0], [1 0], [0 1], [0 1], [1 0]
]
```

`connected_rational_component(P, n=0)`

Return the component of all rational preimage and forward images.

EXAMPLES:
sage: R.<x> = PolynomialRing(QQ)
sage: K.<w> = NumberField(x^3+1/4*x^2-41/16*x+23/64)
sage: PS.<x,y> = ProjectiveSpace(1,K)
sage: H = End(PS)
sage: f = H([x^2 - 29/16*y^2, y^2])
sage: P = PS([w,1])
sage: f.connected_rational_component(P)
doctest:warning
...
[(w : 1),
 (w^2 - 29/16 : 1),
 (-w^2 - w + 25/16 : 1),
 (w^2 + w - 25/16 : 1),
 (-w : 1),
 (-w^2 + 29/16 : 1),
 (w + 1/2 : 1),
 (-w - 1/2 : 1),
 (-w^2 + 21/16 : 1),
 (w^2 - 21/16 : 1),
 (w^2 + w - 33/16 : 1),
 (-w^2 - w + 33/16 : 1)]

indeterminacy_locus()

Return the indeterminacy locus of this map.

Only for rational maps on projective space defined over a field. The indeterminacy locus is the set of points
in projective space at which all of the defining polynomials of the rational map simultaneously vanish.

OUTPUT:

• subscheme of the domain of the map. The empty subscheme is returned as the vanishing of the
coordinate functions of the domain.

EXAMPLES:

sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: H = End(P)
sage: f = H([x*z-y*z, x^2-y^2, z^2])
sage: f.indeterminacy_locus()
Closed subscheme of Projective Space of dimension 2 over Rational Field
  defined by:
  x*z - y*z,
  x^2 - y^2,
  z^2

sage: P1.<x,y,z> = ProjectiveSpace(QQ,2)
sage: P2.<t,u,v,w> = ProjectiveSpace(QR,3)
sage: H = Hom(P1,P2)

(continues on next page)
sage: h = H([y^3*z^3, x^3*z^3, y^3*z^3, x^2*y^2*z^2])
sage: h.indeterminacy_locus()
Closed subscheme of Projective Space of dimension 2 over Real Field with 53 bits of precision defined by:
   y^3*z^3,
   x^3*z^3,
   y^3*z^3,
   x^2*y^2*z^2
If defining polynomials are not normalized, output scheme will not be normalized:

sage: P.<x,y,z>=ProjectiveSpace(QQ,2)
sage: H=End(P)
sage: f=H([x*x^2,x*y^2,x*z^2])
sage: f.indeterminacy_locus()
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
   x^3,
   x*y^2,
   x*z^2
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: X = P.subscheme(x-y)
sage: H = End(X)
sage: f = H([x^2-4*y^2, y^2-z^2, 4*z^2-x^2])
sage: Z = f.indeterminacy_locus(); Z
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
   x - y,
   x^2 - 4*y^2,
   y^2 - z^2,
   -x^2 + 4*z^2
sage: Z.dimension()
-1

**indeterminacy_points** *(F=None)*

Return the indeterminacy locus of this map defined over \( F \).

Only for rational maps on projective space. Returns the set of points in projective space at which all of the defining polynomials of the rational map simultaneously vanish.

**INPUT:**

- \( F \) - a field (optional).

**OUTPUT:**

- indeterminacy points of the map defined over \( F \), provided the indeterminacy scheme is 0-dimensional.

**EXAMPLES:**

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: H = End(P)
sage: f = H([x*z-y*z, x^2-y^2, z^2])
sage: f.indeterminacy_points()
[(-1 : 1 : 0), (1 : 1 : 0)]
sage: P1.<x,y,z> = ProjectiveSpace(RR,2)
sage: P2.<t,u,v,w> = ProjectiveSpace(RR,3)

  O(3^20) : 1 + O(3^20))]

is_conjugate(other)
Return if this map and other are conjugate.

14.2. Morphisms on projective varieties 139
EXAMPLES:

```python
sage: K.<w> = CyclotomicField(3)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: H = End(P)
sage: D8 = H([y^2, x^2])
sage: D8.is_conjugate(D8)
doctest:warning
...  
True
```

**is_polynomial()**

Return if this map is a polynomial.

EXAMPLES:

```python
sage: R.<x> = QQ[]
sage: K.<w> = QuadraticField(7)
sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: H = End(P)
sage: f = H([x**2 + 2*x*y - 5*y**2, 2*x*y])
sage: f.is_polynomial()
doctest:warning
...  
False
```

**lift_to_rational_periodic**(points_modp, B=None)

Return the rational lift of the modp periodic points.

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2 - y^2, y^2])
sage: f.lift_to_rational_periodic([[P(0,1).change_ring(GF(7)), 4]])
doctest:warning
...  
[[[0 : 1), 2]]
```

**normal_form**(return_conjugation=False)

Return a normal form conjugate to this map.

EXAMPLES:

```python
sage: R.<x> = QQ[]
sage: K.<w> = NumberField(x^2 - 5)
sage: P.<x,y> = ProjectiveSpace(K,1)
sage: H = End(P)
sage: f = H([x^2 + w*x*y, y^2])
sage: g,m,psi = f.normal_form(return_conjugation = True);m
doctest:warning
...  
[ 1 -1/2 *w
  0 1]
```

**rational_periodic_points**(**kwds)**

Return the list of all rational periodic points.

EXAMPLES:
```
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = End(P)
sage: f = H([x^2-3/4*y^2, y^2])
sage: sorted(f.rational_periodic_points(prime_bound=20, lifting_prime=7))
# long time
doctest:warning
...
[(-1/2 : 1), (1 : 0), (3/2 : 1)]
```

### rational_preimages(Q, k=1)

Determine all of the rational $k$-th preimages of $Q$ by this map.

Given a rational point $Q$ in the domain of this map, return all the rational points $P$ in the domain with $f^k(P) = Q$. In other words, the set of $k$-th preimages of $Q$. The map must be defined over a number field and be an endomorphism for $k > 1$.

If $Q$ is a subscheme, then return the subscheme that maps to $Q$ by this map. In particular, $f^{-k}(V(h_1,\ldots,h_t)) = V(h_1 \circ f^k,\ldots,h_t \circ f^k)$.

**INPUT:**

- $Q$ - a rational point or subscheme in the domain of this map.
- $k$ - positive integer.

**OUTPUT:**

- a list of rational points or a subscheme in the domain of this map.

**Examples:**

```
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([16*x^2 - 29*y^2, 16*y^2])
sage: f.rational_preimages(P(-1, 4))
[(-5/4 : 1), (5/4 : 1)]
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: H = End(P)
sage: f = H([76*x^2 - 180*x*y + 45*y^2 + 14*x*z + 45*y*z - 90*z^2, 67*x^2 - 180*x*y - 157*x*z + 90*y*z, -90*z^2])
sage: f.rational_preimages(P(-9, -4, 1))
[(0 : 4 : 1)]
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2 + y^2, 2*x*y])
sage: f.rational_preimages(P(17, 15))
[(3/5 : 1), (5/3 : 1)]
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: H = End(P)
sage: f = H([x^2 - 2*y*w - 3*w^2, -2*x^2 + y^2 - 2*x*z + 4*y*w + 3*w^2, x^2 - y^2 + 2*x*z + z^2 - 2*y*w - w^2, w^2])
sage: f.rational_preimages(P(0, -1, 0, 1))
[]
```

A non-periodic example

```
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2 + y^2, 2*x*y])
sage: f.rational_preimages(P(17, 15))
[(3/5 : 1), (5/3 : 1)]
```

**14.2. Morphisms on projective varieties**
```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2 + y^2, 2*x*y])
sage: f.rational_preimages([CC.0, 1])
Traceback (most recent call last):
  ...  
TypeError: point must be in codomain of self
```

A number field example

```python
sage: z = QQ['z'].0
sage: K.<a> = NumberField(z^2 - 2);
sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: H = End(P)
sage: f = H([x^2 + y^2, y^2])
sage: f.rational_preimages(P(3, 1))
[(-a : 1), (a : 1)]
```

```python
sage: z = QQ['z'].0
sage: K.<a> = NumberField(z^2 - 2);
sage: P.<x,y,z> = ProjectiveSpace(K, 2)
sage: X = P.subscheme([x^2 - z^2])
sage: H = End(X)
sage: f= H([x^2-z^2, a*y^2, z^2-x^2])
sage: f.rational_preimages(X([1, 2, -1]))
[]
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: X = P.subscheme([x^2 - z^2])
sage: H = End(X)
sage: f= H([x^2-z^2, y^2, z^2-x^2])
sage: f.rational_preimages(X([0, 1, 0]))
Traceback (most recent call last):
  ...  
NotImplementedError: subschemes as preimages not implemented
```

```python
sage: P.<x, y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2-y^2, y^2])
sage: f.rational_preimages(P.subscheme([x]))
Closed subscheme of Projective Space of dimension 1 over Rational Field

defined by:
   x^2 - y^2
```

```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([x^2 - 29/16*y^2, y^2])
sage: f.rational_preimages(P(5/4, 1), k=4)
[(-3/4 : 1), (3/4 : 1), (-7/4 : 1), (7/4 : 1)]
```

```python
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: P2.<u,v,w> = ProjectiveSpace(QQ, 2)
sage: H = Hom(P, P2)
sage: f = H([x^2, y^2, x^2-y^2])
sage: f.rational_preimages(P2(1, 1, 0))
[(-1 : 1), (1 : 1)]
```
rational_preperiodic_graph(**kwds)
Return the digraph of rational preperiodic points.

EXAMPLES:

```
sage: PS.<x,y> = ProjectiveSpace(1,QQ)
sage: H = End(PS)
sage: f = H([7*x^2 - 28*y^2, 24*x*y])
sage: f.rational_preperiodic_graph()
...
doctest:warning
Looped digraph on 12 vertices
```

rational_preperiodic_points(**kwds)
Return the list of all rational preperiodic points.

EXAMPLES:

```
sage: PS.<x,y> = ProjectiveSpace(1,QQ)
sage: H = End(PS)
sage: f = H([x^2 -y^2, 3*x*y])
sage: sorted(f.rational_preperiodic_points())
...
doctest:warning
[(-2 : 1), (-1 : 1), (-1/2 : 1), (0 : 1), (1/2 : 1), (1 : 0), (1 : 1), (2 : 1)]
```

class sage.schemes.projective.projective_morphism.SchemeMorphism_polynomial_projective_space

Bases: sage.schemes.projective.projective_morphism.SchemeMorphism_polynomial_projective_space_field

automorphism_group(**kwds)
return the automorphism group of this map.

EXAMPLES:

```
sage: R.<x,y> = ProjectiveSpace(GF(7^3,'t'),1)
sage: H = End(R)
sage: f = H([x^2-y^2, x*y])
sage: f.automorphism_group()
...
doctest:warning
[ [1 0] [6 0]
 [0 1], [0 1]
]
```
cyclegraph()
Return the digraph of the map.

EXAMPLES:

```
sage: P.<x,y> = ProjectiveSpace(GF(13),1)
sage: H = End(P)
sage: f = H([x^2-y^2, y^2])
sage: f.cyclegraph()
...
doctest:warning
```
Looped digraph on 14 vertices

orbit\_structure(P)

Return the tail and period of the point.

EXAMPLES:

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(5),2)
sage: H = End(P)
sage: f = H([x^2 + y^2, y^2, z^2 + y*z])
sage: f.orbit_structure(P(2,1,2))
doctest:warning...
[0, 6]
```

possible\_periods(return\_points=False)

Return the possible periods of a periodic point of this map.

EXAMPLES:

```python
sage: P.<x,y> = ProjectiveSpace(GF(23),1)
sage: H = End(P)
sage: f = H([x^2-2*y^2, y^2])
sage: f.possible_periods()
doctest:warning...
[1, 5, 11, 22, 110]
```

## 14.3 Points on projective varieties

Scheme morphism for points on projective varieties

AUTHORS:

- David Kohel, William Stein
- William Stein (2006-02-11): fixed bug where \( P(0,0,0) \) was allowed as a projective point.
- Volker Braun (2011-08-08): Renamed classes, more documentation, misc cleanups.
- Ben Hutz (June 2012) added support for projective ring; (March 2013) iteration functionality and new directory structure for affine/projective, height functionality

```python
class sage.schemes.projective.projective_point.SchemeMorphism_point_abelian_variety_field(X, v, check=True):
    ...
```

A rational point of an abelian variety over a field.

EXAMPLES:

```python
sage: E = EllipticCurve([0,0,1,-1,0])
sage: origin = E(0)
sage: origin.domain()
```

Spectrum of Rational Field
sage: origin.codomain()
Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field

class sage.schemes.projective.projective_point.SchemeMorphism_point_projective_field(X, v, check=True)

Bases: sage.schemes.projective.projective_point.SchemeMorphism_point_projective_ring

A rational point of projective space over a field.

INPUT:

• X – a homset of a subscheme of an ambient projective space over a field $K$.
• v – a list or tuple of coordinates in $K$.
• check – boolean (optional, default: True). Whether to check the input for consistency.

EXAMPLES:

```
sage: P = ProjectiveSpace(3, RR)
sage: P(2, 3, 4, 5)
(0.400000000000000 : 0.600000000000000 : 0.800000000000000 : 1.000000000000000)
```

clear_denominators()
scales by the least common multiple of the denominators.

OUTPUT: None.

EXAMPLES:

```
sage: R.<t> = PolynomialRing(QQ)
sage: P.<x,y,z> = ProjectiveSpace(FractionField(R), 2)
sage: Q = P([t, 3/t^2, 1])
sage: Q.clear_denominators(); Q
(t^3 : 3 : t^2)
```

```
sage: R.<x> = PolynomialRing(QQ)
sage: K.<w> = NumberField(x^2 - 3)
sage: P.<x,y,z> = ProjectiveSpace(K, 2)
sage: Q = P([1/w, 3, 0])
sage: Q.clear_denominators(); Q
(w : 9 : 0)
```

```
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: X = P.subscheme(x^2 - y^2);
sage: Q = X([1/2, 1/2, 1]);
sage: Q.clear_denominators(); Q
(1 : 1 : 2)
```

```
sage: PS.<x,y> = ProjectiveSpace(QQ, 1)
sage: Q = PS.point([1, 2/3], False); Q
(1 : 2/3)
sage: Q.clear_denominators(); Q
(3 : 2)
```

intersection_multiplicity(X)

Return the intersection multiplicity of the codomain of this point and $X$ at this point.

14.3. Points on projective varieties 145
This uses the intersection_multiplicity implementations for projective/affine subschemes. This point must be a point of a projective subscheme.

**INPUT:**

- $X$ – a subscheme in the same ambient space as that of the codomain of this point.

**OUTPUT:** Integer.

**EXAMPLES:**

```
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: X = P.subscheme([x*z - y^2])
sage: Y = P.subscheme([x^3 - y*w^2 + z*w^2, x*y - z*w])
sage: Q1 = X([1/2, 1/4, 1/8, 1])
sage: Q1.intersection_multiplicity(Y)
1
sage: Q2 = X([0,0,0,1])
sage: Q2.intersection_multiplicity(Y)
5
sage: Q3 = X([0,0,1,0])
sage: Q3.intersection_multiplicity(Y)
6
```

```
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: X = P.subscheme([x^2 - y^2])
sage: Q = P([1,1,0,0])
sage: Q.intersection_multiplicity(X)
Traceback (most recent call last):
  ... TypeError: this point must be a point on a projective subscheme
```

**multiplicity()**

Return the multiplicity of this point on its codomain.

Uses the subscheme multiplicity implementation. This point must be a point on a projective subscheme.

**OUTPUT:** an integer.

**EXAMPLES:**

```
sage: P.<x,y,z,w,t> = ProjectiveSpace(QQ, 4)
sage: X = P.subscheme([y^6 - x^3*w^2*t + t^5*w, x^2 - t^2])
sage: Q1 = X([1,0,2,1,1])
sage: Q1.multiplicity()
1
sage: Q2 = X([0,0,-2,1,0])
sage: Q2.multiplicity()
8
```

**normalize_coordinates()**

Normalizes the point so that the last non-zero coordinate is 1.

**OUTPUT:** None.

**EXAMPLES:**

```
sage: P.<x,y,z> = ProjectiveSpace(GF(5),2)
sage: Q = P.point([GF(5)(1), GF(5)(3), GF(5)(0)], False); Q
(1 : 3 : 0)
```

(continues on next page)
sage: Q.normalize_coordinates(); Q
(2 : 1 : 0)

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: X = P.subscheme(x^2-y^2);
sage: Q = X.point([23, 23, 46], False); Q
(23 : 23 : 46)

sage: Q.normalize_coordinates(); Q
(1/2 : 1/2 : 1)

class sage.schemes.projective.projective_point.SchemeMorphism_point_projective_finite_field

Bases: sage.schemes.projective.projective_point.SchemeMorphism_point_projective_field

orbit_structure(f)
This function returns the pair \([m, n]\) where \(m\) is the preperiod and \(n\) is the period of the point by the map \(f\).

Every point is preperiodic over a finite field so this is always possible.

INPUT:

• \(f\) – a SchemeMorphism_polynomial with this point in \(f\).domain().

OUTPUT:

• a list \([m, n]\) of integers.

EXAMPLES:

sage: P.<x,y,z> = ProjectiveSpace(GF(5),2)
sage: f = DynamicalSystem_projective([x^2 + y^2, y^2, z^2 + y*z], domain=P)
sage: P(1, 0, 1).orbit_structure(f)
doctest:warning...
[0, 1]

class sage.schemes.projective.projective_point.SchemeMorphism_point_projective_ring

Bases: sage.schemes.generic.morphism.SchemeMorphism_point

A rational point of projective space over a ring.

INPUT:

• \(X\) – a homset of a subscheme of an ambient projective space over a ring \(K\).
• \(v\) – a list or tuple of coordinates in \(K\).
• check – boolean (optional, default:True). Whether to check the input for consistency.

EXAMPLES:

sage: P = ProjectiveSpace(2, ZZ)
sage: P(2,3,4)
(2 : 3 : 4)
canonical_height \( (F, **\text{kwds}) \)
Evaluates the (absolute) canonical height of this point with respect to the map \( F \).

Must be over number field or order of a number field or \( \mathbb{Q} \bar{\mathbb{Q}} \). Specify either the number of terms of the series to evaluate or the error bound required.

ALGORITHM:
The sum of the Green’s function at the archimedean places and the places of bad reduction.

If function is defined over \( \mathbb{Q} \) uses Wells’ Algorithm, which allows us to not have to factor the resultant.

INPUT:
• \( F \) - a projective morphism.

kwds:
• \( \text{badprimes} \) - a list of primes of bad reduction (optional).
• \( N \) - positive integer. number of terms of the series to use in the local green functions. (optional - default:10)
• \( \text{prec} \) - positive integer, float point or p-adic precision, default:100.
• \( \text{error_bound} \) - a positive real number (optional).

OUTPUT: a real number.

AUTHORS:
• Original algorithm written by Elliot Wells [WELLS]
• Wells’ Algorithm implemented as part of GSOC 2017 by Rebecca Lauren Miller and Paul Fili

EXAMPLES:

```
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: f = DynamicalSystem_projective([1000*x^2-29*y^2, 1000*y^2], domain=P)
sage: Q = P(-1/4, 1)
sage: Q.canonical_height(f, error_bound=0.01)
doctest:warning...
3.7996079979254623065837411853
```

```
sage: RSA768 = ...
\ldots
dehomogenize(n)
Dehomogenizes at the nth coordinate.
```
INPUT:

- \( n \) – non-negative integer.

OUTPUT:

- `SchemeMorphism_point_affine`.

EXAMPLES:

```sage
sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: X = P.subscheme(x^2-y^2);
sage: Q = X(23, 23, 46)
sage: Q.dehomogenize(2)
(1/2, 1/2)
```

```sage
sage: R.<t> = PolynomialRing(QQ)
sage: S = R.quo(R.ideal(t^3))
sage: P.<x,y,z> = ProjectiveSpace(S,2)
sage: Q = P(t, 1, 1)
sage: Q.dehomogenize(1)
(1bar, 1)
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(GF(5),2)
sage: Q = P(1, 3, 1)
sage: Q.dehomogenize(0)
(3, 1)
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(GF(5),2)
sage: Q = P(1, 3, 0)
sage: Q.dehomogenize(2)
Traceback (most recent call last):
  ... 
ValueError: can't dehomogenize at 0 coordinate
```

`global_height (prec=None)`

Returns the absolute logarithmic height of the point.

INPUT:

- `prec` – desired floating point precision (default: default RealField precision).

OUTPUT:

- a real number.

EXAMPLES:

```sage
sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: Q = P.point([4, 4, 1/30])
sage: Q.global_height()
4.78749174278205
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(ZZ,2)
sage: Q = P([4, 1, 30])
sage: Q.global_height()
3.40119738166216
```

14.3. Points on projective varieties
```python
sage: R.<x> = PolynomialRing(QQ)
sage: k.<w> = NumberField(x^2+5)
sage: A = ProjectiveSpace(k, 2, 'z')
sage: A([3, 5*w+1, 1]).global_height(prec=100)
2.418140953475738998656376694
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQbar,2)
sage: Q = P([QQbar(sqrt(3)), QQbar(sqrt(-2)), 1])
sage: Q.global_height()
0.549306144334055
```

**green_function** *(G, v, **kwds)*

Evaluates the local Green’s function with respect to the morphism *G* at the place *v* for this point with *N* terms of the series or to within a given error bound.

Must be over a number field or order of a number field. Note that this is the absolute local Green’s function so is scaled by the degree of the base field.

Use *v*=0 for the archimedean place over *Q* or field embedding. Non-archimedean places are prime ideals for number fields or primes over *Q*.

**ALGORITHM:**

See Exercise 5.29 and Figure 5.6 of [Sil2007].

**INPUT:**

- *G* - a projective morphism whose local Green’s function we are computing.
- *v* - non-negative integer. a place, use *v*=0 for the archimedean place.

**kwds:**

- *N* - positive integer. number of terms of the series to use, default: 10.
- *prec* - positive integer, float point or p-adic precision, default: 100.
- *error_bound* - a positive real number.

**OUTPUT:**

- a real number.

**EXAMPLES:**

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: H = Hom(P,P)
sage: f = H([x^2+y^2, x*y]);
sage: Q = P(5, 1)
sage: Q.green_function(f, 0, N=200, prec=200)
doctest:warning
...    1.6460930160038721802875250367738355497198064992657997569827
```

**is_preperiodic** *(f, err=0.1, return_period=False)*

Determine if the point is preperiodic with respect to the map *f*.

This is only implemented for projective space (not subschemes). There are two optional keyword arguments: `error_bound` sets the `error_bound` used in the canonical height computation and `return_period` a boolean which controls if the period is returned if the point is preperiodic. If `return_period` is `True` and this point is not preperiodic, then (0, 0) is returned for the period.

**ALGORITHM:**
We know that a point is preperiodic if and only if it has canonical height zero. However, we can only compute the canonical height up to numerical precision. This function first computes the canonical height of the point to the given error bound. If it is larger than that error bound, then it must not be preperiodic. If it is less than the error bound, then we expect preperiodic. In this case we begin computing the orbit stopping if either we determine the orbit is finite, or the height of the point is large enough that it must be wandering. We can determine the height cutoff by computing the height difference constant, i.e., the bound between the height and the canonical height of a point (which depends only on the map and not the point itself). If the height of the point is larger than the difference bound, then the canonical height cannot be zero so the point cannot be preperiodic.

**INPUT:**

- \( f \) – an endomorphism of this point’s codomain.

**kwds:**

- `error_bound` – a positive real number (optional - default: 0.1).

**OUTPUT:**

- boolean – True if preperiodic.
- if `return_period` is `True`, then (0, 0) if wandering, and (m, n) if preperiod m and period n.

**EXAMPLES:**

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: f = DynamicalSystem_projective([x^3-3*x*y^2, y^3], domain=P)
sage: Q = P(-1, 1)
sage: Q.is_preperiodic(f)
True
```

```python
sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: f = DynamicalSystem_projective([x^2-29/16*y^2, y^2], domain=P)
sage: Q = P(1, 4)
sage: Q.is_preperiodic(f, return_period=True)
(1, 3)
sage: Q = P(1, 1)
sage: Q.is_preperiodic(f, return_period=True)
(0, 0)
```

```python
sage: R.<x> = PolynomialRing(QQ)
sage: K.<a> = NumberField(x^2+1)
sage: P.<x,y> = ProjectiveSpace(K, 1)
sage: f = DynamicalSystem_projective([x^5 + 5/4*x*y^4, y^5], domain=P)
sage: Q = P([-1/2*a+1/2, 1])
sage: Q.is_preperiodic(f)
True
sage: Q = P([a, 1])
sage: Q.is_preperiodic(f)
False
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: f = DynamicalSystem_projective([-38/45*x^2 + (2*y - 7/45*z)*x + (-1/2*y)*\rightarrow2 - 1/2*y*z + z^2),
-67/90*x^2 + (2*y + z*157/90)*x - y*z, z^2], domain=P)
sage: Q = P([1, 3, 1])
```

(continues on next page)
sage: Q.is_preperiodic(f, return_period=True)
(0, 9)

sage: P.<x,y,z,w> = ProjectiveSpace(QQ,3)
sage: f = DynamicalSystem_projective([(-y - w)*x + (-13/30*y^2 + 13/30*w*y + w^2),
-1/2*x^2 + (-y + 3/2*w)*x + (-1/3*y^2 + 4/3*w*y),-3/2*z^2 + 5/2*z*w + w^2,w^2], domain=P)
sage: Q = P([3,0,4/3,1])
sage: Q.is_preperiodic(f, return_period=True)
(2, 24)

sage: setVerbose(-1)

sage: P.<x,y,z> = ProjectiveSpace(QQbar,2)
sage: f = DynamicalSystem_projective([x^2, QQbar(sqrt(-1))*y^2, z^2], domain=P)
sage: Q = P([1, 1, 1])
sage: Q.is_preperiodic(f)
True

sage: setVerbose(-1)

sage: P.<x,y,z> = ProjectiveSpace(QQbar,2)
sage: f = DynamicalSystem_projective([x^2, y^2, z^2], domain=P)
sage: Q = P([QQbar(sqrt(-1)), 1, 1])
sage: Q.is_preperiodic(f)
True

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: f = DynamicalSystem_projective([16*x^2-29*y^2, 16*y^2], domain=P)
sage: Q = P(-1,4)
sage: Q.is_preperiodic(f)
True

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: H = End(P)
sage: f = H([16*x^2-29*y^2, 16*y^2])
sage: Q = P(-1,4)
sage: Q.is_preperiodic(f)
Traceback (most recent call last):
...
TypeError: map must be a dynamical system

**local_height** *(v, prec=None)*

Returns the maximum of the local height of the coordinates of this point.

**INPUT:**

- *v* – a prime or prime ideal of the base ring.
- *prec* – desired floating point precision (default: default RealField precision).

**OUTPUT:**

- a real number.

**EXAMPLES:**
\texttt{sage}: \texttt{P.<x,y,z>= ProjectiveSpace(QQ,2)}
\texttt{sage}: \texttt{Q = P.point([4,4,1/150], False)}
\texttt{sage}: \texttt{Q.local_height(5)}
\texttt{3.21887582486820}

\texttt{sage}: \texttt{P.<x,y,z> = ProjectiveSpace(QQ,2)}
\texttt{sage}: \texttt{Q = P([4, 1, 30])}
\texttt{sage}: \texttt{Q.local_height(2)}
\texttt{0.693147180559945}

\textbf{local\_height\_arch}(i, prec=None)

Returns the maximum of the local heights at the \textit{i}-th infinite place of this point.

INPUT:

\begin{itemize}
  \item \textit{i} – an integer.
  \item \textit{prec} – desired floating point precision (default: default RealField precision).
\end{itemize}

OUTPUT:

\begin{itemize}
  \item a real number.
\end{itemize}

EXAMPLES:

\texttt{sage}: \texttt{P.<x,y,z> = ProjectiveSpace(QQ,2)}
\texttt{sage}: \texttt{Q = P.point([4, 4, 1/150], False)}
\texttt{sage}: \texttt{Q.local_height_arch(0)}
\texttt{1.38629436111989}

\texttt{sage}: \texttt{P.<x,y,z> = ProjectiveSpace(QuadraticField(5, 'w'), 2)}
\texttt{sage}: \texttt{Q = P.point([4, 1, 30], False)}
\texttt{sage}: \texttt{Q.local_height_arch(1)}
\texttt{3.401197381662155375413236691607}

\textbf{multiplier}(f, n, check=True)

Returns the multiplier of this point of period \textit{n} by the function \textit{f}.

\textit{f} must be an endomorphism of projective space.

INPUT:

\begin{itemize}
  \item \textit{f} - a endomorphism of this point’s codomain.
  \item \textit{n} - a positive integer, the period of this point.
  \item \textit{check} – check if \textit{P} is periodic of period \textit{n}, Default:True.
\end{itemize}

OUTPUT:

\begin{itemize}
  \item a square matrix of size self.codomain().dimension_relative() in the base_ring of this point.
\end{itemize}

EXAMPLES:

\texttt{sage}: \texttt{P.<x,y,z,w> = ProjectiveSpace(QQ,3)}
\texttt{sage}: \texttt{f = DynamicalSystem_projective([x^2, y^2, 4*w^2, 4*z^2], domain=P)}
\texttt{sage}: \texttt{Q = P.point([4, 4, 1, 1], False)}
\texttt{sage}: \texttt{Q.multiplier(f, 1)}
\begin{verbatim}
[ 2 0 -8]
[ 0 2 -8]
[ 0 0 -2]
\end{verbatim}
normalize_coordinates()

Removes the gcd from the coordinates of this point (including $-1$).

**Warning:** The gcd will depend on the base ring.

**OUTPUT:** None.

**EXAMPLES:**

```sage
sage: P = ProjectiveSpace(ZZ,2,'x')
sage: p = P([-5, -15, -20])
sage: p.normalize_coordinates(); p
(1 : 3 : 4)
```

```sage
sage: P = ProjectiveSpace(Zp(7),2,'x')
sage: p = P([-5, -15, -2])
sage: p.normalize_coordinates(); p
(5 + O(7^20) : 1 + 2*7 + O(7^20) : 2 + O(7^20))
```

```sage
sage: R.<t> = PolynomialRing(QQ)
sage: P = ProjectiveSpace(R,2,'x')
sage: p = P([3/5*t^3, 6*t, t])
sage: p.normalize_coordinates(); p
(3/5*t^2 : 6 : 1)
```

```sage
sage: P.<x,y> = ProjectiveSpace(Zmod(20),1)
sage: Q = P(3, 6)
sage: Q.normalize_coordinates();Q
(1 : 2)
```

Since the base ring is a polynomial ring over a field, only the gcd $c$ is removed.

```sage
sage: R.<c> = PolynomialRing(QQ)
sage: P = ProjectiveSpace(R,1)
sage: Q = P(2*c, 4*c)
sage: Q.normalize_coordinates();Q
(2 : 4)
```

A polynomial ring over a ring gives the more intuitive result.

```sage
sage: R.<c> = PolynomialRing(ZZ)
sage: P = ProjectiveSpace(R,1)
sage: Q = P(2*c, 4*c)
sage: Q.normalize_coordinates();Q
(1 : 2)
```

```sage
sage: R.<t> = PolynomialRing(QQ,1)
sage: S = R.quotient_ring(R.ideal(t^3))
sage: P.<x,y> = ProjectiveSpace(S,1)
sage: Q = P(t, t^2)
sage: Q.normalize_coordinates()
sage: Q
(1 : tbar)
```
**nth_iterate**\((f, n, **kwds)\)

Return the \(n\)-th iterate of this point for the map \(f\).

If `normalize==True`, then the coordinates are automatically normalized. If `check==True`, then the initialization checks are performed on the new point.

**INPUT:**

- \(f\) – a SchmemMorphism_polynomial with the points in its domain.
- \(n\) – a positive integer.

**kwds:**

- `check` – Boolean (optional - default: True).
- `normalize` – Boolean (optional Default: False).

**OUTPUT:**

- A point in the domain of \(f\).

**EXAMPLES:**

```python
sage: P.<x,y> = ProjectiveSpace(ZZ, 1)
sage: f = DynamicalSystem_projective([x^2+y^2, 2*y^2], domain=P)
sage: P(1, 1).nth_iterate(f, 4)
doctest:warning...
(32768 : 32768)
```

**orbit** \((f, N, **kwds)\)

Returns the orbit of this point by the map \(f\).

If \(N\) is an integer it returns \([P, self(P), \ldots, self^N(P)]\). If \(N\) is a list or tuple \(N = [m, k]\) it returns \([self^m(P), \ldots, self^k(P)]\). Automatically normalize the points if `normalize=True`. Perform the checks on point initialization if `check=True`.

**INPUT:**

- \(f\) – a SchemeMorphism_polynomial with this point in the domain of \(f\).
- \(N\) – a non-negative integer or list or tuple of two non-negative integers.

**kwds:**

- `check` – boolean (optional - default: True).
- `normalize` – boolean (optional - default: False).

**OUTPUT:**

- a list of points in the domain of \(f\).

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(ZZ, 2)
sage: f = DynamicalSystem_projective([x^2+y^2, y^2-z^2, 2*z^2], domain=P)
sage: P(1, 2, 1).orbit(f, 3)
doctest:warning...
[(1 : 2 : 1), (5 : 3 : 2), (34 : 5 : 8), (1181 : -39 : 128)]
```

**scale_by** \((t)\)

Scale the coordinates of the point by \(t\).
A `TypeError` occurs if the point is not in the base_ring of the codomain after scaling.

**INPUT:**

- `t` – a ring element.

**OUTPUT:** None.

**EXAMPLES:**

```sage
sage: R.<t> = PolynomialRing(QQ)
sage: P = ProjectiveSpace(R, 2, 'x')
sage: p = P([3/5*t^3, 6*t, t])
sage: p.scale_by(1/t); p
(3/5*t^2 : 6 : 1)
```

```sage
sage: R.<t> = PolynomialRing(QQ)
sage: S = R.quo(R.ideal(t^3))
sage: P.<x,y,z> = ProjectiveSpace(S, 2)
sage: Q = P(t, 1, 1)
sage: Q.scale_by(t); Q
(tbar^2 : tbar : tbar)
```

```sage
sage: P.<x,y,z> = ProjectiveSpace(ZZ,2)
sage: Q = P(2, 2, 2)
sage: Q.scale_by(1/2);Q
(1 : 1 : 1)
```

### 14.4 Subschemes of projective space

**AUTHORS:**

- Volker Braun (2010-12-24): documentation of schemes and refactoring. Added coordinate neighborhoods and `is_smooth()`
- Ben Hutz (2013) refactoring

**class** `sage.schemes.projective.projective_subscheme.AlgebraicScheme_subscheme_projective` (A. polynomials)

**Bases:** `sage.schemes.generic.algebraic_scheme.AlgebraicScheme_subscheme`

Construct an algebraic subscheme of projective space.

**Warning:** You should not create objects of this class directly. The preferred method to construct such subschemes is to use `subscheme()` method of `projective space`.

**INPUT:**

- `A` – ambient `projective space`.
- `polynomials` – single polynomial, ideal or iterable of defining homogeneous polynomials.
EXAMPLES:

```
sage: P.<x, y, z> = ProjectiveSpace(2, QQ)
sage: P.subscheme([x^2-y*z])
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
 x^2 - y*z
```

**Chow_form()**

Returns the Chow form associated to this subscheme.

For a \( k \)-dimensional subvariety of \( \mathbb{P}^N \) of degree \( D \). The \( (N-k-1) \)-dimensional projective linear subspaces of \( \mathbb{P}^N \) meeting \( X \) form a hypersurface in the Grassmannian \( G(N-k-1, N) \). The homogeneous form of degree \( D \) defining this hypersurface in Plucker coordinates is called the Chow form of \( X \).

The base ring needs to be a number field, finite field, or \( \overline{\mathbb{Q}} \).

**ALGORITHM:**

For a \( k \)-dimension subscheme \( X \) consider the \( k+1 \) linear forms \( l_i = u_{i0}x_0 + \cdots + u_{in}x_n \). Let \( J \) be the ideal in the polynomial ring \( K[x_i, u_{ij}] \) defined by the equations of \( X \) and the \( l_i \). Let \( J' \) be the saturation of \( J \) with respect to the irrelevant ideal of the ambient projective space of \( X \). The elimination ideal \( I = J' \cap K[u_{ij}] \) is a principal ideal, let \( R \) be its generator. The Chow form is obtained by writing \( R \) as a polynomial in Plucker coordinates (i.e. bracket polynomials). [DalbecSturmfels].

**OUTPUT:** a homogeneous polynomial.

**REFERENCES:** a homogeneous polynomial.

**EXAMPLES:**

```
sage: P.<x0,x1,x2,x3> = ProjectiveSpace(GF(17), 3)
sage: X = P.subscheme([x3+x1,x2-x0,x2-x3])
sage: X.Chow_form()
t0 - t1 + t2 + t3
```

```
sage: P.<x0,x1,x2,x3> = ProjectiveSpace(QQ,3)
sage: X = P.subscheme([x3^2 -101*x1^2 - 3*x2*x0])
sage: X.Chow_form()
t0^2 - 101*t2^2 - 3*t1*t3
```

```
sage: P.<x0,x1,x2,x3>=ProjectiveSpace(QQ,3)
sage: X = P.subscheme([x0*x2-x1^2, x0*x3-x1*x2, x1*x3-x2^2])
sage: Ch = X.Chow_form(); Ch
t2^3 + 2*t2^2*t3 + t2*t3^2 - 3*t1*t2*t4 - t1*t3*t4 + t0*t4^2 + t1^2*t5
```

```
sage: X = P.subscheme_from_Chow_form(Ch, 1); Y
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
  x2^2*x3 - x1*x3^2,
 -x2^3 + x0*x3^2,
 -x2^2*x3 + x1*x3^2,
 x1*x2*x3 - x0*x3^2,
 3*x1*x2^2 - 3*x0*x2*x3,
 -2*x1^2*x3 + 2*x0*x2*x3,
 -3*x1^2*x2 + 3*x0*x1*x3,
 x1^3 - x0^2*x3,
 x2^3 - x1*x2*x3,
-3*x1*x2^2 + 2*x1^2*x3 + x0*x2*x3,
 2*x0*x2^2 - 2*x0*x1*x3,
```

(continues on next page)
affine_patch \( (i, AA=None) \)

Return the \( i \)th affine patch of this projective scheme. This is the intersection with this \( i \)th affine patch of its ambient space.

**INPUT:**

- \( i \) – integer between 0 and dimension of self, inclusive.
- \( AA \) – (default: None) ambient affine space, this is constructed if it is not given.

**OUTPUT:**

An affine algebraic scheme with fixed embedding_morphism() equal to the default projective_embedding() map'.

**EXAMPLES:**

```
sage: PP = ProjectiveSpace(2, QQ, names='X,Y,Z')
sage: X, Y, Z = PP.gens()
sage: C = PP.subscheme(X^3*Y + Y^3*Z + Z^3*X)
sage: U = C.affine_patch(0)
sage: U
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
Y^3*Z + Z^3 + Y
sage: U.embedding_morphism()
Scheme morphism:
From: Closed subscheme of Affine Space of dimension 2 over Rational Field
       defined by:
       Y^3*Z + Z^3 + Y
To:   Closed subscheme of Projective Space of dimension 2 over Rational Field
       defined by:
       X^3*Y + Y^3*Z + X*Z^3
       Defn: Defined on coordinates by sending (Y, Z) to
             (1 : Y : Z)
sage: U.projective_embedding() is U.embedding_morphism()
True
```

```
sage: A.<x,y,z> = AffineSpace(QQ,3)
sage: X = A.subscheme([x-y*z])
sage: Y = X.projective_embedding(1).codomain()
sage: Y.affine_patch(1,A).ambient_space() == A
True
```

```
sage: P.<u,v,w> = ProjectiveSpace(2,ZZ)
sage: S = P.subscheme([u^2-v*w])
sage: A.<x,y> = AffineSpace(2, ZZ)
sage: S.affine_patch(1, A)  
```

(continues on next page)
**Closed subscheme of Affine Space of dimension 2 over Integer Ring defined by:**
\[ x^2 - y \]

**degree()**
Return the degree of this projective subscheme.

If \( P(t) = a_m t^m + \ldots + a_0 \) is the Hilbert polynomial of this subscheme, then the degree is \( a_m m! \).

**OUTPUT:** Integer.

**EXAMPLES:**
```
sage: P.<x,y,z,w,t,u> = ProjectiveSpace(QQ, 5)
sage: X = P.subscheme([x^7 + x*y*z*t^4 - u^7])
sage: X.degree()
7

sage: P.<x,y,z,w> = ProjectiveSpace(GF(13), 3)
sage: X = P.subscheme([y^3 - w^3, x + 7*z])
sage: X.degree()
3

sage: P.<x,y,z,w,u> = ProjectiveSpace(QQ, 4)
sage: C = P.curve([x^7 - y*z^3*w^2*u, w*x^2 - y*u^2, z^3 + y^3])
sage: C.degree()
63
```

**dimension()**
Return the dimension of the projective algebraic subscheme.

**OUTPUT:**
Integer.

**EXAMPLES:**
```
sage: P2.<x,y,z> = ProjectiveSpace(2, QQ)
sage: P2.subscheme([]).dimension()
2

sage: P2.subscheme([x]).dimension()
1

sage: P2.subscheme([x^5]).dimension()
1

sage: P2.subscheme([x^2 + y^2 - z^2]).dimension()
1

sage: P2.subscheme([x*(x-z), y*(y-z)]).dimension()
0
```

Something less obvious:
```
sage: P3.<x,y,z,w,t> = ProjectiveSpace(4, QQ)
sage: X = P3.subscheme([x^2, x^2*y^2 + z^2*t^2, z^2 - w^2, 10*x^2 + w^2 - z^2])
sage: X
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
\[ x^2, \]
```

(continues on next page)
\textbf{dual()}\par Return the projective dual of the given subscheme of projective space.\par

\textbf{INPUT:}\par
\begin{itemize}
  \item $X$ – A subscheme of projective space. At present, $X$ is required to be an irreducible and reduced hypersurface defined over $\mathbb{Q}$ or a finite field.
\end{itemize}

\textbf{OUTPUT:}\par
\begin{itemize}
  \item The dual of $X$ as a subscheme of the dual projective space.
\end{itemize}

\textbf{EXAMPLES:}\par

The dual of a smooth conic in the plane is also a smooth conic:
\begin{verbatim}
sage: R.<x, y, z> = QQ[]
sage: P.<x, y, z> = ProjectiveSpace(2, QQ)
sage: I = R.ideal(x^2 + y^2 + z^2)
sage: X = P.subscheme(I)
sage: X.dual()
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
y0^2 + y1^2 + y2^2
\end{verbatim}

The dual of the twisted cubic curve in projective 3-space is a singular quartic surface. In the following example, we compute the dual of this surface, which by double duality is equal to the twisted cubic itself. The output is the twisted cubic as an intersection of three quadrics:
\begin{verbatim}
sage: R.<x, y, z, w> = QQ[]
sage: P.<x, y, z, w> = ProjectiveSpace(3, QQ)
sage: I = R.ideal(y^2*z^2 - 4*x*z^3 - 4*y^3*w + 18*x*y*z*w - 27*x^2*w^2)
sage: X = P.subscheme(I)
sage: X.dual()
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
y2^2 - y1*y3,
y1*y2 - y0*y3,
y1^2 - y0*y2
\end{verbatim}

The singular locus of the quartic surface in the last example is itself supported on a twisted cubic:
\begin{verbatim}
sage: X.Jacobian().radical()
Ideal (z^2 - 3*y*w, y*z - 9*x*w, y^2 - 3*x*z) of Multivariate Polynomial Ring in x, y, z, w over Rational Field
\end{verbatim}

An example over a finite field:
\begin{verbatim}
sage: R = PolynomialRing(GF(61), 'a,b,c')
sage: P.<a, b, c> = ProjectiveSpace(2, R.base_ring())
sage: X = P.subscheme(R.ideal(a*a+2*b*b+3*c*c))
sage: X.dual()
\end{verbatim}
**intersection_multiplicity** \((X, P)\)

Return the intersection multiplicity of this subscheme and the subscheme \(X\) at the point \(P\).

This uses the \(\text{intersection}\_\text{multiplicity}\) function for affine subschemes on affine patches of this subscheme and \(X\) that contain \(P\).

**INPUT:**

- \(X\) – subscheme in the same ambient space as this subscheme.
- \(P\) – a point in the intersection of this subscheme with \(X\).

**OUTPUT:** An integer.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(GF(5), 2)
sage: C = Curve([x^4 - z^2*y^2], P)
sage: D = Curve([y^4*z - x^5 - x^3*z^2], P)
sage: Q1 = P([0,1,0])
sage: C.intersection_multiplicity(D, Q1)
4
sage: Q2 = P([0,0,1])
sage: C.intersection_multiplicity(D, Q2)
6
```

```python
sage: R.<a> = QQ[]
sage: K.<b> = NumberField(a^4 + 1)
sage: P.<x,y,z,w> = ProjectiveSpace(K, 3)
sage: X = P.subscheme([x^2 + y^2 - z*w])
sage: Y = P.subscheme([y*z - x*w, z - w])
sage: Q1 = P([b^2,1,0,0])
sage: X.intersection_multiplicity(Y, Q1)
1
sage: Q2 = P([1/2*b^3-1/2*b,1/2*b^3-1/2*b,1,1])
sage: X.intersection_multiplicity(Y, Q2)
1
```

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: X = P.subscheme([x^2 - z^2, y^3 - w*x^2])
sage: Y = P.subscheme([w^2 - 2*x*y + z^2, y^2 - w^2])
sage: Q = P([1,1,-1,1])
sage: X.intersection_multiplicity(Y, Q)
Traceback (most recent call last):
  ... TypeError: the intersection of this subscheme and (=Closed subscheme of \(\mathbb{A}^3\) over Rational Field defined by:
  \(z^2 + w^2 - 2*y,
  y^2 - w^2\) must be proper and finite
```

**is_smooth** \((point=None)\)

Test whether the algebraic subscheme is smooth.

**INPUT:**
• **point** – A point or None (default). The point to test smoothness at.

**OUTPUT:**

Boolean. If no point was specified, returns whether the algebraic subscheme is smooth everywhere. Otherwise, smoothness at the specified point is tested.

**EXAMPLES:**

```
sage: P2.<x,y,z> = ProjectiveSpace(2,QQ)
sage: cuspidal_curve = P2.subscheme([y^2*z-x^3])
sage: cuspidal_curve
Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
-x^3 + y^2*z
cuspidal_curve.is_smooth([1,1,1])
True
cuspidal_curve.is_smooth([0,0,1])
False
cuspidal_curve.is_smooth()
False
sage: P2.subscheme([y^2*z-x^3+z^3+1/10*x*y*z]).is_smooth()
True
```

**multiplicity**(P)

Return the multiplicity of P on this subscheme.

This is computed as the multiplicity of the corresponding point on an affine patch of this subscheme that contains P. This subscheme must be defined over a field. An error is returned if P not a point on this subscheme.

**INPUT:**

• P – a point on this subscheme.

**OUTPUT:**

An integer.

**EXAMPLES:**

```
sage: P.<x,y,z,w,t> = ProjectiveSpace(QQ, 4)
sage: X = P.subscheme([y^2 - x*t, w^7 - t*w*x^5 - z^7])
sage: Q1 = P([0,0,1,1,1])
sage: X.multiplicity(Q1)
1
sage: Q2 = P([1,0,0,0,0])
sage: X.multiplicity(Q2)
3
sage: Q3 = P([0,0,0,0,1])
sage: X.multiplicity(Q3)
7
```

```
sage: P.<x,y,z,w> = ProjectiveSpace(CC, 3)
sage: X = P.subscheme([z^5*x^2*w - y^8])
sage: Q = P([2,0,0,1])
sage: X.multiplicity(Q)
5
```
sage: P.<x,y,z,w> = ProjectiveSpace(GF(29), 3)
sage: C = Curve([y^17 - x^5*w^4*z^8, x*y - z^2], P)
sage: Q = P([3,0,0,1])
sage: C.multiplicity(Q)
8

neighborhood(point)
Return an affine algebraic subscheme isomorphic to a neighborhood of the point.

INPUT:
• point – a point of the projective subscheme.

OUTPUT:
An affine algebraic scheme (polynomial equations in affine space) result such that
• embedding_morphism is an isomorphism to a neighborhood of point
• embedding_center is mapped to point.

EXAMPLES:

sage: P.<x,y,z>= ProjectiveSpace(QQ,2)
sage: S = P.subscheme(x+2*y+3*z)
sage: s = S.point([0,-3,2]); s
(0 : -3/2 : 1)
sage: patch = S.neighborhood(s); patch
Closed subscheme of Affine Space of dimension 2 over Rational Field defined by:
    x + 3*z
sage: patch.embedding_morphism()
Scheme morphism:
    From: Closed subscheme of Affine Space of dimension 2 over Rational Field
    Defined by:
        x + 3*z
    To: Closed subscheme of Projective Space of dimension 2 over Rational Field
    Defined on coordinates by sending (x, z) to
    (x : -3/2 : z + 1)
sage: patch.embedding_center()
(0, 0)
sage: patch.embedding_morphism()([0,0])
(0 : -3/2 : 1)
sage: patch.embedding_morphism()(patch.embedding_center())
(0 : -3/2 : 1)

nth_iterate(f,n)
The nth forward image of this scheme by the map f.

INPUT:
• f – a DynamicalSystem_projective with self in f.domain()
• n – a positive integer.

OUTPUT:
• A subscheme in f.codomain()

EXAMPLES:
orbit \((f, N)\)

Returns the orbit of this scheme by \(f\).

If \(N\) is an integer it returns \([self, f(self), \ldots, f^N(self)]\). If \(N\) is a list or tuple \(N = [m, k]\) it returns \([f^m(self), \ldots, f^k(self)]\).

**INPUT:**

- \(f\) – a DynamicalSystem_projective with \(self\) in \(f\).domain()

- \(N\) – a non-negative integer or list or tuple of two non-negative integers

**OUTPUT:**

- a list of projective subschemes

**EXAMPLES:**

```python
sage: P.<x,y,z,w> = ProjectiveSpace(QQ, 3)
sage: f = DynamicalSystem_projective([\(x^2+y^2, z^2, x^2, w^2\)])
sage: f.orbit(P.subscheme([x-w,y-z]), 5)
[Closed subscheme of Projective Space of dimension 3 over Rational Field
defined by:
  y - z,
  x - w]
```
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
   \( w, \)
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
   \( z - w, \)
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
   \( y - z, \)
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
   \( x - y, \)
Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
   \( x - w \]

sage: PS.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: P1.<u,v> = ProjectiveSpace(QQ, 1)
sage: H = Hom(PS, P1)
sage: f = H([x^2, y^2])
sage: X = PS.subscheme([x-y])
sage: X.orbit(f,2)
Traceback (most recent call last):
  ... TypeError: map must be a dynamical system for iteration

sage: PS.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: f = DynamicalSystem_projective([x^2, y^2, z^2])
sage: X = PS.subscheme([x-y])
sage: X.orbit(f,[-1,2])
Traceback (most recent call last):
  ... TypeError: orbit bounds must be non-negative

point \((v, check=True)\)
Create a point on this projective subscheme.

INPUT:

- \(v\) – anything that defines a point
- \(check\) – boolean (optional, default: True); whether to check the defining data for consistency

OUTPUT: A point of the subscheme.

EXAMPLES:

```python
sage: P2.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: X = P2.subscheme([x-y,y-z])
sage: X.point([1,1,1])
(1 : 1 : 1)
```

```python
sage: P2.<x,y> = ProjectiveSpace(QQ, 1)
sage: X = P2.subscheme([y])
sage: X.point(infinity)
(1 : 0)
```
sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: X = P.subscheme(x^2 + 2*y^2)
sage: X.point(infinity)
Traceback (most recent call last):
  ...    TypeError: Coordinates [1, 0] do not define a point on Closed subscheme of Projective Space of dimension 1 over Rational Field defined by: x^2 + 2*y^2

preimage \( (f, k=1, \text{check}=\text{True}) \)

The subscheme that maps to this scheme by the map \( f^k \).

In particular, \( f^{-k}(V(h_1, \ldots, h_t)) = V(h_1 \circ f^k, \ldots, h_t \circ f^k) \). Map must be a morphism and also must be an endomorphism for \( k > 1 \).

INPUT:

- \( f \) - a map whose codomain contains this scheme
- \( k \) - a positive integer
- \( \text{check} \) – Boolean, if \( \text{False} \) no input checking is done

OUTPUT:

- a subscheme in the domain of \( f \).

Examples:

```
sage: PS.<x,y,z> = ProjectiveSpace(ZZ, 2)
sage: H = End(PS)
sage: f = H([y^2, x^2, z^2])
sage: X = PS.subscheme([x-y])
sage: X.preimage(f)
Closed subscheme of Projective Space of dimension 2 over Integer Ring defined by:
-x^2 + y^2
```

```
sage: P.<x,y,z,w,t> = ProjectiveSpace(QQ, 4)
sage: H = End(P)
sage: f = H([x^2-y^2, y^2, z^2, w^2, t^2+w^2])
sage: f.rational_preimages(P.subscheme([x-z, t^2, w-t]))
Closed subscheme of Projective Space of dimension 4 over Rational Field defined by:
x^2 - y^2 - z^2,
w^4 + 2*w^2*t^2 + t^4,
-t^2
```

```
sage: P1.<x,y> = ProjectiveSpace(QQ, 1)
sage: P3.<u,v,w,t> = ProjectiveSpace(QQ, 3)
sage: H = Hom(P1, P3)
sage: X = P3.subscheme([u-v, 2*u-w, u+t])
sage: f = H([x^2, y^2, x^2+y^2, x+y])
sage: X.preimage(f)
Closed subscheme of Projective Space of dimension 1 over Rational Field defined by:
x^2 - y^2,
x^2 - y^2,
x^2 + x*y
```
```python
sage: P1.<x,y> = ProjectiveSpace(QQ, 1)
sage: P3.<u,v,w,t> = ProjectiveSpace(QQ, 3)
sage: H = Hom(P3, P1)
sage: X = P1.subscheme([x-y])
sage: f = H([u^2, v^2])
x: preimage(f)
Traceback (most recent call last):
...:
TypeError: map must be a morphism
```

```python
sage: PS.<x,y,z> = ProjectiveSpace(ZZ, 2)
sage: H = End(PS)
sage: f = H([x^2, x^2, x^2])
sage: X = PS.subscheme([x-y])
x: preimage(f)
x: Traceback (most recent call last):
...:
TypeError: map must be a morphism
```

```python
sage: PS.<x,y,z> = ProjectiveSpace(ZZ, 2)
sage: P1.<u,v> = ProjectiveSpace(ZZ, 1)
sage: Y = P1.subscheme([u^2-v^2])
sage: H = End(PS)
sage: f = H([x^2, y^2, z^2])
x: preimage(f)
x: Traceback (most recent call last):
...:
TypeError: subscheme must be in ambient space of codomain
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: Y = P.subscheme([x-y])
sage: H = End(P)
sage: f = H([x^2, y^2, z^2])
x: preimage(f, k=2)
Closed subscheme of Projective Space of dimension 2 over Rational Field
defined by:
x^4 - y^4
```

**veronese_embedding**

(d, CS=None, order='lex')

Return the degree d Veronese embedding of this projective subscheme.

**INPUT:**

- **d** – a positive integer.
- **CS** – a projective ambient space to embed into. If the projective ambient space of this subscheme is of dimension \(N\), the dimension of CS must be \(\binom{N+d}{d} - 1\). This is constructed if not specified. Default: None.
- **order** – a monomial order to use to arrange the monomials defining the embedding. The monomials will be arranged from greatest to least with respect to this order. Default: 'lex'.

**OUTPUT:**

- a scheme morphism from this subscheme to its image by the degree d Veronese embedding.

**EXAMPLES:**
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: L = P.subscheme([y - x])
sage: v = L.veronese_embedding(2)
sage: v
Scheme morphism:
  From: Closed subscheme of Projective Space of dimension 2 over Rational Field defined by:
      -x + y
  To:   Closed subscheme of Projective Space of dimension 5 over Rational Field defined by:
        -x4 + x3*x5,
        x2 - x4,
        x1 - x3,
        x0 - x3
Defn: Defined on coordinates by sending (x : y : z) to
      (x^2 : x*y : x*z : y^2 : y*z : z^2)
sage: v.codomain().degree()
2
sage: C = P.subscheme([y*z - x^2])
sage: C.veronese_embedding(2).codomain().degree()
4
twisted cubic:

sage: P.<x,y> = ProjectiveSpace(QQ, 1)
sage: Q.<u,v,s,t> = ProjectiveSpace(QQ, 3)
sage: P.subscheme([]).veronese_embedding(3, Q)
Scheme morphism:
  From: Closed subscheme of Projective Space of dimension 1 over Rational Field defined by:
      (no polynomials)
  To:   Closed subscheme of Projective Space of dimension 3 over Rational Field defined by:
        -s^2 + v*t,
        -v*s + u*t,
        -v^2 + u*s
Defn: Defined on coordinates by sending (x : y) to
      (x^3 : x^2*y : x*y^2 : y^3)

14.5 Enumeration of rational points on projective schemes

Naive algorithms for enumerating rational points over $\mathbb{Q}$ or finite fields over for general schemes.

