Symbolic Calculus

Release 10.0

The Sage Development Team

May 25, 2023
## CONTENTS

1 Using calculus  

2 Internal functionality supporting calculus  
   2.1 Symbolic Expressions  
   2.2 Callable Symbolic Expressions  
   2.3 Assumptions  
   2.4 Symbolic Equations and Inequalities  
   2.5 Symbolic Computation  
   2.6 Units of measurement  
   2.7 The symbolic ring  
   2.8 Subrings of the Symbolic Ring  
   2.9 Classes for symbolic functions  
   2.10 Factory for symbolic functions  
   2.11 Functional notation support for common calculus methods  
   2.12 Symbolic Integration  
   2.13 TESTS::  
   2.14 A Sample Session using SymPy  
   2.15 Conversion of symbolic expressions to other types  
   2.16 Complexity Measures  
   2.17 Further examples from Wester’s paper  
   2.18 Solving ordinary differential equations  
   2.19 Discrete Wavelet Transform  
   2.20 Discrete Fourier Transforms  
   2.21 Numerical Integration  
   2.22 Riemann Mapping  
   2.23 Access to Maxima methods  
   2.24 Operators  
   2.25 Substitution Maps  
   2.26 Randomized tests of GiNaC / PyNaC  

3 Indices and Tables  

i
Calculus is done using symbolic expressions which consist of symbols and numeric objects linked by operators (functions).

**Note:** While polynomial manipulation can be done with expressions, it is more efficient to use polynomial ring elements.
• **Symbolic Computation**

• **Examples**
  – *Calculus examples*
  – *Calculus Tests and Examples*
  – *Further examples from Wester’s paper*

• **More about symbolic variables and functions**

• **Main operations on symbolic expressions**

• **Assumptions about symbols and functions**

• **Symbolic Equations and Inequalities**

• **Symbolic Integration**

• **Solving ordinary differential equations**

• **Solving ODE numerically by GSL**

• **Numerical Integration**

• **Real Interpolation using GSL**

• **Transforms**
  – *Discrete Wavelet Transform*
  – *Discrete Fourier Transforms*
  – *Fast Fourier Transforms Using GSL*

• **Vector Calculus**

• **Riemann Mapping**

• **Other calculus functionality**

• **Complexity Measures**

• **Units of measurement**
INTERNAL FUNCTIONALITY SUPPORTING CALCULUS

- The symbolic ring
- Subrings of the Symbolic Ring
- Operators
- Classes for symbolic functions
- Functional notation support for common calculus methods
- Factory for symbolic functions
- Internals of Callable Symbolic Expressions
- Conversion of symbolic expressions to other types
- Substitution Maps
- Benchmarks
- Randomized tests of GiNaC / PyNaC
- Access to Maxima methods
- External integrators
- External interpolators

2.1 Symbolic Expressions

RELATIONAL EXPRESSIONS:

We create a relational expression:

```sage
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.subs(x == 5)
16 <= 18
```

Notice that squaring the relation squares both sides.

```sage
sage: eqn^2
(x - 1)^4 <= (x^2 - 2*x + 3)^2
sage: eqn.expand()
x^2 - 2*x + 1 <= x^2 - 2*x + 3
```

This can transform a true relation into a false one:
We can do arithmetic with relations:

```
sage: e = x+1 <= x-2
sage: e + 2
x + 3 <= x
sage: e - 1
x <= x - 3
sage: e*(-1)
-x - 1 <= -x + 2
sage: (-2)*e
-2*x - 2 <= -2*x + 4
sage: e^5
5*x + 5 <= 5*x - 10
sage: e/5
1/5*x + 1/5 <= 1/5*x - 2/5
sage: 5/e
typeError: incompatible relations
```

We can even add together two relations, as long as the operators are the same:

```
sage: (x^3 + x <= x - 17) + (-x <= x - 10)
x^3 <= 2*x - 27
```

Here they are not:

```
sage: (x^3 + x <= x - 17) + (-x >= x - 10)
Traceback (most recent call last):
...  
TypeError: incompatible relations
```

ARBITRARY SAGE ELEMENTS:

You can work symbolically with any Sage data type. This can lead to nonsense if the data type is strange, e.g., an element of a finite field (at present).

We mix Singular variables with symbolic variables:

```
sage: R.<u,v> = QQ[]
sage: var('a,b,c')
(a, b, c)
sage: expand((u + v + a + b + c)^2)
```

(continues on next page)
\[a^2 + 2a\cdot b + b^2 + 2a\cdot c + 2b\cdot c + c^2 + 2a\cdot u + 2b\cdot u + 2c\cdot u + u^2 + 2a\cdot v + 2b\cdot v + 2c\cdot v + 2u\cdot v + v^2\]

```python
class sage.symbolic.expression.E:
    Bases: Expression

    Dummy class to represent base of the natural logarithm.
    The base of the natural logarithm \(e\) is not a constant in GiNaC/Sage. It is represented by \(\exp(1)\).
    This class provides a dummy object that behaves well under addition, multiplication, etc. and on exponentiation calls the function \(\exp\).

    EXAMPLES:
    The constant defined at the top level is just \(\exp(1)\):

    ```
sage: e.operator()
    exp
    sage: e.operands()
    [1]
    ```
    Arithmetic works:

    ```
sage: e + 2
    e + 2
    sage: 2 + e
    e + 2
    sage: 2*e
    2*e
    sage: e^2
    2*e
    sage: x*e
    x*e
    sage: var('a,b')
    (a, b)
    sage: t = e^(a+b); t
    e^(a + b)
    sage: t.operands()
    [a + b]
    ```
    Numeric evaluation, conversion to other systems, and pickling works as expected. Note that these are properties of the \(\exp()\) function, not this class:

    ```
sage: RR(e)
    2.71828182845905
    sage: R = RealField(200); R
    Real Field with 200 bits of precision
    sage: R(e)
    2.71828182845904523536028747135266249775724709369999595749670
    sage: em = 1 + e^(1-e); em
    e^(e - 1) + 1
    sage: R(em)
    1.1793740787336111142547078259208511629102700303930668622020
    sage: maxima(e).float()...
    ```

(continues on next page)
class sage.symbolic.expression.Expression

Bases: Expression

Nearly all expressions are created by calling new_Expression_from_*, but we need to make sure this at least does not leave self._gobj uninitialized and segfault.

Order(hold=False)

Return the order of the expression, as in big oh notation.

OUTPUT:

A symbolic expression.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & n = \text{var}'(n)' \\
\text{sage: } & t = (17^n n^3).\text{Order}(); t \\
& \text{Order}(n^3) \\
\text{sage: } & t.\text{derivative}(n) \\
& \text{Order}(n^2)
\end{align*}
\]

To prevent automatic evaluation use the hold argument:

\[
\begin{align*}
\text{sage: } & (17^n n^3).\text{Order}(\text{hold=}\text{True}) \\
& \text{Order}(17^n n^3)
\end{align*}
\]

WZ_certificate(n, k)

Return the Wilf-Zeilberger certificate for this hypergeometric summand in n, k.

To prove the identity \[ \sum_k F(n, k) = \text{const it suffices to show that } F(n + 1, k) - F(n, k) = G(n, k + 1) - G(n, k), \] with \[ G = RF \] and \( R \) the WZ certificate.

EXAMPLES:

To show that \[ \sum_k \binom{n}{k} = 2^n \] do:
Symbolic Calculus, Release 10.0

```python
sage: _ = var('k n')
sage: F(n,k) = binomial(n,k) / 2^n
c
sage: G(n,k) = c * F(n,k); G
(n, k) |--> 1/2*k*binomial(n, k)/(2^n*(k - n - 1))
sage: (F(n+1,k) - F(n,k) - G(n,k+1) + G(n,k)).simplify_full()
0
```

```
abs

Return the absolute value of this expression.

EXAMPLES:

```python
sage: var('x, y')
(x, y)
sage: (x+y).abs()
abs(x + y)
```

Using the hold parameter it is possible to prevent automatic evaluation:

```python
sage: SR(-5).abs(hold=True)
abs(-5)
```

To then evaluate again, we use unhold():

```python
sage: a = SR(-5).abs(hold=True); a.unhold()
5
```

```
add

Return the sum of the current expression and the given arguments.

To prevent automatic evaluation use the hold argument.

EXAMPLES:

```python
sage: x.add(x)
2*x
sage: x.add(x, hold=True)
x + x
sage: x.add(x, (2+x), hold=True)
(x + 2) + x + x
sage: x.add(x, (2+x), x, hold=True)
(x + 2) + x + x + x
sage: x.add(x, (2+x), x, 2*x, hold=True)
(x + 2) + 2*x + x + x + x
```

To then evaluate again, we use unhold():

```python
sage: a = x.add(x, hold=True); a.unhold()
2*x
```

```
add_to_both_sides

Return a relation obtained by adding x to both sides of this relation.

EXAMPLES:
```

2.1. Symbolic Expressions
Symbolic Calculus, Release 10.0

sage: var('x y z')
(x, y, z)

sage: eqn = x^2 + y^2 + z^2 <= 1
sage: eqn.add_to_both_sides(-z^2)
x^2 + y^2 <= -z^2 + 1
sage: eqn.add_to_both_sides(I)
x^2 + y^2 + z^2 + I <= (I + 1)

arccos(hold=False)
Return the arc cosine of self.

EXAMPLES:

sage: x.arccos()
arccos(x)
sage: SR(1).arccos()
0
sage: SR(1/2).arccos()
1/3*pi
sage: SR(0.4).arccos()
1.15927948072741
sage: plot(lambda x: SR(x).arccos(), -1,1)
Graphics object consisting of 1 graphics primitive

To prevent automatic evaluation use the hold argument:

sage: SR(1).arccos(hold=True)
arccos(1)

This also works using functional notation:

sage: arccos(1,hold=True)
arccosh(1)
sage: arccosh(1)
0

To then evaluate again, we use unhold():

sage: a = SR(1).arccos(hold=True); a.unhold()
0

arccosh(hold=False)
Return the inverse hyperbolic cosine of self.

EXAMPLES:

sage: x.arccosh()
arccosh(x)
sage: SR(0).arccosh()
1/2*I*pi
sage: SR(1/2).arccosh()
arccosh(1/2)
sage: SR(CDF(1/2)).arccosh() # rel tol 1e-15
1.0471975511965976*I

(continues on next page)
To prevent automatic evaluation use the hold argument:

```
sage: SR(-1).arccosh()
I*pi
sage: SR(-1).arccosh(hold=True)
arccosh(-1)
```

This also works using functional notation:

```
sage: arccosh(-1,hold=True)
arccosh(-1)
sage: arccosh(-1)
I*pi
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(-1).arccosh(hold=True); a.unhold()
I*pi
```

```
arcsin

Return the arcsin of x, i.e., the number y between -pi and pi such that sin(y) == x.

EXAMPLES:

```
sage: x.arcsin()
arcsin(x)
sage: SR(0.5).arcsin()
1/6*pi
sage: SR(0.999).arcsin()
1.52607123962616
sage: SR(1/3).arcsin()
arcsin(1/3)
sage: SR(-1/3).arcsin()
-arcsin(1/3)
```

To prevent automatic evaluation use the hold argument:

```
sage: SR(0).arcsin()
0
sage: SR(0).arcsin(hold=True)
arcsin(0)
```

This also works using functional notation:

```
sage: arcsin(0,hold=True)
arcsin(0)
sage: arcsin(0)
0
```

To then evaluate again, we use `unhold()`:

```
2.1. Symbolic Expressions

11
```
arcsinh\,(\text{hold}=\text{False})

Return the inverse hyperbolic sine of self.

EXAMPLES:

\begin{verbatim}
 sage: x.arcsinh()
arcsinh(x)
sage: SR(0).arcsinh()
0
sage: SR(1).arcsinh()
arcsinh(1)
sage: SR(1.0).arcsinh()
0.881373587019543
sage: maxima('asinh(2.0)')
1.4436354751788...
\end{verbatim}

Sage automatically applies certain identities:

\begin{verbatim}
 sage: SR(3/2).arcsinh().cosh()
1/2*sqrt(13)
\end{verbatim}

To prevent automatic evaluation use the \text{hold} argument:

\begin{verbatim}
 sage: SR(-2).arcsinh()
-arcsinh(2)
sage: SR(-2).arcsinh(hold=True)
arcsinh(-2)
\end{verbatim}

This also works using functional notation:

\begin{verbatim}
 sage: arcsinh(-2,hold=True)
arcsinh(-2)
sage: arcsinh(-2)
-arcsinh(2)
\end{verbatim}

To then evaluate again, we use \text{unhold()}:

\begin{verbatim}
 sage: a = SR(-2).arcsinh(hold=True); a.unhold()
-arcsinh(2)
\end{verbatim}

arctan\,(\text{hold}=\text{False})

Return the arc tangent of self.

EXAMPLES:

\begin{verbatim}
 sage: x = var('x')
sage: x.arctan()
arctan(x)
sage: SR(1).arctan()
1/4*pi
sage: SR(1/2).arctan()
\end{verbatim}

(continues on next page)
arctan(1/2)
sage: SR(0.5).arctan()
0.463647609000806
sage: plot(lambda x: SR(x).arctan(), -20,20)
Graphics object consisting of 1 graphics primitive

To prevent automatic evaluation use the hold argument:

sage: SR(1).arctan(hold=True)
arctan(1)

This also works using functional notation:

sage: arctan(1,hold=True)
arctan(1)
sage: arctan(1)
1/4*pi

To then evaluate again, we use unhold():

sage: a = SR(1).arctan(hold=True); a.unhold()
1/4*pi

arctan2(x, hold=False)

Return the inverse of the 2-variable tan function on self and x.

EXAMPLES:

sage: var('x,y')
(x, y)
sage: x.arctan2(y)
arctan2(x, y)
sage: SR(1/2).arctan2(1/2)
1/4*pi
sage: maxima.eval('atan2(1/2,1/2)')
'(%pi/4'
sage: SR(-0.7).arctan2(SR(-0.6))
-2.27942259892257

To prevent automatic evaluation use the hold argument:

sage: SR(1/2).arctan2(1/2, hold=True)
arctan2(1/2, 1/2)

This also works using functional notation:

sage: arctan2(1,2,hold=True)
arctan2(1, 2)
sage: arctan2(1,2)
arctan(1/2)

To then evaluate again, we use unhold():

2.1. Symbolic Expressions
Symbolic Calculus, Release 10.0

\[ \text{sage: } a = \text{SR}(1/2).\text{arctan2}(1/2, \text{hold=}\text{True}); \text{a.unhold()} \]
\[ 1/4*\pi \]

\text{arctanh}(\text{hold=False})

Return the inverse hyperbolic tangent of self.

\text{EXAMPLES:}

\[ \text{sage: } x.\text{arctanh()} \]
\[ \text{arctanh}(x) \]
\[ \text{sage: } \text{SR}(0).\text{arctanh()} \]
\[ @ \]
\[ \text{sage: } \text{SR}(1/2).\text{arctanh()} \]
\[ 1/2*\log(3) \]
\[ \text{sage: } \text{SR}(0.5).\text{arctanh()} \]
\[ 0.549306144334055 \]
\[ \text{sage: } \text{SR}(0.5).\text{arctanh().tanh()} \]
\[ 0.500000000000000 \]
\[ \text{sage: } \text{maxima('atanh(0.5)')} \]  # abs tol 2e-16
\[ 0.5493061443340548 \]

To prevent automatic evaluation use the hold argument:

\[ \text{sage: } \text{SR}(-1/2).\text{arctanh()} \]
\[ -1/2*\log(3) \]
\[ \text{sage: } \text{SR}(-1/2).\text{arctanh(hold=} \text{True}) \]
\[ \text{arctanh}(-1/2) \]

This also works using functional notation:

\[ \text{sage: } \text{arctanh}(-1/2, \text{hold=} \text{True}) \]
\[ \text{arctanh}(-1/2) \]
\[ \text{sage: } \text{arctanh}(-1/2) \]
\[ -1/2*\log(3) \]

To then evaluate again, we use \text{unhold}():

\[ \text{sage: } \text{a = SR}(-1/2).\text{arctanh(hold=} \text{True}); \text{a.unhold()} \]
\[ -1/2*\log(3) \]

\text{args}()

\text{EXAMPLES:}

\[ \text{sage: } x,y = \text{var('x,y')} \]
\[ \text{sage: } f = x + y \]
\[ \text{sage: } f.\text{arguments()} \]
\[ (x, y) \]
\[ \text{sage: } g = f.\text{function}(x) \]
\[ \text{sage: } g.\text{arguments()} \]
\[ (x,) \]

\text{arguments}()

\text{EXAMPLES:}
Symbolic Calculus, Release 10.0

\begin{verbatim}
sage: x, y = var('x, y')
sage: f = x + y
sage: f.arguments()
(x, y)
sage: g = f.function(x)
sage: g.arguments()
(x,)

assume()

Assume that this equation holds. This is relevant for symbolic integration, among other things.

EXAMPLES: We call the assume method to assume that \( x > 2 \):

\begin{verbatim}
sage: (x > 2).assume()

 Bool returns True below if the inequality is \textit{definitely} known to be True.

\begin{verbatim}
sage: bool(x > 0)
True
sage: bool(x < 0)
False
\end{verbatim}

This may or may not be True, so bool returns False:

\begin{verbatim}
sage: bool(x > 3)
False
\end{verbatim}

If you make inconsistent or meaningless assumptions, Sage will let you know:

\begin{verbatim}
sage: forget()
sage: assume(x<0)
sage: assume(x>0)
Traceback (most recent call last):
  ...
ValueError: Assumption is inconsistent
sage: assumptions()
[x < 0]
sage: forget()
\end{verbatim}

\texttt{binomial}(k, hold=False)

Return binomial coefficient “self choose k”.

OUTPUT:
A symbolic expression.

EXAMPLES:

\begin{verbatim}
sage: var('x, y')
(x, y)
sage: SR(5).binomial(SR(3))
10
sage: x.binomial(SR(3))
1/6*(x - 1)*(x - 2)*x
\end{verbatim}
\end{verbatim}

(continues on next page)

2.1. Symbolic Expressions 15

To prevent automatic evaluation use the `hold` argument:

```
sage: x.binomial(3, hold=True)
binomial(x, 3)
sage: SR(5).binomial(3, hold=True)
binomial(5, 3)
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(5).binomial(3, hold=True); a.unhold()
10
```

The `hold` parameter is also supported in functional notation:

```
sage: binomial(5,3, hold=True)
binomial(5, 3)
```

### canonicalize_radical()

Choose a canonical branch of the given expression.

The square root, cube root, natural log, etc. functions are multi-valued. The `canonicalize_radical()` method will choose one of these values based on a heuristic.

For example, \( \sqrt{x^2} \) has two values: \( x \), and \( -x \). The `canonicalize_radical()` function will choose one of them, consistently, based on the behavior of the expression as \( x \) tends to positive infinity. The solution chosen is the one which exhibits this same behavior. Since \( \sqrt{x^2} \) approaches positive infinity as \( x \) does, the solution chosen is \( x \) (which also tends to positive infinity).

**Warning:** As shown in the examples below, a canonical form is not always returned, i.e., two mathematically identical expressions might be converted to different expressions.

Assumptions are not taken into account during the transformation. This may result in a branch choice inconsistent with your assumptions.

**ALGORITHM:**

This uses the Maxima `radcan()` command. From the Maxima documentation:

Simplifies an expression, which can contain logs, exponentials, and radicals, by converting it into a form which is canonical over a large class of expressions and a given ordering of variables; that is, all functionally equivalent forms are mapped into a unique form. For a somewhat larger class of expressions, radcan produces a regular form. Two equivalent expressions in this class do not necessarily have the same appearance, but their difference can be simplified by radcan to zero.

For some expressions radcan is quite time consuming. This is the cost of exploring certain relationships among the components of the expression for simplifications based on factoring and partial fraction expansions of exponents.

**EXAMPLES:**

`canonicalize_radical()` can perform some of the same manipulations as `log_expand()`:
Symbolic Calculus, Release 10.0

sage: y = SR.symbol('y')
sage: f = log(x*y)
sage: f.log_expand()
log(x) + log(y)
sage: f.canonicalize_radical()
log(x) + log(y)

And also handles some exponential functions:

sage: f = (e^x-1)/(1+e^(x/2))
sage: f.canonicalize_radical()
e^(1/2*x) - 1

It can also be used to change the base of a logarithm when the arguments to \log() are positive real numbers:

sage: f = log(8)/log(2)
sage: f.canonicalize_radical()
3

The simplest example of counter-intuitive behavior is what happens when we take the square root of a square:

sage: sqrt(x^2).canonicalize_radical()
x

If you don’t want this kind of “simplification,” don’t use canonicalize_radical().

This behavior can also be triggered when the expression under the radical is not given explicitly as a square:

sage: sqrt(x^2 - 2*x + 1).canonicalize_radical()
x - 1

Another place where this can become confusing is with logarithms of complex numbers. Suppose \( x \) is complex with \( x = r*e^{(I*t)} \) (r real). Then \( \log(x) = \log(r) + I*(t + 2*k*pi) \) for some integer \( k \).

Calling canonicalize_radical() will choose a branch, eliminating the solutions for all choices of \( k \) but one. Simplified by hand, the expression below is \( (1/2)*log(2) + I*pi*k \) for integer \( k \). However, canonicalize_radical() will take each log expression, and choose one particular solution, dropping the other. When the results are subtracted, we’re left with no imaginary part:

sage: f = (1/2)*log(2^x) + (1/2)*log(1/x)
sage: f.canonicalize_radical()
1/2*log(2)

Naturally the result is wrong for some choices of \( x \):

sage: f(x = -1)
I*pi + 1/2*log(2)

2.1. Symbolic Expressions 17
The example below shows two expressions e1 and e2 which are “simplified” to different expressions, while their difference is “simplified” to zero; thus canonicalize_radical() does not return a canonical form:

```sage
sage: e1 = 1/(sqrt(5)+sqrt(2))
sage: e2 = (sqrt(5)-sqrt(2))/3
sage: e1.canonicalize_radical()
1/(sqrt(5) + sqrt(2))
sage: e2.canonicalize_radical()
1/3*sqrt(5) - 1/3*sqrt(2)
sage: (e1-e2).canonicalize_radical()
0
```

The issue reported in github issue #3520 is a case where canonicalize_radical() causes a numerical integral to be calculated incorrectly:

```sage
sage: f1 = sqrt(25 - x) * sqrt( 1 + 1/(4*(25-x)) )
sage: f2 = f1.canonicalize_radical()
sage: numerical_integral(f1.real(), 0, 1)[0] # abs tol 1e-10
4.974852579915647
sage: numerical_integral(f2.real(), 0, 1)[0] # abs tol 1e-10
-4.974852579915647
```

**coefficient**(s, n=1)

Return the coefficient of \( s^n \) in this symbolic expression.

**INPUT:**

- s - expression
- n - expression, default 1

**OUTPUT:**

A symbolic expression. The coefficient of \( s^n \).

Sometimes it may be necessary to expand or factor first, since this is not done automatically.

**EXAMPLES:**

```sage
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.collect(x)
x^3*sin(x*y) + (a + y + 1/y)*x + 2*sin(x*y)/x + 100
sage: f.coefficient(x,0)
100
sage: f.coefficient(x,-1)
2*sin(x*y)
sage: f.coefficient(x,1)
a + y + 1/y
sage: f.coefficient(x,2)
0
sage: f.coefficient(x,3)
sin(x*y)
sage: f.coefficient(x^3)
sin(x*y)
```

(continues on next page)
sage: f.coefficient(sin(x*y))
x^3 + 2/x
sage: f.collect(sin(x*y))
a*x + x*y + (x^3 + 2/x)*sin(x*y) + x/y + 100
sage: var('a, x, y, z')
(a, x, y, z)
sage: f = (a*sqrt(2))*x^2 + sin(y)*x^(1/2) + z^z
sage: f.coefficient(sin(y))
sqrt(x)
sage: f.coefficient(x^2)
sqrt(2)*a
sage: f.coefficient(x^(1/2))
sin(y)
sage: f.coefficient(1)
0
sage: f.coefficient(x, 0)
z^z

Any coefficient can be queried:

sage: (x^2 + 3*x^pi).coefficient(x, pi)
3
sage: (2^x + 5*x^x).coefficient(x, x)
5

coefficients(x=None, sparse=True)
Return the coefficients of this symbolic expression as a polynomial in x.

INPUT:
• x – optional variable.

OUTPUT:
Depending on the value of sparse,
• A list of pairs (expr, n), where expr is a symbolic expression and n is a power (sparse=True, default)
• A list of expressions where the n-th element is the coefficient of x^n when self is seen as polynomial in x (sparse=False).

EXAMPLES:

sage: var('x, y, a')
(x, y, a)
sage: p = x^3 - (x-3)*(x^2+x) + 1
sage: p.coefficients()
[[1, 0], [3, 1], [2, 2]]
sage: p.coefficients(sparse=False)
[1, 3, 2]
sage: p = x - x^3 + 5/7*x^5
sage: p.coefficients()
[[1, 1], [-1, 3], [5/7, 5]]
sage: p.coefficients(sparse=False)
\[0, 1, 0, -1, 0, 5/7\]  
\[
\text{sage: } p = \text{expand}((x-a*\sqrt{2})^2 + x + 1); p  
-2*a*\sqrt{2}*x + 2*a^2 + x^2 + x + 1
\]
\[
\text{sage: } p.\text{coefficients}(a)  
[[x^2 + x + 1, 0], [-2*\sqrt{2}*a, 1], [2, 2]]
\]
\[
\text{sage: } p.\text{coefficients}(a, \text{sparse}=\text{False})  
[x^2 + x + 1, -2*\sqrt{2}*a, 2]
\]
\[
\text{sage: } p.\text{coefficients}(x)  
[[2*a^2 + 1, 0], [-2*\sqrt{2}*a + 1, 1], [1, 2]]
\]
\[
\text{sage: } p.\text{coefficients}(x, \text{sparse}=\text{False})  
[2*a^2 + 1, -2*\sqrt{2}*a + 1, 1]
\]

\section*{collect($s$)}

Collect the coefficients of $s$ into a group.

\textbf{INPUT:}

- $s$ – the symbol whose coefficients will be collected.

\textbf{OUTPUT:}

A new expression, equivalent to the original one, with the coefficients of $s$ grouped.

\textbf{Note:} The expression is not expanded or factored before the grouping takes place. For best results, call \textit{expand()} on the expression before \textit{collect()}.  

\textbf{EXAMPLES:}

In the first term of $f$, $x$ has a coefficient of $4y$. In the second term, $x$ has a coefficient of $z$. Therefore, if we collect those coefficients, $x$ will have a coefficient of $4y + z$:

\[
\text{sage: } x,y,z = \text{var}(\text{'}x,y,z\text{')}
\]
\[
\text{sage: } f = 4*x*y + x*z + 20*y^2 + 21*y*z + 4*z^2 + x^2*y^2*z^2
\]
\[
\text{sage: } f.\text{collect}(x)
\]
\[
x^2*y^2*z^2 + x*(4*y + z) + 20*y^2 + 21*y*z + 4*z^2
\]

Here we do the same thing for $y$ and $z$; however, note that we do not factor the $y^2$ and $z^2$ terms before collecting coefficients:

\[
\text{sage: } f.\text{collect}(y)
\]
\[
(x^2*z^2 + 20)*y^2 + (4*x + 21*z)*y + x*z + 4*z^2
\]
\[
\text{sage: } f.\text{collect}(z)
\]
\[
(x^2*y^2 + 4)*z^2 + x*(4*y + z) + 20*y^2 + 21*y*z + 4*z^2
\]

The terms are collected, whether the expression is expanded or not:

\[
\text{sage: } f = (x + y)^*(x - z)
\]
\[
\text{sage: } f.\text{collect}(x)
\]
\[
x^4 - x*(y - z)^2 - y*z
\]
\[
\text{sage: } f.\text{expand().collect}(x)
\]
\[
x^4 - x*(y - z)^2 - y*z
\]

\section*{collect_common_factors()}

This function does not perform a full factorization but only looks for factors which are already explicitly present.
Polynomials can often be brought into a more compact form by collecting common factors from the terms of sums. This is accomplished by this function.

**EXAMPLES:**

```python
sage: var('x')
x
sage: (x/(x^2 + x)).collect_common_factors()
1/(x + 1)
```

```python
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: (a*x+a*y).collect_common_factors()
a*(x + y)
sage: (a*x^2+2*a*x*y+a*y^2).collect_common_factors()
(x^2 + 2*x*y + y^2)*a
sage: (a*(b*(a+c)*x+b*((a+c)*x+(a+c)*y)*y)).collect_common_factors()
((x + y)*y + x)*(a + c)*a*b
```

**combine** *(deep=False)*

Return a simplified version of this symbolic expression by combining all toplevel terms with the same denominator into a single term.

Please use the keyword **deep=True** to apply the process recursively.

**EXAMPLES:**

```python
sage: var('x, y, a, b, c')
(x, y, a, b, c)
sage: f = x*(x-1)/(x^2 - 7) + y^2/(x^2-7) + 1/(x+1) + b/a + c/a; f
(x - 1)*x/(x^2 - 7) + y^2/(x^2 - 7) + b/a + c/a + 1/(x + 1)
sage: f.combine()
((x - 1)*x + y^2)/(x^2 - 7) + (b + c)/a + 1/(x + 1)
sage: (1/x + 1/x^2 + (x+1)/x).combine()
(x + 2)/x + 1/x^2
```

```python
sage: ex = 1/x + ((x + 1)/x - 1/x)/x^2 + (x+1)/x; ex
1/x + ((x + 1)/x - 1/x)/x^2 + (x+1)/x
sage: ex.combine(deep=True)
(x + 2)/x + 1/x^2
sage: (1+sin((x + 1)/x - 1/x)).combine(deep=True)
sin(1) + 1
```

**conjugate** *(hold=False)*

Return the complex conjugate of this symbolic expression.

**EXAMPLES:**

```python
sage: a = 1 + 2*I
sage: a.conjugate()
-2*I + 1
```

```python
sage: a = sqrt(2) + 3^(1/3)*I; a
sqrt(2) + I*3^(1/3)
sage: a.conjugate()
```

(continues on next page)
Using the \texttt{hold} parameter it is possible to prevent automatic evaluation:

\begin{Verbatim}
sage: SR(I).conjugate(hold=True)
conjugate(I)
\end{Verbatim}

This also works in functional notation:

\begin{Verbatim}
sage: conjugate(I)
-I
sage: conjugate(I,hold=True)
conjugate(I)
\end{Verbatim}

To then evaluate again, we use \texttt{unhold()}:

\begin{Verbatim}
sage: a = SR(I).conjugate(hold=True); a.unhold()
-I
\end{Verbatim}

\texttt{content(s)}

Return the content of this expression when considered as a polynomial in \(s\).

See also \texttt{unit()}, \texttt{primitive_part()}, and \texttt{unit_content_primitive()}.

INPUT:

\begin{itemize}
  \item \(s\) – a symbolic expression.
\end{itemize}

OUTPUT:

The content part of a polynomial as a symbolic expression. It is defined as the \texttt{gcd} of the coefficients.

\textbf{Warning:} The expression is considered to be a univariate polynomial in \(s\). The output is different from the \texttt{content()} method provided by multivariate polynomial rings in Sage.

\textbf{EXAMPLES:}

\begin{Verbatim}
sage: (2*x+4).content(x)
2
sage: (2*x+1).content(x)
1
\end{Verbatim}
Symbolic Calculus, Release 10.0

(continued from previous page)

```python
sage: (2*x+1/2).content(x)
1/2
sage: var('y')
y
sage: (2*x + 4*sin(y)).content(sin(y))
2
```

**contradicts(soln)**

Return True if this relation is violated by the given variable assignment(s).

EXAMPLES:

```python
sage: (x<3).contradicts(x==0)
False
sage: (x<3).contradicts(x==3)
True
sage: (x<=3).contradicts(x==3)
False
sage: y = var('y')
sage: (x<y).contradicts(x==30)
False
sage: (x<y).contradicts({x: 30, y: 20})
True
```

**convert(target=None)**

Call the convert function in the units package. For symbolic variables that are not units, this function just returns the variable.

INPUT:

- **self** – the symbolic expression converting from
- **target** – (default None) the symbolic expression converting to

OUTPUT:

A symbolic expression.

EXAMPLES:

```python
sage: units.length.foot.convert()
381/1250*meter
sage: units.mass.kilogram.convert(units.mass.pound)
100000000/45359237*pound
```

We do not get anything new by converting an ordinary symbolic variable:

```python
sage: a = var('a')
sage: a - a.convert()
0
```

Raises ValueError if self and target are not convertible:

```python
sage: units.mass.kilogram.convert(units.length.foot)
Traceback (most recent call last):
  ...
Recognizes derived unit relationships to base units and other derived units:

```python
sage: (units.length.foot/units.time.second^2).convert(units.acceleration.galileo)
762/25*galileo
sage: (units.mass.kilogram*units.length.meter/units.time.second^2).convert(units.force.newton)
newton
sage: (units.length.foot^3).convert(units.area.acre*units.length.inch)
1/3630*(acre*inch)
```

For decimal answers multiply by 1.0:

```python
sage: (units.pressure.pascal*units.si_prefixes.kilo).convert(units.pressure.pounds_per_square_inch)*1.0
0.145037737730209*pounds_per_square_inch
```

Converting temperatures works as well:

```python
sage: s = 68*units.temperature.fahrenheit
sage: s.convert(units.temperature.celsius)
20*celsius
sage: s.convert()
293.150000000000*kelvin
```

Trying to multiply temperatures by another unit then converting raises a ValueError:

```python
sage: wrong = 50*units.temperature.celsius*units.length.foot
sage: wrong.convert()
Traceback (most recent call last):
  ... ValueError: cannot convert
```

```
(continues on previous page)
```
Symbolic Calculus, Release 10.0

(continued from previous page)

\[\text{sage}: \cos(\text{sage}.\text{symbolic}.\text{constants}.\pi)\]
\[-1\]
\[\text{sage}: \cos(\text{SR}(1))\]
\[\cos(1)\]
\[\text{sage}: \cos(\text{SR}(\text{RealField}(150)(1)))\]
\[0.54030230586813971740093660744297660373231042\]

In order to get a numeric approximation use .n():

\[\text{sage}: \text{SR}(\text{RR}(1)).\cos().\text{n}()\]
\[0.540302305868140\]
\[\text{sage}: \text{SR}(\text{float}(1)).\cos().\text{n}()\]
\[0.540302305868140\]

To prevent automatic evaluation use the \text{hold} argument:

\[\text{sage}: \pi.\cos()\]
\[-1\]
\[\text{sage}: \pi.\cos(\text{hold}=\text{True})\]
\[\cos(\pi)\]

This also works using functional notation:

\[\text{sage}: \cos(\pi,\text{hold}=\text{True})\]
\[\cos(\pi)\]
\[\text{sage}: \cos(\pi)\]
\[-1\]

To then evaluate again, we use \text{unhold}():

\[\text{sage}: a = \pi.\cos(\text{hold}=\text{True}); a.\text{unhold}()\]
\[-1\]

\text{cosh}(\text{hold}=\text{False})

Return \cosh of self.

We have \(\cosh(x) = \frac{e^x + e^{-x}}{2}\).

\text{EXAMPLES:}

\[\text{sage}: x.\cosh()\]
\[\cosh(x)\]
\[\text{sage}: \text{SR}(1).\cosh()\]
\[\cosh(1)\]
\[\text{sage}: \text{SR}(0).\cosh()\]
\[1\]
\[\text{sage}: \text{SR}(1.0).\cosh()\]
\[1.54308063481524\]
\[\text{sage}: \text{maxima}'(\text{cosh}(1.0))'\]
\[1.54308063481524\]
\[\text{sage}: \text{SR}(1.00000000000000000000000000).\cosh()\]
\[1.543080634815243784779056\]
\[\text{sage}: \text{SR}(\text{RIF}(1)).\cosh()\]
\[1.5430806348152447\]
To prevent automatic evaluation use the \texttt{hold} argument:

\begin{verbatim}
sage: arcsinh(x).cosh()
sqrt(x^2 + 1)
sage: arcsinh(x).cosh(hold=True)
cosh(arcsinh(x))
\end{verbatim}

This also works using functional notation:

\begin{verbatim}
sage: cosh(arcsinh(x),hold=True)
cosh(arcsinh(x))
sage: cosh(arcsinh(x))
sqrt(x^2 + 1)
\end{verbatim}

To then evaluate again, we use \texttt{unhold()}:

\begin{verbatim}
sage: a = arcsinh(x).cosh(hold=True); a.unhold()
sqrt(x^2 + 1)
\end{verbatim}

\texttt{csgn(hold=False)}

Return the sign of self, which is \(-1\) if self < 0, 0 if self == 0, and 1 if self > 0, or unevaluated when self is a nonconstant symbolic expression.

If self is not real, return the complex half-plane (left or right) in which the number lies. If self is pure imaginary, return the sign of the imaginary part of self.

EXAMPLES:

\begin{verbatim}
sage: x = var('x')
sage: SR(-2).csgn()
-1
sage: SR(0.0).csgn()
0
sage: SR(10).csgn()
1
sage: x.csgn()
csgn(x)
sage: SR(CDF.0).csgn()
1
sage: SR(I).csgn()
1
sage: SR(-I).csgn()
-1
sage: SR(1+I).csgn()
1
sage: SR(1-I).csgn()
1
sage: SR(-1+I).csgn()
-1
sage: SR(-1-I).csgn()
-1
\end{verbatim}

Using the \texttt{hold} parameter it is possible to prevent automatic evaluation:
decl_assume

decl_forget

default_variable()

Return the default variable, which is by definition the first variable in self, or \( x \) is there are no variables in self. The result is cached.

EXAMPLES:

```sage
sage: sqrt(2).default_variable()
x
sage: x, theta, a = var('x, theta, a')
sage: f = x^2 + theta^3 - a*x
sage: f.default_variable()
a
```

Note that this is the first variable, not the first argument:

```sage
sage: f(theta, a, x) = a + theta^3
sage: f.default_variable()
a
sage: f.variables()
(a, theta)
sage: f.arguments()
(theta, a, x)
```

degree(s)

Return the exponent of the highest power of \( s \) in self.

OUTPUT:

An integer

EXAMPLES:

```sage
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y^10 + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + 2*sin(x*y)/x + x/y^10 + 100
sage: f.degree(x)
3
sage: f.degree(y)
1
sage: f.degree(sin(x*y))
1
sage: (x^3+y).degree(x)
0
sage: (1/x+1/x**2).degree(x)
-1
```
demoivre(force=False)

Return this symbolic expression with complex exponentials (optionally all exponentials) replaced by (at least partially) trigonometric/hyperbolic expressions.

EXAMPLES:

```python
sage: x, a, b = SR.var("x, a, b")
sage: exp(a + I*b).demoivre()
(cos(b) + I*sin(b))*e^a
sage: exp(I*x).demoivre()
cos(x) + I*sin(x)
sage: exp(x).demoivre(force=True)
cosh(x) + sinh(x)
```

denominator(normalize=True)

Return the denominator of this symbolic expression

INPUT:

- **normalize** – (default: True) a boolean.

If normalize is True, the expression is first normalized to have it as a fraction before getting the denominator.

If normalize is False, the expression is kept and if it is not a quotient, then this will just return 1.

See also:

normalize(), numerator(), numerator_denominator(), combine()

EXAMPLES:

```python
sage: x, y, z, theta = var('x, y, z, theta')
sage: f = (sqrt(x) + sqrt(y) + sqrt(z))/(x^10 - y^10 - sqrt(theta))
sage: f.numerator()
sqrt(x) + sqrt(y) + sqrt(z)
sage: f.denominator()
x^10 - y^10 - sqrt(theta)
sage: f.numerator(normalize=False)
(sqrt(x) + sqrt(y) + sqrt(z))
sage: f.denominator(normalize=False)
x^10 - y^10 - sqrt(theta)
sage: y = var('y')
sage: g = x + y/(x + 2); g
x + y/(x + 2)
sage: g.numerator(normalize=False)
x + y/(x + 2)
sage: g.denominator(normalize=False)
1
```

derivative(*args)

Return the derivative of this expressions with respect to the variables supplied in args.
Multiple variables and iteration counts may be supplied; see documentation for the global \texttt{derivative()} function for more details.

\textbf{See also:}

This is implemented in the \texttt{\_derivative} method (see the source code).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
t(x^2 + y)^2
t.derivative(x)
4*(x^2 + y)*x
t.derivative(x, 2)
12*x^2 + 4*y
t.derivative(x, 2, y)
4
t.derivative(y)
2*x^2 + 2*y
\end{verbatim}

If the function depends on only one variable, you may omit the variable. Giving just a number (for the order of the derivative) also works:

\begin{verbatim}
sage: f(x) = x^3 + sin(x)
f(x) = x^3 + sin(x)
sage: f.derivative()
x |--> 3*x^2 + cos(x)
sage: f.derivative(2)
x |--> 6*x - sin(x)
\end{verbatim}

Some expressions can’t be cleanly differentiated by the chain rule:

\begin{verbatim}
sage: _ = var(‘x’, domain=’real’) _ = var(‘w z’) (x*z).conjugate().diff(x) conjugate(x^(z - 1))*(conjugate(z) sage: (w*z).conjugate().diff(w) w^(z - 1)*z*D[0](conjugate)(w*z) sage: atanh(x).real_part().diff(x) -1/(x^2 - 1) sage: atanh(x).imag_part().diff(x) 0 sage: atanh(w).real_part().diff(w) -D[0](real_part)(arctanh(w))/(w^2 - 1) sage: atanh(w).imag_part().diff(w) -D[0](imag_part)(arctanh(w))/(w^2 - 1) sage: abs(log(x)).diff(x) 1/2*(conjugate(log(x))/x + log(x)/x)/abs(log(x)) sage: abs(log(z)).diff(z) 1/2*(conjugate(log(z))/z + log(z)/conjugate(z))/abs(log(z)) sage: forget()
sage: t = sin(x+y^2)*tan(x^y)
t = sin(x+y^2)*tan(x^y)
sage: t.derivative(x)
(tan(x*y)^2 + 1)*y^2*sin(y^2 + x) + cos(y^2 + x)*tan(x^y)
\end{verbatim}

(continues on next page)
sage: t.derivative(y)
(tan(x*y)^2 + 1)*x*sin(y^2 + x) + 2*y*cos(y^2 + x)*tan(x*y)

sage: h = sin(x)/cos(x)
sage: derivative(h,x,x,x)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2
sage: derivative(h,x,3)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2

sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*(cos(x) - sin(y))
sage: derivative(u,x,y)
-cos(x)*cos(y) + sin(x)*sin(y)

sage: f = ((x^2+1)/(x^2-1))^(1/4)
sage: g = derivative(f, x); g
# this is a complex expression
-1/2*((x^2 + 1)*x/(x^2 - 1)^2 - x/(x^2 - 1))/((x^2 + 1)/(x^2 - 1))^(3/4)
sage: g.factor()
-x/((x + 1)^2*(x - 1)^2*((x^2 + 1)/(x^2 - 1))^(3/4))

sage: y = var('y')
sage: f = y^(sin(x))
sage: derivative(f, x)
y^sin(x)*cos(x)*log(y)

sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3

sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)

sage: g = 1/(sqrt((x^2-1)*(x+5)^6))
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x^2 - 1)*(x + 5)^5)/((x^2 - 1)*(x + 5)^6)^(3/2)

diff(*args)
Return the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative function for more details.

See also:
This is implemented in the _derivative method (see the source code).

EXAMPLES:

sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
If the function depends on only one variable, you may omit the variable. Giving just a number (for the order of the derivative) also works:

\[
\begin{align*}
\text{sage: } & f(x) = x^3 + \sin(x) \\
\text{sage: } & f.\text{derivative()} \\
& x |\rightarrow 3x^2 + \cos(x) \\
\text{sage: } & f.\text{derivative(2)} \\
& x |\rightarrow 6x - \sin(x)
\end{align*}
\]

Some expressions can't be cleanly differentiated by the chain rule:

\[
\begin{align*}
\text{sage: } & (x^z).\text{conjugate().diff(x)} \\
& \text{conjugate}(x^{(z - 1)})*\text{conjugate}(z) \\
\text{sage: } & (w^z).\text{conjugate().diff(w)} \\
& w^{(z - 1)}*z*D[0](\text{conjugate})(w^z) \\
\text{sage: } & \text{atanh}(x).\text{real_part().diff(x)} \\
& -1/(x^2 - 1) \\
\text{sage: } & \text{atanh}(x).\text{imag_part().diff(x)} \\
& 0 \\
\text{sage: } & \text{atanh}(w).\text{real_part().diff(w)} \\
& -D[0](\text{real_part})(\text{arctanh}(w))/(w^2 - 1) \\
\text{sage: } & \text{atanh}(w).\text{imag_part().diff(w)} \\
& -D[0](\text{imag_part})(\text{arctanh}(w))/(w^2 - 1) \\
\text{sage: } & \text{abs}(\log(x)).\text{diff(x)} \\
& 1/2*(\text{conjugate}(\log(x))/x + \log(x)/x)/\text{abs}(\log(x)) \\
\text{sage: } & \text{abs}(\log(z)).\text{diff(z)} \\
& 1/2*(\text{conjugate}(\log(z))/z + \log(z)/\text{conjugate}(z))/\text{abs}(\log(z)) \\
\text{sage: } & \text{forget()}
\end{align*}
\]

2.1. Symbolic Expressions
symbolic calculus, release 10.0

sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*(cos(x) - sin(y))
sage: derivative(u, x, y)
-cos(x)*cos(y) + sin(x)*sin(y)
sage: f = ((x^2+1)/(x^2-1))^(1/4)
sage: g = derivative(f, x); g # this is a complex expression
-1/2*((x^2 + 1)*x/(x^2 - 1)^2 - x/(x^2 - 1))/((x^2 + 1)/(x^2 - 1))^(3/4)
sage: g.factor()
-x/((x + 1)^2*(x - 1)^2*((x^2 + 1)/(x^2 - 1))^(3/4))
sage: y = var('y')
sage: f = y^(sin(x))
sage: derivative(f, x)
y*sin(x)*cos(x)*log(y)
sage: g(x) = sqrt(5-2*x)
sage: g_3 = derivative(g, x, 3); g_3(2)
-3
sage: f = x*e^(-x)
sage: derivative(f, 100)
x*e^(-x) - 100*e^(-x)
sage: g = 1/sqrt((x^2-1)*(x+5)^6)
sage: derivative(g, x)
-(x + 5)^6*x + 3*(x^2 - 1)*(x + 5)^5)/((x^2 - 1)*(x + 5)^6)^(3/2)

differentiate(*args)
Return the derivative of this expressions with respect to the variables supplied in args.

Multiple variables and iteration counts may be supplied; see documentation for the global derivative() function for more details.

See also:
This is implemented in the _derivative method (see the source code).

EXAMPLES:
sage: var("x y")
(x, y)
sage: t = (x^2+y)^2
sage: t.derivative(x)
4*(x^2 + y)*x
sage: t.derivative(x, 2)
12*x^2 + 4*y
sage: t.derivative(x, 2, y)
4
sage: t.derivative(y)
2*x^2 + 2*y

If the function depends on only one variable, you may omit the variable. Giving just a number (for the order of the derivative) also works:
Symbolic Calculus, Release 10.0

sage: f(x) = x^3 + sin(x)
sage: f.derivative()
x |--> 3*x^2 + cos(x)
sage: f.derivative(2)
x |--> 6*x - sin(x)

Some expressions can't be cleanly differentiated by the chain rule:

sage: _ = var('x', domain='real')
sage: _ = var('w z')
sage: (x^z).conjugate().diff(x)  
conjugate(x^(z - 1))*conjugate(z)
sage: (w^z).conjugate().diff(w)  
w^(z - 1)*z*D[0](conjugate(w^z))
sage: atanh(x).real_part().diff(x)  
-1/(x^2 - 1)
sage: atanh(x).imag_part().diff(x)  
@

sage: forget()

sage: h = sin(x)/cos(x)
sage: derivative(h, x, 3)  
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2
sage: derivative(h, x, 3)
8*sin(x)^2/cos(x)^2 + 6*sin(x)^4/cos(x)^4 + 2

sage: var('x, y')
(x, y)
sage: u = (sin(x) + cos(y))*((cos(x) - sin(y))
sage: derivative(u, x, y)  
-cos(x)*cos(y) + sin(x)*sin(y)
sage: f = ((x^2+1)/(x^2-1))^4/(1/4)
sage: g = derivative(f, x); g # this is a complex expression  
-1/2*(x^2 + 1)*x/(x^2 - 1)^2 - x/(x^2 - 1)/((x^2 + 1)/(x^2 - 1))^3/4
sage: g.factor()  
-x/((x + 1)^2*(x - 1)^2*(x^2 + 1)/(x^2 - 1))^3/4)

sage: y = var('y')

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

\[
sage: f = y^\sin(x)
sage: derivative(f, x)
y^\sin(x)\cos(x)\log(y)
\]

\[
sage: g(x) = \sqrt{5-2^x}
sage: g_3 = derivative(g, x, 3); g_3(2)
-3
\]

\[
sage: f = x^e^{-x}
sage: derivative(f, 100)
x^e^{-x} - 100^e^{-x}
\]

\[
sage: g = 1/\sqrt{(x^2-1)^*(x+5)^6)}
sage: derivative(g, x)
-((x + 5)^6*x + 3*(x^2 - 1)*(x + 5)^5)/((x^2 - 1)*(x + 5)^6)^(3/2)
\]

distribute\(_{\text{recursive}=\text{True}}\)

Distribute some indexed operators over similar operators in order to allow further groupings or simplifications.

Implemented cases (so far):

- Symbolic sum of a sum ==\> sum of symbolic sums
- Integral (definite or not) of a sum ==\> sum of integrals.
- Symbolic product of a product ==\> product of symbolic products.

INPUT:

- recursive – (default : True) the distribution proceeds along the subtrees of the expression.

AUTHORS:

- Emmanuel Charpentier, Ralf Stephan (05-2017)

divide\(_{\text{both\_sides}}\)(x, checksign=None)

Return a relation obtained by dividing both sides of this relation by \(x\).

Note: The checksign keyword argument is currently ignored and is included for backward compatibility reasons only.

EXAMPLES:

\[
sage: theta = var('\theta')
sage: eqn = (x^3 + theta < \sin(x*theta))
sage: eqn.divide_both_sides(theta, checksign=False)
(x^3 + theta)/theta < \sin(theta*x)/theta
sage: eqn.divide_both_sides(theta)
(x^3 + theta)/theta < \sin(theta*x)/theta
sage: eqn/theta
(x^3 + theta)/theta < \sin(theta*x)/theta
\]
\texttt{exp(hold=False)}

Return exponential function of self, i.e., $e$ to the power of self.

EXAMPLES:

\begin{verbatim}
sage: x.exp()
e^x
sage: SR(0).exp()
1
sage: SR(1/2).exp()
e^{1/2}
\end{verbatim}

\begin{verbatim}
sage: SR(0.5).exp()
1.64872127070013
sage: math.exp(0.5)
1.6487212707001282
sage: SR(0.5).exp().log()
0.500000000000000
sage: (pi*I).exp()
-1
\end{verbatim}

To prevent automatic evaluation use the \texttt{hold} argument:

\begin{verbatim}
sage: (pi*I).exp(hold=True)
e^{I*pi}
\end{verbatim}

This also works using functional notation:

\begin{verbatim}
sage: exp(I*pi,hold=True)
e^{I*pi}
sage: exp(I*pi)
-1
\end{verbatim}

To then evaluate again, we use \texttt{unhold()}:

\begin{verbatim}
sage: a = (pi*I).exp(hold=True); a.unhold()
-1
\end{verbatim}

\texttt{expand(side=None)}

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

EXAMPLES:

We expand the expression $(x - y)^5$ using both method and functional notation.

\begin{verbatim}
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
sage: expand(a)
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
\end{verbatim}

We expand some other expressions:
Symbolic Calculus, Release 10.0

\[\text{sage: } \text{expand}\left(\frac{(x-1)^3}{(y-1)}\right)\]
\[x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)\]
\[\text{sage: } \text{expand}\left((x+\sin((x+y)^2))^2\right)\]
\[x^2 + 2*x*sin(x^2 + 2*x*y + y^2) + \sin(x^2 + 2*x*y + y^2)^2\]

Observe that \text{expand()} also expands function arguments:

\[\text{sage: } f(x) = \text{function('f')}(x)\]
\[\text{sage: } fx = f(x*(x+1)); fx\]
\[f((x + 1)*x)\]
\[\text{sage: } fx.\text{expand()}\]
\[f(x^2 + x)\]

We can expand individual sides of a relation:

\[\text{sage: } a = (16*x-13)^2 == (3*x+5)^2/2\]
\[\text{sage: } a.\text{expand()}\]
\[256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2\]
\[\text{sage: } a.\text{expand('left')}\]
\[256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2\]
\[\text{sage: } a.\text{expand('right')}\]
\[(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2\]

\textbf{expand\_log(algorithm='products')}\]

Simplify symbolic expression, which can contain logs.

Expands logarithms of powers, logarithms of products and logarithms of quotients. The option \text{algorithm} specifies which expression types should be expanded.

INPUT:

• \textbf{self} - expression to be simplified

• \textbf{algorithm} - (default: ‘products’) optional, governs which expression is expanded. Possible values are

  – ‘nothing’ (no expansion),
  – ‘powers’ (\log(a^r) is expanded),
  – ‘products’ (like ‘powers’ and also \log(a*b) are expanded),
  – ‘all’ (all possible expansion).

DETAILS: This uses the Maxima simplifier and sets \text{logexpand} option for this simplifier. From the Maxima documentation: “\text{Logexpand:true causes log(a\^r) to become b*log(a). If it is set to all, log(a\^b) will also simplify to log(a)+log(b). If it is set to super, then log(a/b) will also simplify to log(a)-log(b) for rational numbers a/b, a#1. (log(1/b), for integer b, always simplifies.) If it is set to false, all of these simplifications will be turned off.”

ALIAS: \text{log\_expand()} and \text{expand\_log()} are the same

EXAMPLES:

By default powers and products (and quotients) are expanded, but not quotients of integers:

\[\text{sage: } \left(\log\left(\frac{3/4*x}{pi}\right)\right).\text{log\_expand()}\]
\[\pi^*\log(x) + \log(3/4)\]
To expand also \( \log(3/4) \) use `algorithm='all'`:

```
sage: (log(3/4*x^pi)).log_expand('all')
pi*log(x) + log(3) - 2*log(2)
```

To expand only the power use `algorithm='powers'`:

```
sage: (log(x^6)).log_expand('powers')
6*log(x)
```

The expression \( \log((3^x)^6) \) is not expanded with `algorithm='powers'`, since it is converted into product first:

```
sage: (log((3^x)^6)).log_expand('powers')
log(729*x^6)
```

This shows that the option `algorithm` from the previous call has no influence to future calls (we changed some default Maxima flag, and have to ensure that this flag has been restored):

```
sage: (log(3/4*x^pi)).log_expand()
pi*log(x) + log(3/4)
sage: (log(3/4*x^pi)).log_expand('all')
pi*log(x) + log(3) - 2*log(2)
sage: (log(3/4*x^pi)).log_expand()
pi*log(x) + log(3/4)
```

AUTHORS:

- Robert Marik (11-2009)

### expand_rational

**expand_rational**(side=None)

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

**EXAMPLES:**

We expand the expression \((x - y)^5\) using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x-y)^2))^2)
x^2 + 2*x*sin(x^2 + 2*x*y + y^2) + sin(x^2 + 2*x*y + y^2)^2
```

Observe that `expand()` also expands function arguments:
sage: f(x) = function('f')(x)
sage: fx = f(x*(x+1)); fx
f((x + 1)*x)
sage: fx.expand()
f(x^2 + x)

We can expand individual sides of a relation:

sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
sage: a.expand('right')
(16*x - 13)^2 == 9/2*x^2 + 15*x + 25/2

expand_sum()

For every symbolic sum in the given expression, try to expand it, symbolically or numerically.

While symbolic sum expressions with constant limits are evaluated immediately on the command line, unevaluated sums of this kind can result from, e.g., substitution of limit variables.

INPUT:

• self - symbolic expression

EXAMPLES:

sage: (k,n) = var('k,n')
sage: ex = sum(abs(-k*k+n),k,1,n)(n=8); ex
sum(abs(-k^2 + 8), k, 1, 8)
sage: ex.expand_sum()
162
sage: f(x,k) = sum((2/n)*(sin(n*x)*(-1)^(n+1)), n, 1, k)
sage: f(x,2)
-2*sum((-1)^n*sin(n*x)/n, n, 1, 2)
sage: f(x,2).expand_sum()
-sin(2*x) + 2*sin(x)

We can use this to do floating-point approximation as well:

sage: (k,n) = var('k,n')
sage: f(n)=sum(sqrt(abs(-k*k+n)),k,1,n)
sage: f(n=8)
sum(sqrt(abs(-k^2 + 8)), k, 1, 8)
sage: f(8).expand_sum()
sqrt(41) + sqrt(17) + 2*sqrt(14) + 3*sqrt(7) + 2*sqrt(2) + 3
sage: f(8).expand_sum().n()
31.7752256945384

See github issue #9424 for making the following no longer raise an error:

sage: f(8).n()
31.7752256945384
**expand_trig**(*full=False, half_angles=False, plus=True, times=True*)

Expand trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in self.

For best results, self should already be expanded.

**INPUT:**

- **full** – (default: False) To enhance user control of simplification, this function expands only one level at a time by default, expanding sums of angles or multiple angles. To obtain full expansion into sines and cosines immediately, set the optional parameter full to True.
- **half_angles** - (default: False) If True, causes half-angles to be simplified away.
- **plus** – (default: True) Controls the sum rule; expansion of sums (e.g. \(\sin(x + y)\)) will take place only if plus is True.
- **times** – (default: True) Controls the product rule, expansion of products (e.g. \(\sin(2x)\)) will take place only if times is True.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```python
sage: sin(5*x).expand_trig()
5*cos(x)^4*sin(x) - 10*cos(x)^2*sin(x)^3 + sin(x)^5
sage: cos(2*x + var('y')).expand_trig()
cos(2*x)*cos(y) - sin(2*x)*sin(y)
```

We illustrate various options to this function:

```python
sage: f = sin(sin(3*cos(2*x))*x)
sage: f.expand_trig()
sin((3*cos(cos(2*x))^2*sin(cos(2*x)) - sin(cos(2*x))^3)*x)
sage: f.expand_trig(full=True)
sin((2*(cos(sin(x)^2)*sin(cos(x)^2) - cos(cos(x)^2)*sin(sin(x)^2)) - (cos(sin(x)^2)*sin(cos(x)^2) - cos(cos(x)^2)*sin(sin(x)^2))^3)*x)
sage: sin(2*x).expand_trig(times=False)
sin(2*x)
sage: sin(2*x).expand_trig(times=True)
2*cos(x)*sin(x)
sage: sin(x/2).expand_trig(half_angles=False)
sin(x/2)
sage: sin(x/2).expand_trig(half_angles=True)
(-1)^floor(1/2*x/pi)*sqrt(-1/2*cos(x) + 1/2)
```

If the expression contains terms which are factored, we expand first:

```python
sage: (x, k1, k2) = var('x, k1, k2')
sage: cos((k1-k2)*x).expand().expand_trig()
cos(k1*x)*cos(k2*x) + sin(k1*x)*sin(k2*x)
```
ALIAS:

\texttt{trig\_expand()} and \texttt{expand\_trig()} are the same

\texttt{exponentialize()}

Return this symbolic expression with all circular and hyperbolic functions replaced by their respective
exponential expressions.

EXAMPLES:

\begin{verbatim}
sage: x = SR.var("x")
sage: sin(x).exponentialize()
-1/2*I*e^(I*x) + 1/2*I*e^(-I*x)
sage: sec(x).exponentialize()
2/(e^(I*x) + e^(-I*x))
sage: tan(x).exponentialize()
(-I*e^(I*x) + I*e^(-I*x))/(e^(I*x) + e^(-I*x))
sage: sinh(x).exponentialize()
-1/2*e^(-x) + 1/2*e^x
sage: sech(x).exponentialize()
2/(e^(-x) + e^x)
sage: tanh(x).exponentialize()
-(e^(-x) - e^x)/(e^(-x) + e^x)
\end{verbatim}

\texttt{factor(dontfactor=None)}

Factor the expression, containing any number of variables or functions, into factors irreducible over the
integers.

INPUT:

- \texttt{self} - a symbolic expression
- \texttt{dontfactor} - list (default: []), a list of variables with respect to which factoring is not to occur.

Factoring also will not take place with respect to any variables which are less important (using the
variable ordering assumed for CRE form) than those on the ‘dontfactor’ list.

EXAMPLES:

\begin{verbatim}
sage: x,y,z = var('x, y, z')
sage: (x^3-y^3).factor()
(x^2 + x*y + y^2)*(x - y)
sage: factor(-8*y - 4*x + z^2*(2*y + x))
(x + 2*y)*(z + 2)*(z - 2)
sage: f = -1 - 2*x - x^2 + y^2 + 2*x*y^2 + x^2*y^2
sage: F = factor(f/(36*(1 + 2*y + y^2)), dontfactor=[x]); F
1/36*(x^2 + 2*x + 1)*(y - 1)/(y + 1)
\end{verbatim}

If you are factoring a polynomial with rational coefficients (and \texttt{dontfactor} is empty) the factorization is
done using Singular instead of Maxima, so the following is very fast instead of dreadfully slow:

\begin{verbatim}
sage: var('x,y')
(x, y)
sage: (x^99 + y^99).factor()
(x^60 + x^57*y^3 - x^51*y^9 - x^48*y^12 + x^42*y^18 + x^39*y^21 -
x^33*y^27 - x^30*y^30 - x^27*y^33 + x^21*y^39 + x^18*y^42 -
x^12*y^48 - x^9*y^51 + x^3*y^57 + y^60)*(x^20 + x^19*y -
x^17*y^3 - x^16*y^4 + x^14*y^6 + x^13*y^7 - x^11*y^9 -
\end{verbatim}

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

\[x^{10}y^{10} - x^9y^{11} + x^7y^{13} + x^6y^{14} - x^4y^{16} -
\]
\[x^3y^{17} + x^2y^{19} + y^{20})^2(x^{10} - x^9y + x^8y^2 - x^7y^3 +
\]
\[x^6y^4 - x^5y^5 + x^4y^6 - x^3y^7 + x^2y^8 - x^2y^9 +
\]
\[y^{10} + (x^6 - x^3y^3 + y^6)^2(x^2 - x^2y + y^2)^2(x + y)
\]

factor_list(dontfactor=None)

Return a list of the factors of self, as computed by the factor command.

INPUT:

- **self** – a symbolic expression
- **dontfactor** – see docs for factor()

Note: If you already have a factored expression and just want to get at the individual factors, use the _factor_list method instead.

EXAMPLES:

sage: var('x, y, z')
(x, y, z)
sage: f = x^3-y^3
sage: f.factor()
(x^2 + x*y + y^2)*(x - y)

Notice that the -1 factor is separated out:

sage: f.factor_list()
[(x^2 + x*y + y^2, 1), (x - y, 1)]

We factor a fairly straightforward expression:

sage: factor(-8*y - 4*x + z^2*(2*y + x)).factor_list()
[(x + 2*y, 1), (z + 2, 1), (z - 2, 1)]

A more complicated example:

sage: var('x, u, v')
(x, u, v)
sage: f = expand((2*u*v^2-v^2-4*u^3)^2 * (-u)^3 * (x-sin(x))^3)
sage: f.factor()
-(4*u^3 - 2*u*v^2 + v^2)^2*u^3*(x - sin(x))^3
sage: g = f.factor_list(); g
[(4*u^3 - 2*u*v^2 + v^2, 2), (u, 3), (x - sin(x), 3), (-1, 1)]

This function also works for quotients:

sage: f = -1 - 2*x - x^2 + y^2 + 2*x*y^2 + x^2*y^2
sage: g = f/(36*(1 + 2*y + y^2)); g
1/36*(x^2*y^2 + 2*x*y^2 + y^2 - x^2 + y^2 - 2*x - 1)/(y^2 + 2*y + 1)
sage: g.factor(dontfactor=[x])
1/36*(x^2 + 2*x + 1)^2*(y - 1)/(y + 1)
sage: g.factor_list(dontfactor=[x])
[(x^2 + 2*x + 1, 1), (y + 1, -1), (y - 1, 1), (1/36, 1)]

2.1. Symbolic Expressions 41
This example also illustrates that the exponents do not have to be integers:

```
sage: f = x^(2*sin(x)) * (x-1)^(sqrt(2)*x); f
(x - 1)^(sqrt(2)*x)*x^(2*sin(x))
sage: f.factor_list()
[(x - 1, sqrt(2)*x), (x, 2*sin(x))]
```

**factorial**(hold=False)

Return the factorial of self.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```
sage: var('x, y')
(x, y)
sage: SR(5).factorial()
120
sage: x.factorial()
factorial(x)
sage: (x^2+y^3).factorial()
factorial(y^3 + x^2)
```

To prevent automatic evaluation use the `hold` argument:

```
sage: SR(5).factorial(hold=True)
factorial(5)
```

This also works using functional notation:

```
sage: factorial(5,hold=True)
factorial(5)
sage: factorial(5)
120
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(5).factorial(hold=True); a.unhold()
120
```

**factorial_simplify()**

Simplify by combining expressions with factorials, and by expanding binomials into factorials.

**ALIAS:** `factorial_simplify` and `simplify_factorial` are the same

**EXAMPLES:**

Some examples are relatively clear:

```
sage: var('n,k')
(n, k)
sage: f = factorial(n+1)/factorial(n); f
factorial(n + 1)/factorial(n)
sage: f.simplify_factorial()
n + 1
```
Symbolic Calculus, Release 10.0

\begin{verbatim}
sage: f = factorial(n)*(n+1); f
(n + 1)*factorial(n)
sage: simplify(f)
(n + 1)*factorial(n)
sage: f.simplify_factorial()
factorial(n + 1)

sage: f = binomial(n, k)*factorial(k)*factorial(n-k); f
binomial(n, k)*factorial(k)*factorial(-k + n)
sage: f.simplify_factorial()
factorial(n)

A more complicated example, which needs further processing:

sage: f = factorial(x)/factorial(x-2)/2 + factorial(x+1)/factorial(x)/2; f
1/2*factorial(x + 1)/factorial(x) + 1/2*factorial(x)/factorial(x - 2)
sage: g = f.simplify_factorial(); g
1/2*(x - 1)*x + 1/2*x + 1/2
sage: g.simplify_rational()
1/2*x^2 + 1/2
\end{verbatim}

\textbf{find(pattern)}

Find all occurrences of the given pattern in this expression.

Note that once a subexpression matches the pattern, the search does not extend to subexpressions of it.

**EXAMPLES:**

\begin{verbatim}
sage: var('x,y,z,a,b')
(x, y, z, a, b)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: (sin(x)*sin(y)).find(sin(w0))
[sin(y), sin(x)]
sage: ((sin(x)+sin(y))*(a+b)).expand().find(sin(w0))
[sin(y), sin(x)]
sage: (1+x+x^2+x^3).find(x)
[x]
sage: (1+x+x^2+x^3).find(x^w0)
[x^2, x^3]
sage: (1+x+x^2+x^3).find(y)
[

# subexpressions of a match are not listed
sage: ((x*y)^z).find(w0^w1)
[(x*y)^z]
\end{verbatim}

\textbf{find_local_maximum}(a, b, var=None, tol=1.48e-08, maxfun=500, imaginary_tolerance=1e-08)

Numerically find a local maximum of the expression self on the interval [a,b] (or [b,a]) along with the point at which the maximum is attained.

See the documentation for \texttt{find_local_minimum()} for more details.
EXAMPLES:

```
sage: f = x*cos(x)
sage: f.find_local_maximum(0,5)
(0.5610963381910451, 0.8603335890...)
sage: f.find_local_maximum(0,5, tol=0.1, maxfun=10)
(0.561090323458081..., 0.857926501456...)
```

```
find_local_minimum(a, b, var=None, tol=1.48e-08, maxfun=500, imaginary_tolerance=1e-08)
```

Numerically find a local minimum of the expression `self` on the interval `[a,b]` (or `[b,a]`) and the point at which it attains that minimum. Note that `self` must be a function of (at most) one variable.

**INPUT:**

- `a` - real number; left endpoint of interval on which to minimize
- `b` - real number; right endpoint of interval on which to minimize
- `var` - variable (default: first variable in `self`); the variable in `self` to maximize over
- `tol` - positive real (default: 1.48e-08); the convergence tolerance
- `maxfun` - natural number (default: 500); maximum function evaluations
- `imaginary_tolerance` – (default: 1e-8); if an imaginary number arises (due, for example, to numerical issues), this tolerance specifies how large it has to be in magnitude before we raise an error. In other words, imaginary parts smaller than this are ignored when we are expecting a real answer.

**OUTPUT:**

A tuple `(minval, x)`, where

- `minval` – float. The minimum value that `self` takes on in the interval `[a,b]`.
- `x` – float. The point at which `self` takes on the minimum value.

EXAMPLES:

```
sage: f = x*cos(x)
sage: f.find_local_minimum(1, 5)
(-3.288371395590..., 3.4256184695...)
sage: f.find_local_minimum(1, 5, tol=1e-3)
(-3.288371361890..., 3.4257507903...)
sage: f.find_local_minimum(1, 5, tol=1e-2, maxfun=10)
(-3.288370845983..., 3.4250840220...)
sage: show(f.plot(0, 20))
sage: f.find_local_minimum(1, 15)
(-9.477294259479..., 9.5293344109...)
```

**ALGORITHM:**

Uses `sage.numerical.optimize.find_local_minimum()`.

**AUTHORS:**

- William Stein (2007-12-07)

```
find_root(a, b, var=None, xtol=1e-12, rtol=8.881784197001252e-16, maxiter=100, full_output=False, imaginary_tolerance=1e-08)
```

Numerically find a root of `self` on the closed interval `[a,b]` (or `[b,a]`) if possible, where `self` is a function in the one variable. Note: this function only works in fixed (machine) precision, it is not possible to get arbitrary precision approximations with it.
INPUT:

- a, b - endpoints of the interval
- var - optional variable
- xtol, rtol - the routine converges when a root is known to lie within xtol of the value return. Should be >= 0. The routine modifies this to take into account the relative precision of doubles.
- maxiter - integer; if convergence is not achieved in maxiter iterations, an error is raised. Must be >= 0.
- full_output - bool (default: False), if True, also return object that contains information about convergence.
- imaginary_tolerance – (default: 1e-8); if an imaginary number arises (due, for example, to numerical issues), this tolerance specifies how large it has to be in magnitude before we raise an error. In other words, imaginary parts smaller than this are ignored when we are expecting a real answer.

EXAMPLES:

Note that in this example both f(-2) and f(3) are positive, yet we still find a root in that interval:

```
sage: f = x^2 - 1
sage: f.find_root(-2, 3)
1.0
sage: f.find_root(-2, 3, x)
1.0
sage: z, result = f.find_root(-2, 3, full_output=True)
sage: result.converged
True
sage: result.flag
'converged'
sage: result.function_calls
11
sage: result.iterations
10
sage: result.root
1.0
```

More examples:

```
sage: (sin(x) + exp(x)).find_root(-10, 10)
-0.588532743981862...
sage: sin(x).find_root(-1,1)
0.0
```

This example was fixed along with github issue #4942 - there was an error in the example pi is a root for tan(x), but an asymptote to 1/tan(x) added an example to show handling of both cases:

```
sage: (tan(x)).find_root(3,3.5)
3.1415926535...
sage: (1/tan(x)).find_root(3, 3.5)
Traceback (most recent call last):
...  
NotImplementedError: Brent's method failed to find a zero for f on the interval
```

An example with a square root:
Some examples that Ted Kosan came up with:

```python
sage: t = var('t')
sage: v = 0.004*(9600*e^(-t) - 2400*e^(-3t))
sage: v.find_root(0, 0.002)
0.001540327067911417...
```

With this expression, we can see there is a zero very close to the origin:

```python
sage: a = .004*(8*e^(-3t) - 8*e^(-12t)) * (720000*e^(-12t) - 11520000*e^-3t) + .004*(9600*e^-3t - 2400*e^-12t)

sage: show(plot(a, 0, .002), xmin=0, xmax=.002)
```

It is easy to approximate with `find_root`:

```python
sage: a.find_root(0,0.002)
0.0004110514049349...
```

Using `solve` takes more effort, and even then gives only a solution with free (integer) variables:

```python
sage: a.solve(t)
[]
sage: b = a.canonicalize_radical(); b
(46080.0*e^(1800*t) - 576000.0*e^(900*t) + 737280.0)*e^(-2400*t)

sage: b.solve(t)
[]
sage: b.solve(t, to_poly_solve=True)
[t == 1/450*I*pi*z... + 1/900*log(-3/4*sqrt(41) + 25/4),
 t == 1/450*I*pi*z... + 1/900*log(3/4*sqrt(41) + 25/4)]

sage: n(1/900*log(-3/4*sqrt(41) + 25/4))
0.000411051404934985
```

We illustrate that root finding is only implemented in one dimension:

```python
sage: x, y = var('x,y')
sage: (x-y).find_root(-2,2)
Traceback (most recent call last):
...
NotImplementedError: root finding currently only implemented in 1 dimension.
```

```
forget()
```

Forget the given constraint.

**EXAMPLES:**

```python
sage: var('x,y')
(x, y)
sage: forget()
sage: assume(x>0, y < 2)
sage: assumptions()
[x > 0, y < 2]
```
\begin{verbatim}
sage: forget(y < 2)
sage: assumptions()
[x > 0]
\end{verbatim}

\textbf{fraction}(\textit{base\_ring})

Return this expression as element of the algebraic fraction field over the base ring given.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: fr = (1/x).fraction(ZZ); fr
1/x
sage: parent(fr)
Fraction Field of Univariate Polynomial Ring in x over Integer Ring
sage: parent(((pi+sqrt(2))/x).fraction(SR))
Fraction Field of Univariate Polynomial Ring in x over Symbolic Ring
sage: y = var('y')
sage: fr = ((3*x^5 - 5*y^5)^7/(x*y)).fraction(GF(7)); fr
(3*x^35 + 2*y^35)/(x*y)
sage: parent(fr)
Fraction Field of Multivariate Polynomial Ring in x, y over Finite Field of size 7
\end{verbatim}

\textbf{free\_variables}()

Return sorted tuple of unbound variables that occur in this expression.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: (x,y,z) = var('x,y,z')
sage: (x+y).free_variables()
(x, y)
sage: (2*x).free_variables()
(x,
)sage: (x*y).free_variables()
(x, y)
sage: sin(x+y^z).free_variables()
(x, y, z)
sage: _ = function('f')
sage: e = limit( f(x,y), x=0 ); e
limit(f(x, y), x, 0)
sage: e.free_variables()
(y,
\end{verbatim}

\textbf{full\_simplify}()

Apply \texttt{simplify\_factorial()}, \texttt{simplify\_rectform()}, \texttt{simplify\_trig()}, \texttt{simplify\_rational()}, and then \texttt{expand\_sum()} to self (in that order).

\textbf{ALIAS}: \texttt{simplify\_full} and \texttt{full\_simplify} are the same.

\textbf{EXAMPLES}:
Symbolic Calculus, Release 10.0

```python
sage: f = sin(x)^2 + cos(x)^2
sage: f.simplify_full()
1

sage: f = sin(x/(x^2 + x))
sage: f.simplify_full()
\sin(1/(x + 1))

sage: var('n,k')
(n, k)
sage: f = binomial(n,k)*factorial(k)*factorial(n-k)
sage: f.simplify_full()
\text{factorial}(n)
```

**function(*args)**

Return a callable symbolic expression with the given variables.

**EXAMPLES:**

We will use several symbolic variables in the examples below:

```python
sage: var('x, y, z, t, a, w, n')
(x, y, z, t, a, w, n)
sage: u = sin(x) + x*cos(y)
sage: g = u.function(x,y)
sage: g(x,y)
x*cos(y) + \sin(x)
sage: g(t,z)
t*cos(z) + \sin(t)
sage: g(x^2, x^y)
x^2*cos(x^y) + \sin(x^2)
sage: f = (x^2 + \sin(a*w)).function(a,x,w); f
(a, x, w) \mapsto x^2 + \sin(a*w)
sage: f(1,2,3)
\sin(3) + 4
```

Using the `function()` method we can obtain the above function \(f\), but viewed as a function of different variables:

```python
sage: h = f.function(w,a); h
(w, a) \mapsto x^2 + \sin(a*w)
```

This notation also works:

```python
sage: h(w,a) = f
sage: h
(w, a) \mapsto x^2 + \sin(a*w)
```

You can even make a symbolic expression \(f\) into a function by writing \(f(x,y) = f\):
```
sage: f = x^n + y^n; f
x^n + y^n
sage: f(x,y) = f
sage: f
(x, y) |--> x^n + y^n
sage: f(2,3)
3^n + 2^n
```

\texttt{gamma}(\texttt{hold=False})

Return the Gamma function evaluated at self.

EXAMPLES:

```
sage: x = var('x')
sage: x.gamma()
gamma(x)
sage: SR(2).gamma()
1
sage: SR(10).gamma()
362880
sage: SR(10.0r).gamma()  # For ARM: rel tol 2e-15
362880.0
sage: SR(CDF(1,1)).gamma()
0.49801566811835607 - 0.15494982830181067*I
sage: gp('gamma(1+I)')
0.4980156681183560427136911175 - 0.154949828301810651249551305*I # 32-bit
0.49801566811835604271369111746219809195 - 0.
˓→0.15494982830181068512495513048388660520*I # 64-bit
```

We plot the familiar plot of this log-convex function:

```
sage: plot(gamma(x), -6,4).show(ymin=-3,ymax=3)
```

To prevent automatic evaluation use the \texttt{hold} argument:

```
sage: SR(1/2).gamma()
sqrt(pi)
sage: SR(1/2).gamma(hold=True)
gamma(1/2)
```

This also works using functional notation:

```
sage: gamma(1/2,hold=True)
gamma(1/2)
sage: gamma(1/2)
sqrt(pi)
```

To then evaluate again, we use \texttt{unhold()}:

```
sage: a = SR(1/2).gamma(hold=True); a.unhold()
sqrt(pi)
```
**gamma_normalize()**

Return the expression with any gamma functions that have a common base converted to that base. Additionally the expression is normalized so any fractions can be simplified through cancellation.

**EXAMPLES:**

```python
sage: m, n = var('m n', domain='integer')
sage: (gamma(n+2)/gamma(n)).gamma_normalize()
(n + 1)*n
sage: (gamma(n+2)*gamma(n)).gamma_normalize()
(n + 1)*n*gamma(n)^2
sage: (gamma(n+2)*gamma(m-1)/gamma(n)/gamma(m+1)).gamma_normalize()
(n + 1)*n/((m - 1)*m)
```

Check that github issue #22826 is fixed:

```python
sage: _ = var('n')
sage: (n-1).gcd(n+1)
1
sage: ex = (n-1)^2*gamma(2*n+5)/gamma(n+3) + gamma(2*n+3)/gamma(n+1)
sage: ex.gamma_normalize()
(4*n^3 - 2*n^2 - 7*n + 7)*gamma(2*n + 3)/((n + 1)*gamma(n + 1))
```

**gcd(b)**

Return the symbolic gcd of self and b.

Note that the polynomial GCD is unique up to the multiplication by an invertible constant. The following examples make sure all results are caught.

**EXAMPLES:**

```python
sage: var('x,y')
(x, y)
sage: SR(10).gcd(SR(15))
5
sage: (x^3 - 1).gcd(x-1) / (x-1) in QQ
True
sage: (x^3 - 1).gcd(x^2+x+1) / (x^2+x+1) in QQ
True
sage: (x^3 - x^2*pi + x^2 - pi^2).gcd(x-pi) / (x-pi) in QQ
True
sage: gcd(sin(x)^2 + sin(x), sin(x)^2 - 1) / (sin(x) + 1) in QQ
True
sage: gcd(x^3 - y^3, x-y) / (x-y) in QQ
True
sage: gcd(x^100-y^100, x^10-y^10) / (x^10-y^10) in QQ
True
sage: r = gcd(expand((x^2+17*x+3/7*y)*(x^5 - 17*y + 2/3)), expand((x^13+17*x+3/7*y)*(x^5 - 17*y + 2/3)))
sage: r / (x^5 - 17*y + 2/3) in QQ
True
```

Embedded Sage objects of all kinds get basic support. Note that full algebraic GCD is not implemented yet:
sage: gcd(1 - I*x, x^2 - 1)
x - 1
sage: gcd(1 + I*x, x^2 - 1)
x + 1
sage: alg = SR(QQbar(sqrt(2) + I*sqrt(3)))
sage: gcd(alg + alg*x, x^2 - 1)  # known bug (trac #28489)
x + 1
sage: gcd(alg - alg*x, x^2 - 1)  # known bug (trac #28489)
x - 1
sage: sqrt2 = SR(QQbar(sqrt(2)))
sage: gcd(sqrt2 + x, x^2 - 2)  # known bug
1

gosper_sum(*args)
Return the summation of this hypergeometric expression using Gosper’s algorithm.

