Term map from \{\texttt{a}, \texttt{b}, \texttt{c}\} to Free module generated by \{'a', \texttt{b}', \texttt{c}'\}→ over Rational Field
```

\texttt{to\_ambient\_space\_morphism}()

The morphism from \texttt{self} to its associated ambient space.

\textbf{EXAMPLES}:

```python
sage: CartanType([\texttt{A},2]).root_system().root_lattice().to_ambient_space_morphism()
Generic morphism:
From: Root lattice of the Root system of type \{'A', 2\}
To: Ambient space of the Root system of type \{'A', 2\}
```

\texttt{to\_coroot\_space\_morphism}()

Returns the \texttt{nu} map to the coroot space over the same base ring, using the symmetrizer of the Cartan matrix.

It does not map the root lattice to the coroot lattice, but has the property that any root is mapped to some scalar multiple of its associated coroot.

\textbf{EXAMPLES}:
sage: R = RootSystem(['A',3]).root_space()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()   # needs sage.graphs
sage: f(alpha[1])   # needs sage.graphs
alphacheck[1]
sage: f(alpha[1] + alpha[2])   # needs sage.graphs

sage: R = RootSystem(['A',3]).root_lattice()
sage: alpha = R.simple_roots()
sage: f = R.to_coroot_space_morphism()   # needs sage.graphs
sage: f(alpha[1])   # needs sage.graphs
alphacheck[1]
sage: f(alpha[1] + alpha[2])   # needs sage.graphs

sage: S = RootSystem(['G',2]).root_space()
sage: alpha = S.simple_roots()
sage: f = S.to_coroot_space_morphism()   # needs sage.graphs
sage: f(alpha[1])   # needs sage.graphs
alphacheck[1]
sage: f(alpha[1] + alpha[2])   # needs sage.graphs

>>> from sage.all import *
>>> R = RootSystem(['A',Integer(3)]).root_space()
>>> alpha = R.simple_roots()
>>> f = R.to_coroot_space_morphism()   # needs sage.graphs
>>> f(alpha[Integer(1)])   # needs sage.graphs
alphacheck[1]
>>> f(alpha[Integer(1)] + alpha[Integer(2)])   # needs sage.graphs

>>> R = RootSystem(['A',Integer(3)]).root_lattice()
>>> alpha = R.simple_roots()
>>> f = R.to_coroot_space_morphism()   # needs sage.graphs
>>> f(alpha[Integer(1)])   # needs sage.graphs
alphacheck[1]
>>> f(alpha[Integer(1)] + alpha[Integer(2)])   # needs sage.graphs

>>> S = RootSystem(['G',Integer(2)]).root_space()
>>> alpha = S.simple_roots()
>>> f = S.to_coroot_space_morphism()  # needs sage.graphs
    # needs sage.graphs
alphacheck[1]
>>> f(alpha[Integer(1)] + alpha[Integer(2)])  # needs sage.graphs

Class `sage.combinat.root_system.root_space.RootSpaceElement`

**Bases:** `IndexedFreeModuleElement`

**associated_coroot()**

Returns the coroot associated to this root

**OUTPUT:**

An element of the coroot space over the same base ring; in particular the result is in the coroot lattice whenever `self` is in the root lattice.

**EXAMPLES:**

```
sage: L = RootSystem(["B", 3]).root_space()
sage: alpha = L.simple_roots()
    # needs sage.graphs
alphacheck[1]
sage: alpha[1].associated_coroot().parent()  # needs sage.graphs
Coroot space over the Rational Field of the Root system of type ['B', 3]

sage: L.highest_root()  # needs sage.graphs
sage: L.highest_root().associated_coroot()  # needs sage.graphs
sage: alpha = RootSystem(["B", 3]).root_lattice().simple_roots()
    # needs sage.graphs
alphacheck[1]
sage: alpha[1].associated_coroot().parent()  # needs sage.graphs
Coroot lattice of the Root system of type ['B', 3]
```

```python
>>> from sage.all import *
>>> L = RootSystem(["B", Integer(3)]).root_space()
>>> alpha = L.simple_roots()  # needs sage.graphs
    # needs sage.graphs
alphacheck[1]
>>> alpha[Integer(1)].associated_coroot().parent()  # needs sage.graphs
Coroot space over the Rational Field of the Root system of type ['B', 3]
```
is_positive_root()

Checks whether an element in the root space lies in the nonnegative cone spanned by the simple roots.

EXAMPLES:

```
sage: R = RootSystem(['A',3,1]).root_space()
sage: B = R.basis()
sage: w = B[0] + B[3]
sage: w.is_positive_root()
True
sage: w.is_positive_root()
False
```

max_coroot_le()

Return the highest positive coroot whose associated root is less than or equal to self.

INPUT:

- self – an element of the nonnegative integer span of simple roots.

Returns None for the zero element.

Really self is an element of a coroot lattice and this method returns the highest root whose associated coroot is \( \leq \) self.

**Warning:** This implementation only handles finite Cartan types
Combinatorics, Release 10.4

```sage
# needs sage.graphs
root_lattice = RootSystem(['C',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
sage: root_lattice.from_vector(vector([2,1])).max_coroot_le()
sage: root_lattice = RootSystem(['B',2]).root_lattice()
sage: root_lattice.from_vector(vector([1,1])).max_coroot_le()
sage: root_lattice.from_vector(vector([1,2])).max_coroot_le()
sage: root_lattice.zero().max_coroot_le() is None  
True
sage: root_lattice.from_vector(vector([-1,0])).max_coroot_le()  
Traceback (most recent call last):
  ...  
ValueError: -alpha[1] is not in the positive cone of roots
sage: root_lattice = RootSystem(['A',2,1]).root_lattice()
sage: root_lattice.simple_root(1).max_coroot_le()  
Traceback (most recent call last):
  ...  
NotImplementedError: Only implemented for finite Cartan type
>>> from sage.all import *
>>> # needs sage.graphs
>>> root_lattice = RootSystem(['C',Integer(2)]).root_lattice()
>>> root_lattice.from_vector(vector([Integer(1),Integer(1)])).max_coroot_le()
>>> root_lattice.from_vector(vector([Integer(2),Integer(1)])).max_coroot_le()
>>> root_lattice = RootSystem(['B',Integer(2)]).root_lattice()
>>> root_lattice.from_vector(vector([Integer(1),Integer(1)])).max_coroot_le()
>>> root_lattice.from_vector(vector([Integer(1),Integer(2)])).max_coroot_le()
>>> root_lattice.zero().max_coroot_le() is None  
True
>>> root_lattice.from_vector(vector([-Integer(1),Integer(0)])).max_coroot_le()  
Traceback (most recent call last):
  ...

>>> root_lattice = RootSystem(['A',Integer(2),Integer(1)]).root_lattice()
>>> root_lattice.simple_root(Integer(1)).max_coroot_le()  
Traceback (most recent call last):
  ...  
NotImplementedError: Only implemented for finite Cartan type
```

max_quantum_element()

Return a reduced word for the longest element of the Weyl group whose shortest path in the quantum Bruhat
Combinatorics, Release 10.4

graph to the identity has sum of quantum coroots at most self.

INPUT:

- self – an element of the nonnegative integer span of simple roots.

Really self is an element of a coroot lattice.

**Warning:** This implementation only handles finite Cartan types

**EXAMPLES:**

```python
sage: # needs sage.graphs sage.libs.gap
sage: Qvee = RootSystem(['C',2]).coroot_lattice()
sage: Qvee.from_vector(vector([1,2])).max_quantum_element()
[2, 1, 2, 1]
sage: Qvee.from_vector(vector([1,1])).max_quantum_element()
[1, 2, 1]
sage: Qvee.from_vector(vector([0,2])).max_quantum_element()
[2]
```

**quantum_root ()**

Check whether self is a quantum root.

INPUT:

- self – an element of the nonnegative integer span of simple roots.

A root $\alpha$ is a quantum root if $\ell(s_\alpha) = \langle 2\rho, \alpha^\vee \rangle - 1$ where $\ell$ is the length function, $s_\alpha$ is the reflection across the hyperplane orthogonal to $\alpha$, and $2\rho$ is the sum of positive roots.

**Warning:** This implementation only handles finite Cartan types and assumes that self is a root.

**Todo:** Rename to is_quantum_root

**EXAMPLES:**

```python
>>> from sage.all import *
>>> # needs sage.graphs sage.libs.gap
>>> Qvee = RootSystem(['C',Integer(2)]).coroot_lattice()
>>> Qvee.from_vector(vector([Integer(1),Integer(2)])).max_quantum_element()
[2, 1, 2, 1]
>>> Qvee.from_vector(vector([Integer(1),Integer(1)])).max_quantum_element()
[1, 2, 1]
>>> Qvee.from_vector(vector([Integer(0),Integer(2)])).max_quantum_element()
[2]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

\[ 2\alpha[1] + \alpha[2] \text{ True} \]
\[ \alpha[2] \text{ True} \]

```python
>>> from sage.all import *
```

```python
>>> Q = RootSystem(['C', Integer(2)]).root_lattice()
>>> positive_roots = Q.positive_roots()
>>> for x in sorted(positive_roots):
    # needs sage.graphs
    ... print("{} {}".format(x, x.quantum_root()))
alpha[1] True
alpha[2] True
```

**scalar (\(\lambda_\check\))**

The scalar product between the root lattice and the coroot lattice.

**EXAMPLES:**

```python
sage: L = RootSystem(['B',4]).root_lattice()
sage: alpha = L.simple_roots()
sage: alphacheck = L.simple_coroots()
sage: alpha[1].scalar(alphacheck[1])  # needs sage.graphs
2
```

```python
sage: alpha[1].scalar(alphacheck[2])  # needs sage.graphs
-1
```

```python
>>> from sage.all import *
```

```python
>>> L = RootSystem(['B', Integer(4)]).root_lattice()
>>> alpha = L.simple_roots()
>>> alphacheck = L.simple_coroots()
>>> alpha[Integer(1)].scalar(alphacheck[Integer(1)])  # needs sage.graphs
2
>>> alpha[Integer(1)].scalar(alphacheck[Integer(2)])  # needs sage.graphs
-1
```

The scalar products between the roots and coroots are given by the Cartan matrix:

```python
sage: matrix([ [ alpha[i].scalar(alphacheck[j]) ] for i in L.index_set() ] for j in L.index_set() ]
[[ 2 -1  0  0]
 [-1  2 -1  0]
 [ 0 -1  2 -1]
 [ 0  0 -2  2]]
```

```python
sage: L.cartan_type().cartan_matrix()  # needs sage.graphs
[[ 2 -1  0  0]
 [-1  2 -1  0]
 [ 0 -1  2 -1]
 [ 0  0 -2  2]]
```

(continues on next page)

```python
>>> from sage.all import *
>>> matrix([[ alpha[i].scalar(alphacheck[j]) #
 ˓→needs sage.graphs
 ˓→for i in L.index_set() ]
 ˓→for j in L.index_set() ])
[ 2  -1  0  0]
[-1  2  -1  0]
[ 0  -1  2  -1]
[ 0   0  -2  2]
```

```python
>>> L.cartan_type().cartan_matrix() #
 ˓→needs sage.graphs
[ 2  -1  0  0]
[-1  2  -1  0]
[ 0  -1  2  -1]
[ 0   0  -2  2]
```

to_ambient()

Map self to the ambient space.

EXAMPLES:

```python
sage: alpha = CartanType(["B",2]).root_system().root_lattice().an_element(); #
 ˓→alpha
sage: alpha.to_ambient()
(2, 0)
sage: alphacheck = CartanType(["B",2]).root_system().coroot_lattice().an_ ˓→element(); alphacheck
sage: alphacheck.to_ambient()
(2, 2)
```

```python
>>> from sage.all import *
>>> alpha = CartanType(["B",Integer(2)]).root_system().root_lattice().an_ ˓→element(); alpha
>>> alpha.to_ambient()
(2, 0)
>>> alphacheck = CartanType(["B",Integer(2)]).root_system().coroot_lattice().an_ ˓→element(); alphacheck
>>> alphacheck.to_ambient()
(2, 2)
```
5.1.241 Root systems

See *Root Systems* for an overview.

class sage.combinat.root_system.root_system.RootSystem(cartan_type, as_dual_of=None)

Bases: UniqueRepresentation, SageObject

A class for root systems.

EXAMPLES:

We construct the root system for type $B_3$:

```
sage: R = RootSystem(['B',3]); R
Root system of type ['B', 3]
```

$R$ models the root system abstractly. It comes equipped with various realizations of the root and weight lattices, where all computations take place. Let us play first with the root lattice:

```
sage: space = R.root_lattice(); space
Root lattice of the Root system of type ['B', 3]
```

This is the free $\mathbb{Z}$-module $\bigoplus_i \mathbb{Z} \alpha_i$ spanned by the simple roots:

```
sage: space.base_ring()
Integer Ring
sage: list(space.basis())
[alpha[1], alpha[2], alpha[3]]
```

Let us do some computations with the simple roots:

```
sage: alpha = space.simple_roots()
```

There is a canonical pairing between the root lattice and the coroot lattice:
We construct the simple coroots, and do some computations (see comments about duality below for some caveat):

```python
sage: alphacheck = space.simple_coroots()
sage: list(alphacheck)
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

We can carry over the same computations in any of the other realizations of the root lattice, like the root space $\bigoplus_i \mathbb{Q}.\alpha_i$, the weight lattice $\bigoplus_i \mathbb{Z}.\alpha_i$, the weight space $\bigoplus_i \mathbb{Q}.\Lambda_i$. For example:

```python
sage: space = R.weight_space(); space
Weight space over the Rational Field of the Root system of type ['B', 3]
```

```python
sage: space.base_ring()
Rational Field
sage: list(space.basis())
[Lambda[1], Lambda[2], Lambda[3]]
```

```python
sage: alpha = space.simple_roots()  # needs sage.graphs
```

The fundamental weights are the dual basis of the coroots:
Let us use the simple reflections. In the weight space, they work as in the number game: firing the node $i$ on an element $x$ adds $c$ times the simple root $\alpha_i$, where $c$ is the coefficient of $i$ in $x$:

```python
sage: # needs sage.graphs
sage: Lambda[1].simple_reflection(1)  
sage: Lambda[2].simple_reflection(1)  
Lambda[2]
sage: Lambda[3].simple_reflection(1)  
Lambda[3]
```

(continues on next page)
Lambda[2]
>>> Lambda[Integer(3)].simple_reflection(Integer(1))
Lambda[3]
>>> (-Integer(2)*Lambda[Integer(1)] + Lambda[Integer(2)] + Lambda[Integer(3)]).simple_reflection(Integer(1))

It can be convenient to manipulate the simple reflections themselves:

```python
sage: # needs sage.graphs
sage: s = space.simple_reflections()

sage: s[1](Lambda[1])

sage: s[1](Lambda[2])
Lambda[2]

sage: s[1](Lambda[3])
Lambda[3]
```

Ambient spaces

The root system may also come equipped with an ambient space. This is a \(\mathbb{Q}\)-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings of the (extended) weight and the (extended) coweight lattice, and therefore the root and the coroot lattice. This is implemented on a type by type basis for the finite crystallographic root systems following Bourbaki’s conventions and is extended to the affine cases. Coefficients permitting, this is also available as an ambient lattice.

See also:

- `ambient_space()` and `ambient_lattice()` for details

In finite type \(A\), we recover the natural representation of the symmetric group as group of permutation matrices:

```python
sage: RootSystem(["A",2]).ambient_space().weyl_group().simple_reflections()  # needs sage.libs.gap sage.libs.pari
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1],
2: [1 0 0]
[0 0 1]
[0 1 0]}

sage: RootSystem(["A",Integer(2)]).ambient_space().weyl_group().simple_reflections()  # needs sage.libs.gap sage.libs.pari
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1],
2: [1 0 0]
[0 0 1]
[0 1 0]}
```
\[
\begin{bmatrix}
1 & 0 & 0 \\
0 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
1 & 0 & 0 \\
0 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\]

In type \(B, C, \) and \(D\), we recover the natural representation of the Weyl group as groups of signed permutation matrices:

```python
sage: RootSystem(["B",3]).ambient_space().weyl_group().simple_reflections()
# needs sage.libs.gap sage.libs.pari
Finite family {1: 
\[
\begin{bmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
1 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{bmatrix},
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -1
\end{bmatrix}
\]

>>> from sage.all import *

>>> RootSystem(["B",Integer(3)]).ambient_space().weyl_group().simple_reflections()
# needs sage.libs.gap sage.libs.pari
Finite family {1: 
\[
\begin{bmatrix}
0 & 1 & 0 \\
1 & 0 & 0 \\
0 & 0 & 1
\end{bmatrix},
\begin{bmatrix}
1 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{bmatrix},
\begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & -1
\end{bmatrix}
\]
```

In (untwisted) affine types \(A, …, D\), one can recover from the ambient space the affine permutation representation, in window notation. Let us consider the ambient space for affine type \(A\):

```python
sage: L = RootSystem(["A",2,1]).ambient_space(); L
Ambient space of the Root system of type ['A', 2, 1]

>>> from sage.all import *

>>> L = RootSystem(["A",Integer(2),Integer(1)]).ambient_space(); L
Ambient space of the Root system of type ['A', 2, 1]
```

Define the “identity” by an appropriate vector at level \(-3\):

```python
sage: e = L.basis(); Lambda = L.fundamental_weights()  # needs sage.graphs
```

```python
>>> from sage.all import *

>>> e = L.basis(); Lambda = L.fundamental_weights()  # needs sage.graphs

>>> id = e[Integer(0)] + Integer(2)*e[Integer(1)] + Integer(3)*e[Integer(2)] - Integer(3)*Lambda[Integer(0)]  # needs sage.graphs
```
The corresponding permutation is obtained by projecting it onto the classical ambient space:

```python
sage: L.classical()
Ambient space of the Root system of type ['A', 2]
sage: L.classical()(id) # needs sage.graphs
(1, 2, 3)
```

Here is the orbit of the identity under the action of the finite group:

```python
sage: W = L.weyl_group()
sage: S3 = [ w.action(id) for w in W.classical() ]
sage: [L.classical()(x) for x in S3]
[(1, 2, 3), (3, 1, 2), (2, 3, 1), (2, 1, 3), (1, 3, 2), (3, 2, 1)]
```

And the action of \(s_0\) on these yields:

```python
sage: s = W.simple_reflections()
sage: [L.classical()(s[0].action(x)) for x in S3]
[(0, 2, 4), (-1, 1, 6), (-2, 3, 5), (0, 1, 5), (-1, 3, 4), (-2, 2, 6)]
```

We can also plot various components of the ambient spaces:

```python
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot() # needs sage.plot sage.symbolic
Graphics object consisting of 13 graphics primitives
```

For more on plotting, see Tutorial: visualizing root systems.
Dual root systems

The root system is aware of its dual root system:

```
sage: R.dual
Dual of root system of type ['B', 3]
```

```
>>> from sage.all import *

>>> R.dual
Dual of root system of type ['B', 3]
```

$R.dual$ is really the root system of type $C_3$:

```
sage: R.dual.cartan_type()
['C', 3]
```

```
>>> from sage.all import *

>>> R.dual.cartan_type()
['C', 3]
```

And the coroot lattice that we have been manipulating before is really implemented as the root lattice of the dual root system:

```
sage: R.dual.root_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

```
>>> from sage.all import *

>>> R.dual.root_lattice()
Coroot lattice of the Root system of type ['B', 3]
```

In particular, the coroots for the root lattice are in fact the roots of the coroot lattice:

```
sage: list(R.root_lattice().simple_coroots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
sage: list(R.coroot_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
sage: list(R.dual.root_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
>>> from sage.all import *

>>> list(R.root_lattice().simple_coroots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
>>> list(R.coroot_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
>>> list(R.dual.root_lattice().simple_roots())
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

The coweight lattice and space are defined similarly. Note that, to limit confusion, all the output have been tweaked appropriately.

See also:

- sage.combinat.root_system
- RootSpace
- WeightSpace
• AmbientSpace
• RootLatticeRealizations
• WeightLatticeRealizations

ambient_lattice()

Return the ambient lattice for this root_system.

This is the ambient space, over \(\mathbb{Z}\).

See also:

• ambient_space()
• root_lattice()
• weight_lattice()

EXAMPLES:

```
sage: RootSystem(['A',4]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4]
sage: RootSystem(['A',4,1]).ambient_lattice()
Ambient lattice of the Root system of type ['A', 4, 1]
```

Except in type A, only an ambient space can be realized:

```
sage: RootSystem(['B',4]).ambient_lattice()
sage: RootSystem(['C',4]).ambient_lattice()
sage: RootSystem(['D',4]).ambient_lattice()
sage: RootSystem(['E',6]).ambient_lattice()
sage: RootSystem(['F',4]).ambient_lattice()
sage: RootSystem(['G',2]).ambient_lattice()
```

ambient_space(base_ring=Rational Field)

Return the usual ambient space for this root_system.

INPUT:

• base_ring – a base ring (default: \(\mathbb{Q}\))

This is a base_ring-module, endowed with its canonical Euclidean scalar product, which admits simultaneous embeddings into the weight and the coweight lattice, and therefore the root and the coroot lattice, and preserves scalar products between elements of the coroot lattice and elements of the root or weight lattice (and dually).
There is no mechanical way to define the ambient space just from the Cartan matrix. Instead it is constructed from hard coded type by type data, according to the usual Bourbaki conventions. Such data is provided for all the finite (crystallographic) types. From this data, ambient spaces can be built as well for dual types, reducible types and affine types. When no data is available, or if the base ring is not large enough, None is returned.

**Warning:** for affine types

See also:

- The section on ambient spaces in `RootSystem`
- `ambient_lattice()`
- `AmbientSpace`
- `ambient_lattice()`
- `AmbientSpace`
- `root_space()`
- `weight:space()`

**EXAMPLES:**

```python
sage: RootSystem(['A',4]).ambient_space()
Ambient space of the Root system of type ['A', 4]

sage: RootSystem(['A',Integer(4)]).ambient_space()
Ambient space of the Root system of type ['A', 4]

sage: RootSystem(['B',4]).ambient_space()
Ambient space of the Root system of type ['B', 4]

sage: RootSystem(['B',Integer(4)]).ambient_space()
Ambient space of the Root system of type ['B', 4]

sage: RootSystem(['C',4]).ambient_space()
Ambient space of the Root system of type ['C', 4]

sage: RootSystem(['C',Integer(4)]).ambient_space()
Ambient space of the Root system of type ['C', 4]

sage: RootSystem(['D',4]).ambient_space()
Ambient space of the Root system of type ['D', 4]

sage: RootSystem(['D',Integer(4)]).ambient_space()
Ambient space of the Root system of type ['D', 4]

sage: RootSystem(['E',6]).ambient_space()
Ambient space of the Root system of type ['E', 6]
```
An alternative base ring can be provided as an option:

```python
e = RootSystem(['B',3]).ambient_space(RR)
sage: TestSuite(e).run() # needs sage.graphs
```

It should contain the smallest ring over which the ambient space can be defined (\(\mathbb{Z}\) in type \(A\) or \(\mathbb{Q}\) otherwise). Otherwise \texttt{None} is returned:

```python
e = RootSystem(['B',2]).ambient_space(ZZ)
```

The base ring should also be totally ordered. In practice, only \(\mathbb{Z}\) and \(\mathbb{Q}\) are really supported at this point, but you are welcome to experiment:

```python
e = RootSystem(['G',2]).ambient_space(RR)
sage: TestSuite(e).run() # needs sage.graphs
```

```
Failure in _test_root_lattice_realization:
  Traceback (most recent call last):
    ...
  AssertionError: 2.00000000000000 != 2.00000000000000
```

**cartan_matrix()**

EXAMPLES:

```python
sage: RootSystem(['A',3]).cartan_matrix()  # needs sage.graphs
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
```

```python
>>> from sage.all import *
>>> RootSystem(['A',Integer(3)]).cartan_matrix()  # needs sage.graphs
[ 2 -1  0]
[-1  2 -1]
[ 0 -1  2]
```

**cartan_type()**

Return the Cartan type of the root system.

EXAMPLES:

```python
sage: R = RootSystem(['A',3])
sage: R.cartan_type()
['A', 3]
```

```python
>>> from sage.all import *
>>> R = RootSystem(['A',Integer(3)])
>>> R.cartan_type()
['A', 3]
```

**coambient_space** (*base_ring=*Rational Field*)

Return the coambient space for this root system.

This is the ambient space of the dual root system.

See also:

- `ambient_space()`

EXAMPLES:

```python
sage: L = RootSystem(['B',2]).ambient_space(); L
Ambient space of the Root system of type ['B', 2]
sage: coL = RootSystem(['B',2]).coambient_space(); coL
Coambient space of the Root system of type ['B', 2]
```

```python
>>> from sage.all import *
>>> L = RootSystem(['B',Integer(2)]).ambient_space(); L
```

(continues on next page)
The roots and coroots are interchanged:

```sage
coL.simple_roots()
Finite family {1: (1, -1), 2: (0, 2)}
sage: L.simple_coroots()
Finite family {1: (1, -1), 2: (0, 2)}

sage: coL.simple_coroots()
Finite family {1: (1, -1), 2: (0, 1)}
sage: L.simple_roots()
Finite family {1: (1, -1), 2: (0, 1)}
```

```sage
>>> from sage.all import *
>>> coL.simple_roots()
Finite family {1: (1, -1), 2: (0, 2)}
>>> L.simple_coroots()
Finite family {1: (1, -1), 2: (0, 2)}

>>> coL.simple_coroots()
Finite family {1: (1, -1), 2: (0, 1)}
>>> L.simple_roots()
Finite family {1: (1, -1), 2: (0, 1)}
```
- \texttt{coweight\_space()}
- \texttt{weight\_space()}, \texttt{weight\_lattice()}
- \texttt{WeightSpace}

**EXAMPLES:**

\begin{verbatim}
sage: RootSystem(['A',3]).coweight_lattice()
Coweight lattice of the Root system of type ['A', 3]
sage: RootSystem(['A',3,1]).coweight_lattice(extended=True)
Extended coweight lattice of the Root system of type ['A', 3, 1]

>>> from sage.all import *

from sage.all import *

>>> RootSystem(['A',Integer(3)]).coweight_lattice()
Coweight lattice of the Root system of type ['A', 3]

>>> RootSystem(['A',Integer(3),Integer(1)]).coweight_lattice(extended=True)
Extended coweight lattice of the Root system of type ['A', 3, 1]
\end{verbatim}

\textbf{coweight\_space}(\texttt{base\_ring=Rational Field, extended=False})

Return the coweight space associated to \texttt{self}.

This is the weight space of the dual root system.

See also:

- \texttt{coweight\_lattice()}
- \texttt{weight\_space()}, \texttt{weight\_lattice()}
- \texttt{WeightSpace}

**EXAMPLES:**

\begin{verbatim}
sage: RootSystem(['A',3]).coweight_space()
Coweight space over the Rational Field of the Root system of type ['A', 3]
sage: RootSystem(['A',3,1]).coweight_space(extended=True)
Extended coweight space over the Rational Field of the Root system of type ['A', 3, 1]

>>> from sage.all import *

from sage.all import *

>>> RootSystem(['A',Integer(3)]).coweight_space()
Coweight space over the Rational Field of the Root system of type ['A', 3]

>>> RootSystem(['A',Integer(3),Integer(1)]).coweight_space(extended=True)
Extended coweight space over the Rational Field of the Root system of type ['A', 3, 1]
\end{verbatim}

dynkin\_diagram()

Return the Dynkin diagram of the root system.

**EXAMPLES:**

\begin{verbatim}
sage: R = RootSystem(['A',3])
sage: R.dynkin_diagram()
#...
\end{verbatim}

(continues on next page)
from sage.all import *

R = RootSystem(['A', Integer(3)])
R.dynkin_diagram()

index_set()
EXAMPLES:

sage: RootSystem(['A', 3]).index_set()
(1, 2, 3)

is_finite()
Return True if self is a finite root system.
EXAMPLES:

sage: RootSystem(['A', 3]).is_finite()
True
sage: RootSystem(['A', 3, 1]).is_finite()
False

is_irreducible()
Return True if self is an irreducible root system.
EXAMPLES:

sage: RootSystem(['A', 3]).is_irreducible()
True
sage: RootSystem('A2xB2').is_irreducible()
False
**root_lattice()**

Return the root lattice associated to self.

**EXAMPLES:**

```python
sage: RootSystem(['A',3]).root_lattice()
Root lattice of the Root system of type ['A', 3]
```

```python
>>> from sage.all import *

>>> RootSystem(['A',Integer(3)]).root_lattice()
Root lattice of the Root system of type ['A', 3]
```

**root_poset (restricted=False, facade=False)**

Return the (restricted) root poset associated to self.

The elements are given by the positive roots (resp. non-simple, positive roots), and \( \alpha \leq \beta \) iff \( \beta - \alpha \) is a non-negative linear combination of simple roots.

**INPUT:**

- **restricted** — (default: False) if True, only non-simple roots are considered.
- **facade** — (default: False) passes facade option to the poset generator.

**EXAMPLES:**

```python
sage: Phi = RootSystem(['A',2]).root_poset(); Phi
# needs sage.graphs
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
# needs sage.graphs

sage: Phi = RootSystem(['A',3]).root_poset(restricted=True); Phi
# needs sage.graphs
Finite poset containing 3 elements
sage: sorted(Phi.cover_relations(), key=str)
# needs sage.graphs

sage: Phi = RootSystem(['B',2]).root_poset(); Phi
# needs sage.graphs
Finite poset containing 4 elements
sage: Phi.cover_relations()
# needs sage.graphs

>>> from sage.all import *

>>> Phi = RootSystem(['A',Integer(2)]).root_poset(); Phi
# needs sage.graphs
Finite poset containing 3 elements
>>> sorted(Phi.cover_relations(), key=str)
# needs sage.graphs

>>> Phi = RootSystem(['A',Integer(3)]).root_poset(restricted=True); Phi
# needs sage.graphs
```

(continues on next page)
Finite poset containing 3 elements

```python
>>> sorted(Phi.cover_relations(), key=str)  #...
    # needs sage.graphs
```

```python
>>> Phi = RootSystem(['B', Integer(2)]).root_poset(); Phi   #...
    # needs sage.graphs
Finite poset containing 4 elements
>>> Phi.cover_relations()  #...
    # needs sage.graphs
```

**root_space** *(base_ring=Rational Field)*

Return the root space associated to self.

**EXAMPLES:**

```python
sage: RootSystem(['A',3]).root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

```python
>>> from sage.all import *
```

```python
>>> RootSystem(['A',Integer(3)]).root_space()
Root space over the Rational Field of the Root system of type ['A', 3]
```

**weight_lattice** *(extended=False)*

Return the weight lattice associated to self.

See also:

- weight_space()
- coweight_space(), coweight_lattice()
- WeightSpace

**EXAMPLES:**

```python
sage: RootSystem(['A',3]).weight_lattice()
Weight lattice of the Root system of type ['A', 3]
```

```python
sage: RootSystem(['A',3,1]).weight_space(extended=True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]
```

```python
>>> from sage.all import *
```

```python
>>> RootSystem(['A',Integer(3)]).weight_lattice()
Weight lattice of the Root system of type ['A', 3]
```

```python
>>> RootSystem(['A',Integer(3),Integer(1)]).weight_space(extended=True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]
```

**weight_space** *(base_ring=Rational Field, extended=False)*

Returns the weight space associated to self.
Combinatorics, Release 10.4

See also:

- `weight_lattice()`
- `coweight_space()`, `coweight_lattice()`
- `WeightSpace`

EXAMPLES:

```python
sage: RootSystem(['A',3]).weight_space()
Weight space over the Rational Field of the Root system of type ['A', 3]
sage: RootSystem(['A',3,1]).weight_space(extended=True)
Extended weight space over the Rational Field of the Root system of type ['A', 3, 1]
```

```python
>>> from sage.all import *

WeylDim(ct, coeffs)
The Weyl Dimension Formula.

INPUT:

- `ct` – a Cartan type
- `coeffs` – a list of nonnegative integers

The length of the list must equal the rank type[1]. A dominant weight hwv is constructed by summing the fundamental weights with coefficients from this list. The dimension of the irreducible representation of the semisimple complex Lie algebra with highest weight vector hwv is returned.

EXAMPLES:

For \( SO(7) \), the Cartan type is \( B_3 \), so:

```python
sage: WeylDim(['B',3],[1,0,0])  # standard representation of SO(7)
7
sage: WeylDim(['B',3],[0,1,0])  # exterior square
21
sage: WeylDim(['B',3],[0,0,1])  # spin representation of spin(7)
8
sage: WeylDim(['B',3],[1,0,1])  # sum of the first and third fundamental weights
48
```

```python
sage: [WeylDim(['F',4],x) for x in ([1,0,0,0],[0,1,0,0],[0,0,1,0],[0,0,0,1])]
[52, 1274, 273, 27]

sage: [WeylDim(['E', 6], x) for x in ([0, 0, 0, 0, 0, 0], [0, 1, 0, 0, 0, 0], [0, 0, 1, 0, 0, 0], [0, 0, 0, 1, 0, 0], [0, 0, 0, 0, 1, 0], [0, 0, 0, 0, 0, 1], [1, 0, 0, 0, 0, 0], [1, 0, 0, 0, 0, 1], [2, 0, 0, 0, 0, 0])]
[1, 78, 27, 351, 351, 351, 27, 650, 351]
```
5.1.242 Root system data for super type A

class sage.combinat.root_system.type_super_A.AmbientSpace(root_system, base_ring, index_set=None)

Bases: ambient_space.AmbientSpace

The ambient space for (super) type $A(m|n)$.

EXAMPLES:

sage: R = RootSystem(['A', [2,1]])
sage: AL = R.ambient_space(); AL
Ambient space of the Root system of type ['A', [2, 1]]
sage: AL.basis()
Finite family {-3: (1, 0, 0, 0, 0), -2: (0, 1, 0, 0, 0), -1: (0, 0, 1, 0, 0), 1: (0, 0, 0, 1, 0), 2: (0, 0, 0, 0, 1)}

...
>>> AL = R.ambient_space(); AL
Ambient space of the Root system of type ['A', [2, 1]]
>>> AL.basis()
Finite family {-3: (1, 0, 0, 0, 0),
-2: (0, 1, 0, 0, 0),
-1: (0, 0, 1, 0, 0),
 1: (0, 0, 0, 1, 0),
 2: (0, 0, 0, 0, 1)}
\texttt{coroot()}

(0, 0, 1, 0, -1, -1, 1)

\textbf{dot_product \texttt{(lambdacheck)}}

The scalar product with elements of the coroot lattice embedded in the ambient space.

**EXAMPLES:**

\begin{verbatim}
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in ...
       L.index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> L = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_space()
>>> a = L.simple_roots()
>>> matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.
       index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
\end{verbatim}

\textbf{has_descent \texttt{(i, positive=False)}}

Test if \texttt{self} has a descent at position \texttt{i}, that is if \texttt{self} is on the strict negative side of the \texttt{i}th simple reflection hyperplane.

If \texttt{positive} is \texttt{True}, tests if it is on the strict positive side instead.

**EXAMPLES:**

\begin{verbatim}
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: al = L.simple_roots()
sage: [al[i].has_descent(1) for i in L.index_set()]
[False, False, True, False]

sage: [(-al[i]).has_descent(1) for i in L.index_set()]
[False, False, False, True]

sage: [al[i].has_descent(1, True) for i in L.index_set()]
[False, False, True, False]

sage: all(all(not la.has_descent(i) for i in L.index_set())
       ....: for la in L.fundamental_weights())
True
\end{verbatim}
```python
>>> from sage.all import *

>>> L = RootSystem(['A', [Integer(2), Integer(1)]]).ambient_space()

>>> al = L.simple_roots()

>>> [al[i].has_descent(Integer(1)) for i in L.index_set()]
[False, False, True, False]

>>> [(-al[i]).has_descent(Integer(1)) for i in L.index_set()]
[False, False, False, True]

>>> [al[i].has_descent(Integer(1), True) for i in L.index_set()]
[False, False, False, True]

>>> [(-al[i]).has_descent(Integer(1), True) for i in L.index_set()]
[False, False, True, False]

>>> (al[-Integer(2)] + al[Integer(0)] + al[Integer(1)]).has_descent(-Integer(1))
True

>>> (al[-Integer(2)] + al[Integer(0)] + al[Integer(1)]).has_descent(Integer(1))
False

>>> (al[-Integer(2)] + al[Integer(0)] + al[Integer(1)]).has_descent(Integer(1), positive=True)
True

>>> all(all(not la.has_descent(i) for i in L.index_set()) for la in L.fundamental_weights())
True
```

inner_product (lambdacheck)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```
sage: L = RootSystem(['A', [2,1]]).ambient_space()
sage: a = L.simple_roots()
sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```

```python
>>> from sage.all import *

>>> L = RootSystem(['A', [Integer(2), Integer(1)]]).ambient_space()

>>> a = L.simple_roots()

>>> matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])
[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```

is_dominant_weight()

Test whether self is a dominant element of the weight lattice.

EXAMPLES:

```
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
```
```
Combinatorics, Release 10.4

(continued from previous page)

```
sage: (3*Lambda[1]+Lambda[2]).is_dominant()
True
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
```

```python
>>> from sage.all import *

>>> L = RootSystem(['A', Integer(2)]).ambient_lattice()

>>> Lambda = L.fundamental_weights()

>>> [x.is_dominant() for x in Lambda]
[True, True]

>>> (Integer(3)*Lambda[Integer(1)]+Lambda[Integer(2)]).is_dominant()
True

>>> (Lambda[Integer(1)]-Lambda[Integer(2)]).is_dominant()
False

>>> (-Lambda[Integer(1)]+Lambda[Integer(2)]).is_dominant()
False
```

Tests that the scalar products with the coroots are all nonnegative integers. For example, if $x$ is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports $x$ to be a dominant weight:

```
sage: x = Lambda[1] + L([-1,-1,-1])

sage: x.is_dominant_weight()
True
```

```python
>>> from sage.all import *

>>> x = Lambda[Integer(1)] + L([-Integer(1),-Integer(1),-Integer(1)])

>>> x.is_dominant_weight()
True
```

**scalar** *(lambdacheck)*

The scalar product with elements of the coroot lattice embedded in the ambient space.

**EXAMPLES:**

```
sage: L = RootSystem(['A', [2,1]]).ambient_space()

sage: a = L.simple_roots()

sage: matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])

[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```

```python
>>> from sage.all import *

>>> L = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_space()

>>> a = L.simple_roots()

>>> matrix([[a[i].inner_product(a[j]) for j in L.index_set()] for i in L.index_set()])

[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  0  1]
[ 0  0  1 -2]
```
**dimension()**

Return the dimension of this ambient space.

**EXAMPLES:**

```python
sage: e = RootSystem(['A', [4,2]]).ambient_space()
sage: e.dimension()
8
```

```python
>>> from sage.all import *

```

**fundamental_weight(i)**

Return the fundamental weight \( \Lambda_i \) of self.

**EXAMPLES:**

```python
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: L.fundamental_weight(-1)
(1, 1, 1, 0, 0, 0, 0)
sage: L.fundamental_weight(0)
(1, 1, 1, 0, 0, 0, 0)
sage: L.fundamental_weight(2)
(1, 1, 1, -1, -1, -2)
sage: list(L.fundamental_weights())
[(1, 0, 0, 0, 0, 0, 0),
 (1, 1, 0, 0, 0, 0, 0),
 (1, 1, 1, 0, 0, 0, 0),
 (1, 1, 1, 1, 0, 0, 0),
 (1, 1, 1, 1, -1, -2, -2),
 (1, 1, 1, 1, -1, -1, -2)]
```

```python
>>> from sage.all import *

```
[ 0 0 1 0 0 0]
[ 0 0 0 -1 0 0]
[ 0 0 0 0 -1 0]
[ 0 0 0 0 0 -1]

>>> from sage.all import *
>>> L = RootSystem(['A', [Integer(2),Integer(3)]]).ambient_space()
>>> La = L.fundamental_weights()
>>> I = L.index_set()
>>> matrix([[al[i].scalar(La[j]) for i in I] for j in I])
[ 1 0 0 0 0 0]
[ 0 1 0 0 0 0]
[ 0 0 1 0 0 0]
[ 0 0 0 -1 0 0]
[ 0 0 0 0 -1 0]
[ 0 0 0 0 0 -1]

highest_root()

Return the highest root of self.

EXAMPLES:

sage: e = RootSystem(['A', [4,2]]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, 0, 0, 0, 0, -1)

>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(4),Integer(2)]]).ambient_lattice()
>>> e.highest_root()
(1, 0, 0, 0, 0, 0, 0, -1)

negative_even_roots()

Return the negative even roots of self.

EXAMPLES:

sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_even_roots()
[(0, -1, 1, 0, 0), (-1, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0), (0, 0, 0, -1, 1)]

>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_lattice()
>>> e.negative_even_roots()
[(0, -1, 1, 0, 0), (-1, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0), (0, 0, 0, -1, 1)]

negative_odd_roots()

Return the negative odd roots of self.

EXAMPLES:

sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_odd_roots()
negative_roots()

Return the negative roots of self.

EXAMPLES:

```python
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.negative_roots()
[(-1, 1, 0, 0, 0),
 (0, 0, 0, -1, 1),
 (0, 0, -1, 1, 0),
 (0, 0, -1, 0, 1),
 (-1, 0, 0, 1, 0),
 (-1, 0, 0, 0, 1)]
```

positive_even_roots()

Return the positive even roots of self.

EXAMPLES:

```python
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_even_roots()
```
([(0, 1, -1, 0, 0), (1, 0, -1, 0, 0),
(1, -1, 0, 0, 0), (0, 0, 0, 1, -1)]

>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_lattice()
>>> e.positive_even_roots()
[(0, 1, -1, 0, 0), (1, 0, -1, 0, 0),
(1, -1, 0, 0, 0), (0, 0, 0, 1, -1)]

positive_odd_roots()
Return the positive odd roots of self.

EXAMPLES:

sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_odd_roots()
[(0, 0, 1, -1, 0),
(0, 0, 1, 0, -1),
(0, 1, 0, -1, 0),
(0, 1, 0, 0, -1),
(1, 0, 0, -1, 0),
(1, 0, 0, 0, -1)]

>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_lattice()
>>> e.positive_odd_roots()
[(0, 0, 1, -1, 0),
(0, 0, 1, 0, -1),
(0, 1, 0, -1, 0),
(0, 1, 0, 0, -1),
(1, 0, 0, -1, 0),
(1, 0, 0, 0, -1)]

positive_roots()
Return the positive roots of self.

EXAMPLES:

sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: e.positive_roots()
[(0, 1, -1, 0, 0),
(1, 0, -1, 0, 0),
(1, -1, 0, 0, 0),
(0, 0, 0, 1, -1),
(0, 0, 1, -1, 0),
(0, 0, 1, 0, -1),
(0, 1, 0, -1, 0),
(0, 1, 0, 0, -1),
(1, 0, 0, -1, 0),
(1, 0, 0, 0, -1)]

>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_lattice()
>>> e.positive_roots()
[(0, 1, -1, 0, 0),
(1, 0, -1, 0, 0),
(1, -1, 0, 0, 0),
(0, 0, 0, 1, -1),
(0, 0, 1, -1, 0),
(0, 0, 1, 0, -1),
(0, 1, 0, -1, 0),
(0, 1, 0, 0, -1),
(1, 0, 0, -1, 0),
(1, 0, 0, 0, -1)]

(continues on next page)
(1, 0, -1, 0, 0),
(1, -1, 0, 0, 0),
(0, 0, 0, 1, -1),
(0, 0, 1, -1, 0),
(0, 0, 1, 0, -1),
(0, 1, 0, -1, 0),
(0, 1, 0, 0, -1),
(1, 0, 0, -1, 0),
(1, 0, 0, 0, -1)]

simple_coroot(\(i\))

Return the simple coroot \(h_i\) of self.

EXAMPLES:

```python
sage: L = RootSystem(['A', [3,2]]).ambient_space()
sage: L.simple_coroot(-2)
(0, 1, -1, 0, 0, 0)
sage: L.simple_coroot(0)
(0, 0, 0, 1, -1, 0)
sage: L.simple_coroot(2)
(0, 0, 0, 0, 0, -1)
sage: list(L.simple_coroots())
[(1, -1, 0, 0, 0, 0),
 (1, -1, 0, 0, 0, 0),
 (0, 0, 1, -1, 0, 0),
 (0, 0, 0, 1, -1, 0),
 (0, 0, 0, 0, 0, -1)]
```

>>> from sage.all import *

```python
>>> L = RootSystem(['A', [Integer(3),Integer(2)]]).ambient_space()
>>> L.simple_coroot(-Integer(2))
(0, 1, -1, 0, 0, 0)
>>> L.simple_coroot(Integer(0))
(0, 0, 0, 1, -1, 0)
>>> L.simple_coroot(Integer(2))
(0, 0, 0, 0, 0, -1)
>>> list(L.simple_coroots())
[(1, -1, 0, 0, 0, 0),
 (1, -1, 0, 0, 0, 0),
 (0, 0, 1, -1, 0, 0),
 (0, 0, 0, 1, -1, 0),
 (0, 0, 0, 0, 0, -1)]
```

simple_root(\(i\))

Return the \(i\)-th simple root of self.

EXAMPLES:

```python
sage: e = RootSystem(['A', [2,1]]).ambient_lattice()
sage: list(e.simple_roots())
[(1, -1, 0, 0, 0), (0, 1, -1, 0, 0), (0, 0, 1, -1, 0), (0, 0, 0, 1, -1)]
```
```python
>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(2),Integer(1)]]).ambient_lattice()
>>> list(e.simple_roots())
[(1, -1, 0, 0, 0), (0, 1, -1, 0, 0), (0, 0, 1, -1, 0), (0, 0, 0, 1, -1)]
```

classmethod smallest_base_ring(cartan_type=None)

Return the smallest base ring the ambient space can be defined upon.

See also:

smallest_base_ring()

EXAMPLES:

```python
sage: e = RootSystem(['A', [3,1]]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

```python
>>> from sage.all import *
>>> e = RootSystem(['A', [Integer(3),Integer(1)]]).ambient_space()
>>> e.smallest_base_ring()
Integer Ring
```

```python
class sage.combinat.root_system.type_super_A.CartanType(m, n)
Bases: SuperCartanType_standard

Cartan Type A(m|n).

See also:

CartanType()

AmbientSpace
alias of AmbientSpace

asci_art (label=None, node=None)

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```python
sage: t = CartanType(['A', [3,2]])
sage: print(t.ascii_art())
O---O---O---X---O---O
-3 -2 -1 0 1 2
sage: t = CartanType(['A', [3,7]])
sage: print(t.ascii_art())
O---O---O---X---O---O---O---O---O---O---O
-3 -2 -1 0 1 2 3 4 5 6 7
sage: t = CartanType(['A', [0,7]])
sage: print(t.ascii_art())
X---O---O---O---O---O---O---O---O---O---O---O
-3 -2 -1 0 1 2 3 4 5 6 7
```
```
```
Combinatorics, Release 10.4  

```python
sage: print(t.ascii_art())
0---O---O---O---O---X
-5 -4 -3 -2 -1 0

>>> from sage.all import *

>>> t = CartanType(['A', [Integer(3),Integer(2)]]

>>> print(t.ascii_art())
0---O---O---X---O---O
-3 -2 -1 0 1 2

>>> t = CartanType(['A', [Integer(3),Integer(7)]]

>>> print(t.ascii_art())
0---O---O---X---O---O---O---O---O---O---O
-3 -2 -1 0 1 2 3 4 5 6 7

>>> t = CartanType(['A', [Integer(0),Integer(7)]]

>>> print(t.ascii_art())
X---O---O---O---O---O---O---O
0 1 2 3 4 5 6 7

>>> t = CartanType(['A', [Integer(0),Integer(0)]]

>>> print(t.ascii_art())
X
0

>>> t = CartanType(['A', [Integer(5),Integer(0)]]

>>> print(t.ascii_art())
O---O---O---O---O---X
-5 -4 -3 -2 -1 0
```

cartan_matrix()

Return the Cartan matrix associated to self.

EXAMPLES:

```python
sage: ct = CartanType(['A', [2,3]])
sage: ct.cartan_matrix()
#...

[2 -1 0 0 0 0]
[-1 2 -1 0 0 0]
[0 -1 0 1 0 0]
[0 0 -1 2 -1 0]
[0 0 0 -1 2 -1]
[0 0 0 0 -1 2]
```

dual()

Return dual of self.

EXAMPLES:

```python
>>> from sage.all import *

>>> ct = CartanType(['A', [Integer(2),Integer(3)]]

>>> ct.dual_matrix()
#...

[2 -1 0 0 0 0]
[-1 2 -1 0 0 0]
[0 -1 0 1 0 0]
[0 0 -1 2 -1 0]
[0 0 0 -1 2 -1]
[0 0 0 0 -1 2]
```
```python
sage: CartanType(['A', [2,3]]).dual()
['A', [2, 3]]

>>> from sage.all import *
>>> CartanType(['A', [Integer(2),Integer(3)]]).dual()
['A', [2, 3]]
```

**dynkin_diagram()**

Return the Dynkin diagram of super type A.

**EXAMPLES:**

```python
sage: a = CartanType(['A', [4,2]]).dynkin_diagram(); a
# needs sage.graphs
O---O---O---O---X---O---O
-4 -3 -2 -1 0 1 2
A4|2
sage: a.edges(sort=True)
# needs sage.graphs
[(-4, -3, 1), (-3, -4, 1), (-3, -2, 1), (-2, -3, 1),
 (-2, -1, 1), (-1, -2, 1), (-1, 0, 1), (0, -1, 1),
 (0, 1, 1), (1, 0, -1), (1, 2, 1), (2, 1, 1)]
```

```python
>>> from sage.all import *
>>> a = CartanType(['A', [Integer(4),Integer(2)]]).dynkin_diagram(); a
# needs sage.graphs
O---O---O---O---X---O---O
-4 -3 -2 -1 0 1 2
A4|2
```

```python
>>> a.edges(sort=True)
# needs sage.graphs
[(-4, -3, 1), (-3, -4, 1), (-3, -2, 1), (-2, -3, 1),
 (-2, -1, 1), (-1, -2, 1), (-1, 0, 1), (0, -1, 1),
 (0, 1, 1), (1, 0, -1), (1, 2, 1), (2, 1, 1)]
```

**index_set()**

Return the index set of self.

**EXAMPLES:**

```python
sage: CartanType(['A', [2,3]]).index_set()
(-2, -1, 0, 1, 2, 3)
```

```python
>>> from sage.all import *
>>> CartanType(['A', [Integer(2),Integer(3)]]).index_set()
(-2, -1, 0, 1, 2, 3)
```

**is_affine()**

Return whether self is affine or not.

**EXAMPLES:**

```python
sage: CartanType(['A', [2,3]]).is_affine()
False
```
from sage.all import *

CartanType(['A', [2,3]]).is_affine()
False

is_finite()
Return whether self is finite or not.

EXAMPLES:
sage: CartanType(['A', [2,3]]).is_finite()
True

CartanType(['A', [2,3]]).is_finite()
True

is_irreducible()
Return whether self is irreducible, which is True.

EXAMPLES:
sage: CartanType(['A', [3,4]]).is_irreducible()
True

CartanType(['A', [3,4]]).is_irreducible()
True

relabel(relabelling)
Return a relabelled copy of this Cartan type.

INPUT:
• relabelling – a function (or a list or dictionary)

OUTPUT:
an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label $i$ is relabelled $f(i)$ (or, by $f[i]$ if $f$ is a list or dictionary).

EXAMPLES:
sage: ct = CartanType(['A', [1,2]])
sage: ct.dynkin_diagram() #...
\texttt{needs sage.graphs}
0---X---0---0
-1 0 1 2
A1|2
sage: f = {1:2, 2:1, 0:0, -1:-1}
sage: ct.relabel(f)
['A', [1, 2]] relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}
sage: ct.relabel(f).dynkin_diagram() #...
\texttt{needs sage.graphs}
0---X---0---0
-1 0 2 1
A1|2 relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}
>>> from sage.all import *

>>> ct = CartanType(['A', [Integer(1), Integer(2)]])

>>> ct.dynkin_diagram()

O---X---O---O
-1 0 1 2
A1|2

>>> f = {Integer(1):Integer(2), Integer(2):Integer(1), Integer(0):Integer(0),

-1: -Integer(1):-Integer(1)}

>>> ct.relabel(f)

[‘A’, [1, 2]] relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}

>>> ct.relabel(f).dynkin_diagram()

O---X---O---O
-1 0 2 1
A1|2 relabelled by {-1: -1, 0: 0, 1: 2, 2: 1}

root_system()

Return root system of self.

EXAMPLES:

sage: CartanType(['A', [2,3]]).root_system()
Root system of type ['A', [2, 3]]

symsmetrizer()

Return symmetrizing matrix for self.

EXAMPLES:

sage: CartanType(['A', [2,3]]).symmetrizer()
Finite family {-2: 1, -1: 1, 0: 1, 1: -1, 2: -1, 3: -1}

sage: CartanType(['A', [2,3]]).symmetrizer()
Finite family {-2: 1, -1: 1, 0: 1, 1: -1, 2: -1, 3: -1}

sage: CartanType(['A', [2,3]]).type()
'A'

sage: CartanType(['A', [2,3]]).type()
'A'
5.1.243 Root system data for type A

```python
class sage.combinat.root_system.type_A.AmbientSpace(root_system, base_ring, index_set=None)
```

**Bases:** `AmbientSpace`

**EXAMPLES:**

```python
sage: R = RootSystem(['A',3])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3]
sage: TestSuite(e).run()  # needs sage.graphs

>>> from sage.all import *
>>> R = RootSystem(['A',Integer(3)])
>>> e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3]
>>> TestSuite(e).run()  # needs sage.graphs
```

By default, this ambient space uses the barycentric projection for plotting:

```python
sage: # needs sage.symbolic
sage: L = RootSystem(['A',2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
```

```python
>>> from sage.all import *
>>> # needs sage.symbolic
>>> L = RootSystem(['A',Integer(3)]).ambient_space()
>>> l = L.an_element(); l
(2, 2, 3, 0)
>>> L._plot_projection(l)
(0, -1121/1189, 7/3)
```

**See also:**

- `sage.combinat.root_system.root_lattice_realizations`. 
RootLatticeRealizations.ParentMethods._plot_projection()

\textbf{det} (k=1)

returns the vector \((1, \ldots, 1)\) which in the ['A',r] weight lattice, interpreted as a weight of GL(r+1,CC) is the determinant. If the optional parameter \(k\) is given, returns \((k, \ldots, k)\), the k-th power of the determinant.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.det(1/2)
[1/2, 1/2, 1/2, 1/2]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> e = RootSystem(['A',Integer(3)]).ambient_space()
>>> e.det(Integer(1)/Integer(2))
[1/2, 1/2, 1/2, 1/2]
\end{verbatim}

dimension()

\textbf{EXAMPLES:}

\begin{verbatim}
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.dimension()
4
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> e = RootSystem(['A',Integer(3)]).ambient_space()
>>> e.dimension()
4
\end{verbatim}

\textbf{fundamental_weight} (i)

\textbf{EXAMPLES:}

\begin{verbatim}
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()
>>> e.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}
\end{verbatim}

\textbf{highest_root}()

\textbf{EXAMPLES:}

\begin{verbatim}
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.highest_root()
(1, 0, 0, -1)
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()
>>> e.highest_root()
(1, 0, 0, -1)
\end{verbatim}

\textbf{negative_roots}()

\textbf{EXAMPLES:}
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 1, 0),
 (0, -1, 0, 1),
 (0, 0, -1, 1)]

>>> from sage.all import *
>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()
>>> e.negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 1, 0),
 (0, -1, 0, 1),
 (0, 0, -1, 1)]

positive_roots()

EXAMPLES:

sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.positive_roots()
[(1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]

>>> from sage.all import *
>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()
>>> e.positive_roots()
[(1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]

root (i, j)

Note that indexing starts at 0.

EXAMPLES:

sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.root(0,1)
(1, -1, 0, 0)

>>> from sage.all import *
>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()
>>> e.root(Integer(0),Integer(1))
(1, -1, 0, 0)

simple_root (i)

EXAMPLES:
```python
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

```python
>>> from sage.all import *

>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()

>>> e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

class method smallest_base_ring(cartan_type=None)

Returns the smallest base ring the ambient space can be defined upon

See also:

smallest_base_ring()

EXAMPLES:

```python
sage: e = RootSystem(['A',3]).ambient_space()
sage: e.smallest_base_ring()
Integer Ring
```

```python
>>> from sage.all import *

>>> e = RootSystem(['A',Integer(3)]).ambient_space()

>>> e.smallest_base_ring()
Integer Ring
```

class sage.combinat.root_system.type_A.CartanType(n)

Bases: `CartanType_standard_finite, CartanType_simply_laced, CartanType_simple`

Cartan Type $A_n$

See also:

CartanType()

AmbientSpace

alias of `AmbientSpace`

PieriFactors

alias of `PieriFactors_type_A`

ascii_art(label=None, node=None)

Return an ascii art representation of the Dynkin diagram.

EXAMPLES:

```python
sage: print(CartanType(['A',0]).ascii_art())
sage: print(CartanType(['A',1]).ascii_art())
O
1
sage: print(CartanType(['A',3]).ascii_art())
O---O---O
1 2 3
sage: print(CartanType(['A',12]).ascii_art())
1 2 3 4 5 6 7 8 9 10 11 12
sage: print(CartanType(['A',5]).ascii_art(label = lambda x: x+2))
(continues on next page)
```
### sage: print(CartanType(['A', 5]).ascii_art(label = lambda x: x-2))
```
O---O---O---O---O
  3 4 5 6 7
```

```plaintext
>>> from sage.all import *

```plaintext
>>> print(CartanType(['A', Integer(0)]).ascii_art())
```
```
O
  1
```

```plaintext
>>> print(CartanType(['A', Integer(1)]).ascii_art())
```
```
O---O
  1 2
```

```plaintext
>>> print(CartanType(['A', Integer(3)]).ascii_art())
```
```
O---O---O
  1 2 3
```

```plaintext
>>> print(CartanType(['A', Integer(12)]).ascii_art())
```
```
  1 2 3 4 5 6 7 8 9 10 11 12
```

```plaintext
>>> print(CartanType(['A', Integer(5)]).ascii_art(label = lambda x: x+2))
```
```
O---O---O---O---O
  3 4 5 6 7
```

```plaintext
>>> print(CartanType(['A', Integer(5)]).ascii_art(label = lambda x: x-2))
```
```
O---O---O---O---O
  -1 0 1 2 3
```

coxeter_number()
Return the Coxeter number associated with self.

EXAMPLES:

```plaintext
sage: CartanType(['A', 4]).coxeter_number()
```
```
5
```

```plaintext
>>> from sage.all import *

```plaintext
>>> CartanType(['A', Integer(4)]).coxeter_number()
```
```
5
```
dual_coxeter_number()
Return the dual Coxeter number associated with self.

EXAMPLES:

```plaintext
sage: CartanType(['A', 4]).dual_coxeter_number()
```
```
5
```

```plaintext
>>> from sage.all import *

```plaintext
>>> CartanType(['A', Integer(4)]).dual_coxeter_number()
```
```
5
```
dynkin_diagram()
Returns the Dynkin diagram of type A.

EXAMPLES:
5.1.244 Root system data for (untwisted) type A affine

```python
class sage.combinat.root_system.type_A_affine.CartanType(n):
    Bases: CartanType_standard_untwisted_affine

    EXAMPLES:
    sage: ct = CartanType(['A', 4, 1])
    sage: ct
    ['A', 4, 1]
    sage: ct._repr_(compact = True)
    'A4~'
    sage: ct.is_irreducible()
    True
    sage: ct.is_finite()
    False
    sage: ct.is_affine()
    True
    sage: ct.is_untwisted_affine()
    True
    sage: ct.is_crystallographic()
    True
    sage: ct.is_simply_laced()
    True
    sage: ct.classical()
    ['A', 4]
    sage: ct.dual()
    ['A', 4, 1]
    sage: ct = CartanType(['A', 1, 1])
    sage: ct.is_simply_laced()
    False
    sage: ct.dual()
    ['A', 1, 1]
```

```python
sage: a = CartanType(['A', 3]).dynkin_diagram(); a

O---O---O
1 2 3
A3

sage: a.edges(sort=True)

[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1)]

>>> from sage.all import *
>>> a = CartanType(['A', Integer(3)]).dynkin_diagram(); a

O---O---O
1 2 3
A3

>>> a.edges(sort=True)

[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1)]
```
>>> from sage.all import *
>>> ct = CartanType(['A',Integer(4),Integer(1)])
["A", 4, 1]
>>> ct._repr_(compact = True)
'A4~'

>>> ct.is_irreducible()
True
>>> ct.is_finite()
False
>>> ct.is_affine()
True
>>> ct.is_untwisted_affine()
True
>>> ct.is_crystallographic()
True
>>> ct.is_simply_laced()
True
>>> ct.classical()
["A", 4]
>>> ct.dual()
["A", 4, 1]

>>> ct = CartanType(['A', Integer(1), Integer(1)])
>>> ct.is_simply_laced()
False
>>> ct.dual()
['A', 1, 1]

PieriFactors
alias of PieriFactors_type_A_affine

ascii_art (label=None, node=None)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

sage: print(CartanType(['A',3,1]).ascii_art())
0
  O-------+
    | |
    | |
  O----O----O
  1 2 3

sage: print(CartanType(['A',5,1]).ascii_art(label = lambda x: x+2))
 2
  O---------------+
    | |
    | |
  O---O---O---O---O
  3 4 5 6 7

sage: print(CartanType(['A',1,1]).ascii_art())
0<=0
  0  1
sage: print(CartanType(['A',1,1]).ascii_art(label = lambda x: x+2))
O<=>O
2 3

>>> from sage.all import *

>>> print(CartanType(['A',Integer(3),Integer(1)]).ascii_art())
0
O-------+
| |
| |
O---O---O
1 2 3

>>> print(CartanType(['A',Integer(5),Integer(1)]).ascii_art(label = lambda x: x+Integer(2)))
2
O---------------+
| |
| |
O---O---O---O---O
3 4 5 6 7

>>> print(CartanType(['A',Integer(1),Integer(1)]).ascii_art())
O<=>O
0 1

>>> print(CartanType(['A',Integer(1),Integer(1)]).ascii_art(label = lambda x: x+Integer(2)))
O<=>O
2 3
dual()

Type $A_1^1$ is self dual despite not being simply laced.

EXAMPLES:

sage: CartanType(['A',1,1]).dual()
['A', 1, 1]

>>> from sage.all import *

>>> CartanType(['A',1,1]).dual()
['A', 1, 1]
dynkin_diagram()

Returns the extended Dynkin diagram for affine type A.

EXAMPLES:

sage: a = CartanType(['A',3,1]).dynkin_diagram(); a
# needs sage.graphs
0
O-------+
| |
| |
O---O---O

(continues on next page)
sage: a.edges(sort=True)  # needs sage.graphs
[(0, 1, 1),
 (0, 3, 1),
 (1, 0, 1),
 (1, 2, 1),
 (2, 1, 1),
 (2, 3, 1),
 (3, 0, 1),

>>> a.edges(sort=True)  # needs sage.graphs
[(0, 1, 2), (1, 0, 2)]
5.1.245 Root system data for type A infinity

```python
class sage.combinat.root_system.type_A_infinity.CartanType(index_set):
    Bases: CartanType_standard, CartanType_simple

The Cartan type $A_\infty$.

We use $\mathbb{N}$ and $\mathbb{Z}$ to explicitly differentiate between the $A_{\infty}$ and $A_\infty$ root systems, respectively. While $\infty$ is the same as $+\text{Infinity}$ in Sage, it is used as an alias for $\mathbb{Z}$.

```
```python
>>> from sage.all import *
>>> CartanType(['A', NN]).index_set()
Non negative integer semiring
>>> CartanType(['A', ZZ]).index_set()
Integer Ring
```

**is_affine()**

Return False because self is not (untwisted) affine.

**EXAMPLES:**

```
sage: CartanType(['A', NN]).is_affine()
False
sage: CartanType(['A', ZZ]).is_affine()
False
```

```python
>>> from sage.all import *
>>> CartanType(['A', NN]).is_affine()
False
>>> CartanType(['A', ZZ]).is_affine()
False
```

**is_crystallographic()**

Return False because self is not crystallographic.

**EXAMPLES:**

```
sage: CartanType(['A', NN]).is_crystallographic()
True
sage: CartanType(['A', ZZ]).is_crystallographic()
True
```

```python
>>> from sage.all import *
>>> CartanType(['A', NN]).is_crystallographic()
True
>>> CartanType(['A', ZZ]).is_crystallographic()
True
```

**is_finite()**

Return True because self is not finite.

**EXAMPLES:**

```
sage: CartanType(['A', NN]).is_finite()
False
sage: CartanType(['A', ZZ]).is_finite()
False
```

```python
>>> from sage.all import *
>>> CartanType(['A', NN]).is_finite()
False
>>> CartanType(['A', ZZ]).is_finite()
False
```

**is_simply_laced()**

Return True because self is simply laced.
Combinatorics, Release 10.4

EXAMPLES:

```python
sage: CartanType(['A', NN]).is_simply_laced()
True
sage: CartanType(['A', ZZ]).is_simply_laced()
True

>>> from sage.all import *

>>> CartanType(['A', NN]).is_simply_laced()
True
>>> CartanType(['A', ZZ]).is_simply_laced()
True
```

`is_untwisted_affine()`

Return `False` because `self` is not (untwisted) affine.

EXAMPLES:

```python
sage: CartanType(['A', NN]).is_untwisted_affine()
False
sage: CartanType(['A', ZZ]).is_untwisted_affine()
False

>>> from sage.all import *

>>> CartanType(['A', NN]).is_untwisted_affine()
False
>>> CartanType(['A', ZZ]).is_untwisted_affine()
False
```

`rank()`

Return the rank of `self` which for type $X_n$ is $n$.

EXAMPLES:

```python
sage: CartanType(['A', NN]).rank()
+Infinity
sage: CartanType(['A', ZZ]).rank()
+Infinity

>>> from sage.all import *

>>> CartanType(['A', NN]).rank()
+Infinity
>>> CartanType(['A', ZZ]).rank()
+Infinity
```

As this example shows, the rank is slightly ambiguous because the root systems of type $[\prime A', NN]$ and type $[\prime A', ZZ]$ have the same rank. Instead, it is better ot use `index_set()` to differentiate between these two root systems.

`type()`

Return the type of `self`.

EXAMPLES:

```python
sage: CartanType(['A', NN]).type()
'A'
sage: CartanType(['A', ZZ]).type()
'A'
```
```python
>>> from sage.all import *

>>> CartanType(['A', NN]).type()
'A'

>>> CartanType(['A', ZZ]).type()
'A'
```

### 5.1.246 Root system data for type B

```python
class sage.combinat.root_system.type_B.AmbientSpace(root_system, base_ring, index_set=None)
```

**Bases:** AmbientSpace

**dimension()**

**EXAMPLES:**

```python
sage: e = RootSystem(['B',3]).ambient_space()
sage: e.dimension()
3
```

```python
>>> from sage.all import *

>>> e = RootSystem(['B',Integer(3)]).ambient_space()

>>> e.dimension()
3
```

**fundamental_weight(i)**

**EXAMPLES:**

```python
sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

```python
>>> from sage.all import *

>>> RootSystem(['B',Integer(3)]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

**negative_roots()**

**EXAMPLES:**

```python
sage: RootSystem(['B',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, -1, 0),
 (-1, 0, 1),
 (-1, 0, -1),
 (0, -1, 1),
 (0, -1, -1),
 (-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1)]

>>> from sage.all import *

>>> RootSystem(['B',Integer(3)]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, -1, 0),
 (-1, 0, 1),
 (continues on next page)]
```
\begin{align*}
(-1, 0, -1), \\
(0, -1, 1), \\
(0, -1, -1), \\
(-1, 0, 0), \\
(0, -1, 0), \\
(0, 0, -1)
\end{align*}

**positive_roots()**

**EXAMPLES:**

\begin{verbatim}
sage: RootSystem(['B',3]).ambient_space().positive_roots()
[(1, -1, 0), \\
 (1, 1, 0), \\
 (1, 0, -1), \\
 (1, 0, 1), \\
 (0, 1, -1), \\
 (0, 1, 1), \\
 (1, 0, 0), \\
 (0, 1, 0), \\
 (0, 0, 1)]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

RootSystem(['B',Integer(3)]).ambient_space().positive_roots()
[(1, -1, 0), \\
 (1, 1, 0), \\
 (1, 0, -1), \\
 (1, 0, 1), \\
 (0, 1, -1), \\
 (0, 1, 1), \\
 (1, 0, 0), \\
 (0, 1, 0), \\
 (0, 0, 1)]
\end{verbatim}

**root (i, j)**

Note that indexing starts at 0.

**EXAMPLES:**

\begin{verbatim}
sage: e = RootSystem(['B',3]).ambient_space()
sage: e.root(0,1)
(1, -1, 0)
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

RootSystem(['B',Integer(3)]).ambient_space()
>>> e.root(Integer(0),Integer(1))
(1, -1, 0)
\end{verbatim}

**simple_root (i)**

**EXAMPLES:**

\begin{verbatim}
sage: e = RootSystem(['B',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 1)}
sage: e.positive_roots()
\end{verbatim}
Combinatorics, Release 10.4

AmbientSpace

alias of AmbientSpace

PieriFactors

alias of PieriFactors_type_B

5.1. Comprehensive Module List 4147
**ascii_art** (label=None, node=None)

Return an ascii art representation of the Dynkin diagram.

**EXAMPLES:**

```python
sage: print(CartanType(['B',1]).ascii_art())
O
1
sage: print(CartanType(['B',2]).ascii_art())
O=>=O
1 2
sage: print(CartanType(['B',5]).ascii_art(label = lambda x: x+2))
O---O---O---O=>=O
3 4 5 6 7
```

```python
>>> from sage.all import *
>>> print(CartanType(['B',1]).ascii_art())
O
1
>>> print(CartanType(['B',2]).ascii_art())
O=>=O
1 2
>>> print(CartanType(['B',5]).ascii_art(label = lambda x: x+Integer(2)))
O---O---O---O=>=O
3 4 5 6 7
```

**coxeter_number**

Return the Coxeter number associated with *self*.

**EXAMPLES:**

```python
sage: CartanType(['B',4]).coxeter_number()
8
```

```python
>>> from sage.all import *
>>> CartanType(['B',4]).coxeter_number()
8
```

**dual**

Types B and C are in duality:

**EXAMPLES:**

```python
sage: CartanType(['C', 3]).dual()
['B', 3]
```

```python
>>> from sage.all import *
>>> CartanType(['C', 3]).dual()
['B', 3]
```

**dual_coxeter_number**

Return the dual Coxeter number associated with *self*.

**EXAMPLES:**

```python
```
sage: CartanType(['B',4]).dual_coxeter_number()
7

>>> from sage.all import *
>>> CartanType(['B',Integer(4)]).dual_coxeter_number()
7

dynkin_diagram()

Returns a Dynkin diagram for type B.

EXAMPLES:

sage: b = CartanType(['B',3]).dynkin_diagram(); b
O---O=>=O
 1 2 3
B3

sage: b.edges(sort=True)

[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

sage: b = CartanType(['B',1]).dynkin_diagram(); b
O
 1
B1

sage: b.edges(sort=True)

[]

>>> from sage.all import *

>>> b = CartanType(['B',Integer(3)]).dynkin_diagram(); b
O---O=>=O
 1 2 3
B3

>>> b.edges(sort=True)

[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

>>> b = CartanType(['B',Integer(1)]).dynkin_diagram(); b
O
 1
B1

>>> b.edges(sort=True)

[]
5.1.247 Root system data for type BC affine

```python
class sage.combinat.root_system.type_BC_affine.CartanType(n):
    Bases: CartanType_standard_affine

    EXAMPLES:

    sage: ct = CartanType(['BC', 4, 2])
    sage: ct
    ['BC', 4, 2]
    sage: ct._repr_(compact=True)
    'BC4~'

>>> print(CartanType(['BC',Integer(1),Integer(2)]).ascii_art(label = lambda x: x+Integer(2)))
4
0=<x=0
2 3

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

sage: CartanType(['A', 2, 2]).basic_untwisted()
['A', 2]

sage: CartanType(['A', 4, 2]).basic_untwisted()
['A', 4]

sage: CartanType(['BC', 4, 2]).basic_untwisted()
['A', 8]

classical()

Returns the classical Cartan type associated with self

    sage: CartanType(['BC', 3, 2]).classical() ['C', 3]

dynkin_diagram()

Returns the extended Dynkin diagram for affine type BC.

EXAMPLES:
sage: c = CartanType(['BC', 3, 2]).dynkin_diagram(); c
# needs sage.graphs
O=<=O---O=<=O
0 1 2 3
BC3~
sage: c.edges(sort=True)
# needs sage.graphs
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: c = CartanType(['A', 6, 2]).dynkin_diagram()  # should be the same as above; did fail at some point! # needs sage.graphs
sage: c
# needs sage.graphs
O=<=O---O=<=O
0 1 2 3
BC3~
sage: c.edges(sort=True)
# needs sage.graphs
[(0, 1, 1), (1, 0, 2), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: c = CartanType(['BC', 2, 2]).dynkin_diagram(); c
# needs sage.graphs
O=<=O=<=O
0 1 2

>>> ct.is_untwisted_affine()
True

>>> ct.is_crystallographic()
True

>>> ct.is_simply_laced()
False

>>> ct.classical()
['B', 4]

>>> ct.dual()
['B', 4, 1]^

>>> ct.dual().is_untwisted_affine()
False

PieriFactors

alias of PieriFactors_type_B_affine

ascii_art (label=None, node=None)

Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:

```
sage: print(CartanType(['B',3,1]).ascii_art())
  0 0
   |  |
0---O=>=O
  1 2 3

sage: print(CartanType(['B',5,1]).ascii_art(label = lambda x: x+2))
  0 2
   |  |
O---O---O---O=>=O
  3 4 5 6 7

sage: print(CartanType(['B',2,1]).ascii_art(label = lambda x: x+2))
  O=O=O=O
  0=O=O=O
  2 4 3

sage: print(CartanType(['B',1,1]).ascii_art(label = lambda x: x+2))
  0<=O<=O
  2 3
```

>>> from sage.all import *

>>> print(CartanType(['B',Integer(3),Integer(1)]).ascii_art())
(continues on next page)
dynkin_diagram()

Return the extended Dynkin diagram for affine type $B$.

EXAMPLES:

.. code-block:: python

    sage: # needs sage.graphs
    sage: b = CartanType(['B',3,1]).dynkin_diagram(); b
    O 0
    |   
    |   
    O---O=>=O
    1 2 3
    B3~
    sage: b.edges(sort=True)
    [(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]

    sage: b = CartanType(['B',2,1]).dynkin_diagram(); b
    O=>=O=<=O
    0 2 1
    B2~
    sage: b.edges(sort=True)
    [(0, 2, 2), (1, 2, 2), (2, 0, 1), (2, 1, 1)]

    sage: b = CartanType(['B',1,1]).dynkin_diagram(); b
    O<=>O
    0 1
    B1~
    sage: b.edges(sort=True)
    [(0, 1, 2), (1, 0, 2)]

    >>> from sage.all import *

5.1.249 Root system data for type C

\textbf{class} \textit{sage.combinat.root_system.type_C.AmbientSpace}(\textit{root_system, base_ring, index_set=None})

Bases: \textit{AmbientSpace}

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: e = RootSystem(['C',2]).ambient_space(); e
  Ambient space of the Root system of type ['C', 2]
  >>> from sage.all import *
  >>> e = RootSystem(['C',Integer(2)]).ambient_space(); e
  Ambient space of the Root system of type ['C', 2]
  
  One cannot construct the ambient lattice because the fundamental coweights have rational coefficients:

  sage: e.smallest_base_ring()
  Rational Field

  sage: RootSystem(['B',2]).ambient_space().fundamental_weights()
  Finite family {1: (1, 0), 2: (1/2, 1/2)}

  >>> from sage.all import *
  >>> e.smallest_base_ring()
  Rational Field

  >>> RootSystem(['B',Integer(2)]).ambient_space().fundamental_weights()
  Finite family {1: (1, 0), 2: (1/2, 1/2)}

  \textbf{dimension}()

  \textbf{EXAMPLES:}
\end{verbatim}
sage: e = RootSystem(['C',3]).ambient_space()
sage: e.dimension()
3

>>> from sage.all import *
>>> e = RootSystem(['C',Integer(3)]).ambient_space()
>>> e.dimension()
3

fundamental_weight (i)
EXAMPLES:

sage: RootSystem(['C',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1, 1, 1)}

>>> from sage.all import *
>>> RootSystem(['C',Integer(3)]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1, 1, 1)}

negative_roots()
EXAMPLES:

sage: RootSystem(['C',3]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, 0, 1),
 (0, -1, 1),
 (-1, -1, 0),
 (-1, 0, -1),
 (0, -1, -1),
 (-2, 0, 0),
 (0, -2, 0),
 (0, 0, -2)]

>>> from sage.all import *
>>> RootSystem(['C',Integer(3)]).ambient_space().negative_roots()
[(-1, 1, 0),
 (-1, 0, 1),
 (0, -1, 1),
 (-1, -1, 0),
 (-1, 0, -1),
 (0, -1, -1),
 (-2, 0, 0),
 (0, -2, 0),
 (0, 0, -2)]

positive_roots()
EXAMPLES:

sage: RootSystem(['C',3]).ambient_space().positive_roots()
[(1, 1, 0),
 (1, 0, 1),
 (0, 1, 1),
 (1, -1, 0),
 (1, 0, -1),
 (0, 1, -1),
 (0, 1, -1),
 (0, 1, -1),
 (0, 1, -1),
 (0, 1, -1),
 (continues on next page)
\[(2, 0, 0),
\(0, 2, 0),
\(0, 0, 2)\]

\[

['C', 1, 1]

AmbientSpace
    alias of AmbientSpace

ascii_art (label=None, node=None)

    Return a ascii art representation of the extended Dynkin diagram.

    EXAMPLES:

        sage: print(CartanType(['C',1]).ascii_art())
        0
        1
        sage: print(CartanType(['C',2]).ascii_art())
        0=<=0
        1  2

(continues on next page)
sage: print(CartanType(['C',3]).ascii_art())
O---O=<=O
1 2 3
sage: print(CartanType(['C',5]).ascii_art(label = lambda x: x+2))
O---O---O---O=<=O
3 4 5 6 7

>>> from sage.all import *
>>> print(CartanType(['C',Integer(1)]).ascii_art())
O
1
>>> print(CartanType(['C',Integer(2)]).ascii_art())
O=<=O
1 2
>>> print(CartanType(['C',Integer(3)]).ascii_art())
O---O=<=O
1 2 3
>>> print(CartanType(['C',Integer(5)]).ascii_art(label = lambda x: x+Integer(2)))
O---O---O---O=<=O
3 4 5 6 7

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

sage: CartanType(['C',4]).coxeter_number()
8

>>> from sage.all import *
>>> CartanType(['C',Integer(4)]).coxeter_number()
8
dual()

Types B and C are in duality:

EXAMPLES:

sage: CartanType(['C',3]).dual() ['B', 3]

>>> from sage.all import *
>>> CartanType(['C', Integer(3)]).dual() ['B', 3]
dual_coxeter_number()

Return the dual Coxeter number associated with self.

EXAMPLES:

sage: CartanType(['C',4]).dual_coxeter_number()
5
>>> from sage.all import *
>>> CartanType(['C',Integer(4)]).dual_coxeter_number()
5

dynkin_diagram()

Returns a Dynkin diagram for type C.

EXAMPLES:

```
sage: c = CartanType(['C',3]).dynkin_diagram(); c
O---O=<=O
 1  2  3
C3
sage: c.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: b = CartanType(['C',1]).dynkin_diagram(); b
O
 1
C1
sage: b.edges(sort=True)
[]
```

```
>>> from sage.all import *
>>> c = CartanType(['C',Integer(3)]).dynkin_diagram(); c
O---O=<=O
 1  2  3
C3
>>> c.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
>>> b = CartanType(['C',Integer(1)]).dynkin_diagram(); b
O
 1
C1
>>> b.edges(sort=True)
[]
```
5.1.250 Root system data for (untwisted) type C affine

```
class sage.combinat.root_system.type_C_affine.CartanType(n):
    Bases: CartanType_standard_untwisted_affine

    EXAMPLES:

    sage: ct = CartanType(['C', 4, 1])
    sage: ct
    ['C', 4, 1]
    sage: ct._repr_(compact = True)
    'C4~'
    sage: ct.is_irreducible()
    True
    sage: ct.is_finite()
    False
    sage: ct.is_affine()
    True
    sage: ct.is_untwisted_affine()
    True
    sage: ct.is_crystallographic()
    True
    sage: ct.is_simply_laced()
    False
    sage: ct.classical()
    ['C', 4]
    sage: ct.dual()
    ['C', 4, 1]^*
    sage: ct.dual().is_untwisted_affine()
    False
```

```python
>>> from sage.all import *

>>> ct = CartanType(['C', Integer(4), Integer(1)])

>>> ct
['C', 4, 1]

>>> ct._repr_(compact = True)
'C4~'

>>> ct.is_irreducible()
True

>>> ct.is_finite()
False

>>> ct.is_affine()
True

>>> ct.is_untwisted_affine()
True

>>> ct.is_crystallographic()
True

>>> ct.is_simply_laced()
False

>>> ct.classical()
['C', 4]

>>> ct.dual()
['C', 4, 1]^*

>>> ct.dual().is_untwisted_affine()
False
```
PieriFactors
alias of \texttt{PieriFactors\_type\_C\_affine}

\textbf{ascii\_art (label=None, node=None)}

Return a ascii art representation of the extended Dynkin diagram.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: print(CartanType(['C',5,1]).ascii_art(label = lambda x: x+2))
O=>=O---O---O---O=<=O
2 3 4 5 6 7
sage: print(CartanType(['C',3,1]).ascii_art())
O=>=O---O=<=O
0 1 2 3
sage: print(CartanType(['C',2,1]).ascii_art())
O=>=O=<=O
0 1 2
sage: print(CartanType(['C',1,1]).ascii_art())
O<=>O
0 1

>>> from sage.all import *

>>> print(CartanType(['C',Integer(5),Integer(1)]).ascii_art(label = lambda x: x+Integer(2)))
O=>=O---O---O---O=<=O
2 3 4 5 6 7

>>> print(CartanType(['C',Integer(3),Integer(1)]).ascii_art())
O=>=O---O=<=O
0 1 2 3

>>> print(CartanType(['C',Integer(2),Integer(1)]).ascii_art())
O=>=O=<=O
0 1 2

>>> print(CartanType(['C',Integer(1),Integer(1)]).ascii_art())
O<=>O
0 1
\end{verbatim}

\textbf{dynkin\_diagram()}

Returns the extended Dynkin diagram for affine type C.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: c = CartanType(['C',3,1]).dynkin_diagram(); c
\texttt{#--- needs sage.graphs}
O=>=O---O=<=O
0 1 2 3
C3

sage: c.edges(sort=True)
\texttt{#--- needs sage.graphs}
[(0, 1, 2), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
\end{verbatim}
>>> from sage.all import *
>>> c = CartanType(['C', Integer(3), Integer(1)]).dynkin_diagram(); c
O=>=O---O=<=O
0 1 2 3  # needs sage.graphs
C3~
>>> c.edges(sort=True)
# needs sage.graphs
[(0, 1, 2), (1, 0, 1), (1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]

5.1.251 Root system data for type D

class sage.combinat.root_system.type_D.AmbientSpace(root_system, base_ring, index_set=None)

Bases: AmbientSpace
dimension()

EXAMPLES:
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.dimension()
3

>>> from sage.all import *
>>> e = RootSystem(['D',Integer(3)]).ambient_space()
>>> e.dimension()
3

fundamental_weight(i)

EXAMPLES:
sage: RootSystem(['D',4]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1/2, 1/2, 1/2, -1/2), 4: (1/2, 1/2, 1/2, 1/2)}

>>> from sage.all import *
>>> RootSystem(['D',Integer(4)]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1/2, 1/2, 1/2, -1/2), 4: (1/2, 1/2, 1/2, 1/2)}

negative_roots()

EXAMPLES:
sage: RootSystem(['D',4]).ambient_space().negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (0, -1, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 0, 1),
 (0, 0, -1, 1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
 (0, -1, -1, 0),
(continues on next page)
>>> from sage.all import *

>>> RootSystem(['D', Integer(4)]).ambient_space().negative_roots()
[(-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (0, -1, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 0, 1),
 (0, 0, -1, 1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
 (0, -1, -1, 0),
 (-1, 0, 0, -1),
 (0, -1, 0, -1),
 (0, 0, -1, -1)]

positive_roots()

EXAMPLES:

sage: RootSystem(['D', 4]).ambient_space().positive_roots()
[(1, 1, 0, 0),
 (1, 0, 1, 0),
 (0, 1, 1, 0),
 (1, 0, 0, 1),
 (0, 1, 0, 1),
 (0, 0, 1, 1),
 (1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]

>>> from sage.all import *

>>> RootSystem(['D', Integer(4)]).ambient_space().positive_roots()
[(1, 1, 0, 0),
 (1, 0, 1, 0),
 (0, 1, 1, 0),
 (1, 0, 0, 1),
 (0, 1, 0, 1),
 (0, 0, 1, 1),
 (1, -1, 0, 0),
 (1, 0, -1, 0),
 (0, 1, -1, 0),
 (1, 0, 0, -1),
 (0, 1, 0, -1),
 (0, 0, 1, -1)]

root (i, j, p1, p2)

Note that indexing starts at 0.

EXAMPLES:
sage: e = RootSystem(['D',3]).ambient_space()
sage: e.root(0, 1, 1, 1)
(-1, -1, 0)
sage: e.root(0, 0, 1, 1)
(-1, 0, 0)

>>> from sage.all import *
>>> e = RootSystem(['D',Integer(3)]).ambient_space()
>>> e.root(Integer(0), Integer(1), Integer(1), Integer(1))
(-1, -1, 0)
>>> e.root(Integer(0), Integer(0), Integer(1), Integer(1))
(-1, 0, 0)

**simple_root** *(i)*

**EXAMPLES:**

```python
sage: RootSystem(['D',4]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, -1, 1)}
```

```python
>>> from sage.all import *
>>> RootSystem(['D',Integer(4)]).ambient_space().simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, -1, 1)}
```

**class** `sage.combinat.root_system.type_D.CartonType(n)`

**Bases:** `CartanType_standard_finite, CartanType_simply_laced`

**EXAMPLES:**

```python
sage: ct = CartanType(['D',4])
sage: ct
['D', 4]
sage: ct._repr_(compact = True)
'D4'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.dual()
['D', 4]
sage: ct.affine()
['D', 4, 1]
```
ValueError: ['D', 2, 1] is not a valid Cartan type

>>> from sage.all import *
>>> ct = CartanType(['D',Integer(4)])
>>> ct
['D', 4]
>>> ct._repr_(compact = True)
'D4'

>>> ct.is_irreducible()
True
>>> ct.is_finite()
True
>>> ct.is_crystallographic()
True
>>> ct.is_simply_laced()
True
>>> ct.dual()
['D', 4]
>>> ct.affine()
['D', 4, 1]

>>> ct = CartanType(['D',Integer(2)])
>>> ct.is_irreducible()
False
>>> ct.dual()
['D', 2]
>>> ct.affine()
Traceback (most recent call last):
...
ValueError: ['D', 2, 1] is not a valid Cartan type

AmbientSpace

alias of AmbientSpace

ascii_art (label=None, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

sage: print(CartanType(['D',3]).ascii_art())
0 3
| |
0---0
1 2
sage: print(CartanType(['D',4]).ascii_art())
0 4
| |
0---0---0
1 2 3
sage: print(CartanType(['D',4]).ascii_art(label = lambda x: x+2))
0 6
| |
| 0---0---0
3 4 5

sage: print(CartanType(['D',6]).ascii_art(lambda x: x+2))

O 8
|
|
O---O---O---O---O
3 4 5 6 7

```
>>> from sage.all import *

>>> print(CartanType(['D',Integer(3)]).ascii_art())

O 3
|
|
O---0
1 2

>>> print(CartanType(['D',Integer(4)]).ascii_art())

O 4
|
|
O---O---O
1 2 3

>>> print(CartanType(['D',Integer(4)]).ascii_art(label = lambda x:x+Integer(2)))

O 6
|
|
O---O---O
3 4 5

>>> print(CartanType(['D',Integer(6)]).ascii_art(label = lambda x:x+Integer(2)))

O 8
|
|
O---O---O---O---O
3 4 5 6 7
```

coxeter_number()  
Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['D',4]).coxeter_number()
6

>>> from sage.all import *

>>> CartanType(['D',Integer(4)]).coxeter_number()
6
```

dual_coxeter_number()  
Return the dual Coxeter number associated with self.

EXAMPLES:
```sage
CartanType(['D',4]).dual_coxeter_number()
6
```

```sage
from sage.all import *
CartanType(['D',Integer(4)]).dual_coxeter_number()
6
```

dynkin_diagram()

Returns a Dynkin diagram for type D.

EXAMPLES:

```sage
d = CartanType(['D',5]).dynkin_diagram(); d
# needs sage.graphs
O 5
| |
O---O---O---O
1 2 3 4
D5
```

```sage
d.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 1),
 (3, 4, 1), (3, 5, 1), (4, 3, 1), (5, 3, 1)]
```

```sage
d = CartanType(['D',4]).dynkin_diagram(); d
# needs sage.graphs
O 4
| |
O---O---O---O
1 2 3 4
D4
```

```sage
d.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (2, 4, 1), (3, 2, 1), (4, 2, 1)]
```

```sage
d = CartanType(['D',3]).dynkin_diagram(); d
# needs sage.graphs
O 3
| |
O---O---O
1 2 3
D3
```

```sage
d.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (1, 3, 1), (2, 1, 1), (3, 1, 1)]
```

```sage
d = CartanType(['D',2]).dynkin_diagram(); d
# needs sage.graphs
O 0
| |
O---O---O
1 2
D2
```

```sage
d.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (1, 3, 1), (2, 1, 1), (3, 1, 1)]
```

(continues on next page)
is_atomic()

    Implements CartanType_abstract.is_atomic()

    $D_2$ is atomic, like all $D_n$, despite being non irreducible.

    EXAMPLES:
Combinatorics, Release 10.4

```python
sage: CartanType(['D',2]).is_atomic()
True
sage: CartanType(['D',2]).is_irreducible()
False
```

```python
>>> from sage.all import *

>>>
```  

5.1.252 Root system data for (untwisted) type D affine

```python
class sage.combinat.root_system.type_D_affine.CartanType(n)

Bases: CartanType_standard_untwisted_affine, CartanType_simply_laced

EXAMPLES:

```python
sage: ct = CartanType(['D',4,1])
sage: ct
['D', 4, 1]
sage: ct._repr_(compact = True)
'D4~'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
True
sage: ct.classical()
['D', 4]
sage: ct.dual()
['D', 4, 1]
```

```python
>>> from sage.all import *

>>> ct = CartanType(['D',Integer(4),Integer(1)])

>>> ct
['D', 4, 1]

>>> ct._repr_(compact = True)
'D4~'

>>> ct.is_irreducible()
True
>>> ct.is_finite()
False
>>> ct.is_affine()
True
>>> ct.is_untwisted_affine()
```

(continues on next page)
True
c.t.is_crystallographic()
True
c.t.is_simply_laced()
True
c.t.classical()
['D', 4]
c.t.dual()
['D', 4, 1]

**PieriFactors**

alias of *PieriFactors_type_D_affine*

**ascii_art**(label=None, node=None)

Return an ascii art representation of the extended Dynkin diagram.

**dynkin_diagram()**

Returns the extended Dynkin diagram for affine type D.

**EXAMPLES:**

```sage
sage: d = CartanType(["D", 6, 1]).dynkin_diagram(); d
\[\begin{array}{ccc}
0 & 0 & 0 6 \\
0 & 0 & 0 6
\end{array}\]
D6~
sage: d.edges(sort=True)
\[[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 1),
(3, 2, 1), (3, 4, 1), (4, 3, 1), (4, 5, 1), (4, 6, 1), (5, 4, 1), (6, 4, 1)]\]
```

```sage
sage: d = CartanType(["D", 4, 1]).dynkin_diagram(); d
\[\begin{array}{ccc}
0 & 4 5
\end{array}\]
D4~
sage: d.edges(sort=True)
\[[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 1),
(2, 4, 1), (3, 2, 1), (3, 4, 1)]\]
```

```sage
sage: d = CartanType(["D", 3, 1]).dynkin_diagram(); d
\[\begin{array}{ccc}
0 & 4
\end{array}\]
D3~
sage: d.edges(sort=True)
\[[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 1),
(2, 4, 1), (3, 2, 1), (4, 2, 1)]\]
```
\begin{verbatim}
>>> from sage.all import *

```python
>>> d = CartanType(['D', Integer(6), Integer(1)]).dynkin_diagram(); d
0  O---O---O---O---O
  0  1  2  3  4  5
D6~

sage: d.edges(sort=True)
# needs sage.graphs
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 1), (2, 3, 1),
 (3, 2, 1), (4, 2, 1), (4, 5, 1), (4, 6, 1), (5, 4, 1), (6, 4, 1)]
```

```

### 5.1.253 Root system data for type E

```python
class sage.combinat.root_system.type_E.AmbientSpace(root_system, baseRing)
```

The lattice behind E6, E7, or E8. The computations are based on Bourbaki, Groupes et Algèbres de Lie, Ch. 4,5,6 (planche V-VII).

**dimension()**

**EXAMPLES:**

```python
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.dimension()
8
```

**fundamental_weights()**

**EXAMPLES:**

```python
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (0, 0, 0, 0, 0, -2/3, -2/3, 2/3), 2: (1/2, 1/2, 1/2, 1/2, 1/2, -1/2, -1/2, 1/2), 3: (-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6), 4: (0, -1/2, -1/2, 1, 1, -5/6, -5/6, 5/6), 5: (0, 0, 0, 1, 1, -2/3, -2/3, 2/3), 6: (0, 0, 0, 0, 1, 1, -1/3, -1/3, 1/3)}
```

**negative_roots()**

The negative roots.

**EXAMPLES:**

```python
sage: e = RootSystem(['E',6]).ambient_space()
sage: e.negative_roots()
```

(continues on next page)
>>> from sage.all import *

>>> e = RootSystem(['E', Integer(6)]).ambient_space()

>>> e.negative_roots()

 (1/2, 1/2, 1/2, 1/2, 1/2, 1/2, 1/2, −1/2)
]
positive_roots()
These are the roots positive w.r. to lexicographic ordering of the basis elements (e1<...<e4).

EXAMPLES:

sage: e = RootSystem(['E', 6]).ambient_space()
sage: e.positive_roots()
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 0, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0, 1, 0, 0),
 (-1, 1, 0, 0, 0, 0, 0, 0),
 (-1, 0, 1, 0, 0, 0, 0, 0),
 (-1, 0, 0, 1, 0, 0, 0, 0),
 (-1, 0, 0, 0, 1, 0, 0, 0),
 (0, -1, 1, 0, 0, 0, 0, 0),

```
>>> e.rho()
(0, 1, 2, 3, 4, 5, 6, 23)
```

```
root (i1, i2=None, i3=None, i4=None, i5=None, i6=None, i7=None, i8=None, p1=0, p2=0, p3=0, p4=0, p5=0, p6=0, p7=0, p8=0)

Compute an element of the underlying lattice, using the specified elements of the standard basis, with signs dictated by the corresponding 'pi' arguments. We rely on the caller to provide the correct arguments. This is typically used to generate roots, although the generated elements need not be roots themselves. We assume that if one of the indices is not given, the rest are not as well. This should work for E6, E7, E8.

EXAMPLES:
```
sage: e = RootSystem(['E',6]).ambient_space()
sage: [ e.root(i, j, p3=1) for i in range(e.n) for j in range(i+1, e.n) ]
[(1, 1, 0, 0, 0, 0, 0, 0),
 (1, 0, 1, 0, 0, 0, 0, 0),
 (1, 0, 0, 1, 0, 0, 0, 0),
 (1, 0, 0, 0, 1, 0, 0, 0),
 (1, 0, 0, 0, 0, 1, 0, 0),
 (1, 0, 0, 0, 0, 0, 1, 0),
 (1, 0, 0, 0, 0, 0, 0, 1),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 1, 0, 0, 0, 1, 0, 0),
 (0, 1, 0, 0, 0, 0, 1, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0, 1, 0, 0),
 (0, 0, 1, 0, 0, 0, 1, 0),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (0, 0, 0, 1, 0, 1, 0, 0),
 (0, 0, 0, 1, 0, 0, 1, 0),
 (0, 0, 0, 0, 1, 1, 0, 0),
 (0, 0, 0, 0, 1, 0, 1, 0),
 (0, 0, 0, 0, 0, 1, 1, 0),
 (0, 0, 0, 0, 0, 0, 1, 1)]
```
```python
>>> from sage.all import *

>>> e = RootSystem(['E', Integer(6)]).ambient_space()

>>> [ e.root(i, j, p3=Integer(1)) for i in range(e.n) for j in range(i+Integer(1), e.n) ]

[(1, 1, 0, 0, 0, 0, 0, 0),

 (1, 0, 0, 0, 0, 0, 1, 0),
 (0, 1, 1, 0, 0, 0, 0, 0),
 (0, 1, 0, 1, 0, 0, 0, 0),
 (0, 1, 0, 0, 1, 0, 0, 0),
 (0, 1, 0, 0, 0, 1, 0, 0),
 (0, 1, 0, 0, 0, 0, 1, 0),
 (0, 0, 1, 1, 0, 0, 0, 0),
 (0, 0, 1, 0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0, 1, 0, 0),
 (0, 0, 1, 0, 0, 0, 1, 0),
 (0, 0, 0, 1, 1, 0, 0, 0),
 (0, 0, 0, 1, 0, 1, 0, 0),
 (0, 0, 0, 1, 0, 0, 1, 0),
 (0, 0, 0, 1, 0, 0, 0, 1),
 (0, 0, 0, 0, 1, 0, 0, 0),
 (0, 0, 0, 0, 0, 1, 0, 0),
 (0, 0, 0, 0, 0, 1, 0, 1),
 (0, 0, 0, 0, 0, 0, 1, 1),
 (0, 0, 0, 0, 0, 0, 0, 1)]
```

The simple roots `i` are computed as what Bourbaki calls the Base:

\[ a_1 = e_2 - e_3, a_2 = e_3 - e_4, a_3 = e_4, a_4 = 1/2(e_1 - e_2 - e_3 - e_4) \]

EXAMPLES:

```python
sage: LE6 = RootSystem(['E',6]).ambient_space()
sage: LE6.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2), 2: (1, 1, 0, 0, 0, 0, 0, 0), 3: (-1, 1, 0, 0, 0, 0, 0, 0), 4: (0, -1, 1, 0, 0, 0, 0, 0), 5: (0, 0, -1, 1, 0, 0, 0, 0), 6: (0, 0, 0, -1, 1, 0, 0, 0)}
```

```python
>>> from sage.all import *

>>> LE6 = RootSystem(['E',Integer(6)]).ambient_space()

>>> LE6.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2, -1/2, -1/2, -1/2, 1/2), 2: (1, 1, 0, 0, 0, 0, 0, 0), 3: (-1, 1, 0, 0, 0, 0, 0, 0), 4: (0, -1, 1, 0, 0, 0, 0, 0), 5: (0, 0, -1, 1, 0, 0, 0, 0), 6: (0, 0, 0, -1, 1, 0, 0, 0)}
```

```
```
sage: ct = CartanType(['E',6])
sage: ct
['E', 6]
sage: ct._repr_(compact = True)

['E', 6]

AmbientSpace

alias of AmbientSpace

asci_art (label=None, node=None)

Return a ascii art representation of the extended Dynkin diagram.

EXAMPLES:

sage: print(CartanType(['E',6]).asci_art(label = lambda x: x+2))

   0  4
     |
     0--0--0--0--0--0--0
   3  5  6  7  8

sage: print(CartanType(['E',7]).asci_art(label = lambda x: x+2))

   0  4
coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```python
sage: CartanType(['E', 6]).coxeter_number()
12
sage: CartanType(['E', 7]).coxeter_number()
18
sage: CartanType(['E', 8]).coxeter_number()
30
```

```python
>>> from sage.all import *

>>> print(CartanType(['E', Integer(6)]).ascii_art(label = lambda x: x+1))
O 3
|
O---O---O---O---O---O
3 5 6 7 8 9
```

```python
>>> print(CartanType(['E', Integer(7)]).ascii_art(label = lambda x: x+Integer(2)))
O 4
|
O---O---O---O---O---O---O
3 5 6 7 8 9
```

```python
>>> print(CartanType(['E', Integer(8)]).ascii_art(label = lambda x: x+Integer(1)))
O 3
|
O---O---O---O---O---O---O---O---O
2 4 5 6 7 8 9
```

dual_coxeter_number()

Return the dual Coxeter number associated with self.

```python
>>> from sage.all import *

>>> print(CartanType(['E', Integer(6)]).ascii_art(label = lambda x: x+1))
O 3
|
O---O---O---O---O---O---O
3 5 6 7 8 9
```

```python
>>> print(CartanType(['E', Integer(7)]).ascii_art(label = lambda x: x+Integer(2)))
O 4
|
O---O---O---O---O---O---O---O---O---O
3 5 6 7 8 9
```

```python
>>> print(CartanType(['E', Integer(8)]).ascii_art(label = lambda x: x+Integer(1)))
O 3
|
2 4 5 6 7 8 9
```
EXAMPLES:

```python
sage: CartanType(['E', 6]).dual_coxeter_number()
12
sage: CartanType(['E', 7]).dual_coxeter_number()
18
sage: CartanType(['E', 8]).dual_coxeter_number()
30
```

```python
>>> from sage.all import *
```

```python
>>> CartanType(['E', Integer(6)]).dual_coxeter_number()
12
>>> CartanType(['E', Integer(7)]).dual_coxeter_number()
18
>>> CartanType(['E', Integer(8)]).dual_coxeter_number()
30
```

dynkin_diagram()

Returns a Dynkin diagram for type E.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: e = CartanType(['E', 6]).dynkin_diagram(); e
O 2
  |
O---O---O---O---O
1 3 4 5 6
```

```
E6
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1)]
```

```
sage: e = CartanType(['E', 7]).dynkin_diagram(); e
O 2
  |
O---O---O---O---O---O
1 3 4 5 6 7
```

```
E7
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1),
 (6, 7, 1), (7, 6, 1)]
```

```
sage: e = CartanType(['E', 8]).dynkin_diagram(); e
O 2
  |
O---O---O---O---O---O---O
1 3 4 5 6 7 8
```

```
E8
sage: e.edges(sort=True)
[(1, 3, 1), (2, 4, 1), (3, 1, 1), (3, 4, 1), (4, 2, 1),
 (4, 3, 1), (4, 5, 1), (5, 4, 1), (5, 6, 1), (6, 5, 1),
 (6, 7, 1), (7, 6, 1), (7, 8, 1), (8, 7, 1)]
```

```python
>>> from sage.all import *
```

 (6, 5, 1), (6, 7, 1), (7, 6, 1)]
```

(continues on next page)
5.1.255 Root system data for type F

class sage.combinat.root_system.type_F.AmbientSpace(root_system, base_ring)

Bases: AmbientSpace

The lattice behind $F_4$. The computations are based on Bourbaki, Groupes et Algèbres de Lie, Ch. 4,5,6 (planche VIII).

dimension()
Return the dimension of self.

EXAMPLES:

sage: e = RootSystem(['F',4]).ambient_space()
sage: e.dimension()
4

>>> from sage.all import *

>>> e = RootSystem(['F',Integer(4)]).ambient_space()

>>> e.dimension()
4

fundamental_weights()
Return the fundamental weights of self.

EXAMPLES:

sage: e = RootSystem(['F',4]).ambient_space()
sage: e.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4:-(1, 0, 0, 0)}
negative_roots()  
Return the negative roots.

EXAMPLES:

```python
sage: e = RootSystem(['F', 4]).ambient_space()
sage: e.negative_roots()
[(-1, 0, 0, 0),
 (0, -1, 0, 0),
 (0, 0, -1, 0),
 (0, 0, 0, -1),
 (-1, -1, 0, 0),
 (-1, 0, -1, 0),
 (-1, 0, 0, -1),
 (0, -1, -1, 0),
 (0, 0, -1, -1),
 (-1, 1, 0, 0),
 (-1, 0, 1, 0),
 (-1, 0, 0, 1),
 (0, -1, 1, 0),
 (0, -1, 0, 1),
 (0, 0, -1, 1),
 (-1/2, -1/2, -1/2, 1/2),
 (-1/2, -1/2, 1/2, -1/2),
 (-1/2, 1/2, -1/2, 1/2),
 (-1/2, 1/2, 1/2, -1/2),
 (-1/2, 1/2, 1/2, 1/2)]
```
positive_roots()

Return the positive roots.

These are the roots which are positive with respect to the lexicographic ordering of the basis elements ($\epsilon_1 < \epsilon_2 < \epsilon_3 < \epsilon_4$).

EXAMPLES:

```
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.positive_roots()
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1), (1, 1, 0, 0), (1, 0, 1, 0), (1, 0, 0, 1), (0, 1, 1, 0), (0, 1, 0, 1), (0, 0, 1, 1), (1, -1, 0, 0), (1, 0, -1, 0), (1, 0, 0, -1), (0, 1, -1, 0), (0, 1, 0, -1), (0, 0, 1, -1), (1/2, 1/2, 1/2, 1/2), (1/2, 1/2, 1/2, 1/2), (1/2, 1/2, -1/2, -1/2), (1/2, -1/2, 1/2, 1/2), (1/2, -1/2, 1/2, -1/2), (1/2, -1/2, -1/2, 1/2), (1/2, -1/2, -1/2, -1/2)]
sage: e.rho()
(11/2, 5/2, 3/2, 1/2)
```

```python
>>> from sage.all import *
>>> e = RootSystem(['F',Integer(4)]).ambient_space()
>>> e.positive_roots()
[(1, 0, 0, 0), (0, 1, 0, 0), (0, 0, 1, 0), (0, 0, 0, 1), (1, 1, 0, 0), (1, 0, 1, 0), (1, 0, 0, 1), (0, 1, 1, 0), (0, 1, 0, 1), (0, 0, 1, 1), (1, -1, 0, 0), (1, 0, -1, 0), (1, 0, 0, -1), (0, 1, -1, 0), (0, 1, 0, -1), (0, 0, 1, -1), (1/2, 1/2, 1/2, 1/2), (1/2, 1/2, 1/2, 1/2), (1/2, 1/2, -1/2, -1/2), (1/2, -1/2, 1/2, 1/2), (1/2, -1/2, 1/2, -1/2), (1/2, -1/2, -1/2, 1/2), (1/2, -1/2, -1/2, -1/2)]
```
root \( (i, j=None, k=None, l=None, p1=0, p2=0, p3=0, p4=0) \)

Compute a root from base elements of the underlying lattice. The arguments specify the basis elements and the signs. Sadly, the base elements are indexed zero-based. We assume that if one of the indices is not given, the rest are not as well.

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: [ e.root(i,j,p2=1) for i in range(e.n) for j in range(i+1,e.n) ]
[(1, -1, 0, 0), (1, 0, -1, 0), (1, 0, 0, -1), (0, 1, -1, 0), (0, 1, 0, -1), ...
    (0, 0, 1, -1),
(1/2, 1/2, 1/2, 1/2), (1/2, 1/2, 1/2, -1/2), (1/2, 1/2, -1/2, 1/2), ...
    (1/2, -1/2, 1/2, 1/2), (1/2, -1/2, 1/2, -1/2), (1/2, -1/2, -1/2, 1/2), ...
    (1/2, -1/2, -1/2, -1/2)]
```

simple_root \( (i) \)

Return the \( i \)-th simple root.

It is computed according to what Bourbaki calls the Base:

\[
\alpha_1 = \epsilon_2 - \epsilon_3, \alpha_2 = \epsilon_3 - \epsilon_4, \alpha_3 = \epsilon_4, \alpha_4 = \frac{1}{2} (\epsilon_1 - \epsilon_2 - \epsilon_3 - \epsilon_4).
\]

EXAMPLES:

```python
sage: e = RootSystem(['F',4]).ambient_space()
sage: e.simple_roots()
Finite family {1: (0, 1, 0, 1), 2: (0, 0, 1, 1), 3: (0, 1, 1, 0), 4: (1/2, 1/2, 1/2, 1/2), ...
```

(continues on next page)
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}

```python
class sage.combinat.root_system.type_F.CartanType:
    Bases: CartanType_standard_finite, CartanType_simple, CartanType_crystallographic

    EXAMPLES:
    sage: ct = CartanType(['F',4])
    sage: ct
    ['F', 4]
    sage: ct._repr_(compact = True)
    'F4'
    sage: ct.is_irreducible()
    True
    sage: ct.is_finite()
    True
    sage: ct.is_crystallographic()
    True
    sage: ct.is_simply_laced()
    False
    sage: ct.dual()
    ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
    sage: ct.affine()
    ['F', 4, 1]
```

```python
>>> from sage.all import *
>>> ct = CartanType(['F',Integer(4)])
>>> ct
['F', 4]
>>> ct._repr_(compact = True)
'F4'

>>> ct.is_irreducible()
True
>>> ct.is_finite()
True
>>> ct.is_crystallographic()
True
>>> ct.is_simply_laced()
False
>>> ct.dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
>>> ct.affine()
['F', 4, 1]
```

`AmbientSpace`  
alias of `AmbientSpace`

`ascii_art (label=None, node=None)`  
Return an ascii art representation of the extended Dynkin diagram.

EXAMPLES:
```
sage: print(CartanType(['F',4]).ascii_art(label = lambda x: x+2))
O---O=>=O---O
 3 4 5 6
sage: print(CartanType(['F',4]).ascii_art(label = lambda x: x-2))
O---O=>=O---O
-1 0 1 2
```

```
>>> from sage.all import *
>>> print(CartanType(['F',Integer(4)]).ascii_art(label = lambda x: x+Integer(2)))
O---O=>=O---O
 3 4 5 6
>>> print(CartanType(['F',Integer(4)]).ascii_art(label = lambda x: x-Integer(2)))
O---O=>=O---O
-1 0 1 2
```
F4.dynkin_diagram()  
# needs sage.graphs
O---O=>=O---O
1 2 3 4
F4

F4.dual().dynkin_diagram()  
# needs sage.graphs
O---O=>=O---O
4 3 2 1
F4 relabelled by {1: 4, 2: 3, 3: 2, 4: 1}

**dual_coxeter_number()**

Return the dual Coxeter number associated with self.

**EXAMPLES:**

```python
sage: CartanType(['F',4]).dual_coxeter_number()
9
```

```python
from sage.all import *

>>> CartanType(['F',Integer(4)]).dual_coxeter_number()
9
```

**dynkin_diagram()**

Returns a Dynkin diagram for type F.

**EXAMPLES:**

```python
sage: f = CartanType(['F',4]).dynkin_diagram(); f  
# needs sage.graphs
O---O=>=O---O
1 2 3 4
F4

sage: f.edges(sort=True)  
# needs sage.graphs
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

```python
from sage.all import *

>>> f = CartanType(['F',Integer(4)]).dynkin_diagram(); f  
# needs sage.graphs
O---O=>=O---O
1 2 3 4
F4

>>> f.edges(sort=True)  
# needs sage.graphs
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```
5.1.256 Root system data for (untwisted) type F affine

```python
class sage.combinat.root_system.type_F_affine.CartanType
    Bases: CartanType_standard_untwisted_affine

EXAMPLES:

sage: ct = CartanType(['F',4,1])
sage: ct
['F', 4, 1]
sage: ct._repr_(compact = True)
'F4~'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['F', 4]
sage: ct.dual()
['F', 4, 1]^*
sage: ct.dual().is_untwisted_affine()
False
```

```python
>>> from sage.all import *

>>> ct = CartanType(['F',Integer(4),Integer(1)])

>>> ct
['F', 4, 1]

>>> ct._repr_(compact = True)
'F4~'

>>> ct.is_irreducible()
True

>>> ct.is_finite()
False

>>> ct.is_affine()
True

>>> ct.is_untwisted_affine()
True

>>> ct.is_crystallographic()
True

>>> ct.is_simply_laced()
False

>>> ct.classical()
['F', 4]

>>> ct.dual()
['F', 4, 1]^*

>>> ct.dual().is_untwisted_affine()
False
```
**ascii_art** *(label=None, node=None)*  
Returns a ascii art representation of the extended Dynkin diagram

**EXAMPLES:**

```python
sage: print(CartanType(['F',4,1]).ascii_art(label = lambda x: x+2))
```
```
O---O---O=>=O---O
  0  1  2  3  4
```

```python
>>> from sage.all import *
```  
```python
>>> print(CartanType(['F',Integer(4),Integer(1)]).ascii_art(label = lambda x:-
˓→x+Integer(2)))
```
```
O---O---O=>=O---O
  0  1  2  3  4
```

**dynkin_diagram()**

Returns the extended Dynkin diagram for affine type F.

**EXAMPLES:**

```python
sage: f = CartanType(['F', 4, 1]).dynkin_diagram(); f
```
```
O---O---O=>=O---O
 0 1 2 3 4
F4~
```

```python
>>> f.edges(sort=True)
```
```
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 1),
 (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

```python
>>> from sage.all import *
```  
```python
>>> f = CartanType(['F', Integer(4), Integer(1)]).dynkin_diagram(); f
```
```
O---O---O=>=O---O
 0 1 2 3 4
F4~
```

```python
>>> f.edges(sort=True)
```
```
[(0, 1, 1), (1, 0, 1), (1, 2, 1), (2, 1, 1),
 (2, 3, 2), (3, 2, 1), (3, 4, 1), (4, 3, 1)]
```

### 5.1.257 Root system data for type G

**class** `sage.combinat.root_system.type_G.AmbientSpace(root_system, base_ring, index_set=None)`  
**Bases:** `AmbientSpace`

**EXAMPLES:**

```python
sage: e = RootSystem(['G',2]).ambient_space(); e
```
```
Ambient space of the Root system of type ['G', 2]
```

```python
>>> from sage.all import *
```  
```python
>>> e = RootSystem(['G',Integer(2)]).ambient_space(); e
```
```
Ambient space of the Root system of type ['G', 2]
```
One cannot construct the ambient lattice because the simple coroots have rational coefficients:

```python
sage: e.simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
sage: e.smallest_base_ring()
Rational Field
```

By default, this ambient space uses the barycentric projection for plotting:

```python
sage: # needs sage.symbolic
sage: L = RootSystem(["G",2]).ambient_space()
sage: e = L.basis()
sage: L._plot_projection(e[0])
(1/2, 989/1142)
sage: L._plot_projection(e[1])
(-1, 0)
sage: L._plot_projection(e[2])
(1/2, -989/1142)
sage: L = RootSystem(["A",3]).ambient_space()
sage: l = L.an_element(); l
(2, 2, 3, 0)
sage: L._plot_projection(l)
(0, -1121/1189, 7/3)
```

See also:

- sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations.ParentMethods._plot_projection()

`dimension()`

`EXAMPLES:`

```python
sage: e = RootSystem(["G",2]).ambient_space()
sage: e.dimension()
3
```
from sage.all import *
e = RootSystem(['G',Integer(2)]).ambient_space()
e.dimension()
3

fundamental_weights()
EXAMPLES:
sage: CartanType(['G',2]).root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}

negative_roots()
EXAMPLES:
sage: CartanType(['G',2]).root_system().ambient_space().negative_roots()
[(0, -1, 1), (-1, 2, -1), (-1, 1, 0), (-1, 0, 1), (-1, -1, 2), (-2, 1, 1)]

positive_roots()
EXAMPLES:
sage: CartanType(['G',2]).root_system().ambient_space().positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]

simple_root(i)
EXAMPLES:
sage: CartanType(['G',2]).root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}

class sage.combinat.root_system.type_G.CartanType
Bases: CartanType_standard_finite, CartanType_simple, CartanType_crystallographic
EXAMPLES:
```python
sage: ct = CartanType(['G',2])
sage: ct
['G', 2]
sage: ct._repr_(compact = True)
'G2'

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.dual()
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1]
```

```python
>>> from sage.all import *
>>> ct = CartanType(['G',Integer(2)])
>>> ct
['G', 2]
>>> ct._repr_(compact = True)
'G2'

>>> ct.is_irreducible()
True
>>> ct.is_finite()
True
>>> ct.is_crystallographic()
True
>>> ct.is_simply_laced()
False
>>> ct.dual()
['G', 2] relabelled by {1: 2, 2: 1}
>>> ct.affine()
['G', 2, 1]
```

**AmbientSpace**

alias of `AmbientSpace`

**asci_art** *(label=None, node=None)*

Return an ascii art representation of the Dynkin diagram.

**EXAMPLES:**

```python
sage: print(CartanType(['G',2]).asci_art(label=lambda x: x+2))
   3
0=<<=O
   3  4

>>> from sage.all import *
>>> print(CartanType(['G',Integer(2)]).asci_art(label=lambda x:... 
  \rightarrow x+Integer(2)))
   3
```

(continues on next page)
**coxeter_number()**

Return the Coxeter number associated with self.

**EXAMPLES:**

```python
cartan_type = CartanType(['G',2]).coxeter_number()
cartan_type
```

```
6
```

```python
from sage.all import *
cartan_type = CartanType(['G',Integer(2)]).coxeter_number()
cartan_type
```

```
6
```

**dual()**

Return the dual Cartan type.

This uses that $G_2$ is self-dual up to relabelling.

**EXAMPLES:**

```python
cartan_type = CartanType(['G',2])
cartan_type.dual()
cartan_type.dynkin_diagram()  # needs sage.graphs
```

```
[\{1: 2, 2: 1\}] relabelled by \{1: 2, 2: 1\}
O=<=O 1 2 G2
```

```python
cartan_type = CartanType(['G',Integer(2)])
cartan_type.dual()
cartan_type.dynkin_diagram()  # needs sage.graphs
```

```
[\{1: 2, 2: 1\}] relabelled by \{1: 2, 2: 1\}
O=<=O 2 1 G2 relabelled by \{1: 2, 2: 1\}
```
### dual_coxeter_number()

Return the dual Coxeter number associated with self.

**EXAMPLES:**

```python
sage: CartanType(['G',2]).dual_coxeter_number()
4
```

```
>>> from sage.all import *

>>> CartanType(['G',Integer(2)]).dual_coxeter_number()
4
```

### dynkin_diagram()

Returns a Dynkin diagram for type G.

**EXAMPLES:**

```python
sage: g = CartanType(['G',2]).dynkin_diagram(); g
# needs sage.graphs
3
O=<=O
1  2
G2

sage: g.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (2, 1, 3)]
```

```
>>> from sage.all import *

>>> g = CartanType(['G',Integer(2)]).dynkin_diagram(); g
# needs sage.graphs
3
O=<=O
1  2
G2

>>> g.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (2, 1, 3)]
```

### 5.1.258 Root system data for (untwisted) type G affine

**class** `sage.combinat.root_system.type_G_affine.CartanType`

**Bases:** `CartanType_standard_untwisted_affine`

**EXAMPLES:**

```python
sage: ct = CartanType(['G',2,1])
sage: ct
['G', 2, 1]
sage: ct._repr_(compact = True)
'G2~'
sage: ct.is_irreducible()
True
sage: ct.is_finite()
False
```

(continues on next page)
sage: ct.is_affine()
True
sage: ct.is_untwisted_affine()
True
sage: ct.is_crystallographic()
True
sage: ct.is_simply_laced()
False
sage: ct.classical()
['G', 2]
sage: ct.dual()
['G', 2, 1]^*
sage: ct.dual().is_untwisted_affine()
False

>>> from sage.all import *

>>> ct = CartanType(['G', Integer(2), Integer(1)])

>>> ct
['G', 2, 1]

>>> ct._repr_(compact = True)
'G2~'

>>> ct.is_irreducible()
True

>>> ct.is_finite()
False

>>> ct.is_affine()
True

>>> ct.is_untwisted_affine()
True

>>> ct.is_crystallographic()
True

>>> ct.is_simply_laced()
False

>>> ct.classical()
['G', 2]

>>> ct.dual()
['G', 2, 1]^*

>>> ct.dual().is_untwisted_affine()
False

ascii_art (label=None, node=None)

Returns an ascii art representation of the Dynkin diagram

EXAMPLES:
sage: print(CartanType(['G',2,1]).ascii_art(label = lambda x: x+2))
3
0<=0---0
3 4 2

>>> from sage.all import *

>>> print(CartanType(['G',Integer(2),Integer(1)]).ascii_art(label = lambda x: x+Integer(2)))
3
0<=0---0

(continues on next page)
dynkin_diagram()

Returns the extended Dynkin diagram for type G.

EXAMPLES:

```python
sage: g = CartanType(['G',2,1]).dynkin_diagram(); g
# needs sage.graphs
3
O=<=O---O
1  2  0
G2~
sage: g.edges(sort=True)
# needs sage.graphs
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 3)]
```

```python
>>> from sage.all import *
>>>
g = CartanType(['G',Integer(2),Integer(1)]).dynkin_diagram(); g
# needs sage.graphs
3
O=<=O---O
1  2  0
G2~
>>> g.edges(sort=True)
# needs sage.graphs
[(0, 2, 1), (1, 2, 1), (2, 0, 1), (2, 1, 3)]
```

5.1.259 Root system data for type H

```python
class sage.combinat.root_system.type_H.CartanType(n)
Bases: CartanType_standard_finite, CartanType_simple

EXAMPLES:
```
```python
sage: ct = CartanType(['H',3])
sage: ct
['H', 3]
sage: ct._repr_(compact = True)
'H3'
sage: ct.rank()
3

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False
```
>>> from sage.all import *
>>> ct = CartanType(['H',Integer(3)])
>>> ct
['H', 3]
>>> ct._repr_(compact = True)
'H3'
>>> ct.rank()
3

>>> ct.is_irreducible()
True
>>> ct.is_finite()
True
>>> ct.is_affine()
False
>>> ct.is_crystallographic()
False
>>> ct.is_simply_laced()
False

coxeter_diagram()

Returns a Coxeter diagram for type H.

EXAMPLES:

```
sage: ct = CartanType(['H',3])
sage: ct.coxeter_diagram()  # needs sage.graphs
Graph on 3 vertices
sage: ct.coxeter_diagram().edges(sort=True)  # needs sage.graphs
[(1, 2, 3), (2, 3, 5)]
sage: ct.coxeter_matrix()  # needs sage.graphs
[1 3 2]
[3 1 5]
[2 5 1]
```

```
sage: ct = CartanType(['H',4])
sage: ct.coxeter_diagram()  # needs sage.graphs
Graph on 4 vertices
sage: ct.coxeter_diagram().edges(sort=True)  # needs sage.graphs
[(1, 2, 3), (2, 3, 3), (3, 4, 5)]
sage: ct.coxeter_matrix()  # needs sage.graphs
[1 3 2 2]
[3 1 3 2]
[2 3 1 5]
[2 2 5 1]
```

```
>>> ct.coxeter_diagram().edges(sort=True)  # needs sage.graphs
[(1, 2, 3), (2, 3, 5)]

\[1 3 2\]
\[3 1 5\]
\[2 5 1\]

>>> ct = CartanType(['H',Integer(4)])

... needs sage.graphs
Graph on 4 vertices

>>> ct.coxeter_diagram().edges(sort=True)  # needs sage.graphs
[(1, 2, 3), (2, 3, 3), (3, 4, 5)]

>>> ct.coxeter_matrix()  # needs sage.graphs
\[1 3 2 2\]
\[3 1 3 2\]
\[2 3 1 5\]
\[2 2 5 1\]

\textbf{coxeter\_number()}\textbf{ }

Return the Coxeter number associated with \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: CartanType(['H',3]).coxeter_number()
10
sage: CartanType(['H',4]).coxeter_number()
30
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> CartanType(['H',Integer(3)]).coxeter_number()
10
>>> CartanType(['H',Integer(4)]).coxeter_number()
30
\end{verbatim}

\section{5.1.260 Root system data for type I}

\textbf{class} \texttt{sage.combinat.root_system.type_I.CartonType(n)}

\textbf{Bases:} \texttt{CartanType\_standard\_finite, CartanType\_simple}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: ct = CartanType(['I',5])
sage: ct
['I', 5]
sage: ct._repr_(compact = True)
'I5'
sage: ct.rank()
2
sage: ct.index_set()
\end{verbatim}
(1, 2)

sage: ct.is_irreducible()
True
sage: ct.is_finite()
True
sage: ct.is_affine()
False
sage: ct.is_crystallographic()
False
sage: ct.is_simply_laced()
False

>>> from sage.all import *

>>> ct = CartanType(['I',Integer(5)])

>>> ct
['I', 5]

>>> ct._repr_(compact = True)
'I5'

>>> ct.rank()
2

>>> ct.index_set()
(1, 2)

>>> ct.is_irreducible()
True

>>> ct.is_finite()
True

>>> ct.is_affine()
False

>>> ct.is_crystallographic()
False

>>> ct.is_simply_laced()
False

coxeter_diagram()

Returns the Coxeter matrix for this type.

EXAMPLES:

sage: ct = CartanType(['I', 4])
sage: ct.coxeter_diagram()  # needs sage.graphs
Graph on 2 vertices

Graph on 2 vertices
sage: ct.coxeter_diagram().edges(sort=True)  # needs sage.graphs
[(1, 2, 4)]

sage: ct.coxeter_matrix()  # needs sage.graphs
[1 4]
[4 1]

>>> from sage.all import *

>>> ct = CartanType(['I', Integer(4)])

>>> ct.coxeter_diagram()  # needs sage.graphs
Graph on 2 vertices

```
>>> ct.coxeter_diagram().edges(sort=True)  
˓→needs sage.graphs
[(1, 2, 4)]
>>> ct.coxeter_matrix()  
˓→needs sage.graphs
[1 4]
[4 1]
```

coxeter_number()

Return the Coxeter number associated with self.

EXAMPLES:

```
sage: CartanType(['I', 3]).coxeter_number()
3
sage: CartanType(['I', 12]).coxeter_number()
12
```

index_set()

Type $I_2(p)$ is indexed by \{1, 2\}.

EXAMPLES:

```
sage: CartanType(['I', 5]).index_set()
(1, 2)
```

rank()

Type $I_2(p)$ is of rank 2.

EXAMPLES:

```
sage: CartanType(['I', 5]).rank()
2
```
5.1.261 Root system data for type Q

```python
class sage.combinat.root_system.type_Q.CartanType(m):
    Bases: CartanType_standard_finite
    Cartan Type Q_n
    See also:
    CartanType()

dual()
    Return dual of self.

    EXAMPLES:
    sage: Q = CartanType(['Q',3])
    sage: Q.dual()
    ['Q', 3]

    >>> from sage.all import *
    >>> Q = CartanType(['Q',Integer(3)])
    >>> Q.dual()
    ['Q', 3]

index_set()
    Return the index set for Cartan type Q.
    The index set for type Q is of the form \{-n, \ldots, -1, 1, \ldots, n\}.

    EXAMPLES:
    sage: CartanType(['Q', 3]).index_set()
    (1, 2, -2, -1)

    >>> from sage.all import *
    >>> CartanType(['Q', Integer(3)]).index_set()
    (1, 2, -2, -1)

is_irreducible()
    Return whether this Cartan type is irreducible.

    EXAMPLES:
    sage: Q = CartanType(['Q',3])
    sage: Q.is_irreducible()
    True

    >>> from sage.all import *
    >>> Q = CartanType(['Q',Integer(3)])
    >>> Q.is_irreducible()
    True

is_simply_laced()
    Return whether this Cartan type is simply-laced.

    EXAMPLES:
sage: Q = CartanType(['Q',3])
sage: Q.is_simply_laced()
True

>>> from sage.all import *
>>> Q = CartanType(['Q',Integer(3)])
>>> Q.is_simply_laced()
True

root_system()

Return the root system of self.

EXAMPLES:

sage: Q = CartanType(['Q',3])
sage: Q.root_system()
Root system of type ['A', 2]

>>> from sage.all import *
>>> Q = CartanType(['Q',Integer(3)])
>>> Q.root_system()
Root system of type ['A', 2]

5.1.262 Root system data for affine Cartan types

class sage.combinat.root_system.type_affine.AmbientSpace(root_system, base_ring)

Bases: CombinatorialFreeModule

Ambient space for affine types.

This is constructed from the data in the corresponding classical ambient space. Namely, this space is obtained by adding two elements \( \delta \) and \( \delta^\vee \) to the basis of the classical ambient space, and by endowing it with the canonical scalar product.

The coefficient of an element in \( \delta^\vee \), thus its scalar product with \( \delta^\vee \) gives its level, and dually for the colevel. The canonical projection onto the classical ambient space (by killing \( \delta \) and \( \delta^\vee \)) maps the simple roots (except \( \alpha_0 \)) onto the corresponding classical simple roots, and similarly for the coroots, fundamental weights, ... Altogether, this uniquely determines the embedding of the root, coroot, weight, and coweight lattices. See simple_root() and fundamental_weight() for the details.

Warning: In type BC, the null root is in fact:

```python
sage: R = RootSystem(['BC',3,2]).ambient_space()
sage: R.null_root() #--
2*e['delta']
```

```python
>>> from sage.all import *
>>> R = RootSystem(['BC',Integer(3),Integer(2)]).ambient_space()
>>> R.null_root() #--
2*e['delta']
```
**Warning:** In the literature one often considers a larger affine ambient space obtained from the classical ambient space by adding four dimensions, namely for the fundamental weight $\Lambda_0$, the fundamental coweight $\Lambda_0^\vee$, the null root $\delta$, and the null coroot $\epsilon$ (aka central element). In this larger ambient space, the scalar product is degenerate: $\langle \delta, \delta \rangle = 0$ and similarly for the null coroot.

In the current implementation, $\Lambda_0$ and the null coroot are identified:

```python
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: Lambda = L.fundamental_weights()  # needs sage.graphs
sage: Lambda[0]  # needs sage.graphs
e[delta]
e[delta]
sage: L.null_coroot()  # needs sage.graphs
e[delta]
```

Therefore the scalar product of the null coroot with itself differs from the larger ambient space:

```python
sage: L.null_coroot().scalar(L.null_coroot())  # needs sage.graphs
1
```

In general, scalar products between two elements that do not live on “opposite sides” won’t necessarily match.

**EXAMPLES:**

```python
sage: R = RootSystem(["A",3,1])
sage: e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3, 1]
sage: TestSuite(e).run()
```

```python
>>> from sage.all import *

>>> R = RootSystem(["A",Integer(3),Integer(1)])

>>> e = R.ambient_space(); e
Ambient space of the Root system of type ['A', 3, 1]

>>> TestSuite(e).run()
```

Systematic checks on all affine types:

```python
sage: for ct in CartanType.samples(affine=True, crystallographic=True):
    (continues on next page)```
if ct.classical().root_system().ambient_space() is not None:
    print(ct)
L = ct.root_system().ambient_space()
assert L
TestSuite(L).run()
Bases: IndexedFreeModuleElement

associated_coroot()

Return the coroot associated to self.

INPUT:
 • self – a root

EXAMPLES:

```
sage: # needs sage.graphs
sage: alpha = RootSystem(["C",2,1]).ambient_space().simple_roots()
sage: alpha
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: alpha[0].associated_coroot()
-e[0] + e['deltacheck']
sage: alpha[1].associated_coroot()
e[0] - e[1]
sage: alpha[2].associated_coroot()
e[1]
```

inner_product(other)

Implement the canonical inner product of self with other.

EXAMPLES:

```
sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0 0 0 0 0]
[0 0 0 1 0 0 0 0 0 0 0 0]
[0 0 0 0 1 0 0 0 0 0 0 0]
[0 0 0 0 0 2*e[0] + 2*e[1] + 3*e[2]]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

(continued from previous page)

```
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
>>> x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
>>> x.inner_product(x)
17
```

**scalar()** is an alias for this method:

```
sage: x.scalar(x)
17
```

```python
>>> from sage.all import *
>>> x.scalar(x)
17
```

**Todo:** Lift to CombinatorialFreeModule.Element as canonical_inner_product

**scalar (other)**

Implement the canonical inner product of *self* with *other.*

**EXAMPLES:**

```
sage: e = RootSystem(['B',3,1]).ambient_space()
sage: B = e.basis()
sage: matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
sage: x.inner_product(x)
17
```

```python
>>> from sage.all import *
>>> e = RootSystem(['B',Integer(3),Integer(1)]).ambient_space()
>>> B = e.basis()
>>> matrix([[x.inner_product(y) for x in B] for y in B])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
>>> x = e.an_element(); x
2*e[0] + 2*e[1] + 3*e[2]
>>> x.inner_product(x)
17
```

**scalar()** is an alias for this method:
Todo: Lift to CombinatorialFreeModule.Element as canonical_inner_product

coroot_lattice()

EXAMPLES:

```sage
sage: RootSystem(['A',3,1]).ambient_lattice().coroot_lattice()
Ambient lattice of the Root system of type ['A', 3, 1]
```

```sage
>>> from sage.all import *

sage: RootSystem(['A',3,1]).ambient_lattice().coroot_lattice()
Ambient lattice of the Root system of type ['A', 3, 1]
```

Todo: Factor out this code with the classical ambient space.

fundamental_weight(i)

Return the fundamental weight \( \Lambda_i \) in this ambient space.

It is constructed by taking the corresponding fundamental weight of the classical ambient space (or 0 for \( \Lambda_0 \)) and raising it to the appropriate level by adding a suitable multiple of \( \delta^\vee \).

EXAMPLES:

```sage
sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight(2)  
˓→ needs sage.graphs
# e[0] + e[1] + e['deltacheck']

sage: RootSystem(['A',3,1]).ambient_space().fundamental_weights()  
˓→ needs sage.graphs

sage: RootSystem(['A',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)}

sage: A3wl = RootSystem(['A',3,1]).weight_lattice()  
˓→ needs sage.graphs
sage: A3wl.fundamental_weights().map(attrcall("level"))  
˓→ needs sage.graphs
Finite family {0: 1, 1: 1, 2: 1, 3: 1}

sage: RootSystem(['B',3,1]).ambient_space().fundamental_weights()  
˓→ needs sage.graphs

sage: RootSystem(['B',3]).ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

(continues on next page)
sage: B31wl = RootSystem(['B',3,1]).weight_lattice()
sage: B31wl.fundamental_weights().map(attrcall("level"))  # needs sage.graphs
Finite family {0: 1, 1: 1, 2: 2, 3: 1}

>>> from sage.all import *
>>> RootSystem(['A',Integer(3),Integer(1)]).ambient_space().fundamental_weights()
# needs sage.graphs
Finite family {0: e['deltacheck'],
  1: e[0] + e['deltacheck'],
  2: e[0] + e[1] + e['deltacheck'],
>>> RootSystem(['A',Integer(3),Integer(1)]).ambient_space().fundamental_weights()
# needs sage.graphs
Finite family {0: e['deltacheck'],
  1: e[0] + e['deltacheck'],
  2: e[0] + e[1] + 2*e['deltacheck'],
>>> RootSystem(['B',Integer(3)]) .ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'],
  1: e[0] + e['deltacheck'],
  2: e[0] + e[1] + e['deltacheck'],
>>> RootSystem(['B',Integer(3)]) .ambient_space().fundamental_weights()
Finite family {0: e['deltacheck'],
  1: e[0] + e['deltacheck'],
  2: e[0] + e[1] + e['deltacheck'],

In type $BC$ dual, the coefficient of ‘$\delta^\vee$’ is the level divided by 2 to take into account that the null coroot is $2\delta^\vee$:

sage: R = CartanType(['BC',3,2]).dual().root_system()
sage: R.ambient_space().fundamental_weights()
# needs sage.graphs
Finite family {0: e['deltacheck'],
  1: e[0] + e['deltacheck'],
  2: e[0] + e[1] + 2*e['deltacheck'],

sage: R.weight_lattice().fundamental_weights().map(attrcall("level"))  # needs sage.graphs
Finite family {0: 1, 1: 1, 2: 2, 3: 1}

sage: R.ambient_space().null_coroot()
# needs sage.graphs
2*e['deltacheck']

>>> from sage.all import *
>>> R = CartanType(['BC',Integer(3),Integer(2)]).dual().root_system()
>>> R.ambient_space().fundamental_weights()
# needs sage.graphs
Finite family {0: 1, 1: 1, 2: 1, 3: 1}

(continues on next page)
Finite family {0: e['deltacheck'],
    1: e[0] + e['deltacheck'],
    2: e[0] + e[1] + e['deltacheck'],

>>> R.weight_lattice().fundamental_weights().map(attrcall("level"))

# needs sage.graphs

Finite family {0: 2, 1: 2, 2: 2, 3: 1}

>>> R.ambient_space().null_coroot()

# needs sage.graphs

2*e['deltacheck']

By a slight naming abuse this function also accepts “delta” as input so that it can be used to implement the embedding from the extended weight lattice:

```python
sage: RootSystem(['A',3,1]).ambient_space().fundamental_weight("delta")
e['deltacheck']
```

```python
>>> from sage.all import *
```

```python
sage: RootSystem(['A',Integer(3),Integer(1)]).ambient_space().fundamental_weight("delta")
e['deltacheck']
```

is_extended()

Return whether this is a realization of the extended weight lattice: yes!

See also:

• `sage.combinat.root_system.weight_space.WeightSpace`
• `sage.combinat.root_system.weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.is_extended()`

EXAMPLES:

```python
sage: RootSystem(['A',3,1]).ambient_space().is_extended()
True
```

```python
>>> from sage.all import *
```

```python
sage: RootSystem(['A',Integer(3),Integer(1)]).ambient_space().is_extended()
True
```

simple_coroot(i)

Return the i-th simple coroot $\alpha_i^\vee$ of this affine ambient space.

EXAMPLES:

```python
sage: RootSystem(['A',3,1]).ambient_space().simple_coroot(1)
e[0] - e[1]
```

```python
>>> from sage.all import *
```

```python
sage: RootSystem(['A',Integer(3),Integer(1)]).ambient_space().simple_coroot(Integer(1))
e[0] - e[1]
```

It is built as the coroot associated to the simple root $\alpha_i$: 
sage: RootSystem(["B",3,1]).ambient_space().simple_roots()  # needs sage.graphs
Finite family {0: -e[0] - e[1] + e['delta'], 1: e[0] - e[1],
sage: RootSystem(["B",3,1]).ambient_space().simple_coroots()  # needs sage.graphs
Finite family {0: -e[0] - e[1] + e['deltacheck'], 1: e[0] - e[1],

Todo: Factor out this code with the classical ambient space.

**simple_root** *(i)*

Return the *i*-th simple root of this affine ambient space.

EXAMPLES:

It is built straightforwardly from the corresponding simple root \(\alpha_i\) in the classical ambient space:

sage: RootSystem(["A",3,1]).ambient_space().simple_root(1)
e[0] - e[1]

For the special node (typically \(i = 0\)), \(\alpha_0\) is built from the other simple roots using the column annihilator of the Cartan matrix and adding \(\delta\), where \(\delta\) is the null root:

sage: RootSystem(["A",3,1]).ambient_space().simple_roots()

>>> from sage.all import *

Here is a twisted affine example:
Combinatorics, Release 10.4

sage: B31v = RootSystem(CartanType(["B",3,1]).dual()).ambient_space().simple_roots()  # needs sage.graphs

>>> from sage.all import *
>>> B31v = RootSystem(CartanType(["B",Integer(3),Integer(1)]).dual()).ambient_space().simple_roots()  # needs sage.graphs

In fact $\delta$ is really $1/a_0$ times the null root (see the discussion in WeightSpace) but this only makes a difference in type $BC$:

sage: L = RootSystem(CartanType(["BC",3,2])).ambient_space() 

sage: L.simple_roots()  # needs sage.graphs
Finite family {0: -e[0] + e[\delta], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}

sage: L.null_root()  # needs sage.graphs
2*e[\delta]

>>> from sage.all import *
>>> L = RootSystem(CartanType(["BC",Integer(3),Integer(2)]).ambient_space() 

>>> L.simple_roots()  # needs sage.graphs
Finite family {0: -e[0] + e[\delta], 1: e[0] - e[1], 2: e[1] - e[2], 3: 2*e[2]}

>>> L.null_root()  # needs sage.graphs
2*e[\delta]

Note: An alternative would have been to use the default implementation of the simple roots as linear combinations of the fundamental weights. However, as in type $A_n$ it is preferable to take a slight variant to avoid rational coefficient (the usual $GL_n$ vs $SL_n$ issue).

See also:

- simple_root()
- WeightSpace
- CartanType.col_annihilator()
- null_root()

classmethod smallest_base_ring(cartan_type)

Return the smallest base ring the ambient space can be defined on.

This is the smallest base ring for the associated classical ambient space.

See also:

smallest_base_ring()
EXAMPLES:

```python
cartan_type = CartanType(['A', 3, 1])
cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Integer Ring
cartan_type = CartanType(['B', 3, 1])
cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Rational Field
```

```python
from sage.all import *
cartan_type = CartanType(['A', Integer(3), Integer(1)])
cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Integer Ring
cartan_type = CartanType(['B', Integer(3), Integer(1)])
cartan_type.AmbientSpace.smallest_base_ring(cartan_type)
Rational Field
```

5.1.263 Root system data for dual Cartan types

class sage.combinat.root_system.type_dual.AmbientSpace (root_system, base_ring, 
index_set=None)

Bases: AmbientSpace

Ambient space for a dual finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type by switching the roles of simple roots, fundamental weights, etc.

**Note:** Recall that, for any finite Cartan type, and in particular the a simply laced one, the dual Cartan type is constructed as another preexisting Cartan type. Furthermore the ambient space for an affine type is constructed from the ambient space for its classical type. Thus this code is not actually currently used.

It is kept for cross-checking and for reference in case it could become useful, e.g., for dual of general Kac-Moody types.

For the doctests, we need to explicitly create a dual type. Subsequently, since reconstruction of the dual of type \( F_4 \) is the relabelled Cartan type, pickling fails on the TestSuite run.

EXAMPLES:

```python
c = sage.combinat.root_system.type_dual.CartanType(CartanType(['F', 4]))
L = c.root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4]^*
TestSuite(L).run(skip=['_test_elements','_test_pickling'])
```

```python
from sage.all import *
c = sage.combinat.root_system.type_dual.CartanType(CartanType(['F', Integer(4)]))
L = c.root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4]^*
TestSuite(L).run(skip=['_test_elements','_test_pickling'])
```

5.1. Comprehensive Module List 4223
**dimension()**

Return the dimension of this ambient space.

See also:

```
sage.combinat.root_system.ambient_space.AmbientSpace.dimension()
```

**EXAMPLES:**

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(["F",4]))
sage: L = ct.root_system().ambient_space()
sage: L.dimension()
4
```

```
>>> from sage.all import *
>>> ct = sage.combinat.root_system.type_dual.CartanType(CartanType(["F", Integer(4)]))
>>> L = ct.root_system().ambient_space()
>>> L.dimension()
4
```

**fundamental_weights()**

Return the fundamental weights.

They are computed from the simple roots by inverting the Cartan matrix. This is acceptable since this is only about ambient spaces for finite Cartan types. Also, we do not have to worry about the usual $GL_n$ vs $SL_n$ catch because type $A$ is self dual.

An alternative would have been to start from the fundamental coweights in the dual ambient space, but those are not yet implemented.

**EXAMPLES:**

```
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(["F",4]))
sage: L = ct.root_system().ambient_space()
sage: L.fundamental_weights()  # needs sage.graphs
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3, 1, 1, 1), 4: (2, 0, 0, 0)}
```

```
>>> from sage.all import *
>>> ct = sage.combinat.root_system.type_dual.CartanType(CartanType(["F", Integer(4)]))
>>> L = ct.root_system().ambient_space()
>>> L.fundamental_weights()  # needs sage.graphs
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3, 1, 1, 1), 4: (2, 0, 0, 0)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing $F_4$ dual by relabelling:

```
sage: ct = CartanType(["F",4]).dual(); ct
["F", 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (3/2, 1/2, 1/2, 1/2), 3: (2, 1, 1, 0), 4:
  (1, 1, 0, 0)}
```
```python
>>> from sage.all import *
>>> ct = CartanType(['F',Integer(4)]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
>>> ct.root_system().ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (3/2, 1/2, 1/2, 1/2), 3: (2, 1, 1, 0), 4:...
˓→(1, 1, 0, 0)}

simple_root (i)

Return the i-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the dual Cartan type.

EXAMPLES:

```python
sage: ct = sage.combinat.root_system.type_dual.CartanType(CartanType(['F',4]))
sage: ct.root_system().ambient_space().simple_root(1)
(0, 1, -1, 0)
sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, ...
˓→-1, -1)}
sage: ct.dual().root_system().ambient_space().simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, ...
˓→-1, -1)}
```

Note that this ambient space is isomorphic, but not equal, to that obtained by constructing $F_4$ dual by relabelling:

```python
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.root_system().ambient_space().simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 0, 0, 1), 3: (0, 0, 1, -1),...
˓→4: (0, 1, -1, 0)}
```

```python
>>> from sage.all import *
>>> ct = CartanType(['F',Integer(4)]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
>>> ct.root_system().ambient_space().simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 0, 0, 1), 3: (0, 0, 1, -1),...
˓→4: (0, 1, -1, 0)}
```

class sage.combinat.root_system.type_dual.CartanType(type)
Bases: `CartanType_decorator`, `CartanType_crystallographic`

A class for dual Cartan types.

The dual of a (crystallographic) Cartan type is a Cartan type with the same index set, but all arrows reversed in the Dynkin diagram (otherwise said, the Cartan matrix is transposed). It shares a lot of properties in common with its dual. In particular, the Weyl group is isomorphic to that of the dual as a Coxeter group.

**EXAMPLES:**

For all finite Cartan types, and in particular the simply laced ones, the dual Cartan type is given by another preexisting Cartan type:

```python
sage: CartanType(['A', 4]).dual()
['A', 4]
sage: CartanType(['B', 4]).dual()
['C', 4]
sage: CartanType(['C', 4]).dual()
['B', 4]
sage: CartanType(['F', 4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

So to exercise this class we consider some non simply laced affine Cartan types and also create explicitly $F_4^*$ as a dual cartan type:

```python
>>> from sage.combinat.root_system.type_dual import CartanType as CartanTypeDual
>>> F4d = CartanTypeDual(CartanType(['F', 4])); F4d
['F', 4]^*
>>> G21d = CartanType(['G', 2, 1]).dual(); G21d
['G', 2, 1]^*
```

They share many properties with their original Cartan types:

```python
sage: F4d.is_irreducible()
True
sage: F4d.is_crystallographic()
True
sage: F4d.is_simply_laced()
False
sage: F4d.is_finite()
```

(continues on next page)
True
sage: G21d.is_finite()
False
sage: F4d.is_affine()
False
sage: G21d.is_affine()
True

>>> from sage.all import *

>>> F4d.is_irreducible()
True
>>> F4d.is_crystallographic()
True
>>> F4d.is_simply_laced()
False
>>> F4d.is_finite()
True
>>> G21d.is_finite()
False
>>> F4d.is_affine()
False
>>> G21d.is_affine()
True

Note: F4d is pickled by construction as F4.dual() hence the above failure.

ascii_art (label=None, node=None)
Return an ascii art representation of this Cartan type
(by hacking the ascii art representation of the dual Cartan type)

EXAMPLES:

sage: print(CartanType(["B", 3, 1]).dual().ascii_art())
  _1_
O 0
  |
  0---0<=0
  1 2 3
sage: print(CartanType(["C", 4, 1]).dual().ascii_art())
  _1_
0=<0---0---0=>=0
  0 1 2 3 4
sage: print(CartanType(["G", 2, 1]).dual().ascii_art())
  _3_
0=>=0---0
  1 2 0
sage: print(CartanType(["F", 4, 1]).dual().ascii_art())
  _3_
0---0---0=<0---0
  0 1 2 3 4
sage: print(CartanType(["BC", 4, 2]).dual().ascii_art())
  _3_
0=>=0---0---0=>=0
  0 1 2 3 4

>>> from sage.all import *

>>> print(CartanType(["B", Integer(3), Integer(1)]).dual().ascii_art())
(continues on next page)
\[\begin{array}{c}
0 & 0 \\
\mid & \\
O---O=<=O \\
1 & 2 & 3
\end{array}\]

```
>>> print(CartanType(['C', Integer(4), Integer(1)]).dual().ascii_art())
O=<=O---O---O=>=O
0 1 2 3 4
```

```
>>> print(CartanType(['G', Integer(2), Integer(1)]).dual().ascii_art())
3
O=>=O---O
1 2 0
```

```
>>> print(CartanType(['F', Integer(4), Integer(1)]).dual().ascii_art())
O---O---O=<=O---O
0 1 2 3 4
```

```
>>> print(CartanType(['BC', Integer(4), Integer(2)]).dual().ascii_art())
O=>=O---O---O=>=O
0 1 2 3 4
```

dual()

EXAMPLES:

```
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dual()
['F', 4, 1]
```

```
>>> from sage.all import *
```

```
>>> ct = CartanType(['F', Integer(4), Integer(1)]).dual()
>>> ct.dual()
['F', 4, 1]
```

dynkin_diagram()

EXAMPLES:

```
sage: ct = CartanType(['F', 4, 1]).dual()
sage: ct.dynkin_diagram()  #...
˓needs sage.graphs
O---O---O=<=O---O
0 1 2 3 4
#F4~*
```

```
>>> from sage.all import *
```

```
>>> ct = CartanType(['F', Integer(4), Integer(1)]).dual()
>>> ct.dynkin_diagram()  #...
˓needs sage.graphs
O---O---O=<=O---O
0 1 2 3 4
#F4~*
```

class sage.combinat.root_system.type_dual.CartanType_affine(type)

Bases: CartanType, CartanType_affine

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.
Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

EXAMPLES:

```python
sage: CartanType(['A', 7, 2]).basic_untwisted()
['A', 7]
sage: CartanType(['E', 6, 2]).basic_untwisted()
['E', 6]
sage: CartanType(['D', 4, 3]).basic_untwisted()
['D', 4]
```

The special node of the dual of an affine type $T$ is the special node of $T$.

EXAMPLES:

```python
>>> from sage.all import *

>>> CartanType(['A', Integer(3), Integer(1)]).dual().special_node()
0
```
class sage.combinat.root_system.type_dual.CartanType_finite(type)

Bases: CartanType, CartanType_finite

5.1.264 Extended Affine Weyl Groups

AUTHORS:

• Daniel Bump (2012): initial version
• Daniel Orr (2012): initial version
• Anne Schilling (2012): initial version
• Mark Shimozono (2012): initial version
• Nicolas M. Thiery (2012): initial version
• Mark Shimozono (2013): twisted affine root systems, multiple realizations, GL_n

sage.combinat.root_system.extended_affine_weyl_group.ExtendedAffineWeylGroup(cartan_type, general_linear=None, **print_options)

The extended affine Weyl group.

INPUT:

• cartan_type – An affine or finite Cartan type (a finite Cartan type is an abbreviation for its untwisted affinization)

• general_linear – (default: None) If True and cartan_type indicates untwisted type A, returns the universal central extension

• print_options – Special instructions for printing elements (see below)
Mnemonics

- “P” – subgroup of translations
- “Pv” – subgroup of translations in a dual form
- “W0” – classical Weyl group
- “W” – affine Weyl group
- “F” – fundamental group of length zero elements

There are currently six realizations: “PW0”, “W0P”, “WF”, “FW”, “PvW0”, and “W0Pv”.

“PW0” means the semidirect product of “P” with “W0” acting from the right. “W0P” is similar but with “W0” acting from the left. “WF” is the semidirect product of “W” with “F” acting from the right, etc.

Recognized arguments for print_options are:
- print_tuple – True or False (default: False) If True, elements are printed \((a, b)\), otherwise as \(a \ast b\)
- affine – Prefix for simple reflections in the affine Weyl group
- classical – Prefix for simple reflections in the classical Weyl group
- translation – Prefix for the translation elements
- fundamental – Prefix for the elements of the fundamental group

These options are not mutable.

The extended affine Weyl group was introduced in the following references.

REFERENCES:
- [Ka1990]

Notation

- \(R\) – An irreducible affine root system
- \(I\) – Set of nodes of the Dynkin diagram of \(R\)
- \(R_0\) – The classical subsystem of \(R\)
- \(I_0\) – Set of nodes of the Dynkin diagram of \(R_0\)
- \(E\) – Extended affine Weyl group of type \(R\)
- \(W\) – Affine Weyl group of type \(R\)
- \(W_0\) – finite (classical) Weyl group (of type \(R_0\))
- \(M\) – translation lattice for \(W\)
- \(L\) – translation lattice for \(E\)
- \(F\) – Fundamental subgroup of \(E\) (the length zero elements)
- \(P\) – Finite weight lattice
- \(Q\) – Finite root lattice
- \(P^\vee\) – Finite coweight lattice
- \(Q^\vee\) – Finite coroot lattice
Translation lattices

The styles "PW0" and "W0P" use the following lattices:

- Untwisted affine: \( L = P^\vee, M = Q^\vee \)
- Dual of untwisted affine: \( L = P, M = Q \)
- \( BC_n (A^{(2)}_{2n}) \): \( L = M = P \)
- Dual of \( BC_n (A^{(2)}_{2n}) \): \( L = M = P^\vee \)

The styles "PvW0" and "W0Pv" use the following lattices:

- Untwisted affine: The weight lattice of the dual finite Cartan type.
- Dual untwisted affine: The same as for "PW0" and "W0P".

For mixed affine type \( (A^{(2)}_{2n}, \text{aka } \tilde{BC}_n, \text{ and their affine duals}) \) the styles "PvW0" and "W0Pv" are not implemented.

Finite and affine Weyl groups \( W_0 \) and \( W \)

The finite Weyl group \( W_0 \) is generated by the simple reflections \( s_i \) for \( i \in I_0 \) where \( s_i \) is the reflection across a suitable hyperplane \( H_i \) through the origin in the real span \( V \) of the lattice \( M \).

\( R \) specifies another (affine) hyperplane \( H_0 \). The affine Weyl group \( W \) is generated by \( W_0 \) and the reflection \( S_0 \) across \( H_0 \).

Extended affine Weyl group \( E \)

The complement in \( V \) of the set \( H \) of hyperplanes obtained from the \( H_i \) by the action of \( W \), has connected components called alcoves. \( W \) acts freely and transitively on the set of alcoves. After the choice of a certain alcove (the fundamental alcove), there is an induced bijection from \( W \) to the set of alcoves under which the identity in \( W \) maps to the fundamental alcove.

Then \( L \) is the largest sublattice of \( V \), whose translations stabilize the set of alcoves.

There are isomorphisms
\[
W \cong M \rtimes W_0 \cong W_0 \ltimes M \\
E \cong L \rtimes W_0 \cong W_0 \ltimes L
\]

Fundamental group of affine Dynkin automorphisms

Since \( L \) acts on the set of alcoves, the group \( F = L/M \) may be viewed as a subgroup of the symmetries of the fundamental alcove or equivalently the symmetries of the affine Dynkin diagram. \( F \) acts on the set of alcoves and hence on \( W \). Conjugation by an element of \( F \) acts on \( W \) by permuting the indices of simple reflections.

There are isomorphisms
\[
E \cong F \ltimes W \cong W \ltimes F
\]

An affine Dynkin node is special if it is conjugate to the zero node under some affine Dynkin automorphism.

There is a bijection \( i \mapsto \pi_i \) from the set of special nodes to the group \( F \), where \( \pi_i \) is the unique element of \( F \) that sends \( 0 \) to \( i \). When \( L = P \) (resp. \( L = P^\vee \)) the element \( \pi_i \) is induced (under the isomorphism \( F \cong L/M \)) by addition of the coset of the \( i \)-th fundamental weight (resp. coweight).
The length function of the Coxeter group $W$ may be extended to $E$ by $\ell(w\pi) = \ell(w)$ where $w \in W$ and $\pi \in F$. This is the number of hyperplanes in $H$ separating the fundamental alcove from its image by $w\pi$ (or equivalently $w$).

It is known that if $G$ is the compact Lie group of adjoint type with root system $R_0$ then $F$ is isomorphic to the fundamental group of $G$, or to the center of its simply-connected covering group. That is why we call $F$ the fundamental group.

In the future we may want to build an element of the group from an appropriate linear map $f$ on some of the root lattice realizations for this Cartan type: $W$.from_endomorphism($f$).

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1]); E
Extended affine Weyl group of type ['A', 2, 1]
sage: type(E)
<class 'sage.combinat.root_system.extended_affine_weyl_group.
   _ExtendedAffineWeylGroup_class_with_category'>
sage: PW0 = E.PW0(); PW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
   acted upon by Weyl Group of type ['A', 2]
   (as a matrix group acting on the coweight lattice)
sage: W0P = E.W0P(); W0P
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
   acting on Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
sage: PvW0 = E.PvW0(); PvW0
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Multiplicative form of Weight lattice of the Root system of type ['A', 2]
   acted upon by Weyl Group of type ['A', 2]
   (as a matrix group acting on the weight lattice)
sage: W0Pv = E.W0Pv(); W0Pv
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
   acting on Multiplicative form of Weight lattice of the Root system of type ['A', 2]
sage: WF = E.WF(); WF
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
   Fundamental group of type ['A', 2, 1] acting on Weyl Group of type ['A', 2, 1]
   (as a matrix group acting on the root lattice)

>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]); E
Extended affine Weyl group of type ['A', 2, 1]

(continues on next page)
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Multiplicative form of Coweight lattice of the Root system of type ['A', 2] acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

When the realizations are constructed from each other as above, there are built-in coercions between them.

```python
sage: F = E.fundamental_group()
sage: x = WF.from_reduced_word([0,1,2]) * WF(F(2)); x
S0*S1*S2 * pi[2]
sage: FW(x)
pi[2] * S1*S2*S0
sage: W0P(x)
s1*s2*s1 * t[-2*Lambdacheck[1] - Lambdacheck[2]]
sage: PW0(x)
t[Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1
sage: PvW0(x)
```

```python
>>> from sage.all import *
>>> F = E.fundamental_group()
>>> x = WF.from_reduced_word([Integer(0),Integer(1),Integer(2)]) *...
    WF(F(Integer(2)))); x
S0*S1*S2 * pi[2]
>>> FW(x)
```
The translation lattice and its distinguished basis are obtained from $E$:

\begin{verbatim}
>>> from sage.all import *
>>> L = E.lattice(); L
Coweight lattice of the Root system of type ['A', 2]
Finite family {1: Lambda[1], 2: Lambda[2]}
\end{verbatim}

Translation lattice elements can be coerced into any realization:

\begin{verbatim}
>>> from sage.all import *
>>> PW0(b[Integer(1)]-b[Integer(2)])
pi[2] * S0*S1
\end{verbatim}

The dual form of the translation lattice and its basis are similarly obtained:

\begin{verbatim}
>>> from sage.all import *
>>> Lv = E.dual_lattice(); Lv
Weight lattice of the Root system of type ['A', 2]
Finite family {1: Lambda[1], 2: Lambda[2]}
\end{verbatim}

The abstract fundamental group is accessed from $E$:

\begin{verbatim}
>>> F = E.fundamental_group(); F
Fundamental group of type ['A', 2, 1]
\end{verbatim}
Its elements are indexed by the set of special nodes of the affine Dynkin diagram:

```python
sage: E.cartan_type().special_nodes()
(0, 1, 2)
sage: F.special_nodes()
(0, 1, 2)
sage: [F(i) for i in F.special_nodes()]
[pi[0], pi[1], pi[2]]
```

There is a coercion from the fundamental group into each realization:

```python
sage: F(2)
pi[2]
sage: WF(F(2))
pi[2]
sage: W0P(F(2))
s2*s1 * t[-Lambda[1]]
sage: W0Pv(F(2))
s2*s1 * t[-Lambda[1]]
```

Using E one may access the classical and affine Weyl groups and their morphisms into each realization:

```python
sage: W0 = E.classical_weyl(); W0
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: v = W0.from_reduced_word([1,2,1]); v
s1*s2*s1
sage: PW0(v)
s1*s2*s1
sage: WF(v)
S1*S2*S1
sage: W = E.affine_weyl(); W
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
sage: w = W.from_reduced_word([2,1,0]); w
S2*S1*S0
sage: WF(w)
```

(continues on next page)
**Combinatorics, Release 10.4**

(continued from previous page)

```
S2*S1*S0
sage: PW0(w)
t[Lambda[1] - 2*Lambda[2]] * s1

>>> from sage.all import *
>>> W0 = E.classical_weyl(); W0
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
>>> v = W0.from_reduced_word([1,2,1]); v
s1*s2*s1
>>> PW0(v)
s1*s2*s1
>>> WF(v)
S1*S2*S1
>>> W = E.affine_weyl(); W
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
>>> w = W.from_reduced_word([2,1,0]); w
S2*S1*S0
>>> WF(w)
S2*S1*S0
>>> PW0(w)
t[Lambda[1] - 2*Lambda[2]] * s1
```

Note that for untwisted affine type, the dual form of the classical Weyl group is isomorphic to the usual one, but acts on a different lattice and is therefore different to `sage`:

```
sage: W0v = E.dual_classical_weyl(); W0v
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: v = W0v.from_reduced_word([1,2])
sage: x = PvW0(v); x
s1*s2
sage: y = PW0(v); y
s1*s2
sage: x.parent() == y.parent()
False
```

```
>>> from sage.all import *
>>> W0v = E.dual_classical_weyl(); W0v
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
>>> v = W0v.from_reduced_word([1,2])
>>> x = PvW0(v); x
s1*s2
>>> y = PW0(v); y
s1*s2
>>> x.parent() == y.parent()
False
```

However, because there is a coercion from `PvW0` to `PW0`, the elements `x` and `y` compare as equal:

```
sage: x == y
True
```

```
>>> from sage.all import *
>>> x == y
True
```

An element can be created directly from a reduced word:

```
sage: x == y
True
```

5.1. Comprehensive Module List 4237
Here is a demonstration of the printing options:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1], affine="sx", classical="Sx", translation="x", fundamental="pix")
sage: PW0 = E.PW0()
sage: y = PW0(E.lattice_basis()[1]); y
x[Lambdacheck[1]]
sage: FW = E.FW()
sage: FW(y)
pix[1] * sx2*sx1
sage: PW0.an_element()
```

```
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], affine="sx",
˓→classical="Sx",
...
translation="x", fundamental="pix")
>>> PW0 = E.PW0()
>>> y = PW0(E.lattice_basis()[Integer(1)]); y
x[Lambdacheck[1]]
>>> FW = E.FW()
>>> FW(y)
pix[1] * sx2*sx1
>>> PW0.an_element()
```

Todo:

- Implement a “slow” action of $E$ on any affine root or weight lattice realization.
- Implement the level $m$ actions of $E$ and $W$ on the lattices of finite type.
- Implement the relevant methods from the usual affine Weyl group
- Implementation by matrices: style “M”.
- Use case: implement the Hecke algebra on top of this

The semidirect product construction in sage currently only admits multiplicative groups. Therefore for the styles involving “P” and “Pv”, one must convert the additive group of translations $L$ into a multiplicative group by applying the `sage.groups.group_exp.GroupExp` functor.
The general linear case

The general linear group is not semisimple. Sage can build its extended affine Weyl group:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], general_linear=True); E
Extended affine Weyl group of GL(3)
```

If the Cartan type is ['A', n-1, 1] and the parameter general_linear is not True, the extended affine Weyl group that is built will be for \( SL_n \), not \( GL_n \). But if general_linear is True, let \( W_a \) and \( W_e \) be the affine and extended affine Weyl groups. We make the following nonstandard definition: the extended affine Weyl group \( W_e(GL_n) \) is defined by

\[
W_e(GL_n) = P(GL_n) \rtimes W
\]

where \( W \) is the finite Weyl group (the symmetric group \( S_n \)) and \( P(GL_n) \) is the weight lattice of \( GL_n \), which is usually identified with the lattice \( \mathbb{Z}^n \) of \( n \)-tuples of integers:

```python
sage: PW0 = E.PW0(); PW0
Extended affine Weyl group of GL(3) realized by Semidirect product of
Multiplicative form of Ambient space of the Root system of type ['A', 2] acted upon
by Weyl Group of type ['A', 2] (as a matrix group acting on the ambient space)
sage: PW0.an_element()
t[(2, 2, 3)] * s1*s2
```

There is an isomorphism

\[
W_e(GL_n) = \mathbb{Z} \times W_a
\]

where the group of integers \( \mathbb{Z} \) (with generator \( \pi \)) acts on \( W_a \) by

\[
\pi s_i \pi^{-1} = s_{i+1}
\]

and the indices of the simple reflections are taken modulo \( n \):
We regard $\mathbb{Z}$ as the fundamental group of affine type $GL_n$:

```python
def F = E.fundamental_group(); F
Fundamental group of GL(3)
sage: F.special_nodes()
Integer Ring
sage: x = FW.from_fundamental(F(10)); x
pi[10]
sage: x*x
pi[20]
sage: E.PvW0()(x*x)
t[(7, 7, 6)] * s2*s1
```
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...

Example:
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...

**Element**

alias of ExtendedAffineWeylGroupFWElement

**from_affine_weyl** *(w)*

Return the image of *w* under the map of the affine Weyl group into the right (affine Weyl group) factor in the “FW” style.

Examples:

```sage
sage: E = ExtendedAffineWeylGroup(['A',2,1], print_tuple=True)
sage: E.FW().from_affine_weyl(E.affine_weyl().from_reduced_word([0,2,1]))
(pi[0], S0*S2*S1)
```

**from_fundamental** *(f)*

Return the image of the fundamental group element *f* into self.

Examples:

```sage
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], print_tuple=True)
>>> E.FW().from_fundamental(E.fundamental_group()(Integer(2)))
(pi[2], 1)
```

**simple_reflections** *

Return the family of simple reflections of self.

Examples:
class ExtendedAffineWeylGroupFWElement

Bases: GroupSemidirectProductElement

The element class for the “FW” realization.

action_on_affine_roots(beta)

Act by self on the affine root lattice element beta.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A',2,1], affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: v = RootSystem(['A',2,1]).root_lattice().an_element(); v
sage: x.action_on_affine_roots(v)
alpha[0] + alpha[1]

has_descent (i, side='right', positive=False)

Return whether self has descent at i.

INPUT:
• i – an affine Dynkin index.

OPTIONAL:
• side = 'left' or 'right' (default: 'right')
• positive – True or False (default: False)

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, False), (1, False), (2, True)]

>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], affine="s")
>>> x = E.FW().an_element(); x
pi[2] * S0*S1*S2
>>> v = RootSystem(['A',Integer(2),Integer(1)]).root_lattice().an_element(); v
>>> x.action_on_affine_roots(v)
alpha[0] + alpha[1]
to_affine_weyl_right()

Project self to the right (affine Weyl group) factor in the “FW” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().from_translation(E.lattice_basis()[1]); x
pi[1] * S2*S1
sage: x.to_affine_weyl_right()
S2*S1
```

```python
>>> from sage.all import *
```  
```python
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> x = E.FW().from_translation(E.lattice_basis()[Integer(1)]); x
pi[1] * S2*S1
>>> x.to_affine_weyl_right()
S2*S1
```

to_fundamental_group()

Return the projection of self to the fundamental group in the “FW” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.FW().from_translation(E.lattice_basis()[2]); x
pi[2] * S1*S2
sage: x.to_fundamental_group()
pi[2]
```

```python
>>> from sage.all import *
```  
```python
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> x = E.FW().from_translation(E.lattice_basis()[Integer(2)]); x
pi[2] * S1*S2
>>> x.to_fundamental_group()
pi[2]
```

class ExtendedAffineWeylGroupPW0(E)

Bases: GroupSemidirectProduct, BindableClass

Extended affine Weyl group, realized as the semidirect product of the translation lattice by the finite Weyl group.

INPUT:

- E – A parent with realization in `ExtendedAffineWeylGroup_Class`

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
```

Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2]
(as a matrix group acting on the coweight lattice)

Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
of
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2]
(as a matrix group acting on the coweight lattice)

Element

alias of ExtendedAffineWeylGroupPW0Element

S0()

Return the affine simple reflection.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup("A3",print_tuple=True)
sage: E.PW0().from_classical_weyl(E.classical_weyl().from_reduced_word([1, 2]))
(t[0], s1*s2)

from_translation(la)

Map the translation lattice element la into self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup("A2", translation="tau",
              print_tuple=True)
sage: la = E.lattice().an_element(); la
sage: E.PW0().from_translation(la)
```python
>>> from sage.all import *

E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], translation="tau",
... print_tuple=True)

>>> la = E.lattice().an_element(); la

>>> E.PW0().from_translation(la)
```

**simple_reflection(i)**

Return the i-th simple reflection in self.

**EXAMPLES:**

```
sage: E = ExtendedAffineWeylGroup("G2")
sage: [(i, E.PW0().simple_reflection(i)) for i in E.cartan_type().index_→set()]
[(0, t[Lambdacheck[2]] * s2*s1*s2*s1*s2), (1, s1), (2, s2)]
```

```
>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup("G2")

>>> [(i, E.PW0().simple_reflection(i)) for i in E.cartan_type().index_→set()]
[(0, t[Lambdacheck[2]] * s2*s1*s2*s1*s2), (1, s1), (2, s2)]
```

**simple_reflections()**

Return a family for the simple reflections of self.

**EXAMPLES:**

```
sage: ExtendedAffineWeylGroup("A3").PW0().simple_reflections()
Finite family {0: t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1,
1: s1, 2: s2, 3: s3}
```

```
>>> from sage.all import *

>>> ExtendedAffineWeylGroup("A3").PW0().simple_reflections()
Finite family {0: t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1,
1: s1, 2: s2, 3: s3}
```

**class ExtendedAffineWeylGroupPW0Element**

Bases: GroupSemidirectProductElement

The element class for the “PW0” realization.

**action(la)**

Return the action of self on an element la of the translation lattice.

**EXAMPLES:**

```
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0 = E.PW0()
sage: x = PW0.an_element(); x
sage: la = E.lattice().an_element(); la
sage: x.action(la)
```
```python
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]); PW0 = E.
˓→PW0()
>>> x = PW0.an_element(); x
>>> la = E.lattice().an_element(); la
>>> x.action(la)
```

**has_descent** *(i, side='right', positive=False)*

Return whether self has i as a descent.

**INPUT:**
* i – an affine Dynkin node

**OPTIONAL:**
* side – 'left' or 'right' (default: 'right')
* positive – True or False (default: False)

**EXAMPLES:**

```python
sage: w = ExtendedAffineWeylGroup(['A',4,2]).PW0().from_reduced_word([0,
˓→1]); w
t[Lambda[1]] * s1*s2
sage: w.has_descent(0, side='left')
True
```

**to_classical_weyl()**

Return the image of self under the homomorphism that projects to the classical Weyl group factor after rewriting it in either style “PW0” or “W0P”.

**EXAMPLES:**

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PW0().S0(); s
t[Lambda[1] + Lambda[2]] * s1*s2*s1
sage: s.to_classical_weyl()
s1*s2*s1
```

**to_translation_left()**

The image of self under the map that projects to the translation lattice factor after factoring it to the left as in style “PW0”.

**EXAMPLES:**
```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().S0(); s
t[Lambdacheck[1] + Lambdacheck[2]] * s_1*s_2*s_1
sage: s.to_translation_left()
```
from dual_translation(la)

Map the dual translation lattice element la into self.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau",
                              print_tuple=True)
...:
  sage: la = E.dual_lattice().an_element(); la
  sage: E.PvW0().from_dual_translation(la)
```

simple_reflections()

Return a family for the simple reflections of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1,
  1: s1, 2: s2, 3: s3}
```

class ExtendedAffineWeylGroupPvW0Element

Bases: GroupSemidirectProductElement

The element class for the “PvW0” realization.

dual_action(la)

Return the action of self on an element la of the dual version of the translation lattice.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.PvW0().an_element(); x
sage: la = E.dual_lattice().an_element(); la
sage: x.dual_action(la)
```
```python
>>> from sage.all import *

```
EXAMPLES:

```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).PvW0().simple_reflection(0);
    s
    t[Lambda[1] + Lambda[2]] * s1*s2*s1
sage: s.to_dual_translation_left()
```

```python
>>> from sage.all import *
    s = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).PvW0().
    simple_reflection(Integer(0)); s
    t[Lambda[1] + Lambda[2]] * s1*s2*s1
    >>> s.to_dual_translation_left()
```

class ExtendedAffineWeylGroupW0P(E)

Bases: GroupSemidirectProduct, BindableClass

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group by the translation lattice.

INPUT:

• E – A parent with realization in ExtendedAffineWeylGroup_Class

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).W0P()
    Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
    of Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
    acting on Multiplicative form of Coweight lattice of the Root system of type
    ['A', 2]
```

```python
>>> from sage.all import *
    ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).W0P()
    Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
    of Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
    acting on Multiplicative form of Coweight lattice of the Root system of type
    ['A', 2]
```

Element

alias of ExtendedAffineWeylGroupW0PElement

S0 ()

Return the zero-th simple reflection in style “W0P”.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().S0()
    s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]
```

```python
>>> from sage.all import *
    ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).W0P().S0()
    s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]]
```
from_classical_weyl\(w\)

Return the image of the classical Weyl group element \(w\) in self.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.W0P().from_classical_weyl(E.classical_weyl().from_reduced_word([2, -1]))
(s2*s1, t[0])
```

from_translation\(l_{a}\)

Return the image of the lattice element \(l_{a}\) in self.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1],print_tuple=True)
sage: E.W0P().from_translation(E.lattice().an_element())
```

simple_reflection\(i\)

Return the \(i\)-th simple reflection in self.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); W0P = E.W0P()
sage: [(i, W0P.simple_reflection(i)) for i in E.cartan_type().index_set()]
[(0, s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]]),
 (1, s1), (2, s2), (3, s3)]
```

```
from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)],print_tuple=True)
>>> E.W0P().from_translation(E.lattice().an_element())
```

simple_reflections()

Return the family of simple reflections.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]],
 1: s1, 2: s2, 3: s3}
```
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda check[1] - Lambda check[3]],
1: s1, 2: s2, 3: s3}

class ExtendedAffineWeylGroupW0PElement
Bases: GroupSemidirectProductElement

The element class for the W0P realization.

has_descent (i, side='right', positive=False)
Return whether self has i as a descent.

INPUT:
• i – an index.

OPTIONAL:
• side – 'left' or 'right' (default: 'right')
• positive – True or False (default: False)

EXAMPLES:

sage: W0P = ExtendedAffineWeylGroup(['A',4,2]).W0P()
sage: w = W0P.from_reduced_word([0,1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True

>>> from sage.all import *
>>> W0P = ExtendedAffineWeylGroup(['A',Integer(4),Integer(2)]).W0P()
>>> w = W0P.from_reduced_word([Integer(0),Integer(1)]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
>>> w.has_descent(Integer(0), side='left')
True

to_classical_weyl ()
Project self into the classical Weyl group.

EXAMPLES:

sage: x = ExtendedAffineWeylGroup(['A',2,1]).W0P().simple_reflection(0); x
s1*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[2]]
sage: x.to_classical_weyl()
s1*s2*s1

>>> from sage.all import *
>>> x = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).W0P().simple_reflection(Integer(0)); x
s1*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[2]]
>>> x.to_classical_weyl()
s1*s2*s1

to_translation_right ()
Project onto the right (translation) factor in the “W0P” style.

EXAMPLES:
**class** `ExtendedAffineWeylGroupW0Pv(E)`

**Bases:** GroupSemidirectProduct, BindableClass

Extended affine Weyl group, realized as the semidirect product of the finite Weyl group, acting on the dual form of the translation lattice.

**INPUT:**

- `E` – A parent with realization in `ExtendedAffineWeylGroup_Class`

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).W0Pv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice) acting on Multiplicative form of Weight lattice of the Root system of type ['A', 2]
```

```python
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).W0Pv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice) acting on Multiplicative form of Weight lattice of the Root system of type ['A', 2]
```

**Element**

alias of `ExtendedAffineWeylGroupW0PvElement`

**from_dual_classical_weyl(w)**

Return the image of `w` under the homomorphism of the dual form of the classical Weyl group into `self`.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1],print_tuple=True)
sage: E.W0Pv().from_dual_classical_weyl(E.dual_classical_weyl().from_reduced_word([1,2]))
(s1*s2, t[0])
```

```python
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)],print_tuple=True)
>>> E.W0Pv().from_dual_classical_weyl(E.dual_classical_weyl().from_reduced_word([Integer(1),Integer(2)]))
(s1*s2, t[0])
```
from_dual_translation($la$)

Map the dual translation lattice element $la$ into self.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], translation="tau",
....:     print_tuple=True)
sage: la = E.dual_lattice().an_element(); la
sage: E.W0Pv().from_dual_translation(la)
```

simple_reflections()

Return a family for the simple reflections of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).W0Pv().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambda[1] - Lambda[3]],
                   1: s1, 2: s2, 3: s3}
```

class ExtendedAffineWeylGroupW0PvElement

Bases: GroupSemidirectProductElement

The element class for the “W0Pv” realization.

dual_action($la$)

Return the action of self on an element $la$ of the dual version of the translation lattice.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.W0Pv().an_element(); x
sage: la = E.dual_lattice().an_element(); la
sage: x.dual_action(la)
```

(continues on next page)
\begin{verbatim}
Combinatorics, Release 10.4

>>> la = E.dual_lattice().an_element(); la
>>> x.dual_action(la)

\textbf{has_descent} \textit{(i, side='right', positive=False)}

Return whether \texttt{self} has \texttt{i} as a descent.

\textbf{INPUT:}

\begin{itemize}
\item \texttt{i} – an affine Dynkin index
\end{itemize}

\textbf{OPTIONAL:}

\begin{itemize}
\item \texttt{side} – ‘left’ or ‘right’ (default: ‘right’)
\item \texttt{positive} – True or False (default: False)
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: w = ExtendedAffineWeylGroup(['A',4,2]).W0Pv().from_reduced_word([0, ˓→1]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
sage: w.has_descent(0, side='left')
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> w = ExtendedAffineWeylGroup(['A',Integer(4),Integer(2)]).W0Pv().from_ ˓→reduced_word([Integer(0),Integer(1)]); w
s1*s2 * t[Lambda[1] - Lambda[2]]
>>> w.has_descent(Integer(0), side='left')
True
\end{verbatim}

\textbf{to_dual_classical_weyl()}  

Return the image of \texttt{self} under the homomorphism that projects to the dual classical Weyl group factor after rewriting it in either style “PvW0” or “W0Pv”.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: s = ExtendedAffineWeylGroup(['A',2,1]).W0Pv().simple_reflection(0); ˓→s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_classical_weyl()
s1*s2*s1
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> s = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).W0Pv(). ˓→simple_reflection(Integer(0)); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
>>> s.to_dual_classical_weyl()
s1*s2*s1
\end{verbatim}

\textbf{to_dual_translation_right()}  

The image of \texttt{self} under the map that projects to the dual translation lattice factor after factoring it to the right as in style “W0Pv”.

\textbf{EXAMPLES:}

\end{verbatim}

\end{verbatim}
```python
sage: s = ExtendedAffineWeylGroup(['A',2,1]).W0Pv().simple_reflection(0);
˓→s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
sage: s.to_dual_translation_right()
```

```python
nen >> from sage.all import *
>> s = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).W0Pv().
˓→simple_reflection(Integer(0)); s
s1*s2*s1 * t[-Lambda[1] - Lambda[2]]
>> s.to_dual_translation_right()
```

```python
class ExtendedAffineWeylGroupWF(E)
    Bases: GroupSemidirectProduct, BindableClass

    Extended affine Weyl group, realized as the semidirect product of the affine Weyl group by the fundamental group.

    INPUT:

    • E – A parent with realization in `ExtendedAffineWeylGroup_Class`

    EXAMPLES:

    sage: ExtendedAffineWeylGroup(['A',2,1]).WF()
    Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
        of
        Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
        acted upon by Fundamental group of type ['A', 2, 1]

    >>> from sage.all import *
    >>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).WF()
    Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
        of
        Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
        acted upon by Fundamental group of type ['A', 2, 1]
```

```python
Element
    alias of `ExtendedAffineWeylGroupWFElement`

from_affine_weyl(w)
    Return the image of the affine Weyl group element w in self.

    EXAMPLES:

    sage: E = ExtendedAffineWeylGroup(['C',2,1], print_tuple=True)
sage: E.WF().from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,˓→0]))
(S1*S2*S1*S0, pi[0])

>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['C',Integer(2),Integer(1)], print_
˓→tuple=True)
>>> E.WF().from_affine_weyl(E.affine_weyl().from_reduced_word([Integer(1),
˓→Integer(2),Integer(1),Integer(0)]))
(S1*S2*S1*S0, pi[0])
```
from fundamental \((f)\)

Return the image of \(f\) under the homomorphism from the fundamental group into the right (fundamental group) factor in “WF” style.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['E', 6, 1], print_tuple=True); WF = E.WF()
sage: F = E.fundamental_group()
sage: [(x, WF.from_fundamental(x)) for x in F]
[(pi[0], (1, pi[0])), (pi[1], (1, pi[1])), (pi[6], (1, pi[6]))]
```

simple_reflections()

Return the family of simple reflections.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A', 3, 1], affine="r").WF().simple_reflections()
Finite family {0: r0, 1: r1, 2: r2, 3: r3}
```

class ExtendedAffineWeylGroupWFElement

Bases: GroupSemidirectProductElement

Element class for the “WF” realization.

bruhat_le \((x)\)

Return whether \texttt{self} is less than or equal to \(x\) in the Bruhat order.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A', 2, 1], affine="s",
                print_tuple=True); WF = E.WF()
sage: r = E.affine_weyl().from_reduced_word
sage: v = r([1,0])
sage: w = r([1,2,0])
sage: v.bruhat_le(w)
True
sage: vv = WF.from_affine_weyl(v); vv
(s1*s0, pi[0])
sage: ww = WF.from_affine_weyl(w); ww
(s1*s2*s0, pi[0])
sage: vv.bruhat_le(ww)
True
sage: f = E.fundamental_group()(2); f
```
\begin{verbatim}
pi[2]
 sage: ff = WF.from_fundamental(f); ff
(1, pi[2])
sage: vv.bruhat_le(ww*ff)
False
sage: (vv*ff).bruhat_le(ww*ff)
True

from sage.all import *
E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], affine="s",
... print_tuple=True); WF = E.WF()

r = E.affine_weyl().from_reduced_word
v = r([Integer(1),Integer(0)])
w = r([Integer(1),Integer(2),Integer(0)])
vv = WF.from_affine_weyl(v); vv
(s1*s0, pi[0])
ww = WF.from_affine_weyl(w); ww
(s1*s2*s0, pi[0])
vv.bruhat_le(ww)
True

f = E.fundamental_group()(Integer(2)); f
pi[2]

>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
>>> [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]

to_affine_weyl_left()

E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
>>> [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]
\end{verbatim}

\textbf{has_descent} \((i, \text{side}='right', \text{positive}=False)\)

Return whether \texttt{self} has \(i\) as a descent.

**INPUT:**
- \(i\) – an affine Dynkin index

**OPTIONAL:**
- \texttt{side} – 'left' or 'right' (default: 'right')
- \texttt{positive} – True or False (default: False)

**EXAMPLES:**

\texttt{sage: E = ExtendedAffineWeylGroup(['A',2,1])}
\texttt{sage: x = E.WF().an_element(); x}
S0*S1*S2 * pi[2]
\texttt{sage: [(i, x.has_descent(i)) for i in E.cartan_type().index_set()]
[(0, True), (1, False), (2, False)]}

\texttt{to_affine_weyl_left()}

Project \texttt{self} to the left (affine Weyl group) factor in the "WF" style.
EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_affine_weyl_left()
S0*S2
```

```
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> x = E.WF().from_translation(E.lattice_basis()[Integer(1)]); x
S0*S2 * pi[1]
>>> x.to_affine_weyl_left()
S0*S2
```

`to_fundamental_group()`

Project `self` to the right (fundamental group) factor in the “WF” style.

EXAMPLES:

```
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: x = E.WF().from_translation(E.lattice_basis()[1]); x
S0*S2 * pi[1]
sage: x.to_fundamental_group()
pi[1]
```

```
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> x = E.WF().from_translation(E.lattice_basis()[Integer(1)]); x
S0*S2 * pi[1]
>>> x.to_fundamental_group()
pi[1]
```

`FW()`

Realizes `self` in “FW”-style.

EXAMPLES:

```
sage: ExtendedAffineWeylGroup(['A',2,1]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
˓→of
  Fundamental group of type ['A', 2, 1] acting on
  Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root...
˓→lattice)
```

```
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).FW()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
˓→of
  Fundamental group of type ['A', 2, 1] acting on
  Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root...
˓→lattice)
```

`PW0()`

Realizes `self` in “PW0”-style.

EXAMPLES:
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by
Semidirect product of Multiplicative form of
Coweight lattice of the Root system of type ['A', 2] acted upon by
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight_‐
lattice)

>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).PW0()
Extended affine Weyl group of type ['A', 2, 1] realized by
Semidirect product of Multiplicative form of
Coweight lattice of the Root system of type ['A', 2] acted upon by
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight_‐
lattice)

PW0_to_WF_func(x)
Implements coercion from style “PW0” to “WF”.

EXAMPLES:
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.PW0().an_element(); x
\(t[2*\Lambda_1 + 2*\Lambda_2] * s_1 * s_2\)
sage: E.PW0_to_WF_func(x)
\(S_0 * S_1 * S_2 * S_0 * S_1 * S_0\)

>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A', Integer(2), Integer(1)])
>>> x = E.PW0().an_element(); x
\(t[2*\Lambda_1 + 2*\Lambda_2] * s_1 * s_2\)
>>> E.PW0_to_WF_func(x)
\(S_0 * S_1 * S_2 * S_0 * S_1 * S_0\)

Warning: This function cannot use coercion, because it is used to define the coercion maps.

PvW0()
Realizes self in “PvW0”-style.

EXAMPLES:
sage: ExtendedAffineWeylGroup(['A',2,1]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
‐of
Multiplicative form of Weight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the...
‐weight lattice)

>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).PvW0()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product...
‐of
Multiplicative form of Weight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the...
‐weight lattice)
class Realizations(
-parent_with_realization)
Bases: Category_realization_of_parent

The category of the realizations of an extended affine Weyl group

class ElementMethods
Bases: object

\texttt{action}(la)

Action of \texttt{self} on a lattice element \texttt{la}.

\textbf{INPUT:}

- \texttt{self} – an element of the extended affine Weyl group
- \texttt{la} – an element of the translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic “P” in the documentation for \texttt{ExtendedAffineWeylGroup}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: E = ExtendedAffineWeylGroup(['A',2,1], affine="s")
sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2
sage: la = E.lattice().an_element(); la
sage: x.action(la)
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], affine="s")
>>> x = E.FW().an_element(); x
pi[2] * s0*s1*s2
>>> la = E.lattice().an_element(); la
>>> x.action(la)
\end{verbatim}

\begin{verbatim}
Warning: Must be implemented by style “PW0”.
\end{verbatim}

\texttt{action_on_affine_roots}(beta)

Act by \texttt{self} on the affine root lattice element \texttt{beta}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: beta = E.cartan_type().root_system().root_lattice().an_element();
- beta
\end{verbatim}
(continues on next page)
sage: x = E.FW().an_element(); x
pi[2] * S0*S1*S2
sage: x.action_on_affine_roots(beta)
alpha[0] + alpha[1]

>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> beta = E.cartan_type().root_system().root_lattice().an_element();
>>> x = E.FW().an_element(); x
pi[2] * S0*S1*S2
>>> x.action_on_affine_roots(beta)
alpha[0] + alpha[1]

Warning: Must be implemented by style “FW”.

**alcove_walk_signs**

Return a signed alcove walk for self.

**INPUT:**
- An element self of the extended affine Weyl group.

**OUTPUT:**
- A 3-tuple (g, rw, signs).

**ALGORITHM:**

The element self can be uniquely written self = g * w where g has length zero and w is an element of the nonextended affine Weyl group. Let w have reduced word rw. Starting with g and applying simple reflections from rw, one obtains a sequence of extended affine Weyl group elements (that is, alcoves) and simple roots. The signs give the sequence of sides on which the alcoves lie, relative to the face indicated by the simple roots.

**EXAMPLES:**

sage: E = ExtendedAffineWeylGroup(['A',3,1]); FW=E.FW()
sage: w = FW.from_reduced_word([0,2,1,3,0])*FW.from_fundamental(1); w
pi[1] * S3*S1*S2*S0*S3
sage: w.alcove_walk_signs()
(pi[1], [3, 1, 2, 0, 3], [-1, 1, -1, -1, 1])

sage: E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]); FW=E.FW()
sage: w = FW.from_reduced_word([Integer(0),Integer(2),Integer(1),
Integer(3),Integer(0)])*FW.from_fundamental(Integer(1)); w
pi[1] * S3*S1*S2*S0*S3
sage: w.alcove_walk_signs()
(pi[1], [3, 1, 2, 0, 3], [-1, 1, -1, -1, 1])

**apply_simple_projection** (i, side='right', length_increasing=True)

Return the product of self by the simple reflection s_i if that product is of greater length than self and otherwise return self.

**INPUT:**
- self – an element of the extended affine Weyl group
• $i$ -- a Dynkin node (index of a simple reflection $s_i$)
• `side='right'` or `side='left'` (default: `side='right'`) according to which side of `self` the reflection $s_i$ should be multiplied
• `length_increasing=True` or `False` (default `True`). If `False`, do the above with the word “greater” replaced by “less”.

**EXAMPLES:**

```python
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_projection(1)
S0*S1*S2*S3*S0 * pi[3]
sage: x.apply_simple_projection(1, length_increasing=False)
S0*S1*S2*S3 * pi[3]
```

```python
>>> from sage.all import *

>>> x = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
```

```python
>>> x.apply_simple_projection(Integer(1))
S0*S1*S2*S3*S0 * pi[3]
```

```python
>>> x.apply_simple_projection(Integer(0), side='left')
S1*S2*S3 * pi[3]
```

**apply_simple_reflection** ($i$, `side='right'`)  
Apply the $i$-th simple reflection to `self`.

**EXAMPLES:**

```python
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.apply_simple_reflection(1)
S0*S1*S2*S3*S0 * pi[3]
sage: x.apply_simple_reflection(0, side='left')
S1*S2*S3 * pi[3]
```

```python
>>> from sage.all import *

>>> x = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
```

```python
>>> x.apply_simple_reflection(Integer(1))
S0*S1*S2*S3*S0 * pi[3]
```

```python
>>> x.apply_simple_reflection(Integer(0), side='left')
S1*S2*S3 * pi[3]
```

**bruhat_le** ($x$)  
Return whether `self <= x` in Bruhat order.

**INPUT:**  
• `self` -- an element of the extended affine Weyl group  
• `x` -- another element with the same parent as `self`

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1], print_tuple=True); WF = E.WF()  
sage: W = E.affine_weyl()  
sage: v = W.from_reduced_word([2,1,0])
```
Warning: Must be implemented by “WF”.

coset_representative(index_set, side='right')

Return the minimum length representative in the coset of self with respect to the subgroup generated by the reflections given by index_set.

INPUT:
• self—an element of the extended affine Weyl group
• index_set—a subset of the set of Dynkin nodes
• side—'right' or 'left' (default: 'right') the side on which the subgroup acts

EXAMPLES:

```sage: E = ExtendedAffineWeylGroup(['A',3,1]); WF = E.WF()
```

(continues on next page)
\begin{verbatim}

>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]); WF = E.

>>> b = E.lattice_basis()

>>> I0 = E.cartan_type().classical().index_set()

>>> [WF.from_translation(x).coset_representative(index_set=I0) for x in b]

\end{verbatim}

\textbf{dual_action (la)}

Action of \texttt{self} on a dual lattice element \texttt{la}.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{self} – an element of the extended affine Weyl group
  \item \texttt{la} – an element of the dual translation lattice of the extended affine Weyl group, the lattice denoted by the mnemonic “Pv” in the documentation for \texttt{ExtendedAffineWeylGroup()}.
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}

sage: E = ExtendedAffineWeylGroup(['A',2,1], affine="s")

sage: x = E.FW().an_element(); x
pi[2] * s0*s1*s2

sage: la = E.dual_lattice().an_element(); la

sage: x.dual_action(la)

sage: E = ExtendedAffineWeylGroup(['C',2,1], affine="s")

sage: x = E.PvW0().from_dual_translation(E.dual_lattice_basis()[1])

sage: x.dual_action(E.dual_lattice_basis()[2])

\end{verbatim}

\begin{verbatim}

>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], affine="s")

>>> x = E.FW().an_element(); x
pi[2] * s0*s1*s2

>>> la = E.dual_lattice().an_element(); la

>>> x.dual_action(la)

>>> E = ExtendedAffineWeylGroup(['C',Integer(2),Integer(1)], affine="s")

>>> x = E.PvW0().from_dual_translation(E.dual_lattice_basis()[Integer(1)])

>>> x.dual_action(E.dual_lattice_basis()[Integer(2)])

\end{verbatim}

\textbf{Warning:} Must be implemented by style “PvW0”.

\textbf{face_data (i)}

Return a description of one of the bounding hyperplanes of the alcove of an extended affine Weyl group element.
INPUT:
• self – An element of the extended affine Weyl group
• i – an affine Dynkin node

OUTPUT:
• A 2-tuple \((m, \beta)\) defined as follows.

ALGORITHM:
Each element of the extended affine Weyl group corresponds to an alcove, and each alcove has a face for each affine Dynkin node. Given the data of \(self\) and \(i\), let the extended affine Weyl group element \(self\) act on the affine simple root \(\alpha_i\), yielding a real affine root, which can be expressed uniquely as

\[
``self`` \cdot \alpha_i = m\delta + \beta
\]

where \(m\) is an integer (the height of the \(i\)-th bounding hyperplane of the alcove of \(self\)) and \(\beta\) is a classical root (the normal vector for the hyperplane which points towards the alcove).

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',2,1]).PW0().an_element(); x
\[t[2*Lambdacheck[1] + 2*Lambdacheck[2]] \cdot s1*s2\]
sage: x.face_data(0)
(-1, alpha[1])
```

```python
>>> from sage.all import *
>>> x = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).PW0().an_element(); x
\[t[2*Lambdacheck[1] + 2*Lambdacheck[2]] \cdot s1*s2\]
```

**first_descent** *(side='right', positive=False, index_set=None)*

Return the first descent of \(self\).

INPUT:
• side= 'left' or 'right' (default: 'right')
• positive= True or False (default: False)
• index_set= an optional subset of Dynkin nodes

If \(index_set\) is not None, then the descent must be in the \(index_set\).

EXAMPLES:

```
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
sage: x.first_descent()
0
sage: x.first_descent(side='left')
0
sage: x.first_descent(positive=True)
1
sage: x.first_descent(side='left',positive=True)
1
```

```python
>>> from sage.all import *
>>> x = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).WF().an_element(); x
S0*S1*S2*S3 * pi[3]
```
has_descent \( (i, \text{side}=\text{right}, \text{positive}=\text{False}) \)

Return whether \( \text{self} \ast s_i < \text{self} \) where \( s_i \) is the \( i \)-th simple reflection in the realized group.

INPUT:

- \( i \) – an affine Dynkin index

OPTIONAL:

- \( \text{side}='\text{right}' \) or 'left' (default: 'right')
- \( \text{positive}=\text{True} \) or False (default: False)

If \( \text{side}='\text{left}' \), then the reflection acts on the left. If \( \text{positive}=\text{True} \), then the inequality is reversed.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); WF = E.WF()
sage: F = E.fundamental_group()
sage: x = WF.an_element(); x
S0*S1*S2*S3 * pi[3]
sage: I = E.cartan_type().index_set()
sage: [(i, x.has_descent(i)) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i,side='left')) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
sage: [(i, x.has_descent(i,positive=\text{True})) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

```
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',\text{Integer}(3),\text{Integer}(1)]); WF = E.WF()
>>> F = E.fundamental_group()
>>> x = WF.an_element(); x
S0*S1*S2*S3 * pi[3]
```

```
>>> [(i, x.has_descent(i)) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
>>> [(i, x.has_descent(i,side='left')) for i in I]
[(0, True), (1, False), (2, False), (3, False)]
>>> [(i, x.has_descent(i,positive=\text{True})) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

**Warning:** This method is abstract because it is used in the recursive coercions between “PW0” and “WF” and other methods use this coercion.

is_affine_grassmannian()

Return whether \( \text{self} \) is affine Grassmannian.

EXAMPLES:
is_grassmannian \( (\text{index_set, side='right'}) \)

Return whether self is of minimum length in its coset with respect to the subgroup generated by the reflections of index_set.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()
sage: x = PW0.from_translation(E.lattice_basis()[1]); x
{\lambda_{1}}
sage: I = E.cartan_type().index_set()
sage: [(i, x.is_grassmannian(index_set=[i])) for i in I]
[(0, True), (1, False), (2, True), (3, True)]
sage: [(i, x.is_grassmannian(index_set=[i], side='left')) for i in I]
[(0, False), (1, True), (2, True), (3, True)]
```

is_translation()

Return whether self is a translation element or not.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1]); FW = E.FW()
sage: FW.from_affine_weyl(E.affine_weyl().from_reduced_word([1,2,1,0])).is_translation()
True
sage: FW.from_translation(E.lattice_basis()[1]).is_translation()
```

(continues on next page)
True

```
sage: FW.simple_reflection(0).is_translation()
False
```

```
>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]); FW = E.
˓→FW()

>>> F = E.fundamental_group()

>>> FW.from_affine_weyl(E.affine_weyl().from_reduced_word([Integer(1),
˓→Integer(2),Integer(1),Integer(0)])).is_translation()
True

>>> FW.from_translation(E.lattice_basis()[Integer(1)]).is_translation()
True

>>> FW.simple_reflection(Integer(0)).is_translation()
False
```

### length()

Return the length of `self` in the Coxeter group sense.

**EXAMPLES:**

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()

sage: I0 = E.cartan_type().classical().index_set()

sage: [PW0.from_translation(E.lattice_basis()[i]).length() for i in I0]
[3, 4, 3]
```

```
>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]); PW0 = E.
˓→PW0()

>>> I0 = E.cartan_type().classical().index_set()

>>> [PW0.from_translation(E.lattice_basis()[i]).length() for i in I0]
[3, 4, 3]
```

### to_affine_grassmannian()

Return the unique affine Grassmannian element in the same coset of `self` with respect to the finite Weyl group acting on the right.

**EXAMPLES:**

```
sage: elts = ExtendedAffineWeylGroup(['A',2,1]).PW0().some_elements()

sage: [(x, x.to_affine_grassmannian()) for x in elts]
[(t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2,
  t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1)]
```

```
>>> from sage.all import *

>>> elts = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).PW0().
˓→some_elements()

```

```
>>> [(x, x.to_affine_grassmannian()) for x in elts]
[(t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2,
  t[2*Lambdacheck[1] + 2*Lambdacheck[2]] * s1*s2*s1)]
```

### to_affine_weyl_left()

Return the projection of `self` to the affine Weyl group on the left, after factorizing using the style “WF”.

**EXAMPLES:**
\textbf{sage}: \quad E = \text{ExtendedAffineWeylGroup}([\text{`A'},3,1]); \quad \text{PW0} = E.\text{PW0}()
\textbf{sage}: \quad b = E.\text{lattice\_basis}()
\textbf{sage}: \quad [ (x, \text{PW0}.\text{from\_translation}(x).\text{to\_affine\_weyl\_left}()) \text{ for } x \text{ in } b ]
\quad \begin{aligned} & (\text{Lambdacheck}[1], S0*S3*S2), \\
& (\text{Lambdacheck}[2], S0*S3*S1*S0), \\
& (\text{Lambdacheck}[3], S0*S1*S2) \end{aligned}

\begin{verbatim}
>>> from sage.all import * 
>>> E = ExtendedAffineWeylGroup([\text{`A'},\text{Integer}(3),\text{Integer}(1)]); \quad \text{PW0} = E.\text{\_\_\_\_\_\_\_\_\_PW0}()
>>> b = E.\text{lattice\_basis}()
>>> [ (x, \text{PW0}.\text{from\_translation}(x).\text{to\_affine\_weyl\_left}()) \text{ for } x \text{ in } b ]
\quad \begin{aligned} & (\text{Lambdacheck}[1], S0*S3*S2), \\
& (\text{Lambdacheck}[2], S0*S3*S1*S0), \\
& (\text{Lambdacheck}[3], S0*S1*S2) \end{aligned}
\end{verbatim}

\textbf{Warning:} Must be implemented in style “WF”.

\textbf{to\_affine\_weyl\_right}()

Return the projection of \texttt{self} to the affine Weyl group on the right, after factorizing using the style “FW”.

\textbf{EXAMPLES:}

\begin{verbatim}
\textbf{sage}: \quad E = \text{ExtendedAffineWeylGroup}([\text{`A'},3,1]); \quad \text{PW0} = E.\text{PW0}()
\textbf{sage}: \quad b = E.\text{lattice\_basis}()
\textbf{sage}: \quad [ (x, \text{PW0}.\text{from\_translation}(x).\text{to\_affine\_weyl\_right}()) \text{ for } x \text{ in } b ]
\quad \begin{aligned} & (\text{Lambdacheck}[1], S3*S2*S1), \\
& (\text{Lambdacheck}[2], S2*S3*S1*S2), \\
& (\text{Lambdacheck}[3], S1*S2*S3) \end{aligned}
\end{verbatim}

\begin{verbatim}
>>> from sage.all import * 
>>> E = ExtendedAffineWeylGroup([\text{`A'},\text{Integer}(3),\text{Integer}(1)]); \quad \text{PW0} = E.\text{\_\_\_\_\_\_\_\_\_PW0}()
>>> b = E.\text{lattice\_basis}()
>>> [ (x, \text{PW0}.\text{from\_translation}(x).\text{to\_affine\_weyl\_right}()) \text{ for } x \text{ in } b ]
\quad \begin{aligned} & (\text{Lambdacheck}[1], S3*S2*S1), \\
& (\text{Lambdacheck}[2], S2*S3*S1*S2), \\
& (\text{Lambdacheck}[3], S1*S2*S3) \end{aligned}
\end{verbatim}

\textbf{Warning:} Must be implemented in style “FW”.

\textbf{to\_classical\_weyl}()

Return the image of \texttt{self} under the homomorphism to the classical Weyl group.

\textbf{EXAMPLES:}

\begin{verbatim}
\textbf{sage}: \quad \text{ExtendedAffineWeylGroup}([\text{`A'},3,1]).\text{WF}().\text{simple\_reflection}(0).\text{to\_classical\_weyl}()
\quad s1*s2*s3*s2*s1
\end{verbatim}
**Warning:** Must be implemented in style “PW0”.

**to_dual_classical_weyl()**

Return the image of `self` under the homomorphism to the dual form of the classical Weyl group.

**EXAMPLES:**

```
sage: x = ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflection(0).to_dual_classical_weyl(); x
s1*s2*s3*s2*s1
```

```
sage: x.parent()
Weyl Group of type ['A', 3] (as a matrix group acting on the weight\_lattice)
```

```
>>> from sage.all import *
>>> x = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).WF().simple_reflection(Integer(0)).to_dual_classical_weyl(); x
s1*s2*s3*s2*s1
```

```
Warning: Must be implemented in style “PvW0”.
```

**to_dual_translation_left()**

Return the projection of `self` to the dual translation lattice after factorizing it to the left using the style “PvW0”.

**EXAMPLES:**

```
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflection(0).to_dual_translation_left()
Lambda[1] + Lambda[3]
```

```
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PvW0().simple_reflection(Integer(0)).to_dual_translation_left()
Lambda[1] + Lambda[3]
```

```
Warning: Must be implemented in style “PvW0”.
```

**to_dual_translation_right()**

Return the projection of `self` to the dual translation lattice after factorizing it to the right using the style “W0Pv”.

**EXAMPLES:**
Combinatorics, Release 10.4

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_right()
```

```python
>>> from sage.all import *

ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PW0().simple_reflection(Integer(0)).to_translation_right()
```

**Warning:** Must be implemented in style “W0Pv”.

### to_fundamental_group()

Return the image of `self` under the homomorphism to the fundamental group.

**EXAMPLES:**

```python
sage: PW0 = ExtendedAffineWeylGroup(['A',3,1]).PW0()
sage: b = PW0.realization_of().lattice_basis()
sage: [(x, PW0.from_translation(x).to_fundamental_group()) for x in b]
[(Lambdacheck[1], pi[1]), (Lambdacheck[2], pi[2]), (Lambdacheck[3], →pi[3])]
```

```python
>>> from sage.all import *

ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PW0().realization_of().lattice_basis()
[(Lambdacheck[1], pi[1]), (Lambdacheck[2], pi[2]), (Lambdacheck[3], →pi[3])]
```

**Warning:** Must be implemented in style “WF”.

### to_translation_left()

Return the projection of `self` to the translation lattice after factorizing it to the left using the style “PW0”.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_left()
Lambdacheck[1] + Lambdacheck[3]
```

```python
>>> from sage.all import *

ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PW0().simple_reflection(Integer(0)).to_translation_left()
Lambdacheck[1] + Lambdacheck[3]
```

**Warning:** Must be implemented in style “PW0”.

### to_translation_right()

The to_translation_right() method projects `self` to the translation lattice after factorizing it to the left using the style “PW0”.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0).to_translation_right()
```

```python
>>> from sage.all import *

ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PW0().simple_reflection(Integer(0)).to_translation_right()
```

**Warning:** Must be implemented in style “W0Pv”.

---

4272 Chapter 5. Comprehensive Module List
Return the projection of \texttt{self} to the translation lattice after factorizing it to the right using the style "W0P".

\textbf{EXAMPLES:}

```
```

```
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PW0().simple_reflection(Integer(0)).to_translation_right() -Lambdacheck[1] - Lambdacheck[3]
```

\textbf{Warning:} Must be implemented in style "W0P".

\textbf{class ParentMethods}

\textbf{Bases:} \texttt{object}

\textbf{from affine_weyl}(\textit{\texttt{w}})

Return the image of \texttt{\textit{w}} under the homomorphism from the affine Weyl group into \texttt{self}.

\textbf{EXAMPLES:}

```
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0 = E.PW0()
sage: W = E.affine_weyl()
sage: w = W.from_reduced_word([2,1,3,0])
sage: x = PW0.from_affine_weyl(w); x t[Lambdacheck[1] - 2*Lambdacheck[2] + Lambdacheck[3]] * s3*s1
sage: FW = E.FW()
sage: y = FW.from_affine_weyl(w); y S2*S3*S1*S0
sage: FW(x) == y True
```

```
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]); PW0 = E.
>>> W = E.affine_weyl()
>>> w = W.from_reduced_word([Integer(2),Integer(1),Integer(3),
>>> Integer(0)])
>>> x = PW0.from_affine_weyl(w); x t[Lambdacheck[1] - 2*Lambdacheck[2] + Lambdacheck[3]] * s3*s1
>>> FW = E.FW()
>>> y = FW.from_affine_weyl(w); y S2*S3*S1*S0
>>> FW(x) == y True
```

\textbf{Warning:} Must be implemented in style "WF" and "FW".

\textbf{from classical_weyl}(\textit{\texttt{w}})

Return the image of \texttt{\textit{w}} from the finite Weyl group into \texttt{self}.
EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PW0=E.PW0()
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([2,1,3])
sage: y = PW0.from_classical_weyl(w); y
s2*s3*s1
sage: y.parent() == PW0
True
sage: y.to_classical_weyl() == w
True
sage: W0P = E.W0P()
sage: z = W0P.from_classical_weyl(w); z
s2*s3*s1
sage: z.parent() == W0P
True
sage: W0P(y) == z
True
sage: FW = E.FW()
sage: x = FW.from_classical_weyl(w); x
S2*S3*S1
sage: x.parent() == FW
True
sage: FW(y) == x
True
sage: FW(z) == x
True
```

```python
>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]); PW0=E.PW0()
>>> W0 = E.classical_weyl()
>>> w = W0.from_reduced_word([Integer(2),Integer(1),Integer(3)])
>>> y = PW0.from_classical_weyl(w); y
s2*s3*s1
>>> y.parent() == PW0
True
>>> y.to_classical_weyl() == w
True
>>> W0P = E.W0P()
>>> z = W0P.from_classical_weyl(w); z
s2*s3*s1
>>> z.parent() == W0P
True
>>> W0P(y) == z
True
>>> FW = E.FW()
>>> x = FW.from_classical_weyl(w); x
S2*S3*S1
>>> x.parent() == FW
True
>>> FW(y) == x
True
>>> FW(z) == x
True
```
Warning: Must be implemented in style “PW0” and “W0P”.

**from_dual_classical_weyl (w)**

Return the image of \( w \) from the finite Weyl group of dual form into self.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',3,1]); PvW0 = E.PvW0()
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([2,1,3])
sage: y = PvW0.from_dual_classical_weyl(w)
s2*s3*s1
sage: y.parent() == PvW0
True
sage: y.to_dual_classical_weyl() == w
True
```

```python
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]); PvW0 = E.PvW0()
>>> W0v = E.dual_classical_weyl()
>>> w = W0v.from_reduced_word([Integer(2),Integer(1),Integer(3)])
>>> y = PvW0.from_dual_classical_weyl(w)
s2*s3*s1
>>> y.parent() == PvW0
True
```

Warning: Must be implemented in style “PvW0” and “W0Pv”.

**from_dual_translation (λa)**

Return the image of \( λa \) under the homomorphism of the dual version of the translation lattice into self.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PvW0 = E.PvW0()
sage: bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: x = PvW0.from_dual_translation(2*bv[1] - bv[2]); x
S0*S2*S0*S1
```

```python
>>> E = ExtendedAffineWeylGroup(['A',2,1]); PvW0 = E.PvW0()
>>> bv = E.dual_lattice_basis(); bv
Finite family {1: Lambda[1], 2: Lambda[2]}
>>> x = PvW0.from_dual_translation(2*bv[1] - bv[2]); x
S0*S2*S0*S1
```

(continues on next page)
from sage.all import *

E = ExtendedAffineWeylGroup(['A', Integer(2), Integer(1)]);
PW0 = E.PW0()

bv = E.dual_lattice_basis();

x = PW0.from_dual_translation(Integer(2)*bv[Integer(1)] - bv[Integer(2)]);
x = t[2*Lambda[1] - Lambda[2]].from_dual_translation(Integer(2)*bv[Integer(1)] - bv[Integer(2)]);
FW = E.FW()

y = FW.from_dual_translation(Integer(2)*bv[Integer(1)] - bv[Integer(2)]);
y = S0*S2*S0*S1
FW(x) == y
True

from_fundamental(x)

Return the image of x under the homomorphism from the fundamental group into self.

EXAMPLES:

sage: E = ExtendedAffineWeylGroup(['A', 3, Integer(1)])
sage: PW0=E.PW0()
sage: F = E.fundamental_group()
sage: Is = F.special_nodes()

[[i, PW0.from_fundamental(F(i))] for i in Is]
[(0, 1),
 (1, t[Lambdacheck[1]] * s1*s2*s3),
 (2, t[Lambdacheck[2]] * s2*s3*s1*s2),
 (3, t[Lambdacheck[3]] * s3*s2*s1)]

[[i, E.WOP().from_fundamental((F(i))) for i in Is]
[(0, 1),
 (1, s1*s2*s3 * t[-Lambdacheck[3]]),
 (2, s2*s3*s1*s2 * t[-Lambdacheck[2]]),
 (3, s3*s2*s1 * t[-Lambdacheck[1]])]

[[i, E.WF().from_fundamental(F(i))] for i in Is]
[(0, 1), (1, pi[1]), (2, pi[2]), (3, pi[3])]

(continues on next page)
Warning: This method must be implemented by the “WF” and “FW” realizations.

**from_reduced_word**(word)

Converts an affine or finite reduced word into a group element.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).PW0().from_reduced_word([1,0,1,2])
t[-Lambdacheck[1] + 2*Lambdacheck[2]]
```

```python
>>> from sage.all import *

>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).PW0().from_reduced_word([Integer(1),Integer(0),Integer(1),Integer(2)])
t[-Lambdacheck[1] + 2*Lambdacheck[2]]
```

**from_translation**(la)

Return the element of translation by la in self.