**Warning:** Incorrect results and infinite loops may occur if using a wrong function. (For instance using an affine function for a projective scheme or a finite field function for a scheme defined over an infinite field.)

**EXAMPLES:**

Projective, over $\mathbb{Q}$:

sage: from sage.schemes.projective.projective_rational_point import enum_projective_rational_field
sage: P.<X,Y,Z> = ProjectiveSpace(2,QQ)
sage: C = P.subscheme([X+Y-Z])
sage: enum_projective_rational_field(C, 3)
[(-2 : 3 : 1), (-1 : 1 : 0), (-1 : 2 : 1), (-1/2 : 3/2 : 1),
 (0 : 1 : 1), (1/3 : 2/3 : 1), (1/2 : 1/2 : 1), (2/3 : 1/3 : 1),
 (1 : 0 : 1), (3/2 : -1/2 : 1), (2 : -1 : 1), (3 : -2 : 1)]

Projective over a finite field:

sage: from sage.schemes.projective.projective_rational_point import enum_projective_rational_field
sage: E = EllipticCurve('72').change_ring(GF(19))
sage: enum_projective_finite_field(E)
[(0 : 1 : 0), (1 : 0 : 1), (3 : 0 : 1), (4 : 9 : 1), (4 : 10 : 1),
 (9 : 15 : 1), (12 : 8 : 1), (12 : 11 : 1), (13 : 8 : 1), (13 : 11 : 1),
 (14 : 3 : 1), (14 : 16 : 1), (15 : 0 : 1), (16 : 9 : 1), (16 : 10 : 1),
 (17 : 7 : 1), (17 : 12 : 1), (18 : 9 : 1), (18 : 10 : 1)]

sage.schemes.projective.projective_rational_point.enum_projective_finite_field(X)
Enumerates projective points on scheme X defined over a finite field.

INPUT:

• X - a scheme defined over a finite field or a set of abstract rational points of such a scheme.

OUTPUT:

• a list containing the projective points of X over the finite field, sorted.

EXAMPLES:

sage: F = GF(53)
sage: P.<X,Y,Z> = ProjectiveSpace(2,F)
sage: from sage.schemes.projective.projective_rational_point import enum_projective_rational_field
sage: len(enum_projective_finite_field(P(F)))
2863
sage: 53^2+53+1
2863

sage: F = GF(9,'a')
sage: P.<X,Y,Z> = ProjectiveSpace(2,F)
sage: C = Curve(X^3-Y^3+Z^2*Y)
sage: enum_projective_finite_field(C(F))
[(0 : 0 : 1), (0 : 1 : 1), (0 : 2 : 1), (1 : 1 : 0), (a + 1 : 2*a : 1),
 (a + 1 : 2*a + 1 : 1), (a + 1 : 2*a + 2 : 1), (2*a + 2 : a : 1),
 (2*a + 2 : a + 1 : 1), (2*a + 2 : a + 2 : 1)]

sage: F = GF(5)
sage: P2F.<X,Y,Z> = ProjectiveSpace(2,F)

14.5. Enumeration of rational points on projective schemes 169
sage: enum_projective_finite_field(P2F)
[(0 : 0 : 1), (0 : 1 : 0), (0 : 1 : 1), (0 : 2 : 1), (0 : 3 : 1), (0 : 4 : 1),
(1 : 0 : 0), (1 : 0 : 1), (1 : 1 : 0), (1 : 1 : 1), (1 : 2 : 1), (1 : 3 : 1),
(1 : 4 : 1), (2 : 0 : 1), (2 : 1 : 0), (2 : 1 : 1), (2 : 2 : 1), (2 : 3 : 1),
(2 : 4 : 1), (3 : 0 : 1), (3 : 1 : 0), (3 : 1 : 1), (3 : 2 : 1), (3 : 3 : 1),
(3 : 4 : 1), (4 : 0 : 1), (4 : 1 : 0), (4 : 1 : 1), (4 : 2 : 1), (4 : 3 : 1),
(4 : 4 : 1)]

ALGORITHM:

Checks all points in projective space to see if they lie on $X$.

**Warning:** If $X$ is defined over an infinite field, this code will not finish!

AUTHORS:

- John Cremona and Charlie Turner (06-2010).

sage.schemes.projective.projective_rational_point.enum_projective_number_field($X$, **kwds)

Enumerates projective points on scheme $X$ defined over a number field.

Simply checks all of the points of absolute height of at most $B$ and adds those that are on the scheme to the list.

This algorithm computes 2 lists: $L$ containing elements $x$ in $K$ such that $H_k(x) \leq B$, and a list $L'$ containing elements $x$ in $K$ that, due to floating point issues, may be slightly larger than the bound. This can be controlled by lowering the tolerance.

ALGORITHM:

This is an implementation of the revised algorithm (Algorithm 4) in [Doyle-Krumm]. Algorithm 5 is used for imaginary quadratic fields.

INPUT:

kwds:
- **bound** - a real number
- **tolerance** - a rational number in $(0,1]$ used in doyle-krumm algorithm-4
- **precision** - the precision to use for computing the elements of bounded height of number fields.

OUTPUT:

- a list containing the projective points of $X$ of absolute height up to $B$, sorted.

EXAMPLES:

```sage
sage: from sage.schemes.projective.projective_rational_point import enum_
˓→projective_number_field
sage: u = QQ['u'].0
sage: K = NumberField(u^3 - 5, 'v')
sage: P.<x,y,z> = ProjectiveSpace(K, 2)
sage: X = P.subscheme([x - y])
sage: enum_projective_number_field(X(K), bound=RR(5^(1/3)), prec=2^10)
[(0 : 0 : 1), (-1 : -1 : 1), (1 : 1 : 1), (-1/5*v^2 : -1/5*v^2 : 1), (-v : -v :
˓→1),
(1/5*v^2 : 1/5*v^2 : 1), (v : v : 1), (1 : 1 : 0)]
```
sage: u = QQ['u'].0
sage: K = NumberField(u^2 + 3, 'v')

sage: A.<x,y> = ProjectiveSpace(K,1)

sage: X = A.subscheme(x-y)

sage: from sage.schemes.projective.projective_rational_point import enum_projective_rational_field

sage: enum_projective_rational_field(X, bound=2)
[(1 : 1)]

sage.schemes.projective.projective_rational_point.enum_projective_rational_field(X, bound=2)

Enumerates projective, rational points on scheme $X$ of height up to bound $B$.

**INPUT:**
- $X$ - a scheme or set of abstract rational points of a scheme.
- $B$ - a positive integer bound.

**OUTPUT:**
- a list containing the projective points of $X$ of height up to $B$, sorted.

**EXAMPLES:**

```python
sage: P.<X,Y,Z> = ProjectiveSpace(2, QQ)
sage: C = P.subscheme([X+Y-Z])

sage: from sage.schemes.projective.projective_rational_point import enum_projective_rational_field

sage: enum_projective_rational_field(C(QQ), 6)
[(-5 : 6 : 1), (-4 : 5 : 1), (-3 : 4 : 1), (-2 : 3 : 1),
 (-1/2 : 3/2 : 1), (-1/3 : 4/3 : 1), (-1/4 : 5/4 : 1),
 (-1/5 : 6/5 : 1), (0 : 1 : 1), (1/6 : 5/6 : 1), (1/5 : 4/5 : 1),
 (1/4 : 3/4 : 1), (1/3 : 2/3 : 1), (2/5 : 3/5 : 1), (1/2 : 1/2 : 1),
 (5/6 : 1/6 : 1), (1/0 : 1), (6/5 : -1/5 : 1), (5/4 : -1/4 : 1),
 (5/2 : -3/2 : 1), (3 : -2 : 1), (4 : -3 : 1), (5 : -4 : 1),
 (6 : -5 : 1)]

sage: enum_projective_rational_field(C,6) == enum_projective_rational_field(C(QQ), 6)
True
```

```

sage: P3.<W,X,Y,Z> = ProjectiveSpace(3, QQ)

sage: enum_projective_rational_field(P3, 1)
[(-1 : -1 : -1 : 1), (-1 : -1 : 0 : 1), (-1 : -1 : 1 : 0), (-1 : -1 : 1 : 1),
 (-1 : 0 : -1 : 1), (-1 : 0 : 0 : 1), (-1 : 0 : 1 : 0), (-1 : 0 : 1 : 1),
 (-1 : 1 : -1 : 1), (-1 : 1 : 0 : 0), (-1 : 1 : 0 : 1), (-1 : 1 : 1 : 0),
 (-1 : 1 : 1 : 1), (-1 : 1 : 0 : 0), (-1 : 1 : 0 : 1), (-1 : 1 : 1 : 0),
 (0 : 0 : -1 : 1), (0 : 0 : 0 : 1), (0 : 0 : 1 : 0), (0 : 0 : 1 : 1),
 (0 : 1 : -1 : 1), (0 : 1 : 0 : 0), (0 : 1 : 0 : 1), (0 : 1 : 1 : 0),
 (0 : 1 : 1 : 1), (1 : -1 : -1 : 1), (1 : -1 : 0 : 0), (1 : -1 : 0 : 1),
 (1 : -1 : 1 : 0), (1 : -1 : 1 : 1), (1 : 0 : -1 : 1), (1 : 0 : 0 : 0),
 (1 : 0 : 0 : 1), (1 : 0 : 1 : 0), (1 : 0 : 1 : 1), (1 : 1 : -1 : 1),
 (1 : 1 : 0 : 0), (1 : 1 : 0 : 1), (1 : 1 : 1 : 0), (1 : 1 : 1 : 1)]
```

**ALGORITHM:**
We just check all possible projective points in correct dimension of projective space to see if they lie on $X$. 

---

14.5. Enumeration of rational points on projective schemes 171
AUTHORS:

- John Cremona and Charlie Turner (06-2010)

**sage.schemes.projective.projective_rational_point.sieve** *(X, bound)*

Returns the list of all projective, rational points on scheme X of height up to bound.

Height of a projective point $X = (x_1, x_2, \ldots, x_n)$ is given by $H_X = \max(y_1, y_2, \ldots, y_n)$, where $H_X$ is height of point X and $y_i$'s are the normalized coordinates such that all $y_i$ are integers and $\gcd(y_1, y_2, \ldots, y_n) = 1$.

**ALGORITHM:**

Main idea behind the algorithm is to find points modulo primes and then reconstruct them using chinese remainder theorem. We find modulo primes parallely and then lift them and apply LLL in parallel.

For the algorithm to work correctly, sufficient primes need to be present, these are calculated using the bound given in this([Hutz2015]) paper.

**INPUT:**

- *X* - a scheme with ambient space defined over projective space
- *bound* - a positive integer bound

**OUTPUT:**

- a list containing the projective rational points of $X$ of height up to $bound$, sorted

**EXAMPLES:**

```python
sage: from sage.schemes.projective.projective_rational_point import sieve
sage: P.<x,y,z,q>=ProjectiveSpace(QQ,3)
\[
\begin{align*}
\text{sage: } & Y=P.subscheme([x^2-3^2*y^2+z*q,x+z+4*q]) \\
\text{sage: } & \text{sorted(sieve}(Y, 12)) \\
\text{sage: } & [(-4 : -4/3 : 0 : 1), (-4 : 4/3 : 0 : 1), \\
\text{sage: } & (-1 : -1/3 : 1 : 0), (-1 : 1/3 : 1 : 0)]
\end{align*}
```

```python
sage: from sage.schemes.projective.projective_rational_point import sieve
sage: E = EllipticCurve('37a')
\[
\begin{align*}
\text{sage: } & \text{sorted(sieve}(E, 14)) \\
\text{sage: } & [( -1 : -1 : 1), ( -1 : 0 : 1), ( 0 : -1 : 1), \\
\text{sage: } & ( 0 : 0 : 1), ( 0 : 1 : 0), ( 1/4 : -5/8 : 1), \\
\text{sage: } & ( 1/4 : -3/8 : 1), ( 1 : -1 : 1), ( 1 : 0 : 1), \\
\text{sage: } & ( 2 : -3 : 1), ( 2 : 2 : 1), ( 6 : 14 : 1)]
\end{align*}
```

14.6 Set of homomorphisms between two projective schemes

For schemes $X$ and $Y$, this module implements the set of morphisms $\text{Hom}(X, Y)$. This is done by $\text{SchemeHomset\_generic}$.

As a special case, the Hom-sets can also represent the points of a scheme. Recall that the $K$-rational points of a scheme $X$ over $k$ can be identified with the set of morphisms $\text{Spec}(K) \to X$. In Sage the rational points are implemented by such scheme morphisms. This is done by $\text{SchemeHomset\_points}$ and its subclasses.

**Note:** You should not create the Hom-sets manually. Instead, use the $\text{Hom()}$ method that is inherited by all schemes.

AUTHORS:
• Volker Braun (2011-08-11): significant improvement and refactoring.
• Ben Hutz (June 2012): added support for projective ring
• Ben Hutz (2018): add numerical point support

class sage.schemes.projective.projective_homset.SchemeHomset_points_abelian_variety_field(X, Y, cat-
egory=None, check=True, base=IntegerRing)

Bases: sage.schemes.projective.projective_homset.SchemeHomset_points_projective_field

Set of rational points of an Abelian variety.

INPUT:

See SchemeHomset_generic.

base_extend (R)

Extend the base ring.

This is currently not implemented except for the trivial case R==ZZ.

INPUT:

• R – a ring.

EXAMPLES:

sage: E = EllipticCurve('37a')
sage: Hom = E.point_homset(); Hom
Abelian group of points on Elliptic Curve defined by y^2 + y = x^3 - x over Rational Field
sage: Hom.base_ring()
Integer Ring
sage: Hom.base_extend(QQ)
Traceback (most recent call last):
  ... Not ImplementedError: Abelian variety point sets are not implemented as modules over rings other than ZZ

class sage.schemes.projective.projective_homset.SchemeHomset_points_projective_field(X, Y, category=None, check=True, base=IntegerRing)

Bases: sage.schemes.generic.homset.SchemeHomset_points

Set of rational points of a projective variety over a field.

INPUT:

See SchemeHomset_generic.
EXAMPLES:

```python
sage: from sage.schemes.projective.projective_homset import SchemeHomset_points_˓→projective_field
sage: SchemeHomset_points_projective_field(Spec(QQ), ProjectiveSpace(QQ,2))
Set of rational points of Projective Space of dimension 2 over Rational Field
```

`numerical_points(F=None, **kwds)`

Return some or all numerical approximations of rational points of a projective scheme.

This is for dimension 0 subschemes only and the points are determined through a groebner calculation over the base ring and then numerically approximating the roots of the resulting polynomials. If the base ring is a number field, the embedding into $F$ must be known.

**INPUT:**

- $F$ - numerical ring

**kwds:**

- `point_tolerance` - positive real number (optional, default=$10^{-10}$). For numerically inexact fields, two points are considered the same if their coordinates are within tolerance.
- `zero_tolerance` - positive real number (optional, default=$10^{-10}$). For numerically inexact fields, points are on the subscheme if they satisfy the equations to within tolerance.

**OUTPUT:** A list of points in the ambient space.

**Warning:** For numerically inexact fields the list of points returned may contain repeated or be missing points due to tolerance.

**EXAMPLES:**

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: E = P.subscheme([y^3 - x^3 - x*z^2, x*y*z])
sage: L = E(QQ).numerical_points(F=RR); L
[(0.000000000000000 : 0.000000000000000 : 1.000000000000000),
 (1.000000000000000 : 1.000000000000000 : 0.000000000000000)]
sage: L[0].codomain()
Projective Space of dimension 2 over Real Field with 53 bits of precision
```

```python
sage: S.<a> = QQ[]
sage: K.<v> = NumberField(a^5 - 7, embedding=CC((7)**(1/5)))
sage: P.<x,y,z> = ProjectiveSpace(K,2)
sage: X = P.subscheme([x^2 - v^2*z^2, y-v*z])
sage: len(X(K).numerical_points(F=CDF))
2
```

```python
sage: P.<x1, x2, x3> = ProjectiveSpace(QQ, 2)
sage: E = P.subscheme([3000*x1^50 + 9875643*x2^2*x3^48 + 12334545*x2^50, x1 + x2])
sage: len(E(P.base_ring()).numerical_points(F=CDF, zero_tolerance=1e-6))
49
```

```python
sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: E = P.subscheme([y^3 - x^3 - x*z^2, x*y*z])
sage: E(QQ).numerical_points(F=CC, zero_tolerance=-1)
```

(continues on next page)
Traceback (most recent call last):
...

sage: P.<x,y,z> = ProjectiveSpace(QQ, 2)
sage: E = P.subscheme([y^3 - x^3 - x*z^2, x*y*z])
sage: E(QQ).numerical_points(F=QQbar)
Traceback (most recent call last):
...
TypeError: F must be a numerical field

points (**kwds)

Return some or all rational points of a projective scheme.

For dimension 0 subschemes points are determined through a groebner basis calculation. For schemes or subschemes with dimension greater than 1 points are determined through enumeration up to the specified bound.

INPUT:

kwds:

• bound - real number (optional, default=0). The bound for the coordinates for subschemes with dimension at least 1.

• precision - integer (optional, default=53). The precision to use to compute the elements of bounded height for number fields.

• point_tolerance - positive real number (optional, default=10^(-10)). For numerically inexact fields, two points are considered the same if their coordinates are within tolerance.

• zero_tolerance - positive real number (optional, default=10^(-10)). For numerically inexact fields, points are on the subscheme if they satisfy the equations to within tolerance.

• tolerance - a rational number in (0,1] used in doyle-krumm algorithm-4 for enumeration over number fields.

OUTPUT:

• a list of rational points of a projective scheme

Warning: For numerically inexact fields such as ComplexField or RealField the list of points returned is very likely to be incomplete. It may also contain repeated points due to tolerances.

EXAMPLES:

sage: P.<x,y> = ProjectiveSpace(QQ,1)
sage: P(QQ).points(bound=4)
[(-4 : 1), (-3 : 1), (-2 : 1), (-3/2 : 1), (-4/3 : 1), (-1 : 1),
(-3/4 : 1), (-2/3 : 1), (-1/2 : 1), (-1/3 : 1), (-1/4 : 1), (0 : 1),
(1/4 : 1), (1/3 : 1), (1/2 : 1), (2/3 : 1), (3/4 : 1), (1 : 0), (1 : 1),
(4/3 : 1), (3/2 : 1), (2 : 1), (3 : 1), (4 : 1)]

sage: u = QQ['u'].0
sage: K.<v> = NumberField(u^2 + 3)
sage: P.<x,y,z> = ProjectiveSpace(K,2)

14.6. Set of homomorphisms between two projective schemes
sage: len(P(K).points(bound=1.8))
381

sage: P1 = ProjectiveSpace(GF(2),1)
sage: F.<a> = GF(4,'a')
sage: P1(F).points()
[(0 : 1), (1 : 0), (1 : 1), (a : 1), (a + 1 : 1)]

sage: P.<x,y,z> = ProjectiveSpace(QQ,2)
sage: E = P.subscheme([(y^3-y*z^2) - (x^3-x*z^2), (y^3-y*z^2) + (x^3-x*z^2)])
sage: E(P.base_ring()).points()
[(-1 : -1 : 1), (-1 : 0 : 1), (-1 : 1 : 1), (0 : -1 : 1), (0 : 0 : 1), (0 : 1 : 1),
(1 : -1 : 1), (1 : 0 : 1), (1 : 1 : 1)]

sage: P.<x,y,z> = ProjectiveSpace(CC, 2)
sage: E = P.subscheme([y^3 - x^3 - x*z^2, x*y*z])
sage: len(E(P.base_ring()).points())
verbose 0 (71: projective_homset.py, points) Warning: computations in the numerical fields are inexact; points may be computed partially or incorrectly.
6

class sage.schemes.projective.projective_homset.SchemeHomset_points_projective_ring(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.generic.homset.SchemeHomset_points

Set of rational points of a projective variety over a commutative ring.

INPUT:

See SchemeHomset_generic.

EXAMPLES:
```python
sage: from sage.schemes.projective.projective_homset import SchemeHomset_points -->projective_ring
sage: SchemeHomset_points_projective_ring(Spec(ZZ), ProjectiveSpace(ZZ,2))
Set of rational points of Projective Space of dimension 2 over Integer Ring

points (B=0)

Return some or all rational points of a projective scheme.

INPUT:

• B – integer (optional, default=0). The bound for the coordinates.

EXAMPLES:

```python
sage: from sage.schemes.projective.projective_homset import SchemeHomset_points -->projective_ring
sage: H = SchemeHomset_points_projective_ring(Spec(ZZ), ProjectiveSpace(ZZ,2))
sage: H.points(3)
```

14.6. Set of homomorphisms between two projective schemes 177
15.1 Products of projective spaces

This class builds on the projective space class and its point and morphism classes.

Products of projective spaces of varying dimension are convenient ambient spaces for complete intersections.

Group actions on them, and the interplay with representation theory, provide many interesting examples of algebraic varieties.

EXAMPLES:

We construct products projective spaces of various dimensions over the same ring:

```
sage: P1 = ProjectiveSpace(ZZ, 1, 'x')
sage: P2 = ProjectiveSpace(ZZ, 2, 'y')
sage: ProductProjectiveSpaces([P1, P2])
Product of projective spaces $\mathbb{P}^1 \times \mathbb{P}^2$ over Integer Ring
```

We can also construct the product by specifying the dimensions and the base ring:

```
sage: ProductProjectiveSpaces([1, 2, 3], QQ, 'z')
Product of projective spaces $\mathbb{P}^1 \times \mathbb{P}^2 \times \mathbb{P}^3$ over Rational Field
```

```
sage: P2xP2 = ProductProjectiveSpaces([2, 2], QQ, names=['x', 'y'])
sage: P2xP2.coordinate_ring().inject_variables()
Defining x0, x1, x2, y0, y1, y2
```

sage.schemes.product_projective.space.ProductProjectiveSpaces(n, \hspace{1cm} R=None, \hspace{1cm} \hspace{1cm} names='x')

Return the Cartesian product of projective spaces.

Can input either a list of projective space over the same base ring or the list of dimensions, the base ring, and the variable names.

INPUT:

• n – a list of integers or a list of projective spaces.
• R – a ring.
• names – a string or list of strings.

EXAMPLES:
sage: P1 = ProjectiveSpace(QQ, 2, 'x')
sage: P2 = ProjectiveSpace(QQ, 3, 'y')
sage: ProductProjectiveSpaces([P1, P2])
Product of projective spaces P^2 x P^3 over Rational Field

sage: ProductProjectiveSpaces([2, 2],GF(7), 'y')
Product of projective spaces P^2 x P^2 over Finite Field of size 7

sage: P1 = ProjectiveSpace(ZZ, 2, 'x')
sage: P2 = ProjectiveSpace(QQ, 3, 'y')
sage: ProductProjectiveSpaces([P1, P2])
Traceback (most recent call last):
  ...  
AttributeError: components must be over the same base ring

class sage.schemes.product_projective.space.ProductProjectiveSpaces_field(N, 
                      R=Rational 
                       Field, 
                       names=None)

Bases: sage.schemes.product_projective.space.ProductProjectiveSpaces_ring

points_of_bounded_height(**kwds)
    Returns an iterator of the points in this product of projective spaces 
    with the absolute heights of the components of at most the given bound. 
    
    Bound check is strict for the rational field. Requires the base field of 
    this space to be a number field. Uses the Doyle-Krumm algorithm 4 
    (algorithm 5 for imaginary quadratic) for computing algebraic numbers 
    up to a given height [Doyle-Krumm].
    
    The algorithm requires floating point arithmetic, so the user is 
    allowed to specify the precision for such calculations. Additionally, 
    due to floating point issues, points slightly larger than the bound 
    may be returned. This can be controlled by lowering the tolerance.

    INPUT:
    • bound - a real number
    • tolerance - a rational number in (0,1] used in doyle-krumm algorithm-4
    • precision - the precision to use for computing the elements of bounded height of number fields.

    OUTPUT:
    • an iterator of points in this space

    EXAMPLES:

    sage: PP = ProductProjectiveSpaces(QQ, [1, 2])
sage: sorted(list(PP.points_of_bounded_height(bound=1)))
    [(-1 : 1 , -1 : -1 : 1), (-1 : 1 , -1 : 0 : 1), (-1 : 1 , -1 : 1 : 0), (-1 : -1 , -1 : 1 : 1),
     (-1 : 1 , 0 : -1 : 1), (-1 : 1 , 0 : 0 : 1), (-1 : 1 , 0 : 1 : 0), (-1 : 1 , 0 : 0 : -1),
     (-1 : 1 , 0 : 1 : -1), (0 : 1 , -1 : -1 : 1), (0 : 1 , -1 : 0 : 1), (0 : 1 , -1 : 1 : 0),
     (0 : 1 , 0 : -1 : 1), (0 : 1 , 0 : 0 : 1), (0 : 1 , 0 : 1 : 0), (0 : 1 , 0 : -1 : -1),
     (0 : 1 , 0 : -1 : 0), (0 : 1 , 0 : 1 : 0), (0 : 1 , 1 : -1 : 1), (0 : 1 , 1 : 0 : 0), (0 : 1 , 1 : 0 : -1),
     (0 : 1 , 1 : 1 : 0), (0 : 1 , 1 : 1 : 0), (0 : 1 , 1 : 1 : -1), (0 : 1 , 1 : 0 : 0), (0 : 1 , 1 : -1 : 0),
     (0 : 1 , 1 : -1 : 1), (0 : 1 , 0 : 0 : 1), (0 : 1 , 0 : 0 : 0), (0 : 1 , 0 : 0 : -1),
     (0 : 1 , 0 : 1 : 1), (0 : 1 , 0 : 1 : 0), (0 : 1 , 0 : -1 : 0), (0 : 1 , 0 : -1 : 1),
     (0 : 1 , 0 : -1 : 0), (0 : 1 , 0 : 0 : 0), (0 : 1 , 0 : 0 : -1), (0 : 1 , 0 : 1 : 0),
     (0 : 1 , 0 : 0 : 0), (0 : 1 , 0 : 0 : -1), (0 : 1 , 0 : 1 : 0), (0 : 1 , 0 : 0 : 0),
     (0 : 1 , 0 : 0 : 0)]
(continued from previous page)

```
sage: u = QQ['u'].0
sage: P = ProductProjectiveSpaces([1, 1], NumberField(u^2 - 2, 'v'))
sage: sorted(list(P.points_of_bounded_height(bound=1.5))

class sage.schemes.product_projective.space.ProductProjectiveSpaces_ring(N, R=RationalField, names=None)

Bases: sage.schemes.generic.ambient_space.AmbientSpace

Cartesian product of projective spaces \( \mathbb{P}^{n_1} \times \cdots \times \mathbb{P}^{n_r} \).

EXAMPLES:

sage: P.<x0,x1,x2,x3,x4> = ProductProjectiveSpaces([1, 2], QQ); P
Product of projective spaces P^1 x P^2 over Rational Field
sage: P.coordinate_ring()
Multivariate Polynomial Ring in x0, x1, x2, x3, x4 over Rational Field
sage: P[0]
Projective Space of dimension 1 over Rational Field
sage: P[1]
Projective Space of dimension 2 over Rational Field
sage: Q = P(5, 3, 2, 2, 2); Q
(2 : 1 , 1 : 1)
sage: Q[0]
(2 : 1)
sage: H = Hom(P,P)
sage: f = H([x0^2*x3, x2*x1^2, x2^2, 2*x3^2, x4^2])
sage: f(Q)
(4 : 1 , 1 : 2 : 1)

affine_patch(I, return_embedding=False)

Return the \( I^{th} \) affine patch of this projective space product where \( I \) is a multi-index.

INPUT:
• $I$ – a list or tuple of positive integers.
• $\text{return\_embedding}$ – Boolean, if true the projective embedding is also returned.

OUTPUT:
• An affine space.
• An embedding into a product of projective spaces (optional).

EXAMPLES:

```sage
sage: PP = ProductProjectiveSpaces([2, 2, 2], ZZ, 'x')
sage: phi = PP.affine_patch([0, 1, 2], True)
sage: phi.domain()
Affine Space of dimension 6 over Integer Ring
sage: phi
Scheme morphism:
    From: Affine Space of dimension 6 over Integer Ring
    To:    Product of projective spaces $P^2 \times P^2 \times P^2$ over Integer Ring
    Defn: Defined on coordinates by sending $(x0, x1, x2, x3, x4, x5)$ to
          $(1 : x0 : x1, x2 : 1 : x3, x4 : x5 : 1)$
```

`change\_ring(R)`
Return a product of projective spaces over a ring $R$ and otherwise the same as this projective space.

INPUT:
• $R$ – commutative ring or morphism.

OUTPUT:
• Product of projective spaces over $R$.

**Note:** There is no need to have any relation between $R$ and the base ring of this space, if you want to have such a relation, use `self.base_extend(R)` instead.

EXAMPLES:

```sage
sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 2], QQ)
sage: T.change_ring(GF(17))
Product of projective spaces $P^2 \times P^2$ over Finite Field of size 17
```

`components()`
Return the components of this product of projective spaces.

OUTPUT: A list of projective spaces.

EXAMPLES:

```sage
sage: P.<x,y,z,u,v> = ProductProjectiveSpaces(QQ,[2,1])
sage: P.components()
[Projective Space of dimension 2 over Rational Field,
  Projective Space of dimension 1 over Rational Field]
```

`dimension()`
Return the absolute dimension of the product of projective spaces.

OUTPUT: A positive integer.

EXAMPLES:
sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 2], GF(17))
sage: T.dimension_absolute()
4
sage: T.dimension()
4

dimension_absolute()
Return the absolute dimension of the product of projective spaces.

OUTPUT: A positive integer.

EXAMPLES:

sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 2], GF(17))
sage: T.dimension_absolute()
4
sage: T.dimension()
4

dimension_absolute_components()
Return the absolute dimension of the product of projective spaces.

OUTPUT: A list of positive integers.

EXAMPLES:

sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 2], GF(17))
sage: T.dimension_absolute_components()
[2, 2]
sage: T.dimension_components()
[2, 2]

dimension_components()
Return the absolute dimension of the product of projective spaces.

OUTPUT: A list of positive integers.

EXAMPLES:

sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 2], GF(17))
sage: T.dimension_absolute_components()
[2, 2]
sage: T.dimension_components()
[2, 2]

dimension_relative()
Return the relative dimension of the product of projective spaces.

OUTPUT: A positive integer.

EXAMPLES:

sage: T.<a,x,y,z,u,v,w> = ProductProjectiveSpaces([3, 2], QQ)
sage: T.dimension_relative()
5

dimension_relative_components()
Return the relative dimension of the product of projective spaces.

OUTPUT: A list of positive integers.
ngens() Return the number of generators of this space.
This is the number of variables in the coordinate ring of the projective space.
OUTPUT: An integer.
EXAMPLES:

```python
sage: T = ProductProjectiveSpaces([1, 1, 1], GF(5), 'x')
sage: T.ngens()
6
```

num_components() Returns the number of components of this space.
OUTPUT: An integer.
EXAMPLES:

```python
sage: T = ProductProjectiveSpaces([1, 1, 1], GF(5), 'x')
sage: T.num_components()
3
```

seGRE_embedding(PP=None, var='u') Return the Segre embedding of this space into the appropriate projective space.

INPUT:

- `PP` – (default: None) ambient image projective space; this is constructed if it is not given.
- `var` – string, variable name of the image projective space, default u (optional).

OUTPUT:

Hom – from this space to the appropriate subscheme of projective space.

Todo: Cartesian products with more than two components.

EXAMPLES:

```python
sage: X.<y0,y1,y2,y3,y4,y5> = ProductProjectiveSpaces(ZZ, [2, 2])
sage: phi = X.segre_embedding(); phi
Scheme morphism:
From: Product of projective spaces P^2 x P^2 over Integer Ring
To: Closed subscheme of Projective Space of dimension 8 over Integer Ring
˓→ defined by:
-55*u7 + 45*u8,
-55*u6 + 35*u8,
-45*u6 + 35*u7,
-35*u6 + 25*u7,
-25*u7 + 15*u8,
-25*u4 + 25*u5,
-25*u6 + 05*u8,
-15*u6 + 05*u7,
```

(continues on next page)
-u2*u3 + u0*u5,
-u1*u3 + u0*u4

Defn: Defined by sending (y0 : y1 : y2 , y3 : y4 : y5) to
\[(y0*y3 : y0*y4 : y0*y5 : y1*y3 : y1*y4 : y1*y5 : y2*y3 : y2*y4 : y2*y5).

::

sage: T = ProductProjectiveSpaces([1, 2], CC, 'z')
sage: T.segre_embedding()
Scheme morphism:

From: Product of projective spaces P^1 x P^2 over Complex Field with 53 bits of precision
To: Closed subscheme of Projective Space of dimension 5 over Complex Field with 53 bits of precision defined by:
- u2*u4 + u1*u5,
- u2*u3 + u0*u5,
- u1*u3 + u0*u4

Defn: Defined by sending (z0 : z1 , z2 : z3 : z4) to
\[(z0*z2 : z0*z3 : z0*z4 : z1*z2 : z1*z3 : z1*z4).

::

sage: T = ProductProjectiveSpaces([1, 2, 1], QQ, 'z')
sage: T.segre_embedding()
Scheme morphism:

From: Product of projective spaces P^1 x P^2 x P^1 over Rational Field
To: Closed subscheme of Projective Space of dimension 11 over Rational Field defined by:
- u9*u10 + u8*u11,
- u7*u10 + u6*u11,
- u7*u8 + u6*u9,
- u5*u10 + u4*u11,
- u5*u8 + u4*u9,
- u5*u6 + u4*u7,
- u5*u9 + u3*u11,
- u5*u8 + u3*u10,
- u5*u8 + u2*u11,
- u4*u8 + u2*u10,
- u3*u8 + u2*u9,
- u3*u6 + u2*u7,
- u3*u4 + u2*u5,
- u5*u7 + u1*u11,
- u5*u6 + u1*u10,
- u3*u7 + u1*u9,
- u3*u6 + u1*u8,
- u5*u6 + u0*u11,
- u4*u6 + u0*u10,
- u3*u6 + u0*u9,
- u2*u6 + u0*u8,
- u1*u6 + u0*u7,
- u1*u4 + u0*u5,
- u1*u2 + u0*u3

Defn: Defined by sending (z0 : z1 , z2 : z3 : z4 , z5 : z6) to
\[(z0*z2*z5 : z0*z2*z6 : z0*z3*z5 : z0*z3*z6 : z0*z4*z5 : z0*z4*z6 : z1*z2*z5 : z1*z2*z6 : z1*z3*z5 : z1*z3*z6 : z1*z4*z5 : z1*z4*z6).
subscheme($X$)
Return the closed subscheme defined by $X$.

INPUT:
• $X$ - a list or tuple of equations.

OUTPUT:
AlgebraicScheme_subscheme_projective_cartesian_product.

EXAMPLES:

```
sage: P.<x,y,z,w> = ProductProjectiveSpaces([1, 1],GF(5))
sage: X = P.subscheme([x-y, z-w]);X
Closed subscheme of Product of projective spaces $\mathbb{P}^1 \times \mathbb{P}^1$ over Finite Field of size 5 defined by:
  x - y,
  z - w
sage: X.defining_polynomials ()
[x - y, z - w]
sage: I = X.defining_ideal(); I
Ideal (x - y, z - w) of Multivariate Polynomial Ring in x, y, z, w over Finite Field of size 5
sage: X.dimension ()
0
sage: X.base_ring ()
Finite Field of size 5
sage: X.base_scheme ()
Spectrum of Finite Field of size 5
sage: X.structure_morphism ()
Scheme morphism:
  From: Closed subscheme of Product of projective spaces $\mathbb{P}^1 \times \mathbb{P}^1$ over Finite Field of size 5 defined by:
    x - y,
    z - w
  To:    Spectrum of Finite Field of size 5
  Defn: Structure map
```

sage.schemes.product_projective.space.is_ProductProjectiveSpaces($x$)
Return True if $x$ is a product of projective spaces.

This is an ambient space defined by $\mathbb{P}^n_R \times \cdots \times \mathbb{P}^m_R$, where $R$ is a ring and $n, \ldots, m \geq 0$ are integers.

OUTPUT: Boolean.

EXAMPLES:

```
sage: is_ProductProjectiveSpaces(ProjectiveSpace(5, names='x'))
False
sage: is_ProductProjectiveSpaces(ProductProjectiveSpaces([1, 2, 3], ZZ, 'x'))
True
```

15.2 Set of homomorphisms

AUTHORS:
• Volker Braun and Ben Hutz (2014): initial version
• Raghukul Raman (2018): code cleanup and added support for rational field
class sage.schemes.product_projective.homset.SchemeHomset_points_product_projective_spaces_field(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.product_projective.homset.SchemeHomset_points_product_projective_spaces

points(**kwds)
    Return some or all rational points of a projective scheme.

    Over a finite field, all points are returned. Over an infinite field, all points satisfying the bound are returned. For a zero-dimensional subscheme, all points are returned regardless of whether the base ring is a field or not.

    For number fields, this uses the Doyle-Krumm algorithm 4 (algorithm 5 for imaginary quadratic) for computing algebraic numbers up to a given height [Doyle-Krumm].

    The algorithm requires floating point arithmetic, so the user is allowed to specify the precision for such calculations. Additionally, due to floating point issues, points slightly larger than the bound may be returned. This can be controlled by lowering the tolerance.

    INPUT:
    - bound - a real number
    - tolerance - a rational number in (0,1] used in doyle-krumm algorithm-4
    - precision - the precision to use for computing the elements of bounded height of number fields.

    OUTPUT:
    - a list of rational points of a projective scheme

    EXAMPLES:

```
sage: P.<x,y,z,w> = ProductProjectiveSpaces([1, 1], QQ)
sage: X = P.subscheme([x - y, z^2 - 2*w^2])
sage: X(P.base_ring()).points()
[]
sage: u = QQ['u'].0
sage: P.<x,y,z,w> = ProductProjectiveSpaces([1,1], NumberField(u^2 - 2, 'v'))
sage: X = P.subscheme([x^2 - y^2, z^2 - 2*w^2])
sage: X(P.base_ring()).points()
[(-1 : 1 , -v : 1), (1 : 1 , v : 1), (1 : 1 , -v : 1), (-1 : 1 , v : 1)]
sage: u = QQ['u'].0
sage: K = NumberField(u^2 + 1, 'v')
sage: P.<x,y,z,w> = ProductProjectiveSpaces([1, 1], K)
sage: P(K).points(bound=1)
[(-1 : 1 , -1 : 1), (-1 : 1 , -v : 1), (-1 : 1 , 0 : 1), (-1 : 1 , v : 1),
 (-1 : 1 , 1 : 0), (-v : 1 , 1 : 1), (-v : 1 , -1 : 1), (-v : 1 , -v : 1),
 (-v : 1 , 0 : 1), (v : 1 , v : 1), (v : 1 , 1 : 0), (v : 1 , 1 : 1),
 (0 : 1 , -1 : 1), (0 : 1 , -v : 1), (0 : 1 , 0 : 1), (0 : 1 , v : 1),
 (0 : 1 , 1 : 0), (v : 1 , 1 : 1), (v : 1 , -1 : 1), (v : 1 , -v : 1),
 (v : 1 , 0 : 1), (v : 1 , v : 1), (v : 1 , 1 : 0), (v : 1 , 1 : 1),
```
class sage.schemes.product_projective.homset.SchemeHomset_points_product_projective_spaces_ring

Bases: sage.schemes.generic.homset.SchemeHomset_points

Set of rational points of a product of projective spaces.

INPUT:

See SchemeHomset_generic.

EXAMPLES:

sage: from sage.schemes.product_projective.homset import SchemeHomset_points_product_projective_spaces_ring
sage: SchemeHomset_points_product_projective_spaces_ring(Spec(QQ), ProductProjectiveSpaces([1, 1], QQ, 'z'))

Set of rational points of Product of projective spaces P^1 x P^1 over RationalField.
15.3 Polynomial morphisms for products of projective spaces

This class builds on the projective space class and its point and morphism classes.

EXAMPLES:

```python
sage: P1xP1.<x,y,u,v> = ProductProjectiveSpaces(QQ, [1, 1])
sage: H = End(P1xP1)
sage: H([x^2*u, y^2*v, x*v^2, y*u^2])
Scheme endomorphism of Product of projective spaces P^1 x P^1 over Rational Field
  Defn: Defined by sending (x : y , u : v) to
  (x^2*u : y^2*v , x*v^2 : y*u^2).
```

class `sage.schemes.product_projective.morphism.ProductProjectiveSpaces_morphism_ring` (*parent*, *polys*, *check=True*)

Bases: `sage.schemes.generic.morphism.SchemeMorphism_polynomial`

The class of morphisms on products of projective spaces.

The components are projective space morphisms.

EXAMPLES:

```python
sage: T.<x,y,z,w,u> = ProductProjectiveSpaces([2, 1], QQ)
sage: H = T.Hom(T)
sage: H([x^2, y^2, z^2, w^2, u^2])
Scheme endomorphism of Product of projective spaces P^2 x P^1 over Rational Field
  Defn: Defined by sending (x : y : z , w : u) to
  (x^2 : y^2 : z^2 , w^2 : u^2).
```

`as_dynamical_system()`

Return this endomorphism as a `DynamicalSystem_producte_projective`.

OUTPUT:

* DynamicalSystem_producte_projective

EXAMPLES:

```python
sage: Z.<a,b,x,y,z> = ProductProjectiveSpaces([1 , 2], ZZ)
sage: H = End(Z)
sage: f = H([a^3, b^3, x^2, y^2, z^2])
sage: type(f.as_dynamical_system())
<class 'sage.dynamics.arithmetic_dynamics.product_projective_ds.DynamicalSystem_product_projective'>
```

`global_height(prec=0)`

Returns the maximum of the absolute logarithmic heights of the coefficients in any of the coordinate functions of this map.

INPUT:

* prec – desired floating point precision (default: default RealField precision).

OUTPUT:

* a real number.
Todo: Add functionality for \( \mathbb{Q} \), implement function to convert the map defined over \( \mathbb{Q} \) to map over a number field.

EXAMPLES:

```python
sage: P1xP1.<x,y,u,v> = ProductProjectiveSpaces([1, 1], ZZ)
sage: H = End(P1xP1)
sage: f = H([x^2*u, 3*y^2+v, 5*x*v^2, y*u^2])
sage: f.global_height()
1.60943791243410

sage: u = QQ['u'].0
sage: R = NumberField(u^2 - 2, 'v')
sage: PP.<x,y,a,b> = ProductProjectiveSpaces([1, 1], R)
sage: H = End(PP)
sage: O = R.maximal_order()
sage: g = H([3*O(u)*x^2, 13*x*y, 7*a*y, 5*b*x + O(u)*a*y])
sage: g.global_height()
2.56494935746154
```

`is_morphism()`

Returns True if this mapping is a morphism of products of projective spaces.

For each component space of the codomain of this mapping we consider the subscheme of the domain of this map generated by the corresponding coordinates of the map. This map is a morphism if and only if each of these subschemes has no points.

OUTPUT: Boolean.

EXAMPLES:

```python
sage: Z.<a,b,x,y,z> = ProductProjectiveSpaces([1, 2], ZZ)
sage: H = End(Z)
sage: f = H([a^2, b^2, x+z-y*z, x^2-y^2, z^2])
sage: f.is_morphism()
False

sage: P.<x,y,z,u,v,w>=ProductProjectiveSpaces([2, 2], QQ)
sage: H = End(P)
sage: f = H([u, v, w, u^2, v^2, w^2])
sage: f.is_morphism()
True

sage: P.<x,y,z,w,u> = ProductProjectiveSpaces([2, 1], QQ)
sage: Q.<a,b,c,d,e> = ProductProjectiveSpaces([1, 2], QQ)
sage: H = Hom(P, Q)
sage: f = H([x^2, y^2, u^3, w^3, u^3])
sage: f.is_morphism()
False
```

`local_height(v, prec=None)`

Returns the maximum of the local height of the coefficients in any of the coordinate functions of this map.

INPUT:

- \( v \) – a prime or prime ideal of the base ring.
• \texttt{prec} – desired floating point precision (default: default RealField precision).

OUTPUT:

• a real number.

EXAMPLES:

```python
sage: T.<x,y,z,w,u> = ProductProjectiveSpaces([2, 1], QQ)
sage: H = T.Hom(T)
sage: f = H([4*x^2+3/100*y^2, 8/210*x*y, 1/10000*z^2, 20*w^2, 1/384+u*w])
sage: f.local_height(2)
4.85203026391962
```

```python
sage: R.<z> = PolynomialRing(QQ)
sage: K.<w> = NumberField(z^2-5)
sage: P.<x,y,a,b> = ProductProjectiveSpaces([1, 1], K)
sage: H = Hom(P,P)
sage: f = H([2*x^2 + w/3*y^2, 1/w*y^2, a^2, 6*b^2 + 1/9*a*b])
sage: f.local_height(K.ideal(3))
2.19722457733622
```

\textbf{\texttt{nth\_iterate}} \texttt{(P, n, normalize=False)}

Return the nth iterate of the point.

EXAMPLES:

```python
sage: Z.<a,b,x,y,z> = ProductProjectiveSpaces([1, 2], QQ)
sage: H = End(Z)
sage: f = H([a^3, b^3, x^2, y^2, z^2])
sage: f.nth_iterate_map(3)
doctest:warning...
Dynamical System of Product of projective spaces P^1 x P^2 over Rational Field
Defn: Defined by sending (a : b , x : y : z) to
(a^27 : b^27 , x^8 : y^8 : z^8).
```

\textbf{\texttt{orbit}} \texttt{(P, N, **kwds)}

Return the orbit of this point.

EXAMPLES:

```python
sage: Z.<a,b,x,y,z> = ProductProjectiveSpaces([1, 2], QQ)
sage: H = End(Z)
```

(continues on next page)
sage: f = H([a^3, b^3 + a*b^2, x^2, y^2 - z^2, z*y])
sage: P = Z([1, 1, 1, 1, 1])
sage: f.orbit(P, 3)
doctest:warning
...
[(1 : 1 , 1 : 1 : 1), (1/2 : 1 , 1 : 0 : 1), (1/12 : 1 , -1 : 1 : 0), (1/1872, 1 : 1 : 1 : 0)]

15.4 Points for products of projective spaces

This class builds on the projective space class and its point and morphism classes.

EXAMPLES:

We construct products projective spaces of various dimensions over the same ring:

```python
sage: P1xP1.<x,y, u,v> = ProductProjectiveSpaces(QQ, [2,1])
sage: P1xP1([2, 1, 3, 1])
(2 : 1 , 3 : 1)
```

class sage.schemes.product_projective.point.ProductProjectiveSpaces_point_field

Bases: sage.schemes.product_projective.point.ProductProjectiveSpaces_point_ring

```
intersection_multiplicity(X)
```

Return the intersection multiplicity of the codomain of this point and subscheme X at this point.

This uses the subscheme implementation of intersection_multiplicity. This point must be a point on a subscheme of a product of projective spaces.

INPUT:

- **X** – a subscheme in the same ambient space as the codomain of this point.

OUTPUT: An integer.

EXAMPLES:

```python
sage: PP.<x,y,z,u,v> = ProductProjectiveSpaces(QQ, [2,1])
sage: X = PP.subscheme([y^2*z^3*u - x^5*v])
sage: Y = PP.subscheme([u^3 - v^3, x - y])
sage: Q = X([0,0,1,1,1])
sage: Q.intersection_multiplicity(Y)
2
```

```
multiplicity()
```

Return the multiplicity of this point on its codomain.

This uses the subscheme implementation of multiplicity. This point must be a point on a subscheme of a product of projective spaces.

OUTPUT: an integer.

EXAMPLES:
sage: PP.<x,y,z,w,u,v,t> = ProductProjectiveSpaces(QQ, [3,2])
sage: X = PP.subscheme([x^8*t - y^8*t + z^5*w^3*v])
sage: Q1 = X([1,1,0,0,-1,-1,1])
sage: Q1.multiplicity()
1
sage: Q2 = X([0,0,0,1,0,1,1])
sage: Q2.multiplicity()
5
sage: Q3 = X([0,0,0,1,1,0,0])
sage: Q3.multiplicity()
6

class sage.schemes.product_projective.point.ProductProjectiveSpaces_point_finite_field(parent, polys, check=True)

Bases: sage.schemes.product_projective.point.ProductProjectiveSpaces_point_field

class sage.schemes.product_projective.point.ProductProjectiveSpaces_point_ring(parent, polys, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism_point

The class of points on products of projective spaces.

The components are projective space points.

EXAMPLES:

sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 1], QQ)
sage: T.point([1, 2, 3, 4, 2, 6]);
(1/3 : 2/3 : 1 , 4/5 : 1)

dehomogenize(L)

Dehomogenize $k^{th}$ point at $L[k]^{th}$ coordinate.
This function computes the appropriate affine patch using \( L \) and then returns the dehomogenized point on of this affine space.

**INPUT:**
- \( L \) - a list of non-negative integers

**OUTPUT:**
- \( \text{SchemeMorphism\_point\_affine} \)

**EXAMPLES:**

```python
sage: PP = ProductProjectiveSpaces([2, 2, 2], QQ, 'x')
sage: A = PP([2, 4, 6, 23, 46, 23, 9, 3, 1])
sage: A.dehomogenize([0, 1, 2])
(2, 3, 1/2, 1/2, 9, 3)
sage: PP.<a,b,x,y,z> = ProductProjectiveSpaces([1, 2], CC)
sage: X = PP.subscheme([a^2 + b^2])
sage: P = X([2, 2*i, -3, 6*i, 3 - 6*i])
sage: P.dehomogenize([1,0])
(-1.00000000000000*I, -2.00000000000000*I, -1.00000000000000 + 2.00000000000000*I)
```

**global_height** *(prec=None)*

Return the absolute logarithmic height of the point.

This function computes the maximum of global height of each component point in the product. Global height of component point is computed using function for projective point.

**INPUT:**
- \( \text{prec} \) - desired floating point precision (default: default RealField precision).

**OUTPUT:**
- a real number.

**EXAMPLES:**

```python
sage: PP = ProductProjectiveSpaces(QQ, [2,2], 'x')
sage: Q = PP([1, 7, 5, 18, 2, 3])
sage: Q.global_height()
1.94591014905531
sage: PP = ProductProjectiveSpaces(ZZ, [1,1], 'x')
sage: A = PP([-30, 2, 1, 6])
sage: A.global_height()
3.40119738166216
```

(continues on next page)
sage: PP = ProductProjectiveSpaces(k, [1, 2], 'y')
sage: Q = PP([3, 5*w+1, 1, 7*w, 10])
sage: Q.global_height()
2.30258509299405

sage: PP = ProductProjectiveSpaces(QQbar, [1, 1], 'x')
sage: Q = PP([1, QQbar(sqrt(2)), QQbar(5^(1/3)), QQbar(3^(1/3))])
sage: Q.global_height()
0.536479304144700

local_height \( v, prec=None \)

Return the maximum of the local height of the coordinates of this point.

This function computes the maximum of local height of each component point in the product. Local height of component point is computed using function for projective point.

**INPUT:**

- \( v \) – a prime or prime ideal of the base ring.
- \( prec \) – desired floating point precision (default: default RealField precision).

**OUTPUT:**

- a real number.

**EXAMPLES:**

```sage
sage: PP = ProductProjectiveSpaces(QQ, [1, 1], 'x')
sage: A = PP([11, 5, 10, 2])
sage: A.local_height(5)
1.60943791243410
sage: P = ProductProjectiveSpaces(QQ, [1,2], 'x')
sage: Q = P([1, 4, 1/2, 2, 32])
sage: Q.local_height(2)
4.15888308335967
```

normalize_coordinates ()

Remove common factors (componentwise) from the coordinates of this point (including \(-1\)).

**OUTPUT:** None.

**EXAMPLES:**

```sage
sage: T.<x,y,z,u,v,w> = ProductProjectiveSpaces([2, 2], ZZ)
sage: P = T.point([5, 10, 15, 4, 2, 6]);
sage: P.normalize_coordinates()
sage: P
(1 : 2 : 3 , 2 : 1 : 3)
```

nth_iterate \( f, n, normalize=False \)

For a map of this point and a point \( P \) in self.domain() this function returns the nth iterate of \( P \) by this point.

If \( normalize == True \), then the coordinates are automatically normalized.

**INPUT:**

- \( f \) – a ProductProjectiveSpaces_morphism_ring with self in f.domain().
• \( n \) – a positive integer.
• normalize – Boolean (optional Default: False).

**OUTPUT:**

• A point in self.codomain()

**EXAMPLES:**

```sage
tests: E.<a,b,x,y> = ProductProjectiveSpaces([1, 1], ZZ)
tests: f = DynamicalSystem_projective([a+b, b^2, x^3 - y^3, y^2*x], domain=E)
tests: P = E([2, 6, 2, 4])
tests: P.nth_iterate(f, 2, normalize = True)
doctest:warning
...
(1 : 3 , 407 : 112)
```

**Todo:** Is there a more efficient way to do this?

**orbit** \((f, N, **kwds)\)

Return the orbit this point by \( f \).

If \( N \) is an integer it returns \([P, self(P), \ldots, self^N(P)]\).

If \( N \) is a list or tuple \( N = [m, k] \) it returns \([self^m(P), \ldots, self^k(P)]\). Automatically normalize the points if normalize == True. Perform the checks on point initialization if check==True

**INPUT:**

• \( f \) – a \ProductProjectiveSpaces_morphism_ring with the orbit of \( P \) in \( f \).domain().
• \( N \) – a non-negative integer or list or tuple of two non-negative integers.

**kwds:**

• check – Boolean (optional - default: True).
• normalize – Boolean (optional - default: False).

**OUTPUT:**

• a list of points in self.codomain().

**EXAMPLES:**

```sage
tests: E.<a,b,x,y> = ProductProjectiveSpaces([1, 1], ZZ)
tests: f = DynamicalSystem_projective([a+b, b^2, x^3 - y^3, y^2*x], domain=E)
tests: P = E([2, 6, 2, 4])
tests: P.orbit(f, 3, normalize = True)
doctest:warning
...
[(1 : 3 , 1 : 2), (1 : 3 , -7 : 4), (1 : 3 , 407 : 112), (1 : 3 , 66014215 : 5105408)]
```

**scale_by** \((t)\)

Scale the coordinates of the point by \( t \), done componentwise.

A TypeError occurs if the point is not in the base ring of the codomain after scaling.

**INPUT:**

• \( t \) – a ring element
EXAMPLES:

```
sage: T.<x, y, z, u, v, w> = ProductProjectiveSpaces([1, 1, 1], ZZ)
sage: P = T.point([5, 10, 15, 4, 2, 6]);
sage: P.scale_by([2, 1, 1])
sage: P
(10 : 20 , 15 : 4 , 2 : 6)
```

15.5 Subschemes of products of projective spaces

AUTHORS:

- Ben Hutz (2014): subschemes of Cartesian products of projective space

```
class sage.schemes.product_projective.subscheme.AlgebraicScheme_subscheme_product_projective
Bases: sage.schemes.projective.projective_subscheme.AlgebraicScheme_subscheme_projective

Construct an algebraic subscheme of a product of projective spaces.

**Warning:** You should not create objects of this class directly. The preferred method to construct such subschemes is to use `subscheme()` method of `Product of Projective Spaces`.

**INPUT:**

- `A` – ambient `Product of Projective Spaces`
- `polynomials` – single polynomial, ideal or iterable of defining multi-homogeneous polynomials.

**EXAMPLES:**

```
sage: P.<x, y, u, v> = ProductProjectiveSpaces([1,1], QQ)
sage: P.subscheme([u*x^2-v*y*x])
Closed subscheme of Product of projective spaces P^1 x P^1 over Rational Field defined by:
  x^2*u - x*y*v
```

**affine_patch**(*I*, *return_embedding=False*)

Return the $I^{th}$ affine patch of this projective scheme where `$I$` is a multi-index.

**INPUT:**

- `I` – a list or tuple of positive integers
- `return_embedding` – Boolean, if true the projective embedding is also returned

**OUTPUT:**

- An affine algebraic scheme
- An embedding into a product of projective space (optional)

**EXAMPLES:**
sage: PP.<x,y,z,w,u,v> = ProductProjectiveSpaces([3,1],QQ)
sage: W = PP.subscheme([y^2*z-x^3,z^2-w^2,u^3-v^3])
sage: W.affine_patch([0,1],True)

(Closed subscheme of Affine Space of dimension 4 over Rational Field defined by:
  x0^2*x1 - 1,
x1^2 - x2^2,
x3^3 - 1, Scheme morphism:
  From: Closed subscheme of Affine Space of dimension 4 over Rational Field defined by:
  x0^2*x1 - 1,
x1^2 - x2^2,
x3^3 - 1
to:  Closed subscheme of Product of projective spaces P^3 x P^1 over Rational Field defined by:
  -x^3 + y^2*z,
z^2 - w^2,
u^3 - v^3
  Defn: Defined on coordinates by sending (x0, x1, x2, x3) to
  (1 : x0 : x1 : x2 , x3 : 1))

dimension()  
Return the dimension of the algebraic subscheme.

OUTPUT:

Integer.

