3 Indices and Tables
Calculus is done using symbolic expressions which consist of symbols and numeric objects linked by operators (functions).

Note: While polynomial manipulation can be done with expressions, it is more efficient to use polynomial ring elements.
CHAPTER ONE

USING CALCULUS

• Symbolic Computation

• Examples
  – Calculus examples
  – Calculus Tests and Examples
  – Further examples from Wester’s paper

• More about symbolic variables and functions

• Main operations on symbolic expressions

• Assumptions about symbols and functions

• Symbolic Equations and Inequalities

• Symbolic Integration

• Solving ordinary differential equations

• Solving ODE numerically by GSL

• Numerical Integration

• Real Interpolation using GSL

• Transforms
  – Discrete Wavelet Transform
  – Discrete Fourier Transforms
  – Fast Fourier Transforms Using GSL

• Vector Calculus

• Riemann Mapping

• Other calculus functionality

• Complexity Measures

• Units of measurement
INTERNAL FUNCTIONALITY SUPPORTING CALCULUS

• The symbolic ring
• Subrings of the Symbolic Ring
• Operators
• Classes for symbolic functions
• Functional notation support for common calculus methods
• Factory for symbolic functions
• Internals of Callable Symbolic Expressions
• Conversion of symbolic expressions to other types
• Substitution Maps
• Benchmarks
• Randomized tests of GiNaC / PyNaC
• Access to Maxima methods
• External integrators
• External interpolators

2.1 Symbolic Expressions

RELATIONAL EXPRESSIONS:
We create a relational expression:

```
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.subs(x == 5)
16 <= 18
```

Notice that squaring the relation squares both sides.

```
sage: eqn^2
(x - 1)^4 <= (x^2 - 2*x + 3)^2
sage: eqn.expand()
x^2 - 2*x + 1 <= x^2 - 2*x + 3
```

This can transform a true relation into a false one:
We can do arithmetic with relations:

\[
\begin{align*}
\text{sage: } & \quad e = x + 1 \leq x - 2 \\
\text{sage: } & \quad e + 2 \\
& \quad x + 3 \leq x \\
\text{sage: } & \quad e - 1 \\
& \quad x \leq x - 3 \\
\text{sage: } & \quad e^*(-1) \\
& \quad -x - 1 \leq -x + 2 \\
\text{sage: } & \quad (-2)*e \\
& \quad -2*x - 2 \leq -2*x + 4 \\
\text{sage: } & \quad e^5 \\
& \quad 5*x + 5 \leq 5*x - 10 \\
\text{sage: } & \quad e/5 \\
& \quad 1/5*x + 1/5 \leq 1/5*x - 2/5 \\
\text{sage: } & \quad 5/(x + 1) \leq 5/(x - 2) \\
\text{sage: } & \quad e/(-2) \\
& \quad -1/2*x - 1/2 \leq -1/2*x + 1 \\
\text{sage: } & \quad -2/e \\
& \quad -2/(x + 1) \leq -2/(x - 2)
\end{align*}
\]

We can even add together two relations, as long as the operators are the same:

\[
\begin{align*}
\text{sage: } & \quad (x^3 + x \leq x - 17) + (-x \leq x - 10) \\
& \quad x^3 \leq 2*x - 27
\end{align*}
\]

Here they are not:

\[
\begin{align*}
\text{sage: } & \quad (x^3 + x \leq x - 17) + (-x \geq x - 10) \\
\text{Traceback (most recent call last):} \\
& \quad ... \\
\text{TypeError: incompatible relations}
\end{align*}
\]

ARBITRARY SAGE ELEMENTS:

You can work symbolically with any Sage data type. This can lead to nonsense if the data type is strange, e.g., an element of a finite field (at present).

We mix Singular variables with symbolic variables:

\[
\begin{align*}
\text{sage: } & \quad R.<u,v> = QQ[] \\
\text{sage: } & \quad \text{var('a,b,c')} \\
& \quad (a, b, c) \\
\text{sage: } & \quad \text{expand}((u + v + a + b + c)^2)
\end{align*}
\]
\[ a^2 + 2a^2b + b^2 + 2a^2c + 2b^2c + c^2 + 2a^2u + 2b^2u + 2c^2u + u^2 + 2a^2v + 2b^2v + 2c^2v + 2uv + v^2 \]

```python
class sage.symbolic.expression.E:
    # Dummy class to represent base of the natural logarithm.
    # The base of the natural logarithm e is not a constant in GiNaC/Sage. It is represented by \( \exp(1) \).
    # This class provides a dummy object that behaves well under addition, multiplication, etc. and on exponentiation calls the function \( \exp \).
    Bases: Expression

    EXAMPLES:
    # The constant defined at the top level is just \( \exp(1) \):

    sage: e.operator()
    exp
    sage: e.operands()
    [1]

    Arithmetic works:

    sage: e + 2
    e + 2
    sage: 2 + e
    e + 2
    sage: 2*e
    2*e
    sage: e^2
    e^2
    sage: x*e
    x*e
    sage: var('a,b')
    (a, b)
    sage: t = e^(a+b); t
    e^(a + b)
    sage: t.operands()
    [a + b]

    Numeric evaluation, conversion to other systems, and pickling works as expected. Note that these are properties of the \( \exp() \) function, not this class:

    sage: RR(e)
    2.71828182845905
    sage: R = RealField(200); R
    Real Field with 200 bits of precision

import sympy
sage: sympy.E == e  # indirect doctest
True

class sage.symbolic.expression.Expression
Bases: Expression

Nearly all expressions are created by calling new_Expression_from_*, but we need to make sure this at least
does not leave self._gobj uninitialized and segfault.

**Order**(*hold=False*)

Return the order of the expression, as in big oh notation.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```python
sage: n = var('n')
sage: t = (17*n^3).Order(); t
Order(n^3)
sage: t.derivative(n)
Order(n^2)
```

To prevent automatic evaluation use the hold argument:

```python
sage: (17*n^3).Order(hold=True)
Order(17*n^3)
```

**WZ_certificate**(n, k)

Return the Wilf-Zeilberger certificate for this hypergeometric summand in n, k.

To prove the identity \(\sum_k F(n, k) = \text{const} \) it suffices to show that \(F(n+1, k) - F(n, k) = G(n, k+1) - G(n, k)\), with \(G = RF\) and \(R\) the WZ certificate.

**EXAMPLES:**

To show that \(\sum_k \binom{n}{k} = 2^n\) do:
Symbolic Calculus, Release 10.1

```
sage: _ = var('k n')
sage: F(n,k) = binomial(n,k) / 2^n
sage: c = F(n,k).WZ_certificate(n,k); c
1/2^k/(k - n - 1)
sage: G(n,k) = c * F(n,k); G
(n, k) |--> 1/2^k*binomial(n, k)/(2^n*(k - n - 1))
sage: (F(n+1,k) - F(n,k) - G(n,k+1) + G(n,k)).simplify_full()
0
```

`abs(hold=False)`

Return the absolute value of this expression.

EXAMPLES:

```
sage: var('x, y')
(x, y)
sage: (x+y).abs()
abs(x + y)
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```
sage: SR(-5).abs(hold=True)
abs(-5)
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(-5).abs(hold=True); a.unhold()
5
```

`add(hold=False, *args)`

Return the sum of the current expression and the given arguments.

To prevent automatic evaluation use the `hold` argument.

EXAMPLES:

```
sage: x.add(x)
2*x
sage: x.add(x, hold=True)
x + x
sage: x.add(x, (2+x), hold=True)
(2*x + x + x)
```

To then evaluate again, we use `unhold()`:

```
sage: a = x.add(x, hold=True); a.unhold()
2*x
```

`add_to_both_sides(x)`

Return a relation obtained by adding $x$ to both sides of this relation.

EXAMPLES:
Symbolic Calculus, Release 10.1

```python
sage: var('x y z')
(x, y, z)
sage: eqn = x^2 + y^2 + z^2 <= 1
sage: eqn.add_to_both_sides(-z^2)
x^2 + y^2 <= -z^2 + 1
sage: eqn.add_to_both_sides(I)
x^2 + y^2 + z^2 + I <= (I + 1)
```

**arccos**(hold=False)

Return the arc cosine of self.

EXAMPLES:

```python
sage: x.arccos()
arccos(x)
sage: SR(1).arccos()
0
sage: SR(1/2).arccos()
1/3*pi
sage: SR(0.4).arccos()
1.15927948072741
sage: plot(lambda x: SR(x).arccos(), -1,1)
Graphics object consisting of 1 graphics primitive
```

To prevent automatic evaluation use the `hold` argument:

```python
sage: SR(1).arccos(hold=True)
arccos(1)
```

This also works using functional notation:

```python
sage: arccos(1,hold=True)
arccos(1)
sage: arccos(1)
0
```

To then evaluate again, we use `unhold()`:

```python
sage: a = SR(1).arccos(hold=True); a.unhold()
0
```

**arccosh**(hold=False)

Return the inverse hyperbolic cosine of self.

EXAMPLES:

```python
sage: x.arccosh()
arccosh(x)
sage: SR(0).arccosh()
1/2*I*pi
sage: SR(1/2).arccosh()
arccosh(1/2)
sage: SR(CDF(1/2)).arccosh()
# rel tol 1e-15
1.0471975511965976*I
```

(continues on next page)
sage: z = maxima('acosh(0.5)')
sage: z.real(), z.imag()  # abs tol 1e-15
(0.0, 1.047197551196598)

To prevent automatic evaluation use the hold argument:

sage: SR(-1).arccosh()
I*pi
sage: SR(-1).arccosh(hold=True)
arccosh(-1)

This also works using functional notation:

sage: arccosh(-1,hold=True)
arccosh(-1)
sage: arccosh(-1)
I*pi

To then evaluate again, we use unhold():

sage: a = SR(-1).arccosh(hold=True); a.unhold()
I*pi

arcsin(hold=False)
Return the arcsin of x, i.e., the number y between -pi and pi such that sin(y) == x.

EXAMPLES:

sage: x.arcsin()
arcsin(x)
sage: SR(0.5).arcsin()
1/6*pi
sage: SR(0.999).arcsin()
1.52607123962616
sage: SR(1/3).arcsin()
arcsin(1/3)
sage: SR(-1/3).arcsin()
-arcsin(1/3)

To prevent automatic evaluation use the hold argument:

sage: SR(0).arcsin()
0
sage: SR(0).arcsin(hold=True)
arcsin(0)

This also works using functional notation:

sage: arcsin(0,hold=True)
arcsin(0)
sage: arcsin(0)
0

To then evaluate again, we use unhold():
Symbolic Calculus, Release 10.1

```python
sage: a = SR(0).arcsin(hold=True); a.unhold()
0
```

**arcsinh**(hold=False)

Return the inverse hyperbolic sine of self.

**EXAMPLES:**

```python
sage: x.arcsinh()
arcsinh(x)
sage: SR(0).arcsinh()
0
sage: SR(1).arcsinh()
arcsinh(1)
sage: SR(1.0).arcsinh()
0.881373587019543
sage: maxima('asinh(2.0)')
1.4436354751788...
```

Sage automatically applies certain identities:

```python
sage: SR(3/2).arcsinh().cosh()
1/2*sqrt(13)
```

To prevent automatic evaluation use the hold argument:

```python
sage: SR(-2).arcsinh()
-arsinh(2)
sage: SR(-2).arcsinh(hold=True)
arcsinh(-2)
```

This also works using functional notation:

```python
sage: arcsinh(-2,hold=True)
arcsinh(-2)
sage: arcsinh(-2)
-arsinh(2)
```

To then evaluate again, we use **unhold()**:

```python
sage: a = SR(-2).arcsinh(hold=True); a.unhold()
-arsinh(2)
```

**arctan**(hold=False)

Return the arc tangent of self.

**EXAMPLES:**

```python
sage: x = var('x')
sage: x.arctan()
arctan(x)
sage: SR(1).arctan()
1/4*pi
sage: SR(1/2).arctan()  # (continues on next page)
```

(continues on next page)
arctan(1/2)
sage: SR(0.5).arctan()
0.463647609000806
sage: plot(lambda x: SR(x).arctan(), -20,20)
Graphics object consisting of 1 graphics primitive

To prevent automatic evaluation use the hold argument:

sage: SR(1).arctan(hold=True)
arctan(1)

This also works using functional notation:

sage: arctan(1, hold=True)
arctan(1)
sage: arctan(1)
1/4*pi

To then evaluate again, we use unhold():

sage: a = SR(1).arctan(hold=True); a.unhold()
1/4*pi

arctan2(x, hold=False)
Return the inverse of the 2-variable tan function on self and x.

EXAMPLES:

sage: var('x,y')
(x, y)
sage: x.arctan2(y)
arctan2(x, y)
sage: SR(1/2).arctan2(1/2)
1/4*pi
sage: maxima.eval('atan2(1/2,1/2)')
'/%pi/4'
sage: SR(-0.7).arctan2(SR(-0.6))
-2.27942259892257

To prevent automatic evaluation use the hold argument:

sage: SR(1/2).arctan2(1/2, hold=True)
arctan2(1/2, 1/2)

This also works using functional notation:

sage: arctan2(1,2,hold=True)
arctan2(1, 2)
sage: arctan2(1,2)
arctan(1/2)

To then evaluate again, we use unhold():

2.1. Symbolic Expressions
Symbolic Calculus, Release 10.1

sage: a = SR(1/2).arctan2(1/2, hold=True); a.unhold()
1/4*pi

arctanh\(\text{hold=False}\)
Return the inverse hyperbolic tangent of self.

EXAMPLES:

```
sage: x.arctanh()
arctanh(x)
sage: SR(0).arctanh()
0
sage: SR(1/2).arctanh()
1/2*log(3)
sage: SR(0.5).arctanh()
0.549306144334055
sage: SR(0.5).arctanh().tanh()
0.000000000000000
sage: maxima('atanh(0.5)') # abs tol 2e-16
0.5493061443340548
```

To prevent automatic evaluation use the hold argument:

```
sage: SR(-1/2).arctanh()
-1/2*log(3)
sage: SR(-1/2).arctanh(hold=True)
arctanh(-1/2)
```

This also works using functional notation:

```
sage: arctanh(-1/2,hold=True)
arctanh(-1/2)
sage: arctanh(-1/2)
-1/2*log(3)
```

To then evaluate again, we use unhold():

```
sage: a = SR(-1/2).arctanh(hold=True); a.unhold()
-1/2*log(3)
```

args()

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.arguments()
(x, y)
sage: g = f.function(x)
sage: g.arguments()
(x,)
```

arguments()

EXAMPLES:
Symbolic Calculus, Release 10.1

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.arguments()
(x, y)
sage: g = f.function(x)
sage: g.arguments()
(x,)
```

**assume()**

Assume that this equation holds. This is relevant for symbolic integration, among other things.

**EXAMPLES:** We call the `assume` method to assume that \( x > 2 \):

```
sage: (x > 2).assume()
```

`bool` returns True below if the inequality is *definitely* known to be True.

```
sage: bool(x > 0)
True
sage: bool(x < 0)
False
```

This may or may not be True, so `bool` returns False:

```
sage: bool(x > 3)
False
```

If you make inconsistent or meaningless assumptions, Sage will let you know:

```
sage: forget()
sage: assume(x<0)
sage: assume(x>0)
Traceback (most recent call last):
...
ValueError: Assumption is inconsistent
sage: assumptions()
[x < 0]
sage: forget()
```

**binomial\((k, hold=False)\)**

Return binomial coefficient “self choose k”.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```
sage: var('x, y')
(x, y)
sage: SR(5).binomial(SR(3))
10
sage: x.binomial(SR(3))
1/6*(x - 1)*(x - 2)*x
```

(continues on next page)
To prevent automatic evaluation use the `hold` argument:

```
sage: x.binomial(3, hold=True)
binomial(x, 3)
sage: SR(5).binomial(3, hold=True)
binomial(5, 3)
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(5).binomial(3, hold=True); a.unhold()
10
```

The `hold` parameter is also supported in functional notation:

```
sage: binomial(5,3, hold=True)
binomial(5, 3)
```

**canonicalize_radical()**

Choose a canonical branch of the given expression.

The square root, cube root, natural log, etc. functions are multi-valued. The `canonicalize_radical()` method will choose one of these values based on a heuristic.

For example, `sqrt(x^2)` has two values: x, and -x. The `canonicalize_radical()` function will choose one of them, consistently, based on the behavior of the expression as x tends to positive infinity. The solution chosen is the one which exhibits this same behavior. Since `sqrt(x^2)` approaches positive infinity as x does, the solution chosen is x (which also tends to positive infinity).

**Warning:** As shown in the examples below, a canonical form is not always returned, i.e., two mathematically identical expressions might be converted to different expressions.

Assumptions are not taken into account during the transformation. This may result in a branch choice inconsistent with your assumptions.

**ALGORITHM:**

This uses the Maxima `radcan()` command. From the Maxima documentation:

Simplifies an expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables; that is, all functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, radcan produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero.

For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents.

**EXAMPLES:**

`canonicalize_radical()` can perform some of the same manipulations as `log_expand()`:
Symbolic Calculus, Release 10.1

```
sage: y = SR.symbol('y')
sage: f = log(x*y)
sage: f.log_expand()
log(x) + log(y)
sage: f.canonicalize_radical()
log(x) + log(y)
```

And also handles some exponential functions:

```
sage: f = (e^x-1)/(1+e^(x/2))
sage: f.canonicalize_radical()
e^(1/2*x) - 1
```

It can also be used to change the base of a logarithm when the arguments to `log()` are positive real numbers:

```
sage: f = log(8)/log(2)
sage: f.canonicalize_radical()
3
```

And also handles some exponential functions:

```
sage: a = SR.symbol('a')
sage: f = (log(x+x^2)-log(x))^a/log(1+x)^(a/2)
sage: f.canonicalize_radical()
log(x + 1)^(1/2*a)
```

The simplest example of counter-intuitive behavior is what happens when we take the square root of a square:

```
sage: sqrt(x^2).canonicalize_radical()
x
```

If you don’t want this kind of “simplification,” don’t use `canonicalize_radical()`.

This behavior can also be triggered when the expression under the radical is not given explicitly as a square:

```
sage: sqrt(x^2 - 2*x + 1).canonicalize_radical()
x - 1
```

Another place where this can become confusing is with logarithms of complex numbers. Suppose \( x \) is complex with \( x = r\,e^{i\,t} \) (\( r \) real). Then \( \log(x) = \log(r) + i\,(t + 2\,k\,\pi) \) for some integer \( k \).

Calling `canonicalize_radical()` will choose a branch, eliminating the solutions for all choices of \( k \) but one. Simplified by hand, the expression below is \( \frac{1}{2}\log(2) + i\,\pi\,k \) for integer \( k \). However, `canonicalize_radical()` will take each log expression, and choose one particular solution, dropping the other. When the results are subtracted, we’re left with no imaginary part:

```
sage: f = (1/2)*log(2^x) + (1/2)*log(1/x)
sage: fcanonicalize_radical()
1/2*log(2)
```

Naturally the result is wrong for some choices of \( x \):

```
sage: f(x = -1)
I\,\pi + 1/2*\log(2)
```
The example below shows two expressions $e_1$ and $e_2$ which are “simplified” to different expressions, while their difference is “simplified” to zero; thus `canonicalize_radical()` does not return a canonical form:

```sage
sage: e1 = 1/(sqrt(5)+sqrt(2))
sage: e2 = (sqrt(5)-sqrt(2))/3
sage: e1.canonicalize_radical()
1/(sqrt(5) + sqrt(2))
sage: e2.canonicalize_radical()
1/3*sqrt(5) - 1/3*sqrt(2)
sage: (e1-e2).canonicalize_radical()
0
```

The issue reported in github issue #3520 is a case where `canonicalize_radical()` causes a numerical integral to be calculated incorrectly:

```sage
sage: f1 = sqrt(25 - x) * sqrt( 1 + 1/(4*(25-x)) )
sage: f2 = f1.canonicalize_radical()
sage: numerical_integral(f1.real(), 0, 1)[0] # abs tol 1e-10
4.974852579915647
sage: numerical_integral(f2.real(), 0, 1)[0] # abs tol 1e-10
-4.974852579915647
```

### `coefficient(s, n=1)`

Return the coefficient of $s^n$ in this symbolic expression.

**INPUT:**
- • $s$ - expression
- • $n$ - expression, default 1

**OUTPUT:**
A symbolic expression. The coefficient of $s^n$.

Sometimes it may be necessary to expand or factor first, since this is not done automatically.

**EXAMPLES:**

```sage
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.collect(x)
x^3*sin(x*y) + (a + y + 1/y)*x + 2*sin(x*y)/x + 100
sage: f.coefficient(x,0)
100
sage: f.coefficient(x,-1)
2*sin(x*y)
```

(continues on next page)
Any coefficient can be queried:

```
sage: (x^2 + 3*x^pi).coefficient(x, pi)
3
sage: (2^x + 5*x^x).coefficient(x, x)
5
```

`coefficients(x=None, sparse=True)`

Return the coefficients of this symbolic expression as a polynomial in x.

INPUT:

* x – optional variable.

OUTPUT:

Depending on the value of sparse,

* A list of pairs (expr, n), where expr is a symbolic expression and n is a power (sparse=True, default)

* A list of expressions where the n-th element is the coefficient of x^n when self is seen as polynomial in x (sparse=False).

EXAMPLES:

```
sage: var('x, y, a')
(x, y, a)
sage: p = x^3 - (x-3)*(x^2+x) + 1
sage: p.coefficients()  
[[1, 0], [3, 1], [2, 2]]
sage: p.coefficients(sparse=False)
[1, 3, 2]
sage: p = x - x^3 + 5/7*x^5
sage: p.coefficients()  
[[1, 1], [-1, 3], [5/7, 5]]
sage: p.coefficients(sparse=False)
```

(continues on next page)
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*a*sqrt(2)*x + 2*a^2 + x^2 + x + 1
sage: p.coefficients(a)
[[x^2 + x + 1, 0], [-2*a*sqrt(2)*x, 1], [2, 2]]
sage: p.coefficients(a, sparse=False)
[x^2 + x + 1, -2*a*sqrt(2)*x, 2]
sage: p.coefficients(x)
[[2*a^2 + 1, 0], [-2*sqrt(2)*a + 1, 1], [1, 2]]
sage: p.coefficients(x, sparse=False)
[2*a^2 + 1, -2*sqrt(2)*a + 1, 1]

### collect(s)

Collect the coefficients of $s$ into a group.

**INPUT:**

- $s$ – the symbol whose coefficients will be collected.

**OUTPUT:**

A new expression, equivalent to the original one, with the coefficients of $s$ grouped.

**Note:** The expression is not expanded or factored before the grouping takes place. For best results, call `expand()` on the expression before `collect()`.

**EXAMPLES:**

In the first term of $f$, $x$ has a coefficient of $4y$. In the second term, $x$ has a coefficient of $z$. Therefore, if we collect those coefficients, $x$ will have a coefficient of $4y + z$:

sage: x,y,z = var('x,y,z')
sage: f = 4*x*y + x*z + 20*y^2 + 21*y*z + 4*z^2 + x^2*y^2*z^2
sage: f.collect(x)
x^2*y^2*z^2 + x*(4*y + z) + 20*y^2 + 21*y*z + 4*z^2

Here we do the same thing for $y$ and $z$; however, note that we do not factor the $y^2$ and $z^2$ terms before collecting coefficients:

sage: f.collect(y)
(x^2*z^2 + 20)*y^2 + (4*x + 21*z)*y + x*z + 4*z^2
sage: f.collect(z)
(x^2*y^2 + 4)*z^2 + 4*x*y + 20*y^2 + 21*y*z + 4*z^2

The terms are collected, whether the expression is expanded or not:

sage: f = (x + y)*(x - z)
sage: f.expand().collect(x)
x^2 + x*(y - z) - y*z

### collect_common_factors()

This function does not perform a full factorization but only looks for factors which are already explicitly present.
Polynomials can often be brought into a more compact form by collecting common factors from the terms of sums. This is accomplished by this function.

EXAMPLES:

```sage
sage: var('x')
x
sage: (x/(x^2 + x)).collect_common_factors()
1/(x + 1)
```

```sage
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: (a*x+a*y).collect_common_factors()
a*(x + y)
sage: (a*x^2+2*a*x*y+a*y^2).collect_common_factors()
(x^2 + 2*x*y + y^2)*a
sage: (a*(b*(a+c)^x+b*((a+c)^x+(a+c)^y)*y)).collect_common_factors()
((x + y)^y + x)*(a + c)*a*b
```

**combine**(deep=False)

Return a simplified version of this symbolic expression by combining all toplevel terms with the same denominator into a single term.

Please use the keyword `deep=True` to apply the process recursively.

EXAMPLES:

```sage
sage: var('x, y, a, b, c')
(x, y, a, b, c)
sage: f = x*(x-1)/(x^2 - 7) + y^2/(x^2-7) + 1/(x+1) + b/a + c/a; f
(x - 1)*x/(x^2 - 7) + y^2/(x^2 - 7) + b/a + c/a + 1/(x + 1)
sage: f.combine()
((x - 1)*x + y^2)/(x^2 - 7) + (b + c)/a + 1/(x + 1)
sage: (1/x + 1/x^2 + (x+1)/x).combine()
(x + 2)/x + 1/x^2
sage: ex = 1/x + ((x + 1)/x - 1/x)/x^2 + (x+1)/x; ex
1/x + ((x + 1)/x - 1/x)/x^2 + (x+1)/x
sage: ex.combine()
(x + 2)/x + ((x + 1)/x - 1/x)/x^2
sage: ex.combine(deep=True)
(x + 2)/x + 1/x^2
sage: (1+sin((x + 1)/x - 1/x)).combine(deep=True)
sin(1) + 1
```

**conjugate**(hold=False)

Return the complex conjugate of this symbolic expression.

EXAMPLES:

```sage
sage: a = 1 + 2*I
sage: a.conjugate()
-2*I + 1
sage: a = sqrt(2) + 3^(1/3)*I; a
sqrt(2) + I*3^(1/3)
sage: a.conjugate()
```

(continues on next page)
\[
\sqrt{2} - i \cdot 3^{1/3}
\]

\[
sage: \text{SR(CDF.0).conjugate()}
\]
-1.0*I
\[
sage: \text{x.conjugate()}
\]
\text{conjugate(x)}
\[
sage: \text{SR(RDF(1.5)).conjugate()}
\]
1.5
\[
sage: \text{SR(float(1.5)).conjugate()}
\]
1.5
\[
sage: \text{SR(I).conjugate()}
\]
-I
\[
sage: (1+i + (2-3*i)*x).conjugate()
\]
\((3*i + 2)*\text{conjugate(x)} - i + 1\)

Using the \texttt{hold} parameter it is possible to prevent automatic evaluation:

\[
sage: \text{SR(I).conjugate(hold=True)}
\]
\text{conjugate(I)}

This also works in functional notation:

\[
sage: \text{conjugate(I)}
\]
-I
\[
sage: \text{conjugate(I,hold=True)}
\]
\text{conjugate(I)}

To then evaluate again, we use \texttt{unhold()}:

\[
sage: a = \text{SR(I).conjugate(hold=True)}; a.unhold()\]
-I

\texttt{content(s)}

Return the content of this expression when considered as a polynomial in \(s\).

See also \texttt{unit()}, \texttt{primitive_part()}, and \texttt{unit_content_primitive()}.

\textbf{INPUT:}
- \(s\) – a symbolic expression.

\textbf{OUTPUT:}

The content part of a polynomial as a symbolic expression. It is defined as the gcd of the coefficients.

\textbf{Warning:} The expression is considered to be a univariate polynomial in \(s\). The output is different from the \texttt{content()} method provided by multivariate polynomial rings in Sage.

\textbf{EXAMPLES:}

\[
sage: (2*x+4).content(x)
\]
2
\[
sage: (2*x+1).content(x)
\]
1

(continues on next page)
Symbolic Calculus, Release 10.1

sage: (2*x+1/2).content(x)
1/2
sage: var('y')
y
sage: (2*x + 4*sin(y)).content(sin(y))
2

contradicts(soln)

Return True if this relation is violated by the given variable assignment(s).

EXAMPLES:

sage: (x<3).contradicts(x==0)
False
sage: (x<3).contradicts(x==3)
True
sage: (x<=3).contradicts(x==3)
False
sage: y = var('y')
sage: (x<y).contradicts(x==30)
False
sage: (x<y).contradicts({x: 30, y: 20})
True

convert(target=None)

Call the convert function in the units package. For symbolic variables that are not units, this function just returns the variable.

INPUT:

• self – the symbolic expression converting from

• target – (default None) the symbolic expression converting to

OUTPUT:

A symbolic expression.

EXAMPLES:

sage: units.length.foot.convert()
381/1250*meter
sage: units.mass.kilogram.convert(units.mass.pound)
100000000/45359237*pound

We do not get anything new by converting an ordinary symbolic variable:

sage: a = var('a')
sage: a - a.convert()
0

 Raises ValueError if self and target are not convertible:

sage: units.mass.kilogram.convert(units.length.foot)
Traceback (most recent call last): ...

(continues on next page)
ValueError: Incompatible units

```python
sage: (units.length.meter^2).convert(units.length.foot)
Traceback (most recent call last):
...
ValueError: Incompatible units
```

Recognizes derived unit relationships to base units and other derived units:

```python
sage: (units.length.foot/units.time.second^2).convert(units.acceleration.
  → galileo)
762/25*galileo
sage: (units.mass.kilogram*units.length.meter/units.time.second^2).
  →convert(units.force.newton)
newton
sage: (units.length.foot^3).convert(units.area.acre*units.length.inch)
1/3630*(acre*inch)
```

For decimal answers multiply by 1.0:

```python
sage: (units.pressure.pascal*units.si_prefixes.kilo).convert(units.pressure.
  →pounds_per_square_inch)*1.0
0.145037737730209*pounds_per_square_inch
```

Converting temperatures works as well:

```python
sage: s = 68*units.temperature.fahrenheit
sage: s.convert(units.temperature.celsius)
20*celsius
sage: s.convert()
293.150000000000*kelvin
```

Trying to multiply temperatures by another unit then converting raises a ValueError:

```python
sage: wrong = 50*units.temperature.celsius*units.length.foot
sage: wrong.convert()
Traceback (most recent call last):
...
ValueError: cannot convert
```

**cos** *(hold=False)*

Return the cosine of self.

**EXAMPLES:**

```python
sage: var('x, y')
(x, y)
sage: cos(x^2 + y^2)
cos(x^2 + y^2)
```

(continues on next page)
In order to get a numeric approximation use .n():

```sage
sage: SR(RR(1)).cos().n()
0.540302305868140
sage: SR(float(1)).cos().n()
0.540302305868140
```

To prevent automatic evaluation use the `hold` argument:

```sage
sage: pi.cos()
-1
sage: pi.cos(hold=True)
cos(pi)
```

This also works using functional notation:

```sage
sage: cos(pi,hold=True)
cos(pi)
sage: cos(pi)
-1
```

To then evaluate again, we use `unhold()`:

```sage
sage: a = pi.cos(hold=True); a.unhold()
-1
```

**cosh**(`**hold**=False)

Return cosh of self.

We have \( \cosh(x) = (e^x + e^{-x})/2 \).

EXAMPLES:

```sage
sage: x.cosh()
cosh(x)
sage: SR(1).cosh()
cosh(1)
sage: SR(0).cosh()
1
sage: SR(1.0).cosh()
1.54308063481524
sage: maxima('cosh(1.0)')
1.54308063481524...
sage: SR(1.00000000000000000000000000).cosh()
1.543080634815243784779056
sage: SR(RIF(1)).cosh()
1.5430806348152447
```
To prevent automatic evaluation use the hold argument:

```
sage: arcsinh(x).cosh()
sqrt(x^2 + 1)
sage: arcsinh(x).cosh(hold=True)
cosh(arcsinh(x))
```

This also works using functional notation:

```
sage: cosh(arcsinh(x),hold=True)
cosh(arcsinh(x))
sage: cosh(arcsinh(x))
sqrt(x^2 + 1)
```

To then evaluate again, we use `unhold()`:

```
sage: a = arcsinh(x).cosh(hold=True); a.unhold()
sqrt(x^2 + 1)
```

**csgn**(_hold=False_)

Return the sign of self, which is -1 if self < 0, 0 if self == 0, and 1 if self > 0, or unevaluated when self is a nonconstant symbolic expression.

If self is not real, return the complex half-plane (left or right) in which the number lies. If self is pure imaginary, return the sign of the imaginary part of self.

**EXAMPLES:**

```
sage: x = var('x')
sage: SR(-2).csgn()
-1
sage: SR(0.0).csgn()
0
sage: SR(10).csgn()
1
sage: x.csgn()
csgn(x)
sage: SR(CDF.0).csgn()
1
sage: SR(I).csgn()
1
sage: SR(-I).csgn()
-1
sage: SR(1+I).csgn()
1
sage: SR(1-I).csgn()
1
sage: SR(-1+I).csgn()
-1
sage: SR(-1-I).csgn()
-1
```

Using the hold parameter it is possible to prevent automatic evaluation:
Symbolic Calculus, Release 10.1

```
sage: SR(I).csgn(hold=True)
csgn(I)
```

decl_assume(decl)

decl_forget(decl)

default_variable()

Return the default variable, which is by definition the first variable in self, or \( x \) is there are no variables in self. The result is cached.

EXAMPLES:

```
sage: sqrt(2).default_variable()
x
```

```
sage: x, theta, a = var('x, theta, a')
sage: f = x^2 + theta^3 - a*x
sage: f.default_variable()
a
```

Note that this is the first variable, not the first argument:

```
sage: f(theta, a, x) = a + theta^3
sage: f.default_variable()
a
```

```
sage: f.variables()
(a, theta)
sage: f.arguments()
(theta, a, x)
```

degree(s)

Return the exponent of the highest power of \( s \) in self.

OUTPUT:

An integer

EXAMPLES:

```
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y^10 + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + 2*sin(x*y)/x + x/y^10 + 100
sage: f.degree(x)
3
sage: f.degree(y)
1
sage: f.degree(sin(x*y))
1
sage: (x^3+y).degree(x)
0
sage: (1/x+1/x**2).degree(x)
-1
```

2.1. Symbolic Expressions 27
demoivre(force=False)

Return this symbolic expression with complex exponentials (optionally all exponentials) replaced by (at least partially) trigonometric/hyperbolic expressions.

EXAMPLES:

```sage
x, a, b = SR.var("x, a, b")
exp(a + I*b).demoivre()
(cos(b) + I*sin(b))*e^a
exp(I*x).demoivre()
exp(x).demoivre(force=True)
cosh(x) + sinh(x)
```

denominator(normalize=True)

Return the denominator of this symbolic expression

INPUT:

* normalize – (default: True) a boolean.

If normalize is True, the expression is first normalized to have it as a fraction before getting the denominator.

If normalize is False, the expression is kept and if it is not a quotient, then this will just return 1.

See also:

`normalize()`, `numerator()`, `numerator_denominator()`, `combine()`

EXAMPLES:

```sage
x, y, z, theta = var('x, y, z, theta')
f = (sqrt(x) + sqrt(y) + sqrt(z))/(x^10 - y^10 - sqrt(theta))
f.numerator()
sqrt(x) + sqrt(y) + sqrt(z)
f.denominator()
x^10 - y^10 - sqrt(theta)
f.numerator(normalize=False)
(sqrt(x) + sqrt(y) + sqrt(z))
f.denominator(normalize=False)
x^10 - y^10 - sqrt(theta)
sage: y = var('y')
g = x + y/(x + 2); g
x + y/(x + 2)
g.numerator(normalize=False)
x + y/(x + 2)
g.denominator(normalize=False)
1
```

derivative(*args)

Return the derivative of this expressions with respect to the variables supplied in args.
Multiple variables and iteration counts may be supplied; see documentation for the global `derivative()` function for more details.

**See also:**

This is implemented in the `_derivative` method (see the source code).

**EXAMPLES:**

```python
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
sage: t.derivative(x)
4*(x^2 + y)*x
sage: t.derivative(x, 2)
12*x^2 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y
```

If the function depends on only one variable, you may omit the variable. Giving just a number (for the order of the derivative) also works:

```python
sage: f(x) = x^3 + sin(x)
sage: f.derivative()
x |--> 3*x^2 + cos(x)
sage: f.derivative(2)
x |--> 6*x - sin(x)
```

Some expressions can’t be cleanly differentiated by the chain rule:

```python
sage: _ = var('x', domain='real')
sage: _ = var('w z')
sage: (x^z).conjugate().diff(x)
conjugate(x^(z - 1))*conjugate(z)
sage: (w^z).conjugate().diff(w)
w^(z - 1)*z*D[0](conjugate)(w^z)
sage: atanh(x).real_part().diff(x)
-1/(x^2 - 1)
sage: atanh(x).imag_part().diff(x)
0	sage: atanh(w).real_part().diff(w)
-D[0](real_part)(arctanh(w))/(w^2 - 1)
sage: atanh(w).imag_part().diff(w)
-D[0](imag_part)(arctanh(w))/(w^2 - 1)
sage: abs(log(x)).diff(x)
1/2*(conjugate(log(x))/x + log(x)/x)/abs(log(x))
sage: abs(log(z)).diff(z)
1/2*(conjugate(log(z))/z + log(z)/conjugate(z))/abs(log(z))
sage: forget()
sage: t = sin(x^y)*tan(x*y)
sage: t.derivative(x)
(tan(x^y)*x^2 + 1)*y*sin(y^2 + x) + cos(y^2 + x)*tan(x^y)
```

(continues on next page)
**Symbolic Calculus, Release 10.1**

```
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)

sage: h = sin(x)/cos(x)
```

```
sage: derivative(h,x,x,x)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2
sage: derivative(h,x,3)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2
```

```
sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*(cos(x) - sin(y))
```

```
sage: derivative(u,x,y)
-cos(x)*cos(y) + sin(x)*sin(y)
```

```
sage: f = ((x^2+1)/(x^2-1))^(1/4)
sage: g = derivative(f, x); g
# this is a complex expression
-1/2*((x^2 + 1)*x/(x^2 - 1)^2 - x/(x^2 - 1))/((x^2 + 1)/(x^2 - 1))^(3/4)
sage: g.factor()
-x/((x + 1)^2*(x - 1)^2*((x^2 + 1)/(x^2 - 1))^(3/4))
```

```
sage: y = var('y')
sage: f = y^(sin(x))
```

```
sage: derivative(f, x)
y^sin(x)*cos(x)*log(y)
```

```
sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3
```

```
sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)
```

```
sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x^2 - 1)*x/(x^2 - 1))/(x^2 - 1)/(x + 5)^6)^3/2
```

**diff(*args)**

Return the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global `derivative()` function for more details.

**See also:**

This is implemented in the `_derivative` method (see the source code).

**EXAMPLES:**

```
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
```
Symbolic Calculus, Release 10.1

(continued from previous page)

sage: t.derivative(x)
4*(x^2 + y)*x
sage: t.derivative(x, 2)
12*x^4 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y

If the function depends on only one variable, you may omit the variable. Giving just a number (for the order of the derivative) also works:

sage: f(x) = x^3 + sin(x)
sage: f.derivative()
x |--> 3*x^2 + cos(x)
sage: f.derivative(2)
x |--> 6*x - sin(x)

Some expressions can't be cleanly differentiated by the chain rule:

sage: _ = var('x', domain='real')
sage: _ = var('w z')
sage: (x^z).conjugate().diff(x)
conjugate(x^(z - 1))*conjugate(z)
sage: (w^z).conjugate().diff(w)
w^(z - 1)*z*D[0](conjugate)(w^z)
sage: atanh(x).real_part().diff(x)
-1/(x^2 - 1)
sage: atanh(x).imag_part().diff(x)
0
sage: atanh(w).real_part().diff(w)
-D[0](real_part)(arctanh(w))/(w^2 - 1)
sage: atanh(w).imag_part().diff(w)
-D[0](imag_part)(arctanh(w))/(w^2 - 1)
sage: abs(log(x)).diff(x)
1/2*(conjugate(log(x))/x + log(x)/x)/abs(log(x))
sage: abs(log(z)).diff(z)
1/2*(conjugate(log(z))/z + log(z)/conjugate(z))/abs(log(z))
sage: forget()

sage: t = sin(x+y^2)*tan(x*y)
sage: t.derivative(x)
(tan(x*y)^2 + 1)*y^2*sin(y^2 + x) + cos(y^2 + x)*tan(x*y)
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*y*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)

sage: h = sin(x)/cos(x)
sage: derivative(h, x, x, x)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2
sage: derivative(h, x, 3)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2

2.1. Symbolic Expressions

31
```python
sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*(cos(x) - sin(y))
sage: derivative(u, x, y)
-cos(x)*cos(y) + sin(x)*sin(y)
sage: f = ((x^2+1)/(x^2-1))^(1/4)
sage: g = derivative(f, x); g
# this is a complex expression
-1/2*((x^2 + 1)*x/(x^2 - 1)^2 - x/(x^2 - 1))/((x^2 + 1)/(x^2 - 1))^(3/4)
sage: g.factor()
-x/((x + 1)^2*(x - 1)^2*((x^2 + 1)/(x^2 - 1))^(3/4))
sage: y = var('y')
sage: f = y^(sin(x))
sage: derivative(f, x)
y^sin(x)*cos(x)*log(y)
sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3
sage: f = x^*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)
sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x^2 - 1)*(x + 5)^5)/((x^2 - 1)*(x + 5)^6)^(3/2)
```

differentiate(*args)

Return the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global `derivative()` function for more details.

See also:

This is implemented in the `_derivative` method (see the source code).

EXAMPLES:

```python
sage: var("x y")
(x, y)
sage: t = (x^2*y)^2
sage: t.derivative(x)
4*(x^2 + y)^x
sage: t.derivative(x, 2)
12*x^2 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y
```

If the function depends on only one variable, you may omit the variable. Giving just a number (for the order of the derivative) also works:
Symbolic Calculus, Release 10.1

```
sage: f(x) = x^3 + sin(x)
sage: f.derivative()
x |--> 3*x^2 + cos(x)
sage: f.derivative(2)
x |--> 6*x - sin(x)
```

Some expressions can't be cleanly differentiated by the chain rule:

```
sage: _ = var('x', domain='real')
sage: _ = var('w z')
sage: (x^z).conjugate().diff(x)
conjugate(x^(z - 1))*conjugate(z)
sage: (w^z).conjugate().diff(w)
w^(z - 1)*z*D[0](conjugate)(w^z)
sage: atanh(x).real_part().diff(x)
-1/(x^2 - 1)
sage: atanh(x).imag_part().diff(x)
0
sage: (w^z).conjugate().diff(w)
-w^(z - 1)*z*D[0](conjugate)(w^z)
sage: atanh(w).real_part().diff(w)
-D[0](real_part)(arctanh(w))/(w^2 - 1)
sage: atanh(w).imag_part().diff(w)
-D[0](imag_part)(arctanh(w))/(w^2 - 1)
sage: abs(log(x)).diff(x)
1/2*(conjugate(log(x))/x + log(x)/x)/abs(log(x))
sage: abs(log(z)).diff(z)
1/2*(conjugate(log(z))/z + log(z)/conjugate(z))/abs(log(z))
sage: forget()
sage: t = sin(x+y^2)*tan(x*y)
sage: t.derivative(x)
(tan(x*y)^2 + 1)*y*sin(y^2 + x) + cos(y^2 + x)*tan(x*y)
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)
sage: h = sin(x)/cos(x)
sage: derivative(h, x, x, x)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2
```

(continues on next page)
sage: f = y^(sin(x))
sage: derivative(f, x)
y^sin(x)*cos(x)*log(y)

sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3

sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)

sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-(x + 5)^6*x + 3*(x^2 - 1)*(x + 5)^5)/((x^2 - 1)*(x + 5)^6)^(3/2)

distribute(recursive=True)
Distribute some indexed operators over similar operators in order to allow further groupings or simplifications.

Implemented cases (so far):
- Symbolic sum of a sum ==> sum of symbolic sums
- Integral (definite or not) of a sum ==> sum of integrals.
- Symbolic product of a product ==> product of symbolic products.

INPUT:
- recursive – (default : True) the distribution proceeds along the subtrees of the expression.

AUTHORS:
- Emmanuel Charpentier, Ralf Stephan (05-2017)

divide_both_sides(x, checksign=None)
Return a relation obtained by dividing both sides of this relation by x.

Note: The checksign keyword argument is currently ignored and is included for backward compatibility reasons only.

EXAMPLES:

sage: theta = var('theta')
sage: eqn = (x^3 + theta < sin(x*theta))
sage: eqn.divide_both_sides(theta, checksign=False)
(x^3 + theta)/theta < sin(theta*x)/theta
sage: eqn.divide_both_sides(theta)
(x^3 + theta)/theta < sin(theta*x)/theta
sage: eqn/theta
(x^3 + theta)/theta < sin(theta*x)/theta
\texttt{exp(\textit{hold}=False)}

Return exponential function of self, i.e., e to the power of self.

\textbf{EXAMPLES:}

\begin{Verbatim}
\texttt{sage: x.exp()}
\texttt{e^x}
\texttt{sage: SR(0).exp()}
\texttt{1}
\texttt{sage: SR(1/2).exp()}
\texttt{e^(1/2)}
\texttt{sage: SR(0.5).exp()}
\texttt{1.64872127070013}
\texttt{sage: math.exp(0.5)}
\texttt{1.6487212707001282}
\texttt{sage: SR(0.5).exp().log()}
\texttt{0.500000000000000}
\texttt{sage: (pi*I).exp()}
\texttt{-1}
\end{Verbatim}

To prevent automatic evaluation use the \texttt{hold} argument:

\begin{Verbatim}
\texttt{sage: (pi*I).exp(hold=True)}
\texttt{e^{I\pi}}
\end{Verbatim}

This also works using functional notation:

\begin{Verbatim}
\texttt{sage: exp(I*pi,hold=True)}
\texttt{e^{I\pi}}
\texttt{sage: exp(I*pi)}
\texttt{-1}
\end{Verbatim}

To then evaluate again, we use \texttt{unhold()}:

\begin{Verbatim}
\texttt{sage: a = (pi*I).exp(hold=True); a.unhold()}
\texttt{-1}
\end{Verbatim}

\texttt{expand(side=None)}

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

\textbf{EXAMPLES:}

We expand the expression \((x - y)^5\) using both method and functional notation.

\begin{Verbatim}
\texttt{sage: x,y = var('x,y')}
\texttt{sage: a = (x-y)^5}
\texttt{sage: a.expand()}
\texttt{x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5}
\texttt{sage: expand(a)}
\texttt{x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5}
\end{Verbatim}

We expand some other expressions:
Observe that \texttt{expand()} also expands function arguments:

\begin{verbatim}sage: f(x) = function('f')(x)
sage: fx = f((x+1)*x); fx
f((x + 1)*x)
sage: fx.expand()
f(x^2 + x)
\end{verbatim}

We can expand individual sides of a relation:

\begin{verbatim}sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
sage: a.expand('right')
(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2
\end{verbatim}

\texttt{expand\_log(algorithm='products')}  
Simplify symbolic expression, which can contain logs.  

Expands logarithms of powers, logarithms of products and logarithms of quotients. The option \texttt{algorithm} specifies which expression types should be expanded.  

\begin{verbatim}
INPUT:
• \texttt{self} - expression to be simplified
• \texttt{algorithm} - (default: ‘products’) optional, governs which expression is expanded. Possible values are
  – ‘nothing’ (no expansion),
  – ‘powers’ (log(a^r) is expanded),
  – ‘products’ (like ‘powers’ and also log(a*b) are expanded),
  – ‘all’ (all possible expansion).

DETAILS: This uses the Maxima simplifier and sets \texttt{logexpand} option for this simplifier. From the Maxima documentation: “\texttt{Logexpand:}true causes log(a^b) to become b*log(a). If it is set to all, log(a*b) will also simplify to log(a)+log(b). If it is set to super, then log(a/b) will also simplify to log(a)-log(b) for rational numbers a/b, a\neq1. (log(1/b), for integer b, always simplifies.) If it is set to false, all of these simplifications will be turned off.”

ALIAS: \texttt{log\_expand()} and \texttt{expand\_log()} are the same

EXAMPLES:
By default powers and products (and quotients) are expanded, but not quotients of integers:

\begin{verbatim}sage: (log(3/4*x*pi)).log_expand()
pi*log(x) + log(3/4)
\end{verbatim}
\end{verbatim}
To expand also log(3/4) use algorithm='all':

```
sage: (log(3/4*x^pi)).log_expand('all')
pi*log(x) + log(3) - 2*log(2)
```

To expand only the power use algorithm='powers':

```
sage: (log(x^6)).log_expand('powers')
6*log(x)
```

The expression log((3*x)^6) is not expanded with algorithm='powers', since it is converted into product first:

```
sage: (log((3*x)^6)).log_expand('powers')
log(729*x^6)
```

This shows that the option algorithm from the previous call has no influence to future calls (we changed some default Maxima flag, and have to ensure that this flag has been restored):

```
sage: (log(3/4*x^pi)).log_expand()
pi*log(x) + log(3/4)
sage: (log(3/4*x^pi)).log_expand('all')
pi*log(x) + log(3) - 2*log(2)
sage: (log(3/4*x^pi)).log_expand()
pi*log(x) + log(3/4)
```

AUTHORS:

• Robert Marik (11-2009)

**expand_rational**(side=None)

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

EXAMPLES:

We expand the expression (x - y)^5 using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x+y)^2))^2)
x^2 + 2*x*sin(x^2 + 2*x*y + y^2) + sin(x^2 + 2*x*y + y^2)^2
```

Observe that **expand()** also expands function arguments:
Symbolic Calculus, Release 10.1

```
sage: f(x) = function('f')(x)
sage: fx = f(x*(x+1)); fx
f((x + 1)*x)
sage: fx.expand()
f(x^2 + x)
```

We can expand individual sides of a relation:

```
sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('right')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
```

```
def expand_sum()
    For every symbolic sum in the given expression, try to expand it, symbolically or numerically.
    While symbolic sum expressions with constant limits are evaluated immediately on the command line,
    unevaluated sums of this kind can result from, e.g., substitution of limit variables.
    INPUT:
        • self - symbolic expression
    EXAMPLES:
        sage: (k,n) = var('k,n')
        sage: ex = sum(abs(-k*k+n),k,1,n)(n=8); ex
        sum(abs(-k^2 + 8), k, 1, 8)
        sage: ex.expand_sum()
162
        sage: f(x,k) = sum((2/n)*(sin(n*x)*(-1)^(n+1)), n, 1, k)
        sage: f(x,2)
-2*sum((-1)^n*sin(n*x)/n, n, 1, 2)
        sage: f(x,2).expand_sum()
-sin(2*x) + 2*sin(x)
```

We can use this to do floating-point approximation as well:

```
sage: (k,n) = var('k,n')
sage: f(n)=sum(sqrt(abs(-k*k+n)),k,1,n)
```

```
sage: f(8).expand_sum().n() 
31.7752256945384
```

See [github issue #9424](https://github.com/sagemath/sage/issues/9424) for making the following no longer raise an error:

```
sage: f(8).n() 
31.7752256945384
```
**expand_trig** *(full=False, half_angles=False, plus=True, times=True)*

Expand trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in `self`.

For best results, `self` should already be expanded.

**INPUT:**

- **full** – (default: `False`) To enhance user control of simplification, this function expands only one level at a time by default, expanding sums of angles or multiple angles. To obtain full expansion into sines and cosines immediately, set the optional parameter `full` to `True`.
- **half_angles** - (default: `False`) If `True`, causes half-angles to be simplified away.
- **plus** – (default: `True`) Controls the sum rule; expansion of sums (e.g. `sin(x + y)`) will take place only if `plus` is `True`.
- **times** – (default: `True`) Controls the product rule, expansion of products (e.g. `sin(2x)`) will take place only if `times` is `True`.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```python
sage: sin(5*x).expand_trig()
5*cos(x)^4*sin(x) - 10*cos(x)^2*sin(x)^3 + sin(x)^5
sage: cos(2*x + var('y')).expand_trig()
cos(2*x)*cos(y) - sin(2*x)*sin(y)
```

We illustrate various options to this function:

```python
sage: f = sin(sin(3*cos(2*x))*x)
sage: f.expand_trig()
sin((3*cos(cos(2*x))^2*sin(cos(2*x)) - sin(cos(2*x))^3)*x)
sage: f.expand_trig(full=True)
sin((3*(cos(cos(x)^2)*cos(sin(x)^2) + sin(cos(x)^2)*sin(sin(x)^2))^2 + 2*(cos(sin(x)^2)*sin(cos(x)^2) + cos(cos(x)^2)*sin(sin(x)^2))^3)*x)
sage: sin(2*x).expand_trig(times=False)
sin(2*x)
sage: sin(2*x).expand_trig(times=True)
2*cos(x)*sin(x)
sage: sin(2 + x).expand_trig(plus=False)
sin(x + 2)
sage: sin(2 + x).expand_trig(plus=True)
cos(x)*sin(2) + cos(2)*sin(x)
sage: sin(x/2).expand_trig(half_angles=False)
sin(1/2*x)
sage: sin(x/2).expand_trig(half_angles=True)
(-1)^floor(1/2*x/pi)*sqrt(-1/2*cos(x) + 1/2)
```

If the expression contains terms which are factored, we expand first:

```python
sage: (x, k1, k2) = var('x, k1, k2')
sage: cos((k1-k2)*x).expand().expand_trig()
cos(k1*x)*cos(k2*x) + sin(k1*x)*sin(k2*x)
```
ALIAS:

*trig_expand()* and *expand_trig()* are the same

**exponentialize()**

Return this symbolic expression with all circular and hyperbolic functions replaced by their respective exponential expressions.

**EXAMPLES:**

```sage
sage: x = SR.var("x")
sage: sin(x).exponentialize()
-1/2*I*e^(I*x) + 1/2*I*e^(-I*x)
sage: sec(x).exponentialize()
2/(e^(I*x) + e^(-I*x))
sage: tan(x).exponentialize()
(-I*e^(I*x) + I*e^(-I*x))/(e^(I*x) + e^(-I*x))
sage: sinh(x).exponentialize()
-1/2*e^(-x) + 1/2*e^x
sage: sech(x).exponentialize()
2/(e^(-x) + e^x)
sage: tanh(x).exponentialize()
-(e^(-x) - e^x)/(e^(-x) + e^x)
```

**factor(dontfactor=None)**

Factor the expression, containing any number of variables or functions, into factors irreducible over the integers.

**INPUT:**

- *self* - a symbolic expression
- *dontfactor* - list (default: []), a list of variables with respect to which factoring is not to occur. Factoring also will not take place with respect to any variables which are less important (using the variable ordering assumed for CRE form) than those on the ‘dontfactor’ list.

**EXAMPLES:**

```sage
sage: x,y,z = var(’x, y, z’) 
sage: (x^3-y^3).factor()
(x^2 + x*y + y^2)*(x - y)
sage: factor(-8*y - 4*x + z^2*(2*y + x))
(x + 2*y)*(z + 2)*(z - 2)
sage: f = -1 - 2*x - x^2 + y^2 + 2*x*y^2 + x^2*y^2
sage: F = factor(f/(36*(1 + 2*y + y^2)), dontfactor=[x]); F
1/36*(x^2 + 2*x + 1)*(y - 1)/(y + 1)
```

If you are factoring a polynomial with rational coefficients (and dontfactor is empty) the factorization is done using Singular instead of Maxima, so the following is very fast instead of dreadfully slow:

```sage
sage: var(’x,y’) 
(x, y)
sage: (x^99 + y^99).factor()
(x^68 + x^57*y^3 - x^51*y^9 - x^48*y^12 + x^42*y^18 + x^39*y^21 - x^33*y^27 - x^30*y^30 - x^27*y^33 + x^21*y^39 + x^18*y^42 - x^12*y^48 - x^9*y^51 + x^3*y^57 + y^60)*(x^20 + x^19*y - x^17*y^3 - x^16*y^4 + x^14*y^6 + x^13*y^7 - x^11*y^9 -
```

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

\[ x^{10}y^{10} - x^9y^{11} + x^7y^{13} + x^6y^{14} - x^4y^{16} - x^3y^{17} + x^2y^{19} + y^{20} \]

\[ \times (x^{10} - x^9y + x^8y^2 - x^7y^3 + x^6y^4 - x^5y^5 + x^4y^6 - x^3y^7 + x^2y^8 - xy^9 + y^{10}) \times (x^6 - x^3y^3 + y^6) \times (x^2 - x^2y + y^2) \times (x + y) \]

\textbf{factor_list}(\text{dontfactor}=\text{None})

Return a list of the factors of self, as computed by the factor command.

**INPUT:**

- \textit{self} – a symbolic expression
- \textit{dontfactor} – see docs for \texttt{factor()}

**Note:** If you already have a factored expression and just want to get at the individual factors, use the \_factor_list method instead.

**EXAMPLES:**

```
sage: var('x, y, z')
(x, y, z)
sage: f = x^3-y^3
sage: f.factor()
(x^2 + x*y + y^2)*(x - y)
```

Notice that the -1 factor is separated out:

```
sage: f.factor_list()
[(x^2 + x*y + y^2, 1), (x - y, 1)]
```

We factor a fairly straightforward expression:

```
sage: factor(-8*y - 4*x + z^2*(2*y + x)).factor_list()
[(x + 2*y, 1), (z + 2, 1), (z - 2, 1)]
```

A more complicated example:

```
sage: var('x, u, v')
(x, u, v)
sage: f = expand((2*u*v^2-v^2-4*u^3)^2 * (-u)^3 * (x-sin(x))^3)
sage: f.factor()
-(4*u^3 - 2*u*v^2 + v^2)^2*u^3*(x - sin(x))^3
sage: g = f.factor_list(); g
[(4*u^3 - 2*u*v^2 + v^2, 2), (u, 3), (x - sin(x), 3), (-1, 1)]
```

This function also works for quotients:

```
sage: f = -1 - 2*x - x^2 + y^2 + 2*x*y^2 + x^2*y^2
sage: g = f/(36*(1 + 2*y + y^2)); g
1/36*(x^2*y^2 + 2*x*y^2 - x^2 + y^2 - 2*x - 1)/(y^2 + 2*y + 1)
sage: g.factor(dontfactor=[x])
1/36*(x^2 + 2*x + 1)*(y - 1)/(y + 1)
sage: g.factor_list(dontfactor=[x])
[(x^2 + 2*x + 1, 1), (y + 1, -1), (y - 1, 1), (1/36, 1)]
```

2.1. Symbolic Expressions 41
This example also illustrates that the exponents do not have to be integers:

```sage
sage: f = x^(2*sin(x)) * (x-1)^(sqrt(2)*x); f
(x - 1)^(sqrt(2)*x)*x^(2*sin(x))
sage: f.factor_list()
[(x - 1, sqrt(2)*x), (x, 2*sin(x))]
```

**factorial**(hold=False)

Return the factorial of self.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```sage
sage: var('x, y')
(x, y)
sage: SR(5).factorial()
120
sage: x.factorial()
factorial(x)
sage: (x^2+y^3).factorial()
factorial(y^3 + x^2)
```

To prevent automatic evaluation use the hold argument:

```sage
sage: SR(5).factorial(hold=True)
factorial(5)
```

This also works using functional notation:

```sage
sage: factorial(5,hold=True)
factorial(5)
sage: factorial(5)
120
```

To then evaluate again, we use `unhold()`:

```sage
sage: a = SR(5).factorial(hold=True); a.unhold()
120
```

**factorial_simplify()**

Simplify by combining expressions with factorials, and by expanding binomials into factorials.

**ALIAS:** `factorial_simplify` and `simplify_factorial` are the same

**EXAMPLES:**

Some examples are relatively clear:

```sage
sage: var('n,k')
(n, k)
sage: f = factorial(n+1)/factorial(n); f
factorial(n + 1)/factorial(n)
sage: f.simplify_factorial()
n + 1
```
Symbolic Calculus, Release 10.1

```sage
sage: f = factorial(n)*(n+1); f
(n + 1)*factorial(n)
sage: simplify(f)
(n + 1)*factorial(n)
sage: f.simplify_factorial()
factorial(n + 1)
```

```sage
sage: f = binomial(n, k)*factorial(k)*factorial(n-k); f
binomial(n, k)*factorial(k)*factorial(-k + n)
sage: f.simplify_factorial()
factorial(n)
```

A more complicated example, which needs further processing:

```sage
sage: f = factorial(x)/factorial(x-2)/2 + factorial(x+1)/factorial(x)/2; f
1/2*factorial(x + 1)/factorial(x) + 1/2*factorial(x)/factorial(x - 2)
sage: g = f.simplify_factorial(); g
1/2*(x - 1)*x + 1/2*x + 1/2
sage: g.simplify_rational()
1/2*x^2 + 1/2
```

**find**(pattern)

Find all occurrences of the given pattern in this expression.

Note that once a subexpression matches the pattern, the search does not extend to subexpressions of it.

EXAMPLES:

```sage
sage: var('x,y,z,a,b')
(x, y, z, a, b)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: (sin(x)*sin(y)).find(sin(w0))
[sin(y), sin(x)]
sage: ((sin(x)+sin(y))*(a+b)).expand().find(sin(w0))
[sin(y), sin(x)]
sage: (1+x+x^2+x^3).find(x)
[x]
sage: (1+x+x^2+x^3).find(x^w0)
[x^2, x^3]
sage: (1+x+x^2+x^3).find(y)
[]
```

```
# subexpressions of a match are not listed
sage: ((x^y)^z).find(w0^w1)
[(x^y)^z]
```

**find_local_maximum**(a, b, var=None, tol=1.48e-08, maxfun=500, imaginary_tolerance=1e-08)

Numerically find a local maximum of the expression self on the interval [a,b] (or [b,a]) along with the point at which the maximum is attained.

See the documentation for **find_local_minimum()** for more details.
EXAMPLES:

```
sage: f = x*cos(x)
sage: f.find_local_maximum(0,5)
(0.5610963381910451, 0.8603335890...)  
sage: f.find_local_maximum(0,5, tol=0.1, maxfun=10)
(0.561090323458081..., 0.857926501456...)  
```

**find_local_minimum**

```
(a, b, var=None, tol=1.48e-08, maxfun=500, imaginary_tolerance=1e-08)
```

Numerically find a local minimum of the expression `self` on the interval \([a, b]\) (or \([b, a]\)) and the point at which it attains that minimum. Note that `self` must be a function of (at most) one variable.

**INPUT:**

- `a` - real number; left endpoint of interval on which to minimize
- `b` - real number; right endpoint of interval on which to minimize
- `var` - variable (default: first variable in `self`); the variable in `self` to maximize over
- `tol` - positive real (default: 1.48e-08); the convergence tolerance
- `maxfun` - natural number (default: 500); maximum function evaluations
- `imaginary_tolerance` – (default: 1e-8); if an imaginary number arises (due, for example, to numerical issues), this tolerance specifies how large it has to be in magnitude before we raise an error. In other words, imaginary parts smaller than this are ignored when we are expecting a real answer.

**OUTPUT:**

A tuple `(minval, x)`, where

- `minval` – float. The minimum value that `self` takes on in the interval \([a, b]\).
- `x` – float. The point at which `self` takes on the minimum value.

**EXAMPLES:**

```
sage: f = x*cos(x)
sage: f.find_local_minimum(1, 5)
(-3.288371395590..., 3.4256184695...)  
sage: f.find_local_minimum(1, 5, tol=1e-3)
(-3.288370845983..., 3.4250840220...)  
sage: f.find_local_minimum(1, 5, tol=1e-2, maxfun=10)
(-3.28837...04259479..., 9.5293344109...)  
```

**ALGORITHM:**

Uses `sage.numerical.optimize.find_local_minimum()`.

**AUTHORS:**

- William Stein (2007-12-07)

```
(a, b, var=None, xtol=1e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, imaginary_tolerance=1e-08)
```

Numerically find a root of `self` on the closed interval \([a, b]\) (or \([b, a]\)) if possible, where `self` is a function in the one variable. Note: this function only works in fixed (machine) precision, it is not possible to get arbitrary precision approximations with it.

**find_root**
INPUT:

• \( a, b \) - endpoints of the interval
• \( \text{var} \) - optional variable
• \( \text{xtol, rtol} \) - the routine converges when a root is known to lie within xtol of the value returned. Should be \( >= 0 \). The routine modifies this to take into account the relative precision of doubles.
• \( \text{maxiter} \) - integer; if convergence is not achieved in maxiter iterations, an error is raised. Must be \( >= 0 \).
• \( \text{full_output} \) - bool (default: False), if True, also return object that contains information about convergence.
• \( \text{imaginary_tolerance} \) – (default: \( 1e-8 \)); if an imaginary number arises (due, for example, to numerical issues), this tolerance specifies how large it has to be in magnitude before we raise an error. In other words, imaginary parts smaller than this are ignored when we are expecting a real answer.

EXAMPLES:

Note that in this example both \( f(-2) \) and \( f(3) \) are positive, yet we still find a root in that interval:

```
sage: f = x^2 - 1
sage: f.find_root(-2, 3)
1.0
sage: z, result = f.find_root(-2, 3, full_output=True)
sage: result.converged
True
sage: result.flag
'converged'
sage: result.function_calls
11
sage: result.iterations
10
sage: result.root
1.0
```

More examples:

```
sage: (sin(x) + exp(x)).find_root(-10, 10)
-0.588532743981862...
sage: sin(x).find_root(-1,1)
0.0
```

This example was fixed along with github issue #4942 - there was an error in the example pi is a root for \( \tan(x) \), but an asymptote to \( 1/\tan(x) \) added an example to show handling of both cases:

```
sage: (tan(x)).find_root(3,3.5)
3.1415926535...
sage: (1/tan(x)).find_root(3, 3.5)
Traceback (most recent call last):
...
NotImplementedError: Brent's method failed to find a zero for f on the interval
```

An example with a square root:
Some examples that Ted Kosan came up with:

```sage
sage: t = var('t')
sage: v = 0.004*(9600*e^(-(1200*t)) - 2400*e^(-(300*t)))
sage: v.find_root(0, 0.002)
0.001540327067911417...
```

With this expression, we can see there is a zero very close to the origin:

```sage
sage: a = .004*(8*e^(-(300*t)) - 8*e^(-(1200*t)))*(720000*e^(-(300*t)) - 11520000*e^(-(1200*t)) + .004*(9600*e^(-(1200*t)) - 2400*e^(-(300*t))))^2
sage: show(plot(a, 0, .002), xmin=0, xmax=.002)
```

It is easy to approximate with `find_root`:

```sage
sage: a.find_root(0,0.002)
0.0004110514049349...
```

Using `solve` takes more effort, and even then gives only a solution with free (integer) variables:

```sage
sage: a.solve(t)
[]
sage: b = a.canonicalize_radical(); b
(46080.0*e^(1800*t) - 576000.0*e^(900*t) + 737280.0)*e^(-2400*t)
sage: b.solve(t)
[]
sage: b.solve(t, to_poly_solve=True)
[t == 1/450*I*pi*z... + 1/900*log(-3/4*sqrt(41) + 25/4),
 t == 1/450*I*pi*z... + 1/900*log(3/4*sqrt(41) + 25/4)]
sage: n(1/900*log(-3/4*sqrt(41) + 25/4))
0.000411051404934985
```

We illustrate that root finding is only implemented in one dimension:

```sage
sage: x, y = var('x,y')
sage: (x-y).find_root(-2,2)
Traceback (most recent call last):
...
NotImplementedError: root finding currently only implemented in 1 dimension.
```

```
forget()
```

Forget the given constraint.

EXAMPLES:

```sage
sage: var('x,y')
(x, y)
sage: forget()
sage: assume(x>0, y < 2)
sage: assumptions()
[x > 0, y < 2]
```
Symbolic Calculus, Release 10.1

(continued from previous page)

```
sage: forget(y < 2)
sage: assumptions()
[x > 0]
```

### fraction(base_ring)

Return this expression as element of the algebraic fraction field over the base ring given.

**EXAMPLES:**

```
sage: fr = (1/x).fraction(ZZ); fr
1/x
sage: parent(fr)
Fraction Field of Univariate Polynomial Ring in x over Integer Ring
sage: parent(((pi+sqrt(2))/x).fraction(SR))
Fraction Field of Univariate Polynomial Ring in x over Symbolic Ring
sage: parent(((pi+sqrt(2))/x).fraction(SR))
Fraction Field of Univariate Polynomial Ring in x over Symbolic Ring
sage: y = var('y')
sage: fr = ((3*x^5 - 5*y^5)^7/(x*y)).fraction(GF(7)); fr
(3*x^35 + 2*y^35)/(x*y)
sage: parent(fr)
Fraction Field of Multivariate Polynomial Ring in x, y over Finite Field of size 7
```

### free_variables()

Return sorted tuple of unbound variables that occur in this expression.

**EXAMPLES:**

```
sage: (x,y,z) = var('x,y,z')
sage: (x+y).free_variables()
(x, y)
sage: (2*x).free_variables()
(x,)
sage: (x*y).free_variables()
(x, y)
sage: sin(x+y^z).free_variables()
(x, y, z)
sage: _ = function('f')
sage: e = limit( f(x,y), x=0 ); e
limit(f(x, y), x, 0)
sage: e.free_variables()
(y,)
```

### full_simplify()

Apply \texttt{simplify_factorial()}, \texttt{simplify_rectform()}, \texttt{simplify_trig()}, \texttt{simplify_rational()}, and then \texttt{expand_sum()} to self (in that order).

**ALIAS:** simplify_full and full_simplify are the same.

**EXAMPLES:**
sage: f = sin(x)^2 + cos(x)^2
sage: f.simplify_full()
1

sage: f = sin(x/(x^2 + x))
\text{sin}(1/(x + 1))

\textbf{function(*args)}

Return a callable symbolic expression with the given variables.

\textbf{EXAMPLES:}

We will use several symbolic variables in the examples below:

sage: var('n,k')
(n, k)
sage: f = binomial(n,k)*factorial(k)*factorial(n-k)
\text{factorial}(n)

\textbf{function(*args)}

Return a callable symbolic expression with the given variables.

\textbf{EXAMPLES:}

We will use several symbolic variables in the examples below:

sage: var('x, y, z, t, a, w, n')
(x, y, z, t, a, w, n)
sage: u = sin(x) + x*cos(y)
sage: g = u.function(x,y)
sage: g(x,y)
x*cos(y) + \sin(x)
sage: g(t,z)
t*cos(z) + \sin(t)
sage: g(x^2, x^y)
x^2*cos(x^y) + \sin(x^2)
sage: f = (x^2 + \sin(a*w)).function(a,x,w); f
\text{(a, x, w) \rightarrow x^2 + \sin(a*w)}
sage: f(1,2,3)
\sin(3) + 4

Using the \texttt{function()} method we can obtain the above function \(f\), but viewed as a function of different variables:

sage: h = f.function(w,a); h
\text{(w, a) \rightarrow x^2 + \sin(a*w)}

This notation also works:

sage: h(w,a) = f
sage: h
\text{(w, a) \rightarrow x^2 + \sin(a*w)}

You can even make a symbolic expression \(f\) into a function by writing \(f(x,y) = f\):
Symbolic Calculus, Release 10.1

\[\text{sage: } f = x^n + y^n; f\]
\[x^n + y^n\]
\[\text{sage: } f(x,y) = f\]
\[\text{sage: } f\]
\[(x, y) \rightarrow x^n + y^n\]
\[\text{sage: } f(2,3)\]
\[3^n + 2^n\]

\textbf{gamma\((\text{hold}=\text{False})\)}

Return the Gamma function evaluated at self.

\textbf{EXAMPLES:}

\[\text{sage: } x = \text{var('x')}\]
\[\text{sage: } x.\text{gamma()}\]
\[\text{gamma}(x)\]
\[\text{sage: } \text{SR}(2).\text{gamma()}\]
\[1\]
\[\text{sage: } \text{SR}(10).\text{gamma()}\]
\[362880\]
\[\text{sage: } \text{SR}(10.0r).\text{gamma()}\quad\text{\# For ARM: rel tol 2e-15}\]
\[362880.0\]
\[\text{sage: } \text{SR}((1,1)).\text{gamma()}\]
\[0.4980156681835607 - 0.15494982830181067*I\]
\[\text{sage: } \text{gp}('\text{gamma}(1+I)')\]
\[0.498015668183560427136911175 - 0.154949828301810651249551305*I\quad\text{\# 32-bit}\]
\[0.4980156681835604271369111746219809795 - 0.1549498283018106512495513048338660520*I\quad\text{\# 64-bit}\]

We plot the familiar plot of this log-convex function:

\[\text{sage: } \text{plot(gamma(x), -6,4).show(ymin=-3,ymax=3)}\]

To prevent automatic evaluation use the \texttt{hold} argument:

\[\text{sage: } \text{SR}(1/2).\text{gamma()}\]
\[\text{sqrt}(\pi)\]
\[\text{sage: } \text{SR}(1/2).\text{gamma(\text{hold}=\text{True})}\]
\[\text{gamma}(1/2)\]

This also works using functional notation:

\[\text{sage: } \text{gamma}(1/2,\text{hold}=\text{True})\]
\[\text{gamma}(1/2)\]
\[\text{sage: } \text{gamma}(1/2)\]
\[\text{sqrt}(\pi)\]

To then evaluate again, we use \texttt{unhold()}:
gamma_normalize()

Return the expression with any gamma functions that have a common base converted to that base. Additionally the expression is normalized so any fractions can be simplified through cancellation.

EXAMPLES:

```python
sage: m, n = var('m n', domain='integer')
sage: (gamma(n+2)/gamma(n)).gamma_normalize()
(n + 1)*n
sage: (gamma(n+2)*gamma(n)).gamma_normalize()
(n + 1)*n*gamma(n)^2
sage: (gamma(n+2)*gamma(m-1)/gamma(n)/gamma(m+1)).gamma_normalize()
(n + 1)*n/((m - 1)*m)
```

Check that github issue #22826 is fixed:

```python
sage: _ = var('n')
sage: (n-1).gcd(n+1)
1
sage: ex = (n-1)^2*gamma(2*n+5)/gamma(n+3) + gamma(2*n+3)/gamma(n+1)
sage: ex.gamma_normalize()
(4*n^3 - 2*n^2 - 7*n + 7)*gamma(2*n + 3)/((n + 1)*gamma(n + 1))
```

gcd(b)

Return the symbolic gcd of self and b.

Note that the polynomial GCD is unique up to the multiplication by an invertible constant. The following examples make sure all results are caught.

EXAMPLES:

```python
sage: var('x,y')
(x, y)
sage: SR(10).gcd(SR(15))
5
sage: (x^3 - 1).gcd(x-1) / (x-1) in QQ
True
sage: (x^3 - 1).gcd(x^2+x+1) / (x^2+x+1) in QQ
True
sage: (x^3 - x^2*pi + x^2 - pi^2).gcd(x-pi) / (x-pi) in QQ
True
sage: gcd(sin(x)^2 + sin(x), sin(x)^2 - 1) / (sin(x) + 1) in QQ
True
sage: gcd(x^3 - y^3, x-y) / (x-y) in QQ
True
sage: gcd(x^100-y^100, x^10-y^10) / (x^10-y^10) in QQ
True
sage: r = gcd(expand((x^2+17*x+3/7*y)*(x^5 - 17*y + 2/3)), expand((x^13+17*x+3/7*y)*(x^5 - 17*y + 2/3)))
sage: r / (x^5 - 17*y + 2/3) in QQ
True
```

Embedded Sage objects of all kinds get basic support. Note that full algebraic GCD is not implemented yet:
Symbolic Calculus, Release 10.1

```python
sage: gcd(I - I*x, x^2 - 1)
x - 1
sage: gcd(I + I*x, x^2 - 1)
x + 1
sage: alg = SR(QQbar(sqrt(2) + I*sqrt(3)))
sage: gcd(alg + alg*x, x^2 - 1)  # known bug (trac #28489)
x + 1
sage: gcd(alg - alg*x, x^2 - 1)  # known bug (trac #28489)
x - 1
sage: sqrt2 = SR(QQbar(sqrt(2)))
sage: gcd(sqrt2 + x, x^2 - 2)  # known bug
1
```

gosper_sum(*args)

Return the summation of this hypergeometric expression using Gosper’s algorithm.

INPUT:

- a symbolic expression that may contain rational functions, powers, factorials, gamma function terms, binomial coefficients, and Pochhammer symbols that are rational-linear in their arguments
- the main variable and, optionally, summation limits

EXAMPLES:

```python
sage: a,b,k,m,n = var('a b k m n')
sage: SR(1).gosper_sum(n)
n
sage: SR(1).gosper_sum(n,5,8)
4
sage: n.gosper_sum(n)
1/2*(n - 1)*n
sage: n.gosper_sum(n,0,5)
15
sage: n.gosper_sum(n,0,m)
1/2*(m + 1)*m
sage: n.gosper_sum(n,a,b)
-1/2*(a + b)*(a - b - 1)
```

```python
sage: (factorial(m + n)/factorial(n)).gosper_sum(n)
n*factorial(m + n)/(m + 1)*factorial(n))
sage: (binomial(m + n, n)).gosper_sum(n)
n*binomial(m + n, n)/(m + 1)
sage: (binomial(m + n, n)).gosper_sum(n, 0, a)
(a + m + 1)*binomial(a + m, a)/(m + 1)
sage: (binomial(m + n, n)).gosper_sum(n, 0, 5)
1/120*(m + 6)*(m + 5)*(m + 4)*(m + 3)*(m + 2)
sage: (rising_factorial(a,n)/rising_factorial(b,n)).gosper_sum(n)
(b + n - 1)*gamma(a + n)*gamma(b)/((a - b + 1)*gamma(a)*gamma(b + n))
sage: factorial(n).gosper_term(n)
Traceback (most recent call last):
...
ValueError: expression not Gosper-summable
```

gosper_term(n)
Return Gosper's hypergeometric term for \texttt{self}.

Suppose \( f = \texttt{self} \) is a hypergeometric term such that:

\[
s_n = \sum_{k=0}^{n-1} f_k
\]

and \( f_k \) doesn't depend on \( n \). Return a hypergeometric term \( g_n \) such that \( g_{n+1} - g_n = f_n \).

\textbf{EXAMPLES:}

```python
sage: _ = var('n')
sage: SR(1).gosper_term(n)
n
sage: n.gosper_term(n)
1/2*(n^2 - n)/n
sage: (n*factorial(n)).gosper_term(n)
1/n
sage: factorial(n).gosper_term(n)
Traceback (most recent call last):
  ... ValueError: expression not Gosper-summable
```

\textbf{gradient(\texttt{variables=\texttt{None}})}

Compute the gradient of a symbolic function.

This function returns a vector whose components are the derivatives of the original function with respect to the arguments of the original function. Alternatively, you can specify the variables as a list.