INPUT:
• a symbolic expression that may contain rational functions, powers, factorials, gamma function terms,
  binomial coefficients, and Pochhammer symbols that are rational-linear in their arguments
• the main variable and, optionally, summation limits

EXAMPLES:

sage: a,b,k,m,n = var('a b k m n')
sage: SR(1).gosper_sum(n)
n
sage: SR(1).gosper_sum(n,5,8)
4
sage: n.gosper_sum(n)
1/2*(n - 1)*n
sage: n.gosper_sum(n,0,5)
15
sage: n.gosper_sum(n,0,m)
1/2*(m + 1)*m
sage: n.gosper_sum(n,a,b)
-1/2*(a + b)*(a - b - 1)

sage: (factorial(m + n)/factorial(n)).gosper_sum(n)
n*factorial(m + n)/((m + 1)*factorial(n))
sage: (binomial(m + n, n)).gosper_sum(n)
n*binomial(m + n, n)/(m + 1)
sage: (binomial(m + n, n)).gosper_sum(n, 0, a)
(a + m + 1)*binomial(a + m, a)/(m + 1)
sage: (binomial(m + n, n)).gosper_sum(n, 0, 5)
1/120*(m + 6)*(m + 5)*(m + 4)*(m + 3)*(m + 2)
sage: (rising_factorial(a,n)/rising_factorial(b,n)).gosper_sum(n)
(b + n - 1)*gamma(a + n)*gamma(b)/((a - b + 1)*gamma(a)*gamma(b + n))
sage: factorial(n).gosper_term(n)
Traceback (most recent call last):
...
ValueError: expression not Gosper-summable

gosper_term(n)
Return Gosper’s hypergeometric term for self.

Suppose \( f \) is a hypergeometric term such that:

\[
s_n = \sum_{k=0}^{n-1} f_k
\]

and \( f_k \) doesn’t depend on \( n \). Return a hypergeometric term \( g_n \) such that \( g_{n+1} - g_n = f_n \).

EXAMPLES:

```
sage: _ = var('n')
sage: SR(1).gosper_term(n)
  n
sage: n.gosper_term(n)
  1/2*(n^2 - n)/n
sage: (n*factorial(n)).gosper_term(n)
  1/n
sage: factorial(n).gosper_term(n)
  Traceback (most recent call last):
    ... ValueError: expression not Gosper-summable
```

### gradient(variables=None)

Compute the gradient of a symbolic function.

This function returns a vector whose components are the derivatives of the original function with respect to the arguments of the original function. Alternatively, you can specify the variables as a list.

EXAMPLES:

```
sage: x, y = var('x y')
sage: f = x^2 + y^2
sage: f.gradient()
  (2*x, 2*y)
sage: g(x, y) = x^2 + y^2
sage: g.gradient()
  (x, y) |--> (2*x, 2*y)
sage: n = var('n')
sage: f(x, y) = x^n + y^n
sage: f.gradient()
  (x, y) |--> (n*x^(n - 1), n*y^(n - 1))
sage: f.gradient([y, x])
  (x, y) |--> (n*y^(n - 1), n*x^(n - 1))
```

See also:

gradient() of scalar fields on Euclidean spaces (and more generally pseudo-Riemannian manifolds), in particular for computing the gradient in curvilinear coordinates.

### has(pattern)

EXAMPLES:

```
sage: var('x, y, a'); w0 = SR.wild(); w1 = SR.wild()
(x, y, a)
(continues on next page)```
Symbolic Calculus, Release 10.0

sage: (x*sin(x + y + 2*a)).has(y)
True

Here “x+y” is not a subexpression of “x+y+2*a” (which has the subexpressions “x”, “y” and “2*a”):

sage: (x*sin(x + y + 2*a)).has(x+y)
False
sage: (x*sin(x + y + 2*a)).has(x + y + w0)
True

The following fails because “2*(x+y)” automatically gets converted to “2*x+2*y” of which “x+y” is not a subexpression:

sage: (x*sin(2*(x+y) + 2*a)).has(x+y)
False

Although x^1==x and x^0==1, neither “x” nor “1” are actually of the form “x^something”:

sage: (x+1).has(x^w0)
False

Here is another possible pitfall, where the first expression matches because the term “-x” has the form “(-1)*x” in GiNaC. To check whether a polynomial contains a linear term you should use the coeff() function instead.

sage: (4*x^2 - x + 3).has(w0*x)
True
sage: (4*x^2 + x + 3).has(w0*x)
False
sage: (4*x^2 + x + 3).has(x)
True
sage: (4*x^2 - x + 3).coefficient(x,1)
-1
sage: (4*x^2 + x + 3).coefficient(x,1)
1

has_wild()

Return True if this expression contains a wildcard.

EXAMPLES:

sage: (1 + x^2).has_wild()
False
sage: (SR.wild(0) + x^2).has_wild()
True
sage: SR.wild(0).has_wild()
True

hessian()

Compute the hessian of a function. This returns a matrix components are the 2nd partial derivatives of the original function.

EXAMPLES:
\begin{verbatim}
sage: x, y = var('x y')
sage: f = x^2 + y^2
sage: f.hessian()
[2 0]
[0 2]
sage: g(x,y) = x^2+y^2
sage: g.hessian()
[(x, y) |--> 2 (x, y) |--> 0]
[(x, y) |--> 0 (x, y) |--> 2]
\end{verbatim}

\textbf{horner}(x)

Rewrite this expression as a polynomial in Horner form in \(x\).

**EXAMPLES:**

\begin{verbatim}
sage: add((i+1)*x^i for i in range(5)).horner(x)
(((5*x + 4)*x + 3)*x + 2)*x + 1
sage: x, y, z = SR.var('x,y,z')
sage: (x^5 + y*cos(x) + z^3 + (x + y)^2 + y^x).horner(x)
z^3 + ((x^3 + 1)*x + 2*y)*x + y^2 + y*cos(x) + y^x
sage: expr = sin(5*x).expand_trig(); expr
5*cos(x)^4*sin(x) - 10*cos(x)^2*sin(x)^3 + sin(x)^5
sage: expr.horner(sin(x))
(5*cos(x)^4 - (10*cos(x)^2 - sin(x)^2)*sin(x)^2)*sin(x)
sage: expr.horner(cos(x))
sin(x)^5 + 5*(cos(x)^2*sin(x) - 2*sin(x)^3)*cos(x)^2
\end{verbatim}

\textbf{hypergeometric_simplify(algorithm='maxima')}

Simplify an expression containing hypergeometric or confluent hypergeometric functions.

**INPUT:**

- `algorithm` – (default: 'maxima') the algorithm to use for for simplification. Implemented are 'maxima', which uses Maxima's hgfred function, and 'sage', which uses an algorithm implemented in the hypergeometric module

**ALIAS:** hypergeometric_simplify() and simplify_hypergeometric() are the same

**EXAMPLES:**

\begin{verbatim}
sage: hypergeometric((5, 4), (4, 1, 2, 3), x).simplify_hypergeometric()
1/144*x^2*hypergeometric((, (3, 4), x) +...
1/3*x^2*hypergeometric((, (2, 3), x) + hypergeometric((, (1, 2), x)
sage: (2*hypergeometric((, (1, x)).simplify_hypergeometric()
2*e^x
sage: (nest(lambda y: hypergeometric([y], [1], x), 3, 1)) # not tested, unstable
....: .simplify_hypergeometric())
laguerre(-laguerre(-e^x, x), x)
sage: (nest(lambda y: hypergeometric([y], [1], x), 3, 1)) # not tested, unstable
....: .simplify_hypergeometric(algorithm='sage'))
hypergeometric(hypergeometric(e^x, (1,), (1,)), (1,), x)
sage: hypergeometric_M(1, 3, x).simplify_hypergeometric()
\end{verbatim}
-2*((x + 1)*e^(-x) - 1)*e^x/x^2

\[\text{sage: } (2 \times \text{hypergeometric}_U(1, 3, x)).\text{simplify_hypergeometric}()\]
\[2*(x + 1)/x^2\]

```
imag(hold=False)
Return the imaginary part of this symbolic expression.

EXAMPLES:
```
```
sage: sqrt(-2).imag_part()
sqrt(2)
```

We simplify \(\ln(\exp(z))\) to \(z\). This should only be for \(-\pi < \text{Im}(z) \leq \pi\), but Maxima does not have a symbolic imaginary part function, so we cannot use assume to assume that first:

```
sage: z = var('z')
sage: f = log(exp(z))
sage: f
log(e^z)
sage: f.simplify()
z
sage: forget()
```

A more symbolic example:

```
sage: var('a, b')
(a, b)
sage: f = log(a + b*I)
sage: f.imag_part()
arctan2(imag_part(a) + real_part(b), -imag_part(b) + real_part(a))
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```
sage: SR(I).imag_part()
1
sage: SR(I).imag_part(hold=True)
imag_part(I)
```

This also works using functional notation:

```
sage: imag_part(I, hold=True)
imag_part(I)
sage: imag_part(SR(I))
1
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(I).imag_part(hold=True); a.unhold()
1
```

```
imag_part(hold=False)
Return the imaginary part of this symbolic expression.

EXAMPLES:
```
We simplify $\ln(\exp(z))$ to $z$. This should only be for $-\pi < \text{Im}(z) <= \pi$, but Maxima does not have a symbolic imaginary part function, so we cannot use `assume` to assume that first:

```
sage: z = var('z')
sage: f = log(exp(z))
sage: f
log(e^z)
sage: f.simplify()
z
sage: forget()
```

A more symbolic example:

```
sage: var('a, b')
(a, b)
sage: f = log(a + b*I)
sage: f.imag_part()
arctan2(imag_part(a) + real_part(b), -imag_part(b) + real_part(a))
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```
sage: SR(I).imag_part()
1
sage: SR(I).imag_part(hold=True)
imag_part(I)
```

This also works using functional notation:

```
sage: imag_part(I, hold=True)
imag_part(I)
sage: imag_part(SR(I))
1
```

To then evaluate again, we use `unhold()`:

```
sage: a = SR(I).imag_part(hold=True); a.unhold()
1
```

**implicit_derivative(Y, X, n=1)**

Return the n'th derivative of Y with respect to X given implicitly by this expression.

**INPUT:**

- Y - The dependent variable of the implicit expression.
- X - The independent variable with respect to which the derivative is taken.
- n - (default: 1) the order of the derivative.

**EXAMPLES:**

```
sage: var('x, y')
(x, y)
```
Symbolic Calculus, Release 10.0

(continued from previous page)

\begin{verbatim}
sage: f = cos(x)*sin(y)
sage: f.implicit_derivative(y, x)
sin(x)*sin(y)/(cos(x)*cos(y))
sage: g = x^2*y^2
sage: g.implicit_derivative(y, x, 3)
-1/4*(y + 2*y/x)/x^2 + 1/4*(2*y^2/x - y^2/x^2)/(x*y) - 3/4*y/x^3
\end{verbatim}

It is an error to not include an independent variable term in the expression:

\begin{verbatim}
sage: (cos(x)*sin(x)).implicit_derivative(y, x)
Traceback (most recent call last):
... ValueError: Expression cos(x)*sin(x) contains no y terms
\end{verbatim}

\textbf{integral(*args, **kwds)}

Compute the integral of self. Please see \texttt{sage.symbolic.integration.integral.integrate()} for more details.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: sin(x).integral(x,0,3)
-cos(3) + 1
sage: sin(x).integral(x)
-cos(x)
\end{verbatim}

\textbf{integrate(*args, **kwds)}

Compute the integral of self. Please see \texttt{sage.symbolic.integration.integral.integrate()} for more details.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: sin(x).integral(x,0,3)
-cos(3) + 1
sage: sin(x).integral(x)
-cos(x)
\end{verbatim}

\textbf{inverse_laplace(t, s)}

Return inverse Laplace transform of self. See \texttt{sage.calculus.calculus.inverse_laplace}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var('w, m')
(w, m)
sage: f = (1/(w^2+10)).inverse_laplace(w, m); f
1/10*sqrt(10)*sin(sqrt(10)*m)
\end{verbatim}

\textbf{is_algebraic()}

Return True if this expression is known to be algebraic.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: sqrt(2).is_algebraic()
True
sage: (5*sqrt(2)).is_algebraic()
\end{verbatim}

(continues on next page)
True

**sage:** (sqrt(2) + 2^(1/3) - 1).is_algebraic()
True

**sage:** (I*golden_ratio + sqrt(2)).is_algebraic()
True

**sage:** (sqrt(2) + pi).is_algebraic()
False

**sage:** SR(QQ(2/3)).is_algebraic()
True

**sage:** SR(1.2).is_algebraic()
False

**sage:** complex_root_of(x^3 - x^2 - x - 1, 0).is_algebraic()
True

### is_callable()

Return True if self is a callable symbolic expression.

**EXAMPLES:**

```plaintext
sage: var('a x y z')
(a, x, y, z)
sage: f(x, y) = a + 2*x + 3*y + z
sage: f.is_callable()
True
sage: (a+2*x).is_callable()
False
```

### is_constant()

Return whether this symbolic expression is a constant.

A symbolic expression is constant if it does not contain any variables.

**EXAMPLES:**

```plaintext
sage: pi.is_constant()
True
sage: SR(1).is_constant()
True
sage: SR(2).is_constant()
True
sage: log(2).is_constant()
True
sage: SR(I).is_constant()
True
sage: x.is_constant()
False
```

### is_exact()

Return True if this expression only contains exact numerical coefficients.

**EXAMPLES:**

```plaintext
sage: pi.is_exact()  # or SR(pi).is_exact()
True
```
sage: x, y = var('x, y')
sage: (x+y-1).is_exact()
True
sage: (x+y-1.9).is_exact()
False
sage: x.is_exact()
True
sage: pi.is_exact()
True
sage: (sqrt(x-y) - 2*x + 1).is_exact()
True
sage: ((x-y)^0.5 - 2*x + 1).is_exact()
False

is_infinity()
Return True if self is an infinite expression.

EXAMPLES:

sage: SR(oo).is_infinity()
True
sage: x.is_infinity()
False

is_integer()
Return True if this expression is known to be an integer.

EXAMPLES:

sage: SR(5).is_integer()
True

is_negative()
Return True if this expression is known to be negative.

EXAMPLES:

sage: SR(-5).is_negative()
True

Check if we can correctly deduce negativity of mul objects:

sage: t0 = SR.symbol("t0", domain='positive')
sage: t0.is_negative()
False
sage: (-t0).is_negative()
True
sage: (-pi).is_negative()
True

Assumptions on symbols are handled correctly:

sage: y = var('y')
sage: assume(y < 0)

(continues on next page)
is_negative_infinity()
Return True if self is a negative infinite expression.

EXAMPLES:

```python
sage: SR(oo).is_negative_infinity()
False
sage: SR(-oo).is_negative_infinity()
True
sage: x.is_negative_infinity()
False
```

is_numeric()
A Pynac numeric is an object you can do arithmetic with that is not a symbolic variable, function, or constant. Return True if this expression only consists of a numeric object.

EXAMPLES:

```python
sage: SR(1).is_numeric()
True
sage: x.is_numeric()
False
sage: pi.is_numeric()
False
sage: sin(x).is_numeric()
False
```

is_polynomial(var)
Return True if self is a polynomial in the given variable.

EXAMPLES:

```python
sage: var('x,y,z')
(x, y, z)
sage: t = x^2 + y; t
x^2 + y
sage: t.is_polynomial(x)
True
sage: t.is_polynomial(y)
True
sage: t.is_polynomial(z)
True
sage: t = sin(x) + y; t
y + sin(x)
sage: t.is_polynomial(x)
False
```

(continues on next page)
Symbolic Calculus, Release 10.0

is_positive()

Return True if this expression is known to be positive.

EXAMPLES:

```sage
sage: t0 = SR.symbol("t0", domain='positive')
sage: t0.is_positive()
True
sage: t0.is_negative()
False
sage: t0.is_real()
True
sage: t1 = SR.symbol("t1", domain='positive')
sage: (t0*t1).is_positive()
True
sage: (t0 + t1).is_positive()
True
sage: (t0*x).is_positive()
False
```

sage: forget()
sage: assume(x>0)
sage: x.is_positive()
True
sage: cosh(x).is_positive()
True
sage: f = function('f')(x)
sage: assume(f>0)
sage: f.is_positive()
True
sage: forget()

is_positive_infinity()

Return True if self is a positive infinite expression.

EXAMPLES:

```sage
sage: SR(oo).is_positive_infinity()
True
sage: SR(-oo).is_positive_infinity()
False
sage: x.is_infinity()
False
```

is_rational_expression()

Return True if this expression is a rational expression, i.e., a quotient of polynomials.

EXAMPLES:
Symbolic Calculus, Release 10.0

| sage: var('x y z') |
| (x, y, z) |
| sage: ((x + y + z)/(1 + x^2)).is_rational_expression() |
| True |
| sage: ((1 + x + y)^10).is_rational_expression() |
| True |
| sage: ((1/x + z)^5 - 1).is_rational_expression() |
| True |
| sage: (1/(x + y)).is_rational_expression() |
| True |
| sage: (exp(x) + 1).is_rational_expression() |
| False |
| sage: (sin(x*y) + z^3).is_rational_expression() |
| False |
| sage: (exp(x) + exp(-x)).is_rational_expression() |
| False |

**is_real()**

Return True if this expression is known to be a real number.

**EXAMPLES:**

| sage: t0 = SR.symbol("t0", domain='real') |
| sage: t0.is_real() |
| True |
| sage: t0.is_positive() |
| False |
| sage: t1 = SR.symbol("t1", domain='positive') |
| sage: (t0+t1).is_real() |
| True |
| sage: (t0*x).is_real() |
| False |
| sage: (t0^t1).is_real() |
| True |
| sage: t2 = SR.symbol("t2", domain='positive') |
| sage: (t1**t2).is_real() |
| True |
| sage: (t0^x).is_real() |
| False |
| sage: (t0^t1).is_real() |
| False |
| sage: (t1^t2).is_real() |
| True |
| sage: gamma(pi).is_real() |
| True |
| sage: cosh(-3).is_real() |
| True |
| sage: cos(exp(-3) + log(2)).is_real() |
| True |
| sage: gamma(t1).is_real() |
| True |
| sage: (x*pi).is_real() |
| False |
Symbolic Calculus, Release 10.0

sage: (cos(exp(t0) + log(t1))^8).is_real()
True
sage: cos(I + 1).is_real()
False
sage: sin(2 - I).is_real()
False
sage: (2^t0).is_real()
True

The following is real, but we cannot deduce that:

sage: (x*x.conjugate()).is_real()
False

Assumption of real has the same effect as setting the domain:

sage: forget()
sage: assume(x, 'real')
sage: x.is_real()
True
sage: cosh(x).is_real()
True
sage: forget()

The real domain is also set with the integer domain:

sage: SR.var('x', domain='integer').is_real()
True

is_reational()  
Return True if self is a relational expression.

EXAMPLES:

sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.is_relational()
True
sage: sin(x).is_relational()
False

is_square()  
Return True if self is the square of another symbolic expression.

This is True for all constant, non-relational expressions (containing no variables or comparison), and not implemented otherwise.

EXAMPLES:

sage: SR(4).is_square()
True
sage: SR(5).is_square()
True
sage: pi.is_square()

(continues on next page)
True

```sage```
x.is_square()
```
Traceback (most recent call last):
...
NotImplementedError: is_square() not implemented for non-constant
or relational elements of Symbolic Ring

```sage```
r = SR(4) == SR(5)
```
```sage```
r.is_square()
```
Traceback (most recent call last):
...
NotImplementedError: is_square() not implemented for non-constant
or relational elements of Symbolic Ring

```
is_symbol()
```
Return True if this symbolic expression consists of only a symbol, i.e., a symbolic variable.

**EXAMPLES:**

```sage```
x.is_symbol() # True
```
```sage```
var('y')
```
```sage```
y.is_symbol() # True
```
```sage```
(x*y).is_symbol() # False
```
```sage```
pi.is_symbol() # False
```
```sage```
((x*y)/y).is_symbol() # True
```
```sage```
(13).is_symbol() # False

```
is_terminating_series()
```
Return True if self is a series without order term.

A series is terminating if it can be represented exactly, without requiring an order term. You can explicitly
request terminating series by setting the order to positive infinity.

**OUTPUT:**

Boolean. Whether self was constructed by series() and has no order term.

**EXAMPLES:**

```sage```
(x^5+x^2+1).series(x, +oo)
```
```sage```
1 + 1*x^2 + 1*x^5
```
```sage```
(x^5+x^2+1).series(x,+oo).is_terminating_series() # True
```
```sage```
SR(5).is_terminating_series() # False
```
```sage```
var('x')
```
x
```sage```
((x^5+x^2+1)/y).is_terminating_series() # False
```
Symbolic Calculus, Release 10.0

(continued from previous page)

```
sage: x.is_terminating_series()
False
sage: exp(x).series(x,10).is_terminating_series()
False
```

**is_trivial_zero()**

Check if this expression is trivially equal to zero without any simplification.

This method is intended to be used in library code where trying to obtain a mathematically correct result by applying potentially expensive rewrite rules is not desirable.

**EXAMPLES:**

```
sage: SR(0).is_trivial_zero()
True
sage: SR(0.0).is_trivial_zero()
True
sage: SR(float(0.0)).is_trivial_zero()
True
sage: (SR(1)/2^1000).is_trivial_zero()
False
sage: SR(1./2^10000).is_trivial_zero()
False
```

The **is_zero()** method is more capable:

```
sage: t = pi + (pi - 1)*pi - pi^2
sage: t.is_trivial_zero()
False
sage: t.is_zero()
True
sage: t = pi + x*pi + (pi - 1 - x)*pi - pi^2
sage: t.is_zero()
True
sage: u = sin(x)^2 + cos(x)^2 - 1
sage: u.is_trivial_zero()
False
sage: u.is_zero()
True
```

**is_trivially_equal(other)**

Check if this expression is trivially equal to the argument expression, without any simplification.

Note that the expressions may still be subject to immediate evaluation.

This method is intended to be used in library code where trying to obtain a mathematically correct result by applying potentially expensive rewrite rules is not desirable.

**EXAMPLES:**

```
sage: (x^2).is_trivially_equal(x^2)
True
sage: ((x+1)^2 - 2*x - 1).is_trivially_equal(x^2)
False
```

(continues on next page)

2.1. Symbolic Expressions 65
sage: (x*(x+1)).is_trivially_equal((x+1)*x)
True
sage: (x^2 + x).is_trivially_equal((x+1)*x)
False
sage: ((x+1)^2*(x+1)).is_trivially_equal((x+1)^2)
True
sage: (x^2 + 2*x + 1).is_trivially_equal((x+1)^2)
False
sage: (x^-1).is_trivially_equal(1/x)
True
sage: (x/x^2).is_trivially_equal(1/x)
True
sage: ((x^2+x) / (x+1)).is_trivially_equal(1/x)
False

is_unit()

Return True if this expression is a unit of the symbolic ring.

Note that a proof may be attempted to get the result. To avoid this use (ex-1).is_trivial_zero().

EXAMPLES:

```python
sage: SR(1).is_unit()
True
sage: SR(-1).is_unit()
True
sage: SR(0).is_unit()
False
```

iterator()

Return an iterator over the operands of this expression.

EXAMPLES:

```python
sage: x, y, z = var('x,y,z')
sage: list((x+y+z).iterator())
[x, y, z]
sage: list((x^y*z*(x+y)).iterator())
[x + y, x^y, z]
```

Note that symbols, constants and numeric objects do not have operands, so the iterator function raises an error in these cases:

```python
sage: x.iterator()
Traceback (most recent call last):
...
ValueError: expressions containing only a numeric coefficient, constant or symbol have no operands
sage: pi.iterator()
Traceback (most recent call last):
...
ValueError: expressions containing only a numeric coefficient, constant or symbol have no operands
```
Symbolic Calculus, Release 10.0

(continued from previous page)

→ symbol have no operands
sage: SR(5).iterator()
Traceback (most recent call last):
...
ValueError: expressions containing only a numeric coefficient, constant or
→ symbol have no operands

laplace(t, s)

Return Laplace transform of self. See sage.calculus.calculus.laplace

EXAMPLES:

sage: var('x,s,z')
(x, s, z)
sage: (z + exp(x)).laplace(x, s)
z/s + 1/(s - 1)

laurent_polynomial(base_ring=None, ring=None)

Return this symbolic expression as a Laurent polynomial over the given base ring, if possible.

INPUT:

• base_ring - (optional) the base ring for the polynomial
• ring - (optional) the parent for the polynomial

You can specify either the base ring (base_ring) you want the output Laurent polynomial to be over, or you can specify the full laurent polynomial ring (ring) you want the output laurent polynomial to be an element of.

EXAMPLES:

sage: f = x^2 -2/3/x + 1
sage: f.laurent_polynomial(QQ)
-2/3*x^-1 + 1 + x^2
sage: f.laurent_polynomial(GF(19))
12*x^-1 + 1 + x^2

lcm(b)

Return the lcm of self and b.

The lcm is computed from the gcd of self and b implicitly from the relation self * b = gcd(self, b) * lcm(self, b).

Note: In agreement with the convention in use for integers, if self * b == 0, then gcd(self, b) == max(self, b) and lcm(self, b) == 0.

Note: Since the polynomial lcm is computed from the gcd, and the polynomial gcd is unique up to a constant factor (which can be negative), the polynomial lcm is unique up to a factor of -1.

EXAMPLES:
Symbolic Calculus, Release 10.0

```python
sage: var('x, y')
(x, y)
sage: SR(10).lcm(SR(15))
30
sage: (x^3 - 1).lcm(x-1)
x^3 - 1
sage: (x^3 - 1).lcm(x^2+x+1)
x^3 - 1
sage: (x^3 - sage.symbolic.constants.pi).lcm(x-sage.symbolic.constants.pi)
(pi - x^3)*(pi - x)
sage: lcm(x^3 - y^3, x-y) / (x^3 - y^3) in [1,-1]
True
sage: lcm(x^100-y^100, x^10-y^10) / (x^100 - y^100) in [1,-1]
True
sage: a = expand( (x^2+17*x+3/7*y)*(x^5 - 17*y + 2/3) )
sage: b = expand((x^13+17*x+3/7*y)*(x^5 - 17*y + 2/3) )
sage: gcd(a,b) * lcm(a,b) / (a * b) in [1,-1]
True
```

The result is not automatically simplified:

```python
sage: ex = lcm(sin(x)^2 - 1, sin(x)^2 + sin(x)); ex
(sin(x)^2 + sin(x))*(sin(x)^2 - 1)/(sin(x) + 1)
sage: ex.simplify_full()
sin(x)^3 - sin(x)
```

**leading_coeff**

Return the leading coefficient of \( s \) in \( \text{self} \).

**EXAMPLES:**

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.leading_coefficient(x)
sin(x*y)
sage: f.leading_coefficient(y)
x
sage: f.leading_coefficient(sin(x*y))
x^3 + 2/x
```

**leading_coefficient**

Return the leading coefficient of \( s \) in \( \text{self} \).

**EXAMPLES:**

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.leading_coefficient(x)
sin(x*y)
sage: f.leading_coefficient(y)
```

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

```
x
sage: f.leading_coefficient(sin(x*y))
x^3 + 2/x
```

**left()**

If `self` is a relational expression, return the left hand side of the relation. Otherwise, raise a `ValueError`.

**EXAMPLES:**

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2
```

**left_hand_side()**

If `self` is a relational expression, return the left hand side of the relation. Otherwise, raise a `ValueError`.

**EXAMPLES:**

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2
```

**lhs()**

If `self` is a relational expression, return the left hand side of the relation. Otherwise, raise a `ValueError`.

**EXAMPLES:**

```
sage: x = var('x')
sage: eqn = (x-1)^2 == x^2 - 2*x + 3
sage: eqn.left_hand_side()
(x - 1)^2
sage: eqn.lhs()
(x - 1)^2
sage: eqn.left()
(x - 1)^2
```

**limit(*args, **kwds)**

Return a symbolic limit. See `sage.calculus.calculus.limit`

**EXAMPLES:**

```
sage: (sin(x)/x).limit(x=0)
1
```
\textbf{list}(x=None)

Return the coefficients of this symbolic expression as a polynomial in \(x\).

\textbf{INPUT:}

\begin{itemize}
\item \(x\) – optional variable.
\end{itemize}

\textbf{OUTPUT:}

A list of expressions where the \(n\)-th element is the coefficient of \(x^n\) when self is seen as polynomial in \(x\).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var('x, y, a')
(x, y, a)
sage: (x^5).list()
[0, 0, 0, 0, 0, 1]
sage: p = x - x^3 + 5/7*x^5
sage: p.list()
[0, 1, 0, -1, 0, 5/7]
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*a*sqrt(2)*x + 2*a^2 + x^2 + x + 1
sage: p.list(a)
[x^2 + x + 1, -2*a*sqrt(2)*x, 2]
sage: s = (1/(1-x)).series(x,6); s
1 + 1*x + 1*x^2 + 1*x^3 + 1*x^4 + 1*x^5 + Order(x^6)
sage: s.list()
[1, 1, 1, 1, 1, 1]
\end{verbatim}

\textbf{log}(b=None, \textit{hold}=False)

Return the logarithm of self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: x, y = var('x, y')
sage: x.log()
log(x)
sage: (x^y + y^x).log()
log(x^y + y^x)
sage: SR(0).log()
-Infinity
sage: SR(-1).log()
I*pi
sage: SR(1).log()
0
sage: SR(1/2).log()
log(1/2)
sage: SR(0.5).log()
-0.693147180559945
sage: SR(0.5).log().exp()
0.500000000000000
sage: math.log(0.5)
-0.6931471805599453
sage: plot(lambda x: SR(x).log(), 0.1,10)
Graphics object consisting of 1 graphics primitive
\end{verbatim}

To prevent automatic evaluation use the \textit{hold} argument:
Symbolic Calculus, Release 10.0

\begin{verbatim}
\verb+\sage+\verb+I.log()\
+1/2*I*pi
\verb+\sage+\verb+I.log(hold=True)\
+log(I)
\end{verbatim}

To then evaluate again, we use \texttt{unhold}:

\begin{verbatim}
\verb+\sage+ a = \verb+I.log(hold=True); a.unhold()\
+1/2*I*pi
\end{verbatim}

The \texttt{hold} parameter also works in functional notation:

\begin{verbatim}
\verb+\sage+ log(-1,hold=True)\
+log(-1)
\verb+\sage+ log(-1)\
+I*pi
\end{verbatim}

\texttt{log\_expand(algorithm='products')}

Simplify symbolic expression, which can contain logs.

Expands logarithms of powers, logarithms of products and logarithms of quotients. The option \texttt{algorithm} specifies which expression types should be expanded.

INPUT:

- \texttt{self} - expression to be simplified
- \texttt{algorithm} - (default: ‘products’) optional, governs which expression is expanded. Possible values are
  - ‘nothing’ (no expansion),
  - ‘powers’ (log(a^r) is expanded),
  - ‘products’ (like ‘powers’ and also log(a*b) are expanded),
  - ‘all’ (all possible expansion).

See also examples below.

DETAILS: This uses the Maxima simplifier and sets \texttt{logexpand} option for this simplifier. From the Maxima documentation: \texttt{‘Logexpand: true} causes log(a^b) to become b*log(a). If it is set to all, log(a*b) will also simplify to log(a)+log(b). If it is set to super, then log(a/b) will also simplify to log(a)-log(b) for rational numbers a/b, a\#1. (log(1/b), for integer b, always simplifies.) If it is set to false, all of these simplifications will be turned off. “

ALIAS: \texttt{log\_expand()} and \texttt{expand\_log()} are the same

EXAMPLES:

By default powers and products (and quotients) are expanded, but not quotients of integers:

\begin{verbatim}
\verb+\sage+ (log(3/4*x*pi)).log\_expand()\
+pi*\log(x) + \log(3/4)
\end{verbatim}

To expand also log(3/4) use \texttt{algorithm='all'}:

\begin{verbatim}
\verb+\sage+ (log(3/4*x*pi)).log\_expand('all')\
+pi*\log(x) + \log(3) - 2*\log(2)
\end{verbatim}
To expand only the power use `algorithm='powers'`:

```
sage: (log(x^6)).log_expand('powers')
6*log(x)
```

The expression `log((3*x)^6)` is not expanded with `algorithm='powers'`, since it is converted into product first:

```
sage: (log((3*x)^6)).log_expand('powers')
log(729*x^6)
```

This shows that the option `algorithm` from the previous call has no influence to future calls (we changed some default Maxima flag, and have to ensure that this flag has been restored):

```
sage: (log(3/4*x^pi)).log_expand()
pi*log(x) + log(3/4)
sage: (log(3/4*x^pi)).log_expand('all')
pi*log(x) + log(3) - 2*log(2)
sage: (log(3/4*x^pi)).log_expand()
pi*log(x) + log(3/4)
```

AUTHORS:

- Robert Marik (11-2009)

**log_gamma** *(hold=False)*

Return the log gamma function evaluated at self. This is the logarithm of gamma of self, where gamma is a complex function such that \(\gamma(n)\) equals \(factorial(n-1)\).

EXAMPLES:

```
sage: x = var('x')
sage: x.log_gamma()
log_gamma(x)
sage: SR(2).log_gamma()
0
sage: SR(5).log_gamma()
log(24)
sage: a = SR(5).log_gamma(); a.n()
3.17805383034795
sage: SR(5-1).factorial().log()
log(24)
sage: from sage.misc.verbose import set_verbose
sage: set_verbose(-1); plot(lambda x: SR(x).log_gamma(), -7,8, plot_points=1000).show()
sage: math.exp(0.5)
1.6487212707001282
sage: plot(lambda x: (SR(x).exp() - SR(-x).exp())/2 - SR(x).sinh(), -1, 1)
```

To prevent automatic evaluation use the `hold` argument:

```
sage: SR(5).log_gamma(hold=True)
log_gamma(5)
```
To evaluate again, currently we must use numerical evaluation via \texttt{n}():

\begin{verbatim}
sage: a = SR(5).log_gamma(hold=True); a.n()
sage: a.n()
3.17805383034795
\end{verbatim}

\texttt{log\_simplify(algorithm=None)}

Simplify a (real) symbolic expression that contains logarithms.

The given expression is scanned recursively, transforming subexpressions of the form \(a \log(b) + c \log(d)\) into \(\log(b^a d^c)\) before simplifying within the \texttt{log}().

The user can specify conditions that \(a\) and \(c\) must satisfy before this transformation will be performed using the optional parameter \texttt{algorithm}.

\textbf{Warning:} This is only safe to call if every variable in the given expression is assumed to be real. The simplification it performs is in general not valid over the complex numbers. For example:

\begin{verbatim}
sage: x, y = SR.var('x,y')
sage: f = log(x*y) - (log(x) + log(y))
sage: f(x=-1, y=i)
sage: f.simplify_log()
-2*I*pi
sage: f.simplify_log()
0
\end{verbatim}

\textbf{INPUT:}
- \texttt{self} - expression to be simplified
- \texttt{algorithm} - (default: None) optional, governs the condition on \(a\) and \(c\) which must be satisfied to contract expression \(a \log(b) + c \log(d)\). Values are
  - \texttt{None} (use Maxima default, integers),
  - \texttt{'one'} (1 and -1),
  - \texttt{'ratios'} (rational numbers),
  - \texttt{'constants'} (constants),
  - \texttt{'all'} (all expressions).

\textbf{ALGORITHM:}
This uses the Maxima \texttt{logcontract()} command.

\textbf{ALIAS:}
\texttt{log\_simplify()} and \texttt{simplify\_log()} are the same.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: x, y, t = var('x y t')
sage: f = log(x)+2*log(y)+1/2*log(t)
sage: f.simplify_log()
log(x*y^2) + 1/2*log(t)
\end{verbatim}
To contract all terms in the previous example, we use the 'ratios' algorithm:

```python
sage: f.simplify_log(algorithm='ratios')
log(sqrt(t)*x*y^2)
```

To contract terms with no coefficient (more precisely, with coefficients 1 and -1), we use the 'one' algorithm:

```python
sage: f = log(x)+2*log(y)-log(t)
sage: f.simplify_log(algorithm='one')
2*log(y) + log(x/t)
```

```python
sage: f = log(x)+log(y)-1/3*log((x+1))
sage: f.simplify_log()
log(x*y) - 1/3*log(x + 1)
sage: f.simplify_log(algorithm='ratios')
log(x*y/(x + 1)^(1/3))
```

\(\pi\) is an irrational number; to contract logarithms in the following example we have to set algorithm to 'constants' or 'all':

```python
sage: f = log(x)+log(y)-pi*log((x+1))
sage: f.simplify_log(algorithm='constants')
log(x*y/(x + 1)^pi)
```

\(x^*\log(9)\) is contracted only if algorithm is 'all':

```python
sage: (x*log(9)).simplify_log()
2*x*log(3)
sage: (x*log(9)).simplify_log(algorithm='all')
log(3^(2*x))
```

AUTHORS:
- Robert Marik (11-2009)

**low_degree(s)**

Return the exponent of the lowest power of \(s\) in self.

OUTPUT:
An integer

EXAMPLES:

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y^10 + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + 2*sin(x*y)/x + x/y^10 + 100
sage: f.low_degree(x)
-1
sage: f.low_degree(y)
-10
sage: f.low_degree(sin(x*y))
0
```
sage: (x^3+y).low_degree(x)
0
sage: (x+x**2).low_degree(x)
1

match(pattern)
Check if self matches the given pattern.

INPUT:

• pattern – a symbolic expression, possibly containing wildcards to match for

OUTPUT:

One of

None if there is no match, or a dictionary mapping the wildcards to the matching values if a match was found. Note that the dictionary is empty if there were no wildcards in the given pattern.

See also http://www.ginac.de/tutorial/Pattern-matching-and-advanced-substitutions.html

EXAMPLES:

sage: var('x,y,z,a,b,c,d,f,g')
(x, y, z, a, b, c, d, f, g)
sage: w0 = SR.wild(0); w1 = SR.wild(1); w2 = SR.wild(2)
sage: ((x+y)^a).match((x+y)^a)  # no wildcards, so empty dict
{}
sage: print(((x+y)^a).match((x+y)^b))
None
sage: t = ((x+y)^a).match(w0^w1)
sage: t[w0], t[w1]
(x + y, a)
sage: print(((x+y)^a).match(w0^w0))
None
sage: ((x+y)^(x+y)).match(w0^w0)
{$0: x + y}$
sage: t = ((a+b)*(a+c)).match((a+w0)*(a+w1))
sage: set([t[w0], t[w1]]) == set([b, c])
True
sage: ((a+b)*(a+c)).match((w0+b)*(w0+c))
{$0: a}$
sage: t = ((a+b)*(a+c)).match((w0+w1)*(w0+w2))
sage: t[w0]
a
sage: set([t[w1], t[w2]]) == set([b, c])
True
sage: t = ((a+b)*(a+c)).match((w0+w1)*(w1+w2))
sage: t[w1]
a
sage: set([t[w0], t[w2]]) == set([b, c])
True
sage: t = (a*(x+y)+a*z+b).match(a*w0+w1)
sage: s = set([t[w0], t[w1]])
sage: s == set([x+y, a*z+b]) or s == set([z, a*(x+y)+b])

(continues on next page)
True
sage: print((a+b+c+d+f+g).match(c))
None
sage: (a+b+c+d+f+g).has(c)
True
sage: (a+b+c+d+f+g).match(c+w0)
{$0: a + b + d + f + g}$

sage: (a+b+c+d+f+g).match(c+g+w0)
{$0: a + b + d + f}$

sage: (a+b).match(a+b+w0)  # known bug
{$0: 0}$

sage: print(((a*b^2).match(a*w0*b^w1))
None
sage: (a*b^2).match(a*b^w1)
{$1: 2}$

sage: (x*x.arctan2(x^2)).match(w0*w0.arctan2(w0^2))
{$0: x}$

Beware that behind-the-scenes simplification can lead to surprising results in matching:
sage: print((x+x).match(w0+w1))
None

sage: t = x+x; t
2*x
sage: t.operator()
<function mul_vararg ...>

Since asking to match w0+w1 looks for an addition operator, there is no match.

maxima_methods()

Provide easy access to maxima methods, converting the result to a Sage expression automatically.

EXAMPLES:
sage: t = log(sqrt(2) - 1) + log(sqrt(2) + 1); t
log(sqrt(2) + 1) + log(sqrt(2) - 1)
sage: res = t.maxima_methods().logcontract(); res
log((sqrt(2) + 1)*(sqrt(2) - 1))
sage: type(res)
<class 'sage.symbolic.expression.Expression'>

minpoly(*args, **kwds)

Return the minimal polynomial of this symbolic expression.

EXAMPLES:
sage: golden_ratio.minpoly()
x^2 - x - 1

mul(hold=False, *args)

Return the product of the current expression and the given arguments.

To prevent automatic evaluation use the hold argument.

EXAMPLES:
Symbolic Calculus, Release 10.0

sage: x.mul(x)
x^2
sage: x.mul(x, hold=True)
x^2
sage: x.mul(x, (2+x), hold=True)
(2*x)*(x + 2)*x*x
sage: x.mul(x, (2+x), x, hold=True)
(2*x)*(x + 2)*x*x*x

To then evaluate again, we use unhold():

sage: a = x.mul(x, hold=True); a.unhold()
x^2

multiply_both_sides(x, checksign=None)

Return a relation obtained by multiplying both sides of this relation by \( x \).

Note: The checksign keyword argument is currently ignored and is included for backward compatibility reasons only.

EXAMPLES:

sage: var('x,y'); f = x + 3 < y - 2
(x, y)
sage: f.multiply_both_sides(7)
7*x + 21 < 7*y - 14
sage: f.multiply_both_sides(-1/2)
-1/2*x - 3/2 < -1/2*y + 1
sage: f*(-2/3)
-2/3*x - 2 < -2/3*y + 4/3
sage: f*(-pi)
-pi*(x + 3) < -pi*(y - 2)

Since the direction of the inequality never changes when doing arithmetic with equations, you can multiply or divide the equation by a quantity with unknown sign:

sage: f*(1+I)
(I + 1)*x + 3*I + 3 < (I + 1)*y - 2*I - 2
sage: f = sqrt(2) + x == y^3
sage: f.multiply_both_sides(I)
I*x + I*sqrt(2) == I*y^3
sage: f.multiply_both_sides(-1)
-x - sqrt(2) == -y^3

Note that the direction of the following inequalities is not reversed:

sage: (x^3 + 1 > 2*sqrt(3)) * (-1)
-x^3 - 1 > -2*sqrt(3)
sage: (x^3 + 1 >= 2*sqrt(3)) * (-1)
-x^3 - 1 >= -2*sqrt(3)

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

```
sage: (x^3 + 1 <= 2*sqrt(3)) * (-1)
-x^3 - 1 <= -2*sqrt(3)
```

**negation()**

Return the negated version of `self`.
This is the relation that is False iff `self` is True.

**EXAMPLES:**

```
sage: (x < 5).negation()
x >= 5
sage: (x == sin(3)).negation()
x != sin(3)
sage: (2*x >= sqrt(2)).negation()
2*x < sqrt(2)
```

**nintegral(**args, **kwds)**

Compute the numerical integral of `self`. Please see `sage.calculus.calculus.nintegral` for more details.

**EXAMPLES:**

```
sage: sin(x).nintegral(x,0,3)
(1.989992496600..., 2.209335488557...e-14, 21, 0)
```

**nintegrate(**args, **kwds)**

Compute the numerical integral of `self`. Please see `sage.calculus.calculus.nintegral` for more details.

**EXAMPLES:**

```
sage: sin(x).nintegral(x,0,3)
(1.989992496600..., 2.209335488557...e-14, 21, 0)
```

**nops()**

Return the number of operands of this expression.

**EXAMPLES:**

```
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: a.number_of_operands()
0
sage: (a^2 + b^2 + (x+y)^2).number_of_operands()
3
sage: (a^2).number_of_operands()
2
sage: (a*b^2*c).number_of_operands()
3
```

**norm()**

Return the complex norm of this symbolic expression, i.e., the expression times its complex conjugate. If \( c = a + bi \) is a complex number, then the norm of \( c \) is defined as the product of \( c \) and its complex conjugate

\[
\text{norm}(c) = \text{norm}(a + bi) = c \cdot \overline{c} = a^2 + b^2.
\]
The norm of a complex number is different from its absolute value. The absolute value of a complex number is defined to be the square root of its norm. A typical use of the complex norm is in the integral domain \( \mathbb{Z}[i] \) of Gaussian integers, where the norm of each Gaussian integer \( c = a + bi \) is defined as its complex norm.

**See also:**

```
sage.misc.functional.norm()
```

**EXAMPLES:**

```
sage: a = 1 + 2*I
sage: a.norm()
5
sage: a = sqrt(2) + 3^(1/3)*I; a
sqrt(2) + I*3^(1/3)
sage: a.norm()
3^(2/3) + 2
sage: CDF(a).norm()
4.080083823051...
sage: CDF(a.norm())
4.080083823051904
```

**normalize()**

Return this expression normalized as a fraction

**See also:**

```
numerator(), denominator(), numerator_denominator(), combine()
```

**EXAMPLES:**

```
sage: var('x, y, a, b, c')
(x, y, a, b, c)
sage: g = x + y/(x + 2)
sage: g.normalize()
(x^2 + 2*x + y)/(x + 2)
sage: f = x*(x-1)/(x^2 - 7) + y^2/(x^2-7) + 1/(x+1) + b/a + c/a
sage: f.normalize()
(a*x^3 + b*x^3 + c*x^3 + a*x*y^2 + a^2*x^2 + b*x^2 + c*x^2 +
 a*y^2 - a*x - 7*b*x - 7*c*x - 7*a - 7*b - 7*c)/((x^2 - 7)*a*(x + 1))
```

**number_of_arguments()**

**EXAMPLES:**

```
sage: x,y = var('x,y')
sage: f = x + y
sage: f.number_of_arguments()
2
sage: g = f.function(x)
sage: g.number_of_arguments()
1
```
Symbolic Calculus, Release 10.0

```python
sage: x,y,z = var('x,y,z')
sage: (x+y).number_of_arguments()
2
sage: (x+1).number_of_arguments()
1
sage: (sin(x)+1).number_of_arguments()
1
sage: (sin(z)+x+y).number_of_arguments()
3
sage: (sin(x+y)).number_of_arguments()
2
```

**number_of_operands()**

Return the number of operands of this expression.

**EXAMPLES:**

```python
sage: a, b, c, x, y = var('a,b,c,x,y')
sage: a.number_of_operands()
0
sage: (a^2 + b^2 + (x+y)^2).number_of_operands()
3
sage: (a^2).number_of_operands()
2
sage: (a*b^2*c).number_of_operands()
3
```

**numerator**(normalize=True)

Return the numerator of this symbolic expression

**INPUT:**

- normalize – (default: True) a boolean.

If normalize is True, the expression is first normalized to have it as a fraction before getting the numerator.

If normalize is False, the expression is kept and if it is not a quotient, then this will return the expression itself.

**See also:**

`normalize()`, `denominator()`, `numerator_denominator()`, `combine()`

**EXAMPLES:**

```python
sage: a, x, y = var('a,x,y')
sage: f = x*(x-a)/((x^2 - y)*(x-a)); f
x/(x^2 - y)
sage: f.numerator()
x
sage: f.denominator()
x^2 - y
sage: f.numerator(normalize=False)
x
sage: f.denominator(normalize=False)
```

(continues on next page)
\[ x^2 - y \]

**sage:** \( y = \text{var('y')} \)
**sage:** \( g = x + y/(x + 2); g \)

\[ x + y/(x + 2) \]

**sage:** \( g.\text{numerator()} \)

\[ x^2 + 2*x + y \]

**sage:** \( g.\text{denominator()} \)

\[ x + 2 \]

**sage:** \( g.\text{numerator(normalize=False)} \)

\[ x + y/(x + 2) \]

**sage:** \( g.\text{denominator(normalize=False)} \)

\[ 1 \]

**numerator_denominator**(normalize=True)

Return the numerator and the denominator of this symbolic expression

**INPUT:**

* normalize – (default: True) a boolean.

If normalize is True, the expression is first normalized to have it as a fraction before getting the numerator and denominator.

If normalize is False, the expression is kept and if it is not a quotient, then this will return the expression itself together with 1.

**See also:**

normalize(), numerator(), denominator(), combine()

**EXAMPLES:**

**sage:** \( x, y, a = \text{var("x y a")} \)
**sage:** \((x+y)^2/(x-y)^3*x^3).\text{numerator_denominator()} \)

\[ ((x + y)^2*x^3, (x - y)^3) \]

**sage:** \((x+y)^2/(x-y)^3*x^3).\text{numerator_denominator(False)} \)

\[ ((x + y)^2*x^3, (x - y)^3) \]

**sage:** \( g = x + y/(x + 2) \)
**sage:** \( g.\text{numerator_denominator()} \)

\[ (x^2 + 2*x + y, x + 2) \]

**sage:** \( g.\text{numerator_denominator(normalize=False)} \)

\[ (x + y/(x + 2), 1) \]

**sage:** \( g = x^2*(x + 2) \)
**sage:** \( g.\text{numerator_denominator()} \)

\[ ((x + 2)*x^2, 1) \]

**sage:** \( g.\text{numerator_denominator(normalize=False)} \)

\[ ((x + 2)*x^2, 1) \]

**numerical_approx**(prec=None, digits=None, algorithm=None)

Return a numerical approximation of self with prec bits (or decimal digits) of precision.

No guarantee is made about the accuracy of the result.
INPUT:

- `prec` – precision in bits
- `digits` – precision in decimal digits (only used if `prec` is not given)
- `algorithm` – which algorithm to use to compute this approximation

If neither `prec` nor `digits` is given, the default precision is 53 bits (roughly 16 digits).

**EXAMPLES:**

```python
sage: sin(x).subs(x=5).n()
-0.958924274663138
sage: sin(x).subs(x=5).n(100)
-0.95892427466313846889315440616
sage: sin(x).subs(x=5).n(digits=50)
-0.95892427466313846889315440615599397335246154396460
sage: zeta(x).subs(x=2).numerical_approx(digits=50)
1.6449340668482264364724151666460251892189499012068
sage: cos(3).numerical_approx(200)
-0.98999249660044545727157279473126130239367909661558832881409
sage: numerical_approx(cos(3), 200)
-0.98999249660044545727157279473126130239367909661558832881409
sage: numerical_approx(cos(3), digits=10)
-0.989924966
sage: (i + 1).numerical_approx(32)
1.00000000 + 1.00000000*I
sage: (pi + e + sqrt(2)).numerical_approx(100)
7.2740880444219335226246195788
```

**op**

Provide access to the operands of an expression through a property.

**EXAMPLES:**

```python
sage: t = 1+x+x^2
sage: t.op
Operands of x^2 + x + 1
sage: x.op
Traceback (most recent call last):
...
TypeError: expressions containing only a numeric coefficient, constant or symbol have no operands
sage: t.op[0]
x^2
```

Indexing directly with `t[1]` causes problems with numpy types.

```python
sage: t[1] Traceback (most recent call last): ... TypeError: ‘sage.symbolic.expression.Expression’ object ...
```

**operands()**

Return a list containing the operands of this expression.

**EXAMPLES:**
```python
sage: var('a,b,c,x,y')
(a, b, c, x, y)
sage: (a^2 + b^2 + (x+y)^2).operands()
[a^2, b^2, (x + y)^2]
sage: (a^2).operands()
[a, 2]
sage: (a^b^2*c).operands()
[a, b^2, c]
```

**operator()**

Return the topmost operator in this expression.

**EXAMPLES:**

```python
sage: x,y,z = var('x,y,z')
sage: (x+y).operator()
<function add_vararg ...>
sage: (x^y).operator()
<built-in function pow>
sage: (x^y * z).operator()
<function mul_vararg ...>
sage: (x < y).operator()
<built-in function lt>
sage: abs(x).operator()
abs
sage: r = gamma(x).operator(); type(r)
<class 'sage.functions.gamma.Function_gamma'>
sage: psi = function('psi', nargs=1)
sage: psi(x).operator()
psi
sage: r = psi(x).operator()
sage: r == psi
True
sage: f = function('f', nargs=1, conjugate_func=lambda self, x: 2*x)
sage: nf = f(x).operator()
sage: nf(x).conjugate()
2*x
sage: f = function('f')
sage: a = f(x).diff(x); a
diff(f(x), x)
sage: a.operator()
D[0](f)
```

**partial_fraction**(var=None)

Return the partial fraction expansion of self with respect to the given variable.

**INPUT:**

- var – variable name or string (default: first variable)
OUTPUT:
A symbolic expression

See also:

partial_fraction_decomposition()

EXAMPLES:

```python
sage: f = x^2/(x+1)^3
sage: f.partial_fraction()
1/(x + 1) - 2/(x + 1)^2 + 1/(x + 1)^3
```

Notice that the first variable in the expression is used by default:

```python
sage: y = var('y')
sage: f = y^2/(y+1)^3
sage: f.partial_fraction()
1/(y + 1) - 2/(y + 1)^2 + 1/(y + 1)^3
```

You can explicitly specify which variable is used:

```python
sage: f = y^2/(y+1)^3 + x/(x-1)^3
sage: f.partial_fraction(y)
x/(x^3 - 3*x^2 + 3*x - 1) + 1/(y + 1) - 2/(y + 1)^2 + 1/(y + 1)^3
```

partial_fraction_decomposition(var=None)

Return the partial fraction decomposition of self with respect to the given variable.

INPUT:

• var – variable name or string (default: first variable)

OUTPUT:

A list of symbolic expressions

See also:

partial_fraction()

EXAMPLES:

```python
sage: f = x^2/(x+1)^3
sage: f.partial_fraction_decomposition()
[1/(x + 1), -2/(x + 1)^2, (x + 1)^(-3)]
```

Notice that the first variable in the expression is used by default:

```python
sage: y = var('y')
sage: f = y^2/(y+1)^3
sage: f.partial_fraction_decomposition()
[1/(y + 1), -2/(y + 1)^2, (y + 1)^(-3)]
```

(continues on next page)
Symbolic Calculus, Release 10.0

You can explicitly specify which variable is used:

```
sage: f.partial_fraction_decomposition(y)
[1/(y + 1), -2/(y + 1)^2, (y + 1)^(-3), x/(x^3 - 3*x^2 + 3*x - 1)]
```

The `plot(*args,**kwds)` function is used to plot symbolic expressions. All arguments are passed onto the standard plot command.

**EXAMPLES:**

This displays a straight line:

```
sage: sin(2).plot((x,0,3))
```

This draws a red oscillatory curve:

```
sage: sin(x^2).plot((x,0,2*pi), rgbcolor=(1,0,0))
```

Another plot using the variable theta:

```
sage: var('theta')
theta
sage: (cos(theta) - erf(theta)).plot((theta,-2*pi,2*pi))
```

A very thick green plot with a frame:

```
sage: sin(x).plot((x,-4*pi, 4*pi), thickness=20, rgbcolor=(0,0.7,0)).show(frame=True)
```

You can embed 2d plots in 3d space as follows:

```
sage: plot(sin(x^2), (x,-pi, pi), thickness=2).plot3d(z = 1)
```

A more complicated family:

```
sage: G = sum([plot(sin(n*x), (x,-2*pi, 2*pi)).plot3d(z=n) for n in [0,0.1,...,-1]])
sage: G.show(frame_aspect_ratio=[1,1,1/2])
```

A plot involving the floor function:

```
sage: plot(1.0 - x * floor(1/x), (x,0.00001,1.0))
```

Sage used to allow symbolic functions with “no arguments”; this no longer works:

```
sage: f = y^2/(y+1)^3 + x/(x-1)^3
sage: f.partial_fraction_decomposition()
[y^2/(y^3 + 3*y^2 + 3*y + 1), (x - 1)^(-2), (x - 1)^(-3)]
```
Symbolic Calculus, Release 10.0

```python
sage: plot(2*sin, -4, 4)
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: 'Integer Ring' and '<class 'sage.functions.trig.Function_sin'>'
```

You should evaluate the function first:

```python
sage: plot(2*sin(x), -4, 4)
Graphics object consisting of 1 graphics primitive
```

**poly**(x=None)

Express this symbolic expression as a polynomial in x. If this is not a polynomial in x, then some coefficients may be functions of x.

**Warning:** This is different from polynomial() which returns a Sage polynomial over a given base ring.

**EXAMPLES:**

```python
sage: var('a, x')
(a, x)
sage: p = expand((x-a*sqrt(2))^2 + x + 1); p
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: p.poly(a)
-2*sqrt(2)*a*x + 2*a^2 + x^2 + x + 1
sage: bool(p.poly(a) == (x-a*sqrt(2))^2 + x + 1)
True
sage: p.poly(x)
2*a^2 - (2*sqrt(2)*a - 1)*x + x^2 + 1
```

**polynomial**(base_ring=None, ring=None)

Return this symbolic expression as an algebraic polynomial over the given base ring, if possible.

The point of this function is that it converts purely symbolic polynomials into optimised algebraic polynomials over a given base ring.

You can specify either the base ring (base_ring) you want the output polynomial to be over, or you can specify the full polynomial ring (ring) you want the output polynomial to be an element of.

**INPUT:**

- base_ring - (optional) the base ring for the polynomial
- ring - (optional) the parent for the polynomial

**Warning:** This is different from poly() which is used to rewrite self as a polynomial in terms of one of the variables.

**EXAMPLES:**

```python
sage: f = x^2 -2/3*x + 1
sage: f.polynomial(QQ)
```

(continues on next page)
Polynomials can be useful for getting the coefficients of an expression:

\[
sage: g = 6x^2 - 5
\]
\[
sage: g.coefficients()
\]
\[
\begin{bmatrix}
-5, 0 \\
6, 2
\end{bmatrix}
\]
\[
sage: g.polynomial(QQ).list()
\]
\[
\begin{bmatrix}
-5, 0, 6
\end{bmatrix}
\]
\[
sage: g.polynomial(QQ).dict()
\]
\[
\{0: -5, 2: 6\}
\]

We coerce a multivariate polynomial with complex symbolic coefficients:

\[
sage: x, y, n = var('x, y, n')
\]
\[
sage: f = pi^3*x - y^2*e - I; f
\]
\[
pi^3*x - y^2*e - I
\]
\[
sage: f.polynomial(CDF)  # abs tol 1e-15
\]
\[
(-2.718281828459045)*y^2 + 31.006276680299820175*x - 1.0000000000000000000*I
\]
\[
sage: f.polynomial(CC)
\]
\[
(-2.71828182845905)*y^2 + 31.0062766802998*x - 1.000000000000000
\]
\[
sage: f.polynomial(ComplexField(70))
\]
\[
(-2.7182818284590452354)*y^2 + 31.006276680299820175*x - 1.0000000000000000000*I
\]

Another polynomial:

\[
sage: f = sum((e*I)^n*x^n for n in range(5)); f
\]
\[
x^4*e^4 - I*x^3*e^3 - x^2*e^2 + I*x*e + 1
\]
\[
sage: f.polynomial(CDF)  # abs tol 5e-16
\]
\[
54.598150033144236*x^4 - 20.085536923187668*I*x^3 - 7.38905609893065*x^2 + 2.
\]
\[
\rightarrow 7182182845905*I*x + 1.0
\]
\[
sage: f.polynomial(CC)
\]
\[
54.598150033144234*x^4 - 20.0855369231877*I*x^3 - 7.38905609893065*x^2 + 2.
\]
\[
\rightarrow 7182182845905*I*x + 1.000000000000000
\]

A multivariate polynomial over a finite field:
Symbolic Calculus, Release 10.0

```
sage: f = (3*x^5 - 5*y^5)^7; f
(3*x^5 - 5*y^5)^7
sage: g = f.polynomial(GF(7)); g
3*x^35 + 2*y^35
sage: parent(g)
Multivariate Polynomial Ring in x, y over Finite Field of size 7
```

We check to make sure constants are converted appropriately:

```
sage: (pi*x).polynomial(SR)
pi*x
```

Using the `ring` parameter, you can also create polynomials rings over the symbolic ring where only certain variables are considered generators of the polynomial ring and the others are considered “constants”:

```
sage: a, x, y = var('a,x,y')
sage: f = a*x^10*y+3*x
sage: B = f.polynomial(ring=SR['x,y'])
sage: B.coefficients()
[a, 3]
```

`power(exp, hold=False)`

Return the current expression to the power `exp`.

To prevent automatic evaluation use the `hold` argument.

**EXAMPLES:**

```
sage: (x^2).power(2)
x^4
sage: (x^2).power(2, hold=True)
(x^2)^2
```

To then evaluate again, we use `unhold()`:

```
sage: a = (x^2).power(2, hold=True); a.unhold()
x^4
```

`power_series(base_ring)`

Return algebraic power series associated to this symbolic expression, which must be a polynomial in one variable, with coefficients coercible to the base ring.

The power series is truncated one more than the degree.

**EXAMPLES:**

```
sage: theta = var('theta')
sage: f = theta^3 + (1/3)*theta - 17/3
sage: g = f.power_series(QQ); g
-17/3 + 1/3*theta + theta^3 + O(theta^4)
sage: g^3
-4913/27 + 289/9*theta - 17/9*theta^2 + 2602/27*theta^3 + O(theta^4)
sage: g.parent()
Power Series Ring in theta over Rational Field
```
**primitive_part(s)**
Return the primitive polynomial of this expression when considered as a polynomial in \( s \).

See also \( \text{unit()} \), \( \text{content()} \), and \( \text{unit_content_primitive()} \).

**INPUT:**
- \( s \) – a symbolic expression.

**OUTPUT:**
The primitive polynomial as a symbolic expression. It is defined as the quotient by the \( \text{unit()} \) and \( \text{content()} \) parts (with respect to the variable \( s \)).

**EXAMPLES:**

```
sage: (2*x+4).primitive_part(x)
x + 2
sage: (2*x+1).primitive_part(x)
2*x + 1
sage: (2*x+1/2).primitive_part(x)
4*x + 1
sage: var('y')
y
sage: (2*x + 4*sin(y)).primitive_part(sin(y))
x + 2*sin(y)
```

**prod(*args, **kwds)**
Return the symbolic product \( \prod_{v=a}^{b} \text{expression} \) with respect to the variable \( v \) with endpoints \( a \) and \( b \).

**INPUT:**
- \( \text{expression} \) - a symbolic expression
- \( v \) - a variable or variable name
- \( a \) - lower endpoint of the product
- \( b \) - upper endpoint of the product
- \( \text{algorithm} \) - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'giac' - (optional) use Giac
  - 'sympy' - use SymPy
- \( \text{hold} \) - (default: False) if True don’t evaluate

**pyobject()**
Get the underlying Python object.

**OUTPUT:**
The Python object corresponding to this expression, assuming this expression is a single numerical value or an infinity representable in Python. Otherwise, a \( \text{TypeError} \) is raised.

**EXAMPLES:**

```
sage: var('x')
x
sage: b = -17.3
```
Integers and Rationals are converted internally though, so you won’t get back the same object:

```
sage: b = -17/3
sage: a = SR(b)
sage: a.pyobject()
-17/3
sage: a.pyobject() is b
False
```

**rational_expand** (*side=None*)

Expand this symbolic expression. Products of sums and exponentiated sums are multiplied out, numerators of rational expressions which are sums are split into their respective terms, and multiplications are distributed over addition at all levels.

**EXAMPLES:**

We expand the expression \((x - y)^5\) using both method and functional notation.

```
sage: x,y = var('x,y')
sage: a = (x-y)^5
sage: a.expand()
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
sage: expand(a)
x^5 - 5*x^4*y + 10*x^3*y^2 - 10*x^2*y^3 + 5*x*y^4 - y^5
```

We expand some other expressions:

```
sage: expand((x-1)^3/(y-1))
x^3/(y - 1) - 3*x^2/(y - 1) + 3*x/(y - 1) - 1/(y - 1)
sage: expand((x+sin((x+y)^2))^2)
x^2 + 2*x*sin(x^2 + 2*x*y + y^2) + sin(x^2 + 2*x*y + y^2)^2
```

Observe that **expand()** also expands function arguments:

```
sage: f(x) = function('f')(x)
sage: fx = f(x*(x+1)); fx
f((x + 1)*x)
sage: fx.expand()
f(x^2 + x)
```

We can expand individual sides of a relation:

```
sage: a = (16*x-13)^2 == (3*x+5)^2/2
sage: a.expand()
256*x^2 - 416*x + 169 == 9/2*x^2 + 15*x + 25/2
sage: a.expand('left')
256*x^2 - 416*x + 169 == 1/2*(3*x + 5)^2
```
\texttt{sage}: \texttt{a.expand('right')}
\begin{verbatim}
(16\times - 13)^2 == 9/2\times^2 + 15\times + 25/2
\end{verbatim}

\textbf{rational\_simplify}(algorithm='full', map=False)

Simplify rational expressions.

\textbf{INPUT}:

\begin{itemize}
\item \texttt{self} - symbolic expression
\item \texttt{algorithm} - (default: \texttt{`full'}) string which switches the algorithm for simplifications. Possible values are
  \begin{itemize}
  \item \texttt{simple} (simplify rational functions into quotient of two polynomials),
  \item \texttt{full} (apply repeatedly, if necessary)
  \item \texttt{noexpand} (convert to common denominator and add)
  \end{itemize}
\item \texttt{map} - (default: \texttt{False}) if True, the result is an expression whose leading operator is the same as that of the expression \texttt{self} but whose subparts are the results of applying simplification rules to the corresponding subparts of the expressions.
\end{itemize}

\textbf{ALIAS}: \texttt{rational\_simplify()} and \texttt{simplify\_rational()} are the same

\textbf{DETAILS}: We call Maxima functions \texttt{ratsimp}, \texttt{fullratsimp} and \texttt{xthru}. If each part of the expression has to be simplified separately, we use Maxima function map.

\textbf{EXAMPLES}:

\begin{verbatim}
\texttt{sage}: f = \sin(x/(x^2 + x))
\texttt{sage}: f
\sin(x/(x^2 + x))
\texttt{sage}: f.simplify_rational()
\sin(1/(x + 1))
\end{verbatim}

\begin{verbatim}
\texttt{sage}: f = ((x - 1)^(3/2) - (x + 1)\sqrt{x - 1})/\sqrt{x^2 - 1}; f
-((x + 1)\sqrt{x - 1} - (x - 1)^(3/2))/\sqrt{x^2 - 1}
\texttt{sage}: f.simplify_rational()
-2*\sqrt{x - 1}/\sqrt{x^2 - 1}
\end{verbatim}

With \texttt{map=True} each term in a sum is simplified separately and thus the results are shorter for functions which are combination of rational and nonrational functions. In the following example, we use this option if we want not to combine logarithm and the rational function into one fraction:

\begin{verbatim}
\texttt{sage}: f = (x^2 - 1)/(x + 1) - \ln(x)/(x + 2)
\texttt{sage}: f.simplify_rational()
(x^2 + x - \log(x) - 2)/(x + 2)
\texttt{sage}: f.simplify_rational(map=True)
x - \log(x)/(x + 2) - 1
\end{verbatim}

Here is an example from the Maxima documentation of where \texttt{algorithm='simple'} produces an (possibly useful) intermediate step:

\begin{verbatim}
\texttt{sage}: y = \texttt{var('y')}
\texttt{sage}: g = (x^y + 1)^2*(x^y - 1)^2/(x^y - 1)
\texttt{sage}: g.simplify_rational(algorithm='simple')
\end{verbatim}
\[(x^{2*y} - 2*x^y + 1)/(x^y - 1)\]
\[\text{sage: } g.\text{simplify}\_\text{rational}()\]
\[x^y - 1\]

With option \texttt{algorithm='noexpand'} we only convert to common denominators and add. No expansion of products is performed:

\[\text{sage: } f = 1/(x+1)+x/(x+2)^2\]
\[\text{sage: } f.\text{simplify}\_\text{rational}()\]
\[(2*x^2 + 5*x + 4)/(x^3 + 5*x^2 + 8*x + 4)\]
\[\text{sage: } f.\text{simplify}\_\text{rational(algorithm='noexpand')}\]
\[((x + 2)^2 + (x + 1)*x)/((x + 2)^2*(x + 1))\]

\[\text{real}(\text{hold=False})\]

Return the real part of this symbolic expression.

\text{EXAMPLES:}

\[\text{sage: } x = \text{var('x')}\]
\[\text{sage: } x.\text{real}\_\text{part}()\]
\[\text{real}\_\text{part}(x)\]
\[\text{sage: } \text{SR}(2+3*I).\text{real}\_\text{part}()\]
\[2\]
\[\text{sage: } \text{SR}(\text{CDF}(2,3)).\text{real}\_\text{part}()\]
\[2.0\]
\[\text{sage: } \text{SR}(\text{CC}(2,3)).\text{real}\_\text{part}()\]
\[2.00000000000000\]

\[\text{sage: } f = \log(x)\]
\[\text{sage: } f.\text{real}\_\text{part}()\]
\[\log(\text{abs}(x))\]

Using the \texttt{hold} parameter it is possible to prevent automatic evaluation:

\[\text{sage: } \text{SR}(2).\text{real}\_\text{part()}\]
\[2\]
\[\text{sage: } \text{SR}(2).\text{real}\_\text{part(hold=True)}\]
\[\text{real}\_\text{part}(2)\]

This also works using functional notation:

\[\text{sage: } \text{real}\_\text{part}(\text{I},\text{hold=True})\]
\[\text{real}\_\text{part}(\text{I})\]
\[0\]

To then evaluate again, we use \texttt{unhold()}:

\[\text{sage: } a = \text{SR}(2).\text{real}\_\text{part(hold=True)}; a.\text{unhold}()\]
\[2\]

\[\text{real}\_\text{part}(\text{hold=False})\]

Return the real part of this symbolic expression.

\text{EXAMPLES:}
Symbolic Calculus, Release 10.0

sage: x = var('x')
sage: x.real_part()
real_part(x)
sage: SR(2+3*I).real_part()
2
sage: SR(CDF(2,3)).real_part()
2.0
sage: SR(CC(2,3)).real_part()
2.00000000000000
sage: f = log(x)
sage: f.real_part()
log(abs(x))

Using the hold parameter it is possible to prevent automatic evaluation:

sage: SR(2).real_part()
2
sage: SR(2).real_part(hold=True)
real_part(2)

This also works using functional notation:

sage: real_part(I,hold=True)
real_part(I)

To then evaluate again, we use unhold():

sage: a = SR(2).real_part(hold=True); a.unhold()
2

rectform()

Convert this symbolic expression to rectangular form; that is, the form \(a + bi\) where \(a\) and \(b\) are real numbers and \(i\) is the imaginary unit.

Note: The name "rectangular" comes from the fact that, in the complex plane, \(a\) and \(bi\) are perpendicular.

INPUT:

• self – the expression to convert.

OUTPUT:

A new expression, equivalent to the original, but expressed in the form \(a + bi\).

ALGORITHM:

We call Maxima’s rectform() and return the result unmodified.

EXAMPLES:

The exponential form of \(\sin(x)\):
\[
\text{sage: } f = \frac{e^{i \cdot x} - e^{-i \cdot x}}{2i} \\
\text{sage: } f.\text{rectform()} \\
\sin(x)
\]

And \(\cos(x)\):

\[
\text{sage: } f = \frac{e^{i \cdot x} + e^{-i \cdot x}}{2} \\
\text{sage: } f.\text{rectform()} \\
\cos(x)
\]

In some cases, this will simplify the given expression. For example, here, \(e^{ik\pi}, \sin(k\pi) = 0\) should cancel leaving only \(\cos(k\pi)\) which can then be simplified:

\[
\text{sage: } k = \text{var('k')} \\
\text{sage: } \text{assume(k, 'integer')} \\
\text{sage: } f = e^{i \cdot \pi \cdot k} \\
\text{sage: } f.\text{rectform()} \\
(-1)^k
\]

However, in general, the resulting expression may be more complicated than the original:

\[
\text{sage: } f = e^{i \cdot x} \\
\text{sage: } f.\text{rectform()} \\
\cos(x) + i\sin(x)
\]

**reduce_trig**(var=None)

Combine products and powers of trigonometric and hyperbolic sin’s and cos’s of \(x\) into those of multiples of \(x\). It also tries to eliminate these functions when they occur in denominators.

**INPUT:**

- **self** - a symbolic expression
- **var** - (default: None) the variable which is used for these transformations. If not specified, all variables are used.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

\[
\text{sage: } y = \text{var('y')} \\
\text{sage: } f = \sin(x)^2 \cdot \cos(x)^3 + \sin(y)^2 \\
\text{sage: } f.\text{reduce_trig()} \\
-1/2 \cdot \cos(2\cdot y) + 1/8 \cdot \sin(4\cdot x) + 1/4 \cdot \sin(2\cdot x) + 1/2
\]

To reduce only the expressions involving \(x\) we use optional parameter:

\[
\text{sage: } f.\text{reduce_trig(x)} \\
\sin(y)^2 + 1/8 \cdot \sin(4\cdot x) + 1/4 \cdot \sin(2\cdot x)
\]

**ALIAS:** **trig_reduce()** and **reduce_trig()** are the same

**residue**(symbol)

Calculate the residue of **self** with respect to **symbol**.

**INPUT:**
• symbol - a symbolic variable or symbolic equality such as \( x = 5 \). If an equality is given, the expansion is around the value on the right hand side of the equality, otherwise at 0.

**OUTPUT:**

The residue of self.

Say, symbol is \( x = a \), then this function calculates the residue of self at \( x = a \), i.e., the coefficient of \( 1/(x - a) \) of the series expansion of self around \( a \).

**EXAMPLES:**

```
sage: (1/x).residue(x == 0)
1
sage: (1/x).residue(x == oo)
-1
sage: (1/x^2).residue(x == 0)
0
sage: (1/sin(x)).residue(x == 0)
1
sage: var('q, n, z')
(q, n, z)
```

We can also compute the residue at more general places, given that the pole is recognized:

```
sage: k = var('k', domain='integer')
sage: (gamma(1+x)/(1 - exp(-x))).residue(x==2*I*pi*k)
gamma(2*I*pi*k + 1)
sage: csc(x).residue(x==2*pi*k)
1
```

**resultant**(other, var)

Compute the resultant of this polynomial expression and the first argument with respect to the variable given as the second argument.

**EXAMPLES:**

```
sage: _ = var('a b n k u x y')
sage: x.resultant(y, x)
y
sage: (x+y).resultant(x-y, x)
-2*y
sage: r = (x^4*y^2+x^2*y-y).resultant(x^2*y^2-a^2*b+a*b+a*b+u,x)
sage: r.coefficient(a^4)
b^4*y^2 - 4*b^3*y^3 + 6*b^2*y^4 - 4*b*y^5 + y^6
sage: x.resultant(sin(x), x)
Traceback (most recent call last):
...  
RuntimeError: resultant(): arguments must be polynomials
```
Symbolic Calculus, Release 10.0

\textbf{rhs()}

If \texttt{self} is a relational expression, return the right hand side of the relation. Otherwise, raise a \texttt{ValueError}.

**EXAMPLES:**

\begin{verbatim}
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
\end{verbatim}

\textbf{right()}

If \texttt{self} is a relational expression, return the right hand side of the relation. Otherwise, raise a \texttt{ValueError}.

**EXAMPLES:**

\begin{verbatim}
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
\end{verbatim}

\textbf{right\_hand\_side()}

If \texttt{self} is a relational expression, return the right hand side of the relation. Otherwise, raise a \texttt{ValueError}.

**EXAMPLES:**

\begin{verbatim}
sage: x = var('x')
sage: eqn = (x-1)^2 <= x^2 - 2*x + 3
sage: eqn.right_hand_side()
x^2 - 2*x + 3
sage: eqn.rhs()
x^2 - 2*x + 3
sage: eqn.right()
x^2 - 2*x + 3
\end{verbatim}

\textbf{roots}(x=None, explicit_solutions=True, multiplicities=True, ring=None)

Return roots of \texttt{self} that can be found exactly, possibly with multiplicities. Not all roots are guaranteed to be found.

**Warning:** This is not a numerical solver - use \texttt{find_root} to solve for \texttt{self == 0} numerically on an interval.

**INPUT:**

- \texttt{x} - variable to view the function in terms of (use default variable if not given)
- \texttt{explicit_solutions} - bool (default True); require that roots be explicit rather than implicit
- \texttt{multiplicities} - bool (default True); when True, return multiplicities
• ring - a ring (default None): if not None, convert self to a polynomial over ring and find roots over ring

OUTPUT:
A list of pairs (root, multiplicity) or list of roots.
If there are infinitely many roots, e.g., a function like \( \sin(x) \), only one is returned.

EXAMPLES:

```
sage: var('x, a')
(x, a)
```

A simple example:

```
sage: ((x^2-1)^2).roots()
[(-1, 2), (1, 2)]
sage: ((x^2-1)^2).roots(multiplicities=False)
[-1, 1]
```

A complicated example:

```
sage: f = expand((x^2 - 1)^3*(x^2 + 1)*(x-a)); f
-a*x^8 + x^9 + 2*a*x^6 - 2*x^7 - 2*a*x^2 + 2*x^3 + a - x
```

The default variable is \( a \), since it is the first in alphabetical order:

```
sage: f.roots()
[(x, 1)]
```

As a polynomial in \( a \), \( x \) is indeed a root:

```
sage: f.poly(a)
x^9 - 2*x^7 + 2*x^3 - (x^8 - 2*x^6 + 2*x^2 - 1)*a - x
sage: f(a=x)
0
```

The roots in terms of \( x \) are what we expect:

```
sage: f.roots(x)
[(a, 1), (-I, 1), (I, 1), (1, 3), (-1, 3)]
```

Only one root of \( \sin(x) = 0 \) is given:

```
sage: f = sin(x)
sage: f.roots(x)
[(0, 1)]
```

Note: It is possible to solve a greater variety of equations using solve() and the keyword to_poly_solve, but only at the price of possibly encountering approximate solutions. See documentation for f.solve for more details.

We derive the roots of a general quadratic polynomial:
By default, all the roots are required to be explicit rather than implicit. To get implicit roots, pass `explicit_solutions=False` to `.roots()`.

