```

AmbientSpace

alias of *AmbientSpace*

ascii_art (*label=None*, *node=None*)

Return an ascii art representation of this reducible Cartan type.

EXAMPLES:

```
sage: print(CartanType("F4xA2").ascii_art(label = lambda x: x+2))
O---O=>=O---O
3   4   5   6
O---O
7   8

sage: print(CartanType(["BC",5,2], ["A",4]).ascii_art())
O=<=O---O---O---O=<=O
1   2   3   4   5   6
O---O---O---O
7   8   9   10

sage: print(CartanType(["A",4], ["BC",5,2], ["C",3]).ascii_art())
O---O---O---O

↪Integer(3)]).ascii_art())
O---O---O---O
1   2   3   4
O=<=O---O---O---O=<=O
5   6   7   8   9   10
O---O=<=O
11   12   13
```

cartan_matrix(*subdivide=True*)

Return the Cartan matrix associated with `self`. By default the Cartan matrix is a subdivided block matrix showing the reducibility but the subdivision can be suppressed with the option `subdivide = False`.

EXAMPLES:

```
sage: ct = CartanType("A2","B2")
sage: ct.cartan_matrix()                                                    #␣
↪needs sage.graphs
[ 2 -1| 0  0]
[-1  2| 0  0]
[-----+-----]
[ 0  0| 2 -1]
[ 0  0|-2  2]
sage: ct.cartan_matrix(subdivide=False)                                     #␣
↪needs sage.graphs
[ 2 -1  0  0]
[-1  2  0  0]
[ 0  0  2 -1]
[ 0  0 -2  2]
sage: ct.index_set() == ct.cartan_matrix().index_set()                      #␣
↪needs sage.graphs
True
```

```
>>> from sage.all import *
>>> ct = CartanType("A2","B2")
>>> ct.cartan_matrix()                                                    #␣
↪needs sage.graphs
[ 2 -1| 0  0]
[-1  2| 0  0]
[-----+-----]
```

(continues on next page)

(continued from previous page)

```
[ 0  0| 2 -1]
[ 0  0|-2  2]
>>> ct.cartan_matrix(subdivide=False)                                    #␣
↪needs sage.graphs
[ 2 -1  0  0]
[-1  2  0  0]
[ 0  0  2 -1]
[ 0  0 -2  2]
>>> ct.index_set() == ct.cartan_matrix().index_set()                     #␣
↪needs sage.graphs
True
```

component_types()

A list of Cartan types making up the reducible type.

EXAMPLES:

```
sage: CartanType(['A',2],['B',2]).component_types()
[['A', 2], ['B', 2]]
```

```
>>> from sage.all import *
>>> CartanType(['A',Integer(2)],['B',Integer(2)]).component_types()
[['A', 2], ['B', 2]]
```

coxeter_diagram()

Return the Coxeter diagram for `self`.

EXAMPLES:

```
sage: cd = CartanType("A2xB2xF4").coxeter_diagram(); cd                    #␣
↪needs sage.graphs
Graph on 8 vertices
sage: cd.edges(sort=True)                                                  #␣
↪needs sage.graphs
[(1, 2, 3), (3, 4, 4), (5, 6, 3), (6, 7, 4), (7, 8, 3)]

sage: CartanType("F4xA2").coxeter_diagram().edges(sort=True)               #␣
↪needs sage.graphs
[(1, 2, 3), (2, 3, 4), (3, 4, 3), (5, 6, 3)]

sage: cd = CartanType("A1xH3").coxeter_diagram(); cd                       #␣
↪needs sage.graphs
Graph on 4 vertices
sage: cd.edges(sort=True)                                                  #␣
↪needs sage.graphs
[(2, 3, 3), (3, 4, 5)]
```

```
>>> from sage.all import *
>>> cd = CartanType("A2xB2xF4").coxeter_diagram(); cd                     #␣
↪needs sage.graphs
Graph on 8 vertices
>>> cd.edges(sort=True)                                                   #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.graphs
[(1, 2, 3), (3, 4, 4), (5, 6, 3), (6, 7, 4), (7, 8, 3)]

>>> CartanType("F4xA2").coxeter_diagram().edges(sort=True)                     #␣
↪needs sage.graphs
[(1, 2, 3), (2, 3, 4), (3, 4, 3), (5, 6, 3)]

>>> cd = CartanType("A1xH3").coxeter_diagram(); cd                             #␣
↪needs sage.graphs
Graph on 4 vertices
>>> cd.edges(sort=True)                                                        #␣
↪needs sage.graphs
[(2, 3, 3), (3, 4, 5)]
```

dual()

EXAMPLES:

```
sage: CartanType("A2xB2").dual()
A2xC2
```

```
>>> from sage.all import *
>>> CartanType("A2xB2").dual()
A2xC2
```

dynkin_diagram()

Return a Dynkin diagram for type reducible.

EXAMPLES:

```
sage: dd = CartanType("A2xB2xF4").dynkin_diagram(); dd                          #␣
↪needs sage.graphs
O---O
1   2
O=>=O
3   4
O---O=>=O---O
5   6   7   8
A2xB2xF4
sage: dd.edges(sort=True)                                                       #␣
↪needs sage.graphs
[(1, 2, 1), (2, 1, 1), (3, 4, 2), (4, 3, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 2), (7, 6, 1), (7, 8, 1), (8, 7, 1)]

sage: CartanType("F4xA2").dynkin_diagram()                                      #␣
↪needs sage.graphs
O---O=>=O---O
1   2   3   4
O---O
5   6
F4xA2
```

```
>>> from sage.all import *
>>> dd = CartanType("A2xB2xF4").dynkin_diagram(); dd                    #␣
↪needs sage.graphs
O---O
1   2
O=>=O
3   4
O---O=>=O---O
5   6   7   8
A2xB2xF4
>>> dd.edges(sort=True)                                                 #␣
↪needs sage.graphs
[(1, 2, 1), (2, 1, 1), (3, 4, 2), (4, 3, 1), (5, 6, 1),
 (6, 5, 1), (6, 7, 2), (7, 6, 1), (7, 8, 1), (8, 7, 1)]

>>> CartanType("F4xA2").dynkin_diagram()                                #␣
↪needs sage.graphs
O---O=>=O---O
1   2   3   4
O---O
5   6
F4xA2
```

index_set()

Implement *CartanType_abstract.index_set()*.

For the moment, the index set is always of the form $\{1, \ldots, n\}$.

EXAMPLES:

```
sage: CartanType("A2","A1").index_set()
(1, 2, 3)
```

```
>>> from sage.all import *
>>> CartanType("A2","A1").index_set()
(1, 2, 3)
```

is_affine()

Report that this reducible Cartan type is not affine.

EXAMPLES:

```
sage: CartanType(['A',2],['B',2]).is_affine()
False
```

```
>>> from sage.all import *
>>> CartanType(['A',Integer(2)],['B',Integer(2)]).is_affine()
False
```

is_finite()

EXAMPLES:

```
sage: ct1 = CartanType(['A',2],['B',2])
sage: ct1.is_finite()
```

(continues on next page)

(continued from previous page)

```
True
sage: ct2 = CartanType(['A',2],['B',2,1])
sage: ct2.is_finite()
False
```

```
>>> from sage.all import *
>>> ct1 = CartanType(['A',Integer(2)],['B',Integer(2)])
>>> ct1.is_finite()
True
>>> ct2 = CartanType(['A',Integer(2)],['B',Integer(2),Integer(1)])
>>> ct2.is_finite()
False
```

is_irreducible()

Report that this Cartan type is not irreducible.

EXAMPLES:

```
sage: ct = CartanType(['A',2],['B',2])
sage: ct.is_irreducible()
False
```

```
>>> from sage.all import *
>>> ct = CartanType(['A',Integer(2)],['B',Integer(2)])
>>> ct.is_irreducible()
False
```

rank()

Return the rank of `self`.

EXAMPLES:

```
sage: CartanType("A2","A1").rank()
3
```

```
>>> from sage.all import *
>>> CartanType("A2","A1").rank()
3
```

type()

Return `"reducible"` since the type is reducible.

EXAMPLES:

```
sage: CartanType(['A',2],['B',2]).type()
'reducible'
```

```
>>> from sage.all import *
>>> CartanType(['A',Integer(2)],['B',Integer(2)]).type()
'reducible'
```

5.1.269 Root system data for relabelled Cartan types

class sage.combinat.root_system.type_relabel.**AmbientSpace**(*root_system*, *base_ring*, *index_set=None*)

Bases: *AmbientSpace*

Ambient space for a relabelled finite Cartan type.

It is constructed in the canonical way from the ambient space of the original Cartan type, by relabelling the simple roots, fundamental weights, etc.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space(); L
Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4,
↪ 4: 1}
sage: TestSuite(L).run()                                                    #␣
↪needs sage.graphs
```

```
>>> from sage.all import *
>>> cycle = {Integer(1):Integer(2), Integer(2):Integer(3), Integer(3):Integer(4),␣
↪Integer(4):Integer(1)}
>>> L = CartanType(["F",Integer(4)]).relabel(cycle).root_system().ambient_space();
↪ L
Ambient space of the Root system of type ['F', 4] relabelled by {1: 2, 2: 3, 3: 4,
↪ 4: 1}
>>> TestSuite(L).run()                                                    #␣
↪needs sage.graphs
```

dimension()

Return the dimension of this ambient space.

See also

sage.combinat.root_system.ambient_space.AmbientSpace.dimension()

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: L.dimension()
4
```

```
>>> from sage.all import *
>>> cycle = {Integer(1):Integer(2), Integer(2):Integer(3),␣
↪Integer(3):Integer(4), Integer(4):Integer(1)}
>>> L = CartanType(["F",Integer(4)]).relabel(cycle).root_system().ambient_
↪space()
>>> L.dimension()
4
```

fundamental_weight(*i*)

Return the `i`-th fundamental weight.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(["F",4]).root_system().ambient_space()
sage: K.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4:␣
↪(1, 0, 0, 0)}
sage: L.fundamental_weight(1)
(1, 0, 0, 0)
sage: L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (2, 1, 1, 0), 4: (3/2, 1/
↪2, 1/2, 1/2)}
```

```
>>> from sage.all import *
>>> cycle = {Integer(1):Integer(2), Integer(2):Integer(3),␣
↪Integer(3):Integer(4), Integer(4):Integer(1)}
>>> L = CartanType(["F",Integer(4)]).relabel(cycle).root_system().ambient_
↪space()
>>> K = CartanType(["F",Integer(4)]).root_system().ambient_space()
>>> K.fundamental_weights()
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4:␣
↪(1, 0, 0, 0)}
>>> L.fundamental_weight(Integer(1))
(1, 0, 0, 0)
>>> L.fundamental_weights()
Finite family {1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (2, 1, 1, 0), 4: (3/2, 1/
↪2, 1/2, 1/2)}
```

simple_root(*i*)

Return the i-th simple root.

It is constructed by looking up the corresponding simple coroot in the ambient space for the original Cartan type.

EXAMPLES:

```
sage: cycle = {1:2, 2:3, 3:4, 4:1}
sage: L = CartanType(["F",4]).relabel(cycle).root_system().ambient_space()
sage: K = CartanType(["F",4]).root_system().ambient_space()
sage: K.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -
↪1/2, -1/2, -1/2)}
sage: K.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1,
↪ -1, -1)}
sage: L.simple_root(1)
(1/2, -1/2, -1/2, -1/2)

sage: L.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1),
↪ 4: (0, 0, 0, 1)}
```

(continues on next page)

(continued from previous page)

```
sage: L.simple_coroots()
Finite family {1: (1, -1, -1, -1), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0,␣
↪0, 0, 2)}
```

```
>>> from sage.all import *
>>> cycle = {Integer(1):Integer(2), Integer(2):Integer(3),␣
↪Integer(3):Integer(4), Integer(4):Integer(1)}
>>> L = CartanType(["F",Integer(4)]).relabel(cycle).root_system().ambient_
↪space()
>>> K = CartanType(["F",Integer(4)]).root_system().ambient_space()
>>> K.simple_roots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 1), 4: (1/2, -
↪1/2, -1/2, -1/2)}
>>> K.simple_coroots()
Finite family {1: (0, 1, -1, 0), 2: (0, 0, 1, -1), 3: (0, 0, 0, 2), 4: (1, -1,
↪ -1, -1)}
>>> L.simple_root(Integer(1))
(1/2, -1/2, -1/2, -1/2)

>>> L.simple_roots()
Finite family {1: (1/2, -1/2, -1/2, -1/2), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1),
↪ 4: (0, 0, 0, 1)}

>>> L.simple_coroots()
Finite family {1: (1, -1, -1, -1), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1), 4: (0,␣
↪0, 0, 2)}
```

class sage.combinat.root_system.type_relabel.**CartanType**(*type*, *relabelling*)

Bases: *CartanType_decorator*

A class for relabelled Cartan types.

ascii_art(*label=None*, *node=None*)

Return an ascii art representation of this Cartan type.

EXAMPLES:

```
sage: print(CartanType(["G", 2]).relabel({1:2,2:1}).ascii_art())
  3
O=<=O
2   1
sage: print(CartanType(["B", 3, 1]).relabel([1,3,2,0]).ascii_art())
    O 1
    |
    |
O---O=>=O
3   2   0
sage: print(CartanType(["F", 4, 1]).relabel(lambda n: 4-n).ascii_art())
O---O---O=>=O---O
4   3   2   1   0
```

```
>>> from sage.all import *
>>> print(CartanType(["G", Integer(2)]).relabel({Integer(1):Integer(2),
↪Integer(2):Integer(1)}).ascii_art())
  3
O=<=O
2   1
>>> print(CartanType(["B", Integer(3), Integer(1)]).relabel([Integer(1),
↪Integer(3),Integer(2),Integer(0)]).ascii_art())
    O 1
    |
    |
O---O=>=O
3   2   0
>>> print(CartanType(["F", Integer(4), Integer(1)]).relabel(lambda n:␣
↪Integer(4)-n).ascii_art())
O---O---O=>=O---O
4   3   2   1   0
```

coxeter_diagram()

Return the Coxeter diagram for `self`.

EXAMPLES:

```
sage: ct = CartanType(['H', 3]).relabel({1:3,2:2,3:1})
sage: G = ct.coxeter_diagram(); G                                        #␣
↪needs sage.graphs
Graph on 3 vertices
sage: G.edges(sort=True)                                                 #␣
↪needs sage.graphs
[(1, 2, 5), (2, 3, 3)]
```

```
>>> from sage.all import *
>>> ct = CartanType(['H', Integer(3)]).relabel({Integer(1):Integer(3),
↪Integer(2):Integer(2),Integer(3):Integer(1)})
>>> G = ct.coxeter_diagram(); G                                        #␣
↪needs sage.graphs
Graph on 3 vertices
>>> G.edges(sort=True)                                                 #␣
↪needs sage.graphs
[(1, 2, 5), (2, 3, 3)]
```

dual()

Implement *sage.combinat.root_system.cartan_type.CartanType_abstract.dual()*, using that taking the dual and relabelling are commuting operations.

EXAMPLES:

```
sage: T = CartanType(["BC",3, 2])
sage: cycle = {1:2, 2:3, 3:0, 0:1}
sage: T.relabel(cycle).dual().dynkin_diagram()                           #␣
↪needs sage.graphs
O=>=O---O=>=O
1   2   3   0
```

(continues on next page)

(continued from previous page)

```
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
sage: T.dual().relabel(cycle).dynkin_diagram()                          #␣
↪needs sage.graphs
O=>=O---O=>=O
1   2   3   0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
```

```
>>> from sage.all import *
>>> T = CartanType(["BC",Integer(3), Integer(2)])
>>> cycle = {Integer(1):Integer(2), Integer(2):Integer(3),␣
↪Integer(3):Integer(0), Integer(0):Integer(1)}
>>> T.relabel(cycle).dual().dynkin_diagram()                          #␣
↪needs sage.graphs
O=>=O---O=>=O
1   2   3   0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
>>> T.dual().relabel(cycle).dynkin_diagram()                          #␣
↪needs sage.graphs
O=>=O---O=>=O
1   2   3   0
BC3~* relabelled by {0: 1, 1: 2, 2: 3, 3: 0}
```

dynkin_diagram()

Return the Dynkin diagram for this Cartan type.

EXAMPLES:

```
sage: CartanType(["G", 2]).relabel({1:2,2:1}).dynkin_diagram()          #␣
↪needs sage.graphs
  3
O=<=O
2   1
G2 relabelled by {1: 2, 2: 1}
```

```
>>> from sage.all import *
>>> CartanType(["G", Integer(2)]).relabel({Integer(1):Integer(2),
↪Integer(2):Integer(1)}).dynkin_diagram()          # needs sage.graphs
  3
O=<=O
2   1
G2 relabelled by {1: 2, 2: 1}
```

index_set()

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.index_set()
(1, 2)
```

```
>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
↪Integer(2):Integer(1)})
```

(continues on next page)

(continued from previous page)

```
>>> ct.index_set()
(1, 2)
```

type()

Return the type of `self` or `None` if unknown.

EXAMPLES:

```
sage: ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.type()
'G'
```

```
>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
↪Integer(2):Integer(1)})
>>> ct.type()
'G'
```

class sage.combinat.root_system.type_relabel.**CartanType_affine**(*type*, *relabelling*)

Bases: *CartanType*, *CartanType_affine*

basic_untwisted()

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is X_n. In other words, it is the classical Cartan type that is twisted to obtain `self`.

EXAMPLES:

```
sage: ct = CartanType(['A', 5, 2]).relabel({0:1, 1:0, 2:2, 3:3})
sage: ct.basic_untwisted()
['A', 5]
```

```
>>> from sage.all import *
>>> ct = CartanType(['A', Integer(5), Integer(2)]).relabel(
↪{Integer(0):Integer(1), Integer(1):Integer(0), Integer(2):Integer(2),␣
↪Integer(3):Integer(3)})
>>> ct.basic_untwisted()
['A', 5]
```

classical()

Return the classical Cartan type associated with `self`.

EXAMPLES:

```
sage: A41 = CartanType(['A',4,1])
sage: A41.dynkin_diagram()                                              #␣
↪needs sage.graphs
0
O-----------+
|           |
|           |

↪needs sage.graphs
O---O---O---O
2   3   4   0
A4 relabelled by {1: 2, 2: 3, 3: 4, 4: 0}
```

is_untwisted_affine()

Implement *CartanType_affine.is_untwisted_affine()*.

A relabelled Cartan type is untwisted affine if the original is.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).is_untwisted_
↪affine()
True
```

```
>>> from sage.all import *
>>> CartanType(['B', Integer(3), Integer(1)]).relabel({Integer(1):Integer(2),␣
↪Integer(2):Integer(3), Integer(3):Integer(0), Integer(0):Integer(1)}).is_
↪untwisted_affine()
True
```

special_node()

Return a special node of the Dynkin diagram.

See also

special_node()

It is obtained by relabelling of the special node of the non relabelled Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['B', 3, 1]).special_node()
0
sage: CartanType(['B', 3, 1]).relabel({1:2, 2:3, 3:0, 0:1}).special_node()
1
```

```
>>> from sage.all import *
>>> CartanType(['B', Integer(3), Integer(1)]).special_node()
0
>>> CartanType(['B', Integer(3), Integer(1)]).relabel({Integer(1):Integer(2),␣
↪Integer(2):Integer(3), Integer(3):Integer(0), Integer(0):Integer(1)}).
↪special_node()
1
```

class sage.combinat.root_system.type_relabel.**CartanType_finite**(*type*, *relabelling*)

Bases: *CartanType*, *CartanType_finite*

AmbientSpace
alias of *AmbientSpace*

affine()
Return the affine Cartan type associated with `self`.

EXAMPLES:

```
sage: B4 = CartanType(['B',4])
sage: B4.dynkin_diagram()                                                    #␣
↪needs sage.graphs
O---O---O=>=O
1   2   3   4
B4
sage: B4.affine().dynkin_diagram()                                           #␣
↪needs sage.graphs
    O 0
    |
    |
O---O---O=>=O
1   2   3   4
B4~
```

```
>>> from sage.all import *
>>> B4 = CartanType(['B',Integer(4)])
>>> B4.dynkin_diagram()                                                    #␣
↪needs sage.graphs
O---O---O=>=O
1   2   3   4
B4
>>> B4.affine().dynkin_diagram()                                           #␣
↪needs sage.graphs
    O 0
    |
    |
O---O---O=>=O
1   2   3   4
B4~
```

If possible, this reuses the original label for the special node:

```
sage: T = B4.relabel({1:2, 2:3, 3:4, 4:1}); T.dynkin_diagram()               #␣
↪needs sage.graphs
O---O---O=>=O
2   3   4   1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
sage: T.affine().dynkin_diagram()                                            #␣
↪needs sage.graphs
    O 0
    |
    |
O---O---O=>=O
2   3   4   1
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}
```

```
>>> from sage.all import *
>>> T = B4.relabel({Integer(1):Integer(2), Integer(2):Integer(3),␣
↪Integer(3):Integer(4), Integer(4):Integer(1)}); T.dynkin_diagram()                ␣
↪     # needs sage.graphs
O---O---O=>=O
2   3   4   1
B4 relabelled by {1: 2, 2: 3, 3: 4, 4: 1}
>>> T.affine().dynkin_diagram()                                                   #␣
↪needs sage.graphs
    O 0
    |
    |
O---O---O=>=O
2   3   4   1
B4~ relabelled by {0: 0, 1: 2, 2: 3, 3: 4, 4: 1}
```

Otherwise, it chooses a label for the special_node in $0, 1, \ldots$:

```
sage: T = B4.relabel({1:0, 2:1, 3:2, 4:3}); T.dynkin_diagram()                      #␣
↪needs sage.graphs
O---O---O=>=O
0   1   2   3
B4 relabelled by {1: 0, 2: 1, 3: 2, 4: 3}
sage: T.affine().dynkin_diagram()                                                   #␣
↪needs sage.graphs
    O 4
    |
    |
O---O---O=>=O
0   1   2   3
B4~ relabelled by {0: 4, 1: 0, 2: 1, 3: 2, 4: 3}
```

```
>>> from sage.all import *
>>> T = B4.relabel({Integer(1):Integer(0), Integer(2):Integer(1),␣
↪Integer(3):Integer(2), Integer(4):Integer(3)}); T.dynkin_diagram()                ␣
↪     # needs sage.graphs
O---O---O=>=O
0   1   2   3
B4 relabelled by {1: 0, 2: 1, 3: 2, 4: 3}
>>> T.affine().dynkin_diagram()                                                   #␣
↪needs sage.graphs
    O 4
    |
    |
O---O---O=>=O
0   1   2   3
B4~ relabelled by {0: 4, 1: 0, 2: 1, 3: 2, 4: 3}
```

This failed before Issue #13724:

```
sage: ct = CartanType(["G",2]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
sage: ct.affine()
```

(continues on next page)

(continued from previous page)

```
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}

sage: ct = CartanType(["F",4]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}
```

```
>>> from sage.all import *
>>> ct = CartanType(["G",Integer(2)]).dual(); ct
['G', 2] relabelled by {1: 2, 2: 1}
>>> ct.affine()
['G', 2, 1] relabelled by {0: 0, 1: 2, 2: 1}

>>> ct = CartanType(["F",Integer(4)]).dual(); ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
>>> ct.affine()
['F', 4, 1] relabelled by {0: 0, 1: 4, 2: 3, 3: 2, 4: 1}
```

Check that we don't inadvertently change the internal relabelling of `ct`:

```
sage: ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

```
>>> from sage.all import *
>>> ct
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

5.1.270 Weight lattice realizations

class `sage.combinat.root_system.weight_lattice_realizations.`**`WeightLatticeRealizations`**(*base*, *name=None*)

Bases: `Category_over_base_ring`

The category of weight lattice realizations over a given base ring.

A *weight lattice realization* L over a base ring R is a free module (or vector space if R is a field) endowed with an embedding of the root lattice of some root system. By restriction, this embedding defines an embedding of the root lattice of this root system, which makes L a root lattice realization.

Typical weight lattice realizations over **Z** include the weight lattice, and ambient lattice. Typical weight lattice realizations over **Q** include the weight space, and ambient space.

To describe the embedding, a weight lattice realization must implement a method `fundamental_weight`(i) returning for each `i()` in the index set the image of the fundamental weight Λ_i under the embedding.

In order to be a proper root lattice realization, a weight lattice realization should also implement the scalar product with the coroot lattice; on the other hand, the embedding of the simple roots is given for free.

See also

- *RootSystem*
- *RootLatticeRealizations*

- *WeightSpace*
- *AmbientSpace*

EXAMPLES:

Here, we consider the root system of type A_7, and embed the weight lattice element $x = \Lambda_1 + 2\Lambda_3$ in several root lattice realizations:

```
sage: R = RootSystem(["A",7])
sage: Lambda = R.weight_lattice().fundamental_weights()
sage: x = Lambda[2] + 2 * Lambda[5]

sage: L = R.weight_space()
sage: L(x)
Lambda[2] + 2*Lambda[5]

sage: L = R.ambient_lattice()
sage: L(x)
(3, 3, 2, 2, 2, 0, 0, 0)
```

```
>>> from sage.all import *
>>> R = RootSystem(["A",Integer(7)])
>>> Lambda = R.weight_lattice().fundamental_weights()
>>> x = Lambda[Integer(2)] + Integer(2) * Lambda[Integer(5)]

>>> L = R.weight_space()
>>> L(x)
Lambda[2] + 2*Lambda[5]

>>> L = R.ambient_lattice()
>>> L(x)
(3, 3, 2, 2, 2, 0, 0, 0)
```

We embed the weight space element $x = \Lambda_1 + 1/2\Lambda_3$ in the ambient space:

```
sage: Lambda = R.weight_space().fundamental_weights()
sage: x = Lambda[2] + 1/2 * Lambda[5]

sage: L = R.ambient_space()
sage: L(x)
(3/2, 3/2, 1/2, 1/2, 1/2, 0, 0, 0)
```

```
>>> from sage.all import *
>>> Lambda = R.weight_space().fundamental_weights()
>>> x = Lambda[Integer(2)] + Integer(1)/Integer(2) * Lambda[Integer(5)]

>>> L = R.ambient_space()
>>> L(x)
(3/2, 3/2, 1/2, 1/2, 1/2, 0, 0, 0)
```

Of course, one can't embed the weight space in the ambient lattice:

```
sage: L = R.ambient_lattice()
sage: L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[2] + 1/2*Lambda[5])
an element of self (=Ambient lattice of the Root system of type ['A', 7])
```

```
>>> from sage.all import *
>>> L = R.ambient_lattice()
>>> L(x)
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[2] + 1/2*Lambda[5])
an element of self (=Ambient lattice of the Root system of type ['A', 7])
```

If K_1 is a subring of K_2, then one could in theory have an embedding from the weight space over K_1 to any weight lattice realization over K_2; this is not implemented:

```
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.ambient_space(K2)

sage: Lambda = R.weight_space(K2).fundamental_weights()
sage: L(Lambda[1])
(1, 0, 0, 0, 0, 0, 0, 0)

sage: Lambda = R.weight_space(K1).fundamental_weights()
sage: L(Lambda[1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[1]) an element
of self (=Ambient space of the Root system of type ['A', 7])
```

```
>>> from sage.all import *
>>> K1 = QQ
>>> K2 = QQ['q']
>>> L = R.ambient_space(K2)

>>> Lambda = R.weight_space(K2).fundamental_weights()
>>> L(Lambda[Integer(1)])
(1, 0, 0, 0, 0, 0, 0, 0)

>>> Lambda = R.weight_space(K1).fundamental_weights()
>>> L(Lambda[Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= Lambda[1]) an element
of self (=Ambient space of the Root system of type ['A', 7])
```

class ElementMethods

Bases: `object`

symmetric_form(*la*)

Return the symmetric form of `self` with `la`.

Return the pairing $(|)$ on the weight lattice. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

> **Warning**
>
> For affine root systems, if you are not working in the extended weight lattice/space, this may return incorrect results.

EXAMPLES:

```
sage: # needs sage.graphs
sage: P = RootSystem(['C',2]).weight_lattice()
sage: al = P.simple_roots()
sage: al[1].symmetric_form(al[1])
2
sage: al[1].symmetric_form(al[2])
-2
sage: al[2].symmetric_form(al[1])
-2
sage: Q = RootSystem(['C',2]).root_lattice()
sage: alQ = Q.simple_roots()
sage: all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])
....:     for i in P.index_set() for j in P.index_set())
True

sage: # needs sage.graphs

[1, 0, 0]

>>> P = RootSystem(['C',Integer(2),Integer(1)]).weight_lattice()
>>> Q = RootSystem(['C',Integer(2),Integer(1)]).root_lattice()
>>> al = P.simple_roots()                                                    #␣
↪needs sage.graphs
>>> alQ = Q.simple_roots()                                                   #␣
↪needs sage.graphs
```

(continues on next page)

(continued from previous page)

```
>>> all(al[i].symmetric_form(al[j]) == alQ[i].symmetric_form(alQ[j])   #␣
↪needs sage.graphs
...     for i in P.index_set() for j in P.index_set())
True
```

The result of $(\Lambda_0|\alpha_0)$ should be 1, however we get 0 because we are not working in the extended weight lattice:

```
sage: La = P.basis()
sage: [La[0].symmetric_form(al) for al in P.simple_roots()]           #␣
↪needs sage.graphs
[0, 0, 0]
```

```
>>> from sage.all import *
>>> La = P.basis()
>>> [La[Integer(0)].symmetric_form(al) for al in P.simple_roots()]          ␣
↪     # needs sage.graphs
[0, 0, 0]
```

to_weight_space(*base_ring=None*)

Map `self` to the weight space.

> **Warning**
>
> Implemented for finite Cartan type.

EXAMPLES:

```
sage: b = CartanType(['B',2]).root_system().ambient_space().from_
↪vector(vector([1,-2])); b
(1, -2)
sage: b.to_weight_space()
3*Lambda[1] - 4*Lambda[2]
sage: b = CartanType(['B',2]).root_system().ambient_space().from_
↪vector(vector([1/2,0])); b
(1/2, 0)
sage: b.to_weight_space()
1/2*Lambda[1]
sage: b.to_weight_space(ZZ)
Traceback (most recent call last):
...

sage: b.to_weight_space()
-6*Lambda[1] + 5*Lambda[2]
```

```
>>> from sage.all import *
>>> b = CartanType(['B',Integer(2)]).root_system().ambient_space().from_
```

(continues on next page)

(continued from previous page)

```
↪vector(vector([Integer(1),-Integer(2)])); b
(1, -2)
>>> b.to_weight_space()
3*Lambda[1] - 4*Lambda[2]
>>> b = CartanType(['B',Integer(2)]).root_system().ambient_space().from_
↪vector(vector([Integer(1)/Integer(2),Integer(0)])); b
(1/2, 0)
>>> b.to_weight_space()
1/2*Lambda[1]
>>> b.to_weight_space(ZZ)
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
>>> b = CartanType(['G',Integer(2)]).root_system().ambient_space().from_
↪vector(vector([Integer(4),-Integer(5),Integer(1)])); b
(4, -5, 1)
>>> b.to_weight_space()
-6*Lambda[1] + 5*Lambda[2]
```

class ParentMethods

Bases: `object`

dynkin_diagram_automorphism_of_alcove_morphism(*f*)

Return the Dynkin diagram automorphism induced by an alcove morphism.

INPUT:

- `f` – a linear map from `self` to `self` which preserves alcoves

This method returns the Dynkin diagram automorphism for the decomposition $f = dw$ (see `reduced_word_of_alcove_morphism()`), as a dictionary mapping elements of the index set to itself.

EXAMPLES:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()                                          #␣
↪needs sage.graphs
sage: Lambda = R.fundamental_weights()
```

```
>>> from sage.all import *
>>> R = RootSystem(["A",Integer(2),Integer(1)]).weight_lattice()
>>> alpha = R.simple_roots()                                        #␣
↪needs sage.graphs
>>> Lambda = R.fundamental_weights()
```

Translations by elements of the root lattice induce a trivial Dynkin diagram automorphism:

```
sage: # needs sage.graphs sage.libs.gap
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[0].
↪translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].
↪translation)
{0: 0, 1: 1, 2: 2}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[2].
```

(continues on next page)

(continued from previous page)

```
↪translation)
{0: 0, 1: 1, 2: 2}
```

```
>>> from sage.all import *
>>> # needs sage.graphs sage.libs.gap
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[Integer(0)].
↪translation)
{0: 0, 1: 1, 2: 2}
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[Integer(1)].
↪translation)
{0: 0, 1: 1, 2: 2}
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[Integer(2)].
↪translation)
{0: 0, 1: 1, 2: 2}
```

This is no more the case for translations by general elements of the (classical) weight lattice at level 0:

```
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - Lambda[0]

sage: # needs sage.graphs sage.libs.gap
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 2, 2: 0}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 2, 1: 0, 2: 1}

sage: # needs sage.graphs sage.libs.gap
sage: R = RootSystem(['C',2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[1].
↪translation)
{0: 2, 1: 1, 2: 0}

sage: # needs sage.graphs sage.libs.gap
sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 0, 2: 2, 3: 3, 4: 5, 5: 4}
sage: R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 0, 1: 1, 2: 2, 3: 3, 4: 4, 5: 5}
```

```
>>> from sage.all import *
>>> omega1 = Lambda[Integer(1)] - Lambda[Integer(0)]
>>> omega2 = Lambda[Integer(2)] - Lambda[Integer(0)]

>>> # needs sage.graphs sage.libs.gap
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 2, 2: 0}
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 2, 1: 0, 2: 1}
```

(continues on next page)

(continued from previous page)

```
>>> # needs sage.graphs sage.libs.gap
>>> R = RootSystem(['C',Integer(2),Integer(1)]).weight_lattice()
>>> alpha = R.simple_roots()
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(alpha[Integer(1)].
↪translation)
{0: 2, 1: 1, 2: 0}

>>> # needs sage.graphs sage.libs.gap
>>> R = RootSystem(['D',Integer(5),Integer(1)]).weight_lattice()
>>> Lambda = R.fundamental_weights()
>>> omega1 = Lambda[Integer(1)] - Lambda[Integer(0)]
>>> omega2 = Lambda[Integer(2)] - Integer(2)*Lambda[Integer(0)]
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(omega1.translation)
{0: 1, 1: 0, 2: 2, 3: 3, 4: 5, 5: 4}
>>> R.dynkin_diagram_automorphism_of_alcove_morphism(omega2.translation)
{0: 0, 1: 1, 2: 2, 3: 3, 4: 4, 5: 5}
```

Algorithm: computes w of the decomposition, and see how $f \circ w^{-1}$ permutes the simple roots.

embed_at_level(*x*, *level=1*)

Embed the classical weight x in the level `level` hyperplane.

This is achieved by translating the straightforward embedding of x by $c\Lambda_0$ for c some appropriate scalar.

INPUT:

- `x` – an element of the corresponding classical weight/ambient lattice
- `level` – integer or element of the base ring (default: 1)

EXAMPLES:

```
sage: # needs sage.graphs
sage: L = RootSystem(["B",3,1]).weight_space()
sage: L0 = L.classical()
sage: alpha = L0.simple_roots()
sage: omega = L0.fundamental_weights()
sage: L.embed_at_level(omega[1], 1)
Lambda[1]
sage: L.embed_at_level(omega[2], 1)
-Lambda[0] + Lambda[2]
sage: L.embed_at_level(omega[3], 1)
Lambda[3]
sage: L.embed_at_level(alpha[1], 1)
Lambda[0] + 2*Lambda[1] - Lambda[2]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> L = RootSystem(["B",Integer(3),Integer(1)]).weight_space()
>>> L0 = L.classical()
>>> alpha = L0.simple_roots()
>>> omega = L0.fundamental_weights()
>>> L.embed_at_level(omega[Integer(1)], Integer(1))
Lambda[1]
>>> L.embed_at_level(omega[Integer(2)], Integer(1))
```

(continues on next page)

(continued from previous page)

```
-Lambda[0] + Lambda[2]
>>> L.embed_at_level(omega[Integer(3)], Integer(1))
Lambda[3]
>>> L.embed_at_level(alpha[Integer(1)], Integer(1))
Lambda[0] + 2*Lambda[1] - Lambda[2]
```

fundamental_weight(*i*)

Return the i-th fundamental weight.

INPUT:

- i – an element of the index set

By a slight notational abuse, for an affine type this method should also accept 'delta' as input, and return the image of δ of the extended weight lattice in this realization.

This should be overridden by any subclass, and typically be implemented as a cached method for efficiency.

EXAMPLES:

```
sage: L = RootSystem(["A",3]).ambient_lattice()
sage: L.fundamental_weight(1)
(1, 0, 0, 0)

sage: L = RootSystem(["A",3,1]).weight_lattice(extended=True)
sage: L.fundamental_weight(1)
Lambda[1]
sage: L.fundamental_weight("delta")
delta
```

```
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(3)]).ambient_lattice()
>>> L.fundamental_weight(Integer(1))
(1, 0, 0, 0)

>>> L = RootSystem(["A",Integer(3),Integer(1)]).weight_
↪lattice(extended=True)
>>> L.fundamental_weight(Integer(1))
Lambda[1]
>>> L.fundamental_weight("delta")
delta
```

fundamental_weights()

Return the family $(\Lambda_i)_{i\in I}$ of the fundamental weights.

EXAMPLES:

```
sage: e = RootSystem(['A',3]).ambient_lattice()
sage: f = e.fundamental_weights()
sage: [f[i] for i in [1,2,3]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

```
>>> from sage.all import *
>>> e = RootSystem(['A',Integer(3)]).ambient_lattice()
```

(continues on next page)

(continued from previous page)

```
>>> f = e.fundamental_weights()
>>> [f[i] for i in [Integer(1),Integer(2),Integer(3)]]
[(1, 0, 0, 0), (1, 1, 0, 0), (1, 1, 1, 0)]
```

is_extended()

Return whether this is a realization of the extended weight lattice.

See also

sage.combinat.root_system.weight_space.WeightSpace

EXAMPLES:

```
sage: RootSystem(["A",3,1]).weight_lattice().is_extended()
False
sage: RootSystem(["A",3,1]).weight_lattice(extended=True).is_extended()
True
```

```
>>> from sage.all import *
>>> RootSystem(["A",Integer(3),Integer(1)]).weight_lattice().is_extended()
False
>>> RootSystem(["A",Integer(3),Integer(1)]).weight_lattice(extended=True).
↪is_extended()
True
```

This method is irrelevant for finite root systems, since the weight lattice need not be extended to ensure that the root lattice embeds faithfully:

```
sage: RootSystem(["A",3]).weight_lattice().is_extended()
False
```

```
>>> from sage.all import *
>>> RootSystem(["A",Integer(3)]).weight_lattice().is_extended()
False
```

reduced_word_of_alcove_morphism(f)

Return the reduced word of an alcove morphism.

INPUT:

- `f` – a linear map from `self` to `self` which preserves alcoves

Let A be the fundamental alcove. This returns a reduced word $i_1, \dots, i_k$ such that the affine Weyl group element $w = s_{i_1} \circ \cdots \circ s_{i_k}$ maps the alcove $f(A)$ back to A. In other words, the alcove walk $i_1, \dots, i_k$ brings the fundamental alcove to the corresponding translated alcove.

Let us throw in a bit of context to explain the main use case. It is customary to realize the alcove picture in the coroot or coweight lattice $R^\vee$. The extended affine Weyl group is then the group of linear maps on $R^\vee$ which preserve the alcoves. By [Kac "Infinite-dimensional Lie algebra", Proposition 6.5] the affine Weyl group is the semidirect product of the associated finite Weyl group and the group of translations in the coroot lattice (the extended affine Weyl group uses the coweight lattice instead). In other words, an element of the extended affine Weyl group admits a unique decomposition of the form:

$$f = dw,$$

where w is in the Weyl group, and d is a function which maps the fundamental alcove to itself. As d permutes the walls of the fundamental alcove, it permutes accordingly the corresponding simple roots, which induces an automorphism of the Dynkin diagram.

This method returns a reduced word for w, whereas the method *dynkin_diagram_automorphism_of_alcove_morphism()* returns d as a permutation of the nodes of the Dynkin diagram.

Nota bene: recall that the coroot (resp. coweight) lattice is implemented as the root (resp weight) lattice of the dual root system. Hence, this method is implemented for weight lattice realizations, but in practice is most of the time used on the dual side.

EXAMPLES:

We start with type A which is simply laced; hence we do not have to worry about the distinction between the weight and coweight lattice:

```
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()                                              #␣
↪needs sage.graphs
sage: Lambda = R.fundamental_weights()
```

```
>>> from sage.all import *
>>> R = RootSystem(["A",Integer(2),Integer(1)]).weight_lattice()
>>> alpha = R.simple_roots()                                            #␣
↪needs sage.graphs
>>> Lambda = R.fundamental_weights()
```

We consider first translations by elements of the root lattice:

```
sage: R.reduced_word_of_alcove_morphism(alpha[0].translation)              #␣
↪needs sage.graphs
[1, 2, 1, 0]
sage: R.reduced_word_of_alcove_morphism(alpha[1].translation)              #␣
↪needs sage.graphs
[0, 2, 0, 1]
sage: R.reduced_word_of_alcove_morphism(alpha[2].translation)              #␣
↪needs sage.graphs
[0, 1, 0, 2]
```

```
>>> from sage.all import *
>>> R.reduced_word_of_alcove_morphism(alpha[Integer(0)].translation)      ␣
↪     # needs sage.graphs
[1, 2, 1, 0]
>>> R.reduced_word_of_alcove_morphism(alpha[Integer(1)].translation)      ␣
↪     # needs sage.graphs
[0, 2, 0, 1]
>>> R.reduced_word_of_alcove_morphism(alpha[Integer(2)].translation)      ␣
↪     # needs sage.graphs
[0, 1, 0, 2]
```

We continue with translations by elements of the classical weight lattice, embedded at level 0:

sage: omega1 = Lambda[1] - Lambda[0] sage: omega2 = Lambda[2] - Lambda[0]

sage: R.reduced_word_of_alcove_morphism(omega1.translation) # needs sage.graphs [0, 2] sage: R.reduced_word_of_alcove_morphism(omega2.translation) # needs sage.graphs [0, 1]

The following tests ensure that the code agrees with the tables in Kashiwara's private notes on affine quantum algebras (2008).

reduced_word_of_translation(*t*)

Given an element of the root lattice, this returns a reduced word $i_1, \ldots, i_k$ such that the Weyl group element $s_{i_1} \circ \cdots \circ s_{i_k}$ implements the "translation" where x maps to $x + level(x) * t$. In other words, the alcove walk $i_1, \ldots, i_k$ brings the fundamental alcove to the corresponding translated alcove.

Note

There are some technical conditions for t to actually be a translation; those are not tested (TODO: detail).

EXAMPLES:

```
sage: # needs sage.graphs
sage: R = RootSystem(["A",2,1]).weight_lattice()
sage: alpha = R.simple_roots()
sage: R.reduced_word_of_translation(alpha[1])
[0, 2, 0, 1]
sage: R.reduced_word_of_translation(alpha[2])
[0, 1, 0, 2]
sage: R.reduced_word_of_translation(alpha[0])
[1, 2, 1, 0]

sage: R = RootSystem(['D',5,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: omega1 = Lambda[1] - Lambda[0]
sage: omega2 = Lambda[2] - 2*Lambda[0]
sage: R.reduced_word_of_translation(omega1)                              #␣
↪needs sage.graphs
[0, 2, 3, 4, 5, 3, 2, 0]
sage: R.reduced_word_of_translation(omega2)                              #␣
↪needs sage.graphs
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> R = RootSystem(["A",Integer(2),Integer(1)]).weight_lattice()
>>> alpha = R.simple_roots()
>>> R.reduced_word_of_translation(alpha[Integer(1)])
[0, 2, 0, 1]
>>> R.reduced_word_of_translation(alpha[Integer(2)])
[0, 1, 0, 2]
>>> R.reduced_word_of_translation(alpha[Integer(0)])
[1, 2, 1, 0]

>>> R = RootSystem(['D',Integer(5),Integer(1)]).weight_lattice()
>>> Lambda = R.fundamental_weights()
>>> omega1 = Lambda[Integer(1)] - Lambda[Integer(0)]
>>> omega2 = Lambda[Integer(2)] - Integer(2)*Lambda[Integer(0)]
>>> R.reduced_word_of_translation(omega1)                              #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.graphs
[0, 2, 3, 4, 5, 3, 2, 0]
>>> R.reduced_word_of_translation(omega2)                                    #␣
↪needs sage.graphs
[0, 2, 1, 3, 2, 4, 3, 5, 3, 2, 1, 4, 3, 2]
```

A non simply laced case:

```
sage: R = RootSystem(["C",2,1]).weight_lattice()
sage: Lambda = R.fundamental_weights()
sage: c = R.cartan_type().translation_factors(); c                             #␣
↪needs sage.graphs
Finite family {0: 1, 1: 2, 2: 1}
sage: R.reduced_word_of_translation((Lambda[1]-Lambda[0]) * c[1])             #␣
↪needs sage.graphs
[0, 1, 2, 1]
sage: R.reduced_word_of_translation((Lambda[2]-Lambda[0]) * c[2])             #␣
↪needs sage.graphs
[0, 1, 0]
```

```
>>> from sage.all import *
>>> R = RootSystem(["C",Integer(2),Integer(1)]).weight_lattice()
>>> Lambda = R.fundamental_weights()
>>> c = R.cartan_type().translation_factors(); c                             #␣
↪needs sage.graphs
Finite family {0: 1, 1: 2, 2: 1}
>>> R.reduced_word_of_translation((Lambda[Integer(1)]-Lambda[Integer(0)])␣
↪* c[Integer(1)])        # needs sage.graphs
[0, 1, 2, 1]
>>> R.reduced_word_of_translation((Lambda[Integer(2)]-Lambda[Integer(0)])␣
↪* c[Integer(2)])        # needs sage.graphs
[0, 1, 0]
```

See also `_test_reduced_word_of_translation()`.

Todo

- Add a picture in the doc
- Add a method which, given an element of the classical weight lattice, constructs the appropriate value for t

rho()

EXAMPLES:

```
sage: RootSystem(['A',3]).ambient_lattice().rho()
(3, 2, 1, 0)
```

```
>>> from sage.all import *
>>> RootSystem(['A',Integer(3)]).ambient_lattice().rho()
(3, 2, 1, 0)
```

rho_classical()

Return the embedding at level 0 of ρ of the classical lattice.

EXAMPLES:

```
sage: RootSystem(['C',4,1]).weight_lattice().rho_classical()                    #␣
↪needs sage.graphs
-4*Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3] + Lambda[4]
sage: L = RootSystem(['D',4,1]).weight_lattice()
sage: L.rho_classical().scalar(L.null_coroot())                                 #␣
↪needs sage.graphs
0
```

```
>>> from sage.all import *
>>> RootSystem(['C',Integer(4),Integer(1)]).weight_lattice().rho_
↪classical()            # needs sage.graphs
-4*Lambda[0] + Lambda[1] + Lambda[2] + Lambda[3] + Lambda[4]
>>> L = RootSystem(['D',Integer(4),Integer(1)]).weight_lattice()
>>> L.rho_classical().scalar(L.null_coroot())                                 #␣
↪needs sage.graphs
0
```

Warning: In affine type BC dual, this does not live in the weight lattice:

```
sage: L = CartanType(["BC",2,2]).dual().root_system().weight_space()
sage: L.rho_classical()                                                         #␣
↪needs sage.graphs
-3/2*Lambda[0] + Lambda[1] + Lambda[2]
sage: L = CartanType(["BC",2,2]).dual().root_system().weight_lattice()
sage: L.rho_classical()                                                         #␣
↪needs sage.graphs
Traceback (most recent call last):
...

```

signs_of_alcovewalk(*walk*)

Let walk = $[i_1, \ldots, i_n]$ denote an alcove walk starting from the fundamental alcove y_0, crossing at step

1 the wall i_1, and so on.

For each k, set $w_k = s_{i_1} \circ s_{i_k}$, and denote by $y_k = w_k(y_0)$ the alcove reached after k steps. Then, y_k is obtained recursively from y_{k-1} by applying the following reflection:

$$y_k = s_{w_{k-1}\alpha_{i_k}} y_{k-1}.$$

The step is said positive if $w_{k-1}\alpha_{i_k}$ is a negative root (considering w_{k-1} as element of the classical Weyl group and α_{i_k} as a classical root) and negative otherwise. The algorithm implemented here use the equivalent property:

```
.. MATH:: \langle w_{k-1}^{-1} \rho_0, \alpha^\vee_{i_k}\rangle > 0
```

Where ρ_0 is the sum of the classical fundamental weights embedded at level 0 in this space (see `rho_classical()`), and $\alpha^\vee_{i_k}$ is the simple coroot associated to α_{i_k}.

This function returns a list of the form $[+1, +1, -1, ...]$, where the k-th entry denotes whether the k-th step was positive or negative.

See equation 3.4, of Ram: Alcove walks …, arXiv math/0601343v1

EXAMPLES:

```
sage: L = RootSystem(['C',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([1,2,0,1,2,1,2,0,1,2])                           #␣
↪needs sage.libs.gap
[-1, -1, 1, -1, 1, 1, 1, 1, 1, 1]

sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,1,2,0,1,2,0,1,2,0])                       #␣
↪needs sage.libs.gap
[1, 1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1]

sage: L = RootSystem(['B',2,1]).coweight_lattice()
sage: L.signs_of_alcovewalk([0,1,2,0,1,2])                                   #␣
↪needs sage.libs.gap
[1, -1, 1, -1, 1, 1]
```

```
>>> from sage.all import *
>>> L = RootSystem(['C',Integer(2),Integer(1)]).weight_lattice()
>>> L.signs_of_alcovewalk([Integer(1),Integer(2),Integer(0),Integer(1),
↪Integer(2),Integer(1),Integer(2),Integer(0),Integer(1),Integer(2)])    ␣
↪                 # needs sage.libs.gap
[-1, -1, 1, -1, 1, 1, 1, 1, 1, 1]

>>> L = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice()
>>> L.signs_of_alcovewalk([Integer(0),Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(0),Integer(1),Integer(2),Integer(0),Integer(1),
↪Integer(2),Integer(0)])                  # needs sage.libs.gap
[1, 1, 1, 1, -1, 1, -1, 1, -1, 1, -1, 1]

>>> L = RootSystem(['B',Integer(2),Integer(1)]).coweight_lattice()
>>> L.signs_of_alcovewalk([Integer(0),Integer(1),Integer(2),Integer(0),
↪Integer(1),Integer(2)])                              # needs sage.libs.
↪gap
[1, -1, 1, -1, 1, 1]
```

> **Warning**
>
> This method currently does not work in the weight lattice for type BC dual because ρ_0 does not live in this lattice (but an integral multiple of it would do the job as well).

simple_root(*i*)

Return the i-th simple root.

This default implementation takes the i-th simple root in the weight lattice and embeds it in `self`.

EXAMPLES:

Since all the weight lattice realizations in Sage currently implement a `simple_root` method, we have to call this one by hand:

```
sage: from sage.combinat.root_system.weight_lattice_realizations import␣
↪WeightLatticeRealizations
sage: simple_root = WeightLatticeRealizations(QQ).parent_class.simple_
↪root.f
sage: L = RootSystem("A3").ambient_space()
sage: simple_root(L, 1)                                                    #␣
↪needs sage.graphs
(1, -1, 0, 0)
sage: simple_root(L, 2)                                                    #␣
↪needs sage.graphs
(0, 1, -1, 0)
sage: simple_root(L, 3)                                                    #␣
↪needs sage.graphs
(1, 1, 2, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.root_system.weight_lattice_realizations import␣
↪WeightLatticeRealizations
>>> simple_root = WeightLatticeRealizations(QQ).parent_class.simple_root.f
>>> L = RootSystem("A3").ambient_space()
>>> simple_root(L, Integer(1))                                              ␣
↪     # needs sage.graphs
(1, -1, 0, 0)
>>> simple_root(L, Integer(2))                                              ␣
↪     # needs sage.graphs
(0, 1, -1, 0)
>>> simple_root(L, Integer(3))                                              ␣
↪     # needs sage.graphs
(1, 1, 2, 0)
```

Note that this last root differs from the one implemented in `L` by a multiple of the vector `(1,1,1,1)`:

```
sage: L.simple_roots()                                                     #␣
↪needs sage.graphs
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

```
>>> from sage.all import *
>>> L.simple_roots()                                                       #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.graphs
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```

This is a harmless artefact of the SL versus GL interpretation of type A; see the thematic tutorial on Lie Methods and Related Combinatorics in Sage for details.

weyl_dimension(*highest_weight*)

Return the dimension of the highest weight representation of highest weight `highest_weight`.

EXAMPLES:

```
sage: RootSystem(['A',3]).ambient_lattice().weyl_dimension([2,1,0,0])
20
sage: P = RootSystem(['C',2]).weight_lattice()
sage: La = P.basis()
sage: P.weyl_dimension(La[1]+La[2])                                         #␣
↪needs sage.graphs
16

sage: type(RootSystem(['A',3]).ambient_lattice().weyl_dimension([2,1,0,
↪0]))
<class 'sage.rings.integer.Integer'>
```

```
>>> from sage.all import *
>>> RootSystem(['A',Integer(3)]).ambient_lattice().weyl_
↪dimension([Integer(2),Integer(1),Integer(0),Integer(0)])
20
>>> P = RootSystem(['C',Integer(2)]).weight_lattice()
>>> La = P.basis()
>>> P.weyl_dimension(La[Integer(1)]+La[Integer(2)])                         ␣
↪              # needs sage.graphs
16

>>> type(RootSystem(['A',Integer(3)]).ambient_lattice().weyl_
↪dimension([Integer(2),Integer(1),Integer(0),Integer(0)]))
<class 'sage.rings.integer.Integer'>
```

super_categories()

EXAMPLES:

```
sage: from sage.combinat.root_system.weight_lattice_realizations import␣
↪WeightLatticeRealizations
sage: WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```

```
>>> from sage.all import *
>>> from sage.combinat.root_system.weight_lattice_realizations import␣
↪WeightLatticeRealizations
>>> WeightLatticeRealizations(QQ).super_categories()
[Category of root lattice realizations over Rational Field]
```

5.1.271 Weight lattices and weight spaces

class sage.combinat.root_system.weight_space.**WeightSpace**(*root_system*, *base_ring*, *extended*)

Bases: *CombinatorialFreeModule*

INPUT:

- root_system – a root system
- base_ring – a ring R
- extended – boolean (default: False)

The weight space (or lattice if base_ring is $\mathbf{Z}$) of a root system is the formal free module $\bigoplus_i R\Lambda_i$ generated by the fundamental weights $(\Lambda_i)_{i\in I}$ of the root system.

This class is also used for coweight spaces (or lattices).

See also

- *RootSystem()*
- *RootSystem.weight_lattice()* and *RootSystem.weight_space()*
- *WeightLatticeRealizations()*

EXAMPLES:

```
sage: Q = RootSystem(['A', 3]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3]
sage: Q.simple_roots()                                                          #␣
↪needs sage.graphs
Finite family {1: 2*Lambda[1] -   Lambda[2],
               2:  -Lambda[1] + 2*Lambda[2] -   Lambda[3],
               3:               -Lambda[2] + 2*Lambda[3]}

sage: Q = RootSystem(['A', 3, 1]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3, 1]
sage: Q.simple_roots()                                                          #␣
↪needs sage.graphs
Finite family {0: 2*Lambda[0] -   Lambda[1]               -   Lambda[3],
               1:  -Lambda[0] + 2*Lambda[1] -   Lambda[2],
               2:               -Lambda[1] + 2*Lambda[2] -   Lambda[3],
               3:  -Lambda[0]               -   Lambda[2] + 2*Lambda[3]}
```

```
>>> from sage.all import *
>>> Q = RootSystem(['A', Integer(3)]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3]
>>> Q.simple_roots()                                                          #␣
↪needs sage.graphs
Finite family {1: 2*Lambda[1] -   Lambda[2],
               2:  -Lambda[1] + 2*Lambda[2] -   Lambda[3],
               3:               -Lambda[2] + 2*Lambda[3]}

>>> Q = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(); Q
Weight lattice of the Root system of type ['A', 3, 1]
```

(continues on next page)

(continued from previous page)

```
>>> Q.simple_roots()                                                    #␣
↪needs sage.graphs
Finite family {0: 2*Lambda[0] -   Lambda[1]               -   Lambda[3],
               1:  -Lambda[0] + 2*Lambda[1] -   Lambda[2],
               2:               -Lambda[1] + 2*Lambda[2] -   Lambda[3],
               3:  -Lambda[0]               -   Lambda[2] + 2*Lambda[3]}
```

For infinite types, the Cartan matrix is singular, and therefore the embedding of the root lattice is not faithful:

```
sage: sum(Q.simple_roots())                                             #␣
↪needs sage.graphs
0
```

```
>>> from sage.all import *
>>> sum(Q.simple_roots())                                               #␣
↪needs sage.graphs
0
```

In particular, the null root is zero:

```
sage: Q.null_root()                                                     #␣
↪needs sage.graphs
0
```

```
>>> from sage.all import *
>>> Q.null_root()                                                       #␣
↪needs sage.graphs
0
```

This can be compensated by extending the basis of the weight space and slightly deforming the simple roots to make them linearly independent, without affecting the scalar product with the coroots. This feature is currently only implemented for affine types. In that case, if `extended` is set, then the basis of the weight space is extended by an element δ:

```
sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended=True); Q
Extended weight lattice of the Root system of type ['A', 3, 1]
sage: Q.basis().keys()
{0, 1, 2, 3, 'delta'}
```

```
>>> from sage.all import *
>>> Q = RootSystem(['A', Integer(3), Integer(1)]).weight_lattice(extended=True); Q
Extended weight lattice of the Root system of type ['A', 3, 1]
>>> Q.basis().keys()
{0, 1, 2, 3, 'delta'}
```

And the simple root α_0 associated to the special node is deformed as follows:

```
sage: Q.simple_roots()                                                  #␣
↪needs sage.graphs
Finite family {0: 2*Lambda[0] -   Lambda[1]               -   Lambda[3] + delta,
               1:  -Lambda[0] + 2*Lambda[1] -   Lambda[2],
```

(continues on next page)

(continued from previous page)

```
              2:                -Lambda[1] + 2*Lambda[2] -   Lambda[3],
              3:  -Lambda[0]               -   Lambda[2] + 2*Lambda[3]}
```

```
>>> from sage.all import *
>>> Q.simple_roots()                                                    #␣
↪needs sage.graphs
Finite family {0: 2*Lambda[0] -   Lambda[1]              -   Lambda[3] + delta,
              1:  -Lambda[0] + 2*Lambda[1] -   Lambda[2],
              2:                -Lambda[1] + 2*Lambda[2] -   Lambda[3],
              3:  -Lambda[0]               -   Lambda[2] + 2*Lambda[3]}
```

Now, the null root is nonzero:

```
sage: Q.null_root()                                                      #␣
↪needs sage.graphs
delta
```

```
>>> from sage.all import *
>>> Q.null_root()                                                       #␣
↪needs sage.graphs
delta
```

Warning

By a slight notational abuse, the extra basis element used to extend the fundamental weights is called `\delta` in the current implementation. However, in the literature, `\delta` usually denotes instead the null root. Most of the time, those two objects coincide, but not for type BC (aka. $A_{2n}^{(2)}$). Therefore we currently have:

```
sage: Q = RootSystem(["A",4,2]).weight_lattice(extended=True)
sage: Q.simple_root(0)                                                  #␣
↪needs sage.graphs
2*Lambda[0] - Lambda[1] + delta
sage: Q.null_root()                                                     #␣
↪needs sage.graphs
2*delta
```

```
>>> from sage.all import *
>>> Q = RootSystem(["A",Integer(4),Integer(2)]).weight_lattice(extended=True)
>>> Q.simple_root(Integer(0))                                            ␣
↪    # needs sage.graphs
2*Lambda[0] - Lambda[1] + delta
>>> Q.null_root()                                                     #␣
↪needs sage.graphs
2*delta
```

whereas, with the standard notations from the literature, one would expect to get respectively $2\Lambda_0 - \Lambda_1 + 1/2\delta$ and δ.

Other than this notational glitch, the implementation remains correct for type BC.

The notations may get improved in a subsequent version, which might require changing the index of the extra basis element. To guarantee backward compatibility in code not included in Sage, it is recommended to use the following idiom to get that index:

```
sage: F = Q.basis_extension(); F
Finite family {'delta': delta}
sage: index = F.keys()[0]; index
'delta'
```

```
>>> from sage.all import *
>>> F = Q.basis_extension(); F
Finite family {'delta': delta}
>>> index = F.keys()[Integer(0)]; index
'delta'
```

Then, for example, the coefficient of an element of the extended weight lattice on that basis element can be recovered with:

```
sage: Q.null_root()[index]                                              #␣
↪needs sage.graphs
2
```

```
>>> from sage.all import *
>>> Q.null_root()[index]                                                #␣
↪needs sage.graphs
2
```

Element

alias of *WeightSpaceElement*

basis_extension()

Return the basis elements used to extend the fundamental weights.

EXAMPLES:

```
sage: Q = RootSystem(["A",3,1]).weight_lattice()
sage: Q.basis_extension()
Family ()

sage: Q = RootSystem(["A",3,1]).weight_lattice(extended=True)
sage: Q.basis_extension()
Finite family {'delta': delta}
```

```
>>> from sage.all import *
>>> Q = RootSystem(["A",Integer(3),Integer(1)]).weight_lattice()
>>> Q.basis_extension()
Family ()

>>> Q = RootSystem(["A",Integer(3),Integer(1)]).weight_lattice(extended=True)
>>> Q.basis_extension()
Finite family {'delta': delta}
```

This method is irrelevant for finite types:

```
sage: Q = RootSystem(["A",3]).weight_lattice()
sage: Q.basis_extension()
Family ()
```

```
>>> from sage.all import *
>>> Q = RootSystem(["A",Integer(3)]).weight_lattice()
>>> Q.basis_extension()
Family ()
```

fundamental_weight(*i*)

Return the i-th fundamental weight.

INPUT:

- `i` – an element of the index set or `'delta'`

By a slight notational abuse, for an affine type this method also accepts `'delta'` as input, and returns the image of δ of the extended weight lattice in this realization.

See also

`fundamental_weight()`

EXAMPLES:

```
sage: Q = RootSystem(["A",3]).weight_lattice()
sage: Q.fundamental_weight(1)
Lambda[1]

sage: Q = RootSystem(["A",3,1]).weight_lattice(extended=True)
sage: Q.fundamental_weight(1)
Lambda[1]
sage: Q.fundamental_weight("delta")
delta
```

```
>>> from sage.all import *
>>> Q = RootSystem(["A",Integer(3)]).weight_lattice()
>>> Q.fundamental_weight(Integer(1))
Lambda[1]

>>> Q = RootSystem(["A",Integer(3),Integer(1)]).weight_lattice(extended=True)
>>> Q.fundamental_weight(Integer(1))
Lambda[1]
>>> Q.fundamental_weight("delta")
delta
```

is_extended()

Return whether this is an extended weight lattice.

See also

`is_extended()`

EXAMPLES:

```
sage: RootSystem(["A",3,1]).weight_lattice().is_extended()
False
sage: RootSystem(["A",3,1]).weight_lattice(extended=True).is_extended()
True
```

```
>>> from sage.all import *
>>> RootSystem(["A",Integer(3),Integer(1)]).weight_lattice().is_extended()
False
>>> RootSystem(["A",Integer(3),Integer(1)]).weight_lattice(extended=True).is_
↪extended()
True
```

simple_root(*j*)

Return the j-th simple root.

EXAMPLES:

```
sage: L = RootSystem(["C",4]).weight_lattice()
sage: L.simple_root(3)                                                  #␣
↪needs sage.graphs
-Lambda[2] + 2*Lambda[3] - Lambda[4]
```

```
>>> from sage.all import *
>>> L = RootSystem(["C",Integer(4)]).weight_lattice()
>>> L.simple_root(Integer(3))                                            ␣
↪      # needs sage.graphs
-Lambda[2] + 2*Lambda[3] - Lambda[4]
```

Its coefficients are given by the corresponding column of the Cartan matrix:

```
sage: L.cartan_type().cartan_matrix()[:,2]                              #␣
↪needs sage.graphs
[ 0]
[-1]
[ 2]
[-1]
```

```
>>> from sage.all import *
>>> L.cartan_type().cartan_matrix()[:,Integer(2)]                        ␣
↪      # needs sage.graphs
[ 0]
[-1]
[ 2]
[-1]
```

Here are all simple roots:

```
sage: L.simple_roots()                                                  #␣
↪needs sage.graphs
Finite family {1:  2*Lambda[1]   - Lambda[2],
               2:   -Lambda[1] + 2*Lambda[2]   - Lambda[3],
               3:   -Lambda[2] + 2*Lambda[3]   - Lambda[4],
               4:              -2*Lambda[3] + 2*Lambda[4]}
```

```
>>> from sage.all import *
>>> L.simple_roots()                                                         #␣
↪needs sage.graphs
Finite family {1:  2*Lambda[1]    - Lambda[2],
               2:   -Lambda[1] + 2*Lambda[2]    - Lambda[3],
               3:   -Lambda[2] + 2*Lambda[3]    - Lambda[4],
               4:               -2*Lambda[3] + 2*Lambda[4]}
```

For the extended weight lattice of an affine type, the simple root associated to the special node is deformed by adding δ, where δ is the null root:

```
sage: L = RootSystem(["C",4,1]).weight_lattice(extended=True)
sage: L.simple_root(0)                                                         #␣
↪needs sage.graphs
2*Lambda[0] - 2*Lambda[1] + delta
```

```
>>> from sage.all import *
>>> L = RootSystem(["C",Integer(4),Integer(1)]).weight_lattice(extended=True)
>>> L.simple_root(Integer(0))                                                  ␣
↪     # needs sage.graphs
2*Lambda[0] - 2*Lambda[1] + delta
```

In fact δ is really $1/a_0$ times the null root (see the discussion in *WeightSpace*) but this only makes a difference in type BC:

```
sage: L = RootSystem(CartanType(["BC",4,2])).weight_lattice(extended=True)
sage: L.simple_root(0)                                                         #␣
↪needs sage.graphs
2*Lambda[0] - Lambda[1] + delta
sage: L.null_root()                                                            #␣
↪needs sage.graphs
2*delta
```

```
>>> from sage.all import *
>>> L = RootSystem(CartanType(["BC",Integer(4),Integer(2)])).weight_
↪lattice(extended=True)
>>> L.simple_root(Integer(0))                                                  ␣
↪     # needs sage.graphs
2*Lambda[0] - Lambda[1] + delta
>>> L.null_root()                                                            #␣
↪needs sage.graphs
2*delta
```

See also:

- *simple_root()*
- CartanType.col_annihilator()

to_ambient_space_morphism()

The morphism from self to its associated ambient space.

EXAMPLES:

```
sage: CartanType(['A',2]).root_system().weight_lattice().to_ambient_space_
↪morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To:   Ambient space of the Root system of type ['A', 2]
```

```
>>> from sage.all import *
>>> CartanType(['A',Integer(2)]).root_system().weight_lattice().to_ambient_
↪space_morphism()
Generic morphism:
From: Weight lattice of the Root system of type ['A', 2]
To:   Ambient space of the Root system of type ['A', 2]
```

Warning: Implemented only for finite Cartan type.

class sage.combinat.root_system.weight_space.**WeightSpaceElement**

Bases: IndexedFreeModuleElement

is_dominant()

Check whether an element in the weight space lies in the positive cone spanned by the basis elements (fundamental weights).

EXAMPLES:

```
sage: W = RootSystem(['A',3]).weight_space()
sage: Lambda = W.basis()
sage: w = Lambda[1] + Lambda[3]
sage: w.is_dominant()
True
sage: w = Lambda[1] - Lambda[2]
sage: w.is_dominant()
False
```

```
>>> from sage.all import *
>>> W = RootSystem(['A',Integer(3)]).weight_space()
>>> Lambda = W.basis()
>>> w = Lambda[Integer(1)] + Lambda[Integer(3)]
>>> w.is_dominant()
True
>>> w = Lambda[Integer(1)] - Lambda[Integer(2)]
>>> w.is_dominant()
False
```

In the extended affine weight lattice, `'delta'` is orthogonal to the positive coroots, so adding or subtracting it should not affect dominance:

```
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=true)
sage: Lambda = P.fundamental_weights()
```

(continues on next page)

(continued from previous page)

```
sage: delta = P.null_root()                                             #␣
↪needs sage.graphs
sage: w = Lambda[1] - delta                                             #␣
↪needs sage.graphs
sage: w.is_dominant()                                                   #␣
↪needs sage.graphs
True
```

```
>>> from sage.all import *
>>> P = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true)
>>> Lambda = P.fundamental_weights()
>>> delta = P.null_root()                                             #␣
↪needs sage.graphs
>>> w = Lambda[Integer(1)] - delta                                      ␣
↪     # needs sage.graphs
>>> w.is_dominant()                                                   #␣
↪needs sage.graphs
True
```

is_dominant_weight()

Check whether an element in the weight space lies in the positive $\mathbf{Z}$-lattice cone spanned by the basis elements (fundamental weights).

EXAMPLES:

```
sage: W = RootSystem(['A',3]).weight_space()
sage: Lambda = W.basis()
sage: w = Lambda[1] + Lambda[3]
sage: w.is_dominant_weight()
True
sage: w = Lambda[1] + 2/3*Lambda[3]
sage: w.is_dominant_weight()
False
sage: w = Lambda[1] - Lambda[2]
sage: w.is_dominant_weight()
False
```

```
>>> from sage.all import *
>>> W = RootSystem(['A',Integer(3)]).weight_space()
>>> Lambda = W.basis()
>>> w = Lambda[Integer(1)] + Lambda[Integer(3)]
>>> w.is_dominant_weight()
True
>>> w = Lambda[Integer(1)] + Integer(2)/Integer(3)*Lambda[Integer(3)]
>>> w.is_dominant_weight()
False
>>> w = Lambda[Integer(1)] - Lambda[Integer(2)]
>>> w.is_dominant_weight()
False
```

In the extended affine weight lattice, `'delta'` is orthogonal to the positive coroots, so adding or subtracting it should not affect dominance:

```
sage: P = RootSystem(['A',2,1]).weight_lattice(extended=true)
sage: Lambda = P.fundamental_weights()
sage: delta = P.null_root()                                          #␣
↪needs sage.graphs
sage: w = Lambda[1] - delta                                          #␣
↪needs sage.graphs
sage: w.is_dominant_weight()                                         #␣
↪needs sage.graphs
True
```

```
>>> from sage.all import *
>>> P = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true)
>>> Lambda = P.fundamental_weights()
>>> delta = P.null_root()                                          #␣
↪needs sage.graphs
>>> w = Lambda[Integer(1)] - delta                                   ␣
↪     # needs sage.graphs
>>> w.is_dominant_weight()                                         #␣
↪needs sage.graphs
True
```

scalar(*lambdacheck*)

The canonical scalar product between the weight lattice and the coroot lattice.

Todo

- merge with_apply_multi_module_morphism
- allow for any root space / lattice
- define properly the return type (depends on the base rings of the two spaces)
- make this robust for extended weight lattices (i might be "delta")

EXAMPLES:

```
sage: L = RootSystem(["C",4,1]).weight_lattice()
sage: Lambda     = L.fundamental_weights()
sage: alphacheck = L.simple_coroots()
sage: Lambda[1].scalar(alphacheck[1])
1
sage: Lambda[1].scalar(alphacheck[2])
0
```

```
>>> from sage.all import *
>>> L = RootSystem(["C",Integer(4),Integer(1)]).weight_lattice()
>>> Lambda     = L.fundamental_weights()
>>> alphacheck = L.simple_coroots()
>>> Lambda[Integer(1)].scalar(alphacheck[Integer(1)])
1
>>> Lambda[Integer(1)].scalar(alphacheck[Integer(2)])
0
```

The fundamental weights and the simple coroots are dual bases:

```
sage: matrix([ [ Lambda[i].scalar(alphacheck[j])
....:              for i in L.index_set() ]
....:            for j in L.index_set() ])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

```
>>> from sage.all import *
>>> matrix([ [ Lambda[i].scalar(alphacheck[j])
...              for i in L.index_set() ]
...            for j in L.index_set() ])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
```

Note that the scalar product is not yet implemented between the weight space and the coweight space; in any cases, that won't be the job of this method:

```
sage: R = RootSystem(["A",3])
sage: alpha = R.weight_space().roots()                                    #␣
↪needs sage.graphs
sage: alphacheck = R.coweight_space().roots()                             #␣
↪needs sage.graphs
sage: alpha[1].scalar(alphacheck[1])                                      #␣
↪needs sage.graphs
Traceback (most recent call last):
...
ValueError: -Lambdacheck[1] + 2*Lambdacheck[2] - Lambdacheck[3]
is not in the coroot space
```

```
>>> from sage.all import *
>>> R = RootSystem(["A",Integer(3)])
>>> alpha = R.weight_space().roots()                                    #␣
↪needs sage.graphs
>>> alphacheck = R.coweight_space().roots()                             #␣
↪needs sage.graphs
>>> alpha[Integer(1)].scalar(alphacheck[Integer(1)])                      ␣
↪              # needs sage.graphs
Traceback (most recent call last):
...
ValueError: -Lambdacheck[1] + 2*Lambdacheck[2] - Lambdacheck[3]
is not in the coroot space
```

to_ambient()

Map `self` to the ambient space.

EXAMPLES:

```
sage: mu = CartanType(['B',2]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2]
sage: mu.to_ambient()
(3, 1)
```

```
>>> from sage.all import *
>>> mu = CartanType(['B',Integer(2)]).root_system().weight_lattice().an_
↪element(); mu
2*Lambda[1] + 2*Lambda[2]
>>> mu.to_ambient()
(3, 1)
```

Warning

Only implemented in finite Cartan type. Does not work for coweight lattices because there is no implemented map from the coweight lattice to the ambient space.

to_weight_space()

Map `self` to the weight space.

Since $self.parent()$ is the weight space, this map just returns `self`. This overrides the generic method in $WeightSpaceRealizations$.

EXAMPLES:

```
sage: mu = CartanType(['A',2]).root_system().weight_lattice().an_element(); mu
2*Lambda[1] + 2*Lambda[2]
sage: mu.to_weight_space()
2*Lambda[1] + 2*Lambda[2]
```

```
>>> from sage.all import *
>>> mu = CartanType(['A',Integer(2)]).root_system().weight_lattice().an_
↪element(); mu
2*Lambda[1] + 2*Lambda[2]
>>> mu.to_weight_space()
2*Lambda[1] + 2*Lambda[2]
```

5.1.272 Weyl Character Rings

class sage.combinat.root_system.weyl_characters.**WeightRing**(*parent*, *prefix*)

Bases: `CombinatorialFreeModule`

The weight ring, which is the group algebra over a weight lattice.

A Weyl character may be regarded as an element of the weight ring. In fact, an element of the weight ring is an element of the `Weyl character ring` if and only if it is invariant under the action of the Weyl group.

The advantage of the weight ring over the Weyl character ring is that one may conduct calculations in the weight ring that involve sums of weights that are not Weyl group invariant.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: wd = prod(a2(x/2)-a2(-x/2) for x in a2.space().positive_roots()); wd
a2(-1,1,0) - a2(-1,0,1) - a2(1,-1,0) + a2(1,0,-1) + a2(0,-1,1) - a2(0,1,-1)
sage: chi = A2([5,3,0]); chi
A2(5,3,0)
sage: a2(chi)
a2(1,2,5) + 2*a2(1,3,4) + 2*a2(1,4,3) + a2(1,5,2) + a2(2,1,5)
+ 2*a2(2,2,4) + 3*a2(2,3,3) + 2*a2(2,4,2) + a2(2,5,1) + 2*a2(3,1,4)
+ 3*a2(3,2,3) + 3*a2(3,3,2) + 2*a2(3,4,1) + a2(3,5,0) + a2(3,0,5)
+ 2*a2(4,1,3) + 2*a2(4,2,2) + 2*a2(4,3,1) + a2(4,4,0) + a2(4,0,4)
+ a2(5,1,2) + a2(5,2,1) + a2(5,3,0) + a2(5,0,3) + a2(0,3,5)
+ a2(0,4,4) + a2(0,5,3)
sage: a2(chi)*wd
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
sage: sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w in a2.space().
↪weyl_group())
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
sage: a2(chi)*wd == sum((-1)^w.length()*a2([6,3,-1]).weyl_group_action(w) for w␣
↪in a2.space().weyl_group())
True
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing(['A',Integer(2)])
>>> a2 = WeightRing(A2)
>>> wd = prod(a2(x/Integer(2))-a2(-x/Integer(2)) for x in a2.space().positive_
↪roots()); wd
a2(-1,1,0) - a2(-1,0,1) - a2(1,-1,0) + a2(1,0,-1) + a2(0,-1,1) - a2(0,1,-1)
>>> chi = A2([Integer(5),Integer(3),Integer(0)]); chi
A2(5,3,0)
>>> a2(chi)
a2(1,2,5) + 2*a2(1,3,4) + 2*a2(1,4,3) + a2(1,5,2) + a2(2,1,5)
+ 2*a2(2,2,4) + 3*a2(2,3,3) + 2*a2(2,4,2) + a2(2,5,1) + 2*a2(3,1,4)
+ 3*a2(3,2,3) + 3*a2(3,3,2) + 2*a2(3,4,1) + a2(3,5,0) + a2(3,0,5)
+ 2*a2(4,1,3) + 2*a2(4,2,2) + 2*a2(4,3,1) + a2(4,4,0) + a2(4,0,4)
+ a2(5,1,2) + a2(5,2,1) + a2(5,3,0) + a2(5,0,3) + a2(0,3,5)
+ a2(0,4,4) + a2(0,5,3)
>>> a2(chi)*wd
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
>>> sum((-Integer(1))**w.length()*a2([Integer(6),Integer(3),-Integer(1)]).weyl_
↪group_action(w) for w in a2.space().weyl_group())
-a2(-1,3,6) + a2(-1,6,3) + a2(3,-1,6) - a2(3,6,-1) - a2(6,-1,3) + a2(6,3,-1)
>>> a2(chi)*wd == sum((-Integer(1))**w.length()*a2([Integer(6),Integer(3),-
↪Integer(1)]).weyl_group_action(w) for w in a2.space().weyl_group())
True
```

class Element

Bases: `IndexedFreeModuleElement`

A class for weight ring elements.

cartan_type()

Return the Cartan type.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2([0,1,0]).cartan_type()
['A', 2]
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> a2([Integer(0),Integer(1),Integer(0)]).cartan_type()
['A', 2]
```

character()

Assuming that `self` is invariant under the Weyl group, this will express it as a linear combination of characters. If `self` is not Weyl group invariant, this method will not terminate.

EXAMPLES:

```
sage: A2 = WeylCharacterRing(['A',2])
sage: a2 = WeightRing(A2)
sage: W = a2.space().weyl_group()
sage: mu = a2(2,1,0)
sage: nu = sum(mu.weyl_group_action(w) for w in W) ; nu
a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,2,1)
sage: nu.character()
-2*A2(1,1,1) + A2(2,1,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing(['A',Integer(2)])
>>> a2 = WeightRing(A2)
>>> W = a2.space().weyl_group()
>>> mu = a2(Integer(2),Integer(1),Integer(0))
>>> nu = sum(mu.weyl_group_action(w) for w in W) ; nu
a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) + a2(0,2,1)
>>> nu.character()
-2*A2(1,1,1) + A2(2,1,0)
```

demazure(*w*, *debug=False*)

Return the result of applying the Demazure operator ∂_w to `self`.

INPUT:

- `w` – a Weyl group element, or its reduced word

If $w = s_i$ is a simple reflection, the operation ∂_w sends the weight λ to

$$\frac{\lambda - s_i \cdot \lambda + \alpha_i}{1 + \alpha_i},$$

where the numerator is divisible the denominator in the weight ring. This is extended by multiplicativity to all w in the Weyl group.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style='coroots')
sage: b2 = WeightRing(B2)
```

(continues on next page)

(continued from previous page)

```
sage: b2(1,0).demazure([1])
b2(1,0) + b2(-1,2)
sage: b2(1,0).demazure([2])
b2(1,0)
sage: r = b2(1,0).demazure([1,2]); r
b2(1,0) + b2(-1,2)
sage: r.demazure([1])
b2(1,0) + b2(-1,2)
sage: r.demazure([2])
b2(0,0) + b2(1,0) + b2(1,-2) + b2(-1,2)
```

```
>>> from sage.all import *
>>> B2 = WeylCharacterRing("B2",style='coroots')
>>> b2 = WeightRing(B2)
>>> b2(Integer(1),Integer(0)).demazure([Integer(1)])
b2(1,0) + b2(-1,2)
>>> b2(Integer(1),Integer(0)).demazure([Integer(2)])
b2(1,0)
>>> r = b2(Integer(1),Integer(0)).demazure([Integer(1),Integer(2)]); r
b2(1,0) + b2(-1,2)
>>> r.demazure([Integer(1)])
b2(1,0) + b2(-1,2)
>>> r.demazure([Integer(2)])
b2(0,0) + b2(1,0) + b2(1,-2) + b2(-1,2)
```

demazure_lusztig(*i*, *v*)

Return the result of applying the Demazure-Lusztig operator T_i to `self`.

INPUT:

- `i` – an element of the index set (or a reduced word or Weyl group element)
- `v` – an element of the base ring

If R is the parent WeightRing, the Demazure-Lusztig operator T_i is the linear map $R \to R$ that sends (for a weight λ) $R(\lambda)$ to

$$(R(\alpha_i) - 1)^{-1}\big(R(\lambda) - R(s_i\lambda) - v(R(\lambda) - R(\alpha_i + s_i\lambda))\big)$$

where the numerator is divisible by the denominator in R. The Demazure-Lusztig operators give a representation of the Iwahori–Hecke algebra associated to the Weyl group. See

- Lusztig, Equivariant K-theory and representations of Hecke algebras, Proc. Amer. Math. Soc. 94 (1985), no. 2, 337-342.
- Cherednik, *Nonsymmetric Macdonald polynomials*. IMRN 10, 483-515 (1995).

In the examples, we confirm the braid and quadratic relations for type B_2.

EXAMPLES:

```
sage: P.<v> = PolynomialRing(QQ)
sage: B2 = WeylCharacterRing("B2",style='coroots',base_ring=P); b2 = B2.
↪ambient()
sage: def T1(f): return f.demazure_lusztig(1, v)
sage: def T2(f): return f.demazure_lusztig(2, v)
sage: T1(T2(T1(T2(b2(1,-1)))))
(v^2-v)*b2(0,-1) + v^2*b2(-1,1)
sage: [T1(T1(f))==(v-1)*T1(f)+v*f for f in [b2(0,0), b2(1,0), b2(2,3)]]
```

(continues on next page)

(continued from previous page)

```
[True, True, True]
sage: [T1(T2(T1(T2(b2(i,j))))) == T2(T1(T2(T1(b2(i,j))))) for i in [-2..
↪2] for j in [-1,1]]
[True, True, True, True, True, True, True, True, True, True]
```

```
>>> from sage.all import *
>>> P = PolynomialRing(QQ, names=('v',)); (v,) = P._first_ngens(1)
>>> B2 = WeylCharacterRing("B2",style='coroots',base_ring=P); b2 = B2.
↪ambient()
>>> def T1(f): return f.demazure_lusztig(Integer(1), v)
>>> def T2(f): return f.demazure_lusztig(Integer(2), v)
>>> T1(T2(T1(T2(b2(Integer(1),-Integer(1))))))
(v^2-v)*b2(0,-1) + v^2*b2(-1,1)
>>> [T1(T1(f))==(v-Integer(1))*T1(f)+v*f for f in [b2(Integer(0),
↪Integer(0)), b2(Integer(1),Integer(0)), b2(Integer(2),Integer(3))]]
[True, True, True]
>>> [T1(T2(T1(T2(b2(i,j))))) == T2(T1(T2(T1(b2(i,j))))) for i in␣
↪(ellipsis_range(-Integer(2),Ellipsis,Integer(2))) for j in [-Integer(1),
↪Integer(1)]]
[True, True, True, True, True, True, True, True, True, True]
```

Instead of an index i one may use a reduced word or Weyl group element:

```
sage: b2(1,0).demazure_lusztig([2,1],v)==T2(T1(b2(1,0)))
True
sage: W = B2.space().weyl_group(prefix='s')
sage: [s1,s2]=W.simple_reflections()
sage: b2(1,0).demazure_lusztig(s2*s1,v)==T2(T1(b2(1,0)))
True
```

```
>>> from sage.all import *
>>> b2(Integer(1),Integer(0)).demazure_lusztig([Integer(2),Integer(1)],
↪v)==T2(T1(b2(Integer(1),Integer(0))))
True
>>> W = B2.space().weyl_group(prefix='s')
>>> [s1,s2]=W.simple_reflections()
>>> b2(Integer(1),Integer(0)).demazure_lusztig(s2*s1,
↪v)==T2(T1(b2(Integer(1),Integer(0))))
True
```

scale(k)

Multiply a weight by k.

The operation is extended by linearity to the weight ring.

INPUT:

- k – nonzero integer

EXAMPLES:

```
sage: g2 = WeylCharacterRing("G2",style='coroots').ambient()
sage: g2(2,3).scale(2)
g2(4,6)
```

```
>>> from sage.all import *
>>> g2 = WeylCharacterRing("G2",style='coroots').ambient()
>>> g2(Integer(2),Integer(3)).scale(Integer(2))
g2(4,6)
```

shift(*mu*)

Add μ to any weight.

Extended by linearity to the weight ring.

INPUT:

- mu – a weight

EXAMPLES:

```
sage: g2 = WeylCharacterRing("G2",style='coroots').ambient()
sage: [g2(1,2).shift(fw) for fw in g2.fundamental_weights()]
[g2(2,2), g2(1,3)]
```

```
>>> from sage.all import *
>>> g2 = WeylCharacterRing("G2",style='coroots').ambient()
>>> [g2(Integer(1),Integer(2)).shift(fw) for fw in g2.fundamental_
↪weights()]
[g2(2,2), g2(1,3)]
```

weyl_group_action(*w*)

Return the action of the Weyl group element w on self.

EXAMPLES:

```
sage: G2 = WeylCharacterRing(['G',2])
sage: g2 = WeightRing(G2)
sage: L = g2.space()
sage: [fw1, fw2] = L.fundamental_weights()
sage: sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-
↪2) + 2*g2(2,-1,-1)
```

```
>>> from sage.all import *
>>> G2 = WeylCharacterRing(['G',Integer(2)])
>>> g2 = WeightRing(G2)
>>> L = g2.space()
>>> [fw1, fw2] = L.fundamental_weights()
>>> sum(g2(fw2).weyl_group_action(w) for w in L.weyl_group())
2*g2(-2,1,1) + 2*g2(-1,-1,2) + 2*g2(-1,2,-1) + 2*g2(1,-2,1) + 2*g2(1,1,-
↪2) + 2*g2(2,-1,-1)
```

cartan_type()

Return the Cartan type.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: WeightRing(A2).cartan_type()
['A', 2]
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> WeightRing(A2).cartan_type()
['A', 2]
```

fundamental_weights()

Return the fundamental weights.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

```
>>> from sage.all import *
>>> WeightRing(WeylCharacterRing("G2")).fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

one_basis()

Return the index of 1.

EXAMPLES:

```
sage: A3 = WeylCharacterRing("A3")
sage: WeightRing(A3).one_basis()
(0, 0, 0, 0)
sage: WeightRing(A3).one()
a3(0,0,0,0)
```

```
>>> from sage.all import *
>>> A3 = WeylCharacterRing("A3")
>>> WeightRing(A3).one_basis()
(0, 0, 0, 0)
>>> WeightRing(A3).one()
a3(0,0,0,0)
```

parent()

Return the parent Weyl character ring.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.parent()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: a2.parent() == A2
True
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> a2.parent()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
>>> a2.parent() == A2
True
```

positive_roots()

Return the positive roots.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

```
>>> from sage.all import *
>>> WeightRing(WeylCharacterRing("G2")).positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

product_on_basis(*a*, *b*)

Return the product of basis elements indexed by `a` and `b`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2(1,0,0) * a2(0,1,0) # indirect doctest
a2(1,1,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> a2(Integer(1),Integer(0),Integer(0)) * a2(Integer(0),Integer(1),
↪Integer(0)) # indirect doctest
a2(1,1,0)
```

simple_roots()

Return the simple roots.

EXAMPLES:

```
sage: WeightRing(WeylCharacterRing("G2")).simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

```
>>> from sage.all import *
>>> WeightRing(WeylCharacterRing("G2")).simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

some_elements()

Return some elements of `self`.

EXAMPLES:

```
sage: A3 = WeylCharacterRing("A3")
sage: a3 = WeightRing(A3)
sage: a3.some_elements()
[a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

```
>>> from sage.all import *
>>> A3 = WeylCharacterRing("A3")
>>> a3 = WeightRing(A3)
```

(continues on next page)

(continued from previous page)

```
>>> a3.some_elements()
[a3(1,0,0,0), a3(1,1,0,0), a3(1,1,1,0)]
```

space()

Return the weight space realization associated to `self`.

EXAMPLES:

```
sage: E8 = WeylCharacterRing(['E',8])
sage: e8 = WeightRing(E8)
sage: e8.space()
Ambient space of the Root system of type ['E', 8]
```

```
>>> from sage.all import *
>>> E8 = WeylCharacterRing(['E',Integer(8)])
>>> e8 = WeightRing(E8)
>>> e8.space()
Ambient space of the Root system of type ['E', 8]
```

weyl_character_ring()

Return the parent Weyl Character Ring.

A synonym for `self.parent()`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: a2.weyl_character_ring()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> a2.weyl_character_ring()
The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

wt_repr(*wt*)

Return a string representing the irreducible character with highest weight vector `wt`.

Uses coroot notation if the associated Weyl character ring is defined with `style="coroots"`.

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2")
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0,-1)', 'g2(2,-1,-1)']
sage: G2 = WeylCharacterRing("G2",style='coroots')
sage: [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0)', 'g2(0,1)']
```

```
>>> from sage.all import *
>>> G2 = WeylCharacterRing("G2")
```

(continues on next page)

(continued from previous page)

```
>>> [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0,-1)', 'g2(2,-1,-1)']
>>> G2 = WeylCharacterRing("G2",style='coroots')
>>> [G2.ambient().wt_repr(x) for x in G2.fundamental_weights()]
['g2(1,0)', 'g2(0,1)']
```

class sage.combinat.root_system.weyl_characters.**WeylCharacterRing**(*ct*, *base_ring=Integer Ring*, *prefix=None*, *style='lattice'*, *k=None*, *conjugate=False*, *cyclotomic_order=None*, *fusion_labels=None*, *inject_variables=False*)

Bases: *CombinatorialFreeModule*

A class for rings of Weyl characters.

Let K be a compact Lie group, which we assume is semisimple and simply-connected. Its complexified Lie algebra L is the Lie algebra of a complex analytic Lie group G. The following three categories are equivalent: finite-dimensional representations of K; finite-dimensional representations of L; and finite-dimensional analytic representations of G. In every case, there is a parametrization of the irreducible representations by their highest weight vectors. For this theory of Weyl, see (for example):

- Adams, *Lectures on Lie groups*
- Broecker and Tom Dieck, *Representations of Compact Lie groups*
- Bump, *Lie Groups*
- Fulton and Harris, *Representation Theory*
- Goodman and Wallach, *Representations and Invariants of the Classical Groups*
- Hall, *Lie Groups, Lie Algebras and Representations*
- Humphreys, *Introduction to Lie Algebras and their representations*
- Procesi, *Lie Groups*
- Samelson, *Notes on Lie Algebras*
- Varadarajan, *Lie groups, Lie algebras, and their representations*
- Zhelobenko, *Compact Lie Groups and their Representations*.

Computations that you can do with these include computing their weight multiplicities, products (thus decomposing the tensor product of a representation into irreducibles) and branching rules (restriction to a smaller group).

There is associated with K, L or G as above a lattice, the weight lattice, whose elements (called weights) are characters of a Cartan subgroup or subalgebra. There is an action of the Weyl group W on the lattice, and elements of a fixed fundamental domain for W, the positive Weyl chamber, are called dominant. There is for each representation a unique highest dominant weight that occurs with nonzero multiplicity with respect to a certain partial order, and it is called the highest weight vector.

EXAMPLES:

```
sage: L = RootSystem("A2").ambient_space()
sage: [fw1,fw2] = L.fundamental_weights()
sage: R = WeylCharacterRing(['A',2], prefix='R')
sage: [R(1),R(fw1),R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

```
>>> from sage.all import *
>>> L = RootSystem("A2").ambient_space()
>>> [fw1,fw2] = L.fundamental_weights()
>>> R = WeylCharacterRing(['A',Integer(2)], prefix='R')
>>> [R(Integer(1)),R(fw1),R(fw2)]
[R(0,0,0), R(1,0,0), R(1,1,0)]
```

Here `R(1)`, `R(fw1)`, and `R(fw2)` are irreducible representations with highest weight vectors 0, Λ_1, and Λ_2 respectively (the first two fundamental weights).