\textbf{EXAMPLES:}

```python
sage: x, y = var('x y')
sage: f = x^2+y^2
sage: f.gradient()
(2*x, 2*y)
sage: g(x,y) = x^2+y^2
sage: g.gradient()
(x, y) |--> (2*x, 2*y)
sage: n = var('n')
sage: f(x,y) = x^n+y^n
sage: f.gradient()
(x, y) |--> (n*x^(n - 1), n*y^(n - 1))
sage: f.gradient([y,x])
(x, y) |--> (n*y^(n - 1), n*x^(n - 1))
```

See also:

\textbf{gradient()} of scalar fields on Euclidean spaces (and more generally pseudo-Riemannian manifolds), in particular for computing the gradient in curvilinear coordinates.

\textbf{has(\texttt{pattern})}

\textbf{EXAMPLES:}

```python
sage: var('x,y,a'); w0 = SR.wild(); w1 = SR.wild()
(x, y, a)
```
Symbolic Calculus, Release 10.1

sage: (x*sin(x + y + 2*a)).has(y)
True

Here “x+y” is not a subexpression of “x+y+2*a” (which has the subexpressions “x”, “y” and “2*a”):

sage: (x*sin(x + y + 2*a)).has(x+y)
False
sage: (x*sin(x + y + 2*a)).has(x + y + w0)
True

The following fails because “2*(x+y)” automatically gets converted to “2*x+2*y” of which “x+y” is not a subexpression:

sage: (x*sin(2*(x+y) + 2*a)).has(x+y)
False

Although x^1==x and x^0==1, neither “x” nor “1” are actually of the form “x^something”:

sage: (x+1).has(x^w0)
False

Here is another possible pitfall, where the first expression matches because the term “-x” has the form “(-1)*x” in GiNaC. To check whether a polynomial contains a linear term you should use the coeff() function instead.

sage: (4*x^2 - x + 3).has(w0*x)
True
sage: (4*x^2 + x + 3).has(w0*x)
False
sage: (4*x^2 + x + 3).has(x)
True
sage: (4*x^2 - x + 3).coefficient(x,1)
-1
sage: (4*x^2 + x + 3).coefficient(x,1)
1

has_wild()

Return True if this expression contains a wildcard.

EXAMPLES:

sage: (1 + x^2).has_wild()
False
sage: (SR.wild(0) + x^2).has_wild()
True
sage: SR.wild(0).has_wild()
True

hessian()

Compute the hessian of a function. This returns a matrix components are the 2nd partial derivatives of the original function.

EXAMPLES:
Symbolic Calculus, Release 10.1

\[
\text{sage: } x, y = \text{var}('x y') \\
\text{sage: } f = x^2 + y^2 \\
\text{sage: } f.\text{hessian}() \\
\begin{bmatrix}
2 & 0 \\
0 & 2 \\
\end{bmatrix}
\]

\[
\text{sage: } g(x, y) = x^2 + y^2 \\
\text{sage: } g.\text{hessian}() \\
\begin{bmatrix}
(x, y) \mapsto 2 & (x, y) \mapsto 0 \\
(x, y) \mapsto 0 & (x, y) \mapsto 2 \\
\end{bmatrix}
\]

**horner** \(x\)

Rewrite this expression as a polynomial in Horner form in \(x\).

**EXAMPLES:**

\[
\text{sage: } \text{add}((i+1)^*x^i \text{ for } i \text{ in range}(5)).\text{horner}(x) \\
(((5^*x + 4)*x + 3)*x + 2)*x + 1
\]

\[
\text{sage: } x, y, z = \text{SR}.\text{var}('x,y,z') \\
\text{sage: } (x^5 + y*cos(x) + z^3 + (x + y)^2 + y^x).\text{horner}(x) \\
z^3 + ((x^3 + 1)*x + 2*y)*x + y^2 + y*cos(x) + y^x
\]

\[
\text{sage: } \text{expr} = \sin(5^*x).\text{expand}\_\text{trig}(); \text{expr} \\
5*cos(x)^4*sin(x) - 10*cos(x)^2*sin(x)^3 + sin(x)^5
\]

\[
\text{sage: } \text{expr}.\text{horner}(\sin(x)) \\
(5*cos(x)^4 - (10*cos(x)^2 - sin(x)^2)*sin(x)^3)*sin(x)
\]

\[
\text{sage: } \text{expr}.\text{horner}(\cos(x)) \\
sin(x)^5 + 5*(cos(x)^2*sin(x) - 2*sin(x)^3)*cos(x)^2
\]

**hypergeometric_simplify** \((\text{algorithm}=\text{'maxima'})\)

Simplify an expression containing hypergeometric or confluent hypergeometric functions.

**INPUT:**

- **algorithm** – (default: 'maxima') the algorithm to use for for simplification. Implemented are 'maxima', which uses Maxima's hgfred function, and 'sage', which uses an algorithm implemented in the hypergeometric module

**ALIAS:** hypergeometric_simplify() and simplify_hypergeometric() are the same

**EXAMPLES:**

\[
\text{sage: } \text{hypergeometric}((5, 4), (4, 1, 2, 3), x).\text{simplify}\_\text{hypergeometric}() \\
1/144*x^2*\text{hypergeometric}([], (3, 4), x) +... \\
1/3*x^3*\text{hypergeometric}([], (2, 3), x) + \text{hypergeometric}([], (1, 2), x)
\]

\[
\text{sage: } (2^*\text{hypergeometric}([], [], x)).\text{simplify}\_\text{hypergeometric}() \\
2*e^x
\]

\[
\text{sage: } (\text{nest}(\text{lambda } y: \text{hypergeometric}([y], [1], x), 3, 1)) \# \text{ not tested, unstable} \\
\text{...: } \text{simplify}\_\text{hypergeometric}()
\]

laguerre(-laguerre(-e^x, x), x)

\[
\text{sage: } (\text{nest}(\text{lambda } y: \text{hypergeometric}([y], [1], x), 3, 1)) \# \text{ not tested, unstable} \\
\text{...: } \text{simplify}\_\text{hypergeometric}(\text{algorithm}=\text{'sage'})
\]

\[
\text{hypergeometric}((e^x,), (1,), (1,)), (1,), x)
\]

\[
\text{sage: } \text{hypergeometric}\_\text{M}(1, 3, x).\text{simplify}\_\text{hypergeometric}()
\]

(continues on next page)
Symbolic Calculus, Release 10.1

-2*((x + 1)*e^(-x) - 1)*e^x/x^2
sage: (2 * hypergeometric_U(1, 3, x)).simplify_hypergeometric()  
2*(x + 1)/x^2

imag(hold=False)
Return the imaginary part of this symbolic expression.

EXAMPLES:

sage: sqrt(-2).imag_part()  
sqrt(2)

We simplify $\ln(e^z)$ to $z$. This should only be for $-\pi < \text{Im}(z) \leq \pi$, but Maxima does not have a symbolic imaginary part function, so we cannot use assume to assume that first:

sage: z = var('z')  
sage: f = log(exp(z))  
sage: f  
log(e^z)  
sage: f.simplify()  
z  
sage: forget()

A more symbolic example:

sage: var('a, b')  
(a, b)  
sage: f = log(a + b*I)  
sage: f.imag_part()  
arctan2(imag_part(a) + real_part(b), -imag_part(b) + real_part(a))

Using the hold parameter it is possible to prevent automatic evaluation:

sage: SR(I).imag_part()  
1  
sage: SR(I).imag_part(hold=True)  
imag_part(I)

This also works using functional notation:

sage: imag_part(I, hold=True)  
imag_part(I)  
sage: imag_part(SR(I))  
1

To then evaluate again, we use unhold():

sage: a = SR(I).imag_part(hold=True); a.unhold()  
1

imag_part(hold=False)
Return the imaginary part of this symbolic expression.

EXAMPLES:
We simplify $\ln(\exp(z))$ to $z$. This should only be for $-\pi < \Im(z) \leq \pi$, but Maxima does not have a symbolic imaginary part function, so we cannot use `assume` to assume that first:

```python
sage: z = var('z')
sage: f = log(exp(z))
sage: f
log(e^z)
sage: f.simplify()
z
sage: forget()
```

A more symbolic example:

```python
sage: var('a, b')
(a, b)
sage: f = log(a + b*I)
sage: f.imag_part()
arctan2(imag_part(a) + real_part(b), -imag_part(b) + real_part(a))
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```python
sage: SR(I).imag_part()
1
sage: SR(I).imag_part(hold=True)
imag_part(I)
```

This also works using functional notation:

```python
sage: imag_part(I, hold=True)
imag_part(I)
sage: imag_part(SR(I))
1
```

To then evaluate again, we use `unhold()`:

```python
sage: a = SR(I).imag_part(hold=True); a.unhold()
1
```

**implicit_derivative($Y, X, n=1$)**

Return the $n$'th derivative of $Y$ with respect to $X$ given implicitly by this expression.

**INPUT:**

- $Y$ - The dependent variable of the implicit expression.
- $X$ - The independent variable with respect to which the derivative is taken.
- $n$ - (default : 1) the order of the derivative.

**EXAMPLES:**

```python
sage: var('x, y')
(x, y)
```
Symbolic Calculus, Release 10.1

(continued from previous page)

\begin{verbatim}
sage: f = cos(x)*sin(y)
sage: f.implicit_derivative(y, x)
sin(x)*sin(y)/(cos(x)*cos(y))
sage: g = x^2*y^2
sage: g.implicit_derivative(y, x, 3)
-1/4*(y + 2*y/x)/x^2 + 1/4*(2*y^2/x - y^2/x^2)/(x*y) - 3/4*y/x^3
\end{verbatim}

It is an error to not include an independent variable term in the expression:

\begin{verbatim}
sage: (cos(x)*sin(x)).implicit_derivative(y, x)
Traceback (most recent call last):
...
ValueError: Expression cos(x)*sin(x) contains no y terms
\end{verbatim}

\texttt{integral(*args, **kwds)}

Compute the integral of self. Please see \texttt{sage.symbolic.integration.integral.integrate()} for more details.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: sin(x).integral(x,0,3)
-cos(3) + 1
sage: sin(x).integral(x)
-cos(x)
\end{verbatim}

\texttt{integrate(*args, **kwds)}

Compute the integral of self. Please see \texttt{sage.symbolic.integration.integral.integrate()} for more details.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: sin(x).integral(x,0,3)
-cos(3) + 1
sage: sin(x).integral(x)
-cos(x)
\end{verbatim}

\texttt{inverse_laplace(t, s)}

Return inverse Laplace transform of self. See \texttt{sage.calculus.calculus.inverse_laplace}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var('w, m')
(w, m)
sage: f = (1/(w^2+10)).inverse_laplace(w, m); f
1/10*sqrt(10)*sin(sqrt(10)*m)
\end{verbatim}

\texttt{is_algebraic()}\n
Return True if this expression is known to be algebraic.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: sqrt(2).is_algebraic()
True
sage: (5*sqrt(2)).is_algebraic()
\end{verbatim}

(continues on next page)
True
sage: (sqrt(2) + 2^(1/3) - 1).is_algebraic()
True
sage: (I*golden_ratio + sqrt(2)).is_algebraic()
True
sage: (sqrt(2) + pi).is_algebraic()
False
sage: SR(QQ(2/3)).is_algebraic()
True
sage: SR(1.2).is_algebraic()
False
sage: complex_root_of(x^3 - x^2 - x - 1, 0).is_algebraic()
True

is_callable()
Return True if self is a callable symbolic expression.

EXAMPLES:

sage: var('a x y z')
(a, x, y, z)
sage: f(x, y) = a + 2*x + 3*y + z
sage: f.is_callable()
True
sage: (a+2*x).is_callable()
False

is_constant()
Return whether this symbolic expression is a constant.
A symbolic expression is constant if it does not contain any variables.

EXAMPLES:

sage: pi.is_constant()
True
sage: SR(1).is_constant()
True
sage: SR(2).is_constant()
True
sage: log(2).is_constant()
True
sage: SR(I).is_constant()
True
sage: x.is_constant()
False

is_exact()
Return True if this expression only contains exact numerical coefficients.

EXAMPLES:
\begin{example}
\begin{verbatim}
sage: x, y = var('x, y')
sage: (x+y-1).is_exact()
True
sage: (x+y-1.9).is_exact()
False
sage: x.is_exact()
True
sage: pi.is_exact()
True
sage: (sqrt(x-y) - 2^x + 1).is_exact()
True
sage: ((x-y)^0.5 - 2^x + 1).is_exact()
False
\end{verbatim}
\end{example}

**is_infinity()**

Return True if self is an infinite expression.

**is_integer()**

Return True if this expression is known to be an integer.

**is_negative()**

Return True if this expression is known to be negative.

Assumptions on symbols are handled correctly:

\begin{example}
\begin{verbatim}
sage: y = var('y')
sage: assume(y < 0)
\end{verbatim}
\end{example}
sage: y.is_positive()
False
sage: y.is_negative()
True
sage: forget()

is_negative_infinity()

Return True if self is a negative infinite expression.

EXAMPLES:

sage: SR(oo).is_negative_infinity()
False
sage: SR(-oo).is_negative_infinity()
True
sage: x.is_negative_infinity()
False

is_numeric()

A Pynac numeric is an object you can do arithmetic with that is not a symbolic variable, function, or constant. Return True if this expression only consists of a numeric object.

EXAMPLES:

sage: SR(1).is_numeric()
True
sage: x.is_numeric()
False
sage: pi.is_numeric()
False
sage: sin(x).is_numeric()
False

is_polynomial(var)

Return True if self is a polynomial in the given variable.

EXAMPLES:

sage: var('x,y,z')
(x, y, z)
sage: t = x^2 + y; t
x^2 + y
sage: t.is_polynomial(x)
True
sage: t.is_polynomial(y)
True
sage: t.is_polynomial(z)
True
sage: t = sin(x) + y; t
y + sin(x)
sage: t.is_polynomial(x)
False
\begin{verbatim}
sage: t.is_polynomial(y)
True
sage: t.is_polynomial(sin(x))
True

is_positive()

Return True if this expression is known to be positive.

EXAMPLES:

sage: t0 = SR.symbol("t0", domain='positive')
sage: t0.is_positive()
True
sage: t0.is_negative()
False
sage: t0.is_real()
True
sage: t1 = SR.symbol("t1", domain='positive')
sage: (t0*t1).is_positive()
True
sage: (t0 + t1).is_positive()
True
sage: (t0*x).is_positive()
False
sage: forget()
sage: assume(x>0)
sage: x.is_positive()
True
sage: cosh(x).is_positive()
True
sage: f = function('f')(x)
sage: assume(f>0)
sage: f.is_positive()
True
sage: forget()

is_positive_infinity()

Return True if self is a positive infinite expression.

EXAMPLES:

sage: SR(oo).is_positive_infinity()
True
sage: SR(-oo).is_positive_infinity()
False
sage: x.is_infinity()
False

is_rational_expression()

Return True if this expression if a rational expression, i.e., a quotient of polynomials.

EXAMPLES:
\begin{lstlisting}[language=Python]
sage: var('x y z')
(x, y, z)
sage: ((x + y + z)/(1 + x^2)).is_rational_expression()
True
sage: ((1 + x + y)^10).is_rational_expression()
True
sage: ((1/x + z)^5 - 1).is_rational_expression()
True
sage: (1/(x + y)).is_rational_expression()
True
sage: (exp(x) + 1).is_rational_expression()
False
sage: (sin(x*y) + z^3).is_rational_expression()
False
sage: (exp(x) + exp(-x)).is_rational_expression()
False

is_real()

Return True if this expression is known to be a real number.

EXAMPLES:

\begin{lstlisting}[language=Python]
sage: t0 = SR.symbol("t0", domain='real')
sage: t0.is_real()
True
sage: t0.is_positive()
False
sage: t1 = SR.symbol("t1", domain='positive')
sage: (t0+t1).is_real()
True
sage: (t0+x).is_real()
False
sage: (t0*t1).is_real()
True
sage: t2 = SR.symbol("t2", domain='positive')
sage: (t1**t2).is_real()
True
sage: (t0^x).is_real()
False
sage: (t0^t1).is_real()
False
sage: (t1^t2).is_real()
False
sage: gamma(pi).is_real()
True
sage: cosh(-3).is_real()
True
sage: cos(exp(-3) + log(2)).is_real()
True
sage: gamma(t1).is_real()
True
sage: (x*pi).is_real()
False
\end{lstlisting}

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```
sage: (cos(exp(t0) + log(t1))^8).is_real()
True
sage: cos(I + 1).is_real()
False
sage: sin(2 - I).is_real()
False
sage: (2^t0).is_real()
True
```

The following is real, but we cannot deduce that:

```
sage: (x*x.conjugate()).is_real()
False
```

Assumption of real has the same effect as setting the domain:

```
sage: forget()
sage: assume(x, 'real')
sage: x.is_real()
True
sage: cosh(x).is_real()
True
sage: forget()
```

The real domain is also set with the integer domain:

```
sage: SR.var('x', domain='integer').is_real()
True
```

**is_relational()**

Return True if self is a relational expression.

**EXAMPLES:**

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.is_relational()
True
sage: sin(x).is_relational()
False
```

**is_square()**

Return True if self is the square of another symbolic expression.

This is True for all constant, non-relational expressions (containing no variables or comparison), and not implemented otherwise.

**EXAMPLES:**

```
sage: SR(4).is_square()
True
sage: SR(5).is_square()
True
sage: pi.is_square()
```

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

True
sage: x.is_square()
Traceback (most recent call last):
...
NotImplementedError: is_square() not implemented for non-constant or relational elements of Symbolic Ring

sage: r = SR(4) == SR(5)
sage: r.is_square()
Traceback (most recent call last):
...
NotImplementedError: is_square() not implemented for non-constant or relational elements of Symbolic Ring

is_symbol()
Return True if this symbolic expression consists of only a symbol, i.e., a symbolic variable.

EXAMPLES:

sage: x.is_symbol()
True
sage: var('y')
y
sage: y.is_symbol()
True
sage: (x*y).is_symbol()
False
sage: pi.is_symbol()
False
sage: ((x*y)/y).is_symbol()
True
sage: (x^y).is_symbol()
False

is_terminating_series()
Return True if self is a series without order term.

A series is terminating if it can be represented exactly, without requiring an order term. You can explicitly request terminating series by setting the order to positive infinity.

OUTPUT:
Boolean. Whether self was constructed by series() and has no order term.

EXAMPLES:

sage: (x^5+x^2+1).series(x, +oo)
1 + 1*x^2 + 1*x^5
sage: (x^5+x^2+1).series(x,+oo).is_terminating_series()
True
sage: SR(5).is_terminating_series()
False
sage: var('x')
x

(continues on next page)
is_trivial_zero()

Check if this expression is trivially equal to zero without any simplification.

This method is intended to be used in library code where trying to obtain a mathematically correct result by applying potentially expensive rewrite rules is not desirable.

EXAMPLES:

```python
sage: SR(0).is_trivial_zero()
True
sage: SR(0.0).is_trivial_zero()
True
sage: SR(float(0.0)).is_trivial_zero()
True
sage: (SR(1)/2^1000).is_trivial_zero()
False
sage: SR(1./2^10000).is_trivial_zero()
False
```

The is_zero() method is more capable:

```python
sage: t = pi + (pi - 1)*pi - pi^2
sage: t.is_trivial_zero()
False
sage: t.is_zero()
True
sage: t = pi + x*pi + (pi - 1 - x)*pi - pi^2
sage: t.is_trivial_zero()
True
sage: t.is_zero()
True
sage: u = sin(x)^2 + cos(x)^2 - 1
sage: u.is_trivial_zero()
False
sage: u.is_zero()
True
```

is_trivially_equal(other)

Check if this expression is trivially equal to the argument expression, without any simplification.

Note that the expressions may still be subject to immediate evaluation.

This method is intended to be used in library code where trying to obtain a mathematically correct result by applying potentially expensive rewrite rules is not desirable.

EXAMPLES:

```python
sage: (x^2).is_trivially_equal(x^2)
True
sage: ((x+1)^2 - 2*x - 1).is_trivially_equal(x^2)
False
```
Symbolic Calculus, Release 10.1

sage: (x*(x+1)).is_trivially_equal((x+1)*x)
True
sage: (x^2 + x).is_trivially_equal((x+1)*x)
False
sage: ((x+1)^2).is_trivially_equal((x+1)^2)
True
sage: (x^2 + 2*x + 1).is_trivially_equal((x+1)^2)
False
sage: (x^-1).is_trivially_equal(1/x)
True
sage: (x/x^2).is_trivially_equal(1/x)
True
sage: ((x^2+x) / (x+1)).is_trivially_equal(1/x)
False

is_unit()
Return True if this expression is a unit of the symbolic ring.

Note that a proof may be attempted to get the result. To avoid this use (ex-1).is_trivial_zero().

EXAMPLES:

sage: SR(1).is_unit()
True
sage: SR(-1).is_unit()
True
sage: SR(0).is_unit()
False

iterator()
Return an iterator over the operands of this expression.

EXAMPLES:

sage: x,y,z = var('x,y,z')
sage: list((x+y+z).iterator())
[x, y, z]
sage: list((x^y*z*(x+y)).iterator())
[x + y, x^y, z]

Note that symbols, constants and numeric objects do not have operands, so the iterator function raises an error in these cases:

sage: x.iterator()
Traceback (most recent call last):
... ValueError: expressions containing only a numeric coefficient, constant or symbol have no operands
sage: pi.iterator()
Traceback (most recent call last):
... ValueError: expressions containing only a numeric coefficient, constant or symbol have no operands

symbol have no operands
sage: SR(5).iterator()
Traceback (most recent call last):
...
ValueError: expressions containing only a numeric coefficient, constant or
symbol have no operands

laplace(t, s)
Return Laplace transform of self. See sage.calculus.calculus.laplace

EXAMPLES:

sage: var('x,s,z')
(x, s, z)
sage: (z + exp(x)).laplace(x, s)
z/s + 1/(s - 1)

laurent_polynomial(base_ring=None, ring=None)
Return this symbolic expression as a Laurent polynomial over the given base ring, if possible.

INPUT:
• base_ring - (optional) the base ring for the polynomial
• ring - (optional) the parent for the polynomial

You can specify either the base ring (base_ring) you want the output Laurent polynomial to be over, or you can specify the full laurent polynomial ring (ring) you want the output laurent polynomial to be an element of.

EXAMPLES:

sage: f = x^2 -2/3/x + 1
sage: f.laurent_polynomial(QQ)
-2/3*x^-1 + 1 + x^2
sage: f.laurent_polynomial(GF(19))
12*x^-1 + 1 + x^2

lcm(b)
Return the lcm of self and b.

The lcm is computed from the gcd of self and b implicitly from the relation self * b = gcd(self, b) * lcm(self, b).

Note: In agreement with the convention in use for integers, if self * b == 0, then gcd(self, b) == max(self, b) and lcm(self, b) == 0.

Note: Since the polynomial lcm is computed from the gcd, and the polynomial gcd is unique up to a constant factor (which can be negative), the polynomial lcm is unique up to a factor of -1.

EXAMPLES:
Symbolic Calculus, Release 10.1

sage: var('x,y')
(x, y)
sage: SR(10).lcm(SR(15))
30
sage: (x^3 - 1).lcm(x-1)
x^3 - 1
sage: (x^3 - 1).lcm(x^2+x+1)
x^3 - 1
sage: (x^3 - sage.symbolic.constants.pi).lcm(x-sage.symbolic.constants.pi)
(pi - x^3)*(pi - x)
sage: lcm(x^3 - y^3, x-y) / (x^3 - y^3) in [1,-1]
True
sage: lcm(x^100-y^100, x^10-y^10) / (x^100 - y^100) in [1,-1]
True
sage: a = expand((x^2+17*x+3/7*y)*(x^5 - 17*y + 2/3))
sage: b = expand((x^13+17*x+3/7*y)*(x^5 - 17*y + 2/3))
sage: gcd(a,b) * lcm(a,b) / (a * b) in [1,-1]
True

The result is not automatically simplified:
sage: ex = lcm(sin(x)^2 - 1, sin(x)^2 + sin(x)); ex
(x^3*sin(x*y) + 2*sin(x*y)/x + 100)
sage: ex.simplify_full()
sin(x)^3 - sin(x)

leading_coeff(s)
Return the leading coefficient of s in self.
EXAMPLES:
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.leading_coefficient(x)
sin(x*y)
sage: f.leading_coefficient(y)
x
sage: f.leading_coefficient(sin(x*y))
x^3 + 2/x

leading_coefficient(s)
Return the leading coefficient of s in self.
EXAMPLES:
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.leading_coefficient(x)
sin(x*y)
sage: f.leading_coefficient(y)
x

sage: f.leading_coefficient(sin(x*y))
x^3 + 2/x

left()

If self is a relational expression, return the left hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2

left_hand_side()

If self is a relational expression, return the left hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2

lhs()

If self is a relational expression, return the left hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2

limit(*args, **kwds)

Return a symbolic limit. See sage.calculus.calculus.limit

EXAMPLES:

sage: (sin(x)/x).limit(x=0)
1
**list**($x$=None)

Return the coefficients of this symbolic expression as a polynomial in $x$.

**INPUT:**

- $x$ – optional variable.

**OUTPUT:**

A list of expressions where the $n$-th element is the coefficient of $x^n$ when self is seen as polynomial in $x$.

**EXAMPLES:**

```sage
sage: var('x, y, a')
(x, y, a)
sage: (x^5).list()
[0, 0, 0, 0, 1]
sage: p = x - x^3 + 5/7*x^5
sage: p.list()
[0, 1, 0, -1, 5/7]
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*sqrt(2)*x + 2*a^2 + x^2 + x + 1
sage: p.list(a)
[x^2 + x + 1, -2*sqrt(2)*x, 2]
sage: s = (1/(1-x)).series(x,6); s
1 + 1*x + 1*x^2 + 1*x^3 + 1*x^4 + 1*x^5 + Order(x^6)
sage: s.list()
[1, 1, 1, 1, 1, 1]
```

**log**($b$=None, $hold=False$)

Return the logarithm of self.

**EXAMPLES:**

```sage
sage: x, y = var('x, y')
sage: x.log()
log(x)
sage: (x^y + y^x).log()
log(x^y + y^x)
sage: SR(0).log()
-Infinity
sage: SR(-1).log()
I*pi
sage: SR(1).log()
0
sage: SR(1/2).log()
log(1/2)
sage: SR(0.5).log()
-0.693147180559945
sage: SR(0.5).log().exp()
0.5
sage: math.log(0.5)
-0.693147180559945
sage: plot(lambda x: SR(x).log(), 0.1,10)
Graphics object consisting of 1 graphics primitive
```

To prevent automatic evaluation use the $hold$ argument:
\texttt{sage}: \texttt{I.log()}
\[1/2*\texttt{I*pi}\]
\texttt{sage}: \texttt{I.log(hold=True)}
\[\log(1)\]

To then evaluate again, we use \texttt{unhold()}: 
\texttt{sage}: \texttt{a = I.log(hold=True); a.unhold()}
\[1/2*\texttt{I*pi}\]

The hold parameter also works in functional notation:
\texttt{sage}: \texttt{log(-1,hold=True)}
\[\log(-1)\]
\texttt{sage}: \texttt{\log(-1)}
\[\texttt{I*pi}\]

\texttt{log\_expand(algorithm='products')}

Simplify symbolic expression, which can contain logs.

Expands logarithms of powers, logarithms of products and logarithms of quotients. The option \texttt{algorithm} specifies which expression types should be expanded.

**INPUT:**

- \texttt{self} - expression to be simplified
- \texttt{algorithm} - (default: ‘products’) optional, governs which expression is expanded. Possible values are
  - ‘nothing’ (no expansion),
  - ‘powers’ (log(a^r) is expanded),
  - ‘products’ (like ‘powers’ and also log(a*b) are expanded),
  - ‘all’ (all possible expansion).

See also examples below.

**DETAILS:** This uses the Maxima simplifier and sets \texttt{logexpand} option for this simplifier. From the Maxima documentation: ‘Logexpand: true causes \texttt{log(a^b)} to become \texttt{b*log(a)}. If it is set to all, \texttt{log(a*b)} will also simplify to \texttt{log(a)+log(b)}. If it is set to super, then \texttt{log(a/b)} will also simplify to \texttt{log(a)-log(b)} for rational numbers \texttt{a/b}, \texttt{a\neq 1}. (\texttt{log(1/b)}, for integer \texttt{b}, always simplifies.) If it is set to false, all of these simplifications will be turned off.

**ALIAS:** \texttt{log\_expand()} and \texttt{expand\_log()} are the same

**EXAMPLES:**

By default powers and products (and quotients) are expanded, but not quotients of integers:

\texttt{sage}: \texttt{(log(3/4*x*pi)).log\_expand()}
\[\pi*x*log(3/4)\]

To expand also log(3/4) use \texttt{algorithm='all'}:

\texttt{sage}: \texttt{(log(3/4*x\pi)).log\_expand('all')}
\[\pi*x*log(3) - 2*log(2)\]
To expand only the power use \texttt{algorithm='powers'}:

\begin{verbatim}
sage: (log(x^6)).log_expand('powers')
6*log(x)
\end{verbatim}

The expression \( \log((3x)^6) \) is not expanded with \texttt{algorithm='powers'}, since it is converted into product first:

\begin{verbatim}
sage: (log((3x)^6)).log_expand('powers')
\log(729x^6)
\end{verbatim}

This shows that the option \texttt{algorithm} from the previous call has no influence to future calls (we changed some default Maxima flag, and have to ensure that this flag has been restored):

\begin{verbatim}
sage: (log(3/4x^pi)).log_expand()
pi*log(x) + log(3/4)
sage: (log(3/4x^pi)).log_expand('all')
pi*log(x) + log(3) - 2*log(2)
sage: (log(3/4x^pi)).log_expand()
pi*log(x) + log(3/4)
\end{verbatim}

AUTHORS:

- Robert Marik (11-2009)

\texttt{log_gamma}(\texttt{hold=False})

Return the log gamma function evaluated at self. This is the logarithm of gamma of self, where gamma is a complex function such that \( \gamma(n) \) equals \texttt{factorial(n - 1)}.

EXAMPLES:

\begin{verbatim}
sage: x = var('x')
sage: x.log_gamma()
log_gamma(x)
sage: SR(5).log_gamma()
log(24)
sage: a = SR(5).log_gamma(); a.n()
3.17805383034795
sage: SR(5-1).factorial().log()
log(24)
sage: from sage.misc.verbose import set_verbose
sage: set_verbose(-1); plot(lambda x: SR(x).log_gamma(), -7,8, plot_points=1000).show()
sage: math.exp(0.5)
1.6487212707001282
sage: plot(lambda x: (SR(x).exp() - SR(-x).exp())/2 - SR(x).sinh(), -1, 1)
Graphics object consisting of 1 graphics primitive
\end{verbatim}

To prevent automatic evaluation use the \texttt{hold} argument:

\begin{verbatim}
sage: SR(5).log_gamma(hold=True)
log_gamma(5)
\end{verbatim}
To evaluate again, currently we must use numerical evaluation via \texttt{n()}:

```
sage: a = SR(5).log_gamma(hold=True); a.n()
3.17805383034795
```

\textbf{log\_simplify(\texttt{algorithm=None})}

Simplify a (real) symbolic expression that contains logarithms.

The given expression is scanned recursively, transforming subexpressions of the form $a \log(b) + c \log(d)$ into $\log(b^a d^c)$ before simplifying within the $\log()$.

The user can specify conditions that $a$ and $c$ must satisfy before this transformation will be performed using the optional parameter \texttt{algorithm}.

\textbf{Warning:} This is only safe to call if every variable in the given expression is assumed to be real. The simplification it performs is in general not valid over the complex numbers. For example:

```
sage: x,y = SR.var('x,y')
sage: f = log(x*y) - (log(x) + log(y))
sage: f(x=-1, y=i)
-2*I*pi
sage: f.simplify_log()
0
```

\textbf{INPUT:}

- \texttt{self} - expression to be simplified
- \texttt{algorithm} - (default: None) optional, governs the condition on $a$ and $c$ which must be satisfied to contract expression $a \log(b) + c \log(d)$. Values are
  - \texttt{None} (use Maxima default, integers),
  - \texttt{'one'} (1 and -1),
  - \texttt{'ratios'} (rational numbers),
  - \texttt{'constants'} (constants),
  - \texttt{'all'} (all expressions).

\textbf{ALGORITHM:}
This uses the Maxima \texttt{logcontract()} command.

\textbf{ALIAS:}
\texttt{log\_simplify()} and \texttt{simplify\_log()} are the same.

\textbf{EXAMPLES:}

```
sage: x,y,t = var('x y t')
```

Only two first terms are contracted in the following example; the logarithm with coefficient $\frac{1}{2}$ is not contracted:

```
sage: f = log(x)+2*log(y)+1/2*log(t)
sage: f.simplify_log()
log(x*y^2) + 1/2*log(t)
```
To contract all terms in the previous example, we use the 'ratios' algorithm:

```sage
f.simplify_log(algorithm='ratios')
log(sqrt(t)*x*y^2)
```

To contract terms with no coefficient (more precisely, with coefficients 1 and −1), we use the 'one' algorithm:

```sage
f = log(x)+2*log(y)-log(t)
sage: f.simplify_log('one')
2*log(y) + log(x/t)
```

```sage
f = log(x)+log(y)-1/3*log((x+1))
sage: f.simplify_log()
log(x*y) - 1/3*log(x + 1)
sage: f.simplify_log('ratios')
log(x*y/(x + 1)^(1/3))
```

\(\pi\) is an irrational number; to contract logarithms in the following example we have to set algorithm to 'constants' or 'all':

```sage
f = log(x)+log(y)-pi*log((x+1))
sage: f.simplify_log('constants')
log(x*y/(x + 1)^pi)
```

\(x\log(9)\) is contracted only if algorithm is 'all':

```sage
(x*log(9)).simplify_log()
2*x*log(3)
sage: (x*log(9)).simplify_log('all')
log(3^(2*x))
```

AUTHORS:

• Robert Marik (11-2009)

**low_degree(s)**

Return the exponent of the lowest power of s in self.

OUTPUT:

An integer

EXAMPLES:

```sage
var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y^10 + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + 2*sin(x*y)/x + x/y^10 + 100
sage: f.low_degree(x)
-1
sage: f.low_degree(y)
-10
sage: f.low_degree(sin(x*y))
0
```
sage: (x^3+y).low_degree(x)
0
sage: (x+x**2).low_degree(x)
1

\textbf{match}(\textit{pattern})

Check if self matches the given pattern.

\textbf{INPUT:}

- \textit{pattern} – a symbolic expression, possibly containing wildcards to match for

\textbf{OUTPUT:}

One of

None if there is no match, or a dictionary mapping the wildcards to the matching values if a match was found. Note that the dictionary is empty if there were no wildcards in the given pattern.

See also http://www.ginac.de/tutorial/Pattern-matching-and-advanced-substitutions.html

\textbf{EXAMPLES:}

sage: var('x,y,z,a,b,c,d,f,g')
(x, y, z, a, b, c, d, f, g)
sage: w0 = SR.wild(0); w1 = SR.wild(1); w2 = SR.wild(2)
sage: ((x+y)^a).match((x+y)^a)  # no wildcards, so empty dict
{}
sage: print(((x+y)^a).match((x+y)^b))
None
sage: t = ((x+y)^a).match(w0^w1)
sage: t[w0], t[w1]
(x + y, a)
sage: print(((x+y)^a).match(w0^w0))
None
sage: ((x+y)^x+y).match(w0^w0)
(a: x + y)
sage: t = ((a+b)*(a+c)).match((a+w0)*(a+w1))
sage: set([t[w0], t[w1]]) == set([b, c])
True
sage: ((a+b)*(a+c)).match((w0+b)*(w0+c))
(a: a)
sage: t = ((a+b)*(a+c)).match((w0+w1)*(w0+w2))
sage: t[w0]
a
sage: set([t[w1], t[w2]]) == set([b, c])
True
sage: t = ((a+b)*(a+c)).match((w0+w1)*(w1+w2))
sage: t[w1]
a
sage: set([t[w0], t[w2]]) == set([b, c])
True
sage: t = (a^((x+y)+a*z+b)).match(a^w0+w1)
sage: s = set([t[w0], t[w1]])
sage: s == set([x+y, a*z+b]) or s == set([z, a^((x+y)+b)])

(continues on next page)
Symbolic Calculus, Release 10.1

True
sage: print((a+b+c+d+f+g).match(c))
None
sage: (a+b+c+d+f+g).has(c)
True
sage: (a+b+c+d+f+g).match(c+w0)
{$0: a + b + d + f + g}$
sage: (a+b+c+d+f+g).match(c+g+w0)
{$0: a + b + d + f}$
sage: (a+b).match(a+b+w0) # known bug
{$0: 0}$
sage: print(((a*b^2).match(a^w0*b^w1))
None
sage: (a*b^2).match(a*b^w1)
{$1: 2}$
sage: (x*x.arctan2(x^2)).match(w0*w0.arctan2(w0^2))
{$0: x}$

Beware that behind-the-scenes simplification can lead to surprising results in matching:

sage: print((x+x).match(w0+w1))
None
sage: t = x+x; t
2*x
sage: t.operator()
<function mul_vararg ...>

Since asking to match w0+w1 looks for an addition operator, there is no match.

maxima_methods()
Provide easy access to maxima methods, converting the result to a Sage expression automatically.

EXAMPLES:

sage: t = log(sqrt(2) - 1) + log(sqrt(2) + 1); t
log(sqrt(2) + 1) + log(sqrt(2) - 1)
sage: res = t.maxima_methods().logcontract(); res
log((sqrt(2) + 1)*(sqrt(2) - 1))
sage: type(res)
<class 'sage.symbolic.expression.Expression'>

minpoly(*args, **kwds)
Return the minimal polynomial of this symbolic expression.

EXAMPLES:

sage: golden_ratio.minpoly()
x^2 - x - 1

mul(hold=False, *args)
Return the product of the current expression and the given arguments.

To prevent automatic evaluation use the hold argument.

EXAMPLES:
To then evaluate again, we use \texttt{unhold()}:

```
sage: a = x.mul(x, hold=True); a.unhold()
x^2
```

\textbf{multiply\_both\_sides}(x, checksign=None)

Return a relation obtained by multiplying both sides of this relation by \( x \).

\textbf{Note:} The \texttt{checksign} keyword argument is currently ignored and is included for backward compatibility reasons only.

\textbf{EXAMPLES:}

```
sage: var('x,y'); f = x + 3 < y - 2
(x, y)
sage: f.multiply_both_sides(7)
7*x + 21 < 7*y - 14
sage: f.multiply_both_sides(-1/2)
-1/2*x - 3/2 < -1/2*y + 1
sage: f*(-2/3)
-2/3*x < -2/3*y + 4/3
sage: f*(-pi)
-pi*(x + 3) < -pi*(y - 2)
```

Since the direction of the inequality never changes when doing arithmetic with equations, you can multiply or divide the equation by a quantity with unknown sign:

```
sage: f*(1+I)
(I + 1)*x + 3*I + 3 < (I + 1)*y - 2*I - 2
sage: f = sqrt(2) + x == y^3
sage: f.multiply_both_sides(I)
I*x + I*sqrt(2) == I*y^3
sage: f.multiply_both_sides(-1)
-x - sqrt(2) == -y^3
```

Note that the direction of the following inequalities is not reversed:

```
sage: (x^3 + 1 > 2*sqrt(3)) * (-1)
-x^3 - 1 > -2*sqrt(3)
sage: (x^3 + 1 >= 2*sqrt(3)) * (-1)
-x^3 - 1 >= -2*sqrt(3)
```

(continues on next page)
sage: (x^3 + 1 <= 2*sqrt(3)) * (-1)
-x^3 - 1 <= -2*sqrt(3)

negation()
Return the negated version of self.
This is the relation that is False iff self is True.

EXAMPLES:

sage: (x < 5).negation()
x >= 5
sage: (x == sin(3)).negation()
x != sin(3)

sage: (2*x >= sqrt(2)).negation()
2*x < sqrt(2)

nintegral(*args, **kwds)
Compute the numerical integral of self. Please see \texttt{sage.calculus.calculus.nintegral} for more details.

EXAMPLES:

sage: sin(x).nintegral(x,0,3)
(1.989992496600..., 2.209335488557...e-14, 21, 0)

nintegrate(*args, **kwds)
Compute the numerical integral of self. Please see \texttt{sage.calculus.calculus.nintegral} for more details.

EXAMPLES:

sage: sin(x).nintegral(x,0,3)
(1.989992496600..., 2.209335488557...e-14, 21, 0)

nops()
Return the number of operands of this expression.

EXAMPLES:

sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: a.number_of_operands()
0
sage: (a^2 + b^2 + (x+y)^2).number_of_operands()
3
sage: (a^2).number_of_operands()
2
sage: (a*b^2*c).number_of_operands()
3

norm()
Return the complex norm of this symbolic expression, i.e., the expression times its complex conjugate. If $c = a + bi$ is a complex number, then the norm of $c$ is defined as the product of $c$ and its complex conjugate $\overline{c}$.

\[
\text{norm}(c) = \text{norm}(a + bi) = c \cdot \overline{c} = a^2 + b^2.
\]
The norm of a complex number is different from its absolute value. The absolute value of a complex number is defined to be the square root of its norm. A typical use of the complex norm is in the integral domain $\mathbb{Z}[i]$ of Gaussian integers, where the norm of each Gaussian integer $c = a + bi$ is defined as its complex norm.

See also:

```
sage.misc.functional.norm()
```

EXAMPLES:

```
sage: a = 1 + 2*I
sage: a.norm()
5
sage: a = sqrt(2) + 3^(1/3)*I; a
sqrt(2) + I*3^(1/3)
sage: a.norm()
3^(2/3) + 2
sage: CDF(a).norm()
4.080083823051...
sage: CDF(a.norm())
4.080083823051904
```

**normalize()**

Return this expression normalized as a fraction

See also:

```
numerator(), denominator(), numerator_denominator(), combine()
```

EXAMPLES:

```
sage: var('x, y, a, b, c')
(x, y, a, b, c)
sage: g = x + y/(x + 2)
sage: g.normalize()
(x^2 + 2*x + y)/(x + 2)
sage: f = x*(x-1)/(x^2 - 7) + y^2/(x^2-7) + 1/(x+1) + b/a + c/a
sage: f.normalize()
(a*x^3 + b*x^3 + c*x^3 + a*x*y^2 + a*x^2 + b*x^2 + c*x^2 +
    a*y^2 - a*x - 7*b*x - 7*c*x - 7*a - 7*b - 7*c)/((x^2 -
    7)*a*(x + 1))
```

**number_of_arguments()**

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.number_of_arguments()
2
sage: g = f.function(x)
sage: g.number_of_arguments()
1
```
Symbolic Calculus, Release 10.1

\begin{Verbatim}[commandchars=\][\#] sage: x,y,z = var('x,y,z')
sage: (x+y).number_of_arguments()
2
sage: (x+1).number_of_arguments()
1
sage: (sin(x)+1).number_of_arguments()
1
sage: (sin(z)+x+y).number_of_arguments()
3
sage: (sin(x+y)).number_of_arguments()
2
\end{Verbatim}

\textbf{number_of_operands()}

Return the number of operands of this expression.

\textbf{EXAMPLES:}

\begin{Verbatim}[commandchars=\][\#] sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: a.number_of_operands()
0
sage: (a^2 + b^2 + (x+y)^2).number_of_operands()
3
sage: (a^2).number_of_operands()
2
sage: (a*b^2*c).number_of_operands()
3
\end{Verbatim}

\textbf{numerator\texttt{(normalize=True)}}

Return the numerator of this symbolic expression.

\textbf{INPUT:}

\begin{itemize}
\item normalize – (default: True) a boolean.
\end{itemize}

If normalize is True, the expression is first normalized to have it as a fraction before getting the numerator.

If normalize is False, the expression is kept and if it is not a quotient, then this will return the expression itself.

\textbf{See also:}

\texttt{normalize()}, \texttt{denominator()}, \texttt{numerator_denominator()}, \texttt{combine()}

\textbf{EXAMPLES:}

\begin{Verbatim}[commandchars=\][\#] sage: a, x, y = var('a,x,y')
sage: f = x*(x-a)/((x^2 - y)*(x-a)); f
x/(x^2 - y)
sage: f.numerator()
x
sage: f.denominator()
x^2 - y
sage: f.numerator(normalize=False)
x
sage: f.denominator(normalize=False)
\end{Verbatim}

(continues on next page)
```
x^2 - y
sage: y = var('y')
sage: g = x + y/(x + 2); g
x + y/(x + 2)
sage: g.numerator()
x^2 + 2*x + y
sage: g.denominator()
x + 2
sage: g.numerator(normalize=False)
x + y/(x + 2)
sage: g.denominator(normalize=False)
1
```

**numerator_denominator**(normalize=True)

Return the numerator and the denominator of this symbolic expression.

**INPUT:**

- normalize – (default: True) a boolean.

If normalize is True, the expression is first normalized to have it as a fraction before getting the numerator and denominator.

If normalize is False, the expression is kept and if it is not a quotient, then this will return the expression itself together with 1.

**See also:**

normalize(), numerator(), denominator(), combine()

**EXAMPLES:**

```
sage: x, y, a = var("x y a")
sage: ((x+y)^2/(x-y)^3*x^3).numerator_denominator()
((x + y)^2*x^3, (x - y)^3)
sage: ((x+y)^2/(x-y)^3*x^3).numerator_denominator(False)
((x + y)^2*x^3, (x - y)^3)
sage: g = x + y/(x + 2)
sage: g.numerator_denominator()
(x^2 + 2*x + y, x + 2)
sage: g.numerator_denominator(normalize=False)
(x + y/(x + 2), 1)
sage: g = x^2*(x + 2)
sage: g.numerator_denominator()
((x + 2)*x^2, 1)
sage: g.numerator_denominator(normalize=False)
((x + 2)*x^2, 1)
```

**numerical_approx**(prec=None, digits=None, algorithm=None)

Return a numerical approximation of self with prec bits (or decimal digits) of precision.

No guarantee is made about the accuracy of the result.
Symbolic Calculus, Release 10.1

INPUT:

- **prec** – precision in bits
- **digits** – precision in decimal digits (only used if **prec** is not given)
- **algorithm** – which algorithm to use to compute this approximation

If neither **prec** nor **digits** is given, the default precision is 53 bits (roughly 16 digits).

EXAMPLES:

```python
sage: sin(x).subs(x=5).n()
-0.958924274663138
sage: sin(x).subs(x=5).n(100)

sage: (pi + e + sqrt(2)).numerical_approx(100)
7.2740880444219335226246195788
```

op

Provide access to the operands of an expression through a property.

EXAMPLES:

```python
sage: t = 1+x+x^2
sage: t.op
Operands of x^2 + x + 1
sage: x.op
Traceback (most recent call last):
...
TypeError: expressions containing only a numeric coefficient, constant or symbol have no operands
sage: t.op[0]
x^2
```

Indexing directly with `t[1]` causes problems with numpy types.

```python
sage: t[1] Traceback (most recent call last): ...
TypeError: 'sage.symbolic.expression.Expression' object ...
```

operands()

Return a list containing the operands of this expression.

EXAMPLES:
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: (a^2 + b^2 + (x+y)^2).operands()
[a^2, b^2, (x + y)^2]
sage: (a^2).operands()
[a, 2]
sage: (a*b^2*c).operands()
[a, b^2, c]

operator()

Return the topmost operator in this expression.

EXAMPLES:

sage: x,y,z = var('x,y,z')
sage: (x+y).operator()<function add_vararg ...>
sage: (x^y).operator()<built-in function pow>
sage: (x^y * z).operator()<function mul_vararg ...>
sage: (x < y).operator()<built-in function lt>
sage: abs(x).operator()abs
sage: r = gamma(x).operator(); type(r)<class 'sage.functions.gamma.Function_gamma'>
sage: psi = function('psi', nargs=1)
sage: psi(x).operator()psi
sage: r = psi(x).operator()
sage: r == psiTrue
sage: f = function('f', nargs=1, conjugate_func=lambda self, x: 2*x)
sage: nf = f(x).operator()
sage: nf(x).conjugate()
2*x

partial_fraction(var=None)

Return the partial fraction expansion of self with respect to the given variable.

INPUT:

• var – variable name or string (default: first variable)
OUTPUT:
A symbolic expression

See also:

`partial_fraction_decomposition()`

EXAMPLES:
```
sage: f = x^2/(x+1)^3
sage: f.partial_fraction()
1/(x + 1) - 2/(x + 1)^2 + 1/(x + 1)^3
```

Notice that the first variable in the expression is used by default:
```
sage: y = var('y')
sage: f = y^2/(y+1)^3
sage: f.partial_fraction()
1/(y + 1) - 2/(y + 1)^2 + 1/(y + 1)^3
```

You can explicitly specify which variable is used:
```
sage: f.partial_fraction(y)
x/(x^3 - 3*x^2 + 3*x - 1) + 1/(y + 1) - 2/(y + 1)^2 + 1/(y + 1)^3
```

`partial_fraction_decomposition(var=None)`

Return the partial fraction decomposition of `self` with respect to the given variable.

INPUT:

• `var` – variable name or string (default: first variable)

OUTPUT:

A list of symbolic expressions

See also:

`partial_fraction()`

EXAMPLES:
```
sage: f = x^2/(x+1)^3
sage: f.partial_fraction_decomposition()
[1/(x + 1), -2/(x + 1)^2, (x + 1)^(-3)]
sage: (4+f).partial_fraction_decomposition()
[1/(x + 1), -2/(x + 1)^2, (x + 1)^(-3), 4]
```

Notice that the first variable in the expression is used by default:
```
sage: y = var('y')
sage: f = y^2/(y+1)^3
sage: f.partial_fraction_decomposition()
[1/(y + 1), -2/(y + 1)^2, (y + 1)^(-3)]
```
Symbolic Calculus, Release 10.1

You can explicitly specify which variable is used:

\[
sage: f = y^2/(y+1)^3 + x/(x-1)^3
\]
\[
sage: f.partial_fraction_decomposition(y)
\[[1/(y + 1), -2/(y + 1)^2, (y + 1)^(-3), x/(x^3 - 3*x^2 + 3*x - 1)]
\]

\[
plot(*args, **kwds)
\]
Plot a symbolic expression. All arguments are passed onto the standard plot command.

**EXAMPLES:**

This displays a straight line:

\[
sage: sin(2).plot((x,0,3))
Graphics object consisting of 1 graphics primitive
\]

This draws a red oscillatory curve:

\[
sage: sin(x^2).plot((x,0,2*pi), rgbcolor=(1,0,0))
Graphics object consisting of 1 graphics primitive
\]

Another plot using the variable theta:

\[
sage: var('theta')
theta
sage: (cos(theta) - erf(theta)).plot((theta,-2*pi,2*pi))
Graphics object consisting of 1 graphics primitive
\]

A very thick green plot with a frame:

\[
sage: sin(x).plot((x,-4*pi, 4*pi), thickness=20, rgbcolor=(0,0.7,0)).show(frame=True)
\]

You can embed 2d plots in 3d space as follows:

\[
sage: plot(sin(x^2), (x,-2*pi, 2*pi), thickness=2).plot3d(z = 1)
# long time
Graphics3d Object
\]

A more complicated family:

\[
sage: G = sum([plot(sin(n*x), (x,-2*pi, 2*pi)).plot3d(z=n) for n in [0,0.1,,.. ,1]])
\]
\[
sage: G.show(frame_aspect_ratio=[1,1,1/2])
# long time (5s on sage.math, 2012)
\]

A plot involving the floor function:

\[
sage: plot(1.0 - x * floor(1/x), (x,0.00001,1.0))
Graphics object consisting of 1 graphics primitive
\]

Sage used to allow symbolic functions with “no arguments”; this no longer works:

\[
2.1. Symbolic Expressions
\]
symbolic_expression

```
sage: plot(2*sin, -4, 4)
```

```
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: 'Integer Ring' and '<class 'sage.functions.trig.Function_sin'>'
```

You should evaluate the function first:

```
sage: plot(2*sin(x), -4, 4)
```

```
Graphics object consisting of 1 graphics primitive
```

**poly**

Express this symbolic expression as a polynomial in \( x \). If this is not a polynomial in \( x \), then some coefficients may be functions of \( x \).

**Warning:** This is different from `polynomial()` which returns a Sage polynomial over a given base ring.

**EXAMPLES:**

```
sage: var('a, x')
(a, x)
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: p.poly(a)
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: bool(p.poly(a) == (x-a*sqrt(2))^2 + x + 1)
True
sage: p.poly(x)
2*a^2 - (2*sqrt(2)*a - 1)*x + x^2 + 1
```

**polynomial**

`polynomial()` returns this symbolic expression as an algebraic polynomial over the given base ring, if possible.

The point of this function is that it converts purely symbolic polynomials into optimised algebraic polynomials over a given base ring.

You can specify either the base ring (`base_ring`) you want the output polynomial to be over, or you can specify the full polynomial ring (`ring`) you want the output polynomial to be an element of.

**INPUT:**

- `base_ring` - (optional) the base ring for the polynomial
- `ring` - (optional) the parent for the polynomial

**Warning:** This is different from `poly()` which is used to rewrite self as a polynomial in terms of one of the variables.

**EXAMPLES:**

```
sage: f = x^2 -2/3*x + 1
sage: f.polynomial(QQ)
```
Polynomials can be useful for getting the coefficients of an expression:

```
sage: g = 6*x^2 - 5
sage: g.coefficients()
[[-5, 0], [6, 2]]
sage: g.polynomial(QQ).list()
[-5, 0, 6]
sage: g.polynomial(QQ).dict()
{0: -5, 2: 6}
```

Another polynomial:

```
sage: f = sum((e*I)^n*x^n for n in range(5)); f
x^4*e^4 - I*x^3*e^3 - x^2*e^2 + I*x*e + 1
```

A multivariate polynomial over a finite field:
We check to make sure constants are converted appropriately:

```python
sage: (pi*x).polynomial(SR)
pi*x
```

Using the `ring` parameter, you can also create polynomials rings over the symbolic ring where only certain variables are considered generators of the polynomial ring and the others are considered “constants”:

```python
sage: a, x, y = var('a,x,y')
sage: f = a*x^10*y+3*x
sage: B = f.polynomial(ring=SR['x,y'])
sage: B.coefficients()
[a, 3]
```

**power** *(exp, hold=False)*

Return the current expression to the power `exp`.

To prevent automatic evaluation use the `hold` argument.

**EXAMPLES:**

```python
sage: (x^2).power(2)
x^4
sage: (x^2).power(2, hold=True)
(x^2)^2
```

To then evaluate again, we use `unhold()`:

```python
sage: a = (x^2).power(2, hold=True); a.unhold()
x^4
```

**power_series** *(base_ring)*

Return algebraic power series associated to this symbolic expression, which must be a polynomial in one variable, with coefficients coercible to the base ring.

The power series is truncated one more than the degree.

**EXAMPLES:**

```python
sage: theta = var('theta')
sage: f = theta^3 + (1/3)*theta - 17/3
sage: g = f.power_series(QQ); g
-17/3 + 1/3*theta + theta^3 + O(theta^4)
```

```python
sage: g^3
-4913/27 + 289/9*theta - 17/9*theta^2 + 2602/27*theta^3 + O(theta^4)
```

```python
sage: g.parent()
Power Series Ring in theta over Rational Field
```
**primitive_part(s)**

Return the primitive polynomial of this expression when considered as a polynomial in \( s \).

See also `unit()`, `content()`, and `unit_content_primitive()`.

**INPUT:**

- \( s \) – a symbolic expression.

**OUTPUT:**

The primitive polynomial as a symbolic expression. It is defined as the quotient by the `unit()` and `content()` parts (with respect to the variable \( s \)).

**EXAMPLES:**

```sage
sage: (2*x+4).primitive_part(x)
x + 2
sage: (2*x+1).primitive_part(x)
2*x + 1
sage: (2*x+1/2).primitive_part(x)
4*x + 1
sage: var('y')
y
sage: (2*x + 4*sin(y)).primitive_part(sin(y))
x + 2*sin(y)
```

**prod(**args, **kwds)**

Return the symbolic product \( \prod_{v=a}^{b} \text{expression} \) with respect to the variable \( v \) with endpoints \( a \) and \( b \).

**INPUT:**

- `expression` - a symbolic expression
- `v` - a variable or variable name
- `a` - lower endpoint of the product
- `b` - upper endpoint of the product
- `algorithm` - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'giac' - (optional) use Giac
  - 'sympy' - use SymPy
- `hold` - (default: False) if True don’t evaluate

**pyobject()**

Get the underlying Python object.

**OUTPUT:**

The Python object corresponding to this expression, assuming this expression is a single numerical value or an infinity representable in Python. Otherwise, a `TypeError` is raised.

**EXAMPLES:**

```sage
sage: var('x')
x
sage: b = -17.3
(continues on next page)```
Integers and Rationals are converted internally though, so you won’t get back the same object:

```
sage: b = -17/3
sage: a = SR(b)
sage: a.pyobject() is b
False
```

**rational_expand**(side=None)

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

**EXAMPLES:**

We expand the expression \((x - y)^5\) using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
sage: expand(a)
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x+y)^2))^2)
x^2 + 2*x*sin(x^2 + 2*x*y + y^2) + sin(x^2 + 2*x*y + y^2)^2
```

Observe that **expand()** also expands function arguments:

```
sage: f(x) = function('f')(x)
sage: fx = f(x*(x+1)); fx
f((x + 1)*x)
sage: fx.expand()
f(x^2 + x)
```

We can expand individual sides of a relation:

```
sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
```
Symbolic Calculus, Release 10.1

\[ \text{sage: } a \text{.expand('right')} \]
\[ (16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2 \]

\textbf{rational\_simplify}(\text{algorithm='full', map=False})

Simplify rational expressions.

\textbf{INPUT:}

- \textit{self} - symbolic expression
- \textit{algorithm} - (default: ‘full’) string which switches the algorithm for simplifications. Possible values are
  - ‘simple’ (simplify rational functions into quotient of two polynomials),
  - ‘full’ (apply repeatedly, if necessary)
  - ‘noexpand’ (convert to common denominator and add)
- \textit{map} - (default: False) if True, the result is an expression whose leading operator is the same as that of the expression \texttt{self} but whose subparts are the results of applying simplification rules to the corresponding subparts of the expressions.

\textbf{ALIAS:} \texttt{rational\_simplify()} and \texttt{simplify\_rational()} are the same

\textbf{DETAILS:} We call Maxima functions ratsimp, fullratsimp and xthru. If each part of the expression has to be simplified separately, we use Maxima function map.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: f = sin(x/(x^2 + x))
sage: f
sin(x/(x^2 + x))
sage: f.simplify_rational()
sin(1/(x + 1))
\end{verbatim}

\begin{verbatim}
sage: f = ((x - 1)^(3/2) - (x + 1)*sqrt(x - 1))/sqrt((x - 1)*(x + 1)); f
-((x + 1)*sqrt(x - 1) - (x - 1)^(3/2))/sqrt((x + 1)*(x - 1))
sage: f.simplify_rational()
-2*sqrt(x - 1)/sqrt(x^2 - 1)
\end{verbatim}

With \texttt{map=True} each term in a sum is simplified separately and thus the results are shorter for functions which are combination of rational and nonrational functions. In the following example, we use this option if we want not to combine logarithm and the rational function into one fraction:

\begin{verbatim}
sage: f = (x^2-1)/(x+1)-ln(x)/(x+2)
sage: f.simplify_rational()
(x^2 + x - log(x) - 2)/(x + 2)
sage: f.simplify_rational(map=True)
x - log(x)/(x + 2) - 1
\end{verbatim}

Here is an example from the Maxima documentation of where \texttt{algorithm='simple'} produces an (possibly useful) intermediate step:

\begin{verbatim}
sage: y = var('y')
sage: g = (x^y/2 + 1)^2*(x^y/2 - 1)/2/(x^y - 1)
sage: g.simplify_rational(algorithm='simple')
\end{verbatim}
(x^(2*y) - 2*x^y + 1)/(x^y - 1)
sage: g.simplify_rational()
x^y - 1

With option algorithm='noexpand' we only convert to common denominators and add. No expansion of products is performed:

sage: f = 1/(x+1)+x/(x+2)^2
sage: f.simplify_rational()
(2*x^2 + 5*x + 4)/(x^3 + 5*x^2 + 8*x + 4)
sage: f.simplify_rational(algorithm='noexpand')
((x + 2)^2 + (x + 1)*x)/((x + 2)^2*(x + 1))

real(hold=False)
Return the real part of this symbolic expression.

EXAMPLES:

sage: x = var('x')
sage: x.real_part()
real_part(x)
sage: SR(2+3*I).real_part()
2
sage: SR(CDF(2,3)).real_part()
2.0
sage: SR(CC(2,3)).real_part()
2.00000000000000
sage: f = log(x)
sage: f.real_part()
log(abs(x))

Using the hold parameter it is possible to prevent automatic evaluation:

sage: SR(2).real_part()
2
sage: SR(2).real_part(hold=True)
real_part(2)

This also works using functional notation:

sage: real_part(I,hold=True)
real_part(I)
0

To then evaluate again, we use unhold():

sage: a = SR(2).real_part(hold=True); a.unhold()
2

real_part(hold=False)
Return the real part of this symbolic expression.

EXAMPLES:
Using the \texttt{hold} parameter it is possible to prevent automatic evaluation:

\begin{verbatim}
sage: SR(2).real_part()
2
sage: SR(2).real_part(hold=True)
real_part(2)
\end{verbatim}

This also works using functional notation:

\begin{verbatim}
sage: real_part(I,hold=True)
real_part(I)
0
\end{verbatim}

To then evaluate again, we use \texttt{unhold()}:  

\begin{verbatim}
sage: a = SR(2).real_part(hold=True); a.unhold()
2
\end{verbatim}

\texttt{rectform()}  
Convert this symbolic expression to rectangular form; that is, the form $a + bi$ where $a$ and $b$ are real numbers and $i$ is the imaginary unit.

\textbf{Note:} The name "rectangular" comes from the fact that, in the complex plane, $a$ and $bi$ are perpendicular.

\begin{itemize}
    \item \texttt{self} – the expression to convert.
\end{itemize}

\textbf{OUTPUT:}
A new expression, equivalent to the original, but expressed in the form $a + bi$.

\textbf{ALGORITHM:}
We call Maxima's \texttt{rectform()} and return the result unmodified.

\textbf{EXAMPLES:}
The exponential form of $\sin(x)$:
Symbolic Calculus, Release 10.1

\[
sage: f = (e^{I*x} - e^{-I*x}) / (2*I) \\
\text{sage: } f.\text{rectform()}
\]
\[
\sin(x)
\]

And \(\cos(x)\):

\[
sage: f = (e^{I*x} + e^{-I*x}) / 2 \\
\text{sage: } f.\text{rectform()}
\]
\[
\cos(x)
\]

In some cases, this will simplify the given expression. For example, here, \(e^{ik\pi}\), \(\sin(k\pi) = 0\) should cancel leaving only \(\cos(k\pi)\) which can then be simplified:

\[
sage: k = var(\text{'k'}) \\
\text{sage: } assume(k, \text{'integer'}) \\
\text{sage: } f = e^{I*pi*k} \\
\text{sage: } f.\text{rectform()}
\]
\[
(-1)^k
\]

However, in general, the resulting expression may be more complicated than the original:

\[
sage: f = e^{I*x} \\
\text{sage: } f.\text{rectform()}
\]
\[
\cos(x) + I*\sin(x)
\]

\textbf{reduce_trig}(\text{var=\text{None}})

Combine products and powers of trigonometric and hyperbolic \(\sin\)'s and \(\cos\)'s of \(x\) into those of multiples of \(x\). It also tries to eliminate these functions when they occur in denominators.

\textbf{INPUT}:

- \text{self} - a symbolic expression
- \text{var} - (default: None) the variable which is used for these transformations. If not specified, all variables are used.

\textbf{OUTPUT}:

A symbolic expression.

\textbf{EXAMPLES}:

\[
sage: y = var(\text{'y'}) \\
\text{sage: } f = \sin(x)^3*\cos(x) + \sin(y)^2 \\
\text{sage: } f.\text{reduce_trig()}
\]
\[
-1/2*\cos(2*y) + 1/8*\sin(4*x) + 1/4*\sin(2*x) + 1/2
\]

To reduce only the expressions involving \(x\) we use optional parameter:

\[
sage: f.\text{reduce_trig(x)}
\]
\[
\sin(y)^2 + 1/8*\sin(4*x) + 1/4*\sin(2*x)
\]

\textbf{ALIAS}: \textit{trig_reduce()} and \textit{reduce_trig()} are the same

\textbf{residue} (\text{symbol})

Calculate the residue of \(\text{self}\) with respect to \(\text{symbol}\).

\textbf{INPUT}:
• symbol - a symbolic variable or symbolic equality such as \( x == 5 \). If an equality is given, the expansion is around the value on the right hand side of the equality, otherwise at 0.

OUTPUT:
The residue of \( \text{self} \).

Say, symbol is \( x == a \), then this function calculates the residue of \( \text{self} \) at \( x = a \), i.e., the coefficient of \( 1/(x-a) \) of the series expansion of \( \text{self} \) around \( a \).

EXAMPLES:

```
sage: (1/x).residue(x == 0)
1
sage: (1/x).residue(x == oo)
-1
sage: (1/x^2).residue(x == 0)
0
sage: (1/sin(x)).residue(x == 0)
1
sage: var('q, n, z')
(q, n, z)
sage: (-z^(-n-1)/(1-z/q)^2).residue(z == q).simplify_full()
(n + 1)/q^n
sage: var('s')
sage: zeta(s).residue(s == 1)
1
```

We can also compute the residue at more general places, given that the pole is recognized:

```
sage: k = var('k', domain='integer')
sage: (gamma(1+x)/(1 - exp(-x))).residue(x==2*I*pi*k)
gamma(2*I*pi*k + 1)
sage: csc(x).residue(x==2*pi*k)
1
```

resultant(other, var)
Compute the resultant of this polynomial expression and the first argument with respect to the variable given as the second argument.

EXAMPLES:

```
sage: _ = var('a b n k u x y')
sage: x.resultant(y, x)
y
sage: (x+y).resultant(x-y, x)
-2*y
sage: r = (x^4*y^2+x^2*y-y).resultant(x^y-y^a-x^b+a*b+u,x)
sage: r.coefficient(a^4)
b^4*y^2 - 4*b^3*y^3 + 6*b^2*y^4 - 4*b*y^5 + y^6
sage: x.resultant(sin(x), x)
Traceback (most recent call last):
  ...
RuntimeError: resultant(): arguments must be polynomials
```
rhs()

If self is a relational expression, return the right hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```python
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
```

right()

If self is a relational expression, return the right hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```python
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
```

right_hand_side()

If self is a relational expression, return the right hand side of the relation. Otherwise, raise a ValueError.

EXAMPLES:

```python
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
```

roots(x=None, explicit_solutions=True, multiplicities=True, ring=None)

Return roots of self that can be found exactly, possibly with multiplicities. Not all roots are guaranteed to be found.

**Warning:** This is not a numerical solver - use find_root to solve for self == 0 numerically on an interval.

**INPUT:**

- x - variable to view the function in terms of (use default variable if not given)
- explicit_solutions - bool (default True); require that roots be explicit rather than implicit
- multiplicities - bool (default True); when True, return multiplicities
• ring - a ring (default None): if not None, convert self to a polynomial over ring and find roots over ring

OUTPUT:
A list of pairs (root, multiplicity) or list of roots.
If there are infinitely many roots, e.g., a function like \( \sin(x) \), only one is returned.

EXAMPLES:

```sage
define \( x \) and \( a \) as variables:

A simple example:

```sage
((x^2-1)^2).roots()
```

\[ (-1, 2), (1, 2) \]

```sage
((x^2-1)^2).roots(multiplicities=False)
```

\[-1, 1 \]

A complicated example:

```sage
f = expand((x^2 - 1)^3*(x^2 + 1)*(x-a)); f
```

\[-a*x^8 + x^9 + 2*a*x^6 - 2*x^7 - 2*a*x^2 + 2*x^3 + a - x \]

The default variable is \( a \), since it is the first in alphabetical order:

```sage
f.roots()
```

\[(x, 1) \]

As a polynomial in \( a \), \( x \) is indeed a root:

```sage
f.poly(a)
```

\[ x^9 - 2*x^7 + 2*x^3 - (x^8 - 2*x^6 + 2*x^2 - 1)*a - x \]

```sage
f(a=x)
```

0

The roots in terms of \( x \) are what we expect:

```sage
f.roots(x)
```

\[ [(a, 1), (-I, 1), (I, 1), (1, 3), (-1, 3)] \]

Only one root of \( \sin(x) = 0 \) is given:

```sage
f = \sin(x)
```

```sage
f.roots(x)
```

\[ [(0, 1)] \]

**Note:** It is possible to solve a greater variety of equations using `solve()` and the keyword `to_poly_solve`, but only at the price of possibly encountering approximate solutions. See documentation for `f.solve` for more details.

We derive the roots of a general quadratic polynomial:
Symbolic Calculus, Release 10.1

By default, all the roots are required to be explicit rather than implicit. To get implicit roots, pass `explicit_solutions=False` to `.roots()`

```python
sage: var('x')
x
sage: f = x^(1/9) + (2^(8/9) - 2^(1/9))*(x - 1) - x^(8/9)
sage: f.roots()
Traceback (most recent call last):
...
RuntimeError: no explicit roots found
sage: f.roots(explicit_solutions=False)
[((2^(8/9) + x^(8/9) - 2^(1/9) - x^(1/9))/(2^(8/9) - 2^(1/9)), 1)]
```

Another example, but involving a degree 5 poly whose roots do not get computed explicitly:

```python
sage: f = x^5 + x^3 + 17*x + 1
sage: f.roots()
Traceback (most recent call last):
...
RuntimeError: no explicit roots found
sage: f.roots(explicit_solutions=False)
[(x^5 + x^3 + 17*x + 1, 1)]
```

Now let us find some roots over different rings:

```python
sage: f.roots(ring=CC)
[(-0.058811522318449..., 1), (-1.331099917875796? - 1.518808722099650?*I, 1), (1.360505679035020? + 1.518808722099650?*I, 1)]
```

Now let us find some roots over different rings:

```python
sage: f.roots(ring=QQbar, multiplicities=False)
[-0.0588115223184494?, -1.331099917875796? - 1.518808722099650?*I, 1.360505679035020? + 1.518808722099650?*I]
```

Root finding over finite fields:

```python
sage: f.roots(ring=GF(7^2, 'a'))
[(3, 1), (4*a + 6, 2), (3*a + 3, 2)]
```
round()
Round this expression to the nearest integer.

EXAMPLES:

```
sage: u = sqrt(43203735824841025516773866131535024)
sage: u.round()
207855083711803945
```

```
sage: t = sqrt(Integer('1'*1000)).round(); print(str(t)[-10:])
3333333333
```

```
sage: (-sqrt(110)).round()
-10
```

```
sage: (-sqrt(115)).round()
-11
```

```
sage: (sqrt(-3)).round()
Traceback (most recent call last):
  ...
ValueError: could not convert sqrt(-3) to a real number
```

series(symbol, order=None)
Return the power series expansion of self in terms of the given variable to the given order.

INPUT:

• symbol – a symbolic variable or symbolic equality such as x == 5; if an equality is given, the expansion is around the value on the right hand side of the equality
• order – an integer; if nothing given, it is set to the global default (20), which can be changed using set_series_precision()

OUTPUT:
A power series.
To truncate the power series and obtain a normal expression, use the truncate() command.

EXAMPLES:

We expand a polynomial in $x$ about 0, about 1, and also truncate it back to a polynomial:

```
sage: var('x,y')
(x, y)
sage: f = (x^3 - sin(y)*x^2 - 5*x + 3); f
x^3 - x^2*sin(y) - 5*x + 3
sage: g = f.series(x, 4); g
3 + (-5)*x + (-sin(y))*x^2 + 1*x^3 + Order(x^4)
sage: g.truncate()
x^3 - x^2*sin(y) - 5*x + 3
sage: g = f.series(x==1, 4); g
(-sin(y) - 1) + (-2*sin(y) - 2)*(x - 1) + (-sin(y) + 3)*(x - 1)^2 + 1*(x - 1)^3
  + Order((x - 1)^4)
sage: h = g.truncate(); h
(x - 1)^3 - (x - 1)^2*(sin(y) - 3) - 2*(x - 1)*(sin(y) + 1) - sin(y) - 1
sage: h.expand()
x^3 - x^2*sin(y) - 5*x + 3
```

We compute another series expansion of an analytic function:
Expressions formed by combining series can be expanded by applying series again:

\[
\text{sage: } f = \frac{1}{1-x} + \frac{1}{1+x} \\
\text{sage: } f.\text{series}(x, 3)
\]

\[
(1 + x + x^2 + \text{Order}(x^3)) + (1 + (-1)x + 1x^2 + \text{Order}(x^3))
\]

\[
\text{sage: } _\text{series}(x, 3) \\
2 + 2x^2 + \text{Order}(x^3)
\]

Following the GiNaC tutorial, we use John Machin’s amazing formula π = 16 tan⁻¹(1/5) − 4 tan⁻¹(1/239) to compute digits of π. We expand the arc tangent around 0 and insert the fractions 1/5 and 1/239.

\[
\text{sage: } x = \text{var}(\text{\textquoteright}x\text{\textquoteright}) \\
\text{sage: } f = \text{atan}(x).\text{series}(x, 10); f \\
1x + (-1/3)x^3 + 1/5x^5 + (-1/7)x^7 + 1/9x^9 + \text{Order}(x^10)
\]

\[
\text{sage: } \text{float}(16*b.\text{subs}(x==1/5) - 4*f.\text{subs}(x==1/239)) \\
3.1415926824043994
\]

\textit{show}()

Pretty-print this symbolic expression.

This typesets it nicely and prints it immediately.

\textbf{OUTPUT:}

This method does not return anything. Like \texttt{print}, output is sent directly to the screen.

Note that the output depends on the display preferences. For details, see \texttt{pretty_print()}.

\textbf{EXAMPLES:}

\[
\text{sage: } (x^2 + 1).\text{show}() \\
x^2 + 1
\]

\textbf{EXAMPLES:}

\[
\text{sage: } \text{%display ascii_art} \ # \text{not tested} \\
\text{sage: } (x^2 + 1).\text{show}() \\
2 \\
x + 1
\]
simplify(algorithm='maxima', **kwds)

Return a simplified version of this symbolic expression.

INPUT:

• algorithm – one of :
  – maxima : (default) sends the expression to maxima and converts it back to Sage
  – sympy : converts the expression to sympy, simplifies it (passing any optional keyword(s)), and converts the result to Sage
  – giac : converts the expression to giac, simplifies it, and converts the result to Sage
  – fricas : converts the expression to fricas, simplifies it, and converts the result to Sage

See also:
simplify_full(), simplify_trig(), simplify_rational(), simplify_rectform(), simplify_factorial(), simplify_log(), simplify_real(), simplify_hypergeometric(), canonicalize_radical()

EXAMPLES:

sage: a = var('a'); f = x*sin(2)/(x^a); f
x*sin(2)/x^a
sage: f.simplify()
x^(-a + 1)*sin(2)
Some simplifications are quite algorithm-specific:

sage: x, t = var("x, t")
sage: ex = cos(t).exponentialize()  
sage: ex = ex.subs((sin(t).exponentialize()==x).solve(t)[0])
sage: ex
1/2*I*x + 1/2*I*sqrt(x^2 - 1) + 1/(2*I*x + 2*I*sqrt(x^2 - 1))
sage: ex.simplify()
1/2*I*x + 1/2*I*sqrt(x^2 - 1) + 1/(2*I*x + 2*I*sqrt(x^2 - 1))
sage: ex.simplify(algorithm="sympy")
I*(x^2 + sqrt(x^2 - 1)*x - 1)/(x + sqrt(x^2 - 1))
sage: ex.simplify(algorithm="giac")
I*sqrt(x^2 - 1)
sage: ex.simplify(algorithm="fricas")  # optional - fricas
(I*x^2 + I*sqrt(x^2 - 1)*x - I)/(x + sqrt(x^2 - 1))

simplify_factorial()

Simplify by combining expressions with factorials, and by expanding binomials into factorials.

ALIAS: factorial_simplify and simplify_factorial are the same

EXAMPLES:

Some examples are relatively clear:

sage: var('n,k')
(n, k)
sage: f = factorial(n+1)/factorial(n); f
factorial(n + 1)/factorial(n)
sage: f.simplify_factorial()
n + 1
Symbolic Calculus, Release 10.1

```
sage: f = factorial(n)*(n+1); f
(n + 1)*factorial(n)
sage: simplify(f)
(n + 1)*factorial(n)
sage: f.simplify_factorial()
factorial(n + 1)
```

```
sage: f = binomial(n, k)*factorial(k)*factorial(n-k); f
binomial(n, k)*factorial(k)*factorial(-k + n)
sage: f.simplify_factorial()
factorial(n)
```

A more complicated example, which needs further processing:

```
sage: f = factorial(x)/factorial(x-2)/2 + factorial(x+1)/factorial(x)/2; f
1/2*factorial(x + 1)/factorial(x) + 1/2*factorial(x)/factorial(x - 2)
sage: g = f.simplify_factorial(); g
1/2*(x - 1)*x + 1/2*x + 1/2
sage: g.simplify_rational()
1/2*x^2 + 1/2
```

`simplify_full()`

Apply `simplify_factorial()`, `simplify_rectform()`, `simplify_trig()`, `simplify_rational()`, and then `expand_sum()` to self (in that order).

ALIAS: `simplify_full` and `full_simplify` are the same.

EXAMPLES:

```
sage: f = sin(x)^2 + cos(x)^2
sage: f.simplify_full()
1
```

```
sage: f = sin(x/(x^2 + x))
sage: f.simplify_full()
sin(1/(x + 1))
```

```
sage: var('n,k')
(n, k)
sage: f = binomial(n,k)*factorial(k)*factorial(n-k)
sage: f.simplify_full()
factorial(n)
```

`simplify_hypergeometric(algorithm='maxima')`

Simplify an expression containing hypergeometric or confluent hypergeometric functions.

INPUT:

- `algorithm` – (default: 'maxima') the algorithm to use for for simplification. Implemented are 'maxima', which uses Maxima's `hgfred` function, and 'sage', which uses an algorithm implemented in the hypergeometric module

ALIAS: `hypergeometric_simplify()` and `simplify_hypergeometric()` are the same

EXAMPLES:
sage: hypergeometric((5, 4), (4, 1, 2, 3), x).simplify_hypergeometric()
1/144*x^2*hypergeometric(((), (3, 4), x) + ...
1/3*x*hypergeometric(((), (2, 3), x) + hypergeometric(((), (1, 2), x))
sage: (2*hypergeometric(((), (1, x))).simplify_hypergeometric()
2*e^x

sage: (nest(lambda y: hypergeometric([y], [1], x), 3, 1) # not tested, unstable
...: .simplify_hypergeometric())
laguerre(-laguerre(-e^x, x), x)
sage: (nest(lambda y: hypergeometric([y], [1], x), 3, 1) # not tested, unstable
...: .simplify_hypergeometric(algorithm='sage'))
hypergeometric(hypergeometric((e^x,), (1,), x),), (1,), x)
sage: hypergeometric_M(1, 3, x).simplify_hypergeometric()
-2*((x + 1)*e^(-x) - 1)*e^x/x^2
sage: (2 * hypergeometric_U(1, 3, x)).simplify_hypergeometric()
2*(x + 1)/x^2

simplify_log(algorithm=None)

Simplify a (real) symbolic expression that contains logarithms.