EXAMPLES:

sage: X.<x,y,z,w,u,v> = ProductProjectiveSpaces([2,2],QQ)
sage: L = (-w - v)*x + (-w*y - u*z)
sage: Q = (-u*w - v^2)*x^2 + ((-w^2 - u*w - (-u*v - u^2))*y + (-w^2 - (-v - u)*w)*z*y + (-w^2 + (-v - u)*w)*z^2)
sage: W = X.subscheme([L,Q])
sage: W.dimension()
2

sage: PP.<x,y,z,u,v,s,t> = ProductProjectiveSpaces([2,1,1], QQ)
sage: X = PP.subscheme([x^3, x^5+y^5, z^6, x*u-v*y, s^2-t^2])
sage: X.dimension()
-1

sage: PP = ProductProjectiveSpaces([2,1,3], CC, 't')
sage: PP.subscheme([]).dimension()
6

sage: PP = ProductProjectiveSpaces([1,3,1], ZZ, 't')
sage: PP.subscheme([]).dimension()
5

sage: PP.<x,y,u,v,s,t> = ProductProjectiveSpaces([1,1,1], CC)
sage: X = PP.subscheme([x^2-y^2, u-v, s^2-t^2])
sage: X.dimension()
0
**intersection_multiplicity** \((X, P)\)

Return the intersection multiplicity of this subscheme and the subscheme \(X\) at the point \(P\).

This uses the intersection_multiplicity function for affine subschemes on affine patches of this subscheme and \(X\) that contain \(P\).

**INPUT:**

- \(X\) – subscheme in the same ambient space as this subscheme.
- \(P\) – a point in the intersection of this subscheme with \(X\).

**OUTPUT:** An integer.

**EXAMPLES:**

Multiplicity of a fixed point of the map \(z^2 + \frac{1}{4}\):

```python
sage: PP.<x,y,u,v> = ProductProjectiveSpaces(QQ, [1,1])
sage: G = PP.subscheme([(x^2 + 1/4*y^2)*v - y^2*u])
sage: D = PP.subscheme([x*v - y*u])
sage: G.intersection(D).rational_points()
[(1 : 0 , 1 : 0), (1/2 : 1 , 1/2 : 1)]
sage: Q = PP([1/2,1,1/2,1])
sage: G.intersection_multiplicity(D, Q)
2
```

```python
sage: F.<a> = GF(4)
sage: PP.<x,y,z,u,v,w> = ProductProjectiveSpaces(F, [2,2])
sage: X = PP.subscheme([x^2*u^3 + y*z*u*v^2, x - y])
sage: Y = PP.subscheme([u^3 - w^3, x*v - y*w, z^3*w^2 - y^3*u*v])
sage: Q = PP([a,a+1,a,a,a,1])
sage: X.intersection_multiplicity(Y, Q)
16
```

```python
sage: F.<a> = GF(4)
sage: PP.<x,y,z,u,v,w> = ProductProjectiveSpaces(QQ, [2,2])
sage: X = PP.subscheme([x^2*u^3 + y*z*u*v^2, x - y])
sage: Y = PP.subscheme([u^3 - w^3, x*v - y*w, z^3*w^2 - y^3*u*v])
sage: Q = PP([0,0,0,0,0,0])
sage: X.intersection_multiplicity(Y, Q)
Traceback (most recent call last):
... 
TypeError: the intersection of this subscheme and (=Closed subscheme of˓→Affine Space of dimension 4 over Rational Field defined by: x2^3 - x3^3, -x1*x3 + x0, -x1^3*x2 + x3^2) must be proper and finite
```

**is_smooth** \((point=None)\)

Test whether the algebraic subscheme is smooth.

**EXAMPLES:**

```python
sage: X.<x,y,z,w,u,v> = ProductProjectiveSpaces([2,2],QQ)
sage: L = (-w - v)*x + (-w*y - u*z)
sage: Q = (-u*v - w^2)*x^2 + ((-w^2 - u*w + (-u*v - u^2))*y + (-w^2 - u*v)*x + \n((-w^2 - u*w - u^2)*y^2 + (-u*w - v^2)*z*y + (-w^2 + (-v - u)*w)*z^2)
sage: W = X.subscheme([L,Q])
sage: W.is_smooth()
Traceback (most recent call last):
... 
TypeError: the intersection of this subscheme and (=Closed subscheme of˓→Affine Space of dimension 4 over Rational Field defined by: x2^3 - x3^3, -x1*x3 + x0, -x1^3*x2 + x3^2) must be proper and finite
```

...  
NotImplementedError: Not Implemented

**multiplicity** *(P)*  
Return the multiplicity of *P* on this subscheme.

This is computed as the multiplicity of the corresponding point on an affine patch of this subscheme that contains *P*. This subscheme must be defined over a field. An error is returned if *P* not a point on this subscheme.

**INPUT:**

- *P* – a point on this subscheme.

**OUTPUT:** an integer.

**EXAMPLES:**

```python
sage: PP.<x,y,z,w> = ProductProjectiveSpaces(QQ, [1,1])
sage: X = PP.subscheme([x^4*z^3 - y^4*w^3])
sage: Q1 = PP([1,1,1,1])
sage: X.multiplicity(Q1)
1
sage: Q2 = PP([0,1,1,0])
sage: X.multiplicity(Q2)
3
```

```python
sage: PP.<x,y,z,w,u> = ProductProjectiveSpaces(GF(11), [1,2])
sage: X = PP.subscheme([x^7*u - y^7*z, u^6*x^2 - w^3*z^3*x*y - w^6*y^2])
sage: Q1 = PP([1,0,1,0,1])
sage: X.multiplicity(Q1)
1
sage: Q2 = PP([1,0,1,0,0])
sage: X.multiplicity(Q2)
4
```

**segre_embedding** *(PP=None)*  
Return the Segre embedding of this subscheme into the appropriate projective space.

**INPUT:**

- *PP* – (default: None) ambient image projective space; this is constructed if it is not given.

**OUTPUT:** 
Hom from this subscheme to the appropriate subscheme of projective space

**EXAMPLES:**

```python
sage: X.<x,y,z,w,u,v> = ProductProjectiveSpaces([2,2], QQ)
sage: P = ProjectiveSpace(QQ, 8, 't')
sage: L = (w - v)*x + (-w*y - u*z)
sage: Q = (-u*w - v^2)*x^2 + ((-w^2 - u*w - (-v - u)*w)*x*y + (-w^2 - u^2)*z)*x + 
((-w^2 - u^2)*y^2 + (-u*w - v^2)*z*y + (-w^2 + (-v - u)*w)*z^2)
sage: W = X.subscheme([L,Q])
sage: phi = W.segre_embedding(P)
sage: phi.codomain().ambient_space() == P
True
```
15.6 Enumeration of rational points on product projective schemes

Naive algorithms for enumerating rational points over \( \mathbb{Q} \), number fields or finite fields over general schemes.
Warning: Incorrect results and infinite loops may occur if using a wrong function. (For instance using an affine function for a product projective scheme or a finite field function for a scheme defined over an infinite field.)

EXAMPLES:

Product Projective, over $\mathbb{Q}$:

```python
sage: PP.<x,y,z> = ProductProjectiveSpaces([1,0], QQ)
sage: from sage.schemes.product_projective.rational_point import 
    enum_product_projective_rational_field
sage: enum_product_projective_rational_field(PP,3)
[(-3 : 1 , 1), (-2 : 1 , 1), (-3/2 : 1 , 1),
 (-1 : 1 , 1), (-2/3 : 1 , 1), (-1/2 : 1 , 1),
 (-1/3 : 1 , 1), (0 : 1 , 1), (1/3 : 1 , 1),
 (1/2 : 1 , 1), (2/3 : 1 , 1), (1 : 0 , 1),
 (1 : 1 , 1), (3/2 : 1 , 1), (2 : 1 , 1),
 (3 : 1 , 1)]
```

Product projective over finite field:

```python
sage: P1.<x,y,a,b> = ProductProjectiveSpaces([1,1], GF(7))
sage: X = P1.subscheme([2*x+3*y])
sage: from sage.schemes.product_projective.rational_point import 
    enum_product_projective_finite_field
sage: enum_product_projective_finite_field(X)
[(2 : 1 , 0 : 1), (2 : 1 , 1 : 0), (2 : 1 , 1 : 1),
 (2 : 1 , 2 : 1), (2 : 1 , 3 : 1), (2 : 1 , 4 : 1),
 (2 : 1 , 5 : 1), (2 : 1 , 6 : 1)]
```

AUTHORS:

- Volker Braun and Ben Hutz (2014): initial version
- Raghukul Raman (2018): code cleanup and added support for rational fields

`sage.schemes.product_projective.rational_point.enum_product_projective_finite_field(X)`

Enumerates projective points on scheme $X$ defined over a finite field.

INPUT:

- $X$ - a scheme defined over a finite field or a set of abstract rational points of such a scheme.

OUTPUT:

- a list containing the projective points of $X$ over the finite field, sorted.

EXAMPLES:

```python
sage: PP.<x,y,z,w> = ProductProjectiveSpaces([1, 1], GF(3))
sage: from sage.schemes.product_projective.rational_point import 
    enum_product_projective_finite_field
sage: enum_product_projective_finite_field(PP)
[(0 : 1 , 0 : 1), (0 : 1 , 1 : 0), (0 : 1 , 1 : 1),
 (0 : 1 , 2 : 1), (1 : 0 , 0 : 1), (1 : 0 , 1 : 0),
 (1 : 0 , 1 : 1), (1 : 0 , 2 : 1), (1 : 1 , 0 : 1),
 (1 : 1 , 1 : 0), (1 : 1 , 1 : 1), (1 : 1 , 2 : 1),
 (2 : 1 , 0 : 1), (2 : 1 , 1 : 0), (2 : 1 , 1 : 1),
 (2 : 1 , 2 : 1)]
```
sage: PP.<x0,x1,x2,x3> = ProductProjectiveSpaces([1, 1], GF(17))
sage: X = PP.subscheme({x0^2 + 2*x1^2})
sage: from sage.schemes.product_projective.rational_point import \  
   enum_product_projective_finite_field
sage: len(enum_product_projective_finite_field(X))
36

sage.schemes.product_projective.rational_point.enum_product_projective_number_field(X, \  **kwds)

Enumerates product projective points on scheme X defined over a number field.

Simply checks all of the points of absolute height of at most B and adds those that are on the scheme to the list.

This algorithm computes 2 lists: L containing elements x in K such that H_k(x) <= B, and a list L' containing elements x in K that, due to floating point issues, may be slightly larger then the bound. This can be controlled by lowering the tolerance.

ALGORITHM:

This is an implementation of the revised algorithm (Algorithm 4) in [Doyle-Krumm]. Algorithm 5 is used for imaginary quadratic fields.

INPUT:

kwds:
• bound - a real number
• tolerance - a rational number in (0,1] used in doyle-krumm algorithm-4
• precision - the precision to use for computing the elements of bounded height of number fields.

OUTPUT:
• a list containing the product projective points of X of absolute height up to B, sorted.

EXAMPLES:

sage: u = QQ['u'].0
sage: K = NumberField(u^2 + 2, 'v')
sage: PP.<x,y,z,w> = ProductProjectiveSpaces([1, 1], K)
sage: X = PP.subscheme({x^2 + 2*y^2})
sage: from sage.schemes.product_projective.rational_point import \  
   enum_product_projective_number_field
sage: enum_product_projective_number_field(X, bound=1.5)
[(-v : 1 , -1 : 1), (-v : 1 , -v : 1), (-v : 1 , -1/2*v : 1),
 (-v : 1 , 0 : 1), (-v : 1 , 1/2*v : 1), (-v : 1 , v : 1),
 (-v : 1 , 1 : 0), (-v : 1 , 1 : 1), (v : 1 , -1 : 1),
 (v : 1 , -v : 1), (v : 1 , -1/2*v : 1), (v : 1 , 0 : 1),
 (v : 1 , 1/2*v : 1), (v : 1 , v : 1), (v : 1 , 1 : 0),
 (v : 1 , 1 : 1)]
• a list containing the product projective points of \( X \) of height up to \( B \), sorted.

**EXAMPLES:**

```python
sage: PP.<x0,x1,x2,x3,x4> = ProductProjectiveSpaces([1, 2], QQ)
sage: from sage.schemes.product_projective.rational_point import enum_product_projective_rational_field
sage: enum_product_projective_rational_field(PP,1)
[(-1 : 1 , -1 : -1 : 1), (-1 : 1 , -1 : 0 : 1), (-1 : 1 , -1 : 1 : 0),
(-1 : 1 , -1 : 1 : 1), (-1 : 1 , 0 : -1 : 1), (-1 : 1 , 0 : 0 : 1),
(-1 : 1 , 0 : 1 : 0), (-1 : 1 , 1 : -1 : 1), (-1 : 1 , 1 : 0 : 1),
(-1 : 1 , 1 : 1 : 0), (0 : 1 , -1 : -1 : 1), (0 : 1 , -1 : 0 : 1),
(0 : 1 , -1 : 1 : 0), (0 : 1 , 0 : -1 : 1), (0 : 1 , 0 : 0 : 1),
(0 : 1 , 0 : 1 : 0), (0 : 1 , 0 : 1 : 1), (0 : 1 , 1 : -1 : 1),
(0 : 1 , 1 : 0 : 0), (0 : 1 , 1 : 0 : 1), (0 : 1 , 1 : 1 : 0),
(0 : 1 , 1 : 1 : 1)]
```

```python
sage: PP.<x,y,z,u,v> = ProductProjectiveSpaces([2,1], QQ)
sage: X = PP.subscheme([x^2 + x*y + y*z, u*u-v*u])
sage: from sage.schemes.product_projective.rational_point import enum_product_projective_rational_field
sage: enum_product_projective_rational_field(X,4)
[(-2/3 : -4/3 : 1 , 0 : 1), (-2/3 : -4/3 : 1 , 1 : 1),
(-1/2 : -1/2 : 1 , 0 : 1), (-1/2 : -1/2 : 1 , 1 : 1),
(0 : 0 : 1 , 0 : 1), (0 : 0 : 1 , 1 : 1), (0 : 1 : 0 , 0 : 1),
(0 : 1 : 0 , 1 : 1), (1 : -1/2 : 1 , 0 : 1), (1 : -1/2 : 1 , 1 : 1)]
```
16.1 Toric varieties

This module provides support for (normal) toric varieties, corresponding to rational polyhedral fans. See also fano_variety for a more restrictive class of (weak) Fano toric varieties.

An excellent reference on toric varieties is the book “Toric Varieties” by David A. Cox, John B. Little, and Hal Schenck [CLS].

The interface to this module is provided through functions AffineToricVariety() and ToricVariety(), although you may also be interested in normalize_names().

Note: We do NOT build “general toric varieties” from affine toric varieties. Instead, we are using the quotient representation of toric varieties with the homogeneous coordinate ring (a.k.a. Cox’s ring or the total coordinate ring). This description works best for simplicial fans of the full dimension.

REFERENCES:

AUTHORS:

• Andrey Novoseltsev (2010-05-17): initial version.
• Volker Braun (2010-07-24): Cohomology and characteristic classes added.

EXAMPLES:

We start with constructing the affine plane as an affine toric variety. First, we need to have a corresponding cone:

\[
\text{sage: quadrant = Cone([\{(1,0), (0,1)\}])}
\]

If you don’t care about variable names and the base field, that’s all we need for now:

\[
\begin{align*}
\text{sage: A2 = AffineToricVariety(quadrant)} \\
\text{sage: A2} \\
\text{2-d affine toric variety} \\
\text{sage: origin = A2(0,0)} \\
\text{sage: origin} \\
\text{[0 : 0]}
\end{align*}
\]

Only affine toric varieties have points whose (homogeneous) coordinates are all zero.

\[
\text{sage: parent(origin)}
\]

Set of rational points of 2-d affine toric variety

As you can see, by default toric varieties live over the field of rational numbers:
While usually toric varieties are considered over the field of complex numbers, for computational purposes it is more convenient to work with fields that have exact representation on computers. You can also always do

```
sage: C2 = AffineToricVariety(quadrant, base_field=CC)
sage: C2.base_ring()
Complex Field with 53 bits of precision
go: C2(1,2+i)
[1.00000000000000 : 2.00000000000000 + 1.00000000000000*I]
```
or even

```
sage: F = CC["a, b"].fraction_field()
sage: F.inject_variables()
Defining a, b
sage: A2 = AffineToricVariety(quadrant, base_field=F)
sage: A2(a,b)
[a : b]
```

OK, if you need to work only with affine spaces, `AffineSpace()` may be a better way to construct them. Our next example is the product of two projective lines realized as the toric variety associated to the face fan of the "diamond":

```
sage: diamond = lattice_polytope.cross_polytope(2)
sage: diamond.vertices()
M( 1, 0),
M( 0, 1),
M(-1, 0),
M( 0, -1)
in 2-d lattice M
sage: fan = FaceFan(diamond)
sage: PlxP1 = ToricVariety(fan)
sage: PlxP1
2-d toric variety covered by 4 affine patches
sage: PlxP1.fan().rays()
M( 1, 0),
M( 0, 1),
M(-1, 0),
M( 0, -1)
in 2-d lattice M
sage: PlxP1.gens()
(z0, z1, z2, z3)
```

We got four coordinates - two for each of the projective lines, but their names are perhaps not very well chosen. Let's make \((x, y)\) to be coordinates on the first line and \((s, t)\) on the second one:

```
sage: PlxP1 = ToricVariety(fan, coordinate_names="x s y t")
sage: PlxP1.gens()
(x, s, y, t)
```

Now, if we want to define subschemes of this variety, the defining polynomials must be homogeneous in each of these pairs:

```
sage: PlxP1.inject_variables()
Defining x, s, y, t
```

(continues on next page)
sage: P1xP1.subscheme(x)
Closed subscheme of 2-d toric variety covered by 4 affine patches defined by:
    x
sage: P1xP1.subscheme(x^2 + y^2)
Closed subscheme of 2-d toric variety covered by 4 affine patches defined by:
    x^2 + y^2
sage: P1xP1.subscheme(x^2 + s^2)
Traceback (most recent call last):
  ...  
ValueError: x^2 + s^2 is not homogeneous on 2-d toric variety covered by 4 affine patches!

sage: P1xP1.subscheme([x^2*s^2 + x*y*t^2 + y^2*t^2, s^3 + t^3])
Closed subscheme of 2-d toric variety covered by 4 affine patches defined by:
    x^2*s^2 + x*y*t^2 + y^2*t^2,  s^3 + t^3

While we don’t build toric varieties from affine toric varieties, we still can access the “building pieces”:

sage: patch = P1xP1.affine_patch(2)
sage: patch
2-d affine toric variety
sage: patch.fan().rays()
M(1, 0),
M(0, 1)
in 2-d lattice M
sage: patch.embedding_morphism()
Scheme morphism:
    From: 2-d affine toric variety
    To:  2-d toric variety covered by 4 affine patches
    Defn: Defined on coordinates by sending [x : s] to
          [x : s : 1 : 1]

The patch above was specifically chosen to coincide with our representation of the affine plane before, but you can get the other three patches as well. (While any cone of a fan will correspond to an affine toric variety, the main interest is usually in the generating fans as “the biggest” affine subvarieties, and these are precisely the patches that you can get from affine_patch().)

All two-dimensional toric varieties are “quite nice” because any two-dimensional cone is generated by exactly two rays. From the point of view of the corresponding toric varieties, this means that they have at worst quotient singularities:

sage: P1xP1.is_orbifold()
True
sage: P1xP1.is_smooth()
True
sage: TV = ToricVariety(NormalFan(diamond))
sage: TV.fan().rays()
N( 1, 1),
N( 1, -1),
N(-1, -1),
N(-1, 1)
in 2-d lattice N
sage: TV.is_orbifold()
(continues on next page)
In higher dimensions worse things can happen:

```python
sage: TV3 = ToricVariety(NormalFan(lattice_polytope.cross_polytope(3)))
sage: TV3.fan().rays()
N( 1, -1, -1),
N( 1, 1, -1),
N( 1, 1, 1),
N( 1, -1, 1),
N(-1, -1, 1),
N(-1, -1, -1),
N(-1, 1, -1),
N(-1, 1, 1),
in 3-d lattice N
sage: TV3.is_orbifold()
False
```

Fortunately, we can perform a (partial) resolution:

```python
sage: TV3_res = TV3.resolve_to_orbifold()
sage: TV3_res.is_orbifold()
True
sage: TV3_res.fan().ngenerating_cones()
12
sage: TV3.fan().ngenerating_cones()
6
```

In this example we had to double the number of affine patches. The result is still singular:

```python
sage: TV3_res.is_smooth()
False
```

You can resolve it further using `resolve()` method, but (at least for now) you will have to specify which rays should be inserted into the fan. See also `CPRFanoToricVariety()`, which can construct some other “nice partial resolutions.”

The intersection theory on toric varieties is very well understood, and there are explicit algorithms to compute many quantities of interest. The most important tools are the cohomology ring and the Chow group. For $d$-dimensional compact toric varieties with at most orbifold singularities, the rational cohomology ring $H^*(X, \mathbb{Q})$ and the rational Chow ring $A^*(X, \mathbb{Q}) = A_{d-*}(X) \otimes \mathbb{Q}$ are isomorphic except for a doubling in degree. More precisely, the Chow group has the same rank

\[ A_{d-k}(X) \otimes \mathbb{Q} \simeq H^{2k}(X, \mathbb{Q}) \]

and the intersection in of Chow cycles matches the cup product in cohomology.

In this case, you should work with the cohomology ring description because it is much faster. For example, here is a weighted projective space with a curve of $\mathbb{Z}_3$-orbifold singularities:

```python
sage: P4_11133 = toric_varieties.P4_11133()
sage: P4_11133.is_smooth(), P4_11133.is_orbifold()
```
Every cone defines a torus orbit closure, and hence a (co)homology class:

```
sage: HH.gens()
([3*z4], [3*z4], [z4], [z4], [z4])
sage: list(map(HH, P4_11133.fan(1)))
[[3*z4], [3*z4], [z4], [z4], [z4]]
sage: list(map(HH, P4_11133.fan(4)))
[[9*z4^4], [9*z4^4], [9*z4^4], [9*z4^4], [9*z4^4]]
sage: HH(cone)
[3*z4^3]
```

We can compute intersection numbers by integrating top-dimensional cohomology classes:

```
sage: D = P4_11133.divisor(0)
sage: HH(D)
[3*z4]
sage: P4_11133.integrate( HH(D)^4 )
9
sage: P4_11133.integrate( HH(D) * HH(cone) )
1
```

Although computationally less efficient, we can do the same computations with the rational Chow group:

```
sage: AA = P4_11133.Chow_group(QQ)
sage: list(map(AA, P4_11133.fan(1))) # long time (5s on sage.math, 2012)
[(0 | 0 | 0 | 3 | 0), (0 | 0 | 0 | 3 | 0), (0 | 0 | 0 | 1 | 0), (0 | 0 | 0 | 0 | 0)]
sage: list(map(AA, P4_11133.fan(4))) # long time (5s on sage.math, 2012)
[(1 | 0 | 0 | 0 | 0), (1 | 0 | 0 | 0 | 0), (1 | 0 | 0 | 0 | 0), (1 | 0 | 0 | 0 | 0)]
sage: AA(cone).intersection_with_divisor(D) # long time (4s on sage.math, 2013)
(1 | 0 | 0 | 0 | 0)
sage: AA(cone).intersection_with_divisor(D).count_points() # long time
1
```

The real advantage of the Chow group is that

- it works just as well over \( \mathbb{Z} \), so torsion information is also easily available, and
- its combinatorial description also works over worse-than-orbifold singularities. By contrast, the cohomology groups can become very complicated to compute in this case, and one usually only has a spectral sequence but no toric algorithm.

Below you will find detailed descriptions of available functions. If you are familiar with toric geometry, you will likely see that many important objects and operations are unavailable. However, this module is under active development and hopefully will improve in future releases of Sage. If there are some particular features that you would like to see implemented ASAP, please consider reporting them to the Sage Development Team or even implementing them on your own as a patch for inclusion!

16.1. Toric varieties 211
sage.schemes.toric.variety.AffineToricVariety(cone, *args, **kwds)

Construct an affine toric variety.

**INPUT:**

- `cone` — strictly convex rational polyhedral cone.

This cone will be used to construct a rational polyhedral fan, which will be passed to `ToricVariety()` with the rest of positional and keyword arguments.

**OUTPUT:**

- toric variety.

**Note:** The generating rays of the fan of this variety are guaranteed to be listed in the same order as the rays of the original cone.

**EXAMPLES:**

We will create the affine plane as an affine toric variety:

```python
sage: quadrant = Cone([(1,0), (0,1)])
sage: A2 = AffineToricVariety(quadrant)
sage: origin = A2(0,0)
sage: origin
[0 : 0]
sage: parent(origin)
Set of rational points of 2-d affine toric variety
```

Only affine toric varieties have points whose (homogeneous) coordinates are all zero.

**class** `sage.schemes.toric.variety.CohomologyClass(cohomology_ring, representative)`

**Bases:** `sage.rings.quotient_ring_element.QuotientRingElement`

An element of the `CohomologyRing`.

**Warning:** You should not create instances of this class manually. The generators of the cohomology ring as well as the cohomology classes associated to cones of the fan can be obtained from `ToricVariety_field.cohomology_ring()`.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2.cohomology_ring().gen(0)
[z]
sage: HH = P2.cohomology_ring()
sage: HH.gen(0)
[z]
sage: cone = P2.fan(1)[0]; HH(cone)
[z]
```

**deg()**

The degree of the cohomology class.

**OUTPUT:**

An integer $d$ such that the cohomology class is in degree $2d$. If the cohomology class is of mixed degree, the highest degree is returned.
EXAMPLES:

```
sage: P2 = toric_varieties.P2()
sage: P2.cohomology_ring().gen(0).deg()
1
sage: P2.cohomology_ring().zero().deg()
-1
```

**exp()**

Exponentiate self.

**Note:** The exponential \( \exp(x) \) of a rational number \( x \) is usually not rational. Therefore, the cohomology class must not have a constant (degree zero) part. The coefficients in the Taylor series of \( \exp \) are rational, so any cohomology class without constant term can be exponentiated.

**OUTPUT:**

The cohomology class \( \exp(\text{self}) \) if the constant part vanishes, otherwise a \texttt{ValueError} is raised.

**EXAMPLES:**

```
sage: P2 = toric_varieties.P2()
sage: H_class = P2.cohomology_ring().gen(0)
sage: H_class
[\{z\}]
sage: H_class.exp()
[1/2*z^2 + z + 1]
```

**part_of_degree\( (d) \)**

Project the (mixed-degree) cohomology class to the given degree.

\[
pr_d : H^*(X_\Delta, \mathbb{Q}) \rightarrow H^{2d}(X_\Delta, \mathbb{Q})
\]

**INPUT:**

- An integer \( d \)

**OUTPUT:**

- The degree-\( 2d \) part of the cohomology class.

**EXAMPLES:**

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: t = P1xP1.cohomology_ring().gen(0)
sage: y = P1xP1.cohomology_ring().gen(2)
sage: 3*t+4*t^2*y+y+t*y+t+1
[t*y + 4*t + y + 1]
sage: (3*t+4*t^2*y+y+t*y+t+1).part_of_degree(1)
[4*t + y]
```

**class** `sage.schemes.toric.variety.CohomologyRing\( (\text{variety}) \)`

Bases: `sage.rings.quotient_ring.QuotientRing_generic`, `sage.structure.unique_representation.UniqueRepresentation`

The (even) cohomology ring of a toric variety.

Irregardless of the variety’s base ring, we always work with the variety over \( \mathbb{C} \) and its topology.
The cohomology is always the singular cohomology with $\mathbb{Q}$-coefficients. Note, however, that the cohomology of smooth toric varieties is torsion-free, so there is no loss of information in that case.

Currently, the toric variety must not be “too singular”. See `ToricVariety_field.cohomology_ring()` for a detailed description of which toric varieties are admissible. For such varieties the odd-dimensional cohomology groups vanish.

**Warning:** You should not create instances of this class manually. Use `ToricVariety_field.cohomology_ring()` to generate the cohomology ring.

**INPUT:**
- `variety` – a toric variety. Currently, the toric variety must be at least an orbifold. See `ToricVariety_field.cohomology_ring()` for a detailed description of which toric varieties are admissible.

**EXAMPLES:**

```
sage: P2 = toric_varieties.P2()
sage: P2.cohomology_ring()
Rational cohomology ring of a 2-d CPR-Fano toric variety covered by 3 affine patches
```

This is equivalent to:

```
sage: from sage.schemes.toric.variety import CohomologyRing
sage: CohomologyRing(P2)
Rational cohomology ring of a 2-d CPR-Fano toric variety covered by 3 affine patches
```

**gen**

Return the generators of the cohomology ring.

**INPUT:**
- `i` – integer.

**OUTPUT:**

The $i$-th generator of the cohomology ring. If we denote the toric variety by $X$, then this generator is associated to the ray $X$.fan().ray($i$), which spans the one-cone $X$.fan(1)[$i$].

**EXAMPLES:**

```
sage: P2 = toric_varieties.P2()
sage: P2.cohomology_ring().gen(2)
[z]
```

**gens**

Return the generators of the cohomology ring.

**OUTPUT:**

A tuple of generators, one for each toric divisor of the toric variety $X$. The order is the same as the ordering of the rays of the fan $X$.fan().rays(), which is also the same as the ordering of the one-cones in $X$.fan(1).

**EXAMPLES:**
Construct a toric variety.

**INPUT:**

- `fan` – rational polyhedral fan;
- `coordinate_names` – names of variables for the coordinate ring, see `normalize_names()` for acceptable formats. If not given, indexed variable names will be created automatically;
- `names` – an alias of `coordinate_names` for internal use. You may specify either `names` or `coordinate_names`, but not both;
- `coordinate_indices` – list of integers, indices for indexed variables. If not given, the index of each variable will coincide with the index of the corresponding ray of the fan;
- `base_ring` – base ring of the toric variety (default: `Q`). Must be a field.
- `base_field` – alias for `base_ring`. Takes precedence if both are specified.

**OUTPUT:**

- toric variety.

**EXAMPLES:**

We will create the product of two projective lines:

```python
sage: fan = FaceFan(lattice_polytope.cross_polytope(2))
sage: fan.rays()
M( 1, 0),
M( 0, 1),
M(-1, 0),
M( 0, -1)
in 2-d lattice M
sage: P1xP1 = ToricVariety(fan)
sage: P1xP1.gens()
(z0, z1, z2, z3)
```

Let’s create some points:

```python
sage: P1xP1(1,1,1,1)
[1 : 1 : 1 : 1]
sage: P1xP1(0,1,1,1)
[0 : 1 : 1 : 1]
sage: P1xP1(0,0,1,1)
Traceback (most recent call last):
...
TypeError: coordinates (0, 1, 0, 1) are in the exceptional set!
```

We cannot set to zero both coordinates of the same projective line!

Let’s change the names of the variables. We have to re-create our toric variety:
```python
sage: P1xP1 = ToricVariety(fan, "x s y t")
```

```python
sage: P1xP1.gens()
(x, s, y, t)
```

Now \((x, y)\) correspond to one line and \((s, t)\) to the other one.

```python
sage: P1xP1.inject_variables()
Defining x, s, y, t
sage: P1xP1.subscheme(x*s-y*t)
Closed subscheme of 2-d toric variety covered by 4 affine patches defined by:
  x*s - y*t
```

Here is a shorthand for defining the toric variety and homogeneous coordinates in one go:

```python
sage: P1xP1.<a,b,c,d> = ToricVariety(fan)
```

```python
sage: (a^2+b^2) * (c+d)
```

```
2^2*c + b^2*c + a^2*d + b^2*d
```

```python
class sage.schemes.toric.variety.ToricVariety_field(fan, coordinate_names, coordinate_indices, base_field)

Bases: sage.schemes.generic.ambient_space.AmbientSpace

Construct a toric variety associated to a rational polyhedral fan.

**Warning:** This class does not perform any checks of correctness of input. Use `ToricVariety()` and `AffineToricVariety()` to construct toric varieties.

**INPUT:**

- `fan` - rational polyhedral fan;
- `coordinate_names` – names of variables, see `normalize_names()` for acceptable formats. If None, indexed variable names will be created automatically;
- `coordinate_indices` – list of integers, indices for indexed variables. If None, the index of each variable will coincide with the index of the corresponding ray of the fan;
- `base_field` – base field of the toric variety.

**OUTPUT:**

- `toric variety`.

**Aut_dimension()**

Return the dimension of the automorphism group

There are three kinds of symmetries of toric varieties:

- Toric automorphisms (rescaling of homogeneous coordinates)
- Demazure roots. These are translations \(x_i \rightarrow x_i + \epsilon x^m\) of a homogeneous coordinate \(x_i\) by a monomial \(x^m\) of the same homogeneous degree.
- Symmetries of the fan. These yield discrete subgroups.

**OUTPUT:**

An integer. The dimension of the automorphism group. Equals the dimension of the \(M\)-lattice plus the number of Demazure roots.
EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: P2.Aut_dimension()
8
```

**Chern_character** *(deg=None)*

Return the Chern character (of the tangent bundle) of the toric variety.

**INPUT:**

- `deg` – integer (optional). The degree of the Chern character.

**OUTPUT:**

- If the degree is specified, the degree-`deg` part of the Chern character.
- If no degree is specified, the total Chern character.

**REFERENCES:**

- Wikipedia article Chern_character#The_Chern_character

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: dP6.Chern_character()
[3*w^2 + y + 2*v + 2*z + w + 2]
sage: dP6.ch()
[3*w^2 + y + 2*v + 2*z + w + 2]
sage: dP6.ch(1) == dP6.c(1)
True
```

**Chern_class** *(deg=None)*

Return Chern classes of the (tangent bundle of the) toric variety.

**INPUT:**

- `deg` – integer (optional). The degree of the Chern class.

**OUTPUT:**

- If the degree is specified, the `deg`-th Chern class.
- If no degree is specified, the total Chern class.

**REFERENCES:**

- Wikipedia article Chern_class

**EXAMPLES:**

```python
sage: X = toric_varieties.dP6()
sage: X.Chern_class()
[-6*w^2 + y + 2*v + 2*z + w + 1]
sage: X.c()  
[-6*w^2 + y + 2*v + 2*z + w + 1]
sage: X.c(1)
[y + 2*v + 2*z + w]
sage: X.c(2)
[-6*w^2]
sage: X.integrate( X.c(2) )
6
```
Chow group \( (\text{base\_ring} = \text{Integer Ring}) \)

Return the toric Chow group.

**INPUT:**

- base\_ring – either \( \mathbb{Z} \) (default) or \( \mathbb{Q} \). The coefficient ring of the Chow group.

**OUTPUT:**

A `sage.schemes.toric.chow_group.ChowGroup_class`

**EXAMPLES:**

```python
sage: A = toric_varieties.P2().Chow_group(); A
Chow group of 2-d CPR-Fano toric variety covered by 3 affine patches
sage: A.gens()
((1 | 0 | 0), (0 | 1 | 0), (0 | 0 | 1))
```

Demazure roots

Return the Demazure roots.

**OUTPUT:**

The roots as points of the \( \mathcal{M} \)-lattice.

**REFERENCES:**

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2.Demazure_roots()
(M(-1, 0), M(-1, 1), M(0, -1), M(0, 1), M(1, -1), M(1, 0))
```

Here are the remaining three examples listed in [Bazhov], Example 2.1 and 2.3:

```python
sage: s = 3
sage: cones = [(0,1),(1,2),(2,3),(3,0)]
sage: Hs = ToricVariety(Fan(rays=[(1,0),(0,-1),(-1,s),(0,1)], cones=cones))
sage: Hs.Demazure_roots()
(M(-1, 0), M(1, 0), M(0, 1), M(1, 1), M(2, 1), M(3, 1))
sage: E1s = ToricVariety(Fan(rays=[(1,0),(0,-1),(-1,s)], cones=[(0,1),(1,2),
→(2,0)]))
sage: E1s.Demazure_roots()
(M(-1, 0), M(1, 0), M(0, 1), M(1, 1), M(2, 1), M(3, 1))
sage: E1s.Demazure_roots() == Hs.Demazure_roots()
True
sage: Bs = ToricVariety(Fan(rays=[(s,1),(s,-1),(-s,1),(-s,1)], cones=cones))
sage: Bs.Demazure_roots()()
```

Euler number

Return the topological Euler number of the toric variety.

Sometimes, this is also called the Euler characteristic. `chi()` is a synonym for `Euler_number()`.

**REFERENCES:**
• Wikipedia article Euler_characteristic

EXAMPLES:

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1xP1.Euler_number()
4
sage: P1xP1.chi()
4
```

\( K() \)

Returns the canonical divisor of the toric variety.

EXAMPLES:

Lets test that the del Pezzo surface \(dP_6\) has degree 6, as its name implies:

```python
sage: dP6 = toric_varieties.dP6()
sage: HH = dP6.cohomology_ring()
sage: dP6.K()
-V(x) - V(u) - V(y) - V(v) - V(z) - V(w)
sage: dP6.integrate( HH(dP6.K())^2 )
6
```

\( \text{Kaehler\_cone}() \)

Return the closure of the Kähler cone of \(self\).

OUTPUT:

• cone.

\[ \text{Note: This cone sits in the rational divisor class group of } \text{self} \text{ and the choice of coordinates agrees with } \text{rational\_class\_group()}. \]

EXAMPLES:

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: Kc = P1xP1.Kaehler_cone()
sage: Kc
2-d cone in 2-d lattice
sage: Kc.rays()
Divisor class [0, 1],
Divisor class [1, 0]
in Basis lattice of The toric rational divisor class group of a 2-d CPR-Fano toric variety covered by 4 affine patches
sage: [ divisor_class.lift() for divisor_class in Kc.rays() ]
[V(x), V(s)]
sage: Kc.lattice()
Basis lattice of The toric rational divisor class group of a 2-d CPR-Fano toric variety covered by 4 affine patches
```

\( \text{Mori\_cone}() \)

Returns the Mori cone of \(self\).

OUTPUT:

• cone.

\[ \text{Note:} \]

16.1. Toric varieties
The Mori cone is dual to the Kähler cone.

We think of the Mori cone as living inside the row span of the Gale transform matrix (computed by `self.fan().Gale_transform()`).

The points in the Mori cone are the effective curves in the variety.

The $i$-th entry in each Mori vector is the intersection number of the curve corresponding to the generator of the $i$-th ray of the fan with the corresponding divisor class. The very last entry is associated to the origin of the fan lattice.

The Mori vectors are also known as the gauged linear sigma model charge vectors.

**EXAMPLES:**

```python
sage: P4_11169 = toric_varieties.P4_11169_resolved()
sage: P4_11169.Mori_cone()
2-d cone in 7-d lattice
sage: P4_11169.Mori_cone().rays()
(3, 2, 0, 0, 1, -6),
(0, 0, 1, 1, 1, -3, 0)
in Ambient free module of rank 7
over the principal ideal domain Integer Ring
```

`Spec (cone=None, names=None)`

Return the spectrum associated to the dual cone.

Let $\sigma \in \mathbb{N}_R$ be a cone and $\sigma^\vee \cap M$ the associated semigroup of lattice points in the dual cone. Then

$$S = \mathbb{C}[\sigma^\vee \cap M]$$

is a $\mathbb{C}$-algebra. It is spanned over $\mathbb{C}$ by the points of $\sigma \cap N$, addition is formal linear combination of lattice points, and multiplication of lattice points is the semigroup law (that is, addition of lattice points). The $\mathbb{C}$-algebra $S$ then defines a scheme $Spec(S)$.

For example, if $\sigma = \{(x,y) | x \geq 0, y \geq 0\}$ is the first quadrant then $S$ is the polynomial ring in two variables. The associated scheme is $Spec(S) = \mathbb{C}^2$.

The same construction works over any base field, this introduction only used $\mathbb{C}$ for simplicity.

**INPUT:**

* cone – a `Cone`. Can be omitted for an affine toric variety, in which case the (unique) generating cone is used.

* names – (optional). Names of variables for the semigroup ring, see `normalize_names()` for acceptable formats. If not given, indexed variable names will be created automatically.

**Output:**

The spectrum of the semigroup ring $\mathbb{C}[\sigma^\vee \cap M]$.

**EXAMPLES:**

```python
sage: quadrant = Cone([(1,0),(0,1)])
sage: AffineToricVariety(quadrant).Spec()
Spectrum of Multivariate Polynomial Ring in z0, z1 over Rational Field
```

A more interesting example:
sage: A2Z2 = Cone([(0,1),(2,1)])
sage: AffineToricVariety(A2Z2).Spec(names='u,v,t')
Spectrum of Quotient of Multivariate Polynomial Ring
in u, v, t over Rational Field by the ideal (-u*v + t^2)

Stanley_Reisner_ideal()
Return the Stanley-Reisner ideal.

OUTPUT:

• The Stanley-Reisner ideal in the polynomial ring over $\mathbb{Q}$ generated by the homogeneous coordinates.

EXAMPLES:

sage: fan = Fan([(0,1,3),(3,4),[2,0],[1,2,4]),
(-3, -2, 1), (0, 0, 1), (3, -2, 1), (-1, -1, 1), (1, -1, 1))
sage: X = ToricVariety(fan, coordinate_names='A B C D E', base_field=GF(5))
sage: SR = X.Stanley_Reisner_ideal(); SR
Ideal (A*E, C*D, A*B*C, B*D*E) of Multivariate Polynomial Ring in A, B, C, D, E over Rational Field

Td (deg=None)
Return the Todd class (of the tangent bundle) of the toric variety.

INPUT:

• deg – integer (optional). The desired degree part.

OUTPUT:

• If the degree is specified, the degree-$deg$ part of the Todd class.

• If no degree is specified, the total Todd class.

REFERENCES:

• Wikipedia article Todd_class

EXAMPLES:

sage: dP6 = toric_varieties.dP6()
sage: dP6.Todd_class()
[-w^2 + 1/2*y + v + z + 1/2*w + 1]
sage: dP6.Td()
[-w^2 + 1/2*y + v + z + 1/2*w + 1]
sage: dP6.integrate( dP6.Td() )
1

Todd_class (deg=None)
Return the Todd class (of the tangent bundle) of the toric variety.

INPUT:

• deg – integer (optional). The desired degree part.

OUTPUT:

• If the degree is specified, the degree-$deg$ part of the Todd class.

• If no degree is specified, the total Todd class.

REFERENCES:

• Wikipedia article Todd_class
EXAMPLES:

```
sage: dP6 = toric_varieties.dP6()
sage: dP6.Todd_class()
[-w^2 + 1/2*y + v + z + 1/2*w + 1]
sage: dP6.Td()
[-w^2 + 1/2*y + v + z + 1/2*w + 1]
sage: dP6.integrate( dP6.Td() )
1
```

**affine_algebraic_patch** *(cone=None, names=None)*

Return the patch corresponding to $\sigma$ as an affine algebraic subvariety.

**INPUT:**

- **cone** – a Cone $\sigma$ of the fan. It can be omitted for an affine toric variety, in which case the single generating cone is used.

**OUTPUT:**

An **affine algebraic subscheme** corresponding to the patch $\text{Spec}(\sigma^\vee \cap M)$ associated to the cone $\sigma$.

See also **affine_patch()**, which expresses the patches as subvarieties of affine space instead.

**EXAMPLES:**

```
sage: cone = Cone([(0,1),(2,1)])
sage: A2Z2 = AffineToricVariety(cone)
sage: A2Z2.affine_algebraic_patch()
Closed subscheme of Affine Space of dimension 3 over Rational Field defined by:
-z0*z1 + z2^2
sage: A2Z2.affine_algebraic_patch(Cone([(0,1)]), names='x, y, t')
Closed subscheme of Affine Space of dimension 3 over Rational Field defined by:
1
```

**affine_patch** *(i)*

Return the $i$-th affine patch of self.

**INPUT:**

- **i** – integer, index of a generating cone of the fan of self.

**OUTPUT:**

- **affine toric variety** corresponding to the $i$-th generating cone of the fan of self.

The result is cached, so the $i$-th patch is always the same object in memory.

See also **affine_algebraic_patch()**, which expresses the patches as subvarieties of affine space instead.

**EXAMPLES:**

```
sage: fan = FaceFan(lattice_polytope.cross_polytope(2))
sage: P1xP1 = ToricVariety(fan, "x s y t")
sage: patch0 = P1xP1.affine_patch(0)
sage: patch0
2-d affine toric variety
sage: patch0.embedding_morphism()
```

(continues on next page)
Scheme morphism:
From: 2-d affine toric variety
To: 2-d toric variety covered by 4 affine patches
Defn: Defined on coordinates by sending [y : t] to
[1 : 1 : y : t]
sage: patch1 = P1xP1.affine_patch(1)
sage: patch1.embedding_morphism()
Scheme morphism:
From: 2-d affine toric variety
To: 2-d toric variety covered by 4 affine patches
Defn: Defined on coordinates by sending [s : y] to
[1 : s : y : 1]
sage: patch1 is P1xP1.affine_patch(1)
True

\texttt{c}(\texttt{deg}=\texttt{None})

Return Chern classes of the (tangent bundle of the) toric variety.

\textbf{INPUT:}

- \texttt{deg} – integer (optional). The degree of the Chern class.

\textbf{OUTPUT:}

- If the degree is specified, the \texttt{deg}-th Chern class.
- If no degree is specified, the total Chern class.

\textbf{REFERENCES:}

- Wikipedia article Chern_class

\textbf{EXAMPLES:}

\begin{verbatim}
sage: X = toric_varieties.dP6() sage: X.Chern_class()
[-6*w^2 + y + 2*v + 2*z + w + 1]
sage: X.c()
[-6*w^2 + y + 2*v + 2*z + w + 1]
sage: X.c(1)
[y + 2*v + 2*z + w]
sage: X.c(2)
[-6*w^2]
sage: X.integrate( X.c(2) )
6
sage: X.integrate( X.c(2) ) == X.Euler_number()
True
\end{verbatim}

cartesian_product (\texttt{other}, \texttt{coordinate_names}=\texttt{None}, \texttt{coordinate_indices}=\texttt{None})

Return the Cartesian product of \texttt{self} with \texttt{other}.

\textbf{INPUT:}

- \texttt{other} – a toric variety;
- \texttt{coordinate_names} – names of variables for the coordinate ring, see \texttt{normalize_names()} for acceptable formats. If not given, indexed variable names will be created automatically;
- \texttt{coordinate_indices} – list of integers, indices for indexed variables. If not given, the index of each variable will coincide with the index of the corresponding ray of the fan.
OUTPUT:

—a toric variety.

EXAMPLES:

```
sage: P1 = ToricVariety(Fan([Cone([(1,)]), Cone([(-1,)])]))
sage: P1xP1 = P1.cartesian_product(P1); P1xP1
2-d toric variety covered by 4 affine patches
sage: P1xP1.fan().rays()
N+N(-1, 0),
N+N( 1, 0),
N+N( 0, -1),
N+N( 0, 1)
in 2-d lattice N+N
```

`ch (deg=None)`

Return the Chern character (of the tangent bundle) of the toric variety.

INPUT:

- `deg`: integer (optional). The degree of the Chern character.

OUTPUT:

- If the degree is specified, the degree-`deg` part of the Chern character.
- If no degree is specified, the total Chern character.

REFERENCES:

- Wikipedia article Chern_character#The_Chern_character

EXAMPLES:

```
sage: dP6 = toric_varieties.dP6()
sage: dP6.Chern_character()
[3*w^2 + y + 2*v + 2*z + w + 2]
sage: dP6.ch()
[3*w^2 + y + 2*v + 2*z + w + 2]
sage: dP6.ch(1) == dP6.c(1)
True
```

`change_ring (F)`

Return a toric variety over `F` and otherwise the same as `self`.

INPUT:

- `F`: field.

OUTPUT:

- toric variety over `F`.

**Note:** There is no need to have any relation between `F` and the base field of `self`. If you do want to have such a relation, use `base_extend()` instead.

EXAMPLES:
chi()
Return the topological Euler number of the toric variety.

Sometimes, this is also called the Euler characteristic. `chi()` is a synonym for `Euler_number()`.

REFERENCES:
- Wikipedia article Euler_characteristic

EXAMPLES:

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1xP1.Euler_number()
4
sage: P1xP1.chi()
4
```

cohomology_basis(d=None)
Return a basis for the cohomology of the toric variety.

INPUT:
- d (optional) – integer.

OUTPUT:
- Without the optional argument, a list whose d-th entry is a basis for $H^{2d}(X, \mathbb{Q})$
- If the argument is an integer d, returns basis for $H^{2d}(X, \mathbb{Q})$

EXAMPLES:

```
sage: X = toric_varieties.dP8()
sage: X.cohomology_basis()
(((1,1), ([z], [y])), ([y*z],))
sage: X.cohomology_basis(1)
([z], [y])
sage: X.cohomology_basis(dimension(X))[0] == X.volume_class()
True
```
cohomology_ring()
Return the cohomology ring of the toric variety.

OUTPUT:

- If the toric variety is over $\mathbb{C}$ and has at most finite orbifold singularities: $H^*(X, \mathbb{Q})$ as a polynomial quotient ring.
- Other cases are not handled yet.

Note:

- Toric varieties over any field of characteristic 0 are treated as if they were varieties over $\mathbb{C}$.
- The integral cohomology of smooth toric varieties is torsion-free, so in this case there is no loss of information when going to rational coefficients.
- $\text{self.cohomology_ring().gen(i)}$ is the divisor class corresponding to the $i$-th ray of the fan.

EXAMPLES:

```
sage: X = toric_varieties.dP6()
sage: X.cohomology_ring()
Rational cohomology ring of a 2-d CPR-Fano toric variety covered by 6 affine patches
sage: X.cohomology_ring().defining_ideal()
Ideal (-u - y + z + w, x - y - v + w, x*y, x*v, x*z, u*v, u*z, u*w, y*z, y*w, v*w) of Multivariate Polynomial Ring in x, u, y, v, z, w over Rational Field
sage: X.cohomology_ring().defining_ideal().ring()
Multivariate Polynomial Ring in x, u, y, v, z, w over Rational Field
sage: X.variable_names()
('x', 'u', 'y', 'v', 'z', 'w')
sage: X.cohomology_ring().gens()
([y + v - w], [-y + z + w], [y], [v], [z], [w])
```

coordinate_ring()
Return the coordinate ring of self.

For toric varieties this is the homogeneous coordinate ring (a.k.a. Cox’s ring and total ring).

OUTPUT:

- polynomial ring.

EXAMPLES:

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1xP1.coordinate_ring()
Multivariate Polynomial Ring in s, t, x, y over Rational Field
```

count_points()
Return the number of points of self.

This is an alias for point_set().cardinality(), see cardinality() for details.

EXAMPLES:
```
sage: o = lattice_polytope.cross_polytope(3)
sage: V = ToricVariety(FaceFan(o))
sage: V2 = V.change_ring(GF(2))
sage: V2.point_set().cardinality()
27
sage: V2.count_points()
27
```

dimension_singularities()
Return the dimension of the singular set.

OUTPUT:

Integer. The dimension of the singular set of the toric variety. Often the singular set is a reducible subvariety, and this method will return the dimension of the largest-dimensional component.

Returns -1 if the toric variety is smooth.

EXAMPLES:
```
sage: toric_varieties.P4_11169().dimension_singularities()
1
sage: toric_varieties.Conifold().dimension_singularities()
0
sage: toric_varieties.P2().dimension_singularities()
-1
```

divisor(arg, base_ring=None, check=True, reduce=True)
Return a divisor.

INPUT:

The arguments are the same as in :meth:`sage.schemes.toric.divisor.ToricDivisor`, with the exception of defining a divisor with a single integer: this method considers it to be the index of a ray of the :meth:`fan` of self.

OUTPUT:

- A :class:`sage.schemes.toric.divisor.ToricDivisor_generic`

EXAMPLES:
```
sage: dP6 = toric_varieties.dP6()
sage: dP6.coordinate_ring()
Multivariate Polynomial Ring in x, u, y, v, z, w
over Rational Field
sage: dP6.divisor(list(range(6)))
V(u) + 2*V(y) + 3*V(v) + 4*V(z) + 5*V(w)
sage: dP6.inject_variables()
Defining x, u, y, v, z, w
sage: dP6.divisor(x*u^3)
V(x) + 3*V(u)
```

You can also construct divisors based on ray indices:
```
sage: dP6.divisor(0)
V(x)
sage: for i in range(dP6.fan().nrays()):
    ....:     print('() : generated by ray {}\'.format(dP6.divisor(i),
    ....:     dP6.fan().ray(i))
```

(continues on next page)
V(x) : generated by ray N(0, 1)
V(u) : generated by ray N(-1, 0)
V(y) : generated by ray N(-1, -1)
V(v) : generated by ray N(0, -1)
V(z) : generated by ray N(1, 0)
V(w) : generated by ray N(1, 1)

\textbf{divisor\_group} (\texttt{base\_ring=Integer\_Ring})

Return the group of Weil divisors.

\textbf{INPUT:}

- \texttt{base\_ring} – the coefficient ring, usually \texttt{ZZ} (default) or \texttt{QQ}.

\textbf{OUTPUT:}

The (free abelian) group of Cartier divisors, that is, formal linear combinations of polynomial equations over the coefficient ring \texttt{base\_ring}.

These need not be toric (=defined by monomials), but allow general polynomials. The output will be an instance of \texttt{sage.schemes.generic.divisor\_group.Divisor\_Group\_generic}.

\textbf{Warning:} You almost certainly want the group of toric divisors, see \texttt{toric\_divisor\_group()}. The toric divisor group is generated by the rays of the fan. The general divisor group has no toric functionality implemented.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: dP6 = toric_varieties.dP6()
sage: Div = dP6.divisor_group(); Div
Group of ZZ-Divisors on 2-d CPR-Fano toric variety covered by 6 affine patches
sage: Div(x)
V(x)
\end{verbatim}

\textbf{embedding\_morphism}()

Return the default embedding morphism of \texttt{self}.

Such a morphism is always defined for an affine patch of a toric variety (which is also a toric varieties itself).

\textbf{OUTPUT:}

- \texttt{scheme\_morphism} if the default embedding morphism was defined for \texttt{self}, otherwise a \texttt{ValueError} exception is raised.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: fan = FaceFan(lattice_polytope.cross_polytope(2))
sage: P1xP1 = ToricVariety(fan, "x s y t")
sage: P1xP1.embedding_morphism()
Traceback (most recent call last):
  ...
ValueError: no default embedding was defined for this toric variety!
sage: patch = P1xP1.affine_patch(0)
sage: patch
\end{verbatim}
2-d affine toric variety

```
sage: patch.embedding_morphism()
```

Scheme morphism:
  From: 2-d affine toric variety
  To: 2-d toric variety covered by 4 affine patches
  Defn: Defined on coordinates by sending [y : t] to
         [1 : 1 : y : t]

```
fan (dim=None, codim=None)
```

Return the underlying fan of `self` or its cones.

**INPUT:**

- `dim` – dimension of the requested cones;
- `codim` – codimension of the requested cones.

**OUTPUT:**

- `rational polyhedral fan` if no parameters were given, `tuple of cones` otherwise.

**EXAMPLES:**

```
sage: fan = FaceFan(lattice_polytope.cross_polytope(2))
sage: P1xP1 = ToricVariety(fan)
sage: P1xP1.fan() is fan
True
sage: P1xP1.fan(1)[0]
1-d cone of Rational polyhedral fan in 2-d lattice M
```

```
inject_coefficients (scope=None, verbose=True)
```

Inject generators of the base field of `self` into `scope`.

This function is useful if the base field is the field of rational functions.

**INPUT:**

- `scope` – namespace (default: global, not just the scope from which this function was called);
- `verbose` – if `True` (default), names of injected generators will be printed.

**OUTPUT:**

- `none`.

**EXAMPLES:**

```
sage: fan = FaceFan(lattice_polytope.cross_polytope(2))
sage: F = QQ["a, b"].fraction_field()
sage: P1xP1 = ToricVariety(fan, base_field=F)
sage: P1xP1.inject_coefficients()
```

We check that we can use names `a` and `b`, `trac ticket #10498` is fixed:

```
sage: a + b
a + b
sage: a + b in P1xP1.coordinate_ring()
True
```
**integrate** *(cohomology_class)*

Integrate a cohomology class over the toric variety.

**INPUT:**

- cohomology_class – A cohomology class given as a polynomial in self.
  
  cohomology_ring()

**OUTPUT:**

The integral of the cohomology class over the variety. The volume normalization is given by `volume_class()`, that is, `self.integrate(self.volume_class())` is always one (if the volume class exists).

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: HH = dP6.cohomology_ring()
sage: D = [ HH(c) for c in dP6.fan(dim=1) ]
sage: matrix([ [ dP6.integrate(D[i]*D[j]) for i in range(0,6) ] for j in range(0,6) ])

[-1 1 0 0 0 1]
[ 1 -1 1 0 0 0]
[ 0 1 -1 1 0 0]
[ 0 0 1 -1 1 0]
[ 1 0 0 0 1 -1]
```

If the toric variety is an orbifold, the intersection numbers are usually fractional:

```python
sage: P2_123 = toric_varieties.P2_123()
sage: HH = P2_123.cohomology_ring()
sage: D = [ HH(c) for c in P2_123.fan(dim=1) ]
sage: matrix([ [ P2_123.integrate(D[i]*D[j]) for i in range(0,3) ] for j in range(0,3) ])

[2/3 1 1/3]
[ 1 3/2 1/2]
[ 1/3 1/2 1/6]
```

**is_affine()**

Check if self is an affine toric variety.

An affine toric variety is a toric variety whose fan is the face lattice of a single cone. See also `AffineToricVariety()`.

**OUTPUT:**

230 Chapter 16. Toric Varieties
Boolean.

EXAMPLES:

```python
sage: toric_varieties.A2().is_affine()
True
sage: toric_varieties.P1xA1().is_affine()
False
```

**is_complete()**
Check if `self` is complete.

OUTPUT:

- True if `self` is complete and False otherwise.

EXAMPLES:

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1xP1.is_complete()
True
sage: P1xP1.affine_patch(0).is_complete()
False
```

**is_homogeneous** (polynomial)
Check if `polynomial` is homogeneous.

The coordinate ring of a toric variety is multigraded by relations between generating rays of the underlying fan.