For type A (also G_2, F_4, E_6 and E_7) we will take as the weight lattice not the weight lattice of the semisimple group, but for a larger one. For type A, this means we are concerned with the representation theory of $K = U(n)$ or $G = GL(n, \mathbf{C})$ rather than $SU(n)$ or $SU(n, \mathbf{C})$. This is useful since the representation theory of $GL(n)$ is ubiquitous, and also since we may then represent the fundamental weights (in *sage.combinat.root_system.root_system*) by vectors with integer entries. If you are only interested in $SL(3)$, say, use `WeylCharacterRing(['A',2])` as above but be aware that `R([a,b,c])` and `R([a+1,b+1,c+1])` represent the same character of $SL(3)$ since `R([1,1,1])` is the determinant.

For more information, see the thematic tutorial *Lie Methods and Related Combinatorics in Sage*, available at:

https://doc.sagemath.org/html/en/thematic_tutorials/lie.html

class Element

Bases: `IndexedFreeModuleElement`

A class for Weyl characters.

adams_operation(*r*)

Return the r-th Adams operation of `self`.

INPUT:

- `r` – positive integer

This is a virtual character, whose weights are the weights of `self`, each multiplied by r.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operator(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> A2(Integer(1),Integer(1),Integer(0)).adams_operator(Integer(3))
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

adams_operator(*r*)

Return the r-th Adams operation of `self`.

INPUT:

- `r` – positive integer

This is a virtual character, whose weights are the weights of `self`, each multiplied by r.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2(1,1,0).adams_operator(3)
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> A2(Integer(1),Integer(1),Integer(0)).adams_operator(Integer(3))
A2(2,2,2) - A2(3,2,1) + A2(3,3,0)
```

branch(*S*, *rule='default'*)

Return the restriction of the character to the subalgebra.

If no rule is specified, we will try to specify one.

INPUT:

- `S` – a Weyl character ring for a Lie subgroup or subalgebra
- `rule` – a branching rule

See `branch_weyl_character()` for more information about branching rules.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: A2 = WeylCharacterRing(['A',2])
sage: [B3(w).branch(A2,rule='levi') for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/
↪2)]
```

```
>>> from sage.all import *
>>> B3 = WeylCharacterRing(['B',Integer(3)])
>>> A2 = WeylCharacterRing(['A',Integer(2)])
>>> [B3(w).branch(A2,rule='levi') for w in B3.fundamental_weights()]
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/
↪2)]
```

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2([1,0,0]).cartan_type()
['A', 2]
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> A2([Integer(1),Integer(0),Integer(0)]).cartan_type()
['A', 2]
```

degree()

Return the degree of `self`.

This is the dimension of the associated module.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]
```

```
>>> from sage.all import *
>>> B3 = WeylCharacterRing(['B',Integer(3)])
>>> [B3(x).degree() for x in B3.fundamental_weights()]
[7, 21, 8]
```

dual()

The involution that replaces a representation with its contragredient. (For Fusion rings, this is the conjugation map.)

EXAMPLES:

```
sage: A3 = WeylCharacterRing("A3", style='coroots')
sage: A3(1,0,0)^2
A3(0,1,0) + A3(2,0,0)
sage: (A3(1,0,0)^2).dual()
A3(0,1,0) + A3(0,0,2)
```

```
>>> from sage.all import *
>>> A3 = WeylCharacterRing("A3", style='coroots')
>>> A3(Integer(1),Integer(0),Integer(0))**Integer(2)
A3(0,1,0) + A3(2,0,0)
>>> (A3(Integer(1),Integer(0),Integer(0))**Integer(2)).dual()
A3(0,1,0) + A3(0,0,2)
```

exterior_power(k)

Return the k-th exterior power of `self`.

INPUT:

- `k` – nonnegative integer

The algorithm is based on the identity $ke_k = \sum_{r=1}^{k}(-1)^{k-1}p_k e_{k-r}$ relating the power-sum and elementary symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation `self`, the e_k become exterior powers and the p_k become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3",style='coroots')
sage: spin = B3(0,0,1)
sage: spin.exterior_power(6)
B3(1,0,0) + B3(0,1,0)
```

```
>>> from sage.all import *
>>> B3 = WeylCharacterRing("B3",style='coroots')
>>> spin = B3(Integer(0),Integer(0),Integer(1))
>>> spin.exterior_power(Integer(6))
B3(1,0,0) + B3(0,1,0)
```

exterior_square()

Return the exterior square of the character.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style='coroots')
sage: A2(1,0).exterior_square()
A2(0,1)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2",style='coroots')
>>> A2(Integer(1),Integer(0)).exterior_square()
A2(0,1)
```

frobenius_schur_indicator()

Return:

- 1 if the representation is real (orthogonal)
- -1 if the representation is quaternionic (symplectic)
- 0 if the representation is complex (not self dual)

The Frobenius-Schur indicator of a character χ of a compact group G is the Haar integral over the group of $\chi(g^2)$. Its value is 1, -1 or 0. This method computes it for irreducible characters of compact Lie groups by checking whether the symmetric and exterior square characters contain the trivial character.

Todo

Try to compute this directly without actually calculating the full symmetric and exterior squares.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style='coroots')
sage: B2(1,0).frobenius_schur_indicator()
 1
sage: B2(0,1).frobenius_schur_indicator()
 -1
```

```
>>> from sage.all import *
>>> B2 = WeylCharacterRing("B2",style='coroots')
>>> B2(Integer(1),Integer(0)).frobenius_schur_indicator()
 1
>>> B2(Integer(0),Integer(1)).frobenius_schur_indicator()
 -1
```

highest_weight()

Return the parametrizing dominant weight of an irreducible character.

This method is only available for basis elements.

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2", style='coroots')
sage: [x.highest_weight() for x in [G2(1,0),G2(0,1)]]
[(1, 0, -1), (2, -1, -1)]
```

```
>>> from sage.all import *
>>> G2 = WeylCharacterRing("G2", style='coroots')
```

(continues on next page)

(continued from previous page)

```
>>> [x.highest_weight() for x in [G2(Integer(1),Integer(0)),G2(Integer(0),
↪Integer(1))]]
[(1, 0, -1), (2, -1, -1)]
```

inner_product(*other*)

Compute the inner product with another character.

The irreducible characters are an orthonormal basis with respect to the usual inner product of characters, interpreted as functions on a compact Lie group, by Schur orthogonality.

INPUT:

- `other` – another character

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: [f1,f2] = A2.fundamental_weights()
sage: r1 = A2(f1)*A2(f2); r1
A2(1,1,1) + A2(2,1,0)
sage: r2 = A2(f1)^3; r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
sage: r1.inner_product(r2)
3
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> [f1,f2] = A2.fundamental_weights()
>>> r1 = A2(f1)*A2(f2); r1
A2(1,1,1) + A2(2,1,0)
>>> r2 = A2(f1)**Integer(3); r2
A2(1,1,1) + 2*A2(2,1,0) + A2(3,0,0)
>>> r1.inner_product(r2)
3
```

invariant_degree()

Return the multiplicity of the trivial representation in `self`.

Multiplicities of other irreducibles may be obtained using `multiplicity()`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style='coroots')
sage: rep = A2(1,0)^2*A2(0,1)^2; rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
sage: rep.invariant_degree()
2
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2",style='coroots')
>>> rep = A2(Integer(1),Integer(0))**Integer(2)*A2(Integer(0),
↪Integer(1))**Integer(2); rep
2*A2(0,0) + A2(0,3) + 4*A2(1,1) + A2(3,0) + A2(2,2)
>>> rep.invariant_degree()
2
```

is_irreducible()

Return whether `self` is an irreducible character.

EXAMPLES:

```
sage: B3 = WeylCharacterRing(['B',3])
sage: [B3(x).is_irreducible() for x in B3.fundamental_weights()]
[True, True, True]
sage: sum(B3(x) for x in B3.fundamental_weights()).is_irreducible()
False
```

```
>>> from sage.all import *
>>> B3 = WeylCharacterRing(['B',Integer(3)])
>>> [B3(x).is_irreducible() for x in B3.fundamental_weights()]
[True, True, True]
>>> sum(B3(x) for x in B3.fundamental_weights()).is_irreducible()
False
```

multiplicity(*other*)

Return the multiplicity of the irreducible `other` in `self`.

INPUT:

- `other` – an irreducible character

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style='coroots')
sage: rep = B2(1,1)^2; rep
B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) +
→B2(2,2)
sage: rep.multiplicity(B2(0,2))
2
```

```
>>> from sage.all import *
>>> B2 = WeylCharacterRing("B2",style='coroots')
>>> rep = B2(Integer(1),Integer(1))**Integer(2); rep
B2(0,0) + B2(1,0) + 2*B2(0,2) + B2(2,0) + 2*B2(1,2) + B2(0,4) + B2(3,0) +
→B2(2,2)
>>> rep.multiplicity(B2(Integer(0),Integer(2)))
2
```

symmetric_power(k)

Return the k-th symmetric power of `self`.

INPUT:

- `k` – nonnegative integer

The algorithm is based on the identity $kh_k = \sum_{r=1}^{k} p_k h_{k-r}$ relating the power-sum and complete symmetric polynomials. Applying this to the eigenvalues of an element of the parent Lie group in the representation `self`, the h_k become symmetric powers and the p_k become Adams operations, giving an efficient recursive implementation.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3",style='coroots')
sage: spin = B3(0,0,1)
```

(continues on next page)

(continued from previous page)

```
sage: spin.symmetric_power(6)
B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
```

```
>>> from sage.all import *
>>> B3 = WeylCharacterRing("B3",style='coroots')
>>> spin = B3(Integer(0),Integer(0),Integer(1))
>>> spin.symmetric_power(Integer(6))
B3(0,0,0) + B3(0,0,2) + B3(0,0,4) + B3(0,0,6)
```

symmetric_square()

Return the symmetric square of the character.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style='coroots')
sage: A2(1,0).symmetric_square()
A2(2,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2",style='coroots')
>>> A2(Integer(1),Integer(0)).symmetric_square()
A2(2,0)
```

weight_multiplicities()

Return the dictionary of weight multiplicities for the Weyl character `self`.

The character does not have to be irreducible.

EXAMPLES:

```
sage: B2 = WeylCharacterRing("B2",style='coroots')
sage: B2(0,1).weight_multiplicities()
{(-1/2, -1/2): 1, (-1/2, 1/2): 1, (1/2, -1/2): 1, (1/2, 1/2): 1}
```

```
>>> from sage.all import *
>>> B2 = WeylCharacterRing("B2",style='coroots')
>>> B2(Integer(0),Integer(1)).weight_multiplicities()
{(-1/2, -1/2): 1, (-1/2, 1/2): 1, (1/2, -1/2): 1, (1/2, 1/2): 1}
```

adjoint_representation()

Return the adjoint representation as an element of the WeylCharacterRing.

EXAMPLES:

```
sage: G2 = WeylCharacterRing("G2",style='coroots')
sage: G2.adjoint_representation()
G2(0,1)
```

```
>>> from sage.all import *
>>> G2 = WeylCharacterRing("G2",style='coroots')
>>> G2.adjoint_representation()
G2(0,1)
```

affine_reflect(*wt*, *k=0*)

Return the reflection of wt in the hyperplane θ.

Optionally, this also shifts by a multiple k of θ.

INPUT:

- wt – a weight
- k – (optional) a positive integer

EXAMPLES:

```
sage: B22 = FusionRing("B2",2)
sage: fw = B22.fundamental_weights(); fw
Finite family {1: (1, 0), 2: (1/2, 1/2)}
sage: [B22.affine_reflect(x,2) for x in fw]
[(2, 1), (3/2, 3/2)]
```

```
>>> from sage.all import *
>>> B22 = FusionRing("B2",Integer(2))
>>> fw = B22.fundamental_weights(); fw
Finite family {1: (1, 0), 2: (1/2, 1/2)}
>>> [B22.affine_reflect(x,Integer(2)) for x in fw]
[(2, 1), (3/2, 3/2)]
```

ambient()

Return the weight ring of self.

EXAMPLES:

```
sage: WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer␣
↪Ring coefficients
```

```
>>> from sage.all import *
>>> WeylCharacterRing("A2").ambient()
The Weight ring attached to The Weyl Character Ring of Type A2 with Integer␣
↪Ring coefficients
```

base_ring()

Return the base ring of self.

EXAMPLES:

```
sage: R = WeylCharacterRing(['A',3], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

```
>>> from sage.all import *
>>> R = WeylCharacterRing(['A',Integer(3)], base_ring = CC); R.base_ring()
Complex Field with 53 bits of precision
```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: WeylCharacterRing("A2").cartan_type()
['A', 2]
```

```
>>> from sage.all import *
>>> WeylCharacterRing("A2").cartan_type()
['A', 2]
```

char_from_weights(*mdict*)

Construct a Weyl character from an invariant linear combination of weights.

INPUT:

- `mdict` – dictionary mapping weights to coefficients, and representing a linear combination of weights which shall be invariant under the action of the Weyl group

OUTPUT: the corresponding Weyl character

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: d = dict([(x,1) for x in v.orbit()]); d
{(1, 3, 0): 1,
 (1, 0, 3): 1,
 (3, 1, 0): 1,
 (3, 0, 1): 1,
 (0, 1, 3): 1,
 (0, 3, 1): 1}
sage: A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> v = A2._space([Integer(3),Integer(1),Integer(0)]); v
(3, 1, 0)
>>> d = dict([(x,Integer(1)) for x in v.orbit()]); d
{(1, 3, 0): 1,
 (1, 0, 3): 1,
 (3, 1, 0): 1,
 (3, 0, 1): 1,
 (0, 1, 3): 1,
 (0, 3, 1): 1}
>>> A2.char_from_weights(d)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

demazure_character(*hwv*, *word*, *debug=False*)

Compute the Demazure character.

INPUT:

- `hwv` – a (usually dominant) weight
- `word` – a Weyl group word

Produces the Demazure character with highest weight `hwv` and `word` as an element of the weight ring. Only available if `style="coroots"`. The Demazure operators are also available as methods of `WeightRing` elements, and as methods of crystals. Given a *CrystalOfTableaux* with given highest weight vector, the Demazure method on the crystal will give the equivalent of this method, except that the Demazure character of the crystal is given as a sum of monomials instead of an element of the *WeightRing*.

See *WeightRing.Element.demazure()* and sage.categories.classical_crystals.ClassicalCrystals.ParentMethods.demazure_character()

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2",style='coroots')
sage: h = sum(A2.fundamental_weights()); h
(2, 1, 0)
sage: A2.demazure_character(h,word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
sage: A2.demazure_character((1,1),word=[1,2])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2",style='coroots')
>>> h = sum(A2.fundamental_weights()); h
(2, 1, 0)
>>> A2.demazure_character(h,word=[Integer(1),Integer(2)])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
>>> A2.demazure_character((Integer(1),Integer(1)),word=[Integer(1),
↪Integer(2)])
a2(0,0) + a2(-2,1) + a2(2,-1) + a2(1,1) + a2(-1,2)
```

dot_reduce(*a*)

Auxiliary function for *product_on_basis()*.

Return a pair $[\epsilon, b]$ where b is a dominant weight and ϵ is 0, 1 or -1. To describe b, let w be an element of the Weyl group such that $w(a+\rho)$ is dominant. If $w(a+\rho)-\rho$ is dominant, then ϵ is the sign of w and b is $w(a+\rho)-\rho$. Otherwise, ϵ is zero.

INPUT:

- a – a weight

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: weights = sorted(A2(2,1,0).weight_multiplicities().keys(), key=str);␣
↪weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
sage: [A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0,␣
↪0)], [0, (0, 0, 0)], [1, (2, 1, 0)]]
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> weights = sorted(A2(Integer(2),Integer(1),Integer(0)).weight_
↪multiplicities().keys(), key=str); weights
[(0, 1, 2), (0, 2, 1), (1, 0, 2), (1, 1, 1), (1, 2, 0), (2, 0, 1), (2, 1, 0)]
>>> [A2.dot_reduce(x) for x in weights]
[[0, (0, 0, 0)], [-1, (1, 1, 1)], [-1, (1, 1, 1)], [1, (1, 1, 1)], [0, (0, 0,␣
↪0)], [0, (0, 0, 0)], [1, (2, 1, 0)]]
```

dynkin_diagram()

Return the Dynkin diagram of `self`.

EXAMPLES:

```
sage: WeylCharacterRing("E7").dynkin_diagram()
        O 2
        |
        |
O---O---O---O---O---O
1   3   4   5   6   7
E7
```

```
>>> from sage.all import *
>>> WeylCharacterRing("E7").dynkin_diagram()
        O 2
        |
        |
O---O---O---O---O---O
1   3   4   5   6   7
E7
```

extended_dynkin_diagram()

Return the extended Dynkin diagram, which is the Dynkin diagram of the corresponding untwisted affine type.

EXAMPLES:

```
sage: WeylCharacterRing("E7").extended_dynkin_diagram()
            O 2
            |
            |
O---O---O---O---O---O---O
0   1   3   4   5   6   7
E7~
```

```
>>> from sage.all import *
>>> WeylCharacterRing("E7").extended_dynkin_diagram()
            O 2
            |
            |
O---O---O---O---O---O---O
0   1   3   4   5   6   7
E7~
```

fundamental_weights()

Return the fundamental weights.

EXAMPLES:

```
sage: WeylCharacterRing("G2").fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

```
>>> from sage.all import *
>>> WeylCharacterRing("G2").fundamental_weights()
Finite family {1: (1, 0, -1), 2: (2, -1, -1)}
```

highest_root()

Return the highest root.

EXAMPLES:

```
sage: WeylCharacterRing("G2").highest_root()
 (2, -1, -1)
```

```
>>> from sage.all import *
>>> WeylCharacterRing("G2").highest_root()
 (2, -1, -1)
```

irr_repr(*hwv*)

Return a string representing the irreducible character with highest weight vector `hwv`.

EXAMPLES:

```
sage: B3 = WeylCharacterRing("B3")
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(1,1,0)', 'B3(1/2,1/2,1/2)']
sage: B3 = WeylCharacterRing("B3", style='coroots')
sage: [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(0,1,0)', 'B3(0,0,1)']
```

```
>>> from sage.all import *
>>> B3 = WeylCharacterRing("B3")
>>> [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(1,1,0)', 'B3(1/2,1/2,1/2)']
>>> B3 = WeylCharacterRing("B3", style='coroots')
>>> [B3.irr_repr(v) for v in B3.fundamental_weights()]
['B3(1,0,0)', 'B3(0,1,0)', 'B3(0,0,1)']
```

level(*wt*)

Return the level of the weight, defined to be the value of the weight on the coroot associated with the highest root.

EXAMPLES:

```
sage: R = FusionRing("F4",2); [R.level(x) for x in R.fundamental_weights()]
[2, 3, 2, 1]
sage: [CartanType("F4~").dual().a()[x] for x in [1..4]]
[2, 3, 2, 1]
```

```
>>> from sage.all import *
>>> R = FusionRing("F4",Integer(2)); [R.level(x) for x in R.fundamental_
↪weights()]
[2, 3, 2, 1]
>>> [CartanType("F4~").dual().a()[x] for x in (ellipsis_range(Integer(1),
↪Ellipsis,Integer(4)))]
[2, 3, 2, 1]
```

lift()

The embedding of `self` into its weight ring.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: A2.lift
Generic morphism:
  From: The Weyl Character Ring of Type A2 with Integer Ring coefficients
  To:   The Weight ring attached to The Weyl Character Ring of Type A2 with␣
↪Integer Ring coefficients
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> A2.lift
Generic morphism:
  From: The Weyl Character Ring of Type A2 with Integer Ring coefficients
  To:   The Weight ring attached to The Weyl Character Ring of Type A2 with␣
↪Integer Ring coefficients
```

```
sage: x = -A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2.lift(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

```
>>> from sage.all import *
>>> x = -A2(Integer(2),Integer(1),Integer(1)) - A2(Integer(2),Integer(2),
↪Integer(0)) + A2(Integer(3),Integer(1),Integer(0))
>>> A2.lift(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

As a shortcut, you may also do:

```
sage: x.lift()
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

```
>>> from sage.all import *
>>> x.lift()
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

Or even:

```
sage: a2 = WeightRing(A2)
sage: a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

```
>>> from sage.all import *
>>> a2 = WeightRing(A2)
>>> a2(x)
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
```

lift_on_basis(*irr*)

Expand the basis element indexed by the weight `irr` into the weight ring of `self`.

INPUT:

- `irr` – a dominant weight

This is used to implement *lift()*.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: v = A2._space([2,1,0]); v
(2, 1, 0)
sage: A2.lift_on_basis(v)
2*a2(1,1,1) + a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) +␣
↪a2(0,2,1)
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> v = A2._space([Integer(2),Integer(1),Integer(0)]); v
(2, 1, 0)
>>> A2.lift_on_basis(v)
2*a2(1,1,1) + a2(1,2,0) + a2(1,0,2) + a2(2,1,0) + a2(2,0,1) + a2(0,1,2) +␣
↪a2(0,2,1)
```

This is consistent with the analogous calculation with symmetric Schur functions:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s[Integer(2),Integer(1)].expand(Integer(3))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
```

maximal_subgroup(*ct*)

Return a branching rule or a list of branching rules.

INPUT:

- `ct` – the Cartan type of a maximal subgroup of `self`

In rare cases where there is more than one maximal subgroup (up to outer automorphisms) with the given Cartan type, the function returns a list of branching rules.

EXAMPLES:

```
sage: WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2
sage: WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]
```

```
>>> from sage.all import *
>>> WeylCharacterRing("E7").maximal_subgroup("A2")
miscellaneous branching rule E7 => A2
>>> WeylCharacterRing("E7").maximal_subgroup("A1")
[iii branching rule E7 => A1, iv branching rule E7 => A1]
```

For more information, see the related method *maximal_subgroups()*.

maximal_subgroups()

This method is only available if the Cartan type of `self` is irreducible and of rank no greater than 8. This method produces a list of the maximal subgroups of `self`, up to (possibly outer) automorphisms. Each line in the output gives the Cartan type of a maximal subgroup followed by a command that creates the branching rule.

EXAMPLES:

```
sage: WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")
```

```
>>> from sage.all import *
>>> WeylCharacterRing("E6").maximal_subgroups()
D5:branching_rule("E6","D5","levi")
C4:branching_rule("E6","C4","symmetric")
F4:branching_rule("E6","F4","symmetric")
A2:branching_rule("E6","A2","miscellaneous")
G2:branching_rule("E6","G2","miscellaneous")
A2xG2:branching_rule("E6","A2xG2","miscellaneous")
A1xA5:branching_rule("E6","A1xA5","extended")
A2xA2xA2:branching_rule("E6","A2xA2xA2","extended")
```

Note that there are other embeddings of (for example A_2 into E_6 as nonmaximal subgroups. These embeddings may be constructed by composing branching rules through various subgroups.

Once you know which maximal subgroup you are interested in, to create the branching rule, you may either paste the command to the right of the colon from the above output onto the command line, or alternatively invoke the related method *maximal_subgroup()*:

```
sage: branching_rule("E6","G2","miscellaneous")
miscellaneous branching rule E6 => G2
sage: WeylCharacterRing("E6").maximal_subgroup("G2")
miscellaneous branching rule E6 => G2
```

```
>>> from sage.all import *
>>> branching_rule("E6","G2","miscellaneous")
miscellaneous branching rule E6 => G2
>>> WeylCharacterRing("E6").maximal_subgroup("G2")
miscellaneous branching rule E6 => G2
```

It is believed that the list of maximal subgroups is complete, except that some subgroups may be not be invariant under outer automorphisms. It is reasonable to want a list of maximal subgroups that is complete up to conjugation, but to obtain such a list you may have to apply outer automorphisms. The group of outer automorphisms modulo inner automorphisms is isomorphic to the group of symmetries of the Dynkin diagram, and these are available as branching rules. The following example shows that while a branching rule from D_4 to $A_1 \times C_2$ is supplied, another different one may be obtained by composing it with the triality automorphism of D_4:

```
sage: [D4,A1xC2]=[WeylCharacterRing(x,style='coroots') for x in ["D4","A1xC2
↪"]]
sage: fw = D4.fundamental_weights()
sage: b = D4.maximal_subgroup("A1xC2")
sage: [D4(fw).branch(A1xC2,rule=b) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(0,0,1)]
sage: b1 = branching_rule("D4","D4","triality")*b
sage: [D4(fw).branch(A1xC2,rule=b1) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(2,0,0) + A1xC2(0,0,1),
A1xC2(1,1,0)]
```

```
>>> from sage.all import *
>>> [D4,A1xC2]=[WeylCharacterRing(x,style='coroots') for x in ["D4","A1xC2"]]
>>> fw = D4.fundamental_weights()
>>> b = D4.maximal_subgroup("A1xC2")
>>> [D4(fw).branch(A1xC2,rule=b) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(0,0,1)]
>>> b1 = branching_rule("D4","D4","triality")*b
>>> [D4(fw).branch(A1xC2,rule=b1) for fw in D4.fundamental_weights()]
[A1xC2(1,1,0),
A1xC2(2,0,0) + A1xC2(2,0,1) + A1xC2(0,2,0),
A1xC2(2,0,0) + A1xC2(0,0,1),
A1xC2(1,1,0)]
```

one_basis()

Return the index of 1 in `self`.

EXAMPLES:

```
sage: WeylCharacterRing("A3").one_basis()
(0, 0, 0, 0)
sage: WeylCharacterRing("A3").one()
A3(0,0,0,0)
```

```
>>> from sage.all import *
>>> WeylCharacterRing("A3").one_basis()
(0, 0, 0, 0)
>>> WeylCharacterRing("A3").one()
A3(0,0,0,0)
```

positive_roots()

Return the positive roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

```
>>> from sage.all import *
>>> WeylCharacterRing("G2").positive_roots()
[(0, 1, -1), (1, -2, 1), (1, -1, 0), (1, 0, -1), (1, 1, -2), (2, -1, -1)]
```

product_on_basis(*a*, *b*)

Compute the tensor product of two irreducible representations `a` and `b`.

EXAMPLES:

```
sage: D4 = WeylCharacterRing(['D',4])
sage: spin_plus = D4(1/2,1/2,1/2,1/2)
sage: spin_minus = D4(1/2,1/2,1/2,-1/2)
sage: spin_plus * spin_minus # indirect doctest
D4(1,0,0,0) + D4(1,1,1,0)
sage: spin_minus * spin_plus
D4(1,0,0,0) + D4(1,1,1,0)
```

```
>>> from sage.all import *
>>> D4 = WeylCharacterRing(['D',Integer(4)])
>>> spin_plus = D4(Integer(1)/Integer(2),Integer(1)/Integer(2),Integer(1)/
↪Integer(2),Integer(1)/Integer(2))
>>> spin_minus = D4(Integer(1)/Integer(2),Integer(1)/Integer(2),Integer(1)/
↪Integer(2),-Integer(1)/Integer(2))
>>> spin_plus * spin_minus # indirect doctest
D4(1,0,0,0) + D4(1,1,1,0)
>>> spin_minus * spin_plus
D4(1,0,0,0) + D4(1,1,1,0)
```

Uses the Brauer-Klimyk method.

rank()

Return the rank.

EXAMPLES:

```
sage: WeylCharacterRing("G2").rank()
2
```

```
>>> from sage.all import *
>>> WeylCharacterRing("G2").rank()
2
```

retract()

The partial inverse map from the weight ring into `self`.

EXAMPLES:

```
sage: A2 = WeylCharacterRing("A2")
sage: a2 = WeightRing(A2)
sage: A2.retract
Generic morphism:
```

(continues on next page)

(continued from previous page)

```
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with␣
↪Integer Ring coefficients
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

```
>>> from sage.all import *
>>> A2 = WeylCharacterRing("A2")
>>> a2 = WeightRing(A2)
>>> A2.retract
Generic morphism:
  From: The Weight ring attached to The Weyl Character Ring of Type A2 with␣
↪Integer Ring coefficients
  To:   The Weyl Character Ring of Type A2 with Integer Ring coefficients
```

```
sage: v = A2._space([3,1,0]); v
(3, 1, 0)
sage: chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
sage: A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

```
>>> from sage.all import *
>>> v = A2._space([Integer(3),Integer(1),Integer(0)]); v
(3, 1, 0)
>>> chi = a2.sum_of_monomials(v.orbit()); chi
a2(1,3,0) + a2(1,0,3) + a2(3,1,0) + a2(3,0,1) + a2(0,1,3) + a2(0,3,1)
>>> A2.retract(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
```

The input should be invariant:

```
sage: A2.retract(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

```
>>> from sage.all import *
>>> A2.retract(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

As a shortcut, you may use conversion:

```
sage: A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
sage: A2(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

```
>>> from sage.all import *
>>> A2(chi)
-A2(2,1,1) - A2(2,2,0) + A2(3,1,0)
>>> A2(a2.monomial(v))
Traceback (most recent call last):
...
ValueError: multiplicity dictionary may not be Weyl group invariant
```

simple_coroots()

Return the simple coroots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
```

```
>>> from sage.all import *
>>> WeylCharacterRing("G2").simple_coroots()
Finite family {1: (0, 1, -1), 2: (1/3, -2/3, 1/3)}
```

simple_roots()

Return the simple roots.

EXAMPLES:

```
sage: WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

```
>>> from sage.all import *
>>> WeylCharacterRing("G2").simple_roots()
Finite family {1: (0, 1, -1), 2: (1, -2, 1)}
```

some_elements()

Return some elements of `self`.

EXAMPLES:

```
sage: WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]
```

```
>>> from sage.all import *
>>> WeylCharacterRing("A3").some_elements()
[A3(1,0,0,0), A3(1,1,0,0), A3(1,1,1,0)]
```

space()

Return the weight space associated to `self`.

EXAMPLES:

```
sage: WeylCharacterRing(['E',8]).space()
Ambient space of the Root system of type ['E', 8]
```

```
>>> from sage.all import *
>>> WeylCharacterRing(['E',Integer(8)]).space()
Ambient space of the Root system of type ['E', 8]
```

sage.combinat.root_system.weyl_characters.**irreducible_character_freudenthal**(*hwv*, *debug=False*)

Return the dictionary of multiplicities for the irreducible character with highest weight λ.

The weight multiplicities are computed by the Freudenthal multiplicity formula. The algorithm is based on recursion relation that is stated, for example, in Humphrey's book on Lie Algebras. The multiplicities are invariant under the Weyl group, so to compute them it would be sufficient to compute them for the weights in the positive Weyl chamber. However after some testing it was found to be faster to compute every weight using the recursion, since the use of the Weyl group is expensive in its current implementation.

INPUT:

- hwv – a dominant weight in a weight lattice
- L – the ambient space

EXAMPLES:

```
sage: WeylCharacterRing("A2")(2,1,0).weight_multiplicities() # indirect doctest
{(1, 1, 1): 2, (1, 2, 0): 1, (1, 0, 2): 1, (2, 1, 0): 1,
 (2, 0, 1): 1, (0, 1, 2): 1, (0, 2, 1): 1}
```

```
>>> from sage.all import *
>>> WeylCharacterRing("A2")(Integer(2),Integer(1),Integer(0)).weight_
↪multiplicities() # indirect doctest
{(1, 1, 1): 2, (1, 2, 0): 1, (1, 0, 2): 1, (2, 1, 0): 1,
 (2, 0, 1): 1, (0, 1, 2): 1, (0, 2, 1): 1}
```

5.1.273 Weyl Groups

AUTHORS:

- Daniel Bump (2008): initial version
- Mike Hansen (2008): initial version
- Anne Schilling (2008): initial version
- Nicolas Thiéry (2008): initial version
- Volker Braun (2013): LibGAP-based matrix groups

EXAMPLES:

The Cayley graph of the Weyl Group of type ['A', 3]:

```
sage: w = WeylGroup(['A',3])
sage: d = w.cayley_graph(); d
Digraph on 24 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03)            #␣
↪needs sage.plot
```

```
>>> from sage.all import *
>>> w = WeylGroup(['A',Integer(3)])
>>> d = w.cayley_graph(); d
Digraph on 24 vertices
>>> d.show3d(color_by_label=True, edge_size=RealNumber('0.01'), vertex_
↪size=RealNumber('0.03'))                # needs sage.plot
```

The Cayley graph of the Weyl Group of type ['D', 4]:

```
sage: w = WeylGroup(['D',4])
sage: d = w.cayley_graph(); d
Digraph on 192 vertices
sage: d.show3d(color_by_label=True, edge_size=0.01, vertex_size=0.03)        # long␣
↪time (less than one minute), needs sage.plot
```

```
>>> from sage.all import *
>>> w = WeylGroup(['D',Integer(4)])
>>> d = w.cayley_graph(); d
Digraph on 192 vertices
>>> d.show3d(color_by_label=True, edge_size=RealNumber('0.01'), vertex_
↪size=RealNumber('0.03'))        # long time (less than one minute), needs sage.plot
```

Todo

More examples on Weyl Groups should be added here.

class sage.combinat.root_system.weyl_group.**ClassicalWeylSubgroup**(*domain*, *prefix*)

Bases: *WeylGroup_gens*

A class for Classical Weyl Subgroup of an affine Weyl Group.

EXAMPLES:

```
sage: G = WeylGroup(["A",3,1]).classical()
sage: G
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group␣
↪acting on the root space)
sage: G.category()
Category of finite irreducible Weyl groups
sage: G.cardinality()
24
sage: G.index_set()
(1, 2, 3)
sage: TestSuite(G).run()
```

```
>>> from sage.all import *
>>> G = WeylGroup(["A",Integer(3),Integer(1)]).classical()
>>> G
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1] (as a matrix group␣
↪acting on the root space)
>>> G.category()
Category of finite irreducible Weyl groups
```

(continues on next page)

(continued from previous page)

```
>>> G.cardinality()
24
>>> G.index_set()
(1, 2, 3)
>>> TestSuite(G).run()
```

Todo

implement:

- Parabolic subrootsystems
- Parabolic subgroups with a set of nodes as argument

cartan_type()

EXAMPLES:

```
sage: WeylGroup(['A',3,1]).classical().cartan_type()
['A', 3]
sage: WeylGroup(['A',3,1]).classical().index_set()
(1, 2, 3)
```

```
>>> from sage.all import *
>>> WeylGroup(['A',Integer(3),Integer(1)]).classical().cartan_type()
['A', 3]
>>> WeylGroup(['A',Integer(3),Integer(1)]).classical().index_set()
(1, 2, 3)
```

Note: won't be needed, once the lattice will be a parabolic sub root system

simple_reflections()

EXAMPLES:

```
sage: WeylGroup(['A',2,1]).classical().simple_reflections()
Finite family {1: [ 1  0  0]
                  [ 1 -1  1]
                  [ 0  0  1],
               2: [ 1  0  0]
                  [ 0  1  0]
                  [ 1  1 -1]}
```

```
>>> from sage.all import *
>>> WeylGroup(['A',Integer(2),Integer(1)]).classical().simple_reflections()
Finite family {1: [ 1  0  0]
                  [ 1 -1  1]
                  [ 0  0  1],
               2: [ 1  0  0]
                  [ 0  1  0]
                  [ 1  1 -1]}
```

Note: won't be needed, once the lattice will be a parabolic sub root system

weyl_group(*prefix='hereditary'*)

Return the Weyl group associated to the parabolic subgroup.

EXAMPLES:

```
sage: WeylGroup(['A',4,1]).classical().weyl_group()
Weyl Group of type ['A', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['C',4,1]).classical().weyl_group()
Weyl Group of type ['C', 4, 1] (as a matrix group acting on the root space)
sage: WeylGroup(['E',8,1]).classical().weyl_group()
Weyl Group of type ['E', 8, 1] (as a matrix group acting on the root space)
```

```
>>> from sage.all import *
>>> WeylGroup(['A',Integer(4),Integer(1)]).classical().weyl_group()
Weyl Group of type ['A', 4, 1] (as a matrix group acting on the root space)
>>> WeylGroup(['C',Integer(4),Integer(1)]).classical().weyl_group()
Weyl Group of type ['C', 4, 1] (as a matrix group acting on the root space)
>>> WeylGroup(['E',Integer(8),Integer(1)]).classical().weyl_group()
Weyl Group of type ['E', 8, 1] (as a matrix group acting on the root space)
```

sage.combinat.root_system.weyl_group.**WeylGroup**(*x*, *prefix=None*, *implementation='matrix'*)

Return the Weyl group of the root system defined by the Cartan type (or matrix) `ct`.

INPUT:

- `x` – a root system or a Cartan type (or matrix)

OPTIONAL:

- `prefix` – changes the representation of elements from matrices to products of simple reflections
- `implementation` – one of the following:
  - `'matrix'` – as matrices acting on a root system
  - `'permutation'` – as a permutation group acting on the roots

EXAMPLES:

The following constructions yield the same result, namely a weight lattice and its corresponding Weyl group:

```
sage: G = WeylGroup(['F',4])
sage: L = G.domain()
```

```
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> L = G.domain()
```

or alternatively and equivalently:

```
sage: L = RootSystem(['F',4]).ambient_space()
sage: G = L.weyl_group()
sage: W = WeylGroup(L)
```

```
>>> from sage.all import *
>>> L = RootSystem(['F',Integer(4)]).ambient_space()
>>> G = L.weyl_group()
>>> W = WeylGroup(L)
```

Either produces a weight lattice, with access to its roots and weights.

```
sage: G = WeylGroup(['F',4])
sage: G.order()
1152
sage: [s1,s2,s3,s4] = G.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: type(w) == G.element_class
True
sage: w.order()
12
sage: w.length() # length function on Weyl group
4
```

```
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> G.order()
1152
>>> [s1,s2,s3,s4] = G.simple_reflections()
>>> w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
>>> type(w) == G.element_class
True
>>> w.order()
12
>>> w.length() # length function on Weyl group
4
```

The default representation of Weyl group elements is as matrices. If you prefer, you may specify a prefix, in which case the elements are represented as products of simple reflections.

```
sage: W=WeylGroup("C3",prefix='s')
sage: [s1,s2,s3]=W.simple_reflections() # lets Sage parse its own output
sage: s2*s1*s2*s3
s1*s2*s3*s1
sage: s2*s1*s2*s3 == s1*s2*s3*s1
True
sage: (s2*s3)^2==(s3*s2)^2
True
sage: (s1*s2*s3*s1).matrix()
[ 0  0 -1]
[ 0  1  0]
[ 1  0  0]
```

```
>>> from sage.all import *
>>> W=WeylGroup("C3",prefix='s')
```

(continues on next page)

(continued from previous page)

```
>>> [s1,s2,s3]=W.simple_reflections() # lets Sage parse its own output
>>> s2*s1*s2*s3
s1*s2*s3*s1
>>> s2*s1*s2*s3 == s1*s2*s3*s1
True
>>> (s2*s3)**Integer(2)==(s3*s2)**Integer(2)
True
>>> (s1*s2*s3*s1).matrix()
[ 0  0 -1]
[ 0  1  0]
[ 1  0  0]
```

```
sage: L = G.domain()
sage: fw = L.fundamental_weights(); fw
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1,␣
↪0, 0, 0)}
sage: rho = sum(fw); rho
(11/2, 5/2, 3/2, 1/2)
sage: w.action(rho) # action of G on weight lattice
(5, -1, 3, 2)
```

```
>>> from sage.all import *
>>> L = G.domain()
>>> fw = L.fundamental_weights(); fw
Finite family {1: (1, 1, 0, 0), 2: (2, 1, 1, 0), 3: (3/2, 1/2, 1/2, 1/2), 4: (1,␣
↪0, 0, 0)}
>>> rho = sum(fw); rho
(11/2, 5/2, 3/2, 1/2)
>>> w.action(rho) # action of G on weight lattice
(5, -1, 3, 2)
```

We can also do the same for arbitrary Cartan matrices:

```
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
sage: W = WeylGroup(cm)
sage: W.gens()
(
[-1  5  0]  [ 1  0  0]  [ 1  0  0]
[ 0  1  0]  [ 2 -1  1]  [ 0  1  0]
[ 0  0  1], [ 0  0  1], [ 0  1 -1]
)
sage: s0,s1,s2 = W.gens()
sage: s1*s2*s1
[ 1  0  0]
[ 2  0 -1]
[ 2 -1  0]
sage: s2*s1*s2
[ 1  0  0]
[ 2  0 -1]
[ 2 -1  0]
sage: s0*s1*s0*s2*s0
[ 9  0 -5]
```

(continues on next page)

(continued from previous page)

```
[ 2  0 -1]
[ 0  1 -1]
```

```
>>> from sage.all import *
>>> cm = CartanMatrix([[Integer(2),-Integer(5),Integer(0)],[-Integer(2),
↪Integer(2),-Integer(1)],[Integer(0),-Integer(1),Integer(2)]])
>>> W = WeylGroup(cm)
>>> W.gens()
(
[-1  5  0]  [ 1  0  0]  [ 1  0  0]
[ 0  1  0]  [ 2 -1  1]  [ 0  1  0]
[ 0  0  1], [ 0  0  1], [ 0  1 -1]
)
>>> s0,s1,s2 = W.gens()
>>> s1*s2*s1
[ 1  0  0]
[ 2  0 -1]
[ 2 -1  0]
>>> s2*s1*s2
[ 1  0  0]
[ 2  0 -1]
[ 2 -1  0]
>>> s0*s1*s0*s2*s0
[ 9  0 -5]
[ 2  0 -1]
[ 0  1 -1]
```

Same Cartan matrix, but with a prefix to display using simple reflections:

```
sage: W = WeylGroup(cm, prefix='s')
sage: s0,s1,s2 = W.gens()
sage: s0*s2*s1
s2*s0*s1
sage: (s1*s2)^3
1
sage: (s0*s1)^5
s0*s1*s0*s1*s0*s1*s0*s1*s0*s1
sage: s0*s1*s2*s1*s2
s2*s0*s1
sage: s0*s1*s2*s0*s2
s0*s1*s0
```

```
>>> from sage.all import *
>>> W = WeylGroup(cm, prefix='s')
>>> s0,s1,s2 = W.gens()
>>> s0*s2*s1
s2*s0*s1
>>> (s1*s2)**Integer(3)
1
>>> (s0*s1)**Integer(5)
s0*s1*s0*s1*s0*s1*s0*s1*s0*s1
>>> s0*s1*s2*s1*s2
```

(continues on next page)

(continued from previous page)

```
s2*s0*s1
>>> s0*s1*s2*s0*s2
s0*s1*s0
```

class sage.combinat.root_system.weyl_group.**WeylGroupElement**(*parent*, *g*, *check=False*)

Bases: MatrixGroupElement_gap

Class for a Weyl Group elements

action(*v*)

Return the action of self on the vector v.

EXAMPLES:

```
sage: W = WeylGroup(['A',2])
sage: s = W.simple_reflections()
sage: v = W.domain()([1,0,0])
sage: s[1].action(v)
(0, 1, 0)

sage: W = WeylGroup(RootSystem(['A',2]).root_lattice())
sage: s = W.simple_reflections()
sage: alpha = W.domain().simple_roots()
sage: s[1].action(alpha[1])
-alpha[1]

sage: W=WeylGroup(['A',2,1])
sage: alpha = W.domain().simple_roots()
sage: s = W.simple_reflections()
sage: s[1].action(alpha[1])
-alpha[1]
sage: s[1].action(alpha[0])
alpha[0] + alpha[1]
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(2)])
>>> s = W.simple_reflections()
>>> v = W.domain()([Integer(1),Integer(0),Integer(0)])
>>> s[Integer(1)].action(v)
(0, 1, 0)

>>> W = WeylGroup(RootSystem(['A',Integer(2)]).root_lattice())
>>> s = W.simple_reflections()
>>> alpha = W.domain().simple_roots()
>>> s[Integer(1)].action(alpha[Integer(1)])
-alpha[1]

>>> W=WeylGroup(['A',Integer(2),Integer(1)])
>>> alpha = W.domain().simple_roots()
>>> s = W.simple_reflections()
>>> s[Integer(1)].action(alpha[Integer(1)])
-alpha[1]
>>> s[Integer(1)].action(alpha[Integer(0)])
```

(continues on next page)

(continued from previous page)

```
alpha[0] + alpha[1]
```

apply_simple_reflection(*i*, *side='right'*)

domain()

Return the ambient lattice associated with `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A',2])
sage: s1 = W.simple_reflection(1)
sage: s1.domain()
Ambient space of the Root system of type ['A', 2]
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(2)])
>>> s1 = W.simple_reflection(Integer(1))
>>> s1.domain()
Ambient space of the Root system of type ['A', 2]
```

has_descent(*i*, *positive=False*, *side='right'*)

Test if `self` has a descent at position `i`.

An element w has a descent in position i if w is on the strict negative side of the i-th simple reflection hyperplane.

If `positive` is `True`, tests if it is on the strict positive side instead.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [s[3].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
sage: W = WeylGroup(['A',3,1])
sage: s = W.simple_reflections()
sage: [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False, False]
sage: [s[0].has_descent(i) for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[1]
sage: [w.has_descent(i) for i in W.domain().index_set()]
[False, True, False, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, False, False]
sage: w = s[0] * s[2]
```

(continues on next page)

(continued from previous page)

```
sage: [w.has_descent(i) for i in W.domain().index_set()]
[True, False, True, False]
sage: [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, True, False]

sage: W = WeylGroup(['A',3])
sage: W.one().has_descent(0)
True
sage: W.w0.has_descent(0)
False
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> s = W.simple_reflections()
>>> [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False]
>>> [s[Integer(1)].has_descent(i) for i in W.domain().index_set()]
[True, False, False]
>>> [s[Integer(2)].has_descent(i) for i in W.domain().index_set()]
[False, True, False]
>>> [s[Integer(3)].has_descent(i) for i in W.domain().index_set()]
[False, False, True]
>>> [s[Integer(3)].has_descent(i, True) for i in W.domain().index_set()]
[True, True, False]
>>> W = WeylGroup(['A',Integer(3),Integer(1)])
>>> s = W.simple_reflections()
>>> [W.one().has_descent(i) for i in W.domain().index_set()]
[False, False, False, False]
>>> [s[Integer(0)].has_descent(i) for i in W.domain().index_set()]
[True, False, False, False]
>>> w = s[Integer(0)] * s[Integer(1)]
>>> [w.has_descent(i) for i in W.domain().index_set()]
[False, True, False, False]
>>> [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, False, False]
>>> w = s[Integer(0)] * s[Integer(2)]
>>> [w.has_descent(i) for i in W.domain().index_set()]
[True, False, True, False]
>>> [w.has_descent(i, side = "left") for i in W.domain().index_set()]
[True, False, True, False]

>>> W = WeylGroup(['A',Integer(3)])
>>> W.one().has_descent(Integer(0))
True
>>> W.w0.has_descent(Integer(0))
False
```

has_left_descent(*i*)

Test if `self` has a left descent at position `i`.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_left_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_left_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_left_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> s = W.simple_reflections()
>>> [W.one().has_left_descent(i) for i in W.domain().index_set()]
[False, False, False]
>>> [s[Integer(1)].has_left_descent(i) for i in W.domain().index_set()]
[True, False, False]
>>> [s[Integer(2)].has_left_descent(i) for i in W.domain().index_set()]
[False, True, False]
>>> [s[Integer(3)].has_left_descent(i) for i in W.domain().index_set()]
[False, False, True]
>>> [(s[Integer(3)]*s[Integer(2)]).has_left_descent(i) for i in W.domain().
↪index_set()]
[False, False, True]
```

has_right_descent(*i*)

Test if `self` has a right descent at position `i`.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: s = W.simple_reflections()
sage: [W.one().has_right_descent(i) for i in W.domain().index_set()]
[False, False, False]
sage: [s[1].has_right_descent(i) for i in W.domain().index_set()]
[True, False, False]
sage: [s[2].has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
sage: [s[3].has_right_descent(i) for i in W.domain().index_set()]
[False, False, True]
sage: [(s[3]*s[2]).has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> s = W.simple_reflections()
>>> [W.one().has_right_descent(i) for i in W.domain().index_set()]
[False, False, False]
>>> [s[Integer(1)].has_right_descent(i) for i in W.domain().index_set()]
[True, False, False]
```

(continues on next page)

(continued from previous page)

```
>>> [s[Integer(2)].has_right_descent(i) for i in W.domain().index_set()]
[False, True, False]
>>> [s[Integer(3)].has_right_descent(i) for i in W.domain().index_set()]
[False, False, True]
>>> [(s[Integer(3)]*s[Integer(2)]).has_right_descent(i) for i in W.domain().
↪index_set()]
[False, True, False]
```

to_matrix()

Return `self` as a matrix.

EXAMPLES:

```
sage: G = WeylGroup(['A',2])
sage: s1 = G.simple_reflection(1)
sage: s1.to_matrix() == s1.matrix()
True
```

```
>>> from sage.all import *
>>> G = WeylGroup(['A',Integer(2)])
>>> s1 = G.simple_reflection(Integer(1))
>>> s1.to_matrix() == s1.matrix()
True
```

to_permutation()

A first approximation of to_permutation …

This assumes types A,B,C,D on the ambient lattice

This further assume that the basis is indexed by 0,1,… and returns a permutation of (5,4,2,3,1) (beuargl), as a tuple

to_permutation_string()

EXAMPLES:

```
sage: W = WeylGroup(["A",3])
sage: s = W.simple_reflections()
sage: (s[1]*s[2]*s[3]).to_permutation_string()
'2341'
```

```
>>> from sage.all import *
>>> W = WeylGroup(["A",Integer(3)])
>>> s = W.simple_reflections()
>>> (s[Integer(1)]*s[Integer(2)]*s[Integer(3)]).to_permutation_string()
'2341'
```

class sage.combinat.root_system.weyl_group.**WeylGroup_gens**(*domain*, *prefix*)

Bases: `UniqueRepresentation`, `FinitelyGeneratedMatrixGroup_gap`

EXAMPLES:

```
sage: G = WeylGroup(['B',3])
sage: TestSuite(G).run()
sage: cm = CartanMatrix([[2,-5,0],[-2,2,-1],[0,-1,2]])
```

(continues on next page)

(continued from previous page)

```
sage: W = WeylGroup(cm)
sage: TestSuite(W).run() # long time
```

```
>>> from sage.all import *
>>> G = WeylGroup(['B',Integer(3)])
>>> TestSuite(G).run()
>>> cm = CartanMatrix([[Integer(2),-Integer(5),Integer(0)],[-Integer(2),
↪Integer(2),-Integer(1)],[Integer(0),-Integer(1),Integer(2)]])
>>> W = WeylGroup(cm)
>>> TestSuite(W).run() # long time
```

Element

alias of `WeylGroupElement`

cartan_type()

Return the `CartanType` associated to `self`.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.cartan_type()
['F', 4]
```

```
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> G.cartan_type()
['F', 4]
```

character_table()

Return the character table as a matrix.

Each row is an irreducible character. For larger tables you may preface this with a command such as gap.eval("SizeScreen([120,40])") in order to widen the screen.

EXAMPLES:

```
sage: WeylGroup(['A',3]).character_table()
CT1

     2  3  2  2  .  3
     3  1  .  .  1  .

       1a 4a 2a 3a 2b

X.1     1 -1 -1  1  1
X.2     3  1 -1  . -1
X.3     2  .  . -1  2
X.4     3 -1  1  . -1
X.5     1  1  1  1  1
```

```
>>> from sage.all import *
>>> WeylGroup(['A',Integer(3)]).character_table()
CT1
```

(continues on next page)

(continued from previous page)

```
<BLANKLINE>
     2  3  2  2  .  3
     3  1  .  .  1  .
<BLANKLINE>
       1a 4a 2a 3a 2b
<BLANKLINE>
X.1      1 -1 -1  1  1
X.2      3  1 -1  . -1
X.3      2  .  . -1  2
X.4      3 -1  1  . -1
X.5      1  1  1  1  1
```

classical()

If `self` is a Weyl group from an affine Cartan Type, this give the classical parabolic subgroup of `self`.

Caveat: we assume that 0 is a special node of the Dynkin diagram

Todo

extract parabolic subgroup method

EXAMPLES:

```
sage: G = WeylGroup(['A',3,1])
sage: G.classical()
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1]
 (as a matrix group acting on the root space)
sage: WeylGroup(['A',3]).classical()
Traceback (most recent call last):
...
ValueError: classical subgroup only defined for affine types
```

```
>>> from sage.all import *
>>> G = WeylGroup(['A',Integer(3),Integer(1)])
>>> G.classical()
Parabolic Subgroup of the Weyl Group of type ['A', 3, 1]
 (as a matrix group acting on the root space)
>>> WeylGroup(['A',Integer(3)]).classical()
Traceback (most recent call last):
...
ValueError: classical subgroup only defined for affine types
```

domain()

Return the domain of the element of `self`, that is the root lattice realization on which they act.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.domain()
Ambient space of the Root system of type ['F', 4]
sage: G = WeylGroup(['A',3,1])
```

(continues on next page)

(continued from previous page)

```
sage: G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]
```

```
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> G.domain()
Ambient space of the Root system of type ['F', 4]
>>> G = WeylGroup(['A',Integer(3),Integer(1)])
>>> G.domain()
Root space over the Rational Field of the Root system of type ['A', 3, 1]
```

from_morphism(*f*)

index_set()

Return the index set of `self`.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.index_set()
(1, 2, 3, 4)
sage: G = WeylGroup(['A',3,1])
sage: G.index_set()
(0, 1, 2, 3)
```

```
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> G.index_set()
(1, 2, 3, 4)
>>> G = WeylGroup(['A',Integer(3),Integer(1)])
>>> G.index_set()
(0, 1, 2, 3)
```

long_element_hardcoded()

Return the long Weyl group element (hardcoded data).

Do we really want to keep it? There is a generic implementation which works in all cases. The hardcoded should have a better complexity (for large classical types), but there is a cache, so does this really matter?

EXAMPLES:

```
sage: types = [ ['A',5],['B',3],['C',3],['D',4],['G',2],['F',4],['E',6] ]
sage: [WeylGroup(t).long_element().length() for t in types]
[15, 9, 9, 12, 6, 24, 36]
sage: all(WeylGroup(t).long_element() == WeylGroup(t).long_element_
↪hardcoded() for t in types)  # long time (17s on sage.math, 2011)
True
```

```
>>> from sage.all import *
>>> types = [ ['A',Integer(5)],['B',Integer(3)],['C',Integer(3)],['D',
↪Integer(4)],['G',Integer(2)],['F',Integer(4)],['E',Integer(6)] ]
>>> [WeylGroup(t).long_element().length() for t in types]
[15, 9, 9, 12, 6, 24, 36]
```

(continues on next page)

(continued from previous page)

```
>>> all(WeylGroup(t).long_element() == WeylGroup(t).long_element_hardcoded()␣
↪for t in types)   # long time (17s on sage.math, 2011)
True
```

morphism_matrix(*f*)

one()

Return the unit element of the Weyl group.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
>>> type(e) == W.element_class
True
```

reflections()

Return the reflections of `self`.

The reflections of a Coxeter group W are the conjugates of the simple reflections. They are in bijection with the positive roots, for given a positive root, we may have the reflection in the hyperplane orthogonal to it. This method returns a family indexed by the positive roots taking values in the reflections. This requires `self` to be a finite Weyl group.

> **Note**
>
> Prior to Issue #20027, the reflections were the keys of the family and the values were the positive roots.

EXAMPLES:

```
sage: W = WeylGroup("B2", prefix='s')
sage: refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (0, 1): s2, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1}
sage: [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]

sage: W = WeylGroup(['A',2,1], prefix='s')
sage: W.reflections()
```

(continues on next page)

(continued from previous page)

```
Lazy family (real root to reflection(i))_{i in
             Positive real roots of type ['A', 2, 1]}
```

```
>>> from sage.all import *
>>> W = WeylGroup("B2", prefix='s')
>>> refdict = W.reflections(); refdict
Finite family {(1, -1): s1, (0, 1): s2, (1, 1): s2*s1*s2, (1, 0): s1*s2*s1}
>>> [r+refdict[r].action(r) for r in refdict.keys()]
[(0, 0), (0, 0), (0, 0), (0, 0)]

>>> W = WeylGroup(['A',Integer(2),Integer(1)], prefix='s')
>>> W.reflections()
Lazy family (real root to reflection(i))_{i in
             Positive real roots of type ['A', 2, 1]}
```

simple_reflection(*i*)

Return the i-th simple reflection.

EXAMPLES:

```
sage: G = WeylGroup(['F',4])
sage: G.simple_reflection(1)
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]
sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflection(1)
[ 1  0  0]
[ 1 -1  1]
[ 0  0  1]
```

```
>>> from sage.all import *
>>> G = WeylGroup(['F',Integer(4)])
>>> G.simple_reflection(Integer(1))
[1 0 0 0]
[0 0 1 0]
[0 1 0 0]
[0 0 0 1]
>>> W=WeylGroup(['A',Integer(2),Integer(1)])
>>> W.simple_reflection(Integer(1))
[ 1  0  0]
[ 1 -1  1]
[ 0  0  1]
```

simple_reflections()

Return the simple reflections of `self`, as a family.

EXAMPLES:

There are the simple reflections for the symmetric group:

```
sage: W=WeylGroup(['A',2])
sage: s = W.simple_reflections(); s
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1], 2: [1 0 0]
[0 0 1]
[0 1 0]}
```

```
>>> from sage.all import *
>>> W=WeylGroup(['A',Integer(2)])
>>> s = W.simple_reflections(); s
Finite family {1: [0 1 0]
[1 0 0]
[0 0 1], 2: [1 0 0]
[0 0 1]
[0 1 0]}
```

As a special feature, for finite irreducible root systems, s[0] gives the reflection along the highest root:

```
sage: s[0]
[0 0 1]
[0 1 0]
[1 0 0]
```

```
>>> from sage.all import *
>>> s[Integer(0)]
[0 0 1]
[0 1 0]
[1 0 0]
```

We now look at some further examples:

```
sage: W=WeylGroup(['A',2,1])
sage: W.simple_reflections()
Finite family {0: [-1  1  1]
[ 0  1  0]
[ 0  0  1], 1: [ 1  0  0]
[ 1 -1  1]
[ 0  0  1], 2: [ 1  0  0]
[ 0  1  0]
[ 1  1 -1]}
sage: W = WeylGroup(['F',4])
sage: [s1,s2,s3,s4] = W.simple_reflections()
sage: w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
sage: s4^2 == W.one()
True
sage: type(w) == W.element_class
True
```

```
>>> from sage.all import *
>>> W=WeylGroup(['A',Integer(2),Integer(1)])
>>> W.simple_reflections()
Finite family {0: [-1  1  1]
[ 0  1  0]
[ 0  0  1], 1: [ 1  0  0]
[ 1 -1  1]
[ 0  0  1], 2: [ 1  0  0]
[ 0  1  0]
[ 1  1 -1]}
>>> W = WeylGroup(['F',Integer(4)])
>>> [s1,s2,s3,s4] = W.simple_reflections()
>>> w = s1*s2*s3*s4; w
[ 1/2  1/2  1/2  1/2]
[-1/2  1/2  1/2 -1/2]
[ 1/2  1/2 -1/2 -1/2]
[ 1/2 -1/2  1/2 -1/2]
>>> s4**Integer(2) == W.one()
True
>>> type(w) == W.element_class
True
```

unit()

Return the unit element of the Weyl group.

EXAMPLES:

```
sage: W = WeylGroup(['A',3])
sage: e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: type(e) == W.element_class
True
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> e = W.one(); e
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
>>> type(e) == W.element_class
True
```

class sage.combinat.root_system.weyl_group.**WeylGroup_permutation**(*cartan_type*, *prefix*)

Bases: UniqueRepresentation, PermutationGroup_generic

A Weyl group given as a permutation group.

class Element

Bases: RealReflectionGroupElement

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation='permutation')
sage: W.cartan_type()
['A', 4]
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation='permutation')
>>> W.cartan_type()
['A', 4]
```

distinguished_reflections()

Return the reflections of self.

EXAMPLES:

```
sage: W = WeylGroup(['B',2], implementation='permutation')
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
               3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

```
>>> from sage.all import *
>>> W = WeylGroup(['B',Integer(2)], implementation='permutation')
>>> W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
               3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

independent_roots()

Return the simple roots of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation='permutation')
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
               3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation='permutation')
>>> W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
               3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```

index_set()

Return the index set of self.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation='permutation')
sage: W.index_set()
(1, 2, 3, 4)
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation='permutation')
>>> W.index_set()
(1, 2, 3, 4)
```

iteration(*algorithm='breadth'*, *tracking_words=True*)

Return an iterator going through all elements in `self`.

INPUT:

- `algorithm` – (default: `'breadth'`) must be one of the following:
  - `'breadth'` – iterate over in a linear extension of the weak order
  - `'depth'` – iterate by a depth-first-search
- `tracking_words` – boolean (default: `True`); whether or not to keep track of the reduced words and store them in `_reduced_word`

Note

The fastest iteration is the depth first algorithm without tracking words. In particular, `'depth'` is ~1.5x faster.

EXAMPLES:

```
sage: W = WeylGroup(["B",2], implementation='permutation')

sage: for w in W.iteration("breadth",True):
....:     print("%s %s"%(w, w._reduced_word))
() []
(1,3)(2,6)(5,7) [1]
(1,5)(2,4)(6,8) [0]
(1,7,5,3)(2,4,6,8) [0, 1]
(1,3,5,7)(2,8,6,4) [1, 0]
(2,8)(3,7)(4,6) [1, 0, 1]
(1,7)(3,5)(4,8) [0, 1, 0]
(1,5)(2,6)(3,7)(4,8) [0, 1, 0, 1]

sage: for w in W.iteration("depth", False): w
()
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,3,5,7)(2,8,6,4)
(1,7)(3,5)(4,8)
(1,7,5,3)(2,4,6,8)
(2,8)(3,7)(4,6)
(1,5)(2,6)(3,7)(4,8)
```

```
>>> from sage.all import *
>>> W = WeylGroup(["B",Integer(2)], implementation='permutation')

>>> for w in W.iteration("breadth",True):
...     print("%s %s"%(w, w._reduced_word))
```

(continues on next page)

(continued from previous page)

```
() []
(1,3)(2,6)(5,7) [1]
(1,5)(2,4)(6,8) [0]
(1,7,5,3)(2,4,6,8) [0, 1]
(1,3,5,7)(2,8,6,4) [1, 0]
(2,8)(3,7)(4,6) [1, 0, 1]
(1,7)(3,5)(4,8) [0, 1, 0]
(1,5)(2,6)(3,7)(4,8) [0, 1, 0, 1]

>>> for w in W.iteration("depth", False): w
()
(1,3)(2,6)(5,7)
(1,5)(2,4)(6,8)
(1,3,5,7)(2,8,6,4)
(1,7)(3,5)(4,8)
(1,7,5,3)(2,4,6,8)
(2,8)(3,7)(4,6)
(1,5)(2,6)(3,7)(4,8)
```

number_of_reflections()

Return the number of reflections in `self`.

EXAMPLES:

```
sage: W = WeylGroup(['D',4], implementation='permutation')
sage: W.number_of_reflections()
12
```

```
>>> from sage.all import *
>>> W = WeylGroup(['D',Integer(4)], implementation='permutation')
>>> W.number_of_reflections()
12
```

positive_roots()

Return the positive roots of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['C',3], implementation='permutation')
sage: W.positive_roots()
((1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (0, 2, 1),
 (1, 1, 1),
 (2, 2, 1),
 (1, 2, 1))
```

```
>>> from sage.all import *
>>> W = WeylGroup(['C',Integer(3)], implementation='permutation')
```

(continues on next page)

(continued from previous page)

```
>>> W.positive_roots()
((1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (0, 2, 1),
 (1, 1, 1),
 (2, 2, 1),
 (1, 2, 1))
```

rank()

Return the rank of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation='permutation')
sage: W.rank()
4
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation='permutation')
>>> W.rank()
4
```

reflection_index_set()

Return the index set of reflections of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A',3], implementation='permutation')
sage: W.reflection_index_set()
(1, 2, 3, 4, 5, 6)
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)], implementation='permutation')
>>> W.reflection_index_set()
(1, 2, 3, 4, 5, 6)
```

reflections()

Return the reflections of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['B',2], implementation='permutation')
sage: W.distinguished_reflections()
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
               3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

```
>>> from sage.all import *
>>> W = WeylGroup(['B',Integer(2)], implementation='permutation')
>>> W.distinguished_reflections()
```

(continues on next page)

(continued from previous page)

```
Finite family {1: (1,5)(2,4)(6,8), 2: (1,3)(2,6)(5,7),
               3: (2,8)(3,7)(4,6), 4: (1,7)(3,5)(4,8)}
```

roots()

Return the roots of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['G',2], implementation='permutation')
sage: W.roots()
((1, 0),
 (0, 1),
 (1, 1),
 (3, 1),
 (2, 1),
 (3, 2),
 (-1, 0),
 (0, -1),
 (-1, -1),
 (-3, -1),
 (-2, -1),
 (-3, -2))
```

```
>>> from sage.all import *
>>> W = WeylGroup(['G',Integer(2)], implementation='permutation')
>>> W.roots()
((1, 0),
 (0, 1),
 (1, 1),
 (3, 1),
 (2, 1),
 (3, 2),
 (-1, 0),
 (0, -1),
 (-1, -1),
 (-3, -1),
 (-2, -1),
 (-3, -2))
```

simple_reflection(i)

Return the `i`-th simple reflection of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation='permutation')
sage: W.simple_reflection(1)
(1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20)
sage: W.simple_reflections()
Finite family {1: (1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20),
               2: (1,5)(2,12)(3,6)(7,9)(11,15)(13,16)(17,19),
               3: (2,6)(3,13)(4,7)(5,8)(12,16)(14,17)(15,18),
               4: (3,7)(4,14)(6,9)(8,10)(13,17)(16,19)(18,20)}
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation='permutation')
>>> W.simple_reflection(Integer(1))
(1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20)
>>> W.simple_reflections()
Finite family {1: (1,11)(2,5)(6,8)(9,10)(12,15)(16,18)(19,20),
               2: (1,5)(2,12)(3,6)(7,9)(11,15)(13,16)(17,19),
               3: (2,6)(3,13)(4,7)(5,8)(12,16)(14,17)(15,18),
               4: (3,7)(4,14)(6,9)(8,10)(13,17)(16,19)(18,20)}
```

simple_root_index(i)

Return the index of the simple root α_i.

This is the position of α_i in the list of simple roots.

EXAMPLES:

```
sage: W = WeylGroup(['A',3], implementation='permutation')
sage: [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)], implementation='permutation')
>>> [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]
```

simple_roots()

Return the simple roots of `self`.

EXAMPLES:

```
sage: W = WeylGroup(['A',4], implementation='permutation')
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
               3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```

```
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)], implementation='permutation')
>>> W.simple_roots()
Finite family {1: (1, 0, 0, 0), 2: (0, 1, 0, 0),
               3: (0, 0, 1, 0), 4: (0, 0, 0, 1)}
```

5.1.274 Rooted (Unordered) Trees

AUTHORS:

- Florent Hivert (2011): initial version

class sage.combinat.rooted_tree.**LabelledRootedTree**(*parent*, *children*, *label=None*, *check=True*)

Bases: *AbstractLabelledClonableTree*, *RootedTree*

Labelled rooted trees.

A labelled rooted tree is a rooted tree with a label attached at each node.

More formally: The *labelled rooted trees* are an inductive datatype defined as follows: A labelled rooted tree is a multiset of labelled rooted trees, endowed with a label (which can be any object, including `None`). The trees that belong to this multiset are said to be the *children* of the tree. (Notice that the labels of these children may and may not be of the same type as the label of the tree). A labelled rooted tree which has no children (so the only information it carries is its label) is said to be a *leaf*.

Every labelled rooted tree gives rise to an unlabelled rooted tree (`RootedTree`) by forgetting the labels. (This is implemented as a conversion.)

INPUT:

- `children` – list or tuple or more generally any iterable of trees or objects convertible to trees
- `label` – any hashable Sage object (default: `None`)

> **Note**
>
> It is required that all labels are comparable.

EXAMPLES:

```
sage: x = LabelledRootedTree([], label = 3); x
3[]
sage: LabelledRootedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]
sage: LabelledRootedTree([[],[[], []]], label = 3)
3[None[], None[None[], None[]]]
```

```
>>> from sage.all import *
>>> x = LabelledRootedTree([], label = Integer(3)); x
3[]
>>> LabelledRootedTree([x, x, x], label = Integer(2))
2[3[], 3[], 3[]]
>>> LabelledRootedTree((x, x, x), label = Integer(2))
2[3[], 3[], 3[]]
>>> LabelledRootedTree([[],[[], []]], label = Integer(3))
3[None[], None[None[], None[]]]
```

Children are reordered using the value of the `sort_key()` method:

```
sage: y = LabelledRootedTree([], label = 5); y
5[]
sage: xyy2 = LabelledRootedTree((x, y, y), label = 2); xyy2
2[3[], 5[], 5[]]
sage: yxy2 = LabelledRootedTree((y, x, y), label = 2); yxy2
2[3[], 5[], 5[]]
sage: xyy2 == yxy2
True
```

```
>>> from sage.all import *
>>> y = LabelledRootedTree([], label = Integer(5)); y
5[]
```

(continues on next page)

(continued from previous page)

```
>>> xyy2 = LabelledRootedTree((x, y, y), label = Integer(2)); xyy2
2[3[], 5[], 5[]]
>>> yxy2 = LabelledRootedTree((y, x, y), label = Integer(2)); yxy2
2[3[], 5[], 5[]]
>>> xyy2 == yxy2
True
```

Converting labelled into unlabelled rooted trees by forgetting the labels, and back (the labels are initialized as `None`):

```
sage: yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
sage: LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

```
>>> from sage.all import *
>>> yxy2crude = RootedTree(yxy2); yxy2crude
[[], [], []]
>>> LabelledRootedTree(yxy2crude)
None[None[], None[], None[]]
```

sort_key()

Return a tuple of nonnegative integers encoding the labelled rooted tree `self`.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the labelled rooted tree uniquely, and can be used to sort the labelled rooted trees provided that the labels belong to a type which is totally ordered.

Note

The tree `self` must be normalized before calling this method (see `normalize()`). This does not matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note

This method overrides *RootedTree.sort_key()* and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of `RootedOrderedTree`; under some circumstances they could inherit it from another superclass instead of from *RootedTree*, which would cause the method to forget the labelling. See the docstrings of *RootedTree.sort_key()* and *sage.combinat.ordered_tree.OrderedTree.sort_key()*.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
```

(continues on next page)

(continued from previous page)

```
sage: x = LRT([], label = 3); x
3[]
sage: x.sort_key()
((0, 3),)
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
sage: LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
sage: lb = RootedTrees()([[],[[], []]]).canonical_labelling()
sage: lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

```
>>> from sage.all import *
>>> LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
>>> x = LRT([], label = Integer(3)); x
3[]
>>> x.sort_key()
((0, 3),)
>>> y = LRT([x, x, x], label = Integer(2)); y
2[3[], 3[], 3[]]
>>> y.sort_key()
((3, 2), (0, 3), (0, 3), (0, 3))
>>> LRT.an_element().sort_key()
((3, 'alpha'), (0, 3), (1, 5), (0, None), (2, 42), (0, 3), (0, 3))
>>> lb = RootedTrees()([[],[[], []]]).canonical_labelling()
>>> lb.sort_key()
((2, 1), (0, 2), (2, 3), (0, 4), (0, 5))
```

class sage.combinat.rooted_tree.**LabelledRootedTrees**

Bases: UniqueRepresentation, Parent

This is a parent stub to serve as a factory class for labelled rooted trees.

EXAMPLES:

```
sage: LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
sage: x = LRT([], label = 3); x
3[]
sage: x.parent() is LRT
True
sage: y = LRT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
sage: y.parent() is LRT
True
```

```
>>> from sage.all import *
>>> LRT = LabelledRootedTrees(); LRT
Labelled rooted trees
```

(continues on next page)

(continued from previous page)

```
>>> x = LRT([], label = Integer(3)); x
3[]
>>> x.parent() is LRT
True
>>> y = LRT([x, x, x], label = Integer(2)); y
2[3[], 3[], 3[]]
>>> y.parent() is LRT
True
```

Todo

Add the possibility to restrict the labels to a fixed set.

class sage.combinat.rooted_tree.**LabelledRootedTrees_all**(*category=None*)

Bases: *LabelledRootedTrees*

Class of all (unordered) labelled rooted trees.

See *LabelledRootedTree* for a definition.

Element

alias of *LabelledRootedTree*

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: LabelledRootedTrees().labelled_trees()
Labelled rooted trees
```

```
>>> from sage.all import *
>>> LabelledRootedTrees().labelled_trees()
Labelled rooted trees
```

unlabelled_trees()

Return the set of unlabelled trees associated to self.

EXAMPLES:

```
sage: LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

```
>>> from sage.all import *
>>> LabelledRootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.**RootedTree**(*parent=None*, *children=[]*, *check=True*)

Bases: *AbstractClonableTree*, NormalizedClonableList

The class for unordered rooted trees.

The *unordered rooted trees* are an inductive datatype defined as follows: An unordered rooted tree is a multiset of unordered rooted trees. The trees that belong to this multiset are said to be the *children* of the tree. The tree that has no children is called a *leaf*.

The *labelled rooted trees* (`LabelledRootedTree`) form a subclass of this class; they carry additional data.

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree.

EXAMPLES:

```
sage: RootedTree([])
[]
sage: RootedTree([[], [[]]])
[[], [[]]]
sage: RootedTree([[[]], []])
[[], [[]]]
sage: O = OrderedTree([[[]], []]); O
[[[]], []]
sage: RootedTree(O)  # this is O with the ordering forgotten
[[], [[]]]
```

```
>>> from sage.all import *
>>> RootedTree([])
[]
>>> RootedTree([[], [[]]])
[[], [[]]]
>>> RootedTree([[[]], []])
[[], [[]]]
>>> O = OrderedTree([[[]], []]); O
[[[]], []]
>>> RootedTree(O)  # this is O with the ordering forgotten
[[], [[]]]
```

One can also enter any small rooted tree ("small" meaning that no vertex has more than 15 children) by using a simple numerical encoding of rooted trees, namely, the `from_hexacode()` function. (This function actually parametrizes ordered trees, and here we make it parametrize unordered trees by forgetting the ordering.)

```
sage: from sage.combinat.abstract_tree import from_hexacode
sage: RT = RootedTrees()
sage: from_hexacode('32001010', RT)
[[[]], [[]], [[], []]]
```

```
>>> from sage.all import *
>>> from sage.combinat.abstract_tree import from_hexacode
>>> RT = RootedTrees()
>>> from_hexacode('32001010', RT)
[[[]], [[]], [[], []]]
```

Note

Unlike an ordered tree, an (unordered) rooted tree is a multiset (rather than a list) of children. That is, two ordered trees which differ from each other by switching the order of children are equal to each other as (unordered) rooted trees. Internally, rooted trees are encoded as `sage.structure.list_clone.NormalizedClonableList` instances, and instead of storing their children as an actual multiset, they store their children as a list which is sorted according to their `sort_key()` value. This is as good as storing them as multisets, since the `sort_key()` values are sortable and distinguish different (unordered) trees. However, if you wish to define a subclass of `RootedTree` which implements rooted trees with extra structure (say, a class of edge-colored rooted trees, or a class of rooted trees with a cyclic order on the list of children), then the inherited `sort_key()` method will no longer distinguish different trees (and, as a consequence, equal trees will be regarded as distinct). Thus, you will have to override the method by one that does distinguish different trees.

graft_list(*other*)

Return the list of trees obtained by grafting `other` on `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, chooses a node of `self`, and adds the root of `other` to the list of children of this node. The root of the resulting tree is the root of `self`. (This can be done for each node of `self`; this method returns the list of all results.)

This is useful for free pre-Lie algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_list(x)
[[[]]]
sage: l = y.graft_list(x); l
[[[], [], []], [[], [[]]], [[], [[]]]]
sage: [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> x = RT([])
>>> y = RT([x, x])
>>> x.graft_list(x)
[[[]]]
>>> l = y.graft_list(x); l
[[[], [], []], [[], [[]]], [[], [[]]]]
>>> [parent(i) for i in l]
[Rooted trees, Rooted trees, Rooted trees]
```

graft_on_root(*other*)

Return the tree obtained by grafting `other` on the root of `self`.

Here grafting means that one takes the disjoint union of `self` and `other`, and adds the root of `other` to the list of children of `self`. The root of the resulting tree is the root of `self`.

This is useful for free Nap algebras.

EXAMPLES:

```
sage: RT = RootedTree
sage: x = RT([])
sage: y = RT([x, x])
sage: x.graft_on_root(x)
[[]]
```

(continues on next page)

(continued from previous page)

```
sage: y.graft_on_root(x)
[[], [], []]
sage: x.graft_on_root(y)
[[[], []]]
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> x = RT([])
>>> y = RT([x, x])
>>> x.graft_on_root(x)
[[]]
>>> y.graft_on_root(x)
[[], [], []]
>>> x.graft_on_root(y)
[[[], []]]
```

is_empty()

Return if `self` is the empty tree.

For rooted trees, this always returns `False`.

Note

This is not the same as `bool(t)`, which returns whether `t` has some child or not.

EXAMPLES:

```
sage: t = RootedTrees(4)([[],[[]]])
sage: t.is_empty()
False
sage: bool(t)
True
sage: t = RootedTrees(1)([])
sage: t.is_empty()
False
sage: bool(t)
False
```

```
>>> from sage.all import *
>>> t = RootedTrees(Integer(4))([[],[[]]])
>>> t.is_empty()
False
>>> bool(t)
True
>>> t = RootedTrees(Integer(1))([])
>>> t.is_empty()
False
>>> bool(t)
False
```

normalize()

Normalize `self`.

This function is at the core of the implementation of rooted (unordered) trees. The underlying structure is provided by ordered rooted trees. Every rooted tree is represented by a normalized element in the set of its planar embeddings.

There should be no need to call `normalize` directly as it is called automatically upon creation and cloning or modification (by `NormalizedClonableList`).

The normalization has a recursive definition. It means first that every sub-tree is itself normalized, and also that sub-trees are sorted. Here the sort is performed according to the values of the `sort_key()` method.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[],[[]]]) == RT([[[]],[]])  # indirect doctest
True
sage: rt1 = RT([[],[[]]])
sage: rt2 = RT([[[]],[]])
sage: rt1 is rt2
False
sage: rt1 == rt2
True
sage: rt1._get_list() == rt2._get_list()
True
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> RT([[],[[]]]) == RT([[[]],[]])  # indirect doctest
True
>>> rt1 = RT([[],[[]]])
>>> rt2 = RT([[[]],[]])
>>> rt1 is rt2
False
>>> rt1 == rt2
True
>>> rt1._get_list() == rt2._get_list()
True
```

single_graft(*x*, *grafting_function*, *path_prefix=()*)

Graft subtrees of x on `self` using the given function.

Let $x_1, x_2, \ldots, x_p$ be the children of the root of x. For each i, the subtree of x comprising all descendants of x_i is joined by a new edge to the vertex of `self` specified by the i-th path in the grafting function (i.e., by the path `grafting_function[i]`).

The number of vertices of the result is the sum of the numbers of vertices of `self` and x minus one, because the root of x is not used.

This is used to define the product of the Grossman-Larson algebras.

INPUT:

- `x` – a rooted tree
- `grafting_function` – list of paths in `self`
- `path_prefix` – tuple (default: `()`)

The `path_prefix` argument is only used for internal recursion.

EXAMPLES:

```
sage: LT = LabelledRootedTrees()
sage: y = LT([LT([],label='b')], label='a')
sage: x = LT([LT([],label='d')], label='c')
sage: y.single_graft(x,[(0,)])
a[b[d[]]]
sage: t = LT([LT([],label='b'),LT([],label='c')], label='a')
sage: s = LT([LT([],label='d'),LT([],label='e')], label='f')
sage: t.single_graft(s,[(0,),(1,)])
a[b[d[]], c[e[]]]
```

```
>>> from sage.all import *
>>> LT = LabelledRootedTrees()
>>> y = LT([LT([],label='b')], label='a')
>>> x = LT([LT([],label='d')], label='c')
>>> y.single_graft(x,[(Integer(0),)])
a[b[d[]]]
>>> t = LT([LT([],label='b'),LT([],label='c')], label='a')
>>> s = LT([LT([],label='d'),LT([],label='e')], label='f')
>>> t.single_graft(s,[(Integer(0),),(Integer(1),)])
a[b[d[]], c[e[]]]
```

sort_key()

Return a tuple of nonnegative integers encoding the rooted tree `self`.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is obtained as follows: List the tuples corresponding to all children (we are regarding the children themselves as trees). Order this list (not the tuples!) in lexicographically increasing order, and flatten it into a single tuple.

This tuple characterizes the rooted tree uniquely, and can be used to sort the rooted trees.

Note

The tree `self` must be normalized before calling this method (see *normalize()*). This does not matter unless you are inside the `clone()` context manager, because outside of it every rooted tree is already normalized.

Note

By default, this method does not encode any extra structure that `self` might have. If you have a subclass inheriting from *RootedTree* which allows for some extra structure, you need to override *sort_key()* in order to preserve this structure (for example, the *LabelledRootedTree* class does this in *LabelledRootedTree.sort_key()*). See the note in the docstring of *sage.combinat.ordered_tree.OrderedTree.sort_key()* for a pitfall.

EXAMPLES:

```
sage: RT = RootedTree
sage: RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[]]).sort_key()
(2, 0, 1, 0)
```

```
>>> from sage.all import *
>>> RT = RootedTree
>>> RT([[],[[]]]).sort_key()
(2, 0, 1, 0)
>>> RT([[[]],[]]).sort_key()
(2, 0, 1, 0)
```

class sage.combinat.rooted_tree.**RootedTrees**

Bases: UniqueRepresentation, Parent

Factory class for rooted trees.

INPUT:

- size – integer (optional)

OUTPUT:

the set of all rooted trees (of the given size size if specified)

EXAMPLES:

```
sage: RootedTrees()
Rooted trees

sage: RootedTrees(2)
Rooted trees with 2 nodes
```

```
>>> from sage.all import *
>>> RootedTrees()
Rooted trees

>>> RootedTrees(Integer(2))
Rooted trees with 2 nodes
```

class sage.combinat.rooted_tree.**RootedTrees_all**

Bases: DisjointUnionEnumeratedSets, *RootedTrees*

Class of all (unordered, unlabelled) rooted trees.

See *RootedTree* for a definition.

Element

alias of *RootedTree*

labelled_trees()

Return the set of labelled trees associated to self.

EXAMPLES:

```
sage: RootedTrees().labelled_trees()
Labelled rooted trees
```

```
>>> from sage.all import *
>>> RootedTrees().labelled_trees()
Labelled rooted trees
```

As a consequence:

```
sage: lb = RootedTrees()([[],[[], []]]).canonical_labelling()
sage: lb
1[2[], 3[4[], 5[]]]
sage: lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.
↪element_class'>
sage: lb.parent()
Labelled rooted trees
```

```
>>> from sage.all import *
>>> lb = RootedTrees()([[],[[], []]]).canonical_labelling()
>>> lb
1[2[], 3[4[], 5[]]]
>>> lb.__class__
<class 'sage.combinat.rooted_tree.LabelledRootedTrees_all_with_category.
↪element_class'>
>>> lb.parent()
Labelled rooted trees
```

leaf()

Return a leaf tree with `self` as parent.

EXAMPLES:

```
sage: RootedTrees().leaf()
[]
```

```
>>> from sage.all import *
>>> RootedTrees().leaf()
[]
```

unlabelled_trees()

Return the set of unlabelled trees associated to `self`.

EXAMPLES:

```
sage: RootedTrees().unlabelled_trees()
Rooted trees
```

```
>>> from sage.all import *
>>> RootedTrees().unlabelled_trees()
Rooted trees
```

class sage.combinat.rooted_tree.**RootedTrees_size**(n)

Bases: *RootedTrees*

The enumerated set of rooted trees with a given number of nodes.

The number of nodes of a rooted tree is defined recursively: The number of nodes of a rooted tree with a children is a plus the sum of the number of nodes of each of these children.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: RootedTrees(1).cardinality()
1
sage: RootedTrees(3).cardinality()
2
```

```
>>> from sage.all import *
>>> RootedTrees(Integer(1)).cardinality()
1
>>> RootedTrees(Integer(3)).cardinality()
2
```

check_element(*el*, *check=True*)

Check that a given tree actually belongs to `self`.

This just checks the number of vertices.

EXAMPLES:

```
sage: RT3 = RootedTrees(3)
sage: RT3([[],[]])     # indirect doctest
[[], []]
sage: RT3([[],[],[]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: wrong number of nodes
```

```
>>> from sage.all import *
>>> RT3 = RootedTrees(Integer(3))

element_class()

sage.combinat.rooted_tree.**number_of_rooted_trees**()

Return the number of rooted trees with n nodes.

Compute the number $a(n)$ of rooted trees with n nodes using the recursive formula ([SL000081]):

$$a(n+1) = \frac{1}{n}\sum_{k=1}^{n}\left(\sum_{d|k} da(d)\right) a(n-k+1)$$

EXAMPLES:

```
sage: from sage.combinat.rooted_tree import number_of_rooted_trees
sage: [number_of_rooted_trees(i) for i in range(10)]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

```
>>> from sage.all import *
>>> from sage.combinat.rooted_tree import number_of_rooted_trees
```

(continues on next page)

(continued from previous page)

```
>>> [number_of_rooted_trees(i) for i in range(Integer(10))]
[0, 1, 1, 2, 4, 9, 20, 48, 115, 286]
```

Introduction

The Robinson-Schensted-Knuth (RSK) correspondence is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape.

The basic operation in the RSK correspondence is a row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Different insertion algorithms have been implemented for the RSK correspondence and can be specified as an argument in the function call.

EXAMPLES:

We can perform RSK and its inverse map on a variety of objects:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK(*gp) # RSK of a biword
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
sage: RSK([2,3,2,1,2,3]) # Robinson-Schensted of a word
[[[1, 2, 2, 3], [2], [3]], [[1, 2, 5, 6], [3], [4]]]
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG) # Edelman-Greene
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
sage: m = RSK_inverse(p, q, 'matrix'); m # output as matrix
[0 1]
[1 0]
[0 2]
sage: RSK(m) # RSK of a matrix
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> gp = RSK_inverse(p, q); gp
[[1, 2, 3, 3], [2, 1, 2, 2]]
>>> RSK(*gp) # RSK of a biword
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
>>> RSK([Integer(2),Integer(3),Integer(2),Integer(1),Integer(2),Integer(3)]) #␣
↪Robinson-Schensted of a word
```

(continues on next page)

(continued from previous page)

```
[[[1, 2, 2, 3], [2], [3]], [[1, 2, 5, 6], [3], [4]]]
>>> RSK([Integer(2),Integer(3),Integer(2),Integer(1),Integer(2),Integer(3)],␣
↪insertion=RSK.rules.EG) # Edelman-Greene
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
>>> m = RSK_inverse(p, q, 'matrix'); m # output as matrix
[0 1]
[1 0]
[0 2]
>>> RSK(m) # RSK of a matrix
[[[1, 2, 2], [2]], [[1, 3, 3], [2]]]
```

Insertions currently available

The following insertion algorithms for RSK correspondence are currently available:

- RSK insertion (*RuleRSK*).
- Edelman-Greene insertion (*RuleEG*), an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion).
- Hecke RSK algorithm (*RuleHecke*) , defined using the Hecke insertion studied in [BKSTY06] (but using rows instead of columns).
- Dual RSK insertion (*RuleDualRSK*).
- CoRSK insertion (*RuleCoRSK*), defined in [GR2018v5sol].
- Super RSK insertion (*RuleSuperRSK*), a combination of row and column insertions defined in [Muth2019].
- Star insertion (*RuleStar*), defined in [MPPS2020].

Implementing your own insertion rule

The functions *RSK()* and *RSK_inverse()* are written so that it is easy to implement insertion algorithms you come across in your research.

To implement your own insertion algorithm, you first need to import the base class for a rule:

```
sage: from sage.combinat.rsk import Rule
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import Rule
```

Using the `Rule` class as parent class for your insertion rule, first implement the insertion and the reverse insertion algorithm for *RSK()* and *RSK_inverse()* respectively (as methods `forward_rule` and `backward_rule`). If your insertion algorithm uses the same forward and backward rules as `RuleRSK`, differing only in how an entry is inserted into a row, then this is not necessary, and it suffices to merely implement the `insertion` and `reverse_insertion` methods.

For more information, see *Rule*.

sage.combinat.rsk.**RSK**(*obj1=None*, *obj2=None*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*, *check_standard=False*, ***options*)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, ...) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i-th step inserts the number k_i into the i-th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i-th row, then k_i is simply appended to the row and the algorithm terminates at this point.

A *generalized permutation* (or *biword*) is a list $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ of pairs such that the letters $j_0, j_1, \ldots, j_{\ell-1}$ are weakly increasing (that is, $j_0 \leq j_1 \leq \cdots \leq j_{\ell-1}$), whereas the letters k_i satisfy $k_i \leq k_{i+1}$ whenever $j_i = j_{i+1}$. The ℓ-tuple $(j_0, j_1, \ldots, j_{\ell-1})$ is called the *top line* of this generalized permutation, whereas the ℓ-tuple $(k_0, k_1, \ldots, k_{\ell-1})$ is called its *bottom line*.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p, and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as "Construction A".

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \ldots, n)$ where n is the length of w.

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- `obj1`, `obj2` – can be one of the following:
  - a word in an ordered alphabet (in this case, `obj1` is said word, and `obj2` is `None`)
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \ldots, j_{\ell-1})$ and $(k_0, k_1, \ldots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$)
  - any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, `obj1` is said object, and `obj2` is `None`).
- `insertion` – (default: `RSK.rules.RSK`) the following types of insertion are currently supported:
  - `RSK.rules.RSK` (or `'RSK'`) – Robinson-Schensted-Knuth insertion (*RuleRSK*)
  - `RSK.rules.EG` (or `'EG'`) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
  - `RSK.rules.Hecke` – (or `'hecke'`) Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
  - `RSK.rules.dualRSK` (or `'dualRSK'`) – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
  - `RSK.rules.coRSK` (or `'coRSK'`) – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
  - `RSK.rules.superRSK` (or `'super'`) – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
  - `RSK.rules.Star` (or `'Star'`) – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular *Rule* class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1, 2, \ldots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(1), Integer(2)])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
>>> RSK(Word([Integer(1),Integer(1),Integer(3),Integer(4),Integer(4)]),␣
↪[Integer(1),Integer(4),Integer(2),Integer(1),Integer(3)])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
>>> RSK([Integer(1),Integer(3),Integer(3),Integer(4),Integer(4)],␣
↪Word([Integer(6),Integer(2),Integer(2),Integer(1),Integer(7)]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(2),Integer(1)]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(2),Integer(1)]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(1), Integer(2)]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(1), Integer(2)])
```

(continues on next page)

(continued from previous page)

```
>>> RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

sage.combinat.rsk.**RSK_inverse**(*p*, *q*, *output='array'*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*)

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see *RSK()*.

INPUT:

- p, q – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)
- output – (default: 'array') if q is semi-standard:
  - 'array' – as a two-line array (i.e. generalized permutation or biword)
  - 'matrix' – as an integer matrix

  and if q is standard, we can also have the output:
  - 'word' – as a word

  and additionally if p is standard, we can also have the output:
  - 'permutation' – as a permutation
- insertion – (default: RSK.rules.RSK) the insertion algorithm used in the bijection. Currently the following are supported:
  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (*RuleRSK*)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
  - RSK.rules.Hecke (or 'hecke') – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
  - RSK.rules.Star (or 'Star') – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)

For precise information about constraints on the input and output, see the particular *Rule* class.

Note

In the case of Hecke insertion, the input variable q should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both p and q are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
↪[Integer(5)]])
>>> RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word')
word: 14532
>>> RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(3)]]); q =␣
↪Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
>>> RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
>>> RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

```
>>> from sage.all import *
>>> w = [Integer(5), Integer(4), Integer(3), Integer(1), Integer(4), Integer(2),␣
↪Integer(5), Integer(5)]
>>> pq = RSK(w, insertion=RSK.rules.Hecke)
>>> RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

Note

The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

class `sage.combinat.rsk.`**`Rule`**

Bases: `UniqueRepresentation`

Generic base class for an insertion rule for an RSK-type correspondence.