The given expression is scanned recursively, transforming subexpressions of the form \(a \log(b) + c \log(d)\)
into \(\log(b^a d^c)\) before simplifying within the \(\log()\).

The user can specify conditions that \(a\) and \(c\) must satisfy before this transformation will be performed using the optional parameter \texttt{algorithm}.

\begin{center}
\begin{verbatim}
Warning: This is only safe to call if every variable in the given expression is assumed to be real. The simplification it performs is in general not valid over the complex numbers. For example:
sage: x, y = SR.var('x,y')
sage: f = log(x*y) - (log(x) + log(y))
sage: f(x=-1, y=i)
-2*I*pi
sage: f.simplify_log()
0
\end{verbatim}
\end{center}

INPUT:

\begin{itemize}
\item \texttt{self} - expression to be simplified
\item \texttt{algorithm} - (default: None) optional, governs the condition on \(a\) and \(c\) which must be satisfied to contract expression \(a \log(b) + c \log(d)\). Values are
  \begin{itemize}
  \item \texttt{None} (use Maxima default, integers),
  \item \texttt{'one'} (1 and -1),
  \item \texttt{'ratios'} (rational numbers),
  \item \texttt{'constants'} (constants),
  \item \texttt{'all'} (all expressions).
  \end{itemize}
\end{itemize}

ALGORITHM:

This uses the Maxima \texttt{logcontract()} command.

ALIAS:
\texttt{log_simplify()} and \texttt{simplify_log()} are the same.

EXAMPLES:

\begin{verbatim}
sage: x,y,t = var('x y t')
\end{verbatim}

Only two first terms are contracted in the following example; the logarithm with coefficient $\frac{1}{2}$ is not contracted:

\begin{verbatim}
sage: f = log(x)+2*log(y)+1/2*log(t)
sage: f.simplify_log()
\end{verbatim}

\begin{verbatim}
log(x*y^2) + 1/2*log(t)
\end{verbatim}

To contract all terms in the previous example, we use the 'ratios' algorithm:

\begin{verbatim}
sage: f.simplify_log(algorithm='ratios')
\end{verbatim}

\begin{verbatim}
log(sqrt(t)*x*y^2)
\end{verbatim}

To contract terms with no coefficient (more precisely, with coefficients 1 and $-1$), we use the 'one' algorithm:

\begin{verbatim}
sage: f = log(x)+2*log(y)-log(t)
sage: f.simplify_log('one')
\end{verbatim}

\begin{verbatim}
2*log(y) + log(x/t)
\end{verbatim}

\begin{verbatim}
sage: f = log(x)+log(y)-1/3*log((x+1))
sage: f.simplify_log()
\end{verbatim}

\begin{verbatim}
log(x*y) - 1/3*log(x + 1)
\end{verbatim}

\begin{verbatim}
sage: f.simplify_log('ratios')
\end{verbatim}

\begin{verbatim}
log(x*y/(x + 1)^{1/3})
\end{verbatim}

$\pi$ is an irrational number; to contract logarithms in the following example we have to set algorithm to 'constants' or 'all':

\begin{verbatim}
sage: f = log(x)+log(y)-pi*log((x+1))
sage: f.simplify_log('constants')
\end{verbatim}

\begin{verbatim}
log(x*y/(x + 1)^(pi))
\end{verbatim}

\begin{verbatim}
(x*log(9)).simplify_log()
\end{verbatim}

\begin{verbatim}
2*x*log(3)
\end{verbatim}

\begin{verbatim}
sage: (x*log(9)).simplify_log('all')
\end{verbatim}

\begin{verbatim}
log(3^(2*x))
\end{verbatim}

AUTHORS:

• Robert Marik (11-2009)

\texttt{simplify_rational(algorithm='full', map=False)}

Simplify rational expressions.

INPUT:

• self - symbolic expression

Chapter 2. Internal functionality supporting calculus
• **algorithm** - (default: ‘full’) string which switches the algorithm for simplifications. Possible values are
  – ‘simple’ (simplify rational functions into quotient of two polynomials),
  – ‘full’ (apply repeatedly, if necessary)
  – ‘noexpand’ (convert to common denominator and add)

• **map** - (default: False) if True, the result is an expression whose leading operator is the same as that of the expression `self` but whose subparts are the results of applying simplification rules to the corresponding subparts of the expressions.

**ALIAS:** `rational_simplify()` and `simplify_rational()` are the same

**DETAILS:** We call Maxima functions `ratsimp`, `fullratsimp` and `xthru`. If each part of the expression has to be simplified separately, we use Maxima function `map`.

**EXAMPLES:**

```sage
f = sin(x/(x^2 + x))
sage: f
sin(x/(x^2 + x))
sage: f.simplify_rational()
sin(1/(x + 1))
```

```sage
f = ((x - 1)^(3/2) - (x + 1)*sqrt(x - 1))/sqrt((x - 1)*(x + 1)); f
-((x + 1)*sqrt(x - 1) - (x - 1)^(3/2))/sqrt((x + 1)*(x - 1))
sage: f.simplify_rational()
-2*sqrt(x - 1)/sqrt(x^2 - 1)
```

With `map=True` each term in a sum is simplified separately and thus the results are shorter for functions which are combination of rational and nonrational functions. In the following example, we use this option if we want not to combine logarithm and the rational function into one fraction:

```sage
f = (x^2-1)/(x+1)-ln(x)/(x+2)
sage: f.simplify_rational()
(x^2 + x - log(x) - 2)/(x + 2)
sage: f.simplify_rational(map=True)
x - log(x)/(x + 2) - 1
```

Here is an example from the Maxima documentation of where `algorithm='simple'` produces an (possibly useful) intermediate step:

```sage
y = var('y')
sage: g = (x^(y/2) + 1)^2*(x^(y/2) - 1)/(x^y - 1)
sage: g.simplify_rational(algorithm='simple')
(x^(2*y) - 2*x^y + 1)/(x^y - 1)
sage: g.simplify_rational()
x^y - 1
```

With option `algorithm='noexpand'` we only convert to common denominators and add. No expansion of products is performed:

```sage
f = 1/(x+1)+x/(x+2)^2
sage: f.simplify_rational()
(2*x^2 + 5*x + 4)/(x^3 + 5*x^2 + 8*x + 4)
```

(continues on next page)
sage: f.simplify_rational(algorithm='noexpand')

\(((x + 2)^2 + (x + 1)\cdot x)/((x + 2)^2\cdot (x + 1))\)

**simplify_real()**

Simplify the given expression over the real numbers. This allows the simplification of \(\sqrt{x^2}\) into \(|x|\) and the contraction of \(\log(x) + \log(y)\) into \(\log(xy)\).

**INPUT:**

- `self` – the expression to convert.

**OUTPUT:**

A new expression, equivalent to the original one under the assumption that the variables involved are real.

**EXAMPLES:**

```python
sage: f = sqrt(x^2)
sage: f.simplify_real()
abs(x)
```

```python
sage: y = SR.var('y')
sage: f = log(x) + 2*log(y)
sage: f.simplify_real()
log(x*y^2)
```

**simplify_rectform(complexity_measure='string_length')**

Attempt to simplify this expression by expressing it in the form \(a + bi\) where both \(a\) and \(b\) are real. This transformation is generally not a simplification, so we use the given `complexity_measure` to discard non-simplifications.

**INPUT:**

- `self` – the expression to simplify.
- `complexity_measure` – (default: `sage.symbolic.complexity_measures.string_length`) a function taking a symbolic expression as an argument and returning a measure of that expression’s complexity. If `None` is supplied, the simplification will be performed regardless of the result.

**OUTPUT:**

If the transformation produces a simpler expression (according to `complexity_measure`) then that simpler expression is returned. Otherwise, the original expression is returned.

**ALGORITHM:**

We first call `rectform()` on the given expression. Then, the supplied complexity measure is used to determine whether or not the result is simpler than the original expression.

**EXAMPLES:**

The exponential form of \(\tan(x)\):

```python
sage: f = ( e^(I*x) - e^(-I*x) ) / ( I*e^(I*x) + I*e^(-I*x) )
sage: f.simplify_rectform()
sin(x)/cos(x)
```
This should not be expanded with Euler’s formula since the resulting expression is longer when considered as a string, and the default complexity_measure uses string length to determine which expression is simpler:

```
sage: f = e^(I*x)
sage: f.simplify_rectform()
e^(I*x)
```

However, if we pass `None` as our complexity measure, it is:

```
sage: f = e^(I*x)
sage: f.simplify_rectform(complexity_measure = None)
cos(x) + I*sin(x)
```

`simplify_trig(expand=True)`

Optionally expand and then employ identities such as \(\sin(x)^2 + \cos(x)^2 = 1\), \(\cosh(x)^2 - \sinh(x)^2 = 1\), \(\sin(x) \csc(x) = 1\), or \(\tanh(x) = \sinh(x)/\cosh(x)\) to simplify expressions containing tan, sec, etc., to sin, cos, sinh, cosh.

**INPUT:**

- `self` - symbolic expression
- `expand` - (default:True) if True, expands trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in `self` first. For best results, `self` should be expanded. See also `expand_trig()` to get more controls on this expansion.

**ALIAS:** `trig_simplify()` and `simplify_trig()` are the same

**EXAMPLES:**

```
sage: f = sin(x)^2 + cos(x)^2; f
\cos(x)^2 + \sin(x)^2
sage: f.simplify()
\cos(x)^2 + \sin(x)^2
sage: f.simplify_trig()
1
sage: h = sin(x)*csc(x)
sage: h.simplify_trig()
1
sage: k = tanh(x)*cosh(2*x)
sage: k.simplify_trig()
(2*sinh(x)^3 + sinh(x))/cosh(x)
```

In some cases we do not want to expand:

```
sage: f = tan(3*x)
sage: f.simplify_trig()
-(4*cos(x)^2 - 1)*sin(x)/(4*cos(x)*sin(x)^2 - cos(x))
sage: f.simplify_trig(False)
sin(3*x)/cos(3*x)
```

`sin(hold=False)`

**EXAMPLES:**

### 2.1. Symbolic Expressions

107
Symbolic Calculus, Release 10.1

```
sage: var('x, y')
(x, y)
sage: sin(x^2 + y^2)
\sin(x^2 + y^2)
sage: sin(sage.symbolic.constants.pi)
0
sage: sin(SR(1))
\sin(1)
sage: sin(SR(RealField(150)(1)))
0.8414709848078965066525023216302989962256306
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```
sage: SR(0).sin()
0
sage: SR(0).sin(hold=True)
\sin(0)
```

This also works using functional notation:

```
sage: sin(0, hold=True)
\sin(0)
sage: sin(0)
0
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(0).sin(hold=True); a.unhold()
0
```

**sinh**

```
\sinh(hold=False)
```

Return sinh of self.

We have \( \sinh(x) = (e^x - e^{-x})/2 \).

**EXAMPLES:**

```
sage: x.sinh()
\sinh(x)
sage: SR(1).sinh()
\sinh(1)
sage: SR(0).sinh()
0
sage: SR(1.0).sinh()
1.1752011936438014568823819
sage: maxima('\sinh(1.0)')
1.17520119364380...
```

To prevent automatic evaluation use the `hold` argument:

```
sage: SR(1).sinh().n(90)
1.1752011936438014568823819
sage: SR(1).sinh().n(90)
1.1752011936438014568823819
```

```
sage: SR(1).sinh().n(90)
1.1752011936438014568823819
sage: SR(1).sinh().n(90)
1.1752011936438014568823819
```

```
sage: SR(1).sinh().n(90)
1.1752011936438014568823819
sage: SR(1).sinh().n(90)
1.1752011936438014568823819
```
symbolic:

\[
sage: \text{arccosh}(x).\sinh()
\]
\[
sqrt{x + 1}*\sqrt{x - 1}
\]
\[
sage: \text{arccosh}(x).\sinh(hold=True)
\]
\[
\sinh(\text{arccosh}(x))
\]

This also works using functional notation:

\[
sage: \sin(\text{arccosh}(x),\text{hold=True})
\]
\[
\sinh(\text{arccosh}(x))
\]
\[
sqrt{x + 1}*\sqrt{x - 1}
\]

To then evaluate again, we use \textit{unhold()}:

\[
sage: a = \text{arccosh}(x).\sinh(hold=True); a.\text{simplify()}
\]
\[
\sqrt{x + 1}*\sqrt{x - 1}
\]

\textbf{solve}(x, \text{multiplicities=}False, \text{solution_dict=}False, \text{explicit_solutions=}False, \text{to_poly_solve=}False, \\
\text{algorithm=}None, \text{domain=}None)

Analytically solve the equation \textit{self} == 0 or a univariate inequality for the variable \textit{x}.

\textbf{Warning:} This is not a numerical solver - use \textit{find_root} to solve for \textit{self} == 0 numerically on an interval.

**INPUT:**

- \textit{x} - variable(s) to solve for
- \textit{multiplicities} - bool (default: False); if True, return corresponding multiplicities. This keyword is incompatible with \textit{to_poly_solve}=True and does not make any sense when solving an inequality.
- \textit{solution_dict} - bool (default: False); if True or non-zero, return a list of dictionaries containing solutions. Not used when solving an inequality.
- \textit{explicit_solutions} - bool (default: False); require that all roots be explicit rather than implicit. Not used when solving an inequality.
- \textit{to_poly_solve} - bool (default: False) or string; use Maxima’s \textit{to_poly_solver} package to search for more possible solutions, but possibly encounter approximate solutions. This keyword is incompatible with \textit{multiplicities=}True and is not used when solving an inequality. Setting \textit{to_poly_solve} to ‘force’ omits Maxima’s solve command (useful when some solutions of trigonometric equations are lost).

**EXAMPLES:**

\[
sage: z = \text{var('z')}
\]
\[
sage: (z^5 - 1).\text{solve}(z)
\]

\[
[z == 1/4*\text{sqrt}(5) + 1/4*I*\text{sqrt}(2*\text{sqrt}(5) + 10) - 1/4, z == -1/4*\text{sqrt}(5) + 1/4*I*\text{sqrt}(-2*\text{sqrt}(5) + 10) - 1/4, z == -1/4*\text{sqrt}(5) - 1/4*I*\text{sqrt}(-2*\text{sqrt}(5) + 10) - 1/4, z == 1/4*\text{sqrt}(5) - 1/4*I*\text{sqrt}(2*\text{sqrt}(5) + 10) - 1/4, z == 1]
\]

\[
sage: \text{solve}((z^3-1)^3, z, \text{multiplicities=}True)
\]

\[
[[z == 1/2*I*\text{sqrt}(3) - 1/2, z == -1/2*I*\text{sqrt}(3) - 1/2, z == 1], [3, 3, 3]]
\]
**solve_diophantine**(*x=None, solution_dict=False*)

Solve a polynomial equation in the integers (a so called Diophantine).

If the argument is just a polynomial expression, equate to zero. If `solution_dict=True` return a list of dictionaries instead of a list of tuples.

**EXAMPLES:**

```python
sage: x, y = var('x, y')
sage: solve_diophantine(3*x == 4)
[]
sage: solve_diophantine(x^2 - 9)
[-3, 3]
sage: sorted(solve_diophantine(x^2 + y^2 == 25))
[(-5, 0), (-4, -3), (-4, 3), (-3, -4), (-3, 4), (0, -5)...
```

The function is used when `solve()` is called with all variables assumed integer:

```python
sage: assume(x, 'integer')
sage: assume(y, 'integer')
sage: sorted(solve(x*y == 1, (x,y)))
[(-1, -1), (1, 1)]
```

You can also pick specific variables, and get the solution as a dictionary:

```python
sage: solve_diophantine(x*y == 10, x)
[-10, -5, -2, -1, 1, 2, 5, 10]
sage: sorted(solve_diophantine(x*y - y == 10, (x,y)))
[(-9, -1), (-4, -2), (-1, -5), (0, -10), (2, 10), (3, 5), (6, 2), (11, 1)]
sage: res = solve_diophantine(x*y - y == 10, solution_dict=True)
sage: sol = [{y: -5, x: -1}, {y: -10, x: 0}, {y: -1, x: -9}, {y: -2, x: -4}, ...
```

If the solution is parametrized the parameter(s) are not defined, but you can substitute them with specific integer values:

```python
sage: x, y, z = var('x, y, z')
sage: sol = solve_diophantine(x^2-y==0); sol
(t, t^2)
sage: [(sol[0].subs(t=t),sol[1].subs(t=t)) for t in range(-3,4)]
[(-3, 9), (-2, 4), (-1, 1), (0, 0), (1, 1), (2, 4), (3, 9)]
sage: sol = solve_diophantine(x^2 + y^2 == z^2); sol
(2*p*q, p^2 - q^2, p^2 + q^2)
```

Solve Brahmagupta-Pell equations:

```python
sage: sol = sorted(solve_diophantine(x^2 - 2*y^2 == 1), key=str)
sage: sol
[(-sqrt(2)*(2*sqrt(2) + 3)^t + sqrt(2)*(-2*sqrt(2) + 3)^t - 3/2*(2*sqrt(2) + 3)^t...
```

(continues on next page)
\[\rightarrow t - \frac{3}{2}(-2\sqrt{2} + 3)^t, \ldots\]

\[
\begin{align*}
sage: \ &[(sol[1][0].subs(t=t).simplify_full(),sol[1][1].subs(t=t).simplify_full()) \text{ for } t \text{ in range}(-1,5)] \\
&[(1, 0), (3, -2), (17, -12), (99, -70), (577, -408), (3363, -2378)]
\end{align*}
\]

See also:

http://docs.sympy.org/latest/modules/solvers/diophantine.html

\sage{sqrt}(\text{\texttt{hold=False}})

Return the square root of this expression

EXAMPLES:

\[
\begin{align*}
\sage: \ &\text{var('x, y')} \\
&\text{(x, y)} \\
\sage: \ &\text{SR(2).sqrt()} \\
&\sqrt{2} \\
\sage: \ &(x^2+y^2).sqrt() \\
&\sqrt{x^2 + y^2} \\
\sage: \ &(x^2).sqrt() \\
&\sqrt{x^2}
\end{align*}
\]

Immediate simplifications are applied:

\[
\begin{align*}
\sage: \ &\sqrt{x^2} \\
&\sqrt{x^2} \\
\sage: \ &x = \text{SR.symbol('x', domain='real')} \\
\sage: \ &\sqrt{x^2} \\
&\sqrt{x^2} \\
\sage: \ &\text{abs(x)} \\
\sage: \ &\text{forget()} \\
\sage: \ &\text{assume(x<0)} \\
\sage: \ &\sqrt{x^2} \\
&-x \\
\sage: \ &\sqrt{x^4} \\
&x^2 \\
\sage: \ &\text{forget()} \\
\sage: \ &x = \text{SR.symbol('x', domain='real')} \\
\sage: \ &\sqrt{x^4} \\
&x^2 \\
\sage: \ &\sqrt{\sin(x)^2} \\
&\sqrt{\sin(x)} \\
\sage: \ &\sqrt{(x+1)^2} \\
&\sqrt{x + 1} \\
\sage: \ &\text{forget()} \\
\sage: \ &\text{assume(x<0)} \\
\sage: \ &\sqrt{(x-1)^2} \\
&-x + 1 \\
\sage: \ &\text{forget()}
\end{align*}
\]

Using the \texttt{hold} parameter it is possible to prevent automatic evaluation:

\[
\begin{align*}
\sage: \ &\text{SR(4).sqrt()} \\
&2
\end{align*}
\]
To then evaluate again, we use `unhold()`:

```sage
sage: a = SR(4).sqrt(hold=True); a.unhold()
sage: 2
```

To use this parameter in functional notation, you must coerce to the symbolic ring:

```sage
sage: sqrt(SR(4),hold=True)
sage: sqrt(4)
sage: sqrt(4,hold=True)
Traceback (most recent call last):
... typeerror: __do_sqrt() got an unexpected keyword argument 'hold'
```

### step

```
step(hold=False)
```

Return the value of the unit step function, which is 0 for negative x, 1 for 0, and 1 for positive x.

See also:

`sage.functions.generalized.FunctionUnitStep`

EXAMPLES:

```sage
sage: x = var('x')
sage: SR(1.5).step()
sage: 1
sage: SR(0).step()
sage: 1
sage: SR(-1/2).step()
sage: 0
sage: SR(float(-1)).step()
sage: 0
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```sage
sage: SR(2).step()
sage: 1
sage: SR(2).step(hold=True)
sage: unit_step(2)
```

### subs

```
subs(*args, **kwds)
```

Substitute the given subexpressions in this expression.

EXAMPLES:

```sage
sage: var('x,y,z,a,b,c,d,f,g')
(x, y, z, a, b, c, d, f, g)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: t = a^2 + b^2 + (x+y)^3
```

Substitute with keyword arguments (works only with symbols):
Symbolic Calculus, Release 10.1

```
sage: t.subs(a=c)
(x + y)^3 + b^2 + c^2
sage: t.subs(b=19, x=z)
(y + z)^3 + a^2 + 361

Substitute with a dictionary argument:

sage: t.subs({a^2: c})
(x + y)^3 + b^2 + c
sage: t.subs({w0^2: w0^3})
a^3 + b^3 + (x + y)^3

Substitute with one or more relational expressions:

sage: t.subs(w0^2 == w0^3)
a^3 + b^3 + (x + y)^3
sage: t.subs(w0 == w0^2)
a^8 + b^8 + (x^2 + y^2)^6
sage: t.subs(a == b, b == c)
(x + y)^3 + b^2 + c^2

Any number of arguments is accepted:

sage: t.subs(a=b, b=c)
(x + y)^3 + b^2 + c^2
sage: t.subs({a:b}, b=c)
(x + y)^3 + b^2 + c^2
sage: t.subs([x == 3, y == 2], a == 2, {b:3})
138

It can even accept lists of lists:

sage: eqn1 = (a*x + b*y == 0)
sage: eqn2 = (1 + y == 0)
sage: soln = solve([eqn1, eqn2], [x, y])
sage: soln
[[x == b/a, y == -1]]
sage: f = x + y
sage: f.subs(soln)
b/a - 1

Duplicate assignments will throw an error:

sage: t.subs({a:b}, a=c)
Traceback (most recent call last):
...
ValueError: duplicate substitution for a, got values b and c
sage: t.subs([x == 1], a = 1, b = 2, x = 2)
```

(continues on next page)
Traceback (most recent call last):
...
ValueError: duplicate substitution for x, got values 1 and 2

All substitutions are performed at the same time:

```
sage: t.subs({a:b, b:c})
(x + y)^3 + b^2 + c^2
```

Substitutions are done term by term, in other words Sage is not able to identify partial sums in a substitution (see github issue #18396):

```
sage: f = x + x^2 + x^4
sage: f.subs(x = y)
y^4 + y^2 + y
sage: f.subs(x^2 == y)  # one term is fine
x^4 + x + y
sage: f.subs(x + x^2 == y)  # partial sum does not work
x^4 + x^2 + x
sage: f.subs(x + x^2 + x^4 == y)  # whole sum is fine
y
```

Note that it is the very same behavior as in Maxima:

```
sage: E = 'x^4 + x^2 + x'
sage: subs = [('x', 'y'), ('x^2', 'y'), ('x^2+x', 'y'), ('x^4+x^2+x', 'y')]
sage: cmd = '{}, {}={}'.
for s1,s2 in subs:
....:
    maxima.eval(cmd.format(E, s1, s2))
'y^4+y^2+y'
'y+x^4+x'
'x^4+x^2+x'
'y'
```

Or as in Maple:

```
sage: cmd = 'subs({}=={}, {})'.  # optional - maple
for s1,s2 in subs:  # optional - maple
....:
    maple.eval(cmd.format(s1,s2, E))
'y^4+y^2+y'
'x^4+x+y'
'x^4+x^2+x'
'y'
```

But Mathematica does something different on the third example:

```
sage: cmd = '{} /. {} -> {}'.  # optional - mathematica
for s1,s2 in subs:  # optional - mathematica
....:
    mathematica.eval(cmd.format(E,s1,s2))
2 4
y + y + y
4
```

(continues on next page)
Warning: Unexpected results may occur if the left-hand side of some substitution is not just a single variable (or a “wildcard” variable). For example, the result of \( \cos(\cos(\cos(x))) \).subs({\( \cos(x) \) : \( x \)}) is \( x \), because the substitution is applied repeatedly. Such repeated substitutions (and pattern-matching code that may be somewhat unpredictable) are disabled only in the basic case where the left-hand side of every substitution is a variable. In particular, although the result of \( (x^2) \).subs({\( x \) : \( \sqrt{x} \)}) is \( x \), the result of \( (x^2) \).subs({\( x \) : \( \sqrt{x} \), \( y^2 \) : \( y \)}) is \( \sqrt{x} \), because repeated substitution is enabled by the presence of the expression \( y^2 \) in the left-hand side of one of the substitutions, even though that particular substitution does not get applied.

\[\text{substitute}(^{*}\text{args},^{**}\text{kwds})\]

Substitute the given subexpressions in this expression.

\[\text{EXAMPLES:}\]

\[\text{sage: var(}'x{',',y,z,a,b,c,d,f,g'}{')}\]
\[(x, y, z, a, b, c, d, f, g)\]
\[\text{sage: w0 = SR.wild(0); w1 = SR.wild(1)}\]
\[\text{sage: t = a^2 + b^2 + (x+y)^3}\]

Substitute with keyword arguments (works only with symbols):

\[\text{sage: t.subs(a=c)}\]
\[(x + y)^3 + b^2 + c^2\]
\[\text{sage: t.subs(b=19, x=z)}\]
\[(y + z)^3 + a^2 + 361\]

Substitute with a dictionary argument:

\[\text{sage: t.subs({a^2: c})}\]
\[(x + y)^3 + b^2 + c\]
\[\text{sage: t.subs({w0^2: w0^3})}\]
\[a^3 + b^2 + (x + y)^3\]

Substitute with one or more relational expressions:
Symbolic Calculus, Release 10.1

```
sage: t.subs(w0^2 == w0^3)
a^3 + b^3 + (x + y)^3

sage: t.subs(w0 == w0^2)
a^8 + b^8 + (x^2 + y^2)^6

sage: t.subs(a == b, b == c)
(x + y)^3 + b^2 + c^2
```

Any number of arguments is accepted:

```
sage: t.subs(a=b, b=c)
(x + y)^3 + b^2 + c^2

sage: t.subs({a:b}, b=c)
(x + y)^3 + b^2 + c^2

sage: t.subs([x == 3, y == 2], a == 2, {b:3})
138
```

It can even accept lists of lists:

```
sage: eqn1 = (a*x + b*y == 0)
sage: eqn2 = (1 + y == 0)
sage: soln = solve([eqn1, eqn2], [x, y])
sage: soln
[[x == b/a, y == -1]]
sage: f = x + y
sage: f.subs(soln)
b/a - 1
```

Duplicate assignments will throw an error:

```
sage: t.subs({a:b}, a=c)
Traceback (most recent call last):
  ...
ValueError: duplicate substitution for a, got values b and c
```

```
sage: t.subs([x == 1], a = 1, b = 2, x = 2)
Traceback (most recent call last):
  ...
ValueError: duplicate substitution for x, got values 1 and 2
```

All substitutions are performed at the same time:

```
sage: t.subs({a:b, b:c})
(x + y)^3 + b^2 + c^2
```

Substitutions are done term by term, in other words Sage is not able to identify partial sums in a substitution (see github issue #18396):

```
sage: f = x + x^2 + x^4
sage: f.subs(x = y)
y^4 + y^2 + y
```

(continues on next page)
Note that it is the very same behavior as in Maxima:

```python
sage: E = 'x^4 + x^2 + x'
sage: subs = [('x','y'), ('x^2','y'), ('x^2+x','y'), ('x^4+x^2+x','y')]
sage: cmd = '{}{}, {}={}'
sage: for s1,s2 in subs:
    ....:    maxima.eval(cmd.format(E, s1, s2))
    'y^4+y^2+y'
    'y+x^4+x'
    'x^4+x^2+x'
    'y'
```

Or as in Maple:

```python
sage: cmd = 'subs({}, {}={})'                     # optional - maple
sage: for s1,s2 in subs:                         # optional - maple
    ....:    maple.eval(cmd.format(s1, s2, E))
    'y^4+y^2+y'
    'x^4+x+y'
    'x^4+x^2+x'
    'y'
```

But Mathematica does something different on the third example:

```python
sage: cmd = '{} /. {} -> {}'                      # optional - mathematica
sage: for s1,s2 in subs:                         # optional - mathematica
    ....:    mathematica.eval(cmd.format(E,s1,s2))
    2  y + y + y
    4
    x + x + y
    4
    x + y
    y
```

The same, with formatting more suitable for cut and paste:

```python
sage: for s1,s2 in subs:                         # optional - mathematica
    ....:    mathematica(cmd.format(E,s1,s2))
    y + y^2 + y^4
    x + x^4 + y
    x^4 + y
    y
```
**Symbolic Calculus, Release 10.1**

---

**Warning:** Unexpected results may occur if the left-hand side of some substitution is not just a single variable (or is a “wildcard” variable). For example, the result of \( \cos(\cos(\cos(x))) \).subs({\( \cos(x) \) : \( x \)}) is \( x \), because the substitution is applied repeatedly. Such repeated substitutions (and pattern-matching code that may be somewhat unpredictable) are disabled only in the basic case where the left-hand side of every substitution is a variable. In particular, although the result of \( (x^2) \).subs({\( x \) : \( \sqrt{x} \)}) is \( x \), the result of \( (x^2) \).subs({\( x \) : \( \sqrt{x} \), \( y^2 \) : \( y \)}) is \( \sqrt{x} \), because repeated substitution is enabled by the presence of the expression \( y^2 \) in the left-hand side of one of the substitutions, even though that particular substitution does not get applied.

---

**substitute_function(**\*args, **kwds)**

Substitute the given functions by their replacements in this expression.

**EXAMPLES:**

```python
sage: x, y = var('x,y')
sage: foo = function('foo'); bar = function('bar')
sage: f = foo(x) + 1/foo(pi*y)
```

Substitute with a dictionary:

```python
sage: f.substitute_function({foo: bar})
1/bar(pi*y) + bar(x)
sage: f.substitute_function({foo(x): bar(x)})
1/bar(pi*y) + bar(x)
```

If the function expression to be substituted includes its arguments, the right hand side can be an arbitrary symbolic expression:

```python
sage: f.substitute_function({foo(x): x^2})
x^2 + 1/(pi^2*y^2)
```

Substitute with keyword arguments (works only if no function arguments are given):

```python
sage: f.substitute_function(foo=bar)
1/bar(pi*y) + bar(x)
```

Substitute with a relational expression:

```python
sage: f.substitute_function(foo(x)==bar(x))
1/bar(pi*y) + bar(x)
sage: f.substitute_function(foo(x)==bar(x+1))
1/bar(pi*y + 1) + bar(x + 1)
```

All substitutions are performed at the same time:

```python
sage: g = foo(x) + 1/bar(pi*y)
sage: g.substitute_function({foo: bar, bar: foo})
1/foo(pi*y) + bar(x)
```

Any number of arguments is accepted:

```python
sage: g.substitute_function({foo: bar}, bar(x) == x^2)
1/(pi^2*y^2) + bar(x)
```
As well as lists of substitutions:

```
sage: g.substitute_function([foo(x) == 1, bar(x) == x])
1/(pi*y) + 1
```

Alternative syntax:

```
sage: g.substitute_function(foo, bar)
1/bar(pi*y) + bar(x)
```

Duplicate assignments will throw an error:

```
sage: g.substitute_function({foo:bar}, foo(x) == x^2)
Traceback (most recent call last):
...  
ValueError: duplicate substitution for foo, got values bar and x |--> x^2
```

```
sage: g.substitute_function([foo(x) == x^2], foo = bar)
Traceback (most recent call last):
...
ValueError: duplicate substitution for foo, got values x |--> x^2 and bar
```

`substitution_delayed(pattern, replacement)`

Replace all occurrences of pattern by the result of replacement.

In contrast to `subs()`, the pattern may contain wildcards and the replacement can depend on the particular term matched by the pattern.

**INPUT:**

- `pattern` – an `Expression`, usually containing wildcards.
- `replacement` – a function. Its argument is a dictionary mapping the wildcard occurring in `pattern` to the actual values. If it returns `None`, this occurrence of `pattern` is not replaced. Otherwise, it is replaced by the output of `replacement`.

**OUTPUT:**

An `Expression`.

**EXAMPLES:**

```
sage: var('x y')
(x, y)
sage: w0 = SR.wild(0)
sage: sqrt(1 + 2*x + x^2).substitution_delayed(
    ....:     sqrt(w0),
    ....:     lambda d: sqrt(factor(d[w0])))
    ....:     )
sqrt((x + 1)^2)
sage: def r(d):
    ....:     if x not in d[w0].variables():
    ....:         return cos(d[w0])
    ....:     (sin(x^2 + x) + sin(y^2 + y)).substitution_delayed(sin(w0), r)
cos(y^2 + y) + sin(x^2 + x)
```

See also:

`match()`
**subtract_from_both_sides(x)**

Return a relation obtained by subtracting \( x \) from both sides of this relation.

**EXAMPLES:**

```
sage: eqn = x*sin(x)*sqrt(3) + sqrt(2) > cos(sin(x))
sage: eqn.subtract_from_both_sides(sqrt(2))
sqrt(3)*x*sin(x) > -sqrt(2) + cos(sin(x))
sage: eqn.subtract_from_both_sides(cos(sin(x)))
sqrt(3)*x*sin(x) + sqrt(2) - cos(sin(x)) > 0
```

**sum(*args, **kwds)**

Return the symbolic sum \( \sum_{v=a}^{b} self \)

with respect to the variable \( v \) with endpoints \( a \) and \( b \).

**INPUT:**

- \( v \) - a variable or variable name
- \( a \) - lower endpoint of the sum
- \( b \) - upper endpoint of the sum
- \( \text{algorithm} \) - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'maple' - (optional) use Maple
  - 'mathematica' - (optional) use Mathematica
  - 'giac' - (optional) use Giac
  - 'sympy' - use SymPy

**EXAMPLES:**

```
sage: k, n = var('k,n')
sage: k.sum(k, 1, n).factor()
1/2*(n + 1)*n

sage: (1/k^4).sum(k, 1, oo)
1/90*pi^4

sage: (1/k^5).sum(k, 1, oo)
zeta(5)

A well known binomial identity:

```
sage: assume(n>=0)
sage: binomial(n,k).sum(k, 0, n)
2^n
```

And some truncations thereof:

```
sage: binomial(n,k).sum(k,1,n)
2^n - 1

sage: binomial(n,k).sum(k,2,n)
```

(continues on next page)
The binomial theorem:

\[
sage: x, y = var('x, y')
\]

\[
sage: (\text{binomial}(n,k) * x^k * y^{n-k}).\text{sum}(k, 0, n)
\]

\[(x + y)^n\]

\[
\text{sage: } (k * \text{binomial}(n, k)).\text{sum}(k, 1, n)
\]

\[2^n - 2\]

\[
\text{sage: } (\text{binomial}(n,k) \cdot \text{factorial}(k) / \text{factorial}(n+1+k)).\text{sum}(k, 0, n)
\]

\[1/2 * \sqrt{\pi} / \text{factorial}(n + 1/2)\]

We check a well known identity:

\[
\text{sage: } \text{bool}(\text{sum}(k^3, 1, n) == k\cdot\text{sum}(k, 1, n)^2)
\]

True

A geometric sum:

\[
\text{sage: } a, q = var('a, q')
\]

\[
\text{sage: } (a*q^k).\text{sum}(k, 0, n)
\]

\[(a^q^k(1 - a)) / (q - 1)\]

The geometric series:

\[
\text{sage: } \text{assume(abs}(q < 1))
\]

\[
\text{sage: } (a^q^k).\text{sum}(k, 0, oo)
\]

\[-a / (q - 1)\]

A divergent geometric series. Do not forget to \textit{forget} your assumptions:

\[
\text{sage: } \text{forget()}
\]

\[
\text{sage: } \text{assume}(q > 1)
\]

\[
\text{sage: } (a^q^k).\text{sum}(k, 0, oo)
\]

Traceback (most recent call last):
...
ValueError: Sum is divergent.
Symbolic Calculus, Release 10.1

```
sage: (1/(1+k^2)).sum(k, -oo, oo, algorithm = 'mathematica')  # optional -w
     → mathematica
pi*coth(pi)
```

Use Giac to perform this summation:

```
sage: (sum(1/(1+k^2), k, -oo, oo, algorithm = 'giac')).factor()
     → giac
pi*(e^(2*pi) + 1)/((e^pi + 1)*(e^pi - 1))
```

Use Maple as a backend for summation:

```
sage: (binomial(n,k)*x^k).sum(k, 0, n, algorithm = 'maple')  # optional -w
     → maple
(x + 1)^n
```

Note:

1. Sage can currently only understand a subset of the output of Maxima, Maple and Mathematica, so even if the chosen backend can perform the summation the result might not be convertible into a usable Sage expression.

**tan**

Examples:

```
sage: var('x, y')
(x, y)
sage: tan(x^2 + y^2)
      → x^2 + y^2
sage: tan(sage.symbolic.constants.pi/2)
Infinity
sage: tan(SR(1))
tan(1)
sage: tan(SR(RealField(150)(1)))
1.5574077246549022305069748074583601730872508
```

To prevent automatic evaluation use the **hold** argument:

```
sage: (pi/12).tan
-sqrt(3) + 2
sage: (pi/12).tan(hold=True)
tan(1/12*pi)
```

This also works using functional notation:

```
sage: tan(pi/12,hold=True)
tan(1/12*pi)
sage: tan(pi/12)
-sqrt(3) + 2
```

To then evaluate again, we use **unhold()**:

```
sage: a = (pi/12).tan(hold=True); a.unhold()
-sqrt(3) + 2
```
\texttt{tanh(\textit{hold}=False)}

Return \texttt{tanh} of self.

We have \( \text{tanh}(x) = \frac{\sinh(x)}{\cosh(x)} \).

EXAMPLES:

\begin{verbatim}
sage: x.tanh()
tanh(x)
sage: SR(1).tanh()
tanh(1)
sage: SR(0).tanh()
0
sage: SR(1.0).tanh()
0.761594155955765
sage: maxima('tanh(1.0)')
0.7615941559557649
sage: plot(lambda x: SR(x).tanh(), -1, 1)
Graphics object consisting of 1 graphics primitive
\end{verbatim}

To prevent automatic evaluation use the \texttt{hold} argument:

\begin{verbatim}
sage: arcsinh(x).tanh()
x/sqrt(x^2 + 1)
sage: arcsinh(x).tanh(hold=True)
tanh(arcsinh(x))
\end{verbatim}

This also works using functional notation:

\begin{verbatim}
sage: tanh(arcsinh(x),hold=True)
tanh(arcsinh(x))
sage: tanh(arcsinh(x))
x/sqrt(x^2 + 1)
\end{verbatim}

To then evaluate again, we use \texttt{unhold()}:

\begin{verbatim}
sage: a = arcsinh(x).tanh(hold=True); a.unhold()
x/sqrt(x^2 + 1)
\end{verbatim}

\texttt{taylor(*args)}

Expand this symbolic expression in a truncated Taylor or Laurent series in the variable \( v \) around the point \( a \), containing terms through \((x - a)^n\). Functions in more variables is also supported.

\textbf{INPUT:}

- \texttt{*args} - the following notation is supported
  - \( x, a, n \) - variable, point, degree
  - \((x, a), (y, b), n\) - variables with points, degree of polynomial

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var('a, x, z')
(a, x, z)
sage: taylor(a^log(z), z, 2, 3)
1/24*a*(z - 2)^3 - 1/8*a*(z - 2)^2 + 1/2*a*(z - 2) + a*log(2)
\end{verbatim}
Symbolic Calculus, Release 10.1

\[
sage: \text{taylor}(\sqrt{\sin(x) + a \cdot x + 1}), x, 0, 3
\]
\[
\frac{1}{48} (3 a^3 + 9 a^2 + 9 a - 1) x^3 - \frac{1}{8} (a^2 + 2 a + 1) x^2 + \frac{1}{2} (a + 1) x + 1
\]

\[
sage: \text{taylor}(\sqrt{x + 1}), x, 0, 5
\]
\[
\frac{7}{256} x^5 - \frac{5}{128} x^4 + \frac{11}{16} x^3 - \frac{1}{8} x^2 + \frac{1}{2} x + 1
\]

\[
sage: \text{taylor}(\frac{1}{\log(x + 1)}), x, 0, 3
\]
\[
-\frac{19}{720} x^3 + \frac{1}{12} x^2 - \frac{1}{x} + 1/2
\]

\[
sage: \text{taylor} (\cos(x) - \sec(x)), x, 0, 5
\]
\[
-\frac{1}{6} x^4 - x^2
\]

\[
sage: \text{taylor} ((\cos(x) - \sec(x))^3), x, 0, 9
\]
\[
-15377/7983360 x^4 - 6767/604800 x^2 + 11/120/x^2 + 1/2/x^4 - 1/x^6 - 347/15120
\]

`test_relation(ntests=20, domain=None, proof=True)`

Test this relation at several random values, attempting to find a contradiction. If this relation has no variables, it will also test this relation after casting into the domain.

Because the interval fields never return false positives, we can be assured that if True or False is returned (and proof is False) then the answer is correct.

**INPUT:**

- `ntests` – (default 20) the number of iterations to run
- `domain` – (optional) the domain from which to draw the random values defaults to CIF for equality testing and RIF for order testing
- `proof` – (default True) if False and the domain is an interval field, regard overlapping (potentially equal) intervals as equal, and return True if all tests succeeded.

**OUTPUT:**

Boolean or `NotImplemented`, meaning

- **True** – this relation holds in the domain and has no variables.
- **False** – a contradiction was found.
- **NotImplemented** – no contradiction found.

**EXAMPLES:**

\[
sage: (3 < pi).test_relation()
\]
```
True
```

\[
sage: (0 >= pi).test_relation()
\]
```
False
```

\[
sage: (exp(pi) - pi).n()
\]
```
19.999999999999996
```

\[
sage: (exp(pi) - pi == 20).test_relation()
\]
```
False
```

\[
sage: (\sin(x)^2 + \cos(x)^2 == 1).test_relation()
\]
```
NotImplemented
```

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```python
sage: (sin(x)^2 + cos(x)^2 == 1).test_relation(proof=False)
True
sage: (x == 1).test_relation()
False
sage: var('x,y')
(x, y)
sage: (x < y).test_relation()
False
```

**to_gamma()**

Convert factorial, binomial, and Pochhammer symbol expressions to their gamma function equivalents.

**EXAMPLES:**

```python
sage: m,n = var('m n', domain='integer')
sage: factorial(n).to_gamma()
gamma(n + 1)
sage: binomial(m,n).to_gamma()
gamma(m + 1)/(gamma(m - n + 1)*gamma(n + 1))
```

**trailing_coeff(s)**

Return the trailing coefficient of s in self, i.e., the coefficient of the smallest power of s in self.

**EXAMPLES:**

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.trailing_coefficient(x)
2*sin(x*y)
sage: f.trailing_coefficient(y)
x
sage: f.trailing_coefficient(sin(x*y))
a*x + x*y + x/y + 100
```

**trailing_coefficient(s)**

Return the trailing coefficient of s in self, i.e., the coefficient of the smallest power of s in self.

**EXAMPLES:**

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.trailing_coefficient(x)
2*sin(x*y)
sage: f.trailing_coefficient(y)
x
sage: f.trailing_coefficient(sin(x*y))
a*x + x*y + x/y + 100
```

**trig_expand**(full=False, half_angles=False, plus=True, times=True)

Expand trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in self.
For best results, self should already be expanded.

INPUT:

- **full** – (default: False) To enhance user control of simplification, this function expands only one level at a time by default, expanding sums of angles or multiple angles. To obtain full expansion into sines and cosines immediately, set the optional parameter full to True.

- **half_angles** - (default: False) If True, causes half-angles to be simplified away.

- **plus** – (default: True) Controls the sum rule; expansion of sums (e.g. sin(x + y)) will take place only if plus is True.

- **times** – (default: True) Controls the product rule, expansion of products (e.g. sin(2x)) will take place only if times is True.

OUTPUT:

A symbolic expression.

EXAMPLES:

```sage
sage: sin(5*x).expand_trig()
sin(5*x)
```

```sage
sage: cos(2*x + var('y')).expand_trig()
cos(2*x)*cos(y) - sin(2*x)*sin(y)
```

We illustrate various options to this function:

```sage
sage: f = sin(sin(3*cos(2*x))*x)
sage: f.expand_trig()  # default
sin((3*cos(3*cos(2*x))*x)^2*sin(3*cos(2*x))*x) - sin(3*cos(2*x))^2*x)
```

```sage
sage: f.expand_trig(full=True)
sin((3*cos(3*cos(2*x))^2*cos(3*cos(2*x))^2 + sin(3*cos(2*x))^2*sin(3*cos(2*x))^2))^2
```

```sage
sage: sin(2*x).expand_trig(times=False)
sin(2*x)
```

```sage
sage: sin(2*x).expand_trig(times=True)
2*cos(x)*sin(x)
```

```sage
sage: sin(x/2).expand_trig(half_angles=False)
sin(x/2)
```

```sage
sage: sin(x/2).expand_trig(half_angles=True)
(-1)^floor(1/2*x/pi)*sqrt(-1/2*cos(x) + 1/2)
```

If the expression contains terms which are factored, we expand first:

```sage
sage: (x, k1, k2) = var('x, k1, k2')
sage: cos((k1-k2)^2*x).expand().expand_trig()
cos(k1*x)*cos(k2*x) + sin(k1*x)*sin(k2*x)
```

ALIAS:

trig_expand() and expand_trig() are the same
**trig_reduce** *(var=None)*

Combine products and powers of trigonometric and hyperbolic sin’s and cos’s of \(x\) into those of multiples of \(x\). It also tries to eliminate these functions when they occur in denominators.

**INPUT:**
- `self` - a symbolic expression
- `var` - (default: None) the variable which is used for these transformations. If not specified, all variables are used.

**OUTPUT:**
A symbolic expression.

**EXAMPLES:**

```sage
y = var('y')
f = sin(x)*cos(x)^3+sin(y)^2
f.reduce_trig()
```

To reduce only the expressions involving \(x\) we use optional parameter:

```sage
f.reduce_trig(x)
```

**ALIAS:** `trig_reduce()` and `reduce_trig()` are the same

---

**trig_simplify** *(expand=True)*

Optionally expand and then employ identities such as \(\sin(x)^2 + \cos(x)^2 = 1\), \(\cosh(x)^2 - \sinh(x)^2 = 1\), \(\sin(x) \csc(x) = 1\), or \(\tanh(x) = \sinh(x)/\cosh(x)\) to simplify expressions containing tan, sec, etc., to sin, cos, sinh, cosh.

**INPUT:**
- `self` - symbolic expression
- `expand` - (default: True) if True, expands trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in `self` first. For best results, `self` should be expanded. See also `expand_trig()` to get more controls on this expansion.

**ALIAS:** `trig_simplify()` and `simplify_trig()` are the same

**EXAMPLES:**

```sage
f = sin(x)^2 + cos(x)^2; f
f.simplify_trig()
h = sin(x)*csc(x)
h.simplify_trig()
k = tanh(x)*cosh(2*x)
k.simplify_trig()
```

In some cases we do not want to expand:
**Symbolic Calculus, Release 10.1**

```python
sage: f = tan(3*x)
sage: f.simplify_trig()
-(4*cos(x)^2 - 1)*sin(x)/(4*cos(x)*sin(x)^2 - cos(x))
sage: f.simplify_trig(False)
sin(3*x)/cos(3*x)
```

**truncate()**

Given a power series or expression, return the corresponding expression without the big oh.

INPUT:

- `self` – a series as output by the `series()` command.

OUTPUT:

A symbolic expression.

EXAMPLES:

```python
sage: f = sin(x)/x^2
sage: f.truncate()
sin(x)/x^2
sage: f.series(x,7)
1*x^(-1) + (-1/6)*x + 1/120*x^3 + (-1/5040)*x^5 + Order(x^7)
sage: f.series(x,7).truncate()
-1/5040*x^5 + 1/120*x^3 - 1/6*x + 1/x
sage: f.series(x==1,3).truncate().expand()
-2*x^2*cos(1) + 5/2*x^2*sin(1) + 5*x*cos(1) - 7*x*sin(1) - 3*cos(1) + 11/2*sin(1)
```

**unhold(exclude=None)**

Evaluates any held operations (with the `hold` keyword) in the expression

INPUT:

- `self` – an expression with held operations
- `exclude` – (default: None) a list of operators to exclude from evaluation. Excluding arithmetic operators does not yet work (see github issue #10169).

OUTPUT:

A new expression with held operations, except those in `exclude`, evaluated

EXAMPLES:

```python
sage: a = exp(I * pi, hold=True)
sage: a
e^(I*pi)
sage: a.unhold()
-1
sage: b = x.add(x, hold=True)
sage: b
x + x
sage: b.unhold()
2*x
sage: (a + b).unhold()
2*x - 1
```

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```
sage: c = (x.mul(x, hold=True)).add(x.mul(x, hold=True), hold=True)
sage: c
x*x + x*x
sage: c.unhold()
2*x^2
sage: sin(tan(0, hold=True), hold=True).unhold()
0
sage: sin(tan(0, hold=True), hold=True).unhold(exclude=[sin])
sin(0)
sage: (e^sgn(0, hold=True)).unhold()
e^0
sage: log(3).unhold()
log(3)
```

**unit(s)**

Return the unit of this expression when considered as a polynomial in s.

See also `content()`, `primitive_part()`, and `unit_content_primitive()`.

**INPUT:**

- s – a symbolic expression.

**OUTPUT:**

The unit part of a polynomial as a symbolic expression. It is defined as the sign of the leading coefficient.

**EXAMPLES:**

```
sage: (2*x+4).unit(x)
1
sage: (-2*x+1).unit(x)
-1
sage: (2*x+1/2).unit(x)
1
sage: var('y')
y
sage: (2*x - 4*sin(y)).unit(sin(y))
-1
```

**unit_content_primitive(s)**

Return the factorization into unit, content, and primitive part.

**INPUT:**

- s – a symbolic expression, usually a symbolic variable. The whole symbolic expression `self` will be considered as a univariate polynomial in s.

**OUTPUT:**

A triple `(unit, content, primitive polynomial)` containing the `unit`, `content`, and `primitive polynomial`. Their product equals `self`.

**EXAMPLES:**
Symbolic Calculus, Release 10.1

```python
sage: var('x,y')
(x, y)
sage: ex = 9*x^3*y+3*y
sage: ex.unit_content_primitive(x)
(1, 3*y, 3*x^3 + 1)
sage: ex.unit_content_primitive(y)
(1, 9*x^3 + 3, y)
```

**variables()**

Return sorted tuple of variables that occur in this expression.

**EXAMPLES:**

```python
sage: (x,y,z) = var('x,y,z')
sage: (x+y).variables()
(x, y)
sage: (2*x).variables()
(x,)
sage: (x*y).variables()
(x, y)
sage: sin(x+y^z).variables()
(x, y, z)
```

**zeta** *(hold=False)*

**EXAMPLES:**

```python
sage: x, y = var('x, y')
sage: (x/y).zeta()
zeta(x/y)
sage: SR(2).zeta()
1/6*pi^2
sage: SR(3).zeta()
zeta(3)
sage: SR(CDF(0,1)).zeta()  # abs tol 1e-16
0.003300223685324103 - 0.4181554491413217*I
sage: CDF(0,1).zeta()  # abs tol 1e-16
0.003300223685324103 - 0.4181554491413217*I
sage: plot(lambda x: SR(x).zeta(), -10,10).show(ymin=-3,ymax=3)
```

To prevent automatic evaluation use the hold argument:

```python
sage: SR(2).zeta(hold=True)
zeta(2)
```

This also works using functional notation:

```python
sage: zeta(2,hold=True)
zeta(2)
sage: zeta(2)
1/6*pi^2
```

To then evaluate again, we use `unhold()`:

```python
```
```python
sage: a = SR(2).zeta(hold=True); a.unhold()
1/6*pi^2
```

```python
class sage.symbolic.expression.ExpressionIterator
   Bases: object

class sage.symbolic.expression.OperandsWrapper
   Bases: SageObject

   Operands wrapper for symbolic expressions.

   EXAMPLES:

```python
sage: x,y,z = var('x,y,z')
sage: e = x + x*y + z^y + 3*y*z; e
x*y + 3*y*z + x + z^y
sage: e.op[1]
3*y*z
sage: e.op[1,1]
z
sage: e.op[-1]
z^y
sage: e.op[1:]
[3*y*z, x, z^y]
sage: e.op[:2]
[x, 3*y*z]
sage: e.op[-2:]
[x, z^y]
sage: e.op[:-2]
[3*y*z, x]
sage: e.op[-5]
Traceback (most recent call last):

```

```python
class sage.symbolic.expression.PynacConstant
   Bases: object
```

### 2.1. Symbolic Expressions

131
**symbolic.calculus**

**expression()**

Returns this constant as an Expression.

EXAMPLES:

```
sage: from sage.symbolic.expression import PynacConstant
sage: f = PynacConstant('foo', 'foo', 'real')
sage: f + 2
Traceback (most recent call last):
  ...TypeError: unsupported operand parent(s) for +: '<class 'sage.symbolic.expression.PynacConstant'>' and 'Integer Ring'
sage: foo = f.expression(); foo
foo
sage: foo + 2
foo + 2
```

**name()**

Returns the name of this constant.

EXAMPLES:

```
sage: from sage.symbolic.expression import PynacConstant
sage: f = PynacConstant('foo', 'foo', 'real')
sage: f.name()
'foo'
```

**serial()**

Returns the underlying Pynac serial for this constant.

EXAMPLES:

```
sage: from sage.symbolic.expression import PynacConstant
sage: f = PynacConstant('foo', 'foo', 'real')
sage: f.serial()  #random
15
```

**class** `sage.symbolic.expression.SubstitutionMap`

Bases: `SageObject`

**apply_to(expr, options)**

Apply the substitution to a symbolic expression

EXAMPLES:

```
sage: from sage.symbolic.expression import make_map
sage: subs = make_map({x:x+1})
sage: subs.apply_to(x^2, 0)
(x + 1)^2
```

**class** `sage.symbolic.expression.SymbolicSeries`

Bases: `Expression`

Trivial constructor.

EXAMPLES:
coefficients($x=None, \text{sparse}=\text{True}$)

Return the coefficients of this symbolic series as a list of pairs.

**INPUT:**
- $x$ – optional variable.
- \text{sparse} – Boolean. If \text{False} return a list with as much entries as the order of the series.

**OUTPUT:**
Depending on the value of \text{sparse},
- A list of pairs $(\text{expr}, n)$, where \text{expr} is a symbolic expression and $n$ is a power (\text{sparse}=\text{True}, default)
- A list of expressions where the $n$-th element is the coefficient of $x^n$ when self is seen as polynomial in $x$ (\text{sparse}=\text{False}).

**EXAMPLES:**

```python
sage: s = (1/(1-x)).series(x,6); s
1 + 1*x + 1*x^2 + 1*x^3 + 1*x^4 + 1*x^5 + Order(x^6)
sage: s.coefficients()
[[1, 0], [1, 1], [1, 2], [1, 3], [1, 4], [1, 5]]
sage: s.coefficients(x, sparse=\text{False})
[1, 1, 1, 1, 1, 1]
sage: x,y = var("x,y")
sage: s = (1/(1-y^2-x)).series(x,3); s
1 + (y + 1)*x + ((y + 1)^2)*x^2 + Order(x^3)
sage: s.coefficients(x, sparse=\text{False})
[1, y + 1, (y + 1)^2]
```

default_variable()

Return the expansion variable of this symbolic series.

**EXAMPLES:**

```python
sage: s = (1/(1-x)).series(x,3); s
1 + 1*x + 1*x^2 + Order(x^3)
sage: s.default_variable()
x
```

is_terminating_series()

Return \text{True} if the series is without order term.

A series is terminating if it can be represented exactly, without requiring an order term. You can explicitly request terminating series by setting the order to positive infinity.

**OUTPUT:**
Boolean. \text{True} if the series has no order term.

**EXAMPLES:**

```python
```
Symbolic Calculus, Release 10.1

```latex
\begin{verbatim}
sage: (x^5+x^2+1).series(x, +oo)
1 + 1*x^2 + 1*x^5
sage: (x^5+x^2+1).series(x, +oo).is_terminating_series()
True
sage: SR(5).is_terminating_series()
False
sage: exp(x).series(x,10).is_terminating_series()
False
\end{verbatim}
```

**power_series(base_ring)**

Return the algebraic power series associated to this symbolic series.

The coefficients must be coercible to the base ring.

**EXAMPLES:**

```latex
\begin{verbatim}
sage: ex = (gamma(1-x)).series(x,3); ex
1 + euler_gamma*x + (1/2*euler_gamma^2 + 1/12*pi^2)*x^2 + Order(x^3)
sage: g = ex.power_series(SR); g
1 + euler_gamma*x + (1/2*euler_gamma^2 + 1/12*pi^2)*x^2 + O(x^3)
sage: g.parent()
Power Series Ring in x over Symbolic Ring
\end{verbatim}
```

**truncate()**

Given a power series or expression, return the corresponding expression without the big oh.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```latex
\begin{verbatim}
sage: f = sin(x)/x^2
sage: f.truncate()
\sin(x)/x^2
sage: f.series(x,7)
1*x^(-1) + (-1/6)*x + 1/120*x^3 + (-1/5040)*x^5 + Order(x^7)
sage: f.series(x,7).truncate()
-1/5040*x^5 + 1/120*x^3 - 1/6*x + 1/x
sage: f.series(x==1,3).truncate().expand()
-2*x^2*cos(1) + 5/2*x^2*sin(1) + 5*x*cos(1) - 7*x*sin(1) - 3*cos(1) + 11/2*sin(1)
\end{verbatim}
```

**sage.symbolic.expression.call_registered_function**(*serial*, *nargs*, *args*, *hold*, *allow_numeric_result*, *result_parent*)

Call a function registered with Pynac (GiNaC).

**INPUT:**

- `serial` - serial number of the function
- `nargs` - declared number of args (0 is variadic)
- `args` - a list of arguments to pass to the function; each must be an `Expression`
- `hold` - whether to leave the call unevaluated
- `allow_numeric_result` - if True, keep numeric results numeric; if False, make all results symbolic expressions
• result_parent - an instance of SymbolicRing

EXAMPLES:

```
sage: from sage.symbolic.expression import find_registered_function, call_registered_function
sage: s_arctan = find_registered_function('arctan', 1)
sage: call_registered_function(s_arctan, 1, [SR(1)], False, True, SR)
1/4*pi
sage: call_registered_function(s_arctan, 1, [SR(1)], True, True, SR)
arctan(1)
sage: call_registered_function(s_arctan, 1, [SR(0)], False, True, SR)
0
sage: call_registered_function(s_arctan, 1, [SR(0)], False, False, SR).parent()
Integer Ring
sage: call_registered_function(s_arctan, 1, [SR(0)], True, False, SR).parent()
Symbolic Ring
```

```
sage.symbolic.expression.doublefactorial(n)
The double factorial combinatorial function:

\[ n!! = n \times (n-2) \times (n-4) \times \ldots \times \{1,2\} \text{ with } 0!! = (-1)!! = 1. \]

INPUT:

• n - an integer \( \geq 1 \)

EXAMPLES:

```
sage: from sage.symbolic.expression import doublefactorial
sage: doublefactorial(-1)
1
sage: doublefactorial(0)
1
sage: doublefactorial(1)
1
sage: doublefactorial(5)
15
sage: doublefactorial(20)
3715891200
sage: prod([20,18,...,2])
3715891200
```

```
sage.symbolic.expression.find_registered_function(name, nargs)
Look up a function registered with Pynac (GiNaC).
Raise a ValueError if the function is not registered.

OUTPUT:

• serial number of the function, for use in call_registered_function()

EXAMPLES:

```
sage: from sage.symbolic.expression import find_registered_function
sage: find_registered_function('arctan', 1)  # random
19
sage: find_registered_function('archenemy', 1)
(continues on next page)
```

2.1. Symbolic Expressions 135
Traceback (most recent call last):
... 
ValueError: cannot find GiNaC function with name archenemy and 1 arguments

sage.symbolic.expression.get_fn_serial()
Return the overall size of the Pynac function registry which corresponds to the last serial value plus one.

EXAMPLES:

```python
sage: from sage.symbolic.expression import get_fn_serial
sage: get_fn_serial() > 125
True
sage: print(get_sfunction_from_serial(get_fn_serial()))
None
sage: get_sfunction_from_serial(get_fn_serial() - 1) is not None
True
```

sage.symbolic.expression.get_ginac_serial()
Number of C++ level functions defined by GiNaC. (Defined mainly for testing.)

EXAMPLES:

```python
sage: sage.symbolic.expression.get_ginac_serial() >= 35
True
```

sage.symbolic.expression.get_sfunction_from_hash(myhash)
Return an already created SymbolicFunction given the hash.

EXAMPLES:

```python
sage: from sage.symbolic.expression import get_sfunction_from_hash
sage: get_sfunction_from_hash(1) # random
```

sage.symbolic.expression.get_sfunction_from_serial(serial)
Return an already created SymbolicFunction given the serial.

These are stored in the dictionary sfunction_serial_dict.

EXAMPLES:

```python
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: get_sfunction_from_serial(65) #random
```

class sage.symbolic.expression.hold_class
Bases: object

Instances of this class can be used with Python with.

EXAMPLES:

```python
sage: with hold:
....:   tan(1/12*pi)
....:
```
\texttt{tan}(1/12^\pi) \\
\texttt{sage}: \texttt{tan}(1/12^\pi) \\
\quad \texttt{-sqrt}(3) + 2 \\
\texttt{sage}: \texttt{with} \ \texttt{hold}: \\
\quad \texttt{....} \quad \texttt{2}^5 \\
\quad \texttt{....} \\
\quad \texttt{32} \\
\texttt{sage}: \texttt{with} \ \texttt{hold}: \\
\quad \texttt{....} \quad \texttt{SR}(2)^5 \\
\quad \texttt{....} \\
\quad \texttt{2}^5 \\
\texttt{sage}: \texttt{with} \ \texttt{hold}: \\
\quad \texttt{....} \quad \texttt{t=tan}(1/12^\pi) \\
\quad \texttt{....} \\
\texttt{sage}: \texttt{t} \\
\texttt{\tan}(1/12^\pi) \\
\texttt{sage}: \texttt{t.unhold()} \\
\quad \texttt{-sqrt}(3) + 2

\textbf{start()} \\
Start a hold context.

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage}: \texttt{hold.start()} \\
\texttt{sage}: \texttt{SR}(2)^5 \\
\quad 2^5 \\
\texttt{sage}: \texttt{hold.stop()} \\
\texttt{sage}: \texttt{SR}(2)^5 \\
\quad 32
\end{verbatim}

\textbf{stop()} \\
Stop any hold context.

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage}: \texttt{hold.start()} \\
\texttt{sage}: \texttt{SR}(2)^5 \\
\quad 2^5 \\
\texttt{sage}: \texttt{hold.stop()} \\
\texttt{sage}: \texttt{SR}(2)^5 \\
\quad 32
\end{verbatim}

\texttt{sage.symbolic.expression.} \texttt{init\_function\_table()} \\
Initializes the function pointer table in Pynac. This must be called before Pynac is used; otherwise, there will be segfaults.

\texttt{sage.symbolic.expression.} \texttt{init\_pynac\_I()} \\
Initialize the numeric I object in pynac. We use the generator of \texttt{QQ}(i).

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage}: \texttt{from sage.symbolic.constants import I as symbolic_I} \\
\texttt{sage}: \texttt{symbolic_I}
\end{verbatim}
Note that conversions to real fields will give `TypeError`:

```
sage: float(symbolic_I)
Traceback (most recent call last):
  ...  
TypeError: unable to simplify to float approximation
sage: gp(symbolic_I)
I
sage: RR(symbolic_I)
Traceback (most recent call last):
  ...
TypeError: unable to convert '1.0000000000000000000000000000000000000000000000000000000000*I' to a real number
```

We can convert to complex fields:

```
sage: C = ComplexField(200); C
Complex Field with 200 bits of precision
sage: C(symbolic_I)
1.0000000000000000000000000000000000000000000000000000000000*I
sage: symbolic_I._complex_mpfr_field_(ComplexField(53))
1.00000000000000*I
sage: symbolic_I._complex_double_(CDF)
1.0*I
sage: CDF(symbolic_I)
1.0*I
sage: z = symbolic_I + symbolic_I; z
2*I
sage: C(z)
2.0000000000000000000000000000000000000000000000000000000000*I
sage: 1e8*symbolic_I
1.00000000000000e8*I
sage: complex(symbolic_I)
1j
sage: QQbar(symbolic_I)
I
sage: abs(symbolic_I)
1
sage: symbolic_I.minpoly()
x^2 + 1
sage: maxima(2*symbolic_I)
2*%i
```

`sage.symbolic.expression.is_Expression(x)`
Return True if $x$ is a symbolic expression.

This method is deprecated. Use `isinstance()` with `sage.structure.element.Expression` instead.

EXAMPLES:

```python
sage: from sage.symbolic.expression import is_Expression
sage: is_Expression(x)
doctest:warning...
DeprecationWarning: is_Expression is deprecated; use isinstance(..., sage.structure.element.Expression) instead
See https://github.com/sagemath/sage/issues/32638 for details.
True
sage: is_Expression(2)
False
sage: is_Expression(SR(2))
True
```

`sage.symbolic.expression.is_SymbolicEquation(x)`

Return True if $x$ is a symbolic equation.

This function is deprecated.

EXAMPLES:

The following two examples are symbolic equations:

```python
sage: from sage.symbolic.expression import is_SymbolicEquation
sage: is_SymbolicEquation(sin(x) == x)
doctest:warning...
DeprecationWarning: is_SymbolicEquation is deprecated; use 'isinstance(x, sage.structure.element.Expression) and x.is_relational()' instead
See https://github.com/sagemath/sage/issues/35505 for details.
True
sage: is_SymbolicEquation(sin(x) < x)
True
sage: is_SymbolicEquation(x)
False
```

This is not, since 2==3 evaluates to the boolean False:

```python
sage: is_SymbolicEquation(2 == 3)
False
```

However here since both 2 and 3 are coerced to be symbolic, we obtain a symbolic equation:

```python
sage: is_SymbolicEquation(SR(2) == SR(3))
True
```

`sage.symbolic.expression.make_map(subs_dict)`

Construct a new substitution map

OUTPUT:

A new `SubstitutionMap` for doctesting

EXAMPLES:
Symbolic Calculus, Release 10.1

```
sage: from sage.symbolic.expression import make_map
sage: make_map({x:x+1})
SubsMap
```

**sage.symbolic.expression.math_sorted(expressions)**

Sort a list of symbolic numbers in the “Mathematics” order

**INPUT:**

- expressions – a list/tuple/iterable of symbolic expressions, or something that can be converted to one.

**OUTPUT:**

The list sorted by ascending (real) value. If an entry does not define a real value (or plus/minus infinity), or if the comparison is not known, a **ValueError** is raised.

**EXAMPLES:**

```
sage: from sage.symbolic.expression import math_sorted
sage: math_sorted([SR(1), SR(e), SR(pi), sqrt(2)])
[1, sqrt(2), e, pi]
```

**sage.symbolic.expression.mixed_order(lhs, rhs)**

Comparison in the mixed order

**INPUT:**

- lhs, rhs – two symbolic expressions or something that can be converted to one.

**OUTPUT:**

Either −1, 0, or +1 indicating the comparison. An exception is raised if the arguments cannot be converted into the symbolic ring.

**EXAMPLES:**

```
sage: from sage.symbolic.expression import mixed_order
sage: mixed_order(1, oo)
-1
sage: mixed_order(e, oo)
-1
sage: mixed_order(pi, oo)
-1
sage: mixed_order(1, sqrt(2))
-1
sage: mixed_order(x + x^2, x*(x+1))
-1
```

Check that github issue #12967 is fixed:

```
sage: mixed_order(SR(oo), sqrt(2))
1
```

Ensure that github issue #32185 is fixed:

```
sage: mixed_order(pi, 0)
1
sage: mixed_order(golden_ratio, 0)
```
sage.symbolic.expression.mixed_sorted(expressions)
Sort a list of symbolic numbers in the "Mixed" order

INPUT:

• expressions – a list/tuple/iterable of symbolic expressions, or something that can be converted to one.

OUTPUT:

In the list the numeric values are sorted by ascending (real) value, and the expressions with variables according to print order. If an entry does not define a real value (or plus/minus infinity), or if the comparison is not known, a ValueError is raised.

EXAMPLES:

```python
sage: from sage.symbolic.expression import mixed_sorted
sage: mixed_sorted([SR(1), SR(e), SR(pi), sqrt(2), x, sqrt(x), sin(1/x)])
[1, sqrt(2), e, pi, sin(1/x), sqrt(x), x]
```

sage.symbolic.expression.new_Expression(parent, x)
Convert x into the symbolic expression ring parent.

This is the element constructor.

EXAMPLES:

```python
sage: a = SR(-3/4); a
-3/4
sage: type(a)
<class 'sage.symbolic.expression.Expression'>
```

sage.symbolic.expression.new_Expression_from_pyobject(parent, x, force=True, recursive=True)
Wrap the given Python object in a symbolic expression even if it cannot be coerced to the Symbolic Ring.

INPUT:

• parent - a symbolic ring.

• x - a Python object.

• force - bool, default True, if True, the Python object is taken as is without attempting coercion or list traversal.
• recursive - bool, default True, disables recursive traversal of lists.

EXAMPLES:

```python
sage: t = SR._force_pyobject(QQ); t  # indirect doctest
Rational Field
sage: type(t)
<class 'sage.symbolic.expression.Expression'>

sage: from sage.symbolic.expression import new_Expression_from_pyobject
sage: t = new_Expression_from_pyobject(SR, 17); t
17
sage: type(t)
<class 'sage.symbolic.expression.Expression'>

sage: t2 = new_Expression_from_pyobject(SR, t, False); t2
17
sage: t2 is t
True

sage: tt = new_Expression_from_pyobject(SR, t, True); tt
17
sage: tt is t
False
```

`sage.symbolic.expression.new_Expression_symbol(parent, name=None, latex_name=None, domain=None)`

Look up or create a symbol.

EXAMPLES:

```python
sage: t0 = SR.symbol("t0")
sage: t0.conjugate()
conjugate(t0)

sage: t1 = SR.symbol("t1", domain='real')
sage: t1.conjugate()
t1

sage: t0.abs()
abs(t0)

sage: t0_2 = SR.symbol("t0", domain='positive')
sage: t0_2.abs()
t0
sage: bool(t0_2 == t0)
True
sage: t0.conjugate()
t0

sage: SR.symbol()  # temporary variable
symbol...
```

`sage.symbolic.expression.new_Expression_wild(parent, n=0)`

Return the n-th wild-card for pattern matching and substitution.
INPUT:
- parent - a symbolic ring.
- n - a nonnegative integer.

OUTPUT:
- n-th wildcard expression.

EXAMPLES:
```
sage: x,y = var('x,y')
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: pattern = sin(x)*w0*w1^2; pattern
$1^2*$0*sin(x)
sage: f = atan(sin(x)*3*x^2); f
arctan(3*x^2*sin(x))
sage: f.has(pattern)
True
sage: f.subs(pattern == x^2)
arctan(x^2)
```

sage.symbolic.expression.normalize_index_for_doctests(arg, nops)
Wrapper function to test normalize_index.

sage.symbolic.expression.paramset_from_Expression(e)
EXAMPLES:
```
sage: from sage.symbolic.expression import paramset_from_Expression
sage: f = function('f')
sage: paramset_from_Expression(f(x).diff(x))
[0]
```

sage.symbolic.expression.print_order(lhs, rhs)
Comparison in the print order

INPUT:
- lhs, rhs – two symbolic expressions or something that can be converted to one.

OUTPUT:
Either −1, 0, or +1 indicating the comparison. An exception is raised if the arguments cannot be converted into the symbolic ring.

EXAMPLES:
```
sage: from sage.symbolic.expression import print_order
sage: print_order(1, oo)
1
sage: print_order(e, oo)
-1
sage: print_order(pi, oo)
1
sage: print_order(1, sqrt(2))
1
```

Check that github issue #12967 is fixed:
sage: print_order(SR(oo), sqrt(2))
1

sage.symbolic.expression.print_sorted(expressions)
Sort a list in print order

<table>
<thead>
<tr>
<th>INPUT:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• expressions – a list/tuple/iterable of symbolic expressions, or something that can be converted to one.</td>
</tr>
</tbody>
</table>

| OUTPUT: |
| The list sorted by print_order(). |

EXAMPLES:

```python
sage: from sage.symbolic.expression import print_sorted
sage: print_sorted([SR(1), SR(e), SR(pi), sqrt(2)])
[e, sqrt(2), pi, 1]
```

sage.symbolic.expression.py_atan2_for_doctests(x, y)
Wrapper function to test py_atan2.

sage.symbolic.expression.py_denom_for_doctests(n)
This function is used to test py_denom().

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_denom_for_doctests
sage: py_denom_for_doctests(2/3)
3
```

sage.symbolic.expression.py_eval_infinity_for_doctests()
This function tests py_eval_infinity.

sage.symbolic.expression.py_eval_neg_infinity_for_doctests()
This function tests py_eval_neg_infinity.

sage.symbolic.expression.py_eval_unsigned_infinity_for_doctests()
This function tests py_eval_unsigned_infinity.

sage.symbolic.expression.py_exp_for_doctests(x)
This function tests py_exp.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_exp_for_doctests
sage: py_exp_for_doctests(CC(2))
7.38905609893065
```

sage.symbolic.expression.py_factorial_py(x)
This function is a python wrapper around py_factorial(). This wrapper is needed when we override the eval() method for GiNaC’s factorial function in sage.functions.other.Function_factorial.

sage.symbolic.expression.py_float_for_doctests(n, kwds)
This function is for testing py_float.

EXAMPLES:
Symbolic Calculus, Release 10.1

```
sage: from sage.symbolic.expression import py_float_for_doctests
sage: py_float_for_doctests(pi, {'parent':RealField(80)})
3.1415926535897932384626
sage: py_float_for_doctests(I, {'parent':RealField(80)})
1.0000000000000000000000*I
sage: py_float_for_doctests(I, {'parent':float})
1j
sage: py_float_for_doctests(pi, {'parent':complex})
(3.141592653589793+0j)
sage.symbolic.expression.py_imag_for_doctests(x)
Used for doctesting py_imag.
sage.symbolic.expression.py_is_cinteger_for_doctest(x)
Returns True if pynac should treat this object as an element of \mathbb{Z}(i).
sage.symbolic.expression.py_is_crational_for_doctest(x)
Return True if pynac should treat this object as an element of \mathbb{Q}(i).
sage.symbolic.expression.py_is_integer_for_doctests(x)
Used internally for doctesting purposes.
sage.symbolic.expression.py_latex_fderivative_for_doctests(id, params, args)
Used internally for writing doctests for certain cdef’d functions.

EXAMPLES:
```
sage: from sage.symbolic.expression import py_latex_fderivative_for_doctests as py_...
l考点_fderivative, get_ginac_serial, get_fn_serial
sage: var('x,y,z')
(x, y, z)
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_fderivative(i, (0, 1, 0, 1), (x, y^z))
\mathrm{D}_{0, 1, 0, 1}\left({\rm foo}\right)\left(x, y^{z}\right)
Test latex_name:
```
sage: foo = function('foo', nargs=2, latex_name=r'\text{bar}')
sage: for i in range(get_ginac_serial(), get_fn_serial()):
....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_fderivative(i, (0, 1, 0, 1), (x, y^z))
\text{D}_{0, 1, 0, 1}\left(\text{foo}\right)\left(x, y^{z}\right)
Test custom func:

2.1. Symbolic Expressions
sage: def my_print(self, *args): return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('foo', nargs=2, print_latex_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial())[2:]:
    if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'my args are: x, y^z'

sage.symbolic.expression.py_latex_function_pystring(id, args, fname_paren=False)

Return a string with the latex representation of the symbolic function specified by the given id applied to args.

See documentation of py_print_function_pystring for more information.

EXAMPLES:

sage: from sage.symbolic.expression import py_latex_function_pystring, get_ginac_serial, get_fn_serial
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: var('x,y,z')
(x, y, z)
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial())[2:]:
    if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'foo(x, y^z)'
sage: py_latex_function_pystring(i, (x,y^z), True)
'foo(x, y^z(\text{foo}) (x, y^z))'
sage: py_latex_function_pystring(i, (\text{int}(0),x))
'foo(0, x)'

Test latex_name:

sage: foo = function('foo', nargs=2, latex_name=r'\text{bar}')
sage: for i in range(get_ginac_serial(), get_fn_serial())[2:]:
    if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'\text{bar}(x, y^z)'

Test custom func:

sage: def my_print(self, *args): return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('foo', nargs=2, print_latex_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial())[2:]:
    if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'my args are: x, y^z'
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'my args are: x, y^z'

sage.symbolic.expression.py_latex_variable_for_doctests(x)
Internal function used so we can doctest a certain cdef’d method.

EXAMPLES:

```python
sage: x = sage.symbolic.expression.py_latex_variable_for_doctests('x')
sage: sage.symbolic.expression.py_latex_variable_for_doctests('sigma')
\sigma
```

sage.symbolic.expression.py_lgamma_for_doctests(x)
This function tests py_lgamma.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_lgamma_for_doctests
sage: py_lgamma_for_doctests(CC(I))
-0.650923199301856 - 1.87243664726243*I
```

sage.symbolic.expression.py_li2_for_doctests(x)
This function is a python wrapper so py_psi2 can be tested. The real tests are in the docstring for py_psi2.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_li2_for_doctests
sage: py_li2_for_doctests(-1.1)
-0.890838090262283
```

sage.symbolic.expression.py_li_for_doctests(x, n, parent)
This function is a python wrapper so py_li can be tested. The real tests are in the docstring for py_li.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_li_for_doctests
sage: py_li_for_doctests(0,2,float)
0.000000000000000
```

sage.symbolic.expression.py_log_for_doctests(x)
This function tests py_log.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_log_for_doctests
sage: py_log_for_doctests(CC(e))
1.00000000000000
```

sage.symbolic.expression.py_mod_for_doctests(x, n)
This function is a python wrapper so py_mod can be tested. The real tests are in the docstring for py_mod.

EXAMPLES:
sage: from sage.symbolic.expression import py_mod_for_doctests
sage: py_mod_for_doctests(5, 2)
1

sage.symbolic.expression.py_numer_for_doctests(n)
This function is used to test py_numer().