```
sage: f = x^(1/9) + (2^(8/9) - 2^(1/9))*(x - 1) - x^(8/9)
sage: f.roots()
Traceback (most recent call last):
  ... 
RuntimeError: no explicit roots found
sage: f.roots(explicit_solutions=False)
[[(2^(8/9) + x^(8/9) - 2^(1/9) - x^(1/9))/(2^(8/9) - 2^(1/9)), 1]]
```

Another example, but involving a degree 5 poly whose roots do not get computed explicitly:

```
sage: f = x^5 + x^3 + 17*x + 1
sage: f.roots()
Traceback (most recent call last):
  ... 
RuntimeError: no explicit roots found
sage: f.roots(explicit_solutions=False)
[[(x^5 + x^3 + 17*x + 1, 1)]
```

Now let us find some roots over different rings:

```
sage: f.roots(ring=CC)
[(-0.0588115223184..., 1), (-1.331099917875... - 1.52241655183732*I, 1), (-1.331099917875... + 1.52241655183732*I, 1), (1.36050567903502 - 1.51880872209965*I, 1), (1.36050567903502 + 1.51880872209965*I, 1)]
sage: (2.5*f).roots(ring=RR)
[(-0.0588115223184..., 1)]
sage: f.roots(ring=CC, multiplicities=False)
[-0.0588115223184..., -1.331099917875..., -1.331099917875..., 1.36050567903502, 1.36050567903502]
sage: f.roots(ring=QQ)
[]
sage: f.roots(ring=QQbar, multiplicities=False)
[-0.0588115223184..., -1.331099917875..., -1.331099917875..., 1.36050567903502, 1.36050567903502]
```

Root finding over finite fields:

```
sage: f.roots(ring=GF(7^2, 'a'))
[(3, 1), (4*a + 6, 2), (3*a + 3, 2)]
```
round()
Round this expression to the nearest integer.

EXAMPLES:

```
sage: u = sqrt(43203735824841025516773866131535024)
sage: u.round()
207855083711803945
sage: t = sqrt(Integer('1'*1000)).round(); print(str(t)[-10:])
3333333333
sage: (-sqrt(110)).round()
-10
sage: (-sqrt(115)).round()
-11
sage: (sqrt(-3)).round()
Traceback (most recent call last):
... ValueError: could not convert sqrt(-3) to a real number
```

series(symbol, order=None)
Return the power series expansion of self in terms of the given variable to the given order.

INPUT:
- symbol – a symbolic variable or symbolic equality such as x == 5; if an equality is given, the expansion is around the value on the right hand side of the equality
- order – an integer; if nothing given, it is set to the global default (20), which can be changed using set_series_precision()

OUTPUT:
A power series.
To truncate the power series and obtain a normal expression, use the truncate() command.

EXAMPLES:
We expand a polynomial in $x$ about 0, about 1, and also truncate it back to a polynomial:

```
sage: var('x,y')
(x, y)
sage: f = (x^3 - sin(y)*x^2 - 5*x + 3); f
x^3 - x^2*sin(y) - 5*x + 3
sage: g = f.series(x, 4); g
3 + (-5)*x + (-sin(y))*x^2 + 1*x^3 + Order(x^4)
sage: g.truncate()
x^3 - x^2*sin(y) - 5*x + 3
sage: g = f.series(x==1, 4); g
(-sin(y) - 1) + (-2*sin(y) - 2)*(x - 1) + (-sin(y) + 3)*(x - 1)^2 + 1*(x - 1)^3 + Order((x - 1)^4)
→+ Order((x - 1)^4)
sage: h = g.truncate(); h
(x - 1)^3 - (x - 1)^2*(sin(y) - 3) - 2*(x - 1)*(sin(y) + 1) - sin(y) - 1
sage: h.expand()
x^3 - x^2*sin(y) - 5*x + 3
```
We compute another series expansion of an analytic function:
Symbolic Calculus, Release 10.0

\[ \text{sage: } f = \frac{\sin(x)}{x^2} \]
\[ \text{sage: } f.\text{series}(x, 7) \]
\[ 1^*x^(-1) + (-1/6)^*x + 1/120^*x^3 + (-1/5040)^*x^5 + \text{Order}(x^7) \]
\[ \text{sage: } f.\text{series}(x) \]
\[ 1^*x^(-1) + (-1/6)^*x + \ldots + \text{Order}(x^20) \]
\[ \text{sage: } f.\text{series}(x==1, 3) \]
\[ (\sin(1)) + (\cos(1) - 2^*\sin(1))*(x - 1) + (-2^*\cos(1) + 5/2^*\sin(1))*(x - 1)^2 + \ldots \]
\[ \rightarrow \text{Order}((x - 1)^3) \]
\[ \text{sage: } f.\text{series}(x==1, 3).\text{truncate}().\text{expand}() \]
\[ -2^*x^2^*\cos(1) + 5/2^*x^2^*\sin(1) + 5^*x^*\cos(1) - 7^*x^*\sin(1) - 3^*\cos(1) + 11/\rightarrow 2^*\sin(1) \]

Expressions formed by combining series can be expanded by applying series again:

\[ \text{sage: } (1/(1-x)).\text{series}(x, 3) + (1/(1+x)).\text{series}(x, 3) \]
\[ (1 + 1^*x + 1^*x^2 + \text{Order}(x^3)) + (1 + (-1)^*x + 1^*x^2 + \text{Order}(x^3)) \]
\[ \text{sage: } _.\text{series}(x, 3) \]
\[ 2 + 2^*x^2 + \text{Order}(x^3) \]
\[ \text{sage: } (1/(1-x)).\text{series}(x, 3)*(1/(1+x)).\text{series}(x, 3) \]
\[ (1 + 1^*x + 1^*x^2 + \text{Order}(x^3))*(1 + (-1)^*x + 1^*x^2 + \text{Order}(x^3)) \]
\[ \text{sage: } _.\text{series}(x, 3) \]
\[ 1 + 1^*x^2 + \text{Order}(x^3) \]

Following the GiNaC tutorial, we use John Machin’s amazing formula \( \pi = 16 \tan^{-1}(1/5) - 4 \tan^{-1}(1/239) \) to compute digits of \( \pi \). We expand the arc tangent around 0 and insert the fractions 1/5 and 1/239.

\[ \text{sage: } x = \text{var}('x') \]
\[ \text{sage: } f = \text{atan}(x).\text{series}(x, 10); f \]
\[ 1^*x + (-1/3)^*x^3 + 1/5^*x^5 + (-1/7)^*x^7 + 1/9^*x^9 + \text{Order}(x^10) \]
\[ \text{sage: } \text{float}(16^*f.\text{subs}(x==1/5) - 4^*f.\text{subs}(x==1/239)) \]
\[ 3.1415926824043994 \]

\text{show()} \]

Pretty-print this symbolic expression.

This typesets it nicely and prints it immediately.

OUTPUT:

This method does not return anything. Like \text{print}, output is sent directly to the screen.

Note that the output depends on the display preferences. For details, see \text{pretty_print()}. 

EXAMPLES:

\[ \text{sage: } (x^2 + 1).\text{show()} \]
\[ x^2 + 1 \]

EXAMPLES:

\[ \text{sage: } \%\text{display} \text{ asciic} \text{ai} \text{_art} \ # \ not \ tested \]
\[ \text{sage: } (x^2 + 1).\text{show()} \]
\[ 2 \]
\[ x + 1 \]
simplify(algorithm='maxima')

Return a simplified version of this symbolic expression.

Note: When using algorithm='maxima', this just sends the expression to Maxima and converts it back to Sage. When algorithm='sympy', sympy's simplify method is used.

INPUT:

• self – an expression with held operations
• algorithm - (default: 'maxima') one of
  – 'maxima' - use Maxima (the default)
  – 'sympy' - use SymPy

See also:
simplify_full(), simplify_trig(), simplify_rational(), simplify_rectform()
simplify_factorial(), simplify_log(), simplify_real(), simplify_hypergeometric(),
canonicalize_radical()

EXAMPLES:

```
sage: a = var('a'); f = x*sin(2)/(x^a); f
x*sin(2)/x^a
sage: f.simplify()
x^(-a + 1)*sin(2)
```

simplify_factorial()

Simplify by combining expressions with factorials, and by expanding binomials into factorials.

ALIAS: factorial_simplify and simplify_factorial are the same

EXAMPLES:

Some examples are relatively clear:

```
sage: var('n,k')
(n, k)
sage: f = factorial(n+1)/factorial(n); f
factorial(n + 1)/factorial(n)
sage: f.simplify_factorial()
n + 1
```

```
sage: f = factorial(n)*(n+1); f
(n + 1)*factorial(n)
sage: simplify(f)
(n + 1)*factorial(n)
sage: f.simplify_factorial()
factorial(n + 1)
```
Symbolic Calculus, Release 10.0

```
sage: f = binomial(n, k)*factorial(k)*factorial(n-k); finomial(n, k)*factorial(k)*factorial(-k + n)
sage: f.simplify_factorial()
factorial(n)
```

A more complicated example, which needs further processing:

```
sage: f = factorial(x)/factorial(x-2)/2 + factorial(x+1)/factorial(x)/2; f
1/2*factorial(x + 1)/factorial(x) + 1/2*factorial(x)/factorial(x - 2)
sage: g = f.simplify_factorial(); g
1/2*(x - 1)*x + 1/2*x + 1/2
sage: g.simplify_rational()
1/2*x^2 + 1/2
```

`simplify_full()`

Apply `simplify_factorial()`, `simplify_rectform()`, `simplify_trig()`, `simplify_rational()`, and then `expand_sum()` to self (in that order).

ALIAS: `simplify_full` and `full_simplify` are the same.

EXAMPLES:

```
sage: f = sin(x)^2 + cos(x)^2
sage: f.simplify_full()
1
sage: f = sin(x/(x^2 + x))
1/(x + 1)
sage: var('n,k')
(n, k)
sage: f = binomial(n,k)*factorial(k)*factorial(n-k)
sage: f.simplify_full()
factorial(n)
```

`simplify_hypergeometric(algorithm='maxima')`

Simplify an expression containing hypergeometric or confluent hypergeometric functions.

INPUT:

- `algorithm` – (default: 'maxima') the algorithm to use for for simplification. Implemented are 'maxima', which uses Maxima's hgfred function, and 'sage', which uses an algorithm implemented in the hypergeometric module.

ALIAS: `hypergeometric_simplify()` and `simplify_hypergeometric()` are the same.

EXAMPLES:

```
sage: hypergeometric((5, 4), (4, 1, 2, 3),
1/144*x^2*hypergeometric((), (3, 4), x) +...
1/3*x*hypergeometric((), (2, 3), x) + hypergeometric((), (1, 2), x)
sage: (2*hypergeometric((), (), x)).simplify_hypergeometric()
2*e^x
```

(continues on next page)
Symbolic Calculus, Release 10.0

sage: (nest(lambda y: hypergeometric([y], [1], x), 3, 1))  # not tested, unstable
....: .simplify_hypergeometric())
laguerre(-laguerre(-e^x, x), x)
sage: (nest(lambda y: hypergeometric([y], [1], x), 3, 1))  # not tested, unstable
....: .simplify_hypergeometric(algorithm='sage'))
hypergeometric(hypergeometric((e^x,), (1,), x),), (1,), x)
sage: hypergeometric_M(1, 3, x).simplify_hypergeometric()
-2*((x + 1)*e^(-x) - 1)*e^x/x^2
sage: (2 * hypergeometric_U(1, 3, x)).simplify_hypergeometric()
2*(x + 1)/x^2

simplify_log(algorithm=None)

Simplify a (real) symbolic expression that contains logarithms.

The given expression is scanned recursively, transforming subexpressions of the form \(a \log(b) + c \log(d)\) into \(\log(b^a d^c)\) before simplifying within the \(\log()\).

The user can specify conditions that \(a\) and \(c\) must satisfy before this transformation will be performed using the optional parameter algorithm.

```
Warning: This is only safe to call if every variable in the given expression is assumed to be real. The simplification it performs is in general not valid over the complex numbers. For example:

sage: x, y = SR.var('x, y')
sage: f = log(x*y) - (log(x) + log(y))
sage: f(x=-1, y=i)
-2*I*pi
sage: f.simplify_log()
0
```

INPUT:

- **self** - expression to be simplified
- **algorithm** - (default: None) optional, governs the condition on \(a\) and \(c\) which must be satisfied to contract expression \(a \log(b) + c \log(d)\). Values are
  - None (use Maxima default, integers),
  - 'one' (1 and -1),
  - 'ratios' (rational numbers),
  - 'constants' (constants),
  - 'all' (all expressions).

ALGORITHM:

This uses the Maxima logcontract() command.

ALIAS:

`log_simplify()` and `simplify_log()` are the same.

EXAMPLES:
Symbolic Calculus, Release 10.0

```sage
x, y, t = var('x y t')
```

Only two first terms are contracted in the following example; the logarithm with coefficient $\frac{1}{2}$ is not contracted:

```sage
f = log(x)+2*log(y)+1/2*log(t)
sage: f.simplify_log()
log(x*y^2) + 1/2*log(t)
```

To contract all terms in the previous example, we use the 'ratios' algorithm:

```sage
f.simplify_log(algorithm='ratios')
log(sqrt(t)*x*y^2)
```

To contract terms with no coefficient (more precisely, with coefficients 1 and $-1$), we use the 'one' algorithm:

```sage
f = log(x)+2*log(y)-log(t)
sage: f.simplify_log('one')
2*log(y) + log(x/t)
```

```sage
f = log(x)+log(y)-1/3*log((x+1))
sage: f.simplify_log()
log(x*y) - 1/3*log(x + 1)
sage: f.simplify_log('ratios')
log(x*y/(x + 1)^(1/3))
```

$\pi$ is an irrational number; to contract logarithms in the following example we have to set algorithm to 'constants' or 'all':

```sage
f = log(x)+log(y)-pi*log((x+1))
sage: f.simplify_log('constants')
log(x*y/(x + 1)^pi)
```

$x*log(9)$ is contracted only if algorithm is 'all':

```sage
(x*log(9)).simplify_log()
```

AUTHORS:

- Robert Marik (11-2009)

`simplify_rational(algorithm='full', map=False)`

Simplify rational expressions.

INPUT:

- `self` - symbolic expression
- `algorithm` - (default: ‘full’) string which switches the algorithm for simplifications. Possible values are
  - ‘simple’ (simplify rational functions into quotient of two polynomials),
- ‘full’ (apply repeatedly, if necessary)
- ‘noexpand’ (convert to common denominator and add)

• map - (default: False) if True, the result is an expression whose leading operator is the same as that of the expression self but whose subparts are the results of applying simplification rules to the corresponding subparts of the expressions.

ALIAS: `rational_simplify()` and `simplify_rational()` are the same

DETAILS: We call Maxima functions ratsimp, fullratsimp and xthru. If each part of the expression has to be simplified separately, we use Maxima function map.

EXAMPLES:

```sage
f = sin(x/(x^2 + x))
sage: f
sin(x/(x^2 + x))
sage: f.simplify_rational()
sin(1/(x + 1))
```

```sage
f = ((x - 1)^(3/2) - (x + 1)*sqrt(x - 1))/sqrt((x - 1)*(x + 1)); f
-((x + 1)*sqrt(x - 1) - (x - 1)^(3/2))/sqrt((x + 1)*(x - 1))
sage: f.simplify_rational()
-2*sqrt(x - 1)/sqrt(x^2 - 1)
```

With map=True each term in a sum is simplified separately and thus the results are shorter for functions which are combination of rational and nonrational functions. In the following example, we use this option if we want not to combine logarithm and the rational function into one fraction:

```sage
f = (x^2-1)/(x+1)-ln(x)/(x+2)
sage: f.simplify_rational()
(x^2 + x - log(x) - 2)/(x + 2)
sage: f.simplify_rational(map=True)
x - log(x)/(x + 2) - 1
```

Here is an example from the Maxima documentation of where algorithm='simple' produces an (possibly useful) intermediate step:

```sage
y = var('y')
sage: g = (x^(y/2) + 1)^2*(x^(y/2) - 1)^2/(x^y - 1)
sage: g.simplify_rational(algorithm='simple')
(x^((2*y)/2) - 2*x*y + 1)/(x*y - 1)
sage: g.simplify_rational()
x^y - 1
```

With option algorithm='noexpand' we only convert to common denominators and add. No expansion of products is performed:

```sage
f = 1/(x+1)+x/(x+2)^2
sage: f.simplify_rational()
(2*x^2 + 5*x + 4)/(x^3 + 5*x^2 + 8*x + 4)
sage: f.simplify_rational(algorithm='noexpand')
((x + 2)^2 + (x + 1)^2*x)/((x + 2)^2*(x + 1))
sage: simplify_real()
```
Simplify the given expression over the real numbers. This allows the simplification of $\sqrt{x^2}$ into $|x|$ and the contraction of $\log(x) + \log(y)$ into $\log(xy)$.

**INPUT:**

- self – the expression to convert.

**OUTPUT:**

A new expression, equivalent to the original one under the assumption that the variables involved are real.

**EXAMPLES:**

```sage
f = sqrt(x^2)
sage: f.simplify_real()
abs(x)
```

```sage
y = SR.var('y')
sage: f = log(x) + 2*log(y)
sage: f.simplify_real()
log(x*y^2)
```

**simplify_rectform**(complexity_measure='string_length')

Attempt to simplify this expression by expressing it in the form $a + bi$ where both $a$ and $b$ are real. This transformation is generally not a simplification, so we use the given complexity_measure to discard non-simplifications.

**INPUT:**

- self – the expression to simplify.
- complexity_measure – (default: sage.symbolic.complexity_measures.string_length) a function taking a symbolic expression as an argument and returning a measure of that expression's complexity. If None is supplied, the simplification will be performed regardless of the result.

**OUTPUT:**

If the transformation produces a simpler expression (according to complexity_measure) then that simpler expression is returned. Otherwise, the original expression is returned.

**ALGORITHM:**

We first call rectform() on the given expression. Then, the supplied complexity measure is used to determine whether or not the result is simpler than the original expression.

**EXAMPLES:**

The exponential form of $\tan(x)$:

```sage
f = ( e^(I*x) - e^(-I*x) ) / ( I*e^(I*x) + I*e^(-I*x) )
sage: f.simplify_rectform()
sin(x)/cos(x)
```

This should not be expanded with Euler's formula since the resulting expression is longer when considered as a string, and the default complexity_measure uses string length to determine which expression is simpler:

```sage
f = e^(I*x)
sage: f.simplify_rectform()
e^(I*x)
```
However, if we pass None as our complexity measure, it is:

```python
sage: f = e^(I*x)
sage: f.simplify_rectform(complexity_measure = None)
cos(x) + I*sin(x)
```

`simplify_trig(expand=True)`

Optionally expand and then employ identities such as $\sin(x)^2 + \cos(x)^2 = 1$, $\cosh(x)^2 - \sinh(x)^2 = 1$, $\sin(x) \csc(x) = 1$, or $\tanh(x) = \sinh(x) / \cosh(x)$ to simplify expressions containing tan, sec, etc., to sin, cos, sinh, cosh.

INPUT:

- `self` - symbolic expression
- `expand` - (default:True) if True, expands trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in `self` first. For best results, `self` should be expanded. See also `expand_trig()` to get more controls on this expansion.

ALIAS: `trig_simplify()` and `simplify_trig()` are the same

EXAMPLES:

```python
sage: f = sin(x)^2 + cos(x)^2; f
cos(x)^2 + sin(x)^2
sage: f.simplify()
cos(x)^2 + sin(x)^2
sage: f.simplify_trig()
1
sage: h = sin(x)*csc(x)
sage: h.simplify_trig()
1
sage: k = tanh(x)*cosh(2*x)
sage: k.simplify_trig()
(2*sinh(x)^3 + sinh(x))/cosh(x)
```

In some cases we do not want to expand:

```python
sage: f = tan(3*x)
sage: f.simplify_trig()
-(4*cos(x)^2 - 1)*sin(x)/(4*cos(x)*sin(x)^2 - cos(x))
sage: f.simplify_trig(False)
sin(3*x)/cos(3*x)
```

`sin(hold=False)`

EXAMPLES:

```python
sage: var('x, y')
(x, y)
sage: sin(x^2 + y^2)
sin(x^2 + y^2)
sage: sin(sage.symbolic.constants.pi)
0
sage: sin(SR(1))
sin(1)
sage: sin(SR(RealField(150)(1)))
0.84147098480789650665250232163029899962256306
```
Using the `hold` parameter it is possible to prevent automatic evaluation:

```python
sage: SR(0).sin()
0
sage: SR(0).sin(hold=True)
sin(0)
```

This also works using functional notation:

```python
sage: sin(0, hold=True)
sin(0)
sage: sin(0)
0
```

To then evaluate again, we use `unhold()`:

```python
sage: a = SR(0).sin(hold=True); a.unhold()
0
```

### sinh

**Synopsis**

```python
sinh(x)
```

**Returns**

Return sinh of self.

We have \( \sinh(x) = \frac{e^x - e^{-x}}{2} \).

**Examples**:

```python
sage: x.sinh()
sinh(x)
sage: SR(1).sinh()
sinh(1)
sage: SR(0).sinh()
0
sage: SR(1.0).sinh()
1.17520119364380
sage: maxima('sinh(1.0)')
1.17520119364380...
```

\[
\sinh(1.0000000000000000000000000)
\]

To prevent automatic evaluation use the `hold` argument:

```python
sage: arccosh(x).sinh()
sqrt(x + 1)*sqrt(x - 1)
sage: arccosh(x).sinh(hold=True)
sinh(arccosh(x))
```

This also works using functional notation:

```python
sage: sinh(arccosh(x), hold=True)
sinh(arccosh(x))
sage: sinh(arccosh(x))
sqrt(x + 1)*sqrt(x - 1)
```
To then evaluate again, we use `unhold()`:

```python
sage: a = arccosh(x).sinh(hold=True); a.simplify()
sqrt(x + 1)*sqrt(x - 1)
```

`solve(self == 0 or a, x, multiplicities=False, solution_dict=False, explicit_solutions=False, to_poly_solve=False, algorithm=None, domain=None)`

Analytically solve the equation `self == 0` or a univariate inequality for the variable `x`.

**Warning:** This is not a numerical solver - use `find_root` to solve for `self == 0` numerically on an interval.

**INPUT:**
- `x` - variable(s) to solve for
- `multiplicities` - bool (default: False); if True, return corresponding multiplicities. This keyword is incompatible with `to_poly_solve=True` and does not make any sense when solving an inequality.
- `solution_dict` - bool (default: False); if True or non-zero, return a list of dictionaries containing solutions. Not used when solving an inequality.
- `explicit_solutions` - bool (default: False); require that all roots be explicit rather than implicit. Not used when solving an inequality.
- `to_poly_solve` - bool (default: False) or string; use Maxima's `to_poly_solver` package to search for more possible solutions, but possibly encounter approximate solutions. This keyword is incompatible with `multiplicities=True` and is not used when solving an inequality. Setting `to_poly_solve` to 'force' omits Maxima's solve command (useful when some solutions of trigonometric equations are lost).

**EXAMPLES:**

```python
sage: z = var('z')
sage: solve(z**5 - 1, z)
[z == 1/4*sqrt(5) + 1/4*I*sqrt(2*sqrt(5) + 10) - 1/4, z == -1/4*sqrt(5) + 1/4*I*sqrt(-2*sqrt(5) + 10) - 1/4, z == -1/4*sqrt(5) - 1/4*I*sqrt(-2*sqrt(5) + 10) - 1/4, z == 1/4*sqrt(5) - 1/4*I*sqrt(2*sqrt(5) + 10) - 1/4, z == 1]
```

```python
sage: solve_diophantine(x**3 - 1, z, multiplicities=True)
([z == 1/2*I*sqrt(3) - 1/2, z == -1/2*I*sqrt(3) - 1/2, z == 1], [3, 3, 3])
```

`solve_diophantine(x=None, solution_dict=False)`

Solve a polynomial equation in the integers (a so called Diophantine).

If the argument is just a polynomial expression, equate to zero. If `solution_dict=True` return a list of dictionaries instead of a list of tuples.

**EXAMPLES:**

```python
sage: x,y = var('x,y')
sage: solve_diophantine(3*x == 4)
[]
sage: solve_diophantine(x^2 - 9)
[-3, 3]
```
The function is used when `solve()` is called with all variables assumed integer:

```python
sage: assume(x, 'integer')
sage: assume(y, 'integer')
sage: sorted(solve(x*y == 1, (x,y)))
[(-1, -1), (1, 1)]
```

You can also pick specific variables, and get the solution as a dictionary:

```python
sage: solve_diophantine(x*y == 10, x)
[-10, -5, -2, -1, 1, 2, 5, 10]
sage: sorted(solve_diophantine(x*y - y == 10, (x,y)))
[(-9, -1), (-4, -2), (-1, -5), (0, -10), (2, 10), (3, 5), (6, 2), (11, 1)]
sage: res = solve_diophantine(x*y - y == 10, solution_dict=True)
sage: sol = [{y: -5, x: -1}, {y: -10, x: 0}, {y: -1, x: -9}, {y: -2, x: -4}, ...
    → {y: 10, x: 2}, {y: 1, x: 11}, {y: 2, x: 6}, {y: 5, x: 3}]
sage: all(solution in res for solution in sol) and bool(len(res) == len(sol))
True
```

If the solution is parametrized the parameter(s) are not defined, but you can substitute them with specific integer values:

```python
sage: x,y,z = var('x,y,z')
sage: sol = solve_diophantine(x^2-y==0); sol
(t, t^2)
sage: [(sol[0].subs(t=t),sol[1].subs(t=t)) for t in range(-3,4)]
[(-3, 9), (-2, 4), (-1, 1), (0, 0), (1, 1), (2, 4), (3, 9)]
sage: sol = solve_diophantine(x^2 + y^2 == z^2); sol
(2*p*q, p^2 - q^2, p^2 + q^2)
sage: [(sol[0].subs(p=p,q=q),sol[1].subs(p=p,q=q),sol[2].subs(p=p,q=q)) for p...
    → in range(1,4) for q in range(1,4)]
[(2, 0, 2), (4, -3, 5), (6, -8, 10), (4, 3, 5), (8, 0, 8), (12, -5, 13), (6, 8, ...
    → -10), (12, 5, 13), (18, 0, 18)]
```

Solve Brahmagupta-Pell equations:

```python
sage: sol = sorted(solve_diophantine(x^2 - 2*y^2 == 1), key=str)
sage: sol
((-sqrt(2)*(2*sqrt(2) + 3)^t + sqrt(2)*(-2*sqrt(2) + 3)^t - 3/2*(2*sqrt(2) + 3)^t...
    → -3/2*(-2*sqrt(2) + 3)^t),...)
sage: [(sol[1][0].subs(t=t).simplify_full(),sol[1][1].subs(t=t).simplify_
    → full()) for t in range(-1,5)]
[(1, 0), (3, -2), (17, -12), (99, -70), (577, -408), (3363, -2378)]
```

See also:

http://docs.sympy.org/latest/modules/solvers/diophantine.html

`sqrt(hold=False)`

Return the square root of this expression

EXAMPLES:
Symbolic Calculus, Release 10.0

sage: var('x, y')
(x, y)
sage: SR(2).sqrt()
sqrt(2)
sage: (x^2+y^2).sqrt()
sqrt(x^2 + y^2)
sage: (x^2).sqrt()
sqrt(x^2)

Immediate simplifications are applied:

sage: sqrt(x^2)
sqrt(x^2)
sage: x = SR.symbol('x', domain='real')
sage: sqrt(x^2)
abs(x)
sage: forget()
sage: assume(x<0)
sage: sqrt(x^2)
-x
sage: sqrt(x^4)
abs(sin(x))
sage: sqrt((x+1)^2)
abs(x + 1)

Using the hold parameter it is possible to prevent automatic evaluation:

sage: SR(4).sqrt()
2
sage: SR(4).sqrt(hold=True)
sqrt(4)

To then evaluate again, we use unhold():

sage: a = SR(4).sqrt(hold=True); a.unhold()
2

To use this parameter in functional notation, you must coerce to the symbolic ring:

sage: sqrt(SR(4),hold=True)
sqrt(4)
sage: sqrt(4,hold=True)
Symbolic Calculus, Release 10.0

(continued from previous page)

Traceback (most recent call last):
...
TypeError: ..._do_sqrt() got an unexpected keyword argument 'hold'

**step** *(hold=False)*

Return the value of the unit step function, which is 0 for negative \(x\), 1 for 0, and 1 for positive \(x\).

**See also:**

`sage.functions.generalized.FunctionUnitStep`

**EXAMPLES:**

```sage
sage: x = var('x')
sage: SR(1.5).step()
1
sage: SR(0).step()
1
sage: SR(-1/2).step()
0
sage: SR(float(-1)).step()
0
```

Using the `hold` parameter it is possible to prevent automatic evaluation:

```sage
sage: SR(2).step()
1
sage: SR(2).step(hold=True)
unit_step(2)
```

**subs** *(*args, **kwds)*

Substitute the given subexpressions in this expression.

**EXAMPLES:**

```sage
sage: var('x,y,z,a,b,c,d,f,g')
(x, y, z, a, b, c, d, f, g)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: t = a^2 + b^2 + (x+y)^3
sage: t.subs(a=c)
(x + y)^3 + b^2 + c^2
sage: t.subs(b=19, x=z)
(y + z)^3 + a^2 + 361
```

Substitute with keyword arguments (works only with symbols):

```sage
sage: t.subs(a=c)
(x + y)^3 + b^2 + c^2
```

Substitute with a dictionary argument:

```sage
sage: t.subs({a^2: c})
(x + y)^3 + b^2 + c
sage: t.subs({w0^2: w0^3})
a^3 + b^3 + (x + y)^3
```

112 Chapter 2. Internal functionality supporting calculus
Substitute with one or more relational expressions:

```python
sage: t.subs(w0^2 == w0^3)
a^3 + b^3 + (x + y)^3
sage: t.subs(w0 == w0^2)
a^8 + b^8 + (x^2 + y^2)^6
sage: t.subs(a == b, b == c)
(x + y)^3 + b^2 + c^2
```

Any number of arguments is accepted:

```python
sage: t.subs(a=b, b=c)
(x + y)^3 + b^2 + c^2
sage: t.subs({a:b}, b=c)
(x + y)^3 + b^2 + c^2
sage: t.subs([x == 3, y == 2], a == 2, {b:3})
138
```

It can even accept lists of lists:

```python
sage: eqn1 = (a*x + b*y == 0)
sage: eqn2 = (1 + y == 0)
sage: soln = solve([eqn1, eqn2], [x, y])
sage: soln
[[x == b/a, y == -1]]
sage: f = x + y
sage: f.subs(soln)
b/a - 1
```

Duplicate assignments will throw an error:

```python
sage: t.subs({a:b}, a=c)
Traceback (most recent call last):
  ... ValueError: duplicate substitution for a, got values b and c
sage: t.subs([x == 1], a = 1, b = 2, x = 2)
Traceback (most recent call last):
  ... ValueError: duplicate substitution for x, got values 1 and 2
```

All substitutions are performed at the same time:

```python
sage: t.subs({a:b, b:c})
(x + y)^3 + b^2 + c^2
```

Substitutions are done term by term, in other words Sage is not able to identify partial sums in a substitution (see github issue #18396):

```python
sage: f = x + x^2 + x^4
sage: f.subs(x = y)
```

(continues on next page)
\( y^4 + y^2 + y \)

\texttt{sage: } f\texttt{.subs(x^2 == y)} \hfill \# \text{ one term is fine}
\( x^4 + x + y \)

\texttt{sage: } f\texttt{.subs(x + x^2 == y)} \hfill \# \text{ partial sum does not work}
\( x^4 + x^2 + x \)

\texttt{sage: } f\texttt{.subs(x + x^2 + x^4 == y)} \hfill \# \text{ whole sum is fine}
\( y \)

Note that it is the very same behavior as in Maxima:

\texttt{sage: } E = \texttt{''x^4 + x^2 + x''}
\texttt{sage: } \texttt{subs = [(x',y'), (x^2','y'), (x^2+x','y'), (x^4+x^2+x','y')]}

\texttt{sage: } \texttt{cmd = ''{}, {}={}''} \hfill \# \text{ optional - maple}
\texttt{sage: } \texttt{for s1,s2 in subs:}
\texttt{.....: maxima.eval(cmd.format(E, s1, s2))}
\texttt{\'y^4+y^2+y'\}
\texttt{\'y+x^4+x'\}
\texttt{\'x^4+x^2+x'\}
\texttt{\'y'\}

Or as in Maple:

\texttt{sage: } \texttt{cmd = 'subs({}=[], {})'} \hfill \# \text{ optional - maple}
\texttt{sage: } \texttt{for s1,s2 in subs:}
\texttt{.....: maple.eval(cmd.format(s1,s2, E))}
\texttt{\'y^4+y^2+y'\}
\texttt{\'x^4+x+y'\}
\texttt{\'x^4+x^2+x'\}
\texttt{\'y'\}

But Mathematica does something different on the third example:

\texttt{sage: } \texttt{cmd = '{}/. {} -> {}'} \hfill \# \text{ optional - mathematica}
\texttt{sage: } \texttt{for s1,s2 in subs:}
\texttt{.....: mathematica.eval(cmd.format(E,s1,s2))}
\texttt{2 4}
\texttt{y + y + y}
\texttt{4}
\texttt{x + x + y}
\texttt{4}
\texttt{x + y}
\texttt{y}

The same, with formatting more suitable for cut and paste:

\texttt{sage: } \texttt{for s1,s2 in subs:} \hfill \# \text{ optional - mathematica}
\texttt{.....: mathematica(cmd.format(E,s1,s2))}
\texttt{y + y^2 + y^4}
\texttt{x + x^4 + y}
\texttt{x^4 + y}
\texttt{y}
Warning: Unexpected results may occur if the left-hand side of some substitution is not just a single variable (or is a “wildcard” variable). For example, the result of `cos(cos(cos(x))).subs({cos(x) : x})` is x, because the substitution is applied repeatedly. Such repeated substitutions (and pattern-matching code that may be somewhat unpredictable) are disabled only in the basic case where the left-hand side of every substitution is a variable. In particular, although the result of `(x^2).subs({x : sqrt(x)})` is x, the result of `(x^2).subs({x : sqrt(x), y^2 : y})` is `sqrt(x)`, because repeated substitution is enabled by the presence of the expression `y^2` in the left-hand side of one of the substitutions, even though that particular substitution does not get applied.

**substitute(**args, **kwds)**

Substitute the given subexpressions in this expression.

**EXAMPLES:**

```sage
sage: var('x,y,z,a,b,c,d,f,g')
(x, y, z, a, b, c, d, f, g)
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: t = a^2 + b^2 + (x+y)^3
```

Substitute with keyword arguments (works only with symbols):

```sage
sage: t.subs(a=c)
(x + y)^3 + b^2 + c^2
sage: t.subs(b=19, x=z)
(y + z)^3 + a^2 + 361
```

Substitute with a dictionary argument:

```sage
sage: t.subs({a^2: c})
(x + y)^3 + b^2 + c
sage: t.subs({w0^2: w0^3})
a^3 + b^3 + (x^2 + y^2)^6
```

Substitute with one or more relational expressions:

```sage
sage: t.subs(w0^2 == w0^3)
a^3 + b^3 + (x + y)^3
sage: t.subs(w0 == w0^2)
a^8 + b^8 + (x^2 + y^2)^6
sage: t.subs(a == b, b == c)
(x + y)^3 + b^2 + c^2
```

Any number of arguments is accepted:

```sage
sage: t.subs(a=b, b=c)
(x + y)^3 + b^2 + c^2
sage: t.subs({a:b}, b=c)
(x + y)^3 + b^2 + c^2
```

(continues on next page)
It can even accept lists of lists:

```
sage: eqn1 = (a*x + b*y == 0)
sage: eqn2 = (1 + y == 0)
sage: soln = solve([eqn1, eqn2], [x, y])
sage: soln
[[x == b/a, y == -1]]
sage: f = x + y
sage: f.subs(soln)
b/a - 1
```

Duplicate assignments will throw an error:

```
sage: t.subs({a:b}, a=c)
Traceback (most recent call last):
  ... ValueError: duplicate substitution for a, got values b and c
sage: t.subs([x == 1], a = 1, b = 2, x = 2)
Traceback (most recent call last):
  ... ValueError: duplicate substitution for x, got values 1 and 2
```

All substitutions are performed at the same time:

```
sage: t.subs({a:b, b:c})
(x + y)^3 + b^2 + c^2
```

Substitutions are done term by term, in other words Sage is not able to identify partial sums in a substitution (see github issue #18396):

```
sage: f = x + x^2 + x^4
sage: f.subs(x = y)
y^4 + y^2 + y
sage: f.subs(x^2 == y)                      # one term is fine
x^4 + x + y
sage: f.subs(x + x^2 == y)                 # partial sum does not work
x^4 + x^2 + x
sage: f.subs(x + x^2 + x^4 == y)           # whole sum is fine
y
```

Note that it is the very same behavior as in Maxima:

```
sage: E = 'x^4 + x^2 + x'
sage: subs = [('x^4', 'y^4'), ('x^2', 'y^2'), ('x^2+x', 'y^2+x'), ('x^4+x^2+x+x^4', 'y')]
sage: cmd = '{}, {}={}'
sage: for s1,s2 in subs:
    ....:     maxima.eval(cmd.format(E, s1, s2))
'y^4+y^2+x^2+y'
```
Or as in Maple:

```
sage: cmd = 'subs({}={}, {})'  # optional - maple
sage: for s1, s2 in subs:      # optional - maple
....:         maple.eval(cmd.format(s1, s2, E))
'y^4+y^2+y'
'x^4+x+y'
'x^4+x^2+x'
'y'
```

But Mathematica does something different on the third example:

```
sage: cmd = '{} /. {} -> {}'     # optional - mathematica
sage: for s1, s2 in subs:       # optional - mathematica
....:         mathematica.eval(cmd.format(E, s1, s2))
2 4
y + y + y
4
x + x + y
4
x + y
y
```

The same, with formatting more suitable for cut and paste:

```
sage: for s1, s2 in subs:       # optional - mathematica
....:         mathematica(cmd.format(E, s1, s2))
y + y^2 + y^4
x + x^4 + y
x^4 + y
y
```

**Warning:** Unexpected results may occur if the left-hand side of some substitution is not just a single variable (or is a “wildcard” variable). For example, the result of \(\cos(\cos(x))\).subs({\(\cos(x)\) : \(x\)}) is \(x\), because the substitution is applied repeatedly. Such repeated substitutions (and pattern-matching code that may be somewhat unpredictable) are disabled only in the basic case where the left-hand side of every substitution is a variable. In particular, although the result of \((x^2).subs({x : sqrt(x)})\) is \(x\), the result of \((x^2).subs({x : sqrt(x), y^2 : y})\) is \(\sqrt{x}\), because repeated substitution is enabled by the presence of the expression \(y^2\) in the left-hand side of one of the substitutions, even though that particular substitution does not get applied.

### substitute_function(*args, **kwds)**

Substitute the given functions by their replacements in this expression.

**EXAMPLES:**
Symbolic Calculus, Release 10.0

```
sage: x,y = var('x,y')
sage: foo = function('foo'); bar = function('bar')
sage: f = foo(x) + 1/foo(pi*y)

Substitute with a dictionary:
```
sage: f.substitute_function({foo: bar})
1/bar(pi*y) + bar(x)
sage: f.substitute_function({foo(x): bar(x)})
1/bar(pi*y) + bar(x)

If the function expression to be substituted includes its arguments, the right hand side can be an arbitrary symbolic expression:
```
sage: f.substitute_function({foo(x): x^2})
x^2 + 1/(pi^2*y^2)

Substitute with keyword arguments (works only if no function arguments are given):
```
sage: f.substitute_function(foo=bar)
1/bar(pi*y) + bar(x)

Substitute with a relational expression:
```
sage: f.substitute_function(foo(x)==bar(x))
1/bar(pi*y) + bar(x)
sage: f.substitute_function(foo(x)==bar(x+1))
1/bar(pi*y + 1) + bar(x + 1)

All substitutions are performed at the same time:
```
sage: g = foo(x) + 1/bar(pi*y)
sage: g.substitute_function({foo: bar, bar: foo})
1/foo(pi*y) + bar(x)

Any number of arguments is accepted:
```
sage: g.substitute_function({foo: bar}, bar(x) == x^2)
1/(pi^2*y^2) + bar(x)

As well as lists of substitutions:
```
sage: g.substitute_function([foo(x) == 1, bar(x) == x])
1/(pi*y) + 1

Alternative syntax:
```
sage: g.substitute_function(foo, bar)
1/bar(pi*y) + bar(x)

Duplicate assignments will throw an error:
```
sage: g.substitute_function({foo:bar}, foo(x) == x^2)
Traceback (most recent call last):
```
...  
ValueError: duplicate substitution for foo, got values bar and x |--> x^2  
sage: g.substitute_function([foo(x) == x^2], foo = bar)  
Traceback (most recent call last):  
...  
ValueError: duplicate substitution for foo, got values x |--> x^2 and bar

substitution_delayed(pattern, replacement)
Replace all occurrences of pattern by the result of replacement.
In contrast to subs(), the pattern may contains wildcards and the replacement can depend on the particular term matched by the pattern.

INPUT:
• pattern – an Expression, usually containing wildcards.
• replacement – a function. Its argument is a dictionary mapping the wildcard occurring in pattern to the actual values. If it returns None, this occurrence of pattern is not replaced. Otherwise, it is replaced by the output of replacement.

OUTPUT:
An Expression.

EXAMPLES:

sage: var('x y')
(x, y)
sage: w0 = SR.wild(0)
sage: sqrt(1 + 2*x + x^2).substitution_delayed(
    ....:     sqrt(w0), lambda d: sqrt(factor(d[w0])))
    ....: )
sqrt((x + 1)^2)
sage: def r(d):
    ....:     if x not in d[w0].variables():
    ....:         return cos(d[w0])
sage: (sin(x^2 + x) + sin(y^2 + y)).substitution_delayed(sin(w0), r)
cos(y^2 + y) + sin(x^2 + x)

See also:
match()

subtract_from_both_sides(x)
Return a relation obtained by subtracting x from both sides of this relation.

EXAMPLES:

sage: eqn = x*sin(x)*sqrt(3) + sqrt(2) > cos(sin(x))
sage: eqn.subtract_from_both_sides(sqrt(2))
sqrt(3)*x*sin(x) > -sqrt(2) + cos(sin(x))
sage: eqn.subtract_from_both_sides(cos(sin(x)))
sqrt(3)*x*sin(x) + sqrt(2) - cos(sin(x)) > 0
sum(*args, **kwds)

Return the symbolic sum $\sum_{v=a}^{b} self$
with respect to the variable $v$ with endpoints $a$ and $b$.

INPUT:

- $v$ - a variable or variable name
- $a$ - lower endpoint of the sum
- $b$ - upper endpoint of the sum
- algorithm - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'maple' - (optional) use Maple
  - 'mathematica' - (optional) use Mathematica
  - 'giac' - (optional) use Giac
  - 'sympy' - use SymPy

EXAMPLES:

```python
sage: k, n = var('k,n')
sage: k.sum(k, 1, n).factor()
1/2*(n + 1)*n
```

```python
sage: (1/k^4).sum(k, 1, oo)
1/90*pi^4
```

```python
sage: (1/k^5).sum(k, 1, oo)
zeta(5)
```

A well known binomial identity:

```python
sage: assume(n>=0)
sage: binomial(n,k).sum(k, 0, n)
2^n
```

And some truncations thereof:

```python
sage: binomial(n,k).sum(k,1,n)
2^n - 1
sage: binomial(n,k).sum(k,2,n)
2^n - n - 1
sage: binomial(n,k).sum(k,0,n-1)
2^n - 1
sage: binomial(n,k).sum(k,1,n-1)
2^n - 2
```

The binomial theorem:

```python
sage: x, y = var('x, y')
sage: (binomial(n,k) * x^k * y^(n-k)).sum(k, 0, n)
(x + y)^n
```
Symbolic Calculus, Release 10.0

```
sage: (k * binomial(n, k)).sum(k, 1, n)
2^(n - 1)*n

sage: ((-1)^k*binomial(n,k)).sum(k, 0, n)
0

sage: (2*(-k)/(k*(k+1))).sum(k, 1, oo)
-ln(2) + 1
```

Summing a hypergeometric term:

```
sage: (binomial(n, k) * factorial(k) / factorial(n+1+k)).sum(k, 0, n)
1/2*sqrt(pi)/factorial(n + 1/2)
```

We check a well known identity:

```
sage: bool((k^3).sum(k, 1, n) == k.sum(k, 1, n)^2)
True
```

A geometric sum:

```
sage: a, q = var('a, q')
sage: (a*q^k).sum(k, 0, n)
(a*q^(n + 1) - a)/(q - 1)
```

The geometric series:

```
sage: assume(abs(q) < 1)
sage: (a*q^k).sum(k, 0, oo)
-a/(q - 1)
```

A divergent geometric series. Do not forget to `forget` your assumptions:

```
sage: forget()
sage: assume(q > 1)
sage: (a*q^k).sum(k, 0, oo)
Traceback (most recent call last):
  ...TypeError: Sum is divergent.
```

This summation only Mathematica can perform:

```
sage: (1/(1+k^2)).sum(k, -oo, oo, algorithm = 'mathematica')  # optional -...
pi*coth(pi)
```

Use Giac to perform this summation:

```
sage: factor((sum(1/(1+k^2), k, -oo, oo, algorithm = 'giac')).factor())
pi*(e^(2*pi) + 1)/(e^pi + 1)*(e^pi - 1))
```

Use Maple as a backend for summation:
Symbolic Calculus, Release 10.0

```
sage: (binomial(n,k)*x^k).sum(k, 0, n, algorithm = 'maple')  # optional ~
    ¬maple
(x + 1)^n
```

**Note:**

1. Sage can currently only understand a subset of the output of Maxima, Maple and Mathematica, so even if the chosen backend can perform the summation the result might not be convertible into a usable Sage expression.

---

### tan (hold=False)

**EXAMPLES:**

```
sage: var('x, y')
(x, y)
sage: tan(x^2 + y^2)
tan(x^2 + y^2)
sage: tan(sage.symbolic.constants.pi/2)
Infinity
sage: tan(SR(1))
tan(1)
sage: tan(SR(RealField(150)(1)))
1.5574077246549022305069748074583601730872508
```

To prevent automatic evaluation use the hold argument:

```
sage: (pi/12).tan()
-sqrt(3) + 2
sage: (pi/12).tan(hold=True)
tan(1/12*pi)
```

This also works using functional notation:

```
sage: tan(pi/12,hold=True)
tan(1/12*pi)
sage: tan(pi/12)
-sqrt(3) + 2
```

To then evaluate again, we use *unhold()*:

```
sage: a = (pi/12).tan(hold=True); a.unhold()
-sqrt(3) + 2
```

### tanh (hold=False)

Return tanh of self.

We have tanh(x) = sinh(x)/cosh(x).

**EXAMPLES:**

```
sage: x.tanh()
    tanh(x)
sage: SR(1).tanh()
```

(continues on next page)
tanh(1)
sage: SR(0).tanh()
0
sage: SR(1.0).tanh()
0.761594155955765
sage: maxima('tanh(1.0)')
0.7615941559557649
sage: plot(lambda x: SR(x).tanh(), -1, 1)
Graphics object consisting of 1 graphics primitive

To prevent automatic evaluation use the hold argument:

sage: arcsinh(x).tanh()
x/sqrt(x^2 + 1)
sage: arcsinh(x).tanh(hold=True)
tanh(arcsinh(x))

This also works using functional notation:

sage: tanh(arcsinh(x),hold=True)
tanh(arcsinh(x))
x/sqrt(x^2 + 1)

To then evaluate again, we use unhold():

sage: a = arcsinh(x).tanh(hold=True); a.unhold()
x/sqrt(x^2 + 1)

taylor(*args)
Expand this symbolic expression in a truncated Taylor or Laurent series in the variable \( v \) around the point \( a \), containing terms through \( (x - a)^n \). Functions in more variables is also supported.

INPUT:

- *args - the following notation is supported
  - \( x, a, n \) - variable, point, degree
  - \( (x, a), (y, b), n \) - variables with points, degree of polynomial

EXAMPLES:

sage: var('a, x, z')
(a, x, z)
sage: taylor(a*log(z), z, 2, 3)
1/24*a*(z - 2)^3 - 1/8*a*(z - 2)^2 + 1/2*a*(z - 2) + a*log(2)
sage: taylor(sqrt (sin(x) + a*x + 1), x, 0, 3)
1/48*(3*a^3 + 9*a^2 + 9*a - 1)*x^3 - 1/8*(a^2 + 2*a + 1)*x^2 + 1/2*(a + 1)*x + 1
sage: taylor (sqrt (x + 1), x, 0, 5)
7/256*x^5 - 5/128*x^4 + 1/16*x^3 - 1/8*x^2 + 1/2*x + 1
sage: taylor (1/log (x + 1), x, 0, 3)
-19/720*x^3 + 1/24*x^2 - 1/12*x + 1/x + 1/2

sage: taylor (cos(x) - sec(x), x, 0, 5)
-1/6*x^4 - x^2

sage: taylor ((cos(x) - sec(x))^3, x, 0, 9)
-1/2*x^8 - x^6

sage: taylor (1/(cos(x) - sec(x))^3, x, 0, 5)
-15377/7983360*x^4 - 6767/604800*x^2 + 11/120/x^2 + 1/2/x^4 - 1/x^6 - 347/15120

test_relation(ntests=20, domain=None, proof=True)
Test this relation at several random values, attempting to find a contradiction. If this relation has no variables, it will also test this relation after casting into the domain.
Because the interval fields never return false positives, we can be assured that if True or False is returned (and proof is False) then the answer is correct.
INPUT:
• ntests – (default 20) the number of iterations to run
• domain – (optional) the domain from which to draw the random values defaults to CIF for equality testing and RIF for order testing
• proof – (default True) if False and the domain is an interval field, regard overlapping (potentially equal) intervals as equal, and return True if all tests succeeded.
OUTPUT:
Boolean or NotImplemented, meaning
• True – this relation holds in the domain and has no variables.
• False – a contradiction was found.
• NotImplemented – no contradiction found.
EXAMPLES:

sage: (3 < pi).test_relation()
True
sage: (0 >= pi).test_relation()
False
sage: (exp(pi) - pi).n()
19.999999971895
sage: (exp(pi) - pi == 20).test_relation()
False
sage: (sin(x)^2 + cos(x)^2 == 1).test_relation()
NotImplemented
sage: (sin(x)^2 + cos(x)^2 == 1).test_relation(proof=False)
True
sage: (x == 1).test_relation()
False
sage: var('x,y')
(x, y)
Symbolic Calculus, Release 10.0

(continued from previous page)

```python
sage: (x < y).test_relation()
False
```

**to_gamma()**

Convert factorial, binomial, and Pochhammer symbol expressions to their gamma function equivalents.

**EXAMPLES:**

```python
sage: m,n = var('m n', domain='integer')
sage: factorial(n).to_gamma()
gamma(n + 1)
sage: binomial(m,n).to_gamma()
gamma(m + 1)/(gamma(m - n + 1)*gamma(n + 1))
```

**trailing_coeff(s)**

Return the trailing coefficient of s in self, i.e., the coefficient of the smallest power of s in self.

**EXAMPLES:**

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.trailing_coefficient(x)
2*sin(x*y)
sage: f.trailing_coefficient(y)
x
sage: f.trailing_coefficient(sin(x*y))
a*x + x*y + x/y + 100
```

**trailing_coefficient(s)**

Return the trailing coefficient of s in self, i.e., the coefficient of the smallest power of s in self.

**EXAMPLES:**

```python
sage: var('x,y,a')
(x, y, a)
sage: f = 100 + a*x + x^3*sin(x*y) + x*y + x/y + 2*sin(x*y)/x; f
x^3*sin(x*y) + a*x + x*y + x/y + 2*sin(x*y)/x + 100
sage: f.trailing_coefficient(x)
2*sin(x*y)
sage: f.trailing_coefficient(y)
x
sage: f.trailing_coefficient(sin(x*y))
a*x + x*y + x/y + 100
```

**trig_expand(full=False, half_angles=False, plus=True, times=True)**

Expand trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in self.

For best results, self should already be expanded.

**INPUT:**

- `full` – (default: False) To enhance user control of simplification, this function expands only one level at a time by default, expanding sums of angles or multiple angles. To obtain full expansion into sines and cosines immediately, set the optional parameter full to True.
• **half_angles** - (default: False) If True, causes half-angles to be simplified away.

• **plus** – (default: True) Controls the sum rule; expansion of sums (e.g. \(\sin(x + y)\)) will take place only if plus is True.

• **times** – (default: True) Controls the product rule, expansion of products (e.g. \(\sin(2x)\)) will take place only if times is True.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```sage
sage: sin(5*x).expand_trig()
sin(x) - 10*cos(x)^2*sin(x)^3 + sin(x)^5
sage: cos(2*x + var('y')).expand_trig()
cos(2*x)*cos(y) - sin(2*x)*sin(y)
```

We illustrate various options to this function:

```sage
sage: f = sin(sin(3*cos(2*x))^x)
sage: f.expand_trig()          
sin((3*cos(cos(2*x)))*2*sin(cos(2*x)) - sin(2*x))^3)*x)

sage: f.expand_trig(full=True)  
(3*(cos(cos(x)^2)*cos(sin(x)^2) + sin(cos(x)^2)*sin(sin(x)^2))
→2*(cos(sin(x)^2)*sin(cos(x)^2) - cos(cos(x)^2)*sin(sin(x)^2)) - (cos(sin(x)^2)
→2)*sin(cos(x)^2) - cos(cos(x)^2)*sin(sin(x)^2))^3)*x)

sage: sin(2*x).expand_trig(times=False)
sin(2*x)

sage: sin(2*x).expand_trig(times=True)
2*cos(x)*sin(x)

sage: sin(x + 2).expand_trig(plus=False)

sin(x + 2)

sage: sin(x + 2).expand_trig(plus=True)

cos(x)*sin(2) + cos(2)*sin(x)

sage: sin(x/2).expand_trig(half_angles=False)

sin(1/2*x)

sage: sin(x/2).expand_trig(half_angles=True)
(-1)^floor(1/2*x/pi)*sqrt(-1/2*cos(x) + 1/2)
```

If the expression contains terms which are factored, we expand first:

```sage

(sage: (x, k1, k2) = var('x, k1, k2')
sage: cos((k1-k2)*x).expand().expand_trig()
cos(k1*x)*cos(k2*x) + sin(k1*x)*sin(k2*x)
```

**ALIAS:**

`trig_expand()` and `expand_trig()` are the same

`trig_reduce(var=None)`

Combine products and powers of trigonometric and hyperbolic sin’s and cos’s of x into those of multiples of x. It also tries to eliminate these functions when they occur in denominators.

**INPUT:**

• **self** - a symbolic expression
• var - (default: None) the variable which is used for these transformations. If not specified, all variables are used.

OUTPUT:
A symbolic expression.

EXAMPLES:

```
SAGE: y = var('y')
SAGE: f = sin(x)*cos(x)^3+sin(y)^2
SAGE: f.reduce_trig()
-1/2*cos(2*y) + 1/8*sin(4*x) + 1/4*sin(2*x) + 1/2
```

To reduce only the expressions involving x we use optional parameter:

```
SAGE: f.reduce_trig(x)
sin(y)^2 + 1/8*sin(4*x) + 1/4*sin(2*x)
```

ALIAS: trig_reduce() and reduce_trig() are the same

```
sage: trig_simplify(expand=True)
```

Optionally expand and then employ identities such as \(\sin(x)^2 + \cos(x)^2 = 1, \cosh(x)^2 - \sinh(x)^2 = 1, \sin(x)\csc(x) = 1,\) or \(\tan(x) = \sin(x)/\cos(x)\) to simplify expressions containing tan, sec, etc., to sin, cos, sinh, cosh.

INPUT:

• self - symbolic expression

• expand - (default:True) if True, expands trigonometric and hyperbolic functions of sums of angles and of multiple angles occurring in self first. For best results, self should be expanded. See also expand_trig() to get more controls on this expansion.

ALIAS: trig_simplify() and simplify_trig() are the same

EXAMPLES:

```
sage: f = sin(x)^2 + cos(x)^2; f
\cos(x)^2 + \sin(x)^2
sage: f.simplify()
\cos(x)^2 + \sin(x)^2
sage: f.simplify_trig()
1
sage: h = sin(x)*csc(x)
\sin(x)*\csc(x)
sage: h.simplify_trig()
1
sage: k = tanh(x)*cosh(2*x)
\tanh(x)*\cosh(2*x)
```

In some cases we do not want to expand:

```
sage: f = tan(3*x)
sage: f.simplify_trig()
-(4*cos(x)^2 - 1)*\sin(x)/(4*cos(x)*\sin(x)^2 - \cos(x))
sage: f.simplify_trig(False)
\sin(3*x)/\cos(3*x)
```
**truncate()**

Given a power series or expression, return the corresponding expression without the big oh.

**INPUT:**

- `self` – a series as output by the `series()` command.

**OUTPUT:**

A symbolic expression.

**EXAMPLES:**

```python
sage: f = sin(x)/x^2
sage: f.truncate()
sin(x)/x^2
sage: f.series(x,7)
1*x^(-1) + (-1/6)*x + 1/120*x^3 + (-1/5040)*x^5 + Order(x^7)
sage: f.series(x,7).truncate()
-1/5040*x^5 + 1/120*x^3 - 1/6*x + 1/x
sage: f.series(x==1,3).truncate().expand()
-2*x^2*cos(1) + 5/2*x^2*sin(1) + 5*x*cos(1) - 7*x*sin(1) - 3*cos(1) + 11/2*sin(1)
```

**unhold(exclude=None)**

Evaluates any held operations (with the `hold` keyword) in the expression

**INPUT:**

- `self` – an expression with held operations
- `exclude` – (default: None) a list of operators to exclude from evaluation. Excluding arithmetic operators does not yet work (see github issue #10169).

**OUTPUT:**

A new expression with held operations, except those in `exclude`, evaluated

**EXAMPLES:**

```python
sage: a = exp(I * pi, hold=True)
sage: a
e^(I*pi)
sage: a.unhold()
-1
sage: b = x.add(x, hold=True)
sage: b
x + x
sage: b.unhold()
2*x
sage: (a + b).unhold()
2*x - 1
sage: c = (x.mul(x, hold=True)).add(x.mul(x, hold=True), hold=True)
sage: c
x^2 + x^2
sage: c.unhold()
2*x^2
sage: sin(tan(θ, hold=True), hold=True).unhold()
0
```
(continued from previous page)

\begin{verbatim}
sage: sin(tan(0, hold=True), hold=True).unhold(exclude=[sin])
\sin(0)
sage: (e^sgn(0, hold=True)).unhold()
e^0
sage: log(3).unhold()
log(3)
\end{verbatim}

\section*{unit(s)}

Return the unit of this expression when considered as a polynomial in \( s \).

See also \texttt{content()}, \texttt{primitive_part()}, and \texttt{unit_content_primitive()}.

\textbf{INPUT:}

- \( s \) – a symbolic expression.

\textbf{OUTPUT:}

The unit part of a polynomial as a symbolic expression. It is defined as the sign of the leading coefficient.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: (2*x+4).unit(x)
1
sage: (-2*x+1).unit(x)
-1
sage: (2*x+1/2).unit(x)
1
sage: var('y')
y
sage: (2*x - 4*\sin(y)).unit(sin(y))
-1
\end{verbatim}

\section*{unit_content_primitive(s)}

Return the factorization into unit, content, and primitive part.

\textbf{INPUT:}

- \( s \) – a symbolic expression, usually a symbolic variable. The whole symbolic expression \texttt{self} will be considered as a univariate polynomial in \( s \).

\textbf{OUTPUT:}

A triple (unit, content, primitive polynomial) containing the \texttt{unit}, \texttt{content}, and \texttt{primitive polynomial}. Their product equals \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: var('x,y')
(x, y)
sage: ex = 9*x^3*y+3*y
sage: ex.unit_content_primitive(x)
(1, 3*y, 3*x^3 + 1)
sage: ex.unit_content_primitive(y)
(1, 9*x^3 + 3, y)
\end{verbatim}
variables()
Return sorted tuple of variables that occur in this expression.

EXAMPLES:

```
sage: (x,y,z) = var('x,y,z')
sage: (x+y).variables()
(x, y)
sage: (2*x).variables()
(x,)
sage: (x*y).variables()
(x, y)
sage: sin(x+y+z).variables()
(x, y, z)
```

zeta(hold=False)

EXAMPLES:

```
sage: x, y = var('x, y')
sage: (x/y).zeta()
zeta(x/y)
sage: SR(2).zeta()
1/6*pi^2
sage: SR(3).zeta()
zeta(3)
sage: SR(CDF(0,1)).zeta()  # abs tol 1e-16
0.003300223685324103 - 0.4181554491413217*I
sage: plot(lambda x: SR(x).zeta(), -10,10).show(ymin=-3,ymax=3)
```

To prevent automatic evaluation use the hold argument:

```
sage: SR(2).zeta(hold=True)
zeta(2)
```

This also works using functional notation:

```
sage: zeta(2,hold=True)
zeta(2)
sage: zeta(2)
1/6*pi^2
```

To then evaluate again, we use unhold():

```
sage: a = SR(2).zeta(hold=True); a.unhold()
1/6*pi^2
```

class sage.symbolic.expression.ExpressionIterator
Bases: object

class sage.symbolic.expression.OperandsWrapper
   Bases: sage.multivariate.polynomial.mv_polynomial.MPolyElementWrapper

Operands wrapper for symbolic expressions.
EXAMPLES:

```python
sage: x, y, z = var('x, y, z')
```

```python
sage: e = x + x*y + z*y + 3*y^z; e
x*y + 3*y*z + x + z*y
```

```python
sage: e.op[1]
3*y*z
```

```python
sage: e.op[1, 1]
z
```

```python
sage: e.op[-1]
z^y
```

```python
sage: e.op[1:] 
[3*y*z, x, z^y]
```

```python
sage: e.op[2]
x*y, 3*y^z
```

```python
sage: e.op[-2:]
x, z^y
```

```python
sage: e.op[:2] 
[3*y*z, x, z^y]
```

```python
sage: e.op[-5]
Traceback (most recent call last):
...
IndexError: operand index out of range, got -5, expect between -4 and 3
```

```python
sage: e.op[5]
Traceback (most recent call last):
...
IndexError: operand index out of range, got 5, expect between -4 and 3
```

```python
sage: e.op[1, 1, 0]
Traceback (most recent call last):
...
TypeError: expressions containing only a numeric coefficient, constant or symbol have no operands
```

```python
sage: e.op[:1.5]
Traceback (most recent call last):
...
TypeError: slice indices must be integers or None or have an __index__ method
```

```python
sage: e.op[:2:1.5]
Traceback (most recent call last):
...
ValueError: step value must be an integer
```

```python
class sage.symbolic.expression.PynacConstant
Bases: object
evaluation()

Returns this constant as an Expression.

EXAMPLES:
```
```
TypeError: unsupported operand parent(s) for +: '<class 'sage.symbolic.expression.PynacConstant'> and 'Integer Ring'

```python
sage: foo = f.expression(); foo
foo
sage: foo + 2
foo + 2
```

def name()

Returns the name of this constant.

EXAMPLES:

```python
sage: from sage.symbolic.expression import PynacConstant
sage: f = PynacConstant('foo', 'foo', 'real')
sage: f.name()
'foo'
```

def serial()

Returns the underlying Pynac serial for this constant.

EXAMPLES:

```python
sage: from sage.symbolic.expression import PynacConstant
sage: f = PynacConstant('foo', 'foo', 'real')
sage: f.serial()  #random
15
```

class sage.symbolic.expression.SubstitutionMap

Bases: SageObject

apply_to(expr, options)

Apply the substitution to a symbolic expression

EXAMPLES:

```python
sage: from sage.symbolic.expression import make_map
sage: subs = make_map({x:x+1})
sage: (x + 1)^2
```

class sage.symbolic.expression.SymbolicSeries

Bases: Expression

Trivial constructor.

EXAMPLES:

```python
sage: loads(dumps((x+x^3).series(x,2)))
1*x + Order(x^2)
```

coefficients(x=\text{None}, \text{sparse}=\text{True})

Return the coefficients of this symbolic series as a list of pairs.

INPUT:
• \( x \) – optional variable.

• **sparse** – Boolean. If False return a list with as much entries as the order of the series.

**OUTPUT:**

Depending on the value of `sparse`,

• A list of pairs \((expr, n)\), where `expr` is a symbolic expression and `n` is a power (`sparse=True`, default)

• A list of expressions where the `n`-th element is the coefficient of \(x^n\) when self is seen as polynomial in \(x\) (`sparse=False`).

**EXAMPLES:**

```
sage: s = (1/(1-x)).series(x,6); s
1 + 1*x + 1*x^2 + 1*x^3 + 1*x^4 + 1*x^5 + Order(x^6)
sage: s.coefficients()
[[1, 0], [1, 1], [1, 2], [1, 3], [1, 4], [1, 5]]
sage: s = (1/(1-y*x-x)).series(x,3); s
1 + (y + 1)*x + ((y + 1)^2)*x^2 + Order(x^3)
sage: s.coefficients(x, sparse=False)
[1, y + 1, (y + 1)^2]
```

**default_variable()**

Return the expansion variable of this symbolic series.

**EXAMPLES:**

```
sage: s = (1/(1-x)).series(x,3); s
1 + 1*x + 1*x^2 + Order(x^3)
sage: s.default_variable()
x
```

**is_terminating_series()**

Return True if the series is without order term.

A series is terminating if it can be represented exactly, without requiring an order term. You can explicitly request terminating series by setting the order to positive infinity.

**OUTPUT:**

Boolean. True if the series has no order term.

**EXAMPLES:**

```
sage: (x^5+x^2+1).series(x, +oo)
1 + 1*x^2 + 1*x^5
sage: (x^5+x^2+1).series(x, +oo).is_terminating_series()
True
sage: SR(5).is_terminating_series()
False
sage: exp(x).series(x,10).is_terminating_series()
False
```
power_series(base_ring)

Return the algebraic power series associated to this symbolic series.

The coefficients must be coercible to the base ring.

EXAMPLES:

```
sage: ex = (gamma(1-x)).series(x,3); ex
1 + euler_gamma*x + (1/2*euler_gamma^2 + 1/12*pi^2)*x^2 + Order(x^3)
sage: g = ex.power_series(SR); g
1 + euler_gamma*x + (1/2*euler_gamma^2 + 1/12*pi^2)*x^2 + O(x^3)
sage: g.parent()
Power Series Ring in x over Symbolic Ring
```

truncate()

Given a power series or expression, return the corresponding expression without the big oh.

OUTPUT:

A symbolic expression.

EXAMPLES:

```
sage: f = sin(x)/x^2
sage: f.truncate()
sin(x)/x^2
sage: f.series(x,7)
1*x^(-1) + (-1/6)*x + 1/120*x^3 + (-1/5040)*x^5 + Order(x^7)
sage: f.series(x,7).truncate()
-1/5040*x^5 + 1/120*x^3 - 1/6*x + 1/x
sage: f.series(x==1,3).truncate().expand()
-2*x^2*cos(1) + 5/2*x^2*sin(1) + 5*x*cos(1) - 7*x*sin(1) - 3*cos(1) + 11/
˓→2*sin(1)
```

sage.symbolic.expression.call_registered_function(serial, nargs, args, hold, allow_numeric_result, result_parent)

Call a function registered with Pynac (GiNaC).

INPUT:

• serial - serial number of the function
• nargs - declared number of args (0 is variadic)
• args - a list of arguments to pass to the function; each must be an Expression
• hold - whether to leave the call unevaluated
• allow_numeric_result - if True, keep numeric results numeric; if False, make all results symbolic expressions
• result_parent - an instance of SymbolicRing

EXAMPLES:

```
sage: from sage.symbolic.expression import find_registered_function, call_registered_function
sage: s_arctan = find_registered_function('arctan', 1)
sage: call_registered_function(s_arctan, 1, [SR(1)], False, True, SR)
```
Symbolic Calculus, Release 10.0

(continued from previous page)

\[ \frac{1}{4}\pi \]

\[
\text{sage: } \text{call\_registered\_function}(s\_arctan, 1, \text{[SR(1)]}, \text{True, True, SR})
\]

\[ \text{arctan}(1) \]

\[
\text{sage: } \text{call\_registered\_function}(s\_arctan, 1, \text{[SR(0)]}, \text{False, True, SR})
\]

\[ 0 \]

\[
\text{sage: } \text{call\_registered\_function}(s\_arctan, 1, \text{[SR(0)]}, \text{False, False, SR}).\text{parent()}
\]

\[ \text{Integer Ring} \]

\[
\text{sage: } \text{call\_registered\_function}(s\_arctan, 1, \text{[SR(0)]}, \text{False, False, SR}).\text{parent()}
\]

\[ \text{Symbolic Ring} \]

\[
\text{sage.symbolic.expression.}\text{doublefactorial}(n)
\]

The double factorial combinatorial function:

\[ n!! = n \times (n-2) \times (n-4) \times \ldots \times (\lceil \frac{n}{2} \rceil) \text{ with } 0!! = (-1)!! = 1. \]

INPUT:

* \( n \) – an integer \( \geq 1 \)

EXAMPLES:

\[
\text{sage: from sage.symbolic.expression import doublefactorial}
\]

\[
\text{sage: doublefactorial(-1)}
\]

\[ 1 \]

\[
\text{sage: doublefactorial(0)}
\]

\[ 1 \]

\[
\text{sage: doublefactorial(1)}
\]

\[ 1 \]

\[
\text{sage: doublefactorial(5)}
\]

\[ 15 \]

\[
\text{sage: doublefactorial(20)}
\]

\[ 3715891200 \]

\[
\text{sage: prod([20,18,\ldots,2])}
\]

\[ 3715891200 \]

\[
\text{sage.symbolic.expression.}\text{find\_registered\_function}(name, nargs)
\]

Look up a function registered with Pynac (GiNaC).

Raise a ValueError if the function is not registered.

OUTPUT:

* serial number of the function, for use in call\_registered\_function()

EXAMPLES:

\[
\text{sage: from sage.symbolic.expression import find\_registered\_function}
\]

\[
\text{sage: find\_registered\_function('arctan', 1)} \quad \# \text{ random}
\]

\[ 19 \]

\[
\text{sage: find\_registered\_function('archenemy', 1)}
\]

Traceback (most recent call last):

ValueError: cannot find GiNaC function with name archenemy and 1 arguments

\[
\text{sage.symbolic.expression.}\text{get\_fn\_serial()}
\]

Return the overall size of the Pynac function registry which corresponds to the last serial value plus one.

2.1. Symbolic Expressions 135
Symbolic Calculus, Release 10.0

EXAMPLES:

```python
sage: from sage.symbolic.expression import get_fn_serial
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: get_fn_serial() > 125
True
sage: print(get_sfunction_from_serial(get_fn_serial()))
None
sage: get_sfunction_from_serial(get_fn_serial() - 1) is not None
True
```

`sage.symbolic.expression.get_ginac_serial()`
Number of C++ level functions defined by GiNaC. (Defined mainly for testing.)

EXAMPLES:

```python
sage: sage.symbolic.expression.get_ginac_serial() >= 35
True
```

`sage.symbolic.expression.get_sfunction_from_hash(myhash)`
Return an already created SymbolicFunction given the hash.

EXAMPLES:

```python
sage: from sage.symbolic.expression import get_sfunction_from_hash
sage: get_sfunction_from_hash(1)  # random
```

`sage.symbolic.expression.get_sfunction_from_serial(serial)`
Return an already created SymbolicFunction given the serial.
These are stored in the dictionary `sfunction_serial_dict`.

EXAMPLES:

```python
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: get_sfunction_from_serial(65)  # random
```

**class** `sage.symbolic.expression.hold_class`
Bases: object

Instances of this class can be used with Python `with`.

EXAMPLES:

```python
sage: with hold:
    ....:    tan(1/12*pi)
    ....:
    tan(1/12*pi)
```

(s continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

....:   SR(2)^5
....:
2^5
sage: with hold:
....:       t=tan(1/12*pi)
....:
sage: t
tan(1/12*pi)
sage: t.unhold()
-sqrt(3) + 2

start()

Start a hold context.

EXAMPLES:

sage: hold.start()
sage: SR(2)^5
2^5
sage: hold.stop()
sage: SR(2)^5
32

stop()

Stop any hold context.

EXAMPLES:

sage: hold.start()
sage: SR(2)^5
2^5
sage: hold.stop()
sage: SR(2)^5
32

sage.symbolic.expression.init_function_table()

Initializes the function pointer table in Pynac. This must be called before Pynac is used; otherwise, there will be segfaults.

sage.symbolic.expression.init_pynac_I()

Initialize the numeric I object in pynac. We use the generator of QQ(i).

EXAMPLES:

sage: from sage.symbolic.constants import I as symbolic_I
sage: symbolic_I
I
sage: symbolic_I^2
-1

Note that conversions to real fields will give TypeError:

sage: float(symbolic_I)
Traceback (most recent call last):

(continues on next page)
...  
TypeError: unable to simplify to float approximation  
sage: gp(symbolic_I)  
I  
sage: RR(symbolic_I)  
Traceback (most recent call last):  
...  
TypeError: unable to convert '1.0000000000000000000000000000000000000000000000000000000000*I' to a real number

We can convert to complex fields:

```
sage: C = ComplexField(200); C  
Complex Field with 200 bits of precision  
sage: C(symbolic_I)  
1.0000000000000000000000000000000000000000000000000000000000*I  
sage: symbolic_I._complex_mpfr_field_(ComplexField(53))  
1.00000000000000*I  
sage: symbolic_I._complex_double_(CDF)  
1.0*I  
sage: CDF(symbolic_I)  
1.0*I  
sage: z = symbolic_I + symbolic_I; z  
2*I  
sage: C(z)  
2.0000000000000000000000000000000000000000000000000000000000*I  
sage: 1e8*symbolic_I  
1.00000000000000e8*I  
sage: complex(symbolic_I)  
1j  
sage: QQbar(symbolic_I)  
I  
sage: abs(symbolic_I)  
1  
sage: symbolic_I.minpoly()  
x^2 + 1  
sage: maxima(2*symbolic_I)  
2*%i
```

`sage.symbolic.expression.is_Expression(x)`  
Return True if x is a symbolic expression.  

This method is deprecated. Use `isinstance()` with `sage.structure.element.Expression` instead.  

EXAMPLES:

```
sage: from sage.symbolic.expression import is_Expression  
sage: is_Expression(x)  
```
Symbolic Calculus, Release 10.0

(continued from previous page)

```

sage:

Is 2 a symbolic equation?

sage:

Is SR(2) a symbolic equation?

sage:

Is x a symbolic equation?

sage:

Is 2 == 3 a symbolic equation?

sage:

Is SR(2) == SR(3) a symbolic equation?

sage:

Make a substitution map.

sage:

Mathematically sort symbolic expressions.

2.1. Symbolic Expressions

139
```
The list sorted by ascending (real) value. If an entry does not define a real value (or plus/minus infinity), or if the comparison is not known, a `ValueError` is raised.

**EXAMPLES:**

```python
sage: from sage.symbolic.expression import math_sorted
gsage: math_sorted([SR(1), SR(e), SR(pi), sqrt(2)])
[1, sqrt(2), e, pi]
```

`sage.symbolic.expression.mixed_order(lhs, rhs)`
Comparison in the mixed order

**INPUT:**
- `lhs`, `rhs` – two symbolic expressions or something that can be converted to one.

**OUTPUT:**
Either $-1$, $0$, or $+1$ indicating the comparison. An exception is raised if the arguments cannot be converted into the symbolic ring.

**EXAMPLES:**

```python
sage: from sage.symbolic.expression import mixed_order
gsage: mixed_order(1, oo)
-1
gsage: mixed_order(e, oo)
-1
gsage: mixed_order(pi, oo)
-1
gsage: mixed_order(1, sqrt(2))
-1
gsage: mixed_order(x + x^2, x*(x+1))
-1
gsage: mixed_order(SR(oo), sqrt(2))
1
gsage: mixed_order(pi, 0)
1
gsage: mixed_order(golden_ratio, 0)
1
gsage: mixed_order(log2, 0)
1
```

`sage.symbolic.expression.mixed_sorted(expressions)`
Sort a list of symbolic numbers in the “Mixed” order

**INPUT:**
- `expressions` – a list/tuple/iterable of symbolic expressions, or something that can be converted to one.

**OUTPUT:**
In the list the numeric values are sorted by ascending (real) value, and the expressions with variables according
to print order. If an entry does not define a real value (or plus/minus infinity), or if the comparison is not known,
a ValueError is raised.

EXAMPLES:

```python
sage: from sage.symbolic.expression import mixed_sorted
sage: mixed_sorted([SR(1), SR(e), SR(pi), sqrt(2), x, sqrt(x), sin(1/x)])
[1, sqrt(2), e, pi, sin(1/x), sqrt(x), x]
```

```
sage.symbolic.expression.new_Expression(parent, x)

Convert x into the symbolic expression ring parent.

This is the element constructor.

EXAMPLES:

```python
sage: a = SR(-3/4); a
-3/4
sage: type(a)
<class 'sage.symbolic.expression.Expression'>
sage: a.parent()
Symbolic Ring
sage: K.<a> = QuadraticField(-3)
sage: a + sin(x)
I*sqrt(3) + sin(x)
sage: x = var('x'); y0,y1 = PolynomialRing(ZZ,2,'y').gens()
sage: x+y0/y1
x + y0/y1
sage: x.subs(x=y0/y1)
y0/y1
sage: x + int(1)
x + 1
```

```
sage.symbolic.expression.new_Expression_from_pyobject(parent, x, force=True, recursive=True)

Wrap the given Python object in a symbolic expression even if it cannot be coerced to the Symbolic Ring.

INPUT:

- parent - a symbolic ring.
- x - a Python object.
- force - bool, default True, if True, the Python object is taken as is without attempting coercion or list
  traversal.
- recursive - bool, default True, disables recursive traversal of lists.

EXAMPLES:

```python
sage: t = SR._force_pyobject(QQ); t  # indirect doctest
Rational Field
sage: type(t)
<class 'sage.symbolic.expression.Expression'>
sage: from sage.symbolic.expression import new_Expression_from_pyobject
sage: t = new_Expression_from_pyobject(SR, 17); t
17
```

(continues on next page)
sage: type(t)
<class 'sage.symbolic.expression.Expression'>

sage: t2 = new_Expression_from_pyobject(SR, t, False); t2
17
sage: t2 is t
True

sage: tt = new_Expression_from_pyobject(SR, t, True); tt
17
sage: tt is t
False

sage.symbolic.expression.new_Expression_symbol(parent, name=None, latex_name=None, domain=None)

Look up or create a symbol.

EXAMPLES:

sage: t0 = SR.symbol("t0")
sage: t0.conjugate()
conjugate(t0)

sage: t1 = SR.symbol("t1", domain='real')
sage: t1.conjugate()
t1

sage: t0.abs()
abs(t0)

sage: t0_2 = SR.symbol("t0", domain='positive')
sage: t0_2.abs()
t0
sage: bool(t0_2 == t0)
True
sage: t0.conjugate()
t0

sage: SR.symbol() # temporary variable
symbol...

sage.symbolic.expression.new_Expression_wild(parent, n=0)

Return the n-th wild-card for pattern matching and substitution.

INPUT:

- parent - a symbolic ring.
- n - a nonnegative integer.

OUTPUT:

- n-th wildcard expression.

EXAMPLES:
Symbolic Calculus, Release 10.0

```
sage: x,y = var('x,y')
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: pattern = sin(x)*w0*w1^2; pattern
$1^2*$0*sin(x)
sage: f = atan(sin(x)*3*x^2); f
arctan(3*x^2*sin(x))
sage: f.has(pattern)
True
sage: f.subs(pattern == x^2)
arctan(x^2)
```

```
sage.symbolic.expression.normalize_index_for_doctests(arg, nops)
Wrapper function to test normalize_index.

sage.symbolic.expression.paramset_from_Expression(e)
EXAMPLES:

```
sage: from sage.symbolic.expression import paramset_from_Expression
sage: f = function('f')
sage: paramset_from_Expression(f(x).diff(x))
[0]
```

```
sage.symbolic.expression.print_order(lhs, rhs)
Comparison in the print order

INPUT:
• lhs, rhs – two symbolic expressions or something that can be converted to one.

OUTPUT:
Either −1, 0, or +1 indicating the comparison. An exception is raised if the arguments cannot be converted into the symbolic ring.

EXAMPLES:

```
sage: from sage.symbolic.expression import print_order
sage: print_order(1, oo)
1
sage: print_order(e, oo)
-1
sage: print_order(pi, oo)
1
sage: print_order(1, sqrt(2))
1
Check that github issue #12967 is fixed:
```
sage: print_order(SR(oo), sqrt(2))
1
```

```
sage.symbolic.expression.print_sorted(expressions)
Sort a list in print order

INPUT:
• expressions – a list/tuple/iterable of symbolic expressions, or something that can be converted to one.
```

2.1. Symbolic Expressions 143
OUTPUT:
The list sorted by print_order().

EXAMPLES:

```python
sage: from sage.symbolic.expression import print_sorted
sage: print_sorted([SR(1), SR(e), SR(pi), sqrt(2)])
[e, sqrt(2), pi, 1]
```

```
sage.symbolic.expression.py_atan2_for_doctests(x, y)
Wrapper function to test py_atan2.
```

```
sage.symbolic.expression.py_denom_for_doctests(n)
This function is used to test py_denom().

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_denom_for_doctests
sage: py_denom_for_doctests(2/3)
3
```

```
sage.symbolic.expression.py_eval_infinity_for_doctests()
This function tests py_eval_infinity.
```

```
sage.symbolic.expression.py_eval_neg_infinity_for_doctests()
This function tests py_eval_neg_infinity.
```

```
sage.symbolic.expression.py_eval_unsigned_infinity_for_doctests()
This function tests py_eval_unsigned_infinity.
```

```
sage.symbolic.expression.py_exp_for_doctests(x)
This function tests py_exp.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_exp_for_doctests
sage: py_exp_for_doctests(CC(2))
7.38905609893065
```

```
sage.symbolic.expression.py_factorial_py(x)
This function is a python wrapper around py_factorial(). This wrapper is needed when we override the eval() method for GiNaC’s factorial function in sage.functions.other.Function_factorial.
```

```
sage.symbolic.expression.py_float_for_doctests(n, kwds)
This function is for testing py_float.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_float_for_doctests
sage: py_float_for_doctests(pi, {'parent':RealField(80)})
3.1415926535897932384626
sage: py_float_for_doctests(I, {'parent':RealField(80)})
1.0000000000000000000000*I
sage: py_float_for_doctests(I, {'parent':float})
j
sage: py_float_for_doctests(pi, {'parent':complex})
(3.141592653589793+0j)
```
sage.symbolic.expression.py_imag_for_doctests(x)
Used for doctesting `py_imag`.

sage.symbolic.expression.py_is_cinteger_for_doctests(x)
Returns True if pynac should treat this object as an element of \( \mathbb{Z}(i) \).

sage.symbolic.expression.py_is_crational_for_doctests(x)
Return True if pynac should treat this object as an element of \( \mathbb{Q}(i) \).

sage.symbolic.expression.py_is_integer_for_doctests(x)
Used internally for doctesting purposes.

sage.symbolic.expression.py_latex_fderivative_for_doctests(id, params, args)
Used internally for writing doctests for certain cdef’d functions.