INPUT:

- `polynomial` – polynomial in the coordinate ring of `self` or its quotient.

OUTPUT:

- True if `polynomial` is homogeneous and False otherwise.

EXAMPLES:

We will use the product of two projective lines with coordinates \((x, y)\) for one and \((s, t)\) for the other:

```python
sage: P1xP1.<x,y,s,t> = toric_varieties.P1xP1()
sage: P1xP1.is_homogeneous(x - y)
True
sage: P1xP1.is_homogeneous(x*s + y*t)
True
sage: P1xP1.is_homogeneous(x - t)
False
sage: P1xP1.is_homogeneous(1)
True
```

Note that by homogeneous, we mean well-defined with respect to the homogeneous rescalings of `self`. So a polynomial that you would usually not call homogeneous can be homogeneous if there are no homogeneous rescalings, for example:

```python
sage: A1.<z> = toric_varieties.A1()
sage: A1.is_homogeneous(z^3+z^7)
True
```
Finally, the degree group is really the Chow group $A_{d-1}(X)$ and can contain torsion. For example, take $\mathbb{C}^2/\mathbb{Z}_2$. Here, the Chow group is $A_{d-1}(\mathbb{C}^2/\mathbb{Z}_2) = \mathbb{Z}_2$ and distinguishes even-degree homogeneous polynomials from odd-degree homogeneous polynomials:

```
sage: A2_Z2.<x,y> = toric_varieties.A2_Z2()
sage: A2_Z2.is_homogeneous(x+y+x^3+y^5+x^3*y^4)
True
sage: A2_Z2.is_homogeneous(x^2+x*y+y^4+(x+y)^5+x^4*y^4)
True
sage: A2_Z2.is_homogeneous(x+y^2)
False
```

**is_isomorphic** *(another)*

Check if self is isomorphic to another.

**INPUT:**

- another - toric variety.

**OUTPUT:**

- True if self and another are isomorphic, False otherwise.

**EXAMPLES:**

```
sage: TV1 = toric_varieties.P1xA1()
sage: TV2 = toric_varieties.P1xP1()
```

Only the most trivial case is implemented so far:

```
sage: TV1.is_isomorphic(TV1)
True
sage: TV1.is_isomorphic(TV2)
Traceback (most recent call last):
  ...
NotImplementedError:
isomorphism check is not yet implemented!
```

**is_orbifold**

Check if self has only quotient singularities.

A toric variety with at most orbifold singularities (in this sense) is often called a simplicial toric variety. In this package, we generally try to avoid this term since it mixes up differential geometry and cone terminology.

**OUTPUT:**

- True if self has at most quotient singularities by finite groups, False otherwise.

**EXAMPLES:**

```
sage: fan1 = FaceFan(lattice_polytope.cross_polytope(2))
sage: P1xP1 = ToricVariety(fan1)
sage: P1xP1.is_orbifold()
True
sage: fan2 = NormalFan(lattice_polytope.cross_polytope(3))
sage: TV = ToricVariety(fan2)
sage: TV.is_orbifold()
False
```
**is_smooth()**
Check if `self` is smooth.

**OUTPUT:**
- True if `self` is smooth and `False` otherwise.

**EXAMPLES:**
```
sage: fan1 = FaceFan(lattice_polytope.cross_polytope(2))
sage: P1xP1 = ToricVariety(fan1)
sage: P1xP1.is_smooth()
True
sage: fan2 = NormalFan(lattice_polytope.cross_polytope(2))
sage: TV = ToricVariety(fan2)
sage: TV.is_smooth()
False
```

**linear_equivalence_ideal()**
Return the ideal generated by linear relations

**OUTPUT:**
- The ideal generated by the linear relations of the rays in the polynomial ring over \( \mathbb{Q} \) generated by the homogeneous coordinates.

**EXAMPLES:**
```
sage: fan = Fan([\[0,1,3\],\[3,4\],\[2,0\],\[1,2,4\]], \[\(-3, -2, 1\), \(0, 0, 1\), \(3, -2, 1\), \(-1, -1, 1\), \(1, -1, 1\)]

sage: X = ToricVariety(fan, coordinate_names='A B C D E', base_field=GF(5))
sage: lin = X.linear_equivalence_ideal(); lin
Ideal (-3*A + 3*C - D + E, -2*A - 2*C - D - E, A + B + C + D + E) of
  Multivariate Polynomial Ring in A, B, C, D, E over Rational Field
```

**orbit_closure(cone)**
Return the orbit closure of `cone`.

The cones \( \sigma \) of a fan \( \Sigma \) are in one-to-one correspondence with the torus orbits \( O(\sigma) \) of the corresponding toric variety \( X_\Sigma \). Each orbit is isomorphic to a lower dimensional torus (of dimension equal to the codimension of \( \sigma \)). Just like the toric variety \( X_\Sigma \) itself, these orbits are (partially) compactified by lower-dimensional orbits. In particular, one can define the closure \( V(\sigma) \) of the torus orbit \( O(\sigma) \) in the ambient toric variety \( X_\Sigma \), which is again a toric variety.

See Proposition 3.2.7 of [CLS] for more details.

**INPUT:**
- `cone` - a cone of the fan.

**OUTPUT:**
- a torus orbit closure associated to `cone` as a toric variety.

**EXAMPLES:**
```
sage: P1xP1 = toric_varieties.P1xP1()
sage: H = P1xP1.fan(1)[0]
sage: V = P1xP1.orbit_closure(H); V
1-d toric variety covered by 2 affine patches
sage: V.embedding_morphism()
Scheme morphism:
```
From: 1-d toric variety covered by 2 affine patches
To: 2-d CPR-Fano toric variety covered by 4 affine patches
Defn: Defined by embedding the torus closure associated to the 1-d
cone of Rational polyhedral fan in 2-d lattice N.
sage: V.embedding_morphism().as_polynomial_map()
Scheme morphism:
From: 1-d toric variety covered by 2 affine patches
To: 2-d CPR-Fano toric variety covered by 4 affine patches
Defn: Defined on coordinates by sending \([z0 : z1]\) to
\([0 : 1 : z1 : z0]\)

plot(**options)
Plot self, i.e. the corresponding fan.

INPUT:
  • any options for toric plots (see toric_plotter.options), none are mandatory.

OUTPUT:
  • a plot.

Note: The difference between \(X.plot()\) and \(X.fan().plot()\) is that in the first case default ray
labels correspond to variables of \(X\).

EXAMPLES:

```sage
sage: X = toric_varieties.Cube_deformation(4)
sage: X.plot()
Graphics3d Object
```

rational_class_group()
Return the rational divisor class group of self.

Let \(X\) be a toric variety.

The **Weil divisor class group** \(Cl(X)\) is a finitely generated abelian group and can contain torsion. Its rank
equals the number of rays in the fan of \(X\) minus the dimension of \(X\).

The **rational divisor class group** is \(Cl(X) \otimes \mathbb{Q}\) and never includes torsion. If \(X\) is **smooth**, this equals the
**Picard group** of \(X\), whose elements are the isomorphism classes of line bundles on \(X\). The group law
(which we write as addition) is the tensor product of the line bundles. The Picard group of a toric variety
is always torsion-free.

OUTPUT:
  • rational divisor class group.

Note:
  • Coordinates correspond to the rows of self.fan().gale_transform().
  • Kaehler_cone() yields a cone in this group.

EXAMPLES:
**resolve(****kwds**)  
Construct a toric variety whose fan subdivides the fan of **self**.

The name of this function reflects the fact that usually such subdivisions are done for resolving singularities of the original variety.

**INPUT:**

This function accepts only keyword arguments, none of which are mandatory.

- **coordinate_names** – names for coordinates of the new variety. If not given, will be constructed from the coordinate names of **self** and necessary indexed ones. See `normalize_names()` for the description of acceptable formats;
- **coordinate_indices** – coordinate indices which should be used for indexed variables of the new variety;
- all other arguments will be passed to `subdivide()` method of the underlying **rational polyhedral fan**, see its documentation for the available options.

**OUTPUT:**

- **toric variety**.

**EXAMPLES:**

First we will “manually” resolve a simple orbifold singularity:

```sage  
cone = Cone([(1,1), (-1,1)])  
sage: fan = Fan([cone])  
sage: TV = ToricVariety(fan)  
sage: TV.is_smooth()  
False  
sage: TV_res = TV.resolve(new_rays=[(0,1)])  
sage: TV_res.is_smooth()  
True  
sage: TV_res.fan().rays()  
N( 1, 1),  
N(-1, 1),  
N( 0, 1)  
in 2-d lattice N  
sage: [cone.ambient_ray_indices() for cone in TV_res.fan()]  
[(0, 2), (1, 2)]
```

Now let’s “automatically” partially resolve a more complicated fan:

```sage  
fan = NormalFan(lattice_polytope.cross_polytope(3))  
sage: TV = ToricVariety(fan)  
sage: TV.is_smooth()  
False  
sage: TV.is_orbifold()  
False  
sage: TV.fan().nrays()  
8  
sage: TV.fan().ngenerating_cones()  
```
sage: TV_res = TV.resolve(make_simplicial=True)
sage: TV_res.is_smooth()
False
sage: TV_res.is_orbifold()
True
sage: TV_res.fan().nrays()
8
sage: TV_res.fan().ngenerating_cones()
12
sage: TV.gens()
(z0, z1, z2, z3, z4, z5, z6, z7)
sage: TV_res.gens()
(x0, x1, x2, x3, x4, x5, x6, x7)

**resolve_to_orbifold** (**kwds**)

Construct an orbifold whose fan subdivides the fan of self.

It is a synonym for resolve() with make_simplicial=True option.

**INPUT:**

- this function accepts only keyword arguments. See resolve() for documentation.

**OUTPUT:**

- toric variety.

**EXAMPLES:**

```python
sage: fan = NormalFan(lattice_polytope.cross_polytope(3))
sage: TV = ToricVariety(fan)
sage: TV.is_orbifold()
False
sage: TV.fan().nrays()
8
sage: TV.fan().ngenerating_cones()
6
sage: TV_res = TV.resolve_to_orbifold()
sage: TV_res.is_orbifold()
True
sage: TV_res.fan().nrays()
8
sage: TV_res.fan().ngenerating_cones()
12
```

**sheaves**

Return the factory object for sheaves on the toric variety.

See sage.schemes.toric.sheaf.constructor.SheafLibrary for details.

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: dP6.sheaves
```
Sheaf constructor on 2-d CPR-Fano toric variety covered by 6 affine patches

```
sage: dP6.sheaves.trivial_bundle()
```

Rank 1 bundle on 2-d CPR-Fano toric variety covered by 6 affine patches.

---

**subscheme** *(polynomials)*

Return the subscheme of *self* defined by *polynomials*.

**INPUT:**

- *polynomials* – list of polynomials in the coordinate ring of *self*.

**OUTPUT:**

- *subscheme of a toric variety*.

**EXAMPLES:**

We will construct a subscheme of the product of two projective lines with coordinates \((x, y)\) for one and \((s, t)\) for the other:

```
sage: PlxPl.<x,y,s,t> = toric_varieties.P1xP1()
sage: X = PlxPl.subscheme([x*s + y*t, x^3 + y^3])
sage: X
```

Closed subscheme of 2-d CPR-Fano toric variety covered by 4 affine patches defined by:

\[x*s + y*t, \quad x^3 + y^3\]

```
sage: X.defining_polynomials()
```

\((x*s + y*t, x^3 + y^3)\)

```
sage: X.defining_ideal()
```

Ideal \((x*s + y*t, x^3 + y^3)\)

of Multivariate Polynomial Ring in x, y, s, t over Rational Field

```
sage: X.base_ring()
```

Rational Field

```
sage: X.base_scheme()
```

Spectrum of Rational Field

```
sage: X.structure_morphism()
```

Scheme morphism:

- From: Closed subscheme of 2-d CPR-Fano toric variety covered by 4 affine patches defined by:

\[x*s + y*t, \quad x^3 + y^3\]

- To: Spectrum of Rational Field

  Defn: Structure map

---

**toric_divisor_group** *(base_ring=Integer Ring)*

Return the group of toric (T-Weil) divisors.

**INPUT:**

- *base_ring* – the coefficient ring, usually \(\mathbb{Z}\) (default) or \(\mathbb{Q}\).

**OUTPUT:**

The free Abelian group of toric Weil divisors, that is, formal \(\text{base\_ring}\)-linear combinations of codimension-one toric subvarieties. The output will be an instance of `sage.schemes.toric.divisor.ToricDivisorGroup`.

The \(i\)-th generator of the divisor group is the divisor where the \(i\)-th homogeneous coordinate vanishes, \(\{z_i = 0\}\).

---

16.1. Toric varieties 237
EXAMPLES:

```python
sage: dP6 = toric_varieties.dP6()
sage: TDiv = dP6.toric_divisor_group(); TDiv
Group of toric ZZ-Weil divisors on 2-d CPR-Fano toric variety
covered by 6 affine patches
sage: TDiv == dP6.toric_divisor_group()
True
sage: TDiv.gens()
(V(x), V(u), V(y), V(v), V(z), V(w))
sage: dP6.coordinate_ring()
Multivariate Polynomial Ring in x, u, y, v, z, w over Rational Field
```

`volume_class()`

Return the cohomology class of the volume form on the toric variety.

Note that we are using cohomology with compact supports. If the variety is non-compact this is dual
to homology without any support condition. In particular, for non-compact varieties the volume form
\(dVol = \bigwedge_i (dx_i \wedge dy_i)\) does not define a (non-zero) cohomology class.

**OUTPUT:**

A `CohomologyClass`. If it exists, it is the class of the (properly normalized) volume form, that is, it is
the Poincaré dual of a single point. If it does not exist, a `ValueError` is raised.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2.volume_class()
[z^2]
sage: A2_Z2 = toric_varieties.A2_Z2()
sage: A2_Z2.volume_class()
Traceback (most recent call last):
  ...
ValueError: Volume class does not exist.
```

If none of the maximal cones is smooth things get more tricky. In this case no torus-fixed point is smooth.
If we want to count an ordinary point as 1, then a \(G\)-orbifold point needs to count as \(\frac{1}{|\Gamma|}\). For example, take \(\mathbb{P}^1 \times \mathbb{P}^1\) inhomogeneous coordinates \((t, y)\). Take the quotient by the action \((t, y) \mapsto (-t, -y)\).
The \(\mathbb{Z}_2\)-invariant Weil divisors \(\{t = 0\}\) and \(\{y = 0\}\) intersect in a \(\mathbb{Z}_2\)-fixed point, so they ought to have intersection number \(\frac{1}{2}\). This means that the cohomology class \([t] \cap [y]\) should be \(\frac{1}{2}\) times the volume class.

Note that this is different from the volume normalization chosen in [Schubert]:

```python
sage: P1xP1_Z2 = toric_varieties.P1xP1_Z2()
sage: Dt = P1xP1_Z2.divisor(1); Dt
V(t)
sage: Dy = P1xP1_Z2.divisor(3); Dy
V(y)
sage: P1xP1_Z2.volume_class()
[2*t*y]
sage: HH = P1xP1_Z2.cohomology_ring()
sage: HH(Dt) * HH(Dy) == 1/2 * P1xP1_Z2.volume_class()
True
```

The fractional coefficients are also necessary to match the normalization in the rational Chow group for
simplicial toric varieties:
sage: A = P1xP1_22.Chow_group(QQ)
sage: A(Dt).intersection_with_divisor(Dy).count_points()
1/2

REFERENCES:

sage.schemes.toric.variety.is_CohomologyClass(x)

Check whether x is a cohomology class of a toric variety.

INPUT:

• x – anything.

OUTPUT:

True or False depending on whether x is an instance of CohomologyClass

EXAMPLES:

sage: P2 = toric_varieties.P2()
sage: HH = P2.cohomology_ring()
sage: from sage.schemes.toric.variety import is_CohomologyClass
sage: is_CohomologyClass( HH.one() )
True
sage: is_CohomologyClass( HH(P2.fan(1)[0]) )
True
sage: is_CohomologyClass('z')
False

sage.schemes.toric.variety.is_ToricVariety(x)

Check if x is a toric variety.

INPUT:

• x – anything.

OUTPUT:

• True if x is a toric variety and False otherwise.

Note: While projective spaces are toric varieties mathematically, they are not toric varieties in Sage due to efficiency considerations, so this function will return False.

EXAMPLES:

sage: from sage.schemes.toric.variety import is_ToricVariety
sage: is_ToricVariety(1)
False
sage: fan = FaceFan(lattice_polytope.cross_polytope(2))
sage: P = ToricVariety(fan)
2-d toric variety covered by 4 affine patches
sage: is_ToricVariety(P)
True
sage: is_ToricVariety(ProjectiveSpace(2))
False

sage.schemes.toric.variety.normalize_names(names=None, ngens=None, prefix=None, indices=None, return_prefix=False)

Return a list of names in the standard form.

16.1. Toric varieties
INPUT:

All input parameters are optional.

- names – names given either as a single string (with individual names separated by commas or spaces) or a list of strings with each string specifying a name. If the last name ends with the plus sign, “+”, this name will be used as prefix (even if prefix was given explicitly);
- ngens – number of names to be returned;
- prefix – prefix for the indexed names given as a string;
- indices – list of integers (default: range(ngens)) used as indices for names with prefix. If given, must be of length ngens;
- return_prefix – if True, the last element of the returned list will contain the prefix determined from names or given as the parameter prefix. This is useful if you may need more names in the future.

OUTPUT:

- list of names given as strings.

These names are constructed in the following way:

1. If necessary, split names into separate names.
2. If the last name ends with “+”, put it into prefix.
3. If ngens was given, add to the names obtained so far as many indexed names as necessary to get this number. If the k-th name of the total list of names is indexed, it is prefix + str(indices[k]). If there were already more names than ngens, discard “extra” ones.
4. Check if constructed names are valid. See certify_names() for details.
5. If the option return_prefix=True was given, add prefix to the end of the list.

EXAMPLES:

As promised, all parameters are optional:

```
sage: from sage.schemes.toric.variety import normalize_names
sage: normalize_names()
[]
```

One of the most common uses is probably this one:

```
sage: normalize_names("x+", 4)
['x0', 'x1', 'x2', 'x3']
```

Now suppose that you want to enumerate your variables starting with one instead of zero:

```
sage: normalize_names("x+", 4, indices=list(range(1,5)))
['x1', 'x2', 'x3', 'x4']
```

You may actually have an arbitrary enumeration scheme:

```
sage: normalize_names("x+", 4, indices=[1, 10, 100, 1000])
['x1', 'x10', 'x100', 'x1000']
```

Now let’s add some “explicit” names:

```
sage: normalize_names("x y z t+", 4)
['x', 'y', 'z', 't3']
```
Note that the “automatic” name is \(t3\) instead of \(t0\). This may seem weird, but the reason for this behaviour is that the fourth name in this list will be the same no matter how many explicit names were given:

```
sage: normalize_names("x y t+", 4)
['x', 'y', 't2', 't3']
```

This is especially useful if you get names from a user but want to specify all default names:

```
sage: normalize_names("x, y", 4, prefix="t")
['x', 'y', 't2', 't3']
```

In this format, the user can easily override your choice for automatic names:

```
sage: normalize_names("x y s+", 4, prefix="t")
['x', 'y', 's2', 's3']
```

Let’s now use all parameters at once:

```
sage: normalize_names("x, y, s+", 4, prefix="t",
....:    indices=list(range(1,5)), return_prefix=True)
['x', 'y', 's3', 's4', 's']
```

Note that you still need to give indices for all names, even if some of the first ones will be “wasted” because of the explicit names. The reason is the same as before - this ensures consistency of automatically generated names, no matter how many explicit names were given.

The prefix is discarded if \(ngens\) was not given:

```
sage: normalize_names("alpha, beta, gamma, zeta+")
['alpha', 'beta', 'gamma']
```

Finally, let’s take a look at some possible mistakes:

```
sage: normalize_names("123")
Traceback (most recent call last):
...
ValueError: variable name '123' does not start with a letter
```

A more subtle one:

```
sage: normalize_names("xl", 4, prefix="x")
Traceback (most recent call last):
...
ValueError: variable name 'xl' appears more than once
```

## 16.2 Fano toric varieties

This module provides support for (Crepant Partial Resolutions of) Fano toric varieties, corresponding to crepant subdivisions of face fans of reflexive lattice polytopes. The interface is provided via \(CPRFanoToricVariety()\).

A careful exposition of different flavours of Fano varieties can be found in the paper by Benjamin Nill [Nill2005]. The main goal of this module is to support work with Gorenstein weak Fano toric varieties. Such a variety corresponds to a coherent crepant refinement of the normal fan of a reflexive polytope \(\Delta\), where crepant means that primitive generators of the refining rays lie on the facets of the polar polytope \(\Delta^\circ\) and coherent (a.k.a. regular or projective) means that there exists a strictly upper convex piecewise linear function whose domains of linearity are precisely the

16.2. Fano toric varieties 241
maximal cones of the subdivision. These varieties are important for string theory in physics, as they serve as ambient spaces for mirror pairs of Calabi-Yau manifolds via constructions due to Victor V. Batyrev [Batyrev1994] and Lev A. Borisov [Borisov1993].

From the combinatorial point of view “crepant” requirement is much more simple and natural to work with than “coherent.” For this reason, the code in this module will allow work with arbitrary crepant subdivisions without checking whether they are coherent or not. We refer to corresponding toric varieties as **CPR-Fano toric varieties**.

REFERENCES:

AUTHORS:

EXAMPLES:

Most of the functions available for Fano toric varieties are the same as for general toric varieties, so here we will concentrate only on Calabi-Yau subvarieties, which were the primary goal for creating this module.

For our first example we realize the projective plane as a Fano toric variety:

```sage
sage: simplex = LatticePolytope([(1,0), (0,1), (-1,-1)])
sage: P2 = CPRFanoToricVariety(Delta_polar=simplex)
```

Its anticanonical “hypersurface” is a one-dimensional Calabi-Yau manifold:

```sage
sage: P2.anticanonical_hypersurface(
......:   monomial_points="all")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
   a0*z0^3 + a9*z0^2*z1 + a7*z0*z1^2
 + a1*z1^3 + a8*z0^2*z2 + a6*z0*z1*z2
 + a4*z1^2*z2 + a5*z0*z2^2
 + a3*z1*z2^2 + a2*z2^3
```

In many cases it is sufficient to work with the “simplified polynomial moduli space” of anticanonical hypersurfaces:

```sage
sage: P2.anticanonical_hypersurface(
......:   monomial_points="simplified")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
   a0*z0^3 + a1*z1^3 + a6*z0*z1*z2 + a2*z2^3
```

The mirror family to these hypersurfaces lives inside the Fano toric variety obtained using `simplex` as `Delta` instead of `Delta_polar`:

```sage
sage: FTV = CPRFanoToricVariety(Delta=simplex,
......:   coordinate_points="all")
sage: FTV.anticanonical_hypersurface(
......:   monomial_points="simplified")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 9 affine patches defined by:
   a2*z2^3*z3^2*z4*z5^2*z8
 + a1*z1^3*z3*z4^2*z7^2*z9
 + a3*z0*z1*z2*z3*z4*z5*z7*z8*z9
 + a0*z0^3*z5*z7*z8^2*z9^2
```

Here we have taken the resolved version of the ambient space for the mirror family, but in fact we don’t have to resolve singularities corresponding to the interior points of facets - they are singular points which do not lie on a generic anticanonical hypersurface:
This looks very similar to our second version of the anticanonical hypersurface of the projective plane, as expected, since all one-dimensional Calabi-Yau manifolds are elliptic curves!

Now let’s take a look at a toric realization of $M$-polarized K3 surfaces studied by Adrian Clingher and Charles F. Doran in \cite{CD2007}:

```
sage: p4318 = ReflexivePolytope(3, 4318)
sage: FTV = CPRFanoToricVariety(Delta_polar=p4318)
sage: FTV.anticanonical_hypersurface()  
Closed subscheme of 3-d CPR-Fano toric variety 
covered by 4 affine patches defined by:
    a0*z2^12 + a4*z2^6*z3^6 + a3*z3^12 
    + a8*z0*z1*z2*z3 + a2*z1^3 + a1*z0^2
```

Below you will find detailed descriptions of available functions. Current functionality of this module is very basic, but it is under active development and hopefully will improve in future releases of Sage. If there are some particular features that you would like to see implemented ASAP, please consider reporting them to the Sage Development Team or even implementing them on your own as a patch for inclusion!

```
class sage.schemes.toric.fano_variety.AnticanonicalHypersurface(P_Delta,  
    monomial_points=None,  
    coefficient_names=None,  
    coefficient_name_indices=None,  
    coefficients=None)  
Bases: sage.schemes.toric.toric_subscheme.AlgebraicScheme_subscheme_toric
```

Construct an anticanonical hypersurface of a CPR-Fano toric variety.

**INPUT:**

- **P_Delta** — CPR-Fano toric variety associated to a reflexive polytope $\Delta$;
- **see** CPRFanoToricVariety_field.anticanonical_hypersurface() for documentation on all other acceptable parameters.

**OUTPUT:**

- anticanonical hypersurface of $P\_\text{Delta}$ (with the extended base field, if necessary).

**EXAMPLES:**

```
sage: P1xP1 = toric_varieties.P1xP1()  
sage: import sage.schemes.toric.fano_variety as ftv  
sage: ftv.AnticanonicalHypersurface(P1xP1)  
Closed subscheme of 2-d CPR-Fano toric variety 
covered by 4 affine patches defined by:
    a0*s^2*x^2 + a3*t^2*x^2 + a6*s*t*x*y + a1*s^2*y^2 + a2*t^2*y^2
```
Construct a CPR-Fano toric variety.

Note: See documentation of the module \texttt{fano\_variety} for the used definitions and supported varieties.

Due to the large number of available options, it is recommended to always use keyword parameters.

INPUT:

• \texttt{Delta} – \texttt{reflexive lattice polytope}. The fan of the constructed CPR-Fano toric variety will be a crepant subdivision of the \textit{normal fan} of \texttt{Delta}. Either \texttt{Delta} or \texttt{Delta\_polar} must be given, but not both at the same time, since one is completely determined by another via \texttt{polar} method;

• \texttt{Delta\_polar} – \texttt{reflexive lattice polytope}. The fan of the constructed CPR-Fano toric variety will be a crepant subdivision of the \textit{face fan} of \texttt{Delta\_polar}. Either \texttt{Delta} or \texttt{Delta\_polar} must be given, but not both at the same time, since one is completely determined by another via \texttt{polar} method;

• \texttt{coordinate\_points} – list of integers or string. A list will be interpreted as indices of (boundary) points of \texttt{Delta\_polar} which should be used as rays of the underlying fan. It must include all vertices of \texttt{Delta\_polar} and no repetitions are allowed. A string must be one of the following descriptions of points of \texttt{Delta\_polar}:
  – “vertices” (default),
  – “all” (will not include the origin),
  – “all but facets” (will not include points in the relative interior of facets);

• \texttt{charts} – list of lists of elements from \texttt{coordinate\_points}. Each of these lists must define a generating cone of a fan subdividing the normal fan of \texttt{Delta}. Default \texttt{charts} correspond to the normal fan of \texttt{Delta} without subdivision. The fan specified by \texttt{charts} will be subdivided to include all of the requested \texttt{coordinate\_points};

• \texttt{coordinate\_names} – names of variables for the coordinate ring, see \texttt{normalize\_names()} for acceptable formats. If not given, indexed variable names will be created automatically;

• \texttt{names} – an alias of \texttt{coordinate\_names} for internal use. You may specify either \texttt{names} or \texttt{coordinate\_names}, but not both;

• \texttt{coordinate\_name\_indices} – list of integers, indices for indexed variables. If not given, the index of each variable will coincide with the index of the corresponding point of \texttt{Delta\_polar};

• \texttt{make\_simplicial} – if \texttt{True}, the underlying fan will be made simplicial (default: \texttt{False});

• \texttt{base\_ring} – base field of the CPR-Fano toric variety (default: \texttt{Q});

• \texttt{base\_field} – alias for \texttt{base\_ring}. Takes precedence if both are specified.
• check – by default the input data will be checked for correctness (e.g. that charts do form a subdivision of the normal fan of Delta). If you know for sure that the input is valid, you may significantly decrease construction time using check=False option.

OUTPUT:

• CPR-Fano toric variety.

EXAMPLES:

We start with the product of two projective lines:

```python
sage: diamond = lattice_polytope.cross_polytope(2)
sage: diamond.vertices()
M( 1, 0),
M( 0, 1),
M(-1, 0),
M( 0, -1)
in 2-d lattice M
sage: P1xP1 = CPRFanoToricVariety(Delta_polar=diamond)
sage: P1xP1
2-d CPR-Fano toric variety covered by 4 affine patches
sage: P1xP1.fan()
Rational polyhedral fan in 2-d lattice M
sage: P1xP1.fan().rays()
M( 1, 0),
M( 0, 1),
M(-1, 0),
M( 0, -1)
in 2-d lattice M
```

“Unfortunately,” this variety is smooth to start with and we cannot perform any subdivisions of the underlying fan without leaving the category of CPR-Fano toric varieties. Our next example starts with a square:

```python
sage: square = diamond.polar()
sage: square.vertices()
N( 1, 1),
N( 1, -1),
N(-1, -1),
N(-1, 1)
in 2-d lattice N
sage: square.points()
N( 1, 1),
N( 1, -1),
N(-1, -1),
N(-1, 1),
N( 0, 0),
N( 0, 1),
N( 0, -1),
in 2-d lattice N
```

We will construct several varieties associated to it:

```python
sage: FTV = CPRFanoToricVariety(Delta_polar=square)
sage: FTV.fan().rays()
N( 1, 1),
N( 1, -1),
```

(continues on next page)
N(-1, -1),
N(-1, 1)
in 2-d lattice N
sage: FTV.gens()
(z0, z1, z2, z3)

sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....: coordinate_points=[0, 1, 2, 3, 8])
sage: FTV.fan().rays()
N( 1, 1),
N( 1, -1),
N(-1, -1),
N(-1, 1),
N( 1, 0)
in 2-d lattice N
sage: FTV.gens()
(z0, z1, z2, z3, z8)

sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....: coordinate_points=[8, 0, 2, 1, 3],
.....: coordinate_names="x+")
sage: FTV.fan().rays()
N( 1, 0),
N( 1, 1),
N(-1, -1),
N( 1, -1),
N(-1, 1)
in 2-d lattice N
sage: FTV.gens()
(x8, x0, x2, x1, x3)

sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....: coordinate_points="all",
.....: coordinate_names="x y Z+")
sage: FTV.fan().rays()
N( 1, 1),
N( 1, -1),
N(-1, -1),
N(-1, 1),
N(-1, 0),
N( 0, -1),
N( 0, 1),
N( 1, 0)
in 2-d lattice N
sage: FTV.gens()
(x, y, Z2, Z3, Z4, Z5, Z7, Z8)

Note that Z6 is “missing”. This is due to the fact that the 6-th point of square is the origin, and all automatically created names have the same indices as corresponding points of Delta_polar(). This is usually very convenient, especially if you have to work with several partial resolutions of the same Fano toric variety. However, you can change it, if you want:

sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....: coordinate_points="all",
.....: coordinate_names="x y Z+",
.....: coordinate_name_indices=list(range(8)))

(continues on next page)
sage: FTV.gens()
(x, y, Z2, Z3, Z4, Z5, Z6, Z7)

Note that you have to provide indices for all variables, including those that have “completely custom” names. Again, this is usually convenient, because you can add or remove “custom” variables without disturbing too much “automatic” ones:

sage: FTV = CPRFanoToricVariety(Delta_polar=square, ....: coordinate_points="all",
....: coordinate_names="x 2+",
....: coordinate_name_indices=list(range(8)))
sage: FTV.gens()
(x, Z1, Z2, Z3, Z4, Z5, Z6, Z7)

If you prefer to always start from zero, you will have to shift indices accordingly:

sage: FTV = CPRFanoToricVariety(Delta_polar=square, ....: coordinate_points="all",
....: coordinate_names="x Z+",
....: coordinate_name_indices=[0] + list(range(7)))
sage: FTV.gens()
(x, Z0, Z1, Z2, Z3, Z4, Z5, Z6)

sage: FTV = CPRFanoToricVariety(Delta_polar=square, ....: coordinate_points="all",
....: coordinate_names="x y Z+",
....: coordinate_name_indices=[0]*2 + list(range(6)))
sage: FTV.gens()
(x, y, Z0, Z1, Z2, Z3, Z4, Z5)

So you always can get any names you want, somewhat complicated default behaviour was designed with the hope that in most cases you will have no desire to provide different names.

Now we will use the possibility to specify initial charts:

sage: charts = [(0,1), (1,2), (2,3), (3,0)]

(these charts actually form exactly the face fan of our square)

sage: FTV = CPRFanoToricVariety(Delta_polar=square, ....: coordinate_points=[0,1,2,3,4],
....: charts=charts)
sage: FTV.fan().rays()
N( 1, 1),
N( 1, -1),
N(-1, -1),
N(-1, 1),
N(-1, 0)
in 2-d lattice N
sage: [cone.ambient_ray_indices() for cone in FTV.fan()]
[(0, 1), (1, 2), (3, 4), (2, 4), (0, 3)]

If charts are wrong, it should be detected:

sage: bad_charts = charts + [(3,0)]
sage: FTV = CPRFanoToricVariety(Delta_polar=square,
These charts are technically correct, they just happened to list one of them twice, but it is assumed that such a situation will not happen. It is especially important when you try to speed up your code:

```
sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....:     coordinate_points=[0,1,2,3,4],
.....:     charts=bad_charts,
.....:     check=False)
Traceback (most recent call last):
... IndexError: list assignment index out of range
```

In this case you still get an error message, but it is harder to figure out what is going on. It may also happen that "everything will still work" in the sense of not crashing, but work with such an invalid variety may lead to mathematically wrong results, so use check=False carefully!

Here are some other possible mistakes:

```
sage: bad_charts = charts + [(0,2)]
sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....:     coordinate_points=[0,1,2,3,4],
.....:     charts=bad_charts)
Traceback (most recent call last):
... ValueError: (0, 2) does not form a chart of a subdivision of
the face fan of 2-d reflexive polytope #14 in 2-d lattice N!
```

```
sage: bad_charts = charts[:-1]
sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....:     coordinate_points=[0,1,2,3,4],
.....:     charts=bad_charts)
Traceback (most recent call last):
... ValueError: given charts do not form a complete fan!
```

```
sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....:     coordinate_points=[1,2,3,4])
Traceback (most recent call last):
... ValueError: all 4 vertices of Delta_polar
must be used for coordinates!
Got: [1, 2, 3, 4]
```

```
sage: FTV = CPRFanoToricVariety(Delta_polar=square,
.....:     coordinate_points=[0,0,1,2,3,4])
Traceback (most recent call last):
... ValueError: no repetitions are
allowed for coordinate points!
Got: [0, 0, 1, 2, 3, 4]
```
Here is a shorthand for defining the toric variety and homogeneous coordinates in one go:

```python
sage: P1xP1.<a,b,c,d> = CPRFanoToricVariety(Delta_polar=diamond)
sage: (a^2+b^2) * (c+d)
a^2*c + b^2*c + a^2*d + b^2*d
```

### class `sage.schemes.toric.fano_variety.CPRFanoToricVariety_field`

Construct a CPR-Fano toric variety associated to a reflexive polytope.

**Warning:** This class does not perform any checks of correctness of input and it does assume that the internal structure of the given parameters is coordinated in a certain way. Use `CPRFanoToricVariety()` to construct CPR-Fano toric varieties.

**Note:** See documentation of the module `fano_variety` for the used definitions and supported varieties.

**INPUT:**
- `Delta_polar` - reflexive polytope;
- `fan` - rational polyhedral fan subdividing the face fan of `Delta_polar`;
- `coordinate_points` - list of indices of points of `Delta_polar` used for rays of `fan`;
- `point_to_ray` - dictionary mapping the index of a coordinate point to the index of the corresponding ray;
- `coordinate_names` - names of the variables of the coordinate ring in the format accepted by `normalize_names()`;
- `coordinate_name_indices` - indices for indexed variables, if `None`, will be equal to `coordinate_points`;
- `base_field` - base field of the CPR-Fano toric variety.

**OUTPUT:**
- CPR-Fano toric variety.
Delta()

Return the reflexive polytope associated to self.

OUTPUT:

• reflexive lattice polytope. The underlying fan of self is a coherent subdivision of the normal fan of this polytope.

EXAMPLES:

```python
sage: diamond = lattice_polytope.cross_polytope(2)
sage: P1xP1 = CPRFanoToricVariety(Delta_polar=diamond)
sage: P1xP1.Delta()
2-d reflexive polytope #14 in 2-d lattice N
sage: P1xP1.Delta() is diamond.polar()
True
```

Delta_polar()

Return polar of Delta().

OUTPUT:

• reflexive lattice polytope. The underlying fan of self is a coherent subdivision of the face fan of this polytope.

EXAMPLES:

```python
sage: diamond = lattice_polytope.cross_polytope(2)
sage: P1xP1 = CPRFanoToricVariety(Delta_polar=diamond)
sage: P1xP1.Delta_polar()
2-d reflexive polytope #3 in 2-d lattice M
sage: P1xP1.Delta_polar() is diamond
True
sage: P1xP1.Delta_polar() is P1xP1.Delta().polar()
True
```

anticanonical_hypersurface(**kwds)

Return an anticanonical hypersurface of self.

Note: The returned hypersurface may be actually a subscheme of another CPR-Fano toric variety: if the base field of self does not include all of the required names for generic monomial coefficients, it will be automatically extended.

Below $\Delta$ is the reflexive polytope corresponding to self, i.e. the fan of self is a refinement of the normal fan of $\Delta$. This function accepts only keyword parameters.

INPUT:

• monomial points – a list of integers or a string. A list will be interpreted as indices of points of $\Delta$ which should be used for monomials of this hypersurface. A string must be one of the following descriptions of points of $\Delta$:
  – “vertices”,
  – “vertices+origin”,
  – “all”,
  – “simplified” (default) – all points of $\Delta$ except for the interior points of facets, this choice corresponds to working with the “simplified polynomial moduli space” of anticanonical hypersurfaces;

250 Chapter 16. Toric Varieties
• `coefficient_names` – names for the monomial coefficients, see `normalize_names()` for acceptable formats. If not given, indexed coefficient names will be created automatically;

• `coefficient_name_indices` – a list of integers, indices for indexed coefficients. If not given, the index of each coefficient will coincide with the index of the corresponding point of $\Delta$;

• `coefficients` – as an alternative to specifying coefficient names and/or indices, you can give the coefficients themselves as arbitrary expressions and/or strings. Using strings allows you to easily add “parameters”: the base field of `self` will be extended to include all necessary names.

OUTPUT:

• an anticanonical hypersurface of `self` (with the extended base field, if necessary).

EXAMPLES:

We realize the projective plane as a Fano toric variety:

```sage```
```python
sage: simplex = LatticePolytope([(1,0), (0,1), (-1,-1)])
sage: P2 = CPRFanoToricVariety(Delta_polar=simplex)
```

Its anticanonical “hypersurface” is a one-dimensional Calabi-Yau manifold:

```sage```
```python
sage: P2.anticanonical_hypersurface(  ....: monomial_points="all")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
  a0*z0^3 + a9*z0^2*z1 + a7*z0*z1^2
+ a1*z1^3 + a8*z0^2*z2 + a6*z0*z1*z2
+ a4*z1^2*z2 + a5*z0*z2^2
+ a3*z1*z2^2 + a2*z2^3
```

In many cases it is sufficient to work with the “simplified polynomial moduli space” of anticanonical hypersurfaces:

```sage```
```python
sage: P2.anticanonical_hypersurface(  ....: monomial_points="simplified")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
  a0*z0^3 + a1*z1^3 + a6*z0*z1*z2 + a2*z2^3
```

The mirror family to these hypersurfaces lives inside the Fano toric variety obtained using `simplex` as `Delta` instead of `Delta_polar`:

```sage```
```python
sage: FTV = CPRFanoToricVariety(Delta=simplex,  ....: coordinate_points="all")
sage: FTV.anticanonical_hypersurface(  ....: monomial_points="simplified")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 9 affine patches defined by:
  a2*z2^3*z3^2*z4*z5^2*z8
+ a1*z1^3*z3*z4^2*z7^2*z9
+ a3*z0*z1*z2*z3*z4*z5*z7*z8*z9
+ a0*z0^3*z5*z7*z8^2*z9^2
```

Here we have taken the resolved version of the ambient space for the mirror family, but in fact we don’t have to resolve singularities corresponding to the interior points of facets - they are singular points which do not lie on a generic anticanonical hypersurface:

`16.2. Fano toric varieties 251`
sage: FTV = CPRFanoToricVariety(Delta=simplex,
....:    coordinate_points="all but facets")
sage: FTV.anticanonical_hypersurface(
....:    monomial_points="simplified")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
a0*z0^3 + a1*z1^3 + a3*z0*z1*z2 + a2*z2^3

This looks very similar to our second anticanonical hypersurface of the projective plane, as expected, since all one-dimensional Calabi-Yau manifolds are elliptic curves!

All anticanonical hypersurfaces constructed above were generic with automatically generated coefficients. If you want, you can specify your own names

sage: FTV.anticanonical_hypersurface(
....:    coefficient_names="a b c d")
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
a*z0^3 + b*z1^3 + d*z0*z1*z2 + c*z2^3

or give concrete coefficients

sage: FTV.anticanonical_hypersurface(
....:    coefficients=[1, 2, 3, 4])
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
z0^3 + 2*z1^3 + 4*z0*z1*z2 + 3*z2^3

or even mix numerical coefficients with some expressions

sage: H = FTV.anticanonical_hypersurface(
....:    coefficients=[0, "t", "1/t", "psi/(psi^2 + phi)"])
sage: H
Closed subscheme of 2-d CPR-Fano toric variety
covered by 3 affine patches defined by:
t*z1^3 + (psi/(psi^2 + phi))*z0*z1*z2 + 1/t*z2^3
sage: R = H.ambient_space().base_ring()
sage: R
Fraction Field of
Multivariate Polynomial Ring in phi, psi, t
over Rational Field

cartesian_product (other, coordinate_names=None, coordinate_indices=None)

Return the Cartesian product of self with other.

INPUT:

• other – a (possibly CPR-Fano) toric variety;

• coordinate_names – names of variables for the coordinate ring, see normalize_names() for acceptable formats. If not given, indexed variable names will be created automatically;

• coordinate_indices – list of integers, indices for indexed variables. If not given, the index of each variable will coincide with the index of the corresponding ray of the fan.

OUTPUT:

• a toric variety, which is CPR-Fano if other was.

EXAMPLES:
sage: P1 = toric_varieties.P1()
sage: P2 = toric_varieties.P2()
sage: P1xP2 = P1.cartesian_product(P2); P1xP2
3-d CPR-Fano toric variety covered by 6 affine patches
sage: P1xP2.fan().rays()
N+N( 1, 0, 0),
N+N(-1, 0, 0),
N+N( 0, 1, 0),
N+N( 0, 0, 1),
N+N( 0, -1, -1)
in 3-d lattice N+N
sage: P1xP2.Delta_polar()
3-d reflexive polytope in 3-d lattice N+N

change_ring\((F)\)

Return a CPR-Fano toric variety over field \(F\), otherwise the same as \(self\).

INPUT:

- \(F\) – field.

OUTPUT:

- CPR-Fano toric variety over \(F\).

Note: There is no need to have any relation between \(F\) and the base field of \(self\). If you do want to have such a relation, use base_extend() instead.

EXAMPLES:

sage: P1xP1 = toric_varieties.P1xP1()
sage: P1xP1.base_ring()
Rational Field
sage: P1xP1.RR = P1xP1.change_ring(RR)
sage: P1xP1.RR.base_ring()
Real Field with 53 bits of precision
sage: P1xP1.QQ = P1xP1.RR.change_ring(QQ)
sage: P1xP1.QQ.base_ring()
Rational Field
sage: P1xP1.RR.base_extend(QQ)
Traceback (most recent call last):
... ValueError: no natural map from the base ring (=Rational Field) to R (=Rational Field)!
sage: R = PolynomialRing(QQ, 2, 'a')
sage: P1xP1.change_ring(R)
Traceback (most recent call last):
...
TypeError: need a field to construct a Fano toric variety!
Got Multivariate Polynomial Ring in a0, a1 over Rational Field

coordinate_point_to_coordinate\((point)\)

Return the variable of the coordinate ring corresponding to \(point\).

INPUT:

- \(point\) – integer from the list of coordinate_points().
OUTPUT:

• the corresponding generator of the coordinate ring of self.

EXAMPLES:

```
sage: diamond = lattice_polytope.cross_polytope(2)
sage: FTV = CPRFanoToricVariety(diamond,  
.....:     coordinate_points=[0,1,2,3,8])
sage: FTV.coordinate_points()  
(0, 1, 2, 3, 8)
sage: FTV.gens()  
(z0, z1, z2, z3, z8)
sage: FTV.coordinate_point_to_coordinate(8)  
z8
```

**coordinate_points()**

Return indices of points of $\Delta_{polar}$ used for coordinates.

OUTPUT:

• tuple of integers.

EXAMPLES:

```
sage: diamond = lattice_polytope.cross_polytope(2)
sage: square = diamond.polar()
sage: FTV = CPRFanoToricVariety(Delta_polar=square,  
.....:     coordinate_points=[0,1,2,3,8])
sage: FTV.coordinate_points()  
(0, 1, 2, 3, 8)
sage: FTV.gens()  
(z0, z1, z2, z3, z8)
sage: FTV = CPRFanoToricVariety(Delta_polar=square,  
.....:     coordinate_points="all")
sage: FTV.coordinate_points()  
(0, 1, 2, 3, 4, 5, 7, 8)
sage: FTV.gens()  
(z0, z1, z2, z3, z4, z5, z7, z8)
```

Note that one point is missing, namely

```
sage: square.origin()  
6
```

**nef_complete_intersection**(nef_partition, **kwds)**

Return a nef complete intersection in self.

**Note:** The returned complete intersection may be actually a subscheme of another CPR-Fano toric variety: if the base field of self does not include all of the required names for monomial coefficients, it will be automatically extended.

Below $\Delta$ is the reflexive polytope corresponding to self, i.e. the fan of self is a refinement of the normal fan of $\Delta$. Other polytopes are described in the documentation of nef-partitions of reflexive polytopes.

Except for the first argument, nef_partition, this method accepts only keyword parameters.
INPUT:

- **nef_partition** – a $k$-part nef-division of $\Delta^\circ$, all other parameters (if given) must be lists of length $k$;

- **monomial_points** – the $i$-th element of this list is either a list of integers or a string. A list will be interpreted as indices of points of $\Delta_i$ which should be used for monomials of the $i$-th polynomial of this complete intersection. A string must be one of the following descriptions of points of $\Delta_i$:
  - “vertices”,
  - “vertices+origin”,
  - “all” (default),

when using this description, it is also OK to pass a single string as `monomial_points` instead of repeating it $k$ times;

- **coefficient_names** – the $i$-th element of this list specifies names for the monomial coefficients of the $i$-th polynomial, see `normalize_names()` for acceptable formats. If not given, indexed coefficient names will be created automatically;

- **coefficient_name_indices** – the $i$-th element of this list specifies indices for indexed coefficients of the $i$-th polynomial. If not given, the index of each coefficient will coincide with the index of the corresponding point of $\Delta_i$;

- **coefficients** – as an alternative to specifying coefficient names and/or indices, you can give the coefficients themselves as arbitrary expressions and/or strings. Using strings allows you to easily add “parameters”: the base field of `self` will be extended to include all necessary names.

OUTPUT:

- a nef complete intersection of `self` (with the extended base field, if necessary).

EXAMPLES:

We construct several complete intersections associated to the same nef-partition of the 3-dimensional reflexive polytope #2254:

```
sage: p = ReflexivePolytope(3, 2254)
sage: np = p.nef_partitions()[1]
sage: np
Nef-partition {2, 3, 4, 7, 8} U {0, 1, 5, 6}
sage: X = CPRFanoToricVariety(Delta_polar=p)
sage: X.nef_complete_intersection(np)
Closed subscheme of 3-d CPR-Fano toric variety
covered by 10 affine patches defined by:
a0*z1*z4^2*z5^2*z7^3 + a2*z2*z4*z5*z6*z7^2*z8^2 + a3*z2*z3*z4*z7*z8 + a1*z0*z2,
b3*z1*z4*z5^2*z6^2*z7^2*z8^2 + b0*z2*z5*z6^3*z7*z8^4 + b2*z2*z3*z6^2*z8^3 + b1*z1*z3^2*z4 + b4*z0*z1*z5*z6
```

Now we include only monomials associated to vertices of $\Delta_i$:

```
sage: X.nef_complete_intersection(np, monomial_points="vertices")
Closed subscheme of 3-d CPR-Fano toric variety
covered by 10 affine patches defined by:
a0*z1*z4^2*z5^2*z7^3 + a2*z2*z4*z5*z6*z7^2*z8^2 + a3*z2*z3*z4*z7*z8 + a1*z0*z2,
b3*z1*z4*z5^2*z6^2*z7^2*z8^2 + b0*z2*z5*z6^3*z7*z8^4 + b2*z2*z3*z6^2*z8^3 + b1*z1*z3^2*z4 + b4*z0*z1*z5*z6
```

16.2. Fano toric varieties  255
(effectively, we set $b_5=0$). Next we provide coefficients explicitly instead of using default generic names:

```python
sage: X.nef_complete_intersection(np,
.....: monomial_points="vertices",
.....: coefficients=[("a", "a^2", "a/e", "c_i"), list(range(1,6))])
Closed subscheme of 3-d CPR-Fano toric variety
covered by 10 affine patches defined by:
  a*z1*z4^2*z5^2*z7^3 + a/e*z2*z5*z6*z7^2*z8^2
  + c_i*z2*z3*z4*z7*z8 + a^2*z0*z2,
  4*z1*z4*z5^2*z6^2*z7^2*z8^2 + z2*z5*z6^3*z7*z8^4
  + 3*z2*z3*z6^2*z8^3 + 2*z1*z3^2*z4 + 5*z0*z1*z5*z6
```

Finally, we take a look at the generic representative of these complete intersections in a completely resolved ambient toric variety:

```python
sage: X = CPRFanoToricVariety(Delta_polar=p,
.....: coordinate_points="all")
```

```python
sage: X.nef_complete_intersection(np)
Closed subscheme of 3-d CPR-Fano toric variety
covered by 22 affine patches defined by:
  a2*z2*z4*z5*z6*z7^2*z8^2*z9^2*z10^2*z11*z12 +
  a0*z1*z4^2*z5^2*z7^3*z9^2*z10^2*z12 +
  a3*z2*z3*z4*z7*z8*z9*z10*z11 + a1*z0 + z2,
  b0*z2*z5*z6*z7*z8^4*z9^3*z10^2*z11^2*z12 +
  b3*z1*z4*z5^2*z6^2*z7^2*z8^2*z9^2*z10^2*z11^2*z13 +
  b2*z2*z3*z6^2*z8^3*z9^2*z10*z11*z12 +
  b5*z1*z3*z4*z5*z6*z7*z8*z9*z10*z11*z12 +
  b1*z1*z3^2*z4*z11 + b4*z0 + z1*z5*z6 + z13
```

`resolve(**kwds)`

Construct a toric variety whose fan subdivides the fan of `self`.

This function accepts only keyword arguments, none of which are mandatory.

**INPUT:**

- `new_points` – list of integers, indices of boundary points of `Delta_polar()`, which should be added as rays to the subdividing fan;
- all other arguments will be passed to `resolve()` method of (general) toric varieties, see its documentation for details.

**OUTPUT:**

- CPR-Fano toric variety if there was no `new_rays` argument and toric variety otherwise.

**EXAMPLES:**

```python
sage: diamond = lattice_polytope.cross_polytope(2)
sage: FTV = CPRFanoToricVariety(Delta=diamond)
sage: FTV.coordinate_points()
(0, 1, 2, 3)
sage: FTV.gens()
(z0, z1, z2, z3)
sage: FTV_res = FTV.resolve(new_points=[6, 8])
Traceback (most recent call last):
  ...
ValueError: the origin (point #6) cannot be used for subdivision!
```

(continues on next page)
sage: FTV_res = FTV.resolve(new_points=[8,5])
sage: FTV_res
2-d CPR-Fano toric variety covered by 6 affine patches
sage: FTV_res.coordinate_points()
(0, 1, 2, 3, 8, 5)
sage: FTV_res.gens()
(z0, z1, z2, z3, z8, z5)

sage: TV_res = FTV.resolve(new_rays=[(1,2)])
sage: TV_res
2-d toric variety covered by 5 affine patches
sage: TV_res.gens()
(z0, z1, z2, z3, z4)

class sage.schemes.toric.fano_variety.NefCompleteIntersection(P_Delta, nef_partition, monomial_points='all', coefficient_names=None, coefficient_name_indices=None, coefficients=None)

Bases: sage.schemes.toric.toric_subscheme.AlgebraicScheme_subscheme_toric

Construct a nef complete intersection in a CPR-Fano toric variety.

INPUT:

• P_Delta — a CPR-Fano toric variety associated to a reflexive polytope ∆;
• see CPRFanoToricVariety_field.nef_complete_intersection() for documentation on all other acceptable parameters.

OUTPUT:

• a nef complete intersection of P_Delta (with the extended base field, if necessary).

EXAMPLES:

sage: o = lattice_polytope.cross_polytope(3)
sage: np = o.nef_partitions()[0]
sage: np
Nef-partition {0, 1, 3} U {2, 4, 5}
sage: X = CPRFanoToricVariety(Delta_polar=o)
sage: X.nef_complete_intersection(np)
Closed subscheme of 3-d CPR-Fano toric variety covered by 8 affine patches defined by:
a2*z0^2*z1 + a5*z0*z1*z3 + a1*z1*z3^2 + a3*z0^2*z4 + a4*z0*z3*z4 + a0*z3^2*z4,
b1*z1*z2^2 + b2*z2^2*z4 + b5*z1*z2*z5 + b4*z2*z4*z5 + b3*z1*z5^2 + b0*z4*z5^2

See CPRFanoToricVariety_field.nef_complete_intersection() for a more elaborate example.

cohomology_class()

Return the class of self in the ambient space cohomology ring.

16.2. Fano toric varieties
OUTPUT:

- a cohomology class.

EXAMPLES:

```python
sage: o = lattice_polytope.cross_polytope(3)
sage: np = o.nef_partitions()[0]
sage: np
Nef-partition {0, 1, 3} U {2, 4, 5}
sage: X = CPRFanoToricVariety(Delta_polar=o)
sage: CI = X.nef_complete_intersection(np)
sage: CI
Closed subscheme of 3-d CPR-Fano toric variety covered by 8 affine patches defined by:
  a2*z0^2*z1 + a5*z0*z1*z3 + a1*z1*z3^2
  + a3*z0^2*z4 + a4*z0*z3*z4 + a0*z3^2*z4,
  b1*z1*z2^2 + b2*z2^2*z4 + b5*z1*z2*z5
  + b4*z2*z4*z5 + b3*z1*z5^2 + b0*z4*z5^2
sage: CI.cohomology_class()
[2*z3*z4 + 4*z3*z5 + 2*z4*z5]
```

**nef_partition()**

Return the nef-partition associated to self.

OUTPUT:

- a nef-partition.

EXAMPLES:

```python
sage: o = lattice_polytope.cross_polytope(3)
sage: np = o.nef_partitions()[0]
sage: np
Nef-partition {0, 1, 3} U {2, 4, 5}
sage: X = CPRFanoToricVariety(Delta_polar=o)
sage: CI = X.nef_complete_intersection(np)
sage: CI
Closed subscheme of 3-d CPR-Fano toric variety covered by 8 affine patches defined by:
  a2*z0^2*z1 + a5*z0*z1*z3 + a1*z1*z3^2
  + a3*z0^2*z4 + a4*z0*z3*z4 + a0*z3^2*z4,
  b1*z1*z2^2 + b2*z2^2*z4 + b5*z1*z2*z5
  + b4*z2*z4*z5 + b3*z1*z5^2 + b0*z4*z5^2
sage: CI.nef_partition()
Nef-partition {0, 1, 3} U {2, 4, 5}
sage: CI.nef_partition() is np
True
```

**sage.schemes.toric.fano_variety.add_variables(field, variables)**

Extend field to include all variables.

INPUT:

- field - a field;
- variables - a list of strings.