EXAMPLES:

sage: from sage.symbolic.expression import py_numer_for_doctests
sage: py_numer_for_doctests(2/3)
2

sage.symbolic.expression.py_print_fderivative_for_doctests(id, params, args)
Used for testing a cdef’d function.

EXAMPLES:

sage: from sage.symbolic.expression import py_print_fderivative_for_doctests as py_˓→print_fderivative, get_ginac_serial, get_fn_serial
sage: var('x,y,z')
(x, y, z)
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: foo = function('foo', nargs=2)

sage: for i in range(get_ginac_serial(), get_fn_serial()):
....:     if get_sfunction_from_serial(i) == foo: break

sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_fderivative(i, (0, 1, 0, 1), (x, y^z))
D[0, 1, 0, 1](foo)(x, y^z)

Test custom print function:

sage: def my_print(self, *args): return "func_with_args(" + ', '.join(map(repr,˓→args)) + ")"

sage: foo = function('foo', nargs=2, print_func=my_print)

sage: for i in range(get_ginac_serial(), get_fn_serial()):
....:     if get_sfunction_from_serial(i) == foo: break

sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_fderivative(i, (0, 1, 0, 1), (x, y^z))
D[0, 1, 0, 1]func_with_args(x, y^z)

sage.symbolic.expression.py_print_function_pystring(id, args, fname_paren=False)
Return a string with the representation of the symbolic function specified by the given id applied to args.

INPUT:

• id – serial number of the corresponding symbolic function
• params – Set of parameter numbers with respect to which to take the derivative.
• args – arguments of the function.

EXAMPLES:
sage: from sage.symbolic.expression import py_print_function_pystring, get_ginac_serial, get_fn_serial
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: var('x,y,z')
(x, y, z)
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_function_pystring(i, (x,y))
'foo(x, y)'
sage: py_print_function_pystring(i, (x,y), True)
'(foo)(x, y)'
sage: def my_print(self, *args):
    return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('foo', nargs=2, print_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_function_pystring(i, (x,y))
'my args are: x, y'

sage.symbolic.expression.py_psi2_for_doctests(n, x)
This function is a python wrapper so py_psi2 can be tested. The real tests are in the docstring for py_psi2.

EXAMPLES:

```
sage: from sage.symbolic.expression import py_psi2_for_doctests
sage: py_psi2_for_doctests(1, 2)
0.644934066848226
```

sage.symbolic.expression.py_psi_for_doctests(x)
This function is a python wrapper so py_psi can be tested. The real tests are in the docstring for py_psi.

EXAMPLES:

```
sage: from sage.symbolic.expression import py_psi_for_doctests
sage: py_psi_for_doctests(2)
0.422784335098467
```

sage.symbolic.expression.py_real_for_doctests(x)
Used for doctesting py_real.

sage.symbolic.expression.py_stieltjes_for_doctests(x)
This function is for testing py_stieltjes().

EXAMPLES:

```
sage: from sage.symbolic.expression import py_stieltjes_for_doctests
sage: py_stieltjes_for_doctests(0.0)
0.577215664901533
```
Symbolic Calculus, Release 10.1

sage.symbolic.expression.py_tgamma_for_doctests(x)
This function is for testing py_tgamma().

sage.symbolic.expression.py_zeta_for_doctests(x)
This function is for testing py_zeta().

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_zeta_for_doctests
sage: py_zeta_for_doctests(CC.0)
0.00330022368532410 - 0.418155449141322*I
```

sage.symbolic.expression.register_or_update_function(self, name, latex_name, nargs, evalf_params_first, update)
Register the function self with Pynac (GiNaC).

OUTPUT:

• serial number of the function, for use in call_registered_function()

EXAMPLES:

```python
sage: from sage.symbolic.function import BuiltinFunction
sage: class Archosaurian(BuiltinFunction):
....:     def __init__(self):
....:         BuiltinFunction.__init__(self, 'archsaur', nargs=1)
....:     def _eval_(self, x):
....:         return x * exp(x)
sage: archsaur = Archosaurian()    # indirect doctest
sage: archsaur(2)
2*e^2
```

sage.symbolic.expression.register_symbol(obj, conversions, nargs=None)
Add an object to the symbol table, along with how to convert it to other systems such as Maxima, Mathematica, etc. This table is used to convert from other systems back to Sage.

INPUT:

• obj – a symbolic object or function.

• conversions – a dictionary of conversions, where the keys are the names of interfaces (e.g., 'maxima'), and the values are the string representation of obj in that system.

• nargs – optional number of arguments. For most functions, this can be deduced automatically.

EXAMPLES:

```python
sage: from sage.symbolic.expression import register_symbol as rs
sage: rs(SR(5), {'maxima': 'five'})
5
```

sage.symbolic.expression.restore_op_wrapper(expr)
sage.symbolic.expression.solve_diophantine(f, *args, **kwds)
Solve a Diophantine equation.
The argument, if not given as symbolic equation, is set equal to zero. It can be given in any form that can be converted to symbolic. Please see `Expression.solve_diophantine()` for a detailed synopsis.

**EXAMPLES:**

```
sage: R.<a,b> = PolynomialRing(ZZ); R
Multivariate Polynomial Ring in a, b over Integer Ring
sage: solve_diophantine(a^2-3*b^2+1)
[]
sage: sorted(solve_diophantine(a^2-3*b^2+2), key=str)
[(-1/2*sqrt(3)*(sqrt(3) + 2)^t + 1/2*sqrt(3)*(-sqrt(3) + 2)^t - 1/2*(sqrt(3) + 2)^t, -1/6*sqrt(3)*(sqrt(3) + 2)^t + 1/6*sqrt(3)*(-sqrt(3) + 2)^t - 1/2*(sqrt(3) + 2)^t),
 (-1/2*(-sqrt(3) + 2)^t, 1/6*sqrt(3)*(-sqrt(3) + 2)^t - 1/6*sqrt(3)*(sqrt(3) + 2)^t + 1/2*(-sqrt(3) + 2)^t + 1/2*(-sqrt(3) + 2)^t]
```

### `sage.symbolic.expression.test_binomial(n, k)`

The Binomial coefficients. It computes the binomial coefficients. For integer $n$ and $k$ and positive $n$ this is the number of ways of choosing $k$ objects from $n$ distinct objects. If $n$ is negative, the formula $\binom{n}{k} = (-1)^k \binom{k-n-1}{k}$ is used to compute the result.

**INPUT:**

- $n$, $k$ – integers, with $k \geq 0$.

**OUTPUT:**

integer

**EXAMPLES:**

```
sage: import sage.symbolic.expression
sage: sage.symbolic.expression.test_binomial(5,2)
10
sage: sage.symbolic.expression.test_binomial(-5,3)
-35
sage: -sage.symbolic.expression.test_binomial(3-(-5)-1, 3)
-35
```

### `sage.symbolic.expression.tolerant_is_symbol(a)`

Utility function to test if something is a symbol.

Returns `False` for arguments that do not have an `is_symbol` attribute. Returns the result of calling the `is_symbol` method otherwise.

**EXAMPLES:**

```
sage: from sage.symbolic.expression import tolerant_is_symbol
sage: tolerant_is_symbol(var("x"))
True
sage: tolerant_is_symbol(None)
False
sage: None.is_symbol()
Traceback (most recent call last):
```

(continues on next page)
symbolic calculus, release 10.1

...attributeerror: 'nontype' object has no attribute 'is_symbol'
sage.symbolic.expression.unpack_operands(ex)

examples:
sage: from sage.symbolic.expression import unpack_operands
sage: t = sr._force_pyobject((1, 2, x, x+1, x+2))
sage: unpack_operands(t)
(1, 2, x, x + 1, x + 2)
sage: type(unpack_operands(t))
<... 'tuple'>
sage: list(map(type, unpack_operands(t)))
[<class 'sage.rings.integer.integer'>, <class 'sage.rings.integer.integer'>, <class 'sage.symbolic.expression.expression'>, <class 'sage.symbolic.expression.expression'>, <class 'sage.symbolic.expression.expression'>]
sage: u = sr._force_pyobject((t, x^2))
sage: unpack_operands(u)
((1, 2, x, x + 1, x + 2), x^2)
sage: type(unpack_operands(u)[0])
<... 'tuple'>

2.2 callable symbolic expressions

examples:

when you do arithmetic with:
sage: f(x, y, z) = sin(x+y+z)
sage: g(x, y) = y + 2*x
sage: f + g
(x, y, z) |---> 2*x + y + sin(x + y + z)

sage: f(x, y, z) = sin(x+y+z)
sage: g(w, t) = cos(w - t)
sage: f + g
(t, w, x, y, z) |---> cos(-t + w) + sin(x + y + z)

sage: f(x, y, t) = y*(x^2-t)
sage: g(x, y, w) = x + y - cos(w)
sage: f*g
(x, y, t, w) |---> (x^2 - t)*(x + y - cos(w))*y

sage: f(x,y, t) = x+y
sage: g(x, y, w) = w + t
sage: f + g
(x, y, t, w) |---> t + w + x + y

class sage.symbolic.callable.callable_symbolic_expression_functor( arguments)
    bases: constructionfunctor
A functor which produces a CallableSymbolicExpressionRing from the SymbolicRing.

EXAMPLES:

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x,y = var('x,y')
sage: f = CallableSymbolicExpressionFunctor((x,y)); f
CallableSymbolicExpressionFunctor(x, y)
sage: f(SR)
Callable function ring with arguments (x, y)
sage: loads(dumps(f))
CallableSymbolicExpressionFunctor(x, y)
```

**arguments()**

EXAMPLES:

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x,y = var('x,y')
sage: a = CallableSymbolicExpressionFunctor((x,y))
sage: a.arguments()
(x, y)
```

**merge(other)**

EXAMPLES:

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x,y = var('x,y')
sage: a = CallableSymbolicExpressionFunctor((x,))
sage: b = CallableSymbolicExpressionFunctor((y,))
sage: a.merge(b)
CallableSymbolicExpressionFunctor(x, y)
```

**unify_arguments(x)**

Takes the variable list from another CallableSymbolicExpression object and compares it with the current CallableSymbolicExpression object's variable list, combining them according to the following rules:

Let a be self's variable list, let b be y's variable list.

1. If a == b, then the variable lists are identical, so return that variable list.
2. If a != b, then check if the first n items in a are the first n items in b, or vice versa. If so, return a list with these n items, followed by the remaining items in a and b sorted together in alphabetical order.

**Note:** When used for arithmetic between CallableSymbolicExpression's, these rules ensure that the set of CallableSymbolicExpression's will have certain properties. In particular, it ensures that the set is a *commutative* ring, i.e., the order of the input variables is the same no matter in which order arithmetic is done.

**INPUT:**

- x - A CallableSymbolicExpression

**OUTPUT:** A tuple of variables.

**EXAMPLES:**
```python
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x, y = var('x, y')
```
```
sage: a = CallableSymbolicExpressionFunctor((x,))
sage: b = CallableSymbolicExpressionFunctor((y,))
sage: a.unify_arguments(b)
(x, y)
```

AUTHORS:
- Bobby Moretti: thanks to William Stein for the rules

```python
class sage.symbolic.callable.CallableSymbolicExpressionRingFactory
Bases: UniqueFactory
create_key(args, check=True)
```
```
EXAMPLES:

```python
sage: x, y = var('x, y')
sage: CallableSymbolicExpressionRing.create_key((x, y))
(x, y)
```
```
create_object(version, key, **extra_args)
Return a CallableSymbolicExpressionRing given a version and a key.
```
```
EXAMPLES:

```python
sage: x, y = var('x, y')
sage: CallableSymbolicExpressionRing.create_object(0, (x, y))
Callable function ring with arguments (x, y)
```
```
class sage.symbolic.callable.CallableSymbolicExpressionRing_class(arguments)
Bases: SymbolicRing, CallableSymbolicExpressionRing
```
```
EXAMPLES:

We verify that coercion works in the case where x is not an instance of SymbolicExpression, but its parent is still the SymbolicRing:

```python
sage: f(x) = 1
sage: f*e
x |--> e
```
```
args()
Return the arguments of self.
```
```
The order that the variables appear in self.arguments() is the order that is used in evaluating the elements of self.
```
```
EXAMPLES:

```python
sage: x, y = var('x, y')
sage: f(x, y) = 2*x+y
sage: f.parent().arguments()
(x, y)
sage: f(y, x) = 2*x+y
sage: f.parent().arguments()
(y, x)
```
```
arguments()  
Return the arguments of self.

The order that the variables appear in self.arguments() is the order that is used in evaluating the elements of self.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f(x,y) = 2*x+y
sage: f.parent().arguments()
(x, y)
sage: f(y,x) = 2*y+x
sage: f.parent().arguments()
(y, x)
```

construction()  
EXAMPLES:

```
sage: f(x,y) = x^2 + y
sage: f.parent().construction()
(CallableSymbolicExpressionFunctor(x, y), Symbolic Ring)
```

sage.symbolic.callable.is_CallableSymbolicExpression(x)  
Return True if x is a callable symbolic expression.

EXAMPLES:

```
sage: from sage.symbolic.callable import is_CallableSymbolicExpression
sage: var('a x y z')
(a, x, y, z)
sage: f(x,y) = a + 2*x + 3*y + z
sage: is_CallableSymbolicExpression(f)
```

sage: from sage.symbolic.callable import is_CallableSymbolicExpression  
    is_CallableSymbolicExpression is deprecated; use isinstance(..., Expression) and ....is_callable() instead
    See https://github.com/sagemath/sage/issues/34215 for details.

```
True
```

```
sage: is_CallableSymbolicExpression(a+2*x)
False
```

```
sage: def foo(n):
        return n^2
...
sage: is_CallableSymbolicExpression(foo)
False
```

sage.symbolic.callable.is_CallableSymbolicExpressionRing(x)  
Return True if x is a callable symbolic expression ring.

INPUT:

* x - object

OUTPUT: bool

EXAMPLES:
2.3 Assumptions

The `GenericDeclaration` class provides assumptions about a symbol or function in verbal form. Such assumptions can be made using the `assume()` function in this module, which also can take any relation of symbolic expressions as argument. Use `forget()` to clear all assumptions. Creating a variable with a specific domain is equivalent with making an assumption about it.

There is only rudimentary support for consistency and satisfiability checking in Sage. Assumptions are used both in Maxima and Pynac to support or refine some computations. In the following we show how to make and query assumptions. Please see the respective modules for more practical examples.

In addition to the global `assumptions()` database, `assuming()` creates reusable, stackable context managers allowing for temporary updates of the database for evaluation of a (block of) statements.

**EXAMPLES:**

The default domain of a symbolic variable is the complex plane:

```python
sage: var('x')
x
sage: x.is_real()
False
sage: assume(x,'real')
sage: x.is_real()
True
sage: forget()
sage: x.is_real()
False
```

Here is the list of acceptable features:

```python
sage: ', '.join(map(str, maxima("features")._sage_()))
'integer, noninteger, even, odd, rational, irrational, real, imaginary, complex, analytic, increasing, decreasing, oddfun, evenfun, posfun, constant, commutative, lassociative, rassociative, symmetric, antisymmetric, integervalued'
```

Set positive domain using a relation:

```python
sage: assume(x>0)
sage: x.is_positive()
```

(continues on next page)
True
sage: x.is_real()
True
sage: assumptions()
[x > 0]

Assumptions also affect operations that do not use Maxima:

sage: forget()
sage: assume(x, 'even')
sage: assume(x, 'real')
sage: (-1)^x
1
sage: (-gamma(pi))^x
gamma(pi)^x
sage: binomial(2*x, x).is_integer()
True

Assumptions are added and in some cases checked for consistency:

sage: assume(x>0)
sage: assume(x<0)
Traceback (most recent call last):
...
ValueError: Assumption is inconsistent
sage: forget()

```
class sage.symbolic.assumptions.GenericDeclaration(var, assumption)
    Bases: UniqueRepresentation

    This class represents generic assumptions, such as a variable being an integer or a function being
    increasing. It passes such information to Maxima’s declare (wrapped in a context so it is able to
    forget) and to Pynac.

    INPUT:

    • var – the variable about which assumptions are being made
    • assumption – a string containing a Maxima feature, either user defined or in the list given by
      maxima('features')

    EXAMPLES:

    sage: from sage.symbolic.assumptions import GenericDeclaration
    sage: decl = GenericDeclaration(x, 'integer')
    sage: decl.assume()
    sage: sin(x*pi)
    0
    sage: decl.forget()
    sage: sin(x*pi)
    sin(pi*x)
    sage: sin(x*pi).simplify()
    sin(pi*x)
```

Here is the list of acceptable features:

2.3. Assumptions
Test unique representation behavior:

```
sage:GenericDeclaration(x, 'integer') is GenericDeclaration(SR.var("x"), 'integer')
True
```

`assume()`

Make this assumption.

`contradicts(soln)`

Return True if this assumption is violated by the given variable assignment(s).

**INPUT:**

- `soln` – Either a dictionary with variables as keys or a symbolic relation with a variable on the left hand side.

**EXAMPLES:**

```
sage: from sage.symbolic.assumptions import GenericDeclaration
sage: GenericDeclaration(x, 'integer').contradicts(x==4)
False
sage: GenericDeclaration(x, 'integer').contradicts(x==4.0)
False
sage: GenericDeclaration(x, 'integer').contradicts(x==4.5)
True
sage: GenericDeclaration(x, 'integer').contradicts(x==sqrt(17))
True
sage: GenericDeclaration(x, 'noninteger').contradicts(x==sqrt(17))
False
sage: GenericDeclaration(x, 'noninteger').contradicts(x==17)
True
sage: GenericDeclaration(x, 'even').contradicts(x==3)
True
sage: GenericDeclaration(x, 'complex').contradicts(x==3)
False
sage: GenericDeclaration(x, 'imaginary').contradicts(x==3)
True
sage: GenericDeclaration(x, 'imaginary').contradicts(x==I)
False
sage: var(’y,z’)  
(y, z)
sage: GenericDeclaration(x, 'imaginary').contradicts(x==y+z)
False
sage: GenericDeclaration(x, 'rational').contradicts(y==pi)
False
sage: GenericDeclaration(x, 'rational').contradicts(x==pi)
True
```
forget()

Forget this assumption.

has(arg)

Check if this assumption contains the argument arg.

EXAMPLES:

```
sage: from sage.symbolic.assumptions import GenericDeclaration as GDecl
sage: var('y')
y
sage: d = GDecl(x, 'integer')
sage: d.has(x)
True
sage: d.has(y)
False
```

```
sage.symbolic.assumptions.assume(*args)

Make the given assumptions.

INPUT:

• *args – a variable-length sequence of assumptions, each consisting of:
  – any number of symbolic inequalities, like 0 < x, x < 1
  – a subsequence of variable names, followed by some property that should be assumed for those variables; for example, x, y, z, 'integer' would assume that each of x, y, and z are integer variables, and x, 'odd' would assume that x is odd (as opposed to even).

The two types can be combined, but a symbolic inequality cannot appear in the middle of a list of variables.

OUTPUT:

If everything goes as planned, there is no output.

If you assume something that is not one of the two forms above, then an AttributeError is raised as we try to call its assume method.

If you make inconsistent assumptions (for example, that x is both even and odd), then a ValueError is raised.

Warning: Do not use Python’s chained comparison notation in assumptions. Python literally translates the expression 0 < x < 1 to (0 < x) and (x < 1), but the value of bool(0 < x) is False when x is a symbolic variable. Therefore, by the definition of Python’s logical “and” operator, the entire expression is equal to 0 < x.

EXAMPLES:

Assumptions are typically used to ensure certain relations are evaluated as true that are not true in general.
Here, we verify that for $x > 0$, $\sqrt{x^2} = x$:

```
sage: assume(x > 0)
sage: bool(sqrt(x^2) == x)
True
```

This will be assumed in the current Sage session until forgotten:

```
sage: bool(sqrt(x^2) == x)
True
sage: forget()
sage: bool(sqrt(x^2) == x)
False
```

Another major use case is in taking certain integrals and limits where the answers may depend on some sign condition:

```
sage: var('x, n')
(x, n)
sage: assume(n+1>0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
sage: var('q, a, k')
(q, a, k)
sage: assume(q > 1)
sage: sum(a*q^k, k, 0, oo)
Traceback (most recent call last):
...  
ValueError: Sum is divergent.
sage: forget()
sage: assume(abs(q) < 1)
sage: sum(a*q^k, k, 0, oo)
-a/(q - 1)
sage: forget()
```

An integer constraint:

```
sage: n,P,r,r2 = SR.var('n, P, r, r2')
sage: assume(n, 'integer')
sage: c = P*e^(r*n)
sage: d = P*(1+r2)^n
sage: solve(c==d,r2)
[r2 == e^r - 1]
sage: forget()
```

Simplifying certain well-known identities works as well:

```
sage: n = SR.var('n')
sage: assume(n, 'integer')
sage: sin(n*pi)
0
sage: forget()
```

(continues on next page)
Instead of using chained comparison notation, each relationship should be passed as a separate assumption:

```python
sage: x = SR.var('x')
sage: assume(0 < x, x < 1)  # instead of assume(0 < x < 1)
sage: assumptions()
[0 < x, x < 1]
sage: forget()
```

If you make inconsistent or meaningless assumptions, Sage will let you know:

```python
sage: assume(x<0)
sage: assume(x>0)
Traceback (most recent call last):
  ... ValueError: Assumption is inconsistent
sage: assume(x<1)
Traceback (most recent call last):
  ... ValueError: Assumption is redundant
sage: assumptions()
[x < 0]
sage: forget()
sage: assume(x,'even')
sage: assume(x,'odd')
Traceback (most recent call last):
  ... ValueError: Assumption is inconsistent
sage: forget()
```

You can also use assumptions to evaluate simple truth values:

```python
sage: x, y, z = var('x, y, z')
sage: assume(x>=y,y>=z,z>=x)
sage: bool(x==z)
True
sage: bool(z<x)
False
sage: bool(z>y)
False
sage: bool(y==z)
True
sage: forget()
sage: assume(x>=1,x<=1)
sage: bool(x==1)
True
sage: bool(x>1)
False
sage: forget()
```

```python
class sage.symbolic.assumptions.assuming(*args, **kwds)

2.3. Assumptions
```
Bases: object

Temporarily modify assumptions.

Create a context manager in which temporary assumptions are added (or substituted) to the current assumptions set.

The set of possible assumptions and declarations is the same as for assume().

This can be useful in interactive mode to discover the assumptions necessary to a given integration, or the exact solution to a system of equations.

It can also be used to explore the branches of a cases() expression.

As with assume(), it is an error to add an assumption either redundant or inconsistent with the current assumption set (unless replace=True is used). See examples.

INPUT:

• *args – assumptions (same format as for assume()).

• replace – a boolean (default [False]). Specifies whether the new assumptions are added to (default) or replace (if replace=True) the current assumption set.

OUTPUT:

A context manager useable in a with statement (see examples).

EXAMPLES:

Basic functionality : inside a with assuming:() block, Sage uses the updated assumptions database. After exit, the original database is restored.

```
sage: var("x")
x
sage: forget(assumptions())
sage: solve(x^2 == 4,x)
[x == -2, x == 2]
sage: with assuming(x > 0):
....: solve(x^2 == 4,x)
[x == 2]
sage: assumptions()
[]
```

The local assumptions can be stacked. We can use this functionality to discover incrementally the assumptions necessary to a given calculation (and by the way, to check that Sage’s default integrator (Maxima’s, that is), sometimes nitpicks for naught).

```
sage: var("y,k,theta")
(y, k, theta)
sage: dgamma(y,k,theta)=y^(k-1)*e^(-y/theta)/(theta^k*gamma(k))
sage: integrate(dgamma(y,k,theta),y,0,oo)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using...
the 'assume' command before evaluation *may* help (example of legal syntax is...
'assume(theta>0)', see 'assume?' for more details)
Is theta positive or negative?
```

(continues on next page)
As mentioned above, it is an error to try to introduce redundant or inconsistent assumptions.

```
sage: assume(x > 0)
sage: with assuming(x > -1): "I won't see this"
Traceback (most recent call last):
... ValueError: Assumption is redundant
```

```
sage: with assuming(x < -1): "I won't see this"
Traceback (most recent call last):
... ValueError: Assumption is inconsistent
```

`sage.symbolic.assumptions.assumptions(*args)``

List all current symbolic assumptions.

**INPUT:**

- args – list of variables which can be empty.

**OUTPUT:**

- list of assumptions on variables. If args is empty it returns all assumptions

**EXAMPLES:**

```
sage: var('x, y, z, w')
(x, y, z, w)
sage: forget()
sage: assume(x^2+y^2 > 0)
sage: assumptions()
[x^2 + y^2 > 0]
```
sage: forget(x^2+y^2 > 0)
sage: assumptions()
[]
sage: assume(x > y)
sage: assume(z > w)
sage: sorted(assumptions(), key=lambda x: str(x))
[x > y, z > w]
sage: forget()
sage: assumptions()
[]

It is also possible to query for assumptions on a variable independently:

sage: x, y, z = var('x y z')
sage: assume(x, 'integer')
sage: assume(y > 0)
sage: assume(y^2 + z^2 == 1)
sage: assume(x < 0)
sage: assumptions()
[x is integer, y > 0, y^2 + z^2 == 1, x < 0]
sage: assumptions(x)
[x is integer, x < 0]
sage: assumptions(x, y)
[x is integer, x < 0, y > 0, y^2 + z^2 == 1]
sage: assumptions(z)
[y^2 + z^2 == 1]

sage.symbolic.assumptions.forget(*args)

Forget the given assumption, or call with no arguments to forget all assumptions.

Here an assumption is some sort of symbolic constraint.

INPUT:

• *args – assumptions (default: forget all assumptions)

EXAMPLES:

We define and forget multiple assumptions:

sage: forget()
sage: var('x,y,z')
(x, y, z)
sage: assume(x>0, y>0, z == 1, y>0)
sage: sorted(assumptions(), key=lambda x: str(x))
[x > 0, y > 0, z == 1]
sage: forget(x>0, z==1)
sage: assumptions()
[y > 0]
sage: assume(y, 'even', z, 'complex')
sage: assumptions()
[y > 0, y is even, z is complex]
sage: cos(y*pi).simplify()
1
sage: cos(pi*y).simplify()
sage: assumptions()
[y > 0, z is complex]
sage: forget()
sage: assumptions()
[]

sage.symbolic.assumptions.preprocess_assumptions(\texttt{args})

Turn a list of the form (\texttt{var1}, \texttt{var2}, ..., 'property') into a sequence of declarations (\texttt{var1 is property}), (\texttt{var2 is property}), ...

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.symbolic.assumptions import preprocess_assumptions
sage: preprocess_assumptions([x, 'integer', x > 4])
[x is integer, x > 4]
sage: var('x, y')
(x, y)
sage: preprocess_assumptions([x, y, 'integer', x > 4, y, 'even'])
[x is integer, y is integer, x > 4, y is even]
\end{verbatim}

\section*{2.4 Symbolic Equations and Inequalities}

Sage can solve symbolic equations and inequalities. For example, we derive the quadratic formula as follows:

\begin{verbatim}
sage: a,b,c = var('a,b,c')
sage: qe = (a*x^2 + b*x + c == 0)
sage: qe
a*x^2 + b*x + c == 0
sage: print(solve(qe, x))
[ x == -1/2*(b + sqrt(b^2 - 4*a*c))/a, x == -1/2*(b - sqrt(b^2 - 4*a*c))/a ]
\end{verbatim}

\subsection*{2.4.1 The operator, left hand side, and right hand side}

Operators:

\begin{verbatim}
sage: eqn = x^3 + 2/3 >= x - pi
sage: eqn.operator()
<built-in function ge>
sage: (x^3 + 2/3 < x - pi).operator()
<built-in function lt>
sage: (x^3 + 2/3 == x - pi).operator()
<built-in function eq>
\end{verbatim}

Left hand side:
Symbolic Calculus, Release 10.1

\begin{verbatim}
sage: eqn = x^3 + 2/3 >= x - pi
sage: eqn.lhs()
x^3 + 2/3
sage: eqn.left()
x^3 + 2/3
sage: eqn.left_hand_side()
x^3 + 2/3

Right hand side:

\begin{verbatim}
sage: (x + sqrt(2) >= sqrt(3) + 5/2).right()
sqrt(3) + 5/2
sage: (x + sqrt(2) >= sqrt(3) + 5/2).rhs()
sqrt(3) + 5/2
sage: (x + sqrt(2) >= sqrt(3) + 5/2).right_hand_side()
sqrt(3) + 5/2
\end{verbatim}

2.4.2 Arithmetic

Add two symbolic equations:

\begin{verbatim}
sage: var('a,b')
(a, b)
sage: m = 144 == -10 * a + b
sage: n = 136 == 10 * a + b
sage: m + n
280 == 2*b
sage: int(-144) + m
0 == -10*a + b - 144
\end{verbatim}

Subtract two symbolic equations:

\begin{verbatim}
sage: var('a,b')
(a, b)
sage: m = 144 == 20 * a + b
sage: n = 136 == 10 * a + b
sage: m - n
8 == 10*a
sage: int(144) - m
0 == -20*a - b + 144
\end{verbatim}

Multiply two symbolic equations:

\begin{verbatim}
sage: x = var('x')
sage: m = x == 5*x + 1
sage: n = sin(x) == sin(x+2*pi, hold=True)
sage: m * n
x*sin(x) == (5*x + 1)*sin(2*pi + x)
sage: m = 2*x == 3*x^2 - 5
sage: int(-1) * m
-2*x == -3*x^2 + 5
\end{verbatim}

Divide two symbolic equations:

\end{verbatim}
2.4.3 Substitution

Substitution into relations:

```
sage: x, a = var('x, a')
sage: eq = (x^3 + a == sin(x/a)); eq
x^3 + a == sin(x/a)
sage: eq.substitute(x=5*x)
125*x^3 + a == sin(5*x/a)
sage: eq.substitute(a=1)
x^3 + 1 == sin(x)
sage: eq.substitute(a=x)
x^3 + x == sin(1)
sage: eq.substitute({a:x, x:1})
x + 1 == sin(1/x)
```

You can even substitute multivariable and matrix expressions:

```
sage: x,y = var('x, y')
sage: M = Matrix([[x+1,y],[x^2,y^3]]); M
[x + 1  y]
[  x^2  y^3]
sage: M.substitute({x:0,y:1})
[1 1]
[0 1]
```

You can even substitute multivariable and matrix expressions:

2.4.4 Solving

We can solve equations:

```
sage: x = var('x')
sage: S = solve(x^3 - 1 == 0, x)
sage: S
[x == 1/2*I*sqrt(3) - 1/2, x == -1/2*I*sqrt(3) - 1/2, x == 1]
sage: S[0]
x == 1/2*I*sqrt(3) - 1/2
```
We can also solve equations involving matrices. The following example defines a multivariable function $f(x,y)$, then solves for where the partial derivatives with respect to $x$ and $y$ are zero. Then it substitutes one of the solutions into the Hessian matrix $H$ for $f$:

```
sage: f(x,y) = x^2*y+y^2+y
sage: solutions = solve(list(f.diff()),[x,y],solution_dict=True)
sage: solutions == [{x: -I, y: 0}, {x: I, y: 0}, {x: 0, y: -1/2}]
True
sage: H = f.diff(2) # Hessian matrix
sage: H.subs(solutions[2])
[(x, y) |--> -1 (x, y) |--> 0]
[ (x, y) |--> 0 (x, y) |--> 2]
sage: H(x,y).subs(solutions[2])
[-1 0]
[ 0 2]
```

We illustrate finding multiplicities of solutions:

```
sage: f = (x-1)^5*(x^2+1)
sage: solve(f == 0, x)
[x == -I, x == I, x == 1]
sage: solve(f == 0, x, multiplicities=True)
((x == -I, x == I, x == 1), [1, 1, 5])
```

We can also solve many inequalities:

```
sage: solve(1/(x-1)<=8,x)
[[x < 1], [x >= (9/8)]]
```

We can numerically find roots of equations:

```
sage: (x == sin(x)).find_root(-2,2)
0.0
sage: (x^5 + 3*x + 2 == 0).find_root(-2,2,x)
-0.6328345202421523
sage: (cos(x) == sin(x)).find_root(10,20)
19.634954084936208
```

We illustrate some valid error conditions:

```
sage: (cos(x) != sin(x)).find_root(10,20)
Traceback (most recent call last):
... 
ValueError: Symbolic equation must be an equality.
```
Continued from previous page:

```python
sage: (SR(3)==SR(2)).find_root(-1,1)
Traceback (most recent call last):
  ...  
RuntimeError: no zero in the interval, since constant expression is not 0.
```

There must be at most one variable:

```python
sage: x, y = var('x,y')
sage: (x == y).find_root(-2,2)
Traceback (most recent call last):
  ...  
NotImplementedError: root finding currently only implemented in 1 dimension.
```

### 2.4.5 Assumptions

Forgetting assumptions:

```python
sage: var('x,y')
(x, y)
sage: forget()  # Clear assumptions
sage: assume(x>0, y < 2)
sage: assumptions()
[x > 0, y < 2]
sage: (y < 2).forget()
sage: assumptions()
[x > 0]
sage: forget()
sage: assumptions()
[]
```

### 2.4.6 Miscellaneous

Conversion to Maxima:

```python
sage: x = var('x')
sage: eq = (x^(3/5) >= pi^2 + e^i)
sage: eq._maxima_init_()
'(_SAGE_VAR_x)^(3/5) >= ((%pi)^(2))+(exp(0+%i*1))'
sage: e1 = x^3 + x == sin(2*x)
sage: z = e1._maxima_()
sage: z.parent() is sage.calculus.calculus.maxima
True
sage: z = e1._maxima_(maxima)
sage: z.parent() is maxima
True
sage: z = maxima(e1)
sage: z.parent() is maxima
True
```

Conversion to Maple:

2.4. Symbolic Equations and Inequalities 169
Symbolic Calculus, Release 10.1

```
sage: x = var('x')
sage: eq = (x == 2)
sage: eq._maple_init_()
'x = 2'
```

Comparison:

```
sage: x = var('x')
sage: (x>0) == (x>0)
True
sage: (x>0) == (x>1)
False
sage: (x>0) != (x>1)
True
```

Variables appearing in the relation:

```
sage: var('x,y,z,w')
(x, y, z, w)
sage: f = (x+y+w) == (x^2 - y^2 - z^3); f
w + x + y == -z^3 + x^2 - y^2
sage: f.variables()
(w, x, y, z)
```

LaTeX output:

```
sage: latex(x^(3/5) >= pi)
x^\frac{3}{5} \geq \pi
```

When working with the symbolic complex number $i$, notice that comparisons do not automatically simplify even in trivial situations:

```
sage: SR(I)^2 == -1
-1 == -1
sage: SR(I)^2 < 0
-1 < 0
sage: (SR(I)+1)^4 > 0
-4 > 0
```

Nevertheless, if you force the comparison, you get the right answer (github issue #7160):

```
sage: bool(SR(I)^2 == -1)
True
sage: bool(SR(I)^2 < 0)
True
sage: bool((SR(I)+1)^4 > 0)
False
```
2.4.7 More Examples

```
sage: x,y,a = var('x,y,a')
sage: f = x^2 + y^2 == 1
sage: f.solve(x)
[x == -sqrt(-y^2 + 1), x == sqrt(-y^2 + 1)]

sage: f = x^5 + a
sage: solve(f==0,x)
[x == 1/4*(-a)^(1/5)*(sqrt(5) + I*sqrt(2*sqrt(5) + 10) - 1),
  x == -1/4*(-a)^(1/5)*(-a)^(1/5)*(sqrt(5) - I*sqrt(-2*sqrt(5) + 10) + 1),
  x == -1/4*(-a)^(1/5)*(-a)^(1/5)*(sqrt(5) + I*sqrt(-2*sqrt(5) + 10) + 1),
  x == 1/4*(-a)^(1/5)*(sqrt(5) - I*sqrt(2*sqrt(5) + 10) - 1),
  x == -(-a)^(1/5)]
```

You can also do arithmetic with inequalities, as illustrated below:

```
sage: var('x y')
(x, y)
sage: f = x + 3 == y - 2
sage: f
x + 3 == y - 2
sage: g = f - 3; g
x == y - 5
sage: h = x^3 + sqrt(2) == x*y*sin(x)
```

```
sage: h
x^3 + sqrt(2) == x*y*sin(x)
```

```
sage: h - sqrt(2)
(x^3 == x*y*sin(x) - sqrt(2))
```

```
sage: h + f
x^3 + x + sqrt(2) + 3 == x*y*sin(x) + y - 2
```

```
sage: g = 2 < x+10
```

```
sage: f - g
x + 1 < -x + y - 12
```

```
sage: f + g
(x + 5 < x + y + 8)
```

```
sage: f^(-1)
-x - 3 < -y + 2
```

AUTHORS:

- Bobby Moretti: initial version (based on a trick that Robert Bradshaw suggested).
- William Stein: second version
- William Stein (2007-07-16): added arithmetic with symbolic equations

```
sage.symbolic.relation.solve(f, *args, **kwds)
```

Algebraically solve an equation or system of equations (over the complex numbers) for given variables. Inequalities and systems of inequalities are also supported.

**INPUT:**

- \( f \) - equation or system of equations (given by a list or tuple)
- \(*args\) - variables to solve for.
• solution_dict - bool (default: False); if True or non-zero, return a list of dictionaries containing the solutions. If there are no solutions, return an empty list (rather than a list containing an empty dictionary). Likewise, if there’s only a single solution, return a list containing one dictionary with that solution.

There are a few optional keywords if you are trying to solve a single equation. They may only be used in that context.

• multiplicities - bool (default: False); if True, return corresponding multiplicities. This keyword is incompatible with to_poly_solve=True and does not make any sense when solving inequalities.

• explicit_solutions - bool (default: False); require that all roots be explicit rather than implicit. Not used when solving inequalities.

• to_poly_solve - bool (default: False) or string; use Maxima’s to_poly_solver package to search for more possible solutions, but possibly encounter approximate solutions. This keyword is incompatible with multiplicities=True and is not used when solving inequalities. Setting to_poly_solve to ‘force’ (string) omits Maxima’s solve command (useful when some solutions of trigonometric equations are lost).

• algorithm - string (default: ‘maxima’); to use SymPy’s solvers set this to ‘sympy’. Note that SymPy is always used for diophantine equations. Another choice is ‘giac’.

• domain - string (default: ‘complex’); setting this to ‘real’ changes the way SymPy solves single equations; inequalities are always solved in the real domain.

EXAMPLES:

```sage
sage: x, y = var('x, y')
sage: solve([x+y==6, x-y==4], x, y)
[[x == 5, y == 1]]
sage: solve([x^2+2*y^2 == 1, y^2 == x^3 + x + 1], x, y)
[[x == -1/2*I*sqrt(3) - 1/2, y == -sqrt(-1/2*I*sqrt(3) + 3/2)],
 [x == 1/2*I*sqrt(3) - 1/2, y == sqrt(1/2*I*sqrt(3) + 3/2)],
 [x == 0, y == -1],
 [x == 0, y == 1]]
sage: solve([sqrt(x) + sqrt(y) == 5, x + y == 10], x, y)
# abs tol 1e-15
([x == 0, y == 0],
 [x == (0.3090169943749475 + 0.9510565162951535*I),
  y == (-0.8090169943749475 + 0.5877852522924731*I)])
```

Whenever possible, answers will be symbolic, but with systems of equations, at times approximations will be given by Maxima, due to the underlying algorithm:

```sage
sage: sols = solve([x^3==y, y^2==x], [x,y]); sols[-1], sols[0] # abs tol 1e-15
([x == 0, y == 0],
 [x == (0.3090169943749475 + 0.9510565162951535*I),
  y == (-0.8090169943749475 + 0.5877852522924731*I)])
```
Here we demonstrate very basic use of the optional keywords:

```python
sage: ((x^2 - 1)^2).solve(x)
[x == -1, x == 1]
sage: ((x^2 - 1)^2).solve(x, multiplicities=True)
([x == -1, x == 1], [2, 2])
sage: solve(sin(x) == x, x)
[x == sin(x)]
sage: solve(sin(x) == x, x, explicit_solutions=True)
[]
sage: solve(abs(1 - abs(1 - x)) == 10, x)
[abs(abs(x - 1) - 1) == 10]
sage: solve(abs(1 - abs(1 - x)) == 10, x, to_poly_solve=True)
[x == -10, x == 12]
sage: from sage.symbolic.expression import Expression
sage: Expression.solve(x^2 == 1, x)
[x == -1, x == 1]
```

We must solve with respect to actual variables:

```python
sage: z = 5
sage: solve([8*z + y == 3, -z + 7*y == 0], y, z)
Traceback (most recent call last):
...    TypeError: 5 is not a valid variable.
```

If we ask for dictionaries containing the solutions, we get them:

```python
sage: solve([x^2 - 1], x, solution_dict=True)
[\{x: -1\}, \{x: 1\}]
sage: solve([x^2 - 4*x + 4], x, solution_dict=True)
[\{x: 2\}]
sage: res = solve([x^2 == y, y == 4], x, y, solution_dict=True)
sage: for soln in res: print("x: %s, y: %s" % (soln[x], soln[y]))
x: 2, y: 4
x: -2, y: 4
```

If there is a parameter in the answer, that will show up as a new variable. In the following example, \(r1\) is an arbitrary constant (because of the \(r\):

```python
2.4. Symbolic Equations and Inequalities
```
\begin{verbatim}
sage: forget()
sage: x, y = var('x, y')
sage: solve([x+y == 3, 2*x+2*y == 6], x, y)
[[x == -r1 + 3, y == r1]]
sage: var('b, c')
(b, c)
sage: solve((b-1)*(c-1), [b,c])
[[b == 1, c == r...], [b == r..., c == 1]]
\end{verbatim}

Especially with trigonometric functions, the dummy variable may be implicitly an integer (hence the z):

\begin{verbatim}
sage: solve( sin(x)==cos(x), x, to_poly_solve=True)
[x == 1/4*pi + pi*z...]
sage: solve([cos(x)*sin(x) == 1/2, x+y == 0], x, y)
[[x == 1/4*pi + pi*z..., y == -1/4*pi - pi*z...]]
\end{verbatim}

Expressions which are not equations are assumed to be set equal to zero, as with \(x\) in the following example:

\begin{verbatim}
sage: solve([x, y == 2], x, y)
[[x == 0, y == 2]]
\end{verbatim}

If \texttt{True} appears in the list of equations it is ignored, and if \texttt{False} appears in the list then no solutions are returned. E.g., note that the first \(3==3\) evaluates to \texttt{True}, not to a symbolic equation.

\begin{verbatim}
sage: solve([3==3, 1.00000000000000*x^3 == 0], x)
[x == 0]
sage: solve([1.00000000000000*x^3 == 0], x)
[x == 0]
\end{verbatim}

Here, the first equation evaluates to \texttt{False}, so there are no solutions:

\begin{verbatim}
sage: solve([1==3, 1.00000000000000*x^3 == 0], x)
[]
\end{verbatim}

Completely symbolic solutions are supported:

\begin{verbatim}
sage: var('s,j,b,m,g')
(s, j, b, m, g)
sage: sys = [ m*(1-s) - b*s*j, b*s*j-g*j ]
sage: solve(sys, s, j)
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
sage: solve(sys, [s, j])
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
sage: solve(sys, [s, j])
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
sage: z = var('z')
sage: solve((x-z)^2==2, x)
[x == z - sqrt(2), x == z + sqrt(2)]
\end{verbatim}

Inequalities can be also solved:
A simple example to show the use of the keyword multiplicities:

\[
\text{sage: } ((x^2-1)^2).solve(x)
\]
\[
[x = -1, x = 1]
\]
\[
\text{sage: } ((x^2-1)^2).solve(x, multiplicities=True)
\]
\[
([x = -1, x = 1], [2, 2])
\]
\[
\text{sage: } ((x^2-1)^2).solve(x, multiplicities=True, to_poly_solve=True)
\]
\[
\text{Traceback (most recent call last):}
\]
\[
\text{...}
\]
\[
\text{NotImplementedError: to_poly_solve does not return multiplicities}
\]

Here is how the explicit_solutions keyword functions:

\[
\text{sage: } solve(sin(x)==x,x)
\]
\[
[x = \sin(x)]
\]
\[
\text{sage: } solve(sin(x)==x,x, explicit_solutions=True)
\]
\[
[]
\]
\[
\text{sage: } solve(x^2sin(x)==x^2,x)
\]
\[
[x = 0, x = \sin(x)]
\]
\[
\text{sage: } solve(x^2sin(x)==x^2,x, explicit_solutions=True)
\]
\[
[x = 0]
\]

The following examples show the use of the keyword to_poly_solve:

\[
\text{sage: } solve(abs(1-abs(1-x)) == 10, x)
\]
\[
[abs(abs(x-1)-1) == 10]
\]
\[
\text{sage: } solve(abs(1-abs(1-x)) == 10, x, to_poly_solve=True)
\]
\[
[x = -10, x = 12]
\]
\[
\text{sage: } var('Q')
\]
\[
Q
\]
\[
\text{sage: } solve(Q^2sqrt(Q^2 + 2) - 1, Q)
\]
\[
[Q == 1/sqrt(Q^2 + 2)]
\]

The following example is a regression in Maxima 5.39.0. It used to be possible to get one more solution here, namely \(1/sqrt(sqrt(2) + 1)\), see https://sourceforge.net/p/maxima/bugs/3276/:

\[
\text{sage: } solve(Q^2sqrt(Q^2 + 2) - 1, Q, to_poly_solve=True)
\]
\[
[Q == -sqrt(-sqrt(2) - 1), Q == sqrt(sqrt(2) + 1)*(sqrt(2) - 1)]
\]

An effort is made to only return solutions that satisfy the current assumptions:

\[
\text{sage: } solve(x^2==4, x)
\]
\[
[x = -2, x = 2]
\]
\[
\text{sage: } assume(x<0)
\]
\[
\text{sage: } solve(x^2==4, x)
\]

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```python
[x == -2]
sage: solve((x^2-4)^2 == 0, x, multiplicities=True)
([x == -2], [2])
sage: solve(x^2==2, x)
[x == -sqrt(2)]
sage: z = var('z')
sage: solve(x^2==2-z, x)
[x == -sqrt(-z + 2)]
sage: assume(x, 'rational')
sage: solve(x^2 == 2, x)
[]
```

In some cases it may be worthwhile to directly use `to_poly_solve` if one suspects some answers are being missed:

```python
sage: forget()
sage: solve(cos(x)==0, x)
[x == 1/2*pi]
sage: solve(cos(x)==0, x, to_poly_solve=True)
[x == 1/2*pi]
sage: solve(cos(x)==0, x, to_poly_solve='force')
[x == 1/2*pi + pi*z...]
```

The same may also apply if a returned unsolved expression has a denominator, but the original one did not:

```python
sage: solve(cos(x) * sin(x) == 1/2, x, to_poly_solve=True)
[sin(x) == 1/2/cos(x)]
sage: solve(cos(x) * sin(x) == 1/2, x, to_poly_solve='force')
[x == 1/4*pi + pi*z...]
```

We use `use_grobner` in Maxima if no solution is obtained from Maxima’s `to_poly_solve`:

```python
sage: x,y = var('x y')
sage: c1(x,y) = (x-5)^2+y^2-16
sage: c2(x,y) = (y-3)^2+x^2-9
sage: solve([c1(x,y),c2(x,y)],[x,y])
[[x == -9/68*sqrt(55) + 135/68, y == -15/68*sqrt(55) + 123/68],
 [x == 9/68*sqrt(55) + 135/68, y == 15/68*sqrt(55) + 123/68]]
```

We use SymPy for Diophantine equations, see `Expression.solve_diophantine`:

```python
sage: assume(x, 'integer')
sage: assume(z, 'integer')
sage: solve((x-z)^2==2, x)
[]
sage: forget()
```

The following shows some more of SymPy’s capabilities that cannot be handled by Maxima:
```python
sage: _ = var('t')
sage: r = solve([x^2 - y^2/exp(x), y-1], x, y, algorithm='sympy')
(2*lambert_w(-1/2), 1)
sage: solve(-2*x**3 + 4*x**2 - 2*x + 6 > 0, x, algorithm='sympy')
[x < 1/3*(1/2)^(1/3)*(9*sqrt(77) + 79)^(1/3) + 2/3*(1/2)^(2/3)/(9*sqrt(77) + 79)^(1/3) + 2/3]
sage: solve(sqrt(2*x^2 - 7) - (3 - x), x, algorithm='sympy')
[x == -8, x == 2]
sage: solve(sqrt(2*x + 9) - sqrt(x + 1) - sqrt(x + 4), x, algorithm='sympy')
[x == 0]
sage: r = solve([x + y + z + t, -z - t], x, y, z, t, algorithm='sympy')
(-y, -t)
sage: solve(abs(x + 3) - 2*abs(x - 3), x, algorithm='sympy', domain='real')
[x == 1, x == 9]
```

We cannot translate all results from SymPy but we can at least print them:

```python
sage: solve(sinh(x) - 2*cosh(x), x, algorithm='sympy')
[ImageSet(Lambda(_n, I*(2*_n*pi + pi/2) + log(sqrt(3))), Integers),
 ImageSet(Lambda(_n, I*(2*_n*pi - pi/2) + log(sqrt(3))), Integers)]
sage: solve(2*sin(x) - 2*sin(2*x), x, algorithm='sympy')
[ImageSet(Lambda(_n, 2*_n*pi), Integers),
 ImageSet(Lambda(_n, 2*_n*pi + pi), Integers),
 ImageSet(Lambda(_n, 2*_n*pi + 5*pi/3), Integers),
 ImageSet(Lambda(_n, 2*_n*pi + pi/3), Integers)]
sage: x^5 + 3*x^3 + 7, x, algorithm='sympy')[0] # known bug
complex_root_of(x^5 + 3*x^3 + 7, 0)
```

A basic interface to Giac is provided:

```python
sage: solve([(2/3)^x-2], [x], algorithm='giac')
...[[[-log(2)/(log(3) - log(2))]]]
sage: f = (sin(x) - 8*cos(x)*sin(x))*(sin(x)^2 + cos(x)) - (2*cos(x)*sin(x) - sin(x))^2 - 2*cos(x)^2 - cos(x))
sage: solve(f, x, algorithm='giac')
...[-2*arctan(sqrt(2)), 0, 2*arctan(sqrt(2)), pi]
sage: x, y = SR.var('x,y')
sage: solve([x+y-4, x*y-3], [x,y], algorithm='giac')
[[[1, 3], [3, 1]]]
```

```python
def solve_ineq(ineq, vars=None):
    """Solves inequalities and systems of inequalities using Maxima. Switches between rational inequalities (solve_ineq_rational) and Fourier elimination (solve_ineq_fourier). See the documentation of these functions for more details."""
    pass
```

### 2.4. Symbolic Equations and Inequalities

177
INPUT:

- `ineq` - one inequality or a list of inequalities
  
  Case 1: If `ineq` is one equality, then it should be a rational expression in one variable. This input is passed to `sage.symbolic.relation.solve_ineq_univar` function.

  Case 2: If `ineq` is a list involving one or more inequalities, than the input is passed to `sage.symbolic.relation.solve_ineq_fourierfunction`. This function can be used for system of linear inequalities and for some types of nonlinear inequalities. See [http://maxima.cvs.sourceforge.net/viewvc/maxima/maxima/share/contrib/fortier_elim/rtest_fouri_elim.mac](http://maxima.cvs.sourceforge.net/viewvc/maxima/maxima/share/contrib/fortier_elim/rtest_fouri_elim.mac) for a big gallery of problems covered by this algorithm.

- `vars` - optional parameter with list of variables. This list is used only if Fourier elimination is used. If omitted or if rational inequality is solved, then variables are determined automatically.

OUTPUT:

- `list` - output is list of solutions as a list of simple inequalities output `[A,B,C]` means `(A or B or C)` each `A, B, C` is again a list and if `A=[a,b]`, then `A` means `(a and b)`.

EXAMPLES:

```
sage: from sage.symbolic.relation import solve_ineq
```

Inequalities in one variable. The variable is detected automatically:

```
sage: solve_ineq(x^2-1>3)
[[x < -2], [x > 2]]
sage: solve_ineq(1/(x-1)<=8)
[[x < 1], [x >= (9/8)]]
```

System of inequalities with automatically detected inequalities:

```
sage: y = var('y')
sage: solve_ineq([x-y<0,x+y-3<0],[y,x])
[[x < y, y < -x + 3, x < (3/2)]]
sage: solve_ineq([[x-y<0,x+y-3<0],[x,y]])
[[x < min(-y + 3, y)]]
```

Note that although Sage will detect the variables automatically, the order it puts them in may depend on the system, so the following command is only guaranteed to give you one of the above answers:

```
sage: solve_ineq([x-y<0,x+y-3<0]) # random
[[x < y, y < -x + 3, x < (3/2)]]
```

ALGORITHM:

Calls `solve_ineq_fourier` if inequalities are list and `solve_ineq_univar` of the inequality is symbolic expression. See the description of these commands for more details related to the set of inequalities which can be solved. The list is empty if there is no solution.

AUTHORS:

- Robert Marik (01-2010)

`sage.symbolic.relation.solve_ineq_fourier(ineq, vars=None)`

Solves system of inequalities using Maxima and Fourier elimination.
Can be used for system of linear inequalities and for some types of nonlinear inequalities. For examples, see the example section below and http://maxima.cvs.sourceforge.net/viewvc/maxima/maxima/share/contrib/fourier_elim/rtest_fourier_elim.mac

**INPUT:**

- `ineq` - list with system of inequalities
- `vars` - optionally list with variables for Fourier elimination.

**OUTPUT:**

- `list` - output is list of solutions as a list of simple inequalities output [A,B,C] means (A or B or C) each
  A, B, C is again a list and if A=[a,b], then A means (a and b). The list is empty if there is no solution.

**EXAMPLES:**

```sage
from sage.symbolic.relation import solve_ineq_fourier
sage: y = var('y')
sage: solve_ineq_fourier([x+y<9,x-y>4],[x,y])
[[y + 4 < x, x < -y + 9, y < (5/2)]]
sage: solve_ineq_fourier([x+y<9,x-y>4],[y,x])[0]
(x=42)
y < -33
sage: solve_ineq_fourier([x^2>=0])
[[x < +Infinity]]
sage: solve_ineq_fourier([log(x)>log(y)],[x,y])
[[y < x, 0 < y]]
sage: solve_ineq_fourier([log(x)>log(y)],[y,x])
[[0 < y, y < x, 0 < x]]
```

Note that different systems will find default variables in different orders, so the following is not tested:

```sage
sage: solve_ineq_fourier([log(x)>log(y)])  # random (one of the following appears)
[[0 < y, y < x, 0 < x]]
[[y < x, 0 < y]]
```

**ALGORITHM:**

Calls Maxima command `fourier_elim`

**AUTHORS:**

- Robert Marik (01-2010)

**Function solves rational inequality in one variable.**

**INPUT:**

- `ineq` - inequality in one variable

**OUTPUT:**

- `list` – output is list of solutions as a list of simple inequalities output [A,B,C] means (A or B or C) each
  A, B, C is again a list and if A=[a,b], then A means (a and b). The list is empty if there is no solution.

**EXAMPLES:**

```sage
from sage.symbolic.relation import solve_ineq_univar
sage: solve_ineq_univar(ineq)
```

Calls Maxima command `solve_ineq_univar()`
sage: from sage.symbolic.relation import solve_ineq_univar
sage: solve_ineq_univar(x-1/x>0)
[[x > -1, x < 0], [x > 1]]
sage: solve_ineq_univar(x^2-1/x>0)
[[x < 0], [x > 1]]
sage: solve_ineq_univar((x^3-1)*x<=0)
[[x >= 0, x <= 1]]

ALGORITHM:
Calls Maxima command solve_rat_ineq

AUTHORS:
- Robert Marik (01-2010)

sage.symbolic.relation.solve_mod(eqns, modulus, solution_dict=False)
Return all solutions to an equation or list of equations modulo the given integer modulus. Each equation must
involve only polynomials in 1 or many variables.
By default the solutions are returned as \( n \)-tuples, where \( n \) is the number of variables appearing anywhere in the
given equations. The variables are in alphabetical order.

INPUT:
- eqns - equation or list of equations
- modulus - an integer
- solution_dict - bool (default: False); if True or non-zero, return a list of dictionaries containing the
  solutions. If there are no solutions, return an empty list (rather than a list containing an empty dictionary).
  Likewise, if there’s only a single solution, return a list containing one dictionary with that solution.

EXAMPLES:

sage: var('x,y')
(x, y)
sage: solve_mod([x^2 + 2 == x, x^2 + y == y^2], 14)
[(4, 2), (4, 6), (4, 9), (4, 13)]
sage: solve_mod([x^2 == 1, 4*x == 11], 15)
[(14,)]
Fermat’s equation modulo 3 with exponent 5:
sage: var('x,y,z')
(x, y, z)
sage: solve_mod([x^5 + y^5 == z^5], 3)
[(0, 0, 0), (0, 1, 1), (0, 2, 2), (1, 0, 1), (1, 1, 2), (1, 2, 0), (2, 0, 2), (2, 1, 0), (2, 2, 1)]

We can solve with respect to a bigger modulus if it consists only of small prime factors:

sage: [d] = solve_mod([5*x + y == 3, 2^5*x - 3^5*y == 9], 3^5*7*11*19*23*29, solution_dict = True)
sage: d[x]
12915279

(continues on next page)
Symbolic Calculus, Release 10.1

sage: d[y]
8610183

For cases where there are relatively few solutions and the prime factors are small, this can be efficient even if the modulus itself is large:

sage: sorted(solve_mod([x^2 == 41], 10^20))
[(4538602480526452429,), (11445932736758703821,), (38554067263241296179,), (45461397519473547571,), (54538602480526452429,), (61445932736758703821,), (88554067263241296179,), (95461397519473547571,)]

We solve a simple equation modulo 2:

sage: x,y = var('x,y')
sage: solve_mod([x == y], 2)
[(0, 0), (1, 1)]

Warning: The current implementation splits the modulus into prime powers, then naively enumerates all possible solutions (starting modulo primes and then working up through prime powers), and finally combines the solution using the Chinese Remainder Theorem. The interface is good, but the algorithm is very inefficient if the modulus has some larger prime factors! Sage does have the ability to do something much faster in certain cases at least by using Groebner basis, linear algebra techniques, etc. But for a lot of toy problems this function as is might be useful. At least it establishes an interface.

sage.symbolic.relation.string_to_list_of_solutions(s)
Used internally by the symbolic solve command to convert the output of Maxima's solve command to a list of solutions in Sage's symbolic package.

EXAMPLES:
We derive the (monic) quadratic formula:

sage: var('x,a,b')
(x, a, b)
sage: solve(x^2 + a*x + b == 0, x)
[x == -1/2*a - 1/2*sqrt(a^2 - 4*b), x == -1/2*a + 1/2*sqrt(a^2 - 4*b)]

Behind the scenes when the above is evaluated the function string_to_list_of_solutions() is called with input the string s below:

sage: s = '[x=-(sqrt(a^2-4*b)+a)/2,x=(sqrt(a^2-4*b)-a)/2]'
sage: sage.symbolic.relation.string_to_list_of_solutions(s)
[x == -1/2*a - 1/2*sqrt(a^2 - 4*b), x == -1/2*a + 1/2*sqrt(a^2 - 4*b)]

sage.symbolic.relation.test_relation_maxima(relation)
Return True if this (in)equality is definitely true. Return False if it is false or the algorithm for testing (in)equality is inconclusive.

EXAMPLES:

sage: from sage.symbolic.relation import test_relation_maxima
sage: k = var('k')
(continues on next page)
sage: pol = 1/(k-1) - 1/k - 1/k/(k-1)
sage: test_relation_maxima(pol == 0)
True
sage: f = sin(x)^2 + cos(x)^2 - 1
sage: test_relation_maxima(f == 0)
True
sage: test_relation_maxima( x == x )
True
sage: test_relation_maxima( x != x )
False
sage: test_relation_maxima( x > x )
False
sage: test_relation_maxima( x^2 > x )
False
sage: test_relation_maxima( x + 2 > x )
True
sage: test_relation_maxima( x - 2 > x )
False

Here are some examples involving assumptions:

sage: x, y, z = var('x, y, z')
sage: assume(x>=y,y>=z,z>=x)
sage: test_relation_maxima(x==z)
True
sage: test_relation_maxima(z<x)
False
sage: test_relation_maxima(z>y)
False
sage: test_relation_maxima(y==z)
True
sage: forget()
sage: assume(x>=1,x<=1)
sage: test_relation_maxima(x==1)
True
sage: test_relation_maxima(x>1)
False
sage: test_relation_maxima(x>=1)
True
sage: test_relation_maxima(x!=1)
False
sage: forget()
sage: assume(x>0)
sage: test_relation_maxima(x==0)
False
sage: test_relation_maxima(x>-1)
True
sage: test_relation_maxima(x!=0)
True
sage: test_relation_maxima(x!=1)
False
sage: forget()
2.5 Symbolic Computation

AUTHORS:

- Bobby Moretti and William Stein (2006-2007)
- Robert Bradshaw (2007-10): minpoly(), numerical algorithm
- Robert Bradshaw (2008-10): minpoly(), algebraic algorithm
- Golam Mortuza Hossain (2009-06-22): _laplace_latex(), _inverse_laplace_latex()
- Tom Coates (2010-06-11): fixed github issue #9217

EXAMPLES:

The basic units of the calculus package are symbolic expressions which are elements of the symbolic expression ring (SR). To create a symbolic variable object in Sage, use the var() function, whose argument is the text of that variable. Note that Sage is intelligent about LaTeXing variable names.

```
sage: x1 = var('x1'); x1
x1
sage: latex(x1)
x_{1}
```

Sage predefines x to be a global indeterminate. Thus the following works:

```
sage: x^2
x^2
sage: type(x)
<class 'sage.symbolic.expression.Expression'>
```

More complicated expressions in Sage can be built up using ordinary arithmetic. The following are valid, and follow the rules of Python arithmetic: (The '=' operator represents assignment, and not equality)

```
sage: var('x,y,z')
(x, y, z)
sage: f = x + y + z/(2*sin(y*z/55))
sage: g = f^f; g
(x + y + 1/2*z/sin(1/55*y*z))^(x + y + 1/2*z/sin(1/55*y*z))
```

Differentiation and integration are available, but behind the scenes through Maxima:

```
sage: f = sin(x)/cos(2*y)
sage: f.derivative(y)
2*sin(x)*sin(2*y)/cos(2*y)^2
sage: g = f.integral(x); g
-cos(x)/cos(2*y)
```

Note that these methods usually require an explicit variable name. If none is given, Sage will try to find one for you.
If the expression is a callable symbolic expression (i.e., the variable order is specified), then Sage can calculate the matrix derivative (i.e., the gradient, Jacobian matrix, etc.) if no variables are specified. In the example below, we use the second derivative test to determine that there is a saddle point at (0,-1/2).

```sage
f(x,y) = x^2*y + y^2 + y
sage: f.diff()  # gradient
(x, y) |--> (2*x*y, x^2 + 2*y + 1)
sage: solve(list(f.diff()), [x,y])
[[x == -I, y == 0], [x == I, y == 0], [x == 0, y == (-1/2)]]
```

Here we calculate the Jacobian for the polar coordinate transformation:

```sage
T(r,theta) = [r*cos(theta),r*sin(theta)]
sage: T
(r, theta) |--> (r*cos(theta), r*sin(theta))
sage: T.diff()  # Jacobian matrix
[ r |--> cos(theta) (r, theta) |--> -r*sin(theta)]
[ r |--> sin(theta) (r, theta) |--> r*cos(theta)]
sage: T.diff().det()  # Jacobian
(r, theta) |--> r*cos(theta)^2 + r*sin(theta)^2
```

When the order of variables is ambiguous, Sage will raise an exception when differentiating:

```sage
f = sin(x+y); f.derivative()
Traceback (most recent call last):
...
ValueError: No differentiation variable specified.
```

Simplifying symbolic sums is also possible, using the `sum()` command, which also uses Maxima in the background:

```sage
k, m = var('k, m')
sage: sum(1/k^4, k, 1, oo)
1/90*pi^4
sage: sum(binomial(m,k), k, 0, m)
2^m
```

Symbolic matrices can be used as well in various ways, including exponentiation:

```sage
M = matrix([[x,x^2],[1/x,x]])
sage: M^2
```

(continues on next page)
Complex exponentiation works, but may require a patched version of maxima (github issue #32898) for now:

```sage
sage: M = i*matrix([[pi]])
sage: e^M  # not tested, requires patched maxima
[-1]
sage: M = i*matrix([[pi,0],[0,2*pi]])
sage: e^M
[-1 0]
[ 0 1]
sage: M = matrix([[0,pi],[-pi,0]])
sage: e^M
[-1 0]
[ 0 -1]
```

Substitution works similarly. We can substitute with a python dict:

```sage
sage: f = sin(x*y - z)
sage: f({x: var('t'), y: z})
sin(t*z - z)
```

Also we can substitute with keywords:

```sage
sage: f = sin(x*y - z)
sage: f(x=t, y=z)
sin(t*z - z)
```

Another example:

```sage
sage: f = sin(2*pi*x/y)
sage: f(x=4)
sin(8*pi/y)
```

It is no longer allowed to call expressions with positional arguments:

```sage
sage: f = sin(x)
sage: f(y)
Traceback (most recent call last):
...
TypeError: Substitution using function-call syntax and unnamed arguments has been removed. You can use named arguments instead, like EXPR(x=..., y=...)
sage: f(x=pi)
0
```

We can also make a CallableSymbolicExpression, which is a SymbolicExpression that is a function of specified variables in a fixed order. Each SymbolicExpression has a function(...) method that is used to create a
CallableSymbolicExpression, as illustrated below:

```sage
sage: u = log((2-x)/(y+5))
sage: f = u.function(x, y); f
(x, y) |--> log(-(x - 2)/(y + 5))
```

There is an easier way of creating a CallableSymbolicExpression, which relies on the Sage preparser.

```sage
sage: f(x,y) = log(x)*cos(y); f
(x, y) |--> cos(y)*log(x)
```

Then we have fixed an order of variables and there is no ambiguity substituting or evaluating:

```sage
sage: f(x,y) = log((2-x)/(y+5))
sage: f(7,t)
log(-5/(t + 5))
```

Some further examples:

```sage
sage: f = 5*sin(x)
sage: f
5*sin(x)
sage: f(x=2)
5*sin(2)
sage: f(x=pi)
0
sage: float(f(x=pi))
0.0
```

Another example:

```sage
sage: f = integrate(1/sqrt(9+x^2), x); f
arcsinh(1/3*x)
sage: f(x=3)
arcsinh(1)
sage: f.derivative(x)
1/sqrt(x^2 + 9)
```

We compute the length of the parabola from 0 to 2:

```sage
sage: x = var('x')
sage: y = x^2
sage: dy = derivative(y,x)
sage: z = integral(sqrt(1 + dy^2), x, 0, 2)
sage: z
sqrt(17) + 1/4*arcsinh(4)
sage: n(z,200)
4.6467837624329358733826155674904591885104869874232887508703
sage: float(z)
4.646783762432936
```

We test pickling:

```sage
sage: x, y = var('x,y')
sage: f = -sqrt(pi)*(x^3 + sin(x/cos(y)))
```

(continues on next page)
Coercion examples:

We coerce various symbolic expressions into the complex numbers:

```python
sage: CC(I)
1.00000000000000*I
sage: CC(2*I)
2.00000000000000*I
sage: ComplexField(200)(2*I)
2.0000000000000000000000000000000000000000000000000000000000*I
sage: ComplexField(200)(sin(I))
1.1752011936438014568823818505956008151557179813340958702296*I
sage: f = sin(I) + cos(I/2); f
\cosh(1/2) + I*\sinh(1)
sage: CC(f)
1.12762596520638 + 1.17520119364380*I
sage: ComplexField(200)(f)
1.1276259652063807852262251614026720125478471180986674836290 + 1.1752011936438014568823818505956008151557179813340958702296*I
sage: ComplexField(100)(f)
1.1276259652063807852262251614026720125478471180986674836290 + 1.1752011936438014568823818505956008151557179813340958702296*I
```

We illustrate construction of an inverse sum where each denominator has a new variable name:

```python
sage: f = sum(1/var('n%s%s' %i)^i for i in range(10))
sage: f
1/n1 + 1/n2^2 + 1/n3^3 + 1/n4^4 + 1/n5^5 + 1/n6^6 + 1/n7^7 + 1/n8^8 + 1/n9^9 + 1
```

Note that after calling `var`, the variables are immediately available for use:

```python
sage: (n1 + n2)^5
(n1 + n2)^5
```

We can, of course, substitute:

```python
sage: f(n9=9, n7=n6)
1/n1 + 1/n2^2 + 1/n3^3 + 1/n4^4 + 1/n5^5 + 1/n6^6 + 1/n7^7 + 1/n8^8 + 1/n9^9 + 1
```

```
sage.calculus.calculus.at(ex, *args, **kwds)
  Parses at formulations from other systems, such as Maxima. Replaces evaluation ‘at’ a point with substitution method of a symbolic expression.

  EXAMPLES:
  We do not import at at the top level, but we can use it as a synonym for substitution if we import it:
  
```

```python
sage: g = x^3 - 3
sage: from sage.calculus.calculus import at
sage: at(g, x=1)
-2
```
Sage: g.subs(x=1)
-2

We find a formal Taylor expansion:

\[
\begin{align*}
&\text{sage: } h, x = \text{var('h, x')} \\
&\text{sage: } u = \text{function('u')} \\
&\text{sage: } u(x + h) \\
&u(h + x) \\
&\text{sage: } \text{diff}(u(x+h), x) \\
&\text{D}[0](u)(h + x) \\
&\text{sage: } \text{taylor}(u(x+h), h, 0, 4) \\
&1/24*\text{h}^4*\text{diff}(u(x), x, x, x, x) + 1/6*\text{h}^3*\text{diff}(u(x), x, x, x) \\
&+ 1/2*\text{h}^2*\text{diff}(u(x), x, x) + \text{h}*\text{diff}(u(x), x) + u(x)
\end{align*}
\]

We compute a Laplace transform:

\[
\begin{align*}
&\text{sage: } \text{var('s, t')} \\
&(s, t) \\
&\text{sage: } f = \text{function('f')}(t) \\
&\text{sage: } \text{f.diff(t, 2)} \\
&\text{diff}(f(t), t, t) \\
&\text{sage: } \text{f.diff(t, 2)}.\text{laplace}(t, s) \\
&s^2*\text{laplace}(f(t), t, s) - s*\text{f}(0) - \text{D}[0]\text{(f)(0)}
\end{align*}
\]

We can also accept a non-keyword list of expression substitutions, like Maxima does (github issue #12796):

\[
\begin{align*}
&\text{sage: } \text{from sage.calculus.calculus import at} \\
&\text{sage: } f = \text{function('f')} \\
&\text{sage: } \text{at}(f(x), [x == 1]) \\
&f(1)
\end{align*}
\]

\begin{verbatim}
sage.calculus.calculus.dummy_diff(*args)
This function is called when 'diff' appears in a Maxima string.

EXAMPLES:
\end{verbatim}

\[
\begin{align*}
&\text{sage: } \text{from sage.calculus.calculus import dummy_diff} \\
&\text{sage: } x, y = \text{var('x, y')} \\
&\text{sage: } \text{dummy_diff}(\text{sin}(x*y), x, \text{SR}(2), y, \text{SR}(1)) \\
&-x^2*y^2*\text{cos}(x*y) - 2*y^3*\text{sin}(x*y)
\end{align*}
\]

Here the function is used implicitly:

\[
\begin{align*}
&\text{sage: } a = \text{var('a')} \\
&\text{sage: } f = \text{function('cr')}(a) \\
&\text{sage: } g = \text{f.diff(a)}; g \\
&\text{diff}\text{(cr(a), a)}
\end{align*}
\]

\begin{verbatim}
sage.calculus.calculus.dummy_integrate(*args)
This function is called to create formal wrappers of integrals that Maxima can't compute:

EXAMPLES:
\end{verbatim}
```python
sage: from sage.calculus.calculus import dummy_integrate
sage: f = function('f(x, x)
integrate(f(x), x)
sage: a,b = var('a,b')
sage: dummy_integrate(f(x), x, a, b)
integrate(f(x), x, a, b)
```

`sage.calculus.calculus.dummy_inverse_laplace(*args)`

This function is called to create formal wrappers of inverse Laplace transforms that Maxima can’t compute:

EXAMPLES:

```python
sage: from sage.calculus.calculus import dummy_inverse_laplace
sage: s,t = var('s,t')
sage: F = function('F')
sage: dummy_inverse_laplace(F(s), s, t)
ilt(F(s), s, t)
```

`sage.calculus.calculus.dummy_laplace(*args)`

This function is called to create formal wrappers of laplace transforms that Maxima can’t compute:

EXAMPLES:

```python
sage: from sage.calculus.calculus import dummy_laplace
sage: s,t = var('s,t')
sage: f = function('f')
sage: dummy_laplace(f(t), t, s)
laplace(f(t), t, s)
```

`sage.calculus.calculus.dummy_pochhammer(*args)`

This function is called to create formal wrappers of Pochhammer symbols

EXAMPLES:

```python
sage: from sage.calculus.calculus import dummy_pochhammer
sage: s,t = var('s,t')
sage: dummy_pochhammer(s, t)
gamma(s + t)/gamma(s)
```

`sage.calculus.calculus.inverse_laplace(ex, s, t, algorithm='maxima')`

Return the inverse Laplace transform with respect to the variable $t$ and transform parameter $s$, if possible.

If this function cannot find a solution, a formal function is returned. The function that is returned may be viewed as a function of $t$.

**DEFINITION:**

The inverse Laplace transform of a function $F(s)$ is the function $f(t)$, defined by

$$f(t) = \frac{1}{2\pi i} \int_{\gamma - i\infty}^{\gamma + i\infty} e^{st} F(s) ds,$$

where $\gamma$ is chosen so that the contour path of integration is in the region of convergence of $F(s)$.

**INPUT:**

- `ex` – a symbolic expression

2.5. Symbolic Computation
Symbolic Calculus, Release 10.1

- \( s \) – transform parameter
- \( t \) – independent variable
- \texttt{algorithm} – (default: 'maxima') one of
  - 'maxima' – use Maxima (the default)
  - 'sympy' – use SymPy
  - 'giac' – use Giac

See also:
\texttt{laplace()}

EXAMPLES:

```python
sage: var('w, m')
(w, m)
sage: f = (1/(w^2+10)).inverse_laplace(w, m); f
1/10*sqrt(10)*sin(sqrt(10)*m)
sage: laplace(f, m, w)
1/(w^2 + 10)
sage: f(t) = t*cos(t)
sage: s = var('s')
sage: L = laplace(f, t, s); L
(t |--> 2*s^2/(s^2 + 1)^2 - 1/(s^2 + 1))
sage: inverse_laplace(L, s, t)
t |--> t*cos(t)
sage: inverse_laplace(1/(s^3+1), s, t)
1/3*(sqrt(3)*sin(1/2*sqrt(3)*t) - cos(1/2*sqrt(3)*t))*e^(1/2*t) + 1/3*e^(-t)
```

No explicit inverse Laplace transform, so one is returned formally a function \( \text{ilt} \):

```python
sage: inverse_laplace(cos(s), s, t)
\text{ilt}(\cos(s), s, t)
```

Transform an expression involving a time-shift, via SymPy:

```python
sage: inverse_laplace(1/s^2*exp(-s), s, t, algorithm='sympy').simplify()
(t - 1)*heaviside(t - 1)
```

The same instance with Giac:

```python
sage: inverse_laplace(1/s^2*exp(-s), s, t, algorithm='giac')
(t - 1)*heaviside(t - 1)
```

Transform a rational expression:

```python
sage: inverse_laplace((2*s^2*exp(-2*s) - exp(-s))/(s^3+1), s, t, 
....: algorithm='giac')
-1/3*(sqrt(3)*e^(1/2*t - 1/2)*sin(1/2*sqrt(3)*(t - 1)) 
  - cos(1/2*sqrt(3)*(t - 1))*e^(1/2*t - 1/2) + e^(-t + 1))*heaviside(t - 1) 
  + 2/3*2*cos(1/2*sqrt(3)*(t - 2))*e^(1/2*t - 1) + e^(-t + 2))*heaviside(t - 2)
sage: inverse_laplace(1/(s - 1), s, x)
e^x
```
The inverse Laplace transform of a constant is a delta distribution:

```python
sage: inverse_laplace(1, s, t)
dirac_delta(t)
```

```python
sage: inverse_laplace(1, s, t, algorithm='sympy')
dirac_delta(t)
```

```python
sage: inverse_laplace(1, s, t, algorithm='giac')
dirac_delta(t)
```

```python
sage.calculus.calculus.laplace(ex, t, s, algorithm='maxima')
```

Return the Laplace transform with respect to the variable \( t \) and transform parameter \( s \), if possible.

If this function cannot find a solution, a formal function is returned. The function that is returned may be viewed as a function of \( s \).

**DEFINITION:**

The Laplace transform of a function \( f(t) \), defined for all real numbers \( t \geq 0 \), is the function \( F(s) \) defined by

\[
F(s) = \int_{0}^{\infty} e^{-st} f(t) dt.
\]

**INPUT:**

- \( \text{ex} \) – a symbolic expression
- \( \text{t} \) – independent variable
- \( \text{s} \) – transform parameter
- \( \text{algorithm} \) – (default: 'maxima') one of
  - 'maxima' – use Maxima (the default)
  - 'sympy' – use SymPy
  - 'giac' – use Giac

**Note:** The 'sympy' algorithm returns the tuple \((F, a, \text{cond})\) where \( F \) is the Laplace transform of \( f(t) \), \( \text{Re}(s) > a \) is the half-plane of convergence, and \( \text{cond} \) are auxiliary convergence conditions.

**See also:**

`inverse_laplace()`

**EXAMPLES:**

We compute a few Laplace transforms:

```python
sage: var('x, s, z, t, t0')
(x, s, z, t, t0)
sage: sin(x).laplace(x, s)
1/(s^2 + 1)
sage: (z + exp(x)).laplace(x, s)
z/s + 1/(s - 1)
sage: log(t/t0).laplace(t, s)
-(euler_gamma + log(s) + log(t0))/s
```

We do a formal calculation:
A BATTLE BETWEEN the X-women and the Y-men (by David Joyner): Solve

\[ x' = -16y, \ x(0) = 270, \ y' = -x + 1, \ y(0) = 90. \]

This models a fight between two sides, the “X-women” and the “Y-men”, where the X-women have 270 initially and the Y-men have 90, but the Y-men are better at fighting, because of the higher factor of “-16” vs “-1”, and also get an occasional reinforcement, because of the “+1” term.