EXAMPLES:

```
sage: from sage.symbolic.expression import py_latex_fderivative_for_doctests as py_latex_fderivative, get_ginac_serial, get_fn_serial
sage: var('x,y,z')
(x, y, z)
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_fderivative(i, (0, 1, 0, 1), (x, y^z))
\mathrm{D}_{0, 1, 0, 1}\left({\rm foo}\right)\left(x, y^{z}\right)
```

Test latex name:

```
sage: foo = function('foo', nargs=2, latex_name=r'\mathrm\{bar\}\right)\left(x, y^\{z\}\right)'
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_fderivative(i, (0, 1, 0, 1), (x, y^z))
\mathsf{D}_{\{0, 1, 0, 1\}}\left(\text{\{foo\}}\right)\left(x, y^{\{z\}}\right)
```

Test custom func:

```
sage: def my_print(self, *args): return "func_with_args(" + ', '.join(map(repr, args)) + ')
sage: foo = function('foo', nargs=2, print_latex_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....: if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_fderivative(i, (0, 1, 0, 1), (x, y^z))
func_with_args\left(x, y^{z}\right)
```

2.1. Symbolic Expressions 145
sage.symbolic.expression.py_latex_function_pystring(id, args, fname_paren=False)

Return a string with the latex representation of the symbolic function specified by the given id applied to args.

See documentation of py_print_function_pystring for more information.

EXAMPLES:

```python
sage: from sage.symbolic.expression import py_latex_function_pystring, get_ginac_serial, get_fn_serial
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: var('x,y,z')
(x, y, z)
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....:     if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'\{\text{foo}\}\left(x, y^{z}\right)'
```

Test latex_name:

```python
sage: foo = function('foo', nargs=2, latex_name=r'\text{bar}')
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....:     if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'\text{bar}\left(x, y^{z}\right)'
```

Test custom func:

```python
sage: def my_print(self, *args):
    return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('foo', nargs=2, print_latex_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....:     if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_latex_function_pystring(i, (x,y^z))
'my args are: x, y^{z}'
```

sage.symbolic.expression.py_latex_variable_for_doctests(x)

Internal function used so we can doctest a certain cdef’d method.

EXAMPLES:

```python
sage: sage.symbolic.expression.py_latex_variable_for_doctests('x')
x
```
sage.symbolic.expression.py_lgamma_for_doctests(x)

This function tests py_lgamma.

EXAMPLES:

sage: from sage.symbolic.expression import py_lgamma_for_doctests
sage: py_lgamma_for_doctests(CC(I))
-0.650923199301856 - 1.87243664726243*I

sage.symbolic.expression.py_li2_for_doctests(x)

This function is a python wrapper so py_psi2 can be tested. The real tests are in the docstring for py_psi2.

EXAMPLES:

sage: from sage.symbolic.expression import py_li2_for_doctests
sage: py_li2_for_doctests(-1.1)
-0.890838090262283

sage.symbolic.expression.py_li_for_doctests(x, n, parent)

This function is a python wrapper so py_li can be tested. The real tests are in the docstring for py_li.

EXAMPLES:

sage: from sage.symbolic.expression import py_li_for_doctests
sage: py_li_for_doctests(0,2,float)
0.000000000000000

sage.symbolic.expression.py_log_for_doctests(x)

This function tests py_log.

EXAMPLES:

sage: from sage.symbolic.expression import py_log_for_doctests
sage: py_log_for_doctests(CC(e))
1.00000000000000

sage.symbolic.expression.py_mod_for_doctests(x, n)

This function is a python wrapper so py_mod can be tested. The real tests are in the docstring for py_mod.

EXAMPLES:

sage: from sage.symbolic.expression import py_mod_for_doctests
sage: py_mod_for_doctests(5, 2)
1

sage.symbolic.expression.py_numer_for_doctests(n)

This function is used to test py_numer().

EXAMPLES:

sage: from sage.symbolic.expression import py_numer_for_doctests
sage: py_numer_for_doctests(2/3)
2
symbolic_calculus.py

sage.symbolic.expression.py_print_fderivative_for_doctests(id, params, args)

Used for testing a cdef’d function.

EXAMPLES:

```
sage: from sage.symbolic.expression import py_print_fderivative_for_doctests as py_print_fderivative, get_ginac_serial, get_fn_serial
sage: var('x,y,z')
(x, y, z)
sage: from sage.symbolic.function import get_sfunction_from_serial
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....:     if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_fderivative(i, (0, 1, 0, 1), (x, y^z))
D[0, 1, 0, 1](foo)(x, y^z)
```

Test custom print function:

```
sage: def my_print(self, *args):
    return "func_with_args(" + ', '.join(map(repr, args)) + "")"
sage: foo = function('foo', nargs=2, print_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....:     if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_fderivative(i, (0, 1, 0, 1), (x, y^z))
D[0, 1, 0, 1]func_with_args(x, y^z)
```

sage.symbolic.expression.py_print_function_pystring(id, args, fname_paren=False)

Return a string with the representation of the symbolic function specified by the given id applied to args.

INPUT:

- id – serial number of the corresponding symbolic function
- params – Set of parameter numbers with respect to which to take the derivative.
- args – arguments of the function.

EXAMPLES:

```
sage: from sage.symbolic.expression import py_print_function_pystring, get_ginac_serial, get_fn_serial
sage: var('x,y,z')
(x, y, z)
sage: foo = function('foo', nargs=2)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....:     if get_sfunction_from_serial(i) == foo: break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_function_pystring(i, (0, 1, 0, 1), (x, y^z))
D[0, 1, 0, 1]foo(x, y^z)
```
(continues on next page)
sage: py_print_function_pystring(i, (x,y))
'foo(x, y)'
sage: py_print_function_pystring(i, (x,y), True)
'(foo)(x, y)'
sage: def my_print(self, *args):
    return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('foo', nargs=2, print_func=my_print)
sage: for i in range(get_ginac_serial(), get_fn_serial()):
    ....: if get_sfunction_from_serial(i) == foo:
        break
sage: get_sfunction_from_serial(i) == foo
True
sage: py_print_function_pystring(i, (x,y))
'my args are: x, y'

sage.symbolic.expression.py_psi2_for_doctests(n, x)
This function is a python wrapper so py_psi2 can be tested. The real tests are in the docstring for py_psi2.

EXAMPLES:

sage: from sage.symbolic.expression import py_psi2_for_doctests
sage: py_psi2_for_doctests(1, 2)
0.644934066848226

sage.symbolic.expression.py_psi_for_doctests(x)
This function is a python wrapper so py_psi can be tested. The real tests are in the docstring for py_psi.

EXAMPLES:

sage: from sage.symbolic.expression import py_psi_for_doctests
sage: py_psi_for_doctests(2)
0.422784335098467

sage.symbolic.expression.py_real_for_doctests(x)
Used for doctesting py_real.

sage.symbolic.expression.py_stieltjes_for_doctests(x)
This function is for testing py_stieltjes().

EXAMPLES:

sage: from sage.symbolic.expression import py_stieltjes_for_doctests
sage: py_stieltjes_for_doctests(0.0)
0.577215664901533

sage.symbolic.expression.py_tgamma_for_doctests(x)
This function is for testing py_tgamma().

sage.symbolic.expression.py_zeta_for_doctests(x)
This function is for testing py_zeta().

EXAMPLES:
Symbolic Calculus, Release 10.0

sage.symbolic.expression.register_or_update_function(self, name, latex_name, nargs, evalf_params_first, update)

Register the function self with Pynac (GiNaC).

OUTPUT:

• serial number of the function, for use in call_registered_function()

EXAMPLES:

sage: from sage.symbolic.function import BuiltinFunction
sage: class Archosaurian(BuiltinFunction):
  ....: def __init__(self):
  ....:     BuiltinFunction.__init__(self, 'archsaur', nargs=1)
  ....: def _eval_(self, x):
  ....:     return x * exp(x)
  ....: archsaur = Archosaurian()
  ....: # indirect doctest
sage: archsaur(2)
2*e^2

sage.symbolic.expression.register_symbol(obj, conversions, nargs=None)

Add an object to the symbol table, along with how to convert it to other systems such as Maxima, Mathematica, etc. This table is used to convert from other systems back to Sage.

INPUT:

• obj – a symbolic object or function.
• conversions – a dictionary of conversions, where the keys are the names of interfaces (e.g., ‘maxima’), and the values are the string representation of obj in that system.
• nargs – optional number of arguments. For most functions, this can be deduced automatically.

EXAMPLES:

sage: from sage.symbolic.expression import register_symbol as rs
sage: rs(SR(5), {'maxima': 'five'})
SR(maxima_calculus('five'))
5

sage.symbolic.expression.restore_op_wrapper(expr)

sage.symbolic.expression.solve_diophantine(f, *args, **kwds)

Solve a Diophantine equation.

The argument, if not given as symbolic equation, is set equal to zero. It can be given in any form that can be converted to symbolic. Please see Expression.solve_diophantine() for a detailed synopsis.

EXAMPLES:

sage: R.<a,b> = PolynomialRing(ZZ); R
Multivariate Polynomial Ring in a, b over Integer Ring
sage: solve_diophantine(a^2-3*b^2+1)
[]
sage: sorted(solve_diophantine(a^2-3*b^2+2), key=str)
[(-1/2*sqrt(3)*(sqrt(3) + 2)^t + 1/2*sqrt(3)*(-sqrt(3) + 2)^t - 1/2*(-sqrt(3) + 2)^t, (continues on next page)
sage.symbolic.expression.test_binomial(n, k)

The Binomial coefficients. It computes the binomial coefficients. For integer n and k and positive n this is the
number of ways of choosing k objects from n distinct objects. If n is negative, the formula \( \binom{n}{k} = (-1)^k \binom{k-n-1}{k} \) is used to compute the result.

**INPUT:**

- n, k – integers, with k >= 0.

**OUTPUT:**

integer

**EXAMPLES:**

```python
sage: import sage.symbolic.expression
sage: sage.symbolic.expression.test_binomial(5, 2)
10
sage: sage.symbolic.expression.test_binomial(-5, 3)
-35
sage: -sage.symbolic.expression.test_binomial(3-(-5)-1, 3)
-35
```

sage.symbolic.expression.tolerant_is_symbol(a)

Utility function to test if something is a symbol.

Returns False for arguments that do not have an is_symbol attribute. Returns the result of calling the is_symbol
method otherwise.

**EXAMPLES:**

```python
sage: from sage.symbolic.expression import tolerant_is_symbol
sage: tolerant_is_symbol(var("x"))
True
sage: tolerant_is_symbol(None)
False
sage: None.is_symbol()
Traceback (most recent call last):
  ... AttributeError: 'NoneType' object has no attribute 'is_symbol'
```

sage.symbolic.expression.unpack_operands(ex)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression import unpack_operands
sage: t = SR._force_pyobject((1, 2, x, x+1, x+2))
sage: unpack_operands(t)
(1, 2, x, x + 1, x + 2)
```
2.2 Callable Symbolic Expressions

EXAMPLES:

When you do arithmetic with:

```
sage: f(x, y, z) = sin(x+y+z)
sage: g(x, y) = y + 2*x
sage: f + g
(x, y, z) |--> 2*x + y + sin(x + y + z)
```

```
sage: f(x, y, z) = sin(x+y+z)
sage: g(w, t) = cos(w - t)
sage: f + g
(t, w, x, y, z) |--> cos(-t + w) + sin(x + y + z)
```

```
sage: f(x, y, t) = y*(x^2-t)
sage: g(x, y, w) = x + y - cos(w)
sage: f*g
(x, y, t, w) |--> (x^2 - t)*(x + y - cos(w))*y
```

```
sage: f(x,y, t) = x+y
sage: g(x, y, w) = w + t
sage: f + g
(x, y, t, w) |--> t + w + x + y
```

class sage.symbolic.callable.CallableSymbolicExpressionFunctor

Bases: ConstructionFunctor

A functor which produces a CallableSymbolicExpressionRing from the SymbolicRing.

EXAMPLES:

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x, y = var('x, y')
sage: f = CallableSymbolicExpressionFunctor((x, y)); f
CallableSymbolicExpressionFunctor(x, y)
sage: f(SR)
Callable function ring with arguments (x, y)
```
Symbolic Calculus, Release 10.0

(continued from previous page)

```
sage: loads(dumps(f))
CallableSymbolicExpressionFunctor(x, y)
```

**arguments()**

EXAMPLES:

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x,y = var('x,y')
sage: a = CallableSymbolicExpressionFunctor((x,y))
sage: a.arguments()
(x, y)
```

**merge(other)**

EXAMPLES:

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x,y = var('x,y')
sage: a = CallableSymbolicExpressionFunctor((x,))
sage: b = CallableSymbolicExpressionFunctor((y,))
sage: a.merge(b)
CallableSymbolicExpressionFunctor(x, y)
```

**unify_arguments(x)**

Takes the variable list from another CallableSymbolicExpression object and compares it with the current CallableSymbolicExpression object’s variable list, combining them according to the following rules:

Let \( a \) be self’s variable list, let \( b \) be \( y \)’s variable list.

1. If \( a == b \), then the variable lists are identical, so return that variable list.
2. If \( a \neq b \), then check if the first \( n \) items in \( a \) are the first \( n \) items in \( b \), or vice versa. If so, return a list with these \( n \) items, followed by the remaining items in \( a \) and \( b \) sorted together in alphabetical order.

**Note:** When used for arithmetic between CallableSymbolicExpression’s, these rules ensure that the set of CallableSymbolicExpression’s will have certain properties. In particular, it ensures that the set is a commutative ring, i.e., the order of the input variables is the same no matter in which order arithmetic is done.

**INPUT:**

- \( x \) - A CallableSymbolicExpression

**OUTPUT:** A tuple of variables.

**EXAMPLES:**

```
sage: from sage.symbolic.callable import CallableSymbolicExpressionFunctor
sage: x,y = var('x,y')
sage: a = CallableSymbolicExpressionFunctor((x,))
sage: b = CallableSymbolicExpressionFunctor((y,))
sage: a.unify_arguments(b)
(x, y)
```

2.2. Callable Symbolic Expressions
AUTHORS:

- Bobby Moretti: thanks to William Stein for the rules

class sage.symbolic.callable.CallableSymbolicExpressionRingFactory
Bases: UniqueFactory

create_key(args, check=True)

EXAMPLES:

```
sage: x,y = var('x,y')
sage: CallableSymbolicExpressionRingFactory.create_key((x,y))
\( (x, y) \)
```

create_object(version, key, **extra_args)

Returns a CallableSymbolicExpressionRing given a version and a key.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: CallableSymbolicExpressionRingFactory.create_object(0, (x, y))
Callable function ring with arguments \((x, y)\)
```

class sage.symbolic.callable.CallableSymbolicExpressionRing_class(arguments)
Bases: SymbolicRing, CallableSymbolicExpressionRing

EXAMPLES:

We verify that coercion works in the case where \(x\) is not an instance of SymbolicExpression, but its parent is still the SymbolicRing:

```
sage: f(x) = 1
sage: f*e
\(x \mapsto e\)
```

args()

Returns the arguments of self. The order that the variables appear in self.arguments() is the order that is used in evaluating the elements of self.

EXAMPLES:

```
sage: x,y = var('x,y')
sage: f(x,y) = 2*x+y
sage: f.parent().arguments()
\((x, y)\)
sage: f(y,x) = 2*x+y
sage: f.parent().arguments()
\((y, x)\)
```

arguments()

Returns the arguments of self. The order that the variables appear in self.arguments() is the order that is used in evaluating the elements of self.

EXAMPLES:
Symbolic Calculus, Release 10.0

```
sage: x,y = var('x,y')
sage: f(x,y) = 2*x+y
sage: f.parent().arguments()  
(x, y)
sage: f(y,x) = 2*x+y
sage: f.parent().arguments()  
(y, x)

classification()

EXAMPLES:
```
sage: f(x,y) = x^2 + y
sage: f.parent().construction()  
(CallableSymbolicExpressionFunctor(x, y), Symbolic Ring)

```
sage.symbolic.callable.is_CallableSymbolicExpression(x)

Returns True if x is a callable symbolic expression.

EXAMPLES:
```
sage: from sage.symbolic.callable import is_CallableSymbolicExpression
sage: var('a x y z')
(a, x, y, z)
sage: f(x,y) = a + 2*x + 3*y + z
sage: is_CallableSymbolicExpression(f)  
True
sage: is_CallableSymbolicExpression(a+2*x)  
False
sage: def foo(n): return n^2
...
```
sage: is_CallableSymbolicExpression(foo)
False

sage.symbolic.callable.is_CallableSymbolicExpressionRing(x)

Return True if x is a callable symbolic expression ring.

INPUT:
- x - object

OUTPUT: bool

EXAMPLES:
```
sage: from sage.symbolic.callable import is_CallableSymbolicExpressionRing
sage: is_CallableSymbolicExpressionRing(QQ)
```

(continues on next page)
2.3 Assumptions

The GenericDeclaration class provides assumptions about a symbol or function in verbal form. Such assumptions can be made using the `assume()` function in this module, which also can take any relation of symbolic expressions as argument. Use `forget()` to clear all assumptions. Creating a variable with a specific domain is equivalent with making an assumption about it.

There is only rudimentary support for consistency and satisfiability checking in Sage. Assumptions are used both in Maxima and Pynac to support or refine some computations. In the following we show how to make and query assumptions. Please see the respective modules for more practical examples.

In addition to the global `assumptions()` database, `assuming()` creates reusable, stackable context managers allowing for temporary updates of the database for evaluation of a (block of) statements.

EXAMPLES:

The default domain of a symbolic variable is the complex plane:

```
sage: var('x')
x
sage: x.is_real()
False
sage: assume(x,'real')
sage: x.is_real()
True
sage: forget()
sage: x.is_real()
False
```

Here is the list of acceptable features:

```
sage: ', '.join(map(str, maxima("features")._sage_()))
'integer, noninteger, even, odd, rational, irrational, real, imaginary,
complex, analytic, increasing, decreasing, oddfun, evenfun, posfun,
constant, commutative, lassociative, rassociative, symmetric,
antisymmetric, integervalued'
```

Set positive domain using a relation:

```
sage: assume(x>0)
sage: x.is_positive()
True
sage: x.is_real()
True
sage: assumptions()
[x > 0]
```

Assumptions also affect operations that do not use Maxima:
Symbolic Calculus, Release 10.0

 sage: forget()
 sage: assume(x, 'even')
 sage: assume(x, 'real')
 sage: (-1)^x
 1
 sage: (-gamma(pi))^x
 gamma(pi)^x
 sage: binomial(2*x, x).is_integer()
 True

Assumptions are added and in some cases checked for consistency:

 sage: assume(x>0)
 sage: assume(x<0)
 Traceback (most recent call last):
 ... ValueError: Assumption is inconsistent
 sage: forget()

class sage.symbolic.assumptions.GenericDeclaration(var, assumption)

Bases: UniqueRepresentation

This class represents generic assumptions, such as a variable being an integer or a function being increasing. It passes such information to Maxima’s declare (wrapped in a context so it is able to forget) and to Pynac.

INPUT:

• var – the variable about which assumptions are being made
• assumption – a string containing a Maxima feature, either user defined or in the list given by maxima('features')

EXAMPLES:

 sage: from sage.symbolic.assumptions import GenericDeclaration
 sage: decl = GenericDeclaration(x, 'integer')
 sage: decl.assume()
 sin(x*pi)
 0
 sage: decl.forget()
 sage: sin(x*pi)
 sin(pi*x)
 sage: sin(x*pi).simplify()
 sin(pi*x)

Here is the list of acceptable features:

 sage: ', '.join(map(str, maxima("features")._sage_()))
 'integer, noninteger, even, odd, rational, irrational, real, imaginary, complex, analytic, increasing, decreasing, oddfun, evenfun, posfun, constant, commutative, lassociative, rassociative, symmetric, antisymmetric, integervalued'

Test unique representation behavior:

2.3. Assumptions 157
Symbolic Calculus, Release 10.0

\begin{verbatim}
sage: GenericDeclaration(x, 'integer') is GenericDeclaration(SR.var("x"), 'integer')
True

assume()
Make this assumption.

contradicts(soln)
Return True if this assumption is violated by the given variable assignment(s).

INPUT:
• soln – Either a dictionary with variables as keys or a symbolic relation with a variable on the left hand side.

EXAMPLES:

sage: from sage.symbolic.assumptions import GenericDeclaration
sage: GenericDeclaration(x, 'integer').contradicts(x==4)
False
sage: GenericDeclaration(x, 'integer').contradicts(x==4.0)
False
sage: GenericDeclaration(x, 'integer').contradicts(x==4.5)
True
sage: GenericDeclaration(x, 'integer').contradicts(x==sqrt(17))
True
sage: GenericDeclaration(x, 'noninteger').contradicts(x==sqrt(17))
False
sage: GenericDeclaration(x, 'noninteger').contradicts(x==17)
True
sage: GenericDeclaration(x, 'even').contradicts(x==3)
True
sage: GenericDeclaration(x, 'complex').contradicts(x==3)
False
sage: GenericDeclaration(x, 'imaginary').contradicts(x==3)
True
sage: GenericDeclaration(x, 'imaginary').contradicts(x==I)
False
sage: var('y, z')
(y, z)
sage: GenericDeclaration(x, 'imaginary').contradicts(x==y+z)
False
sage: GenericDeclaration(x, 'rational').contradicts(y==pi)
False
sage: GenericDeclaration(x, 'rational').contradicts(x==pi)
True
sage: GenericDeclaration(x, 'irrational').contradicts(x!=pi)
False
sage: GenericDeclaration(x, 'rational').contradicts({x: pi, y: pi})
True
sage: GenericDeclaration(x, 'rational').contradicts({z: pi, y: pi})
False

forget()
\end{verbatim}
Forget this assumption.

\texttt{has(arg)}

Check if this assumption contains the argument \texttt{arg}.

**EXAMPLES:**

\begin{verbatim}
sage: from sage.symbolic.assumptions import GenericDeclaration as GDecl
sage: var('y')
y
sage: d = GDecl(x, 'integer')
sage: d.has(x)
True
sage: d.has(y)
False
\end{verbatim}

\begin{verbatim}
sage.symbolic.assumptions.assume(*args)

Make the given assumptions.

INPUT:

- \texttt{*args} – a variable-length sequence of assumptions, each consisting of:
  - any number of symbolic inequalities, like \(0 < x, x < 1\)
  - a subsequence of variable names, followed by some property that should be assumed for those variables; for example, \(x, y, z, 'integer'\) would assume that each of \(x, y,\) and \(z\) are integer variables, and \(x, 'odd'\) would assume that \(x\) is odd (as opposed to even).

The two types can be combined, but a symbolic inequality cannot appear in the middle of a list of variables.

OUTPUT:

If everything goes as planned, there is no output.

If you assume something that is not one of the two forms above, then an \texttt{AttributeError} is raised as we try to call its \texttt{assume} method.

If you make inconsistent assumptions (for example, that \(x\) is both even and odd), then a \texttt{ValueError} is raised.

**Warning:** Do not use Python’s chained comparison notation in assumptions. Python literally translates the expression \(0 < x < 1\) to \((0 < x) \text{ and } (x < 1)\), but the value of \texttt{bool(0 < x)} is \texttt{False} when \(x\) is a symbolic variable. Therefore, by the definition of Python’s logical “and” operator, the entire expression is equal to \(0 < x\).

**EXAMPLES:**

Assumptions are typically used to ensure certain relations are evaluated as true that are not true in general.

Here, we verify that for \(x > 0\), \(\sqrt{x^2} = x\):

\begin{verbatim}
sage: assume(x > 0)
sage: bool(sqrt(x^2) == x)
True
\end{verbatim}

This will be assumed in the current Sage session until forgotten:
Another major use case is in taking certain integrals and limits where the answers may depend on some sign condition:

```python
sage: var('x, n')
(x, n)
sage: assume(n+1>0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
```

```python
sage: var('q, a, k')
(q, a, k)
sage: assume(q > 1)
sage: sum(a*q^k, k, 0, oo)
Traceback (most recent call last):
  ...  ValueError: Sum is divergent.
sage: forget()
```

```python
sage: assume(abs(q) < 1)
sage: sum(a*q^k, k, 0, oo)
-a/(q - 1)
sage: forget()
```

An integer constraint:

```python
sage: n,P,r,r2 = SR.var('n, P, r, r2')
sage: assume(n, 'integer')
sage: c = P*e^(r*n)
sage: d = P*(1+r2)^n
sage: solve(c==d,r2)
[r2 == e^r - 1]
sage: forget()
```

Simplifying certain well-known identities works as well:

```python
sage: n = SR.var('n')
sage: assume(n, 'integer')
sage: sin(n*pi)
0
sage: forget()
sage: sin(n*pi).simplify()
```

Instead of using chained comparison notation, each relationship should be passed as a separate assumption:

```python
sage: x = SR.var('x')
sage: assume(0 < x, x < 1) # instead of assume(0 < x < 1)
```
If you make inconsistent or meaningless assumptions, Sage will let you know:

```python
sage: assume(x<0)
sage: assume(x>0)
Traceback (most recent call last):
... ValueError: Assumption is inconsistent
sage: assume(x<1)
Traceback (most recent call last):
... ValueError: Assumption is redundant
```

You can also use assumptions to evaluate simple truth values:

```python
sage: x, y, z = var('x, y, z')
sage: assume(x>=y,y>=z,z>=x)
sage: bool(x==z)
True
sage: bool(z<x)
False
sage: bool(z>y)
False
sage: bool(y==z)
True
```

```python
class sage.symbolic.assumptions.assuming(*args, **kwds)
Bases: object

Temporarily modify assumptions.

Create a context manager in which temporary assumptions are added (or substituted) to the current assumptions set.

The set of possible assumptions and declarations is the same as for `assume()`.
```
This can be useful in interactive mode to discover the assumptions necessary to a given integration, or the exact solution to a system of equations.

It can also be used to explore the branches of a `cases()` expression.

As with `assume()`, it is an error to add an assumption either redundant or inconsistent with the current assumption set (unless `replace=True` is used). See examples.

INPUT:

- `*args` – assumptions (same format as for `assume()`).

- `replace` – a boolean (default `[False].`) Specifies whether the new assumptions are added to (default) or replace (if `replace=True`) the current assumption set.

OUTPUT:

A context manager useable in a `with` statement (see examples).

EXAMPLES:

Basic functionality: inside a `with assuming:` block, Sage uses the updated assumptions database. After exit, the original database is restored.

```python
sage: var("x")
x
sage: forget(assumptions())
sage: solve(x^2 == 4,x)
[2, -2]
sage: with assuming(x > 0):
....: solve(x^2 == 4,x)
[2]
sage: assumptions()
[]
```

The local assumptions can be stacked. We can use this functionality to discover incrementally the assumptions necessary to a given calculation (and by the way, to check that Sage's default integrator (Maxima's, that is), sometimes nitpicks for naught).

```python
sage: var("y,k,theta")
(y, k, theta)
sage: dgamma(y,k,theta)=y^(k-1)*e^(-y/theta)/(theta^k*gamma(k))
sage: integrate(dgamma(y,k,theta),y,0,oo)
Traceback (most recent call last):
... ValueError: Computation failed since Maxima requested additional constraints; using
→'assume' command before evaluation *may* help (example of legal syntax is
→'assume(theta>0)', see 'assume?' for more details)
Is theta positive or negative?
sage: a1=assuming(theta>0)
sage: with a1:integrate(dgamma(y,k,theta),y,0,oo)
Traceback (most recent call last):
... ValueError: Computation failed since Maxima requested additional constraints; using
→'assume' command before evaluation *may* help (example of legal syntax is
→'assume(k>0)', see 'assume?' for more details)
Is k positive, negative or zero?
```

(continues on next page)
As mentioned above, it is an error to try to introduce redundant or inconsistent assumptions.

```
sage: assume(x > 0)
sage: with assuming(x > -1): "I won't see this"
Traceback (most recent call last):
...
ValueError: Assumption is redundant
```

```
sage: with assuming(x < -1): "I won't see this"
Traceback (most recent call last):
...
ValueError: Assumption is inconsistent
```

`sage.symbolic.assumptions.assumptions(*args)`

List all current symbolic assumptions.

INPUT:

• `args` – list of variables which can be empty.

OUTPUT:

• list of assumptions on variables. If `args` is empty it returns all assumptions

EXAMPLES:

```
sage: var('x, y, z, w')
(x, y, z, w)
sage: forget()
sage: assume(x^2+y^2 > 0)
sage: assumptions()
[x^2 + y^2 > 0]
sage: forget(x^2+y^2 > 0)
sage: assumptions()
[]
sage: assume(x > y)
sage: assume(z > w)
sage: sorted(assumptions(), key=lambda x: str(x))
[x > y, z > w]
sage: forget()
```
It is also possible to query for assumptions on a variable independently:

```
sage: x, y, z = var('x y z')
sage: assume(x, 'integer')
sage: assume(y > 0)
sage: assume(y**2 + z**2 == 1)
sage: assume(x < 0)
sage: assumptions()
[x is integer, y > 0, y^2 + z^2 == 1, x < 0]
sage: assumptions(x)
[x is integer, x < 0]
sage: assumptions(x, y)
[x is integer, x < 0, y > 0, y^2 + z^2 == 1]
sage: assumptions(z)
[y^2 + z^2 == 1]
```

```
sage.symbolic.assumptions.forget(*args)
```

Forget the given assumption, or call with no arguments to forget all assumptions.

Here an assumption is some sort of symbolic constraint.

**INPUT:**

- `*args` – assumptions (default: forget all assumptions)

**EXAMPLES:**

We define and forget multiple assumptions:

```
sage: forget()
sage: var('x,y,z')
(x, y, z)
sage: assume(x>0, y>0, z == 1, y>0)
sage: sorted(assumptions(), key=lambda x: str(x))
[x > 0, y > 0, z == 1]
sage: forget(x>0, z==1)
sage: assumptions()
y > 0
sage: assume(y, 'even', z, 'complex')
sage: assumptions()
y > 0, y is even, z is complex
sage: cos(y*pi).simplify()
1
sage: forget(y,'even')
sage: cos(y*pi).simplify()
cos(pi*y)
sage: assumptions()
y > 0, z is complex
sage: forget()
sage: assumptions()
[]
```
sage.symbolic.assumptions.preprocess_assumptions(args)

Turn a list of the form (var1, var2, ..., 'property') into a sequence of declarations (var1 is property), (var2 is property), ...

EXAMPLES:

```python
sage: from sage.symbolic.assumptions import preprocess_assumptions
sage: preprocess_assumptions([x, 'integer', x > 4])
[x is integer, x > 4]
sage: var('x, y')
(x, y)
sage: preprocess_assumptions([x, y, 'integer', x > 4, y, 'even'])
[x is integer, y is integer, x > 4, y is even]
```

2.4 Symbolic Equations and Inequalities

Sage can solve symbolic equations and inequalities. For example, we derive the quadratic formula as follows:

```python
sage: a,b,c = var('a,b,c')
sage: qe = (a*x^2 + b*x + c == 0)
sage: qe
a*x^2 + b*x + c == 0
sage: print(solve(qe, x))
[x == -1/2*(b + sqrt(b^2 - 4*a*c))/a, x == -1/2*(b - sqrt(b^2 - 4*a*c))/a]
```

2.4.1 The operator, left hand side, and right hand side

Operators:

```python
sage: eqn = x^3 + 2/3 >= x - pi
sage: eqn.operator()
<built-in function ge>
sage: (x^3 + 2/3 < x - pi).operator()
<built-in function lt>
sage: (x^3 + 2/3 == x - pi).operator()
<built-in function eq>
```

Left hand side:

```python
sage: eqn = x^3 + 2/3 >= x - pi
sage: eqn.lhs()
x^3 + 2/3
sage: eqn.left()
x^3 + 2/3
sage: eqn.left_hand_side()
x^3 + 2/3
```

Right hand side:
2.4.2 Arithmetic

Add two symbolic equations:

```sage
sage: var('a,b')
(a, b)
sage: m = 144 == -10 * a + b
sage: n = 136 == 10 * a + b
sage: m + n
280 == 2*b
sage: int(-144) + m
0 == -10*a + b - 144
```

Subtract two symbolic equations:

```sage
sage: var('a,b')
(a, b)
sage: m = 144 == 20 * a + b
sage: n = 136 == 10 * a + b
sage: m - n
8 == 10*a
sage: int(144) - m
0 == -20*a - b + 144
```

Multiply two symbolic equations:

```sage
sage: x = var('x')
sage: m = x == 5*x + 1
sage: n = sin(x) == sin(x+2*pi, hold=True)
sage: m * n
x*sin(x) == (5*x + 1)*sin(2*pi + x)
sage: int(-1) * m
-2*x == -3*x^2 + 5
```

Divide two symbolic equations:

```sage
sage: x = var('x')
sage: m = x == 5*x + 1
sage: n = sin(x) == sin(x+2*pi, hold=True)
sage: m/n
x/sin(x) == (5*x + 1)/sin(2*pi + x)
sage: int(-1) * m
x != 5^x + 1
sage: n = sin(x) != sin(x+2*pi, hold=True)
```

(continues on next page)
sage: m/n
x/sin(x) != (5*x + 1)/sin(2*pi + x)

2.4.3 Substitution

Substitution into relations:

```
sage: x, a = var('x, a')
sage: eq = (x^3 + a == sin(x/a)); eq
x^3 + a == sin(x/a)
sage: eq.substitute(x=5*x)
125*x^3 + a == sin(5*x/a)
sage: eq.substitute(a=1)
x^3 + 1 == sin(x)
sage: eq.substitute(a=x)
x^3 + x == sin(1)
sage: eq.substitute(a=x, x=1)
x + 1 == sin(1/x)
sage: eq.substitute({a:x, x:1})
x + 1 == sin(1/x)
```

You can even substitute multivariable and matrix expressions:

```
sage: x,y = var('x, y')
sage: M = Matrix([[x+1,y],[x^2,y^3]]); M
[ x + 1   y]
[ x^2   y^3]
sage: M.substitute({x:0,y:1})
[ 1   1]
[0 1]
```

2.4.4 Solving

We can solve equations:

```
sage: x = var('x')
sage: S = solve(x^3 - 1 == 0, x)
sage: S
[x == 1/2*I*sqrt(3) - 1/2, x == -1/2*I*sqrt(3) - 1/2, x == 1]
sage: S[0]
x == 1/2*I*sqrt(3) - 1/2
sage: S[0].right()
1/2*I*sqrt(3) - 1/2
sage: S = solve(x^3 - 1 == 0, x, solution_dict=True)
sage: S
[{x: 1/2*I*sqrt(3) - 1/2}, {x: -1/2*I*sqrt(3) - 1/2}, {x: 1}]
sage: z = 5
sage: solve(z^2 == sqrt(3),z)
Traceback (most recent call last):
```

(continues on next page)
We can also solve equations involving matrices. The following example defines a multivariable function \( f(x,y) \), then solves for where the partial derivatives with respect to \( x \) and \( y \) are zero. Then it substitutes one of the solutions into the Hessian matrix \( H \) for \( f \):

\[
\begin{align*}
\text{sage: } & f(x,y) = x^2 + 2y + y^2, \\
\text{sage: } & \text{solve(list}(f\text{.diff()})\text{,[}x\text{,}y\text{]},\text{solution_dict=}\text{True}) \\
\text{sage: } & \text{solve} = \{\{x: -i, y: 0\}, \{x: i, y: 0\}, \{x: 0, y: -1/2\}\} \\
\text{sage: } & H = f\text{.diff}(2) \quad \# \quad \text{Hessian matrix} \\
\text{sage: } & H\text{.subs(solutions[2])} \\
\text{sage: } & [-1 0] \\
\text{sage: } & [ 0 2]
\end{align*}
\]

We illustrate finding multiplicities of solutions:

\[
\begin{align*}
\text{sage: } & f = (x-1)^5(x^2+1) \\
\text{sage: } & \text{solve}(f == 0, x) \\
\text{sage: } & \text{solve}(f == 0, x, \text{multiplicities}=\text{True}) \\
\text{sage: } & ([x == -i, x == i, x == 1], [1, 1, 5])
\end{align*}
\]

We can also solve many inequalities:

\[
\begin{align*}
\text{sage: } & \text{solve}(1/(x-1) <= 8, x) \\
\text{sage: } & \text{solve}(1/(x-1) <= 8, x) \\
\end{align*}
\]

We can numerically find roots of equations:

\[
\begin{align*}
\text{sage: } & \text{find_root}(\cos(x) == \sin(x), 10, 20) \\
\text{sage: } & \text{find_root}(\cos(x) == \sin(x), 10, 20) \\
\end{align*}
\]

We illustrate some valid error conditions:

\[
\begin{align*}
\text{sage: } & \text{find_root}\text{.exception}(\cos(x) != \sin(x), 10, 20) \\
\text{sage: } & \text{find_root}\text{.exception}(\cos(x) != \sin(x), 10, 20) \\
\end{align*}
\]

There must be at most one variable:
```
sage: x, y = var('x,y')
sage: (x == y).find_root(-2,2)
Traceback (most recent call last):
...
NotImplementedError: root finding currently only implemented in 1 dimension.
```

### 2.4.5 Assumptions

Forgetting assumptions:
```
sage: var('x,y')
(x, y)
sage: forget()  # Clear assumptions
sage: assume(x>0, y < 2)
sage: assumptions()
[x > 0, y < 2]
sage: (y < 2).forget()
sage: assumptions()
[x > 0]
sage: forget()
sage: assumptions()
[]
```

### 2.4.6 Miscellaneous

Conversion to Maxima:
```
sage: x = var('x')
sage: eq = (x^(3/5) >= pi^2 + e^i)
sage: eq._maxima_init_()
'(_SAGE_VAR_x)^(3/5) >= ((%pi)^(2))+(exp(0+%i*1))'
sage: e1 = x^3 + x == sin(2*x)
sage: z = e1._maxima_()
sage: z.parent() is sage.calculus.calculus.maxima
True
sage: z = e1._maxima_(maxima)
sage: z.parent() is maxima
True
sage: z = maxima(e1)
sage: z.parent() is maxima
True
```

Conversion to Maple:
```
sage: x = var('x')
sage: eq = (x == 2)
sage: eq._maple_init_()
'x = 2'
```

Comparison:
Symbolic Calculus, Release 10.0

sage: x = var('x')
sage: (x>0) == (x>0)
True
sage: (x>0) == (x>1)
False
sage: (x>0) != (x>1)
True

Variables appearing in the relation:

sage: var('x,y,z,w')
(x, y, z, w)
sage: f = (x+y+w) == (x^2 - y^2 - z^3); f
w + x + y == -z^3 + x^2 - y^2
sage: f.variables()
(w, x, y, z)

LaTeX output:

sage: latex(x^(3/5) >= pi)
x^\frac{3}{5} \geq \pi

When working with the symbolic complex number $i$, notice that comparisons do not automatically simplify even in trivial situations:

sage: SR(I)^2 == -1
-1 == -1
sage: SR(I)^2 < 0
-1 < 0
sage: (SR(I)+1)^4 > 0
-4 > 0

Nevertheless, if you force the comparison, you get the right answer (github issue #7160):

sage: bool(SR(I)^2 == -1)
True
sage: bool(SR(I)^2 < 0)
True
sage: bool((SR(I)+1)^4 > 0)
False

2.4.7 More Examples

sage: x,y,a = var('x,y,a')
sage: f = x^2 + y^2 == 1
sage: f.solve(x)
[x == -sqrt(-y^2 + 1), x == sqrt(-y^2 + 1)]

sage: f = x^5 + a
sage: solve(f==0,x)
[x == 1/4*(-a)^(1/5)*(sqrt(5) + I*sqrt(2*sqrt(5) + 10) - 1), x == -1/4*(-a)^(1/5)*(sqrt(5) + I*sqrt(2*sqrt(5) + 10) + 1), x == 1/4*(-a)^(1/5)*(-sqrt(5) + I*sqrt(2*sqrt(5) + 10))]

(continues on next page)
You can also do arithmetic with inequalities, as illustrated below:

```
sage: var('x y')
(x, y)
sage: f = x + 3 == y - 2
sage: f
x + 3 == y - 2
sage: g = f - 3; g
x == y - 5
sage: h = x^3 + sqrt(2) == x*y*sin(x)
```

```
sage: h
x^3 + sqrt(2) == x*y*sin(x)
sage: h - sqrt(2)
```

```
x^3 == x*y*sin(x) - sqrt(2)
sage: h + f
```

```
x^3 + x + sqrt(2) + 3 == x*y*sin(x) + y - 2
sage: f = x + 3 < y - 2
sage: f
x + 3 < y - 2
sage: g = 2 < x+10
sage: f - g
x + 1 < -x + y - 12
sage: f + g
x + 5 < x + y + 8
sage: f*(-1)
-x - 3 < -y + 2
```

AUTHORS:

- Bobby Moretti: initial version (based on a trick that Robert Bradshaw suggested).
- William Stein: second version
- William Stein (2007-07-16): added arithmetic with symbolic equations

\[ -5^*(\sqrt{5} - i\sqrt{-2*\sqrt{5} + 10} + 1), x == -1/4*(-a)^{(1/5)}*(\sqrt{5} + i\sqrt{2*\sqrt{5} + 10} + 1), x == 1/4*(-a)^{(1/5)}*(\sqrt{5} - i\sqrt{-2*\sqrt{5} + 10} - 1), x == (-a)^{(1/5)} \]

\[ \text{sage.symbolic.relation.solve}(f, \text{*args, **kws}) \]

Algebraically solve an equation or system of equations (over the complex numbers) for given variables. Inequalities and systems of inequalities are also supported.

**INPUT:**

- \( f \) - equation or system of equations (given by a list or tuple)
- \( \text{*args} \) - variables to solve for.
- \( \text{solution_dict} \) - bool (default: False); if True or non-zero, return a list of dictionaries containing the solutions. If there are no solutions, return an empty list (rather than a list containing an empty dictionary). Likewise, if there’s only a single solution, return a list containing one dictionary with that solution.

There are a few optional keywords if you are trying to solve a single equation. They may only be used in that context.

- \( \text{multiplicities} \) - bool (default: False); if True, return corresponding multiplicities. This keyword is incompatible with \( \text{to_poly_solve} = \text{True} \) and does not make any sense when solving inequalities.
Symbolic Calculus, Release 10.0

- **explicit_solutions** - bool (default: False); require that all roots be explicit rather than implicit. Not used when solving inequalities.

- **to_poly_solve** - bool (default: False) or string; use Maxima’s to_poly_solver package to search for more possible solutions, but possibly encounter approximate solutions. This keyword is incompatible with multiplicities=True and is not used when solving inequalities. Setting to_poly_solve to ‘force’ (string) omits Maxima’s solve command (useful when some solutions of trigonometric equations are lost).

- **algorithm** - string (default: ‘maxima’); to use SymPy’s solvers set this to ‘sympy’. Note that SymPy is always used for diophantine equations. Another choice is ‘giac’.

- **domain** - string (default: ‘complex’); setting this to ‘real’ changes the way SymPy solves single equations; inequalities are always solved in the real domain.

**EXAMPLES:**

```python
sage: x, y = var('x, y')
sage: solve([x+y==6, x-y==4], x, y)
[[x == 5, y == 1]]
sage: solve([x^2+y^2 == 1, y^2 == x^3 + x + 1], x, y)
[[x == -1/2*I*sqrt(3) - 1/2, y == sqrt(-1/2*I*sqrt(3) + 3/2)],
 [x == -1/2*I*sqrt(3) - 1/2, y == sqrt(-1/2*I*sqrt(3) + 3/2)],
 [x == 1/2*I*sqrt(3) - 1/2, y == -sqrt(1/2*I*sqrt(3) + 3/2)],
 [x == 1/2*I*sqrt(3) - 1/2, y == sqrt(1/2*I*sqrt(3) + 3/2)],
 [x == 0, y == -1],
 [x == 0, y == 1]]
sage: solve([sqrt(x) + sqrt(y) == 5, x + y == 10], x, y)
[[x == -5/2*I*sqrt(5) + 5, y == 5/2*I*sqrt(5) + 5], [x == 5/2*I*sqrt(5) + 5, y == -5/2*I*sqrt(5) + 5]]
sage: solutions = solve([x^3==y,y^2==x], [x,y]); solutions[-1], solutions[0]
([x == 0, y == 0],
 [x == (0.3090169943749475 + 0.9510565162951535*I),
  y == (-0.8090169943749475 - 0.5877852522924731*I)])
sage: solutions[0][0].rhs().pyobject().parent()
Complex Double Field
```

Whenever possible, answers will be symbolic, but with systems of equations, at times approximations will be given by Maxima, due to the underlying algorithm:

```python
sage: sols = solve([x^3==y,y^2==x], [x,y]); sols[-1], sols[0]
([x == 0, y == 0],
 [x == (0.3090169943749475 + 0.9510565162951535*I),
  y == (-0.8090169943749475 - 0.5877852522924731*I)])
sage: sols[0][0].rhs().pyobject().parent()
Complex Double Field

sage: solve([y^6==y],y)
[y == 1/4*I*sqrt(5) + 1/4*I*sqrt(2*I*sqrt(5) + 10) - 1/4,
 y == -1/4*I*sqrt(5) + 1/4*I*sqrt(-2*I*sqrt(5) + 10) - 1/4,
 y == -1/4*I*sqrt(5) - 1/4*I*sqrt(-2*I*sqrt(5) + 10) - 1/4,
 y == 1/4*I*sqrt(5) - 1/4*I*sqrt(2*I*sqrt(5) + 10) - 1/4,
 y == 1,]
```

(continues on next page)
y == 0]
sage: solve( [y^6 == y], y)==solve( y^6 == y, y)
True

Here we demonstrate very basic use of the optional keywords:

```
sage: (x^2-1)^2.solve(x)
[x == -1, x == 1]
sage: (x^2-1)^2.solve(x,multiplicities=True)
([x == -1, x == 1], [2, 2])
sage: solve(sin(x)==x,x)
[x == sin(x)]
sage: solve(sin(x)==x,x,explicit_solutions=True)
[]
sage: solve(abs(1-abs(1-x)) == 10, x)
[abs(abs(x - 1) - 1) == 10]
sage: solve(abs(1-abs(1-x)) == 10, x, to_poly_solve=True)
[x == -10, x == 12]
```

We must solve with respect to actual variables:

```
sage: z = 5
sage: solve([8*z + y == 3, -z +7*y == 0],y,z)
Traceback (most recent call last):
...:
TypeError: 5 is not a valid variable.
```

If we ask for dictionaries containing the solutions, we get them:

```
sage: solve([x^2-1],x,solution_dict=True)
[\{x: -1\}, \{x: 1\}]
sage: solve([x^2-4*x+4],x,solution_dict=True)
[\{x: 2\}]
sage: res = solve([x^2 == y, y == 4],x,y,solution_dict=True)
sage: for soln in res: print("x: %s, y: %s" % (soln[x], soln[y]))
x: 2, y: 4
x: -2, y: 4
```

If there is a parameter in the answer, that will show up as a new variable. In the following example, r1 is an arbitrary constant (because of the r):

```
sage: forget()
sage: x, y = var('x, y')
sage: solve([x+y == 3, 2*x+2*y == 6],x,y)
[[x == -r1 + 3, y == r1]]
sage: var('b, c')
(b, c)
```

(continues on next page)
sage: solve((b-1)*(c-1), [b,c])
[[b == 1, c == r...], [b == r..., c == 1]]

Especially with trigonometric functions, the dummy variable may be implicitly an integer (hence the z):

\[
\text{sage: solve( } \sin(x)==\cos(x), x, \text{ to_poly_solve=True)}
\]
\[
[x == 1/4\pi + pi*z...]
\]

Expressions which are not equations are assumed to be set equal to zero, as with \(x\) in the following example:

\[
\text{sage: solve([x, y == 2],x,y)}
\]
\[
[[x == 0, y == 2]]
\]

If True appears in the list of equations it is ignored, and if False appears in the list then no solutions are returned. E.g., note that the first 3==3 evaluates to True, not to a symbolic equation.

\[
\text{sage: solve([3==3, 1.00000000000000*x^3 == 0], x)}
\]
\[
[x == 0]
\]

Here, the first equation evaluates to False, so there are no solutions:

\[
\text{sage: solve([1==3, 1.00000000000000*x^3 == 0], x)}
\]
\[
[]
\]

Completely symbolic solutions are supported:

\[
\text{sage: var('s,j,b,m,g')}\]
\[
(s, j, b, m, g)
\]
\[
\text{sage: sys = [ m*(1-s) - b*s*j, b*s*j-g*j ]}
\]
\[
\text{sage: solve(sys,s,j)}
\]
\[
[[s == 1, j == 0], [s == g/b, j == (b - g)*m/(b*g)]]
\]

Inequalities can be also solved:

\[
\text{sage: solve(x^2>8,x)}
\]
\[
[[x < -2*sqrt(2)], [x > 2*sqrt(2)]]
\]
\[
\text{sage: x,y = var('x,y'); (ln(x)-ln(y)>0).solve(x)}
\]
\[
[[\text{log(x) - log(y) > 0}]]
\]
\[
\text{sage: x,y = var('x,y'); (ln(x)>ln(y)).solve(x)}\quad \# \text{ random}
\]
\[
[[0 < y, y < x, 0 < x]]
\]
\[
[[y < x, 0 < y]]
\]
A simple example to show the use of the keyword multiplicities:

```python
sage: ((x^2-1)^2).solve(x)
[x == -1, x == 1]
sage: ((x^2-1)^2).solve(x, multiplicities=True)
([x == -1, x == 1], [2, 2])
sage: ((x^2-1)^2).solve(x, multiplicities=True, to_poly_solve=True)
Traceback (most recent call last):
  ... Not ImplementedError: to_poly_solve does not return multiplicities
```

Here is how the explicit_solutions keyword functions:

```python
sage: solve(sin(x)==x, x)
[x == sin(x)]
sage: solve(sin(x)==x, x, explicit_solutions=True)
[]
sage: solve(x*sin(x)==x^2, x)
[x == 0, x == sin(x)]
sage: solve(x*sin(x)==x^2, x, explicit_solutions=True)
[x == 0]
```

The following examples show the use of the keyword to_poly_solve:

```python
sage: solve(abs(1-abs(1-x)) == 10, x)
[abs(abs(x - 1) - 1) == 10]
sage: solve(abs(1-abs(1-x)) == 10, x, to_poly_solve=True)
[x == -10, x == 12]
sage: var('Q')
Q
sage: solve(Q*sqrt(Q^2 + 2) - 1, Q)
[Q == 1/sqrt(Q^2 + 2)]
```

The following example is a regression in Maxima 5.39.0. It used to be possible to get one more solution here, namely 1/sqrt(sqrt(2) + 1), see https://sourceforge.net/p/maxima/bugs/3276/:

```python
sage: solve(Q*sqrt(Q^2 + 2) - 1, Q, to_poly_solve=True)
[Q == -sqrt(-sqrt(2) - 1), Q == sqrt(sqrt(2) + 1)*(sqrt(2) - 1)]
```

An effort is made to only return solutions that satisfy the current assumptions:

```python
sage: solve(x^2==4, x)
[x == -2, x == 2]
sage: assume(x<0)
sage: solve(x^2==4, x)
[x == -2]
sage: solve((x^2-4)^2 == 0, x, multiplicities=True)
([x == -2], [2])
sage: solve(x^2==2, x)
[x == -sqrt(2)]
sage: z = var('z')
sage: solve(x^2==2-z, x)
[x == -sqrt(-z + 2)]
```

(continues on next page)
In some cases it may be worthwhile to directly use `to_poly_solve` if one suspects some answers are being missed:

```plaintext
sage: forget()
sage: solve(cos(x)==0, x)
[x == 1/2*pi]
sage: solve(cos(x)==0, x, to_poly_solve=True)
[x == 1/2*pi]
sage: solve(cos(x)==0, x, to_poly_solve='force')
[x == 1/2*pi + pi*z...]
```

The same may also apply if a returned unsolved expression has a denominator, but the original one did not:

```plaintext
sage: solve(cos(x) * sin(x) == 1/2, x, to_poly_solve=True)
[sin(x) == 1/2/cos(x)]
sage: solve(cos(x) * sin(x) == 1/2, x, to_poly_solve=True, explicit_solutions=True)
[x == 1/4*pi + pi*z...]
sage: solve(cos(x) * sin(x) == 1/2, x, to_poly_solve='force')
[x == 1/4*pi + pi*z...]
```

We use `use_grobner` in Maxima if no solution is obtained from Maxima’s `to_poly_solve`:

```plaintext
sage: x,y = var('x y')
sage: c1(x,y) = (x-5)^2+y^2-16
sage: c2(x,y) = (y-3)^2+x^2-9
sage: solve([c1(x,y),c2(x,y)],[x,y])
[[x == -9/68*sqrt(55) + 135/68, y == -15/68*sqrt(55) + 123/68],
 [x == 9/68*sqrt(55) + 135/68, y == 15/68*sqrt(55) + 123/68]]
```

We use SymPy for Diophantine equations, see `Expression.solve_diophantine`:

```plaintext
sage: assume(x, 'integer')
sage: assume(z, 'integer')
sage: solve((x-z)^2==2, x)
[]
sage: forget()
```

The following shows some more of SymPy’s capabilities that cannot be handled by Maxima:

```plaintext
sage: t = var('t')
sage: r = solve([x^2 - y^2/exp(x), y-1], x, y, algorithm='sympy')
sage: (r[0][x], r[0][y])
(2*lambert_w(-1/2), 1)
sage: solve(-2*x**3 + 4*x**2 - 2*x + 6 > 0, x, algorithm='sympy')
[x < 1/3*(1/2)^(1/3)*(9*sqrt(77) + 79)^(1/3) + 2/3*(1/2)^(2/3)/(9*sqrt(77) + 79)^(1/3) - 3/2 + 2/3]
sage: solve(sqrt(2*x^2 - 7) - (3 - x),x,algorithm='sympy')
[x == -8, x == 2]
```
sage: solve(sqrt(2*x + 9) - sqrt(x + 1) - sqrt(x + 4), x, algorithm='sympy')
[x == 0]

sage: r = solve([x + y + z + t, -z - t], x, y, z, t, algorithm='sympy')
(r[0][x], r[0][y], r[0][z])

sage: (r[0][x], r[0][y], r[0][z])
(-y, -t)

sage: r = solve([x^2+y+z, y+x^2+z, x+y+z^2], x, y, z, algorithm='sympy')
(r[0][x], r[0][y], r[0][z])

sage: (r[0][x], r[0][y], r[0][z])
(z, -(z + 1)^2)

sage: solve(abs(x + 3) - 2*abs(x - 3), x, algorithm='sympy', domain='real')
[x == 1, x == 9]

We cannot translate all results from SymPy but we can at least print them:

sage: solve(sinh(x) - 2*cosh(x), x, algorithm='sympy')
[ImageSet(Lambda(_n, I*(2*_n*pi + pi/2) + log(sqrt(3))), Integers),
 ImageSet(Lambda(_n, I*(2*_n*pi - pi/2) + log(sqrt(3))), Integers)]

sage: solve(2*sin(x) - 2*sin(2*x), x, algorithm='sympy')
[ImageSet(Lambda(_n, 2*_n*pi), Integers),
 ImageSet(Lambda(_n, 2*_n*pi + pi), Integers),
 ImageSet(Lambda(_n, 2*_n*pi + 5*pi/3), Integers),
 ImageSet(Lambda(_n, 2*_n*pi + pi/3), Integers)]

sage: solve(x^5 + 3*x^3 + 7, x, algorithm='sympy')
[complex_root_of(x^5 + 3*x^3 + 7 + 0)]

A basic interface to Giac is provided:

sage: solve(([(2/3)^x-2], [x], algorithm='giac')
...[-log(2)/(log(3) - log(2))]

sage: f = (sin(x) - 8*cos(x)*sin(x))*(sin(x)^2 + cos(x)) - (2*cos(x)*sin(x) - sin(x))*(-2*sin(x)^2 + 2*cos(x)^2 - cos(x))

sage: solve(f, x, algorithm='giac')
...[-2*arctan(sqrt(2)), 0, 2*arctan(sqrt(2)), pi]

sage: x, y = SR.var('x,y')

sage: solve([(x+y-4,x*y-3),[x,y],algorithm='giac')
[[1, 3], [3, 1]]

sage.symbolic.relation.solve_ineq(ineq, vars=None)
Solves inequalities and systems of inequalities using Maxima. Switches between rational inequalities (sage.symbolic.relation.solve_ineq_rational) and Fourier elimination (sage.symbolic.relation.solve_ineq_fourier). See the documentation of these functions for more details.

INPUT:

- ineq - one inequality or a list of inequalities

Case1: If ineq is one equality, then it should be rational expression in one variable. This input is passed to sage.symbolic.relation.solve_ineq_univar function.

Case2: If ineq is a list involving one or more inequalities, than the input is passed to sage.symbolic.relation.solve_ineq_fourier function. This function can be used for system of linear inequal-
Symbolic Calculus, Release 10.0

...ties and for some types of nonlinear inequalities. See http://maxima.cvs.sourceforge.net/viewvc/maxima/maxima/share/contrib/fourier_elim/rtest_fourier_elim.mac for a big gallery of problems covered by this algorithm.

- **vars** - optional parameter with list of variables. This list is used only if Fourier elimination is used. If omitted or if rational inequality is solved, then variables are determined automatically.

**OUTPUT:**

- **list** – output is list of solutions as a list of simple inequalities output [A,B,C] means (A or B or C) each A, B, C is again a list and if A=[a,b], then A means (a and b).

**EXAMPLES:**

```python
sage: from sage.symbolic.relation import solve_ineq
```

Inequalities in one variable. The variable is detected automatically:

```python
sage: solve_ineq(x^2-1>3)
[[x < -2], [x > 2]]
sage: solve_ineq(1/(x-1)<=8)
[[x < 1], [x >= (9/8)]]
```

System of inequalities with automatically detected inequalities:

```python
sage: y = var('y')
sage: solve_ineq([x-y<0,x+y-3<0],[y,x])
[[x < y, y < -x + 3, x < (3/2)]]
sage: solve_ineq([x-y<0,x+y-3<0],[x,y])
[[x < min(-y + 3, y)]
```

Note that although Sage will detect the variables automatically, the order it puts them in may depend on the system, so the following command is only guaranteed to give you one of the above answers:

```python
sage: solve_ineq([x-y<0,x+y-3<0])  # random
[[x < y, y < -x + 3, x < (3/2)]]
```

**ALGORITHM:**

Calls `solve_ineq_fourier` if inequalities are list and `solve_ineq_univar` of the inequality is symbolic expression. See the description of these commands for more details related to the set of inequalities which can be solved. The list is empty if there is no solution.

**AUTHORS:**

- Robert Marik (01-2010)

---

**sage.symbolic.relation.solve_ineq_fourier(ineq, vars=None)**

Solves system of inequalities using Maxima and Fourier elimination

Can be used for system of linear inequalities and for some types of nonlinear inequalities. For examples, see the example section below and http://maxima.cvs.sourceforge.net/viewvc/maxima/maxima/share/contrib/fourier_elim/rtest_fourier_elim.mac

**INPUT:**

- **ineq** - list with system of inequalities
- **vars** - optionally list with variables for Fourier elimination.
Symbolic Calculus, Release 10.0

OUTPUT:

- list - output is list of solutions as a list of simple inequalities output [A,B,C] means (A or B or C) each A, B, C is again a list and if A=[a,b], then A means (a and b). The list is empty if there is no solution.

EXAMPLES:

```
sage: from sage.symbolic.relation import solve_ineq_fourier
sage: y = var('y')
sage: solve_ineq_fourier([x+y<9,x-y>4],[x,y])
[[y + 4 < x, x < -y + 9, y < (5/2)]]
sage: solve_ineq_fourier([x+y<9,x-y>4],[y,x])
[[y < min(x - 4, -x + 9)]]

sage: solve_ineq_fourier([x^2>=0])
[[x < +Infinity]]

sage: solve_ineq_fourier([log(x)>log(y)], [x,y])
[[y < x, 0 < y]]

sage: solve_ineq_fourier([log(x)>log(y)], [y,x])
[[0 < y, y < x, 0 < x]]
```

Note that different systems will find default variables in different orders, so the following is not tested:

```
sage: solve_ineq_fourier([log(x)>log(y)]) # random (one of the following appears)
[[y < x, 0 < y]]
[[0 < y, y < x, 0 < x]]
```

ALGORITHM:
Calls Maxima command fourier_elim

AUTHORS:
- Robert Marik (01-2010)

sage.symbolic.relation.solve_ineq_univar(ineq)
Function solves rational inequality in one variable.

INPUT:
- ineq - inequality in one variable

OUTPUT:
- list – output is list of solutions as a list of simple inequalities output [A,B,C] means (A or B or C) each A, B, C is again a list and if A=[a,b], then A means (a and b). The list is empty if there is no solution.

EXAMPLES:

```
sage: from sage.symbolic.relation import solve_ineq_univar
sage: solve_ineq_univar(x-1/x>0)
[[x > -1, x < 0], [x > 1]]

sage: solve_ineq_univar(x^2-1/x>0)
[[x < 0], [x > 1]]

sage: solve_ineq_univar((x^3-1)*x<=0)
[[x >= 0, x <= 1]]
```

2.4. Symbolic Equations and Inequalities 179
ALGORITHM:
Calls Maxima command solve_rat_ineq

AUTHORS:
- Robert Marik (01-2010)

`sage.symbolic.relation.solve_mod(eqs, modulus, solution_dict=False)`

Return all solutions to an equation or list of equations modulo the given integer modulus. Each equation must involve only polynomials in 1 or many variables.

By default the solutions are returned as \( n \)-tuples, where \( n \) is the number of variables appearing anywhere in the given equations. The variables are in alphabetical order.

INPUT:
- `eqns` - equation or list of equations
- `modulus` - an integer
- `solution_dict` - bool (default: False); if True or non-zero, return a list of dictionaries containing the solutions. If there are no solutions, return an empty list (rather than a list containing an empty dictionary). Likewise, if there’s only a single solution, return a list containing one dictionary with that solution.

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: solve_mod([x^2 + 2 == x, x^2 + y == y^2], 14)
[(4, 2), (4, 6), (4, 9), (4, 13)]
sage: solve_mod([x^2 == 1, 4*x == 11], 15)
[(14,)]
```

Fermat’s equation modulo 3 with exponent 5:

```
sage: var('x,y,z')
(x, y, z)
sage: solve_mod([x^5 + y^5 == z^5], 3)
[(0, 0, 0), (0, 1, 1), (0, 2, 2), (1, 0, 1), (1, 1, 2), (1, 2, 0), (2, 0, 2), (2, 1, 0), (2, 2, 1)]
```

We can solve with respect to a bigger modulus if it consists only of small prime factors:

```
sage: [d] = solve_mod([5*x + y == 3, 2*x - 3*y == 9], 3*5*7*11*19*23*29, solution_dict = True)
sage: d[x]
12915279
sage: d[y]
8610183
```

For cases where there are relatively few solutions and the prime factors are small, this can be efficient even if the modulus itself is large:

```
sage: sorted(solve_mod([x^2 == 41], 10^20))
[(4538602480526452429,), (11445932736758703821,), (38554067263241296179,), (4546139751947354751,), (5438602480526452429,), (61445932736758703821,), (88554067263241296179,), (9546139751947354751,)]
```

We solve a simple equation modulo 2:
 sage: x, y = var('x,y')
 sage: solve_mod([x == y], 2)
 [(0, 0), (1, 1)]

**Warning:** The current implementation splits the modulus into prime powers, then naively enumerates all possible solutions (starting modulo primes and then working up through prime powers), and finally combines the solution using the Chinese Remainder Theorem. The interface is good, but the algorithm is very inefficient if the modulus has some larger prime factors! Sage *does* have the ability to do something much faster in certain cases at least by using Groebner basis, linear algebra techniques, etc. But for a lot of toy problems this function as is might be useful. At least it establishes an interface.

**sage.symbolic.relation.string_to_list_of_solutions(s)**

Used internally by the symbolic solve command to convert the output of Maxima's solve command to a list of solutions in Sage's symbolic package.

**EXAMPLES:**

We derive the (monic) quadratic formula:

 sage: var('x,a,b')
 (x, a, b)
 sage: solve(x^2 + a*x + b == 0, x)
 [x == -1/2*a - 1/2*sqrt(a^2 - 4*b), x == -1/2*a + 1/2*sqrt(a^2 - 4*b)]

Behind the scenes when the above is evaluated the function `string_to_list_of_solutions()` is called with input the string `s` below:

 sage: s = '[x=-(sqrt(a^2-4*b)+a)/2,x=(sqrt(a^2-4*b)-a)/2]'
 sage: sage.symbolic.relation.string_to_list_of_solutions(s)
 [x == -1/2*a - 1/2*sqrt(a^2 - 4*b), x == -1/2*a + 1/2*sqrt(a^2 - 4*b)]

**sage.symbolic.relation.test_relation_maxima(relation)**

Return True if this (in)equality is definitely true. Return False if it is false or the algorithm for testing (in)equality is inconclusive.

**EXAMPLES:**

 sage: from sage.symbolic.relation import test_relation_maxima
 sage: k = var('k')
 sage: pol = 1/(k-1) - 1/k - 1/k/(k-1)
 sage: test_relation_maxima(pol == 0)
 True
 sage: f = sin(x)^2 + cos(x)^2 - 1
 sage: test_relation_maxima(f == 0)
 True
 sage: test_relation_maxima( x == x )
 True
 sage: test_relation_maxima( x != x )
 False
 sage: test_relation_maxima( x > x )
 False
 sage: test_relation_maxima( x^2 > x )

(continues on next page)
False
sage: test_relation_maxima( x + 2 > x )
True
sage: test_relation_maxima( x - 2 > x )
False

Here are some examples involving assumptions:

sage: x, y, z = var('x, y, z')
sage: assume(x>=y,y>=z,z>=x)
sage: test_relation_maxima(x==z)
True
test_relation_maxima(z<x)
False
sage: test_relation_maxima(z>y)
False
sage: test_relation_maxima(y==z)
True
sage: forget()

sage: assume(x>=1,x<=1)
sage: test_relation_maxima(x==1)
True
sage: test_relation_maxima(x>1)
False
sage: test_relation_maxima(x>=1)
True
sage: test_relation_maxima(x!=1)
False
sage: forget()

sage: assume(x>0)
sage: test_relation_maxima(x==0)
False
sage: test_relation_maxima(x>-1)
True
sage: test_relation_maxima(x!=0)
True
sage: test_relation_maxima(x!=1)
False
sage: forget()

2.5 Symbolic Computation

AUTHORS:

• Bobby Moretti and William Stein (2006-2007)
• Robert Bradshaw (2007-10): minpoly(), numerical algorithm
• Robert Bradshaw (2008-10): minpoly(), algebraic algorithm
• Golam Mortuza Hossain (2009-06-15): _limit_latex()
• Golam Mortuza Hossain (2009-06-22): _laplace_latex(), _inverse_laplace_latex()
EXAMPLES:
The basic units of the calculus package are symbolic expressions which are elements of the symbolic expression ring (SR). To create a symbolic variable object in Sage, use the `var()` function, whose argument is the text of that variable. Note that Sage is intelligent about LaTeXing variable names.

```python
sage: x1 = var('x1'); x1
x1
sage: latex(x1)
x_{1}
```

```python
sage: theta = var('theta'); theta
theta
sage: latex(theta)
\theta
```

Sage predefines `x` to be a global indeterminate. Thus the following works:

```python
sage: x^2
x^2
sage: type(x)
<class 'sage.symbolic.expression.Expression'>
```

More complicated expressions in Sage can be built up using ordinary arithmetic. The following are valid, and follow the rules of Python arithmetic: (The `=` operator represents assignment, and not equality)

```python
sage: var('x,y,z')
(x, y, z)
sage: f = x + y + z/(2*sin(y*z/55))
sage: g = f^f; g
(x + y + 1/2*z/sin(1/55*y*z))^(x + y + 1/2*z/sin(1/55*y*z))
```

Differentiation and integration are available, but behind the scenes through Maxima:

```python
sage: f = sin(x)/cos(2*y)
sage: f.derivative(y)
2*sin(x)*sin(2*y)/cos(2*y)^2
sage: g = f.integral(x); g
-cos(x)/cos(2*y)
```

Note that these methods usually require an explicit variable name. If none is given, Sage will try to find one for you.

```python
sage: f = sin(x); f.derivative()
cos(x)
```

If the expression is a callable symbolic expression (i.e., the variable order is specified), then Sage can calculate the matrix derivative (i.e., the gradient, Jacobian matrix, etc.) if no variables are specified. In the example below, we use the second derivative test to determine that there is a saddle point at (0,-1/2).

```python
sage: f(x,y)=x^2*y+y^2+y
sage: f.diff() # gradient
(2*x*y, x^2 + 2*y + 1)
sage: solve(list(f.diff()),[x,y])
[[x == -1, y == 0], [x == 1, y == 0], [x == 0, y == (-1/2)]]
```

(continues on next page)
Here we calculate the Jacobian for the polar coordinate transformation:

\[
\begin{align*}
T(r, \theta) &= (r \cos(\theta), r \sin(\theta)) \\
T &\quad \text{Jacobian matrix} \\
\begin{bmatrix}
\cos(\theta) & -r \sin(\theta) \\
\sin(\theta) & r \cos(\theta)
\end{bmatrix}
\end{align*}
\]

When the order of variables is ambiguous, Sage will raise an exception when differentiating:

\[
f = \sin(x+y); f.derivative()
\]

Traceback (most recent call last):
...
ValueError: No differentiation variable specified.

Simplifying symbolic sums is also possible, using the sum command, which also uses Maxima in the background:

\[
sage: k, m = var('k, m') \\
sage: sum(1/k^4, k, 1, oo) = \frac{1}{90} \pi^4 \\
sage: sum(binomial(m,k), k, 0, m) = 2^m
\]

Symbolic matrices can be used as well in various ways, including exponentiation:

\[
sage: M = matrix([[x,x^2],[1/x,x]]) \\
sage: M^2 \\
\begin{bmatrix}
x^2 + x & 2x^3 \\
2x^2 + x
\end{bmatrix}
\]

\[
e^M \\
\begin{bmatrix}
\frac{1}{2}e^{x\sqrt{x} + 1}e^{2\sqrt{x} - x} & \frac{1}{2}e^{x\sqrt{x} + 1}e^{2\sqrt{x} - x} \\
\frac{1}{2}e^{x\sqrt{x} + 1}e^{2\sqrt{x} - x} & \frac{1}{2}e^{x\sqrt{x} + 1}e^{2\sqrt{x} - x}
\end{bmatrix}
\]

And complex exponentiation works now:
Substitution works similarly. We can substitute with a python dict:

```
sage: f = sin(x*y - z)
sage: f({x: var('t'), y: z})
sin(t*z - z)
```

Also we can substitute with keywords:

```
sage: f = sin(x*y - z)
sage: f(x=t, y=z)
sin(t*z - z)
```

Another example:

```
sage: f = sin(2*pi*x/y)
sage: f(x=4)
sin(8*pi/y)
```

It is no longer allowed to call expressions with positional arguments:

```
sage: f = sin(x)
sage: f(y)
Traceback (most recent call last):
...
TypeError: Substitution using function-call syntax and unnamed arguments has been removed. You can use named arguments instead, like EXPR(x=..., y=...)
sage: f(x=pi)
0
```

We can also make a CallableSymbolicExpression, which is a SymbolicExpression that is a function of specified variables in a fixed order. Each SymbolicExpression has a function(...) method that is used to create a CallableSymbolicExpression, as illustrated below:

```
sage: u = log((2-x)/(y+5))
sage: f = u.function(x, y); f
(x, y) |--> log(-(-x - 2)/(y + 5))
```

There is an easier way of creating a CallableSymbolicExpression, which relies on the Sage preparser.

```
sage: f(x,y) = log(x)*cos(y); f
(x, y) |--> cos(y)*log(x)
```
Then we have fixed an order of variables and there is no ambiguity substituting or evaluating:

```
sage: f(x,y) = log((2-x)/(y+5))
sage: f(7,t)
log(-5/(t + 5))
```

Some further examples:

```
sage: f = 5*sin(x)
sage: f
5*sin(x)
sage: f(x=2)
5*sin(2)
sage: f(x=pi)
0
sage: float(f(x=pi))
0.0
```

Another example:

```
sage: f = integrate(1/sqrt(9+x^2), x); f
arcsinh(1/3*x)
sage: f(x=3)
arcsinh(1)
sage: f.derivative(x)
1/sqrt(x^2 + 9)
```

We compute the length of the parabola from 0 to 2:

```
sage: x = var('x')
sage: y = x^2
sage: dy = derivative(y,x)
sage: z = integral(sqrt(1 + dy^2), x, 0, 2)
sage: z
sqrt(17) + 1/4*arcsinh(4)
sage: n(z,200)
4.6467837624329358733826155674904591885104869874232887508703
sage: float(z)
4.646783762432936
```

We test pickling:

```
sage: x, y = var('x,y')
sage: f = -sqrt(pi)*(x^3 + sin(x/cos(y)))
sage: bool(loads(dumps(f)) == f)
True
```

Coercion examples:

We coerce various symbolic expressions into the complex numbers:

```
sage: CC(I)
1.00000000000000*I
sage: CC(2*I)
2.00000000000000*I
```

(continues on next page)
We illustrate construction of an inverse sum where each denominator has a new variable name:

\[
\text{sage: } f = \sum \frac{1}{\text{var('n%s')^i}} \text{ for } i \in \text{range(10)}
\]

\[
\text{sage: } f
\]

\[
\frac{1}{n1} + \frac{1}{n2^2} + \frac{1}{n3^3} + \frac{1}{n4^4} + \frac{1}{n5^5} + \frac{1}{n6^6} + \frac{1}{n7^7} + \frac{1}{n8^8} + \frac{1}{n9^9} + 1
\]

Note that after calling var, the variables are immediately available for use:

\[
\text{sage: } (n1 + n2)^5
\]

\[
(n1 + n2)^5
\]

We can, of course, substitute:

\[
\text{sage: } f(n9=9, n7=n6)
\]

\[
\frac{1}{n1} + \frac{1}{n2^2} + \frac{1}{n3^3} + \frac{1}{n4^4} + \frac{1}{n5^5} + \frac{1}{n6^6} + \frac{1}{n6^7} + \frac{1}{n8^8} + \frac{1}{n9^9} + 1
\]

\[
\text{sage: } \text{at} \left(\text{ex}, *\text{args}, **\text{kwds}\right)
\]

Parses at formulations from other systems, such as Maxima. Replaces evaluation ‘at’ a point with substitution method of a symbolic expression.

**EXAMPLES:**

We do not import at at the top level, but we can use it as a synonym for substitution if we import it:

\[
\text{sage: } g = x^3 - 3
\]

\[
\text{sage: from sage.calculus.calculus import at}
\]

\[
\text{sage: at(g, x=1)}
\]

\[-2\]

\[
\text{sage: g.subs(x=1)}
\]

\[-2\]

We find a formal Taylor expansion:

\[
\text{sage: } h, x = \text{var('h, x')}
\]

\[
\text{sage: } u = \text{function('u')}
\]

\[
\text{sage: } u(x + h)
\]

\[
u(h + x)
\]

\[
\text{sage: } \text{diff}(u(x+h), x)
\]

\[
D[0](u)(h + x)
\]

\[
\text{sage: } \text{taylor}(u(x+h), h, 0, 4)
\]
We compute a Laplace transform:

```
sage: var('s,t')
(s, t)
sage: f=function('f')(t)
sage: f.diff(t,2)
diff(f(t), t, t)
sage: f.diff(t,2).laplace(t,s)
s^2*laplace(f(t), t, s) - s*f(0) - D[0](f)(0)
```

We can also accept a non-keyword list of expression substitutions, like Maxima does (github issue #12796):

```
sage: from sage.calculus.calculus import at
sage: f = function('f')
sage: at(f(x), [x == 1])
f(1)
```

```
sage.calculus.calculus.dummy_diff(*args)

This function is called when `diff` appears in a Maxima string.

EXAMPLES:
```
sage: from sage.calculus.calculus import dummy_diff
sage: x,y = var('x,y')
sage: dummy_diff(sin(x*y), x, SR(2), y, SR(1))
-x*y^2*cos(x*y) - 2*y*sin(x*y)
```

Here the function is used implicitly:

```
sage: a = var('a')
sage: f = function('cr')(a)
sage: g = f.diff(a); g
diff(cr(a), a)
```

```
sage.calculus.calculus.dummy_integrate(*args)

This function is called to create formal wrappers of integrals that Maxima can’t compute:

EXAMPLES:
```
sage: from sage.calculus.calculus import dummy_integrate
sage: f = function('f')
sage: dummy_integrate(f(x), x)
integrate(f(x), x)
sage: a,b = var('a,b')
sage: dummy_integrate(f(x), x, a, b)
integrate(f(x), x, a, b)
```

```
sage.calculus.calculus.dummy_inverse_laplace(*args)

This function is called to create formal wrappers of inverse laplace transforms that Maxima can’t compute:

EXAMPLES:
```
sage: from sage.calculus.calculus import dummy_inverse_laplace
sage: s,t = var('s, t')
sage: F = function('F')
sage: dummy_inverse_laplace(F(s), s, t)
ilt(F(s), s, t)

sage.calculus.calculus.dummy_laplace(*args)
This function is called to create formal wrappers of laplace transforms that Maxima can’t compute:

EXAMPLES:

sage: from sage.calculus.calculus import dummy_laplace
sage: s,t = var('s, t')
sage: f = function('f')
sage: dummy_laplace(f(t), t, s)
laplace(f(t), t, s)

sage.calculus.calculus.dummy_pochhammer(*args)
This function is called to create formal wrappers of Pochhammer symbols

EXAMPLES:

sage: from sage.calculus.calculus import dummy_pochhammer
sage: s,t = var('s, t')
sage: dummy_pochhammer(s,t)
gamma(s + t)/gamma(s)

sage.calculus.calculus.inverse_laplace(ex, s, t, algorithm='maxima')
Return the inverse Laplace transform with respect to the variable \( t \) and transform parameter \( s \), if possible.

If this function cannot find a solution, a formal function is returned. The function that is returned may be viewed as a function of \( t \).

DEFINITION:
The inverse Laplace transform of a function \( F(s) \) is the function \( f(t) \), defined by

\[
f(t) = \frac{1}{2\pi i} \int_{\gamma-i\infty}^{\gamma+i\infty} e^{st} F(s) ds,
\]

where \( \gamma \) is chosen so that the contour path of integration is in the region of convergence of \( F(s) \).

INPUT:

- \( ex \) - a symbolic expression
- \( s \) - transform parameter
- \( t \) - independent variable
- \( algorithm \) - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'sympy' - use SymPy
  - 'giac' - use Giac

See also:

laplace()
EXAMPLES:

```
sage: var('w, m')
(w, m)
sage: f = (1/(w^2+10)).inverse_laplace(w, m); f
1/10*sqrt(10)*sin(sqrt(10)*m)
sage: laplace(f, m, w)
1/(w^2 + 10)
sage: f(t) = t*cos(t)
sage: s = var('s')
sage: L = laplace(f, t, s); L
|--> 2*s^2/(s^2 + 1)^2 - 1/(s^2 + 1)
sage: inverse_laplace(L, s, t)
|--> t*cos(t)
sage: inverse_laplace(1/(s^3+1), s, t)
|--> 1/3*(sqrt(3)*sin(1/2*sqrt(3)*(t - 1)) - cos(1/2*sqrt(3)*(t - 1)))*e^(1/2*t) + 1/3*e^(-t)
```

No explicit inverse Laplace transform, so one is returned formally a function \(\text{ilt}\):

```
sage: inverse_laplace(cos(s), s, t)
\text{ilt}(\cos(s), s, t)
```

Transform an expression involving a time-shift, via SymPy:

```
sage: inverse_laplace(1/s^2*exp(-s), s, t, algorithm='sympy')
-\log(e^{(-t)}) + 1)*heaviside(t - 1)
```

The same instance with Giac:

```
sage: inverse_laplace(1/s^2*exp(-s), s, t, algorithm='giac')
(t - 1)*heaviside(t - 1)
```

Transform a rational expression:

```
sage: inverse_laplace((2*s^2*exp(-2*s) - exp(-s))/(s^3+1), s, t, algorithm='giac')
-1/3*(sqrt(3)*e^(1/2*t) - 1/2)*heaviside(t - 1) + 2/3*(2*cos(1/2*sqrt(3)*(t - 2)))*e^(1/2*t) + e^(-t)*heaviside(t - 2)
```

The inverse Laplace transform of a constant is a delta distribution:

```
sage: inverse_laplace(1, s, t)
dirac_delta(t)
sage: inverse_laplace(1, s, t, algorithm='sympy')
dirac_delta(t)
sage: inverse_laplace(1, s, t, algorithm='giac')
dirac_delta(t)
```

sage.calculus.calculus.laplace\((ex, t, s, algorithm='maxima')\)
Return the Laplace transform with respect to the variable \(t\) and transform parameter \(s\), if possible.
If this function cannot find a solution, a formal function is returned. The function that is returned may be viewed as a function of $s$.

**DEFINITION:**

The Laplace transform of a function $f(t)$, defined for all real numbers $t \geq 0$, is the function $F(s)$ defined by

$$F(s) = \int_0^\infty e^{-st} f(t) dt.$$

**INPUT:**

- `ex` - a symbolic expression
- `t` - independent variable
- `s` - transform parameter
- `algorithm` - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'sympy' - use SymPy
  - 'giac' - use Giac

**Note:** The 'sympy' algorithm returns the tuple $(F, a, cond)$ where $F$ is the Laplace transform of $f(t)$, $Re(s) > a$ is the half-plane of convergence, and cond are auxiliary convergence conditions.

**See also:**

`inverse_laplace()`

**EXAMPLES:**

We compute a few Laplace transforms:

```sage
sage: var('x, s, z, t, t0')
(s, z, t, t0)
sage: sin(x).laplace(x, s)
1/(s^2 + 1)
sage: (z + exp(x)).laplace(x, s)
z/s + 1/(s - 1)
sage: log(t/t0).laplace(t, s)
-(Euler_gamma + log(s) + log(t0))/s
```

We do a formal calculation:

```sage
sage: f = function('f')(x)
sage: g = f.diff(x); g
diff(f(x), x)
sage: g.laplace(x, s)
s*laplace(f(x), x, s) - f(0)
```

A BATTLE BETWEEN the X-women and the Y-men (by David Joyner): Solve

$$x' = -16y, x(0) = 270, y' = -x + 1, y(0) = 90.$$  

This models a fight between two sides, the “X-women” and the “Y-men”, where the X-women have 270 initially and the Y-men have 90, but the Y-men are better at fighting, because of the higher factor of “-16” vs “-1”, and also get an occasional reinforcement, because of the “+1” term.
Symbolic Calculus, Release 10.0

```
sage: var('t')
t
sage: t = var('t')
sage: x = function('x')(t)
sage: y = function('y')(t)
sage: de1 = x.diff(t) + 16*y
sage: de2 = y.diff(t) + x - 1
sage: de1.laplace(t, s)
s*laplace(x(t), t, s) + 16*laplace(y(t), t, s) - x(0)
sage: de2.laplace(t, s)
s*laplace(y(t), t, s) - 1/s + laplace(x(t), t, s) - y(0)
```

Next we form the augmented matrix of the above system:

```
sage: A = matrix([[s, 16, 270], [1, s, 90+1/s]])
sage: E = A.echelon_form()
sage: xt = E[0,2].inverse_laplace(s,t)
sage: yt = E[1,2].inverse_laplace(s,t)
sage: xt
-91/2*e^(4*t) + 629/2*e^(-4*t) + 1
sage: yt
91/8*e^(4*t) + 629/8*e^(-4*t)
sage: p1 = plot(xt,0,1/2,rgbcolor=(1,0,0))
sage: p2 = plot(yt,0,1/2,rgbcolor=(0,1,0))
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix='.png') as f:
    (p1+p2).save(f.name)
```

Another example:

```
sage: var('a,s,t')
(a, s, t)
sage: f = exp (2*t + a) * sin(t) * t; f
t*e^(a + 2*t)*sin(t)
sage: L = laplace(f, t, s); L
2*(s - 2)*e^a/(s^2 - 4*s + 5)^2
sage: inverse_laplace(L, s, t)
t*e^(a + 2*t)*sin(t)
```

The Laplace transform of the exponential function:

```
sage: laplace(exp(x), x, s)
1/(s - 1)
```

Dirac’s delta distribution is handled (the output of SymPy is related to a choice that has to be made when defining Laplace transforms of distributions):

```
sage: laplace(dirac_delta(t), t, s)
1
sage: F, a, cond = laplace(dirac_delta(t), t, s, algorithm='sympy')
sage: a, cond  # random - sympy <1.10 gives (-oo, True)
(0, True)
sage: F      # random - sympy <1.9 includes undefined heaviside(0) in answer
```

(continues on next page)
Heaviside step function can be handled with different interfaces. Try with Maxima:

```
sage: laplace(heaviside(t-1), t, s)
e^(-s)/s
```

Try with giac:

```
sage: laplace(heaviside(t-1), t, s, algorithm='giac')
e^(-s)/s
```

Try with SymPy:

```
sage: laplace(heaviside(t-1), t, s, algorithm='sympy')
(e^(-s)/s, 0, True)
```

`sage.calculus.calculus.lim`(ex, dir=None, taylor=False, algorithm='maxima', **argv)

Return the limit as the variable \( v \) approaches \( a \) from the given direction.