**INPUT:**
- **self** – a realization of the extended affine Weyl group
- **la** – an element of the translation lattice

In the notation of the documentation for `ExtendedAffineWeylGroup()`, la must be an element of “P”.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1]); PW0 = E.PW0()
sage: b = E.lattice_basis(); b
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
sage: x = PW0.from_translation(2*b[1] - b[2]); x
sage: FW = E.FW()
sage: y = FW.from_translation(2*b[1] - b[2]); y
S0*S2*S0*S1
sage: FW(x) == y
True
```

```python
>>> from sage.all import *

>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]); PW0 = E.PW0()

>>> b = E.lattice_basis(); b
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}

```
Since the implementation as a semidirect product requires wrapping the lattice group to make it multiplicative, we cannot declare that this map is a morphism for `sage Groups()`.

**Warning:** This method must be implemented by the “PW0” and “W0P” realizations.

**simple_reflection** (*i*)

Return the *i*-th simple reflection in `self`.

**INPUT:**
- `self` – a realization of the extended affine Weyl group
- `i` – An affine Dynkin node

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).PW0().simple_reflection(0)
t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1
sage: ExtendedAffineWeylGroup(['C',2,1]).WF().simple_reflection(0)
S0
sage: ExtendedAffineWeylGroup(['D',3,2]).PvW0().simple_reflection(1)
s1
```

```python
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PW0().simple_reflection(Integer(0))
t[Lambdacheck[1] + Lambdacheck[3]] * s1*s2*s3*s2*s1
>>> ExtendedAffineWeylGroup(['C',Integer(2),Integer(1)]).WF().simple_reflection(Integer(0))
S0
>>> ExtendedAffineWeylGroup(['D',Integer(3),Integer(2)]).PvW0().simple_reflection(Integer(1))
s1
```

**simple_reflections()**

Return a family from the set of affine Dynkin nodes to the simple reflections in the realization of the extended affine Weyl group.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',3,1]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]],
1: s1, 2: s2, 3: s3}
sage: ExtendedAffineWeylGroup(['A',3,1]).WF().simple_reflections()
Finite family {0: S0, 1: S1, 2: S2, 3: S3}
sage: ExtendedAffineWeylGroup(['A',3,1],
....: print_tuple=True).FW().simple_reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1),
2: (pi[0], S2), 3: (pi[0], S3)}
sage: ExtendedAffineWeylGroup(['A',3,1],
....: fundamental="f",
....: print_tuple=True).FW().simple_reflections()
Finite family {0: (f[0], S0), 1: (f[0], S1),
2: (f[0], S2), 3: (f[0], S3)}
sage: ExtendedAffineWeylGroup(['A',3,1]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1,
1: s1, 2: s2, 3: s3}
```
Combinatorics, Release 10.4

>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).W0P().simple_reflections()
Finite family {0: s1*s2*s3*s2*s1 * t[-Lambdacheck[1] - Lambdacheck[3]],
1: s1, 2: s2, 3: s3}
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).WF().simple_reflections()
Finite family {0: S0, 1: S1, 2: S2, 3: S3}
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)],
... print_tuple=True).FW().simple_reflections()
Finite family {0: (pi[0], S0), 1: (pi[0], S1),
2: (pi[0], S2), 3: (pi[0], S3)}
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)],
... fundamental="f",
... print_tuple=True).FW().simple_reflections()
Finite family {0: (f[0], S0), 1: (f[0], S1),
2: (f[0], S2), 3: (f[0], S3)}
>>> ExtendedAffineWeylGroup(['A',Integer(3),Integer(1)]).PvW0().simple_reflections()
Finite family {0: t[Lambda[1] + Lambda[3]] * s1*s2*s3*s2*s1,
1: s1, 2: s2, 3: s3}

super_categories()

EXAMPLES:

sage: R = ExtendedAffineWeylGroup(['A',2,1]).Realizations(); R
Category of realizations of Extended affine Weyl group of type ['A', 2, 1]
sage: R.super_categories()
[Category of associative inverse realizations of unital magmas]

>>> from sage.all import *
>>> R = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).Realizations(); R
Category of realizations of Extended affine Weyl group of type ['A', 2, 1]
>>> R.super_categories()
[Category of associative inverse realizations of unital magmas]

W0P()

Realizes self in “W0P”-style.

EXAMPLES:

sage: ExtendedAffineWeylGroup(['A',2,1]).W0P()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
acting on Multiplicative form of Coweight lattice of the Root system of type ['A', 2]

>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).W0P()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)

(continues on next page)
acting on Multiplicative form of Coweight lattice of the Root system of type 
\( \rightarrow [A', 2] \)

**WOPv()**

Realizes self in “WOPv”-style.

**EXAMPLES:**

```sage
sage: ExtendedAffineWeylGroup(['A',2,1]).WOPv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
\( \rightarrow \) of
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
acting on Multiplicative form of Weight lattice of the Root system of type 
\( \rightarrow [A', 2] \)
```

```python
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).WOPv()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
\( \rightarrow \) of
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
acting on Multiplicative form of Weight lattice of the Root system of type 
\( \rightarrow [A', 2] \)
```

**WF()**

Realizes self in “WF”-style.

**EXAMPLES:**

```sage
sage: ExtendedAffineWeylGroup(['A',2,1]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
\( \rightarrow \) of
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
acted upon by Fundamental group of type ['A', 2, 1]
```

```python
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).WF()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
\( \rightarrow \) of
Weyl Group of type ['A', 2, 1] (as a matrix group acting on the root lattice)
acted upon by Fundamental group of type ['A', 2, 1]
```

**WF_to_PW0_func(x)**

Coercion from style “WF” to “PW0”.

**EXAMPLES:**

```sage
sage: E = ExtendedAffineWeylGroup(['A', 2, 1])
sage: x = E.WF().an_element(); x
S0*S1*S2 * pi[2]
sage: E.WF_to_PW0_func(x)
t[Lambda(check[1] + 2*Lambda(check[2])] * s1*s2*s1
```

```python
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A', Integer(2), Integer(1)])
>>> x = E.WF().an_element(); x
```
Warning: Since this is used to define some coercion maps it cannot itself use coercion.

a_realization()

Return the default realization of an extended affine Weyl group.

EXAMPLES:

```sage```
ExtendedAffineWeylGroup(['A',2,1]).a_realization()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product of
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the...

```sage```
ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).a_realization()
Extended affine Weyl group of type ['A', 2, 1] realized by Semidirect product
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]
acted upon by Weyl Group of type ['A', 2] (as a matrix group acting on the...```
cartan_type()

The Cartan type of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup("D",3,2).cartan_type()
['C', 2, 1]^*
```

```python
>>> from sage.all import *
>>> ExtendedAffineWeylGroup("D",Integer(3),Integer(2)).cartan_type()
['C', 2, 1]^*
```

classical_weyl()

Return the classical Weyl group of self.

EXAMPLES:

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',4,2]).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the coweight lattice)
```

```python
>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the coweight lattice)
>>> ExtendedAffineWeylGroup(['A',Integer(5),Integer(2)]).classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
>>> ExtendedAffineWeylGroup(['A',Integer(4),Integer(2)]).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the weight lattice)
>>> ExtendedAffineWeylGroup(CartanType(['A',Integer(4),Integer(2)]).dual()).classical_weyl()
Weyl Group of type ['C', 2] (as a matrix group acting on the coweight lattice)
```

classical_weyl_to_affine(w)

The image of \( w \) under the homomorphism from the classical Weyl group into the affine Weyl group.

EXAMPLES:

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0 = E.classical_weyl()
sage: w = W0.from_reduced_word([1,2]); w
s1*s2
sage: v = E.classical_weyl_to_affine(w); v
S1*S2
```

```python
>>> from sage.all import *
>>> E = ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)])
>>> W0 = E.classical_weyl()
>>> w = W0.from_reduced_word([Integer(1),Integer(2)]); w
s1*s2
>>> v = E.classical_weyl_to_affine(w); v
S1*S2
```
**dual_classical_weyl()**

Return the dual version of the classical Weyl group of self.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_classical_weyl()
Weyl Group of type ['A', 2] (as a matrix group acting on the weight lattice)
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_classical_weyl()
Weyl Group of type ['C', 3] (as a matrix group acting on the weight lattice)
```

**dual_classical_weyl_to_affine(w)**

The image of \( w \) under the homomorphism from the dual version of the classical Weyl group into the affine Weyl group.

**EXAMPLES:**

```python
sage: E = ExtendedAffineWeylGroup(['A',2,1])
sage: W0v = E.dual_classical_weyl()
sage: w = W0v.from_reduced_word([1,2]); w
s1*s2
sage: v = E.dual_classical_weyl_to_affine(w); v
S1*S2
```

**dual_lattice()**

Return the dual version of the translation lattice for self.

**EXAMPLES:**

```python
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice()
Weight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice()
Weight lattice of the Root system of type ['C', 3]
```

**dual_lattice_basis()**

Return the distinguished basis of the dual version of the translation lattice for self.

**EXAMPLES:**

```python
```
sage: ExtendedAffineWeylGroup(['A',2,1]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}

>>> from sage.all import *

ExtendedAffineWeylGroup(['A',5,2]).dual_lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}

\textbf{exp_dual_lattice}()

Return the multiplicative version of the dual version of the translation lattice for \texttt{self}.

EXAMPLES:

sage: ExtendedAffineWeylGroup(['A',2,1]).exp_dual_lattice()
Multiplicative form of Weight lattice of the Root system of type ['A', 2]

>>> from sage.all import *

ExtendedAffineWeylGroup(['A',2,1]).exp_dual_lattice()
Multiplicative form of Weight lattice of the Root system of type ['A', 2]

\textbf{exp_lattice}()

Return the multiplicative version of the translation lattice for \texttt{self}.

EXAMPLES:

sage: ExtendedAffineWeylGroup(['A',2,1]).exp_lattice()
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]

>>> from sage.all import *

ExtendedAffineWeylGroup(['A',2,1]).exp_lattice()
Multiplicative form of Coweight lattice of the Root system of type ['A', 2]

\textbf{fundamental_group}()

Return the abstract fundamental group.

EXAMPLES:

sage: F = ExtendedAffineWeylGroup(['D',5,1]).fundamental_group(); F
Fundamental group of type ['D', 5, 1]
sage: [a for a in F]
[pi[0], pi[1], pi[4], pi[5]]

>>> from sage.all import *

F = ExtendedAffineWeylGroup(['D',5,1]).fundamental_group(); F
Fundamental group of type ['D', 5, 1]
[a for a in F]
[pi[0], pi[1], pi[4], pi[5]]

\textbf{group_generators}()

Return a set of generators for the default realization of \texttt{self}.

EXAMPLES:
Combinatorics, Release 10.4

sage: ExtendedAffineWeylGroup(['A',2,1]).group_generators()
(t[Lambdacheck[1]], t[Lambdacheck[2]], s1, s2)

>>> from sage.all import *
>>> ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).group_generators()
(t[Lambdacheck[1]], t[Lambdacheck[2]], s1, s2)

lattice()

Return the translation lattice for self.

EXAMPLES:

sage: ExtendedAffineWeylGroup(['A',2,1]).lattice()
Coweight lattice of the Root system of type ['A', 2]
sage: ExtendedAffineWeylGroup(['A',5,2]).lattice()
Weight lattice of the Root system of type ['C', 3]
sage: ExtendedAffineWeylGroup(['A',4,2]).lattice()
Weight lattice of the Root system of type ['C', 2]
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice()
Coweight lattice of the Root system of type ['B', 2]
sage: ExtendedAffineWeylGroup(CartanType(['A',2,1]),
....:     general_linear=True).lattice()
Ambient space of the Root system of type ['A', 2]

>>> from sage.all import *

ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).lattice()

ExtendedAffineWeylGroup(['A',Integer(5),Integer(2)]).lattice()

lattice_basis()

Return the distinguished basis of the translation lattice for self.

EXAMPLES:

sage: ExtendedAffineWeylGroup(['A',2,1]).lattice_basis()
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}
sage: ExtendedAffineWeylGroup(['A',5,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
sage: ExtendedAffineWeylGroup(['A',4,2]).lattice_basis()
Finite family {1: Lambda[1], 2: Lambda[2]}
sage: ExtendedAffineWeylGroup(CartanType(['A',4,2]).dual()).lattice()
Finite family {1: Lambdacheck[1], 2: Lambdacheck[2]}

>>> from sage.all import *

ExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).lattice_basis()

ExtendedAffineWeylGroup(['A',Integer(5),Integer(2)]).lattice_basis()
5.1.265 Fundamental Group of an Extended Affine Weyl Group

AUTHORS:

- Mark Shimozono (2013) initial version

```
class sage.combinat.root_system.fundamental_group.FundamentalGroupElement (parent, x)

Bases: MultiplicativeGroupElement

This should not be called directly

EXAMPLES:
```

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
```

```
sage: x = FundamentalGroupOfExtendedAffineWeylGroup(['A', 4, 1], prefix="f").an_element()
sage: TestSuite(x).run()
```

```
>>> from sage.all import *
```

```
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
```

```
>>> x = FundamentalGroupOfExtendedAffineWeylGroup(['A', Integer(4), Integer(1)], prefix="f").an_element()
```

```
>>> TestSuite(x).run()
```

```
act_on_affine_lattice (wt)
```

Act by self on the element wt of an affine root/weight lattice realization.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
```

```
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1])
sage: wt = RootSystem(F.cartan_type()).weight_lattice().an_element(); wt
sage: F(3).act_on_affine_lattice(wt)
```

```
>>> from sage.all import *
```

```
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
```

```
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A', Integer(3), Integer(1)])
>>> wt = RootSystem(F.cartan_type()).weight_lattice().an_element(); wt
```
Continued from previous page

```python
>>> F(Integer(3)).act_on_affine_lattice(wt)
```

**Warning:** Doesn’t work on ambient spaces.

**act_on_affine_weyl**(*w*)

Act by self on the element *w* of the affine Weyl group.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: W = WeylGroup(F.cartan_type(),prefix="s")
sage: w = W.from_reduced_word([2,3,0])
sage: F(1).act_on_affine_weyl(w).reduced_word()
[3, 0, 1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>>
```

```python
F = FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(3),Integer(1)], prefix="f")
```

```python
>>> F.special_nodes()
(0, 1, 2, 3, 4)
```

```python
>>> x = F(Integer(4)); x
f[4]
>>> x.value()
4
```

**value**()

Return the special node which indexes the special automorphism self.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',4,1], prefix="f")
sage: F.special_nodes()
(0, 1, 2, 3, 4)
sage: x = F(4); x
f[4]
sage: x.value()
4
```

5.1. Comprehensive Module List
class sage.combinat.root_system.fundamental_group.FundamentalGroupGL(cartan_type, prefix='pi')

Bases: FundamentalGroupOfExtendedAffineWeylGroup_Class

Fundamental group of $GL_n$. It is just the integers with extra privileges.

Element

alias of FundamentalGroupGLElement

action(i)

The action of the $i$-th automorphism on the affine Dynkin node set.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import...
    →FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)

sage: F.action(4)(2)
0
sage: F.action(-4)(2)
1
```

an_element()

An element of self.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import...
    →FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).an_element()
pi[5]
```

dual_node(i)

The node whose special automorphism is inverse to that of $i$.

EXAMPLES:
```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.dual_node(2)
-2
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], general_linear=True)
>>> F.dual_node(Integer(2))
-2
```

**family()**

The family associated with the set of special nodes.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: fam = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).family() # indirect doctest
sage: fam
Lazy family (<lambda>(i))_{i in Integer Ring}
sage: fam[-3]
-3
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>>
>>> fam = FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], general_linear=True).family() # indirect doctest
>>> fam
Lazy family (<lambda>(i))_{i in Integer Ring}
>>> fam[-Integer(3)]
-3
```

**group_generators()**

Return group generators for self.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).group_generators()
(pi[1],)
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>>
>>> FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], general_linear=True).group_generators()
(pi[1],)
```
one()

Return the identity element of the fundamental group.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).one()
pi[0]
```

product(x, y)

Return the product of \(x\) and \(y\).

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
sage: F.special_nodes()
Integer Ring
sage: F(2)*F(3)
pi[5]
sage: F(1)*F(3)^(-1)
pi[-2]
```

reduced_word(i)

A reduced word for the finite permutation part of the special automorphism indexed by \(i\).

More precisely, return a reduced word for the finite Weyl group element \(u\) where \(i\)-th automorphism (expressed in the extended affine Weyl group) has the form \(tu\) where \(t\) is a translation element.

EXAMPLES:

```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True)
```

(continues on next page)
sage: F.reduced_word(10)
(1, 2)

>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)],
    general_linear=True)
>>> F.reduced_word(Integer(10))
(1, 2)

some_elements()
Return some elements of self.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1],
    general_linear=True).some_elements()
[pi[-2], pi[2], pi[5]]

>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>>
FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)],
    general_linear=True).some_elements()
[pi[-2], pi[2], pi[5]]

class sage.combinat.root_system.fundamental_group.FundamentalGroupGLElement(par-ent, x)

Bases: FundamentalGroupElement

act_on_classical_ambient(wt)
Act by self on the classical ambient weight vector wt.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1],
    general_linear=True)
sage: f = F.an_element(); f
pi[5]
sage: la = F.cartan_type().classical().root_system().ambient_space().an-
element(); la
(2, 2, 3)
sage: f.act_on_classical_ambient(la)
(2, 3, 2)

>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
(continues on next page)
Factory for the fundamental group of an extended affine Weyl group.

INPUT:

- **cartan_type** – a Cartan type that is either affine or finite, with the latter being a shorthand for the untwisted affinization
- **prefix** (default: ‘pi’) – string that labels the elements of the group
- **general_linear** – (default: None, meaning False) In untwisted type A, if True, use the universal central extension

**Fundamental group**

Associated to each affine Cartan type $\tilde{X}$ is an extended affine Weyl group $E$. Its subgroup of length-zero elements is called the fundamental group $F$. The group $F$ can be identified with a subgroup of the group of automorphisms of the affine Dynkin diagram. As such, every element of $F$ can be viewed as a permutation of the set $I$ of affine Dynkin nodes.

Let $0 \in I$ be the distinguished affine node; it is the one whose removal produces the associated finite Cartan type (call it $X$). A node $i \in I$ is called *special* if some automorphism of the affine Dynkin diagram, sends $0$ to $i$. The node $0$ is always special due to the identity automorphism. There is a bijection of the set of special nodes with the fundamental group. We denote the image of $i$ by $\pi_i$. The structure of $F$ is determined as follows.

- $\tilde{X}$ is untwisted – $F$ is isomorphic to $P^\vee/Q^\vee$ where $P^\vee$ and $Q^\vee$ are the coweight and coroot lattices of type $X$. The group $P^\vee/Q^\vee$ consists of the cosets $\omega_i^\vee + Q^\vee$ for special nodes $i$, where $\omega_0^\vee = 0$ by convention. In this case the special nodes $i$ are the *cominuscule* nodes, the ones such that $\omega_i^\vee(\alpha_j) = 1$ for all $j \in I_0 = I \setminus \{0\}$. For $i$ special, addition by $\omega_i^\vee + Q^\vee$ permutes $P^\vee/Q^\vee$ and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.

- $\tilde{X}$ is dual untwisted – (that is, the dual of $\tilde{X}$ is untwisted) $F$ is isomorphic to $P/Q$ where $P$ and $Q$ are the weight and root lattices of type $X$. The group $P/Q$ consists of the cosets $\omega_i + Q$ for special nodes $i$, where $\omega_0 = 0$ by convention. In this case the special nodes $i$ are the *minuscule* nodes, the ones such that $\alpha_i(\omega_j) = 1$ for all $j \in I_0$. For $i$ special, addition by $\omega_i + Q$ permutes $P/Q$ and therefore permutes the set of special nodes. This permutation extends uniquely to an automorphism of the affine Dynkin diagram.

- $\tilde{X}$ is mixed – (that is, not of the above two types) $F$ is the trivial group.

**EXAMPLES:**

```python
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A', Integer(2), Integer(1)],
       general_linear=True)
>>> f = F.an_element(); f
pi[5]
>>> la = F.cartan_type().classical().root_system().ambient_space().an_element(); la
(2, 2, 3)
>>> f.act_on_classical_ambient(la)
(2, 3, 2)
```

We also implement a fundamental group for $GL_n$. It is defined to be the group of integers, which is the covering group of the fundamental group $\mathbb{Z}/n\mathbb{Z}$ for affine $SL_n$:

```
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True); F
Fundamental group of GL(3)
sage: x = F.an_element(); x
pi[5]
sage: x*x
pi[10]
sage: x.inverse()
pi[-5]
```

```
sage: wt = F.cartan_type().classical().root_system().ambient_space().an_element(); wt
(2, 2, 3)
sage: x.act_on_classical_ambient(wt)
(2, 3, 2)
sage: w = WeylGroup(F.cartan_type(),prefix="s").an_element(); w
s0*s1*s2
sage: x.act_on_affine_weyl(w)
s2*s0*s1

>>> from sage.all import *
```
>>> x.inverse()
pi[-5]
>>> wt = F.cartan_type().classical().root_system().ambient_space().an_element();...
wt
(2, 2, 3)
>>> x.act_on_classical_ambient(wt)
(2, 3, 2)
>>> w = WeylGroup(F.cartan_type(),prefix="s").an_element(); w
s0*s1*s2

class sage.combinat.root_system.fundamental_group.FundamentalGroupOfExtendedAffineWeylGroup

Bases: UniqueRepresentation, Parent

The group of length zero elements in the extended affine Weyl group.

Element

alias of FundamentalGroupElement

action(i)

Return a function which permutes the affine Dynkin node set by the \( i \)-th special automorphism.

EXAMPLES:

```python
sage: from sage.combinat.root_system.fundamental_group import...
    FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1])
sage: [[(i, j, F.action(i)(j)) for j in F.index_set()] for i in F.special_
    nodes()]
[[[0, 0, 0], [0, 1, 1], [0, 2, 2]], [[1, 0, 1], [1, 1, 2], [1, 2, 0]], [[2, 0,
    1], [2, 1, 0], [2, 2, 1]]

sage: G = FundamentalGroupOfExtendedAffineWeylGroup(['D',4,1])
sage: [[(i, j, G.action(i)(j)) for j in G.index_set()] for i in G.special_
    nodes()]
[[[0, 0, 0], [0, 1, 1], [0, 2, 2], [0, 3, 3], [0, 4, 4]], [[1, 0, 1], [1, 1,
    0], [1, 2, 2], [1, 3, 4], [1, 4, 3]], [[3, 0, 3], [3, 1, 4], [3, 2, 2], [3,
    3, 0], [3, 4, 1]], [[4, 0, 4], [4, 1, 3], [4, 2, 2], [4, 3, 1], [4, 4, 0]]]
```
an_element()

Return an element of self.

EXAMPLES:

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 4, 1])
sage: F.an_element()
f[4]
```

cartan_type()

The Cartan type of self.

EXAMPLES:

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 3, 1])
sage: F.cartan_type() ['A', 3, 1]
```

dual_node(i)

Return the node that indexes the inverse of the i-th element.

EXAMPLES:

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A', 4, 1])
sage: [(i, F.dual_node(i)) for i in F.special_nodes()]
[(0, 0), (1, 4), (2, 3), (3, 2), (4, 1)]
```
```python
>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A', Integer(4), Integer(1)])
>>> [(i, F.dual_node(i)) for i in F.special_nodes()]
[(0, 0), (1, 4), (2, 3), (3, 2), (4, 1)]
>>> G = FundamentalGroupOfExtendedAffineWeylGroup(['E', Integer(6), Integer(1)])
>>> [(i, G.dual_node(i)) for i in G.special_nodes()]
[(0, 0), (1, 6), (6, 1)]
>>> H = FundamentalGroupOfExtendedAffineWeylGroup(['D', Integer(5), Integer(1)])
>>> [(i, H.dual_node(i)) for i in H.special_nodes()]
[(0, 0), (1, 1), (4, 5), (5, 4)]
```

### group_generators()

Return a tuple of generators of the fundamental group.

**Warning:** This returns the entire group, a necessary behavior because it is used in `__iter__()`.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: FundamentalGroupOfExtendedAffineWeylGroup(['E', 6, 1], prefix='f').group_generators()
Finite family {0: f[0], 1: f[1], 6: f[6]}
```

### index_set()

The node set of the affine Cartan type of `self`.

**EXAMPLES:**

```python
sage: FundamentalGroupOfExtendedAffineWeylGroup(['A', 2, 1]).index_set()
(0, 1, 2)
```

### one()

Return the identity element of the fundamental group.

**EXAMPLES:**

```python
>>> FundamentalGroupOfExtendedAffineWeylGroup(['A', Integer(2), Integer(1)]).index_set()
(0, 1, 2)
```
sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: F.one()
pi[0]

>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(3),Integer(1)])
>>> F.one()
pi[0]

product (x, y)

Return the product of $x$ and $y$.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
sage: F.special_nodes()
(0, 1, 2, 3)
sage: F(2)*F(3)
pi[1]
sage: F(1)*F(3)**(-1)
pi[2]

>>> from sage.all import *
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(3),Integer(1)])
>>> F.special_nodes()
(0, 1, 2, 3)
>>> F(Integer(2))*F(Integer(3))
pi[1]
>>> F(Integer(1))*F(Integer(3))**(-Integer(1))
pi[2]

reduced_word (i)

Return a reduced word for the finite Weyl group element associated with the $i$-th special automorphism.

More precisely, for each special node $i$, self.reduced_word(i) is a reduced word for the element $v$ in the finite Weyl group such that in the extended affine Weyl group, the $i$-th special automorphism is equal to $tv$ where $t$ is a translation element.

EXAMPLES:

sage: from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup
sage: F = FundamentalGroupOfExtendedAffineWeylGroup(['A',3,1])
[4, (3, 1, 2, 3, 2)]

(continues on next page)
FundamentalGroupOfExtendedAffineWeylGroup

>>> F = FundamentalGroupOfExtendedAffineWeylGroup(['A', Integer(3), Integer(1)])

>>> [(i, F.reduced_word(i)) for i in F.special_nodes()]
[(0, ()), (1, (1, 2, 3)), (2, (2, 1, 3, 2)), (3, (3, 2, 1))]

\textbf{special\_nodes()}

Return the special nodes of self.

See \texttt{sage.combinat.root_system.cartan_type.special\_nodes()}. 

\textbf{EXAMPLES:}

\begin{verbatim}
>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup

>>> FundamentalGroupOfExtendedAffineWeylGroup(['D',4,1]).special_nodes()
(0, 1, 3, 4)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1]).special_nodes()
(0, 1, 2)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['C',3,1]).special_nodes()
(0, 3)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['D',4,2]).special_nodes()
(0, 3)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['A',2,1], general_linear=True).special_nodes()
Integer Ring
\end{verbatim}

\begin{verbatim}
>> from sage.all import *

>>> from sage.combinat.root_system.fundamental_group import FundamentalGroupOfExtendedAffineWeylGroup

>>> FundamentalGroupOfExtendedAffineWeylGroup(['D',Integer(4),Integer(1)]).special_nodes()
(0, 1, 3, 4)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)]).special_nodes()
(0, 1, 2)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['C',Integer(3),Integer(1)]).special_nodes()
(0, 3)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['D',Integer(4),Integer(2)]).special_nodes()
(0, 3)

>>> FundamentalGroupOfExtendedAffineWeylGroup(['A',Integer(2),Integer(1)], general_linear=True).special_nodes()
Integer Ring
\end{verbatim}

\textbf{5.1.266 Root system data for folded Cartan types}

\textbf{AUTHORS:}

- Travis Scrimshaw (2013-01-12) - Initial version

\textbf{class} \texttt{sage.combinat.root_system.type_folded.CartanTypeFolded}(\texttt{cartan\_type}, \texttt{folding\_of}, \texttt{orbit})

\textbf{Bases:} \texttt{UniqueRepresentation}, \texttt{SageObject}

A Cartan type realized from a (Dynkin) diagram folding.
Given a Cartan type $X$, we say $\tilde{X}$ is a folded Cartan type of $X$ if there exists a diagram folding of the Dynkin diagram of $\tilde{X}$ onto $X$.

A folding of a simply-laced Dynkin diagram $D$ with index set $I$ is an automorphism $\sigma$ of $D$ where all nodes any orbit of $\sigma$ are not connected. The resulting Dynkin diagram $\tilde{D}$ is induced by $I/\sigma$ where we identify edges in $\tilde{D}$ which are not incident and add a $k$-edge if we identify $k$ incident edges and the arrow is pointing towards the incident note. We denote the index set of $\tilde{D}$ by $\tilde{I}$, and by abuse of notation, we denote the folding by $\sigma$.

We also have scaling factors $\gamma_i$ for $i \in \tilde{I}$ and defined as the unique numbers such that the map $\Lambda_j \mapsto \gamma_j \sum_{i \in \sigma^{-1}(j)} \Lambda_i$ is the smallest proper embedding of the weight lattice of $X$ to $\tilde{X}$.

If the Cartan type is simply laced, the default folding is the one induced from the identity map on $D$.

If $X$ is affine type, the default embeddings we consider here are:

\[
\begin{align*}
C^{(1)}_n, A^{(2)}_{2n}, A^{(2)}_{2n}, D^{(2)}_{n+1} & \mapsto A^{(1)}_{2n-1}, \\
A^{(2)}_{2n-1}, B^{(1)}_n & \mapsto D^{(1)}_{n+1}, \\
E^{(2)}_6, F^{(1)}_4 & \mapsto E^{(1)}_6, \\
D^{(3)}_4, G^{(1)}_2 & \mapsto D^{(1)}_4,
\end{align*}
\]

and were chosen based on virtual crystals. In particular, the diagram foldings extend to crystal morphisms and gives a realization of Kirillov-Reshetikhin crystals for non-simply-laced types as simply-laced types. See [OSShimo03] and [FOS2009] for more details. Here we can compute $\gamma_i = \max(c_i)/c_i$ where $(c_i)$ are the translation factors of the root system. In a more type-dependent way, we can define $\gamma_i$ as follows:

1. There exists a unique arrow (multiple bond) in $X$.
   a. Suppose the arrow points towards 0. Then $\gamma_i = 1$ for all $i \in I$.
   b. Otherwise $\gamma_i$ is the order of $\sigma$ for all $i$ in the connected component of 0 after removing the arrow, else $\gamma_i = 1$.

2. There is not a unique arrow. Thus $\tilde{X} = A^{(1)}_{2n-1}$ and $\gamma_i = 1$ for all $1 \leq i \leq n - 1$. If $i \in \{0, n\}$, then $\gamma_i = 2$ if the arrow incident to $i$ points away and is 1 otherwise.

We note that $\gamma_i$ only depends upon $X$.

If the Cartan type is finite, then we consider the classical foldings/embeddings induced by the above affine foldings/embeddings:

\[
\begin{align*}
C_n & \mapsto A_{2n-1}, \\
B_n & \mapsto D_{n+1}, \\
F_4 & \mapsto E_6, \\
G_2 & \mapsto D_4.
\end{align*}
\]

For more information on Cartan types, see `sage.combinat.root_system.cartan_type`.

Other foldings may be constructed by passing in an optional `folding_of` second argument. See below.

INPUT:

- `cartan_type` – the Cartan type $X$ to create the folded type
- `folding_of` – the Cartan type $\tilde{X}$ which $X$ is a folding of
- `orbit` – the orbit of the Dynkin diagram automorphism $\sigma$ given as a list of lists where the $a$-th list corresponds to the $a$-th entry in $I$ or a dictionary with keys in $I$ and values as lists

Note: If $X$ is an affine type, we assume the special node is fixed under $\sigma$.

EXAMPLES:
sage: fct = CartanType(['C',4,1]).as_folding(); fct
['C', 4, 1] as a folding of ['A', 7, 1]
sage: fct.scaling_factors()  #...

Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

fct = CartanType(['C',4,1]).as_folding(); fct
['C', 4, 1] as a folding of ['A', 7, 1]
fct.scaling_factors()  #...

Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

fct = CartanType(['C',4,1]).as_folding(); fct
['C', 4, 1] as a folding of ['A', 7, 1]
fct.scaling_factors()  #...

Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

A simply laced Cartan type can be considered as a virtual type of itself:

sage: fct = CartanType(['A',4,1]).as_folding(); fct
['A', 4, 1] as a folding of ['A', 4, 1]
sage: fct.scaling_factors()  #...

Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1,), 2: (2,), 3: (3,), 4: (4,)}

fct = CartanType(['A',4,1]).as_folding(); fct
['A', 4, 1] as a folding of ['A', 4, 1]
fct.scaling_factors()  #...

Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
fct.folding_orbit()
Finite family {0: (0,), 1: (1,), 2: (2,), 3: (3,), 4: (4,)}

Finite types:

sage: fct = CartanType(['C',4]).as_folding(); fct
['C', 4] as a folding of ['A', 7]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 1, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}

sage: fct = CartanType(['F',4]).dual().as_folding(); fct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1} as a folding of ['E', 6]
sage: fct.scaling_factors()
Finite family {1: 1, 2: 1, 3: 2, 4: 2}
sage: fct.folding_orbit()
Finite family {1: (1, 6), 2: (3, 5), 3: (4,), 4: (2,)}

fct = CartanType(['C',4]).as_folding(); fct
['C', 4] as a folding of ['A', 7]
fct.scaling_factors()  #...

Finite family {1: 1, 2: 1, 3: 1, 4: 2}
fct.folding_orbit()
Finite family {1: (1, 6), 2: (3, 5), 3: (4,), 4: (2,)}

fct = CartanType(['C',4]).as_folding(); fct
['C', 4] as a folding of ['A', 7]
fct.scaling_factors()  #...

Finite family {1: 1, 2: 1, 3: 1, 4: 2}
fct.folding_orbit()
Finite family {1: (1, 6), 2: (3, 5), 3: (4,), 4: (2,)}

(continues on next page)
REFERENCES:

- Wikipedia article Dynkin_diagram#Folding

**cartan_type()**

Return the Cartan type of `self`.

**EXAMPLES:**

```python
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.cartan_type()
['C', 4, 1]
```

```python
>>> from sage.all import *

>>> fct = CartanType(['C', Integer(4), Integer(1)]).as_folding()

>>> fct.cartan_type()
['C', 4, 1]
```

**folding_of()**

Return the Cartan type of the virtual space.

**EXAMPLES:**

```python
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_of()
['A', 7, 1]
```

```python
>>> from sage.all import *

>>> fct = CartanType(['C', Integer(4), Integer(1)]).as_folding()

>>> fct.folding_of()
['A', 7, 1]
```

**folding_orbit()**

Return the orbits under the automorphism $\sigma$ as a dictionary (of tuples).

**EXAMPLES:**

```python
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}
```

```python
>>> from sage.all import *

>>> fct = CartanType(['C', Integer(4), Integer(1)]).as_folding()

>>> fct.folding_orbit()
Finite family {0: (0,), 1: (1, 7), 2: (2, 6), 3: (3, 5), 4: (4,)}
```
scaling_factors()

Return the scaling factors of self.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: fct = CartanType(['C', 4, 1]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).as_folding()
sage: fct.scaling_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 2}
sage: fct = CartanType(['BC', 4, 2]).dual().as_folding()
sage: fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
sage: CartanType(['BC', 4, 2]).relabel({0:4, 1:3, 2:2, 3:1, 4:0}).as_folding().scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
```

```python
>>> from sage.all import *
>>> # needs sage.graphs

>>> fct = CartanType(['C', Integer(4), Integer(1)]).as_folding()
>>> fct.scaling_factors()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 2}
```

5.1.267 Root system data for Cartan types with marked nodes

```python
class sage.combinat.root_system.type_marked.AmbientSpace(root_system, base_ring, index_set=None)
```

Ambient space for a marked finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type.

EXAMPLES:

```python
sage: L = CartanType(['F',4]).marked_nodes([1,3]).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] with nodes (1, 3) marked
sage: TestSuite(L).run()
```

```python
>>> from sage.all import *
```

5.1. Comprehensive Module List

(continues on next page)
dimension()

Return the dimension of this ambient space.

See also:

sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

EXAMPLES:

```python
sage: L = CartanType(['F', 4]).marked_nodes([1, 3]).root_system().ambient_space()
sage: L.dimension()
4
```

fundamental_weight(i)

Return the i-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```python
sage: L = CartanType(['F', 4]).marked_nodes([1, 3]).root_system().ambient_space()
sage: L.fundamental_weight(1)
(1, 1, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, 0, 0, 0)}
```

simple_root(i)

Return the i-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:
```python
sage: L = CartanType(["F",4]).marked_nodes([1,3]).root_system().ambient_space()

sage: L.simple_root(1)
(0, 1, -1, 0)
sage: L.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
sage: L.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

```
from sage.all import *

L = CartanType(["F",Integer(4)]).marked_nodes([Integer(1),Integer(3)]).root_system().ambient_space()

L.simple_root(Integer(1))
(0, 1, -1, 0)
L.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -1/2, -1/2, -1/2)}
L.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1, -1, -1)}
```

---

class sage.combinat.root_system.type_marked.CartanType(ct, marked_nodes)

Bases: CartanType_decorator

A class for Cartan types with marked nodes.

INPUT:

- `ct` – a Cartan type
- `marked_nodes` – a list of marked nodes

EXAMPLES:

We take the Cartan type $B_4$:

```
sage: T = CartanType(['B',4])
sage: T.dynkin_diagram()
#...

- needs sage.graphs
O---O---O=>=O
1 2 3 4
B4
```

```
>>> from sage.all import *
>>> T = CartanType(['B',Integer(4)])
>>> T.dynkin_diagram()
#...
- needs sage.graphs
O---O---O=>=O
1 2 3 4
B4
```

And mark some of its nodes:

```
sage: T = T.marked_nodes([2,3])
sage: T.dynkin_diagram()
#...
- needs sage.graphs
```
```
Markings are not additive:

>>> from sage.all import *

>>> T.marked_nodes([1, 4]).dynkin_diagram()

# needs sage.graphs
X---O---O=>=X
1 2 3 4
B4 with nodes (1, 4) marked

And trivial relabelling are honoured nicely:

>>> from sage.all import *

>>> T = T.marked_nodes([])

>>> T.dynkin_diagram()

# needs sage.graphs
O---O---O=>=O
1 2 3 4
B4

ascii_art (label=None, node=None)

Return an ascii art representation of this Cartan type.

EXAMPLES:

sage: print(CartanType("G", 2).marked_nodes([2]).ascii_art())
  3
O=<=X
1 2
sage: print(CartanType("B", 3, 1).marked_nodes([0, 3]).ascii_art())
  X 0
dual()  Implements  

\[ \text{sage.combinat.root_system.cartan_type.CartanType_abstract.dual()} \], using that taking the dual and marking nodes are commuting operations.

EXAMPLES:

\[ \text{sage: } T = \text{CartanType(['BC', 3, 2])} \]
\[ \text{sage: } T.\text{marked_nodes([1,3]).dual().dynkin_diagram()} \]  # needs sage.graphs
\[ O=\Rightarrow X \]
\[ 0 \ 1 \ 2 \ 3 \]
\[ \text{BC3}^\sim \text{ with nodes (1, 3) marked} \]
\[ \text{sage: } T.\text{dual().marked_nodes([1,3]).dynkin_diagram()} \]  # needs sage.graphs
\[ O=\Rightarrow X \]
\[ 0 \ 1 \ 2 \ 3 \]
\[ \text{BC3}^\sim \text{ with nodes (1, 3) marked} \]

\[ \text{>>> from sage.all import } * \]
\[ \text{>>> print(CartanType(['G', Integer(2)]).marked_nodes([Integer(2)]).ascii_art())} \]
\[ O=\Rightarrow X \]
\[ 0 \ 1 \ 2 \ 3 \]
\[ \text{>>> print(CartanType(['B', Integer(3), Integer(1)]).marked_nodes([Integer(0),} \]
\[ \rightarrow \text{Integer(3)]).ascii_art()}} \]
\[ X \ 0 \]
\[ 1 \]
\[ 0=\Rightarrow X \]
\[ 1 \ 2 \ 3 \]
\[ \text{>>> print(CartanType(['F', Integer(4), Integer(1)]).marked_nodes([Integer(0),} \]
\[ \rightarrow \text{Integer(2)]).ascii_art()}} \]
\[ X \ 0 \]
\[ 1 \ 2 \ 3 \ 4 \]
**dynkin_diagram()**

Return the Dynkin diagram for this Cartan type.

**EXAMPLES:**

```python
sage: CartanType(['G', 2]).marked_nodes([2]).dynkin_diagram()  # needs sage.graphs
\[ O=<=X \\
\| 1 2 \\
G2 with node 2 marked
```

```python
>>> from sage.all import *

>>> CartanType(['G', Integer(2)]).marked_nodes([Integer(2)]).dynkin_diagram()  # needs sage.graphs
\[ O=<=X \\
\| 1 2 \\
G2 with node 2 marked
```

**marked_nodes**

Return `self` with nodes marked.

**EXAMPLES:**

```python
sage: ct = CartanType(['A',12])
sage: m = ct.marked_nodes([1,4,6,7,8,12]); m
\[ 'A', 12 \] with nodes (1, 4, 6, 7, 8, 12) marked
sage: m.marked_nodes([2])
\[ 'A', 12 \] with node 2 marked
sage: m.marked_nodes([]) is ct
True
```

```python
>>> from sage.all import *

>>> ct = CartanType(['A',Integer(12)])

>>> m = ct.marked_nodes([Integer(1),Integer(4),Integer(6),Integer(7), Integer(8),Integer(12)]); m
\[ 'A', 12 \] with nodes (1, 4, 6, 7, 8, 12) marked

>>> m.marked_nodes([Integer(2)])
\[ 'A', 12 \] with node 2 marked

>>> m.marked_nodes([]) is ct
True
```

**relabel**

Return the relabelling of `self`.

**EXAMPLES:**

```python
sage: T = CartanType(['BC',3, 2])
sage: T.marked_nodes([1,3]).relabel(lambda x: x+2).dynkin_diagram()  # needs sage.graphs
\[ O=<=X---O=<=X \\
2 3 4 5 \\
BC3\textsuperscript{\dagger} relabelled by \{0: 2, 1: 3, 2: 4, 3: 5\} with nodes (3, 5) marked

sage: T.relabel(lambda x: x+2).marked_nodes([3,5]).dynkin_diagram()  # needs sage.graphs
\[ O=<=X---O=<=X \\
```

(continues on next page)
BC3~ relabelled by \{0: 2, 1: 3, 2: 4, 3: 5\} with nodes (3, 5) marked

```python
>>> from sage.all import *

>>> T = CartanType(['BC', Integer(3), Integer(2)])
>>> T.marked_nodes([Integer(1), Integer(3)]).relabel(lambda x: x+Integer(2)).dynkin_diagram()  # needs sage.graphs
O=<=X---O=<=X
2 3 4 5
BC3~ relabelled by \{0: 2, 1: 3, 2: 4, 3: 5\} with nodes (3, 5) marked
```

```python
>>> T.relabel(lambda x: x+Integer(2)).marked_nodes([Integer(3), Integer(5)]).dynkin_diagram()  # needs sage.graphs
O=<=X---O=<=X
2 3 4 5
BC3~ relabelled by \{0: 2, 1: 3, 2: 4, 3: 5\} with nodes (3, 5) marked
```

type()

Return the type of `self` or None if unknown.

EXAMPLES:

```python
sage: ct = CartanType(['F', 4]).marked_nodes([1,3])
sage: ct.type()
'F'
```

```python
>>> from sage.all import *

>>> ct = CartanType(['F', Integer(4)]).marked_nodes([Integer(1), Integer(3)])
>>> ct.type()
'F'
```

class sage.combinat.root_system.type_marked.CartanType_affine(ct, marked_nodes)

Bases: CartanType, CartanType_affine

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```python
sage: CartanType(['A', 7, 2]).marked_nodes([1,3]).basic_untwisted()
['A', 7] with nodes (1, 3) marked
sage: CartanType(['D', 4, 3]).marked_nodes([0,2]).basic_untwisted()
['D', 4] with node 2 marked
```

```python
>>> from sage.all import *

>>> CartanType(['A', Integer(7), Integer(2)]).marked_nodes([Integer(1), Integer(3)]).basic_untwisted()
['A', 7] with nodes (1, 3) marked
>>> CartanType(['D', Integer(4), Integer(3)]).marked_nodes([Integer(0), Integer(2)]).basic_untwisted()
['D', 4] with node 2 marked
```

classical()

Return the classical Cartan type associated with `self`.  

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: T = CartanType(['A',4,1]).marked_nodes([0,2,4])
sage: T.dynkin_diagram()  #...
--- needs sage.graphs
0
X-----------+
|      |
|      |
O---X---O---X
1 2 3 4
A4~ with nodes (0, 2, 4) marked

sage: T0 = T.classical(); T0
['A', 4] with nodes (2, 4) marked
sage: T0.dynkin_diagram()  #...
--- needs sage.graphs
0---X---O---X
1 2 3 4
A4 with nodes (2, 4) marked
```

```python
>>> from sage.all import *

>>> T = CartanType(['A',Integer(4),Integer(1)]).marked_nodes([Integer(0), Integer(2),Integer(4)])

>>> T.dynkin_diagram()  #...
--- needs sage.graphs
0
X-----------+
|      |
|      |
O---X---O---X
1 2 3 4
A4~ with nodes (0, 2, 4) marked

>>> T0 = T.classical(); T0
[A, 4] with nodes (2, 4) marked

>>> T0.dynkin_diagram()  #...
--- needs sage.graphs
O---X---O---X
1 2 3 4
A4 with nodes (2, 4) marked
```

**is_untwisted_affine()**

Implement `CartanType_affine.is_untwisted_affine()`.
A marked Cartan type is untwisted affine if the original is.

**EXAMPLES:**

```python
sage: CartanType(['B', 3, 1]).marked_nodes([1,3]).is_untwisted_affine()
True
```

```python
>>> from sage.all import *

>>> CartanType(['B', Integer(3), Integer(1)]).marked_nodes([Integer(1), Integer(3)]).is_untwisted_affine()
True
```

**special_node()**
Return the special node of the Cartan type.

See also:
special_node()

It is the special node of the non-marked Cartan type.

EXAMPLES:

```sage
CartanType(['B', 3, 1]).marked_nodes([1, 3]).special_node()
```

```sage
>>> from sage.all import *
>>> CartanType(['B', Integer(3), Integer(1)]).marked_nodes([Integer(1), Integer(3)]).special_node()
```

class sage.combinat.root_system.type_marked.CartanType_finite(ct, marked_nodes)

Bases: CartanType, CartanType_finite

AmbientSpace

alias of AmbientSpace

affine()

Return the affine Cartan type associated with self.

EXAMPLES:

```sage
B4 = CartanType(['B', 4]).marked_nodes([1, 3])
sage: B4.dynkin_diagram()
X--O---X=>=O
1 2 3 4
B4 with nodes (1, 3) marked
```

```sage
sage: B4.affine().dynkin_diagram()
```

```sage
>>> from sage.all import *
>>> B4 = CartanType(['B', Integer(4)]).marked_nodes([Integer(1), Integer(3)])
>>> B4.dynkin_diagram()
X--O---X=>=O
1 2 3 4
B4 with nodes (1, 3) marked
```

```sage
sage: B4.affine().dynkin_diagram()
```

(continues on next page)
5.1.268 Root system data for reducible Cartan types

class sage.combinat.root_system.type_reducible.AmbientSpace(root_system, base_ring, index_set=None)

Bases: AmbientSpace

EXAMPLES:

sage: RootSystem("A2xB2").ambient_space()
Ambient space of the Root system of type A2xB2

>>> from sage.all import *
>>> RootSystem("A2xB2").ambient_space()
Ambient space of the Root system of type A2xB2

ambient_spaces()

Returns a list of the irreducible Cartan types of which the given reducible Cartan type is a product.

EXAMPLES:

sage: RootSystem("A2xB2").ambient_space().ambient_spaces()
[Ambient space of the Root system of type ['A', 2],
 Ambient space of the Root system of type ['B', 2]]

>>> from sage.all import *
>>> RootSystem("A2xB2").ambient_space().ambient_spaces()
[Ambient space of the Root system of type ['A', 2],
 Ambient space of the Root system of type ['B', 2]]

cartan_type()

EXAMPLES:

sage: RootSystem("A2xB2").ambient_space().cartan_type()
A2xB2

>>> from sage.all import *
>>> RootSystem("A2xB2").ambient_space().cartan_type()
A2xB2

component_types()

EXAMPLES:

sage: RootSystem("A2xB2").ambient_space().component_types()
[[['A', 2], ['B', 2]]

>>> from sage.all import *
>>> RootSystem("A2xB2").ambient_space().component_types()
[[['A', 2], ['B', 2]]
dimension()  
EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().dimension()
5
```

```
>>> from sage.all import *

```

```
>>> RootSystem("A2xB2").ambient_space().dimension()
5
```

fundamental_weights()  
EXAMPLES:

```
sage: RootSystem("A2xB2").ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0, 0), 2: (1, 1, 0, 0, 0), 3: (0, 0, 0, 1, 0), 4:
→ (0, 0, 0, 1/2, 1/2)}
```

```
>>> from sage.all import *

```

```
>>> RootSystem("A2xB2").ambient_space().fundamental_weights()
Finite family {1: (1, 0, 0, 0, 0), 2: (1, 1, 0, 0, 0), 3: (0, 0, 0, 1, 0), 4:
→ (0, 0, 0, 1/2, 1/2)}
```

inject_weights(i, v)  
Producesthecorrespondingelementofthelattice.  

INPUT:

• i – an integer in range(self.components)  
• v – a vector in the i-th component weight lattice  

EXAMPLES:

```
sage: V = RootSystem("A2xB2").ambient_space()
sage: [V.inject_weights(i,V.ambient_spaces()[i].fundamental_weights()[1])
for i in range(2)]
[(1, 0, 0, 0, 0), (0, 0, 0, 1, 0)]
```

```
>>> from sage.all import *

```

```
>>> V = RootSystem("A2xB2").ambient_space()
```

```
>>> [V.inject_weights(i,V.ambient_spaces()[i].fundamental_weights()[2])
for i in range(2)]
[(1, 1, 0, 0, 0), (0, 0, 0, 1/2, 1/2)]
```

negative_roots()  
EXAMPLES:

```
sage: RootSystem("A1xA2").ambient_space().negative_roots()
[(-1, 1, 0, 0, 0), (0, 0, -1, 1, 0), (0, 0, -1, 0, 1), (0, 0, 0, -1, 1)]
```

```
```python
>>> from sage.all import *
>>> RootSystem("A1xA2").ambient_space().negative_roots()
[(-1, 1, 0, 0, 0), (0, 0, -1, 1, 0), (0, 0, 0, -1, 0), (0, 0, 0, 0, 1)]

positive_roots()

EXAMPLES:

```sage
sage: RootSystem("A1xA2").ambient_space().positive_roots()
[(1, -1, 0, 0, 0), (0, 0, 1, -1, 0), (0, 0, 1, 0, -1), (0, 0, 0, 1, -1)]
```n
```python
>>> from sage.all import *
>>> RootSystem("A1xA2").ambient_space().positive_roots()
[(1, -1, 0, 0, 0), (0, 0, 1, -1, 0), (0, 0, 1, 0, -1), (0, 0, 0, 1, -1)]

simple_coroot(i)

EXAMPLES:

```sage
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_coroot(2)
(0, 0, 1, -1)
sage: A.simple_coroots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2)}
```n
```python
>>> from sage.all import *
>>> A = RootSystem("A1xB2").ambient_space()
>>> A.simple_coroot(Integer(2))
(0, 0, 1, -1)
>>> A.simple_coroots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2)}

simple_root(i)

EXAMPLES:

```sage
sage: A = RootSystem("A1xB2").ambient_space()
sage: A.simple_root(2)
(0, 0, 1, -1)
sage: A.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1)}
```n
```python
>>> from sage.all import *
>>> A = RootSystem("A1xB2").ambient_space()
>>> A.simple_root(Integer(2))
(0, 0, 1, -1)
>>> A.simple_roots()
Finite family {1: (1, -1, 0, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1)}

class sage.combinat.root_system.type_reducible.CartonType(types)

Bases: sage.combinat.root_system.type_reducible.CartonType

A class for reducible Cartan types.

Reducible root systems are ones that can be factored as direct products. Strictly speaking type $D_2$ (corresponding to orthogonal groups of degree 4) is reducible since it is isomorphic to $A_1 \times A_1$. However type $D_2$ is not built using this class for our purposes.

INPUT:
- **types** – a list of simple Cartan types

**EXAMPLES:**

```python
sage: t1, t2 = [CartanType(x) for x in (['A',1], ['B',2])]
sage: CartanType([t1, t2])
A1xB2
sage: t = CartanType("A2xB2")
```

```python
>>> from sage.all import *

>>> t1, t2 = [CartanType(x) for x in (['A','1'], ['B','2'])]

>>> CartanType([t1, t2])
A1xB2

>>> t = CartanType("A2xB2")
```

A reducible Cartan type is finite (resp. crystallographic, simply laced) if all its components are:

```python
sage: t.is_finite()
True

sage: t.is_crystallographic()
True

sage: t.is_simply_laced()
False
```

```python
>>> from sage.all import *

>>> t.is_finite()
True

>>> t.is_crystallographic()
True

>>> t.is_simply_laced()
False
```

This is implemented by inserting the appropriate abstract super classes (see `_add_abstract_superclass()`):

```python
sage: t._class_.mro()
```

```python
>>> from sage.all import *

>>> t._class_.mro()
```

The index set of the reducible Cartan type is obtained by relabelling successively the nodes of the Dynkin diagrams of the components by 1,2,...:

```python
sage: t = CartanType(["A",4], ["BC",5,2], ["C",3])
sage: t.index_set()
```

(continues on next page)
(1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13)

sage: t.dynkin_diagram()
   # needs sage.graphs
O---O---O---O
  1 2 3 4
O=<=O---O---O=<=O=<=O
  5 6 7 8 9 10
O---O=<=O
  11 12 13
A4xBC5~xC3

AmbientSpace

alias of AmbientSpace

ascii_art (label=None, node=None)

Return an ascii art representation of this reducible Cartan type.

EXAMPLES:

sage: print(CartanType("F4xA2").ascii_art(label = lambda x: x+2))
   O--O=>=O---O
  3 4 5 6
  7 8

sage: print(CartanType(["BC", 5, 2], ["A", 4]).ascii_art())
O=<=O---O---O=<=O=<=O
  1 2 3 4 5 6
  7 8 9 10

sage: print(CartanType(["A", 4], ["BC", 5, 2], ["C", 3]).ascii_art())
   O---O---O---O
  1 2 3 4
O=<=O---O---O=<=O=<=O
  5 6 7 8 9 10
O---O=<=O
  11 12 13
```python
>>> from sage.all import *

>>> print(CartanType("F4xA2").ascii_art(label = lambda x: x+Integer(2)))
O---O=<=O---O
3 4 5 6
O---O
7 8

>>> print(CartanType(["BC",Integer(5),Integer(2)], ["A",Integer(4)]).ascii_art())
O=<=O---O---O---O=<=O
1 2 3 4 5 6
O---O---O---O
7 8 9 10

>>> print(CartanType(["A",Integer(4)], ["BC",Integer(5),Integer(2)], ["C", Integer(3)]).ascii_art())
O---O---O---O
1 2 3 4
O=<=O---O---O---O=<=O
5 6 7 8 9 10
O---O=<=O
11 12 13
```

**cartan_matrix**(subdivide=True)

Return the Cartan matrix associated with self. By default the Cartan matrix is a subdivided block matrix showing the reducibility but the subdivision can be suppressed with the option subdivide = False.

**EXAMPLES:**

```python
sage: ct = CartanType("A2","B2")
sage: ct.cartan_matrix()  # needs sage.graphs
[ 2 -1| 0 0]
[-1 2| 0 0]
[-----+-----]
[ 0 0| 2 -1]
[ 0 0|-2 2]
sage: ct.cartan_matrix(subdivide=False)  # needs sage.graphs
[ 2 -1 0 0]
[-1 2 0 0]
[ 0 0 2 -1]
[ 0 0 -2 2]
sage: ct.index_set() == ct.cartan_matrix().index_set()  # needs sage.graphs
True
```
component_types()

A list of Cartan types making up the reducible type.

EXAMPLES:

```python
sage: CartanType(['A',2],['B',2]).component_types()
[['A', 2], ['B', 2]]
```

```python
>>> from sage.all import *
```

```python
>>> CartanType(['A',Integer(2)],[B,Integer(2)]).component_types()
[['A', 2], ['B', 2]]
```

coxeter_diagram()

Return the Coxeter diagram for self.

EXAMPLES:

```python
sage: cd = CartanType("A2xB2xF4").coxeter_diagram(); cd
Graph on 8 vertices
sage: cd.edges(sort=True)
[(1, 2, 3), (3, 4, 4), (5, 6, 3), (6, 7, 4), (7, 8, 3)]
```

```python
sage: CartanType("F4xA2").coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3), (5, 6, 3)]
```

```python
sage: cd = CartanType("A1xH3").coxeter_diagram(); cd
Graph on 4 vertices
sage: cd.edges(sort=True)
[(2, 3, 3), (3, 4, 5)]
```

```python
>>> from sage.all import *
```

```python
>>> cd = CartanType("A2xB2xF4").coxeter_diagram(); cd
Graph on 8 vertices
```

```python
>>> cd.edges(sort=True)
[(1, 2, 3), (3, 4, 4), (5, 6, 3), (6, 7, 4), (7, 8, 3)]
```

```python
>>> CartanType("F4xA2").coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3), (5, 6, 3)]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> cd = CartanType("A1xH3").coxeter_diagram(); cd
# needs sage.graphs
Graph on 4 vertices
```

```python
>>> cd.edges(sort=True)
# needs sage.graphs
[(2, 3, 3), (3, 4, 5)]
```

dual()

EXAMPLES:

```python
sage: CartanType("A2xB2").dual()
A2xC2
```

```python
>>> from sage.all import *
```

```python
>>> CartanType("A2xB2").dual()
A2xC2
```

dynkin_diagram()

Returns a Dynkin diagram for type reducible.

EXAMPLES:

```python
sage: dd = CartanType("A2xB2xF4").dynkin_diagram(); dd
# needs sage.graphs
O---O
 1 2
O=>=O
 3 4
O---O=>=O---O
 5 6 7 8
A2xB2xF4
sage: dd.edges(sort=True)
# needs sage.graphs
[(1, 2, 1), (2, 1, 1), (3, 4, 2), (4, 3, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 2), (7, 6, 1), (7, 8, 1), (8, 7, 1)]
```

```python
sage: CartanType("F4xA2").dynkin_diagram()
# needs sage.graphs
O---O=>=O---O
 1 2 3 4
O---O
 5 6
F4xA2
```

```python
>>> from sage.all import *
```

```python
>>> dd = CartanType("A2xB2xF4").dynkin_diagram(); dd
# needs sage.graphs
O---O
 1 2
O=>=O
 3 4
O---O=>=O---O
 5 6 7 8
A2xB2xF4
```

```python
>>> dd.edges(sort=True)
# needs sage.graphs
```

(continues on next page)
Combinatorics, Release 10.4

>>> CartanType("F4xA2").dynkin_diagram()
\[\begin{array}{c}
\text{needs sage.graphs}
\text{O---O=>=O---O}
1 2 3 4
\text{O---O}
5 6
\end{array}\]

\text{F4xA2}

\text{index_set()}

Implements \textit{CartanType\_abstract.index\_set()}. For the moment, the index set is always of the form \{1,\ldots,n\}.

EXAMPLES:

\texttt{sage:}\ CartanType("A2","A1").index\_set()
\(\{1, 2, 3\}\)

\texttt{from sage.all import *}

\texttt{sage: CartanType("A2","A1").index\_set()}
\(\{1, 2, 3\}\)

\text{is\_affine()}

Report that this reducible Cartan type is not affine

EXAMPLES:

\texttt{sage:}\ CartanType(['A',2],['B',2]).is\_affine()
\texttt{False}

\texttt{from sage.all import *}

\texttt{sage: CartanType(['A',Integer(2)],['B',Integer(2)]).is\_affine()}
\texttt{False}

\text{is\_finite()}

EXAMPLES:

\texttt{sage:}\ ct1 = CartanType(['A',2],['B',2])
\texttt{sage:}\ ct1.is\_finite()
\texttt{True}
\texttt{sage:}\ ct2 = CartanType(['A',2],['B',2,1])
\texttt{sage:}\ ct2.is\_finite()
\texttt{False}

\texttt{from sage.all import *}

\texttt{sage:}\ ct1 = CartanType(['A',Integer(2)],['B',Integer(2)])
\texttt{sage:}\ ct1.is\_finite()
\texttt{True}
\texttt{sage:}\ ct2 = CartanType(['A',Integer(2)],['B',Integer(2),Integer(1)])
\texttt{sage:}\ ct2.is\_finite()
\texttt{False}
**is_irreducible()**

Report that this Cartan type is not irreducible.

**EXAMPLES:**

```python
sage: ct = CartanType(['A',2],['B',2])
sage: ct.is_irreducible()
False
```

```python
>>> from sage.all import *
>>> ct = CartanType(['A',Integer(2)],['B',Integer(2)])
>>> ct.is_irreducible()
False
```

**rank()**

Returns the rank of self.

**EXAMPLES:**

```python
sage: CartanType('A2','A1').rank()
3
```

```python
>>> from sage.all import *
>>> CartanType('A2','A1').rank()
3
```

**type()**

Returns “reducible” since the type is reducible.

**EXAMPLES:**

```python
sage: CartanType(['A',2],['B',2]).type()
'reducible'
```

```python
>>> from sage.all import *
>>> CartanType(['A',Integer(2)],['B',Integer(2)]).type()
'reducible'
```

### 5.1.269 Root system data for relabelled Cartan types

**class** `sage.combinat.root_system.type_relabel.AmbientSpace(root_system, base_ring, index_set=None)`

**Bases:** ` AmbientSpace`

Ambient space for a relabelled finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type, by relabelling the simple roots, fundamental weights, etc.

**EXAMPLES:**

```python
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(['F',4]).relabel(cycle).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
```

(continues on next page)
>>> from sage.all import *
  Integer(4):Integer(1)}
>>> L = CartanType(['F',Integer(4)]).relabel(cycle).root_system().ambient_space();
  L
Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4,
  4: 1}
>>> TestSuite(L).run()

# needs sage.graphs

dimension()

Return the dimension of this ambient space.

See also:
sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

EXAMPLES:

sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(['F',4]).relabel(cycle).root_system().ambient_space()
sage: L.dimension()
4

  Integer(4):Integer(1)}
>>> L = CartanType(['F',Integer(4)]).relabel(cycle).root_system().ambient_space()
>>> L.dimension()
4

fundamental_weight(i)

Return the i-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(['F',4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(['F',4]).root_system().ambient_space()
sage: K.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4:
  (1, 0, 0, 0)}
sage: L.fundamental_weight(1)(1, 0, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (1, 1, 0, 0), 3: (2, 1, 1, 0), 4: (3/2, 1/2,
  1/2, 1/2)}
simple_root \(i\)

Return the \(i\)-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```python
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType("F",4).relabel(cycle).root_system().ambient_space()
sage: K = CartanType("F",4).root_system().ambient_space()
sage: L.simple_root(1)
(1/2, -1/2, -1/2, -1/2)
sage: L.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 1)}
sage: L.simple_coroots()
Finite family {1: (1, -1, -1, -1), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0, 0, 0, 2)}
```
class sage.combinat.root_system.type_relabel.CartanType(type, relabelling)

    A class for relabelled Cartan types.

    ascii_art (label=None, node=None)

        Return an ascii art representation of this Cartan type.

        EXAMPLES:

        sage: print(CartanType(['G', 2]).relabel({1:2,2:1}).ascii_art())
        3
        0=<=O
        2   1
        sage: print(CartanType(['B', 3, 1]).relabel([1,3,2,0]).ascii_art())
        O 1
        | |
        O---O=>=O
        3 2 0
        sage: print(CartanType(['F', 4, 1]).relabel(lambda n: 4-n).ascii_art())
        O---O---O=>=O---O
        4 3 2 1 0

        >>> from sage.all import *
        >>> print(CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2), Integer(2):Integer(1)}).ascii_art())
        3
        0=<=O
        2   1
        >>> print(CartanType(['B', Integer(3), Integer(1)]).relabel([Integer(1), Integer(3), Integer(2), Integer(0)]).ascii_art())
        O 1
        | |
        O---O=>=O
        3 2 0
        >>> print(CartanType(['F', Integer(4), Integer(1)]).relabel(lambda n: Integer(4)-n).ascii_art())
        O---O---O=>=O---O
        4 3 2 1 0

    coxeter_diagram()

        Return the Coxeter diagram for self.

        EXAMPLES:
sage: ct = CartanType(['H', 3]).relabel({1:3,2:2,3:1})
sage: G = ct.coxeter_diagram(); G
Graph on 3 vertices
sage: G.edges(sort=True)
[(1, 2, 5), (2, 3, 3)]

>>> from sage.all import *
>>> ct = CartanType(['H', Integer(3)]).relabel({Integer(1):Integer(3),
Integer(2):Integer(2),Integer(3):Integer(1)})
>>> G = ct.coxeter_diagram(); G
Graph on 3 vertices
>>> G.edges(sort=True)
[(1, 2, 5), (2, 3, 3)]

dual()

Implements sage.combinat.root_system.cartan_type.CartanType_abstract.dual(), using that taking the dual and relabelling are commuting operations.

EXAMPLES:

sage: T = CartanType(['BC',3, 2])
sage: cycle = {1:2, 2:3, 3:0, 0:1}
sage: T.relabel(cycle).dual().dynkin_diagram()
O=>=O---O=>=O
1 2 3 0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
sage: T.dual().relabel(cycle).dynkin_diagram()
O=>=O---O=>=O
1 2 3 0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}

>>> from sage.all import *

>>> T = CartanType(['BC',Integer(3), Integer(2)])
>>> cycle = {1:2, 2:3, 3:0, 0:1}

BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}

>>> T.dual().relabel(cycle).dynkin_diagram()

BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}

dynkin_diagram()

Returns the Dynkin diagram for this Cartan type.

EXAMPLES:
sage: CartanType(["G", 2]).relabel({1:2,2:1}).dynkin_diagram()  # needs sage.graphs
    3
O="O
 2- 1
G2 relabelled by {1: 2, 2: 1}

>>> from sage.all import *
>>> CartanType(["G", Integer(2)]).relabel({Integer(1):Integer(2),
    \rightarrow Integer(2):Integer(1)}).dynkin_diagram()  # needs sage.graphs
    3
O="O
 2- 1
G2 relabelled by {1: 2, 2: 1}

index_set()

EXAMPLES:

sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.index_set()
(1, 2)

>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
    \rightarrow Integer(2):Integer(1)})
>>> ct.index_set()
(1, 2)

type()

Return the type of self or None if unknown.

EXAMPLES:

sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.type()
'G'

>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
    \rightarrow Integer(2):Integer(1)})
>>> ct.type()
'G'

class sage.combinat.root_system.type_relabel.CartanType_affine(type, relabelling)

Bases: CartanType, CartanType_affine

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that
is twisted to obtain self.

EXAMPLES:

sage: ct = CartanType(['A', 5, 2]).relabel({0:1, 1:0, 2:2, 3:3})
sage: ct.basic_untwisted()
['A', 5]
```python
>>> from sage.all import *
>>> ct = CartanType(['A', Integer(5), Integer(2)]).relabel({
    Integer(0):Integer(1), Integer(1):Integer(0), Integer(2):Integer(2),
    Integer(3):Integer(3)})
>>> ct.basic_untwisted()
['A', 5]
```

### classical()

Return the classical Cartan type associated with self.

**EXAMPLES:**

```python
sage: A41 = CartanType(['A', 4, 1])
sage: A41.dynkin_diagram()  # needs sage.graphs
0
O-----------+
| |
| |
O---O---O---O
1 2 3 4
A4~

sage: T = A41.relabel({0:1, 1:2, 2:3, 3:4, 4:0})
sage: T
['A', 4, 1] relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}
sage: T.dynkin_diagram()  # needs sage.graphs
1
O-----------+
| |
| |
O---O---O---O
2 3 4 0
A4~ relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}

sage: T0 = T.classical()
sage: T0
['A', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
sage: T0.dynkin_diagram()  # needs sage.graphs
O---O---O---O
2 3 4 0
A4 relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
```

```python
>>> from sage.all import *
>>> A41 = CartanType(['A', Integer(4), Integer(1)])
>>> A41.dynkin_diagram()  # needs sage.graphs
0
O-----------+
| |
| |
O---O---O---O
1 2 3 4
A4~
```

(continues on next page)
T = A41.relabel({Integer(0):Integer(1), Integer(1):Integer(2),
Integer(2):Integer(3), Integer(3):Integer(4), Integer(4):Integer(0)})

T
['A', 4, 1] relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}

T.dynkin_diagram()
needs sage.graphs
1
O---------+
| |
| |
O---O---O---O
2 3 4 0
A4~ relabelled by {0: 1, 1: 2, 2: 3, 3: 4, 4: 0}

T0 = T.classical()

T0
['A', 4] relabelled by {1: 2, 2: 3, 3: 4, 4: 0}

T0.dynkin_diagram()
needs sage.graphs
O---O---O---O
2 3 4 0
A4 relabelled by {1: 2, 2: 3, 3: 4, 4: 0}

is_untwisted_affine()
Implement CartanType_affine.is_untwisted_affine()
A relabelled Cartan type is untwisted affine if the original is.

EXAMPLES:

>>> from sage.all import *

>>> CartanType(['B', Integer(3), Integer(1)]).relabel({Integer(1):Integer(2),
Integer(2):Integer(3), Integer(3):Integer(0), Integer(0):Integer(1)}).is_untwisted_affine()
True

special_node()
Returns a special node of the Dynkin diagram

See also:
special_node()

It is obtained by relabelling of the special node of the non relabelled Dynkin diagram.

EXAMPLES:

sage: CartanType(['B', 3, 1]).special_node()
0
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).special_node()
1
from sage.all import *
CartanType(['B', Integer(3), Integer(1)]).special_node()
0
CartanType(['B', Integer(3), Integer(1)]).relabel({Integer(1):Integer(2),
       Integer(2):Integer(3), Integer(3):Integer(0), Integer(0):Integer(1)}).special_node()
1

class sage.combinat.root_system.type_relabel.CartanType_finite(type, relabelling)
    Bases: CartanType, CartanType_finite

AmbientSpace
    alias of AmbientSpace

affine()

    Return the affine Cartan type associated with self.

    EXAMPLES:

    sage: B4 = CartanType(['B',4])
    sage: B4.dynkin_diagram()
    # needs sage.graphs
    O---O---O=>=O
    1 2 3 4
    B4
    sage: B4.affine().dynkin_diagram()
    # needs sage.graphs
    O 0
    | |
    O---O---O=>=O
    1 2 3 4
    B4~

    >>> from sage.all import *
    >>> B4 = CartanType(['B',Integer(4)])
    >>> B4.dynkin_diagram()
    # needs sage.graphs
    O---O---O=>=O
    1 2 3 4
    B4
    >>> B4.affine().dynkin_diagram()
    # needs sage.graphs
    O 0
    | |
    O---O---O=>=O
    1 2 3 4
    B4~

If possible, this reuses the original label for the special node:

sage: T = B4.relabel({1:2, 2:3, 3:4, 4:1}); T.dynkin_diagram()
# needs sage.graphs
O---O---O=>=O
2 3 4 1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: T.affine().dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1
2  3  4
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}

>>> from sage.all import *
    Integer(3):Integer(4), Integer(4):Integer(1)}); T.dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1  2  3  4
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
>>> T.affine().dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1  2  3
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}

Otherwise, it chooses a label for the special_node in 0, 1, ...:

sage: T = B4.relabel({1:0, 2:1, 3:2, 4:3}); T.dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1  2  3
B4 relabelled by {1: 0, 2: 1, 3: 2, 4: 3}
sage: T.affine().dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1  2  3
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}

>>> from sage.all import *
>>> T = B4.relabel({Integer(1):Integer(0), Integer(2):Integer(1),
    Integer(3):Integer(2), Integer(4):Integer(3)}); T.dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1  2  3
B4~ relabelled by {1: 0, 2: 1, 3: 2, 4: 3}

sage: T.affine().dynkin_diagram()  # needs sage.graphs
O---O---O=>=O
0  1  2  3
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}
This failed before Issue #13724:

```python
sage: ct = CartanType(['G',2]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}
sage: ct = CartanType(['F',4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}
```

```python
>>> from sage.all import *
>>> ct = CartanType(['G',Integer(2)]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
>>> ct.affine()
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}
>>> ct = CartanType(['F',Integer(4)]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
>>> ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}
```

Check that we don’t inadvertently change the internal relabelling of `ct`:

```python
sage: ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
>>> from sage.all import *
>>> ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

### 5.1.270 Weight lattice realizations

**class** `sage.combinat.root_system.weight_lattice_realizations.WeightLatticeRealizations(base, name=None)`

**Bases:** `Category_over_base_ring`

The category of weight lattice realizations over a given base ring

A weight lattice realization $L$ over a base ring $R$ is a free module (or vector space if $R$ is a field) endowed with an embedding of the root lattice of some root system. By restriction, this embedding defines an embedding of the root lattice of this root system, which makes $L$ a root lattice realization.

Typical weight lattice realizations over $\mathbb{Z}$ include the weight lattice, and ambient lattice. Typical weight lattice realizations over $\mathbb{Q}$ include the weight space, and ambient space.

To describe the embedding, a weight lattice realization must implement a method `fundamental_weight(i)` returning for each `$\Lambda_i$` in the index set the image of the fundamental weight $\Lambda_i$ under the embedding.

In order to be a proper root lattice realization, a weight lattice realization should also implement the scalar product with the coroot lattice; on the other hand, the embedding of the simple roots is given for free.

See also:

- `RootSystem`
EXAMPLES:
Here, we consider the root system of type $A_7$, and embed the weight lattice element $x = \Lambda_1 + 2\Lambda_3$ in several root lattice realizations:

```
sage: R = RootSystem(['A',7])
sage: Lambda = R.weight_lattice().fundamental_weights()
sage: L = R.weight_space()
sage: L(x)
sage: L = R.ambient_lattice()
sage: L(x)
(3, 3, 2, 2, 2, 0, 0, 0)
```

We embed the weight space element $x = \Lambda_1 + 1/2\Lambda_3$ in the ambient space:

```
sage: Lambda = R.weight_space().fundamental_weights()
sage: L = R.ambient_space()
sage: L(x)
(3/2, 3/2, 1/2, 1/2, 1/2, 0, 0, 0)
```

Of course, one can’t embed the weight space in the ambient lattice:

```
sage: L = R.ambient_lattice()
sage: L(x)
Traceback (most recent call last):
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *

>>> L = R.ambient_lattice()
>>> L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[2] + 1/2*Lambda[5])
an element of self (=Ambient lattice of the Root system of type ['A', 7])
```

If $K_1$ is a subring of $K_2$, then one could in theory have an embedding from the weight space over $K_1$ to any weight lattice realization over $K_2$; this is not implemented:

```python
sage: K1 = QQ
sage: K2 = QQ['q']

sage: L = R.ambient_space(K2)

sage: Lambda = R.weight_space(K2).fundamental_weights()
sage: L(Lambda[1])
(1, 0, 0, 0, 0, 0, 0, 0)

sage: Lambda = R.weight_space(K1).fundamental_weights()
sage: L(Lambda[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[1]) an element
of self (=Ambient space of the Root system of type ['A', 7])
```

class ElementMethods

Bases: object

```python
symmetric_form(la)
```

Return the symmetric form of self with la.

Return the pairing (|) on the weight lattice. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.
**Warning:** For affine root systems, if you are not working in the extended weight lattice/space, this may return incorrect results.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: P = RootSystem(['C',2]).weight_lattice()
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[2].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2]).root_lattice()
sage: alQ = Q.simple_roots()

sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....: for i in P.index_set() for j in P.index_set())
True

sage: Q = RootSystem(['C',2,1]).weight_lattice()
sage: alQ = Q.simple_roots()

sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....: for i in P.index_set() for j in P.index_set())
True

sage: P = RootSystem(['C',2,1]).weight_lattice(extended=True)
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[1].symmetric_form(al[0])
-2
sage: al[0].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2,1]).root_lattice()
sage: alQ = Q.simple_roots()

sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....: for i in P.index_set() for j in P.index_set())
True

sage: La = P.basis()
sage: [La[delta].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[1, 0, 0]
```

```bash
>>> from sage.all import *
>>> # needs sage.graphs
>>> P = RootSystem(['C',Integer(2)]).weight_lattice()
```

(continues on next page)
```python
>>> al = P.simple_roots()
>>> al[Integer(1)].symmetric_form(al[Integer(1)])
2
>>> al[Integer(1)].symmetric_form(al[Integer(2)])
-2
>>> al[Integer(2)].symmetric_form(al[Integer(1)])
-2
>>> Q = RootSystem(['C', Integer(2)]).root_lattice()
>>> alQ = Q.simple_roots()
>>> all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
... for i in P.index_set() for j in P.index_set())
True

>>> # needs sage.graphs
>>> P = RootSystem(['C', Integer(2), Integer(1)]).weight_lattice(extended=True)
>>> al = P.simple_roots()
>>> al[Integer(1)].symmetric_form(al[Integer(1)])
2
>>> al[Integer(1)].symmetric_form(al[Integer(2)])
-2
>>> al[Integer(2)].symmetric_form(al[Integer(0)])
-2
>>> al[Integer(0)].symmetric_form(al[Integer(1)])
-2
>>> Q = RootSystem(['C', Integer(2), Integer(1)]).root_lattice()
>>> alQ = Q.simple_roots()
>>> all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
... for i in P.index_set() for j in P.index_set())
True
```

The result of \((\Lambda_0|\alpha_0)\) should be 1, however we get 0 because we are not working in the extended weight lattice:

```python
sage: La = P.basis()
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]
[0, 0, 0]
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

>>> La = P.basis()
>>> [La[Integer(0)].symmetric_form(al) for al in P.simple_roots()]  
    # needs sage.graphs
[0, 0, 0]

to_weight_space \text{(base\_ring=}None\text{)}

Map self to the weight space.

\textbf{Warning:} Implemented for finite Cartan type.

\textbf{EXAMPLES:}

sage: b = CartanType(['B',2]).root_system().ambient_space().from_  
    \rightarrow vector(vector([1,-2])); b
(1, -2)
sage: b.to_weight_space()
sage: b = CartanType(['B',2]).root_system().ambient_space().from_  
    \rightarrow vector(vector([1/2,0])); b
(1/2, 0)
sage: b.to_weight_space()
1/2*Lambda[1]
sage: b.to_weight_space(ZZ)
Traceback (most recent call last):

>>> b = CartanType(['B',Integer(2)]).root_system().ambient_space().from_  
    \rightarrow vector(vector([Integer(1)/Integer(2),Integer(0)])); b
(1/2, 0)
>>> b.to_weight_space()
1/2*Lambda[1]
>>> b.to_weight_space(ZZ)
Traceback (most recent call last):
  ...  
TypeError: no conversion of this rational to integer
>>> b = CartanType(['G',Integer(2)]).root_system().ambient_space().from_  
    \rightarrow vector(vector([Integer(4),-Integer(5),Integer(1)])); b
(4, -5, 1)
>>> b.to_weight_space()

\texttt{class ParentMethods}

\texttt{Bases: object}
Return the Dynkin diagram automorphism induced by an alcove morphism

INPUT:
• $f$ — a linear map from self to self which preserves alcoves

This method returns the Dynkin diagram automorphism for the decomposition $f = dw$ (see `reduced_word_of_alcove_morphism()`), as a dictionary mapping elements of the index set to itself.

EXAMPLES:

```python
sage: R = RootSystem(['A', 2, 1]).weight_lattice()
sage: alpha = R.simple_roots()  # needs sage.graphs
sage: Lambda = R.fundamental_weights()

>>> from sage.all import *
>>> # needs sage.graphs sage.libs.gap
>>> R = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice()
>>> alpha = R.simple_roots()
>>> Lambda = R.fundamental_weights()

Translations by elements of the root lattice induce a trivial Dynkin diagram automorphism:

```python
sage: # needs sage.graphs sage.libs.gapsage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[0].translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].translation)
{0: 0, 1: 1, 2: 2}
{0: 0, 1: 1, 2: 2}
```

This is no more the case for translations by general elements of the (classical) weight lattice at level 0:

```python
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - Lambda[0]

>>> from sage.all import *
>>> # needs sage.graphs sage.libs.gap
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 2, 2: 0}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 2, 1: 0, 2: 1}
```

(continues on next page)
Algorithm: computes $w$ of the decomposition, and see how $f \circ w^{-1}$ permutes the simple roots.

**embed_at_level** $(x, \text{level}=1)$

Embed the classical weight $x$ in the level $\text{level}$ hyperplane.

This is achieved by translating the straightforward embedding of $x$ by $c\Lambda_0$ for $c$ some appropriate scalar.

**INPUT:**
- $x$ – an element of the corresponding classical weight/ambient lattice
- $\text{level}$ – an integer or element of the base ring (default: 1)

**EXAMPLES:**
sage: # needs sage.graphs
sage: L = RootSystem(["B",3,1]).weight_space()

sage: L0 = L.classical()

sage: alpha = L0.simple_roots()

sage: omega = L0.fundamental_weights()

sage: L.embed_at_level(omega[1], 1)
Lambda[1]

sage: L.embed_at_level(omega[2], 1)
-Lambda[0] + Lambda[2]

sage: L.embed_at_level(omega[3], 1)
Lambda[3]

sage: L.embed_at_level(alpha[1], 1)

>>> from sage.all import *

>>> # needs sage.graphs

>>> L = RootSystem(["B",Integer(3),Integer(1)]).weight_space()

>>> L0 = L.classical()

>>> alpha = L0.simple_roots()

>>> omega = L0.fundamental_weights()

>>> L.embed_at_level(omega[Integer(1)], Integer(1))
Lambda[1]

>>> L.embed_at_level(omega[Integer(2)], Integer(1))
-Lambda[0] + Lambda[2]

>>> L.embed_at_level(omega[Integer(3)], Integer(1))
Lambda[3]

>>> L.embed_at_level(alpha[Integer(1)], Integer(1))

fundamental_weight(i)

Returns the $i^{th}$ fundamental weight

INPUT:

• $i$ – an element of the index set

By a slight notational abuse, for an affine type this method should also accept "delta" as input, and return the image of $\delta$ of the extended weight lattice in this realization.

This should be overridden by any subclass, and typically be implemented as a cached method for efficiency.

EXAMPLES:

sage: L = RootSystem(["A",3]).ambient_lattice()

sage: L.fundamental_weight(1)
(1, 0, 0, 0)

sage: L = RootSystem(["A",3,1]).weight_lattice(extended=True)

sage: L.fundamental_weight(1)
Lambda[1]

sage: L.fundamental_weight("delta")
delta

>>> from sage.all import *

>>> L = RootSystem(["A",Integer(3)]).ambient_lattice()

>>> L.fundamental_weight(Integer(1))
(1, 0, 0, 0)

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> L = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(extended=True)
>>> L.fundamental_weight(Integer(1))
Lambda[1]
>>> L.fundamental_weight("delta")
delta
```

**fundamental_weights()**

Returns the family \( (\Lambda_i)_{i \in I} \) of the fundamental weights.

**EXAMPLES:**

```python
sage: e = RootSystem(['A', 3]).ambient_lattice()
sage: f = e.fundamental_weights()
sage: [f[i] for i in [1, 2, 3]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

```python
>>> from sage.all import *
>>> e = RootSystem(['A', Integer(3)]).ambient_lattice()
>>> f = e.fundamental_weights()
>>> [f[i] for i in [Integer(1), Integer(2), Integer(3)]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

**is_extended()**

Return whether this is a realization of the extended weight lattice

See also:

`sage.combinat.root_system.weight_space.WeightSpace`

**EXAMPLES:**

```python
sage: RootSystem(['A', 3, 1]).weight_lattice().is_extended()
False
sage: RootSystem(['A', 3, 1]).weight_lattice(extended=True).is_extended()
True
```

```python
>>> from sage.all import *
>>> RootSystem(['A', 3, 1]).weight_lattice().is_extended()
False
>>> RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(extended=True).is_extended()
True
```

This method is irrelevant for finite root systems, since the weight lattice need not be extended to ensure that the root lattice embeds faithfully:

```python
sage: RootSystem(['A', 3]).weight_lattice().is_extended()
False
```

```python
>>> from sage.all import *
>>> RootSystem(['A', Integer(3)]).weight_lattice().is_extended()
False
```

**reduced_word_of_alcove_morphism(f)**

Return the reduced word of an alcove morphism.
INPUT:

• $f$ - a linear map from self to self which preserves alcoves

Let $A$ be the fundamental alcove. This returns a reduced word $i_1, \ldots, i_k$ such that the affine Weyl group element $w = s_{i_1} \circ \cdots \circ s_{i_k}$ maps the alcove $f(A)$ back to $A$. In other words, the alcove walk $i_1, \ldots, i_k$ brings the fundamental alcove to the corresponding translated alcove.

Let us throw in a bit of context to explain the main use case. It is customary to realize the alcove picture in the coroot or coweight lattice $R^\vee$. The extended affine Weyl group is then the group of linear maps on $R^\vee$ which preserve the alcoves. By [Kac “Infinite-dimensional Lie algebra”, Proposition 6.5] the affine Weyl group is the semidirect product of the associated finite Weyl group and the group of translations in the coroot lattice (the extended affine Weyl group uses the coweight lattice instead). In other words, an element of the extended affine Weyl group admits a unique decomposition of the form:

$$f = dw,$$

where $w$ is in the Weyl group, and $d$ is a function which maps the fundamental alcove to itself. As $d$ permutes the walls of the fundamental alcove, it permutes accordingly the corresponding simple roots, which induces an automorphism of the Dynkin diagram.

This method returns a reduced word for $w$, whereas the method `dynkin_diagram_automorphism_of_alcove_morphism()` returns $d$ as a permutation of the nodes of the Dynkin diagram.

Nota bene: recall that the coroot (resp. coweight) lattice is implemented as the root (resp weight) lattice of the dual root system. Hence, this method is implemented for weight lattice realizations, but in practice is most of the time used on the dual side.

EXAMPLES:

We start with type $A$ which is simply laced; hence we do not have to worry about the distinction between the weight and coweight lattice:

```python
sage: R = RootSystem("A",2,1).weight_lattice()
sage: alpha = R.simple_roots() # needs sage.graphs
data: Lambda = R.fundamental_weights()

>>> from sage.all import *
>>> R = RootSystem("A",Integer(2),Integer(1)).weight_lattice()
>>> alpha = R.simple_roots() # needs sage.graphs
>>> Lambda = R.fundamental_weights()
```

We consider first translations by elements of the root lattice:

```python
sage: R.reduced_word_of_alcove_morphism(alpha[0].translation) # needs sage.graphs
[1, 2, 1, 0]
sage: R.reduced_word_of_alcove_morphism(alpha[1].translation) # needs sage.graphs
[0, 2, 0, 1]
sage: R.reduced_word_of_alcove_morphism(alpha[2].translation) # needs sage.graphs
[0, 1, 0, 2]
```

```python
>>> from sage.all import *
>>> R.reduced_word_of_alcove_morphism(alpha[Integer(0)].translation) # needs sage.graphs
[1, 2, 1, 0]
```

(continues on next page)
We continue with translations by elements of the classical weight lattice, embedded at level 0:

```
sage: R.reduced_word_of_translation(omega1.translation) # needs sage.graphs [0, 2]
sage: R.reduced_word_of_translation(omega2.translation) # needs sage.graphs [0, 1]
```

The following tests ensure that the code agrees with the tables in Kashiwara's private notes on affine quantum algebras (2008).

```
EXAMPLES:
```

```
sage: # needs sage.graphs
sage: R = RootSystem(['A',2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.reduced_word_of_translation(alpha[1])
[0, 2, 0, 1]
sage: R.reduced_word_of_translation(alpha[2])
[0, 1, 0, 2]
sage: R.reduced_word_of_translation(alpha[0])
[1, 2, 1, 0]
sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: R.reduced_word_of_translation(omega1)
[0, 2, 3, 4, 5, 3, 2, 0]
sage: R.reduced_word_of_translation(omega2)
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> R = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice()
>>> alpha = R.simple_roots()
>>> R.reduced_word_of_translation(alpha[Integer(1)])
[0, 2, 0, 1]
>>> R.reduced_word_of_translation(alpha[Integer(2)])
[0, 1, 0, 2]
>>> R.reduced_word_of_translation(alpha[Integer(0)])
```

(continues on next page)
\[ [1, 2, 1, 0] \]

```python
>>> R = RootSystem(['D',Integer(5),Integer(1)]).weight_lattice()
>>> Lambda = R.fundamental_weights()
>>> omega1 = Lambda[Integer(1)] - Lambda[Integer(0)]
>>> omega2 = Lambda[Integer(2)] - Integer(2)*Lambda[Integer(0)]
>>> R.reduced_word_of_translation(omega1)  # needs sage.graphs
[0, 2, 3, 4, 5, 3, 2, 0]
>>> R.reduced_word_of_translation(omega2)  # needs sage.graphs
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

A non simply laced case:

```python
sage: R = RootSystem(['C',2,1]).weight_lattice()
 sage: Lambda = R.fundamental_weights()
 sage: c = R.cartan_type().translation_factors(); c  # needs sage.graphs
 Finite family {0: 1, 1: 2, 2: 1}
 sage: R.reduced_word_of_translation((Lambda[1]-Lambda[0]) * c[1])  # needs sage.graphs
[0, 1, 2, 1]
 sage: R.reduced_word_of_translation((Lambda[2]-Lambda[0]) * c[2])  # needs sage.graphs
[0, 1, 0]
```

See also `_test_reduced_word_of_translation()`.

**Todo:**
- Add a picture in the doc
- Add a method which, given an element of the classical weight lattice, constructs the appropriate value for \( \rho \)

**rho()**

**EXAMPLES:**

```python
sage: RootSystem(['A',3]).ambient_lattice().rho()
(3, 2, 1, 0)
```
rho_classical()

Return the embedding at level 0 of $\rho$ of the classical lattice.

EXAMPLES:

```python
sage: RootSystem(['C', 4, 1]).weight_lattice().rho_classical()
```

```python
sage: L = RootSystem(['D', 4, 1]).weight_lattice()
sage: L.rho_classical().scalar(L.null_coroot())
0
```

**Warning:** In affine type BC dual, this does not live in the weight lattice:

```python
sage: L = CartanType(['BC', 2, 2]).dual().root_system().weight_space()
sage: L.rho_classical()
```

```python
sage: L = CartanType(['BC', 2, 2]).dual().root_system().weight_lattice()
sage: L.rho_classical()
Traceback (most recent call last):
  ... Value Error: 5 is not divisible by 2
```

signs_of_alcove_walk(walk)

Let $\text{walk} = [i_1, \ldots, i_n]$ denote an alcove walk starting from the fundamental alcove $y_0$, crossing at step
1 the wall $i_1$, and so on.

For each $k$, set $w_k = s_{i_1} \circ s_{i_k}$, and denote by $y_k = w_k(y_0)$ the alcove reached after $k$ steps. Then, $y_k$ is obtained recursively from $y_{k-1}$ by applying the following reflection:

$$y_k = s_{w_{k-1} \alpha_{i_k}} y_{k-1}.$$ 

The step is said positive if $w_{k-1} \alpha_{i_k}$ is a negative root (considering $w_{k-1}$ as element of the classical Weyl group and $\alpha_{i_k}$ as a classical root) and negative otherwise. The algorithm implemented here use the equivalent property:

.. MATH:: $\langle w_{k-1}^{-1} \rho_0, \alpha^\vee_{i_k}\rangle > 0$

Where $\rho_0$ is the sum of the classical fundamental weights embedded at level 0 in this space (see rho_classical()), and $\alpha^\vee_{i_k}$ is the simple coroot associated to $\alpha_{i_k}$.

This function returns a list of the form [+1, +1, −1, ...], where the $k^{th}$ entry denotes whether the $k^{th}$ step was positive or negative.

See equation 3.4, of Ram: Alcove walks ..., arXiv:math/0601343v1

EXAMPLES:

```python
sage: L = RootSystem(['C',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([1,2,0,1,2,0,0,1,2])
[-1, -1, 1, -1, 1, 1, 1, 1, 1]
```

```python
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,1,2,0,1,2,0])
[1, 1, 1, -1, 1, -1, 1, -1, 1]
```

```python
sage: L = RootSystem(['B',2,1]).coweight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,0,1])
[1, -1, 1, -1, 1]
```

```python
>>> from sage.all import *
```

```python
>>> L = RootSystem(['C',Integer(2),Integer(1)]).weight_lattice()
>>> L.signs_of_alcovewalk([Integer(1),Integer(2),Integer(0),Integer(1),
\*\* Integer(2),Integer(1),Integer(2),Integer(0),Integer(1),Integer(2)])
[-1, -1, 1, -1, 1, 1, 1, 1, 1, 1]
```

```python
>>> L = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice()
>>> L.signs_of_alcovewalk([Integer(0),Integer(1),Integer(2),Integer(1),
\*\* Integer(2),Integer(0),Integer(1),Integer(2),Integer(0),Integer(1),Integer(2)])
[1, 1, 1, -1, 1, -1, 1, -1, 1]
```

```python
>>> L = RootSystem(['B',Integer(2),Integer(1)]).coweight_lattice()
>>> L.signs_of_alcovewalk([Integer(0),Integer(1),Integer(2),Integer(0),
\*\* Integer(1),Integer(2)])
[1, -1, 1, -1, 1]
```
**Warning:** This method currently does not work in the weight lattice for type BC dual because $\rho_0$ does not live in this lattice (but an integral multiple of it would do the job as well).

**simple_root**(i)

Returns the $i$-th simple root

This default implementation takes the $i$-th simple root in the weight lattice and embeds it in `self`.

**EXAMPLES:**

Since all the weight lattice realizations in Sage currently implement a `simple_root` method, we have to call this one by hand:

```python
sage: from sage.combinat.root_system.weight_lattice_realizations import...
   - WeightLatticeRealizations
sage: simple_root = WeightLatticeRealizations(QQ).parent_class.simple_
   root.f
sage: L = RootSystem("A3").ambient_space()
sage: simple_root(L, 1)  # needs sage.graphs
(1, -1, 0, 0)
sage: simple_root(L, 2)  # needs sage.graphs
(0, 1, -1, 0)
sage: simple_root(L, 3)  # needs sage.graphs
(1, 1, 2, 0)
```

Note that this last root differs from the one implemented in $L$ by a multiple of the vector $(1, 1, 1, 1)$:

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.weight_lattice_realizations import...
   - WeightLatticeRealizations
>>> simple_root = WeightLatticeRealizations(QQ).parent_class.simple_root.f
>>> L = RootSystem("A3").ambient_space()
>>> simple_root(L, Integer(1))  # needs sage.graphs
(1, -1, 0, 0)
>>> simple_root(L, Integer(2))  # needs sage.graphs
(0, 1, -1, 0)
>>> simple_root(L, Integer(3))  # needs sage.graphs
(1, 1, 2, 0)
```

This is a harmless artefact of the SL versus GL interpretation of type $A$; see the thematic tutorial on Lie Methods and Related Combinatorics in Sage for details.
weyl_dimension \((\text{highest\_weight})\)

Return the dimension of the highest weight representation of \text{highest\_weight}.

EXAMPLES:

```
sage: RootSystem(['A',3]).ambient_lattice().weyl_dimension([2,1,0,0])
20
sage: P = RootSystem(['C',2]).weight_lattice()
sage: La = P.basis()
sage: P.weyl_dimension(La[1]+La[2]) # needs sage.graphs
16
sage: type(RootSystem(['A',3]).ambient_lattice().weyl_dimension([2,1,0,0]))
<class 'sage.rings.integer.Integer'>
```

```
>>> from sage.all import *
>>> RootSystem(['A',Integer(3)]).ambient_lattice().weyl_dimension([Integer(2),Integer(1),Integer(0),Integer(0)])
20
>>> P = RootSystem(['C',Integer(2)]).weight_lattice()
>>> La = P.basis()
>>> P.weyl_dimension(La[Integer(1)]+La[Integer(2)]) # needs sage.graphs
16
>>> type(RootSystem(['A',Integer(3)]).ambient_lattice().weyl_dimension([Integer(2),Integer(1),Integer(0),Integer(0)]))
<class 'sage.rings.integer.Integer'>
```

```
sage: from sage.combinat.root_system.weight_lattice_realizations import WeightLatticeRealizations
sage: WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```

```
>>> from sage.all import *
>>> from sage.combinat.root_system.weight_lattice_realizations import WeightLatticeRealizations
>>> WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```

5.1.271 Weight lattices and weight spaces

```
class sage.combinat.root_system.weight_space.WeightSpace(root_system, base_ring, extended)
```

INPUT:

- \text{root\_system} – a root system
- \text{base\_ring} – a ring \(R\)
• **extended** — a boolean (default: False)

The weight space (or lattice if `base_ring` is \( \mathbb{Z} \)) of a root system is the formal free module \( \bigoplus_i R \Lambda_i \) generated by the fundamental weights \( \{ \Lambda_i \}_{i \in I} \) of the root system.

This class is also used for coweight spaces (or lattices).

**See also:**

- `RootSystem()`
- `RootSystem.weight_lattice()` and `RootSystem.weight_space()`
- `WeightLatticeRealizations()`

**EXAMPLES:**

```
sage: Q = RootSystem(['A', 3]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3]
sage: Q.simple_roots()  # needs sage.graphs
Finite family {1: 2*Lambda[1] - Lambda[2],
```

```
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3, 1]
sage: Q.simple_roots()  # needs sage.graphs
Finite family {0: 2*Lambda[0] - Lambda[1] - Lambda[3],
               1: -Lambda[0] + 2*Lambda[1] - Lambda[2],
```

```python
>>> from sage.all import *
>>> Q = RootSystem(['A', Integer(3)]).weight_lattice(); Q
>>> Q.simple_roots()  # needs sage.graphs
Finite family {1: 2*Lambda[1] - Lambda[2],
```

```python
>>> Q = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(); Q
>>> Q.simple_roots()  # needs sage.graphs
Finite family {0: 2*Lambda[0] - Lambda[1] - Lambda[3],
               1: -Lambda[0] + 2*Lambda[1] - Lambda[2],
```

For infinite types, the Cartan matrix is singular, and therefore the embedding of the root lattice is not faithful:

```
sage: sum(Q.simple_roots())  # needs sage.graphs
0
```
In particular, the null root is zero:

```
>>> from sage.all import *
>>> sum(Q.simple_roots())  #...
˓→needs sage.graphs
0
```

This can be compensated by extending the basis of the weight space and slightly deforming the simple roots to make them linearly independent, without affecting the scalar product with the coroots. This feature is currently only implemented for affine types. In that case, if extended is set, then the basis of the weight space is extended by an element $\delta$:

```
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended=True); Q
Extended weight lattice of the Root system of type ['A', 3, 1]
sage: Q.basis().keys()
{0, 1, 2, 3, 'delta'}
```

And the simple root $\alpha_0$ associated to the special node is deformed as follows:

```
sage: Q.simple_roots()  #...
˓→needs sage.graphs
  1: -Lambda[0] + 2*Lambda[1] - Lambda[2],
```

Now, the null root is nonzero:

```
sage: Q.null_root()  #...
˓→needs sage.graphs
delta
```
Warning: By a slight notational abuse, the extra basis element used to extend the fundamental weights is called \( \delta \) in the current implementation. However, in the literature, \( \delta \) usually denotes instead the null root. Most of the time, those two objects coincide, but not for type \( BC \) (aka. \( A_{2n}^{(2)} \)). Therefore we currently have:

```python
>>> from sage.all import *
>>> Q.null_root()
# needs sage.graphs
\delta
```

```python
sage: Q = RootSystem(["A", 4, 2]).weight_lattice(extended=True)
sage: Q.simple_root(0)  # needs sage.graphs
2*Lambda[0] - Lambda[1] + \delta
sage: Q.null_root()  # needs sage.graphs
2*\delta
```

whereas, with the standard notations from the literature, one would expect to get respectively

\[ 2\Lambda_0 - \Lambda_1 + \frac{1}{2}\delta \]

and \( \delta \).

Other than this notational glitch, the implementation remains correct for type \( BC \).

The notations may get improved in a subsequent version, which might require changing the index of the extra basis element. To guarantee backward compatibility in code not included in Sage, it is recommended to use the following idiom to get that index:

```python
sage: F = Q.basis_extension(); F
Finite family {\delta: \delta}
sage: index = F.keys()[0]; index
\delta
```

Then, for example, the coefficient of an element of the extended weight lattice on that basis element can be recovered with:

```python
>>> from sage.all import *
>>> Q.null_root()[index]  # needs sage.graphs
2
```

```python
sage: Q.null_root()[index]  # needs sage.graphs
2
```
Element
     alias of WeightSpaceElement

basis_extension()
     Return the basis elements used to extend the fundamental weights

     EXAMPLES:

     sage: Q = RootSystem("A",3,1).weight_lattice()
     sage: Q.basis_extension()
     Family ()

     sage: Q = RootSystem("A",3,1).weight_lattice(extended=True)
     sage: Q.basis_extension()
     Finite family {delta: delta}

     >>> from sage.all import *
     >>> Q = RootSystem("A",Integer(3),Integer(1)).weight_lattice()
     >>> Q.basis_extension()
     Family ()

     >>> Q = RootSystem("A",Integer(3),Integer(1)).weight_lattice(extended=True)
     >>> Q.basis_extension()
     Finite family {delta: delta}

     This method is irrelevant for finite types:

     sage: Q = RootSystem("A",3).weight_lattice()
     sage: Q.basis_extension()
     Family ()

     >>> from sage.all import *
     >>> Q = RootSystem("A",Integer(3)).weight_lattice()
     >>> Q.basis_extension()
     Family ()

fundamental_weight(i)
     Returns the \( i \)-th fundamental weight

     INPUT:

     - \( i \) – an element of the index set or "delta"

     By a slight notational abuse, for an affine type this method also accepts "delta" as input, and returns the image of \( \delta \) of the extended weight lattice in this realization.

     See also:

     fundamental_weight()

     EXAMPLES:

     sage: Q = RootSystem("A",3).weight_lattice()
     sage: Q.fundamental_weight(1)
     Lambda[1]

     >>> from sage.all import *
     >>> Q = RootSystem("A",Integer(3)).weight_lattice()
     >>> Q.fundamental_weight(1)
     Lambda[1]

     sage: Q = RootSystem("A",3,1).weight_lattice(extended=True)
     sage: Q.fundamental_weight(1)
     Lambda[1]

     (continues on next page)
Combinatorics, Release 10.4

```python
sage: Q.fundamental_weight("delta")
delta
```

```python
>>> from sage.all import *

```python
>>> Q = RootSystem(["A",Integer(3)]).weight_lattice()
```

```python
>>> Q.fundamental_weight(Integer(1))
Lambda[1]
```

```python
>>> Q = RootSystem(["A",Integer(3),Integer(1)]).weight_lattice(extended=True)
```

```python
>>> Q.fundamental_weight(Integer(1))
Lambda[1]
```

```python
>>> Q.fundamental_weight("delta")
delta
```

is_extended()

Return whether this is an extended weight lattice.

See also:

is_extended()

EXAMPLES:

```python
sage: RootSystem(["A",3,1]).weight_lattice().is_extended()
False
```

```python
sage: RootSystem(["A",3,1]).weight_lattice(extended=True).is_extended()
True
```

```python
>>> from sage.all import *

```python
>>> Q = RootSystem(["A",Integer(3),Integer(1)]).weight_lattice().is_extended()
False
```

```python
>>> Q = RootSystem(["A",Integer(3),Integer(1)]).weight_lattice(extended=True).is_˓→extended()
True
```

simple_root(j)

Returns the $j^{th}$ simple root

EXAMPLES:

```python
sage: L = RootSystem(["C",4]).weight_lattice()
sage: L.simple_root(3)  # needs sage.graphs
```

```python
>>> L = RootSystem(["C",Integer(4)]).weight_lattice()
```

```python
>>> L.simple_root(Integer(3))  # needs sage.graphs
```

Its coefficients are given by the corresponding column of the Cartan matrix:

```python
sage: L.cartan_type().cartan_matrix()[:,2]  # needs sage.graphs
[ 0]
```

(continues on next page)
Here are all simple roots:

```python
sage: L.simple_roots()
# needs sage.graphs
Finite family {1: 2*Lambda[1] - Lambda[2],
```

For the extended weight lattice of an affine type, the simple root associated to the special node is deformed by adding \( \delta \), where \( \delta \) is the null root:

```python
sage: L = RootSystem(['C',4,1]).weight_lattice(extended=True)
sage: L.simple_root(0)
# needs sage.graphs
```

In fact \( \delta \) is really \( 1/a_0 \) times the null root (see the discussion in `WeightSpace`) but this only makes a difference in type \( BC \):
>>> from sage.all import *
>>> L = RootSystem(CartanType(["BC",Integer(4),Integer(2)])).weight_lattice(extended=True)
>>> L.simple_root(Integer(0))  # needs sage.graphs
2*Lambda[0] - Lambda[1] + delta
>>> L.null_root()  # needs sage.graphs
2*delta

See also:

- simple_root()
- CartanType.col_annihilator()

to_ambient_space_morphism()

The morphism from self to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A',2]).root_system().weight_lattice().to_ambient_space_morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To: Ambient space of the Root system of type ['A', 2]
```

```
>>> from sage.all import *
>>> CartanType(['A',Integer(2)]).root_system().weight_lattice().to_ambient_space_morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To: Ambient space of the Root system of type ['A', 2]
```

**Warning:** Implemented only for finite Cartan type.

```
class sage.combinat.root_system.weight_space.WeightSpaceElement
    Bases: IndexedFreeModuleElement

    is_dominant()

    Checks whether an element in the weight space lies in the positive cone spanned by the basis elements (fundamental weights).

    EXAMPLES:

    sage: W = RootSystem(['A',3]).weight_space()
sage: Lambda = W.basis()
sage: w = Lambda[1] + Lambda[3]
sage: w.is_dominant()
    True
sage: w.is_dominant()
    False
```

4356 Chapter 5. Comprehensive Module List
```python
>>> from sage.all import *
>>> W = RootSystem(['A',Integer(3)]).weight_space()
>>> Lambda = W.basis()
>>> w = Lambda[Integer(1)] + Lambda[Integer(3)]
>>> w.is_dominant()
True
>>> w = Lambda[Integer(1)] - Lambda[Integer(2)]
>>> w.is_dominant()
False
```

In the extended affine weight lattice, ‘delta’ is orthogonal to the positive coroots, so adding or subtracting it should not affect dominance

```python
sage: P = RootSystem(['A','2','1']).weight_lattice(extended=true)
sage: Lambda = P.fundamental_weights()
sage: delta = P.null_root()  # needs sage.graphs
sage: w = Lambda[1] - delta  # needs sage.graphs
sage: w.is_dominant()  # needs sage.graphs
True
```

```python
>>> from sage.all import *
>>> P = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true)
>>> Lambda = P.fundamental_weights()
>>> delta = P.null_root()  # needs sage.graphs
>>> w = Lambda[Integer(1)] - delta  # needs sage.graphs
>>> w.is_dominant()  # needs sage.graphs
True
```

`scalar(lambdacheck)`

The canonical scalar product between the weight lattice and the coroot lattice.

**Todo:**

- merge with apply_multi_module_morphism
- allow for any root space / lattice
- define properly the return type (depends on the base rings of the two spaces)
- make this robust for extended weight lattices (i might be “delta”)

**EXAMPLES:**

```python
sage: L = RootSystem(['C',4,1]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: alphacheck = L.simple_coroots()
sage: Lambda[1].scalar(alphacheck[1])
1
sage: Lambda[1].scalar(alphacheck[2])
0
```
>>> from sage.all import *
>>> L = RootSystem(["C", Integer(4), Integer(1)]).weight_lattice()
>>> Lambda = L.fundamental_weights()
>>> alphacheck = L.simple_coroots()
>>> Lambda[Integer(1)].scalar(alphacheck[Integer(1)])
1
>>> Lambda[Integer(1)].scalar(alphacheck[Integer(2)])
0
The fundamental weights and the simple coroots are dual bases:

```
sage: matrix([ [ Lambda[i].scalar(alphacheck[j])
        ....: for i in L.index_set() ]
        ....: for j in L.index_set() ])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

Note that the scalar product is not yet implemented between the weight space and the coweight space; in any cases, that won’t be the job of this method:

```
sage: R = RootSystem(["A",3])
sage: alpha = R.weight_space().roots() # needs sage.graphs
sage: alphacheck = R.coweight_space().roots() # needs sage.graphs
sage: alpha[1].scalar(alphacheck[1]) # needs sage.graphs
Traceback (most recent call last):
...
is not in the coroot space
```

```
to_ambient()  
Maps self to the ambient space.

EXAMPLES:

```python
sage: mu = CartanType(['B',2]).root_system().weight_lattice().an_element(); mu
sage: mu.to_ambient()
(3, 1)
```

```
>>> from sage.all import *

>>> mu = CartanType(['B',Integer(2)]).root_system().weight_lattice().an_element(); mu
```

```
>>> mu.to_ambient()
(3, 1)
```

**Warning:** Only implemented in infinite Cartan type. Does not work for coweight lattices because there is no implemented map from the coweight lattice to the ambient space.

to_weight_space()  
Map self to the weight space.

Since self.parent() is the weight space, this map just returns self. This overrides the generic method in WeightSpaceRealizations.

EXAMPLES:

```python
sage: mu = CartanType(['A',2]).root_system().weight_lattice().an_element(); mu
sage: mu.to_weight_space()
```

```
>>> from sage.all import *

>>> mu = CartanType(['A',Integer(2)]).root_system().weight_lattice().an_element(); mu
```

```
>>> mu.to_weight_space()
```

5.1.272 Weyl Character Rings

class sage.combinat.root_system.weyl_characters.WeightRing (parent, prefix)  

Bases: CombinatorialFreeModule

The weight ring, which is the group algebra over a weight lattice.

A Weyl character may be regarded as an element of the weight ring. In fact, an element of the weight ring is an element of the Weyl character ring if and only if it is invariant under the action of the Weyl group.

The advantage of the weight ring over the Weyl character ring is that one may conduct calculations in the weight ring that involve sums of weights that are not Weyl group invariant.

EXAMPLES:
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: wd = prod(a2(x/2)-a2(-x/2) for x in a2.space().positive_roots()); wd
a2(-1,1,0) - a2(-1,0,1) - a2(1,-1,0) + a2(1,0,-1) + a2(0,-1,1) - a2(0,1,-1)

sage: chi = A2([5,3,0]); chi
A2(5,3,0)

sage: a2(chi)
a2(1,2,5) + 2*a2(1,3,4) + 2*a2(1,4,3) + a2(1,5,2) + a2(2,1,5)
+ 2*a2(2,2,4) + 3*a2(2,3,3) + 2*a2(2,4,2) + a2(2,5,1) + 2*a2(3,1,4)
+ 3*a2(3,2,3) + 3*a2(3,3,2) + 2*a2(3,4,1) + a2(3,5,0) + a2(3,0,5)
+ 2*a2(4,1,3) + 2*a2(4,2,2) + 2*a2(4,3,1) + a2(4,4,0) + a2(4,0,4)
+ a2(5,1,2) + a2(5,2,1) + a2(5,3,0) + a2(5,0,3) + a2(0,3,5)
+ a2(0,4,4) + a2(0,5,3)

sage: a2(chi)*wd
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)

sage: sum((-1)**w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().weyl_group())
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)

sage: a2(chi)*wd == sum((-1)**w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().weyl_group())
True
sage: A2 = WeylCharacterRing("A2")

>>> from sage.all import *

>>> A2 = WeylCharacterRing("A2")

character()

Assuming that self is invariant under the Weyl group, this will express it as a linear combination of characters. If self is not Weyl group invariant, this method will not terminate.

EXAMPLES:

sage: A2 = WeylCharacterRing([A,Integer(2)])

demazure(w, debug=False)

Return the result of applying the Demazure operator $\partial_w$ to self.

INPUT:

• w – a Weyl group element, or its reduced word

If $w = s_i$ is a simple reflection, the operation $\partial_w$ sends the weight $\lambda$ to

$$
\frac{\lambda - s_i \cdot \lambda + \alpha_i}{1 + \alpha_i},
$$

where the numerator is divisible the denominator in the weight ring. This is extended by multiplicativity to all $w$ in the Weyl group.

EXAMPLES:

sage: B2 = WeylCharacterRing("B2", style="coroots")

(continues on next page)
demazure_lusztig($i, v$)

Return the result of applying the Demazure-Lusztig operator $T_i$ to self.

**INPUT:**
- $i$ – an element of the index set (or a reduced word or Weyl group element)
- $v$ – an element of the base ring

If $R$ is the parent WeightRing, the Demazure-Lusztig operator $T_i$ is the linear map $R \rightarrow R$ that sends (for a weight $\lambda$) $R(\lambda)$ to

$$R(\lambda) - \frac{1}{(R(\lambda) - R(s_i \lambda) - v(R(\lambda) - R(\alpha_i + s_i \lambda)))}$$

where the numerator is divisible by the denominator in $R$. The Demazure-Lusztig operators give a representation of the Iwahori–Hecke algebra associated to the Weyl group. See

In the examples, we confirm the braid and quadratic relations for type $B_2$.

**EXAMPLES:**

```python
sage: P.<v> = PolynomialRing(QQ)
sage: B2 = WeylCharacterRing("B2", style="coroots", base_ring=P); b2 = B2.ambient()
sage: def T1(f):
    return f.demazure_lusztig(1,v)
sage: def T2(f):
    return f.demazure_lusztig(2,v)
sage: T1(T2(T1(T2(b2(1,-1))))) (v^2-v)*b2(0,-1) + v^2*b2(-1,1)
sage: [T1(T1(f))==(v-1)*T1(f)+v*f for f in [b2(0,0), b2(1,0), b2(2,3)]] [True, True, True]
sage: [T1(T2(T1(T2(b2(i,j)))))) == T2(T1(T2(T1(b2(i,j)))))) for i in [-2..-2] for j in [-1,1]] [True, True, True, True, True, True, True, True, True, True]
```

>>> from sage.all import *

```python
>>> P = PolynomialRing(QQ, names=('v',)); (v,)=P._first_ngens(1)
```
```python
>>> ambient()
```
• \( \mu \) – a weight

**EXAMPLES:**

```
sage: g2 = WeylCharacterRing("G2", style="coroots").ambient()
sage: [g2(1,2).shift(fw) for fw in g2.fundamental_weights()]
[g2(2,2), g2(1,3)]
```

```
>>> from sage.all import *

>>> g2 = WeylCharacterRing("G2", style="coroots").ambient()

>>> [g2(Integer(1),Integer(2)).shift(fw) for fw in g2.fundamental_weights()]
[g2(2,2), g2(1,3)]
```

**weyl_group_action** (\( w \))

Return the action of the Weyl group element \( w \) on \( \text{self} \).

**EXAMPLES:**

```
sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: L = g2.space()
sage: [fw1, fw2] = L.fundamental_weights()
sage: sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-2) + 2*g2(2,-1,-1)
```

```
>>> from sage.all import *

>>> G2 = WeylCharacterRing(['G',Integer(2)])

>>> g2 = WeightRing(G2)

>>> L = g2.space()

>>> [fw1, fw2] = L.fundamental_weights()

>>> sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-2) + 2*g2(2,-1,-1)
```

**cartan_type** ()

Return the Cartan type.

**EXAMPLES:**

```
sage: A2 = WeylCharacterRing("A2")

sage: WeightRing(A2).cartan_type()
['A', 2]
```

```
>>> from sage.all import *

>>> A2 = WeylCharacterRing("A2")

>>> WeightRing(A2).cartan_type()
['A', 2]
```

**fundamental_weights** ()

Return the fundamental weights.

**EXAMPLES:**

```
sage: WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```
```python
>>> from sage.all import *
>>> WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

one_basis()

Return the index of 1.

EXAMPLES:

```python
sage: A3 = WeylCharacterRing("A3")
sage: WeightRing(A3).one_basis()
(0, 0, 0, 0)
sage: WeightRing(A3).one()
a3(0,0,0,0)
```

parent()

Return the parent Weyl character ring.

EXAMPLES:

```python
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.parent()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: a2.parent() == A2
True
```

positive_roots()

Return the positive roots.

EXAMPLES:

```python
sage: WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

product_on_basis(a, b)

Return the product of basis elements indexed by a and b.

```python
>>> from sage.all import *
>>> WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```
EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2(1,0,0) * a2(0,1,0)  # indirect doctest
a2(1,1,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> a2(Integer(1),Integer(0),Integer(0)) * a2(Integer(0),Integer(0),Integer(1),
... Integer(0))  # indirect doctest
a2(1,1,0)
```

```
simple_roots()  
Return the simple roots.
EXAMPLES:
```
sage: WeightRing(WeylCharacterRing("G2")).simple_roots()  
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

```
>>> from sage.all import *
>>> WeightRing(WeylCharacterRing("G2")).simple_roots()  
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

```
some_elements()  
Return some elements of self.
EXAMPLES:
```
sage: A3 = WeylCharacterRing("A3")
sage: a3 = WeightRing(A3)
sage: a3.some_elements()
[a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

```
>>> from sage.all import *
>>> A3 = WeylCharacterRing("A3")
>>> a3 = WeightRing(A3)
>>> a3.some_elements()
[a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

```
space()  
Return the weight space realization associated to self.
EXAMPLES:
```
sage: E8 = WeylCharacterRing([\'E\',8])
sage: e8 = WeightRing(E8)
sage: e8.space()  
Ambient space of the Root system of type [\'E\', 8]
```

```
>>> from sage.all import *
>>> E8 = WeylCharacterRing([\'E\',Integer(8)])
>>> e8 = WeightRing(E8)
>>> e8.space()  
Ambient space of the Root system of type [\'E\', 8]
```
weyl_character_ring()

Return the parent Weyl Character Ring.

A synonym for self.parent().

EXAMPLES:

```python
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.weyl_character_ring()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

wt_repr(wt)

Return a string representing the irreducible character with highest weight vector wt.

Uses coroot notation if the associated Weyl character ring is defined with style="coroots".

EXAMPLES:

```python
sage: G2 = WeylCharacterRing("G2")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
["g2(1,0,-1)", "g2(2,-1,-1)"]
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
["g2(1,0)", "g2(0,1)"
```

class sage.combinat.root_system.weyl_characters.WeylCharacterRing (ct, base_ring=Integer Ring, prefix=None, style='lattice', k=None, conjugate=False, cyclotomic_order=None, fusion_labels=None, inject_variables=False)

Bases: CombinatorialFreeModule

A class for rings of Weyl characters.
Let $K$ be a compact Lie group, which we assume is semisimple and simply-connected. Its complexified Lie algebra $L$ is the Lie algebra of a complex analytic Lie group $G$. The following three categories are equivalent: finite-dimensional representations of $K$; finite-dimensional representations of $L$; and finite-dimensional analytic representations of $G$. In every case, there is a parametrization of the irreducible representations by their highest weight vectors. For this theory of Weyl, see (for example):

- Adams, *Lectures on Lie groups*
- Broecker and Tom Dieck, *Representations of Compact Lie groups*
- Bump, *Lie Groups*
- Fulton and Harris, *Representation Theory*
- Goodman and Wallach, *Representations and Invariants of the Classical Groups*
- Hall, *Lie Groups, Lie Algebras and Representations*
- Humphreys, *Introduction to Lie Algebras and their representations*
- Procesi, *Lie Groups*
- Samelson, *Notes on Lie Algebras*
- Varadarajan, *Lie groups, Lie algebras, and their representations*
- Zhelobenko, *Compact Lie Groups and their Representations*.

Computations that you can do with these include computing their weight multiplicities, products (thus decomposing the tensor product of a representation into irreducibles) and branching rules (restriction to a smaller group).

There is associated with $K$, $L$ or $G$ as above a lattice, the weight lattice, whose elements (called weights) are characters of a Cartan subgroup or subalgebra. There is an action of the Weyl group $W$ on the lattice, and elements of a fixed fundamental domain for $W$, the positive Weyl chamber, are called dominant. There is for each representation a unique highest dominant weight that occurs with nonzero multiplicity with respect to a certain partial order, and it is called the highest weight vector.

**EXAMPLES:**

```python
sage: L = RootSystem("A2").ambient_space()
sage: [fw1,fw2] = L.fundamental_weights()
sage: R = WeylCharacterRing(["A",2], prefix="R")
sage: [R(1),R(fw1),R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

```python
>>> from sage.all import *
>>> L = RootSystem("A2").ambient_space()
>>> [fw1,fw2] = L.fundamental_weights()
>>> R = WeylCharacterRing(["A", Integer(2)], prefix="R")
>>> [R(Integer(1)),R(fw1),R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

Here $R(1)$, $R(fw1)$, and $R(fw2)$ are irreducible representations with highest weight vectors $0$, $\Lambda_1$, and $\Lambda_2$ respectively (the first two fundamental weights).

For type $A$ (also $G_2$, $F_4$, $E_6$ and $E_7$) we will take as the weight lattice not the weight lattice of the semisimple group, but for a larger one. For type $A$, this means we are concerned with the representation theory of $K = U(n)$ or $G = GL(n, \mathbb{C})$ rather than $SU(n)$ or $SU(n, \mathbb{C})$. This is useful since the representation theory of $GL(n)$ is ubiquitous, and also since we may then represent the fundamental weights (in `sage.combinat.root_system.root_system`) by vectors with integer entries. If you are only interested in $SL(3)$, say, use `WeylCharacterRing(["A",2])` as above but be aware that $R([a,b,c])$ and $R([a+1,b+1,c+1])$ represent the same character of $SL(3)$ since $R([1,1,1])$ is the determinant.
For more information, see the thematic tutorial *Lie Methods and Related Combinatorics in Sage*, available at:

### class Element

**Bases:** IndexedFreeModuleElement

A class for Weyl characters.

#### adams_operation(r)

Return the $r$-th Adams operation of `self`.

**INPUT:**

- $r$ – a positive integer

This is a virtual character, whose weights are the weights of `self`, each multiplied by $r$.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operator(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

#### adams_operator(r)

Return the $r$-th Adams operation of `self`.

**INPUT:**

- $r$ – a positive integer

This is a virtual character, whose weights are the weights of `self`, each multiplied by $r$.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operator(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

#### branch(S, rule='default')

Return the restriction of the character to the subalgebra.

If no rule is specified, we will try to specify one.

**INPUT:**

- $S$ – a Weyl character ring for a Lie subgroup or subalgebra
- rule – a branching rule

See `branch_weyl_character()` for more information about branching rules.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> A2(Integer(1),Integer(1),Integer(0)).adams_operator(Integer(3))
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```
sage: B3 = WeylCharacterRing(['B',3])
sage: A2 = WeylCharacterRing(['A',2])
sage: [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
 A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
 A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]

>>> from sage.all import *

B3 = WeylCharacterRing(['B',Integer(3)])
A2 = WeylCharacterRing(['A',Integer(2)])
>>> [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
 A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
 A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]

cartan_type()

Return the Cartan type of self.

EXAMPLES:

sage: A2 = WeylCharacterRing("A2")
sage: A2([1,0,0]).cartan_type()
['A', 2]

degree()

Return the degree of self.

This is the dimension of the associated module.

EXAMPLES:

sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]

>>> from sage.all import *

>>> B3 = WeylCharacterRing(['B',Integer(3)])
>>> [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]

dual()

The involution that replaces a representation with its contragredient. (For Fusion rings, this is the conjugation map.)

EXAMPLES:

sage: A3 = WeylCharacterRing("A3", style="coroots")
sage: A3(1,0,0)^2
A3(0,1,0) + A3(2,0,0)

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

sage: (A3(1,0,0)^2).dual()
A3(0,1,0) + A3(0,0,2)

>>> from sage.all import *
>>> A3 = WeylCharacterRing("A3", style="coroots")
>>> A3(Integer(1),Integer(0),Integer(0))**Integer(2)
A3(0,1,0) + A3(2,0,0)
>>> (A3(Integer(1),Integer(0),Integer(0))**Integer(2)).dual()
A3(0,1,0) + A3(0,0,2)

exterior_power(k)

Return the \(k\)-th exterior power of self.

INPUT:

- \(k\) - a nonnegative integer

The algorithm is based on the identity \(ke_k = \sum_{r=1}^{k} (-1)^{k-1} p_{k-r} e_{k-r}\) relating the power-sum and elementary symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation self, the \(e_k\) become exterior powers and the \(p_k\) become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

sage: B3 = WeylCharacterRing("B3",style="coroots")
sage: spin = B3(0,0,1)
sage: spin.exterior_power(6)
B3(1,0,0) + B3(0,1,0)

>>> from sage.all import *
>>> B3 = WeylCharacterRing("B3",style="coroots")
>>> spin = B3(Integer(0),Integer(0),Integer(1))
>>> spin.exterior_power(Integer(6))
B3(1,0,0) + B3(0,1,0)

exterior_square()

Return the exterior square of the character.

EXAMPLES:

sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: A2(1,0).exterior_square()
A2(0,1)

>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2",style="coroots")
>>> A2(Integer(1),Integer(0)).exterior_square()
A2(0,1)

frobenius_schur_indicator()

Return:

- 1 if the representation is real (orthogonal)
- \(-1\) if the representation is quaternionic (symplectic)
- 0 if the representation is complex (not self dual)

The Frobenius-Schur indicator of a character \(\chi\) of a compact group \(G\) is the Haar integral over the group of \(\chi(g^2)\). Its value is 1, -1 or 0. This method computes it for irreducible characters of compact Lie groups by checking whether the symmetric and exterior square characters contain the trivial character.

5.1. Comprehensive Module List
Todo: Try to compute this directly without actually calculating the full symmetric and exterior squares.

EXAMPLES:

```sage
sage: B2 = WeylCharacterRing("B2", style="coroots")
sage: B2(1,0).frobenius_schur_indicator()
1
sage: B2(0,1).frobenius_schur_indicator()
-1
```

```python
>>> from sage.all import *

>>> B2 = WeylCharacterRing("B2", style="coroots")

>>> B2(Integer(1),Integer(0)).frobenius_schur_indicator()
1

>>> B2(Integer(0),Integer(1)).frobenius_schur_indicator()
-1
```

**highest_weight()**

Return the parametrizing dominant weight of an irreducible character.

This method is only available for basis elements.

EXAMPLES:

```sage
sage: G2 = WeylCharacterRing("G2", style="coroots")
sage: [x.highest_weight() for x in [G2(1,0), G2(0,1)]]
[(1, 0, -1), (2, -1, -1)]
```

```python
>>> from sage.all import *

>>> G2 = WeylCharacterRing("G2", style="coroots")

>>> [x.highest_weight() for x in [G2(Integer(1),Integer(0)), G2(Integer(0), Integer(1))]]
[(1, 0, -1), (2, -1, -1)]
```

**inner_product**(other)

Compute the inner product with another character.

The irreducible characters are an orthonormal basis with respect to the usual inner product of characters, interpreted as functions on a compact Lie group, by Schur orthogonality.

INPUT:

• other — another character

EXAMPLES:

```sage
sage: A2 = WeylCharacterRing("A2")
sage: [f1,f2] = A2.fundamental_weights()
sage: r1 = A2(f1)*A2(f2); r1
A2(1,1,1) + A2(2,1,0)
sage: r2 = A2(f1)^3; r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
sage: r1.inner_product(r2)
3
```

```python
>>> from sage.all import *

>>> A2 = WeylCharacterRing("A2")

```
>>> [f1,f2] = A2.fundamental_weights()
>>> r1 = A2(f1)**A2(f2); r1
A2(1,1,1) + A2(2,1,0)
>>> r2 = A2(f1)**Integer(3); r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
>>> r1.inner_product(r2)
3

invariant_degree()

Return the multiplicity of the trivial representation in self.

Multiplicities of other irreducibles may be obtained using multiplicity().

EXAMPLES:

sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: rep = A2(1,0)^2*A2(0,1)^2; rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
sage: rep.invariant_degree()
2

>> from sage.all import *
>> A2 = WeylCharacterRing("A2",style="coroots")
>> rep = A2(Integer(1),Integer(1))**Integer(2); rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
>> rep.invariant_degree()
2

is_irreducible()

Return whether self is an irreducible character.

EXAMPLES:

sage: B2 = WeylCharacterRing("B2",style="coroots")
sage: rep = B2(1,1)^2; rep
(continues on next page)
B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) + → B2(2,2)

sage: rep.multiplicity(B2(0,2))
2

```python
>>> from sage.all import *

>>> B2 = WeylCharacterRing("B2",style="coroots")
>>> rep = B2(Integer(1),Integer(1))**Integer(2); rep
B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) + → B2(2,2)
>>> rep.multiplicity(B2(Integer(0),Integer(2)))
2
```

**symmetric_power** \((k)\)

Return the \(k\)-th symmetric power of \(self\).

**INPUT:**

- \(k\) – a nonnegative integer

The algorithm is based on the identity \(kh_k = \sum_{r=1}^{k} p_k h_{k-r}\) relating the power-sum and complete symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation \(self\), the \(h_k\) become symmetric powers and the \(p_k\) become Adams operations, giving an efficient recursive implementation.

**EXAMPLES:**

```python
sage: B3 = WeylCharacterRing("B3",style="coroots")

sage: spin = B3(0,0,1)

sage: spin.symmetric_power(6)
B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
```

```python
>>> from sage.all import *

>>> B3 = WeylCharacterRing("B3",style="coroots")

>>> spin = B3(Integer(0),Integer(0),Integer(1))

>>> spin.symmetric_power(Integer(6))
B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
```

**symmetric_square**()

Return the symmetric square of the character.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2",style="coroots")

sage: A2(1,0).symmetric_square()
A2(2,0)
```

```python
>>> from sage.all import *

>>> A2 = WeylCharacterRing("A2",style="coroots")

>>> A2(Integer(1),Integer(0)).symmetric_square()
A2(2,0)
```

**weight_multiplicities**()

Return the dictionary of weight multiplicities for the Weyl character \(self\).

The character does not have to be irreducible.

**EXAMPLES:**
**adjoint_representation()**

Return the adjoint representation as an element of the WeylCharacterRing.

**EXAMPLES:**

```
sage: G2 = WeylCharacterRing("G2",style="coroots")
sage: G2(adjoint_representation())
G2(0,1)
```

**affine_reflect**(wt,k=0)

Return the reflection of wt in the hyperplane θ.

Optionally, this also shifts by a multiple k of θ.

**INPUT:**

- wt – a weight
- k – (optional) a positive integer

**EXAMPLES:**

```
sage: B22 = FusionRing("B2",2)
sage: fw = B22.fundamental_weights(); fw
Finite family {1: (1, 0), 2: (1/2, 1/2)}
sage: [B22.affine_reflect(x,2) for x in fw]
[(2, 1), (3/2, 3/2)]
```

**ambient()**

Return the weight ring of self.

**EXAMPLES:**

```
sage: WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer...
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer...
---Ring coefficients

base_ring()

Return the base ring of self.

EXAMPLES:

```python
sage: R = WeylCharacterRing(['A',3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

```python
>>> from sage.all import *

>>> R = WeylCharacterRing(['A',Integer(3)], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```python
sage: WeylCharacterRing("A2").cartan_type()
['A', 2]
```

```python
>>> from sage.all import *

>>> WeylCharacterRing("A2").cartan_type()
['A', 2]
```

char_from_weights (mdict)

Construct a Weyl character from an invariant linear combination of weights.

INPUT:

- mdict -- a dictionary mapping weights to coefficients, and representing a linear combination of weights which shall be invariant under the action of the Weyl group

OUTPUT: the corresponding Weyl character

EXAMPLES:

```python
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: d = dict([(x,1) for x in v.orbit()]); d
{(1, 3, 0): 1,
 (1, 0, 3): 1,
 (3, 1, 0): 1,
 (3, 0, 1): 1,
 (0, 1, 3): 1,
 (0, 3, 1): 1}
sage: A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

```python
>>> from sage.all import *

>>> A2 = WeylCharacterRing("A2")

>>> v = A2._space([Integer(3),Integer(1),Integer(0)]); v
```

(continues on next page)
\[(3, 1, 0)\]

```python
>>> d = dict([(x,Integer(1)) for x in v.orbit()]); d
{(1, 3, 0): 1,
 (1, 0, 3): 1,
 (3, 1, 0): 1,
 (3, 0, 1): 1,
 (0, 1, 3): 1,
 (0, 3, 1): 1}
>>> A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

**demazure_character** *(hwv, word, debug=False)*

Compute the Demazure character.

**INPUT:**

- `hwv` – a (usually dominant) weight
- `word` – a Weyl group word

Produces the Demazure character with highest weight `hwv` and `word` as an element of the weight ring. Only available if `style="coroots"`. The Demazure operators are also available as methods of `WeightRing` elements, and as methods of crystals. Given a `CrystalOfTableaux` with given highest weight vector, the Demazure method on the crystal will give the equivalent of this method, except that the Demazure character of the crystal is given as a sum of monomials instead of an element of the `WeightRing`.

**EXAMPLES:**

```python
sage: A2 = WeylCharacterRing("A2",style="coroots")
sage: h = sum(A2.fundamental_weights()); h
(2, 1, 0)
sage: A2.demazure_character(h,word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
sage: A2.demazure_character((1,1),word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
```

**dot_reduce** *(a)*

Auxiliary function for `product_on_basis()`.

Return a pair \([\epsilon, b]\) where \(b\) is a dominant weight and \(\epsilon\) is 0, 1 or -1. To describe \(b\), let \(w\) be an element of the Weyl group such that \(w(a + \rho)\) is dominant. If \(w(a + \rho) - \rho\) is dominant, then \(\epsilon\) is the sign of \(w\) and \(b\) is \(w(a + \rho) - \rho\). Otherwise, \(\epsilon\) is zero.

**INPUT:**

- `a` – a weight
EXAMPLES:

```python
sage: A2 = WeylCharacterRing("A2")

sage: weights = sorted(A2(2,1,0).weight_multiplicities().keys(), key=str);
weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]

sage: [A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0, 0)], [0, (0, 0, 0)], [1, (2, 1, 0)]]
```

```
>>> from sage.all import *

A2 = WeylCharacterRing("A2")

weights = sorted(A2(Integer(2),Integer(1),Integer(0)).weight_multiplicities().keys(), key=str); weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]

[A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0, 0)], [0, (0, 0, 0)], [1, (2, 1, 0)]]
```

dynkin_diagram()

Return the Dynkin diagram of self.

EXAMPLES:

```python
sage: WeylCharacterRing("E7").dynkin_diagram()

O 2
|
O---O---O---O---O---O
1 3 4 5 6 7

E7
```

```python
>>> from sage.all import *

>>> WeylCharacterRing("E7").dynkin_diagram()

O 2
|
O---O---O---O---O---O---O
0 1 3 4 5 6 7

E7~
```

extended_dynkin_diagram()

Return the extended Dynkin diagram, which is the Dynkin diagram of the corresponding untwisted affine type.

EXAMPLES:

```python
sage: WeylCharacterRing("E7").extended_dynkin_diagram()

O 2
|
0 1 3 4 5 6 7

E7~
```

```python
>>> from sage.all import *

>>> WeylCharacterRing("E7").extended_dynkin_diagram()

(continues on next page)
```
fundamental_weights()

Return the fundamental weights.

EXAMPLES:

```sage
definitions:
    WeylCharacterRing("G2").fundamental_weights()
    Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

highest_root()

Return the highest root.

EXAMPLES:

```sage
definitions:
    WeylCharacterRing("G2").highest_root()
    (2, -1, -1)
```

irr_repr(hwv)

Return a string representing the irreducible character with highest weight vector hwv.

EXAMPLES:

```sage
B3 = WeylCharacterRing("B3")
definitions:
    [B3.irr_repr(v) for v in B3.fundamental_weights()]
    ['B3(1,0,0)', 'B3(1,1,0)', 'B3(1/2,1/2,1/2)']
```

level(wt)

Return the level of the weight, defined to be the value of the weight on the coroot associated with the highest root.

EXAMPLES:
lift()

The embedding of self into its weight ring.

EXAMPLES:

sage: A2 = WeylCharacterRing("A2")
sage: A2.lift
Generic morphism:
    From: The Weyl Character Ring of Type A2 with Integer Ring coefficients
    To:   The Weight ring attached to The Weyl Character Ring of Type A2 with...

sage: x = -A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2.lift(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)

As a shortcut, you may also do:

sage: x.lift()
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)

Or even:
sage: a2 = WeightRing(A2)
sage: a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)

>>> from sage.all import *
>>> a2 = WeightRing(A2)
>>> a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)

lift_on_basis(irr)
Expand the basis element indexed by the weight irr into the weight ring of self.

INPUT:

- irr – a dominant weight

This is used to implement lift().

EXAMPLES:

sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([2,1,0]); v
(2, 1, 0)
sage: A2.lift_on_basis(v)
2*a2(1,1,1) + a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) +
   → a2(0,2,1)

>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> v = A2._space([Integer(2),Integer(1),Integer(0)]); v
(2, 1, 0)
>>> A2.lift_on_basis(v)
2*a2(1,1,1) + a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) +
   → a2(0,2,1)

This is consistent with the analogous calculation with symmetric Schur functions:

sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2

>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s[Integer(2),Integer(1)].expand(Integer(3))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2

maximal_subgroup(ct)
Return a branching rule or a list of branching rules.

INPUT:

- ct – the Cartan type of a maximal subgroup of self.

In rare cases where there is more than one maximal subgroup (up to outer automorphisms) with the given Cartan type, the function returns a list of branching rules.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2
sage: WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]

>>> from sage.all import *
>>> WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2
>>> WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]
```

For more information, see the related method `maximal_subgroups()`.

**maximal_subgroups()**

This method is only available if the Cartan type of `self` is irreducible and of rank no greater than 8. This method produces a list of the maximal subgroups of `self`, up to (possibly outer) automorphisms. Each line in the output gives the Cartan type of a maximal subgroup followed by a command that creates the branching rule.

**EXAMPLES:**

```python
sage: WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")
```

```python
>>> from sage.all import *
>>> WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")
```

Note that there are other embeddings of (for example A2 into E6) as nonmaximal subgroups. These embeddings may be constructed by composing branching rules through various subgroups.

Once you know which maximal subgroup you are interested in, to create the branching rule, you may either paste the command to the right of the colon from the above output onto the command line, or alternatively invoke the related method `maximal_subgroup()`:.

```python
sage: branching_rule("E6","G2","miscellaneous")
miscellaneous branching rule E6 => G2
sage: WeylCharacterRing("E6").maximal_subgroup("G2")
miscellaneous branching rule E6 => G2
```

```python
>>> from sage.all import *
>>> branching_rule("E6","G2","miscellaneous")
```

(continues on next page)
miscellaneous branching rule E6 \Rightarrow G2

\[\text{WeylCharacterRing}("E6").maximal_subgroup("G2")}\]

It is believed that the list of maximal subgroups is complete, except that some subgroups may be not be invariant under outer automorphisms. It is reasonable to want a list of maximal subgroups that is complete up to conjugation, but to obtain such a list you may have to apply outer automorphisms. The group of outer automorphisms modulo inner automorphisms is isomorphic to the group of symmetries of the Dynkin diagram, and these are available as branching rules. The following example shows that while a branching rule from \(D_4\) to \(A_1 \times C_2\) is supplied, another different one may be obtained by composing it with the triality automorphism of \(D_4\):

\[
\text{sage: } \text{D4, A1xC2} = \text{[WeylCharacterRing(x, style="coroots") for x in ["D4", "A1xC2"]}
\text{sage: } \text{fw = D4.fundamental_weights()}
\text{sage: } \text{b = D4.maximal_subgroup("A1xC2")}
\text{sage: } \text{[D4(fw).branch(A1xC2, rule=b) for fw in D4.fundamental_weights()]
}[\text{A1xC2}(1,1,0),
\text{A1xC2}(2,0,0) + \text{A1xC2}(2,0,1) + \text{A1xC2}(0,2,0),
\text{A1xC2}(1,1,0),
\text{A1xC2}(2,0,0) + \text{A1xC2}(0,0,1)]
\text{sage: } \text{b1 = branching_rule("D4","D4","triality")*b}
\text{sage: } \text{[D4(fw).branch(A1xC2, rule=b1) for fw in D4.fundamental_weights()]
}[\text{A1xC2}(1,1,0),
\text{A1xC2}(2,0,0) + \text{A1xC2}(2,0,1) + \text{A1xC2}(0,2,0),
\text{A1xC2}(2,0,0) + \text{A1xC2}(0,0,1),
\text{A1xC2}(1,1,0)]
\]

one_basis()

Return the index of 1 in self.

EXAMPLES:

\[
\text{sage: } \text{WeylCharacterRing("A3").one_basis()}
(0, 0, 0)
\text{sage: } \text{WeylCharacterRing("A3").one()}
\text{A3}(0,0,0)
\]
positive_roots()

Return the positive roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

product_on_basis(a, b)

Compute the tensor product of two irreducible representations a and b.

EXAMPLES:

```
sage: D4 = WeylCharacterRing(["D",4])
sage: spin_plus = D4(1/2,1/2,1/2,1/2)
sage: spin_minus = D4(1/2,1/2,1/2,-1/2)
sage: spin_plus * spin_minus
D4(1,0,0,0) + D4(1,1,1,0)
sage: spin_minus * spin_plus
D4(1,0,0,0) + D4(1,1,1,0)
```

rank()

Return the rank.

EXAMPLES:

```
sage: WeylCharacterRing("G2").rank()
2
```
retract()

The partial inverse map from the weight ring into self.

EXAMPLES:

```python
sage: A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> A2.retract
Generic morphism:
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with...
  → Integer Ring coefficients
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients

>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> A2.retract
Generic morphism:
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with...
  → Integer Ring coefficients
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients

sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
sage: A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)

>>> from sage.all import *
>>> v = A2._space([Integer(3),Integer(1),Integer(0)]); v
(3, 1, 0)
>>> chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
>>> A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)

The input should be invariant:

sage: A2.retract(a2.monomial(v))
Traceback (most recent call last):
  ... ValueError: multiplicity dictionary may not be Weyl group invariant

>>> from sage.all import *
>>> A2.retract(a2.monomial(v))
Traceback (most recent call last):
  ... ValueError: multiplicity dictionary may not be Weyl group invariant

As a shortcut, you may use conversion:

sage: A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2(a2.monomial(v))
Traceback (most recent call last):
(continues on next page)
ValueError: multiplicity dictionary may not be Weyl group invariant

```python
>>> from sage.all import *
>>> A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
>>> A2(a2.monomial(v))
Traceback (most recent call last):
... 
ValueError: multiplicity dictionary may not be Weyl group invariant
```

### simple_coroots()

Return the simple coroots.

**EXAMPLES:**

```python
sage: WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
```

```python
>>> from sage.all import *
>>> WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
```

### simple_roots()

Return the simple roots.

**EXAMPLES:**

```python
sage: WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

```python
>>> from sage.all import *
>>> WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

### some_elements()

Return some elements of self.

**EXAMPLES:**

```python
sage: WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]
```

```python
>>> from sage.all import *
>>> WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]
```

### space()

Return the weight space associated to self.

**EXAMPLES:**

```python
sage: WeylCharacterRing(["E",8]).space()
Ambient space of the Root system of type ["E", 8]
```
Return the dictionary of multiplicities for the irreducible character with highest weight $\lambda$.

The weight multiplicities are computed by the Freudenthal multiplicity formula. The algorithm is based on recursion relation that is stated, for example, in Humphrey's book on Lie Algebras. The multiplicities are invariant under the Weyl group, so to compute them it would be sufficient to compute them for the weights in the positive Weyl chamber. However after some testing it was found to be faster to compute every weight using the recursion, since the use of the Weyl group is expensive in its current implementation.

INPUT:

- $hwv$ – a dominant weight in a weight lattice.
- $L$ – the ambient space

EXAMPLES:

```python
sage: WeylCharacterRing("A2"){(2,1,0)}.weight_multiplicities()  # indirect doctest
{(1, 1, 1): 2, (1, 2, 0): 1, (1, 0, 2): 1, (2, 1, 0): 1,
 (2, 0, 1): 1, (0, 1, 2): 1, (0, 2, 1): 1}
```

5.1.273 Weyl Groups

AUTHORS:

- Daniel Bump (2008): initial version
- Mike Hansen (2008): initial version
- Anne Schilling (2008): initial version
- Nicolas Thiéry (2008): initial version
- Volker Braun (2013): LibGAP-based matrix groups

EXAMPLES:

The Cayley graph of the Weyl Group of type ['A', 3]:

```python
sage: w = WeylGroup(['A',3])
sage: d = w.cayley_graph(); d
Digraph on 24 vertices
```

5.1. Comprehensive Module List
The Cayley graph of the Weyl Group of type ['D', 4]:

```
sage: w = WeylGroup(['D',4])
sage: d = w.cayley_graph(); d
Digraph on 192 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03)  # long time (less than one minute), needs sage.plot
```

Todo: More examples on Weyl Groups should be added here.

```
class sage.combinat.root_system.weyl_group.ClassicalWeylSubgroup(domain, prefix)
Bases: WeylGroup_gens

A class for Classical Weyl Subgroup of an affine Weyl Group

EXAMPLES:
```
```
sage: G = WeylGroup(['A',3,1]).classical()
sage: G
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group... acting on the root space)
sage: G.category()
Category of finite irreducible Weyl groups
sage: G.cardinality()
24
sage: G.index_set()
(1, 2, 3)
sage: TestSuite(G).run()
```
```
Todo: implement:
- Parabolic subroot systems
- Parabolic subgroups with a set of nodes as argument

cartan_type()
EXAMPLES:

```sage
sage: WeylGroup(['A', 3, 1]).classical().cartan_type()
['A', 3]
sage: WeylGroup(['A', 3, 1]).classical().index_set()
(1, 2, 3)
```

Note: won’t be needed, once the lattice will be a parabolic sub root system

simple_reflections()
EXAMPLES:

```sage
sage: WeylGroup(['A', 2, 1]).classical().simple_reflections()
Finite family {1: [ 1 0 0]
  [ 1 -1 1]
  [ 0 0 1],
  2: [ 1 0 0]
  [ 0 1 0]
  [ 1 1 -1]}
```

Note: won’t be needed, once the lattice will be a parabolic sub root system

weyl_group (prefix='hereditary')
Return the Weyl group associated to the parabolic subgroup.

EXAMPLES:

```sage
sage: WeylGroup(['A', 4, 1]).classical().weyl_group()
Weyl Group of type ['A', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['C', 4, 1]).classical().weyl_group()
Weyl Group of type ['C', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['E', 8, 1]).classical().weyl_group()
Weyl Group of type ['E', 8, 1] (as a matrix group acting on the root space)
```
\begin{verbatim}
>>> from sage.all import *
>>> WeylGroup(['A', Integer(4), Integer(1)]).classical().weyl_group()
Weyl Group of type ['A', 4, 1] (as a matrix group acting on the root space)
>>> WeylGroup(['C', Integer(4), Integer(1)]).classical().weyl_group()
Weyl Group of type ['C', 4, 1] (as a matrix group acting on the root space)
>>> WeylGroup(['E', Integer(8), Integer(1)]).classical().weyl_group()
Weyl Group of type ['E', 8, 1] (as a matrix group acting on the root space)
\end{verbatim}

\texttt{sage.combinat.root_system.weyl_group.WeylGroup(x, prefix=None, implementation='matrix')}

Return the Weyl group of the root system defined by the Cartan type (or matrix) \(ct\).

INPUT:

- \(x\) – a root system or a Cartan type (or matrix)

OPTIONAL:

- prefix - changes the representation of elements from matrices to products of simple reflections
- implementation – one of the following:
  - 'matrix' – as matrices acting on a root system
  - "permutation" – as a permutation group acting on the roots

EXAMPLES:

The following constructions yield the same result, namely a weight lattice and its corresponding Weyl group:

\begin{verbatim}
sage: G = WeylGroup(['F',4])
sage: L = G.domain()

>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> L = G.domain()

or alternatively and equivalently:

sage: L = RootSystem(['F',4]).ambient_space()
sage: G = L.weyl_group()
sage: W = WeylGroup(L)

>>> from sage.all import *
>>> L = RootSystem(['F',Integer(4)]).ambient_space()
>>> G = L.weyl_group()
>>> W = WeylGroup(L)

Either produces a weight lattice, with access to its roots and weights.

\begin{verbatim}
sage: G = WeylGroup(['F',4])
sage: G.order()
1152
sage: [s1,s2,s3,s4] = G.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: type(w) == G.element_class
\end{verbatim}

(continues on next page)
The default representation of Weyl group elements is as matrices. If you prefer, you may specify a prefix, in which case the elements are represented as products of simple reflections.

\[
\begin{bmatrix}
0 & 0 & -1 \\
0 & 1 & 0 \\
1 & 0 & 0
\end{bmatrix}
\]
Finite family \( \{1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1, \rightarrow 0, 0, 0) \} \)

\[
\text{sage: } \rho = \text{sum}(\text{fw}); \rho \\
(11/2, 5/2, 3/2, 1/2)
\]

\[
\text{sage: } W.\text{action}(\rho) \# \text{ action of } G \text{ on weight lattice} \\
(5, -1, 3, 2)
\]

We can also do the same for arbitrary Cartan matrices:

\[
\text{sage: } \text{cm} = \text{CartanMatrix}([[2, -5, 0], [-2, 2, -1], [0, -1, 2]]) \\
\text{sage: } W = \text{WeylGroup}(\text{cm}) \\
\text{sage: } W.\text{gens() (}
\text{[[-1 0 0] [1 0 0] [1 0 0]} \\
\text{[0 1 0] [2 -1 1] [0 1 0]} \\
\text{[0 0 1], [0 0 1], [0 1 -1] })
\]

\[
\text{sage: } s0, s1, s2 = W.\text{gens() (}
\text{[1 0 0] [2 0 -1] [2 -1 0] }
\text{[2 0 -1] [2 -1 0] [1 0 0]}
\text{[0 1 -1] [0 1 -1] [2 0 -1]}
\]

\[
\text{>>> from sage.all import *}
\text{>>> cm = CartanMatrix([[Integer(2),-Integer(5),Integer(0)],[-Integer(2),}
\text{Integer(2),-Integer(1)], [Integer(0),-Integer(1),Integer(2)]])}
\text{>>> W = WeylGroup(cm)}
\text{>>> W.\text{gens() (}
\text{[[-1 5 0] [1 0 0] [1 0 0]} \\
\text{[0 1 0] [2 -1 1] [0 1 0]} \\
\text{[0 0 1], [0 0 1], [0 1 -1] })}
\]

\[
\text{>>> s0, s1, s2 = W.\text{gens() (}
\text{[1 0 0] [2 0 -1] [2 -1 0] }
\text{[2 0 -1] [2 -1 0] [1 0 0]}
\text{[0 1 -1] [0 1 -1] [2 0 -1]}
\]

(continues on next page)
$$s_2s_1s_2$$

$$[1\ 0\ 0]$$

$$[2\ 0\ -1]$$

$$[2\ -1\ 0]$$

$$s_0s_1s_0s_2s_0$$

$$[9\ 0\ -5]$$

$$[2\ 0\ -1]$$

$$[0\ 1\ -1]$$

Same Cartan matrix, but with a prefix to display using simple reflections:

```
sage: W = WeylGroup(cm, prefix='s')
sage: s0, s1, s2 = W.gens()
sage: s0*s2*s1
s2*s0*s1
sage: (s1*s2)**3
1
sage: (s0*s1)**5
s0*s1*s0*s1*s0*s1*s0*s1
sage: s0*s1*s2*s1*s2
s2*s0*s1
sage: s0*s1*s2*s0*s2
s0*s1*s0
```

```
>>> from sage.all import *
```

```
sage: W = WeylGroup(cm, prefix='s')
sage: s0, s1, s2 = W.gens()
```

```
class sage.combinat.root_system.weyl_group.WeylGroupElement(parent, g, check=False)
Bases: MatrixGroupElement_gap
Class for a Weyl Group elements

action(v)

Return the action of self on the vector v.

EXAMPLES:

```
sage: W = WeylGroup(['A', 2])
sage: s = W.simple_reflections()
sage: v = W.domain()([1,0,0])
sage: s[1].action(v)
(0, 1, 0)
```

```
sage: W = WeylGroup(RootSystem(['A', 2]).root_lattice())
sage: s = W.simple_reflections()
sage: alpha = W.domain().simple_roots()
```
```python
sage: s[1].action(alpha[1])
-alpha[1]

sage: W=WeylGroup(['A',2,1])
sage: alpha = W.domain().simple_roots()
sage: s = W.simple_reflections()
sage: s[1].action(alpha[1])
-alpha[1]
sage: s[1].action(alpha[0])
alpha[0] + alpha[1]
```

```python
>>> from sage.all import *

>>> W = WeylGroup(['A',Integer(2)])

>>> s1 = W.simple_reflection(Integer(1))

>>> s1.domain()
Ambient space of the Root system of type ['A', 2]
```

```python
apply_simple_reflection (i, side='right')

domain()

Return the ambient lattice associated with self.

EXAMPLES:

```python
sage: W = WeylGroup(['A',2])
sage: s1 = W.simple_reflection(1)
sage: s1.domain()
Ambient space of the Root system of type ['A', 2]
```

```python
>>> from sage.all import *

>>> W = WeylGroup(['A',Integer(2)])

>>> s1 = W.simple_reflection(Integer(1))

>>> s1.domain()
Ambient space of the Root system of type ['A', 2]
```

```python
has_descent (i, positive=False, side='right')

Test if self has a descent at position i.

An element w has a descent in position i if w is on the strict negative side of the i\text{th} simple reflection hyperplane.

If positive is True, tests if it is on the strict positive side instead.
```
EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [s[3].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
sage: W = WeylGroup(['A',3,1])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False, False]
sage: [s[0].has_descent(i) for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[1]
sage: [w.has_descent(i) for i in W.domain().index_set()]
[False, True, False, False]
sage: w = s[0] * s[2]
sage: [w.has_descent(i) for i in W.domain().index_set()]
[True, False, True, False]
sage: W = WeylGroup(['A',3])
sage: W.one().has_descent(0)
True
sage: W.w0.has_descent(0)
False

>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> s = W.simple_reflections()
>>> [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
>>> [s[Integer(1)].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
>>> [s[Integer(2)].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
>>> [s[Integer(3)].has_descent(i) for i in W.domain().index_set()]
[False, True, True]
>>> [s[Integer(3)].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
>>> W = WeylGroup(['A',Integer(3),Integer(1)])
>>> s = W.simple_reflections()
>>> [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False, False]
>>> [s[Integer(0)].has_descent(i) for i in W.domain().index_set()]
[True, False, False, False]
>>> w = s[Integer(0)] * s[Integer(1)]
>>> [w.has_descent(i) for i in W.domain().index_set()]
```

(continues on next page)
has_left_descent \( i \)

Test if \( \text{self} \) has a left descent at position \( i \).

EXAMPLES:

```python
sage: W = WeylGroup(['A', 3])
sage: s = W.simple_reflections()
sage: [W.one().has_left_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_left_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_left_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
```

has_right_descent \( i \)

Test if \( \text{self} \) has a right descent at position \( i \).

EXAMPLES:

```python
sage: W = WeylGroup(['A', 3])
sage: s = W.simple_reflections()
sage: [W.one().has_right_descent(i) for i in W.domain().index_set()]
[False, True, False, False]
```
sage: [s[1].has_right_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_right_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]

to_matrix()
Return self as a matrix.

EXAMPLES:

sage: G = WeylGroup(['A',2])
sage: s1 = G.simple_reflection(1)
sage: s1.to_matrix() == s1.matrix()
True

from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> s = W.simple_reflections()
>>> [W.one().has_right_descent(i) for i in W.domain().index_set()]
[False, False, False]

This assumes type $A, B, C, D$ on the ambient lattice

This further assume that the basis is indexed by $0, 1, \ldots$ and returns a permutation of $(5, 4, 2, 3, 1)$ (beuargl), as a tuple

to_permutation_string()
EXAMPLES:

sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: (s[1]*s[2]*s[3]).to_permutation_string()
'2341'
```python
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> s = W.simple_reflections()
>>> (s[Integer(1)]*s[Integer(2)]*s[Integer(3)]).to_permutation_string()
'2341'
```

```python
class sage.combinat.root_system.weyl_group.WeylGroup_gens(domain, prefix)
    Bases: UniqueRepresentation, FinitelyGeneratedMatrixGroup_gap

    EXAMPLES:
    sage: G = WeylGroup(['B',3])
    sage: TestSuite(G).run()
    sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
    sage: W = WeylGroup(cm)
    sage: TestSuite(W).run()  # long time
>>> from sage.all import *
>>> G = WeylGroup(['B',Integer(3)])
>>> TestSuite(G).run()
>>> cm = CartanMatrix([[Integer(2),-Integer(5),Integer(0)],[Integer(0),-Integer(1),Integer(2)],
                    [Integer(0),-Integer(1),Integer(2)]])
>>> W = WeylGroup(cm)
>>> TestSuite(W).run()  # long time
```

```python
class Element
    alias of WeylGroupElement

cartan_type()
    Return the CartanType associated to self.

    EXAMPLES:
    sage: G = WeylGroup(['F',4])
    sage: G.cartan_type()    ['F', 4]
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> G.cartan_type()    ['F', 4]
```

```python
character_table()
    Return the character table as a matrix.

    Each row is an irreducible character. For larger tables you may preface this with a command such as
gap.eval("SizeScreen([120,40])") in order to widen the screen.

    EXAMPLES:
    sage: WeylGroup(['A',3]).character_table()
    CT1
    2 3 2 2 . 3
    3 1 . . 1 .
    1a 4a 2a 3a 2b
```

classical()

If self is a Weyl group from an affine Cartan Type, this give the classical parabolic subgroup of self.

Caveat: we assume that 0 is a special node of the Dynkin diagram

Todo: extract parabolic subgroup method

EXAMPLES:

```
sage: G = WeylGroup(['A',3,1])
sage: G.classical()
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1]
(as a matrix group acting on the root space)
sage: WeylGroup(['A',3]).classical()
Traceback (most recent call last):
...
ValueError: classical subgroup only defined for affine types
```

domain()

Return the domain of the element of self, that is the root lattice realization on which they act.

EXAMPLES:
sage: W = WeylGroup(['F',4])
sage: W.domain()
Ambient space of the Root system of type ['F', 4]
sage: G = WeylGroup(['A',3,1])
sage: G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]

>>> from sage.all import *

>>> G = WeylGroup(['F',Integer(4)])

>>> G.domain()
Ambient space of the Root system of type ['F', 4]

>>> G = WeylGroup(['A',Integer(3),Integer(1)])

>>> G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]

from_morphism($f$)

index_set()

Return the index set of self.

EXAMPLES:

sage: G = WeylGroup(['F',4])

sage: G.index_set()
(1, 2, 3, 4)

sage: G = WeylGroup(['A',3,1])

sage: G.index_set()
(0, 1, 2, 3)

long_element_hardcoded()

Return the long Weyl group element (hardcoded data).

Do we really want to keep it? There is a generic implementation which works in all cases. The hardcoded
should have a better complexity (for large classical types), but there is a cache, so does this really matter?

EXAMPLES:

sage: types = [ ['A',5], ['B',3], ['C',3], ['D',4], ['G',2], ['F',4], ['E',6] ]

sage: [WeylGroup(t).long_element().length() for t in types]
[15, 9, 9, 12, 6, 24, 36]

sage: all(WeylGroup(t).long_element() == WeylGroup(t).long_element_.
˓hardcoded() for t in types)  # long time (17s on sage.math, 2011)
True

>>> from sage.all import *

>>> types = [ ['A',Integer(5)], ['B',Integer(3)], ['C',Integer(3)], ['D',
˓Integer(4)], ['G',Integer(2)], ['F',Integer(4)], ['E',Integer(6)] ]

>>> [WeylGroup(t).long_element().length() for t in types]
Combinatorics, Release 10.4

>>> all(WeylGroup(t).long_element() == WeylGroup(t).long_element_hardcoded() for t in types)  # long time (17s on sage.math, 2011)
True

\textbf{morphism\_matrix}(f)

\textbf{one}()

Return the unit element of the Weyl group.

**EXAMPLES:**

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

```
>>> from sage.all import *

>>> W = WeylGroup(['A',Integer(3)])

>>> e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]

>>> type(e) == W.element_class
True
```

\textbf{reflections}()

Return the reflections of \textit{self}.

The reflections of a Coxeter group \(W\) are the conjugates of the simple reflections. They are in bijection with the positive roots, for given a positive root, we may have the reflection in the hyperplane orthogonal to it. This method returns a family indexed by the positive roots taking values in the reflections. This requires \textit{self} to be a finite Weyl group.

**Note:** Prior to Issue #20027, the reflections were the keys of the family and the values were the positive roots.

**EXAMPLES:**

```
sage: W = WeylGroup("B2", prefix="s")
sage: refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (0, 1): s2, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1}
sage: [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]
```

```
sage: W = WeylGroup(['A',2,1], prefix="s")
sage: W.reflections()
Lazy family (real root to reflection(i))_{i in Positive real roots of type ['A', 2, 1]}
```
>>> from sage.all import *
>>> W = WeylGroup("B2", prefix="s")
>>> refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (0, 1): s2, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1}
>>> [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]

>>> W = WeylGroup(["A",Integer(2),Integer(1)], prefix="s")
>>> W.reflections()
Lazy family (real root to reflection(i))_{i in Positive real roots of type ["A", 2, 1]}
simple_reflection(i)
Return the $i$th simple reflection.

EXAMPLES:

sage: G = WeylGroup(["F",4])
sage: G.simple_reflection(1)
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]
sage: W=WeylGroup(["A",2,1])
sage: W.simple_reflection(1)
[ 1 0 0]
[ 1 -1 1]
[ 0 0 1]

>>> from sage.all import *

>>> from sage.all import *

>>> G = WeylGroup(["F",Integer(4)])

>>> G.simple_reflection(Integer(1))
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]

simple_reflections()
Return the simple reflections of self, as a family.

EXAMPLES:

There are the simple reflections for the symmetric group:

sage: W=WeylGroup(["A",2])
sage: s = W.simple_reflections(); s
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1], 2: [1 0 0]
[0 0 1], 0: [1 0 0]}

4402 Chapter 5. Comprehensive Module List
As a special feature, for finite irreducible root systems, \(s[0]\) gives the reflection along the highest root:

```
sage: s[0]
[0 0 1]
[0 1 0]
[1 0 0]
```

We now look at some further examples:

```
sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflections()
Finite family {0: [-1 1 1]
[ 0 1 0]
[ 0 0 1], 1: [ 1 0 0]
[ 1 -1 1]
[ 0 1 0], 2: [ 1 0 0]
[ 0 0 1]
[ 1 1 -1]}
sage: W = WeylGroup(['F',4])
sage: [s1,s2,s3,s4] = W.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2 1/2 1/2 1/2]
[-1/2 1/2 1/2 -1/2]
[ 1/2 1/2 -1/2 -1/2]
[ 1/2 -1/2 1/2 -1/2]
sage: s4^2 == W.one()
True
sage: type(w) == W.element_class
True
```
unit()

Return the unit element of the Weyl group.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```
distinguished_reflections()  
Return the reflections of self.

EXAMPLES:

```sage
W = WeylGroup(['B',2], implementation="permutation")
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
  3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

independent_roots()  
Return the simple roots of self.

EXAMPLES:

```sage
W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
  3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```

index_set()  
Return the index set of self.

EXAMPLES:

```sage
W = WeylGroup(['A',4], implementation="permutation")
sage: W.index_set()
(1, 2, 3, 4)
```

iteration(algorithm='breadth', tracking_words=True)  
Return an iterator going through all elements in self.

INPUT:

- algorithm (default: 'breadth') – must be one of the following:
  - 'breadth' – iterate over in a linear extension of the weak order
  - 'depth' – iterate by a depth-first-search
- tracking_words (default: True) – whether or not to keep track of the reduced words and store them in _reduced_word
Note: The fastest iteration is the depth first algorithm without tracking words. In particular, 'depth' is ~1.5x faster.

EXAMPLES:

```
sage: W = WeylGroup(['B',2], implementation='permutation')
sage: for w in W.iteration('breadth', True):
    print("%s %s")%(w, w._reduced_word)
() []
(1,3) (2,6) (5,7) [1]
(1,5) (2,4) (6,8) [0]
(1,7,5,3) (2,4,6,8) [0, 1]
(1,3,5,7) (2,8,6,4) [1, 0]
(2,8) (3,7) (4,6) [1, 0, 1]
(1,7) (3,5) (4,8) [0, 1, 0]
(1,5) (2,6) (3,7) (4,8) [0, 1, 0, 1]
sage: for w in W.iteration('depth', False): w
() ()
(1,3) (2,6) (5,7)
(1,5) (2,4) (6,8)
(1,3,5,7) (2,8,6,4)
(1,7) (3,5) (4,8)
(1,7,5,3) (2,4,6,8)
(2,8) (3,7) (4,6)
(1,5) (2,6) (3,7) (4,8)
```

```
>>> from sage.all import *
>>> W = WeylGroup(['B',Integer(2)], implementation='permutation')

>>> for w in W.iteration('breadth', True):
    print("%s %s")%(w, w._reduced_word)
() []
(1,3) (2,6) (5,7) [1]
(1,5) (2,4) (6,8) [0]
(1,7,5,3) (2,4,6,8) [0, 1]
(1,3,5,7) (2,8,6,4) [1, 0]
(2,8) (3,7) (4,6) [1, 0, 1]
(1,7) (3,5) (4,8) [0, 1, 0]
(1,5) (2,6) (3,7) (4,8) [0, 1, 0, 1]
```

```
>>> for w in W.iteration('depth', False): w
() ()
(1,3) (2,6) (5,7)
(1,5) (2,4) (6,8)
(1,3,5,7) (2,8,6,4)
(1,7) (3,5) (4,8)
(1,7,5,3) (2,4,6,8)
(2,8) (3,7) (4,6)
(1,5) (2,6) (3,7) (4,8)
```

```
number_of_reflections()

Return the number of reflections in self.

EXAMPLES:
```
sage: W = WeylGroup(['D',4], implementation="permutation")
sage: W.number_of_reflections()
12

>>> from sage.all import *
>>> W = WeylGroup(['D',Integer(4)], implementation="permutation")
>>> W.number_of_reflections()
12

positive_roots()
Return the positive roots of self.

EXAMPLES:

\begin{verbatim}
\textbf{sage: } W = WeylGroup(['C',3], implementation="permutation")
\textbf{sage: } W.positive_roots()
((1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (0, 2, 1),
 (1, 1, 1),
 (2, 2, 1),
 (1, 2, 1))
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> W = WeylGroup(['C',Integer(3)], implementation="permutation")
>>> W.positive_roots()
((1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (0, 2, 1),
 (1, 1, 1),
 (2, 2, 1),
 (1, 2, 1))
\end{verbatim}

rank()
Return the rank of self.

EXAMPLES:

\begin{verbatim}
\textbf{sage: } W = WeylGroup(['A',4], implementation="permutation")
\textbf{sage: } W.rank()
4
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation="permutation")
>>> W.rank()
4
\end{verbatim}

reflection_index_set()
Return the index set of reflections of self.

EXAMPLES:
sage: W = WeylGroup(['A',3], implementation="permutation")
sage: W.reflection_index_set()
(1, 2, 3, 4, 5, 6)

>>> from sage.all import *

>>> W = WeylGroup(['A',Integer(3)], implementation="permutation")

>>> W.reflection_index_set()
(1, 2, 3, 4, 5, 6)

reflections()

Return the reflections of self.

EXAMPLES:

sage: W = WeylGroup(['B',2], implementation="permutation")
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}

>>> from sage.all import *

>>> W = WeylGroup(['B',Integer(2)], implementation="permutation")

>>> W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}

roots()

Return the roots of self.

EXAMPLES:

sage: W = WeylGroup(['G',2], implementation="permutation")
sage: W.roots()
((1, 0),
 (0, 1),
 (1, 1),
 (3, 1),
 (2, 1),
 (3, 2),
 (-1, 0),
 (0, -1),
 (-1, -1),
 (-3, -1),
 (-2, -1),
 (-3, -2))

>>> from sage.all import *

>>> W = WeylGroup(['G',Integer(2)], implementation="permutation")

>>> W.roots()
((1, 0),
 (0, 1),
 (1, 1),
 (3, 1),
 (2, 1),
 (3, 2),
 (-1, 0),
 (0, -1),
 (continues on next page)
(-1, -1),
(-3, -1),
(-2, -1),
(-3, -2))

simple_reflection($i$)

Return the $i$-th simple reflection of self.

EXAMPLES:

```python
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_reflection(1)
(1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20)
sage: W.simple_reflections()
Finite family {1: (1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20),
             2: (1,5)(2,12)(3,6)(7,9)(11,15)(13,16)(17,19),
             3: (2,6)(3,13)(4,7)(5,8)(12,16)(14,17)(15,18),
             4: (3,7)(4,14)(6,9)(8,10)(13,17)(16,19)(18,20)}
```

>>> from sage.all import *

```
>>>
```

simple_root_index($i$)

Return the index of the simple root $\alpha_i$.

This is the position of $\alpha_i$ in the list of simple roots.

EXAMPLES:

```python
sage: W = WeylGroup(['A',3], implementation="permutation")
sage: [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]
```

>>> from sage.all import *

```
>>>
```

simple_roots()

Return the simple roots of self.

EXAMPLES:

```python
sage: W = WeylGroup(['A',4], implementation="permutation")
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
             3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation="permutation")
>>> W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
    3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}

5.1.274 Rooted (Unordered) Trees

AUTHORS:

• Florent Hivert (2011): initial version

class sage.combinat.rooted_tree.LabelledRootedTree (parent, children, label=None,
    check=True)

Bases: AbstractLabelledClonableTree, RootedTree

Labelled rooted trees.

A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The labelled rooted trees are an inductive datatype defined as follows: A labelled rooted tree is a
multiset of labelled rooted trees, endowed with a label (which can be any object, including None). The trees that
belong to this multiset are said to be the children of the tree. (Notice that the labels of these children may and
may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the only
information it carries is its label) is said to be a leaf.

Every labelled rooted tree gives rise to an unlabelled rooted tree (RootedTree) by forgetting the labels. (This is
implemented as a conversion.)

INPUT:

• children – a list or tuple or more generally any iterable of trees or objects convertible to trees

• label – any hashable Sage object (default is None)

Note: It is required that all labels are comparable.

EXAMPLES:

sage: x = LabelledRootedTree([[]], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[],[], []], label = 3)
3[None[], None[None[], None[]]]

>>> from sage.all import *
>>> x = LabelledRootedTree([[]], label = Integer(3)); x
3[]
>>> LabelledRootedTree([x, x, x], label = Integer(2))
2[3[], 3[], 3[]]
>>> LabelledRootedTree((x, x, x), label = Integer(2))
2[3[], 3[], 3[]]

(continues on next page)
Children are reordered using the value of the \texttt{sort_key()} method:

```python
sage: y = LabelledRootedTree([], label = 5); y
5[

sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]

sage: yxy2 = LabelledRootedTree((y, x, y), label = 2); yxy2
2[3[], 5[], 5[]]

sage: xyy2 == yxy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as None):

```python
sage: xyy2crude = RootedTree(xyy2)); xyy2crude
[[], [3, 5, 5]]

sage: LabelledRootedTree(xyy2crude)
None[None[], None[], None[]]
```

**sort_key()**

Return a tuple of nonnegative integers encoding the labelled rooted tree \texttt{self}.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

**Note:** The tree \texttt{self} must be normalized before calling this method (see \texttt{normalize()}). This does not matter unless you are inside the \texttt{clone()} context manager, because outside of it every rooted tree is already normalized.

**Note:** This method overrides \texttt{RootedTree.sort_key()} and returns a result different from what the
latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `RootedOrderedTree`; under some circumstances they could inherit it from another superclass instead of from `RootedTree`, which would cause the method to forget the labelling. See the docstrings of `RootedTree.sort_key()` and `sage.combinat.ordered_tree.OrderedTree.sort_key()`.

**EXAMPLES:**

```python
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.sort_key()
((0, 3),)
```

```python
sage: y = LRT([x, x, x], label = 2);
y
(3, 2), (0, 3), (0, 3), (0, 3)
sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
sage: lb = RootedTrees([[[], [], []]]).canonical_labelling()
sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

```python
>>> from sage.all import *
>>> LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
>>> x = LRT([], label = Integer(3)); x
3[]
```

```python
>>> y = LRT([x, x, x], label = Integer(2)); y
3, 2), (0, 3), (0, 3), (0, 3)
```

```python
>>> y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
```

```python
>>> LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
```

```python
>>> lb = RootedTrees([[[], [], []]]).canonical_labelling()
```

```python
>>> lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```
Todo: Add the possibility to restrict the labels to a fixed set.

class sage.combinat.rooted_tree.LabelledRootedTrees_all(category=None)
Bases: LabelledRootedTrees
Class of all (unordered) labelled rooted trees.
See LabelledRootedTree for a definition.
Element
    alias of LabelledRootedTree
labelled_trees()
    Return the set of labelled trees associated to self.
    EXAMPLES:

    sage: LabelledRootedTrees().labelled_trees()
    Labelled rooted trees

    >>> from sage.all import *
    >>> LabelledRootedTrees().labelled_trees()
    Labelled rooted trees

unlabelled_trees()
    Return the set of unlabelled trees associated to self.
    EXAMPLES:

    sage: LabelledRootedTrees().unlabelled_trees()
    Rooted trees

    >>> from sage.all import *
    >>> LabelledRootedTrees().unlabelled_trees()
    Rooted trees

class sage.combinat.rooted_tree.RootedTree(parent=None, children=[], check=True)
Bases: AbstractClonableTree, NormalizedClonableList
The class for unordered rooted trees.
The unordered rooted trees are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the children of the tree. The tree that has no children is called a leaf.

The labelled rooted trees (LabelledRootedTree) form a subclass of this class; they carry additional data.

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

EXAMPLES:

```python
sage: RootedTree([])
[]
sage: RootedTree([[], [[]]])
[[], [[]]]
sage: RootedTree([[[], []]])
[[], []]
sage: O = OrderedTree([[[], []]]); O
[[], []]
sage: RootedTree(O)  # this is O with the ordering forgotten
[[], []]
```

One can also enter any small rooted tree (“small” meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the from_hexacode() function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```python
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[[], [], [], []]]
```

Note: Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as sage.structure.list_clone.NormalizedClonableList instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their sort_key() value. This is as good as storing them as multisets, since the sort_key() values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of RootedTree which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited sort_key() method will no longer distinguish different trees (and, as a consequence, equal trees will be
Thus, you will have to override the method by one that does distinguish different trees.

**`graft_list(other)`**

Return the list of trees obtained by grafting `other` on `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, chooses a node of `self`, and adds the root of `other` to the list of children of this node. The root of the resulting tree is the root of `self`.

(This can be done for each node of `self`; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

**EXAMPLES:**

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[[]]]
sage: l = y.graft_list(x); l
[[[], [[]], [[]], [[]], [[]], [[[]]]], [[], [[[]]]], [[], [[[]]]], [[], [[[]]]], [[], [[]], [[]], [[]], [[]], [[[]]]], [[], [[]], [[]], [[]], [[]], [[[]]]], [[], [[]], [[]], [[]], [[]], [[[]]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

**`graft_on_root(other)`**

Return the tree obtained by grafting `other` on the root of `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, and adds the root of `other` to the list of children of `self`. The root of the resulting tree is the root of `self`.

This is useful for free Nap algebras.

**EXAMPLES:**

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_on_root(x)
[[[]]]
sage: y.graft_on_root(x)
[[[], [[]], [[]], [[]], [[]], [[[]]]], [[], [[[]]]], [[], [[[]]]], [[], [[[]]]], [[], [[]], [[]], [[]], [[]], [[[]]]], [[], [[]], [[]], [[]], [[]], [[[]]]], [[], [[]], [[]], [[]], [[]], [[[]]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

(continues on next page)
is_empty()

Return if self is the empty tree.

For rooted trees, this always returns False.

**Note:** This is not the same as bool(t), which returns whether t has some child or not.

EXAMPLES:

```python
sage: t = RootedTrees(4)([[],[[]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1)([])
sage: t.is_empty()
False
sage: bool(t)
False
```

normalize()

Normalize self.

This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call normalize directly as it is called automatically upon creation and cloning or modification (by NormalizedClonableList).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the sort_key() method.

EXAMPLES:
sage: RT = RootedTree
sage: RT([[[]],[[]]]) == RT([[[]],[[]]])  # indirect doctest
True
sage: rt1 = RT([[[]],[[]]])
sage: rt2 = RT([[[]],[[]]])
sage: rt1 is rt2
False
sage: rt1 == rt2
True
sage: rt1._get_list() == rt2._get_list()
True

>>> from sage.all import *
>>> RT = RootedTree
>>> RT([[[]],[[]]]) == RT([[[]],[[]]])  # indirect doctest
True
>>> rt1 = RT([[[]],[[]]])
>>> rt2 = RT([[[]],[[]]])
>>> rt1 is rt2
False
>>> rt1 == rt2
True
>>> rt1._get_list() == rt2._get_list()
True

single_graft(x, grafting_function, path_prefix=())

Graft subtrees of \( x \) on \( \text{self} \) using the given function.

Let \( x_1, x_2, \ldots, x_p \) be the children of the root of \( x \). For each \( i \), the subtree of \( x \) comprising all descendants of \( x_i \) is joined by a new edge to the vertex of \( \text{self} \) specified by the \( i \)-th path in the grafting function (i.e., by the path \( \text{grafting\_function}[i] \)).

The number of vertices of the result is the sum of the numbers of vertices of \( \text{self} \) and \( x \) minus one, because the root of \( x \) is not used.

This is used to define the product of the Grossman-Larson algebras.

INPUT:

- \( x \) – a rooted tree
- \( \text{grafting\_function} \) – a list of paths in \( \text{self} \)
- \( \text{path\_prefix} \) – optional tuple (default ())

The \( \text{path\_prefix} \) argument is only used for internal recursion.

EXAMPLES:

sage: LT = LabelledRootedTrees()
sage: y = LT([LT([]), label='b'), label='a'])
sage: x = LT([LT([]), label='d'), label='c'])
sage: y.single_graft(x, [(0,)])
a[b][d[]]
sage: t = LT([LT([]), label='b'], LT([]), label='c'), label='a')
sage: s = LT([LT([]), label='d'], LT([]), label='e'), label='f')
sage: t.single_graft(s, [[0,],(1,)])
a[b[d[]], c[e[]]]
from sage.all import *
LT = LabelledRootedTrees()
y = LT([LT([],label='b')], label='a')
x = LT([LT([],label='d')], label='c')
y.single_graft(x,[(Integer(0),)])
a[b[d[]]]
t = LT([LT([],label='b'),LT([],label='c')], label='a')
s = LT([LT([],label='d'),LT([],label='e')], label='f')
t.single_graft(s,[(Integer(0),),(Integer(1),)])
a[b[d[]], c[e[]]]

class sage.combinat.rooted_tree.RootedTrees
    Bases: UniqueRepresentation, Parent

Factory class for rooted trees.

INPUT:

    * size – (optional) an integer

OUTPUT:

sort_key()

Return a tuple of nonnegative integers encoding the rooted tree self.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

**Note:** The tree self must be normalized before calling this method (see normalize()). This does not matter unless you are inside the clone() context manager, because outside of it every rooted tree is already normalized.

**Note:** By default, this method does not encode any extra structure that self might have. If you have a subclass inheriting from RootedTree which allows for some extra structure, you need to override sort_key() in order to preserve this structure (for example, the LabelledRootedTree class does this in LabelledRootedTree.sort_key()). See the note in the docstring of sage.combinat.ordered_tree.OrderedTree.sort_key() for a pitfall.

**EXAMPLES:**

```python
sage: RT = RootedTree
sage: RT([[[],[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[[]]]).sort_key()
(2, 0, 1, 0)
```
the set of all rooted trees (of the given size \texttt{size} if specified)

**EXAMPLES:**

```python
sage: RootedTrees()
Rooted trees
```

```python
sage: RootedTrees(2)
Rooted trees with 2 nodes
```

```python
>>> from sage.all import *

>>> RootedTrees()
Rooted trees
```

```python
>>> RootedTrees(Integer(2))
Rooted trees with 2 nodes
```

**class** `sage.combinat.rooted_tree.RootedTrees_all`

**Bases:** `DisjointUnionEnumeratedSets, RootedTrees`

Class of all (unordered, unlabelled) rooted trees.

See `RootedTree` for a definition.

**Element**

alias of `RootedTree`

**labelled_trees()**

Return the set of labelled trees associated to \texttt{self}.

**EXAMPLES:**

```python
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

```python
>>> from sage.all import *

>>> RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```python
sage: lb = RootedTrees()([[[]]], [[]], [[]])).canonical_labelling()
sage: lb
1[[2], 3[[4], 5]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.element_class'>
sage: lb.parent()
Labelled rooted trees
```

```python
>>> from sage.all import *

>>> lb = RootedTrees()([[[]]], [[]], [[]])).canonical_labelling()
>>> lb
1[[2], 3[[4], 5]]
>>> lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.element_class'>
>>> lb.parent()
Labelled rooted trees
```
leaf()

    Return a leaf tree with self as parent.

    EXAMPLES:

    sage: RootedTrees().leaf()
    []

    >>> from sage.all import *
    >>> RootedTrees().leaf()
    []

unlabelled_trees()

    Return the set of unlabelled trees associated to self.

    EXAMPLES:

    sage: RootedTrees().unlabelled_trees()
    Rooted trees

    >>> from sage.all import *
    >>> RootedTrees().unlabelled_trees()
    Rooted trees

class sage.combinat.rooted_tree.RootedTrees_size(n)

    Bases: RootedTrees

    The enumerated set of rooted trees with a given number of nodes.

    The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with \( a \) children is \( a \) plus the sum of the number of nodes of each of these children.

cardinality()

    Return the cardinality of self.

    EXAMPLES:

    sage: RootedTrees(1).cardinality()
    1
    sage: RootedTrees(3).cardinality()
    2

    >>> from sage.all import *
    >>> RootedTrees(Integer(1)).cardinality()
    1
    >>> RootedTrees(Integer(3)).cardinality()
    2

check_element(el, check=True)

    Check that a given tree actually belongs to self.

    This just checks the number of vertices.

    EXAMPLES:

    sage: RT3 = RootedTrees(3)
sage: RT3([[[]],[]]) # indirect doctest
    []

    (continues on next page)
Combinatorics, Release 10.4

```
sage: RT3([[[]]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

```
>>> from sage.all import *
>>> RT3 = RootedTrees(Integer(3))
>>> RT3([[[]]]) # indirect doctest
[[[]]]
>>> RT3([[[]],[[]]]) # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

**element_class()**

`sage.combinat.rooted_tree.number_of_rooted_trees()`

Return the number of rooted trees with \( n \) nodes.

Compute the number \( a(n) \) of rooted trees with \( n \) nodes using the recursive formula ([SL000081]):

\[
a(n + 1) = \frac{1}{n} \sum_{k=1}^{n} \left( \sum_{d|k} da(d) \right) a(n - k + 1)
\]

**EXAMPLES:**

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

```
>>> from sage.all import *
>>> from sage.combinat.rooted_tree import number_of_rooted_trees
>>> [number_of_rooted_trees(i) for i in range(Integer(10))]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

Introduction

The Robinson-Schensted-Knuth (RSK) correspondence is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, …) and pairs of semi-standard Young tableaux \((P, Q)\) of identical shape.

The basic operation in the RSK correspondence is a row insertion \(P \leftarrow k\) (where \(P\) is a given semi-standard Young tableau, and \(k\) is an integer). Different insertion algorithms have been implemented for the RSK correspondence and can be specified as an argument in the function call.

EXAMPLES:

We can perform RSK and its inverse map on a variety of objects:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp)  # RSK of a biword
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: RSK([[2,3,2,1,2,3]])  # Robinson-Schensted of a word
[[[1, 2, 2, 3], [2], [3]], [[1, 2, 5, 6], [3], [4]]]
sage: RSK([[2,3,2,1,2,3], insertion=RSK.rules.EG])  # Edelman-Greene
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
sage: m = RSK_inverse(p, q, 'matrix'); m  # output as matrix
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
```
Insertions currently available

The following insertion algorithms for RSK correspondence are currently available:

- RSK insertion (RuleRSK).
- Edelman-Greene insertion (RuleEG), an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion).
- Hecke RSK algorithm (RuleHecke), defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns).
- Dual RSK insertion (RuleDualRSK).
- CoRSK insertion (RuleCoRSK), defined in [GR2018v5sol].
- Super RSK insertion (RuleSuperRSK), a combination of row and column insertions defined in [Muth2019].
- Star insertion (RuleStar), defined in [MPPS2020].

Implementing your own insertion rule

The functions $\text{RSK}()$ and $\text{RSK\_inverse}()$ are written so that it is easy to implement insertion algorithms you come across in your research.

To implement your own insertion algorithm, you first need to import the base class for a rule:

```
sage: from sage.combinat.rsk import Rule
```

Using the Rule class as parent class for your insertion rule, first implement the insertion and the reverse insertion algorithm for $\text{RSK}()$ and $\text{RSK\_inverse}()$ respectively (as methods $\text{forward\_rule}$ and $\text{backward\_rule}$). If your insertion algorithm uses the same forward and backward rules as RuleRSK, differing only in how an entry is inserted into a row, then this is not necessary, and it suffices to merely implement the $\text{insertion}$ and $\text{reverse\_insertion}$ methods.

For more information, see Rule.

sage.combinat.rsk.RSK(obj1=None, obj2=None, insertion=None, check_standard=False, **options)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux \((P, Q)\) of identical shape. The tableau \(P\) is known as the insertion tableau, and \(Q\) is known as the recording tableau.

The basic operation is known as row insertion \(P \leftarrow k\) (where \(P\) is a given semi-standard Young tableau, and \(k\) is an integer). Row insertion is a recursive algorithm which starts by setting \(k_0 = k\), and in its \(i\)-th step inserts the number \(k_i\) into the \(i\)-th row of \(P\) (we start counting the rows at 0) by replacing the first integer greater than \(k_i\) in the row by \(k_i\) and defines \(k_{i+1}\) as the integer that has been replaced. If no integer greater than \(k_i\) exists in the \(i\)-th row, then \(k_i\) is simply appended to the row and the algorithm terminates at this point.

A generalized permutation (or biword) is a list \((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1})\) of pairs such that the letters \(j_0, j_1, \ldots, j_{\ell-1}\) are weakly increasing (that is, \(j_0 \leq j_1 \leq \cdots \leq j_{\ell-1}\)), whereas the letters \(k_0, k_1, \ldots, k_{\ell-1}\) satisfy \(k_0 \leq \cdots \leq k_{\ell-1}\) whenever \(j_1 = j_{i+1}\). The \(\ell\)-tuple \((j_0, j_1, \ldots, j_{\ell-1})\) is called the top line of this generalized permutation, whereas the \(\ell\)-tuple \((k_0, k_1, \ldots, k_{\ell-1})\) is called its bottom line.

Now the RSK algorithm, applied to a generalized permutation \(p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))\) (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux \(P_0 \) and \(Q_0 \) as empty tableaux. For each nonnegative integer \(t\) starting at 0, take the pair \((j_t, k_t)\) from \(p\) and set \(P_{t+1} = P_t \leftarrow k_t\), and define \(Q_{t+1}\) by adding a new box filled with \(j_t\) to the tableau \(Q_t\) at the same location the row insertion on \(P_t\) ended (that is to say, adding a new box with entry \(j_t\) such that \(P_{t+1}\) and \(Q_{t+1}\) have the same shape). The iterative process stops when \(t\) reaches the size of \(p\), and the pair \((P_t, Q_t)\) at this point is the image of \(p\) under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A”.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word \(w\) (and, in particular, any permutation) to a generalized permutation by considering the top row to be \((1, 2, \ldots, n)\) where \(n\) is the length of \(w\).

The optional argument insertion allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- \(\text{obj1}, \text{obj2}\) – can be one of the following:
  - a word in an ordered alphabet (in this case, \text{obj1} is said word, and \text{obj2} is \text{None})
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists \((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1})\) represent the generalized permutation \(((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))\))
  - any object which has a method \_rsk\_iter\_() which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, \text{obj1} is said object, and \text{obj2} is \text{None}).
• insertion – (default: RSK.rules.RSK) the following types of insertion are currently supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (RuleRSK)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (RuleEG)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (RuleHecke)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (RuleDualRSK)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (RuleCoRSK)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (RuleSuperRSK)
  - RSK.rules.Star (or 'Star') – ⋆-insertion (only for fully commutative words in the 0-Hecke monoid) (RuleStar)

• check_standard – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular Rule class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1, 2, \ldots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

```python
>>> from sage.all import *
```

```python
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1), Integer(1), Integer(1), Integer(1), Integer(3), Integer(2), Integer(3)])
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

[Continues on next page]
We can provide a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python * on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P, Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

```
sage.combinat.rsk.RSK_inverse(p, q, output='array', insertion=<class 'sage.combinat.rsk.RuleRSK'>)
```

Return the generalized permutation corresponding to the pair of tableaux \((p, q)\) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see `RSK()`.

**INPUT:**

- \(p, q\) – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- `output` – (default: 'array') if \(q\) is semi-standard:
- 'array' – as a two-line array (i.e. generalized permutation or biword)
- 'matrix' – as an integer matrix

and if \( q \) is standard, we can also have the output:
- 'word' – as a word

and additionally if \( p \) is standard, we can also have the output:
- 'permutation' – as a permutation

- insertion – (default: \( \texttt{RSK.rules.RSK} \)) the insertion algorithm used in the bijection. Currently the following are supported:
  - \( \texttt{RSK.rules.RSK} \) (or \( \texttt{RSK} \)) – Robinson-Schensted-Knuth insertion (\( \texttt{RuleRSK} \))
  - \( \texttt{RSK.rules.EG} \) (or \( \texttt{EG} \)) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type \( A \) Coxeter group) (\( \texttt{RuleEG} \))
  - \( \texttt{RSK.rules.Hecke} \) (or \( \texttt{hecke} \)) – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (\( \texttt{RuleHecke} \))
  - \( \texttt{RSK.rules.dualRSK} \) (or \( \texttt{dualRSK} \)) – Dual RSK insertion (only for strict biwords) (\( \texttt{RuleDualRSK} \))
  - \( \texttt{RSK.rules.coRSK} \) (or \( \texttt{coRSK} \)) – CoRSK insertion (only for strict cobiwords) (\( \texttt{RuleCoRSK} \))
  - \( \texttt{RSK.rules.superRSK} \) (or \( \texttt{super} \)) – Super RSK insertion (only for restricted super biwords) (\( \texttt{RuleSuperRSK} \))
  - \( \texttt{RSK.rules.Star} \) (or \( \texttt{Star} \)) – \( \star \)-insertion (only for fully commutative words in the 0-Hecke monoid) (\( \texttt{RuleStar} \))

For precise information about constraints on the input and output, see the particular \( \texttt{Rule} \) class.

**Note:** In the case of Hecke insertion, the input variable \( q \) should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

**EXAMPLES:**

If both \( p \) and \( q \) are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
```

(continues on next page)
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]

>>> from sage.all import *

>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)]], [Integer(3)],
               [Integer(4)])

>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)]], [Integer(4)],
               [Integer(5)])

>>> RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]

>>> RSK_inverse(t1, t2, 'word')
word: 14532

>>> RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 1 0 0 0]

>>> RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]

>>> RSK_inverse(t1, t1, permutation)
[1, 4, 3, 2, 5]

>>> RSK_inverse(t2, t2, permutation)
[1, 2, 5, 4, 3]

>>> RSK_inverse(t2, t1, permutation)
[1, 5, 4, 2, 3]

If the first tableau is semistandard:

sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]

sage: RSK_inverse(p, q, 'word')
word: 1322

>>> from sage.all import *

>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]);
    q = Tableau([[Integer(1),Integer(3)],[Integer(2)]])

>>> ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]

>>> RSK_inverse(p, q, 'word')
word: 1322

In general:

sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]

sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]

>>> from sage.all import *

>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]);
    q = Tableau([[Integer(1),Integer(2)],[Integer(2)]]);

(continues on next page)
Using Hecke insertion:

```
sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

```
>> from sage.all import *
>> w = [Integer(5), Integer(4), Integer(3), Integer(1), Integer(4), Integer(2),
\[Integer(5), Integer(5)]
>> pq = RSK(w, insertion=RSK.rules.Hecke)
>> RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

**Note:** The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke').`) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

```python
class sage.combinat.rsk.Rule
Bases: UniqueRepresentation

Generic base class for an insertion rule for an RSK-type correspondence.

An instance of this class should implement a method `insertion()` (which can be applied to a letter \( j \) and a list \( r \), and modifies \( r \) in place by “bumping” \( j \) into it appropriately; it then returns the bumped-out entry or None if no such entry exists) and a method `reverse_insertion()` (which does the same but for reverse bumping). It may also implement `backward_format_output()` and `forward_format_output()` if the RSK correspondence should return something other than (semi)standard tableaux (in the forward direction) and matrices or biwords (in the backward direction). The `to_pairs()` method should also be overridden if the input for the (forward) RSK correspondence is not the usual kind of biwords (i.e., pairs of two \( n \)-tuples \([a_1, a_2, \ldots, a_n]\) and \([b_1, b_2, \ldots, b_n]\) satisfying \((a_1, b_1) \leq (a_2, b_2) \leq \cdots \leq (a_n, b_n)\) in lexicographic order). Finally, it `forward_rule()` and `backward_rule()` have to be overridden if the overall structure of the RSK correspondence differs from that of classical RSK (see, e.g., the case of Hecke insertion, in which a letter bumped into a row may change a different row).

`backward_rule(p, q, output)`

Return the generalized permutation obtained by applying reverse insertion to a pair of tableaux \((p, q)\).

**INPUT:**

- \( p, q \) – two tableaux of the same shape.
- `output` – (default: 'array') if \( q \) is semi-standard:
  - 'array' – as a two-line array (i.e. generalized permutation or biword)
  - 'matrix' – as an integer matrix
and if $q$ is standard, we can also have the output:

- 'word' – as a word

and additionally if $p$ is standard, we can also have the output:

- 'permutation' – as a permutation

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleRSK
sage: t1 = Tableau([[1, 3, 4], [2], [3]])
sage: t2 = Tableau([[1, 2, 4], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]

sage: t1 = Tableau([[1, 1, 1, 3, 7]])
sage: t2 = Tableau([[1, 2, 3, 4, 5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]

sage: t1 = Tableau([[1, 3], [3], [6], [7]])
sage: t2 = Tableau([[1, 4], [2], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

```python
>>> from sage.all import *

>>> from sage.combinat.rsk import RuleRSK

>>> t1 = Tableau([Integer(1), Integer(3), Integer(4), [Integer(2), ...
                        Integer(3)]])

>>> t2 = Tableau([Integer(1), Integer(2), Integer(4), [Integer(3), ...
                        Integer(5)]])

>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]

>>> t1 = Tableau([Integer(1), Integer(1), Integer(1), Integer(3), ...
                        Integer(7)])

>>> t2 = Tableau([Integer(1), Integer(2), Integer(3), Integer(4), ...
                        Integer(5)])

>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

forward_rule (obj1, obj2, check_standard=False, check=True)

Return a pair of tableaux obtained by applying forward insertion to the generalized permutation [obj1, obj2].

INPUT:

- obj1, obj2 – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword
  - a matrix obj1 of nonnegative integers, to be interpreted as the generalized permutation in matrix form (in this case, obj2 is None)
- a word \( \text{obj1} \) in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, \( \text{obj2} \) is None; the top row of the biword is understood to be \((1, 2, \ldots, n)\) by default)

- any object \( \text{obj1} \) which has a method \_rsk_iter(), as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, \( \text{obj2} \) is None)

  - \text{check\_standard} – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typcast it as such

  - \text{check} – (default: True) whether to check that \( \text{obj1} \) and \( \text{obj2} \) actually define a valid biword

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleRSK
sage: RuleRSK().forward_rule([3,3,2,4,1], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RuleRSK().forward_rule([1, 1, 1, 3, 7], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
sage: RuleRSK().forward_rule([7, 6, 3, 3, 1], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> RuleRSK().forward_rule([Integer(3),Integer(3),Integer(2),Integer(4),...
→ Integer(1)], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RuleRSK().forward_rule([Integer(1), Integer(1), Integer(1), Integer(3),...
→ Integer(7)], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
>>> RuleRSK().forward_rule([Integer(7), Integer(6), Integer(3), Integer(3),...
→ Integer(1)], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

\text{to\_pairs} (\( \text{obj1}=\text{None}, \text{obj2}=\text{None}, \text{check}=\text{True} \))

Given a valid input for the RSK algorithm, such as two \( n \)-tuples \( \text{obj1} = [a_1, a_2, \ldots, a_n] \) and \( \text{obj2} = [b_1, b_2, \ldots, b_n] \) forming a biword (i.e., satisfying \( a_1 \leq a_2 \leq \cdots \leq a_n \), and if \( a_i = a_{i+1} \), then \( b_i \leq b_{i+1} \)), or a matrix (“generalized permutation”), or a single word, return the array \([((a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n))\].

**INPUT:**

- \( \text{obj1}, \text{obj2} \) – anything representing a biword (see the doc of \text{forward\_rule()} for the encodings accepted).

- \text{check} – (default: True) whether to check that \( \text{obj1} \) and \( \text{obj2} \) actually define a valid biword.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import Rule
sage: list(Rule().to_pairs([1, 2, 2, 2], [2, 1, 1, 2]))
[(1, 2), (2, 1), (2, 1), (2, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: list(Rule().to_pairs(m))
[[[1, 2], [2, 1], [2, 1], [2, 2]]]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.rsk import Rule

>>> list(Rule().to_pairs([Integer(1), Integer(2), Integer(2), Integer(2)],
                        [(Integer(2), Integer(1), Integer(1), Integer(2))])
[(1, 2), (2, 1), (2, 1), (2, 2)]

>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0), Integer(1), Integer(1),
                                             [Integer(0), Integer(0), Integer(2)]]) ; m
[0 1]
[1 0]
[0 2]

>>> list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

class sage.combinat.rsk.RuleCoRSK

**Bases:** RuleRSK

Rule for coRSK insertion.

CoRSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer a biword, but rather a strict cobiword – i.e., a pair of two lists \([a_1, a_2, \ldots, a_n]\) and \([b_1, b_2, \ldots, b_n]\) that satisfy the strict inequalities \((a_1, b_1) < (a_2, b_2) < \cdots < (a_n, b_n)\), where the binary relation \(<\) on pairs of integers is defined by having \((u_1, v_1) < (u_2, v_2)\) if and only if either \(u_1 < u_2\) or \((u_1 = u_2\) and \(v_1 > v_2\)). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a \(\{0, 1\}\)-matrix (i.e., a matrix whose entries are 0's and 1's).

- The output still consists of two tableaux \((P, Q)\) of equal shapes, but rather than both of them being semistandard, now \(Q\) is row-strict (i.e., its transpose is semistandard) while \(P\) is semistandard.

Bumping proceeds in the same way as for RSK insertion.

The RSK and coRSK algorithms agree for permutation matrices.

For more information, see Section A.4 in [Ful1997] (specifically, construction (1d)) or the second solution to Exercise 2.7.12(a) in [GR2018v5sol].

**EXAMPLES:**

```python
sage: RSK([1, 2, 5, 3, 1], insertion = RSK.rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]]
sage: RSK(Word([2, 3, 2, 1, 3, 2, 3]), insertion = RSK.rules.coRSK)
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3, 3, 2, 4, 1]), insertion = RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: from sage.combinat.rsk import to_matrix

sage: RSK(to_matrix([1, 1, 3, 3, 4], [3, 2, 2, 1, 3]), insertion = RSK.rules.coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]]

```
Using coRSK insertion with a \{0, 1\}-matrix:

\[
\begin{align*}
\text{sage: } & \text{RSK(matrix}([([0,1],[1,0]), \text{insertion = RSK.rules.coRSK}) \\
& [[[1], [2]], [[1], [2]]]
\end{align*}
\]

We can also give it something looking like a matrix:

\[
\begin{align*}
\text{sage: } & \text{RSK}([[0,1],[1,0]), \text{insertion = RSK.rules.coRSK}) \\
& [[[1], [2]], [[1], [2]]]
\end{align*}
\]

We can also use the inverse correspondence:

\[
\begin{align*}
\text{sage: } & \text{RSK_inverse}(*RSK([1, 2, 2, 2], [2, 3, 2, 1], \text{insertion=RSK.rules.coRSK}) \\
& \text{[[1, 2, 2, 2], [2, 3, 2, 1]]}
\end{align*}
\]

When applied to two standard tableaux, backwards coRSK insertion behaves identically to the usual backwards RSK insertion:

\[
\begin{align*}
\text{sage: } & \text{t1 = Tableau}([[1, 2, 5], [3], [4]]) \\
\text{sage: } & \text{t2 = Tableau}([[1, 2, 3], [4], [5]]) \\
\text{sage: } & \text{RSK_inverse(t1, t2, insertion=RSK.rules.coRSK)} \\
& \text{[[1, 2, 2, 2, 2], [2, 3, 2, 1]]}
\end{align*}
\]

(continues on next page)
backward_rule\( (p, q, output) \)

Return the strict co-biword obtained by applying reverse coRSK insertion to a pair of tableaux \((p, q)\).
INPUT:

- \(p, q\) – two tableaux of the same shape
- `output` – (default: 'array') if \(q\) is row-strict:
  - 'array' – as a two-line array (i.e. strict cobiword)
  - 'matrix' – as a \(\{0,1\}\)-matrix

and if \(q\) is standard, we can have the output:

- 'word' – as a word

and additionally if \(p\) is standard, we can also have the output:

- 'permutation' – as a permutation

EXAMPLES:

```python
def to_pairs(obj1=None, obj2=None, check=True):
    # Implementation code...
```

Given a valid input for the coRSK algorithm, such as two \(n\)-tuples \(\{a_1, a_2, \ldots, a_n\}\) and \(\{b_1, b_2, \ldots, b_n\}\) forming a strict cobiword (i.e., satisfying \(a_1 \leq a_2 \leq \cdots \leq a_n\), and if \(a_i = a_{i+1}\), then \(b_i > b_{i+1}\)), or a \(\{0,1\}\)-matrix (“rook placement”), or a single word, return the array 

```
[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)].
```

INPUT:

- \(obj1, obj2\) – anything representing a strict cobiword (see the doc of `forward_rule()` for the encodings accepted)
- `check` – (default: True) whether to check that \(obj1\) and \(obj2\) actually define a valid strict cobiword

EXAMPLES:

```python
def to_pairs(obj1=None, obj2=None, check=True):
    # Implementation code...
```

ValueError: coRSK requires a (0, 1)-matrix
```

class sage.combinat.rsk.RuleDualRSK

Bases: Rule

Rule for dual RSK insertion.

Dual RSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a strict biword (i.e., a pair of two lists \( [a_1, a_2, \ldots, a_n] \) and \( [b_1, b_2, \ldots, b_n] \) that satisfy the strict inequalities \( (a_1, b_1) < (a_2, b_2) < \cdots < (a_n, b_n) \) in lexicographic order). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a \{0, 1\}-matrix (i.e., a matrix whose entries are 0’s and 1’s).

- The output still consists of two tableaux \( (P, Q) \) of equal shapes, but rather than both of them being semistandard, now \( P \) is row-strict (i.e., its transpose is semistandard) while \( Q \) is semistandard.

- The main difference is in the way bumping works. Namely, when a number \( k_i \) is inserted into the \( i \)-th row of \( P \), it bumps out the first integer greater or equal to \( k_i \) in this row (rather than greater than \( k_i \)).

The RSK and dual RSK algorithms agree for permutation matrices.

For more information, see Chapter 7, Section 14 in [Sta-EC2] (where dual RSK is called RSK\(^*\)) or the third solution to Exercise 2.7.12(a) in [GR2018v5sol].
EXAMPLES:

```python
sage: RSK([3,3,2,4,1], insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]

sage: RSK(Word([3,3,2,4,1]), insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]

sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]
```

Using dual RSK insertion with a strict biword:

```python
sage: RSK([1,1,2,4,4,5],[2,4,1,1,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2], [1, 3], [2, 4]], [[1, 1], [2, 4], [4, 5]]

sage: RSK([1,1,2,3,3,4,5],[1,3,2,1,3,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1, 2], [3], [3]], [[1, 1, 3], [2, 4], [3], [4]]

sage: RSK([1,2,2,2],[2,1,2,4], insertion=RSK.rules.dualRSK)
[[[1, 2, 4], [2]], [[1, 2, 2], [2]]

sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1], [4]], [[1, 1, 4], [3], [4]]
```

Using dual RSK insertion with a \([0,1]\)-matrix:

```python
sage: RSK(matrix([[0,1],[1,1]]), insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]
```

Using dual RSK insertion with a \([0,1]\)-matrix:

```python
sage: RSK(matrix([[0,1],[1,1]]), insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]
```
```python
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)], [Integer(1),Integer(1)]]), insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]

We can also give it something looking like a matrix:

```python
sage: RSK([[0,1],[1,1]], insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]

```python
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(1),Integer(1)]], insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]

Let us now call the inverse correspondence:

```python
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 2, 3], insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[[1, 2, 2, 2], [2, 1, 2, 3]]

```python
```python
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],insertion=RSK.rules.dualRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[[1, 2, 2, 2], [2, 1, 2, 3]]

```python
```python
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1), Integer(2), Integer(3)], insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[[1, 2, 2, 2], [2, 1, 2, 3]]

```python
```python
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1), Integer(2), Integer(3)],insertion=RSK.rules.dualRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[[1, 2, 2, 2], [2, 1, 2, 3]]

When applied to two standard tableaux, reverse dual RSK insertion behaves identically to the usual reverse RSK insertion:

```python
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]

```python
```python
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532

```python
```python
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[[1 0 0 0 0]
 [0 0 0 1 0]
 [0 0 0 1 0]
 [0 0 0 0 1]
 [0 1 0 0 0]]

```python
```python
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]

```python
```python
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]

```python
```python
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]

```python
```python
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]
```
>>> from sage.all import *

>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],
   ...
   -> [Integer(4)]])

>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],
   ...
   -> [Integer(5)]])

>>> RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[1, 3, 4, 5], [1, 4, 5, 3, 2]]

>>> RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532

>>> RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[[0 0 0 0]
 [0 0 0 1]
 [0 0 1 0]
 [0 1 0 0]]

>>> RSK_inverse(t1, t1, permutation, insertion=RSK.rules.dualRSK)
[1, 4, 3, 2, 5]

>>> RSK_inverse(t2, t2, permutation, insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]

>>> RSK_inverse(t2, t1, permutation, insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]

Let us check that forward and backward dual RSK are mutually inverse when the first tableau is merely transpose semistandard:

```sage
p = Tableau([[1,2,2],[1]]); q = Tableau([[1,2,4],[3]])
ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
[[1, 2, 3, 4], [1, 2, 1, 2]]

RSK_inverse(p, q, word, insertion=RSK.rules.dualRSK)
word: 1212
```

In general for dual RSK:

```sage
p = Tableau([[1,1,2],[1]]); q = Tableau([[1,3,3],[2]])
RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 3], [1, 1, 1, 2]]

RSK_inverse(p, q, matrix, insertion=RSK.rules.dualRSK)
[[0 0]
 [0 0]]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

\[ \begin{bmatrix}
1 & 0 \\
1 & 0 \\
1 & 1 \\
\end{bmatrix} \]

insertion \( (j, r) \)

Insert the letter \( j \) from the second row of the biword into the row \( r \) using dual RSK insertion, if there is bumping to be done.

The row \( r \) is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.rsk import RuleDualRSK
tsage: r = [1, 3, 4, 5]
tsage: j = RuleDualRSK().insertion(4, r); j
4
sage: r
[1, 3, 4, 5]
tsage: r = [1, 2, 3, 6, 7]
tsage: j = RuleDualRSK().insertion(4, r); j
6
sage: r
[1, 2, 3, 4, 7]
tsage: r = [1, 3]
tsage: j = RuleDualRSK().insertion(4, r); j
is None
True
sage: r
[1, 3]
\end{verbatim}

reverse_insertion \( (x, row) \)

Reverse bump the row \( row \) of the current insertion tableau with the number \( x \) using dual RSK insertion.

The row \( row \) is modified in place. The bumped-out entry is returned.

EXAMPLES:

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> r = [Integer(1), Integer(3), Integer(4), Integer(5)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
4
>>> r
[1, 3, 4, 5]
>>> r = [Integer(1), Integer(2), Integer(3), Integer(6), Integer(7)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
6
>>> r
[1, 2, 3, 4, 7]
>>> r = [Integer(1), Integer(3)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
is None
True
>>> r
[1, 3]
\end{verbatim}

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
[1, 2, 4, 6, 7]
sage: x
6
sage: r = [1, 2, 4, 5, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
5
```

```python
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK

>>> r = [Integer(1), Integer(2), Integer(4), Integer(6), Integer(7)]
>>> x = RuleDualRSK().reverse_insertion(Integer(6), r); r
[1, 2, 4, 6, 7]
```

```python
... to_pairs (obj1=None, obj2=None, check=True)
```

to_pairs (obj1=None, obj2=None, check=True)

Given a valid input for the dual RSK algorithm, such as two \(n\)-tuples \(\text{obj1} = [a_1, a_2, \ldots, a_n]\) and \(\text{obj2} = [b_1, b_2, \ldots, b_n]\) forming a strict biword (i.e., satisfying \(a_1 \leq a_2 \leq \cdots \leq a_n\), and if \(a_i = a_{i+1}\), then \(b_i < b_{i+1}\)) or a \(\{0, 1\}\)-matrix (“rook placement”), or a single word, return the array \([((a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n))\].