Next we form the augmented matrix of the above system:

\[
\begin{bmatrix}
s & 16 & 270 \\
1 & s & 90 + 1/s \\
\end{bmatrix}
\]

(continues on next page)
The Laplace transform of the exponential function:

```python
sage: laplace(exp(x), x, s)
sage: 1/(s - 1)
```

Dirac’s delta distribution is handled (the output of SymPy is related to a choice that has to be made when defining Laplace transforms of distributions):

```python
sage: laplace(dirac_delta(t), t, s)
sage: 1
```

Heaviside step function can be handled with different interfaces. Try with Maxima:

```python
sage: laplace(heaviside(t-1), t, s)
sage: e^(-s)/s
```

Try with giac:

```python
sage: laplace(heaviside(t-1), t, s, algorithm='giac')
sage: e^(-s)/s
```

Try with SymPy:

```python
sage: laplace(heaviside(t-1), t, s, algorithm='sympy')
sage: (e^(-s)/s, 0, True)
```

**Note:** The output may also use und (undefined), ind (indefinite but bounded), and infinity (complex infinity).
EXAMPLES:

```
sage: x = var('x')
sage: f = (1 + 1/x)^x
sage: f.limit(x=oo)
e
sage: f.limit(x=5)
7776/3125
```

Domain to real, a regression in 5.46.0, see https://sf.net/p/maxima/bugs/4138

```
sage: maxima_calculus.eval("domain:real")
...
sage: f.limit(x=1.2).n()
2.06961575467...
sage: maxima_calculus.eval("domain:complex");
...
```

Otherwise, it works

```
sage: f.limit(x=I, taylor=True)
(-I + 1)^I
sage: f(x=1.2)
2.0696157546720...
sage: CDF(f(x=I))
2.0628722350809046 + 0.7450070621797239*I
sage: CDF(f.limit(x=I))
2.0628722350809046 + 0.7450070621797239*I
```

Notice that Maxima may ask for more information:

```
sage: var('a')
a
sage: limit(x^a,x=0)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a positive, negative or zero?
```

With this example, Maxima is looking for a LOT of information:

```
sage: assume(a>0)
sage: limit(x^a,x=0)  # random - maxima 5.46.0 does not need extra assumption
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
```

(continues on next page)
Is a an integer?
```
sage: assume(a, 'integer')
```
```
sage: limit(x^a, x=0)  # random - maxima 5.46.0 does not need extra assumption
Traceback (most recent call last):
 ... 
ValueError: Computation failed since Maxima requested additional constraints; using the `assume` command before evaluation *may* help
(example of legal syntax is `assume(a>0)`, see `assume?` for more details)
```
Is a an even number?
```
sage: assume(a, 'even')
```
sage: limit(x^a, x=0)
0
```
```
sage: forget()
```

More examples:
```
sage: limit(x^log(x), x=0, dir='+')
0
```
```
sage: limit((x+1)^(1/x), x=0)
e
```
```
sage: limit(e^x/x, x=-oo)
0
```
```
sage: limit(-e^x/x, x=oo)
-Infinity
```
```
sage: limit((cos(x))/(x^2), x=0)
+Infinity
```
```
sage: limit(sqrt(x^2+1) - x, x=oo)
0
```
```
sage: limit(x^2/(sec(x)-1), x=0)
2
```
```
sage: limit(cos(x)/(cos(x)-1), x=0)
-Infinity
```
```
sage: limit(x*sin(1/x), x=0)
0
```
```
sage: limit(e^(-1/x), x=0, dir='right')
0
```
```
sage: limit(e^(-1/x), x=0, dir='left')
+Infinity
```
```
sage: f = log(log(x)) / log(x)
```
```
sage: forget(); assume(x <-2); limit(f, x=0, taylor=True)
0
```
```
sage: forget()
```

Here ind means “indefinite but bounded”:
```
sage: lim(sin(1/x), x = 0)
ind
```

We can use other packages than maxima, namely “sympy”, “giac”, “fricas”.

2.5. Symbolic Computation
With the standard package Giac:

```python
sage: from sage.libs.giac.giac import libgiac               # random
sage: (exp(-x)/(2+sin(x))).limit(x=oo, algorithm='giac')
0
sage: limit(e^(-1/x), x=0, dir='right', algorithm='giac')
0
sage: limit(e^(-1/x), x=0, dir='left', algorithm='giac')
+Infinity
sage: (x / (x+2^x+cos(x))).limit(x=-infinity, algorithm='giac')
1
```

With the optional package FriCAS:

```python
sage: (x / (x+2^x+cos(x))).limit(x=-infinity, algorithm='fricas')  # optional - fricas
1
sage: limit(e^(-1/x), x=0, dir='right', algorithm='fricas')  # optional - fricas
0
sage: limit(e^(-1/x), x=0, dir='left', algorithm='fricas')  # optional - fricas
+Infinity
```

One can also call Mathematica's online interface:

```python
sage: limit(pi+log(x)/x,x=oo, algorithm='mathematica_free')  # optional - internet
pi
```

```python
sage.calculus.calculus.limit(expr, dir=None, taylor=False, algorithm='maxima', **argv)

Return the limit as the variable \( v \) approaches \( a \) from the given direction.

expr.limit(x = a)
expr.limit(x = a, dir='+')
```

**INPUT:**

- **dir** – (default: None); may have the value 'plus' (or '+' or 'right' or 'above') for a limit from above, 'minus' (or '-' or 'left' or 'below') for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- **taylor** – (default: False); if True, use Taylor series, which allows more limits to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- **argv** - 1 named parameter

**Note:** The output may also use und (undefined), ind (indefinite but bounded), and infinity (complex infinity).

**EXAMPLES:**

```python
sage: x = var('x')
sage: f = (1 + 1/x)^x
sage: f.limit(x=oo)
e
```
sage: f.limit(x=5)
7776/3125

Domain to real, a regression in 5.46.0, see https://sf.net/p/maxima/bugs/4138

sage: maxima_calculus.eval("domain:real")
...
sage: f.limit(x=1.2).n()
2.06961575467...
sage: maxima_calculus.eval("domain:complex");
...

Otherwise, it works

sage: f.limit(x=I, taylor=True)
(-I + 1)^I
sage: f(x=1.2)
2.0696157546720...
sage: CDF(f(x=1))
2.0628722350809046 + 0.7450070621797239*I

Notice that Maxima may ask for more information:

sage: var('a')
a
sage: limit(x^a, x=0)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a positive, negative or zero?

With this example, Maxima is looking for a LOT of information:

sage: assume(a>0)
sage: limit(x^a, x=0)  # random - maxima 5.46.0 does not need extra assumption
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a an integer?
sage: assume(a,'integer')
sage: limit(x^a, x=0)  # random - maxima 5.46.0 does not need extra assumption
Traceback (most recent call last):
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?` for more details)

Is a an even number?
```
sage: assume(a, 'even')
sage: limit(x^a, x=0)
0
```
```
sage: forget()
```

More examples:
```
sage: limit(x*log(x), x=0, dir='+')
0
sage: limit((x+1)^(1/x), x=0)
e
sage: limit(e^x/x, x=oo)
+Infinity
sage: limit(e^x/x, x=-oo)
0
sage: limit(-e^x/x, x=oo)
-Infinity
sage: limit((cos(x))/(x^2), x=0)
+Infinity
sage: limit(sqrt(x^2+1) - x, x=oo)
0
sage: limit(x^2/(sec(x)-1), x=0)
2
sage: limit(cos(x)/(cos(x)-1), x=0)
-Infinity
sage: limit(x*sin(1/x), x=0)
0
sage: limit(e^(-1/x), x=0, dir='right')
0
sage: limit(e^(-1/x), x=0, dir='left')
+Infinity
```
```
sage: f = log(log(x)) / log(x)
sage: forget(); assume(x < -2); lim(f, x=0, taylor=True)
0
```
```
sage: forget()
```

Here ind means “indefinite but bounded”:
```
sage: lim(sin(1/x), x=0)
ind
```

We can use other packages than maxima, namely “sympy”, “giac”, “fricas”.

With the standard package Giac:
```
sage: from sage.libs.giac.giac import libgiac  # random
sage: (exp(-x)/(2+sin(x))).limit(x=oo, algorithm='giac')
```

(continues on next page)
\[
\begin{align*}
\textbf{sage: } & \text{limit}(e^{-1/x}, x=0, \text{dir}=\text{'right'}, \text{algorithm}=\text{'giac'}) \\
& 0 \\
\textbf{sage: } & \text{limit}(e^{-1/x}, x=0, \text{dir}=\text{'left'}, \text{algorithm}=\text{'giac'}) \\
& +\infty \\
\textbf{sage: } & (x / (x+2^x+\cos(x))).\text{limit}(x=-\infty, \text{algorithm}=\text{'giac'}) \\
& 1
\end{align*}
\]

With the optional package FriCAS:

\[
\begin{align*}
\textbf{sage: } & (x / (x+2^x+\cos(x))).\text{limit}(x=-\infty, \text{algorithm}=\text{'fricas'}) \\
& 1 \\
\textbf{sage: } & \text{limit}(e^{-1/x}, x=0, \text{dir}=\text{'right'}, \text{algorithm}=\text{'fricas'}) \\
& 0 \\
\textbf{sage: } & \text{limit}(e^{-1/x}, x=0, \text{dir}=\text{'left'}, \text{algorithm}=\text{'fricas'}) \\
& +\infty
\end{align*}
\]

One can also call Mathematica’s online interface:

\[
\begin{align*}
\textbf{sage: } & \text{limit}(\pi+\log(x)/x,x=\infty, \text{algorithm}=\text{'mathematica_free'}) \\
& \pi
\end{align*}
\]

\[
\begin{align*}
\text{sage.calculus.calculus.mapped_opts(v)} \\
\text{Used internally when creating a string of options to pass to Maxima.}
\end{align*}
\]

\[
\begin{align*}
\text{INPUT:} \\
\bullet \ v \ - \ \text{an object}
\end{align*}
\]

\[
\begin{align*}
\text{OUTPUT:} \ \text{a string.}
\end{align*}
\]

The main use of this is to turn Python bools into lower case strings.

\[
\begin{align*}
\text{EXAMPLES:}
\end{align*}
\]

\[
\begin{align*}
\textbf{sage: } & \text{sage.calculus.calculus.mapped_opts(} \text{True} \text{)} \\

\textbf{sage: } & \text{sage.calculus.calculus.mapped_opts(} \text{False} \text{)} \\
& 'false' \\
\textbf{sage: } & \text{sage.calculus.calculus.mapped_opts(} \text{'bar'} \text{)} \\
& 'bar'
\end{align*}
\]

\[
\begin{align*}
\text{sage.calculus.calculus.maxima_options(**kwds)} \\
\text{Used internally to create a string of options to pass to Maxima.}
\end{align*}
\]

\[
\begin{align*}
\text{EXAMPLES:}
\end{align*}
\]

\[
\begin{align*}
\textbf{sage: } & \text{sage.calculus.calculus.maxima_options(} \text{an_option=} \text{True, another=} \text{False, foo=} \text{'bar'} \text{)} \\
& 'an_option=true,another=false,foo=bar'
\end{align*}
\]

\[
\begin{align*}
\text{sage.calculus.calculus.minpoly(ex, var='x', algorithm=None, bits=None, degree=None, epsilon=0)} \\
\text{Return the minimal polynomial of self, if possible.}
\end{align*}
\]

2.5. Symbolic Computation
INPUT:
- **var** – polynomial variable name (default 'x')
- **algorithm** – 'algebraic' or 'numerical' (default both, but with numerical first)
- **bits** – the number of bits to use in numerical approx
- **degree** – the expected algebraic degree
- **epsilon** – return without error as long as f(self) epsilon, in the case that the result cannot be proven.

All of the above parameters are optional, with epsilon=0, bits and degree tested up to 1000 and 24 by default respectively. The numerical algorithm will be faster if bits and/or degree are given explicitly. The algebraic algorithm ignores the last three parameters.

OUTPUT: The minimal polynomial of *self*. If the numerical algorithm is used, then it is proved symbolically when epsilon=0 (default).

If the minimal polynomial could not be found, two distinct kinds of errors are raised. If no reasonable candidate was found with the given bits/degree parameters, a ValueError will be raised. If a reasonable candidate was found but (perhaps due to limits in the underlying symbolic package) was unable to be proved correct, a NotImplementedError will be raised.

ALGORITHM: Two distinct algorithms are used, depending on the algorithm parameter. By default, the numerical algorithm is attempted first, then the algebraic one.

Algebraic: Attempt to evaluate this expression in QQbar, using cyclotomic fields to resolve exponential and trig functions at rational multiples of π, field extensions to handle roots and rational exponents, and computing compositums to represent the full expression as an element of a number field where the minimal polynomial can be computed exactly. The bits, degree, and epsilon parameters are ignored.

Numerical: Computes a numerical approximation of *self* and use PARI’s pari:algdep to get a candidate minpoly *f*. If *f*(self), evaluated to a higher precision, is close enough to 0 then evaluate *f*(self) symbolically, attempting to prove vanishing. If this fails, and epsilon is non-zero, return *f* if and only if *f*(self) < epsilon. Otherwise raise a ValueError (if no suitable candidate was found) or a NotImplementedError (if a likely candidate was found but could not be proved correct).

EXAMPLES: First some simple examples:

```python
sage: sqrt(2).minpoly()
x^2 - 2
sage: minpoly(2^(1/3))
x^3 - 2
sage: minpoly(sqrt(2) + sqrt(-1))
x^4 - 2*x^2 + 9
sage: minpoly(sqrt(2)-3^(1/3))
x^6 - 6*x^4 + 6*x^3 + 12*x^2 + 36*x + 1
```

Works with trig and exponential functions too.

```python
sage: sin(pi/3).minpoly()
x^2 - 3/4
sage: sin(pi/7).minpoly()
x^6 - 7/4*x^4 + 7/8*x^2 - 7/64
sage: minpoly(exp(I*pi/17))
x^16 - x^15 + x^14 - x^13 + x^12 - x^11 + x^10 - x^9 + x^8 - x^7 + x^6 - x^5 + x^4 - x^3 + x^2 - x + 1
```

Here we verify it gives the same result as the abstract number field.
The `minpoly()` function is used implicitly when creating number fields:

```python
sage: x = var('x')
sage: eqn = x^3 + sqrt(2)*x + 5 == 0
sage: a = solve(eqn, x)[0].rhs()
sage: QQ[a]
Number Field in a with defining polynomial x^6 + 10*x^3 - 2*x^2 + 25
with a = 0.7185272465828846? - 1.721353471724806?*I
```

Here we solve a cubic and then recover it from its complicated radical expansion.

```python
sage: f = x^3 - x + 1
sage: a = f.solve(x)[0].rhs(); a
-1/2*(1/18*sqrt(23)*sqrt(3) - 1/2)^(1/3)*(I*sqrt(3) + 1)
- 1/6*(-I*sqrt(3) + 1)/(1/18*sqrt(23)*sqrt(3) - 1/2)^(1/3)
sage: a.minpoly()
x^3 - x + 1
```

Note that simplification may be necessary to see that the minimal polynomial is correct.

```python
sage: a = sqrt(2)+sqrt(3)+sqrt(5)
sage: f = a.minpoly(); f
x^8 - 40*x^6 + 352*x^4 - 960*x^2 + 576
sage: f(a)
(sqrt(5) + sqrt(3) + sqrt(2))^8 - 40*(sqrt(5) + sqrt(3) + sqrt(2))^6
+ 352*(sqrt(5) + sqrt(3) + sqrt(2))^4 - 960*(sqrt(5) + sqrt(3) + sqrt(2))^2
+ 576
sage: f(a).expand()
0
```

The degree must be high enough (default tops out at 24).

```python
sage: a = sin(pi/7)
sage: f = a.minpoly(algorithm='numerical'); f
x^6 - 7/4*x^4 + 7/8*x^2 - 7/64
sage: f(a).horner(a).numerical_approx(100)
0.0000000000000000000000000000
```

The degree must be high enough (default tops out at 24).

```python
sage: a = sqrt(3) + sqrt(2)
sage: a.minpoly(algorithm='numerical', bits=100, degree=3)
Traceback (most recent call last):
...
ValueError: Could not find minimal polynomial (100 bits, degree 3).
sage: a.minpoly(algorithm='numerical', bits=100, degree=10)
x^4 - 10*x^2 + 1
```
Symbolic Calculus, Release 10.1

```
sage: cos(pi/33).minpoly(algorithm='algebraic')
x^10 + 1/2*x^9 - 5/2*x^8 - 5/4*x^7 + 17/8*x^6 + 17/16*x^5
- 43/64*x^4 - 43/128*x^3 + 3/64*x^2 + 3/128*x + 1/1024
sage: cos(pi/33).minpoly(algorithm='numerical')
x^10 + 1/2*x^9 - 5/2*x^8 - 5/4*x^7 + 17/8*x^6 + 17/16*x^5
- 43/64*x^4 - 43/128*x^3 + 3/64*x^2 + 3/128*x + 1/1024
```

Sometimes it fails, as it must given that some numbers aren’t algebraic:

```
sage: sin(1).minpoly(algorithm='numerical')
Traceback (most recent call last):
...
ValueError: Could not find minimal polynomial (1000 bits, degree 24).
```

**Note:** Of course, failure to produce a minimal polynomial does not necessarily indicate that this number is transcendental.

`sage.calculus.calculus.mma_free_limit(expression, v, a=0, dir=None)`
Limit using Mathematica’s online interface.

**INPUT:**
- `expression` – symbolic expression
- `v` – variable
- `a` – value where the variable goes to
- `dir` – `'+'`, `'-'` or `None` (optional, default: `None`)

**EXAMPLES:**

```
sage: from sage.calculus.calculus import mma_free_limit
sage: mma_free_limit(sin(x)/x, x, a=0) # optional - internet
1
```

Another simple limit:

```
sage: mma_free_limit(e^(-x), x, a=oo) # optional - internet
0
```

`sage.calculus.calculus.nintegral(expression, x, a, b, desiredRelativeError='1e-8', maximumNumSubintervals=200)`

Return a floating point machine precision numerical approximation to the integral of self from `a` to `b`, computed using floating point arithmetic via maxima.

**INPUT:**
- `x` – variable to integrate with respect to
- `a` – lower endpoint of integration
- `b` – upper endpoint of integration
- `desiredRelativeError` – (default: `1e-8`) the desired relative error
- `maximumNumSubintervals` – (default: `200`) maximal number of subintervals
OUTPUT:

- float: approximation to the integral
- float: estimated absolute error of the approximation
- the number of integrand evaluations
- an error code:
  - 0 – no problems were encountered
  - 1 – too many subintervals were done
  - 2 – excessive roundoff error
  - 3 – extremely bad integrand behavior
  - 4 – failed to converge
  - 5 – integral is probably divergent or slowly convergent
  - 6 – the input is invalid; this includes the case of desired_relative_error being too small to be achieved

ALIAS: \texttt{nintegrate()} is the same as \texttt{nintegral()}

REMARK: There is also a function \texttt{numerical_integral()} that implements numerical integration using the GSL C library. It is potentially much faster and applies to arbitrary user defined functions.

Also, there are limits to the precision to which Maxima can compute the integral due to limitations in quadpack. In the following example, remark that the last value of the returned tuple is 6, indicating that the input was invalid, in this case because of a too high desired precision.

```sage
sage: f = x
sage: f.nintegral(x, 0, 1, 1e-14)
(0.0, 0.0, 0, 6)
```

EXAMPLES:

```sage
sage: f(x) = exp(-sqrt(x))
sage: f.nintegral(x, 0, 1)
(0.5284822353142306, 4.163...e-11, 231, 0)
```

We can also use the \texttt{numerical_integral()} function, which calls the GSL C library.

```sage
sage: numerical_integral(f, 0, 1)
(0.52848223225314206, 6.83928460...e-07)
```

Note that in exotic cases where floating point evaluation of the expression leads to the wrong value, then the output can be completely wrong:

```sage
sage: f = exp(pi*sqrt(163)) - 262537412640768744
```

Despite appearance, $f$ is really very close to 0, but one gets a nonzero value since the definition of \texttt{float(f)} is that it makes all constants inside the expression floats, then evaluates each function and each arithmetic operation using float arithmetic:

```sage
sage: float(f)
-480.0
```

Computing to higher precision we see the truth:
Now numerically integrating, we see why the answer is wrong:

\[
\text{sage: } \text{f.nintegrate(x,0,1)} \\
\text{(-480.000000000000..., 5.32907051820075...e-12, 21, 0)}
\]

It is just because every floating point evaluation of \(f\) returns \(-480.0\) in floating point.

Important note: using PARI/GP one can compute numerical integrals to high precision:

\[
\text{sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')} \\
'2.5657285005610514897356396130495741774610003917 E-127'
\]

Note that the input function above is a string in PARI syntax.

```python
sage.calculus.calculus.nintegrate(ex, x, a, b, desired_relative_error='1e-8', maximum_num_subintervals=200)
```

Return a floating point machine precision numerical approximation to the integral of \(\text{self}\) from \(a\) to \(b\), computed using floating point arithmetic via maxima.

**INPUT:**

- \(x\) – variable to integrate with respect to
- \(a\) – lower endpoint of integration
- \(b\) – upper endpoint of integration
- \(\text{desired\_relative\_error}\) – (default: 1e-8) the desired relative error
- \(\text{maximum\_num\_subintervals}\) – (default: 200) maximal number of subintervals

**OUTPUT:**

- float: approximation to the integral
- float: estimated absolute error of the approximation
- the number of integrand evaluations
- an error code:
  - 0 – no problems were encountered
  - 1 – too many subintervals were done
  - 2 – excessive roundoff error
  - 3 – extremely bad integrand behavior
- 4 – failed to converge
- 5 – integral is probably divergent or slowly convergent
- 6 – the input is invalid; this includes the case of desired_relative_error being too small to be achieved

ALIAS: nintegrate() is the same as nintegral()

REMARK: There is also a function numerical_integral() that implements numerical integration using the GSL C library. It is potentially much faster and applies to arbitrary user defined functions.

Also, there are limits to the precision to which Maxima can compute the integral due to limitations in quadpack. In the following example, remark that the last value of the returned tuple is 6, indicating that the input was invalid, in this case because of a too high desired precision.

```
sage: f = x
sage: f.nintegral(x, 0, 1, 1e-14)
(0.0, 0.0, 0, 6)
```

**EXAMPLES:**

```
sage: f(x) = exp(-sqrt(x))
sage: f.nintegral(x, 0, 1)
(0.5284822353142306, 4.163...e-11, 231, 0)
```

We can also use the numerical_integral() function, which calls the GSL C library.

```
sage: numerical_integral(f, 0, 1)
(0.528482232253147, 6.83928460...e-07)
```

Note that in exotic cases where floating point evaluation of the expression leads to the wrong value, then the output can be completely wrong:

```
sage: f = exp(pi*sqrt(163)) - 262537412640768744
```

Despite appearance, \( f \) is really very close to 0, but one gets a nonzero value since the definition of float(\( f \)) is that it makes all constants inside the expression floats, then evaluates each function and each arithmetic operation using float arithmetic:

```
sage: float(f)
-480.0
```

Computing to higher precision we see the truth:

```
sage: f.n(200)
-7.49927402801814311206461436662234865207889513653359355718e-13
sage: f.n(300)
-7.4992740280181431120646143666263009137292462589621789352095066181709095575681963967103004e-13
```

Now numerically integrating, we see why the answer is wrong:

```
sage: f.nintegrate(x,0,1)
(-480.0000000000000..., 5.32907051820075...e-12, 21, 0)
```
It is just because every floating point evaluation of \( f \) returns \(-480.0\) in floating point.

Important note: using PARI/GP one can compute numerical integrals to high precision:

```plaintext
gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
```

Note that the input function above is a string in PARI syntax.

```
sage.calculus.calculus.symbolic_expression_from_maxima_string(x, equals_sub=False,
maxima=Maxima_lib)
```

Given a string representation of a Maxima expression, parse it and return the corresponding Sage symbolic expression.

INPUT:

- \( x \) – a string
- \( \text{equals_sub} \) – (default: False) if True, replace '=' by '==' in self
- \( \text{maxima} \) – (default: the calculus package’s copy of Maxima) the Maxima interpreter to use.

EXAMPLES:

```
sage: from sage.calculus.calculus import symbolic_expression_from_maxima_string as sefms
sage: sefms('x^%e + %e^%pi + %i + sin(0)')
x^e + e^pi + I
```

```
sage: f = function('f')(x)
sage: sefms('??at(f(x),x=2)#1')
f(2) != 1
```

```
sage: a = sage.calculus.calculus.maxima("x#0"); a
x # 0
sage: a.sage()
x # 0
```

```
sage.calculus.calculus.symbolic_expression_from_string(s, syms, accept_sequence=None,
parser=False)
```

Given a string, (attempt to) parse it and return the corresponding Sage symbolic expression. Normally used to return Maxima output to the user.

INPUT:

- \( s \) – a string
- \( \text{syms} \) – (default: {}) dictionary of strings to be regarded as symbols or functions; keys are pairs (string, number of arguments)
- \( \text{accept_sequence} \) – (default: False) controls whether to allow a (possibly nested) set of lists and tuples as input
- \( \text{parser} \) – (default: SR_parser) parser for internal use

EXAMPLES:
symbolic_expression_from_string('[sin(0)*x^2,3*spam+e^pi]', **{('spam',0): y}, accept_sequence=True)

\[ 0, 3 y + e^{\pi} \]

sage.calculus.calculus.symbolic_product(expression, v, a, b, algorithm='maxima', hold=False)

Return the symbolic product \( \prod_{v=a}^{b} \text{expression} \) with respect to the variable \( v \) with endpoints \( a \) and \( b \).

**INPUT:**
- \( \text{expression} \) – a symbolic expression
- \( v \) – a variable or variable name
- \( a \) – lower endpoint of the product
- \( b \) – upper endpoint of the product
- \( \text{algorithm} \) – (default: 'maxima') one of
  - 'maxima' – use Maxima (the default)
  - 'giac' – use Giac
  - 'sympy' – use SymPy
  - 'mathematica' – (optional) use Mathematica
- \( \text{hold} \) - (default: False) if True, don't evaluate

**EXAMPLES:**

```
sage: i, k, n = var('i,k,n')
sage: from sage.calculus.calculus import symbolic_product
sage: symbolic_product(x + i*(i+1)/2, i, 1, 4)
2401600
sage: f = function('f')
sage: symbolic_product(f(i), i, 1, 7)
f(7)*f(6)*f(5)*f(4)*f(3)*f(2)*f(1)
sage: assume(k>0)
sage: symbolic_product(integrate(x^k, x, 0, 1), k, 1, n)
1/factorial(n + 1)
sage: symbolic_product(f(i), i, 1, n).log().log_expand()
sum(log(f(i)), i, 1, n)
```

sage.calculus.calculus.symbolic_sum(expression, v, a, b, algorithm='maxima', hold=False)

Return the symbolic sum \( \sum_{v=a}^{b} \text{expression} \) with respect to the variable \( v \) with endpoints \( a \) and \( b \).

**INPUT:**
- \( \text{expression} \) – a symbolic expression
- \( v \) – a variable or variable name

---

**2.5. Symbolic Computation**

207
Symbolic Calculus, Release 10.1

- a – lower endpoint of the sum
- b – upper endpoint of the sum
- algorithm – (default: 'maxima') one of
  - 'maxima' – use Maxima (the default)
  - 'maple' – (optional) use Maple
  - 'mathematica' – (optional) use Mathematica
  - 'giac' – (optional) use Giac
  - 'sympy' – use SymPy
- hold – (default: False) if True, don’t evaluate

EXAMPLES:

```python
sage: k, n = var('k,n')
sage: from sage.calculus.calculus import symbolic_sum
sage: symbolic_sum(k, k, 1, n).factor()
1/2*(n + 1)*n
```

```python
sage: symbolic_sum(1/k^4, k, 1, oo)
1/90*pi^4
```

```python
sage: symbolic_sum(1/k^5, k, 1, oo)
zeta(5)
```

A well known binomial identity:

```python
sage: symbolic_sum(binomial(n,k), k, 0, n)
2^n
```

And some truncations thereof:

```python
sage: assume(n>1)
sage: symbolic_sum(binomial(n,k), k, 1, n)
2^n - 1
sage: symbolic_sum(binomial(n,k), k, 2, n)
2^n - n - 1
sage: symbolic_sum(binomial(n,k), k, 0, n-1)
2^n - 1
sage: symbolic_sum(binomial(n,k), k, 1, n-1)
2^n - 2
```

The binomial theorem:

```python
sage: x, y = var('x, y')
sage: symbolic_sum(binomial(n,k) * x^k * y^(n-k), k, 0, n)
(x + y)^n
```

```python
sage: symbolic_sum(k * binomial(n, k), k, 1, n)
2^n*(n - 1)*n
```
sage: symbolic_sum((-1)^k*binomial(n,k), k, 0, n) 0

sage: symbolic_sum(2^(-k)/(k*(k+1)), k, 1, oo) -log(2) + 1

Summing a hypergeometric term:

sage: symbolic_sum(binomial(n, k) * factorial(k) / factorial(n+1+k), k, 0, n) 1/2*sqrt(pi)/factorial(n + 1/2)

We check a well known identity:

sage: bool(symbolic_sum(k^3, k, 1, n) == symbolic_sum(k, k, 1, n)^2) True

A geometric sum:

sage: a, q = var('a, q')
sage: symbolic_sum(a*q^k, k, 0, n) (a*q^(n + 1) - a)/(q - 1)

For the geometric series, we will have to assume the right values for the sum to converge:

sage: assume(abs(q) < 1)
sage: symbolic_sum(a*q^k, k, 0, oo) -a/(q - 1)

A divergent geometric series. Don’t forget to forget your assumptions:

sage: forget() sage: assume(q > 1) sage: symbolic_sum(a*q^k, k, 0, oo) Traceback (most recent call last): ... ValueError: Sum is divergent.
sage: forget() sage: assumptions() # check the assumptions were really forgotten []

A summation performed by Mathematica:

sage: symbolic_sum(1/(1+k^2), k, -oo, oo, algorithm='mathematica') # optional -w mathematica pi*coth(pi)

An example of this summation with Giac:

sage: symbolic_sum(1/(1+k^2), k, -oo, oo, algorithm='giac') (pi*e^(2*pi) - pi*e^(-2*pi))/(e^(2*pi) + e^(-2*pi) - 2)

The same summation is solved by SymPy:

sage: symbolic_sum(1/(1+k^2), k, -oo, oo, algorithm='sympy') pi/tanh(pi)
SymPy and Maxima 5.39.0 can do the following (see github issue #22005):

```sage
sage: sum(1/((2*n+1)^2-4)^2, n, 0, Infinity, algorithm='sympy')
sage: 1/64*pi^2
```

Use Maple as a backend for summation:

```sage
sage: symbolic_sum(binomial(n,k)*x^k, k, 0, n, algorithm='maple')
    # optional - maple
(x + 1)^n
```

If you don't want to evaluate immediately give the hold keyword:

```sage
sage: s = sum(n, n, 1, k, hold=True); s
sum(n, n, 1, k)
sage: s.unhold()
1/2*k^2 + 1/2*k
sage: s.subs(k == 10)
sum(n, n, 1, 10)
sage: s.subs(k == 10).unhold()
55
sage: s.subs(k == 10).n()
55.0000000000000
```

Note: Sage can currently only understand a subset of the output of Maxima, Maple and Mathematica, so even if the chosen backend can perform the summation the result might not be convertible into a Sage expression.

### 2.6 Units of measurement

This is the units package. It contains information about many units and conversions between them.

**TUTORIAL:**

To return a unit:

```sage
sage: units.length.meter
meter
```

This unit acts exactly like a symbolic variable:

```sage
sage: s = units.length.meter
sage: s^2
meter^2
sage: s + var('x')
meter + x
```

Units have additional information in their docstring:

```sage
sage: # You would type: units.force.dyne?
sage: print(units.force.dyne.__doc__)
(continues on next page)
```
CGS unit for force defined to be gram*centimeter/second^2. Equal to 10^-5 newtons.

You may call the convert function with units:

```sage
t = units.mass.gram*units.length.centimeter/units.time.second^2
t.convert(units.mass.pound*units.length.foot/units.time.hour^2)
sage: 5400000000000/5760623099*(foot*pound/hour^2)
t.convert(units.force.newton)
sage: 1/100000*newton
```

Calling the convert function with no target returns base SI units:

```sage
t.convert()
sage: 1/100000*kilogram*meter/second^2
```

Giving improper units to convert to raises a ValueError:

```sage
t.convert(units.charge.coulomb)
Traceback (most recent call last):
  ... ValueError: Incompatible units
```

Converting temperatures works as well:

```sage
s = 68*units.temperature.fahrenheit
s.convert(units.temperature.celsius)
sage: 20*celsius
ts.convert()
sage: 293.150000000000*kelvin
```

Trying to multiply temperatures by another unit then converting raises a ValueError:

```sage
wrong = 50*units.temperature.celsius*units.length.foot
wrong.convert()
Traceback (most recent call last):
  ... ValueError: cannot convert
```

AUTHORS:

- David Ackerman
- William Stein

```python
class sage.symbolic.units.UnitExpression
    Bases: Expression
    A symbolic unit.

    EXAMPLES:
    sage: acre = units.area.acre
    sage: type(acre)
    <class 'sage.symbolic.units.UnitExpression'>
```

2.6. Units of measurement
Symbolic Calculus, Release 10.1

```python
class sage.symbolic.units.Units(data, name='r')
    Bases: ExtraTabCompletion

    A collection of units of some type.

    EXAMPLES:

    sage: units.power
    Collection of units of power: cheval_vapeur horsepower watt

sage.symbolic.units.base_units(unit)

    Converts unit to base SI units.

    INPUT:
    •  unit – a unit

    OUTPUT:
    •  a symbolic expression

    EXAMPLES:

    sage: sage.symbolic.units.base_units(units.length.foot)
    381/1250*meter

    If unit is already a base unit, it just returns that unit:

    sage: sage.symbolic.units.base_units(units.length.meter)
    meter

    Derived units get broken down into their base parts:

    sage: sage.symbolic.units.base_units(units.force.newton)
    kilogram*meter/second^2
    sage: sage.symbolic.units.base_units(units.volume.liter)
    1/1000*meter^3

    Returns variable if 'unit' is not a unit:

    sage: sage.symbolic.units.base_units(var('x'))
    x

sage.symbolic.units.convert(expr, target)

    Converts units between expr and target. If target is None then converts to SI base units.

    INPUT:
    •  expr – the symbolic expression converting from
    •  target – (default None) the symbolic expression converting to

    OUTPUT:
    •  a symbolic expression

    EXAMPLES:
```
Sage: sage.symbolic.units.convert(units.length.foot, None)
381/1250*meter
Sage: sage.symbolic.units.convert(units.mass.kilogram, units.mass.pound)
100000000/45359237*pound

Raises ValueError if expr and target are not convertible:

Sage: sage.symbolic.units.convert(units.mass.kilogram, units.length.foot)
Traceback (most recent call last):
... ValueError: Incompatible units
Sage: sage.symbolic.units.convert(units.length.meter^2, units.length.foot)
Traceback (most recent call last):
... ValueError: Incompatible units

Recognizes derived unit relationships to base units and other derived units:

Sage: sage.symbolic.units.convert(units.length.foot/units.time.second^2, units.acceleration.galileo)
762/25*galileo
Sage: sage.symbolic.units.convert(units.mass.kilogram*units.length.meter/units.time.second^2, units.force.newton)
newton
Sage: sage.symbolic.units.convert(units.length.foot^3, units.area.acre*units.length.inch)
1/3630*(acre*inch)
Sage: sage.symbolic.units.convert(units.charge.coulomb, units.current.ampere*units.time.second)
(ampere*second)
Sage: sage.symbolic.units.convert(units.pressure.pascal*units.si_prefixes.kilo, units.pressure.pounds_per_square_inch)
1290320000000/8896443230521*pounds_per_square_inch

For decimal answers multiply 1.0:

Sage: sage.symbolic.units.convert(units.pressure.pascal*units.si_prefixes.kilo, units.pressure.pounds_per_square_inch)*1.0
0.145037737730209*pounds_per_square_inch

You can also convert quantities of units:

Sage: sage.symbolic.units.convert(cos(50) * units.angles.radian, units.angles.degree)
degree*(180*cos(50)/pi)
Sage: sage.symbolic.units.convert(cos(30) * units.angles.radian, units.angles.degree).polynomial(RR)
8.83795706233228*degree
Sage: sage.symbolic.units.convert(50 * units.length.light_year / units.time.year, units.length.foot / units.time.second)
6249954068750/127*(foot/second)

Quantities may contain variables (not for temperature conversion, though):

2.6. Units of measurement
Symbolic Calculus, Release 10.1

```python
sage: sage.symbolic.units.convert(50 * x * units.area.square_meter, units.area.acre)
acre*(1953125/158080329*x)
```

**sage.symbolic.units.convert_temperature**(expr, target)
Function for converting between temperatures.

**INPUT:**
- expr – a unit of temperature
- target – a units of temperature

**OUTPUT:**
- a symbolic expression

**EXAMPLES:**

```python
sage: t = 32*units.temperature.fahrenheit
sage: t.convert(units.temperature.celsius)
0
sage: t.convert(units.temperature.kelvin)
273.150000000000*kelvin
```

If target is None then it defaults to kelvin:

```python
sage: t.convert()
273.150000000000*kelvin
```

Raises ValueError when either input is not a unit of temperature:

```python
sage: t.convert(units.length.foot)
Traceback (most recent call last):
  ... ValueError: cannot convert
sage: wrong = units.length.meter*units.temperature.fahrenheit
sage: wrong.convert()
Traceback (most recent call last):
  ... ValueError: cannot convert
```

We directly call the convert_temperature function:

```python
sage: sage.symbolic.units.convert_temperature(37*units.temperature.celsius, units.
    temperature.fahrenheit)
493/5*fahrenheit
sage: 493/5.0
98.6000000000000
```

**sage.symbolic.units.evalunitdict()**
Replace all the string values of the unitdict variable by their evaluated forms, and builds some other tables for ease of use. This function is mainly used internally, for efficiency (and flexibility) purposes, making it easier to describe the units.

**EXAMPLES:**
sage: sage.symbolic.units.evalunitdict()

sage.symbolic.units.is_unit(s)
Return a boolean when asked whether the input is in the list of units.

INPUT:
• s – an object

OUTPUT:
• a boolean

EXAMPLES:

```python
sage: sage.symbolic.units.is_unit(1)
False
sage: sage.symbolic.units.is_unit(units.length.meter)
True
```

The square of a unit is not a unit:

```python
sage: sage.symbolic.units.is_unit(units.length.meter^2)
False
```

You can also directly create units using var, though they won’t have a nice docstring describing the unit:

```python
sage: sage.symbolic.units.is_unit(var('meter'))
True
```

sage.symbolic.units.str_to_unit(name)
Create the symbolic unit with given name. A symbolic unit is a class that derives from symbolic expression, and has a specialized docstring.

INPUT:
• name – a string

OUTPUT:
• a UnitExpression

EXAMPLES:

```python
sage: sage.symbolic.units.str_to_unit('acre')
acre
sage: type(sage.symbolic.units.str_to_unit('acre'))
<class 'sage.symbolic.units.UnitExpression'>
```

sage.symbolic.units.unit_derivations_expr(v)
Given derived units name, returns the corresponding units expression. For example, given ‘acceleration’ output the symbolic expression length/time^2.

INPUT:
• v – a string, name of a unit type such as ‘area’, ‘volume’, etc.

OUTPUT:
• a symbolic expression
EXAMPLES:

```
sage: sage.symbolic.units.unit_derivations_expr('volume')
length^3
sage: sage.symbolic.units.unit_derivations_expr('electric_potential')
length^2*mass/(current*time^3)
```

If the unit name is unknown, a KeyError is raised:

```
sage: sage.symbolic.units.unit_derivations_expr('invalid')
Traceback (most recent call last):
...
KeyError: 'invalid'
```

```
sage.symbolic.units.unitdocs(unit)
```

Returns docstring for the given unit.

INPUT:

• unit – a unit

OUTPUT:

• a string

EXAMPLES:

```
sage: sage.symbolic.units.unitdocs('meter')
'SI base unit of length.
Defined to be the distance light travels in vacuum in 1/
\sim 299792458 of a second.'
sage: sage.symbolic.units.unitdocs('amu')
'Abbreviation for atomic mass unit.
Approximately equal to 1.660538782*10^-27\sim kilograms.'
```

Units not in the list unit_docs will raise a ValueError:

```
sage: sage.symbolic.units.unitdocs('earth')
Traceback (most recent call last):
...
ValueError: no documentation exists for the unit earth
```

```
sage.symbolic.units.vars_in_str(s)
```

Given a string like ‘mass/(length*time)’, return the list ['mass', 'length', 'time'].
2.7 The symbolic ring

**class** sage.symbolic.ring.NumpyToSRMorphism
Bases: Morphism
A morphism from numpy types to the symbolic ring.

**class** sage.symbolic.ring.SymbolicRing
Bases: SymbolicRing
Symbolic Ring, parent object for all symbolic expressions.

**I()**
The imaginary unit, viewed as an element of the symbolic ring.

**EXAMPLES:**
```
sage: SR.I()^2
-1
sage: SR.I().parent()
Symbolic Ring
```

**characteristic()**
Return the characteristic of the symbolic ring, which is 0.

**OUTPUT:**
- a Sage integer

**EXAMPLES:**
```
sage: c = SR.characteristic(); c
0
sage: type(c)
<class 'sage.rings.integer.Integer'>
```

**cleanup_var(symbol)**
Cleans up a variable, removing assumptions about the variable and allowing for it to be garbage collected

**INPUT:**
- symbol – a variable or a list of variables

**is_exact()**
Return False, because there are approximate elements in the symbolic ring.

**EXAMPLES:**
```
sage: SR.is_exact()
False
```

Here is an inexact element.
```
sage: SR(1.9393)
1.93930000000000
```
**is_field**(proof=True)

Returns True, since the symbolic expression ring is (for the most part) a field.

EXAMPLES:

```
sage: SR.is_field()
True
```

**is_finite()**

Returns False, since the Symbolic Ring is infinite.

EXAMPLES:

```
sage: SR.is_finite()
False
```

**pi()**

EXAMPLES:

```
sage: SR.pi() is pi
True
```

**subring**(*args, **kwds)**

Create a subring of this symbolic ring.

INPUT:

Choose one of the following keywords to create a subring.

- **accepting_variables** (default: None) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in only these variables is created.

- **rejecting_variables** (default: None) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in variables distinct to these variables is created.

- **no_variables** (default: False) – a boolean. If set, then a symbolic subring of constant expressions (i.e., expressions without a variable) is created.

OUTPUT:

A ring.

EXAMPLES:

Let us create a couple of symbolic variables first:

```
sage: V = var('a, b, r, s, x, y')
```

Now we create a symbolic subring only accepting expressions in the variables a and b:

```
sage: A = SR.subring(accepting_variables=(a, b)); A
Symbolic Subring accepting the variables a, b
```

An element is

```
sage: A.an_element()
a
```

From our variables in V the following are valid in A:
Next, we create a symbolic subring rejecting expressions with given variables:

```python
sage: R = SR.subring(rejecting_variables=(r, s)); R
Symbolic Subring rejecting the variables r, s
```

An element is

```python
sage: R.an_element()
some_variable
```

From our variables in $V$ the following are valid in $R$:

```python
sage: tuple(v for v in V if v in R)
(a, b, x, y)
```

We have a third kind of subring, namely the subring of symbolic constants:

```python
sage: C = SR.subring(no_variables=True); C
Symbolic Constants Subring
```

Note that this subring can be considered as a special accepting subring; one without any variables.

An element is

```python
sage: C.an_element()
I*pi*e
```

None of our variables in $V$ is valid in $C$:

```python
sage: tuple(v for v in V if v in C)
()
```

See also:

* Subrings of the Symbolic Ring

```python
symbol(name=None, latex_name=None, domain=None)
```

**EXAMPLES:**

```python
sage: t0 = SR.symbol("t0")
sage: t0.conjugate()
conjugate(t0)
sage: t1 = SR.symbol("t1", domain='real')
sage: t1.conjugate()
t1
sage: t0.abs()
abs(t0)
sage: t0_2 = SR.symbol("t0", domain='positive')
sage: t0_2.abs()
```

(continues on next page)
We propagate the domain to the assumptions database:

```python
sage: n = var('n', domain='integer')
sage: solve([n^2 == 3],n)
[]
```

symbols

temp_var

Return one or multiple new unique symbolic variables as an element of the symbolic ring. Use this instead of SR.var() if there is a possibility of name clashes occurring. Call SR.cleanup_var() once the variables are no longer needed or use a `with SR.temp_var() as ...` construct.

INPUT:

- n – (optional) positive integer; number of symbolic variables
- domain – (optional) specify the domain of the variable(s);

EXAMPLES:

Simple definition of a functional derivative:

```python
sage: def functional_derivative(expr,f,x):
    ....:     with SR.temp_var() as a:
    ....:         return expr.subs({f(x):a}).diff(a).subs({a:f(x)})
sage: f = function('f')
sage: a = var('a')
sage: functional_derivative(f(a)^2+a,f,a)
2*f(a)
```

Contrast this to a similar implementation using SR.var(), which gives a wrong result in our example:

```python
sage: def functional_derivative(expr,f,x):
    ....:     a = SR.var('a')
    ....:     return expr.subs({f(x):a}).diff(a).subs({a:f(x)})
sage: f = function('f')
sage: a = var('a')
sage: functional_derivative(f(a)^2+a,f,a)
2*f(a) + 1
```

var

Return a symbolic variable as an element of the symbolic ring.

INPUT:

- name – string or list of strings with the name(s) of the symbolic variable(s)
Symbolic expression or tuple of symbolic expressions.

See also:
This function does not inject the variable(s) into the global namespace. For that purpose see \texttt{var()}.

\textbf{Note:} For a comprehensive list of acceptable features type \texttt{'maxima('features')'}, and see also the documentation of \texttt{Assumptions}.

\textbf{EXAMPLES:}
Create a variable \texttt{zz} (complex by default):

\texttt{sage: zz = SR.var('zz'); zz}
\texttt{zz}

The return type is a symbolic expression:

\texttt{sage: type(zz)}
\texttt{<class 'sage.symbolic.expression.Expression'>}

We can specify the domain as well:

\texttt{sage: zz = SR.var('zz', domain='real')}
\texttt{sage: zz.is_real()}
\texttt{True}

The real domain is also set with the integer domain:

\texttt{sage: SR.var('x', domain='integer').is_real()}
\texttt{True}

The name argument does not have to match the left-hand side variable:

\texttt{sage: t = SR.var('theta2'); t}
\texttt{theta2}

Automatic indexing is available as well:

\texttt{sage: x = SR.var('x', 4)}
\texttt{sage: x[0], x[3]}
\texttt{(x0, x3)}
\texttt{sage: sum(x)}
\texttt{x0 + x1 + x2 + x3}
wild\((n=0)\)

Return the n-th wild-card for pattern matching and substitution.

**INPUT:**
- \(n\) - a nonnegative integer

**OUTPUT:**
- \(n\)-th wildcard expression

**EXAMPLES:**

```sage
x, y = var('x, y')
w0 = SR.wild(0); w1 = SR.wild(1)

pattern = sin(x)*w0*w1^2; pattern
$1^2*0^0*sin(x)$
f = atan(sin(x)*3*x^2); f
arctan(3*x^2*sin(x))
f.has(pattern)
True
f.subs(pattern == x^2)
arctan(x^2)
```

**class** `sage.symbolic.ring.TemporaryVariables(iterable=(),)`

Bases: `tuple`

Instances of this class can be used with Python `with` to automatically clean up after themselves.

**class** `sage.symbolic.ring.UnderscoreSageMorphism`

Bases: `Morphism`

A Morphism which constructs Expressions from an arbitrary Python object by calling the `_sage_()` method on the object.

**EXAMPLES:**

```sage
import sympy
from sage.symbolic.ring import UnderscoreSageMorphism
b = sympy.var('b')
f = UnderscoreSageMorphism(type(b), SR)
f(b)
b
__.parent__()
Symbolic Ring
```

**sage.symbolic.ring.is_SymbolicExpressionRing**\(R\)**

Return True if \(R\) is the symbolic expression ring.

This function is deprecated. Instead, either use \(R\) is SR (to test whether \(R\) is the unique symbolic ring SR); or `isinstance` with `SymbolicRing` (when also symbolic subrings and callable symbolic rings should be accepted).

**EXAMPLES:**

```sage
from sage.symbolic.ring import is_SymbolicExpressionRing
is_SymbolicExpressionRing(ZZ)
doctest:warning...
```
DeprecationWarning: is_SymbolicExpressionRing is deprecated; use "... is SR" or isinstance(..., sage.rings.abc.SymbolicRing) instead
See https://github.com/sagemath/sage/issues/32665 for details.
False
sage: is_SymbolicExpressionRing(SR)
True

sage.symbolic.ring.isidentifier(x)
Return whether x is a valid identifier.

INPUT:

* x – a string

OUTPUT:

Boolean. Whether the string x can be used as a variable name.

This function should return False for keywords, so we can not just use the isidentifier method of strings, because, for example, it returns True for “def” and for “None”.

EXAMPLES:

sage: from sage.symbolic.ring import isidentifier
sage: isidentifier('x')
True
sage: isidentifier(' x')  # can't start with space
False
sage: isidentifier('ceci_n_est_pas_une_pipe')
True
sage: isidentifier('1 + x')
False
sage: isidentifier('2good')
False
sage: isidentifier('good2')
False
sage: isidentifier('lambda s:s+1')
False
sage: isidentifier('None')
False
sage: isidentifier('lambda')
False
sage: isidentifier('def')
False

sage.symbolic.ring.the_SymbolicRing()
Return the unique symbolic ring object.

(This is mainly used for unpickling.)

EXAMPLES:

sage: sage.symbolic.ring.the_SymbolicRing()
Symbolic Ring
sage: sage.symbolic.ring.the_SymbolicRing()
is sage.symbolic.ring.the_SymbolicRing()
True
sage: sage.symbolic.ring.the_SymbolicRing() is SR
True

sage.symbolic.ring.var(name, **kwds)

EXAMPLES:

sage: from sage.symbolic.ring import var
sage: var("x y z")
(x, y, z)
sage: var("x,y,z")
(x, y, z)
sage: var("x , y , z")
(x, y, z)
sage: var("z")
z

2.8 Subrings of the Symbolic Ring

Subrings of the symbolic ring can be created via the subring() method of SR. This will call SymbolicSubring of this module.

The following kinds of subrings are supported:

• A symbolic subring of expressions, whose variables are contained in a given set of symbolic variables (see SymbolicSubringAcceptingVars). E.g.

  sage: SR.subring(accepting_variables=('a', 'b'))
  Symbolic Subring accepting the variables a, b

• A symbolic subring of expressions, whose variables are disjoint to a given set of symbolic variables (see SymbolicSubringRejectingVars). E.g.

  sage: SR.subring(rejecting_variables=('r', 's'))
  Symbolic Subring rejecting the variables r, s

• The subring of symbolic constants (see SymbolicConstantsSubring). E.g.

  sage: SR.subring(no_variables=True)
  Symbolic Constants Subring

AUTHORS:

• Daniel Krenn (2015)
### 2.8.1 Classes and Methods

**class** sage.symbolic.subring.GenericSymbolicSubring(var\$)

**Bases:** SymbolicRing

An abstract base class for a symbolic subring.

**INPUT:**

- `vars` – a tuple of symbolic variables.

**has_valid_variable**(variable)

Return whether the given variable is valid in this subring.

**INPUT:**

- `variable` – a symbolic variable.

**OUTPUT:**

A boolean.

**EXAMPLES:**

```
sage: from sage.symbolic.subring import GenericSymbolicSubring
sage: GenericSymbolicSubring(vars=tuple()).has_valid_variable(x)
Traceback (most recent call last):
  ...implemented in this abstract base class
```

**class** sage.symbolic.subring.GenericSymbolicSubringFunctor(var\$)

**Bases:** ConstructionFunctor

A base class for the functors constructing symbolic subrings.

**INPUT:**

- `vars` – a tuple, set, or other iterable of symbolic variables.

**EXAMPLES:**

```
sage: from sage.symbolic.subring import SymbolicSubring
sage: SymbolicSubring(no_variables=True).construction()[0]  # indirect doctest
Subring<accepting no variable>
```

**See also:**

sage.categories.pushout.ConstructionFunctor.

**coercion_reversed** = True

**merge**(other)

Merge this functor with other if possible.

**INPUT:**

- `other` – a functor.

**OUTPUT:**

A functor or None.

**EXAMPLES:**
```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: F = SymbolicSubring(accepting_variables=('a',)).construction()[0]
sage: F.merge(F) is F
True
rank = 11
```

```python
class sage.symbolic.subring.SymbolicConstantsSubring(vars)

Bases: SymbolicSubringAcceptingVars

The symbolic subring consisting of symbolic constants.

has_valid_variable(variable)

Return whether the given variable is valid in this subring.

INPUT:

• variable – a symbolic variable.

OUTPUT:

A boolean.

EXAMPLES:

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: S = SymbolicSubring(no_variables=True)
sage: S.has_valid_variable('a')
False
sage: S.has_valid_variable('r')
False
sage: S.has_valid_variable('x')
False
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```

```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
```
OUTPUT:
A boolean.
EXAMPLES:

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: S = SymbolicSubring(accepting_variables=('a',))
sage: S.has_valid_variable('a')
True
sage: S.has_valid_variable('r')
False
sage: S.has_valid_variable('x')
False
```

class `sage.symbolic.subring.SymbolicSubringAcceptingVarsFunctor`(`vars`)
Bases: `GenericSymbolicSubringFunctor`

`merge(other)`
Merge this functor with `other` if possible.

INPUT:
• `other` – a functor.

OUTPUT:
A functor or `None`.

EXAMPLES:

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: F = SymbolicSubring(accepting_variables=('a',)).construction()[0]
sage: G = SymbolicSubring(rejecting_variables=('r',)).construction()[0]
sage: F.merge(F)
is F
True
sage: F.merge(G)
is G
True
```

class `sage.symbolic.subring.SymbolicSubringFactory`
Bases: `UniqueFactory`

A factory creating a symbolic subring.

INPUT:
Specify one of the following keywords to create a subring.

• `accepting_variables` (default: `None`) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in only these variables is created.

• `rejecting_variables` (default: `None`) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in variables distinct to these variables is created.

• `no_variables` (default: `False`) – a boolean. If set, then a symbolic subring of constant expressions (i.e., expressions without a variable) is created.

EXAMPLES:

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: V = var('a, b, c, r, s, t, x, y, z')
```

2.8. Subrings of the Symbolic Ring
```
sage: A = SymbolicSubring(accepting_variables=(a, b, c)); A
Symbolic Subring accepting the variables a, b, c
sage: tuple((v, v in A) for v in V)
((a, True), (b, True), (c, True),
 (r, False), (s, False), (t, False),
 (x, False), (y, False), (z, False))

sage: R = SymbolicSubring(rejecting_variables=(r, s, t)); R
Symbolic Subring rejecting the variables r, s, t
sage: tuple((v, v in R) for v in V)
((a, True), (b, True), (c, True),
 (r, False), (s, False), (t, False),
 (x, True), (y, True), (z, True))

sage: C = SymbolicSubring(no_variables=True); C
Symbolic Constants Subring
sage: tuple((v, v in C) for v in V)
((a, False), (b, False), (c, False),
 (r, False), (s, False), (t, False),
 (x, False), (y, False), (z, False))
```

```
class sage.symbolic.subring.SymbolicSubringRejectingVars(vars)
   Bases: GenericSymbolicSubring
   The symbolic subring consisting of symbolic expressions whose variables are none of the given variables.

   construction()
      Return the functorial construction of this symbolic subring.

      OUTPUT:
      A tuple whose first entry is a construction functor and its second is the symbolic ring.

      EXAMPLES:
      sage: from sage.symbolic.subring import SymbolicSubring
      sage: SymbolicSubring(rejecting_variables=('r',)).construction()
      (Subring<rejecting r>, Symbolic Ring)

   has_valid_variable(variable)
      Return whether the given variable is valid in this subring.

      INPUT:
      • variable – a symbolic variable.
```
OUTPUT:
A boolean.

EXAMPLES:

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: S = SymbolicSubring(rejecting_variables=('r',))
sage: S.has_valid_variable('a')
True
sage: S.has_valid_variable('r')
False
sage: S.has_valid_variable('x')
True
```

```python
class sage.symbolic.subring.SymbolicSubringRejectingVarsFunctor(vars)
Bases: GenericSymbolicSubringFunctor
merge(other)
    Merge this functor with other if possible.
    INPUT:
    • other – a functor.
    OUTPUT:
    A functor or None.
```

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: F = SymbolicSubring(accepting_variables=('a',)).construction()[0]
sage: G = SymbolicSubring(rejecting_variables=('r',)).construction()[0]
sage: G.merge(G)
True
sage: G.merge(F)
True
```

### 2.9 Classes for symbolic functions

To enable their usage as part of symbolic expressions, symbolic function classes are derived from one of the subclasses of `Function`:

- **BuiltinFunction**: the code of these functions is written in Python; many special functions are of this type
- **GinacFunction**: the code of these functions is written in C++ and part of the Pynac support library; most elementary functions are of this type
- **SymbolicFunction**: symbolic functions defined on the Sage command line are of this type

Sage uses `BuiltinFunction` and `GinacFunction` for its symbolic builtin functions. Users can define any other additional `SymbolicFunction` through the `function()` factory, see [Factory for symbolic functions](#). Several parameters are supported by the superclass’ `__init__()` method. Examples follow below.

- **nargs**: the number of arguments
• **name**: the string that is printed on the CLI; the name of the member functions that are attempted for evaluation of Sage element arguments; also the name of the Pynac function that is associated with a GinacFunction

• **alt_name**: the second name of the member functions that are attempted for evaluation of Sage element arguments

• **latex_name**: what is printed when `latex(f(...))` is called

• **conversions**: a dict containing the function’s name in other CAS

• **evalf_params_first**: if False, when floating-point evaluating the expression do not evaluate function arguments before calling the `_evalf_()` member of the function

• **preserved_arg**: if nonzero, the index (starting with 1) of the function argument that determines the return type. Note that, e.g., `atan2()` uses both arguments to determine return type, through a different mechanism

Function classes can define the following Python member functions:

• **_eval_(*args)**: the only mandatory member function, evaluating the argument and returning the result; if None is returned the expression stays unevaluated

• **_eval_numpy_(*args)**: evaluation of `f(args)` with arguments of numpy type

• **_eval_(*args, **kwd)**: called when the expression is floating-point evaluated; may receive a parent keyword specifying the expected parent of the result. If not defined an attempt is made to convert the result of `_eval_()`.

• **_conjugate_(*args)**, **real_part_(*args)**, **imag_part_(*args)**: return conjugate, real part, imaginary part of the expression `f(args)`

• **_derivative_(*args, index)**: return derivative with respect to the parameter indexed by `index` (starting with 0) of `f(args)`

• **_tderivative_**: same as `_derivative_()` but don’t apply chain rule; only one of the two functions may be defined

• **_power_(*args, expo)**: return `f(args)^expo`

• **_series_(*args, **kwds)**: return the power series at `at` up to `order` with respect to `var` of `f(args)`; these three values are received in `kwds`. If not defined the series is attempted to be computed by differentiation.

• **print(*args)**: return what should be printed on the CLI with `f(args)`

• **print_latex(*args)**: return what should be output with `latex(f(args))`

The following examples are intended for Sage developers. Users can define functions interactively through the `function()` factory, see `Factory for symbolic functions`.

**EXAMPLES:**

The simplest example is a function returning nothing, it practically behaves like a symbol. Setting `nargs=0` allows any number of arguments:

```
sage: from sage.symbolic.function import BuiltinFunction
sage: class Test1(BuiltinFunction):
    ....:     def __init__(self):
    ....:         BuiltinFunction.__init__(self, 'test', nargs=0)
    ....:     def _eval_(self, *args):
    ....:         pass
sage: f = Test1()
sage: f()
test()
sage: f(1,2,3)*f(1,2,3)
test(1, 2, 3)^2
```
In the following the \( \sin \) function of \( \text{CBF}(0) \) is called because with floating point arguments the \( \text{CBF} \) element's \( \text{my_sin()} \) member function is attempted, and after that \( \sin() \) which succeeds:

```python
sage: class Test2(BuiltinFunction):
    ....:     def __init__(self):
    ....:         BuiltinFunction.__init__(self, 'my_sin', alt_name='sin',
    ....:                                  latex_name=r'\SIN', nargs=1)
    ....:     def _eval_(self, x):
    ....:         return 5
    ....:     def _evalf_(self, x, **kwds):
    ....:         return 3.5
sage: f = Test2()
sage: f(0)
5
sage: f(0, hold=True)
my_sin(0)
sage: f(0, hold=True).n()
3.50000000000000
sage: f(CBF(0))
0
sage: latex(f(0, hold=True))\SIN\left(0\right)

Traceback (most recent call last):
  ... TypeError: Symbolic function my_sin takes exactly 1 arguments (2 given)
```

**class** `sage.symbolic.function.BuiltinFunction`

Bases: `Function`

This is the base class for symbolic functions defined in Sage.

If a function is provided by the Sage library, we don’t need to pickle the custom methods, since we can just initialize the same library function again. This allows us to use Cython for custom methods.

We assume that each subclass of this class will define one symbolic function. Make sure you use subclasses and not just call the initializer of this class.

**class** `sage.symbolic.function.Function`

Bases: `SageObject`

Base class for symbolic functions defined through Pynac in Sage.

This is an abstract base class, with generic code for the interfaces and a \_call\_() method. Subclasses should implement the _is_registered() and _register_function() methods.

This class is not intended for direct use, instead use one of the subclasses `BuiltinFunction` or `SymbolicFunction`.

**default_variable()**

Return a default variable.

**EXAMPLES:**

```python
sage: sin.default_variable()
x
```
name()

Return the name of this function.

EXAMPLES:

```python
sage: foo = function("foo", nargs=2)
sage: foo.name()
'foo'
```

d number_of_arguments()

Return the number of arguments that this function takes.

EXAMPLES:

```python
sage: foo = function("foo", nargs=2)
sage: foo.number_of_arguments()
2
sage: foo(x,x)
foo(x, x)
sage: foo(x)
Traceback (most recent call last):
...
TypeError: Symbolic function foo takes exactly 2 arguments (1 given)
```

d variables()

Return the variables (of which there are none) present in this function.

EXAMPLES:

```python
sage: sin.variables()
()
```

class sage.symbolic.function.GinacFunction

Bases: BuiltinFunction

This class provides a wrapper around symbolic functions already defined in Pynac/GiNaC.

GiNaC provides custom methods for these functions defined at the C++ level. It is still possible to define new custom functionality or override those already defined.

There is also no need to register these functions.

class sage.symbolic.function.SymbolicFunction

Bases: Function

This is the basis for user defined symbolic functions. We try to pickle or hash the custom methods, so subclasses must be defined in Python not Cython.

sage.symbolic.function.pickle_wrapper(f)

Return a pickled version of the function f.

If f is None, just return None.

This is a wrapper around pickle_function().

EXAMPLES:
sage: from sage.symbolic.function import pickle_wrapper
sage: def f(x):
    return x*x
sage: isinstance(pickle_wrapper(f), bytes)
True
sage: pickle_wrapper(None) is None
True

sage.symbolic.function.unpickle_wrapper(p)

Return a unpickled version of the function defined by p.

If p is None, just return None.

This is a wrapper around unpickle_function().

EXAMPLES:

sage: from sage.symbolic.function import pickle_wrapper, unpickle_wrapper
sage: def f(x):
    return x*x
sage: s = pickle_wrapper(f)
sage: g = unpickle_wrapper(s)
sage: g(2)
4
sage: unpickle_wrapper(None) is None
True

2.10 Factory for symbolic functions

sage.symbolic.function_factory.function(s, **kwds)

Create a formal symbolic function with the name s.

INPUT:

- nargs=0 - number of arguments the function accepts, defaults to variable number of arguments, or 0
- latex_name - name used when printing in latex mode
- conversions - a dictionary specifying names of this function in other systems, this is used by the interfaces internally during conversion
- eval_func - method used for automatic evaluation
- evafl_func - method used for numeric evaluation
- evafl_params_first - bool to indicate if parameters should be evaluated numerically before calling the custom evafl function
- conjugate_func - method used for complex conjugation
- real_part_func - method used when taking real parts
- imag_part_func - method used when taking imaginary parts
- derivative_func - method to be used for (partial) derivation This method should take a keyword argument deriv_param specifying the index of the argument to differentiate w.r.t
- tderivative_func - method to be used for derivatives
- power_func - method used when taking powers This method should take a keyword argument power_param specifying the exponent
Symbolic Calculus, Release 10.1

- **series_func** - method used for series expansion. This method should expect keyword arguments:
  - order - order for the expansion to be computed
  - var - variable to expand w.r.t.
  - at - expand at this value

- **print_func** - method for custom printing

- **print_latex_func** - method for custom printing in latex mode

Note that custom methods must be instance methods, i.e., expect the instance of the symbolic function as the first argument.

EXAMPLES:

```python
sage: from sage.symbolic.function_factory import function
sage: var('a, b')
(a, b)
sage: cr = function('cr')
sage: f = cr(a)
sage: g = f.diff(a).integral(b); g
b*diff(cr(a), a)
sage: foo = function("foo", nargs=2)
sage: x,y,z = var("x y z")
sage: foo(x, y) + foo(y, z)^2
foo(y, z)^2 + foo(x, y)
```

You need to use `substitute_function()` to replace all occurrences of a function with another:

```python
sage: g.substitute_function(cr, cos)
-b*sin(a)
sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))
b*(cos(a) - sin(a))
```

Basic arithmetic with unevaluated functions is no longer supported:

```python
sage: x = var('x')
sage: f = function('f')
sage: 2*f
Traceback (most recent call last):
  ...TypeError: unsupported operand parent(s) for *: 'Integer Ring' and '<class 'sage.symbolic.function_factory...NewSymbolicFunction'>'
```

You now need to evaluate the function in order to do the arithmetic:

```python
sage: 2*f(x)
2*f(x)
```

We create a formal function of one variable, write down an expression that involves first and second derivatives, and extract off coefficients.

```python
sage: r, kappa = var('r,kappa')
sage: psi = function('psi', nargs=1)(r); psi
psi(r)
sage: g = 1/r^4*2*(2*r^2*psi.derivative(r,1) + r^2*psi.derivative(r,2)); g
(r^2*diff(psi(r), r, r) + 2*r^2*diff(psi(r), r))/r^2
sage: g.expand()
```

(continues on next page)
2*diff(psi(r), r)/r + diff(psi(r), r, r)
sage: g.coefficient(psi.derivative(r,2))
1
sage: g.coefficient(psi.derivative(r,1))
2/r

Defining custom methods for automatic or numeric evaluation, derivation, conjugation, etc. is supported:

```
sage: def ev(self, x):
    return 2*x
sage: foo = function("foo", nargs=1, eval_func=ev)
sage: foo(x)
2*x
sage: foo = function("foo", nargs=1, eval_func=lambda self, x: 5)
sage: foo(x)
5
sage: def ef(self, x):
    pass
sage: bar = function("bar", nargs=1, eval_func=ef)
sage: bar(x)
bar(x)
```

```
sage: def evalf_f(self, x, parent=None, algorithm=None):
    return 6
sage: foo = function("foo", nargs=1, evalf_func=evalf_f)
sage: foo(x)
foo(x)
sage: foo(x).n()
6

sage: def deriv(self, *args,**kwds):
    print("{} {}".format(args, kwds))
    return args[kwds['diff_param']]^2
sage: foo = function("foo", nargs=2, derivative_func=deriv)
sage: foo(x,y).derivative(y)
(x, y) {'diff_param': 1}
y^2
```

```
sage: def pow(self, x, power_param=None):
    print("{} {}".format(x, power_param))
    return x^power_param
sage: foo = function("foo", nargs=1, power_func=pow)
sage: foo(y)^(x+y)
y x + y
(x + y)^y
```

```
sage: def expand(self, *args, **kwds):
    print("{} {}".format(args, sorted(kwds.items())))
    return sum(args[0]^i for i in range(kwds['order']))
sage: foo = function("foo", nargs=1, series_func=expand)
sage: foo(y).series(y, 5)
```

Symbolic Calculus, Release 10.1

(continued from previous page)

\[(y,) \left[ ('at', 0), ('options', 0), ('order', 5), ('var', y)] \]
y^4 + y^3 + y^2 + y + 1

```
sage: def my_print(self, *args): return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('t', nargs=2, print_func=my_print)
sage: foo(x,y^z)
my args are: x, y^z

sage: latex(foo(x,y^z))
t\left(x, y^{z}\right)
sage: foo = function('t', nargs=2, print_latex_func=my_print)
sage: foo(x,y^z)
t(x, y^z)

sage: latex(foo(x,y^z))
my args are: x, y^z

sage: foo = function('t', nargs=2, latex_name='foo')
sage: latex(foo(x,y^z))
foo(x, y^z)
```

Chain rule:

```
sage: def print_args(self, *args, **kwds): print("args: {}").format(args)); print("kwds: {}").format(kwds)); return args[0]
sage: foo = function('t', nargs=2, tderivative_func=print_args)
sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {'diff_param': x}
x

sage: foo = function('t', nargs=2, derivative_func=print_args)
sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {'diff_param': 0}
args: (x, x)
kwds: {'diff_param': 1}
2*x
```

sage.symbolic.function_factory.\texttt{function}\_factory\texttt{(name, nargs=0, latex_name=None, conversions=None, evalf_params_first=True, eval_func=None, evalf_func=None, conjugate_func=None, real_part_func=None, imag_part_func=None, derivative_func=None, tderivative_func=None, power_func=None, series_func=None, print_func=None, print_latex_func=None)}

Create a formal symbolic function. For an explanation of the arguments see the documentation for the method \texttt{function()}. EXAMPLES:

```
sage: from sage.symbolic.function_factory import function_factory
sage: f = function_factory('f', 2, '\\foo', {'mathematica':'Foo'})
sage: f(2,4)
f(2, 4)
```
sage: latex(f(1,2))
\foo\left(1, 2\right)
sage: f._mathematica_init_()
'Foo'
sage: def evalf_f(self, x, parent=None, algorithm=None): return x*.5r
sage: g = function_factory('g',1,evalf_func=evalf_f)
g(2)
sage: g(2).n()
1.00000000000000

sage.symbolic.function_factory.unpickle_function(name, nargs, latex_name, conversions, evalf_params_first, pickledfuncs)
This is returned by the \_reduce\_ method of symbolic functions to be called during unpickling to recreate the given function.

It calls function\_factory() with the supplied arguments.

EXAMPLES:

sage: from sage.symbolic.function_factory import unpickle_function
sage: nf = unpickle_function('f', 2, '\\foo\', {'mathematica':'Foo'}, True, [])
sage: nf
f
sage: nf(1,2)
f(1, 2)
sage: latex(nf(x,x))
\foo\left(x, x\right)
sage: nf._mathematica_init_()
'Foo'

sage: from sage.symbolic.function import pickle_wrapper
sage: def evalf_f(self, x, parent=None, algorithm=None): return 2r*x + 5r
sage: def conjugate_f(self, x): return x/2r
sage: def function_factory(name, nargs, latex_name, conversions, evalf_params_first, pickledfuncs):
    ...def evalf_func(self, x, parent=None, algorithm=None): return
    ...def conjugate_func(self, x): return

sage: nf = unpickle_function('g', 1, None, None, True, [None, pickle_wrapper(evalf_f), pickle_wrapper(conjugate_f)])
[None]8)
sage: nf

sage: nf(2)
g(2)
sage: nf(2).n()
9.00000000000000
sage: nf(2).conjugate()
1

2.10. Factory for symbolic functions
2.11 Functional notation support for common calculus methods

EXAMPLES: We illustrate each of the calculus functional functions.

```sage
sage: simplify(x - x)
0
sage: a = var('a')
sage: derivative(x^a + sin(x), x)
a*x^(a - 1) + cos(x)
sage: diff(x^a + sin(x), x)
a*x^(a - 1) + cos(x)
sage: derivative(x^a + sin(x), x)
a*x^(a - 1) + cos(x)
sage: integral(a*x^sin(x), x)
-(x*cos(x) - sin(x))*a
sage: integrate(a*x^sin(x), x)
-(x*cos(x) - sin(x))*a
sage: limit(a*sin(x)/x, x=0)
a
sage: taylor(a*sin(x)/x, x, 0, 4)
1/120*a*x^4 - 1/6*a*x^2 + a
sage: expand((x - a)^3)
-a^3 + 3*a^2*x - 3*a*x^2 + x^3
```

```
sage.calculus.functional.derivative(f, *args, **kwds)
The derivative of f.
Repeated differentiation is supported by the syntax given in the examples below.

ALIAS: diff

EXAMPLES: We differentiate a callable symbolic function:

```sage
sage: f(x,y) = x*y + sin(x^2) + e^(-x)
sage: f(x, y) |--> x*y + e^(-x) + sin(x^2)
sage: derivative(f, x)
(x, y) |--> 2*x*cos(x^2) + y - e^(-x)
sage: derivative(f, y)
(x, y) |--> x
```

We differentiate a polynomial:

```sage
t = polygen(QQ, 't')
sage: f = (1-t)^5; f
-t^5 + 5*t^4 - 10*t^3 + 10*t^2 - 5*t + 1
sage: derivative(f)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
```

(continues on next page)
We differentiate a symbolic expression:

```python
sage: var('a x')
(a, x)
sage: f = exp(sin(a - x^2))/x
sage: derivative(f, x)
-2*cos(-x^2 + a)*e^(sin(-x^2 + a)) - e^(sin(-x^2 + a))/x^2
sage: derivative(f, a)
cos(-x^2 + a)*e^(sin(-x^2 + a))/x
```

Syntax for repeated differentiation:

```python
sage: R.<u, v> = PolynomialRing(QQ)
sage: f = u^4*v^5
sage: derivative(f, u)
4*u^3*v^5
sage: f.derivative(u)  # can always use method notation too
4*u^3*v^5
sage: derivative(f, u, u)
12*u^2*v^5
sage: derivative(f, u, u, u)
24*u*v^5
sage: derivative(f, u, 3)
24*u*v^5
sage: derivative(f, u, v)
20*u^3*v^4
sage: derivative(f, u, 2, v)
60*u^2*v^4
sage: derivative(f, u, v, 2)
80*u^3*v^3
sage: derivative(f, [u, v, v])
80*u^3*v^3
```

We differentiate a scalar field on a manifold:

```python
sage: M = Manifold(2, 'M')
sage: X.<x, y> = M.chart()
sage: f = M.scalar_field(x^2*y, name='f')
sage: derivative(f)
1-form df on the 2-dimensional differentiable manifold M
sage: derivative(f).display()
df = 2*x*y dx + x^2 dy
```

We differentiate a differentiable form, getting its exterior derivative:

```python
sage: a = M.one_form(-y, x, name='a'); a.display()
a = -y dx + x dy
```

(continues on next page)
sage: derivative(a)
2-form da on the 2-dimensional differentiable manifold M
sage: derivative(a).display()
da = 2 dx∧dy

sage.calculus.functional.diff(f, *args, **kwds)
The derivative of \( f \).

Repeated differentiation is supported by the syntax given in the examples below.

ALIAS: diff

EXAMPLES: We differentiate a callable symbolic function:

sage: f(x,y) = x*y + sin(x^2) + e^(-x)
sage: f
(x, y) |--> x*y + e^(-x) + sin(x^2)
sage: derivative(f, x)
(x, y) |--> 2*x*cos(x^2) + y - e^(-x)
sage: derivative(f, y)
(x, y) |--> x

We differentiate a polynomial:

sage: t = polygen(QQ, 't')
sage: f = (1-t)^5; f
-t^5 + 5*t^4 - 10*t^3 + 10*t^2 - 5*t + 1
sage: derivative(f)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t, t)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, t, 2)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, 2)
-20*t^3 + 60*t^2 - 60*t + 20

We differentiate a symbolic expression:

sage: var('a x')
(a, x)
sage: f = exp(sin(a - x^2))/x
sage: derivative(f, x)
-2*cos(-x^2 + a)*e^(sin(-x^2 + a)) - e^(sin(-x^2 + a))/x^2
sage: derivative(f, a)
cos(-x^2 + a)*e^(sin(-x^2 + a))/x

Syntax for repeated differentiation:

sage: R.<u, v> = PolynomialRing(QQ)
sage: f = u^4*v^5
sage: derivative(f, u)
4*u^3*v^5
(continues on next page)
We differentiate a scalar field on a manifold:

```python
sage: M = Manifold(2, 'M')
sage: X.<x,y> = M.chart()
sage: f = M.scalar_field(x^2*y, name='f')
sage: derivative(f)
1-form df on the 2-dimensional differentiable manifold M
sage: derivative(f).display()
df = 2*x*y dx + x^2 dy
```

We differentiate a differentiable form, getting its exterior derivative:

```python
sage: a = M.one_form(-y, x, name='a'); a.display()
a = -y dx + x dy
sage: derivative(a)
2-form da on the 2-dimensional differentiable manifold M
sage: derivative(a).display()
da = 2 dx ∧ dy
```

You can also use expand on polynomial, integer, and other factorizations:

```python
sage: x = polygen(ZZ)
sage: F = factor(x^12 - 1); F
(x - 1) * (x + 1) * (x^2 - x + 1) * (x^2 + 1) * (x^4 - x^2 + 1)
sage: expand(F)
```

(continues on next page)
\[ x^{12} - 1 \]
```
sage: F.expand()
```
\[ x^{12} - 1 \]
```
sage: F = factor(2007); F
```
\[ 3^2 \times 223 \]
```
sage: expand(F)
```
\[ 2007 \]

Note: If you want to compute the expanded form of a polynomial arithmetic operation quickly and the coefficients of the polynomial all lie in some ring, e.g., the integers, it is vastly faster to create a polynomial ring and do the arithmetic there.
```
sage: x = polygen(ZZ)  # polynomial over a given base ring.
sage: f = sum(x^n for n in range(5))
sage: f^f  # much faster, even if the degree is huge
```
\[ x^8 + 2^x^7 + 3^x^6 + 4^x^5 + 5^x^4 + 6^x^3 + 7^x^2 + 8^x + 1 \]

`sage.calculus.functional.integral(f, *args, **kwds)`

The integral of \( f \).