```
expr.limit(x = a)
expr.limit(x = a, dir='+')
```

**INPUT:**

- **dir** - (default: None); dir may have the value ‘plus’ (or ‘+’ or ‘right’ or ‘above’) for a limit from above, ‘minus’ (or ‘-’ or ‘left’ or ‘below’) for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- **taylor** - (default: False); if True, use Taylor series, which allows more limits to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- **argv** - 1 named parameter

**Note:** The output may also use ‘und’ (undefined), ‘ind’ (indefinite but bounded), and ‘infinity’ (complex infinity).

**EXAMPLES:**

```
sage: x = var('x')
sage: f = (1 + 1/x)^x
sage: f.limit(x=oo)
e
sage: f.limit(x=5)
7776/3125
sage: f.limit(x=1.2)
2.06961575467...
```

(continues on next page)
Notice that Maxima may ask for more information:

```plaintext
sage: var('a')
a
sage: limit(x^a, x=0)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see 'assume?' for more details)
Is a positive, negative or zero?
```

With this example, Maxima is looking for a LOT of information:

```plaintext
sage: assume(a>0)
sage: limit(x^a, x=0)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see 'assume?' for more details)
Is a an integer?
```

```plaintext
sage: assume(a, 'integer')
sage: limit(x^a, x=0)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see 'assume?' for more details)
Is a an even number?
```

```plaintext
sage: assume(a, 'even')
sage: limit(x^a, x=0)
0
sage: forget()
```

More examples:

```plaintext
sage: limit(x^log(x), x=0, dir='+')
0
sage: limit((x+1)^(1/x), x=0)
e
sage: limit(e^x/x, x=oo)
+Infinity
```
\begin{verbatim}
sage: lim(e^x/x, x=-oo) 0
sage: lim(-e^x/x, x=oo)
-Infinity
sage: lim((cos(x))/(x^2), x=0)
+Infinity
sage: lim(sqrt(x^2+1) - x, x=oo)
0
sage: lim(x^2/(sec(x)-1), x=0)
2
sage: lim(cos(x)/(cos(x)-1), x=0)
-Infinity
sage: lim(x*sin(1/x), x=0)
0
sage: limit(e^(-1/x), x=0, dir='right')
0
sage: limit(e^(-1/x), x=0, dir='left')
+Infinity

sage: f = log(log(x)) / log(x)
sage: forget(); assume(x < -2); lim(f, x=0, taylor=True)
0
sage: forget()

Here ind means "indefinite but bounded":

sage: lim(sin(1/x), x = 0)
ind

We can use other packages than maxima, namely "sympy", "giac", "fricas".

With the standard package Giac:

\begin{verbatim}
sage: from sage.libs.giac.giac import libgiac # random
sage: limit(exp(-x)/(2+sin(x)).limit(x=oo, algorithm='giac')
0
sage: limit(e^(-1/x), x=0, dir='right', algorithm='giac')
0
sage: limit(e^(-1/x), x=0, dir='left', algorithm='giac')
+Infinity
sage: (x / (x+2^x+cos(x))).limit(x=-infinity, algorithm='giac')
1
\end{verbatim}

With the optional package FriCAS:

\begin{verbatim}
sage: (x / (x+2^x+cos(x))).limit(x=-infinity, algorithm='fricas') # optional - 
fricas
1
sage: limit(e^(-1/x), x=0, dir='right', algorithm='fricas') # optional - 
fricas
0
sage: limit(e^(-1/x), x=0, dir='left', algorithm='fricas') # optional -
\end{verbatim}
\end{verbatim}

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

\[ \texttt{fricas} + \infty \]

One can also call Mathematica's online interface:

\begin{Verbatim}
\texttt{sage: limit(pi+log(x)/x,x=oo, algorithm='mathematica_free') # optional - internet}
\texttt{pi}
\end{Verbatim}

\texttt{sage.calculus.calculus.limit}(ex, dir=None, taylor=False, algorithm='maxima', **argv)

Return the limit as the variable \( v \) approaches \( a \) from the given direction.

\begin{Verbatim}
expr.limit(x = a)
expr.limit(x = a, dir='+')
\end{Verbatim}

INPUT:

- \texttt{dir} - (default: None); dir may have the value 'plus' (or '+' or 'right' or 'above') for a limit from above, 'minus' (or '-' or 'left' or 'below') for a limit from below, or may be omitted (implying a two-sided limit is to be computed).
- \texttt{taylor} - (default: False); if True, use Taylor series, which allows more limits to be computed (but may also crash in some obscure cases due to bugs in Maxima).
- \texttt{**argv} - 1 named parameter

Note: The output may also use 'und' (undefined), 'ind' (indefinite but bounded), and 'infinity' (complex infinity).

    0
sage: limit(e^(-1/x), x=0, dir='left', algorithm='fricas')  
    # optional - fricas
    +Infinity

One can also call Mathematica’s online interface:

sage: limit(pi+log(x)/x,x=oo, algorithm='mathematica_free')  
    # optional - internet
    pi

sage.calculus.calculus.mapped_opts(v)

Used internally when creating a string of options to pass to Maxima.

INPUT:
• v - an object

OUTPUT: a string.

The main use of this is to turn Python bools into lower case strings.

EXAMPLES:

```python
sage: sage.calculus.calculus.mapped_opts(True) 'true'
sage: sage.calculus.calculus.mapped_opts(False) 'false'
sage: sage.calculus.calculus.mapped_opts('bar') 'bar'
```

`sage.calculus.calculus.maxima_options(**kwds)`

Used internally to create a string of options to pass to Maxima.

EXAMPLES:

```python
sage: sage.calculus.calculus.maxima_options(an_option=True, another=False, foo='bar') 'an_option=true,another=false,foo=bar'
```

`sage.calculus.calculus.minpoly(ex, var='x', algorithm=None, bits=None, degree=None, epsilon=0)`

Return the minimal polynomial of self, if possible.

INPUT:

• var - polynomial variable name (default 'x')
• algorithm - 'algebraic' or 'numerical' (default both, but with numerical first)
• bits - the number of bits to use in numerical approx
• degree - the expected algebraic degree
• epsilon - return without error as long as f(self) epsilon, in the case that the result cannot be proven.

All of the above parameters are optional, with epsilon=0, bits and degree tested up to 1000 and 24 by default respectively. The numerical algorithm will be faster if bits and/or degree are given explicitly. The algebraic algorithm ignores the last three parameters.

OUTPUT: The minimal polynomial of self. If the numerical algorithm is used then it is proved symbolically when epsilon=0 (default).

If the minimal polynomial could not be found, two distinct kinds of errors are raised. If no reasonable candidate was found with the given bit/degree parameters, a ValueError will be raised. If a reasonable candidate was found but (perhaps due to limits in the underlying symbolic package) was unable to be proved correct, a NotImplementedError will be raised.

ALGORITHM: Two distinct algorithms are used, depending on the algorithm parameter. By default, the numerical algorithm is attempted first, then the algebraic one.

Algebraic: Attempt to evaluate this expression in QQbar, using cyclotomic fields to resolve exponential and trig functions at rational multiples of pi, field extensions to handle roots and rational exponents, and computing compositums to represent the full expression as an element of a number field where the minimal polynomial can be computed exactly. The bits, degree, and epsilon parameters are ignored.

Numerical: Computes a numerical approximation of self and use PARI's pari:algdep to get a candidate minpoly f. If f(self), evaluated to a higher precision, is close enough to 0 then evaluate f(self) symbolically, attempting to prove vanishing. If this fails, and epsilon is non-zero, return f if and only if f(self) < epsilon.
Otherwise raise a `ValueError` (if no suitable candidate was found) or a `NotImplementedError` (if a likely candidate was found but could not be proved correct).

EXAMPLES: First some simple examples:

```python
sage: sqrt(2).minpoly()
x^2 - 2
sage: minpoly(2^(1/3))
x^3 - 2
sage: minpoly(sqrt(2) + sqrt(-1))
x^4 - 2*x^2 + 9
sage: minpoly(sqrt(2)-3^(1/3))
x^6 - 6*x^4 + 6*x^3 + 12*x^2 + 36*x + 1
```

Works with trig and exponential functions too.

```python
sage: sin(pi/3).minpoly()
x^2 - 3/4
sage: sin(pi/7).minpoly()
x^6 - 7/4*x^4 + 7/8*x^2 - 7/64
sage: minpoly(exp(I*pi/17))
x^16 - x^15 + x^14 - x^13 + x^12 - x^11 + x^10 - x^9 + x^8 - x^7 + x^6 - x^5 + x^4 - x^3 + x^2 - x + 1
```

Here we verify it gives the same result as the abstract number field.

```python
sage: (sqrt(2) + sqrt(3) + sqrt(6)).minpoly()
x^4 - 22*x^2 - 48*x - 23
sage: K.<a,b> = NumberField([x^2-2, x^2-3])
sage: (a+b+a*b).absolute_minpoly()
x^4 - 22*x^2 - 48*x - 23
```

The `minpoly` function is used implicitly when creating number fields:

```python
sage: x = var('x')
sage: eqn = x^3 + sqrt(2)*x + 5 == 0
sage: a = solve(eqn, x)[0].rhs(); a
-1/2*(1/18*sqrt(23)*sqrt(3) - 1/2)^(1/3)*(I*sqrt(3) + 1) - 1/6*(-I*sqrt(3) + 1)/(1/18*sqrt(23)*sqrt(3) - 1/2)^(1/3)
sage: a.minpoly()
x^3 - x + 1
```

Note that simplification may be necessary to see that the minimal polynomial is correct.
sage: f(a)
(sqrt(5) + sqrt(3) + sqrt(2))^8 - 40*(sqrt(5) + sqrt(3) + sqrt(2))^6 + 352*(sqrt(5)...
+ sqrt(3) + sqrt(2))^4 - 960*(sqrt(5) + sqrt(3) + sqrt(2))^2 + 576
sage: f(a).expand()
0

sage: a = sin(pi/7)
sage: f = a.minpoly(algorithm='numerical'); f
x^6 - 7/4*x^4 + 7/8*x^2 - 7/64
sage: f(a).horner(a).numerical_approx(100)
0.000000000000000000000000000

The degree must be high enough (default tops out at 24).

sage: a = sqrt(3) + sqrt(2)
sage: a.minpoly(algorithm='numerical', bits=100, degree=3)
Traceback (most recent call last):
...  
ValueError: Could not find minimal polynomial (100 bits, degree 3).
sage: a.minpoly(algorithm='numerical', bits=100, degree=10)
x^4 - 10*x^2 + 1

sage: cos(pi/33).minpoly(algorithm='algebraic')
x^10 + 1/2*x^9 - 5/2*x^8 - 5/4*x^7 + 17/8*x^6 + 17/16*x^5 - 43/64*x^4 - 43/128*x^3...
+ 3/64*x^2 + 3/128*x + 1/1024
sage: cos(pi/33).minpoly(algorithm='numerical')
x^10 + 1/2*x^9 - 5/2*x^8 - 5/4*x^7 + 17/8*x^6 + 17/16*x^5 - 43/64*x^4 - 43/128*x^3...
+ 3/64*x^2 + 3/128*x + 1/1024

Sometimes it fails, as it must given that some numbers aren’t algebraic:

sage: sin(1).minpoly(algorithm='numerical')
Traceback (most recent call last):
...  
ValueError: Could not find minimal polynomial (1000 bits, degree 24).

Note: Of course, failure to produce a minimal polynomial does not necessarily indicate that this number is transcendental.

sage.calculus.calculus.mma_free_limit(expression, v, a, dir=None)
Limit using Mathematica’s online interface.

INPUT:
• expression – symbolic expression
• v – variable
• a – value where the variable goes to
• dir – ‘+’, ‘-’ or None (optional, default=None)

EXAMPLES:
Another simple limit:

```
sage: mma_free_limit(e^(-x), x, a=oo) # optional - internet
0
```

`sage.calculus.calculus.nintegral` *(ex, x, a, b, desired_relative_error='1e-8', maximum_num_subintervals=200)*

Return a floating point machine precision numerical approximation to the integral of `self` from `a` to `b`, computed using floating point arithmetic via maxima.

**INPUT:**
- `x` - variable to integrate with respect to
- `a` - lower endpoint of integration
- `b` - upper endpoint of integration
- `desired_relative_error` - (default: `'1e-8`) the desired relative error
- `maximum_num_subintervals` - (default: 200) maxima number of subintervals

**OUTPUT:**
- float: approximation to the integral
- float: estimated absolute error of the approximation
- the number of integrand evaluations
- an error code:
  - 0 - no problems were encountered
  - 1 - too many subintervals were done
  - 2 - excessive roundoff error
  - 3 - extremely bad integrand behavior
  - 4 - failed to converge
  - 5 - integral is probably divergent or slowly convergent
  - 6 - the input is invalid; this includes the case of `desired_relative_error` being too small to be achieved

**ALIAS:** `nintegrate` is the same as `nintegral`

**REMARK:** There is also a function `numerical_integral` that implements numerical integration using the GSL C library. It is potentially much faster and applies to arbitrary user defined functions.

Also, there are limits to the precision to which Maxima can compute the integral due to limitations in quadpack. In the following example, remark that the last value of the returned tuple is 6, indicating that the input was invalid, in this case because of a too high desired precision.

```
sage: f = x
sage: f.nintegral(x,0,1,1e-14)
(0.0, 0.0, 0.0, 0, 6)
```
EXAMPLES:

```
sage: f(x) = exp(-sqrt(x))
sage: f.nintegral(x, 0, 1)
(0.5284822353142306, 4.163e-11, 231, 0)
```

We can also use the `numerical_integral` function, which calls the GSL C library.

```
sage: numerical_integral(f, 0, 1)
(0.528482232253147, 6.839e-07)
```

Note that in exotic cases where floating point evaluation of the expression leads to the wrong value, then the output can be completely wrong:

```
sage: f = exp(pi^sqrt(163)) - 262537412640768744
```

Despite appearance, \( f \) is really very close to 0, but one gets a nonzero value since the definition of \( \text{float}(f) \) is that it makes all constants inside the expression floats, then evaluates each function and each arithmetic operation using float arithmetic:

```
sage: float(f)
-480.0
```

Computing to higher precision we see the truth:

```
sage: f.n(200)
-7.499274028018143111206461436662234865207889513653359335718e-13
sage: f.n(300)
-7.49992740280181311120646143666266309137292462589621789352095066181709095575681963967103004e-13
```

Now numerically integrating, we see why the answer is wrong:

```
sage: f.nintegrate(x,0,1)
(-480.0000000000001, 5.32907051820075...e-12, 21, 0)
```

It is just because every floating point evaluation of return \(-480.0\) in floating point.

Important note: using PARI/GP one can compute numerical integrals to high precision:

```
sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
'2.565728500561051474934096410 E-127'  # 32-bit
'sage: old_prec = gp.set_real_precision(50)
sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
'2.565728500561051482917356396130495741774610003917 E-127'
sage: gp.set_real_precision(old_prec)
sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')
```

Note that the input function above is a string in PARI syntax.

```
sage.calculus.calculus.nintegrate(ex, x, a, b, desired_relative_error='1e-8',
maximum_num_subintervals=200)
```

Return a floating point machine precision numerical approximation to the integral of \( \text{self} \) from \( a \) to \( b \), computed using floating point arithmetic via maxima.
Symbolic Calculus, Release 10.0

INPUT:
• \( x \) - variable to integrate with respect to
• \( a \) - lower endpoint of integration
• \( b \) - upper endpoint of integration
• \texttt{desired\_relative\_error}\ - (default: ‘1e-8’) the desired relative error
• \texttt{maximum\_num\_subintervals}\ - (default: 200) maxima number of subintervals

OUTPUT:
• float: approximation to the integral
• float: estimated absolute error of the approximation
• the number of integrand evaluations
• an error code:
  – 0 - no problems were encountered
  – 1 - too many subintervals were done
  – 2 - excessive roundoff error
  – 3 - extremely bad integrand behavior
  – 4 - failed to converge
  – 5 - integral is probably divergent or slowly convergent
  – 6 - the input is invalid; this includes the case of
    \texttt{desired\_relative\_error} being too small to be achieved

ALIAS: \texttt{nintegrate} is the same as \texttt{nintegral}

REMARK: There is also a function \texttt{numerical\_integral} that implements numerical integration using the GSL C library. It is potentially much faster and applies to arbitrary user defined functions.

Also, there are limits to the precision to which Maxima can compute the integral due to limitations in quadpack. In the following example, remark that the last value of the returned tuple is 6, indicating that the input was invalid, in this case because of a too high desired precision.

\texttt{sage: f = x}
\texttt{sage: f.nintegral(x, 0, 1, 1e-14)}
\texttt{(0.0, 0.0, 0, 6)}

EXAMPLES:

\texttt{sage: f(x) = \exp(-sqrt(x))}
\texttt{sage: f.nintegral(x, 0, 1)}
\texttt{(0.528482235142306, 4.163...e-11, 231, 0)}

We can also use the \texttt{numerical\_integral} function, which calls the GSL C library.

\texttt{sage: numerical\_integral(f, 0, 1)}
\texttt{(0.528482232253147, 6.83928460...e-07)}

Note that in exotic cases where floating point evaluation of the expression leads to the wrong value, then the output can be completely wrong:
Despite appearance, \( f \) is really very close to 0, but one gets a nonzero value since the definition of \( \text{float}(f) \) is that it makes all constants inside the expression floats, then evaluates each function and each arithmetic operation using float arithmetic:

\[
\text{sage: float(f)}
\]

\[-480.0\]

Computing to higher precision we see the truth:

\[
\text{sage: f.n(200)}
\]

\[-7.499927402801814311206461436622348652078895136533593355718e-13\]

\[
\text{sage: f.n(300)}
\]

\[-7.49992740280181431120646143662663009137292462589621789352095066181709095575681963967103004e-13\]

Now numerically integrating, we see why the answer is wrong:

\[
\text{sage: f.nintegrate(x,0,1)}
\]

\[(-480.0000000000001, 5.32907051820075...e-12, 21, 0)\]

It is just because every floating point evaluation of return -480.0 in floating point.

Important note: using PARI/GP one can compute numerical integrals to high precision:

\[
\text{sage: gp.eval('intnum(x=17,42,exp(-x^2)*log(x))')}\]

\[2.5657285005610514749340996410 \times 10^{-127}\]

\[2.5657285005610514829177417746108003917 \times 10^{-127}\]

Note that the input function above is a string in PARI syntax.

\[
\text{sage: from sage.calculus.calculus import symbolic_expression_from_maxima_string as \( \text{sefms} \)}
\]

\[
\text{sefms('x^e + %e^pi + %i + sin(0)')}\]

\[x^e + e^\pi + i\]

Given a string representation of a Maxima expression, parse it and return the corresponding Sage symbolic expression.

INPUT:
- \( x \) - a string
- \( \text{equals_sub} \) - (default: False) if True, replace ‘=’ by ‘==’ in self
- \( \text{maxima} \) - (default: the calculus package’s Maxima) the Maxima interpreter to use.

EXAMPLES:
sage: f = function('f')(x)
sage: sefms('?%at(f(x),x=2)#1')
f(2) != 1
sage: a = sage.calculus.calculus.maxima("x#0"); a
x # 0
sage: a.sage()
x != 0

sage.calculus.calculus.symbolic_expression_from_string(s, syms, accept_sequence=None, parser=False)
Given a string, (attempt to) parse it and return the corresponding Sage symbolic expression. Normally used to return Maxima output to the user.

INPUT:
- s - a string
- syms - (default: {}) dictionary of strings to be regarded as symbols or functions; keys are pairs (string, number of arguments)
- accept_sequence - (default: False) controls whether to allow a (possibly nested) set of lists and tuples as input
- parser – (default: SR_parser) parser for internal use

EXAMPLES:

sage: y = var('y')
sage: sage.calculus.calculus.symbolic_expression_from_string('[sin(0)*x^2,3*spam+e^-pi]', syms={'spam':0}, accept_sequence=True)

[0, 3*y + e^-pi]

sage.calculus.calculus.symbolic_product(expression, v, a, b, algorithm='maxima', hold=False)
Return the symbolic product \( \prod_{v=a}^{b} expression \) with respect to the variable \( v \) with endpoints \( a \) and \( b \).

INPUT:
- expression - a symbolic expression
- v - a variable or variable name
- a - lower endpoint of the product
- b - upper endpoint of the product
- algorithm - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'giac' - use Giac
  - 'sympy' - use SymPy
  - 'mathematica' - (optional) use Mathematica
- hold - (default: False) if True don't evaluate

EXAMPLES:
Symbolic Calculus, Release 10.0

```
sage: i, k, n = var('i,k,n')
sage: from sage.calculus.calculus import symbolic_product
sage: symbolic_product(k, k, 1, n)
factorial(n)
sage: symbolic_product(x + i*(i+1)/2, i, 1, 4)
x^4 + 20*x^3 + 127*x^2 + 288*x + 180
sage: symbolic_product(i^2, i, 1, 7)
25401600
sage: f = function('f')
sage: symbolic_product(f(i), i, 1, n)
product(f(i), i, 1, n)
```

```
sage: f = function('f')
sage: symbolic_product(f(i), i, 1, 7)
f(7)*f(6)*f(5)*f(4)*f(3)*f(2)*f(1)
sage: symbolic_product(f(i), i, 1, n)
product(f(i), i, 1, n)
sage: assume(k>0)
sage: symbolic_product(integrate (x^k, x, 0, 1), k, 1, n)
1/factorial(n + 1)
```

```
sage: assume(k>0)
sage: symbolic_product(integrate (x^k, x, 0, 1), k, 1, n)
1/factorial(n + 1)
sage: symbolic_product(f(i), i, 1, n).log().log_expand()
sum(log(f(i)), i, 1, n)
```

**sage.calculus.calculus.symbolic_sum**(expression, v, a, b, algorithm='maxima', hold=False)

Return the symbolic sum \( \sum_{v=a}^{b} \text{expression} \) with respect to the variable \( v \) with endpoints \( a \) and \( b \).

**INPUT:**
- expression - a symbolic expression
- v - a variable or variable name
- a - lower endpoint of the sum
- b - upper endpoint of the sum
- algorithm - (default: 'maxima') one of
  - 'maxima' - use Maxima (the default)
  - 'maple' - (optional) use Maple
  - 'mathematica' - (optional) use Mathematica
  - 'giac' - (optional) use Giac
  - 'sympy' - use SymPy
- hold - (default: False) if True don't evaluate

**EXAMPLES:**

```
sage: k, n = var('k,n')
sage: from sage.calculus.calculus import symbolic_sum
sage: symbolic_sum(k, k, 1, n).factor()
1/2*(n + 1)*n
```

```
sage: symbolic_sum(1/k^4, k, 1, oo)
1/90*pi^4
```

```
sage: symbolic_sum(1/k^5, k, 1, oo)
zeta(5)
```
A well known binomial identity:

```sage
sage: symbolic_sum(binomial(n,k), k, 0, n)
2^n
```

And some truncations thereof:

```sage
sage: assume(n>1)
sage: symbolic_sum(binomial(n,k),k,1,n)
2^n - 1
sage: symbolic_sum(binomial(n,k),k,2,n)
2^n - n - 1
sage: symbolic_sum(binomial(n,k),k,0,n-1)
2^n - 1
sage: symbolic_sum(binomial(n,k),k,1,n-1)
2^n - 2
```

The binomial theorem:

```sage
sage: x, y = var('x, y')
sage: symbolic_sum(binomial(n,k) * x^k * y^(n-k), k, 0, n)
(x + y)^n
sage: symbolic_sum(k * binomial(n, k), k, 1, n)
2^(n - 1)*n
sage: symbolic_sum((-1)^k*binomial(n,k), k, 0, n)
0
sage: symbolic_sum(2^(-k)/(k*(k+1)), k, 1, oo)
-log(2) + 1
```

Summing a hypergeometric term:

```sage
sage: symbolic_sum(binomial(n, k) * factorial(k) / factorial(n+1+k), k, 0, n)
1/2*sqrt(pi)/factorial(n + 1/2)
```

We check a well known identity:

```sage
sage: bool(symbolic_sum(k^3, k, 1, n) == symbolic_sum(k, k, 1, n)^2)
True
```

A geometric sum:

```sage
sage: a, q = var('a, q')
sage: symbolic_sum(a*q^k, k, 0, n)
(a*q^(n + 1) - a)/(q - 1)
```

For the geometric series, we will have to assume the right values for the sum to converge:

```sage
sage: assume(abs(q) < 1)
sage: symbolic_sum(a*q^k, k, 0, oo)
-a/(q - 1)
```

A divergent geometric series. Don’t forget to forget your assumptions:
sage: forget()
sage: assume(q > 1)
sage: symbolic_sum(a*q^k, k, 0, oo)
Traceback (most recent call last):
  ...  
ValueError: Sum is divergent.
sage: forget()
sage: assumptions()  # check the assumptions were really forgotten
[]

A summation performed by Mathematica:

sage: symbolic_sum(1/(1+k^2), k, -oo, oo, algorithm = 'mathematica')  # optional,mathematica
pi*coth(pi)

An example of this summation with Giac:

sage: symbolic_sum(1/(1+k^2), k, -oo, oo, algorithm = 'giac')
(pi*e^(2*pi) - pi*e^(-2*pi))/(e^(2*pi) + e^(-2*pi) - 2)

The same summation is solved by SymPy:

sage: symbolic_sum(1/(1+k^2), k, -oo, oo, algorithm = 'sympy')
pi/tanh(pi)

SymPy and Maxima 5.39.0 can do the following (see github issue #22005):

sage: sum(1/((2*n+1)^2-4)^2, n, 0, Infinity, algorithm='sympy')
1/64*pi^2
sage: sum(1/((2*n+1)^2-4)^2, n, 0, Infinity)
1/64*pi^2

Use Maple as a backend for summation:

sage: symbolic_sum(binomial(n,k)*x^k, k, 0, n, algorithm = 'maple')  # optional,maple
(x + 1)^n

If you don’t want to evaluate immediately give the hold keyword:

sage: s = sum(n, n, 1, k, hold=True); s
sum(n, n, 1, k)
sage: s.unhold()
1/2*k^2 + 1/2*k
sage: s.subs(k == 10)
sum(n, n, 1, 10)
sage: s.subs(k == 10).unhold()
55
sage: s.subs(k == 10).n()
55.0000000000000

Note: Sage can currently only understand a subset of the output of Maxima, Maple and Mathematica, so even
if the chosen backend can perform the summation the result might not be convertible into a Sage expression.

### 2.6 Units of measurement

This is the units package. It contains information about many units and conversions between them.

**TUTORIAL:**

To return a unit:

```sage
sage: units.length.meter
meter
```

This unit acts exactly like a symbolic variable:

```sage
sage: s = units.length.meter
sage: s^2
meter^2
sage: s + var('x')
meter + x
```

Units have additional information in their docstring:

```sage
sage: # You would type: units.force.dyne?
sage: print(units.force.dyne.__doc__)
CGS unit for force defined to be gram*centimeter/second^2.
Equal to 10^-5 newtons.
```

You may call the convert function with units:

```sage
sage: t = units.mass.gram*units.length.centimeter/units.time.second^2
sage: t.convert(units.mass.pound*units.length.foot/units.time.hour^2)
540000000000/5760623099*(foot*pound/hour^2)
sage: t.convert(units.force.newton)
1/100000*newton
```

Calling the convert function with no target returns base SI units:

```sage
sage: t.convert()
1/100000*kilogram*meter/second^2
```

Giving improper units to convert to raises a `ValueError`:

```sage
sage: t.convert(units.charge.coulomb)
Traceback (most recent call last):
  ...
ValueError: Incompatible units
```

Converting temperatures works as well:

```sage
sage: s = 68*units.temperature.fahrenheit
sage: s.convert(units.temperature.celsius)
20*celsius
```

(continues on next page)
Trying to multiply temperatures by another unit then converting raises a ValueError:

```
sage: wrong = 50*units.temperature.celsius*units.length.foot
sage: wrong.convert()
Traceback (most recent call last):
... 
ValueError: cannot convert
```

AUTHORS:
- David Ackerman
- William Stein

class `sage.symbolic.units.UnitExpression`

Bases: `Expression`

A symbolic unit.

EXAMPLES:

```
sage: acre = units.area.acre
sage: type(acre)
<class 'sage.symbolic.units.UnitExpression'>
```

class `sage.symbolic.units.Units(data, name='')`

Bases: `ExtraTabCompletion`

A collection of units of some type.

EXAMPLES:

```
sage: units.power
Collection of units of power: cheval_vapeur horsepower watt
```

`sage.symbolic.units.base_units(unit)`

Converts unit to base SI units.

INPUT:
- `unit` – a unit

OUTPUT:
- a symbolic expression

EXAMPLES:

```
sage: sage.symbolic.units.base_units(units.length.foot)
381/1250*meter
```

If unit is already a base unit, it just returns that unit:

```
sage: sage.symbolic.units.base_units(units.length-meter)
meter
```
Derived units get broken down into their base parts:

```sage
sage: sage.symbolic.units.base_units(units.force.newton)
kilogram*meter/second^2
sage: sage.symbolic.units.base_units(units.volume.liter)
1/1000*meter^3
```

Returns variable if 'unit' is not a unit:

```sage
sage: sage.symbolic.units.base_units(var('x'))
x
```

`sage.symbolic.units.convert(expr, target)`

Converts units between `expr` and `target`. If `target` is None then converts to SI base units.

**INPUT:**
- `expr` – the symbolic expression converting from
- `target` – (default None) the symbolic expression converting to

**OUTPUT:**
- a symbolic expression

**EXAMPLES:**

```sage
sage: sage.symbolic.units.convert(units.length.foot, None)
381/1250*meter
sage: sage.symbolic.units.convert(units.mass.kilogram, units.mass.pound)
100000000/45359237*pound
```

Raises ValueError if `expr` and `target` are not convertible:

```sage
sage: sage.symbolic.units.convert(units.mass.kilogram, units.length.foot)
Traceback (most recent call last):
...
ValueError: Incompatible units
```

Recognizes derived unit relationships to base units and other derived units:

```sage
sage: sage.symbolic.units.convert(units.length.foot/units.time.second^2, units.
˓acceleration.galileo)
762/25*galileo
sage: sage.symbolic.units.convert(units.mass.kilogram*units.length.meter/units.time.
˓second^2, units.force.newton)
newton
sage: sage.symbolic.units.convert(units.length.foot^3, units.area.acre*units.length.
˓inch)
1/3630*(acre*inch)
sage: sage.symbolic.units.convert(units.charge.coulomb, units.current.ampere*units.
˓time.second)
(continues on next page)
```
Symbolic Calculus, Release 10.0

(continued from previous page)

\begin{verbatim}
\texttt{sage: sage.symbolic.units.convert(units.pressure.pascal*units.si_prefixes.kilo, \dots units.pressure.pounds_per_square_inch)}
1290320000000/8896443230521*pounds_per_square_inch
\end{verbatim}

For decimal answers multiply 1.0:

\begin{verbatim}
\texttt{sage: sage.symbolic.units.convert(units.pressure.pascal*units.si_prefixes.kilo, \dots units.pressure.pounds_per_square_inch)*1.0}
0.145037737730209*pounds_per_square_inch
\end{verbatim}

You can also convert quantities of units:

\begin{verbatim}
\texttt{sage: sage.symbolic.units.convert(cos(50)*units.angles.radian, units.angles.\dots degree)}
degree*(180*cos(50)/pi)
\texttt{sage: sage.symbolic.units.convert(cos(30)*units.angles.radian, units.angles.\dots degree).polynomial(RR)}
8.83795706233228*degree
\texttt{sage: sage.symbolic.units.convert(50*units.length.light_year / units.time.year, \dots units.length.foot / units.time.second)}
6249954068750/127*(foot/second)
\end{verbatim}

Quantities may contain variables (not for temperature conversion, though):

\begin{verbatim}
\texttt{sage: sage.symbolic.units.convert(50*x*units.area.square_meter, units.area.acre)}
acre*(1953125/158080329*x)
\end{verbatim}

\begin{verbatim}
\texttt{sage.symbolic.units.\_convert\_temperature(expr, target)}
Function for converting between temperatures.
\texttt{INPUT:}
\begin{itemize}
  \item expr – a unit of temperature
  \item target – a units of temperature
\end{itemize}
\texttt{OUTPUT:}
\begin{itemize}
  \item a symbolic expression
\end{itemize}
\texttt{EXAMPLES:}
\begin{verbatim}
\texttt{sage: t = 32*units.temperature.fahrenheit}
\texttt{sage: t.convert(units.temperature.celsius)}
0
\texttt{sage: t.convert(units.temperature.kelvin)}
273.1500000000000*kelvin
\end{verbatim}

If target is None then it defaults to kelvin:

\begin{verbatim}
\texttt{sage: t.convert()}  
273.1500000000000*kelvin
\end{verbatim}

Raises ValueError when either input is not a unit of temperature:

\begin{verbatim}
\texttt{sage.symbolic.units.\_convert\_temperature(50, units.pressure.pascal)}
ValueError
\end{verbatim}

2.6. Units of measurement

213
Symbolic Calculus, Release 10.0

```
sage: t.convert(units.length.foot)
Traceback (most recent call last):
  ... 
ValueError: cannot convert
sage: wrong = units.length.meter*units.temperature.fahrenheit
sage: wrong.convert()
Traceback (most recent call last):
  ... 
ValueError: cannot convert
```

We directly call the convert_temperature function:

```
sage: sage.symbolic.units.convert_temperature(37*units.temperature.celsius, units.temperature.fahrenheit)
493/5*fahrenheit
sage: 493/5.0
98.6
```

`sage.symbolic.units.evalunitdict()`

Replace all the string values of the unitdict variable by their evaluated forms, and builds some other tables for ease of use. This function is mainly used internally, for efficiency (and flexibility) purposes, making it easier to describe the units.

EXAMPLES:

```
sage: sage.symbolic.units.evalunitdict()
```

`sage.symbolic.units.is_unit()`

Returns a boolean when asked whether the input is in the list of units.

INPUT:

• `s` – an object

OUTPUT:

• a boolean

EXAMPLES:

```
sage: sage.symbolic.units.is_unit(1)
False
sage: sage.symbolic.units.is_unit(units.length.meter)
True
```

The square of a unit is not a unit:

```
sage: sage.symbolic.units.is_unit(units.length.meter^2)
False
```

You can also directly create units using var, though they won’t have a nice docstring describing the unit:

```
sage: sage.symbolic.units.is_unit(var('meter'))
True
```

214 Chapter 2. Internal functionality supporting calculus
sage.symbolic.units.str_to_unit(name)
Create the symbolic unit with given name. A symbolic unit is a class that derives from symbolic expression, and
has a specialized docstring.

INPUT:
• name – a string

OUTPUT:
• a UnitExpression

EXAMPLES:

```
sage: sage.symbolic.units.str_to_unit('acre')
acre
sage: type(sage.symbolic.units.str_to_unit('acre'))
<class 'sage.symbolic.units.UnitExpression'>
```

sage.symbolic.units.unit_derivations_expr(v)
Given derived units name, returns the corresponding units expression. For example, given ‘acceleration’ output
the symbolic expression length/time^2.

INPUT:
• v – a string, name of a unit type such as ‘area’, ‘volume’, etc.

OUTPUT:
• a symbolic expression

EXAMPLES:

```
sage: sage.symbolic.units.unit_derivations_expr('volume')
length^3
sage: sage.symbolic.units.unit_derivations_expr('electric_potential')
length^2*mass/(current*time^3)
```

If the unit name is unknown, a KeyError is raised:

```
sage: sage.symbolic.units.unit_derivations_expr('invalid')
Traceback (most recent call last):
  ...(KeyError: 'invalid'
```

sage.symbolic.units.unitdocs(unit)
Returns docstring for the given unit.

INPUT:
• unit – a unit

OUTPUT:
• a string

EXAMPLES:

```
sage: sage.symbolic.units.unitdocs('meter')
'SI base unit of length. Defined to be the distance light travels in vacuum in 1/
~299792458 of a second.'
```

(continues on next page)
`sage: sage.symbolic.units.unitdocs('amu')`

'Abbreviation for atomic mass unit. 
Approximately equal to 1.660538782\times10^{-27} \text{ kilograms}.'

Units not in the list `unit_docs` will raise a `ValueError`:

```
sage: sage.symbolic.units.unitdocs('earth')
Traceback (most recent call last):
...
ValueError: No documentation exists for the unit earth.
```

`sage.symbolic.units.vars_in_str(s)`

Given a string like `mass/(length*time)`, return the list `['mass', 'length', 'time']`.

**INPUT:**

- `s` – a string

**OUTPUT:**

- a list of strings (unit names)

**EXAMPLES:**

```
sage: sage.symbolic.units.vars_in_str('mass/(length*time)')
['mass', 'length', 'time']
```

## 2.7 The symbolic ring

### class `sage.symbolic.ring.NumpyToSRMorphism`

**Bases:** `Morphism`

A morphism from numpy types to the symbolic ring.

### class `sage.symbolic.ring.SymbolicRing`

**Bases:** `SymbolicRing`

Symbolic Ring, parent object for all symbolic expressions.

**I()**

The imaginary unit, viewed as an element of the symbolic ring.

**EXAMPLES:**

```
sage: SR.I()^2
-1
sage: SR.I().parent()
Symbolic Ring
```

**characteristic()**

Return the characteristic of the symbolic ring, which is 0.

**OUTPUT:**

- a Sage integer
EXAMPLES:

```
sage: c = SR.characteristic(); c
0
sage: type(c)
<class 'sage.rings.integer.Integer'>
```

**cleanup_var**(symbol)

Cleans up a variable, removing assumptions about the variable and allowing for it to be garbage collected.

**INPUT:**

- symbol – a variable or a list of variables

**is_exact**()

Return False, because there are approximate elements in the symbolic ring.

**EXAMPLES:**

```
sage: SR.is_exact()
False
```

Here is an inexact element.

```
sage: SR(1.9393)
1.93930000000000
```

**is_field**(proof=True)

Returns True, since the symbolic expression ring is (for the most part) a field.

**EXAMPLES:**

```
sage: SR.is_field()
True
```

**is_finite**()

Return False, since the Symbolic Ring is infinite.

**EXAMPLES:**

```
sage: SR.is_finite()
False
```

**pi**()

**EXAMPLES:**

```
sage: SR.pi() is pi
True
```

**subring**(*args, **kwds)

Create a subring of this symbolic ring.

**INPUT:**

Choose one of the following keywords to create a subring.

- accepting_variables (default: None) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in only these variables is created.
Symbolic Calculus, Release 10.0

- **rejecting_variables** (default: None) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in variables distinct to these variables is created.

- **no_variables** (default: False) – a boolean. If set, then a symbolic subring of constant expressions (i.e., expressions without a variable) is created.

OUTPUT:
A ring.

EXAMPLES:
Let us create a couple of symbolic variables first:

```
sage: V = var('a, b, r, s, x, y')
```

Now we create a symbolic subring only accepting expressions in the variables \(a\) and \(b\):

```
sage: A = SR.subring(accepting_variables=(a, b)); A
Symbolic Subring accepting the variables a, b
```

An element is

```
sage: A.an_element()
a
```

From our variables in \(V\) the following are valid in \(A\):

```
sage: tuple(v for v in V if v in A)
(a, b)
```

Next, we create a symbolic subring rejecting expressions with given variables:

```
sage: R = SR.subring(rejecting_variables=(r, s)); R
Symbolic Subring rejecting the variables r, s
```

An element is

```
sage: R.an_element()
some_variable
```

From our variables in \(V\) the following are valid in \(R\):

```
sage: tuple(v for v in V if v in R)
(a, b, x, y)
```

We have a third kind of subring, namely the subring of symbolic constants:

```
sage: C = SR.subring(no_variables=True); C
Symbolic Constants Subring
```

Note that this subring can be considered as a special accepting subring; one without any variables.

An element is

```
sage: C.an_element()
I*pi*e
```

None of our variables in \(V\) is valid in \(C\):
Symbolic Calculus, Release 10.0

sage: tuple(v for v in V if v in C)
()

See also:

Subrings of the Symbolic Ring

symbol(name=None, latex_name=None, domain=None)

EXAMPLES:

sage: t0 = SR.symbol("t0")
sage: t0.conjugate()
conjugate(t0)

sage: t1 = SR.symbol("t1", domain='real')
sage: t1.conjugate()
t1

sage: t0.abs()
abs(t0)

sage: t0_2 = SR.symbol("t0", domain='positive')
sage: t0_2.abs()
t0

sage: bool(t0_2 == t0)
True

sage: t0.conjugate()
t0

sage: SR.symbol() # temporary variable
symbol...

We propagate the domain to the assumptions database:

sage: n = var('n', domain='integer')
sage: solve([n^2 == 3],n)
[]

symbols
temp_var(n=None, domain=None)

Return one or multiple new unique symbolic variables as an element of the symbolic ring. Use this instead of SR.var() if there is a possibility of name clashes occurring. Call SR.cleanup_var() once the variables are no longer needed or use a with SR.temp_var() as... construct.

INPUT:

• n – (optional) positive integer; number of symbolic variables

• domain – (optional) specify the domain of the variable(s);

EXAMPLES:

Simple definition of a functional derivative:
sage: def functional_derivative(expr,f,x):
....:     with SR.temp_var() as a:
....:         return expr.subs({f(x):a}).diff(a).subs({a:f(x)})
sage: f = function('f')
sage: a = var('a')
sage: functional_derivative(f(a)^2+a,f,a)
2*f(a)

Contrast this to a similar implementation using SR.var(), which gives a wrong result in our example:

sage: def functional_derivative(expr,f,x):
....:     a = SR.var('a')
....:     return expr.subs({f(x):a}).diff(a).subs({a:f(x)})
sage: f = function('f')
sage: a = var('a')
sage: functional_derivative(f(a)^2+a,f,a)
2*f(a) + 1

var(name, latex_name=None, n=None, domain=None)

Return a symbolic variable as an element of the symbolic ring.

INPUT:

• name – string or list of strings with the name(s) of the symbolic variable(s)
• latex_name – (optional) string used when printing in latex mode, if not specified use 'name'
• n – (optional) positive integer; number of symbolic variables, indexed from 0 to n − 1
• domain – (optional) specify the domain of the variable(s); it is the complex plane by default, and possible options are (non-exhaustive list, see note below): 'real', 'complex', 'positive', 'integer' and 'noninteger'

OUTPUT:

Symbolic expression or tuple of symbolic expressions.

See also:

This function does not inject the variable(s) into the global namespace. For that purpose see var().

Note: For a comprehensive list of acceptable features type 'maxima('features')', and see also the documentation of Assumptions.

EXAMPLES:

Create a variable zz (complex by default):

sage: zz = SR.var('zz'); zz

zz

The return type is a symbolic expression:

sage: type(zz)
<class 'sage.symbolic.expression.Expression'>

We can specify the domain as well:
Symbolic Calculus, Release 10.0

```
sage: zz = SR.var('zz', domain='real')
sage: zz.is_real()
True
```

The real domain is also set with the integer domain:

```
sage: SR.var('x', domain='integer').is_real()
True
```

The name argument does not have to match the left-hand side variable:

```
sage: t = SR.var('theta2'); t
theta2
```

Automatic indexing is available as well:

```
sage: x = SR.var('x', 4)
sage: x[0], x[3]
(x0, x3)
sage: sum(x)
x0 + x1 + x2 + x3
```

```
\texttt{wild} (n=0)

Return the $n$-th wild-card for pattern matching and substitution.

\begin{itemize}
\item $n$ - a nonnegative integer
\end{itemize}

\textbf{OUTPUT:}

\begin{itemize}
\item $n$-th wildcard expression
\end{itemize}

\textbf{EXAMPLES:}

```
sage: x,y = var('x,y')
sage: w0 = SR.wild(0); w1 = SR.wild(1)
sage: pattern = \sin(x)^{w0}w1^2; pattern
$1^2*$0*sin(x)
sage: f = \arctan(\sin(x)*3*x^2); f
\arctan(3*x^2*sin(x))
sage: f.has(pattern)
True
sage: f.subs(pattern == x^2)
\arctan(x^2)
```

```
class sage.symbolic.ring.TemporaryVariables(iterable=(), /)

Bases: tuple

Instances of this class can be used with Python \texttt{with} to automatically clean up after themselves.
```

```
class sage.symbolic.ring.UnderscoreSageMorphism

Bases: Morphism

A Morphism which constructs Expressions from an arbitrary Python object by calling the \texttt{._sage_()} method on the object.

\textbf{EXAMPLES:}

```
```

2.7. The symbolic ring
symbolic.ring.is_SymbolicExpressionRing(R)

Return True if R is the symbolic expression ring.

This function is deprecated. Instead, either use R is SR (to test whether R is the unique symbolic ring SR); or isinstance with SymbolicRing (when also symbolic subrings and callable symbolic rings should be accepted).

EXAMPLES:

sage: from sage.symbolic.ring import is_SymbolicExpressionRing
sage: is_SymbolicExpressionRing(ZZ)
False
sage: is_SymbolicExpressionRing(SR)
True

symbolic.ring.isidentifier(x)

Return whether x is a valid identifier.

INPUT:

- x – a string

OUTPUT:

Boolean. Whether the string x can be used as a variable name.

This function should return False for keywords, so we can not just use the isidentifier method of strings, because, for example, it returns True for "def" and for "None".

EXAMPLES:

sage: from sage.symbolic.ring import isidentifier
sage: isidentifier('x')
True
sage: isidentifier(' x') # can't start with space
False
sage: isidentifier('ceci_n_est_pas_une_pipe')
True
sage: isidentifier('1 + x')
False
sage: isidentifier('2good')
False
sage: isidentifier('good2')
(continues on next page)
True
sage: isidentifier('lambda s:s+1')
False
sage: isidentifier('None')
False
sage: isidentifier('lambda')
False
sage: isidentifier('def')
False

sage.symbolic.ring.the_SymbolicRing()
Return the unique symbolic ring object.
(This is mainly used for unpickling.)
EXAMPLES:

sage: sage.symbolic.ring.the_SymbolicRing()
Symbolic Ring
sage: sage.symbolic.ring.the_SymbolicRing() is sage.symbolic.ring.the_SymbolicRing()
True
sage: sage.symbolic.ring.the_SymbolicRing() is SR
True

sage.symbolic.ring.var(name, **kwds)
EXAMPLES:

sage: from sage.symbolic.ring import var
sage: var("x y z")
(x, y, z)
sage: var("x,y,z")
(x, y, z)
sage: var("x , y , z")
(x, y, z)
sage: var("z")
z

2.8 Subrings of the Symbolic Ring

Subrings of the symbolic ring can be created via the subring() method of SR. This will call SymbolicSubring of this module.

The following kinds of subrings are supported:

- A symbolic subring of expressions, whose variables are contained in a given set of symbolic variables (see SymbolicSubringAcceptingVars). E.g.

  sage: SR.subring(accepting_variables=('a', 'b'))
  Symbolic Subring accepting the variables a, b

- A symbolic subring of expressions, whose variables are disjoint to a given set of symbolic variables (see SymbolicSubringRejectingVars). E.g.
```
sage: SR.subring(rejecting_variables=('r', 's'))
Symbolic Subring rejecting the variables r, s
```

- The subring of symbolic constants (see `SymbolicConstantsSubring`). E.g.
```
sage: SR.subring(no_variables=True)
Symbolic Constants Subring
```

AUTHORS:
- Daniel Krenn (2015)

### 2.8.1 Classes and Methods

**class** `sage.symbolic.subring.GenericSymbolicSubring`(*vars*)

Bases: `SymbolicRing`

An abstract base class for a symbolic subring.

INPUT:
- `vars` – a tuple of symbolic variables.

**has_valid_variable**(*variable*)

Return whether the given variable is valid in this subring.

INPUT:
- `variable` – a symbolic variable.

OUTPUT:
A boolean.

EXAMPLES:
```
sage: from sage.symbolic.subring import GenericSymbolicSubring
generic_subring = GenericSymbolicSubring(v=vars=tuple()).has_valid_variable(x)
Traceback (most recent call last):
  ... Not implemented in this abstract base class
```

**class** `sage.symbolic.subring.GenericSymbolicSubringFunctor`(*vars*)

Bases: `ConstructionFunctor`

A base class for the functors constructing symbolic subrings.

INPUT:
- `vars` – a tuple, set, or other iterable of symbolic variables.

EXAMPLES:
```
sage: from sage.symbolic.subring import SymbolicSubring
sage: SymbolicSubring(no_variables=True).construction()[0]  # indirect doctest
Subring<accepting no variable>
```

See also:
`sage.categories.pushout.ConstructionFunctor`.

224 Chapter 2. Internal functionality supporting calculus
coercion_reversed = True

merge(other)
    Merge this functor with other if possible.
    INPUT:
    • other – a functor.
    OUTPUT:
    A functor or None.
    EXAMPLES:

sage: from sage.symbolic.subring import SymbolicSubring
sage: F = SymbolicSubring(accepting_variables=('a',)).construction()[0]
sage: F.merge(F) is F
True

rank = 11

class sage.symbolic.subring.SymbolicConstantsSubring(vars)
    Bases: SymbolicSubringAcceptingVars
    The symbolic subring consisting of symbolic constants.
    has_valid_variable(variable)
        Return whether the given variable is valid in this subring.
        INPUT:
        • variable – a symbolic variable.
        OUTPUT:
        A boolean.
        EXAMPLES:

sage: from sage.symbolic.subring import SymbolicSubring
sage: S = SymbolicSubring(no_variables=True)
sage: S.has_valid_variable('a')
False
sage: S.has_valid_variable('r')
False
sage: S.has_valid_variable('x')
False

class sage.symbolic.subring.SymbolicSubringAcceptingVars(vars)
    Bases: GenericSymbolicSubring
    The symbolic subring consisting of symbolic expressions in the given variables.
    construction()
        Return the functorial construction of this symbolic subring.
        OUTPUT:
        A tuple whose first entry is a construction functor and its second is the symbolic ring.
        EXAMPLES:
Symbolic Calculus, Release 10.0

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: SymbolicSubring(accepting_variables=('a',)).construction()
(Subring<accepting a>, Symbolic Ring)
```

**has_valid_variable(variable)**
Return whether the given variable is valid in this subring.

**INPUT:**
- variable – a symbolic variable.

**OUTPUT:**
A boolean.

**EXAMPLES:**
```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: S = SymbolicSubring(accepting_variables=('a',))
sage: S.has_valid_variable('a')
True
sage: S.has_valid_variable('r')
False
sage: S.has_valid_variable('x')
False
```

**class sage.symbolic.subring.SymbolicSubringAcceptingVarsFunctor(vars)**
Bases: `GenericSymbolicSubringFunctor`

**merge(other)**
Merge this functor with other if possible.

**INPUT:**
- other – a functor.

**OUTPUT:**
A functor or None.

**EXAMPLES:**
```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: F = SymbolicSubring(accepting_variables=('a',)).construction()[0]
sage: G = SymbolicSubring(rejecting_variables=('r',)).construction()[0]
sage: F.merge(F) is F
True
sage: F.merge(G) is G
True
```

**class sage.symbolic.subring.SymbolicSubringFactory**
Bases: `UniqueFactory`

A factory creating a symbolic subring.

**INPUT:**
Specify one of the following keywords to create a subring.
Symbolic Calculus, Release 10.0

• **accepting_variables** (default: `None`) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in only these variables is created.

• **rejecting_variables** (default: `None`) – a tuple or other iterable of variables. If specified, then a symbolic subring of expressions in variables distinct to these variables is created.

• **no_variables** (default: `False`) – a boolean. If set, then a symbolic subring of constant expressions (i.e., expressions without a variable) is created.

EXAMPLES:

```python
sage: from sage.symbolic.subring import SymbolicSubring
sage: V = var('a, b, c, r, s, t, x, y, z')
sage: A = SymbolicSubring(accepting_variables=(a, b, c)); A
Symbolic Subring accepting the variables a, b, c
sage: tuple((v, v in A) for v in V)
((a, True), (b, True), (c, True),
 (r, False), (s, False), (t, False),
 (x, False), (y, False), (z, False))
```

```python
sage: R = SymbolicSubring(rejecting_variables=(r, s, t)); R
Symbolic Subring rejecting the variables r, s, t
sage: tuple((v, v in R) for v in V)
((a, True), (b, True), (c, True),
 (r, False), (s, False), (t, False),
 (x, True), (y, True), (z, True))
```

```python
sage: C = SymbolicSubring(no_variables=True); C
Symbolic Constants Subring
sage: tuple((v, v in C) for v in V)
((a, False), (b, False), (c, False),
 (r, False), (s, False), (t, False),
 (x, False), (y, False), (z, False))
```

**create_key_and_extra_args**(accepting_variables=None, rejecting_variables=None, no_variables=False, **kwds)

Given the arguments and keyword, create a key that uniquely determines this object.

See `SymbolicSubringFactory` for details.

**create_object**(version, key, **kwds)

Create an object from the given arguments.

See `SymbolicSubringFactory` for details.

**class** `sage.symbolic.subring.SymbolicSubringRejectingVars`(vars)

Bases: `GenericSymbolicSubring`

The symbolic subring consisting of symbolic expressions whose variables are none of the given variables.

**construction**

Return the functorial construction of this symbolic subring.

**OUTPUT:**

A tuple whose first entry is a construction functor and its second is the symbolic ring.

**EXAMPLES:**
sage: from sage.symbolic.subring import SymbolicSubring
sage: SymbolicSubring(rejecting_variables=('r',)).construction()
(Subring<rejecting r>, Symbolic Ring)

has_valid_variable(variable)
Return whether the given variable is valid in this subring.

INPUT:
• variable – a symbolic variable.

OUTPUT:
A boolean.

EXAMPLES:

sage: from sage.symbolic.subring import SymbolicSubring
sage: S = SymbolicSubring(rejecting_variables=('r',))
sage: S.has_valid_variable('a')
True
sage: S.has_valid_variable('r')
False
sage: S.has_valid_variable('x')
True

class sage.symbolic.subring.SymbolicSubringRejectingVarsFunctor(vars)
Bases: GenericSymbolicSubringFunctor

merge(other)
Merge this functor with other if possible.

INPUT:
• other – a functor.

OUTPUT:
A functor or None.

EXAMPLES:

sage: from sage.symbolic.subring import SymbolicSubring
sage: F = SymbolicSubring(accepting_variables=('a',)).construction()[0]
sage: G = SymbolicSubring(rejecting_variables=('r',)).construction()[0]
sage: G.merge(G) is G
True
sage: G.merge(F) is G
True
2.9 Classes for symbolic functions

To enable their usage as part of symbolic expressions, symbolic function classes are derived from one of the subclasses of Function:

- **BuiltinFunction**: the code of these functions is written in Python; many special functions are of this type
- **GinacFunction**: the code of these functions is written in C++ and part of the Pynac support library; most elementary functions are of this type
- **SymbolicFunction**: symbolic functions defined on the Sage command line are of this type

Sage uses BuiltinFunction and GinacFunction for its symbolic builtin functions. Users can define any other additional SymbolicFunction through the function() factory, see Factory for symbolic functions

Several parameters are supported by the superclass’ __init__() method. Examples follow below.

- nargs: the number of arguments
- name: the string that is printed on the CLI; the name of the member functions that are attempted for evaluation of Sage element arguments; also the name of the Pynac function that is associated with a GinacFunction
- alt_name: the second name of the member functions that are attempted for evaluation of Sage element arguments
- latex_name: what is printed when latex(f(...)) is called
- conversions: a dict containing the function’s name in other CAS
- evalf_params_first: if False, when floating-point evaluating the expression do not evaluate function arguments before calling the _evalf_() member of the function
- preserved_arg: if nonzero, the index (starting with 1) of the function argument that determines the return type. Note that, e.g., atan2() uses both arguments to determine return type, through a different mechanism

Function classes can define the following Python member functions:

- _eval_(args): the only mandatory member function, evaluating the argument and returning the result; if None is returned the expression stays unevaluated
- _eval_numpy_(args): evaluation of f(args) with arguments of numpy type
- _evalf_(args, **kwd): called when the expression is floating-point evaluated; may receive a parent keyword specifying the expected parent of the result. If not defined an attempt is made to convert the result of _eval_.
- _conjugate_(args), _real_part_(args), _imag_part_(args): return conjugate, real part, imaginary part of the expression f(args)
- _derivative_(args, index): return derivative with respect to the parameter indexed by index (starting with 0) of f(args)
- _tderivative_(): same as _derivative_() but don’t apply chain rule; only one of the two functions may be defined
- _power_(args, expo): return f(args)^expo
- _series_(args, **kwd): return the power series at at up to order with respect to var of f(args); these three values are received in kwd. If not defined the series is attempted to be computed by differentiation.
- print(args): return what should be printed on the CLI with f(args)
- print_latex(args): return what should be output with latex(f(args))
The following examples are intended for Sage developers. Users can define functions interactively through the
function() factory, see Factory for symbolic functions.

EXAMPLES:
The simplest example is a function returning nothing, it practically behaves like a symbol. Setting nargs=0 allows any
number of arguments:

```
sage: from sage.symbolic.function import BuiltinFunction
sage: class Test1(BuiltinFunction):
    ....: def __init__(self):
    ....:     BuiltinFunction.__init__(self, 'test', nargs=0)
    ....:     pass
sage: f = Test1()
sage: f()
test()
sage: f(1,2,3)*f(1,2,3)
test(1, 2, 3)^2
```

In the following the sin function of CBF(0) is called because with floating point arguments the CBF element's
my_sin() member function is attempted, and after that sin() which succeeds:

```
sage: class Test2(BuiltinFunction):
    ....: def __init__(self):
    ....:     BuiltinFunction.__init__(self, 'my_sin', alt_name='sin',
                                  latex_name=r'$\SIN$', nargs=1)
    ....:     def _eval_(self, x):
    ....:         return 5
    ....:     def _evalf_(self, x, **kwds):
    ....:         return 3.5
sage: f = Test2()
sage: f(0)
5
sage: f(0, hold=True)
my_sin(0)
sage: f(0, hold=True).n()
3.5000000000000
sage: f(CBF(0))
0
sage: latex(f(0, hold=True))
\SIN\left(0\right)
sage: f(1,2)
Traceback (most recent call last):
  ...
TypeError: Symbolic function my_sin takes exactly 1 arguments (2 given)
```

**class** sage.symbolic.function.BuiltinFunction

**Bases:** Function

This is the base class for symbolic functions defined in Sage.

If a function is provided by the Sage library, we don’t need to pickle the custom methods, since we can just
initialize the same library function again. This allows us to use Cython for custom methods.
We assume that each subclass of this class will define one symbolic function. Make sure you use subclasses and not just call the initializer of this class.

```python
class sage.symbolic.function.Function

Bases: SageObject

Base class for symbolic functions defined through Pynac in Sage.

This is an abstract base class, with generic code for the interfaces and a `__call__()` method. Subclasses should implement the `_is_registered()` and `_register_function()` methods.

This class is not intended for direct use, instead use one of the subclasses `BuiltinFunction` or `SymbolicFunction`.
```

default_variable()

Return a default variable.

```python
sage: sin.default_variable()
x
```

name()

Return the name of this function.

```python
sage: foo = function("foo", nargs=2)
sage: foo.name()
'foo'
```

number_of_arguments()

Return the number of arguments that this function takes.

```python
sage: foo = function("foo", nargs=2)
sage: foo.number_of_arguments()
2
sage: foo(x,x)
foo(x, x)
sage: foo(x)
Traceback (most recent call last):
  ...TypeError: Symbolic function foo takes exactly 2 arguments (1 given)
```

variables()

Return the variables (of which there are none) present in this function.

```python
sage: sin.variables()
()```

```python
class sage.symbolic.function.GinacFunction

Bases: BuiltinFunction
```
This class provides a wrapper around symbolic functions already defined in Pynac/GiNaC. GiNaC provides custom methods for these functions defined at the C++ level. It is still possible to define new custom functionality or override those already defined. There is also no need to register these functions.

```python
sage.symbolic.function.SymbolicFunction
```

Bases: `Function`

This is the basis for user defined symbolic functions. We try to pickle or hash the custom methods, so subclasses must be defined in Python not Cython.

```python
sage.symbolic.function.pickle_wrapper(f)
```

Return a pickled version of the function `f`.

If `f` is `None`, just return `None`.

This is a wrapper around `pickle_function()`.

**EXAMPLES:**

```python
sage: from sage.symbolic.function import pickle_wrapper
sage: def f(x):
    return x*x
sage: isinstance(pickle_wrapper(f), bytes)
True
sage: pickle_wrapper(None)
```

```python
sage.symbolic.function.unpickle_wrapper(p)
```

Return a unpickled version of the function defined by `p`.

If `p` is `None`, just return `None`.

This is a wrapper around `unpickle_function()`.

**EXAMPLES:**

```python
sage: from sage.symbolic.function import pickle_wrapper, unpickle_wrapper
sage: def f(x):
    return x*x
sage: s = pickle_wrapper(f)
sage: g = unpickle_wrapper(s)
sage: g(2)
4
sage: unpickle_wrapper(None)
```

## 2.10 Factory for symbolic functions

```python
sage.symbolic.function_factory.function(s, **kwds)
```

Create a formal symbolic function with the name `s`.

**INPUT:**

- `nargs=0` - number of arguments the function accepts, defaults to variable number of arguments, or 0
- `latex_name` - name used when printing in latex mode
• conversions - a dictionary specifying names of this function in other systems, this is used by the interfaces internally during conversion
• eval_func - method used for automatic evaluation
• evalf_func - method used for numeric evaluation
• evalf_params_first - bool to indicate if parameters should be evaluated numerically before calling the custom evalf function
• conjugate_func - method used for complex conjugation
• real_part_func - method used when taking real parts
• imag_part_func - method used when taking imaginary parts
• derivative_func - method to be used for (partial) derivation. This method should take a keyword argument deriv_param specifying the index of the argument to differentiate w.r.t
• tderivative_func - method to be used for derivatives
• power_func - method used when taking powers. This method should take a keyword argument power_param specifying the exponent
• series_func - method used for series expansion. This method should expect keyword arguments - order - order for the expansion to be computed - var - variable to expand w.r.t. - at - expand at this value
• print_func - method for custom printing
• print_latex_func - method for custom printing in latex mode

Note that custom methods must be instance methods, i.e., expect the instance of the symbolic function as the first argument.

EXAMPLES:

```python
sage: from sage.symbolic.function_factory import function
sage: var('a, b')
(a, b)
sage: cr = function('cr')
sage: f = cr(a)
sage: g = f.diff(a).integral(b); g
b*diff(cr(a), a)
sage: foo = function("foo", nargs=2)
sage: x,y,z = var("x y z")
sage: foo(x, y) + foo(y, z)^2
foo(y, z)^2 + foo(x, y)
```

You need to use substitute_function() to replace all occurrences of a function with another:

```python
sage: g.substitute_function(cr, cos)
-b*sin(a)
sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))
b*(cos(a) - sin(a))
```

Basic arithmetic with unevaluated functions is no longer supported:

```python
sage: x = var('x')
sage: f = function('f')
sage: 2*f
```

You now need to evaluate the function in order to do the arithmetic:

```
2*f(x)
```

We create a formal function of one variable, write down an expression that involves first and second derivatives, and extract off coefficients.

```
sage: \(r, \kappa = \text{var('r, kappa')}\)
sage: psi = \text{function('psi', nargs=1)}(r); psi
psi(r)
sage: g = \frac{1}{r^2} \left(2r \frac{\text{diff}(psi(r), r)}{r} + r^2 \frac{\text{diff}(psi(r), r)}{r}\right)\frac{\text{diff}(psi(r), r)}{r^2}
\frac{\text{diff}(psi(r), r)}{r} + \frac{\text{diff}(psi(r), r)}{r}
sage: g.expand()
2 \frac{\text{diff}(psi(r), r)}{r} + \frac{\text{diff}(psi(r), r)}{r}
sage: g.coefficient(psi.derivative(r, 2))
1
sage: g.coefficient(psi.derivative(r, 1))
\frac{2}{r}
```

Defining custom methods for automatic or numeric evaluation, derivation, conjugation, etc. is supported:

```
sage: \text{def \textit{ev}(self, x): return 2^*x}\n\text{foo = function('foo', nargs=1, eval_func=ev)}
foo(x)
\text{foo = function('foo', nargs=1, eval_func=\text{lambda self, x: 5})}
foo(x)
5
sage: \text{def \textit{ef}(self, x): pass}
\text{bar = function('bar', nargs=1, eval_func=ef)}
bar(x)
bar(x)
```

```
sage: \text{def \textit{evalf}_f(self, x, parent=None, algorithm=None): return 6}
\text{foo = function('foo', nargs=1, evalf_func=evalf_f)}
foo(x)
foo(x).
6
```

```
sage: foo = function('foo', nargs=1, conjugate_func=ev)
sage: foo(x).conjugate()
\text{2^*x}
```

```
sage: \text{def \textit{deriv}(self, *args, **kwds):
....: print("{} {}".format(args, kwds))
....: return args[kwds['\textit{diff}_param']]^2}
```
sage: foo = function("foo", nargs=2, derivative_func=deriv)
(x, y) {'diff_param': 1}
y^2

sage: def pow(self, x, power_param=None):
    ...:     print("{} {}".format(x, power_param))
    ...:     return x^power_param
sage: foo = function("foo", nargs=1, power_func=pow)

sage: foo(y)**(x+y)
y x + y
(x + y)^y

sage: def expand(self, *args, **kwds):
    ...:     print("{} {}".format(args, sorted(kwds.items())))
    ...:     return sum(args[0]^i for i in range(kwds['order']))

sage: foo = function("foo", nargs=1, series_func=expand)

sage: foo(y).series(y, 5)
y^4 + y^3 + y^2 + y + 1

sage: def my_print(self, *args):
    return "my args are: " + ', '.join(map(repr, args))

sage: foo = function('t', nargs=2, print_func=my_print)

my args are: x, y^z

sage: latex(foo(x,y^z))
t\left(x, y^{z}\right)

sage: foo = function('t', nargs=2, print_latex_func=my_print)

my args are: x, y^z

sage: latex(foo(x,y^z))
t(x, y^z)

sage: latex(foo(x,y^z))
my args are: x, y^z

sage: foo = function('t', nargs=2, latex_name='foo')

sage: latex(foo(x,y^z))
foo\left(x, y^{z}\right)

Chain rule:

sage: def print_args(self, *args, **kwds):
    print("args: {}".format(args));
    print("kwds: {}".format(kwds));
    return args[0]

sage: foo = function('t', nargs=2, tderivative_func=print_args)

sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {'diff_param': x}
x

sage: foo = function('t', nargs=2, derivative_func=print_args)

sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {'diff_param': 0}
args: (x, x)
kwds: {'diff_param': 1}
sage.symbolic.function_factory.function_factory(name, nargs=0, latex_name=None, conversions=None, evalf_params_first=True, eval_func=None, evalf_func=None, conjugate_func=None, real_part_func=None, imag_part_func=None, derivative_func=None, tderivative_func=None, power_func=None, series_func=None, print_func=None, print_latex_func=None)

Create a formal symbolic function. For an explanation of the arguments see the documentation for the method function().

EXAMPLES:

```python
sage: from sage.symbolic.function_factory import function_factory
sage: f = function_factory('f', 2, '\foo', {'mathematica':'Foo'})
```

```python
sage: f(2, 4)
f(2, 4)
sage: latex(f(1, 2))\foo\left(1, 2\right)
```

```python
sage: def evalf_f(self, x, parent=None, algorithm=None): return x*.5r
```

```python
sage: g = function_factory('g', 1, evalf_func=evalf_f)
```

```python
sage: g(2)
g(2)
sage: g(2).n()
1.00000000000000
```

sage.symbolic.function_factory.unpickle_function(name, nargs, latex_name, conversions, evalf_params_first, pickled_funcs)

This is returned by the __reduce__ method of symbolic functions to be called during unpickling to recreate the given function.

It calls function_factory() with the supplied arguments.

EXAMPLES:

```python
sage: from sage.symbolic.function_factory import unpickle_function
sage: nf = unpickle_function('f', 2, '\foo', {'mathematica':'Foo'}, True, [])
```

```python
sage: nf
```

```python
sage: nf(1, 2)
f(1, 2)
sage: latex(nf(x, x))\foo\left(x, x\right)
```

```python
sage: nf._mathematica_init_()
'Foo'
```

```python
sage: from sage.symbolic.function import pickle_wrapper
sage: def evalf_f(self, x, parent=None, algorithm=None): return 2r*x + 5r
```

(continues on next page)
sage: def conjugate_f(self, x): return x/2

sage: nf = unpickle_function('g', 1, None, None, True, [None, pickle_wrapper(evalf_), pickle_wrapper(conjugate_f)] + [None]*8)

sage: nf

g

sage: nf(2)
g(2)

sage: nf(2).n()
9.00000000000000

sage: nf(2).conjugate()
1

2.11 Functional notation support for common calculus methods

EXAMPLES: We illustrate each of the calculus functional functions.

sage: simplify(x - x)
0

sage: a = var('a')
sage: derivative(x^a + sin(x), x)
a*x^(a - 1) + cos(x)

sage: diff(x^a + sin(x), x)
a*x^(a - 1) + cos(x)

sage: derivative(x^a + sin(x), x)
a*x^(a - 1) + cos(x)

sage: integral(a*x*sin(x), x)
-(x*cos(x) - sin(x))*a

sage: integrate(a*x*sin(x), x)
-(x*cos(x) - sin(x))*a

sage: limit(a*sin(x)/x, x=0)
a

sage: taylor(a*sin(x)/x, x, 0, 4)
1/120*a*x^4 - 1/6*a*x^2 + a

sage: expand((x - a)^3)
-a^3 + 3*a^2*x - 3*a*x^2 + x^3

sage.calculus.functional.derivative(f, *args, **kwds)

The derivative of \( f \).

Repeated differentiation is supported by the syntax given in the examples below.

ALIAS: diff

EXAMPLES: We differentiate a callable symbolic function:

sage: f(x,y) = x*y + sin(x^2) + e^(-x)
sage: f

\((x, y) \mapsto x*y + e^(-x) + \sin(x^2)\)

sage: derivative(f, x)
\((x, y) \mapsto 2*x*cos(x^2) + y - e^(-x)\)

sage: derivative(f, y)
\((x, y) \mapsto x\)
We differentiate a polynomial:

```
sage: t = polygen(QQ, 't')
sage: f = (1-t)^5; f
-t^5 + 5*t^4 - 10*t^3 + 10*t^2 - 5*t + 1
sage: derivative(f)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t, t)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, t, 2)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, 2)
-20*t^3 + 60*t^2 - 60*t + 20
```

We differentiate a symbolic expression:

```
sage: var('a x')
(a, x)
sage: f = exp(sin(a - x^2))/x
sage: derivative(f, x)
-2*cos(-x^2 + a)*e^(sin(-x^2 + a)) - e^(sin(-x^2 + a))/x^2
sage: derivative(f, a)
cos(-x^2 + a)*e^(sin(-x^2 + a))/x
```

Syntax for repeated differentiation:

```
sage: R.<u, v> = PolynomialRing(QQ)
sage: f = u^4*v^5
sage: derivative(f, u)
4*u^3*v^5
sage: f.derivative(u)  # can always use method notation too
4*u^3*v^5
sage: derivative(f, u, u)
12*u^2*v^5
sage: derivative(f, u, u, u)
24*u*v^5
sage: derivative(f, u, 3)
24*u*v^5
sage: derivative(f, u, v)
20*u^3*v^4
sage: derivative(f, u, 2, v)
60*u^2*v^4
sage: derivative(f, u, v, 2)
80*u^3*v^3
sage: derivative(f, [u, v, v])
80*u^3*v^3
```

We differentiate a scalar field on a manifold:
sage: M = Manifold(2, 'M')
sage: X.<x,y> = M.chart()
sage: f = M.scalar_field(x^2*y, name='f')
sage: derivative(f)
1-form df on the 2-dimensional differentiable manifold M
sage: derivative(f).display()
df = 2*x*y dx + x^2 dy

We differentiate a differentiable form, getting its exterior derivative:

sage: a = M.one_form(-y, x, name='a'); a.display()
a = -y dx + x dy
sage: derivative(a)
2-form da on the 2-dimensional differentiable manifold M
sage: derivative(a).display()
da = 2 dx ∧ dy

\texttt{sage.calculus.functional.diff}(f, *\texttt{args}, **\texttt{kwds})

The derivative of $f$.

Repeated differentiation is supported by the syntax given in the examples below.

ALIAS: diff

EXAMPLES: We differentiate a callable symbolic function:

\begin{verbatim}sage: f(x,y) = x*y + \sin(x^2) + e^{-x}
sage: f(x, y) |--> x*y + e^{-x} + \sin(x^2)
sage: derivative(f, x)
(x, y) |--> 2*x*cos(x^2) + y - e^{-x}
sage: derivative(f, y)
(x, y) |--> x
\end{verbatim}

We differentiate a polynomial:

\begin{verbatim}sage: t = polygen(QQ, 't')
sage: f = (1-t)^5; f
-t^5 + 5*t^4 - 10*t^3 + 10*t^2 - 5*t + 1
sage: derivative(f)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t)
-5*t^4 + 20*t^3 - 30*t^2 + 20*t - 5
sage: derivative(f, t, t)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, t, 2)
-20*t^3 + 60*t^2 - 60*t + 20
sage: derivative(f, 2)
-20*t^3 + 60*t^2 - 60*t + 20
\end{verbatim}

We differentiate a symbolic expression:

\begin{verbatim}sage: var('a x')
(a, x)
sage: f = exp(sin(a - x^2))/x
\end{verbatim}
Symbolic Calculus, Release 10.0

\begin{verbatim}
(sage) derivative(f, x)
-2*cos(-x^2 + a)*e^(sin(-x^2 + a)) - e^(sin(-x^2 + a))/x^2
(sage) derivative(f, a)
cos(-x^2 + a)*e^(sin(-x^2 + a))/x

Syntax for repeated differentiation:

(sage) R.<u, v> = PolynomialRing(QQ)
(sage) f = u^4*v^5
(sage) derivative(f, u)
4*u^3*v^5
(sage) f.derivative(u)  # can always use method notation too
4*u^3*v^5
(sage) derivative(f, u, u)
12*u^2*v^5
(sage) derivative(f, u, u, u)
24*u*v^5
(sage) derivative(f, [u, v, v])
80*u^3*v^3

We differentiate a scalar field on a manifold:

(sage) M = Manifold(2, 'M')
(sage) X.<x,y> = M.chart()
(sage) f = M.scalar_field(x^2*y, name='f')
(sage) derivative(f)
1-form df on the 2-dimensional differentiable manifold M
(sage) derivative(f).display()
df = 2*x*y dx + x^2 dy

We differentiate a differentiable form, getting its exterior derivative:

(sage) a = M.one_form(-y, x, name='a'); a.display()
a = -y dx + x dy
(sage) derivative(a)
2-form da on the 2-dimensional differentiable manifold M
(sage) derivative(a).display()
da = 2 dx∧dy

sage.calculus.functional.expand(x, *args, **kwds)

EXAMPLES:
\end{verbatim}
```
sage: a = (x-1)*(x^2 - 1); a
(x^2 - 1)*(x - 1)
sage: expand(a)
x^3 - x^2 - x + 1
```

You can also use `expand` on polynomial, integer, and other factorizations:

```
sage: x = polygen(ZZ)
sage: F = factor(x^12 - 1); F
(x - 1) * (x + 1) * (x^2 - x + 1) * (x^2 + 1) * (x^2 + x + 1) * (x^4 - x^2 + 1)
sage: expand(F)
x^12 - 1
sage: F.expand()
x^12 - 1
sage: F = factor(2007); F
3^2 * 223
sage: expand(F)
2007
```

Note: If you want to compute the expanded form of a polynomial arithmetic operation quickly and the coefficients of the polynomial all lie in some ring, e.g., the integers, it is vastly faster to create a polynomial ring and do the arithmetic there.