INPUT:

- \(\text{obj1, obj2}\) – anything representing a strict biword (see the doc of `forward_rule()` for the encodings accepted)
- \(\text{check}\) – (default: True) whether to check that \(\text{obj1}\) and \(\text{obj2}\) actually define a valid strict biword

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleDualRSK
sage: list(RuleDualRSK().to_pairs([1, 2, 2, 2], [2, 1, 2, 3]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
sage: RuleDualRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
... ValueError: invalid strict biword
sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1])
[0 1]
[1 1]
[0 1]
sage: RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
... ValueError: invalid strict biword
```

(continues on next page)
ValueError: dual RSK requires a \{0, 1\}-matrix

>>> list(RuleDualRSK().to_pairs([Integer(1), Integer(2), Integer(2),
    →Integer(2)], [Integer(2), Integer(1), Integer(2), Integer(3)]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
```

Traceback (most recent call last):
...
ValueError: invalid strict biword

```python
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
    →Integer(1),Integer(0),Integer(1)]) ; m
[0 1]
[1 1]
[0 1]
```

```python
>>> list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
```

Traceback (most recent call last):
...
ValueError: dual RSK requires a \{0, 1\}-matrix

### class sage.combinat.rsk.RuleEG

Bases: `Rule`

Rule for Edelman-Greene insertion.

For a reduced word of a permutation (i.e., an element of a type \(A\) Coxeter group), one can use Edelman-Greene insertion, an algorithm defined in \[EG1987\] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that (using the notations in the documentation of `RSK()` if \(k_i\) and \(k_i + 1\) both exist in row \(i\), we only set \(k_{i+1} = k_i + 1\) and continue.

**EXAMPLES:**

Let us reproduce figure 6.4 in \[EG1987\]:

```python
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG)
```

```python
>>> from sage.all import *
>>> RSK([Integer(2),Integer(3),Integer(2),Integer(1),Integer(2),Integer(3)],
    →insertion=RSK.rules.EG)
```

Some more examples:

```python
sage: a = [2, 1, 2, 3, 2]
sage: pq = RSK(a, insertion=RSK.rules.EG); pq
```

```python
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
```
The RSK algorithm (\texttt{RSK()}) built using the Edelman-Greene insertion rule \texttt{RuleEG} is a bijection from reduced words of permutations/elements of a type $A$ Coxeter group to pairs consisting of an increasing tableau and a standard tableau of the same shape (see [EG1987] Theorem 6.25). The inverse of this bijection is obtained using \texttt{RSK\_inverse()}. If the optional parameter \texttt{output = 'permutation'} is set in \texttt{RSK\_inverse()}, then the function returns not the reduced word itself but the permutation (of smallest possible size) whose reduced word it is (although the order of the letters is reverse to the usual Sage convention):

\begin{verbatim}
>> from sage.all import *
>>> a = [Integer(2), Integer(1), Integer(2), Integer(3), Integer(2)]
>>> pq = RSK(a, insertion=RSK.rules.EG); pq
[[(1, 2, 3), (2, 3)], [(1, 3, 4), (2, 5)]]
>>> RSK(RSK\_inverse(*pq, insertion=RSK.rules.EG, output='matrix'),
..... insertion=RSK.rules.EG)
[[(1, 2, 3), (2, 3)], [(1, 3, 4), (2, 5)]]
>>> RSK\_inverse(*pq, insertion=RSK.rules.EG)
[(1, 2, 3, 4, 5), (2, 1, 2, 3, 2)]
\end{verbatim}

\texttt{insertion}(j,r)

Insert the letter $j$ from the second row of the biword into the row $r$ using Edelman-Greene insertion, if there is bumping to be done.

The row $r$ is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.rsk import RuleEG
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleEG().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [2,3,4,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 4, 5, 8]
sage: j
4
sage: qr, r = [1,2,3,4,5], [2,3,5,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 3, 5, 8]
\end{verbatim}

(continues on next page)
reverse_insertion\( (x, \text{row}) \)
Reverse bump the row \text{row} of the current insertion tableau with the number \(x\).

The row \text{row} is modified in place. The bumped-out entry is returned.

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleEG
sage: r = [1,1,1,2,3,3]
```
```python
sage: x = RuleEG().reverse_insertion(3, r); r
[1, 1, 1, 2, 3, 3]
```
```python
sage: x
2
```

class sage.combinat.rsk.RuleHecke
Bases: Rule

Rule for Hecke insertion.

The Hecke RSK algorithm is similar to the classical RSK algorithm, but is defined using the Hecke insertion introduced in [BKSTY06] (but using rows instead of columns). It is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword \(p\) has top row \((1, 2, \ldots, n)\) (or, at least, has its top row strictly increasing).

The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If \(p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))\), then the algorithm recursively constructs pairs.
Combinatorics, Release 10.4

\((P_0, Q_0), (P_1, Q_1), \ldots, (P_\ell, Q_\ell)\) of tableaux. The construction of \(P_{t+1}\) and \(Q_{t+1}\) from \(P_t, Q_t, j_t\) and \(k_t\) proceeds as follows: Set \(i = j_t, x = k_t, P = P_t\) and \(Q = Q_t\). We are going to insert \(x\) into the increasing tableau \(P\) and update the set-valued “recording tableau” \(Q\) accordingly. As in the classical RSK algorithm, we first insert \(x\) into row 1 of \(P\), then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting \(x\) into row \(R\) of \(P\) such that \(x < y\), then let \(y\) be the minimal such entry. We replace this entry \(y\) with \(x\) if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting \(y\) into the next row of \(P\). If, on the other hand, \(\text{(Case 2)}\) no such \(y\) exists, then we append \(x\) to the end of \(R\) if the result is an increasing tableau \(\text{(Subcase 2.1)}\), and otherwise \(\text{(Subcase 2.2)}\) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with \(x\) in \(P\) to the shape of \(Q\), and fill it with the one-element set \(\{i\}\). In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row \(R\), and add \(i\) to the entry of \(Q\) in this box \(\text{(this entry is a set, since \(Q\) is set-valued)}\). In either subcase, we terminate the recursion, and set \(P_{t+1} = P\) and \(Q_{t+1} = Q\).

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set \(\text{(namely, the set of its entries)}\).

EXAMPLES:

As an example of Hecke insertion, we reproduce Example 2.1 in arXiv 0801.1319v2:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]

[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
[[1, (4,), (5,), (7,)],
[(2,), (9,), (11, 13)],
[(3,), (12,)],
[(6,)],
[(8, 10)]]
sage: wp = RSK_inverse(P, Q, insertion=RSK.rules.Hecke,
... output=list); wp

[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: wp == w
True
```

```
>>> from sage.all import *

>>> w = [Integer(5), Integer(4), Integer(1), Integer(3), Integer(4), Integer(2),
       Integer(5), Integer(1), Integer(2), Integer(1), Integer(4), Integer(2),
       Integer(4)]

>>> P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]

[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
[[1, (4,), (5,), (7,)],
[(2,), (9,), (11, 13)],
[(3,), (12,)],
[(6,)],
[(8, 10)]]

>>> wp = RSK_inverse(P, Q, insertion=RSK.rules.Hecke,
... output=list); wp

[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]

>>> wp == w
True
```

```
backward_rule (p, q, output)

Return the generalized permutation obtained by applying reverse Hecke insertion to a pair of tableaux \((p, q)\).

INPUT:

\* p, q – two tableaux of the same shape
```
• output – (default: 'array') if $q$ is semi-standard:
  • 'array' – as a two-line array (i.e. generalized permutation or biword)
and if $q$ is standard set-valued, we can have the output:
  • 'word' – as a word
  • 'list' – as a list

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleHecke
sage: t1 = Tableau([[1, 4], [2], [3]])
sage: t2 = Tableau([[1, 2], [4], [3], [5]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 4], [2, 3]])
sage: t2 = Tableau([[1, 2], [4], [3], [5]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):
  ... ValueError: p(=[[1, 4], [2, 3]]) and 
q(=[[1, 2], [4], [3], [5]]) must have the same shape
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> t1 = Tableau([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)]])
>>> t2 = Tableau([[Integer(1), Integer(2)], [Integer(4)], [Integer(5)]])
>>> RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
>>> t1 = Tableau([[Integer(1), Integer(2)], [Integer(4)], [Integer(5)]]
>>> t2 = Tableau([[Integer(1), Integer(2)], [Integer(4)], [Integer(3)]]
>>> RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):
  ... ValueError: p(=[[1, 4], [2, 3]]) and 
q(=[[1, 2], [4], [3], [5]]) must have the same shape
```

`forward_rule(obj1, obj2, check_standard=False)`

Return a pair of tableaux obtained by applying Hecke insertion to the generalized permutation $[\text{obj1}, \text{obj2}]$.

INPUT:

• obj1, obj2 – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  – two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword
  – a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be (1, 2, ..., n) by default)

• check_standard – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:
"sage: from sage.combinat.rsk import RuleHecke
sage: p, q = RuleHecke().forward_rule([3,3,2,4,1], None);p
\[[[1, 4]], [[2,], [3]]\]
sage: q
\[[[(1, 2), (4,)], [(3,)], [(5,)]\]
sage: isinstance(p, SemistandardTableau)
True
sage: isinstance(q, Tableau)
True

>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>>
p, q = RuleHecke().forward_rule([Integer(3),Integer(3),Integer(2),
Integer(4),Integer(1)], None);p
\[[[1, 4]], [[2,], [3]]\]
>>> q
\[[[(1, 2), (4,)], [(3,)], [(5,)]\]
>>> isinstance(p, SemistandardTableau)
True
>>> isinstance(q, Tableau)
True

insertion \((j, \text{ir}, r, p)\)

Insert the letter \(j\) from the second row of the biword into the row \(r\) of the increasing tableau \(p\) using Hecke insertion, provided that \(r\) is the \(\text{ir}\)-throw of \(p\), and provided that there is bumping to be done.

The row \(r\) is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_right
sage: p, q, r = [], [], [3,3,8,8,8,9]
sage: j, ir = 8, 1
sage: j1 = RuleHecke().insertion(j, ir, r, p)
sage: j1 == r[bisect_right(r, j)]
True

>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> from bisect import bisect_right
>>>
p, q, r = [], [], [Integer(3),Integer(3),Integer(8),Integer(8),
Integer(4),Integer(1)]
>>> j, ir = Integer(8), Integer(1)
>>> j1 = RuleHecke().insertion(j, ir, r, p)
>>> j1 == r[bisect_right(r, j)]
True

reverse_insertion \((i, x, \text{row}, p)\)

Reverse bump the row \(\text{row}\) of the current insertion tableau \(p\) with the number \(x\), provided that \(\text{row}\) is the \(i\)-th row of \(p\).

The row \(\text{row}\) is modified in place. The bumped-out entry is returned.

EXAMPLES:
```python
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_left
sage: r = [2, 3, 3, 4, 8, 9]
sage: x, i, p = 9, 1, [1, 2]
sage: x1 = RuleHecke().reverse_insertion(i, x, r, p)
sage: x1 == r[bisect_left(r, x) - 1]
True

>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> from bisect import bisect_left

>>> r = [Integer(2), Integer(3), Integer(3), Integer(4), Integer(8), Integer(9)]
>>> x, i, p = Integer(9), Integer(1), [Integer(1), Integer(2)]
>>> x1 = RuleHecke().reverse_insertion(i, x, r, p)
>>> x1 == r[bisect_left(r, x) - Integer(1)]
True
```

```python
class sage.combinat.rsk.RuleRSK

Bases: Rule

Rule for the classical Robinson-Schensted-Knuth insertion.

See `RSK()` for the definition of this operation.

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleRSK
sage: qr, r = [1, 2, 3, 4, 5], [3, 3, 2, 4, 8]
sage: j = RuleRSK().insertion(9, r)
sage: j

True
sage: qr, r = [1, 2, 3, 4, 5], [3, 3, 2, 4, 8]
sage: j = RuleRSK().insertion(3, r)
sage: j

4
```
\[
\begin{align*}
\text{reverse_insertion}(x, \text{row})
\text{ Reverse bump the row \text{row} of the current insertion tableau with the number } x. \\
\text{The row } \text{row} \text{ is modified in place. The bumped-out entry is returned.}
\end{align*}
\]

**EXAMPLES:**

```sage
sage: from sage.combinat.rsk import RuleRSK
sage: r = [2, 3, 4, 4, 8]
sage: x = RuleRSK().reverse_insertion(4, r); r
[2, 3, 4, 4, 8]
sage: x
3
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> r = [Integer(2),Integer(3),Integer(3),Integer(4),Integer(8)]
>>> x = RuleRSK().reverse_insertion(Integer(4), r); r
[2, 3, 4, 4, 8]
>>> x
3
```
sage: from sage.combinat.rsk import RuleStar
sage: p, q = RuleStar().forward_rule([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])

sage: ascii_art(p, q)

1 2 4 1 1 2
1 4 2 4
3 4

sage: line1, line2 = RuleStar().backward_rule(p, q)

sage: line1, line2

([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])

sage: RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')

(4, 2)()(4, 2)(3, 1)

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import...

sage: h = DecreasingHeckeFactorization([[4, 2], [], [4, 2], [3, 1]])

sage: RSK_inverse(*RSK(h, insertion='Star'), insertion='Star', output='DecreasingHeckeFactorization')

(4, 2)()(4, 2)(3, 1)

sage: p, q = RSK(h, insertion='Star')

sage: ascii_art(p, q)

1 2 4 1 1 2
1 4 2 4
3 4

sage: RSK_inverse(p, q, insertion='Star')

[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]

sage: f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')

sage: f == h
True

(continues on next page)
backward_rule \((p, q, output='array')\)

Return the increasing Hecke biword obtained by applying reverse \(*\)-insertion to a pair of tableaux \((p, q)\).

**INPUT:**

- \(p, q\) – two tableaux of the same shape, where \(p\) is the conjugate of a semistandard tableau, whose reading word is fully commutative and \(q\) is a semistandard tableau.
- \(output\) – (default: 'array') if \(q\) is semi-standard:
  - 'array' – as a two-line array (i.e. generalized permutation or biword) that is an increasing Hecke biword
  - 'DecreasingHeckeFactorization' – as a decreasing factorization in the 0-Hecke monoid
  - 'word' – as a (possibly non-reduced) word in the 0-Hecke monoid
**Warning:** When output is 'DecreasingHeckeFactorization', the number of factors in the output is the largest number in \( \text{obj1} \).

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
1 2 4 1 1 2
1 4 2 4
3 4
sage: line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)(4, 2)(3, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),
˓→Integer(2),Integer(4),Integer(4)], [Integer(1),Integer(3),Integer(2),
˓→Integer(4),Integer(2),Integer(4)])
>>> ascii_art(p, q)
1 2 4 1 1 2
1 4 2 4
3 4
>>> line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
>>> RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)(4, 2)(3, 1)
```

**forward_rule** (**obj1**, **obj2=None, check_braid=True**)  
Return a pair of tableaux obtained by applying forward insertion to the increasing Hecke biword \([\text{obj1}, \text{obj2}]\).

**INPUT:**

- **obj1, obj2** – can be one of the following ways to represent a biword (or, equivalently, an increasing 0-Hecke factorization) that is fully commutative:
  - two lists \( \text{obj1} \) and \( \text{obj2} \) of equal length, to be interpreted as the top row and the bottom row of the biword.
  - a word \( \text{obj1} \) in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, \( \text{obj2} \) is None; the top row of the biword is understood to be \((1, 2, \ldots, n)\) by default).
  - a DecreasingHeckeFactorization \( \text{obj1} \), whose increasing Hecke biword will be interpreted as the bottom row; the top row is understood to be the indices of the factors for each letter in this biword.

- **check_braid** – (default: True) indicator to validate that input is associated to a fully commutative word in the 0-Hecke monoid, validation is performed if set to True; otherwise, this validation is ignored.

**EXAMPLES:**

```python
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,3,3], [2,3,3,1,3])
```

(continues on next page)
sage: p,q = RuleStar().forward_rule([2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 2], [3, 5], [4]])
sage: p,q = RSK([1,1,2,3,3], [2,3,3,1,3], insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[3, 1], [3]])
sage: p,q = RSK(h, insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])

>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),Integer(3),Integer(3)], [Integer(2),Integer(3),Integer(3),Integer(2),Integer(3)]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
>>> p,q = RSK([Integer(1),Integer(1),Integer(2),Integer(3),Integer(3)], [Integer(2),Integer(3),Integer(3),Integer(1),Integer(3)], insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])

**insertion** \((b, r)\)

Insert the letter \(b\) from the second row of the biword into the row \(r\) using \(\star\)-insertion defined in [MPPS2020]. The row \(r\) is modified in place if bumping occurs and \(b\) is not in row \(r\). The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().insertion(3, [1,2,4,5])
4
sage: RuleStar().insertion(3, [1,2,3,5])
1
sage: RuleStar().insertion(6, [1,2,3,5]) is None
True

>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> RuleStar().insertion(Integer(3), [Integer(1),Integer(2),Integer(4),Integer(5)]); p,q
4
>>> RuleStar().insertion(Integer(3), [Integer(1),Integer(2),Integer(3),Integer(5)]); p,q
1
reverse_insertion \((x, r)\)

Reverse bump the row \(r\) of the current insertion tableau \(p\) with number \(x\), provided that \(r\) is the \(i\)-th row of \(p\).

The row \(r\) is modified in place. The bumped-out entry is returned.

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().reverse_insertion(4, [1, 2, 3, 5])
3
sage: RuleStar().reverse_insertion(1, [1, 2, 3, 5])
3
sage: RuleStar().reverse_insertion(5, [1, 2, 3, 5])
5
```

```python
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> RuleStar().reverse_insertion(Integer(4), [Integer(1), Integer(2),
 → Integer(3), Integer(5)])
3
>>> RuleStar().reverse_insertion(Integer(1), [Integer(1), Integer(2),
 → Integer(3), Integer(5)])
3
>>> RuleStar().reverse_insertion(Integer(5), [Integer(1), Integer(2),
 → Integer(3), Integer(5)])
5
```

class sage.combinat.rsk.RuleSuperRSK

Bases: RuleRSK

Rule for super RSK insertion.

Super RSK is based on \(\epsilon\)-insertion, a combination of row and column classical RSK insertion.

Super RSK insertion differs from the classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a restricted super biword (i.e., a pair of two lists \([a_1, a_2, \ldots, a_n]\) and \([b_1, b_2, \ldots, b_n]\) that contains entries with even and odd parity and pairs with mixed parity entries do not repeat).

- The output still consists of two tableaux \((P, Q)\) of equal shapes, but rather than both of them being semistandard, now they are semistandard super tableaux.

- The main difference is in the way bumping works. Instead of having only row bumping super RSK uses \(\epsilon\)-insertion, a combination of classical RSK bumping along the rows and a dual RSK like bumping (i.e. when a number \(k_i\) is inserted into the \(i\)-th row of \(P\), it bumps out the first integer greater or equal to \(k_i\) in the column) along the column.

EXAMPLES:

```python
sage: RSK([[1], [1]], insertion='superRSK')
[[[1]], [[1]]]
```

```python
sage: RSK([[1, 2], [1, 3]], insertion='superRSK')
```
\[
\begin{bmatrix}
1, 3
\end{bmatrix}, 
\begin{bmatrix}
1, 2
\end{bmatrix}
\]

\[
\text{sage: RSK([1, 2, 3], [1, 3, "3p"], insertion='superRSK')}
\]

\[
\begin{bmatrix}
1, 3
\end{bmatrix}, 
\begin{bmatrix}
1, 2, [3]
\end{bmatrix}
\]

\[
\text{sage: RSK([1, 3, "3p", "2p"], insertion='superRSK')}
\]

\[
\begin{bmatrix}
1, 3,
\end{bmatrix}, 
\begin{bmatrix}
[1', 2', [2]]
\end{bmatrix}
\]

\[
\text{sage: RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3], [1', 1, 2', [2']])}
\]

\[
\text{sage: P = SemistandardSuperTableau([[1', '3p'], [2']])}
\]

\[
\text{sage: Q = SemistandardSuperTableau([[1p], 1, '2p'], [2])}
\]

\[
\text{sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)}
\]

\[
\begin{bmatrix}
1, 2, 3, 3
\end{bmatrix}, 
\begin{bmatrix}
1, 3
\end{bmatrix}, 
\begin{bmatrix}
2
\end{bmatrix}, 
\begin{bmatrix}
3
\end{bmatrix}
\]

\[
\begin{bmatrix}
1, 2, 3, 3
\end{bmatrix}, 
\begin{bmatrix}
2, 3
\end{bmatrix}, 
\begin{bmatrix}
2
\end{bmatrix}, 
\begin{bmatrix}
3
\end{bmatrix}
\]

We apply super RSK on Example 5.1 in [Muth2019]:

\[
\]

\[
\text{sage: ascii_art((P, Q))}
\]

\[
( 1 2 3 3 1 2 2 3 )
\]

\[
( 1 2 3 2 3 3 )
\]

\[
( 3 , 3 )
\]

\[
\text{sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)}
\]

\[
\begin{bmatrix}
1, 2, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 3, 2, 2, 2, 2, 2, 2, 2, 1'
\end{bmatrix}
\]

\[
\text{from sage.all import *}
\]

\[
\]

\[
\text{ascii_art((P, Q))}
\]

\[
( 1 2 3 3 1 2 2 3 )
\]

\[
( 1 2 3 2 3 3 )
\]

\[
( 3 , 3 )
\]

(continues on next page)
Example 6.1 in [Muth2019]:

```python
>>> from sage.all import *

>>> P, Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3], ["3p", 1, 2, 3, "3p", "3p", 2, 1], insertion=superRSK)

sage: ascii_art((P, Q))

( 1 2 3 3 1 2 2 3 )

( 1 2 3 2 3 3 )

( 3 , 3 )

sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)

[[1, 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 2', 1']]

sage: ascii_art((P, Q))

( 1 2 2 3' 1' 2 3' 3 )

( 2' 3 3 1 2 3' )

( 3', 3' )

sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)

[[1', 1', 2', 2', 3', 3', 3', 3'], [3', 2', 3, 2, 3', 3', 1', 2]]
```

Let us now call the inverse correspondence:

```python
>>> sage: P, Q = RSK([1, 2, 2, 2], [2, 1, 2, 3], insertion=RSK.rules.superRSK)

sage: ascii_art((P, Q))

( 1 2 3 3 1 2 2 3 )

( 1 2 3 2 3 3 )

( 3', 3' )

sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)

[[1, 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 2', 1']]

>>> P, Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), ... Integer(3)], insertion='superRSK')

>>> ascii_art((P, Q))

( 1 2 3 3 1 2 2 3 )

( 1 2 3 2 3 3 )

( 3', 3' )

>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)

[[1', 1', 2', 2', 3', 3', 3', 3'], [3', 2', 3, 2, 3', 3', 1', 2]]
```
When applied to two tableaux with only even parity elements, reverse super RSK insertion behaves identically to the usual reverse RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[1, 2, 5], [3], [4]])
sage: t2 = SemistandardSuperTableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
```

```python
from sage.all import *
```

```
sage: t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)], [Integer(4)]]
sage: t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)], [Integer(5)]]
sage: RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(5)], [Integer(3), [Integer(4)]
sage: t2 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)], [Integer(5)]]
sage: RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
```

**backward_rule** *(p, q, output='array')*

Return the restricted super biword obtained by applying reverse super RSK insertion to a pair of tableaux *(p, q).*

**INPUT:**

- p, q – two tableaux of the same shape
- output – *(default: 'array')* if q is row-strict:
  - 'array' – as a two-line array (i.e. restricted super biword)
  - 'word' – as a word

**EXAMPLES:**

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: t1 = SemistandardSuperTableau([('1p', '3p', '4p'), [2], [3]])
sage: t2 = SemistandardSuperTableau([(1, 2), [3], [5]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [4', 3, 3', 2, 1']]
sage: t1 = SemistandardSuperTableau([('1', 3), ['3p']])
sage: t2 = SemistandardSuperTableau([(1, 2), [3]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3']]
```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK

>>> t1 = SemistandardSuperTableau([[1p, 3p, 4p], [Integer(2)], ...
˓→[Integer(3)]])

>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(4)], ...
˓→[Integer(3)],[Integer(5)]])

>>> RuleSuperRSK().backward_rule(t1, t2, array)
[[1, 2, 3, 4, 5], [4, 3, 3, 2, 1]]

>>> t1 = SemistandardSuperTableau([[Integer(1), Integer(3)], [3p]])

>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2)], [Integer(3)]])

>>> RuleSuperRSK().backward_rule(t1, t2, array)
[[1, 2, 3], [1, 3, 3]]

forward_rule(obj1, obj2, check_standard=False, check=True)

Return a pair of tableaux obtained by applying forward insertion to the restricted super biword [obj1, obj2].

INPUT:

- obj1, obj2 – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists obj1 and obj2 of equal length, to be interpreted as the top row and the bottom row of the biword
  - a word obj1 in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, obj2 is None; the top row of the biword is understood to be (1, 2, ..., n) by default)
  - any object obj1 which has a method _rsk_iter(), as long as this method returns an iterator yielding pairs of numbers, which then are interpreted as top entries and bottom entries in the biword (in this case, obj2 is None)
- check_standard – (default: False) check if either of the resulting tableaux is a standard super tableau, and if so, typecast it as such
- check – (default: True) whether to check that obj1 and obj2 actually define a valid restricted super biword

EXAMPLES:

sage: from sage.combinat.rsk import RuleSuperRSK
sage: p, q = RuleSuperRSK().forward_rule([1, 2], [1, 3]); p
[[1, 3]]
sage: q
[[1, 2]]
sage: isinstance(p, SemistandardSuperTableau)
True
sage: isinstance(q, SemistandardSuperTableau)
True

(continues on next page)
**insertion** \((j, r, \text{epsilon}=0)\)

Insert the letter \(j\) from the second row of the biword into the row \(r\) using dual RSK insertion or classical Schensted insertion depending on the value of \(\text{epsilon}\), if there is bumping to be done.

The row \(r\) is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

**EXAMPLES:**

```python
>>> from sage.combinat.rsk import RuleSuperRSK
>>> from bisect import bisect_left, bisect_right

sage: r = [1, 3, 3, 3, 4]
sage: j = 3

sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=0); r
[1, 3, 3, 3, 3]
sage: j
4
sage: y_pos
4

sage: r = [1, 3, 3, 3, 4]
sage: j = 3

sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y_pos
1
```

**reverse_insertion** \((x, \text{row}, \text{epsilon}=0)\)

Reverse bump the row \(\text{row}\) of the current insertion tableau with the number \(x\) using dual RSK insertion or classical Schensted insertion depending on the value of \(\text{epsilon}\).

The row \(\text{row}\) is modified in place. The bumped-out entry is returned along with the bumped position.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> from bisect import bisect_left, bisect_right

>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]

>>> j = Integer(3)

>>> j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=Integer(0)); r
[1, 3, 3, 3, 3]
>>> j
4
>>> y_pos
4

>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]

>>> j = Integer(3)

>>> j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=Integer(1)); r
[1, 3, 3, 3, 4]
>>> j
3
>>> y_pos
1
```
from sage.combinat.rsk import RuleSuperRSK
from bisect import bisect_left, bisect_right
r = [1, 3, 3, 3, 4]
j = 2
j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=1); r

from sage.all import *
from sage.combinat.rsk import RuleSuperRSK
from bisect import bisect_left, bisect_right

r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
j = Integer(2)
j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(0)); r

j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(1)); r

to_pairs (obj1=None, obj2=None, check=True)

Given a valid input for the super RSK algorithm, such as two n-tuples obj1 = [a1, a2, ..., an] and obj2
= [b_1, b_2, \ldots, b_n] forming a restricted super biword (i.e., entries with even and odd parity and no repetition of corresponding pairs with mixed parity entries) return the array [(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)].

INPUT:

- obj1, obj2 – anything representing a restricted super biword (see the doc of forward_rule() for the encodings accepted)
- check – (default: True) whether to check that obj1 and obj2 actually define a valid restricted super biword

EXAMPLES:

```python
sage: from sage.combinat.rsk import RuleSuperRSK
sage: list(RuleSuperRSK().to_pairs([Integer(1), Integer(1)], [1p, 1p]))
[(1, 1), (1, 1), (2, 2)]
sage: list(RuleSuperRSK().to_pairs([1, 1p, 2p]))
[(2, 1), (1, 1), (1, 1)]
```

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion P \leftarrow k (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting k_0 = k, and in its i-th step inserts the number k_i into the i-th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_{i+1} and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i-th row, then k_{i+1} is simply appended to the row and the algorithm terminates at this point.

A generalized permutation (or biword) is a list \((j_0, k_0), (j_1, k_1), \ldots, (j_\ell-1, k_{\ell-1})\) of pairs such that the letters \(j_0, j_1, \ldots, j_{\ell-1}\) are weakly increasing (that is, \(j_0 \leq j_1 \leq \cdots \leq j_{\ell-1}\)), whereas the letters \(k_1, k_2, \ldots, k_{\ell-1}\) satisfy \(k_i \leq k_{i+1}\) whenever \(j_i = j_{i+1}\). The \(\ell\)-tuple \((j_0, j_1, \ldots, j_{\ell-1})\) is called the top line of this generalized permutation, whereas the \(\ell\)-tuple \((k_0, k_1, \ldots, k_{\ell-1})\) is called its bottom line.

Now the RSK algorithm, applied to a generalized permutation \(p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))\) (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux \(P_0\) and \(Q_0\) as empty tableaux. For each nonnegative integer \(t\) starting at 0, take the pair \((j_t, k_t)\) from \(p\) and set \(P_{t+1} = P_t \leftarrow k_t, Q_{t+1} = Q_t \leftarrow j_t,

5.1. Comprehensive Module List
and define $Q_{t+1}$ by adding a new box filled with $j_t$ to the tableau $Q_t$ at the same location the row insertion on $P_t$ ended (that is to say, adding a new box with entry $j_t$ such that $P_{t+1}$ and $Q_{t+1}$ have the same shape). The iterative process stops when $t$ reaches the size of $p$, and the pair $(P_t, Q_t)$ at this point is the image of $p$ under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as “Construction A”.

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word $w$ (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1,2,\ldots,n)$ where $n$ is the length of $w$.

The optional argument insertion allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- obj1, obj2 – can be one of the following:
  - a word in an ordered alphabet (in this case, obj1 is said word, and obj2 is None)
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists $(j_0,j_1,\ldots,j_{t-1})$ and $(k_0,k_1,\ldots,k_{t-1})$ represent the generalized permutation $((j_0,k_0),(j_1,k_1),\ldots,(j_{t-1},k_{t-1}))$)
  - any object which has a method _rsk_iter() which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, obj1 is said object, and obj2 is None).
- insertion – (default: RSK.rules.RSK) the following types of insertion are currently supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (RuleRSK)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type $A$ Coxeter group) (RuleEG)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (RuleHecke)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (RuleDualRSK)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (RuleCoRSK)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (RuleSuperRSK)
  - RSK.rules.Star (or 'Star') – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (RuleStar)
- check_standard – (default: False) check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular Rule class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1,2,\ldots,n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
```
Combinatorics, Release 10.4

sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]

>>> from sage.all import *

>>> RSK([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]

>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]

>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3), Integer(2),Integer(3)]))
[[[1, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]

We can provide a generalized permutation:

sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]

sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]

>>> from sage.all import *

>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1), Integer(1), Integer(2)])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

>>> RSK(Word([Integer(1),Integer(1),Integer(3),Integer(4),Integer(4)]), [Integer(1),Integer(4),Integer(2),Integer(1),Integer(3)])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]

>>> RSK([Integer(1),Integer(3),Integer(3),Integer(4),Integer(4)], Word([Integer(6),Integer(2),Integer(2),Integer(1),Integer(7)]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]

We can provide a matrix:

sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

>>> from sage.all import *

>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(2),Integer(1)]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

We can also provide something looking like a matrix:

sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

>>> from sage.all import *

>>> RSK([[Integer(0),Integer(1)],[Integer(2),Integer(1)]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

There is also RSK_inverse() which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with RSK(), we need to use the python * on the output:

5.1. Comprehensive Module List 4463
sage: RSK_inverse(RSK([[1, 2, 2, 2], [2, 1, 1, 2]]))
[[1, 2, 2, 2], [2, 1, 1, 2]]

sage: P, Q = RSK([[1, 2, 2, 2], [2, 1, 1, 2]])

sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]

>>> from sage.all import *

>>> RSK_inverse(RSK([[Integer(1), Integer(2), Integer(2), Integer(2)],
   →[Integer(2), Integer(1), Integer(1), Integer(2)]])
[[1, 2, 2, 2], [2, 1, 1, 1]]

>>> P, Q = RSK([[Integer(1), Integer(2), Integer(2), Integer(2)],
   →[Integer(1), Integer(1), Integer(2)]])

>>> RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]

sage.combinat.rsk.robinson_schensted_knuth_inverse(p, q, output='array', insertion=<class 'sage.combinat.rsk.RuleRSK'>)

Return the generalized permutation corresponding to the pair of tableaux \((p, q)\) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see RSK().

INPUT:

- **p, q** – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- **output** – (default: 'array') if q is semi-standard:
  - 'array' – as a two-line array (i.e. generalized permutation or biword)
  - 'matrix' – as an integer matrix
and if q is standard, we can also have the output:
- 'word' – as a word
and additionally if p is standard, we can also have the output:
- 'permutation' – as a permutation
- **insertion** – (default: RSK.rules.RSK) the insertion algorithm used in the bijection. Currently the following are supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (RuleRSK)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (RuleEG)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (RuleHecke)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (RuleDualRSK)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (RuleCoRSK)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (RuleSuperRSK)
  - RSK.rules.Star (or 'Star') – *-insertion (only for fully commutative words in the 0-Hecke monoid) (RuleStar)
For precise information about constraints on the input and output, see the particular Rule class.

**Note:** In the case of Hecke insertion, the input variable $q$ should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

**EXAMPLES:**

If both $p$ and $q$ are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
>>> from sage.all import *

>>> t1 = Tableau([[1, 2, 5], [3], [4]])
>>> t2 = Tableau([[1, 2, 3], [4], [5]])

>>> RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word')
word: 14532
>>> RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322

>>> from sage.all import *

>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(3)]]); q = Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]]))
>>> ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]

In general:

sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]

>>> from sage.all import *

>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q = Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]]))
>>> RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]

Using Hecke insertion:

sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]

>>> from sage.all import *

>>> w = [Integer(5), Integer(4), Integer(3), Integer(1), Integer(4), Integer(2), Integer(3), Integer(5)]
>>> pq = RSK(w, insertion=RSK.rules.Hecke)
>>> RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]

Note: The constructor of Tableau accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau \( q \) that is passed to \( \text{RSK\_inverse}(p, q, \text{insertion=hecke}) \).) The user is responsible for ensuring that the tableaux passed to \( \text{RSK\_inverse} \) are of the right types (semistandard, standard, increasing, set-valued as needed).

sage.combinat.rsk.to_matrix(t, b)

Return the integer matrix corresponding to a two-line array.
INPUT:
- \( t \) – the top row of the array
- \( b \) – the bottom row of the array

OUTPUT:
An \( m \times n \)-matrix (where \( m \) and \( n \) are the maximum entries in \( t \) and \( b \) respectively) whose \((i, j)\)-th entry, for any \( i \) and \( j \), is the number of all positions \( k \) satisfying \( t_k = i \) and \( b_k = j \).

EXAMPLES:
```python
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
[0 1 1] [0 0 0] [2 0 0] [0 0 1]
```

5.1.276 Schubert Polynomials

See Wikipedia article Schubert_polynomial and SymmetricFunctions.com. Schubert polynomials are representatives of cohomology classes in flag varieties. In \( n \) variables, they are indexed by permutations \( w \in S_n \). They also form a basis for the coinvariant ring of the \( S_n \) action on \( \mathbb{Z}[x_1, x_2, \ldots, x_n] \).

EXAMPLES:
```python
sage: X = SchubertPolynomialRing(ZZ)
sage: w = [1,2,5,4,3]; # a list representing an element of \( S_5 \)
sage: X(w)
x[1, 2, 5, 4, 3]
```

This can be expanded in terms of polynomial variables:
```python
sage: X(w).expand() x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0^2*x3 + x0*x1*x3 + x1^2*x3 + x0*x2*x3 + x1*x2*x3 + x2^2*x3
```
We can also convert back from polynomial variables. For example, the longest permutation is a single term. In $S_5$, this is the element (in one line notation) $w_0 = 54321$:

```
sage: w0 = [5,4,3,2,1]
sage: R.<x0, x1, x2, x3, x4> = PolynomialRing(ZZ)
sage: Sw0 = X(x0^4*x1^3*x2^2*x3); Sw0
X[5, 4, 3, 2, 1]
```

The polynomials also have the property that if the indexing permutation $w$ is multiplied by a simple transposition $s_i = (i, i + 1)$ such that the length of $w$ is more than the length of $ws_i$, then the Schubert polynomial of the permutation $ws_i$ is computed by applying the divided difference operator $\partial_2$ to the Schubert polynomial $S_w$.

```
sage: Sw0.divided_difference(2)
X[5, 3, 4, 2, 1]
```

We can also check the properties listed in Wikipedia article Schubert_polynomial:

```
sage: w = [4,5,1,2,3]
sage: s = SymmetricFunctions(QQ).schur()
sage: s[3,3].expand(2)
x0^3*x1^3
```

(continues on next page)
X([Integer(2),Integer(4),Integer(5),Integer(3),Integer(1)]).expand()
x0^2*x1^2*x2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3

w = [Integer(4),Integer(5),Integer(1),Integer(2),Integer(3)]
s = SymmetricFunctions(QQ).schur()
s[Integer(3),Integer(3)].expand(Integer(2))
x0^3*x1^3
X(w).expand()
x0^3*x1^3

sage.combinat.schubert_polynomial.SchubertPolynomialRing(R)

Return the Schubert polynomial ring over R on the X basis.

This is the basis made of the Schubert polynomials.

EXAMPLES:

>>> from sage.all import *

class sage.combinat.schubert_polynomial.SchubertPolynomialRing_xbasis(R)

Bases: CombinatorialFreeModule

EXAMPLES:
sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True

>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X == loads(dumps(X))
True

Element

alias of SchubertPolynomial_class

one_basis()

Return the index of the unit of this algebra.

EXAMPLES:

sage: X = SchubertPolynomialRing(QQ)
sage: X.one()  # indirect doctest
X[1]

>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X.one()  # indirect doctest
X[1]

product_on_basis(left, right)

EXAMPLES:

sage: p1 = Permutation([3,2,1])
sage: p2 = Permutation([2,1,3])
sage: X = SchubertPolynomialRing(QQ)
sage: X.product_on_basis(p1,p2)
X[4, 2, 1, 3]

>>> from sage.all import *
>>> p1 = Permutation([Integer(3),Integer(2),Integer(1)])
>>> p2 = Permutation([Integer(2),Integer(1),Integer(3)])
>>> X = SchubertPolynomialRing(QQ)
>>> X.product_on_basis(p1,p2)
X[4, 2, 1, 3]

some_elements()

Return some elements.

EXAMPLES:

sage: X = SchubertPolynomialRing(QQ)
sage: X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]

>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
class sage.combinat.schubert_polynomial.SchubertPolynomial_class

Bases: IndexedFreeModuleElement

divided_difference(i, algorithm='sage')

Return the i-th divided difference operator, applied to self.

Here, i can be either a permutation or a positive integer.

INPUT:

• i – permutation or positive integer
• algorithm – (default: 'sage') either 'sage' or 'symmetrica'; this determines which software is called for the computation

OUTPUT:

The result of applying the i-th divided difference operator to self.

If i is a positive integer, then the i-th divided difference operator \( \delta_i \) is the linear operator sending each polynomial \( f = f(x_1, x_2, \ldots, x_n) \) (in \( n \geq i + 1 \) variables) to the polynomial

\[
\frac{f - f_i}{x_i - x_{i+1}}, \quad \text{where } f_i = f(x_1, x_2, \ldots, x_{i-1}, x_{i+1}, x_i, x_{i+1}, \ldots, x_n).
\]

If \( \sigma \) is a permutation in the n-th symmetric group, then the \( \sigma \)-th divided difference operator \( \delta_\sigma \) is the composition \( \delta_{i_1} \delta_{i_2} \cdots \delta_{i_k} \), where \( \sigma = s_{i_1} \circ s_{i_2} \circ \cdots \circ s_{i_k} \) is any reduced expression for \( \sigma \) (the precise choice of reduced expression is immaterial).

Note: The expand() method results in a polynomial in \( n \) variables named \( x0, x1, \ldots, x(n-1) \) rather than \( x1, x2, \ldots, x_n \). The variable named \( xi \) corresponds to \( xi+1 \). Thus, self.divided_difference(1) involves the variables \( x(i-1) \) and \( xi \) getting switched (in the numerator).

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
sage: a.divided_difference(5)
0
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([[Integer(3)], [Integer(2)], [Integer(1)]])
>>> a.divided_difference(Integer(1))
X[2, 3, 1]
>>> a.divided_difference([[Integer(3)], [Integer(2)], [Integer(1)]])
X[1]
>>> a.divided_difference(Integer(5))
0
```

Any divided difference of 0 is 0:

```
sage: X.zero().divided_difference(2)
0
```
This is compatible when a permutation is given as input:

```
sage: a = X([3,2,4,1])
sage: a.divided_difference([2,3,1])
0
sage: a.divided_difference(1).divided_difference(2)
0
```

```
sage: a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.divided_difference([Integer(2),Integer(3),Integer(1)])
X[3, 2, 4, 1]
>>> a.divided_difference(Integer(1)).divided_difference(Integer(2))
X[3, 2, 4, 1]
>>> a.divided_difference([Integer(4),Integer(1),Integer(3),Integer(2)])
X[1, 4, 2, 3]
>>> b = X([Integer(4), Integer(1), Integer(3), Integer(2)])
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_difference(Integer(3)).divided_difference(Integer(2))
X[1]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_difference(Integer(3)).divided_difference(Integer(3))
0
```
Combinatorics, Release 10.4

(continued from previous page)

\[
X[1] \\
>>> b.\text{divided}\_\text{difference}(\text{Integer}(1)).\text{divided}\_\text{difference}(\text{Integer}(2)).\text{divided}\_\text{difference}(\text{Integer}(3)).\text{divided}\_\text{difference}(\text{Integer}(1)) \\
0 \\
>>> b.\text{divided}\_\text{difference}(\text{Integer}(1)).\text{divided}\_\text{difference}(\text{Integer}(2)).\text{divided}\_\text{difference}(\text{Integer}(3)) \\
0
\]

**expand()**

**EXAMPLES:**

```sage
sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: [X(p).expand() for p in Permutations(3)]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

```python
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> X([Integer(2),Integer(1),Integer(3)]).expand()
x0
>>> [X(p).expand() for p in Permutations(Integer(3))]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

**multiply_variable(i)**

Return the Schubert polynomial obtained by multiplying `self` by the variable \(x_i\).

**EXAMPLES:**

```sage
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]
```

```python
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.multiply_variable(Integer(0))
X[4, 2, 3, 1]
>>> a.multiply_variable(Integer(1))
X[3, 4, 2, 1]
>>> a.multiply_variable(Integer(2))
>>> a.multiply_variable(Integer(3))
X[3, 2, 4, 5, 1]
```

**scalar_product(x)**

Return the standard scalar product of `self` and `x`.

**EXAMPLES:**
```python
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
```

```python
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.scalar_product(a)
0
>>> b = X([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
>>> Permutation([Integer(1), Integer(3), Integer(4), Integer(6), Integer(2), Integer(7)]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
>>> s = SymmetricFunctions(ZZ).schur()
>>> c = s([Integer(2),Integer(1),Integer(1)])
>>> b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
```

5.1.277 Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).

This module defines a class for immutable partitioning of a set. For mutable version see DisjointSet().
class sage.combinat.set_partition.AbstractSetPartition

Bases: ClonableArray

Methods of set partitions which are independent of the base set

base_set()

Return the base set of self, which is the union of all parts of self.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1,2,3,4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}
```

```
>>> from sage.all import *

>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_set()
{1, 2, 3, 4}
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set()
{1, 2, 3, 4}
>>> SetPartition([]).base_set()
{}
```

base_set_cardinality()

Return the cardinality of the base set of self, which is the sum of the sizes of the parts of self. This is also known as the size (sometimes the weight) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *

>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_set_cardinality()
4
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set_cardinality()
4
```

coarsenings()

Return a list of coarsenings of self.

See also:

refinements()

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).coarsenings()
[{{1, 2, 3, 4}}, {{1}, {2, 4}}]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[{{1, 2, 3, 4}},
 (continues on next page)
An involution exchanging singletons and circular adjacencies.

This method implements the definition of the conjugate of a set partition defined in [Cal2005].

**INPUT:**

- `self` – a set partition of an ordered set

**OUTPUT:**

a set partition

**EXAMPLES:**

```python
sage: SetPartition([[1,6,7],[2,8],[3,4,5]]).conjugate()
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
```

```python
sage: all(sp.conjugate().conjugate()==sp for sp in SetPartitions([1,3,5,7]))
True
```

```python
sage: SetPartition([]).conjugate()
{}
```

The product of the set partitions `self` and `other`.

The product of two set partitions $B$ and $C$ is defined as the set partition whose parts are the nonempty intersections between each part of $B$ and each part of $C$. This product is also the infimum of $B$ and $C$.
in the classical set partition lattice (that is, the coarsest set partition which is finer than each of $B$ and $C$). Consequently, $\inf$ acts as an alias for this method.

See also: $\sup()$

EXAMPLES:

```
sage: x = SetPartition([ [1,2], [3,5,4] ])
sage: y = SetPartition(( (3,1,2), (5,4) ))
sage: x * y
{(1, 2), (3), (4, 5)}

sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[2,4], [3], [1]])
sage: sp1.inf(sp2) == s
True
```

```
>>> from sage.all import *
>>> x = SetPartition([ [Integer(1),Integer(2)], [Integer(3),Integer(5), Integer(4)] ])
>>> y = SetPartition(( (Integer(3),Integer(1),Integer(2)), (Integer(5), Integer(4)) ))
>>> x * y
{(1, 2), (3), (4, 5)}

>>> S = SetPartitions(Integer(4))
>>> sp1 = S([[Integer(2),Integer(3),Integer(4)], [Integer(1)]])
>>> sp2 = S([[Integer(1),Integer(3), [Integer(2),Integer(4)]]]
>>> s = S([[Integer(2),Integer(4), [Integer(3), [Integer(1)]])
>>> sp1.inf(sp2) == s
True
```

max_block_size()

The maximum block size of the diagram.

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.diagram_algebras import PartitionDiagram, ... 
 PartitionDiagrams
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.max_block_size()
3
sage: sorted(d.max_block_size() for d in PartitionDiagrams(2))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
sage: sorted(sp.max_block_size() for sp in SetPartitions(3))
[1, 2, 2, 2, 3]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> from sage.combinat.diagram_algebras import PartitionDiagram, ...
 >>> PartitionDiagrams
>>> pd = PartitionDiagram([[Integer(1),-Integer(3),-Integer(5)], [Integer(2), ...
 >>> Integer(4)], [Integer(3),-Integer(1),-Integer(2)], [Integer(5)], [-
```

(continues on next page)
standard_form()

Return self as a list of lists.

When the ground set is totally ordered, the elements of each block are listed in increasing order.

This is not related to standard set partitions (which simply means set partitions of \([n] = \{1,2,\ldots,n\}\) for some integer \(n\)) or standardization (standardization()).

EXAMPLES:

```python
sage: [x.standard_form() for x in SetPartitions(4, [2,2])]
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]
```

sup(t)

Return the supremum of self and t in the classical set partition lattice.

The supremum of two set partitions \(B\) and \(C\) is obtained as the transitive closure of the relation which relates \(i\) to \(j\) if and only if \(i\) and \(j\) are in the same part in at least one of the set partitions \(B\) and \(C\).

See also:

__mul__()

EXAMPLES:

```python
sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[1,2,3,4]])
sage: sp1.sup(sp2) == s
True
```

class sage.combinat.set_partition.SetPartition(parent, s, check=True)

Bases: AbstractSetPartition

A partition of a set.
A set partition \( p \) of a set \( S \) is a partition of \( S \) into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer \( n \) is the set partition of the integers from 1 to \( n \). The number of set partitions of \( n \) is called the \( n \)-th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of \( n \). The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation \( i \) related to \( j \) if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the length of a set partition \( A = \{ A_1, \ldots, A_k \} \) is the number of parts of \( A \) and is denoted by \( |A| := k \). The size of \( A \) is the cardinality of \( S \). We will also sometimes use the notation \( [n] := \{1, 2, \ldots, n\} \).

EXAMPLES:

There are 5 set partitions of the set \( \{1, 2, 3\} \):

```python
sage: SetPartitions(3).cardinality()  # needs sage.libs.flint
5
```

Here is the list of them:

```python
sage: SetPartitions(3).list()  # needs sage.graphs
[[(1, 2, 3), (1, 2), (3)], [(1, 3), (2)], (1), (2), (3)]
```

There are 6 set partitions of \( \{1, 2, 3, 4\} \) whose underlying partition is \( [2, 1, 1] \):

```python
sage: SetPartitions(4, [2,1,1]).list()  # needs sage.graphs sage.rings.finite_rings
[[(1), (2, 4), (3)], [(1), (2), (3, 4)], [(1, 4), (2), (3)], [(1, 3), (2), (4)], [(1, 2), (3), (4)], [(1), (2, 3), (4)]]
```

(continues on next page)
Since Issue #14140, we can create a set partition directly by `SetPartition`, which creates the base set by taking the union of the parts passed in:

```
sage: s = SetPartition([[[1, 3], [2, 4]]]; s
({1, 3}, {2, 4})
sage: s.parent()
Set partitions
```

`apply_permutation(p)`

Apply $p$ to the underlying set of `self`.

**INPUT:**

- $p$ – a permutation

**EXAMPLES:**

```
sage: x = SetPartition([[1, 2], [3, 5, 4]])
sage: p = Permutation([2, 1, 4, 5, 3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3, 2, 1, 5, 4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}
sage: m = PerfectMatching([(1, 4), (2, 6), (3, 5)])
sage: m.apply_permutation(Permutation([4, 1, 5, 6, 3, 2]))
[(1, 2), (3, 5), (4, 6)]
```

`arcs()`

Return `self` as a list of arcs.
Assuming that the blocks are sorted, the arcs are the pairs of consecutive elements in the blocks.

EXAMPLES:

```
sage: A = SetPartition([[1], [2, 3], [4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1, 3, 6, 7], [2, 5], [4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]

>>> from sage.all import *

>>> A = SetPartition([[Integer(1)], [Integer(2), Integer(3)], [Integer(4)]])

>>> B = SetPartition([[Integer(1), Integer(3), Integer(6), Integer(7)],
                   [Integer(2), Integer(5)], [Integer(4)]])

>>> B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

cardinality()

Return the len of self

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1, 2, 3]))
3

>>> from sage.all import *

>>> from sage.structure.list_clone_demo import IncreasingArrays

>>> len(IncreasingArrays()([Integer(1), Integer(2), Integer(3)]))
3
```

check()

Check that we are a valid set partition.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: s.check()

>>> from sage.all import *

>>> S = SetPartitions(Integer(4))

>>> s = S([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])

>>> s.check()
```

closers()

Return the maximal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1, 2, 4, 7], [3, 9], [5, 6, 10, 11, 13], [8], [12]])
sage: P.closers()
[7, 8, 9, 12, 13]
```
crossings()  
Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns a list of the pairs of crossing lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:
```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.crossings()  
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]```  

crossings_iterator()  
Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of crossing lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:
```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: next(p.crossings_iterator())  
((1, 4), (2, 5))```  

is_atomic()  
Return if self is an atomic set partition.

A (standard) set partition $A$ can be split if there exist $j < i$ such that $\max(A_j) < \min(A_i)$ where $A$ is ordered by minimal elements. This means we can write $A = B|C$ for some nonempty set partitions $B$ and $C$. We call a set partition atomic if it cannot be split and is nonempty. Here, the pipe symbol $|$ is as defined in method pipe().

EXAMPLES:
is_atomic()  
Check if self is atomic.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns True if the picture obtained this way has no crossings.

EXAMPLES:

```python
sage: SetPartition([[1, 4], [2, 5, 7], [3, 6]]).is_atomic()
True
sage: SetPartition([[1, 4], [2, 5], [3, 6]]).is_atomic()
False
sage: SetPartition([[1, 4], [2], [3]]).is_atomic()
True
sage: SetPartition([[1, 3], [2, 4]]).is_atomic()
False
sage: SetPartition([]).is_atomic()
False
```

is_noncrossing()  
Check if self is noncrossing.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns True if the picture obtained this way has no crossings.

EXAMPLES:

```python
sage: p = SetPartition([[1, 4], [2, 5, 7], [3, 6]])
sage: p.is_noncrossing()
False
sage: n = PerfectMatching([(1, 3), (2, 8), (4, 7), (5, 6)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_noncrossing()
False
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

```python
>>> from sage.all import *
>>> SetPartition([[Integer(1), Integer(4)], [Integer(2), Integer(5), Integer(7)], [Integer(3), Integer(6)]]).is_noncrossing()
False
>>> p = SetPartition([[Integer(1), Integer(4)], [Integer(2), Integer(5), Integer(7)], [Integer(3), Integer(6)]]);
>>> p.is_noncrossing()
False
``` (continues on next page)
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
→Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.is_noncrossing()
False
>>> PerfectMatching([(Integer(1), Integer(4)), (Integer(2), Integer(3)),
→(Integer(5), Integer(6))]).is_noncrossing()
True

is_nonnesting()
Return if self is nonnesting or not.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns True if the picture obtained this way has no nestings.

EXAMPLES:
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_nonnesting()
False
sage: PerfectMatching([(1, 3), (2, 5), (4, 6)]).is_nonnesting()
True

latex_options()
Return the latex options for use in the _latex_ function as a dictionary. The default values are set using the global options.

Options can be found in set_latex_options()

EXAMPLES:
sage: SP = SetPartition([[1,6], [3,5,4]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}

>>> from sage.all import *

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
→Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.is_nonnesting()
False
>>> PerfectMatching([(Integer(1), Integer(4)), (Integer(2), Integer(3)),
→(Integer(5), Integer(6))]).is_nonnesting()
True

>>> from sage.all import *

>>> SP = SetPartition([[Integer(1),Integer(6)], [Integer(3),Integer(6)],
→[Integer(3),Integer(5)], [Integer(4),Integer(2)]]); SP
[(1, 6), (3, 6), (3, 5), (4, 2)]

(continues on next page)
nestings()

Return the nestings of self.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the list of the pairs of nesting lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```sage
m = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
m.nestings()
```

```output
[((1, 6), (3, 5)), ((2, 7), (3, 5))]
```

```sage
n = PerfectMatching([3, 8, 1, 7, 6, 5, 4, 2]); n
```

```output
[(1, 3), (2, 8), (4, 7), (5, 6)]
```

```sage
n.nestings()
```

```output
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

```sage
>>> from sage.all import *

>>> m = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),
(Integer(3), Integer(5)), (Integer(4), Integer(8))])

>>> m.nestings()
```

```output
[((1, 6), (3, 5)), ((2, 7), (3, 5))]
```

```sage
>>> n = PerfectMatching([Integer(3), Integer(8), Integer(1), Integer(7),
Integer(6), Integer(5), Integer(4), Integer(2)]); n

>>> n.nestings()
```

```output
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

nestings_iterator()

Iterate over the nestings of self.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of nesting lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```sage
n = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
```

```sage
it = n.nestings_iterator()
```

```output
((1, 6), (3, 5))
```

```sage
next(it)
```

```output
((1, 6), (3, 5))
```
((2, 7), (3, 5))
sage: next(it)
Traceback (most recent call last):
  ... StopIteration

>>> from sage.all import *
>>> n = PerfectMatching(((Integer(1), Integer(6)), (Integer(2), Integer(7)),
  (... (Integer(3), Integer(5)), (Integer(4), Integer(8)))))
>>> it = n.nestings_iterator()
>>> next(it)
((1, 6), (3, 5))
>>> next(it)
((2, 7), (3, 5))
>>> next(it)
Traceback (most recent call last):
  ... StopIteration

number_of_crossings()
Return the number of crossings.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive
elements of each block in the upper half-plane. This function returns the number the pairs of crossing lines.

EXAMPLES:
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.number_of_crossings()
4
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1

>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
  (... (Integer(7)],[Integer(3),Integer(6)])
>>> p.number_of_crossings()
4

>>> n = PerfectMatching((Integer(3),Integer(8),Integer(1),Integer(7),
  (... (Integer(6),Integer(5),Integer(4),Integer(2))); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.number_of_crossings()
1

number_of_nestings()
Return the number of nestings of self.

OUTPUT:
We place the elements of the ground set in order on a line and draw the set partition by linking consecutive
elements of each block in the upper half-plane. This function returns the number the pairs of nesting lines.
EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_nestings()
3
```

```
>>> from sage.all import *

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
"\rightarrow Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]

>>> n.number_of_nestings()
3
```

`openers()`

Return the minimal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.openers()
[1, 3, 5, 8, 12]
```

```
>>> from sage.all import *

>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
"\rightarrow Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
"\rightarrow Integer(13)],[Integer(8)],[Integer(12)])

>>> P.openers()
[1, 3, 5, 8, 12]
```

`ordered_set_partition_action(s)`

Return the action of an ordered set partition $s$ on `self`.

Let $A = \{A_1, A_2, \ldots, A_k\}$ be a set partition of some set $S$ and $s$ be an ordered set partition (i.e., set composition) of a subset of $[k]$. Let $A^s$ denote the standardization of $A$, and $A\{i_1,i_2,\ldots,i_m\}$ denote the sub-partition $\{A_{i_1}, A_{i_2}, \ldots, A_{i_m}\}$ for any subset $\{i_1, \ldots, i_m\}$ of $\{1, \ldots, k\}$. We define the set partition $s(A)$ by

$$s(A) = A_{s_1}^s \mid A_{s_2}^s \mid \cdots \mid A_{s_q}^s,$$

where $s = (s_1, s_2, \ldots, s_q)$. Here, the pipe symbol $\mid$ is as defined in method `pipe()`.

This is $s[A]$ in section 2.3 in [LM2011].

INPUT:

- $s$ – an ordered set partition with base set a subset of $\{1, \ldots, k\}$

EXAMPLES:

```
sage: A = SetPartition([[1], [2,4], [3]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: A.ordered_set_partition_action(s)
({1}, {2}, {3, 4})
sage: s = OrderedSetPartition([[2,3], [1]])
sage: A.ordered_set_partition_action(s)
({1, 3}, {2}, {4})
```
We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```python
>>> from sage.all import *

>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(4)], [Integer(3)]]
>>> s = OrderedSetPartition([[Integer(1),Integer(3)], [Integer(2)]]
>>> A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
>>> s = OrderedSetPartition([[Integer(2),Integer(3)], [Integer(1)]]
>>> A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}

We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```python
sage: A = SetPartition([[1,3], [2,9], [4,5,8], [7]])

sage: B = SetPartition([[1,3], [2,8], [4,5,6], [7]])

sage: C = SetPartition([[1,5], [2,8], [3,4,6], [7]])

sage: s = OrderedSetPartition([[1,3], [2]])

sage: t = OrderedSetPartition([[2], [3,4]])

sage: u = OrderedSetPartition([[1], [2,3,4]])

sage: A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}

sage: A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}

sage: A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}

sage: B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}

sage: B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}

sage: B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}

sage: C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}

sage: C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}

sage: C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}

```
REFERENCES:

- [LM2011]

**pipe** *(other)*

Return the pipe of the set partitions *self* and *other*.

The pipe of two set partitions is defined as follows:

For any integer \( k \) and any subset \( I \) of \( \mathbb{Z} \), let \( I + k \) denote the subset of \( \mathbb{Z} \) obtained by adding \( k \) to every element of \( I \).

If \( B \) and \( C \) are set partitions of \([n]\) and \([m]\), respectively, then the pipe of \( B \) and \( C \) is defined as the set partition

\[
\{B_1, B_2, \ldots, B_b, C_1 + n, C_2 + n, \ldots, C_c + n\}
\]

of \([n + m]\), where \( B = \{B_1, B_2, \ldots, B_b\} \) and \( C = \{C_1, C_2, \ldots, C_c\} \). This pipe is denoted by \( B|C \).

**EXAMPLES:**

```python
sage: SetPartition([[1,3],[2,4]]).pipe(SetPartition([[1,3],[2]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
sage: SetPartition([]).pipe(SetPartition([[1,2],[3,5],[4]]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3,5],[4]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3]]).pipe(SetPartition([[1]]))
{{1, 2}, {3}, {4}}
```

```python
>>> from sage.all import *
```

```python
>>> SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]).pipe(SetPartition([[Integer(1),Integer(3)],[Integer(2)]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
>>> SetPartition([]).pipe(SetPartition([[Integer(1),Integer(2)],[Integer(3),
-> Integer(5)],[Integer(4)]]))
{{1, 2}, {3, 5}, {4}}
>>> SetPartition([[Integer(1),Integer(2)],[Integer(3),Integer(5)],
-> [Integer(4)]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
>>> SetPartition([[Integer(1),Integer(2)],[Integer(3)]]).pipe(SetPartition([]))
{{1, 2}, {3}, {4}}
```

**plot** *(angle=None, color='black', base_set_dict=None)*

Return a plot of *self*.

**INPUT:**
• angle – (default: \(\pi/4\)) the angle at which the arcs take off (if angle is negative, the arcs are drawn below the horizontal line)

• color – (default: 'black') color of the arcs

• base_set_dict – (optional) dictionary with keys elements of base_set() and values as integer or float

EXAMPLES:

```python
sage: p = SetPartition([[1,10,11],[2,3,7],[4,5,6],[8,9]])
sage: p.plot()  # needs sage.plot sage.symbolic
Graphics object consisting of 29 graphics primitives

>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(10),Integer(11)],[Integer(2),Integer(3),Integer(7)], [Integer(4),Integer(5),Integer(6)], [Integer(8),Integer(9)]]
>>> p.plot()  # needs sage.plot sage.symbolic
Graphics object consisting of 29 graphics primitives
```

```python
sage: p = SetPartition([[1,3,4],[2,5]])
sage: print(p.plot().description())
```

  angle 0.0 inside the sector (0.785398163397...,2.35619449019...)

Arc with center (1.0,-1.0) radii (1.4142135623...,1.4142135623...)
  angle 0.0 inside the sector (0.785398163397...,2.35619449019...)
```
refinements()  
Return a list of refinements of self.
See also:

cosenings()

EXAMPLES:

```python
sage: SetPartition([ [1,3], [2,4] ]).refinements() # needs sage.graphs sage.libs.flint
[ [ {1}, {2, 4}, {3} ], [ {1}, {2}, {3}, {4} ] ]
```

```python
sage: SetPartition([ [1], [2,4], [3] ]).refinements() # needs sage.graphs sage.libs.flint
[ [ {1}, {2, 4}, {3} ], [ {1}, {2}, {3}, {4} ] ]
```

```python
sage: SetPartition([]).refinements() # needs sage.graphs sage.libs.flint
[ {} ]
```

```python
>>> from sage.all import *
```

```python
>>> A = SetPartition([ [1], [2,3] ])
```

```python
>>> A.restriction([ Integer(1), Integer(2) ]) # needs sage.graphs sage.libs.flint
[ {1}, {2} ]
```

```python
>>> A.restriction([ Integer(2), Integer(3) ]) # needs sage.graphs sage.libs.flint
[ {2, 3} ]
```

```python
>>> A.restriction([]) # needs sage.graphs sage.libs.flint
[]
```

restriction(I)

Return the restriction of self to a subset I (which is given as a set or list or any other iterable).

EXAMPLES:

```python
sage: A = SetPartition([ [1, 2, 3] ])
```

```python
sage: A.restriction([1,2])
[ {1}, {2} ]
```

```python
sage: A.restriction([2,3])
[ {2, 3} ]
```

```python
sage: A.restriction([])
[]
```

```python
>>> from sage.all import *
```

```python
>>> A = SetPartition([ [Integer(1), Integer(2), Integer(3)] ])
```

```python
>>> A.restriction([Integer(1), Integer(2)]) # needs sage.graphs sage.libs.flint
[ {1}, {2} ]
```

```python
>>> A.restriction([Integer(2), Integer(3)]) # needs sage.graphs sage.libs.flint
[ {2, 3} ]
```

```python
>>> A.restriction([]) # needs sage.graphs sage.libs.flint
[]
```

(continues on next page)
set_latex_options(**kwargs)

Set the latex options for use in the _latex_ function

- **tikz_scale** – (default: 1) scale for use with tikz package
- **plot** – (default: None) None returns the set notation, linear returns a linear plot, cyclic returns a cyclic plot
- **color** – (default: 'black') the arc colors
- **fill** – (default: False) if True then fills color, else you can pass in a color to alter the fill color - only works with cyclic plot
- **show_labels** – (default: True) if True shows labels - only works with plots
- **radius** – (default: "1cm") radius of circle for cyclic plot - only works with cyclic plot
- **angle** – (default: 0) angle for linear plot

EXAMPLES:

```sage
sage: SP = SetPartition([[1,6], [3,5,4]])
sage: SP.set_latex_options(tikz_scale=Integer(2),plot='linear',fill=True,color='blue', angle=Integer(45))
sage: SP.set_latex_options(plot='cyclic')
sage: SP.latex_options()
{'angle': 45, 'color': 'blue', 'fill': True, 'plot': 'cyclic', 'radius': '1cm', 'show_labels': True, 'tikz_scale': 2}
```

shape()

Return the integer partition whose parts are the sizes of the sets in self.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

```python
>>> from sage.all import *

>>> S = SetPartitions(Integer(5))

>>> x = S([[Integer(1), Integer(2)], [Integer(3), Integer(5), Integer(4)]])

>>> x.shape()
[3, 2]

>>> y = S([[Integer(2)], [Integer(3), Integer(1)], [Integer(5), Integer(4)]])

>>> y.shape()
[2, 2, 1]
```

**shape_partition()**

Return the integer partition whose parts are the sizes of the sets in `self`.

**EXAMPLES:**

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

```
>>> from sage.all import *

>>> S = SetPartitions(Integer(5))

>>> x = S([[Integer(1), Integer(2)], [Integer(3), Integer(5), Integer(4)]])

>>> x.shape()
[3, 2]

>>> y = S([[Integer(2)], [Integer(3), Integer(1)], [Integer(5), Integer(4)]])

>>> y.shape()
[2, 2, 1]
```

**size()**

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the size (sometimes the weight) of a set partition.

**EXAMPLES:**

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *

>>> SetPartition([[Integer(1)], [Integer(2), Integer(3)], [Integer(4)]]).base_set_cardinality()
4
```

(continues on next page)
standardization()

Return the standardization of self.

Given a set partition \( A = \{A_1, \ldots, A_n\} \) of an ordered set \( S \), the standardization of \( A \) is the set partition of \( \{1, 2, \ldots, |S|\} \) obtained by replacing the elements of the parts of \( A \) by the integers \( 1, 2, \ldots, |S| \) in such a way that their relative order is preserved (i.e., the smallest element in the whole set partition is replaced by 1, the next-smallest by 2, and so on).

EXAMPLES:

```python
sage: SetPartition([[4], [1, 3]]).standardization()
{(1, 2), (3)}

sage: SetPartition([[4], [6, 3]]).standardization()
{(1, 3), (2)}

sage: SetPartition([]).standardization()
{}

sage: SetPartition([('c', 'b'), ('d', 'f'), ('e', 'a')]).standardization()
{(1, 5), (2, 3), (4, 6)}
```

strict_coarsenings()

Return all strict coarsenings of self.

Strict coarsening is the binary relation on set partitions defined as the transitive-and-reflexive closure of the relation \( \prec \) defined as follows: For two set partitions \( A \) and \( B \), we have \( A \prec B \) if there exist parts \( A_i, A_j \) of \( A \) such that \( \max(A_i) < \min(A_j) \) and \( B = A \setminus \{A_i, A_j\} \cup \{A_i \cup A_j\} \).

EXAMPLES:

```python
sage: A = SetPartition([[1], [2, 3], [4]])
sage: A.strict_coarsenings()
[{{1}, {2, 3}, {4}}, {{1}, {2, 3, 4}}, {{1, 2, 3, 4}}]

sage: SetPartition([[1], [2, 4], [3]]).strict_coarsenings()
[{{1}, {2, 4}, {3}}, {{1, 2, 4}, {3}}, {{1}, {2, 4}}, {{1, 2}, {3}, {4}}]

sage: SetPartition([]).strict_coarsenings()
[{}]
```

(continues on next page)
to_partition()

Return the integer partition whose parts are the sizes of the sets in self.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

>>> from sage.all import *

```
sage: S = SetPartitions(Integer(5))
sage: x = S([[Integer(1),Integer(2)], [Integer(3),Integer(5),Integer(4)]])
sage: x.shape()
[3, 2]
sage: y = S([[Integer(2)], [Integer(3),Integer(1)], [Integer(5),Integer(4)]])
sage: y.shape()
[2, 2, 1]
```

to_permutation()

Convert a set partition of \{1, \ldots, n\} to a permutation by considering the blocks of the partition as cycles.

The cycles are such that the number of exceedences is maximised, that is, each cycle is of the form \( (a_1, a_2, \ldots, a_k) \) with \( a_1 < a_2 < \ldots < a_k \).

EXAMPLES:

```
sage: s = SetPartition([[1,3],[2,4]])
sage: s.to_permutation()
[3, 4, 1, 2]
```

>>> from sage.all import *

```
sage: s = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
sage: s.to_permutation()
[3, 4, 1, 2]
```

to_restricted_growth_word(bijection='blocks')

Convert a set partition of \{1, \ldots, n\} to a word of length \( n \) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

INPUT:

- **bijection** (default: blocks) – defines the map from set partitions to restricted growth functions. These are currently:
  - **blocks**: to_restricted_growth_word_blocks().
  - **intertwining**: to_restricted_growth_word_intertwining().

5.1. Comprehensive Module List  4497
OUTPUT:

A restricted growth word.

See also:

*SetPartitions.from_restricted_growth_word()*

### EXAMPLES:

```python
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
sage: P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

```python
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_restricted_growth_word()
[0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2]
sage: P.to_restricted_growth_word("intertwining")
[0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1]
```

```python
>>> from sage.all import *

>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
    →[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])

>>> P.to_restricted_growth_word()
[0, 1, 2, 0, 2, 2, 3, 1, 2]

>>> P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

### to_restricted_growth_word_blocks():

Convert a set partition of \(\{1, \ldots, n\}\) to a word of length \(n\) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

The word is obtained by sorting the blocks by their minimal element and setting the letters at the positions of the elements in the \(i\)-th block to \(i\).

OUTPUT:

a restricted growth word.

See also:

*to_restricted_growth_word() SetPartitions.from_restricted_growth_word()*

### EXAMPLES:
Combinatorics, Release 10.4

```python
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

```python
>>> from sage.all import *

>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
                   [Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])

>>> P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

`to_restricted_growth_word_intertwining()`

Convert a set partition of \{1, ..., n\} to a word of length \(n\) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before.

The \(i\)-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at \(i\), with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

OUTPUT:

a restricted growth word.

See also:

`to_restricted_growth_word()` `SetPartitions.from_restricted_growth_word()`

EXAMPLES:

```python
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

```python
>>> from sage.all import *

>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
                   [Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])

>>> P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

`to_rook_placement` *(bijection='arcs')*

Return a set of pairs defining a placement of non-attacking rooks on a triangular board.

The cells of the board corresponding to a set partition of \{1, ..., n\} are the pairs \((i, j)\) with \(0 < i < j < n+1\).

INPUT:

- `bijection` (default: `arcs`) – defines the bijection from set partitions to rook placements. These are currently:
  - `arcs`: `arcs()`
  - `gamma`: `to_rook_placement_gamma()`
  - `rho`: `to_rook_placement_rho()`
  - `psi`: `to_rook_placement_psi()`

See also:

`SetPartitions.from_rook_placement()`

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: P = SetPartition([\[1,2,4,7\],\[3,9\],\[5,6,10,11,13\],\[8\],\[12\]])
sage: P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
sage: P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
sage: P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]

from sage.all import *
>>>
P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
                  [Integer(3),Integer(9)],
                  [Integer(5),Integer(6),Integer(10),Integer(11),
                  Integer(13)],
                  [Integer(8)],
                  [Integer(12)]])
>>>
P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
>>>
P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
>>>
P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
>>>
P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

**to_rook_placement_gamma()**

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the left column. If \(n+1-i\) is an opener, column \(i\) remains empty. Otherwise, we place a rook into column \(i\), such that the number of cells below the rook, which are not yet attacked by another rook, equals the index of the block to which \(n+1-i\) belongs.

**OUTPUT:**

A list of coordinates.

**See also:**

- to_rook_placement()
- SetPartitions.from_rook_placement()
- SetPartitions.from_rook_placement_gamma()

**EXAMPLES:**

```python
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

```python
from sage.all import *
>>>
P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
                  [Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]]))
>>>
P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```
Figure 5 in [WW1991]:

```python
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

```python
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
                   [Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
                   Integer(13)],[Integer(8)],[Integer(12)]]
>>> r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

to_rook_placement_psi()

Return the rook diagram obtained by placing rooks according to Yip's bijection psi.

OUTPUT:

A list of coordinates.

See also:

- to_rook_placement()
- SetPartitions.from_rook_placement()
- SetPartitions.from_rook_placement_psi()

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018]:

```python
sage: P = SetPartition([[1, 5], [2], [3, 8, 9], [4], [6, 7]])
sage: P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

```python
>>> from sage.all import *
>>> P = SetPartition([[Integer(1), Integer(5)], [Integer(2)], [Integer(3),
                   Integer(8), Integer(9)], [Integer(4)], [Integer(6), Integer(7)]]
>>> P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

Note that the columns corresponding to the minimal elements of the blocks remain empty.

to_rook_placement_rho()

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with $(i,j)$ to the cell in the $i$-th column from the right and the $j$-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the top row. The columns corresponding to the closers of the set partition remain empty. Let $r_{sj}$ be the number of closers which are larger than $j$ and whose block is before the block of $j$.

We then place a rook into row $j$, such that the number of cells to the left of the rook, which are not yet attacked by another rook and are not in a column corresponding to a closer, equals $r_{sj}$, unless there are not enough cells in this row available, in which case the row remains empty.

One can show that the precisely those rows which correspond to openers of the set partition remain empty.
OUTPUT:
A list of coordinates.

See also:

- `to_rook_placement()`
- `SetPartitions.from_rook_placement()`
- `SetPartitions.from_rook_placement_rho()`

EXAMPLES:

```python
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_rho()
[(1, 5), (2, 6), (3, 4), (5, 9), (6, 8)]
```

```python
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
                      [Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_rook_placement_rho()
[(1, 5), (2, 6), (3, 4), (5, 9), (6, 8)]
```

Figure 6 in [WW1991]:

```python
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_rho(); r
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: sorted(P.closers() + [i for i, _ in r]) == list(range(1,14))
True
sage: sorted(P.openers() + [j for _, j in r]) == list(range(1,14))
True
```

```python
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
                      [Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
                       Integer(13)],[Integer(8)],[Integer(12)]]
>>> r = P.to_rook_placement_rho(); r
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
>>> sorted(P.closers() + [i for i, _ in r]) == list(range(Integer(1),
                                                                 Integer(14)))
True
>>> sorted(P.openers() + [j for _, j in r]) == list(range(Integer(1),
                                                                 Integer(14)))
True
```

class sage.combinat.set_partition.SetPartitions

Bases: UniqueRepresentation, Parent

An (unordered) partition of a set \( S \) is a set of pairwise disjoint nonempty subsets with union \( S \), and is represented by a sorted list of such subsets.

`SetPartitions(s)` returns the class of all set partitions of the set `s`, which can be given as a set or a string; if a string, each character is considered an element.

`SetPartitions(n)`, where `n` is an integer, returns the class of all set partitions of the set \{1, 2, \ldots, n\}. 

4502 Chapter 5. Comprehensive Module List
You may specify a second argument \( k \). If \( k \) is an integer, \texttt{SetPartitions} returns the class of set partitions into \( k \) parts; if it is an integer partition, \texttt{SetPartitions} returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number \( B_n \), named in honor of Eric Temple Bell, is the number of different partitions of a set with \( n \) elements.

**EXAMPLES:**

```
sage: S = [1,2,3,4]
sage: SetPartitions(S, 2)
Set partitions of {1, 2, 3, 4} with 2 parts
sage: SetPartitions([[1,2,3,4], [3,1]].list()  # needs sagegraphs sage.ringsfinite_rings
[(1, 2, 3, 4), (3, 1)]
sage: SetPartitions(7, [3,3,1]).list()  # needs sagegraphs
[{{1}, {2, 3, 4}}, {{1, 2, 3}, {4}}, {{1, 2, 4}, {3}}, {{1, 3, 4}, {2}}]
```

In strings, repeated letters are not considered distinct as of Issue \#14140:

```
sage: SetPartitions('abcde').cardinality()  # needs sage.libflint
52
sage: SetPartitions('aabcd').cardinality()  # needs sage.libflint
15
```

If the number of parts exceeds the length of the set, an empty iterator is returned (Issue \#37643):

```
sage: SetPartitions(range(3), 4).list()  # needs sage.graphs sage.ringsfinite_rings
[]
sage: SetPartitions('abcd', 6).list()  # needs sage.graphs sage.ringsfinite_rings
[]
```
REFERENCES:

- Wikipedia article Partition_of_a_set

Element

alias of SetPartition

from_arcs (arcs, n)

Return the coarsest set partition of \{1, ..., n\} such that any two elements connected by an arc are in the same block.

INPUT:

- n – an integer specifying the size of the set partition to be produced.
- arcs – a list of pairs specifying which elements are in the same block.

See also:

- from_rook_placement()
- SetPartition.to_rook_placement()
- SetPartition.arcs()

EXAMPLES:

```
sage: SetPartitions().from_arcs([(2,3)], 5)
{{1}, {2, 3}, {4}, {5}}
```

```
>>> from sage.all import *

>>> SetPartitions().from_arcs([(Integer(2),Integer(3))], Integer(5))
{{1}, {2, 3}, {4}, {5}}
```

from_restricted_growth_word (w, bijection='blocks')

Convert a word of length \(n\) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of \{1, ..., \(n\)\}.

INPUT:

- w – a restricted growth word.
- bijection (default: blocks) – defines the map from restricted growth functions to set partitions. These are currently:
  - blocks:
  - intertwining: from_restricted_growth_word_intertwining()

OUTPUT:

A set partition.

See also:

SetPartition.to_restricted_growth_word()
from_restricted_growth_word_blocks(w)

Convert a word of length \( n \) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of \( \{1, ..., n\} \).

\( w[i] \) is the index of the block containing \( i+1 \) when sorting the blocks by their minimal element.

**INPUT:**

- \( w \) – a restricted growth word.

**OUTPUT:**

A set partition.

See also:

- from_restricted_growth_word()
- SetPartition.to_restricted_growth_word()

**EXAMPLES:**

```
>>> from sage.all import *

>>> SetPartitions().from_restricted_growth_word_blocks([[0, 0, 1, 0, 2, 0, 3, 1, 2]])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_restricted_growth_word_intertwining(w)

Convert a word of length \( n \) with letters in the non-negative integers such that each letter is at most 1 larger than all the letters before to a set partition of \( \{1, ..., n\} \).
The $i$-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at $i$, with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

**INPUT:**

- $w$ – a restricted growth word.

**OUTPUT:**

A set partition.

**See also:**

`from_restricted_growth_word()`, `SetPartition.to_restricted_growth_word()`

**EXAMPLES:**

```python
sage: SetPartitions().from_restricted_growth_word_intertwining([0, 0, 1, 0, 2, 1, 2, 4, 2])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

```python
from sage.all import *
SetPartitions().from_restricted_growth_word_intertwining([Integer(0), Integer(0), Integer(1), Integer(0), Integer(2), Integer(2), Integer(0), Integer(3), Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

### from_rook_placement (rooks, bijection='arcs', n=None)

Convert a rook placement of the triangular grid to a set partition of $\{1, \ldots, n\}$.

If $n$ is not given, it is first checked whether it can be determined from the parent, otherwise it is the maximal occurring integer in the set of rooks.

**INPUT:**

- `rooks` – a list of pairs $(i, j)$ satisfying $0 < i < j < n + 1$.
- `bijection` *(default: `arcs`)* – defines the map from rook placements to set partitions. These are currently:
  - `arcs`: `from_arcs()`.
  - `gamma`: `from_rook_placement_gamma()`.
  - `rho`: `from_rook_placement_rho()`.
  - `psi`: `from_rook_placement_psi()`.
- `n` – (optional) the size of the ground set.

**See also:**

`SetPartition.to_rook_placement()`

**EXAMPLES:**

```python
sage: SetPartitions(9).from_rook_placement([ [1,4], [2,8], [3,5], [5,6], [6,9] ])  
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}
```

```python
sage: SetPartitions(13).from_rook_placement([ [12,13], [10,12], [8,9], [7,11], [5, 14], [4,6], [3,5], [1,4] ], "gamma")  
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```
from sage.all import *

SetPartitions(Integer(9)).from_rook_placement([[Integer(1), Integer(4)],
→[Integer(2), Integer(8)], [Integer(3), Integer(5)], [Integer(5), Integer(6)],
→[Integer(6), Integer(9)]]).
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

SetPartitions(Integer(13)).from_rook_placement([[Integer(12), Integer(13)],
→[Integer(10), Integer(12)], [Integer(8), Integer(9)], [Integer(7), Integer(11)],
→[Integer(5), Integer(8)], [Integer(4), Integer(6)], [Integer(3), Integer(5)],
→[Integer(1), Integer(4)]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}

from_rook_placement_gamma(rooks, n)
Return the set partition of \{1, \ldots, n\} corresponding to the given rook placement by applying Wachs and White's bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

INPUT:
• \(n\) – an integer specifying the size of the set partition to be produced.
• \(rooks\) – a list of pairs \((i, j)\) such that \(0 < i < j < n + 1\).

OUTPUT:
A set partition.

See also:
• from_rook_placement()
• SetPartition.to_rook_placement()
• SetPartition.to_rook_placement_gamma()

EXAMPLES:
Figure 5 in [WW1991] concerns the following rook placement:

\[
\text{sage: } r = [(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
\]

Note that the rook \((1, 4)\), translated into Wachs and White’s convention, is a rook in row 4 from the top and column 13 from the left. The corresponding set partition is:

\[
\text{sage: } \text{SetPartitions().from_rook_placement_gamma(r, 13)}
\]

\[
\{(1, 2, 4, 7), \{3, 9\}, \{5, 6, 10, 11, 13\}, \{8\}, \{12\}\}
\]

\[
\text{from sage.all import *}
\]

\[
\text{SetPartitions().from_rook_placement_gamma(r, Integer(13))}
\]

\[
\{(1, 2, 4, 7), \{3, 9\}, \{5, 6, 10, 11, 13\}, \{8\}, \{12\}\}
\]
from_rook_placement_psi(\textit{rooks}, \textit{n})

Return the set partition of \{1, ..., \textit{n}\} corresponding to the given rook placement by applying Yip's bijection psi.

INPUT:

• \textit{n} – an integer specifying the size of the set partition to be produced.
• \textit{rooks} – a list of pairs \((i, j)\) such that \(0 < i < j < n + 1\).

OUTPUT:

A set partition.

See also:

• \textit{from_rook_placement()}
• \textit{SetPartition.to_rook_placement()}
• \textit{SetPartition.to_rook_placement_psi()}

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018] concerns the following rook placement:

\begin{verbatim}
sage: r = [(4,5), (1,7), (3, 8), (7,9)]
sage: SetPartitions().from_rook_placement_psi(r, 9)     \\{\{1, 5\}, \{2\}, \{3, 8, 9\}, \{4\}, \{6, 7\}\}
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> r = [(Integer(4),Integer(5)), (Integer(1),Integer(7)), (Integer(3),Integer(8)), (Integer(7),Integer(9))]
>>> SetPartitions().from_rook_placement_psi(r, Integer(9))     \\{\{1, 5\}, \{2\}, \{3, 8, 9\}, \{4\}, \{6, 7\}\}
\end{verbatim}

from_rook_placement_rho(\textit{rooks}, \textit{n})

Return the set partition of \{1, ..., \textit{n}\} corresponding to the given rook placement by applying Wachs and White's bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with \((i, j)\) to the cell in the \(i\)-th column from the right and the \(j\)-th row from the top.

INPUT:

• \textit{n} – an integer specifying the size of the set partition to be produced.
• \textit{rooks} – a list of pairs \((i, j)\) such that \(0 < i < j < n + 1\).

OUTPUT:

A set partition.

See also:

• \textit{from_rook_placement()}
• \textit{SetPartition.to_rook_placement()}
• \textit{SetPartition.to_rook_placement_rho()}
EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
```

```
>>> from sage.all import *
```

```
>>> r = [(Integer(1), Integer(2)), (Integer(2), Integer(6)), (Integer(3), Integer(4)), (Integer(4), Integer(6)), (Integer(5), Integer(9)), (Integer(6), Integer(7)), (Integer(10), Integer(11)), (Integer(11), Integer(13))]
```

Notethattherook (1, 2), translated into Wachs and White’s convention, is a rook in row 2 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_rhoo(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
```

```
>>> SetPartitions().from_rook_placement_rhoo(r, Integer(13))
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

**is_less_than** *(s, t)*

Check if *s* < *t* in the refinement ordering on set partitions.

This means that *s* is a refinement of *t* and satisfies *s* ≠ *t*.

A set partition *s* is said to be a refinement of a set partition *t* of the same set if and only if each part of *s* is a subset of a part of *t*.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: t = S([[1], [2], [3], [4]])
sage: S.is_less_than(t, s)
True
```

```
sage: S.is_less_than(s, t)
False
```

```
sage: S.is_less_than(s, s)
False
```

```
>>> from sage.all import *
```

```
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> t = S([[Integer(1)], [Integer(2), Integer(3)], [Integer(4)]]])
>>> S.is_less_than(t, s)
True
```

```
>>> S.is_less_than(s, t)
False
```

```
>>> S.is_less_than(s, s)
False
```

**is_strict_refinement** *(s, t)*

Return True if *s* is a strict refinement of *t* and satisfies *s* ≠ *t*.
A set partition $s$ is said to be a strict refinement of a set partition $t$ of the same set if and only if one can obtain $t$ from $s$ by repeatedly combining pairs of parts whose convex hulls don't intersect (i.e., whenever we are combining two parts, the maximum of each of them should be smaller than the minimum of the other).

EXAMPLES:

```python
sage: S = SetPartitions(4)
sage: s = S([[1],[2],[3],[4]])
sage: t = S([[1,3],[2,4]])
sage: u = S([[1,2,3,4]])
sage: S.is_strict_refinement(s, t)
True
sage: S.is_strict_refinement(t, u)
False
sage: A = SetPartition([[1,3],[2,4]])
sage: B = SetPartition([[1,2,3,4]])
sage: S.is_strict_refinement(s, A)
True
sage: S.is_strict_refinement(t, B)
False
```

`lt(s, t)`

Check if $s < t$ in the refinement ordering on set partitions.

This means that $s$ is a refinement of $t$ and satisfies $s \neq t$.

A set partition $s$ is said to be a refinement of a set partition $t$ of the same set if and only if each part of $s$ is a subset of a part of $t$.

EXAMPLES:

```python
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1),Integer(3)], [Integer(2),Integer(4)]]
>>> t = S([[Integer(1)], [Integer(2)], [Integer(3)], [Integer(4)]])
>>> S.is_less_than(t, s)
True
>>> S.is_less_than(s, t)
False
>>> S.is_less_than(s, s)
False

class sage.combinat.set_partition.SetPartitions_all

Bases: SetPartitions

All set partitions.

subset (size=None, **kwargs)

Return the subset of set partitions of a given size and additional keyword arguments.

EXAMPLES:

sage: P = SetPartitions()
sage: P.subset(4)
Set partitions of {1, 2, 3, 4}

>>> from sage.all import *
>>> P = SetPartitions()
>>> P.subset(Integer(4))
Set partitions of {1, 2, 3, 4}

class sage.combinat.set_partition.SetPartitions_set(s)

Bases: SetPartitions

Set partitions of a fixed set S.

base_set ()

Return the base set of self.

EXAMPLES:

sage: SetPartitions(3).base_set()
{1, 2, 3}

sage: sorted(SetPartitions(['a', 'b', 'c']).base_set())
['a', 'b', 'c']

>>> from sage.all import *
>>> SetPartitions(Integer(3)).base_set()
{1, 2, 3}

>>> sorted(SetPartitions(['a', 'b', 'c']).base_set())
['a', 'b', 'c']

base_set_cardinality ()

Return the cardinality of the base set of self.

EXAMPLES:
cardinality()

Return the number of set partitions of the set \( S \).

The cardinality is given by the \( n \)-th Bell number where \( n \) is the number of elements in the set \( S \).

EXAMPLES:

```python
sage: # needs sage.libs.flint
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```

random_element()

Return a random set partition.

This is a very naive implementation of Knuth's outline in F3B, 7.2.1.5.

EXAMPLES:

```python
sage: S = SetPartitions(10)
sage: s = S.random_element()  # needs sage.symbolic
sage: s.parent() is S  # needs sage.symbolic
True
sage: assert s in S, s  # needs sage.symbolic
```

(continues on next page)
class sage.combinat.set_partition.SetPartitions_setn(s, k)

    Bases: SetPartitions_set

    Set partitions with a given number of blocks.

cardinality()

    The Stirling number of the second kind is the number of partitions of a set of size \( n \) into \( k \) blocks.

    EXAMPLES:

    >>> SetPartitions(5, 3).cardinality()
    25
    >>> stirling_number2(5, 3)
    25

number_of_blocks()

    Return the number of blocks of the set partitions in self.

    EXAMPLES:

    >>> SetPartitions(5, 3).number_of_blocks()
    3

    >>> SetPartitions(Integer(5), Integer(3)).number_of_blocks()
    3
random_element()

Return a random set partition of self.

See https://mathoverflow.net/questions/141999.

EXAMPLES:

```
sage: S = SetPartitions(10, 4)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
sage: S = SetPartitions(["a", "b", "c"], 2)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10), Integer(4))
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s
```

```
>>> S = SetPartitions(["a", "b", "c"], Integer(2))
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s
```

class sage.combinat.set_partition.SetPartitions_setparts(s, parts)

Bases: SetPartitions_set

Set partitions with fixed partition sizes corresponding to an integer partition \( \lambda \).

cardinality()

Return the cardinality of self.

This algorithm counts for each block of the partition the number of ways to fill it using values from the set. Then, for each distinct value \( v \) of block size, we divide the result by the number of ways to arrange the blocks of size \( v \) in the set partition.

For example, if we want to count the number of set partitions of size 13 having \([3,3,3,2,2]\) as underlying partition we compute the number of ways to fill each block of the partition, which is \( \binom{13}{3} \binom{10}{3} \binom{7}{3} \binom{4}{2} \binom{2}{2} \) and as we have three blocks of size 3 and two blocks of size 2, we divide the result by \( 3!2! \) which gives us 600600.

EXAMPLES:

```
sage: SetPartitions(3, [2,1]).cardinality()
3
```

```
sage: SetPartitions(13, Partition([3,3,3,2,2])).cardinality()
600600
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(3), [Integer(2),Integer(1)]).cardinality()
3
```

random_element()

Return a random set partition of self.

ALGORITHM:

Based on the cardinality method. For each block size $k_i$, we choose a uniformly random subset $X_i \subseteq S_i$ of size $k_i$ of the elements $S_i$ that have not yet been selected. Thus, we define $S_{i+1} = S_i \setminus X_i$ with $S_1 = S$ being the defining set. This is not yet proven to be uniformly distributed, but numerical tests show this is likely uniform.

EXAMPLES:

```
sage: S = SetPartitions(10, [4,3,2,1])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
sage: S = SetPartitions(["a", "b", "c", "d"], [2,2])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

shape()

Return the partition of block sizes of the set partitions in self.

EXAMPLES:

```
sage: SetPartitions(5, [2,2,1]).shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(5), [Integer(2),Integer(2),Integer(1)]).shape()
[2, 2, 1]
```

sage.combinat.set_partition.cyclic_permutations_of_set_partition(set_part)

Return all combinations of cyclic permutations of each cell of the set partition.
AUTHORS:

- Robert L. Miller

EXAMPLES:

```python
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: cyclic_permutations_of_set_partition([[1,2,3,4],[5,6,7]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.set_partition import cyclic_permutations_of_set_partition

>>> cyclic_permutations_of_set_partition([[Integer(1),Integer(2),Integer(3), Integer(4)],[Integer(5),Integer(6),Integer(7)]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

```python
sage.combinat.set_partition.cyclic_permutations_of_set_partition_iterator (set_part)

Iterates over all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```python
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: list(cyclic_permutations_of_set_partition_iterator([[1,2,3,4],[5,6,7]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```
5.1.278 Fast set partition iterators

`sage.combinat.set_partition_iterator.set_partition_iterator(base_set)`

A fast iterator for the set partitions of the base set, which returns lists of lists instead of set partitions types.

**EXAMPLES:**

```python
>>> from sage.combinat.set_partition_iterator import set_partition_iterator
>>> list(set_partition_iterator([1,-1,x]))  # needs sage.symbolic
[[[1, -1], [x]],
 [[1, x], [-1]],
 [[1], [-1], [x]]]
```

`sage.combinat.set_partition_iterator.set_partition_iterator_blocks(base_set, k)`

A fast iterator for the set partitions of the base set into the specified number of blocks, which returns lists of lists instead of set partitions types.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.set_partition_iterator import set_partition_iterator
>>> list(set_partition_iterator([Integer(1),-Integer(1),x]))  # needs sage.symbolic
[[[1, -1, x]],
 [[1, -1], [x]],
 [[1, x], [-1]],
 [[1], [-1], [x]]]
```
sage: from sage.combinat.set_partition_iterator import set_partition_iterator_blocks
sage: list(set_partition_iterator_blocks([1,-1,x], 2))  # needs sage.symbolic
[[[1, x], [-1]], [[1], [-1, x]], [[1, -1], [x]]]

>>> from sage.all import *
>>> from sage.combinat.set_partition_iterator import set_partition_iterator_blocks
>>> list(set_partition_iterator_blocks([Integer(1),-Integer(1),x], Integer(2)))  # needs sage.symbolic
[[[1, x], [-1]], [[1], [-1, x]], [[1, -1], [x]]]

5.1.279 Ordered Set Partitions

AUTHORS:
• Mike Hansen
• MuPAD-Combinat developers (for algorithms and design inspiration)
• Travis Scrimshaw (2013-02-28): Removed CombinatorialClass and added entry point through OrderedSetPartition.

class sage.combinat.set_partition_ordered.OrderedSetPartition(parent, s, check=True)
Bases: ClonableArray

An ordered partition of a set.

An ordered set partition \( p \) of a set \( s \) is a list of pairwise disjoint nonempty subsets of \( s \) such that the union of these subsets is \( s \). These subsets are called the parts of the partition.

We represent an ordered set partition as a list of sets. By extension, an ordered set partition of a nonnegative integer \( n \) is the set partition of the integers from 1 to \( n \). The number of ordered set partitions of \( n \) is called the \( n \)-th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

The number \( T_n \) of ordered set partitions of \( \{1, 2, \ldots, n\} \) is the so-called \( n \)-th Fubini number (also known as the \( n \)-th ordered Bell number; see Wikipedia article Ordered Bell number). Its exponential generating function is

\[
\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.
\]

(See sequence OEIS sequence A000670 in OEIS.)

INPUT:
• parts – an object or iterable that defines an ordered set partition (e.g., a list of pairwise disjoint sets) or a packed word (e.g., a list of letters on some alphabet). If there is ambiguity and if the input should be treated as a packed word, the keyword from_word should be used.

EXAMPLES:
There are 13 ordered set partitions of \( \{1, 2, 3\} \):

sage: OrderedSetPartitions(3).cardinality()
13
Here is the list of them:

```
sage: OrderedSetPartitions(3).list()
[[[1], {2}, {3}],
 [[1], {3}, {2}],
 [[2], {1}, {3}],
 [[3], {1}, {2}],
 [[2], {3}, {1}],
 [[3], {2}, {1}],
 [[1], {2}, {3}],
 [[2], {1}, {3}],
 [[3], {1}, {2}],
 [[2], {3}, {1}],
 [[3], {2}, {1}],
 [[1], {2, 3}],
 [[2], {1, 3}],
 [[3], {1, 2}],
 [[1], {2}, {3}],
 [[2], {1}, {3}],
 [[3], {1}, {2}],
 [[2], {3}, {1}],
 [[3], {2}, {1}],
 [[1], {2, 3}]]
```

There are 12 ordered set partitions of \{1, 2, 3, 4\} whose underlying composition is \{1, 2, 1\}:

```
sage: OrderedSetPartitions(4,[1,2,1]).list()
[[[1], {2, 3}, {4}],
 [[1], {2, 4}, {3}],
 [[1], {3, 4}, {2}],
 [[2], {1, 3}, {4}],
 [[2], {1, 4}, {3}],
 [[3], {1, 2}, {4}],
 [[4], {1, 2}, {3}],
 [[4], {1, 3}, {2}],
 [[3], {1, 4}, {2}],
 [[3], {2, 4}, {1}],
 [[2], {3, 4}, {1}],
 [[4], {2, 3}, {1}]]
```

(continues on next page)
Since Issue #14140, we can create an ordered set partition directly by `OrderedSetPartition` which creates the parent object by taking the union of the partitions passed in. However it is recommended and (marginally) faster to create the parent first and then create the ordered set partition from that.

```
s = OrderedSetPartition([[1,3],[2,4]]); s
\{\{1, 3\}, \{2, 4\}\}
s.parent()  
```
Ordered set partitions of \{1, 2, 3, 4\}

We can construct the ordered set partition from a word, which we consider as packed:

```
s = OrderedSetPartition([2,4,1,2])
\{\{3\}, \{1, 4\}, \{2\}\}
s = OrderedSetPartition(from_word=[2,4,1,2])
\{\{3\}, \{1, 4\}, \{2\}\}
s = OrderedSetPartition(from_word='bdab')
\{\{3\}, \{1, 4\}, \{2\}\}
```

```
sage: from sage.all import *
>>> OrderedSetPartition([[Integer(2),Integer(4),Integer(1),Integer(2)]]
\{\{3\}, \{1, 4\}, \{2\}\}
```

**Warning:** The elements of the underlying set should be hashable.

REFERENCES:

Wikipedia article Ordered_partition_of_a_set

```
base_set()
```
Return the base set of `self`. This is the union of all parts of `self`. 

EXAMPLES:
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set()
frozenset((1, 2, 3, 4))
sage: OrderedSetPartition([[1,2,3,4]]).base_set()
frozenset((1, 2, 3, 4))
sage: OrderedSetPartition([]).base_set()
frozenset()

>>> from sage.all import *

OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],
                   [Integer(4)])].base_set()
frozenset((1, 2, 3, 4))
OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)])].base_set()
frozenset((1, 2, 3, 4))
OrderedSetPartition([]).base_set()
frozenset()

**base_set_cardinality()**

Return the cardinality of the base set of self.

This is the sum of the sizes of the parts of self.

This is also known as the size (sometimes the weight) of an ordered set partition.

**EXAMPLES:**

```python
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```python
>>> from sage.all import *

OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],
                   [Integer(4)])].base_set_cardinality()
4
OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)])].base_set_cardinality()
4
```

**static bottom_up_osp**(X, comp)

Return the ordered set partition obtained by listing the elements of the set X in increasing order, and placing bars between some of them according to the integer composition comp (namely, the bars are placed in such a way that the lengths of the resulting blocks are exactly the entries of comp).

**INPUT:**

- X – a finite set (or list or tuple)
- comp – a composition whose sum is the size of X (can be given as a list or tuple or composition)

**EXAMPLES:**

```python
sage: buo = OrderedSetPartition.bottom_up_osp
sage: buo(Set([1, 4, 7, 9]), [2, 1, 1])
[[1, 4], {7}, {9}]
sage: buo(Set([1, 4, 7, 9]), [1, 3])
[[1], {4, 7}, {9}]
sage: buo(Set([1, 4, 7, 9]), [1, 1, 1])
(continues on next page)
```
Combinatorics, Release 10.4

[[1], {4}, {7}, {9}]
sage: buo(range(8), [1, 4, 2, 1])
[[0], {1, 2, 3, 4}, {5, 6}, {7}]
sage: buo([], [])
[]

>>> from sage.all import *
>>> buo = OrderedSetPartition.bottom_up_osp
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(2), Integer(1)])
[[1, 4, {7}, {9}]
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(1), Integer(3)])
[[1, {4, 7, 9}]
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(1), Integer(1), Integer(1)])
[[1, {4}, {7}, {9}]
>>> buo(range(Integer(8)), [Integer(1), Integer(4), Integer(2), Integer(1)])
[[0, {1, 2, 3, 4}, {5, 6}, {7}]
>>> buo,[],[]
[]

check()

Check that we are a valid ordered set partition.

EXAMPLES:

sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()

>>> from sage.all import *
>>> OS = OrderedSetPartitions(Integer(4))
>>> s = OS([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.check()

complement()

Return the complement of the ordered set partition self.

This assumes that self is an ordered set partition of an interval of \( Z \).

Let \((P_1, P_2, \ldots, P_k)\) be an ordered set partition of some interval \( I \) of \( Z \). Let \( \omega \) be the unique strictly decreasing bijection \( I \to I \). Then, the complement of \((P_1, P_2, \ldots, P_k)\) is defined to be the ordered set partition \((\omega(P_1), \omega(P_2), \ldots, \omega(P_k))\).

EXAMPLES:

sage: OrderedSetPartition([[1, 2], [3]]).complement()
[[2, 3, 1]]
sage: OrderedSetPartition([[1, 3], [2]]).complement()
[[1, 3, 2]]
sage: OrderedSetPartition([[2, 3]]).complement()
[[2, 3]]
sage: OrderedSetPartition([[1, 5], [2, 3], [4]]).complement()
[[1, 5], [3, 4], [2]]
sage: OrderedSetPartition([[-1], [-2], [1, 2], [0]]).complement()

Combinatorics, Release 10.4

fatten (grouping)

Return the ordered set partition fatter than self, obtained by grouping together consecutive parts according to the integer composition grouping.

See finer() for the definition of “fatter”.

INPUT:

• grouping – a composition whose sum is the length of self

EXAMPLES:

Let us start with the ordered set partition:

```python
sage: c = OrderedSetPartition([ [2, 5], [1], [3, 4] ])```

With grouping equal to (1,...,1), c is left unchanged:

```python
sage: c.fatten(Composition([1,1,1]))
[ [2, 5], [1], [3, 4] ]
```

With grouping equal to (ℓ) where ℓ is the length of c, this yields the coarsest ordered set partition above c:

```python
sage: c.fatten(Composition([3]))
[ [1, 2, 3, 4, 5] ]
```
Other values for grouping yield (all the) other ordered set partitions coarser than \( c \):

\[
\begin{align*}
\text{sage: } & c.\text{fatten}() \text{Composition}([2,1]) \\
& \{\{1, 2, 5\}, \{3, 4\}\} \\
\text{sage: } & c.\text{fatten}() \text{Composition}([1,2]) \\
& \{\{2, 5\}, \{1, 3, 4\}\}
\end{align*}
\]

\[\begin{align*}
\text{fatter}(\) \\
\text{Return the set of ordered set partitions which are fatter than self.}
\text{See finer()} for the definition of “fatter”.
\text{EXAMPLES:}
\begin{align*}
\text{sage: } & C = \text{OrderedSetPartition}([[2, 5], [1], [3, 4]]).\text{fatter}() \\
\text{sage: } & C.\text{cardinality}() \\
& 4 \\
\text{sage: } & \text{sorted}(C) \\
& [[[2, 5], \{1\}, \{3, 4\}], \\
& \{2, 5\}, \{1, 3, 4\}], \\
& \{[1, 2, 5], \{3, 4\}\}, \\
& \{[1, 2, 3, 4, 5]\}]
\end{align*}
\]

\[\begin{align*}
\text{sage: } & \text{OrderedSetPartition}([[4, 9], [-1, 2]]).\text{fatter}().\text{list}() \\
& [[[4, 9], \{-1, 2\}], \{-1, 2, 4, 9\}\}]
\end{align*}
\]

Some extreme cases:

\[\begin{align*}
\text{sage: } & \text{list}((\text{OrderedSetPartition})([[5]]).\text{fatter}()) \\
& [[5]]
\end{align*}\]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).fatter())

[[1, 2, 3, 4],
 [1, 2, 3], {4}],
 [1, 2], {3, 4}],
 [1, 2], {3}, {4}],
 [1, 2], {2}, {3, 4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}]]

>>> from sage.all import *

>>> list(OrderedSetPartition([[Integer(5)]]).fatter())
[[[5]]]

>>> list(Composition([]).fatter())
[[[]]]

>>> sorted(OrderedSetPartition([[Integer(1), Integer(2), Integer(3), Integer(4)]]).fatter())

[[1, 2, 3, 4],
 [1, 2, 3], {4}],
 [1, 2], {3, 4}],
 [1, 2], {3}, {4}],
 [1, 2], {2, 3}, {4}],
 [1, 2], {2, 3, 4}],
 [1, 2], {2}, {3, 4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}],
 [1, 2], {2}, {3}, {4}]]

finer()  

Return the set of ordered set partitions which are finer than self.  

See is_finer() for the definition of “finer”.  

EXAMPLES:

sage: C = OrderedSetPartition([[1, 3], [2]]).finer()  
sage: C.cardinality()
3  
sage: C.list()

[[[1], {3}, {2}], [[3], {1}, {2}], [[[1], {3}, {2}]]]

sage: OrderedSetPartition([]).finer()

[[]]

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])

sage: W.finer().list()

 ]]]

3.1. Comprehensive Module List 4525
is_finer (co2)
Return True if the ordered set partition self is finer than the ordered set partition co2; otherwise, return False.

If $A$ and $B$ are two ordered set partitions of the same set, then $A$ is said to be finer than $B$ if $B$ can be obtained from $A$ by (repeatedly) merging consecutive parts. In this case, we say that $B$ is fatter than $A$.

EXAMPLES:

```python
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
```

```python
>>> A.is_finer(B)
False
```

```python
sage: C = OrderedSetPartition([[3], [1], [2]])
```

```python
>>> A.is_finer(C)
False
```

```python
sage: A.is_finer(A)
True
```

```python
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_finer(OrderedSetPartition([[2], [5], [1], [4]]))
True
```

```python
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_finer(OrderedSetPartition([[2], [5], [1], [4]]))
False
```

```python
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_finer(OrderedSetPartition([[2], [5], [1], [4]]))
False
```

```python
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_finer(OrderedSetPartition([[2, 5], [1, 4]]))
```

```python
>>> from sage.all import *
```

```python
>>> A = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]])
```

```python
>>> B = OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)]])
```
is_strongly_finer (co2)

Return True if the ordered set partition self is strongly finer than the ordered set partition co2; otherwise, return False.

If A and B are two ordered set partitions of the same set, then A is said to be strongly finer than B if B can be obtained from A by (repeatedly) merging consecutive parts, provided that every time we merge two consecutive parts $C_i$ and $C_{i+1}$, we have $\max C_i < \min C_{i+1}$. In this case, we say that B is strongly fatter than A.

**EXAMPLES:**

```python
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_strongly_finer(B)
False
sage: B.is_strongly_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_strongly_finer(C)
False
sage: C.is_strongly_finer(A)
False
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
```
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_strongly_finer(OrderedSetPartition([[2, 5], [1, 4]]))
False

>>> from sage.all import *
>>> A = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]))
>>> B = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]))
>>> A.is_strongly_finer(B)
False
>>> B.is_strongly_finer(A)
True
>>> C = OrderedSetPartition([[Integer(3)], [Integer(1), Integer(2)]])
>>> A.is_strongly_finer(C)
False
>>> C.is_strongly_finer(A)
False
>>> OrderedSetPartition([[Integer(2)], [Integer(5)], [Integer(1)]]).is_strongly_finer(OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(5)], [Integer(2)], [Integer(1)]]).is_strongly_finer(OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2)], [Integer(5)], [Integer(1)]]).is_strongly_finer(OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2), Integer(5), Integer(1)], [Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1), Integer(4)]]))
False

length()
Return the number of parts of self.

EXAMPLES:

sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.length()
2

number_of_inversions()
Return the number of inversions in self.

An inversion of an ordered set partition with blocks \([B_1, B_2, \ldots, B_k]\) is a pair of letters \(i\) and \(j\) with \(i < j\) such that \(i\) is minimal in \(B_m\), \(j \in B_l\), and \(l < m\).

REFERENCES:
• [Wilson2016]

EXAMPLES:

```python
sage: OrderedSetPartition([[2, 5], [4, 6], [1, 3]]).number_of_inversions()
5
sage: OrderedSetPartition([[1, 3, 8], [2, 4], [5, 6, 7]]).number_of_inversions()
3
```

```python
>>> from sage.all import *
```

```python
>>> OrderedSetPartition([[Integer(2), Integer(5)], [Integer(4), Integer(6)],
  →[Integer(1), Integer(3)]]).number_of_inversions()
5
```

```python
>>> OrderedSetPartition([[Integer(1), Integer(3), Integer(8)], [Integer(2),
  →Integer(4)], [Integer(5), Integer(6), Integer(7)]]).number_of_inversions()
3
```

```python
reversed()
```

Return the reversal of the ordered set partition `self`.

The reversal of an ordered set partition \((P_1, P_2, \ldots, P_k)\) is defined to be the ordered set partition \((P_k, P_{k-1}, \ldots, P_1)\).

EXAMPLES:

```python
sage: OrderedSetPartition([[1, 3], [2]]).reversed()
[2], [1, 3]
```

```python
sage: OrderedSetPartition([[1, 5], [2, 4]]).reversed()
[2, 4], [1, 5]
```

```python
sage: OrderedSetPartition([[-1], [-2], [3, 4], [0]]).reversed()
[0], [3, 4], [-2], [-1]
```

```python
sage: OrderedSetPartition([]).reversed()
[]
```

```python
>>> from sage.all import *
```

```python
>>> OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).reversed()
[2], [1, 3]
```

```python
>>> OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).reversed()
[2], [1, 3]
```

```python
>>> OrderedSetPartition([[Integer(1), Integer(3), Integer(8)], [Integer(2),
  →Integer(4)], [Integer(5), Integer(6), Integer(7)]]).number_of_inversions()
3
```

```python
size()
```

Return the cardinality of the base set of `self`.

This is the sum of the sizes of the parts of `self`.

This is also known as the size (sometimes the weight) of an ordered set partition.

EXAMPLES:

```python
sage: OrderedSetPartition([[1], [2, 3], [4]]).base_set_cardinality()
4
```

```python
sage: OrderedSetPartition([[1, 2, 3, 4]]).base_set_cardinality()
4
```
strongly_fatter()

Return the set of ordered set partitions which are strongly fatter than self.

See strongly_finer() for the definition of “strongly fatter”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).strongly_fatter()
sage: C.cardinality()
2
sage: sorted(C)
[[[2, 5], [1], {3, 4}], [[2, 5], {1, 3, 4}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).strongly_fatter())
[[[5]]]
sage: list(OrderedSetPartition([]).strongly_fatter())
[[[]]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).strongly_fatter())

[[[1], {2}, {3}, {4}]],
[[1], {2}, {3, 4}],
[[1], {2, 3}, {4}],
[[1], {2, 3, 4}],
[[1, 2], {3}, {4}],
[[1, 2], {3, 4}],
[[1, 2, 3], {4}],
[[1, 2, 3, 4]]]
sage: sorted(OrderedSetPartition([[1], [3], [2], [4]]).strongly_fatter())

[[[1], {3}, {2}, {4}]],
[[1], {3}, {2, 4}],
[[1, 3], {2}, {4}],
[[1, 3], {2, 4}]
sage: sorted(OrderedSetPartition([[4], [1], [5], [3]]).strongly_fatter())

[[[4], {1}, {5}, {3}]], [[4], {1}, {5, 3}]]
```
strongly_finer()

Return the set of ordered set partitions which are strongly finer than self.

See is_strongly_finer() for the definition of “strongly finer”.

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).strongly_finer()
sage: C.cardinality()
2
sage: C.list()
[[(1), (3), (2)], [(1, 3), (2)]]

sage: OrderedSetPartition([]).strongly_finer()
[]

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.strongly_finer().list()
[[(4), (9), (-1), (2)],
 [(4), (9), (-1, 2)],
 [(4, 9), (-1), (2)],
 [(4, 9), (-1, 2)]]
```
W = OrderedSetPartition([[Integer(4), Integer(9)],
                        [-Integer(1),
                        Integer(2)]]))

W.strongly_finer().list()

>>> W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]

static sum(osps)

Return the concatenation of the given ordered set partitions osps (provided they have no elements in common).

INPUT:

- osps – a list (or iterable) of ordered set partitions

EXAMPLES:

sage: OrderedSetPartition.sum([OrderedSetPartition([[4, 1], [3]]),
                             OrderedSetPartition([[7], [2]]), OrderedSetPartition([[5, 6]])])

[[{1, 4}, {3}, {7}, {2}, {5, 6}]]

>>> from sage.all import *

>>> OrderedSetPartition.sum([OrderedSetPartition([[Integer(4), Integer(1)],
                                               [Integer(3)]]),
                           OrderedSetPartition([[Integer(7), [Integer(2)]]),
                           OrderedSetPartition([[Integer(5), Integer(6)]])])

[[{1, 4}, {3}, {7}, {2}, {5, 6}]]

Any iterable can be provided as input:

sage: OrderedSetPartition.sum([OrderedSetPartition([[2*i,2*i+1]])
                             for i in [4,
                                        1, 3]])

[[{8, 9}, {2, 3}, {6, 7}]]

>>> from sage.all import *

>>> OrderedSetPartition.sum([OrderedSetPartition([[Integer(2)*i,
                                               Integer(2)*i+Integer(1)])
                           for i in [Integer(4),Integer(1),Integer(3)]]))

[[{8, 9}, {2, 3}, {6, 7}]]

Empty inputs are handled gracefully:

sage: OrderedSetPartition.sum([]) == OrderedSetPartition([])

True

>>> from sage.all import *

>>> OrderedSetPartition.sum([]) == OrderedSetPartition([])

True

to_composition()

Return the integer composition whose parts are the sizes of the sets in self.

EXAMPLES:
```python
sage: S = OrderedSetPartitions(5)
sage: x = S([[3, 5, 4], [1, 2]])
sage: x.to_composition()
[3, 2]
sage: y = S([[3, 1], [2], [5, 4]])
sage: y.to_composition()
[2, 1, 2]
```

```python
>>> from sage.all import *

>>> S = OrderedSetPartitions(Integer(5))

>>> x = S([[Integer(3),Integer(5),Integer(4)], [Integer(1), Integer(2)]])

>>> x.to_composition()
[3, 2]

>>> y = S([[Integer(3),Integer(1)], [Integer(2)], [Integer(5),Integer(4)]])

>>> y.to_composition()
[2, 1, 2]
```

to_packed_word()

Return the packed word on alphabet \(\{1, 2, 3, \ldots\}\) corresponding to self.

A packed word on alphabet \(\{1, 2, 3, \ldots\}\) is any word whose maximum letter is the same as its total number of distinct letters. Let \(P\) be an ordered set partition of a set \(X\). The corresponding packed word \(w_1 w_2 \cdots w_n\) is constructed by having letter \(w_i = j\) if the \(i\)-th smallest entry in \(X\) occurs in the \(j\)-th block of \(P\).

See also:

Word.to_ordered_set_partition()

Warning: This assumes there is a total order on the underlying set.

EXAMPLES:

```python
sage: S = OrderedSetPartitions()
sage: x = S([[3, 5], [2], [1, 4, 6]])
sage: x.to_packed_word()
word: 321313

sage: x = S([['a', 'c', 'e'], ['b', 'd']])
sage: x.to_packed_word()
word: 12121
```

```python
>>> from sage.all import *

>>> S = OrderedSetPartitions()

>>> x = S([[Integer(3),Integer(5)], [Integer(2)], [Integer(1),Integer(4), Integer(6)]])

>>> x.to_packed_word()
word: 321313

>>> x = S([['a', 'c', 'e'], ['b', 'd']])

>>> x.to_packed_word()
word: 12121
```

class sage.combinat.set_partition_ordered.OrderedSetPartitions(s)

Bases: UniqueRepresentation, Parent

Return the combinatorial class of ordered set partitions of \(s\).
The optional argument \(c\), if specified, restricts the parts of the partition to have certain sizes (the entries of \(c\)).

**EXAMPLES:**

```python
sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of \{1, 2, 3, 4\}

sage: OS.cardinality()
75

sage: OS.first()
\[
\{1\}, \{2\}, \{3\}, \{4\}\n\]

sage: OS.last()
\[
\{1, 2, 3, 4\}\n\]

sage: OS.random_element().parent() is OS
True
```

```python
>>> from sage.all import *

>>> OS = OrderedSetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)]); OS
Ordered set partitions of \{1, 2, 3, 4\}

>>> OS.cardinality()
75

>>> OS.first()
\[
\{1\}, \{2\}, \{3\}, \{4\}\n\]

>>> OS.last()
\[
\{1, 2, 3, 4\}\n\]

>>> OS.random_element().parent() is OS
True
```

```python
sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of \{1, 2, 3, 4\} into parts of size \[2, 2\]

sage: OS.cardinality()
6

sage: OS.first()
\[
\{1, 2\}, \{3, 4\}\n\]

sage: OS.last()
\[
\{3, 4\}, \{1, 2\}\n\]

sage: OS.list()
\[
\{1, 2\}, \{3, 4\}, \{1, 3\}, \{2, 4\}, \{2, 3\}, \{1, 4\}\n\]

```

```python
>>> from sage.all import *

>>> OS = OrderedSetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)], [Integer(2),Integer(2)]); OS
Ordered set partitions of \{1, 2, 3, 4\} into parts of size \[2, 2\]

>>> OS.cardinality()
6

>>> OS.first()
\[
\{1, 2\}, \{3, 4\}\n\]

>>> OS.last()
\[
\{3, 4\}, \{1, 2\}\n\]

>>> OS.list()
\[
\{1, 2\}, \{3, 4\}, \{1, 3\}, \{2, 4\}, \{2, 3\}\n\]
```

(continues on next page)
[(2, 3), (1, 4)],
[(2, 4), (1, 3)],
[(3, 4), (1, 2)]

sage: OS = OrderedSetPartitions("cat")

sage: OS

Element

alias of OrderedSetPartition

from_finite_word(w, check=True)

Return the unique ordered set partition of \{1, 2, \ldots, n\} corresponding to a word \(w\) of length \(n\).

See also:

Word.to_ordered_set_partition()

EXAMPLES:

sage: A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
[(1, 4, 7), (2, 5, 8), (3, 6), (9)]

sage: B = OrderedSetPartitions().from_finite_word([1,2,3,1,2,3,1,2,4])
\[
\text{sage: } A == B \\
\text{True}
\]

```python
>>> from sage.all import *
>>> A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
\{{{1, 4, 7}, {2, 5, 8}, {3, 6}, {9}}
>>> B = OrderedSetPartitions().from_finite_word([Integer(1),Integer(2), \rightarrow Integer(3),Integer(1),Integer(2),Integer(3),Integer(1),Integer(2), \rightarrow Integer(4)])
>>> A == B \\
\text{True}
```

```python
class sage.combinat.set_partition_ordered.OrderedSetPartitions_all
    Bases: OrderedSetPartitions

    Ordered set partitions of \{1, \ldots, n\} for all \(n \in \mathbb{Z}_{\geq 0}\).

class Element (parent, s, check=True)
    Bases: OrderedSetPartition

    subset (size=None, **kwargs)

    Return the subset of ordered set partitions of a given size and additional keyword arguments.

    EXAMPLES:

    ```python
    sage: P = OrderedSetPartitions()
    sage: P.subset(4)
    Ordered set partitions of \{1, 2, 3, 4\}
    ```

    ```python
    >>> from sage.all import *
    >>> P = OrderedSetPartitions()
    >>> P.subset(Integer(4))
    Ordered set partitions of \{1, 2, 3, 4\}
    ```

```python
class sage.combinat.set_partition_ordered.OrderedSetPartitions_s(s)
    Bases: OrderedSetPartitions

    Class of ordered partitions of a set \(S\).

cardinality()

    EXAMPLES:

    ```python
    sage: OrderedSetPartitions(0).cardinality()
    1
    sage: OrderedSetPartitions(1).cardinality()
    1
    sage: OrderedSetPartitions(2).cardinality()
    3
    sage: OrderedSetPartitions(3).cardinality()
    13
    sage: OrderedSetPartitions([1,2,3]).cardinality()
    13
    sage: OrderedSetPartitions(4).cardinality()
    75
    sage: OrderedSetPartitions(5).cardinality()
    541
    ```
```python
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(0)).cardinality()
1
>>> OrderedSetPartitions(Integer(1)).cardinality()
1
>>> OrderedSetPartitions(Integer(2)).cardinality()
3
>>> OrderedSetPartitions(Integer(3)).cardinality()
13
>>> OrderedSetPartitions([Integer(1),Integer(2),Integer(3)]).cardinality()
13
>>> OrderedSetPartitions(Integer(4)).cardinality()
75
>>> OrderedSetPartitions(Integer(5)).cardinality()
541
```

```plaintext
class sage.combinat.set_partition_ordered.OrderedSetPartitions_scomp(s, comp)
Bases: OrderedSetPartitions

cardinality()
Return the cardinality of self.
The number of ordered set partitions of a set of length $k$ with composition shape $\mu$ is equal to

$$\frac{k!}{\prod_{\mu_i \neq 0} \mu_i !}.$$  

EXAMPLES:
```
sage: OrderedSetPartitions(5,[2,3]).cardinality()
10
sage: OrderedSetPartitions(0, []).cardinality()
1
sage: OrderedSetPartitions(0, [0]).cardinality()
1
sage: OrderedSetPartitions(0, [0,0]).cardinality()
1
sage: OrderedSetPartitions(5, [2,0,3]).cardinality()
10
```
```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(5),[Integer(2),Integer(3)]).cardinality()
10
>>> OrderedSetPartitions(Integer(0), []).cardinality()
1
>>> OrderedSetPartitions(Integer(0), [Integer(0)]).cardinality()
1
>>> OrderedSetPartitions(Integer(0), [Integer(0),Integer(0)]).cardinality()
1
>>> OrderedSetPartitions(Integer(5), [Integer(2),Integer(0),Integer(3)]).cardinality()
10
```
```
class sage.combinat.set_partition_ordered.OrderedSetPartitions_sn(s, n)
Bases: OrderedSetPartitions

cardinality()
Return the cardinality of self.
```
```
```
The number of ordered partitions of a set of size \( n \) into \( k \) parts is equal to \( k!S(n,k) \) where \( S(n,k) \) denotes the Stirling number of the second kind.

EXAMPLES:

```
sage: OrderedSetPartitions(4,2).cardinality()
sage: OrderedSetPartitions(4,1).cardinality()
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(4),Integer(2)).cardinality()
>>> OrderedSetPartitions(Integer(4),Integer(1)).cardinality()
```

class sage.combinat.set_partition_ordered.SplitNK(s, comp)

Bases: OrderedSetPartitions_Scomp

sage.combinat.set_partition_ordered.multiset_permutation_next_lex(l)

Return the next multiset permutation after \( l \).

EXAMPLES:

```
sage: from sage.combinat.set_partition_ordered import multiset_permutation_next_lex
sage: l = [0, 0, 1, 1, 2]
sage: while multiset_permutation_next_lex(l):
    print(l)
[0, 0, 1, 2, 1]
[0, 0, 2, 1, 1]
[0, 1, 0, 1, 2]
[0, 1, 0, 2, 1]
[0, 1, 1, 0, 2]
[0, 1, 1, 2, 0]
...
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_ordered import multiset_permutation_next_lex
>>> l = [Integer(0), Integer(0), Integer(1), Integer(1), Integer(2)]
>>> while multiset_permutation_next_lex(l):
...
    print(l)
[0, 0, 1, 2, 1]
[0, 0, 2, 1, 1]
[0, 1, 0, 1, 2]
[0, 1, 0, 2, 1]
[0, 1, 1, 0, 2]
[0, 1, 1, 2, 0]
```
(continues on next page)
... 
[1, 1, 2, 0, 0]  
[1, 2, 0, 0, 1]  
[1, 2, 0, 1, 0]  
[1, 2, 1, 0, 0]  
[2, 0, 0, 1, 1]  
[2, 0, 1, 0, 1]  
[2, 0, 1, 1, 0]  
[2, 1, 0, 0, 1]  
[2, 1, 0, 1, 0]  
[2, 1, 1, 0, 0] 

sage.combinat.set_partition_ordered.multiset_permutation_to_ordered_set_partition(l, m)

Convert a multiset permutation to an ordered set partition.

INPUT:

- l – a multiset permutation
- m – number of parts

EXAMPLES:

sage: from sage.combinat.set_partition_ordered import multiset_permutation_to_ordered_set_partition
sage: l = [0, 0, 1, 1, 2]
sage: multiset_permutation_to_ordered_set_partition(l, 3)
[[0, 1], [2, 3], [4]]

>>> from sage.all import *
>>> from sage.combinat.set_partition_ordered import multiset_permutation_to_ordered_set_partition
>>> l = [Integer(0), Integer(0), Integer(1), Integer(1), Integer(2)]
>>> multiset_permutation_to_ordered_set_partition(l, Integer(3))
[[0, 1], [2, 3], [4]]

5.1.280 Symmetric Functions

- Introduction to Symmetric Functions
- Symmetric Functions
- Symmetric functions, with their multiple realizations
- Classical symmetric functions
- Schur symmetric functions
- Monomial symmetric functions
- Multiplicative symmetric functions
- Elementary symmetric functions
- Homogeneous symmetric functions
- Power sum symmetric functions
- Characters of the symmetric group as bases of the symmetric functions

5.1. Comprehensive Module List
5.1.281 Characters of the symmetric group as bases of the symmetric functions

Just as the Schur functions are the irreducible characters of $Gl_n$ and form a basis of the symmetric functions, the irreducible symmetric group character basis are the irreducible characters of of $S_n$ when the group is realized as the permutation matrices.

REFERENCES:

```python
class sage.combinat.sf.character.Character_generic(Sym, basis_name=None, prefix=None, graded=True):
    Bases: SymmetricFunctionAlgebra_generic

class sage.combinat.sf.character.InducedTrivialCharacterBasis(Sym):
    Bases: Character_generic

    The induced trivial symmetric group character basis of the symmetric functions.

    This is a basis of the symmetric functions that has the property that self(la).character_to_frobenius_image(n) is equal to h([n-sum(la)]+la).

    It has the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the complete basis.

    This basis is introduced in [OZ2015].

    EXAMPLES:

    sage: Sym = SymmetricFunctions(QQ)
    sage: s = Sym.s()
    sage: h = Sym.h()
    sage: ht = SymmetricFunctions(QQ).ht()
    sage: st = SymmetricFunctions(QQ).st()
    sage: ht(s[2,1])
    sage: s(ht[2,1])
```

(continues on next page)
sage: ht(h[2,1])
ht[1] + 2*ht[1, 1] + ht[2, 1]
sage: h(ht[2,1])
h[1] - 2*h[1, 1] + h[2, 1]
sage: st(ht[2,1])
sage: ht(st[2,1])
sage: ht[2]*ht[1,1]  
ht[1] + 2*ht[1, 1] + ht[2, 1]

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> h = Sym.h()

>>> h[4,2].kronecker_product(h[4,1,1])
h[2, 2, 1, 1] + 2*h[3, 1, 1, 1] + h[4, 1, 1]

>>> st(s[2,1])
sage: st[s[2,1]]

>>> s(ht[2,1])

>>> st(ht[2,1])

class sage.combinat.sf.character.IrreducibleCharacterBasis(Sym)
Bases: Character_generic

5.1. Comprehensive Module List
The irreducible symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that
\( \text{self}(\lambda) \). \text{character_to_frobenius_image}(n) \) is equal to \( s([n-\sum(\lambda)]+\lambda) \).

It should also have the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the Schur basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: st(ht[2,1])
sage: st(s[2,1])
sage: st[2]*st[1]
sage: st[2,1]*st[1]
sage: st[1,1,1].counit()
-1
sage: all(sum(c*st(la)*st(mu).antipode() for ((la,mu),c) in st(ga).coproduct())==st(st(ga).counit()) for ga in Partitions(3))
True
```
5.1.282 Classical symmetric functions

```
class sage.combinat.sf.classical.SymmetricFunctionAlgebra_classical(Sym, basis_name=None, prefix=None, graded=True):

Bases: SymmetricFunctionAlgebra_generic

The class of classical symmetric functions.

Todo: delete this class once all coercions will be handled by Sage’s coercion model
```

```
class Element

Bases: SymmetricFunctionAlgebra_generic_Element

A symmetric function.
```

```
sage.combinat.sf.classical.init()

Set up the conversion functions between the classical bases.

EXAMPLES:
```
```
sage: from sage.combinat.sf.classical import init
sage: sage.combinat.sf.classical.conversion_functions = {}
sage: init()
<built-in function t_SCHUR_POWSYM_symmetrica>
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.classical import init
>>> sage.combinat.sf.classical.conversion_functions = {}
>>> init()
>>> sage.combinat.sf.classical.conversion_functions[('Schur', 'powersum')]
<built-in function t_SCHUR_POWSYM_symmetrica>
```

The following checks if the bug described in Issue #15312 is fixed.

```
sage: change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur')]
sage: hideme = change({Partition([1]*47):ZZ(1)}) # long time
```

```
>>> from sage.all import *
>>> change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur')]
>>> hideme = change({Partition([Integer(1)]*Integer(47)):ZZ(Integer(1))}) # long time
>>> change({Partition([Integer(2),Integer(2)]:QQ(Integer(1))})
```
5.1.283 Generic dual bases symmetric functions

```python
class sage.combinat.sf.dual.DualBasisFunctor(basis):
    Bases: SymmetricFunctionsFunctor
    A constructor for algebras of symmetric functions constructed by duality.
    EXAMPLES:
    sage: w = SymmetricFunctions(ZZ).witt()
    sage: w.dual_basis().construction()
    (SymmetricFunctionsFunctor[dual Witt], Integer Ring)
    >>> from sage.all import *
    >>> w = SymmetricFunctions(ZZ).witt()
    >>> w.dual_basis().construction()
    (SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

```python
class sage.combinat.sf.dual.SymmetricFunctionAlgebra_dual(dual_basis, scalar, scalar_name, basis_name, prefix):
    Bases: SymmetricFunctionAlgebra_classical
    Generic dual basis of a basis of symmetric functions.
    INPUT:
    • dual_basis -- a basis of the ring of symmetric functions
    • scalar -- A function \( z \) on partitions which determines the scalar product on the power sum basis by 
      \( \langle p_\mu, p_\mu \rangle = z(\mu) \). (Independently on the function chosen, the power sum basis will always be orthogonal; 
      the function scalar only determines the norms of the basis elements.) This defaults to the function \( zee \) 
      defined in `sage.combinat.sf.sfa`, that is, the function is defined by:
      \[
      \lambda \mapsto \prod_{i=1}^{\infty} m_i(\lambda)!^{m_i(\lambda)},
      \]
      where \( m_i(\lambda) \) means the number of times \( i \) appears in \( \lambda \). This default function gives the standard Hall scalar 
      product on the ring of symmetric functions.
    • scalar_name -- (default: the empty string) a string giving a description of the scalar product specified by 
      the parameter scalar
    • basis_name -- (optional) a string to serve as name for the basis to be generated (such as "forgotten" in "the 
      forgotten basis"); don’t set it to any of the already existing basis names (such as homogeneous, monomial, 
      forgotten, etc.).
    • prefix -- (default: 'd' and the prefix for dual_basis) a string to use as the symbol for the basis
    OUTPUT:
    The basis of the ring of symmetric functions dual to the basis `dual_basis` with respect to the scalar product 
    determined by `scalar`.
    EXAMPLES:
    sage: e = SymmetricFunctions(QQ).e()
    sage: f = e.dual_basis(prefix="m", basis_name="Forgotten symmetric functions"); f
    Symmetric Functions over Rational Field in the Forgotten symmetric functions basis
    sage: TestSuite(f).run(elements=[f[1,1]+2*f[2], f[1]+3*f[1,1]])
    sage: TestSuite(f).run() # long time (11s on sage.math, 2011)
```
```python
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> f = e.dual_basis(prefix="m", basis_name="Forgotten symmetric functions"); f
Symmetric Functions over Rational Field in the Forgotten symmetric functions basis

>>> TestSuite(f).run(elements=[f[Integer(1),Integer(1)]+Integer(2)*f[Integer(2)],...
→f[Integer(1)]+Integer(3)*f[Integer(1),Integer(1)])]
>>> TestSuite(f).run()  # long time (11s on sage.math, 2011)
```

This class defines canonical coercions between `self` and `self^*`, as follow:

Look up for the canonical isomorphism from `self` to `P` (=powersum), and build the adjoint isomorphism from `P^*` to `self^*`. Since `P` is self-adjoint for this scalar product, derive an isomorphism from `P` to `self^*`, and by composition with the above get an isomorphism from `self` to `self^*` (and similarly for the isomorphism `self^*` to `self`).

This should be stripped down to just (auto?) defining canonical isomorphism by adjunction (as in MuPAD-Combinat), and let the coercion handle the rest.

Inversions may not be possible if the base ring is not a field:

```python
sage: m = SymmetricFunctions(ZZ).m()
sage: h = m.dual_basis(lambda x: 1)
sage: h[2,1]
Traceback (most recent call last):
... TypeError: no conversion of this rational to integer
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(ZZ).m()
>>> h = m.dual_basis(lambda x: Integer(1))
>>> h[Integer(2),Integer(1)]
Traceback (most recent call last):
... TypeError: no conversion of this rational to integer
```

By transitivity, this defines indirect coercions to and from all other bases:

```python
sage: s = SymmetricFunctions(QQ['t'].fraction_field()).s()
sage: t = QQ['t'].fraction_field().gen()
sage: zee_hl = lambda x: x.centralizer_size(t=t)
sage: S = s.dual_basis(zee_hl)
sage: S(s([2,1]))
(-t/(t^5-2*t^4+t^3-2*t^2+2*t-1))*d_s[1, 1, 1] + ((-t^2-1)/(t^5-2*t^4+t^3-2*t^2+2*t-1))*d_s[2, 1] + (-t/(t^5-2*t^4+t^3-2*t^2+2*t-1))*d_s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ['t'].fraction_field()).s()
>>> t = QQ['t'].fraction_field().gen()
>>> zee_hl = lambda x: x.centralizer_size(t=t)
>>> S = s.dual_basis(zee_hl)
>>> S(s([Integer(2),Integer(1)]))
(-t/(t^5-2*t^4+t^3-2*t^2+2*t-1))*d_s[1, 1, 1] + ((-t^2-1)/(t^5-2*t^4+t^3-2*t^2+2*t-1))*d_s[2, 1] + (-t/(t^5-2*t^4+t^3-2*t^2+2*t-1))*d_s[3]
```

```python
class Element(A, dictionary=None, dual=None)
    Bases: Element

    An element in the dual basis.
```
INPUT:
At least one of the following must be specified. The one (if any) which is not provided will be computed.
• dictionary – an internal dictionary for the monomials and coefficients of self
• dual – self as an element of the dual basis.

dual()
Return self in the dual basis.

OUTPUT:
• the element self expanded in the dual basis to self.parent()

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial→basis
sage: a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]
```

```python
>>> from sage.all import *

>>> m = SymmetricFunctions(QQ).monomial()

>>> zee = sage.combinat.sf.sfa.zee

>>> h = m.dual_basis(scalar=zee)

>>> a = h([Integer(2),Integer(1)])

>>> a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial→basis

>>> a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]
```

expand(n, alphabet='x')
Expand the symmetric function self as a symmetric polynomial in n variables.

INPUT:
• n – a nonnegative integer
• alphabet – (default: 'x') a variable for the expansion

OUTPUT:
A monomial expansion of self in the n variables labelled by alphabet.

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: a = h([2,1])+h([3])
sage: a.expand(2)
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3

sage: a.dual().expand(2)
3*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3

sage: a.expand(2,alphabet=y)
2*y0^3 + 3*y0^2*y1 + 3*y0*y1^2 + 2*y1^3

sage: a.expand(2,alphabet=x,y)
```

(continues on next page)
omega ()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies ω(ek) = hk for all positive integers k (where ek stands for the k-th elementary symmetric function, and hk stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function pk to (−1)k−1pk for every positive integer k.

The images of some bases under the omega automorphism are given by

\[ \omega(\ell^\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|−\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'}, \]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (length()) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (conjugate()) of \( \lambda \), and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

omega_involution() is a synonym for the omega() method.

OUTPUT:
• the result of applying omega to self

EXAMPLES:

```python
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(zee)
>>> a = h([Integer(2),Integer(1)])+h([Integer(3)])
>>> a.expand(Integer(2))
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
>>> a.dual().expand(Integer(2))
2*x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + 2*x1^3
>>> a.expand(Integer(2),alphabet='y')
2*y0^3 + 3*y0^2*y1 + 3*y0*y1^2 + 2*y1^3
>>> a.expand(Integer(2),alphabet='x,y')
2*x0^3 + 3*x0^2*y + 3*x*y^2 + 2*y^3
>>> h([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*h([1])).expand(Integer(0))
3
```
omega_involution()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_\lambda',
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (length()) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (conjugate()) of \( \lambda \), and where the usual notations for bases are used (\( e = \) elementary, \( h = \) complete homogeneous, \( p = \) powersum, \( s = \) Schur).

omega_involution() is a synonym for the omega() method.

OUTPUT:
• the result of applying omega to self

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([Integer(2),Integer(1)]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([Integer(2),Integer(1)]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

scalar(x)

Return the standard scalar product of self and x.

INPUT:
• x – element of the symmetric functions

OUTPUT:
• the scalar product between $x$ and $self$

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar(a)
2
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2),Integer(1)])
>>> a.scalar(a)
2
```

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar_hl(a)
(-t - 2)/(t^4 - 2*t^3 + 2*t - 1)
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2),Integer(1)])
>>> a.scalar_hl(a)
(-t - 2)/(t^4 - 2*t^3 + 2*t - 1)
```

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.basis_name()
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2),Integer(1)])
>>> a.basis_name()
'forgotten'
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> f = Sym.f()
>>> f.basis_name()
'forgotten'
```

**construction()**

Return a pair \((F, R)\), where \(F\) is a `SymmetricFunctionsFunctor` and \(R\) is a ring, such that \(F(R)\) returns `self`.

**EXAMPLES:**

```python
sage: w = SymmetricFunctions(ZZ).witt()
sage: w.dual_basis().construction()
(SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

```python
>>> from sage.all import *
>>> w = SymmetricFunctions(ZZ).witt()
>>> w.dual_basis().construction()
(SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

**product**(left, right)

Return product of `left` and `right`.

Multiplication is done by performing the multiplication in the dual basis of `self` and then converting back to `self`.

**INPUT:**

- `left, right` – elements of `self`

**OUTPUT:**

- the product of `left` and `right` in the basis `self`

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([Integer(2)])
sage: b = a*a; b # indirect doctest
d_m[2, 2]
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2)])
>>> b = a*a; b # indirect doctest
d_m[2, 2]
```

```python
6*m[1, 1, 1, 1] + 4*m[2, 1, 1] + 3*m[2, 2] + 2*m[3, 1] + m[4]
```

**transition_matrix**(basis, \(n\))

Returns the transition matrix between the \(n^{th}\) homogeneous components of `self` and `basis`.

**INPUT:**
• **basis** – a target basis of the ring of symmetric functions

• **n** – nonnegative integer

**OUTPUT:**

• A transition matrix from `self` to `basis` for the elements of degree `n`. The indexing order of the rows and columns is the order of `Partitions(n)`.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: e = Sym.elementary()
sage: f = e.dual_basis()
sage: f.transition_matrix(s, 5)
[ 1 -1 0 1 0 -1 1]
[-2 1 1 -1 -1 1 0]
[-2 2 -1 -1 1 0 0]
[ 3 -1 -1 1 0 0 0]
[ 3 -2 1 0 0 0 0]
[-4 1 0 0 0 0 0]
[ 1 0 0 0 0 0 0]
sage: Partitions(5).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: s(f[2,2,1])
sage: e.transition_matrix(s, 5).inverse().transpose()
[ 1 -1 0 1 0 -1 1]
[-2 1 1 -1 -1 1 0]
[-2 2 -1 -1 1 0 0]
[ 3 -1 -1 1 0 0 0]
[ 3 -2 1 0 0 0 0]
[-4 1 0 0 0 0 0]
[ 1 0 0 0 0 0 0]
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> s = Sym.schur()

>>> e = Sym.elementary()

>>> f = e.dual_basis()

>>> f.transition_matrix(s, Integer(5))
[ 1 -1 0 1 0 -1 1]
[-2 1 1 -1 -1 1 0]
[-2 2 -1 -1 1 0 0]
[ 3 -1 -1 1 0 0 0]
[ 3 -2 1 0 0 0 0]
[-4 1 0 0 0 0 0]
[ 1 0 0 0 0 0 0]

>>> Partitions(Integer(5)).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]

>>> s(f[Integer(2),Integer(2),Integer(1)])

5.1.284 Elementary symmetric functions

class sage.combinat.sf.elementary.SymmetricFunctionAlgebra_elementary(Sym)
    Bases: SymmetricFunctionAlgebra_multiplicative
    A class for methods for the elementary basis of the symmetric functions.
    INPUT:
    • self -- an elementary basis of the symmetric functions
    • Sym -- an instance of the ring of symmetric functions

class Element
    Bases: Element
    expand(n, alphabet='x')
    Expand the symmetric function self as a symmetric polynomial in n variables.
    INPUT:
    • n -- a nonnegative integer
    • alphabet -- (default: 'x') a variable for the expansion
    OUTPUT:
    A monomial expansion of self in the n variables labelled by alphabet.
    EXAMPLES:

    sage: e = SymmetricFunctions(QQ).e()
    sage: e([2,1]).expand(3)
    x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
    sage: e([1,1,1]).expand(2)
    x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
    sage: e([3]).expand(2)
    0
    sage: e([2]).expand(3)
    x0*x1 + x0*x2 + x1*x2
    sage: e([3]).expand(4,alphabet='x,y,z,t')
    x*y*z + x*y*t + x*z*t + y*z*t
    sage: e([3]).expand(4,alphabet='y')
    y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
    sage: e([]).expand(2)
    1
    sage: e([]).expand(0)
    1
    sage: (3*e([])).expand(0)
    3

    >>> from sage.all import *
    >>> e = SymmetricFunctions(QQ).e()
    >>> e([Integer(2),Integer(1)]).expand(Integer(3))
    x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
    >>> e([Integer(1),Integer(1),Integer(1)]).expand(Integer(2))
Combinatorics, Release 10.4

(continued from previous page)

x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3

>>> e([Integer(3)]).expand(Integer(2))
0

>>> e([Integer(2)]).expand(Integer(3))
x0*x1 + x0*x2 + x1*x2

>>> e([Integer(3)]).expand(Integer(4), alphabet='x, y, z, t')
x*y*z + x*y*t + x*z*t + y*z*t

>>> e([Integer(3)]).expand(Integer(4), alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3

>>> e([]).expand(Integer(2))
1

>>> e([]).expand(Integer(0))
1

>>> (Integer(3)*e([])).expand(Integer(0))
3

exponential_specialization (t=None, q=1)

Return the exponential specialization of a symmetric function (when \( q = 1 \)), or the \( q \)-exponential specialization (when \( q \neq 1 \)).

The exponential specialization \( ex \) at \( t \) is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \). It is defined whenever the base ring \( K \) is a \( \mathbb{Q} \)-algebra and \( t \) is an element of \( R \). The easiest way to define it is by specifying its values on the powersum symmetric functions to be \( p_1 = t \) and \( p_n = 0 \) for \( n > 1 \). Equivalently, on the homogeneous functions it is given by \( ex(h_n) = t^n/n! \); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \( q \)-exponential specialization is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \) that depends on two elements \( t \) and \( q \) of \( R \) for which the elements \( 1 - q^i \) for all positive integers \( i \) are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

\[
ex_q(h_n) = t^n/[n]_q!,
\]

where \([n]_q!\) is the \( q \)-factorial. Equivalently, for \( q \neq 1 \) and a homogeneous symmetric function \( f \) of degree \( n \), we have

\[
ex_q(f) = (1 - q)^n t^n p_{sq}(f),
\]

where \( p_{sq}(f) \) is the stable principal specialization of \( f \) (see principal_specialization()). (See (7.29) in [EnumComb2]).

The limit of \( ex_q \) as \( q \to 1 \) is \( ex \).

INPUT:
- \( t \) (default: None) – the value to use for \( t \); the default is to create a ring of polynomials in \( t \).
- \( q \) (default: 1) – the value to use for \( q \). If \( q \) is None, then a ring (or fraction field) of polynomials in \( q \) is created.

EXAMPLES:

sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,2]
sage: x.exponential_specialization()
1/12*t^5
sage: x = 5*e[2] + 3*e[1] + 1
sage: x.exponential_specialization(t=var("t"), q=var("q"))
# needs sage.symbolic
5*q*t^2/(q + 1) + 3*t + 1
\begin{verbatim}
>>> from sage.all import *

>>> e = SymmetricFunctions(QQ).e()

>>> x = e[Integer(3),Integer(2)]

>>> x.exponential_specialization()
1/12*t^5

>>> x = Integer(5)*e[Integer(2)] + Integer(3)*e[Integer(1)] + Integer(1)

>>> x.exponential_specialization(t=var("t"), q=var("q"))
#...  
5*q*t^2/(q + 1) + 3*t + 1

omega()

Return the image of self under the omega automorphism.

The \textit{omega automorphism} is defined to be the unique algebra endomorphism \(\omega\) of the ring of symmetric functions that satisfies \(\omega(e_k) = h_k\) for all positive integers \(k\) (where \(e_k\) stands for the \(k\)-th elementary symmetric function, and \(h_k\) stands for the \(k\)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the \textit{omega involution}. It sends the power-sum symmetric function \(p_k\) to \((-1)^{k-1}p_k\) for every positive integer \(k\).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{\ell(\lambda) - \ell(\lambda')} p_\lambda, \quad \omega(s_\lambda) = s_\lambda',
\]

where \(\lambda\) is any partition, where \(\ell(\lambda)\) denotes the length (\textit{length}()) of the partition \(\lambda\), where \(\lambda'\) denotes the conjugate partition (\textit{conjugate}()) of \(\lambda\), and where the usual notations for bases are used (\(e =\) elementary, \(h =\) complete homogeneous, \(p =\) powersum, \(s =\) Schur).

\textit{omega_involution()} is a synonym for the \textit{omega()} method.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]

>>> from sage.all import *

>>> e = SymmetricFunctions(QQ).e()

>>> a = e([Integer(2),Integer(1)]); a
e[2, 1]

>>> a.omega()
e[1, 1, 1] - e[2, 1]

>>> from sage.all import *

>>> h = SymmetricFunctions(QQ).h()

>>> h(e([2,1]).omega())
h[2, 1]

>>> from sage.all import *

>>> h = SymmetricFunctions(QQ).h()

>>> h(e([Integer(2),Integer(1)]).omega())
h[2, 1]
\end{verbatim}

\textbf{omega_involution()}

Return the image of self under the omega automorphism.

The \textit{omega automorphism} is defined to be the unique algebra endomorphism \(\omega\) of the ring of symmetric functions that satisfies \(\omega(e_k) = h_k\) for all positive integers \(k\) (where \(e_k\) stands for the \(k\)-th elementary
symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length of $\lambda$, where $\lambda'$ denotes the conjugate partition of $\lambda$, and where the usual notations for bases are used ($e = \text{elementary, } h = \text{complete homogeneous, } p = \text{powersum, } s = \text{Schur}$).

$\omega_{\text{involution}}()$ is a synonym for the $\omega()$ method.

**EXAMPLES:**

```python
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```python
>>> from sage.all import *

>>> e = SymmetricFunctions(QQ).e()
>>> a = e([Integer(2),Integer(1)]); a
e[2, 1]
>>> a.omega()
e[1, 1, 1] - e[2, 1]
```

```python
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
```

```python
>>> from sage.all import *

>>> h = SymmetricFunctions(QQ).h()
>>> h(e([Integer(2),Integer(1)]).omega())
h[2, 1]
```

**principal_specialization** ($n+=\text{Infinity}$, $q=None$)

Return the principal specialization of a symmetric function.

The principal specialization of order $n$ at $q$ is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, $q$ is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at $q$ is the ring homomorphism $ps_q$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

**INPUT:**

- $n$ (default: $\text{infinity}$) – a nonnegative integer or $\text{infinity}$, specifying whether to compute the principal specialization of order $n$ or the stable principal specialization.
- $q$ (default: $\text{None}$) – the value to use for $q$; the default is to create a ring of polynomials in $q$ (or a field of rational functions in $q$) over the given coefficient ring.
We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients \( \binom{n}{\lambda_i}_q \)):

\[
ps_{n,q}(e_\lambda) = \prod_i q^{\binom{\lambda_i}{2}} \binom{n}{\lambda_i}_q,
\]

\[
ps_{n,1}(e_\lambda) = \prod_i \binom{n}{\lambda_i},
\]

\[
ps_q(e_\lambda) = \prod_i q^{\binom{\lambda_i}{2}} / \prod_{j=1}^{\lambda_i}(1 - q^j).
\]

**EXAMPLES:**

```sage
e = SymmetricFunctions(QQ).e()
sage: x = e[3,1]
sage: x.principal_specialization(3)
q^5 + q^4 + q^3
sage: x = 5*e[1,1,1] + 3*e[2,1] + 1
sage: x.principal_specialization(3)
5*q^6 + 18*q^5 + 36*q^4 + 44*q^3 + 36*q^2 + 18*q + 6
```

By default, we return a rational functions in \( q \). Sometimes it is better to obtain an element of the symbolic ring:

```sage
e = SymmetricFunctions(QQ).e()
sage: x = e[Integer(3),Integer(1)]
sage: x.principal_specialization(Integers(3))
q^5 + q^4 + q^3
```

```sage
e = SymmetricFunctions(QQ).e()
sage: x = 5*e[1,1,1] + 3*e[2,1] + 1
sage: x.principal_specialization(Integers(3))
5*q^6 + 18*q^5 + 36*q^4 + 44*q^3 + 36*q^2 + 18*q + 6
```

The \( n \)-th Verschiebung operator \( V_n \) is defined to be the unique algebra endomorphism \( V \) of the ring of symmetric functions that satisfies \( V(h_r) = h_{r/n} \) for every positive integer \( r \) divisible by \( n \), and satisfies \( V(h_r) = 0 \) for every positive integer \( r \) not divisible by \( n \). This operator \( V_n \) is a Hopf algebra endomorphism. For every nonnegative integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}
\]

(where \( h \) is the complete homogeneous basis, \( p \) is the powersum basis, and \( e \) is the elementary basis). For every nonnegative integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.
\]
The $n$-th Verschiebung operator is also called the $n$-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The $n$-th Verschiebung operator is adjoint to the $n$-th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.)

Then, $V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda(i)}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

INPUT:
- $n$ — a positive integer

OUTPUT:
- The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: e[3].verschiebung(2)
0
sage: e[4].verschiebung(4)
-e[1]
```

```bash
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> e[Integer(3)].verschiebung(Integer(2))
0
>>> e[Integer(4)].verschiebung(Integer(4))
-e[1]
```

The Verschiebung endomorphisms are multiplicative:

```python
sage: all( all( e(lam).verschiebung(2) * e(mu).verschiebung(2) == (e(lam) * e(mu)).verschiebung(2) for mu in Partitions(4) ) for lam in Partitions(4) )
True
```

```bash
>>> from sage.all import *
>>> all( all( e(lam).verschiebung(Integer(2)) * e(mu).verschiebung(Integer(2)) == (e(lam) * e(mu)).verschiebung(Integer(2)) for mu in Partitions(Integer(4)) ) for lam in Partitions(Integer(4)) )
True
```
**coproduct_on_generators**\((i)\)

Returns the coproduct on \(\text{self}[i]\).

**INPUT:**
- \(\text{self}\) – an elementary basis of the symmetric functions
- \(i\) – a nonnegative integer

**OUTPUT:**
- returns the coproduct on the elementary generator \(e(i)\)

**EXAMPLES:**
```
sage: Sym = SymmetricFunctions(QQ)
sage: e = Sym.elementary()
sage: e.coproduct_on_generators(2)
sage: e.coproduct_on_generators(0)
e[] # e[]
```

### 5.1.285 Hall-Littlewood Polynomials

Notation used in the definitions follows mainly [Mac1995].

**class** `sage.combinat.sf.hall_littlewood.HallLittlewood`\((\text{Sym}, t)\)

**Bases:** `UniqueRepresentation`

The family of Hall-Littlewood symmetric function bases.

The Hall-Littlewood symmetric functions are a family of symmetric functions that depend on a parameter \(t\).

**INPUT:**
By default the parameter for these functions is \(t\), and whatever the parameter is, it must be in the base ring.

**EXAMPLES:**
```
sage: SymmetricFunctions(QQ).hall_littlewood(1)
Hall-Littlewood polynomials with t=1 over Rational Field
sage: SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in...

>>> from sage.all import *
>>> SymmetricFunctions(QQ).hall_littlewood(Integer(1))
Hall-Littlewood polynomials with t=1 over Rational Field
>>> SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in...
```

---

**Combinatorics, Release 10.4**

---

4558 Chapter 5. Comprehensive Module List
\[
\text{P(}\)
\]

Return the algebra of symmetric functions in the Hall-Littlewood \(P\) basis. This is the same as the \(HL\) basis in John Stembridge's SF examples file.

**INPUT:**

- \text{self} – a class of Hall-Littlewood symmetric function bases

**OUTPUT:**

The class of the Hall-Littlewood \(P\) basis.

**EXAMPLES:**

```sage
Sym = SymmetricFunctions(FractionField(QQ['t']))
HLP = Sym.hall_littlewood().P(); HLP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
˓→over Rational Field in the Hall-Littlewood P basis
sage: SP = Sym.hall_littlewood(t=-1).P(); SP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
˓→over Rational Field in the Hall-Littlewood P with t=-1 basis
sage: s = Sym.schur()
sage: s(HLP([2,1]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]
```

The Hall-Littlewood polynomials in the \(P\) basis at \(t = 0\) are the Schur functions:

```sage
Sym = SymmetricFunctions(QQ)
HLP = Sym.hall_littlewood(t=0).P()
sage: s = Sym.schur()
sage: s(HLP([2,1])) == s([2,1])
True
```

The Hall-Littlewood polynomials in the \(P\) basis at \(t = 1\) are the monomial symmetric functions:

```sage
Sym = SymmetricFunctions(QQ)
HLP = Sym.hall_littlewood(t=1).P()
sage: m = Sym.monomial()
sage: m(HLP([2,2,1])) == m([2,2,1])
True
```
We end with some examples of coercions between:

1. Hall-Littlewood $P$ basis.
2. Hall-Littlewood polynomials in the $Q$ basis
3. Hall-Littlewood polynomials in the $Q'$ basis (via the Schurs)
4. Classical symmetric functions

\begin{verbatim}
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> HLP = Sym.hall_littlewood(t=Integer(1)).P()
>>> m = Sym.monomial()
>>> m(HLP([Integer(2),Integer(2),Integer(1)])) == m([Integer(2),Integer(2),
    __Integer(1)])
True

We end with some examples of coercions between:

1. Hall-Littlewood $P$ basis.
2. Hall-Littlewood polynomials in the $Q$ basis
3. Hall-Littlewood polynomials in the $Q'$ basis (via the Schurs)
4. Classical symmetric functions

\begin{verbatim}
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLQ = Sym.hall_littlewood().Q()
>>> HLQp = Sym.hall_littlewood().Qp()
>>> s = Sym.schur()
>>> p = Sym.power()
>>> HLP(HLQ([Integer(2)])) # indirect doctest
(-t+1)*HLP[2]
>>> HLP(HLQp([Integer(2)]))
t*HLP[1, 1] + HLP[2]
>>> HLP(s([Integer(2)]))
t*HLP[1, 1] + HLP[2]
>>> HLP(p([Integer(2)]))
(t-1)*HLP[1, 1] + HLP[2]
>>> s = HLQp.symmetric_function_ring().s()
>>> HLQp.transition_matrix(s,3)
[ 1 0 0]
[ t 1 0]
[ t^3 t^2 + t 1]
>>> s.transition_matrix(HLP,3)
[ 1 t t^3]
[ 0 1 t^2 + t]
[ 0 0 1]
\end{verbatim}

\end{verbatim}

(continues on next page)
The method `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element.hl_creation_operator()` is a creation operator for the $Q$ basis:

```python
sage: HLQp[1].hl_creation_operator([3]).hl_creation_operator([3])
HLQp[3, 3, 1]
```

Transitions between bases with the parameter $t$ specialized:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['y','z']))
sage: (y,z) = Sym.base_ring().gens()
sage: HLy = Sym.hall_littlewood(t=y)
sage: HLz = Sym.hall_littlewood(t=z)
sage: Qpy = HLy.Qp()
sage: Qpz = HLz.Qp()
sage: s = Sym.schur()
sage: s( Qpy[3,1] + z*Qpy[2,2] )
ys[2, 2] + (y*z+1)*s[3, 1] + (y^2*z+y)*s[4]
sage: s( Qpy[3,1] + y*Qpz[2,2] )
y*y[2, 2] + (y*z+1)*s[3, 1] + (y+z^2+y)*s[4]
sage: s( Qpy[3,1] + y*Qpy[2,2] )
y*y[2, 2] + (y^2+1)*s[3, 1] + (y^3+y)*s[4]
```

```python
sage: Qy = HLy.Q()
sage: Qz = HLz.Q()
sage: Py = HLy.P()
sage: Pz = HLz.P()
sage: Pz(Qpy[2,1])
(z^2-2*z+1)*HLP[2, 1]
sage: Qz(Py[2])
((-y+z)/(z^3-z^2-z+1))*HLQ[1, 1] + (1/(-z+1))*HLQ[2]
sage: Qy(Pz[2])
((y-z)/(y^3-y^2-y+1))*HLQ[1, 1] + (1/(-y+1))*HLQ[2]
sage: Qy.hall_littlewood_family() == HLy
True
sage: Qy.hall_littlewood_family() == HLz
False
sage: Qz.symmetric_function_ring() == Qy.symmetric_function_ring()
True
sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
```
sage: q = Sym.base_ring().gen()
sage: HL = Sym.hall_littlewood(t=q)
sage: HLQp = HL.Qp()
sage: HLQ = HL.Q()
sage: HLP = HL.P()
sage: s = Sym.schur()
sage: s(HLQp[3,2].plethysm((1-q)*s[1]))/(1-q)^2
(-q^5-q^4)*s[1, 1, 1, 1, 1] + (q^3+q^2)*s[2, 1, 1, 1] - q*s[2, 2, 1] - q*s[3, 1, 1] + s[3, 2]

>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['y','z']))
>>> (y,z) = Sym.base_ring().gens()
>>> HLy = Sym.hall_littlewood(t=y)
>>> HLz = Sym.hall_littlewood(t=z)
>>> Qpy = HLy.Qp()
>>> Qpz = HLz.Qp()
>>> s = Sym.schur()
>>> s( Qpy[Integer(3),Integer(1)] + z*Qpy[Integer(2),Integer(2)] )
z*s[2, 2] + (y*z+1)*s[3, 1] + (y^2*z+y)*s[4]
>>> s( Qpy[Integer(3),Integer(1)] + y*Qpz[Integer(2),Integer(2)] )
y*s[2, 2] + (y*z+1)*s[3, 1] + (y*z^2+y)*s[4]
>>> s( Qpy[Integer(3),Integer(1)] + y*Qpy[Integer(2),Integer(2)] )
y*s[2, 2] + (y^2+1)*s[3, 1] + (y^3+y)*s[4]

>>> Qy = HLy.Q()
>>> Qz = HLz.Q()
>>> Py = HLy.P()
>>> Pz = HLz.P()
>>> Pz(Qpy[Integer(2),Integer(1)])
(y*z^3+z^2*z)*HLP[1, 1, 1] + (y*z+1)*HLP[2, 1] + y*HLP[3]
>>> Pz(Qz[Integer(2),Integer(1)])
(z^2-2*z+1)*HLP[2, 1]

>>> Qy.hall_littlewood_family() == HLy
True
>>> Qy.hall_littlewood_family() == HLz
False

>>> Qz.symmetric_function_ring() == Qy.symmetric_function_ring()
True

>>> Sym = SymmetricFunctions(FractionField(QQ['q']))
>>> q = Sym.base_ring().gen()
>>> HL = Sym.hall_littlewood(t=q)
>>> HLQp = HL.Qp()
>>> HLQ = HL.Q()

>>> s = Sym.schur()
>>> s(HLQp[Integer(3),Integer(2)].plethysm((1-q)*s[Integer(1)]))/(1-q)**Integer(2)

(continues on next page)
The $P$ and $Q$-Schur at $t = -1$ indexed by strict partitions are a basis for the space algebraically generated by the odd power sum symmetric functions:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: SP = Sym.hall_littlewood(t=-1).P()
sage: SQ = Sym.hall_littlewood(t=-1).Q()
sage: p = Sym.power()
sage: SP(SQ[3,2,1])
8*HLP[3, 2, 1]
sage: SP(SQ[2,2,1])
0
sage: p(SP[3,2,1])
1/45*p[1, 1, 1, 1, 1, 1] - 1/9*p[3, 1, 1, 1] - 1/9*p[3, 3] + 1/5*p[5, 1]
sage: SP(p[3,3])
HLQ[3, 1] + 2*q*HLQ[4]
```

$Q()$

Returns the algebra of symmetric functions in Hall-Littlewood $Q$ basis. This is the same as the $Q$ basis in John Stembridge's SF examples file.

More extensive examples can be found in the documentation for the Hall-Littlewood $P$ basis.

**INPUT:**
- `self` – a class of Hall-Littlewood symmetric function bases

**OUTPUT:**
- returns the class of the Hall-Littlewood $Q$ basis

**EXAMPLES:**
Qp()  
Returns the algebra of symmetric functions in Hall-Littlewood $Q'$ (Qp) basis. This is dual to the Hall-Littlewood $P$ basis with respect to the standard scalar product. More extensive examples can be found in the documentation for the Hall-Littlewood P basis.  
INPUT:  
• self – a class of Hall-Littlewood symmetric function bases  
OUTPUT:  
• returns the class of the Hall-Littlewood $Q_p$-basis  
EXAMPLES:

```sage
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLQp = Sym.hall_littlewood().Qp(); HLQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Hall-Littlewood Qp basis
```

base_ring()  
Returns the base ring of the symmetric functions where the Hall-Littlewood symmetric functions live  
INPUT:  
• self – a class of Hall-Littlewood symmetric function bases  
OUTPUT:  
The base ring of the symmetric functions.  
EXAMPLES:

```sage
HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood(t=1)
HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```
```python
>>> from sage.all import *
>>> HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood(t=Integer(1))
>>> HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

**symmetric_function_ring()**

The ring of symmetric functions associated to the class of Hall-Littlewood symmetric functions

**INPUT:**

- `self` – a class of Hall-Littlewood symmetric function bases

**OUTPUT:**

- returns the ring of symmetric functions

**EXAMPLES:**

```python
sage: HL = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood()
sage: HL.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

class **sage.combinat.sf.hall_littlewood.HallLittlewood_generic**( `hall_littlewood` )

**Bases:** `SymmetricFunctionAlgebra_generic`

A class with methods for working with Hall-Littlewood symmetric functions which are common to all bases.

**INPUT:**

- `self` – a Hall-Littlewood symmetric function basis
- `hall_littlewood` – a class of Hall-Littlewood bases

**class Element**

**Bases:** `SymmetricFunctionAlgebra_generic.Element`

Methods for elements of a Hall-Littlewood basis that are common to all bases.

**expand** `(n, alphabet='x')`

Expands the symmetric function as a symmetric polynomial in `n` variables.

**INPUT:**

- `self` – an element of a Hall-Littlewood basis
- `n` – a positive integer
- `alphabet` – a string representing a variable name (default: 'x')

**OUTPUT:**

- returns a symmetric polynomial of `self` in `n` variables

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
```

(continues on next page)
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).expand(2)
x0^2 + (-t + 1)*x0*x1 + x1^2
sage: HLQ([2]).expand(2)
(-t + 1)*x0^2 + (t^2 - 2*t + 1)*x0*x1 + (-t + 1)*x1^2
sage: HLQp([2]).expand(2)
x0^2 + x0*x1 + x1^2
sage: HLQp([2]).expand(2, 'y')
y0^2 + y0*y1 + y1^2
sage: HLQp([2]).expand(1)
x^2

```python
from sage.all import *
Sym = SymmetricFunctions(FractionField(QQ['t']))
HLP = Sym.hall_littlewood().P()
HLQ = Sym.hall_littlewood().Q()
HLQp = Sym.hall_littlewood().Qp()

HLP([2]).scalar(HLQp([2]))
1
HLP([2]).scalar(HLQp([1,1]))
0
HLP([2]).scalar(HLQ([2]), lambda mu: mu.centralizer_size(t = HLP.t))
1
HLP([2]).scalar(HLQ([1,1]), lambda mu: mu.centralizer_size(t = HLP.t))
0
```

**scalar** *(x, zee=None)*

Returns standard scalar product between `self` and `x`.

This is the default implementation that converts both `self` and `x` into Schur functions and performs the scalar product that basis.

The Hall-Littlewood $P$ basis is dual to the $Q_P$ basis with respect to this scalar product.

**INPUT:**

- `self` – an element of a Hall-Littlewood basis
- `x` – another symmetric element of the symmetric functions

**OUTPUT:**

- returns the scalar product between `self` and `x`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).scalar(HLQp([2]))
1
sage: HLP([2]).scalar(HLQp([1,1]))
0
sage: HLP([2]).scalar(HLQ([2]), lambda mu: mu.centralizer_size(t = HLP.t))
1
sage: HLP([2]).scalar(HLQ([1,1]), lambda mu: mu.centralizer_size(t = HLP.t))
0
```
```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLQ = Sym.hall_littlewood().Q()
>>> HLQp = Sym.hall_littlewood().Qp()

>>> HLP([Integer(2)]).scalar(HLQp([Integer(2)]))
1
>>> HLP([Integer(2)]).scalar(HLQp([Integer(1),Integer(1)]))
0

>>> HLP([Integer(2)]).scalar(HLQ([Integer(2)]), lambda mu: mu.centralizer_size(t = HLP.t))
1
>>> HLP([Integer(2)]).scalar(HLQ([Integer(1),Integer(1)]), lambda mu: mu.centralizer_size(t = HLP.t))
0
```

**scalar_hl(x, t=None)**

Returns the Hall-Littlewood (with parameter \( t \)) scalar product of \( \text{self} \) and \( x \).

The Hall-Littlewood scalar product is defined in Macdonald's book [Mac1995]. The power sum basis is orthogonal and \( \langle p_\mu, p_\nu \rangle = z_\mu \prod_i \frac{1}{1 - t^{\mu_i}} \)

The Hall-Littlewood \( P \) basis is dual to the \( Q \) basis with respect to this scalar product.

**INPUT:**
- \( \text{self} \) – an element of a Hall-Littlewood basis
- \( x \) – another symmetric element of the symmetric functions
- \( t \) – an optional parameter, if this parameter is not specified then the value of the \( t \) from the basis is used in the calculation

**OUTPUT:**
- returns the Hall-Littlewood scalar product between \( \text{self} \) and \( x \)

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: HLP = Sym.hall_littlewood().P()

sage: HLQ = Sym.hall_littlewood().Q()

sage: HLP([2]).scalar_hl(HLQ([2]))
1

sage: HLP([2]).scalar_hl(HLQ([1,1]))
0

sage: HLQ([2]).scalar_hl(HLQ([2]))
-t + 1

sage: HLQ([2]).scalar_hl(HLQ([1,1]))
0

sage: HLP([2]).scalar_hl(HLP([2]))
-1/(t - 1)
```

(continues on next page)
construction()

Return a pair \((F, R)\), where \(F\) is a SymmetricFunctionsFunctor and \(R\) is a ring, such that \(F(R)\) returns self.

EXAMPLES:

```python
sage: P = SymmetricFunctions(QQ).hall_littlewood(t=2).P()
sage: P.construction()
(SymmetricFunctionsFunctor[Hall-Littlewood P with t=2], Rational Field)
```

hall_littlewood_family()

The family of Hall-Littlewood bases associated to self

INPUT:

- self - a Hall-Littlewood symmetric function basis

OUTPUT:

- returns the class of Hall-Littlewood bases

EXAMPLES:

```python
sage: HLP = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood(1).P()
sage: HLP.hall_littlewood_family()
Hall-Littlewood polynomials with t=1 over Fraction Field of Univariate Algebraic Extension...

>>> from sage.all import *
```
the product of \texttt{left} and \texttt{right} expanded in the basis \texttt{self}

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])**2 # indirect doctest
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ([2])**2 # indirect doctest
HLQ[2, 2] + (-t+1)*HLQ[3, 1] + (-t+1)*HLQ[4]
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp([2])**2 # indirect doctest
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLP([2])**2 # indirect doctest
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
>>> HLQ = Sym.hall_littlewood().Q()
>>> HLQ([2])**2 # indirect doctest
HLQ[2, 2] + (-t+1)*HLQ[3, 1] + (-t+1)*HLQ[4]
>>> HLQp = Sym.hall_littlewood().Qp()
>>> HLQp([2])**2 # indirect doctest
```

**transition_matrix** \((basis, n)\)

Returns the transitions matrix between \texttt{self} and \texttt{basis} for the homogeneous component of degree \texttt{n}.

**INPUT:**

- \texttt{self} – a Hall-Littlewood symmetric function basis
- \texttt{basis} – another symmetric function basis
- \texttt{n} – a non-negative integer representing the degree

**OUTPUT:**

- Returns a \(r \times r\) matrix of elements of the base ring of \texttt{self} where \(r\) is the number of partitions of \(n\).

The entry corresponding to row \(\mu\), column \(\nu\) is the coefficient of \texttt{basis} \((\nu)\) in \texttt{self} \((\mu)\)

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: s = Sym.schur()
sage: HLP.transition_matrix(s, 4)
[ 1 -t 0 t^2 -t^3]
[ 0 1 -t t^3 + t^2]
[ 0 0 1 -t t^3]
[ 0 0 0 1 -t^3 - t^2 - t]
[ 0 0 0 0 1]
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ.transition_matrix(s, 3)
```

class sage.combinat.sf.hall_littlewood.HallLittlewood_p(hall_littlewood)

Bases: HallLittlewood_generic

A class representing the Hall-Littlewood $P$ basis of symmetric functions

class Element

Bases: Element

class sage.combinat.sf.hall_littlewood.HallLittlewood_q(hall_littlewood)

Bases: HallLittlewood_generic

The $Q$ basis is defined as a normalization of the $P$ basis.

INPUT:

- `self` – an instance of the Hall-Littlewood $P$ basis
- `hall_littlewood` – a class for the family of Hall-Littlewood bases

EXAMPLES:
```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Q = Sym.hall_littlewood().Q()
sage: TestSuite(Q).run(skip=['_test_assocativity', '_test_distributivity', '_test_prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long time (depends on previous)
```

```

### 5.1.286 Hecke Character Basis

The basis of symmetric functions given by characters of the Hecke algebra (of type $A$).

**AUTHORS:**

- Travis Scrimshaw (2017-08): Initial version

```python
class sage.combinat.sf.hecke.HeckeCharacter(sym, q)

Bases: SymmetricFunctionAlgebra_multiplicative

Basis of the symmetric functions that gives the characters of the Hecke algebra in analogy to the Frobenius formula for the symmetric group.

Consider the Hecke algebra $H_n(q)$ with quadratic relations

$$T_i^2 = (q - 1)T_i + q.$$  

Let $\mu$ be a partition of $n$ with length $\ell$. The character $\chi$ of a $H_n(q)$-representation is completely determined by the elements $T_{\gamma_{\mu}}$, where

$$\gamma_{\mu} = (\mu_1, \ldots, 1)(\mu_2 + \mu_1, \ldots, 1 + \mu_1) \cdots (n, \ldots, 1 + \sum_{i<\ell} \mu_i),$$

(written in cycle notation). We define a basis of the symmetric functions by

$$\bar{\chi}_{\mu} = \sum_{\lambda \vdash n} \chi^\lambda(T_{\gamma_{\mu}})s_{\lambda}.$$  

**INPUT:**

- `sym` – the ring of symmetric functions
- `q` (default: `'q'`) the parameter $q$

**EXAMPLES:**

```python
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character(q)
sage: s = Sym.s()
sage: s(qbar([2]))
sage: -s[1, 1] + q*s[2]
sage: s(qbar([4]))
sage: -s[1, 1, 1, 1] + q*s[2, 1, 1] - q^2*s[3, 1] + q^3*s[4]
```

(continues on next page)
We compute character tables for Hecke algebras, which correspond to the transition matrix from the $\bar{q}$ basis to the Schur basis:

\begin{verbatim}
>>> from sage.all import *
>>> q = ZZ['q'].fraction_field().gen()
>>> Sym = SymmetricFunctions(q.parent())
>>> qbar = Sym.hecke_character(q)
>>> qbar[Integer(2)] * qbar[Integer(3)] * qbar[Integer(3),Integer(1)]
qbar[3, 3, 2, 1]

>>> s = Sym.s()
>>> s(qbar([Integer(2)]))
-s[1, 1] + q*s[2]
>>> s(qbar([Integer(4)]))
-s[1, 1, 1] + q*s[2, 1, 1] - q^2*s[3, 1] + q^3*s[4]
>>> qbar(s[Integer(2)])
(1/(q+1))*qbar[1, 1] + (1/(q+1))*qbar[2]
>>> qbar(s[Integer(1),Integer(1)])
(q/(q+1))*qbar[1, 1] - (1/(q+1))*qbar[2]

>>> s(qbar([Integer(2),Integer(1)]))
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
>>> qbar(s[Integer(2),Integer(1)])
(q/(q^2+q+1))*qbar[1, 1, 1] + ((q-1)/(q^2+q+1))*qbar[2, 1]
- (1/(q^2+q+1))*qbar[3]
\end{verbatim}
We can do computations with a specialized $q$ to a generic element of the base ring. We compute some examples with $q = 2$:

```
sage: qbar = Sym.qbar(q=2)
sage: s = Sym.schur()
sage: qbar(s[2,1])
2/7*qbar[1, 1, 1] + 1/7*qbar[2, 1] - 1/7*qbar[3]
sage: s(qbar[2,1])
-s[1, 1, 1] + s[2, 1] + 2*s[3]
```

REFERENCES:
- [Ram1991]
- [RR1997]

construction()
Return a pair $(F, R)$, where $F$ is a SymmetricFunctionsFunctor and $R$ is a ring, such that $F(R)$ returns self.

EXAMPLES:
```
sage: qbar = SymmetricFunctions(QQ['q']).qbar('q')
sage: qbar.construction()
(SymmetricFunctionsFunctor[Hecke character with q=q],
 Univariate Polynomial Ring in q over Rational Field)
```

```
sage: qbar = SymmetricFunctions(QQ['q']).qbar('q')
sage: qbar.construction()
(SymmetricFunctionsFunctor[Hecke character with q=q],
 Univariate Polynomial Ring in q over Rational Field)
```

coproduct_on_generators($r$)
Return the coproduct on the generator $\bar{q}_r$ of self.
Define the coproduct on $\bar{q}_r$ by

$$\Delta(\bar{q}_r) = \bar{q}_0 \otimes \bar{q}_r + (q-1) \sum_{j=1}^{r-1} \bar{q}_j \otimes \bar{q}_{r-j} + \bar{q}_r \otimes \bar{q}_0.$$ 

**EXAMPLES:**

```python
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: qbar[2].coproduct()
```

>>> from sage.all import *

```python
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: qbar[Integer(2)].coproduct()
```

### 5.1.287 Homogeneous symmetric functions

By this we mean the basis formed of the complete homogeneous symmetric functions $h_\lambda$, not an arbitrary graded basis.

**class** `sage.combinat.sf.homogeneous.SymmetricFunctionAlgebra_homogeneous(Sym)`

Bases: `SymmetricFunctionAlgebra_multiplicative`

A class of methods specific to the homogeneous basis of symmetric functions.

**INPUT:**

- `self` – a homogeneous basis of symmetric functions
- `Sym` – an instance of the ring of symmetric functions

**class** `Element`

Bases: `Element`

**expand**(\(n, \text{alphabet}='x'\))

Expand the symmetric function `self` as a symmetric polynomial in \(n\) variables.

**INPUT:**

- `n` – a nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

**OUTPUT:**

A monomial expansion of `self` in the \(n\) variables labelled by `alphabet`.

**EXAMPLES:**

```python
sage: h = SymmetricFunctions(QQ).h()
sage: h([3]).expand(2)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
sage: h([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: h([2,1]).expand(3)
```

(continues on next page)
(continued from previous page)

\[ x_0^3 + 2x_0^2x_1 + 2x_0x_1^2 + x_1^3 + 2x_0^2x_2 + 3x_0x_1x_2 + 2x_1^2x_2 \]
\[ \quad \Rightarrow 2x_0^2x_2^2 + 2x_1x_2^2 + x_2^3 \]

```
sage: h([3]).expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
sage: h([3]).expand(2,alphabet='x,y')
x^3 + x^2*y + x*y^2 + y^3
sage: h([3]).expand(3,alphabet='x,y,z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
sage: (h([]) + 2*h([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3
```

```
from sage.all import *

h = SymmetricFunctions(QQ).h()
h([3]).expand(Integer(2))
```

```
>>> from sage.all import *

>>> h = SymmetricFunctions(QQ).h()
>>> h([Integer(3)]).expand(Integer(2))
```

```
>>> h([Integer(1),Integer(1),Integer(1)]).expand(Integer(2))
```

```
>>> h([Integer(2),Integer(1)]).expand(Integer(3))
```

```
>>> h([Integer(3)]).expand(Integer(2),alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
```

```
>>> h([1]).expand(Integer(0))
0
```

```
>>> (Integer(3)*h([])).expand(Integer(0))
3
```

**exponential_specialization** *(t=None, q=1)*

Return the exponential specialization of a symmetric function (when \( q = 1 \)), or the \( q \)-exponential specialization (when \( q \neq 1 \)).

The **exponential specialization** \( ex \) at \( t \) is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \). It is defined whenever the base ring \( K \) is a \( \mathbb{Q} \)-algebra and \( t \) is an element of \( R \). The easiest way to define it is by specifying its values on the powersum symmetric functions to be \( p_1 = t \) and \( p_n = 0 \) for \( n > 1 \). Equivalently, on the homogeneous functions it is given by \( ex(h_n) = t^n/n! \); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \( q \)-exponential specialization is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \) that depends on two elements \( t \) and \( q \) of \( R \) for which the elements \( 1 - q^i \) for all positive integers \( i \) are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

\[ ex_q(h_n) = t^n/[n]_q!, \]

where \([n]_q!\) is the \( q \)-factorial. Equivalently, for \( q \neq 1 \) and a homogeneous symmetric function \( f \) of
degree \( n \), we have

\[
ex_q(f) = (1 - q)^n t^n ps_q(f),
\]

where \( ps_q(f) \) is the stable principal specialization of \( f \) (see `principal_specialization()`).

The limit of \( ex_q \) as \( q \to 1 \) is \( ex \).

INPUT:

- \( t \) (default: None) – the value to use for \( t \); the default is to create a ring of polynomials in \( t \).
- \( q \) (default: 1) – the value to use for \( q \). If \( q \) is None, then a ring (or fraction field) of polynomials in \( q \) is created.

EXAMPLES:

```python
sage: h = SymmetricFunctions(QQ).h()
sage: x = h[5,3]
sage: x.exponential_specialization()
1/720*t^8
sage: factorial(5)*factorial(3)
720
sage: x = 5*h[1,1,1] + 3*h[2,1] + 1
sage: x.exponential_specialization()
13/2*t^3 + 1
```

We also support the \( q \)-exponential_specialization:

```python
sage: factor(h[3].exponential_specialization(q=var("q"), t=var("t")))
# needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> x = h[Integer(5),Integer(3)]
>>> x.exponential_specialization()
1/720*t^8
>>> factorial(Integer(5))*factorial(Integer(3))
720
>>> x = Integer(5)*h[Integer(1),Integer(1),Integer(1)] + Integer(3)*h[Integer(2),Integer(1)] + Integer(1)
>>> x.exponential_specialization()
13/2*t^3 + 1
```

omega ()

Return the image of \( self \) under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1} p_k \) for every positive integer \( k \).
The images of some bases under the omega automorphism are given by

\[
\omega(e_{\lambda}) = h_{\lambda}, \quad \omega(h_{\lambda}) = e_{\lambda}, \quad \omega(p_{\lambda}) = (-1)^{|\lambda| - \ell(\lambda)} p_{\lambda}, \quad \omega(s_{\lambda}) = s_{\lambda'},
\]

where \(\lambda\) is any partition, where \(\ell(\lambda)\) denotes the length \(\text{length}(\lambda)\) of the partition \(\lambda\), where \(\lambda'\) denotes the conjugate partition \(\text{conjugate}(\lambda)\) of \(\lambda\), and where the usual notations for bases are used \((e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur})\).

\text{omega_involution()} is a synonym for the \text{omega()} method.

\text{OUTPUT:}
- the image of self under the omega automorphism

\text{EXAMPLES:}

```sage
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

\text{omega_involution()}

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \(\omega\) of the ring of symmetric functions that satisfies \(\omega(e_k) = h_k\) for all positive integers \(k\) (where \(e_k\) stands for the \(k\)-th elementary symmetric function, and \(h_k\) stands for the \(k\)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \(p_k\) to \((-1)^{k-1} p_k\) for every positive integer \(k\).

The images of some bases under the omega automorphism are given by

\[
\omega(e_{\lambda}) = h_{\lambda}, \quad \omega(h_{\lambda}) = e_{\lambda}, \quad \omega(p_{\lambda}) = (-1)^{|\lambda| - \ell(\lambda)} p_{\lambda}, \quad \omega(s_{\lambda}) = s_{\lambda'},
\]

where \(\lambda\) is any partition, where \(\ell(\lambda)\) denotes the length \(\text{length}(\lambda)\) of the partition \(\lambda\), where \(\lambda'\) denotes the conjugate partition \(\text{conjugate}(\lambda)\) of \(\lambda\), and where the usual notations for bases are used \((e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur})\).

\text{omega_involution()} is a synonym for the \text{omega()} method.

\text{OUTPUT:}
- the image of self under the omega automorphism

\text{EXAMPLES:}

```sage
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
```

(continues on next page)
principal_specialization \((n=\text{Infinity}, q=\text{None})\)

Return the principal specialization of a symmetric function.

The principal specialization of order \(n\) at \(q\) is the ring homomorphism \(\text{ps}_{n,q}\) from the ring of symmetric functions to another commutative ring \(R\) given by \(x_i \mapsto q^{i-1}\) for \(i \in \{1, \ldots, n\}\) and \(x_i \mapsto 0\) for \(i > n\). Here, \(q\) is a given element of \(R\), and we assume that the variables of our symmetric functions are \(x_1, x_2, x_3, \ldots\) (To be more precise, \(\text{ps}_{n,q}\) is a \(K\)-algebra homomorphism, where \(K\) is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at \(q\) is the ring homomorphism \(\text{ps}_q\) from the ring of symmetric functions to another commutative ring \(R\) given by \(x_i \mapsto q^{i-1}\) for all \(i\). This is well-defined only if the resulting infinite sums converge; thus, in particular, setting \(q = 1\) in the stable principal specialization is an invalid operation.

INPUT:
- \(n\) (default: \text{infinity}) – a nonnegative integer or \text{infinity}, specifying whether to compute the principal specialization of order \(n\) or the stable principal specialization.
- \(q\) (default: \text{None}) – the value to use for \(q\); the default is to create a ring of polynomials in \(q\) (or a field of rational functions in \(q\)) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients \(^{n}C_{\lambda}\)):

\[
\text{ps}_{n,q}(h_{\lambda}) = \prod_i \binom{n + \lambda_i - 1}{\lambda_i}_q, \\
\text{ps}_{n,1}(h_{\lambda}) = \prod_i \binom{n + \lambda_i - 1}{\lambda_i}, \\
\text{ps}_q(h_{\lambda}) = 1/\prod_i \sum_{j=1}^{\lambda_i} (1 - q^j).
\]

EXAMPLES:

```python
sage: h = SymmetricFunctions(QQ).h()
sage: x = h[2,1]
sage: x.principal_specialization(3)
q^6 + 2*q^5 + 4*q^4 + 4*q^3 + 4*q^2 + 2*q + 1
sage: x = 3*h[2] + 2*h[1] + 1
```
sage: x.principal_specialization(3, q=var("q"))
# needs sage.symbolic
2*(q^3 - 1)/(q - 1) + 3*(q^4 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1

>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> x = h[Integer(2), Integer(1)]
>>> x.principal_specialization(Integer(3))
q^6 + 2*q^5 + 4*q^4 + 4*q^3 + 4*q^2 + 2*q + 1
>>> x = Integer(3)*h[Integer(2)] + Integer(2)*h[Integer(1)] + Integer(1)
>>> x.principal_specialization(Integer(3), q=var("q"))
# needs sage.symbolic
2*(q^3 - 1)/(q - 1) + 3*(q^4 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1

5.1.288 JackSymmetricFunctions

Jack's symmetric functions appear in [Ma1995] Chapter VI, section 10. Zonal polynomials are the subject of [Ma1995] Chapter VII. The parameter \( \alpha \) in that reference is the parameter \( t \) in this implementation in sage.

REFERENCES:
class sage.combinat.sf.jack.Jack (Sym, t)
    Bases: UniqueRepresentation

    The family of Jack symmetric functions including the \( P, Q, J, Qp \) bases. The default parameter is \( t \).

INPUT:
Combinatorics, Release 10.4

• self – the family of Jack symmetric function bases
• Sym – a ring of symmetric functions
• t – an optional parameter (default: ‘t’)

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).jack()
Jack polynomials over Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: SymmetricFunctions(QQ).jack(1)
Jack polynomials with t=1 over Rational Field
```

\textbf{\textit{J}} ()

Returns the algebra of Jack polynomials in the \textit{J} basis.

\textbf{INPUT:}

• self – the family of Jack symmetric function bases

\textbf{OUTPUT:} the \textit{J} basis of the Jack symmetric functions

\textbf{EXAMPLES:}

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Jack J basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).J()
Symmetric Functions over Rational Field in the Jack J with t=-1 basis
```

At \( t = 1 \), the Jack polynomials in the \textit{J} basis are scalar multiples of the Schur functions with the scalar given by a Partition’s \texttt{hook_product()} method at 1:

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=1).J()
sage: s = Sym.schur()
sage: p = Partition([3,2,1,1])
sage: s(JJ(p)) == p.hook_product(1)*s(p)  # long time (4s on sage.math, 2012)
True
```
At $t = 2$, the Jack polynomials in the $J$ basis are scalar multiples of the zonal polynomials with the scalar given by a Partition's `hook_product()` method at 2.

```python
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=2).J()
sage: Z = Sym.zonal()
sage: p = Partition([2, 2, 1])
sage: Z(JJ(p)) == p.hook_product(2)*Z(p)
True

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J()
sage: JP = Sym.jack().P()
sage: JJ(sum(JP(p) for p in Partitions(Integer(3))))
1/6*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
```
\[(1/3*t-1/3)/(t+2))*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1]\]

```
>>> JJ(s([Integer(1),Integer(1),Integer(1)]))
1/6*JackJ[1, 1, 1]
```

\[P()\]

Returns the algebra of Jack polynomials in the \(P\) basis.

**INPUT:**

- `self` – the family of Jack symmetric function bases

**OUTPUT:**

- the \(P\) basis of the Jack symmetric functions

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack P basis
sage: Sym.jack(t=-1).P()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack P with t=-1 basis
```

At \(t = 1\), the Jack polynomials in the \(P\) basis are the Schur symmetric functions.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=1).P()
sage: s = Sym.schur()
s[2, 2, 1]
sage: JP(s([2,2,1]))
JackP[2, 2, 1]
sage: JP([2,1])**Integer(2)
```

```
>>> from sage.all import *
```

```
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack P basis
>>> Sym.jack(t=-Integer(1)).P()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack P with t=-1 basis
```
At $t = 2$, the Jack polynomials in the $P$ basis are the zonal polynomials.

```python
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P()
sage: Z = Sym.zonal()
sage: Z(JP([2,2,1]))
JackP[2, 2, 1]
sage: JP(Z[2, 2, 1])
JackP[2, 2, 1]
sage: JP([2])**2
sage: Z([2])**2
```

```python
>>> from sage.all import *

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> JP = Sym.jack(t=Integer(2)).P()
>>> Z = Sym.zonal()
>>> Z(JP([Integer(2), Integer(2), Integer(1)]))
JackP[2, 2, 1]
>>> JP(Z[Integer(2), Integer(2), Integer(1)])
JackP[2, 2, 1]
>>> JP([Integer(2)])**Integer(2)
>>> Z([Integer(2)])**Integer(2)
```

```python
sage: Sym = SymmetricFunctions(QQ['a','b'].fraction_field())
sage: (a,b) = Sym.base_ring().gens()
sage: Jacka = Sym.jack(t=a)
sage: Jackb = Sym.jack(t=b)
sage: m = Sym.monomial()
sage: JPa = Jacka.P()
sage: JPb = Jackb.P()
sage: m(JPa[2,1])
(6/(a+2))*m[1, 1, 1] + m[2, 1]
sage: m(JPb[2,1])
(6/(b+2))*m[1, 1, 1] + m[2, 1]
sage: m(a*JPa([2,1]) + b*JPb([2,1]))
((6*a^2+6*b^2+12*a+12*b)/(a*b+2*a+2*b+4))*m[1, 1, 1] + (a+b)*m[2, 1]
sage: JPa(JPb([2,1]))
((6*a-6*b)/(a*b+2*a+2*b+4))*JackP[1, 1, 1] + JackP[2, 1]
```

```python
>>> from sage.all import *

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['a','b'].fraction_field())
>>> (a,b) = Sym.base_ring().gens()
>>> Jacka = Sym.jack(t=a)
>>> Jackb = Sym.jack(t=b)
>>> m = Sym.monomial()
>>> JPa = Jacka.P()
>>> JPb = Jackb.P()
>>> m(JPa[Integer(2), Integer(1)])
(6/(a+2))*m[1, 1, 1] + m[2, 1]
>>> m(JPb[Integer(2), Integer(1)])
(6/(b+2))*m[1, 1, 1] + m[2, 1]
>>> m(a*JPa([Integer(2), Integer(1)]) + b*JPb([Integer(2), Integer(1)]))
((6*a^2+6*b^2+12*a+12*b)/(a*b+2*a+2*b+4))*m[1, 1, 1] + (a+b)*m[2, 1]
```
Combinatorics, Release 10.4

```python
>>> JPa(JPb([Integer(2),Integer(1)]))
(6*a-6*b)/(a*b+2*a+2*b+4))*JackP[1, 1, 1] + JackP[2, 1]
```

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JJ = Sym.jack().J()
```

```python
>>> from sage.all import *

sage: JP(JQ([2,1]))
((1/2*t+1)/(t^3+1/2*t^2))*JackP[2, 1]
sage: JP(JQ([3]))
((1/3*t^2+1/2*t+1/6)/t^3)*JackP[3]
sage: JP(JQ([1,1,1]))
(6/(t^3+3*t^2+2*t))*JackP[1, 1, 1]
```

```python
>>> from sage.all import *

sage: JP(JQ([Integer(2),Integer(1)]))
((1/2*t+1)/(t^3+1/2*t^2))*JackP[2, 1]
sage: JP(JQ([Integer(3)]))
((1/3*t^2+1/2*t+1/6)/t^3)*JackP[3]
sage: JP(JQ([Integer(1),Integer(1),Integer(1)]))
(6/(t^3+3*t^2+2*t))*JackP[1, 1, 1]
```

```python
sage: JP(JJ([3]))
(2*t^2+3*t+1)*JackP[3]
sage: JP(JJ([2,1]))
(t+2)*JackP[2, 1]
sage: JP(JJ([1,1,1]))
6*JackP[1, 1, 1]
```

```python
>>> from sage.all import *

sage: JP(JJ([Integer(3)]))
(2*t^2+3*t+1)*JackP[3]
sage: JP(JJ([Integer(2),Integer(1)]))
(t+2)*JackP[2, 1]
sage: JP(JJ([Integer(1),Integer(1),Integer(1)]))
6*JackP[1, 1, 1]
```

```python
sage: s = Sym.schur()
sage: JP(s([2,1]))
((2*t-2)/(t+2))*JackP[1, 1, 1] + JackP[2, 1]
sage: s(_)
s[2, 1]
```

```python
>>> from sage.all import *

sage: s = Sym.schur()
sage: JP(s([Integer(2),Integer(1)]))
((2*t-2)/(t+2))*JackP[1, 1, 1] + JackP[2, 1]
```
Q()

Returns the algebra of Jack polynomials in the $Q$ basis.

INPUT:

• self – the family of Jack symmetric function bases

OUTPUT:

• the $Q$ basis of the Jack symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Jack $Q$ basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-Integer(1)).Q()
Symmetric Functions over Rational Field in the Jack $Q$ with t=-1 basis
```

```python
>>> from sage.all import *
```

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
>>>
```

```python
sage: JQ = Sym.jack().Q()
```

```python
sage: JP = Sym.jack().P()
```

```python
>>> from sage.all import *
```

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
>>> from sage.all import *
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```python
sage: s = Sym.schur()
sage: JQ(s([3]))  # indirect doctest
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] + (3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```
Qp()  

Returns the algebra of Jack polynomials in the $Q_p$, which is dual to the $P$ basis with respect to the standard scalar product.

**INPUT:**

- self – the family of Jack symmetric function bases

**OUTPUT:**

- the $Q'$ basis of the Jack symmetric functions

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
→ over Rational Field in the Jack Qp basis

sage: a = JQp([2])
sage: a.scalar(JP([2]))
1
sage: a.scalar(JP([1,1]))
0
sage: JP._normalize(JP(JQp([2])))
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
```

**base_ring()**

Returns the base ring of the symmetric functions in which the Jack symmetric functions live
INPUT:
- `self` – the family of Jack symmetric function bases

OUTPUT:
- the base ring of the symmetric functions ring of `self`

EXAMPLES:
```
sage: J2 = SymmetricFunctions(QQ).jack(t=2)
sage: J2.base_ring()
Rational Field
```
```
>>> from sage.all import *

>>> J2 = SymmetricFunctions(QQ).jack(t=Integer(2))
>>> J2.base_ring()
Rational Field
```

```
symmetric_function_ring()
```
Returns the base ring of the symmetric functions of the Jack symmetric function bases

INPUT:
- `self` – the family of Jack symmetric function bases

OUTPUT:
- the symmetric functions ring of `self`

EXAMPLES:
```
sage: Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
sage: Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
˓→ over Rational Field
```
```
>>> from sage.all import *

>>> Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
>>> Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
˓→ over Rational Field
```

```
class sage.combinat.sf.jack.JackPolynomials_generic(jack)
Bases: SymmetricFunctionAlgebra_generic
```
A class of methods which are common to all Jack bases of the symmetric functions

INPUT:
- `self` – a Jack basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:
```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```
```
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P(); JP.base_ring()
Rational Field
```

5.1. Comprehensive Module List

4589
```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field

>>> Sym = SymmetricFunctions(QQ)
>>> JP = Sym.jack(t=Integer(2)).P(); JP.base_ring()
Rational Field
```

class Element

Bases: SymmetricFunctionAlgebra_generic_Element

```python
class Element

Bases: SymmetricFunctionAlgebra_generic_Element

scalar_jack(x, t=None)

A scalar product where the power sums are orthogonal and \( \langle p_\mu, p_\mu \rangle = z_\mu t^{\text{length}(\mu)} \)

INPUT:

• `self` – an element of a Jack basis of the symmetric functions

• `x` – an element of the symmetric functions

• `t` – an optional parameter (default: uses the parameter from the basis)

OUTPUT:

• returns the Jack scalar product between `x` and `self`
```

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQ = Sym.jack().Q()
sage: p = Partitions(3).list()
sage: matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])

[[1 0 0]
 [0 1 0]
 [0 0 1]]
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P()
>>> JQ = Sym.jack().Q()
>>> p = Partitions(Integer(3)).list()
>>> matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])

[[1 0 0]
 [0 1 0]
 [0 0 1]]
```

c1(part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```

```python
c1 (part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```

```python
c1 (part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```

```python
c1 (part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```

```python
c1 (part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```

```python
c1 (part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```

```python
c1 (part)

Returns the \( t \)-Jack scalar product between \( J(part) \) and \( P(part) \).

INPUT:

• `self` – a Jack basis of the symmetric functions

• `part` – a partition

• `t` – an optional parameter (default: uses the parameter \( t \) from the Jack basis)

OUTPUT:

• a polynomial in the parameter \( t \) which is equal to the scalar product of \( J(part) \) and \( P(part) \)
```
c2 (part)

Returns the \(t\)-Jack scalar product between \(J(\text{part})\) and \(Q(\text{part})\).

**INPUT:**
- **self** – a Jack basis of the symmetric functions
- **part** – a partition
- **\(t\)** – an optional parameter (default: uses the parameter \(t\) from the Jack basis)

**OUTPUT:**
- a polynomial in the parameter \(t\) which is equal to the scalar product of \(J(\text{part})\) and \(Q(\text{part})\)

**EXAMPLES:**

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c2(Partition([2,1]))
t + 2
```

construction()

Return a pair \((F, R)\), where \(F\) is a \texttt{SymmetricFunctionsFunctor} and \(R\) is a ring, such that \(F(R)\) returns \self\.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JP.construction()
(SymmetricFunctionsFunctor[Jack P],
Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

coproduct_by_coercion (elt)

Returns the coproduct of the element \elt by coercion to the Schur basis.

**INPUT:**
• self – a Jack symmetric function basis
• elt – an instance of this basis

OUTPUT:
• The coproduct acting on elt, the result is an element of the tensor squared of the Jack symmetric function basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: Sym.jack().P()[2,2].coproduct() # indirect doctest
```

```
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())

>>> Sym.jack().P()[Integer(2),Integer(2)].coproduct() # indirect doctest
```

jack_family()

Returns the family of Jack bases associated to the basis self

INPUT:
• self – a Jack basis of the symmetric functions

OUTPUT:
• the family of Jack symmetric functions associated to self

EXAMPLES:

```
sage: JackP = SymmetricFunctions(QQ).jack(t=2).P()
sage: JackP.jack_family()
Jack polynomials with t=2 over Rational Field
```

```
>>> from sage.all import *

>>> JackP = SymmetricFunctions(QQ).jack(t=Integer(2)).P()

>>> JackP.jack_family()
Jack polynomials with t=2 over Rational Field
```

product(left, right)

The product of two Jack symmetric functions is done by multiplying the elements in the $P$ basis and then expressing the elements in the basis self.

INPUT:
• self – a Jack basis of the symmetric functions
• left, right – symmetric function elements

OUTPUT:
the product of left and right expanded in the basis self

EXAMPLES:
```python
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JJ([1])**2  # indirect doctest
(t/(t+1))*JackJ[1, 1] + (1/(t+1))*JackJ[2]
sage: JJ([2])**2
(t^2/(t^2+3/2*t+1/2))*JackJ[2, 2] + (4/3*t/(t^2+4/3*t+1/3))*JackJ[3, 1] + ((1/6*t+1/6)/(t^2+5/6*t+1/6))*JackJ[4]
sage: JQ = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
sage: JQ([1])**2  # indirect doctest
JackQ[1, 1] + (2/(t+1))*JackQ[2]
sage: JQ([2])**2
JackQ[2, 2] + (2/(t+1))*JackQ[3, 1] + ((t+1)/(t^2+5/6*t+1/6))*JackQ[4]
```

```python
class sage.combinat.sf.jack.JackPolynomials_j(jack)
Bases: JackPolynomials_generic

The \( J \) basis is defined as a normalized form of the \( P \) basis

INPUT:

- self -- an instance of the Jack \( P \) basis of the symmetric functions
- jack -- a family of Jack symmetric function bases

EXAMPLES:

```python
class sage.combinat.sf.jack.JackPolynomials_p(jack)
Bases: JackPolynomials_generic

The \( P \) basis is uni-triangularly related to the monomial basis and orthogonal with respect to the Jack scalar product.
```
INPUT:

- `self` – an instance of the Jack $P$ basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```python
sage: P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: TestSuite(P).run(skip=['_test_associativity', '_test_distributivity', '_test_prod']) # products are too expensive
sage: TestSuite(P).run(elements = [P.t*P[1,1]+P[2], P[1]+(1+P.t)*P[1,1]])
```

```python
>>> from sage.all import *
>>> P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> TestSuite(P).run(elements = [P.t*P[Integer(1),Integer(1)]+P[Integer(2)],
- P[Integer(1)]+(Integer(1)+P.t)*P[Integer(1),Integer(1)])
```

class Element

Bases: `Element`

`scalar_jack(x, t=None)`

The scalar product on the symmetric functions where the power sums are orthogonal and $\langle p_{\mu}, p_{\nu} \rangle = z_{\mu}^{\text{length}(\mu)}$ where the $t$ parameter from the Jack symmetric function family.

INPUT:

- `self` – an element of the Jack $P$ basis
- `x` – an element of the $P$ basis

EXAMPLES:

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: l = [JP(p) for p in Partitions(3)]
sage: matrix([[a.scalar_jack(b) for a in l] for b in l])
```

```python
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> l = [JP(p) for p in Partitions(Integer(3))]
>>> matrix([[a.scalar_jack(b) for a in l] for b in l])
```

`product(left, right)`

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis `self`.

INPUT:
• self – a Jack basis of the symmetric functions
• left, right – symmetric function elements

OUTPUT:
the product of left and right expanded in the basis self

EXAMPLES:

```sage
JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
m = JP.symmetric_function_ring().m()
JP([1])**2 # indirect doctest
(2*t/(t+1))*JackP[1, 1] + JackP[2]
m(_) 2*m[1, 1] + m[2]

sage: JP = SymmetricFunctions(QQ).jack(t=2).P()
m(_) 45*m[1, 1, 1, 1, 1, 1] + 51/2*m[2, 1, 1, 1, 1] + 29/2*m[2, 2, 1, 1] + 33/4*m[2, 2, 2] + 9*m[3, 1, 1, 1] + 5*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]
```

```python
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> m = JP.symmetric_function_ring().m()
>>> JP([1])**2 # indirect doctest
(2*t/(t+1))*JackP[1, 1] + JackP[2]
>>> m(_)
2*m[1, 1] + m[2]
>>> JP = SymmetricFunctions(QQ).jack(t=Integer(2)).P()
>>> m(_) 45*m[1, 1, 1, 1, 1, 1] + 51/2*m[2, 1, 1, 1, 1] + 29/2*m[2, 2, 1, 1] + 33/4*m[2, 2, 2] + 9*m[3, 1, 1, 1] + 5*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]
```

**scalar_jack_basis**(part1, part2=None)

Returns the scalar product of \( P(part1) \) and \( P(part2) \).

This is equation (10.16) of [Mc1995] on page 380.

INPUT:
• self – an instance of the Jack \( P \) basis of the symmetric functions
• part1 – a partition
• part2 – an optional partition (default : None)

OUTPUT:
• the scalar product between \( P(part1) \) and \( P(part2) \) (or itself if \( part2 \) is None)

REFERENCES:

EXAMPLES:
```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: JP._normalize_coefficients(JP.scalar_jack_basis(Partition([3,2,1]),
→ Partition([3,2,1])))
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
sage: JJ(JP[3,2,1]).scalar_jack(JP[3,2,1])
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
```

With a single argument, takes `part2 = part1`:

```python
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([2,1]))
(2*t^3 + t^2)/(t + 2)
sage: JJ(JP[2,1]).scalar_jack(JP[2,1])
(2*t^3 + t^2)/(t + 2)
```

```python
>>> from sage.all import *

>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()

>>> JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()

>>> JP.scalar_jack_basis(Partition([Integer(2),Integer(1)]),
→ Partition([Integer(1),Integer(1),Integer(1)]))
0

>>> JP._normalize_coefficients(JP.scalar_jack_basis(Partition([Integer(3),
→ Integer(2),Integer(1)]), Partition([Integer(3),Integer(2),Integer(1)])))
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)

>>> JJ(JP[Integer(3),Integer(2),Integer(1)]).scalar_jack(JP[Integer(3),
→ Integer(2),Integer(1)])
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
```

---

**class** `sage.combinat.sf.jack.JackPolynomials_q(jack)`

**Bases:** `JackPolynomials_generic`

The *Q* basis is defined as a normalized form of the *P* basis

**INPUT:**

- `self` – an instance of the Jack *Q* basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

**EXAMPLES:**

```python
sage: Q = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '
→_test_prod']) # products are too expensive
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]]) # long
→ time (3s on sage.math, 2012)
```

```python
>>> from sage.all import *

>>> Q = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
```
Combinatorics, Release 10.4

>>> TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_prod']) # products are too expensive

>>> TestSuite(Q).run(elements = [Q.t*Q[Integer(1),Integer(1)]+Q[Integer(2)],
→Q[Integer(1)]+(Integer(1)+Q.t)*Q[Integer(1),Integer(1)]) # long time (3s on...
→sage.math, 2012)

class Element
Bases: Element

class sage.combinat.sf.jack.JackPolynomials_qp(jack)
Bases: JackPolynomials_generic

The $Q_p$ basis is the dual basis to the $P$ basis with respect to the standard scalar product

INPUT:

- self – an instance of the Jack $Q_p$ basis of the symmetric functions
- jack – a family of Jack symmetric function bases

EXAMPLES:

sage: Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_test_prod']) # products are too expensive
sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]]) # long time (3s on sage.math, 2012)

>>> from sage.all import *

>>> Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()

>>> TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_test_prod']) # products are too expensive

>>> TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]]) # long time (3s on sage.math, 2012)

class Element
Bases: Element
coproduct_by_coercion(elt)

Returns the coproduct of the element elt by coercion to the Schur basis.

INPUT:

- elt – an instance of the $Q_p$ basis

OUTPUT:

- The coproduct acting on elt, the result is an element of the tensor squared of the $Q_p$ symmetric function basis

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: JQp = Sym.jack().Qp()
sage: JQp[2,2].coproduct() # indirect doctest
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> JQp = Sym.jack().Qp()
>>> JQp[Integer(2),Integer(2)].coproduct()  # indirect doctest
JackQp[] + (2*t/(t+1))*JackQp[2, 1] + JackQp[1, 1]
→JackQp[2, 1] + ((2*t^3+4*t^2)/(t^3+5/2*t^2+2*t+1/2))*JackQp[2] +
→JackQp[1, 1] + (2*t/(t+1))*JackQp[2, 1] + JackQp[1, 1]
```

**product** *(left, right)*

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis self.

**INPUT:**

- self – an instance of the Jack Qp basis of the symmetric functions
- left, right – symmetric function elements

**OUTPUT:**

the product of left and right expanded in the basis self

**EXAMPLES:**

```python
sage: JQp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: h = JQp.symmetric_function_ring().h()
sage: JQp([1])**2  # indirect doctest
JackQp[1, 1] + (2/(t+1))*JackQp[2]
sage: h(_)
JackQp[1, 1] + (2/(t+1))*JackQp[2]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> JQp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
>>> h = JQp.symmetric_function_ring().h()
>>> JQp([1])**2  # indirect doctest
JackQp[1, 1] + (2/(t+1))*JackQp[2]
```

```python
class sage.combinat.sf.jack.SymmetricFunctionAlgebra_zonal(Sym)

Bases: SymmetricFunctionAlgebra_generic

Returns the algebra of zonal polynomials.
```
INPUT:

- self – a zonal basis of the symmetric functions
- Sym – a ring of the symmetric functions

EXAMPLES:

```python
sage: Z = SymmetricFunctions(QQ).zonal()
sage: Z([2])^2

sage: Z = SymmetricFunctions(QQ).zonal()
sage: TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])
# products are too expensive

```

```python
>>> from sage.all import *

>>> Z = SymmetricFunctions(QQ).zonal()

>>> TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])
# products are too expensive

>>> TestSuite(Z).run(elements = [Z[Integer(1),Integer(1)]+Z[Integer(2)], Z[Integer(1)]+Integer(2)*Z[Integer(1),Integer(1)]])
```

class Element
   Bases: SymmetricFunctionAlgebra_generic_Element

   scalar_zonal(x)

   The zonal scalar product has the power sum basis and the zonal symmetric functions are orthogonal. In particular, \( \langle p_\mu, p_\mu \rangle = z_\mu^{2 \text{length}(\mu)} \).

   INPUT:
   - self – an element of the zonal basis
   - x – an element of the symmetric function

   OUTPUT:
   - the scalar product between self and x

   EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: parts = Partitions(3).list()
sage: matrix([[Z(a).scalar_zonal(Z(b)) for a in parts] for b in parts])
[[16/5  0  0]
 [ 0  5  0]
 [ 0  0  4]]

sage: p = Z.symmetric_function_ring().power()
sage: matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
[[ 6  0  0]
 [ 0  8  0]
 [ 0  0 48]]
```

```python

>>> Sym = SymmetricFunctions(QQ)

>>> TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_test_prod'])
# products are too expensive

>>> TestSuite(Z).run(elements = [Z[Integer(1),Integer(1)]+Z[Integer(2)], Z[Integer(1)]+Integer(2)*Z[Integer(1),Integer(1)]])
```
Combinatorics, Release 10.4

(continued from previous page)

\[
\begin{bmatrix}
16/5 & 0 & 0 \\
0 & 5 & 0 \\
0 & 0 & 4 \\
\end{bmatrix}
\]

```python
>>> p = Z.symmetric_function_ring().power()
>>> matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
\[
\begin{bmatrix}
6 & 0 & 0 \\
0 & 8 & 0 \\
0 & 0 & 48 \\
\end{bmatrix}
\]
```

**product (left, right)**

The product of two zonal symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements in the basis self.