OUTPUT:

- a fraction field extending the original field, which has all variables among its generators.
EXAMPLES:

We start with the rational field and slowly add more variables:

`````````````````````````````
sage: from sage.schemes.toric.fano_variety import *
sage: F = add_variables(QQ, []); F  # No extension
Rational Field
sage: F = add_variables(QQ, ["a"]); F
Fraction Field of Univariate Polynomial Ring
in a over Rational Field
sage: F = add_variables(F, ["a"]); F
Fraction Field of Univariate Polynomial Ring
in a over Rational Field
sage: F = add_variables(F, ["b", "c"]); F
Fraction Field of Multivariate Polynomial Ring
in a, b, c over Rational Field
sage: F = add_variables(F, ["c", "d", "b", "c", "d"]); F
Fraction Field of Multivariate Polynomial Ring
in a, b, c, d over Rational Field
`````````````````````````````
`````````````````````````````

sage.schemes.toric.fano_variety.is_CPRFanoToricVariety(x)
Check if x is a CPR-Fano toric variety.

INPUT:

• x – anything.

OUTPUT:

• True if x is a CPR-Fano toric variety and False otherwise.

Note: While projective spaces are Fano toric varieties mathematically, they are not toric varieties in Sage due to efficiency considerations, so this function will return False.

EXAMPLES:

`````````````````````````````
sage: from sage.schemes.toric.fano_variety import is_CPRFanoToricVariety
sage: is_CPRFanoToricVariety(1)
False
sage: FTV = toric_varieties.P2()
sage: is_CPRFanoToricVariety(FTV)
True
sage: is_CPRFanoToricVariety(ProjectiveSpace(2))
False
`````````````````````````````
`````````````````````````````

16.3 Library of toric varieties

This module provides a simple way to construct often-used toric varieties. Please see the help for the individual methods of toric_varieties for a more detailed description of which varieties can be constructed.

AUTHORS:

• Volker Braun (2010-07-02): initial version
EXAMPLES:

```
sage: toric_varieties.dP6()
2-d CPR-Fano toric variety covered by 6 affine patches
```

You can assign the homogeneous coordinates to Sage variables either with `inject_variables()` or immediately during assignment like this:

```
sage: P2.<x,y,z> = toric_varieties.P2()
sage: x^2 + y^2 + z^2
x^2 + y^2 + z^2
sage: P2.coordinate_ring()
Multivariate Polynomial Ring in x, y, z over Rational Field
```

class sage.schemes.toric.library.ToricVarietyFactory
Bases: sage.structure.sage_object.SageObject

The methods of this class construct toric varieties.

**Warning:** You need not create instances of this class. Use the already-provided object `toric_varieties` instead.

A\((n, \text{name}=\text{'z+'}, \text{base_ring}=\text{Rational Field})\)
Construct the \(n\)-dimensional affine space.

**INPUT:**
- \(n\) – positive integer. The dimension of the affine space.
- \(\text{name}\) – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- \(\text{base_ring}\) – a ring (default: \(\text{Q}\)). The base ring for the toric variety.

**OUTPUT:**
A toric variety.

**EXAMPLES:**

```
sage: A3 = toric_varieties.A(3)
sage: A3
3-d affine toric variety
sage: A3.fan().rays()
N(1, 0, 0),
N(0, 1, 0),
N(0, 0, 1)
in 3-d lattice N
sage: A3.gens()
(z0, z1, z2)
```

A1\((\text{name}=\text{'z'}, \text{base_ring}=\text{Rational Field})\)
Construct the affine line \(A^1\) as a toric variety.

**INPUT:**
- \(\text{name}\) – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- \(\text{base_ring}\) – a ring (default: \(\text{Q}\)). The base ring for the toric variety.
OUTPUT:

A toric variety.

EXAMPLES:

```sage
sage: A1 = toric_varieties.A1()
sage: A1
1-d affine toric variety
sage: A1.fan().rays()
N(1)
in 1-d lattice N
sage: A1.gens()
(z,)
```

A2 (names='x y', base_ring=Rational Field)

Construct the affine plane $\mathbb{A}^2$ as a toric variety.

INPUT:

- `names` - string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- `base_ring` - a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

OUTPUT:

A toric variety.

EXAMPLES:

```sage
sage: A2 = toric_varieties.A2()
sage: A2
2-d affine toric variety
sage: A2.fan().rays()
N(1, 0),
N(0, 1)
in 2-d lattice N
sage: A2.gens()
(x, y)
```

A2_Z2 (names='x y', base_ring=Rational Field)

Construct the orbifold $\mathbb{A}^2/\mathbb{Z}_2$ as a toric variety.

INPUT:

- `names` - string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- `base_ring` - a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

OUTPUT:

A toric variety.

EXAMPLES:

```sage
sage: A2_Z2 = toric_varieties.A2_Z2()
sage: A2_Z2
2-d affine toric variety
sage: A2_Z2.fan().rays()
N(1, 0),
N(1, 2)
```
in 2-d lattice N
\texttt{sage}: A2_Z2.gens()
(x, y)

\textbf{BCdlOG} (\texttt{names}='v1 v2 c1 c2 v4 v5 b e1 e2 e3 f g v6', \texttt{base_ring}=\texttt{Rational Field})
Construct the 5-dimensional toric variety studied in \cite{BCdlOG}, \cite{HLY2002}

\textbf{INPUT}:

\begin{itemize}
  \item \texttt{names} – string. Names for the homogeneous coordinates. See \texttt{normalize_names()} for acceptable formats.
  \item \texttt{base_ring} – a ring (default: \texttt{Q}). The base ring for the toric variety.
\end{itemize}

\textbf{OUTPUT}:

A \textit{CPR-Fano toric variety}.

\textbf{EXAMPLES}:

\begin{verbatim}
\texttt{sage}: X = toric_varieties.BCdlOG()
\texttt{sage}: X
5-d CPR-Fano toric variety covered by 54 affine patches
\texttt{sage}: X.fan().rays()
N(-1, 0, 0, 2, 3),
N( 0, -1, 0, 2, 3),
N( 0, 0, -1, 2, 3),
N( 0, 0, -1, 1, 2),
N( 0, 0, 0, -1, 0),
N( 0, 0, 0, 0, -1),
N( 0, 0, 0, 2, 3),
N( 0, 0, 1, 2, 3),
N( 0, 0, 2, 2, 3),
N( 0, 0, 1, 1, 1),
N( 0, 1, 2, 2, 3),
N( 0, 1, 3, 2, 3),
N( 1, 0, 4, 2, 3)
in 5-d lattice N
\texttt{sage}: X.gens()
(v1, v2, c1, c2, v4, v5, b, el, e2, e3, f, g, v6)
\end{verbatim}

\textbf{REFERENCES}:

\begin{itemize}
  \item \cite{HLY2002}
\end{itemize}

\textbf{BCdlOG_base} (\texttt{names}='d4 d3 r2 r1 d2 u dl', \texttt{base_ring}=\texttt{Rational Field})
Construct the base of the $\mathbb{P}^2(1, 2, 3)$ fibration \texttt{BCdlOG()}.

\textbf{INPUT}:

\begin{itemize}
  \item \texttt{names} – string. Names for the homogeneous coordinates. See \texttt{normalize_names()} for acceptable formats.
  \item \texttt{base_ring} – a ring (default: \texttt{Q}). The base ring for the toric variety.
\end{itemize}

\textbf{OUTPUT}:

A \textit{toric variety}.

\textbf{EXAMPLES}:
sage: base = toric_varieties.BCdlOG_base()
sage: base
3-d toric variety covered by 10 affine patches
sage: base.fan().rays()
N(-1, 0, 0),
N( 0, -1, 0),
N( 0, 0, -1),
N( 0, 0, 1),
N( 0, 1, 2),
N( 0, 1, 3),
N( 1, 0, 4)
in 3-d lattice N
sage: base.gens()
(d4, d3, r2, r1, d2, u, d1)

Conifold (names='u x y v', base_ring=Rational Field)
Construct the conifold as a toric variety.

INPUT:

• names – string. Names for the homogeneous coordinates. See \texttt{normalize_names()} for acceptable formats.

• base_ring – a ring (default: \texttt{Q}). The base ring for the toric variety.

OUTPUT:

A toric variety.

EXAMPLES:

sage: Conifold = toric_varieties.Conifold()
sage: Conifold
3-d affine toric variety
sage: Conifold.fan().rays()
N(0, 0, 1),
N(0, 1, 1),
N(1, 0, 1),
N(1, 1, 1)
in 3-d lattice N
sage: Conifold.gens()
(u, x, y, v)

Cube_deformation (k, names=None, base_ring=Rational Field)
Construct, for each $k \in \mathbb{Z}_{\geq 0}$, a toric variety with $\mathbb{Z}_k$-torsion in the Chow group.

The fans of this sequence of toric varieties all equal the face fan of a unit cube topologically, but the $(1,1,1)$-vertex is moved to $(1,1,2k+1)$. This example was studied in \cite{FS}.

INPUT:

• $k$ – integer. The case $k=0$ is the same as \texttt{Cube_face_fan()}.  

• names – string. Names for the homogeneous coordinates. See \texttt{normalize_names()} for acceptable formats.

• base_ring – a ring (default: \texttt{Q}). The base ring for the toric variety.

OUTPUT:

A toric variety $X_k$. Its Chow group is $A_1(X_k) = \mathbb{Z}_k$.

EXAMPLES:
sage: X_2 = toric_varieties.Cube_deformation(2)
sage: X_2
3-d toric variety covered by 6 affine patches
sage: X_2.fan().rays()
N( 1, 1, 5),
N( 1, -1, 1),
N(-1, 1, 1),
N(-1, -1, 1),
N(-1, -1, -1),
N(-1, 1, -1),
N( 1, -1, -1),
N( 1, 1, -1)
in 3-d lattice N
sage: X_2.gens()
(z0, z1, z2, z3, z4, z5, z6, z7)

REFERENCES:

Cube_face_fan(names='z+', base_ring=Rational Field)
Construct the toric variety given by the face fan of the 3-dimensional unit lattice cube.
This variety has 6 conifold singularities but the fan is still polyhedral.

INPUT:

• names – string. Names for the homogeneous coordinates. See normalize_names() for acceptable formats.
• base_ring – a ring (default: Q). The base ring for the toric variety.

OUTPUT:
A CPR-Fano toric variety.

EXAMPLES:

sage: Cube_face_fan = toric_varieties.Cube_face_fan()
sage: Cube_face_fan
3-d CPR-Fano toric variety covered by 6 affine patches
sage: Cube_face_fan.fan().rays()
N( 1, 1, 1),
N( 1, -1, 1),
N(-1, 1, 1),
N(-1, -1, 1),
N(-1, -1, -1),
N(-1, 1, -1),
N( 1, -1, -1),
N( 1, 1, -1)
in 3-d lattice N
sage: Cube_face_fan.gens()
(z0, z1, z2, z3, z4, z5, z6, z7)

Cube_nonpolyhedral(names='z+', base_ring=Rational Field)
Construct the toric variety defined by a fan that is not the face fan of a polyhedron.
This toric variety is defined by a fan that is topologically like the face fan of a 3-dimensional cube, but with a different N-lattice structure.

INPUT:

• names – string. Names for the homogeneous coordinates. See normalize_names() for acceptable formats.
• base\_ring – a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

OUTPUT:

A toric variety.

Note:

• This is an example of an non-polyhedral fan.
• Its Chow group has torsion: $A_2(X) = \mathbb{Z}^5 \oplus \mathbb{Z}_2$

EXAMPLES:

```sage
sage: Cube\_nonpolyhedral = toric\_varieties.Cube\_nonpolyhedral()
sage: Cube\_nonpolyhedral
3-d toric variety covered by 6 affine patches
sage: Cube\_nonpolyhedral\_fan().rays()
N( 1, 2, 3),
N( 1, -1, 1),
N(-1, 1, 1),
N(-1, -1, 1),
N(-1, -1, -1),
N(-1, 1, -1),
N( 1, -1, -1),
N( 1, 1, -1)
in 3-d lattice N
sage: Cube\_nonpolyhedral\_gens()
(z0, z1, z2, z3, z4, z5, z6, z7)
```

**Cube\_sublattice** (names='z+', base\_ring=Rational Field)

Construct the toric variety defined by a face fan over a 3-dimensional cube, but not the unit cube in the N-lattice. See [FultonP65].

Its Chow group is $A_2(X) = \mathbb{Z}^5$, which distinguishes it from the face fan of the unit cube.

INPUT:

• names – string. Names for the homogeneous coordinates. See `normalize\_names()` for acceptable formats.
• base\_ring – a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

OUTPUT:

A CPR-Fano toric variety.

EXAMPLES:

```sage
sage: Cube\_sublattice = toric\_varieties.Cube\_sublattice()
sage: Cube\_sublattice
3-d CPR-Fano toric variety covered by 6 affine patches
sage: Cube\_sublattice\_fan().rays()
N( 1, 0, 0),
N( 0, 1, 0),
N( 0, 0, 1),
N(-1, 1, 1),
N(-1, 0, 0),
N( 0, -1, 0),
N( 0, 0, -1),
```

(continues on next page)
N( 1, -1, -1)  
in 3-d lattice N  
sage: Cube_sublattice.gens()  
(z0, z1, z2, z3, z4, z5, z6, z7)

REFERENCES:

\( P(\mathbb{n}, names='z+', base\_ring=\text{Rational Field}) \)

Construct the \( n \)-dimensional projective space \( \mathbb{P}^n \).

INPUT:

- \( n \) – positive integer. The dimension of the projective space.
- \( names \) – string. Names for the homogeneous coordinates. See \( \text{normalize\_names()} \) for acceptable formats.
- \( base\_ring \) – a ring (default: \( \mathbb{Q} \)). The base ring for the toric variety.

OUTPUT:

A CPR-Fano toric variety.

EXAMPLES:

```
sage: P3 = toric_varieties.P(3)  
sage: P3  
3-d CPR-Fano toric variety covered by 4 affine patches  
sage: P3.fan().rays()  
N( 1, 0, 0),  
N( 0, 1, 0),  
N( 0, 0, 1),  
N(-1, -1, -1)  
in 3-d lattice N  
sage: P3.gens()  
(z0, z1, z2, z3)
```

\( \mathbb{P}^1(\mathbb{n}, names='s t', base\_ring=\text{Rational Field}) \)

Construct the projective line \( \mathbb{P}^1 \) as a toric variety.

INPUT:

- \( names \) – string. Names for the homogeneous coordinates. See \( \text{normalize\_names()} \) for acceptable formats.
- \( base\_ring \) – a ring (default: \( \mathbb{Q} \)). The base ring for the toric variety.

OUTPUT:

A CPR-Fano toric variety.

EXAMPLES:

```
sage: P1 = toric_varieties.P1()  
sage: P1  
1-d CPR-Fano toric variety covered by 2 affine patches  
sage: P1.fan().rays()  
N( 1),  
N(-1)  
in 1-d lattice N  
sage: P1.gens()  
(s, t)
```
P1xA1 \((\text{name}='s\ t\ z',\ \text{base}\_\text{ring}=\text{Rational Field})\)

Construct the Cartesian product \(\mathbb{P}^1 \times \mathbb{A}^1\) as a toric variety.

**INPUT:**

- \text{names} – string. Names for the homogeneous coordinates. See \text{normalize\_names()} for acceptable formats.
- \text{base}\_\text{ring} – a ring (default: \(\mathbb{Q}\)). The base ring for the toric variety.

**OUTPUT:**

A toric variety.

**EXAMPLES:**

```
sage: P1xA1 = toric_varieties.P1xA1()
sage: P1xA1
2-d toric variety covered by 2 affine patches
sage: P1xA1.fan().rays()
N( 1, 0),
N(-1, 0),
N( 0, 1),
in 2-d lattice N
sage: P1xA1.gens()
(s, t, z)
```

P1xP1 \((\text{name}='s\ t\ x\ y',\ \text{base}\_\text{ring}=\text{Rational Field})\)

Construct the del Pezzo surface \(\mathbb{P}^1 \times \mathbb{P}^1\) as a toric variety.

**INPUT:**

- \text{names} – string. Names for the homogeneous coordinates. See \text{normalize\_names()} for acceptable formats.
- \text{base}\_\text{ring} – a ring (default: \(\mathbb{Q}\)). The base ring for the toric variety.

**OUTPUT:**

A CPR-Fano toric variety.

**EXAMPLES:**

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1xP1
2-d CPR-Fano toric variety covered by 4 affine patches
sage: P1xP1.fan().rays()
N( 1, 0),
N(-1, 0),
N( 0, 1),
N( 0, -1)
in 2-d lattice N
sage: P1xP1.gens()
(s, t, x, y)
```

P1xP1 Z2 \((\text{name}='s\ t\ x\ y',\ \text{base}\_\text{ring}=\text{Rational Field})\)

Construct the toric \(\mathbb{Z}_2\)-orbifold of the del Pezzo surface \(\mathbb{P}^1 \times \mathbb{P}^1\) as a toric variety.

**INPUT:**

- \text{names} – string. Names for the homogeneous coordinates. See \text{normalize\_names()} for acceptable formats.
- \text{base}\_\text{ring} – a ring (default: \(\mathbb{Q}\)). The base ring for the toric variety.
A \textit{CPR-Fano toric variety}.

**EXAMPLES:**

```python
sage: P1xP1_Z2 = toric_varieties.P1xP1_Z2()
sage: P1xP1_Z2
2-d CPR-Fano toric variety covered by 4 affine patches
sage: P1xP1_Z2.fan().rays()
N( 1, 1),
N(-1, -1),
N(-1, 1),
N( 1, -1)
in 2-d lattice N
sage: P1xP1_Z2.gens()
(s, t, x, y)
sage: P1xP1_Z2.Chow_group().degree(1)
C2 x Z^2
```

\textbf{P2} \textit{(names='x y z', base\_ring=Rational Field)}

Construct the projective plane \(\mathbb{P}^2\) as a toric variety.

**INPUT:**

- \texttt{names} – string. Names for the homogeneous coordinates. See \texttt{normalize\_names()} for acceptable formats.
- \texttt{base\_ring} – a ring (default: \texttt{Q}). The base ring for the toric variety.

**OUTPUT:**

A \textit{CPR-Fano toric variety}.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2
2-d CPR-Fano toric variety covered by 3 affine patches
sage: P2.fan().rays()
N( 1, 0),
N( 0, 1),
N(-1, -1)
in 2-d lattice N
sage: P2.gens()
(x, y, z)
sage: P2_112
2-d CPR-Fano toric variety covered by 3 affine patches
sage: P2_112.fan().rays()
N( 1, 0),
N( 0, 1),
N(-1, -1)
in 2-d lattice N
sage: P2_112.gens()
(x, y, z)
sage: P2_112.Chow_group().degree(1)
C2 x Z^2
```

\textbf{P2\_112} \textit{(names='z+', base\_ring=Rational Field)}

Construct the weighted projective space \(\mathbb{P}^2(1,1,2)\).

**INPUT:**

- \texttt{names} – string. Names for the homogeneous coordinates. See \texttt{normalize\_names()} for acceptable formats.
- \texttt{base\_ring} – a ring (default: \texttt{Q}). The base ring for the toric variety.

**OUTPUT:**

A \textit{CPR-Fano toric variety}.

**EXAMPLES:**
sage: P2_112 = toric_varieties.P2_112()
sage: P2_112
2-d CPR-Fano toric variety covered by 3 affine patches
sage: P2_112.fan().rays()
N( 1, 0),
N( 0, 1),
N(-1, -2)
in 2-d lattice N
sage: P2_112.gens()
(z0, z1, z2)

P2_123 (names='z+', base_ring=Rational Field)
Construct the weighted projective space \( \mathbb{P}^2(1, 2, 3) \).

INPUT:

- names – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.

- base_ring – a ring (default: \( \mathbb{Q} \)). The base ring for the toric variety.

OUTPUT:

A \textit{CPR-Fano toric variety}.

EXAMPLES:

sage: P2_123 = toric_varieties.P2_123()
sage: P2_123
2-d CPR-Fano toric variety covered by 3 affine patches
sage: P2_123.fan().rays()
N( 1, 0),
N( 0, 1),
N(-2, -3)
in 2-d lattice N
sage: P2_123.gens()
(z0, z1, z2)

P4_11133 (names='z+', base_ring=Rational Field)
Construct the weighted projective space \( \mathbb{P}^4(1, 1, 1, 3, 3) \).

INPUT:

- names – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.

- base_ring – a ring (default: \( \mathbb{Q} \)). The base ring for the toric variety.

OUTPUT:

A \textit{CPR-Fano toric variety}.

EXAMPLES:

sage: P4_11133 = toric_varieties.P4_11133()
sage: P4_11133
4-d CPR-Fano toric variety covered by 5 affine patches
sage: P4_11133.fan().rays()
N( 1, 0, 0, 0),
N( 0, 1, 0, 0),
N( 0, 0, 1, 0),
N(-2, -3, -3, -3)
in 4-d lattice N
sage: P4_11133.gens()
(z0, z1, z2, z3, z4)
Construct the weighted projective space $\mathbb{P}^4(1,1,1,3,3)$.

**INPUT:**

- `names` – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- `base_ring` – a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

**OUTPUT:**

A CPR-Fano toric variety.

**EXAMPLES:**

```python
sage: P4_11133_resolved = toric_varieties.P4_11133_resolved()
sage: P4_11133_resolved
4-d CPR-Fano toric variety covered by 9 affine patches
sage: P4_11133_resolved.fan().rays()
N( 1, 0, 0, 0),
N( 0, 1, 0, 0),
N( 0, 0, 1, 0),
N( 0, 0, 0, 1),
N(-3, -3, -1, -1),
N(-1, -1, 0, 0)
in 4-d lattice N
sage: P4_11133_resolved.gens()
(z0, z1, z2, z3, z4)
```

Construct the weighted projective space $\mathbb{P}^4(1,1,1,6,9)$.

**INPUT:**

- `names` – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- `base_ring` – a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

**OUTPUT:**

A CPR-Fano toric variety.

**EXAMPLES:**

```python
sage: P4_11169 = toric_varieties.P4_11169()
sage: P4_11169
4-d CPR-Fano toric variety covered by 5 affine patches
sage: P4_11169.fan().rays()
N( 1, 0, 0, 0),
N( 0, 1, 0, 0),
N( 0, 0, 1, 0),
N( 0, 0, 0, 1),
(continues on next page)```
P4_11169_resolved(\textit{names}='z+', \textit{base\_ring}=\texttt{Rational Field})

Construct the blow-up of the weighted projective space $\mathbb{P}^4(1,1,1,6,9)$ at its curve of $\mathbb{Z}_3$ orbifold fixed points.

\textbf{INPUT:}

- \textit{names} – string. Names for the homogeneous coordinates. See \texttt{normalize\_names()} for acceptable formats.
- \textit{base\_ring} – a ring (default: $\mathbb{Q}$). The base ring for the toric variety.

\textbf{OUTPUT:}

A \textit{CPR-Fano toric variety}.

\textbf{EXAMPLES:}

```
sage: P4_11169_resolved = toric\_varieties.P4_11169\_resolved()
sage: P4_11169_resolved
4-d CPR-Fano toric variety covered by 9 affine patches
sage: P4_11169_resolved.fan().rays()
N( 1, 0, 0, 0),
N( 0, 1, 0, 0),
N( 0, 0, 1, 0),
N( 0, 0, 0, 1),
N(-9, -6, -1, -1),
N(-3, -2, 0, 0)
in 4-d lattice N
sage: P4_11169_resolved.gens()
(z0, z1, z2, z3, z4)
```

\texttt{WP(*q, **kw)}

Construct weighted projective $n$-space over a field.

\textbf{INPUT:}

- \textit{q} – a sequence of positive integers relatively prime to one another. The weights $q$ can be given either as a list or tuple, or as positional arguments.

Two keyword arguments:

- \textit{base\_ring} – a field (default: $\mathbb{Q}$).
- \textit{names} – string or list (tuple) of strings (default ‘z+’). See \texttt{normalize\_names()} for acceptable formats.

\textbf{OUTPUT:}

- A \textit{toric variety}. If $q = (q_0, \ldots, q_n)$, then the output is the weighted projective space $\mathbb{P}(q_0, \ldots, q_n)$ over \textit{base\_ring}. \textit{names} are the names of the generators of the homogeneous coordinate ring.

\textbf{EXAMPLES:}

A hyperelliptic curve $C$ of genus 2 as a subscheme of the weighted projective plane $\mathbb{P}(1, 3, 1)$:
sage: X = toric_varieties.WP([1,3,1], names='x y z')
sage: X.inject_variables()
Defining x, y, z
sage: g = y^2-(x^6-z^6)
sage: C = X.subscheme([g]); C
Closed subscheme of 2-d toric variety covered by 3 affine patches defined by:
-x^6 + z^6 + y^2

**dP6** *(names='x u y v z w', base_ring=Rational Field)*

Construct the del Pezzo surface of degree 6 (**P**^2 blown up at 3 points) as a toric variety.

**INPUT:**

- names – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- base_ring – a ring (default: **Q**). The base ring for the toric variety.

**OUTPUT:**

A **CPR-Fano toric variety**.

**EXAMPLES:**

```
sage: dP6 = toric_varieties.dP6()
sage: dP6
2-d CPR-Fano toric variety covered by 6 affine patches
sage: dP6.fan().rays()
N( 0, 1),
N(-1, 0),
N(-1, -1),
N( 0, -1),
N( 1, 0),
N( 1, 1)
in 2-d lattice N
sage: dP6.gens()
(x, u, y, v, z, w)
```

**dP6xdP6** *(names='x0 x1 x2 x3 x4 y0 y1 y2 y3 y4 y5', base_ring=Rational Field)*

Construct the product of two del Pezzo surfaces of degree 6 (**P**^2 blown up at 3 points) as a toric variety.

**INPUT:**

- names – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- base_ring – a ring (default: **Q**). The base ring for the toric variety.

**OUTPUT:**

A **CPR-Fano toric variety**.

**EXAMPLES:**

```
sage: dP6xdP6 = toric_varieties.dP6xdP6()
sage: dP6xdP6
4-d CPR-Fano toric variety covered by 36 affine patches
sage: dP6xdP6.fan().rays()
N( 0, 1, 0, 0),
N(-1, 0, 0, 0),
N(-1, -1, 0, 0),
(continues on next page)```
N( 0, -1, 0, 0),
N( 0, 0, 0, 0),
N( 0, 0, 1, 0),
N( 0, 0, -1, 0),
N( 0, 0, -1, 1),
N( 0, 0, 0, -1),
N( 0, 0, 1, 0),
N( 0, 0, 1, 1)
in 4-d lattice N

sage: dP6xdP6.gens()
(x0, x1, x2, x3, x4, x5, y0, y1, y2, y3, y4, y5)

**dP7** *(names='x u y v z', base_ring=Rational Field)*

Construct the del Pezzo surface of degree 7 (\(\mathbb{P}^2\) blown up at 2 points) as a toric variety.

**INPUT:**

- **names** – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- **base_ring** – a ring (default: Q). The base ring for the toric variety.

**OUTPUT:**

A **CPR-Fano toric variety**.

**EXAMPLES:**

```
sage: dP7 = toric_varieties.dP7()
sage: dP7
2-d CPR-Fano toric variety covered by 5 affine patches
sage: dP7.fan().rays()
N( 0, 1),
N(-1, 0),
N(-1, -1),
N( 0, -1),
N( 1, 0)
in 2-d lattice N
sage: dP7.gens()
(x, u, y, v, z)
```

**dP8** *(names='t x y z', base_ring=Rational Field)*

Construct the del Pezzo surface of degree 8 (\(\mathbb{P}^2\) blown up at 1 point) as a toric variety.

**INPUT:**

- **names** – string. Names for the homogeneous coordinates. See `normalize_names()` for acceptable formats.
- **base_ring** – a ring (default: Q). The base ring for the toric variety.

**OUTPUT:**

A **CPR-Fano toric variety**.

**EXAMPLES:**

```
sage: dP8 = toric_varieties.dP8()
sage: dP8
```

(continues on next page)
A toric variety.

EXAMPLES:

```
sage: T3 = toric_varieties.torus(3); T3
3-d affine toric variety
sage: T3.fan().rays()
Empty collection
in 3-d lattice N
sage: T3.fan().virtual_rays()
N(1, 0, 0),
N(0, 1, 0),
N(0, 0, 1)
in 3-d lattice N
sage: T3.gens()
(z0, z1, z2)
sage: sorted(T3.change_ring(GF(3)).point_set().list())
[[1 : 1 : 1], [1 : 1 : 2], [1 : 2 : 1], [1 : 2 : 2],
```

### 16.4 Toric divisors and divisor classes

Let $X$ be a toric variety corresponding to a rational polyhedral fan $\Sigma$. A toric divisor $D$ is a T-Weil divisor over a given coefficient ring (usually $\mathbb{Z}$ or $\mathbb{Q}$), i.e. a formal linear combination of torus-invariant subvarieties of $X$ of codimension one. In homogeneous coordinates $[z_0 : \cdots : z_k]$, these are the subvarieties $\{z_i = 0\}$. Note that there is a finite number of such subvarieties, one for each ray of $\Sigma$. We generally identify

- Toric divisor $D$,
- Sheaf $\mathcal{O}(D)$ (if $D$ is Cartier, it is a line bundle),
- Support function $\phi_D$ (if $D$ is $\mathbb{Q}$-Cartier, it is a function linear on each cone of $\Sigma$).
EXAMPLES:

We start with an illustration of basic divisor arithmetic:

```python
sage: dP6 = toric_varieties.dP6()
sage: Dx,Du,Dy,Dv,Dz,Dw = dP6.toric_divisor_group().gens()
sage: Dx
V(x)
sage: -Dx
-V(x)
sage: 2*Dx
2*V(x)
sage: Dx*2
2*V(x)
sage: (1/2)*Dx + Dy/3 - Dz
1/2*V(x) + 1/3*V(y) - V(z)
sage: Dx.parent()
Group of toric ZZ-Weil divisors on 2-d CPR-Fano toric variety covered by 6 affine patches
sage: (Dx/2).parent()
Group of toric QQ-Weil divisors on 2-d CPR-Fano toric variety covered by 6 affine patches
```

Now we create a more complicated variety to demonstrate divisors of different types:

```python
sage: F = Fan(cones=[[0,1,2,3], [0,1,4]],
...: rays=[[1,1,1], [1,-1,1], [1,-1,-1], [1,1,-1], [0,0,1]])
sage: X = ToricVariety(F)
sage: QQ_Cartier = X.divisor([2,2,1,1,1])
sage: Cartier = 2 * QQ_Cartier
sage: Weil = X.divisor([1,1,1,0,0])
sage: QQ_Weil = 1/2 * Weil
sage: [QQ_Weil.is_QQ_Weil(), QQ_Weil.is_Weil(), QQ_Weil.is_QQ_Cartier(), QQ_Weil.is_Cartier()]
[True, False, False, False]
```

The toric (Q-Weil) divisors on a toric variety \( X \) modulo linear equivalence generate the divisor **class group** \( \text{Cl}(X) \), implemented by `ToricRationalDivisorClassGroup`. If \( X \) is smooth, this equals the **Picard group** \( \text{Pic}(X) \).

We continue using del Pezzo surface of degree 6 introduced above:

```python
sage: Cl = dP6.rational_class_group(); Cl
```

(continues on next page)
The toric rational divisor class group of a 2-d CPR-Fano toric variety covered by 6 affine patches

```python
sage: C1.ngens()
4
```

```python
c0, c1, c2, c3 = C1.gens()
sage: c = c0 + 2*c1 - c3; c
Divisor class [1, 2, 0, -1]
```

Divisors are mapped to their classes and lifted via:

```python
sage: Dx.divisor_class()
Divisor class [1, 0, 0, 0]
sage: Dv.divisor_class() in C1
True
sage: Dw - Dv + Dy).divisor_class()
Divisor class [1, 0, 0, 0]
sage: c0
Divisor class [1, 0, 0, 0]
sage: c0.lift()
V(x)
```

The (rational) divisor class group is where the Kaehler cone lives:

```python
sage: Kc = dP6.Kaehler_cone(); Kc
4-d cone in 4-d lattice
```

```python
sage: Kc.rays()
Divisor class [0, 1, 1, 0],
Divisor class [0, 0, 1, 1],
Divisor class [1, 1, 0, 0],
Divisor class [1, 1, 1, 0],
Divisor class [0, 1, 1, 1],
in Basis lattice of The toric rational divisor class group of a 2-d CPR-Fano toric variety covered by 6 affine patches
```

```python
sage: Kc.ray(1).lift()
V(y) + V(v)
```

Given a divisor $D$, we have an associated line bundle (or a reflexive sheaf, if $D$ is not Cartier) $\mathcal{O}(D)$. Its sections are:

```python
sage: P2 = toric_varieties.P2()
sage: H = P2.divisor(0); H
V(x)
sage: H.sections()
(M(-1, 0), M(-1, 1), M(0, 0))
sage: H.sections_monomials()
(z, y, x)
```

Note that the space of sections is always spanned by monomials. Therefore, we can grade the sections (as homogeneous monomials) by their weight under rescaling individual coordinates. This weight data amounts to a point of the dual lattice.

In the same way, we can grade cohomology groups by their cohomological degree and a weight:

```python
sage: M = P2.fan().lattice().dual()
sage: H.cohomology(deg=0, weight=M(-1,0))
Vector space of dimension 1 over Rational Field
```

```python
sage: _.dimension()
1
```
Here is a more complicated example with $h^1(dP_6, \mathcal{O}(D)) = 4$

```
sage: D = dP6.divisor([0, 0, -1, 0, 2, -1])
sage: D.cohomology()
{0: Vector space of dimension 0 over Rational Field, 1: Vector space of dimension 4 over Rational Field, 2: Vector space of dimension 0 over Rational Field}
sage: D.cohomology(dim=True)
(0, 4, 0)
```

AUTHORS:

• Volker Braun, Andrey Novoseltsev (2010-09-07): initial version.

Construct a divisor of `toric_variety`.

INPUT:

- `toric_variety` – a `toric variety`;
- `arg` – one of the following description of the toric divisor to be constructed:
  - None or 0 (the trivial divisor);
  - monomial in the homogeneous coordinates;
  - one-dimensional cone of the fan of `toric_variety` or a lattice point generating such a cone;
  - sequence of rational numbers, specifying multiplicities for each of the toric divisors.
- `ring` – usually either $\mathbb{Z}$ or $\mathbb{Q}$. The base ring of the divisor group. If `ring` is not specified, a coefficient ring suitable for `arg` is derived.
- `check` – bool (default: True). Whether to coerce coefficients into base ring. Setting it to `False` can speed up construction.
- `reduce` – reduce (default: True). Whether to combine common terms. Setting it to `False` can speed up construction.

**Warning:** The coefficients of the divisor must be in the base ring and the terms must be reduced. If you set `check=False` and/or `reduce=False` it is your responsibility to pass valid input data `arg`.

OUTPUT:

- A `sage.schemes.toric.divisor.ToricDivisor_generic`

EXAMPLES:

```
sage: from sage.schemes.toric.divisor import ToricDivisor
sage: dP6 = toric_varieties.dP6()
sage: ToricDivisor(dP6, [(1,dP6.gen(2)), (1,dP6.gen(1))])
V(u) + V(y)
sage: ToricDivisor(dP6, (0,1,1,0,0,0), ring=QQ)
V(u) + V(y)
sage: dP6.inject_variables()
Defining x, u, y, v, z, w
sage: ToricDivisor(dP6, u+y)
Traceback (most recent call last):
...
```

(continues on next page)
We attempt to guess the correct base ring:

```python
sage: ToricDivisor(dP6, [(1/2,u)])
1/2*V(u)
sage: _.parent()
Group of toric QQ-Weil divisors on
2-d CPR-Fano toric variety covered by 6 affine patches
sage: ToricDivisor(dP6, [(1/2,u), (1/2,u)])
V(u)
sage: _.parent()
Group of toric ZZ-Weil divisors on
2-d CPR-Fano toric variety covered by 6 affine patches
Traceback (most recent call last):
... TypeError: Cannot deduce coefficient ring for [(u, u)]!
```

**class** `sage.schemes.toric.divisor.ToricDivisorGroup` *(toric_variety, base_ring)*

Bases: `sage.schemes.generic.divisor_group.DivisorGroup_generic`

The group of (Q-T-Weil) divisors on a toric variety.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2.toric_divisor_group()
Group of toric ZZ-Weil divisors
on 2-d CPR-Fano toric variety covered by 3 affine patches
```

**class** `Element` *(v, parent, check=True, reduce=True)*

Bases: `sage.schemes.generic.divisor.Divisor_generic`

**base_extend** *(R)*

Extend the scalars of self to R.

**INPUT:**

- R – ring.

**OUTPUT:**

- toric divisor group.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: DivZZ = P2.toric_divisor_group()
```
gen \(i\)
Return the \(i\)-th generator of the divisor group.

INPUT:

• \(i\) – integer.

OUTPUT:
The divisor \(z_i = 0\), where \(z_i\) is the \(i\)-th homogeneous coordinate.

EXAMPLES:

```sage
P2 = toric_varieties.P2()
TDiv = P2.toric_divisor_group()
TDiv.gen(2)
```

\(V(z)\)

gens()
Return the generators of the divisor group.

EXAMPLES:

```sage
P2 = toric_varieties.P2()
TDiv = P2.toric_divisor_group()
TDiv.gens()

\((V(x), V(y), V(z))\)
```

ngens()
Return the number of generators.

OUTPUT:
The number of generators of \(self\), which equals the number of rays in the fan of the toric variety.

EXAMPLES:

```sage
P2 = toric_varieties.P2()
TDiv = P2.toric_divisor_group()
TDiv.ngens()

3
```

class \texttt{sage.schemes.toric.divisor.ToricDivisor\_generic}(v, parent, check=True, reduce=True)

Bases: \texttt{sage.schemes.generic.divisor.Divisor\_generic}

Construct a \textit{(toric Weil)} divisor on the given toric variety.

INPUT:

• \(v\) – a list of tuples (multiplicity, coordinate).

• \texttt{parent} – \texttt{ToricDivisorGroup}. The parent divisor group.

• \texttt{check} – boolean. Type-check the entries of \(v\), see \texttt{sage.schemes.generic.divisor._DivisorGroup\_generic.__init__()}.
• `reduce` – boolean. Combine coefficients in \( v \), see `sage.schemes.generic.divisor_group.DivisorGroup_generic.__init__()`.

**Warning:** Do not construct `ToricDivisor_generic` objects manually. Instead, use either the function `ToricDivisor()` or the method `divisor()` of toric varieties.

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: ray = dP6.fan().ray(0)
sage: ray
N(0, 1)
sage: D = dP6.divisor(ray); D
V(x)
sage: D.parent()
Group of toric ZZ-Weil divisors
on 2-d CPR-Fano toric variety covered by 6 affine patches
```

**Chern_character**

Return the Chern character of the sheaf \( \mathcal{O}(D) \) defined by the divisor \( D \).

You can also use a shortcut `ch()`.

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: N = dP6.fan().lattice()
sage: D3 = dP6.divisor(dP6.fan().cone_containing( N(0,1) ))
sage: D5 = dP6.divisor(dP6.fan().cone_containing( N(-1,-1) ))
sage: D6 = dP6.divisor(dP6.fan().cone_containing( N(0,-1) ))
sage: D = -D3 + 2*D5 - D6
sage: D.Chern_character()
[5*w^2 + y - 2*v + w + 1]
sage: dP6.integrate( D.ch() * dP6.Td() )
-4
```

**Chow_cycle** *(ring=Integer Ring)*

Returns the Chow homology class of the divisor.

**INPUT:**

• `ring` – Either \( \mathbb{Z} \) (default) or \( \mathbb{Q} \). The base ring of the Chow group.

**OUTPUT:**

The `ChowCycle` represented by the divisor.

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: cone = dP6.fan(1)[0]
sage: D = dP6.divisor(cone); D
V(x)
sage: D.Chow_cycle()
( 0 | -1, 0, 1, 1 | 0 )
sage: dP6.Chow_group()(cone)
( 0 | -1, 0, 1, 1 | 0 )
```
**Kodaira_map**(names='z')

Return the Kodaira map.

The Kodaira map is the rational map $X_\Sigma \to \mathbb{P}^{n-1}$, where $n$ equals the number of sections. It is defined by the monomial sections of the line bundle.

If the divisor is ample and the toric variety smooth or of dimension 2, then this is an embedding.

**INPUT:**

- **names** – string (optional; default 'z'). The variable names for the destination projective space.

**EXAMPLES:**

```
sage: P1.<u,v> = toric_varieties.P1()
sage: D = -P1.K()
sage: D.Kodaira_map()
Scheme morphism:
  From: 1-d CPR-Fano toric variety covered by 2 affine patches
  To: Closed subscheme of Projective Space of dimension 2
      over Rational Field defined by:
      -z1^2 + z0*z2
  Defn: Defined on coordinates by sending [u : v] to
      (v^2 : u*v : u^2)
sage: dP6 = toric_varieties.dP6()
sage: D = -dP6.K()
sage: D.Kodaira_map(names='x')
Scheme morphism:
  From: 2-d CPR-Fano toric variety covered by 6 affine patches
  To: Closed subscheme of Projective Space of dimension 6
      over Rational Field defined by:
      -x1*x5 + x0*x6,
      -x2*x3 + x0*x5,
      -x1*x3 + x0*x4,
      x4*x5 - x3*x6,
      -x1*x2 + x0*x3,
      x3*x5 - x2*x6,
      x3*x4 - x1*x6,
      x3^2 - x1*x5,
      x2*x4 - x1*x5,
      -x1*x5^2 + x2*x3*x6,
      -x1*x5^3 + x2^2*x6^2
  Defn: Defined on coordinates by sending [x : u : y : v : z : w] to
      (x*u^2*y^2*v : x^2*u^2*y*w : u*y^2*v^2*z : x*u*y*v*z*w :
      x^2*u*z*w^2 : y*v^2*z^2*w : x*v*z^2*w^2)
```

**ch()**

Return the Chern character of the sheaf $\mathcal{O}(D)$ defined by the divisor $D$.

You can also use a shortcut `ch()`.

**EXAMPLES:**

```
sage: dP6 = toric_varieties.dP6()
sage: N = dP6.fan().lattice()
sage: D3 = dP6.divisor(dP6.fan().cone_containing( N(0,1) ))
sage: D5 = dP6.divisor(dP6.fan().cone_containing( N(-1,-1) ))
sage: D6 = dP6.divisor(dP6.fan().cone_containing( N(0,-1) ))
sage: D = -D3 + 2*D5 - D6
```

(continues on next page)
**coefficient** $(x)$

Return the coefficient of $x$.

**INPUT:**

- $x$ – one of the homogeneous coordinates, either given by the variable or its index.

**OUTPUT:**

The coefficient of $x$.

**EXAMPLES:**

```
sage: P2 = toric_varieties.P2()
sage: D = P2.divisor((11,12,13)); D
11*V(x) + 12*V(y) + 13*V(z)
sage: D.coefficient(1)
12
sage: P2.inject_variables()
Defining x, y, z
sage: D.coefficient(y)
12
```

**cohomology** $(weight=None, deg=None, dim=False)$

Return the cohomology of the line bundle associated to the Cartier divisor or reflexive sheaf associated to the Weil divisor.

**Note:** The cohomology of a toric line bundle/reflexive sheaf is graded by the usual degree as well as by the $M$-lattice.

**INPUT:**

- $weight$ – (optional) a point of the $M$-lattice.
- $deg$ – (optional) the degree of the cohomology group.
- $dim$ – boolean. If $False$ (default), the cohomology groups are returned as vector spaces. If $True$, only the dimension of the vector space(s) is returned.

**OUTPUT:**

The vector space $H^{deg}(X, \mathcal{O}(D))$ (if $deg$ is specified) or a dictionary {degree: cohomology(degree)) of all degrees between 0 and the dimension of the variety.

If $weight$ is specified, return only the subspace $H^{deg}(X, \mathcal{O}(D))_{weight}$ of the cohomology of the given weight.

If $dim=True$, the dimension of the cohomology vector space is returned instead of actual vector space. Moreover, if $deg$ was not specified, a vector whose entries are the dimensions is returned instead of a dictionary.

**ALGORITHM:**

Roughly, Cech cohomology is used to compute the cohomology. For toric divisors, the local sections can be chosen to be monomials (instead of general homogeneous polynomials), this is the reason for the extra complexities.
grading by $m \in M$. General references would be [Fu1993], [CLS]. Here are some salient features of our implementation:

- First, a finite set of $M$-lattice points is identified that supports the cohomology. The toric divisor determines a (polyhedral) chamber decomposition of $M_R$, see Section 9.1 and Figure 4 of [CLS]. The cohomology vanishes on the non-compact chambers. Hence, the convex hull of the vertices of the chamber decomposition contains all non-vanishing cohomology groups. This is returned by the private method _sheaf_cohomology_support().

It would be more efficient, but more difficult to implement, to keep track of all of the individual chambers. We leave this for future work.

- For each point $m \in M$, the weight-$m$ part of the cohomology can be rewritten as the cohomology of a simplicial complex, see Exercise 9.1.10 of [CLS], [Perling]. This is returned by the private method _sheaf_complex().

The simplicial complex is the same for all points in a chamber, but we currently do not make use of this and compute each point $m \in M$ separately.

- Finally, the cohomology (over $Q$) of this simplicial complex is computed in the private method _sheaf_cohomology(). Summing over the supporting points $m \in M$ yields the cohomology of the sheaf'.

REFERENCES:

EXAMPLES:

Example 9.1.7 of Cox, Little, Schenck: “Toric Varieties” [CLS]:

```python
sage: F = Fan(cones=[(0,1), (1,2), (2,3), (3,4), (4,5), (5,0)],
....:     rays=[(1,0), (1,1), (0,1), (-1,0), (-1,-1), (0,-1)])
sage: dP6 = ToricVariety(F)
sage: D3 = dP6.divisor(2)
sage: D5 = dP6.divisor(4)
sage: D6 = dP6.divisor(5)
sage: D = -D3 + 2*D5 - D6
sage: D.cohomology()
{0: Vector space of dimension 0 over Rational Field,
 1: Vector space of dimension 4 over Rational Field,
 2: Vector space of dimension 0 over Rational Field}
sage: D.cohomology(deg=1)
Vector space of dimension 4 over Rational Field
sage: M = F.dual_lattice()
sage: D.cohomology()
{0: Vector space of dimension 0 over Rational Field,
 1: Vector space of dimension 4 over Rational Field,
 2: Vector space of dimension 0 over Rational Field}
sage: D.cohomology(dim=True)
(0, 4, 0)
sage: dP6.integrate( D.ch() * dP6.Td() )
-4
```

Note the different output options:

```python
sage: D.cohomology()  
{0: Vector space of dimension 0 over Rational Field,
 1: Vector space of dimension 4 over Rational Field,
 2: Vector space of dimension 0 over Rational Field}
sage: D.cohomology(dim=True)  
(0, 4, 0)
```
Here is a Weil (non-Cartier) divisor example:

```
sage: K = toric_varieties.Cube_nonpolyhedral().K()
sage: K.is_Weil()
True
sage: K.is_QQ_Cartier()
False
sage: K.cohomology(dim=True)
(0, 0, 0, 1)
```

**cohomology_class()**

Return the degree-2 cohomology class associated to the divisor.

OUTPUT:

Returns the corresponding cohomology class as an instance of `CohomologyClass`. The cohomology class is the first Chern class of the associated line bundle $\mathcal{O}(D)$.

EXAMPLES:

```
sage: dP6 = toric_varieties.dP6()
sage: D = dP6.divisor(dP6.fan().ray(0) )
sage: D.cohomology_class()
[y + v - w]
```

**cohomology_support()**

Return the weights for which the cohomology groups do not vanish.

OUTPUT:

A tuple of dual lattice points. `self.cohomology(weight=m)` does not vanish if and only if $m$ is in the output.

**Note:** This method is provided for educational purposes and it is not an efficient way of computing the cohomology groups.

EXAMPLES:

```
sage: F = Fan(cones=[(0,1), (1,2), (2,3), (3,4), (4,5), (5,0)],
.....:   rays=[(1,0), (1,1), (0,1), (-1,0), (-1,-1), (0,-1)])
sage: dP6 = ToricVariety(F)```
divisor_class()
Return the linear equivalence class of the divisor.

OUTPUT:
Returns the class of the divisor in $\text{Cl}(X) \otimes \mathbb{Z} \mathbb{Q}$ as an instance of `ToricRationalDivisorClassGroup`.

EXAMPLES:

```python
sage: dP6 = toric_varieties.dP6()
sage: D = dP6.divisor(0)
sage: D.divisor_class()
Divisor class [1, 0, 0, 0]
```

function_value(point)
Return the value of the support function at point.

Let $X$ be the ambient toric variety of `self`, $\Sigma$ the fan associated to $X$, and $N$ the ambient lattice of $\Sigma$.

INPUT:

- point – either an integer, interpreted as the index of a ray of $\Sigma$, or a point of the lattice $N$.

OUTPUT:

- an integer or a rational number.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: D = P2.divisor([11,22,44])  # total degree 77
sage: D.function_value(0)
11
sage: N = P2.fan().lattice()
sage: D.function_value( N(1,1) )
33
sage: D.function_value( P2.fan().ray(0) )
11
```

is_Cartier()
Return whether the divisor is a Cartier-divisor.

Note: The sheaf $\mathcal{O}(D)$ associated to the given divisor $D$ is a line bundle if and only if the divisor is Cartier.

EXAMPLES:

```python
sage: X = toric_varieties.P4_11169()
sage: D = X.divisor(3)
sage: D.is_Cartier()
```

(continues on next page)
is_QQ_Cartier()
Return whether the divisor is a \(\mathbb{Q}\)-Cartier divisor.

A \(\mathbb{Q}\)-Cartier divisor is a divisor such that some multiple of it is Cartier.

EXAMPLES:

```python
sage: X = toric_varieties.P4_11169()
sage: D = X.divisor(3)
sage: D.is_QQ_Cartier()
True
sage: X = toric_varieties.Cube_face_fan()
sage: D = X.divisor(3)
sage: D.is_QQ_Cartier()
False
```

is_QQ_Weil()
Return whether the divisor is a \(\mathbb{Q}\)-Weil-divisor.

Note: This function returns always True since ToricDivisor can only describe \(\mathbb{Q}\)-Weil divisors.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: D = P2.divisor([1,2,3])
sage: D.is_QQ_Weil()
True
sage: (D/2).is_QQ_Weil()
True
```

is_Weil()
Return whether the divisor is a Weil-divisor.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: D = P2.divisor([1,2,3])
sage: D.is_Weil()
True
sage: (D/2).is_Weil()
False
```

is_ample()
Return whether a \(\mathbb{Q}\)-Cartier divisor is ample.

OUTPUT:
- True if the divisor is in the ample cone, False otherwise.

Note:
• For a QQ-Cartier divisor, some positive integral multiple is Cartier. We return whether this associated divisor is ample, i.e. corresponds to an ample line bundle.

• In the orbifold case, the ample cone is an open and full-dimensional cone in the rational divisor class group \texttt{ToricRationalDivisorClassGroup}.

• If the variety has worse than orbifold singularities, the ample cone is a full-dimensional cone within the (not full-dimensional) subspace spanned by the Cartier divisors inside the rational (Weil) divisor class group, that is, \texttt{ToricRationalDivisorClassGroup}. The ample cone is then relative open (open in this subspace).

• See also \texttt{is_nef()}.

• A toric divisor is ample if and only if its support function is strictly convex.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: K = P2.K()
sage: (+K).is_ample()  # False
sage: (0*K).is_ample()  # False
sage: (-K).is_ample()  # True
```

Example 6.1.3, 6.1.11, 6.1.17 of \textit{[CLS]}:

```python
sage: from itertools import product
sage: fan = Fan(cones=[(0,1), (1,2), (2,3), (3,0)],
            rays=[(-1,2), (0,1), (1,0), (0,-1)])

sage: F2 = ToricVariety(fan,'u1, u2, u3, u4')
sage: def D(a,b):
    return a*F2.divisor(2) + b*F2.divisor(3)

sage: [(a,b) for a,b in product(range(-3,3), repeat=2)
    if D(a,b).is_ample()]
[(1, 1), (1, 2), (2, 1), (2, 2)]

sage: [(a,b) for a,b in product(range(-3,3), repeat=2)
    if D(a,b).is_nef()]
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0), (2, 1), (2, 2)]
```

A (worse than orbifold) singular Fano threefold:

```python
sage: points = [(1,0,0),(0,1,0),(0,0,1),(-2,0,-1),(-2,-1,0),(-3,-1,-1),(1,1,1)]
sage: facets = [[0,1,3],[0,1,6],[0,2,4],[0,2,6],[0,3,5],[0,4,5],[1,2,3,4,5,6]]

sage: X = ToricVariety(Fan(cones=facets, rays=points))

sage: X.rational_class_group().dimension()  # 4

sage: X.Kaehler_cone().rays()
Divisor class \([1, 0, 0, 0]\)
in Basis lattice of The toric rational divisor class group of a 3-d toric variety covered by 7 affine patches

sage: antiK = -X.K()
sage: antiK.divisor_class()
Divisor class \([2, 0, 0, 0]\)

sage: antiK.is_ample()  # True
```

16.4. Toric divisors and divisor classes
**is_integral()**
Return whether the coefficients of the divisor are all integral.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: DZZ = P2.toric_divisor_group(base_ring=ZZ).gen(0); DZZ
V(x)
sage: DQQ = P2.toric_divisor_group(base_ring=QQ).gen(0); DQQ
V(x)
sage: DZZ.is_integral()
True
sage: DQQ.is_integral()
True
```

**is_nef()**
Return whether a $\mathbb{Q}$-Cartier divisor is nef.

**OUTPUT:**

- True if the divisor is in the closure of the ample cone, False otherwise.

**Note:**

- For a $\mathbb{Q}$-Cartier divisor, some positive integral multiple is Cartier. We return whether this associated divisor is nef.
- The nef cone is the closure of the ample cone.
- See also `is_ample()`.
- A toric divisor is nef if and only if its support function is convex (but not necessarily strictly convex).
- A toric Cartier divisor is nef if and only if its linear system is basepoint free.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: K = P2.K()
sage: (+K).is_nef()
False
sage: (0*K).is_nef()
True
sage: (-K).is_nef()
True
```

Example 6.1.3, 6.1.11, 6.1.17 of [CLS]:

```python
sage: from itertools import product
sage: fan = Fan(cones=[[(0,1), (1,2), (2,3), (3,0)], ...
....:        rays=[(-1,2), (0,1), (1,0), (0,-1)])
sage: F2 = ToricVariety(fan, ['u1', 'u2', 'u3', 'u4'])
sage: def D(a,b): return a*F2.divisor(2) + b*F2.divisor(3)
sage: [ (a,b) for a,b in product(range(-3,3), repeat=2) ...
....:     if D(a,b).is_ample() ]
[(1, 1), (1, 2), (2, 1), (2, 2)]
sage: [ (a,b) for a,b in product(range(-3,3), repeat=2) ...
....:     if D(a,b).is_nef() ]
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0), (2, 1), (2, 2)]
```
m(cone)

Return \( m_\sigma \) representing \( \phi_D \) on \( \text{cone} \).

Let \( X \) be the ambient toric variety of this divisor \( D \) associated to the fan \( \Sigma \) in lattice \( N \). Let \( M \) be the lattice dual to \( N \). Given the cone \( \sigma = \langle v_1, \ldots, v_k \rangle \) in \( \Sigma \), this method searches for a vector \( m_\sigma \in M_Q \) such that \( \phi_D(v_i) = \langle m_\sigma, v_i \rangle \) for all \( i = 1, \ldots, k \), where \( \phi_D \) is the support function of \( D \).

INPUT:

- cone – A cone in the fan of the toric variety.

OUTPUT:

- If possible, a point of lattice \( M \).
- If the dual vector cannot be chosen integral, a rational vector is returned.
- If there is no such vector (i.e. \( \text{self} \) is not even a \( \mathbb{Q} \)-Cartier divisor), a \text{ValueError} is raised.

EXAMPLES:

```
sage: F = Fan(cones=[(0,1,2,3), (0,1,4)],
    ....: rays=[(1,1,1), (1,-1,1), (1,-1,-1), (1,1,-1), (0,0,1)])
sage: X = ToricVariety(F)
sage: square_cone = X.fan().cone_containing(0,1,2,3)
sage: triangle_cone = X.fan().cone_containing(0,1,4)
sage: ray = X.fan().cone_containing(0)
sage: QQ_Cartier = X.divisor([2,2,1,1,1])
sage: QQ_Cartier.m(ray)
M(0, 2, 0)
sage: QQ_Cartier.m(square_cone)
(3/2, 0, 1/2)
sage: QQ_Cartier.m(triangle_cone)
M(1, 0, 1)
sage: QQ_Cartier.m(Cone(triangle_cone))
M(1, 0, 1)
sage: Weil = X.divisor([1,1,1,0,0])
sage: Weil.m(square_cone)
Traceback (most recent call last):
...
ValueError: V(z0) + V(z1) + V(z2) is not QQ-Cartier, cannot choose a dual vector on 3-d cone of Rational polyhedral fan in 3-d lattice N!
sage: Weil.m(triangle_cone)
M(1, 0, 0)
```

monomial(point)

Return the monomial in the homogeneous coordinate ring associated to the \text{point} in the dual lattice.

INPUT:

- point – a \text{point} in \text{self}.\text{variety()}\.\text{fan()}\.\text{dual_lattice()}.

OUTPUT:

For a fixed divisor \( D \), the sections are generated by monomials in \text{ToricVariety}.\text{coordinate_ring}. Alternatively, the monomials can be described as \( M \)-lattice points in the polyhedron \( D.\text{polyhedron()} \). This method converts the points \( m \in M \) into homogeneous polynomials.

EXAMPLES:
```python
sage: P2 = toric_varieties.P2()
sage: O3_P2 = -P2.K()
sage: M = P2.fan().dual_lattice()
sage: O3_P2.monomial(M(0,0))
x*y*z
```

```python
move_away_from(cone)
```
Move the divisor away from the orbit closure of `cone`.