An instance of this class should implement a method `insertion()` (which can be applied to a letter `j` and a list `r`, and modifies `r` in place by "bumping" `j` into it appropriately; it then returns the bumped-out entry or `None` if no such entry exists) and a method `reverse_insertion()` (which does the same but for reverse bumping). It may also implement `_backward_format_output()` and `_forward_format_output()` if the RSK correspondence should return something other than (semi)standard tableaux (in the forward direction) and matrices or biwords (in the backward direction). The `to_pairs()` method should also be overridden if the input for the (forward) RSK correspondence is not the usual kind of biwords (i.e., pairs of two n-tuples $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ satisfying $(a_1, b_1) \leq (a_2, b_2) \leq \cdots \leq (a_n, b_n)$ in lexicographic order). Finally, it `forward_rule()` and `backward_rule()` have to be overridden if the overall structure of the RSK correspondence differs from that of classical RSK (see, e.g., the case of Hecke insertion, in which a letter bumped into a row may change a different row).

backward_rule(*p*, *q*, *output*)

Return the generalized permutation obtained by applying reverse insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)
  - `'matrix'` – as an integer matrix

  and if `q` is standard, we can also have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: t1 = Tableau([[1, 3, 4], [2], [3]])
sage: t2 = Tableau([[1, 2, 4], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 1, 1, 3, 7]])
sage: t2 = Tableau([[1, 2, 3, 4, 5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]
sage: t1 = Tableau([[1, 3], [3], [6], [7]])
sage: t2 = Tableau([[1, 4], [2], [3], [5]])
sage: RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> t1 = Tableau([[Integer(1), Integer(3), Integer(4)], [Integer(2)],
↪[Integer(3)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(4)], [Integer(3)],
↪[Integer(5)]])
>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
```

(continues on next page)

(continued from previous page)

```
>>> t1 = Tableau([[Integer(1), Integer(1), Integer(1), Integer(3),␣
↪Integer(7)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3), Integer(4),␣
↪Integer(5)]])
>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [1, 1, 1, 3, 7]]
>>> t1 = Tableau([[Integer(1), Integer(3)], [Integer(3)], [Integer(6)],␣
↪[Integer(7)]])
>>> t2 = Tableau([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)],␣
↪[Integer(5)]])
>>> RuleRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [7, 6, 3, 3, 1]]
```

forward_rule(*obj1*, *obj2*, *check_standard=False*, *check=True*)

Return a pair of tableaux obtained by applying forward insertion to the generalized permutation `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword
  - a matrix `obj1` of nonnegative integers, to be interpreted as the generalized permutation in matrix form (in this case, `obj2` is `None`)
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default)
  - any object `obj1` which has a method `_rsk_iter()`, as long as this method returns an iterator yielding pairs of numbers, which then are interperted as top entries and bottom entries in the biword (in this case, `obj2` is `None`)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: RuleRSK().forward_rule([3,3,2,4,1], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RuleRSK().forward_rule([1, 1, 1, 3, 7], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
sage: RuleRSK().forward_rule([7, 6, 3, 3, 1], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> RuleRSK().forward_rule([Integer(3),Integer(3),Integer(2),Integer(4),
↪Integer(1)], None)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RuleRSK().forward_rule([Integer(1), Integer(1), Integer(1), Integer(3),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(7)], None)
[[[1, 1, 1, 3, 7]], [[1, 2, 3, 4, 5]]]
>>> RuleRSK().forward_rule([Integer(7), Integer(6), Integer(3), Integer(3),␣
↪Integer(1)], None)
[[[1, 3], [3], [6], [7]], [[1, 4], [2], [3], [5]]]
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the RSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a biword (i.e., satisfying $a_1 \leq a_2 \leq \cdots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i \leq b_{i+1}$), or a matrix ("generalized permutation"), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a biword (see the doc of *forward_rule()* for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid biword

EXAMPLES:

```
sage: from sage.combinat.rsk import Rule
sage: list(Rule().to_pairs([1, 2, 2, 2], [2, 1, 1, 2]))
[(1, 2), (2, 1), (2, 1), (2, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import Rule
>>> list(Rule().to_pairs([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(1), Integer(2)]))
[(1, 2), (2, 1), (2, 1), (2, 2)]
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
↪Integer(0),Integer(0),Integer(2)]) ; m
[0 1]
[1 0]
[0 2]
>>> list(Rule().to_pairs(m))
[(1, 2), (2, 1), (3, 2), (3, 2)]
```

class sage.combinat.rsk.**RuleCoRSK**

Bases: *RuleRSK*

Rule for coRSK insertion.

CoRSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer a biword, but rather a strict cobiword – i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that satisfy the strict inequalities $(a_1, b_1) \widetilde{<} (a_2, b_2) \widetilde{<} \cdots \widetilde{<} (a_n, b_n)$, where the binary relation $\widetilde{<}$ on pairs of integers is defined by having $(u_1, v_1) \widetilde{<} (u_2, v_2)$ if and only if either $u_1 < u_2$ or ($u_1 = u_2$ and $v_1 > v_2$). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a $\{0, 1\}$-matrix (i.e., a matrix whose entries are 0's and 1's).

- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now Q is row-strict (i.e., its transpose is semistandard) while P is semistandard.

Bumping proceeds in the same way as for RSK insertion.

The RSK and coRSK algorithms agree for permutation matrices.

For more information, see Section A.4 in [Ful1997] (specifically, construction (1d)) or the second solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

```
sage: RSK([1,2,5,3,1], insertion = RSK.rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion = RSK.rules.coRSK)
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
sage: RSK(Word([3,3,2,4,1]), insertion = RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: from sage.combinat.rsk import to_matrix
sage: RSK(to_matrix([1, 1, 3, 3, 4], [3, 2, 2, 1, 3]), insertion = RSK.rules.
↪coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1),Integer(2),Integer(5),Integer(3),Integer(1)], insertion = RSK.
↪rules.coRSK)
[[[1, 1, 3], [2], [5]], [[1, 2, 3], [4], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]), insertion = RSK.rules.coRSK)
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]), insertion␣
↪= RSK.rules.coRSK)
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> from sage.combinat.rsk import to_matrix
>>> RSK(to_matrix([Integer(1), Integer(1), Integer(3), Integer(3), Integer(4)],␣
↪[Integer(3), Integer(2), Integer(2), Integer(1), Integer(3)]), insertion = RSK.
↪rules.coRSK)
[[[1, 2, 3], [2], [3]], [[1, 3, 4], [1], [3]]]
```

Using coRSK insertion with a $\{0, 1\}$-matrix:

```
sage: RSK(matrix([[0,1],[1,0]]), insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(1),Integer(0)]]), insertion =␣
↪RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[1,0]], insertion = RSK.rules.coRSK)
[[[1], [2]], [[1], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(1),Integer(0)]], insertion = RSK.rules.
↪coRSK)
[[[1], [2]], [[1], [2]]]
```

We can also use the inverse correspondence:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 3, 2, 1],
....:          insertion=RSK.rules.coRSK),insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 3, 2, 1],insertion=RSK.rules.coRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],
↪[Integer(2), Integer(3), Integer(2), Integer(1)],
...          insertion=RSK.rules.coRSK),insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),
↪Integer(3), Integer(2), Integer(1)],insertion=RSK.rules.coRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.coRSK)
[[1, 2, 2, 2], [2, 3, 2, 1]]
```

When applied to two standard tableaux, backwards coRSK insertion behaves identically to the usual backwards RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.coRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.coRSK)
word: 14532
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.coRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],
↪[Integer(5)]])
```

(continues on next page)

(continued from previous page)

```
>>> RSK_inverse(t1, t2, insertion=RSK.rules.coRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word', insertion=RSK.rules.coRSK)
word: 14532
>>> RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.coRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.coRSK)
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.coRSK)
[1, 5, 4, 2, 3]
```

For coRSK, the first tableau is semistandard while the second tableau is transpose semistandard:

```
sage: p = Tableau([[1,2,2],[5]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.coRSK); ret
[[1, 2, 3, 4], [1, 5, 2, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.coRSK)
word: 1522
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(5)]]); q =␣
↪Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q, insertion=RSK.rules.coRSK); ret
[[1, 2, 3, 4], [1, 5, 2, 2]]
>>> RSK_inverse(p, q, 'word', insertion=RSK.rules.coRSK)
word: 1522
```

backward_rule(*p*, *q*, *output*)

Return the strict cobiword obtained by applying reverse coRSK insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is row-strict:
  - `'array'` – as a two-line array (i.e. strict cobiword)
  - `'matrix'` – as a $\{0, 1\}$-matrix

  and if `q` is standard, we can have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleCoRSK
sage: t1 = Tableau([[1, 1, 2], [2, 3], [4]])
sage: t2 = Tableau([[1, 4, 5], [1, 4], [2]])
sage: RuleCoRSK().backward_rule(t1, t2, 'array')
[[1, 1, 2, 4, 4, 5], [4, 2, 1, 3, 1, 2]]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleCoRSK
>>> t1 = Tableau([[Integer(1), Integer(1), Integer(2)], [Integer(2),␣
↪Integer(3)], [Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(4), Integer(5)], [Integer(1),␣
↪Integer(4)], [Integer(2)]])
>>> RuleCoRSK().backward_rule(t1, t2, 'array')
[[1, 1, 2, 4, 4, 5], [4, 2, 1, 3, 1, 2]]
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the coRSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a strict cobiword (i.e., satisfying $a_1 \leq a_2 \leq \cdots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i > b_{i+1}$), or a $\{0, 1\}$-matrix ("rook placement"), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a strict cobiword (see the doc of `forward_rule()` for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid strict cobiword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleCoRSK
sage: list(RuleCoRSK().to_pairs([1, 2, 2, 2], [2, 3, 2, 1]))
[(1, 2), (2, 3), (2, 2), (2, 1)]
sage: RuleCoRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):

```

class sage.combinat.rsk.**RuleDualRSK**

Bases: *Rule*

Rule for dual RSK insertion.

Dual RSK insertion differs from classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a strict biword (i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that satisfy the strict inequalities $(a_1, b_1) < (a_2, b_2) < \cdots < (a_n, b_n)$ in lexicographic order). In terms of matrices, this means that the input is not an arbitrary matrix with nonnegative integer entries, but rather a $\{0, 1\}$-matrix (i.e., a matrix whose entries are 0's and 1's).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now P is row-strict (i.e., its transpose is semistandard) while Q is semistandard.
- The main difference is in the way bumping works. Namely, when a number k_i is inserted into the i-th row of P, it bumps out the first integer greater **or equal to** k_i in this row (rather than greater than k_i).

The RSK and dual RSK algorithms agree for permutation matrices.

For more information, see Chapter 7, Section 14 in [Sta-EC2] (where dual RSK is called RSK*) or the third solution to Exercise 2.7.12(a) in [GR2018v5sol].

EXAMPLES:

```
sage: RSK([3,3,2,4,1], insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]), insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
```

(continues on next page)

(continued from previous page)

```
sage: RSK(Word([2,3,3,2,1,3,2,3]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)], insertion=RSK.
↪rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]),␣
↪insertion=RSK.rules.dualRSK)
[[[1, 4], [2], [3], [3]], [[1, 4], [2], [3], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]), insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [2, 3], [2, 3], [3]], [[1, 2, 8], [3, 6], [4, 7], [5]]]
```

Using dual RSK insertion with a strict biword:

```
sage: RSK([1,1,2,4,4,5],[2,4,1,1,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2], [1, 3], [2, 4]], [[1, 1], [2, 4], [4, 5]]]
sage: RSK([1,1,2,3,3,4,5],[1,3,2,1,3,3,2], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1, 2], [3], [3]], [[1, 1, 3], [2, 4], [3], [5]]]
sage: RSK([1, 2, 2, 2], [2, 1, 2, 4], insertion=RSK.rules.dualRSK)
[[[1, 2, 4], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,1,2,1,7]), insertion=RSK.rules.dualRSK)
[[[1, 2, 7], [1], [6]], [[1, 3, 4], [3], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1),Integer(1),Integer(2),Integer(4),Integer(4),Integer(5)],
↪[Integer(2),Integer(4),Integer(1),Integer(1),Integer(3),Integer(2)],␣
↪insertion=RSK.rules.dualRSK)
[[[1, 2], [1, 3], [2, 4]], [[1, 1], [2, 4], [4, 5]]]
>>> RSK([Integer(1),Integer(1),Integer(2),Integer(3),Integer(3),Integer(4),
↪Integer(5)],[Integer(1),Integer(3),Integer(2),Integer(1),Integer(3),Integer(3),
↪Integer(2)], insertion=RSK.rules.dualRSK)
[[[1, 2, 3], [1, 2], [3], [3]], [[1, 1, 3], [2, 4], [3], [5]]]
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(2), Integer(4)], insertion=RSK.rules.dualRSK)
[[[1, 2, 4], [2]], [[1, 2, 2], [2]]]
>>> RSK(Word([Integer(1),Integer(1),Integer(3),Integer(4),Integer(4)]),␣
↪[Integer(1),Integer(4),Integer(2),Integer(1),Integer(3)], insertion=RSK.rules.
↪dualRSK)
[[[1, 2, 3], [1], [4]], [[1, 1, 4], [3], [4]]]
>>> RSK([Integer(1),Integer(3),Integer(3),Integer(4),Integer(4)],␣
↪Word([Integer(6),Integer(1),Integer(2),Integer(1),Integer(7)]), insertion=RSK.
↪rules.dualRSK)
[[[1, 2, 7], [1], [6]], [[1, 3, 4], [3], [4]]]
```

Using dual RSK insertion with a $\{0, 1\}$-matrix:

```
sage: RSK(matrix([[0,1],[1,1]]), insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(1),Integer(1)]]), insertion=RSK.
↪rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

We can also give it something looking like a matrix:

```
sage: RSK([[0,1],[1,1]], insertion=RSK.rules.dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(1),Integer(1)]], insertion=RSK.rules.
↪dualRSK)
[[[1, 2], [2]], [[1, 2], [2]]]
```

Let us now call the inverse correspondence:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 2, 3],
....:           insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],insertion=RSK.rules.dualRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(2), Integer(3)],
...           insertion=RSK.rules.dualRSK),insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(2), Integer(3)],insertion=RSK.rules.dualRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.dualRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

When applied to two standard tableaux, reverse dual RSK insertion behaves identically to the usual reverse RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532
sage: RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 3, 2, 5]
```

(continues on next page)

(continued from previous page)

```
sage: RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
→[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
→[Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word', insertion=RSK.rules.dualRSK)
word: 14532
>>> RSK_inverse(t1, t2, 'matrix', insertion=RSK.rules.dualRSK)
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation', insertion=RSK.rules.dualRSK)
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation', insertion=RSK.rules.dualRSK)
[1, 5, 4, 2, 3]
```

Let us check that forward and backward dual RSK are mutually inverse when the first tableau is merely transpose semistandard:

```
sage: p = Tableau([[1,2,2],[1]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
[[1, 2, 3, 4], [1, 2, 1, 2]]
sage: RSK_inverse(p, q, 'word', insertion=RSK.rules.dualRSK)
word: 1212
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(1)]]); q =␣
→Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q, insertion=RSK.rules.dualRSK); ret
[[1, 2, 3, 4], [1, 2, 1, 2]]
>>> RSK_inverse(p, q, 'word', insertion=RSK.rules.dualRSK)
word: 1212
```

In general for dual RSK:

```
sage: p = Tableau([[1,1,2],[1]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 3], [1, 1, 1, 2]]
sage: RSK_inverse(p, q, 'matrix', insertion=RSK.rules.dualRSK)
```

(continues on next page)

(continued from previous page)

```
[1 0]
[1 0]
[1 1]
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(1)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q, insertion=RSK.rules.dualRSK)
[[1, 2, 3, 3], [1, 1, 1, 2]]
>>> RSK_inverse(p, q, 'matrix', insertion=RSK.rules.dualRSK)
[1 0]
[1 0]
[1 1]
```

insertion (j, r)

Insert the letter `j` from the second row of the biword into the row r using dual RSK insertion, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: r = [1, 3, 4, 5]
sage: j = RuleDualRSK().insertion(4, r); j
4
sage: r
[1, 3, 4, 5]
sage: r = [1, 2, 3, 6, 7]
sage: j = RuleDualRSK().insertion(4, r); j
6
sage: r
[1, 2, 3, 4, 7]
sage: r = [1, 3]
sage: j = RuleDualRSK().insertion(4, r); j is None
True
sage: r
[1, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> r = [Integer(1), Integer(3), Integer(4), Integer(5)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
4
>>> r
[1, 3, 4, 5]
>>> r = [Integer(1), Integer(2), Integer(3), Integer(6), Integer(7)]
>>> j = RuleDualRSK().insertion(Integer(4), r); j
6
>>> r
[1, 2, 3, 4, 7]
>>> r = [Integer(1), Integer(3)]
```

(continues on next page)

(continued from previous page)

```
>>> j = RuleDualRSK().insertion(Integer(4), r); j is None
True
>>> r
[1, 3]
```

reverse_insertion(*x*, *row*)

Reverse bump the row `row` of the current insertion tableau with the number `x` using dual RSK insertion.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: r = [1, 2, 4, 6, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
6
sage: r = [1, 2, 4, 5, 7]
sage: x = RuleDualRSK().reverse_insertion(6, r); r
[1, 2, 4, 6, 7]
sage: x
5
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> r = [Integer(1), Integer(2), Integer(4), Integer(6), Integer(7)]
>>> x = RuleDualRSK().reverse_insertion(Integer(6), r); r
[1, 2, 4, 6, 7]
>>> x
6
>>> r = [Integer(1), Integer(2), Integer(4), Integer(5), Integer(7)]
>>> x = RuleDualRSK().reverse_insertion(Integer(6), r); r
[1, 2, 4, 6, 7]
>>> x
5
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the dual RSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a strict biword (i.e., satisfying $a_1 \leq a_2 \leq \cdots \leq a_n$, and if $a_i = a_{i+1}$, then $b_i < b_{i+1}$) or a $\{0, 1\}$-matrix ("rook placement"), or a single word, return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a strict biword (see the doc of `forward_rule()` for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid strict biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleDualRSK
sage: list(RuleDualRSK().to_pairs([1, 2, 2, 2], [2, 1, 2, 3]))
```

(continues on next page)

(continued from previous page)

```
[(1, 2), (2, 1), (2, 2), (2, 3)]
sage: RuleDualRSK().to_pairs([1, 2, 2, 2], [1, 2, 3, 3])
Traceback (most recent call last):
...
ValueError: invalid strict biword
sage: m = Matrix(ZZ, 3, 2, [0,1,1,1,0,1]) ; m
[0 1]
[1 1]
[0 1]
sage: list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
sage: m = Matrix(ZZ, 3, 2, [0,1,1,0,0,2]) ; m
[0 1]
[1 0]
[0 2]
sage: RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
...
ValueError: dual RSK requires a {0, 1}-matrix
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleDualRSK
>>> list(RuleDualRSK().to_pairs([Integer(1), Integer(2), Integer(2),␣
→Integer(2)], [Integer(2), Integer(1), Integer(2), Integer(3)]))
[(1, 2), (2, 1), (2, 2), (2, 3)]
>>> RuleDualRSK().to_pairs([Integer(1), Integer(2), Integer(2), Integer(2)],␣
→[Integer(1), Integer(2), Integer(3), Integer(3)])
Traceback (most recent call last):
...
ValueError: invalid strict biword
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
→Integer(1),Integer(0),Integer(1)]) ; m
[0 1]
[1 1]
[0 1]
>>> list(RuleDualRSK().to_pairs(m))
[(1, 2), (2, 1), (2, 2), (3, 2)]
>>> m = Matrix(ZZ, Integer(3), Integer(2), [Integer(0),Integer(1),Integer(1),
→Integer(0),Integer(0),Integer(2)]) ; m
[0 1]
[1 0]
[0 2]
>>> RuleDualRSK().to_pairs(m)
Traceback (most recent call last):
...
ValueError: dual RSK requires a {0, 1}-matrix
```

class sage.combinat.rsk.**RuleEG**

Bases: *Rule*

Rule for Edelman-Greene insertion.

For a reduced word of a permutation (i.e., an element of a type A Coxeter group), one can use Edelman-Greene insertion, an algorithm defined in [EG1987] Definition 6.20 (where it is referred to as Coxeter-Knuth insertion). The Edelman-Greene insertion is similar to the standard row insertion except that (using the notations in the documentation of `RSK()`) if k_i and $k_i + 1$ both exist in row i, we *only* set $k_{i+1} = k_i + 1$ and continue.

EXAMPLES:

Let us reproduce figure 6.4 in [EG1987]:

```
sage: RSK([2,3,2,1,2,3], insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(2),Integer(3),Integer(2),Integer(1),Integer(2),Integer(3)],␣
↪insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3], [3]], [[1, 2, 6], [3, 5], [4]]]
```

Some more examples:

```
sage: a = [2, 1, 2, 3, 2]
sage: pq = RSK(a, insertion=RSK.rules.EG); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK(RSK_inverse(*pq, insertion=RSK.rules.EG, output='matrix'),
....:     insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
sage: RSK_inverse(*pq, insertion=RSK.rules.EG)
[[1, 2, 3, 4, 5], [2, 1, 2, 3, 2]]
```

```
>>> from sage.all import *
>>> a = [Integer(2), Integer(1), Integer(2), Integer(3), Integer(2)]
>>> pq = RSK(a, insertion=RSK.rules.EG); pq
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
>>> RSK(RSK_inverse(*pq, insertion=RSK.rules.EG, output='matrix'),
...     insertion=RSK.rules.EG)
[[[1, 2, 3], [2, 3]], [[1, 3, 4], [2, 5]]]
>>> RSK_inverse(*pq, insertion=RSK.rules.EG)
[[1, 2, 3, 4, 5], [2, 1, 2, 3, 2]]
```

The RSK algorithm (`RSK()`) built using the Edelman-Greene insertion rule `RuleEG` is a bijection from reduced words of permutations/elements of a type A Coxeter group to pairs consisting of an increasing tableau and a standard tableau of the same shape (see [EG1987] Theorem 6.25). The inverse of this bijection is obtained using `RSK_inverse()`. If the optional parameter `output = 'permutation'` is set in `RSK_inverse()`, then the function returns not the reduced word itself but the permutation (of smallest possible size) whose reduced word it is (although the order of the letters is reverse to the usual Sage convention):

```
sage: w = RSK_inverse(*pq, insertion=RSK.rules.EG, output='permutation'); w
[4, 3, 1, 2]
sage: list(reversed(a)) in w.reduced_words()
True
```

```
>>> from sage.all import *
>>> w = RSK_inverse(*pq, insertion=RSK.rules.EG, output='permutation'); w
[4, 3, 1, 2]
>>> list(reversed(a)) in w.reduced_words()
True
```

insertion(*j*, *r*)

Insert the letter j from the second row of the biword into the row r using Edelman-Greene insertion, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleEG
sage: qr, r =  [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleEG().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [2,3,4,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 4, 5, 8]
sage: j
4
sage: qr, r = [1,2,3,4,5], [2,3,5,5,8]
sage: j = RuleEG().insertion(3, r); r
[2, 3, 3, 5, 8]
sage: j
5
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleEG
>>> qr, r =  [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(3),Integer(3),Integer(2),Integer(4),Integer(8)]
>>> j = RuleEG().insertion(Integer(9), r)
>>> j is None
True
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(2),Integer(3),Integer(4),Integer(5),Integer(8)]
>>> j = RuleEG().insertion(Integer(3), r); r
[2, 3, 4, 5, 8]
>>> j
4
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(2),Integer(3),Integer(5),Integer(5),Integer(8)]
>>> j = RuleEG().insertion(Integer(3), r); r
[2, 3, 3, 5, 8]
>>> j
5
```

reverse_insertion(*x*, *row*)

Reverse bump the row row of the current insertion tableau with the number x.

The row row is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleEG
sage: r =  [1,1,1,2,3,3]
sage: x = RuleEG().reverse_insertion(3, r); r
[1, 1, 1, 2, 3, 3]
```

(continues on next page)

(continued from previous page)

```
sage: x
2
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleEG
>>> r =  [Integer(1),Integer(1),Integer(1),Integer(2),Integer(3),Integer(3)]
>>> x = RuleEG().reverse_insertion(Integer(3), r); r
[1, 1, 1, 2, 3, 3]
>>> x
2
```

class sage.combinat.rsk.**RuleHecke**

Bases: *Rule*

Rule for Hecke insertion.

The Hecke RSK algorithm is similar to the classical RSK algorithm, but is defined using the Hecke insertion introduced in in [BKSTY06] (but using rows instead of columns). It is not clear in what generality it works; thus, following [BKSTY06], we shall assume that our biword p has top row $(1, 2, \ldots, n)$ (or, at least, has its top row strictly increasing).

The Hecke RSK algorithm returns a pair of an increasing tableau and a set-valued standard tableau. If $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$, then the algorithm recursively constructs pairs $(P_0, Q_0), (P_1, Q_1), \ldots, (P_\ell, Q_\ell)$ of tableaux. The construction of P_{t+1} and Q_{t+1} from P_t, Q_t, j_t and k_t proceeds as follows: Set $i = j_t$, $x = k_t$, $P = P_t$ and $Q = Q_t$. We are going to insert x into the increasing tableau P and update the set-valued "recording tableau" Q accordingly. As in the classical RSK algorithm, we first insert x into row 1 of P, then into row 2 of the resulting tableau, and so on, until the construction terminates. The details are different: Suppose we are inserting x into row R of P. If (Case 1) there exists an entry y in row R such that $x < y$, then let y be the minimal such entry. We replace this entry y with x if the result is still an increasing tableau; in either subcase, we then continue recursively, inserting y into the next row of P. If, on the other hand, (Case 2) no such y exists, then we append x to the end of R if the result is an increasing tableau (Subcase 2.1), and otherwise (Subcase 2.2) do nothing. Furthermore, in Subcase 2.1, we add the box that we have just filled with x in P to the shape of Q, and fill it with the one-element set $\{i\}$. In Subcase 2.2, we find the bottommost box of the column containing the rightmost box of row R, and add i to the entry of Q in this box (this entry is a set, since Q is set-valued). In either subcase, we terminate the recursion, and set $P_{t+1} = P$ and $Q_{t+1} = Q$.

Notice that set-valued tableaux are encoded as tableaux whose entries are tuples of positive integers; each such tuple is strictly increasing and encodes a set (namely, the set of its entries).

EXAMPLES:

As an example of Hecke insertion, we reproduce Example 2.1 in arXiv 0801.1319v2:

```
sage: w = [5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
sage: P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
sage: wp = RSK_inverse(P, Q, insertion=RSK.rules.Hecke,
....:                     output='list'); wp
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
```

(continues on next page)

(continued from previous page)

```
sage: wp == w
True
```

```
>>> from sage.all import *
>>> w = [Integer(5), Integer(4), Integer(1), Integer(3), Integer(4), Integer(2),␣
↪Integer(5), Integer(1), Integer(2), Integer(1), Integer(4), Integer(2),␣
↪Integer(4)]
>>> P,Q = RSK(w, insertion=RSK.rules.Hecke); [P,Q]
[[[1, 2, 4, 5], [2, 4, 5], [3, 5], [4], [5]],
 [[(1,), (4,), (5,), (7,)],
  [(2,), (9,), (11, 13)],
  [(3,), (12,)],
  [(6,)],
  [(8, 10)]]]
>>> wp = RSK_inverse(P, Q, insertion=RSK.rules.Hecke,
...                     output='list'); wp
[5, 4, 1, 3, 4, 2, 5, 1, 2, 1, 4, 2, 4]
>>> wp == w
True
```

backward_rule(*p*, *q*, *output*)

Return the generalized permutation obtained by applying reverse Hecke insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)

  and if `q` is standard set-valued, we can have the output:
  - `'word'` – as a word
  - `'list'` – as a list

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: t1 = Tableau([[1, 4], [2], [3]])
sage: t2 = Tableau([[(1, 2), (4,)], [(3,)], [(5,)]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
sage: t1 = Tableau([[1, 4], [2, 3]])
sage: t2 = Tableau([[(1, 2), (4,)], [(3,)], [(5,)]])
sage: RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):
...
ValueError: p(=[[1, 4], [2, 3]]) and
 q(=[[(1, 2), (4,)], [(3,)], [(5,)]]) must have the same shape
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
```

(continues on next page)

(continued from previous page)

```
>>> t1 = Tableau([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)]])
>>> t2 = Tableau([[(Integer(1), Integer(2)), (Integer(4),)], [(Integer(3),)],␣
↪[(Integer(5),)]])
>>> RuleHecke().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [3, 3, 2, 4, 1]]
>>> t1 = Tableau([[Integer(1), Integer(4)], [Integer(2), Integer(3)]])
>>> t2 = Tableau([[(Integer(1), Integer(2)), (Integer(4),)], [(Integer(3),)],␣
↪[(Integer(5),)]])
>>> RuleHecke().backward_rule(t1, t2, 'array')
Traceback (most recent call last):

 q(=[[(1, 2), (4,)], [(3,)], [(5,)]]) must have the same shape
```

forward_rule(*obj1*, *obj2*, *check_standard=False*)

Return a pair of tableaux obtained by applying Hecke insertion to the generalized permutation `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: p, q = RuleHecke().forward_rule([3,3,2,4,1], None);p
[[1, 4], [2], [3]]
sage: q
[[(1, 2), (4,)], [(3,)], [(5,)]]
sage: isinstance(p, SemistandardTableau)
True
sage: isinstance(q, Tableau)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> p, q = RuleHecke().forward_rule([Integer(3),Integer(3),Integer(2),
↪Integer(4),Integer(1)], None);p
[[1, 4], [2], [3]]
>>> q
[[(1, 2), (4,)], [(3,)], [(5,)]]
>>> isinstance(p, SemistandardTableau)
True
>>> isinstance(q, Tableau)
True
```

insertion(*j*, *ir*, *r*, *p*)

Insert the letter `j` from the second row of the biword into the row r of the increasing tableau p using Hecke insertion, provided that r is the ir-th row of p, and provided that there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_right
sage: p, q, r =  [], [], [3,3,8,8,8,9]
sage: j, ir = 8, 1
sage: j1 = RuleHecke().insertion(j, ir, r, p)
sage: j1 == r[bisect_right(r, j)]
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> from bisect import bisect_right
>>> p, q, r =  [], [], [Integer(3),Integer(3),Integer(8),Integer(8),
↪Integer(8),Integer(9)]
>>> j, ir = Integer(8), Integer(1)
>>> j1 = RuleHecke().insertion(j, ir, r, p)
>>> j1 == r[bisect_right(r, j)]
True
```

reverse_insertion(*i*, *x*, *row*, *p*)

Reverse bump the row `row` of the current insertion tableau `p` with the number `x`, provided that `row` is the i-th row of p.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleHecke
sage: from bisect import bisect_left
sage: r =  [2,3,3,4,8,9]
sage: x, i, p = 9, 1, [1, 2]
sage: x1 = RuleHecke().reverse_insertion(i, x, r, p)
sage: x1 == r[bisect_left(r,x) - 1]
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleHecke
>>> from bisect import bisect_left
>>> r =  [Integer(2),Integer(3),Integer(3),Integer(4),Integer(8),Integer(9)]
>>> x, i, p = Integer(9), Integer(1), [Integer(1), Integer(2)]
>>> x1 = RuleHecke().reverse_insertion(i, x, r, p)
>>> x1 == r[bisect_left(r,x) - Integer(1)]
True
```

class sage.combinat.rsk.**RuleRSK**

Bases: *Rule*

Rule for the classical Robinson-Schensted-Knuth insertion.

See `RSK()` for the definition of this operation.

EXAMPLES:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2], insertion=RSK.rules.RSK)
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q, insertion=RSK.rules.RSK)
[[1, 2, 3, 3], [2, 1, 2, 2]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(1), Integer(2)], insertion=RSK.rules.RSK)
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q, insertion=RSK.rules.RSK)
[[1, 2, 3, 3], [2, 1, 2, 2]]
```

insertion(*j*, *r*)

Insert the letter `j` from the second row of the biword into the row r using classical Schensted insertion, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleRSK().insertion(9, r)
sage: j is None
True
sage: qr, r = [1,2,3,4,5], [3,3,2,4,8]
sage: j = RuleRSK().insertion(3, r)
sage: j
4
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(3),Integer(3),Integer(2),Integer(4),Integer(8)]
>>> j = RuleRSK().insertion(Integer(9), r)
>>> j is None
True
>>> qr, r = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)],␣
↪[Integer(3),Integer(3),Integer(2),Integer(4),Integer(8)]
>>> j = RuleRSK().insertion(Integer(3), r)
>>> j
4
```

reverse_insertion(*x*, *row*)

Reverse bump the row `row` of the current insertion tableau with the number `x`.

The row `row` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleRSK
sage: r =  [2,3,3,4,8]
sage: x = RuleRSK().reverse_insertion(4, r); r
[2, 3, 4, 4, 8]
sage: x
3
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleRSK
>>> r =  [Integer(2),Integer(3),Integer(3),Integer(4),Integer(8)]
>>> x = RuleRSK().reverse_insertion(Integer(4), r); r
[2, 3, 4, 4, 8]
>>> x
3
```

class sage.combinat.rsk.**RuleStar**

Bases: *Rule*

Rule for $\star$-insertion.

The $\star$-insertion is similar to the classical RSK algorithm and is defined in [MPPS2020]. The bottom row of the increasing Hecke biword is a word in the 0-Hecke monoid that is fully commutative. When inserting a letter x into a row R, there are three cases:

- Case 1: If R is empty or $x > \max(R)$, append x to row R and terminate.
- Case 2: Otherwise if x is not in R, locate the smallest y in R with $y > x$. Bump y with x and insert y into the next row.
- Case 3: Otherwise, if x is in R, locate the smallest y in R with $y \leq x$ and interval $[y, x]$ contained in R. Row R remains unchanged and y is to be inserted into the next row.

The $\star$-insertion returns a pair consisting a conjugate of a semistandard tableau and a semistandard tableau. It is a bijection from the collection of all increasing Hecke biwords whose bottom row is a fully commutative word to pairs (P, Q) of tableaux of the same shape such that P is conjugate semistandard, Q is semistandard and the row reading word of P is fully commutative [MPPS2020].

EXAMPLES:

As an example of $\star$-insertion, we reproduce Example 28 in [MPPS2020]:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
sage: ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
sage: line1,line2 = RuleStar().backward_rule(p, q)
sage: line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
(4, 2)()(4, 2)(3, 1)

sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[4, 2], [], [4, 2], [3, 1]])
```

(continues on next page)

(continued from previous page)

```
sage: RSK_inverse(*RSK(h,insertion='Star'),insertion='Star',
....:              output='DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
sage: p,q = RSK(h, insertion='Star')
sage: ascii_art(p, q)
1  2  4  1  1  2
1  4     2  4
3        4
sage: RSK_inverse(p, q, insertion='Star')
[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]
sage: f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star
↪')
sage: f == h
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(4),Integer(4)], [Integer(1),Integer(3),Integer(2),Integer(4),Integer(2),
↪Integer(4)])
>>> ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
>>> line1,line2 = RuleStar().backward_rule(p, q)
>>> line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
>>> RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
(4, 2)()(4, 2)(3, 1)

>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
>>> h = DecreasingHeckeFactorization([[Integer(4), Integer(2)], [], [Integer(4),␣
↪Integer(2)], [Integer(3), Integer(1)]])
>>> RSK_inverse(*RSK(h,insertion='Star'),insertion='Star',
...              output='DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
>>> p,q = RSK(h, insertion='Star')
>>> ascii_art(p, q)
1  2  4  1  1  2
1  4     2  4
3        4
>>> RSK_inverse(p, q, insertion='Star')
[[1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4]]
>>> f = RSK_inverse(p, q, output='DecreasingHeckeFactorization', insertion='Star')
>>> f == h
True
```

Warning

When `output` is set to `'DecreasingHeckeFactorization'`, the inverse of $\star$-insertion of (P, Q) returns a decreasing factorization whose number of factors is the maximum entry of Q:

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
sage: h1 = DecreasingHeckeFactorization([[],[3,1],[1]]); h1
()(3, 1)(1)
sage: P,Q = RSK(h1, insertion='Star')
sage: ascii_art(P, Q)
  1  3  1  2
  1     2
sage: h2 = RSK_inverse(P, Q, insertion='Star',
....: output='DecreasingHeckeFactorization'); h2
(3, 1)(1)
```

```
>>> from sage.all import *
>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
>>> h1 = DecreasingHeckeFactorization([[],[Integer(3),Integer(1)],
↪[Integer(1)]]); h1
()(3, 1)(1)
>>> P,Q = RSK(h1, insertion='Star')
>>> ascii_art(P, Q)
  1  3  1  2
  1     2
>>> h2 = RSK_inverse(P, Q, insertion='Star',
... output='DecreasingHeckeFactorization'); h2
(3, 1)(1)
```

backward_rule(*p*, *q*, *output='array'*)

Return the increasing Hecke biword obtained by applying reverse $\star$-insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape, where `p` is the conjugate of a semistandard tableau, whose reading word is fully commutative and `q` is a semistandard tableau.
- `output` – (default: `'array'`) if `q` is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword) that is an increasing Hecke biword
  - `'DecreasingHeckeFactorization'` – as a decreasing factorization in the 0-Hecke monoid

  and if `q` is standard:
  - `'word'` – as a (possibly non-reduced) word in the 0-Hecke monoid

Warning

When output is ‘DecreasingHeckeFactorization’, the number of factors in the output is the largest number in `obj1`.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,2,4,4], [1,3,2,4,2,4])
```

(continues on next page)

(continued from previous page)

```
sage: ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
sage: line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
sage: RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),
↪Integer(2),Integer(4),Integer(4)], [Integer(1),Integer(3),Integer(2),
↪Integer(4),Integer(2),Integer(4)])
>>> ascii_art(p, q)
  1  2  4  1  1  2
  1  4     2  4
  3        4
>>> line1,line2 = RuleStar().backward_rule(p, q); line1,line2
([1, 1, 2, 2, 4, 4], [1, 3, 2, 4, 2, 4])
>>> RuleStar().backward_rule(p, q, output = 'DecreasingHeckeFactorization')
(4, 2)()(4, 2)(3, 1)
```

forward_rule(*obj1*, *obj2=None*, *check_braid=True*)

Return a pair of tableaux obtained by applying forward insertion to the increasing Hecke biword `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a biword (or, equivalently, an increasing 0-Hecke factorization) that is fully commutative:
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword.
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default).
  - a DecreasingHeckeFactorization `obj1`, the whose increasing Hecke biword will be interpreted as the bottom row; the top row is understood to be the indices of the factors for each letter in this biword.
- `check_braid` – boolean (default: `True`); indicator to validate that input is associated to a fully commutative word in the 0-Hecke monoid, validation is performed if set to `True`. Otherwise, this validation is ignored.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: p,q = RuleStar().forward_rule([1,1,2,3,3], [2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
sage: p,q = RuleStar().forward_rule([2,3,3,1,3]); p,q
([[1, 3], [2, 3], [2]], [[1, 2], [3, 5], [4]])
sage: p,q = RSK([1,1,2,3,3], [2,3,3,1,3], insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

(continues on next page)

(continued from previous page)

```
sage: from sage.combinat.crystals.fully_commutative_stable_grothendieck␣
↪import DecreasingHeckeFactorization
sage: h = DecreasingHeckeFactorization([[3, 1], [3], [3, 2]])
sage: p,q = RSK(h, insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> p,q = RuleStar().forward_rule([Integer(1),Integer(1),Integer(2),
↪Integer(3),Integer(3)], [Integer(2),Integer(3),Integer(3),Integer(1),
↪Integer(3)]); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
>>> p,q = RuleStar().forward_rule([Integer(2),Integer(3),Integer(3),
↪Integer(1),Integer(3)]); p,q
([[1, 3], [2, 3], [2]], [[1, 2], [3, 5], [4]])
>>> p,q = RSK([Integer(1),Integer(1),Integer(2),Integer(3),Integer(3)],␣
↪[Integer(2),Integer(3),Integer(3),Integer(1),Integer(3)], insertion=RSK.
↪rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])

>>> from sage.combinat.crystals.fully_commutative_stable_grothendieck import␣
↪DecreasingHeckeFactorization
>>> h = DecreasingHeckeFactorization([[Integer(3), Integer(1)], [Integer(3)],␣
↪[Integer(3), Integer(2)]])
>>> p,q = RSK(h, insertion=RSK.rules.Star); p,q
([[1, 3], [2, 3], [2]], [[1, 1], [2, 3], [3]])
```

insertion(b, r)

Insert the letter `b` from the second row of the biword into the row `r` using $\star$-insertion defined in [MPPS2020].

The row r is modified in place if bumping occurs and b is not in row r. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().insertion(3, [1,2,4,5])
4
sage: RuleStar().insertion(3, [1,2,3,5])
1
sage: RuleStar().insertion(6, [1,2,3,5]) is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> RuleStar().insertion(Integer(3), [Integer(1),Integer(2),Integer(4),
↪Integer(5)])
4
>>> RuleStar().insertion(Integer(3), [Integer(1),Integer(2),Integer(3),
↪Integer(5)])
1
>>> RuleStar().insertion(Integer(6), [Integer(1),Integer(2),Integer(3),
```

(continues on next page)

(continued from previous page)

```
↪Integer(5)]) is None
True
```

reverse_insertion(*x*, *r*)

Reverse bump the row `r` of the current insertion tableau `p` with number `x`, provided that `r` is the `i`-th row of `p`.

The row `r` is modified in place. The bumped-out entry is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleStar
sage: RuleStar().reverse_insertion(4, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(1, [1,2,3,5])
3
sage: RuleStar().reverse_insertion(5, [1,2,3,5])
5
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleStar
>>> RuleStar().reverse_insertion(Integer(4), [Integer(1),Integer(2),
↪Integer(3),Integer(5)])
3
>>> RuleStar().reverse_insertion(Integer(1), [Integer(1),Integer(2),
↪Integer(3),Integer(5)])
3
>>> RuleStar().reverse_insertion(Integer(5), [Integer(1),Integer(2),
↪Integer(3),Integer(5)])
5
```

class sage.combinat.rsk.**RuleSuperRSK**

Bases: *RuleRSK*

Rule for super RSK insertion.

Super RSK is based on ϵ-insertion, a combination of row and column classical RSK insertion.

Super RSK insertion differs from the classical RSK insertion in the following ways:

- The input (in terms of biwords) is no longer an arbitrary biword, but rather a restricted super biword (i.e., a pair of two lists $[a_1, a_2, \ldots, a_n]$ and $[b_1, b_2, \ldots, b_n]$ that contains entries with even and odd parity and pairs with mixed parity entries do not repeat).
- The output still consists of two tableaux (P, Q) of equal shapes, but rather than both of them being semistandard, now they are semistandard super tableaux.
- The main difference is in the way bumping works. Instead of having only row bumping super RSK uses ϵ-insertion, a combination of classical RSK bumping along the rows and a dual RSK like bumping (i.e. when a number k_i is inserted into the i-th row of P, it bumps out the first integer greater **or equal to** k_i in the column) along the column.

EXAMPLES:

```
sage: RSK([1], [1], insertion='superRSK')
[[[1]], [[1]]]
```

(continues on next page)

(continued from previous page)

```
sage: RSK([1, 2], [1, 3], insertion='superRSK')
[[[1, 3]], [[1, 2]]]
sage: RSK([1, 2, 3], [1, 3, "3p"], insertion='superRSK')
[[[1, 3], [3']], [[1, 2], [3]]]
sage: RSK([1, 3, "3p", "2p"], insertion='superRSK')
[[[1, 3', 3], [2']], [[1', 1, 2'], [2]]]
sage: RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
....:     ["1p", 1, "2p", 2, "3p", "3p", "3p", 3], insertion='superRSK')
[[[1', 2, 3', 3], [1, 3'], [2'], [3']], [[1', 2, 3', 3], [2', 3'], [2], [3]]]
sage: P = SemistandardSuperTableau([[1, '3p', 3], ['2p']])
sage: Q = SemistandardSuperTableau([['1p', 1, '2p'], [2]])
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2], [1, 3, 3', 2']]
```

```
>>> from sage.all import *
>>> RSK([Integer(1)], [Integer(1)], insertion='superRSK')
[[[1]], [[1]]]
>>> RSK([Integer(1), Integer(2)], [Integer(1), Integer(3)], insertion='superRSK')
[[[1, 3]], [[1, 2]]]
>>> RSK([Integer(1), Integer(2), Integer(3)], [Integer(1), Integer(3), "3p"],␣
↪insertion='superRSK')
[[[1, 3], [3']], [[1, 2], [3]]]
>>> RSK([Integer(1), Integer(3), "3p", "2p"], insertion='superRSK')
[[[1, 3', 3], [2']], [[1', 1, 2'], [2]]]
>>> RSK(["1p", "2p", Integer(2), Integer(2), "3p", "3p", Integer(3), Integer(3)],
...     ["1p", Integer(1), "2p", Integer(2), "3p", "3p", "3p", Integer(3)],␣
↪insertion='superRSK')
[[[1', 2, 3', 3], [1, 3'], [2'], [3']], [[1', 2, 3', 3], [2', 3'], [2], [3]]]
>>> P = SemistandardSuperTableau([[Integer(1), '3p', Integer(3)], ['2p']])
>>> Q = SemistandardSuperTableau([['1p', Integer(1), '2p'], [Integer(2)]])
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2], [1, 3, 3', 2']]
```

We apply super RSK on Example 5.1 in [Muth2019]:

```
sage: P,Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
....:           ["3p", 1, 2, 3, "3p", "3p", "2p", "1p"], insertion='superRSK')
sage: (P, Q)
([[1', 2', 3', 3], [1, 2, 3'], [3']], [[1', 2, 2, 3'], [2', 3, 3], [3']])
sage: ascii_art((P, Q))
(  1' 2' 3'  3    1'  2  2 3' )
(   1  2 3'       2'  3  3    )
(  3'         ,   3'          )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]
```

```
>>> from sage.all import *
>>> P,Q = RSK(["1p", "2p", Integer(2), Integer(2), "3p", "3p", Integer(3),␣
↪Integer(3)],
...           ["3p", Integer(1), Integer(2), Integer(3), "3p", "3p", "2p", "1p"],␣
↪insertion='superRSK')
>>> (P, Q)
```

(continues on next page)

(continued from previous page)

```
([[1', 2', 3', 3], [1, 2, 3'], [3']], [[1', 2, 2, 3'], [2', 3, 3], [3']])
>>> ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
(  3'         ,  3'          )
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]
```

Example 6.1 in [Muth2019]:

```
sage: P,Q = RSK(["1p", "2p", 2, 2, "3p", "3p", 3, 3],
....:           ["3p", 1, 2, 3, "3p", "3p", "2p", "1p"], insertion='superRSK')
sage: ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
(  3'         ,  3'          )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]

sage: P,Q = RSK(["1p", 1, "2p", 2, "3p", "3p", "3p", 3],
....:           [3, "2p", 3, 2, "3p", "3p", "1p", 2], insertion='superRSK')
sage: ascii_art((P, Q))
(  1'  2  2 3'   1' 2' 3'  3 )
(  2'  3  3       1  2 3'    )
(  3'         ,  3'          )
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2, 3', 3', 3', 3], [3, 2', 3, 2, 3', 3', 1', 2]]
```

```
>>> from sage.all import *
>>> P,Q = RSK(["1p", "2p", Integer(2), Integer(2), "3p", "3p", Integer(3),␣
↪Integer(3)],
...           ["3p", Integer(1), Integer(2), Integer(3), "3p", "3p", "2p", "1p"],␣
↪insertion='superRSK')
>>> ascii_art((P, Q))
(  1' 2' 3'  3   1'  2  2 3' )
(   1  2 3'      2'  3  3    )
(  3'         ,  3'          )
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 2', 2, 2, 3', 3', 3, 3], [3', 1, 2, 3, 3', 3', 2', 1']]

>>> P,Q = RSK(["1p", Integer(1), "2p", Integer(2), "3p", "3p", "3p", Integer(3)],
...           [Integer(3), "2p", Integer(3), Integer(2), "3p", "3p", "1p",␣
↪Integer(2)], insertion='superRSK')
>>> ascii_art((P, Q))
(  1'  2  2 3'   1' 2' 3'  3 )
(  2'  3  3       1  2 3'    )
(  3'         ,  3'          )
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1', 1, 2', 2, 3', 3', 3', 3], [3, 2', 3, 2, 3', 3', 1', 2]]
```

Let us now call the inverse correspondence:

```
sage: P, Q = RSK([1, 2, 2, 2], [2, 1, 2, 3],
....:            insertion=RSK.rules.superRSK)
sage: RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

```
>>> from sage.all import *
>>> P, Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(2), Integer(3)],
...            insertion=RSK.rules.superRSK)
>>> RSK_inverse(P, Q, insertion=RSK.rules.superRSK)
[[1, 2, 2, 2], [2, 1, 2, 3]]
```

When applied to two tableaux with only even parity elements, reverse super RSK insertion behaves identically to the usual reversel RSK insertion:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: t1 = SemistandardSuperTableau([[1, 2, 5], [3], [4]])
sage: t2 = SemistandardSuperTableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],␣
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],␣
↪[Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.RSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> t1 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(5)],␣
↪[Integer(3)], [Integer(4)]])
>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(3)],␣
↪[Integer(4)], [Integer(5)]])
>>> RSK_inverse(t1, t2, insertion=RSK.rules.superRSK)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
```

backward_rule(*p*, *q*, *output='array'*)

Return the restricted super biword obtained by applying reverse super RSK insertion to a pair of tableaux `(p, q)`.

INPUT:

- `p`, `q` – two tableaux of the same shape
- `output` – (default: `'array'`) if `q` is row-strict:
  - `'array'` – as a two-line array (i.e. restricted super biword)

  and if `q` is standard, we can have the output:
  - `'word'` – as a word

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: t1 = SemistandardSuperTableau([['1p', '3p', '4p'], [2], [3]])
sage: t2 = SemistandardSuperTableau([[1, 2, 4], [3], [5]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [4', 3, 3', 2, 1']]
sage: t1 = SemistandardSuperTableau([[1, 3], ['3p']])
sage: t2 = SemistandardSuperTableau([[1, 2], [3]])
sage: RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3']]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> t1 = SemistandardSuperTableau([['1p', '3p', '4p'], [Integer(2)],
↪[Integer(3)]])
>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2), Integer(4)],
↪[Integer(3)], [Integer(5)]])
>>> RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3, 4, 5], [4', 3, 3', 2, 1']]
>>> t1 = SemistandardSuperTableau([[Integer(1), Integer(3)], ['3p']])
>>> t2 = SemistandardSuperTableau([[Integer(1), Integer(2)], [Integer(3)]])
>>> RuleSuperRSK().backward_rule(t1, t2, 'array')
[[1, 2, 3], [1, 3, 3']]
```

forward_rule(*obj1*, *obj2*, *check_standard=False*, *check=True*)

Return a pair of tableaux obtained by applying forward insertion to the restricted super biword `[obj1, obj2]`.

INPUT:

- `obj1`, `obj2` – can be one of the following ways to represent a generalized permutation (or, equivalently, biword):
  - two lists `obj1` and `obj2` of equal length, to be interpreted as the top row and the bottom row of the biword
  - a word `obj1` in an ordered alphabet, to be interpreted as the bottom row of the biword (in this case, `obj2` is `None`; the top row of the biword is understood to be $(1, 2, \ldots, n)$ by default)
  - any object `obj1` which has a method `_rsk_iter()`, as long as this method returns an iterator yielding pairs of numbers, which then are interperted as top entries and bottom entries in the biword (in this case, `obj2` is `None`)
- `check_standard` – boolean (default: `False`); check if either of the resulting tableaux is a standard super tableau, and if so, typecast it as such
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid restricted super biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: p, q = RuleSuperRSK().forward_rule([1, 2], [1, 3]); p
[[1, 3]]
sage: q
[[1, 2]]
sage: isinstance(p, SemistandardSuperTableau)
```

(continues on next page)

(continued from previous page)

```
True
sage: isinstance(q, SemistandardSuperTableau)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> p, q = RuleSuperRSK().forward_rule([Integer(1), Integer(2)], [Integer(1),␣
↪Integer(3)]); p
[[1, 3]]
>>> q
[[1, 2]]
>>> isinstance(p, SemistandardSuperTableau)
True
>>> isinstance(q, SemistandardSuperTableau)
True
```

insertion(*j*, *r*, *epsilon=0*)

Insert the letter `j` from the second row of the biword into the row `r` using dual RSK insertion or classical Schensted insertion depending on the value of `epsilon`, if there is bumping to be done.

The row r is modified in place if bumping occurs. The bumped-out entry, if it exists, is returned.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=0); r
[1, 3, 3, 3, 3]
sage: j
4
sage: y_pos
4
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y_pos
1
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> from bisect import bisect_left, bisect_right
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(3)
>>> j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=Integer(0)); r
[1, 3, 3, 3, 3]
>>> j
4
```

(continues on next page)

(continued from previous page)

```
>>> y_pos
4
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(3)
>>> j, y_pos = RuleSuperRSK().insertion(j, r, epsilon=Integer(1)); r
[1, 3, 3, 3, 4]
>>> j
3
>>> y_pos
1
```

reverse_insertion(*x*, *row*, *epsilon=0*)

Reverse bump the row `row` of the current insertion tableau with the number `x` using dual RSK insertion or classical Schensted insertion depending on the value of *epsilon*.

The row `row` is modified in place. The bumped-out entry is returned along with the bumped position.

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: from bisect import bisect_left, bisect_right
sage: r = [1, 3, 3, 3, 4]
sage: j = 2
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[2, 3, 3, 3, 4]
sage: j
1
sage: y
0
sage: r = [1, 3, 3, 3, 4]
sage: j = 3
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=0); r
[3, 3, 3, 3, 4]
sage: j
1
sage: y
0
sage: r = [1, 3, 3, 3, 4]
sage: j = (3)
sage: j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=1); r
[1, 3, 3, 3, 4]
sage: j
3
sage: y
3
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> from bisect import bisect_left, bisect_right
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(2)
>>> j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(0)); r
[2, 3, 3, 3, 4]
```

(continues on next page)

(continued from previous page)

```
>>> j
1
>>> y
0
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = Integer(3)
>>> j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(0)); r
[3, 3, 3, 3, 4]
>>> j
1
>>> y
0
>>> r = [Integer(1), Integer(3), Integer(3), Integer(3), Integer(4)]
>>> j = (Integer(3))
>>> j, y = RuleSuperRSK().reverse_insertion(j, r, epsilon=Integer(1)); r
[1, 3, 3, 3, 4]
>>> j
3
>>> y
3
```

to_pairs(*obj1=None*, *obj2=None*, *check=True*)

Given a valid input for the super RSK algorithm, such as two n-tuples `obj1` $= [a_1, a_2, \ldots, a_n]$ and `obj2` $= [b_1, b_2, \ldots, b_n]$ forming a restricted super biword (i.e., entries with even and odd parity and no repetition of corresponding pairs with mixed parity entries) return the array $[(a_1, b_1), (a_2, b_2), \ldots, (a_n, b_n)]$.

INPUT:

- `obj1`, `obj2` – anything representing a restricted super biword (see the doc of *forward_rule()* for the encodings accepted)
- `check` – boolean (default: `True`); whether to check that `obj1` and `obj2` actually define a valid restricted super biword

EXAMPLES:

```
sage: from sage.combinat.rsk import RuleSuperRSK
sage: list(RuleSuperRSK().to_pairs([2, '1p', 1],[1, 1, '1p']))
[(2, 1), (1', 1), (1, 1')]
sage: list(RuleSuperRSK().to_pairs([1, '1p', '2p']))
[(1', 1), (1, 1'), (2', 2')]
sage: list(RuleSuperRSK().to_pairs([1, 1], ['1p', '1p']))
Traceback (most recent call last):
...
ValueError: invalid restricted superbiword
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import RuleSuperRSK
>>> list(RuleSuperRSK().to_pairs([Integer(2), '1p', Integer(1)],[Integer(1),␣
↪Integer(1), '1p']))
[(2, 1), (1', 1), (1, 1')]
>>> list(RuleSuperRSK().to_pairs([Integer(1), '1p', '2p']))
[(1', 1), (1, 1'), (2', 2')]
>>> list(RuleSuperRSK().to_pairs([Integer(1), Integer(1)], ['1p', '1p']))
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: invalid restricted superbiword
```

sage.combinat.rsk.**robinson_schensted_knuth**(*obj1=None*, *obj2=None*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*, *check_standard=False*, ***options*)

Perform the Robinson-Schensted-Knuth (RSK) correspondence.

The Robinson-Schensted-Knuth (RSK) correspondence (also known as the RSK algorithm) is most naturally stated as a bijection between generalized permutations (also known as two-line arrays, biwords, …) and pairs of semi-standard Young tableaux (P, Q) of identical shape. The tableau P is known as the insertion tableau, and Q is known as the recording tableau.

The basic operation is known as row insertion $P \leftarrow k$ (where P is a given semi-standard Young tableau, and k is an integer). Row insertion is a recursive algorithm which starts by setting $k_0 = k$, and in its i-th step inserts the number k_i into the i-th row of P (we start counting the rows at 0) by replacing the first integer greater than k_i in the row by k_i and defines k_{i+1} as the integer that has been replaced. If no integer greater than k_i exists in the i-th row, then k_i is simply appended to the row and the algorithm terminates at this point.

A *generalized permutation* (or *biword*) is a list $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ of pairs such that the letters $j_0, j_1, \ldots, j_{\ell-1}$ are weakly increasing (that is, $j_0 \leq j_1 \leq \cdots \leq j_{\ell-1}$), whereas the letters k_i satisfy $k_i \leq k_{i+1}$ whenever $j_i = j_{i+1}$. The ℓ-tuple $(j_0, j_1, \ldots, j_{\ell-1})$ is called the *top line* of this generalized permutation, whereas the ℓ-tuple $(k_0, k_1, \ldots, k_{\ell-1})$ is called its *bottom line*.

Now the RSK algorithm, applied to a generalized permutation $p = ((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$ (encoded as a lexicographically sorted list of pairs) starts by initializing two semi-standard tableaux P_0 and Q_0 as empty tableaux. For each nonnegative integer t starting at 0, take the pair (j_t, k_t) from p and set $P_{t+1} = P_t \leftarrow k_t$, and define Q_{t+1} by adding a new box filled with j_t to the tableau Q_t at the same location the row insertion on P_t ended (that is to say, adding a new box with entry j_t such that P_{t+1} and Q_{t+1} have the same shape). The iterative process stops when t reaches the size of p, and the pair (P_t, Q_t) at this point is the image of p under the Robinson-Schensted-Knuth correspondence.

This correspondence has been introduced in [Knu1970], where it has been referred to as "Construction A".

For more information, see Chapter 7 in [Sta-EC2].

We also note that integer matrices are in bijection with generalized permutations. Furthermore, we can convert any word w (and, in particular, any permutation) to a generalized permutation by considering the top row to be $(1, 2, \ldots, n)$ where n is the length of w.

The optional argument `insertion` allows to specify an alternative insertion procedure to be used instead of the standard Robinson-Schensted-Knuth insertion.

INPUT:

- `obj1, obj2` – can be one of the following:
  - a word in an ordered alphabet (in this case, `obj1` is said word, and `obj2` is `None`)
  - an integer matrix
  - two lists of equal length representing a generalized permutation (namely, the lists $(j_0, j_1, \ldots, j_{\ell-1})$ and $(k_0, k_1, \ldots, k_{\ell-1})$ represent the generalized permutation $((j_0, k_0), (j_1, k_1), \ldots, (j_{\ell-1}, k_{\ell-1}))$)
  - any object which has a method `_rsk_iter()` which returns an iterator over the object represented as generalized permutation or a pair of lists (in this case, `obj1` is said object, and `obj2` is `None`).
- `insertion` – (default: `RSK.rules.RSK`) the following types of insertion are currently supported:

  - RSK.rules.RSK (or 'RSK') – Robinson-Schensted-Knuth insertion (*RuleRSK*)
  - RSK.rules.EG (or 'EG') – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
  - RSK.rules.Hecke – (or 'hecke') Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
  - RSK.rules.dualRSK (or 'dualRSK') – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
  - RSK.rules.coRSK (or 'coRSK') – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
  - RSK.rules.superRSK (or 'super') – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
  - RSK.rules.Star (or 'Star') – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)
- check_standard – boolean (default: False); check if either of the resulting tableaux is a standard tableau, and if so, typecast it as such

For precise information about constraints on the input and output, as well as the definition of the algorithm (if it is not standard RSK), see the particular *Rule* class.

EXAMPLES:

If we only input one row, it is understood that the top row should be $(1, 2, \ldots, n)$:

```
sage: RSK([3,3,2,4,1])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([3,3,2,4,1]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
sage: RSK(Word([2,3,3,2,1,3,2,3]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)])
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RSK(Word([Integer(3),Integer(3),Integer(2),Integer(4),Integer(1)]))
[[[1, 3, 4], [2], [3]], [[1, 2, 4], [3], [5]]]
>>> RSK(Word([Integer(2),Integer(3),Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)]))
[[[1, 2, 2, 3, 3], [2, 3], [3]], [[1, 2, 3, 6, 8], [4, 7], [5]]]
```

We can provide a generalized permutation:

```
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
sage: RSK(Word([1,1,3,4,4]), [1,4,2,1,3])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
sage: RSK([1,3,3,4,4], Word([6,2,2,1,7]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

```
>>> from sage.all import *
>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2), Integer(1),
↪ Integer(1), Integer(2)])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
>>> RSK(Word([Integer(1),Integer(1),Integer(3),Integer(4),Integer(4)]),␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(1),Integer(4),Integer(2),Integer(1),Integer(3)])
[[[1, 1, 3], [2], [4]], [[1, 1, 4], [3], [4]]]
>>> RSK([Integer(1),Integer(3),Integer(3),Integer(4),Integer(4)],␣
↪Word([Integer(6),Integer(2),Integer(2),Integer(1),Integer(7)]))
[[[1, 2, 7], [2], [6]], [[1, 3, 4], [3], [4]]]
```

We can provide a matrix:

```
sage: RSK(matrix([[0,1],[2,1]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK(matrix([[Integer(0),Integer(1)],[Integer(2),Integer(1)]]))
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

We can also provide something looking like a matrix:

```
sage: RSK([[0,1],[2,1]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

```
>>> from sage.all import *
>>> RSK([[Integer(0),Integer(1)],[Integer(2),Integer(1)]])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```

There is also `RSK_inverse()` which performs the inverse of the bijection on a pair of semistandard tableaux. We note that the inverse function takes 2 separate tableaux as inputs, so to compose with `RSK()`, we need to use the python `*` on the output:

```
sage: RSK_inverse(*RSK([1, 2, 2, 2], [2, 1, 1, 2]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
sage: P,Q = RSK([1, 2, 2, 2], [2, 1, 1, 2])
sage: RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

```
>>> from sage.all import *
>>> RSK_inverse(*RSK([Integer(1), Integer(2), Integer(2), Integer(2)],␣
↪[Integer(2), Integer(1), Integer(1), Integer(2)]))
[[1, 2, 2, 2], [2, 1, 1, 2]]
>>> P,Q = RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),␣
↪Integer(1), Integer(1), Integer(2)])
>>> RSK_inverse(P, Q)
[[1, 2, 2, 2], [2, 1, 1, 2]]
```

`sage.combinat.rsk.`**`robinson_schensted_knuth_inverse`**(*p*, *q*, *output='array'*, *insertion=<class 'sage.combinat.rsk.RuleRSK'>*)

Return the generalized permutation corresponding to the pair of tableaux (p, q) under the inverse of the Robinson-Schensted-Knuth correspondence.

For more information on the bijection, see `RSK()`.

INPUT:

- `p`, `q` – two semi-standard tableaux of the same shape, or (in the case when Hecke insertion is used) an increasing tableau and a set-valued tableau of the same shape (see the note below for the format of the set-valued tableau)

- `output` – (default: `'array'`) if `q` is semi-standard:
  - `'array'` – as a two-line array (i.e. generalized permutation or biword)
  - `'matrix'` – as an integer matrix

  and if `q` is standard, we can also have the output:
  - `'word'` – as a word

  and additionally if `p` is standard, we can also have the output:
  - `'permutation'` – as a permutation
- `insertion` – (default: `RSK.rules.RSK`) the insertion algorithm used in the bijection. Currently the following are supported:
  - `RSK.rules.RSK` (or `'RSK'`) – Robinson-Schensted-Knuth insertion (*RuleRSK*)
  - `RSK.rules.EG` (or `'EG'`) – Edelman-Greene insertion (only for reduced words of permutations/elements of a type A Coxeter group) (*RuleEG*)
  - `RSK.rules.Hecke` (or `'hecke'`) – Hecke insertion (only guaranteed for generalized permutations whose top row is strictly increasing) (*RuleHecke*)
  - `RSK.rules.dualRSK` (or `'dualRSK'`) – Dual RSK insertion (only for strict biwords) (*RuleDualRSK*)
  - `RSK.rules.coRSK` (or `'coRSK'`) – CoRSK insertion (only for strict cobiwords) (*RuleCoRSK*)
  - `RSK.rules.superRSK` (or `'super'`) – Super RSK insertion (only for restricted super biwords) (*RuleSuperRSK*)
  - `RSK.rules.Star` (or `'Star'`) – $\star$-insertion (only for fully commutative words in the 0-Hecke monoid) (*RuleStar*)

For precise information about constraints on the input and output, see the particular *Rule* class.

Note

In the case of Hecke insertion, the input variable `q` should be a set-valued tableau, encoded as a tableau whose entries are strictly increasing tuples of positive integers. Each such tuple encodes the set of its entries.

EXAMPLES:

If both `p` and `q` are standard:

```
sage: t1 = Tableau([[1, 2, 5], [3], [4]])
sage: t2 = Tableau([[1, 2, 3], [4], [5]])
sage: RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
sage: RSK_inverse(t1, t2, 'word')
word: 14532
sage: RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
sage: RSK_inverse(t1, t2, 'permutation')
```

(continues on next page)

(continued from previous page)

```
[1, 4, 5, 3, 2]
sage: RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
sage: RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
sage: RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

```
>>> from sage.all import *
>>> t1 = Tableau([[Integer(1), Integer(2), Integer(5)], [Integer(3)],
↪[Integer(4)]])
>>> t2 = Tableau([[Integer(1), Integer(2), Integer(3)], [Integer(4)],
↪[Integer(5)]])
>>> RSK_inverse(t1, t2)
[[1, 2, 3, 4, 5], [1, 4, 5, 3, 2]]
>>> RSK_inverse(t1, t2, 'word')
word: 14532
>>> RSK_inverse(t1, t2, 'matrix')
[1 0 0 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
[0 0 1 0 0]
[0 1 0 0 0]
>>> RSK_inverse(t1, t2, 'permutation')
[1, 4, 5, 3, 2]
>>> RSK_inverse(t1, t1, 'permutation')
[1, 4, 3, 2, 5]
>>> RSK_inverse(t2, t2, 'permutation')
[1, 2, 5, 4, 3]
>>> RSK_inverse(t2, t1, 'permutation')
[1, 5, 4, 2, 3]
```

If the first tableau is semistandard:

```
sage: p = Tableau([[1,2,2],[3]]); q = Tableau([[1,2,4],[3]])
sage: ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
sage: RSK_inverse(p, q, 'word')
word: 1322
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(3)]]); q =
↪Tableau([[Integer(1),Integer(2),Integer(4)],[Integer(3)]])
>>> ret = RSK_inverse(p, q); ret
[[1, 2, 3, 4], [1, 3, 2, 2]]
>>> RSK_inverse(p, q, 'word')
word: 1322
```

In general:

```
sage: p = Tableau([[1,2,2],[2]]); q = Tableau([[1,3,3],[2]])
sage: RSK_inverse(p, q)
```

(continues on next page)

(continued from previous page)

```
[[1, 2, 3, 3], [2, 1, 2, 2]]
sage: RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

```
>>> from sage.all import *
>>> p = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(2)]]); q =␣
↪Tableau([[Integer(1),Integer(3),Integer(3)],[Integer(2)]])
>>> RSK_inverse(p, q)
[[1, 2, 3, 3], [2, 1, 2, 2]]
>>> RSK_inverse(p, q, 'matrix')
[0 1]
[1 0]
[0 2]
```

Using Hecke insertion:

```
sage: w = [5, 4, 3, 1, 4, 2, 5, 5]
sage: pq = RSK(w, insertion=RSK.rules.Hecke)
sage: RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

```
>>> from sage.all import *
>>> w = [Integer(5), Integer(4), Integer(3), Integer(1), Integer(4), Integer(2),␣
↪Integer(5), Integer(5)]
>>> pq = RSK(w, insertion=RSK.rules.Hecke)
>>> RSK_inverse(*pq, insertion=RSK.rules.Hecke, output='list')
[5, 4, 3, 1, 4, 2, 5, 5]
```

Note

The constructor of `Tableau` accepts not only semistandard tableaux, but also arbitrary lists that are fillings of a partition diagram. (And such lists are used, e.g., for the set-valued tableau `q` that is passed to `RSK_inverse(p, q, insertion='hecke')`.) The user is responsible for ensuring that the tableaux passed to `RSK_inverse` are of the right types (semistandard, standard, increasing, set-valued as needed).

`sage.combinat.rsk.`**`to_matrix`**`(t, b)`

Return the integer matrix corresponding to a two-line array.

INPUT:

- `t` – the top row of the array
- `b` – the bottom row of the array

OUTPUT:

An $m \times n$-matrix (where m and n are the maximum entries in t and b respectively) whose (i, j)-th entry, for any i and j, is the number of all positions k satisfying $t_k = i$ and $b_k = j$.

EXAMPLES:

```
sage: from sage.combinat.rsk import to_matrix
sage: to_matrix([1, 1, 3, 3, 4], [2, 3, 1, 1, 3])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.rsk import to_matrix
>>> to_matrix([Integer(1), Integer(1), Integer(3), Integer(3), Integer(4)],
↪[Integer(2), Integer(3), Integer(1), Integer(1), Integer(3)])
[0 1 1]
[0 0 0]
[2 0 0]
[0 0 1]
```

5.1.276 Schubert Polynomials

See Wikipedia article Schubert_polynomial and SymmetricFunctions.com. Schubert polynomials are representatives of cohomology classes in flag varieties. In n variables, they are indexed by permutations $w \in S_n$. They also form a basis for the coinvariant ring of the S_n action on $\mathbf{Z}[x_1, x_2, \ldots, x_n]$.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: w = [1,2,5,4,3];  # a list representing an element of `S_5`
sage: X(w)
X[1, 2, 5, 4, 3]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> w = [Integer(1),Integer(2),Integer(5),Integer(4),Integer(3)];  # a list
↪representing an element of `S_5`
>>> X(w)
X[1, 2, 5, 4, 3]
```

This can be expanded in terms of polynomial variables:

```
sage: X(w).expand()
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2
 + x0*x2^2 + x1*x2^2 + x0^2*x3 + x0*x1*x3 + x1^2*x3
 + x0*x2*x3 + x1*x2*x3 + x2^2*x3
```

```
>>> from sage.all import *
>>> X(w).expand()
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2
 + x0*x2^2 + x1*x2^2 + x0^2*x3 + x0*x1*x3 + x1^2*x3
 + x0*x2*x3 + x1*x2*x3 + x2^2*x3
```

We can also convert back from polynomial variables. For example, the longest permutation is a single term. In S_5, this is the element (in one line notation) $w_0 = 54321$:

```
sage: w0 = [5,4,3,2,1]
sage: R.<x0, x1, x2, x3, x4> = PolynomialRing(ZZ)
sage: Sw0 = X(x0^4*x1^3*x2^2*x3);  Sw0
X[5, 4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> w0 = [Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)]
>>> R = PolynomialRing(ZZ, names=('x0', 'x1', 'x2', 'x3', 'x4',)); (x0, x1, x2, x3,␣
↪x4,) = R._first_ngens(5)
>>> Sw0 = X(x0**Integer(4)*x1**Integer(3)*x2**Integer(2)*x3);  Sw0
X[5, 4, 3, 2, 1]
```

The polynomials also have the property that if the indexing permutation w is multiplied by a simple transposition $s_i = (i, i+1)$ such that the length of w is more than the length of ws_i, then the Schubert polynomial of the permutation ws_i is computed by applying the divided difference operator *divided_difference()* to the polynomial indexed by w. For example, applying the divided difference operator ∂_2 to the Schubert polynomial $\mathfrak{S}_{w_0}$:

```
sage: Sw0.divided_difference(2)
X[5, 3, 4, 2, 1]
```

```
>>> from sage.all import *
>>> Sw0.divided_difference(Integer(2))
X[5, 3, 4, 2, 1]
```

We can also check the properties listed in Wikipedia article Schubert_polynomial:

```
sage: X([1,2,3,4,5])  # the identity in one-line notation
X[1]
sage: X([1,3,2,4,5]).expand()  # the transposition swapping 2 and 3
x0 + x1
sage: X([2,4,5,3,1]).expand()
x0^2*x1^2*x2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3

sage: w = [4,5,1,2,3]
sage: s = SymmetricFunctions(QQ).schur()
sage: s[3,3].expand(2)
x0^3*x1^3
sage: X(w).expand()
x0^3*x1^3
```

```
>>> from sage.all import *
>>> X([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)])  # the identity in␣
↪one-line notation
X[1]
>>> X([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5)]).expand()  # the␣
↪transposition swapping 2 and 3
x0 + x1
>>> X([Integer(2),Integer(4),Integer(5),Integer(3),Integer(1)]).expand()
x0^2*x1^2*x2*x3 + x0^2*x1*x2^2*x3 + x0*x1^2*x2^2*x3

>>> w = [Integer(4),Integer(5),Integer(1),Integer(2),Integer(3)]
>>> s = SymmetricFunctions(QQ).schur()
```

(continues on next page)

(continued from previous page)

```
>>> s[Integer(3),Integer(3)].expand(Integer(2))
x0^3*x1^3
>>> X(w).expand()
x0^3*x1^3
```

sage.combinat.schubert_polynomial.**SchubertPolynomialRing**(*R*)

Return the Schubert polynomial ring over `R` on the X basis.

This is the basis made of the Schubert polynomials.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
sage: TestSuite(X).run()
sage: X(1)
X[1]
sage: X([1,2,3])*X([2,1,3])
X[2, 1]
sage: X([2,1,3])*X([2,1,3])
X[3, 1, 2]
sage: X([2,1,3])+X([3,1,2,4])
X[2, 1] + X[3, 1, 2]
sage: a = X([2,1,3])+X([3,1,2,4])
sage: a^2
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ); X
Schubert polynomial ring with X basis over Integer Ring
>>> TestSuite(X).run()
>>> X(Integer(1))
X[1]
>>> X([Integer(1),Integer(2),Integer(3)])*X([Integer(2),Integer(1),Integer(3)])
X[2, 1]
>>> X([Integer(2),Integer(1),Integer(3)])*X([Integer(2),Integer(1),Integer(3)])
X[3, 1, 2]
>>> X([Integer(2),Integer(1),Integer(3)])+X([Integer(3),Integer(1),Integer(2),
→Integer(4)])
X[2, 1] + X[3, 1, 2]
>>> a = X([Integer(2),Integer(1),Integer(3)])+X([Integer(3),Integer(1),Integer(2),
→Integer(4)])
>>> a**Integer(2)
X[3, 1, 2] + 2*X[4, 1, 2, 3] + X[5, 1, 2, 3, 4]
```

class sage.combinat.schubert_polynomial.**SchubertPolynomialRing_xbasis**(*R*)

Bases: `CombinatorialFreeModule`

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X == loads(dumps(X))
True
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X == loads(dumps(X))
True
```

Element

alias of *SchubertPolynomial_class*

one_basis()

Return the index of the unit of this algebra.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X.one()   # indirect doctest
X[1]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X.one()   # indirect doctest
X[1]
```

product_on_basis(*left*, *right*)

EXAMPLES:

```
sage: p1 = Permutation([3,2,1])
sage: p2 = Permutation([2,1,3])
sage: X = SchubertPolynomialRing(QQ)
sage: X.product_on_basis(p1,p2)
X[4, 2, 1, 3]
```

```
>>> from sage.all import *
>>> p1 = Permutation([Integer(3),Integer(2),Integer(1)])
>>> p2 = Permutation([Integer(2),Integer(1),Integer(3)])
>>> X = SchubertPolynomialRing(QQ)
>>> X.product_on_basis(p1,p2)
X[4, 2, 1, 3]
```

some_elements()

Return some elements.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(QQ)
sage: X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(QQ)
>>> X.some_elements()
[X[1], X[1] + 2*X[2, 1], -X[3, 2, 1] + X[4, 2, 1, 3]]
```

class sage.combinat.schubert_polynomial.**SchubertPolynomial_class**

Bases: IndexedFreeModuleElement

divided_difference(*i*, *algorithm='sage'*)

Return the i-th divided difference operator, applied to self.

Here, i can be either a permutation or a positive integer.

INPUT:

- i – permutation or positive integer
- algorithm – (default: 'sage') either 'sage' or 'symmetrica'; this determines which software is called for the computation

OUTPUT:

The result of applying the i-th divided difference operator to self.

If i is a positive integer, then the i-th divided difference operator δ_i is the linear operator sending each polynomial $f = f(x_1, x_2, \ldots, x_n)$ (in $n \geq i + 1$ variables) to the polynomial

$$\frac{f - f_i}{x_i - x_{i+1}}, \qquad \text{where } f_i = f(x_1, x_2, ..., x_{i-1}, x_{i+1}, x_i, x_{i+1}, ..., x_n).$$

If σ is a permutation in the n-th symmetric group, then the σ-th divided difference operator δ_σ is the composition $\delta_{i_1} \delta_{i_2} \cdots \delta_{i_k}$, where $\sigma = s_{i_1} \circ s_{i_2} \circ \cdots \circ s_{i_k}$ is any reduced expression for σ (the precise choice of reduced expression is immaterial).

Note: The *expand()* method results in a polynomial in n variables named x0, x1, ..., x(n-1) rather than $x_1, x_2, \ldots, x_n$. The variable named xi corresponds to x_{i+1}. Thus, self.divided_difference(i) involves the variables x(i-1) and xi getting switched (in the numerator).

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,1])
sage: a.divided_difference(1)
X[2, 3, 1]
sage: a.divided_difference([3,2,1])
X[1]
sage: a.divided_difference(5)
0
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(1)])
>>> a.divided_difference(Integer(1))
X[2, 3, 1]
>>> a.divided_difference([Integer(3),Integer(2),Integer(1)])
X[1]
>>> a.divided_difference(Integer(5))
0
```

Any divided difference of 0 is 0:

```
sage: X.zero().divided_difference(2)
0
```

```
>>> from sage.all import *
>>> X.zero().divided_difference(Integer(2))
0
```

This is compatible when a permutation is given as input:

```
sage: a = X([3,2,4,1])
sage: a.divided_difference([2,3,1])
0
sage: a.divided_difference(1).divided_difference(2)
0
```

```
>>> from sage.all import *
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.divided_difference([Integer(2),Integer(3),Integer(1)])
0
>>> a.divided_difference(Integer(1)).divided_difference(Integer(2))
0
```

```
sage: a = X([4,3,2,1])
sage: a.divided_difference([2,3,1])
X[3, 2, 4, 1]
sage: a.divided_difference(1).divided_difference(2)
X[3, 2, 4, 1]
sage: a.divided_difference([4,1,3,2])
X[1, 4, 2, 3]
sage: b = X([4, 1, 3, 2])
sage: b.divided_difference(1).divided_difference(2)
X[1, 3, 4, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3)
X[1, 3, 2]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
↪divided_difference(2)
X[1]
sage: b.divided_difference(1).divided_difference(2).divided_difference(3).
↪divided_difference(3)
0
sage: b.divided_difference(1).divided_difference(2).divided_difference(1)
0
```

```
>>> from sage.all import *
>>> a = X([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> a.divided_difference([Integer(2),Integer(3),Integer(1)])
X[3, 2, 4, 1]
>>> a.divided_difference(Integer(1)).divided_difference(Integer(2))
X[3, 2, 4, 1]
>>> a.divided_difference([Integer(4),Integer(1),Integer(3),Integer(2)])
X[1, 4, 2, 3]
>>> b = X([Integer(4), Integer(1), Integer(3), Integer(2)])
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2))
X[1, 3, 4, 2]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
```

(continues on next page)

(continued from previous page)

```
↪difference(Integer(3))
X[1, 3, 2]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(3)).divided_difference(Integer(2))
X[1]
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(3)).divided_difference(Integer(3))
0
>>> b.divided_difference(Integer(1)).divided_difference(Integer(2)).divided_
↪difference(Integer(1))
0
```

expand()

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: X([2,1,3]).expand()
x0
sage: [X(p).expand() for p in Permutations(3)]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> X([Integer(2),Integer(1),Integer(3)]).expand()
x0
>>> [X(p).expand() for p in Permutations(Integer(3))]
[1, x0 + x1, x0, x0*x1, x0^2, x0^2*x1]
```

multiply_variable(i)

Return the Schubert polynomial obtained by multiplying `self` by the variable x_i.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.multiply_variable(0)
X[4, 2, 3, 1]
sage: a.multiply_variable(1)
X[3, 4, 2, 1]
sage: a.multiply_variable(2)
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
sage: a.multiply_variable(3)
X[3, 2, 4, 5, 1]
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.multiply_variable(Integer(0))
X[4, 2, 3, 1]
>>> a.multiply_variable(Integer(1))
X[3, 4, 2, 1]
>>> a.multiply_variable(Integer(2))
```

(continues on next page)

(continued from previous page)

```
X[3, 2, 5, 1, 4] - X[3, 4, 2, 1] - X[4, 2, 3, 1]
>>> a.multiply_variable(Integer(3))
X[3, 2, 4, 5, 1]
```

scalar_product(*x*)

Return the standard scalar product of `self` and `x`.

EXAMPLES:

```
sage: X = SchubertPolynomialRing(ZZ)
sage: a = X([3,2,4,1])
sage: a.scalar_product(a)
0
sage: b = X([4,3,2,1])
sage: b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
sage: Permutation([1, 3, 4, 6, 2, 5, 7]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
sage: s = SymmetricFunctions(ZZ).schur()
sage: c = s([2,1,1])
sage: b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
sage: c.expand(4)
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
```

```
>>> from sage.all import *
>>> X = SchubertPolynomialRing(ZZ)
>>> a = X([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> a.scalar_product(a)
0
>>> b = X([Integer(4),Integer(3),Integer(2),Integer(1)])
>>> b.scalar_product(a)
X[1, 3, 4, 6, 2, 5]
>>> Permutation([Integer(1), Integer(3), Integer(4), Integer(6), Integer(2),
↪Integer(5), Integer(7)]).to_lehmer_code()
[0, 1, 1, 2, 0, 0, 0]
>>> s = SymmetricFunctions(ZZ).schur()
>>> c = s([Integer(2),Integer(1),Integer(1)])
>>> b.scalar_product(a).expand()
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
>>> c.expand(Integer(4))
x0^2*x1*x2 + x0*x1^2*x2 + x0*x1*x2^2 + x0^2*x1*x3 + x0*x1^2*x3
 + x0^2*x2*x3 + 3*x0*x1*x2*x3 + x1^2*x2*x3 + x0*x2^2*x3 + x1*x2^2*x3
 + x0*x1*x3^2 + x0*x2*x3^2 + x1*x2*x3^2
```

5.1.277 Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration).
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through *SetPartition*.
- Martin Rubey (2017-10-10): Cleanup, add crossings and nestings, add random generation.

This module defines a class for immutable partitioning of a set. For mutable version see `DisjointSet()`.

class sage.combinat.set_partition.**AbstractSetPartition**

Bases: `ClonableArray`

Methods of set partitions which are independent of the base set

base_set()

Return the base set of `self`, which is the union of all parts of `self`.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([[1,2,3,4]]).base_set()
{1, 2, 3, 4}
sage: SetPartition([]).base_set()
{}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_
↪set()
{1, 2, 3, 4}
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set()
{1, 2, 3, 4}
>>> SetPartition([]).base_set()
{}
```

base_set_cardinality()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_
↪set_cardinality()
4
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set_
```

(continues on next page)

(continued from previous page)

```
↪cardinality()
4
```

coarsenings()

Return a list of coarsenings of `self`.

See also:

`refinements()`

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
sage: SetPartition([[1],[2,4],[3]]).coarsenings()
[{{1, 2, 3, 4}},
 {{1, 2, 4}, {3}},
 {{1, 3}, {2, 4}},
 {{1}, {2, 3, 4}},
 {{1}, {2, 4}, {3}}]
sage: SetPartition([]).coarsenings()
[{}]
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]).
↪coarsenings()
[{{1, 2, 3, 4}}, {{1, 3}, {2, 4}}]
>>> SetPartition([[Integer(1)],[Integer(2),Integer(4)],[Integer(3)]]).
↪coarsenings()
[{{1, 2, 3, 4}},
 {{1, 2, 4}, {3}},
 {{1, 3}, {2, 4}},
 {{1}, {2, 3, 4}},
 {{1}, {2, 4}, {3}}]
>>> SetPartition([]).coarsenings()
[{}]
```

conjugate()

An involution exchanging singletons and circular adjacencies.

This method implements the definition of the conjugate of a set partition defined in [Cal2005].

INPUT:

- `self` – set partition of an ordered set

OUTPUT: a set partition

EXAMPLES:

```
sage: SetPartition([[1,6,7],[2,8],[3,4,5]]).conjugate()
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
sage: all(sp.conjugate().conjugate()==sp for sp in SetPartitions([1,3,5,7]))
```

(continues on next page)

(continued from previous page)

```
True
sage: SetPartition([]).conjugate()
{}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(6),Integer(7)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(4),Integer(5)]]).conjugate()
{{1, 4, 7}, {2, 8}, {3}, {5}, {6}}
>>> all(sp.conjugate().conjugate()==sp for sp in SetPartitions([Integer(1),
↪Integer(3),Integer(5),Integer(7)]))
True
>>> SetPartition([]).conjugate()
{}
```

inf(*other*)

The product of the set partitions `self` and `other`.

The product of two set partitions B and C is defined as the set partition whose parts are the nonempty intersections between each part of B and each part of C. This product is also the infimum of B and C in the classical set partition lattice (that is, the coarsest set partition which is finer than each of B and C). Consequently, `inf` acts as an alias for this method.

See also

sup()

EXAMPLES:

```
sage: x = SetPartition([ [1,2], [3,5,4] ])
sage: y = SetPartition(( (3,1,2), (5,4) ))
sage: x * y
{{1, 2}, {3}, {4, 5}}

sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[2,4], [3], [1]])
sage: sp1.inf(sp2) == s
True
```

```
>>> from sage.all import *
>>> x = SetPartition([ [Integer(1),Integer(2)], [Integer(3),Integer(5),
↪Integer(4)] ])
>>> y = SetPartition(( (Integer(3),Integer(1),Integer(2)), (Integer(5),
↪Integer(4)) ))
>>> x * y
{{1, 2}, {3}, {4, 5}}

>>> S = SetPartitions(Integer(4))
>>> sp1 = S([[Integer(2),Integer(3),Integer(4)], [Integer(1)]])
>>> sp2 = S([[Integer(1),Integer(3)], [Integer(2),Integer(4)]])
```

(continues on next page)

(continued from previous page)

```
>>> s = S([[Integer(2),Integer(4)], [Integer(3)], [Integer(1)]])
>>> sp1.inf(sp2) == s
True
```

max_block_size()

The maximum block size of the diagram.

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.diagram_algebras import PartitionDiagram,␣
↪PartitionDiagrams
sage: pd = PartitionDiagram([[1,-3,-5],[2,4],[3,-1,-2],[5],[-4]])
sage: pd.max_block_size()
3
sage: sorted(d.max_block_size() for d in PartitionDiagrams(2))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
sage: sorted(sp.max_block_size() for sp in SetPartitions(3))
[1, 2, 2, 2, 3]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> from sage.combinat.diagram_algebras import PartitionDiagram,␣
↪PartitionDiagrams
>>> pd = PartitionDiagram([[Integer(1),-Integer(3),-Integer(5)],[Integer(2),
↪Integer(4)],[Integer(3),-Integer(1),-Integer(2)],[Integer(5)],[-
↪Integer(4)]])
>>> pd.max_block_size()
3
>>> sorted(d.max_block_size() for d in PartitionDiagrams(Integer(2)))
[1, 2, 2, 2, 2, 2, 2, 2, 2, 2, 3, 3, 3, 3, 4]
>>> sorted(sp.max_block_size() for sp in SetPartitions(Integer(3)))
[1, 2, 2, 2, 3]
```

standard_form()

Return `self` as a list of lists.

When the ground set is totally ordered, the elements of each block are listed in increasing order.

This is not related to standard set partitions (which simply means set partitions of $[n] = \{1, 2, \ldots, n\}$ for some integer n) or standardization (`standardization()`).

EXAMPLES:

```
sage: [x.standard_form() for x in SetPartitions(4, [2,2])]                #␣
↪needs sage.graphs sage.rings.finite_rings
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]
```

```
>>> from sage.all import *
>>> [x.standard_form() for x in SetPartitions(Integer(4), [Integer(2),
↪Integer(2)])]                   # needs sage.graphs sage.rings.finite_rings
[[[1, 2], [3, 4]], [[1, 4], [2, 3]], [[1, 3], [2, 4]]]
```

sup(*t*)

Return the supremum of `self` and `t` in the classical set partition lattice.

The supremum of two set partitions B and C is obtained as the transitive closure of the relation which relates i to j if and only if i and j are in the same part in at least one of the set partitions B and C.