**INPUT:**

- `self` – a zonal basis of the symmetric functions
- `left, right` – symmetric function elements

**OUTPUT:**

the product of `left` and `right` expanded in the basis `self`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: JP = Sym.jack(t=1).P()
sage: Z([2])*Z([3])  
# indirect doctest
sage: Z([2])*JP([2])
sage: JP = Sym.jack(t=Integer(1)).P()
```

```python
sage: Z([2])*JP([2])  
# indirect doctest
```

```python
>>> from sage.all import *  
```

```python
>>> Sym = SymmetricFunctions(QQ)
>>> Z = Sym.zonal()
>>> JP = Sym.jack(t=Integer(1)).P()
```

```python
sage: Z([Integer(2)])*Z([Integer(3)])  
# indirect doctest
sage: Z([Integer(2)])*JP([Integer(2)])
sage: JP = Sym.jack(t=Integer(2)).P()
```

```python
sage: Z([Integer(2)])*JP([Integer(2)])
```

**sage.combinat.sf.jack.c1(part, t)**

Returns the \(t\)-Jack scalar product between \(J(part)\) and \(P(part)\).

**INPUT:**

- `part` – a partition
- `t` – an optional parameter (default: uses the parameter \(t\) from the Jack basis)

**OUTPUT:**

- a polynomial in the parameter \(t\) which is equal to the scalar product of \(J(part)\) and \(P(part)\)
EXAMPLES:

```python
sage: from sage.combinat.sf.jack import c1
sage: t = QQ['t'].gen()
>>> [c1(p,t) for p in Partitions(3)]
[2*t^2 + 3*t + 1, t + 2, 6]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.jack import c1
>>> t = QQ['t'].gen()
>>> [c1(p,t) for p in Partitions(Integer(3))]
[2*t^2 + 3*t + 1, t + 2, 6]
```

`sage.combinat.sf.jack.c2(part, t)`

Returns the t-Jack scalar product between $J(part)$ and $Q(part)$.

**INPUT:**
- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter $t$ from the Jack basis)

**OUTPUT:**
- a polynomial in the parameter $t$ which is equal to the scalar product of $J(part)$ and $Q(part)$

**EXAMPLES:**

```python
sage: from sage.combinat.sf.jack import c2
sage: t = QQ['t'].gen()
>>> [c2(p,t) for p in Partitions(3)]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.jack import c2
>>> t = QQ['t'].gen()
>>> [c2(p,t) for p in Partitions(Integer(3))]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

`sage.combinat.sf.jack.normalize_coefficients(self, c)`

If our coefficient ring is the field of fractions over a univariate polynomial ring over the rationals, then we should clear both the numerator and denominator of the denominators of their coefficients.

**INPUT:**
- `self` – a Jack basis of the symmetric functions
- `c` – a coefficient in the base ring of `self`

**OUTPUT:**
- divide numerator and denominator by the greatest common divisor

**EXAMPLES:**

```python
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: t = JP.base_ring().gen()
sage: a = 2/(1/2*t+1/2)
sage: JP._normalize_coefficients(a)
```
sage.combinat.sf.jack.part_scalar_jack(part1, part2, t)

Returns the Jack scalar product between \( p(part1) \) and \( p(part2) \) where \( p \) is the power-sum basis.

**INPUT:**

- `part1, part2` – two partitions
- `t` – a parameter

**OUTPUT:**

- returns the scalar product between the power sum indexed by `part1` and `part2`
5.1.289 Quotient of symmetric function space by ideal generated by Hall-Littlewood symmetric functions

The quotient of symmetric functions by the ideal generated by the Hall-Littlewood P symmetric functions indexed by partitions with first part greater than \( k \). When \( t = 1 \) this space is the quotient of the symmetric functions by the ideal generated by the monomial symmetric functions indexed by partitions with first part greater than \( k \).

AUTHORS:
- Chris Berg (2012-12-01)
- Mike Zabrocki - \( k \)-bounded Hall-Littlewood P and dual \( k \)-Schur functions (2012-12-02)

```python
class sage.combinat.sf.k_dual.AffineSchurFunctions(kBoundedRing):
    Bases: KBoundedQuotientBasis

    This basis is dual to the \( k \)-Schur functions at \( t = 1 \). This realization follows the monomial expansion given by Lam [Lam2006].

REFERENCES:
```

```python
class sage.combinat.sf.k_dual.DualkSchurFunctions(kBoundedRing):
    Bases: KBoundedQuotientBasis

    This basis is dual to the \( k \)-Schur functions. The expansion is given in Section 4.12 of [LLMSSZ]. When \( t = 1 \) this basis is equal to the AffineSchurFunctions and that basis is more efficient in this case.

REFERENCES:
```

```python
class sage.combinat.sf.k_dual.KBoundedQuotient(Sym, k, t='t'):
    Bases: UniqueRepresentation, Parent

    Initialization of the ring of Symmetric functions modulo the ideal of monomial symmetric functions which are indexed by partitions whose first part is greater than \( k \).

    INPUT:
    - Sym -- an element of class sage.combinat.sf.sf.SymmetricFunctions
    - k -- a positive integer
    - R -- a ring

    EXAMPLES:
```

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3, t=1)
sage: Q
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: km = Q.km()
sage: km
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded monomial basis
sage: F = Q.affineSchur()
sage: F(km(F[[3,1,1]])) == F[[3,1,1]]
True
sage: km(F(km([[3,2]]))) == km[[3,2]]
True
sage: km(F[[3,2]]).lift()  # (continues on next page)

AffineGrothendieckPolynomial \((\lambda, m)\)

Returns the affine Grothendieck polynomial indexed by the partition \(\lambda\). Because this belongs to the completion of the algebra, and hence is an infinite sum, it computes only up to those symmetric functions of degree at most \(m\). See \_AffineGrothendieckPolynomial() for the code.

INPUT:

* \(\lambda\) – A \(k\)-bounded partition

5.1. Comprehensive Module List 4605
• \( m \) – An integer

EXAMPLES:

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.AffineGrothendieckPolynomial([2,1],4)
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]
```

```python
>>> from sage.all import *

>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.AffineGrothendieckPolynomial([Integer(2),Integer(1)],Integer(4))
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]
```

\( F() \)

The affine Schur basis of the \( k \)-bounded quotient of symmetric functions, indexed by \( k \)-bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.stanley_symmetric_function()`) indexed by an affine Grassmannian permutation.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→2-bounded affine Schur basis
```

```python
>>> from sage.all import *

>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
→affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→2-bounded affine Schur basis
```

\( a\_realization() \)

Returns a particular realization of \( self \) (the basis of \( k \)-bounded monomials if \( t = 1 \) and the basis of \( k \)-bounded Hall-Littlewood functions otherwise).

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→3-bounded monomial basis
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> Q = Sym.kBoundedQuotient(Integer(3),t=Integer(1))

>>> Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→3-bounded monomial basis
```

```python
sage: Q = Sym.kBoundedQuotient(3,t=2)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the...
→3-bounded Hall-Littlewood P basis
```

```python
>>> from sage.all import *

>>> Q = Sym.kBoundedQuotient(Integer(3),t=Integer(2))

>>> Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the...
→3-bounded Hall-Littlewood P basis
```
affineSchur()

The affine Schur basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions. This is also equal to the affine Stanley symmetric functions (see WeylGroups.ElementMethods.stanley_symmetric_function()) indexed by an affine Grassmannian permutation.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
→2-bounded affine Schur basis
```

ambient()

Returns the Symmetric Functions over the same ring as self. This is needed to realize our ring as a quotient.

an_element()

Returns an element of the quotient ring of $k$-bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.an_element()
2*m3[] + 2*m3[1] + 3*m3[2]
```

dks()

The dual $k$-Schur basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the affineSchur() basis.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

dual_k_Schur()

The dual $k$-Schur basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the affineSchur() basis.
EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_.
Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
→dual_k_Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

### kHLP()

The Hall-Littlewood P basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions. At $t = 1$ this basis is equal to the $k$-bounded monomial basis and calculations will be faster using elements in the $k$-bounded monomial basis (see `kmonomial()`).

EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).
→kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
basis
```

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
→kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
basis
```

### kHallLittlewoodP()

The Hall-Littlewood P basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions. At $t = 1$ this basis is equal to the $k$-bounded monomial basis and calculations will be faster using elements in the $k$-bounded monomial basis (see `kmonomial()`).

EXAMPLES:

```python
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).
→kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
basis
```

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
→kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate_
Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P_
basis
```

### km()

The monomial basis of the $k$-bounded quotient of symmetric functions, indexed by $k$-bounded partitions.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→ 2-bounded monomial basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
→ kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→ 2-bounded monomial basis

kmonomial()

The monomial basis of the \( k \)-bounded quotient of symmetric functions, indexed by \( k \)-bounded partitions.

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).kBoundedQuotient(3,t=1).
→ kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→ 2-bounded monomial basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
→ kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the...
→ 2-bounded monomial basis

lift (la)

Gives the lift map from the quotient ring of \( k \)-bounded symmetric functions to the symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- \( la \) – A \( k \)-bounded partition

OUTPUT:

- The monomial element or a Hall-Littlewood P element of the symmetric functions indexed by the partition \( la \).

EXAMPLES:

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.lift([[2,1]])
m[2, 1]
sage: Q = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: Q.lift([[2,1]])
HLP[2, 1]

>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.lift([[Integer(3), Integer(1)]])
m[2, 1]
>>> Q = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(3))
>>> Q.lift([[Integer(3), Integer(1)]])
HLP[2, 1]

5.1. Comprehensive Module List
one()

Returns the unit of the quotient ring of $k$-bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.one()
m3[]
```

realizations()

A list of realizations of the $k$-bounded quotient.

EXAMPLES:

```python
sage: kQ = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the 3-bounded monomial basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the 3-bounded affine Schur basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the dual 3-Schur basis]
sage: HLP = kQ.ambient().hall_littlewood().P()
sage: all( rzn(HLP[3,2,1]).lift() == HLP[3,2,1] for rzn in kQ.realizations() )
True
sage: kQ = SymmetricFunctions(QQ).kBoundedQuotient(3,1)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded monomial basis, 3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded Hall-Littlewood P basis, 3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded affine Schur basis, 3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the dual 3-Schur basis]
sage: m = kQ.ambient().m()
sage: all( rzn(m[3,2,1]).lift() == m[3,2,1] for rzn in kQ.realizations() )
True
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

of Univariate Polynomial Ring in t over Rational Field in the dual 3-Schur basis]

```python
>>> HLP = kQ.ambient().hall_littlewood().P()
```

```python
>>> all( rzn(HLP[Integer(3),Integer(2),Integer(1)]).lift() == HLP[Integer(3),
Integer(2),Integer(1)] for rzn in kQ.realizations() )
True
```

```python
>>> kQ = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),Integer(1))
```

```python
>>> kQ.realizations()[3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in
the 3-bounded monomial basis, 3-Bounded Quotient of Symmetric Functions
over Rational Field with t=1 in the 3-bounded Hall-Littlewood P basis, 3-
Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
3-bounded affine Schur basis, 3-Bounded Quotient of Symmetric Functions
over Rational Field with t=1 in the dual 3-Schur basis]
```

```python
>>> m = kQ.ambient().m()
```

```python
>>> all( rzn(m[Integer(3),Integer(2),Integer(1)]).lift() == m[Integer(3),
Integer(2),Integer(1)] for rzn in kQ.realizations() )
True
```

retract (\(\lambda a\))

Gives the retract map from the symmetric functions to the quotient ring of \(k\)-bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- \(\lambda a\) – A partition

OUTPUT:

- The monomial element of the \(k\)-bounded quotient indexed by \(\lambda a\).

EXAMPLES:

```python
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]
```

```python
>>> from sage.all import *
```

```python
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
```

```python
>>> Q.retract([Integer(2),Integer(1)])
m3[2, 1]
```

```
5.1. Comprehensive Module List
```

```python
class sage.combinat.sf.k_dual.KBoundedQuotientBases(base)
```

Bases: Category_realization_of_parent

The category of bases for the \(k\)-bounded subspace of symmetric functions.

```python
class ElementMethods
```

Bases: object

class ParentMethods
```

Bases: object

ambient()

Returns the symmetric functions.

EXAMPLES:
antipode (element)

Return the antipode of element via lifting to the symmetric functions and then retracting into the $k$-bounded quotient basis.

INPUT:
- element – an element in a basis of the ring of symmetric functions

EXAMPLES:

sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3[3,2].antipode()
-dks3[1, 1, 1, 1, 1]
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km[3,2].antipode()
m3[3, 2]
sage: km.antipode(km[3,2])
m3[3, 2]
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]

(continues on next page)
coproduct (element)

Return the coproduct of element via lifting to the symmetric functions and then returning to the \( k \)-bounded quotient basis. This method is implemented for all \( t \) but is (weakly) conjectured to not be the correct operation for arbitrary \( t \) because the coproduct on dual-\( k \)-Schur functions does not have a positive expansion.

INPUT:

• element – an element in a basis of the ring of symmetric functions

EXAMPLES:

sage: Q3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: km = Q3.km()
sage: km[3,2].coproduct() 
sage: dks3 = Q3.dual_k_Schur()
sage: dks3[2,2].coproduct() 
\( -t^2*dks3[1, 1, 1, 1, 1] + (t^2-1)*dks3[2, 2, 1] + (-t^5+t)*dks3[3, 2] \)
sage: km[3,2].coproduct()
sage: dks = Q3t.dks()
sage: dks[2,1,1].coproduct()
dks3[] # dks3[2, 1, 1] + (-t+1)*dks3[1] # dks3[1, 1, 1] + dks3[1] # dks3[2, 1]
sage: kHLP = Q3t.kHLP()
sage: kHLP[2,1].coproduct()
sage: km.coproduct(km[3,2])

from sage.all import *

Q3t = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(Integer(3))
km = Q3t.km()
kHLP = Q3t.kHLP()

km[Integer(3),Integer(2)].coproduct()

km.counit(f)
-3

from sage.all import *

km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(Integer(3)).km()
f = Integer(2)*km[Integer(2),Integer(1)] - Integer(3)*km([])
f.counit()
-3
degree_on_basis(b)

Return the degree of the basis element indexed by $b$.

INPUT:
• $b$ – a partition

EXAMPLES:

```python
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.degree_on_basis(Partition([3,2]))
5
```

indices()

The set of $k$-bounded partitions of all non-negative integers.

EXAMPLES:

```python
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.indices()
3-Bounded Partitions
```

lift(la)

Implements the lift map from the basis $self$ to the monomial basis of symmetric functions.

INPUT:
• $la$ – A $k$-bounded partition.

OUTPUT:
• A symmetric function in the monomial basis.

EXAMPLES:

```python
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.lift([[3,1]])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: Sym = SymmetricFunctions(QQ['t']).fraction_field()
sage: dks = Sym.kBoundedQuotient(3).dual_k_Schur()
sage: dks.lift([[3,1]])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]
sage: dks = Sym.kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks.lift([[3,1]])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```
>>> from sage.all import *

>>> F = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3), t=Integer(1)).affineSchur()
>>> F.lift([Integer(3), Integer(1)])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]

>>> Sym = SymmetricFunctions(QQ[t].fraction_field())
>>> dks = Sym.kBoundedQuotient(Integer(3)).dual_k_Schur()
>>> dks.lift([Integer(3), Integer(1)])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]

one_basis()

Return the basis element indexing 1.

EXAMPLES:

sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3, t=1).affineSchur()
sage: F.one()  # indirect doctest
F3[

product (x, y)

Returns the product of two elements x and y.

INPUT:
  • x, y – Elements of the $k$-bounded quotient of symmetric functions.

OUTPUT:
  • A $k$-bounded symmetric function in the dual $k$-Schur function basis

EXAMPLES:

sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3, t=1).dual_k_Schur()
sage: dks3.product(dks3[2, 1], dks3[1, 1])
2*dks3[1, 1, 1, 1] + 2*dks3[2, 1, 1, 1] + 2*dks3[2, 2, 1] + dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2, 1]+dks3[1], dks3[1, 1])
dks3[1, 1, 1, 1] + 2*dks3[2, 1, 1, 1] + dks3[2, 2, 1] + 2*dks3[2, 1, 1, 1] +
dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2, 1]+dks3[1], dks3[1])
dks3[1, 1, 1, 1] + 2*dks3[2, 1, 1, 1] + dks3[2, 2, 1] + 2*dks3[2, 1, 1, 1] +
dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2, 1], dks3[1, 1])
dks3[1, 1, 1, 1] + dks3[2, 1, 1, 1] + dks3[2, 2, 1] + dks3[2, 1, 1, 1] +
dks3[3, 1, 1] + dks3[3, 2]

\[\text{retract (la)} \]

Given the retract map from the symmetric functions to the quotient ring of $k$-bounded symmetric functions. This method is here to make the TestSuite run properly.

**INPUT:**

- la – A partition

**OUTPUT:**

- The monomial element of the $k$-bounded quotient indexed by la.

**EXAMPLES:**

\[\text{sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3, t=1)} \]
\[\text{sage: Q.retract([2, 1])} \]
\[m3[2, 1] \]
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.retract([Integer(2),Integer(1)])
\[m_3[2, 1] \]

**super_categories()**

The super categories of self.

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.k_dual import KBoundedQuotientBases
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: KQB = KBoundedQuotientBases(Q)
sage: KQB.super_categories()
[Category of realizations of 3-Bounded Quotient of Symmetric Functions over Rational Field, Univariate Polynomial Ring in \( t \) over Rational Field with \( t=1 \), Join of Category of graded Hopf algebras with basis over Univariate Polynomial Ring in \( t \) over Rational Field and Category of quotients of algebras over Univariate Polynomial Ring in \( t \) over Rational Field and Category of quotients of graded modules with basis over Univariate Polynomial Ring in \( t \) over Rational Field]
```
EXAMPLES:

```python
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.lift(Partition([3,1]))
m[3, 1]
sage: km.lift([])
m[]
sage: km.lift(Partition([4,1]))
Traceback (most recent call last):
...TypeError: do not know how to make x (= [4, 1]) an element of self (=3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded monomial basis)
```

```python
>>> from sage.all import *
>>> km = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).km()
>>> km.lift(Partition([Integer(3),Integer(1)]))
m[3, 1]
>>> km.lift([])
m[]
>>> km.lift(Partition([Integer(4),Integer(1)]))
Traceback (most recent call last):
...TypeError: do not know how to make x (= [4, 1]) an element of self (=3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-bounded monomial basis)
```

retract \((\lambda a)\)

Implements the retract function on the monomial basis. Given a partition \(\lambda a\), the retract will return the corresponding \(k\)-bounded monomial basis element if \(\lambda a\) is \(k\)-bounded; zero otherwise.

INPUT:

- \(\lambda a\) – A partition

OUTPUT:

- A \(k\)-bounded monomial symmetric function in the \(k\)-quotient of symmetric functions.

EXAMPLES:

```python
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
0
sage: km.retract([])
m3[]
sage: m = SymmetricFunctions(QQ).m()
sage: km(m[3, 1])
m3[3, 1]
sage: km(m[4, 1])
0
```

```python
>>> from sage.all import *
>>> km = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).km()
>>> km.retract(Partition([Integer(3),Integer(1)]))
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
m3[3, 1]

```

class sage.combinat.sf.k_dual.kbounded_HallLittlewoodP (kBoundedRing)
Bases: KBoundedQuotientBasis

The basis of P Hall-Littlewood symmetric functions indexed by partitions with first part less than or equal to \( k \).

**lift** *(la)*

Implements the lift function on the Hall-Littlewood P basis. Given a \( k \)-bounded partition \( la \), the lift will return the corresponding Hall-Littlewood P basis element.

**INPUT:**

- \( la \) – A \( k \)-bounded partition

**OUTPUT:**

- A Hall-Littlewood symmetric function.

**EXAMPLES:**
retract \(la\)

Implements the retract function on the Hall-Littlewood P basis. Given a partition \(la\), the retract will return the corresponding \(k\)-bounded Hall-Littlewood P basis element if \(la\) is \(k\)-bounded; zero otherwise.

**INPUT:**

- \(la\) – A partition

**OUTPUT:**

- A \(k\)-bounded Hall-Littlewood P symmetric function in the \(k\)-quotient of symmetric functions.

**EXAMPLES:**

```python
sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3).
   →kHallLittlewoodP()
sage: kHLP.retract(Partition([3,1]))
HLP3[3, 1]
sage: kHLP.retract(Partition([4,1]))
0
sage: kHLP.retract([])
HLP3[]
sage: m = kHLP.retract(Partition([2,2]))
(t^4-t^3-t+1)*HLP3[1, 1, 1, 1] + (t-1)*HLP3[2, 1, 1] + HLP3[2, 2]
```
5.1.290 Kostka-Foulkes Polynomials

Based on the algorithms in John Stembridge’s SF package for Maple which can be found at http://www.math.lsa.umich.edu/~jrs/maple.html.

`sage.combinat.sf.kfpoly.KostkaFoulkesPolynomial(mu, nu, t=None)`

Returns the Kostka-Foulkes polynomial $K_{\mu, \nu}(t)$.

**INPUT:**

- $\mu, \nu$ – partitions
- $t$ – an optional parameter (default: None)

**OUTPUT:**

- the Kostka-Foulkes polynomial indexed by partitions $\mu$ and $\nu$ and evaluated at the parameter $t$. If $t$ is None the resulting polynomial is in the polynomial ring $\mathbb{Z}[[t]]$.

**EXAMPLES:**

```python
sage: KostkaFoulkesPolynomial([2,2],[2,2])
1
sage: KostkaFoulkesPolynomial([2,2],[4])
0
sage: KostkaFoulkesPolynomial([2,2],[1,1,1,1])
t^4 + t^2
sage: KostkaFoulkesPolynomial([2,2],[2,1,1,1])
t
sage: q = PolynomialRing(QQ,'q').gen()
sage: KostkaFoulkesPolynomial([2,2],[2,1,1],q)
q
```

```python
>>> from sage.all import *
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(2),Integer(2)])
1
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(4)])
0
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(1),Integer(1),Integer(1)])
t^4 + t^2
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(2),Integer(1),Integer(1)])
t
>>> q = PolynomialRing(QQ,'q').gen()
```

(continues on next page)
sage.combinat.sf.kfpoly.compat(n, mu, nu)

Generate all possible partitions of $n$ that can precede $\mu, \nu$ in a rigging sequence.

**INPUT:**
- $n$ – a positive integer
- $\mu, \nu$ – partitions

**OUTPUT:**
- a list of partitions

**EXAMPLES:**

```sage
from sage.combinat.sf.kfpoly import *
sage: compat(4, [1], [2,1])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
sage: compat(3, [1], [2,1])
[[1, 1, 1], [2, 1], [3]]
sage: compat(2, [1], [])
[[2]]
sage: compat(3, [1], [])
[[2, 1], [3]]
sage: compat(3, [2], [1])
[[3]]
sage: compat(4, [1,1], [])
[[2, 2], [3, 1], [4]]
sage: compat(4, [2], [])
[[4]]
```

sage.combinat.sf.kfpoly.dom(mup, snu)

Return `True` if $\text{sum}(\mu[:i+1]) \geq \text{snu}[i]$ for all $0 \leq i < \text{len}(\text{snu})$; otherwise, it returns `False`.

**INPUT:**
- $\mu$ – a partition conjugate to $\mu$
- $\text{snu}$ – a sequence of positive integers
OUTPUT:

• a boolean value

EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import *
sage: dom([3,2,1],[2,4,5])
True
sage: dom([3,2,1],[2,4,7])
False
sage: dom([3,2,1],[2,6,5])
False
sage: dom([3,2,1],[4,4,4])
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import *
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(4),Integer(5)])
True
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(4),Integer(7)])
False
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(6),Integer(5)])
False
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(4),Integer(4),Integer(4)])
False
```

`sage.combinat.sf.kfpoly.kfpoly(mu, nu, t=None)`

Return the Kostka-Foulkes polynomial $K_{\mu, \nu}(t)$ by generating all rigging sequences for the shape $\mu$, and then selecting those of content $\nu$.

INPUT:

• $\mu, \nu$ – partitions

• $t$ – an optional parameter (default: None)

OUTPUT:

• the Koskta-Foulkes polynomial indexed by partitions $\mu$ and $\nu$ and evaluated at the parameter $t$. If $t$ is None the resulting polynomial is in the polynomial ring $\mathbb{Z}[t']$.

EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import kfpoly
sage: kfpoly([2,2], [2,1,1])
t
sage: kfpoly([4], [2,1,1])
t^3
sage: kfpoly([4], [2,2])
t^2
sage: kfpoly([1,1,1,1], [2,2])
0
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import kfpoly

>>> kfpoly([Integer(2),Integer(2)],[Integer(2),Integer(1),Integer(1)])
t
>>> kfpoly([Integer(4)],[Integer(2),Integer(1),Integer(1)])
t^3
```

(continues on next page)
sage.combinat.sf.kfpoly.rigging(part)

Generate all possible rigging sequences for a fixed partition part.

INPUT:

• part – a partition

OUTPUT:

• a list of riggings associated to the partition part

EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import *
sage: riggings([3])
[[[1, 1, 1], [[2, 1]], [[3]]]
sage: riggings([2,1])
[[[2, 1], [[3], [1]]]
sage: riggings([1,1,1])
[[[3], [[2], [1]]]
sage: riggings([2,2])
[[[2, 2], [[1, 1]]],
[[4], [[2, 1]], [[1, 1]]],
[[5], [[2, 2], [[1, 1]]],
[[6], [[2, 2], [[1, 1]]],
[[5], [[3, 1], [[1, 1]]],
[[6], [[3, 1], [[1, 1]]],
[[6], [[4], [2]]]]
```
• $\mu$ – a partition
• $t$ – an optional parameter (default: the generator from $\mathbb{Z}[[t]]$)

OUTPUT:
• a dictionary with the coefficients $K_{\mu\nu}(t)$ for $\nu$ smaller in dominance order than $\mu$

EXAMPLES:

```python
sage: from sage.combinat.sf.kfpoly import *
sage: schur_to_hl([1,1,1])
([[1, 1, 1], 1])
sage: a = schur_to_hl([2,1])
sage: for mc in sorted(a.items()): print(mc)
(([1, 1, 1], t^2 + t), ([2, 1], 1))
sage: a = schur_to_hl([3])
sage: for mc in sorted(a.items()): print(mc)
(([1, 1, 1], t^3), ([2, 1], t), ([3], 1))
sage: a = schur_to_hl([4])
sage: for mc in sorted(a.items()): print(mc)
(([1, 1, 1, 1], t^6), ([2, 1, 1], t^5 + t^4 + t^3)

sage: a = schur_to_hl([3,1])
sage: for mc in sorted(a.items()): print(mc)
(([1, 1, 1, 1], t^5 + t^4 + t^3), ([2, 1, 1], t^2 + t))
sage: a = schur_to_hl([2,2])
sage: for mc in sorted(a.items()): print(mc)
(([1, 1, 1, 1], t^4 + t^2), ([2, 1, 1], t))
sage: a = schur_to_hl([2,1,1])
sage: for mc in sorted(a.items()): print(mc)
(([1, 1, 1, 1], t^3 + t^2 + t), ([2, 2], 1))
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import *
>>> schur_to_hl([[Integer(1),Integer(1),Integer(1)]])
[[1, 1, 1], 1]
>>> a = schur_to_hl([Integer(2),Integer(1)])
```
(continues on next page)
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1], t^2 + t)
  ([2, 1, 1], 1)
>>> a = schur_to_hl([Integer(3)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1], t^3)
  ([2, 1], t)
  ([3], 1)
>>> a = schur_to_hl([Integer(4)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1, 1], t^6)
  ([2, 1, 1], t^3)
  ([2, 2], t^2)
  ([3, 1], t)
  ([4], 1)
>>> a = schur_to_hl([Integer(3),Integer(1)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1, 1], t^5 + t^4 + t^3)
  ([2, 1, 1], t^2 + t)
  ([3, 1], 1)
>>> a = schur_to_hl([Integer(2),Integer(2)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1, 1], t^4 + t^2)
  ([2, 1, 1], t)
  ([2, 2], 1)
>>> a = schur_to_hl([Integer(2),Integer(1),Integer(1)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1, 1], t^3 + t^2 + t)
  ([2, 1, 1], 1)
>>> a = schur_to_hl([Integer(1),Integer(1),Integer(1),Integer(1)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1, 1])
>>> a = schur_to_hl([Integer(2),Integer(2),Integer(2)])
>>> for mc in sorted(a.items()): print(mc)
  ([1, 1, 1, 1, 1, 1], t^9 + t^7 + t^6 + t^5 + t^3)
  ([2, 1, 1, 1, 1], t^4 + t^2)
  ([2, 2, 1, 1], t)
  ([2, 2, 2], 1)

sage.combinat.sf.kfpoly.weight(rg,t=None)

Return the weight of a rigging.

INPUT:

- rg – a rigging, a list of partitions
- t – an optional parameter, (default: the generator from \(\mathbb{Z}[\tau]\))

OUTPUT:

- a polynomial in the parameter \(t\)

EXAMPLES:

sage: from sage.combinat.sf.kfpoly import weight
sage: weight([[2,1], [1]])
1
`sage: weight([[3], [1]])
t^2 + t`

`sage: weight([[2,1], [3]])
t^4`

`sage: weight([[2, 2], [1, 1]])
1`

`sage: weight([[3, 1], [1, 1]])
t`

`sage: weight([[4], [1, 1]], 2)
16`

`sage: weight([[4], [2]], t=2)
4`

```python
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import weight

>>> weight([[Integer(2),Integer(1)], [Integer(1)]]
1

>>> weight([[Integer(3)], [Integer(1)]]
t^2 + t

>>> weight([[Integer(2),Integer(1)], [Integer(3)]]
t^4

>>> weight([[Integer(2), Integer(2)], [Integer(1), Integer(1)]]
1

>>> weight([[Integer(3), Integer(1)], [Integer(1), Integer(1)]]
t

>>> weight([[Integer(4)], [Integer(2)]]
16

>>> weight([[Integer(4)], [Integer(2)], t=Integer(2)]
4
```

### 5.1.291 LLT symmetric functions

**REFERENCES:**

```python
class sage.combinat.sf.llt.**LLT_class** (Sym, k, t)

Bases: UniqueRepresentation

A class for working with LLT symmetric functions.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3); L3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: HC3 = L3.hcospin(); HC3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT cospin basis
sage: m = Sym.monomial()
sage: m( HC3[1,1] )
(t+1)*m[1, 1] + m[2]
```
We require that the parameter $t$ must be in the base ring:

```
sage: Symxt = SymmetricFunctions(QQ['x','t'].fraction_field())
sage: (x,t) = Symxt.base_ring().gens()
sage: LLT3x = Symxt.llt(Integer(3),t=x)
sage: LLT3 = Symxt.llt(Integer(3))
sage: HS3x = LLT3x.hspin()
sage: HS3t = LLT3.hspin()
sage: s = Symxt.schur()
sage: s(HS3x[2,1])
s[2, 1] + x*s[3]
sage: s(HS3t[2,1])
s[2, 1] + t*s[3]
sage: HS3x(HS3t[2,1])
HSp3[2, 1] + (-x+t)*HSp3[3]
sage: s(HS3x(HS3t[2,1]))
s[2, 1] + t*s[3]
sage: LLT3t2 = Symxt.llt(Integer(3),t=Integer(2))
sage: HC3t2 = LLT3t2.hcospin()
sage: HS3x(HC3t2[3,1])
2*HSp3[3, 1] + (-2*x+1)*HSp3[4]
```
Returns the base ring of self.

INPUT:

• self – a family of LLT symmetric functions bases

OUTPUT:

• returns the base ring of the symmetric function ring associated to self

EXAMPLES:

```python
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```python
>>> from sage.all import *

>>> SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

cospin (skp)

Calculate a single instance of the cospin symmetric functions.

These are the functions defined in [LLT1997] equation (26).

INPUT:

• self – a family of LLT symmetric functions bases

• skp – a partition or a list of partitions or a list of skew partitions

OUTPUT:

the monomial expansion of the LLT symmetric function cospin functions indexed by skp

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3)
sage: L3.cospin([2, 1])
m[1]
sage: L3.cospin([3, 2, 1])
(t+1)*m[1, 1] + m[2]
sage: s = Sym.schur()
sage: s(L3.cospin([[2],[1],[2]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))

>>> L3 = Sym.llt(Integer(3))

>>> L3.cospin([Integer(2),Integer(1)])
m[1]

>>> L3.cospin([[Integer(3),Integer(2),Integer(1)]])
(t+1)*m[1, 1] + m[2]

>>> s = Sym.schur()

>>> s(L3.cospin([[Integer(2)],[Integer(1)],[Integer(2)]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

hcospin ()

Returns the HCospin basis. This basis is defined [LLT1997] equation (27).

INPUT:
• self – a family of LLT symmetric functions bases

OUTPUT:

• returns the h-cospin basis of the LLT symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HCos3 = Sym.llt(3).hcospin(); HCos3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣→ over Rational Field in the level 3 LLT cospin basis
sage: HCos3([1])^2
1/t*HCos3[1, 1] + ((t-1)/t)*HCos3[2]

sage: s = Sym.schur()
sage: HCos3(s([2]))
HCos3[2]

sage: HCos3(s([1,1]))
1/t*HCos3[1, 1] - 1/t*HCos3[2]

sage: s(s(HCos3([2,1])))
t*s[2, 1] + s[3]
```

```
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))

>>> HCos3 = Sym.llt(Integer(3)).hcospin(); HCos3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣→ over Rational Field in the level 3 LLT cospin basis

>>> HCos3([Integer(1)])**Integer(2)
1/t*HCos3[1, 1] + ((t-1)/t)*HCos3[2]

>>> s = Sym.schur()

>>> HCos3(s([Integer(2)]))
HCos3[2]

>>> HCos3(s([Integer(1),Integer(1)]))
1/t*HCos3[1, 1] - 1/t*HCos3[2]

>>> s(s(HCos3([Integer(2),Integer(1)])))
t*s[2, 1] + s[3]
```

**hspin()**

Returns the HSpin basis. This basis is defined [LLT1997] equation (28).

INPUT:

• self – a family of LLT symmetric functions bases

OUTPUT:

• returns the h-spin basis of the LLT symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HSp3 = Sym.llt(3).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣→ over Rational Field in the level 3 LLT spin basis
sage: HSp3([1])^2
HSp3[1, 1] + (-t+1)*HSp3[2]

sage: s = Sym.schur()
```

(continues on next page)
```python
sage: HSp3(s([2]))
HSp3[2]
sage: HSp3(s([1,1]))
HSp3[1, 1] - t*HSp3[2]
sage: s(HSp3([[2,1]]))
s[2, 1] + t*s[3]
```

```python
>>> from sage.all import *

```Sympy = SymmetricFunctions(FractionField(QQ['t']))

```HSp3 = Sym.llt(Integer(3)).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
˓→over Rational Field in the level 3 LLT spin basis

```HSp3([[Integer(1)])]**Integer(2)
HSp3[1, 1] + (-t+1)*HSp3[2]

```s = Sym.schur()

```HSp3(s([[Integer(2)]]))
HSp3[2]
sage: HSp3(s([[Integer(1),Integer(1)]))
HSp3[1, 1] - t*HSp3[2]
sage: s(HSp3([[Integer(2),Integer(1)]))
s[2, 1] + t*s[3]
```

**level()**

Returns the level of `self`.

**INPUT:**

- `self` – a family of LLT symmetric functions bases

**OUTPUT:**

- the level is the parameter of $k$ in the basis

**EXAMPLES:**

```python
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).level()
3

```from sage.all import *

```SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).level()
3
```

**spin_square** (`skp`)

Calculate a single instance of a spin squared LLT symmetric function associated with a partition, list of partitions, or a list of skew partitions.

This family of symmetric functions is defined in [LT2000] equation (43).

**INPUT:**

- `self` – a family of LLT symmetric functions bases
- `skp` – a partition of a list of partitions or a list of skew partitions

**OUTPUT:**

the monomial expansion of the LLT symmetric function spin-square functions indexed by `skp`

**EXAMPLES:**
```python
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.spin_square([2,1])
t*m[1]
sage: L3.spin_square([3,2,1])
(t^3+t)*m[1, 1] + t^3*m[2]
sage: L3.spin_square([[1],[1],[1]])
(2*t^4+3*t^2+1)*m[1, 1, 1] + (t^4+t^2)*m[2, 1, 1] + t^4*m[2, 2]
```

```python
>>> from sage.all import *
>>> L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3))
>>> L3.spin_square([Integer(2),Integer(1)])
t*m[1]
>>> L3.spin_square([Integer(3),Integer(2),Integer(1)])
(t^3+t)*m[1, 1] + t^3*m[2]
```

```python
symmetric_function_ring()
```

The symmetric function algebra associated to the family of LLT symmetric function bases

INPUT:

- self – a family of LLT symmetric functions bases

OUTPUT:

- returns the symmetric function ring associated to self.

EXAMPLES:

```python
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.symmetric_function_ring()
symmetric functions over Fraction Field of Univariate Polynomial Ring in t
- over Rational Field
```

```python
>>> from sage.all import *
>>> L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3))
>>> L3.symmetric_function_ring()
symmetric functions over Fraction Field of Univariate Polynomial Ring in t
- over Rational Field
```

```python
class sage.combinat.sf.llt.LLT_cospin(llt)
```

A class of methods for the h-cospin LLT basis of the symmetric functions.

INPUT:

- self – an instance of the LLT h-cospin basis
- llt – a family of LLT symmetric function bases

```python
class Element
```

Bases: Element
```
```
class sage.combinat.sf.llt.LLT_generic(llt, prefix)

Bases: SymmetricFunctionAlgebra_generic

A class of methods which are common to both the hspin and hcospin of the LLT symmetric functions.

INPUT:

- self – an instance of the LLT hspin or hcospin basis
- llt – a family of LLT symmetric functions

EXAMPLES:

```python
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT spin basis
sage: SymmetricFunctions(QQ).llt(3,t=2).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
sage: QQz = FractionField(QQ['z']); z = QQz.gen()
sage: SymmetricFunctions(QQz).llt(3,t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over Rational Field in the level 3 LLT spin with t=z basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the level 3 LLT spin basis
>>> SymmetricFunctions(QQ).llt(Integer(3),t=Integer(2)).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
>>> QQz = FractionField(QQ['z']); z = QQz.gen()
>>> SymmetricFunctions(QQz).llt(Integer(3),t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over Rational Field in the level 3 LLT spin with t=z basis
```

class Element

Bases: SymmetricFunctionAlgebra_generic_Element

collection()

Return a pair \((F, R)\), where \(F\) is a SymmetricFunctionsFunctor and \(R\) is a ring, such that \(F(R)\) returns self.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HSp3 = Sym.llt(3).hspin()
sage: HSp3.construction()
(SymmetricFunctionsFunctor[level 3 LLT spin], Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HSp3 = Sym.llt(Integer(3)).hspin()
>>> HSp3.construction()
(SymmetricFunctionsFunctor[level 3 LLT spin], Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

level()

Returns the level of self.

INPUT:
• self – an instance of the LLT hspin or hcospin basis

OUTPUT:

• returns the level associated to the basis self.

EXAMPLES:

```sage
HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
HSp3.level()
```

```sage
>>> from sage.all import *
>>> HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
>>> HSp3.level()
```

`llt_family()`

The family of the llt bases of the symmetric functions.

INPUT:

• self – an instance of the LLT hspin or hcospin basis

OUTPUT:

• returns an instance of the family of LLT bases associated to self.

EXAMPLES:

```sage
HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
HSp3.llt_family()
```

```sage
>>> from sage.all import *
>>> HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
>>> HSp3.llt_family()
```

`product(left, right)`

Convert to the monomial basis, do the multiplication there, and convert back to the basis self.

INPUT:

• self – an instance of the LLT hspin or hcospin basis

• left, right – elements of the symmetric functions

OUTPUT:

the product of left and right expanded in the basis self

EXAMPLES:

```sage
HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
HSp3.product(HSp3([1]), HSp3([2]))
```

```sage
HCosp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hcospin()
HCosp3.product(HCosp3([1]), HSp3([2]))
```

5.1. Comprehensive Module List 4637
class sage.combinat.sf.llt.LLT_spin(llt)
Bases: LLT_generic

A class of methods for the h-spin LLT basis of the symmetric functions.

INPUT:

- self – an instance of the LLT hcospin basis
- llt – a family of LLT symmetric function bases

class Element
Bases: Element

5.1.292 Macdonald Polynomials

Notation used in the definitions follows mainly [Mac1995].

The integral forms of the bases $H$ and $H_t$ do not appear in Macdonald's book. They correspond to the two bases

\[ H_\mu[X;q,t] = \sum_\nu K_{\nu\mu}(q,t)s_\mu[X] \]

and

\[ H_\mu[X; q, t] = t^{n(\mu)} \sum_\nu K_{\nu\mu}(q, 1/t)s_\nu[X] \]

where $K_{\nu\mu}(q, t)$ are the Macdonald $q, t$-Koszta coefficients.

The $H_t$ in this case is short for $\tilde{H}$ and is the basis which is the graded Frobenius image of the Garsia-Haiman modules [GH1993].

REFERENCES:

- [Mac1995]
class sage.combinat.sf.macdonald.Macdonald(Sym, q, t)
Bases: UniqueRepresentation

Macdonald Symmetric functions including $P, Q, J, H, H_t$ bases also including the S basis which is the plethystic transformation of the Schur basis (that which is dual to the Schur basis with respect to the Macdonald $q, t$-scalar product)

INPUT:

- self – a family of Macdonald symmetric function bases

EXAMPLES:

```
sage: t = QQ['t'].gen(); SymmetricFunctions(QQ['t']).fraction_field().
   -macdonald(q=t, t=1)
Macdonald polynomials with q=t and t=1 over Fraction Field of Univariate...
   -Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(FractionField(QQ['t'])).macdonald()
Traceback (most recent call last):
...
TypeError: unable to evaluate 'q' in Fraction Field of Univariate Polynomial Ring...
   -in t over Rational Field
```
H()

Returns the Macdonald polynomials on the H basis. When the $H$ basis is expanded on the Schur basis, the coefficients are the $qt$-Kostka numbers.

INPUT:

• `self` – a family of Macdonald symmetric function bases

OUTPUT:

• returns the $H$ Macdonald basis of symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: H = Sym.macdonald().H(); H
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald H basis
sage: s = Sym.schur()
sage: s(H([2]))
q*s[1, 1] + s[2]
sage: s(H([1,1]))
s[1, 1] + t*s[2]
```

Coercions to/from the Schur basis are implemented:

```python
sage: H = Sym.macdonald().H()
sage: s = Sym.schur()
sage: H(s([2]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]
```

```python
sage: H = Sym.macdonald().H()
sage: s = Sym.schur()
sage: H(s([Integer(2)]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]
```
**Ht()**

Returns the Macdonald polynomials on the \(H_t\) basis. The elements of the \(H_t\) basis are eigenvectors of the \(\nabla\) operator. When expanded on the Schur basis, the coefficients are the modified \(qt\)-Kostka numbers.

**INPUT:**

- \(\text{self}\) – a family of Macdonald symmetric function bases

**OUTPUT:**

- returns the \(H_t\) Macdonald basis of symmetric functions

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Ht basis

sage: [Ht(p).nabla() for p in Partitions(3)]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]

>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Ht basis

>>> [Ht(p).nabla() for p in Partitions(Integer(3))]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]

sage: s = Sym.schur()
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: q,t = Ht.base_ring().gens()
sage: s(Ht([2,1]))
q*t*s[1, 1, 1] + (q+t)*s[2, 1] + s[3]

sage: qt_kostka([1,1,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q*t

sage: qt_kostka([2,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q + t

sage: qt_kostka([3],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
1
```

Coercions to/from the Schur basis are implemented:
\( J() \)

Returns the Macdonald polynomials on the \( J \) basis also known as the integral form of the Macdonald polynomials. These are scalar multiples of both the \( P \) and \( Q \) bases. When expressed in the \( P \) or \( Q \) basis, the scaling coefficients are polynomials in \( q \) and \( t \) rather than rational functions.

The \( J \) basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the \( S \)-basis [LLM1998].

**INPUT:**

- \textit{self} – a family of Macdonald symmetric function bases

**OUTPUT:**

- returns the \( J \) Macdonald basis of symmetric functions

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: J = Sym.macdonald().J(); J
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald J basis
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: P(J([2]))
(q^2*t^2-q*t-t+1)*McdP[2]
sage: P(J([1,1]))
t^3-t^2+t+1)*McdP[1, 1]
sage: Q(J([2]))
(q^2-t^2-q+1)*McdQ[2]
sage: Q(J([1,1]))
(q^2*t^2-t^2+t+1)*McdQ[1, 1]
```

(continues on next page)
\[(q^3 - q^2 - q + 1) \cdot \text{McdP}[2] \]
\[(q^2t - q^t - q + 1) \cdot \text{McdQ}[1, 1] \]

Coercions from the \(Q\) and \(J\) basis (proportional) and to/from the Schur basis are implemented:

```
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
sage: J(P([2]))
(1/(q^t^2-q^t-t+1))*McdJ[2]
```

```
sage: from sage.all import *
```

```
sage: J(P([Integer(2)]))
(1/(q^t^2-q^t-t+1))*McdJ[2]
```

```
sage: Q([2])
(1/(q^3-q^2-q+1))*McdJ[2]
```

```
sage: J(s([2]))
((-q^t+t^2+q-t)*s[1, 1] + (q^t^2-q^t-t+1)*s[2])
sage: J(s([2]))
((q-t)/(q^t^4-q^t^3-q^t^2-q^t+q^t^2+q^t+q^t+1))*McdJ[1, 1] + (1/(q^t^2-q^t-t+1))*McdJ[2]
```

```
sage: from sage.all import *
```

```
sage: J(s([Integer(2)]))
((-q^t+t^2+q-t)*s[1, 1] + (q^t^2-q^t-t+1)*s[2])
sage: J(s([Integer(2)]))
((q-t)/(q^t^4-q^t^3-q^t^2-q^t+q^t^2+q^t+q^t+1))*McdJ[1, 1] + (1/(q^t^2-q^t-t+1))*McdJ[2]
```

\(P()\)

Returns Macdonald polynomials in \(P\) basis. The \(P\) basis is defined here as a normalized form of the \(J\) basis.

INPUT:

- \(\text{self}\) – a family of Macdonald symmetric function bases
OUTPUT:

• returns the $P$ Macdonald basis of symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣...
˓→t over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
```

The $P$ Macdonald basis is upper triangularly related to the monomial symmetric functions and are orthogonal with respect to the $qt$-Hall scalar product:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣...
˓→t over Rational Field in the Macdonald P basis
sage: m = Sym.monomial()
sage: P.transition_matrix(m,2)
[ 1 (q*t - q + t - 1)/(q*t - 1)]
[ 0 1]
sage: P([1,1]).scalar_qt(P([2]))
0
sage: P([2]).scalar_qt(P([2]))
(-q^3 + q^2 + q - 1)/(-q*t^2 + q*t + t - 1)
sage: P([1,1]).scalar_qt(P([1,1]))
(-q^2*t + q*t + q - 1)/(-t^3 + t^2 + t - 1)
```

When $q = 0$, the Macdonald polynomials on the $P$ basis are the same as the Hall-Littlewood polynomials on the $P$ basis.
```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.macdonald(q=0).P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field in the Macdonald P with q=0 basis
sage: P([2])**2
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])**2
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
```

Coercions from the \( Q \) and \( J \) basis (proportional) are implemented:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()

>>> from sage.all import *

>>> P(Q([2]))
((q*t^2-q*t-t+1)/(q^3-q^2-q+1))*McdP[2]
>>> P(Q([2,1]))
((-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1)/(-q^4*t+2*q^3*t-q^2*t+q^2-2*q+1))*McdP[2, 1]

>>> from sage.all import *

>>> P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
```

(continues on next page)
By transitivity, one gets coercions from the classical bases:

```
sage: P(s([2]))
((q-t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P(s([2,1]))
((q*t-t^2+q-t)/(q*t^2-1))*McdP[1, 1, 1] + McdP[2, 1]
```

```
from sage.all import *
```

```
sage: Sym = SymmetricFunctions(QQ['x','y','z'].fraction_field())
sage: (x,y,z) = Sym.base_ring().gens()
sage: Macxy = Sym.macdonald(q=x,t=y)
sage: Macyz = Sym.macdonald(q=y,t=z)
sage: Maczx = Sym.macdonald(q=z,t=x)
sage: P1 = Macxy.P()
sage: P2 = Macyz.P()
sage: P3 = Maczx.P()
sage: m(P1[2,1])
((-2*x*y^2+x*y-y^2+x-y+2)/(-x*y^2+1))*m[1, 1, 1] + m[2, 1]
sage: m(P2[2,1])
((-2*y*z^2+y*z-z^2+y-z+2)/(-y*z^2+1))*m[1, 1, 1] + m[2, 1]
sage: m(P1(P2[P3[2,1]]))
((-x*y^2+2*x*y*z-y^2*z-x^2)*y^2*z-x*y*z^2+y^2*z^2-x^2*y^2-2*x*y*z-y*z^2+x*y-y-→y*z+x+z)/(x*y^2*z-x*y-y*z+1)))*m[1, 1] + (x+z)*m[2]
```

```
from sage.all import *
```

```
sage: m(z*P1[2]+x*P2[2])
((x^2*y^2*z+x*y^2*z^2-x^2*y^2+x^2*y*z-x*y*z^2+y^2*z^2-x^2*y^2-2*x*y*z-y*z^2+x*y-→y*z+x+z)/(x*y^2*z-x*y-y*z+1))*m[1, 1] + (x+z)*m[2]
```
\texttt{Q()} 

Returns the Macdonald polynomials on the \(Q\) basis. These are dual to the Macdonald polynomials on the \(P\) basis with respect to the \(qt\)-Hall scalar product. The \(Q\) basis is defined to be a normalized form of the \(J\) basis.

**INPUT:**

- \texttt{self} – a family of Macdonald symmetric function bases

**OUTPUT:**

- returns the \(Q\) Macdonald basis of symmetric functions

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Q basis
sage: P = Sym.macdonald().P()
sage: Q([2]).scalar_qt(P([2]))
1
sage: Q([2]).scalar_qt(P([1,1]))
0
sage: Q([1,1]).scalar_qt(P([2]))
0
sage: Q([1,1]).scalar_qt(P([1,1]))
1
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: Q(P([1,1]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]
```

Coercions from the \(P\) and \(J\) basis (proportional) are implemented:

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Q basis
>>> P = Sym.macdonald().P()
>>> Q([Integer(2)]).scalar_qt(P([Integer(2)]))
1
>>> Q([Integer(2)]).scalar_qt(P([Integer(1),Integer(1)]))
0
>>> Q([Integer(1),Integer(1)]).scalar_qt(P([Integer(2)]))
0
>>> Q([Integer(1),Integer(1)]).scalar_qt(P([Integer(1),Integer(1)]))
1
>>> Q(P([Integer(2)]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
>>> Q(P([Integer(1),Integer(1)]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]
```
>>> from sage.all import *
>>> P = Sym.macdonald().P()
>>> Q = Sym.macdonald().Q()
>>> J = Sym.macdonald().J()
>>> s = Sym.schur()

sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]

>>> from sage.all import *
>>> Q(J([Integer(2)]))
(q^3-q^2-q+1)*McdQ[2]

sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]

sage: P(Q(P([2])))
McdP[2]

sage: Q(P(Q([2])))
McdQ[2]

>>> from sage.all import *
>>> Q(P([Integer(2)]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]

By transitivity, one gets coercions from the classical bases:

sage: Q(s([2]))
(((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdQ[1, 1] + ((q^3-q^2-q+1)/(q*t^2-q*t-
→t+1))*McdQ[2]

S()

Returns the modified Schur functions defined by the plethystic substitution \( S_\mu = s_\mu[X(1-t)/(1-q)]. \) When the Macdonald polynomials in the J basis are expressed in terms of the modified Schur functions at \( q = 0, \) the coefficients are \( qt-\)Kostka numbers.

INPUT:

- self – a family of Macdonald symmetric function bases

OUTPUT:

- returns the \( S \) Macdonald basis of symmetric functions

EXAMPLES:

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S(); S
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t,
Coercions to/from the Schur basis are implemented:

```python
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
```
sage: `s((\(\text{[2]}\)))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-1))*McdS[2]
sage: `s((\([1,1]\)))
((-q^2*t+q*t+t-1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-1))*s[2]

```python
>>> from sage.all import *
>>> S = Sym.macdonald().S()
>>> s = Sym.schur()
>>> S(s((Integer(2)))))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-1))*McdS[2]
>>> s(S((Integer(1),Integer(1)))))
((-q^2*t^2+q*t+t-1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-1))*s[2]
```
```python
>>> from sage.all import *
>>> Mac = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=Integer(0))
>>> Mac.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q→over Rational Field
```

```python
class sage.combinat.sf.macdonald.MacdonaldPolynomials_generic(macdonald)
    
Bases: SymmetricFunctionAlgebra_generic

A class for methods for one of the Macdonald bases of the symmetric functions

INPUT:

- `self` – a Macdonald basis
- `macdonald` – a family of Macdonald symmetric function bases

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename("Sym"); Sym
Sym
sage: Sym.macdonald().P()
Sym in the Macdonald P basis
sage: Sym.macdonald(t=Integer(2)).P()
Sym in the Macdonald P with t=2 basis
sage: Sym.rename()
```
```
```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename("Sym"); Sym
>>> Sym.macdonald().P()
Sym in the Macdonald P basis
>>> Sym.macdonald(t=Integer(2)).P()
Sym in the Macdonald P with t=2 basis
>>> Sym.rename()
```
```
```python
class Element
    
Bases: SymmetricFunctionAlgebra_generic.Element

nabla (q=None, t=None, power=1)

Return the value of the nabla operator applied to self.

The eigenvectors of the nabla operator are the Macdonald polynomials in the $Ht$ basis. For more information see: [BGHT1999].

The operator nabla acts on symmetric functions and has the Macdonald $Ht$ basis as eigenfunctions and the eigenvalues are $q^{n(\mu')} t^{n(\mu)}$ where $n(\mu) = \sum (i-1)\mu_i$, and $\mu'$ is the conjugate shape of $\mu$.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `self` – an element of a Macdonald basis
- `q, t` – optional parameters to specialize
- `power` – an integer (default: 1)

OUTPUT:

- returns the symmetric function of $\nabla$ acting on `self`

EXAMPLES:

```python
```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P([1,1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P([1,1]).nabla(t=1)
((q^2*t+q*t^2-1)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: H = Sym.macdonald().H()
sage: H([1,1]).nabla()
t*McdH[1, 1] + (-t^2+1)*McdH[2]
sage: H([1,1]).nabla(q=1)
((t^2+q*t^2-1)/(q*t-1))*McdH[1, 1] + ((-t^3+t^2*t-1)/(q*t-1))*McdH[2]
sage: H(0).nabla()
0
sage: H([2,2,1]).nabla(t=1/H.t)
((-q^2)/(-t^4))*McdH[2, 2, 1]

>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> P([1,1,1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
>>> P([1,1,1]).nabla(q=1)
((q^2*t+q*t^2-1)/(q*t-1))*McdP[1, 1] + McdP[2]
>>> H = Sym.macdonald().H()

```
c1(part)

Returns the qt-Hall scalar product between J(part) and P(part).

INPUT:

  • self – a Macdonald basis
  • part – a partition

OUTPUT:

  • returns the qt-Hall scalar product between J(part) and P(part)

EXAMPLES:

sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.c1(Partition([2,1]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
>>> P = Sym.macdonald().P()
>>> P.c1(Partition([Integer(2), Integer(1)]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

c2 (part)

Returns the \(qt\)-Hall scalar product between \(J(part)\) and \(Q(part)\).

INPUT:
- **self** – a Macdonald basis
- **part** – a partition

OUTPUT:
- returns the \(qt\)-Hall scalar product between \(J(part)\) and \(Q(part)\)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
sage: P = Sym.macdonald().P()
sage: P.c2(Partition([2,1]))
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

construction()

Return a pair \((F, R)\), where \(F\) is a `SymmetricFunctionsFunctor` and \(R\) is a ring, such that \(F(R)\) returns `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: J = Sym.macdonald(t=Integer(2)).J()
sage: J.construction()
(SymmetricFunctionsFunctor[Macdonald J with t=2],
 Fraction Field of Univariate Polynomial Ring in q over Rational Field)
```

macdonald_family()

Returns the family of Macdonald bases associated to the basis `self`

INPUT:
- **self** – a Macdonald basis

OUTPUT:
• the family of Macdonald symmetric functions associated to self

EXAMPLES:

```
sage: MacP = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0).P()
sage: MacP.macdonald_family()
```

Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial Ring in q over Rational Field

```
>>> from sage.all import *

>>> MacP = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=Integer(0)).P()

>>> MacP.macdonald_family()
```

Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial Ring in q over Rational Field

```
product (left, right)
```

Multiply an element of the Macdonald symmetric function basis self and another symmetric function

Convert to the Schur basis, do the multiplication there, and convert back to self basis.

INPUT:

• self – a Macdonald symmetric function basis
• left – an element of the basis self
• right – another symmetric function

OUTPUT:

the product of left and right expanded in the basis self

EXAMPLES:

```
sage: Mac = SymmetricFunctions(FractionField(QQ['q','t'])).macdonald()
sage: H = Mac.H()
sage: J = Mac.J()
sage: P = Mac.P()
sage: Q = Mac.Q()
sage: Ht = Mac.Ht()
sage: J([1])^2  # indirect doctest
((q-1)/(q*t-1))*McdJ[1, 1] + ((t-1)/(q*t-1))*McdJ[2]
sage: J.product( J[1], J[2] )
((-q^2+1)/(-q^2*t+1))*McdJ[2, 1] + ((t-1)/(-q^2*t+1))*McdJ[3]
sage: H.product( H[1], H[2] )
((q^2-1)/(q^2*t-1))*McdH[2, 1] + ((t-1)/(-q^2*t+1))*McdH[3]
sage: P.product( P[1], P[2] )
((q^2-1)/(q^2*t-1))*McdP[2, 1] + ((t+1)/(-q^2*t+1))*McdP[3]
sage: Q.product(Q[1],Q[2])
McdQ[2, 1] + ((q^2*t-q^2+q*t-q+t-1)/(q^2*t-1))*McdQ[3]
sage: Ht.product(Ht[1],Ht[2])
((q^2-1)/(q^2-t))*McdHt[2, 1] + ((t-1)/(-q^2*t+1))*McdHt[3]
```

```
>>> from sage.all import *

>>> Mac = SymmetricFunctions(FractionField(QQ['q','t'])).macdonald()

>>> H = Mac.H()

>>> J = Mac.J()

>>> P = Mac.P()

>>> Q = Mac.Q()
```

(continues on next page)
class sage.combinat.sf.macdonald.MacdonaldPolynomials_h(macdonald)
Bases: MacdonaldPolynomials_generic

The $H$ basis is defined as $H_\mu = \sum_\lambda K_{\lambda \mu}(q,t)s_\lambda$ where $K_{\lambda \mu}(q,t)$ are the Macdonald Kostka coefficients.

In this implementation, it is calculated by using the Macdonald $Ht$ basis and substituting $t \to 1/t$ and multiplying by $t^{n(\mu)}$.

INPUT:

• self – a Macdonald $H$ basis
• macdonald – a family of Macdonald bases

class Element
Bases: Element

class sage.combinat.sf.macdonald.MacdonaldPolynomials_ht(macdonald)
Bases: MacdonaldPolynomials_generic

The $Ht$ basis is defined as $\tilde{H}_\mu = t^{n(\mu)} \sum_\lambda K_{\lambda \mu}(q,t^{-1})s_\lambda$ where $K_{\lambda \mu}(q,t)$ are the Macdonald $(q,t)$-Kostka coefficients and $n(\mu) = \sum_i (i-1)\mu_i$.

It is implemented here by using a Pieri formula due to F. Bergeron and M. Haiman [BH2013].

INPUT:

• self – a Macdonald $Ht$ basis
• macdonald – a family of Macdonald bases

class Element
Bases: Element

nabla(q=None, t=None, power=1)

Returns the value of the nabla operator applied to self. The eigenvectors of the nabla operator are the Macdonald polynomials in the $Ht$ basis. For more information see: [BGHT1999].

The operator nabla acts on symmetric functions and has the Macdonald $Ht$ basis as eigenfunctions and the eigenvalues are $q^{n(\mu')}t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$.

If the parameter power is an integer then it calculates nabla to that integer. The default value of power is 1.

INPUT:

• self – an element of the Macdonald $Ht$ basis
• q, t – optional parameters to specialize
• **power** – an integer (default: 1)

**OUTPUT:**
• returns the symmetric function of $\nabla$ acting on self

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht()
sage: t = Ht.t; q = Ht.q
sage: s = Sym.schur()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: Ht(0).nabla()
0
sage: a.nabla() == t^3*Ht([1,1,1])+q*t*Ht([2,1]) + q^3*Ht([3])
True
sage: a.nabla(t=3) == 27*Ht([1,1,1])+3*q*Ht([2,1]) + q^3*Ht([3])
True
sage: a.nabla(q=3) == t^3*Ht([1,1,1])+3*t*Ht([2,1]) + 27*Ht([3])
True
sage: Ht[2,1].nabla(power=-1)
1/(q*t)*McdHt[2, 1]
sage: Ht[2,1].nabla(power=4)
q^4*t^4*McdHt[2, 1]
sage: s(a.nabla(q=3))
(t^6+27*q^3+3*q*t^2)*s[1, 1, 1] + (t^5+t^4+27*q^2+3*q*t+3*t^2+27*q)*s[2, 1] + (t^3+3*t+27)*s[3]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> Ht = Sym.macdonald().Ht()
>>> t = Ht.t; q = Ht.q
>>> s = Sym.schur()
>>> a = sum(Ht(p) for p in Partitions(Integer(3)))
>>> Ht(Integer(0)).nabla()
0

>>> s(a.nabla())
(t^6+9*t^2+729)*s[1, 1, 1] + (t^5+t^4+3*t^2+9*t+324)*s[2, 1] + (t^3+3*t+27)*s[3]
\end{verbatim}

class sage.combinat.sf.macdonald.MacdonaldPolynomials_j(macdonald)

Bases: MacdonaldPolynomials_generic

The \( J \) basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the \( S \)-basis.

INPUT:

- \texttt{self} – a Macdonald \( J \) basis
- \texttt{macdonald} – a family of Macdonald bases

class Element

Bases: Element

class sage.combinat.sf.macdonald.MacdonaldPolynomials_p(macdonald)

Bases: MacdonaldPolynomials_generic

The \( P \) basis is defined here as the \( J \) basis times a normalizing coefficient \( c_2 \).

INPUT:

- \texttt{self} – a Macdonald \( P \) basis
- \texttt{macdonald} – a family of Macdonald bases

class Element

Bases: Element

\texttt{scalar_qt_basis(part1,part2=\texttt{None})}

Returns the scalar product of \( P(\texttt{part1}) \) and \( P(\texttt{part2}) \) This scalar product formula is given in equation (4.11) p.323 and (6.19) p.339 of Macdonald’s book [Mac1995].

INPUT:

- \texttt{self} – a Macdonald \( P \) basis
- \texttt{part1,part2} – partitions

OUTPUT:

- returns the scalar product of \( P(\texttt{part1}) \) and \( P(\texttt{part2}) \)

EXAMPLES:

\begin{verbatim}
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.scalar_qt_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: f = P.scalar_qt_basis(Partition([3,2,1]), Partition([3,2,1]))
sage: factor(f.numerator())
(q - 1)^3 * (q^2*t - 1)^2 * (q^3*t^2 - 1)
sage: factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
\end{verbatim}
```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> P.scalar_qt_basis(Partition([2,1]), Partition([2,1]))
0
>>> f = P.scalar_qt_basis(Partition([3,2,1]), Partition([3,2,1]))
>>> factor(f.numerator())
(q - 1)^3 * (q^2*t - 1)^2 * (q^3*t^2 - 1)
>>> factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
```

With a single argument, takes \(part2 = part1\):  
```
sage: P.scalar_qt_basis(Partition([2,1], Partition([2,1]))
(-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1)/(-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1)
```

```python
>>> from sage.all import *
>>> P.scalar_qt_basis(Partition([2,1]), Partition([2,1]))
(-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1)/(-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1)
```

### class sage.combinat.sf.macdonald.MacdonaldPolynomials_q(macdonald)

**Bases:** MacdonaldPolynomials_generic

The \(Q\) basis is defined here as the \(J\) basis times a normalizing coefficient.

**INPUT:**
- `self` -- a Macdonald \(Q\) basis
- `macdonald` -- a family of Macdonald bases

### class Element
**Bases:** Element

### class sage.combinat.sf.macdonald.MacdonaldPolynomials_s(macdonald)

**Bases:** MacdonaldPolynomials_generic

An implementation of the basis \(s_\lambda[(1-t)X/(1-q)]\)

This is perhaps misnamed as a ‘Macdonald’ basis for the symmetric functions but is used in the calculation of the Macdonald \(J\) basis (see method ‘creation’ below) but does use both of the two parameters and can be specialized to \(s_\lambda[(1-t)X]\) and \(s_\lambda[X/(1-t)]\).

**INPUT:**
- `self` -- a Macdonald \(S\) basis
- `macdonald` -- a family of Macdonald bases

### class Element
**Bases:** Element

### creation(k)

This function is a creation operator for the J-basis for which the action is known on the ‘Macdonald’ \(S\)-basis by formula from [LLM1998].

5.1. Comprehensive Module List
INPUT:
- `self` – an element of the Macdonald \(S\) basis
- \(k\) – a positive integer

OUTPUT:
- returns the column adding operator on the \(J\) basis on `self`

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: a = S(1)
sage: a.creation(1)
(-q+1)*McdS[1]
sage: a.creation(2)
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> S = Sym.macdonald().S()
>>> a = S(Integer(1))
>>> a.creation(Integer(1))
(-q+1)*McdS[1]
>>> a.creation(Integer(2))
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

**product** \((left, right)\)

The multiplication of the modified Schur functions behaves the same as the multiplication of the Schur functions.

**INPUT:**
- `self` – a Macdonald \(S\) basis
- `left, right` – a symmetric functions

**OUTPUT:**
the product of `left` and `right`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([2])**2  # indirect doctest
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> S = Sym.macdonald().S()
>>> S([Integer(2)])**Integer(2)  # indirect doctest
```

`sage.combinat.sf.macdonald.c1(part, q, t)`

This function returns the qt-Hall scalar product between \(J(part)\) and \(P(part)\).

This coefficient is \(c_\lambda\) in equation (8.1') p. 352 of Macdonald's book [Mac1995].

**INPUT:**
- `part` – a partition
• $q, t$ – parameters

OUTPUT:
• returns a polynomial of the scalar product between the $J$ and $P$ bases

EXAMPLES:
```
sage: from sage.combinat.sf.macdonald import c1
dsage: R.<q,t> = QQ[]
sage: c1(Partition([2,1]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
sage: c1(Partition([1,1]),q,t)
q^2*t - q*t - q + 1
```

```bash
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import c1
>>> R = QQ[q, t]; (q, t,) = R._first_ngens(2)
>>> c1(Partition([Integer(2),Integer(1)]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
>>> c1(Partition([Integer(1),Integer(1)]),q,t)
q^2*t - q*t - q + 1
```

```
sage.combinat.sf.macdonald.c2(part, q, t)
This function returns the $qt$-Hall scalar product between $J(part)$ and $Q(part)$.
This coefficient is $c_\lambda$ in equation (8.1) p. 352 of Macdonald’s book [Mac1995].

INPUT:
• part – a partition
• q, t – parameters

OUTPUT:
• returns a polynomial of the scalar product between the $J$ and $P$ bases

EXAMPLES:
```
sage: from sage.combinat.sf.macdonald import c2
sage: R.<q,t> = QQ[]
sage: c2(Partition([1,1]),q,t)
t^3 - t^2 - t + 1
sage: c2(Partition([2,1]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

```bash
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import c2
>>> R = QQ[q, t]; (q, t,) = R._first_ngens(2)
>>> c2(Partition([Integer(1),Integer(1)]),q,t)
t^3 - t^2 - t + 1
>>> c2(Partition([Integer(2),Integer(1)]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```
```
sage.combinat.sf.macdonald.cmunu(nu)
Return the coefficient of $\tilde{H}_\nu$ in $h_\nu^\perp H_\mu$.

Proposition 5 of F. Bergeron and M. Haiman [BH2013] states

$$c_{\mu\nu} = \sum_{\alpha \perp \nu} c_{\mu\alpha} c_{\alpha\nu} B_{\alpha/\nu} / B_{\mu/\nu}$$

5.1. Comprehensive Module List 4659
where \( c_{\mu \nu} \) is the coefficient of \( \tilde{H}_\nu \) in \( h_1 \tilde{H}_\mu \) and \( B_{\mu/\nu} \) is the bi-exponent generator implemented in the function \( \text{sage.combinat.sf.macdonald.Bmu()} \).

**INPUT:**

- \( \mu, \nu \) – partitions with \( \nu \) contained in \( \mu \)

**OUTPUT:**

- an element of the fraction field of polynomials in \( q \) and \( t \)

**EXAMPLES:**

```python
sage: from sage.combinat.sf.macdonald import cmunu
sage: cmunu(Partition([2,1]),Partition([1]))
q + t + 1
sage: cmunu(Partition([2,2]),Partition([1,1]))
(-q^3 - q^2 + q*t + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[2,2].skew_by(h[r]).coefficient(nu) == cmunu(Partition([2,2]),nu)
....: for r in range(1,5) for nu in Partitions(4-r))
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import cmunu

sage: cmunu1(Partition([2,1]),Partition([2]))
(-t^2 + q)/(-q + t)
```

**Return the coefficient of \( \tilde{H}_\nu \) in \( h_1 \tilde{H}_\mu \).**

**INPUT:**

- \( \mu, \nu \) – partitions with \( \nu \) precedes \( \mu \)

**OUTPUT:**

- an element of the fraction field of polynomials in \( q \) and \( t \)

**EXAMPLES:**

```python
sage: from sage.combinat.sf.macdonald import cmunu1
sage: cmunu1(Partition([2,1]),Partition([2]))
(-t^2 + q)/(-q - t)
```
\begin{verbatim}
 sage: all(Ht[3,2,1].skew_by(h[1]).coefficient(nu) ....: == cmunu1(Partition([3,2,1]),nu) ....: for nu in Partition([3,2,1]).down_list())
 True

 sage.combinat.sf.macdonald.qt_kostka(lam, mu)

 Returns the $K_{\lambda\mu}(q,t)$ by computing the change of basis from the Macdonald H basis to the Schurs.

 INPUT:

 \begin{itemize}
  \item lam, mu -- partitions of the same size
 \end{itemize}

 OUTPUT:

 \begin{itemize}
  \item returns the $q,t$-Kostka polynomial indexed by the partitions lam and mu
 \end{itemize}

 EXAMPLES:

 sage: from sage.combinat.sf.macdonald import qt_kostka
 sage: qt_kostka([2,1,1],[1,1,1,1])
t^3 + t^2 + t
 sage: qt_kostka([1,1,1,1],[2,1,1])q
 sage: qt_kostka([1,1,1,1],[3,1])q^3
 sage: qt_kostka([1,1,1,1],[1,1,1,1])1
 sage: qt_kostka([2,1,1],[2,2])q^2*t + q*t + q
 sage: qt_kostka([2,2],[2,2])q^2*t^2 + 1
 sage: qt_kostka([4],[3,1])t
 sage: qt_kostka([2,2],[3,1])q^2*t + q
 sage: qt_kostka([3,1],[2,1,1])q*t^3 + t^2 + t
 sage: qt_kostka([2,1,1],[2,1,1])q*t^2 + q*t + 1
 sage: qt_kostka([2,1],[1,1,1,1])0
\end{verbatim}
5.1.293 Monomial symmetric functions

class sage.combinat.sf.monomial.SymmetricFunctionAlgebra_monomial(Sym)

A class for methods related to monomial symmetric functions

INPUT:

• self – a monomial symmetric function basis
• Sym – an instance of the ring of the symmetric functions

class Element

Bases: Element

expand(n, alphabet='x')

Expand the symmetric function self as a symmetric polynomial in n variables.

INPUT:

• n – a nonnegative integer
• alphabet – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of self in the n variables labelled by alphabet.

EXAMPLES:
\textbf{exponential\_specialization}(t=None, q=1)

Return the exponential specialization of a symmetric function (when $q = 1$), or the $q$-exponential specialization (when $q \neq 1$).

The \textit{exponential specialization} $ex$ at $t$ is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$. It is defined whenever the base ring $K$ is a $Q$-algebra and $t$ is an element of $R$. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the $q$-exponential specialization is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$ that depends on two elements $t$ and $q$ of $R$ for which the elements $1 - q^i$ for all positive integers $i$ are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be $ex_q(h_n) = t^n/[n]_q!$,

where $[n]_q!$ is the $q$-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function $f$ of degree $n$, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of $f$ (see \texttt{principal\_specialization()}). (See (7.29) in [EnumComb2].)

The limit of $ex_q$ as $q \to 1$ is $ex$.

INPUT:

- $t$ (default: None) – the value to use for $t$; the default is to create a ring of polynomials in $t$. 

5.1. Comprehensive Module List 4663
• $q$ (default: 1) – the value to use for $q$. If $q$ is None, then a ring (or fraction field) of polynomials in $q$ is created.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: (m[3]+m[2,1]+m[1,1,1]).exponential_specialization()
1/6*t^3

sage: x = 5*m[1,1,1] + 3*m[2,1] + 1
sage: x.exponential_specialization()
5/6*t^3 + 1
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> (m[Integer(3)]+m[Integer(2),Integer(1)]+m[Integer(1),Integer(1),
−Integer(1)]).exponential_specialization()
1/6*t^3

>>> x = Integer(5)*m[Integer(1),Integer(1),Integer(1)] +
−Integer(3)*m[Integer(2),Integer(1)] + Integer(1)
>>> x.exponential_specialization()
5/6*t^3 + 1
```

We also support the $q$-exponential_specialization:

```
sage: factor(m[3].exponential_specialization(q=var("q"), t=var("t")))  # needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

```
>>> from sage.all import *
>>> factor(m[Integer(3)].exponential_specialization(q=var("q"), t=var("t")))  # needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

principal_specialization $(n=\infty, q=\text{None})$

Return the principal specialization of a symmetric function.

The principal specialization of order $n$ at $q$ is the ring homomorphism $p_{s_{n,q}}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, $q$ is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $p_{s_{n,q}}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at $q$ is the ring homomorphism $p_{s_q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

• $n$ (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order $n$ or the stable principal specialization.

• $q$ (default: None) – the value to use for $q$; the default is to create a ring of polynomials in $q$ (or a field of rational functions in $q$) over the given coefficient ring.

For $q=1$ and finite $n$ we use the formula from Proposition 7.8.3 of [EnumComb2]:

\[
p_{s_{n,1}}(m_{\lambda}) = \binom{n}{\ell(\lambda)} \left( \binom{\ell(\lambda)}{m_1(\lambda), m_2(\lambda), \ldots} \right),
\]
where \( \ell(\lambda) \) denotes the length of \( \lambda \).

In all other cases, we convert to complete homogeneous symmetric functions.

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[3,1]
sage: x.principal_specialization(3)
qu^7 + q^6 + q^5 + q^3 + q^2 + q

sage: x = 5*m[2] + 3*m[1] + 1
sage: x.principal_specialization(3, q=var("q"))  # Needs sage.symbolic
-10*(q^3 - 1)*q/(q - 1) + 5*(q^3 - 1)^2/(q - 1)^2 + 3*(q^3 - 1)/(q - 1) + ...
```

The antipode of `element` via coercion to and from the power-sum basis or the Schur basis (depending on whether the power sums really form a basis over the given ground ring).

**INPUT:**

- `element` – element in a basis of the ring of symmetric functions

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.monomial()
>>> m[Integer(3),Integer(2)].antipode()
m[3, 2] + 2*m[5]

>>> m.antipode_by_coercion(m[Integer(3),Integer(2)])
```

(continues on next page)
Todo: Is there a not too difficult way to get the power-sum computations to work over any ring, not just one with coercion from \(\mathbb{Q}\)?

\textbf{from\_polynomial} \((f,\text{check}=\text{True})\)

Return the symmetric function in the monomial basis corresponding to the polynomial \(f\).

\textbf{INPUT:}

- \texttt{self} – a monomial symmetric function basis
- \(f\) – a polynomial in finitely many variables over the same base ring as \texttt{self}. It is assumed that this polynomial is symmetric.
- \texttt{check} – boolean (default: True), checks whether the polynomial is indeed symmetric

\textbf{OUTPUT:}

- This function converts a symmetric polynomial \(f\) in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: m.from_polynomial(f)
m[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: m.from_polynomial(f)
m[2]
sage: f = x[0]**2+x[1]
sage: m.from_polynomial(f)
Traceback (most recent call last):
  ... ValueError: x0^2 + x1 is not a symmetric polynomial
sage: f = (m[2,1]+m[1,1]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + m[2, 1]
sage: f = (2*m[2,1]+m[1,1]+3*m[3]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + 2*m[2, 1] + 3*m[3]
\end{verbatim}
from_polynomial_exp \( p \)

Conversion from polynomial in exponential notation

**INPUT:**

- `self` – a monomial symmetric function basis
- `p` – a polynomial over the same base ring as `self`

**OUTPUT:**

- This returns a symmetric function by mapping each monomial of \( p \) with exponents \( \exp \) into \( m_\lambda \) where \( \lambda \) is the partition with exponential notation \( \exp \).

**EXAMPLES:**

```python
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 5)
sage: x = P.gens()

>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> P = PolynomialRing(QQ, 'x', Integer(5))
>>> x = P.gens()

The exponential notation of the partition \((5, 5, 5, 3, 1, 1)\) is:

```python
sage: Partition([5,5,5,3,1,1]).to_exp()
[2, 0, 1, 0, 3]
```
\texttt{sage}: f = x[0]^2 \ast x[2] \ast x[4]^3

```python
>>> from sage.all import *
>>> f = x[Integer(0)]**Integer(2) \ast x[Integer(2)] \ast x[Integer(4)]**Integer(3)
```

is mapped to:

\texttt{sage}: m.from_polynomial_exp(f)
m[5, 5, 3, 1, 1]

Furthermore, this function is linear:

\texttt{sage}: f = 3 \ast x[3] + 2 \ast x[0]^2 \ast x[2] \ast x[4]^3
\texttt{sage}: m.from_polynomial_exp(f)
3*m[4] + 2*m[5, 5, 3, 1, 1]

See also: \texttt{Partition()}, \texttt{Partition.to_exp()}

\textbf{product (left, right)}

Return the product of left and right.

• left, right – symmetric functions written in the monomial basis self.

\textbf{OUTPUT:}

• the product of left and right, expanded in the monomial basis, as a dictionary whose keys are partitions and whose values are the coefficients of these partitions (more precisely, their respective monomial symmetric functions) in the product.

\textbf{EXAMPLES:}

\texttt{sage}: m = SymmetricFunctions(QQ).m()
\texttt{sage}: a = m([2,1])
\texttt{sage}: a^2
4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]

```python
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> a = m([Integer(2),Integer(1)])
>>> a**Integer(2)
4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]
```
sage: QQx.<x> = QQ['x']
sage: m = SymmetricFunctions(QQx).m()
sage: a = m([2,1]) + x
sage: 2*a  # indirect doctest
2*x*m[] + 2*m[2, 1]
sage: a^2
x^2*m[] + 2*x*m[2, 1] + 4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]

>>> from sage.all import *
>>> QQx = QQ['x']; (x,) = QQx._first_ngens(1)
>>> m = SymmetricFunctions(QQx).m()
>>> a = m([Integer(2),Integer(1)]) + x
>>> Integer(2)*a  # indirect doctest
2*x*m[] + 2*m[2, 1]
>>> a**Integer(2)
x^2*m[] + 2*x*m[2, 1] + 4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] + m[4, 2]

5.1.294 Multiplicative symmetric functions

A realization $h$ of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \ldots)$ we have $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots$.

class sage.combinat.sf.multiplicative.SymmetricFunctionAlgebra_multiplicative(Sym, basis_name=None, prefix=None, graded=True)

Bases: SymmetricFunctionAlgebra_classical

The class of multiplicative bases of the ring of symmetric functions.

A realization $q$ of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \ldots)$ we have $q_\lambda = q_{\lambda_1} q_{\lambda_2} \cdots$ (with $q_\emptyset$ meaning 1).

Examples of multiplicative realizations are the elementary symmetric basis, the complete homogeneous basis, the powersum basis (if the base ring is a $\mathbb{Q}$-algebra), and the Witt basis (but not the Schur basis or the monomial basis).

coproduct_on_basis(mu)

Return the coproduct on a basis element for multiplicative bases.

INPUT:

- mu – a partition

OUTPUT:

- the image of self[mu] under comultiplication; this is an element of the tensor square of self

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_basis([2,1])
Continuing from previous page:

\textbf{sage: } e = Sym.elementary()
\textbf{sage: } e.coproduct_on_basis([3,1])

\textbf{sage: } h = Sym.homogeneous()
\textbf{sage: } h.coproduct_on_basis([3,1])

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.powersum()
>>> p.coproduct_on_basis([Integer(2),Integer(1)])

>>> e = Sym.elementary()
>>> e.coproduct_on_basis([Integer(3),Integer(1)])

>>> h = Sym.homogeneous()
>>> h.coproduct_on_basis([Integer(3),Integer(1)])
```

\textbf{product_on_basis}(\textit{left}, \textit{right})

Return the product of \textit{left} and \textit{right}.

\textbf{INPUT:}

- \textit{left}, \textit{right} – partitions

\textbf{OUTPUT:}

- an element of \textbf{self}

\textbf{EXAMPLES:}

```python
sage: e = SymmetricFunctions(QQ).e()
sage: e.((2,1))^2  # indirect doctest
e[2, 2, 1, 1]

>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> e.([Integer(2),Integer(1)])*Integer(2)  # indirect doctest
e[2, 2, 1, 1]

sage: h = SymmetricFunctions(QQ).h()
sage: h.((2,1))^2
h[2, 2, 1, 1]

>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
```

(continues on next page)
>>> h([Integer(2),Integer(1)])**Integer(2)
h[2, 2, 1, 1]

sage: p = SymmetricFunctions(QQ).p()
sage: p([2,1])^2
p[2, 2, 1, 1]

>>> from sage.all import *

sage: QQx.<x> = QQ[]
sage: p = SymmetricFunctions(QQx).p()
sage: (x*p([2]))^2
x^2*p[2, 2]

sage: TestSuite(p).run() # to silence sage -coverage

>>> from sage.all import *

sage: QQx = QQ['x']; (x,) = QQx._first_ngens(1)
sage: p = SymmetricFunctions(QQx).p()
sage: (x*p([Integer(2)]))**Integer(2)
x^2*p[2, 2]

>>> TestSuite(p).run() # to silence sage -coverage

5.1.295 \(k\)-Schur Functions

class sage.combinat.sf.new_kschur.KBoundedSubspace(Sym, k, t='t')

Bases: UniqueRepresentation, Parent

This class implements the subspace of the ring of symmetric functions spanned by \(\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k} = \{s^{(k)}_{\lambda}[X,t]\}_{\lambda_1 \leq k}\) over the base ring \(\mathbb{Q}[t]\). When \(t = 1\), this space is in fact a subring of the ring of symmetric functions generated by the complete homogeneous symmetric functions \(h_i\) for \(1 \leq i \leq k\).

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational...

>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ['t'])

(continues on next page)
The $k$-Schur function basis can be constructed as follows:

```sage
ks = KB.kschur(); ks
```

\textbf{K\_kschur()}

Return the $k$-bounded basis called the K-$k$-Schur basis.

See [Morse11] and [LamSchillingShimozono10].

REFERENCES:

EXAMPLES:

```sage
kB = SymmetricFunctions(QQ).kBoundedSubspace(3,1)
g = kB.K_kschur()
```

```python
Traceback (most recent call last):
... ValueError: This basis only exists for t=1
```

```sage
kh3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).khomogeneous()
```

```sage
TestSuite(kh3).run()
```
kschur()  
The $k$-Schur basis of this algebra.  

See also:  
kSchur()  

EXAMPLES:

```python
sage: ks3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).kschur()
sage: TestSuite(ks3).run()
```

ksplit()  
The $k$-split basis of this algebra.  

See also:  
kSplit()  

EXAMPLES:

```python
sage: ksp3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).ksplit()
sage: TestSuite(ksp3).run()
```

realizations()  
A list of realizations of this algebra.  

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).kBoundedSubspace(3,1).realizations()  
[3-bounded Symmetric Functions over Rational Field with $t=1$ in the 3-Schur basis,  
3-bounded Symmetric Functions over Rational Field with $t=1$ in the 3-split basis,  
3-bounded Symmetric Functions over Rational Field with $t=1$ in the 3-bounded homogeneous basis,  
3-bounded Symmetric Functions over Rational Field with $t=1$ in the K-3-Schur basis]  
sage: SymmetricFunctions(QQ['t']).kBoundedSubspace(3).realizations()  
[3-bounded Symmetric Functions over Univariate Polynomial Ring in $t$ over Rational Field in the 3-Schur basis,  
3-bounded Symmetric Functions over Univariate Polynomial Ring in $t$ over Rational Field in the 3-split basis]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).realizations()
[3-bounded Symmetric Functions over Rational Field with t=1 in the 3-Schur basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-split basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-bounded homogeneous basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur basis]
```

```python
>>> SymmetricFunctions(QQ['t']).kBoundedSubspace(Integer(3)).realizations()
[3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis,
 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-split basis]
```

```python
retract (sym)

Return the retract of `sym` from the ring of symmetric functions to `self`.

INPUT:

- `sym` – a symmetric function

OUTPUT:

- the analogue of the symmetric function in the $k$-bounded subspace (if possible)

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: KB.retract(s[2]+s[3])
sage: KB.retract(s[2,1,1])
Traceback (most recent call last):
  ... ValueError: s[2, 1, 1] is not in the image
```
```
```
```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> KB = Sym.kBoundedSubspace(Integer(3),Integer(1)); KB
3-bounded Symmetric Functions over Rational Field with t=1
>>> KB.retract(s[Integer(2)]+s[Integer(3)])
>>> KB.retract(s[Integer(2),Integer(1),Integer(1)])
Traceback (most recent call last):
  ... ValueError: s[2, 1, 1] is not in the image
```
```
```
```
```python
class sage.combinat.sf.new_kschur.KBoundedSubspaceBases(base, t='t')

Bases: Category_realization_of_parent

The category of bases for the $k$-bounded subspace of symmetric functions.
```
class ElementMethods
   Bases: object

   expand(*args, **kwargs)
   Return the monomial expansion of self in \( n \) variables.

   INPUT:
   • \( n \) – positive integer
   OUTPUT: monomial expansion of self in \( n \) variables

   EXAMPLES:
   sage: Sym = SymmetricFunctions(QQ)
   sage: ks = Sym.kschur(3,1)
   sage: ks[3,1].expand(2)
   x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
   sage: s = Sym.schur()
   sage: ks[3,1].expand(2) == s(ks[3,1]).expand(2)
   True

   sage: Sym = SymmetricFunctions(QQ['t'])
   sage: ks = Sym.kschur(3)
   sage: f = ks[3,2]-ks[1]
   sage: f.expand(2)
   t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^2*x1^3 + (t^2 + t)*x0*x1^4 + t^2*x1^5 - x0 - x1

   >>> from sage.all import *
   >>> Sym = SymmetricFunctions(QQ)
   >>> ks = Sym.kschur(Integer(3),Integer(1))
   >>> ks[Integer(3),Integer(1)].expand(Integer(2))
   x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
   >>> s = Sym.schur()
   >>> ks[Integer(3),Integer(1)].expand(Integer(2)) == s(ks[Integer(3), Integer(1)]).expand(Integer(2))
   True
   >>> Sym = SymmetricFunctions(QQ['t'])
   >>> ks = Sym.kschur(Integer(3))
   >>> f = ks[Integer(3),Integer(2)]-ks[Integer(1)]
   >>> f.expand(Integer(2))
   t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^2*x1^3 + (t^2 + t)*x0*x1^4 + t^2*x1^5 - x0 - x1

hl_creation_operator \((nu, t=None)\)
   This is the vertex operator that generalizes Jing’s operator.

   It is a linear operator that raises the degree by \(|\nu|\). This creation operator is a \( t \)-analog of multiplication by \( s(\nu) \).

   See also:
   Proposition 5 in [SZ2001].

   INPUT:
   • \( nu \) – a partition or a list of integers
   • \( t \) – (default: None, in which case \( t \) is used) an element of the base ring

   EXAMPLES:
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(4)
sage: s = Sym.schur()
sage: s(ks([3,1,1]).hl_creation_operator([1]))
(t-1)*s[2, 2, 1, 1] + t^2*s[3, 1, 1, 1] + (t^3+t^2-t)*s[3, 2, 1] + (t^3-t^2)*s[3, 3] + (t^4+t^3)*s[4, 1, 1] + t^4*s[4, 2] + t^5*s[5, 1]
sage: ks([3,1,1]).hl_creation_operator([1])
(t-1)*ks4[2, 2, 1, 1] + t^2*ks4[3, 1, 1, 1] + t^3*ks4[3, 2, 1] + (t^3-t^2)*ks4[3, 3] + t^4*ks4[4, 1, 1]

sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(4,t=1)
sage: ks([3,1,1]).hl_creation_operator([1])
ks4[3, 1, 1, 1] + ks4[3, 2, 1] + ks4[4, 1, 1]

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> ks = Sym.kschur(Integer(4))
>>> s = Sym.schur()
>>> s(ks([Integer(3),Integer(1),Integer(1)]).hl_creation_operator([Integer(1)]))
(t-1)*s[2, 2, 1, 1] + t^2*s[3, 1, 1, 1] + (t^3+t^2-t)*s[3, 2, 1] + (t^3-t^2)*s[3, 3] + (t^4+t^3)*s[4, 1, 1] + t^4*s[4, 2] + t^5*s[5, 1]

>>> ks([Integer(3),Integer(1),Integer(1)]).hl_creation_operator([Integer(1)])
(t-1)*ks4[2, 2, 1, 1] + t^2*ks4[3, 1, 1, 1] + t^3*ks4[3, 2, 1] + (t^3-t^2)*ks4[3, 3] + t^4*ks4[4, 1, 1]

>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(4),t=Integer(1))
>>> ks([Integer(3),Integer(1),Integer(1)]).hl_creation_operator([Integer(1)])
ks4[3, 1, 1, 1] + ks4[3, 2, 1] + ks4[4, 1, 1]
```

**is_schur_positive** (*args, **kwargs*)

Return whether `self` is Schur positive.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False
```
omega()

Return the \( \omega \) operator on self.

At \( t = 1, \omega \) maps the \( k \)-Schur function \( s^{(k)}_{\lambda} \) to \( s^{(k)}_{\lambda(k)} \), where \( \lambda(k) \) is the \( k \)-conjugate of the partition \( \lambda \).

See also:

\( k\text{-conjugate}() \).

For generic \( t, \omega \) sends \( s^{(k)}_{\lambda}[X; t] \) to \( t^{d} s^{(k)}_{\lambda(k)}[X; 1/t] \), where \( d \) is the size of the core of \( \lambda \) minus the size of \( \lambda \). Most of the time, this result is not in the \( k \)-bounded subspace.

See also:

\( \omega_{t\text{-inverse}}() \).

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2,2,1,1].omega()
sk3[2, 2, 2]
sage: kh = Sym.khomogeneous(3)
sage: kh[3].omega()
h3[1, 1, 1] - 2*h3[2, 1] + h3[3]
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega()
Traceback (most recent call last):
  ...
ValueError: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
```
\[ h_3[1, 1, 1] - 2h_3[2, 1] + h_3[3] \]

```python
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> ks = Sym.kschur(Integer(3))
>>> ks[Integer(3),Integer(1),Integer(1)].omega()
Traceback (most recent call last):
... ValueError: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
```

**omega_t_inverse()**

Return the map \( t \to 1/t \) composed with \( \omega \) on self.

Unlike the map \( \omega() \), the result of \( \omega_t^{-1}() \) lives in the \( k \)-bounded subspace and hence will return an element even for generic \( t \). For \( t = 1 \), \( \omega() \) and \( \omega_t^{-1}() \) return the same result.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega_t_inverse()
 1/t*ks3[2, 1, 1, 1]
sage: ks[3,2].omega_t_inverse()
 1/t^2*ks3[1, 1, 1, 1]
```

**scalar**

Return standard scalar product between self and x.

**INPUT:**
- x – element of the ring of symmetric functions over the same base ring as self
- zee – an optional function on partitions giving the value for the scalar product between \( \mu \) and \( \mu \)
  (default is to use the standard \( zee() \) function)

**See also:**
- scalar()

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3)
sage: ks3[3,2,1].scalar( ks3[2,2,2] )
t^3 + t
sage: dks3 = Sym.kBoundedQuotient(3).dks()
sage: [ks3[3,2,1].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 1, 0, 0, 0, 0, 0]
sage: dks3 = Sym.kBoundedQuotient(3,t=1).dks()
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, t - 1, 0, 1, 0, 0, 0]
sage: ks3 = Sym.kschur(3,t=1)
```
Combinatorics, Release 10.4

sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 0, 0, 1, 0, 0, 0]
sage: kH = Sym.khomogeneous(4)
sage: kH([2,2,1]).scalar(ks3[2,2,1])
3

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'])
>>> ks3 = Sym.kschur(Integer(3))
>>> ks3[Integer(3),Integer(2),Integer(1)].scalar( ks3[Integer(2),
   →Integer(2),Integer(2) ] )
t^3 + t
>>> dks3 = Sym.kBoundedQuotient(Integer(3)).dks()
>>> [ks3[Integer(3),Integer(2),Integer(1)].scalar(dks3(la)) for la in
   →Partitions(Integer(6), max_part=Integer(3))]  
[0, 1, 0, 0, 0, 0, 0]
>>> dks3 = Sym.kBoundedQuotient(Integer(3),t=Integer(1)).dks()
>>> [ks3[Integer(2),Integer(2),Integer(2)].scalar(dks3(la)) for la in
   →Partitions(Integer(6), max_part=Integer(3))]  
[0, t - 1, 0, 1, 0, 0, 0]
>>> ks3 = Sym.kschur(Integer(3),t=Integer(1))
>>> [ks3[Integer(2),Integer(2),Integer(1)].scalar(dks3(la)) for la in
   →Partitions(Integer(6), max_part=Integer(3))]  
[0, 0, 0, 1, 0, 0, 0]
>>> kH = Sym.khomogeneous(Integer(4))
>>> kH([Integer(2),Integer(2),Integer(1)]).scalar(ks3[Integer(2),
   →Integer(2),Integer(1) ])
3

class ParentMethods

   Bases: object

   an_element()

       Return an element of self.

       EXAMPLES:

       sage: SymmetricFunctions(QQ['t']).kschur(3).an_element()
       2*ks3[] + 2*ks3[1] + 3*ks3[2]

   antipode(element)

       Return the antipode on self by lifting to the space of symmetric functions, computing the antipode, and then converting to self.parent(). This is only the antipode for \( t = 1 \) and for other values of \( t \) the result may not be in the space where the \( k \)-Schur functions live.

       INPUT:

       * element -- an element in a basis of the ring of symmetric functions

       EXAMPLES:

       sage: Sym = SymmetricFunctions(QQ)
       sage: ks3 = Sym.kschur(3,1)

(continues on next page)
Combinatorics, Release 10.4

```
sage: ks3[3,2].antipode()
-ks3[1, 1, 1, 1]
sage: ks3.antipode(ks3[3,2])
-ks3[1, 1, 1, 1]
```

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks3 = Sym.kschur(Integer(3),Integer(1))
>>> ks3[Integer(3),Integer(2)].antipode()
-ks3[1, 1, 1, 1]
>>> ks3.antipode(ks3[Integer(3),Integer(2)])
-ks3[1, 1, 1, 1]

coproduct (element)

Return the coproduct operation on element.

The coproduct is first computed on the homogeneous basis if \( t = 1 \) and on the Hall-Littlewood \( Qp \) basis otherwise. The result is computed then converted to the tensor squared of self.parent().

INPUT:

• element – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[2,1].coproduct()
```

```
sage: h3 = Sym.khomogeneous(3)
sage: h3[2,1].coproduct()
hs3[2] # hs3[1, 1] + hs3[1, 1] # hs3[]
```

```
sage: ks3t = SymmetricFunctions(FractionField(QQ[t])).kschur(3)
sage: ks3t[2,1].coproduct()
```

```
sage: h3 = SymmetricFunctions(FractionField(QQ['t'])).kschur(3)
sage: h3[2,1].coproduct()
h3[2] # h3[1, 1] + h3[1, 1] # h3[]
```

```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> ks3t[Integer(2),Integer(1)].coproduct()

>>> ks3t[Integer(3),Integer(1)].coproduct()
˓→ks3[3, 1] # ks3[]

>>> h3.coproduct(h3[Integer(2),Integer(1)])
```

counit (element)

Return the counit of element.

The counit is the constant term of element.

INPUT:

- element – an element in a basis of the ring of symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: f = 2*ks3[2,1] + 3*ks3[]
sage: f.counit()
3
sage: ks3.counit(f)
3
```

```python
>>> from sage.all import *

from sage.all import *

Sym = SymmetricFunctions(QQ)
ks3 = Sym.kschur(3,1)
f = Integer(2)*ks3[Integer(2),Integer(1)] + Integer(3)*ks3[]
f.counit()
3
ks3.counit(f)
3
```

degree_on_basis (b)

Return the degree of the basis element indexed by b.

INPUT:

- b – a partition

EXAMPLES:

```python
sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.degree_on_basis(Partition([3,2]))
5
```

```python
>>> from sage.all import *

from sage.all import *

ks3 = SymmetricFunctions(QQ).kschur(Integer(3),Integer(1))
ks3.degree_on_basis(Partition([Integer(3),Integer(2)]))
5
```

one_basis ()

Return the basis element indexing 1.
EXAMPLES:

```python
sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.one()  # indirect doctest
ks3[]
```

```python
>>> from sage.all import *
>>> ks3 = SymmetricFunctions(QQ).kschur(Integer(3),Integer(1))
>>> ks3.one()  # indirect doctest
ks3[]
```

def transition_matrix(self, other, n):
    Return the degree n transition matrix between self and other.

    INPUT:
    • other -- a basis in the ring of symmetric functions
    • n -- a positive integer
    The entry in the i-th row and j-th column is the coefficient obtained by writing the i-th element of the basis
    of self in terms of the basis other, and extracting the j-th coefficient.

    EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ); s = Sym.schur()
sage: ks3 = Sym.kschur(3,1)
sage: ks3.transition_matrix(s,5)
[1 1 1 0 0 0 0]
[0 1 0 1 0 0 0]
[0 0 1 0 1 0 0]
[0 0 0 1 0 1 0]
[0 0 0 0 1 1 1]
```

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: s = Sym.schur()
sage: ks = Sym.kschur(3)
sage: ks.transition_matrix(s,5)
[t^2 t 1 0 0 0 0]
[ 0 t 0 1 0 0 0]
[ 0 0 t 0 1 0 0]
[ 0 0 0 t 0 1 0]
[ 0 0 0 0 t^2 t 1]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ); s = Sym.schur()
>>> ks3 = Sym.kschur(Integer(3),Integer(1))
>>> ks3.transition_matrix(s,Integer(5))
[1 1 1 0 0 0 0]
[0 1 0 1 0 0 0]
[0 0 1 0 1 0 0]
[0 0 0 1 0 1 0]
[0 0 0 0 1 1 1]
```

```python
>>> Sym = SymmetricFunctions(QQ['t'])
>>> s = Sym.schur()
>>> ks = Sym.kschur(Integer(3))
>>> ks.transition_matrix(s,Integer(5))
[t^2 t 1 0 0 0 0]
[ 0 t 0 1 0 0 0]
```

(continues on next page)
super_categories()

The super categories of self.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
sage: KB = Sym.kBoundedSubspace(3)
sage: KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over...
    Univariate Polynomial Ring in t over Rational Field
sage: KBB.super_categories()
[Category of realizations of 3-bounded Symmetric Functions over Univariate...
    Polynomial Ring in t over Rational Field,
    Join of Category of graded coalgebras with basis over Univariate Polynomial...
    Ring in t over Rational Field
    and Category of subobjects of filtered modules with basis over...
    Univariate Polynomial Ring in t over Rational Field]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'])
>>> from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
>>> KB = Sym.kBoundedSubspace(Integer(3))
>>> KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over...
    Univariate Polynomial Ring in t over Rational Field
>>> KBB.super_categories()
[Category of realizations of 3-bounded Symmetric Functions over Univariate...
    Polynomial Ring in t over Rational Field,
    Join of Category of graded coalgebras with basis over Univariate Polynomial...
    Ring in t over Rational Field
    and Category of subobjects of filtered modules with basis over...
    Univariate Polynomial Ring in t over Rational Field]
```

```
class sage.combinat.sf.new_kschur.K_kSchur(kBoundedRing)

Bases: CombinatorialFreeModule

This class implements the basis of the k-bounded subspace called the K-k-Schur basis.

See [Morse2011], [LamSchillingShimozono2010].

REFERENCES:

K_k_Schur_non_commutative_variables(la)

Return the K-k-Schur function, as embedded inside the affine zero Hecke algebra.

INPUT:

• la – A k-bounded Partition

OUTPUT:

• An element of the affine zero Hecke algebra.

EXAMPLES:
```
Combinatorics, Release 10.4

\[
sage: g = \text{SymmetricFunctions}(\mathbb{Q}).kBoundedSubspace(3,1).K_kschur()
\]
\[
sage: g.K_k_Schur_non_commutative_variables([2,1])
\]
\[
\]
\[
sage: g.K_k_Schur_non_commutative_variables([1])
\]
\[
sage: g.K_k_Schur_non_commutative_variables([4,1])
\]
\[
\text{Traceback (most recent call last):}
\]
\[
... 
\]
\[
\text{ValueError: Partition should be 3-bounded}
\]

\[
>>> \text{from sage.all import *}
\]
\[
>>> g = \text{SymmetricFunctions}(\mathbb{Q}).kBoundedSubspace(Integer(3),Integer(1)).K_kschur()
\]
\[
>>> g.K_k_Schur_non_commutative_variables([Integer(2),Integer(1)])
\]
\[
\]
\[
\]
\[
\rightarrow T[2,1]
\]
\[
>>> g.K_k_Schur_non_commutative_variables([1])
\]
\[

\]
\[
... 
\]
\[
\text{ValueError: Partition should be 3-bounded}
\]

\textbf{homogeneous\_basis\_noncommutative\_variables\_zero\_Hecke}(la)

Return the homogeneous basis element indexed by \(la\), viewed as an element inside the affine zero Hecke algebra. For the code, see method \_homogeneous\_basis.

**INPUT:**

- \(la\) – A \(k\)-bounded partition

**OUTPUT:**

- An element of the affine zero Hecke algebra.

**EXAMPLES:**

\[
sage: g = \text{SymmetricFunctions}(\mathbb{Q}).kBoundedSubspace(3,1).K_kschur()
\]
\[
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([2,1])
\]
\[
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +
\]
\[
\]
\[
\]
\[
\rightarrow T[2,1]
\]
\[
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([1])
\]

\[
>>> \text{from sage.all import *}
\]
\[
>>> g = \text{SymmetricFunctions}(\mathbb{Q}).kBoundedSubspace(Integer(3),Integer(1)).K_kschur()
\]
\[
>>> g.homogeneous_basis_noncommutative_variables_zero_Hecke([Integer(2),Integer(1)])
\]
\[
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +
\]
\[
\]
\[
\]
\[
\rightarrow T[2,1]
\]
\[
>>> g.homogeneous_basis_noncommutative_variables_zero_Hecke([1])
\]

1
**lift**(*x*)

Return the lift of a \( k \)-bounded symmetric function.

**INPUT:**

- \( x \) – An expression in the \( K-k \)-Schur basis. Equivalently, \( x \) can be a \( k \)-bounded partition (then \( x \) corresponds to the basis element indexed by \( x \))

**OUTPUT:**

- A symmetric function.

**EXAMPLES:**

```sage
g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
g.lift([2,1])
g.lift([])
h[]
g.lift([4,1])
```

```python
>>> from sage.all import *

>>> g = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).K_kschur()

>>> g.lift([Integer(2), Integer(1)])

>>> g.lift([])
h[

>>> g.lift([Integer(4), Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-˓→bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur˓→basis)
```

**product**(*x, y*)

Return the product of the two \( K-k \)-Schur functions.

**INPUT:**

- \( x, y \) – elements of the \( k \)-bounded subspace, in the \( K-k \)-Schur basis.

**OUTPUT:**

- An element of the \( k \)-bounded subspace, in the \( K-k \)-Schur basis

**EXAMPLES:**

```sage
g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
g.product(g([[2,1]]), g([[]])
g.product(g([[2,1]]), g([]))
Kks3[2, 1]
```
```python
>>> from sage.all import *
>>> g = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).K_kschur()
>>> g.product(g([Integer(2),Integer(1)]), g[Integer(1)])
>>> g.product(g([Integer(2),Integer(1)]), g([]))
Kks3[]
```

### retract(x)

Return the retract of a symmetric function.

**INPUT:**

- `x` – A symmetric function.

**OUTPUT:**

- A $k$-bounded symmetric function in the $K$-$k$-Schur basis.

**EXAMPLES:**

```python
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: m = SymmetricFunctions(QQ).m()
sage: g.retract(m[2,1])
sage: g.retract(m([]))
Kks3[]
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> kH = Sym.khomogeneous(Integer(3))

>>> kH[Integer(2)].lift()
```

### class sage.combinat.sf.new_kschur.kHomogeneous(kBoundedRing)

**Bases:** `CombinatorialFreeModule`

Space of $k$-bounded homogeneous symmetric functions.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: kH = Sym.khomogeneous(3)
sage: kH[2]
h3[2]
sage: kH[2].lift()
h[2]
```
class sage.combinat.sf.new_kschur.KSchur(kBoundedRing)

    Bases: CombinatorialFreeModule

    Space of $k$-Schur functions.

    EXAMPLES:

    sage: Sym = SymmetricFunctions(QQ['t'])
    sage: KB = Sym.kBoundedSubspace(3); KB
    3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field

    >>> from sage.all import *
    >>> Sym = SymmetricFunctions(QQ['t'])
    >>> KB = Sym.kBoundedSubspace(Integer(3)); KB
    3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis

    The $k$-Schur function basis can be constructed as follows:

    sage: ks3 = KB.kschur(); ks3
    3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis

    We can convert to any basis of the ring of symmetric functions and, whenever it makes sense, also the other way round:

    sage: s = Sym.schur()
    sage: s(ks3([3, 2, 1]))
    s[3, 2, 1] + t*s[4, 1, 1] + t*s[4, 2] + t^2*s[5, 1]
    sage: t = Sym.base_ring().gen()
    sage: ks3(s([3, 2, 1]))
    ks3[3, 2, 1]
    sage: s(ks3([2, 1, 1]))
    s[2, 1, 1] + t*s[3, 1]
    sage: ks3(s([2, 1, 1]))
    ks3[2, 1, 1]
$k$-Schur functions are indexed by partitions with first part $\leq k$. Constructing a $k$-Schur function for a larger partition raises an error:

```
sage: ks3([4,3,2,1]) #
Traceback (most recent call last):
  ...
TypeError: do not know how to make x (= [4, 3, 2, 1]) an element of self (=3-
  \rightarrow bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
  \rightarrow Field in the 3-Schur basis)
```

Similarly, attempting to convert a function that is not in the linear span of the $k$-Schur functions raises an error:

```
sage: ks3(s([4]))
Traceback (most recent call last):
  ...
ValueError: s[4] is not in the image
```

Note that the product of $k$-Schur functions is not guaranteed to be in the space spanned by the $k$-Schurs. In general, we only have that a $k$-Schur times a $j$-Schur function is in the $(k+j)$-bounded subspace. The multiplication of two $k$-Schur functions thus generally returns the product of the lift of the functions to the ambient symmetric function space. If the result happens to lie in the $k$-bounded subspace, then the result is cast into the $k$-Schur basis:

```
sage: ks2 = Sym.kBoundedSubspace(2).kschur()
s[2, 1] + s[3]
```

Because the target space of the product of a $k$-Schur and a $j$-Schur has several possibilities, the product of a $k$-Schur and $j$-Schur function is not implemented for distinct $k$ and $j$. Let us show how to get around this 'manually':

```
sage: ks3 = Sym.kBoundedSubspace(3).kschur()
sage: ks2([2,1]) * ks3([3,1])
Traceback (most recent call last):
  ...
```
TypeError: unsupported operand parent(s) for *: '2-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis' and '3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 3-Schur basis'

The workaround:

```python
f = s(ks2([2,1])) * s(ks3([3,1])); f # Convert to Schur functions first and multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1] + (2*t+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3] + (2*t+1)*s[5, 1, 1] + (t^2+2*t+1)*s[5, 2] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

or:

```python
f = s(ks2([Integer(2,1)])) * s(ks3([Integer(3,1)])); f # Convert to Schur functions first and multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1] + (2*t+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3] + (2*t+1)*s[5, 1, 1] + (t^2+2*t+1)*s[5, 2] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

For other technical reasons, taking powers of \( k \)-Schur functions is not implemented, even when the answer is still in the \( k \)-bounded subspace:

```python
f = s(ks2([1]))^2
Traceback (most recent call last):
... TypeError: unsupported operand parent(s) for ^: '2-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis' and 'Integer Ring'
```
Todo: Get rid of said technical “reasons”.

However, at \( t = 1 \), the product of \( k \)-Schur functions is in the span of the \( k \)-Schur functions always. Below are some examples at \( t = 1 \):

```python
>>> from sage.all import *
>>> ks2=Integer(2)
>>> ks2([Integer(1)])**Integer(2)
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for ^: '2-bounded Symmetric Functions...
˓→over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis'
˓→and 'Integer Ring'
```

```python
>>> from sage.all import *
>>> ks3=Sym.kBoundedSubspace(3, t=Integer(1)).kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational...
˓→Field with t=1 in the 3-Schur basis
>>> s = SymmetricFunctions(ks3.base_ring()).schur()
>>> ks3(s([3]))
ks3[3]
>>> s(ks3([3,2,1]))
\[3, 2, 1\] + \[4, 1, 1\] + \[4, 2\] + \[5, 1\]
>>> ks3([2,1])**2  # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

```python
>>> from sage.all import *
>>> ks3=Sym.kBoundedSubspace(Integer(3), t=Integer(1)).kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational...
˓→Field with t=1 in the 3-Schur basis
>>> s = SymmetricFunctions(ks3.base_ring()).schur()
>>> ks3(s([3]))
ks3[3]
>>> s(ks3([3,2,1]))
\[3, 2, 1\] + \[4, 1, 1\] + \[4, 2\] + \[5, 1\]
>>> ks3([2,1])**2  # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

**product_on_basis** *(left, right)*

Take the product of two \( k \)-Schur functions.

If \( t \neq 1 \), then take the product by lifting to the Schur functions and then retracting back into the \( k \)-bounded subspace (if possible).

If \( t = 1 \), then the product calls \_product_on_basis_via_rectangles().

**INPUT:**

- \( \text{left, right} \) – partitions

**OUTPUT:**

- an element of the \( k \)-Schur functions

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3,1)
sage: kH = Sym.khomogeneous(3)
```
sage: ks3(kH[2,1,1])
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([[]])*kH[2,1,1]
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([3,3,3,2,2,1,1,1])^2
ks3[3, 3, 3, 3, 3, 3, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1]
sage: ks3([3,3,3,2,2,1,1,1])*ks3([2,2,2,2,2,1,1,1])
ks3[3, 2, 2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1]
sage: ks3([2,2,1,1,1,1])*ks3([2,2,2,1,1,1])
ks3[2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + ks3[2, 2, 2, 2, 2, 2, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: ks3[k2,1]^2
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
sage: ks3 = Sym.kschur(3)
sage: ks3[k2,1]*ks3[k2,1]

class sage.combinat.sf.new_kschur.KSplit(kBoundedRing)

Bases: CombinatorialFreeModule

The $k$-split basis of the space of $k$-bounded-symmetric functions

Fix $k$ a positive integer and $t$ an element of the base ring.

The $k$-split functions are a basis for the space of $k$-bounded symmetric functions that also have the bases

$$\{Q_{\lambda}[X;t]\}_{\lambda_1 \leq k} = \{s_{\lambda}^{(k)}[X;t]\}_{\lambda_1 \leq k}$$

where $Q_{\lambda}[X;t]$ are the Hall-Littlewood symmetric functions (using the notation of [MAC]) and $s_{\lambda}^{(k)}[X;t]$ are the
$k$-Schur functions. If $t$ is not a root of unity, then

$$\{s_\lambda[X/(1-t)]\}_{\lambda_1 \leq k}$$

is also a basis of this space.

The $k$-split basis has the property that $Q'_\lambda[X;t]$ expands positively in the $k$-split basis and the $k$-split basis conjecturally expands positively in the $k$-Schur functions. See [LLMSSZ] p. 81.

The $k$-split basis is defined recursively using the Hall-Littlewood creation operator defined in [SZ2001]. If a partition $\lambda$ is the concatenation (as lists) of a partition $\mu$ and $\nu$ where $\mu$ has maximal hook length equal to $k$ then $\text{ksp}(\lambda) = \text{ksp}(\nu).\text{hl_creation_operator}(\mu)$. If the hook length of $\lambda$ is less than or equal to $k$, then $\text{ksp}(\lambda)$ is equal to the Schur function indexed by $\lambda$.

EXAMPLES:

```sage
sage: Symt = SymmetricFunctions(QQ['t'].fraction_field())
sage: kBS3 = Symt.kBoundedSubspace(3)
sage: ks3 = kBS3.kschur()
sage: ksp3 = kBS3.ksplit()
sage: ks3(ksp3[2,1,1])
ks3[2, 1, 1] + t*ks3[2, 2]
sage: ksp3[2, 1, 1] - t*ksp3[2, 2]
sage: ksp3[2,1]*ksp3[1]
s[2, 1, 1] + s[2, 2] + s[3, 1]
sage: ksp3[2,1].hl_creation_operator([1])
t*ksp3[2, 1, 1] + (-t^2+t)*ksp3[2, 2]
sage: Qp = Symt.hall_littlewood().Qp()
sage: ksp3(Qp[3,2,1])
ksp3[3, 2, 1] + t*ksp3[3, 3]
sage: kBS4 = Symt.kBoundedSubspace(4)
sage: ksp4 = kBS4.ksplit()
sage: ksp4[3, 2, 1] - t*ksp4[3, 3] + t*ksp4[4, 1, 1]
sage: ks4 = kBS4.kschur()
sage: ks4(ksp4[3,2,2,1])
ks4[3, 2, 2, 1] + t*ks4[3, 3, 1, 1] + t*ks4[3, 3, 2]
```

```python
>>> from sage.all import *
>>> Symt = SymmetricFunctions(QQ['t'].fraction_field())
>>> kBS3 = Symt.kBoundedSubspace(Integer(3))
>>> ks3 = kBS3.kschur()
>>> ksp3 = kBS3.ksplit()
>>> ks3(ksp3[Integer(2),Integer(1),Integer(1)])
ks3[2, 1, 1] + t*ks3[2, 2]
>>> ksp3[ks3[Integer(2),Integer(1),Integer(1)]]
ksp3[2, 1, 1] - t*ksp3[2, 2]
>>> ksp3[Integer(2),Integer(1)]*ksp3[Integer(1)]
s[2, 1, 1] + s[2, 2] + s[3, 1]
>>> ksp3[Integer(2),Integer(1)].hl_creation_operator([Integer(1)])
t*ksp3[2, 1, 1] + (-t^2+t)*ksp3[2, 2]
>>> Qp = Symt.hall_littlewood().Qp()
>>> ksp3(Qp[Integer(3),Integer(2),Integer(1)])
ksp3[3, 2, 1] + t*ksp3[3, 3]
```

Combinatorics, Release 10.4

5.1.296 Non-symmetric Macdonald Polynomials

class sage.combinat.sf.ns_macdonald.AugmentedLatticeDiagramFilling(l, pi=None)
Bases: CombinatorialObject

EXAMPLES:

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[5,5]])
sage: a == loads(dumps(a))
True
sage: pi = Permutation([2,3,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[5,5]],pi)
sage: a == loads(dumps(a))
True

are_attacking(i, j, ii, jj)
Return True if the boxes (i, j) and (ii, jj) in self are attacking.

EXAMPLES:

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[5,5]])
sage: all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_boxes() )
True
sage: a.are_attacking(1,1,3,2)
False

5.1. Comprehensive Module List

4693
**attacking_boxes()**

Return a list of pairs of boxes in *self* that are attacking.

**EXAMPLES:**

```
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: a.attacking_boxes()[:5]
[((1, 1), (2, 1)),
 (1, 1), (3, 1)),
 (1, 1), (6, 1)),
 (1, 1), (2, 0)),
 (1, 1), (3, 0))]
```

```
>>> from sage.all import *

>>> a = AugmentedLatticeDiagramFilling([[Integer(1), Integer(6)], [Integer(2)],
  →[Integer(3), Integer(4), Integer(2)], [], [], [Integer(5), Integer(5)]])

>>> a.attacking_boxes()[:Integer(5)]
[((1, 1), (2, 1)),
 (1, 1), (3, 1)),
 (1, 1), (6, 1)),
 (1, 1), (2, 0)),
 (1, 1), (3, 0))]
```

**boxes()**

Return a list of the coordinates of the boxes of *self*, including the ‘basement row’.

**EXAMPLES:**

```
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]
```

```
>>> from sage.all import *

>>> a = AugmentedLatticeDiagramFilling([[Integer(1), Integer(6)], [Integer(2)],
  →[Integer(3), Integer(4), Integer(2)], [], [], [Integer(5), Integer(5)]])

>>> a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (6, 0)]

(continues on next page)
**coeff** \((q, t)\)

Return the coefficient in front of \(self\) in the HHL formula for the expansion of the non-symmetric Macdonald polynomial \(E(self.shape())\).

**EXAMPLES:**

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t') #←needs sage.symbolic
sage: a.coeff(q,t)  #←needs sage.symbolic
(t - 1)^4/((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
    [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]]
>>> q,t = var('q,t') #←needs sage.symbolic
>>> a.coeff(q,t)  #←needs sage.symbolic
(t - 1)^4/((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

**coeff_integral** \((q, t)\)

Return the coefficient in front of \(self\) in the HHL formula for the expansion of the integral non-symmetric Macdonald polynomial \(E(self.shape())\).

**EXAMPLES:**

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t') #←needs sage.symbolic
sage: a.coeff_integral(q,t) #←needs sage.symbolic
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
    [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]]
>>> q,t = var('q,t') #←needs sage.symbolic
>>> a.coeff_integral(q,t) #←needs sage.symbolic
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

**coinv()**

Return \(self\)’s co-inversion statistic.

**EXAMPLES:**

```
```
Combinatorics, Release 10.4

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[5],[5],[5,5]])
sage: a.coinv()
2

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
    [Integer(3),Integer(4),Integer(2)],[5],[5],[Integer(5),Integer(5)]])
>>> a.coinv()
2
```

descents()
Return a list of the descents of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[5],[5],[5,5]])
sage: a.descents()
[(1, 2), (3, 2)]
```

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
    [Integer(3),Integer(4),Integer(2)],[5],[5],[Integer(5),Integer(5)]])
>>> a.descents()
[(1, 2), (3, 2)]
```

inv()
Return self's inversion statistic.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[5],[5],[5,5]])
sage: a.inv()
15
```

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
    [Integer(3),Integer(4),Integer(2)],[5],[5],[Integer(5),Integer(5)]])
>>> a.inv()
15
```

inversions()
Return a list of the inversions of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[5],[5],[5,5]])
sage: a.inversions()[:5]
[((6, 2), (3, 2)),
  ((1, 2), (6, 1)),
  ((1, 2), (3, 1)),
  ((1, 2), (2, 1)),
  ((6, 1), (3, 1))]
sage: len(a.inversions())
25
```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],
       [Integer(2)],
       [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.inversions()[:Integer(5)]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
 ((1, 2), (2, 1)),
 ((6, 1), (3, 1))]
>>> len(a.inversions())
25

is_non_attacking()

Return True if self is non-attacking.

EXAMPLES:

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5,5]])
sage: a.is_non_attacking()
True
sage: a = AugmentedLatticeDiagramFilling([[1, 1, 1],[2,3],[3]])
sage: a.is_non_attacking()
False
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]])
sage: a.is_non_attacking()
False
sage: pi = Permutation([2,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]],pi)
sage: a.is_non_attacking()
True

>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],
       [Integer(2)],
       [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.is_non_attacking()
True

maj()

Return the major index of self.

EXAMPLES:

sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[1],[5,5]])
sage: a.maj()
3

5.1. Comprehensive Module List
```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1), Integer(6)], [Integer(2)],
... [Integer(3), Integer(4), Integer(2)], [], [], [Integer(5), Integer(5)]]
>>> a.maj()
3
```

**permuted_filling** *(sigma)*

EXAMPLES:

```python
sage: pi=Permutation([2,1,4,3]).to_permutation_group_element()
sage: fill=[[2], [1,2,3], [], [3,1]]
sage: AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]
```

```python
>>> from sage.all import *
>>> pi=Permutation([Integer(2), Integer(1), Integer(4), Integer(3)]).to_permutation_group_element()
>>> fill=[[Integer(2)], [Integer(1), Integer(2), Integer(3)], [], [Integer(3), Integer(1)]
>>> AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]
```

**reading_order** ()

Return a list of coordinates of the boxes in self, starting from the top right, and reading from right to left.

Note that this includes the ‘basement row’ of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6], [2], [3,4,2], [], [], [5,5]])
sage: a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
 (3, 1),
 (2, 1),
 (1, 1),
 (6, 0),
 (5, 0),
 (4, 0),
 (3, 0),
 (2, 0),
 (1, 0)]
```

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1), Integer(6)], [Integer(2)],
... [Integer(3), Integer(4), Integer(2)], [], [], [Integer(5), Integer(5)]]
>>> a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
 (3, 1),
 (2, 1),
 (1, 1),
 (6, 0),
 (5, 0),
 (4, 0),
 (3, 0),
 (2, 0),
 (1, 0),
(continues on next page)
reading_word()

Return the reading word of self, obtained by reading the boxes entries of self from right to left, starting in the upper right.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_word()
word: 25465321
```

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
                                          [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]]
>>> a.reading_word()
word: 25465321
```

shape()

Return the shape of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.shape()
[2, 1, 3, 0, 0, 2]
```

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
                                          [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]]
>>> a.shape()
[2, 1, 3, 0, 0, 2]
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.weight()
[1, 2, 1, 1, 2, 1]
```

```python
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
                                          [Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]]
>>> a.weight()
[1, 2, 1, 1, 2, 1]
```

sage.combinat.sf.ns_macdonald.E(\(\mu, q=\text{None}, t=\text{None}, p=\text{None}\))

5.1. Comprehensive Module List 4699
Return the non-symmetric Macdonald polynomial in type A corresponding to a shape \( \mu \), with basement permuted according to \( \pi \).

Note that if both \( q \) and \( t \) are specified, then they must have the same parent.

**REFERENCE:**

**See also:**

*NonSymmetricMacdonaldPolynomials* for a type free implementation where the polynomials are constructed recursively by the application of intertwining operators.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import E

sage: E([0,0,0])
1
sage: E([1,0,0])
x0
sage: E([0,1,0])
(t - 1)/(q*t^2 - 1)*x0 + x1
sage: E([0,0,1])
(t - 1)/(q*t - 1)*x0 + (t - 1)/(q*t - 1)*x1 + x2
sage: E([1,1,0])
x0*x1
sage: E([1,0,1])
(t - 1)/(q*t^2 - 1)*x0*x1 + x0*x2
sage: E([0,1,1])
(t - 1)/(q*t - 1)*x0*x1 + (t - 1)/(q*t - 1)*x0*x2 + x1*x2
sage: E([2,0,0])
x0^2 + (q^2*t^2 - 1)/(q^2*t^3 - q^2*t^2 + q*t^2 - 2*q*t + q - t + 1)/(q^3*t^3 - q^2*t^2 - q*t + 1)*x0*x1 + x1^2 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 - q*t + 1)*x0*x2 + (q*t - q)/(q*t - 1)*x1*x2
sage: E([0,2,0])
(t - 1)/(q^2*t^2 - 1)*x0*x2 + (q^2*t^3 - q^2*t^2 + q*t^2 - 2*q*t + q - t + 1)/(q^3*t^3 - q^2*t^2 - q*t + 1)*x0*x1 + x1^2 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 - q*t + 1)*x0*x2 + (q*t - q)/(q*t - 1)*x1*x2
```

(continues on next page)
Combinatorics, Release 10.4

(t - 1)/(q^2*t^2 - 1)*x0^2 + (q^2*t^3 - q^2*t^2 + q^2*t - q - t + 1)/(q^3*t^3 - q^2*t^2 - q*t^2 - t + 1)*x0*x1 + x1^2 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^2 - q*t + 1)*x0*x2 + (q*t - q)/(q^3*t^3 - q^2*t^2 - q*t + 1)*x1*x2

sage.combinat.sf.ns_macdonald.E_integral (mu=q=None, t=None, pi=None)

Return the integral form for the non-symmetric Macdonald polynomial in type A corresponding to a shape mu.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

EXAMPLES:

sage: from sage.combinat.sf.ns_macdonald import E_integral
sage: E_integral([0,0,0])
1
sage: E_integral([1,0,0])
(-t + 1)*x0
sage: E_integral([0,1,0])
(-q*t^2 + 1)*x0 + (-t + 1)*x1
sage: E_integral([0,0,1])
(-q*t + 1)*x0 + (-q*t + 1)*x1 + (-t + 1)*x2
sage: E_integral([1,1,0])
(t^2 - 2*t + 1)*x0*x1
sage: E_integral([1,0,1])
(q^2*t^3 - q^2*t^2 - q*t^2 - q*t + 1)*x0*x1 + (q*t^2 - q*t + 1)*x0*x2 + (t^2 - 2*t + 1)*x1*x2
sage: E_integral([2,0,0])
(t^2 - 2*t + 1)*x0^2 + (q^2*t^2 - q^2*t - q*t + q)*x0*x1 + (q^2*t^2 - q^2*t - q*t + q)*x0*x2
sage: E_integral([0,2,0])
(q^2*t^3 - q^2*t^2 - q*t^2 - q*t + 1)*x0^2 + (q^4*t^3 - q^3*t^2 - q^2*t + q*t - q - t + 1)*x0*x1 + (t^2 - 2*t + 1)*x1*x2 + (q^4*t^3 - q^3*t^2 - q^2*t^2 - q^2*t + q)*x0*x2 + (t^2 - 2*t + 1)*x1*x2

(q^2*t^3 - q^2*t^2 - q*t^2 - q*t - t + 1)*x0*x1 + (t^2 - 2*t + 1)*x1*x2

(continues on next page)
sage.combinat.sf.ns_macdonald.Ht (mu=None, t=None, pi=None)

Return the symmetric Macdonald polynomial using the Haiman, Haglund, and Loehr formula.

Note that if both \( q \) and \( t \) are specified, then they must have the same parent.

REFERENCE:
  arXiv math/0601693v3.

EXAMPLES:

```python
 sage: from sage.combinat.sf.ns_macdonald import Ht
 sage: Ht = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().Ht()
 sage: Ht([0,0,1])
x0 + x1 + x2
 sage: Ht([1]).expand(3)
x0 + x1 + x2
 sage: Ht([0,0,2])
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
 sage: Ht([2]).expand(3)
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
```
arm \((i, j)\)

Return the arm of the box \((i, j)\) in \(self\).

EXAMPLES:

```python
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm(5,2)
[(1, 2), (3, 2), (8, 1)]
```

>>> from sage.all import *

```python
>>>
a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
                    -> Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.arm(Integer(5),Integer(2))
[(1, 2), (3, 2), (8, 1)]
```

arm_left \((i, j)\)

Return the left arm of the box \((i, j)\) in \(self\).

EXAMPLES:

```python
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_left(5,2)
[(1, 2), (3, 2)]
```

>>> from sage.all import *

```python
>>>
a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
                    -> Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>>
a.arm_left(Integer(5),Integer(2))
[(1, 2), (3, 2)]
```

arm_right \((i, j)\)

Return the right arm of the box \((i, j)\) in \(self\).

EXAMPLES:

```python
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_right(5,2)
[(8, 1)]
```

>>> from sage.all import *

```python
>>>
a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
                    -> Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>>
a.arm_right(Integer(5),Integer(2))
[(8, 1)]
```

boxes()

EXAMPLES:

```python
sage: a = LatticeDiagram([3,0,2])
sage: a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
```

(continues on next page)
Combinatorics, Release 10.4

```python
sage: a = LatticeDiagram([2, 1, 3, 0, 0, 2])
sage: a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

```python
>>> from sage.all import *

>>> a = LatticeDiagram([Integer(3),Integer(0),Integer(2)])

>>> a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]

>>> a = LatticeDiagram([Integer(2), Integer(1), Integer(3), Integer(0), Integer(0), Integer(2)])

>>> a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

**boxes_same_and_lower_right** *(ii, jj)*

Return an iterator of the boxes of `self` that are in row `jj` but not identical with *(ii, jj)*, or lie in the row `jj - 1` (the row directly below `jj`; this might be the basement) and strictly to the right of *(ii, jj)*.

**EXAMPLES:**

```python
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[5,5]])

sage: a = a.shape()

sage: list(a.boxes_same_and_lower_right(1,1))
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]

sage: list(a.boxes_same_and_lower_right(1,2))
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]

sage: list(a.boxes_same_and_lower_right(3,3))
[(6, 2)]

sage: list(a.boxes_same_and_lower_right(2,3))
[(3, 3), (3, 2), (6, 2)]
```

```python
>>> from sage.all import *

>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],[Integer(3),Integer(4),Integer(2)],[5,5]])

>>> a = a.shape()

>>> list(a.boxes_same_and_lower_right(Integer(1),Integer(1)))
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]

>>> list(a.boxes_same_and_lower_right(Integer(1),Integer(2)))
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]

>>> list(a.boxes_same_and_lower_right(Integer(3),Integer(3)))
[(6, 2)]

>>> list(a.boxes_same_and_lower_right(Integer(2),Integer(3)))
[(3, 3), (3, 2), (6, 2)]
```

**flip**

Return the flip of `self`, where flip is defined as follows. Let \( r = \max(self) \). Then `self.flip()[i] = r - self[i]`.

**EXAMPLES:**

```python
sage: a = LatticeDiagram([3,0,2])

sage: a.flip()
[0, 3, 1]
```

```python
>>> from sage.all import *

>>> a = LatticeDiagram([Integer(3),Integer(0),Integer(2)])
```

(continues on next page)
Combinatorics, Release 10.4

>>> a.flip()
[0, 3, 1]

l(i, j)
Return self[i] - j.

EXAMPLES:

sage: a = LatticeDiagram([3, 1, 2, 4, 3, 0, 4, 2, 3])
sage: a.l(5, 2)
1

>>> from sage.all import *

>>> a = LatticeDiagram([Integer(3), Integer(1), Integer(2), Integer(4),
                       Integer(3), Integer(0), Integer(4), Integer(2), Integer(3)])
>>> a.l(Integer(5), Integer(2))
1

leg(i, j)
Return the leg of the box (i, j) in self.

EXAMPLES:

sage: a = LatticeDiagram([3, 1, 2, 4, 3, 0, 4, 2, 3])
sage: a.leg(5, 2)
[(5, 3)]

>>> from sage.all import *

>>> a = LatticeDiagram([Integer(3), Integer(1), Integer(2), Integer(4),
                       Integer(3), Integer(0), Integer(4), Integer(2), Integer(3)])
>>> a.leg(Integer(5), Integer(2))
[(5, 3)]

size()
Return the number of boxes in self.

EXAMPLES:

sage: a = LatticeDiagram([3, 1, 2, 4, 3, 0, 4, 2, 3])
sage: a.size()
22

>>> from sage.all import *

>>> a = LatticeDiagram([Integer(3), Integer(1), Integer(2), Integer(4),
                       Integer(3), Integer(0), Integer(4), Integer(2), Integer(3)])
>>> a.size()
22

class sage.combinat.sf.ns_macdonald.NonattackingBacktracker(shape, pi=None)
Bases: GenericBacktracker

EXAMPLES:

sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: n = NonattackingBacktracker(LatticeDiagram([0, 1, 2]))

(continues on next page)
...Continued from previous page...

```
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
>>> n = NonattackingBacktracker(LatticeDiagram([Integer(0), Integer(1),
                                          Integer(2)]))
>>> n._ending_position
(3, 2)
>>> n._initial_state
(2, 1)
```

**get_next_pos**(ii, jj)

**EXAMPLES:**

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: a = AugmentedLatticeDiagramFilling([[1, 6], [2], [3, 4, 2], [], [], [5, 5]])
sage: n = NonattackingBacktracker(a.shape())
sage: n.get_next_pos(1, 1)
(2, 1)
sage: n.get_next_pos(6, 1)
(1, 2)
sage: n = NonattackingBacktracker(LatticeDiagram([2, 2, 2]))
sage: n.get_next_pos(3, 1)
(1, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
>>> a = AugmentedLatticeDiagramFilling([[Integer(1), Integer(6)], [Integer(2)],
                                       [Integer(3), Integer(4), Integer(2)], [], [], [Integer(5), Integer(5)]])
>>> n = NonattackingBacktracker(a.shape())
>>> n.get_next_pos(Integer(1), Integer(1))
(2, 1)
>>> n.get_next_pos(Integer(6), Integer(1))
(1, 2)
>>> n = NonattackingBacktracker(LatticeDiagram([Integer(2), Integer(2),
                                               Integer(2)]))
>>> n.get_next_pos(Integer(3), Integer(1))
(1, 2)
```

```
sage.combinat.sf.ns_macdonald.NonattackingFillings*(shape, pi=None)*

Returning the finite set of nonattacking fillings of a given shape.

**EXAMPLES:**
```
sage: NonattackingFillings([0, 1, 2])
Nonattacking fillings of [0, 1, 2]

>>> NonattackingFillings([Integer(0),Integer(1),Integer(2)]).flip()
Nonattacking fillings of [2, 1, 0]
ORTHOGONAL SYMMETRIC FUNCTIONS

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class sage.combinat.sf.orthogonal.SymmetricFunctionAlgebra_orthogonal(Sym)
Bases: SymmetricFunctionAlgebra_generic

The orthogonal symmetric function basis (or orthogonal basis, to be short).

The orthogonal basis \( \{ o_\lambda \} \) where \( \lambda \) is taken over all partitions is defined by the following change of basis with the Schur functions:

\[
s_\lambda = \sum_\mu \left( \sum_{\nu \in H} c_{\mu \nu}^\lambda \right) o_\mu
\]

where \( H \) is the set of all partitions with even-width rows and \( c_{\mu \nu}^\lambda \) is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a \( \mathbb{Z} \)-graded basis. However this does respect the induced \( (\mathbb{Z}/2\mathbb{Z}) \)-grading.

INPUT:

- \( \text{Sym} \) – an instance of the ring of the symmetric functions

REFERENCES:

- [ChariKleber2000]
- [KoikeTerada1987]
- [ShimozonoZabrocki2006]

EXAMPLES:

Here are the first few orthogonal symmetric functions, in various bases:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(o([1]))
p[1]
sage: m(o([1]))
m[1]
sage: e(o([1]))
e[1]
sage: h(o([1]))
h[1]
sage: s(o([1]))
s[1]
sage: p(o([2]))
```

>>> e(o([Integer(4)]))
>>> h(o([Integer(4)]))
>>> s(o([Integer(4)]))

Some examples of conversions the other way:

```
sage: o(h[3])
o[1] + o[3]
sage: o(e[3])
o[1, 1, 1]
sage: o(m[2,1])
o[1] - 2*o[1, 1, 1] + o[2, 1]
sage: o(p[3])
o[1, 1, 1] - o[2, 1] + o[3]
```

```
>>> from sage.all import *
>>> o(h[Integer(3)])
o[1] + o[3]
>>> o(e[Integer(3)])
o[1, 1, 1]
>>> o(m[Integer(2), Integer(1)])
o[1] - 2*o[1, 1, 1] + o[2, 1]
```

(continues on next page)
Some multiplication:

```
sage: o([2]) * o([1,1])
sage: o([2,1,1]) * o([2])
sage: o([1,1]) * o([2,1])
```

Examples of the Hopf algebra structure:

```
sage: o([1]).antipode()
-o[1]
sage: o([2]).antipode()
-o[] + o[1, 1]
sage: o([1]).coproduct()
o[] # o[1] + o[1] # o[]
sage: o([2]).coproduct()
sage: o([1]).counit()
0
sage: o.one().counit()
1
```

```
>>> from sage.all import *

>>> o([Integer(2)]) * o([Integer(1),Integer(1)])
>>> o([Integer(2),Integer(1),Integer(1)]) * o([Integer(2)])
>>> o([Integer(1),Integer(1)]) * o([Integer(2),Integer(1)])
```

5.1. Comprehensive Module List 4711
5.1.298 Symmetric functions defined by orthogonality and triangularity

One characterization of Schur functions is that they are upper triangularly related to the monomial symmetric functions and orthogonal with respect to the Hall scalar product. We can use the class SymmetricFunctionAlgebra_orthotriang to obtain the Schur functions from this definition.

```python
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur functions')
sage: s([2,1])**2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +...
← s[4, 2]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang

>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
```

```python
class sage.combinat.sf.orthotriang.OrthotriangBasisFunctor(basis)
Bases: SymmetricFunctionsFunctor

A constructor for algebras of symmetric functions constructed by orthogonality and triangularity.

EXAMPLES:
```
```
Combinatorics, Release 10.4

>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur')
>>> s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)

class sage.combinat.sf.orthotriang.SymmetricFunctionAlgebra_orthotriang

Bases: SymmetricFunctionAlgebra_generic

Initialization of the symmetric function algebra defined via orthotriangular rules.

INPUT:

- self – a basis determined by an orthotriangular definition
- Sym – ring of symmetric functions
- base – an instance of a basis of the ring of symmetric functions (e.g. the Schur functions)
- scalar – a function zee on partitions. The function zee determines the scalar product on the power sum basis with normalization \( \langle \pi, \pi \rangle = zee(\mu) \).
- prefix – the prefix used to display the basis
- basis_name – the name used for the basis

Note: The base ring is required to be a \( \mathbb{Q} \)-algebra for this method to be usable, since the scalar product is defined by its values on the power sum basis.

EXAMPLES:

sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis

>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis

class Element

Bases: SymmetricFunctionAlgebra_generic_Element

5.1. Comprehensive Module List 4713
construction()

Return a pair \((F, R)\), where \(F\) is a \texttt{SymmetricFunctionsFunctor} and \(R\) is a ring, such that \(F(R)\) returns \texttt{self}.

**EXAMPLES:**

```python
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur')
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

product (left, right)

Return \(\text{left} \ast \text{right}\) by converting both to the base and then converting back to \texttt{self}.

**INPUT:**

- \(\text{self}\) – a basis determined by an orthotriangular definition
- \(\text{left, right}\) – elements in \texttt{self}

**OUTPUT:**

- the expansion of the product of \(\text{left}\) and \(\text{right}\) in the basis \texttt{self}.

**EXAMPLES:**

```python
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur_functions')
sage: s([1])*s([2,1])  # indirect doctest
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur_functions')
>>> s([Integer(1)])*s([Integer(2),Integer(1)])  # indirect doctest
s[2, 1, 1] + s[2, 2] + s[3, 1]
```
5.1.299 Power sum symmetric functions

```python
class sage.combinat.sf.powersum.SymmetricFunctionAlgebra_power(Sym):
    Bases: SymmetricFunctionAlgebra_multiplicative

    A class for methods associated to the power sum basis of the symmetric functions

    INPUT:
    • `self` – the power sum basis of the symmetric functions
    • `Sym` – an instance of the ring of symmetric functions

class Element
    Bases: Element

    adams_operation(*args, **kwds)
        Deprecated: Use adams_operator() instead. See Issue #36396 for details.

    adams_operator(n)
        Return the image of the symmetric function `self` under the `n`-th Adams operator.

        The `n`-th Adams operator $f_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $f_n$ is a Hopf algebra endomorphism, and satisfies

        $f_n m(\lambda_1, \lambda_2, \lambda_3, \ldots) = m(n\lambda_1, n\lambda_2, n\lambda_3, \ldots)$

        for every partition $(\lambda_1, \lambda_2, \lambda_3, \ldots)$ (where $m$ means the monomial basis). Moreover, $f_n(p_r) = p_{nr}$ for every positive integer $r$ (where $p_k$ denotes the $k$-th power sum symmetric function).

        The `n`-th Adams operator is also called the `n`-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

        The `n`-th Adams operator is the `n`-th Adams operator of the $\Lambda$-ring of symmetric functions over the integers.

        The `n`-th Adams operator can also be described via plethysm: Every symmetric function $P$ satisfies $f_n(P) = p_n \circ P = P \circ p_n$, where $p_n$ is the `n`-th power sum symmetric function, and $\circ$ denotes (outer) plethysm.

        INPUT:
        • `n` – a positive integer

        OUTPUT:

        The result of applying the `n`-th Adams operator (on the ring of symmetric functions) to `self`.

        EXAMPLES:
```
```
sage: (p([3]) - p([2]) + p([])).adams_operator(3)

>>> from sage.all import *

>>> Sym = SymmetricFunctions(ZZ)

>>> p = Sym.p()

>>> p[Integer(3)].adams_operator(Integer(2))
p[6]

>>> p[integer(4), integer(2), integer(1)].adams_operator(integer(3))
p[12, 6, 3]

>>> p([]).adams_operator(integer(4))
p[]

>>> p[integer(3)].adams_operator(integer(1))
p[3]

>>> (p([integer(3)]) - p([integer(2)]) + p([])).adams_operator(integer(3))

See also:

plethysm()

eval_at_permutation_roots(rho)

Evaluate at eigenvalues of a permutation matrix.

Evaluate an element of the power sum basis at the eigenvalues of a permutation matrix with cycle structure $\rho$.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and $\zeta_m$ is an $m$ root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure $\rho$.

**INPUT:**

- $\rho$ – a partition or a list of non-negative integers

**OUTPUT:**

- an element of the base ring

**EXAMPLES:**

```
sage: p = SymmetricFunctions(QQ).p()
sage: p([3,3]).eval_at_permutation_roots([6])
0
sage: p([3,3]).eval_at_permutation_roots([3])
9
sage: p([3,3]).eval_at_permutation_roots([1])
1
sage: p([3,3]).eval_at_permutation_roots([3,3])
36
sage: p([3,3]).eval_at_permutation_roots([1,1,1,1,1])
25
5
```
```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(6)])
0
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(3)])
9
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(1)])
1
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(3),Integer(3)])
36
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])
25
>>> (p[Integer(1)]+p[Integer(2)]+p[Integer(3)]).eval_at_permutation_roots([Integer(3),Integer(3),Integer(2)])
5
```

**expand** 

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

**INPUT:**
- `n` - a nonnegative integer
- `alphabet` - (default: `'x'`) a variable for the expansion

**OUTPUT:**
A monomial expansion of `self` in the `n` variables labelled by `alphabet`.

**EXAMPLES:**

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2])
sage: a.expand(2)
x0^2 + x1^2
sage: a.expand(3, alphabet=['a','b','c'])
a^2 + b^2 + c^2
sage: p([2,1,1]).expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: p([7]).expand(4)
t0^7 + t1^7 + t2^7 + t3^7
sage: p([7]).expand(4,alphabet='t')
x^7 + y^7 + z^7 + t^7
sage: p([1]).expand(4)
1
sage: p(0).expand(4)
0
sage: (p([[]]) + 2*p([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: p([[]]).expand(0)
0
sage: (3*p([])).expand(0)
3
```

(continues on next page)
```python
>>> a = p([Integer(2)])
x0^2 + x1^2
>>> a.expand(Integer(2))
a^2 + b^2 + c^2
>>> p([Integer(2), Integer(1), Integer(1)]).expand(Integer(2))
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
>>> p([Integer(7)]).expand(Integer(4))
x0^7 + x1^7 + x2^7 + x3^7
>>> p([Integer(7)]).expand(Integer(4), alphabet=[t])
t0^7 + t1^7 + t2^7 + t3^7
>>> p([Integer(7)]).expand(Integer(4), alphabet=[x, y, z, t])
x^7 + y^7 + z^7 + t^7
>>> p(Integer(1)).expand(Integer(4))
1
>>> p(Integer(0)).expand(Integer(4))
0
>>> (p([]) + Integer(2)*p([Integer(1)])).expand(Integer(3))
2*x0 + 2*x1 + 2*x2 + 1
>>> p([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*p([])).expand(Integer(0))
3
```

**exponential_specialization** (t=None, q=1)

Return the exponential specialization of a symmetric function (when \( q = 1 \)), or the \( q \)-exponential specialization (when \( q \neq 1 \)).

The exponential specialization \( ex \) at \( t \) is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \). It is defined whenever the base ring \( K \) is a \( Q \)-algebra and \( t \) is an element of \( R \). The easiest way to define it is by specifying its values on the powersum symmetric functions to be \( p_1 = t \) and \( p_n = 0 \) for \( n > 1 \). Equivalently, on the homogeneous functions it is given by \( ex(h_n) = t^n/n! \); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \( q \)-exponential specialization is a \( K \)-algebra homomorphism from the \( K \)-algebra of symmetric functions to another \( K \)-algebra \( R \) that depends on two elements \( t \) and \( q \) of \( R \) for which the elements \( 1 - q^i \) for all positive integers \( i \) are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

\[
ex_q(h_n) = t^n/[n]_q!,
\]

where \([n]_q!\) is the \( q \)-factorial. Equivalently, for \( q \neq 1 \) and a homogeneous symmetric function \( f \) of degree \( n \), we have

\[
ex_q(f) = (1-q)^n t^n p_{s_q}(f),
\]

where \( p_{s_q}(f) \) is the stable principal specialization of \( f \) (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of \( ex_q \) as \( q \to 1 \) is \( ex \).

**INPUT:**

- \( t \) (default: None) – the value to use for \( t \); the default is to create a ring of polynomials in \( t \).
- \( q \) (default: 1) – the value to use for \( q \). If \( q \) is None, then a ring (or fraction field) of polynomials in \( q \) is created.

**EXAMPLES:**
Combinatorics, Release 10.4

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
sage: x.exponential_specialization()
0
sage: x.exponential_specialization(t=var("t"))  # needs sage.symbolic
5*t^2 + 2*t + 1

>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> x = p[Integer(8),Integer(7),Integer(3),Integer(1)]
>>> x.exponential_specialization()
0
>>> x = p[Integer(3)] + Integer(5)*p[Integer(1),Integer(1)] +
    Integer(2)*p[Integer(1)] + Integer(1)
>>> x.exponential_specialization(t=var("t"))  # needs sage.symbolic
5*t^2 + 2*t + 1
```

We also support the $q$-exponential_specialization:

```
sage: factor(p[3].exponential_specialization(q=var("q"), t=var("t")))  # needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)

>>> from sage.all import *
>>> factor(p[Integer(3)].exponential_specialization(q=var("q"), t=var("t")))  # needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

```
frobenius(*args, **kws)
Deprecated: Use adams_operator() instead. See Issue #36396 for details.
```

```
omega()
Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism $\omega$ of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers $k$ (where $e_k$ stands for the $k$-th elementary symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$
\omega(e_\lambda) = h_\lambda,
\omega(h_\lambda) = e_\lambda,
\omega(p_\lambda) = (-1)^{\ell(\lambda)}p_\lambda,
\omega(s_\lambda) = s_\lambda',
$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length (length()) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition (conjugate()) of $\lambda$, and where the usual notations for bases are used ($e =$ elementary, $h =$ complete homogeneous, $p =$ powersum, $s =$ Schur).

omega_involution() is a synonym for the omega() method.
```

```
OUTPUT:
- the image of self under the omega automorphism
```

```
EXAMPLES:
```

5.1. Comprehensive Module List 4719
Combinatorics, Release 10.4

 omega_involution()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \( (-1)^{k-1} p_k \) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{\ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length \( (\text{length}()) \) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition \( (\text{conjugate}()) \) of \( \lambda \), and where the usual notations for bases are used (\( e = \text{elementary} \), \( h = \text{complete homogeneous} \), \( p = \text{powersum} \), \( s = \text{Schur} \)).

omega_involution() is a synonym for the omega() method.

OUTPUT:
• the image of self under the omega automorphism

>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> a = p([Integer(2),Integer(1)]); a
p[2, 1]
>>> a.omega()
-p[2, 1]
>>> p([[]]).omega()
p[]
```  

```
>>> p = SymmetricFunctions(ZZ).p()
>>> (p([Integer(3),Integer(1),Integer(1)]) - Integer(2) * p([Integer(2),
˓→Integer(1),Integer(1)])).omega()
2*p[2, 1] + p[3, 1, 1]
```

**principal_specialization** (*n=Infinity, q=None*)

Return the principal specialization of a symmetric function.

The principal specialization of order *n* at *q* is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, *q* is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at *q* is the ring homomorphism $ps_{q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

**INPUT:**
- *n* (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order *n* or the stable principal specialization.
- *q* (default: None) – the value to use for *q*; the default is to create a ring of polynomials in *q* (or a field of rational functions in *q*) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2]:

\[
p_{n,q}(\lambda) = \prod_i (1 - q^{i-1})/(1 - q^{i}),
\]

\[
ps_{n,1}(\lambda) = n^{\ell(\lambda)},
\]

\[
ps_{q}(\lambda) = 1/\prod_i (1 - q^{i}),
\]

where $\ell(\lambda)$ denotes the length of $\lambda$, and where the products range from $i = 1$ to $i = \ell(\lambda)$.

**EXAMPLES:**

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
```

(continues on next page)
sage: x.principal_specialization(3, q=var("q"))  
# needs sage.symbolic
(q^24 - 1)*(q^21 - 1)*(q^9 - 1)/((q^8 - 1)*(q^7 - 1)*(q - 1))

sage: x = 5*p[1,1,1] + 3*p[2,1] + 1
sage: x.principal_specialization(3, q=var("q"))  
# needs sage.symbolic
5*(q^3 - 1)^3/(q - 1)^3 + 3*(q^6 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1

>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()

>>> x = p[Integer(8),Integer(7),Integer(3),Integer(1)]
>>> x.principal_specialization(Integer(3), q=var("q"))  
# needs sage.symbolic
(q^24 - 1)*(q^21 - 1)*(q^9 - 1)/((q^8 - 1)*(q^7 - 1)*(q - 1))

>>> x = Integer(5)*p[Integer(1),Integer(1),Integer(1)] +  
Integer(3)*p[Integer(2),Integer(1)] + Integer(1)
>>> x.principal_specialization(Integer(3), q=var("q"))  
# needs sage.symbolic
5*(q^3 - 1)^3/(q - 1)^3 + 3*(q^6 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1

By default, we return a rational function in $q$:

sage: x.principal_specialization(3)
8*q^6 + 18*q^5 + 36*q^4 + 38*q^3 + 36*q^2 + 18*q + 9

>>> from sage.all import *
>>> x.principal_specialization(Integer(3))
8*q^6 + 18*q^5 + 36*q^4 + 38*q^3 + 36*q^2 + 18*q + 9

If $n$ is not given we return the stable principal specialization:

sage: x.principal_specialization(q=var("q"))  
# needs sage.symbolic
3/((q^2 - 1)*(q - 1)) - 5/(q - 1)^3 + 1

>>> from sage.all import *
>>> x.principal_specialization(q=var("q"))  
# needs sage.symbolic
3/((q^2 - 1)*(q - 1)) - 5/(q - 1)^3 + 1

**scalar** $(x, zee=\text{None})$

Return the standard scalar product of $\text{self}$ and $x$.

**INPUT:**

- $x$ - a power sum symmetric function
- $zee$ - (default: uses standard $zee$ function) optional input specifying the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = zee(\mu)$. $zee$ should be a function of partitions. Note that the power-sum symmetric functions are orthogonal under this scalar product. With the default value of $zee$, the value of $\langle p_\lambda, p_\lambda \rangle$ is given by the size of the centralizer in $S_n$ of a permutation of cycle type $\lambda$.

**OUTPUT:**

- the standard scalar product between $\text{self}$ and $x$, or, if the optional parameter $zee$ is specified, then the scalar product with respect to the normalization $\langle p_\mu, p_\mu \rangle = zee(\mu)$ with the power sum
EXAMPLES:

```python
sage: p = SymmetricFunctions(QQ).p()
sage: p4 = Partitions(4)
sage: matrix([[p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4 0 0 0 0]
[ 0 3 0 0 0]
[ 0 0 8 0 0]
[ 0 0 0 4 0]
[ 0 0 0 0 24]
sage: p(0).scalar(p(1))
0
sage: p(1).scalar(p(2))
2
sage: zee = lambda x : 1
sage: matrix([[p[la].scalar(p[mu], zee) for la in Partitions(3)] for mu in Partitions(3)])
[1 0 0]
[0 1 0]
[0 0 1]
```

>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p4 = Partitions(Integer(4))
>>> matrix([[p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4 0 0 0 0]
[ 0 3 0 0 0]
[ 0 0 8 0 0]
[ 0 0 0 4 0]
[ 0 0 0 0 24]
>>> p(Integer(0)).scalar(p(Integer(1)))
0
>>> p(Integer(1)).scalar(p(Integer(2)))
2

```python
>>> zee = lambda x : Integer(1)
>>> matrix([[p[la].scalar(p[mu], zee) for la in Partitions(Integer(3))] for mu in Partitions(Integer(3))])
[1 0 0]
[0 1 0]
[0 0 1]
```

**verschiebung** (*n*)

Return the image of the symmetric function `self` under the *n*-th Verschiebung operator.

The *n*-th Verschiebung operator \( V_n \) is defined to be the unique algebra endomorphism \( V \) of the ring of symmetric functions that satisfies \( V(h_r) = h_{r/n} \) for every positive integer \( r \) divisible by \( n \), and satisfies \( V(h_r) = 0 \) for every positive integer \( r \) not divisible by \( n \). This operator \( V_n \) is a Hopf algebra endomorphism. For every nonnegative integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}
\]

(where \( h \) is the complete homogeneous basis, \( p \) is the powersum basis, and \( e \) is the elementary basis). For every nonnegative integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.
\]
The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The \( n \)-th Verschiebung operator is adjoint to the \( n \)-th Adams operator (see \texttt{adams_operator()} for its definition) with respect to the Hall scalar product (\texttt{scalar()}).

The action of the \( n \)-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let \( \lambda \) be a partition. Let \( n \) be a positive integer. If the \( n \)-core of \( \lambda \) is nonempty, then \( V_n(s_\lambda) = 0 \). Otherwise, the following method computes \( V_n(s_\lambda) \): Write the partition \( \lambda \) in the form \((\lambda_1, \lambda_2, \ldots, \lambda_{ns})\) for some nonnegative integer \( s \). (If \( n \) does not divide the length of \( \lambda \), then this is achieved by adding trailing zeroes to \( \lambda \).) Set \( \beta_i = \lambda_i + ns - i \) for every \( s \in \{1, 2, \ldots, ns\} \). Then, \((\beta_1, \beta_2, \ldots, \beta_{ns})\) is a strictly decreasing sequence of nonnegative integers. Stably sort the list \((1, 2, \ldots, ns)\) in order of (weakly) increasing remainder of \(-1 - \beta_i \) modulo \( n \). Let \( \xi \) be the sign of the permutation that is used for this sorting. Let \( \psi \) be the sign of the permutation that is used to stably sort the list \((1, 2, \ldots, ns)\) in order of (weakly) increasing remainder of \( i - 1 \) modulo \( n \). (Notice that \( \psi = (-1)^{n(n-1)s(s-1)/4} \).)

Then, \( V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda(i)} \), where \((\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})\) is the \( n \)-quotient of \( \lambda \).

**INPUT:**
- \( n \) – a positive integer

**OUTPUT:**
The result of applying the \( n \)-th Verschiebung operator (on the ring of symmetric functions) to \texttt{self}.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].verschiebung(2)
0
sage: p[4].verschiebung(4)
4*p[1]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> p[Integer(3)].verschiebung(Integer(2))
0
>>> p[Integer(4)].verschiebung(Integer(4))
4*p[1]
```

The Verschiebung endomorphisms are multiplicative:

```python
sage: all( all( p(lam).verschiebung(2) * p(mu).verschiebung(2)
....: == (p(lam) * p(mu)).verschiebung(2)
....: for mu in Partitions(4) )
....: for lam in Partitions(4) )
True
```

```python
>>> from sage.all import *
>>> all( all( p(lam).verschiebung(Integer(2)) * p(mu).verschiebung(Integer(2))
.....: == (p(lam) * p(mu)).verschiebung(Integer(2))
.....: for mu in Partitions(Integer(4)) )
.....: for lam in Partitions(Integer(4)) )
True
```
Testing the adjointness between the Adams operators $f_n$ and the Verschiebung operators $V_n$:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: all( all( p(lam).verschiebung(2).scalar(p(mu))
....:     == p(lam).scalar(p(mu).adams_operator(2))
....:     for mu in Partitions(2) )
....:     for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> all( all( p(lam).verschiebung(Integer(2)).scalar(p(mu))
...     == p(lam).scalar(p(mu).adams_operator(Integer(2)))
...     for mu in Partitions(Integer(2)) )
...     for lam in Partitions(Integer(4)) )
True
```

antipode_on_basis(partition)

Return the antipode of self[partition].

The antipode on the generator $p_i$ (for $i > 0$) is $-p_i$, and the antipode on $p_\mu$ is $(-1)^{\text{length}(\mu)}p_\mu$.

INPUT:

• self – the power sum basis of the symmetric functions
• partition – a partition

OUTPUT:

• the result of the antipode on self(partition)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.antipode_on_basis([2])
-p[2]
sage: p.antipode_on_basis([3])
-p[3]
sage: p.antipode_on_basis([2,2])
p[2, 2]
sage: p.antipode_on_basis([])
p[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> p.antipode_on_basis([Integer(2)])
-p[2]
>>> p.antipode_on_basis([Integer(3)])
-p[3]
>>> p.antipode_on_basis([Integer(2),Integer(2)])
p[2, 2]
>>> p.antipode_on_basis([])
p[]
```
**bottom_schur_function** *(partition, degree=None)*

Return the least-degree component of *s[partition]*, where *s* denotes the Schur basis of the symmetric functions, and the grading is not the usual grading on the symmetric functions but rather the grading which gives every *p*<sub>*i* </sub> degree 1.

This least-degree component has its degree equal to the Frobenius rank of *partition*, while the degree with respect to the usual grading is still the size of *partition*.

This method requires the base ring to be a (commutative) Q-algebra. This restriction is unavoidable, since the least-degree component (in general) has noninteger coefficients in all classical bases of the symmetric functions.

The optional keyword degree allows taking any homogeneous component rather than merely the least-degree one. Specifically, if degree is set, then the degree-th component will be returned.

**REFERENCES:**

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.bottom_schur_function([2,2,1])
-1/6*p[3, 2] + 1/4*p[4, 1]
sage: p.bottom_schur_function([2,1])
-1/3*p[3]
sage: p.bottom_schur_function([3])
1/3*p[3]
sage: p.bottom_schur_function([1,1,1])
1/3*p[3]
sage: p.bottom_schur_function(Partition([1,1,1]))
1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=1)
-1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=2)
0
sage: p.bottom_schur_function([2,1], degree=3)
1/3*p[1, 1, 1]
sage: p.bottom_schur_function([2,2,1], degree=3)
1/8*p[2, 2, 1] - 1/6*p[3, 1, 1]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> p.bottom_schur_function([Integer(2),Integer(2),Integer(1)])
-1/6*p[3, 2] + 1/4*p[4, 1]
>>> p.bottom_schur_function([Integer(2),Integer(1)])
-1/3*p[3]
>>> p.bottom_schur_function([Integer(3)])
1/3*p[3]
>>> p.bottom_schur_function([Integer(1),Integer(1),Integer(1)])
1/3*p[3]
>>> p.bottom_schur_function(Partition([Integer(1),Integer(1),Integer(1)]))
1/3*p[3]
>>> p.bottom_schur_function([Integer(2),Integer(1)], degree=Integer(1))
-1/3*p[3]
>>> p.bottom_schur_function([Integer(2),Integer(1)], degree=Integer(2))
0
>>> p.bottom_schur_function([Integer(2),Integer(1)], degree=Integer(3))
1/3*p[1, 1, 1]
```

(continues on next page)
coprodct_on_generators \( (i) \)

Return coproduct on generators for power sums \( p_i \) (for \( i > 0 \)).

The elements \( p_i \) are primitive elements.

INPUT:

- self – the power sum basis of the symmetric functions
- \( i \) – a positive integer

OUTPUT:

- the result of the coproduct on the generator \( p(i) \)

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)

sage: p = Sym.powersum()

sage: p.coproduct_on_generators(2)

```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> p = Sym.powersum()

>>> p.coproduct_on_generators(Integer(2))

```

eval_at_permutation_roots_on_generators \( (k, \rho) \)

Evaluate \( p_k \) at eigenvalues of permutation matrix.

This function evaluates a symmetric function \( p \left( [k] \right) \) at the eigenvalues of a permutation matrix with cycle structure \( \rho \).

This function evaluates a \( p_k \) at the roots of unity

\[ \Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_\ell} \]

where

\[ \Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1} \]

and \( \zeta_m \) is an \( m \) root of unity. This is characterized by \( p_k[A, B] = p_k[A] + p_k[B] \) and \( p_k[\Xi_m] = 0 \) unless \( m \) divides \( k \) and \( p_{r_m}[\Xi_m] = m \).

INPUT:

- \( k \) – a non-negative integer
- \( \rho \) – a partition or a list of non-negative integers

OUTPUT:

- an element of the base ring

EXAMPLES:
```python
sage: p = SymmetricFunctions(QQ).p()
sage: p.eval_at_permutation_roots_on_generators(3, [6])
0
sage: p.eval_at_permutation_roots_on_generators(3, [3])
3
sage: p.eval_at_permutation_roots_on_generators(3, [1])
1
sage: p.eval_at_permutation_roots_on_generators(3, [3,3])
6
sage: p.eval_at_permutation_roots_on_generators(3, [1,1,1,1,1])
5
```

```python
>>> from sage.all import *

>>> p = SymmetricFunctions(QQ).p()

>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(6)])
0

>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(3)])
3

>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(1)])
1

>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(3),
Integer(3)])
6

>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(1),
Integer(1),Integer(1),Integer(1),Integer(1)])
5
```

**5.1.300 Schur symmetric functions**

```python
class sage.combinat.sf.schur.SymmetricFunctionAlgebra_schur(Sym)
    Bases: SymmetricFunctionAlgebra_classical

A class for methods related to the Schur symmetric function basis

INPUT:

- `self` - a Schur symmetric function basis
- `Sym` - an instance of the ring of the symmetric functions

class Element
    Bases: Element

expand(n, alphabet='x')

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` - a nonnegative integer
- `alphabet` - (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the `n` variables labelled by `alphabet`.

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
(continues on next page)
```
```
```python
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> a.expand(Integer(2))
x0^2*x1 + x0*x1^2
>>> a.expand(Integer(3))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
>>> a.expand(Integer(4))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + ...
    → x0^2*x3 + 2*x0*x1*x3 + x1^2*x3 + 2*x0*x2*x3 + 2*x1*x2*x3 + x2^2*x3 + ...
    → x0*x3^2 + x1*x3^2 + x2*x3^2
>>> a.expand(2, alphabet='y')
y0^2*y1 + y0*y1^2
>>> a.expand(2, alphabet=[a,b])
a^2*b + a*b^2
```

exponential_specialization \((t=\text{None}, \ q=1)\)

Return the exponential specialization of a symmetric function (when \(q = 1\), or the \(q\)-exponential specialization (when \(q \neq 1\)).

The exponential specialization \(ex\) at \(t\) is a \(K\)-algebra homomorphism from the \(K\)-algebra of symmetric functions to another \(K\)-algebra \(R\). It is defined whenever the base ring \(K\) is a \(Q\)-algebra and \(t\) is an element of \(R\). The easiest way to define it is by specifying its values on the powersum symmetric functions to be \(p_1 = t\) and \(p_n = 0\) for \(n > 1\). Equivalently, on the homogeneous functions it is given by \(ex(h_n) = t^n/n!\); see Proposition 7.8.4 of [EnumComb2].

By analogy, the \(q\)-exponential specialization is a \(K\)-algebra homomorphism from the \(K\)-algebra of symmetric functions to another \(K\)-algebra \(R\) that depends on two elements \(t\) and \(q\) of \(R\) for which the

5.1. Comprehensive Module List
elements $1 - q^i$ for all positive integers $i$ are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the $q$-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function $f$ of degree $n$, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of $f$ (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of $ex_q$ as $q \to 1$ is $ex$.

**INPUT:**
- $t$ (default: None) – the value to use for $t$; the default is to create a ring of polynomials in $t$.
- $q$ (default: 1) – the value to use for $q$. If $q$ is None, then a ring (or fraction field) of polynomials in $q$ is created.

We use the formula in the proof of Corollary 7.21.6 of [EnumComb2]

$$ex_q(s_\lambda) = t^{\lambda|} q^{\sum{(i-1)\lambda_i}}/ \prod_{u \in \lambda} (1 + q + q^2 + \cdots + q^{h(u)-1})$$

where $h(u)$ is the hook length of a cell $u$ in $\lambda$.

As a limit case, we obtain a formula for $q = 1$

$$ex_1(s_\lambda) = f^\lambda |\lambda|/|\lambda|!$$

where $f^\lambda$ is the number of standard Young tableaux of shape $\lambda$.

**EXAMPLES:**

```
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[5,3]
sage: x.exponential_specialization()
1/1440*t^8
sage: x = 5*s[1,1,1] + 3*s[2,1] + 1
sage: x.exponential_specialization()
11/6*t^3 + 1
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> x = s[Integer(5),Integer(3)]
>>> x.exponential_specialization()
1/1440*t^8
>>> x = Integer(5)*s[Integer(1),Integer(1),Integer(1)] + Integer(3)*s[Integer(2),Integer(1)] + Integer(1)
>>> x.exponential_specialization()
11/6*t^3 + 1
```

We also support the $q$-exponential_specialization:

```
sage: factor(s[3].exponential_specialization(q=var("q"), t=var("t")))  # needs sage.symbolic
(t^3/((q^2 + q + 1)*(q + 1))```
omega()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism $\omega$ of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers $k$ (where $e_k$ stands for the $k$-th elementary symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length ($\text{length}(\lambda)$) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition ($\text{conjugate}(\lambda)$) of $\lambda$, and where the usual notations for bases are used ($e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur}$).

OUTPUT:

- the image of self under the omega automorphism

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

omega_involution()

Return the image of self under the omega automorphism.

The omega automorphism is defined to be the unique algebra endomorphism $\omega$ of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers $k$ (where $e_k$ stands for the $k$-th elementary symmetric function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length ($\text{length}(\lambda)$) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition ($\text{conjugate}(\lambda)$) of $\lambda$, and where the usual notations for bases are used ($e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur}$).
omega_involution() is a synonym for the omega() method.

OUTPUT:
- the image of self under the omega automorphism

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

principal_specialization(n=+Infinity, q=None)

Return the principal specialization of a symmetric function.

The principal specialization of order $n$ at $q$ is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, $q$ is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at $q$ is the ring homomorphism $ps_q$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:
- $n$ (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order $n$ or the stable principal specialization.
- $q$ (default: None) – the value to use for $q$; the default is to create a ring of polynomials in $q$ (or a field of rational functions in $q$) over the given coefficient ring.

For $q = 1$ we use the formula from Corollary 7.21.4 of [EnumComb2]:

$$ps_{n,1}(s_{\lambda}) = \prod_{u \in \lambda} (n + c(u))/h(u),$$

where $h(u)$ is the hook length of a cell $u$ in $\lambda$, and where $c(u)$ is the content of a cell $u$ in $\lambda$.

For $n = infinity$ we use the formula from Corollary 7.21.3 of [EnumComb2]

$$ps_q(s_{\lambda}) = q^{\sum (i-1) \lambda_i} / \prod_{u \in \lambda} (1 - q^{h(u)}).$$

Otherwise, we use the formula from Theorem 7.21.2 of [EnumComb2],

$$ps_{n,q}(s_{\lambda}) = q^{\sum (i-1) \lambda_i} \prod_{u \in \lambda} (1 - q^{n+c(u)}/(1 - q^{h(u)}).$$

EXAMPLES:
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[2]
sage: x.principal_specialization(3)
q^4 + q^3 + 2*q^2 + q + 1

sage: x = 3*s[2,2] + 2*s[1] + 1
sage: x.principal_specialization(3, q=var("q"))
# needs sage.symbolic
3*(q^4 - 1)*(q^3 - 1)*q^2/((q^2 - 1)*(q - 1)) + 2*(q^3 - 1)/(q - 1) + 1

sage: x = 3*s[2,2] + 2*s[1] + 1
sage: x.principal_specialization(q=var("q"))
# needs sage.symbolic
-2/(q - 1) + 3*q^2/((q^3 - 1)*(q^2 - 1)^2*(q - 1)) + 1

```
from sage.all import *

s = SymmetricFunctions(QQ).s()
x = s[2]
x.principal_specialization(3)
q^4 + q^3 + 2*q^2 + q + 1

x = 3*s[2,2] + 2*s[1] + 1
x.principal_specialization(3, q=var("q"))
# needs sage.symbolic
3*(q^4 - 1)*(q^3 - 1)*q^2/((q^2 - 1)*(q - 1)) + 2*(q^3 - 1)/(q - 1) + 1

x.principal_specialization(q=var("q"))
# needs sage.symbolic
-2/(q - 1) + 3*q^2/((q^3 - 1)*(q^2 - 1)^2*(q - 1)) + 1
```

**scalar** \((x, \text{zee=None})\)

Return the standard scalar product between \(\text{self}\) and \(x\).

Note that the Schur functions are self-dual with respect to this scalar product. They are also lower-triangularly related to the monomial symmetric functions with respect to this scalar product.

**INPUT:**

- \(x\) – element of the ring of symmetric functions over the same base ring as \(\text{self}\)
- \(\text{zee}\) – an optional function on partitions giving the value for the scalar product between the power-sum symmetric function \(p_\mu\) and itself (the default value is the standard \(\text{zee()}\) function)

**OUTPUT:**

- the scalar product between \(\text{self}\) and \(x\)

**EXAMPLES:**

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: b = s([1,1,1])
sage: c = 2*s([1,1,1])
sage: d = a + b
sage: a.scalar(a)
1
sage: b.scalar(b)
1
sage: b.scalar(a)
0
sage: b.scalar(c)
2
```

(continues on next page)
sage: c.scalar(c)
4
sage: d.scalar(a)
1
sage: d.scalar(b)
1
sage: d.scalar(c)
2

>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> a = s([[Integer(2),Integer(1)]]
>>> b = s([[Integer(1),Integer(1),Integer(1)]])
>>> c = Integer(2)*s([[Integer(1),Integer(1),Integer(1)]])
>>> d = a + b
>>> a.scalar(a)
1
>>> b.scalar(b)
1
>>> b.scalar(a)
0
>>> b.scalar(c)
2
>>> c.scalar(c)
4
>>> d.scalar(a)
1
>>> d.scalar(b)
1
>>> d.scalar(c)
2

sage: m = SymmetricFunctions(ZZ).monomial()

verschiebung \( (n) \)

Return the image of the symmetric function \( \text{self} \) under the \( n \)-th Verschiebung operator.
The \( n \)-th Verschiebung operator \( V_n \) is defined to be the unique algebra endomorphism \( V \) of the ring of symmetric functions that satisfies \( V(h_r) = h_{r/n} \) for every positive integer \( r \) divisible by \( n \), and satisfies \( V(h_r) = 0 \) for every positive integer \( r \) not divisible by \( n \). This operator \( V_n \) is a Hopf algebra endomorphism. For every nonnegative integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}
\]

(where \( h \) is the complete homogeneous basis, \( p \) is the powersum basis, and \( e \) is the elementary basis). For every nonnegative integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.
\]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The \( n \)-th Verschiebung operator is adjoint to the \( n \)-th Frobenius operator (see \texttt{frobenius()} for its definition) with respect to the Hall scalar product (\texttt{scalar()}).

The action of the \( n \)-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let \( \lambda \) be a partition. Let \( n \) be a positive integer. If the \( n \)-core of \( \lambda \) is nonempty, then \( V_n(s_\lambda) = 0 \). Otherwise, the following method computes \( V_n(s_\lambda) \): Write the partition \( \lambda \) in the form \((\lambda_1, \lambda_2, \ldots, \lambda_{ns})\) for some nonnegative integer \( s \). (If \( n \) does not divide the length of \( \lambda \), then this is achieved by adding trailing zeroes to \( \lambda \).) Set \( \beta_i = \lambda_i + ns - i \) for every \( s \in \{1, 2, \ldots, ns\} \). Then, \((\beta_1, \beta_2, \ldots, \beta_{ns})\) is a strictly decreasing sequence of nonnegative integers. Stably sort the list \((1, 2, \ldots, ns)\) in order of (weakly) increasing remainder of \(-1 - \beta_i \) modulo \( n \). Let \( \xi \) be the sign of the permutation that is used for this sorting. Let \( \psi \) be the sign of the permutation that is used to stably sort the list \((1, 2, \ldots, ns)\) in order of (weakly) increasing remainder of \( i - 1 \) modulo \( n \). (Notice that \( \psi = (-1)^{n(n-1)s(s-1)/4} \).) Then, \( V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda(i)} \), where \((\lambda(0), \lambda(1), \ldots, \lambda(n-1))\) is the \( n \)-quotient of \( \lambda \).

**INPUT:**
- \( n \) – a positive integer

**OUTPUT:**

The result of applying the \( n \)-th Verschiebung operator (on the ring of symmetric functions) to \texttt{self}.

**EXAMPLES:**

```sage
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: s[5].verschiebung(2)
0
sage: s[6].verschiebung(6)
s[1]
sage: s[6,3].verschiebung(3)
s[2, 1] + s[3]
sage: s[6,3,1].verschiebung(2)
-s[3, 2]
sage: s[3,2,1].verschiebung(1)
s[3, 2, 1]
sage: s([]).verschiebung(1)
s[]
sage: s([]).verschiebung(4)
s[]
```

5.1. Comprehensive Module List 4735
```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> s = Sym.s()

>>> s[Integer(5)].verschiebung(Integer(2))
0

>>> s[Integer(6)].verschiebung(Integer(6))
s[1]

>>> s[Integer(6), Integer(3)].verschiebung(Integer(3))
s[2, 1] + s[3]

>>> s[Integer(6), Integer(3), Integer(1)].verschiebung(Integer(2))
-s[3, 2]

>>> s[Integer(3), Integer(2), Integer(1)].verschiebung(Integer(1))
s[3, 2, 1]

>>> s[[]].verschiebung(Integer(1))
s[]

>>> s[[]].verschiebung(Integer(4))
s[]
```

coproduct_on_basis (\(\mu\))

Returns the coproduct of \(\text{self} (\mu)\).

Here \(\text{self}\) is the basis of Schur functions in the ring of symmetric functions.

INPUT:
- \(\text{self}\) – a Schur symmetric function basis
- \(\mu\) – a partition

OUTPUT:
- the image of the \(\mu\)-th Schur function under the comultiplication of the Hopf algebra of symmetric functions; this is an element of the tensor square of the Schur basis

EXAMPLES:
```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s.coproduct_on_basis([2])
```

product_on_basis (\(\text{left}, \text{right}\))

Return the product of \(\text{left}\) and \(\text{right}\).

INPUT:
- \(\text{self}\) – a Schur symmetric function basis
- \(\text{left}, \text{right}\) – partitions

OUTPUT:
- an element of the Schur basis, the product of \(\text{left}\) and \(\text{right}\)
```
5.1.301 Symplectic Symmetric Functions

AUTHORS:

• Travis Scrimshaw (2013-11-10): Initial version

```
class sage.combinat.sf.symplectic.SymmetricFunctionAlgebra_symplectic(Sym)
    Bases: SymmetricFunctionAlgebra_generic

The symplectic symmetric function basis (or symplectic basis, to be short).

The symplectic basis \{sp_\lambda\} where \lambda is taken over all partitions is defined by the following change of basis with the Schur functions:

\[ s_\lambda = \sum_{\mu} \left( \sum_{\nu \in V} c_{\mu\nu}^\lambda \right) sp_\mu \]

where \( V \) is the set of all partitions with even-height columns and \( c_{\mu\nu}^\lambda \) is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a \( \mathbb{Z} \)-graded basis. However this does respect the induced \((\mathbb{Z}/2\mathbb{Z})\)-grading.

INPUT:

• Sym – an instance of the ring of the symmetric functions

REFERENCES:

EXAMPLES:

Here are the first few symplectic symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(sp([1]))
p[1]
sage: m(sp([1]))
m[1]
sage: e(sp([1]))
e[1]
sage: h(sp([1]))
h[1]
sage: s(sp([1]))
s[1]

sage: p(sp([2]))
1/2*p[1, 1] + 1/2*p[2]
sage: m(sp([2]))
m[1, 1] + m[2]
sage: e(sp([2]))
e[1, 1] - e[2]
sage: h(sp([2]))  
```

(continues on next page)
\begin{verbatim}

h[2]
sage: s(sp([2]))
s[2]

sage: p(sp([3]))
1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
sage: m(sp([3]))
m[1, 1, 1] + m[2, 1] + m[3]

sage: e(sp([3]))
e[1, 1, 1] - 2*e[2, 1] + e[3]
sage: h(sp([3]))
h[3]
sage: s(sp([3]))
s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()

sage: m(sp([4]))
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
sage: e(sp([4]))
sage: h(sp([4]))
h[4]
sage: s(sp([4]))
s[4]

>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> sp = Sym.sp()

>>> e = Sym.e()

>>> h = Sym.h()

>>> p = Sym.p()

>>> m = Sym.m()

>>> p(sp([Integer(1)]))
p[1]

>>> m(sp([Integer(1)]))
m[1]

>>> e(sp([Integer(1)]))
e[1]

>>> h(sp([Integer(1)]))
h[1]

>>> s(sp([Integer(1)]))
s[1]

>>> p(sp([Integer(2)]))
1/2*p[1, 1] + 1/2*p[2]

>>> m(sp([Integer(2)]))
m[1, 1] + m[2]

>>> e(sp([Integer(2)]))

\end{verbatim}
Some examples of conversions the other way:

```
sage: sp(h[3])
sp[3]
sage: sp(e[3])
sp[1] + sp[1, 1, 1]
sage: sp(m[2,1])
-sp[1] - 2*sp[1, 1, 1] + sp[2, 1]
sage: sp(p[3])
sp[1, 1, 1] - sp[2, 1] + sp[3]
```

Some multiplication:
Combinatorics, Release 10.4

sage: sp([2]) * sp([1,1])
sage: sp([2,1,1]) * sp([2])
sage: sp([1,1]) * sp([2,1])

Examples of the Hopf algebra structure:

5.1.302 Symmetric functions, with their multiple realizations

```python
class sage.combinat.sf.sf.SymmetricFunctions(R)
    Bases: UniqueRepresentation, Parent

The abstract algebra of commutative symmetric functions
```

**Symmetric Functions in Sage**

*Author: Jason Bandlow, Anne Schilling, Nicolas M. Thiery, Mike Zabrocki*

This document is an introduction to working with symmetric function theory in Sage. It is not intended to be an introduction to the theory of symmetric functions ([MAC] and [STA], Chapter 7, are two excellent references.) The reader is also expected to be familiar with Sage.

**The algebra of symmetric functions**

The algebra of symmetric functions is the unique free commutative graded connected algebra over the given ring, with one generator in each degree. It can also be thought of as the inverse limit (in the category of graded algebras) of the algebra of symmetric polynomials in \( n \) variables as \( n \to \infty \). Sage allows us to construct the algebra of symmetric functions over any ring. We will use a base ring of rational numbers in these first examples:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Sym
Symmetric Functions over Rational Field
```

Sage knows certain categorical information about this algebra:

```python
sage: Sym.category()
Join of Category of Hopf algebras over Rational Field
    and Category of unique factorization domains
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sym
Symmetric Functions over Rational Field
```

```python
sage: Sym.category()
Join of Category of Hopf algebras over Rational Field
    and Category of unique factorization domains
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field
```

---

5.1. Comprehensive Module List

---

4741
Notice that Sym is an abstract algebra. This reflects the fact that there are multiple natural bases. To work with specific elements, we need a realization of this algebra. In practice, this means we need to specify a basis.

An example basis - power sums

Here is an example of how one might use the power sum realization:

```sage
p = Sym.powersum()
p
```

```
Symmetric Functions over Rational Field in the powersum basis
```

```
>>> from sage.all import *

>>> p = Sym.powersum()

>>> p
Symmetric Functions over Rational Field in the powersum basis
```

p now represents the realization of the symmetric function algebra on the power sum basis. The basis itself is accessible through:

```sage
p.basis()
```

```
Lazy family (Term map from Partitions to Symmetric Functions over Rational Field→in the powersum basis(i))_{i in Partitions}
```

```sage
p.basis().keys()
```

```
Partitions
```

This last line means that `p.basis()` is an association between the set of Partitions and the basis elements of the algebra p. To construct a specific element one can therefore do:

```sage
p.basis()[Partition([2,1,1])]
```

```
p[2, 1, 1]
```

As this is rather cumbersome, realizations of the symmetric function algebra allow for the following abuses of notation:

```sage
p[Partition([2,1,1])]
```

```
p[2, 1, 1]
```

```sage
p[[2, 1, 1]]
```

```
p[2, 1, 1]
```

```sage
p[2, 1, 1]
```

```
p[2, 1, 1]
```

```sage
>>> from sage.all import *

>>> p[Partition([Integer(2), Integer(1), Integer(1)])]
```

```
p[2, 1, 1]
```

(continues on next page)
or even:

```python
sage: p[(i for i in [2, 1, 1])]
p[2, 1, 1]
```

In the special case of the empty partition, due to a limitation in Python syntax, one cannot use:

```python
sage: p[] # todo: not implemented
```

Please use instead:

```python
sage: p[[]]
p[]
```

**Note:** When elements are constructed using the `p[something]` syntax, an error will be raised if the input cannot be interpreted as a partition. This is *not* the case when `p.basis()` is used:

```python
sage: p['something']
Traceback (most recent call last):
  ...
ValueError: all parts of 'something' should be nonnegative integers
```

```python
sage: p.basis()['something']
p'something'
```

```python
>>> from sage.all import *
```
Algebra structure

Algebraic combinations of basis elements can be entered in a natural way:

```
3*p[2, 1, 1] + 2*p[4, 1]
```

Let us explore the other operations of \( p \). We can ask for the mathematical properties of \( p \):

```
sage: p.categories()
[Category of graded bases of Symmetric Functions over Rational Field,
 Category of filtered bases of Symmetric Functions over Rational Field,
 Category of bases of Symmetric Functions over Rational Field,
 Category of graded Hopf algebras with basis over Rational Field,
 ...]
```

To start with, \( p \) is a graded algebra, the grading being induced by the size of the partitions. Due to this, the one is the basis element indexed by the empty partition:

```
sage: p.one()
p[
```

The \( p \) basis is multiplicative; that is, multiplication is induced by linearity from the (nonincreasingly sorted) concatenation of partitions:

```
sage: p[3,1] * p[2,1]
p[3, 2, 1, 1]
sage: (p.one() + 2 * p[3,1]) * p[4, 2]
p[4, 2] + 2*p[4, 3, 2, 1]
```

(continues on next page)
p[3, 2, 1, 1]

>>> (p.one() + Integer(2) * p[Integer(3),Integer(1)]) * p[Integer(4), Integer(2)]
>>> p[4, 2] + 2*p[4, 3, 2, 1]

The classical bases

In addition to the power sum basis, other classical bases of the symmetric function algebra include the elementary, complete homogeneous, monomial, and Schur bases:

```python
sage: e = Sym.elementary()
sage: h = Sym.homogeneous()
sage: m = Sym.monomial()
sage: s = Sym.schur()
```

These and others can be defined all at once with the single command:

```python
sage: Sym.inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis
```

```python
>>> from sage.all import *
```

We can then do conversions from one basis to another:
For computations which mix bases, Sage will return a result with respect to a single (not necessarily predictable) basis:

```
>>> from sage.all import *
>>> s(p[Integer(2),Integer(1)])
-1/2*p[2, 1, 1, 1] + 1/2*p[2, 2, 1] + 1/2*p[2, 1, 1]
>>> m(p[Integer(1)])
m[1]
```

The one for different bases such as the power sum and Schur function is the same:

```
sage: s.one() == p.one()
True
```

Basic computations

In this section, we explore some of the many methods that can be applied to an arbitrary symmetric function:

```
sage: f = s[2]**2; f
>>> from sage.all import *
>>> f = s[Integer(2)]**Integer(2); f
```
For more methods than discussed here, create a symmetric function as above, and use \texttt{f.<tab>}.

**Representation theory of the symmetric group**

The Schur functions \( s_\lambda \) can also be interpreted as irreducible characters of the symmetric group \( S_n \), where \( n \) is the size of the partition \( \lambda \). Since the Schur functions of degree \( n \) form a basis of the symmetric functions of degree \( n \), it follows that an arbitrary symmetric function (homogeneous of degree \( n \)) may be interpreted as a function on the symmetric group. In this interpretation the power sum symmetric function \( p_\lambda \) is the characteristic function of the conjugacy class with shape \( \lambda \), multiplied by the order of the centralizer of an element. Hence the irreducible characters can be computed as follows:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: P = Partitions(5).list()
sage: M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P))]] for i in range(len(P)))
sage: M
```

We can indeed check that this agrees with the character table of \( S_5 \):

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> p = Sym.power()
>>> P = Partitions(Integer(5)).list()
>>> P = [P[i] for i in range(len(P)-1,-1,-1)]
>>> M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P))]] for i in range(len(P)))]
>>> M
```

In this interpretation of symmetric functions as characters on the symmetric group, the multiplication and comultiplication are interpreted as induction (from \( S_n \times S_m \) to \( S_{n+m} \)) and restriction, respectively. The Schur functions can also be interpreted as characters of \( GL_n \), see \texttt{Partitions and Schur functions}.

5.1. Comprehensive Module List 4747
The omega involution

The \( \omega \) involution is the linear extension of the map which sends \( e_\lambda \) to \( h_\lambda \):

\[
\begin{align*}
\text{sage: } & h(f) \\
& h[2, 2] \\
\text{sage: } & e(f.omega()) \\
& e[2, 2]
\end{align*}
\]

The Hall scalar product

The Hall scalar product on the algebra of symmetric functions makes the Schur functions into an orthonormal basis:

\[
\begin{align*}
\text{sage: } & f.scalar(f) \\
& 3 \\
\text{sage: } & f.omega() \\
& h[2, 2] \\
\text{sage: } & e(f.omega()) \\
& e[2, 2]
\end{align*}
\]

Skewing

Skewing is the adjoint operation to multiplication with respect to this scalar product:

\[
\begin{align*}
\text{sage: } & f.skew_by(s[1]) \\
& 2s[2, 1] + 2s[3] \\
\text{sage: } & f.skew_by(s[Integer(1)]) \\
& 2s[2, 1] + 2s[3]
\end{align*}
\]

In general, \( s_\lambda . skew_by(s_\mu) \) is the symmetric function typically denoted \( s_\lambda \setminus \mu \) or \( s_\lambda / \mu \).

Expanding into variables

We can expand a symmetric function into a symmetric polynomial in a specified number of variables:

\[
\begin{align*}
\text{sage: } & f.expand(2) \\
& x0^4 + 2x0^3x1 + 3x0^2x1^2 + 2x0x1^3 + x1^4 \\
\text{sage: } & f.expand(Integer(2)) \\
& x0^4 + 2x0^3x1 + 3x0^2x1^2 + 2x0x1^3 + x1^4
\end{align*}
\]

See the documentation for \texttt{expand} for more examples.
The Kronecker product

As in the section on the Representation theory of the symmetric group, a symmetric function may be considered as a class function on the symmetric group where the elements $p_\mu / z_\mu$ are the indicators of a permutation having cycle structure $\mu$. The Kronecker product of two symmetric functions corresponds to the pointwise product of these class functions.

Since the Schur functions are the irreducible characters of the symmetric group under this identification, the Kronecker product of two Schur functions corresponds to the internal tensor product of two irreducible symmetric group representations.

Under this identification, the Kronecker product of $p_\mu / z_\mu$ and $p_\nu / z_\nu$ is $p_\mu / z_\mu$ if $\mu = \nu$, and the result is equal to 0 otherwise.

`internal_product`, `kronecker_product`, `inner_tensor` and `itensor` are different names for the same function.

```python
sage: f.kronecker_product(f)
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 4*s[2, 2] + 5*s[3, 1] + 3*s[4]
```

Plethysm

The plethysm of symmetric functions is the operation corresponding to composition of representations of the general linear group. See [STA] Chapter 7, Appendix 2 for details.

```python
sage: s[2].plethysm(s[2])
s[2, 2] + s[4]
```

Plethysm can also be written as a composition of functions:

```python
sage: s[2]( s[2] )
s[2, 2] + s[4]
```

If the coefficient ring contains degree 1 elements, these are handled properly by plethysm:

```python
sage: R.<t> = QQ[]; s = SymmetricFunctions(R).schur()
sage: (t^2-t)*s[2]( (1-t)*s[1] )
(t^2-t)*s[1, 1] + (-t+1)*s[2]
```
See the documentation for `plethysm` for more information.

### Inner plethysm

The operation of inner plethysm `f.inner_plethysm(g)` models the composition of the $S_n$ representation represented by $g$ with the $GL_m$ representation whose character is $f$. See the documentation of `inner_plethysm`, [ST94] or [STA], exercise 7.74 solutions for more information:

```python
sage: s = SymmetricFunctions(QQ).schur()
sage: f = s[2]**2
sage: f.inner_plethysm(s[2])
s[2]
```

### Hopf algebra structure

The ring of symmetric functions is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; the power sum generators are primitive:

```python
sage: p[1].coproduct()
sage: p[2].coproduct()
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```python
sage: p[2, 1].coproduct()
```

This coproduct, along with the counit which sends every symmetric function to its 0-th homogeneous component, makes the ring of symmetric functions into a graded connected bialgebra. It is known that every graded connected bialgebra has an antipode. For the ring of symmetric functions, the antipode can be characterized explicitly: The antipode is an anti-algebra morphism (thus an algebra morphism, since our algebra is commutative) which sends $p_\lambda$ to $(-1)^{\text{length}(\lambda)}p_\lambda$ for every partition $\lambda$. Thus, in particular, it sends the generators on the $p$ basis to their opposites:

```python
sage: p[3].antipode()
-p[3]
sage: p[3, 2, 1].antipode()
-p[3, 2, 1]
```
The graded connected bialgebra of symmetric functions over a $\mathbf{Q}$-algebra has a rather simply-understood structure: It is (isomorphic to) the symmetric algebra of its space of primitives (which is spanned by the power-sum symmetric functions).

Here are further examples:

```python
sage: f = s[2]^2
sage: f.antipode()
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2]

sage: f.coproduct()
   → s[1, 1] # s[1, 1]
   → s[] + 2*s[3] # s[1]
   + s[3, 1] # s[] + s[4] # s[]

sage: f.coproduct().apply_multilinear_morphism(lambda x, y: x*y.antipode())
0
```

### Transformations of symmetric functions

There are many methods in Sage which make it easy to manipulate symmetric functions. For example, if we have some function which acts on partitions (say, conjugation), it is a simple matter to apply it to the support of a symmetric function. Here is an example:

```python
sage: conj = lambda mu: mu.conjugate()
sage: f.map_support(conj)
h[1, 1, 1, 1] + 2*h[2, 1, 1]
```

We can also easily modify the coefficients:
Combinatorics, Release 10.4

```
sage: def foo(mu, coeff):
    return mu.conjugate(), -coeff

sage: f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

```
>>> from sage.all import *

>>> def foo(mu, coeff):
    return mu.conjugate(), -coeff

>>> f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

See also `map_coefficients`.

There are also methods for building functions directly:

```
sage: s.sum_of_monomials(mu for mu in Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]

sage: s.sum_of_monomials(Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]

sage: s.sum_of_terms( (mu, mu[0]) for mu in Partitions(3))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]
```

```
>>> from sage.all import *

>>> s.sum_of_monomials(mu for mu in Partitions(Integer(3)))
s[1, 1, 1] + s[2, 1] + s[3]

>>> s.sum_of_monomials(Partitions(Integer(3)))
s[1, 1, 1] + s[2, 1] + s[3]

>>> s.sum_of_terms( (mu, mu[Integer(0)]) for mu in Partitions(Integer(3)))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]
```

These are the preferred way to build elements within a program; the result will usually be faster than using `sum()`. It also guarantees that empty sums yield the zero of `s` (see also `s.sum`).

Note also that it is a good idea to use:

```
sage: s.one()
s[]

sage: s.zero()
0
```

```
>>> from sage.all import *

>>> s.one()

>>> s.zero()
0
```

instead of `s(1)` and `s(0)` within programs where speed is important, in order to prevent unnecessary coercions.
**Different base rings**

Depending on the base ring, the different realizations of the symmetric function algebra may not span the same space:

```python
sage: SZ = SymmetricFunctions(ZZ)
sage: p = SZ.power(); s = SZ.schur()
sage: p(s[1,1,1])
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer
```

```python
>>> from sage.all import *

>>> SZ = SymmetricFunctions(ZZ)

>>> p = SZ.power(); s = SZ.schur()

>>> p(s[Integer(1),Integer(1),Integer(1)])
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer
```

Because of this, some functions may not behave as expected when working over the integers, even though they make mathematical sense:

```python
sage: s[1,1,1].plethysm(s[1,1,1])
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer
```

```python
>>> from sage.all import *

>>> s[Integer(1),Integer(1),Integer(1)].plethysm(s[Integer(1),Integer(1),
  →Integer(1)])
Traceback (most recent call last):
  ... TypeError: no conversion of this rational to integer
```

It is possible to work over different base rings simultaneously:

```python
sage: s = SymmetricFunctions(QQ).schur()
sage: p = SymmetricFunctions(QQ).power()
sage: sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'
sage: pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'
sage: p(sz[1,1,1])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3]
sz[1, 1, 1]
```

```python
>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).schur()

>>> p = SymmetricFunctions(QQ).power()

>>> sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'

>>> pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'

>>> p(sz[Integer(1),Integer(1),Integer(1)])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3]

>>> sz( Integer(1)/Integer(6)*p[Integer(1), Integer(1), Integer(1)] - Integer(1)/
  →Integer(2)*p[Integer(2), Integer(1)] + Integer(1)/Integer(3)*p[Integer(3)] )
sz[1, 1, 1]
```
As shown in this example, if you are working over multiple base rings simultaneously, it is a good idea to change the prefix in some cases, so that you can tell from the output which realization your result is in.

Let us change the notation back for the remainder of this tutorial:

```sage
sage: sz._prefix = 's'
sage: pz._prefix = 'p'
```

```bash
>>> from sage.all import *
```

```bash
>>> sz._prefix = 's'
>>> pz._prefix = 'p'
```

One can also use the Sage standard renaming idiom to get shorter outputs:

```sage
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.rename("Sym")
sage: Sym
Sym
sage: Sym.rename()
```

```bash
>>> from sage.all import *
```

```bash
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.rename("Sym")
>>> Sym.rename()
```

And we name it back:

```sage
sage: Sym.rename("Symmetric Functions over Rational Field"); Sym
Symmetric Functions over Rational Field
```

```bash
>>> from sage.all import *
```

```bash
>>> Sym.rename("Symmetric Functions over Rational Field"); Sym
Symmetric Functions over Rational Field
```

### Other bases

There are two additional basis of the symmetric functions which are not considered as classical bases:

- forgotten basis
- Witt basis

The forgotten basis is the dual basis of the elementary symmetric functions basis with respect to the Hall scalar product. The Witt basis can be constructed by

\[
\prod_{d=1}^{\infty} (1 - w_d t)^{-1} = \sum_{n=0}^{\infty} h_n t^n
\]

where \( t \) is a formal variable.

There are further bases of the ring of symmetric functions, in general over fields with parameters such as \( q \) and \( t \):

- Hall-Littlewood bases
- Jack bases
- Macdonald bases
- \(k\)-Schur functions
- Hecke character basis

We briefly demonstrate how to access these bases. For more information, see the documentation of the individual bases.

The *Jack polynomials* can be obtained as:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Jack = Sym.jack()
sage: J(P[2,1])
(1/(t+2))*JackJ[2, 1]
```

The parameter \(t\) can be specialized as follows:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: Jack = Sym.jack(t = 1)
sage: J(P[2,1])
1/3*JackJ[2, 1]
```

Similarly one can access the Hall-Littlewood and Macdonald polynomials, etc:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Mcd = Sym.macdonald()
sage: J(P[2,1])
(1/(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1))*McdJ[2, 1]
```

We can also construct the \(\bar{q}\) basis that can be used to determine character tables for Hecke algebras (with quadratic relation \(T_i^2 = (1-q)T_i + q\)):
$sage$: Sym = SymmetricFunctions($\mathbb{Z}_{\mathbb{Q}}$).fraction_field()
$sage$: qbar = Sym.hecke_character()
$sage$: s = Sym.s()
$sage$: s(qbar[2,1])
$-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]$

>>> from sage.all import *
>>> Sym = SymmetricFunctions($\mathbb{Z}_{\mathbb{Q}}$).fraction_field()
>>> qbar = Sym.hecke_character()
>>> s = Sym.s()
>>> s(qbar[Integer(2),Integer(1)])
$-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]$
The \(k\)-Schur functions are more generally defined with a parameter \(t\) and they are a basis of the subspace spanned by the Hall-Littlewood \(Q_p\) symmetric functions indexed by partitions whose first part is less than or equal to \(k\):

\[
sage: \text{Sym} = \text{SymmetricFunctions}(\QQ['t'].fraction_field())
\]
\[
sage: \text{SymS3} = \text{Sym.kBoundedSubspace}(3) \# \text{default } t='t'
\]
\[
sage: \text{ks} = \text{SymS3.kschur()}
\]
\[
sage: \text{Qp} = \text{Sym.hall_littlewood().Qp()}
\]
\[
sage: \text{ks}(\text{Qp}[2,1,1,1])
\]
\[
\text{ks3}[2, 1, 1, 1] + (t^{2}+t)\ast\text{ks3}[2, 2, 1] + (t^{3}+t^{2})\ast\text{ks3}[3, 1, 1] + t^{4}\ast\text{ks3}[3, 2]
\]

The subspace spanned by the \(k\)-Schur functions with a parameter \(t\) are not known to form a natural algebra. However it is known that the product of a \(k\)-Schur function and an \(\ell\)-Schur function is in the linear span of the \(k+\ell\)-Schur functions:

\[
sage: \text{ks}(\text{ks}[2,1]\ast\text{ks}[1,1])
\]

Traceback (most recent call last):
...

```
ValueError: s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] is not in the image
```

\[
sage: \text{ks6} = \text{Sym.kBoundedSubspace}(6).kschur()
\]
\[
sage: \text{ks6}(\text{ks}[3, 1, 1]\ast\text{ks}[3])
\]
\[
\text{ks6}[3, 3, 1, 1] + \text{ks6}[4, 2, 1, 1] + (t+1)\ast\text{ks6}[4, 3, 1] + t\ast\text{ks6}[4, 4]
\] + \text{ks6}[5, 1, 1, 1] + \text{ks6}[5, 2, 1] + t\ast\text{ks6}[5, 3] + \text{ks6}[6, 1, 1]
\]

The \(k\)-split basis is a second basis of the ring spanned by the \(k\)-Schur functions with a parameter \(t\). The \(k\)-split basis has the property that \(Q'_\lambda[X,t]\) expands positively in the \(k\)-split basis and the \(k\)-split basis conjecturally expands positively in the \(k\)-Schur functions. The definition can be found in [LLMSSZ] p. 81.:
ksp3 = SymS3.ksplit()
ksp3(Qp[Integer(2),Integer(1),Integer(1),Integer(1)])

[ksp3(la) for la in sorted(ksp3(Qp[Integer(2),Integer(1),Integer(1), Integer(1)])].support())

ks3[2, 1, 1, 1] + t*ks3[2, 2, 1], ks3[2, 2, 1], ks3[3, 1, 1], ks3[3, 2, 1]

dual $k$-Schur functions

The dual space to the subspace spanned by the $k$-Schur functions is most naturally realized as a quotient of the ring of symmetric functions by an ideal. When $t = 1$ the ideal is generated by the monomial symmetric functions indexed by partitions whose first part is greater than $k$.

```
sage: Sym = SymmetricFunctions(QQ)
sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: km = SymQ3.kmonomial()
sage: km[2,1]*km[2,1]

4*m3[2, 2, 1, 1] + 6*m3[2, 2, 2] + 2*m3[3, 2, 1] + 2*m3[3, 3]
```

When $t$ is not equal to 1, the subspace spanned by the $k$-Schur functions is realized as a quotient of the ring of symmetric functions by the ideal generated by the Hall-Littlewood symmetric functions in the P basis indexed by partitions with first part greater than $k$.

```
sage: Sym = SymmetricFunctions(FractionField(QQ[t]))
sage: SymQ3 = Sym.kBoundedQuotient(3)
sage: kHLP = SymQ3.kHallLittlewoodP()
sage: kHLP[2,1]*kHLP[2,1]
```

(continues on next page)
In this space, the basis which is dual to the \( k \)-Schur functions conjecturally expands positively in the \( k \)-bounded Hall-Littlewood functions and has positive structure coefficients.:

\[
\begin{align*}
\text{sage: } & \text{dks = SymQ3.dual_k_Schur()} \\
\text{sage: } & \text{kHLP(dks[2,2])} \\
& (t^4+t^2)*HLP3[1, 1, 1, 1] + t*HLP3[2, 1, 1] + HLP3[2, 2] \\
\text{sage: } & \text{dks[2,1]*dks[1,1]} \\
& (t^2+t)*dks3[1, 1, 1, 1, 1] + (t+1)*dks3[2, 1, 1, 1] + (t+1)*dks3[2, 2, 1] \\
& + dks3[3, 1, 1] + dks3[3, 2] \\
\end{align*}
\]

At \( t = 1 \) the \( k \)-bounded Hall-Littlewood basis is equal to the \( k \)-bounded monomial basis and the dual \( k \)-Schur elements are equal to the affine Schur basis. The \( k \)-bounded monomial basis and affine Schur functions are faster and should be used instead of the \( k \)-bounded Hall-Littlewood P basis and dual \( k \)-Schur functions when \( t = 1 \).:

\[
\begin{align*}
\text{sage: } & \text{SymQ3 = Sym.kBoundedQuotient(3,t=1)} \\
\text{sage: } & \text{dks = SymQ3.dual_k_Schur()} \\
\text{sage: } & \text{F = SymQ3.affineSchur()} \\
& F[3,1]==dks[3,1] \\
& True \\
\end{align*}
\]

Implementing new bases

In order to implement a new symmetric function basis, Sage will need to know at a minimum how to change back and forth between at least one other basis (although they do not necessarily have to be the same basis). All of the standard functions associated with the basis will have a default implementation (although a more specific implementation may be more efficient).

To present an idea of how this is done, we will create here the example of how to implement the basis \( s_\mu[X(1-t)] \).

To begin, we import the class `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic()`. Our new basis will inherit all of the default methods from this class:
Now the basis we are creating has a parameter \( t \) which is possible to specialize. In this example we will convert to and from the Schur basis. For this we implement methods \_self_to_s and \_s_to_self. By registering these two functions as coercions, Sage then knows automatically how it possible to change between any two bases for which there is a path of changes of bases.
An instance of this basis is created by calling it with a symmetric function ring \(\text{Sym}\) and a parameter \(t\) which is in the base ring of \(\text{Sym}\). The \texttt{Element} class inherits all of the methods from \texttt{sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element}.

In the reference [MAC] on page 354, this basis is denoted \(S_\lambda(x; t)\) and the change of basis coefficients of the Macdonald \(J\) basis are the coefficients \(K_{\lambda\mu}(q, t)\). Here is an example of its use:

```python
sage: QQqt = QQ['q','t'].fraction_field()
sage: (q,t) = QQqt.gens()
sage: st = SFA_st(SymmetricFunctions(QQqt),t)
sage: st
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Schur functions with a plethystic substitution of X \rightarrow X(1-t) basis
sage: st[[2,1]] * st[1]
sage: st[[2]].coproduct()
sage: J = st.symmetric_function_ring().macdonald().J()
sage: st(J[[2,1]])
q*st[1, 1, 1] + (q*t+1)*st[2, 1] + t*st[3]
```

Acknowledgements

The design is heavily inspired from the implementation of symmetric functions in MuPAD-Combinat (see [HT04] and [FD06]).

REFERENCES:

5.1. Comprehensive Module List 4761
Further tests

Todo:

- Introduce fields with degree 1 elements as in MuPAD-Combinat, to get proper plethysm.
- Use UniqueRepresentation to get rid of all the manual cache handling for the bases
- Devise a mechanism so that pickling bases of symmetric functions pickles the coercions which have a cache.

Schur()
The Schur basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

Witt(coerce_h=None, coerce_e=None, coerce_p=None)
The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

a_realization()
Return a particular realization of self (the Schur basis).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```

complete()
The complete basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis

\texttt{e()}

The elementary basis of the Symmetric Functions

\textbf{EXAMPLES:}

\begin{verbatim}
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
\end{verbatim}

\texttt{elementary()}

The elementary basis of the Symmetric Functions

\textbf{EXAMPLES:}

\begin{verbatim}
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
\end{verbatim}

\texttt{f()}

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
\end{verbatim}

\texttt{forgotten()}

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
\end{verbatim}
**from_polynomial** *(f)*

Converts a symmetric polynomial *f* to a symmetric function.

**INPUT:**

- *f* – a symmetric polynomial

This function converts a symmetric polynomial *f* in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

**EXAMPLES:**

```python
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: S = SymmetricFunctions(QQ)
sage: S.from_polynomial(f)

m[1]
sage: f = x[0] + 2*x[1] + x[2]
sage: S.from_polynomial(f)
Traceback (most recent call last):
... ValueError: x0 + 2*x1 + x2 is not a symmetric polynomial
```

**h()**

The complete basis of the Symmetric Functions

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

**hall_littlewood** *(t=t')*

Returns the entry point for the various Hall-Littlewood bases.

**INPUT:**

- *t* – parameter

Hall-Littlewood symmetric functions including bases *P, Q, Qp*. The Hall-Littlewood *P* and *Q* functions at *t* = −1 are the Schur-P and Schur-Q functions when indexed by strict partitions.
The parameter \( t \) must be in the base ring of parent.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))

sage: P = Sym.hall_littlewood().P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
   over Rational Field in the Hall-Littlewood P basis
sage: P[2]
HLP[2]

sage: Q = Sym.hall_littlewood().Q(); Q
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
   over Rational Field in the Hall-Littlewood Q basis
sage: Q[2]
HLQ[2]

sage: Qp = Sym.hall_littlewood().Qp(); Qp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
   over Rational Field in the Hall-Littlewood Qp basis
sage: Qp[2]
HLQp[2]
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))

>>> P = Sym.hall_littlewood().P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
   over Rational Field in the Hall-Littlewood P basis

>>> P[Integer(2)]
HLP[2]

>>> Q = Sym.hall_littlewood().Q(); Q
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
   over Rational Field in the Hall-Littlewood Q basis

>>> Q[Integer(2)]
HLQ[2]

>>> Qp = Sym.hall_littlewood().Qp(); Qp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t
   over Rational Field in the Hall-Littlewood Qp basis

>>> Qp[Integer(2)]
HLQp[2]
```

**hecke_character** (\( q=q' \))

The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:

```python
sage: SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
    Fraction Field of Univariate Polynomial Ring in q over Integer Ring
    in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2
   →basis
```

```python
>>> from sage.all import *

>>> SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
    Fraction Field of Univariate Polynomial Ring in q over Integer Ring
    in the Hecke character with q=q basis

>>> SymmetricFunctions(QQ).hecke_character(Integer(1)/Integer(2))

(continues on next page)
Symmetric Functions over Rational Field in the Hecke character with \( q = 1/2 \)

**homogeneous()**

The complete basis of the Symmetric Functions

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

```python
>>> from sage.all import *

>>> SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

**ht()**

The induced trivial character basis of the Symmetric Functions.

The trivial character of

\[
S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell}(\lambda)
\]

induced to the group \( S_n \) is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition \( \lambda \) is evaluated at the roots of a permutation of cycle structure \( \rho \) then the value is the coefficient \( \langle h_{(n-|\lambda|,\lambda)}, P_\rho \rangle \).

In terms of methods that are implemented in Sage, if \( n \) is a sufficiently large integer, then \( ht(\lambda).character_to_frobenius_image(n) \) is equal the complete function indexed by \( [n-\text{sum}(\lambda)] + \lambda \).

This basis is introduced in [OZ2015].

**See also:**

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).induced_trivial_character()
Symmetric Functions over Rational Field in the induced trivial symmetric group character basis

sage: ht = SymmetricFunctions(QQ).ht()
sage: h = SymmetricFunctions(QQ).h()
sage: h(ht([3,2]).character_to_frobenius_image(9))
h[4, 3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(7))
h[3, 2, 2]
sage: h(ht([3,2]).character_to_frobenius_image(5))
h[3, 2]
sage: h(ht([3,2]).character_to_frobenius_image(4))
0

sage: p = SymmetricFunctions(QQ).p()
sage: [h([4,1]).scalar(p(rho)) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
sage: [ht([1]).eval_at_permutation_roots(rho) for rho in Partitions(5)]
[0, 1, 0, 2, 1, 3, 5]
```
induced_trivial_character()

The induced trivial character basis of the Symmetric Functions.

The trivial character of

\[ S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_\ell} \]

induced to the group \( S_n \) is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition \( \lambda \) is evaluated at the roots of a permutation of cycle structure \( \rho \) then the value is the coefficient \( \langle h_{n-|\lambda|}, \lambda \rangle \).

In terms of methods that are implemented in Sage, if \( n \) is a sufficiently large integer, then \( \text{ht}((\text{lam}).\text{character_to_frobenius_image}(n)) \) is equal the complete function indexed by \( n-\sum(\text{lam})+\text{lam} \).

This basis is introduced in [OZ2015].