**INPUT:**
- A `cone` of the fan of the toric variety.

**OUTPUT:**
A (rationally equivalent) divisor that is moved off the orbit closure of the given cone.

**Note:** A divisor that is Weil but not Cartier might be impossible to move away. In this case, a `ValueError` is raised.

**EXAMPLES:**
```python
sage: F = Fan(cones=[[(0,1,2,3), (0,1,4)],
....: rays=[(1,1,1), (1,-1,1), (1,-1,-1), (1,1,-1), (0,0,1)]])
sage: X = Toric Variety(F)
sage: square_cone = X.fan().cone_containing(0,1,2,3)
sage: triangle_cone = X.fan().cone_containing(0,1,4)
sage: line_cone = square_cone.intersection(triangle_cone)
sage: Cartier = X.divisor([2,2,1,1,1])
sage: Cartier
2*V(z0) + 2*V(z1) + V(z2) + V(z3) + V(z4)
sage: Cartier.move_away_from(line_cone)
-V(z2) - V(z3) + V(z4)
sage: QQ_Weil = X.divisor([1,0,1,1,0])
sage: QQ_Weil.move_away_from(line_cone)
V(z2)
```

```python
polyhedron()
```
Return the polyhedron $P_D \subset M$ associated to a toric divisor $D$.

**OUTPUT:**
$P_D$ as an instance of `Polyhedron_base`.

**EXAMPLES:**
```python
sage: dP7 = toric_varieties.dP7()
sage: D = dP7.divisor(2)
sage: P_D = D.polyhedron(); P_D
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex
sage: P_D.Vrepresentation()
(A vertex at (0, 0),)
sage: D.is_nef()
False
sage: dP7.integrate( D.ch() * dP7.Td() )
1
sage: P_antiK = (-dP7.K()).polyhedron(); P_antiK
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices
```

(continues on next page)
sage: P_antiK.Vrepresentation()
(A vertex at (1, -1), A vertex at (0, 1), A vertex at (1, 0),
A vertex at (-1, 1), A vertex at (-1, -1))
sage: P_antiK.integral_points()
((-1, -1), (-1, 0), (-1, 1), (0, -1), (0, 0), (0, 1), (1, -1), (1, 0))

Example 6.1.3, 6.1.11, 6.1.17 of [CLS]:

sage: fan = Fan(cones=[(0,1), (1,2), (2,3), (3,0)],
           rays=[(-1,2), (0,1), (1,0), (0,-1)])
sage: F2 = ToricVariety(fan, 'u1, u2, u3, u4')
sage: D = F2.divisor(3)
sage: D.polyhedron().Vrepresentation()
(A vertex at (0, 0), A vertex at (2, 1), A vertex at (0, 1))
sage: Dprime = F2.divisor(1) + D
sage: Dprime.polyhedron().Vrepresentation()
(A vertex at (2, 1), A vertex at (0, 1), A vertex at (0, 0))
sage: D.is_ample()
False
sage: D.is_nef()
True
sage: Dprime.is_nef()
False

A more complicated example where $P_D$ is not a lattice polytope:

sage: X = toric_varieties.BCdlOG_base()
sage: antiK = -X.K()
sage: P_D = antiK.polyhedron()
sage: P_D
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 8 vertices
sage: P_D.Vrepresentation()
(A vertex at (1, -1, 0), A vertex at (1, -3, 1),
A vertex at (1, 1, 1), A vertex at (-5, 1, 1),
A vertex at (1, 1, -1/2), A vertex at (1, 1/2, -1/2),
A vertex at (-5, 1, 0), A vertex at (-5, -3, 1))
sage: P_D.Hrepresentation()
(An inequality (-1, 0, 0) x + 1 >= 0, An inequality (0, -1, 0) x + 1 >= 0,
An inequality (0, 0, -1) x + 1 >= 0, An inequality (1, 0, 4) x + 1 >= 0,
An inequality (0, 1, 3) x + 1 >= 0, An inequality (0, 1, 2) x + 1 >= 0)
sage: P_D.integral_points()
((-1, -1, 0), (0, -1, 0), (1, -1, 0), (-1, 0, 0), (0, 0, 0),
(1, 0, 0), (-1, 1, 0), (0, 1, 0), (1, 1, 0), (-5, -3, 1),
(-4, -3, 1), (-3, -3, 1), (2, -3, 1), (-1, -3, 1), (0, -3, 1),
(1, -3, 1), (-5, -2, 1), (-4, -2, 1), (-3, -2, 1), (-2, -2, 1),
(-1, -2, 1), (0, -2, 1), (1, -2, 1), (-5, -1, 1), (-4, -1, 1),
(-3, -1, 1), (-2, -1, 1), (-1, -1, 1), (0, -1, 1), (1, -1, 1),
(-5, 0, 1), (-4, 0, 1), (-3, 0, 1), (-2, 0, 1), (-1, 0, 1),
(0, 0, 1), (1, 0, 1), (-5, 1, 1), (-4, 1, 1), (-3, 1, 1),
(-2, 1, 1), (-1, 1, 1), (0, 1, 1), (1, 1, 1))

sections()

Return the global sections (as points of the $M$-lattice) of the line bundle (or reflexive sheaf) associated to the divisor.

OUTPUT:

• tuple of points of lattice $M$. 

16.4. Toric divisors and divisor classes 291
**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2.fan().nrays()
3
sage: P2.divisor(0).sections()
(M(-1, 0), M(-1, 1), M(0, 0))
sage: P2.divisor(1).sections()
(M(0, -1), M(0, 0), M(1, -1))
sage: P2.divisor(2).sections()
(M(0, 0), M(0, 1), M(1, 0))
```

The divisor can be non-nef yet still have sections:

```python
sage: rays = [(1,0,0),(0,1,0),(0,0,1),(-2,0,-1),(-2,-1,0),(-3,-1,-1),(1,1,1),
         (-1,0,0)]
sage: cones = [[0,1,3],[0,1,6],[0,2,4],[0,2,6],[0,3,5],[0,4,5],[1,3,7],[1,6,
         7],[2,4,7],[2,6,7],[3,5,7],[4,5,7]]
sage: X = ToricVariety(Fan(rays=rays,cones=cones))
sage: D = X.divisor(2); D
V(z2)
sage: D.is_nef()
False
sage: D.sections()
(M(0, 0, 0),)
sage: D.cohomology(dim=True)
(1, 0, 0, 0)
```

### sections_monomials()

Return the global sections of the line bundle associated to the Cartier divisor.

The sections are described as monomials in the generalized homogeneous coordinates.

**OUTPUT:**

- tuple of monomials in the coordinate ring of `self`.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: P2.fan().nrays()
3
sage: P2.divisor(0).sections_monomials()
(z, y, x)
sage: P2.divisor(1).sections_monomials()
(z, y, x)
sage: P2.divisor(2).sections_monomials()
(z, y, x)
```

From [*CoxTutorial*](#) page 38:

```python
sage: lp = LatticePolytope([(1,0),(1,1),(0,1),(-1,0),(0,-1)])
sage: lp
2-d reflexive polytope #5 in 2-d lattice M
sage: dP7 = Toric Variety( FaceFan(lp), 'x1, x2, x3, x4, x5')
sage: AK = -dP7.K()
sage: AK.sections()
(N(-1, 0), N(-1, 1), N(0, -1), N(0, 0),
 N(0, 1), N(1, -1), N(1, 0), N(1, 1))
```
REFERENCES:

class sage.schemes.toric.divisor.ToricRationalDivisorClassGroup(toric_variety)

Bases: sage.modules.free_module.FreeModule_ambient_field, sage.structure.unique_representation.UniqueRepresentation

The rational divisor class group of a toric variety.

The T-Weil divisor class group $Cl(X)$ of a toric variety $X$ is a finitely generated abelian group and can contain torsion. Its rank equals the number of rays in the fan of $X$ minus the dimension of $X$.

The rational divisor class group is $Cl(X) \otimes \mathbb{Q}$ and never includes torsion. If $X$ is smooth, this equals the Picard group $Pic(X)$, whose elements are the isomorphism classes of line bundles on $X$. The group law (which we write as addition) is the tensor product of the line bundles. The Picard group of a toric variety is always torsion-free.

**Warning:** Do not instantiate this class yourself. Use `rational_class_group()` method of `toric_varieties` if you need the divisor class group. Or you can obtain it as the parent of any divisor class constructed, for example, via `ToricDivisor_generic.divisor_class()`.

INPUT:

- `toric_variety` – toric variety `<sage.schemes.toric.variety.ToricVariety_field`.

OUTPUT:

- rational divisor class group of a toric variety.

EXAMPLES:

```
sage: P2 = toric_varieties.P2()
sage: P2.rational_class_group()
```

The toric rational divisor class group of a 2-d CPR-Fano toric variety covered by 3 affine patches

```
sage: D = P2.divisor(0); D
V(x)
sage: Dclass = D.divisor_class(); Dclass
Divisor class [1]
sage: Dclass.lift()
V(y)
sage: Dclass.parent()
The toric rational divisor class group of a 2-d CPR-Fano toric variety covered by 3 affine patches
```

**Element**

alias of `sage.schemes.toric.divisor_class.ToricRationalDivisorClass`

```python
class sage.schemes.toric.divisor.ToricRationalDivisorClassGroup_basis_lattice(group)

Bases: sage.modules.free_module.FreeModule_ambient_pid

Construct the basis lattice of the group.
```

INPUT:
• group – toric rational divisor class group.

OUTPUT:
• the basis lattice of group.

EXAMPLES:

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: L = P1xP1.Kaehler_cone().lattice()
sage: L
Basis lattice of The toric rational divisor class group of a
2-d CPR-Fano toric variety covered by 4 affine patches
sage: L.basis()
[Divisor class [1, 0],
 Divisor class [0, 1]]
```

Element
alias of sage.schemes.toric.divisor_class.ToricRationalDivisorClass

```
sage.schemes.toric.divisor.is_ToricDivisor(x)
Test whether x is a toric divisor.

INPUT:
• x – anything.

OUTPUT:
• True if x is an instance of ToricDivisor_generic and False otherwise.

EXAMPLES:

```
sage: from sage.schemes.toric.divisor import is_ToricDivisor
sage: is_ToricDivisor(1)
False
sage: P2 = toric_varieties.P2()
sage: D = P2.divisor(0); D
V(x)
sage: is_ToricDivisor(D)
True
```

16.5 Toric rational divisor classes

This module is a part of the framework for toric varieties.

AUTHORS:
• Volker Braun and Andrey Novoseltsev (2010-09-05): initial version.

class sage.schemes.toric.divisor_class.ToricRationalDivisorClass
Bases: sage.modules.vector_rational_dense.Vector_rational_dense

Create a toric rational divisor class.

**Warning:** You probably should not construct divisor classes explicitly.
INPUT:

• same as for Vector_rational_dense.

OUTPUT:

• toric rational divisor class.

lift()
Return a divisor representing this divisor class.

OUTPUT:

An instance of ToricDivisor representing self.

EXAMPLES:

```
sage: X = toric_varieties.Cube_nonpolyhedral()
sage: D = X.divisor([0,1,2,3,4,5,6,7]); D
V(z1) + 2*V(z2) + 3*V(z3) + 4*V(z4) + 5*V(z5) + 6*V(z6) + 7*V(z7)
sage: D.divisor_class()
Divisor class [29, 6, 8, 10, 0]
sage: Dequiv = D.divisor_class().lift(); Dequiv
6*V(z1) - 17*V(z2) - 22*V(z3) - 7*V(z4) + 25*V(z6) + 32*V(z7)
sage: Dequiv == D
False
sage: Dequiv.divisor_class() == D.divisor_class()
True
```

sage.schemes.toric.divisor_class.is_ToricRationalDivisorClass(x)
Check if x is a toric rational divisor class.

INPUT:

• x – anything.

OUTPUT:

• True if x is a toric rational divisor class, False otherwise.

EXAMPLES:

```
sage: from sage.schemes.toric.divisor_class import (....: is_ToricRationalDivisorClass)
sage: is_ToricRationalDivisorClass(1)
False
sage: dP6 = toric_varieties.dP6()
sage: D = dP6.rational_class_group().gen(0)
sage: D
Divisor class [1, 0, 0, 0]
sage: is_ToricRationalDivisorClass(D)
True
```

16.6 The Chow group of a toric variety

In general, the Chow group is an algebraic version of a homology theory. That is, the objects are formal linear combinations of submanifolds modulo relations. In particular, the objects of the Chow group are formal linear combinations of algebraic subvarieties and the equivalence relation is rational equivalence. There is no relative version of the Chow group, so it is not a generalized homology theory.

The Chow groups of smooth or mildly singular toric varieties are almost the same as the homology groups:
• For smooth toric varieties, \( A_k(X) = H_{2k}(X, \mathbb{Z}) \). While they are the same, using the cohomology ring instead of the Chow group will be much faster! The cohomology ring does not try to keep track of torsion and uses Groebner bases to encode the cup product.

• For simplicial toric varieties, \( A_k(X) \otimes \mathbb{Q} = H_{2k}(X, \mathbb{Q}) \).

Note that in these cases the odd-dimensional (co)homology groups vanish. But for sufficiently singular toric varieties the Chow group differs from the homology groups (and the odd-dimensional homology groups no longer vanish). For singular varieties the Chow group is much easier to compute than the (co)homology groups.

The toric Chow group of a toric variety is the Chow group generated by the toric subvarieties, that is, closures of orbits under the torus action. These are in one-to-one correspondence with the cones of the fan and, therefore, the toric Chow group is a quotient of the free Abelian group generated by the cones. In particular, the toric Chow group has finite rank. One can show [FMSS1] that the toric Chow groups equal the “full” Chow group of a toric variety, so there is no need to distinguish these in the following.

AUTHORS:
• Volker Braun (2010-08-09): Initial version

REFERENCES:

EXAMPLES:

```
sage: X = toric_varieties.Cube_deformation(7)
sage: X.is_smooth()
False
sage: X.is_orbifold()
False
sage: A = X.Chow_group()
sage: A.degree()
(Z, C7, C2 x C2 x Z^5, Z)
sage: A.degree(2).ngens()
7
sage: a = sum( A.gen(i) * (i+1) for i in range(A.ngens()) )  # an element of A
sage: a                        # long time (2s on sage.math, 2011)
( 3 | 1 mod 7 | 0 mod 2, 1 mod 2, 4, 5, 6, 7, 8 | 9 )
```

The Chow group elements are printed as \(( a_0 \mid a_1 \bmod 7 \mid a_2 \bmod 2, a_3 \bmod 2, a_4, a_5, a_6, a_7, a_8 \mid a_9 )\), which denotes the element of the Chow group in the same basis as \(A_.degree()\). The \mid separates individual degrees, so the example means:

- The degree-0 part is \(3 \in \mathbb{Z}\).
- The degree-1 part is \(1 \in \mathbb{Z}_7\).
- The torsion of the degree-2 Chow group is \((0, 1) \in \mathbb{Z}_2 \oplus \mathbb{Z}_2\).
- The free part of the degree-2 Chow group is \((4, 5, 6, 7, 8) \in \mathbb{Z}^5\).
- The degree-3 part is \(9 \in \mathbb{Z}\).

Note that the generators \(A_.gens()\) are not sorted in any way. In fact, they may be of mixed degree. Use \(A_.gens(dgree=d)\) to obtain the generators in a fixed degree \(d\). See \texttt{ChowGroup_class.gens()} for more details.

Cones of toric varieties can determine their own Chow cycle:

```
sage: A = X.Chow_group(); A
Chow group of 3-d toric variety covered by 6 affine patches
sage: cone = X.fan(dim=2)[3]; cone
2-d cone of Rational polyhedral fan in 3-d lattice N
```

(continues on next page)
Sage: \( A\text{\_cone} = A(\text{cone}); A\text{\_cone} \)
\[
(0 | 1 \text{ mod } 7 | 0 \text{ mod } 2, 0 \text{ mod } 2, 0, 0, 0, 0, 0 | 0)
\]
Sage: \( A\text{\_cone}.\text{degree}() \)
1
Sage: \( 2 * A\text{\_cone} \)
\[
(0 | 2 \text{ mod } 7 | 0 \text{ mod } 2, 0 \text{ mod } 2, 0, 0, 0, 0, 0 | 0)
\]
Sage: \( A\text{\_cone} + A\text{\_gen}(0) \)
\[
(0 | 1 \text{ mod } 7 | 0 \text{ mod } 2, 1 \text{ mod } 2, 0, 0, 0, 0, 0 | 0)
\]

Chow cycles can be of mixed degrees:

Sage: \( \text{mixed} = \text{sum}(A\text{\_gens}()); \text{mixed} \)
\[
(1 | 4 \text{ mod } 7 | 1 \text{ mod } 2, 1 \text{ mod } 2, 1, 1, 1, 1 | 1)
\]
Sage: \( \text{mixed}.\text{project\_to\_degree}(1) \)
\[
(0 | 4 \text{ mod } 7 | 0 \text{ mod } 2, 0 \text{ mod } 2, 0, 0, 0, 0 | 0)
\]
Sage: \( \text{sum}([\text{mixed}.\text{project\_to\_degree}(i) \text{ for } i \text{ in range}(X\text{\_dimension()+1})]) == \text{mixed} \)
True

class sage.schemes.toric.chow_group.ChowCycle (parent, v, check=True)

Bases: sage.modules.fg_pid.fgp_element.FGP_Element

The elements of the Chow group.

Warning: Do not construct ChowCycle objects manually. Instead, use the parent ChowGroup to obtain generators or Chow cycles corresponding to cones of the fan.

EXAMPLES:

Sage: \( P2 = \text{toric\_varieties.P2()} \)
Sage: \( A = P2.\text{Chow\_group}() \)
Sage: \( A\text{\_gens}() \)
\[
((1 | 0 | 0), (0 | 1 | 0), (0 | 0 | 1))
\]
Sage: \( \text{cone} = P2\text{\_fan}(1)[0] \)
Sage: \( A(\text{cone}) \)
\[
(0 | 1 | 0)
\]
Sage: \( A(\text{\_Cone}([1,0])) \)
\[
(0 | 1 | 0)
\]

cohomology\_class()

Return the (Poincaré-dual) cohomology class.

Consider a simplicial cone of the fan, that is, a \( d \)-dimensional cone spanned by \( d \) rays. Take the product of the corresponding \( d \) homogeneous coordinates. This monomial represents a cohomology classes of the toric variety \( X \), see cohomology\_ring(). Its cohomological degree is \( 2d \), which is the same degree as the Poincaré-dual of the (real) \( \dim(X) - 2d \)-dimensional torus orbit associated to the simplicial cone. By linearity, we can associate a cohomology class to each Chow cycle of a simplicial toric variety.

If the toric variety is compact and smooth, the associated cohomology class actually is the Poincaré dual (over the integers) of the Chow cycle. In particular, integrals of dual cohomology classes perform intersection computations.

If the toric variety is compact and has at most orbifold singularities, the torsion parts in cohomology and the Chow group can differ. But they are still isomorphic as rings over the rationals. Moreover, the normalization of integration (volume\_class) and count\_points() are chosen to agree.
The \texttt{CohomologyClass} which is associated to the Chow cycle.

If the toric variety is not simplicial, that is, has worse than orbifold singularities, there is no way to associate a cohomology class of the correct degree. In this case, \texttt{cohomology_class()} raises a \texttt{ValueError}.

**EXAMPLES:**

```
sage: dP6 = toric_varieties.dP6()
sage: cone = dP6.fan().cone_containing(2,3)
sage: HH = dP6.cohomology_ring()
sage: A = dP6.Chow_group()
sage: HH(cone)
[-w^2]
sage: A(cone)
( 1 | 0, 0, 0, 0 | 0 )
sage: A(cone).cohomology_class()
[-w^2]
```

Here is an example of a toric variety with orbifold singularities, where we can also use the isomorphism with the rational cohomology ring:

```
sage: WP4 = toric_varieties.P4_11169()
sage: A = WP4.Chow_group()
sage: HH = WP4.cohomology_ring()
sage: cone3d = Cone([(0,0,1,0), (0,0,0,1), (-9,-6,-1,-1)])
sage: A(cone3d)
( 0 | 1 | 0 | 0 | 0 )
sage: HH(cone3d)
[3*z4^3]
sage: D = -WP4.K()    # the anticanonical divisor
sage: A(D)
( 0 | 0 | 0 | 18 | 0 )
sage: HH(D)
[18*z4]
sage: WP4.integrate( A(cone3d).cohomology_class() * D.cohomology_class() )
1
sage: WP4.integrate( HH(cone3d) * D.cohomology_class() )
1
sage: A(cone3d).intersection_with_divisor(D).count_points()
1
```

\texttt{count_points()} 
Return the number of points in the Chow cycle.

**OUTPUT:**

An element of \texttt{self.base_ring()}, which is usually \texttt{Z}. The number of points in the Chow cycle.

**EXAMPLES:**

```
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: a = 5*A.gen(0) + 7*A.gen(1); a
( 5 | 7 | 0 )
sage: a.count_points()
5
```
In the case of a smooth complete toric variety, the Chow (homology) groups are Poincaré dual to the integral cohomology groups. Here is such a smooth example:

```python
sage: D = P2.divisor(1)
sage: a = D.Chow_cycle()
sage: aD = a.intersection_with_divisor(D)
sage: aD.count_points()
1
sage: P2.integrate( aD.cohomology_class() )
1
```

For toric varieties with at most orbifold singularities, the isomorphism only holds over \( \mathbb{Q} \). But the normalization of the integral is still chosen such that the intersection numbers (which are potentially rational) computed both ways agree:

```python
sage: P1xP1_Z2 = toric_varieties.P1xP1_Z2()
sage: Dt = P1xP1_Z2.divisor(1); Dt
V(t)
sage: Dy = P1xP1_Z2.divisor(3); Dy
V(y)
sage: Dt.Chow_cycle(QQ).intersection_with_divisor(Dy).count_points()
1/2
sage: P1xP1_Z2.integrate( Dt.cohomology_class() * Dy.cohomology_class() )
1/2
```

**degree()**

The degree of the Chow cycle.

**OUTPUT:**

Integer. The complex dimension of the subvariety representing the Chow cycle. Raises a `ValueError` if the Chow cycle is a sum of mixed degree cycles.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: [ a.degree() for a in A.gens() ]
[0, 1, 2]
```

**intersection_with_divisor(divisor)**

Intersect the Chow cycle with `divisor`.

See [FultonChow] for a description of the toric algorithm.

**INPUT:**

- `divisor` – a `ToricDivisor` that can be moved away from the Chow cycle. For example, any Cartier divisor. See also `ToricDivisor.move_away_from`.

**OUTPUT:**

A new `ChowCycle`. If the divisor is not Cartier then this method potentially raises a `ValueError`, indicating that the divisor cannot be made transversal to the Chow cycle.

**EXAMPLES:**

```python
sage: dP6 = toric_varieties.dP6()
sage: cone = dP6.fan().cone_containing(2); cone
1-d cone of Rational polyhedral fan in 2-d lattice N
```
You can do the same computation over the rational Chow group since there is no torsion in this case:

```python
sage: A_QQ = dP6.Chow_group(base_ring=QQ)
sage: A_QQ(cone)
( 0 | 0, 0, 0, 1 | 0 )
sage: intersection_QQ = A_QQ(cone).intersection_with_divisor(D); intersection_QQ
( -1 | 0, 0, 0, 0 | 0 )
sage: intersection_QQ.count_points()
-1
```

**project_to_degree** *(degree)*

Project a (mixed-degree) Chow cycle to the given degree.

**INPUT:**

- degree – integer. The degree to project to.

**OUTPUT:**

The projection of the Chow class to the given degree as a new *ChowCycle* of the same Chow group.

**EXAMPLES:**

```python
sage: A = toric_varieties.P2().Chow_group()
sage: cycle = 10*A.gen(0) + 11*A.gen(1) + 12*A.gen(2)
sage: cycle
( 10 | 11 | 12 )
sage: cycle.project_to_degree(2)
( 0 | 0 | 12 )
```

**class** *sage.schemes.toric.chow_group.ChowGroupFactory*

Bases: *sage.structure.factory.UniqueFactory*

Factory for *ChowGroup_class*.

**create_key_and_extra_args** *(toric_variety, base_ring=Integer Ring, check=True)*

Create a key that uniquely determines the *ChowGroup_class*.

**INPUT:**

- toric_variety – a toric variety.
- base_ring – either Z (default) or Q. The coefficient ring of the Chow group.
- check – boolean (default: True).

**EXAMPLES:**
sage: from sage.schemes.toric.chow_group import *
sage: P2 = toric_varieties.P2()

sage: ChowGroup(P2, ZZ, check=True) == ChowGroup(P2, ZZ, check=False)  # indirect doctest
True

create_object (version, key, **extra_args)
Create a ChowGroup_class.

INPUT:

• version – object version. Currently not used.

• key – a key created by create_key_and_extra_args().

• **extra_args – Currently not used.

EXAMPLES:

sage: from sage.schemes.toric.chow_group import *

class sage.schemes.toric.chow_group.ChowGroup_class (toric_variety, base_ring, check)

The Chow group of a toric variety.

EXAMPLES:

sage: P2=toric_varieties.P2()
sage: from sage.schemes.toric.chow_group import ChowGroup_class
sage: A = ChowGroup_class(P2,ZZ,True); A

Element

alias of ChowCycle

coordinate_vector (chow_cycle, degree=None, reduce=True)
Return the coordinate vector of the chow_cycle.

INPUT:

• chow_cycle – a ChowCycle.

• degree – None (default) or an integer.

• reduce – boolean (default: True). Whether to reduce modulo the invariants.

OUTPUT:

• If degree is None (default), the coordinate vector relative to the basis self.gens() is returned.

• If some integer degree=d is specified, the chow cycle is projected to the given degree and the coordinate vector relative to the basis self.gens(degree=d) is returned.

EXAMPLES:
degree (k=\text{None})
Return the degree-$k$ Chow group.

INPUT:

- $k$ – an integer or \text{None} (default). The degree of the Chow group.

OUTPUT:

- if $k$ was specified, the Chow group $A_k$ as an Abelian group.
- if $k$ was not specified, a tuple containing the Chow groups in all degrees.

Note:

- For a smooth toric variety, this is the same as the Poincaré-dual cohomology group $H^{d-2k}(X, \mathbb{Z})$.
- For a simplicial toric variety (“orbifold”), $A_k(X) \otimes \mathbb{Q} = H^{d-2k}(X, \mathbb{Q})$.

EXAMPLES:

Four exercises from page 65 of [FultonP65]. First, an example with $A_1(X) = \mathbb{Z} \oplus \mathbb{Z}/3\mathbb{Z}$:

```sage
sage: X = ToricVariety(Fan(cones=[[0,1],[1,2],[2,0]],
....: rays=[[2,-1],[-1,2],[-1,-1]]))
sage: A = X.Chow_group()
sage: A.degree(1)
C3 x \mathbb{Z}
```

Second, an example with $A_2(X) = \mathbb{Z}^2$:

```sage
sage: points = [[1,0,0],[0,1,0],[0,0,1],[1,-1,1],
....: [-1,0,0],[0,-1,0],[0,0,-1],[ 1,-1,-1]]
sage: l = LatticePolytope(points)
sage: X = ToricVariety(FaceFan(l))
sage: A = X.Chow_group()
sage: A.degree(2)
\mathbb{Z}^2
```

Third, an example with $A_2(X) = \mathbb{Z}^5$:

```sage
sage: cube = [[1,0,0],[0,1,0],[0,0,1],[-1,1,1],
....: [-1,0,0],[0,-1,0],[0,0,-1],[ 1,-1,-1]]
sage: lat_cube = LatticePolytope(cube)
sage: X = ToricVariety(FaceFan((Latpolytope(lat_cube))))
sage: X.Chow_group().degree(2)
\mathbb{Z}^5
```

Fourth, a fan that is not the fan over a polytope. Combinatorially, the fan is the same in the third example, only the coordinates of the first point are different. But the resulting fan is not the face fan of a cube, so the variety is “more singular”. Its Chow group has torsion, $A_2(X) = \mathbb{Z}^5 \oplus \mathbb{Z}/2$:
Finally, Example 1.3 of [FS]:

```
sage: points_mod = lambda k: matrix([[1, 1, 2*k+1], [-1, -1, 1], [-1, 1, 1], [-1, -1, 1], [-1, 1, -1], [1, -1, -1], [1, 1, -1]])
sage: rays = lambda k: matrix([[1, 1, 1], [-1, -1, 1], [-1, 1, 1]]).solve_left(points_mod(k)).rows()
sage: cones = [[0,1,2,3], [4,5,6,7], [0,1,7,6], [4,5,3,2], [0,2,5,7], [4,6,1,3]]
sage: X_Delta = lambda k: ToricVariety(Fan(cones=cones, rays=rays(k)))
sage: X_Delta(0).Chow_group().degree()  # long time (3s on sage.math, 2011)
(Z, Z, Z^5)  
sage: X_Delta(1).Chow_group().degree()  # long time (3s on sage.math, 2011)
(Z, 0, Z^5)  
sage: X_Delta(2).Chow_group().degree()  # long time (3s on sage.math, 2011)
(Z, C2, Z^5)  
sage: X_Delta(2).Chow_group(base_ring=QQ).degree()  # long time (4s on sage.math, 2011)
(Q, 0, Q^5)
```

```
gens (degree=None)
Return the generators of the Chow group.

INPUT:

* degree – integer (optional). The degree of the Chow group.

OUTPUT:

* if no degree is specified, the generators of the whole Chow group. The chosen generators may be of
  mixed degree.

* if degree=k was specified, the generators of the degree-k part A_k of the Chow group.

EXAMPLES:

```
sage: A = toric_varieties.P2().Chow_group()
sage: A.gens()  
(( 1 | 0 | 0 ), ( 0 | 1 | 0 ), ( 0 | 0 | 1 ))
sage: A.gens(degree=1)  
(( 0 | 1 | 0 ),)
```

```
relation_gens()
Return the Chow cycles equivalent to zero.

For each d−k−1-dimensional cone \( \rho \in \Sigma^{d−k−1} \), the relations in \( A_k(X) \), that is the cycles equivalent
to zero, are generated by

\[
0 = \div(u) = \sum_{\rho < \sigma \in \Sigma^{d-k-1}} \langle u, n_{\rho,\sigma} \rangle V(\sigma), \quad u \in M(\rho)
\]

where \( n_{\rho,\sigma} \) is a (randomly chosen) lift of the generator of \( N_\rho/N_\rho \cong \mathbb{Z} \). See also Exercise 12.5.7 of [CLS].

16.6. The Chow group of a toric variety 303
See also `relations()` to obtain the relations as submodule of the free module generated by the cones. Or use `self.relations().gens()` to list the relations in the free module.

**OUTPUT:**

A tuple of Chow cycles, each rationally equivalent to zero, that generates the rational equivalence.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: first = A.relation_gens()[0]
sage: first
( 0 | 0 | 0 )
sage: first.is_zero()
True
sage: first.lift()
(0, 1, 0, -1, 0, 0, 0)
```

**scheme()**

Return the underlying toric variety.

**OUTPUT:**

A `ToricVariety`.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: A.scheme()
2-d CPR-Fano toric variety covered by 3 affine patches
sage: A.scheme() is P2
True
```

**class** `sage.schemes.toric.chow_group.ChowGroup_degree_class(A, d)`

**Bases:** `sage.structure.sage_object.SageObject`

A fixed-degree subgroup of the Chow group of a toric variety.

**Warning:** Use `degree()` to construct `ChowGroup_degree_class` instances.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: A
Chow group of 2-d CPR-Fano toric variety covered by 3 affine patches
sage: A.degree()
(Z, Z, Z)
sage: A.degree(2)
Z
sage: type(_)
<class 'sage.schemes.toric.chow_group.ChowGroup_degree_class'>
```

**gen(i)**

Return the i-th generator of the Chow group of fixed degree.

**INPUT:**
• \( i \) – integer. The index of the generator to be returned.

OUTPUT:
A tuple of Chow cycles of fixed degree generating \( \text{module()} \).

EXAMPLES:

```
sage: projective_plane = toric_varieties.P2()
sage: A2 = projective_plane.Chow_group().degree(2)
sage: A2.gen(0)
( 0 | 0 | 1 )
```

\( \text{gens()} \)
Return the generators of the Chow group of fixed degree.

OUTPUT:
A tuple of Chow cycles of fixed degree generating \( \text{module()} \).

EXAMPLES:

```
sage: projective_plane = toric_varieties.P2()
sage: A2 = projective_plane.Chow_group().degree(2)
sage: A2.gens()
(( 0 | 0 | 1 ),)
```

\( \text{module()} \)
Return the submodule of the toric Chow group generated.

OUTPUT:
A \text{sage.modules.fg_pid.fgp_module.FGP_Module_class}

EXAMPLES:

```
sage: projective_plane = toric_varieties.P2()
sage: A2 = projective_plane.Chow_group().degree(2)
sage: A2.module()
Finitely generated module V/W over Integer Ring with invariants (0)
```

\( \text{ngens()} \)
Return the number of generators.

OUTPUT:
An integer.

EXAMPLES:

```
sage: projective_plane = toric_varieties.P2()
sage: A2 = projective_plane.Chow_group().degree(2)
sage: A2.ngens()
1
```

\text{sage.schemes.toric.chow_group.}\text{is_ChowCycle}(x)
Return whether \( x \) is a \text{ChowGroup_class}

INPUT:
• \( x \) – anything.
OUTPUT:
True or False.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: from sage.schemes.toric.chow_group import *
sage: is_ChowCycle(A)
False
sage: is_ChowCycle(A.an_element())
True
sage: is_ChowCycle('Victoria')
False
```

 sage.schemes.toric.chow_group.is_ChowGroup(x)
Return whether x is a ChowGroup_class

INPUT:
• x – anything.

OUTPUT:
True or False.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: A = P2.Chow_group()
sage: from sage.schemes.toric.chow_group import is_ChowGroup
sage: is_ChowGroup(A)
True
sage: is_ChowGroup('Victoria')
False
```

16.7 Toric ideals

A toric ideal (associated to an integer matrix $A$) is an ideal of the form

$$I_A = \langle x^u - x^v : u, v \in \mathbb{Z}_n, u - v \in \ker(A) \rangle$$

In other words, it is an ideal generated by irreducible “binomials”, that is, differences of monomials without a common factor. Since the Buchberger algorithm preserves this property, any Groebner basis is then also generated by binomials.

EXAMPLES:

```python
sage: A = matrix([[1, 1, 1], [0, 1, 2]])
sage: IA = ToricIdeal(A)
sage: IA.ker()
Free module of degree 3 and rank 1 over Integer Ring
User basis matrix:
[-1 2 -1]
sage: IA
Ideal (-z1^2 + z0*z2) of Multivariate Polynomial
Ring in z0, z1, z2 over Rational Field
```
Here, the “naive” ideal generated by \(z_0z_2 - z_2^2\) does already equal the toric ideal. But that is not true in general! For example, this toric ideal \((\text{ProcSympPureMath62}, \text{Example 1.2})\) is the twisted cubic and cannot be generated by \(2 = \dim \ker(A)\) polynomials:

```python
sage: A = matrix([[3,2,1,0],[0,1,2,3]])
sage: IA = ToricIdeal(A)
sage: IA.ker()
Free module of degree 4 and rank 2 over Integer Ring
User basis matrix:
[-1 1 1 -1]
[-1 2 -1 0]
sage: IA
Ideal (-z1*z2 + z0*z3, -z1^2 + z0*z2, z2^2 - z1*z3) of
Multivariate Polynomial Ring in z0, z1, z2, z3 over Rational Field
```

The following family of toric ideals is from Example 4.4 of \([\text{ProcSympPureMath62}]\). One can show that \(I_d\) is generated by one quadric and \(d\) binomials of degree \(d\):

```python
sage: I = lambda d: ToricIdeal(matrix([[1,1,1,1,1],[0,1,1,0,0],[0,0,1,1,d]]))
sage: I(2)
Ideal (-z3^2 + z0*z4, z0*z2 - z1*z3, z2*z3 - z1*z4) of
Multivariate Polynomial Ring in z0, z1, z2, z3 over Rational Field
sage: I(3)
Ideal (-z3^3 + z0^2*z4, z0*z2 - z1*z3, z2*z3^2 - z0*z1*z4, z2^2*z3 - z1^2*z4) of
Multivariate Polynomial Ring in z0, z1, z2, z3 over Rational Field
sage: I(4)
Ideal (-z3^4 + z0^3*z4, z0*z2 - z1*z3, z2*z3^3 - z0^2*z1*z4, z2^2*z3^2 - z0*z1^2*z4, z2^3*z3 - z1^3*z4) of
Multivariate Polynomial Ring in z0, z1, z2, z3 over Rational Field
```

Finally, the example in \([\text{GRIN}]\):

```python
sage: A = matrix(ZZ, [[15, 4, 14, 19, 2, 1, 10, 17],
                ....: [18, 11, 13, 5, 16, 16, 8, 19],
                ....: [11, 7, 8, 19, 15, 18, 14, 6],
                ....: [17, 10, 13, 17, 16, 14, 15, 18]])
sage: IA = ToricIdeal(A)  # long time
sage: IA.ngens()  # long time
213
```

REFERENCES:

AUTHORS:

• Volker Braun (2011-01-03): Initial version

```python
class sage.schemes.toric.ideal.ToricIdeal(A, names='z', base_ring=Rational
Field, polynomial_ring=None, algorithm='HostenSturmfels')

Bases: sage.rings.polynomial.multi_polynomial_ideal.MPolynomialIdeal

This class represents a toric ideal defined by an integral matrix.
```
INPUT:

• **A** – integer matrix. The defining matrix of the toric ideal.

• **names** – string (optional). Names for the variables. By default, this is 'z' and the variables will be named $z_0, z_1, ...$

• **base_ring** – a ring (optional). Default: $\mathbb{Q}$. The base ring of the ideal. A toric ideal uses only coefficients $\pm 1$.

• **polynomial_ring** – a polynomial ring (optional). The polynomial ring to construct the ideal in.

You may specify the ambient polynomial ring via the `polynomial_ring` parameter or via the `names` and `base_ring` parameter. A `ValueError` is raised if you specify both.

• **algorithm** – string (optional). The algorithm to use. For now, must be 'HostenSturmfels' which is the algorithm proposed by Hosten and Sturmfels in [GRIN].

EXAMPLES:

```
sage: A = matrix([[1,1,1],[0,1,2]])
sage: ToricIdeal(A)
Ideal (-z1^2 + z0*z2) of Multivariate Polynomial Ring in z0, z1, z2 over Rational Field
```

First way of specifying the polynomial ring:

```
sage: ToricIdeal(A, names='x,y,z', base_ring=ZZ)
Ideal (-y^2 + x*z) of Multivariate Polynomial Ring in x, y, z over Integer Ring
```

Second way of specifying the polynomial ring:

```
sage: R.<x,y,z> = ZZ[]
sage: ToricIdeal(A, polynomial_ring=R)
Ideal (-y^2 + x*z) of Multivariate Polynomial Ring in x, y, z over Integer Ring
```

It is an error to specify both:

```
sage: ToricIdeal(A, names='x,y,z', polynomial_ring=R)
Traceback (most recent call last):
... ValueError: You must not specify both variable names and a polynomial ring.
```

**A()**

Return the defining matrix.

OUTPUT:

An integer matrix.

EXAMPLES:

```
sage: A = matrix([[1,1,1],[0,1,2]])
sage: IA = ToricIdeal(A)
sage: IA.A()
[1 1 1]
[0 1 2]
```

**ker()**

Return the kernel of the defining matrix.
The kernel of `self.A()`.

**EXAMPLES:**

```python
sage: A = matrix([[1,1,1],[0,1,2]])
sage: IA = ToricIdeal(A)
sage: IA.ker()
Free module of degree 3 and rank 1 over Integer Ring
User basis matrix:
[-1  2 -1]
```

### `nvariables()`

Return the number of variables of the ambient polynomial ring.

**OUTPUT:**

Integer. The number of columns of the defining matrix `A()`.

**EXAMPLES:**

```python
sage: A = matrix([[1,1,1],[0,1,2]])
sage: IA = ToricIdeal(A)
sage: IA.nvariables()
3
```  

## 16.8 Morphisms of toric varieties

There are three “obvious” ways to map toric varieties to toric varieties:

1. Polynomial maps in local coordinates, the usual morphisms in algebraic geometry.
2. Polynomial maps in the (global) homogeneous coordinates.
3. Toric morphisms, that is, algebraic morphisms equivariant with respect to the torus action on the toric variety.

Both 2 and 3 are special cases of 1, which is just to say that we always remain within the realm of algebraic geometry. But apart from that, none is included in one of the other cases. In the examples below, we will explore some algebraic maps that can or cannot be written as a toric morphism. Often a toric morphism can be written with polynomial maps in homogeneous coordinates, but sometimes it cannot.

The toric morphisms are perhaps the most mysterious at the beginning. Let us quickly review their definition (See Definition 3.3.3 of [CLS]). Let $\Sigma_1$ be a fan in $N_1, R$ and $\Sigma_2$ be a fan in $N_2, R$. A morphism $\phi : X_{\Sigma_1} \rightarrow X_{\Sigma_2}$ of the associated toric varieties is toric if $\phi$ maps the maximal torus $T_{N_1} \subseteq X_{\Sigma_1}$ into $T_{N_2} \subseteq X_{\Sigma_2}$ and $\phi|_{T_N}$ is a group homomorphism.

The data defining a toric morphism is precisely what defines a fan morphism (see `fan_morphism`), extending the more familiar dictionary between toric varieties and fans. Toric geometry is a functor from the category of fans and fan morphisms to the category of toric varieties and toric morphisms.

**Note:** Do not create the toric morphisms (or any morphism of schemes) directly from the `SchemeMorphism...` classes. Instead, use the `hom()` method common to all algebraic schemes to create new homomorphisms.

**EXAMPLES:**

First, consider the following embedding of $\mathbb{P}^1$ into $\mathbb{P}^2$
This is a well-defined morphism of algebraic varieties because homogeneously rescaled coordinates of a point of $\mathbb{P}^1$ map to the same point in $\mathbb{P}^2$ up to its homogeneous rescalings. It is not equivariant with respect to the torus actions

$$\mathbb{C}^\times \times \mathbb{P}^1, (\mu, [u:v]) \mapsto [u: \mu v] \quad \text{and} \quad (\mathbb{C}^\times)^2 \times \mathbb{P}^2, ((\alpha, \beta), [x:y:z]) \mapsto [x: \alpha y: \beta z],$$

hence it is not a toric morphism. Clearly, the problem is that the map in homogeneous coordinates contains summands that transform differently under the torus action. However, this is not the only difficulty. For example, consider

This map is actually the embedding of the *orbit_closure()* associated to one of the rays of the fan of $\mathbb{P}^2$. Now the morphism is equivariant with respect to some map $\mathbb{C}^\times \to (\mathbb{C}^\times)^2$ of the maximal tori of $\mathbb{P}^1$ and $\mathbb{P}^2$. But this map of the maximal tori cannot be the same as $\phi$ defined above. Indeed, the image of $\phi$ completely misses the maximal torus $T_{\mathbb{P}^2} = \{ [x:y:z] | x \neq 0, y \neq 0, z \neq 0 \}$ of $\mathbb{P}^2$.

Consider instead the following morphism of fans:

which also defines a morphism of toric varieties:

The fan morphism map is equivalent to the following polynomial map:

Finally, here is an example of a fan morphism that cannot be written using homogeneous polynomials. Consider the blowup $O_{\mathbb{P}^1}(2) \to \mathbb{C}^2/\mathbb{Z}_2$. In terms of toric data, this blowup is:
If we denote the homogeneous coordinates of $\mathbb{P}^1(2)$ by $x, t, y$ corresponding to the rays $(1, 2), (1, 1), \text{and} (1, 0)$ then the blow-up map is $[BB]$:

$$f : \mathbb{P}^1(2) \to \mathbb{C}^2/\mathbb{Z}_2, \quad (x, t, y) \mapsto (x\sqrt{t}, y\sqrt{t})$$

which requires square roots.

### 16.8.1 Fibrations

If a toric morphism is dominant, then all fibers over a fixed torus orbit in the base are isomorphic. Hence, studying the fibers is again a combinatorial question and Sage implements additional methods to study such fibrations that are not available otherwise (however, note that you can always `factor()` to pick out the part that is dominant over the image or its closure).

For example, consider the blow-up restricted to one of the two coordinate charts of $\mathbb{P}^1(2)$

```python
sage: O2_P1_chart = ToricVariety(Fan([O2_P1.fan().generating_cones()[0]]))
sage: single_chart = O2_P1_chart.hom(identity_matrix(2), A2_Z2)
sage: single_chart.is_dominant()
True
sage: single_chart.is_surjective()
False
sage: fiber = single_chart.fiber_generic(); fiber
(0-d affine toric variety, 1)
sage: fiber[0].embedding_morphism().as_polynomial_map()
Scheme morphism:
  From: 0-d affine toric variety
  To: 2-d affine toric variety
  Defn: Defined on coordinates by sending [] to [1 : 1]
```

The fibers are labeled by torus orbits in the base, that is, cones of the codomain fan. In this case, the fibers over lower-dimensional torus orbits are:

```python
sage: A2_Z2_cones = flatten(A2_Z2.fan().cones())
sage: table(['cone', 'dim']) + 
....:     [(cone.ambient_ray_indices(), single_chart.fiber_dimension(cone)) 
....:      for cone in A2_Z2_cones], header_row=True)
  cone  dim
    ()  0
    (0,) 0
    (1,) -1
    (0, 1) 1
```
Lets look closer at the one-dimensional fiber. Although not the case in this example, connected components of fibers over higher-dimensional cones (corresponding to lower-dimensional torus orbits) of the base are often not irreducible. The irreducible components are labeled by the primitive_preimage_cones(), which are certain cones of the domain fan that map to the cone in the base that defines the torus orbit:

<table>
<thead>
<tr>
<th>base cone</th>
<th>primitive preimage cones</th>
</tr>
</thead>
<tbody>
<tr>
<td>()</td>
<td>(0-d cone of Rational polyhedral fan in 2-d lattice N,)</td>
</tr>
<tr>
<td>(0,)</td>
<td>(1-d cone of Rational polyhedral fan in 2-d lattice N,)</td>
</tr>
<tr>
<td>(1,)</td>
<td>()</td>
</tr>
<tr>
<td>(0, 1)</td>
<td>(1-d cone of Rational polyhedral fan in 2-d lattice N,)</td>
</tr>
</tbody>
</table>

The fiber over the trivial cone is the generic fiber that we have already encountered. The interesting fiber is the one over the 2-dimensional cone, which represents the exceptional set of the blow-up in this single coordinate chart. Lets investigate further:

sage: exceptional_cones = single_chart.fan_morphism().primitive_preimage_cones(A2_Z2.fan(2)[0])
sage: exceptional_set = single_chart.fiber_component(exceptional_cones[0])
sage: exceptional_set
1-d affine toric variety
sage: exceptional_set.embedding_morphism().as_polynomial_map()
Scheme morphism:
    From: 1-d affine toric variety
    To: 2-d affine toric variety
    Defn: Defined on coordinates by sending [z0] to [z0 : 0]

So we see that the fiber over this point is an affine line. Together with another affine line in the other coordinate patch, this covers the exceptional $\mathbb{P}^1$ of the blow-up $O_{\mathbb{P}^2}(2) \to \mathbb{C}^2/\mathbb{Z}_2$.

Here is an example with higher dimensional varieties involved:

sage: A3 = toric_varieties.A(3)
sage: P3 = toric_varieties.P(3)
sage: m = matrix([[2,0,0], [1,1,0], [3, 1, 0]])
sage: phi = A3.hom(m, P3)
sage: phi.as_polynomial_map()
Scheme morphism:
    From: 3-d affine toric variety
    To: 3-d CPR-Fano toric variety covered by 4 affine patches
    Defn: Defined on coordinates by sending [z0 : z1 : z2] to [z0^2*z1*z2^3 : z1*z2 : 1 : 1]
sage: phi.fiber_generic()
Traceback (most recent call last):
  ... AttributeError: 'SchemeMorphism_fan_toric_variety' object has no attribute 'fiber_generic'

Let's use factorization mentioned above:

sage: phi_i, phi_b, phi_s = phi.factor()

It is possible to study fibers of the last two morphisms or their composition:
sage: phi_d = phi_b * phi_s
sage: phi_d
Scheme morphism:
    From: 3-d affine toric variety
    To: 2-d toric variety covered by 3 affine patches
    Defn: Defined by sending Rational polyhedral fan in 3-d lattice N to
           Rational polyhedral fan in Sublattice <N(1, 0, 0), N(0, 1, 0)>

sage: phi_d.as_polynomial_map()
Scheme morphism:
    From: 3-d affine toric variety
    To: 2-d toric variety covered by 3 affine patches
    Defn: Defined on coordinates by sending [z0 : z1 : z2] to
           [z0^2*z1*z2^3 : z1*z2 : 1]

sage: phi_d.codomain().fan().rays()
N( 1, 0, 0),
N( 0, 1, 0),
N(-1, -1, 0)
in Sublattice <N(1, 0, 0), N(0, 1, 0)>

sage: for c in phi_d.codomain().fan():
    ....: c.ambient_ray_indices()
(1, 2)
(0, 2)
(0, 1)

We see that codomain fan of this morphism is a projective plane, which can be verified by

sage: phi_d.codomain().fan().is_isomorphic(toric_varieties.P2().fan())
# known bug
True

(Unfortunately it cannot be verified correctly until trac ticket #16012 is fixed.)

We now have access to fiber methods:

sage: fiber = phi_d.fiber_generic()
sage: fiber
(1-d affine toric variety, 2)
sage: fiber[0].embedding_morphism()
Scheme morphism:
    From: 1-d affine toric variety
    To: 3-d affine toric variety
    Defn: Defined by sending
           Rational polyhedral fan in Sublattice <N(1, 1, -1)> to
           Rational polyhedral fan in 3-d lattice N.

sage: fiber[0].embedding_morphism().as_polynomial_map()
Traceback (most recent call last):
...
NotImplementedError: polynomial representations for
fans with virtual rays are not implemented yet

sage: fiber[0].fan().rays()
Empty collection
in Sublattice <N(1, 1, -1)>

We see that generic fibers of this morphism consist of 2 one-dimensional tori each. To see what happens over boundary points we can look at fiber components corresponding to the cones of the domain fan:

sage: fm = phi_d.fan_morphism()
sage: for c in flatten(phi_d.domain().fan().cones()):
    ....: fc, m = phi_d.fiber_component(c, multiplicity=True)
(continues on next page)
print('{} |-> {} ({} rays, multiplicity {}) over {}'.format(c.ambient_ray_indices(), fc, fc.fan().nrays(), m, fm.image_cone(c).ambient_ray_indices()))
() |-> 1-d affine toric variety (0 rays, multiplicity 2) over ()
(0,) |-> 1-d affine toric variety (0 rays, multiplicity 1) over (0,)
(1,) |-> 2-d affine toric variety (2 rays, multiplicity 1) over (0, 1)
(2,) |-> 2-d affine toric variety (2 rays, multiplicity 1) over (0, 1)
(0, 1) |-> 1-d affine toric variety (1 rays, multiplicity 1) over (0, 1)
(1, 2) |-> 1-d affine toric variety (1 rays, multiplicity 1) over (0, 1)
(0, 2) |-> 1-d affine toric variety (1 rays, multiplicity 1) over (0, 1)
(0, 1, 2) |-> 0-d affine toric variety (0 rays, multiplicity 1) over (0, 1)

Now we see that over one of the coordinate lines of the projective plane we also have one-dimensional tori (but only one in each fiber), while over one of the points fixed by torus action we have two affine planes intersecting along an affine line. An alternative perspective is provided by cones of the codomain fan:

for c in flatten(phi_d.codomain().fan().cones):
    print('{} connected components over {}, each with {} irreducible components. →'.format(fm.index(c), c.ambient_ray_indices(), len(fm.primitive_preimage_cones(c))))

2 connected components over (), each with 1 irreducible components.
1 connected components over (0,), each with 1 irreducible components.
None connected components over (1,), each with 0 irreducible components.
None connected components over (2,), each with 0 irreducible components.
None connected components over (1, 2), each with 0 irreducible components.
None connected components over (0, 2), each with 0 irreducible components.
1 connected components over (0, 1), each with 2 irreducible components.

REFERENCES:

class sage.schemes.toric.morphism.SchemeMorphism_fan_fiber_component_toric_variety(toric_morphism, defining_cone)

Bases: sage.schemes.generic.morphism.SchemeMorphism

The embedding of a fiber component of a toric morphism.

Note that the embedding map of a fiber component of a toric morphism is itself not a toric morphism!

INPUT:

• toric_morphism – a toric morphism. The toric morphism whose fiber component we are describing.

• defining_cone – a cone of the fan of the domain of toric_morphism. See fiber_component() for details.

EXAMPLES:

sage: polytope = Polyhedron(
    [(−3,0,−1,−1), (−1,2,−1,−1), (0,−1,0,0), (0,0,0,1), (0,0,1,0),
     (0,1,0,0), (0,2,−1,−1), (1,0,0,0), (2,0,−1,−1)])
sage: coarse_fan = FaceFan(polytope, lattice=ToricLattice(4))
sage: P2 = toric_varieties.P2()
sage: proj24 = matrix([[0,0],[1,0],[0,0],[0,1]])
sage: fm = FanMorphism(proj24, coarse_fan, P2.fan(), subdivide=True)
sage: fibration = ToricVariety(fm.domain_fan()).hom(fm, P2)
sage: primitive_cones = fibration.fan_morphism().primitive_preimage_cones(P2.˓
    →fan(dim=1))

(continues on next page)
as_polynomial_map()  
Express the embedding morphism via homogeneous polynomials.  

OUTPUT:  
A SchemeMorphism_polynomial_toric_variety. Raises a ValueError if the morphism cannot be written in terms of homogeneous polynomials.  

EXAMPLES:  

sage: primitive_cone = Cone([(-1, 0, 0, 0)])  
sage: f = fibration.fiber_component(primitive_cone).embedding_morphism()  
sage: f.as_polynomial_map()  
Traceback (most recent call last):  
...
ValueError: The morphism cannot be written using homogeneous polynomials.
The fiber is constant over the base orbit closure $V(\sigma)$.

**OUTPUT:**

A cone of the base of the toric fibration.

**EXAMPLES:**

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: fc = P1xP1.hom(matrix([[1], [0]]), P1).fiber_component(Cone([[1, 0]]))
sage: f = fc.embedding_morphism()
sage: f.defining_cone().rays()
N(1, 0)
in 2-d lattice N
sage: f.base_cone().rays()
N(1)
in 1-d lattice N
```

**defining_cone()**

Return the cone corresponding to the fiber torus orbit.

**OUTPUT:**

A cone of the fan of the total space of the toric fibration.

**EXAMPLES:**

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: fc = P1xP1.hom(matrix([[1], [0]]), P1).fiber_component(Cone([[1, 0]]))
sage: f = fc.embedding_morphism()
sage: f.defining_cone().rays()
N(1, 0)
in 2-d lattice N
sage: f.base_cone().rays()
N(1)
in 1-d lattice N
```

**pullback_divisor(divisor)**

Pull back a toric divisor.

**INPUT:**

- `divisor` – a torus-invariant QQ-Cartier divisor on the codomain of the embedding map.

**OUTPUT:**

A divisor on the domain of the embedding map (irreducible component of a fiber of a toric morphism) that is isomorphic to the pull-back divisor $f^*(D)$ but with possibly different linearization.

**EXAMPLES:**

```python
sage: A1 = toric_varieties.A1()
sage: fan = Fan([(0,1,2)], [(1,1,0),(1,0,1),(1,-1,-1)]).subdivide(new_rays=[[1,0,0]])
sage: f = ToricVariety(fan).hom(matrix([[1], [0], [0]]), A1)
sage: D = f.domain().divisor([[1,1,3,4]]); D
V(z0) + V(z1) + V(z2) + 4*V(z3)
sage: fc = f.fiber_component(Cone([[1,1,0]]))
sage: fc.embedding_morphism().pullback_divisor(D)
3*V(z0) + 2*V(z2)
```

(continues on next page)
class sage.schemes.toric.morphism.SchemeMorphism_fan_toric_variety(parent, fan_morphism, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism, sage.categories.morphism.Morphism

Construct a morphism determined by a fan morphism

Warning: You should not create objects of this class directly. Use the hom() method of toric varieties instead.

INPUT:

- parent – Hom-set whose domain and codomain are toric varieties.
- fan_morphism – A morphism of fans whose domain and codomain fans equal the fans of the domain and codomain in the parent Hom-set.
- check – boolean (optional, default=True). Whether to check the input for consistency.

Warning: A fibration is a dominant morphism; if you are interested in these then you have to make sure that your fan morphism is dominant. For example, this can be achieved by factoring the morphism. See SchemeMorphism_fan_toric_variety_dominant for additional functionality for fibrations.

OUTPUT:

A SchemeMorphism_fan_toric_variety.