**EXAMPLES:**
```
sage: integral(sin(x), x)
```
\[ -\cos(x) \]
```
sage: integral(sin(x)^2, x, pi, 123*pi/2)
```
\[ 121/4*\pi \]
```
sage: integral( sin(x), x, 0, pi)
```
\[ 2 \]

We integrate a symbolic function:
```
sage: f(x,y,z) = x*y/z + sin(z)
sage: integral(f, z)
```
\[ (x, y, z) \mapsto x*y*log(z) - \cos(z) \]
```
sage: var('a,b')
```
\[ (a, b) \]
```
sage: assume(b-a>0)
```
```
sage: integral( sin(x), x, a, b)
```
\[ \cos(a) - \cos(b) \]
```
sage: forget()
```
```
sage: integral(x/(x^3-1), x)
```
\[ 1/3*sqrt(3)*arctan(1/3*sqrt(3)*(2*x + 1)) - 1/6*log(x^2 + x + 1) + 1/3*log(x - 1) \]
```
```
sage: integral( exp(-x^2), x )
```
\[ 1/2*sqrt(pi)*erf(x) \]

We define the Gaussian, plot and integrate it numerically and symbolically:
```
sage: f(x) = 1/(sqrt(2*pi)) * e^(-x^2/2)
sage: P = plot(f, -4, 4, hue=0.8, thickness=2)
```
(continues on next page)
You can have Sage calculate multiple integrals. For example, consider the function $e^{x^2}$ on the region between the lines $x = y$, $x = 1$, and $y = 0$. We find the value of the integral on this region using the command:

```sage
sage: area = integral(integral(exp(y^2), x, 0, y), y, 0, 1); area
1/2*e - 1/2
sage: float(area)
0.859140914229522...
```

Sage is now (github issue #27958) able to compute the following integral:

```sage
sage: integral(exp(-x^2)*log(x), x) # long time
1/2*sqrt(pi)*erf(x)*log(x) - x*hypergeometric((1/2, 1/2), (3/2, 3/2), -x^2)
```

and its value:

```sage
sage: integral( exp(-x^2)*ln(x), x, 0, oo)
-1/4*sqrt(pi)*(euler_gamma + 2*log(2))
```

This definite integral is easy:

```sage
sage: integral( ln(x)/x, x, 1, 2)
1/2*log(2)^2
```

Sage cannot do this elliptic integral (yet):

```sage
sage: integral(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
```

A double integral:

```sage
sage: y = var('y')
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

This illustrates using assumptions:

```sage
sage: integral(abs(x), x, 0, 5)
25/2
sage: a = var("a")
```
We integrate and differentiate a huge mess:

```
sage: f = (x^2-1+x^3*(1+x^2)^(1/3))/(1+x^2)^(2/3)*x/(x^2+2)^2
sage: g = integral(f, x)
sage: h = f - diff(g, x)
```

```
sage: [float(h(x=i)) for i in range(5)] #random
[0.0, 
 -1.1102230246251565e-16, 
 -5.5511151231257827e-17, 
 -5.5511151231257827e-17, 
 -6.9388939039072284e-17]
sage: h.factor()                      
0
sage: bool(h == 0)
True
```

```
sage.calculus.functional.integrate(f, *args, **kwds)
The integral of f.
EXAMPLS:

sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x)^2, x, pi, 123*pi/2)
121/4*pi
sage: integral( sin(x), x, 0, pi)
2
```

We integrate a symbolic function:

```
sage: f(x,y,z) = x*y/z + sin(z)
sage: integral(f, z)
(x, y, z) |--> x*y*log(z) - cos(z)
```
Symbolic Calculus, Release 10.1

```
sage: var('a,b')
(a, b)
sage: assume(b-a>0)
sage: integral( sin(x), x, a, b)
cos(a) - cos(b)
sage: forget()
sage: integral(x/(x^3-1), x)
1/3*sqrt(3)*arctan(1/3*sqrt(3)*(-2*x + 1)) - 1/6*log(x^2 + x + 1) + 1/3*log(x - 1)
```

We define the Gaussian, plot and integrate it numerically and symbolically:

```
sage: f(x) = 1/(sqrt(2*pi)) * e^(-x^2/2)
sage: P = plot(f, -4, 4, hue=0.8, thickness=2)
sage: P.show(ymin=0, ymax=0.4)
sage: numerical_integral(f, -4, 4)
# random output
(0.99993665751633376, 1.1101527003413533e-14)
sage: integrate(f, x)
x |--> 1/2*erf(1/2*sqrt(2)*x)
```

You can have Sage calculate multiple integrals. For example, consider the function \( e^x (y^2) \) on the region between the lines \( x = y, x = 1 \), and \( y = 0 \). We find the value of the integral on this region using the command:

```
sage: area = integral(integral(exp(y^2),x,0,y),y,0,1); area
1/2*e - 1/2
sage: float(area)
0.859140914229522...
```

We compute the line integral of \( \sin(x) \) along the arc of the curve \( x = y^4 \) from \((1, -1)\) to \((1, 1)\):

```
sage: t = var('t')
sage: (x,y) = (t^4,t)
sage: (dx,dy) = (diff(x,t), diff(y,t))
sage: integral(sin(x)*dx, t,-1, 1)
0
sage: restore('x,y')  # restore the symbolic variables x and y
```

Sage is now (github issue #27958) able to compute the following integral:

```
sage: integral(exp(-x^2)*log(x), x)  # long time
1/2*sqrt(pi)*erf(x)*log(x) - x*hypergeometric((1/2, 1/2), (3/2, 3/2), -x^2)
```

and its value:

```
sage: integral( exp(-x^2)*ln(x), x, 0, oo)
-1/4*sqrt(pi)*(euler_gamma + 2*log(2))
```

This definite integral is easy:

```
sage: integral( ln(x)/x, x, 1, 2)
1/2*log(2)^2
```

2.11. Functional notation support for common calculus methods 245
Sage cannot do this elliptic integral (yet):

```
sage: integral(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
integrate(1/(sqrt(2*t^2 + 1)*sqrt(t^2 - 2)), t, 2, 3)
```

A double integral:

```
sage: y = var('y')
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

This illustrates using assumptions:

```
sage: integral(abs(x), x, 0, 5)
25/2
sage: a = var("a")
sage: integral(abs(x), x, 0, a)
1/2*a*abs(a)
sage: integral(abs(x)*x, x, 0, a)
Traceback (most recent call last):
... ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see 'assume?' for more details)
Is a positive, negative or zero?
sage: assume(a>0)
sage: integral(abs(x)*x, x, 0, a)
1/3*a^3
```

We integrate and differentiate a huge mess:

```
sage: f = (x^2-1+3*(1+x^2)^(1/3))/(1+x^2)^(2/3)*x/(x^2+2)^2
sage: g = integral(f, x)
sage: h = f - diff(g, x)
```

```
sage: [float(h(x=i)) for i in range(5)] #random
[0.0, -1.1102230246251565e-16, -5.5511151231257827e-17, -5.5511151231257827e-17, -6.9388939039072284e-17]
sage: h.factor() 0
sage: bool(h == 0)
True
```

```
sage.calculus.functional.lim(f, dir=None, taylor=False, **argv)
Return the limit as the variable v approaches a from the given direction.
```

```
limit(expr, x = a)
limit(expr, x = a, dir='above')
```
INPUT:

- **dir** - (default: None); dir may have the value
  ‘plus’ (or ‘above’) for a limit from above, ‘minus’ (or ‘below’) for a limit from below, or may be omitted
  (implying a two-sided limit is to be computed).

- **taylor** - (default: False); if True, use Taylor
  series, which allows more limits to be computed (but may also crash in some obscure cases due to bugs
  in Maxima).

- **\*\*argv** - 1 named parameter

ALIAS: You can also use lim instead of limit.

EXAMPLES:

```
sage: limit(sin(x)/x, x=0)
1
sage: limit(exp(x), x=oo)
+Infinity
sage: limit(exp(x), x=-oo)
0
sage: limit(1/x, x=0)
Infinity
sage: limit(sqrt(x^2+x+1)+x, taylor=True, x=-oo)
-1/2
sage: limit((tan(sin(x)) - sin(tan(x)))/x^7, taylor=True, x=0)
1/30
```

Sage does not know how to do this limit (which is 0), so it returns it unevaluated:

```
sage: limit((erf(x) - 1)*e^(x^2), x=+Infinity)
-lim((erf(x) - 1)*e^(x^2), x, +Infinity)
```

```
sage.calculus.functional.limit(f, dir=None, taylor=False, **argv)
Return the limit as the variable \( v \) approaches \( a \) from the given direction.
```

```
limit(expr, x = a)
limit(expr, x = a, dir='above')
```

INPUT:

- **dir** - (default: None); dir may have the value
  ‘plus’ (or ‘above’) for a limit from above, ‘minus’ (or ‘below’) for a limit from below, or may be omitted
  (implying a two-sided limit is to be computed).

- **taylor** - (default: False); if True, use Taylor
  series, which allows more limits to be computed (but may also crash in some obscure cases due to bugs
  in Maxima).

- **\*\*argv** - 1 named parameter

ALIAS: You can also use lim instead of limit.

EXAMPLES:
Symbolic Calculus, Release 10.1

(continued from previous page)

\[ +\infty \]
\begin{verbatim}
sage: lim(exp(x), x=-oo)
0
sage: lim(1/x, x=0)
Infinity
sage: limit(sqrt(x^2+x+1)+x, taylor=True, x=-oo)
-1/2
sage: limit(((tan(sin(x)) - sin(tan(x)))/x^7, taylor=True, x=0)
1/30

Sage does not know how to do this limit (which is 0), so it returns it unevaluated:
\end{verbatim}

\[ -\lim((erf(x) - 1)e^{x^2}), x, +\infty) \]

\texttt{sage.calculus.functional.simplify}(f, \texttt{algorithm}='\texttt{maxima}', **\texttt{kwds})

Simplify the expression \( f \).

See the documentation of the \texttt{simplify()} method of symbolic expressions for details on options.

\textbf{EXAMPLES:}

We simplify the expression \( i + x - x \):

\begin{verbatim}
sage: f = I + x - x; simplify(f)
I
\end{verbatim}

In fact, printing \( f \) yields the same thing - i.e., the simplified form.

Some simplifications are algorithm-specific:

\begin{verbatim}
sage: x, t = var("x, t")
sage: ex = 1/2*I*x + 1/2*I*sqrt(x^2 - 1) + 1/(2*I*x + 2*I*sqrt(x^2 - 1))
sage: simplify(ex)
1/2*I*x + 1/2*I*sqrt(x^2 - 1) + 1/(2*I*x + 2*I*sqrt(x^2 - 1))
sage: simplify(ex, algorithm="giac")
I*sqrt(x^2 - 1)
\end{verbatim}

\texttt{sage.calculus.functional.taylor}(f, *\texttt{args})

Expands self in a truncated Taylor or Laurent series in the variable \( v \) around the point \( a \), containing terms through \((x - a)^n\). Functions in more variables are also supported.

\textbf{INPUT:}

- \*\texttt{args} - the following notation is supported
- \( x, a, n \)- variable, point, degree
- \((x, a), (y, b), \ldots, n\)- variables with points, degree of polynomial

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var('x,k,n')
(x, k, n)
sage: taylor (sqrt (1 - k^2*sin(x)^2), x, 0, 6)
-1/720*(45*k^6 - 60*k^4 + 16*k^2)*x^6 - 1/24*(3*k^4 - 4*k^2)*x^4 - 1/2*k^2*x^2 + 1
\end{verbatim}
\[
\frac{1}{24}(n^4 - 6n^3 + 11n^2 - 6n)x^4 + \frac{1}{6}(n^3 - 3n^2 + 2n)x^3 + \frac{1}{2}(n^2 - n)x^2 + nx + 1
\]

Taylor polynomial in two variables:

\[
(x - 1)(y + 1)^3 - 3(x - 1)(y + 1)^2 + (y + 1)^3 + 3(x - 1)(y + 1) - 3(y + 1)^2 - x + 3y + 3
\]

### 2.12 Symbolic Integration

**class** `sage.symbolic.integration.integral.DefiniteIntegral`

Bases: `BuiltinFunction`

The symbolic function representing a definite integral.

**EXAMPLES:**

```python
sage: from sage.symbolic.integration.integral import definite_integral
sage: definite_integral(sin(x), x, 0, pi)
2
```

**class** `sage.symbolic.integration.integral.IndefiniteIntegral`

Bases: `BuiltinFunction`

Class to represent an indefinite integral.

**EXAMPLES:**

```python
sage: from sage.symbolic.integration.integral import indefinite_integral
sage: indefinite_integral(log(x), x)  # indirect doctest
x*log(x) - x
sage: indefinite_integral(x^2, x)
\frac{1}{3}x^3
sage: indefinite_integral(4*x^2*log(x), x)
2x^2*2*log(x) - x^2
sage: indefinite_integral(exp(x), 2^x)
2*exp(x)
```

`sage.symbolic.integration.integral.integral(expression, v=None, a=None, b=None, algorithm=None, hold=False)`

Return the indefinite integral with respect to the variable \(v\), ignoring the constant of integration. Or, if endpoints \(a\) and \(b\) are specified, returns the definite integral over the interval \([a, b]\).

If \texttt{self} has only one variable, then it returns the integral with respect to that variable.

If definite integration fails, it could be still possible to evaluate the definite integral using indefinite integration with the Newton-Leibniz theorem (however, the user has to ensure that the indefinite integral is continuous on the compact interval \([a, b]\) and this theorem can be applied).
INPUT:

• \( v \) - a variable or variable name. This can also be a tuple of the variable (optional) and endpoints (i.e., \((x,0,1)\) or \((0,1)\)).
• \( a \) - (optional) lower endpoint of definite integral
• \( b \) - (optional) upper endpoint of definite integral
• \texttt{algorithm} - (default: ‘maxima’, ‘libgiac’ and ‘sympy’) one of
  – ‘maxima’ - use maxima
  – ‘sympy’ - use sympy (also in Sage)
  – ‘mathematica_free’ - use http://integrals.wolfram.com/
  – ‘fricas’ - use FriCAS (the optional fricas spkg has to be installed)
  – ‘giac’ - use Giac
  – ‘libgiac’ - use libgiac

To prevent automatic evaluation use the \texttt{hold} argument.

See also:

To integrate a polynomial over a polytope, use the optional \texttt{latte_int} package \texttt{sage.geometry.polyhedron.base.Polyhedron_base.integrate()}.

EXAMPLES:

```sage
sage: x = var('x')
sage: h = sin(x)/(cos(x))^2
sage: h.integral(x)
1/cos(x)
sage: f = x^2/(x+1)^3
sage: f.integral(x)
1/2*(4*x + 3)/(x^2 + 2*x + 1) + log(x + 1)
sage: f = x*cos(x^2)
sage: f.integral(x, 0, sqrt(pi))
0
sage: f.integral(x, a=-pi, b=pi)
0
sage: f(x) = sin(x)
sage: f.integral(x, 0, pi/2)
1
```

The variable is required, but the endpoints are optional:

```sage
sage: y = var('y')
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x), y)
y*sin(x)
sage: integral(sin(x), x, pi, 2*pi)
-2
```

(continues on next page)
Using the `hold` parameter it is possible to prevent automatic evaluation, which can then be evaluated via `simplify()`:

```plaintext
sage: integral(x^2, x, 0, 3, hold=True) ; a
integrate(x^2, x, 0, 3)
sage: a.simplify()
9
```

Constraints are sometimes needed:

```plaintext
sage: integral(x^n,x)
Traceback (most recent call last):
... ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation may help (example of legal syntax is 'assume(n>0)', see 'assume?' for more details)
Is n equal to -1?
sage: assume(n > 0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
```

Usually the constraints are of sign, but others are possible:

```plaintext
sage: assume(n=-1)
sage: integral(x^n,x)
log(x)
```

Note that an exception is raised when a definite integral is divergent:

```plaintext
sage: forget() # always remember to forget assumptions you no longer need
sage: integrate(1/x^3,(x,0,1))
Traceback (most recent call last):
... ValueError: Integral is divergent.
sage: integrate(1/x^3,x,-1,3)
Traceback (most recent call last):
... ValueError: Integral is divergent.
```

But Sage can calculate the convergent improper integral of this function:
sage: integrate(1/x^3, x, 1, infinity)
1/2

The examples in the Maxima documentation:

sage: var('x, y, z, b')
(x, y, z, b)
sage: integral(sin(x)^3, x)
1/3*cos(x)^3 - cos(x)
sage: integral(x/sqrt(b^2-x^2), b)
x*log(2*b + 2*sqrt(b^2 - x^2))
sage: integral(x/sqrt(b^2-x^2), x)
-sqrt(b^2 - x^2)
sage: integral(cos(x)^2 * exp(x), x, 0, pi)
3/5*e^pi - 3/5
sage: integral(x^2 * exp(-x^2), x, -oo, oo)
1/2*sqrt(pi)

We integrate the same function in both Mathematica and Sage (via Maxima):

sage: _ = var('x, y, z')
sage: f = sin(x^2) + y^z
sage: g = mathematica(f)  # optional - mathematica
sage: print(g)  # optional - mathematica
z 2
y + Sin[x]
sage: print(g.Integrate(x))  # optional - mathematica
z Pi 2
x y + Sqrt[---] FresnelS[---] x
2 Pi
sage: print(f.integrate(x))
x*y^z + 1/16*sqrt(pi)*((I + 1)*sqrt(2)*erf((1/2*I + 1/2)*sqrt(2)*x) + (I -
->1)*sqrt(2)*erf((1/2*I - 1/2)*sqrt(2)*x) - (1 - I)*sqrt(2)*erf(sqrt(-I)*x) + (I +
->1)*sqrt(2)*erf((-1)^(1/4)*x))

Alternatively, just use algorithm='mathematica_free' to integrate via Mathematica over the internet (does NOT
require a Mathematica license!):

sage: _ = var('x, y, z')  # optional - internet
sage: f = sin(x^2) + y^z  # optional - internet
sage: f.integrate(x, algorithm="mathematica_free")  # optional - internet
x*y^z + sqrt(1/2)*sqrt(pi)*fresnel_sin(sqrt(2)*x/sqrt(pi))

We can also use Sympy:

sage: integrate(x*sin(log(x)), x)
-1/5*x^2*(cos(log(x)) - 2*sin(log(x)))
sage: integrate(x*sin(log(x)), x, algorithm='sympy')
-1/5*x^2*cos(log(x)) + 2/5*x^2*sin(log(x))
sage: _ = var('y, z')
sage: (x*y - z).integrate(y)
-y*z + x*y/log(x)
sage: (x*y - z).integrate(y, algorithm="sympy")
-y*z + cases(((log(x) != 0, x*y/log(x)), (1, y)))
We integrate the above function in Maple now:

```plaintext
sage: g = maple(f); g.sort()  # optional - maple
y^z+sin(x^2)
```

```plaintext
sage: g.integrate(x).sort()  # optional - maple
x*y^z+1/2*2^(1/2)*Pi^(1/2)*FresnelS(2^(1/2)/Pi^(1/2)*x)
```

We next integrate a function with no closed form integral. Notice that the answer comes back as an expression that contains an integral itself.

```plaintext
sage: A = integral(1/ ((x-4) * (x^4+x+1)), x); A
integrate(1/((x^4 + x + 1)^x - 4), x)
```

Sometimes, in this situation, using the algorithm “maxima” gives instead a partially integrated answer:

```plaintext
sage: integral(1/(x**7-1),x,algorithm='maxima')
-1/7*integrate((x^5 + 2*x^4 + 3*x^3 + 4*x^2 + 5*x + 6)/(x^6 + x^5 + x^4 + x^3 + x^2 + x + 1), x) + 1/7*log(x - 1)
```

We now show that floats are not converted to rationals automatically since we by default have keepfloat: true in maxima.

```plaintext
sage: integral(e^(-x^2),(x, 0, 0.1))
0.05623145800914245*sqrt(pi)
```

An example of an integral that fricas can integrate:

```plaintext
sage: f(x) = sqrt(x+sqrt(1+x^2))/x
sage: integrate(f(x), x, algorithm="fricas")  # optional - fricas
2*sqrt(x + sqrt(x^2 + 1)) - 2*arctan(sqrt(x + sqrt(x^2 + 1))) - log(sqrt(x + sqrt(x^2 + 1)) - 1) + log(sqrt(x + sqrt(x^2 + 1)) - 1)
```

where the default integrator obtains another answer:

```plaintext
sage: integrate(f(x), x, 1, 2, algorithm='maxima')  # long time
1/8*sqrt(x)*gamma(1/4)*gamma(-1/4)*2*hypergeometric((-1/4, -1/4, 1/4), (1/2, 3/4), -1/x^2)/(pi*gamma(3/4))
```

The following definite integral is not found by maxima:

```plaintext
sage: f(x) = (x^4 - 3*x^2 + 6) / (x^6 - 5*x^4 + 5*x^2 + 4)
```

```plaintext
sage: integrate(f(x), x, 1, 2, algorithm='maxima')
integrate((x^4 - 3*x^2 + 6)/(x^6 - 5*x^4 + 5*x^2 + 4), x, 1, 2)
```

but is nevertheless computed:

```plaintext
sage: integrate(f(x), x, 1, 2)
-1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
```

Both fricas and sympy give the correct result:

```plaintext
sage: integrate(f(x), x, 1, 2, algorithm="fricas")  # optional - fricas
-1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
```

```plaintext
sage: integrate(f(x), x, 1, 2, algorithm="sympy")
-1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
```
Using Giac to integrate the absolute value of a trigonometric expression:

```
sage: integrate(abs(cos(x)), x, 0, 2*pi, algorithm='giac')
4
sage: result = integrate(abs(cos(x)), x, 0, 2*pi)
...
result
4
```

ALIASES: integral() and integrate() are the same.

EXAMPLES:

Here is an example where we have to use `assume`:

```
sage: a,b = var('a,b')
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation may help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a positive or negative?
```

So we just assume that $a > 0$ and the integral works:

```
sage: assume(a>0)
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
2/9*sqrt(3)*b^2*arctan(1/3*sqrt(3)*(2*(b*x + a)^(1/3) + a^(1/3))/a^(1/3))/a^(7/3) -
-1/9*b^2*log((b*x + a)^(1/3) - a*(1/3))/(b*x + a) + 1/6*4*(b*x + a)^(5/3)*b^2 - 7*(b*x +
-a)^(2/3)*a*b^2)/(b*x + a)^(2/3) - 2*(b*x + a)*a^3 + a^4)
```

```
sage.symbolic.integration.integral.integrate(expression, v=None, a=None, b=None, algorithm=None, hold=False)
```

Return the indefinite integral with respect to the variable $v$, ignoring the constant of integration. Or, if endpoints $a$ and $b$ are specified, returns the definite integral over the interval $[a, b]$.

If `self` has only one variable, then it returns the integral with respect to that variable.

If definite integration fails, it could be still possible to evaluate the definite integral using indefinite integration with the Newton - Leibniz theorem (however, the user has to ensure that the indefinite integral is continuous on the compact interval $[a, b]$ and this theorem can be applied).

INPUT:

- $v$ - a variable or variable name. This can also be a tuple of the variable (optional) and endpoints (i.e., $(x, 0, 1)$ or $(0, 1)$).
- $a$ - (optional) lower endpoint of definite integral
- $b$ - (optional) upper endpoint of definite integral
- `algorithm` - (default: ‘maxima’, ‘libgiac’ and ‘sympy’) one of
  - ‘maxima’ - use maxima
  - ‘sympy’ - use sympy (also in Sage)
Symbolic Integration

- 'mathematica_free' - use http://integrals.wolfram.com/
- 'fricas' - use FriCAS (the optional fricas spkg has to be installed)
- 'giac' - use Giac
- 'libgiac' - use libgiac

To prevent automatic evaluation use the hold argument.

See also:
To integrate a polynomial over a polytope, use the optional latte_int package sage.geometry.polyhedron.base.Polyhedron_base.integrate().

EXAMPLES:

```sage
sage: x = var('x')
sage: h = sin(x)/(cos(x))^2
sage: h.integral(x)
1/cos(x)
sage: f = x^2/(x+1)^3
sage: f.integral(x)
1/2*(4*x + 3)/(x^2 + 2*x + 1) + log(x + 1)
sage: f = x*cos(x^2)
sage: f.integral(x, 0, sqrt(pi))
0
sage: f.integral(x, a=-pi, b=pi)
0
sage: f(x) = sin(x)
sage: f.integral(x, 0, pi/2)
1
```

The variable is required, but the endpoints are optional:

```sage
sage: y = var('y')
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x), y)
y*sin(x)
sage: integral(sin(x), x, pi, 2*pi)
-2
sage: integral(sin(x), y, pi, 2*pi)
pi*sin(x)
sage: integral(sin(x), (x, pi, 2*pi))
-2
sage: integral(sin(x), (y, pi, 2*pi))
pi*sin(x)
```

Using the hold parameter it is possible to prevent automatic evaluation, which can then be evaluated via simplify():
Symbolic Calculus, Release 10.1

```sage
sage: integral(x^2, x, 0, 3)
\int x^2 \, dx = \frac{9}{3} = 9
sage: a = integral(x^2, x, 0, 3, hold=True) ; a
\int_0^3 x^2 \, dx
sage: a.simplify()
9
```

Constraints are sometimes needed:

```sage
sage: var('x, n')
(x, n)
(\text{please note that } n \text{ is a variable})
sage: integral(x^n,x)
\int x^n \, dx = \frac{x^{n+1}}{n+1}
```

```sage
sage: assume(n > 0)
sage: integral(x^n,x)
\frac{x^{n+1}}{n+1}
```

```sage
sage: forget()
```

```
```

Usually the constraints are of sign, but others are possible:

```sage
sage: assume(n==-1)
sage: integral(x^n,x)
\ln|x|
```

Note that an exception is raised when a definite integral is divergent:

```sage
sage: forget() \# always remember to forget assumptions you no longer need
sage: integrate(1/x^3,(x,0,1))
\text{ValueError: Integral is divergent.}
```

But Sage can calculate the convergent improper integral of this function:

```sage
sage: integrate(1/x^3,x,1,infinity)
\frac{1}{3}
```

The examples in the Maxima documentation:

```sage
sage: var('x, y, z, b')
(x, y, z, b)
sage: integral(sin(x)^3, x)
\frac{1}{3} \cos(x)^3 - \cos(x)
sage: integral(x/sqrt(b^2-x^2), b)
```

(continues on next page)
\[ x \log(2b + 2\sqrt{b^2 - x^2}) \]
\[ \text{sage: integral}(x/\sqrt{b^2-x^2}, x) \]
\[ -\sqrt{b^2 - x^2} \]
\[ \text{sage: integral} \cos(x)^2 \exp(x), x, 0, \pi \]
\[ 3/5 \exp(\pi) - 3/5 \]
\[ \text{sage: integral} x^2 \exp(-x^2), x, -\infty, \infty \]
\[ 1/2 \sqrt{\pi} \]

We integrate the same function in both Mathematica and Sage (via Maxima):

\[ \text{sage: } \var('x, y, z') \]
\[ \text{sage: } f = \sin(x^2) + y^z \]
\[ \text{sage: } g = \text{mathematica}(f) \]
\[ \text{sage: } \text{print}(g) \]
\[ y^z + \sin(x^2) \]
\[ \text{sage: } \text{print}(g.\text{Integrate}(x)) \]
\[ x^z y^2 + \text{Sqrt}[-\text{FresnelS}[-\frac{1}{2} x]] \]

Alternatively, just use \texttt{algorithm='mathematica_free'} to integrate via Mathematica over the internet (does NOT require a Mathematica license!):

\[ \text{sage: } \var('x, y, z') \]
\[ \text{sage: } f = \sin(x^2) + y^z \]
\[ \text{sage: } f.\text{integrate}(x, \text{algorithm}='\text{mathematica_free}') \]
\[ x^z y^z + \sqrt{\frac{1}{2}} \sqrt{\pi} \text{fresnel_sin}(x) \]

We can also use Sympy:

\[ \text{sage: } \int(x^z \sin(\log(x)), x) \]
\[ -1/5 x^2 \cos(\log(x)) - 2 x^2 \sin(\log(x)) \]
\[ \text{sage: } \int(x^z \sin(\log(x)), x, \text{algorithm}='\text{sympy}') \]
\[ -1/5 x^2 \cos(\log(x)) + 2/5 x^2 \sin(\log(x)) \]
\[ \text{sage: } \var('y, z') \]
\[ \text{sage: } (x^y - z).\text{integrate}(y) \]
\[ -y^z + x^y / \log(x) \]
\[ \text{sage: } (x^y - z).\text{integrate}(y, \text{algorithm}='\text{sympy}') \]
\[ -y^z + \text{cases}(((\log(x) != 0, x^y / \log(x)), (1, y))) \]

We integrate the above function in Maple now:

\[ \text{sage: } g = \text{maple}(f); g.\text{sort()} \]
\[ y^z + \text{sin}(x^2) \]
\[ \text{sage: } g.\text{integrate}(x).\text{sort()} \]
\[ x^z y^z + 1/2 \sqrt{\pi} \text{fresnel_sin}(x) \]

We next integrate a function with no closed form integral. Notice that the answer comes back as an expression that contains an integral itself.

2.12. Symbolic Integration 257
Symbolic Calculus, Release 10.1

```python
sage: A = integral(1/ ((x-4) * (x^4+x+1)), x); A
integrate(1/((x^4 + x + 1)*(x - 4)), x)
```

Sometimes, in this situation, using the algorithm “maxima” gives instead a partially integrated answer:

```python
sage: integral(1/(x**7-1),x,algorithm='maxima')
-1/7*integrate((x^5 + 2*x^4 + 3*x^3 + 4*x^2 + 5*x + 6)/(x^6 + x^5 + x^4 + x^3 + x^2+x + 1), x) + 1/7*log(x - 1)
```

We now show that floats are not converted to rationals automatically since we by default have keepfloat: true in maxima.

```python
sage: integral(e^(-x^2),(x, 0, 0.1))
0.05623145800914245*sqrt(pi)
```

An example of an integral that fricas can integrate:

```python
sage: f(x) = sqrt(x+sqrt(1+x^2))/x
sage: integrate(f(x), x, algorithm="fricas")
# optional - fricas
2*sqrt(x + sqrt(x^2 + 1)) - 2*arctan(sqrt(x + sqrt(x^2 + 1))) - log(sqrt(x + sqrt(x^2 + 1)) + 1) + log(sqrt(x + sqrt(x^2 + 1)) - 1)
```

where the default integrator obtains another answer:

```python
sage: integrate(f(x), x, algorithm='maxima')
# long time
1/8*sqrt(x)*gamma(1/4)*gamma(-1/4)^2*hypergeometric((-1/4, -1/4, 1/4), (1/2, 3/4), -1/x^2)/(pi*gamma(3/4))
```

The following definite integral is not found by maxima:

```python
sage: f(x) = (x^4 - 3*x^2 + 6) / (x^6 - 5*x^4 + 5*x^2 + 4)
```

```python
sage: integrate(f(x), x, 1, 2, algorithm='maxima')
integrate((x^4 - 3*x^2 + 6)/(x^6 - 5*x^4 + 5*x^2 + 4), x, 1, 2)
```

but is nevertheless computed:

```python
sage: integrate(f(x), x, 1, 2)
-1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
```

Both fricas and sympy give the correct result:

```python
sage: integrate(f(x), x, 1, 2, algorithm="fricas")
# optional - fricas
-1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
```

```python
sage: integrate(f(x), x, 1, 2, algorithm="sympy")
-1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
```

Using Giac to integrate the absolute value of a trigonometric expression:

```python
sage: integrate(abs(cos(x)), x, 0, 2*pi, algorithm='giac')
4
```

```python
sage: result = integrate(abs(cos(x)), x, 0, 2*pi)
...  
sage: result
4
```
ALIASES: integral() and integrate() are the same.

EXAMPLES:

Here is an example where we have to use assume:

```
sage: a,b = var('a,b')
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
Traceback (most recent call last):
  ...  
ValueError: Computation failed since Maxima requested additional
constraints; using the 'assume' command before evaluation
'may' help (example of legal syntax is 'assume(a>0)', see `assume?' 
for more details)
Is a positive or negative?
```

So we just assume that $a > 0$ and the integral works:

```
sage: assume(a>0)
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
```

```
2/9*sqrt(3)*b^2*arctan(1/3*sqrt(3)*(2*(b*x + a)^(1/3) + a^(1/3))/a^(1/3))/a^(7/3) -  
→ 1/9*b^2*log((b*x + a)^(2/3) + (b*x + a)^(1/3)*a^(1/3) + a^(2/3))/a^(7/3) + 2/9*b^ 
→ 2*log((b*x + a)^(1/3) - a^(1/3))/a^(7/3) + 1/6*(4*(b*x + a)^(5/3)*b^2 - 7*(b*x +  
→ a)^(2/3)*a*b^2)/((b*x + a)^2*a^2 - 2*(b*x + a)*a^3 + a^4)
```

2.13 TESTS::

```
sage.symbolic.integration.external.fricas_integrator(expression, v, a=None, b=None, noPole=True)
Integration using FriCAS
EXAMPLES:
```
```
sage: from sage.symbolic.integration.external import fricas_integrator  
# optional - fricas
sage: fricas_integrator(sin(x), x)  
# optional - fricas
-cos(x)
```

```
sage: fricas_integrator(cos(x), x)  
# optional - fricas
sin(x)
```

```
sage: fricas_integrator(1/(x^2-2), x, 0, 1)  
# optional - fricas
-1/8*sqrt(2)*log(2 - log(-24*sqrt(2) + 34))
```

```
sage: fricas_integrator(1/(x^2+6), x, -oo, oo)  
# optional - fricas
1/6*sqrt(6)*pi
```

```
sage.symbolic.integration.external.giac_integrator(expression, v, a=None, b=None)
Integration using Giac
EXAMPLES:
```
```
```
sage: from sage.symbolic.integration.external import giac_integrator
sage: giac_integrator(sin(x), x)
-cos(x)
sage: giac_integrator(1/(x^2+6), x, -oo, oo)
1/6*sqrt(6)*pi

sage.symbolic.integration.external.libgiac_integrator(expression, v=a=None, b=None)
Integration using libgiac

EXAMPLES:

sage: import sage.libs.giac
...
sage: from sage.symbolic.integration.external import libgiac_integrator
sage: libgiac_integrator(sin(x), x)
-cos(x)
sage: libgiac_integrator(1/(x^2+6), x, -oo, oo)
No checks were made for singular points of antiderivative...
1/6*sqrt(6)*pi

sage.symbolic.integration.external.maxima_integrator(expression, v=a=None, b=None)
Integration using Maxima

EXAMPLES:

sage: from sage.symbolic.integration.external import maxima_integrator
sage: maxima_integrator(sin(x), x)
-cos(x)
sage: maxima_integrator(cos(x), x)
sin(x)
sage: f(x) = function('f')(x)
sage: maxima_integrator(f(x), x)
integrate(f(x), x)

sage.symbolic.integration.external.mma_free_integrator(expression, v=a=None, b=None)
Integration using Mathematica’s online integrator

EXAMPLES:

sage: from sage.symbolic.integration.external import mma_free_integrator
sage: mma_free_integrator(sin(x), x) # optional - internet
-cos(x)
A definite integral:

sage: mma_free_integrator(e^(-x), x, a=0, b=oo) # optional - internet
1

sage.symbolic.integration.external.sympy_integrator(expression, v=a=None, b=None)
Integration using SymPy

EXAMPLES:

sage: from sage.symbolic.integration.external import sympy_integrator
sage: sympy_integrator(sin(x), x)
(continues on next page)
2.14 A Sample Session using SymPy

In this first part, we do all of the examples in the SymPy tutorial (https://github.com/sympy/sympy/wiki/Tutorial), but using Sage instead of SymPy.

```
sage: a = Rational((1,2))
sage: a
1/2
sage: a**2
1
sage: Rational(2)**50 / Rational(10)**50
1/88817841970012523233890533447265625
sage: 1.0/2
0.500000000000000
sage: 1/2
1/2
sage: pi^2
pi^2
sage: float(pi)
3.141592653589793
sage: RealField(200)(pi)
3.1415926535897932384626433832795028841971693993751058209749
sage: float(pi + exp(1))
5.85977548204883...
sage: oo != 2
True
```

```
sage: var('x y')
(x, y)
sage: x + y + x - y
2*x
sage: (x+y)**2
(x + y)^2
sage: ((x+y)^2).expand()
x^2 + 2*x*y + y^2
sage: ((x+y)^2).subs(x=1)
(y + 1)^2
sage: ((x+y)^2).subs(x=y)
4*y^2
```

```
sage: limit(sin(x)/x, x=0)
1
sage: limit(x, x=oo)
+Infinity
sage: limit((5^x + 3^x)^(1/x), x=oo)
5
```

<table>
<thead>
<tr>
<th>sage:</th>

| sage: | cos(x).taylor(x,0,10) |
|     | -1/3628800*x^10 + 1/40320*x^8 - 1/720*x^6 + 1/24*x^4 - 1/2*x^2 + 1 |
| sage: | (1/cos(x)).taylor(x,0,10) |
|     | 50521/3628800*x^10 + 277/8064*x^8 + 61/720*x^6 + 5/24*x^4 + 1/2*x^2 + 1 |

| sage: | matrix([[1,0], [0,1]]) |
|     | [1 0] |
|     | [0 1] |
| sage: | var('x y') |
|     | (x, y) |
| sage: | A = matrix([[1,x], [y,1]]) |
|     | [x y + 1 2*x] |
|     | [ 2*y x*y + 1] |
| sage: | R.<x,y> = QQ[] |
| sage: | A = matrix([[1,x], [y,1]]) |
| sage: | A^10 |
|     | [x^5*y^5 + 45*x^4*y^4 + 210*x^3*y^3 + 210*x^2*y^2 + 45*x*y + 1 10*x^5*y^4 + 120*x^4*y^3 + 252*x^3*y^2 + 210*x^2*y + 10*x] |
|     | [ 10*x^4*y^5 + 120*x^3*y^4 + 252*x^2*y^3 + 210*x*y^2 + 10*y x^5*y^4 + 45*x^4*y^3 + 210*x^3*y^2 + 210*x^2*y^3 + 45*x*y + 1] |

And here are some actual tests of sympy:

| sage: | **from** sympy **import** Symbol, cos, sympify, pprint |
|     | # requires sympy |
| sage: | **from** sympy.abc **import** x |
|     | # requires sympy |

| sage: | e = (1/cos(x)^3)._sympy_(); e |
|     | # requires sympy |
|     | cos(x)**(-3) |

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```python
sage: f = e.series(x, 0, int(10)); f

# needs sympy
1 + 3*x**2/2 + 11*x**4/8 + 241*x**6/240 + 8651*x**8/13440 + O(x**10)
```

And the pretty-printer. Since unicode characters are not working on some architectures, we disable it:

```python
sage: from sympy.printing import pprint_use_unicode

# needs sympy
```

```python
sage: prev_use = pprint_use_unicode(False)

# needs sympy
```

```python
sage: pprint(e)

1 ------- 3
cos (x)
```

```python
sage: pprint(f)

# needs sympy
```

```python
2 4 6 8
3*x 11*x 241*x 8651*x / 10\n1 + ---- + ----- + ------ + ------- + O\ / 2 8 240 13440
```

```python
sage: pprint_use_unicode(prev_use)

# needs sympy
False
```

And the functionality to convert from sympy format to Sage format:

```python
sage: e._sage_()

# needs sympy
cos(x)^(-3)
```

```python
sage: e._sage_().taylor(x._sage_(), 0, 8)

# needs sympy
8651/13440*x^8 + 241/240*x^6 + 11/8*x^4 + 3/2*x^2 + 1
```

Mixing SymPy with Sage:

```python
sage: # needs sympy
sage: import sympy

# needs sympy
```

```python
sage: var("x")._sympy_() + var("y")._sympy_()

x + y
```

```python
sage: o = var("omega")
```

```python
sage: s = sympy.Symbol("x")
```

```python
sage: t1 = s + o
```

```python
sage: type(t1)

<class 'sympy.core.add.Add'>
```

```python
sage: type(t2)

<class 'sage.symbolic.expression.Expression'>
```

(continues on next page)
Symbolic Calculus, Release 10.1

sage: t1, t2
(omega + x, omega + x)
sage: e = sympy.sin(var("y"))+sage.all.cos(sympy.Symbol("x"))
sage: type(e)
<class 'sympy.core.add.Add'>
sage: e
sin(y) + cos(x)
sage: e = e._sage_
<sage.symbolic.expression.Expression>
sage: e
cos(x) + sin(y)
sage: e = sage.all.cos(var("y")**3)**4+var("x")**2
sage: e = e._sympy_
<x**2 + cos(y**3)**4>

2.15 Calculus Tests and Examples

Compute the Christoffel symbol.

sage: var('r t theta phi')
(r, t, theta, phi)
sage: m = matrix(SR, [[[1-1/r],0,0,0],[0,-(1-1/r)**(-1),0,0],[0,0,-r^2,0],[0,0,0,-r^2*(sin(theta))^2]])
sage: m
[-1/r + 1 0 0 0]
[0 1/(1/r - 1) 0 0]
[0 0 -r^2 0]
[0 0 0 -r^2*sin(theta)^2]

sage: def christoffel(i,j,k,vars,g):
....:     s = 0
(continues on next page)
Symbolic Calculus, Release 10.1

....:     ginv = g^(-1)
....:     for l in range(g.nrows()):
....:         s = s + (1/2)*ginv[k,l]*(g[j,l].diff(vars[i])+g[i,l].diff(vars[j])-g[i,j].
˓→diff(vars[l]))
....:     return s

sage: christoffel(3,3,2, [t,r,theta,phi], m)
-cos(theta)*sin(theta)

sage: X = christoffel(1,1,1,[t,r,theta,phi],m)

sage: X
1/2/(r^2*(1/r - 1))

sage: X.rational_simplify()
-1/2/(r^2 - r)

Some basic things:

sage: f(x,y) = x^3 + sinh(1/y)
sage: f
(x, y) |--> x^3 + sinh(1/y)

sage: f^3
(x, y) |--> (x^3 + sinh(1/y))^3

sage: (f^3).expand()
(x, y) |--> x^9 + 3*x^6*sinh(1/y) + 3*x^3*sinh(1/y)^2 + sinh(1/y)^3

A polynomial over a symbolic base ring:

sage: R = SR['x']
sage: f = R([1/sqrt(2), 1/(4*sqrt(2))])
sage: f
1/8*sqrt(2)*x + 1/2*sqrt(2)

sage: -f
-1/8*sqrt(2)*x - 1/2*sqrt(2)

sage: (-f).degree()
1

A big product. Notice that simplifying simplifies the product further:

sage: A = exp(I*pi/7)
sage: b = A^14

We check a statement made at the beginning of Friedlander and Joshi’s book on Distributions:

sage: f(x) = sin(x^2)
sage: g(x) = cos(x) + x^3

\( - (t - x)^3 + \cos(-t + x) + \sin((t + x)^2) \)

sage: u.diff(t,2) - u.diff(x,2)
\emptyset

Restoring variables after they have been turned into functions:

2.15. Calculus Tests and Examples
Symbolic Calculus, Release 10.1

\begin{Verbatim}
sage: x = function('x')
sage: type(x)
<class 'sage.symbolic.function_factory...NewSymbolicFunction'>
sage: x(2/3)
x(2/3)
sage: restore('x')
sage: sin(x).variables()
(x,)
\end{Verbatim}

MATHEMATICA: Some examples of integration and differentiation taken from some Mathematica docs:

\begin{Verbatim}
sage: var('x n a')
(x, n, a)
sage: diff(x^n, x)  # the output looks funny, but is correct
n*x^(n - 1)
sage: diff(x^2 * log(x+a), x)
2*x*log(a + x) + x^2/(a + x)
sage: derivative(arctan(x), x)
1/(x^2 + 1)
sage: derivative(x^n, x, 3)
(n - 1)*n*x^(n - 3)
sage: derivative( function('f')(x), x)
diff(f(x), x)
sage: diff( 2*x^2*f(x^2), x)
4*x^2*D[0](f)(x^2) + 2*f(x^2)
sage: integrate( 1/(x^4 - a^4), x)
-1/2*arctan(x/a)/a^3 - 1/4*log(a + x)/a^3 + 1/4*log(-a + x)/a^3
sage: expand(integrate(log(1-x^2), x))
x*log(-x^2 + 1) - 2*x + log(x + 1) - log(x - 1)
\end{Verbatim}

This is an apparent regression in Maxima 5.39.0, although the antiderivative is correct, assuming we work with (poly)logs of complex argument. More convenient form is \(1/2*\log(x^2)*\log(-x^2 + 1) + 1/2*\text{dilog}(-x^2 + 1)\). See also https://sourceforge.net/p/maxima/bugs/3275/:

\begin{Verbatim}
sage: integrate(log(1-x^2)/x, x)
log(-x)*\log(x + 1) + \log(x)*\log(-x + 1) + \text{dilog}(x + 1) + \text{dilog}(-x + 1)
\end{Verbatim}

No problems here:

\begin{Verbatim}
sage: integrate(exp(1-x^2),x)
1/2*sqrt(pi)*erf(x)*e
sage: integrate(sin(x^2),x)
1/16*sqrt(3)*arctan(1/3*sqrt(3)*(2*x - 1)) - 1/6*log(x^2 - x + 1) + 1/3*log(x + 1)
sage: integrate((1-x^2)^n,x)  # long time
x*hypergeometric((1/2, -n), (3/2,), x^2*exp_polar(2*I*pi))
sage: integrate(x^x, x)
integrate(x^x, x)
sage: integrate(1/(x^3+1), x)
1/3*sqrt(3)*arctan(1/3*sqrt(3)*(2*x - 1)) - 1/6*log(x^2 - x + 1) + 1/3*log(x + 1)
sage: integrate(1/(x^3+1), x, 0, 1)
1/9*sqrt(3)*pi + 1/3*log(2)
\end{Verbatim}
Symbolic Calculus, Release 10.1

```
sage: forget()
sage: c = var('c')
sage: assume(c > 0)
sage: integrate(exp(-c*x^2), x, -oo, oo)
sqrt(pi)/sqrt(c)
sage: forget()
```

Other examples that now (github issue #27958) work:

```
sage: integrate(log(x)*exp(-x^2), x)  # long time
1/2*sqrt(pi)*erf(x)*log(x) - x*hypergeometric((1/2, 1/2), (3/2, 3/2), -x^2)
sage: integrate(log(1+sqrt(1+4*x)/2)/x, x, 0, 1)
Traceback (most recent call last):
...  
ValueError: Integral is divergent.
```

The following is an example of integral that Mathematica can do, but Sage currently cannot do:

```
sage: integrate(ceil(x^2 + floor(x)), x, 0, 5, algorithm='maxima')
integrate(ceil(x^2) + floor(x), x, 0, 5)
```

MAPLE: The basic differentiation and integration examples in the Maple documentation:

```
sage: diff(sin(x), x)
cos(x)
sage: diff(sin(x), y)
0
sage: diff(sin(x), x, 3)
-cos(x)
sage: diff(x*sin(cos(x)), x)
-x*cos(cos(x))*sin(x) + sin(cos(x))
sage: diff(tan(x), x)
tan(x)^2 + 1
sage: f = function('f'); f
f
sage: diff(f(x), x)
diff(f(x), x)
sage: diff(f(x,y), x, y)
diff(f(x, y), x, y)
sage: diff(f(x,y), x, y) - diff(f(x,y), y, x)
0
sage: g = function('g')
sage: var('x y z')
(x, y, z)
sage: diff(g(x,y,z), x,z,z)
diff(g(x, y, z), x, z, z)
sage: integrate(sin(x), x)
-cos(x)
sage: integrate(sin(x), x, 0, pi)
2
```

2.15. Calculus Tests and Examples 267
Symbolic Calculus, Release 10.1

```
sage: var('a b')
(a, b)
sage: integrate(sin(x), x, a, b)
cos(a) - cos(b)
```

```
sage: integrate(x/(x^3-1), x)
1/3*sqrt(3)*arctan(1/3*sqrt(3)*sqrt(x^2 + 1)) - 1/6*log(x^2 + x + 1) + 1/3*log(x - 1)
sage: integrate(exp(-x^2), x)
1/2*sqrt(pi)*erf(x)
sage: integrate(exp(-x^2)*log(x), x)  # long time
1/2*sqrt(pi)*erf(x)*log(x) - x*hypergeometric((1/2, 1/2), (3/2, 3/2), -x^2)
sage: f = exp(-x^2)*log(x)
sage: f.nintegral(x, 0, 999)
(-0.87005772672831..., 7.5584...e-10, 567, 0)
```

```
sage: integral(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)  # long time # todo: maple can do this
```

```
sage: integral(1/(sqrt(2*t^2 + 1)*sqrt(t^2 - 2)), t, 2, 3)
```

```
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

We verify several standard differentiation rules:

```
sage: function('f, g')
(f, g)
sage: diff(f(t)*g(t),t)
g(t)*diff(f(t), t) + f(t)*diff(g(t), t)
sage: diff(f(t)/g(t), t)
diff(f(t), t)/g(t) - f(t)*diff(g(t), t)/g(t)^2
sage: diff(f(t) + g(t), t)
diff(f(t), t) + diff(g(t), t)
sage: diff(c*f(t), t)
c*diff(f(t), t)
```

2.16 Conversion of symbolic expressions to other types

This module provides routines for converting new symbolic expressions to other types. Primarily, it provides a class `Converter` which will walk the expression tree and make calls to methods overridden by subclasses.

```
class sage.symbolic.expression_conversions.AlgebraicConverter(field)
```

Bases: `Converter`

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: a.field
Algebraic Field
```

```
sage: a.reciprocal_trig_functions['cot']
tan
```

`arithmetic(ex, operator)`

Convert a symbolic expression to an algebraic number.
EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: f = 2^(1/2)
sage: a = AlgebraicConverter(QQbar)
sage: a.arithmetic(f, f.operator())
1.414213562373095?
```

composition(\textit{ex, operator})

Coerce to an algebraic number.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: a.composition(exp(I*pi/3, hold=True), exp)
0.500000000000000? + 0.866025403784439?*I
sage: a.composition(sin(pi/7), sin)
0.4338837391175581? + 0.?e-18*I
sage: x = SR.var('x')
sage: a.composition(complex_root_of(x^3 - x^2 - x - 1, 0), complex_root_of)
1.839286755214161?
```

pyobject(\textit{ex, obj})

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: f = SR(2)
sage: a.pyobject(f, f.pyobject())
2
```

```python
class sage.symbolic.expression_conversions.Converter(\textit{use_fake_div=False})
Bases: object

If \textit{use_fake_div} is set to True, then the converter will try to replace expressions whose operator is \texttt{operator.mul} with the corresponding expression whose operator is \texttt{operator.truediv}.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import Converter
sage: c = Converter(use_fake_div=True)
sage: c.use_fake_div
True
```

arithmetic(\textit{ex, operator})
The input to this method is a symbolic expression and the infix operator corresponding to that expression. Typically, one will convert all of the arguments and then perform the operation afterward.

**composition**(ex, operator)

The input to this method is a symbolic expression and its operator. This method will get called when you have a symbolic function application.

**derivative**(ex, operator)

The input to this method is a symbolic expression which corresponds to a relation.

**get_fake_div**(ex)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import Converter
sage: c = Converter(use_fake_div=True)
sage: c.get_fake_div(sin(x)/x)
FakeExpression([sin(x), x], <built-in function truediv>)
sage: c.get_fake_div(-1*sin(x))
FakeExpression([sin(x)], <built-in function neg>)
sage: c.get_fake_div(-x)
FakeExpression([x], <built-in function neg>)
sage: c.get_fake_div((2*x^3+2*x-1)/((x-2)*(x+1)))
FakeExpression([2*x^3 + 2*x - 1, FakeExpression([x + 1, x - 2], <built-in function mul>)], <built-in function truediv>)
```

Check if github issue #8056 is fixed, i.e., if numerator is 1:

```
sage: c.get_fake_div(1/pi/x)
FakeExpression([1, FakeExpression([pi, x], <built-in function mul>)], <built-in function truediv>)
```

**pyobject**(ex, obj)

The input to this method is the result of calling `pyobject()` on a symbolic expression.

**Note:** Note that if a constant such as pi is encountered in the expression tree, its corresponding pyobject which is an instance of `sage.symbolic.constants.Pi` will be passed into this method. One cannot do arithmetic using such an object.

**relation**(ex, operator)

The input to this method is a symbolic expression which corresponds to a relation.

**symbol**(ex)

The input to this method is a symbolic expression which corresponds to a single variable. For example, this method could be used to return a generator for a polynomial ring.

**class** `sage.symbolic.expression_conversions.DeMoivre`(ex, force=False)

A class that walks a symbolic expression tree and replaces occurrences of complex exponentials (optionally, all exponentials) by their respective trigonometric expressions.

**INPUT:**

- `force` – boolean (default: False); replace exp(x) with cosh(x) + sinh(x)
EXAMPLES:

```python
sage: a, b = SR.var("a, b")
sage: from sage.symbolic.expression_conversions import DeMoivre
sage: d = DeMoivre(e^a)
sage: d(e^(a+I*b))
(cos(b) + I*sin(b))*e^a
```

`composition(ex, op)`

Return the composition of `self` with `ex` by `op`.

EXAMPLES:

```python
sage: x, a, b = SR.var('x, a, b')
sage: from sage.symbolic.expression_conversions import DeMoivre
sage: p = exp(x)
sage: s = DeMoivre(p)
sage: q = exp(a+I*b)
sage: s.composition(q, q.operator())
(cos(b) + I*sin(b))*e^a
```

```python
class sage.symbolic.expression_conversions.Exponentialize(ex)
Bases: ExpressionTreeWalker

A class that walks a symbolic expression tree and replace circular and hyperbolic functions by their respective exponential expressions.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import Exponentialize
sage: d = Exponentialize(sin(x))
sage: d(sin(x))
-1/2*I*e^(I*x) + 1/2*I*e^(-I*x)
sage: d(cosh(x))
1/2*e^(-x) + 1/2*e^x
```

CircDict = {sinh: x |--> -1/2*e^(-x) + 1/2*e^x, cosh: x |--> 1/2*e^(-x) + 1/2*e^x, tanh: x |--> -(e^(-x) - e^x)/(e^(-x) + e^x), coth: x |--> -(e^(-x) + e^x)/(e^(-x) - e^x), sech: x |--> 2/(e^(-x) + e^x), csch: x |--> 2*I*(I*e^(-I*x)))/(e^(I*x) + e^(-I*x)), sin: x |--> -1/2*I*e^(I*x) + 1/2*I*e^(-I*x), cos: x |--> 1/2*e^(I*x) + 1/2*e^(-I*x), tan: x |--> (-I*e^(-I*x) + I*e^(I*x))/(e^(I*x) + e^(-I*x)), cot: x |--> (I*e^(I*x) + I*e^(-I*x))/(e^(I*x) + e^(-I*x)), sec: x |--> 2/(e^(I*x) + e^(-I*x)), csc: x |--> 2*I/I*(I*e^(I*x) - e^(-I*x))}
```

Circs = [sin, cos, sec, csc, tan, cot, sinh, cosh, sech, csch, tanh, coth]

I = I

Integer

alias of Integer

SR = Symbolic Ring

composition(ex, op)

Return the composition of `self` with `ex` by `op`.

EXAMPLES:
```python
sage: x = SR.var("x")
sage: from sage.symbolic.expression_conversions import Exponentialize
sage: p = x
sage: s = Exponentialize(p)
sage: q = sin(x)
sage: s.composition(q, q.operator())
-1/2*I*e^(I*x) + 1/2*I*e^(-I*x)
```

\[ \cos = \cos \]
\[ \cosh = \cosh \]
\[ \cot = \cot \]
\[ \coth = \coth \]
\[ \csc = \csc \]
\[ \csch = \csch \]
\[ e = e \]
\[ \exp = \exp \]

```python
function(s, **kwds)
```
Create a formal symbolic function with the name \( s \).

**INPUT:**

- nargs=0 - number of arguments the function accepts, defaults to variable number of arguments, or 0
- latex_name - name used when printing in latex mode
- conversions - a dictionary specifying names of this function in other systems, this is used by the interfaces internally during conversion
- eval_func - method used for automatic evaluation
- evalf_func - method used for numeric evaluation
- evalf_params_first - bool to indicate if parameters should be evaluated numerically before calling the custom evalf function
- conjugate_func - method used for complex conjugation
- real_part_func - method used when taking real parts
- imag_part_func - method used when taking imaginary parts
- derivative_func - method to be used for (partial) derivation This method should take a keyword argument deriv_param specifying the index of the argument to differentiate w.r.t
- tderivative_func - method to be used for derivatives
- power_func - method used when taking powers This method should take a keyword argument power_param specifying the exponent
- series_func - method used for series expansion This method should expect keyword arguments - order - order for the expansion to be computed - var - variable to expand w.r.t. - at - expand at this value
- print_func - method for custom printing
• print latex func - method for custom printing in latex mode

Note that custom methods must be instance methods, i.e., expect the instance of the symbolic function as the first argument.

**Note:** The new function is both returned and automatically injected into the global namespace. If you use this function in library code, it is better to use sage.symbolic.function_factory.function, since it will not touch the global namespace.

**EXAMPLES:**

We create a formal function called supersin

```
sage: function('supersin')
supersin
```

We can immediately use supersin in symbolic expressions:

```
sage: y, z, A = var('y z A')
sage: supersin(y+z) + A^3
A^3 + supersin(y + z)
```

We can define other functions in terms of supersin:

```
sage: g(x,y) = supersin(x)^2 + sin(y/2)
sage: g
(x, y) |--> supersin(x)^2 + sin(1/2*y)
sage: g.diff(y)
(x, y) |--> 1/2*cos(1/2*y)
sage: k = g.diff(x); k
(x, y) |--> 2*supersin(x)*diff(supersin(x), x)
```

We create a formal function of one variable, write down an expression that involves first and second derivatives, and extract off coefficients:

```
sage: r, kappa = var('r,kappa')
sage: psi = function('psi', nargs=1)(r); psi
psi(r)
sage: g = 1/r^2*(2*r*psi.derivative(r,1) + r^2*psi.derivative(r,2)); g
(r^2*diff(psi(r), r, r) + 2*r*diff(psi(r), r))/r^2
sage: g.expand()
2*diff(psi(r), r, r)/r + diff(psi(r), r, r)
sage: g.coefficient(psi.derivative(r,2))
1
sage: g.coefficient(psi.derivative(r,1))
2/r
```

Custom typesetting of symbolic functions in LaTeX, either using latex_name keyword:

```
sage: function('riemann', latex_name="\\mathcal{R}")
riemann
sage: latex(riemann(x))
\mathcal{R}(x)
```

or passing a custom callable function that returns a latex expression:
Symbolic Calculus, Release 10.1

```python
sage: mu,nu = var('mu,nu')
sage: def my_latex_print(self, *args):
    return r'\psi_{%s}'%(', '.join(map(latex, args)))
sage: function('psi', print_latex_func=my_latex_print)
psi
sage: latex(psi(mu,nu))
\psi_{\mu, \nu}
```

Defining custom methods for automatic or numeric evaluation, derivation, conjugation, etc. is supported:

```python
sage: def ev(self, x):
    return 2*x
sage: foo = function('foo', nargs=1, eval_func=ev)
sage: foo(x)
2*x
sage: def ef(self, x):
    pass
sage: bar = function('bar', nargs=1, eval_func=ef)
sage: bar(x)
bar(x)
```

```python
sage: def evalf_f(self, x, parent=None, algorithm=None):
    return 6
sage: foo = function('foo', nargs=1, evalf_func=evalf_f)
sage: foo(x)
foo(x)
```

```python
sage: def deriv(self, *args,**kwds):
    print("{} {}".format(args, kwds));
    return sum(args[0]**i
for i in range(kwds['order']))
```

```python
sage: def pow(self, x, power_param=None):
    print("{} {}".format(x, power_param));
    return x**power_param
sage: from pprint import pformat
sage: def expand(self, *args, **kwds):
    ...:
    print("{} {}".format(args, pformat(kwds)))
    ...:
    return sum([args[0]**i for i in range(kwds['order'])])
```
\[(y, \{ 'at': 0, 'options': 0, 'order': 5, 'var': y \}
\]
y^4 + y^3 + y^2 + y + 1

```python
sage: def my_print(self, *args):
    ....:     return "my args are: " + ', '.join(map(repr, args))

sage: foo = function('t', nargs=2, print_func=my_print)
sage: foo(x,y^z)
my args are: x, y^z
```

```latex
\text{my args are: } x, y^z
```

```python
sage: latex(foo(x,y^z))
t(x, y^z)
```

Since Sage 4.0, basic arithmetic with unevaluated functions is no longer supported:

```python
sage: x = var('x')
sage: f = function('f')
sage: 2*f
```

```
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: 'Integer Ring' and '<class 'sage.symbolic.function_factory...NewSymbolicFunction'>'
```

You now need to evaluate the function in order to do the arithmetic:

```python
sage: 2*f(x)
2*f(x)
```

Since Sage 4.0, you need to use substitute_function() to replace all occurrences of a function with
another:

```python
sage: var('a, b')
(a, b)
sage: cr = function('cr')
sage: f = cr(a)
sage: g = f.diff(a).integral(b)
sage: g
b*diff(cr(a), a)
sage: g.substitute_function(cr, cos)
-b*sin(a)
sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))
b*(cos(a) - sin(a))
```

half = 1/2

sec = sec
sech = sech
sin = sin
sinh = sinh
tan = tan
tanh = tanh
two = 2
x = x

class sage.symbolic.expression_conversions.ExpressionTreeWalker(ex)

Bases: Converter

A class that walks the tree. Mainly for subclassing.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: from sage.symbolic.random_tests import random_expr
sage: ex = sin(atan(0, hold=True)+hypergeometric((1,), (1,), x))
sage: s = ExpressionTreeWalker(ex)
sage: bool(s() == ex)
True
sage: set_random_seed(0)  # random_expr is unstable
sage: foo = random_expr(20, nvars=2)
sage: s = ExpressionTreeWalker(foo)
sage: bool(s() == foo)
True
```

arithmetic(ex, operator)

EXAMPLES:
composition\((ex, \text{operator})\)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
sage: f = foo(atan2(0, 0, hold=True))
```

```python
sage: s = ExpressionTreeWalker(f)
```

```python
sage: bool(s.composition(f, f.operator()) == f)
True
```

derivative\((ex, \text{operator})\)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
```

```python
sage: f = foo(x).diff(x)
```

```python
sage: s = ExpressionTreeWalker(f)
```

```python
sage: bool(s.derivative(f, f.operator()) == f)
True
```

pyobject\((ex, \text{obj})\)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
```

```python
sage: f = SR(2)
```

```python
sage: s = ExpressionTreeWalker(f)
```

```python
sage: bool(s.pyobject(f, f.pyobject()) == f.pyobject())
True
```

relation\((ex, \text{operator})\)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
```

```python
sage: foo = function('foo')
```

```python
sage: eq = foo(x) == x
```

```python
sage: s = ExpressionTreeWalker(eq)
```

```python
sage: s.relation(eq, eq.operator()) == eq
True
```

symbol\((ex)\)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
```

```python
sage: s = ExpressionTreeWalker(x)
```

```python
sage: bool(s.symbol(x) == x)
True
```
tuple(ex)
EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
```

```
sage: f = hypergeometric((1,2,3,), (x,), x)
```

```
sage: s = ExpressionTreeWalker(f)
sage: bool(s() == f)
True
```

class sage.symbolic.expression_conversions.FakeExpression(operands, operator)

Bases: object

Pynac represents \( \frac{x}{y} \) as \( xy^{-1} \). Often, tree-walkers would prefer to see divisions instead of multiplications and negative exponents. To allow for this (since Pynac internally doesn’t have division at all), there is a possibility to pass `use_fake_div=True`; this will rewrite an Expression into a mixture of Expression and FakeExpression nodes, where the FakeExpression nodes are used to represent divisions. These nodes are intended to act sufficiently like Expression nodes that tree-walkers won’t care about the difference.

**operands()**

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.truediv)
sage: f.operands()
```

```
[x, y]
```

**operator()**

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.truediv)
sage: f.operator()
```

```
<built-in function truediv>
```

**pyobject()**

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.truediv)
sage: f.pyobject()
```

```
Traceback (most recent call last):
...
TypeError: self must be a numeric expression
```

class sage.symbolic.expression_conversions.FastCallableConverter(ex, etb)

Bases: Converter

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import FastCallableConverter
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x'])

sage: f = FastCallableConverter(x+2, etb)
sage: f.ex
x + 2
sage: f.etb
<sage.ext.fast_callable.ExpressionTreeBuilder object at 0x...>
sage: f.use_fake_div
True
```

### arithmetic(ex, operator)

#### EXAMPLES:
```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x', 'y'])

sage: var('x,y')
(x, y)
sage: (x+y)._fast_callable_(etb)
add(v_0, v_1)
sage: (-x)._fast_callable_(etb)
neg(v_0)
sage: (x+y+x^2)._fast_callable_(etb)
add(add(ipow(v_0, 2), v_0), v_1)
```

### composition(ex, function)

Given an ExpressionTreeBuilder, return an Expression representing this value.

#### EXAMPLES:
```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x', 'y'])

sage: x,y = var('x,y')
sage: sin(sqrt(x+y))._fast_callable_(etb)
sin(sqrt(add(v_0, v_1)))
sage: arctan2(x,y)._fast_callable_(etb)
{arctan2}(v_0, v_1)
```

### pyobject(ex, obj)

#### EXAMPLES:
```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x'])

sage: pi._fast_callable_(etb)
pi
sage: etb = ExpressionTreeBuilder(vars=['x'], domain=RDF)
sage: pi._fast_callable_(etb)
3.141592653589793
```

### relation(ex, operator)

#### EXAMPLES:
```
```

2.16. Conversion of symbolic expressions to other types 279
symbol(ex)
Given an ExpressionTreeBuilder, return an Expression representing this value.

EXAMPLES:

```python
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x', 'y'])
sage: x, y, z = var('x,y,z')
sage: x._fast_callable_(etb)
\_v_0
sage: y._fast_callable_(etb)
\_v_1
sage: z._fast_callable_(etb)
Traceback (most recent call last):
...  
ValueError: Variable 'z' not found...
```

tuple(ex)
Given a symbolic tuple, return its elements as a Python list.

EXAMPLES:

```python
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x'])

sage: SR._force_pyobject((2, 3, x^2))._fast_callable_(etb)
[2, 3, \text{x}^2]
```

class sage.symbolic.expression_conversions.FriCASConverter
Bases: InterfaceInit
Converts any expression to FriCAS.

EXAMPLES:

```python
sage: var('x,y')
(x, y)
sage: f = exp(x^2) - arcsin(pi+x)/y
sage: f._fricas_()  # optional - fricas
-> fricas
  2  
  x
y %e - asin(x + %pi)
----------------------
y
```
derivative(ex, operator)
Convert the derivative of self in FriCAS.

INPUT:
- ex – a symbolic expression
- operator – operator

Note that ex.operator() == operator.

EXAMPLES:

```
sage: var('x,y,z')
(x, y, z)
sage: f = function("F")
sage: f(x)._fricas_()  # optional - fricas
F(x)
sage: diff(f(x,y,z), x, z, x)._fricas_()  # optional - fricas
F(x,y,z),1,1,3
```

Check that github issue #25838 is fixed:

```
sage: var('x')
x
sage: F = function('F')
sage: integrate(F(x), x, algorithm="fricas")  # optional - fricas
integral(F(x), x)
sage: integrate(diff(F(x), x)*sin(F(x)), x, algorithm="fricas")  # optional - fricas
-cos(F(x))
```

Check that github issue #27310 is fixed:

```
sage: f = function("F")
sage: var("y")
y
sage: ex = (diff(f(x,y), x, x, y)).subs(y=x+y); ex
d[0, 0, 1](F)(x, x + y)
sage: fricas(ex)  # optional - fricas
F(x, y + x),1,1,2
```

pyobject(ex, obj)
Return a string which, when evaluated by FriCAS, returns the object as an expression.

We explicitly add the coercion to the FriCAS domains ExpressionInteger and ExpressionComplexInteger to make sure that elements of the symbolic ring are translated to these. In particular, this is needed for integration, see github issue #28641 and github issue #28647.

EXAMPLES:
symbol(ex)

Convert the argument, which is a symbol, to FriCAS.

In this case, we do not return an ExpressionInteger, because FriCAS frequently requires elements of domain Symbol or Variable as arguments, for example to integrate. Moreover, FriCAS is able to do the conversion itself, whenever the argument should be interpreted as a symbolic expression.
EXAMPLES:

```python
sage: x._fricas_().domainOf() # optional - fricas
Variable(x)

sage: (x^2)._fricas_().domainOf() # optional - fricas
Expression(Integer())

sage: (2^x)._fricas_().integrate(x) # optional - fricas
2
x
```

```python
class sage.symbolic.expression_conversions.HoldRemover(ex, exclude=None)
Bases: ExpressionTreeWalker

A class that walks the tree and evaluates every operator that is not in a given list of exceptions.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import HoldRemover
sage: ex = sin(pi*cos(0, hold=True), hold=True); ex
sin(pi*cos(0))

sage: h = HoldRemover(ex)
sage: h()
0

sage: h = HoldRemover(ex, [sin])
sage: h()
sin(pi)

sage: h = HoldRemover(ex, [cos])
sage: h()
sin(pi*cos(0))

sage: ex = atan2(0, 0, hold=True) + hypergeometric([1,2], [3,4], 0, hold=True)
sage: h = HoldRemover(ex, [atan2])
sage: h()
arctan2(0, 0) + 1

sage: h = HoldRemover(ex, [hypergeometric])
sage: h()
NaN + hypergeometric((1, 2), (3, 4), 0)
```

```python
class sage.symbolic.expression_conversions.InterfaceInit(interface)
Bases: Converter

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import HoldRemover
sage: ex = sin(pi*cos(0, hold=True), hold=True); ex
sin(pi*cos(0))

sage: h = HoldRemover(ex)
sage: h()
0
```

```python
composition(ex, operator)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import HoldRemover
sage: ex = sin(pi*cos(0, hold=True), hold=True); ex
sin(pi*cos(0))

sage: h = HoldRemover(ex)
sage: h()
0
```

```python
class sage.symbolic.expression_conversions.InterfaceInit(interface)
Bases: Converter

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import HoldRemover
```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: a = pi + 2
sage: m(a)
'(\pi)+2'
sage: m(sin(a))
'sin((\pi)+2)'
sage: m(exp(x^2) + pi + 2)
'(\pi)+(e^{(\_SAGE_VAR_x)^2})+2'

\textbf{arithmetic}(ex, operator)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.arithmetic(x+2, sage.symbolic.operators.add_vararg)
'(_SAGE_VAR_x)+(2)'
\end{verbatim}

\textbf{composition}(ex, operator)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.composition(sin(x), sin)
'sin(_SAGE_VAR_x)'
sage: m.composition(ceil(x), ceil)
'ceiling(_SAGE_VAR_x)'
sage: m = InterfaceInit(mathematica)
sage: m.composition(sin(x), sin)
'Sin[x]'
\end{verbatim}

\textbf{derivative}(ex, operator)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: f = function('f')
sage: a = f(x).diff(x); a
diff(f(x), x)
sage: print(m.derivative(a, a.operator()))
diff('f(_SAGE_VAR_x)',_SAGE_VAR_x,1)
sage: b = f(x).diff(x, x)
sage: print(m.derivative(b, b.operator()))
diff('f(_SAGE_VAR_x)',_SAGE_VAR_x,2)
\end{verbatim}

We can also convert expressions where the argument is not just a variable, but the result is an “at” expression using temporary variables:

\begin{verbatim}
sage: y = var('y')
sage: t = (f(x*y).diff(x))/y
sage: t
\end{verbatim}
Symbolic Calculus, Release 10.1

(continued from previous page)

\[
\frac{\partial}{\partial x}(f(x)y)
\]

\[
sage: m.\text{derivative}(t, t.\text{operator})
\]

"at(diff('f(_SAGE_VAR__symbol0), _SAGE_VAR__symbol0, 1), [_SAGE_VAR__symbol0 =_\rightarrow(_SAGE_VAR_x)*(_SAGE_VAR_y)]"

\[
\text{pyobject}(ex, obj)
\]

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: ii = InterfaceInit(gp)
sage: f = 2+SR(I)
sage: ii.pyobject(f, f.pyobject())
'I + 2'
sage: ii.pyobject(SR(2), 2)
'2'
sage: ii.pyobject(pi, pi.pyobject())
'Pi'
```

\[
\text{relation}(ex, operator)
\]

EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.relation(x==3, operator.eq)
'_SAGE_VAR_x = 3'
sage: m.relation(x==3, operator.lt)
'_SAGE_VAR_x < 3'
```

\[
\text{symbol}(ex)
\]

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.symbol(x)
'_SAGE_VAR_x'
sage: f(x) = x
sage: m.symbol(f)
'_SAGE_VAR_x'
sage: ii = InterfaceInit(gp)
sage: ii.symbol(x)
'x'
sage: g = InterfaceInit(giac)
sage: g.symbol(x)
'sageVARx'
```

\[
\text{tuple}(ex)
\]

EXAMPLES:

2.16. Conversion of symbolic expressions to other types 285
Symbolic Calculus, Release 10.1

```python
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: t = SR._force_pyobject((3, 4, e^x))
sage: m.tuple(t)
'[3,4,exp(_SAGE_VAR_x)]'
```

class sage.symbolic.expression_conversions.LaurentPolynomialConverter(ex, base_ring=None, ring=None)

Bases: PolynomialConverter

A converter from symbolic expressions to Laurent polynomials.

See `laurent_polynomial()` for details.

class sage.symbolic.expression_conversions.PolynomialConverter(ex, base_ring=None, ring=None)

Bases: Converter

A converter from symbolic expressions to polynomials.

See `polynomial()` for details.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: x, y = var('x,y')
sage: p = PolynomialConverter(x+y, base_ring=QQ)
sage: p.base_ring
Rational Field
sage: p.ring
Multivariate Polynomial Ring in x, y over Rational Field

sage: p = PolynomialConverter(x, base_ring=QQ)
sage: p.base_ring
Rational Field
sage: p.ring
Univariate Polynomial Ring in x over Rational Field

sage: p = PolynomialConverter(x, ring=QQ['x,y'])
sage: p.base_ring
Rational Field
sage: p.ring
Multivariate Polynomial Ring in x, y over Rational Field

sage: p = PolynomialConverter(x+y, ring=QQ['x'])
Traceback (most recent call last):
  ...
TypeError: y is not a variable of Univariate Polynomial Ring in x over Rational...
```

arithmetic(ex, operator)

EXAMPLES:

```python
sage: import operator
sage: from sage.symbolic.expression_conversions import PolynomialConverter
```

(continues on next page)
sage: x, y = var('x, y')
sage: p = PolynomialConverter(x, base_ring=RR)
sage: p.arithmetic(pi+e, operator.add)
5.8597448204884
sage: p.arithmetic(x^2, operator.pow)
x^2
sage: p = PolynomialConverter(x+y, base_ring=RR)
sage: p.arithmetic(x*y+y^2, operator.add)
x^2 + y^2
sage: p = PolynomialConverter(y^(3/2), ring=SR['x'])
sage: p.arithmetic(y^(3/2), operator.pow)
y^(3/2)
sage: _.parent()
Symbolic Ring

composition(ex, operator)

EXAMPLES:

sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: a = sin(2)
sage: p = PolynomialConverter(a*x, base_ring=RR)
sage: p.composition(a, a.operator())
0.909297426825682

pyobject(ex, obj)

EXAMPLES:

sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: p = PolynomialConverter(x, base_ring=QQ)
sage: f = SR(2)
sage: p.pyobject(f, f.pyobject())
2
sage: _.parent()
Rational Field

relation(ex, op)

EXAMPLES:

sage: import operator
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: x, y = var('x, y')
sage: p = PolynomialConverter(x, base_ring=RR)

sage: p.relation(x==3, operator.eq)
x - 3
sage: p.relation(x==3, operator.lt)
Traceback (most recent call last):
  ... ValueError: Unable to represent as a polynomial
\begin{verbatim}
symbolic_calculus, release 10.1
(continued from previous page)

sage: p = PolynomialConverter(x - y, base_ring=QQ)
sage: p.relation(x^2 - y^3 + 1 == x^3, operator.eq)
-x^3 - y^3 + x^2 + 1

symbol(ex)
Returns a variable in the polynomial ring.

EXAMPLES:
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: p = PolynomialConverter(x, base_ring=QQ)
sage: p.symbol(x)
x
sage: _.parent()
Univariate Polynomial Ring in x over Rational Field
sage: y = var('y')
sage: p = PolynomialConverter(x*y, ring=SR['x'])
sage: p.symbol(y)
y
class sage.symbolic.expression_conversions.RingConverter(R, subs_dict=None)

Bases: Converter

A class to convert expressions to other rings.

EXAMPLES:
sage: from sage.symbolic.expression_conversions import RingConverter
sage: P.<z> = ZZ[]
sage: R = RingConverter(P, subs_dict={x:z})
sage: a = 2*x^2 + x + 3
sage: R(a)
2*z^2 + z + 3

arithmetic(ex, operator)

EXAMPLES:
sage: from sage.symbolic.expression_conversions import RingConverter
sage: P.<z> = ZZ[]
sage: R = RingConverter(P, subs_dict={x:z})
sage: a = 2*z^2 + x + 3
sage: R(a)
2*z^2 + z + 3

composition(ex, operator)

EXAMPLES:
\end{verbatim}

288 Chapter 2. Internal functionality supporting calculus
Symbolic Calculus, Release 10.1

```python
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF)
```

```python
sage: R(cos(2))
-0.4161468365471424?
```

```python
pyobject(ex, obj)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF)
```

```python
sage: R(cos(2))
-0.4161468365471424?
```

```python
symbol(ex)

All symbols appearing in the expression must either appear in subs_dict or be convertible by the ring's element constructor in order for the conversion to be successful.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF, subs_dict={x:2})
```

```python
sage: R(x+pi)
5.141592653589794?
```

```python
sage: R = RingConverter(RIF)
```

```python
sage: R(x+pi)
Traceback (most recent call last):
...
TypeError: unable to simplify to a real interval approximation
```

```python
sage: R = RingConverter(QQ['x'])
```

```python
sage: R(x^2+x)
x^2 + x
```

```python
sage: R(x^2+x).parent()  # Univariate Polynomial Ring in x over Rational Field
```

```python
class sage.symbolic.expression_conversions.SubstituteFunction(ex, *args)

Bases: ExpressionTreeWalker

A class that walks the tree and replaces occurrences of a function with another.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import SubstituteFunction
```

```python
sage: foo = function('foo'); bar = function('bar')
```

```python
sage: s = SubstituteFunction(foo(x), {foo: bar})
```

```python
sage: s(1/foo(foo(x)) + foo(2))
1/bar(bar(x)) + bar(2)
```

```python
composition(ex, operator)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import SubstituteFunction
```

```python
sage: foo = function('foo'); bar = function('bar')
```

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```python
sage: s = SubstituteFunction(foo(x), {foo: bar})
sage: f = foo(x)
sage: s.composition(f, f.operator())
bar(x)
sage: f = foo(foo(x))
sage: s.composition(f, f.operator())
bar(bar(x))
sage: f = sin(foo(x))
sage: s.composition(f, f.operator())
sin(bar(x))
sage: f = foo(sin(x))
sage: s.composition(f, f.operator())
bar(sin(x))
```

**derivative**(ex, operator)

```python
EXAMPLES:
```

```python
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), {foo: bar})
sage: f = foo(x).diff(x)
sage: s.derivative(f, f.operator())
diff(bar(x), x)
```

**class** sage.symbolic.expression_conversions.SympyConverter

Bases: Converter

Converts any expression to SymPy.