See also:

\( \text{character_to_frobenius_image()} \), \( \text{eval_at_permutation_roots()} \)

EXAMPLES:

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).induced_trivial_character()
Symmetric Functions over Rational Field in the induced trivial symmetric group character basis
>>> ht = SymmetricFunctions(QQ).ht()
>>> h = SymmetricFunctions(QQ).h()
>>> h(ht([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(9)))
h[4, 3, 2]
>>> h(ht([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(7)))
h[3, 2, 2]
>>> h(ht([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(5)))
h[3, 2]
>>> h(ht([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(4)))
0
>>> p = SymmetricFunctions(QQ).p()
>>> [h([Integer(4),Integer(1)]).scalar(p(rho)) for rho in Partitions(Integer(5))]
[0, 1, 0, 2, 1, 3, 5]
>>> [ht([Integer(1)]).eval_at_permutation_roots(rho) for rho in Partitions(Integer(5))]
[0, 1, 0, 2, 1, 3, 5]
```
irreducible_symmetric_group_character()

The irreducible $S_n$ character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition $\lambda$ is evaluated at the roots of a permutation of cycle structure $\rho$ then the value is the irreducible character $\chi^{(\rho|-\lambda),\lambda}(\rho)$.

In terms of methods that are implemented in Sage, if $n$ is a sufficiently large integer, then

\[\text{st}(\lambda).\text{character_to_frobenius_image}(n)\]

is equal the Schur function indexed by $[n-\text{sum}(\lambda)]+\lambda$.

This basis is introduced in [OZ2015].

See also:

\text{character_to_frobenius_image()}, \text{eval_at_permutation_roots()}

EXAMPLES:

\begin{verbatim}
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group character basis
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
\end{verbatim}
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho)  
.....: for rho in Partitions(5)]))
[4, 2, 0, 1, -1, 0, -1]

>>> from sage.all import *

>>> SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group character basis
>>> st = SymmetricFunctions(QQ).st()
>>> s = SymmetricFunctions(QQ).s()
>>> s(st([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(3))))
s[4, 3, 2]
>>> s(st([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(7)))
0
>>> s(st([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(6)))
-s[2, 2, 2]
>>> list(SymmetricGroup(Integer(5)).character_table()[-Integer(2)])
[4, 2, 0, 1, -1, 0, -1]
>>> list(reversed([st([Integer(1)]).eval_at_permutation_roots(rho)  
.....: for rho in Partitions(Integer(5))]))
[4, 2, 0, 1, -1, 0, -1]

jack (\(t='t'\))

Returns the entry point for the various Jack bases.

INPUT:

- t – parameter

Jack symmetric functions including bases \(P, Q, Q_p\).

The parameter \(t\) must be in the base ring of parent.

EXAMPLES:

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in \(t\) over Rational Field in the Jack P basis
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in \(t\) over Rational Field in the Jack Q basis
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in \(t\) over Rational Field in the Jack J basis
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in \(t\) over Rational Field in the Jack Qp basis

>>> from sage.all import *

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in \(t\) over Rational Field in the Jack P basis
>>> JQ = Sym.jack().Q(); JQ

5.1. Comprehensive Module List

4769
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack Q basis

```python
>>> JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack J basis

```n

```python
>>> JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t → over Rational Field in the Jack Qp basis
```

kBoundedQuotient \((k, t'=?)\)

Returns the \(k\)-bounded quotient space of the ring of symmetric functions.

**INPUT:**

- \(k\) – a positive integer

The quotient of the ring of symmetric functions ...

**See also:**

`sage.combinat.sf.k_dual.KBoundedQuotient()`

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: KQ = Sym.kBoundedQuotient(3); KQ
Traceback (most recent call last):
...
TypeError: unable to convert 't' to a rational

sage: KQ = Sym.kBoundedQuotient(3,t=1); KQ
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: KQ = Sym.kBoundedQuotient(3); KQ
3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field

```n

```python
>>> from sage.all import *

```n

```python
>>> Sym = SymmetricFunctions(QQ)

```n

```python
>>> KQ = Sym.kBoundedQuotient(Integer(3)); KQ
Traceback (most recent call last):
...
TypeError: unable to convert 't' to a rational

```n

```python
>>> KQ = Sym.kBoundedQuotient(Integer(3),t=Integer(1)); KQ
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1

>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())

```n

```python
>>> KQ = Sym.kBoundedQuotient(Integer(3)); KQ
3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over Rational Field

```n

kBoundedSubspace \((k, t=?)\)

Return the \(k\)-bounded subspace of the ring of symmetric functions.

**INPUT:**

- \(k\) – a positive integer
- \(t\) a formal parameter; \(t = 1\) yields a subring
The subspace of the ring of symmetric functions spanned by \( \{ s_{\lambda}([X/(1-t)]) \}_{\lambda \leq k} = \{ s_{\lambda}^{(k)}(X, t) \}_{\lambda \leq k} \) over the base ring \( \mathbb{Q}[t] \). When \( t = 1 \), this space is in fact a subalgebra of the ring of symmetric functions generated by the complete homogeneous symmetric functions \( h_i \) for \( 1 \leq i \leq k \).

See also:

\[ \text{sage.combinat.sf.new_kschur.KBoundedSubspace()} \]

EXAMPLES:

<table>
<thead>
<tr>
<th>sage</th>
<th>Sym = SymmetricFunctions(QQ)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage</td>
<td>KB = Sym.kBoundedSubspace(3,1); KB</td>
</tr>
<tr>
<td></td>
<td>3-bounded Symmetric Functions over Rational Field with t=1</td>
</tr>
<tr>
<td>sage</td>
<td>Sym = SymmetricFunctions(QQ['t'])</td>
</tr>
<tr>
<td>sage</td>
<td>Sym.kBoundedSubspace(3)</td>
</tr>
<tr>
<td></td>
<td>3-bounded Symmetric Functions over Univariate Polynomial Ring in t over... Rational Field</td>
</tr>
<tr>
<td>sage</td>
<td>Sym = SymmetricFunctions(QQ['z'])</td>
</tr>
<tr>
<td>sage</td>
<td>z = Sym.base_ring().gens()[0]</td>

<td>3-bounded Symmetric Functions over Univariate Polynomial Ring in z over... Rational Field with t=z</td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> KB = Sym.kBoundedSubspace(Integer(3),Integer(1)); KB
3-bounded Symmetric Functions over Rational Field with t=1

>>> Sym = SymmetricFunctions(QQ['t'])

>>> Sym.kBoundedSubspace(Integer(3))
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over... Rational Field

>>> Sym = SymmetricFunctions(QQ['z'])

>>> z = Sym.base_ring().gens()[Integer(0)]

>>> Sym.kBoundedSubspace(Integer(3),t=z)
3-bounded Symmetric Functions over Univariate Polynomial Ring in z over... Rational Field with t=z
```

\textbf{khomogeneous}(k)

Returns the homogeneous symmetric functions in the \( k \)-bounded subspace.

EXAMPLES:

<table>
<thead>
<tr>
<th>sage</th>
<th>Sym = SymmetricFunctions(QQ)</th>
</tr>
</thead>
<tbody>
<tr>
<td>sage</td>
<td>kh = Sym.khomogeneous(4)</td>
</tr>
<tr>
<td>sage</td>
<td>kh[3]*kh[4]</td>
</tr>
<tr>
<td></td>
<td>h4[4, 3]</td>
</tr>
<tr>
<td>sage</td>
<td>kh[4].lift()</td>
</tr>
<tr>
<td></td>
<td>h[4]</td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> kh = Sym.khomogeneous(Integer(4))

>>> kh[Integer(3)]*kh[Integer(4)]

h4[4, 3]
```

(continues on next page)
kschur \((k, t='t')\)

Returns the \(k\)-Schur functions.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2]*ks[2]
ks3[2, 2] + ks3[3, 1]
sage: ks[2,1,1].lift()
s[2, 1, 1] + s[3, 1]
```

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: ks[2,2,1].lift()
s[2, 2, 1] + t*s[3, 2]
```

```python
>>> from sage.all import *
```

ksplit \((k, t='t')\)

Returns the \(k\)-split basis of the \(k\)-bounded subspace.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: ksp = Sym.ksplit(3,1)
sage: ksp[2]*ksp[2]
ksp3[2, 2] + ksp3[3, 1]
sage: ksp[2,1,1].lift()
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```python
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ksp = Sym.ksplit(3)
sage: ksp[2,1,1].lift()
s[2, 1, 1] + t*s[2, 2] + t*s[3, 1]
```

```python
>>> from sage.all import *
```
\( s[2, 1, 1] + s[2, 2] + s[3, 1] \)

```python
>>> Sym = SymmetricFunctions(QQ['t'])
>>> ksp = Sym.ksplit(Integer(3))
>>> ksp[Integer(2),Integer(1),Integer(1)].lift()
```

\( s[2, 1, 1] + t*s[2, 2] + t*s[3, 1] \)

**llt** \((k, t='t')\)

The LLT symmetric functions.

**INPUT:**

- \(k\) – a positive integer indicating the level
- \(t\) – a parameter (default: \(t\))

**LLT polynomials in hspin and hcospin bases.**

**EXAMPLES:**

```python
sage: llt3 = SymmetricFunctions(QQ['t'].fraction_field()).llt(3); llt3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in
˓→ t over Rational Field
```

```python
sage: llt3.hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t˓→ over Rational Field in the level 3 LLT spin basis
```

```python
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t˓→ over Rational Field in the level 3 LLT cospin basis
```

```python
>>> from sage.all import *
<<<
```

\( m() \)

The monomial basis of the Symmetric Functions

**EXAMPLES:**

```python
sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

```python
>>> from sage.all import *
<<<
```
macdonald \( (q=q', t=t') \)

Returns the entry point for the various Macdonald bases.

**INPUT:**

- \( q, t \) – parameters

Macdonald symmetric functions including bases \( P, Q, J, H, H_t \). This also contains the \( S \) basis which is dual to the Schur basis with respect to the \( q, t \) scalar product.

The parameters \( q \) and \( t \) must be in the base_ring of parent.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald Q basis
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
sage: matrix([[S(la).scalar_qt(s(mu)) for la in Partitions(3)] for mu in Partitions(3)])
| 1 0 0 |
| 0 1 0 |
| 0 0 1 |
sage: H = Sym.macdonald().H()
sage: s(H[2,2])
q^2*s[1, 1, 1] + (q^2*t+q*t+q)*s[2, 1, 1] + (q^2*t^2+1)*s[2, 2] + (q*t^2+q*t+t)*s[3, 1] + t^2*s[4]
sage: Sym = SymmetricFunctions(QQ['z','q'].fraction_field())
sage: (z,q) = Sym.base_ring().gens()
sage: Hzq = Sym.macdonald(q=z,t=q).H()
sage: H1z = Sym.macdonald(q=1,t=z).H()
sage: s = Sym.schur()
sage: s(H1z(Hzq[2,2]))
s(z^2*q+z*q+z)*s[1, 1, 1] + (z^2*q^2+z^2*q)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^2+z*q+q)*s[3, 1] + q^2*s[4]
sage: s(Hzq(H1z[2,2]))
s(z^2*q+z*q+z)*s[1, 1, 1] + (z^2*q^2+z^2*q)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^2+z*q+q)*s[3, 1] + q^2*s[4]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field in the Macdonald P basis
>>> P[Integer(2)]
McdP[2]
>>> Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q, t
```

(continues on next page)
Combinatorics, Release 10.4

---

→ \text{t over Rational Field in the Macdonald Q basis}

```python
>>> S = Sym.macdonald().S()
>>> s = Sym.schur()
>>> matrix([[S(la).scalar_qt(s(mu)) for la in Partitions(Integer(3)) for mu in Partitions(Integer(3))]])
[1 0 0]
[0 1 0]
[0 0 1]

>>> H = Sym.macdonald().H()
>>> s(H[[Integer(2),Integer(2)]])
qu^2*s[1, 1, 1, 1] + (q^2*t+q*t+q)*s[2, 1, 1] + (q^2*t^2+1)*s[2, 2] + (q*t^2+q*t+t)*s[3, 1] + t^2*s[4]
```

---

**monomial()**

The monomial basis of the Symmetric Functions

EXAMPLES:

```
sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

```
>>> from sage.all import *

sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

---

**o()**

The orthogonal basis of the symmetric functions.

See also:

*SymmetricFunctionAlgebra_orthogonal*

EXAMPLES:

```
sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```

```
>>> from sage.all import *

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```
orthogonal()

The orthogonal basis of the symmetric functions.

See also:

SymmetricFunctionAlgebra_orthogonal

EXAMPLES:

sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis

p()

The power sum basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis

power()

The power sum basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis

powersum()

The power sum basis of the Symmetric Functions

EXAMPLES:

sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis

qbar (q='q')

The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:
Combinatorics, Release 10.4

```
sage: SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Fraction Field of Univariate Polynomial Ring in q over Integer Ring
in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2→basis
```

**register_isomorphism**(morphism, only_conversion=False)

Register an isomorphism between two bases of `self`, as a canonical coercion (unless the optional keyword `only_conversion` is set to True, in which case the isomorphism is registered as conversion only).

**EXAMPLES:**

We override the canonical coercion from the Schur basis to the powersum basis by a (stupid!) map \( s_\lambda \mapsto 2p_\lambda \).

```
sage: Sym = SymmetricFunctions(QQ['zorglub']) # make sure we are not going to...
   →screw up later tests
sage: s = Sym.s(); p = Sym.p().dual_basis()
sage: phi = s.module_morphism(diagonal = lambda t: 2, codomain = p)
sage: phi(s[2, 1])
2*d_p[2, 1]
sage: Sym.register_isomorphism(phi)
sage: p(s[2, 1])
2*d_p[2, 1]
```

The map is supposed to implement the canonical isomorphism between the two bases. Otherwise, the results will be mathematically wrong, as above. Use with care!

**s()**

The Schur basis of the Symmetric Functions

**EXAMPLES:**

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

**schur()**

The Schur basis of the Symmetric Functions

**EXAMPLES:**

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

**sp()**

The symplectic basis of the symmetric functions.

See also:

`SymmetricFunctionAlgebra_symplectic`

**EXAMPLES:**

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

```python
>>> from sage.all import *
>>> SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

**st()**

The irreducible $S_n$ character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition $\lambda$ is evaluated at the roots of a permutation of cycle structure $\rho$ then the value is the irreducible character $\chi^{(\rho)-\lambda}\lambda(\rho)$.

In terms of methods that are implemented in Sage, if $n$ is a sufficiently large integer, then $\text{st}(\lambda).\text{character_to_frobenius_image}(n)$ is equal the Schur function indexed by $[n-\text{sum}(\lambda)]+\lambda$.

This basis is introduced in [OZ2015].

See also:

`character_to_frobenius_image()`, `eval_at_permutation_roots()`

**EXAMPLES:**

```
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group character basis
```

```
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
```

(continues on next page)
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho)
.....: for rho in Partitions(5)]))
[4, 2, 0, 1, -1, 0, -1]

>> from sage.all import *

symplectic()

The symplectic basis of the symmetric functions.

See also:

SymmetricFunctionAlgebra_symplectic

EXAMPLES:

sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis

w (coerce_h=None, coerce_e=None, coerce_p=None)

The Witt basis of the symmetric functions.

EXAMPLES:

sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis

witt (coerce_h=None, coerce_e=None, coerce_p=None)

The Witt basis of the symmetric functions.
EXAMPLES:

```python
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

zonal()

The zonal basis of the Symmetric Functions

EXAMPLES:

```python
sage: SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis

>>> from sage.all import *
>>> SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis
```

class sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, domain, codomain)

Initialization of self.

INPUT:

- `t` – a function taking a monomial in `CombinatorialFreeModule(QQ, Partitions())`, and returning a `(partition, coefficient)` list.
- `domain, codomain` – parents

Construct a function mapping a partition to an element of codomain.

This is a temporary quick hack to wrap around the existing symmetrica conversions, without changing their specs.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ['x'])
sage: p = Sym.p(); s = Sym.s()
sage: def t(x) : [(p,c)] = x;
      return [(p,2*c), (p.conjugate(), c)]
sage: f = sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, p, s)
sage: f(Partition([3,1]))
s[2, 1, 1] + 2*s[3, 1]

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['x'])
>>> p = Sym.p(); s = Sym.s()
>>> def t(x) : [(p,c)] = x;
      return [(p,Integer(2)*c), (p.conjugate(), c)]
>>> f = sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, p, s)
>>> f(Partition([Integer(3),Integer(1)]))
s[2, 1, 1] + 2*s[3, 1]
```
5.1.303 Symmetric Functions

For a comprehensive tutorial on how to use symmetric functions in Sage

See also:

SymmetricFunctions()

We define the algebra of symmetric functions in the Schur and elementary bases:

```sage
s = SymmetricFunctions(QQ).schur()
sage: e = SymmetricFunctions(QQ).elementary()
```

Each is actually a graded Hopf algebra whose basis is indexed by integer partitions:

```sage
s = SymmetricFunctions(QQ).schur()
sage: s.category()
Category of graded bases of Symmetric Functions over Rational Field
sage: s.basis().keys()
Partitions
```

Let us compute with some elements in different bases:

```sage
f1 = s([2,1]); f1
s[2, 1]
f2 = e(f1); f2 # basis conversion
e[2, 1] - e[3]
f1 == f2
True
f1.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
f2.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

```sage
m = SymmetricFunctions(QQ).monomial()
sage: m([3,1])
```

(continues on next page)
m[3, 1]
sage: m(4) # This is the constant 4, not the partition 4.
4*m[]
sage: m([4]) # This is the partition 4.
m[4]
sage: 3*m([3,1])-1/2*m([4])
3*m[3, 1] - 1/2*m[4]

>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
m[3, 1]
>>> m(Integer(4)) # This is the constant 4, not the partition 4.
4*m[]
>>> m([Integer(4)]) # This is the partition 4.
m[4]
>>> Integer(3)*m([Integer(3),Integer(1)])-Integer(1)/Integer(2)*m([Integer(4)])
3*m[3, 1] - 1/2*m[4]

sage: p = SymmetricFunctions(QQ).power()
sage: f = p(3)
sage: f
3*p[]
sage: f.parent()
Symmetric Functions over Rational Field in the powersum basis
sage: f + p([3,2])
3*p[] + p[3, 2]

>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).power()
>>> f = p(Integer(3))
>>> f
3*p[]
>>> f.parent()
Symmetric Functions over Rational Field in the powersum basis
>>> f + p([Integer(3),Integer(2)])
3*p[] + p[3, 2]

One can convert symmetric functions to symmetric polynomials and vice versa:

sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: h = Sym.homogeneous()
sage: f = h[2,1] + 2*p[3,1]
sage: poly = f.expand(3); poly
2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0*x2^3 + 2*x1*x2^3 + 2*x2^4 + x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^2 + x2^3
sage: Sym.from_polynomial(poly)
sage: Sym.from_polynomial(poly) == f
True
sage: g = h[1,1,1]
sage: poly = g.expand(3)
sage: Sym.from_polynomial(poly) == g
(continues on next page)
False

```
from sage.all import *

Sym = SymmetricFunctions(QQ)
p = Sym.powersum()
h = Sym.homogeneous()
f = h[Integer(2), Integer(1)] + Integer(2)*p[Integer(3), Integer(1)]
poly = f.expand(Integer(3)); poly
2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0*x2^3 + 2*x1*x2^3 + 2*x2^4 + x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^2 + 2*x1*x2^2 + x2^3

Sym.from_polynomial(poly)

Sym.from_polynomial(poly) == f
True

g = h[Integer(1), Integer(1), Integer(1), Integer(1)]
poly = g.expand(Integer(3))

Sym.from_polynomial(poly) == g
False
```

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: p = Sym.p()
sage: e = Sym.e()
sage: m = Sym.m()
sage: a = s([3, 1])
sage: s(a)
s[3, 1]

sage: h(a)

sage: p(a)

sage: e(a)

sage: m(a)
3*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2] + m[3, 1]

sage: a.expand(4)
x0^3*x1 + x0^2*x1^2 + x0*x1^3 + x0^3*x2 + 2*x0^2*x1*x2 + x1^3*x2 + x0^2*x2^2 + x0*x1*x2^2 + x1^2*x2^2 + x0^3*x3 + x1*x2^3 + x0^3*x3 + 2*x0^2*x1*x3 + 2*x0^2*x2*x3 + 3*x0*x1*x2*x3 + 2*x1^2*x2*x3 + 2*x0*x2^2*x3 + x2^3*x3 + x0^2*x3^2 + x0^2*x1*x3^2 + x1^2*x3^2 + 2*x0*x2*x3^2 + 2*x1*x2*x3^2 + 2*x0*x3^3 + x1*x3^3 + x2*x3^3
```

Eventual continuation...

```python
>>> p(a)
```

```python
>>> e(a)
```

```python
>>> m(a)
3*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2] + m[3, 1]
```

```python
>>> a.expand(Integer(4))
x0^3*x1 + x0^2*x1^2 + x0*x1^3 + x0^3*x2 + 2*x0^2*x1*x2 + 2*x0*x1^2*x2 + x1^3*x2 + x0^2*x2^2 + 2*x0*x1*x2^2 + x1^2*x2^2 + x0*x2^3 + x1*x2^3 + x0^3*x3 + 2*x0^2*x2*x3 + 2*x0*x2^2*x3 + x2^3*x3 + x0^2*x3^2 + 2*x0*x2*x3^2 + x1*x2*x3^2 + 2*x0*x3^2 + x1*x3^2 + 2*x2*x3^2
```

Here are further examples:

```python
sage: h(m([1]))
h[1]
sage: h(m([2]) + m([1, 1]))
h[2]
sage: h(m([3]) + m([2, 1]) + m([1, 1, 1]))
h[3]
sage: h(m([4]) + m([3, 1]) + m([2, 2]) + m([2, 1, 1]) + m([1, 1, 1, 1]))
h[4]
sage: k = 5
sage: h(sum([m(part) for part in Partitions(k)]))
h[5]
sage: k = 10
sage: h(sum([m(part) for part in Partitions(k)]))
h[10]
```

```python
>>> from sage.all import *
```

```python
>>> h(m([Integer(1)]))
h[1]
```

```python
>>> h(m([Integer(2)]) + m([Integer(1), Integer(1)]))
h[2]
```

```python
>>> h(m([Integer(3)]) + m([Integer(2), Integer(1)]) + m([Integer(1), Integer(1), Integer(1)]))
h[3]
```

```python
>>> h(m([Integer(4)]) + m([Integer(3), Integer(1)]) + m([Integer(2), Integer(2)]) + m([Integer(2), Integer(1), Integer(1)]) + m([Integer(1), Integer(1), Integer(1), Integer(1)]))
h[4]
```

```python
>>> k = Integer(5)
```

```python
>>> h(sum([m(part) for part in Partitions(k)]))
h[5]
```

```python
>>> k = Integer(10)
```

```python
>>> h(sum([m(part) for part in Partitions(k)]))
h[10]
```

```python
sage: P3 = Partitions(3)
sage: P3.list()
[[3], [2, 1], [1, 1, 1]]
sage: m = SymmetricFunctions(QQ).monomial()
sage: f = sum([m(p) for p in P3])
sage: m.get_print_style()
```

(continues on next page)
'lex'
sage: f

class sage.combinat.sf.sfa.FilteredSymmetricFunctionsBases (parent_with_realization)
Bases: Category_realization_of_parent

The category of filtered bases of the ring of symmetric functions.

super_categories()

The super categories of self.

EXAMPLES:

sage: from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = FilteredSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of bases of Symmetric Functions over Rational Field,
 Category of commutative filtered Hopf algebras with basis over RationalField]

>>> from sage.all import *
>>> from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
>>> Sym = SymmetricFunctions(QQ)
>>> bases = FilteredSymmetricFunctionsBases(Sym)
>>> bases.super_categories()
[Category of bases of Symmetric Functions over Rational Field,
 Category of commutative filtered Hopf algebras with basis over RationalField]
class sage.combinat.sf.sfa.GradedSymmetricFunctionsBases (parent_with_realization)

Bases: Category_realization_of_parent

The category of graded bases of the ring of symmetric functions.

These are further required to have the property that the basis element indexed by the empty partition is 1.

class ElementMethods

Bases: object

degree_negation()

Return the image of self under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree $k$ by $(-1)^k$ (for all $k$).

Calling degree_negation(self) is equivalent to calling self.parent().degree_negation(self).

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[]
sage: f.degree_negation()
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
sage: x = m.zero().degree_negation(); x
0
sage: parent(x) is m
True
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.monomial()
>>> f = Integer(2)*m[Integer(2),Integer(1)] + Integer(4)*m[Integer(1), Integer(1)] - Integer(5)*m[Integer(1)] - Integer(3)*m[]
>>> f.degree_negation()
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
>>> x = m.zero().degree_negation(); x
0
>>> parent(x) is m
True
```

degree_zero_coefficient()

Return the degree zero coefficient of self.

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[]
sage: f.degree_zero_coefficient()
3
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.monomial()
>>> f = Integer(2)*m[Integer(2),Integer(1)] + Integer(3)*m[]
>>> f.degree_zero_coefficient()
3
```

(continues on next page)
is_unit()  
Return whether this element is a unit in the ring.

EXAMPLES:

```python
sage: m = SymmetricFunctions(ZZ).monomial()
sage: (2*m[2,1] + m[]).is_unit()
False

sage: m = SymmetricFunctions(QQ).monomial()
sage: (3/2*m([])).is_unit()
True
```

class ParentMethods

Bases: object

antipode_by_coercion(element)

The antipode of element.

INPUT:

- `element` – element in a basis of the ring of symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: s = Sym.s()
sage: e = Sym.e()
sage: h = Sym.h()
sage: (h([]) + h([1])).antipode() # indirect doctest
h[] - h[1]
sage: (s([]) + s([1]) + s[2]).antipode()
s[] - s[1] + s[1, 1]
sage: (p([2]) + p([3])).antipode()
sage: (e([2]) + e([3])).antipode()
sage: f = Sym.f()
sage: f([3,2,1]).antipode()
```
The antipode is an involution:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: all( s[u].antipode().antipode() == s[u] for u in Partitions(4) )
True
```

The antipode is an algebra homomorphism:

```python
sage: Sym = SymmetricFunctions(FiniteField(23))
sage: h = Sym.h()
sage: all( all( (s[u] * s[v]).antipode() == s[u].antipode() * s[v].antipode() for u in Partitions(3) ) for v in Partitions(3) )
True
```

`counit(element)`

Return the counit of `element`.

The counit is the constant term of `element`.

**INPUT:**

- `element` – element in a basis of the ring of symmetric functions

**EXAMPLES:**
**degree_negation** *(element)*

Return the image of *element* under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree $k$ by $(-1)^k$ (for all $k$).

**INPUT:**

- *element* — symmetric function written in *self*

**EXAMPLES:**

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[]
sage: m.degree_negation(f)
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
```

**super_categories**()

The super categories of *self*.

**EXAMPLES:**

```
sage: from sage.combinat.sf.sfa import GradedSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = GradedSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of filtered bases of Symmetric Functions over Rational Field,
 Category of commutative graded Hopf algebras with basis over Rational Field]
```
class sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic(Sym, basis_name=None, prefix=None, graded=True)

Bases: CombinatorialFreeModule

Abstract base class for symmetric function algebras.

Todo: Most of the methods in this class are generic (manipulations of morphisms, …) and should be generalized (or removed)

Element

alias of SymmetricFunctionAlgebra_generic_Element

basis_name()

Return the name of the basis of self.

This is used for output and, for the classical bases of symmetric functions, to connect this basis with Symmetrica.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: s.basis_name()
'Schur'
sage: p = Sym.p()
sage: p.basis_name()
'powersum'
sage: h = Sym.h()
sage: h.basis_name()
'homogeneous'
sage: e = Sym.e()
sage: e.basis_name()
'elementary'
sage: m = Sym.m()
sage: m.basis_name()
'monomial'
sage: f = Sym.f()
sage: f.basis_name()
'forgotten'
```

change_ring \( (R) \)

Return the base change of \( self \) to \( R \).

EXAMPLES:

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: s.change_ring(QQ)
Symmetric Functions over Rational Field in the Schur basis
```

construction()

Return a pair \( (F, R) \), where \( F \) is a SymmetricFunctionsFunctor and \( R \) is a ring, such that \( F(R) \) returns \( self \).

EXAMPLES:

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Integer Ring)
```

coproduct_by_coercion \( (elt) \)

Return the coproduct of the element \( elt \) by coercion to the Schur basis.

INPUT:

- \( elt \) – an instance of this basis

OUTPUT:

- The image of \( elt \) under the comultiplication (=coproduct) of the coalgebra of symmetric functions. The result is an element of the tensor squared of the basis \( self \).

EXAMPLES:

```python
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,1,1].coproduct()
```

```python
sage: m.coproduct_by_coercion(m[2,1])
sage: m.coproduct_by_coercion(m[2,1]) == m([2,1]).coproduct()
True
```
sage: McdH = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().H()
sage: McdH[2,1].coproduct()
McdH[] # McdH[2, 1] + ((q^2*t-1)/(q*t-1))*McdH[1] # McdH[1, 1] + ((q^2*t^2-1)/
    (q*t-1))*McdH[1] # McdH[2] + ((q^2*t-1)/(q*t-1))*McdH[1, 1] # McdH[1] +
sage: HLQp = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood().Qp()
sage: HLQp[2,1].coproduct()
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: LLT = Sym.llt(3)
sage: LLT.cospin([3,2,1]).coproduct()
(t-1)*m[] # m[1, 1] + m[] # m[2] + (t+1)*m[1] # m[1] + (t+1)*m[1, 1] # m[] +
    m[2] # m[]
sage: f = SymmetricFunctions(ZZ).f()
sage: f[3].coproduct()
sage: f[3,2,1].coproduct()

>>> from sage.all import *

>>> m = SymmetricFunctions(QQ).m()
>>> m[Integer(3),Integer(1),Integer(1)].coproduct()
>>> m.coproduct_by_coercion(m[Integer(2),Integer(1)])
>>> m.coproduct_by_coercion(m[Integer(2),Integer(1)]) == m([Integer(2),
    Integer(1)]).coproduct()
True

>>> McdH = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().H()
>>> McdH[Integer(2),Integer(1)].coproduct()
McdH[] # McdH[2, 1] + ((q^2*t-1)/(q*t-1))*McdH[1] # McdH[1, 1] + ((q^2*t^2-1)/
    (q*t-1))*McdH[1] # McdH[2] + ((q^2*t-1)/(q*t-1))*McdH[1, 1] # McdH[1] +

>>> HLQp = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood().Qp()
>>> HLQp[Integer(2),Integer(1)].coproduct()

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))

>>> LLT = Sym.llt(Integer(3))

>>> LLT.cospin([Integer(3),Integer(2),Integer(1)]).coproduct()
(t+1)*m[] # m[1, 1] + m[] # m[2] + (t+1)*m[1] # m[1] + (t+1)*m[1, 1] # m[] +
    m[2] # m[]

>>> f = SymmetricFunctions(ZZ).f()

>>> f([Integer(3)].coproduct()

**dual_basis** (scalar=None, scalar_name='', basis_name=None, prefix=None)

Return the dual basis of self with respect to the scalar product scalar.

**INPUT:**

**5.1. Comprehensive Module List**

**4793**
• scalar – A function zee from partitions to the base ring which specifies the scalar product by $\langle p_\lambda, p_\mu \rangle = zee(\lambda)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function scalar only determines the norms of the basis elements.) If scalar is None, then the standard (Hall) scalar product is used.

• scalar_name – name of the scalar function

• prefix – prefix used to display the basis

EXAMPLES:
The duals of the elementary symmetric functions with respect to the Hall scalar product are the forgotten symmetric functions.

```
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix='f'); f
Dual basis to Symmetric Functions over Rational Field in the elementary basis
→ with respect to the Hall scalar product
sage: f([2,1])**2
→ f[4, 2]
sage: f([2,1]).scalar(e([2,1]))
1
sage: f([2,1]).scalar(e([1,1,1]))
0
```

Since the power-sum symmetric functions are orthogonal, their duals with respect to the Hall scalar product are scalar multiples of themselves.

```
sage: p = SymmetricFunctions(QQ).p()
sage: q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Functions over Rational Field in the powersum basis
→ with respect to the Hall scalar product
sage: q([2,1])**2
4*q[2, 2, 1, 1]
sage: p([2,1]).scalar(q([2,1]))
1
sage: p([2,1]).scalar(q([1,1,1]))
0
```

(continues on next page)
from_polynomial (poly, check=True)

Convert polynomial to a symmetric function in the monomial basis and then to the basis self.

INPUT:

• poly – a symmetric polynomial

• check – (default: True) boolean, specifies whether the computation checks that the polynomial is indeed symmetric

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: f = (h([]) + h([2,1]) + h([3])).expand(3)
sage: h.from_polynomial(f)
h[] + h[2, 1] + h[3]
sage: s = Sym.s()
sage: g = (s([]) + s([2,1])).expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + 1
sage: s.from_polynomial(g)
s[] + s[2, 1]
```
prefix()

Return the prefix on the elements of self.

EXAMPLES:

```python
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur([3,2,1])
s[3, 2, 1]
sage: schur.prefix()
's'
```

product_by_coercion(left, right)

Return the product of elements left and right by coercion to the Schur basis.

INPUT:

- • left, right – instances of this basis

OUTPUT:

- • the product of left and right expressed in the basis self

EXAMPLES:

```python
sage: p = SymmetricFunctions(QQ).p()
sage: p.product_by_coercion(p[3,1,1], p[2,2])
p[3, 2, 2, 1, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: m.product_by_coercion(m[2,1],m[1,1]) == m[2,1]*m[1,1]
True
```
set_print_style(ps)

Set the value of the current print style to ps.

INPUT:

- ps – a string specifying the printing style

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.get_print_style()
'lex'
>>> s.set_print_style('length')
>>> s.get_print_style()
'length'
>>> s.set_print_style('lex')
```

symmetric_function_ring()

Return the family of symmetric functions associated to the basis self.

OUTPUT:

- returns an instance of the ring of symmetric functions

EXAMPLES:

```
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur.symmetric_function_ring()
Symmetric Functions over Rational Field
sage: power = SymmetricFunctions(QQ['t']).power()
sage: power.symmetric_function_ring()
Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> schur = SymmetricFunctions(QQ).schur()
>>> schur.symmetric_function_ring()
Symmetric Functions over Rational Field
>>> power = SymmetricFunctions(QQ['t']).power()
>>> power.symmetric_function_ring()
Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
```

transition_matrix(basis, n)

Return the transition matrix between self and basis for the homogeneous component of degree n.

INPUT:

- basis – a basis of the ring of symmetric functions
- n – a nonnegative integer

OUTPUT:
• a matrix of coefficients giving the expansion of the homogeneous degree-\(n\) elements of \(\text{self}\) in the degree-\(n\) elements of \(\text{basis}\)

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: m = SymmetricFunctions(QQ).m()
sage: s.transition_matrix(m, 5)

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 1 & 2 & 2 & 3 & 4 \\
0 & 0 & 1 & 1 & 2 & 3 & 5 \\
0 & 0 & 0 & 1 & 1 & 3 & 6 \\
0 & 0 & 0 & 0 & 1 & 2 & 5 \\
0 & 0 & 0 & 0 & 0 & 1 & 4 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

sage: s.transition_matrix(m, 1)

\[
\begin{bmatrix}
1 \\
\end{bmatrix}
\]

sage: s.transition_matrix(m, 0)

\[
\begin{bmatrix}
1 \\
\end{bmatrix}
\]

>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).s()

>>> m = SymmetricFunctions(QQ).m()

>>> s.transition_matrix(m, Integer(5))

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 \\
0 & 1 & 1 & 2 & 2 \\
0 & 0 & 1 & 1 & 2 \\
0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 \\
\end{bmatrix}
\]

>>> s.transition_matrix(m, Integer(1))

\[
\begin{bmatrix}
1 \\
\end{bmatrix}
\]

>>> s.transition_matrix(m, Integer(0))

\[
\begin{bmatrix}
1 \\
\end{bmatrix}
\]

sage: p = SymmetricFunctions(QQ).p()
sage: s.transition_matrix(p, 4)

\[
\begin{bmatrix}
1/4 & 1/3 & 1/8 & 1/4 & 1/24 \\
-1/4 & 0 & -1/8 & 1/4 & 1/8 \\
0 & -1/3 & 1/4 & 0 & 1/12 \\
1/4 & 0 & -1/8 & -1/4 & 1/8 \\
-1/4 & 1/3 & 1/8 & -1/4 & 1/24 \\
\end{bmatrix}
\]

sage: StoP = s.transition_matrix(p, 4)
sage: a = s([3, 1]) + 5*s([1, 1, 1, 1]) - s([4])
sage: a

\[
5s[1, 1, 1, 1] + s[3, 1] - s[4]
\]

sage: mon = sorted(a.support())
sage: coeffs = [a[i] for i in mon]
sage: coeffs

\[
[5, 1, -1]
\]

sage: mon

\[
[[1, 1, 1, 1], [3, 1], [4]]
\]

sage: cm = matrix([[1, 1, 0, 0, 5]])
sage: cm * StoP

\[
\begin{bmatrix}
\end{bmatrix}
\]

sage: p(a)

\[
\]

```
```python
>>> from sage.all import *

>>> p = SymmetricFunctions(QQ).p()

>>> s.transition_matrix(p, Integer(4))
\[
\begin{bmatrix}
 1/4 & 1/3 & 1/8 & 1/4 & 1/24 \\
-1/4 & 0 & -1/8 & 1/4 & 1/8 \\
 0 & -1/3 & 1/4 & 0 & 1/12 \\
 1/4 & 0 & -1/8 & -1/4 & 1/8 \\
-1/4 & 1/3 & 1/8 & -1/4 & 1/24
\end{bmatrix}
\]

>>> StoP = s.transition_matrix(p, Integer(4))

>>> a = s([Integer(3), Integer(1)]) + Integer(5)*s([Integer(1), Integer(1), Integer(1)])

>>> a
5*s[1, 1, 1] + s[3, 1] - s[4]

>>> mon = sorted(a.support())

>>> coeffs = [a[i] for i in mon]

>>> coeffs
[5, 1, -1]

>>> mon
[[1, 1, 1, 1], [3, 1], [4]]

>>> cm = matrix([[-Integer(1), Integer(1), Integer(0), Integer(0), Integer(5)]]

>>> cm * StoP
\[
\begin{bmatrix}
\end{bmatrix}
\]

>>> p(a)

sage: h = SymmetricFunctions(QQ).h()

sage: e = SymmetricFunctions(QQ).e()

sage: s.transition_matrix(m, Integer(7)) == h.transition_matrix(s, Integer(7)).transpose()
True

sage: h.transition_matrix(m, 7) == h.transition_matrix(m, 7).transpose()
True

sage: h.transition_matrix(e, 7) == e.transition_matrix(h, 7)
True

sage: p.transition_matrix(s, 5)
\[
\begin{bmatrix}
 1 & -1 & 0 & 1 & 0 & -1 & 1 \\
 1 & 0 & -1 & 0 & 1 & 0 & -1
\end{bmatrix}
\]
```

\[
\begin{bmatrix}
1 & -1 & 1 & 0 & -1 & 1 & -1 \\
1 & 1 & -1 & 0 & -1 & 1 & 1 \\
1 & 0 & 1 & -2 & 1 & 0 & 1 \\
1 & 2 & 1 & 0 & -1 & -2 & -1 \\
1 & 4 & 5 & 6 & 5 & 4 & 1
\end{bmatrix}
\]

```python
>>> from sage.all import *

>>> p.transition_matrix(s, Integer(5))
\[
\begin{bmatrix}
1 & -1 & 0 & 1 & 0 & -1 & 1 \\
1 & 0 & -1 & 0 & 1 & 0 & -1 \\
1 & -1 & 1 & 0 & -1 & 1 & 1 \\
1 & 1 & -1 & 0 & -1 & 1 & 1 \\
1 & 0 & 1 & -2 & 1 & 0 & 1 \\
1 & 2 & 1 & 0 & -1 & -2 & -1 \\
1 & 4 & 5 & 6 & 5 & 4 & 1
\end{bmatrix}
\]
```

```python
sage: e.transition_matrix(m,7) == e.transition_matrix(m,7).transpose()
True
```

```python
>>> from sage.all import *

>>> e.transition_matrix(m,Integer(7)) == e.transition_matrix(m,Integer(7)).transpose()
True
```

class `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`

Bases: `IndexedFreeModuleElement`

Class of generic elements for the symmetric function algebra.

**adams_operator** (*n*)

Return the image of the symmetric function `self` under the `n`-th Adams operator.

The `n`-th Adams operator `f_n` is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function `P(x_1, x_2, x_3, ...)` to `P(x_1^n, x_2^n, x_3^n, ...)`. This operator `f_n` is a Hopf algebra endomorphism, and satisfies

\[ f_n m(\lambda_1, \lambda_2, \lambda_3, ...) = m(n\lambda_1, n\lambda_2, n\lambda_3, ...) \]

for every partition \((\lambda_1, \lambda_2, \lambda_3, ...)\) (where `m` means the monomial basis). Moreover, `f_n(p_r) = p_{nr}` for every positive integer `r` (where `p_k` denotes the `k`-th powersum symmetric function).

The `n`-th Adams operator is also called the `n`-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The `n`-th Adams operator is also the `n`-th Adams operator of the \(\Lambda\)-ring of symmetric functions over the integers.

The `n`-th Adams operator can also be described via plethysm: Every symmetric function `P` satisfies `f_n(P) = p_n \circ P = P \circ p_n`, where `p_n` is the `n`-th powersum symmetric function, and \(\circ\) denotes (outer) plethysm.

**INPUT:**
- `n` – a positive integer

**OUTPUT:**

The result of applying the `n`-th Adams operator (on the ring of symmetric functions) to `self`.

**EXAMPLES:**
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].adams_operator(2)
sage: m[4,2,1].adams_operator(3)
m[12, 6, 3]
sage: p[4,2,1].adams_operator(3)
p[12, 6, 3]
sage: h[4].adams_operator(2)

>>> from sage.all import *

>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> h = Sym.h()
>>> s = Sym.s()
>>> m = Sym.m()

sage: s[Integer(3)].adams_operator(Integer(2))

>>> m[Integer(4),Integer(2),Integer(1)].adams_operator(Integer(3))
m[12, 6, 3]

>>> p[Integer(4),Integer(2),Integer(1)].adams_operator(Integer(3))
p[12, 6, 3]

>>> h[Integer(4)].adams_operator(Integer(2))

The Adams endomorphisms are multiplicative:

sage: all( all( s(lam).adams_operator(3) * s(mu).adams_operator(3) # long time
....: == (s(lam) * s(mu)).adams_operator(3)
....: for mu in Partitions(3) )
....: for lam in Partitions(3) )
True

sage: all( all( m(lam).adams_operator(2) * m(mu).adams_operator(2)
....: == (m(lam) * m(mu)).adams_operator(2)
....: for mu in Partitions(4) )
....: for lam in Partitions(4) )
True

sage: all( all( p(lam).adams_operator(2) * p(mu).adams_operator(2)
....: == (p(lam) * p(mu)).adams_operator(2)
....: for mu in Partitions(3) )
....: for lam in Partitions(4) )
True

(continues on next page)
... for mu in Partitions(Integer(4)) )
... for lam in Partitions(Integer(4)) )
True

>>> all( all( p(lam).adams_operator(Integer(2)) * p(mu).adams_operator(Integer(2)) == (p(lam) * p(mu)).adams_operator(Integer(2))
... for mu in Partitions(Integer(3)) )
... for lam in Partitions(Integer(4)) )
True

Being Hopf algebra endomorphisms, the Adams operators commute with the antipode:

\[
\text{sage: } \text{all( } p(lam).adams_operator(4).antipode() == p(lam).antipode().adams_operator(4)
\text{ ) for lam in Partitions(3) }
\]

True

>>> from sage.all import *

>>> all( p(lam).adams_operator(Integer(4)).antipode() == p(lam).antipode().adams_operator(Integer(4))
... for lam in Partitions(Integer(3)) )
True

Testing the \( f_n(P) = p_n \circ P = P \circ p_n \) equality (over \( \mathbb{Q} \), since plethysm is currently not defined over \( \mathbb{Z} \) in Sage):

\[
\text{sage: } \text{Sym = SymmetricFunctions(QQ)
}\text{sage: } \text{s = Sym.s()}
\text{sage: } \text{p = Sym.p()}
\text{sage: } \text{all( } s(lam).adams_operator(3) == s(lam).plethysm(p[3])
\text{ ) for lam in Partitions(4) }
\]

True

>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> p = Sym.p()
>>> all( s(lam).adams_operator(Integer(3)) == s(lam).plethysm(p[Integer(3)])
... == s(p[Integer(3)].plethysm(s(lam)))
... for lam in Partitions(Integer(4)) )
True

By Exercise 7.61 in Stanley’s EC2 [STA] (see the errata on his website), \( f_n(h_m) \) is a linear combination of Schur polynomials (of straight shapes) using coefficients 0, 1 and \(-1\) only; moreover, all partitions whose Schur polynomials occur with coefficient \( \neq 0 \) in this combination have empty \( n \)-cores. Let us check this on examples:

\[
\text{sage: } \text{all( all( all( } (coeff == -1 \text{ or coeff == 1)
\text{ ) and lam.core(n) == Partition([]))
\text{ ) for lam, coeff in s([m]).adams_operator(n) )}
\text{ ) for n in range(2, 4) )}
\text{ ) for m in range(4) )}
\]

True
>>> from sage.all import *
>>> all( all( all( (coeff == -Integer(1) or coeff == Integer(1))
... and lam.core(n) == Partition([])
... for lam, coeff in s([m]).adams_operator(n) )
... for n in range(Integer(2), Integer(4)) )
... for m in range(Integer(4)) )
True

See also:
plethysm()

Todo:
This method is fast on the monomial and the powersum bases, while all other bases get converted
to the monomial basis. For most bases, this is probably the quickest way to do, but at least the Schur basis
should have a better option. (Quoting from Stanley’s EC2 [STA]: “D. G. Duncan, J. London Math. Soc. 27

arithmetic_product(x)

Return the arithmetic product of self and x in the basis of self.

The arithmetic product is a binary operation \( \Box \) on the ring of symmetric functions which is bilinear in its two
arguments and satisfies

\[
p_\lambda \Box p_\mu = \prod_{i \geq 1, j \geq 1} p_{\gcd(\lambda_i, \mu_j)}^{\lcm(\lambda_i, \mu_j)}
\]

for any two partitions \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots) \) and \( \mu = (\mu_1, \mu_2, \mu_3, \ldots) \) (where \( p_\nu \) denotes the power-sum symmetric function indexed by the partition \( \nu \), and \( p_i \) denotes the \( i \)-th power-sum symmetric function). This
is enough to define the arithmetic product if the base ring is torsion-free as a \( \mathbb{Z} \)-module; for all other cases
the arithmetic product is uniquely determined by requiring it to be functorial in the base ring. See http://
mathoverflow.net/questions/138148/ for a discussion of this arithmetic product.

If \( f \) and \( g \) are two symmetric functions which are homogeneous of degrees \( a \) and \( b \), respectively, then \( f \Box g \)
is homogeneous of degree \( ab \).

The arithmetic product is commutative and associative and has unity \( e_1 = p_1 = h_1 \).

INPUT:

- \( x \) – element of the ring of symmetric functions over the same base ring as self

OUTPUT:

Arithmetic product of self with \( x \); this is a symmetric function over the same base ring as self.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2]).arithmetic_product(s([2]))
[s[1, 1, 1, 1] + 2*s[2, 2] + s[4]]
sage: s([2]).arithmetic_product(s([1,1]))
[s[2, 1, 1] + s[3, 1]]
```
The symmetric function $e[1]$ is the unity for the arithmetic product:

```sage
e = SymmetricFunctions(ZZ).e()
eall( e([1]).arithmetic_product(e(q)) == e(q) for q in Partitions(4) )
```

```
True
```

```sage
>>> from sage.all import *
>>> e = SymmetricFunctions(ZZ).e()
>>> all( e([Integer(1)]).arithmetic_product(e(q)) == e(q) for q in Partitions(Integer(4)) )
```

```
True
```

The arithmetic product is commutative:

```sage
e = SymmetricFunctions(FiniteField(19)).e()
m = SymmetricFunctions(FiniteField(19)).m()
eall( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_product(e(p)) for q in Partitions(4) ) for p in Partitions(4) )
```

```
True
```

```sage
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> all( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_product(e(p)) for q in Partitions(Integer(4)) ) for p in Partitions(Integer(4)) )
```

```
True
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra (in which case the arithmetic product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the corresponding basis over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

**bernstein_creation_operator** ($n$)

Return the image of self under the $n$-th Bernstein creation operator.

Let $n$ be an integer. The $n$-th Bernstein creation operator $B_n$ is defined as the endomorphism of the space $Sym$ of symmetric functions which sends every $f$ to

$$
\sum_{i \geq 0} (-1)^i h_{n+i} e_i^\perp,
$$

where usual notations are in place ($h$ stands for the complete homogeneous symmetric functions, $e$ for the elementary ones, and $e_i^\perp$ means skewing (skew_by ($i$)) by $e_i$).

This has been studied in [BBSSZ2012], section 2.2, where the following rule is given for computing $B_n$ on a Schur function: If $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ is an $n$-tuple of integers (positive or not), then

$$
B_n s(\alpha_1, \alpha_2, \ldots, \alpha_n) = s(n, \alpha_1, \alpha_2, \ldots, \alpha_n).
$$
Here, $s_{(\alpha_1, \alpha_2, \ldots, \alpha_n)}$ is the “Schur function” associated to the $n$-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_n)$, and defined by literally applying the Jacobi-Trudi identity, i.e., by

$$s_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} = \det \left( (h_{\alpha_i-i+j})_{i,j=1,2,\ldots,n} \right).$$

This notion of a Schur function clearly extends the classical notion of Schur function corresponding to a partition, but is easily reduced to the latter (in fact, for any $n$-tuple $\alpha$ of integers, one easily sees that $s_{\alpha}$ is either 0 or minus-plus a Schur function corresponding to a partition; and it is easy to determine which of these is the case and find the partition by a combinatorial algorithm).

EXAMPLES:

Let us check that what this method computes agrees with the definition:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: def bernstein_creation_by_def(n, f):
    ....:     # 'n'-th Bernstein creation operator applied to 'f'
    ....:     # computed according to its definition.
    ....:     res = f.parent().zero()
    ....:     if not f:
    ....:         return res
    ....:     max_degree = max(sum(m) for m, c in f)
    ....:     for i in range(max_degree + 1):
    ....:         if n + i >= 0:
    ....:             res += (-1) ** i * h[n + i] * f.skew_by(e[i])
    ....:     return res

sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_operator(n) for n in range(-3, 4) for l in Partitions(3) )
True
```

```bash
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> h = Sym.h()
>>> s = Sym.s()
>>> def bernstein_creation_by_def(n, f):
...     # 'n'-th Bernstein creation operator applied to 'f'
...     # computed according to its definition.
...     res = f.parent().zero()
...     if not f:
...         return res
...     max_degree = max(sum(m) for m, c in f)
...     for i in range(max_degree + 1):
...         if n + i >= 0:
...             res += (-Integer(1)) ** i * h[n + i] * f.skew_by(e[i])
...     return res
```

(continues on next page)
Some examples:

```python
sage: s[3,2].bernstein_creation_operator(3)
  s[3, 3, 2]
sage: s[3,2].bernstein_creation_operator(1)
  -s[2, 2, 2]
sage: h[3,2].bernstein_creation_operator(-2)
  h[2, 1]
sage: h[3,2].bernstein_creation_operator(-1)
  h[2, 1, 1] - h[2, 2] - h[3, 1]
sage: h[3,2].bernstein_creation_operator(0)
  -h[3, 1, 1] + h[3, 2]
sage: h[3,2].bernstein_creation_operator(1)
  -h[2, 2, 2] + h[3, 2, 1]
sage: h[3,2].bernstein_creation_operator(2)
  -h[3, 3, 1] + h[4, 2, 1]
```

```python
>>> from sage.all import *
```

```python
>>> s[Integer(3),Integer(2)].bernstein_creation_operator(Integer(3))
  s[3, 3, 2]
>>> s[Integer(3),Integer(2)].bernstein_creation_operator(Integer(1))
  -s[2, 2, 2]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(2))
  h[2, 1]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(1))
  h[2, 1, 1] - h[2, 2] - h[3, 1]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(0)
  -h[3, 1, 1] + h[3, 2]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(1)
  -h[2, 2, 2] + h[3, 2, 1]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(2)
  -h[3, 3, 1] + h[4, 2, 1]
```

**character_to_frobenius_image** \((n)\)

Interpret \texttt{self} as a \(GL_n\) character and then take the Frobenius image of this character of the permutation matrices \(S_n\) which naturally sit inside of \(GL_n\).

To know the value of this character at a permutation of cycle structure \(\rho\) the symmetric function \texttt{self} is evaluated at the eigenvalues of a permutation of cycle structure \(\rho\). The Frobenius image is then defined as \(\sum_{\rho^G \in \mathfrak{S}_n} f[\Xi_\rho]p_\rho/z_\rho\).
See also:

eval_at_permutation_roots()

INPUT:

• \(n\) – a non-negative integer to interpret \(\text{self}\) as a character of \(GL_n\)

OUTPUT:

• a symmetric function of degree \(n\)

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([1,1]).character_to_frobenius_image(5)
s[3, 1, 1] + s[4, 1]
sage: s([2,1]).character_to_frobenius_image(5)
sage: s([2,2,2]).character_to_frobenius_image(3)
s[3]
sage: s([2,2,2]).character_to_frobenius_image(4)
sage: s([2,2,2]).character_to_frobenius_image(5)

>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).s()

>>> s([Integer(1),Integer(1)]).character_to_frobenius_image(Integer(5))
s[3, 1, 1] + s[4, 1]

>>> s([Integer(2),Integer(1)]).character_to_frobenius_image(Integer(5))

>>> s([Integer(2),Integer(2),Integer(2)]).character_to_frobenius_image(Integer(3))
s[3]

>>> s([Integer(2),Integer(2),Integer(2)]).character_to_frobenius_image(Integer(4))

>>> s([Integer(2),Integer(2),Integer(2)]).character_to_frobenius_image(Integer(5))
```

\(\text{degree()}\)

Return the degree of \(\text{self}\) (which is defined to be 0 for the zero element).

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1]) + 3
sage: z.degree()
4
sage: s([1]).degree()
0
sage: s([0]).degree()
0

>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).s()

>>> z = s([Integer(4)]) + s([Integer(2),Integer(1)]) + s([Integer(1)],
```

(continues on next page)
derivative_with_respect_to_p1\( (n=1) \)

Return the symmetric function obtained by taking the derivative of \( \text{self} \) with respect to the power-sum symmetric function \( p_1 \) when the expansion of \( \text{self} \) in the power-sum basis is considered as a polynomial in \( p_k \)'s (with \( k \geq 1 \)).

This is the same as skewing \( \text{self} \) by the first power-sum symmetric function \( p_1 \).

INPUT:

- \( n \) – (default: 1) nonnegative integer which determines which power of the derivative is taken

EXAMPLES:

```python
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([1,1,1])
sage: a.derivative_with_respect_to_p1() 3*p[1, 1]
sage: a.derivative_with_respect_to_p1(1) 3*p[1, 1]
sage: a.derivative_with_respect_to_p1(2) 6*p[1]
sage: a.derivative_with_respect_to_p1(3) 6*p[]
```

```python
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> a = p([Integer(1),Integer(1),Integer(1)])
>>> a.derivative_with_respect_to_p1() 3*p[1, 1]
>>> a.derivative_with_respect_to_p1(Integer(1)) 3*p[1, 1]
>>> a.derivative_with_respect_to_p1(Integer(2)) 6*p[1]
>>> a.derivative_with_respect_to_p1(Integer(3)) 6*p[]
```

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([3]).derivative_with_respect_to_p1()
s[2]
sage: s([2,1]).derivative_with_respect_to_p1()
s[1, 1] + s[2]
sage: s([1,1,1]).derivative_with_respect_to_p1()
s[1, 1]
sage: s([0]).derivative_with_respect_to_p1()
0
sage: s([1]).derivative_with_respect_to_p1()
0
sage: s([1]).derivative_with_respect_to_p1()
s[]
```
Let us check that taking the derivative with respect to \( p[1] \) is equivalent to skewing by \( p[1] \):

```python
sage: p1 = s([1])
sage: all( s(lam).derivative_with_respect_to_p1() == s(lam).skew_by(p1) for lam in Partitions(Integer(4)) )
True
```

### eval_at_permutation_roots(rho)

Evaluate at eigenvalues of a permutation matrix.

Evaluate a symmetric function at the eigenvalues of a permutation matrix whose cycle structure is \( \rho \).

This computation is computed by coercing to the power sum basis where the value may be computed on the generators.

This function evaluates an element at the roots of unity

\[
\Xi_{p_1}, \Xi_{p_2}, \ldots, \Xi_{p_\ell}
\]

where

\[
\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}
\]

and \( \zeta_m \) is an \( m \) root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure \( \rho \).

**INPUT:**

- \( \rho \) – a partition or a list of non-negative integers

**OUTPUT:**

- an element of the base ring

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,3]).eval_at_permutation_roots([6])
0
```
expand \((n, \text{alphabet='x'})\)

Expand the symmetric function \(\text{self}\) as a symmetric polynomial in \(n\) variables.

**INPUT:**

- \(n\) – a nonnegative integer
- \(\text{alphabet}\) – (default: ‘\(x\)’) a variable for the expansion

**OUTPUT:**

A monomial expansion of \(\text{self}\) in the \(n\) variables labelled \(x_0, x_1, ..., x_{n-1}\) (or just \(x\) if \(n = 1\)), where \(x\) is \(\text{alphabet}\).

**EXAMPLES:**

\[
\text{sage: } J = \text{SymmetricFunctions}(\text{QQ}).\text{jack}(t=2).\text{J}()
\text{sage: } J([2,1]).\text{expand}(3)
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 +
\rightarrow 4*x1*x2^2
\text{sage: } (2^*J([2])).\text{expand}(0)
0
\text{sage: } (3^*J([])).\text{expand}(0)
3
\]
exponential_specialization ($t=\text{None}, q=1$)

Return the exponential specialization of a symmetric function (when $q = 1$), or the $q$-exponential specialization (when $q \neq 1$).

The exponential specialization $ex$ at $t$ is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$. It is defined whenever the base ring $K$ is a $\mathbb{Q}$-algebra and $t$ is an element of $R$. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the $q$-exponential specialization is a $K$-algebra homomorphism from the $K$-algebra of symmetric functions to another $K$-algebra $R$ that depends on two elements $t$ and $q$ of $R$ for which the elements $1 - q^i$ for all positive integers $i$ are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,\,$$

where $[n]_q!$ is the $q$-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function $f$ of degree $n$, we have

$$ex_q(f) = (1 - q)^{n}t^{n}ps_q(f),\,$$

where $ps_q(f)$ is the stable principal specialization of $f$ (see principal_specialization()). (See (7.29) in [EnumComb2].)

The limit of $ex_q$ as $q \to 1$ is $ex$.

**INPUT:**

- $t$ (default: None) – the value to use for $t$; the default is to create a ring of polynomials in $t$.
- $q$ (default: 1) – the value to use for $q$. If $q$ is None, then a ring (or fraction field) of polynomials in $q$ is created.

**EXAMPLES:**

```
sage: m = SymmetricFunctions(QQ).m()
sage: (m[2,1]+m[1,1]).exponential_specialization()
1/2*t^2
sage: (m[2,1]+m[1,1]).exponential_specialization(q=1)
1/2*t^2
sage: m[1,1].exponential_specialization(q=\text{None})
(q/(q + 1))*t^2
sage: Qq = PolynomialRing(QQ, "q"); q = Qq.gen()
sage: m[1,1].exponential_specialization(q=q)
(q/(q + 1))*t^2
sage: Qt = PolynomialRing(QQ, "t"); t = Qt.gen()
sage: m[1,1].exponential_specialization(t=t)
1/2*t^2
sage: Qt = PolynomialRing(QQ, ["q", "t"]); q, t = Qt.gens()
sage: m[1,1].exponential_specialization(q=q, t=t)
q*t^2/(q + 1)
```
sage: x = m[3]+m[2,1]+m[1,1,1]
sage: d = x.homogeneous_degree()
sage: var("q t")
# needs sage.symbolic
(q, t)
sage: factor((x.principal_specialization()*(1-q)^d*t^d))
# needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
sage: factor(x.exponential_specialization(q=q, t=t))
# needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))

>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> (m[2,1]+m[1,1]).exponential_specialization()
1/2*t^2
>>> (m[2,1]+m[1,1]).exponential_specialization(q=Integer(1))
1/2*t^2
>>> m[1,1].exponential_specialization(q=None)
(q/(q + 1))*t^2
>>> Qq = PolynomialRing(QQ, "q"); q = Qq.gen()
>>> m[1,1].exponential_specialization(q=q)
(q/(q + 1))*t^2
>>> Qt = PolynomialRing(QQ, "t"); t = Qt.gen()
>>> m[1,1].exponential_specialization(t=t)
1/2*t^2
>>> Qqt = PolynomialRing(QQ, ["q", "t"]); q, t = Qqt.gens()
>>> m[1,1].exponential_specialization(q=q, t=t)
q*t^2/(q + 1)

>>> x = m[3]+m[2,1]+m[1,1,1]
>>> d = x.homogeneous_degree()
>>> var("q t")
# needs sage.symbolic
(q, t)
>>> factor((x.principal_specialization()*(1-q)**d*t**d))
# needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
>>> factor(x.exponential_specialization(q=q, t=t))
# needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))

factor()  
Return the factorization of this symmetric function.

EXAMPLES:

sage: e = SymmetricFunctions(QQ).e()
sage: R.<x, y> = QQ[]
sage: s = SymmetricFunctions(R.fraction_field()).s()

(-s[] + (-x)*s[2, 1] - s[3]) * ((-x*y)*s[] + (-3*y)*s[2] - s[4, 1])

>>> frobenius(*args, **kwds)

Deprecated: Use adams_operator() instead. See Issue #36396 for details.

gcd(other)

Return the greatest common divisor with other.

INPUT:

- other – the other symmetric function

EXAMPLES:

sage: e = SymmetricFunctions(QQ).e()
sage: B = 7*e[2] + e[5,1]
sage: C = 3*e[1,1] + e[2]
sage: gcd(A*B^2, B*C)
7*e[2] + e[5, 1]

sage: p = SymmetricFunctions(QQ).p()
sage: gcd(e[2,1], p[1,1]-p[2])
e[2]
sage: gcd(p[2,1], p[3,2]-p[2,1])
p[2]
This is the vertex operator that generalizes Jing’s operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a $t$-analogue of multiplication by $s(\nu)$.

**See also:**

Proposition 5 in [SZ2001].

**INPUT:**

- $\nu$ – a partition or a list of integers
- $t$ – (default: None, in which case $t$ is used) an element of the base ring

**REFERENCES:**

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ['t']).s()
sage: s([2]).hl_creation_operator([3,2])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.s()
sage: HLQp(s([2]).hl_creation_operator([2]).hl_creation_operator([3]))
HLQp[3, 2, 2]
sage: s([2,2]).hl_creation_operator([3,2])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: s = Sym.s()
sage: HLQp(s([2]).hl_creation_operator([2]).hl_creation_operator([3]))
HLQp[3, 2, 2]
sage: s([2,2]).hl_creation_operator([2,1])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]
sage: s(1).hl_creation_operator([2,1,1])
s[2, 1, 1]
sage: s(0).hl_creation_operator([2,1,1])
0
sage: s([3,2]).hl_creation_operator([2,1,1])
(t^2-t)*s[2, 2, 2, 2, 1] + t^3*s[3, 2, 2, 2, 1]
 + (t^3-t^2)*s[3, 2, 2, 2, 1] + t^3*s[3, 3, 1, 1, 1]
 + t^4*s[3, 3, 2, 1, 1] + t^3*s[4, 2, 1, 1, 1] + t^4*s[4, 2, 2, 1]
 + 2*t^4*s[4, 3, 1, 1] + t^5*s[4, 3, 2] + t^5*s[4, 4, 1]
 + t^4*s[5, 2, 1, 1] + t^5*s[5, 3, 1]
sage: s([3,2]).hl_creation_operator([-2])
(-t^2+t)*s[1, 1, 1] + (-t^2+1)*s[2, 1]
sage: s([3,2]).hl_creation_operator([-2])

```

(continues on next page)
inner_plethysm(x)

Return the inner plethysm of self with x.

Whenever \( R \) is a \( Q \)-algebra, and \( f \) and \( g \) are two symmetric functions over \( R \) such that the constant term of \( f \) is zero, the inner plethysm of \( f \) with \( g \) is a symmetric function over \( R \), and the degree of this symmetric function is the same as the degree of \( g \). We will denote the inner plethysm of \( f \) with \( g \) by \( f \{ g \} \) (in contrast to the notation of outer plethysm which is generally denoted \( f[g] \)); in Sage syntax, it is \( f \text{.inner_plethysm}(g) \).

First we describe the axiomatic definition of the operation; see below for a representation-theoretic interpretation. In the following equations, we denote the outer product (i.e., the standard product on the ring of symmetric functions, \( \text{product()} \)) by \( \cdot \) and the Kronecker product (\( \text{itensor()} \)) by \( * \).

\[
(f + g)\{ h \} = f\{ h \} + g\{ h \}
\]
\[
(f \cdot g)(h) = (f\{ h \}) \ast (g\{ h \})
\]
\[
p_k\{ f + g \} = p_k\{ f \} + p_k\{ g \}
\]

where \( p_k \) is the \( k \)-th power-sum symmetric function for every \( k > 0 \).

Let \( \sigma \) be a permutation of cycle type \( \mu \) and let \( \mu^k \) be the cycle type of \( \sigma^k \). Then,

\[
p_k\{ p_\mu/z_\mu \} = \sum_{\nu: \nu^k = \mu} p_\nu/z_\nu
\]

Since \( (p_\mu/z_\mu)_\mu \) is a basis for the symmetric functions, these four formulas define the symmetric function operation \( f\{ g \} \) for any symmetric functions \( f \) and \( g \) (where \( f \) has constant term 0) by expanding \( f \) in the power sum basis and \( g \) in the dual basis \( p_\mu/z_\mu \).

See also:

\text{itensor()}, \text{partition_power()}, \text{plethysm()}

5.1. Comprehensive Module List 4815
This operation admits a representation-theoretic interpretation in the case where \( f \) is a Schur function \( s_{\lambda} \) and \( g \) is a homogeneous degree \( n \) symmetric function with nonnegative integral coefficients in the Schur basis. The symmetric function \( f \{ g \} \) is the Frobenius image of the \( S_n \)-representation constructed as follows.

The assumptions on \( g \) imply that \( g \) is the Frobenius image of a representation \( \rho \) of the symmetric group \( S_n \):

\[
\rho : S_n \rightarrow GL_N.
\]

If the degree \( N \) of this representation is greater than or equal to the number of parts of \( \lambda \), then \( f \), which denotes \( s_{\lambda} \), corresponds to the character of some irreducible \( GL_N \)-representation, say

\[
\sigma : GL_N \rightarrow GL_M.
\]

The composition \( \sigma \circ \rho : S_n \rightarrow GL_M \) is a representation of \( S_n \) whose Frobenius image is precisely \( f \{ g \} \).

If \( N \) is less than the number of parts of \( \lambda \), then \( f \{ g \} \) is 0 by definition.

When \( f \) is a symmetric function with constant term \( \neq 0 \), the inner plethysm \( f \{ g \} \) isn’t well-defined in the ring of symmetric functions. Indeed, it is not clear how to define \( 1 \{ g \} \). The most sensible way to get around this probably is defining it as the infinite sum \( h_0 + h_1 + h_2 + \cdots \) (where \( h_i \) means the \( i \)-th complete homogeneous symmetric function) in the completion of this ring with respect to its grading. This is how [SchaThi1994] defines \( 1 \{ g \} \). The present method, however, sets it to be the sum of \( h_i \) over all \( i \) for which the \( i \)-th homogeneous component of \( g \) is nonzero. This is rather a hack than a reasonable definition. Use with caution!

**Note:** If a symmetric function \( g \) is written in the form \( g = g_0 + g_1 + g_2 + \cdots \) with each \( g_i \) homogeneous of degree \( i \), then \( f \{ g \} = f \{ g_0 \} + f \{ g_1 \} + f \{ g_2 \} + \cdots \) for every \( f \) with constant term 0. But in general, inner plethysm is not linear in the second variable.

**REFERENCES:**

**INPUT:**

- \( x \) – element of the ring of symmetric functions over the same base ring as \( \text{self} \)

**OUTPUT:**

- an element of symmetric functions in the parent of \( \text{self} \)

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: h = Sym.complete()
sage: s([2,1]).inner_plethysm(s([1,1,1]))
0
sage: s([2]).inner_plethysm(s([2,1]))
\[2, 1\] + \[3\]
sage: s([1,1]).inner_plethysm(s([2,1]))
\[1, 1, 1\]
sage: s([2,1]).inner_tensor(s([2,1]))
\[1, 1, 1\] + \[2, 1\] + \[3\]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> p = Sym.power()
```

(continues on next page)
```python
>>> s([Integer(2), Integer(1)]).inner_plethysm(s([Integer(1), Integer(1), Integer(1)]))
0
>>> s([Integer(2)]).inner_plethysm(s([Integer(2), Integer(1)]))
s[2, 1] + s[3]
>>> s([Integer(1), Integer(1)]).inner_plethysm(s([Integer(2), Integer(1)]))
s[1, 1, 1]
>>> s([Integer(2), Integer(1)]).inner_tensor(s([Integer(2), Integer(1)]))
s[1, 1, 1] + s[2, 1] + s[3]
```

```python
sage: f = s([2, 1]) + 2*s([3, 1])
sage: f.itensor(f)
```

```python
>>> from sage.all import *
```
```python
>>> s([Integer(1), Integer(1)]).inner_plethysm(f)
```

```python
sage: f = s([Integer(2), Integer(1)]) + Integer(2)*s([Integer(3), Integer(1)])
sage: f.itensor(f)
>>> s(h([1,1])).inner_plethysm(f)
```

```python
sage: [s([]).inner_plethysm(s(la)) for la in Partitions(4)]
s[4], s[4], s[4], s[4]
```

```python
sage: s([Integer(3)]).inner_plethysm(s([]))
s[]
```

```python
>>> from sage.all import *
```
```python
>>> s([]).inner_plethysm(s([1,1]) + 2*s([2,1])+s([3]))
s[2] + s[3]
```

```python
sage: p[3].inner_plethysm(p[3])
0
```

```python
sage: p[3,3].inner_plethysm(p[3])
0
```

```python
sage: p[3].inner_plethysm(p[1,1,1])
```

(continues on next page)
inner_tensor(x)

Return the internal (tensor) product of self and x in the basis of self.

The internal tensor product can be defined as the linear extension of the definition on power sums \( p_\lambda \ast p_\mu = \delta_{\lambda, \mu} z_\lambda p_\lambda \), where \( z_\lambda = (1^r_1 r_1!)(2^r_2 r_2! \cdots \) for \( \lambda = (1^r_1 2^r_2 \cdots) \) and where \( \ast \) denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see scalar()).
There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function \( f \) of degree \( n \) with the \( n \)-th complete homogeneous symmetric function \( h[n] \) (a.k.a. \( s[n] \)) is \( f \):

```sage
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function \( s_\lambda \) with the \( n \)-th elementary symmetric function \( e[n] \), where \( n = |\lambda| \), is \( s_\lambda \) (where \( \lambda' \) is the conjugate partition of \( \lambda \)):

```sage
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```sage
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
---Partitions(4) )
True
```
Combinatorics, Release 10.4

(continued from previous page)

```python
    ....: for p in Partitions(4) )
    True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) )
    ....:     for r in Partitions(4) )
    ....: for p in Partitions(3) )
    True
```

```python
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(19))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> def tensor_copr(u, v, w):
    # computes \mu ((u \otimes v) * \Delta(w))
    ....: # meaning Kronecker product and \mu
    ....: # usual multiplication.
    ....: result = w.parent().zero()
    ....: for partition_pair, coeff in w.coproduct():
        ....: result += coeff * w.parent()(u).itensor(partition_pair[0])
        ....: return
    ....: for v in Partitions(2) )
    ....: for u in Partitions(3) )
    True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Noncom- mutative symmetric functions”, arXiv hep-th/9407124, for \( r = 2 \):

```python
sage: e = SymmetricFunctions(FiniteField(29)).e()
>>> s = SymmetricFunctions(FiniteField(29)).s()
>>> m = SymmetricFunctions(FiniteField(29)).m()
>>> def tensor_copr(u, v, w):
    # computes \mu ((u \otimes v) * \Delta(w)) with
    ....: # * meaning Kronecker product and \mu
    ....: # usual multiplication.
    ....: result = w.parent().zero()
    ....: for partition_pair, coeff in w.coproduct():
        ....: result += coeff * w.parent()(u).itensor(partition_pair[0])
        ....: return
    ....: for v in Partitions(5) )
    ....: for w in Partitions(4) )
    ....: for p in Partitions(Integer(4)) )
    True
```

### Chapter 5. Comprehensive Module List

4820
Combinatorics, Release 10.4

(continued from previous page)

```python
... # usual multiplication.
... result = w.parent().zero()
... for partition_pair, coeff in w.coproduct():
...     result += coeff * w.parent()(u).itensor(partition_pair[Integer(0)]) * w.parent()(v).itensor(partition_pair[Integer(1)])
... return result
```

```python
all( all( all( tensor_copr(e[u], s[v], m[w]) == (e[u] * s[v]).itensor(m[w]) for w in Partitions(Integer(5)) ) for v in Partitions(Integer(2)) ) for u in Partitions(Integer(3)) )
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.” arXiv0907.4652:

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
sage: s[4,2].itensor(s[4,2])
```

```python
>>> from sage.all import *
```

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```python
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```python
>>> from sage.all import *
```

```python
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```
internal_coproduct()

Return the inner coproduct of self in the basis of self.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second
comultiplication on the ring of symmetric functions) is a ring homomorphism \( \Delta^\times \) from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

\[
\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,
\]

where \( \lambda \vdash n \) means \( \lambda \) is a partition of \( n \), and \( n \) is any nonnegative integer. It also satisfies

\[
\Delta^\times(p_n) = p_n \otimes p_n
\]

for any positive integer \( n \). If the base ring is a \( \mathbb{Q} \)-algebra, it also satisfies

\[
\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,
\]

where

\[
z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!
\]

with \( m_i(\lambda) \) meaning the number of appearances of \( i \) in \( \lambda \) (see zee()).

The method kronecker_coproduct() is a synonym of internal_coproduct().

EXAMPLES:

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
```

```python
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> a = s([Integer(2),Integer(1)])
>>> e = SymmetricFunctions(QQ).e()
>>> b = e([Integer(2)])
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions \( f, g \) and \( h \) satisfy \( \langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle \), where we write \( \Delta^\times(h) \) as \( \sum_i h'_i \otimes h''_i \). Let us check this in degree 4:
Let us check the formulas for $\Delta^x(h_n)$ and $\Delta^x(p_n)$ given in the description of this method:

```python
sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)])
    ....:     for lam in Partitions(n)])
    ....:     for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))])
    ....:     for lam in Partitions(n)])
    ....:     for n in range(6) )
True
sage: all( factorial(n) * h([n]).internal_coproduct()
    ....:     == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
    ....:         for lam in Partitions(n)])
    ....:     for n in range(6) )
True
```
internal_product(x)

Return the internal (tensor) product of self and x in the basis of self.

The internal tensor product can be defined as the linear extension of the definition on power sums \( p_\lambda \ast p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda \), where \( z_\lambda = (1^{r_1} r_1 !)(2^{r_2} r_2 !) \cdots \) for \( \lambda = (1^{r_1} 2^{r_2} \cdots) \) and where \( \ast \) denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see scalar()).

INPUT:

• x – element of the ring of symmetric functions over the same base ring as self

OUTPUT:

• the internal product of self with x (an element of the ring of symmetric functions in the same basis as self)

The methods itensor(), internal_product(), kronecker_product(), inner_tensor() are all synonyms.

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1] + 2*s[3]
sage: c = s([3,2,1])
sage: c.itensor(c)
```
There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function $f$ of degree $n$ with the $n$-th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is $f$:

```python
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

The Kronecker product of a Schur function $s_\lambda$ with the $n$-th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_\lambda'$ (where $\lambda'$ is the conjugate partition of $\lambda$):

```python
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```python
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
.....: for p in Partitions(4) )
True
```

(continues on next page)
Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Noncommutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```python
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):
    # computes $\mu ((u \otimes v) * \Delta(w))$
    result = w.parent().zero()
    for partition_pair, coeff in w.coproduct():
        result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.parent()(v).itensor(partition_pair[1])
    return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w]) == (e[u] * s[v]).itensor(m[w]) )
            for v in Partitions(2) )
            for w in Partitions(5) )
            for u in Partitions(3) )
True
```

(continues on next page)
... return result
>>> all( all( all( tensor_copr(e[u], s[v], m[w])
# long time
... == (e[u] * s[v]).itensor(m[w])
... for w in Partitions(Integer(5)) )
... for v in Partitions(Integer(2)) )
... for u in Partitions(Integer(3)) )
True

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.”
arXiv 0907.4652:

```sage
s = SymmetricFunctions(ZZ).s()
s[2, 1].itensor(s[2, 1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```sage
from sage.all import *
```

```sage
s = SymmetricFunctions(QQbar).s()
s[2, 1].itensor(s[2, 1])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \( \mathbb{Q} \)-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \( \mathbb{Q} \) (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

```sage
is_schur_positive()
Return True if and only if self is Schur positive.
```

If \( s \) is the space of Schur functions over self’s base ring, then this is the same as self.
_is_positive(s).

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1]) + s([3])
sage: a.is_schur_positive()
True
sage: a = s([2,1]) - s([3])
sage: a.is_schur_positive()
False
```
mogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as “inner product” in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1, 1] + 2*s[2, 2, 2, 1, 1] + 2*s[3, 2, 2, 1, 1] + 4*s[3, 3, 2, 1, 1] + 3*s[4, 2, 2, 1, 1] + 3*s[4, 3, 2, 1, 1] + 2*s[5, 1, 1, 1, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function $f$ of degree $n$ with the $n$-th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is $f$:

```python
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

```python
>>> from sage.all import *

>>> h = SymmetricFunctions(ZZ).h()

>>> all( h([Integer(5)]).itensor(h(p)) == h(p) for p in Partitions(Integer(5)) )
True
```
The Kronecker product of a Schur function $s_\lambda$ with the $n$-th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where $\lambda'$ is the conjugate partition of $\lambda$):

```python
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

The Kronecker product is commutative:

```python
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) )
    for p in Partitions(4) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Noncommutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```python
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w): # computes $\mu((u \otimes v) \Delta(w))$
    ... (continues on next page)
```
with  
....:       # * meaning Kronecker product and \mu_
....:       # usual multiplication.
....:       result = w.parent().zero()
....:       for partition_pair, coeff in w.coproduct():
....:           result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
....:           parent()(v).itensor(partition_pair[1])
....:       return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])
# long time
....:           == (e[u] * s[v]).itensor(m[w])
....:           for w in Partitions(5) )
....:         for v in Partitions(2) )
....:     for u in Partitions(3) )
True

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.”
arXiv 0907.4652:

sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
sage: s[4,2].itensor(s[4,2])

>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()  
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()  
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()  
>>> def tensor_copr(u, v, w):
# computes \mu ((u \otimes v) * \Delta(w)) with
# * meaning Kronecker product and \mu meaning
# usual multiplication.
    ... for partition_pair, coeff in w.coproduct():
    ...     result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
    ...     parent()(v).itensor(partition_pair[1])
    ... return result
>>> all( all( all( tensor_copr(e[u], s[v], m[w])
# long time
....:           == (e[u] * s[v]).itensor(m[w])
....:           for w in Partitions(Integer(5)) )
....:         for v in Partitions(Integer(2)) )
....:     for u in Partitions(Integer(3)) )
True

(continues on previous page)
An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```
>>> from sage.all import *

>>> s = SymmetricFunctions(QQbar).s()

>>> s[Integer(2),Integer(1)].itensor(s[Integer(2),Integer(1)])
s[1, 1, 1] + s[2, 1] + s[3]
```

**Note:** The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

### kronecker_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means $\lambda$ is a partition of $n$, and $n$ is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer $n$. If the base ring is a $\mathbb{Q}$-algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of $i$ in $\lambda$ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

**EXAMPLES:**

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
```
The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions \( f, g \) and \( h \) satisfy
\[
\langle f \ast g, h \rangle = \sum_i \langle f, h_i \rangle \langle g, h_i \rangle ,
\]
where we write \( \Delta \times (h) \) as \( \sum_i h_i ^{'} \otimes h_i ^{''} \).

Let us check this in degree 4:

```python
 sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incorp(f, g, h):
...     result = h.base_ring().zero()
...     for partition_pair, coeff in h.internal_coproduct():
...         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.parent()(g).scalar(partition_pair[1])
...     return result

 sage: all( all( all( tensor_incorp(e[u], s[v], m[w]) == (e[u].itensor(s[v])).scalar(m[w]) )
 ...     for w in Partitions(5) )
 ...     for v in Partitions(2) )
 ...     for u in Partitions(3) )
 True
```
Let us check the formulas for $\Delta \times (h_n)$ and $\Delta \times (p_n)$ given in the description of this method:

```
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)])
  for lam in Partitions(n)])
  for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))])
  for lam in Partitions(n)])
  for n in range(6) )
True
sage: all( factorial(n) * h([n]).internal_coproduct()
    == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
    for lam in Partitions(n)])
  for n in range(Integer(6)) )
True
```

**kronecker_product** ($x$)

Return the internal (tensor) product of self and $x$ in the basis of self.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda \ast p_\mu = \delta_{\lambda\mu} z_\lambda$, where $z_\lambda = (1^{r_1} r_1!) (2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $\ast$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

**Note:** The internal product is sometimes referred to as “inner product” in the literature, but unfortunately
this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

**INPUT:**

- `x` – element of the ring of symmetric functions over the same base ring as `self`

**OUTPUT:**

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
```

```python
sage: c = s([3,2,1])
sage: c.itensor(c)
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function $f$ of degree $n$ with the $n$-th complete homogeneous symmetric function $h[n]$ (a.k.a. $s[n]$) is $f$:

```python
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

```python
>>> from sage.all import *
>>> h = SymmetricFunctions(ZZ).h()
>>> all( h([Integer(5)]).itensor(h(p)) == h(p) for p in Partitions(Integer(5)) )
True
```

The Kronecker product of a Schur function $s_{\lambda}$ with the $n$-th elementary symmetric function $e[n]$, where $n = |\lambda|$, is $s_{\lambda'}$ (where $\lambda'$ is the conjugate partition of $\lambda$):
The Kronecker product is commutative:

```python
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in Partitions(4) ) for p in Partitions(4) )
True
```

```python
sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p)) for r in Partitions(4) ) for p in Partitions(3) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Noncommutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```python
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):
    ...:     # computes \mu ((u \otimes v) * \Delta(w))
    ...:
    ...:     # * meaning Kronecker product and \mu
    ....:     # (continues on next page)
```
Combinatorics, Release 10.4

(continued from previous page)

```python
    ....: # usual multiplication.
    ....:    result = w.parent().zero()
    ....:    for partition_pair, coeff in w.coproduct():
    ....:        result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.parent()(v).itensor(partition_pair[1])
    ....:    return result

sage: all( all( all( tensor_copr(e[u], s[v], m[w])
    == (e[u] * s[v]).itensor(m[w])
    for w in Partitions(5) )
    for v in Partitions(2) )
    for u in Partitions(3) )
True
```

Some examples from Briand, Orellana, Rosas, “The stability of the Kronecker products of Schur functions.”

arXiv 0907.4652:

```python
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()
>>> def tensor_copr(u, v, w):
    # computes \mu ((u \otimes v) \Delta(w)) with
    # * meaning Kronecker product and \mu meaning-
    # usual multiplication.
    ....:    result = w.parent().zero()
    ....:    for partition_pair, coeff in w.coproduct():
    ....:        result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.parent()(v).itensor(partition_pair[1])
    ....:    return result

sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]

sage: s[3,2].itensor(s[3,2])

sage: s[4,2].itensor(s[4,2])
```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric
group representations”, International Journal of Algebra and Computation, 1991:

```python
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```python
>>> from sage.all import *

>>> s = SymmetricFunctions(QQbar).s()

>>> s[Integer(2),Integer(1)].itensor(s[Integer(2),Integer(1)])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a \( \mathbb{Q} \)-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over \( \mathbb{Q} \) (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

**left_padded_kronecker_product**(x)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let \( \star \) denote the Kronecker product (\( \text{itensor()} \)) on the space of symmetric functions. For any partitions \( \alpha, \beta, \gamma \), let \( g_{\gamma}^{\alpha, \beta} \) denote the coefficient of the complete homogeneous symmetric function \( h_{\gamma} \) in the Kronecker product \( h_{\alpha} \star h_{\beta} \). For every partition \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots) \) and every integer \( n > |\lambda| + \lambda_1 \), let \( \lambda[n] \) denote the \( n \)-completion of \( \lambda \) (this is the partition \( (n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots) \); see `t_completion()`). Then, for any partitions \( \alpha \) and \( \beta \) and every integer \( n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1 \), we can write the Kronecker product \( h_{\alpha[n]} \star h_{\beta[n]} \) in the form

\[
h_{\alpha[n]} \star h_{\beta[n]} = \sum_{\gamma} g_{\gamma}^{\alpha[n], \beta[n]} h_{\gamma[n]}
\]

with \( \gamma \) ranging over all partitions. The coefficients \( g_{\gamma}^{\alpha[n], \beta[n]} \) are independent on \( n \). These coefficients \( g_{\gamma}^{\alpha[n], \beta[n]} \) are denoted by \( \overrightarrow{g}_{\alpha, \beta} \), and the symmetric function

\[
\sum_{\gamma} g_{\gamma}^{\alpha, \beta} h_{\gamma}
\]

is said to be the left-padded Kronecker product of \( h_{\alpha} \) and \( h_{\beta} \). By bilinearity, this extends to a definition of a left-padded Kronecker product of any two symmetric functions.

This notion of left-padded Kronecker product can be lifted to the non-commutative symmetric functions (\( \text{left_padded_kronecker_product()} \)).

**Warning:** Do not mistake this product for the reduced Kronecker product (\( \text{reduced_kronecker_product()} \)), which uses the Schur functions instead of the complete homogeneous functions in its definition.

**INPUT:**
- `x` – element of the ring of symmetric functions over the same base ring as `self`

**OUTPUT:**
• the left-padded Kronecker product of \texttt{self} with \texttt{x} (an element of the ring of symmetric functions in the same basis as \texttt{self})

\textbf{EXAMPLES:}

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.h()
sage: h[2,1].left_padded_kronecker_product(h[3])
\[h[1, 1, 1] + h[2, 1] + h[2, 1, 1] + h[2, 1, 1, 1] + h[2, 2, 1] + h[3, 2, 1]\n
sage: h[2,1].left_padded_kronecker_product(h[1])
\[h[1, 1, 1] + h[2, 1] + h[2, 1, 1]\n
sage: h[1].left_padded_kronecker_product(h[2])
\[h[1, 1, 1] + h[2, 1] + h[2, 1, 1]\n
sage: h[1].left_padded_kronecker_product(h[2,1])
\[h[1, 1, 1] + h[2, 1] + h[2, 1, 1]\n
sage: h[1,1].left_padded_kronecker_product(h[2])
\[h[1, 1] + 2*h[1, 1, 1] + h[2, 1, 1]\n
sage: h[1].left_padded_kronecker_product(h[2,1,1])
\[h[1, 1, 1] + 2*h[2, 1, 1] + h[2, 1, 1, 1]\n
sage: h[2].left_padded_kronecker_product(h[3])
\[h[2, 1] + h[2, 1, 1] + h[3, 2]\n```

Taking the left-padded Kronecker product with \(1 = h_\emptyset\) is the identity map on the ring of symmetric functions:

```
sage: all( h[Partition([])] . left_padded_kronecker_product(h[lam]) == h[lam] for i in range(4) for lam in Partitions(i) )
True
```

Here is a rule for the left-padded Kronecker product of \(h_1\) (this is the same as \(h_{(1)}\)) with any complete homogeneous function: Let \(\lambda\) be a partition. Then, the left-padded Kronecker product of \(h_1\) and \(h_\lambda\) is \(\sum a_\mu h_\mu\), where the sum runs over all partitions \(\mu\), and the coefficient \(a_\mu\) is defined as the number of ways to obtain \(\mu\) from \(\lambda\) by one of the following two operations:

- Insert 1 into \(\lambda\).
- Subtract 1 from one of the entries of \(\lambda\) (and remove the entry if it thus becomes 0), and insert a 1 into \(\lambda\).
We check this for partitions of size $\leq 4$:

```
sage: def mults1(I):
....:     # Left-padded Kronecker multiplication by $h[1]$.
....:     res = h[I[:]] + [1]
....:     for k in range(len(I)):
....:         if I2[k] == 1:
....:             I2 = I2[:k] + I2[k+1:]
....:         else:
....:             I2[k] -= 1
....:         res += h[sorted(I2 + [1], reverse=True)]
....:     return res

sage: all( mults1(I) == h[I].left_padded_kronecker_product(h[I])
....:         == h[I].left_padded_kronecker_product(h[1])
....:         for i in range(5) for I in Partitions(i) )
True
```

The left-padded Kronecker product is commutative:

```
>>> from sage.all import *
>>> def mults1(I):
...     # Left-padded Kronecker multiplication by $h[1]$.
...     res = h[I[:]] + [Integer(1)]
...     for k in range(len(I)):
...         if I2[k] == Integer(1):
...             I2 = I2[:k] + I2[k+Integer(1):]
...         else:
...             I2[k] -= Integer(1)
...         res += h[sorted(I2 + [Integer(1)], reverse=True)]
...     return res

>>> all( mults1(I) == h[Integer(1)].left_padded_kronecker_product(h[I])
...         == h[I].left_padded_kronecker_product(h[Integer(1)])
...         for lam in Partitions(Integer(3)) for mu in Partitions(Integer(3)) )
True
```

**nabla** ($q=\text{None}, t=\text{None}, \text{power}=1$)

Return the value of the nabla operator applied to *self*.

The eigenvectors of the nabla operator are the Macdonald polynomials in the $H_t$ basis.

If the parameter *power* is an integer then it calculates nabla to that integer. The default value of *power* is 1.

**INPUT:**

- $q, t$ – optional parameters (default: *None*, in which case $q$ and $t$ are used)
• **power** – (default: 1) an integer indicating how many times to apply the operator \(\nabla\). Negative values of **power** indicate powers of \(\nabla^{-1}\).

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: p = Sym.power()
sage: p([1,1]).nabla()
(-1/2*q^t+1/2*q-1/2*t+1/2)*p[1, 1] + (1/2*q^t-1/2*q-1/2*t+1/2)*p[2]
sage: p([2,1]).nabla(q=1)
(-t)*p[1, 1, 1] + t*p[2, 1]
sage: p([2]).nabla(q=1)*p([1]).nabla(q=1)
(-t)*p[1, 1, 1] + t*p[2, 1]
sage: s = Sym.schur()
sage: s([2,1]).nabla()
(-q^3*t-q^2*t^2-q*t^3)*s[1, 1, 1] + (-q^2*t-q*t^2)*s[2, 1]
sage: s([1,1,1]).nabla()
(q^3+q^2*t+q*t^2+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q)*s[2, 1] + s[3]
sage: s([1,1,1]).nabla(t=1)
(q^3+q^2*t+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q)*s[2, 1] + s[3]
sage: s(0).nabla()
0
sage: s([2,1]).nabla(power=-1)
((-q-t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(q^3*t^3))*s[3]
sage: (s([2])+s([3])).nabla()
(-q*t)*s[1, 1] + (q^3*t^2+q^2*t^3)*s[1, 1, 1] + q^2*t^2*s[2, 1]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> p = Sym.power()
>>> p([1,1,1]).nabla()
((-q-t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(q^3*t^3))*s[3]
>>> s = Sym.schur()
>>> s([2,1]).nabla(q=1)*p([1]).nabla(q=1)
(-t)*p[1, 1, 1] + t*p[2, 1]
>>> s([2]).nabla(q=1)*s([1]).nabla(q=1)
(-t)*p[1, 1, 1] + t*p[2, 1]
>>> s([1,1,1]).nabla(t=1)
(q^3+q^2*t+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q)*s[2, 1] + s[3]
>>> s([1,1,1]).nabla(t=Integer(1))
(q^3+q^2+q)*s[2, 1] + s[3]
>>> s(Integer(0)).nabla()
0
>>> s([1,1,1]).nabla(q=Integer(1))
0
>>> s([1,1,1]).nabla(power=Integer(1))
((-q-t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(q^3*t^3))*s[3]
>>> s([2]).nabla(q=Integer(1))*p([1]).nabla(q=Integer(1))
(-t)*p[1, 1, 1] + t*p[2, 1]
```

**omega**

Return the image of **self** under the omega automorphism.

The **omega automorphism** is defined to be the unique algebra endomorphism \(\omega\) of the ring of symmetric functions that satisfies \(\omega(e_k) = h_k\) for all positive integers \(k\) (where \(e_k\) stands for the \(k\)-th elementary symmetric
function, and $h_k$ stands for the $k$-th complete homogeneous symmetric function. It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function $p_k$ to $(-1)^{k-1}p_k$ for every positive integer $k$.

The images of some bases under the omega automorphism are given by

$$
\omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \quad \omega(s_\lambda) = s_\lambda,
$$

where $\lambda$ is any partition, where $\ell(\lambda)$ denotes the length (length()) of the partition $\lambda$, where $\lambda'$ denotes the conjugate partition (conjugate()) of $\lambda$, and where the usual notations for bases are used ($e = \text{elementary}$, $h = \text{complete homogeneous}$, $p = \text{powersum}$, $s = \text{Schur}$).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

omega_involution() is a synonym for the omega() method.

**EXAMPLES:**

```python
sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
```

omega_involution()

Return the image of self under the omega automorphism.
The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k\) for every positive integer \( k \).

The images of some bases under the omega automorphism are given by

\[
\omega(e_{\lambda}) = h_{\lambda}, \quad \omega(h_{\lambda}) = e_{\lambda}, \quad \omega(p_{\lambda}) = (-1)^{|\lambda|-\ell(\lambda)}p_{\lambda}, \quad \omega(s_{\lambda}) = s_{\lambda},
\]

where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length \( \text{length}(\lambda) \) of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition \( \text{conjugate}(\lambda) \) of \( \lambda \), and where the usual notations for bases are used (\( e \) = elementary, \( h \) = complete homogeneous, \( p \) = powersum, \( s \) = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

\( \omega_{\text{involution}}() \) is a synonym for the \( \omega() \) method.

**EXAMPLES:**

```python
sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]
```

```python
>>> from sage.all import *

>>> J = SymmetricFunctions(QQ).jack(t=Integer(1)).P()
>>> a = J([Integer(2),Integer(1)]) + J([Integer(1),Integer(1),Integer(1)])
>>> a.omega()
>>> J(Integer(0)).omega()
0
>>> J(Integer(1)).omega()
JackP[]
```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.m()
>>> f = Sym.f()
>>> all( f(lam) == m(lam).omega() for lam in Partitions(Integer(3)) )
True
>>> all( m(lam) == f(lam).omega() for lam in Partitions(Integer(3)) )
True
```
om**ega**_qt (q=None, t=None)

Return the image of \( \text{self} \) under the \( q, t \)-deformed omega automorphism which sends \( p_k \) to \((-1)^{k-1} \cdot \frac{1-q^k}{1-t^k} \cdot p_k \) for all positive integers \( k \).

In general, this is well-defined outside of the powersum basis only if the base ring is a \( \mathbb{Q} \)-algebra.

If \( q = t \), then this is the omega automorphism (omega()).

**INPUT:**

- \( q, t \) – parameters (default: None, in which case 'q' and 't' are used)

**EXAMPLES:**

```python
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p[5].omega_qt()
((-q^5+1)/(-t^5+1))*p[5]
sage: p[5].omega_qt(q,t)
((-q^5+1)/(-t^5+1))*p[5]
sage: p([2]).omega_qt(q,t)
((q^2-1)/(-t^2+1))*p[2]
sage: p([2,1]).omega_qt(q,t)
((-q^3+q^2+q-1)/(t^3-t^2-t+1))*p[2, 1]
sage: p([3,2]).omega_qt(5,q)
-2976/(q^5-q^3-q^2+1)*p[3, 2]
sage: p().omega_qt()
0
sage: p().omega_qt()
p[]
sage: H = SymmetricFunctions(QQqt).macdonald().H()
sage: H([1,1]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(q,t)
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(t,q)
((-t^3+t^2+t-1)/(-q^3+q^2+q-1))*McdH[2]
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([1,1]).omega_qt()
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-t+1))*McdS[2]
sage: s = Sym.schur()
sage: s(S([1,1]).omega_qt())
s[2]
```

(continues on next page)
p([Integer(3), Integer(2)]).omega_qt(Integer(5), q)
-(2976/(q^5-q^3-q^2+1))*p[3, 2]
>>> p(Integer(0)).omega_qt()
0
>>> H = SymmetricFunctions(QQqt).macdonald().H()
>>> H([Integer(1), Integer(1)]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
>>> H([Integer(1), Integer(1)]).omega_qt(q,t)
((-t^3+t^2+t-1)/(-q^3+q^2+q-1))*McdH[2]
>>> Sym = SymmetricFunctions(FractionField(QQ['q', 't']))
>>> S = Sym.macdonald().S()
>>> S([Integer(1), Integer(1)]).omega_qt()
((q^2-q*t+q+t)/(t^3-t^2-t+1))*McdS[1, 1] + ((-q^2*t+q*t+q-1)/(-t^3+t^2+t-1))*McdS[2]
>>> s = Sym.schur()
>>> s(S([Integer(1), Integer(1)]).omega_qt())
s[2]

plethysm (x, include=None, exclude=None)

Return the outer plethysm of self with x.

This is implemented only over base rings which are \(\mathbb{Q}\)-algebras. (To compute outer plethysms over general binomial rings, change bases to the fraction field.)

The outer plethysm of \(f\) with \(g\) is commonly denoted by \(f \[g\]\) or by \(f \circ g\). It is an algebra map in \(f\), but not (generally) in \(g\).

By default, the degree one elements are taken to be the generators for the self’s base ring. This setting can be modified by specifying the include and exclude keywords.

INPUT:

- \(x\) – a symmetric function over the same base ring as self
- include – a list of variables to be treated as degree one elements instead of the default degree one elements
- exclude – a list of variables to be excluded from the default degree one elements

OUTPUT:

An element in the parent of \(x\) or the base ring \(R\) of self when \(x\) is in \(R\).

EXAMPLES:
\[ s[4, 1, 1, 1, 1] - s[4, 3, 2] + s[4, 4, 1] - s[5, 1, 1, 1, 1] \\
+ s[5, 2, 2] - s[5, 4] + s[6, 1, 1, 1] - s[6, 2, 1] + s[6, 3] \]

```
sage: p(p3s21)
1/3*p[3, 3, 3] - 1/3*p[9]
sage: e = Sym.e()
sage: e[3](e[2])
```

>>> from sage.all import *

```python
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> h = Sym.h()
>>> h3h2 = h[Integer(3)](h[Integer(2)]); h3h2

# s(h3h2)

>>> s2, s2, s = s[2, 2, 2] + s[4, 2] + s[6]
>>> p = Sym.p()

# p3s21 = p[Integer(3)](s[Integer(2),Integer(1)]); p3s21

```python

Note that the output is in the basis of the input \( x \):

```
sage: s[2,1](h[3])
sage: h[2,1](s[3])
```

Examples over a polynomial ring:

```
sage: R.<t> = QQ[]
sage: s = SymmetricFunctions(R).s()
sage: a = s([3])

# t * s([2])

```

```python

>>> from sage.all import *

```python

(continues on next page)
\[ t^3 s_{[4,2]} + t^3 s_{[6]} \]

```
sage: s(0).plethysm(s[1])
0
sage: s(1).plethysm(s[1])
s[]
sage: s(1).plethysm(s(0))
s[]
```

>>> from sage.all import *

```python
R = QQ['t']; (t,) = R._first_ngens(1)
s = SymmetricFunctions(R).s()
a = s([Integer(3)])
f = t * s([Integer(2)])
a(f)
t^3 s_{[2,2,2]} + t^3 s_{[4,2]} + t^3 s_{[6]}
```

```
f(a)
t^3 s_{[2,2,2]} + t^3 s_{[4,2]} + t^3 s_{[6]}
s = SymmetricFunctions(QQ).s()
X = tensor([s[1],s[]])
Y = tensor([s[],s[1]])
s[1,1,1](X+Y)
```

When \( x \) is a constant, then it is returned as an element of the base ring:

```
sage: s[3](2).parent() is R
True
```

```python
>>> from sage.all import *

>>> s[Integer(3)](Integer(2)).parent() is R
True
```

Sage also handles plethysm of tensor products of symmetric functions:

```
sage: s = SymmetricFunctions(QQ).s()
```

```
X = tensor([s[1],s[]])
Y = tensor([s[],s[1]])
s[1,1,1](X*Y)
```

>>> from sage.all import *

```python
s = SymmetricFunctions(QQ).s()
X = tensor([s[Integer(1)],s[]])
Y = tensor([s[],s[Integer(1)]])
s[1,1,1](X*Y)
```

One can use this to work with symmetric functions in two sets of commuting variables. For example, we verify the Cauchy identities (in degree 5):

```
5.1. Comprehensive Module List
```
Sage can also do the plethysm with an element in the completion:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: L = LazySymmetricFunctions(s)
sage: f = s[2,1]
sage: g = L(s[1]) / (1 - L(s[1])); g
s[1] + (s[1,1]+s[2]) + (s[1,1,1]+2*s[2,1]+s[3])
  + (s[1,1,1,1]+3*s[2,1,1]+2*s[2,2]+3*s[3,1]+s[4])
  + (s[1,1,1,1,1]+4*s[2,1,1,1]+5*s[2,2,1]+6*s[3,1,1]+5*s[3,2]+4*s[4,1]+s[5])
  + ... + O^8
sage: fog = f(g)
sage: fog[:8]
[s[2, 1],
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 2*s[2, 2] + 3*s[3, 1] + s[4],
2*s[1, 1, 1, 1, 1] + 8*s[2, 1, 1, 1] + 10*s[2, 2, 1] + 10*s[3, 1, 1]
+ 12*s[3, 1, 1, 1] + 12*s[3, 2, 1] + 9*s[4, 1] + 2*s[5],
3*s[1, 1, 1, 1, 1, 1] + 17*s[2, 1, 1, 1, 1] + 30*s[2, 2, 1, 1]
+ 16*s[2, 2, 2] + 33*s[3, 1, 1, 1] + 54*s[3, 2, 1] + 16*s[3, 3, 1]
+ 33*s[4, 1, 1] + 30*s[4, 2, 1] + 17*s[5, 1] + 3*s[6],
5*s[1, 1, 1, 1, 1, 1, 1] + 30*s[2, 1, 1, 1, 1, 1] + 70*s[2, 2, 1, 1, 1]
+ 70*s[2, 2, 2, 1] + 75*s[3, 1, 1, 1, 1] + 175*s[3, 2, 1, 1]
+ 105*s[3, 2, 2] + 105*s[3, 3, 1] + 100*s[4, 1, 1, 1] + 175*s[4, 2, 1]
+ 70*s[4, 3] + 75*s[5, 1, 1] + 70*s[5, 2] + 30*s[6, 1] + 5*s[7]]
sage: parent(fog)
Lazy completion of Symmetric Functions over Rational Field in the Schur basis

adams_operator()

Todo:

The implementation of plethysm in sage.data_structures.stream.
Stream_plethysm seems to be faster. This should be investigated.

principal_specialization (n=+Infinity, q=None)

Return the principal specialization of a symmetric function.

The principal specialization of order n at q is the ring homomorphism $p_{s_{n,q}}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, $q$ is a given element of $R$, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$.

(To be more precise, $p_{s_{n,q}}$ is a $K$-algebra homomorphism, where $K$ is the base ring.) See Section 7.8 of [EnumComb2].

The stable principal specialization at $q$ is the ring homomorphism $p_{s_{q}}$ from the ring of symmetric functions to another commutative ring $R$ given by $x_i \mapsto q^{i-1}$ for all $i$. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- n (default: infinity) – a nonnegative integer or infinity, specifying whether to compute the principal specialization of order n or the stable principal specialization.
- q (default: None) – the value to use for $q$; the default is to create a ring of polynomials in $q$ (or a field of rational functions in $q$) over the given coefficient ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[1,1]
sage: x.principal_specialization(3)
q^3 + q^2 + q
```

By default we return a rational function in $q$. Sometimes it is better to obtain an element of the symbolic ring:

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> x = m[Integer(1),Integer(1)]
>>> x.principal_specialization(Integer(3))
q^3 + q^2 + q
```
sage: h = SymmetricFunctions(QQ).h()
sage: (h[3]+h[2]).principal_specialization(q=var("q"))  # needs sage.symbolic
1/((q^2 - 1)*(q - 1)) - 1/((q^3 - 1)*(q^2 - 1)*(q - 1))

In case \(q\) is in the base ring, it must be passed explicitly:

sage: R = QQ['q,t']
sage: Ht = SymmetricFunctions(R).macdonald().Ht()
sage: Ht[2].principal_specialization()
Traceback (most recent call last):
... ValueError: the variable q is in the base ring, pass it explicitly

sage: Ht[2].principal_specialization(q=R("q"))
(q^2 + 1)/(q^3 - q^2 - q + 1)

Note that the principal specialization can be obtained as a plethysm:

sage: R = QQ['q'].fraction_field()
sage: s = SymmetricFunctions(R).s()
sage: one = s.one()
sage: q = R("q")
sage: f = s[3,2,2]
sage: f.principal_specialization(q=q) == f(one/(1-q)).coefficient([])
True

sage: f.principal_specialization(n=Integer(4), q=q) == f(one*(1-q^4)/(1-q)).coefficient([])
True

(continues on next page)
\[
q^n + \text{Int}eger(4))/(\text{Int}eger(1) - q)).\text{coefficient}([])
\]
True

**reduced_kronecker_product** *(x)*

Return the reduced Kronecker product of self and x in the basis of self.

The reduced Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let \(*\) denote the Kronecker product (**tensor**) on the space of symmetric functions. For any partitions \(\alpha, \beta, \gamma\), let \(g_{\alpha, \beta}^\gamma\) denote the coefficient of the Schur function \(s_\gamma\) in the Kronecker product \(s_\alpha \ast s_\beta\) (this is called a Kronecker coefficient). For every partition \(\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)\) and every integer \(n > |\lambda| + \lambda_1\), let \(\lambda[n]\) denote the \(n\)-completion of \(\lambda\) (this is the partition \((n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)\); see **completion**). Then, Theorem 1.2 of [BOR2009] shows that for any partitions \(\alpha, \beta\) and every integer \(n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1\), we can write the Kronecker product \(s_\alpha[n] \ast s_\beta[n]\) in the form

\[
s_{\alpha}[n] \ast s_{\beta}[n] = \sum_{\gamma} g_{\alpha[n], \beta[n]}^\gamma s_{\gamma}[n]
\]

with \(\gamma\) ranging over all partitions. The coefficients \(g_{\alpha[n], \beta[n]}^\gamma\) are independent on \(n\). These coefficients \(g_{\alpha[n], \beta[n]}^\gamma\) are denoted by \(\mathcal{g}_{\alpha, \beta}^\gamma\), and the symmetric function

\[
\sum_{\gamma} \mathcal{g}_{\alpha, \beta}^\gamma s_{\gamma}
\]

is said to be the reduced Kronecker product of \(s_\alpha\) and \(s_\beta\). By bilinearity, this extends to a definition of a reduced Kronecker product of any two symmetric functions.

The definition of the reduced Kronecker product goes back to Murnaghan, and has recently been studied in [BOR2009], [BdVO2012] and other places (our notation \(\mathcal{g}_{\alpha, \beta}^\gamma\) appears in these two sources).

**INPUT:**

- **x** – element of the ring of symmetric functions over the same base ring as self

**OUTPUT:**

- the reduced Kronecker product of self with x (an element of the ring of symmetric functions in the same basis as self)

**EXAMPLES:**

The example from page 2 of [BOR2009]:

\[
sage: \text{Sym} = \text{SymmetricFunctions}(\text{QQ})
sage: s = \text{Sym.schur()}
sage: s[2].\text{reduced_kronecker_product}(s[2])
\[
\begin{align*}
\end{align*}
\]

\[
\text{>>> from sage.all import *}
\]
\[
\text{>>> Sym = SymmetricFunctions(QQ)}
\]
\[
\text{>>> s = Sym.schur()}
\]
\[
\text{>>> s[Integer(2)].\text{reduced_kronecker_product}(s[Integer(2)])}
\]
\[
\begin{align*}
\end{align*}
\]

Taking the reduced Kronecker product with \(1 = s_\emptyset\) is the identity map on the ring of symmetric functions:
While reduced Kronecker products are hard to compute in general, there is a rule for taking reduced Kronecker products with $s_1$. Namely, for every partition $\lambda$, the reduced Kronecker product of $s_\lambda$ with $s_1$ is $\sum \mu a_\mu s_\mu$, where the sum runs over all partitions $\mu$, and the coefficient $a_\mu$ is defined as the number of ways to obtain $\mu$ from $\lambda$ by one of the following three operations:

- Add an addable cell ($\text{addable\_cells}()$) to $\lambda$.
- Remove a removable cell ($\text{removable\_cells}()$) from $\lambda$.
- First remove a removable cell from $\lambda$, then add an addable cell to the resulting Young diagram.

This is, in fact, Proposition 5.15 of [CO2010] in an elementary wording. We check this for partitions of size $\leq 4$:

```
sage: def mults1(lam):
....:     # Reduced Kronecker multiplication by $s[1]$, according
....:     # to [CO2010]_
....:     res = s.zero()
....:     for mu in lam.up_list():
....:         res += s(mu)
....:     for mu in lam.down_list():
....:         res += s(mu)
....:     for nu in mu.up_list():
....:         res += s(nu)
....:     return res
sage: all( mults1(lam) == s[1].reduced_kronecker_product(s[lam])
....:     for i in range(5) for lam in Partitions(i) )
True
```
sage: s[1,1].reduced_kronecker_product(s[2])

```python
>>> from sage.all import *

>>> s[Integer(1),Integer(1)].reduced_kronecker_product(s[Integer(2)])
```

```python
sage: s[3].reduced_kronecker_product(s[2,1])
\(s[1] + 2*s[1, 1] + 2*s[1, 1, 1] + s[1, 1, 1, 1] + 2*s[2] + 5*s[2, 1] + 4*s[2, 1, 1]
+ s[5, 1]\)

>>> from sage.all import *

>>> s[Integer(3)].reduced_kronecker_product(s[Integer(2),Integer(1)])
\(s[1] + 2*s[1, 1] + 2*s[1, 1, 1] + s[1, 1, 1, 1] + 2*s[2] + 5*s[2, 1] + 4*s[2, 1, 1]
+ s[5, 1]\)
```

Todo: This implementation of the reduced Kronecker product is painfully slow.

**restrict_degree** \((d, \text{exact}=\text{True})\)

Return the degree \(d\) component of \(\text{self}\).

INPUT:

- \(d\) – positive integer, degree of the terms to be returned
- \(\text{exact}\) – boolean, if True, returns the terms of degree exactly \(d\), otherwise returns all terms of degree less than or equal to \(d\)

OUTPUT:

- the homogeneous component of \(\text{self}\) of degree \(d\)

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_degree(2)
0
sage: z.restrict_degree(1)
s[1]
sage: z.restrict_degree(3)
s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(3, \text{exact}=\text{False})
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(0)
0
```
>>> from sage.all import *
  s = SymmetricFunctions(QQ).s()
  z = s([Integer(4)]) + s([Integer(2), Integer(1)]) + s([Integer(1),
      →Integer(1), Integer(1)]) + s([Integer(1)])
  z.restrict_degree(Integer(2))
   0
  z.restrict_degree(Integer(1))
   s[1]
  z.restrict_degree(Integer(3))
   s[1, 1, 1] + s[2, 1]
  z.restrict_degree(Integer(3), exact=False)
   s[1] + s[1, 1, 1] + s[2, 1]
  z.restrict_degree(Integer(0))
   0

**restrict_partition_lengths** *(l, exact=True)*

Return the terms of self labelled by partitions of length \( l \).

**INPUT:**

- \( l \) – nonnegative integer
- \( \text{exact} \) – boolean, defaulting to True

**OUTPUT:**

- If True, returns the terms labelled by partitions of length precisely \( l \); otherwise returns all terms labelled by partitions of length less than or equal to \( l \)

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2, 1]) + s([1, 1, 1]) + s([1])
sage: z.restrict_partition_lengths(2)
   s[2, 1]
sage: z.restrict_partition_lengths(0)
   0
sage: z.restrict_partition_lengths(2, exact=False)
```

**restrict_parts** *(n)*

Return the terms of self labelled by partitions \( \lambda \) with \( \lambda_1 \leq n \).

**INPUT:**

- \( n \) – positive integer, to restrict the parts of the partitions of the terms to be returned

**EXAMPLES:**

```python
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> z = s([Integer(4)]) + s([Integer(2), Integer(1)]) + s([Integer(1),
      →Integer(1), Integer(1)]) + s([Integer(1)])
>>> z.restrict_partition_lengths(Integer(2))
   s[2, 1]
>>> z.restrict_partition_lengths(Integer(0))
   0
>>> z.restrict_partition_lengths(Integer(2), exact=False)
```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_parts(2)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_parts(1)
s[1] + s[1, 1, 1]

scalar (x, zee=None)
Return the standard scalar product between self and x.
This is also known as the “Hall inner product” or the “Hall scalar product”.

INPUT:

• x – element of the ring of symmetric functions over the same base ring as self
• zee – an optional function on partitions giving the value for the scalar product between \(p_\mu\) and \(p_\nu\)
  (default is to use the standard \zee() function)

This is the default implementation that converts both self and x into either Schur functions (if zee is not specified) or power-sum functions (if zee is specified) and performs the scalar product in that basis.

EXAMPLES:

sage: e = SymmetricFunctions(QQ).e()
sage: h = SymmetricFunctions(QQ).h()
sage: m = SymmetricFunctions(QQ).m()
sage: p4 = Partitions(4)
sage: matrix([ [e(a).scalar(h(b)) for a in p4] for b in p4])
[ 0 0 0 0 1]
[ 0 0 0 1 4]
[ 0 0 1 2 6]
[ 0 1 2 5 12]
[ 1 4 6 12 24]
sage: matrix([ [h(a).scalar(e(b)) for a in p4] for b in p4])
[ 0 0 0 0 1]
[ 0 0 0 1 4]
[ 0 0 1 2 6]
[ 0 1 2 5 12]
[ 1 4 6 12 24]
sage: matrix([ [m(a).scalar(e(b)) for a in p4] for b in p4])
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 1 0 0]

(continues on next page)
\[
\begin{bmatrix}
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

```python
sage: p = SymmetricFunctions(QQ).p()
sage: m(p[3,2]).scalar(p[3,2], zee=lambda \mu: 2**\mu.length())
4
sage: m(p[3,2]).scalar(p[2,2,1], lambda \mu: 1)
0
sage: m[3,2].scalar(h[3,2], zee=lambda \mu: 2**\mu.length())
2/3
```

```python
>>> from sage.all import *

>>> e = SymmetricFunctions(QQ).e()

>>> h = SymmetricFunctions(QQ).h()

>>> m = SymmetricFunctions(QQ).m()

>>> p4 = Partitions(Integer(4))

>>> matrix([[ e(a).scalar(h(b)) for a in p4] for b in p4])

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 4 \\
0 & 0 & 1 & 2 & 6 \\
0 & 1 & 2 & 5 & 12 \\
1 & 4 & 6 & 12 & 24 \\
\end{bmatrix}
\]

>>> matrix([[ h(a).scalar(e(b)) for a in p4] for b in p4])

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 4 \\
0 & 0 & 1 & 2 & 6 \\
0 & 1 & 2 & 5 & 12 \\
1 & 4 & 6 & 12 & 24 \\
\end{bmatrix}
\]

```python

>>> matrix([[ m(a).scalar(e(b)) for a in p4] for b in p4])

\[
\begin{bmatrix}
-1 & 2 & 1 & -3 & 1 \\
0 & 1 & 0 & -2 & 1 \\
0 & 0 & 1 & -2 & 1 \\
0 & 0 & 0 & -1 & 1 \\
0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

>>> matrix([[ m(a).scalar(h(b)) for a in p4] for b in p4])

\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

```python

```python
sage: p = SymmetricFunctions(QQ).p()

>>> m(p[Integer(3),Integer(2)]).scalar(p[Integer(3),Integer(2)], zee=lambda \mu: Integer(2)**\mu.length())
4

>>> m(p[Integer(3),Integer(2)]).scalar(p[Integer(2),Integer(2),Integer(1)], lambda \mu: Integer(1))
0

>>> m[Integer(3),Integer(2)].scalar(h[Integer(3),Integer(2)], zee=lambda \mu: Integer(2)**\mu.length())
2/3
```

**scalar_hl** (*x, t=None*)

Return the \(t\)-deformed standard Hall-Littlewood scalar product of \(\text{self} \) and \(x\).

**INPUT:**
• $x$ – element of the ring of symmetric functions over the same base ring as self
• $t$ – parameter (default: None, in which case $t$ is used)

EXAMPLES:

```sage
s = SymmetricFunctions(QQ).s()
a = s([2,1])
sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
s = sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```python
from sage.all import *
s = SymmetricFunctions(QQ).s()
a = s([Integer(2),Integer(1)])
sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```python
scalar_jack(x, t=None)
```

Return the Jack-scalar product between self and $x$.

This scalar product is defined so that the power sum elements $p_\mu$ are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\ell(\mu)}$, where $\ell(\mu)$ denotes the length of $\mu$.

INPUT:

• $x$ – element of the ring of symmetric functions over the same base ring as self
• $t$ – an optional parameter (default: None in which case $t$ is used)

EXAMPLES:

```sage
p = SymmetricFunctions(QQ['t']).power()
matrix([[p(mu).scalar_jack(p(nu)) for nu in Partitions(4)] for mu in Partitions(4)]
[[ 4*t 0 0 0 0],
[ 0 3*t^2 0 0 0],
[ 0 0 8*t^2 0 0],
[ 0 0 0 4*t^3 0],
[ 0 0 0 0 24*t^4]]
sage: matrix([[p(mu).scalar_jack(p(nu),2) for nu in Partitions(4)] for mu in Partitions(4)]
[[ 8 0 0 0 0],
[ 0 12 0 0 0],
[ 0 0 32 0 0],
[ 0 0 0 32 0],
[ 0 0 0 0 384]]
```

```sage
JQ = SymmetricFunctions(QQ['t'].fraction_field()).jack().Q()
matrix([[JQ(mu).scalar_jack(JQ(nu)) for nu in Partitions(3)] for mu in Partitions(3)]
[(1/3*t^2 + 1/2*t + 1/6)/t^3 0 0],
[0 0 (1/2*t + 1)/(t^3 + 1/2*t^2) 0],
[0 0 0 6/(t^3 + 3*t^2)]]
```
```python
>>> from sage.all import *

>>> p = SymmetricFunctions(QQ['t']).power()

>>> matrix([[p(mu).scalar_jack(p(nu)) for nu in Partitions(Integer(4))] for mu in Partitions(Integer(4))])

[[4*t 0 0 0 0]
 [0 3*t^2 0 0 0]
 [0 0 8*t^2 0 0]
 [0 0 0 4*t^3 0]
 [0 0 0 0 24*t^4]]

>>> matrix([[p(mu).scalar_jack(p(nu),Integer(2)) for nu in Partitions(Integer(4))] for mu in Partitions(Integer(4))])

[[ 8 0 0 0 0]
 [0 12 0 0 0]
 [0 0 32 0 0]
 [0 0 0 32 0]
 [0 0 0 0 384]]

>>> JQ = SymmetricFunctions(QQ['t'].fraction_field()).jack().Q()

```

**scalar_qt** *(x, q=None, t=None)*

Return the $q, t$-deformed standard Hall-Littlewood scalar product of self and $x$.

**INPUT:**

- $x$ – element of the ring of symmetric functions over the same base ring as self
- $q, t$ – parameters (default: None in which case $q$ and $t$ are used)

**EXAMPLES:**

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_qt(a); factor(sp)
(t - 1)^3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^2 - q + 1)
sage: sp.parent()
Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field
sage: a.scalar_qt(a,q=0)
(t - 1)^3 / (t^2 - 1) / (t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: a.scalar_qt(a,t=0)
q^3 + 2*q^2 - t^2 + q + 1
sage: a.scalar_qt(a,5,7) # q=5 and t=7
490/1539
```

```
sage: (x,y) = var('x,y')

sage: a.scalar_qt(a, q=x, t=y)   # needs sage.symbolic
1/3*(x^3 - 1)/(y^3 - 1) + 2/3*(x - 1)^3/(y - 1)^3
sage: Rn = QQ['q','t','y','z'].fraction_field()
sage: (q,t,y,z) = Rn.gens()
sage: Mac = SymmetricFunctions(Rn).macdonald(q=y,t=z)
```

(continues on next page)
scalar_t \( (x, t=\text{None}) \)

Return the \( t \)-deformed standard Hall-Littlewood scalar product of \( \text{self} \) and \( x \).

**INPUT:**

- \( x \) – element of the ring of symmetric functions over the same base ring as \( \text{self} \)
- \( t \) – parameter (default: None, in which case \( t \) is used)

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
1/3*(-x^3 - 1)/(y^3 - 1) + 2/3*(x - 1)^3/(y - 1)^3
sage: Rn = QQ['q', 't', 'y', 'z'].fraction_field()
sage: (q, t, y, z) = Rn.gens()
sage: Mac = SymmetricFunctions(Rn).macdonald(q=y, t=z)
sage: a = Mac._sym.schur()([2,1], [2,1])
sage: factor(Mac.P()(a).scalar_t(Mac.Q()(a), q, t))
(t - 1)^-3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^2 - q + 1)
sage: factor(Mac.P()(a).scalar_t(Mac.Q()(a)))
(z - 1)^-3 * (y - 1) * (z^2 + z + 1)^-1 * (y^2*z^2 - y*z^2 + y^2 - 2*y*z + z^2 - y + 1)
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).s()

>>> a = s([Integer(2), Integer(1)])

>>> sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)

>>> sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

**skew_by**(x)

Return the result of skewing self by x. (Skewing by x is the endomorphism (as additive group) of the ring of symmetric functions adjoint to multiplication by x with respect to the Hall inner product.)

**INPUT:**

- x – element of the ring of symmetric functions over the same base ring as self

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()

sage: s([[3, 2]]).skew_by(s([2]))
s[2, 1] + s[3]

sage: s([[3, 2]]).skew_by(s([1, 1, 1]))
0

sage: s([[3, 2, 1]]).skew_by(s([2, 1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]
```

```python
>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).s()

>>> s([[3, 2, 1]]).skew_by(s([2, 1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]

>>> s([[3, 2, 1]]).skew_by(s([1, 1, 1]))
0

>>> s([[3, 2, 1]]).skew_by(s([3, 2, 1]))
0

>>> s([[3, 2, 1]]).skew_by(s([2, 1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]
```

```python
sage: p = SymmetricFunctions(QQ).powersum()

sage: p([4, 3, 3, 2, 2, 1]).skew_by(p([2, 1]))
4*p[4, 3, 3, 2, 1]

sage: zee = sage.combinat.sf.sfa.zee

sage: zee([4, 3, 3, 2, 2, 1])/zee([4, 3, 3, 2])
4

sage: s([0]).skew_by(s([1]))
0

sage: s([1]).skew_by(s([1]))
0

sage: s([]).skew_by(s([]))
s[]

sage: s([]).skew_by(s([1])
0

>>> from sage.all import *

>>> p = SymmetricFunctions(QQ).powersum()

>>> p([Integer(4), Integer(3), Integer(3), Integer(2), Integer(2), Integer(1)]).skew_by(p([Integer(2), Integer(1)]))
4*p[4, 3, 3, 2, 1]

>>> zee = sage.combinat.sf.sfa.zee

>>> zee([Integer(4), Integer(3), Integer(3), Integer(2), Integer(2), Integer(1)]))
(continues on next page)
```
theta \((a)\)

Return the image of \(self\) under the theta endomorphism which sends \(p_k\) to \(a \cdot p_k\) for every positive integer \(k\).

In general, this is well-defined outside of the powersum basis only if the base ring is a \(Q\)-algebra.

INPUT:

- \(a\) – an element of the base ring

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).theta(2)
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
sage: p = SymmetricFunctions(QQ).p()
sage: p([2]).theta(2)
2*p[2]
sage: p(0).theta(2)
0
sage: p(1).theta(2)
p[]
```

theta_qt \((q=None, t=None)\)

Return the image of \(self\) under the \(q, t\)-deformed theta endomorphism which sends \(p_k\) to \(\frac{1-q^k}{1-t} \cdot p_k\) for all positive integers \(k\).

In general, this is well-defined outside of the powersum basis only if the base ring is a \(Q\)-algebra.

INPUT:

- \(q, t\) – parameters (default: None, in which case ‘q’ and ‘t’ are used)

EXAMPLES:
verschiebung \((n)\)

Return the image of the symmetric function \(self\) under the \(n\)-th Verschiebung operator.

The \(n\)-th Verschiebung operator \(V_n\) is defined to be the unique algebra endomorphism \(V\) of the ring of symmetric functions that satisfies \(V(h_r) = h_{r/n}\) for every positive integer \(r\) divisible by \(n\), and satisfies \(V(h_r) = 0\) for every positive integer \(r\) not divisible by \(n\). This operator \(V_n\) is a Hopf algebra endomorphism. For every nonnegative integer \(r\) with \(n \mid r\), it satisfies

\[
V_n(h_r) = h_{r/n}, \quad V_n(p_r) = np_{r/n}, \quad V_n(e_r) = (-1)^{r-r/n}e_{r/n}
\]

(where \(h\) is the complete homogeneous basis, \(p\) is the powersum basis, and \(e\) is the elementary basis). For every nonnegative integer \(r\) with \(n \nmid r\), it satisfies

\[
V_n(h_r) = V_n(p_r) = V_n(e_r) = 0.
\]

The \(n\)-th Verschiebung operator is also called the \(n\)-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The \(n\)-th Verschiebung operator is adjoint to the \(n\)-th Adams operator (see \texttt{adams_operator()} for its definition) with respect to the Hall scalar product (\texttt{scalar()}).
The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{(n-1)s(s-1)/4}$.) Then, $V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda(i)}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

**INPUT:**
- $n$ – a positive integer

**OUTPUT:**

The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to self.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].verschiebung(2)
0
sage: s[3].verschiebung(3)
s[1]
sage: p[3].verschiebung(3)
3*p[1]
sage: m[3,2,1].verschiebung(3)
-18*(m[1, 1] - 3*m[2])
sage: p[3,2,1].verschiebung(3)
0
sage: h[4].verschiebung(2)
h[2]
sage: p[2].verschiebung(2)
2*p[1]
sage: m[3,2,1].verschiebung(6)
12*m[1]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> h = Sym.h()
>>> s = Sym.s()
>>> m = Sym.m()
>>> s[Integer(3)].verschiebung(Integer(2))
0
>>> s[Integer(3)].verschiebung(Integer(3))
s[1]
>>> p[Integer(3)].verschiebung(Integer(3))
3*p[1]
>>> m[Integer(3), Integer(2), Integer(1)].verschiebung(Integer(3))
```

(continues on next page)
The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( s(lam).verschiebung(2) * s(mu).verschiebung(2)
.......................... == (s(lam) * s(mu)).verschiebung(2)
.......................... for mu in Partitions(4) )
.......................... for lam in Partitions(4) )
True
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( p(lam).verschiebung(3).antipode()
.......................... == p(lam).antipode().verschiebung(3)
.......................... for lam in Partitions(6) )
True
```

Testing the adjointness between the Adams operators $f_n$ and the Verschiebung operators $V_n$:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( all( s(lam).verschiebung(2).scalar(p(mu))
.......................... == s(lam).scalar(p(mu).adams_operator(2))
.......................... for mu in Partitions(3) )
.......................... for lam in Partitions(6) )
True
```

(continues on next page)
... for mu in Partitions(Integer(3))
... for lam in Partitions(Integer(6))
True

class sage.combinat.sf.sfa.SymmetricFunctionsBases(parent_with_realization)
Bases: Category_realization_of_parent
The category of bases of the ring of symmetric functions.

INPUT:

• self – a category of bases for the symmetric functions
• base – ring of symmetric functions

class ParentMethods
Bases: object

Eulerian(n, j, k=None)

Return the Eulerian symmetric function \( Q_{n,j} \) (with \( n \) either an integer or a partition) or \( Q_{n,j,k} \) (if the optional argument \( k \) is specified) in terms of the basis \( self \).

It is known that the Eulerian quasisymmetric functions are in fact symmetric functions [SW2010]. For more information, see QuasiSymmetricFunctions.Fundamental.Eulerian(), which accepts the same syntax as this method.

INPUT:

• \( n \) – the nonnegative integer \( n \) or a partition
• \( j \) – the number of excedances
• \( k \) – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

EXAMPLES:

sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: m.Eulerian(3, 1)
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
sage: h = Sym.h()
sage: h.Eulerian(4, 2)
sage: s = Sym.s()
sage: s.Eulerian(5, 2)
sage: s.Eulerian([2, 2, 1], 2)
sage: s.Eulerian(5, 2, 2)

>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> m.Eulerian(Integer(3), Integer(1))
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
>>> h = Sym.h()
>>> h.Eulerian(Integer(4), Integer(2))
>>> s = Sym.s()
We check Equation (5.4) in [SW2010]:

\[
\text{sage: } h.\text{Eulerian([6], 3)} \\
\]

\[
\text{sage: } s.\text{Eulerian([6], 3)} \\
\]

\[
\text{from sage.all import *} \\
\text{h.Eulerian([Integer(6)], Integer(3))} \\
\]

\[
\text{s.Eulerian([Integer(6)], Integer(3))} \\
\]

carlitz_shareshian_wachs \( (n, d, s, \text{comparison=None}) \)
Return the Carlitz-Shareshian-Wachs symmetric function \( X_{n, d, s} \) (if \( \text{comparison} \) is None), or \( U_{n, d, s} \) (if \( \text{comparison} \) is \(-1\)), or \( V_{n, d, s} \) (if \( \text{comparison} \) is \(0\)), or \( W_{n, d, s} \) (if \( \text{comparison} \) is \(1\)) written in the basis self. These functions are defined below.

The Carlitz-Shareshian-Wachs symmetric functions have been introduced in [GriRei18], Exercise 2.9.11, as refinements of a certain particular case of chromatic quasisymmetric functions defined by Shareshian and Wachs. Their definitions are as follows:

Let \( n, d \) and \( s \) be three nonnegative integers. Let \( W(n, d, s) \) denote the set of all \( n \)-tuples \((w_1, w_2, \ldots, w_n)\) of positive integers having the property that there exist precisely \( d \) elements \( i \) of \( \{1, 2, \ldots, n-1\} \) satisfying \( w_i > w_{i+1} \), and precisely \( s \) elements \( i \) of \( \{1, 2, \ldots, n-1\} \) satisfying \( w_i = w_{i+1} \). For every \( w = (w_1, w_2, \ldots, w_n) \in W(n, d, s) \), let \( x_w \) be the monomial \( x_{w_1}x_{w_2}\cdots x_{w_n} \).

We then define the power series \( X_{n, d, s} \) by

\[
X_{n, d, s} = \sum_{w \in W(n, d, s)} x_w.
\]

This is a symmetric function (according to [GriRei18], Exercise 2.9.11(b)), and for \( s = 0 \) equals the \( t^d \)-coefficient of the descent enumerator of Smirnov words of length \( n \) (an example of a chromatic quasisymmetric function which happens to be symmetric – see [ShaWach2014], Example 2.5).

Assume that \( n > 0 \). Then, we can define three further power series as follows:

\[
U_{n, d, s} = \sum_{w_1 < w_n} x_w; \quad V_{n, d, s} = \sum_{w_1 = w_n} x_w; \quad W_{n, d, s} = \sum_{w_1 > w_n} x_w;
\]

where all three sums range over \( w = (w_1, w_2, \ldots, w_n) \in W(n, d, s) \). These three power series \( U_{n, d, s}, V_{n, d, s}, \) and \( W_{n, d, s} \) are symmetric functions as well ([GriRei18], Exercise 2.9.11(c)). Their sum is \( X_{n, d, s} \).

REFERENCES:

INPUT:

- \( n \) – a nonnegative integer
- \( d \) – a nonnegative integer
- \( s \) – a nonnegative integer
- \( \text{comparison} \) (default: None) – a variable which can take the forms None, \(-1\), \(0\) and \(1\)
OUTPUT:

The Carlitz-Shareshian-Wachs symmetric function $X_{n,d,s}$ (if `comparison` is None), or $U_{n,d,s}$ (if `comparison` is -1), or $V_{n,d,s}$ (if `comparison` is 0), or $W_{n,d,s}$ (if `comparison` is 1) written in the basis `self`.

EXAMPLES:

The power series $X_{n,d,s}$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: m.carlitz_shareshian_wachs(3, 2, 1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1)
m[2, 1]
```

The power series $U_{n,d,s}$:

```python
>> from sage.all import *
>> Sym = SymmetricFunctions(ZZ)
>> m = Sym.m()
>> m.carlitz_shareshian_wachs(Integer(3), Integer(2), Integer(1))
0
>> m.carlitz_shareshian_wachs(Integer(3), Integer(1), Integer(1))
m[2, 1]
>> m.carlitz_shareshian_wachs(Integer(3), Integer(2), Integer(0))
m[1, 1, 1]
>> m.carlitz_shareshian_wachs(Integer(3), Integer(0), Integer(2))
m[3]
>> m.carlitz_shareshian_wachs(Integer(3), Integer(1), Integer(0))
4*m[1, 1, 1] + m[2, 1]
>> m.carlitz_shareshian_wachs(Integer(3), Integer(0), Integer(1))
m[2, 1]
>> m.carlitz_shareshian_wachs(Integer(3), Integer(0), Integer(0))
m[1, 1, 1]
```
The powerseries $V_{n,d,s}$:

```
sage: m.carlitz_shareshian_wachs(3, 2, 1, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 2, 0, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 0, 2, comparison=0)
0
sage: m.carlitz_shareshian_wachs(3, 1, 0, comparison=0)
2*m[1, 1, 1]
```

(continues on next page)
The power series $W_{n,d,s}$:

```python
sage: m.carlitz_shareshian_wachs(3, 2, 1, comparison=1)
0
sage: m.carlitz_shareshian_wachs(3, 1, 1, comparison=1)
```

(continues on next page)
corresponding_basis_over \((R)\)

Return the realization of symmetric functions corresponding to self but over the base ring \(R\). Only works when self is one of the classical bases, not one of the \(q, t\)-dependent ones. In the latter case, None is returned instead.

INPUT:

- \(R\) – a commutative ring
EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m.corresponding_basis_over(ZZ)
doctest:warning
...
DeprecationWarning: S.corresponding_basis_over(R) is deprecated.
Use S.change_ring(R) instead.
See https://github.com/sagemath/sage/issues/37220 for details.
Symmetric Functions over Integer Ring in the monomial basis
sage: Sym = SymmetricFunctions(CyclotomicField())
sage: s = Sym.schur()
sage: s.corresponding_basis_over(Integers(13))
Symmetric Functions over Ring of integers modulo 13 in the Schur basis
sage: P = ZZ['q','t']
sage: Sym = SymmetricFunctions(P)
sage: mj = Sym.macdonald().J()
sage: mj.corresponding_basis_over(Integers(Integer(13))['q','t'])
Symmetric Functions over Multivariate Polynomial Ring in q, t over
Ring of integers modulo 13 in the Macdonald J basis
```

Todo: This function is an ugly hack using strings. It should be rewritten as soon as the bases of SymmetricFunctions are put on a more robust and systematic footing.

```python
def degree_on_basis(b):
    """Return the degree of the basis element indexed by b."""
    INPUT:
    • self -- a basis of the symmetric functions
    • b -- a partition
```
**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(QQ['q,t'].fraction_field())
sage: m = Sym.monomial()
sage: m.degree_on_basis(Partition([3,2]))
5
sage: P = Sym.macdonald().P()
sage: P.degree_on_basis(Partition([]))
0
```

```python
>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ['q,t'].fraction_field())

>>> m = Sym.monomial()

>>> m.degree_on_basis(Partition([Integer(3),Integer(2)]))
5

>>> P = Sym.macdonald().P()

>>> P.degree_on_basis(Partition([]))
0
```

**formal_series_ring()**

Return the completion of all formal linear combinations of `self` with finite linear combinations in each homogeneous degree (computed lazily).

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(ZZ).s()
sage: L = s.formal_series_ring()
sage: L
Lazy completion of Symmetric Functions over Integer Ring in the Schur→basis

>>> from sage.all import *

>>> s = SymmetricFunctions(ZZ).s()

>>> L = s.formal_series_ring()

>>> L
Lazy completion of Symmetric Functions over Integer Ring in the Schur→basis
```

**gessel_reutenauer(lam)**

Return the Gessel-Reutenauer symmetric function corresponding to the partition `lam` written in the basis `self`.

Let \( \lambda \) be a partition. The **Gessel-Reutenauer symmetric function** \( GR_\lambda \) corresponding to \( \lambda \) is the symmetric function denoted \( L_\lambda \) in [GR1993] and in Exercise 7.89 of [STA] and denoted \( GR_\lambda \) in Definition 6.6.34 of [GriRei18]. It is also called the **higher Lie character**, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials \( x_w \) over all words \( w \) over the alphabet \( \{1, 2, 3, \ldots\} \) which have CFL type \( \lambda \). Here, the monomial \( x_w \) for a word \( w = (w_1, w_2, \ldots, w_k) \) is defined as \( x_{w_1} x_{w_2} \cdots x_{w_k} \), and the CFL type of a word \( w \) is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization of \( w \). The fact that this power series \( GR_\lambda \) is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions \( F_{Des^\sigma} \) over all permutations \( \sigma \) that have cycle type \( \lambda \). See `sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental` for the definition of fundamental quasisymmetric functions, and `cycle_type()` for that of cycle type. For a permutation \( \sigma \), we use `Des^\sigma` to denote the descent composition of \( \sigma \) again, this definition does not make the symmetry of \( GR_\lambda \) obvious.
• For every positive integer $n$, we have

$$GR_n = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},$$

where $p_d$ denotes the $d$-th power-sum symmetric function. This $GR_n$ is also denoted by $L_n$, and is called the Lie character. Now, the higher Lie character $GR_{\lambda}$ is defined as the product:

$$hm_1 [L_1] \cdot hm_2 [L_2] \cdot hm_3 [L_3] \cdots,$$

where $m_i$ denotes the multiplicity of the part $i$ in $\lambda$, and where the square brackets stand for plethysm (plethysm()). This definition makes the symmetry (but not the integrality!) of $GR_{\lambda}$ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

$GR_{\lambda}$ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree-$n$ component $T_n(V)$ of $T(V)$ into $GL(V)$ representations indexed by partitions. The higher Lie characters are the symmetric group $S_n$ characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, Thrall’s problem (see e.g. [Sch2003b]) asks, for $\lambda$ a partition of $n$, can we combinatorially interpret the coefficients $\alpha_{\lambda}^\mu$ in the Schur-expansion of $GR_{\lambda}$:

$$GR_{\lambda} = \sum_{\mu \vdash n} \alpha_{\lambda}^\mu s_\mu.$$

INPUT:
• lam – a partition or a positive integer (in the latter case, it is understood to mean the partition \([lam]\))

OUTPUT:
The Gessel-Reutenauer symmetric function $GR_{\lambda}$, where $\lambda$ is lam, expanded in the basis self.

EXAMPLES:
The first few values of $GR_{(n)} = L_n$:

```sage
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
sage: h.gessel_reutenauer(6)
```

```bash
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
```

(continues on next page)
Gessel-Reutenauer functions indexed by partitions:

```
>>> from sage.all import *

from sage.all import *

h.gessel_reutenauer([Integer(2), Integer(1)])
h[1, 1, 1] - h[2, 1]
```

The Gessel-Reutenauer functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```
sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True
```

They also go by the name higher Lie character:
Of the above three equivalent definitions of $\mathbf{GR}_\lambda$, we use the third one for computations. Let us check that the second one gives the same results:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
def GR_def2(lam):
    # A$\mathbf{GR}_\lambda$A
    n = lam.size()
    r = F.sum_of_monomials([sigma.descents_composition()
        for sigma in Permutations(n)
        if sigma.cycle_type() == lam])
    return r.to_symmetric_function()

sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
    for n in range(5) for lam in Partitions(n) )
True
```

And the first one, too (assuming symmetry):

```python
sage: m = Sym.m()
sage: def GR_def1(lam):
    # A$\mathbf{GR}_\lambda$A
    n = lam.size()
    Permus_mset = sage.combinat.permutation.Permutations_mset
    def coeff_of_m_mu_in_result(mu):
        words_to_check = Permus_mset([i for (i, l) in enumerate(mu)
            for _ in range(l)]
        return sum((1 for w in words_to_check
            if Partition(list(reversed(sorted([len(v) for v in
                Word(w).lyndon_factorization()]))))
                == lam))
    r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
        for mu in Partitions(n)],
        distinct=True)
    return r

sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
    for n in range(5) for lam in Partitions(n) )
True
```
>>> from sage.all import *
>>> m = Sym.m()
>>> def GR_def1(lam):
...     n = lam.size()
...     Permus_mset = sage.combinat.permutation.Permutations_mset
...     def coeff_of_m_mu_in_result(mu):
...         words_to_check = Permus_mset([i for (i, l) in enumerate(mu) for _ in range(l)])
...         return sum((Integer(1) for w in words_to_check if Word(w).lyndon_factorization() == lam))
...     r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu)) for mu in Partitions(n)], distinct=True)
...     return r
>>> all( GR_def1(lam) == h.gessel_reutenauer(lam) for n in range(Integer(5)) for lam in Partitions(n) )
True

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a Q-algebra from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over Q (using the corresponding_basis_over hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

higher_lie_character(lam)

Return the Gessel-Reutenauer symmetric function corresponding to the partition lam written in the basis self.

Let \( \lambda \) be a partition. The Gessel-Reutenauer symmetric function \( \text{GR}_\lambda \) corresponding to \( \lambda \) is the symmetric function denoted \( L_\lambda \) in [GR1993] and in Exercise 7.89 of [STA] and denoted \( \text{GR}_\lambda \) in Definition 6.6.34 of [GriRei18]. It is also called the higher Lie character, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials \( x_w \) over all words \( w \) over the alphabet \( \{1, 2, 3, \ldots\} \) which have CFL type \( \lambda \). Here, the monomial \( x_w \) for a word \( w = (w_1, w_2, \ldots, w_k) \) is defined as \( x_{w_1} x_{w_2} \cdots x_{w_k} \), and the CFL type of a word \( w \) is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization \( (\text{lyndon_factorization}(w)) \) of \( w \). The fact that this power series \( \text{GR}_\lambda \) is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions \( F_{\text{Des } \sigma} \) over all permutations \( \sigma \) that have cycle type \( \lambda \). See [sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions] for the definition of fundamental quasisymmetric functions, and \( \text{cycle_type()} \) for that of cycle type. For a permutation \( \sigma \), we use \( \text{Des } \sigma \) to denote the descent composition \( (\text{descents_composition}(\sigma)) \) of \( \sigma \). Again, this definition does not make the symmetry of \( \text{GR}_\lambda \) obvious.
- For every positive integer \( n \), we have

\[
\text{GR}_{(n)} = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},
\]

where \( p_d \) denotes the \( d \)-th power-sum symmetric function. This \( \text{GR}_{(n)} \) is also denoted by \( L_n \), and is called the Lie character. Now, the higher Lie character \( \text{GR}_\lambda \) is defined as the product:

\[
h_{m_1} [L_1] \cdot h_{m_2} [L_2] \cdot h_{m_3} [L_3] \cdots,
\]

Chapter 5. Comprehensive Module List
where \( m_i \) denotes the multiplicity of the part \( i \) in \( \lambda \), and where the square brackets stand for plethysm \((\text{plethysm}())\). This definition makes the symmetry (but not the integrality!) of \( \GR\lambda \) obvious. The equivalences of these three definitions are proven in \([GR1993]\) Sections 2-3. (See also \([GriRei18]\) Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

\( \GR\lambda \) has further significance in representations afforded by the tensor algebra \( T(V) \) of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree-\( n \) component \( T_n(V) \) of \( T(V) \) into \( GL(V) \) representations indexed by partitions. The higher Lie characters are the symmetric group \( S_n \) characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, Thrall’s problem (see e.g. \([Sch2003b]\)) asks, for \( \lambda \) a partition of \( n \), can we combinatorially interpret the coefficients \( \alpha^\lambda_\mu \) in the Schur-expansion of \( \GR\lambda \):

\[
\GR\lambda = \sum_{\mu \vdash n} \alpha^\lambda_\mu s_\mu.
\]

INPUT:

• \( \text{lam} \) – a partition or a positive integer (in the latter case, it is understood to mean the partition \([\text{lam}]\))

OUTPUT:

The Gessel-Reutenauer symmetric function \( \GR\lambda \), where \( \lambda = \text{lam} \), expanded in the basis \text{self}.

EXAMPLES:

The first few values of \( \GR(n) = L_n \):

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
- 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
>>> h.gessel_reutenauer(Integer(1))
h[1]
>>> h.gessel_reutenauer(Integer(2))
h[1, 1] - h[2]
>>> h.gessel_reutenauer(Integer(3))
h[2, 1] - h[3]
>>> h.gessel_reutenauer(Integer(4))
h[2, 1, 1] - h[2, 2]
>>> h.gessel_reutenauer(Integer(5))
>>> h.gessel_reutenauer(Integer(6))
```

(continues on next page)
Gessel-Reutenauer functions indexed by partitions:

\[
\begin{align*}
\text{sage: } & \ h.gessel_reutenauer([2, 1]) \\
& h[1, 1, 1] - h[2, 1] \\
\text{sage: } & \ h.gessel_reutenauer([2, 2]) \\
\end{align*}
\]

The Gessel-Reutenauer functions are Schur-positive:

\[
\begin{align*}
\text{sage: } & \ s = \text{Sym.s()} \\
\text{sage: } & \ s.gessel_reutenauer([2, 1]) \\
& s[1, 1, 1] + s[2, 1] \\
\text{sage: } & \ s.gessel_reutenauer([2, 2, 1]) \\
& s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2, 1] + s[3, 2] \\
\end{align*}
\]

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

\[
\begin{align*}
\text{sage: } & \ s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1]) \\
& \text{True} \\
\end{align*}
\]

They also go by the name higher Lie character:

\[
\begin{align*}
\text{sage: } & \ s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1]) \\
& \text{True} \\
\end{align*}
\]

Of the above three equivalent definitions of GR\_\(\lambda\), we use the third one for computations. Let us check that the second one gives the same results:
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam): # \textbackslash mathbf{GR}_\lambda
    ....: n = lam.size()
    ....: r = F.sum_of_monomials([sigma.descents_composition()
    ....: for sigma in Permutations(n)
    ....: if sigma.cycle_type() == lam])
    ....: return r.to_symmetric_function()
sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
    ....: for n in range(5) for lam in Partitions(n) )
True

And the first one, too (assuming symmetry):

sage: m = Sym.m()
sage: def GR_def1(lam): # \textbackslash mathbf{GR}_\lambda
    ....: n = lam.size()
    ....: Permus_mset = sage.combinat.permutation.Permutations_mset
    ....: def coeff_of_m_mu_in_result(mu):
        ....: words_to_check = Permus_mset([i for (i, l) in enumerate(mu)
        ....: for _ in range(l)])
        ....: return sum((1 for w in words_to_check if
                      ....: Partition(list(reversed(sorted([len(v)
                      ....: for v in Word(w).lyndon_factorization()]))))
                      ....: == lam))
    ....: r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
                      ....: for mu in Partitions(n)],
                      ....: distinct=True)
    ....: return r
sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
    ....: for n in range(5) for lam in Partitions(n) )
True

(continues on next page)
... == lam))
... r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
... for mu in Partitions(n)],
... distinct=True)
... return r

>>> all( GR_def1(lam) == h.gessel_reutenauer(lam)
... for n in range(Integer(5)) for lam in Partitions(n) )
True

Note: The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbb{Q}$-algebra from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbb{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

**is_commutative()**

Return whether this symmetric function algebra is commutative.

**INPUT:**
- `self` – a basis of the symmetric functions

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_commutative()
True
```

```python
>>> from sage.all import *
```

```python
>>> s = SymmetricFunctions(QQ).s()
>>> s.is_commutative()
True
```

**is_field (proof=True)**

Return whether `self` is a field. (It is not.)

**INPUT:**
- `self` – a basis of the symmetric functions
- `proof` – an optional argument (default value: True)

**EXAMPLES:**

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_field()
False
```

```python
>>> from sage.all import *
```

```python
>>> s = SymmetricFunctions(QQ).s()
>>> s.is_field()
False
```

**is_integral_domain (proof=True)**

Return whether `self` is an integral domain. (It is if and only if the base ring is an integral domain.)

**INPUT:**
- `self` – a basis of the symmetric functions
• proof — an optional argument (default value: True)

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_integral_domain()
True

sage: s = SymmetricFunctions(Zmod(14)).s()
sage: s.is_integral_domain()
False
```

```python
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()

>>> s = SymmetricFunctions(Zmod(Integer(14))).s()
```

### lehrer_solomon(lam)

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition `lam` written in the basis `self`.

Let \( \lambda \vdash n \) be a partition. The Lehrer-Solomon symmetric function \( \text{LS}_\lambda \) corresponding to \( \lambda \) is the Frobenius characteristic of the representation denoted \( \text{Ind}^{S_n}_{Z_\lambda} (\xi_\lambda) \) in Theorem 4.5 of [LS1986] or \( W_\lambda \) in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to \( \lambda \) (after reordering appropriately).

It can be computed using Sundaram’s plethystic formula (see [Sun1994] Theorem 1.8):

\[
\text{LS}_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],
\]

where \( h_{m_j} \) are complete homogeneous symmetric functions, \( e_{m_j} \) are elementary symmetric functions, and \( \pi_j \) are the images of the Gessel-Reutenauer symmetric function \( \text{GR}(j) \) (see `gessel_reutenauer()`) under the involution \( \omega \) (i.e. `omega_involution()`):

```python
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(Integer(2))).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(Integer(1))).omega_involution()
sage: s.lehrer_solomon([Integer(2),Integer(1)]) == pi_2 * pi_1 # since h_1, e_1 are plethystic identities
True
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)

>>> s = Sym.s()

>>> pi_2 = (s.gessel_reutenauer(Integer(2))).omega_involution()

>>> pi_1 = (s.gessel_reutenauer(Integer(1))).omega_involution()

>>> s.lehrer_solomon([Integer(2),Integer(1)]) == pi_2 * pi_1 # since h_1, e_1 are plethystic identities
True
```
Note that this also gives the $S_n$-equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type-$A$ reflection arrangement).

The representation corresponding to $\text{LS}_\lambda$ exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

**INPUT:**

- lam – a partition or a positive integer (in the latter case, it is understood to mean the partition $[\text{lam}]$)

**OUTPUT:**

The Lehrer-Solomon symmetric function $\text{LS}_\lambda$, where $\lambda$ is lam, expanded in the basis self.

**EXAMPLES:**

The first few values of $\text{LS}_{(n)}$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
\[h[1]\]
sage: h.lehrer_solomon(2)
\[h[2]\]
sage: h.lehrer_solomon(3)
\[h[2, 1] - h[3]\]
sage: h.lehrer_solomon(4)
\[h[2, 1, 1] - h[2, 2]\]
sage: h.lehrer_solomon(5)
```

The `whitney_homology_character()` method is an alias:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2, 1])
True
```

```python
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> s = Sym.schur()
>>> s.lehrer_solomon([Integer(2), Integer(2), Integer(1)]) == s.whitney_homology_character([Integer(2), Integer(2), Integer(1)])
True
```
Lehrer-Solomon functions indexed by partitions:

```python
sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])
```

```python
>>> from sage.all import *

```

The Lehrer-Solomon functions are Schur-positive:

```python
sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

```python
>>> from sage.all import *

```

```python
sage: s = Sym.s()
sage: s.lehrer_solomon([Integer(2), Integer(1)])
s[2, 1] + s[3]
sage: s.lehrer_solomon([Integer(2), Integer(2), Integer(1)])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([Integer(4), Integer(1)])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

```python
one_basis()
Return the empty partition, as per `AlgebrasWithBasis.ParentMethods.one_basis`

INPUT:
• `self` – a basis of the ring of symmetric functions

EXAMPLES:

```python
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: s = Sym.s()
sage: s.one_basis()
[]
sage: Q = Sym.hall_littlewood().Q()
sage: Q.one_basis()
[]
```

```python
>>> from sage.all import *

```
skew_schur(x)

Return the skew Schur function indexed by x in self.

INPUT:
  • x – a skew partition

EXAMPLES:

sage: sp = SkewPartition([[5,3,3,1], [3,2,1]])
sage: s = SymmetricFunctions(QQ).s()
sage: s.skew_schur(sp)

whitney_homology_character(lam)

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition lam written in the basis self.

Let \( \lambda \vdash n \) be a partition. The Lehrer-Solomon symmetric function \( \text{LS}_\lambda \) corresponding to \( \lambda \) is the Frobenius characteristic of the representation denoted \( \text{Ind}_{Z_\lambda}^{S_n}(\xi_\lambda) \) in Theorem 4.5 of [LS1986] or \( W_\lambda \) in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to \( \lambda \) (after reordering appropriately).

It can be computed using Sundaram’s plethystic formula (see [Sun1994] Theorem 1.8):

\[
\text{LS}_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],
\]

where \( h_{m_j} \) are complete homogeneous symmetric functions, \( e_{m_j} \) are elementary symmetric functions, and \( \pi_j \) are the images of the Gessel-Reutenauer symmetric function \( \text{GR}_{(j)} \) (see gessel_reutenauer()) under the involution \( \omega \) (i.e. omega_involution()).
Note that this also gives the $S_n$-equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type-$A$ reflection arrangement).

The representation corresponding to $LS_\lambda$ exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

**INPUT:**
- lam – a partition or a positive integer (in the latter case, it is understood to mean the partition $[lam]$)

**OUTPUT:**
The Lehrer-Solomon symmetric function $LS_\lambda$, where $\lambda$ is lam, expanded in the basis self.

**EXAMPLES:**
The first few values of $LS_{(n)}$:

>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
>>> h.lehrer_solomon(Integer(1))
$h[1]$
>>> h.lehrer_solomon(Integer(2))
$h[2]$
>>> h.lehrer_solomon(Integer(3))
$h[2, 1] - h[3]$
>>> h.lehrer_solomon(Integer(4))
$h[2, 1, 1] - h[2, 2]$
>>> h.lehrer_solomon(Integer(5))
The \texttt{whitney\_homology\_character()} method is an alias:

\begin{verbatim}
from sage.all import *

Sym = SymmetricFunctions(ZZ)

s = Sym.schur()

s.lehrer_solomon([Integer(2), Integer(2), Integer(1)]) == s.whitney_homology_character([Integer(2), Integer(2), Integer(1)])
True
\end{verbatim}

Lehrer-Solomon functions indexed by partitions:

\begin{verbatim}
from sage.all import *

h = SymmetricFunctions(ZZ)

h.lehrer_solomon([2, 1])
h[2, 1]
\end{verbatim}

The Lehrer-Solomon functions are Schur-positive:

\begin{verbatim}
from sage.all import *

s = Sym.s()

s.lehrer_solomon([2, 1])
s[2, 1] + s[3]

s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]

s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
\end{verbatim}

\textbf{super\_categories()}

The super categories of \texttt{self}.

\textbf{EXAMPLES:}
sage: from sage.combinat.sf.sfa import SymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of realizations of Symmetric Functions over Rational Field,  
Category of commutative Hopf algebras with basis over Rational Field,  
Join of Category of realizations of Hopf algebras over Rational Field  
and Category of graded algebras over Rational Field  
and Category of graded coalgebras over Rational Field,  
Category of unique factorization domains]

sage: Sym = SymmetricFunctions(ZZ['x'])
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of realizations of Symmetric Functions over Univariate Polynomial → 
Ring in x over Integer Ring,

class sage.combinat.sf.sfa.SymmetricFunctionsFamilyFunctor(basis, family, name, *args)

Bases: SymmetricFunctionsFunctor

Initialize the functor.

INPUT:

5.1. Comprehensive Module List 4887
• basis – the basis of the symmetric function algebra

EXAMPLES:

```python
sage: from sage.combinat.sf.sfa import SymmetricFunctionsFamilyFunctor
sage: R.<t> = ZZ[]
sage: basis = SymmetricFunctions(R).macdonald(q=1).H()
sage: family = sage.combinat.sf.macdonald.Macdonald
sage: name = basis.basis_name()
sage: SymmetricFunctionsFamilyFunctor(basis, family, name, 1, t)
SymmetricFunctionsFunctor[Macdonald H with q=1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import SymmetricFunctionsFamilyFunctor
>>> R = ZZ['t']; (t,) = R._first_ngens(1)
>>> basis = SymmetricFunctions(R).macdonald(q=Integer(1)).H()
>>> family = sage.combinat.sf.macdonald.Macdonald
>>> name = basis.basis_name()
>>> SymmetricFunctionsFamilyFunctor(basis, family, name, Integer(1), t)
SymmetricFunctionsFunctor[Macdonald H with q=1]
```

**class** `sage.combinat.sf.sfa.SymmetricFunctionsFunctor(basis, name, *args)`

Bases: `ConstructionFunctor`

A constructor for algebras of symmetric functions.

EXAMPLES:

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

```python
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

```python
rank = 9

sage.combinat.sf.sfa.is_SymmetricFunction(x)
Checks whether x is a symmetric function.

EXAMPLES:

```
```

```python
sage: from sage.combinat.sf.sfa import is_SymmetricFunction
sage: s = SymmetricFunctions(QQ).s()
sage: is_SymmetricFunction(2)
False
sage: is_SymmetricFunction(s(2))
True
sage: is_SymmetricFunction(s([2,1]))
True
```
sage.combinat.sf.sfa.is_SymmetricFunctionAlgebra(x)

Checks whether \( x \) is a symmetric function algebra.

EXAMPLES:

```python
sage: from sage.combinat.sf.sfa import is_SymmetricFunctionAlgebra
sage: is_SymmetricFunctionAlgebra(5)
False
sage: is_SymmetricFunctionAlgebra(ZZ)
False
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(ZZ).schur())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).e())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).macdonald(q=Integer(1), t=Integer(1)).P())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(FractionField(QQ[q,t])).macdonald().P())
True
```

sage.combinat.sf.sfa.zee(part)

Return the size of the centralizer of any permutation of cycle type \( \text{part} \).

Note that the size of the centralizer is the inner product between \( p(\text{part}) \) and itself, where \( p \) is the power-sum symmetric functions.

INPUT:
• part – an integer partition (for example, \([2, 1, 1]\))

OUTPUT:
• the integer \(\prod_i i^{m_i(part)} m_i(part)!\) where \(m_i(part)\) is the number of parts in the partition \(part\) equal to \(i\)

EXAMPLES:
```python
sage: from sage.combinat.sf.sfa import zee
sage: zee([2,1,1])
4
```

5.1.304 Witt symmetric functions

class sage.combinat.sf.witt.SymmetricFunctionAlgebra_witt(Sym)

Bases: SymmetricFunctionAlgebra_multiplicative

The Witt symmetric function basis (or Witt basis, to be short).

The Witt basis of the ring of symmetric functions is denoted by \((x_\lambda)\) in [HazWitt1], section 9.63, and by \((q_\lambda)\) in [DoranIV1996]. We will denote this basis by \((w_\lambda)\) (which is precisely how it is denoted in [GriRei18], Exercise 2.9.3(d)). It is a multiplicative basis (meaning that \(w_\emptyset = 1\) and that every partition \(\lambda\) satisfies \(w_\lambda = w_{\lambda_1} w_{\lambda_2} w_{\lambda_3} \cdots\), where \(w_i\) means \(w(i)\) for every nonnegative integer \(i\)).

This basis can be defined in various ways. Probably the most well-known one is using the equation

\[
\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n
\]

where \(t\) is a formal variable and \(h_n\) are the complete homogeneous symmetric functions, extended to 0 by \(h_0 = 1\). This equation allows one to uniquely determine the functions \(w_1, w_2, w_3, \ldots\) by recursion; one consequently extends the definition to all \(w_\lambda\) by requiring multiplicativity.

A way to rewrite the above equation without power series is:

\[
h_n = \sum_{\lambda \vdash n} w_\lambda
\]

for all nonnegative integers \(n\), where \(\lambda \vdash n\) means that \(\lambda\) is a partition of \(n\).

A similar equation (which is easily seen to be equivalent to the former) is

\[
e_n = \sum_{\lambda} \frac{1}{\lambda!} (-1)^{n-\ell(\lambda)} w_\lambda,
\]

with the sum running only over strict partitions \(\lambda\) of \(n\) this time. This equation can also be used to recursively define the \(w_n\). Furthermore, every positive integer \(n\) satisfies

\[
p_n = \sum_{d|n} d w_{n/d}^d,
\]

and this can be used to define the \(w_n\) recursively over any ring which is torsion-free as a \(\mathbb{Z}\)-module. While these equations all yield easy formulas for classical bases of the ring of symmetric functions in terms of the Witt symmetric functions, it seems difficult to obtain explicit formulas in the other direction.
The Witt symmetric functions owe their name to the fact that the ring of symmetric functions can be viewed as the coordinate ring of the group scheme of Witt vectors, and the Witt symmetric functions are the functions that send a Witt vector to its components (whereas the powersum symmetric functions send a Witt vector to its ghost components). Details can be found in [HazWitt1] or section 3.2 of [BorWi2004].

**INPUT:**

- `Sym` – an instance of the ring of the symmetric functions

**REFERENCES:**

**EXAMPLES:**

Here are the first few Witt symmetric functions, in various bases:

```plaintext
sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(w([1]))
p[1]
sage: m(w([1]))
m[1]
sage: e(w([1]))
e[1]
sage: h(w([1]))
h[1]
sage: s(w([1]))
s[1]

sage: p(w([2]))
-1/2*p[1, 1] + 1/2*p[2]
sage: m(w([2]))
-m[1, 1]
sage: e(w([2]))
e[2]
sage: h(w([2]))
-h[1, 1] + h[2]
sage: s(w([2]))
-s[1, 1]

sage: p(w([3]))
-1/3*p[1, 1, 1] + 1/3*p[3]
sage: m(w([3]))
-2*m[1, 1, 1] - m[2, 1]
sage: e(w([3]))
e[2, 1] + e[3]
sage: h(w([3]))
-h[2, 1] + h[3]
sage: s(w([3]))
-s[2, 1]

sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
```

(continues on next page)
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(w([4]))
-9*m[1, 1, 1, 1] - 4*m[2, 1, 1] - 2*m[2, 2] - m[3, 1]
sage: e(w([4]))
sage: h(w([4]))
sage: s(w([4]))
-s[1, 1, 1, 1] - s[2, 1, 1] - s[2, 2] - s[3, 1]

>>> from sage.all import *

>>> Sym = SymmetricFunctions(QQ)

>>> w = Sym.w()

>>> e = Sym.e()

>>> h = Sym.h()

>>> p = Sym.p()

>>> s = Sym.s()

>>> m = Sym.m()

>>> p(w([Integer(1)]))
p[1]

>>> m(w([Integer(1)]))
m[1]

>>> e(w([Integer(1)]))
e[1]

>>> h(w([Integer(1)]))
h[1]

>>> s(w([Integer(1)]))
s[1]

>>> p(w([Integer(2)]))
-1/2*p[1, 1] + 1/2*p[2]

>>> m(w([Integer(2)]))
-m[1, 1]

>>> e(w([Integer(2)]))
e[2]

>>> h(w([Integer(2)]))
-h[1, 1] + h[2]

>>> s(w([Integer(2)]))
s[1, 1]

>>> p(w([Integer(3)]))
-1/3*p[1, 1, 1] + 1/3*p[3]

>>> m(w([Integer(3)]))
-2*m[1, 1, 1] - m[2, 1]

>>> e(w([Integer(3)]))
e[2, 1] + e[3]

>>> h(w([Integer(3)]))
-h[2, 1] + h[3]

>>> s(w([Integer(3)]))
s[2, 1]

>>> Sym = SymmetricFunctions(ZZ)

>>> w = Sym.w()
Some examples of conversions the other way:

```python
sage: w(h[3])
w[1, 1, 1] + w[2, 1] + w[3]
sage: w(e[3])
-w[2, 1] + w[3]
sage: w(m[2, 1])
2*w[2, 1] - 3*w[3]
sage: w(p[3])
w[1, 1, 1] + 3*w[3]
```
The Witt basis does not allow for simple expressions for comultiplication and antipode in general (this is related to the fact that the sum of two Witt vectors isn’t easily described in terms of the components). Therefore, a number of computations with Witt symmetric functions pass through the complete homogeneous symmetric functions by default.

```python
class Element
    Bases: Element

    omega()

    Return the image of self under the omega automorphism.

    The omega automorphism is defined to be the unique algebra endomorphism \( \omega \) of the ring of symmetric functions that satisfies \( \omega(e_k) = h_k \) for all positive integers \( k \) (where \( e_k \) stands for the \( k \)-th elementary symmetric function, and \( h_k \) stands for the \( k \)-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the omega involution. It sends the power-sum symmetric function \( p_k \) to \((-1)^{k-1}p_k \) for every positive integer \( k \).

    The images of some bases under the omega automorphism are given by
    
    \[
    \omega(e_\lambda) = h_\lambda, \quad \omega(h_\lambda) = e_\lambda, \quad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \quad \omega(s_\lambda) = s_{\lambda'},
    \]
    where \( \lambda \) is any partition, where \( \ell(\lambda) \) denotes the length (``\text{length}()\') of the partition \( \lambda \), where \( \lambda' \) denotes the conjugate partition (``\text{conjugate}()\') of \( \lambda \), and where the usual notations for bases are used \((e = \text{elementary}, h = \text{complete homogeneous}, p = \text{powersum}, s = \text{Schur})\).

    omega_involution() is a synonym for the omega() method.

    EXAMPLES:
```

```python
sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: a = w([4,3,1,1]); a
w[4, 3, 1, 1]
sage: a.omega()
-w[3, 1, 1, 1, 1, 1, 1] - w[3, 2, 1, 1, 1, 1] - w[3, 2, 2, 1, 1] - w[4, 3, 1, 1]
sage: h = Sym.h()
sage: all(w(h(w[la]).omega()) == w[la].omega() for n in range(6) for la in Partitions(n))
True
```
**coproduct** \( (\text{elt}) \)

Return the coproduct of the element \( \text{elt} \).

**INPUT:**

- \( \text{elt} \) – a symmetric function written in this basis

**OUTPUT:**

The coproduct acting on \( \text{elt} \); the result is an element of the tensor squared of the basis \( \text{self} \).

**EXAMPLES:**

```python
sage: w = SymmetricFunctions(QQ).w()
sage: w[2].coproduct()
sage: w[2,1].coproduct()
sage: w.coproduct(w[2,1])
```

**verschiebung** \( (n) \)

Return the image of the symmetric function \( \text{self} \) under the \( n \)-th Verschiebung operator.

The \( n \)-th Verschiebung operator \( \text{V}_n \) is defined to be the unique algebra endomorphism \( V \) of the ring of symmetric functions that satisfies \( V(h_r) = h_{r/n} \) for every positive integer \( r \) divisible by \( n \), and satisfies \( V(h_r) = 0 \) for every positive integer \( r \) not divisible by \( n \). This operator \( \text{V}_n \) is a Hopf algebra endomorphism. For every nonnegative integer \( n \) with \( n \mid r \), it satisfies

\[
\text{V}_n(h_r) = h_{r/n}, \quad \text{V}_n(p_r) = np_{r/n}, \quad \text{V}_n(e_r) = (-1)^{r-r/n}e_{r/n}, \quad \text{V}_n(w_r) = w_{r/n},
\]

(where \( h \) is the complete homogeneous basis, \( p \) is the powersum basis, \( e \) is the elementary basis, and \( w \) is the Witt basis). For every nonnegative integer \( r \) with \( n \nmid r \), it satisfies

\[
\text{V}_n(h_r) = \text{V}_n(p_r) = \text{V}_n(e_r) = \text{V}_n(w_r) = 0.
\]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The \( n \)-th Verschiebung operator is adjoint to the \( n \)-th Frobenius operator (see \text{frobenius()} for its definition) with respect to the Hall scalar product (\text{scalar()}).
The action of the $n$-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley's [STA].

Let $\lambda$ be a partition. Let $n$ be a positive integer. If the $n$-core of $\lambda$ is nonempty, then $V_n(s_\lambda) = 0$. Otherwise, the following method computes $V_n(s_\lambda)$: Write the partition $\lambda$ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer $s$. (If $n$ does not divide the length of $\lambda$, then this is achieved by adding trailing zeroes to $\lambda$.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo $n$. Let $\xi$ be the sign of the permutation that is used for this sorting. Let $\psi$ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo $n$. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$. Then, $V_n(s_\lambda) = \xi \psi \prod_{i=0}^{n-1} s_{\lambda(i)}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the $n$-quotient of $\lambda$.

**INPUT:**

- $n$ – a positive integer

**OUTPUT:**

The result of applying the $n$-th Verschiebung operator (on the ring of symmetric functions) to $\text{self}$.

**EXAMPLES:**

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: w[3].verschiebung(2)
0
sage: w[4].verschiebung(4)
w[1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([1,3,4,2])
>>> e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
>>> w[Integer(4)].verschiebung(Integer(4))
w[1]
```

### 5.1.305 Shard intersection order

This file builds a combinatorial version of the shard intersection order of type A (in the classification of finite Coxeter groups). This is a lattice on the set of permutations, closely related to noncrossing partitions and the weak order.

For technical reasons, the elements of the posets are not permutations, but can be easily converted from and to permutations:

```python
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([[Integer(1),Integer(3),Integer(4),Integer(2)]])
```
See also:
A general implementation for all finite Coxeter groups is available as \texttt{shard\_poset()}

REFERENCES:

\texttt{class sage.combinat.shard_order.ShardPosetElement(p)}

Bases: tuple

An element of the shard poset.

This is basically a permutation with extra stored arguments:

• \( p \) – the permutation itself as a tuple
• \( \text{runs} \) – the decreasing runs as a tuple of tuples
• \( \text{run\_indices} \) – a list of integer -> index of the run
• \( \text{dpg} \) – the transitive closure of the shard preorder graph
• \( \text{spg} \) – the transitive reduction of the shard preorder graph

These elements can easily be converted from and to permutations:

\begin{verbatim}
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([Integer(1),Integer(3),Integer(4),Integer(2)])
>>> e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
>>> Permutation(list(e0)) == p0
True
\end{verbatim}

\texttt{sage.combinat.shard_order.shard\_poset(n)}

Return the shard intersection order on permutations of size \( n \).

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension \( n \). The shard poset is given by the inclusion of these cones.

\textbf{See also:}

\texttt{shard\_preorder\_graph()}

\textbf{EXAMPLES:}
sage: P = posets.ShardPoset(4); P  # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_self_dual()
False

>>> from sage.all import *
>>> P = posets.ShardPoset(Integer(4)); P  # indirect doctest
Finite poset containing 24 elements
>>> P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
>>> P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
>>> P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
>>> P.is_self_dual()
False

sage.combinat.shard_order.shard_preorder_graph(runs)

Return the preorder attached to a tuple of decreasing runs.

This is a directed graph, whose vertices correspond to the runs.

There is an edge from a run \( R \) to a run \( S \) if \( R \) is before \( S \) in the list of runs and the two intervals defined by the initial and final indices of \( R \) and \( S \) overlap.

This only depends on the initial and final indices of the runs. For this reason, this input can also be given in that shorten way.

INPUT:
- a tuple of tuples, the runs of a permutation, or
- a tuple of pairs \((i, j)\), each one standing for a run from \( i \) to \( j \).

OUTPUT:

a directed graph, with vertices labelled by integers

EXAMPLES:

sage: from sage.combinat.shard_order import shard_preorder_graph
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: def cut(lr):
....:     return tuple((r[0], r[-1]) for r in lr)
sage: shard_preorder_graph(cut(s.decreasing_runs()))
DiGraph on 5 vertices
sage: s = Permutation([9,4,3,2,8,6,5,1,7])
sage: P = shard_preorder_graph(s.decreasing_runs())
sage: P.is_isomorphic(digraphs.TransitiveTournament(3))
True

(continues on next page)
s = Permutation([Integer(2), Integer(8), Integer(3), Integer(9), Integer(6),
Integer(4), Integer(5), Integer(1), Integer(7)])

def cut(lr):
    return tuple((r[Integer(0)], r[-Integer(1)]) for r in lr)

shard_preorder_graph(cut(s.decreasing_runs()))

Digraph on 5 vertices

s = Permutation([Integer(9), Integer(4), Integer(3), Integer(2), Integer(8),
Integer(6), Integer(5), Integer(1), Integer(7)])

P = shard_preorder_graph(s.decreasing_runs())
P.is_isomorphic(digraphs.TransitiveTournament(Integer(3)))
True

5.1.306 Shifted primed tableaux

AUTHORS:

- Kirill Paramonov (2017-08-18): initial implementation
- Chaman Agrawal (2019-08-12): add parameter to allow primed diagonal entry

class sage.combinat.shifted_primed_tableau.CrystalElementShiftedPrimedTableau(parent, T, skew=None, check=True, preprocessed=False)

Bases: ShiftedPrimedTableau

Class for elements of crystals.ShiftedPrimedTableau.

e(ind)

Compute the action of the crystal operator $e_i$ on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- ind – an element in the index set of the crystal

OUTPUT:

Primed tableau or None.

EXAMPLES:

sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1, i, i, '2p', '3p'], [2, '3p', 3, 3], [3, 4]])
sage: t.pp()
  1 1 1 2' 3'
  2 3' 3 3
  3 4
sage: s = t.e(2)
sage: s.pp()
  1 1 1 2' 3'
  2 2 3 3
  3 4

(continues on next page)
sage: t == s.f(2)
True

sage: SPT = ShiftedPrimedTableaux([2, 1])
sage: t = SPT([[2, '3p'], [3]])
sage: t.e(-1).pp()
1 3'
 3
sage: t.e(1).pp()
1 3'
 3
sage: t.e(2).pp()
2 2
 3

sage: r = SPT([[2, 2], [3]])
sage: r.e(-1).pp()
1 2
 3
sage: r.e(1).pp()
1 2
 3
sage: r.e(2) is None
True

sage: r = SPT([[1, '3p'], [3]])
sage: r.e(-1)
is None
True
sage: r.e(1)
is None
True
sage: r.e(2).pp()
1 2
 3

sage: t = SPT([[2, '3p'], [3]])

sage: t.e(-1).e(2).e(2).e(-1) == t.e(2).e(1).e(1).e(2)
True

sage: all(t.e(-1).e(2).e(2).e(-1).e(i) is None for i in {-1, 1, 2})
True

sage: SPT = ShiftedPrimedTableaux([4])
sage: t = SPT([[2, 2, 2, 2]])
sage: t.e(-1).pp()
1 2 2 2
sage: t.e(1).pp()
1 2 2 2

(continues on next page)
sage: t.e(-1).e(-1) is None
True
sage: t.e(1).e(1).pp()
1 1 2 2

>>> from sage.all import *
>>> SPT = ShiftedPrimedTableaux([Integer(5),Integer(4),Integer(2)])
>>> t = SPT([[Integer(1),Integer(1),Integer(1),'2p','3p'], [Integer(2),'3p',
Integer(3),Integer(3)], [Integer(3),Integer(4)]]
>>> t.pp()
1 1 1 2 3
  2 3' 3 3
  3 4
>>> s = t.e(Integer(2))
>>> s.pp()

True
f (ind)

Compute the action of the crystal operator $f_i$ on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

• ind – element in the index set of the crystal

OUTPUT:

Primed tableau or None.

EXAMPLES:

```python
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,1,3p],[2,2,2,3p],[3,3]])
sage: t.pp()
1 1 1 1 3
  2 2 2 3
  3 3
sage: s = t.f(2)
sage: s.is None
True

sage: t = SPT([[1,1,1,2p,3p],[2,2,3,3],[3,4]])
sage: t.pp()
1 1 1 2' 3
  2 2 3 3
  3 4
sage: s = t.f(2)
sage: s.pp()
1 1 1 2' 3
```
12 3 3 3 3 4

sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[1,1],[2]])
sage: t.f(-1).pp()
 1 2'  
 2
sage: t.f(1).pp()
 1 2'
 2
sage: t.f(2).pp()
 1 1 3

sage: r = SPT([[1,'2p'],[2]])

2 2 2 2
(continues on next page)
is_highest_weight (index_set=None)

Return whether self is a highest weight element of the crystal.

An element is highest weight if it vanishes under all crystal operators $e_i$.

EXAMPLES:

```python
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([(1, 1, 1, 1, 1), (2, 2, 2, "3p"), (3, 3)])
sage: t.is_highest_weight()
True
```

```python
sage: SPT = ShiftedPrimedTableaux([5,4])
sage: s = SPT([(1, 1, 1, 1, 1), (2, 2, "3p", 3)])
sage: s.is_highest_weight(index_set=[1])
True
```

reading_word()

Return the reading word of self.

The reading word of a shifted primed tableau is constructed as follows:

1. List all primed entries in the tableau, column by column, in decreasing order within each column, moving from the rightmost column to the left, and with all the primes removed (i.e. all entries are increased by half a unit).

2. Then list all unprimed entries, row by row, in increasing order within each row, moving from the bottommost row to the top.

EXAMPLES:

```python
sage: SPT = ShiftedPrimedTableaux([4,2])
sage: t = SPT([(1, 2p, 2, 2), (2, 3p)])
sage: t.reading_word()
[3, 2, 2, 1, 2, 2]
```

```python
sage: SPT = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> from sage.all import *
```
weight()
Return the weight of self.

The weight of a shifted primed tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```python
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.weight()
(1, 4, 1)
```

```python
sage: t = ShiftedPrimedTableau([[1,2p,2,2],[2,3p]])
sage: t.weight()
(1, 4, 1)
```

```python
>>> from sage.all import *
```

```python
>>> t = ShiftedPrimedTableau([[Integer(1),2p,Integer(2),Integer(2)],[Integer(2),3p]])
```

```python
>>> t.weight()
(1, 4, 1)
```

class sage.combinat.shifted_primed_tableau.PrimedEntry(entry=None, double=None)

Bases: SageObject

The class of entries in shifted primed tableaux.

An entry in a shifted primed tableau is an element in the alphabet \{1' < 1 < 2' < 2 < \cdots < n' < n\}. The difference between two elements i and i − 1 counts as a whole unit, whereas the difference between i and i' counts as half a unit. Internally, we represent an unprimed element x as 2x and the primed elements as the corresponding odd integer that respects the total order.

INPUT:

- entry – a half integer or a string of an integer possibly ending in p or '
- double – the doubled value

decrease_half()
Decrease self by half a unit.
decrease_one()
Decrease self by one unit.
increase_half()
Increase self by half a unit.
increase_one()
Increase self by one unit.

type()
Return the corresponding integer i for primed entries of the form i or i'.
is_primed()
Checks if self is a primed element.
is_unprimed()
Checks if self is an unprimed element.
primed()
Prime self if it is an unprimed element.

unprimed()
Unprime self if it is a primed element.

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableau

parent, T,
skew=None,
check=True,
preprocessed=False)

Bases: ClonableArray

A shifted primed tableau.

A primed tableau is a tableau of shifted shape in the alphabet \( X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\} \) such that

1. the entries are weakly increasing along rows and columns;
2. a row cannot have two repeated primed elements, and a column cannot have two repeated non-primed elements;

Skew shape of the shifted primed tableaux is specified either with an optional argument skew or with None entries.

Primed entries in the main diagonal can be allowed with the optional boolean parameter primed_diagonal`` (default: ```False).

EXAMPLES:

```python
sage: T = ShiftedPrimedTableaux([4,2])
sage: T([[1,"2","3",3],[2,"3"]])[1]
(2, 3)
sage: t = ShiftedPrimedTableau([[1,"2p",2.5,3],[2,2.5]])
sage: t[1]
(2, 3)
sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: T([[1,"2","3",3],["2","3"]])[1] # With primed diagonal entry
(2, 3)
```
check()

Check that self is a valid primed tableau.

EXAMPLES:

```python
sage: T = ShiftedPrimedTableaux([4,2])
sage: t = T([[1, '2p', 2, 2], [2, '3p']])
sage: t.check()
sage: s = ShiftedPrimedTableau(['2p', 2, 3], [[2, '2p'], [2]], skew=[2, 1])
sage: s.check()
sage: t = T([[1p, '2p', 2, 2], [2, '3p']])
Traceback (most recent call last):
... ValueError: [[1p, '2p', 2, 2], [2, '3p']] is not an element of Shifted Primed Tableaux of shape [4, 2]

sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: t = T([[1p, '2p', 2, 2], [2, '3p']])  # primed_diagonal allowed
sage: t.check()
sage: t = T([[1p, '1p', 2, 2], [2, '3p']])
Traceback (most recent call last):
... ValueError: [[1p, '1p', 2, 2], [2, '3p']] is not an element of Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

```python
>>> from sage.all import *

>>> T = ShiftedPrimedTableaux([Integer(4), Integer(2)])

>>> t = T([[Integer(1), '2p', Integer(2), Integer(2)], [Integer(2), '3p']])

>>> t.check()

>>> s = ShiftedPrimedTableau(['2p', Integer(2), Integer(3)], [[2, '2p'], [2], [2]], skew=[Integer(2), Integer(2), Integer(1)])

>>> s.check()

>>> t = T([[1p, '2p', Integer(2), Integer(2)], [Integer(2), '3p']])

Traceback (most recent call last):
... ValueError: [[1p, '2p', 2, 2], [2, '3p']] is not an element of Shifted Primed Tableaux of shape [4, 2]

>>> T = ShiftedPrimedTableaux([Integer(4), Integer(2)], primed_diagonal=True)

>>> t = T([[1p, '2p', Integer(2), Integer(2)], [Integer(2), '3p']])  # primed_diagonal allowed

>>> t.check()

>>> t = T([[1p, '1p', Integer(2), Integer(2)], [Integer(2), '3p']])

Traceback (most recent call last):
... ValueError: [[1p, '1p', 2, 2], [2, '3p']] is not an element of Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

is_standard()

Return True if the entries of self are in bijection with positive primed integers 1', 1', 2', ..., n.

EXAMPLES:

```python
sage: ShiftedPrimedTableau(['1', '2'], [2, '3']).is_standard()
True
sage: ShiftedPrimedTableau(['1', '2'], ['2', '3']).is_standard()
True
```

(continues on next page)
True
sage: ShiftedPrimedTableau([["1", 1, 1], ["2", 2]],
...: primed_diagonal=True).is_standard()
False
sage: ShiftedPrimedTableau([[1, "2"]], [2]).is_standard()
False
sage: s = ShiftedPrimedTableau([[None, None,"1p","2p",2],[None,"1"]])
sage: s.is_standard()
True

>>> from sage.all import *
>>> ShiftedPrimedTableau([["1", Integer(1), "2"], [Integer(2), "3"]],
...: primed_diagonal=True).is_standard()
True
>>> ShiftedPrimedTableau([["1", Integer(1), Integer(2)], ["2", "3"]],
...: primed_diagonal=True).is_standard()
True
>>> ShiftedPrimedTableau([["1", Integer(1), Integer(1)], ["2", Integer(2)]],
...: primed_diagonal=True).is_standard()
False
>>> ShiftedPrimedTableau([[Integer(1), "2"], [Integer(2)]]).is_standard()
False
>>> s = ShiftedPrimedTableau([[None, None,"1p","2p",Integer(2)],[None,"1"]])
>>> s.is_standard()
True

max_entry()

Return the minimum unprimed letter $x > y$ for all $y$ in self.

EXAMPLES:
sage: Tab = ShiftedPrimedTableau(((1,1,'2p','3p'),(2,2)))
sage: Tab.max_entry()
3

>>> from sage.all import *
>>> Tab = ShiftedPrimedTableau(((Integer(1),Integer(1),'2p','3p'),(Integer(2),
˓→Integer(2)))),
>>> Tab.max_entry()
3

pp()

Pretty print self.

EXAMPLES:
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.pp()
1 2' 2 2
  2 3'
sage: t = ShiftedPrimedTableau([[10,'11p',11,11],[11,'12']])
sage: t.pp()
10 11' 11 11
  11 12
sage: s = ShiftedPrimedTableau([[2p,2,3],[2p']],[skew=[2,1])
sage: s.pp()
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1), '2p', Integer(2), Integer(2)],
                           [ Integer(2), '3p']])
>>> t.pp()
  1  2'  2
  2
>>> t = ShiftedPrimedTableau([[Integer(10), '11p', Integer(11), Integer(11)],
                           [ Integer(11), '12']])
>>> t.pp()
 10  11'  11
  11  12
>>> s = ShiftedPrimedTableau([[ '2p', Integer(2), Integer(3)], ['2p']],
                           skew=[ Integer(2), Integer(1)])
>>> s.pp()
  .  2'  2
  .  2

restrict \(n\)

Return the restriction of the shifted tableau to all the numbers less than or equal to \(n\).

**Note:** If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_outer_shape()` is preferred. Similarly if only the skew shape is needed, use `restriction_shape()`.

**EXAMPLES:**

```python
sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.restrict(2).pp()
  1  2'  2
  2
sage: t.restrict("2p").pp()
  1  2'
sage: s = ShiftedPrimedTableau([["2p", 2, 3], ["2p"]], skew=[2, 1])
sage: s.restrict(2).pp()
  .  2'  2
  .  2'
sage: s.restrict(1.5).pp()
  .  2'
  .  2'
```

```python
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1), '2p', Integer(2), Integer(2)],
                           [ Integer(2), '3p']])
>>> t.restrict(Integer(2)).pp()
  1  2'  2
  2
>>> t.restrict("2p").pp()
  1  2'
```
>>>
>>> s = ShiftedPrimedTableau(
    ["2p", Integer(2), Integer(3)],
    sk=skew=[Integer(2), Integer(1)])
>>> s.restrict(Integer(2)).pp()
  2' 2
  2'
>>> s.restrict(RealNumber(1.5)).pp()
  2'

**restriction_outer_shape** *(n)*

Return the outer shape of the restriction of the shifted tableau *self* to *n*.

If *T* is a (skew) shifted tableau and *n* is a half-integer, then the restriction of *T* to *n* is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the outer shape of the restriction. For the restriction itself, use *restrict()*.

**EXAMPLES:**

```python
sage: s = ShiftedPrimedTableau(
    ["2p", 2, 3],
    skew=[2, 1])
sage: s.restriction_outer_shape(2)
[4, 2]
sage: s.restriction_outer_shape("2p")
[3, 2]
```

```python
from sage.all import *
```

```python
>>> s = ShiftedPrimedTableau(
    ["2p", Integer(2), Integer(3)],
    sk=skew=[Integer(2), Integer(1)])
>>> s.restrict(Integer(2)).pp()
  2' 2 3
  2'
>>> s.restrict(RealNumber(1.5)).pp()
  2'
```

**restriction_shape** *(n)*

Return the skew shape of the restriction of the skew tableau *self* to *n*.

If *T* is a shifted tableau and *n* is a half-integer, then the restriction of *T* to *n* is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than *n* from *T*.

This method computes merely the skew shape of the restriction. For the restriction itself, use *restrict()*.

**EXAMPLES:**

```python
sage: s = ShiftedPrimedTableau(
    ["2p", 2, 3],
    skew=[2, 1])
sage: s.restriction_shape(2)
[4, 2] / [2, 1]
sage: s.restriction_shape("2p")
[3, 2] / [2, 1]
```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau(["2p", Integer(2), Integer(3)],["2p"],
                          skew=[Integer(2), Integer(1)])
>>> s.pp()
 . 2  2 3
 . 2

>>> s.restriction_shape(Integer(2))
[4, 2] / [2, 1]

shape()

Return the shape of the underlying partition of self.

EXAMPLES:

sage: t = ShiftedPrimedTableau([[1, '2p', 2, 2], [2, '3p']])
sage: t.shape()
[4, 2]
sage: s = ShiftedPrimedTableau(["2p", 2, 3],["2p"],skew=[2,1])
sage: s.shape()
[5, 2] / [2, 1]

to_chain()

Return the chain of partitions corresponding to the (skew) shifted tableau self, interlaced by one of the colours 1 isthe added cell is on the diagonal, 2 if an ordinary entry is added and 3 if a primed entry is added.

EXAMPLES:

sage: s = ShiftedPrimedTableau([(1, 2, 3.5, 5, 6.5), (3, 5.5)])
sage: s.pp()
  1  2  4  5  7
  3  6
sage: s.to_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

sage: s = ShiftedPrimedTableau([(1, 3.5), (2.5), (6,)], skew=[2,1])
sage: s.pp()
 . 1  4'
 . 3'
  6
sage: s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```python
>>> from sage.all import *

>>> s = ShiftedPrimedTableau([(Integer(1), Integer(2), RealNumber('3.5'),
    Integer(5), RealNumber('6.5'))], (Integer(3), RealNumber('5.5')))

>>> s.pp()
1 2 4' 5 7'
    3 6'

>>> s.to_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

>>> s = ShiftedPrimedTableau([(Integer(1), RealNumber('3.5'))], (RealNumber('2.'),), (Integer(6),)), skew=[Integer(2),Integer(1)])

>>> s.pp()
. 1 4'
    3'
    6

>>> s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```

weight()

Return the weight of self.

The weight of a shifted primed tableau is defined to be the vector with \(i\)-th component equal to the number of entries \(i\) and \(i'\) in the tableau.

EXAMPLES:

```python
sage: t = ShiftedPrimedTableau([['2p',2,2],[2,'3p']], skew=[1])
sage: t.weight()
(0, 4, 1)
```

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux(skew=None, primed_diagonal=False)

Bases: UniqueRepresentation, Parent

Returns the combinatorial class of shifted primed tableaux subject to the constraints given by the arguments.

A primed tableau is a tableau of shifted shape on the alphabet \(X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\}\) such that

1. the entries are weakly increasing along rows and columns
2. a row cannot have two repeated primed entries, and a column cannot have two repeated non-primed entries

INPUT:

Valid optional keywords:

- `shape` – the (outer skew) shape of tableaux
- `weight` – the weight of tableaux
- `max_entry` – the maximum entry of tableaux
• **skew** – the inner skew shape of tableaux

• **primed_diagonal** – allow primed entries in main diagonal of tableaux

The weight of a tableau is defined to be the vector with \( i \)-th component equal to the number of entries \( i \) and \( i' \) in the tableau. The sum of the coordinates in the weight vector must be equal to the number of entries in the partition.

The **shape** and **skew** must be strictly decreasing partitions. The **primed_diagonal** is a boolean (default: False).

**EXAMPLES:**

```
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2]); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[[1, 2, 2], (3, 3)],
 [[1, 2', 3'], (2, 3)],
 [[1, 2', 3'], (2, 3')],
 [[1, 2', 2], (3, 3)]]

sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2],
....: primed_diagonal=True); SPT

Element

alias of ShiftedPrimedTableau

options = Current options for Tableaux - ascii_art: repr - convention:
English - display: list - latex: diagram

```python
class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_all(skew=None,
 primed_diagonal=False)

Bases: ShiftedPrimedTableaux

The class of all shifted primed tableaux.

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_shape(shape,
 max_entry=None,
 skew=None,
 primed_diagonal=False)

Bases: ShiftedPrimedTableaux

Shifted primed tableaux of a fixed shape.

Shifted primed tableaux admit a type $A_n$ classical crystal structure with highest weights corresponding to a given shape.

The list of module generators consists of all elements of the crystal with nonincreasing weight entries.

The crystal is constructed following operations described in [HPS2017] and [AO2018].

The optional primed_diagonal allows primed entries in the main diagonal of all the Shifted primed tableaux of a fixed shape. If the max_entry is None then max_entry is set to the total number of entries in the tableau if primed_diagonal is True.

EXAMPLES:
We compute some of the crystal structure:

```python
sage: SPTC = crystals.ShiftedPrimedTableaux([3,2], 3)
sage: T = SPTC.module_generators[-1]
sage: T
[(1, 1, 2'), (2, 3')]
sage: T.f(2)
[(1, 1, 3'), (2, 3')]
sage: len(SPTC.module_generators)
7
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
24
```

We compare this implementation with the $q(n)$-crystal on (tensor products) of letters:

```python
sage: tableau_crystal = crystals.ShiftedPrimedTableaux([4,1], 3)
sage: tableau_digraph = tableau_crystal.digraph()
sage: c = crystals.Letters(['Q', 3])
sage: tensor_crystal = tensor([c]*5)
sage: u = tensor_crystal(c(1), c(1), c(1), c(2), c(1))
sage: subcrystal = tensor_crystal.subcrystal(generators=[u],
    index_set=[1,2,-1])
sage: tensor_digraph = subcrystal.digraph()
sage: tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```
tableau_crystal = crystals.ShiftedPrimedTableaux([Integer(4), Integer(1)],...
˓→ Integer(3))

>>> tableau_digraph = tableau_crystal.digraph()

>>> c = crystals.Letters(['Q', Integer(3)])

>>> tensor_crystal = tensor([c]*Integer(5))

>>> u = tensor_crystal(c(Integer(1)), c(Integer(1)), c(Integer(1)), c(Integer(2)),...
˓→ c(Integer(1)))

>>> subcrystal = tensor_crystal.subcrystal(generators=[u],
˓→ index_set=[Integer(1), Integer(2),-
˓→ Integer(1)])

>>> tensor_digraph = subcrystal.digraph()

>>> tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True

If we allow primed entries in the main diagonal:

sage: ShiftedPrimedTableaux([4, 3, 1], max_entry=4, ...
˓→ primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4, 3, 1], max_entry=4, ...
˓→ primed_diagonal=True).cardinality()
3072

sage: SPTC = ShiftedPrimedTableaux([3, 2], max_entry=3, ...
˓→ primed_diagonal=True)

sage: T = SPTC[-1]

sage: T
[(1, 2, 2), (3, 3)]

sage: SPTC[0]
[(1, 1, 1), (2, 2)]

sage: SPTC.cardinality()
96

module_generators()
Return the generators of self as a crystal.

shape()
Return the shape of the shifted tableaux self.
class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_weight(weight, skew=None, primed_diagonal=False)

Bases: ShiftedPrimedTableaux

Shifted primed tableaux of fixed weight.

EXAMPLES:

sage: ShiftedPrimedTableaux(weight=(2,3,1))
Shifted Primed Tableaux of weight (2, 3, 1)
sage: ShiftedPrimedTableaux(weight=(2,3,1)).cardinality()
17
sage: SPT = ShiftedPrimedTableaux(weight=(2,3,1), primed_diagonal=True)
sage: SPT.cardinality()
64
sage: T = ShiftedPrimedTableaux(weight=(3,2), primed_diagonal=True)
sage: T[:5]
[(1, 1, 1, 2, 2), (1, 1, 1, 2, 2), (1, 1, 1, 2, 2), (1, 1, 1, 2, 2), (1, 1, 1, 2, 2), (2, 2), (2, 2)]
sage: T.cardinality()
16

>>> from sage.all import *

>>> ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1)))
Shifted Primed Tableaux of weight (2, 3, 1)
>>> ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1))).cardinality()
17
>>> SPT = ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1)), primed_diagonal=True)
>>> SPT.cardinality()
64
>>> T = ShiftedPrimedTableaux(weight=(Integer(3),Integer(2)), primed_diagonal=True)
>>> T[:Integer(5)]
[[1, 1, 1, 2, 2],
 [1, 1, 1, 2, 2],
 [1', 1, 1, 2, 2],
 [1', 1, 1, 2, 2],
 [1, 1, 1, 2], (2, 2)]
>>> T.cardinality()
16

class sage.combinat.shifted_primed_tableau.ShiftedPrimedTableaux_weight_shape(weight, shape, skew=None, primed_diagonal=False)

Bases: ShiftedPrimedTableaux

Shifted primed tableaux of the fixed weight and shape.
EXAMPLES:

```
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2)).cardinality()
4
sage: T = ShiftedPrimedTableaux([4,2,1], weight=(2,3,2),
....:   primed_diagonal=True)
sage: T[:6]
[[[1, 1, 2, 2), (2, 3), (3,)],
 [[1, 1, 2, 2), (2, 3), (3,)],
 [[1, 1, 2, 2), (2', 3'), (3,)],
 [[1, 1, 2, 2), (2', 3'), (3',)],
 [[1, 1, 2', 3), (2, 2), (3,)],
 [[1, 1, 2', 3), (2, 2), (3',)]]
sage: T.cardinality()
32
```
\[
[a, b, 1, 2, c],
[a, 1, b, 2, c],
[1, a, b, 2, c],
[a, 'b', 'c', 1, 2],
[a, 'b', 1, 'c', 2],
[a, 1, 'b', 'c', 2],
[1, a, 'b', 'c', 2]
\]
The cardinality is defined by the sum of the cardinality of all shuffles. That means by a sum of binomials.

```
class sage.combinat.shuffle.ShuffleProduct(l1, l2, element_constructor=None):
    Bases: ShuffleProduct_abstract

    Shuffle product of two iterables.

    EXAMPLES:
    sage: from sage.combinat.shuffle import ShuffleProduct
    sage: list(ShuffleProduct("abc", "de", element_constructor="".join))
    ['abcde',
     'adbce',
     'dabce',
     'abdce',
     'adebc',
     'daebc',
     'deabc',
     'adbec',
     'dabec',
     'abdec']

    sage: list(ShuffleProduct('', "de", element_constructor="".join))
    ['de']
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct
>>> list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
 'adbce',
 'dabce',
 'abdce',
 'adebc',
 'daebc',
 'deabc',
 'adbec',
 'dabec',
 'abdec']

>>> list(ShuffleProduct('', "de", element_constructor="".join))
['de']
```

cardinality()

Return the number of shuffles of $l_1$ and $l_2$, respectively of lengths $m$ and $n$, which is $\binom{m+n}{n}$. 
class sage.combinat.shuffle.ShuffleProduct_abstract (l1, l2, element_constructor=None)
Bases: Parent

Abstract base class for shuffle products.

class sage.combinat.shuffle.ShuffleProduct_overlapping (w1, w2,
    element_constructor=None,
    add=<built-in function add>)
Bases: ShuffleProduct_abstract

The overlapping shuffle product of the two words \( w_1 \) and \( w_2 \).

If \( u \) and \( v \) are two words whose letters belong to an additive monoid or to another kind of alphabet on which addition is well-defined, then the overlapping shuffle product of \( u \) and \( v \) is a certain multiset of words defined as follows: Let \( a \) and \( b \) be the lengths of \( u \) and \( v \), respectively. Let \( A \) be the set \( \{(0, 1), (0, 2), \ldots, (0, a)\} \), and let \( B \) be the set \( \{(1, 1), (1, 2), \ldots, (1, b)\} \). Notice that the sets \( A \) and \( B \) are disjoint. We can make \( A \) and \( B \) into posets by setting \( (k_i, i) \leq (k_j, j) \) for all \( k \in \{0, 1\} \) and \( i \leq j \). Then, \( A \cup B \) becomes a poset by disjoint union (we don't set \( (0, i) \leq (1, i) \)). Let \( p \) be the map from \( A \cup B \) to the set of all letters which sends every \( (0, i) \) to the \( i \)-th letter of \( u \), and every \( (1, j) \) to the \( j \)-th letter of \( v \). For every nonnegative integer \( c \) and every surjective map \( f : A \cup B \to \{1, 2, \ldots, c\} \) for which both restrictions \( f \mid_A \) and \( f \mid_B \) are strictly increasing, let \( w(f) \) be the length-\( c \) word such that for every \( 1 \leq k \leq c \), the \( k \)-th letter of \( w(f) \) equals \( \sum_{j \in f^{-1}(k)} p(j) \) (this sum always has either one or two addends). The overlapping shuffle product of \( u \) and \( v \) is then the multiset of all \( w(f) \) with \( c \) ranging over all nonnegative integers and \( f \) ranging over the surjective maps \( f : A \cup B \to \{1, 2, \ldots, c\} \) for which both restrictions \( f \mid_A \) and \( f \mid_B \) are strictly increasing.

If one restricts \( c \) to a particular fixed nonnegative integer, then the multiset is instead called the overlapping shuffle product with precisely \( a + b - c \) overlaps. This is nonempty only if \( \max\{a, b\} \leq c \leq a + b \).

If \( c = a + b \), then the overlapping shuffle product with precisely \( a + b - c \) overlaps is plainly the shuffle product (ShuffleProduct_w1w2).

INPUT:

- \( w_1, w_2 \) – iterables
- \( \text{element\_constructor} \) – (default: the parent of \( w_1 \)) the function used to construct the output
- \( \text{add} \) – (default: +) the addition function

EXAMPLES:

\[
\begin{align*}
sage: \text{from sage.combinat.shuffle import ShuffleProduct\_overlapping} \\
sage: w, u = [[2, 9], [9, 1]] \\
sage: S = ShuffleProduct\_overlapping(w, u) \\
sage: sorted(S) \\
[[2, 9, 1, 9], \\
 [2, 9, 9, 1], \\
 [2, 9, 9, 1], \\

([1, 2], {3, 4, 5, 6}])

class sage.combinat.shuffle.ShuffleProduct_overlapping_r(w1, w2, r, 
 element_constructor=None, 
 add=<built-in function add>)

Bases: ShuffleProduct_abstract
The overlapping shuffle product of the two words $w_1$ and $w_2$ with precisely $r$ overlaps.

See `ShuffleProduct_overlapping` for a definition.

EXAMPLES:

```python
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping_r
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])
```

```python
sage: S = ShuffleProduct_overlapping_r(w, u, 1)
sage: list(S)
[word: 11,9,1,
 word: 2,18,1,
 word: 11,1,9,
 word: 2,9,10,
 word: 939,
 word: 9,2,10]
```

```python
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct_overlapping_r
>>> w, u = map(Words(range(Integer(20))), [[Integer(2), Integer(9)], [Integer(9), Integer(1)]])
>>> S = ShuffleProduct_overlapping_r(w, u, Integer(1))
>>> list(S)
[word: 11,9,1,
 word: 2,18,1,
 word: 11,1,9,
 word: 2,9,10,
 word: 939,
 word: 9,2,10]
```

5.1.308 Sidon sets and their generalizations, Sidon $g$-sets

AUTHORS:

- Martin Raum (07-25-2011)

```python
sage.combinat.sidon_sets.sidon_sets(N, g=1)
```

Return the set of all Sidon-$g$ sets that have elements less than or equal to $N$.

A Sidon-$g$ set is a set of positive integers $A \subset [1, N]$ such that any integer $M$ can be obtain at most $g$ times as sums of unordered pairs of elements of $A$ (the two elements are not necessary distinct):

$$\# \{(a_i, a_j) | a_i, a_j \in A, a_i + a_j = M, a_i \leq a_j \} \leq g$$

INPUT:

- $N$ – A positive integer.
- $g$ – A positive integer (default: 1).

OUTPUT:

- A Sage set with categories whose element are also set of integers.

EXAMPLES:

```python
sage: S = sidon_sets(3, 2)
sage: sorted(S, key=str)
[(1, 2, 3), {1, 2}, {1, 3}, {1}, {2, 3}, {2}, {3}, {}]
```
sage.combinat.sidon_sets.sidon_sets_rec(g=1)

Return the set of all Sidon-$g$ sets that have elements less than or equal to $N$ without checking the arguments. This internal function should not be call directly by user.

5.1.309 Similarity class types of matrices with entries in a finite field

The notion of a matrix conjugacy class type was introduced by J. A. Green in [Green55], in the context of computing the irreducible characters of finite general linear groups. The class types are equivalence classes of similarity classes of square matrices with entries in a finite field which, roughly speaking, have the same qualitative properties.

For example, all similarity classes of the same class type have centralizers of the same cardinality and the same degrees of elementary divisors. Qualitative properties of similarity classes such as semisimplicity and regularity descend to class types.

The most important feature of similarity class types is that, for any $n$, the number of similarity class types of $n \times n$ matrices is independent of $q$. This makes it possible to perform many combinatorial calculations treating $q$ as a formal variable.

In order to define similarity class types, recall that similarity classes of $n \times n$ matrices with entries in $\mathbb{F}_q$ correspond to functions

$$c : \text{Irr} \mathbb{F}_q[t] \to \Lambda$$

such that

$$\sum_{f \in \text{Irr} \mathbb{F}_q[t]} |c(f)| \deg f = n,$$

where we denote the set of irreducible monic polynomials in $\mathbb{F}_q[t]$ by $\text{Irr} \mathbb{F}_q[t]$, the set of all partitions by $\Lambda$, and the size of $\lambda \in \Lambda$ by $|\lambda|$.

Similarity classes indexed by functions $c_1$ and $c_2$ as above are said to be of the same type if there exists a degree-preserving self-bijection $\sigma$ of $\text{Irr} \mathbb{F}_q[t]$ such that $c_2 = c_1 \circ \sigma$. Thus, the type of $c$ remembers only the degrees of the polynomials (and
not the polynomials themselves) for which \( c \) takes a certain value \( \lambda \). Replacing each irreducible polynomial of degree \( d \) for which \( c \) takes a non-trivial value \( \lambda \) by the pair \((d, \lambda)\), we obtain a multiset of such pairs. Clearly, \( c_1 \) and \( c_2 \) have the same type if and only if these multisets are equal. Thus a similarity class type may be viewed as a multiset of pairs of the form \((d, \lambda)\).

For \( 2 \times 2 \) matrices there are four types:

```python
sage: for tau in SimilarityClassTypes(2):
    print(tau)
[[[1, [1]], [1, [1]]],
 [ [1, [2]],
 [ [1, [1, 1]],
 [ [1, [1]],
 [ [2, [1]],

>>> from sage.all import *
>>> for tau in SimilarityClassTypes(Integer(2)):
    print(tau)
[[[1, [1]], [1, [1]]],
 [ [1, [2]],
 [ [1, [1, 1]],
 [ [2, [1]],

These four types correspond to the regular split semisimple matrices, the non-semisimple matrices, the central matrices and the irreducible matrices respectively.

For any matrix \( A \) in a given similarity class type, it is possible to calculate the number elements in the similarity class of \( A \), the dimension of the algebra of matrices in \( M_n(A) \) that commute with \( A \), and the cardinality of the subgroup of \( GL_n(\mathbb{F}_q) \) that commute with \( A \). For each similarity class type, it is also possible to compute the number of classes of that type (and hence, the total number of matrices of that type). All these calculations treat the cardinality \( q \) of the finite field as a formal variable:

```python
sage: M = SimilarityClassType([[1, [1]], [1, [1]]])
sage: M.class_card()
q^2 + q
sage: M.centralizer_algebra_dim()
2
sage: M.centralizer_group_card()
q^2 - 2*q + 1
sage: M.number_of_classes()
1/2*q^2 - 1/2*q
sage: M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

We now describe two applications of similarity class types.
We say that an $n \times n$ matrix has rational canonical form type $\lambda$ for some partition $\lambda$ of $n$ if the diagonal blocks in the rational canonical form have sizes given by the parts of $\lambda$. Thus the matrices with rational canonical type $(n)$ are the regular ones, while the matrices with rational canonical type $(1^n)$ are the central ones.

Using similarity class types, it becomes easy to get a formula for the number of matrices with a given rational canonical type:

```python
sage: def matrices_with_rcf(la):
    ...:     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.rcf()==la, SimilarityClassTypes(la.size()))])

sage: matrices_with_rcf(Partition([2,1]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

Similarity class types can also be used to calculate the number of simultaneous similarity classes of $k$-tuples of $n \times n$ matrices with entries in $\mathbb{F}_q$ by using Burnside’s lemma:

```python
sage: from sage.combinat.similarity_class_type import order_of_general_linear_group,
    --centralizer_algebra_dim
sage: q = ZZ['q'].gen()

sage: def simultaneous_similarity_classes(n,k):
    ...:     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_dim(la)), invertible = True)/order_of_general_linear_group(n)

sage: simultaneous_similarity_classes(3, 2)
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

Similarity class types can be used to compute the coefficients of generating functions coming from the cycle index type techniques of Kung and Stong (see Morrison [Morrison06]).

They can also be used to compute the number of invariant subspaces for a matrix over a finite field of any given dimension. For this we use the elegant recursive formula of Ramaré [R17] (see also [PR22]).

Along with the results of [PSS13], similarity class types can be used to calculate the number of similarity classes of matrices of order $n$ with entries in a principal ideal local ring of length two with residue field of cardinality $q$ with centralizer of any given cardinality up to $n = 4$. Among these, the classes which are selftranspose can also be counted:

```python
sage: from sage.combinat.similarity_class_type import matrix_centralizer_cardinalities_length_two

sage: list(matrix_centralizer_cardinalities_length_two(3))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
 (q^6 - 2*q^5 + q^4, q^5 - q^4),
 (q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
 (continues on next page)]
```

(continues on next page)
(continued from previous page)

(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
(q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
(q^6 - q^5, q^4),
(q^10 - 2*q^9 + q^8, q^3),

space generating function

class sage.combinat.similarity_class_type.PrimarySimilarityClassType

Bases: Element

A primary similarity class type is a pair consisting of a partition and a positive integer.
For a partition $\lambda$ and a positive integer $d$, the primary similarity class type $(d, \lambda)$ represents similarity classes of square matrices of order $|\lambda| \cdot d$ with entries in a finite field of order $q$ which correspond to the $F_q[t]$-module

$$\frac{F_q[t]}{p(t)\lambda_1} \oplus \frac{F_q[t]}{p(t)\lambda_2} \oplus \cdots$$

for some irreducible polynomial $p(t)$ of degree $d$.

**centralizer_algebra_dim()**

Return the dimension of the algebra of matrices which commute with a matrix of type `self`. For a partition $(d, \lambda)$ this dimension is given by $d(\lambda_1 + 3\lambda_2 + 5\lambda_3 + \cdots)$.

**EXAMPLES:**

```python
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.centralizer_algebra_dim()
28

>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),
˓→Integer(1)])
>>> PT.centralizer_algebra_dim()
28
```

**centralizer_group_card**(q=None)

Return the cardinality of the centralizer group of a matrix of type `self` in a field of order $q$.