EXAMPLES:

sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: f = P1.hom(matrix([[1],[0]]), P1xP1); f
Scheme morphism:
  From: 1-d CPR-Fano toric variety covered by 2 affine patches
  To:  2-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined by sending Rational polyhedral fan in 1-d lattice N to Rational polyhedral fan in 2-d lattice N.
sage: type(f)
<class 'sage.schemes.toric.morphism.SchemeMorphism_fan_toric_variety'>

Slightly more explicit construction:

sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: hom_set = P1xP1.Hom(P1)
sage: fm = FanMorphism( matrix(ZZ,[[1],[0]]), P1xP1.fan(), P1.fan() )
sage: hom_set(fm)
Scheme morphism:
  From: 2-d CPR-Fano toric variety covered by 4 affine patches
  To:  1-d CPR-Fano toric variety covered by 2 affine patches
Defn: Defined by sending Rational polyhedral fan in 2-d lattice $N$ to Rational polyhedral fan in 1-d lattice $N$.

\begin{verbatim}
 sage: P1xP1.hom(fm, P1)
Scheme morphism:
  From: 2-d CPR-Fano toric variety covered by 4 affine patches
  To:  1-d CPR-Fano toric variety covered by 2 affine patches
  Defn: Defined by sending Rational polyhedral fan in 2-d lattice $N$
  to Rational polyhedral fan in 1-d lattice $N$.
\end{verbatim}

\textbf{as\_polynomial\_map()} \\
Express the morphism via homogeneous polynomials.

\textbf{OUTPUT:}

\begin{verbatim}
 A \texttt{SchemeMorphism\_polynomial\_toric\_variety}. \texttt{Raises a TypeError} if the morphism cannot be written in terms of homogeneous polynomials.
\end{verbatim}

\textbf{EXAMPLES:}

\begin{verbatim}
 sage: A1 = toric_varieties.A1()
 sage: square = A1.hom(matrix([[2]]), A1)
 sage: square.as_polynomial_map()
 Scheme endomorphism of 1-d affine toric variety
  Defn: Defined on coordinates by sending $[z]$ to
         $[z^2]$
 sage: P1 = toric_varieties.P1()
 sage: patch = A1.hom(matrix([[1]]), P1)
 sage: patch.as_polynomial_map()
 Scheme morphism:
  From: 1-d affine toric variety
  To:  1-d CPR-Fano toric variety covered by 2 affine patches
  Defn: Defined on coordinates by sending $[z]$ to
         $[z : 1]$
\end{verbatim}

\textbf{factor()} \\
Factor \texttt{self} into injective * birational * surjective morphisms.

\textbf{OUTPUT:}

\begin{itemize}
  \item a triple of toric morphisms ($\phi_i, \phi_b, \phi_s$), such that $\phi_s$ is surjective, $\phi_b$ is birational, $\phi_i$ is injective, and $\texttt{self}$ is equal to $\phi_i \circ \phi_b \circ \phi_s$.
\end{itemize}

The intermediate varieties are universal in the following sense. Let \texttt{self} map $X$ to $X'$ and let $X_s, X_i$ sit in between, that is,

\[ X \twoheadrightarrow X_s \twoheadrightarrow X_i \hookrightarrow X'. \]

Then any toric morphism from $X$ coinciding with \texttt{self} on the maximal torus factors through $X_s$ and any toric morphism into $X'$ coinciding with \texttt{self} on the maximal torus factors through $X_i$. In particular, $X_i$ is the closure of the image of \texttt{self} in $X'$.

See \texttt{factor()} for a description of the toric algorithm.

\textbf{EXAMPLES:}

We map an affine plane into a projective 3-space in such a way, that it becomes “a double cover of a chart of the blow up of one of the coordinate planes”:
```python
sage: A2 = toric_varieties.A2()
sage: P3 = toric_varieties.P(3)
sage: m = matrix([[2,0,0], [1,1,0]])
sage: phi = A2.hom(m, P3)
sage: phi.as_polynomial_map()
Scheme morphism:
  From: 2-d affine toric variety
  To: 3-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined on coordinates by sending [x : y] to
      [x^2*y : y : 1 : 1]

sage: phi.is_surjective(), phi.is_birational(), phi.is_injective()
(False, False, False)

sage: phi_i, phi_b, phi_s = phi.factor()
sage: phi_s.is_surjective(), phi_b.is_birational(), phi_i.is_injective()
(True, True, True)

sage: prod(phi.factor()) == phi
True

Double cover (surjective):

```
sage: f.fan_morphism()
Fan morphism defined by the matrix
[1]
[0]
Domain fan: Rational polyhedral fan in 2-d lattice N
Codomain fan: Rational polyhedral fan in 1-d lattice N

is_birational()
Check if self is birational.

See is_birational() for fan morphisms for a description of the toric algorithm.

OUTPUT:
Boolean. Whether self is birational.

EXAMPLES:

```
sage: dP8 = toric_varieties.dP8()
sage: P2 = toric_varieties.P2()
sage: dP8.hom(identity_matrix(2), P2).is_birational()
True
sage: X = toric_varieties.A(2)
sage: Y = ToricVariety(Fan([Cone([[(1,0), (1,1)]]])))
sage: m = identity_matrix(2)
sage: f = Y.hom(m, X)
sage: f.is_birational()
True
```

is_bundle()
Check if self is a bundle.

See is_bundle() for fan morphisms for details.

OUTPUT:

• True if self is a bundle, False otherwise.

EXAMPLES:

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: P1xP1.hom(matrix([[1], [0]]), P1).is_bundle()
True
```

is_dominant()
Return whether self is dominant.

See is_dominant() for fan morphisms for a description of the toric algorithm.

OUTPUT:
Boolean. Whether self is a dominant scheme morphism.

EXAMPLES:

```
sage: P1 = toric_varieties.P1()
sage: A1 = toric_varieties.A1()
sage: phi = A1.hom(identity_matrix(1), P1); phi
Scheme morphism:
```
From: 1-d affine toric variety
To: 1-d CPR-Fano toric variety covered by 2 affine patches
Defn: Defined by sending Rational polyhedral fan in 1-d lattice N to Rational polyhedral fan in 1-d lattice N.
sage: phi.is_dominant()
True
sage: phi.is_surjective()
False

is_fibration()  
Check if self is a fibration.

See is_fibration() for fan morphisms for details.

OUTPUT:

• True if self is a fibration, False otherwise.

EXAMPLES:

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: P1xP1.hom(matrix([[1], [0]]), P1).is_fibration()
True
```

is_injective()  
Check if self is injective.

See is_injective() for fan morphisms for a description of the toric algorithm.

OUTPUT:

Boolean. Whether self is injective.

EXAMPLES:

```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: P1xP1.hom(matrix([[1], [0]]), P1).is_injective()
False
```

```
sage: X = toric_varieties.A(2)
sage: m = identity_matrix(2)
sage: f = X.hom(m, X)
sage: f.is_injective()
True
```

```
sage: Y = ToricVariety(Fan([Cone([[1,0], (1,1)])]))
sage: f = Y.hom(m, X)
sage: f.is_injective()
False
```

is_surjective()  
Check if self is surjective.

See is_surjective() for fan morphisms for a description of the toric algorithm.

OUTPUT:

Boolean. Whether self is surjective.
EXAMPLES:

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: P1xP1.hom(matrix([[1],[0]]), P1).is_surjective()
True
sage: X = toric_varieties.A(2)
sage: m = identity_matrix(2)
sage: f = X.hom(m, X)
sage: f.is_surjective()
True
sage: Y = ToricVariety(Fan([Cone([(1,0), (1,1)])]))
sage: f = Y.hom(m, X)
sage: f.is_surjective()
False
```

**pullback_divisor** (*divisor*)
Pull back a toric divisor.

INPUT:
- *divisor* — a torus-invariant QQ-Cartier divisor on the codomain of *self*.

OUTPUT:
The pull-back divisor \( f^*(D) \).

EXAMPLES:

```python
sage: A2_Z2 = toric_varieties.A2_Z2()
sage: A2 = toric_varieties.A2()
sage: f = A2.hom( matrix([[1,0],[1,2]]), A2_Z2)
sage: f.pullback_divisor(A2_Z2.divisor(0))
V(x)
sage: A1 = toric_varieties.A1()
sage: square = A1.hom(matrix([[2]]), A1)
sage: D = A1.divisor(0); D
V(z)
sage: square.pullback_divisor(D)
2*V(z)
```

**class** `sage.schemes.toric.morphism.SchemeMorphism_fan_toric_variety_dominant` (*parent*, *fan_morphism*, *check=True*)

Bases: `sage.schemes.toric.morphism.SchemeMorphism_fan_toric_variety`

Construct a morphism determined by a dominant fan morphism.

A dominant morphism is one that is surjective onto a dense subset. In the context of toric morphisms, this means that it is onto the big torus orbit.

**Warning:** You should not create objects of this class directly. Use the `hom()` method of `toric_varieties` instead.

INPUT:

See `SchemeMorphism_fan_toric_variety`. The given fan morphism must be dominant.
OUTPUT:

A `SchemeMorphism_fan_toric_variety_dominant`.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: dP8 = toric_varieties.dP8()
sage: f = dP8.hom(identity_matrix(2), P2); f
Scheme morphism:
  From: 2-d CPR-Fano toric variety covered by 4 affine patches
  To:  2-d CPR-Fano toric variety covered by 3 affine patches
  Defn: Defined by sending Rational polyhedral fan in 2-d lattice N
to Rational polyhedral fan in 2-d lattice N.
sage: type(f)
<class 'sage.schemes.toric.morphism.SchemeMorphism_fan_toric_variety_dominant'>
```

`fiber_component(domain_cone, multiplicity=False)`

Return a fiber component corresponding to `domain_cone`.

**INPUT:**

- `domain_cone` – a cone of the domain fan of `self`.
- `multiplicity` (default: `False`) – whether to return the number of fiber components corresponding to `domain_cone` as well.

**OUTPUT:**

- either `X` or a tuple `(X, n)`, where `X` is a toric variety with the embedding morphism into domain of `self` and `n` is an integer.

Let \( \phi : \Sigma \to \Sigma' \) be the fan morphism corresponding to `self`. Let \( \sigma \in \Sigma \) and \( \sigma' \in \Sigma' \) be the `image_cone()` of \( \sigma \). The fiber over any point of the torus orbit corresponding to \( \sigma' \) consists of \( n \) isomorphic connected components with each component being a union of toric varieties intersecting along their torus invariant subvarieties. The latter correspond to `preimage_cones()` of \( \sigma' \) and \( X \) is one of the \( n \) components corresponding to \( \sigma \). The irreducible components correspond to `primitive_preimage_cones()`.

**EXAMPLES:**

```python
sage: polytope = LatticePolytope(
....:     [(-3,0,-1,-1),(-1,2,-1,-1),(0,-1,0,0),(0,0,0,1),(0,0,1,0),
....:      (0,1,0,0),(0,2,-1,-1),(1,0,0,0),(2,0,-1,-1)])
sage: coarse_fan = FaceFan(polytope)
sage: P2 = toric_varieties.P2()
sage: proj24 = matrix([[0,0],[1,0],[0,0],[0,1]])
sage: fm = FanMorphism(proj24, coarse_fan, P2.fan(), subdivide=True)
sage: fibration = ToricVariety(fm.domain_fan()).hom(fm, P2)
sage: primitive_cones = fibration.fan_morphism().primitive_preimage_cones(P2.
˓→fan(1)[0])
sage: primitive_cone = primitive_cones[0]
sage: fibration.fiber_component(primitive_cone)
2-d toric variety covered by 4 affine patches
sage: fibration.fiber_component(primitive_cone, True)
(2-d toric variety covered by 4 affine patches, 1)
sage: for primitive_cone in primitive_cones:
....:     print(fibration.fiber_component(primitive_cone))
2-d toric variety covered by 4 affine patches
```

(continues on next page)
fiber_dimension\(\codomain\_cone\)
Return the dimension of the fiber over a particular torus orbit in the base.

INPUT:
• \codomain\_cone – a cone \(\sigma\) of the codomain, specifying a torus orbit \(O(\sigma)\).

OUTPUT:
An integer. The dimension of the fiber over the torus orbit corresponding to \codomain\_cone. If the fiber is the empty set, \(-1\) is returned. Note that all fibers over this torus orbit are isomorphic, and therefore have the same dimension.

EXAMPLES:
```
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: f = P1xP1.hom(matrix([[1],[0]]), P1)
sage: f.fiber_dimension(P1.fan(0)[0])
1
sage: f.fiber_dimension(P1.fan(1)[0])
1
sage: f.fiber_dimension(P1.fan(1)[1])
1
```

Here is a more complicated example that is not a flat fibration:
```
sage: A2_22 = toric_varieties.A2_22()
sage: O2_P1 = A2_22.resolve(new_rays=[(1,1)])
sage: blowup = O2_P1.hom(identity_matrix(2), A2_22)
sage: blowup.fiber_dimension(A2_22.fan(0)[0])
0
sage: blowup.fiber_dimension(A2_22.fan(1)[0])
0
sage: blowup.fiber_dimension(A2_22.fan(2)[0])
1
```

This corresponds to the three different fibers:
```
sage: blowup.fiber_generic()
(0-d affine toric variety, 1)
sage: blowup.fiber_component(Cone([[1,0]]))
0-d affine toric variety
sage: blowup.fiber_component(Cone([[1,1]]))
1-d toric variety covered by 2 affine patches
```

fiber\_generic()
Return the generic fiber.

OUTPUT:
• a tuple \((X, n)\), where \(X\) is a toric variety with the embedding morphism into domain of self and \(n\) is an integer.

The fiber over the base point with homogeneous coordinates \([1 : 1 : \cdots : 1]\) consists of \(n\) disjoint toric varieties isomorphic to \(X\). Note that fibers of a dominant toric morphism are isomorphic over all points of
a fixed torus orbit of its codomain, in particular over all points of the maximal torus, so it makes sense to talk about “the generic” fiber.

The embedding of $X$ is a toric morphism with the \texttt{domain\_fan()} being the \texttt{kernel\_fan()} of the defining fan morphism. By contrast, embeddings of fiber components over lower-dimensional torus orbits of the image are not toric morphisms. Use \texttt{fiber\_component()} for the latter (non-generic) fibers.

**EXAMPLES:**

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: fiber = P1xP1.hom(matrix([[1],[0]]), P1).fiber_generic()
sage: fiber
(1-d toric variety covered by 2 affine patches, 1)
sage: f = fiber[0].embedding_morphism(); f
Scheme morphism:
  From: 1-d toric variety covered by 2 affine patches
  To: 2-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined by sending Rational polyhedral fan in Sublattice $<N(0, 1)>$ to Rational polyhedral fan in 2-d lattice $N$.
sage: f.as_polynomial_map()
Scheme morphism:
  From: 1-d toric variety covered by 2 affine patches
  To: 2-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined on coordinates by sending $[z0 : z1]$ to $[1 : 1 : z0 : z1]$

sage: A1 = toric_varieties.A1()
sage: fan = Fan([(0,1,2)], [(1,1,0),(1,0,1),(1,-1,-1)])
sage: fan = fan.subdivide(new_rays=[(1,0,0)])
sage: f = ToricVariety(fan).hom(matrix([[1],[0],[0]]), A1)
sage: f.fiber_generic()
(2-d affine toric variety, 1)
sage: _.0.fan().generating_cones()
(0-d cone of Rational polyhedral fan in Sublattice $<N(0, 1, 0), N(0, 0, 1)>$,)
```

\textbf{fiber\_graph}(\texttt{codomain\_cone})

Return the fiber over a given torus orbit in the codomain.

**INPUT:**

- \texttt{codomain\_cone} – a cone $\sigma$ of the codomain, specifying a torus orbit $O(\sigma)$.

**OUTPUT:**

A graph whose nodes are the irreducible components of a connected component of the fiber over a point of $O(\sigma)$. If two irreducible components intersect, the corresponding nodes of the graph are joined by an edge. Note that irreducible components do not have to be of the same dimension.

**See also:**

\texttt{fiber\_component()}

**EXAMPLES:**

```
sage: polytope = Polyhedron(
    ....: [(-3,0,-1,-1),(-1,2,-1,-1),(0,-1,0,0),(0,0,0,1),(0,0,1,0),
    ....: (0,1,0,0),(0,2,-1,-1),(1,0,0,0),(2,0,-1,-1)])
sage: coarse_fan = FaceFan(polytope, lattice=ToricLattice(4))
sage: P2 = toric_varieties.P2()
(continues on next page)```
sage: proj34 = block_matrix(2,1,[zero_matrix(2,2), identity_matrix(2)])
sage: fm = FanMorphism(proj34, coarse_fan, P2.fan(), subdivide=True)
sage: fibration = ToricVariety(fm.domain_fan()).hom(fm, P2)

sage: fibration.fiber_graph( P2.fan(0)[0] )
Graph on 1 vertex
sage: for cl in P2.fan(1):
....:   fibration.fiber_graph(cl)
Graph on 1 vertex
Graph on 1 vertex
Graph on 4 vertices

sage: fibration.fiber_graph(P2.fan(1)[2]).get_vertices()
{0: 2-d toric variety covered by 4 affine patches,
 1: 2-d toric variety covered by 3 affine patches,
 2: 2-d toric variety covered by 3 affine patches,
 3: 2-d toric variety covered by 4 affine patches}

sage: fibration
Scheme morphism:
  From: 4-d toric variety covered by 18 affine patches
  To:  2-d CPR-Fano toric variety covered by 3 affine patches
  Defn: Defined by sending Rational polyhedral fan in 4-d lattice N
to Rational polyhedral fan in 2-d lattice N.

class sage.schemes.toric.morphism.SchemeMorphism_orbit_closure_toric_variety (parent, defining_cone, ray_map)

Bases: sage.schemes.generic.morphism.SchemeMorphism, sage.categories.morphism.Morphism

The embedding of an orbit closure.

INPUT:

- parent – the parent homset.
- defining_cone – the defining cone.
- ray_map – a dictionary {ambient ray generator: orbit ray generator}. Note that the image of the ambient ray generator is not necessarily primitive.

Warning: You should not create objects of this class directly. Use the orbit_closure() method of toric varieties instead.

EXAMPLES:

sage: P1xP1 = toric_varieties.P1xP1()
sage: H = P1xP1.fan(1)[0]
sage: V = P1xP1.orbit_closure(H)
sage: V.embedding_morphism()
Scheme morphism:
  From: 1-d toric variety covered by 2 affine patches
  To:  2-d CPR-Fano toric variety covered by 4 affine patches
  Defn: Defined by embedding the torus closure associated to the 1-d cone of Rational polyhedral fan in 2-d lattice N.
as_polynomial_map()  
Express the morphism via homogeneous polynomials.

OUTPUT:

A SchemeMorphism_polynomial_toric_variety. Raises a TypeError if the morphism cannot be written in terms of homogeneous polynomials.

The defining polynomials are not necessarily unique. There are choices if multiple ambient space ray generators project to the same orbit ray generator, and one such choice is made implicitly. The orbit embedding can be written as a polynomial map if and only if each primitive orbit ray generator is the image of at least one primitive ray generator of the ambient toric variety.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: V = P2.orbit_closure(P2.fan(1)[0]); V
1-d toric variety covered by 2 affine patches
dsage: V.embedding_morphism().as_polynomial_map()
Scheme morphism:
  From: 1-d toric variety covered by 2 affine patches
  To: 2-d CPR-Fano toric variety covered by 3 affine patches
  Defn: Defined on coordinates by sending [z0 : z1] to
    [0 : z1 : z0]
```

If the toric variety is singular, then some orbit closure embeddings cannot be written with homogeneous polynomials:

```python
sage: P2_112 = toric_varieties.P2_112()
sage: P1 = P2_112.orbit_closure(Cone([(1,0)]))
sage: P1.embedding_morphism().as_polynomial_map()
Traceback (most recent call last):
  ...  TypeError: The embedding cannot be written with homogeneous polynomials.
```

defining_cone()  
Return the cone corresponding to the torus orbit.

OUTPUT:

A cone of the fan of the ambient toric variety.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: cone = P2.fan(1)[0]
sage: P1 = P2.orbit_closure(cone)
sage: P1.embedding_morphism().defining_cone()
1-d cone of Rational polyhedral fan in 2-d lattice N
sage: _ is cone
True
```

pullback_divisor(divisor)  
Pull back a toric divisor.

INPUT:

- divisor – a torus-invariant QQ-Cartier divisor on the codomain of the embedding map.

OUTPUT:
A divisor on the domain of the embedding map (the orbit closure) that is isomorphic to the pull-back divisor $f^*(D)$ but with possibly different linearization.

EXAMPLES:

```python
sage: P2 = toric_varieties.P2()
sage: P1 = P2.orbit_closure(P2.fan(1)[0])
sage: f = P1.embedding_morphism()
sage: D = P2.divisor([1,2,3]); D
V(x) + 2*V(y) + 3*V(z)
sage: f.pullback_divisor(D)
4*V(z0) + 2*V(z1)
```

```
class sage.schemes.toric.morphism.SchemeMorphism_point_toric_field(X, coordinates, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism_point, sage.categories.morphism.Morphism

A point of a toric variety determined by homogeneous coordinates in a field.

Warning: You should not create objects of this class directly. Use the hom() method of toric varieties instead.

INPUT:

- X – toric variety or subscheme of a toric variety.
- coordinates – list of coordinates in the base field of X.
- check – if True (default), the input will be checked for correctness.

OUTPUT:

A SchemeMorphism_point_toric_field.
```

```
class sage.schemes.toric.morphism.SchemeMorphism_polynomial_toric_variety(parent, polynomials, check=True)

Bases: sage.schemes.generic.morphism.SchemeMorphism_polynomial, sage.categories.morphism.Morphism

A morphism determined by homogeneous polynomials.

Warning: You should not create objects of this class directly. Use the hom() method of toric varieties instead.

INPUT:

Same as for SchemeMorphism_polynomial.

OUTPUT:

A SchemeMorphism_polynomial_toric_variety.
```
as_fan_morphism()  
Express the morphism as a map defined by a fan morphism.

OUTPUT:

A SchemeMorphism_polynomial_toric_variety. Raises a TypeError if the morphism cannot be written in such a way.

EXAMPLES:

```
sage: A1.<z> = toric_varieties.A1()
sage: P1 = toric_varieties.P1()
sage: patch = A1.hom([1,z], P1)
sage: patch.as_fan_morphism()
Traceback (most recent call last):
  ...
NotImplementedError: expressing toric morphisms as fan morphisms is not implemented yet!
```

16.9 Subschemes of toric space

AUTHORS:

class sage.schemes.toric.toric_subscheme.AlgebraicScheme_subscheme_affine_toric(toric_variety, polynomials)

Bases: sage.schemes.toric.toric_subscheme.AlgebraicScheme_subscheme_toric

Construct an algebraic subscheme of an affine toric variety.

Warning: You should not create objects of this class directly. The preferred method to construct such subschemes is to use subscheme() method of toric varieties.

INPUT:

- toric_variety – ambient affine toric variety;
- polynomials – single polynomial, list, or ideal of defining polynomials in the coordinate ring of toric_variety.

OUTPUT:

A algebraic subscheme of an affine toric variety.

dimension()

Return the dimension of self.

OUTPUT:

- integer.

EXAMPLES:
A more complicated example where the ambient toric variety is not smooth:

```
sage: X.<x,y> = toric_varieties.A2_Z2()
sage: X.is_smooth()
False
sage: Y = X.subscheme([x*y, x^2])
sage: Y
Closed subscheme of 2-d affine toric variety defined by:
    x*y,
    x^2
sage: Y.dimension()
1
```

is_smooth(point=None)

Test whether the algebraic subscheme is smooth.

INPUT:

- point – A point or None (default). The point to test smoothness at.

OUTPUT:

Boolean. If no point was specified, returns whether the algebraic subscheme is smooth everywhere. Otherwise, smoothness at the specified point is tested.

EXAMPLES:

```
sage: A2.<x,y> = toric_varieties.A2()
sage: cuspidal_curve = A2.subscheme([y^2-x^3])
sage: cuspidal_curve
Closed subscheme of 2-d affine toric variety defined by:
    -x^3 + y^2
sage: cuspidal_curve.is_smooth([1,1])
True
sage: cuspidal_curve.is_smooth([0,0])
False
sage: cuspidal_curve.is_smooth()
False
sage: circle = A2.subscheme(x^2+y^2-1)
sage: circle.is_smooth([1,0])
True
sage: circle.is_smooth()
True
```

A more complicated example where the ambient toric variety is not smooth:

```
sage: X.<x,y> = toric_varieties.A2_Z2()  # 2-d affine space mod Z/2
sage: X.is_smooth()
False
sage: Y = X.subscheme([x*y, x^2])  # (twice the x=0 curve) mod Z/2
sage: Y
Closed subscheme of 2-d affine toric variety defined by:
    x*y,
    x^2
```
### Examples:

```sage
toric_variety = toric_varieties.P2()
toric_variety.fan().generating_cone(0)
toric_variety.subscheme(x^3 + y^3 + z^3)
toric_variety.affine_algebraic_patch(cone)
```

### REFERENCES:

Here we got two defining equations. The first one describes the singularity of the ambient space and the second is the pull-back of $x^2 + y^2 - 1$.

affine_patch($i$)

Return the $i$-th affine patch of self as an affine toric algebraic scheme.

INPUT:

- $i$ – integer, index of a generating cone of the fan of the ambient space of self.

OUTPUT:

- subscheme of an affine toric variety corresponding to the pull-back of self by the embedding morphism of the $i$-th affine patch of the ambient space of self.

The result is cached, so the $i$-th patch is always the same object in memory.

EXAMPLES:

```sage
sage: P1xP1 = toric_varieties.P1xP1()
sage: patch1 = P1xP1.affine_patch(1)
sage: patch1.embedding_morphism()
Scheme morphism:
   From: 2-d affine toric variety
   To: 2-d CPR-Fano toric variety covered by 4 affine patches
   Defined on coordinates by sending [t : x] to
```

```
[1 : t : x : 1]
sage: PlxP1.inject_variables()
Defining s, t, x, y
sage: P1 = PlxP1.subscheme(x-y)
sage: subpatch = P1.affine_patch(1)
sage: subpatch
Closed subscheme of 2-d affine toric variety defined by:
  x - 1
```

dimension()

Return the dimension of self.

OUTPUT:

Integer. If self is empty, –1 is returned.

EXAMPLES:

```
sage: PlxP1 = toric_varieties.P1xP1()
sage: PlxP1.inject_variables()
Defining s, t, x, y
sage: P1 = PlxP1.subscheme(s-t)
sage: P1.dimension()
1
sage: PlxP1.subscheme([s-t, (s-t)^2]).dimension()
1
sage: PlxP1.subscheme([s, t]).dimension()
-1
```

fan()

Return the fan of the ambient space.

OUTPUT:

A fan.

EXAMPLES:

```
sage: P2.<x,y,z> = toric_varieties.P(2)
sage: E = P2.subscheme([x^2+y^2+z^2])
sage: E.fan()
Rational polyhedral fan in 2-d lattice N
```

is_nondegenerate()

Check if self is nondegenerate.

OUTPUT:

Whether the variety is nondegenerate, that is, the intersection with every open torus orbit is smooth and transversal.

EXAMPLES:

```
sage: P2.<x,y,z> = toric_varieties.P2()
sage: P2.subscheme([x^3 + y^3 + z^3]).is_nondegenerate()
True
sage: P2.subscheme([x*y*z]).is_nondegenerate()
False
sage: X = P2.subscheme([(x-y)^2*(x+y) + x*y*z + z^3])
```

(continues on next page)
A K3 surface in $\mathbb{P}^1 \times \mathbb{P}^1 \times \mathbb{P}^1$:

```
sage: diamond = lattice_polytope.cross_polytope(3)
sage: fan = FaceFan(diamond)
sage: P1xP1xP1 = ToricVariety(fan)
sage: z0, z1, z2, z3, z4, z5 = P1xP1xP1.gens()
sage: t = 5;
sage: F = z0^2*z1^2*z2^2 + z1^2*z2^2*z3^2 + z0^2*z2^2*z4^2 + z2^2*z3^2*z4^2 + t*z0*z1*z2*z3*z4*z5 + z0^2*z1^2*z5^2 + z1^2*z3^2*z5^2 + z0^2*z4^2*z5^2 + z3^2*z4^2*z5^2
sage: X = P1xP1xP1.subscheme([F])
sage: X.is_smooth()  
True
sage: X.is_nondegenerate()  
False
```

Taking a random change of variables breaks the symmetry, but makes the surface nondegenerate:

```
sage: F1 = F.subs(z0 = 1*z0 + 1*z3, z3 = 1*z0 + 2*z3, z1 = -2*z1 + -1*z4, z4 = 1*z1 + 2*z4, z2 = -3*z2 + -1*z5, z5 = -3*z2 + 2*z5 )
sage: Y = P1xP1xP1.subscheme([F1])
sage: Y.is_smooth()  
True
sage: Y.is_nondegenerate()  
True
```

This example is from Hamm, :arxiv:`1106.1826v1`. It addresses an issue raised at :trac:`15239`

```
sage: X = toric_varieties.WP([1,4,2,3], names='z0 z1 z2 z3')
sage: X.inject_variables()  
Defining z0, z1, z2, z3
sage: g0 = z1^3 + z2^6 +z3^4
sage: g = g0-2*z3^2*z0^6+z2*z0^10+z0^12
sage: Y = X.subscheme([g])
sage: Y.is_nondegenerate()  
False
```

It handles nonzero characteristic:

```
sage: P2.<x,y,z> = toric_varieties.P2()
sage: f = x^5 + 2*x*y^4 + y^5 - 2*y^3*z^2 + x*z^4 - 2*z^5
sage: P2.change_ring(GF(5)).subscheme([f]).is_nondegenerate()  
True
sage: P2.change_ring(GF(7)).subscheme([f]).is_nondegenerate()  
False
```

`is_schon()`

Check if self is schon (nondegenerate).

See `is_nondegenerate` for further documentation.
EXAMPLES:

```python
sage: P2.<x,y,z> = toric_varieties.P2()
sage: X = P2.subscheme([(x-y)^2*(x+y) + x*y*z + z^3])
sage: X.is_smooth()
True
sage: X.is_schon()
False
```

`is_smooth(point=None)`

Test whether the algebraic subscheme is smooth.

**INPUT:**

- point – A point or None (default). The point to test smoothness at.

**OUTPUT:**

Boolean. If no point was specified, returns whether the algebraic subscheme is smooth everywhere. Otherwise, smoothness at the specified point is tested.

**EXAMPLES:**

```python
sage: P2.<x,y,z> = toric_varieties.P2()
sage: cuspidal_curve = P2.subscheme([y^2*z-x^3])
sage: cuspidal_curve
Closed subscheme of 2-d CPR-Fano toric variety covered by 3 affine patches
˓→ defined by:
- x^3 + y^2*z
sage: cuspidal_curve.is_smooth([1,1,1])
True
sage: cuspidal_curve.is_smooth([0,0,1])
False
sage: cuspidal_curve.is_smooth()
False
```

Any sufficiently generic cubic hypersurface is smooth:

```python
sage: P2.subscheme([y^2*z-x^3+z^3+1/10*x*y*z]).is_smooth()
True
```

A more complicated example:

```python
sage: dP6.<x0,x1,x2,x3,x4,x5> = toric_varieties.dP6()
sage: disjointPls = dP6.subscheme(x0*x3)
sage: disjointPls.is_smooth()
True
sage: intersectingPls = dP6.subscheme(x0*x1)
sage: intersectingPls.is_smooth()
False
```

A smooth hypersurface in a compact singular toric variety:

```python
sage: lp = LatticePolytope([(1,0,0),(1,1,0),(1,1,1),(1,0,1),(-2,-1,-1)],
                        lattice=ToricLattice(3))
sage: X.<x,y,u,v,t> = CPRFanoToricVariety(Delta_polar=lp)
sage: Y = X.subscheme(x*v+y*u+t)
sage: cone = Cone([(1,0,0),(1,1,0),(1,1,1),(1,0,1)])
sage: Y.is_smooth()
True
```

16.9. Subschemes of toric space 335
neighborhood*(point)*

Return an toric algebraic scheme isomorphic to neighborhood of the point.

**INPUT:**

- point – a point of the toric algebraic scheme.

**OUTPUT:**

An affine toric algebraic scheme (polynomial equations in an affine toric variety) with fixed embedding_morphism() and embedding_center().

**EXAMPLES:**

```
sage: P.<x,y,z> = toric_varieties.P2()
sage: S = P.subscheme(x+2*y+3*z)
sage: s = S.point([0,-3,2]); s
[0 : -3 : 2]
sage: patch = S.neighborhood(s); patch
Closed subscheme of 2-d affine toric variety defined by:
  x + 2*y + 6
sage: patch.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of 2-d affine toric variety defined by:
  x + 2*y + 6
  To:   Closed subscheme of 2-d CPR-Fano toric variety covered by 3 affine patches defined by:
        x + 2*y + 3*z
  Defn: Defined on coordinates by sending [x : y] to
        [-2*y - 6 : y : 2]
sage: patch.embedding_center()
[0 : -3]
sage: patch.embedding_morphism()(patch.embedding_center())
[0 : -3 : 2]
```

A more complicated example:

```
sage: dP6.<x0,x1,x2,x3,x4,x5> = toric_varieties.dP6()
sage: twoP1 = dP6.subscheme(x0*x3)
sage: patch = twoP1.neighborhood([0,1,2, 3,4,5]); patch
Closed subscheme of 2-d affine toric variety defined by:
  3*x0
sage: patch.embedding_morphism()
Scheme morphism:
  From: Closed subscheme of 2-d affine toric variety defined by:
  3*x0
  To:   Closed subscheme of 2-d CPR-Fano toric variety covered by 6 affine patches defined by:
        x0*x3
  Defn: Defined on coordinates by sending [x0 : x1] to
        [0 : x1 : 2 : 3 : 4 : 5]
sage: patch.embedding_center()
[0 : 1]
sage: patch.embedding_morphism()(patch.embedding_center())
[0 : 1 : 2 : 3 : 4 : 5]
```
### 16.10 Weierstrass form of a toric elliptic curve

There are 16 reflexive polygons in the plane, see `ReflexivePolytopes()`. Each of them defines a toric Fano variety. And each of them has a unique crepant resolution to a smooth toric surface [CLSsurfaces] by subdividing the face fan. An anticanonical hypersurface defines an elliptic curve in this ambient space, which we call a toric elliptic curve. The purpose of this module is to write an anticanonical hypersurface equation in the short Weierstrass form $y^2 = x^3 + fx + g$. This works over any base ring as long as its characteristic $\neq 2, 3$.

For an analogous treatment of elliptic curves defined as complete intersection in higher dimensional toric varieties, see the module `weierstrass_higher`.

Technically, this module computes the Weierstrass form of the Jacobian of the elliptic curve. This is why you will never have to specify the origin (or zero section) in the following.

It turns out [VolkerBraun] that the anticanonical hypersurface equation of any one of the above 16 toric surfaces is a specialization (that is, set one or more of the coefficients to zero) of the following three cases. In inhomogeneous coordinates, they are

- **Cubic in $\mathbb{P}^2$:**
  
  $p(x, y) = a_{30}x^3 + a_{21}x^2y + a_{12}xy^2 + a_{03}y^3 + a_{20}x^2 + a_{11}xy + a_{02}y^2 + a_{10}x + a_{01}y + a_{00}$

- **Biquadric in $\mathbb{P}^1 \times \mathbb{P}^1$:**
  
  $p(x, y) = a_{22}x^2y^2 + a_{21}x^2y + a_{20}x^2 + a_{12}xy^2 + a_{11}xy + xa_{10} + y^2a_{02} + ya_{01} + a_{00}$

- **Anticanonical hypersurface in weighted projective space $\mathbb{P}^2[1, 1, 2]$:**
  
  $p(x, y) = a_{40}x^4 + a_{30}x^3 + a_{21}x^2y + a_{20}x^2 + a_{11}xy + a_{02}y^2 + a_{10}x + a_{01}y + a_{00}$

**EXAMPLES:**

The main functionality is provided by `WeierstrassForm()`, which brings each of the above hypersurface equations into Weierstrass form:

```python
sage: R.<x,y> = QQ[]
sage: cubic = x^3 + y^3 + 1
sage: WeierstrassForm(cubic)
(0, -27/4)
sage: WeierstrassForm(x^4 + y^2 + 1)
(-4, 0)
sage: WeierstrassForm(x^2*y^2 + x^2 + y^2 + 1)
(-16/3, 128/27)
```

Only the affine span of the Newton polytope of the polynomial matters. For example:

```python
sage: R.<x,y,z> = QQ[]
sage: cubic = x^3 + y^3 + z^3
sage: WeierstrassForm(x^3 + y^3 + z^3)
(0, -27/4)
sage: WeierstrassForm(x * cubic)
(0, -27/4)
```

This allows you to work with either homogeneous or inhomogeneous variables. For example, here is the del Pezzo surface of degree 8:
By specifying only certain variables we can compute the Weierstrass form over the polynomial ring generated by the remaining variables. For example, here is a cubic over \( \mathbb{Q}[a] \)

```python
sage: R.<a, x, y, z> = QQ[]
sage: cubic = x^3 + a*y^3 + a^2*z^3
sage: WeierstrassForm(cubic, variables=[x,y,z])
(0, -27/4*a^6)
```

REFERENCES:

sage.schemes.toric.weierstrass.Discriminant \( (\text{polynomial}, \text{variables=}\text{None}) \)

The discriminant of the elliptic curve.

INPUT:

See \texttt{WeierstrassForm()} for how to specify the input polynomial(s) and variables.

OUTPUT:

The discriminant of the elliptic curve.

EXAMPLES:

```python
sage: from sage.schemes.toric.weierstrass import Discriminant
sage: R.<x, y, z> = QQ[]
sage: Discriminant(x^3+y^3+z^3)
19683/16
sage: Discriminant(x*y*z)
0
sage: R.<w,x,y,z> = QQ[]
sage: quadratic1 = w^2+x^2+y^2
sage: quadratic2 = z^2 + w*x
sage: Discriminant([quadratic1, quadratic2])
-1/16
```

sage.schemes.toric.weierstrass.Newton_polygon_embedded \( (\text{polynomial}, \text{variables}) \)

Embed the Newton polytope of the polynomial in one of the three maximal reflexive polygons.

This function is a helper for \texttt{WeierstrassForm()}

INPUT:

Same as \texttt{WeierstrassForm()} with only a single polynomial passed.

OUTPUT:

A tuple \((\Delta, P_\ast(x, y))\) where

- \(\Delta\) is the Newton polytope of polynomial.
- \(P_\ast(x, y)\) equals the input polynomial but with redefined variables such that its Newton polytope is \(\Delta\).

EXAMPLES:
from sage.schemes.toric.weierstrass import Newton_polygon_embedded
sage: R.<x,y,z> = QQ[]
sage: cubic = x^3 + y^3 + z^3
sage: Newton_polygon_embedded(cubic, [x,y,z])
(A 2-dimensional lattice polytope in ZZ^3 with 3 vertices,
x^3 + y^3 + 1,
(x, y))
sage: R.<a, x,y,z> = QQ[]
sage: cubic = x^3 + a*y^3 + a^2*z^3
sage: Newton_polygon_embedded(cubic, variables=[x,y,z])
(A 2-dimensional lattice polytope in ZZ^3 with 3 vertices,
a^2*x^3 + y^3 + a,
(x, y))
sage: R.<s,t,x,y> = QQ[]
sage: biquadric = (s+t)^2 * (x+y)^2
sage: Newton_polygon_embedded(biquadric, [s,t,x,y])
(A 2-dimensional lattice polytope in ZZ^4 with 4 vertices,
s^2*t^2 + 2*s^2*t + 2*s*t^2 + s^2 + 4*s*t + t^2 + 2*s + 2*t + 1,
(s, t))

Return the Newton polytope in the given variables.

INPUT:

See WeierstrassForm() for how to specify the input polynomial and variables.

OUTPUT:

A dictionary with keys the integral values of the Newton polytope and values the corresponding coefficient of polynomial.

EXAMPLES:

sage: from sage.schemes.toric.weierstrass import Newton_polytope_vars_coeffs
sage: R.<x,y,z,a30,a21,a12,a03,a20,a11,a02,a10,a01,a00> = QQ[]
sage: p = (a30*x^3 + a21*x^2*y + a12*x*y^2 + a03*y^3 + a20*x^2*z +
.....: a11 *x*y*z + a02*y^2*z + a10*x*z^2 + a01*y*z^2 + a00*z^3)
sage: p_data = Newton_polytope_vars_coeffs(p, [x,y,z]); p_data
{(0, 0, 3): a00,
 (0, 1, 2): a01,
 (0, 2, 1): a02,
 (0, 3, 0): a03,
 (1, 0, 2): a10,
 (1, 1, 1): a11,
 (1, 2, 0): a12,
 (2, 0, 1): a20,
 (2, 1, 0): a21,
 (3, 0, 0): a30)
sage: from sage.geometry.polyhedron.ppl_lattice_polytope import LatticePolytope_PPL
sage: polytope = LatticePolytope_PPL(list(p_data)); polytope
A 2-dimensional lattice polytope in ZZ^3 with 3 vertices
sage: polytope.vertices()
((0, 0, 3), (3, 0, 0), (0, 3, 0)) (continues on next page)
sage: polytope.embed_in_reflexive_polytope()
The map $A \times x + b$ with $A =
\begin{bmatrix}
-1 & -1 \\
0 & 1 \\
1 & 0 \\
\end{bmatrix}
b = (3, 0, 0)

sage.schemes.toric.weierstrass.WeierstrassForm(polynomial, variables=None, transformation=False)

Return the Weierstrass form of an elliptic curve inside either inside a toric surface or $\mathbb{P}^3$.

INPUT:

- `polynomial` -- either a polynomial or a list of polynomials defining the elliptic curve. A single polynomial can be either a cubic, a biquadratic, or the hypersurface in $\mathbb{P}^2[1, 1, 2]$. In this case the equation need not be in any standard form, only its Newton polyhedron is used. If two polynomials are passed, they must both be quadratics in $\mathbb{P}^3$.

- `variables` -- a list of variables of the parent polynomial ring or `None` (default). In the latter case, all variables are taken to be polynomial ring variables. If a subset of polynomial ring variables are given, the Weierstrass form is determined over the function field generated by the remaining variables.

- `transformation` -- boolean (default: `False`). Whether to return the new variables that bring polynomial into Weierstrass form.

OUTPUT:

The pair of coefficients $(f, g)$ of the Weierstrass form $y^2 = x^3 + fx + g$ of the hypersurface equation.

If `transformation=True`, a triple $(X, Y, Z)$ of polynomials defining a rational map of the toric hypersurface or complete intersection in $\mathbb{P}^3$ to its Weierstrass form in $\mathbb{P}^2[2, 3, 1]$ is returned. That is, the triple satisfies

$$Y^2 = X^3 + fXZ^4 + gZ^6$$

when restricted to the toric hypersurface or complete intersection.

EXAMPLES:

sage: R.<x,y,z> = QQ[]
sage: cubic = x^3 + y^3 + z^3
sage: f, g = WeierstrassForm(cubic); (f, g)
(0, -27/4)

Same in inhomogeneous coordinates:

sage: R.<x,y> = QQ[]
sage: cubic = x^3 + y^3 + 1
sage: f, g = WeierstrassForm(cubic); (f, g)
(0, -27/4)

sage: X,Y,Z = WeierstrassForm(cubic, transformation=True); (X,Y,Z)
(-x^3*y^3 - x^3 - y^3,
1/2*x^6*y^3 - 1/2*x^3*y^6 - 1/2*x^6 + 1/2*y^6 + 1/2*x^3 - 1/2*y^3,
x*y)

Note that plugging in $[X : Y : Z]$ to the Weierstrass equation is a complicated polynomial, but contains the hypersurface equation as a factor:
Only the affine span of the Newton polytope of the polynomial matters. For example:

```python
sage: R.<x,y,z> = QQ[]
sage: cubic = x^3 + y^3 + z^3
sage: WeierstrassForm(cubic.subs(z=1))
(0, -27/4)
sage: WeierstrassForm(x * cubic)
(0, -27/4)
```

This allows you to work with either homogeneous or inhomogeneous variables. For example, here is the del Pezzo surface of degree 8:

```python
sage: dP8 = toric_varieties.dP8()
sage: dP8.inject_variables()
Defining t, x, y, z
sage: WeierstrassForm(x*y^2 + y^2*z + t^2*x^3 + t^2*z^3)
(-3, -2)
sage: WeierstrassForm(x*y^2 + y^2 + x^3 + 1)
(-3, -2)
```

By specifying only certain variables we can compute the Weierstrass form over the function field generated by the remaining variables. For example, here is a cubic over \( \mathbb{Q}[a] \):

```python
sage: R.<a, x,y,z> = QQ[]
sage: cubic = x^3 + a*y^3 + a^2*z^3
sage: WeierstrassForm(cubic, variables=[x,y,z])
(0, -27/4*a^6)
```

```python
sage.schemes.toric.weierstrass.WeierstrassForm_P1xP1(biquadric, variables=None)
```

Bring a biquadric into Weierstrass form

Input/output is the same as `WeierstrassForm()`, except that the input polynomial must be a standard biquadric in \( \mathbb{P}^2 \),

\[
p(x, y) = a_{40}x^4 + a_{30}x^3 + a_{21}x^2y + a_{20}x^2 + a_{11}xy + a_{02}y^2 + a_{10}x + a_{01}y + a_{00}
\]

**EXAMPLES:**

```python
sage: from sage.schemes.toric.weierstrass import WeierstrassForm_P1xP1
sage: R.<x0,x1,y0,y1>= QQ[]
sage: biquadric = ( x0^2*y0^2 + x0*x1*y0^2*2 + x1^2*y0^2*3  
..: + x0^2*y0*y1*4 + x0*x1*y0*y1*5 + x1^2*y0*y1*6  
..: + x0^2*y1*y1*2*7 + x0*x1*y1*y1*2*8 )
sage: WeierstrassForm_P1xP1(biquadric, [x0, x1, y0, y1])
(1581/16, -3529/32)
```

Since there is no \( x_1^2y_1^2 \) term in biquadric, we can dehomogenize it and get a cubic:

16.10. Weierstrass form of a toric elliptic curve
sage: from sage.schemes.toric.weierstrass import WeierstrassForm_P2
sage: WeierstrassForm_P2(biquadric(x0=1,y0=1))
(1581/16, -3529/32)

sage.schemes.toric.weierstrass.WeierstrassForm_P2 (polynomial, variables=None)
Bring a cubic into Weierstrass form.

Input/output is the same as WeierstrassForm(), except that the input polynomial must be a standard cubic in \( \mathbb{P}^2 \),

\[
p(x, y) = a_{30}x^3 + a_{21}x^2y + a_{12}xy^2 + a_{03}y^3 + a_{20}x^2 + \]
\[
a_{11}xy + a_{02}y^2 + a_{10}x + a_{01}y + a_{00}
\]

EXAMPLES:

sage: from sage.schemes.toric.weierstrass import WeierstrassForm_P2
sage: R.<x,y,z> = QQ[]
sage: WeierstrassForm_P2( x^3+y^3+z^3)
(0, -27/4)
sage: R.<x,y,z, a,b> = QQ[]
sage: WeierstrassForm_P2( -y^2*z+x^3+a*x*z^2+b*z^3, [x,y,z])
(a, b)

sage.schemes.toric.weierstrass.WeierstrassForm_P2_112 (polynomial, variables=None)
Bring an anticanonical hypersurface in \( \mathbb{P}^2_{[1,1,2]} \) into Weierstrass form.

Input/output is the same as WeierstrassForm(), except that the input polynomial must be a standard anticanonical hypersurface in weighted projective space \( \mathbb{P}^2_{[1,1,2]} \):

\[
p(x, y) = a_{40}x^4 + a_{30}x^3 + a_{21}x^2y + a_{02}y^2 + \]
\[
a_{11}xy + a_{01}y + a_{00}
\]

EXAMPLES:

sage: from sage.schemes.toric.weierstrass import WeierstrassForm_P2_112
sage: fan = Fan(rays=[(1,0),(0,1),(-1,-2),(0,-1)],cones=[[0,1],[1,2],[2,3],[3,0]])
sage: P112.<x,y,z,t> = ToricVariety(fan)
sage: (-P112.K()).sections_monomials()
(z^4*t^2, x*z^3*t^2, x^2*z^2*t^2, x^3*z*t^2, 
 x^4*t^2, y*z^2*t, x*y*z*t, x^2*y*t, y^2)
sage: WeierstrassForm_P2_112(sum(_), [x,y,z,t])
(-97/48, 17/864)

sage.schemes.toric.weierstrass.j_invariant (polynomial, variables=None)
Return the \( j \)-invariant of the elliptic curve.

INPUT:

See WeierstrassForm() for how to specify the input polynomial(s) and variables.

OUTPUT:

The \( j \)-invariant of the (irreducible) cubic. Notable special values:

- The Fermat cubic: \( j(x^3 + y^3 + z^3) = 0 \)
- A nodal cubic: \( j(-y^2 + x^2 + x^3) = \infty \)
- A cuspidal cubic \( y^2 = x^3 \) has undefined \( j \)-invariant. In this case, a ValueError is returned.
16.11 Map to the Weierstrass form of a toric elliptic curve

There are 16 reflexive polygons in 2-d. Each defines a toric Fano variety, which (since it is 2-d) has a unique crepant resolution to a smooth toric surface. An anticanonical hypersurface defines a genus one curve $C$ in this ambient space, with Jacobian elliptic curve $J(C)$ which can be defined by the Weierstrass model $y^2 = x^3 + fx + g$. The coefficients $f$ and $g$ can be computed with the `weierstrass` module. The purpose of this model is to give an explicit rational map $C \to J(C)$. This is an $n^2$-cover, where $n$ is the minimal multi-section of $C$.

Since it is technically often easier to deal with polynomials than with fractions, we return the rational map in terms of homogeneous coordinates. That is, the ambient space for the Weierstrass model is the weighted projective space $\mathbb{P}^2[2,3,1]$ with homogeneous coordinates $[X : Y : Z] = [\lambda^2 X, \lambda^3 Y, AZ]$. The homogenized Weierstrass equation is

$$Y^2 = X^3 + fXZ^4 + gZ^6$$

EXAMPLES:

```python
sage: R.<x,y> = QQ[]
sage: cubic = x^3 + y^3 + 1
gsage: f, g = WeierstrassForm(cubic); (f,g)
(0, -27/4)
```

That is, this hypersurface $C \in \mathbb{P}^2$ has a Weierstrass equation $Y^2 = X^3 + 0 \cdot XZ^4 - \frac{27}{4} Z^6$ where $[X : Y : Z]$ are projective coordinates on $\mathbb{P}^2[2,3,1]$. The form of the map $C \to J(C)$ is:

```python
sage: X,Y,Z = WeierstrassForm(cubic, transformation=True); (X,Y,Z)
(-x^3*y^3 - x^3 - y^3,
1/2*x^6*y^3 - 1/2*x^3*y^6 - 1/2*x^6 + 1/2*y^6 + 1/2*x^3 - 1/2*y^3,
x*y)
```

Note that plugging in $[X : Y : Z]$ to the Weierstrass equation is a complicated polynomial, but contains the hypersurface equation as a factor:

```python
sage: -Y^2 + X^3 + f*X*Z^4 + g*Z^6
-1/4*x^12*y^6 - 1/2*x^9*y^9 - 1/4*x^12*y^3 - 1/4*x^12 - 7/2*x^9 - 7/2*x^6*y^3 45/4*x^6*y^6 - 7/2*x^3*y^9 - 1/4*y^12 - 7/2*x^9 + 7/2*x^6*y^3 7/2*x^3*y^6 - 1/2*y^9 - 1/4*x^6 + 1/2*x^3*y^3 - 1/4*y^6
```

If you prefer you can also use homogeneous coordinates for $C \in \mathbb{P}^2$.
The 16 toric surfaces corresponding to the 16 reflexive polygons can all be blown down to $\mathbb{P}^2$, $\mathbb{P}^1 \times \mathbb{P}^1$, or $\mathbb{P}^2[1,1,2]$. Their (and hence in all 16 cases) anticanonical hypersurface can equally be brought into Weierstrass form. For example, here is an anticanonical hypersurface in $\mathbb{P}^2[1,1,2]$

Finally, you sometimes have to manually specify the variables to use. This is either because the equation is degenerate or because it contains additional variables that you want to treat as coefficients:

REFERENCES:

sage.schemes.toric.weierstrass_covering.WeierstrassMap(polynomial, variables=None)

Return the Weierstrass form of an anticanonical hypersurface.

You should use sage.schemes.toric.weierstrass.WeierstrassForm() with
transformation=True to get the transformation. This function is only for internal use.

INPUT:

- polynomial – a polynomial. The toric hypersurface equation. Can be either a cubic, a biquadric, or the
  hypersurface in $\mathbb{P}^2[1,1,2]$. The equation need not be in any standard form, only its Newton polyhedron is used.

- variables – a list of variables of the parent polynomial ring or None (default). In the latter case, all
  variables are taken to be polynomial ring variables. If a subset of polynomial ring variables are given, the
  Weierstrass form is determined over the function field generated by the remaining variables.

OUTPUT:

A triple $(X,Y,Z)$ of polynomials defining a rational map of the toric hypersurface to its Weierstrass form in
$\mathbb{P}^2[2,3,1]$. That is, the triple satisfies

$$Y^2 = X^3 + fXZ^4 + gZ^6$$

when restricted to the toric hypersurface.
EXAMPLES:

```python
sage: R.<x,y,z> = QQ[]
sage: cubic = x^3 + y^3 + z^3
sage: X,Y,Z = WeierstrassForm(cubic, transformation=True); (X,Y,Z)
(-x^3*y^3 - x^3*z^3 - y^3*z^3,
 1/2*x^6*y^3 - 1/2*x^3*y^6 - 1/2*x^6*z^3 + 1/2*y^6*z^3
  + 1/2*x^3*z^6 - 1/2*y^3*z^6,
  x*y*z)
sage: f, g = WeierstrassForm(cubic); (f,g)
(0, -27/4)
sage: cubic.divides(-Y^2 + X^3 + f*X*Z^4 + g*Z^6)
True
```

Only the affine span of the Newton polytope of the polynomial matters. For example:

```python
sage: WeierstrassForm(cubic.subs(z=1), transformation=True)
(-x^3*y^3 - x^3 - y^3,
 1/2*x^6*y^3 - 1/2*x^3*y^6 - 1/2*x^6
  + 1/2*y^6 + 1/2*x^3 - 1/2*y^3,
  x*y)
sage: WeierstrassForm(x * cubic, transformation=True)
(-x^3*y^3 - x^3*z^3 - y^3*z^3,
 1/2*x^6*y^3 - 1/2*x^3*y^6 - 1/2*x^6*z^3 + 1/2*y^6*z^3
  + 1/2*x^3*z^6 - 1/2*y^3*z^6,
  x*y*z)
```

This allows you to work with either homogeneous or inhomogeneous variables. For example, here is the del Pezzo surface of degree 8:

```python
sage: dP8 = toric_varieties.dP8()
sage: dP8.inject_variables()
Defining t, x, y, z
sage: WeierstrassForm(x*y^2 + y^2*z + t^2*x^3 + t^2*z^3, transformation=True)
(-1/27*t^4*x^6 - 2/27*t^4*x^5*z - 5/27*t^4*x^4*z^2
  - 8/27*t^4*x^3*z^3 - 5/27*t^4*x^2*y^2 - 4/81*t^2*x^2*y^2*z
  - 4/81*t^2*x^2*y^2*z^3 - 4/81*t^2*x^2*y^2*z^4 - 2/81*x^2*y^2*z^4
  - 4/81*x^2*y^2*z^4 - 2/81*y^2*z^4, 0,
  1/3*t^2*x^2*z + 1/3*t^2*x^2*z - 1/9*x*y^2 - 1/9*y^2*z)
sage: WeierstrassForm(x*y^2 + y^2 + x^3 + 1, transformation=True)
(-1/27*x^6 - 4/81*x^4*y^2 - 2/81*x^2*y^2 - 2/27*x^5
  - 4/81*x^3*y^2 - 4/81*x*y^4 - 5/27*x^4 - 8/27*x^3
  - 4/81*x*y^2 - 5/27*x^2 - 4/81*y^2 - 2/27*x - 1/27,
  0,
  -1/9*x^2*y^2 + 1/3*x^2 + 1/3*x^2
```

By specifying only certain variables we can compute the Weierstrass form over the function field generated by the remaining variables. For example, here is a cubic over \( \mathbb{Q}[a] \)

```python
sage: R.<a, x,y,z> = QQ[
  sage: cubic = x^3 + a*y^3 + a^2*z^3
  sage: WeierstrassForm(cubic, variables=[x,y,z], transformation=True)
  (-a^9*y^3*z^3 - a^8*x^3*z^3 - a^7*x^2*y^3 - 1/2*a^14*y^3*z^6 + 1/2*a^13*y^6*z^3 + 1/2*a^13*x^3*z^6
  - 1/2*a^11*x^3*y^6 - 1/2*a^10*x^6*y^3, a^3*x*y+z)
```
Map an anticanonical hypersurface in \(\mathbb{P}^1 \times \mathbb{P}^1\) into Weierstrass form.