```python
EXAMPLES:
```

```python
sage: import sympy
sage: var('x,y')
(x, y)
sage: f = exp(x^2) - arcsin(pi+x)/y
sage: f._sympy_()
exp(x**2) - asin(x + pi)/y
sage: f._sage_()
-arcsin(pi + x)/y + e^(x^2)
```

**arithmetic**(ex, operator)

```python
EXAMPLES:
```

```python
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = x + 2
sage: s.arithmetic(f, f.operator())
x + 2
```

**composition**(ex, operator)

```python
EXAMPLES:
```

```python
```
Symbolic Calculus, Release 10.1

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = sin(2)
sage: s.composition(f, f.operator())
sin(2)
sage: type(_)
sin
sage: f = arcsin(2)
sage: s.composition(f, f.operator())
asin(2)
```

derivative(ex, operator)
Convert the derivative of self in sympy.

**INPUT:**

- `ex` – a symbolic expression
- `operator` – operator

**pyobject(ex, obj)**

**EXAMPLES:**

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = SR(2)
sage: s.pyobject(f, f.pyobject())
2
sage: type(_)
<class 'sympy.core.numbers.Integer'>
```

relation(ex, op)

**EXAMPLES:**

```
sage: import operator
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: s.relation(x == 3, operator.eq)
Eq(x, 3)
sage: s.relation(pi < 3, operator.lt)
pi < 3
sage: s.relation(x != pi, operator.ne)
Ne(x, pi)
sage: s.relation(x > 0, operator.gt)
x > 0
```

symbol(ex)

**EXAMPLES:**

```
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: s.symbol(x)
x
sage: type(_)
<class 'sympy.core.symbol.Symbol'>
```

2.16. Conversion of symbolic expressions to other types 291
tuple(ex)
Conversion of tuples.

EXAMPLES:

```
sage: t = SR._force_pyobject((3, 4, e^x))
sage: t._sympy_()
(3, 4, e^x)
sage: t = SR._force_pyobject((cos(x),))
sage: t._sympy_()
(cos(x),)
```

```
sage.symbolic.expression_conversions.algebraic(ex, field)
Returns the symbolic expression ex as a element of the algebraic field field.

EXAMPLES:

```
sage: a = SR(5/6)
sage: AA(a)
5/6
sage: type(AA(a))
<class 'sage.rings.qqbar.AlgebraicReal'>
sage: QQbar(a)
5/6
sage: type(QQbar(a))
<class 'sage.rings.qqbar.AlgebraicNumber'>
sage: AA(golden_ratio)
1.618033988749895?
sage: QQbar(golden_ratio)
1.618033988749895?
sage: QQbar(sin(pi/3))
0.866025403784439?
sage: QQbar(sqrt(2) + sqrt(8))
4.242640687119285?
sage: AA(sqrt(2) ^ 4) == 4
True
```

```
sage.symbolic.expression_conversions.fast_callable(ex, etb)
Given an ExpressionTreeBuilder etb, return an Expression representing the symbolic expression ex.

EXAMPLES:

```
```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x','y'])

sage: x,y = var('x,y')
sage: f = y+2*x^2
sage: f._fast_callable_(etb)
add(mul(ipow(v_0, 2), 2), v_1)

sage: f = (2*x^3+2*x-1)/((x-2)*(x+1))
sage: f._fast_callable_(etb)
div(add(add(mul(ipow(v_0, 3), 2), mul(v_0, 2)), -1), mul(add(v_0, 1), add(v_0, -2)))

sage.symbolic.expression_conversions.laurent_polynomial(ex, base_ring=None, ring=None)

Return a Laurent polynomial from the symbolic expression `ex`.

INPUT:

- `ex` – a symbolic expression
- `base_ring`, `ring` – Either a `base_ring` or a Laurent polynomial `ring` can be specified for the parent of result. If just a `base_ring` is given, then the variables of the `base_ring` will be the variables of the expression `ex`.

OUTPUT:

A Laurent polynomial.

EXAMPLES:

sage: from sage.symbolic.expression_conversions import laurent_polynomial
sage: f = x^2 + 2/x
sage: laurent_polynomial(f, base_ring=QQ)
2*x^-1 + x^2
sage: _.parent()
Univariate Laurent Polynomial Ring in x over Rational Field

sage: laurent_polynomial(f, ring=LaurentPolynomialRing(QQ, 'x, y'))
x^2 + 2*x^-1
sage: _.parent()
Multivariate Laurent Polynomial Ring in x, y over Rational Field

sage: x, y = var('x, y')
sage: laurent_polynomial(x + 1/y^2, ring=LaurentPolynomialRing(QQ, 'x, y'))
x + y^-2
sage: _.parent()
Multivariate Laurent Polynomial Ring in x, y over Rational Field

sage.symbolic.expression_conversions.polynomial(ex, base_ring=None, ring=None)

Return a polynomial from the symbolic expression `ex`.

INPUT:

- `ex` – a symbolic expression
- `base_ring`, `ring` – Either a `base_ring` or a polynomial `ring` can be specified for the parent of result. If just a `base_ring` is given, then the variables of the `base_ring` will be the variables of the expression `ex`.

OUTPUT:

A polynomial.
EXPERIMENTS:

```python
sage: from sage.symbolic.expression_conversions import polynomial
sage: f = x^2 + 2
sage: polynomial(f, base_ring=QQ)
x^2 + 2
sage: _.parent()  # Univariate Polynomial Ring in x over Rational Field
sage: polynomial(f, ring=QQ['x,y'])
x^2 + 2
sage: _.parent()  # Multivariate Polynomial Ring in x, y over Rational Field
sage: x, y = var('x, y')
sage: polynomial(x + y^2, ring=QQ['x,y'])
y^2 + x
sage: _.parent()  # Multivariate Polynomial Ring in x, y over Rational Field
sage: s,t = var('s, t')
sage: expr = t^2-2*s*t+1
sage: expr.polynomial(None,ring=SR['t'])
t^2 - 2*s*t + 1
sage: _.parent()  # Univariate Polynomial Ring in t over Symbolic Ring
sage: polynomial(x*y, ring=SR['x'])
y*x
sage: polynomial(y - sqrt(x), ring=SR['y'])
y - sqrt(x)
sage: _.list()
[-sqrt(x), 1]
```

The polynomials can have arbitrary (constant) coefficients so long as they coerce into the base ring:

```python
sage: polynomial(2^sin(2)*x^2 + exp(3), base_ring=RR)
1.87813065119873*x^2 + 20.0855369231877
```

## 2.17 Complexity Measures

Some measures of symbolic expression complexity. Each complexity measure is expected to take a symbolic expression as an argument, and return a number.

```python
sage.symbolic.complexity_measures.string_length(expr)
```

Returns the length of `expr` after converting it to a string.

**INPUT:**

- `expr` – the expression whose complexity we want to measure.

**OUTPUT:**

A real number representing the complexity of `expr`.
RATIONALE:

If the expression is longer on-screen, then a human would probably consider it more complex.

EXAMPLES:

This expression has three characters, \( x \), ^, and 2:

```
sage: from sage.symbolic.complexity_measures import string_length
tsage: f = x^2
tsage: string_length(f)
3
```

### 2.18 Further examples from Wester’s paper

These are all the problems at [http://yacas.sourceforge.net/essaysmanual.html](http://yacas.sourceforge.net/essaysmanual.html)

They come from the 1994 paper “Review of CAS mathematical capabilities”, by Michael Wester, who put forward 123 problems that a reasonable computer algebra system should be able to solve and tested the then current versions of various commercial CAS on this list. Sage can do most of the problems natively now, i.e., with no explicit calls to Maxima or other systems.

```
sage: # (YES) factorial of 50, and factor it
sage: factorial(50)
3041409320171337804361260816606476884377641568960512000000000000000
sage: factor(factorial(50))
2^47 * 3^22 * 5^12 * 7^8 * 11^4 * 13^3 * 17^2 * 19^2 * 23^2 * 29 * 31 * 37 * 41 * 43 * 47
```

```
sage: # (YES) 1/2+...+1/10 = 4861/2520
sage: sum(1/n for n in range(2,10+1)) == 4861/2520
True
```

```
sage: # (YES) Evaluate e^(Pi*sqrt(163)) to 50 decimal digits
sage: a = e^(pi*sqrt(163)); a
e^(sqrt(163)*pi)
sage: RealField(150)(a)
2.6253741264076874399999999999925007259719820e17
```

```
sage: # (YES) Evaluate the Bessel function J[2] numerically at z=1+i.
sage: bessel_J(2, 1+i).n()
0.0415798869439621 + 0.247397641513306*I
```

```
sage: # (YES) Obtain period of decimal fraction 1/7=0.(142857).
sage: a = 1/7
sage: a
1/7
sage: a.period()
6
```

```
sage: # (YES) Continued fraction of 3.1415926535
sage: a = 3.1415926535
```

2.19 Solving ordinary differential equations

This file contains functions useful for solving differential equations which occur commonly in a 1st semester differential equations course. For another numerical solver see the \texttt{ode_solver()} function and the optional package Octave.

Solutions from the Maxima package can contain the three constants \_C, \_K1, and \_K2 where the underscore is used to distinguish them from symbolic variables that the user might have used. You can substitute values for them, and make them into accessible usable symbolic variables, for example with \texttt{var("\_C")}.

Commands:

- \texttt{desolve()} - Compute the “general solution” to a 1st or 2nd order ODE via Maxima.
- \texttt{desolve_laplace()} - Solve an ODE using Laplace transforms via Maxima. Initial conditions are optional.
- \texttt{desolve_rk4()} - Solve numerically an IVP for one first order equation, return list of points or plot.
- \texttt{desolve_system_rk4()} - Solve numerically an IVP for a system of first order equations, return list of points.
- \texttt{desolve_odeint()} - Solve numerically a system of first-order ordinary differential equations using \texttt{odeint} from scipy.integrate module.
- \texttt{desolve_system()} - Solve a system of 1st order ODEs of any size using Maxima. Initial conditions are optional.
- \texttt{eulers_method()} - Approximate solution to a 1st order DE, presented as a table.
- \texttt{eulers_method_2x2()} - Approximate solution to a 1st order system of DEs, presented as a table.
- \texttt{eulers_method_2x2_plot()} - Plot the sequence of points obtained from Euler’s method.

The following functions require the optional package \texttt{tides}:
• **desolve_mintides()** - Numerical solution of a system of 1st order ODEs via the Taylor series integrator method implemented in TIDES.

• **desolve_tides_mpfr()** - Arbitrary precision Taylor series integrator implemented in TIDES.

**AUTHORS:**

• David Joyner (3-2006) - Initial version of functions

• Marshall Hampton (7-2007) - Creation of Python module and testing

• Robert Bradshaw (10-2008) - Some interface cleanup.

• Robert Marik (10-2009) - Some bugfixes and enhancements

• Miguel Marco (06-2014) - Tides desolvers

```python
sage.calculus.desolvers.desolve(de, dvar, ics=None, ivar=None, show_method=False, contrib_ode=False, algorithm='maxima')
```

Solve a 1st or 2nd order linear ODE, including IVP and BVP.

**INPUT:**

• **de** – an expression or equation representing the ODE

• **dvar** – the dependent variable (hereafter called \(y\))

• **ics** – (optional) the initial or boundary conditions
  
  – for a first-order equation, specify the initial \(x\) and \(y\)
  
  – for a second-order equation, specify the initial \(x, y,\) and \(dy/dx\), i.e. write \([x_0, y(x_0), y'(x_0)]\)
  
  – for a second-order boundary solution, specify initial and final \(x\) and \(y\) boundary conditions, i.e. write \([x_0, y(x_0), x_1, y(x_1)]\).
  
  – gives an error if the solution is not SymbolicEquation (as happens for example for a Clairaut equation)

• **ivar** – (optional) the independent variable (hereafter called \(x\)), which must be specified if there is more than one independent variable in the equation

• **show_method** – (optional) if True, then Sage returns pair \([\text{solution, method}]\), where method is the string describing the method which has been used to get a solution (Maxima uses the following order for first order equations: linear, separable, exact (including exact with integrating factor), homogeneous, bernoulli, generalized homogeneous) - use carefully in class, see below the example of an equation which is separable but this property is not recognized by Maxima and the equation is solved as exact.

• **contrib_ode** – (optional) if True, desolve allows to solve Clairaut, Lagrange, Riccati and some other equations. This may take a long time and is thus turned off by default. Initial conditions can be used only if the result is one SymbolicEquation (does not contain a singular solution, for example).

• **algorithm** – (default: 'maxima') one of
  
  – 'maxima' - use maxima
  
  – 'fricas' - use FriCAS (the optional fricas spkg has to be installed)

**OUTPUT:**

In most cases return a SymbolicEquation which defines the solution implicitly. If the result is in the form \(y(x) = \ldots\) (happens for linear eqs.), return the right-hand side only. The possible constant solutions of separable ODEs are omitted.

**Note:** Use desolve? <tab> if the output in the Sage notebook is truncated.
EXAMPLES:

```python
sage: x = var('x')
sage: y = function('y')(x)
sage: desolve(diff(y,x) + y - 1, y)
(_C + e^x)*e^(-x)
```

```python
def = desolve(diff(y,x) + y - 1, y, ics=[10,2]); f
e^10 + e^x)*e^(-x)
```

```python
sage: plot(f)
Graphics object consisting of 1 graphics primitive
```

We can also solve second-order differential equations:

```python
sage: x = var('x')
sage: y = function('y')(x)
sage: de = diff(y,x,2) - y == x
sage: desolve(de, y)
_K2*e^(-x) + _K1*e^x - x
```

```python
f = desolve(de, y, [10,2,1]); f
-x + 7*e^(x - 10) + 5*e^(-x + 10)
```

```python
f(x=10)
2
```

```python
diff(f,x)(x=10)
1
```

```python
de = diff(y,x,2) + y == 0
sage: desolve(de, y)
_K2*cos(x) + _K1*sin(x)
```

```python
def = desolve(de, y, [0,1,pi/2,4])
cos(x) + 4*sin(x)
```

```python
desolve(y*diff(y,x)+sin(x)==0,y)
-1/2*y(x)^2 == _C - cos(x)
```

Clairaut equation: general and singular solutions:

```python
def = desolve(diff(y,x)^2+x*diff(y,x)-y==0,y,contrib_ode=True,show_method=True)
[[y(x) == _C^2 + _C*x, y(x) == -1/4*x^2], 'clairau...']
```

For equations involving more variables we specify an independent variable:

```python
sage: a,b,c,n=var('a b c n')
sage: desolve(x^2*diff(y,x)==a+b*x^n+c*x^2*y^2,y,ivar=x,contrib_ode=True)
[[y(x) == 0, (b*x^n*(n - 2) + a*x^2)*c^2*u == 0]]
```
Higher order equations, not involving independent variable:

```python
sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y).expand()
1/6*y(x)^3 + _K1*y(x) == _K2 + x
```

```python
sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,1,3]).expand()
1/6*y(x)^3 - 5/3*y(x) == x - 3/2
```

```python
sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,1,3],show_method=True)
[1/6*y(x)^3 - 5/3*y(x) == x - 3/2, 'freeofx']
```

Separable equations - Sage returns solution in implicit form:

```python
sage: desolve(diff(y,x)*sin(y) == cos(x),y)
-cos(y(x)) == _C + sin(x)
```

```python
sage: desolve(diff(y,x)*sin(y) == cos(x),y,show_method=True)
[-cos(y(x)) == _C + sin(x), 'separable']
```

```python
sage: desolve(diff(y,x)*sin(y) == cos(x),y,[pi/2,1])
-cos(y(x)) == -cos(1) + sin(x) - 1
```

Linear equation - Sage returns the expression on the right hand side only:

```python
sage: desolve(diff(y,x)+(y) == cos(x),y)
1/2*((cos(x) + sin(x))*e^x + 2*_C)*e^(-x)
```

```python
sage: desolve(diff(y,x)+(y) == cos(x),y,show_method=True)
[1/2*((cos(x) + sin(x))*e^x + 2*_C)*e^(-x), 'linear']
```

```python
sage: desolve(diff(y,x)+(y) == cos(x),y,[0,1])
1/2*(cos(x)*e^x + e^x*sin(x) + 1)*e^(-x)
```

This ODE with separated variables is solved as exact. Explanation - factor does not split $e^x-y$ in Maxima into $e^x*e^y$:

```python
sage: desolve(diff(y,x)==exp(x-y),y,show_method=True)
[-e^x + e^y(x) == _C, 'exact']
```

You can solve Bessel equations, also using initial conditions, but you cannot put (sometimes desired) the initial condition at $x = 0$, since this point is a singular point of the equation. Anyway, if the solution should be bounded at $x = 0$, then $K_2=0$.

```python
sage: desolve(x^2*diff(y,x,x)+x*diff(y,x)+(x^2-4)*y==0,y)
_K1*bessel_J(2, x) + _K2*bessel_Y(2, x)
```

Example of difficult ODE producing an error:
Another difficult ODE with error - moreover, it takes a long time:

sage: desolve(sqrt(y)*diff(y,x)+e^y+cos(x)-sin(x+y)==0,y,contrib_ode=True) # not tested

Some more types of ODEs:

sage: desolve(x*diff(y,x)^2-(1+x*y)*diff(y,x)+y==0,y,contrib_ode=True,show_method=True)
[[y(x) == _C + log(x), y(x) == _C*e^x], 'factor']

sage: desolve(diff(y,x)==(x+y)^2,y,contrib_ode=True,show_method=True)
[[[x == _C - arctan(sqrt(t)), y(x) == -x - sqrt(t)], [x == _C + arctan(sqrt(t)), y(x) == -x + sqrt(t)]], 'lagrange']

These two examples produce an error (as expected, Maxima 5.18 cannot solve equations from initial conditions). Maxima 5.18 returns false answer in this case!

sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,
[0,1,2]).expand() # not tested
Traceback (click to the left for traceback)
...
NotImplementedError, "Maxima was unable to solve this ODE. Consider to set option contrib_ode to True."

sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,2],show_method=True) # not tested
Traceback (click to the left for traceback)
...
NotImplementedError, "Maxima was unable to solve this ODE. Consider to set option contrib_ode to True."

Second order linear ODE:

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y)
(_K2*x + _K1)*e^(-x) + 1/2*sin(x)

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,show_method=True)
[(_K2*x + _K1)*e^(-x) + 1/2*sin(x), 'variationofparameters']

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,[0,3,1])
1/2*(7*x + 6)*e^(-x) + 1/2*sin(x)

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,[0,3,1],show_method=True)
[1/2*(7*x + 6)*e^(-x) + 1/2*sin(x), 'variationofparameters']
Symbolic Calculus, Release 10.1

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,
[0,3,pi/2,2])
3*(x*(e^(1/2*pi) - 2)/pi + 1)*e^(-x) + 1/2*sin(x)

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,
[0,3,pi/2,2],show_method=True)
[3*(x*(e^(1/2*pi) - 2)/pi + 1)*e^(-x) + 1/2*sin(x),
'variationofparameters']

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y)
(_K2*x + _K1)*e^(-x)

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,show_method=True)
[(_K2*x + _K1)*e^(-x), 'constcoeff']

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,[0,3,1])
(4*x + 3)*e^(-x)

sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,[0,3,pi/2,2],show_method=True)
[(2*x*(2*e^(1/2*pi) - 3)/pi + 3)*e^(-x), 'constcoeff']

sage: Y = desolve(de, y, ics=[1,3,7], algorithm="fricas")
1/15*(x^5 + 15*x^3 + 50*x^2 - 21)/x

AUTHORS:
• David Joyner (1-2006)
• Robert Bradshaw (10-2008)
• Robert Marik (10-2009)
Symbolic Calculus, Release 10.1

- **de** - a lambda expression representing the ODE (e.g. \( \text{de} = \text{diff}(y, x, 2) == \text{diff}(y, x) + \sin(x) \))
- **dvar** - the dependent variable (e.g. \( y \))
- **ivar** - (optional) the independent variable (hereafter called \( x \)), which must be specified if there is more than one independent variable in the equation.
- **ics** - a list of numbers representing initial conditions, (e.g. \( f(0)=1, f'(0)=2 \) corresponds to \( \text{ics} = [0, 1, 2] \))

**OUTPUT:**
Solution of the ODE as symbolic expression

**EXAMPLES:**

```sage
sage: u=function('u')(x)
sage: eq = diff(u,x) - exp(-x) - u == 0
sage: desolve_laplace(eq,u)
1/2*(2*u(0) + 1)*e^x - 1/2*e^(-x)
```

We can use initial conditions:

```sage
sage: desolve_laplace(eq,u,ics=[0,3])
-1/2*e^(-x) + 7/2*e^x
```

The initial conditions do not persist in the system (as they persisted in previous versions):

```sage
sage: desolve_laplace(eq,u)
1/2*(2*u(0) + 1)*e^x - 1/2*e^(-x)
```

```sage
sage: f=function('f')(x)
sage: eq = diff(f,x) + f == 0
sage: desolve_laplace(eq,f,[0,1])
e^(-x)
```

```sage
sage: x = var('x')
sage: f = function('f')(x)
sage: de = diff(f,x,x) - 2*diff(f,x) + f
sage: desolve_laplace(de,f)
-x*e^x*f(0) + x*e^x*D[0](f)(0) + e^x*f(0)
```

```sage
sage: desolve_laplace(de,f,ics=[0,1,2])
x*e^x + e^x
```

**AUTHORS:**
- David Joyner (1-2006,8-2007)
- Robert Marik (10-2009)

`sage.calculus.desolvers.desolve_mintides(f, ics, initial, final, delta, tolrel=1e-16, tolabsl=1e-16)`

Solve numerically a system of first order differential equations using the taylor series integrator implemented in mintides.

**INPUT:**
- \( f \) - symbolic function. Its first argument will be the independent variable. Its output should be de derivatives of the dependent variables.
Symbolic Calculus, Release 10.1

- **ics** – a list or tuple with the initial conditions.
- **initial** – the starting value for the independent variable.
- **final** – the final value for the independent value.
- **delta** – the size of the steps in the output.
- **tolrel** – the relative tolerance for the method.
- **tolabs** – the absolute tolerance for the method.

**OUTPUT:**
- A list with the positions of the IVP.

**EXAMPLES:**

We integrate a periodic orbit of the Kepler problem along 50 periods:

```sage
sage: var('t,x,y,X,Y')
(t, x, y, X, Y)
sage: f(t,x,y,X,Y)=[X, Y, -x/(x^2+y^2)^(3/2), -y/(x^2+y^2)^(3/2)]
sage: ics = [0.8, 0, 0, 1.22474487139159]
sage: t = 100*pi
sage: sol = desolve_mintides(f, ics, 0, t, t, 1e-12, 1e-12)
# optional -tides
sage: sol
# optional -tides # abs tol 1e-5
[[0.000000000000000, 
  0.800000000000000, 
  0.000000000000000, 
  0.000000000000000, 
  1.22474487139159],
 [3.14159265358979, 
  0.800000000000000, 
  0.000000000000000, 
  -5.91973525754241e-9, 
  7.5688709180590e-9, 
  1.22474487136329]]
```

**ALGORITHM:**
Uses TIDES.

**REFERENCES:**

```python
sage.calculus.desolvers.desolve_odeint(des, ics, times, dvars, ivar=None, compute_jac=False, args=(), rtol=None, atol=None, tcrit=None, h0=0.0, hmax=0.0, hmin=0.0, ixpr=0, mxstep=0, mxhnil=0, mxordn=12, mxords=5, printmessg=0)
```

Solve numerically a system of first-order ordinary differential equations using `odeint` from scipy.integrate module.

**INPUT:**
- **des** – right hand sides of the system
- **ics** – initial conditions

2.19. Solving ordinary differential equations 313
• times – a sequence of time points in which the solution must be found
• dvars – dependent variables. ATTENTION: the order must be the same as in des, that means: d(dvars[i])/dt=des[i]
• ivar – independent variable, optional.
• compute_jac – boolean. If True, the Jacobian of des is computed and used during the integration of stiff systems. Default value is False.

Other Parameters (taken from the documentation of odeint function from scipy.integrate module.)
• rtol, atol : float The input parameters rtol and atol determine the error control performed by the solver. The solver will control the vector, e, of estimated local errors in y, according to an inequality of the form:
  \[
  \max-norm \ of \ \frac{e}{\text{ewt}} \leq 1
  \]
  where ewt is a vector of positive error weights computed as:
  \[
  \text{ewt} = \text{rtol} \times \text{abs}(y) + \text{atol}
  \]
  rtol and atol can be either vectors the same length as y or scalars.
• tcrit : array Vector of critical points (e.g. singularities) where integration care should be taken.
• h0 : float, (0: solver-determined) The step size to be attempted on the first step.
• hmax : float, (0: solver-determined) The maximum absolute step size allowed.
• hmin : float, (0: solver-determined) The minimum absolute step size allowed.
• ixpr : boolean. Whether to generate extra printing at method switches.
• mxstep : integer, (0: solver-determined) Maximum number of (internally defined) steps allowed for each integration point in t.
• mxhnil : integer, (0: solver-determined) Maximum number of messages printed.
• mxordn : integer, (0: solver-determined) Maximum order to be allowed for the nonstiff (Adams) method.
• mxords : integer, (0: solver-determined) Maximum order to be allowed for the stiff (BDF) method.

OUTPUT:
Return a list with the solution of the system at each time in times.

EXAMPLES:
Lotka Volterra Equations:

```
sage: from sage.calculus.desolvers import desolve_odeint
dsage: x,y = var('x,y')
dsage: f = [x*(1-y), -y*(1-x)]
dsage: sol = desolve_odeint(f, [0.5,2], srange(0,10,0.1), [x,y])
# needs scipy
sage: p = line(zip(sol[:,0],sol[:,1]))
# needs scipy sage.plot
sage: p.show()
```

Lorenz Equations:
Symbolic Calculus, Release 10.1

sage: x,y,z = var('x,y,z')
sage: # Next we define the parameters
sage: sigma = 10
sage: rho = 28
sage: beta = 8/3
sage: # The Lorenz equations
sage: lorenz = [sigma*(y-x),x*(rho-z)-y,x*y-beta*z]

sage: # Time and initial conditions
sage: times = srange(0,50.05,0.05)

sage: ics = [0,1,1]
sage: sol = desolve_odeint(lorenz, ics, times, [x,y,z], rtol=1e-13, atol=1e-14)

One-dimensional stiff system:

sage: y = var('y')
sage: epsilon = 0.01
sage: f = y^2*(1-y)

sage: ic = epsilon
sage: t = srange(0,2/epsilon,1)
sage: sol = desolve_odeint(f, ic, t, y, rtol=1e-9, atol=1e-10, compute_jac=True)

Another stiff system with some optional parameters with no default value:

sage: y1,y2,y3 = var('y1,y2,y3')
sage: f1 = 77.27*(y2+y1*(1-8.375*1e-6*y1-y2))
sage: f2 = 1/77.27*(y3-(1+y1)*y2)
sage: f3 = 0.16*(y1-y3)
sage: f = [f1,f2,f3]
sage: ci = [0.2,0.4,0.7]
sage: t = srange(0,10,0.01)
sage: v = [y1,y2,y3]
sage: sol = desolve_odeint(f, ci, t, v, rtol=1e-3, atol=1e-4, h0=0.1, hmax=1, hmin=1e-4, mxstep=1000, mxords=17)

AUTHOR:

- Oriol Castejon (05-2010)

AUTHOR:

Solve numerically one first-order ordinary differential equation.

INPUT:

Input is similar to desolve command. The differential equation can be written in a form close to the plot_slope_field or desolve command.
• Variant 1 (function in two variables)
  – de - right hand side, i.e. the function \( f(x, y) \) from ODE \( y' = f(x, y) \)
  – dvar - dependent variable (symbolic variable declared by var)

• Variant 2 (symbolic equation)
  – de - equation, including term with \( \text{diff}(y, x) \)
  – dvar - dependent variable (declared as function of independent variable)

• Other parameters
  – ivar - should be specified, if there are more variables or if the equation is autonomous
  – ics - initial conditions in the form \([x0, y0]\)
  – end_points - the end points of the interval
    * if \( \text{end_points} \) is a or \([a]\), we integrate between \( \min(ics[0], a) \) and \( \max(ics[0], a) \)
    * if \( \text{end_points} \) is None, we use \( \text{end_points}=ics[0]+10 \)
    * if \( \text{end_points} \) is \([a,b]\) we integrate between \( \min(ics[0], a) \) and \( \max(ics[0], b) \)
  – step - (optional, default:0.1) the length of the step (positive number)
  – output - (optional, default: 'list') one of 'list', 'plot', 'slope_field' (graph of the solution
    with slope field)

OUTPUT:
Return a list of points, or plot produced by list_plot, optionally with slope field.

See also:
\texttt{ode_solver()}

EXAMPLES:

\begin{verbatim}
sage: from sage.calculus.desolvers import desolve_rk4

Variant 2 for input - more common in numerics:

\begin{verbatim}
sage: x,y = var('x,y')
sage: desolve_rk4(x*y*(2-y),y,ics=[0,1],end_points=1,step=0.5)[[0, 1], [0.5, 1.1241912742455784], [1, 1.4615901622888159]]
\end{verbatim}

Variant 1 for input - we can pass ODE in the form used by desolve function In this example we integrate back-
wards, since end_points < ics[0]:

\begin{verbatim}
sage: y = function('y')(x)
sage: desolve_rk4(diff(y,x)+y*(y-1) == x-2,y,ics=[1,1],step=0.5, end_points=0)[[0.0, 8.904257108962114], [0.5, 1.909327945361532], [1, 1]]
\end{verbatim}

Here we show how to plot simple pictures. For more advanced applications use list_plot instead. To see the
resulting picture use show(P) in Sage notebook.

\begin{verbatim}
sage: x,y = var('x,y')
sage: P=desolve_rk4(y*(2-y),y,ics=[0,.1],ivar=x,output='slope_field',end_points=[-4,
→6],thickness=3)
\end{verbatim}

\end{verbatim}
ALGORITHM:

4th order Runge-Kutta method. Wrapper for command rk in Maxima’s dynamics package. Perhaps could be faster by using fast_float instead.

AUTHORS:

- Robert Marik (10-2009)

`sage.calculus.desolvers.desolve_rk4_determine_bounds(ics, end_points=\texttt{None})`

Used to determine bounds for numerical integration.

- If `end_points` is `None`, the interval for integration is from `ics[0]` to `ics[0]+10`
- If `end_points` is `a` or `[a]`, the interval for integration is from `min(ics[0],a)` to `max(ics[0],a)`
- If `end_points` is `[a,b]`, the interval for integration is from `min(ics[0],a)` to `max(ics[0],b)`

EXAMPLES:

```python
sage: from sage.calculus.desolvers import desolve_rk4_determine_bounds
sage: desolve_rk4_determine_bounds([0,2],1)
(0, 1)
sage: desolve_rk4_determine_bounds([0,2])
(0, 10)
sage: desolve_rk4_determine_bounds([0,2],[-2])
(-2, 0)
sage: desolve_rk4_determine_bounds([0,2],[-2,4])
(-2, 4)
```

`sage.calculus.desolvers.desolve_system(des, vars, ics=\texttt{None}, ivar=\texttt{None}, algorithm='maxima')`

Solve a system of any size of 1st order ODEs. Initial conditions are optional.

One dimensional systems are passed to `desolve_laplace()`.

INPUT:

- `des` – list of ODEs
- `vars` – list of dependent variables
- `ics` – (optional) list of initial values for `ivar` and `vars`; if `ics` is defined, it should provide initial conditions for each variable, otherwise an exception would be raised
- `ivar` – (optional) the independent variable, which must be specified if there is more than one independent variable in the equation
- `algorithm` – (default: 'maxima') one of
  - 'maxima' - use maxima
  - 'fricas' - use FriCAS (the optional fricas spkg has to be installed)

EXAMPLES:

```python
sage: t = var('t')
sage: x = function('x')(t)
sage: y = function('y')(t)
```
Symbolic Calculus, Release 10.1

\texttt{sage: de1 = diff(x,t) + y - 1 == 0}
\texttt{sage: de2 = diff(y,t) - x + 1 == 0}
\texttt{sage: desolve_system([de1, de2], [x,y])}
\begin{align*}
\{x(t) &= (x(0) - 1)\cos(t) - (y(0) - 1)\sin(t) + 1, \\
y(t) &= (y(0) - 1)\cos(t) + (x(0) - 1)\sin(t) + 1\}
\end{align*}

The same system solved using FriCAS:

\texttt{sage: desolve_system([de1, de2], [x,y], algorithm='fricas') \# optional - fricas}
\begin{align*}
x(t) &= _C0\cos(t) + \cos(t)^2 + _C1\sin(t) + \sin(t)^2, \\
y(t) &= -_C1\cos(t) + _C0\sin(t) + 1
\end{align*}

Now we give some initial conditions:

\texttt{sage: sol = desolve_system([de1, de2], [x,y], ics=[0,1,2]); sol}
\begin{align*}
\{x(t) &= -\sin(t) + 1, \\
y(t) &= \cos(t) + 1\}
\end{align*}

\texttt{sage: solnx, solny = sol[0].rhs(), sol[1].rhs()}
\texttt{sage: plot([solnx,solny],(0,1)) \# not tested}
\texttt{sage: parametric_plot((solnx,solny),(0,1)) \# not tested}

- Robert Bradshaw (10-2008)
- Sergey Bykov (10-2014)

\texttt{sage.calculus.desolvers.desolve_system_rk4(des, vars, ics=None, ivar=None, end_points=None, step=0.1)}

Solve numerically a system of first-order ordinary differential equations using the 4th order Runge-Kutta method.
Wrapper for Maxima command \texttt{rk}.

INPUT:
input is similar to \texttt{desolve_system} and \texttt{desolve_rk4} commands
- \texttt{des} - right hand sides of the system
- \texttt{vars} - dependent variables
- \texttt{ivar} - (optional) should be specified, if there are more variables or if the equation is autonomous and the independent variable is missing
- \texttt{ics} - initial conditions in the form [x0,y01,y02,y03,...,]
- \texttt{end_points} - the end points of the interval
  - if \texttt{end_points} is a or [a], we integrate on between \texttt{min(ics[0], a)} and \texttt{max(ics[0], a)}
  - if \texttt{end_points} is \texttt{None}, we use \texttt{end_points=ics[0]+10}
  - if \texttt{end_points} is [a,b] we integrate on between \texttt{min(ics[0], a)} and \texttt{max(ics[0], b)}
- \texttt{step} - (optional, default: 0.1) the length of the step

OUTPUT:
Return a list of points.

See also:
\texttt{ode_solver()}.  

318 Chapter 2. Internal functionality supporting calculus
EXAMPLES:

```
sage: from sage.calculus.desolvers import desolve_system_rk4

Lotka Volterra system:
```

```
sage: from sage.calculus.desolvers import desolve_system_rk4
sage: x,y,t = var('x y t')
sage: P = desolve_system_rk4([x*(1-y),-y*(1-x)], [x,y], ics=[0,0.5,2],
....:   ivar=t, end_points=20)
sage: Q = [[i,j] for i,j,k in P]
sage: LP = list_plot(Q)
# needs sage.plot
```

```
sage: Q = [[j,k] for i,j,k in P]
sage: LP = list_plot(Q)
# needs sage.plot
```

ALGORITHM:

4th order Runge-Kutta method. Wrapper for command rk in Maxima’s dynamics package. Perhaps could be faster by using fast_float instead.

AUTHOR:

- Robert Marik (10-2009)

```
sage.calculus.desolvers.desolve_tides_mpfr(f, ics, initial, final, delta, tolrel=1e-16, tolabs=1e-16,
digits=50)
```

Solve numerically a system of first order differential equations using the taylor series integrator in arbitrary precision implemented in tides.

INPUT:

- $f$ – symbolic function. Its first argument will be the independent variable. Its output should be derivatives of the dependent variables.
- ics – a list or tuple with the initial conditions.
- initial – the starting value for the independent variable.
- final – the final value for the independent value.
- delta – the size of the steps in the output.
- tolrel – the relative tolerance for the method.
- tolabs – the absolute tolerance for the method.
- digits – the digits of precision used in the computation.

OUTPUT:

- A list with the positions of the IVP.

EXAMPLES:

We integrate the Lorenz equations with Saltzman values for the parameters along 10 periodic orbits with 100 digits of precision:
sage: var('t,x,y,z')
(t, x, y, z)
sage: s = 10
sage: r = 28
sage: b = 8/3
sage: f(t,x,y,z)= [s*(y-x),x*(r-z)-y,x*y-b*z]
sage: x0 = -13.
sage: y0 = -19.
sage: z0 = 27
sage: T = 15.
sage: sol = desolve_tides_mpfr(f, [x0, y0, z0], 0, T, T, 1e-100, 1e-100, 100)

ALGORITHM:
Uses TIDES.

Warning: This requires the package tides.

sage.calculus.desolvers.eulers_method(f, x0, y0, h, x1, algorithm='table')
This implements Euler’s method for finding numerically the solution of the 1st order ODE $y' = f(x, y), y(a) =
c. The x column of the table increments from \( x_0 \) to \( x_1 \) by \( h \) (so \( (x_1 - x_0)/h \) must be an integer). In the y column, the new \( y \)-value equals the old \( y \)-value plus the corresponding entry in the last column.

**Note:** This function is for pedagogical purposes only.

**EXAMPLES:**

```python
sage: from sage.calculus.desolvers import euler_method
sage: x, y = PolynomialRing(QQ, 2, "xy").gens()
sage: euler_method(5*x + y - 5, 0, 1, 1/2, 1)
\[x \ y \ h*f(x,y)\]
\[0 \ 1 \ -2\]
\[1/2 \ -1 \ -7/4\]
\[1 \ -11/4 \ -11/8\]
```

```python
sage: x, y = PolynomialRing(QQ, 2, "xy").gens()
sage: euler_method(5*x + y - 5, 0, 1, 1/2, 1, algorithm="none")
\[0, 1\]
\[1/2, -1\]
\[1, -11/4\]
\[1/2, -1\]
\[1, -11/4\]
\[1/2, -1\]
\[1, -11/4\]
```

```python
sage: RR = RealField(sci_not=0, prec=4, rnd='RNDU')
sage: x, y = PolynomialRing(RR, 2, "xy").gens()
sage: euler_method(5*x + y - 5, 0, 1, 1/2, 1, algorithm="none")
\[[0], [1], [2], [3]]
```

```python
sage: RR = RealField(sci_not=0, prec=4, rnd='RNDU')
sage: x, y = PolynomialRing(RR, 2, "xy").gens()
sage: euler_method(5*x + y - 5, 0, 1, 1/2, 1)
\[0 \ 1 \ -2\]
\[1/2 \ -1 \ -1.7\]
\[1 \ -2.7 \ -1.3\]
```

```python
sage: x, y = PolynomialRing(QQ, 2, "xy").gens()
sage: euler_method(5*x + y - 5, 1, 1, 1/3, 2)
\[x \ y \ h*f(x,y)\]
\[1 \ 1 \ 1/3\]
\[4/3 \ 4/3 \ 1\]
\[5/3 \ 7/3 \ 17/9\]
\[2 \ 38/9 \ 83/27\]
```

```python
sage: euler_method(5*x + y - 5, 0, 1, 1/2, 1, algorithm="none")
\[[0], [1], [2], [3]]
```

```python
sage: pts = euler_method(5*x + y - 5, 0, 1, 1/2, 1, algorithm="none")
sage: P1 = list_plot(pts)
```

AUTHORS:
This implements Euler’s method for finding numerically the solution of the 1st order system of two ODEs

\[ x' = f(t, x, y), x(t_0) = x_0 \]
\[ y' = g(t, x, y), y(t_0) = y_0. \]

The \( t \) column of the table increments from \( t_0 \) to \( t_1 \) by \( h \) (so \( \frac{t_1 - t_0}{h} \) must be an integer). In the \( x \) column, the new \( x \)-value equals the old \( x \)-value plus the corresponding entry in the next (third) column. In the \( y \) column, the new \( y \)-value equals the old \( y \)-value plus the corresponding entry in the next (last) column.

**Note:** This function is for pedagogical purposes only.

**EXAMPLES:**

```
sage: from sage.calculus.desolvers import eulers_method_2x2
sage: t, x, y = PolynomialRing(QQ, 3, "txy").gens()
sage: f = x + y + t; g = x - y
sage: eulers_method_2x2(f, g, 0, 0, 0, 1/3, 1, algorithm="none")
[[0, 0, 0], [1/3, 0, 0], [2/3, 1/9, 0], [1, 10/27, 1/27], [4/3, 68/81, 4/27]]
```

```
sage: eulers_method_2x2(f, g, 0, 0, 0, 1/3, 1)
\begin{array}{cccc}
 t & x & h^2f(t,x,y) & y \\
 0 & 0 & 0 & 0 \\
 1/3 & 0 & 1/9 & 0 \\
 2/3 & 1/9 & 7/27 & 0 \\
 1 & 10/27 & 38/81 & 1/27 \\
\end{array}
```

```
sage: RR = RealField(sci_not=0, prec=4, rnd='RNDU')
sage: t, x, y = PolynomialRing(RR, 3, "txy").gens()
sage: f = x + y + t; g = x - y
sage: eulers_method_2x2(f, g, 0, 0, 0, 1/3, 1)
\begin{array}{cccc}
 t & x & h^2f(t,x,y) & y \\
 0.00 & 0 & 0.00 & 0 \\
 0.00 & 0.13 & 0.00 & 0 \\
 0.00 & 0.29 & 0.00 & 0 \\
 0.043 & 0.41 & 0.57 & 0.043 \\
 0.15 & 0.41 & 0.57 & 0.043 \\
\end{array}
```

To numerically approximate \( y(1) \), where \((1 + t^2) y'' + y' - y = 0, y(0) = 1, y'(0) = -1\), using 4 steps of Euler’s method, first convert to a system: \( y_1' = y_2, y_1(0) = 1; y_2' = \frac{y_1 - y_2}{1 + t^2}, y_2(0) = -1.\)
Symbolic Calculus, Release 10.1

```
sage: RR = RealField(sci_not=0, prec=4, rnd='RNDU')
sage: f = y; g = (x-y)/(1+t^2)
sage: eulers_method_2x2(f, g, 0, 1, -1, 1/4, 1)
```

*sage.calculus.desolvers.eulers_method_2x2_plot(f, g, t0, x0, y0, h, t1)*

Plot solution of ODE.

This plots the solution in the rectangle with sides $(xrange[0], xrange[1])$ and $(yrange[0], yrange[1])$, and plots using Euler’s method the numerical solution of the 1st order ODEs $x' = f(t, x, y)$, $x(a) = x_0$, $y' = g(t, x, y)$, $y(a) = y_0$.

**Note:** This function is for pedagogical purposes only.

**EXAMPLES:**

The following example plots the solution to $\theta'' + \sin(\theta) = 0$, $\theta(0) = \frac{\pi}{2}$, $\theta'(0) = 0$. Type $P[\theta].show()$ to plot the solution, $(P[\theta]+P[1]).show()$ to plot $(t, \theta(t))$ and $(t, \theta'(t))$: 2.19. Solving ordinary differential equations 323
Symbolic Calculus, Release 10.1

```python
sage: from sage.calculus.desolvers import eulers_method_2x2_plot
sage: f = lambda z : z[2]; g = lambda z : -sin(z[1])
sage: P = eulers_method_2x2_plot(f,g, 0.0, 0.75, 0.0, 0.1, 1.0) # needs sage.plot
```

**sage.calculus.desolvers.fricas_desolve**(de, dvar, ics, ivar)

Solve an ODE using FriCAS.

**EXAMPLES:**

```python
sage: x = var('x')
sage: y = function('y')(x)
sage: desolve(diff(y,x) + y - 1, y, algorithm="fricas") # optional ~
˓→fricas
-C0*e^(-x) + 1

sage: desolve(diff(y,x) + y == y^3*sin(x), y, algorithm="fricas") # optional ~
˓→fricas
-1/5*(2*cos(x)*y(x)^2 + 4*sin(x)*y(x)^2 - 5)*e^(-2*x)/y(x)^2
```

**sage.calculus.desolvers.fricas_desolve_system**(des, dvars, ics, ivar)

Solve a system of first order ODEs using FriCAS.

**EXAMPLES:**

```python
sage: t = var('t')
sage: x = function('x')(t)
sage: y = function('y')(t)
sage: de1 = diff(x,t) + y - 1 == 0
sage: de2 = diff(y,t) - x + 1 == 0
sage: desolve_system([de1, de2], [x, y], algorithm="fricas") # optional ~
˓→fricas
[x(t) == _C0*cos(t) + cos(t)^2 + _C1*sin(t) + sin(t)^2,
y(t) == -_C1*cos(t) + _C0*sin(t) + 1]

sage: desolve_system([de1, de2], [x,y], [0,1,2], algorithm="fricas") # optional ~
˓→fricas
[x(t) == cos(t)^2 + sin(t)^2 - sin(t), y(t) == cos(t) + 1]
```

### 2.20 Discrete Wavelet Transform

Wraps GSL's `gsl_wavelet_transform_forward()` and `gsl_wavelet_transform_inverse()` and creates plot methods.

**AUTHOR:**

• Josh Kantor (2006-10-07) - initial version
• David Joyner (2006-10-09) - minor changes to docstrings and examples.

```
sage: sage.calculus.transforms.dwt.DWT(n, wavelet_type, wavelet_k)
```

This function initializes an GSLDoubleArray of length n which can perform a discrete wavelet transform.
• \(n\) – a power of 2
• \(T\) – the data in the GSLDoubleArray must be real
• \(\text{wavelet\_type}\) – the name of the type of wavelet, valid choices are:
  – 'daubechies'
  – 'daubechies\_centered'
  – 'haar'
  – 'haar\_centered'
  – 'bspline'
  – 'bspline\_centered'

For daubechies wavelets, \(\text{wavelet\_k}\) specifies a daubechie wavelet with \(k/2\) vanishing moments. \(k = 4, 6, \ldots, 20\) for \(k\) even are the only ones implemented.

For Haar wavelets, \(\text{wavelet\_k}\) must be 2.

For bspline wavelets, \(\text{wavelet\_k}\) of 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order \((i, j)\) where \(\text{wavelet\_k}\) is \(100 \times i + j\). The wavelet transform uses \(J = \log_2(n)\) levels.

**OUTPUT:**

An array of the form \((s_{-1, 0}, d_{0, 0}, d_{1, 0}, d_{1, 1}, d_{2, 0}, \ldots, d_{J-1, 2^{J-1}-1})\) for \(d_{j,k}\) the detail coefficients of level \(j\). The centered forms align the coefficients of the sub-bands on edges.

**EXAMPLES:**

```sage
sage: a = WaveletTransform(128, 'daubechies', 4)
sage: for i in range(1, 11):
    ....:     a[i] = 1
    ....:     a[128-i] = 1
sage: a.plot().show(ymin=0)   #→ needs sage.plot
sage: a.forward_transform()
sage: a.plot().show()         #→ needs sage.plot
sage: a = WaveletTransform(128, 'haar', 2)
sage: for i in range(1, 11): a[i] = 1; a[128-i] = 1
sage: a.forward_transform()
sage: a.plot().show(ymin=0)   #→ needs sage.plot
sage: a = WaveletTransform(128, 'bspline\_centered', 10)
sage: for i in range(1, 11): a[i] = 1; a[100+i] = 1
sage: a.forward_transform()
sage: a.plot().show(ymin=0)   #→ needs sage.plot
```

This example gives a simple example of wavelet compression:

```sage
sage: # needs sage\_symbolic
sage: a = DWT(2048, 'daubechies', 6)
sage: for i in range(2048): a[i]=float(sin((i*5/2048)**2))
```

(continues on next page)
```python
sage: a.forward_transform()
sage: for i in range(1800): a[2048-i-1] = 0
sage: a.backward_transform()
sage: a.plot().show()  # long time (7s on sage.math, 2011), needs sage.plot
```

**class** `sage.calculus.transforms.dwt.DiscreteWaveletTransform`

Bases: `GSLDoubleArray`  
Discrete wavelet transform class.

```python
backward_transform()
forward_transform()
plot(xmin=None, xmax=None, **args)
```

**sage.calculus.transforms.dwt.WaveletTransform(n, wavelet_type, wavelet_k)**

This function initializes an GSLDoubleArray of length \( n \) which can perform a discrete wavelet transform.

**INPUT:**

- \( n \) – a power of 2
- \( T \) – the data in the GSLDoubleArray must be real
- `wavelet_type` – the name of the type of wavelet, valid choices are:
  - `'daubechies'`
  - `'daubechies_centered'`
  - `'haar'`
  - `'haar_centered'`
  - `'bspline'`
  - `'bspline_centered'`

For daubechies wavelets, `wavelet_k` specifies a daubechies wavelet with \( k/2 \) vanishing moments. \( k = 4, 6, \ldots, 20 \) for \( k \) even are the only ones implemented.

For Haar wavelets, `wavelet_k` must be 2.

For bspline wavelets, `wavelet_k` of 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order \((i,j)\) where `wavelet_k` is 100 * \( i+j \). The wavelet transform uses \( J = \log_2(n) \) levels.

**OUTPUT:**

An array of the form \((s_{-1,0}, d_{0,0}, d_{1,0}, d_{1,1}, d_{2,0}, \ldots, d_{J-1,2^{J-1}-1})\) for \( d_{j,k} \) the detail coefficients of level \( j \). The centered forms align the coefficients of the sub-bands on edges.

**EXAMPLES:**

```
sage: a = WaveletTransform(128, 'daubechies', 4)
sage: for i in range(1, 11):
    ....:     a[i] = 1
    ....:     a[128-i] = 1
sage: a.plot().show(ymin=0)  # needs sage.plot
```
Symbolic Calculus, Release 10.1

sage: a.forward_transform()
sage: a.plot().show()  # needs sage.plot

sage: a = WaveletTransform(128, 'haar', 2)
sage: for i in range(1, 11): a[i] = 1; a[128-i] = 1
sage: a.forward_transform()
sage: a.plot().show(ymin=0)  # needs sage.plot

sage: a = WaveletTransform(128, 'bspline_centered', 103)
sage: for i in range(1, 11): a[i] = 1; a[100+i] = 1
sage: a.forward_transform()
sage: a.plot().show(ymin=0)  # needs sage.plot

This example gives a simple example of wavelet compression:

sage: # needs sage.symbolic
sage: a = DWT(2048, 'daubechies', 6)
sage: for i in range(2048): a[i]=float(sin((i*5/2048)**2))
sage: a.plot().show()  # long time (7s on sage.math, 2011), needs sage.plot

sage: a.forward_transform()
sage: for i in range(1800): a[2048-i-1] = 0
sage: a.backward_transform()
sage: a.plot().show()  # long time (7s on sage.math, 2011), needs sage.plot

sage.calculus.transforms.dwt.is2pow(n)

## 2.21 Discrete Fourier Transforms

This file contains functions useful for computing discrete Fourier transforms and probability distribution functions for discrete random variables for sequences of elements of $\mathbb{Q}$ or $\mathbb{C}$, indexed by a range($N$), $\mathbb{Z}/N\mathbb{Z}$, an abelian group, the conjugacy classes of a permutation group, or the conjugacy classes of a matrix group.

This file implements:

- `__eq__()`
- `__mul__()` (for right multiplication by a scalar)
- plotting, printing – `IndexedSequence.plot()`, `IndexedSequence.plot_histogram()`, `__repr__()`, `__str__()`
- `dft()` – computes the discrete Fourier transform for the following cases:
  - a sequence (over $\mathbb{Q}$ or CyclotomicField) indexed by range($N$) or $\mathbb{Z}/N\mathbb{Z}$
  - a sequence (as above) indexed by a finite abelian group
  - a sequence (as above) indexed by a complete set of representatives of the conjugacy classes of a finite permutation group
  - a sequence (as above) indexed by a complete set of representatives of the conjugacy classes of a finite matrix group

### 2.21 Discrete Fourier Transforms

327
• idft() – computes the discrete Fourier transform for the following cases:
  – a sequence (over \( \mathbb{Q} \) or CyclotomicField) indexed by range(N) or \( \mathbb{Z}/N\mathbb{Z} \)
• dct(), dst() (for discrete Fourier/Cosine/Sine transform)
• convolution (in IndexedSequence.convolution() and IndexedSequence.convolution_periodic())
• fft(), ifft() – (fast Fourier transforms) wrapping GSL’s gsl_fft_complex_forward(), gsl_fft_complex_inverse(), using William Stein’s FastFourierTransform()
• dwt(), idwt() – (fast wavelet transforms) wrapping GSL’s gsl_dwt_forward(), gsl_dwt_backward() using Joshua Kantor’s WaveletTransform() class. Allows for wavelets of type:
  – “haar”
  – “daubechies”
  – “daubechies_centered”
  – “haar_centered”
  – “bspline”
  – “bspline_centered”

Todo:
• “filtered” DFTs
• more idfts
• more examples for probability, stats, theory of FTs

AUTHORS:
• David Joyner (2006-10)
• William Stein (2006-11) – fix many bugs

class sage.calculus.transforms.dft.IndexedSequence(L, index_object)

Bases: SageObject
An indexed sequence.

INPUT:
• L – A list
• index_object must be a Sage object with an __iter__ method containing the same number of elements as self, which is a list of elements taken from a field.

base_ring()

This just returns the common parent \( R \) of the \( N \) list elements. In some applications (say, when computing the discrete Fourier transform, dft), it is more accurate to think of the base_ring as the group ring \( \mathbb{Q}(\zeta_N)[R] \).

EXAMPLES:

```
sage: J = list(range(10))
sage: A = [1/10 for j in J]
sage: s = IndexedSequence(A, J)
sage: s.base_ring()
Rational Field```
convolution(\textit{other})

Convolves two sequences of the same length (automatically expands the shortest one by extending it by 0 if they have different lengths).

If \( \{a_n\} \) and \( \{b_n\} \) are sequences indexed by \((n = 0, 1, ..., N - 1)\), extended by zero for all \(n\) in \(\mathbb{Z}\), then the convolution is

\[
c_j = \sum_{i=0}^{N-1} a_i b_{j-i}.
\]

INPUT:

- \textit{other} – a collection of elements of a ring with index set a finite abelian group (under +)

OUTPUT:

The Dirichlet convolution of \texttt{self} and \texttt{other}.

EXAMPLES:

\begin{verbatim}
sage: J = list(range(5))
sage: A = [ZZ(1) for i in J]
sage: B = [ZZ(1) for i in J]
sage: s = IndexedSequence(A,J)
sage: t = IndexedSequence(B,J)
sage: s.convolution(t)
[1, 2, 3, 4, 5, 4, 3, 2, 1]
\end{verbatim}

AUTHOR: David Joyner (2006-09)

convolution\textsubscript{periodic}(\textit{other})

Convolves two collections indexed by a \texttt{range(...)} of the same length (automatically expands the shortest one by extending it by 0 if they have different lengths).

If \( \{a_n\} \) and \( \{b_n\} \) are sequences indexed by \((n = 0, 1, ..., N - 1)\), extended periodically for all \(n\) in \(\mathbb{Z}\), then the convolution is

\[
c_j = \sum_{i=0}^{N-1} a_i b_{j-i}.
\]

INPUT:

- \textit{other} – a sequence of elements of \(\mathbb{C}\), \(\mathbb{R}\) or \(\mathbb{F}_q\)

OUTPUT:

The Dirichlet convolution of \texttt{self} and \texttt{other}.

EXAMPLES:

\begin{verbatim}
sage: I = list(range(5))
sage: A = [ZZ(1) for i in I]
sage: B = [ZZ(1) for i in I]
sage: s = IndexedSequence(A,I)
sage: t = IndexedSequence(B,I)
sage: s.convolution_periodic(t)
[5, 5, 5, 5, 5, 5, 5, 5, 5]
\end{verbatim}

AUTHOR: David Joyner (2006-09)
Symbolic Calculus, Release 10.1

dct()
A discrete Cosine transform.

EXAMPLES:

```sage
sage: J = list(range(5))
sage: A = [exp(-2*pi*i*I/5) for i in J] # needs sage.symbolic
→ needs sage.symbolic
sage: s = IndexedSequence(A, J) # needs sage.symbolic
→ needs sage.symbolic
sage: s.dct() # Indexed sequence: [0, 1/16*(sqrt(5) + I*sqrt(-2*sqrt(5) + 10) + ... indexed by [0, 1, 2, 3, 4]
```

dft(chi=<function IndexedSequence.<lambda> at 0x7f8647dc6ef0>)
A discrete Fourier transform “over \( \mathbb{Q} \)” using exact \( N \)-th roots of unity.

EXAMPLES:

```sage
sage: J = list(range(6))
sage: A = [ZZ(1) for i in J]  
sage: s = IndexedSequence(A, J)  
sage: s.dft(lambda x: x^2) # needs sage.rings.number_field
→ needs sage.rings.number_field
Indexed sequence: [6, 0, 0, 6, 0, 0] indexed by [0, 1, 2, 3, 4, 5]
sage: s.dft() # needs sage.rings.number_field
Indexed sequence: [6, 0, 0, 0, 0, 0] indexed by [0, 1, 2, 3, 4, 5]
sage: # needs sage.groups
sage: G = SymmetricGroup(3)
sage: J = G.conjugacy_classes_representatives()
sage: s = IndexedSequence([1,2,3], J) # 1,2,3 are the values of a class fcn on G
sage: s.dft() # the "scalar-valued Fourier transform" of this class fcn
Indexed sequence: [8, 2, 2] indexed by [(), (1,2), (1,2,3)]
sage: J = AbelianGroup(2, [2,3], names='ab')
sage: s = IndexedSequence([1,2,3,4,5,6], J)
sage: s.dft() # the precision of output is somewhat random and architecture-dependent.
Indexed sequence: [21.0000000000000, -2.99999999999997 - 1.73205080756885*I, -2.99999999999999 + 1.73205080756888*I, -9.0000000000000000000000000485744257349999*I, -0.00000000000000000000000000976996261670137 - 0.*I, -0.00000000000000000000000000621724893790087 - 0.*I, -0.00000000000000000000000000106581410364015*I] indexed by Multiplicative Abelian group isomorphic to C2 x C3
sage: J = CyclicPermutationGroup(6)
```
(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

\[
\text{sage: } s = \text{IndexedSequence}([1,2,3,4,5,6], J) \\
\text{sage: } s.\text{dft()} \quad \# \text{ the precision of output is somewhat random and architecture-}
˓→dependent. \\
\text{Indexed sequence: } [21.0000000000000, \\
-2.99999999999997 - 1.73205080756885*I, \\
-2.99999999999999 + 1.73205080756888*I, \\
-9.00000000000000 + 0.0000000000000485744257349999*I, \\

˓→0.000000000000106581410364015*I] \\
\text{indexed by Cyclic group of order 6 as a permutation group}
\]

\[
\text{sage: } \# \text{ needs sage.rings.number_field} \\
\text{sage: } p = 7; J = \text{list(range}(p)); A = [\text{kron}\text{ecker}_\text{symbol}(j,p) \text{ for } j \text{ in } J] \\
\text{sage: } s = \text{IndexedSequence}(A, J) \\
\text{sage: } Fs = s.\text{dft()} \\
\text{sage: } c = Fs.\text{list()}[1]; [x/c \text{ for } x \text{ in } Fs.\text{list()}]; s.\text{list()} \\
[0, 1, 1, -1, 1, -1, -1] \\
[0, 1, 1, -1, 1, -1, -1]
\]

The DFT of the values of the quadratic residue symbol is itself, up to a constant factor (denoted c on the 
last line above).

**Todo:** Read the parent of the elements of S; if Q or C leave as is; if AbelianGroup, use abelian_group_dual; 
if some other implemented Group (permutation, matrix), call .characters() and test if the index list is the 
set of conjugacy classes.

(continues on next page)
dwt\(\)\((\text{other='haar', wavelet_k=2})\)

Wraps the gsl WaveletTransform.forward in \texttt{dwt} (written by Joshua Kantor). Assumes the length of the sample is a power of 2. Uses the GSL function \texttt{gsl_wavelet_transform_forward()}. 

INPUT:

- \texttt{other} – the name of the type of wavelet; valid choices are:
  - 'daubechies'
  - 'daubechies_centered'
  - 'haar' (default)
  - 'haar_centered'
  - 'bspline'
  - 'bspline_centered'

- \texttt{wavelet_k} – For daubechies wavelets, \texttt{wavelet_k} specifies a daubechies wavelet with \(k/2\) vanishing moments. \(k = 4, 6, \ldots, 20\) for \(k\) even are the only ones implemented.

  For Haar wavelets, \texttt{wavelet_k} must be 2.

  For bspline wavelets, \texttt{wavelet_k} equal to 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order \((i, j)\) where \texttt{wavelet_k} equals \(100 \cdot i + j\).

The wavelet transform uses \(J = \log_2(n)\) levels.

EXAMPLES:

\begin{verbatim}
sage: J = list(range(8))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.dwt()
sage: t # slightly random output
Indexed sequence: [2.82842712474999, 0.000000000000000, 0.000000000000000, 0.
˓→000000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000, 0.
˓→000000000000000]
  indexed by [0, 1, 2, 3, 4, 5, 6, 7]
\end{verbatim}

fft\()\)

Wraps the gsl FastFourierTransform.forward() in \texttt{fft}.

If the length is a power of 2 then this automatically uses the radix2 method. If the number of sample points in the input is a power of 2 then the wrapper for the GSL function \texttt{gsl_fft_complex_radix2_forward()} is automatically called. Otherwise, \texttt{gsl_fft_complex_forward()} is used.

EXAMPLES:

\begin{verbatim}
 sage: J = list(range(5))
 sage: A = [RR(1) for i in J]
 sage: s = IndexedSequence(A, J)
 sage: t = s.fft(); t
 Indexed sequence: [5.00000000000000, 0.000000000000000, 0.000000000000000, 0.
 ˓→000000000000000, 0.000000000000000, 0.000000000000000, 0.
 ˓→000000000000000]
\end{verbatim}
idft()

A discrete inverse Fourier transform. Only works over \( \mathbb{Q} \).

**EXAMPLES:**

```python
sage: J = list(range(5))
sage: A = [ZZ(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: fs = s.dft(); fs
# Indexed sequence: [5, 0, 0, 0, 0]
# indexed by [0, 1, 2, 3, 4]
sage: it = fs.idft(); it
# Indexed sequence: [1, 1, 1, 1, 1]
# indexed by [0, 1, 2, 3, 4]
sage: it == s
# True
```

idwt(other='haar', wavelet_k=2)

Implements the gsl WaveletTransform.backward() in dwt.

Assumes the length of the sample is a power of 2. Uses the GSL function gsl_wavelet_transform_backward().

**INPUT:**

- **other** – Must be one of the following:
  - "haar"
  - "daubechies"
  - "daubechies_centered"
  - "haar_centered"
  - "bspline"
  - "bspline_centered"

- **wavelet_k** – For daubechies wavelets, wavelet_k specifies a daubechie wavelet with \( k/2 \) vanishing moments. \( k = 4, 6, ..., 20 \) for \( k \) even are the only ones implemented.

  For Haar wavelets, wavelet_k must be 2.

  For bspline wavelets, wavelet_k equal to 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order \((i, j)\) where wavelet_k equals \( 100 \cdot i + j \).

**EXAMPLES:**

```python
sage: J = list(range(8))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.dwt()
```
**Symbolic Calculus, Release 10.1**

(continued from previous page)

```python
sage: t # random arch dependent output
Indexed sequence: [2.8284271247499999, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000]
    indexed by [0, 1, 2, 3, 4, 5, 6, 7]
sage: t.idwt() # random arch dependent output
Indexed sequence: [1.0000000000000000, 1.0000000000000000, 1.0000000000000000, 1.
˓→0000000000000000, 1.0000000000000000, 1.0000000000000000, 1.0000000000000000, 1.
˓→0000000000000000]
    indexed by [0, 1, 2, 3, 4, 5, 6, 7]
sage: t.idwt() == s
True
sage: J = list(range(16))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.dwt("bspline", 103)
sage: t # random arch dependent output
Indexed sequence: [4.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000]
    indexed by [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
sage: t.idwt("bspline", 103) == s
True
```

### `ifft()`

Implements the `gsl::FastFourierTransform::inverse` in `fft`.

If the number of sample points in the input is a power of 2 then the wrapper for the GSL function `gsl_fft_complex_radix2_inverse()` is automatically called. Otherwise, `gsl_fft_complex_inverse()` is used.

**EXAMPLES:**

```python
sage: J = list(range(5))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.fft(); t
Indexed sequence: [5.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.0000000000000000, 0.
˓→0000000000000000]
    indexed by [0, 1, 2, 3, 4]
sage: t.ifft()
Indexed sequence: [1.0000000000000000, 1.0000000000000000, 1.0000000000000000, 1.
˓→0000000000000000, 1.0000000000000000, 1.0000000000000000, 1.0000000000000000, 1.
˓→0000000000000000]
    indexed by [0, 1, 2, 3, 4]
sage: t.ifft() == s
1
```

### `index_object()`

Return the indexing object.

**EXAMPLES:**

---

334  Chapter 2. Internal functionality supporting calculus
Symbolic Calculus, Release 10.1

```python
sage: J = list(range(10))  
sage: A = [1/10 for j in J]  
sage: s = IndexedSequence(A, J)  
sage: s.index_object()  
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

**list()**

Return the list of self.

**EXAMPLES:**

```python
sage: J = list(range(10))  
sage: A = [1/10 for j in J]  
sage: s = IndexedSequence(A, J)  
sage: s.list()  
[1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10]
```

**plot()**

Plot the points of the sequence.

Elements of the sequence are assumed to be real or from a finite field, with a real indexing set \( I = \text{range}(\text{len}(\text{self})). \)

**EXAMPLES:**

```python
sage: I = list(range(3))  
sage: A = [ZZ(i^2)+1 for i in I]  
sage: s = IndexedSequence(A, I)  
sage: P = s.plot()  
# needs sage.plot
sage: show(P)  
# not tested  
# needs sage.plot
```

**plot_histogram(clr=(0, 0, 1), eps=0.4)**

Plot the histogram plot of the sequence.

The sequence is assumed to be real or from a finite field, with a real indexing set \( I = \text{range}(\text{len}(\text{self})). \)

Options are clr, which is an RGB value, and eps, which is the spacing between the bars.

**EXAMPLES:**

```python
sage: J = list(range(3))  
sage: A = [ZZ(i^2)+1 for i in J]  
sage: s = IndexedSequence(A, J)  
sage: P = s.plot_histogram()  
# needs sage.plot
sage: show(P)  
# not tested  
# needs sage.plot
```
2.22 Fast Fourier Transforms Using GSL

AUTHORS:

• William Stein (2006-9): initial file (radix2)
• D. Joyner (2006-10): Minor modifications (from radix2 to general case and some documentation).
• M. Hansen (2013-3): Fix radix2 backwards transformation
• L.F. Tabera Alonso (2013-3): Documentation

`sage.calculus.transforms.fft.FFT(size, base_ring=None)`
Create an array for fast Fourier transform conversion using gsl.

INPUT:

• `size` – The size of the array
• `base_ring` – Unused (2013-03)

EXAMPLES:

We create an array of the desired size:

```python
sage: a = FastFourierTransform(8)
sage: a
[(0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0)]
```

Now, set the values of the array:

```python
sage: for i in range(8): a[i] = i + 1
sage: a
[(1.0, 0.0), (2.0, 0.0), (3.0, 0.0), (4.0, 0.0), (5.0, 0.0), (6.0, 0.0), (7.0, 0.0), (8.0, 0.0)]
```

We can perform the forward Fourier transform on the array:

```python
sage: a.forward_transform() #abs tol 1e-2
[(36.0, 0.0), (-4.0, 9.65), (-4.0, 4.0), (-4.0, 1.65), (-4.0, 0.0), (-4.0, -1.65), (-4.0, -4.0), (-4.0, -9.65)]
```

And backwards:

```python
sage: a.backward_transform() #abs tol 1e-2
[(8.0, 0.0), (16.0, 0.0), (24.0, 0.0), (32.0, 0.0), (40.0, 0.0), (48.0, 0.0), (56.0, 0.0), (64.0, 0.0)]
```

Other example:

```python
sage: a = FastFourierTransform(128)
sage: for i in range(1, 11):
    ....:     a[i] = 1
    ....:     a[128-i] = 1
sage: a[:6:2]
```

(continues on next page)
sage: a = FastFourierTransform(8)
sage: a
[(0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0)]

Now, set the values of the array:

sage: for i in range(8): a[i] = i + 1
sage: a
[(1.0, 0.0), (2.0, 0.0), (3.0, 0.0), (4.0, 0.0), (5.0, 0.0), (6.0, 0.0), (7.0, 0.0), (8.0, 0.0)]

We can perform the forward Fourier transform on the array:

sage: a.forward_transform()
sage: a
# abs tol 1e-2
[(36.0, 0.0), (-4.00, 9.65), (-4.0, 4.0), (-4.0, 1.65), (-4.0, 0.0), (-4.0, -1.65), -4.0, -4.0), (-4.0, -9.65)]

And backwards:

sage: a.backward_transform()
sage: a
# abs tol 1e-2
[(8.0, 0.0), (16.0, 0.0), (24.0, 0.0), (32.0, 0.0), (40.0, 0.0), (48.0, 0.0), (56.0, 0.0), (64.0, 0.0)]

Other example:

sage: a = FastFourierTransform(128)
sage: for i in range(1, 11):
....: a[i] = 1
....: a[128-i] = 1
sage: a[:6:2]
[(0.0, 0.0), (1.0, 0.0), (1.0, 0.0)]

sage: a.plot().show(ymin=0)
Symbolic Calculus, Release 10.1

```
needs sage.plot
sage: a.forward_transform()
sage: a.plot().show()          # needs sage.plot

```

**class** sage.calculus.transforms.fft.FastFourierTransform_base

Bases: object

**class** sage.calculus.transforms.fft.FastFourierTransform_complex

Bases: FastFourierTransform_base

Wrapper class for GSL’s fast Fourier transform.

**backward_transform()**

Compute the in-place backwards Fourier transform of this data using the Cooley-Tukey algorithm.

**OUTPUT:**

- None, the transformation is done in-place.

This is the same as `inverse_transform()` but lacks normalization so that `f.forward_transform().backward_transform() == n*f`. Where n is the size of the array.

**EXAMPLES:**

```
sage: a = FastFourierTransform(125)
sage: b = FastFourierTransform(125)
sage: for i in range(1, 60): a[i]=1
sage: for i in range(1, 60): b[i]=1
sage: a.forward_transform()
sage: a.backward_transform()
sage: (a.plot() + b.plot()).show(ymin=0)  # long time (2s on sage.math, 2011),
needs sage.plot
sage: abs(sum([CDF(a[i])/125-CDF(b[i]) for i in range(125)])) < 2**-16
True
```

Here we check it with a power of two:

```
sage: a = FastFourierTransform(128)
sage: b = FastFourierTransform(128)
sage: for i in range(1, 60): a[i]=1
sage: for i in range(1, 60): b[i]=1
sage: a.forward_transform()
sage: a.backward_transform()
sage: (a.plot() + b.plot()).show(ymin=0)          # needs sage.plot
```

**forward_transform()**

Compute the in-place forward Fourier transform of this data using the Cooley-Tukey algorithm.

**OUTPUT:**

- None, the transformation is done in-place.

If the number of sample points in the input is a power of 2 then the gsl function `gsl_fft_complex_radix2_forward` is automatically called. Otherwise, `gsl_fft_complex_forward` is called.
EXAMPLES:

```python
sage: a = FastFourierTransform(4)
sage: for i in range(4): a[i] = i
sage: a.forward_transform()
sage: a #abs tol 1e-2
[(6.0, 0.0), (-2.0, 2.0), (-2.0, 0.0), (-2.0, -2.0)]
```

**inverse_transform()**

Compute the in-place inverse Fourier transform of this data using the Cooley-Tukey algorithm.

**OUTPUT:**

- None, the transformation is done in-place.

If the number of sample points in the input is a power of 2 then the function `gsl_fft_complex_radix2_inverse` is automatically called. Otherwise, `gsl_fft_complex_inverse` is called.

This transform is normalized so `f.forward_transform().inverse_transform() == f` modulo round-off errors. See also `backward_transform()`.

**EXAMPLES:**

```python
sage: a = FastFourierTransform(125)
sage: b = FastFourierTransform(125)
sage: for i in range(1, 60): a[i] = 1
sage: for i in range(1, 60): b[i] = 1
sage: a.forward_transform()
sage: a.inverse_transform()
```

Here we check it with a power of two:

```python
sage: a = FastFourierTransform(128)
sage: b = FastFourierTransform(128)
sage: for i in range(1, 60): a[i] = 1
sage: for i in range(1, 60): b[i] = 1
```

**plot(style='rect', xmin=None, xmax=None, **args)**

Plot a slice of the array.

- **style** – Style of the plot, options are "rect" or "polar"
  - **rect** – height represents real part, color represents imaginary part.
  - **polar** – height represents absolute value, color represents argument.
- **xmin** – The lower bound of the slice to plot. 0 by default.
Symbolic Calculus, Release 10.1

- `xmax` – The upper bound of the slice to plot. `len(self)` by default.
- `**args` – passed on to the line plotting function.

OUTPUT:
- A plot of the array.

EXAMPLES:

```python
sage: a = FastFourierTransform(16)
sage: for i in range(16): a[i] = (random(),random())
sage: A = plot(a) # needs sage.plot
sage: B = plot(a, style='polar') # needs sage.plot
sage: type(A) # needs sage.plot
<class 'sage.plot.graphics.Graphics'>
sage: type(B) # needs sage.plot
<class 'sage.plot.graphics.Graphics'>
sage: a = FastFourierTransform(125)
sage: b = FastFourierTransform(125)
sage: for i in range(1, 60): a[i]=1
sage: for i in range(1, 60): b[i]=1
sage: a.forward_transform()
sage: a.inverse_transform()
sage: a.plot() + b.plot() # needs sage.plot
```

```
Graphics object consisting of 250 graphics primitives
```

2.23 Solving ODE numerically by GSL

AUTHORS:
- Joshua Kantor (2004-2006)
- Robert Marik (2010 - fixed docstrings)
class sage.calculus.ode.PyFunctionWrapper
Bases: object
class sage.calculus.ode.ode_solver(function=None, jacobian=None, h=0.01, error_abs=1e-10, error_rel=1e-10, a=False, a_dydt=False, scale_abs=False, algorithm='rkf45', y_0=None, t_span=None, params=[]) Bases: object

`ode_solver()` is a class that wraps the GSL library’s ode solver routines.

To use it, instantiate the class:
To solve a system of the form $\frac{dy_i}{dt} = f_i(t, y)$, you must supply a vector or tuple/list valued function $f$ representing $f_i$. The functions $f$ and the Jacobian should have the form $foo(t, y)$ or $foo(t, y, params)$. $params$ which is optional allows for your function to depend on one or a tuple of parameters. Note if you use it, $params$ must be a tuple even if it only has one component. For example if you wanted to solve $y'' + y = 0$, you would need to write it as a first order system:

$$y_0' = y_1$$
$$y_1' = -y_0$$

In code:

```
sage: f = lambda t, y: [y[1], -y[0]]
sage: T.function = f
```

For some algorithms, the Jacobian must be supplied as well, the form of this should be a function returning a list of lists of the form $[\frac{df_1}{dy_1}, \ldots, \frac{df_1}{dy_n}], \ldots, [\frac{df_n}{dy_1}, \ldots, \frac{df_n}{dy_n}], [\frac{df_1}{dt}, \ldots, \frac{df_n}{dt}]$.

There are examples below, if your Jacobian was the function $my_jacobian$ you would do:

```
sage: T.jacobian = my_jacobian # not tested, since it doesn't make sense to test...
```

There are a variety of algorithms available for different types of systems. Possible algorithms are:

- 'rkf45' – Runge-Kutta-Fehlberg (4,5)
- 'rk2' – embedded Runge-Kutta (2,3)
- 'rk4' – 4th order classical Runge-Kutta
- 'rk8pd' – Runge-Kutta Prince-Dormand (8,9)
- 'rk2imp' – implicit 2nd order Runge-Kutta at gaussian points
- 'rk4imp' – implicit 4th order Runge-Kutta at gaussian points
- 'bsimp' – implicit Burlisch-Stoer (requires Jacobian)
- 'gear1' – M=1 implicit gear
- 'gear2' – M=2 implicit gear

The default algorithm is 'rkf45'. If you instead wanted to use 'bsimp' you would do:

```
sage: T.algorithm = "bsimp"
```

The user should supply initial conditions in $y_0$. For example if your initial conditions are $y_0 = 1, y_1 = 1$, do:

```
sage: T.y_0 = [1,1]
```

The actual solver is invoked by the method $ode_solve()$. It has arguments $t_span, y_0, num_points, params$. $y_0$ must be supplied either as an argument or above by assignment. Params which are optional and only necessary if your system uses $params$ can be supplied to $ode_solve$ or by assignment.

t_span is the time interval on which to solve the ODE. There are two ways to specify t_span:
• If `num_points` is not specified, then the sequence `t_span` is used as the time points for the solution. Note that the first element `t_span[0]` is the initial time, where the initial condition `y_0` is the specified solution, and subsequent elements are the ones where the solution is computed.

• If `num_points` is specified and `t_span` is a sequence with just 2 elements, then these are the starting and ending times, and the solution will be computed at `num_points` equally spaced points between `t_span[0]` and `t_span[1]`. The initial condition is also included in the output so that `num_points + 1` total points are returned. E.g. if `t_span = [0.0, 1.0]` and `num_points = 10`, then solution is returned at the 11 time points `[0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]`.

(Note that if `num_points` is specified and `t_span` is not length 2 then `t_span` are used as the time points and `num_points` is ignored.)

Error is estimated via the expression

\[ D_i = \text{error_abs} * s_i + \text{error_rel} * (a |y_i| + a_dydt * h^2 |y_i'|) \]

The user can specify

- `error_abs` (1e-10 by default),
- `error_rel` (1e-10 by default),
- `a` (1 by default),
- `a_dydt` (0 by default) and
- `s_i` (as `scaling_abs` which should be a tuple and is 1 in all components by default).

If you specify one of `a` or `a_dydt` you must specify the other. You may specify `a` and `a_dydt` without `scaling_abs` (which will be taken =1 be default). `h` is the initial step size, which is 1e-2 by default.

`ode_solve` solves the solution as a list of tuples of the form, `[ (t_0,[y_1,...,y_n]),(t_1,[y_1,...,y_n]),..., (t_n,[y_1,...,y_n]) ]`.

This data is stored in the variable `solutions`:

```sage
t.solutions # not tested
```

EXAMPLES:

Consider solving the Van der Pol oscillator \( x''(t) + u x'(t)(x(t)^2 - 1) + x(t) = 0 \) between \( t = 0 \) and \( t = 100 \).

As a first order system it is \( x' = y, \ y' = -x + uy(1 - x^2) \). Let us take \( u = 10 \) and use initial conditions \( (x,y) = (1,0) \) and use the Runge-Kutta Prince-Dormand algorithm.