See also

`__mul__()`

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: sp1 = S([[2,3,4], [1]])
sage: sp2 = S([[1,3], [2,4]])
sage: s = S([[1,2,3,4]])
sage: sp1.sup(sp2) == s
True
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> sp1 = S([[Integer(2),Integer(3),Integer(4)], [Integer(1)]])
>>> sp2 = S([[Integer(1),Integer(3)], [Integer(2),Integer(4)]])
>>> s = S([[Integer(1),Integer(2),Integer(3),Integer(4)]])
>>> sp1.sup(sp2) == s
True
```

class sage.combinat.set_partition.**SetPartition**(*parent*, *s*, *check=True*)

Bases: *AbstractSetPartition*

A partition of a set.

A set partition p of a set S is a partition of S into subsets called parts and represented as a set of sets. By extension, a set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of set partitions of n is called the n-th Bell number.

There is a natural integer partition associated with a set partition, namely the nonincreasing sequence of sizes of all its parts.

There is a classical lattice associated with all set partitions of n. The infimum of two set partitions is the set partition obtained by intersecting all the parts of both set partitions. The supremum is obtained by transitive closure of the relation i related to j if and only if they are in the same part in at least one of the set partitions.

We will use terminology from partitions, in particular the *length* of a set partition $A = \{A_1, \ldots, A_k\}$ is the number of parts of A and is denoted by $|A| := k$. The *size* of A is the cardinality of S. We will also sometimes use the notation $[n] := \{1, 2, \ldots, n\}$.

EXAMPLES:

There are 5 set partitions of the set $\{1, 2, 3\}$:

```
sage: SetPartitions(3).cardinality()                                    #␣
↪needs sage.libs.flint
5
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).cardinality()                                    ␣
↪      # needs sage.libs.flint
5
```

Here is the list of them:

```
sage: SetPartitions(3).list()                                                 #␣
↪needs sage.graphs
[{{1, 2, 3}}, {{1, 2}, {3}}, {{1, 3}, {2}}, {{1}, {2, 3}}, {{1}, {2}, {3}}]
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).list()                                           ␣
↪      # needs sage.graphs
[{{1, 2, 3}}, {{1, 2}, {3}}, {{1, 3}, {2}}, {{1}, {2, 3}}, {{1}, {2}, {3}}]
```

There are 6 set partitions of $\{1, 2, 3, 4\}$ whose underlying partition is $[2, 1, 1]$:

```
sage: SetPartitions(4, [2,1,1]).list()                                        #␣
↪needs sage.graphs sage.rings.finite_rings
[{{1}, {2, 4}, {3}},
 {{1}, {2}, {3, 4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}},
 {{1}, {2, 3}, {4}}]
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(4), [Integer(2),Integer(1),Integer(1)]).list()       ␣
↪                               # needs sage.graphs sage.rings.finite_rings
[{{1}, {2, 4}, {3}},
 {{1}, {2}, {3, 4}},
 {{1, 4}, {2}, {3}},
 {{1, 3}, {2}, {4}},
 {{1, 2}, {3}, {4}},
 {{1}, {2, 3}, {4}}]
```

Since Issue #14140, we can create a set partition directly by `SetPartition`, which creates the base set by taking the union of the parts passed in:

```
sage: s = SetPartition([[1,3],[2,4]]); s
{{1, 3}, {2, 4}}
sage: s.parent()
Set partitions
```

```
>>> from sage.all import *
>>> s = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]); s
{{1, 3}, {2, 4}}
>>> s.parent()
Set partitions
```

apply_permutation(*p*)

Apply `p` to the underlying set of `self`.

INPUT:

- `p` – a permutation

EXAMPLES:

```
sage: x = SetPartition([[1,2], [3,5,4]])
sage: p = Permutation([2,1,4,5,3])
sage: x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
sage: q = Permutation([3,2,1,5,4])
sage: x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}

sage: m = PerfectMatching([(1,4),(2,6),(3,5)])
sage: m.apply_permutation(Permutation([4,1,5,6,3,2]))
[(1, 2), (3, 5), (4, 6)]
```

```
>>> from sage.all import *
>>> x = SetPartition([[Integer(1),Integer(2)], [Integer(3),Integer(5),
↪Integer(4)]])
>>> p = Permutation([Integer(2),Integer(1),Integer(4),Integer(5),Integer(3)])
>>> x.apply_permutation(p)
{{1, 2}, {3, 4, 5}}
>>> q = Permutation([Integer(3),Integer(2),Integer(1),Integer(5),Integer(4)])
>>> x.apply_permutation(q)
{{1, 4, 5}, {2, 3}}

>>> m = PerfectMatching([(Integer(1),Integer(4)),(Integer(2),Integer(6)),
↪(Integer(3),Integer(5))])
>>> m.apply_permutation(Permutation([Integer(4),Integer(1),Integer(5),
↪Integer(6),Integer(3),Integer(2)]))
[(1, 2), (3, 5), (4, 6)]
```

arcs()

Return `self` as a list of arcs.

Assuming that the blocks are sorted, the arcs are the pairs of consecutive elements in the blocks.

EXAMPLES:

```
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.arcs()
[(2, 3)]
sage: B = SetPartition([[1,3,6,7],[2,5],[4]])
sage: B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)],[Integer(2),Integer(3)],[Integer(4)]])
>>> A.arcs()
[(2, 3)]
>>> B = SetPartition([[Integer(1),Integer(3),Integer(6),Integer(7)],
↪[Integer(2),Integer(5)],[Integer(4)]])
```

(continues on next page)

(continued from previous page)

```
>>> B.arcs()
[(1, 3), (3, 6), (6, 7), (2, 5)]
```

cardinality()

Return the `len` of `self`.

EXAMPLES:

```
sage: from sage.structure.list_clone_demo import IncreasingArrays
sage: len(IncreasingArrays()([1,2,3]))
3
```

```
>>> from sage.all import *
>>> from sage.structure.list_clone_demo import IncreasingArrays
>>> len(IncreasingArrays()([Integer(1),Integer(2),Integer(3)]))
3
```

check()

Check that we are a valid set partition.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1, 3], [2, 4]])
sage: s.check()
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.check()
```

closers()

Return the maximal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.closers()
[7, 8, 9, 12, 13]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.closers()
[7, 8, 9, 12, 13]
```

crossings()

Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns a list of the pairs of crossing lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.crossings()
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> p.crossings()
[((1, 4), (2, 5)), ((1, 4), (3, 6)), ((2, 5), (3, 6)), ((3, 6), (5, 7))]
```

crossings_iterator()

Return the crossing arcs of a set partition on a totally ordered set.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of crossing lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: next(p.crossings_iterator())
((1, 4), (2, 5))
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> next(p.crossings_iterator())
((1, 4), (2, 5))
```

is_atomic()

Return if `self` is an atomic set partition.

A (standard) set partition A can be split if there exist $j < i$ such that $\max(A_j) < \min(A_i)$ where A is ordered by minimal elements. This means we can write $A = B|C$ for some nonempty set partitions B and C. We call a set partition *atomic* if it cannot be split and is nonempty. Here, the pipe symbol | is as defined in method `pipe()`.

EXAMPLES:

```
sage: SetPartition([[1,3], [2]]).is_atomic()
True
sage: SetPartition([[1,3], [2], [4]]).is_atomic()
False
sage: SetPartition([[1], [2,4], [3]]).is_atomic()
False
sage: SetPartition([[1,2,3,4]]).is_atomic()
True
sage: SetPartition([[1, 4], [2], [3]]).is_atomic()
True
sage: SetPartition([]).is_atomic()
False
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)], [Integer(2)]]).is_atomic()
True
>>> SetPartition([[Integer(1),Integer(3)], [Integer(2)], [Integer(4)]]).is_
↪atomic()
False
>>> SetPartition([[Integer(1)], [Integer(2),Integer(4)], [Integer(3)]]).is_
↪atomic()
False
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).is_atomic()
True
>>> SetPartition([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)]]).is_
↪atomic()
True
>>> SetPartition([]).is_atomic()
False
```

is_noncrossing()

Check if `self` is noncrossing.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns `True` if the picture obtained this way has no crossings.

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.is_noncrossing()
False

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_noncrossing()
False
sage: PerfectMatching([(1, 4), (2, 3), (5, 6)]).is_noncrossing()
True
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> p.is_noncrossing()
False

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.is_noncrossing()
False
>>> PerfectMatching([(Integer(1), Integer(4)), (Integer(2), Integer(3)),␣
↪(Integer(5), Integer(6))]).is_noncrossing()
True
```

is_nonnesting()

Return if `self` is nonnesting or not.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns `True` if the picture obtained this way has no nestings.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.is_nonnesting()
False
sage: PerfectMatching([(1, 3), (2, 5), (4, 6)]).is_nonnesting()
True
```

```
>>> from sage.all import *
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.is_nonnesting()
False
>>> PerfectMatching([(Integer(1), Integer(3)), (Integer(2), Integer(5)),␣
↪(Integer(4), Integer(6))]).is_nonnesting()
True
```

latex_options()

Return the latex options for use in the `_latex_` function as a dictionary. The default values are set using the global options.

Options can be found in *set_latex_options()*

EXAMPLES:

```
sage: SP = SetPartition([[1,6], [3,5,4]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}
```

```
>>> from sage.all import *
>>> SP = SetPartition([[Integer(1),Integer(6)], [Integer(3),Integer(5),
↪Integer(4)]]); SP.latex_options()
{'angle': 0,
 'color': 'black',
 'fill': False,
 'plot': None,
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 1}
```

nestings()

Return the nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the list of the pairs of nesting lines (as a line correspond to a pair, it returns a list of pairs of pairs).

EXAMPLES:

```
sage: m = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: m.nestings()
[((1, 6), (3, 5)), ((2, 7), (3, 5))]

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.nestings()
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

```
>>> from sage.all import *
>>> m = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),␣
↪(Integer(3), Integer(5)), (Integer(4), Integer(8))])
>>> m.nestings()
[((1, 6), (3, 5)), ((2, 7), (3, 5))]

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.nestings()
[((2, 8), (4, 7)), ((2, 8), (5, 6)), ((4, 7), (5, 6))]
```

nestings_iterator()

Iterate over the nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns an iterator over the pairs of nesting lines (as a line correspond to a pair, the iterator produces pairs of pairs).

EXAMPLES:

```
sage: n = PerfectMatching([(1, 6), (2, 7), (3, 5), (4, 8)])
sage: it = n.nestings_iterator()
sage: next(it)
((1, 6), (3, 5))
sage: next(it)
((2, 7), (3, 5))
sage: next(it)
Traceback (most recent call last):
...
StopIteration
```

```
>>> from sage.all import *
>>> n = PerfectMatching([(Integer(1), Integer(6)), (Integer(2), Integer(7)),␣
```

(continues on next page)

(continued from previous page)

```
↪(Integer(3), Integer(5)), (Integer(4), Integer(8))])
>>> it = n.nestings_iterator()
>>> next(it)
((1, 6), (3, 5))
>>> next(it)
((2, 7), (3, 5))
>>> next(it)
Traceback (most recent call last):
...
StopIteration
```

number_of_crossings()

Return the number of crossings.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of crossing lines.

EXAMPLES:

```
sage: p = SetPartition([[1,4],[2,5,7],[3,6]])
sage: p.number_of_crossings()
4

sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

```
>>> from sage.all import *
>>> p = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(5),
↪Integer(7)],[Integer(3),Integer(6)]])
>>> p.number_of_crossings()
4

>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.number_of_crossings()
1
```

number_of_nestings()

Return the number of nestings of `self`.

OUTPUT:

We place the elements of the ground set in order on a line and draw the set partition by linking consecutive elements of each block in the upper half-plane. This function returns the number the pairs of nesting lines.

EXAMPLES:

```
sage: n = PerfectMatching([3,8,1,7,6,5,4,2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
```

(continues on next page)

(continued from previous page)

```
sage: n.number_of_nestings()
3
```

```
>>> from sage.all import *
>>> n = PerfectMatching([Integer(3),Integer(8),Integer(1),Integer(7),
↪Integer(6),Integer(5),Integer(4),Integer(2)]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
>>> n.number_of_nestings()
3
```

openers()

Return the minimal elements of the blocks.

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.openers()
[1, 3, 5, 8, 12]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.openers()
[1, 3, 5, 8, 12]
```

ordered_set_partition_action(*s*)

Return the action of an ordered set partition `s` on `self`.

Let $A = \{A_1, A_2, \ldots, A_k\}$ be a set partition of some set S and s be an ordered set partition (i.e., set composition) of a subset of $[k]$. Let $A^{\downarrow}$ denote the standardization of A, and $A_{\{i_1,i_2,\ldots,i_m\}}$ denote the sub-partition $\{A_{i_1}, A_{i_2}, \ldots, A_{i_m}\}$ for any subset $\{i_1, \ldots, i_m\}$ of $\{1, \ldots, k\}$. We define the set partition $s(A)$ by

$$s(A) = A^{\downarrow}_{s_1} | A^{\downarrow}_{s_2} | \cdots | A^{\downarrow}_{s_q}.$$

where $s = (s_1, s_2, \ldots, s_q)$. Here, the pipe symbol | is as defined in method `pipe()`.

This is $s[A]$ in section 2.3 in [LM2011].

INPUT:

- `s` – an ordered set partition with base set a subset of $\{1, \ldots, k\}$

EXAMPLES:

```
sage: A = SetPartition([[1], [2,4], [3]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
sage: s = OrderedSetPartition([[2,3], [1]])
sage: A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(4)], [Integer(3)]])
>>> s = OrderedSetPartition([[Integer(1),Integer(3)], [Integer(2)]])
>>> A.ordered_set_partition_action(s)
{{1}, {2}, {3, 4}}
>>> s = OrderedSetPartition([[Integer(2),Integer(3)], [Integer(1)]])
>>> A.ordered_set_partition_action(s)
{{1, 3}, {2}, {4}}
```

We create Figure 1 in [LM2011] (we note that there is a typo in the lower-left corner of the table in the published version of the paper, whereas the arXiv version gives the correct partition):

```
sage: A = SetPartition([[1,3], [2,9], [4,5,8], [7]])
sage: B = SetPartition([[1,3], [2,8], [4,5,6], [7]])
sage: C = SetPartition([[1,5], [2,8], [3,4,6], [7]])
sage: s = OrderedSetPartition([[1,3], [2]])
sage: t = OrderedSetPartition([[2], [3,4]])
sage: u = OrderedSetPartition([[1], [2,3,4]])
sage: A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
sage: A.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
sage: B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
sage: B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
sage: C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
sage: C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
sage: C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1),Integer(3)], [Integer(2),Integer(9)],
→[Integer(4),Integer(5),Integer(8)], [Integer(7)]])
>>> B = SetPartition([[Integer(1),Integer(3)], [Integer(2),Integer(8)],
→[Integer(4),Integer(5),Integer(6)], [Integer(7)]])
>>> C = SetPartition([[Integer(1),Integer(5)], [Integer(2),Integer(8)],
→[Integer(3),Integer(4),Integer(6)], [Integer(7)]])
>>> s = OrderedSetPartition([[Integer(1),Integer(3)], [Integer(2)]])
>>> t = OrderedSetPartition([[Integer(2)], [Integer(3),Integer(4)]])
>>> u = OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3),
→Integer(4)]])
>>> A.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
>>> A.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 6}, {5}}
>>> A.ordered_set_partition_action(u)
```

(continues on next page)

(continued from previous page)

```
{{1, 2}, {3, 8}, {4, 5, 7}, {6}}
>>> B.ordered_set_partition_action(s)
{{1, 2}, {3, 4, 5}, {6, 7}}
>>> B.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
>>> B.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
>>> C.ordered_set_partition_action(s)
{{1, 4}, {2, 3, 5}, {6, 7}}
>>> C.ordered_set_partition_action(t)
{{1, 2}, {3, 4, 5}, {6}}
>>> C.ordered_set_partition_action(u)
{{1, 2}, {3, 8}, {4, 5, 6}, {7}}
```

REFERENCES:

- [LM2011]

pipe(*other*)

Return the pipe of the set partitions `self` and `other`.

The pipe of two set partitions is defined as follows:

For any integer k and any subset I of $\mathbf{Z}$, let $I + k$ denote the subset of $\mathbf{Z}$ obtained by adding k to every element of k.

If B and C are set partitions of $[n]$ and $[m]$, respectively, then the pipe of B and C is defined as the set partition

$$\{B_1, B_2, \ldots, B_b, C_1 + n, C_2 + n, \ldots, C_c + n\}$$

of $[n + m]$, where $B = \{B_1, B_2, \ldots, B_b\}$ and $C = \{C_1, C_2, \ldots, C_c\}$. This pipe is denoted by $B|C$.

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).pipe(SetPartition([[1,3],[2]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
sage: SetPartition([]).pipe(SetPartition([[1,2],[3,5],[4]]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3,5],[4]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
sage: SetPartition([[1,2],[3]]).pipe(SetPartition([[1]]))
{{1, 2}, {3}, {4}}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]).
↪pipe(SetPartition([[Integer(1),Integer(3)],[Integer(2)]]))
{{1, 3}, {2, 4}, {5, 7}, {6}}
>>> SetPartition([]).pipe(SetPartition([[Integer(1),Integer(2)],[Integer(3),
↪Integer(5)],[Integer(4)]]))
{{1, 2}, {3, 5}, {4}}
>>> SetPartition([[Integer(1),Integer(2)],[Integer(3),Integer(5)],
↪[Integer(4)]]).pipe(SetPartition([]))
{{1, 2}, {3, 5}, {4}}
>>> SetPartition([[Integer(1),Integer(2)],[Integer(3)]]).
```

(continues on next page)

(continued from previous page)

```
↪pipe(SetPartition([[Integer(1)]]))
{{1, 2}, {3}, {4}}
```

plot(*angle=None*, *color='black'*, *base_set_dict=None*)

Return a plot of `self`.

INPUT:

- `angle` – (default: $\pi/4$) the angle at which the arcs take off (if angle is negative, the arcs are drawn below the horizontal line)
- `color` – (default: `'black'`) color of the arcs
- `base_set_dict` – (optional) dictionary with keys elements of `base_set()` and values as integer or float

EXAMPLES:

```
sage: p = SetPartition([[1,10,11],[2,3,7],[4,5,6],[8,9]])
sage: p.plot()                                                        #␣

Text 'd' at the point (-2.3,-0.1)
Text 'e' at the point (5.4,-0.1)
Arc with center (-0.6...,-1.65) radii (2.3334523779...,2.3334523779...)
 angle 0.0 inside the sector (0.785398163397...,2.35619449019...)
Arc with center (1.0,-1.0) radii (1.4142135623...,1.4142135623...)
 angle 0.0 inside the sector (0.785398163397...,2.35619449019...)
```

refinements()

Return a list of refinements of `self`.

See also

`coarsenings()`

EXAMPLES:

```
sage: SetPartition([[1,3],[2,4]]).refinements()                          #␣
↪needs sage.graphs sage.libs.flint
[{{1, 3}, {2, 4}},
 {{1, 3}, {2}, {4}},
```

(continues on next page)

(continued from previous page)

```
 {{1}, {2, 4}, {3}},
 {{1}, {2}, {3}, {4}}]
sage: SetPartition([[1],[2,4],[3]]).refinements()                          #␣
↪needs sage.graphs sage.libs.flint
[{{1}, {2, 4}, {3}}, {{1}, {2}, {3}, {4}}]
sage: SetPartition([]).refinements()                                       #␣
↪needs sage.graphs sage.libs.flint
[{}]
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]).
↪refinements()                                # needs sage.graphs sage.libs.
↪flint
[{{1, 3}, {2, 4}},
 {{1, 3}, {2}, {4}},
 {{1}, {2, 4}, {3}},
 {{1}, {2}, {3}, {4}}]
>>> SetPartition([[Integer(1)],[Integer(2),Integer(4)],[Integer(3)]]).
↪refinements()                               # needs sage.graphs sage.libs.flint
[{{1}, {2, 4}, {3}}, {{1}, {2}, {3}, {4}}]
>>> SetPartition([]).refinements()                                         #␣
↪needs sage.graphs sage.libs.flint
[{}]
```

restriction(*I*)

Return the restriction of `self` to a subset `I` (which is given as a set or list or any other iterable).

EXAMPLES:

```
sage: A = SetPartition([[1], [2,3]])
sage: A.restriction([1,2])
{{1}, {2}}
sage: A.restriction([2,3])
{{2, 3}}
sage: A.restriction([])
{}
sage: A.restriction([4])
{}
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(3)]])
>>> A.restriction([Integer(1),Integer(2)])
{{1}, {2}}
>>> A.restriction([Integer(2),Integer(3)])
{{2, 3}}
>>> A.restriction([])
{}
>>> A.restriction([Integer(4)])
{}
```

set_latex_options(***kwargs*)

Set the latex options for use in the `_latex_` function.

- tikz_scale – (default: 1) scale for use with tikz package
- plot – (default: None) None returns the set notation, linear returns a linear plot, cyclic returns a cyclic plot
- color – (default: 'black') the arc colors
- fill – boolean (default: False); if True then fills color, else you can pass in a color to alter the fill color - *only works with cyclic plot*
- show_labels – boolean (default: True); if True shows labels (*only works with plots*)
- radius – (default: '1cm') radius of circle for cyclic plot - *only works with cyclic plot*
- angle – (default: 0) angle for linear plot

EXAMPLES:

```
sage: SP = SetPartition([[1,6], [3,5,4]])
sage: SP.set_latex_options(tikz_scale=2,plot='linear',fill=True,color='blue',
↪angle=45)
sage: SP.set_latex_options(plot='cyclic')
sage: SP.latex_options()
{'angle': 45,
 'color': 'blue',
 'fill': True,
 'plot': 'cyclic',
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 2}
```

```
>>> from sage.all import *
>>> SP = SetPartition([[Integer(1),Integer(6)], [Integer(3),Integer(5),
↪Integer(4)]])
>>> SP.set_latex_options(tikz_scale=Integer(2),plot='linear',fill=True,color=
↪'blue',angle=Integer(45))
>>> SP.set_latex_options(plot='cyclic')
>>> SP.latex_options()
{'angle': 45,
 'color': 'blue',
 'fill': True,
 'plot': 'cyclic',
 'radius': '1cm',
 'show_labels': True,
 'tikz_scale': 2}
```

shape()

Return the integer partition whose parts are the sizes of the sets in self.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
```

(continues on next page)

(continued from previous page)

```
sage: y.shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(5))
>>> x = S([[Integer(1),Integer(2)], [Integer(3),Integer(5),Integer(4)]])
>>> x.shape()
[3, 2]
>>> y = S([[Integer(2)], [Integer(3),Integer(1)], [Integer(5),Integer(4)]])
>>> y.shape()
[2, 2, 1]
```

shape_partition()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(5))
>>> x = S([[Integer(1),Integer(2)], [Integer(3),Integer(5),Integer(4)]])
>>> x.shape()
[3, 2]
>>> y = S([[Integer(2)], [Integer(3),Integer(1)], [Integer(5),Integer(4)]])
>>> y.shape()
[2, 2, 1]
```

size()

Return the cardinality of the base set of `self`, which is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of a set partition.

EXAMPLES:

```
sage: SetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: SetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(1)], [Integer(2),Integer(3)], [Integer(4)]]).base_
↪set_cardinality()
4
>>> SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_set_
↪cardinality()
4
```

standardization()

Return the standardization of `self`.

Given a set partition $A = \{A_1, \ldots, A_n\}$ of an ordered set S, the standardization of A is the set partition of $\{1, 2, \ldots, |S|\}$ obtained by replacing the elements of the parts of A by the integers $1, 2, \ldots, |S|$ in such a way that their relative order is preserved (i. e., the smallest element in the whole set partition is replaced by 1, the next-smallest by 2, and so on).

EXAMPLES:

```
sage: SetPartition([[4], [1, 3]]).standardization()
{{1, 2}, {3}}
sage: SetPartition([[4], [6, 3]]).standardization()
{{1, 3}, {2}}
sage: SetPartition([]).standardization()
{}
sage: SetPartition([('c','b'),('d','f'),('e','a')]).standardization()
{{1, 5}, {2, 3}, {4, 6}}
```

```
>>> from sage.all import *
>>> SetPartition([[Integer(4)], [Integer(1), Integer(3)]]).standardization()
{{1, 2}, {3}}
>>> SetPartition([[Integer(4)], [Integer(6), Integer(3)]]).standardization()
{{1, 3}, {2}}
>>> SetPartition([]).standardization()
{}
>>> SetPartition([('c','b'),('d','f'),('e','a')]).standardization()
{{1, 5}, {2, 3}, {4, 6}}
```

strict_coarsenings()

Return all strict coarsenings of `self`.

Strict coarsening is the binary relation on set partitions defined as the transitive-and-reflexive closure of the relation $\prec$ defined as follows: For two set partitions A and B, we have $A \prec B$ if there exist parts A_i, A_j of A such that $\max(A_i) < \min(A_j)$ and $B = A \setminus \{A_i, A_j\} \cup \{A_i \cup A_j\}$.

EXAMPLES:

```
sage: A = SetPartition([[1],[2,3],[4]])
sage: A.strict_coarsenings()
[{{1}, {2, 3}, {4}}, {{1, 2, 3}, {4}}, {{1, 4}, {2, 3}},
 {{1}, {2, 3, 4}}, {{1, 2, 3, 4}}]
sage: SetPartition([[1],[2,4],[3]]).strict_coarsenings()
[{{1}, {2, 4}, {3}}, {{1, 2, 4}, {3}}, {{1, 3}, {2, 4}}]
sage: SetPartition([]).strict_coarsenings()
[{}]
```

```
>>> from sage.all import *
>>> A = SetPartition([[Integer(1)],[Integer(2),Integer(3)],[Integer(4)]])
>>> A.strict_coarsenings()
[{{1}, {2, 3}, {4}}, {{1, 2, 3}, {4}}, {{1, 4}, {2, 3}},
 {{1}, {2, 3, 4}}, {{1, 2, 3, 4}}]
>>> SetPartition([[Integer(1)],[Integer(2),Integer(4)],[Integer(3)]]).strict_
↪coarsenings()
[{{1}, {2, 4}, {3}}, {{1, 2, 4}, {3}}, {{1, 3}, {2, 4}}]
```

(continues on next page)

(continued from previous page)

```
>>> SetPartition([]).strict_coarsenings()
[{}]
```

to_partition()

Return the integer partition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = SetPartitions(5)
sage: x = S([[1,2], [3,5,4]])
sage: x.shape()
[3, 2]
sage: y = S([[2], [3,1], [5,4]])
sage: y.shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(5))
>>> x = S([[Integer(1),Integer(2)], [Integer(3),Integer(5),Integer(4)]])
>>> x.shape()
[3, 2]
>>> y = S([[Integer(2)], [Integer(3),Integer(1)], [Integer(5),Integer(4)]])
>>> y.shape()
[2, 2, 1]
```

to_permutation()

Convert a set partition of $\{1, ..., n\}$ to a permutation by considering the blocks of the partition as cycles.

The cycles are such that the number of excedences is maximised, that is, each cycle is of the form $(a_1, a_2, ..., a_k)$ with $a_1 < a_2 < ... < a_k$.

EXAMPLES:

```
sage: s = SetPartition([[1,3],[2,4]])
sage: s.to_permutation()
[3, 4, 1, 2]
```

```
>>> from sage.all import *
>>> s = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> s.to_permutation()
[3, 4, 1, 2]
```

to_restricted_growth_word(*bijection='blocks'*)

Convert a set partition of $\{1, ..., n\}$ to a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before.

INPUT:

- `bijection` – (default: `blocks`) defines the map from set partitions to restricted growth functions. These are currently:
  - `blocks`: *to_restricted_growth_word_blocks()*.
  - `intertwining`: *to_restricted_growth_word_intertwining()*.

OUTPUT: a restricted growth word

See also:

SetPartitions.from_restricted_growth_word()

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word()
[0, 1, 2, 0, 2, 2, 3, 1, 2]

sage: P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]

sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_restricted_growth_word()
[0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2]

sage: P.to_restricted_growth_word("intertwining")
[0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
→[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_restricted_growth_word()
[0, 1, 2, 0, 2, 2, 3, 1, 2]

>>> P.to_restricted_growth_word("intertwining")
[0, 1, 2, 2, 1, 0, 3, 3, 2]

>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
→[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
→Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.to_restricted_growth_word()
[0, 0, 1, 0, 2, 2, 0, 3, 1, 2, 2, 4, 2]

>>> P.to_restricted_growth_word("intertwining")
[0, 0, 1, 1, 2, 0, 1, 3, 3, 3, 0, 4, 1]
```

to_restricted_growth_word_blocks()

Convert a set partition of $\{1, ..., n\}$ to a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before.

The word is obtained by sorting the blocks by their minimal element and setting the letters at the positions of the elements in the i-th block to i.

OUTPUT: a restricted growth word

See also:

to_restricted_growth_word() SetPartitions.from_restricted_growth_word()

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_restricted_growth_word_blocks()
[0, 1, 2, 0, 2, 2, 3, 1, 2]
```

to_restricted_growth_word_intertwining()

Convert a set partition of $\{1, ..., n\}$ to a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before.

The i-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at i, with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

OUTPUT: a restricted growth word

See also

to_restricted_growth_word() SetPartitions.from_restricted_growth_word()

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_restricted_growth_word_intertwining()
[0, 1, 2, 2, 1, 0, 3, 3, 2]
```

to_rook_placement(*bijection='arcs'*)

Return a set of pairs defining a placement of non-attacking rooks on a triangular board.

The cells of the board corresponding to a set partition of $\{1, ..., n\}$ are the pairs (i, j) with $0 < i < j < n+1$.

INPUT:

- `bijection` – (default: `arcs`) defines the bijection from set partitions to rook placements. These are currently:
  - `arcs`: *arcs()*
  - `gamma`: *to_rook_placement_gamma()*
  - `rho`: *to_rook_placement_rho()*
  - `psi`: *to_rook_placement_psi()*

See also

SetPartitions.from_rook_placement()

EXAMPLES:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
sage: P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
sage: P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
sage: P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> P.to_rook_placement()
[(1, 2), (2, 4), (4, 7), (3, 9), (5, 6), (6, 10), (10, 11), (11, 13)]
>>> P.to_rook_placement("gamma")
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
>>> P.to_rook_placement("rho")
[(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11, 13)]
>>> P.to_rook_placement("psi")
[(1, 2), (2, 6), (3, 4), (5, 9), (6, 7), (7, 10), (9, 11), (11, 13)]
```

to_rook_placement_gamma()

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the left column. If $n+1-i$ is an opener, column i remains empty. Otherwise, we place a rook into column i, such that the number of cells below the rook, which are not yet attacked by another rook, equals the index of the block to which $n+1-i$ belongs.

OUTPUT: list of coordinates

See also

- *to_rook_placement()*
- *SetPartitions.from_rook_placement()*
- *SetPartitions.from_rook_placement_gamma()*

EXAMPLES:

```
sage: P = SetPartition([[1,4],[2,8],[3,5,6,9],[7]])
sage: P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(4)],[Integer(2),Integer(8)],
↪[Integer(3),Integer(5),Integer(6),Integer(9)],[Integer(7)]])
>>> P.to_rook_placement_gamma()
[(1, 3), (2, 7), (4, 5), (5, 6), (6, 9)]
```

Figure 5 in [WW1991]:

```
sage: P = SetPartition([[1,2,4,7],[3,9],[5,6,10,11,13],[8],[12]])
sage: r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1),Integer(2),Integer(4),Integer(7)],
↪[Integer(3),Integer(9)],[Integer(5),Integer(6),Integer(10),Integer(11),
↪Integer(13)],[Integer(8)],[Integer(12)]])
>>> r = P.to_rook_placement_gamma(); r
[(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12, 13)]
```

to_rook_placement_psi()

Return the rook diagram obtained by placing rooks according to Yip's bijection psi.

OUTPUT: list of coordinates

See also

- *to_rook_placement()*
- *SetPartitions.from_rook_placement()*
- *SetPartitions.from_rook_placement_psi()*

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018]:

```
sage: P = SetPartition([[1, 5], [2], [3, 8, 9], [4], [6, 7]])
sage: P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

```
>>> from sage.all import *
>>> P = SetPartition([[Integer(1), Integer(5)], [Integer(2)], [Integer(3),␣
↪Integer(8), Integer(9)], [Integer(4)], [Integer(6), Integer(7)]])
>>> P.to_rook_placement_psi()
[(1, 7), (3, 8), (4, 5), (7, 9)]
```

Note that the columns corresponding to the minimal elements of the blocks remain empty.

to_rook_placement_rho()

Return the rook diagram obtained by placing rooks according to Wachs and White's bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

The algorithm proceeds as follows: non-attacking rooks are placed beginning at the top row. The columns corresponding to the closers of the set partition remain empty. Let rs_j be the number of closers which are larger than j and whose block is before the block of j.

We then place a rook into row j, such that the number of cells to the left of the rook, which are not yet attacked by another rook and are not in a column corresponding to a closer, equals rs_j, unless there are not enough cells in this row available, in which case the row remains empty.

One can show that the precisely those rows which correspond to openers of the set partition remain empty.

OUTPUT: list of coordinates

↪Integer(14)))
True
```

class sage.combinat.set_partition.**SetPartitions**

Bases: UniqueRepresentation, Parent

An (unordered) partition of a set S is a set of pairwise disjoint nonempty subsets with union S, and is represented by a sorted list of such subsets.

`SetPartitions(s)` returns the class of all set partitions of the set `s`, which can be given as a set or a string; if a string, each character is considered an element.

`SetPartitions(n)`, where `n` is an integer, returns the class of all set partitions of the set $\{1, 2, \ldots, n\}$.

You may specify a second argument k. If k is an integer, *SetPartitions* returns the class of set partitions into k parts; if it is an integer partition, *SetPartitions* returns the class of set partitions whose block sizes correspond to that integer partition.

The Bell number B_n, named in honor of Eric Temple Bell, is the number of different partitions of a set with n elements.

EXAMPLES:

```
sage: S = [1,2,3,4]
sage: SetPartitions(S, 2)
Set partitions of {1, 2, 3, 4} with 2 parts
sage: SetPartitions([1,2,3,4], [3,1]).list()                              #␣
↪needs sage.graphs sage.rings.finite_rings
[{{1}, {2, 3, 4}}, {{1, 2, 3}, {4}}, {{1, 2, 4}, {3}}, {{1, 3, 4}, {2}}]
sage: SetPartitions(7, [3,3,1]).cardinality()                             #␣
↪needs sage.libs.flint
70
```

```
>>> from sage.all import *
>>> S = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> SetPartitions(S, Integer(2))
Set partitions of {1, 2, 3, 4} with 2 parts
>>> SetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)], [Integer(3),
↪Integer(1)]).list()                              # needs sage.graphs sage.
↪rings.finite_rings
[{{1}, {2, 3, 4}}, {{1, 2, 3}, {4}}, {{1, 2, 4}, {3}}, {{1, 3, 4}, {2}}]
>>> SetPartitions(Integer(7), [Integer(3),Integer(3),Integer(1)]).cardinality()  ␣
↪                              # needs sage.libs.flint
70
```

In strings, repeated letters are not considered distinct as of Issue #14140:

```
sage: SetPartitions('abcde').cardinality()                                #␣
↪needs sage.libs.flint
52
sage: SetPartitions('aabcd').cardinality()                                #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.libs.flint
15
```

```
>>> from sage.all import *
>>> SetPartitions('abcde').cardinality()                                    #␣
↪needs sage.libs.flint
52
>>> SetPartitions('aabcd').cardinality()                                    #␣
↪needs sage.libs.flint
15
```

If the number of parts exceeds the length of the set, an empty iterator is returned (Issue #37643):

```
sage: SetPartitions(range(3), 4).list()
[]
sage: SetPartitions('abcd', 6).list()
[]
```

```
>>> from sage.all import *
>>> SetPartitions(range(Integer(3)), Integer(4)).list()
[]
>>> SetPartitions('abcd', Integer(6)).list()
[]
```

- Wikipedia article Partition_of_a_set

Element

alias of *SetPartition*

from_arcs(*arcs*, *n*)

Return the coarsest set partition of $\{1, ..., n\}$ such that any two elements connected by an arc are in the same block.

INPUT:

- `n` – integer specifying the size of the set partition to be produced
- `arcs` – list of pairs specifying which elements are in the same block

See also

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.arcs()*

EXAMPLES:

```
sage: SetPartitions().from_arcs([(2,3)], 5)
{{1}, {2, 3}, {4}, {5}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_arcs([(Integer(2),Integer(3))], Integer(5))
{{1}, {2, 3}, {4}, {5}}
```

from_restricted_growth_word(*w*, *bijection='blocks'*)

Convert a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, ..., n\}$.

INPUT:

- `w` – a restricted growth word
- `bijection` – (default: `blocks`) defines the map from restricted growth functions to set partitions. These are currently:
  - `blocks`: .
  - `intertwining`: *from_restricted_growth_word_intertwining()*.

OUTPUT: a set partition

See also

SetPartition.to_restricted_growth_word()

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word([0, 1, 2, 0, 2, 2, 3, 1, 2])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

sage: SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1,␣
↪2, 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}

sage: SetPartitions().from_restricted_growth_word([0, 0, 1, 0, 2, 2, 0, 3, 1,␣
↪2, 2, 4, 2], "intertwining")
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_restricted_growth_word([Integer(0), Integer(1),␣
↪Integer(2), Integer(0), Integer(2), Integer(2), Integer(3), Integer(1),␣
↪Integer(2)])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

>>> SetPartitions().from_restricted_growth_word([Integer(0), Integer(0),␣
↪Integer(1), Integer(0), Integer(2), Integer(2), Integer(0), Integer(3),␣
↪Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}

>>> SetPartitions().from_restricted_growth_word([Integer(0), Integer(0),␣
↪Integer(1), Integer(0), Integer(2), Integer(2), Integer(0), Integer(3),␣
↪Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)], "intertwining")
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_restricted_growth_word_blocks(*w*)

Convert a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, ..., n\}$.

`w[i]` is the index of the block containing `i+1` when sorting the blocks by their minimal element.

INPUT:

- `w` – a restricted growth word

OUTPUT: a set partition

See also

from_restricted_growth_word() SetPartition.to_restricted_growth_word()

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word_blocks([0, 0, 1, 0, 2, 2, 0,
→ 3, 1, 2, 2, 4, 2])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_restricted_growth_word_blocks([Integer(0),␣
→Integer(0), Integer(1), Integer(0), Integer(2), Integer(2), Integer(0),␣
→Integer(3), Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_restricted_growth_word_intertwining(*w*)

Convert a word of length n with letters in the nonnegative integers such that each letter is at most 1 larger than all the letters before to a set partition of $\{1, ..., n\}$.

The i-th letter of the word is the numbers of crossings of the arc (or half-arc) in the extended arc diagram ending at i, with arcs (or half-arcs) beginning at a smaller element and ending at a larger element.

INPUT:

- `w` – a restricted growth word

OUTPUT: a set partition

See also

from_restricted_growth_word() SetPartition.to_restricted_growth_word()

EXAMPLES:

```
sage: SetPartitions().from_restricted_growth_word_intertwining([0, 0, 1, 0, 2,
→ 2, 0, 3, 1, 2, 2, 4, 2])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_restricted_growth_word_intertwining([Integer(0),␣
→Integer(0), Integer(1), Integer(0), Integer(2), Integer(2), Integer(0),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(3), Integer(1), Integer(2), Integer(2), Integer(4), Integer(2)])
{{1, 2, 6, 7, 9}, {3, 4}, {5, 10, 13}, {8, 11}, {12}}
```

from_rook_placement(*rooks*, *bijection='arcs'*, *n=None*)

Convert a rook placement of the triangular grid to a set partition of $\{1, ..., n\}$.

If `n` is not given, it is first checked whether it can be determined from the parent, otherwise it is the maximal occurring integer in the set of rooks.

INPUT:

- `rooks` – list of pairs (i, j) satisfying $0 < i < j < n + 1$
- `bijection` – (default: `arcs`) defines the map from rook placements to set partitions. These are currently:
  - `arcs`: *from_arcs()*.
  - `gamma`: *from_rook_placement_gamma()*.
  - `rho`: *from_rook_placement_rho()*.
  - `psi`: *from_rook_placement_psi()*.
- `n` – (optional) the size of the ground set

See also

SetPartition.to_rook_placement()

EXAMPLES:

```
sage: SetPartitions(9).from_rook_placement([[1,4],[2,8],[3,5],[5,6],[6,9]])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

sage: SetPartitions(13).from_rook_placement([[12,13],[10,12],[8,9],[7,11],[5,
↪8],[4,6],[3,5],[1,4]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(9)).from_rook_placement([[Integer(1),Integer(4)],
↪[Integer(2),Integer(8)],[Integer(3),Integer(5)],[Integer(5),Integer(6)],
↪[Integer(6),Integer(9)]])
{{1, 4}, {2, 8}, {3, 5, 6, 9}, {7}}

>>> SetPartitions(Integer(13)).from_rook_placement([[Integer(12),Integer(13)],
↪[Integer(10),Integer(12)],[Integer(8),Integer(9)],[Integer(7),Integer(11)],
↪[Integer(5),Integer(8)],[Integer(4),Integer(6)],[Integer(3),Integer(5)],
↪[Integer(1),Integer(4)]], "gamma")
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_gamma(*rooks*, *n*)

Return the set partition of $\{1, ..., n\}$ corresponding to the given rook placement by applying Wachs and White's bijection gamma.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

INPUT:

- n – integer specifying the size of the set partition to be produced
- rooks – list of pairs (i, j) such that $0 < i < j < n + 1$

OUTPUT: a set partition

See also:

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.to_rook_placement_gamma()*

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 4), (3, 5), (4, 6), (5, 8), (7, 11), (8, 9), (10, 12), (12,
→13)]
```

```
>>> from sage.all import *
>>> r = [(Integer(1), Integer(4)), (Integer(3), Integer(5)), (Integer(4),
→Integer(6)), (Integer(5), Integer(8)), (Integer(7), Integer(11)),
→(Integer(8), Integer(9)), (Integer(10), Integer(12)), (Integer(12),
→Integer(13))]
```

Note that the rook $(1, 4)$, translated into Wachs and White's convention, is a rook in row 4 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_gamma(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_rook_placement_gamma(r, Integer(13))
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

from_rook_placement_psi(*rooks*, *n*)

Return the set partition of $\{1, ..., n\}$ corresponding to the given rook placement by applying Yip's bijection psi.

INPUT:

- n – integer specifying the size of the set partition to be produced
- rooks – list of pairs (i, j) such that $0 < i < j < n + 1$

OUTPUT: a set partition

See also:

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.to_rook_placement_psi()*

EXAMPLES:

Example 36 (arXiv version: Example 4.5) in [Yip2018] concerns the following rook placement:

```
sage: r = [(4,5), (1,7), (3, 8), (7,9)]
sage: SetPartitions().from_rook_placement_psi(r, 9)
{{1, 5}, {2}, {3, 8, 9}, {4}, {6, 7}}
```

```
>>> from sage.all import *
>>> r = [(Integer(4),Integer(5)), (Integer(1),Integer(7)), (Integer(3),
↪Integer(8)), (Integer(7),Integer(9))]
>>> SetPartitions().from_rook_placement_psi(r, Integer(9))
{{1, 5}, {2}, {3, 8, 9}, {4}, {6, 7}}
```

from_rook_placement_rho(*rooks*, *n*)

Return the set partition of $\{1, ..., n\}$ corresponding to the given rook placement by applying Wachs and White's bijection rho.

Note that our index convention differs from the convention in [WW1991]: regarding the rook board as a lower-right triangular grid, we refer with (i, j) to the cell in the i-th column from the right and the j-th row from the top.

INPUT:

- `n` – integer specifying the size of the set partition to be produced
- `rooks` – list of pairs (i, j) such that $0 < i < j < n + 1$

OUTPUT: a set partition

See also

- *from_rook_placement()*
- *SetPartition.to_rook_placement()*
- *SetPartition.to_rook_placement_rho()*

EXAMPLES:

Figure 5 in [WW1991] concerns the following rook placement:

```
sage: r = [(1, 2), (2, 6), (3, 4), (4, 10), (5, 9), (6, 7), (10, 11), (11,
↪13)]
```

```
>>> from sage.all import *
>>> r = [(Integer(1), Integer(2)), (Integer(2), Integer(6)), (Integer(3),
↪Integer(4)), (Integer(4), Integer(10)), (Integer(5), Integer(9)),
↪(Integer(6), Integer(7)), (Integer(10), Integer(11)), (Integer(11),
↪Integer(13))]
```

Note that the rook $(1, 2)$, translated into Wachs and White's convention, is a rook in row 2 from the top and column 13 from the left. The corresponding set partition is:

```
sage: SetPartitions().from_rook_placement_rho(r, 13)
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

```
>>> from sage.all import *
>>> SetPartitions().from_rook_placement_rho(r, Integer(13))
{{1, 2, 4, 7}, {3, 9}, {5, 6, 10, 11, 13}, {8}, {12}}
```

is_less_than(*s*, *t*)

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> t = S([[Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)]])
>>> S.is_less_than(t, s)
True
>>> S.is_less_than(s, t)
False
>>> S.is_less_than(s, s)
False
```

is_strict_refinement(*s*, *t*)

Return `True` if `s` is a strict refinement of `t` and satisfies $s \neq t$.

A set partition s is said to be a strict refinement of a set partition t of the same set if and only if one can obtain t from s by repeatedly combining pairs of parts whose convex hulls don't intersect (i. e., whenever we are combining two parts, the maximum of each of them should be smaller than the minimum of the other).

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1],[2],[3],[4]])
sage: t = S([[1,3],[2,4]])
sage: u = S([[1,2,3,4]])
sage: S.is_strict_refinement(s, t)
```

(continues on next page)

(continued from previous page)

```
True
sage: S.is_strict_refinement(t, u)
False
sage: A = SetPartition([[1,3],[2,4]])
sage: B = SetPartition([[1,2,3,4]])
sage: S.is_strict_refinement(s, A)
True
sage: S.is_strict_refinement(t, B)
False
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)]])
>>> t = S([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> u = S([[Integer(1),Integer(2),Integer(3),Integer(4)]])
>>> S.is_strict_refinement(s, t)
True
>>> S.is_strict_refinement(t, u)
False
>>> A = SetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> B = SetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]])
>>> S.is_strict_refinement(s, A)
True
>>> S.is_strict_refinement(t, B)
False
```

lt (*s*, *t*)

Check if $s < t$ in the refinement ordering on set partitions.

This means that s is a refinement of t and satisfies $s \neq t$.

A set partition s is said to be a refinement of a set partition t of the same set if and only if each part of s is a subset of a part of t.

EXAMPLES:

```
sage: S = SetPartitions(4)
sage: s = S([[1,3],[2,4]])
sage: t = S([[1],[2],[3],[4]])
sage: S.is_less_than(t, s)
True
sage: S.is_less_than(s, t)
False
sage: S.is_less_than(s, s)
False
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(4))
>>> s = S([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> t = S([[Integer(1)],[Integer(2)],[Integer(3)],[Integer(4)]])
>>> S.is_less_than(t, s)
True
>>> S.is_less_than(s, t)
```

(continues on next page)

(continued from previous page)

```
False
>>> S.is_less_than(s, s)
False
```

class sage.combinat.set_partition.**SetPartitions_all**

Bases: *SetPartitions*

All set partitions.

subset (*size=None*, ***kwargs*)

Return the subset of set partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = SetPartitions()
sage: P.subset(4)
Set partitions of {1, 2, 3, 4}
```

```
>>> from sage.all import *
>>> P = SetPartitions()
>>> P.subset(Integer(4))
Set partitions of {1, 2, 3, 4}
```

class sage.combinat.set_partition.**SetPartitions_set** (*s*)

Bases: *SetPartitions*

Set partitions of a fixed set S.

base_set ()

Return the base set of `self`.

EXAMPLES:

```
sage: SetPartitions(3).base_set()
{1, 2, 3}

sage: sorted(SetPartitions(["a", "b", "c"]).base_set())
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).base_set()
{1, 2, 3}

>>> sorted(SetPartitions(["a", "b", "c"]).base_set())
['a', 'b', 'c']
```

base_set_cardinality ()

Return the cardinality of the base set of `self`.

EXAMPLES:

```
sage: SetPartitions(3).base_set_cardinality()
3
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3)).base_set_cardinality()
3
```

cardinality()

Return the number of set partitions of the set S.

The cardinality is given by the n-th Bell number where n is the number of elements in the set S.

EXAMPLES:

```
sage: # needs sage.libs.flint
sage: SetPartitions([1,2,3,4]).cardinality()
15
sage: SetPartitions(3).cardinality()
5
sage: SetPartitions(3,2).cardinality()
3
sage: SetPartitions([]).cardinality()
1
```

```
>>> from sage.all import *
>>> # needs sage.libs.flint
>>> SetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)]).cardinality()
15
>>> SetPartitions(Integer(3)).cardinality()
5
>>> SetPartitions(Integer(3),Integer(2)).cardinality()
3
>>> SetPartitions([]).cardinality()
1
```

random_element()

Return a random set partition.

This is a very naive implementation of Knuths outline in F3B, 7.2.1.5.

EXAMPLES:

```
sage: S = SetPartitions(10)
sage: s = S.random_element()                                                  #␣
↪needs sage.symbolic
sage: s.parent() is S                                                         #␣
↪needs sage.symbolic
True
sage: assert s in S, s                                                        #␣
↪needs sage.symbolic

sage: S = SetPartitions(["a", "b", "c"])
sage: s = S.random_element()                                                  #␣
↪needs sage.symbolic
sage: s.parent() is S                                                         #␣
↪needs sage.symbolic
True
```

(continues on next page)

(continued from previous page)

```
sage: assert s in S, s                                                          #␣
↪needs sage.symbolic
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10))
>>> s = S.random_element()                                                      #␣
↪needs sage.symbolic
>>> s.parent() is S                                                             #␣
↪needs sage.symbolic
True
>>> assert s in S, s                                                            #␣
↪needs sage.symbolic

>>> S = SetPartitions(["a", "b", "c"])
>>> s = S.random_element()                                                      #␣
↪needs sage.symbolic
>>> s.parent() is S                                                             #␣
↪needs sage.symbolic
True
>>> assert s in S, s                                                            #␣
↪needs sage.symbolic
```

class sage.combinat.set_partition.**SetPartitions_setn**(s, k)

Bases: *SetPartitions_set*

Set partitions with a given number of blocks.

cardinality()

The Stirling number of the second kind is the number of partitions of a set of size n into k blocks.

EXAMPLES:

```
sage: SetPartitions(5, 3).cardinality()
25
sage: stirling_number2(5,3)
25
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(5), Integer(3)).cardinality()
25
>>> stirling_number2(Integer(5),Integer(3))
25
```

number_of_blocks()

Return the number of blocks of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, 3).number_of_blocks()
3
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(5), Integer(3)).number_of_blocks()
3
```

random_element()

Return a random set partition of `self`.

See https://mathoverflow.net/questions/141999.

EXAMPLES:

```
sage: S = SetPartitions(10, 4)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

sage: S = SetPartitions(["a", "b", "c"], 2)
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10), Integer(4))
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s

>>> S = SetPartitions(["a", "b", "c"], Integer(2))
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s
```

class sage.combinat.set_partition.**SetPartitions_setparts**(*s*, *parts*)

Bases: *SetPartitions_set*

Set partitions with fixed partition sizes corresponding to an integer partition λ.

cardinality()

Return the cardinality of `self`.

This algorithm counts for each block of the partition the number of ways to fill it using values from the set. Then, for each distinct value v of block size, we divide the result by the number of ways to arrange the blocks of size v in the set partition.

For example, if we want to count the number of set partitions of size 13 having [3,3,3,2,2] as underlying partition we compute the number of ways to fill each block of the partition, which is $\binom{13}{3}\binom{10}{3}\binom{7}{3}\binom{4}{2}\binom{2}{2}$ and as we have three blocks of size 3 and two blocks of size 2, we divide the result by 3!2! which gives us 600600.

EXAMPLES:

```
sage: SetPartitions(3, [2,1]).cardinality()
3
```

(continues on next page)

(continued from previous page)

```
sage: SetPartitions(13, Partition([3,3,3,2,2])).cardinality()
600600
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(3), [Integer(2),Integer(1)]).cardinality()
3
>>> SetPartitions(Integer(13), Partition([Integer(3),Integer(3),Integer(3),
↪Integer(2),Integer(2)])).cardinality()
600600
```

random_element()

Return a random set partition of `self`.

ALGORITHM:

Based on the cardinality method. For each block size k_i, we choose a uniformly random subset $X_i \subseteq S_i$ of size k_i of the elements S_i that have not yet been selected. Thus, we define $S_{i+1} = S_i \setminus X_i$ with $S_i = S$ being the defining set. This is not yet proven to be uniformly distributed, but numerical tests show this is likely uniform.

EXAMPLES:

```
sage: S = SetPartitions(10, [4,3,2,1])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s

sage: S = SetPartitions(["a", "b", "c", "d"], [2,2])
sage: s = S.random_element()
sage: s.parent() is S
True
sage: assert s in S, s
```

```
>>> from sage.all import *
>>> S = SetPartitions(Integer(10), [Integer(4),Integer(3),Integer(2),
↪Integer(1)])
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s

>>> S = SetPartitions(["a", "b", "c", "d"], [Integer(2),Integer(2)])
>>> s = S.random_element()
>>> s.parent() is S
True
>>> assert s in S, s
```

shape()

Return the partition of block sizes of the set partitions in `self`.

EXAMPLES:

```
sage: SetPartitions(5, [2,2,1]).shape()
[2, 2, 1]
```

```
>>> from sage.all import *
>>> SetPartitions(Integer(5), [Integer(2),Integer(2),Integer(1)]).shape()
[2, 2, 1]
```

sage.combinat.set_partition.**cyclic_permutations_of_set_partition**(*set_part*)

Return all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_partition
sage: cyclic_permutations_of_set_partition([[1,2,3,4],[5,6,7]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition import cyclic_permutations_of_set_partition
>>> cyclic_permutations_of_set_partition([[Integer(1),Integer(2),Integer(3),
↪Integer(4)],[Integer(5),Integer(6),Integer(7)]])
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

sage.combinat.set_partition.**cyclic_permutations_of_set_partition_iterator**(*set_part*)

Iterate over all combinations of cyclic permutations of each cell of the set partition.

AUTHORS:

- Robert L. Miller

EXAMPLES:

```
sage: from sage.combinat.set_partition import cyclic_permutations_of_set_
↪partition_iterator
sage: list(cyclic_permutations_of_set_partition_iterator([[1,2,3,4],[5,6,7]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition import cyclic_permutations_of_set_partition_
↪iterator
>>> list(cyclic_permutations_of_set_partition_iterator([[Integer(1),Integer(2),
↪Integer(3),Integer(4)],[Integer(5),Integer(6),Integer(7)]]))
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```

5.1.278 Fast set partition iterators

sage.combinat.set_partition_iterator.**set_partition_iterator**(*base_set*)

A fast iterator for the set partitions of the base set, which returns lists of lists instead of set partitions types.

EXAMPLES:

```
sage: from sage.combinat.set_partition_iterator import set_partition_iterator
sage: list(set_partition_iterator([1,-1,x]))                              #␣
↪needs sage.symbolic
[[[1, -1, x]],
 [[1, -1], [x]],
 [[1, x], [-1]],
 [[1], [-1, x]],
 [[1], [-1], [x]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_iterator import set_partition_iterator
```

(continues on next page)

(continued from previous page)

```
>>> list(set_partition_iterator([Integer(1),-Integer(1),x]))                   ␣
↪                # needs sage.symbolic
[[[1, -1, x]],
 [[1, -1], [x]],
 [[1, x], [-1]],
 [[1], [-1, x]],
 [[1], [-1], [x]]]
```

sage.combinat.set_partition_iterator.**set_partition_iterator_blocks**(*base_set*, *k*)

A fast iterator for the set partitions of the base set into the specified number of blocks, which returns lists of lists instead of set partitions types.

EXAMPLES:

```
sage: from sage.combinat.set_partition_iterator import set_partition_iterator_
↪blocks
sage: list(set_partition_iterator_blocks([1,-1,x], 2))                        #␣
↪needs sage.symbolic
[[[1, x], [-1]], [[1], [-1, x]], [[1, -1], [x]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_iterator import set_partition_iterator_blocks
>>> list(set_partition_iterator_blocks([Integer(1),-Integer(1),x], Integer(2)))  ␣
↪                         # needs sage.symbolic
[[[1, x], [-1]], [[1], [-1, x]], [[1, -1], [x]]]
```

5.1.279 Ordered Set Partitions

AUTHORS:

- Mike Hansen
- MuPAD-Combinat developers (for algorithms and design inspiration)
- Travis Scrimshaw (2013-02-28): Removed `CombinatorialClass` and added entry point through *OrderedSetPartition*.

class sage.combinat.set_partition_ordered.**OrderedSetPartition**(*parent*, *s*, *check=True*)

Bases: `ClonableArray`

An ordered partition of a set.

An ordered set partition p of a set s is a list of pairwise disjoint nonempty subsets of s such that the union of these subsets is s. These subsets are called the parts of the partition.

We represent an ordered set partition as a list of sets. By extension, an ordered set partition of a nonnegative integer n is the set partition of the integers from 1 to n. The number of ordered set partitions of n is called the n-th ordered Bell number.

There is a natural integer composition associated with an ordered set partition, that is the sequence of sizes of all its parts in order.

The number T_n of ordered set partitions of $\{1, 2, \ldots, n\}$ is the so-called n-th *Fubini number* (also known as the n-th ordered Bell number; see Wikipedia article Ordered Bell number). Its exponential generating function is

$$\sum_n \frac{T_n}{n!} x^n = \frac{1}{2 - e^x}.$$

(See sequence OEIS sequence A000670 in OEIS.)

INPUT:

- `parts` – an object or iterable that defines an ordered set partition (e.g., a list of pairwise disjoint sets) or a packed word (e.g., a list of letters on some alphabet). If there is ambiguity and if the input should be treated as a packed word, the keyword `from_word` should be used.

EXAMPLES:

There are 13 ordered set partitions of $\{1, 2, 3\}$:

```
sage: OrderedSetPartitions(3).cardinality()
13
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(3)).cardinality()
13
```

Here is the list of them:

```
sage: OrderedSetPartitions(3).list()
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(3)).list()
[[{1}, {2}, {3}],
 [{1}, {3}, {2}],
 [{2}, {1}, {3}],
 [{3}, {1}, {2}],
 [{2}, {3}, {1}],
 [{3}, {2}, {1}],
 [{1}, {2, 3}],
 [{2}, {1, 3}],
 [{3}, {1, 2}],
 [{1, 2}, {3}],
 [{1, 3}, {2}],
 [{2, 3}, {1}],
 [{1, 2, 3}]]
```

There are 12 ordered set partitions of $\{1, 2, 3, 4\}$ whose underlying composition is $[1, 2, 1]$:

```
sage: OrderedSetPartitions(4,[1,2,1]).list()
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(4),[Integer(1),Integer(2),Integer(1)]).list()
[[{1}, {2, 3}, {4}],
 [{1}, {2, 4}, {3}],
 [{1}, {3, 4}, {2}],
 [{2}, {1, 3}, {4}],
 [{2}, {1, 4}, {3}],
 [{3}, {1, 2}, {4}],
 [{4}, {1, 2}, {3}],
 [{3}, {1, 4}, {2}],
 [{4}, {1, 3}, {2}],
 [{2}, {3, 4}, {1}],
 [{3}, {2, 4}, {1}],
 [{4}, {2, 3}, {1}]]
```

Since Issue #14140, we can create an ordered set partition directly by `OrderedSetPartition` which creates the parent object by taking the union of the partitions passed in. However it is recommended and (marginally) faster to create the parent first and then create the ordered set partition from that.

```
sage: s = OrderedSetPartition([[1,3],[2,4]]); s
[{1, 3}, {2, 4}]
sage: s.parent()
Ordered set partitions of {1, 2, 3, 4}
```

```
>>> from sage.all import *
>>> s = OrderedSetPartition([[Integer(1),Integer(3)],[Integer(2),Integer(4)]]); s
[{1, 3}, {2, 4}]
>>> s.parent()
Ordered set partitions of {1, 2, 3, 4}
```

We can construct the ordered set partition from a word, which we consider as packed:

```
sage: OrderedSetPartition([2,4,1,2])
[{3}, {1, 4}, {2}]
sage: OrderedSetPartition(from_word=[2,4,1,2])
[{3}, {1, 4}, {2}]
sage: OrderedSetPartition(from_word='bdab')
[{3}, {1, 4}, {2}]
```

```
>>> from sage.all import *
>>> OrderedSetPartition([Integer(2),Integer(4),Integer(1),Integer(2)])
[{3}, {1, 4}, {2}]
>>> OrderedSetPartition(from_word=[Integer(2),Integer(4),Integer(1),Integer(2)])
[{3}, {1, 4}, {2}]
>>> OrderedSetPartition(from_word='bdab')
[{3}, {1, 4}, {2}]
```

Warning

The elements of the underlying set should be hashable.

REFERENCES:

Wikipedia article Ordered_partition_of_a_set

base_set()

Return the base set of `self`.

This is the union of all parts of `self`.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set()
frozenset({1, 2, 3, 4})
sage: OrderedSetPartition([[1,2,3,4]]).base_set()
frozenset({1, 2, 3, 4})
sage: OrderedSetPartition([]).base_set()
frozenset()
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],
→[Integer(4)]]).base_set()
frozenset({1, 2, 3, 4})
>>> OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_
→set()
frozenset({1, 2, 3, 4})
>>> OrderedSetPartition([]).base_set()
frozenset()
```

base_set_cardinality()

Return the cardinality of the base set of `self`.

This is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of an ordered set partition.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4)]]).base_set_cardinality()
4
>>> OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_
↪set_cardinality()
4
```

static bottom_up_osp(*X*, *comp*)

Return the ordered set partition obtained by listing the elements of the set `X` in increasing order, and placing bars between some of them according to the integer composition `comp` (namely, the bars are placed in such a way that the lengths of the resulting blocks are exactly the entries of `comp`).

INPUT:

- `X` – a finite set (or list or tuple)
- `comp` – a composition whose sum is the size of `X` (can be given as a list or tuple or composition)

EXAMPLES:

```
sage: buo = OrderedSetPartition.bottom_up_osp
sage: buo(Set([1, 4, 7, 9]), [2, 1, 1])
[{1, 4}, {7}, {9}]
sage: buo(Set([1, 4, 7, 9]), [1, 3])
[{1}, {4, 7, 9}]
sage: buo(Set([1, 4, 7, 9]), [1, 1, 1, 1])
[{1}, {4}, {7}, {9}]
sage: buo(range(8), [1, 4, 2, 1])
[{0}, {1, 2, 3, 4}, {5, 6}, {7}]
sage: buo([], [])
[]
```

```
>>> from sage.all import *
>>> buo = OrderedSetPartition.bottom_up_osp
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(2),␣
↪Integer(1), Integer(1)])
[{1, 4}, {7}, {9}]
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(1),␣
↪Integer(3)])
[{1}, {4, 7, 9}]
>>> buo(Set([Integer(1), Integer(4), Integer(7), Integer(9)]), [Integer(1),␣
↪Integer(1), Integer(1), Integer(1)])
[{1}, {4}, {7}, {9}]
>>> buo(range(Integer(8)), [Integer(1), Integer(4), Integer(2), Integer(1)])
[{0}, {1, 2, 3, 4}, {5, 6}, {7}]
>>> buo([], [])
[]
```

check()

Check that we are a valid ordered set partition.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.check()
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions(Integer(4))
>>> s = OS([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.check()
```

complement()

Return the complement of the ordered set partition `self`.

This assumes that `self` is an ordered set partition of an interval of $\mathbf{Z}$.

Let $(P_1, P_2, \ldots, P_k)$ be an ordered set partition of some interval I of $\mathbf{Z}$. Let ω be the unique strictly decreasing bijection $I \to I$. Then, the *complement* of $(P_1, P_2, \ldots, P_k)$ is defined to be the ordered set partition $(\omega(P_1), \omega(P_2), \ldots, \omega(P_k))$.

EXAMPLES:

```
sage: OrderedSetPartition([[1, 2], [3]]).complement()
[{2, 3}, {1}]
sage: OrderedSetPartition([[1, 3], [2]]).complement()
[{1, 3}, {2}]
sage: OrderedSetPartition([[2, 3]]).complement()
[{2, 3}]
sage: OrderedSetPartition([[1, 5], [2, 3], [4]]).complement()
[{1, 5}, {3, 4}, {2}]
sage: OrderedSetPartition([[-1], [-2], [1, 2], [0]]).complement()
[{1}, {2}, {-2, -1}, {0}]
sage: OrderedSetPartition([]).complement()
[]
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1), Integer(2)], [Integer(3)]]).complement()
[{2, 3}, {1}]
>>> OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).complement()
[{1, 3}, {2}]
>>> OrderedSetPartition([[Integer(2), Integer(3)]]).complement()
[{2, 3}]
>>> OrderedSetPartition([[Integer(1), Integer(5)], [Integer(2), Integer(3)],
↪[Integer(4)]]).complement()
[{1, 5}, {3, 4}, {2}]
>>> OrderedSetPartition([[-Integer(1)], [-Integer(2)], [Integer(1),
↪Integer(2)], [Integer(0)]]).complement()
[{1}, {2}, {-2, -1}, {0}]
>>> OrderedSetPartition([]).complement()
[]
```

fatten(*grouping*)

Return the ordered set partition fatter than `self`, obtained by grouping together consecutive parts according to the integer composition `grouping`.

See *finer()* for the definition of "fatter".

INPUT:

- `grouping` – a composition whose sum is the length of `self`

EXAMPLES:

Let us start with the ordered set partition:

```
sage: c = OrderedSetPartition([[2, 5], [1], [3, 4]])
```

```
>>> from sage.all import *
>>> c = OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1)],␣
↪[Integer(3), Integer(4)]])
```

With `grouping` equal to $(1, \dots, 1)$, c is left unchanged:

```
sage: c.fatten(Composition([1,1,1]))
[{2, 5}, {1}, {3, 4}]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(1),Integer(1),Integer(1)]))
[{2, 5}, {1}, {3, 4}]
```

With `grouping` equal to (ℓ) where ℓ is the length of c, this yields the coarsest ordered set partition above c:

```
sage: c.fatten(Composition([3]))
[{1, 2, 3, 4, 5}]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(3)]))
[{1, 2, 3, 4, 5}]
```

Other values for `grouping` yield (all the) other ordered set partitions coarser than c:

```
sage: c.fatten(Composition([2,1]))
[{1, 2, 5}, {3, 4}]
sage: c.fatten(Composition([1,2]))
[{2, 5}, {1, 3, 4}]
```

```
>>> from sage.all import *
>>> c.fatten(Composition([Integer(2),Integer(1)]))
[{1, 2, 5}, {3, 4}]
>>> c.fatten(Composition([Integer(1),Integer(2)]))
[{2, 5}, {1, 3, 4}]
```

fatter()

Return the set of ordered set partitions which are fatter than `self`.

See *finer()* for the definition of "fatter".

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).fatter()
sage: C.cardinality()
4
```

(continues on next page)

(continued from previous page)

```
sage: sorted(C)
[[{2, 5}, {1}, {3, 4}],
 [{2, 5}, {1, 3, 4}],
 [{1, 2, 5}, {3, 4}],
 [{1, 2, 3, 4, 5}]]

sage: OrderedSetPartition([[4, 9], [-1, 2]]).fatter().list()
[[{4, 9}, {-1, 2}], [{-1, 2, 4, 9}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1)],␣
↪[Integer(3), Integer(4)]]).fatter()
>>> C.cardinality()
4
>>> sorted(C)
[[{2, 5}, {1}, {3, 4}],
 [{2, 5}, {1, 3, 4}],
 [{1, 2, 5}, {3, 4}],
 [{1, 2, 3, 4, 5}]]

>>> OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),␣
↪Integer(2)]]).fatter().list()
[[{4, 9}, {-1, 2}], [{-1, 2, 4, 9}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).fatter())
[[{5}]]
sage: list(Composition([]).fatter())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
```

```
>>> from sage.all import *
>>> list(OrderedSetPartition([[Integer(5)]]).fatter())
[[{5}]]
>>> list(Composition([]).fatter())
[[]]
>>> sorted(OrderedSetPartition([[Integer(1)], [Integer(2)], [Integer(3)],␣
↪[Integer(4)]]).fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
```

(continues on next page)

(continued from previous page)

```
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
```

finer()

Return the set of ordered set partitions which are finer than `self`.

See *is_finer()* for the definition of "finer".

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).finer()
sage: C.cardinality()
3
sage: C.list()
[[{1}, {3}, {2}], [{3}, {1}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).finer()
{[]}

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.finer().list()
[[{9}, {4}, {2}, {-1}],
 [{9}, {4}, {-1}, {2}],
 [{9}, {4}, {-1, 2}],
 [{4}, {9}, {2}, {-1}],
 [{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {2}, {-1}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).finer()
>>> C.cardinality()
3
>>> C.list()
[[{1}, {3}, {2}], [{3}, {1}, {2}], [{1, 3}, {2}]]

>>> OrderedSetPartition([]).finer()
{[]}

>>> W = OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),
↪Integer(2)]])
>>> W.finer().list()
[[{9}, {4}, {2}, {-1}],
 [{9}, {4}, {-1}, {2}],
 [{9}, {4}, {-1, 2}],
 [{4}, {9}, {2}, {-1}],
 [{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {2}, {-1}],
 [{4, 9}, {-1}, {2}],
```

(continues on next page)

(continued from previous page)

```
[{4, 9}, {-1, 2}]]
```

is_finer(*co2*)

Return `True` if the ordered set partition `self` is finer than the ordered set partition `co2`; otherwise, return `False`.

If A and B are two ordered set partitions of the same set, then A is said to be *finer* than B if B can be obtained from A by (repeatedly) merging consecutive parts. In this case, we say that B is *fatter* than A.

EXAMPLES:

```
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_finer(B)
False
sage: B.is_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_finer(C)
False
sage: C.is_finer(A)
True
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_finer(OrderedSetPartition([[2,␣
↪5], [1, 4]]))
False
```

```
>>> from sage.all import *
>>> A = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]])
>>> B = OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)]])
>>> A.is_finer(B)
False
>>> B.is_finer(A)
True
>>> C = OrderedSetPartition([[Integer(3)], [Integer(1)], [Integer(2)]])
>>> A.is_finer(C)
False
>>> C.is_finer(A)
True
>>> OrderedSetPartition([[Integer(2)], [Integer(5)], [Integer(1)],␣
↪[Integer(4)]]).is_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(5)], [Integer(2)], [Integer(1)],␣
↪[Integer(4)]]).is_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
```

(continues on next page)

(continued from previous page)

```
↪[Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(2)], [Integer(1)], [Integer(5)],␣
↪[Integer(4)]]).is_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2), Integer(5), Integer(1)], [Integer(4)]]).
↪is_finer(OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1),␣
↪Integer(4)]]))
False
```

is_strongly_finer(*co2*)

Return `True` if the ordered set partition `self` is strongly finer than the ordered set partition `co2`; otherwise, return `False`.

If A and B are two ordered set partitions of the same set, then A is said to be *strongly finer* than B if B can be obtained from A by (repeatedly) merging consecutive parts, provided that every time we merge two consecutive parts C_i and C_{i+1}, we have $\max C_i < \min C_{i+1}$. In this case, we say that B is *strongly fatter* than A.

EXAMPLES:

```
sage: A = OrderedSetPartition([[1, 3], [2]])
sage: B = OrderedSetPartition([[1], [3], [2]])
sage: A.is_strongly_finer(B)
False
sage: B.is_strongly_finer(A)
True
sage: C = OrderedSetPartition([[3], [1], [2]])
sage: A.is_strongly_finer(C)
False
sage: C.is_strongly_finer(A)
False
sage: OrderedSetPartition([[2], [5], [1], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
True
sage: OrderedSetPartition([[5], [2], [1], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2], [1], [5], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
sage: OrderedSetPartition([[2, 5, 1], [4]]).is_strongly_
↪finer(OrderedSetPartition([[2, 5], [1, 4]]))
False
```

```
>>> from sage.all import *
>>> A = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]])
>>> B = OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)]])
>>> A.is_strongly_finer(B)
False
>>> B.is_strongly_finer(A)
True
```

(continues on next page)

(continued from previous page)

```
>>> C = OrderedSetPartition([[Integer(3)], [Integer(1)], [Integer(2)]])
>>> A.is_strongly_finer(C)
False
>>> C.is_strongly_finer(A)
False
>>> OrderedSetPartition([[Integer(2)], [Integer(5)], [Integer(1)],␣
↪[Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2),␣
↪Integer(5)], [Integer(1), Integer(4)]]))
True
>>> OrderedSetPartition([[Integer(5)], [Integer(2)], [Integer(1)],␣
↪[Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2),␣
↪Integer(5)], [Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2)], [Integer(1)], [Integer(5)],␣
↪[Integer(4)]]).is_strongly_finer(OrderedSetPartition([[Integer(2),␣
↪Integer(5)], [Integer(1), Integer(4)]]))
False
>>> OrderedSetPartition([[Integer(2), Integer(5), Integer(1)], [Integer(4)]]).
↪is_strongly_finer(OrderedSetPartition([[Integer(2), Integer(5)],␣
↪[Integer(1), Integer(4)]]))
False
```

length()

Return the number of parts of `self`.

EXAMPLES:

```
sage: OS = OrderedSetPartitions(4)
sage: s = OS([[1, 3], [2, 4]])
sage: s.length()
2
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions(Integer(4))
>>> s = OS([[Integer(1), Integer(3)], [Integer(2), Integer(4)]])
>>> s.length()
2
```

number_of_inversions()

Return the number of inversions in `self`.

An inversion of an ordered set partition with blocks $[B_1, B_2, \ldots, B_k]$ is a pair of letters i and j with $i < j$ such that i is minimal in B_m, $j \in B_l$, and $l < m$.

REFERENCES:

- [Wilson2016]

EXAMPLES:

```
sage: OrderedSetPartition([{2,5},{4,6},{1,3}]).number_of_inversions()
5
sage: OrderedSetPartition([{1,3,8},{2,4},{5,6,7}]).number_of_inversions()
3
```

```
>>> from sage.all import *
>>> OrderedSetPartition([{Integer(2),Integer(5)},{Integer(4),Integer(6)},
↪{Integer(1),Integer(3)}]).number_of_inversions()
5
>>> OrderedSetPartition([{Integer(1),Integer(3),Integer(8)},{Integer(2),
↪Integer(4)},{Integer(5),Integer(6),Integer(7)}]).number_of_inversions()
3
```

reversed()

Return the reversal of the ordered set partition `self`.

The *reversal* of an ordered set partition $(P_1, P_2, \ldots, P_k)$ is defined to be the ordered set partition $(P_k, P_{k-1}, \ldots, P_1)$.

EXAMPLES:

```
sage: OrderedSetPartition([[1, 3], [2]]).reversed()
[{2}, {1, 3}]
sage: OrderedSetPartition([[1, 5], [2, 4]]).reversed()
[{2, 4}, {1, 5}]
sage: OrderedSetPartition([[-1], [-2], [3, 4], [0]]).reversed()
[{0}, {3, 4}, {-2}, {-1}]
sage: OrderedSetPartition([]).reversed()
[]
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).reversed()
[{2}, {1, 3}]
>>> OrderedSetPartition([[Integer(1), Integer(5)], [Integer(2), Integer(4)]]).
↪reversed()
[{2, 4}, {1, 5}]
>>> OrderedSetPartition([[-Integer(1)], [-Integer(2)], [Integer(3),␣
↪Integer(4)], [Integer(0)]]).reversed()
[{0}, {3, 4}, {-2}, {-1}]
>>> OrderedSetPartition([]).reversed()
[]
```

size()

Return the cardinality of the base set of `self`.

This is the sum of the sizes of the parts of `self`.

This is also known as the *size* (sometimes the *weight*) of an ordered set partition.

EXAMPLES:

```
sage: OrderedSetPartition([[1], [2,3], [4]]).base_set_cardinality()
4
sage: OrderedSetPartition([[1,2,3,4]]).base_set_cardinality()
4
```

```
>>> from sage.all import *
>>> OrderedSetPartition([[Integer(1)], [Integer(2),Integer(3)],␣
↪[Integer(4)]]).base_set_cardinality()
```

(continues on next page)

(continued from previous page)

```
4
>>> OrderedSetPartition([[Integer(1),Integer(2),Integer(3),Integer(4)]]).base_
↪set_cardinality()
4
```

strongly_fatter()

Return the set of ordered set partitions which are strongly fatter than `self`.

See *strongly_finer()* for the definition of "strongly fatter".

EXAMPLES:

```
sage: C = OrderedSetPartition([[2, 5], [1], [3, 4]]).strongly_fatter()
sage: C.cardinality()
2
sage: sorted(C)
[[{2, 5}, {1}, {3, 4}], [{2, 5}, {1, 3, 4}]]

sage: OrderedSetPartition([[4, 9], [-1, 2]]).strongly_fatter().list()
[[{4, 9}, {-1, 2}]]
```

```
>>> from sage.all import *
>>> C = OrderedSetPartition([[Integer(2), Integer(5)], [Integer(1)],
↪[Integer(3), Integer(4)]]).strongly_fatter()
>>> C.cardinality()
2
>>> sorted(C)
[[{2, 5}, {1}, {3, 4}], [{2, 5}, {1, 3, 4}]]

>>> OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),
↪Integer(2)]]).strongly_fatter().list()
[[{4, 9}, {-1, 2}]]
```

Some extreme cases:

```
sage: list(OrderedSetPartition([[5]]).strongly_fatter())
[[{5}]]
sage: list(OrderedSetPartition([]).strongly_fatter())
[[]]
sage: sorted(OrderedSetPartition([[1], [2], [3], [4]]).strongly_fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
sage: sorted(OrderedSetPartition([[1], [3], [2], [4]]).strongly_fatter())
[[{1}, {3}, {2}, {4}],
 [{1}, {3}, {2, 4}],
 [{1, 3}, {2}, {4}],
 [{1, 3}, {2, 4}]]
```

(continues on next page)

(continued from previous page)

```
sage: sorted(OrderedSetPartition([[4], [1], [5], [3]]).strongly_fatter())
[[{4}, {1}, {5}, {3}], [{4}, {1, 5}, {3}]]
```

```
>>> from sage.all import *
>>> list(OrderedSetPartition([[Integer(5)]]).strongly_fatter())
[[{5}]]
>>> list(OrderedSetPartition([]).strongly_fatter())
[[]]
>>> sorted(OrderedSetPartition([[Integer(1)], [Integer(2)], [Integer(3)],␣
↪[Integer(4)]]).strongly_fatter())
[[{1}, {2}, {3}, {4}],
 [{1}, {2}, {3, 4}],
 [{1}, {2, 3}, {4}],
 [{1}, {2, 3, 4}],
 [{1, 2}, {3}, {4}],
 [{1, 2}, {3, 4}],
 [{1, 2, 3}, {4}],
 [{1, 2, 3, 4}]]
>>> sorted(OrderedSetPartition([[Integer(1)], [Integer(3)], [Integer(2)],␣
↪[Integer(4)]]).strongly_fatter())
[[{1}, {3}, {2}, {4}],
 [{1}, {3}, {2, 4}],
 [{1, 3}, {2}, {4}],
 [{1, 3}, {2, 4}]]
>>> sorted(OrderedSetPartition([[Integer(4)], [Integer(1)], [Integer(5)],␣
↪[Integer(3)]]).strongly_fatter())
[[{4}, {1}, {5}, {3}], [{4}, {1, 5}, {3}]]
```

strongly_finer()

Return the set of ordered set partitions which are strongly finer than `self`.

See *is_strongly_finer()* for the definition of "strongly finer".

EXAMPLES:

```
sage: C = OrderedSetPartition([[1, 3], [2]]).strongly_finer()
sage: C.cardinality()
2
sage: C.list()
[[{1}, {3}, {2}], [{1, 3}, {2}]]

sage: OrderedSetPartition([]).strongly_finer()
{[]}

sage: W = OrderedSetPartition([[4, 9], [-1, 2]])
sage: W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

```
>>> from sage.all import *
```

(continues on next page)

(continued from previous page)

```
>>> C = OrderedSetPartition([[Integer(1), Integer(3)], [Integer(2)]]).
↪strongly_finer()
>>> C.cardinality()
2
>>> C.list()
[[{1}, {3}, {2}], [{1, 3}, {2}]]

>>> OrderedSetPartition([]).strongly_finer()
{[]}

>>> W = OrderedSetPartition([[Integer(4), Integer(9)], [-Integer(1),␣
↪Integer(2)]])
>>> W.strongly_finer().list()
[[{4}, {9}, {-1}, {2}],
 [{4}, {9}, {-1, 2}],
 [{4, 9}, {-1}, {2}],
 [{4, 9}, {-1, 2}]]
```

static sum(*osps*)

Return the concatenation of the given ordered set partitions `osps` (provided they have no elements in common).

INPUT:

- `osps` – list (or iterable) of ordered set partitions

EXAMPLES:

```
sage: OrderedSetPartition.sum([OrderedSetPartition([[4, 1], [3]]),␣
↪OrderedSetPartition([[7], [2]]), OrderedSetPartition([[5, 6]])])
[{1, 4}, {3}, {7}, {2}, {5, 6}]
```

```
>>> from sage.all import *
>>> OrderedSetPartition.sum([OrderedSetPartition([[Integer(4), Integer(1)],␣
↪[Integer(3)]]), OrderedSetPartition([[Integer(7)], [Integer(2)]]),␣
↪OrderedSetPartition([[Integer(5), Integer(6)]])])
[{1, 4}, {3}, {7}, {2}, {5, 6}]
```

Any iterable can be provided as input:

```
sage: OrderedSetPartition.sum([OrderedSetPartition([[2*i,2*i+1]]) for i in [4,
↪1,3]])
[{8, 9}, {2, 3}, {6, 7}]
```

```
>>> from sage.all import *
>>> OrderedSetPartition.sum([OrderedSetPartition([[Integer(2)*i,
↪Integer(2)*i+Integer(1)]]) for i in [Integer(4),Integer(1),Integer(3)]])
[{8, 9}, {2, 3}, {6, 7}]
```

Empty inputs are handled gracefully:

```
sage: OrderedSetPartition.sum([]) == OrderedSetPartition([])
True
```

```
>>> from sage.all import *
>>> OrderedSetPartition.sum([]) == OrderedSetPartition([])
True
```

to_composition()

Return the integer composition whose parts are the sizes of the sets in `self`.

EXAMPLES:

```
sage: S = OrderedSetPartitions(5)
sage: x = S([[3,5,4], [1, 2]])
sage: x.to_composition()
[3, 2]
sage: y = S([[3,1], [2], [5,4]])
sage: y.to_composition()
[2, 1, 2]
```

```
>>> from sage.all import *
>>> S = OrderedSetPartitions(Integer(5))
>>> x = S([[Integer(3),Integer(5),Integer(4)], [Integer(1), Integer(2)]])
>>> x.to_composition()
[3, 2]
>>> y = S([[Integer(3),Integer(1)], [Integer(2)], [Integer(5),Integer(4)]])
>>> y.to_composition()
[2, 1, 2]
```

to_packed_word()

Return the packed word on alphabet $\{1, 2, 3, \ldots\}$ corresponding to `self`.

A *packed word* on alphabet $\{1, 2, 3, \ldots\}$ is any word whose maximum letter is the same as its total number of distinct letters. Let P be an ordered set partition of a set X. The corresponding packed word $w_1 w_2 \cdots w_n$ is constructed by having letter $w_i = j$ if the i-th smallest entry in X occurs in the j-th block of P.

See also

`Word.to_ordered_set_partition()`

Warning

This assumes there is a total order on the underlying set.

EXAMPLES:

```
sage: S = OrderedSetPartitions()
sage: x = S([[3,5], [2], [1,4,6]])
sage: x.to_packed_word()
word: 321313

sage: x = S([['a', 'c', 'e'], ['b', 'd']])
sage: x.to_packed_word()
word: 12121
```

```
>>> from sage.all import *
>>> S = OrderedSetPartitions()
>>> x = S([[Integer(3),Integer(5)], [Integer(2)], [Integer(1),Integer(4),
↪Integer(6)]])
>>> x.to_packed_word()
word: 321313

>>> x = S([['a', 'c', 'e'], ['b', 'd']])
>>> x.to_packed_word()
word: 12121
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions**(*s*)

Bases: UniqueRepresentation, Parent

Return the combinatorial class of ordered set partitions of s.

The optional argument c, if specified, restricts the parts of the partition to have certain sizes (the entries of c).

EXAMPLES:

```
sage: OS = OrderedSetPartitions([1,2,3,4]); OS
Ordered set partitions of {1, 2, 3, 4}
sage: OS.cardinality()
75
sage: OS.first()
[{1}, {2}, {3}, {4}]
sage: OS.last()
[{1, 2, 3, 4}]
sage: OS.random_element().parent() is OS
True
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)]); OS
Ordered set partitions of {1, 2, 3, 4}
>>> OS.cardinality()
75
>>> OS.first()
[{1}, {2}, {3}, {4}]
>>> OS.last()
[{1, 2, 3, 4}]
>>> OS.random_element().parent() is OS
True
```

```
sage: OS = OrderedSetPartitions([1,2,3,4], [2,2]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
sage: OS.cardinality()
6
sage: OS.first()
[{1, 2}, {3, 4}]
sage: OS.last()
[{3, 4}, {1, 2}]
sage: OS.list()
[[{1, 2}, {3, 4}],
 [{1, 3}, {2, 4}],
```

(continues on next page)

(continued from previous page)

```
 [{1, 4}, {2, 3}],
 [{2, 3}, {1, 4}],
 [{2, 4}, {1, 3}],
 [{3, 4}, {1, 2}]]
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions([Integer(1),Integer(2),Integer(3),Integer(4)],
↪[Integer(2),Integer(2)]); OS
Ordered set partitions of {1, 2, 3, 4} into parts of size [2, 2]
>>> OS.cardinality()
6
>>> OS.first()
[{1, 2}, {3, 4}]
>>> OS.last()
[{3, 4}, {1, 2}]
>>> OS.list()
[[{1, 2}, {3, 4}],
 [{1, 3}, {2, 4}],
 [{1, 4}, {2, 3}],
 [{2, 3}, {1, 4}],
 [{2, 4}, {1, 3}],
 [{3, 4}, {1, 2}]]
```

```
sage: OS = OrderedSetPartitions("cat")
sage: OS  # random
Ordered set partitions of {'a', 't', 'c'}
sage: sorted(OS.list(), key=str)
[[{'a', 'c', 't'}],
 [{'a', 'c'}, {'t'}],
 [{'a', 't'}, {'c'}],
 [{'a'}, {'c', 't'}],
 [{'a'}, {'c'}, {'t'}],
 [{'a'}, {'t'}, {'c'}],
 [{'c', 't'}, {'a'}],
 [{'c'}, {'a', 't'}],
 [{'c'}, {'a'}, {'t'}],
 [{'c'}, {'t'}, {'a'}],
 [{'t'}, {'a', 'c'}],
 [{'t'}, {'a'}, {'c'}],
 [{'t'}, {'c'}, {'a'}]]
```

```
>>> from sage.all import *
>>> OS = OrderedSetPartitions("cat")
>>> OS  # random
Ordered set partitions of {'a', 't', 'c'}
>>> sorted(OS.list(), key=str)
[[{'a', 'c', 't'}],
 [{'a', 'c'}, {'t'}],
 [{'a', 't'}, {'c'}],
 [{'a'}, {'c', 't'}],
 [{'a'}, {'c'}, {'t'}],
```

(continues on next page)

(continued from previous page)

```
[{'a'}, {'t'}, {'c'}],
[{'c', 't'}, {'a'}],
[{'c'}, {'a', 't'}],
[{'c'}, {'a'}, {'t'}],
[{'c'}, {'t'}, {'a'}],
[{'t'}, {'a', 'c'}],
[{'t'}, {'a'}, {'c'}],
[{'t'}, {'c'}, {'a'}]]
```

Element

alias of *OrderedSetPartition*

from_finite_word(*w*, *check=True*)

Return the unique ordered set partition of $\{1, 2, \ldots, n\}$ corresponding to a word w of length n.

See also

`Word.to_ordered_set_partition()`

EXAMPLES:

```
sage: A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
[{1, 4, 7}, {2, 5, 8}, {3, 6}, {9}]
sage: B = OrderedSetPartitions().from_finite_word([1,2,3,1,2,3,1,2,4])
sage: A == B
True
```

```
>>> from sage.all import *
>>> A = OrderedSetPartitions().from_finite_word('abcabcabd'); A
[{1, 4, 7}, {2, 5, 8}, {3, 6}, {9}]
>>> B = OrderedSetPartitions().from_finite_word([Integer(1),Integer(2),
↪Integer(3),Integer(1),Integer(2),Integer(3),Integer(1),Integer(2),
↪Integer(4)])
>>> A == B
True
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_all**

Bases: *OrderedSetPartitions*

Ordered set partitions of $\{1, \ldots, n\}$ for all $n \in \mathbf{Z}_{\geq 0}$.

class Element(*parent*, *s*, *check=True*)

Bases: *OrderedSetPartition*

subset(*size=None*, ***kwargs*)

Return the subset of ordered set partitions of a given size and additional keyword arguments.

EXAMPLES:

```
sage: P = OrderedSetPartitions()
sage: P.subset(4)
Ordered set partitions of {1, 2, 3, 4}
```

```
>>> from sage.all import *
>>> P = OrderedSetPartitions()
>>> P.subset(Integer(4))
Ordered set partitions of {1, 2, 3, 4}
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_s**(*s*)

Bases: *OrderedSetPartitions*

Class of ordered partitions of a set S.

cardinality()

EXAMPLES:

```
sage: OrderedSetPartitions(0).cardinality()
1
sage: OrderedSetPartitions(1).cardinality()
1
sage: OrderedSetPartitions(2).cardinality()
3
sage: OrderedSetPartitions(3).cardinality()
13
sage: OrderedSetPartitions([1,2,3]).cardinality()
13
sage: OrderedSetPartitions(4).cardinality()
75
sage: OrderedSetPartitions(5).cardinality()
541
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(0)).cardinality()
1
>>> OrderedSetPartitions(Integer(1)).cardinality()
1
>>> OrderedSetPartitions(Integer(2)).cardinality()
3
>>> OrderedSetPartitions(Integer(3)).cardinality()
13
>>> OrderedSetPartitions([Integer(1),Integer(2),Integer(3)]).cardinality()
13
>>> OrderedSetPartitions(Integer(4)).cardinality()
75
>>> OrderedSetPartitions(Integer(5)).cardinality()
541
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_scomp**(*s*, *comp*)

Bases: *OrderedSetPartitions*

cardinality()

Return the cardinality of `self`.

The number of ordered set partitions of a set of length k with composition shape μ is equal to

$$\frac{k!}{\prod_{\mu_i \neq 0} \mu_i!}.$$

EXAMPLES:

```
sage: OrderedSetPartitions(5,[2,3]).cardinality()
10
sage: OrderedSetPartitions(0, []).cardinality()
1
sage: OrderedSetPartitions(0, [0]).cardinality()
1
sage: OrderedSetPartitions(0, [0,0]).cardinality()
1
sage: OrderedSetPartitions(5, [2,0,3]).cardinality()
10
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(5),[Integer(2),Integer(3)]).cardinality()
10
>>> OrderedSetPartitions(Integer(0), []).cardinality()
1
>>> OrderedSetPartitions(Integer(0), [Integer(0)]).cardinality()
1
>>> OrderedSetPartitions(Integer(0), [Integer(0),Integer(0)]).cardinality()
1
>>> OrderedSetPartitions(Integer(5), [Integer(2),Integer(0),Integer(3)]).
↪cardinality()
10
```

class sage.combinat.set_partition_ordered.**OrderedSetPartitions_sn**(*s*, *n*)

Bases: *OrderedSetPartitions*

cardinality()

Return the cardinality of `self`.

The number of ordered partitions of a set of size n into k parts is equal to $k!S(n,k)$ where $S(n,k)$ denotes the Stirling number of the second kind.

EXAMPLES:

```
sage: OrderedSetPartitions(4,2).cardinality()
14
sage: OrderedSetPartitions(4,1).cardinality()
1
```

```
>>> from sage.all import *
>>> OrderedSetPartitions(Integer(4),Integer(2)).cardinality()
14
>>> OrderedSetPartitions(Integer(4),Integer(1)).cardinality()
1
```

class sage.combinat.set_partition_ordered.**SplitNK**(*s*, *comp*)

Bases: *OrderedSetPartitions_scomp*

sage.combinat.set_partition_ordered.**multiset_permutation_next_lex**(*l*)

Return the next multiset permutation after `l`.