```
sage: x = polygen(ZZ)  # polynomial over a given base ring.
sage: f = sum(x^n for n in range(5))
sage: f*f  # much faster, even if the degree is huge
x^8 + 2*x^7 + 3*x^6 + 4*x^5 + 5*x^4 + 4*x^3 + 3*x^2 + 2*x + 1
```

```
sage.calculus.functional.integral(f, *args, **kwds)
```

The integral of $f$.

**EXAMPLES:**

```
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x)^2, x, pi, 123*pi/2)
121/4*pi
sage: integral( sin(x), x, 0, pi)
2
```

We integrate a symbolic function:

```
sage: f(x,y,z) = x*y/z + sin(z)
sage: integral(f, z)
(x, y, z) |--> x*y*log(z) - cos(z)
```

```
sage: var('a,b')
(a, b)
sage: assume(b-a>0)
sage: integral( sin(x), x, a, b)
cos(a) - cos(b)
sage: forget()
```

2.11. Functional notation support for common calculus methods
Symbolic Calculus, Release 10.0

\[
\text{sage: integral}(x/(x^3-1), x) \\
\quad \frac{1}{3}\sqrt{3}\arctan(\frac{1}{3}\sqrt{3}(2x + 1)) - \frac{1}{6}\log(x^2 + x + 1) + \frac{1}{3}\log(x - 1)
\]

\[
\text{sage: integral}(\exp(-x^2), x) \\
\quad \frac{1}{2}\sqrt{\pi}\erf(x)
\]

We define the Gaussian, plot and integrate it numerically and symbolically:

\[
\text{sage: } f(x) = \frac{1}{\sqrt{2\pi}} e^{-x^2/2} \\
\text{sage: } P = \text{plot}(f, -4, 4, \text{hue}=0.8, \text{thickness}=2) \\
\text{sage: } P.\text{show}(\text{ymin}=0, \text{ymax}=0.4) \\
\text{sage: } \text{numerical_integral}(f, -4, 4) \\
\quad \text{# random output} \\
\quad (0.99993665751633376, 1.1101527003413533e-14) \\
\text{sage: } \text{integrate}(f, x) \\
\quad x \midarrow 1/2\erf(1/2\sqrt{2}\times x)
\]

You can have Sage calculate multiple integrals. For example, consider the function \(\exp(y^2)\) on the region between the lines \(x = y, x = 1,\) and \(y = 0.\) We find the value of the integral on this region using the command:

\[
\text{sage: area = integral(integral}(\exp(y^2), x, 0, y), y, 0, 1); \text{area} \\
\quad 1/2\times e \text{ - } 1/2 \\
\text{sage: float(area)} \\
\quad 0.859140914229522...
\]

We compute the line integral of \(\sin(x)\) along the arc of the curve \(x = y^4\) from \((1, -1)\) to \((1, 1)\):

\[
\text{sage: t = var('t')} \\
\text{sage: } (x,y) = (t^4,t) \\
\text{sage: } (dx,dy) = (\text{diff}(x,t), \text{diff}(y,t)) \\
\text{sage: } \text{integral}(\sin(x)\times dx, t, -1, 1) \\
\quad \theta \\
\text{sage: restore('x,y')} \quad \text{# restore the symbolic variables } x \text{ and } y
\]

Sage is now (github issue #27958) able to compute the following integral:

\[
\text{sage: integral}(\exp(-x^2)\times \log(x), x) \quad \text{# long time} \\
\quad 1/2\sqrt{\pi}\erf(x)\times \log(x) - x\times \text{hypergeometric}((1/2, 1/2), (3/2, 3/2), -x^2)
\]

and its value:

\[
\text{sage: integral}(\exp(-x^2)\times \ln(x), x, 0, \infty) \\
\quad -1/4\sqrt{\pi}\times (\text{euler}_\gamma + 2\times \log(2))
\]

This definite integral is easy:

\[
\text{sage: integral}(\ln(x)/x, x, 1, 2) \\
\quad 1/2\times \log(2)^2
\]

Sage cannot do this elliptic integral (yet):

\[
\text{sage: integral}(1/\sqrt{2\times t^4 - 3\times t^2 - 2}), t, 2, 3) \\
\text{integrate}(1/(\sqrt{2\times t^2 + 1}\times \sqrt{t^2 - 2})), t, 2, 3)
\]

A double integral:
Symbolic Calculus, Release 10.0

```python
sage: y = var('y')
sage: integral(integral(x*y^2, x, 0, y), y, -2, 2)
32/5
```

This illustrates using assumptions:

```python
sage: integral(abs(x), x, 0, 5)
25/2
sage: a = var("a")
sage: integral(abs(x), x, 0, a)
1/2*a*abs(a)
sage: integral(abs(x)*x, x, 0, a)
Traceback (most recent call last):
... ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation may help (example of legal syntax is 'assume(a>0)', see 'assume?' for more details)
Is a positive, negative or zero?
sage: assume(a>0)
sage: integral(abs(x)*x, x, 0, a)
1/3*a^3
sage: forget()  # forget the assumptions.
```

We integrate and differentiate a huge mess:

```python
sage: f = (x^2-1+3*(1+x^2)^(1/3))/(1+x^2)^(2/3)*x/(x^2+2)^2
sage: g = integral(f, x)
sage: h = f - diff(g, x)

sage: [float(h(x=i)) for i in range(5)] #random
[0.0, -1.1102230246251565e-16, -5.5511151231257827e-17, -5.5511151231257827e-17, -6.9388939039072284e-17]
sage: h.factor()
0
sage: bool(h == 0)
True
```

sage.calculus.functional.integrate(f, *args, **kwds)

The integral of \( f \).

EXAMPLES:

```python
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x)^2, x, pi, 123*pi/2)
121/4*pi
sage: integral( sin(x), x, 0, pi)
2
```
We integrate a symbolic function:

```sage
sage: f(x,y,z) = x*y/z + sin(z)
sage: integral(f, z)
(x, y, z) |--> x*y*log(z) - cos(z)
```

```sage
sage: var('a,b')
(a, b)
sage: assume(b-a>0)
sage: integral( sin(x), x, a, b)
cos(a) - cos(b)
sage: forget()
```

```sage
sage: integral(x/(x^3-1), x)
1/3*sqrt(3)*arctan(1/3*sqrt(3)*(2*x + 1)) - 1/6*log(x^2 + x + 1) + 1/3*log(x - 1)
```

We define the Gaussian, plot and integrate it numerically and symbolically:

```sage
sage: f(x) = 1/(sqrt(2*pi)) * e^(-x^2/2)
sage: P = plot(f, -4, 4, hue=0.8, thickness=2)
sage: P.show(ymin=0, ymax=0.4)
sage: numerical_integral(f, -4, 4)
# random output
(0.99993665751633376, 1.1101527003413533e-14)
sage: integrate(f, x)
x |--> 1/2*erf(1/2*sqrt(2)*x)
```

You can have Sage calculate multiple integrals. For example, consider the function $e^x$ on the region between the lines $x = y$, $x = 1$, and $y = 0$. We find the value of the integral on this region using the command:

```sage
sage: area = integral(integral(exp(y^2),x,0,y),y,0,1); area
1/2*e - 1/2
sage: float(area)
0.859140914229522...
```

We compute the line integral of $\sin(x)$ along the arc of the curve $x = y^4$ from $(1, -1)$ to $(1, 1)$:

```sage
sage: t = var('t')
sage: (x,y) = (t^4,t)
sage: (dx,dy) = (diff(x,t), diff(y,t))
sage: integral(sin(x)*dx, t,-1, 1)
0
sage: restore('x,y')  # restore the symbolic variables x and y
```

Sage is now (github issue #27958) able to compute the following integral:

```sage
sage: integral(exp(-x^2)*log(x), x)  # long time
1/2*sqrt(pi)*erf(x)*log(x) - x*hypergeometric((1/2, 1/2), (3/2, 3/2), -x^2)
```

and its value:
This definite integral is easy:

\[
\text{sage: } \int \frac{\ln(x)}{x} \, dx, \quad 1 \leq x \leq 2
\]
\[
\frac{1}{2} \log(2)^2
\]

Sage cannot do this elliptic integral (yet):

\[
\text{sage: } \int \frac{1}{\sqrt{2t^4 - 3t^2 - 2}}, \quad t, \quad 2 \leq t \leq 3
\]
\[
\frac{1}{\sqrt{2t^2 + 1}} \sqrt{t^2 - 2}, \quad t, \quad 2 \leq t \leq 3
\]

A double integral:

\[
\text{sage: } y = \text{var}(y)
\]
\[
\text{sage: } \int \int x y^2, \quad 0 \leq x \leq y, \quad y, \quad -2 \leq y \leq 2
\]
\[
\frac{32}{5}
\]

This illustrates using assumptions:

\[
\text{sage: } \int \frac{\ln(x)}{x} \, dx, \quad 0 \leq x \leq 5
\]
\[
\frac{25}{2}
\]

\[
\text{sage: } a = \text{var}(a)
\]
\[
\text{sage: } \int \frac{\ln(x)}{x} \, dx, \quad 0 \leq x \leq a
\]
\[
\frac{1}{2} a \frac{1}{2} a 
\]

```
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a positive, negative or zero?
\text{sage: } \text{assume}(a>0)
\text{sage: } \int \frac{\ln(x)}{x} \, dx, \quad 0 \leq x \leq a
\]
\[
\frac{1}{3} a^3
\]
```

We integrate and differentiate a huge mess:

\[
\text{sage: } f = \frac{x^2-1+3(1+x^2)^{(1/3)}}{(1+x^2)^{(2/3)}x/(x^2+2)^2}
\]
\[
\text{sage: } g = \int f, \quad x
\]
\[
\text{sage: } h = f - \frac{\text{diff}(g, x)}
\]

```
\[
\text{sage: } \left[ \begin{array}{l}
\text{float}(h(x=i)) \text{ for } i \text{ in range(5)} \right] \text{ #random}
\]
\[
[0.0, -1.1102230246251565e-16, -5.5511151231257827e-17, -5.5511151231257827e-17, -6.9388939039072284e-17]
\]
```

(continues on next page)
\[ \theta \]
\[
\text{sage: } \text{bool}(h == \theta)
\]
True

```
sage.calculus.functional.lim(f, dir=None, taylor=False, **argv)
```

Return the limit as the variable \( v \) approaches \( a \) from the given direction.

```
limit(expr, x = a)
limit(expr, x = a, dir='above')
```

**INPUT:**

- **dir** - (default: None); dir may have the value
  'plus' (or 'above') for a limit from above, 'minus' (or 'below') for a limit from below, or may be omitted
  (implying a two-sided limit is to be computed).

- **taylor** - (default: False); if True, use Taylor series, which allows more limits to be computed
  (but may also crash in some obscure cases due to bugs in Maxima).

- **\*\*argv** - 1 named parameter

**ALIAS:** You can also use \text{lim} instead of \text{limit}.

**EXAMPLES:**

```
sage: limit(sin(x)/x, x=0)
1
sage: limit(exp(x), x=oo)
+\infty
sage: limit(exp(x), x=-oo)
0
sage: limit(1/x, x=0)
\infty
sage: limit(sqrt(x^2+x+1)+x, taylor=True, x=-oo)
-\frac{1}{2}
sage: limit((tan(sin(x)) - sin(tan(x)))/x^7, taylor=True, x=0)
\frac{1}{30}
```

Sage does not know how to do this limit (which is 0), so it returns it unevaluated:

```
sage: limit(exp(x^2)*(1-erf(x)), x=infinity)
-\text{limit(}(\text{erf}(x) - 1)\text{e}^{x^2}, x, +\infty)
```

```
sage.calculus.functional.limit(f, dir=None, taylor=False, **argv)
```

Return the limit as the variable \( v \) approaches \( a \) from the given direction.

```
limit(expr, x = a)
limit(expr, x = a, dir='above')
```

**INPUT:**

- **dir** - (default: None); dir may have the value
  'plus' (or 'above') for a limit from above, 'minus' (or 'below') for a limit from below, or may be omitted
  (implying a two-sided limit is to be computed).
• **taylor** - (default: False); if True, use Taylor
  series, which allows more limits to be computed (but may also crash in some obscure cases due to bugs
  in Maxima).

• \\*argv - 1 named parameter

ALIAS: You can also use lim instead of limit.

EXAMPLES:

```python
sage: limit(sin(x)/x, x=0)
1
sage: limit(exp(x), x=oo)
+Infinity
sage: lim(exp(x), x=-oo)
0
sage: lim(1/x, x=0)
Infinity
sage: limit(sqrt(x^2+x+1)+x, taylor=True, x=-oo)
-1/2
sage: limit((tan(sin(x)) - sin(tan(x)))/x^7, taylor=True, x=0)
1/30
```

Sage does not know how to do this limit (which is 0), so it returns it unevaluated:

```python
sage: lim(exp(x^2)*(1-erf(x)), x=+Infinity)
-limit((erf(x) - 1)*e^(x^2), x, +Infinity)
```

---

**sage.calculus.functional.simplify(f)**

Simplify the expression $f$.

EXAMPLES: We simplify the expression $i + x - x$.

```python
sage: f = I + x - x; simplify(f)
I
```

In fact, printing $f$ yields the same thing - i.e., the simplified form.

**sage.calculus.functional.taylor(f, *args)**

Expands self in a truncated Taylor or Laurent series in the variable $v$ around the point $a$, containing terms through $(x-a)^n$. Functions in more variables are also supported.

INPUT:

• *args - the following notation is supported
• $x, a, n$ - variable, point, degree
• $(x, a), (y, b), ..., n$ - variables with points, degree of polynomial

EXAMPLES:

```python
sage: var('x,k,n')
(x, k, n)
sage: taylor (sqrt (1 - k^2*sin(x)^2), x, 0, 6)
-1/720*(45*k^6 - 60*k^4 + 16*k^2)*x^6 - 1/24*(3*k^4 - 4*k^2)*x^4 - 1/2*k^2*x^2 + 1
```
2.12 Symbolic Integration

class sage.symbolic.integration.integral.DefiniteIntegral
Bases: BuiltinFunction

The symbolic function representing a definite integral.

EXAMPLES:

```
sage: from sage.symbolic.integration.integral import definite_integral
sage: definite_integral(sin(x), x, 0, pi)
2
```

class sage.symbolic.integration.integral.IndefiniteIntegral
Bases: BuiltinFunction

Class to represent an indefinite integral.

EXAMPLES:

```
sage: from sage.symbolic.integration.integral import indefinite_integral
sage: indefinite_integral(log(x), x)  # indirect doctest
x*log(x) - x
sage: indefinite_integral(x^2, x)
1/3*x^3
sage: indefinite_integral(4*x^2*log(x), x)
2*x^2*log(x) - x^2
sage: indefinite_integral(exp(x), 2^x)
2^x*e^x
```

sage.symbolic.integration.integral.integral(expression, v=None, a=None, b=None, algorithm=None, hold=False)

Return the indefinite integral with respect to the variable \( v \), ignoring the constant of integration. Or, if endpoints \( a \) and \( b \) are specified, returns the definite integral over the interval \([a, b]\).

If self has only one variable, then it returns the integral with respect to that variable.

If definite integration fails, it could be still possible to evaluate the definite integral using indefinite integration with the Newton - Leibniz theorem (however, the user has to ensure that the indefinite integral is continuous on the compact interval \([a, b]\) and this theorem can be applied).
INPUT:

• v - a variable or variable name. This can also be a tuple of the variable (optional) and endpoints (i.e., (x,0,1) or (0,1)).
• a - (optional) lower endpoint of definite integral
• b - (optional) upper endpoint of definite integral
• algorithm - (default: 'maxima', 'libgiac' and 'sympy') one of
  – ‘maxima’ - use maxima
  – ‘sympy’ - use sympy (also in Sage)
  – ‘mathematica_free’ - use http://integrals.wolfram.com/
  – ‘fricas’ - use FriCAS (the optional fricas spkg has to be installed)
  – ‘giac’ - use Giac
  – ‘libgiac’ - use libgiac

To prevent automatic evaluation use the hold argument.

See also:

To integrate a polynomial over a polytope, use the optional latte_int package sage.geometry.polyhedron. base.Polyhedron_base.integrate().

EXAMPLES:

```
sage: x = var('x')
sage: h = sin(x)/(cos(x))^2
sage: h.integral(x)
1/cos(x)
sage: f = x^2/(x+1)^3
sage: f.integral(x)
1/2*(4*x + 3)/(x^2 + 2*x + 1) + log(x + 1)
sage: f = x*cos(x^2)
sage: f.integral(x, 0, sqrt(pi))
0
sage: f.integral(x, a=-pi, b=pi)
0
sage: f(x) = sin(x)
sage: f.integral(x, 0, pi/2)
1
```

The variable is required, but the endpoints are optional:

```
sage: y = var('y')
sage: integral(sin(x), x)  
-cos(x)
sage: integral(sin(x), y)  
y*sin(x)
sage: integral(sin(x), x, pi, 2*pi)
-2
```

(continues on next page)
Using the \texttt{hold} parameter it is possible to prevent automatic evaluation, which can then be evaluated via \texttt{simplify()}: 

\begin{verbatim}
sage: integral(x^2, x, 0, 3)
9
sage: a = integral(x^2, x, 0, 3, hold=True) ; a
integrate(x^2, x, 0, 3)
sage: a.simplify()
9
\end{verbatim}

Constraints are sometimes needed: 

\begin{verbatim}
sage: var('x, n')
(x, n)
sage: integral(x^n,x)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(n>0)', see 'assume?' for more details)
Is n equal to -1?
sage: assume(n > 0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
\end{verbatim}

Usually the constraints are of sign, but others are possible: 

\begin{verbatim}
sage: assume(n=-1)
sage: integral(x^n,x)
log(x)
\end{verbatim}

Note that an exception is raised when a definite integral is divergent: 

\begin{verbatim}
sage: forget() # always remember to forget assumptions you no longer need
sage: integrate(1/x^3,(x,0,1))
Traceback (most recent call last):
...
ValueError: Integral is divergent.
sage: integrate(1/x^3,x,-1,3)
Traceback (most recent call last):
...
ValueError: Integral is divergent.
\end{verbatim}

But Sage can calculate the convergent improper integral of this function: 

\begin{verbatim}
\end{verbatim}
Symbolic Calculus, Release 10.0

```
sage: integrate(1/x^3,x,1,infinity)
1/2
```

The examples in the Maxima documentation:

```
sage: var('x, y, z, b')
(x, y, z, b)
sage: integral(sin(x)^3, x)
1/3*cos(x)^3 - cos(x)
sage: integral(x/sqrt(b^2-x^2), b)
x*log(2*b + 2*sqrt(b^2 - x^2))
sage: integral(x/sqrt(b^2-x^2), x)
-sqrt(b^2 - x^2)
sage: integral(cos(x)^2 * exp(x), x, 0, pi)
3/5*e^pi - 3/5
sage: integral(x^2 * exp(-x^2), x, -oo, oo)
1/2*sqrt(pi)
```

We integrate the same function in both Mathematica and Sage (via Maxima):

```
sage: _. = var('x, y, z')
sage: f = sin(x^2) + y^z
sage: g = mathematica(f)  # optional - mathematica
sage: print(g)  # optional - mathematica
z 2
y + Sin[x ]
sage: print(g.Integrate(x))  # optional - mathematica
z Pi 2
x y + Sqrt[--] FresnelS[Sqrt[--] x]
2 Pi
sage: print(f.integrate(x))  # optional - mathematica
x*y^z + 1/16*sqrt(pi)*((I + 1)*sqrt(2)*erf((1/2*I + 1/2)*sqrt(2)*x) + (I -
-1)*sqrt(2)*erf((1/2*I - 1/2)*sqrt(2)*x) - (1 - I)*sqrt(2)*erf(sqrt(-I)*x) + (I +
-1)*sqrt(2)*erf((-1)^(1/4)*x))
```

Alternatively, just use algorithm=’mathematica_free’ to integrate via Mathematica over the internet (does NOT require a Mathematica license!):

```
sage: _. = var('x, y, z')  # optional - internet
sage: f = sin(x^2) + y^z  # optional - internet
sage: f.integrate(x, algorithm="mathematica_free")  # optional - internet
x^2*y^z + sqrt(1/2)*sqrt(pi)*fresnel_sin(sqrt(2)*x/sqrt(pi))
```

We can also use Sympy:

```
sage: integrate(x*sin(log(x)), x)
-1/5*x^2*(cos(log(x)) - 2*sin(log(x)))
sage: integrate(x*sin(log(x)), x, algorithm='sympy')
-1/5*x^2*cos(log(x)) + 2/5*x^2*sin(log(x))
sage: _. = var('y, z')
sage: (x*y - z).integrate(y)
-y*z + x*y/log(x)
sage: (x*y - z).integrate(y, algorithm="sympy")
-y*z + cases(((log(x) != 0, x*y/log(x)), (1, y)))
```

2.12. Symbolic Integration 251
We integrate the above function in Maple now:

\[
\text{sage: } g = \text{maple}(f); g.\text{sort()} \quad \# \text{optional - maple}
\]
\[
y^z+\sin(x^2)
\]
\[
\text{sage: } g.\text{integrate(x).sort()} \quad \# \text{optional - maple}
\]
\[
x^y^z+1/2*2^(1/2)*\pi^(1/2)*\text{FresnelS}(2^(1/2)/\pi^(1/2)*x)
\]

We next integrate a function with no closed form integral. Notice that the answer comes back as an expression that contains an integral itself.

\[
\text{sage: } A = \text{integral}(1/ ((x-4) * (x^4+x+1)), x); A
\]
\[
\text{integrate}(1/((x^4 + x + 1)^a(x - 4)), x)
\]

Sometimes, in this situation, using the algorithm “maxima” gives instead a partially integrated answer:

\[
\text{sage: } \text{integral}(1/(x**7-1),x,\text{algorithm='maxima'})
\]
\[
-1/7*\text{integrate}(x^5 + 2*x^4 + 3*x^3 + 4*x^2 + 5*x + 6)/(x^6 + x^5 + x^4 + x^3 + x^2 \rightarrow + x + 1), x) + 1/7*\log(x - 1)
\]

We now show that floats are not converted to rationals automatically since we by default have keepfloat: true in maxima.

\[
\text{sage: } \text{integral}(e^{(-x^2)},(x, 0, 0.1))
\]
\[
0.05623145800914245*\sqrt{\pi}
\]

An example of an integral that fricas can integrate:

\[
\text{sage: } f(x) = \frac{\sqrt{x+\sqrt{1+x^2}}}{x}
\]
\[
\text{sage: } \text{integrate}(f(x), x, \text{algorithm="fricas"}) \quad \# \text{optional - fricas}
\]
\[
2*\sqrt{x + \sqrt{x^2 + 1}} - 2*\arctan(\sqrt{x + \sqrt{x^2 + 1}}) + 1/8*\log(\sqrt{x + \sqrt{x^2 + 1}} - 1)
\]

where the default integrator obtains another answer:

\[
\text{sage: } \text{integrate}(f(x), x) \quad \# \text{long time}
\]
\[
1/8*\sqrt{x}*\text{gamma}(1/4)*\text{gamma}(-1/4)*2^*\text{hypergeometric}((-1/4, -1/4, 1/4), (1/2, 3/4), -1/x^2)/(\pi^*\text{gamma}(3/4))
\]

The following definite integral is not found by maxima:

\[
\text{sage: } f(x) = \frac{(x^4 - 3*x^2 + 6)}{(x^6 - 5*x^4 + 5*x^2 + 4)}
\]
\[
\text{sage: } \text{integrate}(f(x), x, 1, 2, \text{algorithm='maxima'})
\]
\[
\text{integrate}((x^4 - 3*x^2 + 6)/(x^6 - 5*x^4 + 5*x^2 + 4), x, 1, 2)
\]

but is nevertheless computed:

\[
\text{sage: } \text{integrate}(f(x), x, 1, 2)
\]
\[
-1/2^*\pi + \arctan(8) + \arctan(5) + \arctan(2) + \arctan(1/2)
\]

Both fricas and sympy give the correct result:

\[
\text{sage: } \text{integrate}(f(x), x, 1, 2, \text{algorithm="fricas"}) \quad \# \text{optional - fricas}
\]
\[
-1/2^*\pi + \arctan(8) + \arctan(5) + \arctan(2) + \arctan(1/2)
\]
\[
\text{sage: } \text{integrate}(f(x), x, 1, 2, \text{algorithm="sympy"})
\]
\[
-1/2^*\pi + \arctan(8) + \arctan(5) + \arctan(2) + \arctan(1/2)
\]
Using Giac to integrate the absolute value of a trigonometric expression:

```sage
sage: integrate(abs(cos(x)), x, 0, 2*pi, algorithm='giac')
4
sage: result = integrate(abs(cos(x)), x, 0, 2*pi)
...
sage: result
4
```

ALIASES: integral() and integrate() are the same.

EXAMPLES:

Here is an example where we have to use assume:

```sage
sage: a,b = var('a,b')
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
Traceback (most recent call last):
...
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation may help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a positive or negative?
```

So we just assume that \( a > 0 \) and the integral works:

```sage
sage: assume(a>0)
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
2/9*b^2/((b*x + a)^2*a^2 - 2*(b*x + a)*a^3 + a^4)
```

Return the indefinite integral with respect to the variable \( v \), ignoring the constant of integration. Or, if endpoints \( a \) and \( b \) are specified, returns the definite integral over the interval \([a, b]\).

If \( self \) has only one variable, then it returns the integral with respect to that variable.

If definite integration fails, it could be still possible to evaluate the definite integral using indefinite integration with the Newton-Leibniz theorem (however, the user has to ensure that the indefinite integral is continuous on the compact interval \([a, b]\) and this theorem can be applied).

INPUT:

- \( v \) - a variable or variable name. This can also be a tuple of the variable (optional) and endpoints (i.e., (\( x, 0, 1 \)) or (\( 0, 1 \))
- \( a \) - (optional) lower endpoint of definite integral
- \( b \) - (optional) upper endpoint of definite integral
- \( algorithm \) - (default: ‘maxima’, ‘libgiac’ and ‘sympy’) one of
  - ‘maxima’ - use maxima
  - ‘sympy’ - use sympy (also in Sage)
Symbolic Calculus, Release 10.0

- ‘mathematica_free’ - use http://integrals.wolfram.com/
- ‘fricas’ - use FriCAS (the optional fricas spkg has to be installed)
- ‘giac’ - use Giac
- ‘libgiac’ - use libgiac

To prevent automatic evaluation use the hold argument.

See also:

To integrate a polynomial over a polytope, use the optional latte_int package sage.geometry.polyhedron.base.Polyhedron_base.integrate().

EXAMPLES:

```
sage: x = var('x')
sage: h = sin(x)/(cos(x))^2
sage: h.integral(x)
1/cos(x)
```

```
sage: f = x^2/(x+1)^3
sage: f.integral(x)
1/2*(4*x + 3)/(x^2 + 2*x + 1) + log(x + 1)
```

```
sage: f = x*cos(x^2)
sage: f.integral(x, 0, sqrt(pi))
0
```

```
sage: f(x) = sin(x)
sage: f.integral(x, 0, pi/2)
1
```

The variable is required, but the endpoints are optional:

```
sage: y = var('y')
sage: integral(sin(x), x)
-cos(x)
sage: integral(sin(x), y)
y*sin(x)
sage: integral(sin(x), x, pi, 2*pi)
-2
```

```
sage: integral(sin(x), y, pi, 2*pi)
pi*sin(x)
sage: integral(sin(x), (x, pi, 2*pi))
-2
```

Using the hold parameter it is possible to prevent automatic evaluation, which can then be evaluated via simplify():

```
```python
sage: integral(x^2, x, 0, 3)
9
sage: a = integral(x^2, x, 0, 3, hold=True) ; a
integrate(x^2, x, 0, 3)
sage: a.simplify()
9
```

Constraints are sometimes needed:

```python
sage: var('x, n')
(x, n)
sage: integral(x^n,x)
Traceback (most recent call last):
  ... ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation may help (example of legal syntax is 'assume(n>0)', see `assume?' for more details)
Is n equal to -1?
sage: assume(n > 0)
sage: integral(x^n,x)
x^(n + 1)/(n + 1)
sage: forget()
```

Usually the constraints are of sign, but others are possible:

```python
sage: assume(n=-1)
sage: integral(x^n,x)
log(x)
```

Note that an exception is raised when a definite integral is divergent:

```python
sage: forget() # always remember to forget assumptions you no longer need
sage: integrate(1/x^3,(x,0,1))
Traceback (most recent call last):
  ... ValueError: Integral is divergent.
sage: integrate(1/x^3,x,-1,3)
Traceback (most recent call last):
  ... ValueError: Integral is divergent.
```

But Sage can calculate the convergent improper integral of this function:

```python
sage: integrate(1/x^3,x,1,infinity)
1/2
```

The examples in the Maxima documentation:

```python
sage: var('x, y, z, b')
(x, y, z, b)
sage: integral(sin(x)^3, x)
1/3*cos(x)^3 - cos(x)
sage: integral(x/sqrt(b^2-x^2), b)
```

(continues on next page)
\[ x \log(2b + 2\sqrt{b^2 - x^2}) \]
\(\text{sage: } \int \frac{x}{\sqrt{b^2 - x^2}} \, dx \) 
\(-\sqrt{b^2 - x^2} \)
\(\text{sage: } \int \cos(x)^2 \cdot \exp(x) \, dx \) 
\[ 3/5e^{\pi} - 3/5 \]
\(\text{sage: } \int x^2 \cdot \exp(-x^2) \, dx \) 
\[ 1/2\sqrt{\pi} \]

We integrate the same function in both Mathematica and Sage (via Maxima):

\(\text{sage: } \_ = \text{var}(\text{'}x, y, z\text{'}) \)
\(\text{sage: } f = \sin(x^2) + y^z \)
\(\text{sage: } g = \text{mathematica}(f) \)  
\[ y^z + \sin(x^2) \]  
\(\text{sage: } g.\text{Integrate}(x) \)  
\[ x y^z + \frac{1}{2}2^{1/2}\pi^{1/2}\text{fresnel}\_\text{s}(2^{1/2}/\pi^{1/2}x) \]

Alternatively, just use algorithm='mathematica_free' to integrate via Mathematica over the internet (does NOT require a Mathematica license!):

\(\text{sage: } \_ = \text{var}(\text{'}x, y, z\text{'}) \)  
\(\text{sage: } f = \sin(x^2) + y^z \)  
\(\text{sage: } f.\text{integrate}(x, \text{algorithm}='\text{mathematica\_free}') \)
\[ x y^z + \sqrt{1/2}\sqrt{\pi}\text{fresnel}\_\text{s}(2^{1/2}/\pi^{1/2}x) \]

We can also use Sympy:

\(\text{sage: } \int x \sin(\log(x)) \, dx \)  
\[ -1/5x^2\cos(\log(x)) - 2\sin(\log(x)) \]
\(\text{sage: } \int (x^y - z) \, dy \)  
\[ -y^z + x^y/\log(x) \]

We integrate the above function in Maple now:

\(\text{sage: } g = \text{maple}(f); g.\text{sort()} \)  
\[ y^z+\sin(x^2) \]
\(\text{sage: } g.\text{integrate}(x).\text{sort()} \)
\[ x y^z+1/2^2(1/2)^{\text{Pi}}(1/2)^{\text{Pi}}\text{fresnel}S(2^2(1/2)/\text{Pi}(1/2)x) \]

We next integrate a function with no closed form integral. Notice that the answer comes back as an expression that contains an integral itself.
Sometimes, in this situation, using the algorithm “maxima” gives instead a partially integrated answer:

\[
\begin{align*}
sage: & \quad \text{integral(1/((x^4 + x + 1)*(x - 4)), x)} \\
& \quad \integrate(1/((x^4 + x + 1)*(x - 4)), x)
\end{align*}
\]

We now show that floats are not converted to rationals automatically since we by default have keepfloat: true in maxima.

\[
\begin{align*}
sage: & \quad \text{integral(e^(-x^2),(x, 0, 0.1))} \\
& \quad 0.05623145800914245*sqrt(pi)
\end{align*}
\]

An example of an integral that fricas can integrate:

\[
\begin{align*}
sage: & \quad f(x) = sqrt(x+sqrt(1+x^2))/x \\
sage: & \quad \integrate(f(x), x, algorithm="fricas") \\
& \quad 2*sqrt(x + sqrt(x^2 + 1)) - 2*arctan(sqrt(x + sqrt(x^2 + 1))) - log(sqrt(x + sqrt(x^2 + 1)) - 1) + log(sqrt(x + sqrt(x^2 + 1)) + 1)
\end{align*}
\]

where the default integrator obtains another answer:

\[
\begin{align*}
sage: & \quad \text{integral(f(x), x, 1, 2, algorithm='maxima')} \\
& \quad \integrate((x^4 - 3*x^2 + 6)/(x^6 - 5*x^4 + 5*x^2 + 4), x, 1, 2)
\end{align*}
\]

but is nevertheless computed:

\[
\begin{align*}
sage: & \quad \text{integral(f(x), x, 1, 2)} \\
& \quad -1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
\end{align*}
\]

Both fricas and sympy give the correct result:

\[
\begin{align*}
sage: & \quad \text{integrate(f(x), x, 1, 2, algorithm='fricas')} \\
& \quad -1/2*pi + arctan(8) + arctan(5) + arctan(2) + arctan(1/2)
\end{align*}
\]

Using Giac to integrate the absolute value of a trigonometric expression:

\[
\begin{align*}
sage: & \quad \text{integrate(abs(cos(x)), x, 0, 2*pi, algorithm='giac')} \\
& \quad 4
\end{align*}
\]
ALIASES: integral() and integrate() are the same.

EXAMPLES:

Here is an example where we have to use assume:

```
sage: a,b = var('a,b')
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
Traceback (most recent call last):
...  
ValueError: Computation failed since Maxima requested additional constraints; using the 'assume' command before evaluation *may* help (example of legal syntax is 'assume(a>0)', see `assume?' for more details)
Is a positive or negative?
```

So we just assume that \( a > 0 \) and the integral works:

```
sage: assume(a>0)
sage: integrate(1/(x^3 *(a+b*x)^(1/3)), x)
```

2.13 TESTS::

sage.symbolic.integration.external.fricas_integrator(expression, v, a=None, b=None, noPole=True)

Integration using FriCAS

EXAMPLES:

```
sage: from sage.symbolic.integration.external import fricas_integrator   # optional - fricas
sage: fricas_integrator(sin(x), x)                                       # optional - fricas
-cos(x)
sage: fricas_integrator(cos(x), x)                                      # optional - fricas

sin(x)
sage: fricas_integrator(1/(x^2-2), x, 0, 1)                             # optional - fricas
-1/8*sqrt(2)*(log(2) - log(-24*sqrt(2) + 34))
sage: fricas_integrator(1/(x^2+6), x, -oo, oo)                           # optional - fricas
1/6*sqrt(6)*pi
```

sage.symbolic.integration.external.giac_integrator(expression, v, a=None, b=None)

Integration using Giac

EXAMPLES:
sage: from sage.symbolic.integration.external import giac_integrator
sage: giac_integrator(sin(x), x)
-cos(x)

sage: giac_integrator(1/(x^2+6), x, -oo, oo)
1/6*sqrt(6)*pi

sage.symbolic.integration.external.libgiac_integrator(expression, v, a=None, b=None)
Integration using libgiac

EXAMPLES:

sage: import sage.libs.giac
...

sage: from sage.symbolic.integration.external import libgiac_integrator
sage: libgiac_integrator(sin(x), x)
-cos(x)

sage: libgiac_integrator(1/(x^2+6), x, -oo, oo)
No checks were made for singular points of antiderivative...
1/6*sqrt(6)*pi

sage.symbolic.integration.external.maxima_integrator(expression, v, a=None, b=None)
Integration using Maxima

EXAMPLES:

sage: from sage.symbolic.integration.external import maxima_integrator
sage: maxima_integrator(sin(x), x)
-cos(x)

sage: maxima_integrator(cos(x), x)
sin(x)

sage: f(x) = function('f')(x)

sage: maxima_integrator(f(x), x)
integrate(f(x), x)

sage.symbolic.integration.external.mma_free_integrator(expression, v, a=None, b=None)
Integration using Mathematica’s online integrator

EXAMPLES:

sage: from sage.symbolic.integration.external import mma_free_integrator
sage: mma_free_integrator(sin(x), x) # optional - internet
-cos(x)

A definite integral:

sage: mma_free_integrator(e^(-x), x, a=0, b=oo) # optional - internet
1

sage.symbolic.integration.external.sympy_integrator(expression, v, a=None, b=None)
Integration using SymPy

EXAMPLES:

sage: from sage.symbolic.integration.external import sympy_integrator
sage: sympy_integrator(sin(x), x)
-cos(x)
sage: sympy_integrator(cos(x), x)
sin(x)

2.14 A Sample Session using SymPy

In this first part, we do all of the examples in the SymPy tutorial (https://github.com/sympy/sympy/wiki/Tutorial), but using Sage instead of SymPy.

```
sage: a = Rational((1,2))
sage: a
1/2
sage: a^2
1
sage: Rational(2)^50 / Rational(10)^50
1/88817841970012523233890533447265625
sage: 1.0/2
0.500000000000000
sage: 1/2
1/2
sage: pi^2
pi^2
sage: float(pi)
3.141592653589793
sage: RealField(200)(pi)
3.1415926535897932384626433832795028841971693993751058209749
sage: float(pi + exp(1))
5.859775448204883...
sage: oo != 2
True
```

```
sage: var('x y')
(x, y)
sage: x + y + x - y
2*x
sage: (x+y)^2
(x + y)^2
sage: (x+y)^2.expand()
x^2 + 2*x*y + y^2
sage: (x+y)^2.subs(x=1)
(y + 1)^2
sage: ((x+y)^2).subs(x=y)
4*y^2
```

```
sage: limit(sin(x)/x, x=0)
1
sage: limit(x, x=oo)
+Infinity
sage: limit((5^x + 3^x)^1/x, x=oo)
5
```
```
sage: diff(sin(x), x)
cos(x)
sage: diff(sin(2*x), x)
2*cos(2*x)
sage: diff(tan(x), x)
tan(x)^2 + 1
sage: limit((tan(x+y) - tan(x))/y, y=0)
1/cos(x)^2
sage: diff(sin(2*x), x, 1)
2*cos(2*x)
sage: diff(sin(2*x), x, 2)
-4*sin(2*x)
sage: diff(sin(2*x), x, 3)
-8*cos(2*x)
sage: cos(x).taylor(x,0,10)
-x^10/3628800 + x^8/40320 - x^6/720 + x^4/24 - x^2/2 + 1
sage: (1/cos(x)).taylor(x,0,10)
x^10/3628800 + 35*x^8/8064 + 63*x^6/720 + 5*x^4/24 + x^2 + 1
sage: matrix([[1,0], [0,1]])
[1 0]
[0 1]
sage: var('x y')
(x, y)
sage: A = matrix([[1,x], [y,1]])
sage: A
[1 x]
[y 1]
sage: A^2
[x*y + 1 2*x]
[ 2*y x*y + 1]
sage: R.<x,y> = QQ[]
sage: A = matrix([[1,x], [y,1]])
sage: A**10
[x^5*y^5 + 45*x^4*y^4 + 210*x^3*y^3 + 210*x^2*y^2 + 45*x*y + 1 10*x^5*y^4 + 120*x^4*y^3 +...
 -4*y^3 + 252*x^3*y^2 + 120*x^2*y + 10*x]

And here are some actual tests of sympy:
```
sage: from sympy import Symbol, cos, sympify, pprint
sage: from sympy.abc import x
sage: e = (1/cos(x)**3)._sympy_(); e
cos(x)**(-3)
sage: f = e.series(x, 0, int(10)); f
1 + 3*x**2/2 + 11*x**4/8 + 241*x**6/240 + 8651*x**8/13440 + O(x**10)
```

And the pretty-printer. Since unicode characters are not working on some architectures, we disable it:

2.14. A Sample Session using SymPy
sage: from sympy.printing import pprint_use_unicode
sage: prev_use = pprint_use_unicode(False)

sage: pprint(e)
1
-----
3
cos (x)

sage: pprint(f)
2 4 6 8
3*x 11*x 241*x 8651*x / 10\ 
1 + ---- + ----- + ------- + ------- + O\ / 2 8 240 13440

sage: pprint_use_unicode(prev_use)
False

And the functionality to convert from SymPy format to Sage format:

sage: e._sage_()
cos(x)^(-3)
sage: e._sage_().taylor(x._sage_(), 0, 8)
8651/13440*x^8 + 241/240*x^6 + 11/8*x^4 + 3/2*x^2 + 1

sage: f._sage_()
8651/13440*x^8 + 241/240*x^6 + 11/8*x^4 + 3/2*x^2 + Order(x^10) + 1

Mixing SymPy with Sage:

sage: import sympy
sage: var("x")._sympy_() + var("y")._sympy_()
x + y
sage: o = var("omega")
sage: s = sympy.Symbol("x")
sage: t1 = s + o
sage: t2 = o + s
sage: type(t1)
<class 'sympy.core.add.Add'>
sage: type(t2)
<class 'syage.symbolic.expression.Expression'>
sage: t1, t2
(omega + x, omega + x)
sage: e=sympy.sin(var("y"))+sympy.cos(sympy.Symbol("x"))
sage: type(e)
<class 'sympy.core.add.Add'>
sage: e
sin(y) + cos(x)
sage: e=e._sage_()
sage: type(e)
<class 'sage.symbolic.expression.Expression'>
sage: e

(continues on next page)
Symbolic Calculus, Release 10.0

x**2 + cos(y**3)**4

sage: a = sympy.Matrix([[1, 2, 3]])
sage: a[1]
2

sage: sympify(1.5)
1.50000000000000
sage: sympify(2)
2
sage: sympify(-2)
-2

2.15 Calculus Tests and Examples

Compute the Christoffel symbol.

sage: var('r t theta phi')
(r, t, theta, phi)
sage: m = matrix(SR, [[(1-1/r),0,0,0],[-(1-1/r)^(-1),0,0,-r^2*2],[0,0,-r^2,0],[0,0,0,-r^2*(sin(theta))^2]])
sage: m
[ -1/r + 1 0 0 0]
[ 0 1/(1/r - 1) 0 0]
[ 0 0 -r^2 0]
[ 0 0 0 -r^2*sin(theta)^2]

sage: def christoffel(i,j,k,vars,g):
....:     s = 0
....:     ginv = g^(-1)
....:     for l in range(g.nrows()):
....:         s = s + (1/2)*ginv[k,l]*(g[j,l].diff(vars[i])+g[i,l].diff(vars[j])-g[i,j].diff(vars[l]))
....:     return s

sage: christoffel(3,3,2,[t,r,theta,phi],m)
cos(theta)*sin(theta)

sage: X = christoffel(1,1,1,[t,r,theta,phi],m)
sage: X
1/2/(r^2*(1/r - 1))
sage: X.rational_simplify()
-1/2/(r^2 - r)

Some basic things:

sage: f(x,y) = x^3 + sinh(1/y)
sage: f
(x, y) |--> x^3 + sinh(1/y)
sage: f^3

(continues on next page)
(x, y) |--> (x^3 + sinh(1/y))^3
sage: (f^3).expand()
(x, y) |--> x^9 + 3*x^6*sinh(1/y) + 3*x^3*sinh(1/y)^2 + sinh(1/y)^3

A polynomial over a symbolic base ring:

sage: R = SR['x']
sage: f = R([1/sqrt(2), 1/(4*sqrt(2))])
sage: f
1/8*sqrt(2)*x + 1/2*sqrt(2)
sage: -f
-1/8*sqrt(2)*x - 1/2*sqrt(2)
sage: (-f).degree()
1

A big product. Notice that simplifying simplifies the product further:

sage: A = exp(I*pi/7)
sage: b = A^14
sage: b
1

We check a statement made at the beginning of Friedlander and Joshi’s book on Distributions:

sage: f(x) = sin(x^2)
sage: g(x) = cos(x) + x^3
sage: u = f(x+t) + g(x-t)
sage: u
-(t - x)^3 + cos(-t + x) + sin((t + x)^2)
sage: u.diff(t,2) - u.diff(x,2)
0

Restoring variables after they have been turned into functions:

sage: x = function('x')
sage: type(x)
<class 'sage.symbolic.function_factory...NewSymbolicFunction'>
sage: x(2/3)
(x/3)
sage: restore('x')
sage: sin(x).variables()
(x,)

MATHEMATICA: Some examples of integration and differentiation taken from some Mathematica docs:

sage: var('x n a')
(x, n, a)
sage: diff(x^n, x)  # the output looks funny, but is correct
n*x^(n - 1)
sage: diff(x^2 * log(x+a), x)
2*x*log(a + x) + x^2/(a + x)
sage: derivative(arctan(x), x)
1/(x^2 + 1)
This is an apparent regression in Maxima 5.39.0, although the antiderivative is correct, assuming we work with (poly)logs of complex argument. More convenient form is \( \frac{1}{2} \log(x^2) \log(-x^2 + 1) + \frac{1}{2} \text{dilog}(-x^2 + 1) \). See also https://sourceforge.net/p/maxima/bugs/3275/:

\[
\text{sage: integrate}(\log(1-x^2)/x, x) \\
\log(-x^2)\log(x + 1) + \log(x)\log(-x + 1) + \text{dilog}(x + 1) + \text{dilog}(-x + 1)
\]

No problems here:

\[
\text{sage: integrate}(\exp(-c^x^2), x) \\
\frac{1}{2}\sqrt{\pi}\erf(x)e
\]

\[
\text{sage: integrate}(\sin(x^2), x) \\
\frac{1}{16}\sqrt{\pi}\left((I + 1)\sqrt{2}\erf((1/2*I + 1/2)\sqrt{2}\times) + (I - 1)\sqrt{2}\erf((1/2*I - 1/2)\sqrt{2}\times) - (I - 1)\sqrt{2}\erf(I\sqrt{-I}\times) + (I + 1)\sqrt{2}\erf(-1^{1/4}\times))
\]

\[
\text{sage: integrate}(\exp(-c^x^2)^n, x) \quad \# \text{long time} \\
x^2\text{hypergeometric}((1/2, -n), (3/2,), x^2\exp(2*I\pi))
\]

Other examples that now (github issue #27958) work:

\[
\text{sage: integrate}(\log(x)\exp(-x^2), x) \quad \# \text{long time} \\
\frac{1}{2}\sqrt{\pi}\erf(x)\log(x) - x^2\text{hypergeometric}((1/2, 1/2), (3/2, 3/2), -x^2)
\]

\[
\text{sage: integrate}(\log(1+\sqrt{1+4^x^2}/2)/x, x, 0, 1) \\
\text{Traceback (most recent call last)}:
\]

```
... 
ValueError: Integral is divergent.
```
The following is an example of integral that Mathematica can do, but Sage currently cannot do:

```
sage: integrate(ceil(x^2 + floor(x)), x, 0, 5, algorithm='maxima')
integrate(ceil(x^2) + floor(x), x, 0, 5)
```

MAPLE: The basic differentiation and integration examples in the Maple documentation:

```
sage: diff(sin(x), x)
cos(x)
sage: diff(sin(x), y)
0
sage: diff(sin(x), x, 3)
-cos(x)
sage: diff(x*sin(cos(x)), x)
x*cos(cos(x))*sin(x) + sin(cos(x))
sage: diff(tan(x), x)
tan(x)^2 + 1
sage: f = function('f'); f
f
sage: diff(f(x), x)
diff(f(x), x)
sage: diff(f(x,y), x, y)
diff(f(x, y), x, y)
sage: diff(f(x,y), x, y) - diff(f(x,y), y, x)
0
sage: g = function('g')
sage: var('x y z')
(x, y, z)
sage: diff(g(x,y,z), x,z,z)
diff(g(x, y, z), x, z, z)
sage: integrate(sin(x), x)
cos(x)
sage: integrate(sin(x), x, 0, pi)
2
sage: var('a b')
(a, b)
sage: integrate(sin(x), x, a, b)
cos(a) - cos(b)
sage: integrate(1/sqrt(2*t^4 - 3*t^2 - 2), t, 2, 3)
# long time
# todo: maple can do...
```

(continues on next page)
We verify several standard differentiation rules:

```
sage: function('f, g')
(f, g)
sage: diff(f(t)*g(t), t)
g(t)*diff(f(t), t) + f(t)*diff(g(t), t)
sage: diff(f(t)/g(t), t)
diff(f(t), t)/g(t) - f(t)*diff(g(t), t)/g(t)^2
sage: diff(f(t) + g(t), t)
diff(f(t), t) + diff(g(t), t)
sage: diff(c*f(t), t)
c*diff(f(t), t)
```

## 2.16 Conversion of symbolic expressions to other types

This module provides routines for converting new symbolic expressions to other types. Primarily, it provides a class `Converter` which will walk the expression tree and make calls to methods overridden by subclasses.

```python
class sage.symbolic.expression_conversions.AlgebraicConverter(field)
    Bases: Converter

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: a.reciprocal_trig_functions['cot']
tan
```

`arithmetic(ex, operator)`

Convert a symbolic expression to an algebraic number.

```
EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: f = 2^(1/2)
sage: a = AlgebraicConverter(QQbar)
sage: a.arithmetic(f, f.operator())
1.414213562373095?
```

`composition(ex, operator)`

Coerce to an algebraic number.

```
EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: a.composition(exp(I*pi/3, hold=True), exp)
0.500000000000000? + 0.866025403784439?*I
```

(continues on next page)
Symbolic Calculus, Release 10.0

sage: a.composition(sin(pi/7), sin)
0.4338837391175581? + 0.?e-18*I

sage: x = SR.var('x')
sage: a.composition(complex_root_of(x^3 - x^2 - x - 1, 0), complex_root_of)
1.839286755214161?
sage: a.composition(complex_root_of(x^5 - 1, 3), complex_root_of)
0.3090169943749474? - 0.9510565162951536?*I

sage: a.composition(complex_root_of(x^2 + 1, 0), complex_root_of)
1.?e-684 - 0.9999999999999999?*I

sage: a.composition(complex_root_of(x^2 + 1, 1), complex_root_of)
1.?e-684 + 0.9999999999999999?*I

pyobject

EXAMPLES:

sage: from sage.symbolic.expression_conversions import AlgebraicConverter
sage: a = AlgebraicConverter(QQbar)
sage: f = SR(2)
sage: a.pyobject(f, f.pyobject())
2

class sage.symbolic.expression_conversions.Converter

Bases: object

If use_fake_div is set to True, then the converter will try to replace expressions whose operator is operator.mul
with the corresponding expression whose operator is operator.truediv.

EXAMPLES:

sage: from sage.symbolic.expression_conversions import Converter
sage: c = Converter(use_fake_div=True)
sage: c.get_fake_div(sin(x)/x)

arithmetiс

The input to this method is a symbolic expression and the infix operator corresponding to that expression.

Typically, one will convert all of the arguments and then perform the operation afterward.

composition

The input to this method is a symbolic expression and its operator. This method will get called when you
have a symbolic function application.

derivative

The input to this method is a symbolic expression which corresponds to a relation.

get_fake_div

EXAMPLES:
Symbolic Calculus, Release 10.0

FakeExpression([\sin(x), x], <built-in function truediv>)
sage: c.get_fake_div(-1*\sin(x))
FakeExpression([\sin(x)], <built-in function neg>)
sage: c.get_fake_div(-x)
FakeExpression([x], <built-in function neg>)
sage: c.get_fake_div((2*x^3+2*x-1)/((x-2)*(x+1)))
FakeExpression([2*x^3 + 2*x - 1, FakeExpression([x + 1, x - 2], <built-in function mul>)]), <built-in function truediv>)

Check if github issue #8056 is fixed, i.e., if numerator is 1:.
sage: c.get_fake_div(1/pi/x)
FakeExpression([1, FakeExpression([pi, x], <built-in function mul>)]), <built-in function truediv>)

pyobject(ex, obj)
The input to this method is the result of calling pyobject() on a symbolic expression.

Note: Note that if a constant such as pi is encountered in the expression tree, its corresponding pyobject which is an instance of sage.symbolic.constants.Pi will be passed into this method. One cannot do arithmetic using such an object.

relation(ex, operator)
The input to this method is a symbolic expression which corresponds to a relation.

symbol(ex)
The input to this method is a symbolic expression which corresponds to a single variable. For example, this method could be used to return a generator for a polynomial ring.

class sage.symbolic.expression_conversions.DeMoivre(ex, force=False)
Bases: ExpressionTreeWalker
A class that walks a symbolic expression tree and replaces occurrences of complex exponentials (optionally, all exponentials) by their respective trigonometric expressions.

INPUT:
• force – boolean (default: False): replace \exp(x) with \cosh(x) + \sinh(x)

EXAMPLES:

sage: a, b = SR.var("a, b")
sage: from sage.symbolic.expression_conversions import DeMoivre
def moivre_example():
    d = DeMoivre(e^a)
    return d

composition(ex, op)
Return the composition of self with ex by op.

EXAMPLES:

sage: x, a, b = SR.var('x, a, b')
sage: from sage.symbolic.expression_conversions import DeMoivre
```
sage: p = exp(x)
sage: s = DeMoivre(p)
sage: q = exp(a+I*b)
sage: s.composition(q, q.operator())
(cos(b) + I*sin(b))*e^a
```

class sage.symbolic.expression_conversions.Exponentialize(ex)

Bases: ExpressionTreeWalker

A class that walks a symbolic expression tree and replace circular and hyperbolic functions by their respective exponential expressions.

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import Exponentialize
sage: d = Exponentialize(sin(x))
sage: d(sin(x))
-1/2*I*e^(I*x) + 1/2*I*e^(-I*x)
sage: d(cosh(x))
1/2*e^(-x) + 1/2*e^x
```

CircDict = {sinh: x |--> -1/2*e^(-x) + 1/2*e^x, cosh: x |--> 1/2*e^(-x) + 1/2*e^x, tanh: x |--> -(e^(-x) - e^x)/(e^(-x) + e^x), coth: x |--> -(e^(-x) + e^x)/(e^(-x) - e^x), sech: x |--> 2/(e^(-x) + e^x), csch: x |--> -2/(e^(-x) - e^x), sinh: x |--> -1/2*I*e^(I*x) + 1/2*I*e^(-I*x), cos: x |--> 1/2*I*e^(I*x) + 1/2*I*e^(-I*x), tan: x |--> -(I*e^(I*x) + I*e^(-I*x))/(e^(I*x) + e^(-I*x)), cot: x |--> (I*e^(I*x) + I*e^(-I*x))/(e^(I*x) - e^(-I*x)), sec: x |--> 2/(e^(I*x) + e^(-I*x)), csc: x |--> 2*I/(e^(I*x) - e^(-I*x))}

Circs = [sin, cos, sec, csc, tan, cot, sinh, cosh, sech, csch, tanh, coth]

I = I

Integer

alias of Integer

SR = Symbolic Ring

composition(ex, op)

Return the composition of self with ex by op.

EXAMPLES:

```
sage: x = SR.var("x")
sage: from sage.symbolic.expression_conversions import Exponentialize
sage: p = x
sage: s = Exponentialize(p)
sage: q = sin(x)
sage: s.composition(q, q.operator())
-1/2*I*e^(I*x) + 1/2*I*e^(-I*x)
```

cos = cos
cosh = cosh
Symbolic Calculus, Release 10.0

cot = cot
coth = coth
csc = csc
csch = csch
e = e
exp = exp

`function(s, **kwds)`

Create a formal symbolic function with the name `s`.

**INPUT:**
- `nargs=0` - number of arguments the function accepts, defaults to variable number of arguments, or 0
- `latex_name` - name used when printing in latex mode
- `conversions` - a dictionary specifying names of this function in other systems, this is used by the interfaces internally during conversion
- `eval_func` - method used for automatic evaluation
- `evalf_func` - method used for numeric evaluation
- `evalf_params_first` - bool to indicate if parameters should be evaluated numerically before calling the custom evalf function
- `conjugate_func` - method used for complex conjugation
- `real_part_func` - method used when taking real parts
- `imag_part_func` - method used when taking imaginary parts
- `derivative_func` - method to be used for (partial) derivation This method should take a keyword argument `deriv_param` specifying the index of the argument to differentiate w.r.t
- `tderivative_func` - method to be used for derivatives
- `power_func` - method used when taking powers This method should take a keyword argument `power_param` specifying the exponent
- `series_func` - method used for series expansion This method should expect keyword arguments - `order` - order for the expansion to be computed - `var` - variable to expand w.r.t. - `at` - expand at this value
- `print_func` - method for custom printing
- `print_latex_func` - method for custom printing in latex mode

Note that custom methods must be instance methods, i.e., expect the instance of the symbolic function as the first argument.

**Note:** The new function is both returned and automatically injected into the global namespace. If you use this function in library code, it is better to use `sage.symbolic.function_factory.function`, since it will not touch the global namespace.

**EXAMPLES:**
We create a formal function called supersin
We can immediately use supersin in symbolic expressions:

```sage
y, z, A = var('y z A')
s supersin(y+z) + A^3
A^3 + supersin(y + z)
```

We can define other functions in terms of supersin:

```sage
g(x,y) = supersin(x)^2 + sin(y/2)
g(x, y) |--> supersin(x)^2 + sin(1/2*y)
g.diff(y) (x, y) |--> 1/2*cos(1/2*y)
k = g.diff(x); k (x, y) |--> 2*supersin(x)*diff(supersin(x), x)
```

We create a formal function of one variable, write down an expression that involves first and second derivatives, and extract off coefficients:

```sage
r, kappa = var('r, kappa')
psi = function('psi', nargs=1)(r); psi
psi(r)
g = 1/r^2*(2*r*psi.derivative(r,1) + r^2*psi.derivative(r,2)); g 
(r^2*diff(psi(r), r, r) + 2*r^2*diff(psi(r), r))/r^2
g.expand() 2*diff(psi(r), r)/r + diff(psi(r), r, r)
g.coeficient(psi.derivative(r,2)) 1
g.coeficient(psi.derivative(r,1)) 2/r
```

Custom typesetting of symbolic functions in LaTeX, either using latex_name keyword:

```sage
function('riemann', latex_name="\mathcal{R}")
riemann
latex(riemann(x)) \mathcal{R}(x)
```

or passing a custom callable function that returns a latex expression:

```sage
mu,nu = var('mu,nu')
def my_latex_print(self, *args):
    return  "\psi_{%s}"%((''.join(map(latex, args))
function('psi', print_latex_func=my_latex_print)
latex(psi(mu,nu)) \psi_{\mu, \nu}
```

Defining custom methods for automatic or numeric evaluation, derivation, conjugation, etc. is supported:
sage: def ev(self, x): return 2*x
sage: foo = function("foo", nargs=1, eval_func=ev)
sage: foo(x)
2*x
sage: foo = function("foo", nargs=1, eval_func=lambda self, x: 5)
sage: foo(x)
5
sage: def ef(self, x): pass
sage: bar = function("bar", nargs=1, eval_func=ef)
sage: bar(x)
bar(x)

sage: def evalf_f(self, x, parent=None, algorithm=None): return 6
sage: foo = function("foo", nargs=1, evalf_func=evalf_f)
sage: foo(x)
foo(x)
sage: foo(x).n()
6

sage: foo = function("foo", nargs=1, conjugate_func=ev)
sage: foo(x).conjugate()
2*x

sage: def deriv(self, *args,**kwds): print("{} {}".format(args, kwds)); return
    args[kwds['diff_param']]^2
sage: foo = function("foo", nargs=2, derivative_func=deriv)
sage: foo(x,y).derivative(y)
(x, y) {'diff_param': 1}
y^2

sage: def pow(self, x, power_param=None): print("{} {}".format(x, power_param)); return
    x*power_param
sage: foo = function("foo", nargs=1, power_func=pow)
sage: foo(y)^(x+y)
y x + y
(x + y)^y

sage: from pprint import pformat
sage: def expand(self, *args, **kwds):
    ....: print("{} {}".format(args, pformat(kwds)))
    ....: return sum(args[0]^i for i in range(kwds['order']))

sage: foo = function("foo", nargs=1, series_func=expand)
sage: foo(y).series(y, 5)
(y,) {'at': 0, 'options': 0, 'order': 5, 'var': y}
y^4 + y^3 + y^2 + y + 1

sage: def my_print(self, *args):
    ....: return "my args are: " + ', '.join(map(repr, args))

sage: foo = function('t', nargs=2, print_func=my_print)
sage: foo(x,y^z)
my args are: x, y^z

sage: latex(foo(x,y^z))
t(x, y^z)
sage: foo = function(’t’, nargs=2, print_latex_func=my_print)
foo(x,y^z)
t(x, y^z)
sage: latex(foo(x,y^z))
my args are: x, y^z
sage: foo = function(’t’, nargs=2, latex_name=’foo’)  
sage: latex(foo(x,y^z))
foo\left(x, y^{z}\right)

Chain rule:

```python
sage: def print_args(self, *args, **kwds): print("args: {}\n".format(args)); → print("kwds: {}\n".format(kwds)); return args[0]
sage: foo = function(’t’, nargs=2, tderivative_func=print_args)
sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {’diff_param’: x}
x
sage: foo = function(’t’, nargs=2, derivative_func=print_args)
sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {’diff_param’: 0}
args: (x, x)
kwds: {’diff_param’: 1}
2*x
```

Since Sage 4.0, basic arithmetic with unevaluated functions is no longer supported:

```python
sage: x = var(’x’)
sage: f = function(’f’)
sage: 2*f
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: ’Integer Ring’ and ’<class → sage.symbolic.function_factory...NewSymbolicFunction’>
```

You now need to evaluate the function in order to do the arithmetic:

```python
sage: 2*f(x)
2*f(x)
```

Since Sage 4.0, you need to use substitute_function() to replace all occurrences of a function with another:

```python
sage: var(’a, b’)
(a, b)
sage: cr = function(’cr’)
sage: f = cr(a)
sage: g = f.diff(a).integral(b)
sage: g
b*diff(cr(a), a)
sage: g.substitute_function(cr, cos)
```

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

-b*sin(a)

sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))

b*(cos(a) - sin(a))

half = 1/2
sec = sec
sech = sech
sin = sin
sinh = sinh
tan = tan
tanh = tanh
two = 2
x = x

class sage.symbolic.expression_conversions.ExpressionTreeWalker(ex)

Bases: Converter

A class that walks the tree. Mainly for subclassing.

EXAMPLES:

sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: ex = sin(atan(0,hold=True)+hypergeometric((1,),(1,),x))

sage: s = ExpressionTreeWalker(ex)

sage: bool(s() == ex)
True

sage: set_random_seed(0) # random_expr is unstable
sage: foo = random_expr(20, nvars=2)

sage: s = ExpressionTreeWalker(foo)

sage: bool(s() == foo)
True

arithmetic(ex, operator)

EXAMPLES:

sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')

sage: f = x*foo(x) + pi/foo(x)

sage: s = ExpressionTreeWalker(f)

sage: bool(s.arithmetic(f, f.operator()) == f)
True

composition(ex, operator)

EXAMPLES:
```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
sage: f = foo(atan2(0, 0, hold=True))
sage: s = ExpressionTreeWalker(f)
sage: bool(s.composition(f, f.operator()) == f)
True
```

**derivative**\( (ex, \text{operator}) \)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
sage: f = foo(x).diff(x)
sage: s = ExpressionTreeWalker(f)
sage: bool(s.derivative(f, f.operator()) == f)
True
```

**pyobject**\( (ex, \text{obj}) \)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: f = SR(2)
sage: s = ExpressionTreeWalker(f)
sage: bool(s.pyobject(f, f.pyobject()) == f.pyobject())
True
```

**relation**\( (ex, \text{operator}) \)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
sage: eq = foo(x) == x
sage: s = ExpressionTreeWalker(eq)
sage: s.relation(eq, eq.operator()) == eq
True
```

**symbol**\( (ex) \)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: s = ExpressionTreeWalker(x)
sage: bool(s.symbol(x) == x)
True
```

**tuple**\( (ex) \)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import ExpressionTreeWalker
sage: foo = function('foo')
sage: f = hypergeometric([1,2,3],(x,),x)
sage: s = ExpressionTreeWalker(f)
sage: bool(s() == f)
True
```
class sage.symbolic.expression_conversions.FakeExpression(operands, operator)

Bases: object

Pynac represents $x/y$ as $x y^{-1}$. Often, tree-walkers would prefer to see divisions instead of multiplications and negative exponents. To allow for this (since Pynac internally doesn’t have division at all), there is a possibility to pass use_fake_div=True; this will rewrite an Expression into a mixture of Expression and FakeExpression nodes, where the FakeExpression nodes are used to represent divisions. These nodes are intended to act sufficiently like Expression nodes that tree-walkers won’t care about the difference.

operands()

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.truediv)
sage: f.operands()
[x, y]
```

operator()

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.truediv)
sage: f.operator()
<built-in function truediv>
```

pyobject()

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FakeExpression
sage: import operator; x,y = var('x,y')
sage: f = FakeExpression([x, y], operator.truediv)
sage: f.pyobject()
Traceback (most recent call last):
...  
TypeError: self must be a numeric expression
```

class sage.symbolic.expression_conversions.FastCallableConverter(ex, etb)

Bases: Converter

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import FastCallableConverter
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x'])
sage: f = FastCallableConverter(x+2, etb)
sage: f.ex
x + 2
sage: f.etb
<sage.ext.fast_callable.ExpressionTreeBuilder object at 0x...>
sage: f.use_fake_div
True
```
Symbolic Calculus, Release 10.0

**arithmetic**(ex, operator)

EXAMPLES:

```python
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x', 'y'])

sage: var('x, y')
(x, y)

sage: (x+y)._fast_callable_(etb)
add(v_0, v_1)

sage: (-x)._fast_callable_(etb)
neg(v_0)

sage: (x+y+x^2)._fast_callable_(etb)
add(add(ipow(v_0, 2), v_0), v_1)
```

**composition**(ex, function)

Given an ExpressionTreeBuilder, return an Expression representing this value.

EXAMPLES:

```python
sage: from sage.ext.fast_callable import ExpressionTreeBuilder

sage: x, y = var('x, y')

sage: sin(sqrt(x+y))._fast_callable_(etb)
sin(sqrt(add(v_0, v_1)))

sage: arctan2(x,y)._fast_callable_(etb)
{arctan2}(v_0, v_1)
```

**pyobject**(ex, obj)

EXAMPLES:

```python
sage: from sage.ext.fast_callable import ExpressionTreeBuilder

sage: pi._fast_callable_(etb)
pi

sage: etb = ExpressionTreeBuilder(vars=['x'], domain=RDF)

sage: pi._fast_callable_(etb)
3.141592653589793
```

**relation**(ex, operator)

EXAMPLES:

```python
sage: ff = fast_callable(x == 2, vars=['x'])

sage: ff(2)
0

sage: ff(4)
2

sage: ff = fast_callable(x < 2, vars=['x'])
Traceback (most recent call last):
  ...
NotImplementedError
```

**symbol**(ex)

Given an ExpressionTreeBuilder, return an Expression representing this value.

EXAMPLES:
Symbolic Calculus, Release 10.0

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x', 'y'])
sage: x, y, z = var('x, y, z')
sage: x._fast_callable_(etb)
v_0
sage: y._fast_callable_(etb)
v_1
sage: z._fast_callable_(etb)
Traceback (most recent call last):
  ...  
ValueError: Variable 'z' not found...
```

tuple(ex)

Given a symbolic tuple, return its elements as a Python list.

EXAMPLES:

```
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
e tb = ExpressionTreeBuilder(vars=['x'])
sage: SR._force_pyobject((2, 3, x^2))._fast_callable_(etb)
[2, 3, x^2]
```

class sage.symbolic.expression_conversions.FriCASConverter

Bases: InterfaceInit

Converts any expression to FriCAS.

EXAMPLES:

```
sage: var('x,y')
(x, y)
sage: f = exp(x^2) - arcsin(pi+x)/y
sage: f._fricas_()  # optional - fricas
 2
  x
y %e - asin(x + %pi)
 ----------------------
y
```

derivative(ex, operator)

Convert the derivative of self in FriCAS.

INPUT:

- `ex` – a symbolic expression
- `operator` – operator

Note that `ex.operator()` == `operator`.

EXAMPLES:

```
sage: var('x,y,z')
(x, y, z)
sage: f = function("F")
```

2.16. Conversion of symbolic expressions to other types 279
Check that github issue #25838 is fixed:

```python
sage: var('x')
x
sage: F = function('F')
sage: integrate(F(x), x, algorithm="fricas")  # optional - fricas
integral(F(x), x)
sage: integrate(diff(F(x), x)*sin(F(x)), x, algorithm="fricas")  # optional - fricas
-cos(F(x))
```

Check that github issue #27310 is fixed:

```python
sage: f = function("F")
sage: var("y")
y
sage: ex = (diff(f(x,y), x, x, y)).subs(y=x+y); ex
D[0, 0, 1](F)(x, x + y)
sage: fricas(ex)  # optional - fricas
F (x, y + x)
,1,1,2
```

**pyobject** (ex, obj)

Return a string which, when evaluated by FriCAS, returns the object as an expression.

We explicitly add the coercion to the FriCAS domains `ExpressionInteger` and `ExpressionComplexInteger` to make sure that elements of the symbolic ring are translated to these. In particular, this is needed for integration, see github issue #28641 and github issue #28647.

**EXAMPLES:**

```python
sage: 2._fricas_().domainOf()  # optional - fricas
PositiveInteger()
sage: (-1/2)._fricas_().domainOf()  # optional - fricas
Fraction(Integer())
sage: SR(2)._fricas_().domainOf()  # optional - fricas
Expression(Integer())
```

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

```
sage: (sqrt(2))._fricas_().domainOf()  # optional - fricas
Expression(Integer())
sage: pi._fricas_().domainOf()        # optional - fricas
Pi()
sage: asin(pi)._fricas_()             # optional - fricas
asin(%pi)
sage: I._fricas_().domainOf()        # optional - fricas
Complex(Integer())
sage: SR(I)._fricas_().domainOf()    # optional - fricas
Expression(Complex(Integer()))
sage: ex = (I+sqrt(2)+2)
sage: ex._fricas_().domainOf()       # optional - fricas
Expression(Complex(Integer()))
sage: (ex^2)._fricas_()              # optional -
+-+
(4 + 2 %i)\|2 + 5 + 4 %i
```

**symbol**(ex)

Convert the argument, which is a symbol, to FriCAS.

In this case, we do not return an *ExpressionInteger*, because FriCAS frequently requires elements of domain *Symbol* or *Variable* as arguments, for example to *integrate*. Moreover, FriCAS is able to do the conversion itself, whenever the argument should be interpreted as a symbolic expression.

EXAMPLES:

```
sage: x._fricas_().domainOf()       # optional - fricas
Variable(x)
sage: (x^2)._fricas_().domainOf()  # optional - fricas
Expression(Integer())
```

(continues on next page)
symbolic calculus, release 10.0

(continued from previous page)

```python
sage: (2*x)._fricas_().integrate(x)       # optional - fricas
   2
  x
```

class sage.symbolic.expression_conversions.HoldRemover(ex, exclude=None)

Bases: ExpressionTreeWalker

A class that walks the tree and evaluates every operator that is not in a given list of exceptions.

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import HoldRemover
dsage: ex = sin(pi*cos(0, hold=True), hold=True); ex
sin(pi*cos(0))
sage: h = HoldRemover(ex)
sage: h()
0
sage: h = HoldRemover(ex, [sin])
sage: h()

sin(pi)
sage: h = HoldRemover(ex, [cos])
sage: h()

sin(pi*cos(0))
sage: ex = atan2(0, 0, hold=True) + hypergeometric([1,2], [3,4], 0, hold=True)
sage: h = HoldRemover(ex, [atan2])
sage: h()

arctan2(0, 0) + 1
sage: h = HoldRemover(ex, [hypergeometric])
sage: h()
NaN + hypergeometric((1, 2), (3, 4), 0)
```

composition(ex, operator)

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import HoldRemover
dsage: ex = sin(pi*cos(0, hold=True), hold=True); ex
sin(pi*cos(0))
sage: h = HoldRemover(ex)
sage: h()
0
```

class sage.symbolic.expression_conversions.InterfaceInit(interface)

Bases: Converter

EXAMPLES:

```python
sage: from sage.symbolic.expression_conversions import InterfaceInit
dsage: m = InterfaceInit(maxima)
dsage: a = pi + 2
d sage: m(a)
'(%%pi)+2)
sage: m(sin(a))
```
Symbolic Calculus, Release 10.0

(continued from previous page)

'sin((\%pi)+(2))'
sage: m(exp(x^2) + pi + 2)
'(\%pi)+(exp((_SAGE_VAR_x)^2))+2'

arithmetic(ex, operator)
EXAMPLES:

sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.arithmetic(x+2, sage.symbolic.operators.add_vararg)
'(_SAGE_VAR_x)+(2)'

composition(ex, operator)
EXAMPLES:

sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.composition(sin(x), sin)
'sin(_SAGE_VAR_x)'
sage: m.composition(ceil(x), ceil)
'ceiling(_SAGE_VAR_x)'
sage: m = InterfaceInit(mathematica)
sage: m.composition(sin(x), sin)
'Sin[x]'

derivative(ex, operator)
EXAMPLES:

sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: f = function('f')
sage: a = f(x).diff(x); a
diff(f(x), x)
sage: print(m.derivative(a, a.operator()))
diff(_SAGE_VAR_x, 1)
sage: b = f(x).diff(x, x)
sage: print(m.derivative(b, b.operator()))
diff(_SAGE_VAR_x, 2)

We can also convert expressions where the argument is not just a variable, but the result is an “at” expression using temporary variables:

sage: y = var('y')
sage: t = (f(x*y).diff(x))/y
sage: t
D[0](f)(x*y)
sage: m.derivative(t, t.operator())
"at(diff('f(_SAGE_VAR__symbol0), _SAGE_VAR__symbol0, 1), [_SAGE_VAR__symbol0 = _SAGE_VAR_x*y])"
pyobject(ex, obj)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: ii = InterfaceInit(gp)
sage: f = 2+SR(I)
sage: ii.pyobject(f, f.pyobject())
'I + 2'
sage: ii.pyobject(SR(2), 2)
'2'
sage: ii.pyobject(pi, pi.pyobject())
'Pi'
```

relation(ex, operator)

EXAMPLES:

```
sage: import operator
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: m.relation(x==3, operator.eq)
'\_SAGE\_VAR\_x = 3'
sage: m.relation(x==3, operator.lt)
'\_SAGE\_VAR\_x < 3'
```

tuple(ex)

EXAMPLES:

```
sage: from sage.symbolic.expression_conversions import InterfaceInit
sage: m = InterfaceInit(maxima)
sage: t = SR._force_pyobject((3, 4, e^x))
sage: m.tuple(t)
'[3,4,exp(_SAGE\_VAR\_x)]'
```

class sage.symbolic.expression_conversions.LaurentPolynomialConverter(ex, base_ring=None, ring=None)
Bases: \textit{PolynomialConverter}

A converter from symbolic expressions to Laurent polynomials.

See \texttt{laurent\_polynomial()} for details.

\textbf{class} sage.symbolic.expression_conversions.PolynomialConverter(\textit{ex}, \textit{base\_ring=}None, \textit{ring=}None)

Bases: Converter

A converter from symbolic expressions to polynomials.

See \texttt{polynomial()} for details.

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: from sage.symbolic.expression_conversions import PolynomialConverter
  sage: x, y = var('x, y')
  sage: p = PolynomialConverter(x+y, base_ring=QQ)
  sage: p.base_ring
  Rational Field
  sage: p.ring
  Multivariate Polynomial Ring in x, y over Rational Field
  sage: p = PolynomialConverter(x, base_ring=QQ)
  sage: p.base_ring
  Rational Field
  sage: p.ring
  Univariate Polynomial Ring in x over Rational Field
  sage: p = PolynomialConverter(x, ring=QQ['x, y'])
  sage: p.base_ring
  Rational Field
  sage: p.ring
  Multivariate Polynomial Ring in x, y over Rational Field
  sage: p = PolynomialConverter(x+y, ring=QQ['x'])
  Traceback (most recent call last):
    ...
  TypeError: y is not a variable of Univariate Polynomial Ring in x over Rational Field
\end{verbatim}

\textbf{arithmetic}(\textit{ex}, \textit{operator})

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: import operator
  sage: from sage.symbolic.expression_conversions import PolynomialConverter
  sage: x, y = var('x, y')
  sage: p = PolynomialConverter(x, base_ring=RR)
  sage: p.arithmetic(pi+e, operator.add)
  5.859787448204884
  sage: p.arithmetic(x^2, operator.pow)
  x^2
  sage: p = PolynomialConverter(x+y, base_ring=RR)
\end{verbatim}

(continues on next page)
Symbolic Calculus, Release 10.0

(continued from previous page)

\begin{verbatim}
sage: p.arithmetic(x*y+y^2, operator.add)
x*y + y^2
sage: p = PolynomialConverter(y^(3/2), ring=SR['x'])
sage: p.arithmetic(y^(3/2), operator.pow)
y^(3/2)
sage: _.parent()
Symbolic Ring
\end{verbatim}

composition\((ex, operator)\)

EXAMPLES:

\begin{verbatim}
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: a = sin(2)
sage: p = PolynomialConverter(a*x, base_ring=RR)
sage: p.composition(a, a.operator())
0.909297426825682
\end{verbatim}

pyobject\((ex, obj)\)

EXAMPLES:

\begin{verbatim}
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: p = PolynomialConverter(x, base_ring=QQ)
sage: f = SR(2)
sage: p.pyobject(f, f.pyobject())
2
sage: _.parent()
Rational Field
\end{verbatim}

relation\((ex, op)\)

EXAMPLES:

\begin{verbatim}
sage: import operator
sage: from sage.symbolic.expression_conversions import PolynomialConverter

sage: x, y = var('x, y')
sage: p = PolynomialConverter(x, base_ring=RR)

sage: p.relation(x==3, operator.eq)
x - 3.00000000000000
sage: p.relation(x==3, operator.lt)
Traceback (most recent call last):
... ValueError: Unable to represent as a polynomial

sage: p = PolynomialConverter(x - y, base_ring=QQ)
sage: p.relation(x^2 - y^3 + 1 == x^3, operator.eq)
-x^3 - y^3 + x^2 + 1
\end{verbatim}

symbol\((ex)\)

Returns a variable in the polynomial ring.

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import PolynomialConverter
sage: p = PolynomialConverter(x, base_ring=QQ)
sage: p.symbol(x)
x
sage: _.parent()
Univariate Polynomial Ring in x over Rational Field
sage: y = var('y')
sage: p = PolynomialConverter(x*y, ring=SR['x'])
sage: p.symbol(y)
y
class sage.symbolic.expression_conversions.RingConverter(R, subs_dict=None)

Bases: Converter

A class to convert expressions to other rings.

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF, subs_dict={x:2})
sage: R.ring
Real Interval Field with 53 bits of precision
sage: R.subs_dict
{x: 2}
sage: R(pi+e)
5.85987448204884?
sage: loads(dumps(R))
<sage.symbolic.expression_conversions.RingConverter object at 0x...>  
```

```
arithmetic(ex, operator)

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: P.<z> = ZZ[]
sage: R = RingConverter(P, subs_dict={x:z})
sage: a = 2^x^2 + x + 3
sage: R(a)
2^z^2 + z + 3
```

```
composition(ex, operator)

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF)
sage: R(cos(2))
-0.4161468365471424?
```

```
pyobject(ex, obj)

EXAMPLES:
```
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF)
sage: R(SR(5/2))
2.5000000000000000?
```
```
**symbol** *(ex)*

All symbols appearing in the expression must either appear in `subs_dict` or be convertible by the ring's element constructor in order for the conversion to be successful.

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import RingConverter
sage: R = RingConverter(RIF, subs_dict={x:2})
sage: R(x+pi)
5.141592653589794?

sage: R = RingConverter(RIF)
    R(x+pi)
    Traceback (most recent call last):
    ...
    TypeError: unable to simplify to a real interval approximation

sage: R = RingConverter(QQ['x'])
sage: R(x^2+x)
x^2 + x
sage: R(x^2+x).parent()
Univariate Polynomial Ring in x over Rational Field
```

**class** `sage.symbolic.expression_conversions.SubstituteFunction(ex, *args)`

**Bases:** `ExpressionTreeWalker`

A class that walks the tree and replaces occurrences of a function with another.

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
    s = SubstituteFunction(foo(x), {foo: bar})
    s(1/foo(foo(x)) + foo(2))
1/bar(bar(x)) + bar(2)
```

**composition** *(ex, operator)*

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
    s = SubstituteFunction(foo(x), {foo: bar})
    f = foo(x)
    s.composition(f, f.operator())
    bar(x)
    f = foo(foo(x))
    s.composition(f, f.operator())
    bar(bar(x))
    f = sin(foo(x))
    s.composition(f, f.operator())
    sin(bar(x))
    f = foo(sin(x))
    s.composition(f, f.operator())
    bar(sin(x))
```
**derivative** *(ex, operator)*

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SubstituteFunction
sage: foo = function('foo'); bar = function('bar')
sage: s = SubstituteFunction(foo(x), {foo: bar})
sage: f = foo(x).diff(x)
```

```python
sage: s.derivative(f, f.operator())
diff(bar(x), x)
```

**class** **sage.symbolic.expression_conversions.SympyConverter**

**Bases:** Converter

Converts any expression to SymPy.