**INPUT:**

- $q$ – an integer or an indeterminate

**EXAMPLES:**

```python
sage: PT = PrimarySimilarityClassType(1, [])
sage: PT.centralizer_group_card()
1
sage: PT = PrimarySimilarityClassType(2, [1, 1])
sage: PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2

>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(1), [])
>>> PT.centralizer_group_card()
1
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(1), Integer(1)])
>>> PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

**degree()**

Return degree of `self`.

**EXAMPLES:**

```python
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.degree()
2
```
from sage.all import *
PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2), Integer(1)])
PT.degree()
2

invariant_subspace_generating_function (q=None, t=None)
Return the invariant subspace generating function of self.

INPUT:
• q – (optional) an integer or an indeterminate
• t – (optional) an indeterminate

EXAMPLES:
sage: PrimarySimilarityClassType(1, [2, 2]).invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1

partition()
Return partition corresponding to self.

EXAMPLES:
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.partition()
[3, 2, 1]

size()
Return the size of self.

EXAMPLES:
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.size()
12
**statistic** *(func, q=None)*

Return $n_\lambda(q^d)$ where $n_\lambda$ is the value returned by `func` upon input $\lambda$, if `self` is $(d, \lambda)$.

**EXAMPLES:**

```python
sage: PT = PrimarySimilarityClassType(2, [3, 1])
sage: q = ZZ['q'].gen()
sage: PT.statistic(lambda la:q**la.size(), q = q)
q^8
```
```python
from sage.all import *

PTC = PrimarySimilarityClassTypes(Integer(2), min =
PrimarySimilarityClassType(Integer(1), [Integer(1), Integer(1)]))

for PT in PTC:
    print(PT)
[1, [1, 1]]
[2, [1]]
```

**Element**

**class sage.combinat.similarity_class_type.PrimarySimilarityClassType**

A similarity class type.

A matrix type is a multiset of primary similarity class types.

**INPUT:**

- `tau` – a list of primary similarity class types or a square matrix over a finite field

**EXAMPLES:**

```python
sage: PTC = PrimarySimilarityClassTypes(2)
sage: PTC.size()
2
```

**size()**

Return size of elements of `self`.

The size of a primary similarity class type \((d, \lambda)\) is \(d|\lambda|\).

**EXAMPLES:**

```python
sage: PTC = PrimarySimilarityClassTypes(Integer(2))
sage: PTC.size()
2
```

**as_partition_dictionary()**

Return a dictionary whose keys are the partitions of types occurring in `self` and the value at the key \(\lambda\) is the partition formed by sorting the degrees of primary types with partition \(\lambda\).
EXAMPLES:

```python
def centralizer_algebra_dim(self):
    """Return the dimension of the algebra of matrices which commute with a matrix of type self."

    EXAMPLES:
    sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
    sage: tau.centralizer_algebra_dim()
    2
    >>> from sage.all import *
    >>> tau = SimilarityClassType([[Integer(1), [Integer(1)],[Integer(1),...
    ...
    >>> tau.centralizer_algebra_dim()
    2
```

```python
def centralizer_group_card(self, q=None):
    """Return the cardinality of the group of matrices in GL_n(F_q) which commute with a matrix of type self.

    INPUT:
    • q – an integer or an indeterminate

    EXAMPLES:
    sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
    sage: tau.centralizer_group_card()
    q^2 - 2*q + 1
    >>> from sage.all import *
    >>> tau = SimilarityClassType([[Integer(1), [Integer(1)],[Integer(1),...]
    ...
    >>> tau.centralizer_group_card()
    q^2 - 2*q + 1
```

```python
def class_card(self, q=None):
    """Return the number of matrices in each similarity class of type self.

    INPUT:
    • q – an integer or an indeterminate

    EXAMPLES:
    sage: tau = SimilarityClassType([[1, [1, 1, 1, 1]]])
    sage: tau.class_card()
    1
    (continues on next page)
```
Combinatorics, Release 10.4

```python
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.class_card()
q^2 + q

>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1), Integer(1)],
  ...                             Integer(1), Integer(1)]]))
>>> tau.class_card()
1
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),
  ...                             [Integer(1)]]])
>>> tau.class_card()
q^2 + q
```

`invariant_subspace_generating_function (q=Undefined, t=Undefined)`
Return the invariant subspace generating function of `self`.

The invariant subspace generating function is the function that is the polynomial

\[ \sum_{j \geq 0} a_j(q)t^j, \]

where \( a_j(q) \) denotes the number of \( j \)-dimensional invariant subspaces of dimensiona \( j \) for any matrix with the similarity class type `self` with entries in a field of order \( q \).

**EXAMPLES:**

```python
sage: SimilarityClassType([[1, [2, 2]]]).invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
sage: A = Matrix(GF(2),
  ...   [[0, 1, 0, 0], [0, 1, 1, 1], [1, 0, 1, 0], [1, 1, 0, 0]])
>>> SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

```python
>>> from sage.all import *
>>> SimilarityClassType([[Integer(1), [Integer(2), Integer(2)]]]).invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
>>> A = Matrix(GF(Integer(2)),
  ...   [[0, 1, 0, 0], [0, 1, 1, 1], [1, 0, 1, 0], [1, 1, 0, 0]])
>>> SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

`is_regular ()`
Return `True` if every primary type in `self` has partition with one part.

**EXAMPLES:**

```python
sage: tau = SimilarityClassType([[2, [1]], [1, [3]]])
sage: tau.is_regular()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [3]]])
sage: tau.is_regular()
False
```
```python
>>> from sage.all import *
>>>
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]], [Integer(1), [Integer(3)]]])
>>> tau.is_regular()
True
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]], [Integer(1), [Integer(1), Integer(1)]]])
>>> tau.is_regular()
False
```

**is_semisimple()**

Return True if every primary similarity class type in self has all parts equal to 1.

**EXAMPLES:**
```
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_semisimple()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [2]]])
sage: tau.is_semisimple()
False
```

```python
>>> from sage.all import *
>>>
>>> tau = SimilarityClassType([[Integer(1), [Integer(1), Integer(1)]], [Integer(1), [Integer(1), Integer(2)]]])
>>> tau.is_semisimple()
False
```

**number_of_classes**(invertible=False, q=None)

Return the number of similarity classes of matrices of type self.

**INPUT:**
- **invertible** – Boolean; return number of invertible classes if set to True
- **q** – An integer or an indeterminate

**EXAMPLES:**
```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_classes()
1/2*q^2 - 1/2*q
```

```python
>>> from sage.all import *
>>>
>>> tau = SimilarityClassType([Integer(1), [Integer(1), [Integer(1), Integer(1)]], [Integer(1), [Integer(1), Integer(1)]]])
>>> tau.number_of_classes()
1/2*q^2 - 1/2*q
```

**number_of_matrices**(invertible=False, q=None)

Return the number of matrices of type self.

**INPUT:**
- **invertible** – A boolean; return the number of invertible matrices if set

5.1 Comprehensive Module List
EXAMPLES:

```python
sage: tau = SimilarityClassType([[1, [1]]])
sage: tau.number_of_matrices()
q
sage: tau.number_of_matrices(invertible = True)
q - 1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

```python
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]]])
>>> tau.number_of_matrices()
q
>>> tau.number_of_matrices(invertible = True)
q - 1
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1), [Integer(1)]]])
>>> tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

**rcf()**

Return the partition corresponding to the rational canonical form of a matrix of type `self`.

**EXAMPLES:**

```python
sage: tau = SimilarityClassType([[2, [1, 1, 1]], [1, [3, 2]]])
>>> tau.rcf()
[5, 4, 2]
```

```python
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1), Integer(1)]], [Integer(1), [Integer(3), Integer(2)]]])
>>> tau.rcf()
[5, 4, 2]
```

**size()**

Return the sum of the sizes of the primary parts of `self`.

**EXAMPLES:**

```python
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.size()
24
```

```python
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(3), [Integer(3), Integer(2), Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]])
>>> tau.size()
24
```

**statistic**(func, q=None)

Return

\[
\prod_{(d,\lambda) \in \tau} n_\lambda(q^d)
\]
where \( n_\lambda(q) \) is the value returned by \( \text{func} \) on the input \( \lambda \).

**INPUT:**
- \( \text{func} \) – a function that takes a partition to a polynomial in \( q \)
- \( q \) – an integer or an indeterminate

**EXAMPLES:**

```python
sage: tau = SimilarityClassType([[1, [1]], [1, [2, 1]], [2, [1, 1]]])
sage: from sage.combinat.similarity_class_type import fq
sage: tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
sage: q = ZZ['q'].gen()
sage: tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

```python
>>> from sage.all import *
>>> tau = SimilarityClassType([[(Integer(1), [Integer(1)])], [Integer(2), [Integer(1), Integer(1)]], [Integer(2), [Integer(1), Integer(1), Integer(1)]]])
>>> from sage.combinat.similarity_class_type import fq
>>> tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
>>> q = ZZ['q'].gen()
>>> tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

**class** `sage.combinat.similarity_class_type.SimilarityClassTypes(n, min)`

**Bases:** `UniqueRepresentation, Parent`

Class of all similarity class types of size \( n \) with all primary matrix types greater than or equal to the primary matrix type \( \text{min} \).

A similarity class type is a multiset of primary matrix types.

**INPUT:**
- \( n \) – a non-negative integer
- \( \text{min} \) – a primary similarity class type

**EXAMPLES:**

If \( \text{min} \) is not specified, then the class of all matrix types of size \( n \) is constructed:

```python
sage: M = SimilarityClassTypes(2)
sage: for tau in M:
    ...:     print(tau)
[[[1, [1]], [1, [1]]]]
[[[1, [2]]]]
[[[1, [1, 1]]]]
[[[2, [1]]]]
```

```python
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2))
>>> for tau in M:
...     print(tau)
[[[1, [1]], [1, [1]]]]
[[[1, [2]]]]
```

(continues on next page)
If \( \text{min} \) is specified, then the class consists of only those similarity class types which are multisets of primary matrix types which either have size greater than that of \( \text{min} \), or if they have size equal to that of \( \text{min} \), then they occur after \( \text{min} \) in the iterator for \text{PrimarySimilarityClassTypes}(n)\), where \( n \) is the size of \( \text{min} \):

```python
sage: M = SimilarityClassTypes(2, min = [1, [1, 1]])
sage: for tau in M:
    print(tau)
[[1, [1, 1]]]
[[2, [1]]]
```

Element

alias of \text{SimilarityClassType}

\text{size}()\n
Return size of \text{self}.

EXAMPLES:

```python
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.parent().size()
24
```

\text{sum}(\text{stat}, \text{sumover}='\text{matrices}', \text{invertible}=\text{False}, \text{q}=\text{None})\n
Return the sum of a local statistic over all types.

Given a set of functions \( n_{\lambda}(q) \) (these could be polynomials or rational functions in \( q \)), for each similarity class type \( \tau \) define

\[
n_{\tau}(q) = \prod_{(d,\lambda) \in \tau} n_{\lambda}(q^d).
\]

This function returns

\[
\sum n_{\tau(g)}(q)
\]

where \( \tau(g) \) denotes the type of a matrix \( g \), and the sum is over all \( n \times n \) matrices if \text{sumover} is set to "matrices", is over all \( n \times n \) similarity classes if \text{sumover} is set to "classes", and over all \( n \times n \) types if \text{sumover} is set to "types". If \text{invertible} is set to \text{True}, then the sum is only over invertible matrices or classes.

INPUT:
• \texttt{stat} – a function which takes partitions and returns a function of \( q \)

• \texttt{sumover} – can be one of the following:
  - "matrices"
  - "classes"
  - "types"

• \( q \) – an integer or an indeterminate

\textbf{OUTPUT:}

A function of \( q \).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: M = SimilarityClassTypes(2)
sage: M.sum(lambda la:1)
q^4
sage: M.sum(lambda la:1, invertible = True)
q^4 - q^3 - q^2 + q
sage: M.sum(lambda la:1, sumover = "classes")
q^2 + q
sage: M.sum(lambda la:1, sumover = "classes", invertible = True)
q^2 - 1
\end{verbatim}

Burside’s lemma can be used to calculate the number of similarity classes of matrices:

\begin{verbatim}
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2))
>>> M.sum(lambda la:Integer(1))
q^4
>>> M.sum(lambda la:Integer(1), invertible = True)
q^4 - q^3 - q^2 + q
>>> M.sum(lambda la:Integer(1), sumover = "classes")
q^2 + q
>>> M.sum(lambda la:Integer(1), sumover = "classes", invertible = True)
q^2 - 1
\end{verbatim}

sage.combinat.similarity_class_type.centralizer_algebra_dim()
Return the dimension of the centralizer algebra in \( M_n(F_q) \) of a nilpotent matrix whose Jordan blocks are given by \( \text{la} \).

\textbf{EXAMPLES:}
Combinatorics, Release 10.4

```python
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim
sage: centralizer_algebra_dim(Partition([2, 1]))
5

>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_algebra_dim
>>> centralizer_algebra_dim(Partition([Integer(2), Integer(1)]))
5
```

**Note:** If it is a list, `la` is expected to be sorted in decreasing order.

`sage.combinat.similarity_class_type.centralizer_group_cardinality (q=None)`

Return the cardinality of the centralizer group in $GL_n(F_q)$ of a nilpotent matrix whose Jordan blocks are given by `la`.

**INPUT:**
- `lambda` — a partition
- `q` — an integer or an indeterminate

**OUTPUT:**
A polynomial function of `q`.

**EXAMPLES:**

```python
sage: from sage.combinat.similarity_class_type import centralizer_group_cardinality
sage: q = ZZ['q'].gen()
sage: centralizer_group_cardinality(Partition([2, 1]))
q^5 - 2*q^4 + q^3

>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_group_cardinality
>>> q = ZZ['q'].gen()
>>> centralizer_group_cardinality(Partition([Integer(2), Integer(1)]))
q^5 - 2*q^4 + q^3
```

`sage.combinat.similarity_class_type.dictionary_from_generator (gen)`

Given a generator for a list of pairs $(c, f)$, construct a dictionary whose keys are the distinct values for $c$ and whose value at $c$ is the sum of $f$ over all pairs of the form $(c', f)$ such that $c = c'$.

**EXAMPLES:**

```python
sage: from sage.combinat.similarity_class_type import dictionary_from_generator
sage: dictionary_from_generator(((x // 2, x) for x in range(10)))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}

>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import dictionary_from_generator
>>> dictionary_from_generator(((x // Integer(2), x) for x in range(Integer(10))))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

It also works with lists:
Combinatorics, Release 10.4

```python
sage: dictionary_from_generator([(x // 2, x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

Note: Since the generator is first converted to a list, memory usage could be high.

```python
>>> from sage.all import *
>>> dictionary_from_generator([(x // Integer(2), x) for x in range(Integer(10))])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

```
sage.combinat.similarity_class_type.ext_orbit_centralizers (input_data, q=None, selftranspose=False)

Generate pairs consisting of centralizer cardinalities of orbits in Ext^1(M, M) for the action of Aut(M, M), where M is the \( F_{q[t]} \)-module constructed from input and their frequencies.

INPUT:

- input_data – input for input_parsing()
- q – (default: \( q \)) an integer or an indeterminate
- selftranspose – (default: False) boolean stating if we only want selftranspose type
```

```
sage.combinat.similarity_class_type.ext_orbits (input_data, q=None, selftranspose=False)

Return the number of orbits in Ext^1(M, M) for the action of Aut(M, M), where M is the \( F_{q[t]} \)-module constructed from input_data.

INPUT:

- input_data – input for input_parsing()
- q – (default: \( q \)) an integer or an indeterminate
- selftranspose – (default: False) boolean stating if we only want selftranspose type
```

```
sage.combinat.similarity_class_type fq (q=None)

Return \((1 - q^{-1})(1 - q^{-2}) \cdots (1 - q^{-n})\).

INPUT:

- n – a non-negative integer
- q – an integer or an indeterminate

OUTPUT:

A rational function in q.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import fq
sage: fq(0)
1
sage: fq(3)
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import fq
>>> fq(Integer(0))
1
```
```
Combinatorics, Release 10.4

>>> fq(Integer(3))
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6

sage.combinat.similarity_class_type.inputParsing(data)
Recognize and return the intended type of input.

sage.combinat.similarity_class_type.invariant_subspace_generating_function(la, q=None, t=None)
Return the invariant subspace generating function of a nilpotent matrix with Jordan block sizes given by la.

INPUT:
• la – a partition
• q – (optional) an integer or an inderminate
• t – (optional) an indeterminate

OUTPUT:
A polynomial in t whose coefficients are polynomials in q.

EXAMPLES:

sage: from sage.combinat.similarity_class_type import invariant_subspace_generating_function
sage: invariant_subspace_generating_function([2,2])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1

sage.combinat.similarity_class_type.matrix_centralizer_cardinalities(n, q=None, invertible=False)
Generate pairs consisting of centralizer cardinalities of matrices over a finite field and their frequencies.

sage.combinat.similarity_class_type.matrix_centralizer_cardinalities_length_two(n, q=None, selftranspose=False, invertible=False)
Generate pairs consisting of centralizer cardinalities of matrices over a principal ideal local ring of length two with residue field of order q and their frequencies.

INPUT:
• n – the order
• q – (default: q) an integer or an indeterminate
• selftranspose – (default: False) boolean stating if we only want selftranspose type
• invertible – (default: False) boolean stating if we only want invertible type

```
sage.combinat.similarity_class_type.matrix_similarity_classes(n, q=None, invertible=False)
```

Return the number of matrix similarity classes over a finite field of order q.

```
sage.combinat.similarity_class_type.matrix_similarity_classes_length_two(n, q=None, selftranspose=False, invertible=False)
```

Return the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two.

**INPUT:**
- n – the order
- q – (default: q) an integer or an indeterminate
- selftranspose – (default: False) boolean stating if we only want selftranspose type
- invertible – (default: False) boolean stating if we only want invertible type

**EXAMPLES:**

We can generate Table 6 of [PSS13]:

```
sage: from sage.combinat.similarity_class_type import matrix_similarity_classes_length_two
sage: matrix_similarity_classes_length_two(2)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, invertible = True)
q^4 - q
sage: matrix_similarity_classes_length_two(3)
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
sage: matrix_similarity_classes_length_two(3, invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
sage: matrix_similarity_classes_length_two(4)
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
sage: matrix_similarity_classes_length_two(4, invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import matrix_similarity_classes_length_two
>>> matrix_similarity_classes_length_two(Integer(2))
q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(2), invertible = True)
q^4 - q
>>> matrix_similarity_classes_length_two(Integer(3))
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
>>> matrix_similarity_classes_length_two(Integer(3), invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
>>> matrix_similarity_classes_length_two(Integer(4))
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
>>> matrix_similarity_classes_length_two(Integer(4), invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```
And also Table 7:

```python
sage: matrix_similarity_classes_length_two(2, selftranspose = True)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, selftranspose = True, invertible = True)
q^4 - q
sage: matrix_similarity_classes_length_two(3, selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3
sage: matrix_similarity_classes_length_two(3, selftranspose = True, invertible = True)
q^6 - q^3
sage: matrix_similarity_classes_length_two(4, selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(4, selftranspose = True, invertible = True)
q^8 + q^6 - q^5 - q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import order_of_general_linear_group
```

```
order_of_general_linear_group(0)
1
order_of_general_linear_group(Integer(2))
q^4 - q^3 - q^2 + q
```

```
order_of_general_linear_group(q=None)
```

Return the cardinality of the group of \( n \times n \) invertible matrices with entries in a field of order \( q \).

INPUT:

- \( n \) – a non-negative integer
- \( q \) – an integer or an indeterminate

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_group
sage: order_of_general_linear_group(0)
1
sage: order_of_general_linear_group(Integer(2))
q^4 - q^3 - q^2 + q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import order_of_general_linear_group
```
sage.combinat.similarity_class_type.primitives(invertible=False, q=None)

Return the number of similarity classes of simple matrices of order \( n \) with entries in a finite field of order \( q \). This is the same as the number of irreducible polynomials of degree \( d \).

If invertible is True, then only the number of similarity classes of invertible matrices is returned.

**Note:** All primitive classes are invertible unless \( n \) is 1.

**INPUT:**
- \( n \) – a positive integer
- invertible – boolean; if set, only number of non-zero classes is returned
- \( q \) – an integer or an indeterminate

**OUTPUT:**
- a rational function of the variable \( q \)

**EXAMPLES:**

```python
sage: from sage.combinat.similarity_class_type import primitives
sage: primitives(1)
q
sage: primitives(1, invertible = True)
q - 1
sage: primitives(4)
1/4*q^4 - 1/4*q^2
sage: primitives(4, invertible = True)
1/4*q^4 - 1/4*q^2
```

```python
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import primitives
>>> primitives(Integer(1))
q
>>> primitives(Integer(1), invertible = True)
q - 1
>>> primitives(Integer(4))
1/4*q^4 - 1/4*q^2
>>> primitives(Integer(4), invertible = True)
1/4*q^4 - 1/4*q^2
```

### 5.1.310 sine-Gordon Y-system plotter

This class builds the triangulations associated to sine-Gordon and reduced sine-Gordon Y-systems as constructed in [NS].

**AUTHORS:**
- Salvatore Stella (2014-07-18): initial version

**EXAMPLES:**

A reduced sine-Gordon example with 3 generations:

```python
sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.plot()    #not tested
```
The same integer tuple but for the non-reduced case:

```
sage: Y = SineGordonYsystem('D', (6,4,3)); Y
A sine-Gordon Y-system of type D with defining integer tuple (6, 4, 3)
sage: Y.plot()          #not tested
```

Todo: The code for plotting is extremely slow.

REFERENCES:

class sage.combinat.sine_gordon.SineGordonYsystem(X, na)

Bases: SageObject

A class to model a (reduced) sine-Gordon Y-system

Note that the generations, together with all integer tuples, in this implementation are numbered from 0 while in [NS] they are numbered from 1

INPUT:

- X – the type of the Y-system to construct (either ‘A’ or ‘D’)
- na – the tuple of positive integers defining the Y-system with na[0] > 2

See [NS]

EXAMPLES:

```
sage: Y = SineGordonYsystem('A', (6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.intervals()
(((0, 0, 'R'),),
  ((0, 17, 'L'),
   (17, 34, 'L'),
   ...
   (104, 105, 'R'),
  (105, 0, 'R')))  
sage: Y.triangulation()
((17, 89),
 (17, 72),
 (34, 72),
 ...
 (102, 105),
 (103, 105))
sage: Y.plot()          #not tested
```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3))); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
>>> Y.intervals()
((0, 0, 'R'),),
((0, 17, 'L'),
 (17, 34, 'L'),
 ... 
 (104, 105, 'R'),
 (105, 0, 'R')))  
>>> Y.triangulation()
((17, 89),
 (17, 72),
 (34, 72),
 ... 
 (102, 105),
 (103, 105))
>>> Y.plot()  #not tested

F()
Return the number of generations in self.

EXAMPLES:

sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.F()
3

intervals()
Return, divided by generation, the list of intervals used to construct the initial triangulation.

Each such interval is a triple (p, q, X) where p and q are the two extremal vertices of the interval and X is the type of the interval (one of 'L', 'R', 'NL', 'NR').

ALGORITHM:
The algorithm used here is the one described in section 5.1 of [NS]. The only difference is that we get rid of the special case of the first generation by treating the whole disk as a type 'R' interval.

EXAMPLES:

sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.intervals()
((0, 0, 'R'),),
((0, 17, 'L'),
 (17, 34, 'L'),
 ... 
 (104, 105, 'R'),
 (105, 0, 'R')))
na()

Return the sequence of the integers \( n_a \) defining \( \text{self} \).

EXAMPLES:

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.na()
(6, 4, 3)
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))
>>> Y.na()
(6, 4, 3)
```

pa()

Return the sequence of integers \( p_a \), i.e. the total number of intervals of types \('NL'\) and \('NR'\) in the \((a+1)\) -th generation.

EXAMPLES:

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.pa()
(1, 6, 25)
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))
>>> Y.pa()
(1, 6, 25)
```

plot(**kwds)

Plot the initial triangulation associated to \( \text{self} \).

INPUT:

- **radius** – the radius of the disk; by default the length of the circle is the number of vertices
- **points_color** – the color of the vertices; default ‘black’
- **points_size** – the size of the vertices; default 7
- **triangulation_color** – the color of the arcs; default ‘black’
- **triangulation_thickness** – the thickness of the arcs; default 0.5
- **shading_color** – the color of the shading used on neuter intervals; default ‘lightgray’
- **reflections_color** – the color of the reflection axes; default ‘blue’
- **reflections_thickness** – the thickness of the reflection axes; default 1

EXAMPLES:
qa()
Return the sequence of integers $q_a$, i.e. the total number of intervals of types 'L' and 'R' in the $(a+1)$-th generation.

EXAMPLES:

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.qa()
(6, 25, 81)
```

```python
from sage.all import *
Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))
Y.qa()
(6, 25, 81)
```

r()
Return the number of vertices in the polygon realizing `self`.

EXAMPLES:

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.r()
106
```

```python
from sage.all import *
Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))
Y.r()
106
```

rk()
Return the sequence of integers $r^{(k)}$, i.e. the width of an interval of type 'L' or 'R' in the $k$-th generation.

EXAMPLES:

```python
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.rk()
(106, 17, 4)
```

```python
from sage.all import *
Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))
Y.rk()
(106, 17, 4)
```

triangulation()
Return the initial triangulation of the polygon realizing `self` as a tuple of pairs of vertices.
**Warning:** In type 'D' the returned triangulation does NOT contain the two radii.

**ALGORITHM:**

We implement the four cases described by Figure 14 in [NS].

**EXAMPLES:**

```
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.triangulation()
((17, 89),
 (17, 72),
 ..., 
(102, 105),
(103, 105))
```

```
>>> from sage.all import *

>>> Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))

>>> Y.triangulation()
((17, 89),
 (17, 72),
 ..., 
(102, 105),
(103, 105))
```

**type()**

Return the type of `self`.

**EXAMPLES:**

```
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.type()
'A'
```

```
>>> from sage.all import *

>>> Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))

>>> Y.type()
'A'
```

**vertices()**

Return the vertices of the polygon realizing `self` as the ring of integers modulo `self.r()`.

**EXAMPLES:**

```
sage: Y = SineGordonYsystem('A', (6, 4, 3))
sage: Y.vertices()
Ring of integers modulo 106
```

```
>>> from sage.all import *

>>> Y = SineGordonYsystem('A', (Integer(6), Integer(4), Integer(3)))

>>> Y.vertices()
Ring of integers modulo 106
```
5.1.311 Six Vertex Model

 class sage.combinat.six_vertex_model.SixVertexConfiguration
     Bases: ClonableArray

     A configuration in the six vertex model.

     check()
         Check if self is a valid 6 vertex configuration.

     EXAMPLES:

         sage: M = SixVertexModel(3, boundary_conditions='ice')
         sage: M[0].check()

         >>> from sage.all import *
         >>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
         >>> M[Integer(0)].check()

     energy(epsilon)
         Return the energy of the configuration.

         The energy of a configuration \( \nu \) is defined as

         \[
         E(\nu) = n_0 \epsilon_0 + n_1 \epsilon_1 + \cdots + n_5 \epsilon_5
         \]

         where \( n_i \) is the number of vertices of type \( i \) and \( \epsilon_i \) is the \( i \)-th energy constant.

     Note: We number our configurations as:

         0. LR
         1. LU
         2. LD
         3. UD
         4. UR
         5. RD

     which differs from Wikipedia article Ice-type_model.

     EXAMPLES:

         sage: M = SixVertexModel(3, boundary_conditions='ice')
         sage: nu = M[2]; nu

         (continues on next page)
```python
sage: nu.energy([1,2,1,2,1,2])
15

>>> from sage.all import *

>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')

>>> nu = M[Integer(2)]; nu
```

```
--> # -> # <- # <--
^  |  
|  V |
--> # <- # -> # <--
|   ^ |
V   | V
--> # -> # <- # <--
|  |  |
V V V
```

```python
>>> nu.energy([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1),Integer(2)])
15
```

A KDP energy:

```python
sage: nu.energy([1,1,0,1,0,1])
7

>>> from sage.all import *

>>> nu.energy([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(1)])
7
```

A Rys F energy:

```python
sage: nu.energy([0,1,1,0,1,1])
4

>>> from sage.all import *

>>> nu.energy([Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(1)])
4
```

The zero field assumption:

```python
sage: nu.energy([1,2,3,1,3,2])
15

>>> from sage.all import *

>>> nu.energy([Integer(1),Integer(2),Integer(3),Integer(1),Integer(3),Integer(2)])
15
```

`plot(color='sign')`

Return a plot of :math:`self`.

INPUT:
• **color** – can be any of the following:
  
  - 4 – use 4 colors: black, red, blue, and green with each corresponding to up, right, down, and left respectively
  - 2 – use 2 colors: red for horizontal, blue for vertical arrows
  - 'sign' – use red for right and down arrows, blue for left and up arrows
  - a list of 4 colors for each direction
  - a function which takes a direction and a boolean corresponding to the sign

**EXAMPLES:**

```python
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: print(M[0].plot().description())
# needs sage.plot
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

```python
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), boundary_conditions='ice')
>>> print(M[Integer(0)].plot().description())
# needs sage.plot
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
```

**to_signed_matrix()**

Return the signed matrix of *self*.

The signed matrix corresponding to a six vertex configuration is given by 0 if there is a cross flow, a 1 if the outward arrows are vertical and −1 if the outward arrows are horizontal.

**EXAMPLES:**

```python
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: [x.to_signed_matrix() for x in M]
# needs sage.modules
[...]
```
class sage.combinat.six_vertex_model.SixVertexModel(n, m, boundary_conditions)

Bases: UniqueRepresentation, Parent

The six vertex model.

We model a configuration by indicating which configuration by the following six configurations which are determined by the two outgoing arrows in the Up, Right, Down, Left directions:

1. LR:

```
    \[ \begin{array}{ccc}
    \| & \| & \\
    \| & \| & \\
    \| & \| & \\
    \end{array} \]
```

2. LU:

```
    \[ \begin{array}{ccc}
    ^ & \| & \\
    | & \| & \\
    \| & \| & \\
    \end{array} \]
```

3. LD:

```
    \[ \begin{array}{ccc}
    \| & \| & \\
    \| & \| & \\
    \| & \| & \\
    \end{array} \]
```

4. UD:

```
    \[ \begin{array}{ccc}
    ^ & \| & \\
    | & \| & \\
    \| & \| & \\
    \end{array} \]
```

5. UR:
6. RD:

INPUT:

- \( n \) – the number of rows
- \( m \) – (optional) the number of columns, if not specified, then the number of columns is the number of rows
- `boundary_conditions` – (optional) a quadruple of tuples whose entries are either:
  - `True` for an inward arrow,
  - `False` for an outward arrow, or
  - `None` for no boundary condition.

There are also the following predefined boundary conditions:

- `'ice'` – The top and bottom boundary conditions are outward and the left and right boundary conditions are inward; this gives the square ice model. Also called domain wall boundary conditions.
- `'domain wall'` – Same as `'ice'`.
- `'alternating'` – The boundary conditions alternate between inward and outward.
- `'free'` – There are no boundary conditions.

EXAMPLES:

Here are the six types of vertices that can be created:

```python
sage: M = SixVertexModel(1)
sage: list(M)
```

```
^          ^          ^          ^          ^          ^
V          V          V          V          V          V
<-- # -->  <-- # -->  <-- # -->  <-- # -->  <-- # -->  <-- # -->

```

(continues on next page)
When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```python
sage: M = SixVertexModel(1, boundary_conditions='ice')
sage: len(M)
1
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: len(M)
42
```

An example with a specified non-standard boundary condition and non-rectangular shape:

```python
sage: M = SixVertexModel(2, 1, [[None], [True,True], [None], [None,None]])
sage: list(M)
```

(continues on next page)
REFERENCES:

- Wikipedia article Vertex_model
- Wikipedia article Ice-type_model

Element

alias of SixVertexConfiguration

boundary_conditions()

Return the boundary conditions of self.

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), boundary_conditions='ice')
>>> M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

partition_function(beta, epsilon)

Return the partition function of self.

The partition function of a 6 vertex model is defined by:

\[ Z = \sum_{\nu} e^{-\beta E(\nu)} \]

where we sum over all configurations and \( E \) is the energy function. The constant \( \beta \) is known as the inverse temperature and is equal to \( 1/k_B T \) where \( k_B \) is Boltzmann's constant and \( T \) is the system's temperature.

INPUT:

- beta – the inverse temperature constant \( \beta \)
- epsilon – the energy constants, see energy()

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M.partition_function(2, [1,2,1,2,1,2])
# needs sage.symbolic
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> M.partition_function(Integer(2), [Integer(1),Integer(2),Integer(1),Integer(2),Integer(1),Integer(2)])
# needs...
# sage.symbolic
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```
class sage.combinat.six_vertex_model.SquareIceModel(n)
Bases: SixVertexModel

The square ice model.

The square ice model is a 6 vertex model on an $n \times n$ grid with the boundary conditions that the top and bottom boundaries are pointing outward and the left and right boundaries are pointing inward. These boundary conditions are also called domain wall boundary conditions.

Configurations of the 6 vertex model with domain wall boundary conditions are in bijection with alternating sign matrices.

class Element
Bases: SixVertexConfiguration

An element in the square ice model.

to_alternating_sign_matrix()

Return an alternating sign matrix of self.

See also:

to_signed_matrix()

EXAMPLES:

sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: M[6].to_alternating_sign_matrix() # needs sage.modules
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
sage: M[7].to_alternating_sign_matrix() # needs sage.modules
[ 0 1 0 0]
[ 1 -1 1 0]
[ 0 1 -1 1]
[ 0 0 1 0]

>>> from sage.all import *

>>> M = SixVertexModel(Integer(4), boundary_conditions='ice')

>>> M[Integer(6)].to_alternating_sign_matrix() # needs sage.modules
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]

>>> M[Integer(7)].to_alternating_sign_matrix() # needs sage.modules
[ 0 1 0 0]
[ 1 -1 1 0]
[ 0 1 -1 1]
[ 0 0 1 0]
**from_alternating_sign_matrix** *(asm)*

Return a configuration from the alternating sign matrix *asm*.

**EXAMPLES:**

```sage
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])
# needs sage.modules
sage: M.from_alternating_sign_matrix(asm)
# needs sage.modules
```

```
^ ^ ^
| | | --> # -> # <- # <--
^ | ^ | V |
--> # <- # -> # <--
| ^ | V |
--> # <- # <- # <--
| | | V V V
```

```sage
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> asm = AlternatingSignMatrix([[Integer(0),Integer(1),Integer(0)],
# needs sage.modules
[Integer(1),-Integer(1),Integer(1)],[Integer(0),Integer(1),Integer(0)])
# needs sage.modules
>>> M.from_alternating_sign_matrix(asm)
# needs sage.modules
```

```
^ ^ ^
| | | --> # -> # <- # <--
| V |
--> # <- # -> # <--
| ^ | V |
--> # <- # <- # <--
| | | V V V
```

### 5.1.312 Skew Partitions

A skew partition $s kp$ of size $n$ is a pair of partitions $[p_1, p_2]$ where $p_1$ is a partition of the integer $n_1$, $p_2$ is a partition of the integer $n_2$, $p_2$ is an inner partition of $p_1$, and $n = n_1 - n_2$. We say that $p_1$ and $p_2$ are respectively the *inner* and *outer* partitions of $s kp$.

A skew partition can be depicted by a diagram made of rows of cells, in the same way as a partition. Only the cells of the outer partition $p_1$ which are not in the inner partition $p_2$ appear in the picture. For example, this is the diagram of the skew partition $[[5,4,3,1],[3,3,1]]$.

```sage
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).diagram())
**
* **
* **
```
A skew partition can be *connected*, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge. This is the diagram of the connected skew partition $[[5,4,3,1], [3,1]]$:

```python
sage: print(SkewPartition([[5,4,3,1], [3,1]]).diagram())
```

```text
**
***
```

```python
>> from sage.all import *
>> print(SkewPartition([[Integer(5), Integer(4), Integer(3), Integer(1)], [Integer(3), Integer(3), Integer(1)]]).diagram())
```

```text
**
*
```

```python
>> from sage.all import *
>> print(SkewPartition([[Integer(5), Integer(4), Integer(3), Integer(1)], [Integer(3), Integer(3), Integer(1)]]).diagram())
```

```text
**
*
```

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the *conjugate skew partition*, here $[[4,3,3,2,1], [3,3,2]]$:

```python
sage: SkewPartition([[5,4,3,1], [3,3,1]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
sage: print(SkewPartition([[5,4,3,1], [3,3,1]]).conjugate().diagram())
```

```text
*
*
*
```

```python
>> from sage.all import *
>> print(SkewPartition([[Integer(5), Integer(4), Integer(3), Integer(1)], [Integer(3), Integer(3), Integer(1)]]).conjugate().diagram())
```

```text
*
*
*
```
The *outer corners* of a skew partition are the corners of its outer partition. The *inner corners* are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

```python
sage: SkewPartition(([5, 4, 3, 1], [3, 3, 1])).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
sage: SkewPartition(([5, 4, 3, 1], [3, 3, 1])).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

**EXAMPLES:**

There are 9 skew partitions of size 3, with no empty row nor empty column:

```python
sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[3] / []],
[2, 1] / [],
[3, 1] / [1],
[2, 2] / [1],
[3, 2] / [2],
[1, 1, 1] / [],
[2, 2, 1] / [1, 1],
[2, 1, 1] / [1],
[3, 2, 1] / [2, 1]]
```

There are 4 connected skew partitions of size 3:

```python
sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()
[[3] / []],
[2, 1] / [],
[3, 1] / [1],
[2, 2] / [1],
[3, 2] / [2],
[1, 1, 1] / [],
[2, 2, 1] / [1, 1],
[2, 1, 1] / [1],
[3, 2, 1] / [2, 1]]
```

(continues on next page)
This is the conjugate of the skew partition \([4, 3, 1], [2]\]

\[
\text{sage: SkewPartition}([[4, 3, 1], [2]]).conjugate()
\]

\[
[3, 2, 2, 1] / [1, 1]
\]

Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

\[
\text{sage: SkewPartition}([[4, 3, 1], [2]]).conjugate().conjugate()
\]

\[
\]

The \text{jacobi_trudi()} method computes the Jacobi-Trudi matrix. See \cite{Mac1995} for a definition and discussion.

\[
\text{sage: SkewPartition}([[4, 3, 1], [2]]).\text{jacobi_trudi()}\]

\[
\begin{bmatrix}
\end{bmatrix}
\]

This example shows how to compute the corners of a skew partition.

\[
\text{sage: SkewPartition}([[4, 3, 1], [2]]).\text{inner_corners()}
\]

\[
[(0, 2), (1, 0)]
\]

\[
\text{sage: SkewPartition}([[4, 3, 1], [2]]).\text{outer_corners()}
\]

\[
[(0, 3), (1, 2), (2, 0)]
\]

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw (2013-02-11): Factored out CombinatorialClass
A skew partition of shape $\lambda/\mu$ is the Young diagram from the partition $\lambda$ and removing the partition $\mu$ from the upper-left corner in English convention.

**cell_poset** (orientation='SE')

Return the Young diagram of *self* as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of *self* as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to "SE"). Concretely, `orientation` has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for “northwest”, “northeast”, “southwest” and “southeast”, respectively. If `orientation` is "SE", then the order relation of the poset is such that a cell $u$ is greater or equal to a cell $v$ in the poset if and only if $u$ lies weakly southeast of $v$ (this means that $u$ can be reached from $v$ by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of *self*, written as tuples of zero-based coordinates (so that (3, 7) stands for the 8-th cell of the 4-th row, etc.).

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: p = SkewPartition([[3,3,1], [2,1]])
sage: Q = p.cell_poset(); Q
Finite poset containing 4 elements
sage: sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: sorted(Q.minimal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(Q.upper_covers((1, 1)))
[(1, 2)]
sage: sorted(Q.upper_covers((0, 2)))
[(1, 2)]
```

```python
sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
sage: sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
```

```python
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
sage: sorted(R)
```

(continues on next page)
Return the coordinates of the cells of self. Coordinates are given as (row-index, column-index) and are 0 based.
EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[4, 3, 1], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[2], []]).cells()
[(0, 0), (0, 1)]
```

```
>>> from sage.all import *

>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> SkewPartition([[Integer(2)], []]).cells()
[(0, 0), (0, 1)]
```

column_lengths()

Return the column lengths of `self`.

EXAMPLES:

```
sage: SkewPartition([[3, 2, 1], [1, 1]]).column_lengths()
[1, 2, 1]
sage: SkewPartition([[5, 2, 2, 2], [2, 1]]).column_lengths()
[2, 3, 1, 1, 1]
```

```
>>> from sage.all import *

>>> skp = SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(2), Integer(1)]]
>>>
>>> cells = Set([ (Integer(0), Integer(0)), (Integer(0), Integer(1)), (Integer(1), Integer(0)), (Integer(1), Integer(1)), (Integer(2), Integer(0)), (Integer(2), Integer(1))])
>>> skp.columns_intersection_set() == cells
True
```

columns_intersection_set()

Return the set of cells in the columns of the outer shape of `self` which columns intersect the skew diagram of `self`.

EXAMPLES:

```
sage: skp = SkewPartition([[3, 2, 1], [2, 1]])
sage: cells = Set([ (0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (2, 0)])
sage: skp.columns_intersection_set() == cells
True
```

conjugate()
Return the conjugate of the skew partition $skp$.

**EXAMPLES:**

```python
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[[3, 2, 1] / [1, 1]]
```

```python
>>> from sage.all import *

>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2)]]).conjugate()
[[3, 2, 1] / [1, 1]]
```

diagram()

Return the Ferrers diagram of $self$.

**EXAMPLES:**

```python
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
** *
*** *
```

```python
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
** *** *
```

```python
sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
###
```

```python
>>> from sage.all import *

>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),Integer(1)]]).ferrers_diagram())
** *
```

```python
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),Integer(1)]]).diagram())
** *** *
```

```python
>>> SkewPartitions.options(diagram_str='#', convention="French")
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),Integer(1)]]).diagram())
#
###
```

>>> SkewPartitions.options._reset()
**ferrers_diagram()**

Return the Ferrers diagram of `self`.

**EXAMPLES:**

```sage
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
  **
  *  
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
  **
  ***
  ***
  *
sage: SkewPartitions.options(diagram_str='#', convention="French")
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
#
##
# #
sage: SkewPartitions.options._reset()
```

```python
>>> from sage.all import *
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
                     [Integer(3),Integer(3),Integer(1)]]).ferrers_diagram())
  **
  *  
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
                     [Integer(3),Integer(1)]]).diagram())
  **
  ***
  ***
  *
>>> SkewPartitions.options(diagram_str='#', convention="French")
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
                     [Integer(3),Integer(1)]]).diagram())
#
##
# #
```

**frobenius_rank()**

Return the Frobenius rank of the skew partition `self`.

The Frobenius rank of a skew partition $\lambda/\mu$ can be defined in various ways. The quickest one is probably the following: Writing $\lambda$ as $(\lambda_1, \lambda_2, \cdots, \lambda_N)$, and writing $\mu$ as $(\mu_1, \mu_2, \cdots, \mu_N)$, we define the Frobenius rank of $\lambda/\mu$ to be the number of all $1 \leq i \leq N$ such that

$$\lambda_i - i \not\in \{\mu_1 - 1, \mu_2 - 2, \cdots, \mu_N - N\}.$$ 

In other words, the Frobenius rank of $\lambda/\mu$ is the number of rows in the Jacobi-Trudi matrix of $\lambda/\mu$ which don’t contain $h_0$. Further definitions have been considered in [Sta2002] (where Frobenius rank is just being called rank).

5.1. Comprehensive Module List 4969
If $\mu$ is the empty shape, then the Frobenius rank of $\lambda/\mu$ is just the usual Frobenius rank of the partition $\lambda$ (see `frobenius_rank()`).

**EXAMPLES:**

```python
sage: SkewPartition([[8,8,7,4], [4,1,1]]).frobenius_rank()
4
sage: SkewPartition([[2,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1,1]]).frobenius_rank()
2
sage: SkewPartition([[5,4,3,2], [2,1,1]]).frobenius_rank()
3
sage: SkewPartition([[4,2,1], [3,1,1]]).frobenius_rank()
2
sage: SkewPartition([[4,2,1], [3,2,1]]).frobenius_rank()
1
```

If the inner shape is empty, then the Frobenius rank of the skew partition is just the standard Frobenius rank of the partition:

```python
>>> from sage.all import *
>>> all( SkewPartition([lam, Partition([])]).frobenius_rank() == lam.frobenius_rank() for i in range(6) for lam in Partitions(i) )
True
```

If the inner and outer shapes are equal, then the Frobenius rank is zero:

```python
>>> from sage.all import *
>>> all( SkewPartition([lam, Partition([])]).frobenius_rank() == lam.frobenius_rank() for i in range(Integer(6)) for lam in Partitions(i) )
True
```
Combinatorics, Release 10.4

```
sage: all( SkewPartition([lam, lam]).frobenius_rank() == 0
.....:   for i in range(6) for lam in Partitions(i) )
True

>>> from sage.all import *
>>> all( SkewPartition([lam, lam]).frobenius_rank() == Integer(0)
...   for i in range(Integer(6)) for lam in Partitions(i) )
True

inner()

Return the inner partition of self.

EXAMPLES:

sage: SkewPartition([[3,2,1],[1,1]]).inner()
[1, 1]

>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
˓→Integer(1)]]).inner()
[1, 1]

inner_corners()

Return a list of the inner corners of self.

EXAMPLES:

sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4, 3, 1], []]).inner_corners()
[(0, 0)]

>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)],[Integer(2)]]).inner_˓→corners()
[(0, 2), (1, 0)]
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], []]).inner_corners()
[(0, 0)]

is_connected()

Return True if self is a connected skew partition.

A skew partition is said to be connected if for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge.

EXAMPLES:

sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_connected()
False
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True

>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
˓→Integer(3),Integer(1)]]).is_connected()
False

(continues on next page)
is_overlap\( (n) \)

Return True if the overlap of self is at most n.

See also:

\( \text{overlap()} \)

EXAMPLES:

```python
sage: SkewPartition([[5, 4, 3, 1], [3, 1]]).is_overlap(1)
True
```

```python
>>> from sage.all import *
```
**sage:** P.is_ribbon()
True

**sage:** P = SkewPartition([[4,4,3,3],[4,2,2]])
**sage:** P.pp()

**sage:** P.is_ribbon()
True

**sage:** SkewPartition([[2,2,1],[2,2,1]]).is_ribbon()
True

```python
>>> from sage.all import *
```
```python
>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
                    [Integer(3),Integer(2),Integer(2)]])
>>> P.pp()
```
```python
>>> P.is_ribbon()
True
```
```python
>>> P = SkewPartition([[Integer(4),Integer(3),Integer(3)],[Integer(1),
                    [Integer(3),Integer(2),Integer(2)]]])
>>> P.pp()
```
```python
```
>>> P.is_ribbon()
False
```
```python
>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(2)],
                    [Integer(3),Integer(2),Integer(2),Integer(1)]])
>>> P.pp()
```
```python
```
>>> P.is_ribbon()
False
```
```python
>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
                    [Integer(4),Integer(2),Integer(2),Integer(1)]])
>>> P.pp()
```
```python
<BLANKLINE>
```
>>> P.is_ribbon()
```
```
**jacobi_trudi()**

Return the Jacobi-Trudi matrix of `self`.

**EXAMPLES:**

```python
sage: SkewPartition([[3, 2, 1], [2, 1]]).jacobi_trudi() # needs sage.modules
[h[1]  0  0]
```

```python
sage: SkewPartition([[4, 3, 2], [2, 1]]).jacobi_trudi() # needs sage.modules
[h[2] h[]  0]
```

```python
>>> from sage.all import *
```
>>> from sage.all import *

>>> SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(2), Integer(1)]]).k_conjugate(Integer(3))
[2, 1, 1, 1, 1] / [2, 1]

>>> SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(2), Integer(1)]]).k_conjugate(Integer(4))
[2, 2, 1, 1] / [2, 1]

>>> SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(2), Integer(1)]]).k_conjugate(Integer(5))
[3, 2, 1] / [2, 1]

outer()

Return the outer partition of self.

EXAMPLES:

sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]

outer_corners()

Return a list of the outer corners of self.

These are corners that are contained inside of the shape. For the corners which are outside of the shape, use outside_corners().

Warning: In the case that self is an honest (rather than skew) partition, these are the corners() of the outer partition. In the language of [Sag2001] these would be the “inner corners” of the outer partition.

See also:

• sage.combinat.skew_partition.SkewPartition.outside_corners()
• sage.combinat.partition.Partition.outside_corners()

EXAMPLES:

sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]

outside_corners()

Return the outside corners of self.

The outside corners are corners which are outside of the shape. This should not be confused with outer_corners() which consists of corners inside the shape. It returns a result analogous to the outside_corners() method on (non-skew) Partitions.
See also:

- `sage.combinat.skew_partition.SkewPartition.outer_corners()`
- `sage.combinat.partition.Partition.outside_corners()

EXAMPLES:

```python
sage: mu = SkewPartition([[3,2,1],[2,1]])
sage: mu.pp()
* *
*
...
sage: mu.outside_corners()
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

```python
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2), Integer(1)])
>>> mu.pp()
* *
*
>>> mu.outside_corners()
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

**overlap()**

Return the overlap of `self`.

The overlap of two consecutive rows in a skew partition is the number of pairs of cells (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called *connected*.

EXAMPLES:

```python
sage: SkewPartition([[],[]]).overlap()
+Infinity
sage: SkewPartition([[1],[[1]].overlap()
+Infinity
sage: SkewPartition([[10],[[1]].overlap()
+Infinity
sage: SkewPartition([[10],[2]].overlap()
+Infinity
sage: SkewPartition([[10,1],[2]].overlap()
-1
sage: SkewPartition([[10,10],[1]].overlap()
9
```

```python
>>> from sage.all import *
>>> SkewPartition([[],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(1)],[1]].overlap()
+Infinity
>>> SkewPartition([[Integer(10)],[1]].overlap()
+Infinity
>>> SkewPartition([[Integer(10)],[Integer(2)]].overlap()
```

(continues on next page)
Computation of the coefficients which appear in the Pieri formula for Macdonald polynomials given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).pieri_macdonald_coeffs()
1

sage: SkewPartition([[3,2,1],[2,2]]).pieri_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)

sage: SkewPartition([[3,3,2],[3,2,1]]).pieri_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^3*t^4 + q*t^5 - q^3*t^2 + q^2*t^3 - q*t^3 - q^2*t - t^2 + 1)/(q^6*t^8 - q^5*t^7 - q^5*t^6 + q^4*t^5 + 2*q^3*t^4 + q^3*t^3 - q^2*t^2 - q*t^2 - q*t + 1)
```

pp()

Pretty-print self.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).pp()
**
*  
**
*  
```
quotient($k$)
The quotient map extended to skew partitions.

EXAMPLES:
```
sage: SkewPartition([[3, 3, 2, 1], [2, 1]]).quotient(2)
[[3] / [], [] / []]
```

row_lengths()
Return the row lengths of self.

EXAMPLES:
```
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set()
Return the set of cells in the rows of the outer shape of self which rows intersect the skew diagram of self.

EXAMPLES:
```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([(0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.rows_intersection_set() == cells
True
```

size()
Return the size of self.
EXAMPLES:

```sage
sage: SkewPartition([[3,2,1],[1,1]]).size()
4
```

```python
>>> from sage.all import *
>>>
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
˓→Integer(1)]]).size()
4
```

`specht_module (base_ring=None)`

Return the Specht module corresponding to self.

EXAMPLES:

```sage
sage: mu = SkewPartition([[3,2,1], [2]])
sage: SM = mu.specht_module(QQ)  # needs sage.modules
sage: s = SymmetricFunctions(QQ).s()  # needs sage.modules
sage: s(SM.frobenius_image())  # needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```python
>>> from sage.all import *
>>>
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2)]]
˓→)
>>> SM = mu.specht_module(QQ)  # needs sage.modules
>>> s = SymmetricFunctions(QQ).s()  # needs sage.modules
>>> s(SM.frobenius_image())  # needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

We verify that the Frobenius image is the corresponding skew Schur function:

```python
>>> from sage.all import *
>>>
>>> s=Integer(3),Integer(2),Integer(1)]).skew_by(s=Integer(2))  # needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1]
```

```sage
sage: mu = SkewPartition([[4,2,1], [2,1]])
sage: SM = mu.specht_module(QQ)  # needs sage.modules
sage: s(SM.frobenius_image())  # needs sage.modules
sage: s(mu)  # needs sage.modules
```
```python
>>> from sage.all import *

>>> mu = SkewPartition([[Integer(4), Integer(2), Integer(1)], [Integer(2), Integer(1)]])

>>> SM = mu.specht_module(QQ)  # needs sage.modules

>>> s(SM.frobenius_image())  # needs sage.modules

>>> s(mu)  # needs sage.modules
```

**specht_module_dimension** *(base_ring=)*

Return the dimension of the Specht module corresponding to `self`.

This is equal to the number of standard (skew) tableaux of shape `self`.

**EXAMPLES:**

```
sage: mu = SkewPartition([[3, 2, 1], [2]])
sage: mu.specht_module_dimension()  # needs sage.modules
8
sage: mu.specht_module_dimension(GF(2))  # needs sage.modules sage.rings.finite_rings
8
```

```python
>>> from sage.all import *

>>> mu = SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(2)]])

>>> mu.specht_module_dimension()  # needs sage.modules sage.rings.finite_rings
8
```

**to_dag** *(format=)*

Return a directed acyclic graph corresponding to the skew partition `self`.

The directed acyclic graph corresponding to a skew partition `p` is the digraph whose vertices are the cells of `p`, and whose edges go from each cell to its lower and right neighbors (in English notation).

**INPUT:**

- `format` – either 'string' or 'tuple' (default: 'string'); determines whether the vertices of the resulting dag will be strings or 2-tuples of coordinates

**EXAMPLES:**

```
sage: dag = SkewPartition([[3, 3, 1], [1, 1]]).to_dag()
sage: dag.edges(sort=True)
[('0', '1', '0', '2', None),
 ('0', '1', '1', '1', None),
 ('0', '2', '1', '2', None),
 ('1', '1', '1', '2', None)]
sage: dag.vertices(sort=True)
['0', '1', '0', '2', '1', '1', '1', '2', '2', '0']
```

(continues on next page)
### Example

```python
class sage.combinat.skew_partition.SkewPartitions(is_infinite=False):
    Bases: UniqueRepresentation, Parent

Skew partitions.

**Warning:** The iterator of this class only yields skew partitions which are reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column.

**Examples:**

```sage
s = SkewPartitions(4)
s
```
Skew partitions of 4

```sage
s.to_list()
```
```python
[[4, 3, 1], [2]]
```

```sage
type(s.to_list())
```
```
<class 'list'>
```
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
Skew partitions of 4 with a minimum overlap of 2
sage: SkewPartitions(4, overlap=2).list()

>>> from sage.all import *

>>> SkewPartitions(Integer(4))
Skew partitions of 4
>>> SkewPartitions(Integer(4)).cardinality()
28
>>> SkewPartitions(row_lengths=[Integer(2),Integer(1),Integer(2)])
Skew partitions with row lengths [2, 1, 2]
>>> SkewPartitions(Integer(4), overlap=Integer(2))
Skew partitions of 4 with a minimum overlap of 2
>>> SkewPartitions(Integer(4), overlap=Integer(2)).list()

Element

alias of SkewPartition

from_row_and_column_length(rowL, colL)

Construct a partition from its row lengths and column lengths.

INPUT:

• rowL – A composition or a list of positive integers
• colL – A composition or a list of positive integers

OUTPUT:

• If it exists the unique skew-partitions with row lengths rowL and column lengths colL.
• Raise a ValueError if rowL and colL are not compatible.

EXAMPLES:

sage: S = SkewPartitions()
sage: print(S.from_row_and_column_length([3,1,2,2],[2,3,1,1]).diagram())
***
*
**
sage: S.from_row_and_column_length([],[])
[] / []
sage: S.from_row_and_column_length([1],[1])
[1] / []
sage: S.from_row_and_column_length([2,1],[2,1])
[2, 1] / []
sage: S.from_row_and_column_length([1,2],[1,2])
[2, 2] / []
sage: S.from_row_and_column_length([1,2],[1,3])
Traceback (most recent call last):
...
ValueError: sum mismatch: [1, 2] and [1, 3]

```
sage: S.from_row_and_column_length([3,2,1,2],[2,3,1,1,1])
Traceback (most recent call last):
...
ValueError: incompatible row and column length: [3, 2, 1, 2] and [2, 3, 1, 1, 1]
```

```
>>> from sage.all import *
>>> S = SkewPartitions()
>>> print(S.from_row_and_column_length([Integer(3),Integer(1),Integer(2),
   Integer(2)],[Integer(2),Integer(3),Integer(1),Integer(1),Integer(1)]).
   diagram())
***
**
**
>>> S.from_row_and_column_length([],[])
[] / []
>>> S.from_row_and_column_length([Integer(1)],[Integer(1)])
[1] / []
>>> S.from_row_and_column_length([Integer(2),Integer(1)],[Integer(2),
   Integer(1)])
[2, 1] / []
>>> S.from_row_and_column_length([Integer(1),Integer(2)],[Integer(1),
   Integer(2)])
[2, 2] / [1]
>>> S.from_row_and_column_length([Integer(1),Integer(2)],[Integer(1),
   Integer(3)])
Traceback (most recent call last):
...
ValueError: sum mismatch: [1, 2] and [1, 3]
```

```
>>> S.from_row_and_column_length([Integer(3),Integer(2),Integer(1),
   Integer(2)],[Integer(2),Integer(3),Integer(1),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: incompatible row and column length: [3, 2, 1, 2] and [2, 3, 1, 1, 1]
```

**Warning:** If some rows and columns have length zero, there is no way to retrieve unambiguously the skew partition. We therefore raise a `ValueError`. For examples here are two skew partitions with the same row and column lengths:

```
sage: skp1 = SkewPartition([[2,2],[2,2]])
sage: skp2 = SkewPartition([[2,1],[2,1]])
sage: skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
sage: skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
sage: SkewPartitions().from_row_and_column_length([0,0], [0,0])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```
```python
>>> from sage.all import *

skp1 = SkewPartition([[Integer(2), Integer(2)], [Integer(2), Integer(2)]])

skp2 = SkewPartition([[Integer(2), Integer(1)], [Integer(2), Integer(1)]])

skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])

skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])

SkewPartitions().from_row_and_column_length([Integer(0), Integer(0)],
˓→[Integer(0), Integer(0)])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```

```

diagram_str: * - display: quotient - latex: young_diagram -
latex_diagram_str: \ast - latex_marking_str: X

class sage.combinat.skew_partition.SkewPartitions_all
    Bases: SkewPartitions

    Class of all skew partitions.

class sage.combinat.skew_partition.SkewPartitions_n(n, overlap)
    Bases: SkewPartitions

    The set of skew partitions of n with overlap at least overlap and no empty row.

    INPUT:
    
    • n – a non-negative integer
    • overlap – an integer (default: 0)

    Caveat: this set is stable under conjugation only for overlap equal to 0 or 1. What exactly happens for negative overlaps is not yet well specified and subject to change (we may want to introduce vertical overlap constraints as well).

    Todo: As is, this set is essentially the composition of Compositions(n) (which give the row lengths) and SkewPartition(n, row_lengths=...), and one would want to “inherit” list and cardinality from this composition.

    cardinality()

    Return the number of skew partitions of the integer n (with given overlap, if specified; and with no empty rows before the last row).

    EXAMPLES:

    sage: SkewPartitions(0).cardinality()
    1
    sage: SkewPartitions(4).cardinality()
    28
    sage: SkewPartitions(5).cardinality()
    87
    sage: SkewPartitions(4, overlap=1).cardinality()
    9
```

(continues on next page)
sage: SkewPartitions(5, overlap=1).cardinality()
20
sage: s = SkewPartitions(5, overlap=-1)

>>> from sage.all import *

>>> SkewPartitions(Integer(0)).cardinality()
1
>>> SkewPartitions(Integer(4)).cardinality()
28
>>> SkewPartitions(Integer(5)).cardinality()
87
>>> SkewPartitions(Integer(4), overlap=Integer(1)).cardinality()
9
>>> SkewPartitions(Integer(5), overlap=Integer(1)).cardinality()
20
>>> s = SkewPartitions(Integer(5), overlap=-Integer(1))

>>> s = SkewPartitions(Integer(5), overlap=-Integer(1))

>>> s.cardinality() == len(s.list())
True

class sage.combinat.skew_partition.SkewPartitions_rowlengths(co, overlap)

Bases: SkewPartitions

All skew partitions with given row lengths.

5.1.313 Skew Tableaux

AUTHORS:
• Mike Hansen: Initial version
• Travis Scrimshaw, Arthur Lubovsky (2013-02-11): Factored out CombinatorialClass
• Trevor K. Karn (2022-08-03): added backward_slide
class sage.combinat.skew_tableau.SemistandardSkewTableaux (category=None)

Bases: SkewTableaux

Semistandard skew tableaux.

This class can be initialized with several optional variables: the size of the skew tableaux (as a nameless integer variable), their shape (as a nameless skew partition variable), their weight (weight(), as a nameless second variable after either the size or the shape) and their maximum entry (as an optional keyword variable called max_entry, unless the weight has been specified). If neither the weight nor the maximum entry is specified, the maximum entry defaults to the size of the tableau.

Note that “maximum entry” does not literally mean the highest entry; instead it is just an upper bound that no entry is allowed to surpass.

EXAMPLES:
The (infinite) class of all semistandard skew tableaux:

```
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux()
Semistandard skew tableaux
```

The (still infinite) class of all semistandard skew tableaux with maximum entry 2:

```
sage: SemistandardSkewTableaux(max_entry=2)
Semistandard skew tableaux with maximum entry 2
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(max_entry=Integer(2))
Semistandard skew tableaux with maximum entry 2
```

The class of all semistandard skew tableaux of given size 3 and maximum entry 3:

```
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3 and maximum entry 3
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3))
Semistandard skew tableaux of size 3 and maximum entry 3
```

To set a different maximum entry:

```
sage: SemistandardSkewTableaux(3, max_entry = 7)
Semistandard skew tableaux of size 3 and maximum entry 7
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3), max_entry = Integer(7))
Semistandard skew tableaux of size 3 and maximum entry 7
```

Specifying a shape:

```
sage: SemistandardSkewTableaux([[2,1],[1]])
Semistandard skew tableaux of shape [2, 1] / [] and maximum entry 3
```
Specifying both a shape and a maximum entry:

```python
>>> S = SemistandardSkewTableaux([[2,1],[1]], max_entry = 3); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
```

```python
sage: S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
 [[None, 1], [3]],
 [[None, 2], [2]],
 [[None, 3], [2]],
 [[None, 2], [3]],
 [[None, 3], [3]]]
```

```python
sage: for n in range(5):
    print("{} {}").format(n, len(SemistandardSkewTableaux([[2,2,1],[1]], max_entry = n)))
0 0
1 0
2 1
3 9
4 35
```

Specifying a shape and a weight:

```python
>>> S = SemistandardSkewTableaux([[2,1],[1]], [2,1])
Semistandard skew tableaux of shape [2, 1] / [1] and weight [2, 1]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

 SemistandardSkewTableaux([[Integer(2),Integer(1)],[],[Integer(2),Integer(1)]]
Semistandard skew tableaux of shape [2, 1] / [] and weight [2, 1]
```

(the maximum entry is redundant in this case and thus is ignored).

Specifying a size and a weight:

```python
sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

```python
>>> from sage.all import *

>>>
SemistandardSkewTableaux(Integer(3), [Integer(2),Integer(1)])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

**Warning:** If the shape is not specified, the iterator of this class yields only skew tableaux whose shape is reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column. (Otherwise it would go on indefinitely.)

**Warning:** This class acts as a factory. The resulting classes are mainly useful for iteration. Do not rely on their containment tests, as they are not correct, e.g.:

```python
sage: SkewTableau([[None]]) in SemistandardSkewTableaux(2)
True
```

```python
>>> from sage.all import *

>>> SkewTableau([[None]]) in SemistandardSkewTableaux(Integer(2))
True
```

```python
class sage.combinat.skew_tableau.SemistandardSkewTableaux_all(max_entry)
Bases: SemistandardSkewTableaux
Class of all semistandard skew tableaux, possibly with a given maximum entry.
```

```python
class sage.combinat.skew_tableau.SemistandardSkewTableaux_shape(p, max_entry)
Bases: SemistandardSkewTableaux
Class of semistandard skew tableaux of a fixed skew shape \( \lambda/\mu \) with a given max entry.
```

A semistandard skew tableau with max entry \( i \) is required to have all its entries less or equal to \( i \). It is not required to actually contain an entry \( i \).

**INPUT:**

- \( p \) – A skew partition
- \( \text{max\_entry} \) – The max entry; defaults to the size of \( p \).

**Warning:** Input is not checked; please use SemistandardSkewTableaux to ensure the options are properly parsed.

```python
cardinality()
EXAMPLES:
```
sage: SemistandardSkewTableaux([[2,1],[[]]]).cardinality()
8
sage: SemistandardSkewTableaux([[2,1],[[]], max_entry=2].cardinality()
2

>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[[]]].cardinality()
8
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[[]], max_entry=Integer(2)].cardinality()
2

class sage.combinat.skew_tableau.SemistandardSkewTableaux_shape_weight (p, mu)
Bases: SemistandardSkewTableaux
Class of semistandard skew tableaux of a fixed skew shape \(\lambda/\nu\) and weight \(\mu\).

class sage.combinat.skew_tableau.SemistandardSkewTableaux_size (n, max_entry)
Bases: SemistandardSkewTableaux
Class of all semistandard skew tableaux of a fixed size \(n\), possibly with a given maximum entry.

cardinality ()
EXAMPLES:
sage: SemistandardSkewTableaux([2]).cardinality()
8

>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(2)).cardinality()
8

class sage.combinat.skew_tableau.SemistandardSkewTableaux_size_weight (n, mu)
Bases: SemistandardSkewTableaux
Class of semistandard tableaux of a fixed size \(n\) and weight \(\mu\).

cardinality ()
EXAMPLES:
sage: SemistandardSkewTableaux(2,[1,1]).cardinality()
4

>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(2), [Integer(1),Integer(1)]).cardinality()
4

class sage.combinat.skew_tableau.SkewTableau (parent, st)
Bases: ClonableList
A skew tableau.

Note that Sage by default uses the English convention for partitions and tableaux. To change this, see Tableaux. options().

EXAMPLES:
The `expr` form of a skew tableau consists of the inner partition followed by a list of the entries in each row from bottom to top:

```
sage: SkewTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

The `chain` form of a skew tableau consists of a list of partitions $\lambda_1, \lambda_2, \ldots$, such that all cells in $\lambda_{i+1}$ that are not in $\lambda_i$ have entry $i$:

```
sage: SkewTableau(chain=[[2], [2, 1], [3, 1], [4, 3, 2, 1]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

```
backward_slide(corner=None)
```

Apply a backward jeu de taquin slide on the specified outside corner of self.

Backward jeu de taquin slides are defined in Section 3.7 of [Sag2001].

**Warning:** The `inner_corners()` and `outer_corners()` are the `sage.combinat.partition.Partition.corners()` of the inner and outer partitions of the skew shape. They are different from the inner/outer corners defined in [Sag2001].

The “inner corners” of [Sag2001] may be found by calling `outer_corners()`. The “outer corners” of [Sag2001] may be found by calling `self.outer_shape().outside_corners()`.

**EXAMPLES:**

```
sage: T = SkewTableaux()([[2, 2], [4, 4], [5]])
sage: Tableaux.options.display='array'
sage: Q = T.backward_slide(); Q
```
sage: Q.backward_slide((1, 2))
. 2 2
. 4 4
5

sage: Q.reverse_slide((1, 2)) == Q.backward_slide((1, 2))
True

sage: T = SkewTableaux([[1, 3],[3],[5]]); T
1 3
3
5

sage: T.reverse_slide((1,1))
. 1
. 3 3
5

>>> from sage.all import *

>>> T = SkewTableaux([[Integer(2), Integer(2)], [Integer(4), Integer(4)],
˓→[Integer(5)]]);

>>> Tableaux.options.display='array'

>>> Q = T.backward_slide(); Q
. 2 2
. 4 4
5

>>> Q.backward_slide((Integer(1), Integer(2)))
. 2 2
. 4 4
5

>>> Q.reverse_slide((Integer(1), Integer(2))) == Q.backward_slide((Integer(1),
˓→Integer(2)))
True

>>> T = SkewTableaux([[Integer(1), Integer(3)], [Integer(3)], [Integer(5)]]);

>>> T.reverse_slide((Integer(1),Integer(1))
. 1
. 3 3
5

bender_knuth_involution (k, rows=None, check=True)

Return the image of self under the k-th Bender–Knuth involution, assuming self is a skew semistandard tableau.

Let $T$ be a tableau, then a lower free $k$ in $T$ means a cell of $T$ which is filled with the integer $k$ and whose direct lower neighbor is not filled with the integer $k+1$ (in particular, this lower neighbor might not exist at all). Let an upper free $k+1$ in $T$ mean a cell of $T$ which is filled with the integer $k+1$ and whose direct upper neighbor is not filled with the integer $k$ (in particular, this neighbor might not exist at all). It is clear that for any row $r$ of $T$, the lower free $k$’s and the upper free $k+1$’s in $r$ together form a contiguous interval or $r$.

The $k$-th Bender–Knuth switch at row $i$ changes the entries of the cells in this interval in such a way that if
it used to have \( a \) entries of \( k \) and \( b \) entries of \( k + 1 \), it will now have \( b \) entries of \( k \) and \( a \) entries of \( k + 1 \). For fixed \( k \), the \( k \)-th Bender–Knuth switches for different \( i \) commute. The composition of the \( k \)-th Bender–Knuth switches for all rows is called the 'k'-th Bender–Knuth involution. This is used to show that the Schur functions defined by semistandard (skew) tableaux are symmetric functions.

INPUT:

- \( k \) – an integer
- \( \text{rows} \) – (Default None) When set to None, the method computes the \( k \)-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the \( k \)-th Bender–Knuth switches at row \( i \) over all \( i \) in \( \text{rows} \). When set to an integer \( i \), the method computes the \( k \)-th Bender–Knuth switch at row \( i \). Note the indexing of the rows starts with 1.
- \( \text{check} \) – (Default: True) Check to make sure \( \text{self} \) is semistandard. Set to False to avoid this check.

OUTPUT:

The image of \( \text{self} \) under either the \( k \)-th Bender–Knuth involution, the \( k \)-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```python
sage: t = SkewTableau([[None, None, None, 4, 4, 5, 6, 7],
                    [None, 2, 4, 6, 7, 7, 7],
                    ....:
                    [None, 4, 5, 8, 8, 9],
                    [None, 6, 7, 10],
                    [None, 8, 8, 11],
                    [None],
                    [4]])
sage: t
[[None, None, None, 4, 4, 5, 6, 7],

 [None],
 [4]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[None, None, None, 4, 4, 5, 6, 7],
 [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9],
 [None, 6, 7, 10],
 [None, 8, 8, 11],
 [None],
 [4]]
```

```python
>>> from sage.all import *

>>> t = SkewTableau([[None, None, None, Integer(4), Integer(4), Integer(5),
                   Integer(6), Integer(7)],
                   [None, Integer(2), Integer(4), Integer(5), Integer(6), Integer(7),
                   Integer(7), Integer(7)],
                   ...
                   [None, Integer(4), Integer(5), Integer(8), Integer(8),
                   Integer(9)],
                   [None, Integer(4), Integer(6), Integer(7), Integer(10)],
                   [None, Integer(8),
                   Integer(8), Integer(9),
                   Integer(11)],
                   [None]],
                   [4]])

>>> t
[[None, None, None, 4, 4, 5, 6, 7],
 [None, 2, 4, 6, 7, 7, 7],
 (continues on next page)
The Bender–Knuth involution is an involution:

```python
sage: t = SkewTableau([[None, 3, 4, 4], [None, 6, 10], [7, 7, 11], [18]])
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t for k in range(1, 4))
True
```

The same for the single switches:

```python
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t for k in range(1, 5) for j in range(1, 5))
True
```

Locality of the Bender–Knuth involutions:

```python
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.bender_knuth_involution(l).bender_knuth_involution(k) for k in range(1, 5) for l in range(1, 5) if abs(k - l) > 1)
True
```
AUTHORS:

- Darij Grinberg (2013-05-14)

cells()

Return the cells in self.

EXAMPLES:

```python
sage: s = SkewTableau([[None,1,2],[3],[6]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

```python
sage: from sage.all import *
sage: s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3)],[Integer(6)]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

cells_by_content(c)

Return the coordinates of the cells in self with content c.

EXAMPLES:

```python
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.cells_by_content(0)
[(1, 1)]
sage: s.cells_by_content(1)
[(0, 1), (1, 2)]
sage: s.cells_by_content(2)
[(0, 2)]
sage: s.cells_by_content(-1)
[(1, 0)]
sage: s.cells_by_content(-2)
[(2, 0)]
```

```python
sage: from sage.all import *
sage: s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3),Integer(4),
˓→Integer(5)],[Integer(6)]])
sage: s.cells_by_content(Integer(0))
[(1, 1)]
sage: s.cells_by_content(Integer(1))
[(0, 1), (1, 2)]
sage: s.cells_by_content(Integer(2))
[(0, 2)]
sage: s.cells_by_content(-Integer(1))
[(1, 0)]
sage: s.cells_by_content(-Integer(2))
[(2, 0)]
```

cells_containing(i)

Return the list of cells in which the letter i appears in the tableau self. The list is ordered with cells appearing from left to right.
Cells are given as pairs of coordinates \((a, b)\), where both rows and columns are counted from 0 (so \(a = 0\) means the cell lies in the leftmost column of the tableau, etc.).

**EXAMPLES:**

```python
t = SkewTableau([[None, None, 3], [None, 3, 5], [4, 5]])
t.cells_containing(5)
[(2, 1), (1, 2)]
t.cells_containing(4)
[(2, 0)]
t.cells_containing(2)
[]

t = SkewTableau([[None, None, None, None], [None, 4, 5], [None, 5, 6], [None, 9], [None]])
t.cells_containing(2)
[]
t.cells_containing(4)
[(1, 1)]
t.cells_containing(5)
[(2, 1), (1, 2)]

t = SkewTableau([])
t.cells_containing(3)
[]

t = SkewTableau([[None, None], [None]])
t.cells_containing(3)
[]

>>> from sage.all import *
>>> t = SkewTableau([[None, None, Integer(3)], [None, Integer(3), Integer(5)],
current
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]
>>> t.cells_containing(Integer(4))
[(2, 0)]
>>> t.cells_containing(Integer(2))
[]

>>> t = SkewTableau([[None, None, None, None], [None, Integer(4), Integer(5)], [None, Integer(5), Integer(6)], [None, Integer(9), [None]]]
>>> t.cells_containing(Integer(2))
[]
>>> t.cells_containing(Integer(4))
[(1, 1)]
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]

>>> SkewTableau([]).cells_containing(Integer(3))
[]

>>> SkewTableau([[None, None], [None]]).cells_containing(Integer(3))
[]
```

```
check()
Check that self is a valid skew tableau. This is currently far too liberal, and only checks some trivial things.

**EXAMPLES:**
```
```python
sage: t = SkewTableau([[None,1,1],[2]])
sage: t.check()

sage: t = SkewTableau([[None, None, 1], [2, 4], [], [3, 4, 5]])
Traceback (most recent call last):
...  
TypeError: a skew tableau cannot have an empty list for a row

sage: s = SkewTableau([[1, None, None],[2, None],[3]])
Traceback (most recent call last):
...  
TypeError: not a valid skew tableau

>>> from sage.all import *

>>> t = SkewTableau([[None,Integer(1),Integer(1)],[Integer(2)]])

>>> t = SkewTableau([[None, None, Integer(1)], [Integer(2), Integer(4)], [],
                →[Integer(3), Integer(4), Integer(5)]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

>>> s = SkewTableau([[Integer(1), None, None],[Integer(2), None],
                →[Integer(3)]])
Traceback (most recent call last):
...
TypeError: not a valid skew tableau

column_stabilizer()

Return the `PermutationGroup()` corresponding to the column stabilizer of `self`.
This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```python
sage: # needs sage.groups
sage: cs = SkewTableau([[None,2,3],[1,5],[4]]).column_stabilizer()
sage: cs.order() == factorial(2) * factorial(2)
True
sage: PermutationGroupElement(((1,3,2),(4,5))) in cs
False
sage: PermutationGroupElement(((1,4))) in cs
True

>>> from sage.all import *

>>> # needs sage.groups

>>> cs = SkewTableau([([None,Integer(2),Integer(3)],[Integer(1),Integer(5)],
                →[Integer(4)])].column_stabilizer()

>>> cs.order() == factorial(Integer(2)) * factorial(Integer(2))
True

>>> PermutationGroupElement(((Integer(1),Integer(3),Integer(2)),(Integer(4),
                →Integer(5)))) in cs
False

>>> PermutationGroupElement(((Integer(1),Integer(4)))) in cs
True
```

conjugate()
Return the conjugate of self.

EXAMPLES:

```python
sage: SkewTableau([[None,1],[2,3]]).conjugate()
[[None, 2], [1, 3]]
```

```python
>>> from sage.all import *

>>> SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]]).conjugate()
[[None, 2], [1, 3]]
```

**entries_by_content(c)**

Return the entries in self with content c.

EXAMPLES:

```python
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
sage: s.entries_by_content(-2)
[6]
```

```python
>>> s = SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)],
,Integer(5)],[Integer(6)])

>>> s.entries_by_content(Integer(0))
[4]

>>> s.entries_by_content(Integer(1))
[1, 5]

>>> s.entries_by_content(Integer(2))
[2]

>>> s.entries_by_content(-Integer(1))
[3]

>>> s.entries_by_content(-Integer(2))
[6]
```

**evaluation()**

Return the weight (aka evaluation) of the tableau self. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau $T$ is the sequence $(a_1, a_2, a_3, \ldots)$, where $a_k$ is the number of entries of $T$ equal to $k$. This sequence contains only finitely many nonzero entries.

The weight of a skew tableau $T$ is the same as the weight of the reading word of $T$, for any reading order. **evaluation()** is a synonym for this method.

EXAMPLES:

```python
sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]
```

sage: SkewTableau([[None, 2], [None, 4], [None, 5], [None]]).weight()
[0, 1, 0, 1, 1]
sage: SkewTableau([]).weight()
[]
sage: SkewTableau([[None, None, None], [None]]).weight()
[]
sage: SkewTableau([[None, 3, 4], [None, 6, 7], [4, 8], [5, 13], [6], [7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]

>>> from sage.all import *
>>> t = SkewTableau([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]).weight()
[1, 1, 1]
>>> t = SkewTableau([[None, Integer(2)], [None, Integer(4)], [None, Integer(5)],
                    [None]]).weight()
[0, 1, 0, 1, 1]
>>> t = SkewTableau([]).weight()
[]
>>> t = SkewTableau([[None, None, None], [None]]).weight()
[]
>>> t = SkewTableau([[None, Integer(3), Integer(4)], [None, Integer(6), Integer(7)],
                    [None, Integer(4), Integer(8)], [Integer(5), Integer(13)], [Integer(6)],
                    [Integer(7)]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]

filling()

Return a list of the non-empty entries in self.

EXAMPLES:

sage: t = SkewTableau([[None, 1], [2, 3]])
sage: t.filling()
[[1], [2, 3]]

>>> from sage.all import *
>>> t = SkewTableau([[None, Integer(1)], [Integer(2), Integer(3)]]
>>> t.filling()
[[1], [2, 3]]

inner_shape()

Return the inner shape of self.

EXAMPLES:

sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).inner_shape()
[1, 1]
sage: SkewTableau([[1, 2], [3, 4], [7]]).inner_shape()
[]
sage: SkewTableau([ [None, None, None, 2, 3], [None, 1], [None], [2] ]).inner_shape() [3, 1, 1]

>>> from sage.all import *

>>> SkewTableau([ [None, Integer(1), Integer(2)], [None, Integer(3)], ...

.. line:: ...

inner_size()

| Return the size of the inner shape of self. |
| EXAMPLES: |
| sage: SkewTableau([ [None, 2, 4], [None, 3], [1] ]).inner_size() 2 |
| sage: SkewTableau([ [None, 2], [1, 3] ]).inner_size() 1 |

>>> from sage.all import *

>>> SkewTableau([ [None, Integer(2), Integer(3)], [None, Integer(3)], ...

.. line:: ...

is_k_tableau(k)

| Checks whether self is a valid skew weak k-tableau. |
| EXAMPLES: |
| sage: t = SkewTableau([ [None, 2, 3], [2, 3], [3] ]) |
| sage: t.is_k_tableau(3) True |
| sage: t = SkewTableau([ [None, 1, 3], [2, 2], [3] ]) |
| sage: t.is_k_tableau(3) False |

is_ribbon()

| Return True if and only if the shape of self is a ribbon, that is, if it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q. | 5.1. Comprehensive Module List 4999 |
EXAMPLES:

```python
sage: S = SkewTableau([[None, None, 1, 2], [None, None, 3], [1, 3, 4]])
sage: S.pp()
  . . 1 2
  . . 3
  1 3 4
sage: S.is_ribbon()
True

desk
sage: S = SkewTableau([[None, 1, 1, 2], [None, 2, 3], [1, 3, 4]])
sage: S.pp()
  1 1 2
  2 3
  1 3 4
sage: S.is_ribbon()
False

desk
sage: S = SkewTableau([[None, None, 1, 2], [None, None, 3], [1]])
sage: S.pp()
  . . 1 2
  . . 3
  1
sage: S.is_ribbon()
False

desk
sage: S = SkewTableau([[None, None, None, None], [None, None, 3], [1, 2, 4]])
sage: S.pp()
  . . .
  . . 3
  1 2 4
sage: S.is_ribbon()
True

desk
sage: S = SkewTableau([[None, None, None, None], [None, None, 3], [None, 2, 4]])
sage: S.pp()
  . . .
  . . 3
  . 2 4
sage: S.is_ribbon()
True

desk
sage: S = SkewTableau([[None, None], [None]])
sage: S.pp()
  . .
  . .
sage: S.is_ribbon()
True
```

```python
>>> from sage.all import *

>>> S = SkewTableau([[None, None, 1, 2], [None, None, 3], [1, 3, 4]])
```

(continues on next page)
is_semistandard()
Return True if self is a semistandard skew tableau and False otherwise.

EXAMPLES:

```python
sage: SkewTableau([None, None, [None]]).is_semistandard()
True
sage: SkewTableau([None, 2, 1, 3]).is_semistandard()
False
```
sage: SkewTableau([[None, 2, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 3, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [1, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2, 3], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [None, None, 4]]).is_semistandard()
False

```python
>>> from sage.all import *
``` 
```
>>> SkewTableau([[None, Integer(2), Integer(2)], [Integer(1), Integer(3)]]).is_semistandard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_semistandard()
True
>>> SkewTableau([[None, Integer(3)], [Integer(2), Integer(4)]]).is_semistandard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(2)]]).is_semistandard()
False
```

is_standard()

Return True if self is a standard skew tableau and False otherwise.

EXAMPLES:

```python
sage: SkewTableau([[None, 2, 3]]).is_standard()
True
sage: SkewTableau([[None, 2, 3], [1, 4]]).is_standard()
False
sage: SkewTableau([[None, 2, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2, 3], [None, None, 4]]).is_standard()
False
```

```python
>>> from sage.all import *
``` 
```
>>> SkewTableau([[None, Integer(2), Integer(2)], [Integer(1), Integer(3)]]).is_standard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_standard()
```
outer_shape()

Return the outer shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None, 1, 2], [None, 3], [4]]).outer_shape()
[3, 2, 1]
```

```python
>>> from sage.all import *
```  

```python
>> SkewTableau([[None, Integer(1), Integer(2)], [None, Integer(3)],
  →[Integer(4)]]).outer_shape()
[3, 2, 1]
```

outer_size()

Return the size of the outer shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4
```

```python
>>> from sage.all import *
```  

```python
>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],...
  →[Integer(1)]]).outer_size()
6
```  

```python
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).outer_size()
4
```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```python
sage: SkewTableau([[None, 2, 3], [None, 4], [5]]).pp()
 . 2 3
 . 4
 5
```

```python
>>> from sage.all import *
```  

```python
>> SkewTableau([[None, Integer(2), Integer(3)], [None, Integer(4)],...
  →[Integer(5)]]).pp()
 . 2 3
 . 4
 5
```

rectify(algorithm=None)

Return a StandardTableau, SemistandardTableau, or just Tableau formed by applying the jeu de taquin process to self.
See page 15 of [Ful1997].

INPUT:

- **algorithm**—optional: if set to 'jdt', rectifies by jeu de taquin; if set to 'schensted', rectifies by Schensted insertion of the reading word; otherwise, guesses which will be faster.

EXAMPLES:

```python
sage: S = SkewTableau([[None, 1], [2, 3]])
sage: S.rectify()
[[1, 3], [2]]
sage: T = SkewTableau([[None, None, None, 4], [None, None, 1, 6], [None, None, 5], [2, -3]])
sage: T.rectify()
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
  ...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

restrict \((n)\)

Return the restriction of the (semi)standard skew tableau to all the numbers less than or equal to \(n\).

**Note:** If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method `restriction_outer_shape()` is preferred. Similarly if only the skew shape is needed, use `restriction_shape()`.

EXAMPLES:

```python
sage: SkewTableau([[None, 1], [2], [3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None, 1], [2], [3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None, 1], [1], [2]]).restrict(1)
[[None, 1], [1]]
```
```
>>> from sage.all import *

>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).
   restrict(Integer(2))
[[None, 1], [2]]
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).
   restrict(Integer(1))
[[None, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).
   restrict(Integer(1))
[[None, 1], [1]]
```

**restriction_outer_shape**

Return the outer shape of the restriction of the semistandard skew tableau `self` to `n`.

If `T` is a semistandard skew tableau and `n` is a nonnegative integer, then the restriction of `T` to `n` is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than `n` from `T`.

This method computes merely the outer shape of the restriction. For the restriction itself, use `restrict()`.

**EXAMPLES:**

```
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_outer_shape(3)
[2, 2, 1]
sage: SkewTableau([[None,2],[None],[4],[5]]).restriction_outer_shape(2)
[2, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_outer_shape(0)
[2, 1]
sage: T.restriction_outer_shape(2)
[2, 1]
sage: T.restriction_outer_shape(3)
[3, 1]
sage: T.restriction_outer_shape(4)
[3, 3]
sage: T.restriction_outer_shape(19)
[4, 3, 1]
```

```
>>> from sage.all import *

>>> SkewTableau([[None,None],[Integer(2)],[Integer(3)],[Integer(3),
   Integer(4)]]).restriction_outer_shape(Integer(3))
[2, 2, 1]
>>> SkewTableau([[None,Integer(2)],[None],[Integer(4)],[Integer(5)]]).
   restriction_outer_shape(Integer(2))
[2, 1]
>>> T = SkewTableau([[None,None,Integer(3)],[Integer(5)],[None,Integer(4),
   Integer(4)],[Integer(17)]])
>>> T.restriction_outer_shape(Integer(0))
[2, 1]
>>> T.restriction_outer_shape(Integer(2))
[2, 1]
>>> T.restriction_outer_shape(Integer(3))
[3, 1]
>>> T.restriction_outer_shape(Integer(4))
[3, 3]
>>> T.restriction_outer_shape(Integer(19))
[4, 3, 1]
```

**restriction_shape**

5.1. Comprehensive Module List 5005
Return the skew shape of the restriction of the semistandard skew tableau \texttt{self} to \(n\).

If \(T\) is a semistandard skew tableau and \(n\) is a nonnegative integer, then the restriction of \(T\) to \(n\) is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than \(n\) from \(T\).

This method computes merely the skew shape of the restriction. For the restriction itself, use \texttt{restrict()}.  

EXAMPLES:

\begin{verbatim}

sage: SkewTableau([[None, None], [2, 3], [3, 4]]).restriction_shape(3)
[2, 2, 1] / [2]

sage: SkewTableau([[None, 2], [None], [4], [5]]).restriction_shape(2)
[2, 1] / [1, 1]

sage: T = SkewTableau([[None, None, 3, 5], [None, 4, 4], [17]])
sage: T.restriction_shape(0)
[2, 1] / [2, 1]
sage: T.restriction_shape(2)
[2, 1] / [1, 1]
sage: T.restriction_shape(3)
[3, 1] / [2, 1]
sage: T.restriction_shape(4)
[3, 3] / [2, 1]

>>> from sage.all import *
>>> SkewTableau([[None, None], [Integer(2), Integer(3)], [Integer(3), Integer(4)]]).restriction_shape(Integer(3))
[2, 2, 1] / [2]

>>> SkewTableau([[None, Integer(2)], [None], [Integer(4)], [Integer(5)]]).restriction_shape(Integer(2))
[2, 1] / [1, 1]

>>> T = SkewTableau([[None, None, Integer(3), Integer(5)], [None, Integer(4), Integer(4)], [Integer(17)]])

>>> T.restriction_shape(Integer(0))
[2, 1] / [2, 1]

>>> T.restriction_shape(Integer(2))
[2, 1] / [1, 1]

>>> T.restriction_shape(Integer(3))
[3, 1] / [2, 1]

>>> T.restriction_shape(Integer(4))
[3, 3] / [2, 1]
\end{verbatim}

reverse_slide\(\texttt{(corner=}\texttt{None})\)

Apply a backward jeu de taquin slide on the specified outside \texttt{corner} of \texttt{self}.

Backward jeu de taquin slides are defined in Section 3.7 of [Sag2001].

\begin{verbatim}

Warning: The \texttt{inner_corners()} and \texttt{outer_corners()} are the \texttt{sage.combinat.partition.Partition.corners()} of the inner and outer partitions of the skew shape. They are different from the inner/outer corners defined in [Sag2001].

The “inner corners” of [Sag2001] may be found by calling \texttt{outer_corners()}. The “outer corners” of [Sag2001] may be found by calling \texttt{self.outer_shape().outside_corners()}.  

EXAMPLES:
\end{verbatim}
```python
sage: T = SkewTableaux([[2, 2], [4, 4], [5]])
sage: Tableaux.options.display='array'
sage: Q = T.backward_slide(); Q
. 2 2
. 4 4
5
sage: Q.backward_slide((1, 2))
. 2 2
. 4 4
5
sage: Q.reverse_slide((1, 2)) == Q.backward_slide((1, 2))
True
sage: T = SkewTableaux([[1, 3], [3], [5]]); T
1 3
3
5
sage: T.reverse_slide((1,1))
. 1
3 3
5

>>> from sage.all import *
>>> T = SkewTableaux()([[Integer(2), Integer(2)], [Integer(4), Integer(4)],
˓→[Integer(5)]])
>>> Tableaux.options.display='array'
>>> Q = T.backward_slide(); Q
. 2 2
. 4 4
5
>>> Q.backward_slide((Integer(1), Integer(2)))
. 2 2
. 4 4
5
>>> Q.reverse_slide((Integer(1), Integer(2))) == Q.backward_slide((Integer(1),
˓→Integer(2)))
True
>>> T = SkewTableaux()([[Integer(1), Integer(3)], [Integer(3)], [Integer(5)]]);
˓→T
1 3
3
5
>>> T.reverse_slide((Integer(1),Integer(1)))
. 1
3 3
5

row_stabilizer()

Return the PermutationGroup() corresponding to the row stabilizer of self.
This assumes that every integer from 1 to the size of self appears exactly once in self.

EXAMPLES:
```
```
Combinatorics, Release 10.4

```python
sage: rs.order() == factorial(3) * factorial(2)
True
sage: PermutationGroupElement(((1,3,2),(4,5))] in rs
True
sage: PermutationGroupElement(((1,4)]) in rs
False
sage: rs = SkewTableau([[None,1,2],[3]]).row_stabilizer()
>>> PermutationGroupElement(((1,2),(3,))] in rs
True
sage: rs = SkewTableau([[None,1,2],[3]]).row_stabilizer()
>>> PermutationGroupElement(((3,))] in rs
True
sage: rs = SkewTableau([[None,1,2],[3]]).row_stabilizer()
>>> rs.order()
1
```

shape ()

Return the shape of self.

EXAMPLES:

```python
sage: SkewTableau([[None,1,2],[None,3],[4]]).shape()
[3, 2, 1] / [1, 1]
```
shuffle(t2)
Shuffle the standard tableaux self and t2.

Let t1 = self. The shape of t2 must extend the shape of t1, that is, self.outer_shape() == t2.inner_shape(). Then this function computes the pair of tableaux (t2_new, t1_new) obtained by using jeu de taquin slides to move the boxes of t2 behind the boxes of self.

The entries of t2_new are obtained by performing successive inwards jeu de taquin slides on t2 in the order indicated by the entries of t1, from largest to smallest. The entries of t1 then slide outwards one by one and land in the squares vacated successively by t2, forming t1_new.

Note: Equivalently, the entries of t1_new are obtained by performing outer jeu de taquin slides on t1 in the order indicated by the entries of t2, from smallest to largest. In this case the entries of t2 slide backwards and fill the squares successively vacated by t1 and so form t2_new. (This is not how the algorithm is implemented.)

INPUT:

• self, t2 – a pair of standard SkewTableaux with self.outer_shape() == t2.inner_shape()

OUTPUT:

• t2_new, t1_new – a pair of standard SkewTableaux with t2_new.outer_shape() == t1_new.inner_shape()

EXAMPLES:

sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: (t2_new, t1_new) = t1.shuffle(t2)
sage: t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
sage: t2_new
[[None, 2, 3], [1, 4], [5]]
sage: t1_new.outer_shape() == t2.outer_shape()
True
sage: t2_new.inner_shape() == t1.inner_shape()
True

(continues on next page)
Shuffling is an involution:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: sh = lambda x,y : x.shuffle(y)
sage: (t1, t2) == sh(sh(t1, t2))
True
```

Both tableaux must be standard:

```
sage: t1 = SkewTableau([[None, 1, 2], [2, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
  ... ValueError: the tableaux must be standard
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 6]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
  ... ValueError: the tableaux must be standard
```

The shapes (not just the nonempty cells) must be adjacent:
sage: t1 = SkewTableau([[None, None, None], [1]])
sage: t2 = SkewTableau([[None], [None], [1]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
   ...
ValueError: the shapes must be adjacent

>>> from sage.all import *

>>> t1 = SkewTableau([[None, None, None], [Integer(1)]]))

>>> t2 = SkewTableau([[None], [None], [Integer(1)]])

>>> t1.shuffle(t2)
Traceback (most recent call last):
   ...
ValueError: the shapes must be adjacent

size()

Return the number of cells in self.

EXAMPLES:

sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size() 4

sage: SkewTableau([[None, 2], [1, 3]]).size() 3

>>> from sage.all import *

>>> SkewTableau([[None, Integer(2)], [None, Integer(4)],  
                [None, Integer(3)], [None, Integer(1)]]).size() 4

>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).size() 3

slide(corner=None, return_vacated=False)

Apply a jeu de taquin slide to self on the specified inner corner and return the resulting tableau.

If no corner is given, the topmost inner corner is chosen.

The optional parameter return_vacated=True causes the output to be the pair (t, (i, j)) where

\( t \) is the new tableau and \((i, j)\) are the coordinates of thevacated square.

EXAMPLES:

sage: st = SkewTableau([[None, None, None, None, None, None, 6],  
                      [None, 2, 4, 4], [2, 3, 6], [5, 5]])
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6],  
  [None, 2, 4, 4], [2, 3, 6], [5, 5]]
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6],  
  [2, 2, 4, 4], [3, 3, 6], [5, 5]]
sage: st2 = SkewTableau([[None, None, 3], [None, 2, 4], [1, 5]])
sage: st2.slide((1, 0), True)

(continues on next page)
standardization\ (\texttt{check=True})

Return the standardization of \texttt{self}, assuming \texttt{self} is a semistandard skew tableau.

The standardization of a semistandard skew tableau \(T\) is the standard skew tableau \(\text{st}(T)\) of the same shape as \(T\) whose reversed reading word is the standardization of the reversed reading word of \(T\).

The standardization of a word \(w\) can be formed by replacing all 1’s in \(w\) by 1,2,...,\(k_1\) from left to right, all 2’s in \(w\) by \(k_1+1, k_1+2, \ldots, k_2\), and repeating for all letters that appear in \(w\). See also \texttt{Word.standard_permutation()}.

\begin{verbatim}
INPUT:
  \bullet \texttt{check} – (Default: True) Check to make sure \texttt{self} is semistandard. Set to \texttt{False} to avoid this check.

EXAMPLES:
sage: t = SkewTableau([[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3, 5, 6], [5]])
>>> st = SkewTableau([[None, None, Integer(3)], [None, Integer(2)], [Integer(4)], [Integer(1), Integer(5)]])
>>> st.\texttt{slide}((Integer(1), Integer(0)), True)
(([[None, None, 3], [1, 2, 4], [5]], (2, 1))

Standard skew tableaux are fixed under standardization:

sage: p = Partition([4,3,3,2])
sage: q = Partitions(3).random_element()  # needs sage.libs.flint
sage: all(t == t.\texttt{standardization()} for t in StandardSkewTableaux([p, q]))
True

sage: from sage.all import *
>>> p = Partition([Integer(4), Integer(3), Integer(3), Integer(2)])
>>> q = Partitions(Integer(3)).random_element()  # needs sage.libs.flint
>>> all(t == t.\texttt{standardization()} for t in StandardSkewTableaux([p, q]))
True
\end{verbatim}
The reading word of the standardization is the standardization of the reading word:

```
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: t.to_word().standard_permutation() == t.standardization().to_permutation()
True
```

```
>> from sage.all import *
>> t = SkewTableau([[None,Integer(3),Integer(4),Integer(4)],[None,Integer(6),
˓→Integer(10)],[Integer(7),Integer(7),Integer(11)],[Integer(18)]])
>> t.to_word().standard_permutation() == t.standardization().to_permutation()
True
```

```
to_chain (max_entry=None)
```

Return the chain of partitions corresponding to the (semi)standard skew tableau self.

The optional keyword parameter `max_entry` can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer `n`, then the chain is constructed from the positions of the letters 1, 2, ..., n in the tableau.

**EXAMPLES:**

```
sage: SkewTableau([[None,1],[2],[3]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=2)
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=3)
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=1)
[[1], [2, 1]]
sage: SkewTableau([[None,None,2],[None,3],[None,5]]).to_chain(max_entry=6)
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
sage: SkewTableau([]).to_chain()
[[], []]
```

```
>> from sage.all import *
>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_entry=Integer(2))
[[1], [2, 1], [2, 1, 1]]
>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_entry=Integer(3))
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_entry=Integer(1))
[[1], [2, 1]]
>> SkewTableau([[None,None,Integer(2)],[None,Integer(3)],[None,Integer(5)]]).to_chain(max_entry=Integer(6))
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
>> SkewTableau([]).to_chain()
```

(continues on next page)
to_expr()

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if \( t \) is a skew tableau, then \( \text{to_expr} \) gives the same result as \( \text{expr}(t) \) would give in MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableau([[None, 1, 1, 3], [None, 2, 2], [1]]).to_expr()
[[[1, 1], [[1, [2, 2], [1, 1, 3]]]]
sage: SkewTableau([]).to_expr()
[[], []]
```

```
from sage.all import *

>>> SkewTableau([[None, Integer(1), Integer(1), Integer(3)], [None, Integer(2), Integer(2)], [Integer(1)]]).to_expr()
[[[1, 1], [[1, [2, 2], [1, 1, 3]]]]

>>> SkewTableau([]).to_expr()
[[], []]
```

to_list()

Return a (mutable) list representation of self.

EXAMPLES:

```
sage: stlist = [[None, None, 3], [None, 1, 3], [2, 2]]
sage: st = SkewTableau(stlist)
sage: st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
sage: st.to_list() == stlist
True
```

```
from sage.all import *

>>> stlist = [[None, None, Integer(3)], [None, Integer(1), Integer(3)], [None, Integer(2), Integer(2)]

>>> st = SkewTableau(stlist)

>>> st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]

>>> st.to_list() == stlist
True
```

to_permutation()

Return a permutation with the entries of self obtained by reading self row by row, from the bottommost to the topmost row, with each row being read from left to right, in English convention. See \( \text{to_word_by_row()} \).

EXAMPLES:

```
sage: SkewTableau([[None, 2], [3, 4], [None], [1]]).to_permutation()
[1, 3, 4, 2]
sage: SkewTableau([[None, 2], [None, 4], [1], [3]]).to_permutation()
```

(continues on next page)
\[
\begin{align*}
[3, 1, 4, 2] \\
sage: & \text{SkewTableau([None]).to_permutation()} \\
& []
\end{align*}
\]

```python
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2)], [Integer(3), Integer(4)], [None],
               [Integer(1)]]).to_permutation()
[1, 3, 4, 2]
>>> SkewTableau([[None, Integer(2)], [None, Integer(4)], [Integer(1)],
                [Integer(3)]]).to_permutation()
[3, 1, 4, 2]
>>> SkewTableau([[None]]).to_permutation()
[]
```

**to_ribbon** *(check_input=True)*

Return \texttt{self} as a ribbon-shaped tableau \texttt{(RibbonShapedTableau)}, provided that the shape of \texttt{self} is a ribbon.

**INPUT:**

- \texttt{check_input} – (default: True) whether or not to check that \texttt{self} indeed has ribbon shape

**EXAMPLES:**

```python
sage: SkewTableau([[None, 1], [2, 3]]).to_ribbon()
[[None, 1], [2, 3]]
```

```python
>>> from sage.all import *
>>> SkewTableau([[None, Integer(1)], [Integer(2), Integer(3)]]).to_ribbon()
[[None, 1], [2, 3]]
```

**to_tableau**

Returns a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

**EXAMPLES:**

```python
sage: SkewTableau([[1, 2], [3, 4]]).to_tableau()
[[1, 2], [3, 4]]
```

```python
>>> from sage.all import *
>>> SkewTableau([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]).to_tableau()
[[1, 2], [3, 4]]
```

**to_word**

Return a word obtained from a row reading of \texttt{self}.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

**EXAMPLES:**

```python
sage: s = SkewTableau([[None, 1], [2, 3]])
sage: s.pp()
. 1
2 3
```

(continues on next page)
to_word_by_row()

Return the word obtained from a column reading of the skew tableau.

This is the word obtained by concatenating the columns from the rightmost one (in English notation) to the leftmost one.

EXAMPLES:

```python
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.to_word_by_row()
word: 231
```

```python
>>> from sage.all import *

>>> s = SkewTableau([[None, Integer(1)], [Integer(2), Integer(3)]]))

```
to_word_by_row()

Return a word obtained from a row reading of self.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the
topmost one.

EXAMPLES:

```
>>> s = SkewTableau([[None, 1], [2, 3]])
>>> s.pp()
   1
   2 3
>>> s.to_word_by_row()
word: 231
```

```
>>> s = SkewTableau([[None, 2, 4], [None, 3], [1]])
>>> s.pp()
   2 4
   3
   1
>>> s.to_word_by_row()
word: 1324
```
EXAMPLES:

```python
sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None,2],[None,4],[None,5],[None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None,None,None],[None]]).weight()
[]

sage: SkewTableau([[None,3],[None,6,7],[4,8],[5,13],[6],[7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]

>>> from sage.all import *

>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).weight()
[1, 1, 1, 1]

>>> SkewTableau([[None,Integer(2)],[None,Integer(4)],[None,Integer(5)],[None]]).weight()
[0, 1, 0, 1, 1]

>>> SkewTableau([]).weight()
[]

>>> SkewTableau([[None,None,None],[None]]).weight()
[]

>>> SkewTableau([[None,Integer(3)],[None,Integer(4)],[None,Integer(6)],[None,Integer(7)],[None,Integer(4)],[None,Integer(8)],[None,Integer(5)],[None,Integer(13)],[None,Integer(6)],[None,Integer(7)]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

class sage.combinat.skew_tableau.SkewTableau_class (parent, st)

Bases: SkewTableau

This exists solely for unpickling SkewTableau_class objects.

class sage.combinat.skew_tableau.SkewTableaux (category=None)

Bases: UniqueRepresentation, Parent

Class of all skew tableaux.

Element

alias of SkewTableau

from_chain (chain)

Return the tableau corresponding to the chain of partitions.

EXAMPLES:

```python
sage: SkewTableaux().from_chain(([1,1],[2,1],[3,1],[3,2],[3,3],[3,3,1]))
[[None, 1, 2], [None, 3, 4], [5]]
```
from sage.all import *

SkewTableaux().from_chain([[Integer(1),Integer(1)],[Integer(2), Integer(1)],[Integer(3),Integer(1)], [Integer(3),Integer(2)], [Integer(3),Integer(3),Integer(1)]])

[[None, 1, 2], [None, 3, 4], [5]]

from_expr(expr)

Return a SkewTableau from a MuPAD-Combinat expr for a skew tableau.

The first list in expr is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

sage: SkewTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])

[[None, 1, 2], [None, 3, 4], [5]]

from_shape_and_word(shape, word)

Return the skew tableau corresponding to the skew partition shape and the word word obtained from the row reading.

EXAMPLES:

sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()  
sage: word = t.to_word()  
sage: SkewTableaux().from_shape_and_word(shape, word)

[[None, 1, 3], [None, 2], [4]]

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.skew_tableau.StandardSkewTableaux(category=None)

Bases: SkewTableaux

Standard skew tableaux.

EXAMPLES:

sage: S = StandardSkewTableaux(); S
Standard skew tableaux
sage: S.cardinality()
+Infinity

5.1. Comprehensive Module List 5019
```python
from sage.all import *

S = StandardSkewTableaux(); S
Standard skew tableaux
S.cardinality()
+Infinity

S = StandardSkewTableaux(2); S
Standard skew tableaux of size 2
S.cardinality()  # needs sage.modules
4

S = StandardSkewTableaux(Integer(2)); S
S.cardinality()  # needs sage.modules
4

S = StandardSkewTableaux([3, 2, 1], [1, 1]).list()
[[None, 2, 3], [None, 4], [1]],
[[None, 1, 2], [None, 3], [4]],
[[None, 1, 2], [None, 4], [3]],
[[None, 1, 3], [None, 4], [2]],
[[None, 1, 4], [None, 3], [2]],
[[None, 1, 4], [None, 2], [3]],
[[None, 1, 3], [None, 2], [4]],
[[None, 2, 4], [None, 3], [1]]

S = StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[None, 2, 3], [None, 4], [1]],
[[None, 1, 2], [None, 3], [4]],
[[None, 1, 2], [None, 4], [3]],
[[None, 1, 3], [None, 4], [2]],
[[None, 1, 4], [None, 3], [2]],
[[None, 1, 4], [None, 2], [3]],
[[None, 1, 3], [None, 2], [4]],
[[None, 2, 4], [None, 3], [1]]
```

```python
class sage.combinat.skew_tableau.StandardSkewTableaux_all
    Bases: StandardSkewTableaux

    Class of all standard skew tableaux.

class sage.combinat.skew_tableau.StandardSkewTableaux_shape(skp)
    Bases: StandardSkewTableaux

    Standard skew tableaux of a fixed skew shape \( \lambda/\mu \).

cardinality()
    Return the number of standard skew tableaux with shape of the skew partition skp. This uses a formula due to Aitken (see Cor. 7.16.3 of [Sta-EC2]).
```
EXAMPLES:

```python
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()  # needs sage.modules
8
```

```python
>>> from sage.all import *

>>> StandardSkewTableaux([[Integer(3), Integer(2), Integer(1)], [Integer(1), ...
...
# needs sage.modules

8
```

```python
class sage.combinat.skew_tableau.StandardSkewTableaux_size(n):
    Bases: StandardSkewTableaux

    Standard skew tableaux of a fixed size n.

cardinality()
```

EXAMPLES:

```python
sage: # needs sage.modules
sage: StandardSkewTableaux(1).cardinality()
1

sage: StandardSkewTableaux(2).cardinality()
4

sage: StandardSkewTableaux(3).cardinality()
24

sage: StandardSkewTableaux(4).cardinality()
194
```

```python
>>> from sage.all import *

>>> # needs sage.modules

>>> StandardSkewTableaux(Integer(1)).cardinality()
1

>>> StandardSkewTableaux(Integer(2)).cardinality()
4

>>> StandardSkewTableaux(Integer(3)).cardinality()
24

>>> StandardSkewTableaux(Integer(4)).cardinality()
194
```

5.1.314 Functions that compute some of the sequences in Sloane’s tables

EXAMPLES:

Type `sloane.[tab]` to see a list of the sequences that are defined.

```python
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.

sage: a(1)
1

sage: a(6)
4

sage: a(100)
9
```
>>> from sage.all import *
>>> a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
>>> a(Integer(1))
1
>>> a(Integer(6))
4
>>> a(Integer(100))
9

Type \texttt{d._eval??} to see how the function that computes an individual term of the sequence is implemented.

The input must be a positive integer:

\begin{verbatim}
sage: a(0)
Traceback (most recent call last):
  ...
ValueError: input n (=0) must be a positive integer
sage: a(1/3)
Traceback (most recent call last):
  ...
TypeError: input must be an int or Integer
\end{verbatim}

You can also change how a sequence prints:

\begin{verbatim}
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a.rename('(..., tau(n), ...)')
sage: a
(..., tau(n), ...)
sage: a.reset_name()
sage: a
The integer sequence tau(n), which is the number of divisors of n.
\end{verbatim}

See also:

- If you want to get more informations relative to a sequence (references, links, examples, programs, ...), you can use the On-Line Encyclopedia of Integer Sequences provided by the \texttt{OEIS} module.
• If you plan to do a lot of automatic searches for subsequences, you should consider installing SloaneEncyclopedia, a local partial copy of the OEIS.

AUTHORS:

>>> sloane.A000009.list(Integer(14))
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

class sage.combinat.sloane_functions.A000010

Bases: SloaneSequence
The integer sequence A000010 is Euler’s totient function.

Number of positive integers \( i < n \) that are relative prime to \( n \). Number of totatives of \( n \).

Euler totient function \( \phi(n) \): count numbers \( n \) and prime to \( n \). euler\_phi is a standard Sage function implemented in PARI

**INPUT:**

- \( n \) – non negative integer

**OUTPUT:**

- integer – function value

**EXAMPLES:**

```python
sage: a = sloane.A000010; a
Euler's totient function
sage: a(1)
1
sage: a(0)
Traceback (most recent call last):
... ValueError: input n (=0) must be a positive integer
sage: a(11)
10
sage: a.list(12)
[1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 4]
```

**AUTHORS:**

- Jaap Spies (2007-01-12)
• \( n \) – non negative integer

OUTPUT:

AUTHORS:

- Jaap Spies (2007-01-18)

```python
class sage.combinat.sloane_functions.A000027
    Bases: SloaneSequence

    The natural numbers. Also called the whole numbers, the counting numbers or the positive integers.
    The following examples are tests of SloaneSequence more than A000027.

    EXAMPLES:
    
    sage: s = sloane.A000027; s
    The natural numbers.
    sage: s(10)
    10

    >>> from sage.all import *
    >>> s = sloane.A000027; s
    The natural numbers.
    >>> s(Integer(10))
    10

    Index n is interpreted as _eval(n):
    
    sage: s[10]
    10

    >>> from sage.all import *
    >>> s[Integer(10)]
    10

    Slices are interpreted with absolute offsets, so the following returns the terms of the sequence up to but not including
    the third term:
    
    sage: s[:3]
    [1, 2]
    sage: s[3:6]
    [3, 4, 5]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: s.list(5)
[1, 2, 3, 4, 5]
```

```python
>>> from sage.all import *
>>> s[:Integer(3)]
[1, 2]
>>> s[Integer(3):Integer(6)]
[3, 4, 5]
>>> s.list(Integer(5))
[1, 2, 3, 4, 5]
```

```

class sage.combinat.sloane_functions.A000166

Bases: SloaneSequence

Subfactorial or rencontres numbers, or derangements: number of permutations of \(n\) elements with no fixed points.
With offset 1 also the permanent of a (0,1)-matrix of order $n$ with $n$ 0's not on a line.

**INPUT:**
- $n$ – non negative integer

**OUTPUT:**
- integer – function value

**EXAMPLES:**

```sage
a = sloane.A000166;a
Subfactorial or rencontres numbers, or derangements: number of permutations of $n \rightarrow$ elements with no fixed points.
a(0)
1
a(1)

```python
class sage.combinat.sloane_functions.A000203
Bases: SloaneSequence

The sequence $\sigma(n)$, where $\sigma(n)$ is the sum of the divisors of $n$. Also called $\sigma_1(n)$.
The function $\text{sigma}(n, k)$ implements $\sigma_k(n)$ in Sage.

INPUT:

- $n$ – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```sage
sage: a = sloane.A000203; a
sigma(n) = sum of divisors of n. Also called sigma_1(n).
sage: a(1)
(continues on next page)

**class** sage.combinat.sloane_functions.A001222

**Bases:** SloaneSequence

Number of prime divisors of $n$ (counted with multiplicity).

Also called bigomega(n) or $\Omega(n)$. Maximal number of terms in any factorization of $n$. Number of prime powers that divide $n$.

**INPUT:**

- $n$ – non negative integer

**OUTPUT:**

- integer – function value

**EXAMPLES:**

```sage
sage: a = sloane.A001222; a
Number of prime divisors of n (counted with multiplicity).

sage: a(0)
Traceback (most recent call last):
... ValueError: input n (=0) must be a positive integer

sage: a(1)
0

sage: a(8)
3

sage: a(41)
1

sage: a(84792)
5

sage: a.list(12)
[0, 1, 1, 2, 1, 2, 1, 3, 2, 2, 1, 3]
```

```python
>>> from sage.all import *

>>> a = sloane.A001222; a
Number of prime divisors of n (counted with multiplicity).

>>> a(Integer(0))
Traceback (most recent call last):
... ValueError: input n (=0) must be a positive integer

>>> a(Integer(1))
0
```

Traceback (most recent call last):
  ... ValueError: input n (=-1) must be a positive integer
```

AUTHORS:

- Jaap Spies (2007-01-14)

`is_powerful(n)`

Return `True` if and only if `n` is a powerful number.

A positive integer `n` is powerful if for every prime `p` dividing `n`, `p^2` also divides `n`.

See OEIS sequence A001694.

INPUT:

- `n` – integer

OUTPUT:

True if `n` is a powerful number, else `False`

EXAMPLES:
AUTHORS:
- Jaap Spies (2006-12-07)

**list** *(n)*

EXAMPLES:

```python
sage: sloane.A001694.list(9)
[1, 4, 8, 9, 16, 25, 27, 32, 36]
```

```python
>>> from sage.all import *

>>> sloane.A001694.list(Integer(9))
[1, 4, 8, 9, 16, 25, 27, 32, 36]
```

**class** `sage.combinat.sloane_functions.A001836`

Bases: `SloaneSequence`

Numbers *n* such that \( \phi(2n-1) < \phi(2n) \), where \( \phi \) is Euler's totient function.

Euler's totient function is also known as `euler_phi`, `euler_phi` is a standard Sage function.

**INPUT:**
- *n* – non negative integer

**OUTPUT:**
- integer – function value

EXAMPLES:

```python
sage: a = sloane.A001836; a
Numbers n such that phi(2n-1) < phi(2n), where phi is Euler's totient function... A000010.

Bases: SloaneSequence

Thue-Morse sequence.

Let $A_k$ denote the first $2^k$ terms; then $A_0 = 0$, and for $k \geq 0$, $A_{k+1} = A_k B_k$, where $B_k$ is obtained from $A_k$ by interchanging 0’s and 1’s.

INPUT:

• $n$ – non negative integer

OUTPUT:

• integer – function value

EXAMPLES:

sage: a = sloane.A010060;a
Thue-Morse sequence.

AUTHORS:

- Jaap Spies (2007-01-17)

```python
class sage.combinat.sloane_functions.A082411
    Bases: RecurrenceSequence2

    Second-order linear recurrence sequence with \( a(n) = a(n-1) + a(n-2) \).
```
Combinatorics, Release 10.4

\(a(0) = 407389224418,\ a(1) = 76343678551\). This is the second-order linear recurrence sequence with \(a(0)\) and \(a(1)\) co-prime, that R. L. Graham in 1964 stated did not contain any primes.

INPUT:

- \(n\) – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```sage
sage: a = sloane.A082411;a
Second-order linear recurrence sequence with \(a(n) = a(n-1) + a(n-2)\).

sage: a(1)
76343678551
sage: a(2)
483732902969
sage: a(3)

**class** `sage.combinat.sloane_functions.A083103`

**Bases**: `RecurrenceSequence2`

Second-order linear recurrence sequence with \(a(n) = a(n - 1) + a(n - 2)\).

\(a(0) = 1786772701928802632268715130455793,\ a(1) = 1059683225053915111058165141686995\). This is the second-order linear recurrence sequence with \(a(0)\) and \(a(1)\) co-prime, that R. L. Graham in 1964 stated did not contain any primes. It has not been verified. Graham made a mistake in the calculation that was corrected by D. E. Knuth in 1990.

INPUT:

- \(n\) – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:
sage: a = sloane.A083103;a
Second-order linear recurrence sequence with $a(n) = a(n-1) + a(n-2)$.

AUTHORS:

- Jaap Spies (2007-01-23)
class sage.combinat.sloane_functions.A109814

Bases: SloaneSequence

The \( n \)th term of the sequence \( a(n) \) is the largest \( k \) such that \( n \) can be written as sum of \( k \) consecutive integers.

By definition, \( n \) is the sum of at most \( a(n) \) consecutive positive integers. Suppose \( n \) is to be written as sum of \( k \) consecutive integers starting with \( m \), then \( 2n = k(2m + k - 1) \). Only one of the factors is odd. For each odd divisor \( d \) of \( n \) there is a unique corresponding \( k = \min(d, 2n/d) \). \( a(n) \) can be alternatively defined as the largest among those \( k \).

See also:

- Wikipedia article Polite_number
- An exercise sheet (with answers) about sums of consecutive integers.

INPUT:

- \( n \) – non negative integer

OUTPUT:

- integer – function value

EXAMPLES:

```python
sage: a = sloane.A109814; a
\n\n```

\( a(n) \) is the largest \( k \) such that \( n \) can be written as sum of \( k \) consecutive positive integers.

```python
sage: a(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
```

```python
sage: a(2)
1
```

```python
sage: a.list(9)
[1, 1, 2, 1, 2, 3, 2, 1, 3]
```

```python
>>> from sage.all import *

```

```python
>>> a = sloane.A109814; a
\n\n```

\( a(n) \) is the largest \( k \) such that \( n \) can be written as sum of \( k \) consecutive positive integers.

```python
>>> a(Integer(0))
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
```

```python
>>> a(Integer(2))
1
```

```python
>>> a.list(Integer(9))
[1, 1, 2, 1, 2, 3, 2, 1, 3]
```

AUTHORS:

class sage.combinat.sloane_functions.A111774

Bases: SloaneSequence

Sequence of numbers of the third kind, i.e., numbers that can be written as a sum of at least three consecutive positive integers.
Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of \( k \) consecutive integers (other than the trivial \( n = n \) for \( k = 1 \)).

**INPUT:**
- \( n \) – non negative integer

**OUTPUT:**
- integer – function value

**EXAMPLES:**

```python
sage: a = sloane.A111774; a
Numbers that can be written as a sum of at least three consecutive positive integers.
sage: a(1)
6
sage: a(0)
Traceback (most recent call last):
  ... ValueError: input n (=0) must be a positive integer
sage: a(100)
141
sage: a(156)
209
sage: a(302)
386
sage: a.list(12)
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
sage: a(1/3)
Traceback (most recent call last):
  ... TypeError: input must be an int or Integer
```

```python
>>> from sage.all import *
>>> a = sloane.A111774; a
Numbers that can be written as a sum of at least three consecutive positive integers.
>>> a(Integer(1))
6
>>> a(Integer(0))
Traceback (most recent call last):
  ... ValueError: input n (=0) must be a positive integer
>>> a(Integer(100))
141
>>> a(Integer(156))
209
>>> a(Integer(302))
386
>>> a.list(Integer(12))
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
>>> a(Integer(1)/Integer(3))
Traceback (most recent call last):
  ... TypeError: input must be an int or Integer
```
AUTHORS:

• Jaap Spies (2007-01-13)

\textbf{is\_number\_of\_the\_third\_kind}(n)

Return True if and only if \( n \) is a number of the third kind.

A number is of the third kind if it can be written as a sum of at least three consecutive positive integers. Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of \( k \) consecutive integers (other than the trivial \( n = n \) for \( k = 1 \)).

INPUT:

• \( n \) – positive integer

OUTPUT:

True if \( n \) is not prime and not a power of 2

EXAMPLES:

\textbf{list}(n)

EXAMPLES:

<table>
<thead>
<tr>
<th>\textit{sage}</th>
<th>\textit{sloane.A111774.list}(12)</th>
</tr>
</thead>
<tbody>
<tr>
<td>[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]</td>
<td></td>
</tr>
</tbody>
</table>

```python
>>> from sage.all import *

>>> sloane.A111774.list(Integer(12))
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
```

class \texttt{sage.combinat.sloane\_functions.A111775}

Bases: \texttt{SloaneSequence}
Number of ways \( n \) can be written as a sum of at least three consecutive integers.

Powers of 2 and (odd) primes can not be written as a sum of at least three consecutive integers. \( a(n) \) strongly depends on the number of odd divisors of \( n \) (A001227): Suppose \( n \) is to be written as sum of \( k \) consecutive integers starting with \( m \), then \( 2n = k(2m + k - 1) \). Only one of the factors is odd. For each odd divisor of \( n \) there is a unique corresponding \( k \), \( k = 1 \) and \( k = 2 \) must be excluded.

**INPUT:**

- \( n \) – non negative integer

**OUTPUT:**

- integer – function value

**EXAMPLES:**

```sage
def a(n):
    return number_of_ways(n)

sage: a = sloane.A111775; a
Number of ways n can be written as a sum of at least three consecutive integers.

>>> from sage.all import *
>>> a = sloane.A111775; a
Number of ways n can be written as a sum of at least three consecutive integers.

sage: a(1)
0
sage: a(0)
0

>>> from sage.all import *
>>> a(Integer(1))
0
>>> a(Integer(0))
0
```

We have \( a(15) = 2 \) because \( 15 = 4+5+6 \) and \( 15 = 1+2+3+4+5 \). The number of odd divisors of 15 is 4.

```sage
def a(n):
    return number_of_ways(n)

sage: a(15)
2

>>> from sage.all import *
>>> a(Integer(15))
2
```

```sage
def a(n):
    return number_of_ways(n)

sage: a(100)
2
sage: a(256)
0
sage: a(29)
0
sage: a.list(20)
[0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 0, 1, 0, 1, 0, 1, 0, 1, 2, 0, 0, 2, 0]
sage: a(1/3)
Traceback (most recent call last):

```
AUTHORS:
• Jaap Spies (2006-12-09)

class sage.combinat.sloane_functions.A111787
Bases: SloaneSequence

This function returns the $n$-th number of Sloane’s sequence A111787
$a(n) = 0$ if $n$ is an odd prime or a power of 2. For numbers of the third kind (see A111774) we proceed as follows: suppose $n$ is to be written as sum of $k$ consecutive integers starting with $m$, then $2n = k(2m + k - 1)$. Let $p$ be the smallest odd prime divisor of $n$ then $a(n) = \min(p, 2n/p)$.

INPUT:
• n – non negative integer

OUTPUT:
• integer – function value

EXAMPLES:

```python
sage: a = sloane.A111787; a
a(n) is the least $k \geq 3$ such that $n$ can be written as sum of $k$ consecutive integers. $a(n)=0$ if such a $k$ does not exist.
sage: a.offset
1
sage: a(1)
0
sage: a(0)
Traceback (most recent call last):
  ... ValueError: input n (=0) must be a positive integer
sage: a(100)
5
sage: a(256)
0
sage: a(29)
0
sage: a.list(20)
[0, 0, 0, 0, 0, 3, 0, 0, 3, 4, 0, 3, 0, 4, 3, 0, 0, 3, 0, 5]
sage: a(-1)
Traceback (most recent call last):
... TypeError: input must be an int or Integer
```
ValueError: input n (=1) must be a positive integer

>>> from sage.all import *
>>> a = sloane.A111787; a

\(a(n)\) is the least \(k \geq 3\) such that \(n\) can be written as sum of \(k\) consecutive integers. \(a(n)=0\) if such a \(k\) does not exist.

>>> a.offset
1

>>> a(Integer(1))
0

>>> a(Integer(0))
Traceback (most recent call last):

class sage.combinat.sloane_functions.ExponentialNumbers(a)

Bases: SloaneSequence

A sequence of Exponential numbers.

EXAMPLES:

sage: from sage.combinat.sloane_functions import ExponentialNumbers
sage: ExponentialNumbers(0)
Sequence of Exponential numbers around 0

>>> from sage.all import *
>>> from sage.combinat.sloane_functions import ExponentialNumbers

>>> ExponentialNumbers(Integer(0))
Sequence of Exponential numbers around 0

class sage.combinat.sloane_functions.ExtremesOfPermanentsSequence(offset=1)

Bases: SloaneSequence

gen(a0, a1, d)

EXAMPLES:

sage: it = sloane.A000153.gen(0,1,2)
sage: [next(it) for i in range(5)]
[0, 1, 2, 7, 32]
```python
>>> from sage.all import *
>>> it = sloane.A000153.gen(Integer(0), Integer(1), Integer(2))
>>> [next(it) for i in range(Integer(5))]
[0, 1, 2, 7, 32]
```

**list** \(n\)

**EXAMPLES:**

```python
sage: sloane.A000153.list(8)
[0, 1, 2, 7, 32, 181, 1214, 9403]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
>>> e = ExtremesOfPermanentsSequence2()
>>> it = e.gen(Integer(6), Integer(43), Integer(6))
>>> [next(it) for i in range(Integer(5))]
[6, 43, 307, 2542, 23799]
```

**class** sage.combinat.sloane_functions.ExtremesOfPermanentsSequence2 \((offset=1)\)

**Bases:** ExtremesOfPermanentsSequence

**gen** \((a0, a1, d)\)

**EXAMPLES:**

```python
sage: from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
sage: e = ExtremesOfPermanentsSequence2()
sage: it = e.gen(6, 43, 6)
sage: [next(it) for i in range(5)]
[6, 43, 307, 2542, 23799]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
>>> e = ExtremesOfPermanentsSequence2()
>>> it = e.gen(Integer(6), Integer(43), Integer(6))
>>> [next(it) for i in range(Integer(5))]
[6, 43, 307, 2542, 23799]
```

**class** sage.combinat.sloane_functions.RecurrenceSequence \((offset=1)\)

**Bases:** SloaneSequence

**list** \(n\)

**EXAMPLES:**

```python
sage: sloane.A001110.list(8)
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

```python
>>> from sage.all import *
>>> sloane.A001110.list(Integer(8))
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

```python
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
>>> e = ExtremesOfPermanentsSequence2()
>>> it = e.gen(Integer(6), Integer(43), Integer(6))
>>> [next(it) for i in range(Integer(5))]
[6, 43, 307, 2542, 23799]
```

**class** sage.combinat.sloane_functions.RecurrenceSequence2 \((offset=1)\)

**Bases:** SloaneSequence

**list** \(n\)

**EXAMPLES:**

```python
sage: sloane.A001906.list(10)
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]
```
class sage.combinat.sloane_functions.Sloane
    Bases: SageObject

    A collection of Sloane generating functions.

    This class inspects sage.combinat.sloane_functions, accumulating all the SloaneSequence classes starting with ‘A’. These are listed for tab completion, but not instantiated until requested.

    EXAMPLES:

    Ensure we have lots of entries:

    sage: len(sloane.__dir__()) > 100
    True

    Ensure none are being incorrectly returned:

    sage: [None for n in sloane.__dir__() if not n.startswith('A')]
    []

    Ensure we can access dynamic constructions and cache correctly:

    sage: s = sloane.A000587
    sage: s is sloane.A000587
    True

    Ensure that we can access other functions in parent classes:

    sage: sloane.__class__
    <class 'sage.combinat.sloane_functions.Sloane'>

    AUTHORS:
    • Nick Alexander
class sage.combinat.sloane_functions.SloaneSequence(offset=1)

Bases: SageObject

Base class for a Sloane integer sequence.

list(n)

Return n terms of the sequence:

sequence[offset], sequence[offset+1], ..., sequence[offset+n-1].

EXAMPLES:

sage: sloane.A000012.list(4)
[1, 1, 1, 1]

sage.combinat.sloane_functions.perm_mh(m, h)

This function calculates $f(g, h)$ from Sloane’s sequences A079908-A079928

INPUT:

• m – positive integer
• h – non-negative integer

OUTPUT: permanent of the $m \times (m + h)$ matrix, etc.

EXAMPLES:

sage: from sage.combinat.sloane_functions import perm_mh
sage: perm_mh(3,3)
36
sage: perm_mh(3,4)
76

AUTHORS:

• Jaap Spies (2006)

sage.combinat.sloane_functions.recur_gen2 (a0, a1, a2, a3)

homogeneous general second-order linear recurrence generator with fixed coefficients

$a(0) = a0, a(1) = a1, a(n) = a2*a(n-1) + a3*a(n-2)$

EXAMPLES:

sage: from sage.combinat.sloane_functions import recur_gen2
sage: it = recur_gen2(1, 1, 1, 1)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import recur_gen2
>>> it = recur_gen2(Integer(1), Integer(1), Integer(1), Integer(1))
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]

sage.combinat.sloane_functions.recur_gen2b(a0, a1, a2, a3, b)
Inhomogeneous second-order linear recurrence generator with fixed coefficients and \( b = f(n) \)
\[ a(0) = a_0, a(1) = a_1, a(n) = a_2 * a(n-1) + a_3 * a(n-2) + f(n). \]

EXAMPLES:

sage: from sage.combinat.sloane_functions import recur_gen2b
sage: it = recur_gen2b(1, 1, 1, 1, lambda n: 0)
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]

sage.combinat.sloane_functions.recur_gen3(a0, a1, a2, a3, a4, a5)
Homogeneous general third-order linear recurrence generator with fixed coefficients
\[ a(0) = a_0, a(1) = a_1, a(2) = a_2, a(n) = a_3 * a(n-1) + a_4 * a(n-2) + a_5 * a(n-3) \]

EXAMPLES:

sage: from sage.combinat.sloane_functions import recur_gen3
sage: it = recur_gen3(1, 1, 1, 1, 1)
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]

5.1.315 Combinatorial species

Todo: Short blurb about species

Todo: Proofread / point to the main classes rather than the modules?
Introductory material

- Enumeration of trees using generating functions
- Species, decomposable combinatorial classes

Basic Species

- Combinatorial Species
- Empty Species
- Recursive Species
- Characteristic Species
- Cycle Species
- Partition Species
- Permutation species
- Linear-order Species
- Set Species
- Subset Species
- Examples of Combinatorial Species

Operations on Species

- Sum species
- Product species
- Composition species
- Functorial composition species

Miscellaneous

- Species structures
- Miscellaneous Functions

5.1.316 Characteristic Species

class sage.combinat.species.characteristic_species.CharacteristicSpecies(n, min=None, max=None, weight=None)

Bases: GenericCombinatorialSpecies, UniqueRepresentation

Return the characteristic species of order $n$.

This species has exactly one structure on a set of size $n$ and no structures on sets of any other size.

EXAMPLES:
```python
sage: X = species.CharacteristicSpecies(1)
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series()[0:4]
[0, 1, 0, 0]
sage: X.isotype_generating_series()[0:4]
[0, 1, 0, 0]
sage: X.cycle_index_series()[0:4]
# needs sage.modules
[0, p[1], 0, 0]
sage: F = species.CharacteristicSpecies(3)
sage: c = F.generating_series()[0:4]
sage: F._check()
True
sage: F == loads(dumps(F))
True
```

```python
>>> from sage.all import *

>>> X = species.CharacteristicSpecies(Integer(1))

>>> X.structures([Integer(1)]).list()
[1]

>>> X.structures([Integer(1),Integer(2)]).list()
[]

>>> X.generating_series()[Integer(0):Integer(4)]
[0, 1, 0, 0]

>>> X.isotype_generating_series()[Integer(0):Integer(4)]
[0, 1, 0, 0]

>>> X.cycle_index_series()[Integer(0):Integer(4)]
# needs sage.modules
[0, p[1], 0, 0]

>>> F = species.CharacteristicSpecies(Integer(3))

>>> c = F.generating_series()[Integer(0):Integer(4)]

>>> F._check()
True

>>> F == loads(dumps(F))
True
```

class sage.combinat.species.characteristic_species.CharacteristicSpeciesStructure

bases: GenericSpeciesStructure

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the characteristic species, there is only one structure, so every permutation is in its automorphism group.

EXAMPLES:
```python
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(['a', 'b', 'c']).random_element(); a
{'a', 'b', 'c'}
```
Combinatorics, Release 10.4

sage: a.automorphism_group()  #...
Symmetric group of order 3! as a permutation group

>>> from sage.all import *
>>> F = species.CharacteristicSpecies(Integer(3))
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> a.automorphism_group()  #...
Symmetric group of order 3! as a permutation group

canonical_label()

EXAMPLES:

sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}

>>> from sage.all import *
>>> F = species.CharacteristicSpecies(Integer(3))
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> a.canonical_label()
{'a', 'b', 'c'}

transport (perm)

Return the transport of this structure along the permutation perm.

EXAMPLES:

sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))  #...
needs sage.groups
sage: a.transport(p)  #...
needs sage.groups
{'a', 'b', 'c'}

>>> from sage.all import *
>>> F = species.CharacteristicSpecies(Integer(3))
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> p = PermutationGroupElement((Integer(1),Integer(2)))  # needs sage.groups
>>> a.transport(p)  #...
needs sage.groups
{'a', 'b', 'c'}

sage.combinat.species.characteristic_species.CharacteristicSpecies_class
alias of CharacteristicSpecies

5.1. Comprehensive Module List

5149
class sage.combinat.species.characteristic_species.EmptySetSpecies(min=None, max=None, weight=None)

Bases: CharacteristicSpecies

Returns the empty set species.

This species has exactly one structure on the empty set. It is the same (and is implemented) as CharacteristicSpecies(0).

EXAMPLES:

```sage
tax = species.EmptySetSpecies()
tax.structures([]).list()  # {}
tax.structures([1, 2]).list()  # []
tax.generating_series()[0:4]  # [1, 0, 0, 0]
tax.isotype_generating_series()[0:4]  # [1, 0, 0, 0]
tax.cycle_index_series()[0:4]  # needs sage.modules
[p[]], 0, 0, 0
```

```python
>>> from sage.all import *
>>> tax = species.EmptySetSpecies()
>>> tax.structures([]).list()  # {}
>>> tax.structures([1, 2]).list()  # []
>>> tax.generating_series()[0:4]  # [1, 0, 0, 0]
>>> tax.isotype_generating_series()[0:4]  # [1, 0, 0, 0]
>>> tax.cycle_index_series()[0:4]  # needs sage.modules
[p[]], 0, 0, 0
```

sage.combinat.species.characteristic_species.EmptySetSpecies_class

alias of EmptySetSpecies

class sage.combinat.species.characteristic_species.SingletonSpecies(min=None, max=None, weight=None)

Bases: CharacteristicSpecies

Returns the species of singletons.

This species has exactly one structure on a set of size 1. It is the same (and is implemented) as CharacteristicSpecies(1).

EXAMPLES:

```sage
tax = species.SingletonSpecies()
tax.structures([1]).list()  # [1]
tax.structures([1, 2]).list()  # []
tax.generating_series()[0:4]  # [1, 0, 0, 0]
tax.isotype_generating_series()[0:4]  # [1, 0, 0, 0]
tax.cycle_index_series()[0:4]  # needs sage.modules
[p[]], 0, 0, 0
```

(continues on next page)
sage: X = species.SingletonSpecies()

sage: X.structures([Integer(1)]).list()
[1]

sage: X.structures([Integer(1),Integer(2)]).list()
[]

sage: X.generating_series()[0:4]
[0, 1, 0, 0]

sage: X.isotype_generating_series()[0:4]
[0, 1, 0, 0]

sage: X.cycle_index_series()[0:4]

# needs sage.modules
[0, p[1], 0, 0]

>>> from sage.all import *

>>> X = species.SingletonSpecies()

>>> X.structures([Integer(1)]).list()
[1]

>>> X.structures([Integer(1),Integer(2)]).list()
[]

>>> X.generating_series()[0:4]
[0, 1, 0, 0]

>>> X.isotype_generating_series()[0:4]
[0, 1, 0, 0]

>>> X.cycle_index_series()[0:4]

# needs sage.modules
[0, p[1], 0, 0]

sage.combinat.species.characteristic_species.SingletonSpecies_class

alias of species.SingletonSpecies

5.1.317 Composition species

class sage.combinat.species.composition_species.CompositionSpecies(F, G, min=None, max=None, weight=None)

Bases: GenericCombinatorialSpecies, UniqueRepresentation

Returns the composition of two species.

EXAMPLES:

sage: E = species.SetSpecies()

sage: C = species.CycleSpecies()

sage: S = E(C)

sage: S.generating_series()[:5]
[1, 1, 1, 1, 1]

sage: E(C) == S
True

>>> from sage.all import *

>>> E = species.SetSpecies()

>>> C = species.CycleSpecies()

>>> S = E(C)

>>> S.generating_series()[:Integer(5)]
[1, 1, 1, 1, 1]

>>> E(C) == S
True
weight_ring()

Returns the weight ring for this species. This is determined by asking Sage’s coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```python
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: L.weight_ring()
Rational Field
```

```python
>>> from sage.all import *
>>> E = species.SetSpecies(); C = species.CycleSpecies()
>>> L = E(C)
>>> L.weight_ring()
Rational Field
```

```
class sage.combinat.species.composition_species.CompositionSpeciesStructure(parent, labels, pi, f, gs)

Bases: GenericSpeciesStructure

change_labels(labels)

Return a relabelled structure.

INPUT:

• labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```python
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures([a,'b','c']).list()  # needs sage.libs.flint
sage: a = S[2]; a  # needs sage.libs.flint
F-structure: {{a, c}, {b}}; G-structures: ((a, c), (b))
sage: a.change_labels([1,2,3])  # needs sage.libs.flint
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]
```

```python
>>> from sage.all import *
>>> E = species.SetSpecies(); C = species.CycleSpecies()
>>> L = E(C)
>>> S = L.structures(['a','b','c']).list()  # needs sage.libs.flint
>>> a = S[Integer(2)]; a  # needs sage.libs.flint
F-structure: {{a, 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
```

(continues on next page)
transport (perm)

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
# needs sage.groups

sage: E = species.SetSpecies(); C = species.CycleSpecies()

sage: L = E(C)

sage: S = L.structures([a,b,c]).list()
# needs sage.libs.flint

sage: a = S[2]; a
# needs sage.libs.flint

F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))

sage: a.transport(p)
# needs sage.groups sage.libs.flint

F-structure: {{'a', 'b'}, {'c'}}; G-structures: (('a', 'c'), ('b'))
```
>>> from sage.all import *
>>> C = species.CycleSpecies(); C
Cyclic permutation species
>>> C.structures([Integer(1),Integer(2),Integer(3),Integer(4)]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]

class sage.combinat.species.cycle_species.CycleSpeciesStructure

Bases: GenericSpeciesStructure

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

sage: P = species.CycleSpecies()
sage: a = P.structures([1, 2, 3, 4])[0]; a
(1, 2, 3, 4)
sage: a.automorphism_group()  # needs sageroups
Permutation Group with generators [(1,2,3,4)]

sage: a = P.structures([Integer(1), Integer(2), Integer(3),
Integer(4)])[Integer(0)]; a
(1, 2, 3, 4)
sage: a.automorphism_group()  # needs sageroups
Permutation Group with generators [(1,2,3,4)]

sage: [a.transport(perm) for perm in a.automorphism_group()]  # needs sageroups
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]

sage: [a.transport(perm) for perm in a.automorphism_group()]  # needs sageroups
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]

canonical_label()

EXAMPLES:

sage: P = species.CycleSpecies()
sage: P.structures(['a','b','c']).random_element().canonical_label()
('a', 'b', 'c')
```python
>>> from sage.all import *
>>> P = species.CycleSpecies()
>>> P.structures(["a", "b", "c"]).random_element().canonical_label()
('a', 'b', 'c')
```

**permutation_group_element()**

Returns this cycle as a permutation group element.

**EXAMPLES:**

```python
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: a.permutation_group_element() # needs sage.groups
(1,2,3)
```

```python
>>> from sage.all import *
>>> F = species.CycleSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(0)]; a
('a', 'b', 'c')
>>> a.permutation_group_element() # needs sage.groups
(1,2,3)
```

**transport (perm)**

Returns the transport of this structure along the permutation perm.

**EXAMPLES:**

```python
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: p = PermutationGroupElement((1,2)) # needs sage.groups
sage: a.transport(p) # needs sage.groups
('a', 'c', 'b')
```

```python
>>> from sage.all import *
>>> F = species.CycleSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(0)]; a
('a', 'b', 'c')
>>> p = PermutationGroupElement((Integer(1),Integer(2))) # needs sage.groups
>>> a.transport(p) # needs sage.groups
('a', 'c', 'b')
```

sage.combinat.species.cycle_species.CycleSpecies_class

alias of **CycleSpecies**
5.1.319 Empty Species

```python
class sage.combinat.species.empty_species.EmptySpecies (min=None, max=None, weight=None):
    Bases: GenericCombinatorialSpecies, UniqueRepresentation

    Returns the empty species. This species has no structure at all. It is the zero of the semi-ring of species.

    EXAMPLES:
    sage: X = species.EmptySpecies(); X
    Empty species
    sage: X.structures([]).list()
    []
    sage: X.structures([1]).list()
    []
    sage: X.structures([1,2]).list()
    []
    sage: X.generating_series()[:4]
    [0, 0, 0, 0]
    sage: X.isotype_generating_series()[:4]
    [0, 0, 0, 0]
    sage: X.cycle_index_series()[:4]  # needs sage.modules
    [0, 0, 0, 0]

    >>> from sage.all import *
    >>> X = species.EmptySpecies(); X
    Empty species
    >>> X.structures([]).list()
    []
    >>> X.structures([1]).list()
    []
    >>> X.structures([1,2]).list()
    []
    >>> X.generating_series()[:4]
    [0, 0, 0, 0]
    >>> X.isotype_generating_series()[:4]
    [0, 0, 0, 0]
    >>> X.cycle_index_series()[:4]  # needs sage.modules
    [0, 0, 0, 0]
```

The empty species is the zero of the semi-ring of species. The following tests that it is neutral with respect to addition:

```python
sage: Empt = species.EmptySpecies()
sage: S = species.CharacteristicSpecies(2)
sage: X = S + Empt
sage: X == S  # TODO: Not Implemented
True
sage: (X.generating_series()[:4] == 
    ....: S.generating_series()[:4])
True
sage: (X.isotype_generating_series()[:4] ==
    ....: S.isotype_generating_series()[:4])
True
```
sage: (X.cycle_index_series()[0:4] ==
needs sage.modules
....: S.cycle_index_series()[0:4])
True

>>> from sage.all import *
>>> Empt = species.EmptySpecies()
>>> S = species.CharacteristicSpecies(Integer(2))
>>> X = S + Empt
>>> X == S # TODO: Not Implemented
True
>>> (X.generating_series()[Integer(0):Integer(4)] ==
... S.generating_series()[Integer(0):Integer(4)])
True
>>> (X.isotype_generating_series()[Integer(0):Integer(4)] ==
... S.isotype_generating_series()[Integer(0):Integer(4)])
True
>>> (X.cycle_index_series()[Integer(0):Integer(4)] ==
# needs sage.modules
... S.cycle_index_series()[Integer(0):Integer(4)])
True

The following tests that it is the zero element with respect to multiplication:

sage: Y = Empt*S
sage: Y == Empt # TODO: Not Implemented
True
sage: Y.generating_series()[0:4]
[0, 0, 0, 0]
sage: Y.isotype_generating_series()[0:4]
[0, 0, 0, 0]
sage: Y.cycle_index_series()[0:4]
# needs sage.modules
[0, 0, 0, 0]

>>> from sage.all import *
>>> Y = Empt*S
>>> Y == Empt # TODO: Not Implemented
True
>>> Y.generating_series()[Integer(0):Integer(4)]
[0, 0, 0, 0]
>>> Y.isotype_generating_series()[Integer(0):Integer(4)]
[0, 0, 0, 0]
>>> Y.cycle_index_series()[Integer(0):Integer(4)]
# needs sage.modules
[0, 0, 0, 0]

sage.combinat.species.empty_species.EmptySpecies_class
alias of EmptySpecies
Combinatorics, Release 10.4

5.1.320 Functorial composition species

```
class sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies(F, G, min=None, max=None, weight=None):

    Bases: GenericCombinatorialSpecies

    Returns the functorial composition of two species.

    EXAMPLES:

    sage: E = species.SetSpecies()
    sage: E2 = species.SetSpecies(size=2)
    sage: WP = species.SubsetSpecies()
    sage: P2 = E2*E
    sage: G = WP.functorial_composition(P2)
    sage: G.isotype_generating_series()[0:5]
    1, 1, 2, 4, 11
    sage: G = species.SimpleGraphSpecies()
    sage: c = G.generating_series()[0:2]
    sage: type(G)
    <class 'sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies'>
    sage: G == loads(dumps(G))
    True
    sage: G._check()  # False due to isomorphism types not being implemented
    False

    >>> from sage.all import *
    >>> E = species.SetSpecies()
    >>> E2 = species.SetSpecies(size=Integer(2))
    >>> WP = species.SubsetSpecies()
    >>> P2 = E2*E
    >>> G = WP.functorial_composition(P2)
    >>> G.isotype_generating_series()[Integer(0):Integer(5)]  # needs sage.modules
    [1, 1, 2, 4, 11]
    >>> G = species.SimpleGraphSpecies()
    >>> c = G.generating_series()[Integer(0):Integer(2)]
    >>> type(G)
    <class 'sage.combinat.species.functorial_composition_species.FunctorialCompositionSpecies'>
    >>> G == loads(dumps(G))
    True
    >>> G._check()  # False due to isomorphism types not being implemented  # needs...
    False

    weight_ring()
    
    Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.
```
5.1.321 Generating Series

This file makes a number of extensions to lazy power series by endowing them with some semantic content for how they’re to be interpreted.

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse10.html. One notable difference is that we use power-sum symmetric functions as the coefficients of our cycle index series.
Combinatorics, Release 10.4

>>> p = SymmetricFunctions(QQ).power()
>>> CIS = CycleIndexSeriesRing(QQ)
>>> f = CIS([Integer(0), p([Integer(1)]), Integer(2)*p([Integer(1),
                       Integer(1)]), Integer(3)*p([Integer(2), Integer(1)])])
>>> f.coefficient_cycle_type([Integer(1)])
1
>>> f.coefficient_cycle_type([Integer(1), Integer(1)])
2
>>> f.coefficient_cycle_type([Integer(2), Integer(1)])
3

count(t)

Return the number of structures corresponding to a certain cycle type t.

EXAMPLES:

sage: # needs sage.modules
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]), 3*p([2,1])])
sage: f.count([1])
1
sage: f.count([1,1])
4
sage: f.count([2,1])
6

>>> from sage.all import *

>>> # needs sage.modules
>>> from sage.combinat.species.generating_series import CycleIndexSeriesRing

>>> p = SymmetricFunctions(QQ).power()
>>> CIS = CycleIndexSeriesRing(QQ)
>>> f = CIS([Integer(0), p([Integer(1)]), Integer(2)*p([Integer(1),
                       Integer(1)]), Integer(3)*p([Integer(2), Integer(1)])])
>>> f.count([Integer(1)])
1
>>> f.count([Integer(1), Integer(1)])
4
>>> f.count([Integer(2), Integer(1)])
6

derivative(n=1)

Return the species-theoretic n-th derivative of self.

For a cycle index series \( F(p_1, p_2, p_3, \ldots) \), its derivative is the cycle index series \( F' = D_{p_1} F \) (that is, the
formal derivative of \( F \) with respect to the variable \( p_1 \)).

If \( F \) is the cycle index series of a species \( S \) then \( F' \) is the cycle index series of an associated species \( S' \) of
\( S \)-structures with a “hole”.

EXAMPLES:

The species \( E \) of sets satisfies the relationship \( E' = E \):

sage: E = species.SetSpecies().cycle_index_series()  #...

(continues on next page)
sage: E[:8] == E.derivative()[:8]  # needs sage.modules
True

>>> from sage.all import *
>>> E = species.SetSpecies().cycle_index_series()  # needs sage.modules
>>> E[:Integer(8)] == E.derivative()[:Integer(8)]  # needs sage.modules
True

The species $C$ of cyclic orderings and the species $L$ of linear orderings satisfy the relationship $C' = L$:

sage: C = species.CycleSpecies().cycle_index_series()  # needs sage.modules
sage: L = species.LinearOrderSpecies().cycle_index_series()  # needs sage.modules
sage: L[:8] == C.derivative()[:8]  # needs sage.modules
True

exponential()

Return the species-theoretic exponential of self.

For a cycle index $Z_F$ of a species $F$, its exponential is the cycle index series $Z_E \circ Z_F$, where $Z_E$ is the ExponentialCycleIndexSeries().

The exponential $Z_E \circ Z_F$ is then the cycle index series of the species $E \circ F$ of “sets of $F$-structures”.

EXAMPLES:

Let $BT$ be the species of binary trees, $BF$ the species of binary forests, and $E$ the species of sets. Then we have $BF = E \circ BT$:

sage: BT = species.BinaryTreeSpecies().cycle_index_series()  # needs sage.modules
sage: BF = species.BinaryForestSpecies().cycle_index_series()  # needs sage.modules
sage: BT.exponential().isotype_generator_series()[:8] == BF.isotype_generator_series()[:8]  # needs sage.modules
True

>>> from sage.all import *
>>> BT = species.BinaryTreeSpecies().cycle_index_series()  # needs sage.modules
>>> BF = species.BinaryForestSpecies().cycle_index_series()  # needs sage.modules
(continues on next page)
generating_series()
Return the generating series of self.

EXAMPLES:

```python
sage: P = species.PartitionSpecies()
sage: cis = P.cycle_index_series()  # needs sage.modules
sage: f = cis.generating_series()  # needs sage.modules
sage: f[:5]  # needs sage.modules
[1, 1, 5/6, 5/8]
```

isotype_generating_series()
Return the isotype generating series of self.

EXAMPLES:

```python
sage: P = species.PermutationSpecies()
sage: cis = P.cycle_index_series()  # needs sage.modules
sage: f = cis.isotype_generating_series()  # needs sage.modules
sage: f[:10]  # needs sage.modules
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

logarithm()
Return the combinatorial logarithm of self.

For a cycle index $Z_F$ of a species $F$, its logarithm is the cycle index series $Z_{\Omega} \circ Z_F$, where $Z_{\Omega}$ is the `LogarithmCycleIndexSeries()`.
The logarithm $Z_Ω \circ Z_F$ is then the cycle index series of the (virtual) species $Ω \circ F$ of “connected $F$-structures”. In particular, if $F = E^+ \circ G$ for $E^+$ the species of nonempty sets and $G$ some other species, then $Ω \circ F = G$.

**EXAMPLES:**

Let $G$ be the species of nonempty graphs and $CG$ be the species of nonempty connected graphs. Then $G = E^+ \circ CG$, so $CG = Ω \circ G$:

```
sage: G = species.SimpleGraphSpecies().cycle_index_series() - 1  # needs sage.modules
sage: from sage.combinat.species.generating_series import LogarithmCycleIndexSeries
sage: CG = LogarithmCycleIndexSeries()(G)  # needs sage.modules
sage: CG.isotype_generating_series()[0:8]  # needs sage.modules
[0, 1, 1, 2, 6, 21, 112, 853]
```

```
>>> from sage.all import *
>>> G = species.SimpleGraphSpecies().cycle_index_series() - Integer(1)  # needs sage.modules
>>> from sage.combinat.species.generating_series import LogarithmCycleIndexSeries
>>> CG = LogarithmCycleIndexSeries()(G)  # needs sage.modules
>>> CG.isotype_generating_series()[Integer(0):Integer(8)]  # needs sage.modules
[0, 1, 1, 2, 6, 21, 112, 853]
```

**pointing()**

Return the species-theoretic pointing of self.

For a cycle index $F$, its pointing is the cycle index series $F^* = p_1 \cdot F'$.

If $F$ is the cycle index series of a species $S$ then $F^*$ is the cycle index series of an associated species $S^*$ of $S$-structures with a marked “root”.

**EXAMPLES:**

The species $E^*$ of “pointed sets” satisfies $E^* = X \cdot E$:

```
sage: E = species.SetSpecies().cycle_index_series()  # needs sage.modules
sage: X = species.SingletonSpecies().cycle_index_series()  # needs sage.modules
sage: E.pointing()[0:8] == (X*E)[0:8]  # needs sage.modules
True
```

```
>>> from sage.all import *
>>> E = species.SetSpecies().cycle_index_series()  # needs sage.modules
>>> X = species.SingletonSpecies().cycle_index_series()  # needs sage.modules
>>> E.pointing()[Integer(8)] == (X*E)[Integer(8)]  # needs sage.modules
True
```

**class** `sage.combinat.species.generating_series.CycleIndexSeriesRing` *(base_ring, sparse=True)*
Bases: LazySymmetricFunctions

Return the ring of cycle index series over \( R \).

This is the ring of formal power series \( \Lambda[x] \), where \( \Lambda \) is the ring of symmetric functions over \( R \) in the \( p \)-basis. Its purpose is to house the cycle index series of species (in a somewhat nonstandard notation tailored to Sage): If \( F \) is a species, then the cycle index series of \( F \) is defined to be the formal power series

\[
\sum_{n\geq 0} \frac{1}{n!} \left( \sum_{\sigma \in S_n} \text{fix}_F[\sigma] \prod_{\text{length of } z} z^n \right) x^n \in \Lambda_Q[x],
\]

where \( \text{fix}_F[\sigma] \) denotes the number of fixed points of the permutation \( F[\sigma] \) of \( F[n] \). We notice that this power series is “equigraded” (meaning that its \( x^n \)-coefficient is homogeneous of degree \( n \)). A more standard convention in combinatorics would be to use \( x_i \) instead of \( p_i \), and drop the \( x \) (that is, evaluate the above power series at \( x = 1 \)); but this would be more difficult to implement in Sage, as it would be an element of a power series ring in infinitely many variables.

Note that it is just a LazyPowerSeriesRing (whose base ring is \( \Lambda \)) whose elements have some extra methods.

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R
# is Cycle Index Series Ring over Rational Field
sage: p = SymmetricFunctions(QQ).p()
# is Symmetric Functions over Rational Field
sage: R(l lambda n: p[n])
```

Element

alias of CycleIndexSeries

sage.combinat.species.generating_series.ExponentialCycleIndexSeries()

Return the cycle index series of the species \( E \) of sets.

This cycle index satisfies

\[
Z_E = \sum_{n\geq 0} \sum_{\lambda \vdash n} \frac{p_{\lambda}}{z_{\lambda}}.
\]

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import ExponentialCycleIndexSeries
```

(continues on next page)
```python
# needs sage.modules
[p[], p[1], 1/2*p[1, 1] + 1/2*p[2], 1/6*p[1, 1, 1] + 1/2*p[2, 1]
+ 1/3*p[3], 1/24*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] + 1/8*p[2, 2]
+ 1/3*p[3, 1] + 1/4*p[4]]
```

```python
from sage.all import *
from sage.combinat.species.generating_series import ExponentialCycleIndexSeries

ExponentialCycleIndexSeries()[:5]  # ...
```

```python
from sage.all import *
from sage.combinat.species.generating_series import ExponentialCycleIndexSeries

ExponentialCycleIndexSeries()[:Integer(5)]
```

```python
class sage.combinat.species.generating_series.ExponentialGeneratingSeries(
    parent,
    coeff_stream)
Bases: LazyPowerSeries
A class for ordinary generating series.

Note that it is just a LazyPowerSeries whose elements have some extra methods.

EXAMPLES:
```
ExponentialGeneratingSeriesRing

```python
R = ExponentialGeneratingSeriesRing(QQ)
f = R(lambda n: Integer(1))
[f.count(i) for i in range(Integer(7))]
[1, 1, 2, 6, 24, 120, 720]
```

`counts(n)`

Return the number of structures on a set for size $i$ for each $i$ in range($n$).

**EXAMPLES:**

```python
sage: from sage.combinat.species.generating_series import ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(5)
[0, 1, 4, 18, 96]
```

`functorial_composition(y)`

Return the exponential generating series which is the functorial composition of `self` with $y$. If $f = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}$ and $g = \sum_{n=0}^{\infty} g_n \frac{x^n}{n!}$, then functorial composition $f \Box g$ is defined as

$$f \Box g = \sum_{n=0}^{\infty} f_n \frac{g_n}{n!}.$$ 

**REFERENCES:**

- Section 2.2 of [BLL1998].

**EXAMPLES:**

```python
sage: G = species.SimpleGraphSpecies()
sage: g = G.generating_series()
[sage: [g.coefficient(i) for i in range(10)]]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]

sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: g1 = WP.generating_series()
sage: g2 = P2.generating_series()
sage: g1.functorial_composition(g2)[:10]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

---

SimpleGraphSpecies()
```python
>>> g = G.generating_series()
>>> [g.coefficient(i) for i in range(Integer(10))]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]

>>> E = species.SetSpecies()
>>> E2 = E.restricted(min=Integer(2), max=Integer(3))
>>> WP = species.SubsetSpecies()
>>> P2 = E2*E
>>> g1 = WP.generating_series()
>>> g2 = P2.generating_series()
>>> g1.functorial_composition(g2)[:Integer(10)]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

class `sage.combinat.species.generating_series.ExponentialGeneratingSeriesRing`

```
Bases: `LazyPowerSeriesRing`

Return the ring of exponential generating series over R.

Note that it is just a `LazyPowerSeriesRing` whose elements have some extra methods.

EXAMPLES:
```
```
Its defining property is that $\Omega \circ E^+ = E^+ \circ \Omega = X$ (that is, that composition with $E^+$ in both directions yields the multiplicative identity $X$):

```python
sage: Eplus = sage.combinat.species.set_species.SetSpecies(min=Integer(1)).cycle_index_series() # needs sage.modules
sage: LogarithmCycleIndexSeries()(Eplus)[Integer(0):Integer(4)] # needs sage.modules
[0, p[1], 0, 0]
```

## class `sage.combinat.species.generating_series.OrdinaryGeneratingSeries` (`parent`, `coeff_stream`)

A class for ordinary generating series.

Note that it is just a `LazyPowerSeries` whose elements have some extra methods.

### EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(lambda n: n)
sage: f
z + 2*z^2 + 3*z^3 + 4*z^4 + 5*z^5 + 6*z^6 + O(z^7)
```

```python
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(lambda n: n)
>>> f
z + 2*z^2 + 3*z^3 + 4*z^4 + 5*z^5 + 6*z^6 + O(z^7)
```

### count ($n$)

Return the number of structures on a set of size $n$.

**INPUT:**
- $n$ – the size of the set
EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.count(10)
sage: 10
```

```python
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(range(Integer(20)))
>>> f.count(Integer(10))
sage: 10
```

counts\((n)\)

Return the number of structures on a set for size \(i\) for each \(i\) in \(\text{range}(n)\).

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```python
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(range(Integer(20)))
>>> f.counts(Integer(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

class sage.combinat.species.generating_series.OrdinaryGeneratingSeriesRing\((base\_ring)\)

Bases: LazyPowerSeriesRing

Return the ring of ordinary generating series over \(R\).

Note that it is just a LazyPowerSeriesRing whose elements have some extra methods.

EXAMPLES:

```python
sage: from sage.combinat.species.generating_series import OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ); R
Lazy Taylor Series Ring in z over Rational Field
sage: [R(lambda n: 1).coefficient(i) for i in range(4)]
[1, 1, 1, 1]
sage: R(lambda n: 1).counts(4)
[1, 1, 1, 1]
sage: R == loads(dumps(R))
True
```
Element
alias of OrdinaryGeneratingSeries

5.1.322 Examples of Combinatorial Species

sage.combinat.species.library.BinaryForestSpecies()

Return the species of binary forests.

Binary forests are defined as sets of binary trees.

EXAMPLES:

```
sage: F = species.BinaryForestSpecies()
sage: F.generating_series().counts(10)
[1, 1, 3, 19, 193, 2721, 49171, 1084483, 28245729, 848456353]
sage: F.isotype_generating_series().counts(10)  # needs sage.modules
[1, 1, 2, 4, 10, 26, 77, 235, 758, 2504]
sage: F.cycle_index_series()[:7]  # needs sage.modules
[p[], p[1],
  3/2*p[1, 1] + 1/2*p[2],
  19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
]
```

```python
>>> from sage.all import *
>>> F = species.BinaryForestSpecies()
>>> F.generating_series().counts(Integer(10))
[1, 1, 3, 19, 193, 2721, 49171, 1084483, 28245729, 848456353]
```

```python
>>> F.isotype_generating_series().counts(Integer(10))  # needs sage.modules
[1, 1, 2, 4, 10, 26, 77, 235, 758, 2504]
```

```python
>>> F.cycle_index_series()[:Integer(7)]  # needs sage.modules
[p[], p[1],
  3/2*p[1, 1] + 1/2*p[2],
```

19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
907/40*p[1, 1, 1, 1, 1] + 19/12*p[2, 1, 1, 1] + 5/8*p[2, 2, 1] + 1/2*p[3, 1, 1] \rightarrow 1/6*p[3, 2] + 1/4*p[4, 1] + 1/5*p[5],

sage.combinat.species.library.BinaryTreeSpecies()
Return the species of binary trees on n leaves.
The species of binary trees $B$ is defined by $B = X + B \cdot B$, where $X$ is the singleton species.
EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.generating_series().counts(10)
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
sage: B.isotype_generating_series().counts(10)
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
sage: B._check()
True
```

```python
>>> from sage.all import *

>>> B = species.BinaryTreeSpecies()
>>> B.generating_series().counts(Integer(10))
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
>>> B.isotype_generating_series().counts(Integer(10))
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
>>> B._check()
True
```

```
sage: B = species.BinaryTreeSpecies()
sage: a = B.structures([1,2,3,4,5])[187]; a
2*((5*3)*(4*1))
sage: a.automorphism_group() # needs sage.groups
Permutation Group with generators [(1,3,5)]
```

```
>>> from sage.all import *

>>> B = species.BinaryTreeSpecies()
>>> a = B.structures([Integer(1),Integer(2),Integer(3),Integer(4),
... Integer(5)])[Integer(187)]; a
2*((5*3)*(4*1))
>>> a.automorphism_group() # needs sage.groups
Permutation Group with generators [(1,3,5)]
```

sage.combinat.species.library.SimpleGraphSpecies()
Return the species of simple graphs.
EXAMPLES:

```
sage: S = species.SimpleGraphSpecies()
sage: S.generating_series().counts(10)
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]
```

(continues on next page)
sage: S.cycle_index_series()[:5]  
[1, 1, 1, 1, 1]  

sage: S.isotype_generating_series()[:6]  
[1, 1, 2, 4, 11, 34]  

>>> from sage.all import *  
>>> S = species.SimpleGraphSpecies()  
>>> S.generating_series().counts(Integer(10))  
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]  
>>> S.cycle_index_series()[:Integer(5)]  
[1, 1, 1, 1, 1]  

5.1.323 Linear-order Species

class sage.combinat.species.linear_order_species.LinearOrderSpecies(min=None, max=None, weight=None)

Bases: GenericCombinatorialSpecies, UniqueRepresentation

Returns the species of linear orders.

EXAMPLES:

sage: L = species.LinearOrderSpecies()  

sage: L = species.LinearOrderSpecies()  

sage: L = species.LinearOrderSpecies()  

sage: L._check()  
True

sage: L == loads(dumps(L))  
True

>>> from sage.all import *  
>>> L = species.LinearOrderSpecies()  
>>> L = species.LinearOrderSpecies()  

(continues on next page)
class sage.combinat.species.linear_order_species.LinearOrderSpeciesStructure(parent, labels, list)

Bases: GenericSpeciesStructure

automorphism_group()

Returns the group of permutations whose action on this structure leave it fixed. For the species of linear orders, there is no non-trivial automorphism.

EXAMPLES:

```
>>> F = species.LinearOrderSpecies()
>>> a = F.structures(["a", "b", "c"])[0]; a
['a', 'b', 'c']
>>> a.automorphism_group()
Symmetric group of order 1! as a permutation group
```

canonical_label()

EXAMPLES:

```
>>> P = species.LinearOrderSpecies()
>>> s = P.structures(["a", "b", "c"]).random_element()
>>> s.canonical_label()
['a', 'b', 'c']
```

transport(perm)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
>>> F = species.LinearOrderSpecies()
>>> a = F.structures(["a", "b", "c"])[0]; a
['a', 'b', 'c']
>>> p = PermutationGroupElement((1,2))
```
## 5.1.324 Miscellaneous Functions

**sage.combinat.species.misc.accept_size(f)**

The purpose of this decorator is to change calls like species.SetSpecies(size=1) to species.SetSpecies(min=1, max=2). This is to make caching species easier and to restrict the number of parameters that the lower level code needs to know about.

**EXAMPLES:**

```python
sage: from sage.combinat.species.misc import accept_size
sage: def f(*args, **kwds):
    print("{} {}").format(args, sorted(kwds.items()))

sage: f(min=1)
() [('min', 1)]

sage: f(size=2)
() [('max', 3), ('min', 2)]
```

**sage.combinat.species.misc.change_support(perm, support, change_perm=None)**

Changes the support of a permutation defined on [1, ..., n] to support.

**EXAMPLES:**

```python
sage: from sage.combinat.species.misc import change_support
sage: p = PermutationGroupElement((1,2,3)); p
(1,2,3)
```
sage: change_support(p, [3,4,5])
(3,4,5)

>>> from sage.all import *
>>> from sage.combinat.species.misc import change_support
>>>

5.1.325 Partition Species

class sage.combinat.species.partition_species.PartitionSpecies(min=None, max=None, weight=None)

Bases: GenericCombinatorialSpecies

Returns the species of partitions.

EXAMPLES:

sage: P = species.PartitionSpecies()
sage: P.generating_series()[0:5]
[1, 1, 1, 5/6, 5/8]
sage: P.isotype_generating_series()[0:5]
[1, 1, 2, 3, 5]
sage: P = species.PartitionSpecies()
sage: P._check()
True
sage: P == loads(dumps(P))
True

>>> from sage.all import *
>>>

class sage.combinat.species.partition_species.PartitionSpeciesStructure(parent, labels, list)

Bases: GenericSpeciesStructure

EXAMPLES:
```python
sage: from sage.combinat.species.partition_species import \n    PartitionSpeciesStructure
sage: P = species.PartitionSpecies()
sage: s = PartitionSpeciesStructure(P, ['a', 'b', 'c'], [[1, 2], [3]]); s
{{'a', 'b'}, {'c'}}
sage: s == loads(dumps(s))
True

automorphism_group()
Returns the group of permutations whose action on this set partition leave it fixed.

EXAMPLES:

```python
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import \n    PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2, 3, 4], [[1, 2], [3]]); a
{{2, 3}, {4}}
sage: a.automorphism_group()
Permutation Group with generators [(1,2)]
```

```python
>>> from sage.all import *
>>> from sage.combinat.species.partition_species import \n    PartitionSpeciesStructure
>>> a = PartitionSpeciesStructure(None, [Integer(2), Integer(3)], \n    [[Integer(1), Integer(2)], [Integer(3)]]); a
{{2, 3}, {4}}
>>> a.automorphism_group()
Permutation Group with generators [(1,2)]
```

canonical_label()
Returns the canonical label of a set partition.

EXAMPLES:

```python
sage: P = species.PartitionSpecies()
sage: S = P.structures(['a', 'b', 'c'])
sage: [s.canonical_label() for s in S]
[['{a}', '{b}', '{c}'],
 ['{a}', '{b}', '{c}'],
 ['{a}', '{c}', '{b}'],
 ['{b}', '{a}', '{c}'],
 ['{b}', '{c}', '{a}'],
 ['{c}', '{a}', '{b}'],
 ['{c}', '{b}', '{a}']]
```
change_labels(labels)

Return a relabelled structure.

INPUT:

• labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```python
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.change_labels([1,2,3])
{{1, 2}, {3}}
```

transport(perm)

Returns the transport of this set partition along the permutation perm. For set partitions, this is the direct product of the automorphism groups for each of the blocks.

EXAMPLES:

```python
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.transport(p)
{{2, 4}, {3}}
```

(continues on next page)
Continued from previous page

sage.combinat.species.partition_species.PartitionSpecies_class
    alias of PartitionSpecies

5.1.326 Permutation species

class sage.combinat.species.permutation_species.PermutationSpecies(
    min=None, max=None, weight=None)

    Bases: GenericCombinatorialSpecies, UniqueRepresentation

    Returns the species of permutations.

    EXAMPLES:

    sage: P = species.PermutationSpecies()
    sage: P.generating_series()[0:5]
    [1, 1, 1, 1, 1]
    sage: P.isotype_generating_series()[0:5]
    [1, 1, 2, 3, 5]
    sage: P = species.PermutationSpecies()
    sage: c = P.generating_series()[0:3]
    sage: P._check()
    True
    sage: P == loads(dumps(P))
    True

    >>> from sage.all import *
    >>> P = species.PermutationSpecies()
    >>> P.generating_series()[Integer(0):Integer(5)]
    [1, 1, 1, 1, 1]
    >>> P.isotype_generating_series()[Integer(0):Integer(5)]
    [1, 1, 2, 3, 5]
    >>> P = species.PermutationSpecies()
    >>> c = P.generating_series()[Integer(0):Integer(3)]
    >>> P._check()
    True
    >>> P == loads(dumps(P))
    True

class sage.combinat.species.permutation_species.PermutationSpeciesStructure(
    parent, labels, list)

    Bases: GenericSpeciesStructure

    automorphism_group()

    Returns the group of permutations whose action on this structure leave it fixed.
EXAMPLES:

```python
sage: set_random_seed(0)
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]
>>> from sage.all import *
>>> set_random_seed(Integer(0))
>>> p = PermutationGroupElement((Integer(2),Integer(3),Integer(4)))
>>> P = species.PermutationSpecies()
>>> a = P.structures(["a", "b", "c", "d"])[Integer(2)]; a
['a', 'c', 'b', 'd']
>>> a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]
```

```python
sage: [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd']]
```

```python
>>> from sage.all import *
>>> [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd']]
```

canonical_label()

EXAMPLES:

```python
sage: P = species.PermutationSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[['a', 'b', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c']]
```

```python
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.canonical_label() for s in S]
[['a', 'b', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c']]
```

permutation_group_element()
Combinatorics, Release 10.4

Returns self as a permutation group element.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.permutation_group_element()
(2,3)
```

transport (perm)

Returns the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.transport(p)
['a', 'd', 'c', 'b']
```

```
>>> from sage.all import *

>>> p = PermutationGroupElement((Integer(2),Integer(3),Integer(4)))

>>> P = species.PermutationSpecies()

>>> a = P.structures(["a", "b", "c", "d"])[Integer(2)]; a
['a', 'c', 'b', 'd']

>>> a.transport(p)
['a', 'd', 'c', 'b']
```

```
sage.combinat.species.permutation_species.PermutationSpecies_class

alias of PermutationSpecies

5.1.327 Product species

class sage.combinat.species.product_species.ProductSpecies(F, G, min=None, max=None, weight=None)

Bases: GenericCombinatorialSpecies, UniqueRepresentation

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: A = X*X
sage: A.generating_series()[0:4]
[0, 0, 1, 0]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
sage: F == loads(dumps(F))
True
sage: F._check()                          # needs sage.libs.flint
True

>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> A = X*X
>>> A.generating_series()[Integer(0):Integer(4)]
[0, 0, 1, 0]

>>> P = species.PermutationSpecies()
>>> F = P * P; F
Product of (Permutation species) and (Permutation species)
>>> F == loads(dumps(F))
True
>>> F._check()                          # needs sage.libs.flint
True
```

**left_factor()**

Returns the left factor of this product.

**EXAMPLES:**

```
sage: P = species.PermutationSpecies()
>>> X = species.SingletonSpecies()
>>> F = P*X
>>> F.left_factor()
Permutation species
```

**right_factor()**

Returns the right factor of this product.

**EXAMPLES:**

```
sage: P = species.PermutationSpecies()
>>> X = species.SingletonSpecies()
>>> F = P*X
>>> F.right_factor()
Singleton species
```

(continues on next page)
```python
>>> X = species.SingletonSpecies()
>>> F = P*X
>>> F.right_factor()
Singleton species
```

**weight_ring()**

Returns the weight ring for this species. This is determined by asking Sage’s coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

**EXAMPLES:**

```python
sage: S = species.SetSpecies()
sage: C = S*S
sage: C.weight_ring()
Rational Field
```

```python
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> C = S*S
>>> C.weight_ring()
Rational Field
```

```python
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S*S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```python
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> C = (S*S).weighted(QQ['t'].gen())
>>> C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```python
sage: # needs sage.groups
sage: p = PermutationGroupElement((2,3))
```

**class** `sage.combinat.species.product_species.ProductSpeciesStructure` (**parent, labels, subset, left, right**)

**Bases:** `GenericSpeciesStructure`

**automorphism_group()**

**EXAMPLES:**

```python
sage: # needs sage.groups
sage: p = PermutationGroupElement((2,3))
```
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures([1,2,3,4])[1]; a
{1}*{2, 3, 4}
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]

>>> from sage.all import *
>>> # needs sage.groups
>>> p = PermutationGroupElement((Integer(2),Integer(3)))
>>> S = species.SetSpecies()
>>> F = S * S
>>> a = F.structures([Integer(1),Integer(2),Integer(3),
→Integer(4)])[Integer(1)]; a
{1}*{2, 3, 4}
>>> a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]

sage: [a.transport(g) for g in a.automorphism_group()]
# needs sage.groups
[{1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4}]

>>> from sage.all import *
>>> [a.transport(g) for g in a.automorphism_group()]
# needs sage.groups
[{1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4},
 {1}*{2, 3, 4}]

sage: a = F.structures([1,2,3,4])[8]; a
# needs sage.groups
{2, 3}*{1, 4}
sage: [a.transport(g) for g in a.automorphism_group()]
# needs sage.groups
[{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}]

>>> from sage.all import *
>>> a = F.structures([Integer(1),Integer(2),Integer(3),
→Integer(4)])(Integer(8)); a
# needs sage.groups
{2, 3}*{1, 4}
>>> [a.transport(g) for g in a.automorphism_group()]
# needs sage.groups
[{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}]

canonical_label()

EXAMPLES:
sage: S = species.SetSpecies()
sage: F = S * S
sage: S = F.structures(['a', 'b', 'c']).list(); S
[{}*{a, b, c},
 {'a'}*{b, c},
 {'b'}*{a, c},
 {'c'}*{a, b},
 {'a', 'b'}*{c},
 {'a', 'c'}*{b},
 {'b', 'c'}*{a},
 {'a', 'b', 'c'}*{}
]

>>> from sage.all import *
>>> S = species.SetSpecies()
>>> F = S * S
>>> S = F.structures(['a', 'b', 'c']).list(); S
[{}*{a, b, c},
 {'a'}*{b, c},
 {'b'}*{a, c},
 {'c'}*{a, b},
 {'a', 'b'}*{c},
 {'a', 'c'}*{b},
 {'b', 'c'}*{a},
 {'a', 'b', 'c'}*{}
]
sage: F.isotypes(['a', 'b', 'c']).cardinality()
4

>>> from sage.all import *
>>> F.isotypes(['a', 'b', 'c']).cardinality()
4

>>> [s.canonical_label() for s in S]
[{}*{a, b, c},
 {'a'}*{b, c},
 {'b'}*{a, c},
 {'c'}*{a, b},
 {'a', 'b'}*{c},
 {'a', 'c'}*{b},
 {'b', 'c'}*{a},
 {'a', 'b', 'c'}*{}
]
change_labels (labels)

Return a relabelled structure.

INPUT:

- labels, a list of labels.

OUTPUT:
A structure with the i-th label of self replaced with the i-th label of the list.

**EXAMPLES:**

```python
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a', 'b', 'c'])[0]; a
{}*{a, b, c}
sage: a.change_labels([1, 2, 3])
{}*{1, 2, 3}
```

```python
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> F = S * S
>>> a = F.structures(['a', 'b', 'c'])[Integer(0)]; a
{}*{a, b, c}
>>> a.change_labels([Integer(1), Integer(2), Integer(3)])
{}*{1, 2, 3}
```

**transport** *(perm)*

**EXAMPLES:**

```python
sage: # needs sage.groups
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a', 'b', 'c'])[4]; a
{'a', 'b'}*{'c'}
sage: a.transport(p)
{'a', 'c'}*{'b'}
```

```python
>>> from sage.all import *
>>> # needs sage.groups
>>> p = PermutationGroupElement((Integer(2), Integer(3)))
>>> S = species.SetSpecies()
>>> F = S * S
>>> a = F.structures(['a', 'b', 'c'])[Integer(4)]; a
{'a', 'b'}*{'c'}
>>> a.transport(p)
{'a', 'c'}*{'b'}
```

`sage.combinat.species.product_species.ProductSpecies_class`

alias of `ProductSpecies`

### 5.1.328 Recursive Species

**class** `sage.combinat.species.recursive_species.CombinatorialSpecies` *(min=None)*

**Bases:** `GenericCombinatorialSpecies`

**EXAMPLES:**

```python
sage: F = CombinatorialSpecies()
sage: loads(dumps(F))
Combinatorial species
```
>>> from sage.all import *
>>> F = CombinatorialSpecies()
>>> loads(dumps(F))
Combinatorial species

sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series()[0:4]
[1, 1, 1, 1]
sage: LL = loads(dumps(L))
sage: LL.generating_series()[0:4]
[1, 1, 1, 1]

>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> E = species.EmptySetSpecies()
>>> L = CombinatorialSpecies()
>>> L.define(E+X*L)
>>> L.generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]
>>> LL = loads(dumps(L))
>>> LL.generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]

define(x)

Define self to be equal to the combinatorial species x.
This is used to define combinatorial species recursively. All of the real work is done by calling the .set() method for each of the series associated to self.

EXAMPLES: The species of linear orders L can be recursively defined by \( L = 1 + X \times L \) where 1 represents the empty set species and X represents the singleton species.

sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
>>> L.structures([1,2,3]).cardinality()
6
>>> L.structures([1,2,3]).list()
[1*(2*(3*{})),
 1*(3*(2*{})),
 2*(1*(3*{})),
 2*(3*(1*{})),
 3*(1*(2*{})),
 3*(2*(1*{}))]

(continues on next page)
>>> L.generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]
>>> L.structures([Integer(1),Integer(2),Integer(3)]).cardinality()
6
>>> L.structures([Integer(1),Integer(2),Integer(3)]).list()
[1*(2*(3*{})),
  1*(3*(2*{})),

weight_ring()

EXAMPLES:

sage: F = species.CombinatorialSpecies()
sage: F.weight_ring()
Rational Field

>>> from sage.all import *

>>> F = species.CombinatorialSpecies()
>>> F.weight_ring()
Rational Field

sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.weight_ring()
Rational Field

>>> from sage.all import *

>>> X = species.SingletonSpecies()
>>> E = species.EmptySetSpecies()
>>> L = CombinatorialSpecies()
>>> L.define(E+X*L)
>>> L.weight_ring()
Rational Field
5.1.329 Set Species

```python
class sage.combinat.species.set_species.SetSpecies
    Bases: GenericCombinatorialSpecies, UniqueRepresentation

Returns the species of sets.
```

```python
sage: E = species.SetSpecies()
sage: E.structures([1,2,3]).list()  
[[1, 2, 3]]
sage: E.isotype_generating_series()[0:4]   
[1, 1, 1, 1]
sage: S = species.SetSpecies()
sage: c = S.generating_series()[0:3]
sage: S._check()                         
True
sage: S == loads(dumps(S))             
True
```

```python
>>> from sage.all import *
>>> E = species.SetSpecies()
>>> E.structures([Integer(1),Integer(2),Integer(3)]).list()  
[[1, 2, 3]]
>>> E.isotype_generating_series()[Integer(0):Integer(4)]  
[1, 1, 1, 1]
>>> S = species.SetSpecies()
>>> c = S.generating_series()[Integer(0):Integer(3)]
>>> S._check()                         
True
>>> S == loads(dumps(S))             
True
```

```python
class sage.combinat.species.set_species.SetSpeciesStructure
    Bases: GenericSpeciesStructure
    automorphism_group()

Returns the group of permutations whose action on this set leave it fixed. For the species of sets, there is only one isomorphism class, so every permutation is in its automorphism group.
```

```python
sage: F = species.SetSpecies()
sage: a = F.structures(['a', 'b', 'c']).random_element(); a  
{a', 'b', 'c'}
sage: a.automorphism_group()                      
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

needs sage.groups
Symmetric group of order 3! as a permutation group

```python
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> a = F.structures(["a", "b", "c"]).random_element(); a
dict({'a': 'a', 'b': 'b', 'c': 'c'})
>>> a.automorphism_group() # needs sage.groups
Symmetric group of order 3! as a permutation group
```

canonical_label()

EXAMPLES:

```python
sage: S = species.SetSpecies()
sage: a = S.structures(["a", "b", "c"]).random_element(); a
dict({'a': 'a', 'b': 'b', 'c': 'c'})
sage: a.canonical_label()
dict({'a': 'a', 'b': 'b', 'c': 'c'})
```

transport (perm)

Returns the transport of this set along the permutation perm.

EXAMPLES:

```python
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
dict({'a': 'a', 'b': 'b', 'c': 'c'})
sage: p = PermutationGroupElement((1,2)) # needs sage.groups
sage: a.transport(p) # needs sage.groups
dict({'a': 'a', 'b': 'b', 'c': 'c'})
```

sage.combinat.species.set_species.SetSpecies_class
alias of SetSpecies

5.1. Comprehensive Module List
This file defines the main classes for working with combinatorial species, operations on them, as well as some implemen-
tations of basic species required for other constructions.

This code is based on the work of Ralf Hemmecke and Martin Rubey’s Aldor-Combinat, which can be found at http:
//www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file
can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse8.html.

Weighted Species:
As a first application of weighted species, we count unlabeled ordered trees by total number of nodes and number of
internal nodes. To achieve this, we assign a weight of \(1\) to the leaves and of \(q\) to internal nodes:

```python
sage: q = QQ['q'].gen()
sage: leaf = species.SingletonSpecies()
sage: internal_node = species.SingletonSpecies(weight=q)
sage: L = species.LinearOrderSpecies(min=1)
sage: T = species.CombinatorialSpecies(min=1)
sage: T.define(leaf + internal_node*L(T))
sage: T.isotype_generating_series()[0:6]  # needs sage.modules
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

Consider the following:

```python
>>> from sage.all import *
>>> q = QQ['q'].gen()
>>> leaf = species.SingletonSpecies()
>>> internal_node = species.SingletonSpecies(weight=q)
>>> L = species.LinearOrderSpecies(min=Integer(1))
>>> T = species.CombinatorialSpecies(min=Integer(1))
>>> T.define(leaf + internal_node*L(T))
>>> T.isotype_generating_series()[Integer(0):Integer(6)]  # needs sage.modules
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

This means that, among the trees on 4 nodes, one has a single internal node, three have two internal nodes, and one has
three internal nodes.

```python
class sage.combinat.species.species.GenericCombinatorialSpecies (min=None,
max=None,
weight=None)
```

Bases: SageObject

`algebraic_equation_system`()

Return a system of algebraic equations satisfied by this species.

The nodes are numbered in the order that they appear as vertices of the associated digraph.
EXAMPLES:

```python
sage: B = species.BinaryTreeSpecies()
sage: B.algebraic_equation_system()  # needs sage.graphs
[-node3^2 + node1, -node1 + node3 + (-z)]
```

```python
>>> from sage.all import *
>>> B = species.BinaryTreeSpecies()
>>> B.algebraic_equation_system()  # needs sage.graphs
[-node3^2 + node1, -node1 + node3 + (-z)]
```

```python
sage: sorted(B.digraph().vertex_iterator(), key=str)  # needs sage.graphs
[Combinatorial species with min=1, 
 Product of (Combinatorial species with min=1) 
 and (Combinatorial species with min=1), 
 Singleton species, 
 Sum of (Singleton species) 
 and (Product of (Combinatorial species with min=1) 
 and (Combinatorial species with min=1))]
```

```python
>>> from sage.all import *
>>> sorted(B.digraph().vertex_iterator(), key=str)  # needs sage.graphs
[Combinatorial species with min=1, 
 Product of (Combinatorial species with min=1) 
 and (Combinatorial species with min=1), 
 Singleton species, 
 Sum of (Singleton species) 
 and (Product of (Combinatorial species with min=1) 
 and (Combinatorial species with min=1))]
```

```python
sage: B.algebraic_equation_system()[0].parent()  # needs sage.graphs
Multivariate Polynomial Ring in node0, node1, node2, node3 over 
Fraction Field of Univariate Polynomial Ring in z over Rational Field
```

```python
>>> from sage.all import *
>>> B.algebraic_equation_system()[Integer(0)].parent()  
# needs sage.graphs
Multivariate Polynomial Ring in node0, node1, node2, node3 over 
Fraction Field of Univariate Polynomial Ring in z over Rational Field
```

composition\(g\)

EXAMPLES:

```python
sage: S = species.SetSpecies()
sage: S(S)
Composition of (Set species) and (Set species)
```

```python
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> S(S)
Composition of (Set species) and (Set species)
```
**cycle_index_series** *(base_ring=None)*

Return the cycle index series for this species.

The cycle index series is a sequence of symmetric functions.

**EXAMPLES:**

```
sage: P = species.PermutationSpecies()
sage: g = P.cycle_index_series()  # needs sage.modules
sage: g[0:4]  # needs sage.modules
```

**digraph()**

Return a directed graph where the vertices are the individual species that make up this one.

**EXAMPLES:**

```
sage: X = species.SingletonSpecies()
sage: B = species.CombinatorialSpecies()
sage: B.define(X+B*B)
sage: g = B.digraph(); g  # needs sage.graphs
Multi-digraph on 4 vertices
sage: sorted(g, key=str)  # needs sage.graphs
[(Combinatorial species,
  Product of (Combinatorial species) and (Combinatorial species),
  Singleton species,
  Sum of (Singleton species) and
  (Product of (Combinatorial species) and (Combinatorial species)))]
```

(continues on next page)
sorted(g, key=str)  # needs sage.graphs

\[
\begin{align*}
\text{Product of (Combinatorial species) and (Combinatorial species),} \\
\text{Singleton species,} \\
\text{Sum of (Singleton species) and} \\
\text{(Product of (Combinatorial species) and (Combinatorial species))}
\end{align*}
\]

d = {sp: i for i, sp in enumerate(g)}  # needs sage.graphs

g.relabel(d)  # needs sage.graphs

g.canonical_label().edges(sort=True)  # needs sage.graphs

\[(0, 3, \text{None}), (2, 0, \text{None}), (2, 0, \text{None}), (3, 1, \text{None}), (3, 2, \text{None})\]

functorial_composition(g)

Return the functorial composition of self with g.

EXAMPLES:

```python
sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=Integer(2), max=Integer(3))
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)  # needs sage.modules
sage: G.isotype_generating_series()[Integer(0):Integer(5)]
[1, 1, 2, 4, 11]
```

generating_series(base_ring=None)

Return the generating series for this species.

This is an exponential generating series so the $n$-th coefficient of the series corresponds to the number of labeled structures with $n$ labels divided by $n!$.

EXAMPLES:

```python
sage: P = species.PermutationSpecies()
sage: g = P.generating_series()
sage: g[:4]
[1, 1, 1, 1]
sage: g.counts(4)
[1, 1, 2, 6]
sage: P.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```
sage: len(_)
6

>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> g = P.generating_series()
>>> g[:Integer(4)]
[1, 1, 1]
>>> g.counts(Integer(4))
[1, 2, 6]
>>> P.structures([Integer(1),Integer(2),Integer(3)]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

is_weighted()
Return True if this species has a nontrivial weighting associated with it.

EXAMPLES:

sage: C = species.CycleSpecies()
sage: C.is_weighted()
False

isotype_generating_series(base_ring=None)
Return the isotype generating series for this species.

The $n$-th coefficient of this series corresponds to the number of isomorphism types for the structures on $n$ labels.

EXAMPLES:

sage: P = species.PermutationSpecies()
sage: g = P.isotype_generating_series()
sage: g[0:4]  # needs sage.libs.flint
[1, 1, 2, 3]
sage: g.counts(4)  # needs sage.libs.flint
[1, 2, 3, 6]
sage: P.isotypes([1,2,3]).list()  # needs sage.libs.flint
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

(continues on next page)
isotypes (labels, structure_class=None)

EXAMPLES:

```python
sage: F = CombinatorialSpecies()
sage: F.isotypes([1,2,3]).list()
Traceback (most recent call last):
...:
NotImplementedError
```

```python
>>> from sage.all import *
>>> F = CombinatorialSpecies()
>>> F.isotypes([Integer(1),Integer(2),Integer(3)]).list()
Traceback (most recent call last):
...:
NotImplementedError
```

product (g)

Return the product of self and g.

EXAMPLES:

```python
sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
```

```python
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> F = P * P; F
Product of (Permutation species) and (Permutation species)
```

restricted (*args, **kwds)

Return the restriction of the species.

INPUT:

- `min` – optional integer
- `max` – optional integer

EXAMPLES:

```python
sage: S = species.SetSpecies().restricted(min=3); S
Set species with min=3
sage: S.structures([1,2]).list()
```

(continues on next page)
from sage.all import *
S = species.SetSpecies().restricted(min=Integer(3)); S
S.structures([Integer(1),Integer(2)]).list()
S.generating_series()[Integer(0):Integer(5)]

structures (labels, structure_class=None)
EXAMPLES:

F = CombinatorialSpecies()
F.structures([1,2,3]).list()
Traceback (most recent call last):
...NotImplementedError

F = CombinatorialSpecies()
F.structures([Integer(1),Integer(2),Integer(3)]).list()
Traceback (most recent call last):
...NotImplementedError

sum(g)
Return the sum of self and g.

EXAMPLES:

P = species.PermutationSpecies()
P = P + P; F
P.structures([1,2]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]

weight_ring()
Return the ring in which the weights of this species occur.
By default, this is just the field of rational numbers.
EXAMPLES:

species.SetSpecies().weight_ring()
Rational Field
weighted\( (weight) \)

Return a version of this species with the specified weight.

EXAMPLES:

```python
sage: t = ZZ['t'].gen()
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.weighted(t)
Cyclic permutation species with weight=t
```

5.1.331 Species structures

We will illustrate the use of the structure classes using the “balls and bars” model for integer compositions. An integer composition of 6 such as \([2, 1, 3]\) can be represented in this model as ‘oooooo’ where the 6 o’s correspond to the balls and the 2 ‘s correspond to the bars. If BB is our species for this model, the it satisfies the following recursive definition:

\[
BB = o + o*BB + o*|*BB
\]

Here we define this species using the default structures:

```python
sage: ball = species.SingletonSpecies()
sage: bar = species.EmptySetSpecies()
sage: BB = CombinatorialSpecies()
sage: BB.define(ball + ball*BB + ball*bar*BB)
sage: o = var('o')
```

If we ignore the parentheses, we can read off that the integer compositions are \([3], [2, 1], [1, 2], \) and \([1, 1, 1]\).
class sage.combinat.species.structure.GenericSpeciesStructure(parent, labels, list)

Bases: CombinatorialObject

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```python
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

change_labels(labels)

Return a relabelled structure.

INPUT:

- labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```python
sage: P = species.SubsetSpecies()
sage: S = P.structures(['a', 'b', 'c'])
sage: [s.change_labels([1,2,3]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

is_isomorphic(x)

EXAMPLES:

```python
sage: S = species.SetSpecies()
sage: a = S.structures([1,2,3]).random_element(); a
{1, 2, 3}
sage: b = S.structures([a,b,c]).random_element(); b
{'a', 'b', 'c'}
```
sage: a.is_isomorphic(b)
True

>>> from sage.all import *
>>> S = species.SetSpecies()
>>> a = S.structures([Integer(1), Integer(2), Integer(3)]).random_element(); a
{1, 2, 3}
>>> b = S.structures([('a', 'b', 'c')].random_element(); b
('a', 'b', 'c')
>>> a.is_isomorphic(b)
True

labels()

Returns the labels used for this structure.

Note: This includes labels which may not “appear” in this particular structure.

EXAMPLES:

sage: P = species.SubsetSpecies()
sage: s = P.structures(['a', 'b', 'c']).random_element()
sage: s.labels()
['a', 'b', 'c']

parent()

Returns the species that this structure is associated with.

EXAMPLES:

sage: L = species.LinearOrderSpecies()
sage: a, b = L.structures([1, 2])
sage: a.parent()
Linear order species

class sage.combinat.species.structure.IsotypesWrapper(species, labels, structure_class)

Bases: SpeciesWrapper

A base class for the set of isotypes of a species with given set of labels. An object of this type is returned when you call the isotypes() method of a species.

EXAMPLES:
sage: F = species.SetSpecies()
sage: S = F.isotypes([1,2,3])
sage: S == loads(dumps(S))
True

>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.isotypes([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True

class sage.combinat.species.structure.SimpleIsotypesWrapper(species, labels, structure_class)

Bases: SpeciesWrapper

Warning: This is deprecated and currently not used for anything.

EXAMPLES:

sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True

>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.structures([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True

class sage.combinat.species.structure.SimpleStructuresWrapper(species, labels, structure_class)

Bases: SpeciesWrapper

Warning: This is deprecated and currently not used for anything.

EXAMPLES:

sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True

>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.structures([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True

sage.combinat.species.structure.SpeciesStructure
alias of GenericSpeciesStructure
class sage.combinat.species.structure.SpeciesStructureWrapper(\texttt{parent}, s, **\texttt{options})

\textbf{Bases:} GenericSpeciesStructure

This is a class for the structures of species such as the sum species that do not provide “additional” structure. For example, if you have the sum $C$ of species $A$ and $B$, then a structure of $C$ will either be either something from $A$ or $B$. Instead of just returning one of these directly, a “wrapper” is put around them so that they have their parent is $C$ rather than $A$ or $B$:

\begin{verbatim}
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: issubclass(type(s), SpeciesStructureWrapper)
True
\end{verbatim}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> E = species.SetSpecies(); B = E+E
>>> s = B.structures([Integer(1),Integer(2),Integer(3)]).random_element()
>>> s.parent()
Sum of (Set species) and (Set species)
>>> s == loads(dumps(s))
True
\end{verbatim}

\textbf{canonical\_label()}  

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([[1,2,3]])[1]; s
#→ needs sage.libs.flint
{{1}, {3}, {2}}
sage: s.canonical\_label()
#→ needs sage.libs.flint
{{1, 2}, {3}}
\end{verbatim}
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> P = species.PartitionSpecies()
>>> s = (P+P).structures([Integer(1),Integer(2),Integer(3)])[Integer(1)]; s
\{{1, 3}, \{2\}\}

change_labels (labels)

Return a relabelled structure.

INPUT:

- labels, a list of labels.

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```python
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.change_labels(['a'])
'\texttt{a}'
```

transport (perm)

EXAMPLES:

```python
sage: P = species.PartitionSpecies()
>>> s = (P+P).structures([1,2,3])[1]; s
\{{1, 3}, \{2\}\}

sage: s.transport(PermutationGroupElement((2,3)))
\{{1, 2}, \{3\}\}
```
```
class sage.combinat.species.structure.SpeciesWrapper(species, labels, iterator,
generating_series, name, 
structure_class)

Bases: Parent

This is a abstract base class for the set of structures of a species as well as the set of isotypes of the species.

Note: One typically does not use SpeciesWrapper directly, but instead instantiates one of its subclasses: StructuresWrapper or IsotypesWrapper.

EXAMPLES:

```
sage: from sage.combinat.species.structure import SpeciesWrapper
sage: F = species.SetSpecies()
sage: S = SpeciesWrapper(F, [1,2,3], "_structures", "generating_series", 
˓→'Structures', None)
sage: S
Structures for Set species with labels [1, 2, 3]
sage: S.list()

```

```
[1, 2, 3]
```

```
sage: S.cardinality()

```

```
1
```

cardinality()

Returns the number of structures in this set.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).cardinality()

```

```
1
```

```
>>> from sage.all import *

```

```
>>> from sage.combinat.species.structure import SpeciesWrapper

```

```
>>> F = species.SetSpecies()

```

```
>>> S = SpeciesWrapper(F, [Integer(1),Integer(2),Integer(3)], 
˓→"generating_series", 'Structures', None)

```

```
>>> S

```

```
Structures for Set species with labels [1, 2, 3]
```

```
>>> S.list()

```

```
[1, 2, 3]
```

```
>>> S.cardinality()

```

```
1
```

```
cardinality()

```

```
1
```

```
labels()

```

Returns the labels used on these structures. If \( X \) is the species, then labels() returns the preimage of these structures under the functor \( X \).

EXAMPLES:
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).labels()
[1, 2, 3]

>>> from sage.all import *
>>> F = species.SetSpecies()
>>> F.structures([Integer(1),Integer(2),Integer(3)]).labels()
[1, 2, 3]

class sage.combinat.species.structure.StructuresWrapper(species, labels, structure_class)

Bases: SpeciesWrapper

A base class for the set of structures of a species with given set of labels. An object of this type is returned when you call the structures() method of a species.

EXAMPLES:

sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True

>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.structures([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True

5.1.332 Subset Species

class sage.combinat.species.subset_species.SubsetSpecies(min=None, max=None, weight=None)

Bases: GenericCombinatorialSpecies, UniqueRepresentation

Return the species of subsets.

EXAMPLES:

sage: S = species.SubsetSpecies()
sage: S.generating_series()[0:5]
[1, 2, 2, 4/3, 2/3]
sage: S.isotype_generating_series()[0:5]
[1, 2, 3, 4, 5]
sage: S = species.SubsetSpecies()
sage: c = S.generating_series()[0:3]
sage: S._check()
True
sage: S == loads(dumps(S))
True

>>> from sage.all import *
>>> S = species.SubsetSpecies()
>>> S.generating_series()[Integer(0):Integer(5)]
[1, 2, 2, 4/3, 2/3]

(continues on next page)
```python
>>> S.isotype_generating_series()[Integer(0):Integer(5)]
[1, 2, 3, 4, 5]
>>> S = species.SubsetSpecies()
>>> c = S.generating_series()[Integer(0):Integer(3)]
>>> S._check()
True
>>> S == loads(dumps(S))
True
```

```python
class sage.combinat.species.subset_species.SubsetSpeciesStructure(parent, labels, list)

Bases: GenericSpeciesStructure

automorphism_group()

Return the group of permutations whose action on this subset leave it fixed.

EXAMPLES:

```python
sage: F = species.SubsetSpecies()
```
```python
sage: a = F.structures([1,2,3,4])[6]; a
{1, 3}
```
```python
sage: a.automorphism_group()    #---
Permutation Group with generators [(2,4), (1,3)]
```
```python
>>> from sage.all import *
```
```python
>>> F = species.SubsetSpecies()
```
```python
>>> a = F.structures([Integer(1),Integer(2),Integer(3),
                    Integer(4)])[Integer(6)]; a
{1, 3}
```
```python
>>> a.automorphism_group()    #---
Permutation Group with generators [(2,4), (1,3)]
```
```python
sage: [a.transport(g) for g in a.automorphism_group()]
#---
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]
```
```python
>>> from sage.all import *
```
```python
>>> [a.transport(g) for g in a.automorphism_group()]
#---
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]
```
```
canonical_label()

Return the canonical label of self.

EXAMPLES:
```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{}, {'a'}, {'a'}, {'a'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b', 'c'}]
```
```python
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.canonical_label() for s in S]
[{}, {a}, {a}, {a}, {a, b}, {a, b}, {a, b}, {a, b, c}]
```

**complement()**

Return the complement of self.

**EXAMPLES:**

```python
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"][5]); a
{'a', 'c'}
sage: a.complement()
{'b'}
```

```python
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

**label_subset()**

Return a subset of the labels that “appear” in this structure.

**EXAMPLES:**

```python
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

```python
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

**transport**(perm)

Return the transport of this subset along the permutation perm.

**EXAMPLES:**

```python
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"][5]); a
{'a', 'c'}
sage: p = PermutationGroupElement((1,2))
# needs sage.groups
sage: a.transport(p)
# needs sage.groups
{'b', 'c'}
sage: p = PermutationGroupElement((1,3))
# needs sage.groups
sage: a.transport(p)
# (continues on next page)
```
### 5.1.333 Sum species

**class** `sage.combinat.species.sum_species.SumSpecies` *(F, G, min=None, max=None, weight=None)*

**Bases:** `GenericCombinatorialSpecies, UniqueRepresentation`

Returns the sum of two species.

**EXAMPLES:**

```python
sage: S = species.PermutationSpecies()
sage: A = S+S
sage: A.generating_series()[:5]
[2, 2, 2, 2, 2]
sage: P = species.PermutationSpecies()
sage: F = P + P
sage: F._check()  # needs sage.libs.flint
True
sage: F == loads(dumps(F))
True
```
left_summand()

Returns the left summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.left_summand()
Permutation species
```

right_summand()

Returns the right summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.right_summand()
Product of (Permutation species) and (Permutation species)
```

weight_ring()

Returns the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you add elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S+S
sage: C.weight_ring()
Rational Field
```

```
class `sage.combinat.species.sum_species.SumSpeciesStructure`, `SumSpeciesStructure` (parent, s, **options)

Bases: `SpeciesStructureWrapper`

`sage.combinat.species.sum_species.SumSpecies_class`

alias of `SumSpecies`

5.1.334 Specht Modules

AUTHORS:

- Travis Scrimshaw (2023-1-22): initial version
- Travis Scrimshaw (2023-11-23): added simple modules based on code from Sacha Goldman

Todo: Integrate this with the implementations in `sage.modules.with_basis.representation`.

class `sage.combinat.specht_module.MaximalSpechtSubmodule`, `MaximalSpechtSubmodule` (specht_module)

Bases: `SymmetricGroupRepresentation`, `SubmoduleWithBasis`

The maximal submodule $U^\lambda$ of the Specht module $S^\lambda$.

ALGORITHM:

We construct $U^\lambda$ as the intersection $S \cap S^\perp$, where $S^\perp$ is the orthogonal complement of the Specht module $S$ inside of the tabloid module $T$ (with respect to the natural bilinear form on $T$).

EXAMPLES:

\[2^*U[0] + 2^*U[1], 2^*U[2] + 2^*U[3], 2^*U[0] + 2^*U[1], U[0] + 2^*U[2]\]

```python
>>> sum(SGA.basis()) * u
0
```

**Element**

alias of `Element`

class `sage.combinat.specht_module.SimpleModule`(specht_module)

Bases: `SymmetricGroupRepresentation`, `QuotientModuleWithBasis`

The simple $S_n$-module associated with a partition $\lambda$.

The simple module $D^\lambda$ is the quotient of the Specht module $S^\lambda$ by its maximal submodule $U^\lambda$.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,1,1])
sage: D = SM.simple_module()
sage: v = D.an_element(); v
2*D([[1, 3, 5], [2], [4]]) + 2*D([[1, 4, 5], [2], [3]])
sage: SGA.an_element() * v
2*D([[1, 2, 4], [3], [5]]) + 2*D([[1, 3, 5], [2], [4]])
```

```
>>> from sage.all import *
```

```python
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(1),Integer(1)])
>>> D = SM.simple_module()
>>> v = D.an_element(); v
2*D([[1, 3, 5], [2], [4]]) + 2*D([[1, 4, 5], [2], [3]])
>>> SGA.an_element() * v
2*D([[1, 2, 4], [3], [5]]) + 2*D([[1, 3, 5], [2], [4]])
```

We give an example on how to construct the decomposition matrix (the Specht modules are a complete set of irreducible projective modules) and the Cartan matrix of a symmetric group algebra:

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: BM = matrix(SGA.simple_module(1a).brauer_character()
...:     for 1a in Partitions(4, regular=3))
sage: SBT = matrix(SGA.specht_module(1a).brauer_character()
...:     for 1a in Partitions(4))
sage: D = SBT * ~BM; D
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: D.transpose() * D
[2 0 1 0]
[0 1 0 0]
[0 1 0 0]
[0 0 0 1]
```

```python
>>> from sage.all import *
```

```python
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> BM = matrix(SGA.simple_module(1a).brauer_character()
....:     for 1a in Partitions(4, regular=3))
>>> SBT = matrix(SGA.specht_module(1a).brauer_character()
....:     for 1a in Partitions(4))
```
Combinatorics, Release 10.4

(continued from previous page)

```python
... for la in Partitions(Integer(4), regular=Integer(3))
>>> SBT = matrix(SGA.specht_module(la).brauer_character()
... for la in Partitions(Integer(4))
>>> D = SBT * ~BM; D
[1 0 0 0]
[0 1 0 0]
[1 0 1 0]
[0 0 0 1]
[0 0 1 0]
>>> D.transpose() * D
[2 0 1 0]
[0 1 0 0]
[1 0 2 0]
[0 0 0 1]
[0 0 1 0]
```

We verify this against the direct computation (up to reindexing the rows and columns):

```python
sage: SGA.cartan_invariants_matrix()  # long time
[1 0 0 0]
[0 1 0 0]
[0 0 2 1]
[0 0 1 2]
```

```python
>>> from sage.all import *

sage: SGA.cartan_invariants_matrix()  # long time
[1 0 0 0]
[0 1 0 0]
[0 0 2 1]
[0 0 1 2]
```

Element
alias of Element

class sage.combinat.specht_module.SpechtModule(SGA, D)

Bases: SymmetricGroupRepresentation, SubmoduleWithBasis

A Specht module.

Let $S_n$ be the symmetric group on $n$ letters and $R$ be a commutative ring. The Specht module $S_D$ for a diagram $D$ is an $S_n$-module defined as follows. Let

$$R(D) := \sum_{w \in R_D} w,$$
$$C(D) := \sum_{w \in C_D} (-1)^w w,$$

where $R_D$ (resp. $C_D$) is the row (resp. column) stabilizer of $D$. Then, we construct the Specht module $S_D$ as the left ideal

$$S_D = R[S_n]C(D)R(D),$$

where $R[S_n]$ is the group algebra of $S_n$ over $R$.

INPUT:

* SGA – a symmetric group algebra
* D – a diagram

EXAMPLES:

5.1. Comprehensive Module List
We begin by constructing all irreducible Specht modules for the symmetric group $S_4$ and show that they give a full set of irreducible representations both by having distinct Frobenius characters and the sum of the square of their dimensions is equal to $4!$:

```
sage: SP = [la.specht_module(QQ) for la in Partitions(4)]
sage: s = SymmetricFunctions(QQ).s()
sage: [s(S.frobenius_image()) for S in SP]
[s[4], s[3, 1], s[2, 2], s[2, 1, 1], s[1, 1, 1, 1]]
sage: sum(S.dimension()^2 for S in SP)
24
```

Next, we compute the Specht module for a more general diagram for $S_5$ and compute its irreducible decomposition by using its Frobenius character:

```
sage: D = [(0,0), (0,1), (1,1), (1,2), (0,3)]
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module(D)
sage: SM.dimension()
9
sage: s(SM.frobenius_image())
s[3, 2] + s[4, 1]
```

This carries a natural (left) action of the symmetric group (algebra):

```
sage: S5 = SGA.group()
sage: v = SM.an_element(); v
sage: S5([2,1,5,3,4]) * v
sage: x = SGA.an_element(); x
[1, 2, 3, 4, 5] + 2*[1, 2, 3, 5, 4] + 3*[1, 2, 4, 3, 5] + [5, 1, 2, 3, 4]
sage: x * v
```

(continues on next page)

```python
>>> x = SGA.an_element(); x
[1, 2, 3, 4, 5] + 2*[1, 2, 3, 5, 4] + 3*[1, 2, 4, 3, 5] + [5, 1, 2, 3, 4]
```

```python
>>> x * v
```

See also:

*SpechtRepresentation* for an implementation of the representation by matrices.

```python
class Element
    Bases: IndexedFreeModuleElement
class sage.combinat.specht_module.SpechtModuleTableauxBasis(ambient)
    Bases: SpechtModule

A Specht module of a partition in the classical standard tableau basis.

This is constructed as a $S_n$-submodule of the *TabloidModule* (also referred to as the standard module).

See also:

- *SpechtModule* for the generic diagram implementation constructed as a left ideal of the group algebra
- *SpechtRepresentation* for an implementation of the representation by matrices.

bilinear_form($u, v$)

Return the natural bilinear form of self applied to $u$ and $v$.

The natural bilinear form is given by the pullback of the natural bilinear form on the tabloid module (where the tabloid basis is an orthonormal basis).