EXAMPLES:

```
sage: from sage.combinat.set_partition_ordered import multiset_permutation_next_
↪lex
sage: l = [0, 0, 1, 1, 2]
sage: while multiset_permutation_next_lex(l):
....:     print(l)
[0, 0, 1, 2, 1]
[0, 0, 2, 1, 1]
[0, 1, 0, 1, 2]
[0, 1, 0, 2, 1]
[0, 1, 1, 0, 2]
[0, 1, 1, 2, 0]
...
[1, 1, 2, 0, 0]
[1, 2, 0, 0, 1]
[1, 2, 0, 1, 0]
[1, 2, 1, 0, 0]
[2, 0, 0, 1, 1]
[2, 0, 1, 0, 1]
[2, 0, 1, 1, 0]
[2, 1, 0, 0, 1]
[2, 1, 0, 1, 0]
[2, 1, 1, 0, 0]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_ordered import multiset_permutation_next_lex
>>> l = [Integer(0), Integer(0), Integer(1), Integer(1), Integer(2)]
>>> while multiset_permutation_next_lex(l):
...     print(l)
[0, 0, 1, 2, 1]
[0, 0, 2, 1, 1]
[0, 1, 0, 1, 2]
[0, 1, 0, 2, 1]
[0, 1, 1, 0, 2]
[0, 1, 1, 2, 0]
...
[1, 1, 2, 0, 0]
[1, 2, 0, 0, 1]
[1, 2, 0, 1, 0]
[1, 2, 1, 0, 0]
[2, 0, 0, 1, 1]
[2, 0, 1, 0, 1]
[2, 0, 1, 1, 0]
[2, 1, 0, 0, 1]
[2, 1, 0, 1, 0]
[2, 1, 1, 0, 0]
```

sage.combinat.set_partition_ordered.**multiset_permutation_to_ordered_set_partition**(l, m)

Convert a multiset permutation to an ordered set partition.

INPUT:

- `l` – a multiset permutation
- `m` – number of parts

EXAMPLES:

```
sage: from sage.combinat.set_partition_ordered import multiset_permutation_to_
↪ordered_set_partition
sage: l = [0, 0, 1, 1, 2]
sage: multiset_permutation_to_ordered_set_partition(l, 3)
[[0, 1], [2, 3], [4]]
```

```
>>> from sage.all import *
>>> from sage.combinat.set_partition_ordered import multiset_permutation_to_
↪ordered_set_partition
>>> l = [Integer(0), Integer(0), Integer(1), Integer(1), Integer(2)]
>>> multiset_permutation_to_ordered_set_partition(l, Integer(3))
[[0, 1], [2, 3], [4]]
```

5.1.281 Characters of the symmetric group as bases of the symmetric functions

Just as the Schur functions are the irreducible characters of Gl_n and form a basis of the symmetric functions, the irreducible symmetric group character basis are the irreducible characters of of S_n when the group is realized as the permutation matrices.

REFERENCES:

class sage.combinat.sf.character.**Character_generic**(*Sym*, *basis_name=None*, *prefix=None*, *graded=True*)

Bases: *SymmetricFunctionAlgebra_generic*

class sage.combinat.sf.character.**InducedTrivialCharacterBasis**(*Sym*)

Bases: *Character_generic*

The induced trivial symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that `self(la).character_to_frobenius_image(n)` is equal to `h([n-sum(la)]+la)`.

It has the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the complete basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
sage: st = SymmetricFunctions(QQ).st()
sage: ht(s[2,1])
ht[1, 1] + ht[2, 1] - ht[3]
sage: s(ht[2,1])
s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1] + s[3]
sage: ht(h[2,1])
ht[1] + 2*ht[1, 1] + ht[2, 1]
sage: h(ht[2,1])
h[1] - 2*h[1, 1] + h[2, 1]
sage: st(ht[2,1])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
sage: ht(st[2,1])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
sage: ht[2]*ht[1,1]
ht[1, 1] + 2*ht[1, 1, 1] + ht[2, 1, 1]
sage: h[4,2].kronecker_product(h[4,1,1])
h[2, 2, 1, 1] + 2*h[3, 1, 1, 1] + h[4, 1, 1]
sage: s(st[2,1])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
sage: st(s[2,1])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
sage: st[2]*st[1]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
```

(continues on next page)

(continued from previous page)

```
sage: s[4,2].kronecker_product(s[5,1])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> h = Sym.h()
>>> ht = SymmetricFunctions(QQ).ht()
>>> st = SymmetricFunctions(QQ).st()
>>> ht(s[Integer(2),Integer(1)])
ht[1, 1] + ht[2, 1] - ht[3]
>>> s(ht[Integer(2),Integer(1)])
s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1] + s[3]
>>> ht(h[Integer(2),Integer(1)])
ht[1] + 2*ht[1, 1] + ht[2, 1]
>>> h(ht[Integer(2),Integer(1)])
h[1] - 2*h[1, 1] + h[2, 1]
>>> st(ht[Integer(2),Integer(1)])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
>>> ht(st[Integer(2),Integer(1)])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
>>> ht[Integer(2)]*ht[Integer(1),Integer(1)]
ht[1, 1] + 2*ht[1, 1, 1] + ht[2, 1, 1]
>>> h[Integer(4),Integer(2)].kronecker_product(h[Integer(4),Integer(1),
↪Integer(1)])
h[2, 2, 1, 1] + 2*h[3, 1, 1, 1] + h[4, 1, 1]
>>> s(st[Integer(2),Integer(1)])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
>>> st(s[Integer(2),Integer(1)])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
>>> st[Integer(2)]*st[Integer(1)]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
>>> s[Integer(4),Integer(2)].kronecker_product(s[Integer(5),Integer(1)])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]
```

class sage.combinat.sf.character.**IrreducibleCharacterBasis**(*Sym*)

Bases: *Character_generic*

The irreducible symmetric group character basis of the symmetric functions.

This is a basis of the symmetric functions that has the property that `self(la).character_to_frobenius_image(n)` is equal to `s([n-sum(la)]+la)`.

It should also have the property that the (outer) structure constants are the analogue of the stable Kronecker coefficients on the Schur basis.

This basis is introduced in [OZ2015].

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: ht = SymmetricFunctions(QQ).ht()
```

(continues on next page)

(continued from previous page)

```
sage: st = SymmetricFunctions(QQ).st()
sage: st(ht[2,1])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
sage: ht(st[2,1])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
sage: s(st[2,1])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
sage: st(s[2,1])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
sage: st[2]*st[1]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
sage: s[4,2].kronecker_product(s[5,1])
s[3, 2, 1] + s[3, 3] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: st[1,1,1].counit()
-1
sage: all(sum(c*st(la)*st(mu).antipode() for
....:     ((la,mu),c) in st(ga).coproduct())==st(st(ga).counit())
....:     for ga in Partitions(3))
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> h = Sym.h()
>>> ht = SymmetricFunctions(QQ).ht()
>>> st = SymmetricFunctions(QQ).st()
>>> st(ht[Integer(2),Integer(1)])
st[] + 2*st[1] + st[1, 1] + 2*st[2] + st[2, 1] + st[3]
>>> ht(st[Integer(2),Integer(1)])
ht[1] - ht[1, 1] + ht[2, 1] - ht[3]
>>> s(st[Integer(2),Integer(1)])
3*s[1] - 2*s[1, 1] - 2*s[2] + s[2, 1]
>>> st(s[Integer(2),Integer(1)])
st[] + 3*st[1] + 2*st[1, 1] + 2*st[2] + st[2, 1]
>>> st[Integer(2)]*st[Integer(1)]
st[1] + st[1, 1] + st[2] + st[2, 1] + st[3]
>>> s[Integer(4),Integer(2)].kronecker_product(s[Integer(5),Integer(1)])

True
```

5.1.282 Classical symmetric functions

class sage.combinat.sf.classical.**SymmetricFunctionAlgebra_classical**(*Sym*, *basis_name=None*, *prefix=None*, *graded=True*)

Bases: *SymmetricFunctionAlgebra_generic*

The class of classical symmetric functions.

Todo

delete this class once all coercions will be handled by Sage's coercion model

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

A symmetric function.

sage.combinat.sf.classical.**init**()

Set up the conversion functions between the classical bases.

EXAMPLES:

```
sage: from sage.combinat.sf.classical import init
sage: sage.combinat.sf.classical.conversion_functions = {}
sage: init()
sage: sage.combinat.sf.classical.conversion_functions[('Schur', 'powersum')]
<built-in function t_SCHUR_POWSYM_symmetrica>
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.classical import init
>>> sage.combinat.sf.classical.conversion_functions = {}
>>> init()
>>> sage.combinat.sf.classical.conversion_functions[('Schur', 'powersum')]
<built-in function t_SCHUR_POWSYM_symmetrica>
```

The following checks if the bug described in Issue #15312 is fixed.

```
sage: change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur
→')]
sage: hideme = change({Partition([1]*47):ZZ(1)}) # long time
sage: change({Partition([2,2]):QQ(1)})
s[1, 1, 1, 1] - s[2, 1, 1] + 2*s[2, 2] - s[3, 1] + s[4]
```

```
>>> from sage.all import *
>>> change = sage.combinat.sf.classical.conversion_functions[('powersum', 'Schur
→')]
>>> hideme = change({Partition([Integer(1)]*Integer(47)):ZZ(Integer(1))}) # long␣
→time
>>> change({Partition([Integer(2),Integer(2)]):QQ(Integer(1))})
s[1, 1, 1, 1] - s[2, 1, 1] + 2*s[2, 2] - s[3, 1] + s[4]
```

5.1.283 Generic dual bases symmetric functions

class sage.combinat.sf.dual.**DualBasisFunctor**(*basis*)

Bases: *SymmetricFunctionsFunctor*

A constructor for algebras of symmetric functions constructed by duality.

EXAMPLES:

```
sage: w = SymmetricFunctions(ZZ).witt()
sage: w.dual_basis().construction()
(SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

```
>>> from sage.all import *
>>> w = SymmetricFunctions(ZZ).witt()
>>> w.dual_basis().construction()
(SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

class sage.combinat.sf.dual.**SymmetricFunctionAlgebra_dual**(*dual_basis*, *scalar*, *scalar_name*, *basis_name*, *prefix*)

Bases: *SymmetricFunctionAlgebra_classical*

Generic dual basis of a basis of symmetric functions.

INPUT:

- `dual_basis` – a basis of the ring of symmetric functions
- `scalar` – a function z on partitions which determines the scalar product on the power sum basis by $\langle p_\mu, p_\mu \rangle = z(\mu)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function `scalar` only determines the norms of the basis elements.) This defaults to the function `zee` defined in `sage.combinat.sf.sfa`, that is, the function is defined by:

$$\lambda \mapsto \prod_{i=1}^{\infty} m_i(\lambda)! i^{m_i(\lambda)`},$$

  where $m_i(\lambda)$ means the number of times i appears in λ. This default function gives the standard Hall scalar product on the ring of symmetric functions.
- `scalar_name` – (default: the empty string) a string giving a description of the scalar product specified by the parameter `scalar`
- `basis_name` – (optional) a string to serve as name for the basis to be generated (such as "forgotten" in "the forgotten basis"); don't set it to any of the already existing basis names (such as `homogeneous`, `monomial`, `forgotten`, etc.).
- `prefix` – (default: `'d'` and the prefix for `dual_basis`) a string to use as the symbol for the basis

OUTPUT:

The basis of the ring of symmetric functions dual to the basis `dual_basis` with respect to the scalar product determined by `scalar`.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix='m', basis_name="Forgotten symmetric functions"); f
Symmetric Functions over Rational Field in the Forgotten symmetric functions basis
sage: TestSuite(f).run(elements=[f[1,1]+2*f[2], f[1]+3*f[1,1]])
sage: TestSuite(f).run() # long time (11s on sage.math, 2011)
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> f = e.dual_basis(prefix='m', basis_name="Forgotten symmetric functions"); f
Symmetric Functions over Rational Field in the Forgotten symmetric functions basis
>>> TestSuite(f).run(elements=[f[Integer(1),Integer(1)]+Integer(2)*f[Integer(2)],␣
```

(continues on next page)

(continued from previous page)

```
↪f[Integer(1)]+Integer(3)*f[Integer(1),Integer(1)]])
>>> TestSuite(f).run() # long time (11s on sage.math, 2011)
```

This class defines canonical coercions between `self` and `self^*`, as follow:

Lookup for the canonical isomorphism from `self` to P (=powersum), and build the adjoint isomorphism from P^* to `self^*`. Since P is self-adjoint for this scalar product, derive an isomorphism from P to `self^*`, and by composition with the above get an isomorphism from `self` to `self^*` (and similarly for the isomorphism `self^*` to `self`).

This should be striped down to just (auto?) defining canonical isomorphism by adjunction (as in MuPAD-Combinat), and let the coercion handle the rest.

Inversions may not be possible if the base ring is not a field:

```
sage: m = SymmetricFunctions(ZZ).m()
sage: h = m.dual_basis(lambda x: 1)
sage: h[2,1]
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(ZZ).m()
>>> h = m.dual_basis(lambda x: Integer(1))
>>> h[Integer(2),Integer(1)]
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

By transitivity, this defines indirect coercions to and from all other bases:

```
sage: s = SymmetricFunctions(QQ['t'].fraction_field()).s()
sage: t = QQ['t'].fraction_field().gen()
sage: zee_hl = lambda x: x.centralizer_size(t=t)
sage: S = s.dual_basis(zee_hl)
sage: S(s([2,1]))
(-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[1, 1, 1] + ((-t^2-1)/(t^5-2*t^4+t^3-t^2+2*t-
↪1))*d_s[2, 1] + (-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ['t'].fraction_field()).s()
>>> t = QQ['t'].fraction_field().gen()
>>> zee_hl = lambda x: x.centralizer_size(t=t)
>>> S = s.dual_basis(zee_hl)
>>> S(s([Integer(2),Integer(1)]))
(-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[1, 1, 1] + ((-t^2-1)/(t^5-2*t^4+t^3-t^2+2*t-
↪1))*d_s[2, 1] + (-t/(t^5-2*t^4+t^3-t^2+2*t-1))*d_s[3]
```

class Element(*A*, *dictionary=None*, *dual=None*)

Bases: `Element`

An element in the dual basis.

INPUT:

At least one of the following must be specified. The one (if any) which is not provided will be computed.

- `dictionary` – an internal dictionary for the monomials and coefficients of `self`
- `dual` – self as an element of the dual basis

dual()

Return `self` in the dual basis.

OUTPUT:

- the element `self` expanded in the dual basis to `self.parent()`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial␣
↪basis
sage: a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2),Integer(1)])
>>> a.parent()
Dual basis to Symmetric Functions over Rational Field in the monomial␣
↪basis
>>> a.dual()
3*m[1, 1, 1] + 2*m[2, 1] + m[3]
```

expand(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: a = h([2,1])+h([3])
sage: a.expand(2)

>>> h([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*h([])).expand(Integer(0))
3
```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the result of applying omega to `self`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(zee)
>>> hh = SymmetricFunctions(QQ).homogeneous()
>>> hh([Integer(2),Integer(1)]).omega()
h[1, 1, 1] - h[2, 1]
>>> h([Integer(2),Integer(1)]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the result of applying omega to `self`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(zee)
sage: hh = SymmetricFunctions(QQ).homogeneous()
sage: hh([2,1]).omega()
h[1, 1, 1] - h[2, 1]
sage: h([2,1]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(zee)
>>> hh = SymmetricFunctions(QQ).homogeneous()
>>> hh([Integer(2),Integer(1)]).omega()
h[1, 1, 1] - h[2, 1]
>>> h([Integer(2),Integer(1)]).omega()
d_m[1, 1, 1] - d_m[2, 1]
```

scalar(*x*)

Return the standard scalar product of `self` and `x`.

INPUT:

- `x` – element of the symmetric functions

OUTPUT: the scalar product between `x` and `self`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar(a)
2
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2),Integer(1)])
>>> a.scalar(a)
2
```

scalar_hl(*x*)

Return the Hall-Littlewood scalar product of `self` and `x`.

INPUT:

- `x` – element of the same dual basis as `self`

OUTPUT: the Hall-Littlewood scalar product between `x` and `self`

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2,1])
sage: a.scalar_hl(a)
(-t - 2)/(t^4 - 2*t^3 + 2*t - 1)
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2),Integer(1)])
>>> a.scalar_hl(a)
(-t - 2)/(t^4 - 2*t^3 + 2*t - 1)
```

basis_name()

Return the name of the basis of `self`.

This is used for output and, for the classical bases of symmetric functions, to connect this basis with Symmetrica.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: f = Sym.f()
sage: f.basis_name()
'forgotten'
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> f = Sym.f()
>>> f.basis_name()
'forgotten'
```

construction()

Return a pair (F, R), where F is a *SymmetricFunctionsFunctor* and R is a ring, such that F(R) returns self.

EXAMPLES:

```
sage: w = SymmetricFunctions(ZZ).witt()
sage: w.dual_basis().construction()
(SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

```
>>> from sage.all import *
>>> w = SymmetricFunctions(ZZ).witt()
>>> w.dual_basis().construction()
(SymmetricFunctionsFunctor[dual Witt], Integer Ring)
```

product(*left*, *right*)

Return product of left and right.

Multiplication is done by performing the multiplication in the dual basis of self and then converting back to self.

INPUT:

- left, right – elements of self

OUTPUT: the product of left and right in the basis self

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: zee = sage.combinat.sf.sfa.zee
sage: h = m.dual_basis(scalar=zee)
sage: a = h([2])
sage: b = a*a; b # indirect doctest
d_m[2, 2]
sage: b.dual()
6*m[1, 1, 1, 1] + 4*m[2, 1, 1] + 3*m[2, 2] + 2*m[3, 1] + m[4]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> zee = sage.combinat.sf.sfa.zee
>>> h = m.dual_basis(scalar=zee)
>>> a = h([Integer(2)])
>>> b = a*a; b # indirect doctest
```

(continues on next page)

(continued from previous page)

```
d_m[2, 2]
>>> b.dual()
6*m[1, 1, 1, 1] + 4*m[2, 1, 1] + 3*m[2, 2] + 2*m[3, 1] + m[4]
```

transition_matrix(*basis*, *n*)

Return the transition matrix between the n-th homogeneous components of `self` and `basis`.

INPUT:

- `basis` – a target basis of the ring of symmetric functions
- `n` – nonnegative integer

OUTPUT:

- A transition matrix from `self` to `basis` for the elements of degree `n`. The indexing order of the rows and columns is the order of `Partitions(n)`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: e = Sym.elementary()
sage: f = e.dual_basis()
sage: f.transition_matrix(s, 5)
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
sage: Partitions(5).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: s(f[2,2,1])
s[3, 2] - 2*s[4, 1] + 3*s[5]
sage: e.transition_matrix(s, 5).inverse().transpose()
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> e = Sym.elementary()
>>> f = e.dual_basis()
>>> f.transition_matrix(s, Integer(5))
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
```

(continues on next page)

(continued from previous page)

```
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
>>> Partitions(Integer(5)).list()
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
>>> s(f[Integer(2),Integer(2),Integer(1)])
s[3, 2] - 2*s[4, 1] + 3*s[5]
>>> e.transition_matrix(s, Integer(5)).inverse().transpose()
[ 1 -1  0  1  0 -1  1]
[-2  1  1 -1 -1  1  0]
[-2  2 -1 -1  1  0  0]
[ 3 -1 -1  1  0  0  0]
[ 3 -2  1  0  0  0  0]
[-4  1  0  0  0  0  0]
[ 1  0  0  0  0  0  0]
```

5.1.284 Elementary symmetric functions

class sage.combinat.sf.elementary.**SymmetricFunctionAlgebra_elementary**(*Sym*)

Bases: *SymmetricFunctionAlgebra_multiplicative*

A class for methods for the elementary basis of the symmetric functions.

INPUT:

- `self` – an elementary basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class Element

Bases: *Element*

expand(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: e([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: e([3]).expand(2)
0
sage: e([2]).expand(3)
x0*x1 + x0*x2 + x1*x2
sage: e([3]).expand(4,alphabet='x,y,z,t')
x*y*z + x*y*t + x*z*t + y*z*t
```

(continues on next page)

(continued from previous page)

```
sage: e([3]).expand(4,alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
sage: e([]).expand(2)
1
sage: e([]).expand(0)
1
sage: (3*e([])).expand(0)
3
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> e([Integer(2),Integer(1)]).expand(Integer(3))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 3*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
>>> e([Integer(1),Integer(1),Integer(1)]).expand(Integer(2))
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
>>> e([Integer(3)]).expand(Integer(2))
0
>>> e([Integer(2)]).expand(Integer(3))
x0*x1 + x0*x2 + x1*x2
>>> e([Integer(3)]).expand(Integer(4),alphabet='x,y,z,t')
x*y*z + x*y*t + x*z*t + y*z*t
>>> e([Integer(3)]).expand(Integer(4),alphabet='y')
y0*y1*y2 + y0*y1*y3 + y0*y2*y3 + y1*y2*y3
>>> e([]).expand(Integer(2))
1
>>> e([]).expand(Integer(0))
1
>>> (Integer(3)*e([])).expand(Integer(0))
3
```

exponential_specialization(*t=None*, *q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q-exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R. It is defined whenever the base ring K is a $\mathbf{Q}$-algebra and t is an element of R. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q-exponential specialization is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \to 1$ is ex.

INPUT:

- `t` – (default: `None`) the value to use for t. The default is to create a ring of polynomials in t.
- `q` – (default: 1) the value to use for q. If `q` is `None`, then a ring (or fraction field) of polynomials in `q` is created.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,2]
sage: x.exponential_specialization()
1/12*t^5
sage: x = 5*e[2] + 3*e[1] + 1
sage: x.exponential_specialization(t=var("t"), q=var("q"))                #␣
↪needs sage.symbolic
5*q*t^2/(q + 1) + 3*t + 1
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> x = e[Integer(3),Integer(2)]
>>> x.exponential_specialization()
1/12*t^5
>>> x = Integer(5)*e[Integer(2)] + Integer(3)*e[Integer(1)] + Integer(1)
>>> x.exponential_specialization(t=var("t"), q=var("q"))                #␣
↪needs sage.symbolic
5*q*t^2/(q + 1) + 3*t + 1
```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
```

(continues on next page)

(continued from previous page)

```
>>> a = e([Integer(2),Integer(1)]); a
e[2, 1]
>>> a.omega()
e[1, 1, 1] - e[2, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> h(e([Integer(2),Integer(1)]).omega())
h[2, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (*length()*) of the partition λ, where λ' denotes the conjugate partition (*conjugate()*) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

omega_involution() is a synonym for the *omega()* method.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: a = e([2,1]); a
e[2, 1]
sage: a.omega()
e[1, 1, 1] - e[2, 1]
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> a = e([Integer(2),Integer(1)]); a
e[2, 1]
>>> a.omega()
e[1, 1, 1] - e[2, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h(e([2,1]).omega())
h[2, 1]
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> h(e([Integer(2),Integer(1)]).omega())
h[2, 1]
```

principal_specialization(*n=+Infinity*, *q=None*)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a K-algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` – (default: `infinity`) a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` – (default: `None`) the value to use for q; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients $\binom{u}{v}_q$):

$$ps_{n,q}(e_\lambda) = \prod_i q^{\binom{\lambda_i}{2}} \binom{n}{\lambda_i}_q,$$

$$ps_{n,1}(e_\lambda) = \prod_i \binom{n}{\lambda_i},$$

$$ps_q(e_\lambda) = \prod_i q^{\binom{\lambda_i}{2}} / \prod_{j=1}^{\lambda_i} (1 - q^j).$$

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: x = e[3,1]
sage: x.principal_specialization(3)
q^5 + q^4 + q^3
sage: x = 5*e[1,1,1] + 3*e[2,1] + 1
sage: x.principal_specialization(3)
5*q^6 + 18*q^5 + 36*q^4 + 44*q^3 + 36*q^2 + 18*q + 6
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> x = e[Integer(3),Integer(1)]
>>> x.principal_specialization(Integer(3))
q^5 + q^4 + q^3
>>> x = Integer(5)*e[Integer(1),Integer(1),Integer(1)] +␣
↪Integer(3)*e[Integer(2),Integer(1)] + Integer(1)
>>> x.principal_specialization(Integer(3))
5*q^6 + 18*q^5 + 36*q^4 + 44*q^3 + 36*q^2 + 18*q + 6
```

By default, we return a rational functions in q. Sometimes it is better to obtain an element of the symbolic ring:

```
sage: x.principal_specialization(q=var("q"))                                    #␣
↪needs sage.symbolic
-3*q/((q^2 - 1)*(q - 1)^2) - 5/(q - 1)^3 + 1
```

```
>>> from sage.all import *
>>> x.principal_specialization(q=var("q"))                                  #␣
↪needs sage.symbolic

```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n, and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for "shift") endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Frobenius operator (see *frobenius()* for its definition) with respect to the Hall scalar product (*scalar()*).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley [STA].

Let λ be a partition. Let n be a positive integer. If the n-core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, ..., \lambda_{ns})$ for some nonnegative integer s. (If n does not divide the length of λ, then this is achieved by adding trailing zeroes to λ.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, ..., \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n. Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the n-quotient of λ.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
```

(continues on next page)

(continued from previous page)

```
sage: e[3].verschiebung(2)
0
sage: e[4].verschiebung(4)
-e[1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> e[Integer(3)].verschiebung(Integer(2))
0
>>> e[Integer(4)].verschiebung(Integer(4))
-e[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( e(lam).verschiebung(2) * e(mu).verschiebung(2)
....:             == (e(lam) * e(mu)).verschiebung(2)
....:             for mu in Partitions(4) )
....:        for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( e(lam).verschiebung(Integer(2)) * e(mu).
↪verschiebung(Integer(2))
...             == (e(lam) * e(mu)).verschiebung(Integer(2))
...             for mu in Partitions(Integer(4)) )
...        for lam in Partitions(Integer(4)) )
True
```

coproduct_on_generators(*i*)

Return the coproduct on `self[i]`.

INPUT:

- `self` – an elementary basis of the symmetric functions
- `i` – nonnegative integer

OUTPUT: the coproduct on the elementary generator $e(i)$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: e = Sym.elementary()
sage: e.coproduct_on_generators(2)
e[] # e[2] + e[1] # e[1] + e[2] # e[]
sage: e.coproduct_on_generators(0)
e[] # e[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> e = Sym.elementary()
>>> e.coproduct_on_generators(Integer(2))
e[] # e[2] + e[1] # e[1] + e[2] # e[]
```

(continues on next page)

(continued from previous page)

```
>>> e.coproduct_on_generators(Integer(0))
e[] # e[]
```

5.1.285 Hall-Littlewood Polynomials

Notation used in the definitions follows mainly [Mac1995].

class sage.combinat.sf.hall_littlewood.**HallLittlewood**(*Sym*, *t*)

Bases: UniqueRepresentation

The family of Hall-Littlewood symmetric function bases.

The Hall-Littlewood symmetric functions are a family of symmetric functions that depend on a parameter t.

INPUT:

By default the parameter for these functions is t, and whatever the parameter is, it must be in the base ring.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).hall_littlewood(1)
Hall-Littlewood polynomials with t=1 over Rational Field
sage: SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in␣
↪t over Rational Field
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).hall_littlewood(Integer(1))
Hall-Littlewood polynomials with t=1 over Rational Field
>>> SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood()
Hall-Littlewood polynomials over Fraction Field of Univariate Polynomial Ring in␣
↪t over Rational Field
```

P()

Return the algebra of symmetric functions in the Hall-Littlewood P basis. This is the same as the HL basis in John Stembridge's SF examples file.

INPUT:

- self – a class of Hall-Littlewood symmetric function bases

OUTPUT: the class of the Hall-Littlewood P basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P(); HLP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood P basis
sage: SP = Sym.hall_littlewood(t=-1).P(); SP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood P with t=-1 basis
sage: s = Sym.schur()
sage: s(HLP([2,1]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P(); HLP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood P basis
>>> SP = Sym.hall_littlewood(t=-Integer(1)).P(); SP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood P with t=-1 basis
>>> s = Sym.schur()
>>> s(HLP([Integer(2),Integer(1)]))
(-t^2-t)*s[1, 1, 1] + s[2, 1]
```

The Hall-Littlewood polynomials in the P basis at $t = 0$ are the Schur functions:

```
sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=0).P()
sage: s = Sym.schur()
sage: s(HLP([2,1])) == s([2,1])
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> HLP = Sym.hall_littlewood(t=Integer(0)).P()
>>> s = Sym.schur()
>>> s(HLP([Integer(2),Integer(1)])) == s([Integer(2),Integer(1)])
True
```

The Hall-Littlewood polynomials in the P basis at $t = 1$ are the monomial symmetric functions:

```
sage: Sym = SymmetricFunctions(QQ)
sage: HLP = Sym.hall_littlewood(t=1).P()
sage: m = Sym.monomial()
sage: m(HLP([2,2,1])) == m([2,2,1])
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> HLP = Sym.hall_littlewood(t=Integer(1)).P()
>>> m = Sym.monomial()
>>> m(HLP([Integer(2),Integer(2),Integer(1)])) == m([Integer(2),Integer(2),
↪Integer(1)])
True
```

We end with some examples of coercions between:

1. Hall-Littlewood P basis.
2. Hall-Littlewood polynomials in the Q basis
3. Hall-Littlewood polynomials in the Q' basis (via the Schurs)
4. Classical symmetric functions

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP  = Sym.hall_littlewood().P()
```

(continues on next page)

(continued from previous page)

```
sage: HLQ  = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.schur()
sage: p = Sym.power()
sage: HLP(HLQ([2])) # indirect doctest
(-t+1)*HLP[2]
sage: HLP(HLQp([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(s([2]))
t*HLP[1, 1] + HLP[2]
sage: HLP(p([2]))
(t-1)*HLP[1, 1] + HLP[2]
sage: s = HLQp.symmetric_function_ring().s()
sage: HLQp.transition_matrix(s,3)
[      1       0       0]
[      t       1       0]
[    t^3 t^2 + t       1]
sage: s.transition_matrix(HLP,3)
[      1       t     t^3]
[      0       1 t^2 + t]
[      0       0       1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP  = Sym.hall_littlewood().P()
>>> HLQ  = Sym.hall_littlewood().Q()
>>> HLQp = Sym.hall_littlewood().Qp()
>>> s = Sym.schur()
>>> p = Sym.power()
>>> HLP(HLQ([Integer(2)])) # indirect doctest
(-t+1)*HLP[2]
>>> HLP(HLQp([Integer(2)]))
t*HLP[1, 1] + HLP[2]
>>> HLP(s([Integer(2)]))
t*HLP[1, 1] + HLP[2]
>>> HLP(p([Integer(2)]))
(t-1)*HLP[1, 1] + HLP[2]
>>> s = HLQp.symmetric_function_ring().s()
>>> HLQp.transition_matrix(s,Integer(3))
[      1       0       0]
[      t       1       0]
[    t^3 t^2 + t       1]
>>> s.transition_matrix(HLP,Integer(3))
[      1       t     t^3]
[      0       1 t^2 + t]
[      0       0       1]
```

The method *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element.hl_creation_operator()* is a creation operator for the Q basis:

```
sage: HLQp[1].hl_creation_operator([3]).hl_creation_operator([3])
HLQp[3, 3, 1]
```

```
>>> from sage.all import *
>>> HLQp[Integer(1)].hl_creation_operator([Integer(3)]).hl_creation_
↪operator([Integer(3)])
HLQp[3, 3, 1]
```

Transitions between bases with the parameter t specialized:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['y','z']))
sage: (y,z) = Sym.base_ring().gens()
sage: HLy = Sym.hall_littlewood(t=y)
sage: HLz = Sym.hall_littlewood(t=z)
sage: Qpy = HLy.Qp()
sage: Qpz = HLz.Qp()
sage: s = Sym.schur()
sage: s( Qpy[3,1] + z*Qpy[2,2] )
z*s[2, 2] + (y*z+1)*s[3, 1] + (y^2*z+y)*s[4]
sage: s( Qpy[3,1] + y*Qpz[2,2] )
y*s[2, 2] + (y*z+1)*s[3, 1] + (y*z^2+y)*s[4]
sage: s( Qpy[3,1] + y*Qpy[2,2] )
y*s[2, 2] + (y^2+1)*s[3, 1] + (y^3+y)*s[4]

sage: Qy = HLy.Q()

>>> SP(p[Integer(3),Integer(3)])
-4*HLP[3, 2, 1] + 2*HLP[4, 2] - 2*HLP[5, 1] + HLP[6]
>>> SQ( SQ[Integer(1)]*SQ[Integer(3)] -Integer(2)*(Integer(1)-
↪q)*SQ[Integer(4)] )
HLQ[3, 1] + 2*q*HLQ[4]
```

Q()

Return the algebra of symmetric functions in Hall-Littlewood Q basis. This is the same as the Q basis in John Stembridge's SF examples file.

More extensive examples can be found in the documentation for the Hall-Littlewood P basis.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT: the class of the Hall-Littlewood Q basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQ = Sym.hall_littlewood().Q(); HLQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Q basis
sage: SQ = SymmetricFunctions(QQ).hall_littlewood(t=-1).Q(); SQ
Symmetric Functions over Rational Field in the Hall-Littlewood Q with t=-1␣
↪basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLQ = Sym.hall_littlewood().Q(); HLQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Q basis
>>> SQ = SymmetricFunctions(QQ).hall_littlewood(t=-Integer(1)).Q(); SQ
Symmetric Functions over Rational Field in the Hall-Littlewood Q with t=-1␣
↪basis
```

Qp()

Return the algebra of symmetric functions in Hall-Littlewood Q' (Qp) basis. This is dual to the Hall-Littlewood P basis with respect to the standard scalar product.

More extensive examples can be found in the documentation for the Hall-Littlewood P basis.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

OUTPUT: the class of the Hall-Littlewood Qp-basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp(); HLQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Qp basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLQp = Sym.hall_littlewood().Qp(); HLQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Qp basis
```

base_ring()

Return the base ring of the symmetric functions where the Hall-Littlewood symmetric functions live.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

EXAMPLES:

```
sage: HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_littlewood(t=1)
sage: HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> HL = SymmetricFunctions(QQ['t'].fraction_field()).hall_
↪littlewood(t=Integer(1))
>>> HL.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

symmetric_function_ring()

Return the ring of symmetric functions associated to the class of Hall-Littlewood symmetric functions.

INPUT:

- `self` – a class of Hall-Littlewood symmetric function bases

EXAMPLES:

```
sage: HL = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood()
sage: HL.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
```

```
>>> from sage.all import *
>>> HL = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood()
>>> HL.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
```

class sage.combinat.sf.hall_littlewood.**HallLittlewood_generic**(*hall_littlewood*)

Bases: *SymmetricFunctionAlgebra_generic*

A class with methods for working with Hall-Littlewood symmetric functions which are common to all bases.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `hall_littlewood` – a class of Hall-Littlewood bases

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

Methods for elements of a Hall-Littlewood basis that are common to all bases.

expand(*n*, *alphabet='x'*)

Expand the symmetric function as a symmetric polynomial in `n` variables.

INPUT:

- `self` – an element of a Hall-Littlewood basis
- `n` – positive integer
- `alphabet` – string representing a variable name (default: `'x'`)

OUTPUT: a symmetric polynomial of `self` in `n` variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).expand(2)
x0^2 + (-t + 1)*x0*x1 + x1^2
sage: HLQ([2]).expand(2)
(-t + 1)*x0^2 + (t^2 - 2*t + 1)*x0*x1 + (-t + 1)*x1^2
sage: HLQp([2]).expand(2)
x0^2 + x0*x1 + x1^2
sage: HLQp([2]).expand(2, 'y')
y0^2 + y0*y1 + y1^2
sage: HLQp([2]).expand(1)
x^2
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLQ = Sym.hall_littlewood().Q()
>>> HLQp = Sym.hall_littlewood().Qp()
>>> HLP([Integer(2)]).expand(Integer(2))
x0^2 + (-t + 1)*x0*x1 + x1^2
>>> HLQ([Integer(2)]).expand(Integer(2))
(-t + 1)*x0^2 + (t^2 - 2*t + 1)*x0*x1 + (-t + 1)*x1^2
>>> HLQp([Integer(2)]).expand(Integer(2))
x0^2 + x0*x1 + x1^2
>>> HLQp([Integer(2)]).expand(Integer(2), 'y')
y0^2 + y0*y1 + y1^2
>>> HLQp([Integer(2)]).expand(Integer(1))
x^2
```

scalar(*x*, *zee=None*)

Return standard scalar product between `self` and `x`.

This is the default implementation that converts both `self` and `x` into Schur functions and performs the scalar product that basis.

The Hall-Littlewood P basis is dual to the Qp basis with respect to this scalar product.

INPUT:

- `self` – an element of a Hall-Littlewood basis
- `x` – another symmetric element of the symmetric functions

OUTPUT: the scalar product between `self` and `x`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLP([2]).scalar(HLQp([2]))
1
sage: HLP([2]).scalar(HLQp([1,1]))
0
sage: HLP([2]).scalar(HLQ([2]), lambda mu: mu.centralizer_size(t = HLP.t))
1
sage: HLP([2]).scalar(HLQ([1,1]), lambda mu: mu.centralizer_size(t = HLP.
↪t))
0
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLQ = Sym.hall_littlewood().Q()
>>> HLQp = Sym.hall_littlewood().Qp()
>>> HLP([Integer(2)]).scalar(HLQp([Integer(2)]))
1
>>> HLP([Integer(2)]).scalar(HLQp([Integer(1),Integer(1)]))
0
```

(continues on next page)

(continued from previous page)

```
>>> HLP([Integer(2)]).scalar(HLQ([Integer(2)]), lambda mu: mu.centralizer_
↪size(t = HLP.t))
1
>>> HLP([Integer(2)]).scalar(HLQ([Integer(1),Integer(1)]), lambda mu: mu.
↪centralizer_size(t = HLP.t))
0
```

scalar_hl(*x*, *t=None*)

Return the Hall-Littlewood (with parameter `t`) scalar product of `self` and `x`.

The Hall-Littlewood scalar product is defined in Macdonald's book [Mac1995]. The power sum basis is orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu \prod_i 1/(1 - t^{\mu_i})$

The Hall-Littlewood P basis is dual to the Q basis with respect to this scalar product.

INPUT:

- `self` – an element of a Hall-Littlewood basis
- `x` – another symmetric element of the symmetric functions
- `t` – an optional parameter, if this parameter is not specified then the value of the `t` from the basis is used in the calculation

OUTPUT: the Hall-Littlewood scalar product between `self` and `x`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLP([2]).scalar_hl(HLQ([2]))
1
sage: HLP([2]).scalar_hl(HLQ([1,1]))
0
sage: HLQ([2]).scalar_hl(HLQ([2]))
-t + 1
sage: HLQ([2]).scalar_hl(HLQ([1,1]))
0
sage: HLP([2]).scalar_hl(HLP([2]))
-1/(t - 1)
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLQ = Sym.hall_littlewood().Q()
>>> HLP([Integer(2)]).scalar_hl(HLQ([Integer(2)]))
1
>>> HLP([Integer(2)]).scalar_hl(HLQ([Integer(1),Integer(1)]))
0
>>> HLQ([Integer(2)]).scalar_hl(HLQ([Integer(2)]))
-t + 1
>>> HLQ([Integer(2)]).scalar_hl(HLQ([Integer(1),Integer(1)]))
0
>>> HLP([Integer(2)]).scalar_hl(HLP([Integer(2)]))
-1/(t - 1)
```

construction()

Return a pair (F, R), where F is a SymmetricFunctionsFunctor and R is a ring, such that F(R) returns self.

EXAMPLES:

```
sage: P = SymmetricFunctions(QQ).hall_littlewood(t=2).P()
sage: P.construction()
(SymmetricFunctionsFunctor[Hall-Littlewood P with t=2], Rational Field)
```

```
>>> from sage.all import *
>>> P = SymmetricFunctions(QQ).hall_littlewood(t=Integer(2)).P()
>>> P.construction()
(SymmetricFunctionsFunctor[Hall-Littlewood P with t=2], Rational Field)
```

hall_littlewood_family()

The family of Hall-Littlewood bases associated to self.

INPUT:

- self – a Hall-Littlewood symmetric function basis

OUTPUT: the class of Hall-Littlewood bases

EXAMPLES:

```
sage: HLP = SymmetricFunctions(FractionField(QQ['t'])).hall_littlewood(1).P()
sage: HLP.hall_littlewood_family()
Hall-Littlewood polynomials with t=1 over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> HLP = SymmetricFunctions(FractionField(QQ['t'])).hall_
↪littlewood(Integer(1)).P()
>>> HLP.hall_littlewood_family()
Hall-Littlewood polynomials with t=1 over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field
```

product(*left*, *right*)

Multiply an element of the Hall-Littlewood symmetric function basis self and another symmetric function

Convert to the Schur basis, do the multiplication there, and convert back to self basis.

INPUT:

- self – a Hall-Littlewood symmetric function basis
- left – an element of the basis self
- right – another symmetric function

OUTPUT: the product of left and right expanded in the basis self

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])^2 # indirect doctest
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
```

(continues on next page)

(continued from previous page)

```
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ([2])^2 # indirect doctest
HLQ[2, 2] + (-t+1)*HLQ[3, 1] + (-t+1)*HLQ[4]

sage: HLQp = Sym.hall_littlewood().Qp()
sage: HLQp([2])^2 # indirect doctest
HLQp[2, 2] + (-t+1)*HLQp[3, 1] + (-t+1)*HLQp[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HLP = Sym.hall_littlewood().P()
>>> HLP([Integer(2)])**Integer(2) # indirect doctest
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]

>>> HLQ = Sym.hall_littlewood().Q()
>>> HLQ([Integer(2)])**Integer(2) # indirect doctest
HLQ[2, 2] + (-t+1)*HLQ[3, 1] + (-t+1)*HLQ[4]

>>> HLQp = Sym.hall_littlewood().Qp()
>>> HLQp([Integer(2)])**Integer(2) # indirect doctest
HLQp[2, 2] + (-t+1)*HLQp[3, 1] + (-t+1)*HLQp[4]
```

transition_matrix(*basis*, *n*)

Return the transitions matrix between `self` and `basis` for the homogeneous component of degree `n`.

INPUT:

- `self` – a Hall-Littlewood symmetric function basis
- `basis` – another symmetric function basis
- `n` – nonnegative integer representing the degree

OUTPUT:

- Returns a $r \times r$ matrix of elements of the base ring of `self` where r is the number of partitions of `n`. The entry corresponding to row μ, column ν is the coefficient of `basis` (ν) in `self` (μ)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLP = Sym.hall_littlewood().P()
sage: s   = Sym.schur()
sage: HLP.transition_matrix(s, 4)
[             1             -t              0            t^2           -t^3]
[             0              1             -t             -t      t^3 + t^2]
[             0              0              1             -t            t^3]
[             0              0              0              1 -t^3 - t^2 - t]
[             0              0              0              0              1]
sage: HLQ = Sym.hall_littlewood().Q()
sage: HLQ.transition_matrix(s,3)
[                        -t + 1                        t^2 - t                ␣
↪     -t^3 + t^2]
[                             0                  t^2 - 2*t + 1           -t^4␣
```

(continues on next page)

(continued from previous page)

```
↪+ t^3 + t^2 - t]
[                              0                              0 -t^6 + t^5 + t^
↪4 - t^2 - t + 1]
sage: HLQp = Sym.hall_littlewood().Qp()

[    t^3 t^2 + t       1]
```

class sage.combinat.sf.hall_littlewood.**HallLittlewood_p**(*hall_littlewood*)

Bases: *HallLittlewood_generic*

A class representing the Hall-Littlewood P basis of symmetric functions

class Element

Bases: *Element*

class sage.combinat.sf.hall_littlewood.**HallLittlewood_q**(*hall_littlewood*)

Bases: *HallLittlewood_generic*

The Q basis is defined as a normalization of the P basis.

INPUT:

- self – an instance of the Hall-Littlewood P basis
- hall_littlewood – a class for the family of Hall-Littlewood bases

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Q = Sym.hall_littlewood().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_
↪test_prod']) # products are too expensive, long time (3s on sage.math, 2012)
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]])  # long␣
↪time (depends on previous)

```

class Element

Bases: *Element*

5.1.286 Hecke Character Basis

The basis of symmetric functions given by characters of the Hecke algebra (of type A).

AUTHORS:

- Travis Scrimshaw (2017-08): Initial version

class sage.combinat.sf.hecke.**HeckeCharacter**(*sym*, *q*)

Bases: *SymmetricFunctionAlgebra_multiplicative*

Basis of the symmetric functions that gives the characters of the Hecke algebra in analogy to the Frobenius formula for the symmetric group.

Consider the Hecke algebra $H_n(q)$ with quadratic relations

$$T_i^2 = (q-1)T_i + q.$$

Let μ be a partition of n with length ℓ. The character χ of a $H_n(q)$-representation is completely determined by the elements T_{γ_μ}, where

$$\gamma_\mu = (\mu_1, \ldots, 1)(\mu_2 + \mu_1, \ldots, 1 + \mu_1) \cdots (n, \ldots, 1 + \sum_{i<\ell} \mu_i),$$

(written in cycle notation). We define a basis of the symmetric functions by

$$\bar{q}_\mu = \sum_{\lambda \vdash n} \chi^\lambda(T_{\gamma_\mu}) s_\lambda.$$

INPUT:

- `sym` – the ring of symmetric functions
- `q` – (default: `'q'`) the parameter q

EXAMPLES:

```
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character(q)
```

(continues on next page)

(continued from previous page)

```
sage: qbar[2] * qbar[3] * qbar[3,1]
qbar[3, 3, 2, 1]

sage: s = Sym.s()
sage: s(qbar([2]))
-s[1, 1] + q*s[2]
sage: s(qbar([4]))
-s[1, 1, 1, 1] + q*s[2, 1, 1] - q^2*s[3, 1] + q^3*s[4]
sage: qbar(s[2])
(1/(q+1))*qbar[1, 1] + (1/(q+1))*qbar[2]
sage: qbar(s[1,1])
(q/(q+1))*qbar[1, 1] - (1/(q+1))*qbar[2]

sage: s(qbar[2,1])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
sage: qbar(s[2,1])
(q/(q^2+q+1))*qbar[1, 1, 1] + ((q-1)/(q^2+q+1))*qbar[2, 1]
 - (1/(q^2+q+1))*qbar[3]
```

```
>>> from sage.all import *
>>> q = ZZ['q'].fraction_field().gen()
>>> Sym = SymmetricFunctions(q.parent())
>>> qbar = Sym.hecke_character(q)
>>> qbar[Integer(2)] * qbar[Integer(3)] * qbar[Integer(3),Integer(1)]
qbar[3, 3, 2, 1]

>>> s = Sym.s()
>>> s(qbar([Integer(2)]))
-s[1, 1] + q*s[2]
>>> s(qbar([Integer(4)]))
-s[1, 1, 1, 1] + q*s[2, 1, 1] - q^2*s[3, 1] + q^3*s[4]
>>> qbar(s[Integer(2)])
(1/(q+1))*qbar[1, 1] + (1/(q+1))*qbar[2]
>>> qbar(s[Integer(1),Integer(1)])
(q/(q+1))*qbar[1, 1] - (1/(q+1))*qbar[2]

>>> s(qbar[Integer(2),Integer(1)])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
>>> qbar(s[Integer(2),Integer(1)])
(q/(q^2+q+1))*qbar[1, 1, 1] + ((q-1)/(q^2+q+1))*qbar[2, 1]
 - (1/(q^2+q+1))*qbar[3]
```

We compute character tables for Hecke algebras, which correspond to the transition matrix from the $\bar{q}$ basis to the Schur basis:

```
sage: qbar.transition_matrix(s, 1)
[1]
sage: qbar.transition_matrix(s, 2)
[ q -1]
[ 1  1]
sage: qbar.transition_matrix(s, 3)
[  q^2    -q      1]
```

(continues on next page)

(continued from previous page)

```
[    q q - 1     -1]
[    1     2      1]
sage: qbar.transition_matrix(s, 4)
[      q^3      -q^2          0          q         -1]
[      q^2    q^2 - q        -q     -q + 1          1]
[      q^2 q^2 - 2*q   q^2 + 1   -2*q + 1          1]
[        q   2*q - 1     q - 1      q - 2         -1]
[        1         3         2          3          1]
```

```
>>> from sage.all import *
>>> qbar.transition_matrix(s, Integer(1))
[1]
>>> qbar.transition_matrix(s, Integer(2))
[ q -1]
[ 1  1]
>>> qbar.transition_matrix(s, Integer(3))
[  q^2     -q      1]
[    q q - 1     -1]
[    1     2      1]
>>> qbar.transition_matrix(s, Integer(4))
[      q^3      -q^2          0          q         -1]
[      q^2    q^2 - q        -q     -q + 1          1]
[      q^2 q^2 - 2*q   q^2 + 1   -2*q + 1          1]
[        q   2*q - 1     q - 1      q - 2         -1]
[        1         3         2          3          1]
```

We can do computations with a specialized q to a generic element of the base ring. We compute some examples with $q = 2$:

```
sage: qbar = Sym.qbar(q=2)
sage: s = Sym.schur()
sage: qbar(s[2,1])
2/7*qbar[1, 1, 1] + 1/7*qbar[2, 1] - 1/7*qbar[3]
sage: s(qbar[2,1])
-s[1, 1, 1] + s[2, 1] + 2*s[3]
```

```
>>> from sage.all import *
>>> qbar = Sym.qbar(q=Integer(2))
>>> s = Sym.schur()
>>> qbar(s[Integer(2),Integer(1)])
2/7*qbar[1, 1, 1] + 1/7*qbar[2, 1] - 1/7*qbar[3]
>>> s(qbar[Integer(2),Integer(1)])
-s[1, 1, 1] + s[2, 1] + 2*s[3]
```

REFERENCES:

- [Ram1991]
- [RR1997]

construction()

Return a pair `(F, R)`, where `F` is a `SymmetricFunctionsFunctor` and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: qbar = SymmetricFunctions(QQ['q']).qbar('q')
sage: qbar.construction()
(SymmetricFunctionsFunctor[Hecke character with q=q],
 Univariate Polynomial Ring in q over Rational Field)
```

```
>>> from sage.all import *
>>> qbar = SymmetricFunctions(QQ['q']).qbar('q')
>>> qbar.construction()
(SymmetricFunctionsFunctor[Hecke character with q=q],
 Univariate Polynomial Ring in q over Rational Field)
```

coproduct_on_generators(*r*)

Return the coproduct on the generator $\bar{q}_r$ of `self`.

Define the coproduct on $\bar{q}_r$ by

$$\Delta(\bar{q}_r) = \bar{q}_0 \otimes \bar{q}_r + (q-1) \sum_{j=1}^{r-1} \bar{q}_j \otimes \bar{q}_{r-j} + \bar{q}_r \otimes \bar{q}_0.$$

EXAMPLES:

```
sage: q = ZZ['q'].fraction_field().gen()
sage: Sym = SymmetricFunctions(q.parent())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: qbar[2].coproduct()
qbar[] # qbar[2] + (q-1)*qbar[1] # qbar[1] + qbar[2] # qbar[]
```

```
>>> from sage.all import *
>>> q = ZZ['q'].fraction_field().gen()
>>> Sym = SymmetricFunctions(q.parent())
>>> qbar = Sym.hecke_character()
>>> s = Sym.s()
>>> qbar[Integer(2)].coproduct()
qbar[] # qbar[2] + (q-1)*qbar[1] # qbar[1] + qbar[2] # qbar[]
```

5.1.287 Homogeneous symmetric functions

By this we mean the basis formed of the complete homogeneous symmetric functions h_λ, not an arbitrary graded basis.

class sage.combinat.sf.homogeneous.**SymmetricFunctionAlgebra_homogeneous**(*Sym*)

Bases: *SymmetricFunctionAlgebra_multiplicative*

A class of methods specific to the homogeneous basis of symmetric functions.

INPUT:

- `self` – a homogeneous basis of symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class Element

Bases: *Element*

expand(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: h([3]).expand(2)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
sage: h([1,1,1]).expand(2)
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
sage: h([2,1]).expand(3)
x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2
↪+ 2*x0*x2^2 + 2*x1*x2^2 + x2^3
sage: h([3]).expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
sage: h([3]).expand(2,alphabet='x,y')
x^3 + x^2*y + x*y^2 + y^3
sage: h([3]).expand(3,alphabet='x,y,z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
sage: (h([]) + 2*h([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: h([1]).expand(0)
0
sage: (3*h([])).expand(0)
3
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> h([Integer(3)]).expand(Integer(2))
x0^3 + x0^2*x1 + x0*x1^2 + x1^3
>>> h([Integer(1),Integer(1),Integer(1)]).expand(Integer(2))
x0^3 + 3*x0^2*x1 + 3*x0*x1^2 + x1^3
>>> h([Integer(2),Integer(1)]).expand(Integer(3))
x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2
↪+ 2*x0*x2^2 + 2*x1*x2^2 + x2^3
>>> h([Integer(3)]).expand(Integer(2),alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
>>> h([Integer(3)]).expand(Integer(2),alphabet='x,y')
x^3 + x^2*y + x*y^2 + y^3
>>> h([Integer(3)]).expand(Integer(3),alphabet='x,y,z')
x^3 + x^2*y + x*y^2 + y^3 + x^2*z + x*y*z + y^2*z + x*z^2 + y*z^2 + z^3
>>> (h([]) + Integer(2)*h([Integer(1)])).expand(Integer(3))
2*x0 + 2*x1 + 2*x2 + 1
>>> h([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*h([])).expand(Integer(0))
3
```

exponential_specialization(*t=None*, *q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q-exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R. It is defined whenever the base ring K is a **Q**-algebra and t is an element of R. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q-exponential specialization is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n, we have

$$ex_q(f) = (1-q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \to 1$ is ex.

INPUT:

- `t` – (default: `None`) the value to use for t; the default is to create a ring of polynomials in `t`
- `q` – (default: 1) the value to use for q; if `q` is `None`, then a ring (or fraction field) of polynomials in `q` is created

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: x = h[5,3]
sage: x.exponential_specialization()
1/720*t^8
sage: factorial(5)*factorial(3)
720

sage: x = 5*h[1,1,1] + 3*h[2,1] + 1
sage: x.exponential_specialization()
13/2*t^3 + 1
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> x = h[Integer(5),Integer(3)]
>>> x.exponential_specialization()
1/720*t^8
>>> factorial(Integer(5))*factorial(Integer(3))
720

>>> x = Integer(5)*h[Integer(1),Integer(1),Integer(1)] +␣
↪Integer(3)*h[Integer(2),Integer(1)] + Integer(1)
>>> x.exponential_specialization()
13/2*t^3 + 1
```

We also support the q-exponential_specialization:

```
sage: factor(h[3].exponential_specialization(q=var("q"), t=var("t")))    #␣
↪needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

```
>>> from sage.all import *
>>> factor(h[Integer(3)].exponential_specialization(q=var("q"), t=var("t
↪")))    # needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (*length()*) of the partition λ, where λ' denotes the conjugate partition (*conjugate()*) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

omega_involution() is a synonym for the *omega()* method.

OUTPUT: the image of `self` under the omega automorphism

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> a = h([Integer(2),Integer(1)]); a
h[2, 1]
>>> a.omega()
h[1, 1, 1] - h[2, 1]
>>> e = SymmetricFunctions(QQ).e()
>>> e(h([Integer(2),Integer(1)]).omega())
e[2, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the image of `self` under the omega automorphism

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: a = h([2,1]); a
h[2, 1]
sage: a.omega()
h[1, 1, 1] - h[2, 1]
sage: e = SymmetricFunctions(QQ).e()
sage: e(h([2,1]).omega())
e[2, 1]
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> a = h([Integer(2),Integer(1)]); a
h[2, 1]
>>> a.omega()
h[1, 1, 1] - h[2, 1]
>>> e = SymmetricFunctions(QQ).e()
>>> e(h([Integer(2),Integer(1)]).omega())
e[2, 1]
```

principal_specialization(*n=+Infinity*, *q=None*)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a K-algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` – (default: `infinity`) a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` – (default: `None`) the value to use for q; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2] (using Gaussian binomial coefficients $\binom{u}{v}_q$):

$$ps_{n,q}(h_\lambda) = \prod_i \binom{n+\lambda_i-1}{\lambda_i}_q,$$
$$ps_{n,1}(h_\lambda) = \prod_i \binom{n+\lambda_i-1}{\lambda_i},$$
$$ps_q(h_\lambda) = 1/\prod_i \prod_{j=1}^{\lambda_i}(1-q^j).$$

EXAMPLES:

```
sage: h = SymmetricFunctions(QQ).h()
sage: x = h[2,1]
sage: x.principal_specialization(3)
q^6 + 2*q^5 + 4*q^4 + 4*q^3 + 4*q^2 + 2*q + 1
sage: x = 3*h[2] + 2*h[1] + 1
sage: x.principal_specialization(3, q=var("q"))                           #␣
↪needs sage.symbolic
2*(q^3 - 1)/(q - 1) + 3*(q^4 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> x = h[Integer(2),Integer(1)]
>>> x.principal_specialization(Integer(3))
q^6 + 2*q^5 + 4*q^4 + 4*q^3 + 4*q^2 + 2*q + 1
>>> x = Integer(3)*h[Integer(2)] + Integer(2)*h[Integer(1)] + Integer(1)
>>> x.principal_specialization(Integer(3), q=var("q"))                    ␣
↪     # needs sage.symbolic
2*(q^3 - 1)/(q - 1) + 3*(q^4 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1
```

coproduct_on_generators(*i*)

Return the coproduct on h_i.

INPUT:

- `self` – a homogeneous basis of symmetric functions
- `i` – nonnegative integer

OUTPUT: the sum $\sum_{r=0}^{i} h_r \otimes h_{i-r}$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: h.coproduct_on_generators(2)
h[] # h[2] + h[1] # h[1] + h[2] # h[]
sage: h.coproduct_on_generators(0)
h[] # h[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> h = Sym.homogeneous()
```

(continues on next page)

(continued from previous page)

```
>>> h.coproduct_on_generators(Integer(2))
h[] # h[2] + h[1] # h[1] + h[2] # h[]
>>> h.coproduct_on_generators(Integer(0))
h[] # h[]
```

5.1.288 Jack Symmetric Functions

Jack's symmetric functions appear in [Ma1995] Chapter VI, section 10. Zonal polynomials are the subject of [Ma1995] Chapter VII. The parameter α in that reference is the parameter t in this implementation in sage.

REFERENCES:

class sage.combinat.sf.jack.**Jack**(*Sym*, *t*)

Bases: UniqueRepresentation

The family of Jack symmetric functions including the P, Q, J, Qp bases. The default parameter is `t`.

INPUT:

- `self` – the family of Jack symmetric function bases
- `Sym` – a ring of symmetric functions
- `t` – an optional parameter (default: `'t'`)

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).jack()
Jack polynomials over Fraction Field of Univariate Polynomial Ring in t over␣
↪Rational Field
sage: SymmetricFunctions(QQ).jack(1)
Jack polynomials with t=1 over Rational Field
```

```
>>> from sage.all import *
>>> SymmetricFunctions(FractionField(QQ['t'])).jack()
Jack polynomials over Fraction Field of Univariate Polynomial Ring in t over␣
↪Rational Field
>>> SymmetricFunctions(QQ).jack(Integer(1))
Jack polynomials with t=1 over Rational Field
```

J()

Return the algebra of Jack polynomials in the J basis.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the J basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack J basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).J()
Symmetric Functions over Rational Field in the Jack J with t=-1 basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack J basis
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.jack(t=-Integer(1)).J()
Symmetric Functions over Rational Field in the Jack J with t=-1 basis
```

At $t = 1$, the Jack polynomials in the J basis are scalar multiples of the Schur functions with the scalar given by a Partition's `hook_product()` method at 1:

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=1).J()
sage: s = Sym.schur()
sage: p = Partition([3,2,1,1])
sage: s(JJ(p)) == p.hook_product(1)*s(p)  # long time (4s on sage.math, 2012)
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> JJ = Sym.jack(t=Integer(1)).J()
>>> s = Sym.schur()
>>> p = Partition([Integer(3),Integer(2),Integer(1),Integer(1)])
>>> s(JJ(p)) == p.hook_product(Integer(1))*s(p)  # long time (4s on sage.math,
↪ 2012)
True
```

At $t = 2$, the Jack polynomials in the J basis are scalar multiples of the zonal polynomials with the scalar given by a Partition's `hook_product()` method at 2.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JJ = Sym.jack(t=2).J()
sage: Z = Sym.zonal()
sage: p = Partition([2,2,1])
sage: Z(JJ(p)) == p.hook_product(2)*Z(p)
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> JJ = Sym.jack(t=Integer(2)).J()
>>> Z = Sym.zonal()
>>> p = Partition([Integer(2),Integer(2),Integer(1)])
>>> Z(JJ(p)) == p.hook_product(Integer(2))*Z(p)
True
```

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JJ = Sym.jack().J()
sage: JP = Sym.jack().P()
sage: JJ(sum(JP(p) for p in Partitions(3)))
1/6*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JJ = Sym.jack().J()
>>> JP = Sym.jack().P()
>>> JJ(sum(JP(p) for p in Partitions(Integer(3))))
1/6*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
```

```
sage: s = Sym.schur()
sage: JJ(s([3])) # indirect doctest
((1/6*t^2-1/2*t+1/3)/(t^2+3*t+2))*JackJ[1, 1, 1] + ((t-1)/(t^2+5/
→2*t+1))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
sage: JJ(s([2,1]))
((1/3*t-1/3)/(t+2))*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1]
sage: JJ(s([1,1,1]))
1/6*JackJ[1, 1, 1]
```

```
>>> from sage.all import *
>>> s = Sym.schur()
>>> JJ(s([Integer(3)])) # indirect doctest
((1/6*t^2-1/2*t+1/3)/(t^2+3*t+2))*JackJ[1, 1, 1] + ((t-1)/(t^2+5/
→2*t+1))*JackJ[2, 1] + (1/2/(t^2+3/2*t+1/2))*JackJ[3]
>>> JJ(s([Integer(2),Integer(1)]))
((1/3*t-1/3)/(t+2))*JackJ[1, 1, 1] + (1/(t+2))*JackJ[2, 1]
>>> JJ(s([Integer(1),Integer(1),Integer(1)]))
1/6*JackJ[1, 1, 1]
```

P()

Return the algebra of Jack polynomials in the P basis.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the P basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
→over Rational Field in the Jack P basis
sage: Sym.jack(t=-1).P()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
→over Rational Field in the Jack P with t=-1 basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
→over Rational Field in the Jack P basis
>>> Sym.jack(t=-Integer(1)).P()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
→over Rational Field in the Jack P with t=-1 basis
```

At $t = 1$, the Jack polynomials in the P basis are the Schur symmetric functions.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=1).P()
sage: s = Sym.schur()
sage: s(JP([2,2,1]))
s[2, 2, 1]
sage: JP(s([2,2,1]))
JackP[2, 2, 1]
sage: JP([2,1])^2
JackP[2, 2, 1, 1] + JackP[2, 2, 2] + JackP[3, 1, 1, 1] + 2*JackP[3, 2, 1] +␣
↪JackP[3, 3] + JackP[4, 1, 1] + JackP[4, 2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> JP = Sym.jack(t=Integer(1)).P()
>>> s = Sym.schur()
>>> s(JP([Integer(2),Integer(2),Integer(1)]))
s[2, 2, 1]
>>> JP(s([Integer(2),Integer(2),Integer(1)]))
JackP[2, 2, 1]
>>> JP([Integer(2),Integer(1)])**Integer(2)
JackP[2, 2, 1, 1] + JackP[2, 2, 2] + JackP[3, 1, 1, 1] + 2*JackP[3, 2, 1] +␣
↪JackP[3, 3] + JackP[4, 1, 1] + JackP[4, 2]
```

At $t = 2$, the Jack polynomials in the P basis are the zonal polynomials.

```
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P()
sage: Z = Sym.zonal()
sage: Z(JP([2,2,1]))
Z[2, 2, 1]

Q()

Return the algebra of Jack polynomials in the Q basis.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the Q basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack Q basis
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.jack(t=-1).Q()
Symmetric Functions over Rational Field in the Jack Q with t=-1 basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack Q basis
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.jack(t=-Integer(1)).Q()
Symmetric Functions over Rational Field in the Jack Q with t=-1 basis
```

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JQ = Sym.jack().Q()
sage: JP = Sym.jack().P()
sage: JQ(sum(JP(p) for p in Partitions(3)))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] +␣
↪(3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JQ = Sym.jack().Q()
>>> JP = Sym.jack().P()
>>> JQ(sum(JP(p) for p in Partitions(Integer(3))))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1] +␣
↪(3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
```

```
sage: s = Sym.schur()
sage: JQ(s([3])) # indirect doctest
(1/6*t^3-1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3-2*t^2)/(t+2))*JackQ[2, 1] +␣
↪(3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
sage: JQ(s([2,1]))
(1/3*t^3-1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1]
sage: JQ(s([1,1,1]))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1]
```

```
>>> from sage.all import *
>>> s = Sym.schur()
>>> JQ(s([Integer(3)])) # indirect doctest
(1/6*t^3-1/2*t^2+1/3*t)*JackQ[1, 1, 1] + ((2*t^3-2*t^2)/(t+2))*JackQ[2, 1] +␣
↪(3*t^3/(t^2+3/2*t+1/2))*JackQ[3]
>>> JQ(s([Integer(2),Integer(1)]))
(1/3*t^3-1/3*t)*JackQ[1, 1, 1] + ((2*t^3+t^2)/(t+2))*JackQ[2, 1]
>>> JQ(s([Integer(1),Integer(1),Integer(1)]))
(1/6*t^3+1/2*t^2+1/3*t)*JackQ[1, 1, 1]
```

Qp()

Return the algebra of Jack polynomials in the Qp, which is dual to the P basis with respect to the standard scalar product.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the Q' basis of the Jack symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack Qp basis
sage: a = JQp([2])
sage: a.scalar(JP([2]))
1
sage: a.scalar(JP([1,1]))
0
sage: JP(JQp([2]))                        # todo: missing auto normalization
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
sage: JP._normalize(JP(JQp([2])))
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P()
>>> JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack Qp basis
>>> a = JQp([Integer(2)])
>>> a.scalar(JP([Integer(2)]))
1
>>> a.scalar(JP([Integer(1),Integer(1)]))
0
>>> JP(JQp([Integer(2)]))                            # todo: missing auto␣
↪normalization
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
>>> JP._normalize(JP(JQp([Integer(2)])))
((t-1)/(t+1))*JackP[1, 1] + JackP[2]
```

base_ring()

Return the base ring of the symmetric functions in which the Jack symmetric functions live.

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the base ring of the symmetric functions ring of `self`

EXAMPLES:

```
sage: J2 = SymmetricFunctions(QQ).jack(t=2)
sage: J2.base_ring()
Rational Field
```

```
>>> from sage.all import *
>>> J2 = SymmetricFunctions(QQ).jack(t=Integer(2))
>>> J2.base_ring()
Rational Field
```

symmetric_function_ring()

Return the base ring of the symmetric functions of the Jack symmetric function bases

INPUT:

- `self` – the family of Jack symmetric function bases

OUTPUT: the symmetric functions ring of `self`

EXAMPLES:

```
sage: Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
sage: Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
```

```
>>> from sage.all import *
>>> Jacks = SymmetricFunctions(FractionField(QQ['t'])).jack()
>>> Jacks.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
```

class sage.combinat.sf.jack.**JackPolynomials_generic**(*jack*)

Bases: *SymmetricFunctionAlgebra_generic*

A class of methods which are common to all Jack bases of the symmetric functions.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(QQ)
sage: JP = Sym.jack(t=2).P(); JP.base_ring()
Rational Field
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P(); JP.base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
>>> Sym = SymmetricFunctions(QQ)
>>> JP = Sym.jack(t=Integer(2)).P(); JP.base_ring()
Rational Field
```

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

scalar_jack(*x*, *t=None*)

A scalar product where the power sums are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{length(\mu)}$

INPUT:

- `self` – an element of a Jack basis of the symmetric functions
- `x` – an element of the symmetric functions
- `t` – an optional parameter (default: `None`; uses the parameter from the basis)

OUTPUT: the Jack scalar product between `x` and `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JQ = Sym.jack().Q()
sage: p = Partitions(3).list()
sage: matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])
[1 0 0]
[0 1 0]
[0 0 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P()
>>> JQ = Sym.jack().Q()
>>> p = Partitions(Integer(3)).list()
>>> matrix([[JP(a).scalar_jack(JQ(b)) for a in p] for b in p])
[1 0 0]
[0 1 0]
[0 0 1]
```

c1(*part*)

Return the t-Jack scalar product between `J(part)` and `P(part)`.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter `t` which is equal to the scalar product of `J(part)` and `P(part)`

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c1(Partition([2,1]))
t + 2
```

```
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> JP.c1(Partition([Integer(2),Integer(1)]))
t + 2
```

c2(*part*)

Return the t-Jack scalar product between `J(part)` and `Q(part)`.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition

- **t – an optional parameter (default: uses the parameter t from the** Jack basis)

OUTPUT:

- a polynomial in the parameter `t` which is equal to the scalar product of `J(part)` and `Q(part)`

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JP.c2(Partition([2,1]))
2*t^3 + t^2
```

```
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> JP.c2(Partition([Integer(2),Integer(1)]))
2*t^3 + t^2
```

construction()

Return a pair `(F, R)`, where `F` is a `SymmetricFunctionsFunctor` and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P()
sage: JP.construction()
(SymmetricFunctionsFunctor[Jack P],
 Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P()
>>> JP.construction()
(SymmetricFunctionsFunctor[Jack P],
 Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

coproduct_by_coercion(*elt*)

Return the coproduct of the element `elt` by coercion to the Schur basis.

INPUT:

- `self` – a Jack symmetric function basis
- `elt` – an instance of this basis

OUTPUT:

- The coproduct acting on `elt`, the result is an element of the tensor squared of the Jack symmetric function basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: Sym.jack().P()[2,2].coproduct() #indirect doctest
JackP[] # JackP[2, 2] + (2/(t+1))*JackP[1] # JackP[2, 1] + ((8*t+4)/(t^3+4*t^
↪2+5*t+2))*JackP[1, 1] # JackP[1, 1] + JackP[2] # JackP[2] + (2/
↪(t+1))*JackP[2, 1] # JackP[1] + JackP[2, 2] # JackP[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> Sym.jack().P()[Integer(2),Integer(2)].coproduct() #indirect doctest
JackP[] # JackP[2, 2] + (2/(t+1))*JackP[1] # JackP[2, 1] + ((8*t+4)/(t^3+4*t^
→2+5*t+2))*JackP[1, 1] # JackP[1, 1] + JackP[2] # JackP[2] + (2/
→(t+1))*JackP[2, 1] # JackP[1] + JackP[2, 2] # JackP[]
```

jack_family()

Return the family of Jack bases associated to the basis `self`.

INPUT:

- `self` – a Jack basis of the symmetric functions

EXAMPLES:

```
sage: JackP = SymmetricFunctions(QQ).jack(t=2).P()
sage: JackP.jack_family()
Jack polynomials with t=2 over Rational Field
```

```
>>> from sage.all import *
>>> JackP = SymmetricFunctions(QQ).jack(t=Integer(2)).P()
>>> JackP.jack_family()
Jack polynomials with t=2 over Rational Field
```

product(*left*, *right*)

The product of two Jack symmetric functions is done by multiplying the elements in the P basis and then expressing the elements in the basis `self`.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `left`, `right` – symmetric function elements

OUTPUT: the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JJ([1])^2              # indirect doctest
(t/(t+1))*JackJ[1, 1] + (1/(t+1))*JackJ[2]
sage: JJ([2])^2
(t^2/(t^2+3/2*t+1/2))*JackJ[2, 2] + (4/3*t/(t^2+4/3*t+1/3))*JackJ[3, 1] + ((1/
→6*t+1/6)/(t^2+5/6*t+1/6))*JackJ[4]
sage: JQ = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
sage: JQ([1])^2              # indirect doctest
JackQ[1, 1] + (2/(t+1))*JackQ[2]
sage: JQ([2])^2
JackQ[2, 2] + (2/(t+1))*JackQ[3, 1] + ((t+1)/(t^2+5/6*t+1/6))*JackQ[4]
```

```
>>> from sage.all import *
>>> JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
>>> JJ([Integer(1)])**Integer(2)              # indirect doctest
(t/(t+1))*JackJ[1, 1] + (1/(t+1))*JackJ[2]
>>> JJ([Integer(2)])**Integer(2)
```

(continues on next page)

(continued from previous page)

```
(t^2/(t^2+3/2*t+1/2))*JackJ[2, 2] + (4/3*t/(t^2+4/3*t+1/3))*JackJ[3, 1] + ((1/
↪6*t+1/6)/(t^2+5/6*t+1/6))*JackJ[4]
>>> JQ = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
>>> JQ([Integer(1)])**Integer(2)              # indirect doctest
JackQ[1, 1] + (2/(t+1))*JackQ[2]
>>> JQ([Integer(2)])**Integer(2)
JackQ[2, 2] + (2/(t+1))*JackQ[3, 1] + ((t+1)/(t^2+5/6*t+1/6))*JackQ[4]
```

class sage.combinat.sf.jack.**JackPolynomials_j**(*jack*)

Bases: *JackPolynomials_generic*

The J basis is a defined as a normalized form of the P basis.

INPUT:

- `self` – an instance of the Jack P basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: J = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: TestSuite(J).run(skip=['_test_associativity', '_test_distributivity', '_
↪test_prod']) # products are too expensive
sage: TestSuite(J).run(elements = [J.t*J[1,1]+J[2], J[1]+(1+J.t)*J[1,1]])  # long␣
↪time (3s on sage.math, 2012)
```

```
>>> from sage.all import *
>>> J = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
>>> TestSuite(J).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
>>> TestSuite(J).run(elements = [J.t*J[Integer(1),Integer(1)]+J[Integer(2)],␣
↪J[Integer(1)]+(Integer(1)+J.t)*J[Integer(1),Integer(1)]])  # long time (3s on␣
↪sage.math, 2012)
```

class Element

Bases: *Element*

class sage.combinat.sf.jack.**JackPolynomials_p**(*jack*)

Bases: *JackPolynomials_generic*

The P basis is uni-triangularly related to the monomial basis and orthogonal with respect to the Jack scalar product.

INPUT:

- `self` – an instance of the Jack P basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: TestSuite(P).run(skip=['_test_associativity', '_test_distributivity', '_
↪test_prod']) # products are too expensive
sage: TestSuite(P).run(elements = [P.t*P[1,1]+P[2], P[1]+(1+P.t)*P[1,1]])
```

```
>>> from sage.all import *
>>> P = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> TestSuite(P).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
>>> TestSuite(P).run(elements = [P.t*P[Integer(1),Integer(1)]+P[Integer(2)],␣
↪P[Integer(1)]+(Integer(1)+P.t)*P[Integer(1),Integer(1)]])
```

class Element

Bases: *Element*

scalar_jack(*x*, *t=None*)

The scalar product on the symmetric functions where the power sums are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{length(mu)}$ where the t parameter from the Jack symmetric function family.

INPUT:

- `self` – an element of the Jack P basis
- `x` – an element of the P basis

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: l = [JP(p) for p in Partitions(3)]
sage: matrix([[a.scalar_jack(b) for a in l] for b in l])
[3*t^3/(t^2 + 3/2*t + 1/2)                         0                         ␣
↪   0]
[                        0      (2*t^3 + t^2)/(t + 2)                         ␣
↪   0]
[                        0                         0 1/6*t^3 + 1/2*t^2 +␣
↪1/3*t]
```

```
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> l = [JP(p) for p in Partitions(Integer(3))]
>>> matrix([[a.scalar_jack(b) for a in l] for b in l])
[3*t^3/(t^2 + 3/2*t + 1/2)                         0                         ␣
↪   0]
[                        0      (2*t^3 + t^2)/(t + 2)                         ␣
↪   0]
[                        0                         0 1/6*t^3 + 1/2*t^2 +␣
↪1/3*t]
```

product(*left*, *right*)

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis `self`.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `left`, `right` – symmetric function elements

OUTPUT: the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: m = JP.symmetric_function_ring().m()
```

(continues on next page)

(continued from previous page)

```
sage: JP([1])^2 # indirect doctest
(2*t/(t+1))*JackP[1, 1] + JackP[2]
sage: m(_)
2*m[1, 1] + m[2]
sage: JP = SymmetricFunctions(QQ).jack(t=2).P()
sage: JP([2,1])^2
125/63*JackP[2, 2, 1, 1] + 25/12*JackP[2, 2, 2] + 25/18*JackP[3, 1, 1, 1] +
↪12/5*JackP[3, 2, 1] + 4/3*JackP[3, 3] + 4/3*JackP[4, 1, 1] + JackP[4, 2]
sage: m(_)
45*m[1, 1, 1, 1, 1, 1] + 51/2*m[2, 1, 1, 1, 1] + 29/2*m[2, 2, 1, 1] + 33/
↪4*m[2, 2, 2] + 9*m[3, 1, 1, 1] + 5*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] +
↪m[4, 2]
```

```
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> m = JP.symmetric_function_ring().m()
>>> JP([Integer(1)])**Integer(2) # indirect doctest
(2*t/(t+1))*JackP[1, 1] + JackP[2]
>>> m(_)
2*m[1, 1] + m[2]

>>> JP([Integer(2),Integer(1)])**Integer(2)
125/63*JackP[2, 2, 1, 1] + 25/12*JackP[2, 2, 2] + 25/18*JackP[3, 1, 1, 1] +
↪12/5*JackP[3, 2, 1] + 4/3*JackP[3, 3] + 4/3*JackP[4, 1, 1] + JackP[4, 2]
>>> m(_)
45*m[1, 1, 1, 1, 1, 1] + 51/2*m[2, 1, 1, 1, 1] + 29/2*m[2, 2, 1, 1] + 33/
↪4*m[2, 2, 2] + 9*m[3, 1, 1, 1] + 5*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] +
↪m[4, 2]
```

scalar_jack_basis(*part1*, *part2=None*)

Return the scalar product of $P(part1)$ and $P(part2)$.

This is equation (10.16) of [Mc1995] on page 380.

INPUT:

- `self` – an instance of the Jack P basis of the symmetric functions
- `part1` – a partition
- `part2` – an optional partition (default: `None`)

OUTPUT:

- the scalar product between $P(part1)$ and $P(part2)$ (or itself if $part2$ is None)

REFERENCES:

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: JP._normalize_coefficients(JP.scalar_jack_basis(Partition([3,2,1]),
↪Partition([3,2,1])))
```

(continues on next page)

(continued from previous page)

```
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
sage: JJ(JP[3,2,1]).scalar_jack(JP[3,2,1])
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
```

```
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> JJ = SymmetricFunctions(FractionField(QQ['t'])).jack().J()
>>> JP.scalar_jack_basis(Partition([Integer(2),Integer(1)]),␣
↪Partition([Integer(1),Integer(1),Integer(1)]))
0
>>> JP._normalize_coefficients(JP.scalar_jack_basis(Partition([Integer(3),
↪Integer(2),Integer(1)]), Partition([Integer(3),Integer(2),Integer(1)])))
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
>>> JJ(JP[Integer(3),Integer(2),Integer(1)]).scalar_jack(JP[Integer(3),
↪Integer(2),Integer(1)])
(6*t^6 + 10*t^5 + 11/2*t^4 + t^3)/(t^3 + 11/2*t^2 + 10*t + 6)
```

With a single argument, takes $part2 = part1$:

```
sage: JP.scalar_jack_basis(Partition([2,1]), Partition([2,1]))
(2*t^3 + t^2)/(t + 2)
sage: JJ(JP[2,1]).scalar_jack(JP[2,1])
(2*t^3 + t^2)/(t + 2)
```

```
>>> from sage.all import *
>>> JP.scalar_jack_basis(Partition([Integer(2),Integer(1)]),␣
↪Partition([Integer(2),Integer(1)]))
(2*t^3 + t^2)/(t + 2)
>>> JJ(JP[Integer(2),Integer(1)]).scalar_jack(JP[Integer(2),Integer(1)])
(2*t^3 + t^2)/(t + 2)
```

class sage.combinat.sf.jack.**JackPolynomials_q**(*jack*)

Bases: *JackPolynomials_generic*

The Q basis is defined as a normalized form of the P basis.

INPUT:

- self – an instance of the Jack Q basis of the symmetric functions
- jack – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Q = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
sage: TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_
↪test_prod']) # products are too expensive
sage: TestSuite(Q).run(elements = [Q.t*Q[1,1]+Q[2], Q[1]+(1+Q.t)*Q[1,1]])  # long␣
↪time (3s on sage.math, 2012)
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(FractionField(QQ['t'])).jack().Q()
>>> TestSuite(Q).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
```

(continues on next page)

(continued from previous page)

```
>>> TestSuite(Q).run(elements = [Q.t*Q[Integer(1),Integer(1)]+Q[Integer(2)],
↪Q[Integer(1)]+(Integer(1)+Q.t)*Q[Integer(1),Integer(1)]])  # long time (3s on
↪sage.math, 2012)
```

class Element

Bases: *Element*

class sage.combinat.sf.jack.**JackPolynomials_qp**(*jack*)

Bases: *JackPolynomials_generic*

The Qp basis is the dual basis to the P basis with respect to the standard scalar product

INPUT:

- `self` – an instance of the Jack Qp basis of the symmetric functions
- `jack` – a family of Jack symmetric function bases

EXAMPLES:

```
sage: Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_
↪test_prod']) # products are too expensive
sage: TestSuite(Qp).run(elements = [Qp.t*Qp[1,1]+Qp[2], Qp[1]+(1+Qp.t)*Qp[1,1]])
↪# long time (3s on sage.math, 2012)
```

```
>>> from sage.all import *
>>> Qp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
>>> TestSuite(Qp).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
>>> TestSuite(Qp).run(elements = [Qp.t*Qp[Integer(1),Integer(1)]+Qp[Integer(2)],
↪Qp[Integer(1)]+(Integer(1)+Qp.t)*Qp[Integer(1),Integer(1)]])  # long time (3s
↪on sage.math, 2012)
```

class Element

Bases: *Element*

coproduct_by_coercion(*elt*)

Return the coproduct of the element `elt` by coercion to the Schur basis.

INPUT:

- `elt` – an instance of the `Qp` basis

OUTPUT:

- The coproduct acting on `elt`, the result is an element of the tensor squared of the `Qp` symmetric function basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: JQp = Sym.jack().Qp()
sage: JQp[2,2].coproduct()   #indirect doctest
JackQp[] # JackQp[2, 2] + (2*t/(t+1))*JackQp[1] # JackQp[2, 1] + JackQp[1, 1]
↪# JackQp[1, 1] + ((2*t^3+4*t^2)/(t^3+5/2*t^2+2*t+1/2))*JackQp[2] #
↪JackQp[2] + (2*t/(t+1))*JackQp[2, 1] # JackQp[1] + JackQp[2, 2] # JackQp[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> JQp = Sym.jack().Qp()
>>> JQp[Integer(2),Integer(2)].coproduct()   #indirect doctest
JackQp[] # JackQp[2, 2] + (2*t/(t+1))*JackQp[1] # JackQp[2, 1] + JackQp[1, 1]
↪# JackQp[1, 1] + ((2*t^3+4*t^2)/(t^3+5/2*t^2+2*t+1/2))*JackQp[2] #␣
↪JackQp[2] + (2*t/(t+1))*JackQp[2, 1] # JackQp[1] + JackQp[2, 2] # JackQp[]
```

product (*left*, *right*)

The product of two Jack symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements the basis `self`.

INPUT:

- `self` – an instance of the Jack Qp basis of the symmetric functions
- `left`, `right` – symmetric function elements

OUTPUT: the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: JQp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
sage: h = JQp.symmetric_function_ring().h()
sage: JQp([1])^2 # indirect doctest
JackQp[1, 1] + (2/(t+1))*JackQp[2]
sage: h(_)
h[1, 1]
sage: JQp = SymmetricFunctions(QQ).jack(t=2).Qp()
sage: h = SymmetricFunctions(QQ).h()
sage: JQp([2,1])^2
JackQp[2, 2, 1, 1] + 2/3*JackQp[2, 2, 2] + 2/3*JackQp[3, 1, 1, 1] + 48/
↪35*JackQp[3, 2, 1] + 28/75*JackQp[3, 3] + 128/225*JackQp[4, 1, 1] + 28/
↪75*JackQp[4, 2]
sage: h(_)
h[2, 2, 1, 1] - 6/5*h[3, 2, 1] + 9/25*h[3, 3]
```

```
>>> from sage.all import *
>>> JQp = SymmetricFunctions(FractionField(QQ['t'])).jack().Qp()
>>> h = JQp.symmetric_function_ring().h()
>>> JQp([Integer(1)])**Integer(2) # indirect doctest
JackQp[1, 1] + (2/(t+1))*JackQp[2]
>>> h(_)
h[1, 1]
>>> JQp = SymmetricFunctions(QQ).jack(t=Integer(2)).Qp()
>>> h = SymmetricFunctions(QQ).h()
>>> JQp([Integer(2),Integer(1)])**Integer(2)
JackQp[2, 2, 1, 1] + 2/3*JackQp[2, 2, 2] + 2/3*JackQp[3, 1, 1, 1] + 48/
↪35*JackQp[3, 2, 1] + 28/75*JackQp[3, 3] + 128/225*JackQp[4, 1, 1] + 28/
↪75*JackQp[4, 2]
>>> h(_)
h[2, 2, 1, 1] - 6/5*h[3, 2, 1] + 9/25*h[3, 3]
```

class sage.combinat.sf.jack.**SymmetricFunctionAlgebra_zonal** (*Sym*)

Bases: *SymmetricFunctionAlgebra_generic*

Return the algebra of zonal polynomials.

INPUT:

- `self` – a zonal basis of the symmetric functions
- `Sym` – a ring of the symmetric functions

EXAMPLES:

```
sage: Z = SymmetricFunctions(QQ).zonal()
sage: Z([2])^2
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
sage: Z = SymmetricFunctions(QQ).zonal()
sage: TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_
↪test_prod']) # products are too expensive
sage: TestSuite(Z).run(elements = [Z[1,1]+Z[2], Z[1]+2*Z[1,1]])
```

```
>>> from sage.all import *
>>> Z = SymmetricFunctions(QQ).zonal()
>>> Z([Integer(2)])**Integer(2)
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
>>> Z = SymmetricFunctions(QQ).zonal()
>>> TestSuite(Z).run(skip=['_test_associativity', '_test_distributivity', '_test_
↪prod']) # products are too expensive
>>> TestSuite(Z).run(elements = [Z[Integer(1),Integer(1)]+Z[Integer(2)],
↪Z[Integer(1)]+Integer(2)*Z[Integer(1),Integer(1)]])
```

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

scalar_zonal(*x*)

The zonal scalar product has the power sum basis and the zonal symmetric functions are orthogonal. In particular, $\langle p_\mu, p_\mu \rangle = z_\mu 2^{length(\mu)}$.

INPUT:

- `self` – an element of the zonal basis
- `x` – an element of the symmetric function

OUTPUT: the scalar product between `self` and `x`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: parts = Partitions(3).list()
sage: matrix([[Z(a).scalar_zonal(Z(b)) for a in parts] for b in parts])
[16/5    0    0]
[   0    5    0]
[   0    0    4]
sage: p = Z.symmetric_function_ring().power()
sage: matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
[ 6  0  0]
[ 0  8  0]
[ 0  0 48]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Z = Sym.zonal()
>>> parts = Partitions(Integer(3)).list()
>>> matrix([[Z(a).scalar_zonal(Z(b)) for a in parts] for b in parts])
[16/5    0    0]
[   0    5    0]
[   0    0    4]
>>> p = Z.symmetric_function_ring().power()
>>> matrix([[Z(p(a)).scalar_zonal(p(b)) for a in parts] for b in parts])
[ 6  0  0]
[ 0  8  0]
[ 0  0 48]
```

product(*left*, *right*)

The product of two zonal symmetric functions is done by multiplying the elements in the monomial basis and then expressing the elements in the basis `self`.

INPUT:

- `self` – a zonal basis of the symmetric functions
- `left`, `right` – symmetric function elements

OUTPUT: the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Z = Sym.zonal()
sage: JP = Sym.jack(t=1).P()
sage: Z([2])*Z([3])                          # indirect doctest
192/175*Z[3, 2] + 32/45*Z[4, 1] + Z[5]
sage: Z([2])*JP([2])
10/27*Z[2, 1, 1] + 64/45*Z[2, 2] + 23/21*Z[3, 1] + Z[4]
sage: JP = Sym.jack(t=2).P()
sage: Z([2])*JP([2])
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Z = Sym.zonal()
>>> JP = Sym.jack(t=Integer(1)).P()
>>> Z([Integer(2)])*Z([Integer(3)])                          # indirect doctest
192/175*Z[3, 2] + 32/45*Z[4, 1] + Z[5]
>>> Z([Integer(2)])*JP([Integer(2)])
10/27*Z[2, 1, 1] + 64/45*Z[2, 2] + 23/21*Z[3, 1] + Z[4]
>>> JP = Sym.jack(t=Integer(2)).P()
>>> Z([Integer(2)])*JP([Integer(2)])
64/45*Z[2, 2] + 16/21*Z[3, 1] + Z[4]
```

`sage.combinat.sf.jack.`**c1**(*part*, *t*)

Return the t-Jack scalar product between `J(part)` and `P(part)`.