**EXAMPLES:**

```python
sage: import sympy
sage: var('x,y')
(x, y)
sage: f = exp(x^2) - arcsin(pi+x)/y
sage: f._sympy_()
exp(x**2) - asin(x + pi)/y
sage: _.sage_()
-arcsin(pi + x)/y + e^(x^2)
sage: sympy.sympify(x)  # indirect doctest
x
```

**arithmetic** *(ex, operator)*

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = x + 2
sage: s.arithmetic(f, f.operator())
x + 2
```

**composition** *(ex, operator)*

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
sage: f = sin(2)
sage: s.composition(f, f.operator())
```

```python
sin(2)
sage: type(_)
sin
```

```python
sage: f = arcsin(2)
sage: s.composition(f, f.operator())
asin(2)
```

**derivative** *(ex, operator)*

Convert the derivative of *self* in SymPy.
INPUT:

- ex – a symbolic expression
- operator – operator

**pyobject**(ex, obj)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SympyConverter
sage: s = SympyConverter()
```

```python
def f(x):
    return 2
```

```python
sage: s.pyobject(f, f.pyobject())
2
```

```python
sage: type(_)
<class 'sympy.core.numbers.Integer'>
```

**relation**(ex, op)

**EXAMPLES:**

```python
sage: import operator
```

```python
sage: from sage.symbolic.expression_conversions import SympyConverter
```

```python
def f(x):
    return 2
```

```python
sage: s = SympyConverter()
```

```python
sage: s.relation(x == 3, operator.eq)
Eq(x, 3)
```

```python
sage: s.relation(pi < 3, operator.lt)
pi < 3
```

```python
sage: s.relation(x != pi, operator.ne)
Ne(x, pi)
```

```python
sage: s.relation(x > 0, operator.gt)
x > 0
```

**symbol**(ex)

**EXAMPLES:**

```python
sage: from sage.symbolic.expression_conversions import SympyConverter
```

```python
def f(x):
    return 2
```

```python
sage: s = SympyConverter()
```

```python
sage: s.symbol(x)
x
```

```python
sage: type(_)
<class 'sympy.core.symbol.Symbol'>
```

**tuple**(ex)

Conversion of tuples.

**EXAMPLES:**

```python
sage: t = SR._force_pyobject((3, 4, e^x))
```

```python
sage: t._sympy_()
(3, 4, e^x)
```

```python
sage: t = SR._force_pyobject((cos(x),))
```

```python
sage: t._sympy_()
(cos(x),)
```

`sage.symbolic.expression_conversions.algebraic**(ex, field)**`

Returns the symbolic expression `ex` as a element of the algebraic field `field`. 

290 Chapter 2. Internal functionality supporting calculus
EXAMPLES:

```python
sage: a = SR(5/6)
sage: AA(a)
5/6
sage: type(AA(a))
<class 'sage.rings.qqbar.AlgebraicReal'>
sage: QQbar(a)
5/6
sage: type(QQbar(a))
<class 'sage.rings.qqbar.AlgebraicNumber'>
sage: QQbar(i)
I
sage: QQbar(golden_ratio)
1.618033988749895?
sage: QQbar(sin(pi/3))
0.866025403784439?
sage: QQbar(sqrt(2) + sqrt(8))
4.242640687119285?
sage: AA(sqrt(2) ^ 4) == 4
True
sage: AA(-golden_ratio)
-1.618033988749895?
sage: QQbar((2*SR(I))^(1/2))
1 + 1*I
sage: QQbar(e^(pi*I/3))
0.50000000000000000? + 0.866025403784439?*I
sage: AA(x*sin(0))
0
sage: QQbar(x*sin(0))
0
```

### fast_callable

Given an ExpressionTreeBuilder `etb`, return an Expression representing the symbolic expression `ex`.

**EXAMPLES:**

```python
sage: from sage.ext.fast_callable import ExpressionTreeBuilder
sage: etb = ExpressionTreeBuilder(vars=['x', 'y'])
sage: x, y = var('x,y')
sage: f = y+2*x^2
sage: f._fast_callable_(etb)
add(mul(ipow(v_0, 2), 2), v_1)

sage: f = (2*x^3+2*x-1)/((x-2)*(x+1))
```

### laurent_polynomial

Return a Laurent polynomial from the symbolic expression `ex`.

**EXAMPLES:**

```python
sage: laurent_polynomial(f)
```

**2.16. Conversion of symbolic expressions to other types**
Symbolic Calculus, Release 10.0

INPUT:

- **ex** – a symbolic expression
- **base_ring, ring** – Either a base_ring or a Laurent polynomial ring can be specified for the parent of result. If just a base_ring is given, then the variables of the base_ring will be the variables of the expression ex.

OUTPUT:

A Laurent polynomial.

EXAMPLES:

```sage
def laurent_polynomial(f, base_ring=None, ring=None):
    return polynomial(f, base_ring, ring)
```

The input is a symbolic expression **f**, and the output is a Laurent polynomial from that expression. If a base_ring or polynomial ring is specified, the variables of the result are those specified in the ring. If no base_ring or polynomial ring is specified, the variables of the result are the variables of the expression **f**.

```sage
from sage.symbolic.expression_conversions import laurent_polynomial
f = x^2 + 2/x
laurent_polynomial(f, base_ring=QQ)
```

```
2*x^-1 + x^2
```

```sage
_.parent()
```

```
Univariate Laurent Polynomial Ring in x over Rational Field
```

```sage
laurent_polynomial(f, ring=LaurentPolynomialRing(QQ, 'x, y'))
```

```
x^2 + 2*x^-1
```

```sage
_.parent()
```

```
Multivariate Laurent Polynomial Ring in x, y over Rational Field
```

```sage
x, y = var('x, y')
laurent_polynomial(x + 1/y^2, ring=LaurentPolynomialRing(QQ, 'x, y'))
```

```
x + y^-2
```

```sage
_.parent()
```

```
Multivariate Laurent Polynomial Ring in x, y over Rational Field
```

The function `sage.symbolic.expression_conversions.polynomial` takes a symbolic expression **ex** and returns a polynomial. If a base_ring or polynomial ring is specified, the variables of the result are those specified in the ring. If no base_ring or polynomial ring is specified, the variables of the result are the variables of the expression **ex**.

INPUT:

- **ex** – a symbolic expression
- **base_ring, ring** – Either a base_ring or a polynomial ring can be specified for the parent of result. If just a base_ring is given, then the variables of the base_ring will be the variables of the expression ex.

OUTPUT:

A polynomial.

EXAMPLES:

```sage
def polynomial(f, base_ring=None, ring=None):
    return polynomial(f, base_ring, ring)
```

The input is a symbolic expression **f**, and the output is a polynomial from that expression. If a base_ring or polynomial ring is specified, the variables of the result are those specified in the ring. If no base_ring or polynomial ring is specified, the variables of the result are the variables of the expression **f**.

```sage
from sage.symbolic.expression_conversions import polynomial
f = x^2 + 2
polynomial(f, base_ring=QQ)
```

```
x^2 + 2
```

```sage
_.parent()
```

```
Univariate Polynomial Ring in x over Rational Field
```

```sage
polynomial(f, ring=QQ['x,y'])
```

```
x^2 + 2
```

```sage
_.parent()
```

```
Multivariate Polynomial Ring in x, y over Rational Field
```

(continues on next page)
The polynomials can have arbitrary (constant) coefficients so long as they coerce into the base ring:

```
sage: polynomial(2^sin(2)*x^2 + exp(3), base_ring=RR)
1.87813065119873*x^2 + 20.0855369231877
```

## 2.17 Complexity Measures

Some measures of symbolic expression complexity. Each complexity measure is expected to take a symbolic expression as an argument, and return a number.

**sage.symbolic.complexity_measures.string_length**(expr)

Returns the length of expr after converting it to a string.

**INPUT:**

- expr – the expression whose complexity we want to measure.

**OUTPUT:**

A real number representing the complexity of expr.

**RATIONALE:**

If the expression is longer on-screen, then a human would probably consider it more complex.

**EXAMPLES:**

This expression has three characters, x, ^, and 2:
2.18 Further examples from Wester’s paper

These are all the problems at http://yacas.sourceforge.net/essaysmanual.html

They come from the 1994 paper “Review of CAS mathematical capabilities”, by Michael Wester, who put forward 123 problems that a reasonable computer algebra system should be able to solve and tested the then current versions of various commercial CAS on this list. Sage can do most of the problems natively now, i.e., with no explicit calls to Maxima or other systems.

```
sage: # (YES) factorial of 50, and factor it
sage: factorial(50)
30414093201713378043612608166064768843776415689605120000000000000
sage: factor(factorial(50))
2^47 * 3^22 * 5^12 * 7^8 * 11^4 * 13^3 * 17^2 * 19^2 * 23^2 * 29 * 31 * 37 * 41 * 43 * 47
```

```

Chapter 2. Internal functionality supporting calculus
2.19 Solving ordinary differential equations

This file contains functions useful for solving differential equations which occur commonly in a 1st semester differential equations course. For another numerical solver see the `ode_solver()` function and the optional package Octave.

Solutions from the Maxima package can contain the three constants \_C, \_K1, and \_K2 where the underscore is used to distinguish them from symbolic variables that the user might have used. You can substitute values for them, and make them into accessible usable symbolic variables, for example with `var("_C")`.

Commands:

- `desolve()` - Compute the “general solution” to a 1st or 2nd order ODE via Maxima.
- `desolve_laplace()` - Solve an ODE using Laplace transforms via Maxima. Initial conditions are optional.
- `desolve_rk4()` - Solve numerically an IVP for one first order equation, return list of points or plot.
- `desolve_system_rk4()` - Solve numerically an IVP for a system of first order equations, return list of points.
- `desolve_odeint()` - Solve numerically a system of first-order ordinary differential equations using `odeint` from scipy.integrate module.
- `desolve_system()` - Solve a system of 1st order ODEs of any size using Maxima. Initial conditions are optional.
- `eulers_method()` - Approximate solution to a 1st order DE, presented as a table.
- `eulers_method_2x2()` - Approximate solution to a 1st order system of DEs, presented as a table.
- `eulers_method_2x2_plot()` - Plot the sequence of points obtained from Euler’s method.

The following functions require the optional package `tides`:

- `desolve_mintides()` - Numerical solution of a system of 1st order ODEs via the Taylor series integrator method implemented in TIDES.
- `desolve_tides_mpfr()` - Arbitrary precision Taylor series integrator implemented in TIDES.

AUTHORS:

- David Joyner (3-2006) - Initial version of functions
- Marshall Hampton (7-2007) - Creation of Python module and testing
- Robert Marik (10-2009) - Some bugfixes and enhancements
- Miguel Marco (06-2014) - Tides desolvers

```
sage.calculus.desolvers.desolve(de, dvar, ics=None, ivar=None, show_method=False, contrib_ode=False, algorithm='maxima')
```

Solve a 1st or 2nd order linear ODE, including IVP and BVP.

INPUT:

- `de` – an expression or equation representing the ODE
- `dvar` – the dependent variable (hereafter called $y$)
- `ics` – (optional) the initial or boundary conditions
  - for a first-order equation, specify the initial $x$ and $y$
  - for a second-order equation, specify the initial $x$, $y$, and $dy/dx$, i.e. write $[x_0, y(x_0), y'(x_0)]$
- for a second-order boundary solution, specify initial and final \( x \) and \( y \) boundary conditions, i.e. write \([x_0, y(x_0), x_1, y(x_1)]\).

- gives an error if the solution is not SymbolicEquation (as happens for example for a Clairaut equation).

- \textbf{ivar} – (optional) the independent variable (hereafter called \( x \)), which must be specified if there is more than one independent variable in the equation.

- \textbf{show_method} – (optional) if True, then Sage returns pair \([\text{solution, method}]\), where method is the string describing the method which has been used to get a solution (Maxima uses the following order for first order equations: linear, separable, exact (including exact with integrating factor), homogeneous, bernoulli, generalized homogeneous) - use carefully in class, see below the example of an equation which is separable but this property is not recognized by Maxima and the equation is solved as exact.

- \textbf{contrib_ode} – (optional) if True, \texttt{desolve} allows to solve Clairaut, Lagrange, Riccati and some other equations. This may take a long time and is thus turned off by default. Initial conditions can be used only if the result is one SymbolicEquation (does not contain a singular solution, for example).

- \textbf{algorithm} – (default: 'maxima') one of
  - 'maxima' - use maxima
  - 'fricas' - use FriCAS (the optional fricas spkg has to be installed)

\textbf{OUTPUT:}

In most cases return a SymbolicEquation which defines the solution implicitly. If the result is in the form \( y(x) = \ldots \) (happens for linear eqs.), return the right-hand side only. The possible constant solutions of separable ODEs are omitted.

\textbf{Note:} Use \texttt{desolve? <tab>} if the output in the Sage notebook is truncated.

\textbf{EXAMPLES:}

```
sage: x = var('x')
sage: y = function('y')(x)
sage: desolve(diff(y,x) + y - 1, y)
\(_C + e^x*)e^(-x)
```

```
sage: f = desolve(diff(y,x) + y - 1, y, ics=[10,2]); f
(e^10 + e^x)*e^(-x)
```

```
sage: plot(f)
Graphics object consisting of 1 graphics primitive
```

We can also solve second-order differential equations:

```
sage: x = var('x')
sage: y = function('y')(x)
sage: de = diff(y,x,2) - y == x
sage: desolve(de, y)
\_K2*e^(-x) + \_K1*e^x - x
```

```
sage: f = desolve(de, y, [10,2,1]); f
-x + 7*e^(x - 10) + 5*e^(-x + 10)
```
Symbolic Calculus, Release 10.0

```python
sage: f(x=10)
2
sage: diff(f,x)(x=10)
1
sage: de = diff(y,x,2) + y == 0
sage: desolve(de, y)
_K2*cos(x) + _K1*sin(x)

sage: desolve(de, y, [0,1,pi/2,4])
cos(x) + 4*sin(x)

sage: desolve(y*diff(y,x)+sin(x)==0,y)
-1/2*y(x)^2 == _C - cos(x)

sage: desolve(diff(y,x)^2+x*diff(y,x)-y==0,y,contrib_ode=True,show_method=True)
[[y(x) == _C^2 + _C*x, y(x) == -1/4*x^2], 'clairault']

sage: desolve(x^2*diff(y,x)==a+b*x^n+c*x^2*y^2,y,ivar=x,contrib_ode=True)
[[y(x) == 0, (b*x^(n - 2) + a/x^2)*c^2*u == 0], 'riccati']

Higher order equations, not involving independent variable:

sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y).expand()
1/6*y(x)^3 + _K1*y(x) == _K2 + x

sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,1,3]).expand()
1/6*y(x)^3 - 5/3*y(x) == x - 3/2

sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,1,3],show_method=True)
[1/6*y(x)^3 - 5/3*y(x) == x - 3/2, 'freeofx']

Separable equations - Sage returns solution in implicit form:

sage: desolve(diff(y,x)*sin(y) == cos(x),y)
-cos(y(x)) == _C + sin(x)

sage: desolve(diff(y,x)*sin(y) == cos(x),y,show_method=True)
[-cos(y(x)) == _C + sin(x), 'separable']
```

2.19. Solving ordinary differential equations 307
Symbolic Calculus, Release 10.0

```
sage: desolve(diff(y,x)*sin(y) == cos(x),y,[pi/2,1])
-cos(y(x)) == -cos(1) + sin(x) - 1
```

Linear equation - Sage returns the expression on the right hand side only:

```
sage: desolve(diff(y,x)+(y) == cos(x),y)
1/2*((cos(x) + sin(x))*e^x + 2*_C)*e^(-x)
```

```
sage: desolve(diff(y,x)+(y) == cos(x),y,show_method=True)
[1/2*((cos(x) + sin(x))*e^x + 2*_C)*e^(-x), 'linear']
```

```
sage: desolve(diff(y,x)+(y) == cos(x),y,[0,1])
1/2*(cos(x)*e^x + e^x*sin(x) + 1)*e^(-x)
```

This ODE with separated variables is solved as exact. Explanation - factor does not split $e^x - y$ in Maxima into $e^x e^y$:

```
sage: desolve(diff(y,x)==exp(x-y),y,show_method=True)
[-e^x + e^y(x) == _C, 'exact']
```

You can solve Bessel equations, also using initial conditions, but you cannot put (sometimes desired) the initial condition at $x = 0$, since this point is a singular point of the equation. Anyway, if the solution should be bounded at $x = 0$, then $K_2 = 0$.

```
sage: desolve(x^2*diff(y,x,x)+x*diff(y,x)+(x^2-4)*y==0,y)
_K1*bessel_J(2, x) + _K2*bessel_Y(2, x)
```

Example of difficult ODE producing an error:

```
sage: desolve(sqrt(y)*diff(y,x)+e^(y)+cos(x)-sin(x+y)==0,y)
# not tested
Traceback (click to the left for traceback)
...
NotImplementedError, "Maxima was unable to solve this ODE. Consider to set option contrib_ode to True."
```

Another difficult ODE with error - moreover, it takes a long time:

```
sage: desolve(sqrt(y)*diff(y,x)+e^(y)+cos(x)-sin(x+y)==0,y,contrib_ode=True) # not tested
```

Some more types of ODEs:

```
sage: desolve(x*diff(y,x)^2-(1+x*y)*diff(y,x)+y==0,y,contrib_ode=True,show_method=True)
[[y(x) == _C + log(x), y(x) == _C*e^x], 'factor']
```

```
sage: desolve(diff(y,x)==(x+y)^2,y,contrib_ode=True,show_method=True)
[[[x == _C - arctan(sqrt(t)), y(x) == -x - sqrt(t)], [x == _C + arctan(sqrt(t)),
  y(x) == -x + sqrt(t)]], 'lagrange']
```

These two examples produce an error (as expected, Maxima 5.18 cannot solve equations from initial conditions). Maxima 5.18 returns false answer in this case!
Symbolic Calculus, Release 10.0

```python
sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,2]).expand() # not tested
Traceback (click to the left for traceback)
...                      
NotImplementedError, "Maxima was unable to solve this ODE. Consider to set option contrib_ode to True."
```

```
sage: desolve(diff(y,x,2)+y*(diff(y,x,1))^3==0,y,[0,1,2],show_method=True) # not tested
Traceback (click to the left for traceback)
...                      
NotImplementedError, "Maxima was unable to solve this ODE. Consider to set option contrib_ode to True."
```

Second order linear ODE:

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y)
(_K2*x + _K1)*e^(-x) + 1/2*sin(x)
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,show_method='true')
[(_K2*x + _K1)*e^(-x) + 1/2*sin(x), 'variationofparameters']
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,[0,3,1])
1/2*(7*x + 6)*e^(-x) + 1/2*sin(x)
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,[0,3,1],show_method='true')
[1/2*(7*x + 6)*e^(-x) + 1/2*sin(x), 'variationofparameters']
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,[0,3,pi/2,2])
3*(x*(e^(1/2*pi) - 2)/pi + 1)*e^(-x) + 1/2*sin(x)
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == cos(x),y,[0,3,pi/2,2],show_method='true')
[3*(x*(e^(1/2*pi) - 2)/pi + 1)*e^(-x) + 1/2*sin(x), 'variationofparameters']
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y)
(_K2*x + _K1)*e^(-x)
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,show_method='true')
[(_K2*x + _K1)*e^(-x), 'constcoeff']
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,[0,3,1])
(4*x + 3)*e^(-x)
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,[0,3,1],show_method='true')
[(4*x + 3)*e^(-x), 'constcoeff']
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,[0,3,pi/2,2])
(2*x*(2*e^(1/2*pi) - 3)/pi + 3)*e^(-x)
```

```python
sage: desolve(diff(y,x,2)+2*diff(y,x)+y == 0,y,[0,3,pi/2,2],show_method='true')
[(2*x*(2*e^(1/2*pi) - 3)/pi + 3)*e^(-x), 'constcoeff']
```

2.19. Solving ordinary differential equations

---

309
Using \texttt{algorithm='fricas'} we can invoke the differential equation solver from FriCAS. For example, it can solve higher order linear equations:

\begin{verbatim}
 sage: de = x^3*diff(y, x, 3) + x^2*diff(y, x, 2) - 2*x*diff(y, x) + 2*y - 2*x^4
 sage: Y = desolve(de, y, algorithm="fricas"); Y # optional - fricas
 (2*x^3 - 3*x^2 + 1)*_C0/x + (x^3 - 1)*_C1/x
 + (x^3 - 3*x^2 - 1)*_C2/x + 1/15*(x^5 - 10*x^3 + 20*x^2 + 4)/x
\end{verbatim}

The initial conditions are then interpreted as \([x_0, y(x_0), y'(x_0), \ldots, y^{(n)}(x_0)]\):

\begin{verbatim}
 sage: Y = desolve(de, y, ics=[1,3,7], algorithm="fricas"); Y # optional - fricas
 1/15*(x^5 + 15*x^3 + 50*x^2 - 21)/x
\end{verbatim}

FriCAS can also solve some non-linear equations:

\begin{verbatim}
 sage: de = diff(y, x) == y / (x+y*log(y))
 sage: Y = desolve(de, y, algorithm="fricas"); Y # optional - fricas
 1/2*(log(y(x))^2*y(x) - 2*x)/y(x)
\end{verbatim}

\textbf{AUTHORS:}

- David Joyner (1-2006)
- Robert Bradshaw (10-2008)
- Robert Marik (10-2009)

\texttt{sage.calculus.desolvers.desolve_laplace}(de, dvar, ics=None, ivar=None)

Solve an ODE using Laplace transforms. Initial conditions are optional.

\textbf{INPUT:}

- \texttt{de} - a lambda expression representing the ODE (e.g. \texttt{de = diff(y,x,2) \equiv diff(y,x)+sin(x)})
- \texttt{dvar} - the dependent variable (e.g. \texttt{y})
- \texttt{ivar} - (optional) the independent variable (hereafter called \texttt{x}), which must be specified if there is more than one independent variable in the equation.
- \texttt{ics} - a list of numbers representing initial conditions, (e.g. \texttt{f(0)=1, f'(0)=2} corresponds to \texttt{ics = [0, 1, 2]})

\textbf{OUTPUT:}

Solution of the ODE as symbolic expression

\textbf{EXAMPLES:}

\begin{verbatim}
 sage: u=function('u')(x)
 sage: eq = diff(u,x) - exp(-x) - u == 0
 sage: desolve_laplace(eq,u)
 1/2*e^(2*u(0) + 1)*e^x - 1/2*e^(-x)
\end{verbatim}

We can use initial conditions:

\begin{verbatim}
 sage: desolve_laplace(eq,u,ics=[0,3])
 -1/2*e^(-x) + 7/2*e^x
\end{verbatim}

The initial conditions do not persist in the system (as they persisted in previous versions):
Symbolic Calculus, Release 10.0

\begin{align*}
\texttt{sage: desolve_laplace(eq,u)} & \\
& \frac{1}{2} \left( 2u(0) + 1 \right) e^x - \frac{1}{2} e^{-x} \\
\end{align*}

\begin{align*}
\texttt{sage: f=function('f')(x)} & \\
\texttt{sage: eq = diff(f,x) + f == 0} & \\
\texttt{sage: desolve_laplace(eq,f,\{0,1\})} & \\
& e^{-x} \\
\end{align*}

\begin{align*}
\texttt{sage: x = var('x')} & \\
\texttt{sage: f = function('f')(x)} & \\
\texttt{sage: de = diff(f,x,x) - 2*diff(f,x) + f} & \\
\texttt{sage: desolve_laplace(de,f)} & \\
& -x^2 e^x f(0) + x^2 e^x D[0](f)(0) + e^x f(0) \\
\end{align*}

\begin{align*}
\texttt{sage: desolve_laplace(de,f,ics=[0,1,2])} & \\
& x^2 e^x + e^x \\
\end{align*}

AUTHORS:

- Robert Marik (10-2009)

\texttt{sage.calculus.desolvers.desolve_mintides(f, ics, initial, final, delta, tolrel=1e-16, tolabs=1e-16)}

Solve numerically a system of first order differential equations using the taylor series integrator implemented in mintides.

**INPUT:**

- \( f \) – symbolic function. Its first argument will be the independent variable. Its output should be de derivatives of the dependent variables.
- \( ics \) – a list or tuple with the initial conditions.
- \( initial \) – the starting value for the independent variable.
- \( final \) – the final value for the independent value.
- \( delta \) – the size of the steps in the output.
- \( tolrel \) – the relative tolerance for the method.
- \( tolabs \) – the absolute tolerance for the method.

**OUTPUT:**

- A list with the positions of the IVP.

**EXAMPLES:**

We integrate a periodic orbit of the Kepler problem along 50 periods:

\begin{align*}
\texttt{sage: var('t,x,y,X,Y') (t, x, y, X, Y) & \\
\texttt{sage: f(t,x,y,X,Y)=[X, Y, -x/(x^2+y^2)^(3/2), -y/(x^2+y^2)^(3/2)] & \\
\texttt{sage: ics = [0.8, 0, 0, 1.22474487139159] & \\
\texttt{sage: t = 100*pi} & \\
\texttt{sage: sol = desolve_mintides(f, ics, 0, t, t, 1e-12, 1e-12) \# optional -tides} & \\
\texttt{sage: sol \# optional -tides \# abs tol 1e-5} & \\
\end{align*}

[314.159265358979, 0.800000000028622, -5.91973525754241e-9, 7.56887091890590e-9, 1.22474487136329]]

ALGORITHM:
Uses TIDES.

REFERENCES:
• A. Abad, R. Barrio, F. Blesa, M. Rodriguez. TIDES tutorial: Integrating ODEs by using the Taylor Series Method.

sage.calculus.desolvers.desolve_odeint(des, ics, times, dvars, ivar=None, compute_jac=False, args=(), rtol=None, atol=None, tcrit=None, h0=0.0, hmax=0.0, hmin=0.0, ixpr=0, mxstep=0, mxhnil=0, mxordn=12, mxords=5, printmessg=0)

Solve numerically a system of first-order ordinary differential equations using odeint from scipy.integrate module.

INPUT:
• des – right hand sides of the system
• ics – initial conditions
• times – a sequence of time points in which the solution must be found
• dvars – dependent variables. ATTENTION: the order must be the same as in des, that means: d(dvars[i])/dt=des[i]
• ivar – independent variable, optional.
• compute_jac – boolean. If True, the Jacobian of des is computed and used during the integration of stiff systems. Default value is False.

Other Parameters (taken from the documentation of odeint function from scipy.integrate module.)
• rtol, atol : float The input parameters rtol and atol determine the error control performed by the solver. The solver will control the vector, e, of estimated local errors in y, according to an inequality of the form:
  max-norm of (e / ewt) <= 1
where ewt is a vector of positive error weights computed as:
  ewt = rtol * abs(y) + atol
rtol and atol can be either vectors the same length as y or scalars.
• tcrit : array Vector of critical points (e.g. singularities) where integration care should be taken.
Symbolic Calculus, Release 10.0

- \( h0 \) : float, (0: solver-determined) The step size to be attempted on the first step.
- \( hmax \) : float, (0: solver-determined) The maximum absolute step size allowed.
- \( hmin \) : float, (0: solver-determined) The minimum absolute step size allowed.
- \( ixpr \) : boolean. Whether to generate extra printing at method switches.
- \( mxstep \) : integer, (0: solver-determined) Maximum number of (internally defined) steps allowed for each integration point in \( t \).
- \( mxhnil \) : integer, (0: solver-determined) Maximum number of messages printed.
- \( mxordn \) : integer, (0: solver-determined) Maximum order to be allowed for the nonstiff (Adams) method.
- \( mxords \) : integer, (0: solver-determined) Maximum order to be allowed for the stiff (BDF) method.

OUTPUT:

Return a list with the solution of the system at each time in \( \text{times} \).

EXAMPLES:

Lotka Volterra Equations:

```
sage: from sage.calculus.desolvers import desolve_odeint
sage: x,y=var('x,y')
sage: f=[x*(1-y),-y*(1-x)]
sage: sol=desolve_odeint(f,[0.5,2],srange(0,10,0.1),[x,y])
sage: p=line(zip(sol[:,0],sol[:,1]))
sage: p.show()
```

Lorenz Equations:

```
sage: x,y,z=var('x,y,z')
sage: # Next we define the parameters
sage: sigma=10
sage: rho=28
sage: beta=8/3
sage: # The Lorenz equations
sage: lorenz=[sigma*(y-x),x*(rho-z)-y,x*y-beta*z]
sage: # Time and initial conditions
sage: times=srange(0,50.05,0.05)
sage: ics=[0,1,1]
sage: sol=desolve_odeint(lorenz,ics,times,[x,y,z],rtol=1e-13,atol=1e-14)
sage: p=points(zip(times,sol))
sage: p.show()
```

One-dimensional stiff system:

```
sage: y= var('y')
sage: epsilon=0.01
sage: f=y^2*(1-y)
sage: ic=epsilon
sage: t=srange(0,2/epsilon,1)
sage: sol=desolve_odeint(f,ic,t,y,rtol=1e-9,atol=1e-10,compute_jac=True)
sage: p=points(zip(t,sol))
sage: p.show()
```

Another stiff system with some optional parameters with no default value:
AUTHOR:

• Oriol Castejon (05-2010)

sage.calculus.desolvers.desolve_rk4(de, dvar, ics=None, ivar=None, end_points=None, step=0.1, output='list', **kwds)

Solve numerically one first-order ordinary differential equation.

INPUT:

Input is similar to desolve command. The differential equation can be written in a form close to the plot_slope_field or desolve command.

• Variant 1 (function in two variables)
  – de - right hand side, i.e. the function \( f(x, y) \) from ODE \( y' = f(x, y) \)
  – dvar - dependent variable (symbolic variable declared by var)

• Variant 2 (symbolic equation)
  – de - equation, including term with \( \text{diff}(y, x) \)
  – dvar - dependent variable (declared as function of independent variable)

• Other parameters
  – ivar - should be specified, if there are more variables or if the equation is autonomous
  – ics - initial conditions in the form \([x0, y0]\)
  – end_points - the end points of the interval
    * if end_points is a or \([a]\), we integrate between min(ics[0], a) and max(ics[0], a)
    * if end_points is None, we use end_points=ics[0]+10
    * if end_points is \([a, b]\) we integrate between min(ics[0], a) and max(ics[0], b)
  – step - (optional, default:0.1) the length of the step (positive number)
  – output - (optional, default: 'list') one of 'list', 'plot', 'slope_field' (graph of the solution with slope field)

OUTPUT:

Return a list of points, or plot produced by list_plot, optionally with slope field.

See also:

ode_solver().

EXAMPLES:
Symbolic Calculus, Release 10.0

```
sage: from sage.calculus.desolvers import desolve_rk4
```

Variant 2 for input - more common in numerics:

```
sage: x,y = var('x,y')
sage: desolve_rk4(x*y*(2-y),y,ics=[0,1],end_points=1,step=0.5)
[[0, 1], [0.5, 1.12419127424558], [1.0, 1.461590162288825]]
```

Variant 1 for input - we can pass ODE in the form used by desolve function In this example we integrate backwards, since end_points < ics[0]:

```
sage: y = function('y')(x)
sage: desolve_rk4(diff(y,x)+y*(y-1) == x-2,y,ics=[1,1],step=0.5, end_points=0)
[[0.0, 8.904257108962112], [0.5, 1.909327945361535], [1, 1]]
```

Here we show how to plot simple pictures. For more advanced applications use list_plot instead. To see the resulting picture use show(P) in Sage notebook.

```
sage: x,y = var('x,y')
sage: P=desolve_rk4(y*(2-y),y,ics=[0,.1],ivar=x,output='slope_field',end_points=[-4,6],thickness=3)
```

**ALGORITHM:**

4th order Runge-Kutta method. Wrapper for command rk in Maxima’s dynamics package. Perhaps could be faster by using fast_float instead.

**AUTHORS:**

- Robert Marik (10-2009)

```
sage.calculus.desolvers.desolve_rk4_determine_bounds(ics, end_points=None)
```

Used to determine bounds for numerical integration.

- If end_points is None, the interval for integration is from ics[0] to ics[0]+10
- If end_points is a or [a], the interval for integration is from min(ics[0],a) to max(ics[0],a)
- If end_points is [a,b], the interval for integration is from min(ics[0],a) to max(ics[0],b)

**EXAMPLES:**

```
sage: from sage.calculus.desolvers import desolve_rk4_determine_bounds
sage: desolve_rk4_determine_bounds([0,2],1)
(0, 1)
sage: desolve_rk4_determine_bounds([0,2],1)
(0, 10)

sage: desolve_rk4_determine_bounds([0,2],[-2,4])
(-2, 4)
```
Solve a system of any size of 1st order ODEs. Initial conditions are optional.

One dimensional systems are passed to \texttt{desolve_laplace()}. 

INPUT:

\begin{itemize}
\item \texttt{des} – list of ODEs
\item \texttt{vars} – list of dependent variables
\item \texttt{ics} – (optional) list of initial values for \texttt{ivar} and \texttt{vars}; if \texttt{ics} is defined, it should provide initial conditions for each variable, otherwise an exception would be raised
\item \texttt{ivar} – (optional) the independent variable, which must be specified if there is more than one independent variable in the equation
\item \texttt{algorithm} – (default: \texttt{'maxima'}) one of
  \begin{itemize}
  \item \texttt{'maxima'} - use maxima
  \item \texttt{'fricas'} - use FriCAS (the optional fricas spkg has to be installed)
  \end{itemize}
\end{itemize}

EXAMPLES:

\begin{verbatim}
  sage: t = var('t')
  sage: x = function('x')(t)
  sage: y = function('y')(t)
  sage: de1 = diff(x,t) + y - 1 == 0
  sage: de2 = diff(y,t) - x + 1 == 0
  sage: desolve_system([de1, de2], [x,y])
  [x(t) == (x(0) - 1)*cos(t) - (y(0) - 1)*sin(t) + 1,
   y(t) == (y(0) - 1)*cos(t) + (x(0) - 1)*sin(t) + 1]
\end{verbatim}

The same system solved using FriCAS:

\begin{verbatim}
  sage: desolve_system([de1, de2], [x,y], algorithm='fricas')  # optional - fricas
  [x(t) == _C0*cos(t) + cos(t)^2 + _C1*sin(t) + sin(t)^2,
   y(t) == -_C1*cos(t) + _C0*sin(t) + 1]
\end{verbatim}

Now we give some initial conditions:

\begin{verbatim}
  sage: sol = desolve_system([de1, de2], [x,y], ics=[0,1,2]); sol
  [x(t) == -sin(t) + 1, y(t) == cos(t) + 1]
\end{verbatim}

AUTHORS:

\begin{itemize}
\item Robert Bradshaw (10-2008)
\item Sergey Bykov (10-2014)
\end{itemize}
input is similar to desolve_system and desolve_rk4 commands

- **des** - right hand sides of the system
- **vars** - dependent variables
- **ivar** - (optional) should be specified, if there are more variables or if the equation is autonomous and the independent variable is missing
- **ics** - initial conditions in the form \([x_0, y_01, y_02, y_03, \ldots]\)
- **end_points** - the end points of the interval
  - if **end_points** is \(a\) or \([a]\), we integrate on between \(\min(ics[0], a)\) and \(\max(ics[0], a)\)
  - if **end_points** is None, we use \(end_points=ics[0]+10\)
  - if **end_points** is \([a,b]\) we integrate on between \(\min(ics[0], a)\) and \(\max(ics[0], b)\)
- **step** – (optional, default: 0.1) the length of the step

**OUTPUT:**

Return a list of points.

**See also:**

*ode_solver()*.  

**EXAMPLES:**

```sage
from sage.calculus.desolvers import desolve_system_rk4

Lotka Volterra system:
```
```sage
x, y, t = var('x y t')
P = desolve_system_rk4([x*(1-y), -y*(1-x)], [x, y], ics=[0, 0.5, 2], ivar=t, end_points=20)
Q = [[i, j] for i, j, k in P]
LP = list_plot(Q)
```

**ALGORITHM:**

4th order Runge-Kutta method. Wrapper for command rk in Maxima’s dynamics package. Perhaps could be faster by using fast_float instead.

**AUTHOR:**

- Robert Marik (10-2009)
Symbolic Calculus, Release 10.0

- ics – a list or tuple with the initial conditions.
- initial – the starting value for the independent variable.
- final – the final value for the independent variable.
- delta – the size of the steps in the output.
- tolrel – the relative tolerance for the method.
- tolabs – the absolute tolerance for the method.
- digits – the digits of precision used in the computation.

OUTPUT:
- A list with the positions of the IVP.

EXAMPLES:
We integrate the Lorenz equations with Saltzman values for the parameters along 10 periodic orbits with 100 digits of precision:

```
sage: var('t,x,y,z')
(t, x, y, z)
sage: s = 10
sage: r = 28
sage: b = 8/3
sage: f(t,x,y,z)= [s*(y-x),x*(r-z)-y,x*y-b*z]

`sage.calculus.desolvers.eulers_method(f, x0, y0, h, x1, algorithm='table')`

This implements Euler’s method for finding numerically the solution of the 1st order ODE $y' = f(x, y)$, $y(a) = c$. The x column of the table increments from $x_0$ to $x_1$ by $h$ (so $(x_1 - x_0)/h$ must be an integer). In the y column, the new $y$-value equals the old $y$-value plus the corresponding entry in the last column.

**Note:** This function is for pedagogical purposes only.

EXAMPLES:
```
sage: from sage.calculus.desolvers import eulers_method
sage: x, y = PolynomialRing(QQ, 2, "xy").gens()
sage: eulers_method(5*x+y-5, 0, 1, 1/2, 1)
\[
\begin{array}{ccc}
  x & y & h*f(x,y) \\
  0 & 1 & -2 \\
  1/2 & -1 & -7/4 \\
  1 & -11/4 & -11/8 \\
\end{array}
\]
```
```
sage: x, y = PolynomialRing(QQ, 2, "xy").gens()
sage: eulers_method(5*x+y-5, 0, 1, 1/2, 1, algorithm="none")
[[0, 1], [1/2, -1], [1, -11/4], [3/2, -33/8]]
```
```
sage: RR = RealField(sci_not=0, prec=4, rnd='RNDU')
sage: x, y = PolynomialRing(RR, 2, "xy").gens()
sage: eulers_method(5*x+y-5, 0, 1, 1/2, 1, algorithm="None")
[[0, 1], [1/2, -1.0], [1, -2.7], [3/2, -4.0]]
```
```
sage: RR = RealField(sci_not=0, prec=4, rnd='RNDU')
sage: x, y = PolynomialRing(RR, 2, "xy").gens()
sage: eulers_method(5*x+y-5, 0, 1, 1/2, 1)
\[
\begin{array}{ccc}
  x & y & h*f(x,y) \\
  0 & 1 & -2.0 \\
  1/2 & -1.0 & -1.7 \\
  1 & -2.7 & -1.3 \\
\end{array}
\]

AUTHORS:
  • David Joyner

sage.calculus.desolvers.eulers_method_2x2(f, g, t0, x0, y0, h, t1, algorithm='table')

This implements Euler’s method for finding numerically the solution of the 1st order system of two ODEs

\[
\begin{align*}
x' &= f(t, x, y), x(t_0) = x_0 \\
y' &= g(t, x, y), y(t_0) = y_0.
\end{align*}
\]

The t column of the table increments from \( t_0 \) to \( t_1 \) by \( h \) (so \( \frac{t_1 - t_0}{h} \) must be an integer). In the x column, the new \( x \)-value equals the old \( x \)-value plus the corresponding entry in the next (third) column. In the y column, the new \( y \)-value equals the old \( y \)-value plus the corresponding entry in the next (last) column.

Note: This function is for pedagogical purposes only.

EXAMPLES:

```
sage: from sage.calculus.desolvers import eulers_method_2x2
sage: t, x, y = PolynomialRing(QQ,3,"txy").gens()
sage: f = x+y+t; g = x-y
sage: eulers_method_2x2(f,g, 0, 0, 0, 1/3, 1,algorithm="none")

[[0, 0, 0], [1/3, 0, 0], [2/3, 1/9, 0], [1, 10/27, 1/27], [4/3, 68/81, 4/27]]
```

```
sage: eulers_method_2x2(f,g, 0, 0, 0, 1/3, 1)

```
To numerically approximate $y(1)$, where $(1 + t^2)y'' + y' - y = 0$, $y(0) = 1$, $y'(0) = -1$, using 4 steps of Euler's method, first convert to a system: $y_1' = y_2$, $y_1(0) = 1$; $y_2' = \frac{y_1 - y_2}{1+t^2}$, $y_2(0) = -1$.

To numerically approximate $y(1)$, where $y'' + ty' + y = 0$, $y(0) = 1$, $y'(0) = 0$:

AUTHORS:
sage\_calculus\_desolvers.\_eulers\_method\_2x2\_plot(f, g, t0, x0, y0, h, t1)

Plot solution of ODE.

This plots the solution in the rectangle with sides \((\text{xrange}[0],\text{xrange}[1])\) and \((\text{yrange}[0],\text{yrange}[1])\), and plots using Euler’s method the numerical solution of the 1st order ODEs \(x' = f(t,x,y), x(a) = x_0, y' = g(t,x,y), y(a) = y_0\).

**Note:** This function is for pedagogical purposes only.

**EXAMPLES:**

The following example plots the solution to \(\theta'' + \sin(\theta) = 0, \theta(0) = \frac{3}{4}, \theta'(0) = 0\). Type \(P[0].\text{show()}\) to plot the solution, \((P[0]+P[1]).\text{show()}\) to plot \((t, \theta(t))\) and \((t, \theta'(t))\):

```
sage: from sage\_calculus\_desolvers import eulers\_method\_2x2\_plot
sage: f = lambda z : z[2]; g = lambda z : -\sin(z[1])
```

```
sage: P = eulers\_method\_2x2\_plot(f,g, 0.0, 0.75, 0.0, 0.1, 1.0)
```

```
sage: fricas\_desolve(de, dvar, ics, ivar)
Solve an ODE using FriCAS.

**EXAMPLES:**

```
sage: x = var('x')
sage: y = function('y')(x)
sage: desolve(diff(y,x) + y - 1, y, algorithm="fricas")
# optional -

\text{fricas}
_\text{C0}e^(-x) + 1
```

```
sage: desolve(diff(y,x) + y == y^3*sin(x), y, algorithm="fricas")
# optional -

\text{fricas}
-1/5*(2*cos(x)*y(x)^2 + 4*sin(x)*y(x)^2 - 5)*e^(-2*x)/y(x)^2
```

```
sage: fricas\_desolve\_system(des, dvars, ics, ivar)
Solve a system of first order ODEs using FriCAS.

**EXAMPLES:**

```
sage: t = var('t')
sage: x = function('x')(t)
sage: y = function('y')(t)
sage: de1 = diff(x,t) + y - 1 == 0
sage: de2 = diff(y,t) - x + 1 == 0
sage: desolve\_system([de1, de2], [x, y], algorithm="fricas")
# optional -

\text{fricas}
[x(t) == _\text{C0}\cos(t) + \cos(t)^2 + _\text{C1}\sin(t) + \sin(t)^2,
y(t) == -_\text{C1}\cos(t) + _\text{C0}\sin(t) + 1]
```

```
sage: desolve\_system([de1, de2], [x,y], [0,1,2], algorithm="fricas")
# optional -

\text{fricas}
x(t) == \cos(t)^2 + \sin(t)^2 - \sin(t), \ y(t) == \cos(t) + 1
```
2.20 Discrete Wavelet Transform

Wraps GSL’s `gsl_wavelet_transform_forward()` and `gsl_wavelet_transform_inverse()` and creates plot methods.

AUTHOR:
• Josh Kantor (2006-10-07) - initial version
• David Joyner (2006-10-09) - minor changes to docstrings and examples.

`sage.calculus.transforms.dwt.DWT(n, wavelet_type, wavelet_k)`

This function initializes an GSLDoubleArray of length n which can perform a discrete wavelet transform.

INPUT:
• n – a power of 2
• T – the data in the GSLDoubleArray must be real
• wavelet_type – the name of the type of wavelet, valid choices are:
  – 'daubechies'
  – 'daubechies_centered'
  – 'haar'
  – 'haar_centered'
  – 'bspline'
  – 'bspline_centered'

For daubechies wavelets, `wavelet_k` specifies a daubechie wavelet with $k/2$ vanishing moments. $k = 4, 6, \ldots, 20$ for $k$ even are the only ones implemented.

For Haar wavelets, `wavelet_k` must be 2.

For bspline wavelets, `wavelet_k` of 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order $(i, j)$ where `wavelet_k` is $100 * i + j$. The wavelet transform uses $J = \log_2(n)$ levels.

OUTPUT:
An array of the form $(s_{-1,0}, d_{0,0}, d_{1,0}, d_{1,1}, d_{2,0}, \ldots, d_{J-1,2^{J-1}-1})$ for $d_{j,k}$ the detail coefficients of level $j$. The centered forms align the coefficients of the sub-bands on edges.

EXAMPLES:

```
sage: a = WaveletTransform(128, 'daubechies', 4)
sage: for i in range(1, 11):
    ....:     a[i] = 1
    ....:     a[128-i] = 1
sage: a.plot().show(ymin=0)
sage: a.forward_transform()
sage: a.plot().show()
sage: a = WaveletTransform(128, 'haar', 2)
sage: for i in range(1, 11): a[i] = 1; a[128-i] = 1
sage: a.forward_transform()
sage: a.plot().show(ymin=0)
sage: a = WaveletTransform(128, 'bspline_centered', 103)
sage: for i in range(1, 11): a[i] = 1; a[100+i] = 1
```
This example gives a simple example of wavelet compression:

```python
sage: a = DWT(2048, 'daubechies', 6)
sage: for i in range(2048): a[i] = float(sin((i*5/2048)**2))
sage: a.plot().show()  # long time (7s on sage.math, 2011)
sage: a.forward_transform()
sage: for i in range(1800): a[2048-i-1] = 0
sage: a.backward_transform()
sage: a.plot().show()  # long time (7s on sage.math, 2011)
```

```python
class sage.calculus.transforms.dwt.DiscreteWaveletTransform
    Bases: GSLDoubleArray
    Discrete wavelet transform class.
    backward_transform()
    forward_transform()
    plot(xmin=None, xmax=None, **args)
```

```python
sage.calculus.transforms.dwt.WaveletTransform(n, wavelet_type, wavelet_k)
    This function initializes an GSLDoubleArray of length n which can perform a discrete wavelet transform.
    INPUT:
    • n – a power of 2
    • T – the data in the GSLDoubleArray must be real
    • wavelet_type – the name of the type of wavelet, valid choices are:
      - 'daubechies'
      - 'daubechies_centered'
      - 'haar'
      - 'haar_centered'
      - 'bspline'
      - 'bspline_centered'
    For daubechies wavelets, wavelet_k specifies a daubechies wavelet with $k/2$ vanishing moments. $k = 4, 6, ..., 20$ for $k$ even are the only ones implemented.
    For Haar wavelets, wavelet_k must be 2.
    For bspline wavelets, wavelet_k of 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order $(i,j)$ where wavelet_k is 100 * i + j. The wavelet transform uses $J = \log_2(n)$ levels.
    OUTPUT:
    An array of the form $(s_{-1,0}, d_{0,0}, d_{1,0}, d_{1,1}, d_{2,0}, ..., d_{J-2,2J-1-1})$ for $d_{j,k}$ the detail coefficients of level $j$. The centered forms align the coefficients of the sub-bands on edges.
    EXAMPLES:
```
sage: a = WaveletTransform(128, 'daubechies', 4)

sage: for i in range(1, 11):
....:   a[i] = 1
....:   a[128-i] = 1

sage: a.plot().show(ymin=0)
sage: a.forward_transform()
sage: a.plot().show()

sage: a = WaveletTransform(128, 'haar', 2)

sage: for i in range(1, 11):
....:   a[i] = 1; a[128-i] = 1

sage: a.plot().show(ymin=0)

sage: a = WaveletTransform(128, 'bspline_centered', 103)

sage: for i in range(1, 11):
....:   a[i] = 1; a[100+i] = 1

sage: a.forward_transform()

This example gives a simple example of wavelet compression:

sage: a = DWT(2048, 'daubechies', 6)

sage: for i in range(2048): a[i]=float(sin((i*5/2048)**2))

sage: a.plot().show() # long time (7s on sage.math, 2011)

sage: a.forward_transform()

sage: for i in range(1800): a[2048-i-1] = 0

sage: a.backward_transform()

sage: a.plot().show() # long time (7s on sage.math, 2011)

sage.calculus.transforms.dwt.is2pow(n)

## 2.21 Discrete Fourier Transforms

This file contains functions useful for computing discrete Fourier transforms and probability distribution functions for discrete random variables for sequences of elements of $\mathbb{Q}$ or $\mathbb{C}$, indexed by a range($N$), $\mathbb{Z}/N\mathbb{Z}$, an abelian group, the conjugacy classes of a permutation group, or the conjugacy classes of a matrix group.

This file implements:

- __eq__()
- __mul__ (for right multiplication by a scalar)
- plotting, printing – IndexedSequence.plot(), IndexedSequence.plot_histogram(), _repr_, __str__()
- dft – computes the discrete Fourier transform for the following cases:
  - a sequence (over $\mathbb{Q}$ or CyclotomicField) indexed by range($N$) or $\mathbb{Z}/N\mathbb{Z}$
  - a sequence (as above) indexed by a finite abelian group
  - a sequence (as above) indexed by a complete set of representatives of the conjugacy classes of a finite permutation group
  - a sequence (as above) indexed by a complete set of representatives of the conjugacy classes of a finite matrix group
- idft – computes the discrete Fourier transform for the following cases:
Symbolic Calculus, Release 10.0

- a sequence (over $\mathbb{Q}$ or CyclotomicField) indexed by $\text{range}(N)$ or $\mathbb{Z}/N\mathbb{Z}$
- dct, dst (for discrete Fourier/Cosine/Sine transform)
- convolution (in `IndexedSequence.convolution()` and `IndexedSequence.convolution_periodic()`)  
- fft, ifft – (fast Fourier transforms) wrapping GSL’s `gsl_fft_complex_forward()`, `gsl_fft_complex_inverse()`, using William Stein’s `FastFourierTransform()`
- dwt, idwt – (fast wavelet transforms) wrapping GSL’s `gsl_dwt_forward()`, `gsl_dwt_backward()` using Joshua Kantor’s `WaveletTransform()` class. Allows for wavelets of type:
  - “haar”
  - “daubechies”
  - “daubechies_centered”
  - “haar_centered”
  - “bspline”
  - “bspline_centered”

Todo:
- “filtered” DFTs
- more idfts
- more examples for probability, stats, theory of FTs

AUTHORS:
- David Joyner (2006-10)
- William Stein (2006-11) – fix many bugs

class `sage.calculus.transforms.dft.IndexedSequence(L, index_object)`
Bases: `SageObject`

An indexed sequence.

INPUT:
- L – A list
- index_object must be a Sage object with an `__iter__` method containing the same number of elements as `self`, which is a list of elements taken from a field.

`base_ring()`
This just returns the common parent $R$ of the $N$ list elements. In some applications (say, when computing the discrete Fourier transform, dft), it is more accurate to think of the base_ring as the group ring $\mathbb{Q}(\zeta_N)[R]$.

EXAMPLES:
```
sage: J = list(range(10))
sage: A = [1/10 for j in J]
sage: s = IndexedSequence(A,J)
sage: s.base_ring()
Rational Field
```
**convolution**(other)

Convolves two sequences of the same length (automatically expands the shortest one by extending it by 0 if they have different lengths).

If \( \{a_n\} \) and \( \{b_n\} \) are sequences indexed by \( (n = 0, 1, ..., N - 1) \), extended by zero for all \( n \) in \( \mathbb{Z} \), then the convolution is

\[
c_j = \sum_{i=0}^{N-1} a_i b_{j-i}.
\]

**INPUT:**

- **other** – a collection of elements of a ring with index set a finite abelian group (under +)

**OUTPUT:**

The Dirichlet convolution of self and other.

**EXAMPLES:**

```sage
sage: J = list(range(5))
sage: A = [ZZ(1) for i in J]
sage: B = [ZZ(1) for i in J]
sage: s = IndexedSequence(A,J)
sage: t = IndexedSequence(B,J)
sage: s.convolution(t)
[1, 2, 3, 4, 5, 4, 3, 2, 1]
```

**AUTHOR:** David Joyner (2006-09)

**convolution_periodic**(other)

Convolves two collections indexed by a `range(...)` of the same length (automatically expands the shortest one by extending it by 0 if they have different lengths).

If \( \{a_n\} \) and \( \{b_n\} \) are sequences indexed by \( (n = 0, 1, ..., N - 1) \), extended periodically for all \( n \) in \( \mathbb{Z} \), then the convolution is

\[
c_j = \sum_{i=0}^{N-1} a_i b_{j-i}.
\]

**INPUT:**

- **other** – a sequence of elements of \( C, R \) or \( F_q \)

**OUTPUT:**

The Dirichlet convolution of self and other.

**EXAMPLES:**

```sage
sage: I = list(range(5))
sage: A = [ZZ(1) for i in I]
sage: B = [ZZ(1) for i in I]
sage: s = IndexedSequence(A,I)
sage: t = IndexedSequence(B,I)
sage: s.convolution_periodic(t)
[5, 5, 5, 5, 5, 5, 5, 5, 5]
```

**AUTHOR:** David Joyner (2006-09)
Symbolic Calculus, Release 10.0

\texttt{dct()}

A discrete Cosine transform.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: J = list(range(5))
sage: A = [exp(-2*pi*i*I/5) for i in J]
sage: s = IndexedSequence(A,J)
sage: s.dct()
Indexed sequence: [0, 1/16*(sqrt(5) + I*sqrt(-2*sqrt(5) + 10) + ...]
indexed by [0, 1, 2, 3, 4]
\end{verbatim}

\texttt{dft(chi=<function IndexedSequence.<lambda> at 0x7f120eb001f0>)}

A discrete Fourier transform “over \( \mathbb{Q} \)” using exact \( N \)-th roots of unity.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: J = list(range(6))
sage: A = [ZZ(1) for i in J]
sage: s = IndexedSequence(A,J)
sage: s.dft(lambda x:x^2)
Indexed sequence: [6, 0, 0, 6, 0, 0]
indexed by [0, 1, 2, 3, 4, 5]
sage: s.dft()
Indexed sequence: [6, 0, 0, 0, 0, 0]
indexed by [0, 1, 2, 3, 4, 5]
sage: G = SymmetricGroup(3)
sage: J = G.conjugacy_classes_representatives()
sage: s = IndexedSequence([[1,2,3],J]) # 1,2,3 are the values of a class fcn on G
sage: s.dft() # the "scalar-valued Fourier transform" of this class fcn
Indexed sequence: [8, 2, 2]
indexed by [(), (1,2), (1,2,3)]
sage: J = AbelianGroup(2,[2,3],names='ab')
sage: s = IndexedSequence([[1,2,3,4,5,6],J])
sage: s.dft() # the precision of output is somewhat random and architecture-dependent.
Indexed sequence: [21.0000000000000, -2.99999999999997 - 1.73205080756885*I, -2.99999999999999 + 1.73205080756888*I, -9.00000000000000 + 0.00000000000000*I, 0.00000000000000 - 0.00000000000000*I, 0.00000000000000 + 1.73205080756885*I]
indexed by Multiplicative Abelian group isomorphic to C2 x C3
sage: J = CyclicPermutationGroup(6)
sage: s = IndexedSequence([[1,2,3,4,5,6],J])
sage: s.dft() # the precision of output is somewhat random and architecture-dependent.
Indexed sequence: [21.0000000000000, -2.99999999999997 - 1.73205080756885*I, -2.99999999999999 + 1.73205080756888*I, -9.00000000000000 + 0.00000000000000*I, 0.00000000000000 - 0.00000000000000*I, 0.00000000000000 + 1.73205080756885*I]
indexed by Cyclic group of order 6 as a permutation group
sage: p = 7; J = list(range(p)); A = [kronecker_symbol(j,p) for j in J]
sage: s = IndexedSequence(A,J)
\end{verbatim}
sage: Fs = s.dft()
sage: c = Fs.list()[1]; [x/c for x in Fs.list()]; s.list()
[0, 1, 1, -1, 1, -1, -1]
[0, 1, 1, -1, 1, -1, -1]

The DFT of the values of the quadratic residue symbol is itself, up to a constant factor (denoted c on the last line above).

Todo: Read the parent of the elements of S; if Q or C leave as is; if AbelianGroup, use abelian_group_dual; if some other implemented Group (permutation, matrix), call .characters() and test if the index list is the set of conjugacy classes.

dict()

Return a python dict of self where the keys are elements in the indexing set.

EXAMPLES:

sage: J = list(range(10))
sage: A = [1/10 for j in J]
sage: s = IndexedSequence(A,J)
sage: s.dict()
{0: 1/10, 1: 1/10, 2: 1/10, 3: 1/10, 4: 1/10, 5: 1/10, 6: 1/10, 7: 1/10, 8: 1/10, 9: 1/10}

dst()

A discrete Sine transform.

EXAMPLES:

sage: J = list(range(5))
sage: I = CC.0; pi = CC(pi)
sage: A = [exp(-2*pi*i*I/5) for i in J]
sage: s = IndexedSequence(A,J)
sage: s.dst()  # discrete sine
Indexed sequence: [0.000000000000000, 1.11022302462516e-16 - 2.50000000000000*I, ...
indexed by [0, 1, 2, 3, 4]

dwt(\text{other='haar', wavelet_k=2})

Wraps the gsl WaveletTransform.forward in dwt (written by Joshua Kantor). Assumes the length of the sample is a power of 2. Uses the GSL function gsl_wavelet_transform_forward().

INPUT:

\begin{itemize}
  \item other – the name of the type of wavelet; valid choices are:
    \begin{itemize}
      \item 'daubechies'
      \item 'daubechies_centered'
      \item 'haar' (default)
      \item 'haar_centered'
      \item 'bspline'
    \end{itemize}
\end{itemize}
The wavelet transform uses \( J = \log_2(n) \) levels.

**EXAMPLES:**

```python
sage: J = list(range(8))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.dwt()
sage: t  # slightly random output
Indexed sequence: [2.82842712474999, 0.000000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000]
indexed by [0, 1, 2, 3, 4, 5, 6, 7]
```

**fft()**

Wraps the `gsl` `FastFourierTransform.forward()` in `fft`.

If the length is a power of 2 then this automatically uses the radix2 method. If the number of sample points in the input is a power of 2 then the wrapper for the GSL function `gsl_fft_complex_radix2_forward()` is automatically called. Otherwise, `gsl_fft_complex_forward()` is used.

**EXAMPLES:**

```python
sage: J = list(range(5))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.fft(); t
Indexed sequence: [5.00000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000, 0.000000000000000]
indexed by [0, 1, 2, 3, 4]
```

**idft()**

A discrete inverse Fourier transform. Only works over \( \mathbb{Q} \).

**EXAMPLES:**

```python
sage: J = list(range(5))
sage: A = [ZZ(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: fs = s.dft(); fs
Indexed sequence: [5, 0, 0, 0, 0]
indexed by [0, 1, 2, 3, 4]
sage: it = fs.idft(); it
Indexed sequence: [1, 1, 1, 1]
indexed by [0, 1, 2, 3, 4]
sage: it == s
True
```
\texttt{idwt(\texttt{other='haar', wavelet_k=2})}

Implements the \texttt{gsl WaveletTransform.backward()} in \texttt{dwt}.

Assumes the length of the sample is a power of 2. Uses the GSL function \texttt{gsl_wavelet_transform_backward()}

**INPUT:**

- \texttt{other} – Must be one of the following:
  - "haar"
  - "daubechies"
  - "daubechies_centered"
  - "haar_centered"
  - "bspline"
  - "bspline_centered"

- \texttt{wavelet_k} – For daubechies wavelets, \texttt{wavelet_k} specifies a daubechies wavelet with \( k/2 \) vanishing moments. \( k = 4, 6, ..., 20 \) for \( k \) even are the only ones implemented.
  
  For Haar wavelets, \texttt{wavelet_k} must be 2.
  
  For bspline wavelets, \texttt{wavelet_k} equal to 103, 105, 202, 204, 206, 208, 301, 305, 307, 309 will give biorthogonal B-spline wavelets of order \((i, j)\) where \texttt{wavelet_k} equals 100 \( i + j \).

**EXAMPLES:**

```
sage: J = \texttt{list(range}(8))
sage: A = \texttt{[RR(1) for i in J]}
sage: s = \texttt{IndexedSequence(A, J)}
sage: t = s.\texttt{dwt()}
sage: t
\texttt{dwt() \# random arch dependent output}
Indexed sequence: [2.82842712474999, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000]
  indexed by [0, 1, 2, 3, 4, 5, 6, 7]
sage: t.\texttt{idwt()}
\texttt{idwt() \# random arch dependent output}
Indexed sequence: [1.000000000000000, 1.000000000000000, 1.000000000000000, 1.
\texttt{˓→}000000000000000, 1.000000000000000, 1.000000000000000, 1.000000000000000, 1.
\texttt{˓→}000000000000000]
  indexed by [0, 1, 2, 3, 4, 5, 6, 7]
sage: t.\texttt{idwt()} == s
True
sage: J = \texttt{list(range}(16))
sage: A = \texttt{[RR(1) for i in J]}
sage: s = \texttt{IndexedSequence(A, J)}
sage: t = s.\texttt{dwt("bspline", 103)}
sage: t
\texttt{dwt("bspline", 103) \# random arch dependent output}
Indexed sequence: [4.000000000000000, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000, 0.000000000000000, 0.000000000000000, 0.
\texttt{˓→}000000000000000]
  indexed by [0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```
ifft()

Implements the gsl FastFourierTransform.inverse in fft.

If the number of sample points in the input is a power of 2 then the wrapper for the GSL function gsl_fft_complex_radix2_inverse() is automatically called. Otherwise, gsl_fft_complex_inverse() is used.

EXAMPLES:

```python
sage: J = list(range(5))
sage: A = [RR(1) for i in J]
sage: s = IndexedSequence(A, J)
sage: t = s.fft(); t
Indexed sequence: [5.000000000000000000000000000000, 0.000000000000000000000000000000, 0.000000000000000000000000000000, 0.000000000000000000000000000000, 0.000000000000000000000000000000]
    indexed by [0, 1, 2, 3, 4]
sage: t.ifft()
Indexed sequence: [1.000000000000000000000000000000, 1.000000000000000000000000000000, 1.000000000000000000000000000000, 1.000000000000000000000000000000, 1.000000000000000000000000000000]
    indexed by [0, 1, 2, 3, 4]
sage: t.ifft() == s
1
```

index_object()

Return the indexing object.

EXAMPLES:

```python
sage: J = list(range(10))
sage: A = [1/10 for j in J]
sage: s = IndexedSequence(A, J)
sage: s.index_object()
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

list()

Return the list of self.

EXAMPLES:

```python
sage: J = list(range(10))
sage: A = [1/10 for j in J]
sage: s = IndexedSequence(A, J)
sage: s.list()
[1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10, 1/10]
```

plot()

Plot the points of the sequence.

Elements of the sequence are assumed to be real or from a finite field, with a real indexing set I = range(len(self)).

EXAMPLES:
Symbolic Calculus, Release 10.0

```python
sage: I = list(range(3))
sage: A = [ZZ(i^2)+1 for i in I]
sage: s = IndexedSequence(A,I)
sage: P = s.plot()
sage: show(P) # Not tested
```

```python
plot_histogram(clr=(0, 0, 1), eps=0.4)
```

Plot the histogram plot of the sequence.

The sequence is assumed to be real or from a finite field, with a real indexing set \(I\) coercible into \(R\).

Options are \(clr\), which is an RGB value, and \(eps\), which is the spacing between the bars.

**EXAMPLES:**

```python
sage: J = list(range(3))
sage: A = [ZZ(i^2)+1 for i in J]
sage: s = IndexedSequence(A,J)
sage: P = s.plot_histogram()
sage: show(P) # Not tested
```

## 2.22 Fast Fourier Transforms Using GSL

**AUTHORS:**

- William Stein (2006-9): initial file (radix2)
- D. Joyner (2006-10): Minor modifications (from radix2 to general case and some documentation).
- M. Hansen (2013-3): Fix radix2 backwards transformation

```python
sage.calculus.transforms.fft.FFT(size, base_ring=None)
```

Create an array for fast Fourier transform conversion using gsl.

**INPUT:**

- `size` – The size of the array
- `base_ring` – Unused (2013-03)

**EXAMPLES:**

We create an array of the desired size:

```python
sage: a = FastFourierTransform(8)
sage: a
[(0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0)]
```

Now, set the values of the array:

```python
sage: for i in range(8): a[i] = i + 1
sage: a
[(1.0, 0.0), (2.0, 0.0), (3.0, 0.0), (4.0, 0.0), (5.0, 0.0), (6.0, 0.0), (7.0, 0.0), (8.0, 0.0)]
```
We can perform the forward Fourier transform on the array:

```python
sage: a.forward_transform()
sage: a #abs tol 1e-2
[(36.0, 0.0), (-4.00, 9.65), (-4.0, 4.0), (-4.0, 1.65), (-4.0, 0.0), (-4.0, -1.65), ...
  →(-4.0, -4.0), (-4.0, -9.65)]
```

And backwards:

```python
sage: a.backward_transform()
sage: a #abs tol 1e-2
[(8.0, 0.0), (16.0, 0.0), (24.0, 0.0), (32.0, 0.0), (40.0, 0.0), (48.0, 0.0), (56.0, ...
  → 0.0), (64.0, 0.0)]
```

Other example:

```python
sage: a = FastFourierTransform(128)
sage: for i in range(1, 11):
      ....:   a[i] = 1
      ....:   a[128-i] = 1
sage: a[:6:2]
[(0.0, 0.0), (1.0, 0.0), (1.0, 0.0)]
```

```python
sage: a.plot().show(ymin=0)
sage: a.forward_transform()
sage: a.plot().show()
```

`sage.calculus.transforms.fft.FastFourierTransform(size, base_ring=None)`

Create an array for fast Fourier transform conversion using gsl.

**INPUT:**

- `size` – The size of the array
- `base_ring` – Unused (2013-03)

**EXAMPLES:**

We create an array of the desired size:

```python
sage: a = FastFourierTransform(8)
sage: a
[(0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), (0.0, 0.0), ...
  → (0.0, 0.0)]
```

Now, set the values of the array:

```python
sage: for i in range(8): a[i] = i + 1
sage: a
[(1.0, 0.0), (2.0, 0.0), (3.0, 0.0), (4.0, 0.0), (5.0, 0.0), (6.0, 0.0), (7.0, 0.0), ...
  → (8.0, 0.0)]
```

We can perform the forward Fourier transform on the array:

```python
sage: a.forward_transform()
sage: a #abs tol 1e-2
[(36.0, 0.0), (-4.00, 9.65), (-4.0, 4.0), (-4.0, 1.65), (-4.0, 0.0), (-4.0, -1.65), ...
  →(-4.0, -4.0), (-4.0, -9.65)]
```
And backwards:

```python
sage: a.backward_transform()
sage: a #abs tol 1e-2
[(8.0, 0.0), (16.0, 0.0), (24.0, 0.0), (32.0, 0.0), (40.0, 0.0), (48.0, 0.0), (56.0, 0.0), (64.0, 0.0)]
```

Other example:

```python
sage: a = FastFourierTransform(128)
sage: for i in range(1, 11):
    a[i] = 1
    a[128-i] = 1

sage: a[:6:2]
[(0.0, 0.0), (1.0, 0.0), (1.0, 0.0)]

sage: a.plot().show(ymin=0)
sage: a.forward_transform()
sage: a.plot().show()
```

```python
class sage.calculus.transforms.fft.FastFourierTransform_base
    Bases: object

class sage.calculus.transforms.fft.FastFourierTransform_complex
    Bases: FastFourierTransform_base

Wrapper class for GSL's fast Fourier transform.

backward_transform()

Compute the in-place backwards Fourier transform of this data using the Cooley-Tukey algorithm.

OUTPUT:

• None, the transformation is done in-place.

This is the same as inverse_transform() but lacks normalization so that f.forward_transform().backward_transform() == n*f. Where n is the size of the array.

EXAMPLES:

```python
sage: a = FastFourierTransform(125)
sage: b = FastFourierTransform(125)
for i in range(1, 60): a[i]=1
for i in range(1, 60): b[i]=1
sage: a.forward_transform()
sage: a.backward_transform()
```
(continues on next page)
Symbolic Calculus, Release 10.0

sage: a.backward_transform()
sage: (a.plot() + b.plot()).show(ymin=0)

forward_transform()  
Compute the in-place forward Fourier transform of this data using the Cooley-Tukey algorithm.

OUTPUT:
  • None, the transformation is done in-place.

If the number of sample points in the input is a power of 2 then the gsl function 
gsl_fft_complex_radix2_forward is automatically called. Otherwise, gsl_fft_complex_forward 
is called.

EXAMPLES:

inverse_transform()  
Compute the in-place inverse Fourier transform of this data using the Cooley-Tukey algorithm.

OUTPUT:
  • None, the transformation is done in-place.

If the number of sample points in the input is a power of 2 then the function 
gsl_fft_complex_radix2_inverse is automatically called. Otherwise, gsl_fft_complex_inverse 
is called.

This transform is normalized so f.forward_transform().inverse_transform() == f modulo 
round-off errors. See also backward_transform().

EXAMPLES:

Here we check it with a power of two:
```
sage: (a.plot()+b.plot())
Graphics object consisting of 256 graphics primitives

plot(style='rect', xmin=None, xmax=None, **args)
Plot a slice of the array.

- **style** -- Style of the plot, options are "rect" or "polar"
  - *rect* -- height represents real part, color represents imaginary part.
  - *polar* -- height represents absolute value, color represents argument.
- **xmin** -- The lower bound of the slice to plot. 0 by default.
- **xmax** -- The upper bound of the slice to plot. len(self) by default.
- **args** -- passed on to the line plotting function.

OUTPUT:
- A plot of the array.

EXAMPLES:
```
sage: a = FastFourierTransform(16)
sage: for i in range(16): a[i] = (random(),random())
sage: A = plot(a)
sage: B = plot(a, style='polar')
sage: type(A)
<class 'sage.plot.graphics.Graphics'>
sage: type(B)
<class 'sage.plot.graphics.Graphics'>
sage: a = FastFourierTransform(125)
sage: b = FastFourierTransform(125)
sage: for i in range(1, 60): a[i]=1
sage: for i in range(1, 60): b[i]=1
sage: a.forward_transform()
sage: a.inverse_transform()
sage: (a.plot()+b.plot())
Graphics object consisting of 250 graphics primitives
```

class sage.calculus.transforms.fft.FourierTransform_real
    Bases: object
2.23 Solving ODE numerically by GSL

AUTHORS:

- Joshua Kantor (2004-2006)
- Robert Marik (2010 - fixed docstrings)

```python
class sage.calculus.ode.PyFunctionWrapper
    Bases: object

class sage.calculus.ode.ode_solver(function=None, jacobian=None, h=0.01, error_abs=1e-10, error_rel=1e-10, a=False, a_dydt=False, scale_abs=False, algorithm='rkf45', y_0=None, t_span=None, params=[])
    Bases: object
```

`ode_solver()` is a class that wraps the GSL libraries ode solver routines. To use it, instantiate a class:

```python
sage: T = ode_solver()
```

To solve a system of the form \( \frac{dy_i}{dt} = f_i(t, y) \), you must supply a vector or tuple/list valued function `f` representing \( f_i \). The functions `f` and the Jacobian should have the form `foo(t, y)` or `foo(t, y, params)`. `params` which is optional allows for your function to depend on one or a tuple of parameters. Note if you use it, `params` must be a tuple even if it only has one component. For example, if you wanted to solve \( y'' + y = 0 \). You need to write it as a first order system:

```python
y_0' = y_1
y_1' = -y_0
```

In code:

```python
sage: f = lambda t, y: [y[1], -y[0]]
sage: T.function = f
```

For some algorithms, the Jacobian must be supplied as well. The form of this should be a function return a list of lists of the form `[ [df_1/dy_1, ..., df_1/dy_n], ..., [df_n/dy_1, ..., df_n/dy_n], [df_1/dt, ..., df_n/dt] ]`. There are examples below, if your Jacobian was the function `my_jacobian` you would do:

```python
sage: T.jacobian = my_jacobian # not tested, since it doesn't make sense to test
```

There are a variety of algorithms available for different types of systems. Possible algorithms are:

- `rkf45` - runga-kutta-felhberg (4,5)
- `rk2` - embedded runga-kutta (2,3)
- `rk4` - 4th order classical runga-kutta
- `rk8pd` - runga-kutta prince-dormand (8,9)
- `rk2imp` - implicit 2nd order runga-kutta at gaussian points
- `rk4imp` - implicit 4th order runga-kutta at gaussian points
- `bsimp` - implicit burlisch-stoer (requires Jacobian)
- `gear1` - M=1 implicit gear
• gear2 - M=2 implicit gear

The default algorithm is rkf45. If you instead wanted to use bsimp you would do:

```python
sage: T.algorithm="bsimp"
```

The user should supply initial conditions in \( y_0 \). For example if your initial conditions are \( y_0=1, y_1=1 \), do:

```python
sage: T.y_0=[1,1]
```

The actual solver is invoked by the method `ode_solve()`. It has arguments `t_span`, `y_0`, `num_points`, `params`. `y_0` must be supplied either as an argument or above by assignment. Params which are optional and only necessary if your system uses params can be supplied to ode_solve or by assignment.

\( t_{\text{span}} \) is the time interval on which to solve the ode. There are two ways to specify \( t_{\text{span}} \):

- If \texttt{num\_points} is not specified then the sequence \( t_{\text{span}} \) is used as the time points for the solution. Note that the first element \( t_{\text{span}}[0] \) is the initial time, where the initial condition \( y_0 \) is the specified solution, and subsequent elements are the ones where the solution is computed.
- If \texttt{num\_points} is specified and \( t_{\text{span}} \) is a sequence with just 2 elements, then these are the starting and ending times, and the solution will be computed at \texttt{num\_points} equally spaced points between \( t_{\text{span}}[0] \) and \( t_{\text{span}}[1] \). The initial condition is also included in the output so that \texttt{num\_points+1} total points are returned. E.g. if \( t_{\text{span}} = [0.0, 1.0] \) and \texttt{num\_points = 10}, then solution is returned at the 11 time points \([0.0, 0.1, 0.2, 0.3, 0.4, 0.5, 0.6, 0.7, 0.8, 0.9, 1.0]\).

(Note that if \texttt{num\_points} is specified and \( t_{\text{span}} \) is not length 2 then \( t_{\text{span}} \) are used as the time points and \texttt{num\_points} is ignored.)

Error is estimated via the expression \( D_i = \text{error\_abs}\cdot s_i + \text{error\_rel}\cdot (a\cdot|y_i| + a_{dydt}\cdot h\cdot |y_i'|) \). The user can specify \texttt{error\_abs} (1e-10 by default), \texttt{error\_rel} (1e-10 by default) \( a \) (1 by default), \( a_{dydt} \) (0 by default) and \( s_i \) (as \texttt{scaling\_abs} which should be a tuple and is 1 in all components by default). If you specify one of \( a \) or \( a_{dydt} \) you must specify the other. You may specify \( a \) and \( a_{dydt} \) without \texttt{scaling\_abs} (which will be taken \=1 be default). \( h \) is the initial step size which is (1e-2) by default.

\texttt{ode\_solve} solves the solution as a list of tuples of the form, \([ (t_0,\{y_1,...,y_n\}), (t_1,\{y_1,...,y_n\}), ..., (t_n,\{y_1,...,y_n\}) ]\).

This data is stored in the variable `solutions`:

```python
sage: T.solution
```

EXAMPLES:

Consider solving the Van der Pol oscillator \( x''(t) + u x'(t) x(t)^2 - 1 \) \( x(t) = 0 \) between \( t = 0 \) and \( t = 100 \). As a first order system it is \( x' = y, y' = -x + uy(1 - x^2) \). Let us take \( u = 10 \) and use initial conditions \( (x, y) = (1, 0) \) and use the runga-kutta prince-dormand algorithm.

```python
sage: def f_1(t,y,params):
....: return [y[1],-y[0]-params[0]*y[1]*(y[0]**2-1.0)]

sage: def j_1(t,y,params):
....: return [ [0.0, 1.0],[-2.0*params[0]*y[0]*y[1]-1.0,-params[0]*y[0]*y[0]-1.0], [0.0, 0.0] ]

sage: T=ode_solver()
sage: T.algorithm="rk8pd"
sage: T.function=f_1
```
Symbolic Calculus, Release 10.0

(continued from previous page)

```python
sage: T.jacobian=j_1
sage: T.ode_solve(y_0=[1,0],t_span=[0,100],params=[10.0],num_points=1000)
sage: import tempfile
sage: with tempfile.NamedTemporaryFile(suffix=".png") as f:
    ....:    T.plot_solution(filename=f.name)
```

The solver line is equivalent to:

```python
sage: T.ode_solve(y_0=[1,0],t_span=[x/10.0 for x in range(1000)],params = [10.0])
```

Let's try a system:

\[
\begin{align*}
y_0' &= y_1 y_2 \\
y_1' &= -y_0 y_2 \\
y_2' &= -.51 y_0 y_1
\end{align*}
\]

We will not use the jacobian this time and will change the error tolerances.

```python
sage: g_1= lambda t,y: [y[1]*y[2],-y[0]*y[2],-0.51*y[0]*y[1]]
sage: T.function=g_1
sage: T.y_0=[0,1,1]
sage: T.scale_abs=[1e-4,1e-4,1e-5]
sage: T.error_rel=1e-4
sage: T.ode_solve(t_span=[0,12],num_points=100)
```

By default `T.plot_solution()` plots the $y_0$, to plot general $y_i$ use:

```python
sage: with tempfile.NamedTemporaryFile(suffix=".png") as f:
    ....:    T.plot_solution(i=0, filename=f.name)
    ....:    T.plot_solution(i=1, filename=f.name)
    ....:    T.plot_solution(i=2, filename=f.name)
```

The method `interpolate_solution` will return a spline interpolation through the points found by the solver. By default $y_0$ is interpolated. You can interpolate $y_i$ through the keyword argument `i`.