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([2,2,1])
sage: u = SM.an_element(); u
3*S[[1, 2], [3, 5], [4]] + 2*S[[1, 3], [2, 5], [4]] + 2*S[[1, 4], [2, 5], [3]]
sage: v = sum(SM.basis())
sage: SM.bilinear_form(u, v)
140
```

```python
from sage.all import *

>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>> SM = SGA.specht_module([Integer(2),Integer(2),Integer(1)])
>> u = SM.an_element(); u
3*S[[1, 2], [3, 5], [4]] + 2*S[[1, 3], [2, 5], [4]] + 2*S[[1, 4], [2, 5], [3]]
>> v = sum(SM.basis())
>> SM.bilinear_form(u, v)
140
```

gram_matrix()

Return the Gram matrix of the natural bilinear form of self.

**EXAMPLES:**
**intrinsic_arrangement** *(base_ring=None)*

Return the intrinsic arrangement of self.

Consider the Specht module $S^\lambda$ with $\lambda$ a (integer) partition of $n$ (i.e., $S^\lambda$ is an $S_n$-module). The intrinsic arrangement of $S^\lambda$ is the central hyperplane arrangement in $S^\lambda$ given by the hyperplanes $H_\alpha$, indexed by a set partition $\alpha$ of $\{1, \ldots, n\}$ of size $\lambda$, defined by

$$H_\alpha := \bigoplus_{\tau \in T_\alpha} (S^\lambda)^\tau,$$

where $T_\alpha$ is some set of generating transpositions of the Young subgroup $S_\alpha$ and $V^\tau$ denotes the $\tau$-invariant subspace of $V$. (These hyperplanes do not depend on the choice of $T_\alpha$.)

This was introduced in [TVY2020] as a generalization of the braid arrangement, which is the case when $\lambda = (n-1, 1)$ (equivalently, for the irreducible representation of $S_n$ given by the type $A_{n-1}$ root system).

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: SM = SGA.specht_module([2, 1, 1])
sage: A = SM.intrinsic_arrangement()
sage: A.hyperplanes()
(Hyperplane T0 - T1 - 3*T2 + 0,
 Hyperplane T0 - T1 + T2 + 0,
 Hyperplane T0 + 3*T1 + T2 + 0,
 Hyperplane 3*T0 + T1 - T2 + 0)
sage: A.is_free()
False
```
We reproduce Example 3 of [TVY2020]:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(5):
    ....:    SM = SGA.specht_module(la)
    ....:    A = SM.intrinsic_arrangement()
    ....:    print(la, A.characteristic_polynomial())
[5] 1
[4, 1] x^4 - 10*x^3 + 35*x^2 - 50*x + 24
[3, 2] x^5 - 15*x^4 + 90*x^3 - 260*x^2 + 350*x - 166
[3, 1, 1] x^6 - 10*x^5 + 45*x^4 - 115*x^3 + 175*x^2 - 147*x + 51
[2, 2, 1] x^5 - 10*x^4 + 45*x^3 - 105*x^2 + 120*x - 51
[2, 1, 1, 1] x^4 - 5*x^3 + 10*x^2 - 10*x + 4
[1, 1, 1, 1, 1] 1
sage: A = SGA.specht_module([4, 1]).intrinsic_arrangement()
```

```python
sage: A.characteristic_polynomial().factor()
(x - 4) * (x - 3) * (x - 2) * (x - 1)
```

```python
>>> from sage.all import *

>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> for la in Partitions(Integer(5)):
    ...     SM = SGA.specht_module(la)
    ...     A = SM.intrinsic_arrangement()
    ...     print(la, A.characteristic_polynomial())
[5] 1
[4, 1] x^4 - 10*x^3 + 35*x^2 - 50*x + 24
[3, 2] x^5 - 15*x^4 + 90*x^3 - 260*x^2 + 350*x - 166
[3, 1, 1] x^6 - 10*x^5 + 45*x^4 - 115*x^3 + 175*x^2 - 147*x + 51
[2, 2, 1] x^5 - 10*x^4 + 45*x^3 - 105*x^2 + 120*x - 51
[2, 1, 1, 1] x^4 - 5*x^3 + 10*x^2 - 10*x + 4
[1, 1, 1, 1, 1] 1
>>> A = SGA.specht_module([Integer(4), Integer(1)]).intrinsic_arrangement()
```

```python
>>> A.characteristic_polynomial().factor()
(x - 4) * (x - 3) * (x - 2) * (x - 1)
```

lift() The lift (embedding) map from self to the ambient space.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([3, 1, 1])
sage: SM.lift
Generic morphism:
  From: Specht module of [3, 1, 1] over Rational Field
  To:   Tabloid module of [3, 1, 1] over Rational Field
```
```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(3), Integer(1), Integer(1)])
>>> SM.lift
Generic morphism:
  From: Specht module of [3, 1, 1] over Rational Field
  To:   Tabloid module of [3, 1, 1] over Rational Field
```

**maximal_submodule()**

Return the maximal submodule of self.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: U = SM.maximal_submodule()
sage: U.dimension()
4
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> U = SM.maximal_submodule()
>>> U.dimension()
4
```

**retract()**

The retract map from the ambient space.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: X = SGA.tabloid_module([2,2,1])
sage: Y = X.specht_module()
sage: Y.retract
Generic morphism:
  From: Tabloid module of [2, 2, 1] over Rational Field
  To:   Specht module of [2, 2, 1] over Rational Field
sage: all(Y.retract(u.lift()) == u for u in Y.basis())
True
sage: Y.retract(X.zero())
0
sage: Y.retract(sum(X.basis()))
Traceback (most recent call last):
  ...
ValueError: ... is not in the image
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> X = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> Y = X.specht_module()
>>> Y.retract
Generic morphism:
  From: Tabloid module of [2, 2, 1] over Rational Field
  To:   Specht module of [2, 2, 1] over Rational Field
>>> all(Y.retract(u.lift()) == u for u in Y.basis())
(continues on next page)
```
true

>>> Y.retract(X.zero())
0
>>> Y.retract(sum(X.basis()))
Traceback (most recent call last):
... ValueError: ... is not in the image

\textbf{simple\_module}()

Return the simple (or irreducible) $S_n$-submodule of self.

\textbf{See also:}
SimpleModule

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
  sage: SM = SGA.specht_module([3,2])
  sage: L = SM.simple_module()
  sage: L.dimension()
  1

  sage: SGA = SymmetricGroupAlgebra(QQ, 5)
  sage: SM = SGA.specht_module([3,2])
  sage: SM.simple_module() is SM
  True

  >>> from sage.all import *
  >>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
  >>> SM = SGA.specht_module([Integer(3),Integer(2)])
  >>> L = SM.simple_module()
  >>> L.dimension()
  1
  >>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
  >>> SM = SGA.specht_module([Integer(3),Integer(2)])
  >>> SM.simple_module() is SM
  True
\end{verbatim}

class \texttt{sage.combinat.specht\_module.SymmetricGroupRepresentation}(SGA)

\textbf{Bases:} Representation\_abstract

Mixin class for symmetric group (algebra) representations.

\textbf{frobenius\_image}()

Return the Frobenius image of self.

The Frobenius map is defined as the map to symmetric functions

$$F(\chi) = \frac{1}{n!} \sum_{w \in S_n} \chi(w)p_\rho(w),$$

where $\chi$ is the character of the $S_n$-module self, $p_\lambda$ is the powersum symmetric function basis element indexed by $\lambda$, and $\rho(w)$ is the cycle type of $w$ as a partition. Specifically, this map takes irreducible representations indexed by $\lambda$ to the Schur function $s_\lambda$.

\textbf{EXAMPLES:}

5.1. Comprehensive Module List
We verify the regular representation:

```
sage: from sage.all import *
sage: SM = Partition((2,2,1)).specht_module(QQ)
sage: SM.frobenius_image()
s[2, 2, 1]
sage: SM = Partition((4,1)).specht_module(CyclotomicField(5))
sage: SM.frobenius_image()
s[4, 1]
```

```
>>> from sage.all import *
>>> SM = Partition((Integer(2),Integer(2),Integer(1))).specht_module(QQ)
>>> SM.frobenius_image()
s[2, 2, 1]
>>> SM = Partition((Integer(4),Integer(1))).specht_module(CyclotomicField(Integer(5)))
>>> SM.frobenius_image()
s[4, 1]
```

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (3,3), (4,4)])
sage: F = D.specht_module(QQ).frobenius_image(); F
s[1, 1, 1, 1, 1] + 4*s[2, 1, 1, 1] + 5*s[2, 2, 1] + 6*s[3, 1, 1] + 5*s[3, 2] + 4*s[4, 1] + s[5]
sage: s = SymmetricFunctions(QQ).s()
sage: F == sum(StandardTableaux(la).cardinality() * s[la] for la in Partitions(5))
True
sage: all(s[la] == la.specht_module(QQ).frobenius_image() for n in range(1, 5) for la in Partitions(n))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram

>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)), (Integer(1),Integer(2)), (Integer(2),Integer(3)), (Integer(2),Integer(4))])
>>> F = D.specht_module(QQ).frobenius_image(); F
s[1, 1, 1, 1, 1] + 4*s[2, 1, 1, 1] + 5*s[2, 2, 1] + 6*s[3, 1, 1] + 5*s[3, 2] + 4*s[4, 1] + s[5]
>>> s = SymmetricFunctions(QQ).s()
>>> F == sum(StandardTableaux(la).cardinality() * s[la] for la in Partitions(Integer(5)))
True
>>> all(s[la] == la.specht_module(QQ).frobenius_image() for n in range(Integer(1), Integer(5)) for la in Partitions(n))
True
```

```
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)), (Integer(1),Integer(2)), (Integer(2),Integer(3)), (Integer(2),Integer(4))])
>>> SM = D.specht_module(QQ)
>>> SM.frobenius_image()
```
An example using the tabloid module:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2, 2, 1])
sage: TM.frobenius_image()
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2), Integer(2), Integer(1)])
>>> TM.frobenius_image()
```

class sage.combinat.specht_module.TabloidModule(SGA, shape)

The vector space of all tabloids of a fixed shape with the natural symmetric group action.

A tabloid is an OrderedSetPartition whose underlying set is \{1, \ldots, n\}. The symmetric group acts by permuting the entries of the set. Hence, this is a representation of the symmetric group defined over any field.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: TM = SGA.tabloid_module([2, 2, 1])
sage: TM.dimension()
30
sage: TM.brauer_character()
(30, 6, 2, 0, 0)
sage: IM = TM.invariant_module()
sage: IM.dimension()
1
sage: IM.basis()[0].lift() == sum(TM.basis())
True
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> TM = SGA.tabloid_module([Integer(2), Integer(2), Integer(1)])
>>> TM.dimension()
30
>>> TM.brauer_character()
(30, 6, 2, 0, 0)
>>> IM = TM.invariant_module()
>>> IM.dimension()
1
>>> IM.basis()[Integer(0)].lift() == sum(TM.basis())
True
```

class Element

Bases: IndexedFreeModuleElement

bilinear_form(u, v)

Return the natural bilinear form of self applied to u and v.

The natural bilinear form is given by defining the tabloid basis to be orthonormal.

EXAMPLES:
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2,2,1])
sage: u = TM.an_element(); u
2*T[\{1, 2\}, \{3, 4\}, \{5\}] + 2*T[\{1, 2\}, \{3, 5\}, \{4\}] + 3*T[\{1, 2\}, \{4, 5\}, \{3\}]
sage: v = sum(TM.basis())
sage: TM.bilinear_form(u, v)
7
sage: TM.bilinear_form(u, TM.zero())
0

>> from sage.all import *
>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>> TM = SGA.tabloid_module([[Integer(2),Integer(2),Integer(1)]]
>> u = TM.an_element(); u
2*T[\{1, 2\}, \{3, 4\}, \{5\}] + 2*T[\{1, 2\}, \{3, 5\}, \{4\}] + 3*T[\{1, 2\}, \{4, 5\}, \{3\}]
>> v = sum(TM.basis())
>> TM.bilinear_form(u, v)
7
>> TM.bilinear_form(u, TM.zero())
0

specht_module()
Return the Specht submodule of self.
EXAMPLES:

sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2,2,1])
sage: TM.specht_module() is SGA.specht_module([2,2,1])
True

sage.combinat.specht_module.polytabloid(T)
Compute the polytabloid element associated to a tableau T.

For a tableau T, the polytabloid associated to T is

\[ e_T = \sum_{\sigma \in C_T} (-1)^\sigma \{\sigma T\}, \]

where \{\} is the row-equivalence class, i.e. a tabloid, and \( C_T \) is the column stabilizer of T. The sum takes place in the module spanned by tabloids \{T\}.

OUTPUT:
A dict whose keys are tabloids represented by tuples of frozensets and whose values are the coefficient.

EXAMPLES:

sage: from sage.combinat.specht_module import polytabloid
sage: T = StandardTableau([[1,3,4],[2,5]])
sage: polytabloid(T)
\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.specht_module import polytabloid
>>> T = StandardTableau(
[ [Integer(1), Integer(3), Integer(4)],
  [Integer(2), Integer(5)]
])
>>> polytabloid(T)
{(frozenset({1, 3, 4}), frozenset({2, 5})): 1,
  (frozenset({1, 4, 5}), frozenset({2, 3})): -1,
  (frozenset({2, 3, 4}), frozenset({1, 5})): -1,
  (frozenset({2, 4, 5}), frozenset({1, 3})): 1}
\end{verbatim}

\texttt{sage.combinat.specht_module.simple_module_rank}(\textit{la}, \textit{base\_ring})

Return the rank of the simple $S_n$-module corresponding to the partition \textit{la} of size $n$ over \textit{base\_ring}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.specht_module import simple_module_rank
sage: simple_module_rank([3,2,1,1], GF(3))
13
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.specht_module import simple_module_rank
>>> simple_module_rank([Integer(3),Integer(2),Integer(1),Integer(1)],
  GF(Integer(3)))
13
\end{verbatim}

\texttt{sage.combinat.specht_module.specht_module_rank}(\textit{D}, \textit{base\_ring}=None)

Return the rank of the Specht module of diagram \textit{D}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: from sage.combinat.specht_module import specht_module_rank
sage: specht_module_rank([[0, 0], [1, 1], [2, 2]])
6
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.specht_module import specht_module_rank
>>> specht_module_rank([[Integer(0), Integer(0)], [Integer(1), Integer(1)],
  [Integer(2), Integer(2)]])
6
\end{verbatim}

\texttt{sage.combinat.specht_module.specht_module_spanning_set}(\textit{D}, \textit{SGA}=None)

Return a spanning set of the Specht module of diagram \textit{D}.

\textbf{INPUT:}

- \textit{D} – a list of cells $(r, c)$ for row $r$ and column $c$
- \textit{SGA} – optional; a symmetric group algebra

\textbf{EXAMPLES:}
sage: from sage.combinat.specht_module import specht_module_spanning_set
sage: specht_module_spanning_set([(0,0), (1,1), (2,2)])
([1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1])
sage: specht_module_spanning_set([(0,0), (1,1), (2,1)])
([1, 2, 3] - [1, 3, 2], -[1, 2, 3] + [1, 3, 2], [2, 1, 3] - [3, 1, 2],
 [2, 3, 1] - [3, 1, 2] + [3, 1, 2], -[2, 1, 3] + [3, 1, 2], -[2, 3, 1] + [3, 2, 1])
sage: SGA = SymmetricGroup(3).algebra(QQ)
sage: specht_module_spanning_set([(0,0), (1,1), (2,1)], SGA)
(() - (2,3), -(1,2) + (1,3,2), (1,2,3) - (1,3),
 -() + (2,3), -(1,2,3) + (1,3), (1,2) - (1,3,2))

sage.combinat.specht_module.tabloid_gram_matrix(\text{la}, \text{base\_ring})

ComputetheGrammatrixofthebilinearformofaSpechtmodulepulledbackfromthetabloidmodule.

Forthe module spanned by all tabloids, we define an bilinear form by having the tabloids be an orthonormal basis.
We then pull this bilinear form back across the natural injection of the Specht module into the tabloid module.

EXAMPLES:

sage: from sage.combinat.specht_module import tabloid_gram_matrix
sage: tabloid_gram_matrix([3,2], GF(5))
[4 2 1 4]
[2 4 1 2 1]
[2 1 4 2 1]
[1 2 4 2]
[4 1 2 4]

sage: from sage.all import *
sage: from sage.combinat.specht_module import tabloid_gram_matrix
>>> tabloid_gram_matrix([Integer(3),Integer(2)], GF(Integer(5)))
[4 2 1 4]
[2 4 1 2 1]
[2 1 4 2 1]
[1 2 4 2]
[4 1 2 4]
5.1.335 Subsets

The set of subsets of a finite set. The set can be given as a list or a Set or else as an integer $n$ which encodes the set \{1, 2, ..., $n$\}. See Subsets for more information and examples.

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods

class sage.combinat.subset.SubMultiset_s(s)
    Bases: Parent

    The combinatorial class of the sub multisets of $s$.

EXAMPLES:

```python
sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S.cardinality()
12
sage: S.list()
[[], [1], [2], [3], [1, 2], [1, 3], [2, 2], [2, 3], [1, 2, 2], [1, 2, 3], [2, 2, 3], [1, 2, 2, 3]]
sage: S.first()
[]
sage: S.last()
[1, 2, 2, 3]

>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3)], submultiset=True)
>>> S.cardinality()
12
>>> S.list()
[[], [1], [2], [3], [1, 2], [1, 3], [2, 2], [2, 3], [1, 2, 2], [1, 2, 3], [2, 2, 3], [1, 2, 2, 3]]
>>> S.first()
[]
>>> S.last()
[1, 2, 2, 3]
```
cardinality()
Return the cardinality of self.

EXAMPLES:

```sage
S = Subsets([1,1,2,3],submultiset=True)
sage: S.cardinality()
12
sage: len(S.list())
12

S = Subsets([1,1,2,2,3],submultiset=True)
sage: S.cardinality()
18
sage: len(S.list())
18

S = Subsets([1,1,1,2,2,3],submultiset=True)
sage: S.cardinality()
24
sage: len(S.list())
24
```

```python
>>> from sage.all import *

>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(3)], submultiset=True)
>>> S.cardinality()
12

>>> len(S.list())
12

>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(2),Integer(3)], submultiset=True)
>>> S.cardinality()
18

>>> len(S.list())
18

>>> S = Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2), Integer(3)], submultiset=True)
>>> S.cardinality()
24

>>> len(S.list())
24
```

element_class
alias of list
generating_serie(variable='x')
Return the polynomial associated to the counting of the elements of self weighted by the number of element they contain.

EXAMPLES:

```sage
S = Subsets([1,1],submultiset=True).generating_serie()
x^2 + x + 1

S = Subsets([1,1,2,3],submultiset=True).generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
```
sage: Subsets([1,1,1,2,2,3,3,4],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1
sage: S = Subsets([1,1,1,2,2,3,3,4],submultiset=True)
sage: S.cardinality()
72
sage: sum(S.generating_serie())
72

random_element()
Return a random element of self with uniform law.

EXAMPLES:

sage: S = Subsets([1,2,3], submultiset=True)
sage: s in S
True

>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],
˓→submultiset=True)
>>> s = S.random_element()
>>> s in S
True

class sage.combinat.subset.SubMultiset_sk(s,k)
Bases: SubMultiset_s
The combinatorial class of the subsets of size \(k\) of a multiset \(s\). Note that each subset is represented by a list of the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

sage: S = Subsets([1,2,3], 2,submultiset=True)
sage: S._k
2
sage: S.cardinality()
4

(continues on next page)
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]

sage: from sage.all import *

>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(3),Integer(3)],Integer(2),
˓→submultiset=True)

>>> S._k
2

>>> S.cardinality()
4

>>> S.first()
[1, 2]

>>> S.last()
[3, 3]

>>> [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]

cardinality()
Return the cardinality of self.

Examples:

sage: S = Subsets([1,2,2,3,3,3],4,submultiset=True)
sage: S.cardinality()
5

sage: len(list(S))
5

sage: S = Subsets([1,2,2,3,3,3],3,submultiset=True)
sage: S.cardinality()
6

sage: len(list(S))
6

>>> from sage.all import *

>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(3),Integer(3),
˓→Integer(3)],Integer(4),submultiset=True)

>>> S.cardinality()
5

>>> len(list(S))
5

>>> S = Subsets([Integer(1),Integer(2),Integer(3),Integer(3),
˓→Integer(3)],Integer(3),submultiset=True)

>>> S.cardinality()
6

>>> len(list(S))
6

generating_serie(variable='x')
Return the polynomial associated to the counting of the elements of self weighted by the number of elements they contains.
EXAMPLES:

```python
sage: x = ZZ['x'].gen()
sage: l = [1,1,1,1,2,2,3]
sage: for k in range(len(l)):
    ...:     S = Subsets(l,k,submultiset=True)
    ...:     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

```python
>>> from sage.all import *
>>> x = ZZ['x'].gen()
>>> l = [Integer(1),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
     Integer(3)]
>>> for k in range(len(l)):
...     S = Subsets(l,k,submultiset=True)
...     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

**random_element()**

Return a random submultiset of given length.

EXAMPLES:

```python
sage: s = Subsets(7,3).random_element()
sage: s in Subsets(7,3)
True

sage: s = Subsets(7,5).random_element()
sage: s in Subsets(7,5)
True
```

```python
>>> from sage.all import *
>>> s = Subsets(Integer(7),Integer(3)).random_element()
>>> s in Subsets(Integer(7),Integer(3))
True

>>> s = Subsets(Integer(7),Integer(5)).random_element()
>>> s in Subsets(Integer(7),Integer(5))
True
```

`sage.combinat.subset.Subsets(s, k=None, submultiset=False)`

Return the combinatorial class of the subsets of the finite set `s`. The set can be given as a list, Set or any iterable convertible to a set. Alternatively, a non-negative integer `n` can be provided in place of `s`; in this case, the result is the combinatorial class of the subsets of the set `{1, 2, ..., n}` (i.e. of the Sage `range(1, n+1)`).

A second optional parameter `k` can be given. In this case, `Subsets` returns the combinatorial class of subsets of
s of size k.

**Warning:** The subsets are returned as Sets. Do not assume that these Sets are ordered; they often are not! (E.g., \texttt{Subsets(10).list()[619]} returns \lbrace 10, 4, 5, 6, 7 \rbrace on my system.) See \texttt{SubsetsSorted} for a similar class which returns the subsets as sorted tuples.

Finally the option \texttt{submultiset} allows one to deal with sets with repeated elements, usually called multisets. The method then returns the class of all multisets in which every element is contained at most as often as it is contained in s. These multisets are encoded as lists.

**EXAMPLES:**

```python
sage: S = Subsets([1, 2, 3]); S
Subsets of \lbrace 1, 2, 3 \rbrace
sage: S.cardinality()
8
sage: S.first()
\{

sage: S.last()
\{1, 2, 3\}

sage: S.random_element() in S
True
sage: S.list()
[\{\}, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}]
```

```python
>>> from sage.all import *

>>> S = Subsets([Integer(1), Integer(2), Integer(3)]); S
Subsets of \lbrace 1, 2, 3 \rbrace

>>> S.cardinality()
8

>>> S.first()
\{

>>> S.last()
\{1, 2, 3\}

>>> S.random_element() in S
True

>>> S.list()
[\{\}, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}]
```

Here is the same example where the set is given as an integer:

```python
sage: S = Subsets(3)

sage: S.list()
[\{\}, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}]
```

```python
>>> from sage.all import *
>>> S = Subsets(Integer(3))

>>> S.list()
[\{\}, \{1\}, \{2\}, \{3\}, \{1, 2\}, \{1, 3\}, \{2, 3\}, \{1, 2, 3\}]
```

We demonstrate various the effect of the various options:

```python
sage: S = Subsets(3, 2); S
Subsets of \{1, 2, 3\} of size 2
sage: S.list()
```

(continues on next page)
\[
[\{1, 2\}, \{1, 3\}, \{2, 3\}]
\]

\[
\text{sage: } S = \text{Subsets([1, 2, 2], submultiset=} \text{True}; S
\]\n\text{SubMultiset of [1, 2, 2]}

class sage.combinat.subset.SubsetsSorted(s)

    Bases: Subsets_s

    Lightweight class of all subsets of some set S, with each subset being encoded as a sorted tuple.

    Used to model indices of algebras given by subsets (so we don’t have to explicitly build all 2^n subsets in memory).
    For example, CliffordAlgebra.

    element_class
        alias of tuple

    first()
        Return the first element of self.

    EXAMPLES:
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.first()
()

>>> from sage.all import *
>>> from sage.combinat.subset import SubsetsSorted
>>> S = SubsetsSorted(range(Integer(3)))

last()

Return the last element of self.

EXAMPLES:

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.last()
(0, 1, 2)

random_element()

Return a random element of self.

EXAMPLES:

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))

unrank(r)

Return the subset which has rank r.

EXAMPLES:

sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))

(continues on next page)
class sage.combinat.subset.Subsets_s(s)

Bases: Parent

Subsets of a given set.

EXAMPLES:

```python
sage: S = Subsets(4); S
Subsets of {1, 2, 3, 4}
sage: S.cardinality()
16
sage: Subsets(4).list()
[[], [1], [2], [3], [4],
 [1, 2], [1, 3], [1, 4], [2, 3], [2, 4], [3, 4],
 [1, 2, 3], [1, 2, 4], [1, 3, 4], [2, 3, 4],
 [1, 2, 3, 4]]
```

```python
sage: S = Subsets(Subsets(Subsets(GF(3)))); S
Subsets of Subsets of Subsets of Finite Field of size 3
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S.unrank(3149254230)  # random
{{1}, [0, 2]}, {{0, 1, 2}, [0, 1], [1], [1, 2]},
{{2}, [1, 2], [0, 1, 2], [0, 2], [1], [1]},
{{0, 1, 2}, [0, 1], [0, 2], [1, 2]}
```

```python
>>> from sage.all import *
```

```python
sage: S = Subsets(Integer(4)); S
Subsets of {1, 2, 3, 4}
>>
S.cardinality()
16
>>> Subsets(Integer(4)).list()
[[], [1], [2], [3], [4],
 [1, 2], [1, 3], [1, 4], [2, 3], [2, 4], [3, 4],
 [1, 2, 3], [1, 2, 4], [1, 3, 4], [2, 3, 4],
 [1, 2, 3, 4]]
```

```python
>>> S = Subsets(Subsets(Subsets(GF(Integer(3))))); S
Subsets of Subsets of Subsets of Finite Field of size 3
>>> S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
>>> S.unrank(Integer(3149254230))  # random
{{1}, [0, 2]}, {{0, 1, 2}, [0, 1], [1], [1, 2]},
{{2}, [1, 2], [0, 1, 2], [0, 2], [1], [1]},
{{0, 1, 2}, [0, 1], [0, 2], [1, 2]}
```

cardinality()

Return the number of subsets of the set s.

This is given by \(2^{|s|}\).

EXAMPLES:
sage: Subsets(Set([1,2,3])).cardinality()
8
sage: Subsets([1,2,3,3]).cardinality()
8
sage: Subsets(3).cardinality()
8

>>> from sage.all import *

>>> Subsets(Set([Integer(1),Integer(2),Integer(3)])).cardinality()
8
>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)]).cardinality()
8
>>> Subsets(Integer(3)).cardinality()
8

**element_class**

alias of `Set_objectEnumerated`

**first()**

Returns the first subset of $s$. Since we aren't restricted to subsets of a certain size, this is always the empty set.

**EXAMPLES:**

```
sage: Subsets([1,2,3]).first()
{}
sage: Subsets(3).first()
{}
```

```
>>> from sage.all import *

>>> Subsets([Integer(1),Integer(2),Integer(3)]).first()
{}
>>> Subsets(Integer(3)).first()
{}
```

**last()**

Return the last subset of $s$. Since we aren't restricted to subsets of a certain size, this is always the set $s$ itself.

**EXAMPLES:**

```
sage: Subsets([1,2,3]).last()
{1, 2, 3}
sage: Subsets(3).last()
{1, 2, 3}
```

```
>>> from sage.all import *

>>> Subsets([Integer(1),Integer(2),Integer(3)]).last()
{1, 2, 3}
>>> Subsets(Integer(3)).last()
{1, 2, 3}
```

**lattice()**

Return the lattice of subsets ordered by containment.

**EXAMPLES:**
random_element()

Return a random element of the class of subsets of \( s \) (in other words, a random subset of \( s \)).

EXAMPLES:

\[
\begin{align*}
sage: & \text{Subsets(3).random_element() \quad \# \text{ random}} \\
& \quad \text{(2)} \\
sage: & \text{Subsets([4,5,6]).random_element() \quad \# \text{ random}} \\
& \quad \text{(5)} \\
sage: & S = \text{Subsets(\text{Subsets(\text{Subsets([0,1,2])})})} \\
sage: & S.\text{cardinality()} \\
& 115792089237316195423570985008687907853269984665640564039457584007913129639936 \\
sage: & s = S.\text{random_element()} \\
sage: & s \quad \# \text{ random} \\
& \quad \{{\{1, 2\}, \{2\}, \{0\}, \{1\}}, \{{\{1, 2\}, \{0, 1, 2\}, \{0, 2\}, \{0\}, \{0, 1\}\}, ... \{\{1, 2\}, \{2\}, \{1\}\}, \{{2\}, \{0, 2\}, \{\}, \{1\}\}} \\
sage: & s \text{ in } S \\
& \quad \text{True}
\end{align*}
\]

rank (sub)

Return the rank of \( \text{sub} \) as a subset of \( s \).
EXAMPLES:

```python
sage: Subsets(3).rank([])
0
sage: Subsets(3).rank([1, 2])
4
sage: Subsets(3).rank([1, 2, 3])
7
sage: Subsets(3).rank([2, 3, 4])
Traceback (most recent call last):
...
ValueError: {2, 3, 4} is not a subset of {1, 2, 3}
```

```python
>>> from sage.all import *
```

```python
sage: Subsets(Integer(3)).rank([])
0
sage: Subsets(Integer(3)).rank([Integer(1), Integer(2)])
4
sage: Subsets(Integer(3)).rank([Integer(1), Integer(2), Integer(3)])
7
sage: Subsets(Integer(3)).rank([Integer(2), Integer(3), Integer(4)])
Traceback (most recent call last):
...
ValueError: {2, 3, 4} is not a subset of {1, 2, 3}
```

### underlying_set()

Return the set of elements.

EXAMPLES:

```python
sage: Subsets(GF(13)).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}
```

```python
>>> from sage.all import *
```

```python
sage: Subsets(GF(Integer(13))).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}
```

### unrank(r)

Return the subset of $s$ that has rank $k$.

EXAMPLES:

```python
sage: Subsets(3).unrank(0)
()
sage: Subsets([2, 4, 5]).unrank(1)
(2)
sage: Subsets([1, 2, 3]).unrank(257)
Traceback (most recent call last):
...
IndexError: index out of range
```

```python
>>> from sage.all import *
```

```python
sage: Subsets(Integer(3)).unrank(Integer(0))
()
sage: Subsets([Integer(2), Integer(4), Integer(5)]).unrank(Integer(1))
(2)
sage: Subsets([Integer(1), Integer(2), Integer(3)]).unrank(Integer(257))
```

(continues on next page)
class sage.combinat.subset.Subsets_sk(s, k)

Bases: Subsets_s

Subsets of fixed size of a set.

EXAMPLES:

sage: S = Subsets([0,1,2,5,7], 3); S
Subsets of {0, 1, 2, 5, 7} of size 3
sage: S.cardinality()
10
sage: S.first(), S.last()
({0, 1, 2}, {2, 5, 7})
sage: S.random_element() # random
{0, 5, 7}
sage: S([0,2,7])
{0, 2, 7}
sage: S([0,3,5])
Traceback (most recent call last):
  ... IndexError: index out of range
sage: S([0])
Traceback (most recent call last):
  ... ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3

>>> from sage.all import *
>>> S = Subsets([Integer(0),Integer(1),Integer(2),Integer(5),Integer(7)],
   -Integer(3)); S
Subsets of {0, 1, 2, 5, 7} of size 3
>>> S.cardinality()
10
>>> S.first(), S.last()
(({0, 1, 2}, {2, 5, 7})
>>> S.random_element() # random
{0, 5, 7}
>>> S([Integer(0),Integer(2),Integer(7)])
{0, 2, 7}
>>> S([Integer(0),Integer(3),Integer(5)])
Traceback (most recent call last):
  ... ValueError: {0, 3, 5} not in Subsets of {0, 1, 2, 5, 7} of size 3
>>> S([Integer(0)])
Traceback (most recent call last):
  ... ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3

an_element()

Returns an example of subset.

EXAMPLES:
sage: Subsets(0,0).an_element()
{}
sage: Subsets(3,2).an_element()
{1, 3}
sage: Subsets([2,4,5],2).an_element()
{2, 5}

>>> from sage.all import *

>>> Subsets(Integer(0),Integer(0)).an_element()
{}

>>> Subsets(Integer(3),Integer(2)).an_element()
{1, 3}

>>> Subsets([Integer(2),Integer(4),Integer(5)],Integer(2)).an_element()
{2, 5}

cardinality()

EXAMPLES:

sage: Subsets(Set([1,2,3]), 2).cardinality()
3
sage: Subsets([1,2,3,3], 2).cardinality()
3
sage: Subsets([1,2,3], 1).cardinality()
3
sage: Subsets([1,2,3], 3).cardinality()
1
sage: Subsets([1,2,3], 0).cardinality()
1
sage: Subsets([1,2,3], 4).cardinality()
0
sage: Subsets(3,2).cardinality()
3

>>> from sage.all import *

>>> Subsets(Set([Integer(1),Integer(2),Integer(3)]), Integer(2)).cardinality()
3

>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)], Integer(2)).cardinality()
3

>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(1)], Integer(2)).cardinality()
3

>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)], Integer(1)).cardinality()
3

>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(3)).cardinality()
1

>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(0)).cardinality()
1

>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(4)).cardinality()
0

>>> Subsets(Integer(3),Integer(2)).cardinality()
3

>>> Subsets(Integer(3),Integer(4)).cardinality()
0

first()

Return the first subset of sof size k.
EXAMPLES:

```python
def Subsets(s, k):
    """Return the subset of size k."
    return s.subset(k)
```

```
sage: Subsets([1,2,3], 2).first()
{1, 2}
sage: Subsets([1,2,3,3], 2).first()
{1, 2}
sage: Subsets(3,2).first()
{1, 2}
sage: Subsets(3,4).first()
Traceback (most recent call last):
  ... EmptySetError
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

```
sage: s = Subsets(3, 2).random_element()
sage: s in Subsets(3, 2)
True
sage: Subsets(3,4).random_element()
Traceback (most recent call last):
...
EmptySetError

>>> from sage.all import *
>>> s = Subsets(Integer(3), Integer(2)).random_element()
>>> s in Subsets(Integer(3), Integer(2))
True
>>> Subsets(Integer(3),Integer(4)).random_element()
Traceback (most recent call last):
...
EmptySetError
```

**rank** *(sub)*

Return the rank of *sub* as a subset of *s* of size *k*.

**EXAMPLES:**

```
sage: Subsets(3,2).rank([1,2])
0
sage: Subsets([2,3,4],2).rank([3,4])
2
sage: Subsets([2,3,4],2).rank([2])
Traceback (most recent call last):
...
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
sage: Subsets([2,3,4],4).rank([2,3,4,5])
Traceback (most recent call last):
...
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}

>>> from sage.all import *

>>> Subsets(Integer(3),Integer(2)).rank([Integer(1),Integer(2)])
0
>>> Subsets([[Integer(2),Integer(3),Integer(4)],Integer(2)]).rank([Integer(3),
Integer(4)])
2
>>> Subsets([[Integer(2),Integer(3),Integer(4)],Integer(2)]).rank([Integer(2)])
Traceback (most recent call last):
...
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
>>> Subsets([[Integer(2),Integer(3),Integer(4)],Integer(4)]).rank([Integer(2),
Integer(3),Integer(4),Integer(5)])
Traceback (most recent call last):
...
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}
```

**unrank** *(r)*

Return the subset of *s* of size *k* that has rank *r*.

**EXAMPLES:**
Combinatorics, Release 10.4

sage: Subsets(3,2).unrank(0)
\{1, 2\}
sage: Subsets([2,4,5],2).unrank(0)
\{2, 4\}
sage: Subsets([1,2,8],3).unrank(42)
Traceback (most recent call last):
  ...
IndexError: index out of range

>>> from sage.all import *
>>> Subsets(Integer(3),Integer(2)).unrank(Integer(0))
\{1, 2\}

sage.combinat.subset.dict_to_list(d)

Return a list whose elements are the elements of \(i\) of \(d\) repeated with multiplicity \(d[i]\).

EXAMPLES:

sage: from sage.combinat.subset import dict_to_list
sage: dict_to_list({a:1, b:3})
[a, b, b, b]

>>> from sage.all import *
>>> from sage.combinat.subset import dict_to_list
>>>
dict_to_list({a:Integer(1), b:Integer(3)})
({a: 1, b: 3}, [a, b])

sage.combinat.subset.list_to_dict(l)

Return a dictionary of multiplicities and the list of its keys.

INPUT:

a list \(l\) with possibly repeated elements

The keys are the elements of \(l\) (in the same order in which they appear) and values are the multiplicities of each element in \(l\).

EXAMPLES:

sage: from sage.combinat.subset import list_to_dict
sage: list_to_dict([a, b, b, b])
({'a': 1, 'b': 3}, ['a', 'b'])

>>> from sage.all import *
>>> from sage.combinat.subset import list_to_dict
>>> list_to_dict([a, b, b, b])
({'a': 1, 'b': 3}, ['a', 'b'])

sage.combinat.subset.powerset(X)

Iterator over the \textit{list} of all subsets of the iterable \(X\), in no particular order. Each list appears exactly once, up to order.
INPUT:
- \( X \) – an iterable

OUTPUT: iterator of lists

EXAMPLES:

```python
sage: list(powerset([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
sage: [z for z in powerset([0,[1,2]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

Iterating over the power set of an infinite set is also allowed:

```python
sage: i = 0
sage: L = []
sage: for x in powerset(ZZ):
    ....:     if i > 10:
    ....:         break
    ....:     else:
    ....:         i += 1
    ....:         L.append(x)
sage: print(" ".join(map(str, L)))
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

You may also use subsets as an alias for powerset:

```python
>>> from sage.all import *

sage: subsets([1,2,3])
<generator object ...powerset at 0x...>
sage: list(subsets([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
```

The reason we return lists instead of sets is that the elements of sets must be hashable and many structures on which one wants the powerset consist of non-hashable objects.
The reason we return lists instead of sets is that the elements of sets must be hashable and many structures on which one wants the powerset consist of non-hashable objects.

AUTHORS:

• William Stein

• Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects $X$.

$s$.age.combinat.subset.subsets ($X$)

Iterator over the list of all subsets of the iterable $X$, in no particular order. Each list appears exactly once, up to order.

INPUT:

• $X$ – an iterable

OUTPUT: iterator of lists

EXAMPLES:

>>> list(subsets([Integer(1), Integer(2), Integer(3)]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of sets must be hashable and many structures on which one wants the powerset consist of non-hashable objects.

AUTHORS:

• William Stein

• Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects $X$.

$s$.age.combinat.subset.subsets ($X$)

Iterator over the list of all subsets of the iterable $X$, in no particular order. Each list appears exactly once, up to order.

INPUT:

• $X$ – an iterable

OUTPUT: iterator of lists

EXAMPLES:

$s$.age: list(powerset([1, 2, 3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
$s$.age: [z for z in powerset([0, [1, 2]])]
[[], [0], [[1, 2]]]

Iterating over the powerset of an infinite set is also allowed:

$s$.age: i = 0
$s$.age: L = []
$s$.age: for x in powerset($Z$.Z):
... if i > 10:
... break
... else:
... i += 1
... L.append(x)
$s$.age: print(" ".join(str(x) for x in L))
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
You may also use subsets as an alias for powerset:

```python
sage: subsets([1,2,3])
<generator object ...powerset at 0x...>
sage: list(subsets([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
```

The reason we return lists instead of sets is that the elements of sets must be hashable and many structures on which one wants the powerset consist of non-hashable objects.

AUTHORS:

• William Stein
• Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects X.

sage.combinat.subset.uniq(L)
Iterate over the elements of L, yielding every element at most once: keep only the first occurrence of any item.

The items must be hashable.

INPUT:

• L – iterable

EXAMPLES:

```python
sage: L = [1, 1, 8, -5, 3, -5, 'a', 'x', 'a']
sage: it = uniq(L); it
<generator object uniq at ...>
sage: list(it)
[1, 8, -5, 3, 'a', 'x']
```

```python
>>> from sage.all import *
```
5.1.336 Subsets satisfying a hereditary property

`sage.combinat.subsets_hereditary.subsets_with_hereditary_property(f, X, max_obstruction_size=None, ncpus=1)`

Return all subsets $S$ of $X$ such that $f(S)$ is true.

The boolean function $f$ must be decreasing, i.e. $f(S) \Rightarrow f(S')$ if $S' \subseteq S$.

This function is implemented to call $f$ as few times as possible. More precisely, $f$ will be called on all sets $S$ such that $f(S)$ is true, as well as on all inclusionwise minimal sets $S$ such that $f(S)$ is false.

The problem that this function answers is also known as the learning problem on monotone boolean functions, or as computing the set of winning coalitions in a simple game.

**INPUT:**

- $f$ – a boolean function which takes as input a list of elements from $X$.
- $X$ – a list/iterable.
- `max_obstruction_size` (integer) – if you know that there is a $k$ such that $f(S)$ is true if and only if $f(S')$ is true for all $S' \subseteq S$ with $S' \leq k$, set `max_obstruction_size=k`. It may dramatically decrease the number of calls to $f$. Set to `None` by default, meaning $k = |X|$.
- `ncpus` – number of cpus to use for this computation. Note that changing the value from 1 (default) to anything different *enables* parallel computations which can have a cost by itself, so it is not necessarily a good move. In some cases, however, it is a *great* move. Set to `None` to automatically detect and use the maximum number of cpus available.

**Note:** Parallel computations are performed through the `parallel()` decorator. See its documentation for more information, in particular with respect to the memory context.

**EXAMPLES:**

Sets whose elements all have the same remainder mod 2:

```python
sage: from sage.combinat.subsets_hereditary import subsets_with_hereditary_property
sage: def f(x):
...     return (not x) or all(xx % 2 == x[0] % 2 for xx in x)
sage: list(subsets_with_hereditary_property(f, range(4)))
[[], [0], [1], [2], [3], [0, 2], [1, 3]]
```

Same, on two threads:

```python
sage: sorted(subsets_with_hereditary_property(f, range(4), ncpus=2))
[[], [0], [0, 2], [1], [1, 3], [2], [3]]
```
One can use this function to compute the independent sets of a graph. We know, however, that in this case the maximum obstructions are the edges, and have size 2. We can thus set `max_obstruction_size=2`, which reduces the number of calls to `f` from 91 to 56:
5.1.337 Subsets whose elements satisfy a predicate pairwise

```
class sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets(ambient, predicate, maximal=False, element_class=<class 'sage.sets.set.Set_objectEnumerated'>):

    Bases: RecursivelyEnumeratedSet_forest

    The set of all subsets of ambient whose elements satisfy predicate pairwise

    INPUT:

    • ambient -- a set (or iterable)
    • predicate -- a binary predicate

    Assumptions: predicate is symmetric (predicate(x, y) == predicate(y, x)) and reflexive (predicate(x, x) == True).

    Note: in fact, predicate(x, x) is never called.

    Warning: The current name is suboptimal and is subject to change. Suggestions for a good name, and a good
    user entry point are welcome. Maybe Subsets(..., independent = predicate).
```

EXAMPLES:

We construct the set of all subsets of \{4, 5, 6, 8, 9\} whose elements are pairwise relatively prime:

```
sage: from sage.combinat.subsets_pairwise import PairwiseCompatibleSubsets
sage: def predicate(x, y):
    return gcd(x, y) == 1
sage: P = PairwiseCompatibleSubsets([4, 5, 6, 8, 9], predicate); P
An enumerated set with a forest structure
sage: P.list()
[[], [4], [4, 5], [9, 4, 5], [5], [5, 6], [8, 5], [8, 9, 5], [9, 5], [6],
 →[8], [8, 9], [9]]
sage: P.cardinality()
14
sage: P.category()
Category of finite enumerated sets
```

Here we consider only those subsets which are maximal for inclusion (not yet implemented):

```
```
Algorithm

In the following, we order the elements of the ambient set by order of apparition. The elements of self are generated by organizing them in a search tree. Each node of this tree is of the form \((\text{subset}, \text{rest})\), where:

- \(\text{subset}\) represents an element of self, represented by an increasing tuple
- \(\text{rest}\) is the set of all \(y\)'s such that \(y\) appears after \(x\) in the ambient set and \(\text{predicate}(x, y)\) holds, represented by a decreasing tuple

The root of this tree is \((\text{()}, \text{ambient})\). All the other elements are generated by recursive depth first search, which gives lexicographic order.

\(\text{children} (\text{subset}, \text{rest})\)

Returns the children of a node in the tree.

\(\text{post_process} (\text{subset}, \text{rest})\)

5.1.338 Subwords

A subword of a word \(w\) is a word obtained by deleting the letters at some (non necessarily adjacent) positions in \(w\). It is not to be confused with the notion of factor where one keeps adjacent positions in \(w\). Sometimes it is useful to allow repeated uses of the same letter of \(w\) in a “generalized” subword. We call this a subword with repetitions.

For example:

- “bnjr” is a subword of the word “bonjour” but not a factor;
- “njo” is both a factor and a subword of the word “bonjour”;
- “nr” is a subword of “bonjour”;
- “rn” is not a subword of “bonjour”;
- “nnu” is not a subword of “bonjour”;
- “nnu” is a subword with repetitions of “bonjour”;

>>> from sage.all import *
>>> P = PairwiseCompatibleSubsets([Integer(4), Integer(5), Integer(6), Integer(8), Integer(9)], predicate, maximal = True) # todo: not implemented
An enumerated set with a forest structure
>>> P.list() # todo: not implemented
[(9, 4, 5), (5, 6), (8, 9, 5)]
>>> P.cardinality() # todo: not implemented
14
>>> P.category()
Category of finite enumerated sets
A word can be given either as a string, as a list or as a tuple.

As repetition can occur in the initial word, in general subwords of a given word form an enumerated multiset rather than a set!

Todo:

- implement subwords with repetitions
- implement the category of `EnumeratedMultiset` and inheritate from it when needed (i.e. the initial word has repeated letters)

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods + bug fixes

`sage.combinat.subword.Subwords`(*w*, *k=None*, *element_constructor=None*)

Return the set of subwords of *w*.

**INPUT:**

- *w* – a word (can be a list, a string, a tuple or a word)
- *k* – an optional integer to specify the length of subwords
- *element_constructor* – an optional function that will be used to build the subwords

**EXAMPLES:**

```python
sage: S = Subwords(['a', 'b', 'c']); S
Subwords of ['a', 'b', 'c']
sage: S.first()
[]
sage: S.last()
['a', 'b', 'c']
sage: S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

```python
>>> from sage.all import *

>>> S = Subwords(['a', 'b', 'c']); S
Subwords of ['a', 'b', 'c']

>>> S.first()
[]

>>> S.last()
['a', 'b', 'c']

>>> S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

The same example using string, tuple or a word:

```python
sage: S = Subwords('abc'); S
Subwords of 'abc'
sage: S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']
```

```python
sage: S = Subwords((1,2,3)); S
Subwords of (1, 2, 3)
sage: S.list()
```

(continues on next page)
[((), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3))]

sage: w = Word([1,2,3])
sage: S = Subwords(w); S
Subwords of word: 123
sage: S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]

>>> from sage.all import *
>>> S = Subwords('abc'); S
Subwords of 'abc'
>>> S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']

>>> S = Subwords((Integer(1),Integer(2),Integer(3))); S
Subwords of (1, 2, 3)
>>> S.list()
[((), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3))]

>>> w = Word((Integer(1),Integer(2),Integer(3)))
>>> S = Subwords(w); S
Subwords of word: 123
>>> S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]

Using word with specified length:

sage: S = Subwords([a,b,c], 2); S
Subwords of [a, b, c] of length 2
sage: S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]

>>> from sage.all import *
>>> S = Subwords([a,b,c], Integer(2)); S
Subwords of [a, b, c] of length 2
>>> S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]

An example that uses the element_constructor argument:

sage: p = Permutation([3,2,1])
sage: Subwords(p, element_constructor=tuple).list()
[((), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1))]

>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(2),Integer(1)])
>>> Subwords(p, element_constructor=tuple).list()
[((), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1))]

class sage.combinat.subword.Subwords_w(w, element_constructor)

Bases: Parent
Subwords of a given word.

**cardinality()**

EXAMPLES:

```
sage: Subwords([1,2,3]).cardinality()
8

>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)]).cardinality()
8
```

**first()**

EXAMPLES:

```
sage: Subwords([1,2,3]).first()
[]
sage: Subwords((1,2,3)).first()
()
sage: Subwords('123').first()
''

>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)]).first()
[]
>>> Subwords((Integer(1),Integer(2),Integer(3))).first()
()
>>> Subwords('123').first()
''
```

**last()**

EXAMPLES:

```
sage: Subwords([1,2,3]).last()
[1, 2, 3]
sage: Subwords((1,2,3)).last()
(1, 2, 3)
sage: Subwords('123').last()
'123'

>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)]).last()
[1, 2, 3]
>>> Subwords((Integer(1),Integer(2),Integer(3))).last()
(1, 2, 3)
>>> Subwords('123').last()
'123'
```

**random_element()**

Return a random subword with uniform law.

EXAMPLES:

```
sage: S1 = Subwords([1,2,3,2,1,3])
sage: S2 = Subwords([4,6,6,7,4,5,5])
sage: for i in range(100):
    (continues on next page)```
Combinatorics, Release 10.4

(continued from previous page)

```python
...:  w = S1.random_element()
...:  if w in S2:
...:    assert not w

sage:  for i in range(100):
...:      w = S2.random_element()
...:      if w in S1:
...:        assert not w
```

```python
>>> from sage.all import *
>>> S1 = Subwords([Integer(1),Integer(2),Integer(3),Integer(2),Integer(1),
    →  Integer(3)])
>>> S2 = Subwords([Integer(4),Integer(6),Integer(6),Integer(6),Integer(7),
    →  Integer(4),Integer(5),Integer(5)])
>>> for i in range(Integer(100)):
...  w = S1.random_element()
...  if w in S2:
...    assert not w
```

```python
class sage.combinat.subword.Subwords_wk(w, k, element_constructor)
Bases: Subwords_w

Subwords with fixed length of a given word.

cardinality()

Return the number of subwords of w of length k.

EXAMPLES:

```python
sage: Subwords([1,2,3], 2).cardinality()
3
```

```python
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)], Integer(2)).cardinality()
3
```

first()

EXAMPLES:

```python
sage: Subwords([1,2,3],2).first()
[1, 2]
sage: Subwords([1,2,3],0).first()
[]
sage: Subwords((1,2,3),2).first()
(1, 2)
sage: Subwords((1,2,3),0).first()
()  
sage: Subwords('123',2).first()
'12'
sage: Subwords('123',0).first()
```

5.1. Comprehensive Module List
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)],Integer(2)).first()
[1, 2]
>>> Subwords([Integer(1),Integer(2),Integer(3)],Integer(0)).first()
[]
>>> Subwords((Integer(1),Integer(2),Integer(3)),Integer(2)).first()
(1, 2)
>>> Subwords((Integer(1),Integer(2),Integer(3)),Integer(0)).first()
()
>>> Subwords('123',Integer(2)).first()
'12'
>>> Subwords('123',Integer(0)).first()
'
last()

EXAMPLES:

sage: Subwords([1,2,3],2).last()
[2, 3]
sage: Subwords([1,2,3],0).last()
[]
sage: Subwords((1,2,3),2).last()
(2, 3)
sage: Subwords((1,2,3),0).last()
()
sage: Subwords('123',2).last()
'23'
sage: Subwords('123',0).last()
'

random_element()

Return a random subword of given length with uniform law.

EXAMPLES:

sage: S1 = Subwords([1,2,3,2,1],3)
sage: S2 = Subwords([4,4,5,5,4,4,4,4,4],3)
sage: for i in range(100):
....:     w = S1.random_element()
....:     if w in S2:
....:         assert not w
sage: for i in range(100):
....:     w = S2.random_element()
....:  if w in S1:
....:    assert not w

>>> from sage.all import *
>>> S1 = Subwords([Integer(1), Integer(2), Integer(3), Integer(2), Integer(1)], Integer(3))
>>> S2 = Subwords([Integer(4), Integer(4), Integer(5), Integer(5), Integer(4), Integer(4), Integer(4), Integer(4)], Integer(3))
>>> for i in range(Integer(100)):
...    w = S1.random_element()
...    if w in S2:
...        assert not w

>>> for i in range(Integer(100)):
...    w = S2.random_element()
...    if w in S1:
...        assert not w

sage.combinat.subword.smallest_positions(word, subword, pos=0)
Return the smallest positions for which subword appears as a subword of word.
If pos is specified, then it returns the positions of the first appearance of subword starting at pos.
If subword is not found in word, then return False.

EXAMPLES:

sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4])
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],2)
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],3)
[3, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,3])
[1, 2]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [5,5])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,4,5], [3,5])
[1, 4]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3])
[1, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3],2)
[2, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,3,4,4], [2,3,3,1])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5], [3,5,3],3)
False

>>> from sage.all import *
>>> sage.combinat.subword.smallest_positions([Integer(1), Integer(2), Integer(3), Integer(4)], [Integer(2), Integer(4)])
[1, 3]
>>> sage.combinat.subword.smallest_positions([Integer(1), Integer(2), Integer(3), Integer(4), Integer(4)], [Integer(2), Integer(4)])
(continues on next page)
5.1.339 Subword complex

Fix a Coxeter system $(W, S)$. The subword complex $\mathcal{SC}(Q, w)$ associated to a word $Q \in S^*$ and an element $w \in W$ is the simplicial complex whose ground set is the set of positions in $Q$ and whose facets are complements of sets of positions defining a reduced expression for $w$.

A subword complex is a shellable sphere if and only if the Demazure product of $Q$ equals $w$, otherwise it is a shellable ball.

The code is optimized to be used with ReflectionGroup, it works as well with CoxeterGroup, but many methods fail for WeylGroup.

EXAMPLES:

```python
>>> W = ReflectionGroup(['A',3]); I = list(W.index_set()) # optional - gap3
>>> Q = I + W.w0.coxeter_sorting_word(I); Q # optional - gap3
[1, 2, 3, 1, 2, 3, 1, 2, 1]

>>> S = SubwordComplex(Q,W.w0) # optional - gap3
>>> for F in S: print("{} {}".format(F, F.root_configuration()))
```

(continues on next page)
from sage.all import *

W = ReflectionGroup(['A',Integer(3)]); I = list(W.index_set())  # optional - gap3

Q = I + W.w0.coxeter_sorting_word(I); Q  # optional - gap3

S = SubwordComplex(Q,W.w0)  # optional - gap3

for F in S: print("{} {}").format(F, F.root_configuration())  #...

Testing that the implementation also works with CoxeterGroup:

W = CoxeterGroup(['A',3]); I = list(W.index_set())
Q = I + W.w0.coxeter_sorting_word(I); Q
S = SubwordComplex(Q,W.w0); S
P = S.increasing_flip_poset(); P; len(P.cover_relations())

sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I); Q
sage: S = SubwordComplex(Q,W.w0); S
Subword complex of type ['A', 3] for Q = (1, 2, 3, 1, 2, 3, 1, 2, 1) and pi = [1, 2, -3, 1, 2, 1]
sage: P = S.increasing_flip_poset(); P; len(P.cover_relations())
Finite poset containing 14 elements
21

Testing that the implementation also works with CoxeterGroup:

>>> W = CoxeterGroup(['A',3]); I = list(W.index_set())
>>> Q = I + W.w0.coxeter_sorting_word(I); Q
[1, 2, 3, 1, 2, 3, 1, 2, 1]
The root configuration works:

```python
sage: for F in S: print("{} {}\).format(F, F.root_configuration())
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, 0, -1)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

And the weight configuration also works:

```python
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1],w)
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
sage: from sage.all import *
```

(continues on next page)
One finally can compute the brick polytope, using all functionality on weight configurations, though it does not realize to live in real space:

```python
sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q, W.w0)
sage: S.brick_polytope()  # needs sage.geometry.polyhedron
```

A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 14 vertices

```python
doctest:...: RuntimeWarning: the polytope is built with rational vertices
```

A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices
**Warning:** This implementation only works for groups build using `CoxeterGroup`, and does not work with groups build using `WeylGroup`.

**EXAMPLES:**

As an example, dual associahedra are subword complexes in type \(A_{n-1}\) given by the word 
[1, \ldots, n, 1, \ldots, n, 1, \ldots, n - 1, \ldots, 1, 2, 1] and the permutation \(w_0\).

```sage
# optional - gap3
W = ReflectionGroup(['A',2])
w = W.from_reduced_word([1,2,1])
SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

W = CoxeterGroup(['A',2])
w = W.from_reduced_word([1,2,1])
SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

```sage
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],...
... w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
>>> SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],...
... w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
>>> SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

**REFERENCES:** [KnuMil], [PilStu]

**Element**

`barycenter()`

Return the barycenter of the brick polytope of `self`.

**See also:**

`brick_polytope()`

**EXAMPLES:**

```sage
W = ReflectionGroup(['A',2])
SC = SubwordComplex([1,2,1,2,1], W.w0)
```

(continues on next page)
sage: SC.barycenter()  # optional - gap3
(2/3, 4/3)
sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.barycenter()
(4/3, 8/3)

>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])  # optional_
-> gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
-> Integer(1)], W.w0)  # optional - gap3
>>> SC.barycenter()  # optional - gap3
(2/3, 4/3)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
-> Integer(1)], W.w0)
>>> SC.barycenter()  # optional - gap3
(4/3, 8/3)

brick_fan()

Return the brick fan of self.

It is the normal fan of the brick polytope of self. It is formed by the cones generated by the weight configurations of the facets of self.

See also:

weight_cone

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

>>> from sage.all import *  
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
-> Integer(1)], w)
>>> SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

>>> W = CoxeterGroup(['A',Integer(2)])
```
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
→Integer(1)], w)
>>> SC.brick_fan()
Rational polyhedral fan in 2-d lattice N
```

**brick_polytope** (*coefficients=None*)

Return the brick polytope of *self*.

This polytope is the convex hull of the brick vectors of *self*.

**INPUT:**

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

**See also:**

*brick_vectors()*

**EXAMPLES:**

```sage
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: X = SC.brick_polytope(); X # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices
sage: Y = SC.brick_polytope(coefficients=[1,2]); Y # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices
sage: X == Y # optional - gap3
False
sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices
sage: # optional - gap3
sage: W = ReflectionGroup(['H',3])
sage: c = W.index_set(); Q = c + tuple(W.w0.coxeter_sorting_word(c))
sage: SC = SubwordComplex(Q,W.w0)
sage: SC.brick_polytope()
doctest:...:
RuntimeWarning: the polytope is built with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices
```

```sage
>>> from sage.all import *
```

```sage
>>> W = ReflectionGroup(['A', Integer(2)]) # optional - gap3
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
→Integer(1)], W.w0) # optional - gap3
>>> X = SC.brick_polytope(); X # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices
>>> Y = SC.brick_polytope(coefficients=[Integer(1), Integer(2)]); Y #...
# optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices
```
X == Y  # optional - gap3
False

W = CoxeterGroup(['A',Integer(2)])
SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
Integer(1)], W.w0)
X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

# optional - gap3
W = ReflectionGroup(['H',Integer(3)])
c = W.index_set(); Q = c + tuple(W.w0.coxeter_sorting_word(c))
SC = SubwordComplex(Q,W.w0)
SC.brick_polytope()
doctest:...
RuntimeWarning: the polytope is built with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices

brick_vectors (coefficients=None)

Return the list of all brick vectors of facets of self.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

brick_vector

EXAMPLES:

sage: W = ReflectionGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.brick_vectors()
[(5/3, 7/3), (5/3, 1/3), (2/3, 7/3), (-1/3, 4/3), (-1/3, 1/3)]
sage: SC.brick_vectors(coefficients=(1,2))
[(7/3, 11/3), (7/3, 2/3), (4/3, 11/3), (-2/3, 5/3), (-2/3, 2/3)]
sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.brick_vectors()
[(10/3, 14/3), (10/3, 2/3), (4/3, 14/3), (-2/3, 8/3), (-2/3, 2/3)]
sage: SC.brick_vectors(coefficients=(1,2))
[(14/3, 22/3), (14/3, 4/3), (8/3, 22/3), (-4/3, 10/3), (-4/3, 4/3)]
cartan_type()  
Return the Cartan type of self.

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])  
sage: w = W.from_reduced_word([1,2,1])  
sage: SC = SubwordComplex([1,2,1,2,1], w)  
sage: SC.cartan_type()  
['A', 2]

sage: W = CoxeterGroup(['A',2])  
sage: w = W.from_reduced_word([1,2,1])  
sage: SC = SubwordComplex([1,2,1,2,1], w)  
sage: SC.cartan_type()  
['A', 2]

>>> from sage.all import *  
>>> # optional - gap3  
>>> W = ReflectionGroup(['A',Integer(2)])  
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])  
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),  
Integer(1)], w)  
>>> SC.cartan_type()  
['A', 2]

cover_relations(label=False)  
Return the set of cover relations in the associated poset.

INPUT:

• label – boolean (default False) whether or not to label the cover relations by the position of flip

OUTPUT:

a list of pairs of facets

EXAMPLES:

sage: W = ReflectionGroup(['A',2])  
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  
sage: sorted(SC.cover_relations())  
[[(0, 1), (0, 4)),  
((0, 1), (1, 2))],  
# optional - gap3  
# optional - gap3  
# optional - gap3

(continues on next page)
Combinatorics, Release 10.4

((0, 4), (3, 4)),
((1, 2), (2, 3)),
((2, 3), (3, 4))

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: sorted(SC.cover_relations())
[[(0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])
# optional - gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
 Integer(1)], W.w0) # optional - gap3
>>> sorted(SC.cover_relations())
# optional - gap3
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
 Integer(1)], W.w0)
>>> sorted(SC.cover_relations())
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

dimension()
Return the dimension of self.

EXAMPLES:

sage: W = ReflectionGroup(['A',2])
# optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.dimension() # optional - gap3
1

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.dimension() # optional - gap3
1

>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])
# optional - gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
 Integer(1)], W.w0) # optional - gap3
>>> sorted(SC.cover_relations())
# optional - gap3
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

(continues on next page)
W = CoxeterGroup(['A', Integer(2)])
SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
     →Integer(1)], W.w0)
SC.dimension()
1

facets()

Return all facets of self.

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

>>> from sage.all import *

W = ReflectionGroup(['A',2])
w = W.from_reduced_word([1,2,1])
SC = SubwordComplex([1,2,1,2,1], w)
SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

greedy_facet(side='positive')

Return the negative (or positive) greedy facet of self.

This is the lexicographically last (or first) facet of self.

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.greedy_facet(side="positive")
(0, 1)
sage: SC.greedy_facet(side="negative")
(3, 4)
sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.greedy_facet(side="positive")
(0, 1)
sage: SC.greedy_facet(side="negative")
(3, 4)

>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A', Integer(2)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
˓
→ Integer(1)], w)
>>> SC.greedy_facet(side="positive")
(0, 1)
>>> SC.greedy_facet(side="negative")
(3, 4)

>>> W = CoxeterGroup(['A', Integer(2)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
˓
→ Integer(1)], w)
>>> SC.greedy_facet(side="positive")
(0, 1)
>>> SC.greedy_facet(side="negative")
(3, 4)

**group()**

Return the group associated to self.

**EXAMPLES:**

sage: # optional - gap3
sage: W = ReflectionGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.group()
Irreducible real reflection group of rank 2 and type A2

sage: W = CoxeterGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
sage: SC.group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]

>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A', Integer(2)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
˓
→ Integer(1)], w)
>>> SC.group()
Irreducible real reflection group of rank 2 and type A2

```
>>> W = CoxeterGroup(['A', Integer(2)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
                        Integer(1)], w)
>>> SC.group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
  [1 3]
  [3 1]
```

increasing_flip_graph (label=True)

Return the increasing flip graph of the subword complex.

OUTPUT:

a directed graph

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2]) # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0) # optional - gap3
sage: SC.increasing_flip_graph() # optional - gap3
Digraph on 5 vertices
sage: W = CoxeterGroup(['A',2])
  SC = SubwordComplex([1,2,1,2,1], W.w0)
  SC.increasing_flip_graph()
Digraph on 5 vertices
```

increasing_flip_poset ()

Return the increasing flip poset of the subword complex.

OUTPUT:

a poset

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])
  SC = SubwordComplex([1,2,1,2,1], W.w0)
  SC.increasing_flip_poset() # optional - gap3
Finite poset containing 5 elements
```
interval \((I, J)\)

Return the interval \([I, J]\) in the increasing flip graph subword complex.

INPUT:

- \(I, J\) – two facets

OUTPUT:

a set of facets

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{# optional - gap3} \\
\text{sage: } & W = \text{ReflectionGroup(['A',2])} \\
\text{sage: } & SC = \text{SubwordComplex([1,2,1,2,1], W.w0)} \\
\text{sage: } & F = \text{SC([1,2])} \\
\text{sage: } & \text{SC.interval(F, F)} \\
& \{(1, 2)\}
\end{align*}
\]

\[
\begin{align*}
\text{sage: } & \text{# optional - gap3} \\
\text{sage: } & W = \text{ReflectionGroup(['A','2'])} \\
\text{sage: } & SC = \text{SubwordComplex([1,2,1,2,1], W.w0)} \\
\text{sage: } & F = \text{SC([1,2])} \\
\text{sage: } & \text{SC.interval(F, F)} \\
& \{(1, 2)\}
\end{align*}
\]
is_ball()

Return True if the subword complex self is a ball.

This is the case if and only if it is not a sphere.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)
sage: SC.is_ball()  # optional - gap3
False

sage: SC = SubwordComplex([3, 2, 1, 3, 2, 3], w)  # optional - gap3
sage: SC.is_ball()
True
```

is_double_root_free()

Return True if self is double-root-free.

This means that the root configurations of all facets do not contain a root twice.

EXAMPLES:

```python
>>> from sage.all import *
>>> W = ReflectionGroup(['A', Integer(3)])
>>> w = W.from_reduced_word([Integer(2), Integer(3), Integer(2)])
>>> SC = SubwordComplex([Integer(3), Integer(2), Integer(3), Integer(2),
           Integer(3)], w)  # optional - gap3
>>> SC.is_ball()  # optional - gap3
False
```

```python
>>> SC = SubwordComplex([Integer(3), Integer(2), Integer(1), Integer(3),
           Integer(2), Integer(3)], w)  # optional - gap3
>>> SC.is_ball()  # optional - gap3
True
```
```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.is_double_root_free()
True

sage: SC = SubwordComplex([1,1,2,2,1,1], w)  # optional - gap3
sage: SC.is_double_root_free()
True

sage: SC = SubwordComplex([1,2,1,2,1,2], w)  # optional - gap3
sage: SC.is_double_root_free()
False

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.is_double_root_free()
True

>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A', Integer(2)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
→Integer(1)], w)
>>> SC.is_double_root_free()  # optional - gap3
True

>>> SC = SubwordComplex([Integer(1), Integer(1), Integer(2), Integer(2),
→Integer(1), Integer(1)], w)  # optional - gap3
>>> SC.is_double_root_free()
True

>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
→Integer(1), Integer(2)], w)  # optional - gap3
>>> SC.is_double_root_free()
False

>>> W = CoxeterGroup(['A', Integer(2)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(1)])
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
→Integer(1)], w)
>>> SC.is_double_root_free()  # optional - gap3
True
```

**is_pure()**

Return True since all subword complexes are pure.

**EXAMPLES:**

```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_pure()
```

(continues on next page)
sage: W = CoxeterGroup(['A', 3])
sage: w = W.from_reduced_word([2, 3, 2])
sage: SC = SubwordComplex([3, 2, 3, 2, 3], w)
sage: SC.is_pure()
True

>>> from sage.all import *
>>> W = ReflectionGroup(['A', Integer(3)])
>>> w = W.from_reduced_word([Integer(2), Integer(3), Integer(2)])
>>> SC = SubwordComplex([Integer(3), Integer(2), Integer(3), Integer(2),
 Integer(3)], w)
>>> SC.is_pure()
True

is_root_independent()
Return True if self is root-independent.
This means that the root configuration of any (or equivalently all) facets is linearly independent.

EXAMPLES:

sage: W = ReflectionGroup(['A', 2])
# optional - gap3
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
# optional - gap3
sage: SC.is_root_independent()
# optional - gap3
True

sage: SC = SubwordComplex([1, 2, 1, 2, 1, 2], W.w0)
# optional - gap3
sage: SC.is_root_independent()
# optional - gap3
False

sage: W = CoxeterGroup(['A', 2])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], W.w0)
sage: SC.is_root_independent()
True

>>> from sage.all import *
>>> W = ReflectionGroup(['A', Integer(2)])
# optional - gap3
>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
 Integer(1), W.w0])
# optional - gap3
>>> SC.is_root_independent()
# optional - gap3
True

>>> SC = SubwordComplex([Integer(1), Integer(2), Integer(1), Integer(2),
 Integer(1), Integer(2), W.w0])
# optional - gap3
>>> SC.is_root_independent()
# optional - gap3

(continues on next page)
False

```python
>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
                        Integer(1)], W.w0)
>>> SC.is_root_independent()
True
```

**is_sphere()**

Return **True** if the subword complex `self` is a sphere.

**EXAMPLES:**

```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_sphere()
True
```

```python
sage: SC = SubwordComplex([3,2,1,3,2,3], w)  # optional - gap3
sage: SC.is_sphere()
False
```

```python
sage: W = CoxeterGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_sphere()
True
```

```python
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
                        Integer(3)], w)
>>> SC.is_sphere()
True
```

```python
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
                        Integer(3)], w)  # optional - gap3
>>> SC.is_sphere()
False
```

```python
>>> W = CoxeterGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
                        Integer(3)], w)
>>> SC.is_sphere()
True
```

**kappa_preimages()**

Return a dictionary containing facets of `self` as keys, and list of elements of `self.group()` as values.

**See also:**

`kappa_preimage`
EXAMPLES:

```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: kappa = SC.kappa_preimages()

sage: for F in SC: print("{} {}\n".format(F, [w.reduced_word() for w in kappa[F]]))
(0, 1) []
(0, 4) [[2], [2, 1]]
(1, 2) [[]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

sage: W = CoxeterGroup(['A',2])

sage: w = W.from_reduced_word([1,2,1])

sage: SC = SubwordComplex([1,2,1,2,1], w)

sage: kappa = SC.kappa_preimages()

sage: for F in SC: print("{} {}\n".format(F, [w.reduced_word() for w in kappa[F]]))
(0, 1) []
(0, 4) [[2], [2, 1]]
(1, 2) [[]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

sage: from sage.all import *

>>> W = ReflectionGroup(['A',Integer(2)])

>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])

>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
                      Integer(1)], w)

>>> kappa = SC.kappa_preimages()

>>> for F in SC: print("{} {}\n".format(F, [w.reduced_word() for w in kappa[F]]))
(0, 1) []
(0, 4) [[2], [2, 1]]
(1, 2) [[]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]
```

minkowski_summand(i)

Return the \(i\) th Minkowski summand of \(\text{self}\).
INPUT:

\(i\) – an integer defining a position in the word \(Q\)

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])  # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)  # optional - gap3
sage: SC.minkowski_summand(1)  # optional - gap3
A 0-dimensional polyhedron in \(\mathbb{Q}^2\) defined as the convex hull of 1 vertex
```

```
sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.minkowski_summand(1)
A 0-dimensional polyhedron in \(\mathbb{Q}^2\) defined as the convex hull of 1 vertex
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])  # optional - gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
                        Integer(1)], W.w0)  # optional - gap3
>>> SC.minkowski_summand(Integer(1))  # optional - gap3
A 0-dimensional polyhedron in \(\mathbb{Q}^2\) defined as the convex hull of 1 vertex
```

```
>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
                        Integer(1)], W.w0)
>>> SC.minkowski_summand(Integer(1))
A 0-dimensional polyhedron in \(\mathbb{Q}^2\) defined as the convex hull of 1 vertex
```

\(\pi()\)

Return the element in the Coxeter group associated to \(self\).

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]
```

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
                        Integer(1)], w)
>>> SC.pi().reduced_word()
[1, 2, 1]
```

(continues on next page)
>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
˓→Integer(1)], w)
>>> SC.pi().reduced_word()
[1, 2, 1]

word()

Return the word in the simple generators associated to self.

EXAMPLES:

```sage
# optional - gap3
W = ReflectionGroup(['A',2])
w = W.from_reduced_word([1,2,1])
SC = SubwordComplex([1,2,1,2,1], w)
SC.word()
(1, 2, 1, 2, 1)
```
brick_vector(coefficients=None)

Return the brick vector of self.

This is the sum of the weight vectors in the extended weight configuration.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

extended_weight_configuration()

EXAMPLES:

```python
sage: w = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC[0]; F
(0, 1)
```

```python
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)]
˓→)
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)]
˓→, w)
>>> F = SC[Integer(0)]; F
(0, 1)
```

```python
>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)]
˓→)
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)]
˓→, w)
>>> F = SC[Integer(0)]; F
(0, 1)
```

sage: F.brick_vector(coefficients=[1,2])
(8/3, 22/3)

Extended Root Configuration

Return the extended root configuration of self. Let \( Q = q_1 \ldots q_m \in S^* \) and \( w \in W \). The extended root configuration of a facet \( I \) of \( SC(Q, w) \) is the sequence \( r(I, 1), \ldots, r(I, m) \) of roots defined by 
\[
 r(I, k) = \Pi_{Q[k-1] \setminus I} (\alpha_{q_k}) ,
\]
where \( \Pi_{Q[k-1] \setminus I} \) is the product of the simple reflections \( q_i \) for \( i \in [k-1] \setminus I \) in this order.

The extended root configuration is used to perform flips efficiently.

See also:
flip()

EXAMPLES:

sage: F.brick_vector(coefficients=[1,2])
(8/3, 22/3)
```python
sage: F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
-Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

```python
sage: W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
-Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

**extended_weight_configuration** *(coefficients=None)*

Return the extended weight configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The extended weight configuration of a facet $I$ of $SC(Q, w)$ is the sequence $w(I, 1), \ldots, w(I, m)$ of weights defined by $w(I, k) = \Pi Q_{[k-1]\setminus I} (\omega_{q_k})$, where $\Pi Q_{[k-1]\setminus I}$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

The extended weight configuration is used to compute the brick vector.

INPUT:

- coefficients – (optional) a list of coefficients used to scale the fundamental weights

See also:

brick_vector()

EXAMPLES:

```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
```

```python
sage: W = ReflectionGroup(['A',2])
>>> w = W.from_reduced_word([1,2,1])
```
```python
>>> sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

```python
>>> from sage.all import *

>>> # optional - gap3

>>> W = ReflectionGroup(['A',Integer(2)])

>>> w = W.from_reduced_word([[Integer(1),Integer(2),Integer(1)]])

>>> SC = SubwordComplex([[Integer(1),Integer(2),Integer(1),Integer(2),
→Integer(1)],w])

>>> F = SC([[Integer(1),Integer(2)]])

>>> F.extended_weight_configuration()
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]

>>> F.extended_weight_configuration(coefficients=(Integer(1),Integer(2)))
[(2/3, 1/3), (2/3, 4/3), (-1/3, 1/3), (2/3, 4/3), (-1/3, 1/3)]

>>> W = CoxeterGroup(['A',Integer(2)])

>>> w = W.from_reduced_word([[Integer(1),Integer(2),Integer(1)]])

>>> SC = SubwordComplex([[Integer(1),Integer(2),Integer(1),Integer(2),
→Integer(1)],w])

>>> F = SC([[Integer(1),Integer(2)]])

>>> F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]

>>> F.extended_weight_configuration(coefficients=(Integer(1),Integer(2)))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

```python
flip (i, return_position=False)

Return the facet obtained after flipping position i in self.

INPUT:

- i – position in the word Q (integer).
- return_position – boolean (default: False) tells whether the new position should be returned as well.

OUTPUT:

- The new subword complex facet.
- The new position if return_position is True.

EXAMPLES:
```
(continued from previous page)

>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
                       -Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.flip(Integer(1))
(2, 3)
>>> F.flip(Integer(1), return_position=True)
((2, 3), 3)

is_vertex()

Return True if self is a vertex of the brick polytope of self.parent.

A facet is a vertex of the brick polytope if its root cone is pointed. Note that this property is always satisfied for root-independent subword complexes.

See also:

root_cone()

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',1])
sage: w = W.from_reduced_word([1])
sage: SC = SubwordComplex([1,1,1],w)
sage: F = SC([0,1]); F.is_vertex()
True
sage: F = SC([0,2]); F.is_vertex()
False

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w)
sage: F = SC([0,1,2,3]); F.is_vertex()
True
sage: F = SC([0,1,2,6]); F.is_vertex()  
False

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1,2,1],w)
sage: F = SC([0,1,2,3]); F.is_vertex()  
True
sage: F = SC([0,1,2,6]); F.is_vertex()  
False

>>> from sage.all import *

>>> # optional - gap3

>>> W = ReflectionGroup(['A',Integer(1)])
>>> w = W.from_reduced_word([Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(1),Integer(1)],w)
>>> F = SC([Integer(0),Integer(1)]); F.is_vertex()  
True
>>> F = SC([Integer(0),Integer(2)]); F.is_vertex()  
False

>>> # optional - gap3

>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),  
                        Integer(1),Integer(2),Integer(1)],w)
>>> F = SC([Integer(0),Integer(1),Integer(2),Integer(3)]); F.is_vertex()  
True
>>> F = SC([Integer(0),Integer(1),Integer(2),Integer(6)]); F.is_vertex()  
False

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),  
                       Integer(1),Integer(2),Integer(1)],w)
>>> F = SC([Integer(0),Integer(1),Integer(2),Integer(3)]); F.is_vertex()  
True
>>> F = SC([Integer(0),Integer(1),Integer(2),Integer(6)]); F.is_vertex()  
False

\textbf{kappa_preimage()}

Return the fiber of \texttt{self} under the \(\kappa\) map.

The \(\kappa\) map sends an element \(w \in W\) to the unique facet of \(I \in SC(Q,w)\) such that the root configuration of \(I\) is contained in \(w(\Phi^+)\). In other words, \(w\) is in the preimage of \texttt{self} under \(\kappa\) if and only if \(w^{-1}\) sends every root in the root configuration to a positive root.

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: W = ReflectionGroup(['A',2])                   # optional - gap3
  sage: w = W.from_reduced_word([1,2,1])               # optional - gap3
  sage: SC = SubwordComplex([1,2,1,2,1],w)            # optional - gap3

  sage: F = SC([1,2]); F                               # optional - gap3
  (1, 2)

  sage: F.kappa_preimage()                             # optional - gap3
  [(1,4) (2,3) (5,6)]
\end{verbatim}
sage: F = SC([0,4]); F
(0, 4)
sage: F.kappa_preimage()  # optional - gap3
[(1,3) (2,5) (4,6), (1,2,6) (3,4,5)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)

sage: F = SC([1,2]); F
(1, 2)
sage: F.kappa_preimage()  # optional - gap3
[[-1  1]
 [ 0 -1]]

sage: F = SC([0,4]); F
(0, 4)
sage: F.kappa_preimage()  # optional - gap3
[[ 1 0]
 [-1 1], [-1 0]]

sage: from sage.all import *

sage: W = ReflectionGroup(['A',Integer(2)])

sage: w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])

sage: SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],w)

sage: F = SC([Integer(1),Integer(2)]); F  # optional - gap3
(1, 2)
sage: F.kappa_preimage()  # optional - gap3
[(1,4) (2,3) (5,6)]

sage: F = SC([Integer(0),Integer(4)]); F  # optional - gap3
(0, 4)
sage: F.kappa_preimage()  # optional - gap3
[(1,3) (2,5) (4,6), (1,2,6) (3,4,5)]

sage: W = CoxeterGroup(['A',Integer(2)])
sage: w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])

sage: SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],w)

sage: F = SC([Integer(1),Integer(2)]); F
(1, 2)
sage: F.kappa_preimage()  # optional - gap3
[[-1  1]
 [ 0  1]]

5.1. Comprehensive Module List
\begin{verbatim}
[ 0 1 ]

>>> F = SC([Integer(0), Integer(4)]); F
(0, 4)

>>> F.kappa_preimage()
[
[  1  0 ]
[-1  1 ]
]

plot (list_colors=None, labels=[], thickness=3, fontsize=14, shift=(0, 0), compact=False, roots=True, **args)

In type A or B, plot a pseudoline arrangement representing the facet self.

Pseudoline arrangements are graphical representations of facets of types A or B subword complexes.

INPUT:

- list_colors – list (default: []) to change the colors of the pseudolines.
- labels – list (default: []) to change the labels of the pseudolines.
- thickness – integer (default: 3) for the thickness of the pseudolines.
- fontsize – integer (default: 14) for the size of the font used for labels.
- shift – couple of coordinates (default: (0, 0)) to change the origin.
- compact – boolean (default: False) to require a more compact representation.
- roots – boolean (default: True) to print the extended root configuration.

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC([1,2]); F.plot()  #...
  → needs sage.plot
Graphics object consisting of 26 graphics primitives

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC([1,2]); F.plot()  #...
  → needs sage.plot
Graphics object consisting of 26 graphics primitives

sage: # optional - gap3
sage: W = ReflectionGroup(['B',3])
sage: c = W.from_reduced_word([1,2,3])
sage: Q = c.reduced_word()*2 + W.w0.coxeter_sorting_word(c)
sage: SC = SubwordComplex(Q, W.w0)
sage: F = SC[15]; F.plot()  #...
  → needs sage.plot
Graphics object consisting of 53 graphics primitives
\end{verbatim}
REFERENCES: [PilStu]

**root_cone()**

Return the polyhedral cone generated by the root configuration of self.

See also:

**root_configuration()**

EXAMPLES:

```python
>>> W = ReflectionGroup(['A',1])
>>> w = W.from_reduced_word([1])
>>> SC = SubwordComplex([1,1,1],w)
>>> F = SC([0,2]); F.root_cone()
1-d cone in 1-d lattice N

>>> W = CoxeterGroup(['A',1])
>>> w = W.from_reduced_word([1])
>>> SC = SubwordComplex([1,1,1],w)
>>> F = SC([0,2]); F.root_cone()
1-d cone in 1-d lattice N
```
root_configuration()

Return the root configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The root configuration of a facet $I = [i_1, \ldots, i_n]$ of $SC(Q, w)$ is the sequence $r(I, i_1), \ldots, r(I, i_n)$ of roots defined by $r(I, k) = \Pi Q_{k-1} \setminus I (\alpha_{q_k})$, where $\Pi Q_{k-1} \setminus I$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:

```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A', 2])
sage: w = W.from_reduced_word([1, 2, 1])
sage: SC = SubwordComplex([1, 2, 1, 2, 1], w)
>>> F = SC([1, 2]); F
(1, 2)
>>> F.root_configuration()
[(1, 1), (-1, 0)]
```
See also:

$plot()$

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F.show()
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
\[\rightarrow Integer(1)]],w)
>>> F = SC([Integer(1),Integer(2)]); F.show()
```

`upper_root_configuration()`

Return the positive roots of the root configuration of `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.root_configuration()
[(1, 1), (-1, 0)]
sage: F.upper_root_configuration()
[(1, 0)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
\[\rightarrow Integer(1)]],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.root_configuration()
[(1, 1), (-1, 0)]
>>> F.upper_root_configuration()
[(1, 0)]
```
Combinatorics, Release 10.4

>>> W = CoxeterGroup(['A','Integer(2)'])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
˓→Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.upper_root_configuration()
[(1, 0)]

weight_cone()

Return the polyhedral cone generated by the weight configuration of self.

See also:

weight_configuration()

EXAMPLES:

sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: WC = F.weight_cone(); WC
2-d cone in 2-d lattice N
sage: WC.rays()
N( 1, 2),
N(-1, 1)
in 2-d lattice N

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: WC = F.weight_cone(); WC
2-d cone in 2-d lattice N

>>> from sage.all import *

(continues on previous page)
weight_configuration()  
Return the weight configuration of self.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The weight configuration of a facet $I = [i_1, \ldots, i_n]$ of $\mathcal{SC}(Q, w)$ is the sequence $w(I, i_1), \ldots, w(I, i_n)$ of weights defined by $w(I, k) = \Pi Q_{[k-1]\setminus I} (\omega q_k)$, where $\Pi Q_{[k-1]\setminus I}$ is the product of the simple reflections $q_i$ for $i \in [k-1] \setminus I$ in this order.

EXAMPLES:

```python
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])

sage: SC = SubwordComplex([1,2,1,2,1],w)

sage: F = SC([1,2]); F
(1, 2)

sage: F.weight_configuration()
[(1/3, 2/3), (-1/3, 1/3)]
```

```python
sage: # optional - gap3
sage: W = CoxeterGroup(['A',2])

sage: w = W.from_reduced_word([1,2,1])

sage: SC = SubwordComplex([1,2,1,2,1],w)

sage: F = SC([1,2]); F
(1, 2)

sage: F.weight_configuration()
[(2/3, 4/3), (-2/3, 2/3)]
```
5.1.340 Super Tableaux

AUTHORS:
- Matthew Lancellotti (2007): initial version

```python
class sage.combinat.super_tableau.SemistandardSuperTableau (parent, t, check=True, preprocessed=False)
```

Bases: `Tableau`

A semistandard super tableau.

A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of odd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

**INPUT:**
- `t` – a tableau, a list of iterables, or an empty list

**EXAMPLES:**
```python
tax = SemistandardSuperTableau([['1p','2','3'''], [2,3]])
t
```
```python
tax.shape()
[3, 2]
tax.pp () # pretty printing
1' 2 3'
2 3
tax = Tableau([["1p",2],[2]])
tax = SemistandardSuperTableau(t); s
[['1', 2], [2]]
tax = SemistandardSuperTableau([]) # The empty tableau
[]
```

```python
>>> from sage.all import *

>>> t = SemistandardSuperTableau([('1p',Integer(2),'3'''),[Integer(2),Integer(3)])
t
[['1', 2, 3'], [2, 3]]
>>> t.shape()
[3, 2]
>>> t.pp () # pretty printing
1' 2 3'
2 3
>>> t = Tableau([('1p',Integer(2)],[Integer(2)])
>>> s = SemistandardSuperTableau(t); s
[['1', 2], [2]]
>>> SemistandardSuperTableau([]) # The empty tableau
[]
```

**check()**

Check that `self` is a valid semistandard super tableau.

```python
class sage.combinat.super_tableau.SemistandardSuperTableaux (**kwds)
```

Bases: `SemistandardTableaux`

The set of semistandard super tableaux.
A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of odd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

**EXAMPLES:**

```python
sage: SST = SemistandardSuperTableaux(); SST
Semistandard super tableaux

>>> from sage.all import *
>>> SST = SemistandardSuperTableaux(); SST
Semistandard super tableaux
```

**Element**

alias of `SemistandardSuperTableau`

class sage.combinat.super_tableau.SemistandardSuperTableaux_all

Bases: `SemistandardSuperTableaux`

All semistandard super tableaux.

class sage.combinat.super_tableau.StandardSuperTableau(*, parent, t, check=True, preprocessed=False)

Bases: `SemistandardSuperTableau`

A standard super tableau.

A standard super tableau is a semistandard super tableau whose entries are in bijection with positive primed integers 1', 1, 2', 2, 3'... n'.

For more information refer [Muth2019].

**INPUT:**

- t – a Tableau, a list of iterables, or an empty list

**EXAMPLES:**

```python
[[1', 1, 2', 2, 3'], [3, 4']]
sage: t.shape()
[5, 2]
sage: t.pp() # pretty printing
1' 1 2' 2 3'
3 4'
sage: t.is_standard()
True
sage: StandardSuperTableau([]) # The empty tableau
[]
```

```python
>>> from sage.all import *
>>> t = StandardSuperTableau(["1", Integer(1), "2", Integer(2), "3"], [Integer(3), Integer(4)]); t
[[1', 1, 2', 2, 3'], [3, 4']]
>>> t.shape()
[5, 2]
>>> t.pp() # pretty printing
1' 1 2' 2 3'
```

(continues on next page)
```python
>>> t.is_standard()
True
>>> StandardSuperTableau([])  # The empty tableau
[]
```

```python
def check()
    """Check that self is a standard tableau."

    def is_standard()
        return True since self is a standard super tableau.

    EXAMPLES:
    sage: StandardSuperTableau([['1p', 1], ['2p', 2]]).is_standard()
    True
    sage: from sage.all import *
    sage: StandardSuperTableau([['1p', Integer(1)], ['2p', Integer(2)]]).is_standard()
    True
```

class sage.combinat.super_tableau.StandardSuperTableaux(**kwds)
    Bases: SemistandardSuperTableaux, Parent

    The set of standard super tableaux.

    A standard super tableau is a tableau whose entries are primed positive integers, which are strictly increasing in rows and down columns and contains each letters from 1',1,2'…n exactly once.

    For more information refer [Muth2019].

    INPUT:
    
    * n – a non-negative integer or a partition.

    EXAMPLES:
    sage: SST = StandardSuperTableaux()
    sage: SST
    Standard super tableaux
    sage: SST([['1''', '1''', '3'''], ['3''', '4''']])
    [[1', 2', 2', 3'], [3', 4']]
    sage: SST = StandardSuperTableaux(3)
    sage: SST
    Standard super tableaux of size 3
    sage: SST.first()
    [[1', 1', 2']]  # Standard super tableaux of size 3
    sage: SST.last()
    [[1'], [1'], [2']]  # Standard super tableaux of size 3
    sage: SST.cardinality()
    4
    sage: SST.list()
    [[[1', 1', 2']], [[1', 2', 1'], [1']], [[1', 1'], [2']], [[1', 1'], [1'], [2']]]
    sage: SST = StandardSuperTableaux([3, 2])
    sage: SST
    Standard super tableaux of shape [3, 2]
```
```python
>>> from sage.all import *
>>> SST = StandardSuperTableaux()
>>> SST
Standard super tableaux
>>> SST([["1",Integer(1),"2",Integer(2),"3"],[Integer(3),"4"]])
[[1, 1, 2, 2, 3], [3, 4]]
>>> SST = StandardSuperTableaux(Integer(3))
>>> SST
Standard super tableaux of size 3
>>> SST.first()
[[1', 1, 2']]
>>> SST.last()
[[1], [1], [2']]
>>> SST.cardinality()
4
>>> SST.list()
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
>>> SST = StandardSuperTableaux([Integer(3),Integer(2)])
>>> SST
Standard super tableaux of shape [3, 2]
```

Element

alias of `StandardSuperTableau`

```python
class sage.combinat.super_tableau.StandardSuperTableaux_all
    
    Bases: StandardSuperTableaux, DisjointUnionEnumeratedSets

    All standard super tableaux.

class sage.combinat.super_tableau.StandardSuperTableaux_shape(p)
    
    Bases: StandardSuperTableaux

    Standard super tableaux of a fixed shape p.

cardinality()

    Return the number of standard super tableaux of given shape.
```

The standard super tableaux of a fixed shape $p$ are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer to `sage.combinat.tableau.StandardTableaux_shape` for more details.

**EXAMPLES:**

```python
sage: StandardSuperTableaux([3,2,1]).cardinality()
16
sage: StandardSuperTableaux([2,2]).cardinality()
2
sage: StandardSuperTableaux([5]).cardinality()
1
sage: StandardSuperTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardSuperTableaux([]).cardinality()
1
```

```python
>>> from sage.all import *
>>> StandardSuperTableaux([Integer(3),Integer(2),Integer(1)]).cardinality()
16
>>> StandardSuperTableaux([Integer(2),Integer(2)]).cardinality()
(continues on next page)
```
Combinatorics, Release 10.4

(continued from previous page)

2
>>> StandardSuperTableaux([Integer(5)]).cardinality()
1
>>> StandardSuperTableaux([Integer(6),Integer(5),Integer(5),Integer(3)]).
˓
cardinality()
6651216
>>> StandardSuperTableaux([]).cardinality()
1

class sage.combinat.super_tableau.StandardSuperTableaux_size(n)
Bases: StandardSuperTableaux, DisjointUnionEnumeratedSets

Standard super tableaux of fixed size $n$.

EXAMPLES:

sage: [ t for t in StandardSuperTableaux(1) ]
[[[1]']]
sage: [ t for t in StandardSuperTableaux(2) ]
[[[1', 1], [[1'], [1]]]
sage: [ t for t in StandardSuperTableaux(3) ]
[[[1', 1, 2'], [1', 2'], [1], [[1', 1, 2'], [1', 1, [2']], [1', 1, [2']]]]
sage: StandardSuperTableaux(4)[:]
[[[1', 1, 2', 2']],
 [[1', 1, 2', 2], [1]],
 [[1', 1, 2], [2'], [1', 1, 2'], [2]],
 [[1', 1, 2'], [1, 2]],
 [[1', 1], [2', 2]],
 [[1', 2], [1], [2']],
 [[1', 2'], [1], [2]],
 [[1', 1], [2'], [2]],
 [[1', 1, 2'], [2]],
 [[1', 1], [2'], [2]]]

>>> from sage.all import *
>>> [ t for t in StandardSuperTableaux(Integer(1)) ]
[[[1]']]
>>> [ t for t in StandardSuperTableaux(Integer(2)) ]
[[[1', 1], [[1'], [1]]]
>>> [ t for t in StandardSuperTableaux(Integer(3)) ]
[[[1', 1, 2'], [1', 2'], [1], [[1', 1, 2'], [1', 1, [2']], [1', 1, [2']]]]
>>> StandardSuperTableaux(Integer(4))[:]
[[[1', 1, 2', 2]],
 [[1', 1, 2', 2], [1]],
 [[1', 1, 2', 2], [1'], 2'], [2]],
 [[1', 1, 2'], [1, 2]],
 [[1', 1, 2'], [1', 2'], [2]],
 [[1', 1], [2', 2]],
 [[1', 2], [1], [2']],
 [[1', 2'], [1], [2]],
 [[1', 1], [2'], [2]],
 [[1', 1, 2'], [2]],
 [[1', 1], [2'], [2]]]

cardinality()

Return the number of all standard super tableaux of size $n$.

The standard super tableaux of size $n$ are in bijection with the corresponding standard tableaux (under the
alphabet relabeling). Refer \texttt{sage.combinat.tableau.StandardTableaux_size} for more details.

**EXAMPLES:**

```python
sage: StandardSuperTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardSuperTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
sage: StandardSuperTableaux(50).cardinality()  # long time
27886995605342342839104615869259776
```

```python
>>> from sage.all import *
>>> StandardSuperTableaux(Integer(3)).cardinality()
4
>>> ns = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(6)]
>>> sts = [StandardSuperTableaux(n) for n in ns]
>>> all(st.cardinality() == len(st.list()) for st in sts)
True
>>> StandardSuperTableaux(Integer(50)).cardinality()  # long time
27886995605342342839104615869259776
```

## 5.1.341 Super Partitions

**AUTHORS:**

- Mike Zabrocki

A super partition of size $n$ and fermionic sector $m$ is a pair consisting of a strict partition of some integer $r$ of length $m$ (that may end in a 0) and an integer partition of $n - r$.

This module provides tools for manipulating super partitions.

Super partitions are the indexing set for symmetric functions in super space.

Super partitions may be input in two different formats: one as a pair consisting of fermionic (strict partition) and a bosonic (partition) part and the other as a list of integer values where the negative entries come first and are listed in strict order followed by the positive values in weak order.

A super partition is displayed as two partitions separated by a semicolon as a default. Super partitions may also be displayed as a weakly increasing sequence of integers that are strict if the numbers are not positive.

These combinatorial objects index the space of symmetric polynomials in two sets of variables, one commuting and one anti-commuting, and they are known as symmetric functions in super space (hence the origin of the name super partitions).

**EXAMPLES:**

```python
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
sage: [-2, 0, 1, 1] in SuperPartitions(4,2)
True
sage: [-1, 0, 1, 1] in SuperPartitions(4,2)
False
sage: [-2, -2, 2, 1] in SuperPartitions(7,2)
False
```

```python
>>> from sage.all import *
>>> SuperPartitions()
Super Partitions
>>> SuperPartitions(Integer(2))
Super Partitions of 2
>>> SuperPartitions(Integer(2)).cardinality()
8
>>> SuperPartitions(Integer(4),Integer(2))
Super Partitions of 4 and of fermionic sector 2
>>> [[Integer(2),Integer(0)],[Integer(1),Integer(1)]] in SuperPartitions(Integer(4),
   Integer(2))
True
>>> [[Integer(1),Integer(0)],[Integer(1),Integer(1)]] in SuperPartitions(Integer(4),
   Integer(2))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(2),Integer(1)]] in SuperPartitions(Integer(4))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(2),Integer(1)]] in SuperPartitions()
True
>>> [[Integer(1),Integer(1)],[Integer(2),Integer(1)]] in SuperPartitions()
False
>>> [-Integer(2), Integer(0), Integer(1), Integer(1)] in SuperPartitions(Integer(4),
   Integer(2))
True
>>> [-Integer(1), Integer(0), Integer(1), Integer(1)] in SuperPartitions(Integer(4),
   Integer(2))
False
>>> [-Integer(2), -Integer(2), Integer(2), Integer(1)] in SuperPartitions(Integer(7),
   Integer(2))
False
```

class sage.combinat.superpartition.SuperPartition(parent, lst, check=True, immutable=True)
    Bases: ClonableArray
```

Chapter 5. Comprehensive Module List
A super partition.

A super partition of size $n$ and fermionic sector $m$ is a pair consisting of a strict partition of some integer $r$ of length $m$ (that may end in a 0) and an integer partition of $n - r$.

**EXAMPLES:**

```
sage: sp = SuperPartition([[1,0],[2,2,1]]); sp
[1, 0; 2, 2, 1]
sage: sp[0]
(1, 0)
sage: sp[1]
(2, 2, 1)
sage: sp.fermionic_degree()
2
sage: sp.bosonic_degree()
6
sage: sp.length()
5
sage: sp.conjugate()
[4, 2; ]
```

>>> from sage.all import *

```python
>>> sp = SuperPartition([[Integer(1),Integer(0)],[Integer(2),Integer(2), Integer(1)]]); sp
[[1, 0; 2, 2, 1]]
>>> sp[Integer(0)]
(1, 0)
>>> sp[Integer(1)]
(2, 2, 1)
>>> sp.fermionic_degree()
2
>>> sp.bosonic_degree()
6
>>> sp.length()
5
>>> sp.conjugate()
[4, 2; ]
```

**a_part()**

The antisymmetric part as a list of strictly decreasing integers.

**OUTPUT:**

* a list

**EXAMPLES:**

```
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

>>> from sage.all import *

```python
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2), Integer(1)]]).antisymmetric_part()
[3, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
```

(continues on next page)
add_horizontal_border_strip_star(h)
Return a list of super partitions that differ from self by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star basis of symmetric functions in super space (see Theorem 7 from [JL2016]).

INPUT:
• h – number of cells in the horizontal strip

OUTPUT:
• a list of super partitions

EXAMPLES:
```python
sage: SuperPartition([[4, 1], [3]]).add_horizontal_border_strip_star(3)
[[3, 1; 7],
 [4, 1; 6],
 [3, 0; 6, 2],
 [3, 1; 6, 1],
 [4, 0; 5, 2],
 [4, 1; 5, 1],
 [3, 0; 5, 3],
 [3, 1; 5, 2],
 [4, 0; 4, 3],
 [4, 1; 4, 2],
 [4, 1; 3, 3]]
```
```python
sage: SuperPartition([[2, 1], [3]]).add_horizontal_border_strip_star(2)
[[2, 1; 5], [2, 0; 4, 2], [2, 1; 4, 1], [2, 0; 3, 3], [2, 1; 3, 2]]
```
```python
>>> from sage.all import *
>>> SuperPartition([[Integer(4), Integer(1)], [Integer(3)]]).add_horizontal_border_strip_star(Integer(3))
[[3, 1; 7],
 [4, 1; 6],
 [3, 0; 6, 2],
 [3, 1; 6, 1],
 [4, 0; 5, 2],
 [4, 1; 5, 1],
 [3, 0; 5, 3],
 [3, 1; 5, 2],
 [4, 0; 4, 3],
 [4, 1; 4, 2],
 [4, 1; 3, 3]]
```
```python
>>> SuperPartition([[Integer(2), Integer(1)], [Integer(3)]]).add_horizontal_border_strip_star(Integer(2))
[[2, 1; 5], [2, 0; 4, 2], [2, 1; 4, 1], [2, 0; 3, 3], [2, 1; 3, 2]]
```

add_horizontal_border_strip_star_bar(h)
List super partitions that differ from self by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star-bar basis of symmetric functions in super space (see Theorem 10 from [JL2016]).

INPUT:
• h – number of cells in the horizontal strip

OUTPUT:
• a list of super partitions

EXAMPLES:

```sage: SuperPartition([[4,1],[5,4]]).add_horizontal_border_strip_star_bar(3)
[[4, 1; 8, 4],
 [4, 1; 7, 5],
 [4, 2; 7, 4],
 [4, 1; 7, 4, 1],
 [4, 2; 6, 5],
 [4, 1; 6, 5, 1],
 [4, 3; 6, 4],
 [4, 2; 6, 4, 1],
 [4, 1; 6, 4, 2],
 [4, 3; 5, 5],
 [4, 2; 5, 5, 1],
 [4, 1; 5, 5, 2],
 [4, 3; 5, 4, 1],
 [4, 1; 5, 4, 3]]

sage: SuperPartition([[3,1],[5]]).add_horizontal_border_strip_star_bar(2)
[[3, 1; 7],
 [4, 1; 6],
 [3, 2; 6],
 [3, 1; 6, 1],
 [4, 2; 5],
 [4, 1; 5, 1],
 [3, 2; 5, 1],
 [3, 1; 5, 2]]

>>> from sage.all import *

>>> SuperPartition([[Integer(4),Integer(1)],[Integer(5),Integer(4)]]).add_horizontal_border_strip_star_bar(Integer(3))
[[4, 1; 8, 4],
 [4, 1; 7, 5],
 [4, 2; 7, 4],
 [4, 1; 7, 4, 1],
 [4, 2; 6, 5],
 [4, 1; 6, 5, 1],
 [4, 3; 6, 4],
 [4, 2; 6, 4, 1],
 [4, 1; 6, 4, 2],
 [4, 3; 5, 5],
 [4, 2; 5, 5, 1],
 [4, 1; 5, 5, 2],
 [4, 3; 5, 4, 1],
 [4, 1; 5, 4, 3]]

>>> SuperPartition([[Integer(3),Integer(1)],[Integer(5)]]).add_horizontal_border_strip_star_bar(Integer(2))
[[3, 1; 7],
 [4, 1; 6],
 [3, 2; 6],
 [3, 1; 6, 1],
 [4, 2; 5],
 [4, 1; 5, 1],
 [3, 2; 5, 1],
 [3, 1; 5, 2]]
```

(continues on next page)
antisymmetric_part()

The antisymmetric part as a list of strictly decreasing integers.

**OUTPUT:**

- a list

**EXAMPLES:**

```
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

bi_degree()

Return the bidegree of `self`, which is a pair consisting of the bosonic and fermionic degree.

**OUTPUT:**

- a tuple of two integers

**EXAMPLES:**

```
sage: SuperPartition([[3,1],[2,2,1]]).bi_degree()
(9, 2)
sage: SuperPartition([[2,1,0],[3,3]]).bi_degree()
(9, 3)
```

bosonic_degree()

Return the bosonic degree of `self`.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

**OUTPUT:**

- an integer

**EXAMPLES:**

```
bosonic_length()

Return the length of the partition of the symmetric part.

OUTPUT:

• an integer

EXAMPLES:

\[
\text{sage: SuperPartition([[3,1],[2,2,1]]).bosonic_length()}
\]
3

\[
\text{sage: SuperPartition([[2,1,0],[3,3]]).bosonic_length()}
\]
2

check()

Check that self is a valid super partition.

EXAMPLES:

\[
\text{sage: SP = SuperPartition([[1],[1]])}
\]

\[
\text{sage: SP.check()}
\]

conjugate()

Conjugate of a super partition.

The conjugate of a super partition is defined by conjugating the circled diagram.

OUTPUT:

• a SuperPartition

EXAMPLES:
sage: SuperPartition([[3, 1, 0], [4, 3, 2, 1]]).conjugate()
[6, 4, 1; 3]
sage: all(sp == sp.conjugate().conjugate() for sp in SuperPartitions(4))
True
sage: all(sp.conjugate() in SuperPartitions(3, 2) for sp in SuperPartitions(3, 2))
True

>>> from sage.all import *

>>> SuperPartition([[Integer(3), Integer(1), Integer(0)], [Integer(4), Integer(3), Integer(2), Integer(1)]]).conjugate()
[6, 4, 1; 3]
>>> all(sp == sp.conjugate().conjugate() for sp in SuperPartitions(Integer(4)))
True
>>> all(sp.conjugate() in SuperPartitions(Integer(3), Integer(2)) for sp in SuperPartitions(Integer(3), Integer(2)))
True

degree()

Return the bosonic degree of self.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

OUTPUT:

• an integer

EXAMPLES:

sage: SuperPartition([[3,1],[2,2,1]]).bosonic_degree()
9
sage: SuperPartition([[2,1],[2,2,1]]).bosonic_degree()
9

>>> from sage.all import *

>>> SuperPartition([[Integer(3), Integer(1), Integer(0)], [Integer(4), Integer(3), Integer(2), Integer(1)]]).bosonic_degree()
9
>>> SuperPartition([[Integer(2), Integer(1), Integer(0)], [Integer(3), Integer(3)]]).bosonic_degree()
9

dominates(other)

Return True if and only if self dominates other.

If the symmetric and anti-symmetric parts of self and other are not the same size then the result is False.

EXAMPLES:

sage: LA = SuperPartition([[2,1],[2,1,1]])
sage: LA.dominates([[2,1],[3,1]])
False
sage: LA.dominates([[2,1],[1,1,1,1]])
True
sage: LA.dominates([[3],[2,1,1]])
False
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: LA.dominates([[1],[1]*6])
False
```

```python
>>> from sage.all import *

```n
```python
>>> LA = SuperPartition([[Integer(2),Integer(1)],[Integer(2),Integer(1),
→Integer(1)]])
```

```python
>>> LA.dominates([[Integer(2),Integer(1)],[Integer(3),Integer(1)]]))
False
```

```python
>>> LA.dominates([[Integer(2),Integer(1)],[Integer(1),Integer(1),Integer(1),
→Integer(1)]]))
True
```

```python
>>> LA.dominates([[Integer(3)],[Integer(2),Integer(1),Integer(1)]]))
False
```

```python
>>> LA.dominates([[Integer(1)],[Integer(1)]*Integer(6)])
False
```

### fermionic_degree()  

Return the fermionic degree of `self`.  

The **fermionic degree** is the length of the antisymmetric part.  

**OUTPUT:**  

- an integer  

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).fermionic_degree()
2
sage: SuperPartition([[2,1,0],[3,3]]).fermionic_degree()
3
```

```python
>>> from sage.all import *

```n
```python
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
→Integer(1)]]).fermionic_degree()
2
```

```python
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
→Integer(3)]]).fermionic_degree()
3
```

### fermionic_sector()  

Return the fermionic degree of `self`.  

The **fermionic degree** is the length of the antisymmetric part.  

**OUTPUT:**  

- an integer  

**EXAMPLES:**

```python
sage: SuperPartition([[3,1],[2,2,1]]).fermionic_degree()
2
sage: SuperPartition([[2,1,0],[3,3]]).fermionic_degree()
3
```

5.1. Comprehensive Module List
```python
>>> from sage.all import *

>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
        Integer(1)])].fermionic_degree()
2

>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
        Integer(3)])].fermionic_degree()
3
```

### `static from_circled_diagram(shape, corners)`

Construct a super partition from a circled diagram.

A circled diagram consists of a partition of the concatenation of the antisymmetric and symmetric parts and a list of addable cells of the partition which indicate the location of the circled cells.

**INPUT:**

- `shape` – a partition or list of integers
- `corners` – a list of removable cells of `shape`

**OUTPUT:**

- a `SuperPartition`

**EXAMPLES:**

```python
sage: SuperPartition.from_circled_diagram([3, 2, 2, 1, 1], [(0, 3), (3, 1)])
[3, 1; 2, 2, 1]
sage: SuperPartition.from_circled_diagram([3, 3, 2, 1], [(2, 2), (3, 1), (4, 0)])
[2, 1, 0; 3, 3]
sage: from_cd = SuperPartition.from_circled_diagram
sage: all(sp == from_cd(*sp.to_circled_diagram()) for sp in SuperPartitions(4))
True
```

```python
>>> from sage.all import *

>>> SuperPartition.from_circled_diagram([Integer(3), Integer(2), Integer(2),
        Integer(1), Integer(1)], [(Integer(0), Integer(3)), (Integer(3),
        Integer(1))])
[3, 1; 2, 2, 1]

>>> SuperPartition.from_circled_diagram([Integer(3), Integer(3), Integer(2),
        Integer(1)], [(Integer(2), Integer(2)), (Integer(3), Integer(1)),
        (Integer(4), Integer(0))])
[2, 1, 0; 3, 3]

>>> from_cd = SuperPartition.from_circled_diagram
>>> all(sp == from_cd(*sp.to_circled_diagram()) for sp in SuperPartitions(Integer(4)))
True
```

### `length()`

Return the length of `self`, which is the sum of the lengths of the antisymmetric and symmetric part.

**OUTPUT:**

- an integer

**EXAMPLES:**
sage: SuperPartition([[3,1],[2,2,1]]).length()
5
sage: SuperPartition([[2,1,0],[3,3]]).length()
5

>>> from sage.all import *

>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
Integer(1)]]).length()
5
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
Integer(3)]]).length()
5

s_part()

The symmetric part as a list of weakly decreasing integers.

OUTPUT:

• a list

EXAMPLES:

sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]

shape_circled_diagram()

A concatenated partition with an extra cell for each antisymmetric part

OUTPUT:

• a partition

EXAMPLES:

sage: SuperPartition([[3,1],[2,2,1]]).shape_circled_diagram()
[4, 2, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).shape_circled_diagram()
[3, 3, 3, 2, 1]
sign()
Return the sign of a permutation of cycle type the symmetric part of self.

OUTPUT:
• either 1 or -1

EXAMPLES:

```python
sage: SuperPartition([[1,0],[3,1,1]]).sign()
1
sage: SuperPartition([[1,0],[3,2,1]]).sign()
-1
sage: sum(sp.sign()/sp.zee() for sp in SuperPartitions(6,0))
0
```

symmetric_part()
The symmetric part as a list of weakly decreasing integers.

OUTPUT:
• a list

EXAMPLES:

```python
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

to_circled_diagram()
The shape of the circled diagram and a list of addable cells

A circled diagram consists of a partition for the outer shape and a list of removable cells of the partition indicating the location of the circled cells

OUTPUT:
• a list consisting of a partition and a list of pairs of integers

EXAMPLES:
to_composition()

Concatenate the antisymmetric and symmetric parts to a composition.

OUTPUT:

• a (possibly weak) composition

EXAMPLES:

sage: SuperPartition([[3,1],[2,2,1]]).to_composition()
[3, 1, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition()
[2, 1, 0, 3, 3]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition().parent()
Compositions of non-negative integers

to_list()

The list of two lists with the antisymmetric and symmetric parts.

EXAMPLES:

sage: SuperPartition([[1],[1]]).to_list()
[[1], [1]]
from sage.all import *

SuperPartition([[Integer(1)],[Integer(1)]]).to_list()
[[1], [1]]

SuperPartition([[],[Integer(1)]]).to_list()
[[], [1]]

to_partition()
Concatenate and sort the antisymmetric and symmetric parts to a partition.

OUTPUT:

• a partition

EXAMPLES:

sage: SuperPartition([[3,1],[2,2,1]]).to_partition()
[3, 2, 2, 1, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition()
[3, 3, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition().parent()
Partitions

from sage.all import *

SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
\rightarrow Integer(1)]]).to_partition()
[3, 2, 2, 1, 1]

SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
\rightarrow Integer(3)]]).to_partition()
[3, 3, 2, 1]

SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
\rightarrow Integer(3)]]).to_partition().parent()
Partitions

zee()
Return the centralizer size of a permutation of cycle type symmetric part of self.

OUTPUT:

• a positive integer

EXAMPLES:

sage: SuperPartition([[1,0],[3,1,1]]).zee()
6
sage: SuperPartition([[1],[2,2,1]]).zee()
8
sage: sum(1/sp.zee() for sp in SuperPartitions(6,0))
1

from sage.all import *

SuperPartition([[Integer(1),Integer(0)],[Integer(3),Integer(1),
\rightarrow Integer(1)]]).zee()
6

SuperPartition([[Integer(1)],[Integer(2),Integer(2),Integer(1)]]).zee()
8

sum(Integer(1)/sp.zee() for sp in SuperPartitions(Integer(6),Integer(0)))
1
class sage.combinat.superpartition.SuperPartitions(is_infinite=False)

Bases: UniqueRepresentation, Parent

Super partitions.

A super partition of size \( n \) and fermionic sector \( m \) is a pair consisting of a strict partition of some integer \( r \) of length \( m \) (that may end in a 0) and an integer partition of \( n - r \).

INPUT:

- \( n \) – an integer (optional: default None)
- \( m \) – if \( n \) is specified, an integer (optional: default None)

Super partitions are the indexing set for symmetric functions in super space.

EXAMPLES:

```
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
```

```python
>>> from sage.all import *
>>> SuperPartitions()
Super Partitions
>>> SuperPartitions(Integer(2))
Super Partitions of 2
>>> SuperPartitions(Integer(2)).cardinality()
8
>>> SuperPartitions(Integer(4),Integer(2))
Super Partitions of 4 and of fermionic sector 2
>>> [[Integer(2),Integer(0)],[Integer(1),Integer(1)]] in SuperPartitions(Integer(4),Integer(2))
True
>>> [[Integer(1),Integer(0)],[Integer(1),Integer(1)]] in SuperPartitions(Integer(4),Integer(2))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(1)]] in SuperPartitions(Integer(4))
True
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(2),Integer(1)]] in SuperPartitions(Integer(4))
False
```

5.1.342 Symmetric Group Algebra

sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroupT(R, n, q=None)

Return the Hecke algebra of the symmetric group $S_n$ on the T-basis with quantum parameter $q$ over the ring $R$.

If $R$ is a commutative ring and $q$ is an invertible element of $R$, and if $n$ is a nonnegative integer, then the Hecke algebra of the symmetric group $S_n$ over $R$ with quantum parameter $q$ is defined as the algebra generated by the generators $T_1, T_2, \ldots, T_{n-1}$ with relations

$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

for all $i < n - 1$ (“braid relations”),

$$T_i T_j = T_j T_i$$

for all $i$ and $j$ such that $|i - j| > 1$ (“locality relations”), and

$$T_i^2 = q + (q - 1)T_i$$

for all $i$ (the “quadratic relations”, also known in the form $(T_i + 1)(T_i - q) = 0$). (This is only one of several existing definitions in literature, not all of which are fully equivalent. We are following the conventions of [Go1993].) For any permutation $w \in S_n$, we can define an element $T_w$ of this Hecke algebra by setting $T_w = T_{i_1} T_{i_2} \cdots T_{i_k}$, where $w = s_{i_1} s_{i_2} \cdots s_{i_k}$ is a reduced word for $w$ (with $s_i$ meaning the transposition $(i, i+1)$, and the product of permutations being evaluated by first applying $s_{i_k}$, then $s_{i_{k-1}}$, etc.). This element is independent of the choice of the reduced decomposition, and can be computed in Sage by calling $H[w]$ where $H$ is the Hecke algebra and $w$ is the permutation.

The Hecke algebra of the symmetric group $S_n$ with quantum parameter $q$ over $R$ can be seen as a deformation of the group algebra $RS_n$; indeed, it becomes $RS_n$ when $q = 1$. 
Warning: The multiplication on the Hecke algebra of the symmetric group does not follow the global option `mult` of the `Permutations` class (see `options()`). It is always as defined above. It does not match the default option (`mult=12r`) of the symmetric group algebra!

EXAMPLES:

```python
sage: HeckeAlgebraSymmetricGroupT(QQ, 3)
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate...

>>> from sage.all import *

 HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate...

sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2)
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over...

>>> from sage.all import *

 HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(2))
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over...

The multiplication on the Hecke algebra follows a different convention than the one on the symmetric group algebra does by default:

```python
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3([[1, 3, 2]]) * H3([[2, 1, 3]])
T[[3, 1, 2]]
sage: S3 = SymmetricGroupAlgebra(QQ, 3)
sage: S3([[1, 3, 2]]) * S3([[2, 1, 3]])
[2, 3, 1]
sage: TestSuite(H3).run()

```python

```python
>>> from sage.all import *

 H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> H3([[Integer(1), Integer(3), Integer(2)]]) * H3([[Integer(2), Integer(1),

`Integer(3)]])
T[[3, 1, 2]]
>>> S3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> S3([[Integer(1), Integer(3), Integer(2)]]) * S3([[Integer(2), Integer(1),

`Integer(3)]])
[2, 3, 1]
>>> TestSuite(H3).run()

```python

Note: `IwahoriHeckeAlgebra` gives a different implementation of the Iwahori-Hecke algebras of a Coxeter system \((W, S)\). This includes the Hecke algebras of the symmetric group as special case.
Bases: `CombinatorialFreeModule`

**one_basis()**

Return the identity permutation.

**EXAMPLES:**

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).one()  # indirect doctest
T[1, 2, 3]
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3)).one()  # indirect doctest
T[1, 2, 3]
```

**q()**

Return the variable or parameter \( q \).

**EXAMPLES:**

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).q()
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2).q()
```

```
2
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3)).q()
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(2)).q()
```

```
2
```

**class** `sage.combinat.symmetric_group_algebra.HeckeAlgebraSymmetricGroup_t(R, n, q=None)`

Bases: `HeckeAlgebraSymmetricGroup_generic`

**algebra_generators()**

Return the generators of the algebra.

**EXAMPLES:**

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).algebra_generators()
```

```
[T[2, 1, 3], T[1, 3, 2]]
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3)).algebra_generators()
```

```
[T[2, 1, 3], T[1, 3, 2]]
```

**jucys_murphy(k)**

Return the Jucys-Murphy element \( J_k \) of the Hecke algebra.

These Jucys-Murphy elements are defined by

\[
J_k = (T_{k-1}T_{k-2}\cdots T_1)(T_1T_2\cdots T_{k-1}).
\]

More explicitly,

\[
J_k = q^{k-1} + \sum_{l=1}^{k-1} (q^l - q^{l-1})T_{(l,k)}.
\]
For generic $q$, the $J_k$ generate a maximal commutative sub-algebra of the Hecke algebra.

**Warning:** The specialization $q = 1$ does not map these elements $J_k$ to the Young-Jucys-Murphy elements of the group algebra $RS_n$. (Instead, it maps the “reduced” Jucys-Murphy elements $(J_k - q^{k-1})/(q - 1)$ to the Young-Jucys-Murphy elements of $RS_n$.)

**EXAMPLES:**

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: j2 = H3.jucys_murphy(2); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: j3 = H3.jucys_murphy(3); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
sage: j2*j3 == j3*j2
True
sage: j0 = H3.jucys_murphy(1); j0 == H3.one()
True
sage: H3.jucys_murphy(0)
Traceback (most recent call last):
...
ValueError: k (= 0) must be between 1 and n (= 3)
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> j2 = H3.jucys_murphy(Integer(2)); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
>>> j3 = H3.jucys_murphy(Integer(3)); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
>>> j2*j3 == j3*j2
True
>>> j0 = H3.jucys_murphy(Integer(1)); j0 == H3.one()
True
>>> H3.jucys_murphy(Integer(0))
Traceback (most recent call last):
...
ValueError: k (= 0) must be between 1 and n (= 3)
```

**product_on_basis** ($perm1, perm2$)

**EXAMPLES:**

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: a = H3([2,1,3])+2*H3([1,2,3])-H3([3,2,1])
sage: a^2 #indirect doctest
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(1))
>>> a = H3([Integer(2),Integer(1),Integer(3)])+Integer(2)*H3([Integer(1),
... Integer(2),Integer(3)])-H3([Integer(3),Integer(2),Integer(1)])
>>> a**Integer(2) #indirect doctest
```

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3([2,1,3])+2*QS3([1,2,3])-QS3([3,2,1])
```

(continues on next page)
t(i)

Return the element $T_i$ of the Hecke algebra $self$.

EXAMPLES:

```python
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t(1)
T[2, 1, 3]
sage: H3.t(2)
T[1, 3, 2]
sage: H3.t(0)
Traceback (most recent call last):
  ... Value Error: i (= 0) must be between 1 and n-1 (= 2)
```

```python
sage: a = H3([2,1,3]) + 2*H3([1,2,3])
sage: H3.t_action(a, 1)
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
sage: H3.t(1)*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
```

>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> H3.t(Integer(1))
T[2, 1, 3]
>>> H3.t(Integer(2))
T[1, 3, 2]
>>> H3.t(Integer(0))
Traceback (most recent call last):
  ... Value Error: i (= 0) must be between 1 and n-1 (= 2)
```
t_action_on_basis (perm, i)

Return the product $T_i \cdot T_{\text{perm}}$, where \text{perm} is a permutation in the symmetric group $S_n$.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: H3.t_action_on_basis(Permutation([1,2,3]), 1)
T[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
T[1, 2, 3]
sage: H3.t_action_on_basis(Permutation([1,3,2]), 2)
T[1, 2, 3]
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> H3.t_action_on_basis(Permutation([Integer(2),Integer(1),Integer(3)]), Integer(1))
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
>>> H3.t_action_on_basis(Permutation([Integer(1),Integer(2),Integer(3)]), Integer(1))
T[2, 1, 3]
```

class sage.combinat.symmetric_group_algebra.KLCellularBasis (SGA)

Bases: SGACellularBasis

The Kazhdan-Lusztig $C'$ basis (at $q = 1$) of the symmetric group algebra realized as a cellular basis

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: KL = SGA.kazhdan_lusztig_cellular_basis()
sage: for la in KL.simple_module_parameterization():
    CM = KL.cell_module(la)
    print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> KL = SGA.kazhdan_lusztig_cellular_basis()
>>> for la in KL.simple_module_parameterization():
    CM = KL.cell_module(la)
    print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
```

(continues on next page)
class sage.combinat.symmetric_group_algebra.MurphyBasis(SGA)

Bases: SGACellularBasis

The Murphy basis of a symmetric group algebra.

Let $R$ be a commutative ring, and let $A = R[S_n]$ denote the group algebra (over $R$) of $S_n$. The Murphy basis is the basis of $A$ defined as follows. Let $S, T$ be standard tableaux of shape $\lambda$. Define $T^\lambda$ as the standard tableau of shape $\lambda$ with the first row filled with $1, \ldots, \lambda_1$, the second row $\lambda_1 + 1, \ldots, \lambda_1 + \lambda_2$, and so on. Let $d(S)$ be the unique permutation such that $S = T^\lambda d(S)$ under the natural action. Then the Murphy basis element indexed by $S$ and $T$ is

$$M_{S,T'} = d(S)^{-1} R_\lambda d(T),$$

where $S'$ denotes the conjugate tableau. The Murphy basis is a cellular basis of $A$.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: M = SGA.murphy_basis()
sage: for la in M.simple_module_parameterization():
    CM = M.cell_module(la)
    print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1

>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> M = SGA.murphy_basis()
>>> for la in M.simple_module_parameterization():
...     CM = M.cell_module(la)
...     print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1
```

REFERENCES:

- [DJM1998]
- [Mathas2004]

class sage.combinat.symmetric_group_algebra.SGACellularBasis(SGA)

Bases: CellularBasis

A cellular basis of the symmetric group algebra.

one()

Return the element 1 in self.

EXAMPLES:
Combinatorics, Release 10.4

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: M = SGA.murphy_basis()
sage: M.one()
C([4], [[1, 2, 3, 4]], [[1, 2, 3, 4]])
```

>>> from sage.all import *
>>>
SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> M = SGA.murphy_basis()
>>> M.one()
C([4], [[1, 2, 3, 4]], [[1, 2, 3, 4]])

```
sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra (R, W, category=None)
```

Return the symmetric group algebra of order \(W\) over the ring \(R\).

**INPUT:**

- \(W\) – a symmetric group; alternatively an integer \(n\) can be provided, as shorthand for \texttt{Permutations}(n).
- \(R\) – a base ring
- \texttt{category} – a category (default: the category of \(W\))

This supports several implementations of the symmetric group. At this point this has been tested with \(W=\text{Permutations}(n)\) and \(W=\text{SymmetricGroup}(n)\).

**Warning:** Some features are failing in the latter case, in particular if the domain of the symmetric group is not \(1, \ldots, n\).

**Note:** The brave can also try setting \(W=\text{WeylGroup(['A',n-1])}\), but little support for this currently exists.

**EXAMPLES:**

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3); QS3
Symmetric group algebra of order 3 over Rational Field
sage: QS3(1)
[1, 2, 3]
sage: QS3(2)
2*[1, 2, 3]
```

(continues on next page)
We now construct the symmetric group algebra by providing explicitly the underlying group:

```
sage: SGA = SymmetricGroupAlgebra(QQ, Permutations(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Standard permutations of 4
sage: SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]
sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Symmetric group of order 4! as a permutation group
sage: SGA.an_element()
() + (2,3,4) + 2*(1,3)(2,4) + 3*(1,4)(2,3)
sage: SGA = SymmetricGroupAlgebra(QQ, WeylGroup("A",3), prefix='s'); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
```

(continues on next page)
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)

```sage```
sage: SGA.an_element()
s1*s2*s3 + 3*s2*s3*s1*s2 + 2*s3*s1 + 1
```sage```

```python```
from sage.all import *

>>> SGA = SymmetricGroupAlgebra(QQ, Permutations(Integer(4))); SGA
Symmetric group algebra of order 4 over Rational Field

>>> SGA.group()
Standard permutations of 4

>>> SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]

>>> SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(Integer(4))); SGA
Symmetric group algebra of order 4 over Rational Field

>>> SGA.group()
Symmetric group of order 4! as a permutation group

>>> SGA.an_element()
() + (2,3,4) + 2*(1,3)(2,4) + 3*(1,4)(2,3)

>>> SGA = SymmetricGroupAlgebra(QQ, WeylGroup(['A',Integer(3)], prefix='s')); SGA
Symmetric group algebra of order 4 over Rational Field

>>> SGA.group()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)

>>> SGA.an_element()
s1*s2*s3 + 3*s2*s3*s1*s2 + 2*s3*s1 + 1
```python```

The preferred way to construct the symmetric group algebra is to go through the usual `algebra` method:

```sage```
sage: SGA = Permutations(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field

sage: SGA.group()
Standard permutations of 3

sage: SGA = SymmetricGroup(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field

sage: SGA.group()
Symmetric group of order 3! as a permutation group
```sage```

```python```
from sage.all import *

>>> SGA = Permutations(Integer(3)).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field

>>> SGA.group()
Standard permutations of 3

>>> SGA = SymmetricGroup(Integer(3)).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field

>>> SGA.group()
Symmetric group of order 3! as a permutation group
```python```

The canonical embedding from the symmetric group algebra of order $n$ to the symmetric group algebra of order $p > n$ is available as a coercion:

```sage```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.coerce_map_from(QS3)
Generic morphism:
```sage```
From: Symmetric group algebra of order 3 over Rational Field
To: Symmetric group algebra of order 4 over Rational Field

```
sage: x3 = QS3([3,1,2]) + 2 * QS3([2,3,1]); x3
2*[2, 3, 1] + [3, 1, 2]
sage: QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> QS4.coerce_map_from(QS3)
Generic morphism:
    From: Symmetric group algebra of order 3 over Rational Field
    To: Symmetric group algebra of order 4 over Rational Field

>>> x3 = QS3([Integer(3), Integer(1), Integer(2)]) + Integer(2) * QS3([Integer(2),
    → Integer(3), Integer(1)]); x3
2*[2, 3, 1] + [3, 1, 2]
```

```
>>> QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]
```

This allows for mixed expressions:

```
sage: x4 = 3 * QS4([3, 1, 4, 2])
sage: x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]
sage: QS0 = SymmetricGroupAlgebra(QQ, 0)
sage: QS1 = SymmetricGroupAlgebra(QQ, 1)
sage: x0 = QS0([1])
sage: x1 = QS1([1])
sage: x0 * x1
[1]
sage: x3 - (2*x0 + x1) - x4
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

```
>>> from sage.all import *
>>> x4 = Integer(3) * QS4([Integer(3), Integer(1), Integer(4), Integer(2)])
>>> x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]
```

```
>>> QS0 = SymmetricGroupAlgebra(QQ, Integer(0))
>>> QS1 = SymmetricGroupAlgebra(QQ, Integer(1))
>>> x0 = QS0([])
>>> x1 = QS1([Integer(1)])
>>> x0 * x1
[1]
>>> x3 - (Integer(2)*x0 + x1) - x4
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

Caveat: to achieve this, constructing `SymmetricGroupAlgebra(QQ, 10)` currently triggers the construction of all symmetric group algebras of smaller order. Is this a feature we really want to have?
Warning: The semantics of multiplication in symmetric group algebras with index set $\text{Permutations}(n)$ is determined by the order in which permutations are multiplied, which currently defaults to “in such a way that multiplication is associative with permutations acting on integers from the right”, but can be changed to the opposite order at runtime by setting the global variable $\text{Permutations.options}['\text{mult}']$ (see \texttt{sage.combinat.permutation.Permutations.options()}). On the other hand, the semantics of multiplication in symmetric group algebras with index set $\text{SymmetricGroup}(n)$ does not depend on this global variable. (This has the awkward consequence that the coercions between these two sorts of symmetric group algebras do not respect multiplication when this global variable is set to 'r2l'.) In view of this, it is recommended that code not rely on the usual multiplication function, but rather use the methods \texttt{left_action_product()} and \texttt{right_action_product()} for multiplying permutations (these methods don’t depend on the setting). See Issue \#14885 for more information.

We conclude by constructing the algebra of the symmetric group as a monoid algebra:

\begin{verbatim}
sage: QS3 = SymmetricGroupAlgebra(QQ, 3, category=Monoids())
sage: QS3.category()
Category of finite dimensional cellular monoid algebras over Rational Field
sage: TestSuite(QS3).run(skip=['_test_construction'])
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3), category=Monoids())
>>> QS3.category()
Category of finite dimensional cellular monoid algebras over Rational Field
>>> TestSuite(QS3).run(skip=['_test_construction'])
\end{verbatim}

\begin{verbatim}
class sage.combinat.symmetric_group_algebra.SymmetricGroupAlgebra_n(R, W, category)
Bases: GroupAlgebra_class

algebra_generators()

Return generators of this group algebra (as algebra) as a list of permutations.

The generators used for the group algebra of $S_n$ are the transposition $(2, 1)$ and the $n$-cycle $(1, 2, \ldots, n)$, unless $n \leq 1$ (in which case no generators are needed).

EXAMPLES:

\begin{verbatim}
sage: SymmetricGroupAlgebra(ZZ,5).algebra_generators()
Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])
sage: SymmetricGroupAlgebra(QQ,0).algebra_generators()
Family ()
sage: SymmetricGroupAlgebra(QQ,1).algebra_generators()
Family ()
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> SymmetricGroupAlgebra(ZZ,Integer(5)).algebra_generators()
Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])
>>> SymmetricGroupAlgebra(QQ,Integer(0)).algebra_generators()
Family ()
>>> SymmetricGroupAlgebra(QQ,Integer(1)).algebra_generators()
Family ()
\end{verbatim}
antipode(x)

Return the image of the element x of self under the antipode of the Hopf algebra self (where the co-
multiplication is the usual one on a group algebra).

Explicitly, this is obtained by replacing each permutation σ by σ⁻¹ in x while keeping all coefficients as they are.

EXAMPLES:

```python
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.antipode(2 * QS4([1, 3, 4, 2]) - 1/2 * QS4([1, 4, 2, 3]))
-1/2*[1, 3, 4, 2] + 2*[1, 4, 2, 3]
sage: all( QS4.antipode(QS4(p)) == QS4(p.inverse()) 
    ....:     for p in Permutations(4) )
True
sage: ZS3 = SymmetricGroupAlgebra(ZZ, 3)
sage: ZS3.antipode(ZS3.zero())
0
sage: ZS3.antipode(-ZS3(Permutation([2, 3, 1])))
-3, 1, 2
```

binary_unshuffle_sum(k)

Return the k-th binary unshuffle sum in the group algebra self.

The k-th binary unshuffle sum in the symmetric group algebra $RS_n$ over a ring $R$ is defined as the sum of all permutations $σ \in S_n$ satisfying $σ(1) < σ(2) < \cdots < σ(k)$ and $σ(k + 1) < σ(k + 2) < \cdots < σ(n)$.

This element has the property that, if it is denoted by $t_k$, and if the k-th semi-RSW element (see `semi_rsw_element()` is denoted by $s_k$, then $s_k S(t_k)$ and $t_k S(s_k)$ both equal the k-th Reiner-Saliola-Welker shuffling element of $RS_n$ (see `rsw_shuffling_element()`).

The k-th binary unshuffle sum is the image of the complete non-commutative symmetric function $S^{(k,n-k)}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The binary unshuffle sums on $QS_3$:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.binary_unshuffle_sum(0)
[1, 2, 3]
```
Let us check the relation with the $k$-th Reiner-Saliola-Welker shuffling element stated in the docstring:

```python
sage: def test_rsw(n):
    ...:     ZSn = SymmetricGroupAlgebra(ZZ, n)
    ...:     for k in range(1, n):
    ...:         a = ZSn.semi_rsw_element(k)
    ...:         b = ZSn.binary_unshuffle_sum(k)
    ...:         c = ZSn.left_action_product(a, ZSn.antipode(b))
    ...:         d = ZSn.left_action_product(b, ZSn.antipode(a))
    ...:         e = ZSn.rsw_shuffling_element(k)
    ...:         if c != e or d != e:
    ...:             return False
    ...:     return True
sage: test_rsw(3)
True
sage: test_rsw(4)  # long time
True
sage: test_rsw(5)  # long time
True
```
Let us also check the statement about the complete non-commutative symmetric function:

```python
sage: def test_rsw_ncsf(n):
    ...:
    ZSn = SymmetricGroupAlgebra(ZZ, n)
    NSym = NonCommutativeSymmetricFunctions(ZZ)
    S = NSym.S()
    for k in range(1, n):
        a = S(Composition([k, n-k])).to_symmetric_group_algebra()
        if a != ZSn.binary_unshuffle_sum(k):
            return False
    return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5)
# long time
True
```

```python
>>> from sage.all import *
>>> def test_rsw_ncsf(n):
...:
    ZSn = SymmetricGroupAlgebra(ZZ, n)
    NSym = NonCommutativeSymmetricFunctions(ZZ)
    S = NSym.S()
    for k in range(Integer(1), n):
        a = S(Composition([k, n-k])).to_symmetric_group_algebra()
        if a != ZSn.binary_unshuffle_sum(k):
            return False
    return True

>>> test_rsw_ncsf(Integer(3))
True
>>> test_rsw_ncsf(Integer(4))
True
>>> test_rsw_ncsf(Integer(5))
# long time
True
```

canonical_embedding (other)

Return the canonical coercion of self into a symmetric group algebra other.

INPUT:

- other -- a symmetric group algebra with order \( p \) satisfying \( p \geq n \), where \( n \) is the order of self, over a ground ring into which the ground ring of self coerces.

EXAMPLES:

```python
sage: QSn = SymmetricGroupAlgebra(QQ, 2)
sage: QSn = SymmetricGroupAlgebra(QQ, 4)
sage: phi = QSn.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To: Symmetric group algebra of order 4 over Rational Field
```

(continues on next page)
sage: x = QS2([2,1]) + 2 * QS2([1,2])
sage: phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]
sage: loads(dumps(phi))
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:  Symmetric group algebra of order 4 over Rational Field
sage: ZS2 = SymmetricGroupAlgebra(ZZ, 2)
sage: phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:  Symmetric group algebra of order 4 over Rational Field
sage: phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:  Symmetric group algebra of order 2 over Rational Field
sage: QS4.canonical_embedding(QS2)
Traceback (most recent call last):
...
ValueError: There is no canonical embedding from Symmetric group
  algebra of order 2 over Rational Field to Symmetric group
  algebra of order 4 over Rational Field
sage: QS4g = SymmetricGroup(4).algebra(QQ)
sage: QS4.canonical_embedding(QS4g)(QS4([1,3,2,4]))
(2,3)
sage: QS4g.canonical_embedding(QS4)(QS4g((2,3)))
[1, 3, 2, 4]
sage: ZS2 = SymmetricGroupAlgebra(ZZ, 2)
sage: ZS2g = SymmetricGroup(2).algebra(ZZ)
sage: ZS2g.canonical_embedding(QS4)(ZS2g((1,2)))
[2, 1, 3, 4]

>>> from sage.all import *
>>> QS2 = SymmetricGroupAlgebra(QQ, Integer(2))
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> phi = QS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:  Symmetric group algebra of order 4 over Rational Field
>>> x = QS2([Integer(2),Integer(1)]) + Integer(2) * QS2([Integer(1),
Integer(2)])
>>> phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]
>>> loads(dumps(phi))
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:  Symmetric group algebra of order 4 over Rational Field
```python
>>> ZS2 = SymmetricGroupAlgebra(ZZ, Integer(2))
>>> phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:  Symmetric group algebra of order 4 over Rational Field

>>> phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:  Symmetric group algebra of order 2 over Rational Field

>>> QS4.canonical_embedding(QS2)
Traceback (most recent call last):
... ValueError: There is no canonical embedding from Symmetric group algebra of order 2 over Rational Field to Symmetric group algebra of order 4 over Rational Field

>>> QS4g = SymmetricGroup(Integer(4)).algebra(QQ)

>>> QS4.canonical_embedding(QS4g)(QS4([Integer(1),Integer(3),Integer(2), Integer(4)]))
(2,3)

>>> QS4g.canonical_embedding(QS4)(QS4g((Integer(2),Integer(3))))
[1, 3, 2, 4]

>>> ZS2.canonical_embedding(QS4g)(ZS2([Integer(2),Integer(1)]))
(1,2)

>>> ZS2g = SymmetricGroup(Integer(2)).algebra(ZZ)

>>> ZS2g.canonical_embedding(QS4)(ZS2g((Integer(1),Integer(2))))
[2, 1, 3, 4]
```

**cell_module** *(la, **kwds]*)

Return the cell module indexed by la.

**EXAMPLES:**

```python
sage: S = SymmetricGroupAlgebra(QQ, 3)
sage: M = S.cell_module(Partition([2,1])); M
Cell module indexed by [2, 1] of Cellular basis of Symmetric group algebra of order 3 over Rational Field

>>> from sage.all import *

sage: S = SymmetricGroupAlgebra(QQ, Integer(3))
sage: M = S.cell_module(Partition([Integer(2),Integer(1)])); M
Cell module indexed by [2, 1] of Cellular basis of Symmetric group algebra of order 3 over Rational Field

We check that the input la is standardized:

```python
sage: N = S.cell_module([2,1])
sage: M is N
True

>>> from sage.all import *

sage: N = S.cell_module([Integer(2),Integer(1)])
```
cell_module_indices \((la)\)

Return the indices of the cell module of self indexed by la.

This is the finite set \(M(\lambda)\).

EXAMPLES:

```python
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_module_indices([3,1])
Standard tableaux of shape [3, 1]
```

```python
>>> from sage.all import *

>>> S = SymmetricGroupAlgebra(QQ, Integer(4))

>>> S.cell_module_indices([Integer(3),Integer(1)])
Standard tableaux of shape [3, 1]
```

cell_poset()

Return the cell poset of self.

EXAMPLES:

```python
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_poset()
Finite poset containing 5 elements
```

```python
>>> from sage.all import *

>>> S = SymmetricGroupAlgebra(QQ, Integer(4))

>>> S.cell_poset()
Finite poset containing 5 elements
```

central_orthogonal_idempotent \((la, \text{block=True})\)

Return the central idempotent for the symmetric group of order \(n\) corresponding to the indecomposable block to which the partition \(la\) is associated.

If self.base_ring() contains \(Q\), this corresponds to the classical central idempotent corresponding to the irreducible representation indexed by \(la\).

Alternatively, if self.base_ring() has characteristic \(p > 0\), then Theorem 2.8 in [Mur1983] provides that \(la\) is associated to an idempotent \(f_\mu\), where \(\mu\) is the \(p\)-core of \(la\). This \(f_\mu\) is a sum of classical idempotents,

\[
f_\mu = \sum_{c(\lambda) = \mu} e_\lambda,
\]

where the sum ranges over the partitions \(\lambda\) of \(n\) with \(p\)-core equal to \(\mu\).

INPUT:

- \(la\) – a partition of self.n or a self.base_ring().characteristic()-core of such a partition

- \(\text{block} – \text{boolean (default: True); when False, this returns the classical idempotent associated to } la\) (defined over \(Q\))

OUTPUT:

If \(\text{block=False}\) and the corresponding coefficients are not defined over self.base_ring(), then return None. Otherwise return an element of self.

EXAMPLES:
Asking for block idempotents in any characteristic, by passing a partition of \( \text{self}. \ n \):

```sage
sage: S0 = SymmetricGroup(4).algebra(QQ)
sage: S2 = SymmetricGroup(4).algebra(GF(2))
sage: S3 = SymmetricGroup(4).algebra(GF(3))
sage: S0.central_orthogonal_idempotent([2,1,1])
3/8*() - 1/8*(3,4) - 1/8*(2,3) - 1/8*(2,4) - 1/8*(1,2)
  - 1/8*(1,2)(3,4) + 1/8*(1,2,3,4) + 1/8*(1,2,4,3)
  + 1/8*(1,3,4,2) - 1/8*(1,3) - 1/8*(1,3)(2,4)
  + 1/8*(1,3,2,4) + 1/8*(1,4,3,2) - 1/8*(1,4)
  + 1/8*(1,4,2,3) - 1/8*(1,4)(2,3)
sage: S2.central_orthogonal_idempotent([2,1,1])
()
sage: idem = S3.central_orthogonal_idempotent([4]); idem
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: idem == S3.central_orthogonal_idempotent([1,1,1,1])
True
sage: S3.central_orthogonal_idempotent([2,2])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for block idempotents in any characteristic, by passing \( p \)-cores:

```sage
>>> from sage.all import *
>>> S0 = SymmetricGroup(Integer(4)).algebra(QQ)
>>> S2 = SymmetricGroup(Integer(4)).algebra(GF(Integer(2)))
>>> S3 = SymmetricGroup(Integer(4)).algebra(GF(Integer(3)))
>>> S0.central_orthogonal_idempotent([Integer(2),Integer(1),Integer(1)])
3/8*() - 1/8*(3,4) - 1/8*(2,3) - 1/8*(2,4) - 1/8*(1,2)
  - 1/8*(1,2)(3,4) + 1/8*(1,2,3,4) + 1/8*(1,2,4,3)
  + 1/8*(1,3,4,2) - 1/8*(1,3) - 1/8*(1,3)(2,4)
  + 1/8*(1,3,2,4) + 1/8*(1,4,3,2) - 1/8*(1,4)
  + 1/8*(1,4,2,3) - 1/8*(1,4)(2,3)
>>> S2.central_orthogonal_idempotent([Integer(2),Integer(1),Integer(1)])
()
>>> idem = S3.central_orthogonal_idempotent([Integer(4)]); idem
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
>>> idem == S3.central_orthogonal_idempotent([Integer(1),Integer(1),
  Integer(1)])
True
>>> S3.central_orthogonal_idempotent([Integer(2),Integer(2)])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for block idempotents in any characteristic, by passing \( p \)-cores:

```sage
sage: S0.central_orthogonal_idempotent([1,1])
Traceback (most recent call last):
  ...
ValueError: [1, 1] is not a partition of integer 4
sage: S2.central_orthogonal_idempotent([[]])
()
sage: S2.central_orthogonal_idempotent([1])
Traceback (most recent call last):
  ...
ValueError: the 2-core of [1] is not a 2-core of a partition of 4
sage: S3.central_orthogonal_idempotent([1])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: S3.central_orthogonal_idempotent([7])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```
```python
>>> from sage.all import *
>>> S0.central_orthogonal_idempotent([Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: [1, 1] is not a partition of integer 4
>>> S2.central_orthogonal_idempotent([])
()  
>>> S2.central_orthogonal_idempotent([Integer(1)])
Traceback (most recent call last):
...
ValueError: the 2-core of [1] is not a 2-core of a partition of 4
>>> S3.central_orthogonal_idempotent([Integer(1)])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
>>> S3.central_orthogonal_idempotent([Integer(2)])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for classical idempotents:

```python
sage: S3.central_orthogonal_idempotent([2,2], block=False) is None
True
sage: S3.central_orthogonal_idempotent([2,1,1], block=False)
(3,4) + (2,3) + (2,4) + (1,2) + (1,2)(3,4) + 2*(1,2,3,4) 
+ 2*(1,2,4,3) + 2*(1,3,4,2) + (1,3) + (1,3)(2,4) 
+ 2*(1,3,2,4) + 2*(1,4,3,2) + (1,4) + 2*(1,4,2,3) 
+ (1,4)(2,3)
```

```python
>>> from sage.all import *
>>> S3.central_orthogonal_idempotent([Integer(2),Integer(2)], block=False) is None
True
>>> S3.central_orthogonal_idempotent([Integer(2),Integer(1),Integer(1)], block=False)
(3,4) + (2,3) + (2,4) + (1,2) + (1,2)(3,4) + 2*(1,2,3,4) 
+ 2*(1,2,4,3) + 2*(1,3,4,2) + (1,3) + (1,3)(2,4) 
+ 2*(1,3,2,4) + 2*(1,4,3,2) + (1,4) + 2*(1,4,2,3) 
+ (1,4)(2,3)
```

See also:

- `sage.combinat.partition.Partition.core()`

**central_orthogonal_idempotents()**

Return a maximal list of central orthogonal idempotents for `self`.

This method does not require that `self` be semisimple, relying on Nakayama's Conjecture whenever `self`. `base_ring()` has positive characteristic.

**EXAMPLES:**

```python
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: a = QS3.central_orthogonal_idempotents()
sage: a[0]  # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] 
+ 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: a[1]  # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

5.1. Comprehensive Module List
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> a = QS3.central_orthogonal_idempotents()

>>> a[Integer(0)]  # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]

>>> a[Integer(1)]  # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]

See also:

- central_orthogonal_idempotent()

\textbf{dft (form=None, mult=l2r')}

Return the discrete Fourier transform for self.

See [Mur1983] for the construction of central primitive orthogonal idempotents. For each idempotent $e_i$ we have a homomorphic projection $v \mapsto ve_i$. Choose a basis for each submodule spanned by $\{\sigma e_i | \sigma \in S_n\}$. The change-of-basis from the standard basis $\{\sigma\}_{\sigma}$ is returned.

INPUT:

- mult – string (default: l2r'). If set to r2l', this causes the method to use the antipodes (antipode()) of the seminormal basis instead of the seminormal basis.

EXAMPLES:

```sage
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.dft()
[ 1 1 1 1 1 1]
[ 1 1/2 -1 -1/2 -1/2 1/2]
[ 0 3/4 0 3/4 -3/4 -3/4]
[ 0 1 0 -1 1 -1]
[ 1 -1/2 1 -1/2 -1/2 -1/2]
[ 1 -1 -1 1 1 -1]
```

```sage
>>> from sage.all import *

>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))

>>> QS3.dft()
[ 1 1 1 1 1 1]
[ 1 1/2 -1 -1/2 -1/2 1/2]
[ 0 3/4 0 3/4 -3/4 -3/4]
[ 0 1 0 -1 1 -1]
[ 1 -1/2 1 -1/2 -1/2 -1/2]
[ 1 -1 -1 1 1 -1]
```

Over fields of characteristic $p > 0$ such that $p \mid n!$, we use the modular Fourier transform (Issue #37751):

```sage
sage: GF2S3 = SymmetricGroupAlgebra(GF(2), 3)
sage: GF2S3.dft()
matrix([[1, 0, 0, 0, 1, 0],
        [0, 1, 0, 0, 1, 1],
        [0, 1, 0, 0, 1, 1],
        [0, 0, 0, 1, 1, 1],
        [1, 0, 0, 1, 1, 0],
        [0, 1, 1, 0, 0, 1]])
```

Over fields of characteristic $p > 0$ such that $p \mid n!$, we use the modular Fourier transform (Issue #37751):
epsilon_{ik}(itab, ktab, star=0, mult='l2r')

Return the seminormal basis element of self corresponding to the pair of tableaux itab and ktab (or restrictions of these tableaux, if the optional variable star is set).

INPUT:

- itab, ktab – two standard tableaux of size $n$.
- star – integer (default: 0).
- mult – string (default: 'l2r'). If set to 'r2l', this causes the method to return the antipode (antipode()) of $\epsilon(I, K)$ instead of $\epsilon(I, K)$ itself.

OUTPUT:

The element $\epsilon(I, K)$, where $I$ and $K$ are the tableaux obtained by removing all entries higher than $n - star$ from itab and ktab, respectively. Here, we are using the notations from seminormal_basis().

EXAMPLES:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.epsilon_ik([[1,2,3]], [[1,2,3]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
```

Let us take some properties of the seminormal basis listed in the docstring of seminormal_basis(), and verify them on the situation of $S_3$. 
First, check the formula

\[ \epsilon(T) = \frac{1}{\kappa_{sh}(T)} \epsilon(T) \epsilon(T). \]

In fact:

```python
sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn1(n):
    ....:     QSn = SymmetricGroupAlgebra(QQ, n)
    ....:     QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
    ....:     for T in StandardTableaux(n):
    ....:         TT = T.restrict(n-1)
    ....:         eTT = QSn1.epsilon_ik(TT, TT)
    ....:         eT = QSn.epsilon_ik(T, T)
    ....:         kT = prod(T.shape().hooks())
    ....:         if kT * eT != eTT * e(T) * eTT:
    ....:             return False
    ....:     return True
sage: test_sn1(3)
True
sage: test_sn1(4)  # long time
True
```

Next, we check the identity

\[ \epsilon(T, S) = \frac{1}{\kappa_{sh(T)} \pi_{T,S}} \epsilon(T) \epsilon(S) \]

which we used to define \( \epsilon(T, S) \). In fact:

```python
sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn2(n):
    ....:     QSn = SymmetricGroupAlgebra(QQ, n)
    ....:     QSn1 = SymmetricGroupAlgebra(QQ, n - Integer(1))
    ....:     for T in StandardTableaux(n):
    ....:         TT = T.restrict(n-Integer(1))
    ....:         eTT = QSn1.epsilon_ik(TT, TT)
    ....:         eT = QSn.epsilon_ik(T, T)
    ....:         if eT * eT != eTT * e(T) * eTT:
    ....:             return False
    ....:     return True
sage: test_sn2(Integer(3))
True
sage: test_sn2(Integer(4))  # long time
True
```
Let us finally check the identity

$$\epsilon(T, S)\epsilon(U, V) = \delta_{T,V}\epsilon(U, S)$$

In fact:

```sage
def test_sn3(lam):
    n = lam.size()
    QSn = SymmetricGroupAlgebra(QQ, n)
    mul = QSn.left_action_product
    for T in StandardTableaux(lam):
        for S in StandardTableaux(lam):
            TT = T.restrict(n-Integer(1))
            SS = S.restrict(n-Integer(1))
            eTT = QSn1.epsilon_ik(TT, TT)
            eSS = QSn1.epsilon_ik(SS, SS)
            eTS = QSn.epsilon_ik(T, S)
            piTS = [0] * n
            for (i, j) in T.cells():
                piTS[T[i][j] - 1] = S[i][j]
            piTS = QSn(Permutation(piTS))
            if k * eTS != mul(mul(eSS, piTS), mul(e(T), eTT)):
                return False
            return True

# long time
```

True

garsia_procesi_module(la)

Return the Garsia-Procesi module of self indexed by la.

EXAMPLES:

sage: SGA = SymmetricGroupAlgebra(GF(2), 6)
sage: SGA.garsia_procesi_module(Partition([2,2,1,1]))
Garsia-Procesi module of shape [2, 2, 1, 1] over Finite Field of size 2

>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(6))
>>> SGA.garsia_procesi_module(Partition([Integer(2),Integer(2),Integer(1), Integer(1)]))
Garsia-Procesi module of shape [2, 2, 1, 1] over Finite Field of size 2

jucys_murphy(k)

Return the Jucys-Murphy element $J_k$ (also known as a Young-Jucys-Murphy element) for the symmetric group algebra self.
The Jucys-Murphy element $J_k$ in the symmetric group algebra $RS_n$ is defined for every $k \in \{1, 2, \ldots, n\}$ by

$$J_k = (1, k) + (2, k) + \cdots + (k-1, k) \in RS_n,$$

where the addends are transpositions in $S_n$ (regarded as elements of $RS_n$). We note that there is not a dependence on $n$, so it is often suppressed in the notation.

EXAMPLES:

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.jucys_murphy(1)
0
sage: QS3.jucys_murphy(2)
[2, 1, 3]
sage: QS3.jucys_murphy(3)
[1, 3, 2] + [3, 2, 1]

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: j3 = QS4.jucys_murphy(3); j3
[1, 3, 2, 4] + [3, 2, 1, 4]
sage: j4 = QS4.jucys_murphy(4); j4
[1, 2, 4, 3] + [1, 4, 3, 2] + [4, 2, 3, 1]
sage: j3*j4 == j4*j3
True

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.jucys_murphy(4)
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]
```

kazhdan_lusztig_basis_element $(w)$

Return the Kazhdan-Lusztig $C'_q(w)$ basis element at $q = 1$.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: for w in SGA.group():
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(3))
>>> for w in SGA.group():
...     print(w, SGA.kazhdan_lusztig_basis_element(w))
[1, 2, 3] [1, 2, 3]
[1, 3, 2] [1, 2, 3] + [1, 3, 2]
[2, 1, 3] [1, 2, 3] + [2, 1, 3]
[2, 3, 1] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1]
[3, 1, 2] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [3, 1, 2]
[3, 2, 1] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
```

`kazhdan_lusztig_cellular_basis()`

Return the Kazhdan-Lusztig basis (at $q = 1$) of `self` as a cellular basis.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: KL = SGA.kazhdan_lusztig_cellular_basis()
sage: KL(SGA.an_element())
C([2, 1], [[1, 2], [3]], [[1, 2], [3]])
+ 2*C([2, 1], [[1, 3], [2]], [[1, 2], [3]])
- 3*C([3], [[1, 2, 3]], [[1, 2, 3]])
```

`ladder_idemponent (la)`

Return the ladder idempotent of `self`.

Let $F$ be a field of characteristic $p$. The **ladder idempotent** of shape $\lambda$ is the idempotent of $F[S_n]$ defined as follows. Let $T$ be the **ladder tableau** of shape $\lambda$. Let $|T|$ be the set of standard tableaux whose residue sequence is the same as for $T$. Let $\alpha$ be the sizes of the ladders of $\lambda$. Then the ladder idempotent is constructed as

$$
\bar{e}_\lambda := \frac{1}{\alpha!} \left( \sum_{\sigma \in S_n} \sigma \right) \left( \sum_{U \in |T|} E_U \right),
$$

where $E_U$ is the **seminormal_basis()** element over $Q$ and we project the sum to $F$, $S_\alpha$ is the Young subgroup corresponding to $\alpha$, and $\alpha! = \alpha_1! \cdots \alpha_k!$. 

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: for la in Partitions(SGA.n):
    ...:     idem = SGA.ladder_idemponent(la)
    ...:     print(la)
    ...:     print(idem)
    ...:     assert idem^2 == idem
[4]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[3, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + [3, 4, 1, 2] + [3, 4, 2, 1] + [4, 3, 1, 2] + [4, 3, 2, 1]
[2, 2]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[2, 1, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[1, 1, 1, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
```

When $p = 0$, these idempotents will generate all of the simple modules (which are the Specht modules and also projective modules):

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> for la in Partitions(SGA.n):
    ...:     idem = SGA.ladder_idemponent(la)
    ...:     print(la)
    ...:     print(idem)
    ...:     assert idem**Integer(2) == idem
[4]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[3, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + [3, 4, 1, 2] + [3, 4, 2, 1] + [4, 3, 1, 2] + [4, 3, 2, 1]
[2, 2]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[2, 1, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
```

5.1. Comprehensive Module List 5335

left_action_product (left, right)

Return the product of two elements left and right of self, where multiplication is defined in such a way that for two permutations p and q, the product pq is the permutation obtained by first applying q and then applying p. This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the left.

EXAMPLES:

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.left_action_product(QS3(p1), QS3(p2))
[3, 2, 1]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
sage: QS3.left_action_product(0, x)
0

(continues on next page)
p2 = Permutation([Integer(3), Integer(1), Integer(2)])
Q33.left_action_product(Q33(p1), Q33(p2))
[3, 2, 1]
x = Q33([Integer(1), Integer(2), Integer(3)]) -
Integer(2)*Q33([Integer(1), Integer(3), Integer(2)])
y = Integer(1)/Integer(2) * Q33([Integer(3), Integer(1), Integer(2)]) +
Integer(3)*Q33([Integer(1), Integer(2), Integer(3)])
Q33.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
Q33.left_action_product(Integer(0), x)
0

The method coerces its input into the algebra self:

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.left_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.left_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]

Warning: Note that coercion presently works from permutations of $n$ into the $n$-th symmetric group algebra, and also from all smaller symmetric group algebras into the $n$-th symmetric group algebra, but not from permutations of integers smaller than $n$ into the $n$-th symmetric group algebra.

monomial_from_smaller_permutation (permutation)
Convert permutation into a permutation, possibly extending it to the appropriate size, and return the corresponding basis element of self.

EXAMPLES:

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
sage: QS5.monomial_from_smaller_permutation(Permutation([3,1,2]))
[3, 1, 2, 4, 5]
sage: QS5.monomial_from_smaller_permutation(Permutation([5,3,4,1,2]))
[5, 3, 4, 1, 2]
sage: QS5.monomial_from_smaller_permutation(SymmetricGroup(2)((1,2)))
[2, 1, 3, 4, 5]
sage: QS5g = SymmetricGroup(5).algebra(QQ)
sage: QS5g.monomial_from_smaller_permutation([2,1])
(1,2)
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> QS5 = SymmetricGroupAlgebra(QQ, Integer(5))
>>> QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
>>> QS5.monomial_from_smaller_permutation(Permutation([Integer(3),Integer(1),
    Integer(2)]))
[3, 1, 2, 4, 5]
>>> QS5.monomial_from_smaller_permutation([Integer(5),Integer(3),Integer(4),
    Integer(1),Integer(2)])
[5, 3, 4, 1, 2]
>>> QS5.monomial_from_smaller_permutation(SymmetricGroup(Integer(2))((Integer(1),Integer(2))))
[2, 1, 3, 4, 5]

>>> QS5g = SymmetricGroup(Integer(5)).algebra(QQ)
>>> QS5g.monomial_from_smaller_permutation([Integer(2),Integer(1)])
(1,2)
```

```python
murphy_basis()

Return the **Murphy basis** of self.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: M = SGA.murphy_basis()
sage: M(SGA.an_element())
-C([1, 1, 1], [[1], [2], [3]], [[1], [2], [3]])
+ C([2, 1], [[1, 2], [3]], [[1, 2], [3]])
+ C([2, 1], [[1, 2], [3]], [[1, 3], [2]])
+ 2*C([2, 1], [[1, 3], [2]], [[1, 2], [3]])
+ 4*C([2, 1], [[1, 3], [2]], [[1, 3], [2]])
- 3*C([3], [[1, 2, 3]], [[1, 2, 3]])
```

```python
murphy_basis_element(S, T)

Return the Murphy basis element indexed by S and T.

See also:

*MurphyBasis*

**EXAMPLES:**

```python
sage: import itertools
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: for S, T in itertools.product(StandardTableaux([2,1]), repeat=2):
    ....:     print(S, T, SGA.murphy_basis_element(S, T))
[1, 3], [2] [1, 3], [2] [1, 2, 3] + [2, 1, 3]
```
```
Combinatorics, Release 10.4

(continued from previous page)

\[
\begin{array}{cccc}
[1, 3], [2] & [1, 2], [3] & [1, 3, 2] + [3, 1, 2] \\
[1, 2], [3] & [1, 3], [2] & [1, 3, 2] + [2, 3, 1] \\
[1, 2], [3] & [1, 2], [3] & [1, 2, 3] + [3, 2, 1]
\end{array}
\]

```python
>>> from sage.all import *
>>> import itertools

SGA = SymmetricGroupAlgebra(QQ, Integer(3))

for S, T in itertools.product(StandardTableaux([Integer(2), Integer(1)]), repeat=2):
    print(S, T, SGA.murphy_basis_element(S, T))
```

\[
\begin{array}{cccc}
[1, 3], [2] & [1, 3], [2] & [1, 2, 3] + [2, 1, 3] \\
[1, 3], [2] & [1, 2], [3] & [1, 3, 2] + [3, 1, 2] \\
[1, 2], [3] & [1, 3], [2] & [1, 3, 2] + [2, 3, 1] \\
[1, 2], [3] & [1, 2], [3] & [1, 2, 3] + [3, 2, 1]
\end{array}
\]

retract_direct_product \((f, m)\)

Return the direct-product retract of the element \(f \in RS_n\) to \(RS_m\), where \(m \leq n\) (and where \(RS_n\) is self).

If \(m\) is a nonnegative integer less or equal to \(n\), then the direct-product retract from \(S_n\) to \(S_m\) is defined as an \(R\)-linear map \(S_n \rightarrow S_m\) which sends every permutation \(p \in S_n\) to

\[
\begin{cases}
    \text{dret}(p) & \text{if dret}(p) \text{ is defined;} \\
    0 & \text{otherwise}
\end{cases}
\]

Here \(\text{dret}(p)\) denotes the direct-product retract of the permutation \(p\) to \(S_m\), which is defined in \texttt{retract_direct_product()}.

**EXAMPLES:**

```python
sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_direct_product(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,3,2]), 2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_direct_product(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0
sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3,2,1,4,5]), 4)
11*[3, 2, 1, 4]
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3,2,1,4,5]), 3)
-6*[1, 3, 2] + 11*[3, 2, 1]
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3,2,1,4,5]), 2)
0
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) + 11*SGA5([3,2,1,4,5]), 1)
2*[1]
sage: SGA5.retract_direct_product(8*SGA5([1,2,3,4,5]) - 6*SGA5([1,3,2,4,5]) - 3)
8*[1, 2, 3] - 6*[1, 3, 2]
sage: SGA5.retract_direct_product(8*SGA5([1,2,3,4,5]) - 6*SGA5([1,3,2,4,5]) - 4)
2*[1]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: SGA5.retract_direct_product(8*SGA5([[1,2,3,4,5]]) - 6*SGA5([[1,3,2,4,5]]),→0)
2*[[]]
```

```python
>>> from sage.all import *

>>> SGA3 = SymmetricGroupAlgebra(QQ, Integer(3))

retract_plain(), retract_okounkov_vershik()

retract_okounkov_vershik(f, m)

Return the Okounkov-Vershik retract of the element $f \in RS_n$ to $RS_m$, where $m \leq n$ (and where $RS_n$ is self).
If \( m \) is a nonnegative integer less or equal to \( n \), then the Okounkov-Vershik retract from \( S_n \) to \( S_m \) is defined as an \( R \)-linear map \( S_n \to S_m \) which sends every permutation \( p \in S_n \) to the Okounkov-Vershik retract of the permutation \( p \) to \( S_m \), which is defined in \( \text{retract_okounkov_vershik}() \).

**EXAMPLES:**

\[

retract_plain(), retract_direct_product()

retract_plain(f, m)

Return the plain retract of the element \( f \in RS_n \) to \( RS_m \), where \( m \leq n \) (and where \( RS_n \) is self).

If \( m \) is a nonnegative integer less or equal to \( n \), then the plain retract from \( S_n \) to \( S_m \) is defined as an \( R \)-linear map \( S_n \to S_m \) which sends every permutation \( p \in S_n \) to

\[
\begin{cases}
  \text{pret}(p) & \text{if pret}(p) \text{ is defined;} \\
  0 & \text{otherwise}
\end{cases}
\]

Here \( \text{pret}(p) \) denotes the plain retract of the permutation \( p \) to \( S_m \), which is defined in retract_plain().

EXAMPLES:

sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_plain(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,3,2]),
                      →2)

5.1. Comprehensive Module List
See also:

\texttt{retract\_direct\_product()}, \texttt{retract\_okounkov\_vershik()}

\texttt{right\_action\_product} (\textit{left}, \textit{right})

Return the product of two elements \textit{left} and \textit{right} of \textit{self}, where multiplication is defined in such a way that for two permutations \( p \) and \( q \), the product \( pq \) is the permutation obtained by first applying \( p \) and then applying \( q \). This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the right.

**EXAMPLES:**

```python
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.right_action_product(QS3(p1), QS3(p2))
[1, 3, 2]
sage: x = QS3([[1, 2, 3]]) - 2*QS3([[1, 3, 2]])
sage: y = 1/2 * QS3([[3, 1, 2]]) + 3*QS3([[1, 2, 3]])
sage: QS3.right_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] + 1/2*[3, 1, 2] - [3, 2, 1]
sage: QS3.right_action_product(0, x)
0
```

The method coerces its input into the algebra \textit{self}:

```python
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.right_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.right_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]
```
Warning: Note that coercion presently works from permutations of $n$ into the $n$-th symmetric group algebra, and also from all smaller symmetric group algebras into the $n$-th symmetric group algebra, but not from permutations of integers smaller than $n$ into the $n$-th symmetric group algebra.

**rsw_shuffling_element** ($k$)

Return the $k$-th Reiner-Saliola-Welker shuffling element in the group algebra `self`.

The $k$-th Reiner-Saliola-Welker shuffling element in the symmetric group algebra $RS_n$ over a ring $R$ is defined as the sum $\sum_{\sigma \in S_n} \text{noninv}_k(\sigma) \cdot \sigma$, where for every permutation $\sigma$, the number $\text{noninv}_k(\sigma)$ is the number of all $k$-noninversions of $\sigma$ (that is, the number of all $k$-element subsets of $\{1, 2, \ldots, n\}$ on which $\sigma$ restricts to a strictly increasing map). See `sage.combinat.permutation.number_of_noninversions()` for the noninv map.

This element is more or less the operator $\nu_{k,1^{n-k}}$ introduced in [RSW2011]; more precisely, $\nu_{k,1^{n-k}}$ is the left multiplication by this element.

It is a nontrivial theorem (Theorem 1.1 in [RSW2011]) that the operators $\nu_{k,1^{n-k}}$ (for fixed $n$ and varying $k$) pairwise commute. It is a conjecture (Conjecture 1.2 in [RSW2011]) that all their eigenvalues are integers (which, in light of their commutativity and easily established symmetry, yields that they can be simultaneously diagonalized over $Q$ with only integer eigenvalues).

**EXAMPLES:**

The Reiner-Saliola-Welker shuffling elements on $QS_3$:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.rsw_shuffling_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.rsw_shuffling_element(1)
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2, 1]
sage: QS3.rsw_shuffling_element(2)
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + [2, 3, 1] + [3, 1, 2]
sage: QS3.rsw_shuffling_element(3)
[1, 2, 3]
sage: QS3.rsw_shuffling_element(4)
0
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS3.rsw_shuffling_element(Integer(0))
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> QS3.rsw_shuffling_element(Integer(1))
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2, 1]
>>> QS3.rsw_shuffling_element(Integer(2))
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + [2, 3, 1] + [3, 1, 2]
>>> QS3.rsw_shuffling_element(Integer(3))
[1, 2, 3]
>>> QS3.rsw_shuffling_element(Integer(4))
0
```

Checking the commutativity of Reiner-Saliola-Welker shuffling elements (we leave out the ones for which it is trivial):
sage: def test_rsw_comm(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     rsws = [QSn.rsw_shuffling_element(k) for k in range(2, n)]
....:     return all(ri * rsws[j] == rsws[j] * ri
....:                for i, ri in enumerate(rsws) for j in range(i))

sage: test_rsw_comm(3)
True
sage: test_rsw_comm(4)  # long time
True
sage: test_rsw_comm(5)  # not tested
True

>>> from sage.all import *
>>> def test_rsw_comm(n):
...     QSn = SymmetricGroupAlgebra(QQ, n)
...     rsws = [QSn.rsw_shuffling_element(k) for k in range(Integer(2), n)]
...     return all(ri * rsws[j] == rsws[j] * ri
...                for i, ri in enumerate(rsws) for j in range(i))

>>> test_rsw_comm(Integer(3))
True

Note: For large k (relative to n), it might be faster to call QSn.left_action_product(QSn.
semi_rsw_element(k), QSn.antipode(binary_unshuffle_sum(k))) than QSn.
rsw_shuffling_element(n).

See also:

semi_rsw_element(), binary_unshuffle_sum()

semi_rsw_element(k)

Return the k-th semi-RSW element in the group algebra self.

The k-th semi-RSW element in the symmetric group algebra RS_n over a ring R is defined as the sum of all
permutations σ ∈ S_n satisfying σ(1) < σ(2) < ··· < σ(k).

This element has the property that, if it is denoted by s_k, then s_kS(s_k) is (n − k)! times the k-th
Reiner-Saliola-Welker shuffling element of RS_n (see rsw_shuffling_element()). Here, S denotes
the antipode of the group algebra RS_n.

The k-th semi-RSW element is the image of the complete non-commutative symmetric function S(k,1^{n-k})
in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group
algebra (through the descent algebra).

EXAMPLES:
The semi-RSW elements on QS_3:

sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.semi_rsw_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(1)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(2)
(continues on next page)
Let us check the relation with the $k$-th Reiner-Saliola-Welker shuffling element stated in the docstring:

```python
sage: def test_rsw(n):
    ZSn = SymmetricGroupAlgebra(ZZ, n)
    for k in range(1, n):
        a = ZSn.semi_rsw_element(k)
        b = ZSn.left_action_product(a, ZSn.antipode(a))
        if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
            return False
    return True
sage: test_rsw(3)
True
sage: test_rsw(4)
True
sage: test_rsw(5)  # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```python
sage: def test_rsw_ncsf(n):
    ZSn = SymmetricGroupAlgebra(ZZ, n)
    ... for k in range(1, n):
    ... a = ZSn.semi_rsw_element(k)
    ... b = ZSn.left_action_product(a, ZSn.antipode(a))
    ... if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
    ... return False
    ... return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5)  # long time
True
```
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5)  # long time
True

>>> from sage.all import *
>>> def test_rsw_ncsf(n):
...     ZSn = SymmetricGroupAlgebra(ZZ, n)
...     NSym = NonCommutativeSymmetricFunctions(ZZ)
...     S = NSym.S()
...     for k in range(Integer(1), n):
...         a = S(Composition([k] + [Integer(1)]*(n-k))).to_symmetric_group_algebra()
...         if a != ZSn.semi_rsw_element(k):
...             return False
...     return True

>>> test_rsw_ncsf(Integer(3))
True
>>> test_rsw_ncsf(Integer(4))
True
>>> test_rsw_ncsf(Integer(5))  # long time
True

seminormal_basis (mult='l2r')

Return a list of the seminormal basis elements of self.

The seminormal basis of a symmetric group algebra is defined as follows:

Let \( n \) be a nonnegative integer. Let \( R \) be a \( \mathbb{Q} \)-algebra. In the following, we will use the “left action” convention for multiplying permutations. This means that for all permutations \( p \) and \( q \) in \( S_n \), the product \( pq \) is defined in such a way that \( (pq)(i) = p(q(i)) \) for each \( i \in \{1, 2, \ldots, n\} \) (this is the same convention as in \( \text{left_action_product}() \), but not the default semantics of the \( \ast \) operator on permutations in Sage). Thus, for instance, \( s_2s_1 \) is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3 (where \( s_i = (i, i+1) \)).

For every partition \( \lambda \) of \( n \), let

\[
\kappa_\lambda = \frac{n!}{f^\lambda}
\]

where \( f^\lambda \) is the number of standard Young tableaux of shape \( \lambda \). Note that \( \kappa_\lambda \) is an integer, namely the product of all hook lengths of \( \lambda \) (by the hook length formula). In Sage, this integer can be computed by using \( \text{sage.combinat.symmetric_group_algebra.kappa()} \).

Let \( T \) be a standard tableau of size \( n \).

Let \( a(T) \) denote the formal sum (in \( RS_n \)) of all permutations in \( S_n \) which stabilize the rows of \( T \) (as sets), i.e., which map each entry \( i \) of \( T \) to an entry in the same row as \( i \). (See \( \text{sage.combinat.symmetric_group_algebra.a()} \) for an implementation of this.)
Let \( b(T) \) denote the signed formal sum (in \( RS_n \)) of all permutations in \( S_n \) which stabilize the columns of \( T \) (as sets). Here, “signed” means that each permutation is multiplied with its sign. (This is implemented in \texttt{sage.combinat.symmetric_group_algebra.b}().)

Define an element \( e(T) \) of \( RS_n \) to be \( a(T)b(T) \). (This is implemented in \texttt{sage.combinat.symmetric_group_algebra.e()} for \( R = Q \).)

Let \( sh(T) \) denote the shape of \( T \). (See \texttt{shape}().)

Let \( T \) denote the standard tableau of size \( n-1 \) obtained by removing the letter \( n \) (along with its cell) from \( T \) (if \( n \geq 1 \)).

Now, we define an element \( \epsilon(T) \) of \( RS_n \). We define it by induction on the size \( n \) of \( T \), so we set \( \epsilon(\emptyset) = 1 \) and only need to define \( \epsilon(T) \) for \( n \geq 1 \), assuming that \( \epsilon(T) \) is already defined. We do this by setting

\[
\epsilon(T) = \frac{1}{\kappa_{sh(T)}} e(T)e(T)e(T).
\]

This element \( \epsilon(T) \) is implemented as \texttt{sage.combinat.symmetric_group_algebra.epsilon()} for \( R = Q \), but it is also a particular case of the elements \( \epsilon(T, S) \) defined below.

Now let \( S \) be a further tableau of the same shape as \( T \) (possibly equal to \( T \)). Let \( \pi_{T,S} \) denote the permutation in \( S_n \) such that applying this permutation to the entries of \( T \) yields the tableau \( S \). Define an element \( \epsilon(T, S) \) of \( RS_n \) by

\[
\epsilon(T, S) = \frac{1}{\kappa_{sh(T)}} \epsilon(S) \pi_{T,S} \epsilon(T)e(T)e(T)e(T) = \frac{1}{\kappa_{sh(T)}} \epsilon(S) a(S) \pi_{T,S} b(T)e(T).
\]

This element \( \epsilon(T, S) \) is called \textit{Young's seminormal unit corresponding to the bitableau }\texttt{(T, S)}, and is the return value of \texttt{epsilon_ik()} applied to \( T \) and \( S \). Note that \( \epsilon(T, T) = \epsilon(T) \).

If we let \( \lambda \) run through all partitions of \( n \), and \( (T, S) \) run through all pairs of tableaux of shape \( \lambda \), then the elements \( \epsilon(T, S) \) form a basis of \( RS_n \). This basis is called \textit{Young's seminormal basis} and has the properties that

\[
\epsilon(T, S) \epsilon(U, V) = \delta_{T,V} \epsilon(U, S)
\]

(where \( \delta \) stands for the Kronecker delta).

\textbf{Warning:} Because of our convention, we are multiplying our elements in reverse of those given in some papers, for example [Ram1997]. Using the other convention of multiplying permutations, we would instead have \( \epsilon(U, V) \epsilon(T, S) = \delta_{T,V} \epsilon(U, S) \).

In other words, Young’s seminormal basis consists of the matrix units in a (particular) Artin-Wedderburn decomposition of \( RS_n \) into a direct product of matrix algebras over \( Q \).

The output of \texttt{seminormal_basis()} is a list of all elements of the seminormal basis of \texttt{self}.

\textbf{INPUT:}

\begin{itemize}
  \item \texttt{mult} = \texttt{string} (default: '12r'). If set to 'r2l', this causes the method to return the list of the antipodes (\texttt{antipode()})) of all \( \epsilon(T, S) \) instead of the \( \epsilon(T, S) \) themselves.
\end{itemize}

\textbf{EXAMPLES:}

\begin{verbatim}
  sage: QS3 = SymmetricGroupAlgebra(QQ,3)
  sage: QS3.seminormal_basis()
  [1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1,...
\end{verbatim}
\[
\begin{align*}
\rightarrow & 2] + 1/6*[3, 2, 1], \\
1/3*[1, 2, 3] + 1/6*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] - \\
& 1/6*[3, 2, 1], \\
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1], \\
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1], \\
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] - \\
& 1/6*[3, 2, 1], \\
1/6*[1, 2, 3] - 1/6*[1, 3, 2] + 1/6*[2, 1, 3] - 1/6*[2, 3, 1] + 1/6*[3, 1, 2] - \\
& 1/6*[3, 2, 1], \\
& 1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1], \\
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1], \\
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2] - \\
& 1/6*[3, 2, 1], \\
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] - \\
& 1/6*[3, 2, 1].
\end{align*}
\]
sage: SGA = SymmetricGroupAlgebra(GF(5), 6)
sage: SGA.simple_module_dimension(Partition([4,1,1]))
10

>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(5)), Integer(6))
>>> SGA.simple_module_dimension(Partition([Integer(4),Integer(1),Integer(1)]))
10

simple_module_parameterization()

Return a parameterization of the simple modules of self.

The symmetric group algebra of $S_n$ over a field of characteristic $p$ has its simple modules indexed by all $p$-regular partitions of $n$.

EXAMPLES:

sage: SGA = SymmetricGroupAlgebra(QQ, 6)
sage: SGA.simple_module_parameterization()
Partitions of the integer 6

sage: SGA = SymmetricGroupAlgebra(GF(2), 6)
sage: SGA.simple_module_parameterization()
2-Regular Partitions of the integer 6

sage: SGA = SymmetricGroupAlgebra(QQ, 5)

sage: SM = SGA.specht_module(Partition([3,1,1]))
sage: SM
Specht module of [3, 1, 1] over Rational Field

sage: SM.frobenius_image()
s[3, 1, 1]

sage: SM = SGA.specht_module([(1,1),(1,3),(2,2),(3,1),(3,2)])

sage: SM
Specht module of [(1, 1), (1, 3), (2, 2), (3, 1), (3, 2)] over Rational Field

sage: SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + s[3, 2]

>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module(Partition([Integer(3),Integer(1),Integer(1)]))
>>> SM
(continues on next page)
Specht module of \([3, 1, 1]\) over Rational Field

```python
>>> SM.frobenius_image()
s[3, 1, 1]
```

```python
>>> SM = SGA.specht_module([(Integer(1),Integer(1)),(Integer(1),Integer(3)),
    \rightarrow (Integer(2),Integer(2)),(Integer(3),Integer(1)),(Integer(3),
    \rightarrow Integer(2))])
```

```python
>>> SM
Specht module of \([(1, 1), (1, 3), (2, 2), (3, 1), (3, 2)]\) over Rational Field
```

```python
>>> SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
```

**specht_module_dimension** \((D)\)

Return the dimension of the Specht module of \(\text{self}\) indexed by \(D\).

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SGA.specht_module_dimension(Partition([3,1,1]))
6
```

```python
sage: SGA.specht_module_dimension([(1,1),(1,3),(2,2),(3,1),(3,2)])
16
```

```python
>>> from sage.all import *
```

```python
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
```

```python
>>> SGA.specht_module_dimension([(Integer(3),Integer(1),Integer(1))])
6
```

```python
>>> SGA.specht_module_dimension([(Integer(1),Integer(1)),(Integer(1),
    \rightarrow Integer(3)),(Integer(2),Integer(2)),(Integer(3),Integer(1)),(Integer(3),
    \rightarrow Integer(2))])
16
```

**tabloid_module** \((D)\)

Return the module of tabloids with the natural action of \(\text{self}\).

**See also:**

*TabloidModule*

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module(Partition([3,1,1]))
sage: TM
Tabloid module of \([3, 1, 1]\) over Rational Field
```

```python
sage: s = SymmetricFunctions(QQ).s()
sage: s(TM.frobenius_image())
```

```python
>>> from sage.all import *
```

```python
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
```

```python
>>> TM = SGA.tabloid_module(Partition([Integer(3),Integer(1),Integer(1)]))
```

```python
>>> TM
Tabloid module of \([3, 1, 1]\) over Rational Field
```

```python
>>> s = SymmetricFunctions(QQ).s()
```

```python
>>> s(TM.frobenius_image())
```
**young_symmetrizer**(*la*)

Return the Young symmetrizer of shape *la* of self.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(3))
sage: SGA.young_symmetrizer([2,1])
(1 + (1,2) - (1,3,2) - (1,3))
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: SGA.young_symmetrizer([2,1,1])
[1, 2, 3, 4] - [1, 2, 4, 3] + [2, 1, 3, 4] - [2, 1, 4, 3]
- [3, 1, 2, 4] + [3, 1, 4, 2] - [3, 2, 1, 4] + [3, 2, 4, 1]
+ [4, 1, 2, 3] - [4, 1, 3, 2] + [4, 2, 1, 3] - [4, 2, 3, 1]
sage: SGA.young_symmetrizer([5,1,1])
Traceback (most recent call last):
...
ValueError: the partition [5, 1, 1] is not of size 4

>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(Integer(3)))
>>> SGA.young_symmetrizer([Integer(2),Integer(1)])
(1 + (1,2) - (1,3,2) - (1,3))
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> SGA.young_symmetrizer([Integer(2),Integer(1),Integer(1)])
[1, 2, 3, 4] - [1, 2, 4, 3] + [2, 1, 3, 4] - [2, 1, 4, 3]
- [3, 1, 2, 4] + [3, 1, 4, 2] - [3, 2, 1, 4] + [3, 2, 4, 1]
+ [4, 1, 2, 3] - [4, 1, 3, 2] + [4, 2, 1, 3] - [4, 2, 3, 1]
>>> SGA.young_symmetrizer([Integer(5),Integer(1),Integer(1)])
Traceback (most recent call last):

```

.. code-block:: python

```python
sage.combinat.symmetric_group_algebra.a (tableau, star=0, base_ring=Rational Field)
```

The row projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the sum (in the group algebra of the relevant symmetric group over \(\mathbb{Q}\)) of all the permutations which preserve the rows of `tableau`. It is called \(\alpha_{tableau}\) in \[EGHLSVY\], Section 4.2.

**INPUT:**

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once.
- `star` – nonnegative integer (default: 0). When this optional variable is set, the method computes not the row projection operator of `tableau`, but the row projection operator of the restriction of `tableau` to the entries 1, 2, ..., `tableau.size()` - `star` instead.
- `base_ring` – commutative ring (default: \(\mathbb{Q}\)). When this optional variable is set, the row projection operator is computed over a user-determined base ring instead of \(\mathbb{Q}\). (Note that symmetric group algebras currently don’t preserve coercion, so e. g. a symmetric group algebra over \(\mathbb{Z}\) does not coerce into the corresponding one over \(\mathbb{Q}\); so convert manually or choose your base rings wisely!)

**EXAMPLES:**

```python
sage: from sage.combinat.symmetric_group_algebra import a
sage: a([[1],[2]])
[[1], [2]]
sage: a([[1],[2]])
[[1], [2]]
(continues on next page)
```
sage: a([])
[]
sage: a([[1, 5], [2, 3], [4]])
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: a([[1, 4], [2, 3]], base_ring=ZZ)
[1, 2, 3, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]

>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import a
>>> a([[Integer(1),Integer(2)]])
[1, 2] + [2, 1]
>>> a([[Integer(1)],[Integer(2)]]))
[1, 2]
>>> a([])
[]
>>> a([[Integer(1), Integer(5)], [Integer(2), Integer(3)], [Integer(4)]]))
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
>>> a([[Integer(1),Integer(4)], [Integer(2),Integer(3)]]), base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]

The same with a skew tableau:
sage: a([[None,1,4], [2,3]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]

>>> from sage.all import *
>>> a([[None,Integer(1),Integer(4)], [Integer(2),Integer(3)]]), base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]

sage.combinat.symmetric_group_algebra.b(tableau, star=0, base_ring=Rational Field)
The column projection operator corresponding to the Young tableau tableau (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the signed sum (in the group algebra of the relevant symmetric group over Q) of all the permutations which preserve the column of tableau (where the signs are the usual signs of the permutations). It is called \( b_{\text{tableau}} \) in [EGHLSVY], Section 4.2.

INPUT:

- tableau – Young tableau which contains every integer from 1 to its size precisely once.
- star – nonnegative integer (default: 0). When this optional variable is set, the method computes not the column projection operator of tableau, but the column projection operator of the restriction of tableau to the entries 1, 2, ..., tableau.size() - star instead.
- base_ring – commutative ring (default: QQ). When this optional variable is set, the column projection operator is computed over a user-determined base ring instead of Q. (Note that symmetric group algebras currently don’t preserve coercion, so e.g. a symmetric group algebra over Z does not coerce into the corresponding one over Q: so convert manually or choose your base rings wisely!)

EXAMPLES:
The same with a skew tableau:

```
sage: b([[None, 2, 4], [1, 3], [5]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
```

With the \texttt{l2r} setting for multiplication, the unnormalized Young symmetrizer $e(\text{tableau})$ should be the product $b(\text{tableau}) \ast a(\text{tableau})$ for every tableau. Let us check this on the standard tableaux of size 5:

```
sage: from sage.combinat.symmetric_group_algebra import a, b, e
sage: all( e(t) == b(t) * a(t) for t in StandardTableaux(5) )
True
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import b
>>> b([[None, Integer(2)], [Integer(1), Integer(3)], [Integer(5)]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
```

```
sage.combinat.symmetric_group_algebra.e(tableau, star=0)
The unnormalized Young projection operator corresponding to the Young tableau \texttt{tableau} (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

If $n$ is a nonnegative integer, and $T$ is a Young tableau containing every integer from 1 to $n$ exactly once, then the unnormalized Young projection operator $e(T)$ is defined by

$$e(T) = a(T)b(T) \in QS_n,$$

5.1. Comprehensive Module List

5355
where \( a(T) \in QS_n \) is the sum of all permutations in \( S_n \) which fix the rows of \( T \) (as sets), and \( b(T) \in QS_n \) is the signed sum of all permutations in \( S_n \) which fix the columns of \( T \) (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group \( S_n \) is defined in such a way that \( (pq)(i) = p(q(i)) \) for any permutations \( p \) and \( q \) and any \( 1 \leq i \leq n \).

Note that the definition of \( e(T) \) is not uniform across literature. Others define it as \( b(T)a(T) \) instead, or include certain scalar factors (we do not, whence “unnormalized”).

**EXAMPLES:**

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: e([[1,2]])
[1, 2] + [2, 1]
sage: e([[1],[2]])
[1, 2] - [2, 1]
sage: e([])
[]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e
>>> e([[Integer(1),Integer(2)]]]
[1, 2] + [2, 1]
>>> e([[Integer(1)],[Integer(2)]]
[1, 2] - [2, 1]
>>> e([])
[]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e([[1,2],[3]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e
>>> e([[Integer(1),Integer(2)],[Integer(3)]]
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

To obtain the product \( b(T)a(T) \), one has to take the antipode of this:

```
sage: QS3 = parent(e([[1,2],[3]]))
sage: QS3.antipode(e([[1,2],[3]])
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e
>>> e([[Integer(1),Integer(2)],[Integer(3)]]
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

And here is an example for a skew tableau:

```
sage: e([[None, 2, 1], [4, 3]])
[1, 2, 3, 4] + [1, 2, 4, 3] - [1, 3, 2, 4] - [1, 4, 2, 3] + [2, 1, 3, 4] + [2, 1, 4, 3] - [2, 3, 1, 4] - [2, 4, 1, 3]
```

```
>>> from sage.all import *
>>> e([[None, Integer(2), Integer(1)], [Integer(4), Integer(3)]]
(continues on next page)```
\[[1, 2, 3, 4] + [1, 2, 4, 3] - [1, 3, 2, 4] - [1, 4, 2, 3] \\
+ [2, 1, 3, 4] + [2, 1, 4, 3] - [2, 3, 1, 4] - [2, 4, 1, 3]\]

See also:
\[
e_{\text{hat}}()\]

\sage{combinat.symmetric_group_algebra.e_hat}(\textit{tab}, \textit{star}=0)

The Young projection operator corresponding to the Young tableau \textit{tab} (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard). This is an idempotent in the rational group algebra.

If \(n\) is a nonnegative integer, and \(T\) is a Young tableau containing every integer from 1 to \(n\) exactly once, then the Young projection operator \(\hat{e}(T)\) is defined by

\[
\hat{e}(T) = \frac{1}{\kappa_{\lambda}} a(T)b(T) \in \mathbb{Q}S_n,
\]

where \(\lambda\) is the shape of \(T\), where \(\kappa_{\lambda} = n!\) divided by the number of standard tableaux of shape \(\lambda\), where \(a(T) \in \mathbb{Q}S_n\) is the sum of all permutations in \(S_n\) which fix the rows of \(T\) (as sets), and where \(b(T) \in \mathbb{Q}S_n\) is the signed sum of all permutations in \(S_n\) which fix the columns of \(T\) (as sets). Here, “signed” means that each permutation is multiplied with its sign; and the product on the group \(S_n\) is defined in such a way that \((pq)(i) = p(q(i))\) for any permutations \(p\) and \(q\) and any \(1 \leq i \leq n\).

Note that the definition of \(\hat{e}(T)\) is not uniform across literature. Others define it as \(\frac{1}{\kappa_{\lambda}}b(T)a(T)\) instead.

EXAMPLES:

\sage{from sage.combinat.symmetric_group_algebra import e_hat}
\sage{e_hat([[1,2,3]])}
\sage{1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]}
\sage{e_hat([[1],[2]])}
\sage{1/2*[1, 2] - 1/2*[2, 1]}

\[
>>> \text{from sage.all import *} \\
>>> \text{from sage.combinat.symmetric_group_algebra import e_hat} \\
>>> \text{e_hat([[Integer(1),Integer(2),Integer(3)]])} \\
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/6*[3, 2, 1] \\
>>> \text{e_hat([[Integer(1)],[Integer(2)]])} \\
1/2*[1, 2] - 1/2*[2, 1]
\]

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

\sage{e_hat([[1,2],[3]])}
\sage{1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]}

\[
>>> \text{from sage.all import *} \\
>>> \text{e_hat([[Integer(1),Integer(2)], [Integer(3)]]}) \\
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
\]

See also:
\[
e()\]

5.1. Comprehensive Module List
sage.combinat.symmetric_group_algebra.e_ik(itab, ktab, star=0)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_ik
sage: e_ik([[1,2,3]], [[1,2,3]])
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: e_ik([[1,2,3]], [[1,2,3]], star=1)
[1, 2] + [2, 1]
```

sage.combinat.symmetric_group_algebra.epsilon(tab, star=0)

The \((T, T)\)-th element of the seminormal basis of the group algebra \(Q[S_n]\), where \(T\) is the tableau \(tab\) (with its star highest entries removed if the optional variable \(star\) is set).

See the docstring of \texttt{sейminal\_basis()} for the notation used herein.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon
sage: epsilon([[1,2]])
1/2*[1, 2] + 1/2*[2, 1]
sage: epsilon([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

sage.combinat.symmetric_group_algebra.epsilon_ik(itab, ktab, star=0)

Return the seminormal basis element of the symmetric group algebra \(Q[S_n]\) corresponding to the pair of tableaux \(itab\) and \(ktab\) (or restrictions of these tableaux, if the optional variable \(star\) is set).

INPUT:

- \(itab, ktab\) – two standard tableaux of same size.
- \(star\) – integer (default: 0).

OUTPUT:

The element \(\epsilon(I, K) \in Q[S_n]\), where \(I\) and \(K\) are the tableaux obtained by removing all entries higher than \(n – star\) from \(itab\) and \(ktab\), respectively (where \(n\) is the size of \(itab\) and \(ktab\)). Here, we are using the notations from \texttt{seminormal\_basis()}. 

EXAMPLES:
sage: from sage.combinat.symmetric_group_algebra import epsilon_ik
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]])
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
Traceback (most recent call last):
  ...
ValueError: the two tableaux must be of the same shape

sage.combinat.symmetric_group_algebra.kappa(alpha)
Return $\kappa_\alpha$, which is $n!$ divided by the number of standard tableaux of shape $\alpha$ (where $\alpha$ is a partition of $n$).

INPUT:

• alpha – integer partition (can be encoded as a list).

OUTPUT:

The factorial of the size of alpha, divided by the number of standard tableaux of shape alpha. Equivalently, the product of all hook lengths of alpha.

EXAMPLES:

sage: from sage.combinat.symmetric_group_algebra import kappa
sage: kappa(Partition([2,1]))
3
sage: kappa([2,1])
3

sage.combinat.symmetric_group_algebra.pi_ik(itab, ktab)
Return the permutation $p$ which sends every entry of the tableau $itab$ to the respective entry of the tableau $ktab$, as an element of the corresponding symmetric group algebra.

This assumes that $itab$ and $ktab$ are tableaux (possibly given just as lists of lists) of the same shape. Both tableaux are allowed to be skew.

EXAMPLES:
```python
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import pi_ik

>>> pi_ik([[Integer(1),Integer(3)], [Integer(2)]], [[Integer(1), Integer(2)], [Integer(3)]])
[1, 3, 2]
```

The same with skew tableaux:

```python
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[None, 1, 3], [2]], [[None, 1, 2], [3]])
[1, 3, 2]
```

```python
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import pi_ik

>>> pi_ik([[None, Integer(1), Integer(3)], [Integer(2)]], [[None, Integer(1),
       → Integer(2)], [Integer(3)]])
[1, 3, 2]
```

`sage.combinat.symmetric_group_algebra.seminormal_test(n)`

Run a variety of tests to verify that the construction of the seminormal basis works as desired. The numbers appearing are results in James and Kerber’s ‘Representation Theory of the Symmetric Group’ [JK1981].

**EXAMPLES:**

```python
sage: from sage.combinat.symmetric_group_algebra import seminormal_test
sage: seminormal_test(3)
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import seminormal_test

>>> seminormal_test(Integer(3))
True
```

### 5.1.343 Representations of the Symmetric Group

**Todo:**

- construct the product of two irreducible representations.
- implement Induction/Restriction of representations.

**Warning:** This code uses a different convention than in Sagan’s book “The Symmetric Group”

```python
class sage.combinat.symmetric_group_representations.GarsiaProcesiModule(SGA,
shape)

Bases: UniqueRepresentation, QuotientRing_generic, SymmetricGroupRepresentation

A Garsia-Procesi module.

Let $\lambda$ be a partition of $n$ and $R$ be a commutative ring. The Garsia-Procesi module is defined by $R_\lambda := R[x_1, \ldots, x_n]/I_\lambda$, where

$I_\lambda := \langle e_r(x_{i_1}, \ldots, x_{i_k}) \mid \{i_1, \ldots, i_k\} \subseteq [n] \text{ and } k \geq r > k - d_k(\lambda) \rangle,
```
with $e_r$ being the $r$-the elementary symmetric function and $d_k(\lambda) = \lambda'_n + \cdots + \lambda'_{n+1-k}$, is the Tanisaki ideal.

If we consider $R = \mathbb{Q}$, then the Garsia-Procesi module has the following interpretation. Let $\mathcal{F}_n = GL_n/B$ denote the (complex type A) flag variety. Consider the Springer fiber $F_\lambda \subseteq \mathcal{F}_n$ associated to a nilpotent matrix with Jordan blocks sizes $\lambda$. Springer showed that the cohomology ring $H^*(F_\lambda)$ admits a graded $S_n$-action that agrees with the induced representation of the sign representation of the Young subgroup $S_\lambda$. From work of De Concini and Procesi, this $S_n$-representation is isomorphic to $R_\lambda$. Moreover, the graded Frobenius image is known to be a modified Hall-Littlewood polynomial.

**EXAMPLES:**

```sage
sage: SGA = SymmetricGroupAlgebra(QQ, 7)
sage: GP421 = SGA.garsia_procesi_module([4, 2, 1])
sage: GP421.dimension()
105
sage: v = GP421.an_element(); v
 gp1 - gp2 - gp3 - gp4 - gp5 - gp6
sage: SGA.an_element() * v
-6*gp1 - 6*gp2 - 6*gp3 - 6*gp4 - 6*gp5 - 5*gp6
```

We verify the result is a modified Hall-Littlewood polynomial by using the $Q'$ Hall-Littlewood polynomials, replacing $q \rightarrow q^{-1}$ and multiplying by the smallest power of $q$ so the coefficients are again polynomials:

```sage
sage: GP421.graded_frobenius_image()
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
+ (q^2+q)*s[6, 1] + s[7]
sage: R.<q> = QQ[]
sage: Sym = SymmetricFunctions(R)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(q).Qp()
sage: mHL = s(Qp[4,2,1]); mHL
s[4, 2, 1] + q*s[4, 3] + q*s[5, 1, 1] + (q^2+q)*s[5, 2]
+ (q^3+q^2)*s[6, 1] + q^4*s[7]
sage: mHL.map_coefficients(lambda c: R(q^4*c(q^-1)))
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
+ (q^2+q)*s[6, 1] + s[7]
```

(continues on next page)
We show that the maximal degree component corresponds to the Yamanouchi words of content $\lambda$:

```python
sage: B = GP421.graded_decomposition(4).basis()
sage: top_deg = [Word([i+1 for i in b.lift().exponents()[0]]) for b in B]
sage: yamanouchi = [P.to_packed_word() for P in OrderedSetPartitions(range(7), [4, 2, 1])
    if P.to_packed_word().reversal().is_yamanouchi()]
sage: set(top_deg) == set(yamanouchi)
True
```

class **Element** *(parent, rep, reduce=True)*

**Bases:** QuotientRingElement

**degree()**

Return the degree of self.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP22 = SGA.garsia_procesi_module([2, 2])
sage: for b in GP22.basis():
    ....:     print(b, b.degree())
gp2*gp3 2
gp1*gp3 2
gp3 1
gp2 1
gp1 1
1 0
sage: v = sum(GP22.basis())
sage: v.degree()
2
```
homogeneous_degree()

Return the (homogeneous) degree of self if homogeneous otherwise raise an error.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(GF(2), 4)
sage: GP31 = SGA.garsia_procesi_module([3, 1])
sage: for b in GP31.basis():
   ....:     print(b, b.homogeneous_degree())
gp3 1
gp2 1
gp1 1
1 0
sage: v = sum(GP31.basis()); v
gp1 + gp2 + gp3 + 1
sage: v.homogeneous_degree()
Traceback (most recent call last):
... ValueError: element is not homogeneous
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(4))
>>> GP31 = SGA.garsia_procesi_module([Integer(3), Integer(1)])
>>> for b in GP31.basis():
   ...     print(b, b.homogeneous_degree())
gp3 1
gp2 1
gp1 1
1 0
>>> v = sum(GP31.basis()); v
gp1 + gp2 + gp3 + 1
>>> v.homogeneous_degree()
Traceback (most recent call last):
... ValueError: element is not homogeneous
```

monomial_coefficients(copy=None)

Return the monomial coefficients of self.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP31 = SGA.garsia_procesi_module([3, 1])
sage: v = GP31.an_element(); v
-gp1 - gp2 - gp3
sage: v.monomial_coefficients()
{0: 2, 1: 2, 2: 2, 3: 0}
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
(continues on next page)
```
GP31 = SGA.garsia_procesi_module([Integer(3), Integer(1)])
>>> v = GP31.an_element(); v
-gp1 - gp2 - gp3
>>> v.monomial_coefficients()
{0: 2, 1: 2, 2: 2, 3: 0}

**to_vector** *(order=None)*

Return self as a (dense) free module vector.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP22 = SGA.garsia_procesi_module([2, 2])
sage: v = GP22.an_element(); v
-gp1 - gp2 - gp3
sage: v.to_vector()
(0, 0, 2, 2, 2, 0)
```

```python
>>> from sage.all import *
```

```python
SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
GP22 = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> v = GP22.an_element(); v
-gp1 - gp2 - gp3
>>> v.to_vector()
(0, 0, 2, 2, 2, 0)
```

**basis**

Return a basis of self.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.basis()
Family (gp2*gp3, gp1*gp3, gp3, gp2, gp1, 1)
```

```python
>>> from sage.all import *
```

```python
SGA = SymmetricGroupAlgebra(QQ, Integer(4))
GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.basis()
Family (gp2*gp3, gp1*gp3, gp3, gp2, gp1, 1)
```

**dimension**

Return the dimension of self.

The graded Frobenius character of the Garsia-Procesi module $R_\lambda$ is given by the modified Hall-Littlewood polynomial $\tilde{H}_\lambda(x; q)$.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(1).Qp()
sage: for la in Partitions(5):
......:    print(SGA.garsia_procesi_module(la).dimension()),
```

(continues on next page)
Combinatorics, Release 10.4

From previous page:

```python
....:   sum(c * StandardTableaux(la).cardinality()
....:     for la, c in s(Qp[la])))
1 1
5 5
10 10
20 20
30 30
60 60
120 120
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(Integer(1)).Qp()
>>> for la in Partitions(Integer(5)):
...     print(SGA.garsia_procesi_module(la).dimension(),
...           sum(c * StandardTableaux(la).cardinality()
...               for la, c in s(Qp[la])))
1 1
5 5
10 10
20 20
30 30
60 60
120 120
```

**get_order()**

Return the order of the elements in the basis.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.get_order()
(0, 1, 2, 3, 4, 5)
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.get_order()
(0, 1, 2, 3, 4, 5)
```

**graded_brauer_character()**

Return the graded Brauer character of `self`.

**EXAMPLES:**

```python
sage: SGA = SymmetricGroupAlgebra(GF(2), 5)
sage: GP311 = SGA.garsia_procesi_module([3, 1, 1])
sage: GP311.graded_brauer_character()
(6*q^3 + 9*q^2 + 4*q + 1, q + 1, q^3 - q^2 - q + 1)
```

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(5))
```

(continues on next page)
graded_character()

Return the graded character of self.

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: GP = SGA.garsia_procesi_module([2, 2, 1])
sage: gchi = GP.graded_character(); gchi
(5*q^4 + 11*q^3 + 9*q^2 + 4*q + 1, -q^4 + q^3 + 3*q^2 + 2*q + 1,
 q^4 - q^3 + q^2 + 1, -q^4 - q^3 + q + 1, -q^4 + q^3 - q + 1,
 q^4 - q^3 - q^2 + 1, q^3 - q^2 - q + 1)
sage: R.<q> = QQ[]
sage: gchi == sum(q**d * D.character() for d, D in GP.graded_decomposition().items())
True
```

graded_decomposition(k=None)

Return the decomposition of self as a direct sum of representations given by a fixed grading.

INPUT:

- k – (optional) integer; if given, return the k-th graded part

EXAMPLES:

```python
sage: SGA = SymmetricGroupAlgebra(GF(2), 5)
sage: GP32 = SGA.garsia_procesi_module([3, 2])
sage: decomp = GP32.graded_decomposition(); decomp
{0: Subrepresentation with basis {0} of Garsia-Procesi ..., 1: Subrepresentation with basis {0, 1, 2, 3} of Garsia-Procesi ..., 2: Subrepresentation with basis {0, 1, 2, 3, 4} of Garsia-Procesi ...}
sage: decomp[2] is GP32.graded_decomposition(2)
True
sage: GP32.graded_decomposition(10)
Subrepresentation with basis {} of Garsia-Procesi module of shape [3, 2] over Finite Field of size 2
```
Continued from previous page:

(0: Subrepresentation with basis {0} of Garsia-Procesi ...,
1: Subrepresentation with basis {0, 1, 2, 3} of Garsia-Procesi ...
2: Subrepresentation with basis {0, 1, 2, 3, 4} of Garsia-Procesi ...)

```
>>> decomp[Integer(2)] is GP32.graded_decomposition(Integer(2))
True
>>> GP32.graded_decomposition(Integer(10))
Subrepresentation with basis {} of Garsia-Procesi module
of shape [3, 2] over Finite Field of size 2
```

**graded_frobenius_image()**

Return the graded Frobenius image of self.

The graded Frobenius image is the sum of the `frobenius_image()` of each graded component, which is known to result in the modified Hall-Littlewood polynomial $\tilde{H}_\lambda(x; q)$.

**EXAMPLES:**

We verify that the result is the modified Hall-Littlewood polynomial for $n = 5$:

```
sage: R.<q> = QQ[]
sage: Sym = SymmetricFunctions(R)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(q).Qp()
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(5):
  ...: f = SGA.garsia_procesi_module(la).graded_frobenius_image()
  ...: d = f[la].degree()
  ...: assert f.map_coefficients(lambda c: R(c(~q)*q^d)) == s(Qp[la])
```

```
from sage.all import *
R = QQ['q']; (q,) = R._first_ngens(1)
Sym = SymmetricFunctions(R)
s = Sym.s()
Qp = Sym.hall_littlewood(q).Qp()
SGA = SymmetricGroupAlgebra(QQ, Integer(5))
for la in Partitions(Integer(5)):
  f = SGA.garsia_procesi_module(la).graded_frobenius_image()
  d = f[la].degree()
  assert f.map_coefficients(lambda c: R(c(~q)*q**d)) == s(Qp[la])
```

**graded_representation_matrix** *(elt, q=None)*

Return the matrix corresponding to the left action of the symmetric group (algebra) element elt on self.

**EXAMPLES:**

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 3)
sage: GP = SGA.garsia_procesi_module([1, 1, 1])
sage: elt = SGA.an_element(); elt
[1, 2, 3] + 2*[1, 3, 2] + [3, 1, 2]
sage: X = GP.graded_representation_matrix(elt); X
[ 0 0 0 0 0 0]
[ 0 q^2 0 0 0 0]
[ 0 q^2 0 0 0 0]
[ 0 0 0 q 0 0]
[ 0 0 0 q 0 0]
[ 0 0 0 0 0 1]
sage: X.parent()
```
Full MatrixSpace of 6 by 6 dense matrices over
Univariate Polynomial Ring in q over Finite Field of size 3
sage: R.<q> = GF(3)[]
sage: t = R.quotient([q^2+2*q+1]).gen()
sage: GP.graded_representation_matrix(elt, t)
\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & qbar + 2 & 0 & 0 & 0 & 0 \\
0 & qbar + 2 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & qbar & 0 & 0 \\
0 & 0 & 0 & qbar & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

one_basis()
Return the index of the basis element 1.

EXAMPLES:

sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.one_basis()
5

```python
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, 4)
>>> GP = SGA.garsia_procesi_module([2, 2])
>>> GP.one_basis()
5
```
Bases: SymmetricGroupRepresentation_generic_class

representation_matrix(permutation)

Return the matrix representing the permutation in this irreducible representation.

Note: This method caches the results.

EXAMPLES:

```python
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.representation_matrix(Permutation([2,1,3,4]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
sage: spc.representation_matrix(Permutation([3,2,1,4]))
[0  0  1]
[0  1  0]
[1  0  0]
```

scalar_product(u, v)

Return 0 if u+v is not a permutation, and the signature of the permutation otherwise.

This is the scalar product of a vertex u of the underlying Yang-Baxter graph with the vertex v in the ‘dual’ Yang-Baxter graph.

EXAMPLES:

```python
sage: spc = SymmetricGroupRepresentation([3,2], 'specht')
sage: spc.scalar_product((1,0,2,1,0),(0,3,0,3,0))
-1
sage: spc.scalar_product((1,0,2,1,0),(3,0,0,3,0))
0
```

scalar_product_matrix(permutation=None)

Return the scalar product matrix corresponding to permutation.
The entries are given by the scalar products of $u$ and $\text{permutation.action}(v)$, where $u$ is a vertex in the underlying Yang-Baxter graph and $v$ is a vertex in the dual graph.

**EXAMPLES:**

```sage
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
[ 1 0 0]
[ 0 -1 0]
[ 0 0 1]

>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(1)], 'specht')
[ 1 0 0]
[ 0 -1 0]
[ 0 0 1]
```

class sage.combinat.symmetric_group_representations.SpechtRepresentations(n, ring=None, cache_matrices=True)

Bases: SymmetricGroupRepresentations_class

Element

alias of SpechtRepresentation

sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation(partition, implementation='specht', ring=None, cache_matrices=True)

The irreducible representation of the symmetric group corresponding to partition.

**INPUT:**

- **partition** – a partition of a positive integer
- **implementation** – string (default: "specht"), one of:
  - "seminormal" – for Young’s seminormal representation
  - "orthogonal" – for Young’s orthogonal representation
  - "specht" – for Specht’s representation
- **ring** – the ring over which the representation is defined
- **cache_matrices** – boolean (default: True) if True, then any representation matrices that are computed are cached
EXAMPLES:

Young’s orthogonal representation: the matrices are orthogonal.

```python
sage: orth = SymmetricGroupRepresentation([2, 1], "orthogonal"); orth  # needs sage.symbolic
Orthogonal representation of the symmetric group corresponding to [2, 1]
sage: all(a*a.transpose() == a.parent().identity_matrix() for a in orth)  # needs sage.symbolic
True
```

```python
sage: orth = SymmetricGroupRepresentation([3, 2], "orthogonal"); orth  # needs sage.symbolic
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([2, 1, 3, 4, 5])
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 -1 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 -1]
sage: orth([1, 3, 2, 4, 5])
[ 1 0 0 0 0]
[ 0 0 1/2*sqrt(3) 1/2 0]
[ 0 1/2*sqrt(3) 1/2 0 0]
[ 0 0 0 1/2*sqrt(3) 1/2]
[ 0 0 0 1/2*sqrt(3) 1/2]
```

```python
sage: orth = SymmetricGroupRepresentation([Integer(3), Integer(2)], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([Integer(2), Integer(1), Integer(3), Integer(4), Integer(5)])
[ 1 0 0 0 0]
[ 0 1 0 0 0]
[ 0 0 -1 0 0]
[ 0 0 0 1 0]
[ 0 0 0 0 -1]
sage: orth([Integer(1), Integer(3), Integer(2), Integer(4), Integer(5)])
[ 1 0 0 0 0]
[ 0 0 1/2*sqrt(3) 1/2 0]
[ 0 1/2*sqrt(3) 1/2 0 0]
[ 0 0 0 1/2*sqrt(3) 1/2]
[ 0 0 0 1/2*sqrt(3) 1/2]
```

(continues on next page)
The Specht representation:

```python
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc.scalar_product_matrix(Permutation([1,2,3,4,5]))
[ 1 0 0 0 0]
[ 0 -1 0 0 -1]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 0 0 0 -1]
sage: spc.scalar_product_matrix(Permutation([5,4,3,2,1]))
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: spc(Permutation([5,4,3,2,1]))
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: spc.verify_representation()
True
```
By default, any representation matrices that are computed are cached:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: spc._cache__representation_matrix
([(5, 4, 3, 2, 1), ()]: [ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1])
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht")
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
>>> spc._cache__representation_matrix
([(5, 4, 3, 2, 1), ()]: [ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1])
```

This can be turned off with the keyword `cache_matrices`:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht", cache_matrices=False)
sage: spc([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
sage: hasattr(spc, '_cache__representation_matrix')
False
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht", cache_matrices=False)
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
>>> hasattr(spc, '_cache__representation_matrix')
False
```

**Note:** The implementation is based on the paper [Las].
class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class

Bases: Element

Generic methods for a representation of the symmetric group.

to_character()

Return the character of the representation.

EXAMPLES:

The trivial character:

sage: rho = SymmetricGroupRepresentation([3])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, 1, 1]
sage: all(chi(g) == 1 for g in SymmetricGroup(3))
True

>>> from sage.all import *
>>> rho = SymmetricGroupRepresentation([Integer(3)])
>>> chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
>>> chi.values()
[1, 1, 1]
>>> all(chi(g) == Integer(1) for g in SymmetricGroup(Integer(3)))
True

The sign character:

sage: rho = SymmetricGroupRepresentation([1,1,1])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, -1, 1]
sage: all(chi(g) == g.sign() for g in SymmetricGroup(3))
True

>>> from sage.all import *
>>> rho = SymmetricGroupRepresentation([Integer(1),Integer(1),Integer(1)])
>>> chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
>>> chi.values()
[1, -1, 1]
>>> all(chi(g) == g.sign() for g in SymmetricGroup(Integer(3)))
True

The defining representation:
sage: triv = SymmetricGroupRepresentation([4])
sage: hook = SymmetricGroupRepresentation([3,1])
sage: def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
sage: list(map(def_rep, Permutations(4)))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
sage: [p.to_matrix().trace() for p in Permutations(4)]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]

>>> from sage.all import *
>>> triv = SymmetricGroupRepresentation([Integer(4)])
>>> hook = SymmetricGroupRepresentation([Integer(3),Integer(1)])
>>> def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
>>> list(map(def_rep, Permutations(Integer(4))))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
>>> [p.to_matrix().trace() for p in Permutations(Integer(4))]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]

verify_representation()
Verify the representation.

This tests that the images of the simple transpositions are involutions and tests that the braid relations hold.

EXAMPLES:

sage: spc = SymmetricGroupRepresentation([1,1,1])
sage: spc.verify_representation()
True
sage: spc = SymmetricGroupRepresentation([4,2,1])
sage: spc.verify_representation()
True

>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(1),Integer(1),Integer(1)])
>>> spc.verify_representation()
True
>>> spc = SymmetricGroupRepresentation([Integer(4),Integer(2),Integer(1)])
>>> spc.verify_representation()
True

sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations(n, implementation='specht', ring=None, cache_matrices=True)

Irreducible representations of the symmetric group.

INPUT:

- n – positive integer
- implementation – string (default: "specht"), one of:
  - "seminormal" – for Young's seminormal representation
- "orthogonal" – for Young’s orthogonal representation
- "specht" – for Specht’s representation

• ring – the ring over which the representation is defined
• cache_matrices – boolean (default: True) if True, then any representation matrices that are computed are cached

EXAMPLES:

Young’s orthogonal representation: the matrices are orthogonal.