INPUT:

- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter `t` which is equal to the scalar product of `J(part)` and `P(part)`

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c1
sage: t = QQ['t'].gen()
sage: [c1(p,t) for p in Partitions(3)]
[2*t^2 + 3*t + 1, t + 2, 6]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.jack import c1
>>> t = QQ['t'].gen()
>>> [c1(p,t) for p in Partitions(Integer(3))]
[2*t^2 + 3*t + 1, t + 2, 6]
```

`sage.combinat.sf.jack.`**`c2`**`(`*part*, *t*`)`

Return the t-Jack scalar product between `J(part)` and `Q(part)`.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `part` – a partition
- `t` – an optional parameter (default: uses the parameter t from the Jack basis)

OUTPUT:

- a polynomial in the parameter `t` which is equal to the scalar product of `J(part)` and `Q(part)`

EXAMPLES:

```
sage: from sage.combinat.sf.jack import c2
sage: t = QQ['t'].gen()
sage: [c2(p,t) for p in Partitions(3)]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.jack import c2
>>> t = QQ['t'].gen()
>>> [c2(p,t) for p in Partitions(Integer(3))]
[6*t^3, 2*t^3 + t^2, t^3 + 3*t^2 + 2*t]
```

`sage.combinat.sf.jack.`**`normalize_coefficients`**`(`*self*, *c*`)`

If our coefficient ring is the field of fractions over a univariate polynomial ring over the rationals, then we should clear both the numerator and denominator of the denominators of their coefficients.

INPUT:

- `self` – a Jack basis of the symmetric functions
- `c` – a coefficient in the base ring of `self`

OUTPUT: divide numerator and denominator by the greatest common divisor

EXAMPLES:

```
sage: JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
sage: t = JP.base_ring().gen()
sage: a = 2/(1/2*t+1/2)
sage: JP._normalize_coefficients(a)
4/(t + 1)
sage: a = 1/(1/3+1/6*t)
sage: JP._normalize_coefficients(a)
6/(t + 2)
sage: a = 24/(4*t^2 + 12*t + 8)
sage: JP._normalize_coefficients(a)
6/(t^2 + 3*t + 2)
```

```
>>> from sage.all import *
>>> JP = SymmetricFunctions(FractionField(QQ['t'])).jack().P()
>>> t = JP.base_ring().gen()
>>> a = Integer(2)/(Integer(1)/Integer(2)*t+Integer(1)/Integer(2))
>>> JP._normalize_coefficients(a)
4/(t + 1)
>>> a = Integer(1)/(Integer(1)/Integer(3)+Integer(1)/Integer(6)*t)
>>> JP._normalize_coefficients(a)
6/(t + 2)
>>> a = Integer(24)/(Integer(4)*t**Integer(2) + Integer(12)*t + Integer(8))
>>> JP._normalize_coefficients(a)
6/(t^2 + 3*t + 2)
```

sage.combinat.sf.jack.**part_scalar_jack**(*part1*, *part2*, *t*)

Return the Jack scalar product between `p(part1)` and `p(part2)` where p is the power-sum basis.

INPUT:

- `part1`, `part2` – two partitions
- `t` – a parameter

OUTPUT: the scalar product between the power sum indexed by `part1` and `part2`

EXAMPLES:

```
sage: Q.<t> = QQ[]
sage: from sage.combinat.sf.jack import part_scalar_jack
sage: matrix([[part_scalar_jack(p1,p2,t) for p1 in Partitions(4)] for p2 in␣
↪Partitions(4)])
[   4*t       0       0       0       0]
[     0   3*t^2       0       0       0]
[     0       0   8*t^2       0       0]
[     0       0       0   4*t^3       0]
[     0       0       0       0 24*t^4]
```

```
>>> from sage.all import *
>>> Q = QQ['t']; (t,) = Q._first_ngens(1)
>>> from sage.combinat.sf.jack import part_scalar_jack
>>> matrix([[part_scalar_jack(p1,p2,t) for p1 in Partitions(Integer(4))] for p2␣
↪in Partitions(Integer(4))])
[   4*t       0       0       0       0]
[     0   3*t^2       0       0       0]
```

(continues on next page)

(continued from previous page)

```
[      0       0   8*t^2       0       0]
[      0       0       0   4*t^3       0]
[      0       0       0       0  24*t^4]
```

5.1.289 Quotient of symmetric function space by ideal generated by Hall-Littlewood symmetric functions

The quotient of symmetric functions by the ideal generated by the Hall-Littlewood P symmetric functions indexed by partitions with first part greater than k. When $t = 1$ this space is the quotient of the symmetric functions by the ideal generated by the monomial symmetric functions indexed by partitions with first part greater than k.

AUTHORS:

- Chris Berg (2012-12-01)
- Mike Zabrocki - k-bounded Hall Littlewood P and dual k-Schur functions (2012-12-02)

class sage.combinat.sf.k_dual.**AffineSchurFunctions**(*kBoundedRing*)

Bases: *KBoundedQuotientBasis*

This basis is dual to the k-Schur functions at $t = 1$. This realization follows the monomial expansion given by Lam [Lam2006].

REFERENCES:

class sage.combinat.sf.k_dual.**DualkSchurFunctions**(*kBoundedRing*)

Bases: *KBoundedQuotientBasis*

This basis is dual to the k-Schur functions. The expansion is given in Section 4.12 of [LLMSSZ]. When $t = 1$ this basis is equal to the *AffineSchurFunctions* and that basis is more efficient in this case.

REFERENCES:

class sage.combinat.sf.k_dual.**KBoundedQuotient**(*Sym*, *k*, *t='t'*)

Bases: UniqueRepresentation, Parent

Initialization of the ring of Symmetric functions modulo the ideal of monomial symmetric functions which are indexed by partitions whose first part is greater than k.

INPUT:

- Sym – an element of class *sage.combinat.sf.sf.SymmetricFunctions*
- k – positive integer
- R – a ring

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: km = Q.km()
sage: km
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the 3-
↪bounded monomial basis
sage: F = Q.affineSchur()
sage: F(km(F[3,1,1])) == F[3,1,1]
```

```

AffineGrothendieckPolynomial(*la*, *m*)

Return the affine Grothendieck polynomial indexed by the partition `la`. Because this belongs to the completion of the algebra, and hence is an infinite sum, it computes only up to those symmetric functions of degree at most `m`. See `_AffineGrothendieckPolynomial()` for the code.

INPUT:

- `la` – a k-bounded partition
- `m` – integer

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.AffineGrothendieckPolynomial([2,1],4)
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.AffineGrothendieckPolynomial([Integer(2),Integer(1)],Integer(4))
2*m3[1, 1, 1] - 8*m3[1, 1, 1, 1] + m3[2, 1] - 3*m3[2, 1, 1] - m3[2, 2]
```

F()

The affine Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.stanley_symmetric_function()`) indexed by an affine Grassmannian permutation.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪2-bounded affine Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
↪affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪2-bounded affine Schur basis
```

a_realization()

Return a particular realization of `self` (the basis of k-bounded monomials if $t = 1$ and the basis of k-bounded Hall-Littlewood functions otherwise).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪3-bounded monomial basis
sage: Q = Sym.kBoundedQuotient(3,t=2)
sage: Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the
↪3-bounded Hall-Littlewood P basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Q = Sym.kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪3-bounded monomial basis
>>> Q = Sym.kBoundedQuotient(Integer(3),t=Integer(2))
>>> Q.a_realization()
3-Bounded Quotient of Symmetric Functions over Rational Field with t=2 in the
↪3-bounded Hall-Littlewood P basis
```

affineSchur()

The affine Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. This is also equal to the affine Stanley symmetric functions (see `WeylGroups.ElementMethods.stanley_symmetric_function()`) indexed by an affine Grassmannian permutation.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪2-bounded affine Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
↪affineSchur()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the
↪2-bounded affine Schur basis
```

ambient()

Returns the Symmetric Functions over the same ring as `self`. This is needed to realize our ring as a quotient.

an_element()

Return an element of the quotient ring of k-bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.an_element()
2*m3[] + 2*m3[1] + 3*m3[2]
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
```

(continues on next page)

(continued from previous page)

```
>>> Q.an_element()
2*m3[] + 2*m3[1] + 3*m3[2]
```

dks()

The dual k-Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the *affineSchur()* basis.

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_
↪Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
↪dual_k_Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

dual_k_Schur()

The dual k-Schur basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At $t = 1$ this is also equal to the affine Schur basis and calculations will be faster using elements in the *affineSchur()* basis.

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).dual_k_
↪Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
↪dual_k_Schur()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the dual 2-Schur basis
```

kHLP()

The Hall-Littlewood P basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At $t = 1$ this basis is equal to the k-bounded monomial basis and calculations will be faster using elements in the k-bounded monomial basis (see *kmonomial()*).

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).
↪kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P␣
↪basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
↪kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P␣
↪basis
```

kHallLittlewoodP()

The Hall-Littlewood P basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions. At $t = 1$ this basis is equal to the k-bounded monomial basis and calculations will be faster using elements in the k-bounded monomial basis (see *kmonomial()*).

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(2).
↪kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P␣
↪basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(Integer(2)).
↪kHallLittlewoodP()
2-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the 2-bounded Hall-Littlewood P␣
↪basis
```

km()

The monomial basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪2-bounded monomial basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
↪kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪2-bounded monomial basis
```

kmonomial()

The monomial basis of the k-bounded quotient of symmetric functions, indexed by k-bounded partitions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedQuotient(2,t=1).kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪2-bounded monomial basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedQuotient(Integer(2),t=Integer(1)).
```

(continues on next page)

(continued from previous page)

```
↪kmonomial()
2-Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪2-bounded monomial basis
```

lift(*la*)

Give the lift map from the quotient ring of k-bounded symmetric functions to the symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- `la` – a k-bounded partition

OUTPUT:

- **The monomial element or a Hall-Littlewood P element of the symmetric functions** indexed by the partition `la`.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.lift([2,1])
m[2, 1]
sage: Q = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: Q.lift([2,1])
HLP[2, 1]
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.lift([Integer(2),Integer(1)])
m[2, 1]
>>> Q = SymmetricFunctions(QQ['t'].fraction_field()).
↪kBoundedQuotient(Integer(3))
>>> Q.lift([Integer(2),Integer(1)])
HLP[2, 1]
```

one()

Return the unit of the quotient ring of k-bounded symmetric functions. This method is here to make the TestSuite run properly.

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.one()
m3[]
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.one()
m3[]
```

realizations()

A list of realizations of the k-bounded quotient.

EXAMPLES:

```
sage: kQ = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3)
sage: kQ.realizations()
[3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the 3-bounded monomial basis, 3-
↪Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field in the 3-bounded Hall-Littlewood P␣
↪basis, 3-Bounded Quotient of Symmetric Functions over Fraction Field of␣

↪3-bounded affine Schur basis, 3-Bounded Quotient of Symmetric Functions␣
↪over Rational Field with t=1 in the dual 3-Schur basis]
>>> m = kQ.ambient().m()
```

(continues on next page)

(continued from previous page)

```
>>> all( rzn(m[Integer(3),Integer(2),Integer(1)]).lift() == m[Integer(3),
↪Integer(2),Integer(1)] for rzn in kQ.realizations())
True
```

retract(*la*)

Give the retract map from the symmetric functions to the quotient ring of k-bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- `la` – a partition

OUTPUT: the monomial element of the k-bounded quotient indexed by `la`

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.retract([Integer(2),Integer(1)])
m3[2, 1]
```

class sage.combinat.sf.k_dual.**KBoundedQuotientBases**(*base*)

Bases: `Category_realization_of_parent`

The category of bases for the k-bounded subspace of symmetric functions.

class ElementMethods

Bases: `object`

class ParentMethods

Bases: `object`

ambient()

Return the symmetric functions.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.ambient()
Symmetric Functions over Rational Field
```

```
>>> from sage.all import *
>>> km = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).
↪km()
>>> km.ambient()
Symmetric Functions over Rational Field
```

antipode(*element*)

Return the antipode of `element` via lifting to the symmetric functions and then retracting into the k-bounded quotient basis.

INPUT:

- element – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3[3,2].antipode()
-dks3[1, 1, 1, 1, 1]
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km[3,2].antipode()
m3[3, 2]
sage: km.antipode(km[3,2])
m3[3, 2]
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
```

```
>>> from sage.all import *
>>> dks3 = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),
↪t=Integer(1)).dual_k_Schur()
>>> dks3[Integer(3),Integer(2)].antipode()
-dks3[1, 1, 1, 1, 1]
>>> km = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).
↪km()
>>> km[Integer(3),Integer(2)].antipode()
m3[3, 2]
>>> km.antipode(km[Integer(3),Integer(2)])
m3[3, 2]
>>> m = SymmetricFunctions(QQ).m()
>>> m[Integer(3),Integer(2)].antipode()
m[3, 2] + 2*m[5]
```

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↪km()
sage: km[1,1,1,1].antipode()
(t^3-3*t^2+3*t)*m3[1, 1, 1, 1] + (-t^2+2*t)*m3[2, 1, 1] + t*m3[2, 2] +␣
↪t*m3[3, 1]
sage: kHP = SymmetricFunctions(FractionField(QQ['t'])).
↪kBoundedQuotient(3).kHLP()
sage: kHP[2,2].antipode()
(t^9-t^6-t^5+t^2)*HLP3[1, 1, 1, 1] + (t^6-t^3-t^2+t)*HLP3[2, 1, 1] + (t^5-

```

coproduct (*element*)

Return the coproduct of `element` via lifting to the symmetric functions and then returning to the k-bounded quotient basis. This method is implemented for all t but is (weakly) conjectured to not be the correct operation for arbitrary t because the coproduct on dual-k-Schur functions does not have a positive expansion.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Q3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: km = Q3.km()
sage: km[3,2].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
sage: dks3 = Q3.dual_k_Schur()
sage: dks3[2,2].coproduct()
dks3[] # dks3[2, 2] + dks3[1] # dks3[2, 1] + dks3[1, 1] # dks3[1, 1] +␣
↪dks3[2] # dks3[2] + dks3[2, 1] # dks3[1] + dks3[2, 2] # dks3[]
```

```
>>> from sage.all import *
>>> Q3 = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> km = Q3.km()
>>> km[Integer(3),Integer(2)].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
>>> dks3 = Q3.dual_k_Schur()
>>> dks3[Integer(2),Integer(2)].coproduct()
dks3[] # dks3[2, 2] + dks3[1] # dks3[2, 1] + dks3[1, 1] # dks3[1, 1] +␣
↪dks3[2] # dks3[2] + dks3[2, 1] # dks3[1] + dks3[2, 2] # dks3[]
```

```
sage: Q3t = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3)
sage: km = Q3t.km()
sage: km[3,2].coproduct()
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
sage: dks = Q3t.dks()
sage: dks[2,1,1].coproduct()
dks3[] # dks3[2, 1, 1] + (-t+1)*dks3[1] # dks3[1, 1, 1] + dks3[1] #␣

↪dks3[2, 1] + (-t+1)*dks3[1, 1] # dks3[1, 1] + dks3[1, 1] # dks3[2] + (-
↪t+1)*dks3[1, 1, 1] # dks3[1] + dks3[2] # dks3[1, 1] + dks3[2, 1] #
↪dks3[1] + dks3[2, 1, 1] # dks3[]
>>> kHLP = Q3t.kHLP()
>>> kHLP[Integer(2),Integer(1)].coproduct()
HLP3[] # HLP3[2, 1] + (-t^2+1)*HLP3[1] # HLP3[1, 1] + HLP3[1] # HLP3[2] +
↪(-t^2+1)*HLP3[1, 1] # HLP3[1] + HLP3[2] # HLP3[1] + HLP3[2, 1] # HLP3[]
>>> km.coproduct(km[Integer(3),Integer(2)])
m3[] # m3[3, 2] + m3[2] # m3[3] + m3[3] # m3[2] + m3[3, 2] # m3[]
```

counit(*element*)

Return the counit of `element`.

The counit is the constant term of `element`.

INPUT:

- `element` – an element in a basis

EXAMPLES:

```
sage: km = SymmetricFunctions(FractionField(QQ['t'])).kBoundedQuotient(3).
↪km()
sage: f = 2*km[2,1] - 3*km([])
sage: f.counit()
-3
sage: km.counit(f)
-3
```

```
>>> from sage.all import *
>>> km = SymmetricFunctions(FractionField(QQ['t'])).
↪kBoundedQuotient(Integer(3)).km()
>>> f = Integer(2)*km[Integer(2),Integer(1)] - Integer(3)*km([])
>>> f.counit()
-3
>>> km.counit(f)
-3
```

degree_on_basis(*b*)

Return the degree of the basis element indexed by `b`.

INPUT:

- b – a partition

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.degree_on_basis(Partition([3,2]))
5
```

```
>>> from sage.all import *
>>> F = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).
↪affineSchur()
>>> F.degree_on_basis(Partition([Integer(3),Integer(2)]))
5
```

indices()

The set of k-bounded partitions of all nonnegative integers.

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.indices()
3-Bounded Partitions
```

```
>>> from sage.all import *
>>> km = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).
↪km()
>>> km.indices()
3-Bounded Partitions
```

lift(*la*)

Implement the lift map from the basis self to the monomial basis of symmetric functions.

INPUT:

- la – a k-bounded partition

OUTPUT: a symmetric function in the monomial basis

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: dks = Sym.kBoundedQuotient(3).dual_k_Schur()
sage: dks.lift([3,1])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]
sage: dks = Sym.kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks.lift([3,1])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```

```
>>> from sage.all import *
>>> F = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).
↪affineSchur()
>>> F.lift([Integer(3),Integer(1)])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```

(continues on next page)

(continued from previous page)

```
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> dks = Sym.kBoundedQuotient(Integer(3)).dual_k_Schur()
>>> dks.lift([Integer(3),Integer(1)])
t^5*HLP[1, 1, 1, 1] + t^2*HLP[2, 1, 1] + t*HLP[2, 2] + HLP[3, 1]
>>> dks = Sym.kBoundedQuotient(Integer(3),t=Integer(1)).dual_k_Schur()
>>> dks.lift([Integer(3),Integer(1)])
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1]
```

one_basis()

Return the basis element indexing 1.

EXAMPLES:

```
sage: F = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).affineSchur()
sage: F.one()   # indirect doctest
F3[]
```

```
>>> from sage.all import *
>>> F = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).
↪affineSchur()
>>> F.one()   # indirect doctest
F3[]
```

product(*x*, *y*)

Return the product of two elements x and y.

INPUT:

- x, y – elements of the k-bounded quotient of symmetric functions

OUTPUT: a k-bounded symmetric function in the dual k-Schur function basis

EXAMPLES:

```
sage: dks3 = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).dual_k_Schur()
sage: dks3.product(dks3[2,1],dks3[1,1])
2*dks3[1, 1, 1, 1, 1] + 2*dks3[2, 1, 1, 1] + 2*dks3[2, 2, 1] + dks3[3, 1,␣
↪1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1], dks3[1,1])
dks3[1, 1, 1] + 2*dks3[1, 1, 1, 1, 1] + dks3[2, 1] + 2*dks3[2, 1, 1, 1] +␣
↪2*dks3[2, 2, 1] + dks3[3, 1, 1] + dks3[3, 2]
sage: dks3.product(dks3[2,1]+dks3[1], dks3([]))
dks3[1] + dks3[2, 1]
sage: dks3.product(dks3([]), dks3([]))
dks3[]
sage: dks3.product(dks3([]), dks3([4,1]))

↪m3[3, 2]
```

retract(*la*)

Give the retract map from the symmetric functions to the quotient ring of k-bounded symmetric functions. This method is here to make the TestSuite run properly.

INPUT:

- `la` – a partition

OUTPUT: the monomial element of the k-bounded quotient indexed by `la`

EXAMPLES:

```
sage: Q = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1)
sage: Q.retract([2,1])
m3[2, 1]
```

```
>>> from sage.all import *
>>> Q = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1))
>>> Q.retract([Integer(2),Integer(1)])
m3[2, 1]
```

super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.k_dual import KBoundedQuotientBases
sage: Q = Sym.kBoundedQuotient(3,t=1)
sage: KQB = KBoundedQuotientBases(Q)
sage: KQB.super_categories()
[Category of realizations of 3-Bounded Quotient of Symmetric Functions over
↪Univariate Polynomial Ring in t over Rational Field with t=1,
 Join of Category of graded Hopf algebras with basis over Univariate
↪Polynomial Ring in t over Rational Field
     and Category of quotients of algebras over Univariate Polynomial Ring in
↪t over Rational Field
     and Category of quotients of graded modules with basis over Univariate
↪Polynomial Ring in t over Rational Field]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'])
>>> from sage.combinat.sf.k_dual import KBoundedQuotientBases
>>> Q = Sym.kBoundedQuotient(Integer(3),t=Integer(1))
>>> KQB = KBoundedQuotientBases(Q)
>>> KQB.super_categories()
[Category of realizations of 3-Bounded Quotient of Symmetric Functions over
↪Univariate Polynomial Ring in t over Rational Field with t=1,
 Join of Category of graded Hopf algebras with basis over Univariate
↪Polynomial Ring in t over Rational Field
     and Category of quotients of algebras over Univariate Polynomial Ring in
↪t over Rational Field
     and Category of quotients of graded modules with basis over Univariate
↪Polynomial Ring in t over Rational Field]
```

class sage.combinat.sf.k_dual.**KBoundedQuotientBasis**(*kBoundedRing*, *prefix*)

Bases: *CombinatorialFreeModule*

Abstract base class for the bases of the k-bounded quotient.

class sage.combinat.sf.k_dual.**kMonomial**(*kBoundedRing*)

Bases: *KBoundedQuotientBasis*

The basis of monomial symmetric functions indexed by partitions with first part less than or equal to k.

lift(*la*)

Implement the lift function on the monomial basis. Given a k-bounded partition `la`, the lift will return the corresponding monomial basis element.

INPUT:

- `la` – a k-bounded partition

OUTPUT: a monomial symmetric function

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.lift(Partition([3,1]))
m[3, 1]
sage: km.lift([])
m[]
sage: km.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↪Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪3-bounded monomial basis)
```

```
>>> from sage.all import *
>>> km = SymmetricFunctions(QQ).kBoundedQuotient(Integer(3),t=Integer(1)).km()
>>> km.lift(Partition([Integer(3),Integer(1)]))
m[3, 1]
>>> km.lift([])
m[]
>>> km.lift(Partition([Integer(4),Integer(1)]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↪Bounded Quotient of Symmetric Functions over Rational Field with t=1 in the␣
↪3-bounded monomial basis)
```

retract(*la*)

Implement the retract function on the monomial basis. Given a partition `la`, the retract will return the corresponding k-bounded monomial basis element if `la` is k-bounded; zero otherwise.

INPUT:

- `la` – a partition

OUTPUT: a k-bounded monomial symmetric function in the k-quotient of symmetric functions

EXAMPLES:

```
sage: km = SymmetricFunctions(QQ).kBoundedQuotient(3,t=1).km()
sage: km.retract(Partition([3,1]))
m3[3, 1]
sage: km.retract(Partition([4,1]))
```

(continues on next page)

```

class sage.combinat.sf.k_dual.**kbounded_HallLittlewoodP**(*kBoundedRing*)

Bases: *KBoundedQuotientBasis*

The basis of P Hall-Littlewood symmetric functions indexed by partitions with first part less than or equal to k.

lift(*la*)

Implement the lift function on the Hall-Littlewood P basis. Given a k-bounded partition `la`, the lift will return the corresponding Hall-Littlewood P basis element.

INPUT:

- `la` – a k-bounded partition

OUTPUT: a Hall-Littlewood symmetric function

EXAMPLES:

```
sage: kHLP = SymmetricFunctions(QQ['t'].fraction_field()).kBoundedQuotient(3).
↪kHallLittlewoodP()
sage: kHLP.lift(Partition([3,1]))
HLP[3, 1]
sage: kHLP.lift([])
HLP[]
sage: kHLP.lift(Partition([4,1]))
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-

```

5.1.290 Kostka-Foulkes Polynomials

Based on the algorithms in John Stembridge's SF package for Maple which can be found at http://www.math.lsa.umich.edu/~jrs/maple.html .

sage.combinat.sf.kfpoly.**KostkaFoulkesPolynomial**(*mu*, *nu*, *t=None*)

Return the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$.

INPUT:

- mu, nu – partitions
- t – an optional parameter (default: None)

OUTPUT:

- the Koskta-Foulkes polynomial indexed by partitions mu and nu and evaluated at the parameter t. If t is None the resulting polynomial is in the polynomial ring $\mathbf{Z}['t']$.

EXAMPLES:

```
sage: KostkaFoulkesPolynomial([2,2],[2,2])
1
sage: KostkaFoulkesPolynomial([2,2],[4])
0
sage: KostkaFoulkesPolynomial([2,2],[1,1,1,1])
t^4 + t^2
sage: KostkaFoulkesPolynomial([2,2],[2,1,1])
t
sage: q = PolynomialRing(QQ,'q').gen()
```

(continues on next page)

(continued from previous page)

```
sage: KostkaFoulkesPolynomial([2,2],[2,1,1],q)
q
```

```
>>> from sage.all import *
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(2),Integer(2)])
1
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(4)])
0
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(1),Integer(1),
↪Integer(1),Integer(1)])
t^4 + t^2
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(2),Integer(1),
↪Integer(1)])
t
>>> q = PolynomialRing(QQ,'q').gen()
>>> KostkaFoulkesPolynomial([Integer(2),Integer(2)],[Integer(2),Integer(1),
↪Integer(1)],q)
q
```

sage.combinat.sf.kfpoly.**compat**(*n*, *mu*, *nu*)

Generate all possible partitions of n that can precede μ, ν in a rigging sequence.

INPUT:

- `n` – positive integer
- `mu`, `nu` – partitions

OUTPUT: list of partitions

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: compat(4, [1], [2,1])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
sage: compat(3, [1], [2,1])
[[1, 1, 1], [2, 1], [3]]
sage: compat(2, [1], [])
[[2]]
sage: compat(3, [1], [])
[[2, 1], [3]]
sage: compat(3, [2], [1])
[[3]]
sage: compat(4, [1,1], [])
[[2, 2], [3, 1], [4]]
sage: compat(4, [2], [])
[[4]]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import *
>>> compat(Integer(4), [Integer(1)], [Integer(2),Integer(1)])
[[1, 1, 1, 1], [2, 1, 1], [2, 2], [3, 1], [4]]
>>> compat(Integer(3), [Integer(1)], [Integer(2),Integer(1)])
[[1, 1, 1], [2, 1], [3]]
```

(continues on next page)

(continued from previous page)

```
>>> compat(Integer(2), [Integer(1)], [])
[[2]]
>>> compat(Integer(3), [Integer(1)], [])
[[2, 1], [3]]
>>> compat(Integer(3), [Integer(2)], [Integer(1)])
[[3]]
>>> compat(Integer(4), [Integer(1),Integer(1)], [])
[[2, 2], [3, 1], [4]]
>>> compat(Integer(4), [Integer(2)], [])
[[4]]
```

sage.combinat.sf.kfpoly.**dom**(*mup*, *snu*)

Return `True` if `sum(mu[:i+1]) >= snu[i]` for all `0 <= i < len(snu)`; otherwise, it returns `False`.

INPUT:

- `mup` – a partition conjugate to `mu`
- `snu` – a sequence of positive integers

OUTPUT: boolean

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: dom([3,2,1],[2,4,5])
True
sage: dom([3,2,1],[2,4,7])
False
sage: dom([3,2,1],[2,6,5])
False
sage: dom([3,2,1],[4,4,4])
False
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import *
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(4),Integer(5)])
True
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(4),Integer(7)])
False
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(6),Integer(5)])
False
>>> dom([Integer(3),Integer(2),Integer(1)],[Integer(4),Integer(4),Integer(4)])
False
```

sage.combinat.sf.kfpoly.**kfpoly**(*mu*, *nu*, *t=None*)

Return the Kostka-Foulkes polynomial $K_{\mu,\nu}(t)$ by generating all rigging sequences for the shape μ, and then selecting those of content ν.

INPUT:

- `mu`, `nu` – partitions
- `t` – an optional parameter (default: `None`)

OUTPUT:

- the Koskta-Foulkes polynomial indexed by partitions `mu` and `nu` and evaluated at the parameter `t`. If `t` is `None` the resulting polynomial is in the polynomial ring $\mathbf{Z}['t']$.

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import kfpoly
sage: kfpoly([2,2], [2,1,1])
t
sage: kfpoly([4], [2,1,1])
t^3
sage: kfpoly([4], [2,2])
t^2
sage: kfpoly([1,1,1,1], [2,2])
0
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import kfpoly
>>> kfpoly([Integer(2),Integer(2)], [Integer(2),Integer(1),Integer(1)])
t
>>> kfpoly([Integer(4)], [Integer(2),Integer(1),Integer(1)])
t^3
>>> kfpoly([Integer(4)], [Integer(2),Integer(2)])
t^2
>>> kfpoly([Integer(1),Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(2)])
0
```

`sage.combinat.sf.kfpoly.`**`riggings`**(*part*)

Generate all possible rigging sequences for a fixed partition `part`.

INPUT:

- `part` – a partition

OUTPUT: list of riggings associated to the partition `part`

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: riggings([3])
[[[1, 1, 1]], [[2, 1]], [[3]]]
sage: riggings([2,1])
[[[2, 1], [1]], [[3], [1]]]
sage: riggings([1,1,1])
[[[3], [2], [1]]]
sage: riggings([2,2])
[[[2, 2], [1, 1]], [[3, 1], [1, 1]], [[4], [1, 1]], [[4], [2]]]
sage: riggings([2,2,2])
[[[3, 3], [2, 2], [1, 1]],
 [[4, 2], [2, 2], [1, 1]],
 [[5, 1], [2, 2], [1, 1]],
 [[6], [2, 2], [1, 1]],
 [[5, 1], [3, 1], [1, 1]],
 [[6], [3, 1], [1, 1]],
 [[6], [4], [2]]]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.kfpoly import *
>>> riggings([Integer(3)])
[[[1, 1, 1]], [[2, 1]], [[3]]]
>>> riggings([Integer(2),Integer(1)])
[[[2, 1], [1]], [[3], [1]]]
>>> riggings([Integer(1),Integer(1),Integer(1)])
[[[3], [2], [1]]]
>>> riggings([Integer(2),Integer(2)])
[[[2, 2], [1, 1]], [[3, 1], [1, 1]], [[4], [1, 1]], [[4], [2]]]
>>> riggings([Integer(2),Integer(2),Integer(2)])
[[[3, 3], [2, 2], [1, 1]],
 [[4, 2], [2, 2], [1, 1]],
 [[5, 1], [2, 2], [1, 1]],
 [[6], [2, 2], [1, 1]],
 [[5, 1], [3, 1], [1, 1]],
 [[6], [3, 1], [1, 1]],
 [[6], [4], [2]]]
```

sage.combinat.sf.kfpoly.**schur_to_hl**(*mu*, *t=None*)

Return a dictionary corresponding to s_μ in Hall-Littlewood P basis.

INPUT:

- mu – a partition
- t – an optional parameter (default: the generator from $\mathbf{Z}['t']$)

OUTPUT:

- a dictionary with the coefficients $K_{\mu\nu}(t)$ for ν smaller in dominance order than μ

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import *
sage: schur_to_hl([1,1,1])
{[1, 1, 1]: 1}
sage: a = schur_to_hl([2,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^2 + t)
([2, 1], 1)
sage: a = schur_to_hl([3])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^3)
([2, 1], t)
([3], 1)
sage: a = schur_to_hl([4])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^6)
([2, 1, 1], t^3)
([2, 2], t^2)
([3, 1], t)
([4], 1)
sage: a = schur_to_hl([3,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^5 + t^4 + t^3)
```

(continues on next page)

(continued from previous page)

```
([2, 1, 1], t^2 + t)
([2, 2], t)
([3, 1], 1)
sage: a = schur_to_hl([2,2])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^4 + t^2)
([2, 1, 1], t)
([2, 2], 1)
sage: a = schur_to_hl([2,1,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^3 + t^2 + t)
([2, 1, 1], 1)
sage: a = schur_to_hl([1,1,1,1])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], 1)
sage: a = schur_to_hl([2,2,2])
sage: for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1, 1, 1], t^9 + t^7 + t^6 + t^5 + t^3)
([2, 1, 1, 1, 1], t^4 + t^2)
([2, 2, 1, 1], t)
([2, 2, 2], 1)
```

```
>>> from sage.all import *

>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1], t^3)
([2, 1], t)
([3], 1)
>>> a = schur_to_hl([Integer(4)])
>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^6)
([2, 1, 1], t^3)
([2, 2], t^2)
([3, 1], t)
([4], 1)
>>> a = schur_to_hl([Integer(3),Integer(1)])
>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^5 + t^4 + t^3)
([2, 1, 1], t^2 + t)
([2, 2], t)
([3, 1], 1)
>>> a = schur_to_hl([Integer(2),Integer(2)])
>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^4 + t^2)
([2, 1, 1], t)
```

(continues on next page)

(continued from previous page)

```
([2, 2], 1)
>>> a = schur_to_hl([Integer(2),Integer(1),Integer(1)])
>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], t^3 + t^2 + t)
([2, 1, 1], 1)
>>> a = schur_to_hl([Integer(1),Integer(1),Integer(1),Integer(1)])
>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1], 1)
>>> a = schur_to_hl([Integer(2),Integer(2),Integer(2)])
>>> for mc in sorted(a.items()): print(mc)
([1, 1, 1, 1, 1, 1], t^9 + t^7 + t^6 + t^5 + t^3)
([2, 1, 1, 1, 1], t^4 + t^2)
([2, 2, 1, 1], t)
([2, 2, 2], 1)
```

sage.combinat.sf.kfpoly.**weight**(*rg*, *t=None*)

Return the weight of a rigging.

INPUT:

- `rg` – a rigging, a list of partitions
- `t` – an optional parameter, (default: the generator from $\mathbf{Z}['t']$)

OUTPUT: a polynomial in the parameter t

EXAMPLES:

```
sage: from sage.combinat.sf.kfpoly import weight
sage: weight([[2,1], [1]])
1
sage: weight([[3], [1]])
t^2 + t
sage: weight([[2,1], [3]])
t^4

5.1.291 LLT symmetric functions

REFERENCES:

class sage.combinat.sf.llt.**LLT_class**(*Sym*, *k*, *t*)

Bases: UniqueRepresentation

A class for working with LLT symmetric functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3); L3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: HC3 = L3.hcospin(); HC3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over␣
↪Rational Field in the level 3 LLT cospin basis
sage: m = Sym.monomial()
sage: m( HC3[1,1] )
(t+1)*m[1, 1] + m[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> L3 = Sym.llt(Integer(3)); L3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
>>> L3.cospin([Integer(3),Integer(2),Integer(1)])
(t+1)*m[1, 1] + m[2]
>>> HC3 = L3.hcospin(); HC3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over␣
↪Rational Field in the level 3 LLT cospin basis
>>> m = Sym.monomial()
>>> m( HC3[Integer(1),Integer(1)] )
(t+1)*m[1, 1] + m[2]
```

We require that the parameter t must be in the base ring:

```
sage: Symxt = SymmetricFunctions(QQ['x','t'].fraction_field())
sage: (x,t) = Symxt.base_ring().gens()
sage: LLT3x = Symxt.llt(3,t=x)
sage: LLT3 = Symxt.llt(3)
sage: HS3x = LLT3x.hspin()
sage: HS3t = LLT3.hspin()
```

(continues on next page)

(continued from previous page)

```
sage: s = Symxt.schur()
sage: s(HS3x[2,1])
s[2, 1] + x*s[3]
sage: s(HS3t[2,1])
s[2, 1] + t*s[3]
sage: HS3x(HS3t[2,1])
HSp3[2, 1] - (x-t)*HSp3[3]
sage: s(HS3x(HS3t[2,1]))
s[2, 1] + t*s[3]
sage: LLT3t2 = Symxt.llt(3,t=2)
sage: HC3t2 = LLT3t2.hcospin()
sage: HS3x(HC3t2[3,1])
2*HSp3[3, 1] - (2*x-1)*HSp3[4]
```

```
>>> from sage.all import *
>>> Symxt = SymmetricFunctions(QQ['x','t'].fraction_field())
>>> (x,t) = Symxt.base_ring().gens()
>>> LLT3x = Symxt.llt(Integer(3),t=x)
>>> LLT3 = Symxt.llt(Integer(3))
>>> HS3x = LLT3x.hspin()
>>> HS3t = LLT3.hspin()
>>> s = Symxt.schur()
>>> s(HS3x[Integer(2),Integer(1)])
s[2, 1] + x*s[3]
>>> s(HS3t[Integer(2),Integer(1)])
s[2, 1] + t*s[3]
>>> HS3x(HS3t[Integer(2),Integer(1)])
HSp3[2, 1] - (x-t)*HSp3[3]
>>> s(HS3x(HS3t[Integer(2),Integer(1)]))
s[2, 1] + t*s[3]
>>> LLT3t2 = Symxt.llt(Integer(3),t=Integer(2))
>>> HC3t2 = LLT3t2.hcospin()
>>> HS3x(HC3t2[Integer(3),Integer(1)])
2*HSp3[3, 1] - (2*x-1)*HSp3[4]
```

base_ring()

Return the base ring of `self`.

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT: the base ring of the symmetric function ring associated to `self`

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).base_ring()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

cospin(*skp*)

Calculate a single instance of the cospin symmetric functions.

These are the functions defined in [LLT1997] equation (26).

INPUT:

- `self` – a family of LLT symmetric functions bases
- `skp` – a partition or a list of partitions or a list of skew partitions

OUTPUT:

the monomial expansion of the LLT symmetric function cospin functions indexed by `skp`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: L3 = Sym.llt(3)
sage: L3.cospin([2,1])
m[1]
sage: L3.cospin([3,2,1])
(t+1)*m[1, 1] + m[2]
sage: s = Sym.schur()
sage: s(L3.cospin([[2],[1],[2]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> L3 = Sym.llt(Integer(3))
>>> L3.cospin([Integer(2),Integer(1)])
m[1]
>>> L3.cospin([Integer(3),Integer(2),Integer(1)])
(t+1)*m[1, 1] + m[2]
>>> s = Sym.schur()
>>> s(L3.cospin([[Integer(2)],[Integer(1)],[Integer(2)]]))
t^4*s[2, 2, 1] + t^3*s[3, 1, 1] + (t^3+t^2)*s[3, 2] + (t^2+t)*s[4, 1] + s[5]
```

hcospin()

Return the HCospin basis. This basis is defined [LLT1997] equation (27).

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT: the h-cospin basis of the LLT symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HCosp3 = Sym.llt(3).hcospin(); HCosp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT cospin basis
sage: HCosp3([1])^2
1/t*HCosp3[1, 1] + ((t-1)/t)*HCosp3[2]

sage: s = Sym.schur()
sage: HCosp3(s([2]))
HCosp3[2]
```

(continues on next page)

(continued from previous page)

```
sage: HCosp3(s([1,1]))
1/t*HCosp3[1, 1] - 1/t*HCosp3[2]
sage: s(HCosp3([2,1]))
t*s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HCosp3 = Sym.llt(Integer(3)).hcospin(); HCosp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT cospin basis
>>> HCosp3([Integer(1)])**Integer(2)
1/t*HCosp3[1, 1] + ((t-1)/t)*HCosp3[2]

>>> s = Sym.schur()
>>> HCosp3(s([Integer(2)]))
HCosp3[2]
>>> HCosp3(s([Integer(1),Integer(1)]))
1/t*HCosp3[1, 1] - 1/t*HCosp3[2]
>>> s(HCosp3([Integer(2),Integer(1)]))
t*s[2, 1] + s[3]
```

hspin()

Return the HSpin basis.

This basis is defined [LLT1997] equation (28).

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT: the h-spin basis of the LLT symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HSp3 = Sym.llt(3).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT spin basis
sage: HSp3([1])^2
HSp3[1, 1] + (-t+1)*HSp3[2]

sage: s = Sym.schur()
sage: HSp3(s([2]))
HSp3[2]
sage: HSp3(s([1,1]))
HSp3[1, 1] - t*HSp3[2]
sage: s(HSp3([2,1]))
s[2, 1] + t*s[3]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HSp3 = Sym.llt(Integer(3)).hspin(); HSp3
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT spin basis
```

(continues on next page)

(continued from previous page)

```
>>> HSp3([Integer(1)])**Integer(2)
HSp3[1, 1] + (-t+1)*HSp3[2]

>>> s = Sym.schur()
>>> HSp3(s([Integer(2)]))
HSp3[2]
>>> HSp3(s([Integer(1),Integer(1)]))
HSp3[1, 1] - t*HSp3[2]
>>> s(HSp3([Integer(2),Integer(1)]))
s[2, 1] + t*s[3]
```

level()

Return the level of `self`.

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT: the level is the parameter of k in the basis

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).level()
3
```

```
>>> from sage.all import *
>>> SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).level()
3
```

spin_square(*skp*)

Calculate a single instance of a spin squared LLT symmetric function associated with a partition, list of partitions, or a list of skew partitions.

This family of symmetric functions is defined in [LT2000] equation (43).

INPUT:

- `self` – a family of LLT symmetric functions bases
- `skp` – a partition of a list of partitions or a list of skew partitions

OUTPUT:

the monomial expansion of the LLT symmetric function spin-square functions indexed by `skp`

EXAMPLES:

```
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.spin_square([2,1])
t*m[1]
sage: L3.spin_square([3,2,1])
(t^3+t)*m[1, 1] + t^3*m[2]
sage: L3.spin_square([[1],[1],[1]])
(t^6+2*t^4+2*t^2+1)*m[1, 1, 1] + (t^6+t^4+t^2)*m[2, 1] + t^6*m[3]
sage: L3.spin_square([[[2,2],[1]],[[2,1],[]]])
(2*t^4+3*t^2+1)*m[1, 1, 1, 1] + (t^4+t^2)*m[2, 1, 1] + t^4*m[2, 2]
```

```
>>> from sage.all import *
>>> L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3))
>>> L3.spin_square([Integer(2),Integer(1)])
t*m[1]
>>> L3.spin_square([Integer(3),Integer(2),Integer(1)])
(t^3+t)*m[1, 1] + t^3*m[2]
>>> L3.spin_square([[Integer(1)],[Integer(1)],[Integer(1)]])
(t^6+2*t^4+2*t^2+1)*m[1, 1, 1] + (t^6+t^4+t^2)*m[2, 1] + t^6*m[3]
>>> L3.spin_square([[[Integer(2),Integer(2)],[Integer(1)]],[[Integer(2),
↪Integer(1)],[]]])
(2*t^4+3*t^2+1)*m[1, 1, 1, 1] + (t^4+t^2)*m[2, 1, 1] + t^4*m[2, 2]
```

symmetric_function_ring()

The symmetric function algebra associated to the family of LLT symmetric function bases

INPUT:

- `self` – a family of LLT symmetric functions bases

OUTPUT: the symmetric function ring associated to `self`

EXAMPLES:

```
sage: L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3)
sage: L3.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
```

```
>>> from sage.all import *
>>> L3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3))
>>> L3.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field
```

class sage.combinat.sf.llt.**LLT_cospin**(*llt*)

Bases: *LLT_generic*

A class of methods for the h-cospin LLT basis of the symmetric functions.

INPUT:

- `self` – an instance of the LLT hcospin basis
- `llt` – a family of LLT symmetric function bases

class Element

Bases: *Element*

class sage.combinat.sf.llt.**LLT_generic**(*llt*, *prefix*)

Bases: *SymmetricFunctionAlgebra_generic*

A class of methods which are common to both the hspin and hcospin of the LLT symmetric functions.

INPUT:

- `self` – an instance of the LLT hspin or hcospin basis
- `llt` – a family of LLT symmetric functions

EXAMPLES:

```
sage: SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field in the level 3 LLT spin basis
sage: SymmetricFunctions(QQ).llt(3,t=2).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
sage: QQz = FractionField(QQ['z']); z = QQz.gen()
sage: SymmetricFunctions(QQz).llt(3,t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over
↪Rational Field in the level 3 LLT spin with t=z basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t over
↪Rational Field in the level 3 LLT spin basis
>>> SymmetricFunctions(QQ).llt(Integer(3),t=Integer(2)).hspin()
Symmetric Functions over Rational Field in the level 3 LLT spin with t=2 basis
>>> QQz = FractionField(QQ['z']); z = QQz.gen()
>>> SymmetricFunctions(QQz).llt(Integer(3),t=z).hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in z over
↪Rational Field in the level 3 LLT spin with t=z basis
```

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

construction()

Return a pair (F, R), where F is a SymmetricFunctionsFunctor and R is a ring, such that F(R) returns self.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HSp3 = Sym.llt(3).hspin()
sage: HSp3.construction()
(SymmetricFunctionsFunctor[level 3 LLT spin],
 Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> HSp3 = Sym.llt(Integer(3)).hspin()
>>> HSp3.construction()
(SymmetricFunctionsFunctor[level 3 LLT spin],
 Fraction Field of Univariate Polynomial Ring in t over Rational Field)
```

level()

Return the level of self.

INPUT:

- self – an instance of the LLT hspin or hcospin basis

OUTPUT: the level associated to the basis self

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.level()
3
```

```
>>> from sage.all import *
>>> HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
>>> HSp3.level()
3
```

llt_family()

The family of the llt bases of the symmetric functions.

INPUT:

- `self` – an instance of the LLT hspin or hcospin basis

OUTPUT: an instance of the family of LLT bases associated to `self`

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.llt_family()
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in␣
↪t over Rational Field
```

```
>>> from sage.all import *
>>> HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
>>> HSp3.llt_family()
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in␣
↪t over Rational Field
```

product(*left*, *right*)

Convert to the monomial basis, do the multiplication there, and convert back to the basis `self`.

INPUT:

- `self` – an instance of the LLT hspin or hcospin basis
- `left`, `right` – elements of the symmetric functions

OUTPUT: the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hspin()
sage: HSp3.product(HSp3([1]), HSp3([2]))
HSp3[2, 1] + (-t+1)*HSp3[3]
sage: HCosp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(3).hcospin()
sage: HCosp3.product(HCosp3([1]), HSp3([2]))
1/t*HCosp3[2, 1] + ((t-1)/t)*HCosp3[3]
```

```
>>> from sage.all import *
>>> HSp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).hspin()
>>> HSp3.product(HSp3([Integer(1)]), HSp3([Integer(2)]))
HSp3[2, 1] + (-t+1)*HSp3[3]
>>> HCosp3 = SymmetricFunctions(FractionField(QQ['t'])).llt(Integer(3)).
```

(continues on next page)

(continued from previous page)

```
↪hcospin()
>>> HCosp3.product(HCosp3([Integer(1)]), HSp3([Integer(2)]))
1/t*HCosp3[2, 1] + ((t-1)/t)*HCosp3[3]
```

class sage.combinat.sf.llt.**LLT_spin**(*llt*)

Bases: *LLT_generic*

A class of methods for the h-spin LLT basis of the symmetric functions.

INPUT:

- `self` – an instance of the LLT hcospin basis
- `llt` – a family of LLT symmetric function bases

class Element

Bases: *Element*

5.1.292 Macdonald Polynomials

Notation used in the definitions follows mainly [Mac1995].

The integral forms of the bases H and Ht do not appear in Macdonald's book. They correspond to the two bases $H_\mu[X;q,t] = \sum_\nu K_{\nu\mu}(q,t)s_\mu[X]$ and $\tilde{H}_\mu[X;q,t] = t^{n(\mu)}\sum_\nu K_{\nu\mu}(q,1/t)s_\nu[X]$ where $K_{\mu\nu}(q,t)$ are the Macdonald q,t-Koskta coefficients.

The Ht in this case is short for $\tilde{H}$ and is the basis which is the graded Frobenius image of the Garsia-Haiman modules [GH1993].

REFERENCES:

- [Mac1995]

class sage.combinat.sf.macdonald.**Macdonald**(*Sym*, *q*, *t*)

Bases: `UniqueRepresentation`

Macdonald Symmetric functions including P, Q, J, H, Ht bases also including the S basis which is the plethystic transformation of the Schur basis (that which is dual to the Schur basis with respect to the Macdonald q,t-scalar product)

INPUT:

- `self` – a family of Macdonald symmetric function bases

EXAMPLES:

```
sage: t = QQ['t'].gen(); SymmetricFunctions(QQ['t'].fraction_field()).
↪macdonald(q=t,t=1)
Macdonald polynomials with q=t and t=1 over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field
sage: Sym = SymmetricFunctions(FractionField(QQ['t'])).macdonald()
Traceback (most recent call last):
...
TypeError: unable to evaluate 'q' in Fraction Field of Univariate Polynomial Ring␣
↪in t over Rational Field
```

```
>>> from sage.all import *
>>> t = QQ['t'].gen(); SymmetricFunctions(QQ['t'].fraction_field()).macdonald(q=t,
```

(continues on next page)

(continued from previous page)

```
↪t=Integer(1))
Macdonald polynomials with q=t and t=1 over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field
>>> Sym = SymmetricFunctions(FractionField(QQ['t'])).macdonald()
Traceback (most recent call last):
...
TypeError: unable to evaluate 'q' in Fraction Field of Univariate Polynomial Ring␣
↪in t over Rational Field
```

H()

Return the Macdonald polynomials on the H basis. When the H basis is expanded on the Schur basis, the coefficients are the qt-Kostka numbers.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the H Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: H = Sym.macdonald().H(); H
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald H basis
sage: s = Sym.schur()
sage: s(H([2]))
q*s[1, 1] + s[2]
sage: s(H([1,1]))
s[1, 1] + t*s[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> H = Sym.macdonald().H(); H
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald H basis
>>> s = Sym.schur()
>>> s(H([Integer(2)]))
q*s[1, 1] + s[2]
>>> s(H([Integer(1),Integer(1)]))
s[1, 1] + t*s[2]
```

Coercions to/from the Schur basis are implemented:

```
sage: H = Sym.macdonald().H()
sage: s = Sym.schur()
sage: H(s([2]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]
```

```
>>> from sage.all import *
>>> H = Sym.macdonald().H()
>>> s = Sym.schur()
>>> H(s([Integer(2)]))
(q/(q*t-1))*McdH[1, 1] - (1/(q*t-1))*McdH[2]
```

Ht()

Return the Macdonald polynomials on the Ht basis. The elements of the Ht basis are eigenvectors of the $nabla$ operator. When expanded on the Schur basis, the coefficients are the modified qt-Kostka numbers.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the Ht Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald Ht basis
sage: [Ht(p).nabla() for p in Partitions(3)]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> Ht = Sym.macdonald().Ht(); Ht
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald Ht basis
>>> [Ht(p).nabla() for p in Partitions(Integer(3))]
[q^3*McdHt[3], q*t*McdHt[2, 1], t^3*McdHt[1, 1, 1]]
```

```
sage: s = Sym.schur()
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: q,t = Ht.base_ring().gens()
sage: s(Ht([2,1]))
q*t*s[1, 1, 1] + (q+t)*s[2, 1] + s[3]
sage: qt_kostka([1,1,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q*t
sage: qt_kostka([2,1],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
q + t
sage: qt_kostka([3],[2,1]).subs(t=1/t)*t^Partition([2,1]).weighted_size()
1
```

```
>>> from sage.all import *
>>> s = Sym.schur()
>>> from sage.combinat.sf.macdonald import qt_kostka
>>> q,t = Ht.base_ring().gens()
>>> s(Ht([Integer(2),Integer(1)]))
q*t*s[1, 1, 1] + (q+t)*s[2, 1] + s[3]
>>> qt_kostka([Integer(1),Integer(1),Integer(1)],[Integer(2),Integer(1)]).
↪subs(t=Integer(1)/t)*t**Partition([Integer(2),Integer(1)]).weighted_size()
q*t
>>> qt_kostka([Integer(2),Integer(1)],[Integer(2),Integer(1)]).
↪subs(t=Integer(1)/t)*t**Partition([Integer(2),Integer(1)]).weighted_size()
q + t
>>> qt_kostka([Integer(3)],[Integer(2),Integer(1)]).subs(t=Integer(1)/
↪t)*t**Partition([Integer(2),Integer(1)]).weighted_size()
1
```

Coercions to/from the Schur basis are implemented:

```
sage: Ht = Sym.macdonald().Ht()
sage: s = Sym.schur()
sage: Ht(s([2,1]))
(q/(q*t^2-t^3-q^2+q*t))*McdHt[1, 1, 1] - ((q^2+q*t+t^2)/(q^2*t^2-q^3-t^
↪3+q*t))*McdHt[2, 1]
+ (t/(-q^3+q^2*t+q*t-t^2))*McdHt[3]
sage: Ht(s([2]))
-(q/(-q+t))*McdHt[1, 1] + (t/(-q+t))*McdHt[2]
```

```
>>> from sage.all import *
>>> Ht = Sym.macdonald().Ht()
>>> s = Sym.schur()
>>> Ht(s([Integer(2),Integer(1)]))
(q/(q*t^2-t^3-q^2+q*t))*McdHt[1, 1, 1] - ((q^2+q*t+t^2)/(q^2*t^2-q^3-t^
↪3+q*t))*McdHt[2, 1]
+ (t/(-q^3+q^2*t+q*t-t^2))*McdHt[3]
>>> Ht(s([Integer(2)]))
-(q/(-q+t))*McdHt[1, 1] + (t/(-q+t))*McdHt[2]
```

J()

Return the Macdonald polynomials on the J basis also known as the integral form of the Macdonald polynomials. These are scalar multiples of both the P and Q bases. When expressed in the P or Q basis, the scaling coefficients are polynomials in q and t rather than rational functions.

The J basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the S-basis [LLM1998].

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the J Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: J = Sym.macdonald().J(); J
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald J basis
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([1,1]))
(t^3-t^2-t+1)*McdP[1, 1]
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
sage: Q(J([1,1]))
(q^2*t-q*t-q+1)*McdQ[1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> J = Sym.macdonald().J(); J
```

(continues on next page)

(continued from previous page)

```
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald J basis
>>> P = Sym.macdonald().P()
>>> Q = Sym.macdonald().Q()
>>> P(J([Integer(2)]))
(q*t^2-q*t-t+1)*McdP[2]
>>> P(J([Integer(1),Integer(1)]))
(t^3-t^2-t+1)*McdP[1, 1]
>>> Q(J([Integer(2)]))
(q^3-q^2-q+1)*McdQ[2]
>>> Q(J([Integer(1),Integer(1)]))
(q^2*t-q*t-q+1)*McdQ[1, 1]
```

Coercions from the Q and J basis (proportional) and to/from the Schur basis are implemented:

```
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
```

```
>>> from sage.all import *
>>> P = Sym.macdonald().P()
>>> Q = Sym.macdonald().Q()
>>> J = Sym.macdonald().J()
>>> s = Sym.schur()
```

```
sage: J(P([2]))
(1/(q*t^2-q*t-t+1))*McdJ[2]
```

```
>>> from sage.all import *
>>> J(P([Integer(2)]))
(1/(q*t^2-q*t-t+1))*McdJ[2]
```

```
sage: J(Q([2]))
(1/(q^3-q^2-q+1))*McdJ[2]
```

```
>>> from sage.all import *
>>> J(Q([Integer(2)]))
(1/(q^3-q^2-q+1))*McdJ[2]
```

```
sage: s(J([2]))
-(q*t-t^2-q+t)*s[1, 1] + (q*t^2-q*t-t+1)*s[2]
sage: J(s([2]))
((q-t)/(q*t^4-q*t^3-q*t^2-t^3+q*t+t^2+t-1))*McdJ[1, 1] + (1/(q*t^2-q*t-
↪t+1))*McdJ[2]
```

```
>>> from sage.all import *
>>> s(J([Integer(2)]))
-(q*t-t^2-q+t)*s[1, 1] + (q*t^2-q*t-t+1)*s[2]
>>> J(s([Integer(2)]))
```

(continues on next page)

(continued from previous page)

```
((q-t)/(q*t^4-q*t^3-q*t^2-t^3+q*t+t^2+t-1))*McdJ[1, 1] + (1/(q*t^2-q*t-
↪t+1))*McdJ[2]
```

P()

Return Macdonald polynomials in P basis. The P basis is defined here as a normalized form of the J basis.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the P Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald P basis
>>> P[Integer(2)]
McdP[2]
```

The P Macdonald basis is upper triangularly related to the monomial symmetric functions and are orthogonal with respect to the qt-Hall scalar product:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald P basis
sage: m = Sym.monomial()
sage: P.transition_matrix(m,2)
[                          1 (q*t - q + t - 1)/(q*t - 1)]
[                          0                           1]
sage: P([1,1]).scalar_qt(P([2]))
0
sage: P([2]).scalar_qt(P([2]))
(-q^3 + q^2 + q - 1)/(-q*t^2 + q*t + t - 1)
sage: P([1,1]).scalar_qt(P([1,1]))
(-q^2*t + q*t + q - 1)/(-t^3 + t^2 + t - 1)
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald P basis
>>> m = Sym.monomial()
>>> P.transition_matrix(m,Integer(2))
```

(continues on next page)

(continued from previous page)

```
[                          1  (q*t - q + t - 1)/(q*t - 1)]
[                          0                            1]
>>> P([Integer(1),Integer(1)]).scalar_qt(P([Integer(2)]))
0
>>> P([Integer(2)]).scalar_qt(P([Integer(2)]))
(-q^3 + q^2 + q - 1)/(-q*t^2 + q*t + t - 1)
>>> P([Integer(1),Integer(1)]).scalar_qt(P([Integer(1),Integer(1)]))
(-q^2*t + q*t + q - 1)/(-t^3 + t^2 + t - 1)
```

When $q = 0$, the Macdonald polynomials on the P basis are the same as the Hall-Littlewood polynomials on the P basis.

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.macdonald(q=0).P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Macdonald P with q=0 basis
sage: P([2])^2
(t+1)*McdP[2, 2] + (-t+1)*McdP[3, 1] + McdP[4]
sage: HLP = Sym.hall_littlewood().P()
sage: HLP([2])^2
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> P = Sym.macdonald(q=Integer(0)).P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Macdonald P with q=0 basis
>>> P([Integer(2)])**Integer(2)
(t+1)*McdP[2, 2] + (-t+1)*McdP[3, 1] + McdP[4]
>>> HLP = Sym.hall_littlewood().P()
>>> HLP([Integer(2)])**Integer(2)
(t+1)*HLP[2, 2] + (-t+1)*HLP[3, 1] + HLP[4]
```

Coercions from the Q and J basis (proportional) are implemented:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> Q = Sym.macdonald().Q()
>>> J = Sym.macdonald().J()
>>> s = Sym.schur()
```

```
sage: P(Q([2]))
((q*t^2-q*t-t+1)/(q^3-q^2-q+1))*McdP[2]
sage: P(Q([2,1]))
-((q*t^4-2*q*t^3+q*t^2-t^2+2*t-1)/(-q^4*t+2*q^3*t-q^2*t+q^2-2*q+1))*McdP[2, 1]
```

```
>>> from sage.all import *
>>> P(Q([Integer(2)]))
((q*t^2-q*t-t+1)/(q^3-q^2-q+1))*McdP[2]
>>> P(Q([Integer(2),Integer(1)]))
-((q*t^4-2*q*t^3+q*t^2-t^2+2*t-1)/(-q^4*t+2*q^3*t-q^2*t+q^2-2*q+1))*McdP[2, 1]
```

```
sage: P(J([2]))
(q*t^2-q*t-t+1)*McdP[2]
sage: P(J([2,1]))
-(q*t^4-2*q*t^3+q*t^2-t^2+2*t-1)*McdP[2, 1]
```

```
>>> from sage.all import *
>>> P(J([Integer(2)]))
(q*t^2-q*t-t+1)*McdP[2]
>>> P(J([Integer(2),Integer(1)]))
-(q*t^4-2*q*t^3+q*t^2-t^2+2*t-1)*McdP[2, 1]
```

By transitivity, one get coercions from the classical bases:

```
sage: P(s([2]))
((q-t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P(s([2,1]))
((q*t-t^2+q-t)/(q*t^2-1))*McdP[1, 1, 1] + McdP[2, 1]
```

```
>>> from sage.all import *
>>> P(s([Integer(2)]))
((q-t)/(q*t-1))*McdP[1, 1] + McdP[2]
>>> P(s([Integer(2),Integer(1)]))
((q*t-t^2+q-t)/(q*t^2-1))*McdP[1, 1, 1] + McdP[2, 1]
```

```
sage: Sym = SymmetricFunctions(QQ['x','y','z'].fraction_field())
sage: (x,y,z) = Sym.base_ring().gens()
sage: Macxy = Sym.macdonald(q=x,t=y)
sage: Macyz = Sym.macdonald(q=y,t=z)
sage: Maczx = Sym.macdonald(q=z,t=x)
sage: P1 = Macxy.P()
sage: P2 = Macyz.P()
sage: P3 = Maczx.P()
sage: m(P1[2,1])
-((2*x*y^2-x*y+y^2-x+y-2)/(-x*y^2+1))*m[1, 1, 1] + m[2, 1]
sage: m(P2[2,1])
-((2*y*z^2-y*z+z^2-y+z-2)/(-y*z^2+1))*m[1, 1, 1] + m[2, 1]

>>> m(P1(P2(P3[Integer(2),Integer(1)])))
-((2*x^2*z+x^2-x*z+x-z-2)/(-x^2*z+1))*m[1, 1, 1] + m[2, 1]
>>> P1(P2[Integer(2)])
-((x*y^2-2*x*y*z+y^2*z+x-2*y+z)/(x*y^2*z-x*y-y*z+1))*McdP[1, 1] + McdP[2]
>>> m(z*P1[Integer(2)]+x*P2[Integer(2)])
((x^2*y^2*z+x*y^2*z^2-x^2*y^2+x^2*y*z-x*y*z^2+y^2*z^2-x^2*y-2*x*y*z-y*z^2+x*y-
↪y*z+x+z)/(x*y^2*z-x*y-y*z+1))*m[1, 1] + (x+z)*m[2]
```

Q()

Return the Macdonald polynomials on the Q basis. These are dual to the Macdonald polynomials on the P basis with respect to the qt-Hall scalar product. The Q basis is defined to be a normalized form of the J basis.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the Q Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald Q basis
sage: P = Sym.macdonald().P()
sage: Q([2]).scalar_qt(P([2]))
1
sage: Q([2]).scalar_qt(P([1,1]))
0
sage: Q([1,1]).scalar_qt(P([2]))
0
sage: Q([1,1]).scalar_qt(P([1,1]))
1
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: Q(P([1,1]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> Q = Sym.macdonald().Q(); Q
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald Q basis
```

(continues on next page)

(continued from previous page)

```
>>> P = Sym.macdonald().P()
>>> Q([Integer(2)]).scalar_qt(P([Integer(2)]))
1
>>> Q([Integer(2)]).scalar_qt(P([Integer(1),Integer(1)]))
0
>>> Q([Integer(1),Integer(1)]).scalar_qt(P([Integer(2)]))
0
>>> Q([Integer(1),Integer(1)]).scalar_qt(P([Integer(1),Integer(1)]))
1
>>> Q(P([Integer(2)]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
>>> Q(P([Integer(1),Integer(1)]))
((q^2*t-q*t-q+1)/(t^3-t^2-t+1))*McdQ[1, 1]
```

Coercions from the P and J basis (proportional) are implemented:

```
sage: P = Sym.macdonald().P()
sage: Q = Sym.macdonald().Q()
sage: J = Sym.macdonald().J()
sage: s = Sym.schur()
```

```
>>> from sage.all import *
>>> P = Sym.macdonald().P()
>>> Q = Sym.macdonald().Q()
>>> J = Sym.macdonald().J()
>>> s = Sym.schur()
```

```
sage: Q(J([2]))
(q^3-q^2-q+1)*McdQ[2]
```

```
>>> from sage.all import *
>>> Q(J([Integer(2)]))
(q^3-q^2-q+1)*McdQ[2]
```

```
sage: Q(P([2]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
sage: P(Q(P([2])))
McdP[2]
sage: Q(P(Q([2])))
McdQ[2]
```

```
>>> from sage.all import *
>>> Q(P([Integer(2)]))
((q^3-q^2-q+1)/(q*t^2-q*t-t+1))*McdQ[2]
>>> P(Q(P([Integer(2)])))
McdP[2]
>>> Q(P(Q([Integer(2)])))
McdQ[2]
```

By transitivity, one gets coercions from the classical bases:

```
sage: Q(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdQ[1, 1] + ((q^3-q^2-q+1)/(q*t^2-q*t-
↪t+1))*McdQ[2]
```

```
>>> from sage.all import *
>>> Q(s([Integer(2)]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdQ[1, 1] + ((q^3-q^2-q+1)/(q*t^2-q*t-
↪t+1))*McdQ[2]
```

S()

Return the modified Schur functions defined by the plethystic substitution $S_\mu = s_\mu[X(1-t)/(1-q)]$. When the Macdonald polynomials in the J basis are expressed in terms of the modified Schur functions at $q = 0$, the coefficients are qt-Kostka numbers.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the S Macdonald basis of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S(); S
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t
over Rational Field in the Macdonald S basis
sage: p = Sym.power()
sage: p(S[2,1])
((1/3*t^3-t^2+t-1/3)/(q^3-3*q^2+3*q-1))*p[1, 1, 1] - ((1/3*t^3-1/3)/(q^3-
↪1))*p[3]
sage: J = Sym.macdonald().J()
sage: S(J([2]))
(q^3-q^2-q+1)*McdS[2]
sage: S(J([1,1]))
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
sage: S = Sym.macdonald(q=0).S()
sage: S(J[1,1])
McdS[1, 1] + t*McdS[2]
sage: S(J[2])
q*McdS[1, 1] + McdS[2]
sage: p(S[2,1])
-(1/3*t^3-t^2+t-1/3)*p[1, 1, 1] + (1/3*t^3-1/3)*p[3]

sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2],[1,1])
t
sage: qt_kostka([1,1],[2])
q
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> S = Sym.macdonald().S(); S
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
```

(continues on next page)

(continued from previous page)

```
↪t
over Rational Field in the Macdonald S basis
>>> p = Sym.power()
>>> p(S[Integer(2),Integer(1)])
((1/3*t^3-t^2+t-1/3)/(q^3-3*q^2+3*q-1))*p[1, 1, 1] - ((1/3*t^3-1/3)/(q^3-
↪1))*p[3]
>>> J = Sym.macdonald().J()
>>> S(J([Integer(2)]))
(q^3-q^2-q+1)*McdS[2]
>>> S(J([Integer(1),Integer(1)]))

>>> from sage.combinat.sf.macdonald import qt_kostka
>>> qt_kostka([Integer(2)],[Integer(1),Integer(1)])
t
>>> qt_kostka([Integer(1),Integer(1)],[Integer(2)])
q
```

Coercions to/from the Schur basis are implemented:

```
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()
sage: S(s([2]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] - ((q^2*t-q*t-q+1)/(-t^3+t^2+t-
↪1))*McdS[2]
sage: s(S([1,1]))
-((q*t^2-q*t-t+1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-
↪1))*s[2]
```

```
>>> from sage.all import *
>>> S = Sym.macdonald().S()
>>> s = Sym.schur()
>>> S(s([Integer(2)]))
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] - ((q^2*t-q*t-q+1)/(-t^3+t^2+t-
↪1))*McdS[2]
>>> s(S([Integer(1),Integer(1)]))
-((q*t^2-q*t-t+1)/(-q^3+q^2+q-1))*s[1, 1] + ((q*t-t^2-q+t)/(-q^3+q^2+q-
↪1))*s[2]
```

base_ring()

Return the base ring of the symmetric functions where the Macdonald symmetric functions live.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the base ring associated to the corresponding symmetric function ring

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['q'].fraction_field())
sage: Mac = Sym.macdonald(t=0)
sage: Mac.base_ring()
Fraction Field of Univariate Polynomial Ring in q over Rational Field
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['q'].fraction_field())
>>> Mac = Sym.macdonald(t=Integer(0))
>>> Mac.base_ring()
Fraction Field of Univariate Polynomial Ring in q over Rational Field
```

symmetric_function_ring()

Return the base ring of the symmetric functions where the Macdonald symmetric functions live.

INPUT:

- `self` – a family of Macdonald symmetric function bases

OUTPUT: the symmetric function ring associated to the Macdonald bases

EXAMPLES:

```
sage: Mac = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0)
sage: Mac.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q␣
↪over Rational Field
```

```
>>> from sage.all import *
>>> Mac = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=Integer(0))
>>> Mac.symmetric_function_ring()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in q␣
↪over Rational Field
```

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_generic**(*macdonald*)

Bases: *SymmetricFunctionAlgebra_generic*

A class for methods for one of the Macdonald bases of the symmetric functions.

INPUT:

- `self` – a Macdonald basis
- `macdonald` – a family of Macdonald symmetric function bases

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename('Sym'); Sym
Sym
sage: Sym.macdonald().P()
Sym in the Macdonald P basis
sage: Sym.macdonald(t=2).P()
Sym in the Macdonald P with t=2 basis
sage: Sym.rename()
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q,t'])); Sym.rename('Sym'); Sym
Sym
>>> Sym.macdonald().P()
Sym in the Macdonald P basis
>>> Sym.macdonald(t=Integer(2)).P()
Sym in the Macdonald P with t=2 basis
>>> Sym.rename()
```

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

nabla(*q=None*, *t=None*, *power=1*)

Return the value of the nabla operator applied to `self`.

The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis. For more information see: [BGHT1999].

The operator nabla acts on symmetric functions and has the Macdonald Ht basis as eigenfunctions and the eigenvalues are $q^{n(\mu')}t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$ and μ' is the conjugate shape of μ.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `self` – an element of a Macdonald basis
- `q`, `t` – (optional) parameters to specialize
- `power` – integer (default: 1)

OUTPUT: the symmetric function of ∇ acting on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P([1,1]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: P([1,1]).nabla(t=1)
((q^2*t+q*t-t-1)/(q*t-1))*McdP[1, 1] + McdP[2]
sage: H = Sym.macdonald().H()
sage: H([1,1]).nabla()
t*McdH[1, 1] - (t^2-1)*McdH[2]
sage: H([1,1]).nabla(q=1)
((t^2+q-t-1)/(q*t-1))*McdH[1, 1] - ((t^3-t^2-t+1)/(q*t-1))*McdH[2]
sage: H(0).nabla()
0
sage: H([2,2,1]).nabla(t=1/H.t)
-(q^2/(-t^4))*McdH[2, 2, 1]
sage: H([2,2,1]).nabla(t=1/H.t,power=-1)
-(t^4/(-q^2))*McdH[2, 2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> P([Integer(1),Integer(1)]).nabla()
((q^2*t+q*t^2-2*t)/(q*t-1))*McdP[1, 1] + McdP[2]
```

(continues on next page)

(continued from previous page)

```
>>> P([Integer(1),Integer(1)]).nabla(t=Integer(1))
((q^2*t+q*t-t-1)/(q*t-1))*McdP[1, 1] + McdP[2]
>>> H = Sym.macdonald().H()
>>> H([Integer(1),Integer(1)]).nabla()
t*McdH[1, 1] - (t^2-1)*McdH[2]
>>> H([Integer(1),Integer(1)]).nabla(q=Integer(1))
((t^2+q-t-1)/(q*t-1))*McdH[1, 1] - ((t^3-t^2-t+1)/(q*t-1))*McdH[2]
>>> H(Integer(0)).nabla()
0
>>> H([Integer(2),Integer(2),Integer(1)]).nabla(t=Integer(1)/H.t)
-(q^2/(-t^4))*McdH[2, 2, 1]
>>> H([Integer(2),Integer(2),Integer(1)]).nabla(t=Integer(1)/H.t,power=-
↪Integer(1))
-(t^4/(-q^2))*McdH[2, 2, 1]
```

c1 (*part*)

Return the qt-Hall scalar product between `J(part)` and `P(part)`.

INPUT:

- `self` – a Macdonald basis
- `part` – a partition

OUTPUT:

- returns the qt-Hall scalar product between `J(part)` and `P(part)`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.c1(Partition([2,1]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> P.c1(Partition([Integer(2),Integer(1)]))
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

c2 (*part*)

Return the qt-Hall scalar product between `J(part)` and `Q(part)`.

INPUT:

- `self` – a Macdonald basis
- `part` – a partition

OUTPUT:

- returns the qt-Hall scalar product between `J(part)` and `Q(part)`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.c2(Partition([2,1]))
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> P.c2(Partition([Integer(2),Integer(1)]))
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

construction()

Return a pair `(F, R)`, where `F` is a `SymmetricFunctionsFunctor` and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q']))
sage: J = Sym.macdonald(t=2).J()
sage: J.construction()
(SymmetricFunctionsFunctor[Macdonald J with t=2],
 Fraction Field of Univariate Polynomial Ring in q over Rational Field)
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q']))
>>> J = Sym.macdonald(t=Integer(2)).J()
>>> J.construction()
(SymmetricFunctionsFunctor[Macdonald J with t=2],
 Fraction Field of Univariate Polynomial Ring in q over Rational Field)
```

macdonald_family()

Return the family of Macdonald bases associated to the basis `self`.

INPUT:

- `self` – a Macdonald basis

OUTPUT: the family of Macdonald symmetric functions associated to `self`

EXAMPLES:

```
sage: MacP = SymmetricFunctions(QQ['q'].fraction_field()).macdonald(t=0).P()
sage: MacP.macdonald_family()
Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial␣
↪Ring in q over Rational Field
```

```
>>> from sage.all import *
>>> MacP = SymmetricFunctions(QQ['q'].fraction_field()).
↪macdonald(t=Integer(0)).P()
>>> MacP.macdonald_family()
Macdonald polynomials with t=0 over Fraction Field of Univariate Polynomial␣
↪Ring in q over Rational Field
```

product(*left*, *right*)

Multiply an element of the Macdonald symmetric function basis `self` and another symmetric function

Convert to the Schur basis, do the multiplication there, and convert back to `self` basis.

INPUT:

- `self` – a Macdonald symmetric function basis
- `left` – an element of the basis `self`
- `right` – another symmetric function

OUTPUT: the product of `left` and `right` expanded in the basis `self`

EXAMPLES:

```
sage: Mac = SymmetricFunctions(FractionField(QQ['q','t'])).macdonald()
sage: H = Mac.H()
sage: J = Mac.J()
sage: P = Mac.P()
sage: Q = Mac.Q()
sage: Ht = Mac.Ht()
sage: J([1])^2 #indirect doctest
((q-1)/(q*t-1))*McdJ[1, 1] + ((t-1)/(q*t-1))*McdJ[2]
sage: J.product( J[1], J[2] )
-((q^2-1)/(-q^2*t+1))*McdJ[2, 1] - ((t-1)/(-q^2*t+1))*McdJ[3]
sage: H.product( H[1], H[2] )
((q^2-1)/(q^2*t-1))*McdH[2, 1] - ((t-1)/(-q^2*t+1))*McdH[3]
sage: P.product( P[1], P[2] )
-((q^3*t^2-q*t^2-q^2+1)/(-q^3*t^2+q^2*t+q*t-1))*McdP[2, 1] + McdP[3]
sage: Q.product(Q[1],Q[2])
McdQ[2, 1] + ((q^2*t-q^2+q*t-q+t-1)/(q^2*t-1))*McdQ[3]
sage: Ht.product(Ht[1],Ht[2])
((q^2-1)/(q^2-t))*McdHt[2, 1] + ((t-1)/(-q^2+t))*McdHt[3]
```

```
>>> from sage.all import *
>>> Mac = SymmetricFunctions(FractionField(QQ['q','t'])).macdonald()
>>> H = Mac.H()
>>> J = Mac.J()
>>> P = Mac.P()
>>> Q = Mac.Q()
>>> Ht = Mac.Ht()
>>> J([Integer(1)])**Integer(2) #indirect doctest
((q-1)/(q*t-1))*McdJ[1, 1] + ((t-1)/(q*t-1))*McdJ[2]
>>> J.product( J[Integer(1)], J[Integer(2)] )
-((q^2-1)/(-q^2*t+1))*McdJ[2, 1] - ((t-1)/(-q^2*t+1))*McdJ[3]
>>> H.product( H[Integer(1)], H[Integer(2)] )
((q^2-1)/(q^2*t-1))*McdH[2, 1] - ((t-1)/(-q^2*t+1))*McdH[3]
>>> P.product( P[Integer(1)], P[Integer(2)] )
-((q^3*t^2-q*t^2-q^2+1)/(-q^3*t^2+q^2*t+q*t-1))*McdP[2, 1] + McdP[3]
>>> Q.product(Q[Integer(1)],Q[Integer(2)])
McdQ[2, 1] + ((q^2*t-q^2+q*t-q+t-1)/(q^2*t-1))*McdQ[3]
>>> Ht.product(Ht[Integer(1)],Ht[Integer(2)])
((q^2-1)/(q^2-t))*McdHt[2, 1] + ((t-1)/(-q^2+t))*McdHt[3]
```

class `sage.combinat.sf.macdonald.`**`MacdonaldPolynomials_h`**(*macdonald*)

Bases: *MacdonaldPolynomials_generic*

The H basis is defined as $H_\mu = \sum_\lambda K_{\lambda\mu}(q,t) s_\lambda$ where $K_{\lambda\mu}(q,t)$ are the Macdonald Kostka coefficients.

In this implementation, it is calculated by using the Macdonald Ht basis and substituting $t \to 1/t$ and multiplying by $t^{n(\mu)}$.

INPUT:

- `self` – a Macdonald H basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: *Element*

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_ht**(*macdonald*)

Bases: *MacdonaldPolynomials_generic*

The Ht basis is defined as $\tilde{H}_\mu = t^{n(\mu)} \sum_\lambda K_{\lambda\mu}(q, t^{-1}) s_\lambda$ where $K_{\lambda\mu}(q,t)$ are the Macdonald (q,t)-Kostka coefficients and $n(\mu) = \sum_i (i-1)\mu_i$.

It is implemented here by using a Pieri formula due to F. Bergeron and M. Haiman [BH2013].

INPUT:

- `self` – a Macdonald Ht basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: *Element*

nabla(*q=None*, *t=None*, *power=1*)

Return the value of the nabla operator applied to `self`. The eigenvectors of the $nabla$ operator are the Macdonald polynomials in the Ht basis. For more information see: [BGHT1999].

The operator $nabla$ acts on symmetric functions and has the Macdonald Ht basis as eigenfunctions and the eigenvalues are $q^{n(\mu')} t^{n(\mu)}$ where $n(\mu) = \sum_i (i-1)\mu_i$.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `self` – an element of the Macdonald Ht basis
- `q`, `t` – (optional) parameters to specialize
- `power` – integer (default: 1)

OUTPUT: the symmetric function of ∇ acting on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Ht = Sym.macdonald().Ht()
sage: t = Ht.t; q = Ht.q
sage: s = Sym.schur()
sage: a = sum(Ht(p) for p in Partitions(3))
sage: Ht(0).nabla()
0
sage: a.nabla() == t^3*Ht([1,1,1])+q*t*Ht([2,1]) + q^3*Ht([3])
True
sage: a.nabla(t=3) == 27*Ht([1,1,1])+3*q*Ht([2,1]) + q^3*Ht([3])
True
sage: a.nabla(q=3) == t^3*Ht([1,1,1])+3*t*Ht([2,1]) + 27*Ht([3])
True
```

(continues on next page)

(continued from previous page)

```
sage: Ht[2,1].nabla(power=-1)
1/(q*t)*McdHt[2, 1]
sage: Ht[2,1].nabla(power=4)
q^4*t^4*McdHt[2, 1]
sage: s(a.nabla(q=3))
(t^6+27*q^3+3*q*t^2)*s[1, 1, 1] + (t^5+t^4+27*q^2+3*q*t+3*t^2+27*q)*s[2,␣
↪1] + (t^3+3*t+27)*s[3]

↪3+3*t+27)*s[3]
```

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_j**(*macdonald*)

Bases: *MacdonaldPolynomials_generic*

The J basis is calculated using determinantal formulas of Lapointe-Lascoux-Morse giving the action on the S-basis.

INPUT:

- `self` – a Macdonald J basis

- `macdonald` – a family of Macdonald bases

class Element

Bases: *Element*

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_p**(*macdonald*)

Bases: *MacdonaldPolynomials_generic*

The P basis is defined here as the J basis times a normalizing coefficient $c2$.

INPUT:

- `self` – a Macdonald P basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: *Element*

scalar_qt_basis(*part1*, *part2=None*)

Return the scalar product of $P(part1)$ and $P(part2)$ This scalar product formula is given in equation (4.11) p.323 and (6.19) p.339 of Macdonald's book [Mac1995].

INPUT:

- `self` – a Macdonald P basis
- `part1`, `part2` – partitions

OUTPUT:

- returns the scalar product of `P(part1)` and `P(part2)`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P()
sage: P.scalar_qt_basis(Partition([2,1]), Partition([1,1,1]))
0
sage: f = P.scalar_qt_basis(Partition([3,2,1]), Partition([3,2,1]))
sage: factor(f.numerator())
(q - 1)^3 * (q^2*t - 1)^2 * (q^3*t^2 - 1)
sage: factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> P = Sym.macdonald().P()
>>> P.scalar_qt_basis(Partition([Integer(2),Integer(1)]),␣
↪Partition([Integer(1),Integer(1),Integer(1)]))
0
>>> f = P.scalar_qt_basis(Partition([Integer(3),Integer(2),Integer(1)]),␣
↪Partition([Integer(3),Integer(2),Integer(1)]))
>>> factor(f.numerator())
(q - 1)^3 * (q^2*t - 1)^2 * (q^3*t^2 - 1)
>>> factor(f.denominator())
(t - 1)^3 * (q*t^2 - 1)^2 * (q^2*t^3 - 1)
```

With a single argument, takes $part2 = part1$:

```
sage: P.scalar_qt_basis(Partition([2,1]), Partition([2,1]))
(-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1)/(-q*t^4 + 2*q*t^3 - q*t^2 + t^2 -
↪2*t + 1)
```

```
>>> from sage.all import *
>>> P.scalar_qt_basis(Partition([Integer(2),Integer(1)]),
↪Partition([Integer(2),Integer(1)]))
(-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1)/(-q*t^4 + 2*q*t^3 - q*t^2 + t^2 -
↪2*t + 1)
```

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_q**(*macdonald*)

Bases: *MacdonaldPolynomials_generic*

The Q basis is defined here as the J basis times a normalizing coefficient.

INPUT:

- `self` – a Macdonald Q basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: *Element*

class sage.combinat.sf.macdonald.**MacdonaldPolynomials_s**(*macdonald*)

Bases: *MacdonaldPolynomials_generic*

An implementation of the basis $s_\lambda[(1-t)X/(1-q)]$.

This is perhaps misnamed as a 'Macdonald' basis for the symmetric functions but is used in the calculation of the Macdonald J basis (see method 'creation' below) but does use both of the two parameters and can be specialized to $s_\lambda[(1-t)X]$ and $s_\lambda[X/(1-t)]$.

INPUT:

- `self` – a Macdonald S basis
- `macdonald` – a family of Macdonald bases

class Element

Bases: *Element*

creation(*k*)

This function is a creation operator for the J-basis for which the action is known on the 'Macdonald' S-basis by formula from [LLM1998].

INPUT:
- `self` – an element of the Macdonald S basis
- `k` – positive integer

OUTPUT: the column adding operator on the J basis on `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: a = S(1)
sage: a.creation(1)
-(q-1)*McdS[1]
```

(continues on next page)

(continued from previous page)

```
sage: a.creation(2)
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> S = Sym.macdonald().S()
>>> a = S(Integer(1))
>>> a.creation(Integer(1))
-(q-1)*McdS[1]
>>> a.creation(Integer(2))
(q^2*t-q*t-q+1)*McdS[1, 1] + (q^2-q*t-q+t)*McdS[2]
```

product(*left*, *right*)

The multiplication of the modified Schur functions behaves the same as the multiplication of the Schur functions.

INPUT:

- `self` – a Macdonald S basis
- `left`, `right` – a symmetric functions

OUTPUT: the product of `left` and `right`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([2])^2 #indirect doctest
McdS[2, 2] + McdS[3, 1] + McdS[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> S = Sym.macdonald().S()
>>> S([Integer(2)])**Integer(2) #indirect doctest
McdS[2, 2] + McdS[3, 1] + McdS[4]
```

`sage.combinat.sf.macdonald.`**c1**(*part*, *q*, *t*)

This function returns the qt-Hall scalar product between `J(part)` and `P(part)`.

This coefficient is c_λ in equation (8.1') p. 352 of Macdonald's book [Mac1995].

INPUT:

- `part` – a partition
- `q`, `t` – parameters

OUTPUT: a polynomial of the scalar product between the J and P bases

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import c1
sage: R.<q,t> = QQ[]
sage: c1(Partition([2,1]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
```

(continues on next page)

(continued from previous page)

```
sage: c1(Partition([1,1]),q,t)
q^2*t - q*t - q + 1
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import c1
>>> R = QQ['q, t']; (q, t,) = R._first_ngens(2)
>>> c1(Partition([Integer(2),Integer(1)]),q,t)
-q^4*t + 2*q^3*t - q^2*t + q^2 - 2*q + 1
>>> c1(Partition([Integer(1),Integer(1)]),q,t)
q^2*t - q*t - q + 1
```

sage.combinat.sf.macdonald.**c2**(*part*, *q*, *t*)

This function returns the qt-Hall scalar product between J(part) and Q(part).

This coefficient is c_λ in equation (8.1) p. 352 of Macdonald's book [Mac1995].

INPUT:

- part – a partition
- q, t – parameters

OUTPUT: a polynomial of the scalar product between the J and P bases

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import c2
sage: R.<q,t> = QQ[]
sage: c2(Partition([1,1]),q,t)
t^3 - t^2 - t + 1
sage: c2(Partition([2,1]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import c2
>>> R = QQ['q, t']; (q, t,) = R._first_ngens(2)
>>> c2(Partition([Integer(1),Integer(1)]),q,t)
t^3 - t^2 - t + 1
>>> c2(Partition([Integer(2),Integer(1)]),q,t)
-q*t^4 + 2*q*t^3 - q*t^2 + t^2 - 2*t + 1
```

sage.combinat.sf.macdonald.**cmunu**(*nu*)

Return the coefficient of $\tilde{H}_\nu$ in $h_r^\perp \tilde{H}_\mu$.

Proposition 5 of F. Bergeron and M. Haiman [BH2013] states

$$c_{\mu\nu} = \sum_{\alpha \leftarrow \nu} c_{\mu\alpha} c_{\alpha\nu} B_{\alpha/\nu} / B_{\mu/\nu}$$

where $c_{\mu\nu}$ is the coefficient of $\tilde{H}_\nu$ in $h_r^\perp \tilde{H}_\mu$ and $B_{\mu/\nu}$ is the bi-exponent generator implemented in the function sage.combinat.sf.macdonald.Bmu().

INPUT:

- mu, nu – partitions with nu contained in mu

OUTPUT: an element of the fraction field of polynomials in q and t

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import cmunu
sage: cmunu(Partition([2,1]),Partition([1]))
q + t + 1
sage: cmunu(Partition([2,2]),Partition([1,1]))
(-q^3 - q^2 + q*t + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[2,2].skew_by(h[r]).coefficient(nu)
....:     == cmunu(Partition([2,2]),nu)
....:     for r in range(1,5) for nu in Partitions(4-r))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import cmunu
>>> cmunu(Partition([Integer(2),Integer(1)]),Partition([Integer(1)]))
q + t + 1
>>> cmunu(Partition([Integer(2),Integer(2)]),Partition([Integer(1),Integer(1)]))
(-q^3 - q^2 + q*t + t)/(-q + t)
>>> Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
>>> h = Sym.h()
>>> Ht = Sym.macdonald().Ht()
>>> all(Ht[Integer(2),Integer(2)].skew_by(h[r]).coefficient(nu)
...     == cmunu(Partition([Integer(2),Integer(2)]),nu)
...     for r in range(Integer(1),Integer(5)) for nu in Partitions(Integer(4)-r))
True
```

sage.combinat.sf.macdonald.**cmunu1**(*nu*)

Return the coefficient of $\tilde{H}_\nu$ in $h_1^\perp \tilde{H}_\mu$.

INPUT:

- `mu`, `nu` – partitions with `nu` precedes `mu`

OUTPUT: an element of the fraction field of polynomials in q and t

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import cmunu1
sage: cmunu1(Partition([2,1]),Partition([2]))
(-t^2 + q)/(q - t)
sage: cmunu1(Partition([2,1]),Partition([1,1]))
(-q^2 + t)/(-q + t)
sage: Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
sage: h = Sym.h()
sage: Ht = Sym.macdonald().Ht()
sage: all(Ht[3,2,1].skew_by(h[1]).coefficient(nu)
....:     == cmunu1(Partition([3,2,1]),nu)
....:     for nu in Partition([3,2,1]).down_list())
True
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import cmunu1
>>> cmunu1(Partition([Integer(2),Integer(1)]),Partition([Integer(2)]))
(-t^2 + q)/(q - t)
>>> cmunu1(Partition([Integer(2),Integer(1)]),Partition([Integer(1),Integer(1)]))
(-q^2 + t)/(-q + t)
>>> Sym = SymmetricFunctions(QQ['q','t'].fraction_field())
>>> h = Sym.h()
>>> Ht = Sym.macdonald().Ht()
>>> all(Ht[Integer(3),Integer(2),Integer(1)].skew_by(h[Integer(1)]).
↪coefficient(nu)
...     == cmunu1(Partition([Integer(3),Integer(2),Integer(1)]),nu)
...     for nu in Partition([Integer(3),Integer(2),Integer(1)]).down_list())
True
```

sage.combinat.sf.macdonald.**qt_kostka**(*lam*, *mu*)

Return the $K_{\lambda\mu}(q,t)$ by computing the change of basis from the Macdonald H basis to the Schurs.

INPUT:

- lam, mu – partitions of the same size

OUTPUT:

- returns the q,t-Kostka polynomial indexed by the partitions lam and mu

EXAMPLES:

```
sage: from sage.combinat.sf.macdonald import qt_kostka
sage: qt_kostka([2,1,1],[1,1,1,1])
t^3 + t^2 + t
sage: qt_kostka([1,1,1,1],[2,1,1])
q
sage: qt_kostka([1,1,1,1],[3,1])
q^3
sage: qt_kostka([1,1,1,1],[1,1,1,1])
1
sage: qt_kostka([2,1,1],[2,2])
q^2*t + q*t + q
sage: qt_kostka([2,2],[2,2])
q^2*t^2 + 1
sage: qt_kostka([4],[3,1])
t
sage: qt_kostka([2,2],[3,1])
q^2*t + q
sage: qt_kostka([3,1],[2,1,1])
q*t^3 + t^2 + t
sage: qt_kostka([2,1,1],[2,1,1])
q*t^2 + q*t + 1
sage: qt_kostka([2,1],[1,1,1,1])
0
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.macdonald import qt_kostka
>>> qt_kostka([Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1),Integer(1)])
t^3 + t^2 + t
>>> qt_kostka([Integer(1),Integer(1),Integer(1),Integer(1)],[Integer(2),
↪Integer(1),Integer(1)])

```

5.1.293 Monomial symmetric functions

class sage.combinat.sf.monomial.**SymmetricFunctionAlgebra_monomial**(*Sym*)

Bases: *SymmetricFunctionAlgebra_classical*

A class for methods related to monomial symmetric functions.

INPUT:

- `self` – a monomial symmetric function basis
- `Sym` – an instance of the ring of the symmetric functions

class Element

Bases: *Element*

expand(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: m([2,1]).expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: m([1,1,1]).expand(2)
0
sage: m([2,1]).expand(3,alphabet='z')
z0^2*z1 + z0*z1^2 + z0^2*z2 + z1^2*z2 + z0*z2^2 + z1*z2^2
sage: m([2,1]).expand(3,alphabet='x,y,z')
x^2*y + x*y^2 + x^2*z + y^2*z + x*z^2 + y*z^2
sage: m([1]).expand(0)
0
sage: (3*m([])).expand(0)
3
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> m([Integer(2),Integer(1)]).expand(Integer(3))
x0^2*x1 + x0*x1^2 + x0^2*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
>>> m([Integer(1),Integer(1),Integer(1)]).expand(Integer(2))
0
>>> m([Integer(2),Integer(1)]).expand(Integer(3),alphabet='z')
z0^2*z1 + z0*z1^2 + z0^2*z2 + z1^2*z2 + z0*z2^2 + z1*z2^2
>>> m([Integer(2),Integer(1)]).expand(Integer(3),alphabet='x,y,z')
x^2*y + x*y^2 + x^2*z + y^2*z + x*z^2 + y*z^2
>>> m([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*m([])).expand(Integer(0))
3
```

exponential_specialization(*t=None*, *q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q-exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R. It is defined whenever the base ring K is a **Q**-algebra and t is an element of R. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q-exponential specialization is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n, we have

$$ex_q(f) = (1-q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \to 1$ is ex.

INPUT:

- `t` – (default: `None`) the value to use for t; the default is to create a ring of polynomials in `t`
- `q` – (default: 1) the value to use for q; if `q` is `None`, then a ring (or fraction field) of polynomials in `q` is created

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: (m[3]+m[2,1]+m[1,1,1]).exponential_specialization()
1/6*t^3

sage: x = 5*m[1,1,1] + 3*m[2,1] + 1
sage: x.exponential_specialization()
5/6*t^3 + 1
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> (m[Integer(3)]+m[Integer(2),Integer(1)]+m[Integer(1),Integer(1),
↪Integer(1)]).exponential_specialization()
1/6*t^3

>>> x = Integer(5)*m[Integer(1),Integer(1),Integer(1)] +␣
↪Integer(3)*m[Integer(2),Integer(1)] + Integer(1)
>>> x.exponential_specialization()
5/6*t^3 + 1
```

We also support the q-exponential_specialization:

```
sage: factor(m[3].exponential_specialization(q=var("q"), t=var("t")))    #␣
↪needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

```
>>> from sage.all import *
>>> factor(m[Integer(3)].exponential_specialization(q=var("q"), t=var("t
↪")))    # needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

principal_specialization(*n=+Infinity*, *q=None*)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \dots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \dots$. (To be more precise, $ps_{n,q}$ is a K-algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` – (default: `infinity`) a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` – (default: `None`) the value to use for q; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

For q=1 and finite n we use the formula from Proposition 7.8.3 of [EnumComb2]:

$$ps_{n,1}(m_\lambda) = \binom{n}{\ell(\lambda)} \binom{\ell(\lambda)}{m_1(\lambda), m_2(\lambda), \ldots},$$

where $\ell(\lambda)$ denotes the length of λ.