```sage
def f_1(t, y, params):
    return [y[1], -y[0] - params[0]*y[1]*(y[0]**2-1.0)]
def j_1(t, y, params):
    return [[0.0, 1.0],
             [-2.0*params[0]*y[0]*y[1] - 1.0, -params[0]*(y[0]*y[0]-1.0)],
             [0.0, 0.0]]
T = ode_solver()
T.algorithm = "rk8pd"
T.function = f_1
T.jacobian = j_1
T.ode_solve(y_0=[1,0], t_span=[0,100], params=[10.0], num_points=1000)
```
The solver line is equivalent to:

```python
sage: T.ode_solve(y_0=[1,0], t_span=[x/10.0 for x in range(1000)], params=[10.0])
```

Let’s try a system:

```python
y_0'=y_1*y_2
y_1'=-y_0*y_2
y_2'=-.51*y_0*y_1
```

We will not use the jacobian this time and will change the error tolerances.

```python
g_1 = lambda t,y: [y[1]*y[2], -y[0]*y[2], -.51*y[0]*y[1]]
sage: T.function = g_1
sage: T.y_0 = [0,1,1]
sage: T.scale_abs = [1e-4, 1e-4, 1e-5]
sage: T.error_rel = 1e-4
sage: T.ode_solve(t_span=[0,12], num_points=100)
```

By default `T.plot_solution()` plots the $y_0$; to plot general $y_i$, use:

```python
sage: with tempfile.NamedTemporaryFile(suffix=".png") as f:
    T.plot_solution(i=0, filename=f.name)
    T.plot_solution(i=1, filename=f.name)
    T.plot_solution(i=2, filename=f.name)
```

The method `interpolate_solution` will return a spline interpolation through the points found by the solver. By default, $y_0$ is interpolated. You can interpolate $y_i$ through the keyword argument $i$.

```python
sage: f = T.interpolate_solution()
sage: f(pi)
0.5379...
```

The solver attributes may also be set up using arguments to `ode_solver`. The previous example can be rewritten as:

```python
sage: T = ode_solver(g_1, y_0=[0,1,1], scale_abs=[1e-4,1e-4,1e-5],
                error_rel=1e-4, algorithm="rk8pd")
sage: T.ode_solve(t_span=[0,12], num_points=100)
sage: f = T.interpolate_solution()
sage: f(pi)
0.5379...
```

Unfortunately because Python functions are used, this solver is slow on systems that require many function
evaluations. It is possible to pass a compiled function by deriving from the class `ode_system` and overloading `c_f` and `c_j` with C functions that specify the system. The following will work in the notebook:

```cython
cimport sage.calculus.ode
import sage.calculus.ode
from sage.libs.gsl.all cimport *

cdef class van_der_pol(sage.calculus.ode.ode_system):
    cdef int
c_f(self, double t, double *y, double *dydt):
        dydt[0]=y[1]
        dydt[1]=-y[0]-1000*y[1]*(y[0]*y[0]-1)
        return GSL_SUCCESS

cdef int
c_j(self, double t, double *y, double *dfdy, double *dfdt):
        dfdy[0]=0
        dfdy[1]=1.0
        dfdy[2]=-2.0*1000*y[0]*y[1]-1.0
        dfdy[3]=-1000*(y[0]*y[0]-1.0)
        dfdt[0]=0
        dfdt[1]=0
        return GSL_SUCCESS
```

After executing the above block of code you can do the following (WARNING: the following is not automatically doctested):

```python
sage: # not tested
sage: T = ode_solver()
sage: T.algorithm = "bsimp"
sage: vander = van_der_pol()
sage: T.function = vander
sage: T.ode_solve(y_0=[1, 0], t_span=[0, 2000],
....: num_points=1000)
sage: from tempfile import NamedTemporaryFile
sage: with NamedTemporaryFile(suffix=".png") as f:
....:    T.plot_solution(i=0, filename=f.name)
```

**interpolate_solution** *(i=0)*

**ode_solve** *(t_span=False, y_0=False, num_points=False, params=[])*

**plot_solution** *(i=0, filename=None, interpolate=False, **kws)*

Plot a one dimensional projection of the solution.

**INPUT:**

- `i` – (non-negative integer) composant of the projection
- `filename` – (string or None) whether to plot the picture or save it in a file
- `interpolate` – whether to interpolate between the points of the discretized solution
- additional keywords are passed to the graphics primitive

**EXAMPLES:**

```python
sage: T = ode_solver()
sage: T.function = lambda t,y: [cos(y[0]) * sin(t)]
```

(continues on next page)
Symbolic Calculus, Release 10.1

(continued from previous page)

```python
sage: T.jacobian = lambda t,y: [-sin(y[0]) * sin(t)]
sage: T.ode_solve(y_0=[1], t_span=[0,20], num_points=1000)
sage: T.plot_solution()  # needs sage.plot
```

And with some options:

```python
sage: T.plot_solution(color='red', axes_labels=['t', 'x(t)'])  # needs sage.plot
```

```python
class sage.calculus.ode.ode_system
    Bases: object

2.24 Numerical Integration

AUTHORS:

• Josh Kantor (2007-02): first version
• William Stein (2007-02): rewrite of docs, conventions, etc.
• Robert Bradshaw (2008-08): fast float integration
• Jeroen Demeyer (2011-11-23): github issue #12047: return 0 when the integration interval is a point; reformat documentation and add to the reference manual.

class sage.calculus.integration.PyFunctionWrapper
    Bases: object

class sage.calculus.integration.compiled_integrand
    Bases: object

sage.calculus.integration.monte_carlo_integral(func, xl, xu, calls, algorithm='plain', params=None)
    Integrate func by Monte-Carlo method.

    Integrate func over the dim-dimensional hypercubic region defined by the lower and upper limits in the arrays
    xl and xu, each of size dim.

    The integration uses a fixed number of function calls and obtains random sampling points using the default gsl’s
    random number generator.

    ALGORITHM: Uses calls to the GSL (GNU Scientific Library) C library. Documentation can be found in [GSL]
    chapter “Monte Carlo Integration”.

    INPUT:

    • func – the function to integrate
    • params – used to pass parameters to your function
    • xl – list of lower limits
    • xu – list of upper limits
    • calls – number of functions calls used
    • algorithm – valid choices are:

```

2.24. Numerical Integration    345
Symbolic Calculus, Release 10.1

- ‘plain’ – The plain Monte Carlo algorithm samples points randomly from the integration region to estimate the integral and its error.
- ‘miser’ – The MISER algorithm of Press and Farrar is based on recursive stratified sampling
- ‘vegas’ – The VEGAS algorithm of Lepage is based on importance sampling.

OUTPUT:
A tuple whose first component is the approximated integral and whose second component is an error estimate.

EXAMPLES:

```
sage: x, y = SR.var('x,y')
sage: monte_carlo_integral(x*y, [0,0], [2,2], 10000)  # abs tol 0.1
(4.0, 0.0)
sage: integral(integral(x*y, (x,0,2)), (y,0,2))
4
```

An example with a parameter:

```
sage: x, y, z = SR.var('x,y,z')
sage: monte_carlo_integral(x*y*z, [0,0], [2,2], 10000, params=[1.2])  # abs tol 0.1
(4.8, 0.0)
```

Integral of a constant:

```
sage: monte_carlo_integral(3, [0,0], [2,2], 10000)  # abs tol 0.1
(12, 0.0)
```

Test different algorithms:

```
sage: f(x,y,z) = exp(z) * cos(x + sin(y))
sage: for algo in ['plain', 'miser', 'vegas']:  # abs tol 0.01
.....: monte_carlo_integral(f, [0,0,-1], [2,2,1], 10^6, algorithm=algo)
(-1.06, 0.01)
(-1.06, 0.01)
(-1.06, 0.01)
```

Tests with Python functions:

```
sage: def f(u, v):
... return u * v
sage: monte_carlo_integral(f, [0,0], [2,2], 10000)  # abs tol 0.1
(4.0, 0.0)
sage: monte_carlo_integral(lambda u,v: u*v, [0,0], [2,2], 10000)  # abs tol 0.1
(4.0, 0.0)
sage: def f(x1,x2,x3,x4):
... return x1*x2*x3*x4
sage: monte_carlo_integral(f, [0,0], [2,2], 1000, params=[0.6,2])  # abs tol 0.2
(4.8, 0.0)
```

AUTHORS:
- Vincent Delecroix
- Vincent Klein
Return the numerical integral of the function on the interval from \(a\) to \(b\) and an error bound.

**INPUT:**

- \(a, b\) – The interval of integration, specified as two numbers or as a tuple/list with the first element the lower bound and the second element the upper bound. Use \(+\text{Infinity}\) and \(-\text{Infinity}\) for plus or minus infinity.
- **algorithm** – valid choices are:
  - ‘qag’ – for an adaptive integration
  - ‘qags’ – for an adaptive integration with (integrable) singularities
  - ‘qng’ – for a non-adaptive Gauss-Kronrod (samples at a maximum of 87pts)
- **max_points** – sets the maximum number of sample points
- **params** – used to pass parameters to your function
- **eps_abs, eps_rel** – sets the absolute and relative error tolerances which satisfies the relation
  \[|\text{RESULT} - I| \leq \max(\text{eps_abs, eps_rel} \times |I|), \text{where } I = \int_a^b f(x) \, dx.\]
- **rule** – This controls the Gauss-Kronrod rule used in the adaptive integration:
  - rule=1 – 15 point rule
  - rule=2 – 21 point rule
  - rule=3 – 31 point rule
  - rule=4 – 41 point rule
  - rule=5 – 51 point rule
  - rule=6 – 61 point rule

Higher key values are more accurate for smooth functions but lower key values deal better with discontinuities.

**OUTPUT:**

A tuple whose first component is the answer and whose second component is an error estimate.

**REMARK:**

There is also a method `nintegral` on symbolic expressions that implements numerical integration using Maxima. It is potentially very useful for symbolic expressions.

**EXAMPLES:**

To integrate the function \(x^2\) from 0 to 1, we do

```
sage: numerical_integral(x^2, 0, 1, max_points=100)
(0.3333333333333333, 3.700743415417188e-15)
```

To integrate the function \(\sin(x)^3 + \sin(x)\) we do

```
sage: numerical_integral(sin(x)^3 + sin(x), 0, pi)
(3.3333333333333333, 3.700743415417188e-14)
```

The input can be any callable:

```
sage: numerical_integral(lambda x: sin(x)^3 + sin(x), 0, pi)
(3.3333333333333333, 3.700743415417188e-14)
```
We check this with a symbolic integration:

```sage
(sin(x)^3+sin(x)).integral(x,0,pi)
```

\[ \frac{10}{3} \]

If we want to change the error tolerances and Gauss rule used:

```sage
f = x^2
numerical_integral(f, 0, 1, max_points=200, eps_abs=1e-7, eps_rel=1e-7, rule=4)
```

\[ (0.33333333333333333, 3.70074315417188e-15) \]

For a Python function with parameters:

```sage
f(x,a) = 1/(a+x^2)
[numerical_integral(f, 1, 2, max_points=100, params=[n]) for n in range(10)]
```

# random output (architecture and os dependent)

```
[(0.49999999999999857, 5.5511151231256336e-15),
 (0.3217505439664557, 3.572148736706477e-15),
 (0.24830098317249229, 2.6678768435816325e-15),
 (0.19253082576711697, 2.137521557167464e-15),
 (0.16687527719832367, 1.7860743683853337e-15),
 (0.1382754676349412, 1.5351659583939151e-15),
 (0.12129975935702741, 1.3466978571966261e-15),
 (0.10806674191683065, 1.1997818507228991e-15),
 (0.0974544625548845, 1.0819617008493815e-15),
 (0.088750683050217577, 9.8533051773561173e-16)]
```

```
sage: y = var('y')
numerical_integral(x*y, 0, 1)
```

Traceback (most recent call last):

```python
ValueError: The function to be integrated depends on 2 variables (x, y),
and so cannot be integrated in one dimension. Please fix additional
variables with the 'params' argument
```

Note the parameters are always a tuple even if they have one component.

It is possible to integrate on infinite intervals as well by using +Infinity or -Infinity in the interval argument. For example:

```sage
f = exp(-x)
numerical_integral(f, 0, +Infinity) # random output
```

\[ (0.99999999999999857, 1.8429811298996553e-07) \]

Note the coercion to the real field RR, which prevents underflow:

```sage
f = exp(-x^2)
numerical_integral(f, -Infinity, +Infinity) # random output
```

\[ (1.77245385090600035, 3.4295192165889879e-08) \]

One can integrate any real-valued callable function:

```sage
numerical_integral(lambda x: abs(zeta(x)), [1.1,1.5]) # random output
```

\[ (1.8488570602160455, 2.652643677492633e-14) \]
We can also numerically integrate symbolic expressions using either this function (which uses GSL) or the native integration (which uses Maxima):

```
sage: exp(-1/x).nintegral(x, 1, 2)  # via maxima
(0.50479221787318..., 5.60431942934407...e-15, 21, 0)
sage: numerical_integral(exp(-1/x), 1, 2)
(0.50479221787318..., 5.60431942934407...e-15)
```

We can also integrate constant expressions:

```
sage: numerical_integral(2, 1, 7)
(12.0, 0.0)
```

If the interval of integration is a point, then the result is always zero (this makes sense within the Lebesgue theory of integration), see github issue #12047:

```
sage: numerical_integral(log, 0, 0)
(0.0, 0.0)
sage: numerical_integral(lambda x: sqrt(x), (-2.0, -2.0))
(0.0, 0.0)
```

In the presence of integrable singularity, the default adaptive method might fail and it is advised to use 'qags':

```
sage: b = 1.81759643554688
sage: F(x) = sqrt((-x + b)/((x - 1.0)*x))
sage: numerical_integral(F, 1, b)
(inf, nan)
sage: numerical_integral(F, 1, b, algorithm='qags')  # abs tol 1e-10
(1.1817104238446596, 3.387268288079781e-07)
```

ALGORITHM: Uses calls to the GSL (GNU Scientific Library) C library. Documentation can be found in [GSL] chapter “Numerical Integration”.

### 2.25 Riemann Mapping

AUTHORS:

• Ethan Van Andel (2009-2011): initial version and upgrades
• Robert Bradshaw (2009): his “complex_plot” was adapted for plot_colored

Development supported by NSF award No. 0702939.

```python
class sage.calculus.riemann.Riemann_Map
    Bases: object
```

2.25. Riemann Mapping 349
The **Riemann_Map** class computes an interior or exterior Riemann map, or an Ahlfors map of a region given by the supplied boundary curve(s) and center point. The class also provides various methods to evaluate, visualize, or extract data from the map.

A Riemann map conformally maps a simply connected region in the complex plane to the unit disc. The Ahlfors map does the same thing for multiply connected regions.

Note that all the methods are numerical. As a result all answers have some imprecision. Moreover, maps computed with small number of collocation points, or for unusually shaped regions, may be very inaccurate. Error computations for the ellipse can be found in the documentation for `analytic_boundary()` and `analytic_interior()`.

[BSV2010] provides an overview of the Riemann map and discusses the research that lead to the creation of this module.

**INPUT:**

- `fs` – A list of the boundaries of the region, given as complex-valued functions with domain $0$ to $2 \times \pi$. Note that the outer boundary must be parameterized counter clockwise (i.e. $e^{i\times t}$) while the inner boundaries must be clockwise (i.e. $e^{-(i\times t)}$).
- `fprimes` – A list of the derivatives of the boundary functions. Must be in the same order as `fs`.
- `a` – Complex, the center of the Riemann map. Will be mapped to the origin of the unit disc. Note that a MUST be within the region in order for the results to be mathematically valid.

The following inputs may be passed in as named parameters:

- `N` – integer (default: 500), the number of collocation points used to compute the map. More points will give more accurate results, especially near the boundaries, but will take longer to compute.
- `exterior` – boolean (default: False), if set to True, the exterior map will be computed, mapping the exterior of the region to the exterior of the unit circle.

The following inputs may be passed as named parameters in unusual circumstances:

- `ncorners` – integer (default: 4), if mapping a figure with (equally t-spaced) corners – corners that make a significant change in the direction of the boundary – better results may be sometimes obtained by accurately giving this parameter. Used to add the proper constant to the theta correspondence function.
- `opp` – boolean (default: False), set to True in very rare cases where the theta correspondence function is off by pi, that is, if red is mapped left of the origin in the color plot.

**EXAMPLES:**

The unit circle identity map:

```sage
f(t) = e^{i\times t}
fprime(t) = i \times e^{i\times t}
m = Riemann_Map([f], [fprime], 0) # long time (4 sec)
m.plot_colored() + m.plot_spiderweb() # long time
```

Graphics object consisting of 22 graphics primitives

The exterior map for the unit circle:

```sage
m = Riemann_Map([f], [fprime], 0, exterior=True) # long time (4 sec)
sage: spiderwebs are not supported for exterior maps
```

Graphics object consisting of 1 graphics primitive

The unit circle with a small hole:
Symbolic Calculus, Release 10.1

```
[sage:] f(t) = e^(I^*t)
sage: fprime(t) = I*e^(I^*t)
sage: hf(t) = 0.5*e^(-I^*t)
sage: hfprime(t) = 0.5*-I*e^(-I^*t)
sage: m = Riemann_Map([f, hf], [fprime, hfprime], 0.5 + 0.5*I)
sage: #spiderweb and color plots cannot be added for multiply
sage: #connected regions. Instead we do this.
sage: m.plot_spiderweb(withcolor = True) # long time
Graphics object consisting of 3 graphics primitives

A square:

```
[sage:] ps = polygon_spline([(-1, -1), (1, -1), (1, 1), (-1, 1)])
sage: f = lambda t: ps.value(real(t))
sage: fprime = lambda t: ps.derivative(real(t))
sage: m = Riemann_Map([f], [fprime], 0.25, ncorners=4)
sage: m.plot_colored() + m.plot_spiderweb() # long time
Graphics object consisting of 22 graphics primitives

Compute rough error for this map:

```
[sage:] x = 0.75 # long time
sage: print("error = {}".format(m.inverse_riemann_map(m.riemann_map(x)) - x)) # long time
error = (-0.000...+0.0016...j)

A fun, complex region for demonstration purposes:

```
[sage:] f(t) = e^(I^*t)
sage: fp(t) = I*e^(I^*t)
sage: ef1(t) = .2*e^(-I^*t) +.4+.4*I
sage: ef1p(t) = -I*.2*e^(-I^*t)
sage: ef2(t) = .2*e^(-I^*t) -.4+.4*I
sage: ef2p(t) = -I*.2*e^(-I^*t)
sage: pts = [(-.5,-.15-20/1000),(-.6,-.27-10/1000),(-.45,-.45),(0,-.65+10/1000),(.45,-.45),(.6,-.27-10/1000),(.5,-.15-10/1000),(0,-.43+10/1000)]
sage: pts.reverse()
sage: cs = complex_cubic_spline(pts)
sage: mf = lambda x:cs.value(x)
sage: mfprime = lambda x: cs.derivative(x)
sage: m = Riemann_Map([f,ef1,ef2,mf],[fp,ef1p,ef2p,mfprime],0,N = 400) # long time
sage: p = m.plot_colored(plot_points = 400) # long time

ALGORITHM:

This class computes the Riemann Map via the Szego kernel using an adaptation of the method described by [KT1986].

```
compute_on_grid(plot_range, x_points)
```

Compute the Riemann map on a grid of points.

Note that these points are complex of the form z = x + y*i.

INPUT:
**plot_range** – a tuple of the form \([xmin, xmax, ymin, ymax]\). If the value is \([]\), the default plotting window of the map will be used.

**x_points** – int, the size of the grid in the x direction. The number of points in the y_direction is scaled accordingly.

**OUTPUT:**

- a tuple containing \([z_values, xmin, xmax, ymin, ymax]\) where \(z_values\) is the evaluation of the map on the specified grid.

**EXAMPLES:**

General usage:

```
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: data = m.compute_on_grid([],5)
sage: data[0][8,1]
(-0.0879...+0.9709...j)
```

**get_szego(boundary=-1, absolute_value=False)**

Return a discretized version of the Szego kernel for each boundary function.

**INPUT:**

The following inputs may be passed in as named parameters:

- **boundary** – integer (default: -1) if < 0, \(get_theta_points()\) will return the points for all boundaries. If >= 0, \(get_theta_points()\) will return only the points for the boundary specified.

- **absolute_value** – boolean (default: False) if True, will return the absolute value of the (complex valued) Szego kernel instead of the kernel itself. Useful for plotting.

**OUTPUT:**

A list of points of the form \([t value, value of the Szego kernel at that t]\).

**EXAMPLES:**

Generic use:

```
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: sz = m.get_szego(boundary=0)
sage: points = m.get_szego(absolute_value=True)
sage: list_plot(points)
Graphics object consisting of 1 graphics primitive
```

Extending the points by a spline:

```
sage: s = spline(points)
sage: s(3*pi / 4)
0.0012158...
sage: plot(s,0,2*pi) # plot the kernel
Graphics object consisting of 1 graphics primitive
```

The unit circle with a small hole:
Symbolic Calculus, Release 10.1

\begin{verbatim}
sage: f(t) = e^(I*t)
sage: fprime(t) = I*e^(I*t)
sage: hf(t) = 0.5*e^(-I*t)
sage: hfprime(t) = 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f, hf], [fprime, hfprime], 0.5 + 0.5*I)

Getting the szego for a specific boundary:

sage: sz0 = m.get_szego(boundary=0)
sage: sz1 = m.get_szego(boundary=1)

\end{verbatim}

**get_theta_points** *(boundary=-1)*

Return an array of points of the form \([t \text{ value}, \theta \text{ in } e^{I*\theta}]\), that is, a discretized version of the theta/boundary correspondence function. In other words, a point in this array \([t_1, t_2]\) represents that the boundary point given by \(f(t_1)\) is mapped to a point on the boundary of the unit circle given by \(e^{I*t_2}\).

For multiply connected domains, `get_theta_points` will list the points for each boundary in the order that they were supplied.

**INPUT:**

The following input must all be passed in as named parameters:

- `boundary` - integer (default: -1) if < 0, `get_theta_points()` will return the points for all boundaries. If >= 0, `get_theta_points()` will return only the points for the boundary specified.

**OUTPUT:**

A list of points of the form \([t \text{ value}, \theta \text{ in } e^{I*\theta}]\).

**EXAMPLES:**

Getting the list of points, extending it via a spline, getting the points for only the outside of a multiply connected domain:

\begin{verbatim}
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: points = m.get_theta_points()
sage: list_plot(points)
Graphics object consisting of 1 graphics primitive

Extending the points by a spline:

sage: s = spline(points)
sage: s(3*pi / 4)
1.627660...

The unit circle with a small hole:

\end{verbatim}

\begin{verbatim}
sage: f(t) = e^(I*t)
sage: fprime(t) = I*e^(I*t)
sage: hf(t) = 0.5*e^(-I*t)
sage: hfprime(t) = 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f, hf], [hf, hfprime], 0.5 + 0.5*I)

Getting the boundary correspondence for a specific boundary:

sage: sz0 = m.get_szego(boundary=0)
sage: sz1 = m.get_szego(boundary=1)

\end{verbatim}
Symbolic Calculus, Release 10.1

Sage: tp0 = m.get_theta_points(boundary=0)
Sage: tp1 = m.get_theta_points(boundary=1)

inverse_riemann_map(pt)

Return the inverse Riemann mapping of a point.

That is, given pt on the interior of the unit disc, inverse_riemann_map() will return the point on the original region that would be Riemann mapped to pt. Note that this method does not work for multiply connected domains.

INPUT:

• pt – A complex number (usually with absolute value <= 1) representing the point to be inverse mapped.

OUTPUT:

The point on the region that Riemann maps to the input point.

EXAMPLES:

Can work for different types of complex numbers:

Sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
Sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
Sage: m = Riemann_Map([f], [fprime], 0)
Sage: m.inverse_riemann_map(0.5 + sqrt(-0.5))
(0.406880...+0.3614702...j)
Sage: m.inverse_riemann_map(0.95)
(0.486319...-4.90019052...j)
Sage: m.inverse_riemann_map(0.25 - 0.3*I)
(0.1653244...-0.180936...j)
Sage: m.inverse_riemann_map(complex(-0.2, 0.5))
(-0.156280...+0.321819...j)

plot_boundaries(plotjoined=True, rgbcolor=[0, 0, 0], thickness=1)

Plots the boundaries of the region for the Riemann map. Note that this method DOES work for multiply connected domains.

INPUT:

The following inputs may be passed in as named parameters:

• plotjoined – boolean (default: True) If False, discrete points will be drawn; otherwise they will be connected by lines. In this case, if plotjoined=False, the points shown will be the original collocation points used to generate the Riemann map.

• rgbcolor – float array (default: [0, 0, 0]) the red-green-blue color of the boundary.

• thickness – positive float (default: 1) the thickness of the lines or points in the boundary.

EXAMPLES:

General usage:

Sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
Sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
Sage: m = Riemann_Map([f], [fprime], 0)

Default plot:
**plot_colored**(*plot_range=[], plot_points=100, interpolation='catrom', **options*)
Generates a colored plot of the Riemann map. A red point on the colored plot corresponds to a red point on the unit disc.

**INPUT:**

The following inputs may be passed in as named parameters:

- `plot_range` – (default: []) list of 4 values `(xmin, xmax, ymin, ymax)`. Declare if you do not want the plot to use the default range for the figure.
- `plot_points` – integer (default: 100), number of points to plot in the x direction. Points in the y direction are scaled accordingly. Note that very large values can cause this function to run slowly.

**EXAMPLES:**

Given a Riemann map `m`, general usage:

```python
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: m.plot_colored()
```

Graphics object consisting of 1 graphics primitive

Plot zoomed in on a specific spot:

```python
sage: m.plot_colored(plot_range=[0,1,.25,.75])
```

Graphics object consisting of 1 graphics primitive

High resolution plot:

```python
sage: m.plot_colored(plot_points=1000) # long time (29s on sage.math, 2012)
```

Graphics object consisting of 1 graphics primitive

To generate the unit circle map, it’s helpful to see what the colors correspond to:

```python
sage: f(t) = e^(I*t)
sage: fprime(t) = I*e^(I*t)
sage: m = Riemann_Map([f], [fprime], 0, 1000)
sage: m.plot_colored()
```

Graphics object consisting of 1 graphics primitive

**plot_spiderweb**(*spokes=16, circles=4, pts=32, linescale=0.99, rgbcolor=[0, 0, 0], thickness=1,
               plotjoined=True, withcolor=False, plot_points=200, min_mag=0.001,
               interpolation='catrom', **options*)
Generate a traditional “spiderweb plot” of the Riemann map.

This shows what concentric circles and radial lines map to. The radial lines may exhibit erratic behavior near the boundary; if this occurs, decreasing linescale may mitigate the problem.
For multiply connected domains the spiderweb is by necessity generated using the forward mapping. This method is more computationally intensive. In addition, these spiderwebs cannot be added to color plots. Instead the withcolor option must be used.

In addition, spiderweb plots are not currently supported for exterior maps.

INPUT:

The following inputs may be passed in as named parameters:

- **spokes** – integer (default: 16) the number of equally spaced radial lines to plot.
- **circles** – integer (default: 4) the number of equally spaced circles about the center to plot.
- **pts** – integer (default: 32) the number of points to plot. Each radial line is made by $1^{\text{pts}}$ points, each circle has $2^{\text{pts}}$ points. Note that high values may cause erratic behavior of the radial lines near the boundaries. - only for simply connected domains
- **linescale** – float between 0 and 1. Shrinks the radial lines away from the boundary to reduce erratic behavior. - only for simply connected domains
- **rgbcolor** – float array (default: [0, 0, 0]) the red-green-blue color of the spiderweb.
- **thickness** – positive float (default: 1) the thickness of the lines or points in the spiderweb.
- **plotjoined** – boolean (default: True) If False, discrete points will be drawn; otherwise they will be connected by lines. - only for simply connected domains
- **withcolor** – boolean (default: False) If True, The spiderweb will be overlaid on the basic color plot.
- **plot_points** – integer (default: 200) the size of the grid in the x direction. The number of points in the y direction is scaled accordingly. Note that very large values can cause this function to run slowly. - only for multiply connected domains
- **min_mag** – float (default: 0.001) The magnitude cutoff below which spiderweb points are not drawn. This only applies to multiply connected domains and is designed to prevent “fuzz” at the edge of the domain. Some complicated multiply connected domains (particularly those with corners) may require a larger value to look clean outside.

EXAMPLES:

General usage:

```sage
f(t) = e^(I*t) - 0.5*e^(-I*t)
fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
m = Riemann_Map([f], [fprime], 0)
m.plot_spiderweb()
```

Default plot:

```sage
m.plot_spiderweb()
```

Graphics object consisting of 21 graphics primitives

Simplified plot with many discrete points:

```sage
m.plot_spiderweb(spokes=4, circles=1, pts=400, linescale=0.95, plotjoined=False)
```

Graphics object consisting of 6 graphics primitives

Plot with thick, red lines:
To generate the unit circle map, it's helpful to see what the original spiderweb looks like:

```python
sage: f(t) = e^(I*t)
sage: fprime(t) = I*e^(I*t)
sage: m = Riemann_Map([f], [fprime], 0, 1000)
sage: m.plot_spiderweb()
```

A multiply connected region with corners. We set `min_mag` higher to remove “fuzz” outside the domain:

```python
sage: ps = polygon_spline([(-4,-2),(4,-2),(4,2),(-4,2)])
sage: z1 = lambda t: ps.value(t); z1p = lambda t: ps.derivative(t)
sage: z2(t) = -2+exp(-I*t); z2p(t) = -I*exp(-I*t)
sage: z3(t) = 2+exp(-I*t); z3p(t) = -I*exp(-I*t)
sage: m = Riemann_Map([z1,z2,z3],[z1p,z2p,z3p],0,ncorners=4) # long time
sage: p = m.plot_spiderweb(withcolor=True,plot_points=500, thickness = 2.0, min_mag=0.1) # long time
```

### riemann_map(pt)

Return the Riemann mapping of a point.

That is, given `pt` on the interior of the mapped region, `riemann_map` will return the point on the unit disk that `pt` maps to. Note that this method only works for interior points; accuracy breaks down very close to the boundary. To get boundary correspondence, use `get_theta_points()`.

**INPUT:**

- `pt` – A complex number representing the point to be inverse mapped.

**OUTPUT:**

A complex number representing the point on the unit circle that the input point maps to.

**EXAMPLES:**

Can work for different types of complex numbers:

```python
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: m.riemann_map(0.25 + sqrt(-0.5))
(0.137514...+0.876696...j)
sage: I = CDF.gen()
sage: m.riemann_map(1.3*I)
(-1.56...e-05+0.989694...j)
sage: m.riemann_map(0.4)
(0.73324...+3.2...e-06j)
sage: m.riemann_map(complex(-3, 0.0001))
(1.405757...e-05+8.06...e-10j)
```
Symbolic Calculus, Release 10.1

INPUT:
- t – The boundary parameter, from 0 to 2*pi
- n – integer - the number of terms to include. 10 is fairly accurate, 20 is very accurate.
- epsilon – float - the skew of the ellipse (0 is circular)

OUTPUT:
A theta value from 0 to 2*pi, corresponding to the point on the circle e^(I*theta)

sage.calculus.riemann.analytic_interior(z, n, epsilon)
Provides a nearly exact computation of the Riemann Map of an interior point of the ellipse with axes 1 + epsilon and 1 - epsilon. It is primarily useful for testing the accuracy of the numerical Riemann Map.

INPUT:
- z – complex - the point to be mapped.
- n – integer - the number of terms to include. 10 is fairly accurate, 20 is very accurate.

sage.calculus.riemann.cauchy_kernel(t, args)
Intermediate function for the integration in analytic_interior().

INPUT:
- t – The boundary parameter, meant to be integrated over
- args – a tuple containing:
  - epsilon – float - the skew of the ellipse (0 is circular)
  - z – complex - the point to be mapped.
  - n – integer - the number of terms to include. 10 is fairly accurate, 20 is very accurate.
  - part – will return the real ('r'), imaginary ('i') or complex ('c') value of the kernel

sage.calculus.riemann.complex_to_rgb(z_values)
Convert from a (Numpy) array of complex numbers to its corresponding matrix of RGB values. For internal use of plot_colored() only.

INPUT:
- z_values – A Numpy array of complex numbers.

OUTPUT:
An $N \times M \times 3$ floating point Numpy array $X$, where $X[i,j]$ is an (r,g,b) tuple.

EXAMPLES:

```
sage: from sage.calculus.riemann import complex_to_rgb
sage: import numpy
sage: complex_to_rgb(numpy.array([[0, 1, 1000]], dtype=numpy.complex128))
array([[ 1. , 1. , 1. ],
       [ 0.99999999, 0.05558355, 0.05558355],
       [ 0.17301243, 0. , 0. ]])
sage: complex_to_rgb(numpy.array([[0, 1j, 1000j]], dtype=numpy.complex128))
array([[ 1. , 1. , 1. ],
       [ 0.52779177, 1. , 0.05558355],
       [ 0.08650622, 0.17301243, 0. ]])
```
sage.calculus.riemann.complex_to_spiderweb(z_values, dr, dtheta, spokes, circles, rgbcolor, thickness, withcolor, min_mag)

Converts a grid of complex numbers into a matrix containing rgb data for the Riemann spiderweb plot.

INPUT:

- **z_values** – A grid of complex numbers, as a list of lists.
- **dr** – grid of floats, the r derivative of z_values. Used to determine precision.
- **dtheta** – grid of floats, the theta derivative of z_values. Used to determine precision.
- **spokes** – integer - the number of equally spaced radial lines to plot.
- **circles** – integer - the number of equally spaced circles about the center to plot.
- **rgbcolor** – float array - the red-green-blue color of the lines of the spiderweb.
- **thickness** – positive float - the thickness of the lines or points in the spiderweb.
- **withcolor** – boolean - If True the spiderweb will be overlaid on the basic color plot.
- **min_mag** – float - The magnitude cutoff below which spiderweb points are not drawn. This only applies to multiply connected domains and is designed to prevent “fuzz” at the edge of the domain. Some complicated multiply connected domains (particularly those with corners) may require a larger value to look clean outside.

OUTPUT:

An $N \times M \times 3$ floating point Numpy array $X$, where $X[i,j]$ is an (r,g,b) tuple.

EXAMPLES:

```python
sage: from sage.calculus.riemann import complex_to_spiderweb
sage: import numpy
sage: zval = numpy.array([[0,1,1000], [.2+.3j,1,-.3j], [0,0,0]],
                      dtype=numpy.complex128)
sage: deriv = numpy.array([[.1]],dtype = numpy.float64)
sage: complex_to_spiderweb(zval, deriv, deriv, 4, 4, [0,0,0], 1, False, 0.001)
array([[1., 1., 1.],
       [1., 1., 1.],
       [1., 1., 1.]],
      [[1., 1., 1.],
       [0., 0., 0.],
       [1., 1., 1.]],
      [[1., 1., 1.],
       [1., 1., 1.],
       [1., 1., 1.]]])
```

```python
sage: complex_to_spiderweb(zval, deriv, deriv, 4, 4, [0,0,0], 1, True, 0.001)
array([[1.0000000000000002e+00, 1.0000000000000002e+00, 1.0000000000000002e+00],
       [1.0000000000000002e+00, 9.96804683e-01, 9.96804683e-01],
       [0.17301243, 0. , 0. ],
       [0.77351965, 0.5470393 , 1. ]])
```

(continues on next page)
sage.calculus.riemann.get_derivatives(z_values, xstep, ystep)

Computes the r*e^(I*theta) form of derivatives from the grid of points. The derivatives are computed using quick-and-dirty taylor expansion and assuming analyticity. As such get_derivatives is primarily intended to be used for comparisons in plot_spiderweb and not for applications that require great precision.

**INPUT:**
- `z_values` – The values for a complex function evaluated on a grid in the complex plane, usually from compute_on_grid.
- `xstep` – float, the spacing of the grid points in the real direction

**OUTPUT:**
- A tuple of arrays, [dr, dtheta], with each array 2 less in both dimensions than z_values
  - `dr` - the abs of the derivative of the function in the +r direction
  - `dtheta` - the rate of accumulation of angle in the +theta direction

**EXAMPLES:**

Standard usage with compute_on_grid:

```python
sage: from sage.calculus.riemann import get_derivatives
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: data = m.compute_on_grid([],19)
sage: xstep = (data[2]-data[1])/19
sage: ystep = (data[4]-data[3])/19
sage: dr, dtheta = get_derivatives(data[0],xstep,ystep)
```

2.26 Real Interpolation using GSL

**class** sage.calculus.interpolation.Spline

**Bases:** object

Create a spline interpolation object.

Given a list \( v \) of pairs, \( s = \text{spline}(v) \) is an object \( s \) such that \( s(x) \) is the value of the spline interpolation through the points in \( v \) at the point \( x \).

The values in \( v \) do not have to be sorted. Moreover, one can append values to \( v \), delete values from \( v \), or change values in \( v \), and the spline is recomputed.

**EXAMPLES:**
Symbolic Calculus, Release 10.1

```python
sage: S = spline([(0, 1), (1, 2), (4, 5), (5, 3)]); S
[(0, 1), (1, 2), (4, 5), (5, 3)]
sage: S(1.5)
2.76136363636...
```

Changing the points of the spline causes the spline to be recomputed:

```python
sage: S[0] = (0, 2); S
[(0, 2), (1, 2), (4, 5), (5, 3)]
sage: S(1.5)
2.507575757575...
```

We may delete interpolation points of the spline:

```python
sage: del S[2]; S
[(0, 2), (1, 2), (5, 3)]
sage: S(1.5)
2.04296875
```

We may append to the list of interpolation points:

```python
sage: S.append((4, 5)); S
[(0, 2), (1, 2), (5, 3), (4, 5)]
sage: S(1.5)
2.507575757575...
```

If we set the $n$-th interpolation point, where $n$ is larger than len(S), then points (0, 0) will be inserted between the interpolation points and the point to be added:

```python
sage: S[6] = (6, 3); S
[(0, 2), (1, 2), (5, 3), (4, 5), (0, 0), (0, 0), (6, 3)]
```

This example is in the GSL documentation:

```python
sage: v = [(i + RDF(i).sin()/2, i + RDF(i^2).cos()) for i in range(10)]
sage: s = spline(v)
sage: show(point(v) + plot(s,0,9, hue=.8))
# Needs sage.plot
```

We compute the area underneath the spline:

```python
sage: s.definite_integral(0, 9)
41.196516041067...
```

The definite integral is additive:

```python
sage: s.definite_integral(0, 4) + s.definite_integral(4, 9)
41.196516041067...
```

Switching the order of the bounds changes the sign of the integral:

```python
sage: s.definite_integral(9, 0)
-41.196516041067...
```

We compute the first and second-order derivatives at a few points:

2.26. Real Interpolation using GSL
Symbolic Calculus, Release 10.1

```
sage: s.derivative(5)
-0.1623008526180...

sage: s.derivative(6)
0.2099798628571...

sage: s.derivative(5, order=2)
-3.0874707456138...

sage: s.derivative(6, order=2)
2.6187684827485...

```

Only the first two derivatives are supported:

```
sage: s.derivative(4, order=3)
Traceback (most recent call last):
  ... ValueError: Order of derivative must be 1 or 2.
```

append(xy)

**EXAMPLES:**

```
sage: S = spline([(1,1), (2,3), (4,5)]); S.append((5,7)); S
[(1, 1), (2, 3), (4, 5), (5, 7)]
```

The spline is recomputed when points are appended (github issue #13519):

```
sage: S = spline([(1,1), (2,3), (4,5)]); S
[(1, 1), (2, 3), (4, 5)]
sage: S(3)
4.25

sage: S.append((5, 5)); S
[(1, 1), (2, 3), (4, 5), (5, 5)]
sage: S(3)
4.375
```

definite_integral(a, b)

Value of the definite integral between \(a\) and \(b\).

**INPUT:**

- \(a\) – Lower bound for the integral.
- \(b\) – Upper bound for the integral.

**EXAMPLES:**

We draw a cubic spline through three points and compute the area underneath the curve:

```
sage: s = spline([(0, 0), (1, 3), (2, 0)])
sage: s.definite_integral(0, 2)
3.75

sage: s.definite_integral(0, 1)
1.875

sage: s.definite_integral(0, 1) + s.definite_integral(1, 2)
3.75

sage: s.definite_integral(2, 0)
-3.75
```

**derivative**(x, order=1)

Value of the first or second derivative of the spline at x.

INPUT:

- x – value at which to evaluate the derivative.
- order (default: 1) – order of the derivative. Must be 1 or 2.

EXAMPLES:

We draw a cubic spline through three points and compute the derivatives:

```sage
s = spline([(0, 0), (2, 3), (4, 0)])
s.derivative(0)
2.25
s.derivative(2)
0.0
s.derivative(4)
-2.25
s.derivative(1, order=2)
-1.125
s.derivative(3, order=2)
-1.125
```

**list()**

Underlying list of points that this spline goes through.

EXAMPLES:

```sage
S = spline([(1,1), (2,3), (4,5)]); S.list()
[(1, 1), (2, 3), (4, 5)]
```

This is a copy of the list, not a reference (github issue #13530):

```sage
S = spline([(1,1), (2,3), (4,5)])
L = S.list(); L
[(1, 1), (2, 3), (4, 5)]
L[2] = (3, 2)
L
[(1, 1), (2, 3), (3, 2)]
S.list()
[(1, 1), (2, 3), (4, 5)]
```

`sage.calculus.interpolation.spline`

alias of `Spline`
2.27 Complex Interpolation

AUTHORS:

- Ethan Van Andel (2009): initial version

Development supported by NSF award No. 0702939.

class sage.calculus.interpolators.CCSpline

Bases: object

A CCSpline object contains a cubic interpolation of a figure in the complex plane.

EXAMPLES:

A simple square:

sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: cs = complex_cubic_spline(pts)
sage: cs.value(0)
(-1-1j)
sage: cs.derivative(0)
(0.9549296...-0.9549296...j)

\textbf{derivative}(t)

Return the derivative (speed and direction of the curve) of a given point from the parameter \( t \).

INPUT:

- \( t \) – double, the parameter value for the parameterized curve, between 0 and 2*pi.

OUTPUT:

A complex number representing the derivative at the point on the figure corresponding to the input \( t \).

EXAMPLES:

sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: cs = complex_cubic_spline(pts)
sage: cs.derivative(3 / 5)
(1.40578892327...-0.225417136326...j)
sage: from math import pi
sage: cs.derivative(0) - cs.derivative(2 * pi)
0j
sage: cs.derivative(-6)
(2.52047692949...-1.89392588310...j)

\textbf{value}(t)

Return the location of a given point from the parameter \( t \).

INPUT:

- \( t \) – double, the parameter value for the parameterized curve, between 0 and 2*pi.

OUTPUT:

A complex number representing the point on the figure corresponding to the input \( t \).

EXAMPLES:
class sage.calculus.interpolators.PSpline

A CCSpline object contains a polygon interpolation of a figure in the complex plane.

EXAMPLES:

A simple square:

```
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.value(0)
(-1-1j)
sage: ps.derivative(0)
(1.27323954473...+0j)
sage: from math import pi
sage: ps.derivative(0) - ps.derivative(2*pi)
0j
sage: ps.derivative(10)
(-1.27323954473...+0j)
```

derivative(t)

Return the derivative (speed and direction of the curve) of a given point from the parameter t.

INPUT:

- t – double, the parameter value for the parameterized curve, between 0 and 2*pi.

OUTPUT:

A complex number representing the derivative at the point on the polygon corresponding to the input t.

EXAMPLES:

```
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.derivative(1 / 3)
(1.27323954473...+0j)
sage: from math import pi
sage: ps.derivative(0) - ps.derivative(2*pi)
0j
sage: ps.derivative(10)
(-1.27323954473...+0j)
```

value(t)

Return the derivative (speed and direction of the curve) of a given point from the parameter t.

INPUT:

- t – double, the parameter value for the parameterized curve, between 0 and 2*pi.

OUTPUT:

A complex number representing the point on the polygon corresponding to the input t.
EXAMPLES:

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.value(.5)
(0.363380227632...-1j)
sage: ps.value(0) - ps.value(2*RDF.pi())
0j
sage: ps.value(10)
(0.26760455264...+1j)
```

```
sage.calculus.interpolators.complex_cubic_spline(pts)
Creates a cubic spline interpolated figure from a set of complex or (x, y) points. The figure will be a parametric curve from 0 to 2*pi. The returned values will be complex, not (x, y).

INPUT:

• pts – A list or array of complex numbers, or tuples of the form (x, y).

EXAMPLES:

A simple square:

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
```
sage: fx = lambda x: ps.value(x).real
sage: fy = lambda x: ps.value(x).imag
sage: show(parametric_plot((fx, fy), (0, 2*pi)))

Polygon approximation of an circle:

sage: pts = [e^(I*t / 25) for t in range(25)]
sage: ps = polygon_spline(pts)
sage: ps.derivative(2)
(-0.0470303661...+0.1520363883...j)

2.28 Calculus functions

sage.calculus.functions.jacobian(functions, variables)

Return the Jacobian matrix, which is the matrix of partial derivatives in which the i, j entry of the Jacobian matrix is the partial derivative \( \text{diff}(\text{functions}[i], \text{variables}[j]) \).

EXAMPLES:

sage: x,y = var('x,y')
sage: g=x^2-2*x*y
sage: jacobian(g, (x,y))
[2*x - 2*y -2*x]

The Jacobian of the Jacobian should give us the “second derivative”, which is the Hessian matrix:

sage: jacobian(jacobian(g, (x,y)), (x,y))
[ 2 -2]
[-2 0]

sage: f=(x^3*sin(y), cos(x)*sin(y), exp(x))
sage: jacobian(f, (x,y))
[ 3*x^2*sin(y) x^3*cos(y)]
[-sin(x)*sin(y) cos(x)*cos(y)]
[ e^x 0]

sage: jacobian(f, (y,x))
[ x^3*cos(y) 3*x^2*sin(y)]
[ cos(x)*cos(y) -sin(x)*sin(y)]
[ 0 e^x]

sage.calculus.functions.wronskian(*args)

Return the Wronskian of the provided functions, differentiating with respect to the given variable.

If no variable is provided, \( \text{diff}(f) \) is called for each function \( f \).
wronskian(f1, ..., fn, x) returns the Wronskian of f1, ..., fn, with derivatives taken with respect to x.

wronskian(f1, ..., fn) returns the Wronskian of f1, ..., fn where k'th derivatives are computed by doing \( \text{derivative}(k) \) on each function.

The Wronskian of a list of functions is a determinant of derivatives. The nth row (starting from 0) is a list of the nth derivatives of the given functions.

For two functions:

\[
\begin{vmatrix}
  f & g \\
  f' & g'
\end{vmatrix}
\]

\[ W(f, g) = \det \begin{vmatrix} f & g \\ f' & g' \end{vmatrix} = f^*g' - g^*f'. \]

**EXAMPLES:**

\[
\text{sage: wronskian}(\text{e}^x, x^2)
\]

\[-x^2\text{e}^x + 2x\text{e}^x\]

\[
\text{sage: } x,y = \text{var}(\text{'x, y'})
\]

\[
\text{sage: wronskian}(x^*y, \text{log}(x), x)
\]

\[-y^*\text{log}(x) + y\]

If your functions are in a list, you can use \( *\text{t}o\text{t}urn\text{them}\text{into}\text{arguments} \to \text{func}: \text{‘wronskian’} : \]

\[
\text{sage: wronskian}(*[x^k \text{ for } k \text{ in } \text{range}(1, 5)])
\]

\[12x^4\]

If you want to use ‘x’ as one of the functions in the Wronskian, you can’t put it last or it will be interpreted as the variable with respect to which we differentiate. There are several ways to get around this.

Two-by-two Wronskian of sin(x) and e^x:

\[
\text{sage: wronskian}(\text{sin}(x), \text{e}^x, x)
\]

\[-\cos(x)^*\text{e}^x + \text{e}^x^*\text{sin}(x)\]

Or don’t put x last:

\[
\text{sage: wronskian}(x, \text{sin}(x), \text{e}^x)
\]

\[(\cos(x)^*\text{e}^x + \text{e}^x^*\text{sin}(x))^x - 2\text{e}^x^*\text{sin}(x)\]

Example where one of the functions is constant:

\[
\text{sage: wronskian}(1, \text{e}^\text{(-x)}, \text{e}^{(2*x)})
\]

\[-6\text{e}^x\]

**REFERENCES:**

2.29 Symbolic variables

sage.calculus.var.clear_vars()

Delete all 1-letter symbolic variables that are predefined at startup of Sage.

Any one-letter global variables that are not symbolic variables are not cleared.

EXAMPLES:

```python
sage: var('x y z')
(x, y, z)
sage: (x+y)^z
(x + y)^z
sage: k = 15
sage: clear_vars()
sage: (x+y)^z
Traceback (most recent call last):
  ... NameError: name 'x' is not defined
sage: expand((e + i)^2)
e^2 + 2*I*e - 1
sage: k
15
```

sage.calculus.var.function(s, **kwds)

Create a formal symbolic function with the name `s`.

INPUT:

- nargs=0 - number of arguments the function accepts, defaults to variable number of arguments, or 0
- latex_name - name used when printing in latex mode
- conversions - a dictionary specifying names of this function in other systems, this is used by the interfaces internally during conversion
- eval_func - method used for automatic evaluation
- evafl_func - method used for numeric evaluation
- evafl_params_first - bool to indicate if parameters should be evaluated numerically before calling the custom evalf function
- conjugate_func - method used for complex conjugation
- real_part_func - method used when taking real parts
- imag_part_func - method used when taking imaginary parts
- derivative_func - method to be used for (partial) derivation This method should take a keyword argument deriv_param specifying the index of the argument to differentiate w.r.t
- tderivative_func - method to be used for derivatives
- power_func - method used when taking powers This method should take a keyword argument power param specifying the exponent
- series_func - method used for series expansion This method should expect keyword arguments - order - order for the expansion to be computed - var - variable to expand w.r.t. - at - expand at this value
- print_func - method for custom printing
Symbolic Calculus, Release 10.1

- **print_latex_func** - method for custom printing in latex mode

Note that custom methods must be instance methods, i.e., expect the instance of the symbolic function as the first argument.

**Note:** The new function is both returned and automatically injected into the global namespace. If you use this function in library code, it is better to use sage.symbolic.function_factory.function, since it will not touch the global namespace.

**EXAMPLES:**

We create a formal function called supersin

```
sage: function('supersin')
supersin
```

We can immediately use supersin in symbolic expressions:

```
sage: y, z, A = var('y z A')
sage: supersin(y+z) + A^3
A^3 + supersin(y + z)
```

We can define other functions in terms of supersin:

```
sage: g(x,y) = supersin(x)^2 + sin(y/2)
sage: g
(x, y) |--> supersin(x)^2 + sin(1/2*y)
sage: g.diff(y)
(x, y) |--> 1/2*cos(1/2*y)
sage: k = g.diff(x); k
(x, y) |--> 2*supersin(x)*diff(supersin(x), x)
```

We create a formal function of one variable, write down an expression that involves first and second derivatives, and extract off coefficients:

```
sage: r, kappa = var('r, kappa')
sage: psi = function('psi', nargs=1)(r); psi
psi(r)
sage: g = 1/r^2*(2*r*psi.derivative(r,1) + r^2*psi.derivative(r,2)); g
(r^2*diff(psi(r), r, r) + 2*r^2*diff(psi(r), r))/r^2
sage: g.expand()
2*diff(psi(r), r)/r + diff(psi(r), r, r)
sage: g.coefficient(psi.derivative(r,2))
1
sage: g.coefficient(psi.derivative(r,1))
2/r
```

Custom typesetting of symbolic functions in LaTeX, either using latex_name keyword:

```
sage: function('riemann', latex_name="\mathcal{R}")
riemann
```

or passing a custom callable function that returns a latex expression:

```
sage: latex(riemann(x))
\mathcal{R}(x)
```

370 Chapter 2. Internal functionality supporting calculus
Symbolic variables

```python
sage: mu, nu = var('mu, nu')
sage: def my_latex_print(self, *args):
    return r'\psi_{' + ', '.join(map(latex, args)) + r'}'
sage: function('psi', print_latex_func=my_latex_print)
psi
sage: latex(psi(mu, nu))
\psi_{\mu, \nu}
```

Defining custom methods for automatic or numeric evaluation, derivation, conjugation, etc. is supported:

```python
sage: def ev(self, x):
    return 2*x
sage: foo = function('foo', nargs=1, eval_func=ev)
sage: foo(x)
2*x
sage: def ef(self, x):
    pass
sage: bar = function('bar', nargs=1, eval_func=ef)
sage: bar(x)
bar(x)
```

```python
sage: def evalf_f(self, x, parent=None, algorithm=None):
    return 6
sage: foo = function('foo', nargs=1, evalf_func=evalf_f)
sage: foo(x)
foo(x)
sage: foo(x).n()
6
```

```python
sage: def deriv(self, *args, **kwds):
    return args[kwds['diff_param']]^2
sage: foo = function('foo', nargs=2, derivative_func=deriv)
sage: foo(x, y).derivative(y)
(x, y) {'diff_param': 1}
y^2
```

```python
sage: def pow(self, x, power_param=None):
    return x*power_param
sage: foo = function('foo', nargs=1, power_func=pow)
sage: foo(y)^(x+y)
(x + y)*y
```

```python
sage: from pprint import pformat
sage: def expand(self, *args, **kwds):
    print("{} {}".format(args, pformat(kwds))); return
    sum(args[0]^i for i in range(kwds['order']))
```

```python
sage: foo = function('foo', nargs=1, series_func=expand)
sage: foo(y).series(y, 5)
```

(continues on next page)
\( (y, \{ 'at': 0, \text{ 'options': 0, \text{ 'order': 5, \text{ 'var': y \}} } \) \\
\ y^4 + y^3 + y^2 + y + 1 \)

\begin{verbatim}
\sage: def my_print(self, *args):
    ....:     return "my args are: " + ', '.join(map(repr, args))
\sage: foo = function('t', nargs=2, print_func=my_print)
\sage: foo(x,y^z)
my args are: x, y^z
\end{verbatim}

\begin{verbatim}
\sage: latex(foo(x,y^z))
t(x, y^z)
\end{verbatim}

\begin{verbatim}
\sage: def print_args(self, *args, **kwds); print("args: \{\}".format(args)); print(˓→"kwds: \{\}".format(kwds)); return args[0]
\sage: foo = function('t', nargs=2, tderivative_func=print_args)
\sage: foo(x,x).derivative(x)
args: (x, x)
kwds: \{ 'diff_param': x \}
x
\sage: foo = function('t', nargs=2, derivative_func=print_args)
\sage: foo(x,x).derivative(x)
args: (x, x)
kwds: \{ 'diff_param': 0 \}
args: (x, x)
kwds: \{ 'diff_param': 1 \}
2*x
\end{verbatim}

Since Sage 4.0, basic arithmetic with unevaluated functions is no longer supported:

\begin{verbatim}
\sage: x = var('x')
\sage: f = function('f')
\sage: 2*f
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: 'Integer Ring' and '<class 'sage.symbolic.function_factory...NewSymbolicFunction'>'
\end{verbatim}

You now need to evaluate the function in order to do the arithmetic:

\begin{verbatim}
\sage: 2*f(x)
2*f(x)
\end{verbatim}

Since Sage 4.0, you need to use substitute_function() to replace all occurrences of a function with another:
```python
sage: var('a, b')
(a, b)
sage: cr = function('cr')
sage: f = cr(a)
sage: g = f.diff(a).integral(b)
sage: g
b*diff(cr(a), a)
sage: g.substitute_function(cr, cos)
-b*sin(a)
sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))
b*(cos(a) - sin(a))
```

`sage.calculus.var.var(*args, **kwds)`

Create a symbolic variable with the name `s`.

**INPUT:**

- `args` – A single string `var('x y')`, a list of strings `var(['x', 'y'])`, or multiple strings `var('x', 'y')`. A single string can be either a single variable name, or a space or comma separated list of variable names. In a list or tuple of strings, each entry is one variable. If multiple arguments are specified, each argument is taken to be one variable. Spaces before or after variable names are ignored.

- `kwds` – keyword arguments can be given to specify domain and custom latex_name for variables. See EXAMPLES for usage.

**Note:** The new variable is both returned and automatically injected into the global namespace. If you need a symbolic variable in library code, you must use either `SR.var()` or `SR.symbol()`.

**OUTPUT:**

If a single symbolic variable was created, the variable itself. Otherwise, a tuple of symbolic variables. The variable names are checked to be valid Python identifiers and a `ValueError` is raised otherwise.

**EXAMPLES:**

Here are the different ways to define three variables `x, y,` and `z` in a single line:

```python
sage: var('x y z')
(x, y, z)
sage: var('x, y, z')
(x, y, z)
sage: var(['x', 'y', 'z'])
(x, y, z)
sage: var('x', 'y', 'z')
(x, y, z)
sage: var('x'), var('y'), var(z)
(x, y, z)
```

We define some symbolic variables:

```python
sage: var('n xx yy zz')
(n, xx, yy, zz)
```

Then we make an algebraic expression out of them:
Symbolic Calculus, Release 10.1

```
sage: f = xx^n + yy^n + zz^n; f
xx^n + yy^n + zz^n
```

By default, var returns a complex variable. To define real or positive variables we can specify the domain as:

```
sage: x = var('x', domain=RR); x; x.conjugate()
x
x
sage: y = var('y', domain='real'); y.conjugate()
y
sage: y = var('y', domain='positive'); y.abs()
y
```

Custom latex expression can be assigned to variable:

```
sage: x = var('sui', latex_name="s_{u,i}"); x._latex_()
'\{s_{u,i}\}'
```

In notebook, we can also colorize latex expression:

```
sage: x = var('sui', latex_name="\color{red}\{s_{u,i}\}"); x._latex_()
'\{\color{red}\{s_{u,i}\}\}'
```

We can substitute a new variable name for n:

```
sage: f(n = var('sigma'))
xx^sigma + yy^sigma + zz^sigma
```

If you make an important built-in variable into a symbolic variable, you can get back the original value using restore:

```
sage: var('QQ RR')
(QQ, RR)
sage: QQ
QQ
sage: restore('QQ')
sage: QQ
Rational Field
```

We make two new variables separated by commas:

```
sage: var('theta, gamma')
(theta, gamma)
sage: theta^2 + gamma^3
gamma^3 + theta^2
```

The new variables are of type Expression, and belong to the symbolic expression ring:

```
sage: type(theta)
<class 'sage.symbolic.expression.Expression'>
sage: parent(theta)
Symbolic Ring
```
2.30 Access to Maxima methods

```python
class sage.symbolic.maxima_wrapper.MaximaFunctionElementWrapper(obj, name)
    Bases: InterfaceFunctionElement
```

```python
class sage.symbolic.maxima_wrapper.MaximaWrapper(exp)
    Bases: SageObject
    Wrapper around Sage expressions to give access to Maxima methods.

    We convert the given expression to Maxima and convert the return value back to a Sage expression. Tab completion and help strings of Maxima methods also work as expected.

    EXAMPLES:
    sage: t = log(sqrt(2) - 1) + log(sqrt(2) + 1); t
    log(sqrt(2) + 1) + log(sqrt(2) - 1)
    sage: u = t.maxima_methods(); u
    MaximaWrapper(log(sqrt(2) + 1) + log(sqrt(2) - 1))
    sage: type(u)
    <class 'sage.symbolic.maxima_wrapper.MaximaWrapper'>
    sage: u.logcontract()
    log((sqrt(2) + 1)*(sqrt(2) - 1))
    sage: u.logcontract().parent()
    Symbolic Ring
```

```python
sage()
    Return the Sage expression this wrapper corresponds to.
```

```python
    EXAMPLES:
    sage: t = log(sqrt(2) - 1) + log(sqrt(2) + 1); t
    log(sqrt(2) + 1) + log(sqrt(2) - 1)
    sage: u = t.maxima_methods().sage()
    sage: u
    log(sqrt(2) + 1) + log(sqrt(2) - 1)
    sage: u is t
    True
```

2.31 Operators

```python
class sage.symbolic.operators.DerivativeOperator
    Bases: object
    Derivative operator.

    Acting with this operator onto a function gives a new operator (of type FDerivativeOperator) representing
    the function differentiated with respect to one or multiple of its arguments.

    This operator takes a list of indices specifying the position of the arguments to differentiate. For example, D[0, 0, 1] is an operator that differentiates a function twice with respect to its first argument and once with respect to its second argument.

    EXAMPLES:
```

sage: x, y = var('x,y'); f = function('f')
sage: D[0](f)(x)
\text{diff}(f(x), x)
sage: D[0](f)(x, y)
\text{diff}(f(x, y), x)
sage: D[0, 1](f)(x, y)
\text{diff}(f(x, y), x, y)
sage: D[0, 1](f)(x, x^2)
\text{D}[0, 1](f)(x, x^2)

class DerivativeOperatorWithParameters(parameter_set)
    Bases: object
class sage.symbolic.operators.FDerivativeOperator(function, parameter_set)
    Bases: object
Function derivative operators.
    A function derivative operator represents a partial derivative of a function with respect to some variables.
    The underlying data are the function, and the parameter set, a list recording the indices of the variables with respect to which the partial derivative is taken.

change_function(new)
    Return a new function derivative operator with the same parameter set but for a new function.
    EXAMPLES:
    sage: from sage.symbolic.operators import FDerivativeOperator
    sage: f = function('foo')
    sage: b = function('bar')
    sage: op = FDerivativeOperator(f, [0, 1])
    sage: op.change_function(bar)
    D[0, 1](\text{bar})

function()
    Return the function associated to this function derivative operator.
    EXAMPLES:
    sage: from sage.symbolic.operators import FDerivativeOperator
    sage: f = function('foo')
    sage: op = FDerivativeOperator(f, [0, 1])
    sage: op.function()
    \text{foo}

parameter_set()
    Return the parameter set of this function derivative operator.
    This is the list of indices of variables with respect to which the derivative is taken.
    EXAMPLES:
    sage: from sage.symbolic.operators import FDerivativeOperator
    sage: f = function('foo')
    sage: op = FDerivativeOperator(f, [0, 1])
    sage: op.function()
sage: op.parameter_set()
[0, 1]

sage.symbolic.operators.add_vararg(first, *rest)

Return the sum of all the arguments.

INPUT:

• first, *rest – arguments to add

OUTPUT: sum of the arguments

EXAMPLES:

sage: from sage.symbolic.operators import add_vararg
sage: add_vararg(1, 2, 3, 4, 5, 6, 7)
28
sage: x = SR.var('x')
sage: s = 1 + x + x^2  # symbolic sum
sage: bool(s.operator()(*s.operands()) == s)
True

sage.symbolic.operators.mul_vararg(first, *rest)

Return the product of all the arguments.

INPUT:

• first, *rest – arguments to multiply

OUTPUT: product of the arguments

EXAMPLES:

sage: from sage.symbolic.operators import mul_vararg
sage: mul_vararg(9, 8, 7, 6, 5, 4)
60480
sage: x = SR.var('x')
sage: p = x * cos(x) * sin(x)  # symbolic product
sage: bool(p.operator()(*p.operands()) == p)
True

2.32 Substitution Maps

This object wraps Pynac exmap objects. These encode substitutions of symbolic expressions. The main use of this module is to hook into Pynac’s subs() methods and pass a wrapper for the substitution map back to Python.
2.33 Benchmarks

Tests that will take a long time if something is wrong, but be very quick otherwise. See https://wiki.sagemath.org/symbench. The parameters chosen below are such that with pynac most of these take well less than a second, but would not even be feasible using Sage’s Maxima-based symbolics.

Problem R1

Important note. Below we do s.expand().real() because s.real() takes forever (TODO?).

```
sage: f(z) = sqrt(1/3)*z^2 + i/3
sage: s = f(f(f(f(f(f(f(f(f(f(i/2))))))))))
sage: s.expand().real()
-15323490199844318074242736790714109348334942474663857718035703708589611127743908517981666567969026951216095998759224694773994859375773744043160018419104230464668040286318700912682441978171139853325001637680324690025802009761307137504963304640835891588925883135078996398616361571065941964628043214890356454145039464055430143/sqrt(3)
```

Problem R2:

```
sage: def hermite(n,y):
    ....:     if n == 1:
    ....:         return 2*y
    ....:     if n == 0:
    ....:         return 1
    ....:     return expand(2*y*hermite(n-1,y) - 2*(n-1)*hermite(n-2,y))
sage: hermite(15,var('y'))
32768*y^15 - 1720320*y^13 + 33546240*y^11 - 307507200*y^9 + 1383782400*y^7 - 2905943040*y^5 + 2421619200*y^3 - 518918400*y
```

Problem R3:

```
sage: f = sum(var('x,y,z')); a = [bool(f==f) for _ in range(100000)]
```

Problem R4:

```
sage: u = [e,pi,sqrt(2)]; Tuples(u,3).cardinality()
27
```

Problem R5:

```
sage: def blowup(L,n):
    ....:     for i in [0..n]:
    ....:         L.append( (L[i] + L[i+1]) * L[i+2] )
sage: L = list(var('x,y,z'))
sage: blowup(L,15)
sage: len(set(L))
19
```

Problem R6:

```
sage: sum(((x+sin(i))/x+(x-sin(i))/x) for i in range(100)).expand()
200
```

Problem R7:
Symbolic Calculus, Release 10.1

sage: f = x^24+34*x^12+45*x^3+9*x^18 +34*x^10+ 32*x^21
sage: a = [f(x=random()) for _ in range(10^4)]

Problem R10:

sage: v = [float(z) for z in [-pi,-pi+1/100..,pi]]

Problem R11:

sage: a = [random() + random()*I for w in [0..100]]
sage: a.sort()

Problem W3:

sage: acos(cos(x))
arccos(cos(x))

PROBLEM S1:

sage: _ = var('x,y,z')
sage: f = (x+y+z+1)^10
sage: g = expand(f*(f+1))

PROBLEM S2:

sage: _ = var('x,y')
sage: a = expand((x^sin(x) + y^cos(y) - z^(x+y))^100)

PROBLEM S3:

sage: _ = var('x,y,z')
sage: f = expand((x^y + y^z + z^x)^50)
sage: g = f.diff(x)

PROBLEM S4:

sage: w = (sin(x)*cos(x)).series(x,400)

2.34 Randomized tests of GiNaC / PyNaC

sage.symbolic.random_tests.assert_strict_weak_order(a, b, c, cmp_func)

Check that cmp_func is a strict weak order on the elements a,b,c.

A strict weak order is a binary relation < such that

- For all x, it is not the case that x < x (irreflexivity).
- For all x ≠ y, if x < y then it is not the case that y < x (asymmetry).
- For all x, y, and z, if x < y and y < z then x < z (transitivity).
- For all x, y, and z, if x is incomparable with y, and y is incomparable with z, then x is incomparable with z (transitivity of incomparability).

INPUT:
• a, b, c – anything that can be compared by cmp_func.
• cmp_func – function of two arguments that returns their comparison (i.e. either True or False).

OUTPUT:
Does not return anything. Raises a ValueError if cmp_func is not a strict weak order on the three given elements.

REFERENCES:
Wikipedia article Strict_weak_ordering

EXAMPLES:
The usual ordering of integers is a strict weak order:

```python
sage: from sage.symbolic.random_tests import assert_strict_weak_order
sage: a, b, c = [randint(-10, 10) for i in range(3)]
sage: assert_strict_weak_order(a, b, c, lambda x, y: x < y)

sage: x = [-SR(oo), SR(0), SR(oo)]
sage: cmp_M = matrix(3, 3, 0)
    for i in range(3):
        for j in range(3):
            if x[i] < x[j]:
                cmp_M[i, j] = -1
            elif x[i] > x[j]:
                cmp_M[i, j] = 1
sage: cmp_M
[ 0 -1 -1]
[ 1 0 -1]
[ 1 1 0]
```

sage.symbolic.random_tests.choose_from_prob_list(lst)

INPUT:
• lst - A list of tuples, where the first element of each tuple is a nonnegative float (a probability), and the probabilities sum to one.

OUTPUT:
A tuple randomly selected from the list according to the given probabilities.

EXAMPLES:

```python
sage: from sage.symbolic.random_tests import *
sage: v = [(0.1, False), (0.9, True)]
sage: choose_from_prob_list(v) # random
(0.900000000000000, True)
sage: true_count = 0
sage: total_count = 0
sage: def more_samples():
    global true_count, total_count
    for _ in range(10000):
        total_count += 1.0
        if choose_from_prob_list(v)[1]:
            true_count += 1.0
sage: more_samples()
(continues on next page)
```
sage: while abs(true_count/total_count - 0.9) > 0.01:
....:     more_samples()

sage.symbolic.random_tests.normalize_prob_list(pl, extra=())

INPUT:

- pl - A list of tuples, where the first element of each tuple is a floating-point number (representing a relative probability). The second element of each tuple may be a list or any other kind of object.

- extra - A tuple which is to be appended to every tuple in pl.

This function takes such a list of tuples (a “probability list”) and normalizes the probabilities so that they sum to one. If any of the values are lists, then those lists are first normalized; then the probabilities in the list are multiplied by the main probability and the sublist is merged with the main list.

For example, suppose we want to select between group A and group B with 50% probability each. Then within group A, we select A1 or A2 with 50% probability each (so the overall probability of selecting A1 is 25%); and within group B, we select B1, B2, or B3 with probabilities in a 1:2:2 ratio.

EXAMPLES:

```python
sage: from sage.symbolic.random_tests import *

sage: A = [(0.5, 'A1'), (0.5, 'A2')]

sage: B = [(1, 'B1'), (2, 'B2'), (2, 'B3')]

sage: top = [(50, A, 'Group A'), (50, B, 'Group B')]

sage: normalize_prob_list(top)
[(0.250000000000000, 'A1', 'Group A'), (0.250000000000000, 'A2', 'Group A'), (0.1, 'B1', 'Group B'), (0.2, 'B2', 'Group B'), (0.2, 'B3', 'Group B')]
```
sage.symbolic.random_tests.random_expr(size, nvars=1, ncoeffs=None, var_frac=0.5, internal=[], internal=[(0.6, <built-in function add>), (0.3, <built-in function sub>), (0.3, <built-in function mult>), (0.2, <built-in function trueadd>), (0.1, <built-in function pow>), (0.2, [(0.8, <built-in function neg>), (0.2, <built-in function inv>), (0.2, <built-in function mul>), (0.1, <built-in function add>), (0.1, <built-in function sub>), (0.3, <built-in function mul>), (0.2, <built-in function trueadd>), (0.1, <built-in function add>), (0.2, <built-in function trueadd>), (0.1, Order, 1), (1.0, _swap_harmonic, 2), (1.0, abs, 1), (1.0, airy_ai, 1), (1.0, airy_ai_prime, 1), (1.0, airy_bi, 1), (1.0, airy_bi_prime, 1), (1.0, arccos, 1), (1.0, arccosh, 1), (1.0, arcctan, 1), (1.0, arcsec, 1), (1.0, arcsch, 1), (1.0, arcsech, 1), (1.0, arcsin, 1), (1.0, arcsinh, 1), (1.0, arctan, 1), (1.0, arctanh, 1), (1.0, arg, 1), (1.0, bessel_I, 2), (1.0, bessel_J, 2), (1.0, bessel_K, 2), (1.0, bessel_Y, 2), (1.0, beta, 2), (1.0, binomial, 2), (1.0, ceil, 1), (1.0, chebyshev_T, 2), (1.0, chebyshev_U, 2), (1.0, complex_root_of, 2), (1.0, conjugate, 1), (1.0, cos, 1), (1.0, cos_integral, 1), (1.0, cosh, 1), (1.0, cosh_integral, 1), (1.0, cot, 1), (1.0, coth, 1), (1.0, csch, 1), (1.0, dickman_rho, 1), (1.0, dilog, 1), (1.0, dirac_delta, 1), (1.0, elliptic_e, 2), (1.0, elliptic_ec, 1), (1.0, elliptic_en, 2), (1.0, elliptic_f, 2), (1.0, elliptic_kc, 1), (1.0, elliptic_pi, 3), (1.0, erf, 1), (1.0, erfc, 1), (1.0, erfci, 1), (1.0, exp, 1), (1.0, exp_integral_e, 2), (1.0, exp_integral_e1, 1), (1.0, exp_polar, 1), (1.0, factorial, 1), (1.0, floor, 1), (1.0, frac, 1), (1.0, fresnel_cos, 1), (1.0, fresnel_sin, 1), (1.0, gamma_inc_lower, 2), (1.0, gegenbauer, 3), (1.0, gen_laguerre, 3), (1.0, gen_legendre_P, 3), (1.0, gen_legendre_Q, 3), (1.0, hahn, 5), (1.0, hankel, 1), (1.0, hankel2, 2), (1.0, harmonic_number, 1), (1.0, hermite, 2), (1.0, hermite, 2), (1.0, hermite, 2), (1.0, hermite, 2), (1.0, hermite, 2), (1.0, hermite, 2), (1.0, hypergeometric_M, 3), (1.0, hypergeometric_U, 3), (1.0, imag_part, 1), (1.0, integrate, 4), (1.0, inverse_jacobi_cd, 2), (1.0, inverse_jacobi_cn, 2), (1.0, inverse_jacobi_cs, 2), (1.0, inverse_jacobi_dc, 2), (1.0, inverse_jacobi_dn, 2), (1.0, inverse_jacobi_ds, 2), (1.0, inverse_jacobi_nc, 2), (1.0, inverse_jacobi_nd, 2), (1.0, inverse_jacobi_sc, 2), (1.0, inverse_jacobi_sd, 2), (1.0, inverse_jacobi_sn, 2), (1.0, jacobian, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, jacobin, 1), (1.0, krawtchouk, 4), (1.0, kronecker_delta, 2), (1.0, laguerre, 2), (1.0, lambert_w, 2), (1.0, legendre_P, 2), (1.0, legendre_Q, 2), (1.0, log, 2), (1.0, log_gamma, 1), (1.0, log_integral, 1), (1.0, log_integral_offset, 1), (1.0, meijer_g, 4), (1.0, polylog, 2), (1.0, prime_pi, 1), (1.0, product, 4), (1.0, real_nth_root, 2), (1.0, real_part, 1), (1.0, sec, 1), (1.0, sech, 1), (1.0, sign, 1), (1.0, sin, 1), (1.0, sinh, 1), (1.0, sinh_integral, 1), (1.0, spherical_bessel_J, 2), (1.0, spherical_bessel_Y, 2), (1.0, spherical_hankel1, 2), (1.0, spherical_hankel2, 2), (1.0, spherical_harmonic, 4), (1.0, stieltjes, 1), (1.0, struve_H, 2), (1.0, struve_L, 2), (1.0, sum, 4), (1.0, tan, 1), (1.0, tanh, 1), (1.0, unit_step, 1), (1.0, zeta, 1), (1.0, zetaderiv, 2)], nullary=[], nullary=[(1.0, pi, 1.0, e), (0.05, golden_ratio), (0.05, log2), (0.05, euler_gamma), (0.05, catalan), (0.05, khinchin), (0.05, twinprime), (0.05, mertens)], nullary_frac=0.2, coeff_generator=<bound method RationalField.random_element of Rational Field>, verbose=False)
Produce a random symbolic expression of the given size. By default, the expression involves (at most) one variable, an arbitrary number of coefficients, and all of the symbolic functions and constants (from the probability lists full_internal and full_nullary). It is possible to adjust the ratio of leaves between symbolic constants, variables, and coefficients (var_frac gives the fraction of variables, and nullary_frac the fraction of symbolic constants; the remaining leaves are coefficients).

The actual mix of symbolic constants and internal nodes can be modified by specifying different probability lists.

To use a different type for coefficients, you can specify coeff_generator, which should be a function that will return a random coefficient every time it is called.

This function will often raise an error because it tries to create an erroneous expression (such as a division by zero).

EXAMPLES:

```python
sage: from sage.symbolic.random_tests import *
sage: some_functions = [arcsinh, arctan, arctan2, arctanh,
arg, beta, binomial, ceil, conjugate, cos, cosh, cot, coth,
ecnpi, erf, exp, factorial, floor, heaviside, imag_part,
sech, sgn, sin, sinh, tan, tanh, unit_step, zeta, zetaderiv]
sage: my_internal = [(0.6, full_binary, 2), (0.2, full_unary, 1),
(0.2, [(1.0,f,f.number_of_arguments()) for f in some_functions])]
sage: set_random_seed(1)
sage: random_expr(50, nvars=3, internal=my_internal,
(coeff_generator=CDF.random_element)
```

```
(continues on next page)
```

2.34. Randomized tests of GiNaC / PyNaC 383
Symbolic Calculus, Release 10.1

sage: all_exprs = set()
sage: for a in range(-4, 5):
    ....:     for b in range(-4-abs(a), 5-abs(a)):
    ....:         if a % 2 and abs(a) + abs(b) == 4 and sign(a) != sign(b):
    ....:             continue
    ....:         all_exprs.add(a*x + b)
sage: our_exprs = set()
sage: while our_exprs != all_exprs:
    ....:     our_exprs.add(next_expr())

sage.symbolic.random_tests.random_integer_vector(n, length)

Give a random list of length $length$, consisting of nonnegative integers that sum to $n$.

This is an approximation to IntegerVectors(n, length).random_element(). That gives values uniformly at random, but might be slow; this routine is not uniform, but should always be fast.

(This routine is uniform if $length$ is 1 or 2; for longer vectors, we prefer approximately balanced vectors, where all the values are around $n/length$.)

EXAMPLES:

sage: from sage.symbolic.random_tests import *
sage: a = random_integer_vector(100, 2); a  # random
[11, 89]
sage: len(a)
2
sage: sum(a)
100

sage: b = random_integer_vector(10000, 20)
sage: len(b)
20
sage: sum(b)
10000

The routine is uniform if $length$ is 2:

sage: true_count = 0
sage: total_count = 0
sage: def more_samples():
    ....:     global true_count, total_count
    ....:     for _ in range(1000):
    ....:         total_count += 1.0
    ....:         if a == random_integer_vector(100, 2):
    ....:             true_count += 1.0
sage: more_samples()
sage: while abs(true_count/total_count - 0.01) > 0.01:
    ....:     more_samples()

sage.symbolic.random_tests.test_symbolic_expression_order(repetitions=100)

Tests whether the comparison of random symbolic expressions satisfies the strict weak order axioms.

This is important because the C++ extension class uses std::sort() which requires a strict weak order. See also github issue #9880.
EXAMPLES:

```
sage: from sage.symbolic.random_tests import test_symbolic_expression_order
sage: test_symbolic_expression_order(200)
sage: test_symbolic_expression_order(10000)  # long time
```