```python
sage: orth = SymmetricGroupRepresentations(3, "orthogonal"); orth
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
sage: orth.list()
[Orthogonal representation of the symmetric group corresponding to [3],
 Orthogonal representation of the symmetric group corresponding to [2, 1],
 Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
sage: orth([2,1])([1,2,3])
[1 0]
[0 1]
```

Young’s seminormal representation.

```python
sage: snorm = SymmetricGroupRepresentations(3, "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
sage: sgn = snorm([1,1,1]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
sage: list(map(sgn, Permutations(3)))
[[1], [-1], [-1], [1], [1], [-1]]
```

The Specht Representation.
```python
sage: spc = SymmetricGroupRepresentations(5, "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
sage: spc([3,2])([5,4,3,2,1])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
```

```
>>> from sage.all import *

>>> spc = SymmetricGroupRepresentations(Integer(5), "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring

>>> spc([Integer(3),Integer(2)])([Integer(5),Integer(4),Integer(3),Integer(2),
                        Integer(1)])
[ 1 -1 0 1 0]
[ 0 0 -1 0 1]
[ 0 0 0 -1 1]
[ 0 1 -1 -1 1]
[ 0 1 0 -1 1]
```

**Note:** The implementation is based on the paper [Las].

**AUTHORS:**
- Franco Saliola (2009-04-23)

```python
class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentations_class(n, ring=None, cache_matrices=True)
```

Bases: `UniqueRepresentation, Parent`

Generic methods for the CombinatorialClass of irreducible representations of the symmetric group.

**cardinality()**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: sp = SymmetricGroupRepresentations(4, "specht")
sage: sp.cardinality()
5

>>> from sage.all import *

>>> sp = SymmetricGroupRepresentations(Integer(4), "specht")

>>> sp.cardinality()
5
```

```python
class sage.combinat.symmetric_group_representations.YoungRepresentation_Orthogonal(parent, partition)
```

Bases: `YoungRepresentation_generic`

5.1. Comprehensive Module List 5377
class sage.combinat.symmetric_group_representations.YoungRepresentation_Seminormal(parent, partition)

Bases: YoungRepresentation_generic
class sage.combinat.symmetric_group_representations.YoungRepresentation_generic(parent, partition)

Bases: SymmetricGroupRepresentation_generic_class

Generic methods for Young’s representations of the symmetric group.

representation_matrix(permutation)
Return the matrix representing permutation.

EXAMPLES:

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")  # needs sage.symbolic
sage: orth.representation_matrix(Permutation([2,1,3]))  # needs sage.symbolic
[ 1 0]
[ 0 -1]
sage: orth.representation_matrix(Permutation([1,3,2]))  # needs sage.symbolic
[-1/2 1/2*sqrt(3)]
[1/2*sqrt(3) 1/2]
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentation([Integer(2),Integer(1)], "orthogonal")  # needs sage.symbolic
>>> orth.representation_matrix(Permutation([Integer(2),Integer(1), Integer(3)]))  # needs sage.symbolic
[ 1 0]
[ 0 -1]
```

```
sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: p = PermutationGroupElement([2,1,3])
sage: norm.representation_matrix(p)
[ 1 0]
[ 0 -1]
sage: p = PermutationGroupElement([1,3,2])
sage: norm.representation_matrix(p)
[-1/2 3/2]
[ 1/2 1/2]
```

```
>>> from sage.all import *
>>> norm = SymmetricGroupRepresentation([Integer(2),Integer(1)], "seminormal")
```
representation_matrix_for_simple_transposition(i)

Return the matrix representing the transposition that swaps i and i+1.

EXAMPLES:

```python
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")  # needs sage.symbolic
sage: orth.representation_matrix_for_simple_transposition(1)  # needs sage.symbolic
[ 1 0]
[ 0 -1]
sage: orth.representation_matrix_for_simple_transposition(2)
[ -1/2 1/2*sqrt(3)]
[1/2*sqrt(3) 1/2]
sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: norm.representation_matrix_for_simple_transposition(1)
[ 1 0]
[ 0 -1]
sage: norm.representation_matrix_for_simple_transposition(2)
[-1/2 3/2]
[ 1/2 1/2]
```
Combinatorics, Release 10.4

```python
class sage.combinat.symmetric_group_representations.YoungRepresentations_Orthogonal(n, ring=None, cache_matrices=True):
    Bases: SymmetricGroupRepresentations_class
    Element
        alias of YoungRepresentation_Orthogonal
class sage.combinat.symmetric_group_representations.YoungRepresentations_Seminormal(n, ring=None, cache_matrices=True):
    Bases: SymmetricGroupRepresentations_class
    Element
        alias of YoungRepresentation_Seminormal
```

```
sage.combinat.symmetric_group_representations.partition_to_vector_of_contents(partition, reverse=False)
```

Return the "vector of contents" associated to partition.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_representations import partition_to_vector_of_contents
>>> partition_to_vector_of_contents([3,2])
(0, 1, 2, -1, 0)
```

5.1.344 T-sequences

T-sequences are tuples of four (-1, 0, 1) sequences of length \( t \) where for every \( i \) exactly one sequence has a nonzero entry at index \( i \) and for which the nonperiodic autocorrelation function is equal to zero (i.e. they are complementary). See Definition 7.5 of [Seb2017].

These can be constructed from Turyn sequences. In particular, if Turyn sequences of length \( l \) exists, there will be T-sequences of length \( 4l - 1 \) and \( 2l - 1 \).

Turyn sequences are tuples of four (-1, +1) sequences \( X, U, Y, V \) of length \( l, l, l-1, l-1 \) with nonperiodic autocorrelation equal to zero and the additional constraints that:

- the first element of \( X \) is 1
- the last element of \( X \) is -1
- the last element of \( U \) is 1
The nonperiodic autocorrelation of a family of sequences \( X = \{A_1, A_2, ..., A_n\} \) is defined as (see Definition 7.2 of [Seb2017]):

\[
N_X(j) = \sum_{i=1}^{n-j} (a_{1,i}a_{1,i+j} + a_{2,i}a_{2,i+j} + ... + a_{n,i}a_{n,i+j})
\]

AUTHORS:

- Matteo Cati (2022-11-16): initial version

sage.combinat.t_sequences.T_sequences_construction_from_base_sequences(base_sequences, check=True)

Construct T-sequences of length \( 2n + p \) from base sequences of length \( n + p, n + p, n, n \).

Given base sequences \( A, B, C, D \), the T-sequences are constructed as described in [KTR2005]:

\[
\begin{align*}
T_1 &= \frac{1}{2}(A + B); 0_n \\
T_2 &= \frac{1}{2}(A - B); 0_n \\
T_3 &= 0_{n+p} + \frac{1}{2}(C + D) \\
T_4 &= 0_{n+p} + \frac{1}{2}(C - D)
\end{align*}
\]

INPUT:

- base_sequences – the base sequences that should be used to construct the T-sequences.
- check – boolean, if true (default) checks that the sequences created are T-sequences before returning them.

EXAMPLES:

```python
sage: from sage.combinat.t_sequences import turyn_sequences_smallcases, T_sequences_construction_from_base_sequences
sage: seqs = turyn_sequences_smallcases(4)
sage: T_sequences_construction_from_base_sequences(seqs)
[[1, 1, -1, 0, 0, 0, 0],
 [0, 0, 0, -1, 0, 0, 0],
 [0, 0, 0, 0, 1, 0, 1],
 [0, 0, 0, 0, 0, 1, 0]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.t_sequences import turyn_sequences_smallcases, T_sequences_construction_from_base_sequences
>>> seqs = turyn_sequences_smallcases(Integer(4))
>>> T_sequences_construction_from_base_sequences(seqs)
[[1, 1, -1, 0, 0, 0, 0],
 [0, 0, 0, -1, 0, 0, 0],
 [0, 0, 0, 0, 1, 0, 1],
 [0, 0, 0, 0, 0, 1, 0]]
```

sage.combinat.t_sequences.T_sequences_construction_from_turyn_sequences(turyn_sequences, check=True)

Construct T-sequences of length \( 4l - 1 \) from Turyn sequences of length \( l \).
Given Turyn sequences $X, U, Y, V$, the T-sequences are constructed as described in theorem 7.7 of [Seb2017]:

\[
\begin{align*}
T_1 &= 1; 0_{4t-2} \\
T_2 &= 0; X/Y; 0_{2t-1} \\
T_3 &= 0_{2t}; U/0_{t-2} \\
T_4 &= 0_{2t} + 0_t/V
\end{align*}
\]

**INPUT:**

- `turyn_sequences` – the Turyn sequences that should be used to construct the T-sequences.
- `check` – boolean, if true (default) checks that the sequences created are T-sequences before returning them.

**EXAMPLES:**

```python
sage: from sage.combinat.t_sequences import turyn_sequences_smallcases, T_sequence_construction_from_turyn_sequences, is_T_sequences_set
sage: seqs = turyn_sequences_smallcases(4)
sage: T_sequence_construction_from_turyn_sequences(seqs)
[[1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
 [0, 1, 1, 1, 1, -1, 1, -1, 0, 0, 0, 0, 0, 0, 0],
 [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
 [0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0]]
```

By default, this method returns the four T-sequences as the T-sequences for some small values of $t$.

This method will try to use the constructions defined in `T_sequence_construction_from_base_sequences()` and `T_sequence_construction_from_turyn_sequences()` together with the Turyn sequences stored in `turyn_sequences_smallcases()`, or base sequences created by `base_sequences_smallcases()`.

This function contains also some T-sequences taken directly from [CRSKKY1989].

**INPUT:**

- `t` – integer, the length of the T-sequences to construct.
- `existence` – boolean (default false). If true, this method only returns whether a T-sequences of the given size can be constructed.
- `check` – boolean, if true (default) check that the sequences are T-sequences before returning them.

**EXAMPLES:**

By default, this method returns the four T-sequences.

```

See also:

`is_base_sequences_tuple()`

`sage.combinat.t_sequences.base_sequences_smallcases(n, p, existence=False, check=True)`

Construct base sequences of length $n+p, n+p, n, n$ from available data.

The function uses the construction `base_sequences_construction()`, together with Turyn type sequences from `turyn_type_sequences_smallcases()` to construct base sequences with $p = n - 1$.

Furthermore, this function uses also Turyn sequences (i.e. base sequences with $p = 1$) from `turyn_sequences_smallcases()`.

**INPUT:**

- $n$ – integer, the length of the last two base sequences.
- $p$ – integer, $n + p$ will be the length of the first two base sequences.
- `existence` – boolean (default: `False`). If True, the function will only check whether the base sequences can be constructed.
- `check` – boolean, if True (default) check that the resulting sequences are base sequences before returning them.

**OUTPUT:**

If `existence` is `False`, the function returns a list containing the four base sequences, or raises an error if the base sequences cannot be constructed. If `existence` is `True`, the function returns a boolean, which is `True` if the base sequences can be constructed and `False` otherwise.

**EXAMPLES:**

```python
sage: from sage.combinat.t_sequences import base_sequences_smallcases
sage: base_sequences_smallcases(8, 7)
[[1, -1, -1, 1, 1, 1, 1, -1],
[1, -1, -1, 1, 1, 1, 1, -1],
[1, 1, -1, 1, -1, 1, -1],
[1, -1, -1, -1, -1, -1, 1]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.t_sequences import base_sequences_smallcases
>>> base_sequences_smallcases(Integer(8), Integer(7))
[[1, -1, -1, 1, 1, 1, 1, -1],
[1, -1, -1, 1, 1, 1, 1, -1],
[1, 1, -1, 1, -1, 1, -1],
[1, -1, -1, -1, -1, -1, 1]]
```

(continues on next page)
[1, -1, -1, 1, 1, 1, -1, -1, -1, 1, -1, -1, 1],
[1, 1, -1, 1, -1, 1, -1, 1],
[1, -1, -1, -1, -1, -1, -1, 1]

If `existence` is `True`, the function returns a boolean

```plaintext
sage: base_sequences_smallcases(8, 7, existence=True)
True
sage: base_sequences_smallcases(7, 5, existence=True)
False
```

```
>>> from sage.all import *
>>> base_sequences_smallcases(Integer(8), Integer(7), existence=True)
True
>>> base_sequences_smallcases(Integer(7), Integer(5), existence=True)
False
```

`sage.combinat.t_sequences.is_T_sequences_set (sequences, verbose=False)`

Check if a family of sequences is composed of T-sequences.

Given 4 (-1, 0, +1) sequences, they will be T-sequences if (Definition 7.4 of [Seb2017]):

- they have all the same length \( t \)
- for each index \( i \), exactly one sequence is nonzero at \( i \)
- the nonperiodic autocorrelation is equal to 0

**INPUT:**

- `sequences` – a list of four sequences.
- `verbose` – a boolean (default false). If true the function will be verbose when the sequences do not satisfy the contraints.

**EXAMPLES:**

```plaintext
sage: from sage.combinat.t_sequences import is_T_sequences_set
sage: seqs = [[1, 1, 0, 0, 0], [0, 0, 1, 0, 0], [0, 0, 0, 1, -1], [0, 0, 0, 0, 0]]
sage: is_T_sequences_set(seqs)
True
sage: seqs = [[1, 1, 0, 1, 0], [0, 0, 1, 0, 0], [0, 0, 0, 1, -1], [0, 0, 0, 0, 0]]
sage: is_T_sequences_set(seqs, verbose=True)
There should be exactly a nonzero element at every index, found 2 such elements... at index 3
False
```

```plaintext
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_T_sequences_set
>>>
>>>
>>> is_T_sequences_set(seqs)
True
>>> is_T_sequences_set(seqs, verbose=True)
```

(continues on next page)
Combinatorics, Release 10.4

There should be exactly a nonzero element at every index, found 2 such elements...

→ at index 3
False

```
sage.combinat.t_sequences.is_T_sequences_set(seqs, verbose=True)
```

is_T_sequences_set(seqs, verbose=True)

There should be exactly a nonzero element at every index, found 2 such elements...

→ at index 3
False

```
sage.combinat.t_sequences.is_base_sequences_tuple(base_sequences, verbose=False)
```

is_base_sequences_tuple(base_sequences, verbose=False)

Check if the given sequences are base sequences.

Four (-1, +1) sequences $A, B, C, D$ of length $n + p, n + p, n, n$ are called base sequences if for all $j \geq 1$:

$$N_A(j) + N_B(j) + N_C(j) + N_D(j) = 0$$

where $N_X(j)$ is the nonperiodic autocorrelation (See definition in [KTR2005]).

INPUT:

• base_sequences – The list of 4 sequences that should be checked.
• verbose – a boolean (default false). If true the function will be verbose when the sequences do not satisfy the contraints.

EXAMPLES:

```
sage: from sage.combinat.t_sequences import is_base_sequences_tuple
sage: seqs = [[1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1, 1, -1, -1, -1, -1, -1, -1, -1, -1],
          [1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1, 1, -1, -1, -1, -1, -1, -1, -1, -1],
          [1, 1, -1, 1, -1, 1, -1, 1],
          [1, -1, -1, -1, -1, -1, -1, -1, 1]]
sage: is_base_sequences_tuple(seqs)
True

>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_base_sequences_tuple

>>> seqs = [[Integer(1), -Integer(1), -Integer(1), Integer(1), Integer(1), ...
          -Integer(1), Integer(1), Integer(1), -Integer(1), Integer(1), Integer(1), ...
          -Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), -Integer(1), ...
          -Integer(1), Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), ...
          -Integer(1), Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), ...
          -Integer(1), Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), ...
          -Integer(1), Integer(1), Integer(1)]

>>> is_base_sequences_tuple(seqs)
True
```

If verbose is true, the function will be verbose

```
sage: seqs = [[1, -1], [1, 1], [-1], [2]]
sage: is_base_sequences_tuple(seqs, verbose=True)
Base sequences should only contain -1, +1, found 2
False

>>> from sage.all import *
>>> seqs = [[Integer(1), -Integer(1)], [Integer(1), Integer(1)], [-Integer(1)], ...
          [Integer(2)]]

>>> is_base_sequences_tuple(seqs, verbose=True)
Base sequences should only contain -1, +1, found 2
False
```
See also:

base_sequences_construction()

sage.combinat.t_sequences.is_skew(seq, verbose=False)

Check if the given sequence is skew.

A sequence \( X = \{x_1, x_2, ..., x_n\} \) is defined skew (according to Definition 7.4 of [Seb2017]) if \( n \) is even and \( x_i = -x_{n-i+1} \).

INPUT:

- seq – the sequence that should be checked.
- verbose – a boolean (default false). If true the function will be verbose when the sequences do not satisfy the constraints.

EXAMPLES:

```python
sage: from sage.combinat.t_sequences import is_skew
sage: is_skew([1, -1, 1, -1, 1, -1])
True
sage: is_skew([1, -1, -1, -1], verbose=True)
Constraint not satisfied at index 1
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_skew
>>> is_skew([Integer(1), -Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1)])
True
>>> is_skew([Integer(1), -Integer(1), -Integer(1), -Integer(1)], verbose=True)
Constraint not satisfied at index 1
False
```

sage.combinat.t_sequences.is_symmetric(seq, verbose=False)

Check if the given sequence is symmetric.

A sequence \( X = \{x_1, x_2, ..., x_n\} \) is defined symmetric (according to Definition 7.4 of [Seb2017]) if \( n \) is odd and \( x_i = x_{n-i+1} \).

INPUT:

- seq – the sequence that should be checked.
- verbose – a boolean (default false). If true the function will be verbose when the sequences do not satisfy the constraints.

EXAMPLES:

```python
sage: from sage.combinat.t_sequences import is_symmetric
sage: is_symmetric([1, -1, 1, -1, 1])
True
sage: is_symmetric([1, -1, 1, 1, 1], verbose=True)
Constraint not satisfied at index 1
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_symmetric
>>> is_symmetric([Integer(1), -Integer(1), Integer(1), -Integer(1), Integer(1)])
True
>>> is_symmetric([Integer(1), -Integer(1), -Integer(1), -Integer(1)], verbose=True)
Constraint not satisfied at index 1
False
```
True

```python
>>> is_symmetric([Integer(1), -Integer(1), Integer(1), Integer(1), Integer(1)],
               verbose=True)
Constraint not satisfied at index 1
False
```

**sage.combinat.t_sequences.turyn_sequences_smallcases**(*l*, *existence=False*)

Construction of Turyn sequences for small values of *l*.

The data is taken from [Seb2017] and [CRSKKY1989].

**INPUT:**

- *l* – integer, the length of the Turyn sequences.
- *existence* – boolean (default: False). If true, only return whether the Turyn sequences are available for the given length.

**EXAMPLES:**

By default, this method returns the four Turyn sequences

```python
sage: from sage.combinat.t_sequences import turyn_sequences_smallcases
sage: turyn_sequences_smallcases(4)
[[1, 1, -1, -1], [1, 1, -1, 1], [1, 1, 1], [1, -1, 1]]
```

If we pass the *existence* flag, the method will return a boolean

```python
>>> from sage.all import *
>>> from sage.combinat.t_sequences import turyn_sequences_smallcases
>>> turyn_sequences_smallcases(Integer(4), existence=True)
True
```

**sage.combinat.t_sequences.turyn_type_sequences_smallcases**(*n*, *existence=False*)

Construction of Turyn type sequences for small values of *n*.

The data is taken from [KTR2005] for *n* = 36, and from [BDKR2013] for *n* ≤ 32.

**INPUT:**

- *n* – integer, the length of the Turyn type sequences.
- *existence* – boolean (default: False). If true, only return whether the Turyn type sequences are available for the given length.

**EXAMPLES:**

By default, this method returns the four Turyn type sequences

```python
sage: from sage.combinat.t_sequences import turyn_type_sequences_smallcases
sage: turyn_type_sequences_smallcases(4)
[[1, 1, 1, 1], [1, 1, -1, 1], [1, 1, -1, -1], [1, -1, 1]]
```

5388 Chapter 5. Comprehensive Module List
ALGORITHM:

The Turyntype sequences are stored in hexadecimal format. Given \( n \) hexadecimal digits \( h_1, h_2, \ldots, h_n \), it is possible to get the Turyntype sequences by converting each \( h_i \) (\( 1 \leq i \leq n-1 \)) into a four digits binary number. Then, the \( j \)-th binary digit is 0 if the \( i \)-th number in the \( j \)-th sequence is 1, and it is 1 if the number in the sequence is -1.

For the \( n \)-th digit, it should be converted to a 3 digits binary number, and then the same mapping as before can be used (see also [BDKR2013]).

5.1.345 Tableaux

AUTHORS:

- Mike Hansen (2007): initial version
- Jason Bandlow (2011): updated to use Parent/Element model, and many minor fixes
- Andrew Mathas (2012-13): completed the transition to the parent/element model begun by Jason Bandlow
- Travis Scrimshaw (11-22-2012): Added tuple options, changed *katabolism* to *catabolism*. Cleaned up documentation.
- Andrew Mathas (2016-08-11): Row standard tableaux added
- Oliver Pechenik (2018): Added increasing tableaux.

This file consists of the following major classes:

Element classes:

- Tableau
- SemistandardTableau
- StandardTableau
- RowStandardTableau
- IncreasingTableau

Factory classes:

- Tableaux
- SemistandardTableaux
- StandardTableaux
- RowStandardTableaux
• IncreasingTableaux

Parent classes:
• Tableaux_all
• Tableaux_size
• SemistandardTableaux_all (facade class)
• SemistandardTableaux_size
• SemistandardTableaux_size_inf
• SemistandardTableaux_size_weight
• SemistandardTableaux_shape
• SemistandardTableaux_shape_inf
• SemistandardTableaux_shape_weight
• StandardTableaux_all (facade class)
• StandardTableaux_size
• StandardTableaux_shape
• IncreasingTableaux_all (facade class)
• IncreasingTableaux_size
• IncreasingTableaux_size_inf
• IncreasingTableaux_size_weight
• IncreasingTableaux_shape
• IncreasingTableaux_shape_inf
• IncreasingTableaux_shape_weight
• RowStandardTableaux_all (facade class)
• RowStandardTableaux_size
• RowStandardTableaux_shape

For display options, see Tableaux.options().

---

Todo:
• Move methods that only apply to semistandard tableaux from tableau to semistandard tableau
• Copy/move functionality to skew tableaux
• Add a class for tableaux of a given shape (eg Tableaux_shape)

---

class sage.combinat.tableau.IncreasingTableau (parent, t, check=True)
    Bases: Tableau

    A class to model an increasing tableau.

    INPUT:

    • t – a tableau, a list of iterables, or an empty list
An increasing tableau is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns.

**EXAMPLES:**

```python
sage: t = IncreasingTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp()  # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = IncreasingTableau(t); s
[[1, 2], [2]]
sage: IncreasingTableau([])  # The empty tableau
[]
```

You can also construct an `IncreasingTableau` from the appropriate `Parent` object:

```python
>>> from sage.all import *
>>> IT = IncreasingTableaux()
>>> IT([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- Tableaux
- Tableau
- SemistandardTableaux
- SemistandardTableau
- StandardTableaux
- StandardTableau
- IncreasingTableaux
**K_bender_knuth** *(i)*

Return the i-th K-Bender-Knuth operator (as defined in [DPS2017]) applied to `self`.

The i-th K-Bender-Knuth operator swaps the letters i and i + 1 everywhere where doing so would not break increasingness.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_bender_knuth(2)
[[1, 2, 4], [3, 4, 5]]
sage: T.K_bender_knuth(3)
[[1, 3, 4], [2, 4, 5]]
```

```python
>>> from sage.all import *
"""
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2), Integer(4),Integer(5)]]))
>>> T.K_bender_knuth(Integer(2))
[[1, 2, 4], [3, 4, 5]]
>>> T.K_bender_knuth(Integer(3))
[[1, 3, 4], [2, 4, 5]]
```

**K_evacuation** *(ceiling=None)*

Return the K-evacuation involution from [TY2009] to `self`.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

```python
>>> from sage.all import *
"""
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2), Integer(4),Integer(5)]]))
>>> T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
>>> T.K_evacuation(Integer(6))
[[2, 3, 5], [3, 4, 6]]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3), Integer(4),Integer(5)],[Integer(5)])
>>> U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

**K_promotion** *(ceiling=None)*

Return the K-promotion operator from [Pec2014] applied to `self`.

**EXAMPLES:**

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion()
[[1, 2, 3], [3, 4, 5]]
sage: T.K_promotion(6)
(continues on next page)"""

```

```sage
U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion()
[[[1, 2, 3], [3, 4, 6]]
```

The number $i$ is a *descent* of an increasing tableau if some instance of $i + 1$ appears in a lower row than some instance of $i$.

**Note:** This notion is close to the notion of descent for a standard tableau but is unrelated to the notion for semistandard tableaux.
EXAMPLES:

```python
sage: T = IncreasingTableau([[1,2,4],[3,5,6]])
sage: T.descent_set()
[2, 4]
sage: U = IncreasingTableau([[1,3,4],[2,4,5]])
sage: U.descent_set()
[1, 3, 4]
sage: V = IncreasingTableau([[1,3,4],[3,4,5],[4,5]])
sage: V.descent_set()
[3, 4]
```

```python
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(2),Integer(4)],[Integer(3),Integer(5),Integer(6)]])
>>> T.descent_set()
[2, 4]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),Integer(4),Integer(5)]])
>>> U.descent_set()
[1, 3, 4]
>>> V = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),Integer(4),Integer(5)],[Integer(4),Integer(5)]])
>>> V.descent_set()
[3, 4]
```

dual_K_evacuation(ceiling=None)

Return the dual K-evacuation involution applied to self.

EXAMPLES:

```python
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.dual_K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

```python
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),Integer(4),Integer(5)]]
>>> T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
>>> T.dual_K_evacuation(Integer(6))
[[2, 3, 5], [3, 4, 6]]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),Integer(4),Integer(5)],[Integer(5)]]
>>> U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

class sage.combinat.tableau.IncreasingTableaux(**kwds)

Bases: Tableaux

A factory class for the various classes of increasing tableaux.

An increasing tableau is a tableau whose entries are positive integers that are strictly increasing across rows and
strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

**INPUT:**

Keyword arguments:

- **size** – the size of the tableaux
- **shape** – the shape of the tableaux
- **eval** – the weight (also called binary content) of the tableaux, where values can be either 0 or 1 with position $i$ being 1 if and only if $i$ can appear in the tableaux
- **max_entry** – positive integer or infinity (oo); the maximum entry for the tableaux; if size or shape are specified, max_entry defaults to be size or the size of shape

Positional arguments:

- the first argument is interpreted as either size or shape according to whether it is an integer or a partition
- the second keyword argument will always be interpreted as eval

**Warning:** The eval is not the usual notion of eval or weight, where the $i$-th entry counts how many $i$'s appear in the tableau.

**EXAMPLES:**

```sage
sage: IT = IncreasingTableaux([2,1]); IT
Increasing tableaux of shape [2, 1] and maximum entry 3
sage: IT.list()
[[[1, 3], [2]], [[1, 2], [3]], [[1, 2], [2]], [[1, 3], [3]], [[2, 3], [3]]]

sage: IT = IncreasingTableaux(3); IT
Increasing tableaux of size 3 and maximum entry 3
sage: IT.list()
[[[1, 2, 3]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 2], [2]],
 [[1, 3], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: IT = IncreasingTableaux(3, max_entry=2); IT
Increasing tableaux of size 3 and maximum entry 2
sage: IT.list()
[[[1, 2], [2]]]

sage: IT = IncreasingTableaux(3, max_entry=4); IT
Increasing tableaux of size 3 and maximum entry 4
sage: IT.list()
[[[1, 2, 3]],
 [[1, 2, 4]],
 [[1, 3, 4]],
 [[2, 3, 4]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1], [4], [2]],
```

(continues on next page)
sage: IT = IncreasingTableaux(3, max_entry=oo); IT
Increasing tableaux of size 3
sage: IT[123]
[[5, 7], [6]]

sage: IT = IncreasingTableaux(max_entry=2)
sage: list(IT)
[[], [[1]], [[2]], [[1, 2]], [[1], [2]]]
sage: IT[4]
[[1], [2]]
sage: IncreasingTableaux()[0]
[]

>>> from sage.all import *

>>> IT = IncreasingTableaux([Integer(2), Integer(1)]); IT
Increasing tableaux of shape [2, 1] and maximum entry 3
>>> IT.list()
[[[1, 3], [2]], [[1, 2], [3]], [[1, 2], [2]], [[1, 3], [3]], [[2, 3], [3]]]

>>> IT = IncreasingTableaux(Integer(3)); IT
Increasing tableaux of size 3 and maximum entry 3
>>> IT.list()
[[[1, 2, 3]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 2], [2]],
 [[1, 3], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

>>> IT = IncreasingTableaux(Integer(3), max_entry=Integer(2)); IT
Increasing tableaux of size 3 and maximum entry 2
>>> IT.list()
[[[1, 2], [2]]]

>>> IT = IncreasingTableaux(Integer(3), max_entry=Integer(4)); IT
Increasing tableaux of size 3 and maximum entry 4
>>> IT.list()
[[[1, 2, 3]],

(continues on next page)

- StandardTableau
- IncreasingTableau

Element
alias of IncreasingTableau
class sage.combinat.tableau.IncreasingTableaux_all (max_entry=None)
Bases: IncreasingTableaux, DisjointUnionEnumeratedSets
All increasing tableaux.
EXAMPLES:

```python
sage: T = IncreasingTableaux()
sage: T.cardinality()
+Infinity
sage: T = IncreasingTableaux(max_entry=3)
sage: list(T)

[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 3],
 [1, [2]],
 [1, [3]],
 [2, [3]],
 [1, 2, 3],
 [1, 3, [2]],
 [1, 2, [3]],
 [1, 2], [3],
 [1, 3], [3],
 [2, 3], [3],
 [1], [2], [3]]
```

```python
>>> from sage.all import *

>>> T = IncreasingTableaux()

>>> T.cardinality()
+Infinity

>>> T = IncreasingTableaux(max_entry=Integer(3))

>>> list(T)

[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 3],
 [1, [2]],
 [1, [3]],
 [2, [3]],
 [1, 2, 3],
 [1, 3, [2]],
 [1, 2, [3]],
 [1, 2], [3],
 [1, 3], [3],
 [2, 3], [3],
 [1], [2], [3]]
```

```python
class sage.combinat.tableau.IncreasingTableaux_shape(p, max_entry=None)

Bases: IncreasingTableaux

Increasing tableaux of fixed shape $p$ with a given max entry.

An increasing tableau with max entry $i$ is required to have all its entries less or equal to $i$. It is not required to actually contain an entry $i$.```
INPUT:

- \( p \) – a partition
- \( \text{max}_\text{entry} \) – the max entry; defaults to the size of \( p \)

```python
class sage.combinat.tableau.IncreasingTableaux_shape_inf(p):
    Bases: IncreasingTableaux
    Increasing tableaux of fixed shape \( p \) and no maximum entry.

class sage.combinat.tableau.IncreasingTableaux_shape_weight(p, wt):
    Bases: IncreasingTableaux_shape
    Increasing tableaux of fixed shape \( p \) and binary weight \( wt \).

class sage.combinat.tableau.IncreasingTableaux_size(n, max_entry=None):
    Bases: IncreasingTableaux
    Increasing tableaux of fixed size \( n \).

class sage.combinat.tableau.IncreasingTableaux_size_inf(n):
    Bases: IncreasingTableaux
    Increasing tableaux of fixed size \( n \) with no maximum entry.

class sage.combinat.tableau.IncreasingTableaux_size_weight(n, wt):
    Bases: IncreasingTableaux
    Increasing tableaux of fixed size \( n \) and weight \( wt \).

class sage.combinat.tableau.RowStandardTableau(parent, t, check=True):
    Bases: Tableau
    A class to model a row standard tableau.
    A row standard tableau is a tableau whose entries are positive integers from 1 to \( m \) that increase along rows.

INPUT:

- \( t \) – a Tableau, a list of iterables, or an empty list
```

EXAMPLES:

```python
sage: t = RowStandardTableau([[3,4,5],[1,2]]); t
[[3, 4, 5], [1, 2]]
sage: t.shape()
[3, 2]
sage: t.pp()  # pretty printing
3 4 5
1 2
sage: t.is_standard()
False
sage: RowStandardTableau([])  # The empty tableau
[]
sage: RowStandardTableau([[3,4,5],[1,2]]) in StandardTableaux()
False
sage: RowStandardTableau([[1,2,5],[3,4]]) in StandardTableaux()
True
```
When using code that will generate a lot of tableaux, it is more efficient to construct a `RowStandardTableau` from the appropriate `Parent` object:

```
sage: ST = RowStandardTableaux()
sage: ST([[3, 4, 5], [1, 2]])
[[3, 4, 5], [1, 2]]
```

See also:

- `Tableau`
- `StandardTableau`
- `SemistandardTableau`
- `Tableaux`
- `StandardTableaux`
- `RowStandardTableaux`
- `SemistandardTableaux`

`check()`

Check that `self` is a valid row standard tableau.

```python
class sage.combinat.tableau.RowStandardTableaux
    Bases: Tableaux

A factory for the various classes of row standard tableaux.

INPUT:

- either a non-negative integer (possibly specified with the keyword `n`) or a partition
OUTPUT:

• with no argument, the class of all standard tableaux
• with a non-negative integer argument, \( n \), the class of all standard tableaux of size \( n \)
• with a partition argument, the class of all standard tableaux of that shape

A row standard tableau is a tableau that contains each of the entries from 1 to \( n \) exactly once and is increasing along rows.

All classes of row standard tableaux are iterable.

EXAMPLES:

```python
sage: ST = RowStandardTableaux(3); ST
Row standard tableaux of size 3
sage: ST.first()  # needs sage.graphs
[[1, 2, 3]]
```

```python
sage: ST.last()  # needs sage.graphs sage.modules
[[3], [1], [2]]
```

```python
sage: ST.cardinality()  # needs sage.graphs sage.modules
10
```

```python
sage: ST.list()  # needs sage.graphs sage.modules
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

```python
>>> from sage.all import *
>>> ST = RowStandardTableaux(Integer(3)); ST
Row standard tableaux of size 3
>>> ST.first()  # needs sage.graphs
[[1, 2, 3]]
```

```python
>>> ST.last()  # needs sage.graphs sage.modules
[[3], [1], [2]]
```

```python
>>> ST.cardinality()  # needs sage.graphs sage.modules
10
```

```python
>>> ST.list()  # needs sage.graphs sage.modules
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```
See also:

- Tableaux
- Tableau
- SemistandardTableaux
- SemistandardTableau
- RowStandardTableau
- StandardSkewTableaux

Element

alias of `RowStandardTableau`

class `sage.combinat.tableau.RowStandardTableaux_all`

```
Bases: RowStandardTableaux, DisjointUnionEnumeratedSets

All row standard tableaux.
```

class `sage.combinat.tableau.RowStandardTableaux_shape(p)`

```
Bases: RowStandardTableaux

Row Standard tableaux of a fixed shape \( p \).
```

cardinality()

```
Return the number of row standard tableaux of this shape.

This is just the index of the corresponding Young subgroup in the full symmetric group.
```

EXAMPLES:

```
sage: RowStandardTableaux([3, 2, 1]).cardinality()
60
sage: RowStandardTableaux([2, 2]).cardinality()
6
sage: RowStandardTableaux([5]).cardinality()
1
sage: RowStandardTableaux([6, 5, 5, 3]).cardinality()
1955457504
sage: RowStandardTableaux([]).cardinality()
1
```

```python
>>> from sage.all import *

>>> RowStandardTableaux([Integer(3), Integer(2), Integer(1)]).cardinality()
60
>>> RowStandardTableaux([Integer(2), Integer(2)]).cardinality()
6
>>> RowStandardTableaux([Integer(5)]).cardinality()
1
>>> RowStandardTableaux([Integer(6), Integer(5), Integer(5), Integer(3)]).cardinality()
1955457504
```
class sage.combinat.tableau.RowStandardTableaux_size(n)

Bases: RowStandardTableaux, DisjointUnionEnumeratedSets

Row standard tableaux of fixed size n.

EXAMPLES:

sage: [t for t in RowStandardTableaux(1)] # needs sage.graphs
[[[1]]]

sage: [t for t in RowStandardTableaux(2)] # needs sage.graphs

[[[1, 2]], [[2], [1]], [[1], [2]]]

sage: list(RowStandardTableaux(3)) # needs sage.graphs

[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[3], [1], [2]]]

an_element()

Return a particular element of the class.

EXAMPLES:

sage: RowStandardTableaux(4).an_element()
[[1, 2, 3, 4]]
```python
>>> from sage.all import *
>>> RowStandardTableaux(Integer(4)).an_element()
[[1, 2, 3, 4]]
```

```python
class sage.combinat.tableau.SemistandardTableau(parent, t, check=True)
Bases: Tableau
A class to model a semistandard tableau.

INPUT:

- `t` – a tableau, a list of iterables, or an empty list

OUTPUT:

- A SemistandardTableau object constructed from `t`.

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns.

EXAMPLES:

```python
sage: t = SemistandardTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = SemistandardTableau(t); s
[[1, 2], [2]]
sage: SemistandardTableau([]) # The empty tableau
[]
```

```python
>>> from sage.all import *
>>> t = SemistandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(2), Integer(3)]]); t
[[1, 2, 3], [2, 3]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
1 2 3
2 3
```

```python
>>> t = Tableau([[Integer(1),Integer(2)],[Integer(2)]]))
>>> s = SemistandardTableau(t); s
[[1, 2], [2]]
>>> SemistandardTableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a SemistandardTableau from the appropriate `Parent` object:

```python
sage: SST = SemistandardTableaux()
sage: SST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```
```python
>>> from sage.all import *
>>> SST = SemistandardTableaux()
>>> SST([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]]
[[[1, 2, 3], [4, 5]]

See also:

- Tableaux
- Tableau
- SemistandardTableaux
- StandardTableaux
- StandardTableau

check()
Check that self is a valid semistandard tableau.

class sage.combinat.tableau.SemistandardTableaux(**kwds)
Bases: Tableaux
A factory class for the various classes of semistandard tableaux.

INPUT:

Keyword arguments:
- size – The size of the tableaux
- shape – The shape of the tableaux
- eval – The weight (also called content or evaluation) of the tableaux
- max_entry – A maximum entry for the tableaux. This can be a positive integer or infinity (oo). If size or shape are specified, max_entry defaults to be size or the size of shape.

Positional arguments:
- The first argument is interpreted as either size or shape according to whether it is an integer or a partition
- The second keyword argument will always be interpreted as eval

OUTPUT:

The appropriate class, after checking basic consistency tests. (For example, specifying eval implies a value for max_entry).

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

Classes of semistandard tableaux can be iterated over if and only if there is some restriction.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1] and maximum entry 3
sage: SST.list()  #...
[[[1, 1], [2]],
[[1, 1], [3]],
```
(continues on next page)

- `StandardTableau`

**Element**

alias of `SemistandardTableau`

class `sage.combinat.tableau.SemistandardTableaux_all`(max_entry=None)

Bases: `SemistandardTableaux`, `DisjointUnionEnumeratedSets`

All semistandard tableaux.

`list()`

class `sage.combinat.tableau.SemistandardTableaux_shape`(p, max_entry=None)

Bases: `SemistandardTableaux`

Semistandard tableaux of fixed shape \( p \) with a given max entry.

A semistandard tableau with max entry \( i \) is required to have all its entries less or equal to \( i \). It is not required to actually contain an entry \( i \).

**INPUT:**

- \( p \) – a partition
- `max_entry` – the max entry; defaults to the size of \( p \)

**cardinality** *(algorithm='hook')*

Return the cardinality of self.

**INPUT:**

- `algorithm` – (default: 'hook') any one of the following:
  - 'hook' – use Stanley's hook length formula
  - 'sum' – sum over the compositions of `max_entry` the number of semistandard tableau with `shape` and given weight vector

This is computed using *Stanley's hook length formula*:

\[
f_\lambda = \prod_{u \in \lambda} \frac{n + c(u)}{h(u)}.
\]

where \( n \) is the `max_entry`, \( c(u) \) is the content of \( u \), and \( h(u) \) is the hook length of \( u \). See [Sta-EC2] Corollary 7.21.4.

**EXAMPLES:**
random_element() 

Return a uniformly distributed random tableau of the given shape and max_entry.

Uses the algorithm from [Kra1999] based on the Novelli-Pak-Stoyanovskii bijection 

EXAMPLES:

```python
sage: S = SemistandardTableaux([2, 2, 1, 1])
sage: S.random_element() in S
```
True
sage: S = SemistandardTableaux([2, 2, 1, 1], max_entry=7)
sage: S.random_element() in S
True

>>> from sage.all import *
>>> S = SemistandardTableaux([[Integer(2), Integer(2), Integer(1), Integer(1)]])
>>> S.random_element() in S
True
>>> S = SemistandardTableaux([[Integer(2), Integer(2), Integer(1), Integer(1)],
                             → max_entry=Integer(7)])
>>> S.random_element() in S
True

class sage.combinat.tableau.SemistandardTableaux_shape_inf(p)
    Bases: SemistandardTableaux
    Semistandard tableaux of fixed shape p and no maximum entry.
class sage.combinat.tableau.SemistandardTableaux_shape_weight(p, mu)
    Bases: SemistandardTableaux_shape
    Semistandard tableaux of fixed shape p and weight μ.
cardinality()
    Return the number of semistandard tableaux of the given shape and weight, as computed by
    kostka_number function of symmetrica.
    EXAMPLES:
    sage: # needs sage.modules
    sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
    1
    sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).cardinality()
    1
    sage: SemistandardTableaux([2,2,2], [2, 2, 2]).cardinality()
    1
    sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
    2

>>> from sage.all import *
>>> # needs sage.modules
>>> SemistandardTableaux([[Integer(2),Integer(2)], [Integer(2), Integer(1),
                             →Integer(1)]]).cardinality()
1
>>> SemistandardTableaux([[Integer(2),Integer(2),Integer(2)], [Integer(2),
                             →Integer(2), Integer(1),Integer(1)]].cardinality()
1
>>> SemistandardTableaux([[Integer(2),Integer(2),Integer(2)], [Integer(2),
                             →Integer(2), Integer(2)]].cardinality()
1
>>> SemistandardTableaux([[Integer(3),Integer(2),Integer(1)], [Integer(2),
                             →Integer(2), Integer(2)]].cardinality()
2

list()
    Return a list of all semistandard tableaux in self generated by symmetrica.
EXAMPLES:

```python
sage: # needs sage.modules
sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

```python
>>> from sage.all import *
>>> # needs sage.modules
>>> SemistandardTableaux([Integer(2),Integer(2)], [Integer(2), Integer(1),
˓
→Integer(1)]).list()
[[[1, 1], [2, 3]]]
>>> SemistandardTableaux([Integer(2),Integer(2),Integer(2)], [Integer(2),
˓
→Integer(2), Integer(2), Integer(1),Integer(1)]).list()
[[[1, 1], [2, 2], [3, 4]]]
>>> SemistandardTableaux([Integer(2),Integer(2),Integer(2)], [Integer(2),
˓
→Integer(2), Integer(2), Integer(2)]).list()
[[[1, 1], [2, 2], [3, 3]]]
>>> SemistandardTableaux([Integer(3),Integer(2),Integer(1)], [Integer(2),
˓
→Integer(2), Integer(2), Integer(2)]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

```python
class sage.combinat.tableau.SemistandardTableaux_size(n, max_entry=None)
Bases: SemistandardTableaux

Semistandard tableaux of fixed size n.

cardinality()
Return the cardinality of self.

EXAMPLES:

```python
sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: SemistandardTableaux(4, max_entry=2).cardinality()
9
sage: SemistandardTableaux(4, max_entry=10).cardinality()
4225
sage: ns = list(range(1, 6))
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all(sst.cardinality() == len(sst.list()) for sst in ssts)  # needs sage.modules
True
```

```python
>>> from sage.all import *
>>> # needs sage.modules
>>> SemistandardTableaux(Integer(3)).cardinality()
19
>>> SemistandardTableaux(Integer(4)).cardinality()
116
>>> SemistandardTableaux(Integer(4), max_entry=Integer(2)).cardinality()
9
```
random_element()

Generate a random SemistandardTableau with uniform probability.

The RSK algorithm gives a bijection between symmetric $k \times k$ matrices of nonnegative integers that sum to $n$ and semistandard tableaux with size $n$ and maximum entry $k$.

The number of $k \times k$ symmetric matrices of nonnegative integers having sum of elements on the diagonal $i$ and sum of elements above the diagonal $j$ is $\binom{k+i-1}{i} \binom{k+j-1}{j}$. We first choose the sum of the elements on the diagonal randomly weighted by the number of matrices having that trace. We then create random integer vectors of length $k$ having that sum and use them to generate a $k \times k$ diagonal matrix. Then we take a random integer vector of length $\binom{k}{2}$ summing to half the remainder and distribute it symmetrically to the remainder of the matrix.

Applying RSK to the random symmetric matrix gives us a pair of identical SemistandardTableau of which we choose the first.

EXAMPLES:

```
sage: SemistandardTableaux(6).random_element()  # random
[[1, 1, 2], [3, 5, 5]]
sage: SemistandardTableaux(6, max_entry=7).random_element()  # random
[[2, 4, 4, 6, 6, 6]]
```

```
from sage.all import *

sage: SemistandardTableaux(Integer(6)).random_element()  # random
[[1, 1, 2], [3, 5, 5]]
sage: SemistandardTableaux(Integer(6), max_entry=Integer(7)).random_element()  # random
[[2, 4, 4, 6, 6, 6]]
```

class sage.combinat.tableau.SemistandardTableaux_size_inf(n)

Bases: SemistandardTableaux

Semistandard tableaux of fixed size $n$ with no maximum entry.

list()

class sage.combinat.tableau.SemistandardTableaux_size_weight(n, mu)

Bases: SemistandardTableaux

Semistandard tableaux of fixed size $n$ and weight $\mu$.

cardinality()

    Return the cardinality of self.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: SemistandardTableaux(3, [2,1]).cardinality()  # needs sage.modules
2
sage: SemistandardTableaux(4, [2,2]).cardinality()  # needs sage.modules
3

>>> from sage.all import *
>>> SemistandardTableaux(Integer(3), [Integer(2),Integer(1)]).cardinality()  # needs sage.modules
2
>>> SemistandardTableaux(Integer(4), [Integer(2),Integer(2)]).cardinality()  # needs sage.modules
3
```

```python
class sage.combinat.tableau.StandardTableau(parent, t, check=True)
Bases: SemistandardTableau
A class to model a standard tableau.

INPUT:

• t – a Tableau, a list of iterables, or an empty list

A standard tableau is a semistandard tableau whose entries are exactly the positive integers from 1 to \( n \), where \( n \) is the size of the tableau.

EXAMPLES:

```python
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp()  # pretty printing
1 2 3
4 5
sage: t.is_standard()
True
sage: StandardTableau([])  # The empty tableau
[]
sage: StandardTableau([[1,2,3],[4,5]]) in RowStandardTableaux()
True
```
```
When using code that will generate a lot of tableaux, it is more efficient to construct a StandardTableau from the appropriate Parent object:

```python
sage: ST = StandardTableaux()
sage: ST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

See also:

- `Tableaux`
- `Tableau`
- `SemistandardTableaux`
- `SemistandardTableau`
- `StandardTableaux`

`check()`
Check that `self` is a standard tableau.

`dominates(t)`
Return `True` if `self` dominates the tableau `t`.
That is, if the shape of the tableau restricted to `k` dominates the shape of `t` restricted to `k`, for `k = 1, 2, ..., n`.
When the two tableaux have the same shape, then this ordering coincides with the Bruhat ordering for the corresponding permutations.

**INPUT:**
- `t` – a tableau

**EXAMPLES:**

```python
sage: s = StandardTableau([[1,2,3],[4,5]])
sage: t = StandardTableau([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
sage: all(StandardTableau(s).dominates(t) for t in StandardTableaux([3,2]))
True
sage: s.dominates([[1,2,3,4,5]])
False
```

```python
>>> from sage.all import *
```
An iterator for all the standard tableaux that can be obtained from self by removing a cell. Note that this iterates just over a single tableau (or nothing if self is empty).

EXAMPLES:

```python
sage: t = StandardTableau([[1, 2], [3]])
sage: [x for x in t.down()]
[[[1, 2]]]
sage: t = StandardTableau([])
sage: [x for x in t.down()]
[]
```

Return a list of all the standard tableaux that can be obtained from self by removing a cell. Note that this is just a singleton list if self is nonempty, and an empty list otherwise.

EXAMPLES:

```python
sage: t = StandardTableau([[1, 2], [3]])
sage: t.down_list()
[[[1, 2]]]
sage: t = StandardTableau([])
sage: t.down_list()
[]
```

Return True since self is a standard tableau.
EXAMPLES:

```python
sage: StandardTableau([[1, 3], [2, 4]]).is_standard()
True
```

```python
>>> from sage.all import *

>>> StandardTableau([[1, 3], [2, 4]]).is_standard()
True
```

**promotion** (*n=None*)

Return the image of self under the promotion operator.

The promotion operator, applied to a standard tableau \( t \), does the following:

Remove the letter \( n \) from \( t \), thus leaving a hole where it used to be. Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of \( t \). Fill 0 into the hole once jeu de taquin has completed. Finally, add 1 to each letter in the tableau. The resulting standard tableau is the image of \( t \) under the promotion operator.

This definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sag2011] (p. 23) and in [Stan2009].

See the `promotion()` method for a more general operator.

EXAMPLES:

```python
sage: ST = StandardTableaux(7)
sage: all( st.promotion().promotion_inverse() == st for st in ST ) # long time
True

sage: all( st.promotion_inverse().promotion() == st for st in ST ) # long time
True

sage: st = StandardTableau([[1,2,5],[3,4]])
sage: parent(st.promotion())
Standard tableaux
```

**promotion_inverse** (*n=None*)

Return the image of self under the inverse promotion operator. The optional variable \( m \) should be set to the size of self minus 1 for a minimal speedup; otherwise, it defaults to this number.

The inverse promotion operator, applied to a standard tableau \( t \), does the following:

Remove the letter 1 from \( t \), thus leaving a hole where it used to be. Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of \( t \). Fill \( n + 1 \) into this hole, where \( n \) is the size of \( t \). Finally, subtract 1 from each letter in the tableau. This yields a new standard tableau.

This definition of inverse promotion is the map called “promotion” in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).
See the `promotion_inverse()` method for a more general operator.

**EXAMPLES:**

```
sage: t = StandardTableau([[1,3],[2,4]])
```
```
sage: t.promotion_inverse()
[[1, 2], [3, 4]]
```

```>> from sage.all import *
>> t = StandardTableau([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>> t.promotion_inverse()
[[1, 2], [3, 4]]
```

We check the equivalence of two definitions of inverse promotion on standard tableaux:

```
sage: ST = StandardTableaux(7)
sage: def bk_promotion_inverse7(st):
....:     st2 = st
....:     for i in range(1, 7):
....:         st2 = st2.bender_knuth_involution(i, check=False)
....:     return st2
sage: all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST )
# long time
True
```

```
>>> from sage.all import *
>>> ST = StandardTableaux(Integer(7))
>>> def bk_promotion_inverse7(st):
...     st2 = st
...     for i in range(Integer(1), Integer(7)):
...         st2 = st2.bender_knuth_involution(i, check=False)
...     return st2

>>> all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST )
# long time
True
```

**standard_descents()**

Return a list of the integers $i$ such that $i$ appears strictly further north than $i + 1$ in `self` (this is not to say that $i$ and $i + 1$ must be in the same column). The list is sorted in increasing order.

**EXAMPLES:**

```
sage: StandardTableau( [[1,3,4],[2,5]] ).standard_descents()
[1, 4]
sage: StandardTableau( [[1,2],[3,4]] ).standard_descents()
[2]
sage: StandardTableau( [[1,2,5],[3,4],[6,7],[8],[9]] ).standard_descents()
[2, 5, 7, 8]
sage: StandardTableau( [] ).standard_descents()
[]
```

```>> from sage.all import *
>> StandardTableau( [[Integer(1),Integer(3),Integer(4)],[Integer(2),Integer(5)]] ).standard_descents()
[1, 4]
>> StandardTableau( [[Integer(1),Integer(2)],[Integer(3),Integer(4)]] ).
... standard_descents()
```

(continues on next page)
standard_major_index()

Return the major index of the standard tableau self in the standard meaning of the word. The major index is defined to be the sum of the descents of self (see standard_descents() for their definition).

EXAMPLES:

```
sage: StandardTableau( [[1,4,5],[2,6],[3]] ).standard_major_index()
8
sage: StandardTableau( [[1,2],[3,4]] ).standard_major_index()
2
sage: StandardTableau( [[1,2,3],[4,5]] ).standard_major_index()
3
```

standard_number_of_descents()

Return the number of all integers \(i\) such that \(i\) appears strictly further north than \(i + 1\) in self (this is not to say that \(i\) and \(i + 1\) must be in the same column). A list of these integers can be obtained using the standard_descents() method.

EXAMPLES:

```
sage: StandardTableau( [[1,2],[3,4],[5]] ).standard_number_of_descents()
2
sage: StandardTableau( [] ).standard_number_of_descents()
0
```

(continues on next page)
up()

An iterator for all the standard tableaux that can be obtained from self by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

up_list()

Return a list of all the standard tableaux that can be obtained from self by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

class sage.combinat.tableau.StandardTableaux(**kwds)

A factory for the various classes of standard tableaux.

INPUT:

- Either a non-negative integer (possibly specified with the keyword `n`) or a partition.

OUTPUT:

- With no argument, the class of all standard tableaux
- With a non-negative integer argument, `n`, the class of all standard tableaux of size `n`
- With a partition argument, the class of all standard tableaux of that shape.

A standard tableau is a semistandard tableau which contains each of the entries from 1 to `n` exactly once.

All classes of standard tableaux are iterable.

EXAMPLES:

```
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
sage: ST.last()
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
[[[1], [2], [3]]
sage: ST.cardinality()
4
sage: ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]

>>> from sage.all import *
>>> ST = StandardTableaux(Integer(3)); ST
Standard tableaux of size 3
>>> ST.first()
[[1, 2, 3]]
>>> ST.last()
[[[1], [2], [3]]]
>>> ST.cardinality()
4
>>> ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
```

See also:

**Element**

alias of `StandardTableau`

```python
class sage.combinat.tableau.StandardTableaux_all
    Bases: StandardTableaux, DisjointUnionEnumeratedSets

    All standard tableaux.

class sage.combinat.tableau.StandardTableaux_shape(p)
    Bases: StandardTableaux

    Semistandard tableaux of a fixed shape $p$.

cardinality()
```

Return the number of standard Young tableaux of this shape.

This method uses the so-called hook length formula, a formula for the number of Young tableaux associated with a given partition. The formula says the following: Let $\lambda$ be a partition. For each cell $c$ of the Young diagram of $\lambda$, let the hook length of $c$ be defined as 1 plus the number of cells horizontally to the right of $c$ plus the number of cells vertically below $c$. The number of standard Young tableaux of shape $\lambda$ is then $n!$ divided by the product of the hook lengths of the shape of $\lambda$, where $n = |\lambda|$.

For example, consider the partition $[3, 2, 1]$ of 6 with Ferrers diagram:
When we fill in the cells with their respective hook lengths, we obtain:

\[
\begin{array}{ccc}
5 & 3 & 1 \\
3 & 1 \\
1
\end{array}
\]

The hook length formula returns

\[
\frac{6!}{5 \cdot 3 \cdot 1 \cdot 3 \cdot 1 \cdot 1} = 16.
\]

**EXAMPLES:**

```python
sage: StandardTableaux([3,2,1]).cardinality()
sage: StandardTableaux([2,2]).cardinality()
sage: StandardTableaux([5]).cardinality()
sage: StandardTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardTableaux([]).cardinality()
1

>>> from sage.all import *
>>> StandardTableaux([Integer(3),Integer(2),Integer(1)]).cardinality()
16
>>> StandardTableaux([Integer(2),Integer(2)]).cardinality()
2
>>> StandardTableaux([Integer(5)]).cardinality()
1
>>> StandardTableaux([Integer(6),Integer(5),Integer(5),Integer(3)]).cardinality()
6651216
>>> StandardTableaux([]).cardinality()
1
```

**REFERENCES:**

### list()

Return a list of the standard Young tableaux of the specified shape.

**EXAMPLES:**

```python
sage: StandardTableaux([2,2]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
sage: StandardTableaux([5]).list()
[[[1, 2, 3, 4, 5]]]
sage: StandardTableaux([3,2,1]).list()
[[[1, 4, 6], [2, 5], [3]],
[[1, 3, 6], [2, 5], [4]],
[[1, 2, 6], [3, 5], [4]],
[[1, 3, 6], [2, 4], [5]],
[[1, 2, 6], [3, 4], [5]],
[[1, 4, 5], [2, 6], [3]],
[[1, 3, 5], [2, 6], [4]],
[[1, 2, 5], [3, 6], [4]],
```

(continues on next page)
random_element()

Return a random standard tableau of the given shape using the Greene-Nijenhuis-Wilf Algorithm.

**EXAMPLES:**

```python
sage: t = StandardTableaux([2,2]).random_element()
sage: t.shape()
[2, 2]
sage: StandardTableaux([]).random_element()
[]
```

```python
>>> from sage.all import *

>>> StandardTableaux([Integer(2),Integer(2)]).list()=[[1, 3], [2, 4]], [[1, 2], [3, 4]]

>>> StandardTableaux([Integer(3),Integer(2),Integer(1)]).list()
[[1, 4, 6], [2, 5], [3]],
[[1, 3, 6], [2, 5], [4]],
[[1, 2, 6], [3, 5], [4]],
[[1, 3, 6], [2, 4], [5]],
[[1, 2, 6], [3, 4], [5]],
[[1, 4, 5], [2, 6], [3]],
[[1, 3, 5], [2, 6], [4]],
[[1, 2, 5], [3, 6], [4]],
[[1, 2, 4], [3, 6], [5]],
[[1, 2, 3], [4, 6], [5]],
[[1, 3, 5], [2, 4], [6]],
[[1, 2, 5], [3, 4], [6]],
[[1, 3, 4], [2, 5], [6]],
[[1, 2, 4], [3, 5], [6]],
[[1, 2, 3], [4, 5], [6]]]
```

### class `sage.combinat.tableau.StandardTableaux_size(n)`

**Bases:** `StandardTableaux, DisjointUnionEnumeratedSets`

Standard tableaux of fixed size $n$.

**EXAMPLES:**
Combinatorics, Release 10.4

The `StandardTableaux(n)[:]` function returns all standard tableaux of size `n` as lists of lists of integers, with each integer representing a cell in the tableau. Each list represents a row of the tableau, with rows ordered from top to bottom.

```python
sage: StandardTableaux(3)[:]
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
```

The `cardinality()` method returns the number of all standard tableaux of size `n`.

```python
sage: StandardTableaux(3).cardinality()
4
```

The number of standard tableaux of size `n` is equal to the number of involutions in the symmetric group $S_n$. This is a consequence of the symmetry of the RSK correspondence, that if $\sigma \rightarrow (P, Q)$, then $\sigma^{-1} \rightarrow (Q, P)$. For more information, see the Wikipedia article Robinson-Schensted-Knuth correspondence#Symmetry.

**ALGORITHM:**

The algorithm uses the fact that standard tableaux of size `n` are in bijection with the involutions of size `n`, (see page 41 in section 4.1 of [Ful1997]). For each number of fixed points, you count the number of ways to choose those fixed points multiplied by the number of perfect matchings on the remaining values.

**EXAMPLES:**

```python
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
```
The cardinality can be computed without constructing all elements in this set, so this computation is fast (see also Issue #28273):

```
sage: StandardTableaux(500).cardinality()
423107565308608549951551753690...22128599923665743927937253376
```

random_element()

Return a random StandardTableau with uniform probability.

This algorithm uses the fact that the Robinson-Schensted correspondence returns a pair of identical standard Young tableaux (SYTs) if and only if the permutation was an involution. Thus, generating a random SYT is equivalent to generating a random involution.

To generate an involution, we first need to choose its number of fixed points \( k \) (if the size of the involution is even, the number of fixed points will be even, and if the size is odd, the number of fixed points will be odd). To do this, we choose a random integer \( r \) between 0 and the number \( N \) of all involutions of size \( n \). We then decompose the interval \{1, 2, ..., \( N \)\} into subintervals whose lengths are the numbers of involutions of size \( n \) with respectively 0, 1, ..., \( \lfloor N/2 \rfloor \) fixed points. The interval in which our random integer \( r \) lies then decides how many fixed points our random involution will have. We then place those fixed points randomly and then compute a perfect matching (an involution without fixed points) on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(10).random_element()  # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
sage: StandardTableaux(0).random_element()  
[]
sage: StandardTableaux(1).random_element()  
[[1]]
```

```
>>> from sage.all import *
>>> StandardTableaux(Integer(10)).random_element()  # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
```

```
>>> from sage.all import *
>>> StandardTableaux(Integer(0)).random_element()  
[]
```

```
>>> from sage.all import *
>>> StandardTableaux(Integer(1)).random_element()  
[[1]]
```

class sage.combinat.tableau.Tableau(parent, t, check=True)

A class to model a tableau.

INPUT:

- \( t \) – a Tableau, a list of iterables, or an empty list
OUTPUT:

• A Tableau object constructed from $t$.

A tableau is abstractly a mapping from the cells in a partition to arbitrary objects (called entries). It is often represented as a finite list of nonempty lists (or, more generally an iterator of iterables) of weakly decreasing lengths. This list, in particular, can be empty, representing the empty tableau.

Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
sage: t.is_standard()
True
sage: Tableau([['a','c','b'],[[],(2,1)]]
[['a', 'c', 'b'], [[]], (2, 1)]
sage: Tableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Tableau from the appropriate Parent object:

```
sage: T = Tableaux()
sage: T([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> T = Tableaux()
>>> T([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]])
[[1, 2, 3], [4, 5]]
```

See also:

• Tableaux
• *SemistandardTableaux*
• *SemistandardTableau*
• *StandardTableaux*
• *StandardTableau*

`add_entry (cell, m)`

Return the result of setting the entry in cell `cell` equal to `m` in the tableau `self`.

This tableau has larger size than `self` if `cell` does not belong to the shape of `self`; otherwise, the tableau has the same shape as `self` and has the appropriate entry replaced.

**INPUT:**

• `cell` – a pair of nonnegative integers

**OUTPUT:**

The tableau `self` with the entry in cell `cell` set to `m`. This entry overwrites an existing entry if `cell` already belongs to `self`, or is added to the tableau if `cell` is a co-corner of the shape `self`. (Either way, the input is not modified.)

**Note:** Both coordinates of `cell` are interpreted as starting at 0. So, `cell == (0, 0)` corresponds to the northwesternmost cell.

**EXAMPLES:**

```sage
sage: s = StandardTableau([[1,2,5],[3,4]]); s.pp()
  1  2  5
  3  4
sage: t = s.add_entry( (1,2), 6); t.pp()
  1  2  5
  3  4  6
sage: t.category()
Category of elements of Standard tableaux
sage: s.add_entry( (2,0), 6).pp()
  1  2  5
  3  4
  6
sage: u = s.add_entry( (1,2), 3); u.pp()
  1  2  5
  3  4  3
sage: u.category()
Category of elements of Tableaux
sage: s.add_entry( (2,2), 3)
Traceback (most recent call last):
...
IndexError: (2, 2) is not an addable cell of the tableau
```
```
Box 3 4 6
>>> t.category()
Category of elements of Standard tableaux
>>> s.add_entry( (Integer(2),Integer(0)), Integer(6)).pp()
 1 2 5
 3 4 6
>>> u = s.add_entry( (Integer(1),Integer(2)), Integer(3)); u.pp()
 1 2 5
 3 4 3
>>> u.category()
Category of elements of Tableaux
>>> s.add_entry( (Integer(2),Integer(2)),Integer(3))
Traceback (most recent call last):
  ... 
IndexError: (2, 2) is not an addable cell of the tableau

anti_restrict(n)

Return the skew tableau formed by removing all of the cells from self that are filled with a number at most n.

EXAMPLES:

sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]

sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]

sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]

sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]

sage: t.anti_restrict(4)
[[None, None, None], [None, 5]]

sage: t.anti_restrict(5)
[[None, None, None], [None, None]]

>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]); t
[[1, 2, 3], [4, 5]]

>>> t.anti_restrict(Integer(1))
[[None, 2, 3], [4, 5]]

>>> t.anti_restrict(Integer(2))
[[None, None, 3], [4, 5]]

>>> t.anti_restrict(Integer(3))
[[None, None, None], [4, 5]]

>>> t.anti_restrict(Integer(4))
[[None, None, None], [None, 5]]

>>> t.anti_restrict(Integer(5))
[[None, None, None], [None, None]]

atom()

EXAMPLES:

sage: Tableau([[1,2],[3,4]]).atom()
[2, 2]
Combinatorics, Release 10.4

```python
sage: Tableau([[1,2,3],[4,5],[6]]).atom()
[3, 2, 1]
```

```python
>>> from sage.all import *

```

```python
>>> Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).atom()
[2, 2]
```

```python
>>> Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)],[Integer(6)])].atom()
[3, 2, 1]
```

---

**bender_knuth_involution** *(k, rows=None, check=True)*

Return the image of *self* under the *k*-th Bender–Knuth involution, assuming *self* is a semistandard tableau.

Let *T* be a tableau, then a *lower free* *k* in *T* means a cell of *T* which is filled with the integer *k* and whose direct lower neighbor is not filled with the integer *k* + 1 (in particular, this lower neighbor might not exist at all). Let an *upper free* *k* + 1 in *T* mean a cell of *T* which is filled with the integer *k* + 1 and whose direct upper neighbor is not filled with the integer *k* (in particular, this neighbor might not exist at all). It is clear that for any row *r* of *T*, the lower free *k*’s and the upper free *k* + 1’s in *r* together form a contiguous interval or *r*.

The *k*'-th *Bender–Knuth switch at row *i* changes the entries of the cells in this interval in such a way that if it used to have *a* entries of *k* and *b* entries of *k* + 1, it will now have *b* entries of *k* and *a* entries of *k* + 1. For fixed *k*, the *k*-th Bender–Knuth switches for different *i* commute. The composition of the *k*-th Bender–Knuth switches for all rows is called the *k*'-th *Bender–Knuth involution*. This is used to show that the Schur functions defined by semistandard tableaux are symmetric functions.

**INPUT:**

- *k* – an integer
- *rows* = *(Default None)* When set to None, the method computes the *k*-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the *k*-th Bender–Knuth switches at row *i* over all *i* in *rows*. When set to an integer *i*, the method computes the *k*-th Bender–Knuth switch at row *i*. Note the indexing of the rows starts with 1.
- *check* = *(Default: True)* Check to make sure *self* is semistandard. Set to False to avoid this check.

**OUTPUT:**

The image of *self* under either the *k*-th Bender–Knuth involution, the *k*-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

**EXAMPLES:**

```python
sage: t = Tableau([[1,1,3,4,5,6,7],[2,2,4,6,7,7,7],[3,4,5,8,8,9],[6,6,7,10],
    [7,8,8,11],[8]])
sage: t.bender_knuth_involution(1) == t
True
sage: t.bender_knuth_involution(2)
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(3)
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(4)
[[1, 1, 3, 4, 5, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6, 7, 10],
 [7, 8, 8, 11], [8]]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

\[ \rightarrow 7, 10 \], \{ 7, 8, 11 \}, \{ 8 \} ]

sage: t.bender_knuth_involution(5)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 5, 7, 7, 7], [3, 4, 6, 8, 8, 9], [5, 5, 7, 10], [7, 8, 8, 11], [8]]

sage: t.bender_knuth_involution(666) == t
True

sage: t.bender_knuth_involution(4, 2) == t
True

sage: t.bender_knuth_involution(4, 3)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6 \rightarrow 7, 10], [7, 8, 8, 11], [8]]

The \texttt{rows} keyword can be an iterator:

sage: t.bender_knuth_involution(6, \texttt{iter([1,2])}) == t
False

sage: t.bender_knuth_involution(6, \texttt{iter([3,4])}) == t
True

The \textit{Bender–Knuth} involution is an involution:

\[ \rightarrow 7, 10 \], \{ 7, 8, 11 \}, \{ 8 \} ]

sage: t.bender_knuth_involution(6, \texttt{iter([1,2])}) == t
False

sage: t.bender_knuth_involution(6, \texttt{iter([3,4])}) == t
True
Combinatorics, Release 10.4

```
sage: T = SemistandardTableaux(shape=[3,1,1], max_entry=4)
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t # needs sage.modules
   ....: for k in range(1, 5) for t in T)
True

>>> from sage.all import *

>>> T = SemistandardTableaux(shape=[Integer(3),Integer(1),Integer(1)], max_entry=Integer(4))

>>> all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t # needs sage.modules
   ....: for k in range(Integer(1), Integer(5)) for t in T)
True

Thesameholds for the single switches:

```
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t # needs sage.modules
   ....: for k in range(1, 5) for j in range(1, 5) for t in T)
True

>>> from sage.all import *

>>> all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t # needs sage.modules
   ....: for k in range(Integer(1), Integer(5)) for j in range(Integer(1), Integer(5)) for t in T)
True

Locality of the Bender–Knuth involutions:

```
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.bender_knuth_involution(l).bender_knuth_involution(k)
   ....: for k in range(1, 5) for l in range(1, 5) if abs(k - l) > 1
   ....: for t in T)
True

>>> from sage.all import *

>>> all(t.bender_knuth_involution(k).bender_knuth_involution(l) == t.bender_knuth_involution(l).bender_knuth_involution(k)
   ....: for k in range(Integer(1), Integer(5)) for l in range(Integer(1), Integer(5)) if abs(k - l) > Integer(1)
   ....: for t in T)
True

Berenstein and Kirillov [KB1995] have shown that $(s_1 s_2)^6 = id$ (for tableaux of straight shape):

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k + 1)
sage: all(p(p(p(p(p(p(t,1),1),1),1),1),1)) == t for t in T)
True

>>> from sage.all import *

>>> p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k + 1)
(continues on next page)
However, \((s_2 s_3)^6 = id\) is false:

```python
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k + Integer(1))
sage: t = Tableau([[:Integer(1),Integer(2),Integer(2)],[:Integer(3),Integer(4)]]))
sage: x = t
sage: for i in range(Integer(6)): x = p(x, Integer(2))
sage: x
[[1, 2, 3], [2, 4]]
sage: x == t
False
```

**bump** \((x)\)

Insert \(x\) into self using Schensted’s row-bumping (or row-insertion) algorithm.

**EXAMPLES:**

```python
sage: t = Tableau([[:1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t = Tableau([[:1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6, 5]]
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

\[
\begin{bmatrix}
1, 2, [3]
\end{bmatrix}
\]

```python
>>> t.bump(Integer(2))
[[1, 2, 2], [3]]
```

```python
>>> t.bump(Integer(3))
[[1, 2, 3], [3]]
```

```python
>>> t = Tableau([[Integer(1),Integer(2),Integer(3)], [Integer(2), Integer(3),Integer(5),Integer(5)], [Integer(4),Integer(4),Integer(6)], [Integer(5),Integer(6)]])
```

```python
>>> t.bump(Integer(2))
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
```

```python
>>> t.bump(Integer(1))
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

**bump_multiply (other)**

Multiply two tableaux using Schensted's bump.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid. See pp. 11-12 of [Ful1997].

The same product operation is implemented in a different way in *slide_multiply()*.

**EXAMPLES:**

```python
sage: t = Tableau([[1,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

```python
>>> from sage.all import *
```
Tableau([[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]]).
catabolism()
[[1, 2, 3, 4, 5]]

Tableau([[Integer(1),Integer(1),Integer(3),Integer(3)],[Integer(2),
Integer(3)],[[Integer(3)]]]).catabolism()
[[1, 2, 3, 3, 3], [3]]

Tableau([[Integer(1), Integer(1), Integer(2), Integer(3), Integer(3),
Integer(3)],[[Integer(3)]]]).catabolism()
[[1, 2, 3, 3, 3, 3]]

>>> from sage.all import *

Tableau([[Integer(1), Integer(1), Integer(3), Integer(3)],[Integer(2),
Integer(3)],[[Integer(3)]]]).catabolism()
[[1, 2, 3, 3, 3, 3]]

catabolism_projector (parts)
EXAMPLES:

sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.catabolism_projector([[4,2,1]])[[1, 1, 3, 3], [2, 3], [3]]
sage: t.catabolism_projector([[1]])[
]
sage: t.catabolism_projector([[2,1],[1]])[
]
sage: t.catabolism_projector([[1,1],[4,1]])[[1, 1, 3, 3], [2, 3], [3]]

>>> from sage.all import *

>>> t = Tableau([[1,1,3,3],[2,3],[3]])
>>> t.catabolism_projector([[4,2,1]])[[1, 1, 3, 3], [2, 3], [3]]

>>> t.catabolism_projector([[1]])[
]

>>> t.catabolism_projector([[2,1],[1]])[
]

>>> t.catabolism_projector([[1,1],[4,1]])[[1, 1, 3, 3], [2, 3], [3]]

catabolism_sequence ()
Perform catabolism() on self until it returns a tableau consisting of a single row.

EXAMPLES:

sage: t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.catabolism_sequence()[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
[[1, 2, 3, 4, 5, 6, 7, 9], [8]],
[[1, 2, 3, 4, 5, 6, 7, 8], [9]],
[[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
sage: Tableau([]).catabolism_sequence()[
]

>>> from sage.all import *

>>> t = Tableau([[1,2,3,4,5,6,8],[7,9]])
>>> t.catabolism_sequence()[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
[[1, 2, 3, 4, 5, 6, 7, 9], [8]],
[[1, 2, 3, 4, 5, 6, 7, 8], [9]],
[[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
cells()
Return a list of the coordinates of the cells of self.
Coordinates start at 0, so the northwesternmost cell (in English notation) has coordinates (0, 0).

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

```
>> from sage.all import *
>> Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

cells_containing(i)
Return the list of cells in which the letter i appears in the tableau self. The list is ordered with cells appearing from left to right.
Cells are given as pairs of coordinates (a, b), where both rows and columns are counted from 0 (so a = 0 means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = Tableau([[1,1,3],[2,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(6)
[]
```

```
sage: t = Tableau([[1,1,2,4],[2,4,4],[4]])
sage: t.cells_containing(4)
[(2, 0), (1, 1), (1, 2), (0, 3)]
```

```
sage: t = Tableau([[1,1,2,8,9],[2,5,6,11],[3,7,7,13],[4,8,9],[5],[13],[14]])
sage: t.cells_containing(8)
[(3, 1), (0, 3)]
```

```
sage: Tableau([]).cells_containing(3)
[]
```

```
>> from sage.all import *
>> t = Tableau([[Integer(1),Integer(1),Integer(3)],[Integer(2),Integer(3),
Integer(5)],[Integer(4),Integer(5)]])
>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]
>> t.cells_containing(Integer(4))
[(2, 0)]
>> t.cells_containing(Integer(6))
[]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> t = Tableau([[Integer(1), Integer(1), Integer(2), Integer(4)],
              [Integer(2), Integer(4), Integer(4)], [Integer(4)]])
>>> t.cells_containing(Integer(4))
[(2, 0), (1, 1), (1, 2), (0, 3)]
```

```python
>>> t = Tableau([[Integer(1), Integer(1), Integer(2), Integer(8), Integer(9)],
              [Integer(2), Integer(5), Integer(6), Integer(11)],
              [Integer(3), Integer(7), Integer(7), Integer(13)],
              [Integer(4), Integer(8), Integer(9)], [Integer(5),
              [Integer(13), [Integer(14)]]])
>>> t.cells_containing(Integer(8))
[(3, 1), (0, 3)]
```

```python
>>> Tableau([]).cells_containing(Integer(3))
[]
```

charge()

Return the charge of the reading word of self. See charge() for more information.

EXAMPLES:

```python
sage: Tableau([[1,1],[2,2],[3]]).charge()
0
sage: Tableau([[1,1],[2,2]]).charge()
1
sage: Tableau([[1,1,2],[2,3]]).charge()
2
sage: Tableau([[1,1,2],[2]]).charge()
2
sage: Tableau([[1,1,2],[2],[3]]).charge()
3
sage: Tableau([[1,1,2,2],[3]]).charge()
3
```

```python
>>> from sage.all import *
```

```python
>>> Tableau([[Integer(1), Integer(1), Integer(2), Integer(3)]].
  charge()
4
```

5.1. Comprehensive Module List 5435
check()
Check that self is a valid straight-shape tableau.
EXAMPLES:

```
sage: t = Tableau([[1,1],[2]])
sage: t.check()
```

```
sage: t = Tableau([[None, None, 1], [2, 4], [3, 4, 5]])  # indirect doctest
Traceback (most recent call last):
  ...
ValueError: a tableau must be a list of iterables of weakly decreasing length
```

cocharge()
Return the cocharge of the reading word of self. See cocharge() for more information.
EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]).cocharge()
4
sage: Tableau([[1,1],[2,2]]).cocharge()
3
sage: Tableau([[1,1],[2],[3]]).cocharge()
3
sage: Tableau([[1,1],[2,3]]).cocharge()
2
sage: Tableau([[1,1,2],[3]]).cocharge()
1
sage: Tableau([[1,1,2,3]]).cocharge()
0
```

```
>>> from sage.all import *

>>> Tableau([[Integer(1),Integer(1)],[Integer(2),Integer(2)],[Integer(3)]]).cocharge()
4

>>> Tableau([[Integer(1),Integer(1)],[Integer(2),Integer(2)]]).cocharge()
3

>>> Tableau([[Integer(1),Integer(1)],[Integer(2),Integer(3)]]).cocharge()
3

>>> Tableau([[Integer(1),Integer(1)],[Integer(2)],[Integer(3)]]).cocharge()
3

>>> Tableau([[Integer(1),Integer(1)],[Integer(2)],[Integer(3)]]).cocharge()
3

>>> Tableau([[Integer(1),Integer(1)],[Integer(2)],[Integer(3)],[Integer(2)]]).cocharge()
2
```

(continues on next page)
\[
\text{codegree} \ (e, \text{multicharge} = (0,))
\]

Return the Brundan-Kleshchev-Wang [BKW2011] codegree of the standard tableau \(\text{self}\).

The codegree of a tableau is an integer that is defined recursively by successively stripping off the number \(k\), for \(k = n, n-1, \ldots, 1\) and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as \(k\) and are above \(k\) in the diagram.

The codegree of the tableau \(T\) gives the degree of “dual” homogeneous basis element of the Graded Specht module that is indexed by \(T\).

**INPUT:**

- \(e\) – the quantum characteristic
- \text{multicharge} – (default: [0]) the multicharge

**OUTPUT:**

The codegree of the tableau \(\text{self}\), which is an integer.

**EXAMPLES:**

```python
sage: StandardTableau([[1,3,5],[2,4]]).codegree(3) # needs sage.groups
0
sage: StandardTableau([[1,2,5],[3,4]]).codegree(3) # needs sage.groups
1
sage: StandardTableau([[1,2,5],[3,4]]).codegree(4) # needs sage.groups
0

>>> from sage.all import *
>>> StandardTableau([[1,3,5],[2,4,1]]).codegree(Integer(3)) # needs sage.groups
0
>>> StandardTableau([[1,3,5],[2,4,1]]).codegree(Integer(4)) # needs sage.groups
1
>>> StandardTableau([[1,3,5],[2,4,1]]).codegree(Integer(4)) # needs sage.groups
0
```

\[
\text{column_stabilizer}()
\]

Return the PermutationGroup corresponding to the column stabilizer of \(\text{self}\).

This assumes that every integer from 1 to the size of \(\text{self}\) appears exactly once in \(\text{self}\).
EXAMPLES:

```python
sage: # needs sage.groups
sage: cs = Tableau([[1,2,3],[4,5]]).column_stabilizer()
sage: cs.order() == factorial(2)*factorial(2)
True
sage: PermutationGroupElement(((1,3,2),(4,5))) in cs
False
sage: PermutationGroupElement(((1,4))) in cs
True
```

```python
>>> from sage.all import *

>>> # needs sage.groups

>>> cs = Tableau([[Integer(1),Integer(2),Integer(3)], [Integer(4), Integer(5)]]).column_stabilizer()

>>> cs.order() == factorial(Integer(2))*factorial(Integer(2))
True

>>> PermutationGroupElement(((Integer(1),Integer(3),Integer(2)),(Integer(4), Integer(5)))) in cs
False

>>> PermutationGroupElement(((Integer(1),Integer(4)))) in cs
True
```

**components()**

This function returns a list containing itself. It exists mainly for compatibility with `TableauTuple` as it allows constructions like the example below.

EXAMPLES:

```python
sage: t = Tableau([[1,2,3],[4,5]])

sage: for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

```python
>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(2),Integer(3)], [Integer(4), Integer(5)]])

>>> for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

**conjugate()**

Return the conjugate of `self`.

EXAMPLES:

```python
sage: Tableau([[1,2],[3,4]]).conjugate()
[[1, 3], [2, 4]]

sage: c = StandardTableau([[1,2],[3,4]]).conjugate()

sage: c.parent()
Standard tableaux
```

```python
>>> from sage.all import *

>>> Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).conjugate()
[[1, 3], [2, 4]]

>>> c = StandardTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).conjugate()

>>> c.parent()
Standard tableaux
```
content \((k, \text{multicharge}=[0])\)

Return the content of \(k\) in the standard tableau \(self\).

The content of \(k\) is \(c - r\) if \(k\) appears in row \(r\) and column \(c\) of the tableau.

The \text{multicharge} is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with \texttt{sage.combinat.tableau_tuple.TableauTuple()}.

**EXAMPLES:**

```python
sage: StandardTableau([[1,2],[3,4]]).content(3)
-1
sage: StandardTableau([[1,2],[3,4]]).content(6)
Traceback (most recent call last):
  ... ValueError: 6 does not appear in tableau
```

corners()

Return the corners of the tableau \(self\).

**EXAMPLES:**

```python
sage: Tableau([[1, 4, 6], [2, 5], [3]]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Tableau([[1, 3], [2, 4]]).corners()
[(1, 1)]
```

degree \((e, \text{multicharge}=(0,))\)

Return the Brundan-Kleshchev-Wang [BKW2011] degree of \(self\).

The \textit{degree} is an integer that is defined recursively by successively stripping off the number \(k\), for \(k = n, n - 1, \ldots, 1\) and at stage adding the number of addable cells of the same residue minus the number of removable cells of the same residue as \(k\) and which are below \(k\) in the diagram.

The degrees of the tableau \(T\) gives the degree of the homogeneous basis element of the graded Specht module that is indexed by \(T\).

**INPUT:**

- \(e\) – the quantum characteristic
• multicharge – (default: [0]) the multicharge

OUTPUT:

The degree of the tableau self, which is an integer.

EXAMPLES:

```python
sage: StandardTableau([[1,2,5],[3,4]]).degree(3) # needs sage.groups
0
sage: StandardTableau([[1,2,5],[3,4]]).degree(4) # needs sage.groups
1
```

```python
>>> from sage.all import *

>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),Integer(4)]]).degree(Integer(3)) # needs sage.groups
0
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),Integer(4)]]).degree(Integer(4)) # needs sage.groups
1
```

descents()

Return a list of the cells \((i,j)\) such that \(\text{self}[i][j] > \text{self}[i-1][j]\).

**Warning:** This is not to be confused with the descents of a standard tableau.

EXAMPLES:

```python
sage: Tableau([ [1,4],[2,3] ]).descents()
[(1, 0)]
sage: Tableau([ [1,2],[3,4] ]).descents()
[(1, 0), (1, 1)]
sage: Tableau([ [1,2,3],[4,5] ]).descents()
[(1, 0), (1, 1)]

>>> from sage.all import *

>>> Tableau([ [Integer(1),Integer(4)],[Integer(2),Integer(3)] ]).descents()
[(1, 0)]
>>> Tableau([ [Integer(1),Integer(2)],[Integer(3),Integer(4)] ]).descents()
[(1, 0), (1, 1)]
```

entries()

Return the tuple of all entries of self, in the order obtained by reading across the rows from top to bottom (in English notation).

EXAMPLES:

```python
sage: t = Tableau([[1,3], [2]])
sage: t.entries()
(1, 3, 2)
```
>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(3)], [Integer(2)]])

>>> t.entries()
(1, 3, 2)

entry (cell)

Return the entry of cell cell in the tableau self. Here, cell should be given as a tuple (i, j) of zero-based coordinates (so the northwesternmost cell in English notation is (0, 0)).

EXAMPLES:

sage: t = Tableau([[1,2],[3,4]])
sage: t.entry( (0,0) )
1
sage: t.entry( (1,1) )
4

>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]])

>>> t.entry( (Integer(0),Integer(0)) )
1
>>> t.entry( (Integer(1),Integer(1)) )
4

evacuation (n=None, check=True)

Return the evacuation of the tableau self.

This is an alias for schuetzenberger_involution().

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If n is specified, the underlying alphabet is assumed to be [1, 2, ..., n]. If no alphabet is specified, n is the maximal letter appearing in self.

INPUT:

• n – an integer specifying the maximal letter in the alphabet (optional)
• check – (Default: True) Check to make sure self is semistandard. Set to False to avoid this check. (optional)

OUTPUT:

• a tableau, the evacuation of self

EXAMPLES:

sage: t = Tableau([[1,1,1],[2,2]])
sage: t.evacuation(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau([[1,2,3],[4,5]])
sage: t.evacuation()
[[1, 2, 5], [3, 4]]

sage: t = Tableau([[1,3,5,7],[2,4,6],[8,9]])
sage: t.evacuation()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

sage: t = Tableau([])

(continues on next page)
sage: t.evacuation()
[]
sage: t = StandardTableau([[1,2,3],[4,5]])
sage: s = t.evacuation()
sage: s.parent()
Standard tableaux

```python
>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),Integer(2)]]
[[2, 2], [3, 3]]

>>> t.evacuation(Integer(3))
[[2, 2, 3], [3, 3]]

>>> t = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]
[[1, 2, 5], [3, 4]]

>>> t.evacuation()
[[1, 2, 6, 8], [3, 4, 9], [5, 7]]

>>> t = Tableau(

>>> t = Tableau([])

>>> t.evacuation()
[]

>>> t = StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]

>>> s = t.evacuation()

>>> s.parent()
Standard tableaux
```

evaluation()

Return the weight of the tableau self. Trailing zeroes are omitted when returning the weight.

The weight of a tableau \( T \) is the sequence \((a_1, a_2, a_3, \ldots)\), where \( a_k \) is the number of entries of \( T \) equal to \( k \). This sequence contains only finitely many nonzero entries.

The weight of a tableau \( T \) is the same as the weight of the reading word of \( T \), for any reading order.

EXAMPLES:

```python
sage: Tableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]
sage: Tableau([]).weight()
[]
sage: Tableau([[1,3,3,7],[4,2],[2,3]]).weight()
[1, 2, 3, 1, 0, 0, 1]
```

```python
>>> from sage.all import *

>>> Tableau([[[Integer(1),Integer(2)],[Integer(3),Integer(4)]]].weight()
[1, 1, 1]

>>> Tableau([]).weight()
[]
```

first_column_descent()

Return the first cell where self is not column standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell \((r, c)\) with \(r\) and \(c\) minimal such that the entry in position \((r, c)\) is bigger than the entry in position \((r, c+1)\). If there is no such cell then None is returned - in this case the tableau is column strict.

OUTPUT:

The first cell which there is a descent or None if no such cell exists.

EXAMPLES:

```
sage: Tableau([[1,4,5],[2,3]]).first_column_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]).first_column_descent() is None
True
```

first_row_descent()

Return the first cell where the tableau self is not row standard.

Cells are ordered left to right along the rows and then top to bottom. That is, the cell \((r, c)\) with \(r\) and \(c\) minimal such that the entry in position \((r, c)\) is bigger than the entry in position \((r, c+1)\). If there is no such cell then None is returned - in this case the tableau is row strict.

OUTPUT:

The first cell which there is a descent or None if no such cell exists.

EXAMPLES:

```
sage: t = Tableau([[1,3,2],[4]]); t.first_row_descent()
(0, 1)
sage: Tableau([[1,2,3],[4]]).first_row_descent() is None
True
```

```
flush()

Return the number of flush segments in self, as in [Sal2014].

Let $1 \leq i < k \leq r + 1$ and suppose $\ell$ is the smallest integer greater than $k$ such that there exists an $\ell$-segment in the $(i+1)$-st row of $T$. A $k$-segment in the $i$-th row of $T$ is called flush if the leftmost box in the $k$-segment and the leftmost box of the $\ell$-segment are in the same column of $T$. If, however, no such $\ell$ exists, then this $k$-segment is said to be flush if the number of boxes in the $k$-segment is equal to $\theta_i$, where $\theta_i = \lambda_i - \lambda_{i+1}$ and the shape of $T$ is $\lambda = (\lambda_1 > \lambda_2 > \cdots > \lambda_r)$. Denote the number of flush $k$-segments in $T$ by flush($T$).

EXAMPLES:

```
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.flush()
3

sage: B = crystals.Tableaux("A4", shape=[4,3,2,1])
      # needs sage.modules
sage: t = B[32].to_tableau()
      # needs sage.modules
sage: t.flush()
4

sage: t = Tableau([[1,2,3],[4,5]])

sage: t.height()
2

sage: Tableau([[1,2,3]]).height()
1

sage: Tableau([]).height()
0
```

height()

Return the height of self.

EXAMPLES:

```
>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]).height()
2

>>> Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]).height()
2

>>> Tableau([[Integer(1),Integer(2),Integer(3)]]).height()
1

>>> Tableau([]).height()
0
```
hillman_grassl()  
Return the image of the λ-array self under the Hillman-Grassl correspondence (as a WeakReversePlanePartition).

This relies on interpreting self as a λ-array in the sense of hillman_grassl.

Fix a partition λ (see Partition()). We draw all partitions and tableaux in English notation.

A λ-array will mean a tableau of shape λ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape λ (short: λ-rpp) will mean a λ-array whose entries weakly increase along each row and weakly increase along each column.

The Hillman-Grassl correspondence \( H \) is the map that sends a λ-array \( M \) to a λ-rpp \( H(M) \) defined recursively as follows:

- If all entries of \( M \) are 0, then \( H(M) = M \).
- Otherwise, let \( s \) be the index of the leftmost column of \( M \) containing a nonzero entry. Let \( r \) be the index of the bottommost nonzero entry in the \( s \)-th column of \( M \). Let \( M' \) be the λ-array obtained from \( M \) by subtracting 1 from the \((r, s)\)-th entry of \( M \). Let \( Q = (q_{i, j}) \) be the image \( H(M') \) (which is already defined by recursion).
- Define a sequence \((i_1, j_1), (i_2, j_2), \ldots, (i_n, j_n)\) of boxes in the diagram of \( \lambda \) (actually a lattice path made of southward and westward steps) as follows: Set \((i_1, j_1) = (r, \lambda_r) \) (the rightmost box in the \( r \)-th row of \( \lambda \)). If \((i_k, j_k) \) is defined for some \( k \geq 1 \), then \((i_{k+1}, j_{k+1}) \) is constructed as follows: If \( q_{i_k+1, j_k} \) is well-defined and equals \( q_{i_k, j_k} \), then we set \((i_{k+1}, j_{k+1}) = (i_k + 1, j_k) \). Otherwise, if \( j_k = s \), then the sequence ends here. Otherwise, we set \((i_{k+1}, j_{k+1}) = (i_k, j_k - 1) \).

- Let \( H(M) \) be the array obtained from \( Q \) by adding 1 to the \((i_k, j_k)\)-th entry of \( Q \) for each \( k \in \{1, 2, \ldots, n\} \).

See [Gans1981] (Section 3) for this construction.

See also:

hillman_grassl() for the Hillman-Grassl correspondence as a standalone function.

hillman_grassl_inverse() for the inverse map.

EXAMPLES:

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.hillman_grassl(); A
[[2, 2, 4], [2, 3, 4], [3, 5]]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

```python
>>> from sage.all import *
>>> a = Tableau([[Integer(2), Integer(1), Integer(1)], [Integer(0), Integer(2), Integer(0)], [Integer(0), Integer(1), Integer(1)]]
>>> A = a.hillman_grassl(); A
[[2, 2, 4], [2, 3, 4], [3, 5]]
>>> A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

insert_word (w, left=False)

Insert the word \( w \) into the tableau self letter by letter using Schensted insertion. By default, the word \( w \) is being processed from left to right, and the insertion used is row insertion. If the optional keyword left is set to True, the word \( w \) is being processed from right to left, and column insertion is used instead.

5.1. Comprehensive Module List 5445
EXAMPLES:

```python
sage: t0 = Tableau([])
sage: w = [1,1,2,3,3,3,3]
sage: t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
sage: t0.insert_word(w,left=True)
[[1, 1, 2, 3, 3, 3, 3]]
sage: w.reverse()
sage: t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t0.insert_word(w,left=True)
[[1, 1, 3, 3], [2, 3], [3]]
sage: t1 = Tableau([[1,3],[2]])
sage: t1.insert_word([4,5])
[[1, 3, 4, 5], [2]]
sage: t1.insert_word([4,5], left=True)
[[1, 3], [2, 5], [4]]
```

```
>>> from sage.all import *
>>> t0 = Tableau([])
>>> w = [Integer(1),Integer(1),Integer(2),Integer(3),Integer(3),Integer(3),
     Integer(3)]
>>> t0.insert_word(w)
[[1, 1, 2, 3, 3, 3, 3]]
>>> t0.insert_word(w,left=True)
[[1, 1, 2, 3, 3, 3, 3]]
>>> w.reverse()
>>> t0.insert_word(w)
[[1, 1, 3, 3], [2, 3], [3]]
>>> t0.insert_word(w,left=True)
[[1, 1, 3, 3], [2, 3], [3]]
>>> t1 = Tableau([[Integer(1),Integer(3)],[Integer(2)]]))
>>> t1.insert_word([Integer(4),Integer(5)])
[[1, 3, 4, 5], [2]]
>>> t1.insert_word([Integer(4),Integer(5)], left=True)
[[1, 3], [2, 5], [4]]
```

`inversion_number()`

Return the inversion number of `self`.

The inversion number is defined to be the number of inversions of `self` minus the sum of the arm lengths of the descents of `self` (see the `inversions()` and `descents()` methods for the relevant definitions).

**Warning:** This has none of the meanings in which the word “inversion” is used in the theory of standard tableaux.

EXAMPLES:

```python
sage: t = Tableau([[1,2,3],[2,5]])
sage: t.inversion_number()
0
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.inversion_number()
0
```
```python
from sage.all import *
t = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(2), Integer(5)]]
0
>>>
t = Tableau([[Integer(1), Integer(2), Integer(4)], [Integer(3), Integer(5)]]
0
```
is_column_strict()

Return True if self is a column strict tableau and False otherwise.

A tableau is column strict if the entries in each column are in (strictly) increasing order.

EXAMPLES:

```
sage: Tableau([[1, 3], [2, 4]]).is_column_strict()
True
sage: Tableau([[1, 2], [2, 4]]).is_column_strict()
True
sage: Tableau([[2, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([[5, 3], [2, 4]]).is_column_strict()
False
sage: Tableau([]).is_column_strict()
True
sage: Tableau([[1, 4, 2]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 5]]).is_column_strict()
True
sage: Tableau([[1, 4, 2], [2, 3]]).is_column_strict()
False
```

is_increasing()

Return True if self is an increasing tableau and False otherwise.

A tableau is increasing if it is both row strict and column strict.
EXAMPLES:

```python
sage: Tableau([[1, 3], [2, 4]]).is_increasing()
True
sage: Tableau([[1, 2], [2, 4]]).is_increasing()
True
sage: Tableau([[2, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[5, 3], [2, 4]]).is_increasing()
False
sage: Tableau([[1, 2, 3], [2, 3], [3]]).is_increasing()
True
```

```python
>>> from sage.all import *
>>> Tableau([[Integer(1), Integer(3)], [Integer(2), Integer(4)]]).is_increasing()
True
>>> Tableau([[Integer(1), Integer(2)], [Integer(2), Integer(4)]]).is_increasing()
True
>>> Tableau([[Integer(2), Integer(3)], [Integer(2), Integer(4)]]).is_increasing()
False
>>> Tableau([[Integer(5), Integer(3)], [Integer(2), Integer(4)]]).is_increasing()
False
>>> Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(2), Integer(3)],
[Integer(3)]]).is_increasing()
True
```

is_k_tableau($k$)

Checks whether self is a valid weak $k$-tableau.

EXAMPLES:

```python
sage: t = Tableau([[1,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = Tableau([[1,1,3],[2,2],[3]])
sage: t.is_k_tableau(3)
False
```

```python
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(3)], [Integer(2),Integer(3)],
[Integer(3)]]))
>>> t.is_k_tableau(Integer(3))
True
>>> t = Tableau([[Integer(1),Integer(1),Integer(3)], [Integer(2),Integer(2)],
[Integer(3)]]))
>>> t.is_k_tableau(Integer(3))
False
```

is_key_tableau()

Return True if self is a key tableau or False otherwise.

A tableau is a key tableau if the set of entries in the $j$-th column is a subset of the set of entries in the $(j - 1)$-st column.

REFERENCES:
Combinatorics, Release 10.4

- [LS1990]
- [Wil2010]

EXAMPLES:

```python
sage: t = Tableau([[1,1,1],[2,3],[3]])
sage: t.is_key_tableau()
True

sage: t = Tableau([[1,1,2],[2,3],[3]])
sage: t.is_key_tableau()
False
```

```python
>>> from sage.all import *

>>> t = Tableau([Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(3)], [Integer(3)])
>>> t.is_key_tableau()
True

>>> t = Tableau([Integer(1),Integer(1),Integer(2)], [Integer(2),Integer(3)], [Integer(3)])
>>> t.is_key_tableau()
False
```

`is_rectangular()`

Return True if the tableau self is rectangular and False otherwise.

EXAMPLES:

```python
sage: Tableau([[1,2],[3,4]]).is_rectangular()
True

sage: Tableau([[1,2,3],[4,5],[6]]).is_rectangular()
False

sage: Tableau([]).is_rectangular()
True
```

```python
>>> from sage.all import *

>>> Tableau([Integer(1),Integer(1),Integer(2)], [Integer(2),Integer(3)], [Integer(3)]).is_rectangular()
True

>>> Tableau([Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5)], [Integer(6)]).is_rectangular()
False

>>> Tableau([]).is_rectangular()
True
```

`is_row_increasing(weak=False)`

Return True if the entries in each row are in increasing order, and False otherwise.

By default, this checks for strictly increasing rows. Set weak to True to test for weakly increasing rows.

EXAMPLES:

```python
sage: T = Tableau([[1, 1, 3], [1, 2]])

sage: T.is_row_increasing(weak=True)
True

sage: T.is_row_increasing()
```

(continues on next page)
False
```
sage: Tableau([[2, 1]]).is_row_increasing(weak=True)
False
```

```python
>>> from sage.all import *

>>> T = Tableau([[Integer(1), Integer(1), Integer(3)],
               [Integer(1), Integer(2)]])

>>> T.is_row_increasing(weak=True)
True

>>> T.is_row_increasing()
False

>>> Tableau([[Integer(2), Integer(1)]]).is_row_increasing(weak=True)
False
```

**is_row_strict()**

Return `True` if `self` is a row strict tableau and `False` otherwise.

A tableau is row strict if the entries in each row are in (strictly) increasing order.

**EXAMPLES:**

```
sage: Tableau([[1, 3], [2, 4]]).is_row_strict()
True

sage: Tableau([[1, 2], [2, 4]]).is_row_strict()
True

sage: Tableau([[2, 3], [2, 4]]).is_row_strict()
True

sage: Tableau([[5, 3], [2, 4]]).is_row_strict()
False
```

```python
>>> from sage.all import *

>>> Tableau([[Integer(1), Integer(3)],
               [Integer(2), Integer(4)]]).is_row_strict()
True

>>> Tableau([[Integer(1), Integer(2)],
               [Integer(2), Integer(4)]]).is_row_strict()
True

>>> Tableau([[Integer(2), Integer(3)],
               [Integer(2), Integer(4)]]).is_row_strict()
True

>>> Tableau([[Integer(5), Integer(3)],
               [Integer(2), Integer(4)]]).is_row_strict()
False
```

**is_semistandard()**

Return `True` if `self` is a semistandard tableau, and `False` otherwise.

A tableau is semistandard if its rows weakly increase and its columns strictly increase.

**EXAMPLES:**

```
sage: Tableau([[1,1],[1,2]]).is_semistandard()
False

sage: Tableau([[1,2],[1,2]]).is_semistandard()
False

sage: Tableau([[1,1],[2,2]]).is_semistandard()
True
```

(continues on next page)
is_standard()  
Return True if self is a standard tableau and False otherwise.  

EXAMPLES:

```python
sage: Tableau([[1, 3], [2, 4]]).is_standard()
True  
sage: Tableau([[1, 2], [2, 4]]).is_standard()
False  
sage: Tableau([[2, 3], [2, 4]]).is_standard()
False  
sage: Tableau([[5, 3], [2, 4]]).is_standard()
False
```

k_weight\((k)\)  
Return the \(k\)-weight of self.  

A tableau has \(k\)-weight \(\alpha = (\alpha_1, ..., \alpha_n)\) if there are exactly \(\alpha_i\) distinct residues for the cells occupied by the letter \(i\) for each \(i\). The residue of a cell in position \((a, b)\) is \(a - b\) modulo \(k + 1\).  

This definition is the one used in [Ive2012] (p. 12).
EXAMPLES:

```python
sage: Tableau([[1,2],[2,3]]).k_weight(1)
[1, 1, 1]
sage: Tableau([[1,2],[2,3]]).k_weight(2)
[1, 2, 1]
sage: t = Tableau([[1,1,1,2,5],[2,3,6],[3],[4]])
sage: t.k_weight(1)
[2, 1, 1, 1, 1]
sage: t.k_weight(2)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(3)
[3, 1, 2, 1, 1, 1]
sage: t.k_weight(4)
[3, 2, 2, 1, 1, 1]
sage: t.k_weight(5)
[3, 2, 2, 1, 1, 1]

>>> from sage.all import *

>>> Tableau([[Integer(1),Integer(2)],[Integer(2),Integer(3)]]).k_weight(Integer(1))
[1, 1, 1]
>>> Tableau([[Integer(1),Integer(2)],[Integer(2),Integer(3)]]).k_weight(Integer(2))
[1, 2, 1]
>>> t = Tableau([[Integer(1),Integer(1),Integer(1),Integer(2),Integer(5)],[Integer(2),Integer(3),Integer(6)],[Integer(3)],[Integer(4)]]),

```  

\[\text{lambda_catabolism}(\text{part})\]

Return the part-catabolism of self, where part is a partition (which can be just given as an array).

For a partition \(\lambda\) and a tableau \(T\), the \(\lambda\)-catabolism of \(T\) is defined by performing the following steps.

1. Truncate the parts of \(\lambda\) so that \(\lambda\) is contained in the shape of \(T\). Let \(m\) be the length of this partition.
2. Let \(T_a\) be the first \(m\) rows of \(T\), and \(T_b\) be the remaining rows.
3. Let \(S_a\) be the skew tableau \(T_a/\lambda\).
4. Concatenate the reading words of \(S_a\) and \(T_b\), and insert into a tableau.

EXAMPLES:

```python
sage: Tableau([[1,1,3],[2,4,5]]).lambda_catabolism([2,1])
[[3, 5], [4]]
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.lambda_catabolism([1])

(continues on next page)
last_letter_lequal (tab2)

Return True if self is less than or equal to tab2 in the last letter ordering.

EXAMPLES:

```python
>>> from sage.all import *
>>> t = Tableau([[Integer(1), Integer(1), Integer(3)], [Integer(2), Integer(4),
<-Integer(5)]]).lambda_catalysis([Integer(2), Integer(1)])
[[3, 5], [4]]
>>> t = Tableau([[Integer(1), Integer(1), Integer(3), Integer(3)], [Integer(2),
<-Integer(3)], [Integer(3)]])
[[1, 1, 3, 3], [2, 3], [3]]
>>> t.lambda_catalysis([])
[[1, 2, 3, 3, 3], [3]]
>>> t.lambda_catalysis([Integer(1)])
[[1, 3, 3, 3], [3]]
>>> t.lambda_catalysis([Integer(2), Integer(1)])
[[3, 3, 3, 3]]
>>> t.lambda_catalysis([Integer(4), Integer(2), Integer(1)])
[]
>>> t.lambda_catalysis([Integer(5), Integer(1)])
[[3, 3]]
>>> t.lambda_catalysis([Integer(4), Integer(1)])
[[3, 3]]
```
left_key_tableau()

Return the left key tableau of self.

The left key tableau of a tableau $T$ is the key tableau whose entries are weakly lesser than the corresponding entries in $T$, and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

ALGORITHM:

The following algorithm follows [Wil2010]. Note that if $T$ is a key tableau then the output of the algorithm is $T$.

To compute the left key tableau $L$ of a tableau $T$ we iterate over the columns of $T$. Let $T_j$ be the $j$-th column of $T$ and iterate over the entries in $T_j$ from bottom to top. Initialize the corresponding entry $k$ in $L$ as the largest entry in $T_j$. Scan the columns to the left of $T_j$ and with each column update $k$ to be the lowest entry in that column which is weakly less than $k$. Update $T_j$ and all columns to the left by removing all scanned entries.

See also:

• is_key_tableau()

EXAMPLES:

```python
sage: t = Tableau([[1,2],[2,3]])
sage: t.left_key_tableau()
[[1, 1], [2, 2]]
```

leq(secondtab)

Check whether each entry of self is less-or-equal to the corresponding entry of a further tableau secondtab.

INPUT:

• secondtab—a tableau of the same shape as self

EXAMPLES:

```python
sage: T = Tableau([[1, 2], [3]])
sage: S = Tableau([[1, 3], [3]])
sage: G = Tableau([[2, 1], [4]])
sage: H = Tableau([[1, 2], [4]])
```
| sage: | T.leq(S) | True |
|       | T.leq(T) | True |
|       | T.leq(G) | False |
|       | T.leq(H) | True |
|       | S.leq(T) | False |
|       | S.leq(G) | False |
|       | S.leq(H) | False |
|       | G.leq(H) | False |
|       | H.leq(G) | False |

```python
>>> from sage.all import *
>>> T = Tableau([[Integer(1), Integer(2)], [Integer(3)]]
>>> S = Tableau([[Integer(1), Integer(3)], [Integer(3)]]
>>> G = Tableau([[Integer(2), Integer(1)], [Integer(4)]]
>>> H = Tableau([[Integer(1), Integer(2)], [Integer(4)]]
>>> T.leq(S)
True
>>> T.leq(T)
True
>>> T.leq(G)
False
>>> T.leq(H)
True
>>> S.leq(T)
False
>>> S.leq(G)
False
>>> S.leq(H)
False
>>> G.leq(H)
False
>>> H.leq(G)
False
```

**level()**

Return the level of self, which is always 1.

This function exists mainly for compatibility with `TableauTuple`.

**EXAMPLES:**

```python
sage: Tableau([[1,2,3],[4,5]]).level()
1
```

```python
>>> from sage.all import *
>>> Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]]).
˓→level()
1
```
major_index()

Return the major index of self.

The major index of a tableau $T$ is defined to be the sum of the number of descents of $T$ (defined in descents()) with the sum of their legs' lengths.

Warning: This is not to be confused with the major index of a standard tableau.

EXAMPLES:

```
sage: Tableau( [[1,4],[2,3]] ).major_index()
1
sage: Tableau( [[1,2],[3,4]] ).major_index()
2
```

```
>>> from sage.all import *

>>> Tableau( [[Integer(1),Integer(4)], [Integer(2),Integer(3)] ] ).major_index()
1
```

If the major index would be defined in the sense of standard tableaux theory, then the following would give 3 for a result:

```
sage: Tableau( [[1,2,3],[4,5]] ).major_index()
2
```

```
>>> from sage.all import *

>>> Tableau( [[Integer(1),Integer(2),Integer(3)], [Integer(4),Integer(5)] ] ).major_index()
2
```

plot(descents=False)

Return a plot self.

If English notation is set then the first row of the tableau is on the top:

If French notation is set, the first row of the tableau is on the bottom:

If Russian notation is set, we tilt the French notation by 45 degrees:

INPUT:

- descents – boolean (default: False); if True, then the descents are marked in the tableau; only valid if self is a standard tableau
EXAMPLES:

```python
sage: t = Tableau([[1,2,4],[3]])
sage: t.plot()  # needs sage.plot
Graphics object consisting of 11 graphics primitives
sage: t.plot(descents=True)  # needs sage.plot
Graphics object consisting of 12 graphics primitives

sage: t = Tableau([[2,2,4],[3]])
                #<...>
```
needs sage.plot
Traceback (most recent call last):
...
ValueError: the tableau must be standard for 'descents=True'

pp()
Pretty print a string of the tableau.

EXAMPLES:

```
sage: T = Tableau([[1,2,3],[3,4],[5]])
sage: T.pp()
  1 2 3
  3 4
  5
sage: Tableaux.options.convention="french"
sage: T.pp()
  5
  3 4
  1 2 3
sage: Tableaux.options.convention="russian"
sage: T.pp()
  5 4 3
  3 2
  1
sage: Tableaux.options._reset()
```

```
>>> from sage.all import *
>>> T = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(3),Integer(4)],
              [Integer(5)]])
>>> T.pp()
  1 2 3
  3 4
  5
>>> Tableaux.options.convention="french"
>>> T.pp()
  5
  3 4
  1 2 3
>>> Tableaux.options.convention="russian"
>>> T.pp()
  5 4 3
  3 2
  1
>>> Tableaux.options._reset()
```

promotion(n)
Return the image of self under the promotion operator.

**Warning:** You might know this operator as the inverse promotion operator – literature does not agree on the name. You might also be looking for the Lapointe–Lascoux–Morse promotion operator (promotion_operator()).

The promotion operator, applied to a tableau t, does the following:
Iterate over all letters \( n + 1 \) in the tableau \( t \), from left to right. For each of these letters, do the following:

- Remove the letter from \( t \), thus leaving a hole where it used to be.
- Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of \( t \).
- Fill 0 into the hole once jeu de taquin has completed.

Once this all is done, add 1 to each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all \( \leq n + 1 \), this is the usual promotion operator defined on this class.

When \( \text{self} \) is a standard tableau of size \( n + 1 \), this definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called “promotion” in [Sag2011] (p. 23) and in [Stan2009].

Warning: To my (Darij’s) knowledge, the fact that the above promotion operator really is the inverse of the “inverse promotion operator” \( \text{promotion\_inverse()} \) for semistandard tableaux has never been proven in literature. Corrections are welcome.

REFERENCES:
- [Hai1992]
- [Sag2011]

EXAMPLES:

```
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,1,1],[2,2,3],[3,4,4]])
sage: t.promotion(3)
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]

sage: t = Tableau([[1,2],[2]])
sage: t.promotion(3)
[[2, 3], [3]]

sage: t = Tableau([[1,1,3],[2,3]])
sage: t.promotion(2)
[[1, 1, 2], [2, 3]]

sage: t = Tableau([[1,1,3],[2,2]])
sage: t.promotion(2)
[[1, 2, 2], [3, 3]]

sage: t = Tableau([[1,1,3],[2]])
sage: t.promotion(2)
[[1, 2, 2], [3, 3]]

>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(3)]]))
>>> t.promotion(Integer(2))
[[1, 1], [2, 3]]

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

Construct \([\text{Integer}(3)], [\text{Integer}(3), \text{Integer}(4), \text{Integer}(4)]\))

```python
>>> t.promotion(Integer(3))
[[1, 1, 2], [2, 2, 3], [3, 4, 4]]
```

```python
>>> t = Tableau([[Integer(1), Integer(2)], [Integer(2)]])
>>> t.promotion(Integer(3))
[[2, 3], [3]]
```

```python
>>> t = Tableau([[Integer(1), Integer(1), Integer(3)], [Integer(2), Integer(2)]]
>>> t.promotion(Integer(2))
[[1, 2, 2], [3, 3]]
```

```python
>>> t = Tableau([[Integer(1), Integer(1), Integer(3)], [Integer(2), Integer(3)]]
>>> t.promotion(Integer(2))
[[1, 2, 2], [3, 3]]
```

```python
>>> t = Tableau([])
>>> t.promotion(Integer(2))
[]
```

`promotion_inverse(n)`

Return the image of `self` under the inverse promotion operator.

**Warning:** You might know this operator as the promotion operator (without “inverse”) – literature does not agree on the name.

The inverse promotion operator, applied to a tableau `t`, does the following:

1. Iterate over all letters 1 in the tableau `t`, from right to left. For each of these letters, do the following:
   - Remove the letter from `t`, thus leaving a hole where it used to be.
   - Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of `t`.
   - Fill `n + 2` into the hole once jeu de taquin has completed.

Once this all is done, subtract 1 from each letter in the tableau. This is not always well-defined. Restricted to the class of semistandard tableaux whose entries are all \(\leq n + 1\), this is the usual inverse promotion operator defined on this class.

When `self` is a standard tableau of size `n + 1`, this definition of inverse promotion is the map called “promotion” in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called “promotion” in [Hai1992] (p. 90).

**Warning:** To my (Darij’s) knowledge, the fact that the above “inverse promotion operator” really is the inverse of the promotion operator `promotion()` for semistandard tableaux has never been proven in literature. Corrections are welcome.

**EXAMPLES:**

```python
sage: t = Tableau([[1,2],[3,3]])
sage: t.promotion_inverse(2)
[[1, 2], [2, 3]]
```

(continues on next page)
Combinatorics, Release 10.4

sage: t = Tableau([[1,2],[2,3]])
sage: t.promotion_inverse(2)
[[1, 1], [2, 3]]

sage: t = Tableau([[1,2,5],[3,3,6],[4,7]])
sage: t.promotion_inverse(8)
[[1, 2, 4], [2, 5, 9], [3, 6]]

sage: t = Tableau([])
sage: t.promotion_inverse(2)
[]

>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(3)]])
>>> t.promotion_inverse(Integer(2))
[[1, 2], [2, 3]]

>>> t = Tableau([[Integer(1),Integer(2)],[Integer(2),Integer(3)]])
>>> t.promotion_inverse(Integer(2))
[[1, 1], [2, 3]]

promotion_operator(i)
Return a list of semistandard tableaux obtained by the \( i \)-th Lapointe-Lascoux-Morse promotion operator from the semistandard tableau \( self \).

**Warning:** This is not Schuetzenberger’s jeu de taquin promotion! For the latter, see `promotion()` and `promotion_inverse()`.

This operator is defined by taking the maximum entry \( m \) of \( T \), then adding a horizontal \( i \)-strip to \( T \) in all possible ways, each time filling this strip with \( m+1 \)'s, and finally letting the permutation \( \sigma_1\sigma_2\cdots\sigma_m = (2, 3, \ldots, m + 1, 1) \) act on each of the resulting tableaux via the Lascoux-Schuetzenberger action (`sym-metric_group_action_on_values()`). This method returns the list of all resulting tableaux. See [LLM2003] for the purpose of this operator.

**EXAMPLES:**

sage: t = Tableau([[1,2],[3]])
sage: t.promotion_operator(1)
[[[1, 2, 4], [3]], [[1, 2], [3, 4]], [[1, 2], [3], [4]]]

sage: t = Tableau([[]])
sage: t.promotion_operator(2)
[[[1, 1], [2, 3], [4]]]

(continues on next page)
```python
sage: Tableau([[1]]).promotion_operator(2)
[[[1, 1, 2], [2]],
 [[1, 1], [2]]]

sage: Tableau([[1],[2]]).promotion_operator(3)
[[[1, 1, 2, 3], [2]],
 [[1, 1, 3], [2]],
 [[1, 1, 2], [2, 3]],
 [[1, 1], [2, 2], [3]]]

>>> from sage.all import *

>>> t = Tableau([[Integer(1),Integer(2)],[Integer(3)]]

>>> t.promotion_operator(Integer(1))
[[[1, 2, 4], [3]],
 [[1, 2, 3, 4]],
 [[1, 2], [3, 4]]

>>> t.promotion_operator(Integer(2))
[[[1, 1, 2, 4], [3]],
 [[1, 1, 4], [2, 3]],
 [[1, 1, 2], [3], [4]],
 [[1, 1], [2, 3], [4]]

>>> Tableau([[Integer(1)]]).promotion_operator(Integer(2))
[[[1, 1, 2], [3]],
 [[1, 1, 3], [2]],
 [[1, 1, 2], [2], [3]],
 [[1, 1], [2, 2], [3]]]

The example from [LLM2003] p. 12:

```python
sage: Tableau([[1,1],[2,2]]).promotion_operator(3)
[[[1, 1, 1, 3, 3], [2, 2]],
 [[1, 1, 1, 3], [2, 2], [3]],
 [[1, 1, 1], [2, 2], [3, 3]]

>>> from sage.all import *

>>> Tableau([[Integer(1),Integer(1)],[Integer(2),Integer(2)]]).promotion_operator(Integer(3))
[[[1, 1, 1, 2, 3, 3], [2, 2]],
 [[1, 1, 1, 3, 3], [2, 2], [3]],
 [[1, 1, 1], [2, 2], [3, 3]]
```

```python
raise_action_from_words(f, *args)

EXAMPLES:
```
>>> from sage.all import *
>>> from sage.combinat.tableau import symmetric_group_action_on_values
>>> import functools

```
>>> t = Tableau([[Integer(1), Integer(1), Integer(3), Integer(3)],
               [Integer(2), Integer(3)],
               [Integer(3)]]

>>> f = functools.partial(t.raise_action_from_words, symmetric_group_action_on_values)

>>> f([Integer(1), Integer(2), Integer(3)])
[[1, 1, 3, 3], [2, 3], [3]]

>>> f([Integer(3), Integer(2), Integer(1)])
[[1, 1, 1, 1], [2, 3], [3]]

>>> f([Integer(1), Integer(3), Integer(2)])
[[1, 1, 2, 2], [2, 2], [3]]
```

**reading_word_permutation()**

Return the permutation obtained by reading the entries of the standardization of `self` row by row, starting with the bottommost row (in English notation).

**EXAMPLES:**

```
sage: StandardTableau([[1,2],[3,4]]).reading_word_permutation()
[3, 4, 1, 2]
```

Check that Issue #14724 is fixed:

```
sage: SemistandardTableau([[1,1]]).reading_word_permutation()
[1, 2]
```

**reduced_column_word()**

Return the lexicographically minimal reduced expression for the permutation that maps the conjugate of the `initial_tableau()` to `self`.

This reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the columns of the tableau in order from top to bottom.

**EXAMPLES:**

```
sage: StandardTableau([[1,4,6],[2,5],[3]]).reduced_column_word()
[]
sage: StandardTableau([[1,4,5],[2,6],[3]]).reduced_column_word()
[5]
sage: StandardTableau([[1,3,6],[2,5],[4]]).reduced_column_word()
[3]
sage: StandardTableau([[1,3,5],[2,6],[4]]).reduced_column_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_column_word()
[3, 2, 5]
```
reduced_lambda_catabolism (part)

EXAMPLES:

```python
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.reduced_lambda_catabolism([])
[[1, 1, 3, 3], [2, 3], [3]]
sage: t.reduced_lambda_catabolism([1])
[[1, 2, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([1,1])
[[1, 3, 3, 3], [3]]
sage: t.reduced_lambda_catabolism([2,1])
[[3, 3, 3, 3]]
sage: t.reduced_lambda_catabolism([4,2,1])
[]
sage: t.reduced_lambda_catabolism([5,1])
0
sage: t.reduced_lambda_catabolism([4,1])
0
```

reduced_row_word()

Return the lexicographically minimal reduced expression for the permutation that maps the initial_tableau() to self.
The reduced expression is a minimal length coset representative for the corresponding Young subgroup. In one line notation, the permutation is obtained by concatenating the rows of the tableau in order from top to bottom.

EXAMPLES:

```
sage: StandardTableau([[1,2,3],[4,5],[6]]).reduced_row_word()
[]
sage: StandardTableau([[1,2,3],[4,6],[5]]).reduced_row_word()
[5]
sage: StandardTableau([[1,2,4],[3,6],[5]]).reduced_row_word()
[3, 5]
sage: StandardTableau([[1,2,5],[3,6],[4]]).reduced_row_word()
[3, 5, 4]
sage: StandardTableau([[1,2,6],[3,5],[4]]).reduced_row_word()
[3, 4, 5, 4]
```

```python
>>> from sage.all import *
>>> StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),
˓→Integer(5)],[Integer(6)]].reduced_row_word()
[]
>>> StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),
˓→Integer(5)],[Integer(6)]]).reduced_row_word()
[5]
>>> StandardTableau([[Integer(1),Integer(2),Integer(4)],[Integer(3),
˓→Integer(6)],[Integer(5)]]).reduced_row_word()
[3, 5]
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),
˓→Integer(6)],[Integer(4)]]).reduced_row_word()
[3, 5, 4]
>>> StandardTableau([[Integer(1),Integer(2),Integer(6)],[Integer(3),
˓→Integer(5)],[Integer(4)]]).reduced_row_word()
[3, 4, 5, 4]
```

residue \((k, e, \text{multicharge}=(0,))\)

Return the residue of the integer \(k\) in the tableau \(self\).

The residue of \(k\) in a standard tableau is \(c - r + m\) in \(\mathbb{Z}/e\mathbb{Z}\), where \(k\) appears in row \(r\) and column \(c\) of the tableau with multicharge \(m\).

INPUT:

- \(k\) – an integer in \(\{1,2,\ldots,n\}\)
- \(e\) – an integer in \(\{0,2,3,4,5,\ldots\}\)
- \(\text{multicharge}\) – (default: \([0]\)) a list of length 1

Here \(n\) is its size of \(self\).

The multicharge is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with \texttt{residue()}.

OUTPUT:

The residue in \(\mathbb{Z}/e\mathbb{Z}\).

EXAMPLES:

```
sage: StandardTableau([[1,2,5],[3,4]]).residue(1,3)
0
```
sage: StandardTableau([[1,2,5],[3,4]]).residue(2,3)
1
sage: StandardTableau([[1,2,5],[3,4]]).residue(3,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(4,3)
0
sage: StandardTableau([[1,2,5],[3,4]]).residue(5,3)
2
sage: StandardTableau([[1,2,5],[3,4]]).residue(6,3)
Traceback (most recent call last):
  ... ValueError: 6 does not appear in the tableau

>>> from sage.all import *

>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],
                   [Integer(3),Integer(4)]]).residue(Integer(1),Integer(3))
0
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],
                   [Integer(3),Integer(4)]]).residue(Integer(2),Integer(3))
1
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],
                   [Integer(3),Integer(4)]]).residue(Integer(3),Integer(3))
2
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],
                   [Integer(3),Integer(4)]]).residue(Integer(4),Integer(3))
0
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],
                   [Integer(3),Integer(4)]]).residue(Integer(5),Integer(3))
2
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],
                   [Integer(3),Integer(4)]]).residue(Integer(6),Integer(3))
Traceback (most recent call last):
  ... ValueError: 6 does not appear in the tableau

residue_sequence\( (e,\text{ multicharge}=(0,))\)

Return the \texttt{sage.combinat.tableau_residues.ResidueSequence} of the tableau \texttt{self}.

INPUT:

\begin{itemize}
  \item \texttt{e} – an integer in \{0, 2, 3, 4, 5, ...\}
  \item \texttt{multicharge} – (default: [0]) a sequence of integers of length 1
\end{itemize}

The \textit{multicharge} is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with \texttt{residue()}.

OUTPUT:

The corresponding residue sequence of the tableau; see \texttt{ResidueSequence}.

EXAMPLES:

\begin{verbatim}
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(2) #˓→ needs sage.groups
2-residue sequence (0,1,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(3) #˓→ needs sage.groups
\end{verbatim}
3-residue sequence (0,1,2,0) with multicharge (0)
sage: StandardTableauTuple([[1,2],[3,4]]).residue_sequence(4)  # needs sage.groups
4-residue sequence (0,1,3,0) with multicharge (0)

>>> from sage.all import *
>>> StandardTableauTuple([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).residue_sequence(Integer(2))  # needs sage.groups
2-residue sequence (0,1,0) with multicharge (0)
>>> StandardTableauTuple([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).residue_sequence(Integer(3))  # needs sage.groups
3-residue sequence (0,1,0) with multicharge (0)
>>> StandardTableauTuple([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).residue_sequence(Integer(4))  # needs sage.groups
4-residue sequence (0,1,0) with multicharge (0)

\[ \text{restrict} \ (n) \]

Return the restriction of the semistandard tableau \( \text{self} \) to \( n \). If possible, the restricted tableau will have the same parent as this tableau.

If \( T \) is a semistandard tableau and \( n \) is a nonnegative integer, then the restriction of \( T \) to \( n \) is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than \( n \) from \( T \).

\[ \textbf{Note:} \] If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method \texttt{restriction_shape()} is preferred.

\[ \text{EXAMPLES:} \]

\[\text{sage: Tableau([[1,2],[3],[4]]).restrict(3)} \]
\[ [[[1, 2], [3]]] \]
\[\text{sage: Tableau([[1,2],[3],[4]]).restrict(2)} \]
\[ [[[1, 2]]] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)} \]
\[ [] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(2)} \]
\[ [[[1, 2, 3], [2, 4, 4], [3]]] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)} \]
\[ [[[1, 2, 3], [2, 4, 4], [3]]] \]

\[ \text{restrict (n)} \]

Return the restriction of the semistandard tableau \( \text{self} \) to \( n \). If possible, the restricted tableau will have the same parent as this tableau.

If \( T \) is a semistandard tableau and \( n \) is a nonnegative integer, then the restriction of \( T \) to \( n \) is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than \( n \) from \( T \).

\[ \textbf{Note:} \] If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method \texttt{restriction_shape()} is preferred.

\[ \text{EXAMPLES:} \]

\[\text{sage: Tableau([[1,2],[3],[4]]).restrict(3)} \]
\[ [[[1, 2], [3]]] \]
\[\text{sage: Tableau([[1,2],[3],[4]]).restrict(2)} \]
\[ [[[1, 2]]] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)} \]
\[ [] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(2)} \]
\[ [[[1, 2, 3], [2, 4, 4], [3]]] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)} \]
\[ [[[1, 2, 3], [2, 4, 4], [3]]] \]

\[ \text{restrict (n)} \]

Return the restriction of the semistandard tableau \( \text{self} \) to \( n \). If possible, the restricted tableau will have the same parent as this tableau.

If \( T \) is a semistandard tableau and \( n \) is a nonnegative integer, then the restriction of \( T \) to \( n \) is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than \( n \) from \( T \).

\[ \textbf{Note:} \] If only the shape of the restriction, rather than the whole restriction, is needed, then the faster method \texttt{restriction_shape()} is preferred.

\[ \text{EXAMPLES:} \]

\[\text{sage: Tableau([[1,2],[3],[4]]).restrict(3)} \]
\[ [[[1, 2], [3]]] \]
\[\text{sage: Tableau([[1,2],[3],[4]]).restrict(2)} \]
\[ [[[1, 2]]] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)} \]
\[ [] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(2)} \]
\[ [[[1, 2, 3], [2, 4, 4], [3]]] \]
\[\text{sage: Tableau([[1,2,3],[2,4,4],[3]]).restrict(0)} \]
\[ [[[1, 2, 3], [2, 4, 4], [3]]] \]
If possible the restricted tableau will belong to the same category as the original tableau:

```python
sage: S = StandardTableau([[Integer(1),Integer(2),Integer(4),Integer(7)], [Integer(3),Integer(5)], [Integer(6)]]); S.category()
Category of elements of Standard tableaux
sage: S.restrict(Integer(4)).category()
Category of elements of Standard tableaux
sage: SS=StandardTableaux([Integer(4),Integer(2),Integer(1)])([[Integer(1),Integer(2),Integer(4),Integer(7)], [Integer(3),Integer(5)], [Integer(6)]]); SS.category()
Category of elements of Standard tableaux of shape [4, 2, 1]
sage: SS.restrict(Integer(4)).category()
Category of elements of Standard tableaux
sage: Tableau([[Integer(1),Integer(2)], [Integer(3)], [Integer(4)]]).restrict(Integer(3))
[[1, 2], [3]]
sage: Tableau([[Integer(1),Integer(2)], [Integer(3)], [Integer(4)]]).restrict(Integer(2))
[[1, 2]]
sage: SemistandardTableau([[Integer(1),Integer(1)], [Integer(2)]]).restrict(Integer(1))
[[1, 1]]
sage: _.category()
Category of elements of Semistandard tableaux
```

```python
restriction_shape(n)
Return the shape of the restriction of the semistandard tableau `self` to `n`.
If `T` is a semistandard tableau and `n` is a nonnegative integer, then the restriction of `T` to `n` is defined as the (semistandard) tableau obtained by removing all cells filled with entries greater than `n` from `T`.
```
This method computes merely the shape of the restriction. For the restriction itself, use \texttt{restrict()}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Tableau([[1,2],[2,3],[3,4]]).restriction_shape(3) [2, 2, 1]
sage: StandardTableau([[1,2],[3],[4],[5]]).restriction_shape(2) [2]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(0) []
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(2) [1, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(3) [3, 1]
sage: Tableau([[1,3,3,5],[2,4,4],[17]]).restriction_shape(5) [4, 3]
sage: all( T.restriction_shape(i) == Trestrict(i).shape() 
      ....:   for T in StandardTableaux(5) for i in range(1, 5) )
True
\end{verbatim}

\texttt{reverse\_bump(loc)}

Reverse row bump the entry of \texttt{self} at the specified location \texttt{loc} (given as a row index or a corner \((r, c)\) of the tableau).

This is the reverse of Schensted's row-insertionalgorithm. See Section 1.1, page 8, of Fulton's [Ful1997].

\textbf{INPUT:}

- \texttt{loc} – Can be either of the following:
  - The coordinates \((r, c)\) of the square to reverse-bump (which must be a corner of the tableau);
  - The row index \(r\) of this square.
Note that both \( r \) and \( c \) are 0-based, i.e., the topmost row and the leftmost column are the 0-th row and the 0-th column.

**OUTPUT:**

An ordered pair consisting of:

1. The resulting (smaller) tableau;
2. The entry bumped out at the end of the process.

**See also:**

*bump()*

**EXAMPLES:**

This is the reverse of Schensted’s bump:

```python
sage: T = Tableau([[1, 1, 2, 2, 4], [2, 3, 3], [3, 4], [4]])
sage: T.reverse_bump(2)
([[1, 1, 2, 3, 4], [2, 3, 4], [3], [4]], 2)
sage: T == T.reverse_bump(2)[0].bump(2)
True
sage: T.reverse_bump((3, 0))
([[1, 2, 2, 2, 4], [3, 3, 3], [4, 4]], 1)
```

Some errors caused by wrong input:

```python
sage: T.reverse_bump((3, 1))
Traceback (most recent call last):
  ... ValueError: invalid corner
sage: T.reverse_bump(4)
Traceback (most recent call last):
  ... IndexError: list index out of range
sage: Tableau([[2, 2, 1], [3, 3]]).reverse_bump(0)
Traceback (most recent call last):
  ... ValueError: reverse bumping is only defined for semistandard tableaux
```

(continues on next page)
IndexError: list index out of range
>>> Tableau([[Integer(2), Integer(2), Integer(1)], [Integer(3), Integer(3)]]).reverse_bump(Integer(0))
Traceback (most recent call last):
... ValueError: reverse bumping is only defined for semistandard tableaux

Some edge cases:

sage: Tableau([[1]]).reverse_bump(0)
([], 1)
sage: Tableau([[1,1]]).reverse_bump(0)
([], 1)
sage: Tableau([]).reverse_bump(0)
Traceback (most recent call last):
...
IndexError: list index out of range

>>> from sage.all import *

>>> Tableau([[Integer(1)]]).reverse_bump(Integer(0))
([], 1)
>>> Tableau([[Integer(1),Integer(1)]]).reverse_bump(Integer(0))
([], 1)
>>> Tableau([]).reverse_bump(Integer(0))
Traceback (most recent call last):
...
IndexError: list index out of range

Note: Reverse row bumping is only implemented for tableaux with weakly increasing and strictly increasing columns (though the tableau does not need to be an instance of class `SemistandardTableau`).

**right_key_tableau()**

Return the right key tableau of `self`.

The right key tableau of a tableau `T` is a key tableau whose entries are weakly greater than the corresponding entries in `T`, and whose column reading word is subject to certain conditions. See [LS1990] for the full definition.

**ALGORITHM:**

The following algorithm follows [Wil2010]. Note that if `T` is a key tableau then the output of the algorithm is `T`.

To compute the right key tableau `R` of a tableau `T` we iterate over the columns of `T`. Let `T_j` be the `j`-th column of `T` and iterate over the entries in `T_j` from bottom to top. Initialize the corresponding entry `k` in `R` to be the largest entry in `T_j`. Scan the bottom of each column of `T` to the right of `T_j`, updating `k` to be the scanned entry whenever the scanned entry is weakly greater than `k`. Update `T_j` and all columns to the right by removing all scanned entries.

See also:

- `is_key_tableau()`

**EXAMPLES:**
**rotate_180()**

Return the tableau obtained by rotating `self` by 180 degrees.

This only works for rectangular tableaux.

**EXAMPLES:**

```python
sage: Tableau([[1,2],[3,4]]).rotate_180()
[[4, 3], [2, 1]]
```

**row_stabilizer()**

Return the `PermutationGroup` corresponding to the row stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

**EXAMPLES:**

```python
sage: # needs sage.groups
sage: rs = Tableau([[1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3)*factorial(2)
True
sage: PermutationGroupElement(((1,3,2),(4,5))) in rs
True
sage: PermutationGroupElement(((1,4))) in rs
False
sage: rs = Tableau([[1,2],[3]]).row_stabilizer()
sage: PermutationGroupElement(((1,2),(3,))) in rs
True
sage: rs.one().domain()
[1, 2, 3]
sage: rs = Tableau([[1],[2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = Tableau([[2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = Tableau([]).row_stabilizer()
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> # needs sage.groups
>>> rs = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4),
  → Integer(5)]]).row_stabilizer()
>>> rs.order() == factorial(Integer(3)) * factorial(Integer(2))
True
>>> PermutationGroupElement(((Integer(1), Integer(3), Integer(2)),
  (Integer(4), → Integer(5)))) in rs
True
>>> PermutationGroupElement(((Integer(1), Integer(4)),)) in rs
False
>>> rs = Tableau([[Integer(1), Integer(2), [Integer(3)]]]).row_stabilizer()
>>> rs.order()
1
>>> rs = Tableau([[Integer(2), Integer(4), Integer(5), [Integer(1),
  → Integer(3)]]]).row_stabilizer()
>>> rs.order()
12
>>> rs = Tableau([]).row_stabilizer()
>>> rs.order()
1
```

schensted_insert (i, left=False)

Insert i into self using Schensted's row-bumping (or row-insertion) algorithm.

**INPUT:**

- i – a number to insert
- left – (default: False) boolean; if set to True, the insertion will be done from the left. That is, if one thinks of the algorithm as appending a letter to the reading word of self, we append the letter to the left instead of the right

**EXAMPLES:**

```python
sage: t = Tableau([[3, 5], [7]])
sage: t.schensted_insert(8)
[[3, 5, 8], [7]]
sage: t.schensted_insert(8, left=True)
[[3, 5], [7], [8]]
```

schuetzenberger_involution (n=None, check=True)

5474 Chapter 5. Comprehensive Module List
Return the Schützenberger involution of the tableau \texttt{self}.

This method relies on the analogous method on words, which reverts the word and then complements all letters within the underlying ordered alphabet. If \( n \) is specified, the underlying alphabet is assumed to be \( [1,2,\ldots,n] \). If no alphabet is specified, \( n \) is the maximal letter appearing in \texttt{self}.

**INPUT:**

- \( n \) – an integer specifying the maximal letter in the alphabet (optional)
- \texttt{check} – (Default: True) Check to make sure \texttt{self} is semistandard. Set to \texttt{False} to avoid this check. (optional)

**OUTPUT:**

- a tableau, the Schützenberger involution of \texttt{self}

**EXAMPLES:**

```python
sage: t = Tableau(
[[1,1,1],[2,2]])
sage: t.schuetzenberger_involution(3)
[[2, 2, 3], [3, 3]]

sage: t = Tableau(
[[1,2,3],[4,5]])
sage: t.schuetzenberger_involution()
[[1, 2, 5], [3, 4]]

sage: t = Tableau(

>>> t.schuetzenberger_involution()
[]

>>> t = StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),
Integer(5)]]))
```

(continues on next page)
seg()

Return the total number of segments in \texttt{self}, as in [Sal2014].

Let \( T \) be a tableaux. We define a \( k \)-segment of \( T \) (in the \( i \)-th row) to be a maximal consecutive sequence of \( k \)-boxes in the \( i \)-th row for any \( i + 1 \leq k \leq r + 1 \). Denote the total number of \( k \)-segments in \( T \) by \( \text{seg}(T) \).

REFERENCES:

- [Sal2014]

EXAMPLES:

```python
sage: t = Tableau([[1,1,2,3,5],[2,3,5,5],[3,4]])
sage: t.seg()
6
sage: B = crystals.Tableaux("A4", shape=[4,3,2,1])
# needs sage.modules
sage: t = B[31].to_tableau()
# needs sage.modules
sage: t.seg()
3
```

shape()

Return the shape of a tableau \texttt{self}.

EXAMPLES:

```python
sage: Tableau([[1,2,3],[4,5],[6]]).shape()
[3, 2, 1]
```
size()

Return the size of the shape of the tableau self.

EXAMPLES:

```python
sage: Tableau([[1, 4, 6], [2, 5], [3]]).size()
6
sage: Tableau([[1, 3], [2, 4]]).size()
4
```

slide_multiply(other)

Multiply two tableaux using jeu de taquin.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid.

See pp. 15 of [Ful1997].

The same product operation is implemented in a different way in `bump_multiply()`.

EXAMPLES:

```python
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.slide_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

socle()

EXAMPLES:

```python
sage: Tableau([[1,2],[3,4]]).socle()
2
sage: Tableau([[1,2,3,4]]).socle()
4
```

standardization(check=True)

Return the standardization of self, assuming self is a semistandard tableau.
The standardization of a semistandard tableau \( T \) is the standard tableau \( st(T) \) of the same shape as \( T \) whose reversed reading word is the standardization of the reversed reading word of \( T \).

The standardization of a word \( w \) can be formed by replacing all 1's in \( w \) by \( 1, 2, \ldots, k_1 \) from left to right, all 2's in \( w \) by \( k_1 + 1, k_1 + 2, \ldots, k_2 \), and repeating for all letters which appear in \( w \). See also Word.

**standard_permutation()**

**INPUT:**

- **check** – (Default: True) Check to make sure \( self \) is semistandard. Set to \( False \) to avoid this check.

**EXAMPLES:**

```
sage: t = Tableau([[1,3,3,4],[2,4,4],[5,16]])
sage: t.standardization()
[[1, 3, 4, 7], [2, 5, 6], [8, 9]]
```

Standard tableaux are fixed under standardization:

```
sage: all((t == t.standardization() for t in StandardTableaux(6)))
True
```

The reading word of the standardization is the standardization of the reading word:

```
sage: T = SemistandardTableaux(shape=[5,2,2,1], max_entry=4)
sage: all(t.to_word().standard_permutation() == t.standardization().reading_word_permutation() for t in T) # long time
True
```

**sulzgruber_correspondence()**

Return the image of the \( \lambda \)-array \( self \) under the Sulzgruber correspondence (as a \( WeakReversePlanePartition \)).

This relies on interpreting \( self \) as a \( \lambda \)-array in the sense of \( hillman_grassl \). See \( hillman_grassl \) for definitions of the objects involved.
The Sulzgruber correspondence is the map $\Phi_\lambda$ from [Sulzgr2017] Section 7, and is the map $\xi_\lambda^{-1}$ from [Pak2002] Section 5. It is denoted by $\mathcal{RSK}$ in [Hopkins2017]. It is the inverse of the Pak correspondence (pak_correspondence()). The following description of the Sulzgruber correspondence follows [Hopkins2017] (which denotes it by $\mathcal{RSK}$):

Fix a partition $\lambda$ (see Partition()). We draw all partitions and tableaux in English notation.

A $\lambda$-array will mean a tableau of shape $\lambda$ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape $\lambda$ (short: $\lambda$-rpp) will mean a $\lambda$-array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If $(u, v)$ is a cell of $\lambda$, and if $\pi$ is a $\lambda$-rpp, then:

- the lower bound of $\pi$ at $(u, v)$ (denoted by $\pi_{(u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
- the upper bound of $\pi$ at $(u, v)$ (denoted by $\pi^{(u,v)}$) is defined to be $\min\{\pi_{u+1,v}, \pi_{u,v+1}\}$ (where $\pi_{i,j}$ is understood to mean $+\infty$ if $(i,j)$ is not in $\lambda$; thus, the upper bound at a corner cell is $+\infty$).
- toggling $\pi$ at $(u,v)$ means replacing the entry $\pi_{u,v}$ of $\pi$ at $(u,v)$ by $\pi_{<(u,v)} + \pi_{>(u,v)} - \pi_{u,v}$ (this is well-defined as long as $(u,v)$ is not a corner of $\lambda$).

Note that every $\lambda$-rpp $\pi$ and every cell $(u,v)$ of $\lambda$ satisfy $\pi_{< (u,v)} \leq \pi_{u,v} \leq \pi_{> (u,v)}$. Note that toggling a $\lambda$-rpp (at a cell that is not a corner) always results in a $\lambda$-rpp. Also, toggling is an involution.

The Pak correspondence $\xi_\lambda$ sends a $\lambda$-rpp $\pi$ to a $\lambda$-array $\xi_\lambda(\pi)$. It is defined by recursion on $\lambda$ (that is, we assume that $\xi_\mu$ is already defined for every partition $\mu$ smaller than $\lambda$), and its definition proceeds as follows:

- If $\lambda = \emptyset$, then $\xi_\lambda$ is the obvious bijection sending the only $\emptyset$-rpp to the only $\emptyset$-array.
- Pick any corner $c = (i,j)$ of $\lambda$, and let $\mu$ be the result of removing this corner $c$ from the partition $\lambda$. (The exact choice of $c$ is immaterial.)
- Let $\pi'$ be what remains of $\pi$ when the corner cell $c$ is removed.
- For each positive integer $k$ such that $(i-k,j-k)$ is a cell of $\lambda$, toggle $\pi'$ at $(i-k,j-k)$. (All these togglings commute, so the order in which they are made is immaterial.)
- Let $M = \xi_\mu(\pi')$.
- Extend the $\mu$-array $M$ to a $\lambda$-array $M'$ by adding the cell $c$ and writing the number $\pi_{i,j} - \pi_{c(i,j)}$ into this cell.
- Set $\xi_\lambda(\pi) = M'$.

See also:

sulzgruber_correspondence() for the Sulzgruber correspondence as a standalone function.

pak_correspondence() for the inverse map.

EXAMPLES:

```
sage: a = Tableau([[2, 1, 1], [0, 2, 0], [1, 1]])
sage: A = a.sulzgruber_correspondence(); A
[[0, 1, 4], [1, 5, 5], [3, 6]]
sage: A.parent(), a.parent()
(Weak Reverse Plane Partitions, Tableaux)
sage: a = Tableau([[1, 3], [0, 1]])
sage: a.sulzgruber_correspondence()
[[0, 4], [1, 5]]
```
>>> from sage.all import *
>>> a = Tableau([[Integer(2), Integer(1), Integer(1)], [Integer(0),...
→Integer(2), Integer(0)], [Integer(1), Integer(1)]])
>>> A = a.sulzgruber_correspondence(); A
[[0, 1, 4], [1, 5, 5], [3, 6]]

symmetric_group_action_on_entries(w)

Return the tableau obtained form this tableau by acting by the permutation w.

Let T be a standard tableau of size n, then the action of \( w \in S_n \) is defined by permuting the entries of \( T \) (recall they are \( 1, 2, \ldots, n \)). In particular, suppose the entry at cell \( (i, j) \) is \( a \), then the entry becomes \( w(a) \). In general, the resulting tableau \( wT \) may not be standard.

Note: This is different than \( \text{symmetric_group_action_on_values()} \) which is defined on semi-standard tableaux and is guaranteed to return a semistandard tableau.

INPUT:

• \( w \) – a permutation

EXAMPLES:

sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(...
→Permutation(((4,5))) )
[[1, 2, 5], [3, 4]]
sage: _.category()
Category of elements of Standard tableaux
sage: StandardTableau([[1,2,4],[3,5]]).symmetric_group_action_on_entries(...
→Permutation(((1,2))) )
[[2, 1, 4], [3, 5]]
sage: _.category()
Category of elements of Tableaux

>>> from sage.all import *
>>> StandardTableau([[Integer(1),Integer(2),Integer(4)], [Integer(3),
→Integer(5)])].symmetric_group_action_on_entries( Permutation(((Integer(4),
→Integer(5)))) )
[[1, 2, 5], [3, 4]]
>>> _.category()
Category of elements of Standard tableaux
>>> StandardTableau([[Integer(1),Integer(2),Integer(4)], [Integer(3),
→Integer(5)])].symmetric_group_action_on_entries( Permutation(((Integer(1),
→Integer(2)))) )
[[2, 1, 4], [3, 5]]
>>> _.category()
Category of elements of Tableaux

symmetric_group_action_on_values(perm)

Return the image of the semistandard tableau \( \text{self} \) under the action of the permutation \( \text{perm} \) using the Lascoux-Schuetzenberger action of the symmetric group \( S_n \) on the semistandard tableaux with ceiling \( n \).
If $n$ is a nonnegative integer, then the Lascoux-Schuetzenberger action is a group action of the symmetric group $S_n$ on the set of semistandard Young tableaux with ceiling $n$ (that is, with entries taken from the set \{1, 2, \ldots, n\}). It is defined as follows:

Let $i \in \{1, 2, \ldots, n-1\}$, and let $T$ be a semistandard tableau with ceiling $n$. Let $w$ be the reading word \((\text{to_word()})\) of $T$. Replace all letters $i$ in $w$ by closing parentheses, and all letters $i+1$ in $w$ by opening parentheses. Whenever an opening parenthesis stands left of a closing parenthesis without there being any parentheses in between (it is allowed to have letters in-between as long as they are not parentheses), consider these two parentheses as matched with each other, and replace them back by the letters $i+1$ and $i$. Repeat this procedure until there are no more opening parentheses standing left of closing parentheses. Then, let $a$ be the number of opening parentheses in the word, and $b$ the number of closing parentheses (notice that all opening parentheses are right of all closing parentheses). Replace the first $a$ parentheses by the letters $i$, and replace the remaining $b$ parentheses by the letters $i+1$. Let $w'$ be the resulting word. Let $T'$ be the tableau with the same shape as $T$ but with reading word $w'$. This tableau $T'$ can be shown to be semistandard. We define the image of $T$ under the action of the simple transposition $s_i = (i, i+1) \in S_n$ to be this tableau $T'$. It can be shown that these actions of the transpositions $s_1, s_2, \ldots, s_{n-1}$ satisfy the Moore-Coxeter relations of $S_n$, and thus this extends to a unique action of the symmetric group $S_n$ on the set of semistandard tableaux with ceiling $n$. This is the Lascoux-Schuetzenberger action.

This action of the symmetric group $S_n$ on the set of all semistandard tableaux of given shape $\lambda$ with entries in \{1, 2, \ldots, n\} is the one defined in [Loth02] Theorem 5.6.3. In particular, the action of $s_i$ is denoted by $\sigma_i$ in said source. (Beware of the typo in the definition of $\sigma_i$: it should say $\sigma_i(a_i^r a_{i+1}^s) = a_i^r a_{i+1}^s$, not $\sigma_i(a_i^r a_{i+1}^s) = a_i^r a_{i+1}^s$.)

**EXAMPLES:**

```sage
t = Tableau([[1,1,3,3],[2,3],[3]])
t.symmetric_group_action_on_values([1,2,3])
t.symmetric_group_action_on_values([2,1,3])
t.symmetric_group_action_on_values([3,1,2])
t.symmetric_group_action_on_values([2,3,1])
t.symmetric_group_action_on_values([1,1,1,2])
t.symmetric_group_action_on_values([3,2,1])
t.symmetric_group_action_on_values([1,3,2])
```

```python
from sage.all import *
t = Tableau([[Integer(1),Integer(1),Integer(3),Integer(3)],[Integer(2),-Integer(3)],[Integer(3)]])
t.symmetric_group_action_on_values([Integer(1),Integer(2),Integer(3)])
t.symmetric_group_action_on_values([Integer(1),Integer(2),Integer(3)])
t.symmetric_group_action_on_values([Integer(2),Integer(1),Integer(3)])
t.symmetric_group_action_on_values([Integer(2),Integer(1),Integer(3)])
t.symmetric_group_action_on_values([Integer(3),Integer(1),Integer(2)])
t.symmetric_group_action_on_values([Integer(3),Integer(1),Integer(2)])
t.symmetric_group_action_on_values([Integer(3),Integer(2),Integer(1)])
t.symmetric_group_action_on_values([Integer(3),Integer(2),Integer(1)])
t.symmetric_group_action_on_values([Integer(1),Integer(3),Integer(2)])
t.symmetric_group_action_on_values([Integer(1),Integer(3),Integer(2)])
```

**to_Gelfand_Tsetlin_pattern()**

Return the Gelfand-Tsetlin pattern corresponding to self when semistandard.
EXAMPLES:

```python
sage: T = Tableau([[1,2,3],[2,3],[3]])
sage: G = T.to_Gelfand_Tsetlin_pattern(); G
[[3, 2, 1], [2, 1], [1]]
sage: G.to_tableau() == T
True
sage: T = Tableau([[1,3],[2]])
sage: T.to_Gelfand_Tsetlin_pattern()
[[2, 1, 0], [1, 1], [1]]
```

```python
to_chain(max_entry=None)

Return the chain of partitions corresponding to the (semi)standard tableau self.

The optional keyword parameter max_entry can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer n, then the chain is constructed from the positions of the letters 1, 2, ..., n in the tableau.

EXAMPLES:

```python
sage: Tableau([[1,2],[3],[4]]).to_chain()
[[], [1], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain()
[[], [2], [2, 1], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=2)
[[], [2], [2, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=3)
[[], [2], [2, 1, 1]]
sage: Tableau([[1,1],[2],[3]]).to_chain(max_entry=4)
[[], [2], [2, 1, 1], [2, 1, 1]]
sage: Tableau([[1,1,2],[2,3],[4,5]]).to_chain(max_entry=6)
[[], [2], [3, 1], [3, 2], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
```

```python
>>> from sage.all import *

```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> Tableau([[Integer(1), Integer(1)], [Integer(2)], [Integer(3)]]).to_chain(max_entry=Integer(2))
[[], [2], [2, 1]]
>>> Tableau([[Integer(1), Integer(1)], [Integer(2)], [Integer(3)]]).to_chain(max_entry=Integer(3))
[[], [2], [2, 1], [2, 1, 1]]
>>> Tableau([[Integer(1), Integer(1)], [Integer(2)], [Integer(3)]]).to_chain(max_entry=Integer(4))
[[], [2], [2, 1], [2, 1, 1], [2, 1, 1]]
>>> Tableau([[Integer(1), Integer(1), Integer(2)], [Integer(2), Integer(3)], [Integer(4), Integer(5)]]).to_chain(max_entry=Integer(6))
[[], [2], [3, 1], [3, 2], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
```

**to_list()**

Return *self* as a list of lists (not tuples!).

**EXAMPLES:**

```python
sage: t = Tableau([[1, 2], [3, 4]])
sage: l = t.to_list(); l
[[1, 2], [3, 4]]
sage: l[0][0] = 2
sage: t
[[1, 2], [3, 4]]
```

**to_sign_matrix** *(max_entry=None)*

Return the sign matrix of *self*.

A sign matrix is an \(m \times n\) matrix of 0’s, 1’s and -1’s such that the partial sums of each column is either 0 or 1 and the partial sums of each row is non-negative. [Ava2007]

**INPUT:**

- **max_entry** – A non-negative integer, the maximum allowable number in the tableau. Defaults to the largest entry in the tableau if not specified.

**EXAMPLES:**

```python
sage: from sage.all import *
sage: t = Tableau([[1, 2, 4], [3, 5]])
sage: t.to_sign_matrix(7)
# needs sage.modules
[[ 0 0 0 1 0 0]
 [ 0 1 0 -1 0 0]
 [ 1 -1 0 1 0 0]
 [ 0 0 1 -1 1 1]
 [ 0 0 0 1 -1 0]]
sage: t = SemistandardTableau([[1,1,1,2,4],[3,3,4],[4,5],[6,6]])
sage: t.to_sign_matrix(6)  # needs sage.modules
[[ 0 0 0 1 0 0]
 [ 0 1 0 -1 0 0]
 [ 1 -1 0 1 0 0]
 [ 0 0 1 -1 1 1]
 [ 0 0 0 1 -1 0]]
sage: t = Tableau([[1,2,4],[3,5]])
sage: t.to_sign_matrix(7)  # needs sage.modules
```

(continues on next page)

\end{bmatrix}
\]

``` 

```python
>>> s = Tableau([(Integer(1), Integer(0), -Integer(2), Integer(4)), (Integer(3), -Integer(4), Integer(5))])
>>> s.to_sign_matrix(Integer(6))
Traceback (most recent call last):
...
ValueError: the entries must be non-negative integers
``` 

```
to_word()
```

An alias for `to_word_by_row()`.

EXAMPLES:

```python
sage: Tableau([[1, 2], [3, 4]]).to_word()
word: 3412
```

```python
sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word()
word: 325146
```
```python
>>> from sage.all import *

>>> Tableau([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]).to_word()
word: 3412

>>> Tableau([[Integer(1), Integer(4), Integer(6)], [Integer(2), Integer(5)], [Integer(3)]]).to_word()
word: 325146
```

**to_word_by_column()**

Return the word obtained from a column reading of the tableau self (starting with the leftmost column, reading every column from bottom to top).

**EXAMPLES:**

```python
sage: Tableau([[1, 2], [3, 4]]).to_word_by_column()
word: 3142

sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_column()
word: 325146
```

```python
>>> from sage.all import *

>>> Tableau([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]).to_word_by_column()
word: 3142

>>> Tableau([[Integer(1), Integer(4), Integer(6)], [Integer(2), Integer(5)], [Integer(3)]]).to_word_by_column()
word: 325146
```

**to_word_by_row()**

Return the word obtained from a row reading of the tableau self (starting with the lowermost row, reading every row from left to right).

**EXAMPLES:**

```python
sage: Tableau([[1, 2], [3, 4]]).to_word_by_row()
word: 3412

sage: Tableau([[1, 4, 6], [2, 5], [3]]).to_word_by_row()
word: 325146
```

```python
>>> from sage.all import *

>>> Tableau([[Integer(1), Integer(2)], [Integer(3), Integer(4)]]).to_word_by_row()
word: 3412

>>> Tableau([[Integer(1), Integer(4), Integer(6)], [Integer(2), Integer(5)], [Integer(3)]]).to_word_by_row()
word: 325146
```

**vertical_flip()**

Return the tableau obtained by vertically flipping the tableau self.

This only works for rectangular tableaux.

**EXAMPLES:**

```python
sage: Tableau([[1, 2], [3, 4]]).vertical_flip()
[[3, 4], [1, 2]]
```
weight()  
Return the weight of the tableau self. Trailing zeroes are omitted when returning the weight.

The weight of a tableau $T$ is the sequence $(a_1, a_2, a_3, \ldots)$, where $a_k$ is the number of entries of $T$ equal to $k$. This sequence contains only finitely many nonzero entries.

The weight of a tableau $T$ is the same as the weight of the reading word of $T$, for any reading order.

EXAMPLES:

>>> Tableau([ [1,2], [3,4] ]).weight()
[1, 1, 1, 1]

>>> Tableau([[]]).weight()
[]

>>> Tableau([ [1,3,3,7], [4,2], [2,3] ]).weight()
[1, 2, 3, 1, 0, 0, 1]

class sage.combinat.tableau.Tableau_class (parent, t, check=True)  

This exists solely for unpickling Tableau_class objects.

class sage.combinat.tableau.Tableaux  

A factory class for the various classes of tableaux.

INPUT:

- $n$ (optional) – a non-negative integer

OUTPUT:

- If $n$ is specified, the class of tableaux of size $n$. Otherwise, the class of all tableaux.

A tableau in Sage is a finite list of lists, whose lengths are weakly decreasing, or an empty list, representing the empty tableau. The entries of a tableau can be any Sage objects. Because of this, no enumeration through the set of Tableaux is possible.

EXAMPLES:
sage: T = Tableaux(); T
Tableaux
sage: T3 = Tableaux(3); T3
Tableaux of size 3
sage: [['a', 'b']] in T
True
sage: [['a', 'b']] in T3
False
sage: t = T3([[1,1,1]]); t
[[1, 1, 1]]
sage: t in T
True
sage: t.parent()
Tableaux of size 3
sage: T([]) # the empty tableau
[]
sage: T.category()
Category of sets

- StandardTableau

Element

alias of Tableau

options = Current options for Tableaux - ascii_art: repr - convention:
English - display: list - latex: diagram
class sage.combinat.tableau.Tableaux_all
    Bases: Tableaux

    Initializes the class of all tableaux

    an_element()
        Return a particular element of the class.

class sage.combinat.tableau.Tableaux_size(n)
    Bases: Tableaux

    Tableaux of a fixed size $n$.

    an_element()
        Return a particular element of the class.

sage.combinat.tableau.from_chain(chain)
    Return a semistandard tableau from a chain of partitions.

    EXAMPLES:

    sage: from sage.combinat.tableau import from_chain
    sage: from_chain([[], [2], [2, 1], [3, 2, 1]])
    [[1, 1, 3], [2, 3], [3]]

    sage.combinat.tableau.from_shape_and_word(shape, w, convention='French')
    Return a tableau from a shape and word.

    INPUT:

    - shape -- a partition
    - w -- a word whose length equals that of the partition
    - convention -- a string which can take values "French" or "English"; the default is "French"

    OUTPUT:

    A tableau, whose shape is shape and whose reading word is $w$. If the convention is specified as "French", the reading word is to be read starting from the top row in French convention (= the bottom row in English convention). If the convention is specified as "English", the reading word is to be read starting with the top row in English convention.

    EXAMPLES:

    sage: from sage.combinat.tableau import from_shape_and_word
    sage: t = Tableau([[1, 3], [2], [4]])
    sage: shape = t.shape(); shape
    [2, 1, 1]
    sage: word = t.to_word(); word
    word: 4213
    sage: from_shape_and_word(shape, word)
    [[1, 1, 3], [2, 3], [3]]

    sage: word = Word(flatten(t))

(continues on next page)
sage: from_shape_and_word(shape, word, convention="English")
[[1, 3], [2], [4]]

>>> from sage.all import *
>>> from sage.combinat.tableau import from_shape_and_word

>>> t = Tableau([[Integer(1), Integer(3)], [Integer(2)], [Integer(4)]])

>>> shape = t.shape(); shape
[2, 1, 1]

>>> word = t.to_word(); word
word: 4213

>>> from_shape_and_word(shape, word)
[[1, 3], [2], [4]]

word = Word(flatten(t))

>>> from_shape_and_word(shape, word, convention="English")
[[1, 3], [2], [4]]

sage.combinat.tableau.symmetric_group_action_on_values(word, perm)

Return the image of the word word under the Lascoux-Schuetzenberger action of the permutation perm.

See Tableau.symmetric_group_action_on_values() for the definition of the Lascoux-Schuetzenberger action on semistandard tableaux. The transformation that the reading word of the tableau undergoes in said definition is precisely the Lascoux-Schuetzenberger action on words.

EXAMPLES:

sage: from sage.combinat.tableau import symmetric_group_action_on_values

sage: symmetric_group_action_on_values([1,1,1],[1,3,2])
[1, 1, 1]

sage: symmetric_group_action_on_values([1,1,1],[2,1,3])
[2, 2, 2]

sage: symmetric_group_action_on_values([1,2,1],[2,1,3])
[2, 2, 1]

sage: symmetric_group_action_on_values([2,2,2],[2,1,3])
[1, 1, 1]

sage: symmetric_group_action_on_values([2,1,2],[2,1,3])
[2, 1, 1]

sage: symmetric_group_action_on_values([2,2,3,1,1,2,2,3],[1,3,2])
[2, 3, 3, 1, 1, 2, 3, 3]

sage: symmetric_group_action_on_values([2,1,1],[2,1])
[2, 1, 2]

sage: symmetric_group_action_on_values([2,2,1],[2,1])
[1, 2, 1]

sage: symmetric_group_action_on_values([1,2,1],[2,1])
[2, 2, 1]

>>> from sage.all import *

>>> from sage.combinat.tableau import symmetric_group_action_on_values

>>> symmetric_group_action_on_values([[Integer(1),Integer(1),Integer(1)],
                                      ⇒[Integer(1),Integer(3),Integer(2)]])
[1, 1, 1]

>>> symmetric_group_action_on_values([[Integer(1),Integer(1),Integer(1)],
                                      ⇒[Integer(2),Integer(1),Integer(3)]])
[2, 2, 2]

>>> symmetric_group_action_on_values([[Integer(1),Integer(2),Integer(1)],
                                      ⇒[Integer(2),Integer(1),Integer(3)]])
[2, 2, 2]
sage.combinat.tableau.unmatched_places(w, open, close)

Given a word \( w \) and two letters \( \text{open} \) and \( \text{close} \) to be treated as opening and closing parentheses (respectively), return a pair \((xs, ys)\) that encodes the positions of the unmatched parentheses after the standard parenthesis matching procedure is applied to \( w \).

More precisely, \( xs \) will be the list of all \( i \) such that \( w[i] \) is an unmatched closing parenthesis, while \( ys \) will be the list of all \( i \) such that \( w[i] \) is an unmatched opening parenthesis. Both lists returned are in increasing order.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau import unmatched_places
sage: unmatched_places([2,2,2,1,1,1], 2, 1)
([], [])
sage: unmatched_places([1,1,1,2,2,2], 2, 1)
([0, 1, 2], [3, 4, 5])
sage: unmatched_places([], 2, 1)
([], [])
sage: unmatched_places([1,2,4,6,2,1,5,3], 2, 1)
([0], [1])
sage: unmatched_places([3,1,1,1,2,1,2], 2, 1)
([1, 2, 3], [6])
```
5.1.346 Residue sequences of tableaux

A residue sequence for a StandardTableau, or StandardTableauTuple, of size $n$ is an $n$-tuple $(i_1, i_2, \ldots, i_n)$ of elements of $\mathbb{Z}/e\mathbb{Z}$ for some positive integer $e \geq 1$. Such sequences arise in the representation theory of the symmetric group and the closely related cyclotomic Hecke algebras, and cyclotomic quiver Hecke algebras, where the residue sequences play a similar role to weights in the representations of Lie groups and Lie algebras. These Hecke algebras are semisimple when $e$ is “large enough” and in these cases residue sequences are essentially the same as content sequences (see `sage.combinat.partition.Partition.content()`) and it is not difficult to see that residue sequences are in bijection with the set of standard tableaux. In the non-semisimple case, when $e$ is “small”, different standard tableaux can have the same residue sequence. In this case the residue sequences describe how to decompose modules into generalised eigenspaces for the Jucys-Murphy elements for these algebras.

By definition, if $t$ is a StandardTableau of size $n$ then the residue sequence of $t$ is the $n$-tuple $(i_1, \ldots, i_n)$ where $i_m = c - r + eZ$, if $m$ appears in row $r$ and column $c$ of $t$. If $p$ is prime then such sequence arise in the representation theory of the symmetric group $n$ characteristic $p$. More generally, $e$-residue sequences arise in representation theory of the Iwahori-Hecke algebra (see `IwahoriHeckeAlgebra`) the symmetric group with Hecke parameter at an $e$-th root of unity.

More generally, the $e$-residue sequence of a StandardTableau of size $n$ and level $l$ is the $n$-tuple $(i_1, \ldots, i_n)$ determined by $e$ and a multicharge $\kappa = (\kappa_1, \ldots, \kappa_l)$ by setting $i_m = \kappa_k + c - r + eZ$, if $m$ appears in component $k$, row $r$ and column $c$ of $t$. These sequences arise in the representation theory of the cyclotomic Hecke algebras of type $A$, which are also known as Ariki-Koike algebras.

The residue classes are constructed from standard tableaux:

```
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(2)
2-residue sequence (0,1,1,0) with multicharge (0)
sage: StandardTableau([[1,2],[3,4]]).residue_sequence(3)
3-residue sequence (0,1,2,0) with multicharge (0)
```

```
sage: StandardTableauTuple([[5],[1,2],[3,4]]).residue_sequence(3, [0,0])
3-residue sequence (0,1,2,0) with multicharge (0,0)
sage: StandardTableauTuple([[5],[1,2],[3,4]]).residue_sequence(3, [0,1])
3-residue sequence (1,2,0,1) with multicharge (0,1)
sage: StandardTableauTuple([[5],[1,2],[3,4]]).residue_sequence(3, [0,2])
3-residue sequence (2,0,1,2) with multicharge (0,2)
```
3-residue sequence \(0,1,2,0,0\) with multicharge \((0,0)\)

\[
\text{StandardTableauTuple}([[\text{Integer}(5)]],[[\text{Integer}(1),\text{Integer}(2)],[\text{Integer}(3),\text{Integer}(4)]]).\text{residue_sequence}(\text{Integer}(3),[[\text{Integer}(0),\text{Integer}(1)]]
\]

3-residue sequence \((1,2,0,1,0)\) with multicharge \((0,1)\)

\[
\text{StandardTableauTuple}([[\text{Integer}(5)]],[[\text{Integer}(1),\text{Integer}(2)],[\text{Integer}(3),\text{Integer}(4)]]).\text{residue_sequence}(\text{Integer}(3),[[\text{Integer}(0),\text{Integer}(2)]]
\]

3-residue sequence \((2,0,1,2,0)\) with multicharge \((0,2)\)

One of the most useful functions of a \(\text{ResidueSequence}\) is that it can return the \(\text{StandardTableaux}\_\text{residue}\) and \(\text{StandardTableaux}\_\text{residue}\_\text{shape}\) that contain all of the tableaux with this residue sequence. Again, these are best accessed via the standard tableau classes:

\[
sage: \text{res} = \text{StandardTableau}([[1,2],[3,4]]).\text{residue_sequence}(2)
\]

\[
sage: \text{res}\text{.standard_tableaux()}
\]

Standard tableaux with 2-residue sequence \((0,1,1,0)\) and multicharge \((0)\)

\[
sage: \text{res}\text{.standard_tableaux()[:]}\]

\[
[[[1, 2, 4], [3]],
[[1, 2], [3, 4]],
[[1, 2], [3], [4]],
[[1, 3, 4], [2]],
[[1, 3], [2, 4]],
[[1, 3], [2], [4]]
\]

\[
sage: \text{res} = \text{StandardTableauTuple}([[\text{Integer}(5)],[[\text{Integer}(1),\text{Integer}(2)],[\text{Integer}(3),\text{Integer}(4)]]].\text{residue_sequence}(3,[],[\text{Integer}(0),\text{Integer}(0)])
\]

\[
sage: \text{res}\text{.standard_tableaux()}
\]

Standard tableaux with 3-residue sequence \((0,1,2,0,0)\) and multicharge \((0,0)\)

\[
sage: \text{res}\text{.standard_tableaux(shape=[Integer(1),Integer(2),Integer(2)])[:]}\]

\[
[[[\text{Integer}(5)], [[1, 2], [3, 4]]]],
[[[\text{Integer}(4)], [[1, 2], [3, 5]]]
\]

\[
>> \text{from sage.all import } *
\]

\[
>> \text{res} = \text{StandardTableau}([[\text{Integer}(1),\text{Integer}(2)],[\text{Integer}(3),\text{Integer}(4)]]).\text{residue_sequence}(\text{Integer}(2))
\]

\[
>> \text{res}\text{.standard_tableaux()}
\]

Standard tableaux with 2-residue sequence \((0,1,1,0)\) and multicharge \((0)\)

\[
>> \text{res}\text{.standard_tableaux()[:]}\]

\[
[[[1, 2, 4], [3]],
[[1, 2], [3, 4]],
[[1, 2], [3], [4]],
[[1, 3, 4], [2]],
[[1, 3], [2, 4]],
[[1, 3], [2], [4]]
\]

\[
>> \text{res}\text{.standard_tableaux(shape=}\text{Integer}(4)))
\]

Standard \((4)-\text{tableaux}\) with 2-residue sequence \((0,1,1,0)\) and multicharge \((0)\)

\[
>> \text{res}\text{.standard_tableaux(shape=}\text{Integer}(4))[:]
\]

\[
[]
\]

\[
>> \text{res}\text{=StandardTableauTuple}([[\text{Integer}(5)],[[\text{Integer}(1),\text{Integer}(2)],[\text{Integer}(3),\text{Integer}(4)]]].\text{residue_sequence}(\text{Integer}(3),[[\text{Integer}(0),\text{Integer}(0)]]
\]

\[
>> \text{res}\text{.standard_tableaux()}
\]

Standard tableaux with 3-residue sequence \((0,1,2,0,0)\) and multicharge \((0,0)\)

\[
>> \text{res}\text{.standard_tableaux(shape=}[[\text{Integer}(1),\text{Integer}(2),\text{Integer}(2))]])[:]
\]

\[
[[[\text{Integer}(5)], [[1, 2], [3, 4]]]],
[[[\text{Integer}(4)], [[1, 2], [3, 5]]]
\]
These residue sequences are particularly useful in the graded representation theory of the cyclotomic KLR algebras and the cyclotomic Hecke algebras of type \(A\); see [DJM1998] and [BK2009].

This module implements the following classes:

- `ResidueSequence`
- `ResidueSequences`

See also:

- `Partitions`
- `PartitionTuples`
- `StandardTableaux_residue`
- `StandardTableaux_residue_shape`
- `RowStandardTableauTuples_residue`
- `RowStandardTableauTuples_residue_shape`
- `StandardTableaux`
- `StandardTableauTuples`
- `Tableaux`
- `TableauTuples`

**Todo:** Strictly speaking this module implements residue sequences of type \(A_e^{(1)}\). Residue sequences of other types also need to be implemented.

**AUTHORS:**

- Andrew Mathas (2016-07-01): Initial version

```python
class sage.combinat.tableau_residuals.ResidueSequence(parent, residues, check)
    Bases: ClonableArray
    A residue sequence.
    The residue sequence of a tableau \(t\) (of partition or partition tuple shape) is the sequence \((i_1, i_2, \ldots, i_n)\) where \(i_k\) is the residue of \(l\) in \(t\), for \(k = 1, 2, \ldots, n\), where \(n\) is the size of \(t\). Residue sequences are important in the representation theory of the cyclotomic Hecke algebras of type \(G(r, 1, n)\), and of the cyclotomic quiver Hecke algebras, because they determine the eigenvalues of the Jucys-Murphy elements upon all modules. More precisely, they index and completely determine the irreducible representations of the (cyclotomic) Gelfand-Tsetlin algebras. Rather than being called directly, residue sequences are best accessed via the standard tableaux classes `StandardTableau` and `StandardTableauTuple`.

**INPUT:**

Can be of the form:

- `ResidueSequence(e, res)`
- `ResidueSequence(e, multicharge, res)`

where \(e\) is a positive integer not equal to 1 and \(res\) is a sequence of integers (the residues).

**EXAMPLES:**
sage: res = StandardTableauTuple([[1,3],[6]],[[2,7],[4],[5]]).residue_sequence(3,(0,5))
sage: res
3-residue sequence (0,2,1,1,0,2,0) with multicharge (0,2)
sage: res.quantum_characteristic()
3
sage: res.level()
2
sage: res.size()
7
sage: res.residues()
[0, 2, 1, 1, 0, 2, 0]
sage: res.restrict(Integer(2))
3-residue sequence (0,2) with multicharge (0,2)
sage: res.standard_tableaux([[2,1],[1],[2,1]])
Standard (2,1|1|2,1)-tableaux with 3-residue sequence (0,2,1,1,0,2,0) and
multicharge (0,2)
sage: res.standard_tableaux([[2,2],[3]]).list()
[]
sage: res.standard_tableaux([[2,2],[3]])[:]
[]
sage: res.standard_tableaux()
Standard tableaux with 3-residue sequence (0,2,1,1,0,2,0) and multicharge (0,2)
sage: res.standard_tableaux()[:10]
[(([1, 3, 6, 7], [2, 5], [4]), []), (([1, 3, 6], [2, 5, 7], [4]), []),
([1, 3], [2, 5, 6], [4], [7]), [([1, 3], [2, 5], [4, 6], [7]), []),
([1, 3], [2, 5, 4], [6]), [([1, 3, 6, 7], [2, 5], [4, 6]), [([1, 3, 6],
[2, 5, 7], [4]), [([1, 3], [2, 5, 6], [4], [7]), [([1, 3], [2, 5],
[4]), [([1, 3], [2, 7], [4], [5]), [([1, 3], [2], [4], [5], [6]), [
([1, 3], [2], [4], [5], [6]), ([6]), ([1, 3], [2], [4], [5], [6]),
([1, 3], [2], [4], [5]), [([6], [6]))]

>>> from sage.all import *
>>> res = StandardTableauTuple([[Integer(1),Integer(3)],
([Integer(2),Integer(7)], [Integer(4)], [Integer(5)])).residue_sequence(Integer(3), (Integer(0), Integer(5)))
>>> res
3-residue sequence (0,2,1,1,0,2,0) with multicharge (0,2)
>>> res.quantum_characteristic()
3
>>> res.level()
2
>>> res.size()
7
>>> res.residues()
[0, 2, 1, 1, 0, 2, 0]
>>> res.restrict(Integer(2))
3-residue sequence (0,2) with multicharge (0,2)
>>> res.standard_tableaux([[Integer(2),Integer(1)], [Integer(1)], [Integer(2),
Integer(1)]])
Standard (2,1|1|2,1)-tableaux with 3-residue sequence (0,2,1,1,0,2,0) and
multicharge (0,2)
>>> res.standard_tableaux([[Integer(2),Integer(2)], [Integer(3)]]).list()
[]

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> res.standard_tableaux([[Integer(2), Integer(2)], [Integer(3)]]):
[]
>>> res.standard_tableaux()
Standard tableaux with 3-residue sequence (0, 2, 1, 1, 0, 2, 0) and multicharge (0, 2)

```

The TestSuite fails `test_pickling` because `__getitem__` does not support slices, so we skip this.

**base_ring()**

Return the base ring for the residue sequence.

If the `quantum_characteristic()` of the residue sequence `self` is $e$ then the base ring for the sequence is $\mathbb{Z}/e\mathbb{Z}$, or $\mathbb{Z}$ if $e = 0$.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).base_ring()
Ring of integers modulo 3
```

**block()**

Return a dictionary $\beta$ that determines the block associated to the residue sequence `self`.

Two Specht modules for a cyclotomic Hecke algebra of type $A$ belong to the same block, in this sense, if and only if the residue sequences of their standard tableaux have the same block in this sense. The blocks of these algebras are actually indexed by positive roots in the root lattice of an affine special linear group. Instead of than constructing the root lattice, this method simply returns a dictionary $\beta$ where the keys are residues $i$ and where the value of the key $i$ is equal to the numbers of nodes in the residue sequence `self` that are equal to $i$. The dictionary $\beta$ corresponds to the positive root:

$$\sum_{i \in I} \beta_i \alpha_i \in Q^+, \quad \alpha_i \in \Delta.$$  

These positive roots also index the blocks of the cyclotomic KLR algebras of type $A$.

We return a dictionary because when the `quantum_characteristic()` is 0, the Cartan type is $A_\infty$, in which case the simple roots are indexed by the integers, which is infinite.

**EXAMPLES:**

---

5.1. Comprehensive Module List 5495
```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,0], [0,1,2,0,1,2,0,1,2]).block()
{0: 3, 1: 3, 2: 3}
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence

>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),
        -> [Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),
        -> Integer(3),Integer(3)]).check()

>>> ResidueSequence(Integer(3), (Integer(2),Integer(0),Integer(1),
        -> [Integer(2),Integer(0),Integer(1),Integer(1),Integer(2),
        -> Integer(3),Integer(3)]).check()
```

```python
level()
```

Return the level of the residue sequence. That is, the level of the corresponding (tuples of) standard tableaux.

The `level` of a residue sequence is the length of its `multicharge()`. This is the same as the level of the `standard_tableaux()` that belong to the residue class of tableaux determined by `self`.

```python
sage: from sage.combinat.tableau_residues import ResidueSequence

sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).level()
3
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence

>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),
        -> [Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),
        -> Integer(3),Integer(3)]).level()
3
```

```python
multicharge()
```

Return the multicharge for the residue sequence `self`.

The $e$-residue sequences are associated with a cyclotomic Hecke algebra with Hecke parameter $q$ of `quantum_characteristic()` $e$ and multicharge $(\kappa_1, \ldots, \kappa_l)$. This means that the cyclotomic parameters of the Hecke algebra are $q^{\kappa_1}, \ldots, q^{\kappa_l}$. Equivalently, the Hecke algebra is determined by the dominant weight

\[
\sum_{r \in \mathbb{Z}/e\mathbb{Z}} \kappa_r \Lambda_r \in P^+.
\]
EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).multicharge()
(0, 0, 1)
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),
˓→[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
˓→Integer(3),Integer(3)]).multicharge()
(0, 0, 1)
```

**negative()**

Return the negative of the residue sequence `self`.

That is, if `self` is the residue sequence `(i_1,...,i_n)` then return `(-i_1,...,-i_n)`. Taking the negative residue sequences is a shadow of tensoring with the sign representation from the cyclotomic Hecke algebras of type `A`.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,0,1], [0,0,1,1,2,2,3,3]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), [Integer(0),Integer(0),Integer(1)],
˓→[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
˓→Integer(3),Integer(3)]).negative()
3-residue sequence (0,0,2,2,1,1,0,0) with multicharge (0,0,1)
```

**quantum_characteristic()**

Return the quantum characteristic of the residue sequence `self`.

The $e$-residue sequences are associated with a cyclotomic Hecke algebra that has a parameter $q$ of quantum characteristic $e$. This is the smallest positive integer such that $1 + q + \cdots + q^{e-1} = 0$, or $e = 0$ if no such integer exists.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).quantum_characteristic()
3
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(1)),
˓→[Integer(0),Integer(0),Integer(1),Integer(1),Integer(2),Integer(2),
˓→Integer(3),Integer(3)]).quantum_characteristic()
3
```

**residues()**

Return a list of the residue sequence.

EXAMPLES:
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,2,2,3,3]).residues()
[0, 0, 1, 2, 2, 0, 0]

restrict (m)
Return the subsequence of this sequence of length m.

The residue sequence self is of the form \((r_1, \ldots, r_n)\). The function returns the residue sequence \((r_1, \ldots, r_m)\), with the same quantum_characteristic() and multicharge().

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,2,2,3,3]).restrict(7)
3-residue sequence (0,0,1,2,2,0) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [0,0,1,2,2,3,3]).restrict(6)
3-residue sequence (0,0,1,2,2) with multicharge (0,0,1)
sage: ResidueSequence(3, (0,0,1), [0,0,1,2,2,3,3]).restrict(4)
3-residue sequence (0,0,1,1) with multicharge (0,0,1)

restrict_row (cell, row)
Return a residue sequence for the tableau obtained by swapping the row in ending in cell with the row that is row rows above it and which has the same length.

The residue sequence self is of the form \((r_1, \ldots, r_n)\). The function returns the residue sequence \((r_1, \ldots, r_m)\), with the same quantum_characteristic() and multicharge().

EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, [0,1,2,2,0,1]).restrict_row((1,2),1)
3-residue sequence (2,0,1,0,1) with multicharge (0,0,1)
```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> ResidueSequence(Integer(3), [Integer(0), Integer(1), Integer(2), Integer(2),
→ Integer(0), Integer(1)]).restrict_row((Integer(1), Integer(2)), Integer(1))
3-residue sequence (2,0,1,0,1) with multicharge (0)
>>> ResidueSequence(Integer(3), [Integer(1), Integer(0)], [Integer(0),
→ Integer(1), Integer(2), Integer(2), Integer(0), Integer(1)]).restrict_row((Integer(1), Integer(1), Integer(2)), Integer(1))
3-residue sequence (2,0,1,0,1) with multicharge (1,0)

row_standard_tableaux (shape=None)

Return the residue-class of row standard tableaux that have residue sequence self.

INPUT:

  • shape – (optional) a partition or partition tuple of the correct level

OUTPUT:

An iterator for the row standard tableaux with this residue sequence. If the shape is given then only tableaux of this shape are returned, otherwise all of the full residue-class of row standard tableaux, or row standard tableaux tuples, is returned. The residue sequence self specifies the multicharge() of the tableaux which, in turn, determines the level() of the tableaux in the residue class.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).row_standard_tableaux([[],[]])
Row standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
```

```python

size ()

Return the size of the residue sequence.

This is the size, or length, of the residue sequence, which is the same as the size of the standard_tableaux() that belong to the residue class of tableaux determined by self.

EXAMPLES:

```
```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3, (0,0,1), [0,0,1,1,2,2,3,3]).size()
8
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence

ResidueSequence(Integer(3), (Integer(0),Integer(0),Integer(0)), [Integer(0),Integer(0),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2), Integer(3),Integer(3)]).size()
8
```

**standard_tableaux (shape=None)**

Return the residue-class of standard tableaux that have residue sequence `self`.

**INPUT:**

- `shape` – (optional) a partition or partition tuple of the correct level

**OUTPUT:**

An iterator for the standard tableaux with this residue sequence. If the `shape` is given then only tableaux of this shape are returned, otherwise all of the full residue-class of standard tableaux, or standard tableau tuples, is returned. The residue sequence `self` specifies the `multicharge()` of the tableaux which, in turn, determines the `level()` of the tableaux in the residue class.

**EXAMPLES:**

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
sage: ResidueSequence(3,(0,0,0),[0,1,2,0,1,2,0,1,2]).standard_tableaux([3],[3])
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence

ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(0)), [Integer(0),Integer(0),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2), Integer(3),Integer(3)]).standard_tableaux()
Standard tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
```

```python
>>> ResidueSequence(Integer(3),(Integer(0),Integer(0),Integer(0)), [Integer(0),Integer(0),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2), Integer(3),Integer(3)]).standard_tableaux([3],[3])
Standard (3|3|3)-tableaux with 3-residue sequence (0,1,2,0,1,2,0,1,2) and multicharge (0,0,0)
```

**swap_residues (i,j)**

Return the new residue sequence obtained by swapping the residues for `i` and `j`.

**INPUT:**

- `i` and `j` – two integers between 1 and the length of the residue sequence

If residue sequence `self` is of the form \( (r_1, \ldots, r_n) \), and \( i < j \), then the residue sequence \( (r_1, \ldots, r_j, \ldots, r_i, \ldots, r_m) \), with the same `quantum_characteristic()` and `multicharge()`,
is returned.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequence
sage: res = ResidueSequence(3, (0, 0, 1), [0, 0, 1, 1, 2, 2, 0, 0]); res
3-residue sequence (0,0,1,2,2,0,0) with multicharge (0,0,1)
sage: ser = res.swap_residues(2,6); ser
3-residue sequence (0,2,1,2,0,0,0) with multicharge (0,0,1)
sage: res == ser
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequence
>>> res = ResidueSequence(3, (0, 0, 1), [0, 0, 1, 1, 2, 2, 0, 0]); res
3-residue sequence (0,0,1,2,2,0,0) with multicharge (0,0,1)
>>> ser = res.swap_residues(2,6); ser
3-residue sequence (0,2,1,2,0,0,0) with multicharge (0,0,1)
>>> res == ser
False
```

class sage.combinat.tableau_residues.ResidueSequences(e, multicharge=(0,))

Bases: UniqueRepresentation, Parent

A parent class for ResidueSequence.

This class exists because ResidueSequence needs to have a parent. Apart from being a parent the only useful method that it provides is cell_residue(), which is a short-hand for computing the residue of a cell using the ResidueSequence.quantum_characteristic() and ResidueSequence.multicharge() for the residue class.

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(e=0, multicharge=(0,1,2))
0-residue sequences with multicharge (0, 1, 2)
 sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=0, multicharge=(0,1,2))
True
 sage: ResidueSequences(e=0, multicharge=(0,1,2)) == ResidueSequences(e=3, multicharge=(0,1,2))
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequences
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1),Integer(2)))
0-residue sequences with multicharge (0, 1, 2)
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1), Integer(2))) == ResidueSequences(e=Integer(0), multicharge=(Integer(0), Integer(1), Integer(2)))
True
>>> ResidueSequences(e=Integer(0), multicharge=(Integer(0),Integer(1), Integer(2))) == ResidueSequences(e=Integer(3), multicharge=(Integer(0),
Integer(1), Integer(2)))
```

(continues on next page)
Element

alias of ResidueSequence

an_element()

Return a particular element of self.

EXAMPLES:

```python
sage: TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

```python
>>> from sage.all import *

>>> TableauTuples().an_element()
([[1]], [[2]], [[3]], [[4]], [[5]], [[6]], [[7]])
```

cell_residue(*args)

Return the residue a cell with respect to the quantum characteristic and the multicharge of the residue sequence.

INPUT:

- r and c – the row and column indices in level one
- k, r and c – the component, row and column indices in higher levels

EXAMPLES:

```python
sage: from sage.combinat.tableau_residues import ResidueSequences
sage: ResidueSequences(3).cell_residue(1,1)
0
sage: ResidueSequences(3).cell_residue(2,1)
2
sage: ResidueSequences(3).cell_residue(3,1)
1
sage: ResidueSequences(3).cell_residue(3,2)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,0,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,0)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(0,1,2)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,1,0)
0
sage: ResidueSequences(3,(0,1,2)).cell_residue(1,0,1)
2
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,0)
2
```

(continues on next page)
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,1,0)
1
sage: ResidueSequences(3,(0,1,2)).cell_residue(2,0,1)
0

>>> from sage.all import *
>>> from sage.combinat.tableau_residues import ResidueSequences
>>> ResidueSequences(Integer(3)).cell_residue(Integer(1),Integer(1))
0
>>> ResidueSequences(Integer(3)).cell_residue(Integer(2),Integer(1))
2
>>> ResidueSequences(Integer(3)).cell_residue(Integer(3),Integer(1))
1
>>> ResidueSequences(Integer(3)).cell_residue(Integer(3),Integer(2))
2
>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_residue(Integer(0),Integer(0),Integer(0))
0
>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_residue(Integer(0),Integer(1),Integer(0))
2
>>> ResidueSequences(Integer(3),(Integer(0),Integer(1),Integer(2))).cell_residue(Integer(1),Integer(0),Integer(0))
1
check_element(element)
Check that element is a residue sequence with multicharge self.multicharge().
This is weak criterion in that we only require that element is a tuple of elements in the underlying base ring of self. Such a sequence is always a valid residue sequence, although there may be no tableaux with this residue sequence.
EXAMPLES:

sage: from sage.combinat.tableau_residues import ResidueSequence
sage: ResidueSequence(3,(0,0,1),[0,0,1,1,2,2,3,3]) # indirect doctest
3-residue sequence (0,0,1,1,2,2,0,0) with multicharge (0,0,1)
sage: ResidueSequence(3,(0,0,1),[2,0,1,4,2,2,5,3]) # indirect doctest
3-residue sequence (2,0,1,1,2,2,2,0) with multicharge (0,0,1)
5.1.347 TableauTuples

A TableauTuple is a tuple of tableaux. These objects arise naturally in representation theory of the wreath products of cyclic groups and the symmetric groups where the standard tableau tuples index bases for the ordinary irreducible representations. This generalises the well-known fact the ordinary irreducible representations of the symmetric groups have bases indexed by the standard tableaux of a given shape. More generally, TableauTuples, or multitableaux, appear in the representation theory of the degenerate and non-degenerate cyclotomic Hecke algebras and in the crystal theory of the integral highest weight representations of the affine special linear groups.

A TableauTuple is an ordered tuple \((t^{(1)}, t^{(2)}, \ldots, t^{(l)})\) of tableaux. The length of the tuple is its level and the tableaux \(t^{(1)}, t^{(2)}, \ldots, t^{(l)}\) are the components of the TableauTuple.

A tableau can be thought of as the labelled diagram of a partition. Analogously, a TableauTuple is the labelled diagram of a PartitionTuple. That is, a TableauTuple is a tableau of PartitionTuple shape. As much as possible, TableauTuples behave in exactly the same way as Tableaux. There are obvious differences in that the cells of a partition are ordered pairs \((r, c)\), where \(r\) is a row index and \(c\) a column index, whereas the cells of a PartitionTuple are ordered triples \((k, r, c)\), with \(r\) and \(c\) as before and \(k\) indexes the component.

Frequently, we will call a TableauTuple a tableau, or a tableau of PartitionTuple shape. If the shape of the tableau is known this should not cause any confusion.

**Warning:** In sage the convention is that the \((k, r, c)\)-th entry of a tableau tuple \(t\) is the entry in row \(r\), column \(c\) and component \(k\) of the tableau. This is because it makes much more sense to let \(t[k]\) be component of the tableau. In particular, we want \(t(k, r, c) \equiv t[k][r][c]\). In the literature, the cells of a tableau tuple are usually written in the form \((r, c, k)\), where \(r\) is the row index, \(c\) is the column index, and \(k\) is the component index.

The same convention applies to the cells of PartitionTuples.

**Note:** As with partitions and tableaux, the cells are 0-based. For example, the (lexicographically) first cell in any non-empty tableau tuple is \([0, 0, 0]\).

**EXAMPLES:**
One reason for implementing *TableauTuples* is to be able to consider *StandardTableauTuples*. These objects arise in many areas of algebraic combinatorics. In particular, they index bases for the Specht modules of the cyclotomic Hecke algebras of type $G(r,1,n)$. A *StandardTableauTuple* of tableau whose entries are increasing along rows.
and down columns in each component and which contain the numbers 1, 2, ..., \( n \), where the shape of the Standard-TableauTuple is a PartitionTuple of \( n \).

```python
sage: s = StandardTableauTuple([[1,2],[3],[4,5]])
sage: s.category()
Category of elements of Standard tableau tuples
sage: t = TableauTuple([[1,2],[3],[4,5]])
sage: t.is_standard(), t.is_column_strict(), t.is_row_strict()
(True, True, True)
sage: t.category()
Category of elements of Tableau tuples
sage: s == t
True
sage: s is t
False
sage: s == StandardTableauTuple(t)
True
sage: StandardTableauTuples([ [2,1],[1] ])[::]
[([[1, 2], [3]], [[4]]),
 ([[1, 3], [2]], [[4]]),
 ([[1, 2], [4]], [[3]]),
 ([[1, 3], [4]], [[2]]),
 ([[2, 3], [4]], [[1]]),
 ([[1, 4], [2]], [[3]]),
 ([[1, 4], [3]], [[2]]),
 ([[2, 4], [3]], [[1]])]
```

As tableaux (of partition shape) are in natural bijection with 1-tuples of tableaux all of the TableauTuple classes return an ordinary Tableau when given TableauTuple of level 1.
There is one situation where a 1-tuple of tableau is not actually a \texttt{Tableau}; tableaux generated by the \texttt{StandardTableauTuples()} iterators must have the correct parents, so in this one case 1-tuples of tableaux are different from \texttt{Tableaux}:
Element classes:
- TableauTuples
- StandardTableauTuples
- RowStandardTableauTuples

Factory classes:
- TableauTuples
- StandardTableauTuples
- RowStandardTableauTuples

Parent classes:

Todo: Implement semistandard tableau tuples as defined in [DJM1998].

Much of the combinatorics implemented here is motivated by this and subsequent papers on the representation theory of these algebras.

class sage.combinat.tableau_tuple.RowStandardTableauTuple(parent, t, check=True)

Bases: TableauTuple

A class for row standard tableau tuples of shape a partition tuple.

A row standard tableau tuple of size $n$ is an ordered tuple of row standard tableaux (see RowStandardTableau), with entries 1, 2, ..., $n$ such that, in each component, the entries are in increasing order along each row. If the tableau in component $k$ has shape $\lambda^{(k)}$ then $\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)})$ is a PartitionTuple.

Note: The tableaux appearing in a RowStandardTableauTuple are row strict, but individually they are not standard tableaux because the entries in any single component of a RowStandardTableauTuple will typically not be in bijection with $\{1, 2, \ldots, n\}$.

INPUT:

- $t$ – a tableau, a list of (standard) tableau or an equivalent list

OUTPUT:

- A RowStandardTableauTuple object constructed from $t$.

Note: Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with PartitionTuple, in Sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is [0, 0, 0]. Further, the coordinates $[k, r, c]$ in a TableauTuple refer to the component, row and column indices, respectively.

EXAMPLES:

```
sage: t = RowStandardTableauTuple([[[4,7],[3]],[[2,6,8],[1,5]],[[9]]]); t
([[4, 7], [3]], [[2, 6, 8], [1, 5]], [[9]])
sage: t.pp()
  4  7
  3  1  5
sage: t.shape()
([2, 1], [3, 2], [1])
sage: t[0].pp()  # pretty printing
  4  7
  3
sage: t.is_row_strict()
True
sage: t[0].is_standard()
False
sage: RowStandardTableauTuple([[],[],[]])  # An empty tableau tuple
([], [], [])
sage: RowStandardTableauTuple([[[4,5],[6]],[[1,2,3]]]) in StandardTableauTuples()
True
sage: RowStandardTableauTuple([[[5,6],[4]],[[1,2,3]]]) in StandardTableauTuples()
False
```
When using code that will generate a lot of tableaux, it is slightly more efficient to construct a `RowStandardTableauTuple` from the appropriate parent object:

```
sage: RST = RowStandardTableauTuples()
sage: RST([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
([[4, 5], [7]], [[1, 2, 3], [6, 8]], [[9]])
```

- `StandardTableauTuple`
- `RowStandardTableauTuples`

**codegree** *(e, multicharge)*

The codegree of a tableau is an integer that is defined recursively by successively stripping off the number \( k \), for \( k = n, n - 1, \ldots, 1 \) and at stage adding the number of addable cell of the same residue minus the number
of removable cells of the same residue as $k$ and which are above $k$ in the diagram.

The codegree of the tableau self gives the degree of “dual” homogeneous basis element of the graded Specht module which is indexed by self.

**INPUT:**

- $e$ – the quantum characteristic
- multicharge – the multicharge

**OUTPUT:**

The codegree of the tableau self, which is an integer.

**EXAMPLES:**

```python
sage: StandardTableauTuple([[1]], [], []).codegree(0, (0, 0, 0))
0
sage: StandardTableauTuple([], [1], []).codegree(0, (0, 0, 0))
1
sage: StandardTableauTuple([], [], [1]).codegree(0, (0, 0, 0))
2
sage: StandardTableauTuple([[1], [], []]).codegree(0, (0, 0, 0))
-1
sage: StandardTableauTuple([[1], [2], []]).codegree(0, (0, 0, 0))
0
sage: StandardTableauTuple([], [1], [2]).codegree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[1], [1], []]).codegree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[2], [], [1]]).codegree(0, (0, 0, 0))
2
sage: StandardTableauTuple([[], [2], [1]]).codegree(0, (0, 0, 0))
3
```

```python
>>> from sage.all import *
>>> StandardTableauTuple([[Integer(1)], [], []]).codegree(Integer(0),
−→ (Integer(0), Integer(0), Integer(0)))
0
>>> StandardTableauTuple([[], [Integer(1)], []]).codegree(Integer(0),
−→ (Integer(0), Integer(0), Integer(0)))
1
>>> StandardTableauTuple([[], [], [Integer(1)]]).codegree(Integer(0),
−→ (Integer(0), Integer(0), Integer(0)))
2
>>> StandardTableauTuple([[Integer(1)], [], [Integer(2)]].
−→ codegree(Integer(0), (Integer(0), Integer(0), Integer(0)))
−1
>>> StandardTableauTuple([[Integer(1)], [], [Integer(2)]].
−→ codegree(Integer(0), (Integer(0), Integer(0), Integer(0)))
0
>>> StandardTableauTuple([[], [Integer(1)], [Integer(2)]].
−→ codegree(Integer(0), (Integer(0), Integer(0), Integer(0)))
1
>>> StandardTableauTuple([[Integer(2)], [Integer(1)], []].
−→ codegree(Integer(0), (Integer(0), Integer(0), Integer(0)))
1
>>> StandardTableauTuple([[Integer(2)], [], [Integer(1)]].
−→ codegree(Integer(0), (Integer(0), Integer(0), Integer(0)))
(continues on next page)
degree \((e, \text{multicharge})\)

The degree of a tableau is an integer that is defined recursively by successively stripping off the number \(k\), for \(k = n, n - 1, \ldots, 1\), and at stage adding the count of the number of addable cells of the same residue minus the number of removable cells of them same residue as \(k\) and that are below \(k\) in the diagram.

Note that even though this degree function was defined by Brundan-Kleshchev-Wang [BKW2011] the underlying combinatorics is much older, going back at least to Misra and Miwa.

The degrees of the tableau \(T\) gives the degree of the homogeneous basis element of the graded Specht module which is indexed by \(T\).

**INPUT:**

- \(e\) – the quantum characteristic \(e\)
- \text{multicharge} – (default: \([0]\)) the multicharge

**OUTPUT:**

The degree of the tableau \textit{self}, which is an integer.

**EXAMPLES:**

```
sage: StandardTableauTuple([[1]], [], []).degree(0, (0, 0, 0))
2
sage: StandardTableauTuple([[1]], [[1]], []).degree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[1]], [], [[1]]).degree(0, (0, 0, 0))
0
sage: StandardTableauTuple([[1]], [[2]], []).degree(0, (0, 0, 0))
3
sage: StandardTableauTuple([[1]], [], [[2]]).degree(0, (0, 0, 0))
2
sage: StandardTableauTuple([[], [1]], [[2]]).degree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[2]], [[1]], []).degree(0, (0, 0, 0))
1
sage: StandardTableauTuple([[2]], [1], []).degree(0, (0, 0, 0))
0
sage: StandardTableauTuple([[]], [[2]], [[1]]).degree(0, (0, 0, 0))
-1
```

```python
>>> from sage.all import *
```

```python
>>> StandardTableauTuple([[Integer(1)]], [], []).degree(Integer(0), (Integer(0), Integer(0), Integer(0)))
2
>>> StandardTableauTuple([[Integer(1)]], [1]).degree(Integer(0), (Integer(0), Integer(0), Integer(0)))
1
>>> StandardTableauTuple([[], [Integer(1)]]).degree(Integer(0), (Integer(0), Integer(0), Integer(0)))
0
```
inverse\( k \)
Return the cell containing \( k \) in the tableau tuple \( \text{self} \).

**EXAMPLES:**

```python
sage: RowStandardTableauTuple([[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(1)
(0, 1, 0)
sage: RowStandardTableauTuple([[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(2)
(0, 0, 1)
sage: RowStandardTableauTuple([[3,4],[1,2]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(3)
(0, 0, 0)
sage: StandardTableauTuple([[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(1)
(0, 0, 0)
sage: StandardTableauTuple([[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(2)
(0, 0, 1)
sage: StandardTableauTuple([[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(3)
(0, 1, 0)
sage: StandardTableauTuple([[1,2],[3,4]],[[5,6,7],[8]],[[9,10],[11],[12]]).inverse(12)
(2, 2, 0)
```
residue_sequence(e, multicharge)

Return the sage.combinat.tableau_residues.ResidueSequence of self.

INPUT:

• e - integer in {0, 2, 3, 4, 5, ...}

• multicharge - a sequence of integers of length equal to the level/length of self

OUTPUT:

The residue sequence of the tableau.

EXAMPLES:

sage: RowStandardTableauTuple([[5],[[3,4],[1,2]]]).residue_sequence(3,[0,0])
3-residue sequence (2,0,1,0) with multicharge (0,0)

sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).residue_sequence(3,[0,1])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)

sage: StandardTableauTuple([[5],[[1,2],[3,4]]]).residue_sequence(3,[0,2])
3-residue sequence (2,0,1,2,0) with multicharge (0,2)

>>> from sage.all import *

>>> RowStandardTableauTuple([[Integer(5)],[[Integer(3),Integer(4)],[Integer(1),Integer(2)]]]).residue_sequence(Integer(3),[Integer(0),Integer(0)])
3-residue sequence (2,0,1,0) with multicharge (0,0)

>>> StandardTableauTuple([[Integer(5)],[[Integer(1),Integer(2)],[Integer(3),Integer(4)]]]).residue_sequence(Integer(3),[Integer(0),Integer(1)])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)

>>> StandardTableauTuple([[Integer(5)],[[Integer(1),Integer(2)],[Integer(3),Integer(4)]]]).residue_sequence(Integer(3),[Integer(1),Integer(2),Integer(3),[Integer(0),Integer(1),Integer(2),Integer(3)]])
3-residue sequence (1,2,0,1,0) with multicharge (0,1)
class sage.combinat.tableau_tuple.RowStandardTableauTuples

Bases: TableauTuples

A factory class for the various classes of tuples of row standard tableau.

INPUT:

There are three optional arguments:

- **level** – the `level()` of the tuples of tableaux
- **size** – the `size()` of the tuples of tableaux
- **shape** – a list or a partition tuple specifying the `shape()` of the row standard tableau tuples

It is not necessary to use the keywords. If they are not used then the first integer argument specifies the `level()` and the second the `size()` of the tableau tuples.

OUTPUT:

The appropriate subclass of `RowStandardTableauTuples`.

A tuple of row standard tableau is a tableau whose entries are positive integers which increase from left to right along the rows in each component. The entries do NOT need to increase from left to right along the components.

**Note:** Sage uses the English convention for (tuples of) partitions and tableaux: the longer rows are displayed on top. As with `PartitionTuple`, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is `[0, 0, 0]`.

**EXAMPLES:**

```
sage: tabs = RowStandardTableauTuples([[2],[1,1]]); tabs
Row standard tableau tuples of shape ([2], [1, 1])
sage: tabs.cardinality()
12
sage: tabs[:]
#...
([([3, 4], [2], [1])],
([([2, 4], [3], [1])],
([([1, 4], [3], [2])],
([([1, 2], [4], [3])],
([([1, 3], [4], [2])],
([([2, 3], [4], [1])],
([([1, 4], [2], [3])],
([([1, 3], [2], [4])],
([([1, 2], [3], [4])],
([([2, 3], [1], [4])],
([([2, 4], [1], [3])],
([([3, 4], [1], [2])],
([[]], [], [[2, 3], [1]])
```

```
sage: tabs = RowStandardTableauTuples(level=3); tabs
Row standard tableau tuples of level 3
sage: tabs[100]
#...
([[]], [], [[2, 3], [1]])
```

(continues on next page)
Row standard tableau tuples of shape ([2], [1, 1])

Row standard tableau tuples of level 3

Row standard tableau tuples of level 1

Element

alias of RowStandardTableauTuple

level_one_parent_class

alias of RowStandardTableaux_all

shape()

Return the shape of the set of RowStandardTableauTuples, or None if it is not defined.

EXAMPLES:
```python
sage: tabs=RowStandardTableauTuples(shape=[[5,2],[3,2],[],[1,1,1],[3]]); tabs
row standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
sage: RowStandardTableauTuples().shape() is None
True
```

```python
>>> from sage.all import *
>>> tabs=RowStandardTableauTuples(shape=[[Integer(5),Integer(2)],[Integer(3),
Integer(2)],[Integer(1),Integer(1),Integer(1)],[Integer(3)]]); tabs
row standard tableau tuples of shape ([5, 2], [3, 2], [], [1, 1, 1], [3])
>>> tabs.shape()
([5, 2], [3, 2], [], [1, 1, 1], [3])
>>> RowStandardTableauTuples().shape() is None
True
```

**class sage.combinat.tableau_tuple.RowStandardTableauTuples_all**

**Bases:** `RowStandardTableauTuples`, `DisjointUnionEnumeratedSets`

Default class of all `RowStandardTableauTuples` with an arbitrary `level()` and `size()`.

**an_element()**

Return a particular element of the class.

**EXAMPLES:**

```python
sage: RowStandardTableauTuples().an_element()
([[4, 5, 6, 7]], [[2, 3]], [[1]])
```

```python
>> from sage.all import *
>>> RowStandardTableauTuples().an_element()
([[4, 5, 6, 7]], [[2, 3]], [[1]])
```

**class sage.combinat.tableau_tuple.RowStandardTableauTuples_level** *(level)*

**Bases:** `RowStandardTableauTuples`, `DisjointUnionEnumeratedSets`

Class of all `RowStandardTableauTuples` with a fixed `level` and arbitrary `size`.

**an_element()**

Return a particular element of the class.

**EXAMPLES:**

```python
sage: RowStandardTableauTuples(2).an_element()
([[1]], [[2, 3]])
sage: RowStandardTableauTuples(3).an_element()
([[1]], [[2, 3]], [[4, 5, 6, 7]])
```

```python
>> from sage.all import *
>>> RowStandardTableauTuples(Integer(2)).an_element()
([[1]], [[2, 3]])
>>> RowStandardTableauTuples(Integer(3)).an_element()
([[1]], [[2, 3]], [[4, 5, 6, 7]])
```

**class sage.combinat.tableau_tuple.RowStandardTableauTuples_level_size** *(level, size)*

**Bases:** `RowStandardTableauTuples`, `DisjointUnionEnumeratedSets`

Class of all `RowStandardTableauTuples` with a fixed `level` and a fixed `size`. 

---

**5.1. Comprehensive Module List**

---

**5517**
an_element()

Return a particular element of self.

EXAMPLES:

```
sage: RowStandardTableauTuples(5, size=2).an_element()  # needs sage.libs.flint
([], [], [], [], [[1], [2]])
sage: RowStandardTableauTuples(2, size=4).an_element()  # needs sage.libs.flint
([[1]], [[2, 3], [4]])
```

```python
class sage.combinat.tableau_tuple.RowStandardTableauTuples_residue(residue)
   Bases: RowStandardTableauTuples

Class of all row standard tableau tuples with a fixed residue sequence.

Implicitly, this also specifies the quantum characteristic, multicharge and hence the level and size of the tableaux.

**Note:** This class is not intended to be called directly, but rather, it is accessed through the row standard tableaux.

EXAMPLES:

```
sage: RowStandardTableau(([3,4,5],[1,2])).residue_sequence(2).row_standard_tableaux()
Row standard tableaux with 2-residue sequence (1,0,0,1,0) and multicharge (0)
sage: RowStandardTableau(([3,4,5],[1,2])).residue_sequence(3).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (2,0,0,1,2) and multicharge (0)
sage: RowStandardTableauTuple(([5,6],[7]),[[1,2,3],[4]]).residue_sequence(2,(0,0)).row_standard_tableaux()
Row standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,0)
sage: RowStandardTableauTuple(([5,6],[7]),[[1,2,3],[4]]).residue_sequence(3,(0,1)).row_standard_tableaux()
Row standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,1)
```

```python
>>> from sage.all import *

>>> RowStandardTableau(([3,Integer(4),Integer(5)],[Integer(1),Integer(2)]))
Row standard tableaux with 2-residue sequence (1,0,0,1,0) and multicharge (0)
>>> RowStandardTableau(([Integer(3),Integer(4),Integer(5)],[Integer(1),Integer(2)]))
Row standard tableaux with 3-residue sequence (2,0,0,1,2) and multicharge (0)
>>> RowStandardTableauTuple(([Integer(5),Integer(6)],[Integer(7)]),[[Integer(1),Integer(2),Integer(3)],[Integer(4)]])
Row standard tableaux with 3-residue sequence (2,0,0,1,2) and multicharge (0)
```
Row standard tableaux with 2-residue sequence (0,1,0,1,0,1,1) and multicharge (0,→0)

```python
>>> RowStandardTableauTuple([[Integer(5), Integer(6)], [Integer(7)]],
                           [[Integer(1),
                           -> Integer(2), Integer(3)], [Integer(4)]]).residue_sequence(Integer(3),
                           (Integer(0),
                           -> Integer(1))).row_standard_tableaux()
```

Row standard tableaux with 3-residue sequence (1,2,0,0,0,1,2) and multicharge (0,→1)

```python
an_element()
```

Return a particular element of self.

EXAMPLES:

```python
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3).row_standard_tableaux().an_element()
[[2, 3], [1]]
```

```python
sage: StandardTableau([[1,3],[2]]).residue_sequence(3).row_standard_tableaux().an_element()
[[1, 3], [2]]
```

```python
sage: RowStandardTableauTuple([[Integer(4)], [[2,3], [1]]]).residue_sequence(Integer(3),(Integer(0),Integer(1))).row_standard_tableaux().an_element()  # needs sage.libs.flint
([4], [3], [1], [2])
```

```python
from sage.all import *
```

```python
>>> RowStandardTableau([[Integer(2), Integer(3), [Integer(1)]]].residue_sequence(Integer(3)).row_standard_tableaux().an_element()
[[2, 3], [1]]
```

```python
>>> StandardTableau([[Integer(1), Integer(3)], [Integer(2)]]).residue_sequence(Integer(3)).row_standard_tableaux().an_element()
[[1, 3], [2]]
```

```python
>>> RowStandardTableauTuple([[Integer(4)], [[2,3], [1]]]).residue_sequence(Integer(3), (Integer(0), Integer(1))).row_standard_tableaux().an_element()  # needs sage.libs.flint
([4], [3], [1], [2])
```

```python
from sage.all import *
```

```python
>>> StandardTableauTuple([[Integer(4)], [Integer(1), Integer(3), [Integer(2)]]]).residue_sequence(Integer(3), (Integer(0), Integer(1))).row_standard_tableaux().an_element()  # needs sage.libs.flint
([4], [3], [1], [2])
```

```python
level()
```

Return the level of self.

EXAMPLES:

```python
sage: RowStandardTableau([[2,3],[1]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()
2
```

```python
sage: StandardTableau([[1,2],[3]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()
2
```

```python
sage: RowStandardTableauTuple([[4],[[2,3],[1]]]).residue_sequence(3,(0,1)).row_standard_tableaux().level()  # needs sage.libs.flint
2
```
Encapsulation

Return the multicharge of self.

EXAMPLES:

sage: RowStandardTableau([[2, 3], [1]]).residue_sequence(3, (0, 1)).row_standard_tableaux().multicharge()
(0, 1)

sage: StandardTableau([[1, 2], [3]]).residue_sequence(3, (0, 1)).row_standard_tableaux().multicharge()
(0, 1)

sage: RowStandardTableauTuple([[4], [[2], [3], [1]]]).residue_sequence(3, (0, 1)).row_standard_tableaux().multicharge()
(0, 1)

sage: StandardTableauTuple([[4], [[1], [3], [2]]]).residue_sequence(3, (0, 1)).row_standard_tableaux().multicharge()
(0, 1)
quantum_characteristic()

Return the quantum characteristic of self.

EXAMPLES:

```