In all other cases, we convert to complete homogeneous symmetric functions.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[3,1]
sage: x.principal_specialization(3)
q^7 + q^6 + q^5 + q^3 + q^2 + q

sage: x = 5*m[2] + 3*m[1] + 1
sage: x.principal_specialization(3, q=var("q"))                                #␣
↪needs sage.symbolic
-10*(q^3 - 1)*q/(q - 1) + 5*(q^3 - 1)^2/(q - 1)^2 + 3*(q^3 - 1)/(q - 1) +␣
↪1
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> x = m[Integer(3),Integer(1)]
>>> x.principal_specialization(Integer(3))
q^7 + q^6 + q^5 + q^3 + q^2 + q

>>> x = Integer(5)*m[Integer(2)] + Integer(3)*m[Integer(1)] + Integer(1)
>>> x.principal_specialization(Integer(3), q=var("q"))                          ␣
↪     # needs sage.symbolic
-10*(q^3 - 1)*q/(q - 1) + 5*(q^3 - 1)^2/(q - 1)^2 + 3*(q^3 - 1)/(q - 1) +␣
↪1
```

antipode_by_coercion(*element*)

The antipode of `element` via coercion to and from the power-sum basis or the Schur basis (depending on whether the power sums really form a basis over the given ground ring).

INPUT:

- `element` – element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]

sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: m[3,2].antipode()
m[3, 2] + 2*m[5]
sage: m.antipode_by_coercion(m[3,2])
m[3, 2] + 2*m[5]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.monomial()
>>> m[Integer(3),Integer(2)].antipode()
m[3, 2] + 2*m[5]
>>> m.antipode_by_coercion(m[Integer(3),Integer(2)])
m[3, 2] + 2*m[5]

>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.monomial()
>>> m[Integer(3),Integer(2)].antipode()
m[3, 2] + 2*m[5]
>>> m.antipode_by_coercion(m[Integer(3),Integer(2)])
m[3, 2] + 2*m[5]
```

Todo

Is there a not too difficult way to get the power-sum computations to work over any ring, not just one with coercion from **Q**?

from_polynomial(*f*, *check=True*)

Return the symmetric function in the monomial basis corresponding to the polynomial `f`.

INPUT:

- `self` – a monomial symmetric function basis
- `f` – a polynomial in finitely many variables over the same base ring as `self`; it is assumed that this polynomial is symmetric
- `check` – boolean (default: `True`); checks whether the polynomial is indeed symmetric

OUTPUT:

- This function converts a symmetric polynomial f in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: m.from_polynomial(f)
m[1]
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: m.from_polynomial(f)
m[2]
sage: f = x[0]^2+x[1]
sage: m.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a symmetric polynomial
sage: f = (m[2,1]+m[1,1]).expand(3)
sage: m.from_polynomial(f)
```

(continues on next page)

(continued from previous page)

```
m[1, 1] + m[2, 1]
sage: f = (2*m[2,1]+m[1,1]+3*m[3]).expand(3)
sage: m.from_polynomial(f)
m[1, 1] + 2*m[2, 1] + 3*m[3]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> P = PolynomialRing(QQ, 'x', Integer(3))
>>> x = P.gens()
>>> f = x[Integer(0)] + x[Integer(1)] + x[Integer(2)]
>>> m.from_polynomial(f)
m[1]
>>> f =␣
↪x[Integer(0)]**Integer(2)+x[Integer(1)]**Integer(2)+x[Integer(2)]**Integer(2)
>>> m.from_polynomial(f)
m[2]
>>> f = x[Integer(0)]**Integer(2)+x[Integer(1)]
>>> m.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a symmetric polynomial
>>> f = (m[Integer(2),Integer(1)]+m[Integer(1),Integer(1)]).expand(Integer(3))
>>> m.from_polynomial(f)
m[1, 1] + m[2, 1]
>>> f = (Integer(2)*m[Integer(2),Integer(1)]+m[Integer(1),
↪Integer(1)]+Integer(3)*m[Integer(3)]).expand(Integer(3))
>>> m.from_polynomial(f)
m[1, 1] + 2*m[2, 1] + 3*m[3]
```

from_polynomial_exp(p)

Conversion from polynomial in exponential notation.

INPUT:

- `self` – a monomial symmetric function basis
- `p` – a polynomial over the same base ring as `self`

OUTPUT:

- This returns a symmetric function by mapping each monomial of p with exponents `exp` into m_λ where λ is the partition with exponential notation `exp`.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: P = PolynomialRing(QQ,'x',5)
sage: x = P.gens()
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> P = PolynomialRing(QQ,'x',Integer(5))
>>> x = P.gens()
```

The exponential notation of the partition $(5, 5, 5, 3, 1, 1)$ is:

```
sage: Partition([5,5,5,3,1,1]).to_exp()
[2, 0, 1, 0, 3]
```

```
>>> from sage.all import *
>>> Partition([Integer(5),Integer(5),Integer(5),Integer(3),Integer(1),
↪Integer(1)]).to_exp()
[2, 0, 1, 0, 3]
```

Therefore, the monomial:

```
sage: f = x[0]^2 * x[2] * x[4]^3
```

```
>>> from sage.all import *
>>> f = x[Integer(0)]**Integer(2) * x[Integer(2)] * x[Integer(4)]**Integer(3)
```

is mapped to:

```
sage: m.from_polynomial_exp(f)
m[5, 5, 5, 3, 1, 1]
```

```
>>> from sage.all import *
>>> m.from_polynomial_exp(f)
m[5, 5, 5, 3, 1, 1]
```

Furthermore, this function is linear:

```
sage: f = 3 * x[3] + 2 * x[0]^2 * x[2] * x[4]^3
sage: m.from_polynomial_exp(f)
3*m[4] + 2*m[5, 5, 5, 3, 1, 1]
```

```
>>> from sage.all import *
>>> f = Integer(3) * x[Integer(3)] + Integer(2) * x[Integer(0)]**Integer(2) *␣
↪x[Integer(2)] * x[Integer(4)]**Integer(3)
>>> m.from_polynomial_exp(f)
3*m[4] + 2*m[5, 5, 5, 3, 1, 1]
```

See also:

Partition(), *Partition.to_exp()*

product (*left*, *right*)

Return the product of `left` and `right`.

- `left`, `right` – symmetric functions written in the monomial basis `self`

OUTPUT:

- the product of `left` and `right`, expanded in the monomial basis, as a dictionary whose keys are partitions and whose values are the coefficients of these partitions (more precisely, their respective monomial symmetric functions) in the product.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: a = m([2,1])
sage: a^2
4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] +␣
↪m[4, 2]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> a = m([Integer(2),Integer(1)])
>>> a**Integer(2)
4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3, 3] + 2*m[4, 1, 1] +␣
↪m[4, 2]
```

```
sage: QQx.<x> = QQ['x']
sage: m = SymmetricFunctions(QQx).m()
sage: a = m([2,1])+x
sage: 2*a # indirect doctest
2*x*m[] + 2*m[2, 1]
sage: a^2
x^2*m[] + 2*x*m[2, 1] + 4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3,
↪ 3] + 2*m[4, 1, 1] + m[4, 2]
```

```
>>> from sage.all import *
>>> QQx = QQ['x']; (x,) = QQx._first_ngens(1)
>>> m = SymmetricFunctions(QQx).m()
>>> a = m([Integer(2),Integer(1)])+x
>>> Integer(2)*a # indirect doctest
2*x*m[] + 2*m[2, 1]
>>> a**Integer(2)
x^2*m[] + 2*x*m[2, 1] + 4*m[2, 2, 1, 1] + 6*m[2, 2, 2] + 2*m[3, 2, 1] + 2*m[3,
↪ 3] + 2*m[4, 1, 1] + m[4, 2]
```

5.1.294 Multiplicative symmetric functions

A realization h of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \ldots)$ we have $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots$.

class sage.combinat.sf.multiplicative.**SymmetricFunctionAlgebra_multiplicative**(*Sym*, *basis_name=None*, *prefix=None*, *graded=True*)

Bases: *SymmetricFunctionAlgebra_classical*

The class of multiplicative bases of the ring of symmetric functions.

A realization q of the ring of symmetric functions is multiplicative if for a partition $\lambda = (\lambda_1, \lambda_2, \ldots)$ we have $q_\lambda = q_{\lambda_1} q_{\lambda_2} \cdots$ (with q_0 meaning 1).

Examples of multiplicative realizations are the elementary symmetric basis, the complete homogeneous basis, the powersum basis (if the base ring is a **Q**-algebra), and the Witt basis (but not the Schur basis or the monomial basis).

coproduct_on_basis(*mu*)

Return the coproduct on a basis element for multiplicative bases.

INPUT:

- `mu` – a partition

OUTPUT:

- the image of `self[mu]` under comultiplication; this is an element of the tensor square of `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_basis([2,1])
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]

sage: e = Sym.elementary()
sage: e.coproduct_on_basis([3,1])
e[] # e[3, 1] + e[1] # e[2, 1] + e[1] # e[3] + e[1, 1] # e[2] + e[2] # e[1,
↪1] + e[2, 1] # e[1] + e[3] # e[1] + e[3, 1] # e[]

sage: h = Sym.homogeneous()
sage: h.coproduct_on_basis([3,1])
h[] # h[3, 1] + h[1] # h[2, 1] + h[1] # h[3] + h[1, 1] # h[2] + h[2] # h[1,
↪1] + h[2, 1] # h[1] + h[3] # h[1] + h[3, 1] # h[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.powersum()
>>> p.coproduct_on_basis([Integer(2),Integer(1)])
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]

>>> e = Sym.elementary()
>>> e.coproduct_on_basis([Integer(3),Integer(1)])
e[] # e[3, 1] + e[1] # e[2, 1] + e[1] # e[3] + e[1, 1] # e[2] + e[2] # e[1,
↪1] + e[2, 1] # e[1] + e[3] # e[1] + e[3, 1] # e[]

>>> h = Sym.homogeneous()
>>> h.coproduct_on_basis([Integer(3),Integer(1)])
h[] # h[3, 1] + h[1] # h[2, 1] + h[1] # h[3] + h[1, 1] # h[2] + h[2] # h[1,
↪1] + h[2, 1] # h[1] + h[3] # h[1] + h[3, 1] # h[]
```

product_on_basis(*left*, *right*)

Return the product of `left` and `right`.

INPUT:

- `left`, `right` – partitions

OUTPUT: an element of `self`

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: e([2,1])^2  # indirect doctest
e[2, 2, 1, 1]
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> e([Integer(2),Integer(1)])**Integer(2)  # indirect doctest
e[2, 2, 1, 1]
```

```
sage: h = SymmetricFunctions(QQ).h()
sage: h([2,1])^2
h[2, 2, 1, 1]
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> h([Integer(2),Integer(1)])**Integer(2)
h[2, 2, 1, 1]
```

```
sage: p = SymmetricFunctions(QQ).p()
sage: p([2,1])^2
p[2, 2, 1, 1]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p([Integer(2),Integer(1)])**Integer(2)
p[2, 2, 1, 1]
```

```
sage: QQx.<x> = QQ[]
sage: p = SymmetricFunctions(QQx).p()
sage: (x*p([2]))^2
x^2*p[2, 2]

sage: TestSuite(p).run() # to silence sage -coverage
```

```
>>> from sage.all import *
>>> QQx = QQ['x']; (x,) = QQx._first_ngens(1)
>>> p = SymmetricFunctions(QQx).p()
>>> (x*p([Integer(2)]))**Integer(2)
x^2*p[2, 2]

>>> TestSuite(p).run() # to silence sage -coverage
```

5.1.295 k-Schur Functions

class sage.combinat.sf.new_kschur.**KBoundedSubspace**(*Sym*, *k*, *t='t'*)

Bases: UniqueRepresentation, Parent

This class implements the subspace of the ring of symmetric functions spanned by $\{s_\lambda[X/(1-t)]\}_{\lambda_1\le k} = \{s_\lambda^{(k)}[X;t]\}_{\lambda_1\le k}$ over the base ring $\mathbf{Q}[t]$. When $t=1$, this space is in fact a subring of the ring of symmetric functions generated by the complete homogeneous symmetric functions h_i for $1\le i\le k$.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
```

(continues on next page)

(continued from previous page)

```
3-bounded Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> KB = Sym.kBoundedSubspace(Integer(3),Integer(1)); KB
3-bounded Symmetric Functions over Rational Field with t=1

>>> Sym = SymmetricFunctions(QQ['t'])
>>> KB = Sym.kBoundedSubspace(Integer(3)); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field
```

The k-Schur function basis can be constructed as follows:

```
sage: ks = KB.kschur(); ks
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field in the 3-Schur basis
```

```
>>> from sage.all import *
>>> ks = KB.kschur(); ks
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field in the 3-Schur basis
```

K_kschur()

Return the k-bounded basis called the K-k-Schur basis.

See [Morse11] and [LamSchillingShimozono10].

REFERENCES:

EXAMPLES:

```
sage: kB = SymmetricFunctions(QQ).kBoundedSubspace(3,1)
sage: g = kB.K_kschur()
sage: g
3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur␣
↪basis
sage: kB = SymmetricFunctions(QQ['t']).kBoundedSubspace(3)
sage: g = kB.K_kschur()
Traceback (most recent call last):
...
ValueError: This basis only exists for t=1
```

```
>>> from sage.all import *
>>> kB = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1))
>>> g = kB.K_kschur()
>>> g
3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur␣
```

(continues on next page)

(continued from previous page)

```
↪basis
>>> kB = SymmetricFunctions(QQ['t']).kBoundedSubspace(Integer(3))
>>> g = kB.K_kschur()
Traceback (most recent call last):
...
ValueError: This basis only exists for t=1
```

khomogeneous()

The homogeneous basis of this algebra.

See also

kHomogeneous()

EXAMPLES:

```
sage: kh3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).khomogeneous()
sage: TestSuite(kh3).run()
```

```
>>> from sage.all import *
>>> kh3 = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).
↪khomogeneous()
>>> TestSuite(kh3).run()
```

kschur()

The k-Schur basis of this algebra.

See also

kSchur()

EXAMPLES:

```
sage: ks3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).kschur()
sage: TestSuite(ks3).run()
```

```
>>> from sage.all import *
>>> ks3 = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).
↪kschur()
>>> TestSuite(ks3).run()
```

ksplit()

The k-split basis of this algebra.

See also

kSplit()

EXAMPLES:

```
sage: ksp3 = SymmetricFunctions(QQ).kBoundedSubspace(3,1).ksplit()
sage: TestSuite(ksp3).run()
```

```
>>> from sage.all import *
>>> ksp3 = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).
↪ksplit()
>>> TestSuite(ksp3).run()
```

realizations()

A list of realizations of this algebra.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).kBoundedSubspace(3,1).realizations()
[3-bounded Symmetric Functions over Rational Field with t=1 in the 3-Schur␣
↪basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-split␣
↪basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-bounded␣
↪homogeneous basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur␣
↪basis]
sage: SymmetricFunctions(QQ['t']).kBoundedSubspace(3).realizations()
[3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field in the 3-Schur basis,
 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field in the 3-split basis]
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).
↪realizations()
[3-bounded Symmetric Functions over Rational Field with t=1 in the 3-Schur␣
↪basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-split␣
↪basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the 3-bounded␣
↪homogeneous basis,
 3-bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur␣
↪basis]
>>> SymmetricFunctions(QQ['t']).kBoundedSubspace(Integer(3)).realizations()
[3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field in the 3-Schur basis,
 3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field in the 3-split basis]
```

retract(*sym*)

Return the retract of `sym` from the ring of symmetric functions to `self`.

INPUT:

- `sym` – a symmetric function

OUTPUT:

- the analogue of the symmetric function in the k-bounded subspace (if possible)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1
sage: KB.retract(s[2]+s[3])
ks3[2] + ks3[3]
sage: KB.retract(s[2,1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> KB = Sym.kBoundedSubspace(Integer(3),Integer(1)); KB
3-bounded Symmetric Functions over Rational Field with t=1
>>> KB.retract(s[Integer(2)]+s[Integer(3)])
ks3[2] + ks3[3]
>>> KB.retract(s[Integer(2),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

class sage.combinat.sf.new_kschur.**KBoundedSubspaceBases**(*base*, *t='t'*)

Bases: Category_realization_of_parent

The category of bases for the k-bounded subspace of symmetric functions.

class ElementMethods

Bases: object

expand(**args*, ***kwargs*)

Return the monomial expansion of `self` in n variables.

INPUT:

- `n` – positive integer

OUTPUT: monomial expansion of `self` in n variables

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[3,1].expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: s = Sym.schur()
sage: ks[3,1].expand(2) == s(ks[3,1]).expand(2)
True

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]-ks[1]
sage: f.expand(2)
t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^
↪2*x1^3 + (t^2 + t)*x0*x1^4 + t^2*x1^5 - x0 - x1
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(3),Integer(1))
>>> ks[Integer(3),Integer(1)].expand(Integer(2))
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
>>> s = Sym.schur()
>>> ks[Integer(3),Integer(1)].expand(Integer(2)) == s(ks[Integer(3),
↪Integer(1)]).expand(Integer(2))
True

>>> Sym = SymmetricFunctions(QQ['t'])
>>> ks = Sym.kschur(Integer(3))
>>> f = ks[Integer(3),Integer(2)]-ks[Integer(1)]
>>> f.expand(Integer(2))
t^2*x0^5 + (t^2 + t)*x0^4*x1 + (t^2 + t + 1)*x0^3*x1^2 + (t^2 + t + 1)*x0^
↪2*x1^3 + (t^2 + t)*x0*x1^4 + t^2*x1^5 - x0 - x1
```

hl_creation_operator(*nu*, *t=None*)

This is the vertex operator that generalizes Jing's operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a t-analogue of multiplication by `s(nu)` .

See also

Proposition 5 in [SZ2001].

INPUT:

- `nu` – a partition or a list of integers
- `t` – (default: `None`, in which case `t` is used) an element of the base ring

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(4)
sage: s = Sym.schur()
sage: s(ks([3,1,1]).hl_creation_operator([1]))
(t-1)*s[2, 2, 1, 1] + t^2*s[3, 1, 1, 1] + (t^3+t^2-t)*s[3, 2, 1] + (t^3-t^
↪2)*s[3, 3] + (t^4+t^3)*s[4, 1, 1] + t^4*s[4, 2] + t^5*s[5, 1]
sage: ks([3,1,1]).hl_creation_operator([1])
(t-1)*ks4[2, 2, 1, 1] + t^2*ks4[3, 1, 1, 1] + t^3*ks4[3, 2, 1] + (t^3-t^
↪2)*ks4[3, 3] + t^4*ks4[4, 1, 1]

sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(4,t=1)
sage: ks([3,1,1]).hl_creation_operator([1])
ks4[3, 1, 1, 1] + ks4[3, 2, 1] + ks4[4, 1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> ks = Sym.kschur(Integer(4))
>>> s = Sym.schur()
>>> s(ks([Integer(3),Integer(1),Integer(1)]).hl_creation_
```

(continues on next page)

(continued from previous page)

```
↪operator([Integer(1)]))
(t-1)*s[2, 2, 1, 1] + t^2*s[3, 1, 1, 1] + (t^3+t^2-t)*s[3, 2, 1] + (t^3-t^
↪2)*s[3, 3] + (t^4+t^3)*s[4, 1, 1] + t^4*s[4, 2] + t^5*s[5, 1]
>>> ks([Integer(3),Integer(1),Integer(1)]).hl_creation_
↪operator([Integer(1)])
(t-1)*ks4[2, 2, 1, 1] + t^2*ks4[3, 1, 1, 1] + t^3*ks4[3, 2, 1] + (t^3-t^
↪2)*ks4[3, 3] + t^4*ks4[4, 1, 1]

>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(4),t=Integer(1))
>>> ks([Integer(3),Integer(1),Integer(1)]).hl_creation_
↪operator([Integer(1)])
ks4[3, 1, 1, 1] + ks4[3, 2, 1] + ks4[4, 1, 1]
```

is_schur_positive(**args*, ***kwargs*)

Return whether `self` is Schur positive.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: f = ks[3,2]+ks[1]
sage: f.is_schur_positive()
True
sage: f = ks[3,2]-ks[1]
sage: f.is_schur_positive()
False
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(3),Integer(1))
>>> f = ks[Integer(3),Integer(2)]+ks[Integer(1)]
>>> f.is_schur_positive()
True
>>> f = ks[Integer(3),Integer(2)]-ks[Integer(1)]
>>> f.is_schur_positive()
False

>>> Sym = SymmetricFunctions(QQ['t'])
>>> ks = Sym.kschur(Integer(3))
>>> f = ks[Integer(3),Integer(2)]+ks[Integer(1)]
>>> f.is_schur_positive()
True
```

(continues on next page)

(continued from previous page)

```
>>> f = ks[Integer(3),Integer(2)]-ks[Integer(1)]
>>> f.is_schur_positive()
False
```

omega()

Return the ω operator on `self`.

At $t = 1$, ω maps the k-Schur function $s^{(k)}_\lambda$ to $s^{(k)}_{\lambda^{(k)}}$, where $\lambda^{(k)}$ is the k-conjugate of the partition λ.

See also:

k_conjugate().

For generic t, ω sends $s^{(k)}_\lambda[X; t]$ to $t^d s^{(k)}_{\lambda^{(k)}}[X; 1/t]$, where d is the size of the core of λ minus the size of λ. Most of the time, this result is not in the k-bounded subspace.

See also:

omega_t_inverse().

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2,2,1,1].omega()
ks3[2, 2, 2]
sage: kh = Sym.khomogeneous(3)
sage: kh[3].omega()
h3[1, 1, 1] - 2*h3[2, 1] + h3[3]

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega()
Traceback (most recent call last):
...
ValueError: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(3),Integer(1))
>>> ks[Integer(2),Integer(2),Integer(1),Integer(1)].omega()
ks3[2, 2, 2]
>>> kh = Sym.khomogeneous(Integer(3))
>>> kh[Integer(3)].omega()
h3[1, 1, 1] - 2*h3[2, 1] + h3[3]

>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> ks = Sym.kschur(Integer(3))
>>> ks[Integer(3),Integer(1),Integer(1)].omega()
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
ValueError: t*s[2, 1, 1, 1] + s[3, 1, 1] is not in the image
```

omega_t_inverse()

Return the map $t \to 1/t$ composed with ω on `self`.

Unlike the map *omega()*, the result of *omega_t_inverse()* lives in the k-bounded subspace and hence will return an element even for generic t. For $t = 1$, *omega()* and *omega_t_inverse()* return the same result.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: ks = Sym.kschur(3)
sage: ks[3,1,1].omega_t_inverse()
1/t*ks3[2, 1, 1, 1]
sage: ks[3,2].omega_t_inverse()
1/t^2*ks3[1, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> ks = Sym.kschur(Integer(3))
>>> ks[Integer(3),Integer(1),Integer(1)].omega_t_inverse()
1/t*ks3[2, 1, 1, 1]
>>> ks[Integer(3),Integer(2)].omega_t_inverse()
1/t^2*ks3[1, 1, 1, 1, 1]
```

scalar(*x*, *zee=None*)

Return standard scalar product between `self` and `x`.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `zee` – an optional function on partitions giving the value for the scalar product between p_μ and p_μ (default: use the standard *zee()* function)

See also

scalar()

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3)
sage: ks3[3,2,1].scalar( ks3[2,2,2] )
t^3 + t
sage: dks3 = Sym.kBoundedQuotient(3).dks()
sage: [ks3[3,2,1].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, 1, 0, 0, 0, 0, 0]
sage: dks3 = Sym.kBoundedQuotient(3,t=1).dks()
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
[0, t - 1, 0, 1, 0, 0, 0]
sage: ks3 = Sym.kschur(3,t=1)
sage: [ks3[2,2,2].scalar(dks3(la)) for la in Partitions(6, max_part=3)]
```

(continues on next page)

(continued from previous page)

```
[0, 0, 0, 1, 0, 0, 0]
sage: kH = Sym.khomogeneous(4)
sage: kH([2,2,1]).scalar(ks3[2,2,1])
3
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'])
>>> ks3 = Sym.kschur(Integer(3))
>>> ks3[Integer(3),Integer(2),Integer(1)].scalar( ks3[Integer(2),
↪Integer(2),Integer(2)] )
t^3 + t
>>> dks3 = Sym.kBoundedQuotient(Integer(3)).dks()
>>> [ks3[Integer(3),Integer(2),Integer(1)].scalar(dks3(la)) for la in␣
↪Partitions(Integer(6), max_part=Integer(3))]
[0, 1, 0, 0, 0, 0, 0]
>>> dks3 = Sym.kBoundedQuotient(Integer(3),t=Integer(1)).dks()
>>> [ks3[Integer(2),Integer(2),Integer(2)].scalar(dks3(la)) for la in␣
↪Partitions(Integer(6), max_part=Integer(3))]
[0, t - 1, 0, 1, 0, 0, 0]
>>> ks3 = Sym.kschur(Integer(3),t=Integer(1))
>>> [ks3[Integer(2),Integer(2),Integer(2)].scalar(dks3(la)) for la in␣
↪Partitions(Integer(6), max_part=Integer(3))]
[0, 0, 0, 1, 0, 0, 0]
>>> kH = Sym.khomogeneous(Integer(4))
>>> kH([Integer(2),Integer(2),Integer(1)]).scalar(ks3[Integer(2),
↪Integer(2),Integer(1)])
3
```

class ParentMethods

Bases: `object`

an_element()

Return an element of `self`.

EXAMPLES:

```
sage: SymmetricFunctions(QQ['t']).kschur(3).an_element()
2*ks3[] + 2*ks3[1] + 3*ks3[2]
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ['t']).kschur(Integer(3)).an_element()
2*ks3[] + 2*ks3[1] + 3*ks3[2]
```

antipode(*element*)

Return the antipode on `self` by lifting to the space of symmetric functions, computing the antipode, and then converting to `self.parent()`. This is only the antipode for $t = 1$ and for other values of t the result may not be in the space where the k-Schur functions live.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[3,2].antipode()
-ks3[1, 1, 1, 1, 1]
sage: ks3.antipode(ks3[3,2])
-ks3[1, 1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks3 = Sym.kschur(Integer(3),Integer(1))
>>> ks3[Integer(3),Integer(2)].antipode()
-ks3[1, 1, 1, 1, 1]
>>> ks3.antipode(ks3[Integer(3),Integer(2)])
-ks3[1, 1, 1, 1, 1]
```

coproduct (*element*)

Return the coproduct operation on `element`.

The coproduct is first computed on the homogeneous basis if $t = 1$ and on the Hall-Littlewood `Qp` basis otherwise. The result is computed then converted to the tensor squared of `self.parent()`.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: ks3[2,1].coproduct()
ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
→ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
sage: h3 = Sym.khomogeneous(3)
sage: h3[2,1].coproduct()
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
→h3[2] # h3[1] + h3[2, 1] # h3[]
sage: ks3t = SymmetricFunctions(FractionField(QQ['t'])).kschur(3)
sage: ks3t[2,1].coproduct()
ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
→ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
sage: ks3t[3,1].coproduct()
ks3[] # ks3[3, 1] + ks3[1] # ks3[2, 1] + (t+1)*ks3[1] # ks3[3] + ks3[1,
→1] # ks3[2] + ks3[2] # ks3[1, 1]
+ (t+1)*ks3[2] # ks3[2] + ks3[2, 1] # ks3[1] + (t+1)*ks3[3] # ks3[1] +
→ks3[3, 1] # ks3[]
sage: h3.coproduct(h3[2,1])
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
→h3[2] # h3[1] + h3[2, 1] # h3[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks3 = Sym.kschur(Integer(3),Integer(1))
>>> ks3[Integer(2),Integer(1)].coproduct()
ks3[] # ks3[2, 1] + ks3[1] # ks3[1, 1] + ks3[1] # ks3[2] + ks3[1, 1] #
→ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
```

(continues on next page)

(continued from previous page)

```
>>> h3 = Sym.khomogeneous(Integer(3))
>>> h3[Integer(2),Integer(1)].coproduct()
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
↪h3[2] # h3[1] + h3[2, 1] # h3[]
>>> ks3t = SymmetricFunctions(FractionField(QQ['t'])).kschur(Integer(3))
>>> ks3t[Integer(2),Integer(1)].coproduct()

↪ks3[1] + ks3[2] # ks3[1] + ks3[2, 1] # ks3[]
>>> ks3t[Integer(3),Integer(1)].coproduct()
ks3[] # ks3[3, 1] + ks3[1] # ks3[2, 1] + (t+1)*ks3[1] # ks3[3] + ks3[1,
↪1] # ks3[2] + ks3[2] # ks3[1, 1]
+ (t+1)*ks3[2] # ks3[2] + ks3[2, 1] # ks3[1] + (t+1)*ks3[3] # ks3[1] +
↪ks3[3, 1] # ks3[]
>>> h3.coproduct(h3[Integer(2),Integer(1)])
h3[] # h3[2, 1] + h3[1] # h3[1, 1] + h3[1] # h3[2] + h3[1, 1] # h3[1] +
↪h3[2] # h3[1] + h3[2, 1] # h3[]
```

counit(*element*)

Return the counit of `element`.

The counit is the constant term of `element`.

INPUT:

- `element` – an element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks3 = Sym.kschur(3,1)
sage: f = 2*ks3[2,1] + 3*ks3[[]]
sage: f.counit()
3
sage: ks3.counit(f)
3
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks3 = Sym.kschur(Integer(3),Integer(1))
>>> f = Integer(2)*ks3[Integer(2),Integer(1)] + Integer(3)*ks3[[]]
>>> f.counit()
3
>>> ks3.counit(f)
3
```

degree_on_basis(*b*)

Return the degree of the basis element indexed by b.

INPUT:

- `b` – a partition

EXAMPLES:

```
sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.degree_on_basis(Partition([3,2]))
5
```

```
>>> from sage.all import *
>>> ks3 = SymmetricFunctions(QQ).kschur(Integer(3),Integer(1))
>>> ks3.degree_on_basis(Partition([Integer(3),Integer(2)]))
5
```

one_basis()

Return the basis element indexing 1.

EXAMPLES:

```
sage: ks3 = SymmetricFunctions(QQ).kschur(3,1)
sage: ks3.one()  # indirect doctest
ks3[]
```

```
>>> from sage.all import *
>>> ks3 = SymmetricFunctions(QQ).kschur(Integer(3),Integer(1))
>>> ks3.one()  # indirect doctest
ks3[]
```

transition_matrix(*other*, *n*)

Return the degree n transition matrix between self and other.

INPUT:

- other – a basis in the ring of symmetric functions
- n – positive integer

The entry in the i-th row and j-th column is the coefficient obtained by writing the i-th element of the basis of self in terms of the basis other, and extracting the j-th coefficient.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ); s = Sym.schur()
sage: ks3 = Sym.kschur(3,1)
sage: ks3.transition_matrix(s,5)
[1 1 1 0 0 0 0]
[0 1 0 1 0 0 0]
[0 0 1 0 1 0 0]
[0 0 0 1 0 1 0]
[0 0 0 0 1 1 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: s = Sym.schur()
sage: ks = Sym.kschur(3)
sage: ks.transition_matrix(s,5)
[t^2   t   1   0   0   0   0]
[  0   t   0   1   0   0   0]
[  0   0   t   0   1   0   0]
[  0   0   0   t   0   1   0]
[  0   0   0   0 t^2   t   1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ); s = Sym.schur()
>>> ks3 = Sym.kschur(Integer(3),Integer(1))
>>> ks3.transition_matrix(s,Integer(5))
[1 1 1 0 0 0 0]
```

(continues on next page)

(continued from previous page)

```
[0 1 0 1 0 0 0]
[0 0 1 0 1 0 0]
[0 0 0 1 0 1 0]
[0 0 0 0 1 1 1]

>>> Sym = SymmetricFunctions(QQ['t'])
>>> s = Sym.schur()
>>> ks = Sym.kschur(Integer(3))
>>> ks.transition_matrix(s,Integer(5))
[t^2   t   1   0   0   0   0]
[  0   t   0   1   0   0   0]
[  0   0   t   0   1   0   0]
[  0   0   0   t   0   1   0]
[  0   0   0   0 t^2   t   1]
```

super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
sage: KB = Sym.kBoundedSubspace(3)
sage: KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over␣
↪Univariate Polynomial Ring in t over Rational Field
sage: KBB.super_categories()
[Category of realizations of 3-bounded Symmetric Functions over Univariate␣
↪Polynomial Ring in t over Rational Field,
 Join of Category of graded coalgebras with basis over Univariate Polynomial␣
↪Ring in t over Rational Field
     and Category of subobjects of filtered modules with basis over␣
↪Univariate Polynomial Ring in t over Rational Field]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'])
>>> from sage.combinat.sf.new_kschur import KBoundedSubspaceBases
>>> KB = Sym.kBoundedSubspace(Integer(3))
>>> KBB = KBoundedSubspaceBases(KB); KBB
Category of k bounded subspace bases of 3-bounded Symmetric Functions over␣
↪Univariate Polynomial Ring in t over Rational Field
>>> KBB.super_categories()
[Category of realizations of 3-bounded Symmetric Functions over Univariate␣
↪Polynomial Ring in t over Rational Field,
 Join of Category of graded coalgebras with basis over Univariate Polynomial␣
↪Ring in t over Rational Field
     and Category of subobjects of filtered modules with basis over␣
↪Univariate Polynomial Ring in t over Rational Field]
```

class sage.combinat.sf.new_kschur.**K_kSchur**(*kBoundedRing*)

Bases: *CombinatorialFreeModule*

This class implements the basis of the k-bounded subspace called the K-k-Schur basis.

See [Morse2011], [LamSchillingShimozono2010].

REFERENCES:

K_k_Schur_non_commutative_variables(*la*)

Return the K-k-Schur function, as embedded inside the affine zero Hecke algebra.

INPUT:

- `la` – a k-bounded Partition

OUTPUT: an element of the affine zero Hecke algebra

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.K_k_Schur_non_commutative_variables([2,1])
T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +␣
→T[0,3,1] + T[2,3,2] + T[2,3,1] + T[3,1,2] + T[1,2,1] - T[2,0] - T[3,1]
sage: g.K_k_Schur_non_commutative_variables([])
1
sage: g.K_k_Schur_non_commutative_variables([4,1])
Traceback (most recent call last):
...
ValueError: Partition should be 3-bounded
```

```
>>> from sage.all import *
>>> g = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).K_
→kschur()
>>> g.K_k_Schur_non_commutative_variables([Integer(2),Integer(1)])
T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[0,3,0] + T[2,0,3] +␣
→T[0,3,1] + T[2,3,2] + T[2,3,1] + T[3,1,2] + T[1,2,1] - T[2,0] - T[3,1]
>>> g.K_k_Schur_non_commutative_variables([])
1
>>> g.K_k_Schur_non_commutative_variables([Integer(4),Integer(1)])
Traceback (most recent call last):
...
ValueError: Partition should be 3-bounded
```

homogeneous_basis_noncommutative_variables_zero_Hecke(*la*)

Return the homogeneous basis element indexed by `la`, viewed as an element inside the affine zero Hecke algebra. For the code, see method _homogeneous_basis.

INPUT:

- `la` – a k-bounded partition

OUTPUT: an element of the affine zero Hecke algebra

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.homogeneous_basis_noncommutative_variables_zero_Hecke([2,1])
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[1,0,3] +␣
→T[0,3,0] + T[2,0,3] + T[0,3,2] + T[0,3,1] + T[2,3,2] + T[3,2,1] + T[2,3,1]␣
→+ T[3,1,2] + T[1,2,1] - T[1,0] - 2*T[2,0] - T[0,3] - T[3,2] - 2*T[3,1] -␣
→T[2,1]
```

↪Integer(1)])
T[2,1,0] + T[3,1,0] + T[1,2,0] + T[3,2,0] + T[0,1,0] + T[2,0,1] + T[1,0,3] +␣
↪T[0,3,0] + T[2,0,3] + T[0,3,2] + T[0,3,1] + T[2,3,2] + T[3,2,1] + T[2,3,1]␣
↪+ T[3,1,2] + T[1,2,1] - T[1,0] - 2*T[2,0] - T[0,3] - T[3,2] - 2*T[3,1] -␣
↪T[2,1]
>>> g.homogeneous_basis_noncommutative_variables_zero_Hecke([])
1
```

lift (x)

Return the lift of a k-bounded symmetric function.

INPUT:

- **x – an expression in the K-k-Schur basis. Equivalently, x can be a** k-bounded partition (then x corresponds to the basis element indexed by x)

OUTPUT: a symmetric function

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.lift([2,1])
h[2] + h[2, 1] - h[3]
sage: g.lift([])
h[]
sage: g.lift([4,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↪bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur␣
↪basis)
```

```
>>> from sage.all import *
>>> g = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).K_
↪kschur()
>>> g.lift([Integer(2),Integer(1)])
h[2] + h[2, 1] - h[3]
>>> g.lift([])
h[]
>>> g.lift([Integer(4),Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 1]) an element of self (=3-
↪bounded Symmetric Functions over Rational Field with t=1 in the K-3-Schur␣
↪basis)
```

product (x, y)

Return the product of the two K-k-Schur functions.

INPUT:

- x, y – elements of the k-bounded subspace, in the K-k-Schur basis

OUTPUT: an element of the k-bounded subspace, in the K-k-Schur basis

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: g.product(g([2,1]), g[1])
-2*Kks3[2, 1] + Kks3[2, 1, 1] + Kks3[2, 2]
sage: g.product(g([2,1]), g([]))
Kks3[2, 1]
```

```
>>> from sage.all import *
>>> g = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).K_
↪kschur()
>>> g.product(g([Integer(2),Integer(1)]), g[Integer(1)])
-2*Kks3[2, 1] + Kks3[2, 1, 1] + Kks3[2, 2]
>>> g.product(g([Integer(2),Integer(1)]), g([]))
Kks3[2, 1]
```

retract(*x*)

Return the retract of a symmetric function.

INPUT:

- x – a symmetric function

OUTPUT: a k-bounded symmetric function in the K-k-Schur basis

EXAMPLES:

```
sage: g = SymmetricFunctions(QQ).kBoundedSubspace(3,1).K_kschur()
sage: m = SymmetricFunctions(QQ).m()
sage: g.retract(m[2,1])
-2*Kks3[1] + 4*Kks3[1, 1] - 2*Kks3[1, 1, 1] - Kks3[2] + Kks3[2, 1]
sage: g.retract(m([]))
Kks3[]
```

```
>>> from sage.all import *
>>> g = SymmetricFunctions(QQ).kBoundedSubspace(Integer(3),Integer(1)).K_
↪kschur()
>>> m = SymmetricFunctions(QQ).m()
>>> g.retract(m[Integer(2),Integer(1)])
-2*Kks3[1] + 4*Kks3[1, 1] - 2*Kks3[1, 1, 1] - Kks3[2] + Kks3[2, 1]
>>> g.retract(m([]))
Kks3[]
```

class sage.combinat.sf.new_kschur.**kHomogeneous**(*kBoundedRing*)

Bases: *CombinatorialFreeModule*

Space of k-bounded homogeneous symmetric functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: kH = Sym.khomogeneous(3)
sage: kH[2]
h3[2]
sage: kH[2].lift()
h[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> kH = Sym.khomogeneous(Integer(3))
>>> kH[Integer(2)]
h3[2]
>>> kH[Integer(2)].lift()
h[2]
```

class sage.combinat.sf.new_kschur.**kSchur**(*kBoundedRing*)

Bases: *CombinatorialFreeModule*

Space of k-Schur functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: KB = Sym.kBoundedSubspace(3); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'])
>>> KB = Sym.kBoundedSubspace(Integer(3)); KB
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field
```

The k-Schur function basis can be constructed as follows:

```
sage: ks3 = KB.kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field in the 3-Schur basis
```

```
>>> from sage.all import *
>>> ks3 = KB.kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational
↪Field in the 3-Schur basis
```

We can convert to any basis of the ring of symmetric functions and, whenever it makes sense, also the other way round:

```
sage: s = Sym.schur()
sage: s(ks3([3,2,1]))
s[3, 2, 1] + t*s[4, 1, 1] + t*s[4, 2] + t^2*s[5, 1]
sage: t = Sym.base_ring().gen()
sage: ks3(s([3, 2, 1]) + t*s([4, 1, 1]) + t*s([4, 2]) + t^2*s([5, 1]))
ks3[3, 2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: s(ks3[2, 1, 1])
s[2, 1, 1] + t*s[3, 1]
sage: ks3(s[2, 1, 1] + t*s[3, 1])
ks3[2, 1, 1]
```

```
>>> from sage.all import *
>>> s = Sym.schur()
>>> s(ks3([Integer(3),Integer(2),Integer(1)]))
s[3, 2, 1] + t*s[4, 1, 1] + t*s[4, 2] + t^2*s[5, 1]
>>> t = Sym.base_ring().gen()
>>> ks3(s([Integer(3), Integer(2), Integer(1)]) + t*s([Integer(4), Integer(1),␣
↪Integer(1)]) + t*s([Integer(4), Integer(2)]) + t**Integer(2)*s([Integer(5),␣
↪Integer(1)]))
ks3[3, 2, 1]
>>> s(ks3[Integer(2), Integer(1), Integer(1)])
s[2, 1, 1] + t*s[3, 1]
>>> ks3(s[Integer(2), Integer(1), Integer(1)] + t*s[Integer(3), Integer(1)])
ks3[2, 1, 1]
```

k-Schur functions are indexed by partitions with first part $\leq k$. Constructing a k-Schur function for a larger partition raises an error:

```
sage: ks3([4,3,2,1]) #
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 3, 2, 1]) an element of self (=3-
↪bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field in the 3-Schur basis)
```

```
>>> from sage.all import *
>>> ks3([Integer(4),Integer(3),Integer(2),Integer(1)]) #
Traceback (most recent call last):
...
TypeError: do not know how to make x (= [4, 3, 2, 1]) an element of self (=3-
↪bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field in the 3-Schur basis)
```

Similarly, attempting to convert a function that is not in the linear span of the k-Schur functions raises an error:

```
sage: ks3(s([4]))
Traceback (most recent call last):
...
ValueError: s[4] is not in the image
```

```
>>> from sage.all import *
>>> ks3(s([Integer(4)]))
Traceback (most recent call last):
...
ValueError: s[4] is not in the image
```

Note that the product of k-Schur functions is not guaranteed to be in the space spanned by the k-Schurs. In general, we only have that a k-Schur times a j-Schur function is in the $(k+j)$-bounded subspace. The multiplication of two

k-Schur functions thus generally returns the product of the lift of the functions to the ambient symmetric function space. If the result happens to lie in the k-bounded subspace, then the result is cast into the k-Schur basis:

```
sage: ks2 = Sym.kBoundedSubspace(2).kschur()
sage: ks2[1] * ks2[1]
ks2[1, 1] + ks2[2]
sage: ks2[1] * ks2[2]
s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> ks2 = Sym.kBoundedSubspace(Integer(2)).kschur()
>>> ks2[Integer(1)] * ks2[Integer(1)]
ks2[1, 1] + ks2[2]
>>> ks2[Integer(1)] * ks2[Integer(2)]
s[2, 1] + s[3]
```

Because the target space of the product of a k-Schur and a j-Schur has several possibilities, the product of a k-Schur and j-Schur function is not implemented for distinct k and j. Let us show how to get around this 'manually':

```
sage: ks3 = Sym.kBoundedSubspace(3).kschur()
sage: ks2([2,1]) * ks3([3,1])
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: '2-bounded Symmetric Functions␣
↪over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis'␣
↪and '3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field in the 3-Schur basis'
```

```
>>> from sage.all import *
>>> ks3 = Sym.kBoundedSubspace(Integer(3)).kschur()
>>> ks2([Integer(2),Integer(1)]) * ks3([Integer(3),Integer(1)])
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for *: '2-bounded Symmetric Functions␣
↪over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis'␣
↪and '3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field in the 3-Schur basis'
```

The workaround:

```
sage: f = s(ks2([2,1])) * s(ks3([3,1])); f # Convert to Schur functions first and␣
↪multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1]
+ (2*t+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3] + (2*t+1)*s[5, 1, 1]
+ (t^2+2*t+1)*s[5, 2] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

```
>>> from sage.all import *
>>> f = s(ks2([Integer(2),Integer(1)])) * s(ks3([Integer(3),Integer(1)])); f #␣
↪Convert to Schur functions first and multiply there.
s[3, 2, 1, 1] + s[3, 2, 2] + (t+1)*s[3, 3, 1] + s[4, 1, 1, 1]
+ (2*t+2)*s[4, 2, 1] + (t^2+t+1)*s[4, 3] + (2*t+1)*s[5, 1, 1]
+ (t^2+2*t+1)*s[5, 2] + (t^2+2*t)*s[6, 1] + t^2*s[7]
```

or:

```
sage: f = ks2[2,1].lift() * ks3[3,1].lift()
sage: ks5 = Sym.kBoundedSubspace(5).kschur()
sage: ks5(f) # The product of a 'ks2' with a 'ks3' is a 'ks5'.
ks5[3, 2, 1, 1] + ks5[3, 2, 2] + (t+1)*ks5[3, 3, 1] + ks5[4, 1, 1, 1]
+ (t+2)*ks5[4, 2, 1] + (t^2+t+1)*ks5[4, 3] + (t+1)*ks5[5, 1, 1] + ks5[5, 2]
```

```
>>> from sage.all import *
>>> f = ks2[Integer(2),Integer(1)].lift() * ks3[Integer(3),Integer(1)].lift()
>>> ks5 = Sym.kBoundedSubspace(Integer(5)).kschur()
>>> ks5(f) # The product of a 'ks2' with a 'ks3' is a 'ks5'.
ks5[3, 2, 1, 1] + ks5[3, 2, 2] + (t+1)*ks5[3, 3, 1] + ks5[4, 1, 1, 1]
+ (t+2)*ks5[4, 2, 1] + (t^2+t+1)*ks5[4, 3] + (t+1)*ks5[5, 1, 1] + ks5[5, 2]
```

For other technical reasons, taking powers of k-Schur functions is not implemented, even when the answer is still in the k-bounded subspace:

```
sage: ks2([1])^2
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for ^: '2-bounded Symmetric Functions␣
↪over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis'␣
↪and 'Integer Ring'
```

```
>>> from sage.all import *
>>> ks2([Integer(1)])**Integer(2)
Traceback (most recent call last):
...
TypeError: unsupported operand parent(s) for ^: '2-bounded Symmetric Functions␣
↪over Univariate Polynomial Ring in t over Rational Field in the 2-Schur basis'␣
↪and 'Integer Ring'
```

Todo

Get rid of said technical "reasons".

However, at $t = 1$, the product of k-Schur functions is in the span of the k-Schur functions always. Below are some examples at $t = 1$

```
sage: ks3 = Sym.kBoundedSubspace(3, t=1).kschur(); ks3
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field with t=1 in the 3-Schur basis
sage: s = SymmetricFunctions(ks3.base_ring()).schur()
sage: ks3(s([3]))
ks3[3]
sage: s(ks3([3,2,1]))
s[3, 2, 1] + s[4, 1, 1] + s[4, 2] + s[5, 1]
sage: ks3([2,1])^2    # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

```
>>> from sage.all import *
>>> ks3 = Sym.kBoundedSubspace(Integer(3), t=Integer(1)).kschur(); ks3
```

(continues on next page)

(continued from previous page)

```
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over Rational␣
↪Field with t=1 in the 3-Schur basis
>>> s = SymmetricFunctions(ks3.base_ring()).schur()
>>> ks3(s([Integer(3)]))
ks3[3]
>>> s(ks3([Integer(3),Integer(2),Integer(1)]))
s[3, 2, 1] + s[4, 1, 1] + s[4, 2] + s[5, 1]
>>> ks3([Integer(2),Integer(1)])**Integer(2)     # taking powers works for t=1
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

product_on_basis(*left*, *right*)

Take the product of two k-Schur functions.

If $t \neq 1$, then take the product by lifting to the Schur functions and then retracting back into the k-bounded subspace (if possible).

If $t = 1$, then the product calls `_product_on_basis_via_rectangles()`.

INPUT:

- `left`, `right` – partitions

OUTPUT: an element of the k-Schur functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks3 = Sym.kschur(3,1)
sage: kH = Sym.khomogeneous(3)
sage: ks3(kH[2,1,1])
ks3[2, 1, 1] + ks3[2, 2] + ks3[3, 1]
sage: ks3([])*kH[2,1,1]

↪1] + s[4, 2]
```

class sage.combinat.sf.new_kschur.**kSplit**(*kBoundedRing*)

Bases: *CombinatorialFreeModule*

The k-split basis of the space of k-bounded-symmetric functions.

Fix `k` a positive integer and `t` an element of the base ring.

The k-split functions are a basis for the space of k-bounded symmetric functions that also have the bases

$$\{Q'_\lambda[X;t]\}_{\lambda_1\le k} = \{s_\lambda^{(k)}[X;t]\}_{\lambda_1\le k}$$

where $Q'_\lambda[X;t]$ are the Hall-Littlewood symmetric functions (using the notation of [MAC]) and $s_\lambda^{(k)}[X;t]$ are the k-Schur functions. If t is not a root of unity, then

$$\{s_\lambda[X/(1-t)]\}_{\lambda_1\le k}$$

is also a basis of this space.

The k-split basis has the property that $Q'_\lambda[X;t]$ expands positively in the k-split basis and the k-split basis conjecturally expands positively in the k-Schur functions. See [LLMSSZ] p. 81.

The k-split basis is defined recursively using the Hall-Littlewood creation operator defined in [SZ2001]. If a partition `la` is the concatenation (as lists) of a partition `mu` and `nu` where `mu` has maximal hook length equal to `k` then `ksp(la) = ksp(nu).hl_creation_operator(mu)`. If the hook length of `la` is less than or equal to `k`, then `ksp(la)` is equal to the Schur function indexed by `la`.

EXAMPLES:

```
sage: Symt = SymmetricFunctions(QQ['t'].fraction_field())
sage: kBS3 = Symt.kBoundedSubspace(3)
sage: ks3 = kBS3.kschur()
sage: ksp3 = kBS3.ksplit()
sage: ks3(ksp3[2,1,1])
ks3[2, 1, 1] + t*ks3[2, 2]
sage: ksp3(ks3[2,1,1])
ksp3[2, 1, 1] - t*ksp3[2, 2]
```

(continues on next page)

(continued from previous page)

```
sage: ksp3[2,1]*ksp3[1]
s[2, 1, 1] + s[2, 2] + s[3, 1]
sage: ksp3[2,1].hl_creation_operator([1])
t*ksp3[2, 1, 1] + (-t^2+t)*ksp3[2, 2]

sage: Qp = Symt.hall_littlewood().Qp()
sage: ksp3(Qp[3,2,1])
ksp3[3, 2, 1] + t*ksp3[3, 3]

sage: kBS4 = Symt.kBoundedSubspace(4)
sage: ksp4 = kBS4.ksplit()
sage: ksp4(ksp3([3,2,1]))
ksp4[3, 2, 1] - t*ksp4[3, 3] + t*ksp4[4, 1, 1]
sage: ks4 = kBS4.kschur()
sage: ks4(ksp4[3,2,2,1])
ks4[3, 2, 2, 1] + t*ks4[3, 3, 1, 1] + t*ks4[3, 3, 2]
```

```
>>> from sage.all import *
>>> Symt = SymmetricFunctions(QQ['t'].fraction_field())
>>> kBS3 = Symt.kBoundedSubspace(Integer(3))
>>> ks3 = kBS3.kschur()
>>> ksp3 = kBS3.ksplit()
>>> ks3(ksp3[Integer(2),Integer(1),Integer(1)])
ks3[2, 1, 1] + t*ks3[2, 2]
>>> ksp3(ks3[Integer(2),Integer(1),Integer(1)])
ksp3[2, 1, 1] - t*ksp3[2, 2]
>>> ksp3[Integer(2),Integer(1)]*ksp3[Integer(1)]
s[2, 1, 1] + s[2, 2] + s[3, 1]
>>> ksp3[Integer(2),Integer(1)].hl_creation_operator([Integer(1)])

>>> ksp3(Qp[Integer(3),Integer(2),Integer(1)])
ksp3[3, 2, 1] + t*ksp3[3, 3]

>>> kBS4 = Symt.kBoundedSubspace(Integer(4))
>>> ksp4 = kBS4.ksplit()
>>> ksp4(ksp3([Integer(3),Integer(2),Integer(1)]))
ksp4[3, 2, 1] - t*ksp4[3, 3] + t*ksp4[4, 1, 1]
>>> ks4 = kBS4.kschur()
>>> ks4(ksp4[Integer(3),Integer(2),Integer(2),Integer(1)])
ks4[3, 2, 2, 1] + t*ks4[3, 3, 1, 1] + t*ks4[3, 3, 2]
```

5.1.296 Non-symmetric Macdonald Polynomials

class sage.combinat.sf.ns_macdonald.**AugmentedLatticeDiagramFilling**(*l*, *pi=None*)

Bases: *CombinatorialObject*

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a == loads(dumps(a))
```

(continues on next page)

(continued from previous page)

```
True
sage: pi = Permutation([2,3,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]],pi)
sage: a == loads(dumps(a))
True
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a == loads(dumps(a))
True
>>> pi = Permutation([Integer(2),Integer(3),Integer(1)]).to_permutation_group_
↪element()
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]],pi)
>>> a == loads(dumps(a))
True
```

are_attacking(*i*, *j*, *ii*, *jj*)

Return `True` if the boxes `(i,j)` and `(ii,jj)` in `self` are attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_
↪boxes())
True
sage: a.are_attacking(1,1,3,2)
False
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> all( a.are_attacking(i,j,ii,jj) for (i,j),(ii,jj) in a.attacking_boxes())
True
>>> a.are_attacking(Integer(1),Integer(1),Integer(3),Integer(2))
False
```

attacking_boxes()

Return a list of pairs of boxes in `self` that are attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.attacking_boxes()[:5]
[((1, 1), (2, 1)),
 ((1, 1), (3, 1)),
 ((1, 1), (6, 1)),
 ((1, 1), (2, 0)),
 ((1, 1), (3, 0))]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.attacking_boxes()[:Integer(5)]
[((1, 1), (2, 1)),
 ((1, 1), (3, 1)),
 ((1, 1), (6, 1)),
 ((1, 1), (2, 0)),
 ((1, 1), (3, 0))]
```

boxes()

Return a list of the coordinates of the boxes of `self`, including the 'basement row'.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.boxes()
[(1, 1),
 (1, 2),
 (2, 1),
 (3, 1),
 (3, 2),
 (3, 3),
 (6, 1),
 (6, 2),
 (1, 0),
 (2, 0),
 (3, 0),
 (4, 0),
 (5, 0),
 (6, 0)]
```

coeff(q, t)

Return the coefficient in front of `self` in the HHL formula for the expansion of the non-symmetric Macdonald polynomial E(self.shape()).

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')                                                  #␣
↪needs sage.symbolic
sage: a.coeff(q,t)                                                      #␣
↪needs sage.symbolic
(t - 1)^4/((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> q,t = var('q,t')                                                    #␣
↪needs sage.symbolic
>>> a.coeff(q,t)                                                        #␣
↪needs sage.symbolic
(t - 1)^4/((q^2*t^3 - 1)^2*(q*t^2 - 1)^2)
```

coeff_integral(*q*, *t*)

Return the coefficient in front of `self` in the HHL formula for the expansion of the integral non-symmetric Macdonald polynomial E(self.shape())

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: q,t = var('q,t')                                                  #␣
↪needs sage.symbolic
sage: a.coeff_integral(q,t)                                             #␣
↪needs sage.symbolic
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> q,t = var('q,t')                                                    #␣
↪needs sage.symbolic
>>> a.coeff_integral(q,t)                                               #␣
↪needs sage.symbolic
(q^2*t^3 - 1)^2*(q*t^2 - 1)^2*(t - 1)^4
```

coinv()

Return `self`'s co-inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.coinv()
2
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.coinv()
2
```

descents()

Return a list of the descents of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.descents()
[(1, 2), (3, 2)]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.descents()
[(1, 2), (3, 2)]
```

inv()

Return `self`'s inversion statistic.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inv()
15
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.inv()
15
```

inversions()

Return a list of the inversions of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.inversions()[:5]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
 ((1, 2), (2, 1)),
 ((6, 1), (3, 1))]
sage: len(a.inversions())
25
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.inversions()[:Integer(5)]
[((6, 2), (3, 2)),
 ((1, 2), (6, 1)),
 ((1, 2), (3, 1)),
 ((1, 2), (2, 1)),
 ((6, 1), (3, 1))]
```

(continues on next page)

(continued from previous page)

```
>>> len(a.inversions())
25
```

is_non_attacking()

Return `True` if `self` is non-attacking.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.is_non_attacking()
True
sage: a = AugmentedLatticeDiagramFilling([[1, 1, 1], [2, 3], [3]])
sage: a.is_non_attacking()
False
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]])
sage: a.is_non_attacking()
False
sage: pi = Permutation([2,1]).to_permutation_group_element()
sage: a = AugmentedLatticeDiagramFilling([[2,2],[1]],pi)
sage: a.is_non_attacking()
True
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.is_non_attacking()
True
>>> a = AugmentedLatticeDiagramFilling([[Integer(1), Integer(1), Integer(1)],␣
↪[Integer(2), Integer(3)], [Integer(3)]])
>>> a.is_non_attacking()
False
>>> a = AugmentedLatticeDiagramFilling([[Integer(2),Integer(2)],[Integer(1)]])
>>> a.is_non_attacking()
False
>>> pi = Permutation([Integer(2),Integer(1)]).to_permutation_group_element()
>>> a = AugmentedLatticeDiagramFilling([[Integer(2),Integer(2)],[Integer(1)]],
↪pi)
>>> a.is_non_attacking()
True
```

maj()

Return the major index of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.maj()
3
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
```

(continues on next page)

(continued from previous page)

```
>>> a.maj()
3
```

permuted_filling(*sigma*)

EXAMPLES:

```
sage: pi=Permutation([2,1,4,3]).to_permutation_group_element()
sage: fill=[[2],[1,2,3],[],[3,1]]
sage: AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]
```

```
>>> from sage.all import *
>>> pi=Permutation([Integer(2),Integer(1),Integer(4),Integer(3)]).to_
↪permutation_group_element()
>>> fill=[[Integer(2)],[Integer(1),Integer(2),Integer(3)],[],[Integer(3),
↪Integer(1)]]
>>> AugmentedLatticeDiagramFilling(fill).permuted_filling(pi)
[[2, 1], [1, 2, 1, 4], [4], [3, 4, 2]]
```

reading_order()

Return a list of coordinates of the boxes in `self`, starting from the top right, and reading from right to left.

Note that this includes the 'basement row' of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
 (3, 1),
 (2, 1),
 (1, 1),
 (6, 0),
 (5, 0),
 (4, 0),
 (3, 0),
 (2, 0),
 (1, 0)]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.reading_order()
[(3, 3),
 (6, 2),
 (3, 2),
 (1, 2),
 (6, 1),
```

(continues on next page)

(continued from previous page)

```
 (3, 1),
 (2, 1),
 (1, 1),
 (6, 0),
 (5, 0),
 (4, 0),
 (3, 0),
 (2, 0),
 (1, 0)]
```

reading_word()

Return the reading word of `self`, obtained by reading the boxes entries of `self` from right to left, starting in the upper right.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.reading_word()
word: 25465321
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.reading_word()
word: 25465321
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.shape()
[2, 1, 3, 0, 0, 2]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.shape()
[2, 1, 3, 0, 0, 2]
```

weight()

Return the weight of `self`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a.weight()
[1, 2, 1, 1, 2, 1]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a.weight()
[1, 2, 1, 1, 2, 1]
```

sage.combinat.sf.ns_macdonald.**E**(*mu*, *q=None*, *t=None*, *pi=None*)

Return the non-symmetric Macdonald polynomial in type A corresponding to a shape `mu`, with basement permuted according to `pi`.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials*. arXiv math/0601693v3.

See also

NonSymmetricMacdonaldPolynomials for a type free implementation where the polynomials are constructed recursively by the application of intertwining operators.

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import E
sage: E([0,0,0])
1
sage: E([1,0,0])
x0
sage: E([0,1,0])
(t - 1)/(q*t^2 - 1)*x0 + x1
sage: E([0,0,1])
(t - 1)/(q*t - 1)*x0 + (t - 1)/(q*t - 1)*x1 + x2
sage: E([1,1,0])
x0*x1
sage: E([1,0,1])
(t - 1)/(q*t^2 - 1)*x0*x1 + x0*x2
sage: E([0,1,1])
(t - 1)/(q*t - 1)*x0*x1 + (t - 1)/(q*t - 1)*x0*x2 + x1*x2
sage: E([2,0,0])
x0^2 + (q*t - q)/(q*t - 1)*x0*x1 + (q*t - q)/(q*t - 1)*x0*x2
sage: E([0,2,0])
(t - 1)/(q^2*t^2 - 1)*x0^2 + (q^2*t^3 - q^2*t^2 + q*t^2 - 2*q*t + q - t + 1)/(q^
↪3*t^3 - q^2*t^2 - q*t + 1)*x0*x1 + x1^2 + (q*t^2 - 2*q*t + q)/(q^3*t^3 - q^2*t^
↪2 - q*t + 1)*x0*x2 + (q*t - q)/(q*t - 1)*x1*x2
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import E
>>> E([Integer(0),Integer(0),Integer(0)])
1

```

`sage.combinat.sf.ns_macdonald.`**`Ht`**`(`*mu*, *q=None*, *t=None*, *pi=None*`)`

Return the symmetric Macdonald polynomial using the Haiman, Haglund, and Loehr formula.

Note that if both q and t are specified, then they must have the same parent.

REFERENCE:

- J. Haglund, M. Haiman, N. Loehr. *A combinatorial formula for non-symmetric Macdonald polynomials*. arXiv math/0601693v3.

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import Ht
sage: HHt = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().Ht()
sage: Ht([0,0,1])
x0 + x1 + x2
sage: HHt([1]).expand(3)
x0 + x1 + x2
sage: Ht([0,0,2])
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
sage: HHt([2]).expand(3)
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import Ht
>>> HHt = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().Ht()
>>> Ht([Integer(0),Integer(0),Integer(1)])
x0 + x1 + x2
>>> HHt([Integer(1)]).expand(Integer(3))
x0 + x1 + x2
>>> Ht([Integer(0),Integer(0),Integer(2)])
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
```

(continues on next page)

(continued from previous page)

```
>>> HHt([Integer(2)]).expand(Integer(3))
x0^2 + (q + 1)*x0*x1 + x1^2 + (q + 1)*x0*x2 + (q + 1)*x1*x2 + x2^2
```

class sage.combinat.sf.ns_macdonald.**LatticeDiagram**(*l*, *copy=True*)

Bases: `CombinatorialObject`

a(*i*, *j*)

Return the length of the arm of the box `(i,j)` in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.a(5,2)
3
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.a(Integer(5),Integer(2))
3
```

arm(*i*, *j*)

Return the arm of the box `(i,j)` in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm(5,2)
[(1, 2), (3, 2), (8, 1)]
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.arm(Integer(5),Integer(2))
[(1, 2), (3, 2), (8, 1)]
```

arm_left(*i*, *j*)

Return the left arm of the box `(i,j)` in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_left(5,2)
[(1, 2), (3, 2)]
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.arm_left(Integer(5),Integer(2))
[(1, 2), (3, 2)]
```

arm_right(*i*, *j*)

Return the right arm of the box `(i,j)` in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.arm_right(5,2)
[(8, 1)]
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.arm_right(Integer(5),Integer(2))
[(8, 1)]
```

boxes()

EXAMPLES:

```
sage: a = LatticeDiagram([3,0,2])
sage: a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
sage: a = LatticeDiagram([2, 1, 3, 0, 0, 2])
sage: a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(0),Integer(2)])
>>> a.boxes()
[(1, 1), (1, 2), (1, 3), (3, 1), (3, 2)]
>>> a = LatticeDiagram([Integer(2), Integer(1), Integer(3), Integer(0),␣
↪Integer(0), Integer(2)])
>>> a.boxes()
[(1, 1), (1, 2), (2, 1), (3, 1), (3, 2), (3, 3), (6, 1), (6, 2)]
```

boxes_same_and_lower_right(*ii*, *jj*)

Return an iterator of the boxes of `self` that are in row `jj` but not identical with `(ii, jj)`, or lie in the row `jj - 1` (the row directly below `jj`; this might be the basement) and strictly to the right of `(ii, jj)`.

EXAMPLES:

```
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: a = a.shape()
sage: list(a.boxes_same_and_lower_right(1,1))
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]
sage: list(a.boxes_same_and_lower_right(1,2))
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]
sage: list(a.boxes_same_and_lower_right(3,3))
[(6, 2)]
sage: list(a.boxes_same_and_lower_right(2,3))
[(3, 3), (3, 2), (6, 2)]
```

```
>>> from sage.all import *
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> a = a.shape()
>>> list(a.boxes_same_and_lower_right(Integer(1),Integer(1)))
```

(continues on next page)

(continued from previous page)

```
[(2, 1), (3, 1), (6, 1), (2, 0), (3, 0), (4, 0), (5, 0), (6, 0)]
>>> list(a.boxes_same_and_lower_right(Integer(1),Integer(2)))
[(3, 2), (6, 2), (2, 1), (3, 1), (6, 1)]
>>> list(a.boxes_same_and_lower_right(Integer(3),Integer(3)))
[(6, 2)]
>>> list(a.boxes_same_and_lower_right(Integer(2),Integer(3)))
[(3, 3), (3, 2), (6, 2)]
```

flip()

Return the flip of `self`, where flip is defined as follows. Let `r = max(self)`. Then `self.flip()[i] = r - self[i]`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,0,2])
sage: a.flip()
[0, 3, 1]
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(0),Integer(2)])
>>> a.flip()
[0, 3, 1]
```

l(*i*, *j*)

Return `self[i] - j`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.l(5,2)
1
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.l(Integer(5),Integer(2))
1
```

leg(*i*, *j*)

Return the leg of the box `(i,j)` in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.leg(5,2)
[(5, 3)]
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.leg(Integer(5),Integer(2))
[(5, 3)]
```

size()

Return the number of boxes in `self`.

EXAMPLES:

```
sage: a = LatticeDiagram([3,1,2,4,3,0,4,2,3])
sage: a.size()
22
```

```
>>> from sage.all import *
>>> a = LatticeDiagram([Integer(3),Integer(1),Integer(2),Integer(4),
↪Integer(3),Integer(0),Integer(4),Integer(2),Integer(3)])
>>> a.size()
22
```

class sage.combinat.sf.ns_macdonald.**NonattackingBacktracker**(*shape*, *pi=None*)

Bases: *GenericBacktracker*

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: n = NonattackingBacktracker(LatticeDiagram([0,1,2]))
sage: n._ending_position
(3, 2)
sage: n._initial_state
(2, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
>>> n = NonattackingBacktracker(LatticeDiagram([Integer(0),Integer(1),
↪Integer(2)]))
>>> n._ending_position
(3, 2)
>>> n._initial_state
(2, 1)
```

get_next_pos(*ii*, *jj*)

EXAMPLES:

```
sage: from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
sage: a = AugmentedLatticeDiagramFilling([[1,6],[2],[3,4,2],[],[],[5,5]])
sage: n = NonattackingBacktracker(a.shape())
sage: n.get_next_pos(1, 1)
(2, 1)
sage: n.get_next_pos(6, 1)
(1, 2)
sage: n = NonattackingBacktracker(LatticeDiagram([2,2,2]))
sage: n.get_next_pos(3, 1)
(1, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.ns_macdonald import NonattackingBacktracker
>>> a = AugmentedLatticeDiagramFilling([[Integer(1),Integer(6)],[Integer(2)],
```

(continues on next page)

(continued from previous page)

```
↪[Integer(3),Integer(4),Integer(2)],[],[],[Integer(5),Integer(5)]])
>>> n = NonattackingBacktracker(a.shape())
>>> n.get_next_pos(Integer(1), Integer(1))
(2, 1)
>>> n.get_next_pos(Integer(6), Integer(1))
(1, 2)
>>> n = NonattackingBacktracker(LatticeDiagram([Integer(2),Integer(2),
↪Integer(2)]))
>>> n.get_next_pos(Integer(3), Integer(1))
(1, 2)
```

sage.combinat.sf.ns_macdonald.**NonattackingFillings**(*shape*, *pi=None*)

Returning the finite set of nonattacking fillings of a given shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2])
Nonattacking fillings of [0, 1, 2]
sage: NonattackingFillings([0,1,2]).list()
[[[1], [2, 1], [3, 2, 1]],
 [[1], [2, 1], [3, 2, 2]],
 [[1], [2, 1], [3, 2, 3]],
 [[1], [2, 1], [3, 3, 1]],
 [[1], [2, 1], [3, 3, 2]],
 [[1], [2, 1], [3, 3, 3]],
 [[1], [2, 2], [3, 1, 1]],
 [[1], [2, 2], [3, 1, 2]],
 [[1], [2, 2], [3, 1, 3]],
 [[1], [2, 2], [3, 3, 1]],
 [[1], [2, 2], [3, 3, 2]],
 [[1], [2, 2], [3, 3, 3]]]
```

```
>>> from sage.all import *
>>> NonattackingFillings([Integer(0),Integer(1),Integer(2)])
Nonattacking fillings of [0, 1, 2]
>>> NonattackingFillings([Integer(0),Integer(1),Integer(2)]).list()
[[[1], [2, 1], [3, 2, 1]],
 [[1], [2, 1], [3, 2, 2]],
 [[1], [2, 1], [3, 2, 3]],
 [[1], [2, 1], [3, 3, 1]],
 [[1], [2, 1], [3, 3, 2]],
 [[1], [2, 1], [3, 3, 3]],
 [[1], [2, 2], [3, 1, 1]],
 [[1], [2, 2], [3, 1, 2]],
 [[1], [2, 2], [3, 1, 3]],
 [[1], [2, 2], [3, 3, 1]],
 [[1], [2, 2], [3, 3, 2]],
 [[1], [2, 2], [3, 3, 3]]]
```

class sage.combinat.sf.ns_macdonald.**NonattackingFillings_shape**(*shape*, *pi=None*)

Bases: Parent, UniqueRepresentation

EXAMPLES:

```
sage: n = NonattackingFillings([0,1,2])
sage: n == loads(dumps(n))
True
```

```
>>> from sage.all import *
>>> n = NonattackingFillings([Integer(0),Integer(1),Integer(2)])
>>> n == loads(dumps(n))
True
```

flip()

Return the nonattacking fillings of the flipped shape.

EXAMPLES:

```
sage: NonattackingFillings([0,1,2]).flip()
Nonattacking fillings of [2, 1, 0]
```

```
>>> from sage.all import *
>>> NonattackingFillings([Integer(0),Integer(1),Integer(2)]).flip()
Nonattacking fillings of [2, 1, 0]
```

5.1.297 Orthogonal Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class sage.combinat.sf.orthogonal.**SymmetricFunctionAlgebra_orthogonal**(*Sym*)

Bases: *SymmetricFunctionAlgebra_generic*

The orthogonal symmetric function basis (or orthogonal basis, to be short).

The orthogonal basis $\{o_\lambda\}$ where λ is taken over all partitions is defined by the following change of basis with the Schur functions:

$$s_\lambda = \sum_\mu \left(\sum_{\nu \in H} c^\lambda_{\mu\nu} \right) o_\mu$$

where H is the set of all partitions with even-width rows and $c^\lambda_{\mu\nu}$ is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note

This is only a filtered basis, not a $\mathbf{Z}$-graded basis. However this does respect the induced $(\mathbf{Z}/2\mathbf{Z})$-grading.

INPUT:

- `Sym` – an instance of the ring of the symmetric functions

REFERENCES:

- [ChariKleber2000]
- [KoikeTerada1987]
- [ShimozonoZabrocki2006]

EXAMPLES:

Here are the first few orthogonal symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: o = Sym.o()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(o([1]))
p[1]
sage: m(o([1]))
m[1]
sage: e(o([1]))
e[1]
sage: h(o([1]))
h[1]
sage: s(o([1]))
s[1]

sage: p(o([2]))
-p[] + 1/2*p[1, 1] + 1/2*p[2]
sage: m(o([2]))
-m[] + m[1, 1] + m[2]
sage: e(o([2]))
-e[] + e[1, 1] - e[2]
sage: h(o([2]))
-h[] + h[2]
sage: s(o([2]))
-s[] + s[2]

sage: p(o([3]))
-p[1] + 1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
sage: m(o([3]))
-m[1] + m[1, 1, 1] + m[2, 1] + m[3]
sage: e(o([3]))
-e[1] + e[1, 1, 1] - 2*e[2, 1] + e[3]
sage: h(o([3]))
-h[1] + h[3]
sage: s(o([3]))
-s[1] + s[3]

sage: Sym = SymmetricFunctions(ZZ)

>>> e(o([Integer(4)]))
-e[1, 1] + e[1, 1, 1, 1] + e[2] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
>>> h(o([Integer(4)]))
-h[2] + h[4]
>>> s(o([Integer(4)]))
-s[2] + s[4]
```

Some examples of conversions the other way:

```
sage: o(h[3])
o[1] + o[3]
sage: o(e[3])
o[1, 1, 1]
sage: o(m[2,1])
o[1] - 2*o[1, 1, 1] + o[2, 1]
sage: o(p[3])
o[1, 1, 1] - o[2, 1] + o[3]
```

```
>>> from sage.all import *
>>> o(h[Integer(3)])
o[1] + o[3]
>>> o(e[Integer(3)])
o[1, 1, 1]
>>> o(m[Integer(2),Integer(1)])
o[1] - 2*o[1, 1, 1] + o[2, 1]
>>> o(p[Integer(3)])
o[1, 1, 1] - o[2, 1] + o[3]
```

Some multiplication:

```
sage: o([2]) * o([1,1])
o[1, 1] + o[2] + o[2, 1, 1] + o[3, 1]
sage: o([2,1,1]) * o([2])
o[1, 1] + o[1, 1, 1, 1] + 2*o[2, 1, 1] + o[2, 2] + o[2, 2, 1, 1]
 + o[3, 1] + o[3, 1, 1, 1] + o[3, 2, 1] + o[4, 1, 1]
sage: o([1,1]) * o([2,1])
o[1] + o[1, 1, 1] + 2*o[2, 1] + o[2, 1, 1, 1] + o[2, 2, 1]
 + o[3] + o[3, 1, 1] + o[3, 2]
```

```
>>> from sage.all import *
>>> o([Integer(2)]) * o([Integer(1),Integer(1)])
o[1, 1] + o[2] + o[2, 1, 1] + o[3, 1]
>>> o([Integer(2),Integer(1),Integer(1)]) * o([Integer(2)])
o[1, 1] + o[1, 1, 1, 1] + 2*o[2, 1, 1] + o[2, 2] + o[2, 2, 1, 1]
 + o[3, 1] + o[3, 1, 1, 1] + o[3, 2, 1] + o[4, 1, 1]
>>> o([Integer(1),Integer(1)]) * o([Integer(2),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
o[1] + o[1, 1, 1] + 2*o[2, 1] + o[2, 1, 1, 1] + o[2, 2, 1]
 + o[3] + o[3, 1, 1] + o[3, 2]
```

Examples of the Hopf algebra structure:

```
sage: o([1]).antipode()
-o[1]
sage: o([2]).antipode()
-o[] + o[1, 1]
sage: o([1]).coproduct()
o[] # o[1] + o[1] # o[]
sage: o([2]).coproduct()
o[] # o[] + o[] # o[2] + o[1] # o[1] + o[2] # o[]
sage: o([1]).counit()
0
sage: o.one().counit()
1
```

```
>>> from sage.all import *
>>> o([Integer(1)]).antipode()
-o[1]
>>> o([Integer(2)]).antipode()
-o[] + o[1, 1]
>>> o([Integer(1)]).coproduct()
o[] # o[1] + o[1] # o[]
>>> o([Integer(2)]).coproduct()
o[] # o[] + o[] # o[2] + o[1] # o[1] + o[2] # o[]
>>> o([Integer(1)]).counit()
0
>>> o.one().counit()
1
```

5.1.298 Symmetric functions defined by orthogonality and triangularity

One characterization of Schur functions is that they are upper triangularly related to the monomial symmetric functions and orthogonal with respect to the Hall scalar product. We can use the class SymmetricFunctionAlgebra_orthotriang to obtain the Schur functions from this definition.

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur functions')
sage: s([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
>>> Sym = SymmetricFunctions(QQ)
```

(continues on next page)

(continued from previous page)

```
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur functions')
>>> s([Integer(2),Integer(1)])**Integer(2)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

```
sage: s2 = SymmetricFunctions(QQ).s()
sage: s2([2,1])^2
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

```
>>> from sage.all import *
>>> s2 = SymmetricFunctions(QQ).s()
>>> s2([Integer(2),Integer(1)])**Integer(2)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1] +
↪s[4, 2]
```

class sage.combinat.sf.orthotriang.**OrthotriangBasisFunctor**(*basis*)

Bases: *SymmetricFunctionsFunctor*

A constructor for algebras of symmetric functions constructed by orthogonality and triangularity.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↪orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur')
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur')
>>> s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

class sage.combinat.sf.orthotriang.**SymmetricFunctionAlgebra_orthotriang**(*Sym*, *base*, *scalar*, *prefix*, *basis_name*, *leading_coeff*)

Bases: *SymmetricFunctionAlgebra_generic*

Initialization of the symmetric function algebra defined via orthotriangular rules.

INPUT:

- `self` – a basis determined by an orthotriangular definition
- `Sym` – ring of symmetric functions

- `base` – an instance of a basis of the ring of symmetric functions (e.g. the Schur functions)
- `scalar` – a function `zee` on partitions. The function `zee` determines the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = \mathrm{zee}(\mu)$.
- `prefix` – the prefix used to display the basis
- `basis_name` – the name used for the basis

Note

The base ring is required to be a **Q**-algebra for this method to be usable, since the scalar product is defined by its values on the power sum basis.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↪orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_orthotriang
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur'); s
Symmetric Functions over Rational Field in the Schur basis
```

class Element

Bases: *SymmetricFunctionAlgebra_generic_Element*

construction()

Return a pair `(F, R)`, where `F` is a *SymmetricFunctionsFunctor* and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↪orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur')
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↪orthotriang
```

(continues on next page)

(continued from previous page)

```
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur')
>>> s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

product (*left*, *right*)

Return `left * right` by converting both to the base and then converting back to `self`.

INPUT:

- `self` – a basis determined by an orthotriangular definition
- `left`, `right` – elements in `self`

OUTPUT: the expansion of the product of `left` and `right` in the basis `self`

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↪orthotriang
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur␣
↪functions')
sage: s([1])*s([2,1]) #indirect doctest
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> from sage.combinat.sf.orthotriang import SymmetricFunctionAlgebra_
↪orthotriang
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> s = SymmetricFunctionAlgebra_orthotriang(Sym, m, zee, 's', 'Schur␣
↪functions')
>>> s([Integer(1)])*s([Integer(2),Integer(1)]) #indirect doctest
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

5.1.299 Power sum symmetric functions

class sage.combinat.sf.powersum.**SymmetricFunctionAlgebra_power** (*Sym*)

Bases: *SymmetricFunctionAlgebra_multiplicative*

A class for methods associated to the power sum basis of the symmetric functions.

INPUT:

- `self` – the power sum basis of the symmetric functions
- `Sym` – an instance of the ring of symmetric functions

class Element

Bases: *Element*

adams_operation(**args*, ***kwds*)

Deprecated: Use `adams_operator()` instead. See Issue #36396 for details.

adams_operator(*n*)

Return the image of the symmetric function `self` under the n-th Adams operator.

The n-th Adams operator $\mathbf{f}_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1,\lambda_2,\lambda_3,\ldots)} = m_{(n\lambda_1,n\lambda_2,n\lambda_3,\ldots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \ldots)$ (where m means the monomial basis). Moreover, $\mathbf{f}_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k-th powersum symmetric function).

The n-th Adams operator is also called the n-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n-th Adams operator is the n-th Adams operator of the Λ-ring of symmetric functions over the integers.

The n-th Adams operator can also be described via plethysm: Every symmetric function P satisfies $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n-th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Adams operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].adams_operator(2)
p[6]
sage: p[4,2,1].adams_operator(3)
p[12, 6, 3]
sage: p([]).adams_operator(4)
p[]
sage: p[3].adams_operator(1)
p[3]
sage: (p([3]) - p([2]) + p([])).adams_operator(3)
p[] - p[6] + p[9]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> p[Integer(3)].adams_operator(Integer(2))
p[6]
>>> p[Integer(4),Integer(2),Integer(1)].adams_operator(Integer(3))
p[12, 6, 3]
>>> p([]).adams_operator(Integer(4))
p[]
>>> p[Integer(3)].adams_operator(Integer(1))
```

(continues on next page)

(continued from previous page)

```
p[3]
>>> (p([Integer(3)]) - p([Integer(2)]) + p([])).adams_operator(Integer(3))
p[] - p[6] + p[9]
```

See also

plethysm()

eval_at_permutation_roots(*rho*)

Evaluate at eigenvalues of a permutation matrix.

Evaluate an element of the power sum basis at the eigenvalues of a permutation matrix with cycle structure ρ.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure ρ.

INPUT:

- `rho` – a partition or a list of nonnegative integers

OUTPUT: an element of the base ring

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p([3,3]).eval_at_permutation_roots([6])
0
sage: p([3,3]).eval_at_permutation_roots([3])
9
sage: p([3,3]).eval_at_permutation_roots([1])
1
sage: p([3,3]).eval_at_permutation_roots([3,3])
36
sage: p([3,3]).eval_at_permutation_roots([1,1,1,1,1])
25
sage: (p[1]+p[2]+p[3]).eval_at_permutation_roots([3,2])
5
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(6)])
0
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(3)])
9
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(1)])
1
```

(continues on next page)

(continued from previous page)

```
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(3),
↪Integer(3)])
36
>>> p([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(1),
↪Integer(1),Integer(1),Integer(1),Integer(1)])
25
>>> (p[Integer(1)]+p[Integer(2)]+p[Integer(3)]).eval_at_permutation_
↪roots([Integer(3),Integer(2)])
5
```

expand(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled by `alphabet`.

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2])
sage: a.expand(2)
x0^2 + x1^2
sage: a.expand(3, alphabet=['a','b','c'])
a^2 + b^2 + c^2
sage: p([2,1,1]).expand(2)
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
sage: p([7]).expand(4)
x0^7 + x1^7 + x2^7 + x3^7
sage: p([7]).expand(4,alphabet='t')
t0^7 + t1^7 + t2^7 + t3^7
sage: p([7]).expand(4,alphabet='x,y,z,t')
x^7 + y^7 + z^7 + t^7
sage: p(1).expand(4)
1
sage: p(0).expand(4)
0
sage: (p([]) + 2*p([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: p([1]).expand(0)
0
sage: (3*p([])).expand(0)
3
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> a = p([Integer(2)])
>>> a.expand(Integer(2))
x0^2 + x1^2
>>> a.expand(Integer(3), alphabet=['a','b','c'])
```

(continues on next page)

(continued from previous page)

```
a^2 + b^2 + c^2
>>> p([Integer(2),Integer(1),Integer(1)]).expand(Integer(2))
x0^4 + 2*x0^3*x1 + 2*x0^2*x1^2 + 2*x0*x1^3 + x1^4
>>> p([Integer(7)]).expand(Integer(4))
x0^7 + x1^7 + x2^7 + x3^7
>>> p([Integer(7)]).expand(Integer(4),alphabet='t')
t0^7 + t1^7 + t2^7 + t3^7
>>> p([Integer(7)]).expand(Integer(4),alphabet='x,y,z,t')
x^7 + y^7 + z^7 + t^7
>>> p(Integer(1)).expand(Integer(4))
1
>>> p(Integer(0)).expand(Integer(4))
0
>>> (p([]) + Integer(2)*p([Integer(1)])).expand(Integer(3))
2*x0 + 2*x1 + 2*x2 + 1
>>> p([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*p([])).expand(Integer(0))
3
```

exponential_specialization(*t=None*, *q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q-exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R. It is defined whenever the base ring K is a **Q**-algebra and t is an element of R. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q-exponential specialization is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n, we have

$$ex_q(f) = (1-q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \to 1$ is ex.

INPUT:

- `t` – (default: `None`) the value to use for t; the default is to create a ring of polynomials in `t`
- `q` – (default: 1) the value to use for q. If `q` is `None`, then a ring (or fraction field) of polynomials in `q` is created.

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
```

(continues on next page)

(continued from previous page)

```
sage: x.exponential_specialization()
0
sage: x = p[3] + 5*p[1,1] + 2*p[1] + 1
sage: x.exponential_specialization(t=var("t"))                          #␣
↪needs sage.symbolic
5*t^2 + 2*t + 1
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> x = p[Integer(8),Integer(7),Integer(3),Integer(1)]
>>> x.exponential_specialization()
0
>>> x = p[Integer(3)] + Integer(5)*p[Integer(1),Integer(1)] +␣
↪Integer(2)*p[Integer(1)] + Integer(1)
>>> x.exponential_specialization(t=var("t"))                          #␣
↪needs sage.symbolic
5*t^2 + 2*t + 1
```

We also support the q-exponential_specialization:

```
sage: factor(p[3].exponential_specialization(q=var("q"), t=var("t")))    #␣
↪needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

```
>>> from sage.all import *
>>> factor(p[Integer(3)].exponential_specialization(q=var("q"), t=var("t
↪")))    # needs sage.symbolic
(q - 1)^2*t^3/(q^2 + q + 1)
```

frobenius(**args*, ***kwds*)

Deprecated: Use `adams_operator()` instead. See Issue #36396 for details.

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1}p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda|-\ell(\lambda)}p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the image of `self` under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
-p[2, 1]
sage: p([]).omega()
p[]
sage: p(0).omega()
0
sage: p = SymmetricFunctions(ZZ).p()
sage: (p([3,1,1]) - 2 * p([2,1])).omega()
2*p[2, 1] + p[3, 1, 1]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> a = p([Integer(2),Integer(1)]); a
p[2, 1]
>>> a.omega()
-p[2, 1]
>>> p([]).omega()
p[]
>>> p(Integer(0)).omega()
0
>>> p = SymmetricFunctions(ZZ).p()
>>> (p([Integer(3),Integer(1),Integer(1)]) - Integer(2) * p([Integer(2),
↪Integer(1)])).omega()
2*p[2, 1] + p[3, 1, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the image of `self` under the omega automorphism

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([2,1]); a
p[2, 1]
sage: a.omega()
```

(continues on next page)

(continued from previous page)

```
-p[2, 1]
sage: p([]).omega()
p[]
sage: p(0).omega()
0
sage: p = SymmetricFunctions(ZZ).p()
sage: (p([3,1,1]) - 2 * p([2,1])).omega()
2*p[2, 1] + p[3, 1, 1]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> a = p([Integer(2),Integer(1)]); a
p[2, 1]
>>> a.omega()
-p[2, 1]
>>> p([]).omega()
p[]
>>> p(Integer(0)).omega()
0
>>> p = SymmetricFunctions(ZZ).p()
>>> (p([Integer(3),Integer(1),Integer(1)]) - Integer(2) * p([Integer(2),
↪Integer(1)])).omega()
2*p[2, 1] + p[3, 1, 1]
```

principal_specialization(*n=+Infinity*, *q=None*)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1,\dots,n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \dots$. (To be more precise, $ps_{n,q}$ is a K-algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` – (default: `infinity`) a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` – (default: `None`) the value to use for q; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

We use the formulas from Proposition 7.8.3 of [EnumComb2]:

$$ps_{n,q}(p_\lambda) = \prod_i (1 - q^{n\lambda_i})/(1 - q^{\lambda_i}),$$

$$ps_{n,1}(p_\lambda) = n^{\ell(\lambda)},$$

$$ps_q(p_\lambda) = 1/\prod_i (1 - q^{\lambda_i}),$$

where $\ell(\lambda)$ denotes the length of λ, and where the products range from $i = 1$ to $i = \ell(\lambda)$.

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: x = p[8,7,3,1]
sage: x.principal_specialization(3, q=var("q"))                          #␣
↪needs sage.symbolic
(q^24 - 1)*(q^21 - 1)*(q^9 - 1)/((q^8 - 1)*(q^7 - 1)*(q - 1))

sage: x = 5*p[1,1,1] + 3*p[2,1] + 1
sage: x.principal_specialization(3, q=var("q"))                          #␣
↪needs sage.symbolic
5*(q^3 - 1)^3/(q - 1)^3 + 3*(q^6 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> x = p[Integer(8),Integer(7),Integer(3),Integer(1)]
>>> x.principal_specialization(Integer(3), q=var("q"))                   ␣
↪     # needs sage.symbolic
(q^24 - 1)*(q^21 - 1)*(q^9 - 1)/((q^8 - 1)*(q^7 - 1)*(q - 1))

>>> x = Integer(5)*p[Integer(1),Integer(1),Integer(1)] +␣
↪Integer(3)*p[Integer(2),Integer(1)] + Integer(1)
>>> x.principal_specialization(Integer(3), q=var("q"))                   ␣
↪     # needs sage.symbolic
5*(q^3 - 1)^3/(q - 1)^3 + 3*(q^6 - 1)*(q^3 - 1)/((q^2 - 1)*(q - 1)) + 1
```

By default, we return a rational function in q:

```
sage: x.principal_specialization(3)
8*q^6 + 18*q^5 + 36*q^4 + 38*q^3 + 36*q^2 + 18*q + 9
```

```
>>> from sage.all import *
>>> x.principal_specialization(Integer(3))
8*q^6 + 18*q^5 + 36*q^4 + 38*q^3 + 36*q^2 + 18*q + 9
```

If n is not given we return the stable principal specialization:

```
sage: x.principal_specialization(q=var("q"))                             #␣
↪needs sage.symbolic
3/((q^2 - 1)*(q - 1)) - 5/(q - 1)^3 + 1
```

```
>>> from sage.all import *
>>> x.principal_specialization(q=var("q"))                             #␣
↪needs sage.symbolic
3/((q^2 - 1)*(q - 1)) - 5/(q - 1)^3 + 1
```

scalar(*x*, *zee=None*)

Return the standard scalar product of self and x.

INPUT:

- x – a power sum symmetric function
- zee – (default: uses standard zee function) optional input specifying the scalar product on the power sum basis with normalization $\langle p_\mu, p_\mu \rangle = \mathrm{zee}(\mu)$. zee should be a function on partitions.

Note that the power-sum symmetric functions are orthogonal under this scalar product. With the default value of zee, the value of $\langle p_\lambda, p_\lambda \rangle$ is given by the size of the centralizer in S_n of a permutation of cycle type λ.

OUTPUT:

- the standard scalar product between `self` and `x`, or, if the optional parameter `zee` is specified, then the scalar product with respect to the normalization $\langle p_\mu, p_\mu \rangle = \mathrm{zee}(\mu)$ with the power sum basis elements being orthogonal

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p4 = Partitions(4)
sage: matrix([ [p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4  0  0  0  0]
[ 0  3  0  0  0]
[ 0  0  8  0  0]
[ 0  0  0  4  0]
[ 0  0  0  0 24]
sage: p(0).scalar(p(1))
0
sage: p(1).scalar(p(2))
2

sage: zee = lambda x : 1
sage: matrix( [[p[la].scalar(p[mu], zee) for la in Partitions(3)] for mu␣
↪in Partitions(3)])
[1 0 0]
[0 1 0]
[0 0 1]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p4 = Partitions(Integer(4))
>>> matrix([ [p(a).scalar(p(b)) for a in p4] for b in p4])
[ 4  0  0  0  0]
[ 0  3  0  0  0]
[ 0  0  8  0  0]
[ 0  0  0  4  0]
[ 0  0  0  0 24]
>>> p(Integer(0)).scalar(p(Integer(1)))
0
>>> p(Integer(1)).scalar(p(Integer(2)))
2

>>> zee = lambda x : Integer(1)
>>> matrix( [[p[la].scalar(p[mu], zee) for la in Partitions(Integer(3))]␣
↪for mu in Partitions(Integer(3))])
[1 0 0]
[0 1 0]
[0 0 1]
```

verschiebung(n)

Return the image of the symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n, and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n}e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for "shift") endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Adams operator (see `adams_operator()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley's [STA].