```python
sage: f = T.interpolate_solution()
sage: plot(f,0,12).show()
sage: f = T.interpolate_solution(i=1)
sage: plot(f,0,12).show()
sage: f = T.interpolate_solution(i=2)
sage: plot(f,0,12).show()
sage: f(pi)
0.5379...
```

The solver attributes may also be set up using arguments to `ode_solver`. The previous example can be rewritten as:

```python
sage: T = ode_solver(g_1,y_0=[0,1,1],scale_abs=[1e-4,1e-4,1e-5],error_rel=1e-4,algorithm="rk8pd")
sage: T.ode_solve(t_span=[0,12],num_points=100)
sage: f = T.interpolate_solution()
sage: f(pi)
0.5379...
```
Unfortunately because Python functions are used, this solver is slow on systems that require many function evaluations. It is possible to pass a compiled function by deriving from the class `ode_system` and overloading `c_f` and `c_j` with C functions that specify the system. The following will work in the notebook:

```cython
# cython
import sage.calculus.ode
from sage.libs.gsl.all import *

cdef class van_der_pol(sage.calculus.ode.ode_system):
    cdef int c_f(self, double t, double *y, double *dydt):
        dydt[0]=y[1]
        dydt[1]=-y[0]-1000*y[1]*(y[0]*y[0]-1)
        return GSL_SUCCESS

cdef int c_j(self, double t, double *y, double *dfdy, double *dfdt):
    dfdy[0]=0
    dfdy[1]=1.0
    dfdy[2]=-2.0*1000*y[0]*y[1]-1.0
    dfdy[3]=-1000*(y[0]*y[0]-1.0)
    dfdt[0]=0
    dfdt[1]=0
    return GSL_SUCCESS
```

After executing the above block of code you can do the following (WARNING: the following is not automatically doctested):

```sage
sage: T = ode_solver()  # not tested
sage: T.algorithm = "bsimp"  # not tested
sage: vander = van_der_pol()  # not tested
sage: T.function = vander  # not tested
sage: T.ode_solve(y_0=[1, 0], t_span=[0, 2000], num_points=1000)  # not tested
...
sage: from tempfile import NamedTemporaryFile  # not tested
sage: with NamedTemporaryFile(suffix=".png") as f:  # not tested
    T.plot_solution(i=0, filename=f.name)
```

### interpolate_solution(i=0)

### ode_solve(t_span=False, y_0=False, num_points=False, params=[], **kwds)

### plot_solution(i=0, filename=None, interpolate=False, **kwds)

Plot a one dimensional projection of the solution.

**INPUT:**

- `i` – (non-negative integer) composant of the projection
- `filename` – (string or `None`) whether to plot the picture or save it in a file
- `interpolate` – whether to interpolate between the points of the discretized solution
- additional keywords are passed to the graphics primitive

**EXAMPLES:**

```sage
sage: T = ode_solver()
sage: T.function = lambda t,y: [cos(y[0]) * sin(t)]
```

(continues on next page)
sage: T.jacobian = lambda t, y: [-sin(y[0]) * sin(t)]
sage: T.ode_solve(y_0=[1], t_span=[0, 20], num_points=1000)
sage: T.plot_solution()

And with some options:

sage: T.plot_solution(color='red', axes_labels=['t', 'x(t)'])

class sage.calculus.ode.ode_system

2.24 Numerical Integration

AUTHORS:
    • Josh Kantor (2007-02): first version
    • William Stein (2007-02): rewrite of docs, conventions, etc.
    • Robert Bradshaw (2008-08): fast float integration
    • Jeroen Demeyer (2011-11-23): github issue #12047: return 0 when the integration interval is a point; reformat
documentation and add to the reference manual.

class sage.calculus.integration.PyFunctionWrapper
    Bases: object

class sage.calculus.integration.compiled_integrand
    Bases: object

sage.calculus.integration.monte_carlo_integral(func, xl, xu, calls, algorithm='plain', params=None)
    Integrate func by Monte-Carlo method.

    Integrate func over the dim-dimensional hypercubic region defined by the lower and upper limits in the arrays
    xl and xu, each of size dim.

    The integration uses a fixed number of function calls and obtains random sampling points using the default gsl’s
    random number generator.

    ALGORITHM: Uses calls to the GSL (GNU Scientific Library) C library. Documentation can be found in [GSL]
    chapter “Monte Carlo Integration”.

    INPUT:
        • func – the function to integrate
        • params – used to pass parameters to your function
        • xl – list of lower limits
        • xu – list of upper limits
        • calls – number of functions calls used
        • algorithm – valid choices are:
          – ‘plain’ – The plain Monte Carlo algorithm samples points randomly from the integration region to
            estimate the integral and its error.
          – ‘miser’ – The MISER algorithm of Press and Farrar is based on recursive stratified sampling
Symbolic Calculus, Release 10.0

'vgas' – The VEGAS algorithm of Lepage is based on importance sampling.

OUTPUT:

A tuple whose first component is the approximated integral and whose second component is an error estimate.

EXAMPLES:

```python
sage: x, y = SR.var('x,y')
sage: monte_carlo_integral(x*y, [0,0], [2,2], 10000)  # abs tol 0.1
(4.0, 0.0)
sage: integral(integral(x*y, (x,0,2)), (y,0,2))
4
```

An example with a parameter:

```python
sage: x, y, z = SR.var('x,y,z')
sage: monte_carlo_integral(x*y*z, [0,0], [2,2], 10000, params=[1.2])  # abs tol 0.1
(4.8, 0.0)
```

Integral of a constant:

```python
sage: monte_carlo_integral(3, [0,0], [2,2], 10000)  # abs tol 0.1
(12, 0.0)
```

Test different algorithms:

```python
sage: x, y, z = SR.var('x,y,z')
sage: f(x,y,z) = exp(z) * cos(x + sin(y))
sage: for algo in ['plain', 'miser', 'vegas']:  # abs tol 0.01
    ....:    monte_carlo_integral(f, [0,0,-1], [2,2,1], 10^6, algorithm=algo)
(1.06, 0.01)
(1.06, 0.01)
(1.06, 0.01)
```

Tests with Python functions:

```python
sage: def f(u, v):
    return u * v
sage: monte_carlo_integral(f, [0,0], [2,2], 10000)  # abs tol 0.1
(4.0, 0.0)
sage: monte_carlo_integral(lambda u,v: u*v, [0,0], [2,2], 10000)  # abs tol 0.1
(4.0, 0.0)
sage: def f(x1,x2,x3,x4):
    return x1*x2*x3*x4
sage: monte_carlo_integral(f, [0,0], [2,2], 10000, params=[0.6,2])  # abs tol 0.2
(4.8, 0.0)
```

AUTHORS:

- Vincent Delecroix
- Vincent Klein

```
sage.calculus.integration.numerical_integral(func, a=None, b=None, algorithm='qag', max_points=87, params=[], eps_abs=1e-06, eps_rel=1e-06, rule=6)
```

Return the numerical integral of the function on the interval from a to b and an error bound.

INPUT:
Symbolic Calculus, Release 10.0

- \(a, b\) – The interval of integration, specified as two numbers or as a tuple/list with the first element the lower bound and the second element the upper bound. Use \(+\text{Infinity}\) and \(-\text{Infinity}\) for plus or minus infinity.

- algorithm – valid choices are:
  - ‘qag’ – for an adaptive integration
  - ‘qags’ – for an adaptive integration with (integrable) singularities
  - ‘qng’ – for a non-adaptive Gauss-Kronrod (samples at a maximum of 87pts)

- max_points – sets the maximum number of sample points

- params – used to pass parameters to your function

- eps_abs, eps_rel – sets the absolute and relative error tolerances which satisfies the relation \(|\text{RESULT} - I| \leq \text{max(eps_abs, eps_rel * |I|)}\), where \(I = \int_a^b f(x) \, dx\).

- rule – This controls the Gauss-Kronrod rule used in the adaptive integration:
  - rule=1 – 15 point rule
  - rule=2 – 21 point rule
  - rule=3 – 31 point rule
  - rule=4 – 41 point rule
  - rule=5 – 51 point rule
  - rule=6 – 61 point rule

  Higher key values are more accurate for smooth functions but lower key values deal better with discontinuities.

**OUTPUT:**

A tuple whose first component is the answer and whose second component is an error estimate.

**REMARK:**

There is also a method \texttt{nintegral} on symbolic expressions that implements numerical integration using Maxima. It is potentially very useful for symbolic expressions.

**EXAMPLES:**

To integrate the function \(x^2\) from 0 to 1, we do

```
sage: numerical_integral(x^2, 0, 1, max_points=100)
(0.3333333333333333, 3.700743415417188e-15)
```

To integrate the function \(\sin(x)^3 + \sin(x)\) we do

```
sage: numerical_integral(sin(x)^3 + sin(x), 0, pi)
(3.333333333333333, 3.700743415417188e-14)
```

The input can be any callable:

```
sage: numerical_integral(lambda x: sin(x)^3 + sin(x), 0, pi)
(3.333333333333333, 3.700743415417188e-14)
```

We check this with a symbolic integration:

```
sage: (sin(x)^3+sin(x)).integral(x,0,pi)
10/3
```
If we want to change the error tolerances and Gauss rule used:

```
sage: f = x^2
sage: numerical_integral(f, 0, 1, max_points=200, eps_abs=1e-7, eps_rel=1e-7, rule=4)
(0.3333333333333333, 3.700743415417188e-15)
```

For a Python function with parameters:

```
sage: f(x,a) = 1/(a+x^2)
sage: [numerical_integral(f, 1, 2, max_points=100, params=[n]) for n in range(10)]
˓→ # random output (architecture and os dependent)
[(0.49999999999998657, 5.5511151231256336e-15),
 (0.32175055439664557, 3.572148736706477e-15),
 (0.2493098317249229, 2.667868435816325e-15),
 (0.1925308257611697, 2.137521557167464e-15),
 (0.16887527719832367, 1.780743683853337e-15),
 (0.13827545676349412, 1.53516958393151e-15),
 (0.12129975935702741, 1.3466978571966261e-15),
 (0.10806674191683065, 1.1997818507228991e-15),
 (0.0974544625548845, 1.0819617008493815e-15),
 (0.088750638050217577, 9.853305177356117e-16)]
```

```
sage: y = var('y')
sage: numerical_integral(x*y, 0, 1)
Traceback (most recent call last):
  ... ValueError: The function to be integrated depends on 2 variables (x, y),
and so cannot be integrated in one dimension. Please fix additional
variables with the 'params' argument
```

Note the parameters are always a tuple even if they have one component.

It is possible to integrate on infinite intervals as well by using +Infinity or -Infinity in the interval argument. For example:

```
sage: f = exp(-x)
sage: numerical_integral(f, 0, +Infinity)  # random output
(0.99999999999999957279, 1.842981129896553e-07)
```

Note the coercion to the real field RR, which prevents underflow:

```
sage: f = exp(-x**2)
sage: numerical_integral(f, -Infinity, +Infinity)  # random output
(1.7724538509060035, 3.429519216588979e-08)
```

One can integrate any real-valued callable function:

```
sage: numerical_integral(lambda x: abs(zeta(x)), [1.1,1.5])  # random output
(1.8488570602160455, 2.052643677492633e-14)
```

We can also numerically integrate symbolic expressions using either this function (which uses GSL) or the native integration (which uses Maxima):

```
sage: exp(-1/x).nintegral(x, 1, 2)  # via maxima
(0.50479221787318..., 5.60431942934407...e-15, 21, 0)
```

(continues on next page)
We can also integrate constant expressions:

```
sage: numerical_integral(2, 1, 7)
(12.0, 0.0)
```

If the interval of integration is a point, then the result is always zero (this makes sense within the Lebesgue theory of integration), see github issue #12047:

```
sage: numerical_integral(log, 0, 0)
(0.0, 0.0)
sage: numerical_integral(lambda x: sqrt(x), (-2.0, -2.0))
(0.0, 0.0)
```

In the presence of integrable singularity, the default adaptive method might fail and it is advised to use 'qags':

```
sage: b = 1.81759643554688
sage: F(x) = sqrt((-x + b)/((x - 1.0)*x))
sage: numerical_integral(F, 1, b)
(inf, nan)
sage: numerical_integral(F, 1, b, algorithm='qags')  # abs tol 1e-10
(1.1817104238446596, 3.387268288079781e-07)
```

ALGORITHM: Uses calls to the GSL (GNU Scientific Library) C library. Documentation can be found in [GSL] chapter "Numerical Integration".

### 2.25 Riemann Mapping

AUTHORS:

- Ethan Van Andel (2009-2011): initial version and upgrades
- Robert Bradshaw (2009): his “complex_plot” was adapted for plot_colored

Development supported by NSF award No. 0702939.

class `sage.calculus.riemann.Riemann_Map`

Bases: object

The `Riemann_Map` class computes an interior or exterior Riemann map, or an Ahlfors map of a region given by the supplied boundary curve(s) and center point. The class also provides various methods to evaluate, visualize, or extract data from the map.

A Riemann map conformally maps a simply connected region in the complex plane to the unit disc. The Ahlfors map does the same thing for multiply connected regions.
Note that all the methods are numerical. As a result all answers have some imprecision. Moreover, maps computed with small number of collocation points, or for unusually shaped regions, may be very inaccurate. Error computations for the ellipse can be found in the documentation for \texttt{analytic\_boundary()} and \texttt{analytic\_interior()}.

[BSV2010] provides an overview of the Riemann map and discusses the research that lead to the creation of this module.

**INPUT:**

- \( \mathbf{f}_s \) – A list of the boundaries of the region, given as complex-valued functions with domain 0 to \( 2 \times \pi \).
  Note that the outer boundary must be parameterized counter clockwise (i.e. \( e^{(I\times t)} \)) while the inner boundaries must be clockwise (i.e. \( e^{(-I\times t)} \)).
- \( \mathbf{fprimes} \) – A list of the derivatives of the boundary functions. Must be in the same order as \( \mathbf{f}_s \).
- \( \mathbf{a} \) – Complex, the center of the Riemann map. Will be mapped to the origin of the unit disc. Note that \( \mathbf{a} \) MUST be within the region in order for the results to be mathematically valid.

The following inputs may be passed in as named parameters:

- \( \mathbf{N} \) – integer (default: 500), the number of collocation points used to compute the map. More points will give more accurate results, especially near the boundaries, but will take longer to compute.
- \( \mathbf{exterior} \) – boolean (default: False), if set to True, the exterior map will be computed, mapping the exterior of the region to the exterior of the unit circle.

The following inputs may be passed as named parameters in unusual circumstances:

- \( \mathbf{ncorners} \) – integer (default: 4), if mapping a figure with (equally t-spaced) corners – corners that make a significant change in the direction of the boundary – better results may be sometimes obtained by accurately giving this parameter. Used to add the proper constant to the theta correspondence function.
- \( \mathbf{opp} \) – boolean (default: False), set to True in very rare cases where the theta correspondence function is off by \( \pi \), that is, if red is mapped left of the origin in the color plot.

**EXAMPLES:**

The unit circle identity map:

```
sage: f(t) = e^{I\times t}
sage: fprime(t) = I\times e^{I\times t}
sage: m = Riemann_Map([f], [fprime], 0)  # long time (4 sec)
sage: m.plot_colored() + m.plot_spiderweb()  # long time
Graphics object consisting of 22 graphics primitives
```

The exterior map for the unit circle:

```
sage: m = Riemann_Map([f], [fprime], 0, exterior=True)  # long time (4 sec)
sage: #spiderwebs are not supported for exterior maps
sage: m.plot_colored()  # long time
Graphics object consisting of 1 graphics primitive
```

The unit circle with a small hole:

```
sage: f(t) = e^{I\times t}
sage: fprime(t) = I\times e^{I\times t}
sage: hf(t) = 0.5\times e^{(-I\times t)}
sage: hfprime(t) = 0.5\times(-I\times e^{(-I\times t)})
sage: m = Riemann_Map([f, hf], [fprime, hfprime], 0.5 + 0.5*I)
```

(continues on next page)
Symbolic Calculus, Release 10.0

sage: #spiderweb and color plots cannot be added for multiply
sage: #connected regions. Instead we do this.
sage: m.plot_spiderweb(withcolor = True) # long time
Graphics object consisting of 3 graphics primitives

A square:

sage: ps = polygon_spline([(-1, -1), (1, -1), (1, 1), (-1, 1)])

sage: f = lambda t: ps.value(real(t))

sage: fprime = lambda t: ps.derivative(real(t))

sage: m = Riemann_Map([f], [fprime], 0.25, ncorners=4)

sage: m.plot_colored() + m.plot_spiderweb() # long time
Graphics object consisting of 22 graphics primitives

Compute rough error for this map:

sage: x = 0.75 # long time
sage: print("error = {}").format(m.inverse_riemann_map(m.riemann_map(x)) - x) # long time
error = (-0.000...+0.0016...j)

A fun, complex region for demonstration purposes:

sage: f(t) = e^(I*t)
sage: fp(t) = I*e^(I*t)
sage: ef1(t) = .2*e^(-I*t) +.4+.4*I
sage: ef1p(t) = -I*.2*e^(-I*t)
sage: ef2(t) = .2*e^(-I*t) -.4+.4*I
sage: ef2p(t) = -I*.2*e^(-I*t)
sage: pts = 
[(-.5,-.15-20/1000),(-.6,-.27-10/1000),(-.45,-.45),(0,-.65+10/1000),(.45,-.45),(.6,-.27-10/1000),(.5,-.15-10/1000)]
sage: pts.reverse()
sage: cs = complex_cubic_spline(pts)
sage: mf = lambda x:cs.value(x)
sage: mfprime = lambda x:cs.derivative(x)
sage: m = Riemann_Map([f,ef1,ef2,mf],[fp,ef1p,ef2p,mfprime],0,N = 400) # long time
sage: p = m.plot_colored(plot_points = 400) # long time

ALGORITHM:

This class computes the Riemann Map via the Szego kernel using an adaptation of the method described by [KT1986].

compute_on_grid(plot_range, x_points)

Compute the Riemann map on a grid of points.

Note that these points are complex of the form z = x + y*i.

INPUT:

• plot_range -- a tuple of the form [xmin, xmax, ymin, ymax]. If the value is [], the default plotting window of the map will be used.

• x_points -- int, the size of the grid in the x direction The number of points in the y_direction is scaled accordingly.

OUTPUT:
• a tuple containing \([z\_values, \; xmin, \; xmax, \; ymin, \; ymax]\) where \(z\_values\) is the evaluation of the map on the specified grid.

**EXAMPLES:**

**General usage:**

```python
sage: f(t) = e^{(I^*t)} - 0.5*e^{(-I^*t)}
sage: fprime(t) = I*e^{(I^*t)} + 0.5*I*e^{(-I^*t)}
```

```python
sage: m = Riemann_Map([f], [fprime], 0)
sage: data = m.compute_on_grid([],5)
sage: data[0][8,1]
(-0.0879...+0.9709...j)
```

**get_szego**

`get_szego(boundary=-1, absolute_value=False)`

Return a discretized version of the Szego kernel for each boundary function.

**INPUT:**

The following inputs may be passed in as named parameters:

- `boundary` – integer (default: -1) if < 0, `get_theta_points()` will return the points for all boundaries. If >= 0, `get_theta_points()` will return only the points for the boundary specified.

- `absolute_value` – boolean (default: False) if True, will return the absolute value of the (complex valued) Szego kernel instead of the kernel itself. Useful for plotting.

**OUTPUT:**

A list of points of the form `[t value, value of the Szego kernel at that t]`.

**EXAMPLES:**

**Generic use:**

```python
sage: f(t) = e^{(I^*t)} - 0.5*e^{(-I^*t)}
```

```python
sage: fprime(t) = I*e^{(I^*t)} + 0.5*I*e^{(-I^*t)}
```

```python
sage: m = Riemann_Map([f], [fprime], 0)
```

```python
sage: sz = m.get_szego(boundary=0)
sage: points = m.get_szego(absolute_value=True)
```

```python
sage: list_plot(points)
```

Extending the points by a spline:

```python
sage: s = spline(points)
sage: s(3*pi / 4)
0.0012158...
sage: plot(s,0,2*pi) # plot the kernel
```

The unit circle with a small hole:

```python
sage: f(t) = e^{(I^*t)}
```

```python
sage: fprime(t) = I*e^{(I^*t)}
```

```python
sage: hf(t) = 0.5*e^{(-I^*t)}
```

```python
sage: hfprime(t) = 0.5*-I*e^{(-I^*t)}
```

```python
sage: m = Riemann_Map([f, hf], [fprime, hfprime], 0.5 + 0.5*I)
```

Getting the szego for a specific boundary:
Symbolic Calculus, Release 10.0

sage: sz0 = m.get_szego(boundary=0)
sage: sz1 = m.get_szego(boundary=1)

get_theta_points(boundary=-1)

Return an array of points of the form \([t \text{ value}, \theta \text{ in } e^{i\theta}]\), that is, a discretized version of the theta/boundary correspondence function. In other words, a point in this array \([t_1, t_2]\) represents that

the boundary point given by \(f(t_1)\) is mapped to a point on the boundary of the unit circle given by \(e^{i\theta_2}\).

For multiply connected domains, get_theta_points will list the points for each boundary in the order that they were supplied.

INPUT:

The following input must all be passed in as named parameters:

- boundary – integer (default: -1) if < 0, get_theta_points() will return the points for all boundaries. If >= 0, get_theta_points() will return only the points for the boundary specified.

OUTPUT:

A list of points of the form \([t \text{ value}, \theta \text{ in } e^{i\theta}]\).

EXAMPLES:

Getting the list of points, extending it via a spline, getting the points for only the outside of a multiply connected domain:

sage: f(t) = e^{i*t} - 0.5*e^{-i*t}
sage: fprime(t) = i*e^{i*t} + 0.5*i*e^{-i*t}
sage: m = Riemann_Map([f], [fprime], 0)
sage: points = m.get_theta_points()
sage: list_plot(points)
Graphics object consisting of 1 graphics primitive

Extending the points by a spline:

sage: s = spline(points)
sage: s(3*pi / 4)
1.627660...

The unit circle with a small hole:

sage: f(t) = e^{i*t}
sage: fprime(t) = i*e^{i*t}
sage: hf(t) = 0.5*e^{-i*t}
sage: hfprime(t) = 0.5*-i*e^{-i*t}
sage: m = Riemann_Map([f, hf], [hf, hfprime], 0.5 + 0.5*i)

Getting the boundary correspondence for a specific boundary:

sage: tp0 = m.get_theta_points(boundary=0)
sage: tp1 = m.get_theta_points(boundary=1)

inverse_riemann_map(pt)

Return the inverse Riemann mapping of a point.

That is, given pt on the interior of the unit disc, inverse_riemann_map() will return the point on the original region that would be Riemann mapped to pt. Note that this method does not work for multiply connected domains.
INPUT:

- `pt` – A complex number (usually with absolute value <= 1) representing the point to be inverse mapped.

OUTPUT:

The point on the region that Riemann maps to the input point.

EXAMPLES:

Can work for different types of complex numbers:

```sage
f(t) = e^(I*t) - 0.5*e^(-I*t)
fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
m = Riemann_Map([f], [fprime], 0)
m.inverse_riemann_map(0.5 + sqrt(-0.5))
(0.406880...+0.3614702...j)
m.inverse_riemann_map(0.95)
(0.486319...-4.90019052...j)
m.inverse_riemann_map(0.25 - 0.3*I)
(0.1653244...-0.180936...j)
m.inverse_riemann_map(complex(-0.2, 0.5))
(-0.156280...+0.321819...j)
```

`plot_boundaries(plotjoined=True, rgbcolor=[0, 0, 0], thickness=1)`

Plots the boundaries of the region for the Riemann map. Note that this method DOES work for multiply connected domains.

INPUT:

The following inputs may be passed in as named parameters:

- `plotjoined` – boolean (default: True) If False, discrete points will be drawn; otherwise they will be connected by lines. In this case, if `plotjoined=False`, the points shown will be the original collocation points used to generate the Riemann map.

- `rgbcolor` – float array (default: [0, 0, 0]) the red-green-blue color of the boundary.

- `thickness` – positive float (default: 1) the thickness of the lines or points in the boundary.

EXAMPLES:

General usage:

```sage
f(t) = e^(I*t) - 0.5*e^(-I*t)
fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
m = Riemann_Map([f], [fprime], 0)
m.plot_boundaries()
```

Default plot:

```sage
m.plot_boundaries()
Graphics object consisting of 1 graphics primitive
```

Big blue collocation points:

```sage
m.plot_boundaries(plotjoined=False, rgbcolor=[0,0,1], thickness=6)
```

Graphics object consisting of 1 graphics primitive
plot_colored(plot_range=[], plot_points=100, interpolation='catrom', **options)

Generates a colored plot of the Riemann map. A red point on the colored plot corresponds to a red point on the unit disc.

INPUT:

The following inputs may be passed in as named parameters:

• plot_range – (default: []) list of 4 values (xmin, xmax, ymin, ymax). Declare if you do not want the plot to use the default range for the figure.

• plot_points – integer (default: 100), number of points to plot in the x direction. Points in the y direction are scaled accordingly. Note that very large values can cause this function to run slowly.

EXAMPLES:

Given a Riemann map m, general usage:

\[
\begin{align*}
sage: & f(t) = e^{i t} - 0.5 e^{-i t} \\
& fprime(t) = i e^{i t} + 0.5 i e^{-i t} \\
& m = Riemann_Map([f], [fprime], 0) \\
& m.plot_colored() \\
\end{align*}
\]

Graphics object consisting of 1 graphics primitive

Plot zoomed in on a specific spot:

\[
\begin{align*}
sage: & m.plot_colored(plot_range=[0,1,.25,.75]) \\
\end{align*}
\]

Graphics object consisting of 1 graphics primitive

High resolution plot:

\[
\begin{align*}
sage: & m.plot_colored(plot_points=1000) \quad \#\ long\ time\ (29s\ on\ sage.math,\ 2012) \\
\end{align*}
\]

Graphics object consisting of 1 graphics primitive

To generate the unit circle map, it’s helpful to see what the colors correspond to:

\[
\begin{align*}
sage: & f(t) = e^{i t} \\
& fprime(t) = i e^{i t} \\
& m = Riemann_Map([f], [fprime], 0, 1000) \\
& m.plot_colored() \\
\end{align*}
\]

Graphics object consisting of 1 graphics primitive

plot_spiderweb(spokes=16, circles=4, pts=32, linescale=0.99, rgbcolor=[0, 0, 0], thickness=1, plotjoined=True, withcolor=False, plot_points=200, min_mag=0.001, interpolation='catrom', **options)

Generate a traditional “spiderweb plot” of the Riemann map.

This shows what concentric circles and radial lines map to. The radial lines may exhibit erratic behavior near the boundary; if this occurs, decreasing linescale may mitigate the problem.

For multiply connected domains the spiderweb is by necessity generated using the forward mapping. This method is more computationally intensive. In addition, these spiderwebs cannot be added to color plots. Instead the withcolor option must be used.

In addition, spiderweb plots are not currently supported for exterior maps.

INPUT:

The following inputs may be passed in as named parameters:
Symbolic Calculus, Release 10.0

- **spokes** – integer (default: 16) the number of equally spaced radial lines to plot.
- **circles** – integer (default: 4) the number of equally spaced circles about the center to plot.
- **pts** – integer (default: 32) the number of points to plot. Each radial line is made by $1^\text{pts}$ points, each circle has $2^\text{pts}$ points. Note that high values may cause erratic behavior of the radial lines near the boundaries. - only for simply connected domains
- **linescale** – float between 0 and 1. Shrinks the radial lines away from the boundary to reduce erratic behavior. - only for simply connected domains
- **rgbcolor** – float array (default: [0,0,0]) the red-green-blue color of the spiderweb.
- **thickness** – positive float (default: 1) the thickness of the lines or points in the spiderweb.
- **plotjoined** – boolean (default: True) If False, discrete points will be drawn; otherwise they will be connected by lines. - only for simply connected domains
- **withcolor** – boolean (default: False) If True, The spiderweb will be overlaid on the basic color plot.
- **plot_points** – integer (default: 200) the size of the grid in the x direction The number of points in the y direction is scaled accordingly. Note that very large values can cause this function to run slowly. - only for multiply connected domains
- **min_mag** – float (default: 0.001) The magnitude cutoff below which spiderweb points are not drawn. This only applies to multiply connected domains and is designed to prevent “fuzz” at the edge of the domain. Some complicated multiply connected domains (particularly those with corners) may require a larger value to look clean outside.

**EXAMPLES:**

General usage:

```sage
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
```

Default plot:

```sage
sage: m.plot_spiderweb()
Graphics object consisting of 21 graphics primitives
```

Simplified plot with many discrete points:

```sage
sage: m.plot_spiderweb(spokes=4, circles=1, pts=400, linescale=0.95, plotjoined=False)
```

Plot with thick, red lines:

```sage
sage: m.plot_spiderweb(rgbcolor=[1,0,0], thickness=3)
```

To generate the unit circle map, it’s helpful to see what the original spiderweb looks like:

```sage
sage: f(t) = e^(I*t)
sage: fprime(t) = I*e^(I*t)
sage: m = Riemann_Map([f], [fprime], 0, 1000)
```
Symbolic Calculus, Release 10.0

(continued from previous page)

```python
sage: m.plot_spiderweb()
Graphics object consisting of 21 graphics primitives
```

A multiply connected region with corners. We set `min_mag` higher to remove “fuzz” outside the domain:

```python
sage: ps = polygon_spline([(-4,-2),(4,-2),(4,2),(-4,2)])
sage: z1 = lambda t: ps.value(t); z1p = lambda t: ps.derivative(t)
sage: z2(t) = -2+exp(-I*t); z2p(t) = -I*exp(-I*t)
sage: z3(t) = 2+exp(-I*t); z3p(t) = -I*exp(-I*t)
sage: m = Riemann_Map([z1,z2,z3],[z1p,z2p,z3p],0,ncorners=4) # long time
sage: p = m.plot_spiderweb(withcolor=True,plot_points=500, thickness = 2.0, min_mag=0.1) # long time
```

`riemann_map(pt)`

Return the Riemann mapping of a point.

That is, given `pt` on the interior of the mapped region, `riemann_map` will return the point on the unit disk that `pt` maps to. Note that this method only works for interior points; accuracy breaks down very close to the boundary. To get boundary correspondence, use `get_theta_points()`.

**INPUT:**

- `pt` – A complex number representing the point to be inverse mapped.

**OUTPUT:**

A complex number representing the point on the unit circle that the input point maps to.

**EXAMPLES:**

Can work for different types of complex numbers:

```python
sage: f(t) = e^(I*t) - 0.5*e^(-I*t)
sage: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
sage: m = Riemann_Map([f], [fprime], 0)
sage: m.riemann_map(0.25 + sqrt(-0.5))
(0.137514...+0.876696...j)
sage: I = CDF.gen()
sage: m.riemann_map(1.3*I)
(-1.56...e-05+0.989694...j)
sage: m.riemann_map(0.4)
(0.73324...+3.2...e-06j)
sage: m.riemann_map(complex(-3, 0.0001))
(1.405757...e-05+8.06...e-10j)
```

`sage.calculus.riemann.analytic_boundary(t, n, epsilon)`

Provides an exact (for `n` = infinity) Riemann boundary correspondence for the ellipse with axes 1 + `epsilon` and 1 - `epsilon`. The boundary is therefore given by `e^(I*t)+epsilon*e^(-I*t)`. It is primarily useful for testing the accuracy of the numerical `Riemann_Map`.

**INPUT:**

- `t` – The boundary parameter, from 0 to 2*pi
- `n` – integer - the number of terms to include. 10 is fairly accurate, 20 is very accurate.
- `epsilon` – float - the skew of the ellipse (0 is circular)
OUTPUT:
A theta value from 0 to 2*\pi, corresponding to the point on the circle \(e^{i\theta}\)

`sage.calculus.riemann.analytic_interior(z, n, epsilon)`
Provides a nearly exact computation of the Riemann Map of an interior point of the ellipse with axes \(1 + \epsilon\) and \(1 - \epsilon\). It is primarily useful for testing the accuracy of the numerical Riemann Map.

INPUT:
- \(z\) – complex - the point to be mapped.
- \(n\) – integer - the number of terms to include. 10 is fairly accurate, 20 is very accurate.

`sage.calculus.riemann.cauchy_kernel(t, args)`
Intermediate function for the integration in `analytic_interior()`.

INPUT:
- \(t\) – The boundary parameter, meant to be integrated over
- \(args\) – a tuple containing:
  - \(\epsilon\) – float - the skew of the ellipse (0 is circular)
  - \(z\) – complex - the point to be mapped.
  - \(n\) – integer - the number of terms to include. 10 is fairly accurate, 20 is very accurate.
  - \(part\) – will return the real ('r'), imaginary ('i') or complex ('c') value of the kernel

`sage.calculus.riemann.complex_to_rgb(z_values)`
Convert from a (Numpy) array of complex numbers to its corresponding matrix of RGB values. For internal use of `plot_colored()` only.

INPUT:
- \(z\_values\) – A Numpy array of complex numbers.

OUTPUT:
An \(N \times M \times 3\) floating point Numpy array \(X\), where \(X[i,j]\) is an (r,g,b) tuple.

EXAMPLES:
```python
sage: from sage.calculus.riemann import complex_to_rgb
sage: import numpy
sage: complex_to_rgb(numpy.array([[0, 1, 1000]], dtype = numpy.complex128))
array([[1. , 1. , 1. ],
       [1. , 0.05558355, 0.05558355],
       [0.17301243, 0. , 0. ]])
```

```
sage: complex_to_rgb(numpy.array([[0, 1j, 1000j]], dtype = numpy.complex128))
array([[1. , 1. , 1. ],
       [0.52779177, 1. , 0.05558355],
       [0.08650622, 0.17301243, 0. ]])
```

`sage.calculus.riemann.complex_to_spiderweb(z\_values, dr, dtheta, spokes, circles, rgbcolor, thickness, withcolor, min_mag)`
Converts a grid of complex numbers into a matrix containing rgb data for the Riemann spiderweb plot.

INPUT:
- \(z\_values\) – A grid of complex numbers, as a list of lists.
• `dr` – grid of floats, the r derivative of `z_values`. Used to determine precision.
• `dtheta` – grid of floats, the theta derivative of `z_values`. Used to determine precision.
• `spokes` – integer - the number of equally spaced radial lines to plot.
• `circles` – integer - the number of equally spaced circles about the center to plot.
• `rgbcolor` – float array - the red-green-blue color of the lines of the spiderweb.
• `thickness` – positive float - the thickness of the lines or points in the spiderweb.
• `withcolor` – boolean - If `True` the spiderweb will be overlaid on the basic color plot.
• `min_mag` – float - The magnitude cutoff below which spiderweb points are not drawn. This only applies to multiply connected domains and is designed to prevent “fuzz” at the edge of the domain. Some complicated multiply connected domains (particularly those with corners) may require a larger value to look clean outside.

OUTPUT:

An $N \times M \times 3$ floating point Numpy array $X$, where $X[i,j]$ is an (r,g,b) tuple.

EXAMPLES:

```python
sage: from sage.calculus.riemann import complex_to_spiderweb
sage: import numpy
sage: zval = numpy.array([[0, 1, 1000], [.2+.3j, 1, -.3j], [0, 0, 0]], dtype = numpy.complex128)
sage: deriv = numpy.array([[.1]], dtype = numpy.float64)
sage: complex_to_spiderweb(zval, deriv, deriv, 4, 4, [0, 0, 0], 1, False, 0.001)
array([[ 1.,  1.,  1.],
        [ 1.,  1.,  1.],
        [ 1.,  1.,  1.],
        [ 1.,  1.,  1.]],

[[ 1.,  1.,  1.],
[ 0.,  0.,  0.],
[ 1.,  1.,  1.],

[[ 1.,  1.,  1.],
[ 1.,  1.,  1.],
[ 1.,  1.,  1.]],

sage: complex_to_spiderweb(zval, deriv, deriv, 4, 4, [0, 0, 0], 1, True, 0.001)
array([[ 1. ,  1. ,  1. ],
        [ 1. ,  0.05558355,  0.05558355],
        [ 0.17301243,  0. ,  0. ],
        [ 0.96804683,  0.48044583],

[[ 0. ,  0. ,  0. ],
[ 0.77351965,  0.5470393 ,  1. ],

[[ 1. ,  1. ,  1. ],
[ 1. ,  1. ,  1. ],
[ 1. ,  1. ,  1. ]])])
```

`sage.calculus.riemann.get_derivatives(z_values, xstep, ystep)`

Computes the $r \cdot e^{\theta}$ form of derivatives from the grid of points. The derivatives are computed using
quick-and-dirty taylor expansion and assuming analyticity. As such get_derivatives is primarily intended to be used for comparisons in plot_spiderweb and not for applications that require great precision.

**INPUT:**

- **z_values** – The values for a complex function evaluated on a grid in the complex plane, usually from compute_on_grid.
- **xstep** – float, the spacing of the grid points in the real direction

**OUTPUT:**

- A tuple of arrays, [dr, dtheta], with each array 2 less in both dimensions than z_values
  - dr - the abs of the derivative of the function in the +r direction
  - dtheta - the rate of accumulation of angle in the +theta direction

**EXAMPLES:**

Standard usage with compute_on_grid:

```sage
defines: from sage.calculus.riemann import get_derivatives
defines: f(t) = e^(I*t) - 0.5*e^(-I*t)
defines: fprime(t) = I*e^(I*t) + 0.5*I*e^(-I*t)
defines: m = Riemann_Map([f], [fprime], 0)
defines: data = m.compute_on_grid([],19)
defines: xstep = (data[2]-data[1])/19
defines: ystep = (data[4]-data[3])/19
defines: dr, dtheta = get_derivatives(data[0],xstep,ystep)
defines: dr[8,8] 0.241...
defines: dtheta[5,5] 5.907...
```

### 2.26 Real Interpolation using GSL

**class** sage.calculus.interpolation.Spline

Bases: object

Create a spline interpolation object.

Given a list \( v \) of pairs, \( s = \text{spline}(v) \) is an object \( s \) such that \( s(x) \) is the value of the spline interpolation through the points in \( v \) at the point \( x \).

The values in \( v \) do not have to be sorted. Moreover, one can append values to \( v \), delete values from \( v \), or change values in \( v \), and the spline is recomputed.

**EXAMPLES:**

```sage
defines: S = spline([[0, 1], (1, 2), (4, 5), (5, 3)]); S
[[0, 1], (1, 2), (4, 5), (5, 3)]
defines: S(1.5)
defines: 2.76136363636...
```

Changing the points of the spline causes the spline to be recomputed:
Symbolic Calculus, Release 10.0

sage: S[0] = (0, 2); S
[(0, 2), (1, 2), (4, 5), (5, 3)]
sage: S(1.5)
2.507575757575...

We may delete interpolation points of the spline:
sage: del S[2]; S
[(0, 2), (1, 2), (5, 3)]
sage: S(1.5)
2.04296875

We may append to the list of interpolation points:
sage: S.append((4, 5)); S
[(0, 2), (1, 2), (5, 3), (4, 5)]
sage: S(1.5)
2.507575757575...

If we set the \( n \)-th interpolation point, where \( n \) is larger than \texttt{len}(S), then points \((0, 0)\) will be inserted between the interpolation points and the point to be added:
sage: S[6] = (6, 3); S
[(0, 2), (1, 2), (5, 3), (4, 5), (0, 0), (0, 0), (6, 3)]

This example is in the GSL documentation:
sage: v = [(i + sin(i)/2, i+cos(i^2)) for i in range(10)]
sage: s = spline(v)
sage: show(point(v) + plot(s,0,9, hue=.8))

We compute the area underneath the spline:
sage: s.definite_integral(0, 9)
41.196516041067...

The definite integral is additive:
sage: s.definite_integral(0, 4) + s.definite_integral(4, 9)
41.196516041067...

Switching the order of the bounds changes the sign of the integral:
sage: s.definite_integral(9, 0)
-41.196516041067...

We compute the first and second-order derivatives at a few points:
sage: s.derivative(5)
-0.16230085261803...
sage: s.derivative(6)
0.20997986285714...
sage: s.derivative(5, order=2)
-3.08747074561380...

(continues on next page)
Only the first two derivatives are supported:

```
sage: s.derivative(4, order=3)
Traceback (most recent call last):
...
ValueError: Order of derivative must be 1 or 2.
```

 append(xy)

**EXAMPLES:**

```
sage: S = spline([(1,1), (2,3), (4,5)]); S.append((5,7)); S
[(1, 1), (2, 3), (4, 5), (5, 7)]
```

The spline is recomputed when points are appended (github issue #13519):

```
sage: S = spline([(1,1), (2,3), (4,5)]); S
[(1, 1), (2, 3), (4, 5)]
sage: S(3)
4.25
sage: S.append((5, 5)); S
[(1, 1), (2, 3), (4, 5), (5, 5)]
sage: S(3)
4.375
```

definite_integral(a, b)

Value of the definite integral between \( a \) and \( b \).

**INPUT:**

- \( a \) – Lower bound for the integral.
- \( b \) – Upper bound for the integral.

**EXAMPLES:**

We draw a cubic spline through three points and compute the area underneath the curve:

```
sage: s = spline([(0, 0), (1, 3), (2, 0)])
sage: s.definite_integral(0, 2)
3.75
sage: s.definite_integral(0, 1)
1.875
sage: s.definite_integral(0, 1) + s.definite_integral(1, 2)
3.75
sage: s.definite_integral(2, 0)
-3.75
```

derivative(x, order=1)

Value of the first or second derivative of the spline at \( x \).

**INPUT:**

- \( x \) – value at which to evaluate the derivative.
• order (default: 1) – order of the derivative. Must be 1 or 2.

EXAMPLES:

We draw a cubic spline through three points and compute the derivatives:

```
sage: s = spline([(0, 0), (2, 3), (4, 0)])
sage: s.derivative(0)
2.25
sage: s.derivative(2)
0.0
sage: s.derivative(4)
-2.25
sage: s.derivative(1, order=2)
-1.125
sage: s.derivative(3, order=2)
-1.125
```

list()

Underlying list of points that this spline goes through.

EXAMPLES:

```
sage: S = spline([(1,1), (2,3), (4,5)]); S.list()
[(1, 1), (2, 3), (4, 5)]

This is a copy of the list, not a reference (github issue #13530):

```
sage: S = spline([(1,1), (2,3), (4,5)])
sage: L = S.list(); L
[(1, 1), (2, 3), (4, 5)]
sage: L[2] = (3, 2)
sage: L
[(1, 1), (2, 3), (3, 2)]
sage: S.list()
[(1, 1), (2, 3), (4, 5)]
```

sage.calculus.interpolation.spline
alias of Spline

## 2.27 Complex Interpolation

AUTHORS:

• Ethan Van Andel (2009): initial version

Development supported by NSF award No. 0702939.

class sage.calculus.interpolators.CCSpline

Bases: object

A CCSpline object contains a cubic interpolation of a figure in the complex plane.

EXAMPLES:

A simple square:
Symbolic Calculus, Release 10.0

```
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: cs = complex_cubic_spline(pts)
sage: cs.value(0)
(-1-1j)
sage: cs.derivative(0)
(0.9549296...-0.9549296...j)
```

**derivative**

Return the derivative (speed and direction of the curve) of a given point from the parameter \( t \).

**INPUT:**
- \( t \) – double, the parameter value for the parameterized curve, between 0 and 2*\( \pi \).

**OUTPUT:**
A complex number representing the derivative at the point on the figure corresponding to the input \( t \).

**EXAMPLES:**
```
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: cs = complex_cubic_spline(pts)
sage: cs.derivative(3 / 5)
(1.40578892327...-0.225417136326...j)
sage: cs.derivative(0) - cs.derivative(2 * pi)
0j
sage: cs.derivative(-6)
(2.52047692949...-1.89392588310...j)
```

**value**

Return the location of a given point from the parameter \( t \).

**INPUT:**
- \( t \) – double, the parameter value for the parameterized curve, between 0 and 2*\( \pi \).

**OUTPUT:**
A complex number representing the point on the figure corresponding to the input \( t \).

**EXAMPLES:**
```
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: cs = complex_cubic_spline(pts)
sage: cs.value(4 / 7)
(-0.303961332787...-1.34716728183...j)
sage: cs.value(0) - cs.value(2*pi)
0j
sage: cs.value(-2.73452)
(0.934561222231...+0.881366116402...j)
```

**class** `sage.calculus.interpolators.PSpline`

Bases: object

A CCSpline object contains a polygon interpolation of a figure in the complex plane.

**EXAMPLES:**
A simple square:
```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.value(0)
(-1-1j)
sage: ps.derivative(0)
(1.27323954...+0j)
```

**derivative(t)**

Return the derivative (speed and direction of the curve) of a given point from the parameter t.

**INPUT:**

- t – double, the parameter value for the parameterized curve, between 0 and 2*pi.

**OUTPUT:**

A complex number representing the derivative at the point on the polygon corresponding to the input t.

**EXAMPLES:**

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.derivative(1 / 3)
(1.27323954473...+0j)
sage: ps.derivative(0) - ps.derivative(2*pi)
0j
sage: ps.derivative(10)
(-1.27323954473...+0j)
```

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.value(.5)
(-0.363380227632...-1j)
sage: ps.value(0) - ps.value(2*pi)
0j
sage: ps.value(10)
(0.26760455264...+1j)
```

**value(t)**

Return the derivative (speed and direction of the curve) of a given point from the parameter t.

**INPUT:**

- t – double, the parameter value for the parameterized curve, between 0 and 2*pi.

**OUTPUT:**

A complex number representing the point on the polygon corresponding to the input t.

**EXAMPLES:**

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: ps.value(.5)
(-0.363380227632...-1j)
sage: ps.value(0) - ps.value(2*pi)
0j
sage: ps.value(10)
(0.26760455264...+1j)
```

`sage.calculus.interpolators.complex_cubic_spline(pts)`

Creates a cubic spline interpolated figure from a set of complex or (x, y) points. The figure will be a parametric curve from 0 to 2*pi. The returned values will be complex, not (x, y).

**INPUT:**

- pts A list or array of complex numbers, or tuples of the form (x, y).
### EXAMPLES:

A simple square:

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: cs = complex_cubic_spline(pts)
sage: fx = lambda x: cs.value(x).real
sage: fy = lambda x: cs.value(x).imag
sage: show(parametric_plot((fx, fy), (0, 2*pi)))
sage: m = Riemann_Map([lambda x: cs.value(real(x))], [lambda x: cs.
˓derivative(real(x))], 0)
sage: show(m.plot_colored() + m.plot_spiderweb())
```

Polygon approximation of a circle:

```python
sage: pts = [e^(I*t / 25) for t in range(25)]
sage: cs = complex_cubic_spline(pts)
sage: cs.derivative(2)
(-0.0497765406583...+0.151095006434...j)
sage.calculus.interpolators.polygon_spline(pts)
```

Creates a polygon from a set of complex or \((x, y)\) points. The polygon will be a parametric curve from 0 to \(2\pi\). The returned values will be complex, not \((x, y)\).

**INPUT:**

- `pts` – A list or array of complex numbers of tuples of the form \((x, y)\).

**EXAMPLES:**

A simple square:

```python
sage: pts = [(-1, -1), (1, -1), (1, 1), (-1, 1)]
sage: ps = polygon_spline(pts)
sage: fx = lambda x: ps.value(x).real
sage: fy = lambda x: ps.value(x).imag
sage: show(parametric_plot((fx, fy), (0, 2*pi)))
sage: m = Riemann_Map([lambda x: ps.value(real(x))], [lambda x: ps.
˓derivative(real(x))], 0)
sage: show(m.plot_colored() + m.plot_spiderweb())
```

Polygon approximation of a circle:

```python
sage: pts = [e^(I*t / 25) for t in range(25)]
sage: ps = polygon_spline(pts)
sage: ps.derivative(2)
(-0.0470303661...+0.1520363883...j)
```
## 2.28 Calculus functions

sage.calculus.functions.jacobian(functions, variables)

Return the Jacobian matrix, which is the matrix of partial derivatives in which the i,j entry of the Jacobian matrix is the partial derivative \( \text{diff}(\text{functions}[i], \text{variables}[j]) \).

**EXAMPLES:**

```
sage: x,y = var('x,y')
sage: g=x^2-2*x*y
sage: jacobian(g, (x,y))
\[2*x - 2*y  -2*x\]
```

The Jacobian of the Jacobian should give us the “second derivative”, which is the Hessian matrix:

```
sage: jacobian(jacobian(g, (x,y)), (x,y))
\[ 2 -2\]
\[-2 0\]
```

```
sage: g.hessian()
\[ 2 -2\]
\[-2 0\]
```

```
sage: f=(x^3*sin(y), cos(x)*sin(y), exp(x))
sage: jacobian(f, (x,y))
\[ 3*x^2*sin(y) x^3*cos(y)\]
\[ -sin(x)*sin(y) cos(x)*cos(y)\]
\[ e^x 0\]
```

```
sage: jacobian(f, (y,x))
\[ x^3*cos(y) 3*x^2*sin(y)\]
\[ cos(x)*cos(y) -sin(x)*sin(y)\]
\[ 0 e^x\]
```

sage.calculus.functions.wronskian(*args)

Return the Wronskian of the provided functions, differentiating with respect to the given variable.

If no variable is provided, \( \text{diff}(f) \) is called for each function \( f \).

\( \text{wronskian}(f_1,\ldots,f_n, x) \) returns the Wronskian of \( f_1,\ldots,f_n \), with derivatives taken with respect to \( x \).

\( \text{wronskian}(f_1,\ldots,f_n) \) returns the Wronskian of \( f_1,\ldots,f_n \) where \( k \)‘th derivatives are computed by doing \( \text{derivative}(k) \) on each function.

The Wronskian of a list of functions is a determinant of derivatives. The nth row (starting from 0) is a list of the nth derivatives of the given functions.

For two functions:

\[
W(f, g) = \det \begin{vmatrix} f & g \\ f' & g' \end{vmatrix} = f^*g' - g^*f'.
\]

**EXAMPLES:**

```
sage: wronskian(e^x, x^2)
-x^2*e^x + 2*x*e^x
```

(continues on next page)
If your functions are in a list, you can use * to turn them into arguments:

```
sage: wronskian(*[x^k for k in range(1, 5)])
12*x^4
```

If you want to use 'x' as one of the functions in the Wronskian, you can't put it last or it will be interpreted as the variable with respect to which we differentiate. There are several ways to get around this.

Two-by-two Wronskian of \(\sin(x)\) and \(e^x\):

```
sage: wronskian(sin(x), e^x, x)
-cos(x)*e^x + e^x*sin(x)
```

Or don't put x last:

```
sage: wronskian(x, sin(x), e^x)
(cos(x)*e^x + e^x*sin(x))*x - 2*e^x*sin(x)
```

Example where one of the functions is constant:

```
sage: wronskian(1, e^(-x), e^(2*x))
-6*e^x
```

REFERENCES:

AUTHORS:

- Dan Drake (2008-03-12)

# 2.29 Symbolic variables

`sage.calculus.var.clear_vars()`

Delete all 1-letter symbolic variables that are predefined at startup of Sage.

Any one-letter global variables that are not symbolic variables are not cleared.

EXAMPLES:

```
sage: var('x y z')
(x, y, z)
sage: (x+y)^z
(x + y)^z
sage: k = 15
sage: clear_vars()
sage: (x+y)^z
Traceback (most recent call last):  
```
sage: expand((e + i)^2)
\text{\texttt{e}}^2 + 2*I*e - 1

sage: k
15

\texttt{sage.calculus.var.function}(s, **\texttt{kwds})

Create a formal symbolic function with the name \texttt{s}.

\textbf{INPUT:}

- \texttt{nargs=0} - number of arguments the function accepts, defaults to variable number of arguments, or 0
- \texttt{latex\_name} - name used when printing in latex mode
- \texttt{conversions} - a dictionary specifying names of this function in other systems, this is used by the interfaces internally during conversion
- \texttt{eval\_func} - method used for automatic evaluation
- \texttt{evalf\_func} - method used for numeric evaluation
- \texttt{evalf\_params\_first} - bool to indicate if parameters should be evaluated numerically before calling the custom \texttt{evalf} function
- \texttt{conjugate\_func} - method used for complex conjugation
- \texttt{real\_part\_func} - method used when taking real parts
- \texttt{imag\_part\_func} - method used when taking imaginary parts
- \texttt{derivative\_func} - method to be used for (partial) derivation This method should take a keyword argument \texttt{deriv\_param} specifying the index of the argument to differentiate w.r.t
- \texttt{tderivative\_func} - method to be used for derivatives
- \texttt{power\_func} - method used when taking powers This method should take a keyword argument \texttt{power\_param} specifying the exponent
- \texttt{series\_func} - method used for series expansion This method should expect keyword arguments - \texttt{order} - order for the expansion to be computed - \texttt{var} - variable to expand w.r.t. - \texttt{at} - expand at this value
- \texttt{print\_func} - method for custom printing
- \texttt{print\_latex\_func} - method for custom printing in latex mode

Note that custom methods must be instance methods, i.e., expect the instance of the symbolic function as the first argument.

\textbf{Note:} The new function is both returned and automatically injected into the global namespace. If you use this function in library code, it is better to use \texttt{sage.symbolic.function\_factory.function}, since it will not touch the global namespace.

\textbf{EXAMPLES:}

We create a formal function called \texttt{supersin}

\texttt{sage: function('supersin')}
supersin
We can immediately use supersin in symbolic expressions:

```
sage: y, z, A = var('y z A')
sage: supersin(y+z) + A^3
A^3 + supersin(y + z)
```

We can define other functions in terms of supersin:

```
sage: g(x,y) = supersin(x)^2 + sin(y/2)
sage: g
(x, y) |--> supersin(x)^2 + sin(1/2*y)
sage: g.diff(y)
(x, y) |--> 1/2*cos(1/2*y)
sage: k = g.diff(x); k
(x, y) |--> 2*supersin(x)*diff(supersin(x), x)
```

We create a formal function of one variable, write down an expression that involves first and second derivatives, and extract off coefficients:

```
sage: r, kappa = var('r,kappa')
sage: psi = function('psi', nargs=1)(r); psi
psi(r)
sage: g = 1/r^2*(2*r*psi.derivative(r,1) + r^2*psi.derivative(r,2)); g
(r^2*diff(psi(r), r, r) + 2*r*diff(psi(r), r))/r^2
sage: g.expand()
2*diff(psi(r), r)/r + diff(psi(r), r, r)
sage: g.coefficient(psi.derivative(r,2))
1
sage: g.coefficient(psi.derivative(r,1))
2/r
```

Custom typesetting of symbolic functions in LaTeX, either using latex_name keyword:

```
sage: function('riemann', latex_name=r'\mathcal{R}')
riemann
sage: latex(riemann(x))
\mathcal{R}(x)
```

or passing a custom callable function that returns a latex expression:

```
sage: mu,nu = var('mu,nu')
sage: def my_latex_print(self, *args):
    return r'\psi_{%s}'%(\', '.join(map(latex, args)))
sage: function('psi', print_latex_func=my_latex_print)
psi
sage: latex(psi(mu,nu))
\psi_{\mu, \nu}
```

Defining custom methods for automatic or numeric evaluation, derivation, conjugation, etc. is supported:

```
sage: def ev(self, x):
    return 2*x
sage: foo = function("foo", nargs=1, eval_func=ev)
sage: foo(x)
2*x
```

(continues on next page)
Symbolic Calculus, Release 10.0

sage: foo = function("foo", nargs=1, eval_func=lambda self, x: 5)
sage: foo(x)
5
sage: def ef(self, x): pass
sage: bar = function("bar", nargs=1, eval_func=ef)
sage: bar(x)
bar(x)

sage: def evalf_f(self, x, parent=None, algorithm=None): return 6
sage: foo = function("foo", nargs=1, evalf_func=evalf_f)
sage: foo(x)
foo(x)
sage: foo(x).n()
6

sage: foo = function("foo", nargs=1, conjugate_func=ev)
sage: foo(x).conjugate()
2*x

sage: def deriv(self, *args,**kwds): print("{} {}").format(args, kwds)); return
˓→args[kwds['diff_param']]**2
sage: foo = function("foo", nargs=2, derivative_func=deriv)
sage: foo(x,y).derivative(y)
(x, y) {'diff_param': 1}
y^2

sage: def pow(self, x, power_param=None): print("{} {}")
˓→x*power_param
sage: foo = function("foo", nargs=1, power_func=pow)
sage: foo(y)**(x+y)
y^x^2 + y + y
(x + y)^y

sage: from pprint import pformat
sage: def expand(self, *args, **kwds):
˓→print("{} {}".format(args, pformat(kwds)))
˓→return sum(args[0]**i for i in range(kwds['order']))
sage: foo = function("foo", nargs=1, series_func=expand)
sage: foo(y).series(y, 5)
(y,) {'at': 0, 'options': 0, 'order': 5, 'var': y}
y^4 + y^3 + y^2 + y + 1

sage: def my_print(self, *args):
˓→return "my args are: " + ', '.join(map(repr, args))
sage: foo = function('t', nargs=2, print_func=my_print)
sage: foo(x,y^z)
my args are: x, y^z

sage: latex(foo(x,y^z))
t\left(x, y^{z}\right)
sage: foo = function('t', nargs=2, print_latex_func=my_print)
sage: foo(x,y^z)
t(x, y^z)
sage: latex(foo(x,y^z))
my args are: x, y^z
sage: foo = function('t', nargs=2, latex_name='foo')
sage: latex(foo(x,y^z))
foo\left(x, y^{z}\right)

Chain rule:

sage: def print_args(self, *args, **kwds): print("args: ",format(args)); print("kwds: ",format(kwds)); return args[0]
sage: foo = function('t', nargs=2, tderivative_func=print_args)
sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {'diff_param': 0}

sage: foo = function('t', nargs=2, derivative_func=print_args)
sage: foo(x,x).derivative(x)
args: (x, x)
kwds: {'diff_param': 1}
2*x

Since Sage 4.0, basic arithmetic with unevaluated functions is no longer supported:

sage: x = var('x')
sage: f = function('f')
sage: 2*f
Traceback (most recent call last):
...TypeError: unsupported operand parent(s) for *: 'Integer Ring' and '<class 'sage.symbolic.function_factory.NewSymbolicFunction'>'

You now need to evaluate the function in order to do the arithmetic:

sage: 2*f(x)
2*f(x)

Since Sage 4.0, you need to use substitute_function() to replace all occurrences of a function with another:

sage: var('a, b')
(a, b)
sage: cr = function('cr')
sage: f = cr(a)
sage: g = f.diff(a).integral(b)
sage: g
b*diff(cr(a), a)
sage: g.substitute_function(cr, cos)
-b*sin(a)
sage: g.substitute_function(cr, (sin(x) + cos(x)).function(x))
b*(cos(a) - sin(a))
sage.calculus.var.var(*args, **kwds)

Create a symbolic variable with the name $s$.

**INPUT:**

- **args** – A single string `var('x y')`, a list of strings `var(['x', 'y'])`, or multiple strings `var('x', 'y')`. A single string can be either a single variable name, or a space or comma separated list of variable names. In a list or tuple of strings, each entry is one variable. If multiple arguments are specified, each argument is taken to be one variable. Spaces before or after variable names are ignored.

- **kwds** – keyword arguments can be given to specify domain and custom latex_name for variables. See **EXAMPLES** for usage.

**Note:** The new variable is both returned and automatically injected into the global namespace. If you need a symbolic variable in library code, you must use either `SR.var()` or `SR.symbol()`.

**OUTPUT:**

If a single symbolic variable was created, the variable itself. Otherwise, a tuple of symbolic variables. The variable names are checked to be valid Python identifiers and a `ValueError` is raised otherwise.

**EXAMPLES:**

Here are the different ways to define three variables $x$, $y$, and $z$ in a single line:

```
sage: var('x y z')
(x, y, z)
sage: var('x, y, z')
(x, y, z)
sage: var(['x', 'y', 'z'])
(x, y, z)
sage: var('x', 'y', 'z')
(x, y, z)
sage: var('x'), var('y'), var(z)
(x, y, z)
```

We define some symbolic variables:

```
sage: var('n xx yy zz')
(n, xx, yy, zz)
```

Then we make an algebraic expression out of them:

```
sage: f = xx^n + yy^n + zz^n; f
xx^n + yy^n + zz^n
```

By default, var returns a complex variable. To define real or positive variables we can specify the domain as:

```
sage: x = var('x', domain=RR); x; x.conjugate()
x
x
sage: y = var('y', domain='real'); y.conjugate()
y
sage: y = var('y', domain='positive'); y.abs()
y
```

Custom latex expression can be assigned to variable:
Symbolic Calculus, Release 10.0

```python
sage: x = var('sui', latex_name="s_{u,i}"); x._latex_()
'\{s_{u,i}\}'
```

In notebook, we can also colorize latex expression:

```python
sage: x = var('sui', latex_name="\color{red}{s_{u,i}}"); x._latex_()
'\{\color{red}{s_{u,i}}\}'
```

We can substitute a new variable name for \(n\):

```python
sage: f(n = var('sigma'))
xx^sigma + yy^sigma + zz^sigma
```

If you make an important built-in variable into a symbolic variable, you can get back the original value using `restore`:

```python
sage: var('QQ RR')
(QQ, RR)
sage: QQ
QQ
sage: restore('QQ')
sage: QQ
Rational Field
```

We make two new variables separated by commas:

```python
sage: var('theta, gamma')
(theta, gamma)
sage: theta^2 + gamma^3
gamma^3 + theta^2
```

The new variables are of type `Expression`, and belong to the symbolic expression ring:

```python
sage: type(theta)
<class 'sage.symbolic.expression.Expression'>
sage: parent(theta)
Symbolic Ring
```

## 2.30 Access to Maxima methods

```python
class sage.symbolic.maxima_wrapper.MaximaFunctionElementWrapper(obj, name)
    Bases: InterfaceFunctionElement

class sage.symbolic.maxima_wrapper.MaximaWrapper(exp)
    Bases: SageObject
```

Wrapper around Sage expressions to give access to Maxima methods.

We convert the given expression to Maxima and convert the return value back to a Sage expression. Tab completion and help strings of Maxima methods also work as expected.

**EXAMPLES:**
\begin{verbatim}
sage: t = log(sqrt(2) - 1) + log(sqrt(2) + 1); t
log(sqrt(2) + 1) + log(sqrt(2) - 1)
sage: u = t.maxima_methods(); u
MaximaWrapper(log(sqrt(2) + 1) + log(sqrt(2) - 1))
sage: type(u)
<class 'sage.symbolic.maxima_wrapper.MaximaWrapper'>
sage: u.logcontract()
log((sqrt(2) + 1)*(sqrt(2) - 1))
sage: u.logcontract().parent()
Symbolic Ring
\end{verbatim}

\begin{verbatim}
sage()
Return the Sage expression this wrapper corresponds to.
EXAMPLES:
\end{verbatim}

\begin{verbatim}
sage: t = log(sqrt(2) - 1) + log(sqrt(2) + 1); t
log(sqrt(2) + 1) + log(sqrt(2) - 1)
sage: u = t.maxima_methods().sage()
sage: u
is t
True
\end{verbatim}

2.31 Operators

\textbf{class} sage.symbolic.operators.DerivativeOperator

Bases: object

Derivative operator.

Acting with this operator onto a function gives a new operator (of type \texttt{FDerivativeOperator}) representing the function differentiated with respect to one or multiple of its arguments.

This operator takes a list of indices specifying the position of the arguments to differentiate. For example, \texttt{D[0, 0, 1]} is an operator that differentiates a function twice with respect to its first argument and once with respect to its second argument.

\textbf{EXAMPLES}:

\begin{verbatim}
sage: x, y = var('x,y'); f = function('f')
sage: D[0](f)(x)
diff(f(x), x)
sage: D[0](f)(x, y)
diff(f(x, y), x)
sage: D[0, 1](f)(x, y)
diff(f(x, y), x, y)
sage: D[0, 1](f)(x, x^2)
diff(f(x, x^2), x, y)
\end{verbatim}

\textbf{class} FDerivativeOperatorWithParameters(parameter_set)

Bases: object

\textbf{class} sage.symbolic.operators.FDerivativeOperator(function, parameter_set)

Bases: object
Function derivative operators.

A function derivative operator represents a partial derivative of a function with respect to some variables.

The underlying data are the function, and the parameter set, a list recording the indices of the variables with
respect to which the partial derivative is taken.

**change_function(new)**

Return a new function derivative operator with the same parameter set but for a new function.

EXAMPLES:

```python
sage: from sage.symbolic.operators import FDerivativeOperator
sage: f = function('foo')
sage: b = function('bar')
sage: op = FDerivativeOperator(f, [0, 1])
sage: op.change_function(bar)
D[0, 1](bar)
```

**function()**

Return the function associated to this function derivative operator.

EXAMPLES:

```python
sage: from sage.symbolic.operators import FDerivativeOperator
sage: f = function('foo')
sage: op = FDerivativeOperator(f, [0, 1])
sage: op.function()
foo
```

**parameter_set()**

Return the parameter set of this function derivative operator.

This is the list of indices of variables with respect to which the derivative is taken.

EXAMPLES:

```python
sage: from sage.symbolic.operators import FDerivativeOperator
sage: f = function('foo')
sage: op = FDerivativeOperator(f, [0, 1])
sage: op.parameter_set()
[0, 1]
```

`sage.symbolic.operators.add_vararg(first, *rest)`

Return the sum of all the arguments.

**INPUT:**

- first, *rest – arguments to add

**OUTPUT:** sum of the arguments

**EXAMPLES:**

```python
sage: from sage.symbolic.operators import add_vararg
sage: add_vararg(1, 2, 3, 4, 5, 6, 7)
28
sage: x = SR.var('x')
```
sage: \texttt{s} = 1 + x + x^2 \quad \# \textit{symbolic sum}

sage: \texttt{bool(s.\texttt{operator()(*s.\texttt{operands()}) == s})}

True

\begin{verbatim}
sage: \texttt{sage.symbolic.operators.mul_vararg(first, rest)}
\end{verbatim}

Return the product of all the arguments.

**INPUT:**

\begin{itemize}
  \item \texttt{first, rest} – arguments to multiply
\end{itemize}

**OUTPUT:** product of the arguments

**EXAMPLES:**

\begin{verbatim}
sage: from sage.symbolic.operators import mul_vararg
sage: mul_vararg(9, 8, 7, 6, 5, 4)
60480
sage: x = SR.var('x')
\end{verbatim}

\begin{verbatim}
sage: p = x * \texttt{cos(x)} * \texttt{sin(x)} \quad \# \textit{symbolic product}
\end{verbatim}

\begin{verbatim}
sage: bool(p.\texttt{operator()(*p.\texttt{operands()}) == p})
True
\end{verbatim}

## 2.32 Substitution Maps

This object wraps Pynac \texttt{exmap} objects. These encode substitutions of symbolic expressions. The main use of this module is to hook into Pynac’s \texttt{subs()} methods and pass a wrapper for the substitution map back to Python.

## 2.33 Benchmarks

Tests that will take a long time if something is wrong, but be very quick otherwise. See https://wiki.sagemath.org/symbench. The parameters chosen below are such that with pynac most of these take well less than a second, but would not even be feasible using Sage’s Maxima-based symbolics.

**Problem R1**

Important note. Below we do \texttt{s.expand().real()} because \texttt{s.real()} takes forever (TODO?).

\begin{verbatim}
sage: f(z) = sqrt(1/3)*z^2 + i/3
sage: s = f(f(f(f(f(f(f(f(f(f(i/2))))))))))
\end{verbatim}

\begin{verbatim}
-1532349019984431807424736790714109348334942474663857718035703708589611127743908517981686567969026954235811398533250016304714
\end{verbatim}

**Problem R2:**

\begin{verbatim}
sage: def hermite(n,y):
      ....:    if n == 1: return 2*y
      ....:    if n == 0: return 1
\end{verbatim}
....: return expand(2^n*y*hermite(n-1,y) - 2^n*(n-1)*hermite(n-2,y))
sage: hermite(15, var('y'))
32768*y^15 - 1720320*y^13 + 33546240*y^11 - 307507200*y^9 + 1383782400*y^7 - ...
˓→ - 2905943040*y^5 + 2421619200*y^3 - 518918400*y

Problem R3:
sage: f = sum(var('x,y,z')); a = [bool(f==f) for _ in range(100000)]

Problem R4:
sage: u = [e, pi, sqrt(2)]; Tuples(u,3).cardinality()
27

Problem R5:
sage: def blowup(L,n):
    ....: for i in [0..n]:
    ....:     L.append((L[i] + L[i+1]) * L[i+2])
sage: L = list(var('x,y,z'))
sage: blowup(L,15)
sage: len(set(L))
19

Problem R6:
sage: sum(((x+sin(i))/x+(x-sin(i))/x) for i in range(100)).expand()
200

Problem R7:
sage: f = x^24+34*x^12+45*x^3+9*x^18 +34*x^10+ 32*x^21
sage: a = [f(x=random()) for _ in range(10^4)]

Problem R10:
sage: v = [float(z) for z in [-pi,-pi+1/100..,pi]]

Problem R11:
sage: a = [random() + random()*I for w in [0..100]]
sage: a.sort()

Problem W3:
sage: acos(cos(x))
arccos(cos(x))

PROBLEM S1:
sage: _.var('x,y,z')
sage: f = (x+y+z+1)^10
sage: g = expand(f*(f+1))

PROBLEM S2:

2.33. Benchmarks 375
sage: _ = var('x,y')
sage: a = expand((x^sin(x) + y^cos(y) - z^(x+y))^100)

PROBLEM S3:

sage: _ = var('x,y,z')
sage: f = expand((x^y + y^z + z^x)^50)
sage: g = f.diff(x)

PROBLEM S4:

sage: w = (sin(x)*cos(x)).series(x,400)

### 2.34 Randomized tests of GiNaC / PyNaC

sage.symbolic.random_tests.assert_strict_weak_order(a, b, c, cmp_func)

Check that cmp_func is a strict weak order on the elements a,b,c.

A strict weak order is a binary relation < such that

- For all \( x \), it is not the case that \( x < x \) (irreflexivity).
- For all \( x \neq y \), if \( x < y \) then it is not the case that \( y < x \) (asymmetry).
- For all \( x, y, z \), if \( x < y \) and \( y < z \) then \( x < z \) (transitivity).
- For all \( x, y, z \), if \( x \) is incomparable with \( y \), and \( y \) is incomparable with \( z \), then \( x \) is incomparable with \( z \) (transitivity of incomparability).

INPUT:

- a, b, c – anything that can be compared by cmp_func.
- cmp_func – function of two arguments that returns their comparison (i.e. either True or False).

OUTPUT:

Does not return anything. Raises a ValueError if cmp_func is not a strict weak order on the three given elements.

REFERENCES:

Wikipedia article Strict_weak_ordering

EXAMPLES:

The usual ordering of integers is a strict weak order:

```python
sage: from sage.symbolic.random_tests import assert_strict_weak_order
sage: a, b, c = [randint(-10, 10) for i in range(3)]
sage: assert_strict_weak_order(a, b, c, lambda x, y: x < y)

sage: x = [-SR(oo), SR(0), SR(oo)]
sage: cmp_M = matrix(3, 3, 0)
sage: for i in range(3):
    ....:     for j in range(3):
    ....:         if x[i] < x[j]:
    ....:             cmp_M[i, j] = -1
```
....:    elif x[i] > x[j]:
....:        cmp_M[i, j] = 1
sage: cmp_M
[ 0 -1 -1]
[ 1 0 -1]
[ 1 1 0]

sage.symbolic.random_tests.choose_from_prob_list(lst)

INPUT:

- lst - A list of tuples, where the first element of each tuple is a nonnegative float (a probability), and the probabilities sum to one.

OUTPUT:

A tuple randomly selected from the list according to the given probabilities.

EXAMPLES:

```
sage: from sage.symbolic.random_tests import *
sage: v = [(0.1, False), (0.9, True)]
sage: choose_from_prob_list(v)  # random
(0.900000000000000, True)
sage: true_count = 0
sage: total_count = 0
sage: def more_samples():
....:     global true_count, total_count
....:     for _ in range(10000):
....:         total_count += 1.0
....:         if choose_from_prob_list(v)[1]:
....:             true_count += 1.0
sage: more_samples()
sage: while abs(true_count/total_count - 0.9) > 0.01:
....:     more_samples()
```

sage.symbolic.random_tests.normalize_prob_list(pl, extra=())

INPUT:

- pl - A list of tuples, where the first element of each tuple is a floating-point number (representing a relative probability). The second element of each tuple may be a list or any other kind of object.

- extra - A tuple which is to be appended to every tuple in pl.

This function takes such a list of tuples (a “probability list”) and normalizes the probabilities so that they sum to one. If any of the values are lists, then those lists are first normalized; then the probabilities in the list are multiplied by the main probability and the sublist is merged with the main list.

For example, suppose we want to select between group A and group B with 50% probability each. Then within group A, we select A1 or A2 with 50% probability each (so the overall probability of selecting A1 is 25%); and within group B, we select B1, B2, or B3 with probabilities in a 1:2:2 ratio.

EXAMPLES:

```
sage: from sage.symbolic.random_tests import *
sage: A = [[0.5, 'A1'], (0.5, 'A2')]
sage: B = [(1, 'B1'), (2, 'B2'), (2, 'B3')]
```
\texttt{sage: top = [(50, A, 'Group A'), (50, B, 'Group B')]}
\texttt{sage: normalize_prob_list(top)}
\texttt{[([0.250000000000000, 'A1', 'Group A'), (0.250000000000000, 'A2', 'Group A'), (0.1, 'B1', 'Group B'), (0.2, 'B2', 'Group B'), (0.2, 'B3', 'Group B')]}
sage.symbolic.random_tests.random_expr(size, nvars=1, ncoeffs=None, var_frac=0.5, internal=[(0.6, (0.3, \textbf{<built-in function add>}), (0.1, \textbf{<built-in function sub>}), (0.3, \textbf{<built-in function mult>}), (0.2, \textbf{<built-in function truediv>}), (0.1, \textbf{<built-in function pow>})], 2), (0.2, [(0.8, \textbf{<built-in function neg>}), (0.2, \textbf{<built-in function inv>})]), 1], (0.2, [(1.0, Ei, 1), (1.0, Order, 1), (1.0, swap_harmonic, 2), (1.0, abs, 1), (1.0, airy_ai, 1), (1.0, airy_ai_prime, 1), (1.0, airy_bi, 1), (1.0, airy_bi_prime, 1), (1.0, arccos, 1), (1.0, arccosh, 1), (1.0, arccot, 1), (1.0, arccoth, 1), (1.0, arccsc, 1), (1.0, arccsch, 1), (1.0, arcsec, 1), (1.0, arcsech, 1), (1.0, arcsin, 1), (1.0, arctan, 1), (1.0, arcctan, 1), (1.0, arctanh, 1), (1.0, arg, 1), (1.0, bessel_I, 2), (1.0, bessel_J, 2), (1.0, bessel_K, 2), (1.0, bessel_Y, 2), (1.0, beta, 2), (1.0, binomial, 2), (1.0, ceil, 1), (1.0, chebyshev_T, 2), (1.0, chebyshev_U, 2), (1.0, complex_root_of, 2), (1.0, conjugate, 1), (1.0, cos, 1), (1.0, cos_integral, 1), (1.0, cosh, 1), (1.0, cosh_integral, 1), (1.0, cot, 1), (1.0, coth, 1), (1.0, csc, 1), (1.0, csch, 1), (1.0, dickman_rho, 1), (1.0, dilog, 1), (1.0, dirac_delta, 1), (1.0, elliptic_e, 2), (1.0, elliptic_ec, 1), (1.0, elliptic_eu, 2), (1.0, elliptic_f, 2), (1.0, elliptic_kc, 1), (1.0, elliptic_pi, 3), (1.0, erf, 1), (1.0, erfci, 1), (1.0, erfinv, 1), (1.0, exp, 1), (1.0, exp_integral_e, 2), (1.0, exp_integral_e1, 1), (1.0, exp_polar, 1), (1.0, factorial, 1), (1.0, floor, 1), (1.0, frac, 1), (1.0, fresnel_cos, 1), (1.0, fresnel_sin, 1), (1.0, gamma_inc_lower, 2), (1.0, gegenbauer, 3), (1.0, gen_laguerre, 3), (1.0, gen_legendre_P, 3), (1.0, gen_legendre_Q, 3), (1.0, hahn, 5), (1.0, hankel1, 2), (1.0, hankel2, 2), (1.0, harmonic_number, 1), (1.0, heaviside, 1), (1.0, hermite, 2), (1.0, hurwitz_zeta, 2), (1.0, hypergeometric_M, 3), (1.0, hypergeometric_U, 3), (1.0, imag_part, 1), (1.0, integrate, 4), (1.0, inverse_jacobi_cd, 2), (1.0, inverse_jacobi_cn, 2), (1.0, inverse_jacobi_cs, 2), (1.0, inverse_jacobi_dc, 2), (1.0, inverse_jacobi_dn, 2), (1.0, inverse_jacobi_ds, 2), (1.0, inverse_jacobi_nc, 2), (1.0, inverse_jacobi_nd, 2), (1.0, inverse_jacobi_sc, 2), (1.0, inverse_jacobi_sd, 2), (1.0, inverse_jacobi_sn, 2), (1.0, inverse_jacobi_sn, 2), (1.0, inverse_jacobi_sc, 2), (1.0, inverse_jacobi_sc, 2), (1.0, inverse_jacobi_sc, 2), (1.0, inverse_jacobi_sd, 2), (1.0, inverse_jacobi_sn, 2), (1.0, inverse_jacobi_sn, 2), (1.0, jacobian, 2), (1.0, jacobian, 2), (1.0, jacobian, 2), (1.0, jacobina, 2), (1.0, jacobian, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobiana, 2), (1.0, jacobius, 2), (1.0, krawtchouk, 4), (1.0, krawtchouk, 4), (1.0, krawtchouk, 4), (1.0, krawtchouk, 4), (1.0, laguerre, 2), (1.0, lambert_w, 2), (1.0, legendre_P, 2), (1.0, legendre_Q, 2), (1.0, log, 2), (1.0, log_gamma, 1), (1.0, log_integral, 1), (1.0, log_integral_offset, 1), (1.0, meijer_g, 4), (1.0, polylog, 2), (1.0, prime_pi, 1), (1.0, product, 4), (1.0, real_nth_root, 2), (1.0, real_part, 1), (1.0, sec, 1), (1.0, sech, 1), (1.0, sinh, 1), (1.0, sinh_integral, 1), (1.0, sinh_integral, 1), (1.0, spherical_bessel_I, 2), (1.0, spherical_bessel_Y, 2), (1.0, spherical_hankel1, 2), (1.0, spherical_hankel2, 2), (1.0, spherical_harmonic, 4), (1.0, stieltjes, 1), (1.0, struve_H, 2), (1.0, struve_L, 2), (1.0, sum, 4), (1.0, tan, 1), (1.0, tanh, 1), (1.0, unit_step, 1), (1.0, zeta, 1), (1.0, zetaderiv, 2)]), nullary=[(1.0, pi), (1.0, e), (0.05, golden_ratio), (0.05, log2), (0.05, euler_gamma), (0.05, catalan), (0.05, khinchin), (0.05, twoprinm), (0.05, mertens)], nullary_frac=0.2, coeff_generator=<bound method RationalField.random_element of Rational Field>, verbose=False)
Produce a random symbolic expression of the given size. By default, the expression involves (at most) one variable, an arbitrary number of coefficients, and all of the symbolic functions and constants (from the probability lists full_internal and full_nullary). It is possible to adjust the ratio of leaves between symbolic constants, variables, and coefficients (var_frac gives the fraction of variables, and nullary_frac the fraction of symbolic constants; the remaining leaves are coefficients).

The actual mix of symbolic constants and internal nodes can be modified by specifying different probability lists.

To use a different type for coefficients, you can specify coeff_generator, which should be a function that will return a random coefficient every time it is called.

This function will often raise an error because it tries to create an erroneous expression (such as a division by zero).

EXAMPLES:

```python
sage: from sage.symbolic.random_tests import *

sage: some_functions = [arcsinh, arctan, arctan2, arctanh,
...: arg, beta, binomial, ceil, conjugate, cos, csc, cot, coth,
...: elliptic_pi, erf, exp, factorial, floor, heaviside, imag_part,
...: sech, sgn, sin, sinh, tan, tanh, unit_step, zeta, zetaderiv]

sage: my_internal = [(0.6, full_binary, 2), (0.2, full_unary, 1),
...: : (0.2, [(1.0,f,f.number_of_arguments()) for f in some_functions])]

sage: set_random_seed(1)

sage: random_expr(50, nvars=3, internal=my_internal,
...: : coeff_generator=CDF.random_element)

(v1^(0.9713408427702117 + 0.195868299334218*I)/cot(-pi + v1^2 + v3) + tan(arctan(v2 +
...: + arctan2(-0.35859061674557324 + 0.9407509502498164*I, v3) - 0.8419115504372718 +
...: +0.3037517982404615*I) + arctan2((0.2275357305882964 - 0.8258002386106038*I)/
...: +factorial(v2), -v3 - 0.7604559947718565 - 0.5543672548552057*I) + ceil(1/+
...: +arctan2(v1, v1))))/v2

sage: random_expr(5, verbose=True)

About to apply <built-in function inv> to [31]
About to apply sgn to [v1]
About to apply <built-in function add> to [1/31, sgn(v1)]

sgn(v1) + 1/31
```

**sage.symbolic.random_tests.random_expr_helper** (*n_nodes, internal, leaves, verbose*)

Produce a random symbolic expression of size *n_nodes* (or slightly larger). Internal nodes are selected from the *internal* probability list; leaves are selected from *leaves*. If *verbose* is True, then a message is printed before creating an internal node.

EXAMPLES:

```python
sage: from sage.symbolic.random_tests import *

sage: a = random_expr_helper(9, [(0.5, operator.add, 2),
...: (0.5, operator.neg, 1)], [(0.5, 1), (0.5, x)], True)

About to apply <built-in function add> ...
```

In small cases we will see all cases quickly:

```python
sage: def next_expr():
...:     return random_expr_helper(
...:     6, [(0.5, operator.add, 2), (0.5, operator.neg, 1)],
...:     [(0.5, 1), (0.5, x)], False)
```

(continues on next page)
sage: all_exprs = set()
sage: for a in range(-4, 5):
    ....:     for b in range(-4-abs(a), 5-abs(a)):
    ....:         if a % 2 and abs(a) + abs(b) == 4 and sign(a) != sign(b):
    ....:             continue
    ....:     all_exprs.add(a*x + b)
sage: our_exprs = set()
sage: while our_exprs != all_exprs:
    ....:
    ....:     our_exprs.add(next_expr())

sage.symbolic.random_tests.random_integer_vector(n, length)

Give a random list of length length, consisting of nonnegative integers that sum to n.

This is an approximation to IntegerVectors(n, length).random_element(). That gives values uniformly at random, but might be slow; this routine is not uniform, but should always be fast.

(This routine is uniform if length is 1 or 2; for longer vectors, we prefer approximately balanced vectors, where all the values are around n/length.)

EXAMPLES:

sage: from sage.symbolic.random_tests import *
sage: a = random_integer_vector(100, 2); a  # random
[11, 89]
sage: len(a)
2
sage: sum(a)
100

sage: b = random_integer_vector(10000, 20)
sage: len(b)
20
sage: sum(b)
10000

The routine is uniform if length is 2:

sage: true_count = 0
sage: total_count = 0
sage: def more_samples():
    ....:     global true_count, total_count
    ....:     for _ in range(1000):
    ....:         total_count += 1.0
    ....:     if a == random_integer_vector(100, 2):
    ....:         true_count += 1.0
sage: more_samples()

sage.symbolic.random_tests.test_symbolic_expression_order(repetitions=100)

Tests whether the comparison of random symbolic expressions satisfies the strict weak order axioms.

This is important because the C++ extension class uses std::sort() which requires a strict weak order. See also github issue #9880.
EXAMPLES:

```
sage: from sage.symbolic.random_tests import test_symbolic_expression_order
sage: test_symbolic_expression_order(200)
sage: test_symbolic_expression_order(10000)  # long time
```