Input/output is the same as `WeierstrassMap()`, except that the input polynomial must be a standard anticanonical hypersurface in the toric surface \(\mathbb{P}^1 \times \mathbb{P}^1\):

**EXAMPLES:**

```python
sage: from sage.schemes.toric.weierstrass_covering import WeierstrassMap_P1xP1
sage: R.<x0,x1,y0,y1,a>= QQ[]

sage: biquadric = ( x0^2*y0^2 + x1^2*y0^2 + x0^2*y1^2 + x1^2*y1^2 +
    ...: a * x0*x1*y0*y1*5 )

sage: f, g = WeierstrassMap_P1xP1(biquadric, [x0, x1, y0, y1]); (f,g)
(-625/48*a^4 + 25/3*a^2 - 16/3, 15625/864*a^6 - 625/36*a^4 - 100/9*a^2 + 128/27)

sage: X, Y, Z = WeierstrassMap_P1xP1(biquadric, [x0, x1, y0, y1])

sage: (-Y^2 + X^3 + f*X*Z^4 + g*Z^6).reduce(R.ideal(biquadric))
0
```

```python
sage: R = PolynomialRing(QQ, 'x,y,s,t', order='lex')

sage: R.inject_variables()
Defining x, y, s, t

sage: equation = ( s^2*(x^2+2*x*y+3*y^2) + s*t*(4*x^2+5*x*y+6*y^2) +
    ...: t^2 *(7*x^2+8*x*y+9*y^2) )

sage: X, Y, Z = WeierstrassMap_P1xP1(equation, [x,y,s,t])

sage: equation = (-Y^2 + X^3 + f*X*Z^4 + g*Z^6).reduce(R.ideal(equation))
0
```

Map a cubic to its Weierstrass form

Input/output is the same as `WeierstrassMap()`, except that the input polynomial must be a cubic in \(\mathbb{P}^2\),

\[
p(x, y) = a_{30}x^3 + a_{21}x^2y + a_{12}xy^2 + a_{03}y^3 + a_{20}x^2 +
    a_{11}xy + a_{02}y^2 + a_{10}x + a_{01}y + a_{00}
\]

**EXAMPLES:**

```python
sage: from sage.schemes.toric.weierstrass_covering import WeierstrassMap_P2
sage: equation = x^3+y^3+z^3+x*y*z

sage: f, g = WeierstrassMap_P2(equation)

sage: (-Y^2 + X^3 + f*X*Z^4 + g*Z^6).reduce(R.ideal(equation))
0
```

(continues on next page)
Map an anticanonical hypersurface in $\mathbb{P}^2[1,1,2]$ into Weierstrass form.

Input/output is the same as `WeierstrassMap()`, except that the input polynomial must be a standard anticanonical hypersurface in weighted projective space $\mathbb{P}^2[1,1,2]$:

$$p(x,y) = a_4 x^4 + a_3 x^3 + a_2 x^2 y + a_1 xy + a_0 y^2 + a_10 x + a_01 y + a_{00}$$

**EXAMPLES:**

```python
sage: from sage.schemes.toric.weierstrass_covering import WeierstrassMap_P2_112
sage: R = PolynomialRing(QQ, 'x,y,a0,a1,a2,a3,a4', order='lex')
```

Another example, this time in homogeneous coordinates:

```python
sage: fan = Fan(rays=[(1,0),(0,1),(-1,-2),(0,-1)], cones=[[0,1],[1,2],[2,3],[3,0]])
sage: P112.<x,y,z,t> = Toric Variety(fan)
sage: C_eqn = sum(_)
sage: C = P112.subscheme(C_eqn)
sage: WeierstrassForm_P2_112(C_eqn, [x,y,z,t])
(-97/48, 17/864)
```

## 16.12 Weierstrass for elliptic curves in higher codimension

The `weierstrass` module lets you transform a genus-one curve, given as a hypersurface in a toric surface, into Weierstrass form. The purpose of this module is to extend this to higher codimension subschemes of toric varieties. In general, this is an unsolved problem. However, for certain special cases this is known.

The simplest codimension-two case is the complete intersection of two quadratic equations in $\mathbb{P}^3$
```python
sage: R.<w,x,y,z> = QQ[]
sage: quadratic1 = w^2+x^2+y^2
sage: quadratic2 = z^2 + w*x
sage: WeierstrassForm([quadratic1, quadratic2])
(-1/4, 0)
```

Hence, the Weierstrass form of this complete intersection is \( Y^2 = X^3 - \frac{1}{4} X Z^4 \).

Helper function for `WeierstrassForm()`

Currently, only the case of the complete intersection of two quadratic equations in \( \mathbb{P}^3 \) is supported.

INPUT / OUTPUT:

See `WeierstrassForm()`

Example:

```python
sage: from sage.schemes.toric.weierstrass_higher import WeierstrassForm_P3
sage: R.<w,x,y,z> = QQ[]
sage: quadratic1 = w^2+x^2+y^2
sage: quadratic2 = z^2 + w*x
sage: WeierstrassForm_P3(quadratic1, quadratic2)
(-1/4, 0)
```

## Examples

```python
sage: from sage.schemes.toric.weierstrass_higher import WeierstrassMap_P3
....: WeierstrassMap_P3, WeierstrassForm_P3
sage: R.<w,x,y,z> = QQ[]
sage: quadratic1 = w^2+x^2+y^2
sage: quadratic2 = z^2 + w*x
sage: X, Y, Z = WeierstrassMap_P3(quadratic1, quadratic2)
sage: X
1/1024*w^8 + 3/256*w^6*x^2 + 19/512*w^4*x^4 + 3/256*w^2*x^6 + 1/1024*x^8
sage: Y
1/32768*w^12 - 7/16384*w^10*x^2 - 145/32768*w^8*x^4 - 49/8192*w^6*x^6
- 145/32768*w^4*x^8 - 7/16384*w^2*x^10 + 1/32768*x^12
sage: Z
-1/8*w^2+y*z + 1/8*x^2+y*z
sage: a, b = WeierstrassForm_P3(quadratic1, quadratic2); a, b
(-1/4, 0)
```

(continues on next page)
sage: ideal = R.ideal(quadratic1, quadratic2)
sage: (-Y^2 + X^3 + a*X*Z^4 + b*Z^6).reduce(ideal)
0

16.13 Set of homomorphisms between two toric varieties

For schemes $X$ and $Y$, this module implements the set of morphisms $Hom(X,Y)$. This is done by $\text{SchemeHomset\_generic}$.

As a special case, the Hom-sets can also represent the points of a scheme. Recall that the $K$-rational points of a scheme $X$ over $k$ can be identified with the set of morphisms $\text{Spec}(K) \to X$. In Sage, the rational points are implemented by such scheme morphisms. This is done by $\text{SchemeHomset\_points}$ and its subclasses.

**Note:** You should not create the Hom-sets manually. Instead, use the Hom() method that is inherited by all schemes.

**AUTHORS:**

- Volker Braun (2012-02-18): Initial version

**EXAMPLES:**

Here is a simple example, the projection of $\mathbb{P}^1 \times \mathbb{P}^1 \to \mathbb{P}^1$

```python
sage: P1xP1 = toric_varieties.P1xP1()
sage: P1 = toric_varieties.P1()
sage: hom_set = P1xP1.Hom(P1); hom_set
Set of morphisms
  From: 2-d CPR-Fano toric variety covered by 4 affine patches
  To: 1-d CPR-Fano toric variety covered by 2 affine patches
```

In terms of the fan, we can define this morphism by the projection onto the first coordinate. The Hom-set can construct the morphism from the projection matrix alone:

```python
sage: hom_set(matrix([[1],[0]]))
Scheme morphism:
  From: 2-d CPR-Fano toric variety covered by 4 affine patches
  To: 1-d CPR-Fano toric variety covered by 2 affine patches
  Defn: Defined by sending Rational polyhedral fan in 2-d lattice N
to Rational polyhedral fan in 1-d lattice N.
sage: _.as_polynomial_map()
Scheme morphism:
  From: 2-d CPR-Fano toric variety covered by 4 affine patches
  To: 1-d CPR-Fano toric variety covered by 2 affine patches
  Defn: Defined on coordinates by sending [s : t : x : y] to
        [s : t]
```

In the case of toric algebraic schemes (defined by polynomials in toric varieties), this module defines the underlying morphism of the ambient toric varieties:

```python
sage: P1xP1.inject_variables()
Defining s, t, x, y
sage: S = P1xP1.subscheme([s*x-t*y])
sage: type(S.Hom(S))
<class 'sage.schemes.toric.homset.SchemeHomset_toric_variety_with_category'>
```
Finally, you can have morphisms defined through homogeneous coordinates where the codomain is not implemented as a toric variety:

```python
sage: P2_toric.<x,y,z> = toric_varieties.P2()
sage: P2_native.<u,v,w> = ProjectiveSpace(QQ, 2)
sage: toric_to_native = P2_toric.Hom(P2_native); toric_to_native
Set of morphisms
    From: 2-d CPR-Fano toric variety covered by 3 affine patches
    To: Projective Space of dimension 2 over Rational Field
sage: type(toric_to_native)
<class 'sage.schemes.toric.homset.SchemeHomset_toric_variety_with_category'>
sage: toric_to_native([x^2, y^2, z^2])
Scheme morphism:
    From: 2-d CPR-Fano toric variety covered by 3 affine patches
    To: Projective Space of dimension 2 over Rational Field
    Defn: Defined on coordinates by sending [x : y : z] to
          (x^2 : y^2 : z^2)

sage: native_to_toric = P2_native.Hom(P2_toric); native_to_toric
Set of morphisms
    From: Projective Space of dimension 2 over Rational Field
    To: 2-d CPR-Fano toric variety covered by 3 affine patches
sage: type(native_to_toric)
<class 'sage.schemes.generic.homset.SchemeHomset_generic_with_category'>
sage: native_to_toric([u^2, v^2, w^2])
Scheme morphism:
    From: Projective Space of dimension 2 over Rational Field
    To: 2-d CPR-Fano toric variety covered by 3 affine patches
    Defn: Defined on coordinates by sending (u : v : w) to
          [u^2 : v^2 : w^2]
```

```class``
sage.schemes.toric.homset.SchemeHomset_points_subscheme_toric_field(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.toric.homset.SchemeHomset_points_toric_base
cardinality()

Return the number of points of the toric variety.

OUTPUT:

An integer or infinity. The cardinality of the set of points.

EXAMPLES:

```python
sage: P2.<x,y,z> = toric_varieties.P2(base_ring=GF(5))
sage: cubic = P2.subscheme([x^3 + y^3 + z^3])
sage: list(cubic.point_set())
[[0 : 1 : 4], [1 : 0 : 4], [1 : 4 : 0], [1 : 2 : 1], [1 : 1 : 2], [1 : 3 : 3]]
sage: cubic.point_set().cardinality()
6
```
class sage.schemes.toric.homset.SchemeHomset_points_toric_base(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.generic.homset.SchemeHomset_points

Base class for homsets with toric ambient spaces

INPUT:

• same as for SchemeHomset_points.

OUTPUT:

A scheme morphism of type SchemeHomset_points_toric_base.

EXAMPLES:

sage: P1xP1 = toric_varieties.P1xP1()

sage: P1xP1(QQ)
Set of rational points of 2-d CPR-Fano toric variety covered by 4 affine patches

is_finite()

Return whether there are finitely many points.

OUTPUT:

Boolean.

EXAMPLES:

sage: P2 = toric_varieties.P2()

sage: P2.point_set().is_finite()
False

sage: P2.change_ring(GF(7)).point_set().is_finite()
True

class sage.schemes.toric.homset.SchemeHomset_points_toric_field(X, Y, category=None, check=True, base=Integer Ring)

Bases: sage.schemes.toric.homset.SchemeHomset_points_toric_base

Set of rational points of a toric variety.

You should not use this class directly. Instead, use the point_set() method to construct the point set of a toric variety.

INPUT:

• same as for SchemeHomset_points.

OUTPUT:

A scheme morphism of type SchemeHomset_points_toric_field.

EXAMPLES:
The quotient $\mathbb{P}^2/\mathbb{Z}_3$ over $GF(7)$ by the diagonal action. This is tricky because the base field has a 3-rd root of unity:

```python
sage: fan = NormalFan(ReflexivePolytope(2, 0))
sage: X = ToricVariety(fan, base_field=GF(7))
sage: point_set = X.point_set()
sage: point_set.cardinality()
21

sage: sorted(X.point_set().list())
[[0 : 0 : 1], [0 : 1 : 0], [0 : 1 : 1], [0 : 1 : 3],
 [1 : 0 : 0], [1 : 0 : 1], [1 : 0 : 3], [1 : 1 : 0],
 [1 : 1 : 1], [1 : 1 : 2], [1 : 1 : 3], [1 : 1 : 4],
 [1 : 1 : 5], [1 : 1 : 6], [1 : 3 : 0], [1 : 3 : 1],
 [1 : 3 : 2], [1 : 3 : 3], [1 : 3 : 4], [1 : 3 : 5],
 [1 : 3 : 6]]
```

As for a non-compact example, the blow-up of the plane is the line bundle $O_{\mathbb{P}^1}(-1)$. Its point set is the Cartesian product of the points on the base $\mathbb{P}^1$ with the points on the fiber:

```python
sage: fan = Fan([[Cone([[1,0], (1,1)]), Cone([[1,1], (0,1)])]])
sage: blowup_plane = ToricVariety(fan, base_ring=GF(3))
sage: point_set = blowup_plane.point_set()
sage: sorted(point_set.list())
[[0 : 1 : 0], [0 : 1 : 1], [0 : 1 : 2],
 [1 : 0 : 0], [1 : 0 : 1], [1 : 0 : 2],
 [1 : 1 : 0], [1 : 1 : 1], [1 : 1 : 2],
 [1 : 2 : 0], [1 : 2 : 1], [1 : 2 : 2]]
```

Toric varieties with torus factors (that is, where the fan is not full-dimensional) also work:

```python
sage: F_times_Fstar = ToricVariety(Fan([[Cone([1,0])]]), base_field=GF(3))
sage: sorted(F_times_Fstar.point_set().list())
[[0 : 1], [0 : 2], [1 : 1], [1 : 2], [2 : 1], [2 : 2]]
```

**cardinality()**

Return the number of points of the toric variety.

**OUTPUT:**

An integer or infinity. The cardinality of the set of points.

**EXAMPLES:**

```python
sage: o = lattice_polytope.cross_polytope(3)
sage: V = ToricVariety(FaceFan(o))
sage: V.change_ring(GF(2)).point_set().cardinality()
27
sage: V.change_ring(GF(8, "a"))_.point_set().cardinality()
729
```
For non-smooth varieties over finite fields, the homogeneous rescalings are solved. This is somewhat slower:

```sage
fan = NormalFan(ReflexivePolytope(2, 0))
x = Toric Variety(fan, base_field=GF(7))
x.point_set().cardinality()
```

21

Fulton’s formula does not apply since the variety is not smooth. And, indeed, naive application gives a different result:

```sage
q = x.base_ring().order()
n = x.dimension()
d = map(len, fan().cones())
sage: sum(dk * (q-1)**(n-k) for k, dk in enumerate(d))
```

57

Over infinite fields the number of points is not very tricky:

```sage
V.count_points()
```

`+Infinity`

ALGORITHM:

Uses the formula in Fulton \cite{F}, section 4.5.

16.14 Enumerate points of a toric variety

The classes here are not meant to be instantiated manually. Instead, you should always use the methods of the `point_set` of the variety.

In this module, points are always represented by tuples instead of Sage’s class for points of the toric variety. All Sage library code must then convert it to proper point objects before returning it to the user.

**EXAMPLES:**

```python
sage: P2 = toric_varieties.P2(base_ring=GF(3))
sage: point_set = P2.point_set()
sage: point_set.cardinality()
13
sage: next(iter(point_set))
[0 : 0 : 1]
sage: list(point_set)[0:5]
[[0 : 0 : 1], [1 : 0 : 0], [0 : 1 : 0], [0 : 1 : 1], [0 : 1 : 2]]
```

**class** `sage.schemes.toric.points.FiniteFieldPointEnumerator` *(fan, ring)*

**Bases:** `sage.schemes.toric.points.NaiveFinitePointEnumerator`

**cardinality()**

Return the cardinality of the point set.

**OUTPUT:**

Integer. The number of points.

**EXAMPLES:**

```python
sage: fan = NormalFan(ReflexivePolytope(2, 0))
sage: X = ToricVariety(fan, base_ring=GF(7))
sage: point_set = X.point_set()
sage: ffe = point_set._finite_field_enumerator()
sage: ffe.cardinality()
21
```

**cone_points_iter()**

Iterate over the open torus orbits and yield distinct points.

**OUTPUT:**

For each open torus orbit (cone): A triple consisting of the cone, the nonzero homogeneous coordinates in that orbit (list of integers), and the nonzero log coordinates of distinct points as a cokernel.

**EXAMPLES:**
\begin{verbatim}
 sage: fan = NormalFan(ReflexivePolytope(2, 0))
 sage: X = ToricVariety(fan, base_ring=GF(7))
 sage: point_set = X.point_set()
 sage: ffe = point_set._finite_field_enumerator()
 sage: cpi = ffe.cone_points_iter()
 sage: cone, nonzero_points, cokernel = list(cpi)[5]
 sage: cone
 1-d cone of Rational polyhedral fan in 2-d lattice N
 sage: cone.ambient_ray_indices()
 (2,)
 sage: nonzero_points
 [0, 1]
 sage: cokernel
 Finitely generated module V/W over Integer Ring with invariants (2)
 sage: list(cokernel)
 [(0), (1)]
 sage: [p.lift() for p in cokernel]
 [(0, 0), (0, 1)]

 exp(powers)
 Return the component-wise exp of z

 INPUT:

 - powers – a list/tuple/iterable of integers.

 OUTPUT:

 Tuple of finite field elements. The powers of the \texttt{multiplicative_generator()}. 

 EXAMPLES:

 sage: F.<a> = GF(5^2)
 sage: point_set = toric_varieties.P2_123(base_ring=F).point_set()
 sage: ffe = point_set._finite_field_enumerator()
 sage: powers = list(range(24))
 sage: ffe.exp(powers)
 (1, a, a + 3, 4*a + 3, 2*a + 2, 4*a + 1, 2, 2*a, 2*a + 1, 3*a + 1,
 4*a + 4, 3*a + 2, 4, 4*a, 4*a + 2, a + 2, 3*a + 3, a + 4, 3, 3*a,
 3*a + 4, 2*a + 4, a + 1, 2*a + 3)

 sage: ffe.log(ffe.exp(powers)) == tuple(powers)
 True

 log(z)
 Return the component-wise log of z

 INPUT:

 - z – a list/tuple/iterable of non-zero finite field elements.

 OUTPUT:

 Tuple of integers. The logarithm with base the \texttt{multiplicative_generator()}. 

 EXAMPLES:

 sage: F.<a> = GF(5^2)
 sage: point_set = toric_varieties.P2_123(base_ring=F).point_set()
 sage: ffe = point_set._finite_field_enumerator()
 sage: z = tuple(a^i for i in range(25)); z
 (1, a, a + 3, 4*a + 3, 2*a + 2, 4*a + 1, 2, 2*a, 2*a + 1, 3*a + 1,
 4*a + 4, 3*a + 2, 4, 4*a, 4*a + 2, a + 2, 3*a + 3, a + 4, 3, 3*a,
 3*a + 4, 2*a + 4, a + 1, 2*a + 3)

 (continues on next page)
\end{verbatim}
\texttt{multiplicative\_generator}\()\)

Return the multiplicative generator of the finite field.

\textbf{OUTPUT:}

A finite field element.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: point_set = toric_varieties.P2(base_ring=GF(5^2, 'a')).point_set()
sage: ffe = point_set._finite_field_enumerator()
sage: ffe.multiplicative_generator()
a
\end{verbatim}

\textbf{multiplicative\_group\_order}\()\)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: class Foo:
....:     def __init__(self, x):
....:         self._x = x
....: @cached_method
....:     def f(self):
....:         return self._x^2
sage: a = Foo(2)
sage: print(a.f.cache)
None
sage: a.f()
4
sage: a.f.cache
4
\end{verbatim}

\textbf{rescaling\_log\_generators}\()\)

Return the log generators of \texttt{rescalings()}. 

\textbf{OUTPUT:}

A tuple containing the logarithms (see \texttt{log()}) of the generators of the multiplicative group of \texttt{rescalings()}. 

\textbf{EXAMPLES:}

\begin{verbatim}
sage: point_set = toric_varieties.P2_123(base_ring=GF(5)).point_set()
sage: ffe = point_set._finite_field_enumerator()
sage: ffe.rescalings()
((1, 1, 1), (1, 4, 4), (4, 2, 3), (4, 3, 2))
sage: list(map(ffe.log, ffe.rescalings()))
[(0, 0, 0), (0, 2, 2), (2, 1, 3), (2, 3, 1)]
sage: ffe.rescaling_log_generators()
((2, 3, 1),)
\end{verbatim}
root_generator($n$)
Return a generator for roots().

INPUT:

• $n$ integer.

OUTPUT:

A multiplicative generator for roots().

EXAMPLES:

```
sage: point_set = toric_varieties.P2(base_ring=GF(5)).point_set()
sage: ffe = point_set._finite_field_enumerator()
sage: ffe.root_generator(2)
4
sage: ffe.root_generator(3)
1
sage: ffe.root_generator(4)
2
```

class sage.schemes.toric.points.FiniteFieldSubschemePointEnumerator

Bases: sage.schemes.toric.points.NaiveSubschemePointEnumerator

cardinality()

Return the cardinality of the point set.

OUTPUT:

Integer. The number of points.

EXAMPLES:

```
sage: fan = NormalFan(ReflexivePolytope(2, 0))
sage: X.<u,v,w> = ToricVariety(fan, base_ring=GF(7))
sage: Y = X.subscheme(u^3 + v^3 + w^3 + u*v*w)
sage: point_set = Y.point_set()
sage: list(point_set)
[[0 : 1 : 3],
 [1 : 0 : 3],
 [1 : 3 : 0],
 [1 : 1 : 6],
 [1 : 1 : 4],
 [1 : 3 : 2],
 [1 : 3 : 5]]
sage: ffe = point_set._enumerator()
sage: ffe.cardinality()
7
```

homogeneous_coordinates($log_t$, nonzero_coordinates, cokernel)

Convert the log of inhomogeneous coordinates back to homogeneous coordinates

INPUT:

• $log_t$ – log of inhomogeneous coordinates of a point.
• nonzero_coordinates – the nonzero homogeneous coordinates in the patch.
• cokernel – the logs of the nonzero coordinates of all distinct points as a cokernel. See FiniteFieldPointEnumerator.cone_points_iter().
The same point, but as a tuple of homogeneous coordinates.

EXAMPLES:

```python
sage: P2.<x,y,z> = toric_varieties.P2(base_ring=GF(7))
sage: X = P2.subscheme([x^3 + 2*y^3 + 3*z^3, x*y*z + x*y^2])
sage: point_set = X.point_set()
sage: ffe = point_set._enumerator()
sage: cone, nonzero_coordinates, cokernel = list(ffe.ambient.cone_points_iter())[5]
sage: cone.ambient_ray_indices(), nonzero_coordinates
((2,), [0, 1])
sage: ffe.homogeneous_coordinates([0], nonzero_coordinates, cokernel)
(1, 1, 0)
sage: ffe.homogeneous_coordinates([1], nonzero_coordinates, cokernel)
(1, 3, 0)
sage: ffe.homogeneous_coordinates([2], nonzero_coordinates, cokernel)
(1, 2, 0)
```

**inhomogeneous_equations** *(ring, nonzero_coordinates, cokernel)*

Inhomogenize the defining polynomials

**INPUT:**

- ring – the polynomial ring for inhomogeneous coordinates.
- nonzero_coordinates – list of integers. The indices of the non-zero homogeneous coordinates in the patch.
- cokernel – the logs of the nonzero coordinates of all distinct points as a cokernel. See `FiniteFieldPointEnumerator.cone_points_iter()`.

**EXAMPLES:**

```python
sage: R.<s> = QQ[]
sage: P2.<x,y,z> = toric_varieties.P2(base_ring=GF(7))
sage: X = P2.subscheme([x^3 + 2*y^3 + 3*z^3, x*y*z + x*y^2])
sage: point_set = X.point_set()
sage: ffe = point_set._enumerator()
sage: cone, nonzero_coordinates, cokernel = list(ffe.ambient.cone_points_iter())[5]
sage: cone.ambient_ray_indices(), nonzero_coordinates
((2,), [0, 1])
sage: ffe.inhomogeneous_equations(R, nonzero_coordinates, cokernel)
[2*s^3 + 1, s^2]
```

**solutions** *(inhomogeneous_equations, log_range)*

Parallel version of `solutions_serial()`

**INPUT/OUTPUT:**

Same as `solutions_serial()`, except that the output points are in random order. Order depends on the number of processors and relative speed of separate processes.

**EXAMPLES:**

```python
sage: R.<s> = GF(7)[]
sage: P2.<x,y,z> = toric_varieties.P2(base_ring=GF(7))
sage: X = P2.subscheme(1)
```
sage: point_set = X.point_set()
sage: ffe = point_set._enumerator()
sage: ffe.solutions([s^2-1, s^6-s^2], [range(6)])
<generator object ...solutions at 0x...>
sage: sorted(_)
[(0,), (3,)]

solutions_serial (inhomogeneous_equations, log_range)
Iterate over solutions in a range.

INPUT:
- inhomogeneous_equations – list/tuple/iterable of inhomogeneous equations (i.e. output from inhomogeneous_equations()).
- log_range – list/tuple/iterable of integer ranges. One for each inhomogeneous coordinate. The logarithms of the homogeneous coordinates.

OUTPUT:
All solutions (as tuple of log inhomogeneous coordinates) in the Cartesian product of the ranges.

EXAMPLES:

```python
sage: R.<s> = GF(7)[[]]
sage: P2.<x,y,z> = toric_varieties.P2(base_ring=GF(7))
sage: X = P2.subscheme(1)
sage: point_set = X.point_set()
sage: ffe = point_set._enumerator()
sage: ffe.solutions_serial([s^2-1, s^6-s^2], [range(6)])
<generator object ...solutions_serial at 0x...>
sage: list(_)
[(0,), (3,)]
```

class sage.schemes.toric.points.InfinitePointEnumerator (fan, ring)

Point enumerator for infinite fields.

INPUT:
- fan – fan of the toric variety.
- ring – infinite base ring over which to enumerate points.

class sage.schemes.toric.points.NaiveFinitePointEnumerator (fan, ring)

The naive point enumerator.

This is very slow.

INPUT:
- fan – fan of the toric variety.
- ring – finite base ring over which to enumerate points.

EXAMPLES:
```
sage: from sage.schemes.toric.points import NaiveFinitePointEnumerator
sage: fan = toric_varieties.P2().fan()

sage: n = NaiveFinitePointEnumerator(fan, GF(3))

sage: next(iter(n))
(0, 0, 1)
```

**cone_iter()**

Iterate over all cones of the fan

**OUTPUT:**

Iterator over the cones, starting with the high-dimensional ones.

**EXAMPLES:**

```
sage: ne = toric_varieties.dP6(base_ring=GF(11)).point_set()._naive_enumerator()
sage: for cone in ne.cone_iter():
    ....:     print(cone.ambient_ray_indices())
(0, 1)
(1, 2)
(2, 3)
(3, 4)
(4, 5)
(0, 5)
(0,)
(1,)
(2,)
(3,)
(4,)
(5,)
()```

**coordinate_iter()**

Iterate over all distinct homogeneous coordinates.

This method does NOT identify homogeneous coordinates that are equivalent by a homogeneous rescaling.

**OUTPUT:**

An iterator over the points.

**EXAMPLES:**

```
sage: F2 = GF(2)
sage: ni = toric_varieties.P2(base_ring=F2).point_set()._naive_enumerator()
sage: list(ni.coordinate_iter())
[(0, 0, 1), (1, 0, 0), (0, 1, 0), (0, 1, 1), (1, 0, 1), (1, 1, 0), (1, 1, 1)]

sage: ni = toric_varieties.P1xP1(base_ring=F2).point_set()._naive_enumerator()
sage: list(ni.coordinate_iter())
[(0, 1, 0, 1), (1, 0, 0, 1), (1, 0, 1, 0), (0, 1, 1, 0), (0, 1, 1, 1), (1, 0, 1, 1),
 (1, 1, 0, 1), (1, 1, 1, 0), (1, 1, 1, 1)]```

**orbit(point)**

Return the orbit of homogeneous coordinates under rescalings.

**OUTPUT:**

The set of all homogeneous coordinates that are equivalent to `point`.  

---

360  Chapter 16. Toric Varieties
EXAMPLES:

```
sage: ne = toric_varieties.P2_123(base_ring=GF(7)).point_set()._naive_enumerator()
sage: sorted(ne.orbit([1, 0, 0]))
[(1, 0, 0), (2, 0, 0), (4, 0, 0)]
sage: sorted(ne.orbit([0, 1, 0]))
[(0, 1, 0), (0, 6, 0)]
sage: sorted(ne.orbit([0, 0, 1]))
[(0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 0, 4), (0, 0, 5), (0, 0, 6)]
sage: sorted(ne.orbit([1, 1, 0]))
[(1, 1, 0), (1, 6, 0), (2, 1, 0), (2, 6, 0), (4, 1, 0), (4, 6, 0)]
```

```
sage: from sage.schemes.toric.points import NaiveFinitePointEnumerator
sage: fan = toric_varieties.torus(2).fan()
sage: fan.rays()
Empty collection
in 2-d lattice N
sage: n = NaiveFinitePointEnumerator(fan, GF(3))
sage: n.rays()
N(1, 0),
N(0, 1)
in 2-d lattice N
```

```
sage: ni = toric_varieties.P2_123(base_ring=GF(5)).point_set()._naive_enumerator()
sage: ni.rescalings()
((1, 1, 1), (1, 4, 4), (4, 2, 3), (4, 3, 2))
```

```
sage: ni = toric_varieties.dP8(base_ring=GF(3)).point_set()._naive_enumerator()
sage: ni.rescalings()
((1, 1, 1, 1), (1, 2, 2, 2), (2, 1, 2, 1), (2, 2, 1, 2))
```

```
sage: ni = toric_varieties.P1xP1(base_ring=GF(3)).point_set()._naive_enumerator()
sage: ni.rescalings()
((1, 1, 1, 1), (1, 1, 2, 2), (2, 2, 1, 1), (2, 2, 2, 2))
```

```
sage: roots(n)
Return the n-th roots in the base field
```

16.14. Enumerate points of a toric variety
INPUT:

- \( n \) integer.

OUTPUT:

Tuple containing all \( n \)-th roots (not only the primitive ones). In particular, 1 is included.

EXAMPLES:

```python
sage: ne = toric_varieties.P2(base_ring=GF(5)).point_set()._naive_enumerator()
sage: ne.roots(2)
(1, 4)
sage: ne.roots(3)
(1,)
sage: ne.roots(4)
(1, 2, 3, 4)
```

`units()`

Return the units in the base field.

EXAMPLES:

```python
sage: ne = toric_varieties.P2(base_ring=GF(5)).point_set()._naive_enumerator()
sage: ne.units()
(1, 2, 3, 4)
```

**class** sage.schemes.toric.points.NaiveSubschemePointEnumerator

**Bases:** object

Point enumerator for algebraic subschemes of toric varieties.

**INPUT:**

- `polynomials` – list/tuple/iterabel of polynomials. The defining polynomials.
- `ambient` – enumerator for ambient space points.

### 16.15 Construct sheaves on toric varieties

A toric vector bundle (on a toric variety) is a vector bundle that is equivariant with respect to the algebraic torus action.

`sage.schemes.toric.sheaf.constructor.CotangentBundle(X)`

Construct the cotangent bundle of a toric variety.

**INPUT:**

- `X` – a toric variety. The base space of the bundle.

**OUTPUT:**

The cotangent bundle as a Klyachko bundle.

**EXAMPLES:**

```python
sage: dP7 = toric_varieties.dP7()
sage: from sage.schemes.toric.sheaf.constructor import CotangentBundle
sage: CotangentBundle(dP7)
Rank 2 bundle on 2-d CPR-Fano toric variety covered by 5 affine patches.
```
sage.schemes.toric.sheaf.constructor.LineBundle(X, D)
Construct the rank-1 bundle \( O(D) \).

**INPUT:**
- \( X \) – a toric variety. The base space of the bundle.
- \( D \) – a toric divisor.

**OUTPUT:**
The line bundle \( O(D) \) as a Klyachko bundle of rank 1.

**EXAMPLES:**

```python
sage: X = toric_varieties.dP8()
sage: D = X.divisor(0)
sage: from sage.schemes.toric.sheaf.constructor import LineBundle
sage: O_D = LineBundle(X, D)
sage: O_D.cohomology(dim=True, weight=(0,0))
(1, 0, 0)
```

**class** sage.schemes.toric.sheaf.constructor.SheafLibrary(toric_variety)

**Bases:** object

Utility object to construct sheaves on toric varieties.

**Warning:** You should never construct instances manually. Can be accessed from a toric variety via the `sage.schemes.toric.variety.ToricVariety_field.sheaves` attribute.

**EXAMPLES:**

```python
sage: type(toric_varieties.P2().sheaves)
<class 'sage.schemes.toric.sheaf.constructor.SheafLibrary'>
```

**Klyachko** *(multi_filtration)*
Construct a Klyachko bundle (sheaf) from filtration data.

**INPUT:**
- `multi_filtration` – a multi-filtered vectors space with multiple filtrations being indexed by the rays of the fan. Either an instance of `MultiFilteredVectorSpace()` or something (like a dictionary of ordinary filtered vector spaces).

**OUTPUT:**
The Klyachko bundle defined by the filtrations, one for each ray, of a vector space.

**EXAMPLES:**

```python
sage: P1 = toric_varieties.P1()
sage: v1, v2, v3 = [(1,0,0),(0,1,0),(0,0,1)]
sage: F1 = FilteredVectorSpace({1:[v1, v2, v3], 3:[v1]})
sage: F2 = FilteredVectorSpace({0:[v1, v2, v3], 2:[v2, v3]})
sage: P1 = toric_varieties.P1()
sage: r1, r2 = P1.fan().rays()
sage: F = MultiFilteredVectorSpace({r1:F1, r2:F2}); F
```

(continues on next page)
\begin{verbatim}
    sage: P1.sheaves.Klyachko(F)
    Rank 3 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
\end{verbatim}

\textbf{cotangent\_bundle()} \\
Return the cotangent bundle of the toric variety.

\textbf{OUTPUT:} \\
The cotangent bundle as a Klyachko bundle.

\textbf{EXAMPLES:}
\begin{verbatim}
    sage: dP6 = toric_varieties.dP6()
    sage: TX = dP6.sheaves.tangent_bundle()
    sage: TXdual = dP6.sheaves.cotangent_bundle()
    sage: TXdual == TX.dual()
    True
\end{verbatim}

\textbf{divisor(*args, **kwds)} \\
Return a toric divisor.

\textbf{INPUT:} \\
This is just an alias for \texttt{sage.schemes.toric.variety.ToricVariety\_field.divisor()}, see there for details.

By abuse of notation, you can usually use the divisor $D$ interchangeably with the line bundle $O(D)$.

\textbf{OUTPUT:} \\
A toric divisor.

\textbf{EXAMPLES:}
\begin{verbatim}
    sage: dP6 = toric_varieties.dP6()
    sage: dP6.inject_variables()
    Defining x, u, y, v, z, w
    sage: D = dP6.sheaves.divisor(x*u^3); D
    V(x) + 3*V(u)
    sage: D == dP6.divisor(x*u^3)
    True
\end{verbatim}

\textbf{line\_bundle(divisor)} \\
Construct the rank-1 bundle $O(D)$.

\textbf{INPUT:} \\
\begin{itemize}
    \item divisor -- a toric divisor.
\end{itemize}

\textbf{OUTPUT:} \\
The line bundle $O(D)$ for the given divisor as a Klyachko bundle of rank 1.

\textbf{EXAMPLES:}
\begin{verbatim}
    sage: X = toric_varieties.dP8()
    sage: D = X.divisor(0)
    sage: O_D = X.sheaves.line_bundle(D)
    sage: O_D.cohomology(dim=True, weight=(0,0))
    (1, 0, 0)
\end{verbatim}
tangent_bundle()

Return the tangent bundle of the toric variety.

OUTPUT:

The tangent bundle as a Klyachko bundle.

EXAMPLES:

```
sage: toric_varieties.dP6().sheaves.tangent_bundle()
Rank 2 bundle on 2-d CPR-Fano toric variety covered by 6 affine patches.
```

trivial_bundle(rank=1)

Return the trivial bundle of rank $r$.

INPUT:

• rank – integer (optional; default: 1). The rank of the bundle.

OUTPUT:

The trivial bundle as a Klyachko bundle.

EXAMPLES:

```
sage: P2 = toric_varieties.P2()
sage: I3 = P2.sheaves.trivial_bundle(3); I3
Rank 3 bundle on 2-d CPR-Fano toric variety covered by 3 affine patches.
sage: I3.cohomology(weight=(0,0), dim=True)
(3, 0, 0)
```

sage.schemes.toric.sheaf.constructor.TangentBundle(X)

Construct the tangent bundle of a toric variety.

INPUT:

• $X$ – a toric variety. The base space of the bundle.

OUTPUT:

The tangent bundle as a Klyachko bundle.

EXAMPLES:

```
sage: dP7 = toric_varieties.dP7()
sage: from sage.schemes.toric.sheaf.constructor import TangentBundle
sage: TangentBundle(dP7)
Rank 2 bundle on 2-d CPR-Fano toric variety covered by 5 affine patches.
```

sage.schemes.toric.sheaf.constructor.TrivialBundle(X, rank=1)

Return the trivial bundle of rank $r$.

INPUT:

• $X$ – a toric variety. The base space of the bundle.

• rank – the rank of the bundle.

OUTPUT:

The trivial bundle as a Klyachko bundle.

EXAMPLES:
16.16 Klyachko bundles and sheaves

Klyachko bundles are torus-equivariant bundles on toric varieties. That is, the action of the maximal torus on the toric variety lifts to an action on the bundle. There is an equivalence of categories between [Klyachko] bundles and multiple filtrations (one for each ray of the fan) of a vector space. The multi-filtrations are implemented in `sage.modules.multi_filtered_vector_space`.

**EXAMPLES:**

```python
sage: X = toric_varieties.dP6xP6()
sage: TX = X.sheaves.tangent_bundle()
sage: Alt2TX = TX.exterior_power(2); Alt2TX
Rank 6 bundle on 4-d CPR-Fano toric variety covered by 36 affine patches.
sage: K = X.sheaves.line_bundle(X.K())
sage: antiK = X.sheaves.line_bundle(-X.K())
sage: (Alt2TX * K).cohomology(dim=True, weight=(0,0,0,0))  # long time
(0, 0, 18, 0, 0)
sage: G_sum = TX + X.sheaves.trivial_bundle(2)
sage: V = G_sum.wedge(2) * K  # long time
sage: V.cohomology(dim=True, weight=(0,0,0,0))  # long time
(0, 0, 18, 16, 1)
sage: Gtilde = G_sum.random_deformation()
sage: V = Gtilde.wedge(2) * K  # long time
sage: V.cohomology(dim=True, weight=(0,0,0,0))  # long time
(0, 0, 3, 0, 0)
```

**REFERENCES:**

`sage.schemes.toric.sheaf.klyachko.Bundle` *(toric_variety, multi_filtration, check=True)*

Construct a Klyachko bundle

**INPUT:**

- `toric_variety` — a toric variety. The base space of the bundle.
- `multi_filtration` — a multi-filtered vectors space with multiple filtrations being indexed by the one-dimensional cones of the fan. Either an instance of `MultiFilteredVectorSpace()` or something (like a dictionary of ordinary filtered vector spaces).

**EXAMPLES:**

```python
sage: P1 = toric_varieties.P1()
sage: v1, v2, v3 = [(1,0,0),(0,1,0),(0,0,1)]
sage: F1 = FilteredVectorSpace({1:[v1, v2, v3], 3:[v1]})
sage: F2 = FilteredVectorSpace({0:[v1, v2, v3], 2:[v2, v3]})
sage: P1 = toric_varieties.P1()
sage: r1, r2 = P1.fan().rays()
```
You should use the `Klyachko()` method to construct instances:

```python
sage: P1.sheaves.Klyachko(F)
Rank 3 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
sage: P1.sheaves.Klyachko({r1:F1, r2:F2})  # alternative
Rank 3 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
```

The above is just a shorthand for:

```python
sage: from sage.schemes.toric.sheaf.klyachko import Bundle
sage: Bundle(P1, F)
Rank 3 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
```

### class `sage.schemes.toric.sheaf.klyachko.KlyachkoBundle_class`

A toric bundle using Klyachko’s representation.

**Warning:** You should always use the `Bundle()` factory function to construct instances.

#### INPUT:

- `toric_variety` – a toric variety. The base space of the bundle.
- `multi_filtration` – a `MultiFilteredVectorSpace()` with index set the rays of the fan.
- `check` – boolean (default: `True`). Whether to perform consistency checks.

#### EXAMPLES:

```python
sage: P1 = toric_varieties.P1()
sage: r1, r2 = P1.fan().rays()
sage: F = MultiFilteredVectorSpace({
....:     r1:FilteredVectorSpace(3,1),
....:     r2:FilteredVectorSpace(3,0)}); F
Filtrations
    N(-1): QQ^3 >= 0 >= 0
    N(1): QQ^3 >= QQ^3 >= 0

sage: from sage.schemes.toric.sheaf.klyachko import Bundle
sage: Bundle(P1, F)
Rank 3 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
```

### E_degree `(alpha, m)`

Return the vector subspace $E^m(\alpha)$.

**INPUT:**

- `alpha` – a ray of the fan. Can be specified by its index (an integer), a one-dimensional cone, or a $N$-lattice point.
• \( m \) – tuple of integers or \( M \)-lattice point. A point in the dual lattice of the fan.

OUTPUT:

The subspace \( E^\sigma(am) \) of the filtration indexed by the ray \( \alpha \) and at the filtration degree \( \alpha \cdot m \).

EXAMPLES:

```python
sage: X = toric_varieties.P2()
sage: M = X.fan().dual_lattice()
sage: V = X.sheaves.tangent_bundle()
sage: V.E_degree(X.fan().ray(0), (1,0))
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
sage: V.E_degree(X.fan().ray(0), (1,0))
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
sage: V.E_degree(0, (1,0))
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
```

\( E\_intersection(\sigma, m) \)

Return the vector subspace \( E^\sigma(m) \).

See [Klyachko], equation 4.1.

INPUT:

• \( \sigma \) – a cone of the fan of the base toric variety.

• \( m \) – tuple of integers or \( M \)-lattice point. A point in the dual lattice of the fan. Must be immutable.

OUTPUT:

The subspace \( E^\sigma(m) \)

EXAMPLES:

```python
sage: X = toric_varieties.P2()
sage: fan = X.fan()
sage: V = X.sheaves.tangent_bundle()
sage: V.E_intersection(fan(1)[0], (1,0))
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
sage: V.E_intersection(fan(1)[0], (1,0))
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
sage: V.E_intersection(0, (1,0))
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
```

For the empty cone, this is always the whole vector space:

```python
sage: V.E_intersection(fan(0)[0], (1,0))
Vector space of dimension 2 over Rational Field
```

\( E\_quotient(\sigma, m) \)

Return the vector space quotient \( E^\sigma(m) \).

See [Klyachko], equation 4.1.
INPUT:

- \( \sigma \) – a cone of the fan of the base toric variety.
- \( m \) – tuple of integers or \( M \)-lattice point. A point in the dual lattice of the fan. Must be immutable.

OUTPUT:

The subspace \( E_\sigma(m) \)

EXAMPLES:

```python
sage: X = toric_varieties.P2()
sage: fan = X.fan()
sage: M = fan.dual_lattice()
sage: cone = fan(1)[0]
sage: V = X.sheaves.tangent_bundle()
sage: m = M(1, 0)
sage: m.set_immutable()
sage: V.E_quotient(cone, m)
Vector space quotient V/W of dimension 1 over Rational Field where
V: Vector space of dimension 2 over Rational Field
W: Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
sage: V.E_quotient(fan(2)[0], (-1,1))
Vector space quotient V/W of dimension 0 over Rational Field where
V: Vector space of dimension 2 over Rational Field
W: Vector space of degree 2 and dimension 2 over Rational Field
Basis matrix:
[1 0]
[0 1]
```

\( E_{\text{quotient projection}}(\sigma, \tau, m) \)

Return the projection map \( E_\sigma(m) \to E_\tau(m) \) where \( \sigma \) is a face of \( \tau \).

INPUT:

- \( \sigma \) – a cone of the fan of the base toric variety.
- \( \tau \) – a cone of the fan containing \( \sigma \).
- \( m \) – tuple of integers or \( M \)-lattice point. A point in the dual lattice of the fan. Must be immutable.

OUTPUT:

The restriction map

\[ E_\sigma(m) \to E_\tau(m) \]

EXAMPLES:

```python
sage: P3 = toric_varieties.P(3)
sage: rays = [(1,0,0), (0,1,0), (0,0,1)]
sage: F1 = FilteredVectorSpace(rays, {0:[0], 1:[2], 2:[1]})
sage: F2 = FilteredVectorSpace(3, 0)
sage: r = P3.fan().rays()
sage: V = P3.sheaves.Klyachko([r[0]:F1, r[1]:F2, r[2]:F2, r[3]:F2])
sage: tau = Cone([(1,0,0), (0,1,0)])
sage: sigma = Cone([(1,0,0)])
sage: M = P3.fan().dual_lattice()
sage: m = M(2,1,0)
```

(continues on next page)
Vector space quotient V/W of dimension 2 over Rational Field where
V: Vector space of dimension 3 over Rational Field
W: Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
\[
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\]
Vector space quotient V/W of dimension 2 over Rational Field where
V: Vector space of dimension 3 over Rational Field
W: Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
\[
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\]
Vector space morphism represented by the matrix:
\[
\begin{bmatrix}
1 & 0 \\
0 & 1
\end{bmatrix}
\]
Domain: Vector space quotient V/W of dimension 2 over Rational Field where
V: Vector space of dimension 3 over Rational Field
W: Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
\[
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\]
Codomain: Vector space quotient V/W of dimension 2 over Rational Field where
V: Vector space of dimension 3 over Rational Field
W: Vector space of degree 3 and dimension 1 over Rational Field
Basis matrix:
\[
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\]
Return the base field.

OUTPUT:

A field.

EXAMPLES:

```
sage: T_P2 = toric_varieties.P2().sheaves.tangent_bundle()
sage: T_P2.base_ring()
Rational Field
```

Return the bundle cohomology groups.

INPUT:

- degree=None (default) or an integer. The degree of the cohomology group.
- weight=None (default) or a tuple of integers or a \(M\)-lattice point. A point in the dual lattice of the
  fan defining a torus character. The weight of the cohomology group.
- dim=False (default). Whether to return vector spaces or only their dimension.

OUTPUT:

The cohomology group of given cohomological degree and torus weight.

- If no weight is specified, the unweighted group (sum over all weights) is returned.
- If no degree is specified, a dictionary whose keys are integers and whose values are the cohomology
groups is returned. If, in addition, dim=True, then an integral vector of the dimensions is returned.
EXAMPLES:

```
sage: V = toric_varieties.P2().sheaves.tangent_bundle()
sage: V.cohomology(degree=0, weight=(0,0))
Vector space of dimension 2 over Rational Field
sage: V.cohomology(weight=(0,0), dim=True)
(2, 0, 0)
sage: for i,j in cartesian_product((list(range(-2,3)), list(range(-2,3))):
    ....: HH = V.cohomology(weight=(i,j), dim=True)
    ....: if HH.is_zero(): continue
    ....: print('H^*i(P^2, TP^2)_M({}, {}) = {}'.format(i,j,HH))
H^*i(P^2, TP^2)_M(-1, 0) = (1, 0, 0)
H^*i(P^2, TP^2)_M(-1, 1) = (1, 0, 0)
H^*i(P^2, TP^2)_M(0, -1) = (1, 0, 0)
H^*i(P^2, TP^2)_M(0, 0) = (2, 0, 0)
H^*i(P^2, TP^2)_M(0, 1) = (1, 0, 0)
H^*i(P^2, TP^2)_M(1, -1) = (1, 0, 0)
H^*i(P^2, TP^2)_M(1, 0) = (1, 0, 0)
```

cohomology_complex(m)

Return the “cohomology complex” $C^*(m)$

See [Klyachko], equation 4.2.

INPUT:

- $m$ – tuple of integers or $M$-lattice point. A point in the dual lattice of the fan. Must be immutable.

OUTPUT:

The “cohomology complex” as a chain complex over the base_ring().

EXAMPLES:

```
sage: P3 = toric_varieties.P(3)
sage: rays = [(1,0,0), (0,1,0), (0,0,1)]
sage: F1 = FilteredVectorSpace(rays, {0:[0], 1:[2], 2:[1]})
sage: F2 = FilteredVectorSpace(rays, {0:[1,2], 1:[0]})
sage: r = P3.fan().rays()
sage: V = P3.sheaves.Klyachko({r[0]:F1, r[1]:F2, r[2]:F2, r[3]:F2})
sage: tau = Cone([(1,0,0), (0,1,0)])
sage: sigma = Cone([(1,0,0)])
sage: M = P3.fan().dual_lattice()
sage: m = M(1, 1, 0); m.set_immutable()
sage: V.cohomology_complex(m)
Chain complex with at most 2 nonzero terms over Rational Field
sage: F = CyclotomicField(3)
sage: P3 = toric_varieties.P(3).change_ring(F)
sage: V = P3.sheaves.Klyachko({r[0]:F1, r[1]:F2, r[2]:F2, r[3]:F2})
sage: V.cohomology_complex(m)
Chain complex with at most 2 nonzero terms over Cyclotomic Field of order 3 and degree 2
```

direct_sum(other)

Return the sum of two vector bundles.

INPUT:

- `other` – a Klyachko bundle over the same base.

OUTPUT:
The direct sum as a new Klyachko bundle.

**EXAMPLES:**

```
sage: X = toric_varieties.P2()
sage: V1 = X.sheaves.trivial_bundle(1)
sage: V2 = X.sheaves.trivial_bundle(2)
sage: V2.direct_sum(V1)
Rank 3 bundle on 2-d CPR-Fano toric variety covered by 3 affine patches.
sage: V1 = X.sheaves.trivial_bundle(1)
sage: V2 = X.sheaves.trivial_bundle(2)
sage: V2 == V1 + V1
True
```

dual ()

Return the dual bundle.

**OUTPUT:**

The dual bundle as a new Klyachko bundle.

**EXAMPLES:**

```
sage: P1 = toric_varieties.P1()
sage: H = P1.divisor(0)
sage: L = P1.sheaves.line_bundle(H)
sage: L.dual()
Rank 1 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
sage: L.dual() == P1.sheaves.line_bundle(-H)
True
```

**exterior_power**(n)

Return the \( n \)-th exterior power.

**INPUT:**

- \( n \) – integer.

**OUTPUT:**

The \( n \)-th exterior power \( \bigwedge_{i=1}^{n} V \) of the bundle \( V \) as a new Klyachko bundle.

**EXAMPLES:**

```
sage: X = toric_varieties.P2_123()
sage: TX = X.sheaves.tangent_bundle()
sage: antiK = X.sheaves.line_bundle(-X.K())
sage: TX.exterior_power(2) == antiK
True
sage: TX.wedge(2) == antiK  # alias
True
```

**fiber ()**

Return the generic fiber of the vector bundle.

**OUTPUT:**

A vector space over base_ring().

**EXAMPLES:**
sage: T_P2 = toric_varieties.P2().sheaves.tangent_bundle()
sage: T_P2.fiber()
Vector space of dimension 2 over Rational Field

filtration_intersection(sigma, i)
Return the intersection of the filtered subspaces.

INPUT:
- sigma – a cone of the fan of the base toric variety.
- i – integer. The filtration degree.

OUTPUT:
Let the cone be spanned by the rays \( \sigma = \langle r_1, \ldots, r_k \rangle \). This method returns the intersection
\[
\bigcap_{r \in \{r_1, \ldots, r_k\}} E^r(i)
\]

EXAMPLES:

sage: X = toric_varieties.P2()
sage: fan = X.fan()
sage: V = X.sheaves.tangent_bundle()
sage: V.filtration_intersection(fan(1)[0], 1)
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
sage: V.filtration_intersection(fan(2)[0], 1)
Vector space of degree 2 and dimension 0 over Rational Field
Basis matrix:
[]

get_degree(ray, i)
Return the vector subspace \( E^\alpha(i) \).

INPUT:
- ray – Integer, a \( \mathbb{N} \)-lattice point, a one-dimensional cone, or None (default). Specifies a ray of the
  fan of the toric variety, either via its index or its generator.
- i – integer. The filtration degree.

OUTPUT:
A subspace of the \( fiber() \) vector space. The defining data of a Klyachko bundle.

EXAMPLES:

sage: TX = toric_varieties.dP6().sheaves.tangent_bundle()
sage: TX.get_degree(0, 1)
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[0 1]

get_filtration(ray=None)
Return the filtration associated to the ray.

INPUT:
- ray – Integer, a \( \mathbb{N} \)-lattice point, a one-dimensional cone, or None (default). Specifies a ray of the
  fan of the toric variety, either via its index or its generator.
OUTPUT:
The filtered vector space associated to the given ray. If no ray is specified, all filtrations are returned.

EXAMPLES:

```python
sage: TX = toric_varieties.dP6().sheaves.tangent_bundle()
sage: TX.get_filtration(0)
QQ^2 >= QQ^1 >= 0
sage: TX.get_filtration([-1, -1])
QQ^2 >= QQ^1 >= 0
sage: TX.get_filtration(TX.variety().fan(1)[0])
QQ^2 >= QQ^1 >= 0
sage: TX.get_filtration()
Filtrations
    N(-1, -1): QQ^2 >= QQ^1 >= 0
    N(-1, 0): QQ^2 >= QQ^1 >= 0
    N(0, -1): QQ^2 >= QQ^1 >= 0
    N(0, 1): QQ^2 >= QQ^1 >= 0
    N(1, 0): QQ^2 >= QQ^1 >= 0
    N(1, 1): QQ^2 >= QQ^1 >= 0
```

is_isomorphic(other)
Test whether two bundles are isomorphic.

INPUT:
- other - anything.

OUTPUT:
Boolean.

EXAMPLES:

```python
sage: X = toric_varieties.P2()
sage: T_X = X.sheaves.tangent_bundle()
sage: O_X = X.sheaves.trivial_bundle(1)
sage: T_X + O_X == O_X + T_X
False
sage: (T_X + O_X).is_isomorphic(O_X + T_X)
Traceback (most recent call last):
  ... Not ImplementedError
```

random_deformation(epsilon=None)
Return a generic torus-equivariant deformation of the bundle.

INPUT:
- epsilon - an element of the base ring. Scales the random deformation.

OUTPUT:
A new Klyachko bundle with randomly perturbed moduli. In particular, the same Chern classes.

EXAMPLES:

```python
sage: P1 = toric_varieties.P1()
sage: H = P1.divisor(0)
sage: V = P1.sheaves.line_bundle(H) + P1.sheaves.line_bundle(-H)
sage: V.cohomology(dim=True, weight=(0,))
(continues on next page)
```
rank()
Return the rank of the vector bundle.

OUTPUT:
Integer.

EXAMPLES:

```
sage: T_P2 = toric_varieties.P2().sheaves.tangent_bundle()
sage: T_P2.rank()
2
```

symmetric_power(n)
Return the \( n \)-th symmetric power.

INPUT:
• \( n \) – integer.

OUTPUT:
The \( n \)-th symmetric power as a new Klyachko bundle.

EXAMPLES:

```
sage: P1 = toric_varieties.P1()
sage: H = P1.divisor(0)
sage: L = P1.sheaves.line_bundle(H)
sage: (L*L).symmetric_power(2)
Rank 3 bundle on 1-d CPR-Fano toric variety covered by 2 affine patches.
sage: (L*L).symmetric_power(2) == L*L+L*L+L*L
True
```

tensor_product(other)
Return the sum of two vector bundles.

INPUT:
• other – a Klyachko bundle over the same base.

OUTPUT:
The tensor product as a new Klyachko bundle.

EXAMPLES:

```
sage: X = toric_varieties.P2()
sage: OX = X.sheaves.trivial_bundle(1)
sage: X.sheaves.tangent_bundle().tensor_product(OX)
Rank 2 bundle on 2-d CPR-Fano toric variety covered by 3 affine patches.
sage: OX == OX * OX
True
```

variety()
Return the base toric variety.
OUTPUT:
A toric variety.

EXAMPLES:

```python
sage: X = toric_varieties.P2()
sage: V = X.sheaves.tangent_bundle(); V
Rank 2 bundle on 2-d CPR-Fano toric variety covered by 3 affine patches.
sage: V.variety() is X
True
```

**wedge**(\(n\))

Return the \(n\)-th exterior power.

INPUT:

• \(n\) – integer.

OUTPUT:

The \(n\)-th exterior power \(\bigwedge^n\mathcal{V}\) of the bundle \(\mathcal{V}\) as a new Klyachko bundle.

EXAMPLES:

```python
sage: X = toric_varieties.P2_123()
sage: TX = X.sheaves.tangent_bundle()
sage: antiK = X.sheaves.line_bundle(-X.K())
sage: TX.exterior_power(2) == antiK
True
sage: TX.wedge(2) == antiK  # alias
True
```

`sage.schemes.toric.sheaf.klyachko.is_KlyachkoBundle`(\(X\))

Test whether \(X\) is a Klyachko bundle

INPUT:

• \(X\) – anything.

OUTPUT:

Boolean.

EXAMPLES:

```python
sage: from sage.schemes.toric.sheaf.klyachko import is_KlyachkoBundle
sage: is_KlyachkoBundle('test')
False
```