Let λ be a partition. Let n be a positive integer. If the n-core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer s. (If n does not divide the length of λ, then this is achieved by adding trailing zeroes to λ.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n. Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the n-quotient of λ.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: p[3].verschiebung(2)
0
sage: p[4].verschiebung(4)
4*p[1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> p[Integer(3)].verschiebung(Integer(2))
0
>>> p[Integer(4)].verschiebung(Integer(4))
4*p[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( p(lam).verschiebung(2) * p(mu).verschiebung(2)
....:           == (p(lam) * p(mu)).verschiebung(2)
....:           for mu in Partitions(4) )
```

(continues on next page)

(continued from previous page)

```
....:       for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( p(lam).verschiebung(Integer(2)) * p(mu).
↪verschiebung(Integer(2))
...             == (p(lam) * p(mu)).verschiebung(Integer(2))
...             for mu in Partitions(Integer(4)) )
...       for lam in Partitions(Integer(4)) )
True
```

Testing the adjointness between the Adams operators $\mathbf{f}_n$ and the Verschiebung operators $\mathbf{V}_n$:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: all( all( p(lam).verschiebung(2).scalar(p(mu))
....:             == p(lam).scalar(p(mu).adams_operator(2))
....:             for mu in Partitions(2) )
....:       for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> all( all( p(lam).verschiebung(Integer(2)).scalar(p(mu))
...             == p(lam).scalar(p(mu).adams_operator(Integer(2)))
...             for mu in Partitions(Integer(2)) )
...       for lam in Partitions(Integer(4)) )
True
```

antipode_on_basis(*partition*)

Return the antipode of `self[partition]`.

The antipode on the generator p_i (for $i > 0$) is $-p_i$, and the antipode on p_μ is $(-1)^{length(\mu)} p_\mu$.

INPUT:

- `self` – the power sum basis of the symmetric functions
- `partition` – a partition

OUTPUT:

- the result of the antipode on `self(partition)`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.antipode_on_basis([2])
-p[2]
sage: p.antipode_on_basis([3])
-p[3]
sage: p.antipode_on_basis([2,2])
p[2, 2]
```

(continues on next page)

(continued from previous page)

```
sage: p.antipode_on_basis([])
p[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> p.antipode_on_basis([Integer(2)])
-p[2]
>>> p.antipode_on_basis([Integer(3)])
-p[3]
>>> p.antipode_on_basis([Integer(2),Integer(2)])
p[2, 2]
>>> p.antipode_on_basis([])
p[]
```

bottom_schur_function(*partition*, *degree=None*)

Return the least-degree component of `s[partition]`, where `s` denotes the Schur basis of the symmetric functions, and the grading is not the usual grading on the symmetric functions but rather the grading which gives every p_i degree 1.

This least-degree component has its degree equal to the Frobenius rank of `partition`, while the degree with respect to the usual grading is still the size of `partition`.

This method requires the base ring to be a (commutative) **Q**-algebra. This restriction is unavoidable, since the least-degree component (in general) has noninteger coefficients in all classical bases of the symmetric functions.

The optional keyword `degree` allows taking any homogeneous component rather than merely the least-degree one. Specifically, if `degree` is set, then the `degree`-th component will be returned.

REFERENCES:

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: p.bottom_schur_function([2,2,1])
-1/6*p[3, 2] + 1/4*p[4, 1]
sage: p.bottom_schur_function([2,1])
-1/3*p[3]

sage: p.bottom_schur_function([2,1], degree=1)
-1/3*p[3]
sage: p.bottom_schur_function([2,1], degree=2)
0
sage: p.bottom_schur_function([2,1], degree=3)
1/3*p[1, 1, 1]
sage: p.bottom_schur_function([2,2,1], degree=3)
1/8*p[2, 2, 1] - 1/6*p[3, 1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> p.bottom_schur_function([Integer(2),Integer(2),Integer(1)])
-1/6*p[3, 2] + 1/4*p[4, 1]
>>> p.bottom_schur_function([Integer(2),Integer(1)])
-1/3*p[3]
>>> p.bottom_schur_function([Integer(3)])
1/3*p[3]
>>> p.bottom_schur_function([Integer(1),Integer(1),Integer(1)])
1/3*p[3]
>>> p.bottom_schur_function(Partition([Integer(1),Integer(1),Integer(1)]))
1/3*p[3]
>>> p.bottom_schur_function([Integer(2),Integer(1)], degree=Integer(1))
-1/3*p[3]
>>> p.bottom_schur_function([Integer(2),Integer(1)], degree=Integer(2))
0
>>> p.bottom_schur_function([Integer(2),Integer(1)], degree=Integer(3))
1/3*p[1, 1, 1]
>>> p.bottom_schur_function([Integer(2),Integer(2),Integer(1)],␣
↪degree=Integer(3))
1/8*p[2, 2, 1] - 1/6*p[3, 1, 1]
```

coproduct_on_generators(*i*)

Return coproduct on generators for power sums p_i (for $i > 0$).

The elements p_i are primitive elements.

INPUT:

- `self` – the power sum basis of the symmetric functions
- `i` – positive integer

OUTPUT: the result of the coproduct on the generator $p(i)$

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: p.coproduct_on_generators(2)
p[] # p[2] + p[2] # p[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.powersum()
>>> p.coproduct_on_generators(Integer(2))
p[] # p[2] + p[2] # p[]
```

eval_at_permutation_roots_on_generators(*k*, *rho*)

Evaluate p_k at eigenvalues of permutation matrix.

This function evaluates a symmetric function `p([k])` at the eigenvalues of a permutation matrix with cycle structure `\rho`.

This function evaluates a p_k at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. This is characterized by $p_k[A,B] = p_k[A] + p_k[B]$ and $p_k[\Xi_m] = 0$ unless m divides k and $p_{rm}[\Xi_m] = m$.

INPUT:

- `k` – nonnegative integer
- `rho` – a partition or a list of nonnegative integers

OUTPUT: an element of the base ring

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p.eval_at_permutation_roots_on_generators(3, [6])
0
sage: p.eval_at_permutation_roots_on_generators(3, [3])
3
sage: p.eval_at_permutation_roots_on_generators(3, [1])
1
sage: p.eval_at_permutation_roots_on_generators(3, [3,3])
6
sage: p.eval_at_permutation_roots_on_generators(3, [1,1,1,1,1])
5
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(6)])
0
>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(3)])
3
>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(1)])
1
>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(3),
↪Integer(3)])
6
>>> p.eval_at_permutation_roots_on_generators(Integer(3), [Integer(1),
↪Integer(1),Integer(1),Integer(1),Integer(1)])
5
```

5.1.300 Schur symmetric functions

class sage.combinat.sf.schur.**SymmetricFunctionAlgebra_schur**(*Sym*)

Bases: *SymmetricFunctionAlgebra_classical*

A class for methods related to the Schur symmetric function basis.

INPUT:

- `self` – a Schur symmetric function basis

- Sym – an instance of the ring of the symmetric functions

class Element

Bases: *Element*

expand(*n*, *alphabet='x'*)

Expand the symmetric function self as a symmetric polynomial in n variables.

INPUT:

- n – nonnegative integer
- alphabet – (default: 'x') a variable for the expansion

OUTPUT:

A monomial expansion of self in the n variables labelled by alphabet.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: a.expand(2)
x0^2*x1 + x0*x1^2
sage: a.expand(3)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
sage: a.expand(4)
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 +
↪x0^2*x3 + 2*x0*x1*x3 + x1^2*x3 + 2*x0*x2*x3 + 2*x1*x2*x3 + x2^2*x3 +
↪x0*x3^2 + x1*x3^2 + x2*x3^2
sage: a.expand(2, alphabet='y')
y0^2*y1 + y0*y1^2
sage: a.expand(2, alphabet=['a','b'])
a^2*b + a*b^2
sage: s([1,1,1,1]).expand(3)
0
sage: (s([]) + 2*s([1])).expand(3)
2*x0 + 2*x1 + 2*x2 + 1
sage: s([1]).expand(0)
0
sage: (3*s([])).expand(0)
3
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> a.expand(Integer(2))
x0^2*x1 + x0*x1^2
>>> a.expand(Integer(3))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2
>>> a.expand(Integer(4))
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 +
↪x0^2*x3 + 2*x0*x1*x3 + x1^2*x3 + 2*x0*x2*x3 + 2*x1*x2*x3 + x2^2*x3 +
↪x0*x3^2 + x1*x3^2 + x2*x3^2
>>> a.expand(Integer(2), alphabet='y')
y0^2*y1 + y0*y1^2
>>> a.expand(Integer(2), alphabet=['a','b'])
a^2*b + a*b^2
```

(continues on next page)

>>> s([Integer(1)]).expand(Integer(0))
0
>>> (Integer(3)*s([])).expand(Integer(0))
3
```

exponential_specialization(*t=None*, *q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q-exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R. It is defined whenever the base ring K is a **Q**-algebra and t is an element of R. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q-exponential specialization is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n, we have

$$ex_q(f) = (1-q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \to 1$ is ex.

INPUT:

- `t` – (default: `None`) the value to use for t; the default is to create a ring of polynomials in `t`
- `q` – (default: 1) the value to use for q. If `q` is `None`, then a ring (or fraction field) of polynomials in `q` is created.

We use the formula in the proof of Corollary 7.21.6 of [EnumComb2]

$$ex_q(s_\lambda) = t^{|\lambda|} q^{\sum_i (i-1)\lambda_i} / \prod_{u\in\lambda} (1 + q + q^2 + \cdots + q^{h(u)-1})$$

where $h(u)$ is the hook length of a cell u in λ.

As a limit case, we obtain a formula for $q = 1$

$$ex_1(s_\lambda) = f^\lambda t^{|\lambda|}/|\lambda|!$$

where f^λ is the number of standard Young tableaux of shape λ.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[5,3]
sage: x.exponential_specialization()
1/1440*t^8

sage: x = 5*s[1,1,1] + 3*s[2,1] + 1
sage: x.exponential_specialization()
11/6*t^3 + 1
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> x = s[Integer(5),Integer(3)]
>>> x.exponential_specialization()
1/1440*t^8

>>> x = Integer(5)*s[Integer(1),Integer(1),Integer(1)] +␣
↪Integer(3)*s[Integer(2),Integer(1)] + Integer(1)
>>> x.exponential_specialization()
11/6*t^3 + 1
```

We also support the q-exponential_specialization:

```
sage: factor(s[3].exponential_specialization(q=var("q"), t=var("t")))    #␣
↪needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

```
>>> from sage.all import *
>>> factor(s[Integer(3)].exponential_specialization(q=var("q"), t=var("t
↪")))    # needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the image of `self` under the omega automorphism

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(2),Integer(1)]).omega()
s[2, 1]
>>> s([Integer(2),Integer(1),Integer(1)]).omega()
s[3, 1]
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

OUTPUT: the image of `self` under the omega automorphism

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).omega()
s[2, 1]
sage: s([2,1,1]).omega()
s[3, 1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(2),Integer(1)]).omega()
s[2, 1]
>>> s([Integer(2),Integer(1),Integer(1)]).omega()
s[3, 1]
```

principal_specialization(*n=+Infinity*, *q=None*)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R, and we assume that the variables of our symmetric functions are

$x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a K-algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` – (default: `infinity`) a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` – (default: `None`) the value to use for q; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

For $q = 1$ we use the formula from Corollary 7.21.4 of [EnumComb2]:

$$ps_{n,1}(s_\lambda) = \prod_{u\in\lambda} (n + c(u))/h(u),$$

where $h(u)$ is the hook length of a cell u in λ, and where $c(u)$ is the content of a cell u in λ.

For $n = infinity$ we use the formula from Corollary 7.21.3 of [EnumComb2]

$$ps_q(s_\lambda) = q^{\sum_i (i-1)\lambda_i} / \prod_{u\in\lambda} (1 - q^{h(u)}).$$

Otherwise, we use the formula from Theorem 7.21.2 of [EnumComb2],

$$ps_{n,q}(s_\lambda) = q^{\sum_i (i-1)\lambda_i} \prod_{u\in\lambda} (1 - q^{n+c(u)})/(1 - q^{h(u)}).$$

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: x = s[2]
sage: x.principal_specialization(3)
q^4 + q^3 + 2*q^2 + q + 1

sage: x = 3*s[2,2] + 2*s[1] + 1
sage: x.principal_specialization(3, q=var("q"))                               #␣
↪needs sage.symbolic
3*(q^4 - 1)*(q^3 - 1)*q^2/((q^2 - 1)*(q - 1)) + 2*(q^3 - 1)/(q - 1) + 1

sage: x.principal_specialization(q=var("q"))                                  #␣
↪needs sage.symbolic
-2/(q - 1) + 3*q^2/((q^3 - 1)*(q^2 - 1)^2*(q - 1)) + 1
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> x = s[Integer(2)]
>>> x.principal_specialization(Integer(3))
q^4 + q^3 + 2*q^2 + q + 1

>>> x = Integer(3)*s[Integer(2),Integer(2)] + Integer(2)*s[Integer(1)] +␣
↪Integer(1)
>>> x.principal_specialization(Integer(3), q=var("q"))                        ␣
↪    # needs sage.symbolic
```

(continues on next page)

(continued from previous page)

```
3*(q^4 - 1)*(q^3 - 1)*q^2/((q^2 - 1)*(q - 1)) + 2*(q^3 - 1)/(q - 1) + 1

>>> x.principal_specialization(q=var("q"))                         #␣
↪needs sage.symbolic
-2/(q - 1) + 3*q^2/((q^3 - 1)*(q^2 - 1)^2*(q - 1)) + 1
```

scalar(*x*, *zee=None*)

Return the standard scalar product between `self` and x.

Note that the Schur functions are self-dual with respect to this scalar product. They are also lower-triangularly related to the monomial symmetric functions with respect to this scalar product.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `zee` – an optional function on partitions giving the value for the scalar product between the power-sum symmetric function p_μ and itself (the default value is the standard *zee()* function)

OUTPUT: the scalar product between `self` and `x`

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: b = s([1,1,1])
sage: c = 2*s([1,1,1])
sage: d = a + b
sage: a.scalar(a)
1
sage: b.scalar(b)
1
sage: b.scalar(a)
0
sage: b.scalar(c)
2
sage: c.scalar(c)
4
sage: d.scalar(a)
1
sage: d.scalar(b)
1
sage: d.scalar(c)
2
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> a = s([Integer(2),Integer(1)])
>>> b = s([Integer(1),Integer(1),Integer(1)])
>>> c = Integer(2)*s([Integer(1),Integer(1),Integer(1)])
>>> d = a + b
>>> a.scalar(a)
1
>>> b.scalar(b)
1
>>> b.scalar(a)
```

(continues on next page)

(continued from previous page)

```
0
>>> b.scalar(c)
2
>>> c.scalar(c)
4
>>> d.scalar(a)
1
>>> d.scalar(b)
1
>>> d.scalar(c)
2
```

```
sage: m = SymmetricFunctions(ZZ).monomial()
sage: p4 = Partitions(4)
sage: l = [ [s(p).scalar(m(q)) for q in p4] for p in p4]
sage: matrix(l)
[ 1  0  0  0  0]
[-1  1  0  0  0]
[ 0 -1  1  0  0]
[ 1 -1 -1  1  0]
[-1  2  1 -3  1]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(ZZ).monomial()
>>> p4 = Partitions(Integer(4))
>>> l = [ [s(p).scalar(m(q)) for q in p4] for p in p4]
>>> matrix(l)
[ 1  0  0  0  0]
[-1  1  0  0  0]
[ 0 -1  1  0  0]
[ 1 -1 -1  1  0]
[-1  2  1 -3  1]
```

verschiebung(n)

Return the image of the symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n, and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n} e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for "shift") endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley's [STA].

Let λ be a partition. Let n be a positive integer. If the n-core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer s. (If n does not divide the length of λ, then this is achieved by adding trailing zeroes to λ.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n. Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the n-quotient of λ.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: s[5].verschiebung(2)
0
sage: s[6].verschiebung(6)
s[1]
sage: s[6,3].verschiebung(3)
s[2, 1] + s[3]
sage: s[6,3,1].verschiebung(2)
-s[3, 2]
sage: s[3,2,1].verschiebung(1)
s[3, 2, 1]
sage: s([]).verschiebung(1)
s[]
sage: s([]).verschiebung(4)
s[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> s = Sym.s()
>>> s[Integer(5)].verschiebung(Integer(2))
0
>>> s[Integer(6)].verschiebung(Integer(6))
s[1]
>>> s[Integer(6),Integer(3)].verschiebung(Integer(3))
s[2, 1] + s[3]
>>> s[Integer(6),Integer(3),Integer(1)].verschiebung(Integer(2))
-s[3, 2]
>>> s[Integer(3),Integer(2),Integer(1)].verschiebung(Integer(1))
s[3, 2, 1]
>>> s([]).verschiebung(Integer(1))
s[]
>>> s([]).verschiebung(Integer(4))
```

(continues on next page)

(continued from previous page)

```
s[]
```

coproduct_on_basis(*mu*)

Return the coproduct of `self(mu)`.

Here `self` is the basis of Schur functions in the ring of symmetric functions.

INPUT:

- `self` – a Schur symmetric function basis
- `mu` – a partition

OUTPUT:

- the image of the `mu`-th Schur function under the comultiplication of the Hopf algebra of symmetric functions; this is an element of the tensor square of the Schur basis

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s.coproduct_on_basis([2])
s[] # s[2] + s[1] # s[1] + s[2] # s[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> s.coproduct_on_basis([Integer(2)])
s[] # s[2] + s[1] # s[1] + s[2] # s[]
```

product_on_basis(*left*, *right*)

Return the product of `left` and `right`.

INPUT:

- `self` – a Schur symmetric function basis
- `left`, `right` – partitions

OUTPUT: an element of the Schur basis, the product of `left` and `right`

5.1.301 Symplectic Symmetric Functions

AUTHORS:

- Travis Scrimshaw (2013-11-10): Initial version

class sage.combinat.sf.symplectic.**SymmetricFunctionAlgebra_symplectic**(*Sym*)

Bases: *SymmetricFunctionAlgebra_generic*

The symplectic symmetric function basis (or symplectic basis, to be short).

The symplectic basis $\{sp_\lambda\}$ where λ is taken over all partitions is defined by the following change of basis with the Schur functions:

$$s_\lambda = \sum_\mu \left(\sum_{\nu \in V} c^\lambda_{\mu\nu} \right) sp_\mu$$

where V is the set of all partitions with even-height columns and $c^{\lambda}_{\mu\nu}$ is the usual Littlewood-Richardson (LR) coefficients. By the properties of LR coefficients, this can be shown to be a upper unitriangular change of basis.

Note: This is only a filtered basis, not a $\mathbf{Z}$-graded basis. However this does respect the induced $(\mathbf{Z}/2\mathbf{Z})$-grading.

INPUT:

- `Sym` – an instance of the ring of the symmetric functions

REFERENCES:

EXAMPLES:

Here are the first few symplectic symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(sp([1]))
p[1]
sage: m(sp([1]))
m[1]
sage: e(sp([1]))
e[1]
sage: h(sp([1]))
h[1]
sage: s(sp([1]))
s[1]

sage: p(sp([2]))
1/2*p[1, 1] + 1/2*p[2]
sage: m(sp([2]))
m[1, 1] + m[2]
sage: e(sp([2]))
e[1, 1] - e[2]
sage: h(sp([2]))
h[2]
sage: s(sp([2]))
s[2]

sage: p(sp([3]))
1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
sage: m(sp([3]))
m[1, 1, 1] + m[2, 1] + m[3]
sage: e(sp([3]))
e[1, 1, 1] - 2*e[2, 1] + e[3]
sage: h(sp([3]))
```

(continues on next page)

(continued from previous page)

```
h[3]
sage: s(sp([3]))
s[3]

sage: Sym = SymmetricFunctions(ZZ)
sage: sp = Sym.sp()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(sp([4]))
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
sage: e(sp([4]))
e[1, 1, 1, 1] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
sage: h(sp([4]))
h[4]
sage: s(sp([4]))
s[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> sp = Sym.sp()

>>> h = Sym.h()
>>> p = Sym.p()
>>> s = Sym.s()
>>> m = Sym.m()

>>> p(sp([Integer(1)]))
p[1]
>>> m(sp([Integer(1)]))
m[1]
>>> e(sp([Integer(1)]))
e[1]
>>> h(sp([Integer(1)]))
h[1]
>>> s(sp([Integer(1)]))
s[1]

>>> p(sp([Integer(2)]))
1/2*p[1, 1] + 1/2*p[2]
>>> m(sp([Integer(2)]))
m[1, 1] + m[2]
>>> e(sp([Integer(2)]))
e[1, 1] - e[2]
>>> h(sp([Integer(2)]))
h[2]
>>> s(sp([Integer(2)]))
s[2]

>>> p(sp([Integer(3)]))
```

(continues on next page)

(continued from previous page)

```
1/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3]
>>> m(sp([Integer(3)]))
m[1, 1, 1] + m[2, 1] + m[3]
>>> e(sp([Integer(3)]))
e[1, 1, 1] - 2*e[2, 1] + e[3]
>>> h(sp([Integer(3)]))
h[3]
>>> s(sp([Integer(3)]))
s[3]

>>> Sym = SymmetricFunctions(ZZ)
>>> sp = Sym.sp()
>>> e = Sym.e()
>>> h = Sym.h()
>>> s = Sym.s()
>>> m = Sym.m()
>>> p = Sym.p()
>>> m(sp([Integer(4)]))
m[1, 1, 1, 1] + m[2, 1, 1] + m[2, 2] + m[3, 1] + m[4]
>>> e(sp([Integer(4)]))
e[1, 1, 1, 1] - 3*e[2, 1, 1] + e[2, 2] + 2*e[3, 1] - e[4]
>>> h(sp([Integer(4)]))
h[4]
>>> s(sp([Integer(4)]))
s[4]
```

Some examples of conversions the other way:

```
sage: sp(h[3])
sp[3]
sage: sp(e[3])
sp[1] + sp[1, 1, 1]
sage: sp(m[2,1])
-sp[1] - 2*sp[1, 1, 1] + sp[2, 1]
sage: sp(p[3])
sp[1, 1, 1] - sp[2, 1] + sp[3]
```

```
>>> from sage.all import *
>>> sp(h[Integer(3)])
sp[3]
>>> sp(e[Integer(3)])
sp[1] + sp[1, 1, 1]
>>> sp(m[Integer(2),Integer(1)])
-sp[1] - 2*sp[1, 1, 1] + sp[2, 1]
>>> sp(p[Integer(3)])
sp[1, 1, 1] - sp[2, 1] + sp[3]
```

Some multiplication:

```
sage: sp([2]) * sp([1,1])
sp[1, 1] + sp[2] + sp[2, 1, 1] + sp[3, 1]
sage: sp([2,1,1]) * sp([2])
```

(continues on next page)

(continued from previous page)

```
sp[1, 1] + sp[1, 1, 1, 1] + 2*sp[2, 1, 1] + sp[2, 2] + sp[2, 2, 1, 1]
 + sp[3, 1] + sp[3, 1, 1, 1] + sp[3, 2, 1] + sp[4, 1, 1]
sage: sp([1,1]) * sp([2,1])
sp[1] + sp[1, 1, 1] + 2*sp[2, 1] + sp[2, 1, 1, 1] + sp[2, 2, 1]
 + sp[3] + sp[3, 1, 1] + sp[3, 2]
```

```
>>> from sage.all import *
>>> sp([Integer(2)]) * sp([Integer(1),Integer(1)])
sp[1, 1] + sp[2] + sp[2, 1, 1] + sp[3, 1]
>>> sp([Integer(2),Integer(1),Integer(1)]) * sp([Integer(2)])
sp[1, 1] + sp[1, 1, 1, 1] + 2*sp[2, 1, 1] + sp[2, 2] + sp[2, 2, 1, 1]
 + sp[3, 1] + sp[3, 1, 1, 1] + sp[3, 2, 1] + sp[4, 1, 1]
>>> sp([Integer(1),Integer(1)]) * sp([Integer(2),Integer(1)])
sp[1] + sp[1, 1, 1] + 2*sp[2, 1] + sp[2, 1, 1, 1] + sp[2, 2, 1]
 + sp[3] + sp[3, 1, 1] + sp[3, 2]
```

Examples of the Hopf algebra structure:

```
sage: sp([1]).antipode()
-sp[1]
sage: sp([2]).antipode()
sp[] + sp[1, 1]
sage: sp([1]).coproduct()
sp[] # sp[1] + sp[1] # sp[]
sage: sp([2]).coproduct()
sp[] # sp[2] + sp[1] # sp[1] + sp[2] # sp[]
sage: sp([1]).counit()
0
sage: sp.one().counit()
1
```

```
>>> from sage.all import *
>>> sp([Integer(1)]).antipode()
-sp[1]
>>> sp([Integer(2)]).antipode()
sp[] + sp[1, 1]
>>> sp([Integer(1)]).coproduct()
sp[] # sp[1] + sp[1] # sp[]
>>> sp([Integer(2)]).coproduct()
sp[] # sp[2] + sp[1] # sp[1] + sp[2] # sp[]
>>> sp([Integer(1)]).counit()
0
>>> sp.one().counit()
1
```

5.1.302 Symmetric functions, with their multiple realizations

class sage.combinat.sf.sf.**SymmetricFunctions**(R)

Bases: UniqueRepresentation, Parent

The abstract algebra of commutative symmetric functions.

Symmetric Functions in Sage

Author: Jason Bandlow, Anne Schilling, Nicolas M. Thiery, Mike Zabrocki

This document is an introduction to working with symmetric function theory in Sage. It is not intended to be an introduction to the theory of symmetric functions ([MAC] and [STA], Chapter 7, are two excellent references.) The reader is also expected to be familiar with Sage.

The algebra of symmetric functions

The algebra of symmetric functions is the unique free commutative graded connected algebra over the given ring, with one generator in each degree. It can also be thought of as the inverse limit (in the category of graded algebras) of the algebra of symmetric polynomials in n variables as $n \to \infty$. Sage allows us to construct the algebra of symmetric functions over any ring. We will use a base ring of rational numbers in these first examples:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym
Symmetric Functions over Rational Field
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sym
Symmetric Functions over Rational Field
```

Sage knows certain categorical information about this algebra:

```
sage: Sym.category()
Join of Category of Hopf algebras over Rational Field
    and Category of unique factorization domains
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field
```

```
>>> from sage.all import *
>>> Sym.category()
Join of Category of Hopf algebras over Rational Field
    and Category of unique factorization domains
    and Category of graded algebras over Rational Field
    and Category of commutative algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field
```

Notice that `Sym` is an *abstract* algebra. This reflects the fact that there are multiple natural bases. To work with specific elements, we need a *realization* of this algebra. In practice, this means we need to specify a basis.

An example basis - power sums

Here is an example of how one might use the power sum realization:

```
sage: p = Sym.powersum()
sage: p
Symmetric Functions over Rational Field in the powersum basis
```

```
>>> from sage.all import *
>>> p = Sym.powersum()
>>> p
Symmetric Functions over Rational Field in the powersum basis
```

`p` now represents the realization of the symmetric function algebra on the power sum basis. The basis itself is accessible through:

```
sage: p.basis()
Lazy family (Term map from Partitions to Symmetric Functions over Rational Field␣
↪in the powersum basis(i))_{i in Partitions}
sage: p.basis().keys()
Partitions
```

```
>>> from sage.all import *
>>> p.basis()
Lazy family (Term map from Partitions to Symmetric Functions over Rational Field␣
↪in the powersum basis(i))_{i in Partitions}
>>> p.basis().keys()
Partitions
```

This last line means that `p.basis()` is an association between the set of Partitions and the basis elements of the algebra `p`. To construct a specific element one can therefore do:

```
sage: p.basis()[Partition([2,1,1])]
p[2, 1, 1]
```

```
>>> from sage.all import *
>>> p.basis()[Partition([Integer(2),Integer(1),Integer(1)])]
p[2, 1, 1]
```

As this is rather cumbersome, realizations of the symmetric function algebra allow for the following abuses of notation:

```
sage: p[Partition([2, 1, 1])]
p[2, 1, 1]
sage: p[[2, 1, 1]]
p[2, 1, 1]
sage: p[2, 1, 1]
p[2, 1, 1]
```

```
>>> from sage.all import *
>>> p[Partition([Integer(2), Integer(1), Integer(1)])]
p[2, 1, 1]
>>> p[[Integer(2), Integer(1), Integer(1)]]
```

(continues on next page)

(continued from previous page)

```
p[2, 1, 1]
>>> p[Integer(2), Integer(1), Integer(1)]
p[2, 1, 1]
```

or even:

```
sage: p[(i for i in [2, 1, 1])]
p[2, 1, 1]
```

```
>>> from sage.all import *
>>> p[(i for i in [Integer(2), Integer(1), Integer(1)])]
p[2, 1, 1]
```

In the special case of the empty partition, due to a limitation in Python syntax, one cannot use:

```
sage: p[]       # todo: not implemented
```

```
>>> from sage.all import *
>>> p[]       # todo: not implemented
```

Please use instead:

```
sage: p[[]]
p[]
```

```
>>> from sage.all import *
>>> p[[]]
p[]
```

Note: When elements are constructed using the `p[something ]` syntax , an error will be raised if the input cannot be interpreted as a partition. This is *not* the case when `p.basis()` is used:

```
sage: p['something']
Traceback (most recent call last):
...
ValueError: all parts of 'something' should be nonnegative integers
sage: p.basis()['something']
p'something'
```

```
>>> from sage.all import *
>>> p['something']
Traceback (most recent call last):
...
ValueError: all parts of 'something' should be nonnegative integers
>>> p.basis()['something']
p'something'
```

Elements of `p` are linear combinations of such compositions:

```
sage: p.an_element()
2*p[] + 2*p[1] + 3*p[2]
```

```
>>> from sage.all import *
>>> p.an_element()
2*p[] + 2*p[1] + 3*p[2]
```

Algebra structure

Algebraic combinations of basis elements can be entered in a natural way:

```
sage: p[2,1,1] + 2 * p[1] * (p[4] + p[2,1])
3*p[2, 1, 1] + 2*p[4, 1]
```

```
>>> from sage.all import *
>>> p[Integer(2),Integer(1),Integer(1)] + Integer(2) * p[Integer(1)] *␣
↪(p[Integer(4)] + p[Integer(2),Integer(1)])
3*p[2, 1, 1] + 2*p[4, 1]
```

Let us explore the other operations of `p`. We can ask for the mathematical properties of `p`:

```
sage: p.categories()
[Category of graded bases of Symmetric Functions over Rational Field,
 Category of filtered bases of Symmetric Functions over Rational Field,
 Category of bases of Symmetric Functions over Rational Field,
 Category of graded Hopf algebras with basis over Rational Field,
 ...]
```

```
>>> from sage.all import *
>>> p.categories()
[Category of graded bases of Symmetric Functions over Rational Field,
 Category of filtered bases of Symmetric Functions over Rational Field,
 Category of bases of Symmetric Functions over Rational Field,
 Category of graded Hopf algebras with basis over Rational Field,
 ...]
```

To start with, `p` is a graded algebra, the grading being induced by the size of the partitions. Due to this, the one is the basis element indexed by the empty partition:

```
sage: p.one()
p[]
```

```
>>> from sage.all import *
>>> p.one()
p[]
```

The `p` basis is multiplicative; that is, multiplication is induced by linearity from the (nonincreasingly sorted) concatenation of partitions:

```
sage: p[3,1] * p[2,1]
p[3, 2, 1, 1]
```

(continues on next page)

(continued from previous page)

```
sage: (p.one() + 2 * p[3,1]) * p[4, 2]
p[4, 2] + 2*p[4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> p[Integer(3),Integer(1)] * p[Integer(2),Integer(1)]
p[3, 2, 1, 1]

>>> (p.one() + Integer(2) * p[Integer(3),Integer(1)]) * p[Integer(4), Integer(2)]
p[4, 2] + 2*p[4, 3, 2, 1]
```

The classical bases

In addition to the power sum basis, other classical bases of the symmetric function algebra include the elementary, complete homogeneous, monomial, and Schur bases:

```
sage: e = Sym.elementary()
sage: h = Sym.homogeneous()
sage: m = Sym.monomial()
sage: s = Sym.schur()
```

```
>>> from sage.all import *
>>> e = Sym.elementary()
>>> h = Sym.homogeneous()
>>> m = Sym.monomial()
>>> s = Sym.schur()
```

These and others can be defined all at once with the single command:

```
sage: Sym.inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the␣
↪elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the␣
↪forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the␣
↪homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the␣
↪monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the␣
↪powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur␣
↪basis
```

```
>>> from sage.all import *
>>> Sym.inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the␣
↪elementary basis
Defining f as shorthand for Symmetric Functions over Rational Field in the␣
↪forgotten basis
Defining h as shorthand for Symmetric Functions over Rational Field in the␣
↪homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the␣
```

(continues on next page)

(continued from previous page)

```
↪monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the␣
↪powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur␣
↪basis
```

We can then do conversions from one basis to another:

```
sage: s(p[2,1])
-s[1, 1, 1] + s[3]

sage: m(p[3])
m[3]
sage: m(p[3,2])
m[3, 2] + m[5]
```

```
>>> from sage.all import *
>>> s(p[Integer(2),Integer(1)])
-s[1, 1, 1] + s[3]

>>> m(p[Integer(3)])
m[3]
>>> m(p[Integer(3),Integer(2)])
m[3, 2] + m[5]
```

For computations which mix bases, Sage will return a result with respect to a single (not necessarily predictable) basis:

```
sage: p[2] * s[2] - m[4]
1/2*p[2, 1, 1] + 1/2*p[2, 2] - p[4]

sage: p( m[1] * ( e[3]*s[2] + 1 ))
p[1] + 1/12*p[1, 1, 1, 1, 1, 1] - 1/6*p[2, 1, 1, 1, 1] - 1/4*p[2, 2, 1, 1] + 1/
↪6*p[3, 1, 1, 1] + 1/6*p[3, 2, 1]
```

```
>>> from sage.all import *
>>> p[Integer(2)] * s[Integer(2)] - m[Integer(4)]
1/2*p[2, 1, 1] + 1/2*p[2, 2] - p[4]

>>> p( m[Integer(1)] * ( e[Integer(3)]*s[Integer(2)] + Integer(1) ))
p[1] + 1/12*p[1, 1, 1, 1, 1, 1] - 1/6*p[2, 1, 1, 1, 1] - 1/4*p[2, 2, 1, 1] + 1/
↪6*p[3, 1, 1, 1] + 1/6*p[3, 2, 1]
```

The one for different bases such as the power sum and Schur function is the same:

```
sage: s.one() == p.one()
True
```

```
>>> from sage.all import *
>>> s.one() == p.one()
True
```

Basic computations

In this section, we explore some of the many methods that can be applied to an arbitrary symmetric function:

```
sage: f = s[2]^2; f
s[2, 2] + s[3, 1] + s[4]
```

```
>>> from sage.all import *
>>> f = s[Integer(2)]**Integer(2); f
s[2, 2] + s[3, 1] + s[4]
```

For more methods than discussed here, create a symmetric function as above, and use `f.<tab>`.

Representation theory of the symmetric group

The Schur functions s_λ can also be interpreted as irreducible characters of the symmetric group S_n, where n is the size of the partition λ. Since the Schur functions of degree n form a basis of the symmetric functions of degree n, it follows that an arbitrary symmetric function (homogeneous of degree n) may be interpreted as a function on the symmetric group. In this interpretation the power sum symmetric function p_λ is the characteristic function of the conjugacy class with shape λ, multiplied by the order of the centralizer of an element. Hence the irreducible characters can be computed as follows:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: p = Sym.power()
sage: P = Partitions(5).list()
sage: P = [P[i] for i in range(len(P)-1,-1,-1)]
sage: M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P))] for i in␣
↪range(len(P))])
sage: M
[ 1 -1  1  1 -1 -1  1]
[ 4 -2  0  1  1  0 -1]
[ 5 -1  1 -1 -1  1  0]
[ 6  0 -2  0  0  0  1]
[ 5  1  1 -1  1 -1  0]
[ 4  2  0  1 -1  0 -1]
[ 1  1  1  1  1  1  1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> p = Sym.power()
>>> P = Partitions(Integer(5)).list()
>>> P = [P[i] for i in range(len(P)-Integer(1),-Integer(1),-Integer(1))]
>>> M = matrix([[s[P[i]].scalar(p[P[j]]) for j in range(len(P))] for i in␣
↪range(len(P))])
>>> M
[ 1 -1  1  1 -1 -1  1]
[ 4 -2  0  1  1  0 -1]
[ 5 -1  1 -1 -1  1  0]
[ 6  0 -2  0  0  0  1]
[ 5  1  1 -1  1 -1  0]
[ 4  2  0  1 -1  0 -1]
[ 1  1  1  1  1  1  1]
```

We can indeed check that this agrees with the character table of S_5:

```
sage: SymmetricGroup(5).character_table() == M
True
```

```
>>> from sage.all import *
>>> SymmetricGroup(Integer(5)).character_table() == M
True
```

In this interpretation of symmetric functions as characters on the symmetric group, the multiplication and comultiplication are interpreted as induction (from $S_n \times S_m$ to S_{n+m}) and restriction, respectively. The Schur functions can also be interpreted as characters of GL_n, see Partitions and Schur functions.

The omega involution

The ω involution is the linear extension of the map which sends e_λ to h_λ:

```
sage: h(f)
h[2, 2]
sage: e(f.omega())
e[2, 2]
```

```
>>> from sage.all import *
>>> h(f)
h[2, 2]
>>> e(f.omega())
e[2, 2]
```

The Hall scalar product

The Hall scalar product on the algebra of symmetric functions makes the Schur functions into an orthonormal basis:

```
sage: f.scalar(f)
3
```

```
>>> from sage.all import *
>>> f.scalar(f)
3
```

Skewing

Skewing is the adjoint operation to multiplication with respect to this scalar product:

```
sage: f.skew_by(s[1])
2*s[2, 1] + 2*s[3]
```

```
>>> from sage.all import *
>>> f.skew_by(s[Integer(1)])
2*s[2, 1] + 2*s[3]
```

In general, `s[la].skew_by(s[mu])` is the symmetric function typically denoted $s_{\lambda\backslash\mu}$ or $s_{\lambda/\mu}$.

Expanding into variables

We can expand a symmetric function into a symmetric polynomial in a specified number of variables:

```
sage: f.expand(2)
x0^4 + 2*x0^3*x1 + 3*x0^2*x1^2 + 2*x0*x1^3 + x1^4
```

```
>>> from sage.all import *
>>> f.expand(Integer(2))
x0^4 + 2*x0^3*x1 + 3*x0^2*x1^2 + 2*x0*x1^3 + x1^4
```

See the documentation for `expand` for more examples.

The Kronecker product

As in the section on the *Representation theory of the symmetric group*, a symmetric function may be considered as a class function on the symmetric group where the elements p_μ/z_μ are the indicators of a permutation having cycle structure μ. The Kronecker product of two symmetric functions corresponds to the pointwise product of these class functions.

Since the Schur functions are the irreducible characters of the symmetric group under this identification, the Kronecker product of two Schur functions corresponds to the internal tensor product of two irreducible symmetric group representations.

Under this identification, the Kronecker product of p_μ/z_μ and p_ν/z_ν is p_μ/z_μ if $\mu = \nu$, and the result is equal to 0 otherwise.

`internal_product`, `kronecker_product`, `inner_tensor` and `itensor` are different names for the same function.

```
sage: f.kronecker_product(f)
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 4*s[2, 2] + 5*s[3, 1] + 3*s[4]
```

```
>>> from sage.all import *
>>> f.kronecker_product(f)
s[1, 1, 1, 1] + 3*s[2, 1, 1] + 4*s[2, 2] + 5*s[3, 1] + 3*s[4]
```

Plethysm

The *plethysm* of symmetric functions is the operation corresponding to composition of representations of the general linear group. See [STA] Chapter 7, Appendix 2 for details.

```
sage: s[2].plethysm(s[2])
s[2, 2] + s[4]
```

```
>>> from sage.all import *
>>> s[Integer(2)].plethysm(s[Integer(2)])
s[2, 2] + s[4]
```

Plethysm can also be written as a composition of functions:

```
sage: s[2]( s[2] )
s[2, 2] + s[4]
```

```
>>> from sage.all import *
>>> s[Integer(2)]( s[Integer(2)] )
s[2, 2] + s[4]
```

If the coefficient ring contains degree 1 elements, these are handled properly by plethysm:

```
sage: R.<t> = QQ[]; s = SymmetricFunctions(R).schur()
sage: s[2]( (1-t)*s[1] )
(t^2-t)*s[1, 1] + (-t+1)*s[2]
```

```
>>> from sage.all import *
>>> R = QQ['t']; (t,) = R._first_ngens(1); s = SymmetricFunctions(R).schur()
>>> s[Integer(2)]( (Integer(1)-t)*s[Integer(1)] )
(t^2-t)*s[1, 1] + (-t+1)*s[2]
```

See the documentation for `plethysm` for more information.

Inner plethysm

The operation of inner plethysm `f.inner_plethysm(g)` models the composition of the S_n representation represented by g with the GL_m representation whose character is f. See the documentation of `inner_plethysm`, [ST94] or [STA], exercise 7.74 solutions for more information:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: f = s[2]^2
sage: f.inner_plethysm(s[2])
s[2]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()
>>> f = s[Integer(2)]**Integer(2)
>>> f.inner_plethysm(s[Integer(2)])
s[2]
```

Hopf algebra structure

The ring of symmetric functions is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; the power sum generators are primitive:

```
sage: p[1].coproduct()
p[] # p[1] + p[1] # p[]
sage: p[2].coproduct()
p[] # p[2] + p[2] # p[]
```

```
>>> from sage.all import *
>>> p[Integer(1)].coproduct()
p[] # p[1] + p[1] # p[]
>>> p[Integer(2)].coproduct()
p[] # p[2] + p[2] # p[]
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```
sage: p[2, 1].coproduct()
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]
```

```
>>> from sage.all import *
>>> p[Integer(2), Integer(1)].coproduct()
p[] # p[2, 1] + p[1] # p[2] + p[2] # p[1] + p[2, 1] # p[]
```

This coproduct, along with the counit which sends every symmetric function to its 0-th homogeneous component, makes the ring of symmetric functions into a graded connected bialgebra. It is known that every graded connected bialgebra has an antipode. For the ring of symmetric functions, the antipode can be characterized explicitly: The antipode is an anti-algebra morphism (thus an algebra morphism, since our algebra is commutative) which sends p_λ to $(-1)^{\mathrm{length}(\lambda)} p_\lambda$ for every partition λ. Thus, in particular, it sends the generators on the `p` basis to their opposites:

```
sage: p[3].antipode()
-p[3]
sage: p[3,2,1].antipode()
-p[3, 2, 1]
```

```
>>> from sage.all import *
>>> p[Integer(3)].antipode()
-p[3]
>>> p[Integer(3),Integer(2),Integer(1)].antipode()
-p[3, 2, 1]
```

The graded connected bialgebra of symmetric functions over a **Q**-algebra has a rather simply-understood structure: It is (isomorphic to) the symmetric algebra of its space of primitives (which is spanned by the power-sum symmetric functions).

Here are further examples:

```
sage: f = s[2]^2
sage: f.antipode()
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2]
sage: f.coproduct()
s[] # s[2, 2] + s[] # s[3, 1] + s[] # s[4] + 2*s[1] # s[2, 1] + 2*s[1] # s[3] +␣
↪s[1, 1] # s[1, 1]
+ s[1, 1] # s[2] + s[2] # s[1, 1] + 3*s[2] # s[2] + 2*s[2, 1] # s[1] + s[2, 2] #␣
↪s[] + 2*s[3] # s[1]
+ s[3, 1] # s[] + s[4] # s[]
sage: f.coproduct().apply_multilinear_morphism( lambda x,y: x*y.antipode() )
0
```

```
>>> from sage.all import *
>>> f = s[Integer(2)]**Integer(2)
>>> f.antipode()
s[1, 1, 1, 1] + s[2, 1, 1] + s[2, 2]
>>> f.coproduct()
s[] # s[2, 2] + s[] # s[3, 1] + s[] # s[4] + 2*s[1] # s[2, 1] + 2*s[1] # s[3] +␣
↪s[1, 1] # s[1, 1]
+ s[1, 1] # s[2] + s[2] # s[1, 1] + 3*s[2] # s[2] + 2*s[2, 1] # s[1] + s[2, 2] #␣
↪s[] + 2*s[3] # s[1]
+ s[3, 1] # s[] + s[4] # s[]
```

(continues on next page)

(continued from previous page)

```
>>> f.coproduct().apply_multilinear_morphism( lambda x,y: x*y.antipode() )
0
```

Transformations of symmetric functions

There are many methods in Sage which make it easy to manipulate symmetric functions. For example, if we have some function which acts on partitions (say, conjugation), it is a simple matter to apply it to the support of a symmetric function. Here is an example:

```
sage: conj = lambda mu: mu.conjugate()
sage: f = h[4] + 2*h[3,1]
sage: f.map_support(conj)
h[1, 1, 1, 1] + 2*h[2, 1, 1]
```

```
>>> from sage.all import *
>>> conj = lambda mu: mu.conjugate()
>>> f = h[Integer(4)] + Integer(2)*h[Integer(3),Integer(1)]
>>> f.map_support(conj)
h[1, 1, 1, 1] + 2*h[2, 1, 1]
```

We can also easily modify the coefficients:

```
sage: def foo(mu, coeff): return mu.conjugate(), -coeff
sage: f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

```
>>> from sage.all import *
>>> def foo(mu, coeff): return mu.conjugate(), -coeff
>>> f.map_item(foo)
-h[1, 1, 1, 1] - 2*h[2, 1, 1]
```

See also `map_coefficients`.

There are also methods for building functions directly:

```
sage: s.sum_of_monomials(mu for mu in Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_monomials(Partitions(3))
s[1, 1, 1] + s[2, 1] + s[3]
sage: s.sum_of_terms( (mu, mu[0]) for mu in Partitions(3))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]
```

```
>>> from sage.all import *
>>> s.sum_of_monomials(mu for mu in Partitions(Integer(3)))
s[1, 1, 1] + s[2, 1] + s[3]
>>> s.sum_of_monomials(Partitions(Integer(3)))
s[1, 1, 1] + s[2, 1] + s[3]
>>> s.sum_of_terms( (mu, mu[Integer(0)]) for mu in Partitions(Integer(3)))
s[1, 1, 1] + 2*s[2, 1] + 3*s[3]
```

These are the preferred way to build elements within a program; the result will usually be faster than using `sum()`. It also guarantees that empty sums yields the zero of `s` (see also `s.sum`).

Note also that it is a good idea to use:

```
sage: s.one()
s[]
sage: s.zero()
0
```

```
>>> from sage.all import *
>>> s.one()
s[]
>>> s.zero()
0
```

instead of `s(1)` and `s(0)` within programs where speed is important, in order to prevent unnecessary coercions.

Different base rings

Depending on the base ring, the different realizations of the symmetric function algebra may not span the same space:

```
sage: SZ = SymmetricFunctions(ZZ)
sage: p = SZ.power(); s = SZ.schur()
sage: p(s[1,1,1])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

```
>>> from sage.all import *
>>> SZ = SymmetricFunctions(ZZ)
>>> p = SZ.power(); s = SZ.schur()
>>> p(s[Integer(1),Integer(1),Integer(1)])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

Because of this, some functions may not behave as expected when working over the integers, even though they make mathematical sense:

```
sage: s[1,1,1].plethysm(s[1,1,1])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

```
>>> from sage.all import *
>>> s[Integer(1),Integer(1),Integer(1)].plethysm(s[Integer(1),Integer(1),
↪Integer(1)])
Traceback (most recent call last):
...
TypeError: no conversion of this rational to integer
```

It is possible to work over different base rings simultaneously:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: p = SymmetricFunctions(QQ).power()
sage: sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'
sage: pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'
sage: p(sz[1,1,1])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3]
sage: sz( 1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3] )
sz[1, 1, 1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()
>>> p = SymmetricFunctions(QQ).power()
>>> sz = SymmetricFunctions(ZZ).schur(); sz._prefix = 'sz'
>>> pz = SymmetricFunctions(ZZ).power(); pz._prefix = 'pz'
>>> p(sz[Integer(1),Integer(1),Integer(1)])
1/6*p[1, 1, 1] - 1/2*p[2, 1] + 1/3*p[3]
>>> sz( Integer(1)/Integer(6)*p[Integer(1), Integer(1), Integer(1)] - Integer(1)/
↪Integer(2)*p[Integer(2), Integer(1)] + Integer(1)/Integer(3)*p[Integer(3)] )
sz[1, 1, 1]
```

As shown in this example, if you are working over multiple base rings simultaneously, it is a good idea to change the prefix in some cases, so that you can tell from the output which realization your result is in.

Let us change the notation back for the remainder of this tutorial:

```
sage: sz._prefix = 's'
sage: pz._prefix = 'p'
```

```
>>> from sage.all import *
>>> sz._prefix = 's'
>>> pz._prefix = 'p'
```

One can also use the Sage standard renaming idiom to get shorter outputs:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.rename('Sym')
sage: Sym
Sym
sage: Sym.rename()
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.rename('Sym')
>>> Sym
Sym
>>> Sym.rename()
```

And we name it back:

```
sage: Sym.rename('Symmetric Functions over Rational Field'); Sym
Symmetric Functions over Rational Field
```

```
>>> from sage.all import *
>>> Sym.rename('Symmetric Functions over Rational Field'); Sym
Symmetric Functions over Rational Field
```

Other bases

There are two additional basis of the symmetric functions which are not considered as classical bases:

- forgotten basis
- Witt basis

The forgotten basis is the dual basis of the elementary symmetric functions basis with respect to the Hall scalar product. The Witt basis can be constructed by

$$\prod_{d=1}^{\infty}(1-w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n$$

where t is a formal variable.

There are further bases of the ring of symmetric functions, in general over fields with parameters such as q and t:

- Hall-Littlewood bases
- Jack bases
- Macdonald bases
- k-Schur functions
- Hecke character basis

We briefly demonstrate how to access these bases. For more information, see the documentation of the individual bases.

The *Jack polynomials* can be obtained as:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: Jack = Sym.jack()
sage: P = Jack.P(); J = Jack.J(); Q = Jack.Q()
sage: J(P[2,1])
(1/(t+2))*JackJ[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> Jack = Sym.jack()
>>> P = Jack.P(); J = Jack.J(); Q = Jack.Q()
>>> J(P[Integer(2),Integer(1)])
(1/(t+2))*JackJ[2, 1]
```

The parameter t can be specialized as follows:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Jack = Sym.jack(t = 1)
sage: P = Jack.P(); J = Jack.J(); Q = Jack.Q()
sage: J(P[2,1])
1/3*JackJ[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Jack = Sym.jack(t = Integer(1))
>>> P = Jack.P(); J = Jack.J(); Q = Jack.Q()
>>> J(P[Integer(2),Integer(1)])
1/3*JackJ[2, 1]
```

Similarly one can access the Hall-Littlewood and Macdonald polynomials, etc:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: Mcd = Sym.macdonald()
sage: P = Mcd.P(); J = Mcd.J(); Q = Mcd.Q()
sage: J(P[2,1])
(1/(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1))*McdJ[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> Mcd = Sym.macdonald()
>>> P = Mcd.P(); J = Mcd.J(); Q = Mcd.Q()
>>> J(P[Integer(2),Integer(1)])
(1/(-q*t^4+2*q*t^3-q*t^2+t^2-2*t+1))*McdJ[2, 1]
```

We can also construct the $\bar{q}$ basis that can be used to determine character tables for Hecke algebras (with quadratic relation $T_i^2 = (1-q)T_i + q$):

```
sage: Sym = SymmetricFunctions(ZZ['q'].fraction_field())
sage: qbar = Sym.hecke_character()
sage: s = Sym.s()
sage: s(qbar[2,1])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ['q'].fraction_field())
>>> qbar = Sym.hecke_character()
>>> s = Sym.s()
>>> s(qbar[Integer(2),Integer(1)])
-s[1, 1, 1] + (q-1)*s[2, 1] + q*s[3]
```

k-Schur functions

The k-Schur functions live in the k-bounded subspace of the ring of symmetric functions. It is possible to compute in the k-bounded subspace directly:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: f = ks[2,1]*ks[2,1]; f
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(3),Integer(1))
>>> f = ks[Integer(2),Integer(1)]*ks[Integer(2),Integer(1)]; f
ks3[2, 2, 1, 1] + ks3[2, 2, 2] + ks3[3, 1, 1, 1]
```

or to lift to the ring of symmetric functions:

```
sage: f.lift()
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1]␣
↪+ s[4, 2]
```

```
>>> from sage.all import *
>>> f.lift()
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[3, 3] + s[4, 1, 1]␣
↪+ s[4, 2]
```

However, it is not always possible to convert a symmetric function to the k-bounded subspace:

```
sage: s = Sym.schur()
sage: ks(s[2,1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

```
>>> from sage.all import *
>>> s = Sym.schur()
>>> ks(s[Integer(2),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1] is not in the image
```

The k-Schur functions are more generally defined with a parameter t and they are a basis of the subspace spanned by the Hall-Littlewood `Qp` symmetric functions indexed by partitions whose first part is less than or equal to k:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: SymS3 = Sym.kBoundedSubspace(3) # default t='t'
sage: ks = SymS3.kschur()
sage: Qp = Sym.hall_littlewood().Qp()
sage: ks(Qp[2,1,1,1])
ks3[2, 1, 1, 1] + (t^2+t)*ks3[2, 2, 1] + (t^3+t^2)*ks3[3, 1, 1] + t^4*ks3[3, 2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> SymS3 = Sym.kBoundedSubspace(Integer(3)) # default t='t'
>>> ks = SymS3.kschur()
>>> Qp = Sym.hall_littlewood().Qp()
>>> ks(Qp[Integer(2),Integer(1),Integer(1),Integer(1)])
ks3[2, 1, 1, 1] + (t^2+t)*ks3[2, 2, 1] + (t^3+t^2)*ks3[3, 1, 1] + t^4*ks3[3, 2]
```

The subspace spanned by the k-Schur functions with a parameter t are not known to form a natural algebra. However it is known that the product of a k-Schur function and an ℓ-Schur function is in the linear span of the $k+\ell$-Schur functions:

```
sage: ks(ks[2,1]*ks[1,1])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] is not in the image
sage: ks[2,1]*ks[1,1]
```

(continues on next page)

(continued from previous page)

```
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
sage: ks6 = Sym.kBoundedSubspace(6).kschur()
sage: ks6(ks[3,1,1]*ks[3])
ks6[3, 3, 1, 1] + ks6[4, 2, 1, 1] + (t+1)*ks6[4, 3, 1] + t*ks6[4, 4]
+ ks6[5, 1, 1, 1] + ks6[5, 2, 1] + t*ks6[5, 3] + ks6[6, 1, 1]
```

```
>>> from sage.all import *
>>> ks(ks[Integer(2),Integer(1)]*ks[Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] is not in the image
>>> ks[Integer(2),Integer(1)]*ks[Integer(1),Integer(1)]
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
>>> ks6 = Sym.kBoundedSubspace(Integer(6)).kschur()
>>> ks6(ks[Integer(3),Integer(1),Integer(1)]*ks[Integer(3)])
ks6[3, 3, 1, 1] + ks6[4, 2, 1, 1] + (t+1)*ks6[4, 3, 1] + t*ks6[4, 4]
+ ks6[5, 1, 1, 1] + ks6[5, 2, 1] + t*ks6[5, 3] + ks6[6, 1, 1]
```

The k-split basis is a second basis of the ring spanned by the k-Schur functions with a parameter t. The k-split basis has the property that $Q'_\lambda[X;t]$ expands positively in the k-split basis and the k-split basis conjecturally expands positively in the k-Schur functions. The definition can be found in [LLMSSZ] p. 81.:

```
sage: ksp3 = SymS3.ksplit()
sage: ksp3(Qp[2,1,1,1])
ksp3[2, 1, 1, 1] + t^2*ksp3[2, 2, 1] + (t^3+t^2)*ksp3[3, 1, 1] + t^4*ksp3[3, 2]
sage: [ks(ksp3(la)) for la in sorted(ksp3(Qp[2,1,1,1]).support())]
[ks3[2, 1, 1, 1] + t*ks3[2, 2, 1], ks3[2, 2, 1], ks3[3, 1, 1], ks3[3, 2]]
```

```
>>> from sage.all import *
>>> ksp3 = SymS3.ksplit()
>>> ksp3(Qp[Integer(2),Integer(1),Integer(1),Integer(1)])
ksp3[2, 1, 1, 1] + t^2*ksp3[2, 2, 1] + (t^3+t^2)*ksp3[3, 1, 1] + t^4*ksp3[3, 2]
>>> [ks(ksp3(la)) for la in sorted(ksp3(Qp[Integer(2),Integer(1),Integer(1),
→Integer(1)]).support())]
[ks3[2, 1, 1, 1] + t*ks3[2, 2, 1], ks3[2, 2, 1], ks3[3, 1, 1], ks3[3, 2]]
```

dual k-Schur functions

The dual space to the subspace spanned by the k-Schur functions is most naturally realized as a quotient of the ring of symmetric functions by an ideal. When $t = 1$ the ideal is generated by the monomial symmetric functions indexed by partitions whose first part is greater than k.:

```
sage: Sym = SymmetricFunctions(QQ)
sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: km = SymQ3.kmonomial()
sage: km[2,1]*km[2,1]
4*m3[2, 2, 1, 1] + 6*m3[2, 2, 2] + 2*m3[3, 2, 1] + 2*m3[3, 3]
sage: F = SymQ3.affineSchur()
sage: F[2,1]*F[2,1]
2*F3[1, 1, 1, 1, 1, 1] + 4*F3[2, 1, 1, 1, 1] + 4*F3[2, 2, 1, 1] + 4*F3[2, 2, 2]
+ 2*F3[3, 1, 1, 1] + 4*F3[3, 2, 1] + 2*F3[3, 3]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> SymQ3 = Sym.kBoundedQuotient(Integer(3),t=Integer(1))
>>> km = SymQ3.kmonomial()
>>> km[Integer(2),Integer(1)]*km[Integer(2),Integer(1)]
4*m3[2, 2, 1, 1] + 6*m3[2, 2, 2] + 2*m3[3, 2, 1] + 2*m3[3, 3]
>>> F = SymQ3.affineSchur()
>>> F[Integer(2),Integer(1)]*F[Integer(2),Integer(1)]
2*F3[1, 1, 1, 1, 1, 1] + 4*F3[2, 1, 1, 1, 1] + 4*F3[2, 2, 1, 1] + 4*F3[2, 2, 2]
+ 2*F3[3, 1, 1, 1] + 4*F3[3, 2, 1] + 2*F3[3, 3]
```

When t is not equal to 1, the subspace spanned by the k-Schur functions is realized as a quotient of the ring of symmetric functions by the ideal generated by the Hall-Littlewood symmetric functions in the P basis indexed by partitions with first part greater than k.:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: SymQ3 = Sym.kBoundedQuotient(3)
sage: kHLP = SymQ3.kHallLittlewoodP()
sage: kHLP[2,1]*kHLP[2,1]
(t^2+2*t+1)*HLP3[2, 2, 1, 1] + (t^3+2*t^2+2*t+1)*HLP3[2, 2, 2]
+ (-t^4-t^3+t+1)*HLP3[3, 1, 1, 1] + (-t^2+t+2)*HLP3[3, 2, 1] + (t+1)*HLP3[3, 3]
sage: HLP = Sym.hall_littlewood().P()
sage: kHLP(HLP[3,1])
HLP3[3, 1]
sage: kHLP(HLP[4])
0
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> SymQ3 = Sym.kBoundedQuotient(Integer(3))
>>> kHLP = SymQ3.kHallLittlewoodP()
>>> kHLP[Integer(2),Integer(1)]*kHLP[Integer(2),Integer(1)]
(t^2+2*t+1)*HLP3[2, 2, 1, 1] + (t^3+2*t^2+2*t+1)*HLP3[2, 2, 2]
+ (-t^4-t^3+t+1)*HLP3[3, 1, 1, 1] + (-t^2+t+2)*HLP3[3, 2, 1] + (t+1)*HLP3[3, 3]
>>> HLP = Sym.hall_littlewood().P()
>>> kHLP(HLP[Integer(3),Integer(1)])
HLP3[3, 1]
>>> kHLP(HLP[Integer(4)])
0
```

In this space, the basis which is dual to the k-Schur functions conjecturally expands positively in the k-bounded Hall-Littlewood functions and has positive structure coefficients.:

```
sage: dks = SymQ3.dual_k_Schur()
sage: kHLP(dks[2,2])
(t^4+t^2)*HLP3[1, 1, 1, 1] + t*HLP3[2, 1, 1] + HLP3[2, 2]
sage: dks[2,1]*dks[1,1]
(t^2+t)*dks3[1, 1, 1, 1, 1] + (t+1)*dks3[2, 1, 1, 1] + (t+1)*dks3[2, 2, 1]
+ dks3[3, 1, 1] + dks3[3, 2]
```

```
>>> from sage.all import *
>>> dks = SymQ3.dual_k_Schur()
>>> kHLP(dks[Integer(2),Integer(2)])
```

(continues on next page)

(continued from previous page)

```
(t^4+t^2)*HLP3[1, 1, 1, 1] + t*HLP3[2, 1, 1] + HLP3[2, 2]
>>> dks[Integer(2),Integer(1)]*dks[Integer(1),Integer(1)]
(t^2+t)*dks3[1, 1, 1, 1, 1] + (t+1)*dks3[2, 1, 1, 1] + (t+1)*dks3[2, 2, 1]
+ dks3[3, 1, 1] + dks3[3, 2]
```

At $t = 1$ the k-bounded Hall-Littlewood basis is equal to the k-bounded monomial basis and the dual k-Schur elements are equal to the affine Schur basis. The k-bounded monomial basis and affine Schur functions are faster and should be used instead of the k-bounded Hall-Littlewood P basis and dual k-Schur functions when $t = 1$.:

```
sage: SymQ3 = Sym.kBoundedQuotient(3,t=1)
sage: dks = SymQ3.dual_k_Schur()
sage: F = SymQ3.affineSchur()
sage: F[3,1]==dks[3,1]
True
```

```
>>> from sage.all import *
>>> SymQ3 = Sym.kBoundedQuotient(Integer(3),t=Integer(1))
>>> dks = SymQ3.dual_k_Schur()
>>> F = SymQ3.affineSchur()
>>> F[Integer(3),Integer(1)]==dks[Integer(3),Integer(1)]
True
```

Implementing new bases

In order to implement a new symmetric function basis, Sage will need to know at a minimum how to change back and forth between at least one other basis (although they do not necessarily have to be the same basis). All of the standard functions associated with the basis will have a default implementation (although a more specific implementation may be more efficient).

To present an idea of how this is done, we will create here the example of how to implement the basis $s_\mu[X(1-t)]$.

To begin, we import the class *sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic()*. Our new basis will inherit all of the default methods from this class:

```
sage: from sage.combinat.sf.sfa import SymmetricFunctionAlgebra_generic as SFA_
↪generic
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import SymmetricFunctionAlgebra_generic as SFA_
↪generic
```

Now the basis we are creating has a parameter t which is possible to specialize. In this example we will convert to and from the Schur basis. For this we implement methods `_self_to_s` and `_s_to_self`. By registering these two functions as coercions, Sage then knows automatically how it possible to change between any two bases for which there is a path of changes of bases.

```
sage: from sage.categories.morphism import SetMorphism
sage: class SFA_st(SFA_generic):
....:     def __init__(self, Sym, t):
....:         SFA_generic.__init__(self, Sym, basis_name=
....:           "Schur functions with a plethystic substitution of X -> X(1-t)",
....:           prefix='st')
....:         self._s = Sym.s()
```

(continues on next page)

(continued from previous page)

```
....:         self.t = Sym.base_ring()(t)
....:         cat = HopfAlgebras(Sym.base_ring()).WithBasis()
....:         self.register_coercion(
....:           SetMorphism(Hom(self._s, self, cat), self._s_to_self))
....:         self._s.register_coercion(
....:           SetMorphism(Hom(self, self._s, cat), self._self_to_s))
....:     def _s_to_self(self, f):
....:         # f is a Schur function and the output is in the st basis
....:         return self._from_dict(f.theta_qt(0,self.t)._monomial_coefficients)
....:     def _self_to_s(self, f):
....:         # f is in the st basis and the output is in the Schur basis
....:         return self._s.sum(cmu*self._s(mu).theta_qt(self.t,0) for mu,cmu in␣
↪f)
....:     class Element(SFA_generic.Element):
....:         pass
```

```
>>> from sage.all import *
>>> from sage.categories.morphism import SetMorphism
>>> class SFA_st(SFA_generic):
...     def __init__(self, Sym, t):
...         SFA_generic.__init__(self, Sym, basis_name=
...           "Schur functions with a plethystic substitution of X -> X(1-t)",
...           prefix='st')
...         self._s = Sym.s()
...         self.t = Sym.base_ring()(t)
...         cat = HopfAlgebras(Sym.base_ring()).WithBasis()
...         self.register_coercion(
...           SetMorphism(Hom(self._s, self, cat), self._s_to_self))
...         self._s.register_coercion(
...           SetMorphism(Hom(self, self._s, cat), self._self_to_s))
...     def _s_to_self(self, f):
...         # f is a Schur function and the output is in the st basis
...         return self._from_dict(f.theta_qt(Integer(0),self.t)._monomial_
↪coefficients)
...     def _self_to_s(self, f):
...         # f is in the st basis and the output is in the Schur basis
...         return self._s.sum(cmu*self._s(mu).theta_qt(self.t,Integer(0)) for mu,
↪cmu in f)
...     class Element(SFA_generic.Element):
...         pass
```

An instance of this basis is created by calling it with a symmetric function ring `Sym` and a parameter `t` which is in the base ring of `Sym`. The `Element` class inherits all of the methods from `sage.combinat.sf.sfa.SymmetricFunctionAlgebra_generic_Element`.

In the reference [MAC] on page 354, this basis is denoted $S_\lambda(x;t)$ and the change of basis coefficients of the Macdonald `J` basis are the coefficients $K_{\lambda\mu}(q,t)$. Here is an example of its use:

```
sage: QQqt = QQ['q','t'].fraction_field()
sage: (q,t) = QQqt.gens()
sage: st = SFA_st(SymmetricFunctions(QQqt),t)
sage: st
```

>>> st[Integer(2),Integer(1)] * st[Integer(1)]
st[2, 1, 1] + st[2, 2] + st[3, 1]
>>> st([Integer(2)]).coproduct()
st[] # st[2] + st[1] # st[1] + st[2] # st[]
>>> J = st.symmetric_function_ring().macdonald().J()
>>> st(J[Integer(2),Integer(1)])
q*st[1, 1, 1] + (q*t+1)*st[2, 1] + t*st[3]
```

Acknowledgements

The design is heavily inspired from the implementation of symmetric functions in MuPAD-Combinat (see [HT04] and [FD06]).

REFERENCES:

Further tests

Todo

- Introduce fields with degree 1 elements as in MuPAD-Combinat, to get proper plethysm.
- Use UniqueRepresentation to get rid of all the manual cache handling for the bases
- Devise a mechanism so that pickling bases of symmetric functions pickles the coercions which have a cache.

Schur()

The Schur basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

Witt (*coerce_h=None*, *coerce_e=None*, *coerce_p=None*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

a_realization ()

Return a particular realization of `self` (the Schur basis).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> Sym.a_realization()
Symmetric Functions over Rational Field in the Schur basis
```

complete ()

The complete basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

e ()

The elementary basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

elementary()

The elementary basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).elementary()
Symmetric Functions over Rational Field in the elementary basis
```

f()

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

forgotten()

The forgotten basis of the Symmetric Functions (or the basis dual to the elementary basis with respect to the Hall scalar product).

EXAMPLES:

```
sage: SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).forgotten()
Symmetric Functions over Rational Field in the forgotten basis
```

from_polynomial(f)

Convert a symmetric polynomial `f` to a symmetric function.

INPUT:

- `f` – a symmetric polynomial

This function converts a symmetric polynomial f in a polynomial ring in finitely many variables to a symmetric function in the monomial basis of the ring of symmetric functions over the same base ring.

EXAMPLES:

```
sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: S = SymmetricFunctions(QQ)
sage: S.from_polynomial(f)
m[1]

sage: f = x[0] + 2*x[1] + x[2]
sage: S.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a symmetric polynomial
```

```
>>> from sage.all import *
>>> P = PolynomialRing(QQ, 'x', Integer(3))
>>> x = P.gens()
>>> f = x[Integer(0)] + x[Integer(1)] + x[Integer(2)]
>>> S = SymmetricFunctions(QQ)
>>> S.from_polynomial(f)
m[1]

>>> f = x[Integer(0)] + Integer(2)*x[Integer(1)] + x[Integer(2)]
>>> S.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a symmetric polynomial
```

h()

The complete basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

hall_littlewood(*t='t'*)

Return the entry point for the various Hall-Littlewood bases.

INPUT:

- `t` – parameter

Hall-Littlewood symmetric functions including bases P, Q, Qp. The Hall-Littlewood P and Q functions at $t = -1$ are the Schur-P and Schur-Q functions when indexed by strict partitions.

The parameter t must be in the base ring of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: P = Sym.hall_littlewood().P(); P
```

(continues on next page)

(continued from previous page)

```
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood P basis
sage: P[2]
HLP[2]
sage: Q = Sym.hall_littlewood().Q(); Q
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Q basis
sage: Q[2]
HLQ[2]
sage: Qp = Sym.hall_littlewood().Qp(); Qp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Qp basis
sage: Qp[2]
HLQp[2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> P = Sym.hall_littlewood().P(); P
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood P basis
>>> P[Integer(2)]
HLP[2]
>>> Q = Sym.hall_littlewood().Q(); Q
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Q basis
>>> Q[Integer(2)]
HLQ[2]
>>> Qp = Sym.hall_littlewood().Qp(); Qp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Hall-Littlewood Qp basis
>>> Qp[Integer(2)]
HLQp[2]
```

hecke_character(*q='q'*)

The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:

```
sage: SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
 Fraction Field of Univariate Polynomial Ring in q over Integer Ring
 in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
Symmetric Functions over Rational Field in the Hecke character with q=1/2␣
↪basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
 Fraction Field of Univariate Polynomial Ring in q over Integer Ring
 in the Hecke character with q=q basis
>>> SymmetricFunctions(QQ).hecke_character(Integer(1)/Integer(2))
```

(continues on next page)

(continued from previous page)

```
Symmetric Functions over Rational Field in the Hecke character with q=1/2␣
↪basis
```

homogeneous()

The complete basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).complete()
Symmetric Functions over Rational Field in the homogeneous basis
```

ht()

The induced trivial character basis of the Symmetric Functions.

The trivial character of

$$S_{n-|\lambda|} \times S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_{\ell(\lambda)}}$$

induced to the group S_n is a symmetric function in the eigenvalues of a permutation matrix. This basis is that character.

It has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the coefficient $\langle h_{(n-|\lambda|,\lambda)}, p_\rho \rangle$.

In terms of methods that are implemented in Sage, if `n` is a sufficiently large integer, then `ht(lam).character_to_frobenius_image(n)` is equal the complete function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

```

irreducible_symmetric_group_character()

The irreducible S_n character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the irreducible character $\chi^{(|\rho|-|\lambda|,\lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if `n` is a sufficiently large integer, then `st(lam).character_to_frobenius_image(n)` is equal the Schur function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also

character_to_frobenius_image(), *eval_at_permutation_roots()*

EXAMPLES:

```
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group␣
↪character basis
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))

[4, 2, 0, 1, -1, 0, -1]
```

jack (*t='t'*)

Return the entry point for the various Jack bases.

INPUT:

- `t` – parameter

Jack symmetric functions including bases P, Q, Qp.

The parameter t must be in the base ring of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: JP = Sym.jack().P(); JP
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack P basis
sage: JQ = Sym.jack().Q(); JQ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
```

(continues on next page)

(continued from previous page)

```
↪over Rational Field in the Jack Q basis
sage: JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack J basis
sage: JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack Qp basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['t']))
>>> JP = Sym.jack().P(); JP

↪over Rational Field in the Jack Q basis
>>> JJ = Sym.jack().J(); JJ
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack J basis
>>> JQp = Sym.jack().Qp(); JQp
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the Jack Qp basis
```

kBoundedQuotient(*k*, *t='t'*)

Return the k-bounded quotient space of the ring of symmetric functions.

INPUT:

- k – positive integer

The quotient of the ring of symmetric functions …

See also

sage.combinat.sf.k_dual.KBoundedQuotient()

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KQ = Sym.kBoundedQuotient(3); KQ
Traceback (most recent call last):
...
TypeError: unable to convert 't' to a rational
sage: KQ = Sym.kBoundedQuotient(3,t=1); KQ
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: KQ = Sym.kBoundedQuotient(3); KQ
3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
```

(continues on next page)

(continued from previous page)

```
>>> KQ = Sym.kBoundedQuotient(Integer(3)); KQ
Traceback (most recent call last):
...
TypeError: unable to convert 't' to a rational
>>> KQ = Sym.kBoundedQuotient(Integer(3),t=Integer(1)); KQ
3-Bounded Quotient of Symmetric Functions over Rational Field with t=1
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> KQ = Sym.kBoundedQuotient(Integer(3)); KQ
3-Bounded Quotient of Symmetric Functions over Fraction Field of Univariate␣
↪Polynomial Ring in t over Rational Field
```

kBoundedSubspace(k, t='t')

Return the k-bounded subspace of the ring of symmetric functions.

INPUT:

- `k` – positive integer
- `t` – a formal parameter; $t = 1$ yields a subring

The subspace of the ring of symmetric functions spanned by $\{s_\lambda[X/(1-t)]\}_{\lambda_1\le k} = \{s_\lambda^{(k)}[X,t]\}_{\lambda_1\le k}$ over the base ring $\mathbf{Q}[t]$. When $t = 1$, this space is in fact a subalgebra of the ring of symmetric functions generated by the complete homogeneous symmetric functions h_i for $1 \le i \le k$.

See also

sage.combinat.sf.new_kschur.KBoundedSubspace()

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: KB = Sym.kBoundedSubspace(3,1); KB
3-bounded Symmetric Functions over Rational Field with t=1

sage: Sym = SymmetricFunctions(QQ['t'])
sage: Sym.kBoundedSubspace(3)
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
↪Rational Field

sage: Sym = SymmetricFunctions(QQ['z'])
sage: z = Sym.base_ring().gens()[0]
sage: Sym.kBoundedSubspace(3,t=z)
3-bounded Symmetric Functions over Univariate Polynomial Ring in z over␣
↪Rational Field with t=z
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> KB = Sym.kBoundedSubspace(Integer(3),Integer(1)); KB
3-bounded Symmetric Functions over Rational Field with t=1

>>> Sym = SymmetricFunctions(QQ['t'])
>>> Sym.kBoundedSubspace(Integer(3))
3-bounded Symmetric Functions over Univariate Polynomial Ring in t over␣
```

(continues on next page)

(continued from previous page)

```
↪Rational Field

>>> Sym = SymmetricFunctions(QQ['z'])
>>> z = Sym.base_ring().gens()[Integer(0)]
>>> Sym.kBoundedSubspace(Integer(3),t=z)
3-bounded Symmetric Functions over Univariate Polynomial Ring in z over␣
↪Rational Field with t=z
```

khomogeneous(*k*)

Return the homogeneous symmetric functions in the k-bounded subspace.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: kh = Sym.khomogeneous(4)
sage: kh[3]*kh[4]
h4[4, 3]
sage: kh[4].lift()
h[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> kh = Sym.khomogeneous(Integer(4))
>>> kh[Integer(3)]*kh[Integer(4)]
h4[4, 3]
>>> kh[Integer(4)].lift()
h[4]
```

kschur(*k*, *t='t'*)

Return the k-Schur functions.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ks = Sym.kschur(3,1)
sage: ks[2]*ks[2]
ks3[2, 2] + ks3[3, 1]
sage: ks[2,1,1].lift()
s[2, 1, 1] + s[3, 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ks = Sym.kschur(3)
sage: ks[2,2,1].lift()
s[2, 2, 1] + t*s[3, 2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ks = Sym.kschur(Integer(3),Integer(1))
>>> ks[Integer(2)]*ks[Integer(2)]
ks3[2, 2] + ks3[3, 1]
>>> ks[Integer(2),Integer(1),Integer(1)].lift()
s[2, 1, 1] + s[3, 1]
```

(continues on next page)

(continued from previous page)

```
>>> Sym = SymmetricFunctions(QQ['t'])
>>> ks = Sym.kschur(Integer(3))
>>> ks[Integer(2),Integer(2),Integer(1)].lift()
s[2, 2, 1] + t*s[3, 2]
```

ksplit(*k*, *t='t'*)

Return the k-split basis of the k-bounded subspace.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: ksp = Sym.ksplit(3,1)
sage: ksp[2]*ksp[2]
ksp3[2, 2] + ksp3[3, 1]
sage: ksp[2,1,1].lift()
s[2, 1, 1] + s[2, 2] + s[3, 1]

sage: Sym = SymmetricFunctions(QQ['t'])
sage: ksp = Sym.ksplit(3)
sage: ksp[2,1,1].lift()
s[2, 1, 1] + t*s[2, 2] + t*s[3, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> ksp = Sym.ksplit(Integer(3),Integer(1))
>>> ksp[Integer(2)]*ksp[Integer(2)]
ksp3[2, 2] + ksp3[3, 1]
>>> ksp[Integer(2),Integer(1),Integer(1)].lift()
s[2, 1, 1] + s[2, 2] + s[3, 1]

>>> Sym = SymmetricFunctions(QQ['t'])
>>> ksp = Sym.ksplit(Integer(3))
>>> ksp[Integer(2),Integer(1),Integer(1)].lift()
s[2, 1, 1] + t*s[2, 2] + t*s[3, 1]
```

llt(*k*, *t='t'*)

The LLT symmetric functions.

INPUT:

- `k` – positive integer indicating the level
- `t` – a parameter (default: t)

LLT polynomials in $hspin$ and $hcospin$ bases.

EXAMPLES:

```
sage: llt3 = SymmetricFunctions(QQ['t'].fraction_field()).llt(3); llt3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in␣
↪t over Rational Field
sage: llt3.hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT spin basis
```

(continues on next page)

(continued from previous page)

```
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT cospin basis
sage: llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT cospin basis
```

```
>>> from sage.all import *
>>> llt3 = SymmetricFunctions(QQ['t'].fraction_field()).llt(Integer(3)); llt3
level 3 LLT polynomials over Fraction Field of Univariate Polynomial Ring in␣
↪t over Rational Field
>>> llt3.hspin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT spin basis
>>> llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT cospin basis
>>> llt3.hcospin()
Symmetric Functions over Fraction Field of Univariate Polynomial Ring in t␣
↪over Rational Field in the level 3 LLT cospin basis
```

m()

The monomial basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

macdonald(*q='q'*, *t='t'*)

Return the entry point for the various Macdonald bases.

INPUT:

- `q`, `t` – parameters

Macdonald symmetric functions including bases P, Q, J, H, Ht. This also contains the S basis which is dual to the Schur basis with respect to the q,t scalar product.

The parameters q and t must be in the base_ring of parent.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: P = Sym.macdonald().P(); P
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,␣
↪t over Rational Field in the Macdonald P basis
sage: P[2]
McdP[2]
sage: Q = Sym.macdonald().Q(); Q
```

(continues on next page)

(continued from previous page)

```
Symmetric Functions over Fraction Field of Multivariate Polynomial Ring in q,
↪t over Rational Field in the Macdonald Q basis
sage: S = Sym.macdonald().S()
sage: s = Sym.schur()

z^2*s[1, 1, 1, 1] + (z^2*q+z*q+z)*s[2, 1, 1] + (z^2*q^2+1)*s[2, 2] + (z*q^
↪2+z*q+q)*s[3, 1] + q^2*s[4]
```

monomial()

The monomial basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).monomial()
Symmetric Functions over Rational Field in the monomial basis
```

o()

The orthogonal basis of the symmetric functions.

See also

SymmetricFunctionAlgebra_orthogonal

EXAMPLES:

```
sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```

orthogonal()

The orthogonal basis of the symmetric functions.

See also

SymmetricFunctionAlgebra_orthogonal

EXAMPLES:

```
sage: SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).orthogonal()
Symmetric Functions over Rational Field in the orthogonal basis
```

p()

The power sum basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

power()

The power sum basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

powersum()

The power sum basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).powersum()
Symmetric Functions over Rational Field in the powersum basis
```

qbar(*q='q'*)

The basis of symmetric functions that determines the character tables for Hecke algebras.

EXAMPLES:

```
sage: SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
 Fraction Field of Univariate Polynomial Ring in q over Integer Ring
 in the Hecke character with q=q basis
sage: SymmetricFunctions(QQ).hecke_character(1/2)
```

(continues on next page)

(continued from previous page)

```
Symmetric Functions over Rational Field in the Hecke character with q=1/2␣
↪basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(ZZ['q'].fraction_field()).hecke_character()
Symmetric Functions over
 Fraction Field of Univariate Polynomial Ring in q over Integer Ring
 in the Hecke character with q=q basis
>>> SymmetricFunctions(QQ).hecke_character(Integer(1)/Integer(2))
Symmetric Functions over Rational Field in the Hecke character with q=1/2␣
↪basis
```

register_isomorphism(*morphism*, *only_conversion=False*)

Register an isomorphism between two bases of `self`, as a canonical coercion (unless the optional keyword `only_conversion` is set to `True`, in which case the isomorphism is registered as conversion only).

EXAMPLES:

We override the canonical coercion from the Schur basis to the powersum basis by a (stupid!) map $s_\lambda \mapsto 2p_\lambda$.

```
sage: Sym = SymmetricFunctions(QQ['zorglub']) # make sure we are not going to␣
↪screw up later tests
sage: s = Sym.s(); p = Sym.p().dual_basis()
sage: phi = s.module_morphism(diagonal = lambda t: 2, codomain = p)
sage: phi(s[2, 1])
2*d_p[2, 1]
sage: Sym.register_isomorphism(phi)
sage: p(s[2,1])
2*d_p[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['zorglub']) # make sure we are not going to␣
↪screw up later tests
>>> s = Sym.s(); p = Sym.p().dual_basis()
>>> phi = s.module_morphism(diagonal = lambda t: Integer(2), codomain = p)
>>> phi(s[Integer(2), Integer(1)])
2*d_p[2, 1]
>>> Sym.register_isomorphism(phi)
>>> p(s[Integer(2),Integer(1)])
2*d_p[2, 1]
```

The map is supposed to implement the canonical isomorphism between the two bases. Otherwise, the results will be mathematically wrong, as above. Use with care!

s()

The Schur basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

schur()

The Schur basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).schur()
Symmetric Functions over Rational Field in the Schur basis
```

sp()

The symplectic basis of the symmetric functions.

See also

SymmetricFunctionAlgebra_symplectic

EXAMPLES:

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

st()

The irreducible S_n character basis of the Symmetric Functions.

This basis has the property that if the element indexed by the partition λ is evaluated at the roots of a permutation of cycle structure ρ then the value is the irreducible character $\chi^{(|\rho|-|\lambda|,\lambda)}(\rho)$.

In terms of methods that are implemented in Sage, if `n` is a sufficiently large integer, then `st(lam).character_to_frobenius_image(n)` is equal the Schur function indexed by `[n-sum(lam)]+lam`.

This basis is introduced in [OZ2015].

See also

character_to_frobenius_image(), *eval_at_permutation_roots()*

EXAMPLES:

```
sage: SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group␣
↪character basis
```

(continues on next page)

(continued from previous page)

```
sage: st = SymmetricFunctions(QQ).st()
sage: s = SymmetricFunctions(QQ).s()
sage: s(st([3,2]).character_to_frobenius_image(9))
s[4, 3, 2]
sage: s(st([3,2]).character_to_frobenius_image(7))
0
sage: s(st([3,2]).character_to_frobenius_image(6))
-s[2, 2, 2]
sage: list(SymmetricGroup(5).character_table()[-2])
[4, 2, 0, 1, -1, 0, -1]
sage: list(reversed([st([1]).eval_at_permutation_roots(rho)
....:   for rho in Partitions(5)]))
[4, 2, 0, 1, -1, 0, -1]
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).irreducible_symmetric_group_character()
Symmetric Functions over Rational Field in the irreducible symmetric group␣
↪character basis
>>> st = SymmetricFunctions(QQ).st()
>>> s = SymmetricFunctions(QQ).s()
>>> s(st([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(9)))
s[4, 3, 2]
>>> s(st([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(7)))
0
>>> s(st([Integer(3),Integer(2)]).character_to_frobenius_image(Integer(6)))
-s[2, 2, 2]
>>> list(SymmetricGroup(Integer(5)).character_table()[-Integer(2)])
[4, 2, 0, 1, -1, 0, -1]
>>> list(reversed([st([Integer(1)]).eval_at_permutation_roots(rho)
...   for rho in Partitions(Integer(5))]))
[4, 2, 0, 1, -1, 0, -1]
```

symplectic()

The symplectic basis of the symmetric functions.

See also

SymmetricFunctionAlgebra_symplectic

EXAMPLES:

```
sage: SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).symplectic()
Symmetric Functions over Rational Field in the symplectic basis
```

w(*coerce_h=None*, *coerce_e=None*, *coerce_p=None*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

witt(*coerce_h=None*, *coerce_e=None*, *coerce_p=None*)

The Witt basis of the symmetric functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).witt()
Symmetric Functions over Rational Field in the Witt basis
```

zonal()

The zonal basis of the Symmetric Functions.

EXAMPLES:

```
sage: SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis
```

```
>>> from sage.all import *
>>> SymmetricFunctions(QQ).zonal()
Symmetric Functions over Rational Field in the zonal basis
```

class `sage.combinat.sf.sf.`**SymmetricaConversionOnBasis**(*t*, *domain*, *codomain*)

Bases: `object`

Initialization of `self`.

INPUT:

- `t` – a function taking a monomial in CombinatorialFreeModule(QQ, Partitions()), and returning a (partition, coefficient) list
- `domain`, `codomain` – parents

Construct a function mapping a partition to an element of `codomain`.

This is a temporary quick hack to wrap around the existing symmetrica conversions, without changing their specs.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['x'])
sage: p = Sym.p(); s = Sym.s()
sage: def t(x) : [(p, c)] = x; return [ (p, 2*c), (p.conjugate(), c) ]
sage: f = sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, p, s)
sage: f(Partition([3,1]))
s[2, 1, 1] + 2*s[3, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['x'])
>>> p = Sym.p(); s = Sym.s()
>>> def t(x) : [(p, c)] = x; return [ (p, Integer(2)*c), (p.conjugate(), c) ]
>>> f = sage.combinat.sf.sf.SymmetricaConversionOnBasis(t, p, s)
>>> f(Partition([Integer(3),Integer(1)]))
s[2, 1, 1] + 2*s[3, 1]
```

5.1.303 Symmetric Functions

For a comprehensive tutorial on how to use symmetric functions in Sage

See also

SymmetricFunctions()

We define the algebra of symmetric functions in the Schur and elementary bases:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: e = SymmetricFunctions(QQ).elementary()
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).schur()
>>> e = SymmetricFunctions(QQ).elementary()
```

Each is actually a graded Hopf algebra whose basis is indexed by integer partitions:

```
sage: s.category()
Category of graded bases of Symmetric Functions over Rational Field
sage: s.basis().keys()
Partitions
```

```
>>> from sage.all import *
>>> s.category()
Category of graded bases of Symmetric Functions over Rational Field
>>> s.basis().keys()
Partitions
```

Let us compute with some elements in different bases:

```
sage: f1 = s([2,1]); f1
s[2, 1]
sage: f2 = e(f1); f2 # basis conversion
e[2, 1] - e[3]
sage: f1 == f2
True
sage: f1.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
sage: f2.expand(3, alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

```
>>> from sage.all import *
>>> f1 = s([Integer(2),Integer(1)]); f1
s[2, 1]
>>> f2 = e(f1); f2 # basis conversion
e[2, 1] - e[3]
>>> f1 == f2
True
>>> f1.expand(Integer(3), alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
>>> f2.expand(Integer(3), alphabet=['x','y','z'])
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

```
sage: m = SymmetricFunctions(QQ).monomial()
sage: m([3,1])
m[3, 1]
sage: m(4) # This is the constant 4, not the partition 4.
4*m[]
sage: m([4]) # This is the partition 4.
m[4]
sage: 3*m([3,1])-1/2*m([4])
3*m[3, 1] - 1/2*m[4]
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).monomial()
>>> m([Integer(3),Integer(1)])
m[3, 1]
>>> m(Integer(4)) # This is the constant 4, not the partition 4.
4*m[]
>>> m([Integer(4)]) # This is the partition 4.
m[4]
>>> Integer(3)*m([Integer(3),Integer(1)])-Integer(1)/Integer(2)*m([Integer(4)])
3*m[3, 1] - 1/2*m[4]
```

```
sage: p = SymmetricFunctions(QQ).power()
sage: f = p(3)
sage: f
3*p[]
sage: f.parent()
Symmetric Functions over Rational Field in the powersum basis
sage: f + p([3,2])
3*p[] + p[3, 2]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).power()
>>> f = p(Integer(3))
>>> f
3*p[]
>>> f.parent()
Symmetric Functions over Rational Field in the powersum basis
>>> f + p([Integer(3),Integer(2)])
3*p[] + p[3, 2]
```

One can convert symmetric functions to symmetric polynomials and vice versa:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.powersum()
sage: h = Sym.homogeneous()
sage: f = h[2,1] + 2*p[3,1]
sage: poly = f.expand(3); poly
2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0*x2^3 + 2*x1*x2^
↪3 + 2*x2^4
+ x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^
↪2 + 2*x1*x2^2 + x2^3
sage: Sym.from_polynomial(poly)
3*m[1, 1, 1] + 2*m[2, 1] + m[3] + 2*m[3, 1] + 2*m[4]
sage: Sym.from_polynomial(poly) == f
True
sage: g = h[1,1,1,1]
sage: poly = g.expand(3)
sage: Sym.from_polynomial(poly) == g
False
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.powersum()
>>> h = Sym.homogeneous()
>>> f = h[Integer(2),Integer(1)] + Integer(2)*p[Integer(3),Integer(1)]
>>> poly = f.expand(Integer(3)); poly
2*x0^4 + 2*x0^3*x1 + 2*x0*x1^3 + 2*x1^4 + 2*x0^3*x2 + 2*x1^3*x2 + 2*x0*x2^3 + 2*x1*x2^
↪3 + 2*x2^4
+ x0^3 + 2*x0^2*x1 + 2*x0*x1^2 + x1^3 + 2*x0^2*x2 + 3*x0*x1*x2 + 2*x1^2*x2 + 2*x0*x2^
↪2 + 2*x1*x2^2 + x2^3
>>> Sym.from_polynomial(poly)
3*m[1, 1, 1] + 2*m[2, 1] + m[3] + 2*m[3, 1] + 2*m[4]
>>> Sym.from_polynomial(poly) == f
True
>>> g = h[Integer(1),Integer(1),Integer(1),Integer(1)]
>>> poly = g.expand(Integer(3))
>>> Sym.from_polynomial(poly) == g
False
```

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: p = Sym.p()

class sage.combinat.sf.sfa.**FilteredSymmetricFunctionsBases**(*parent_with_realization*)

Bases: Category_realization_of_parent

The category of filtered bases of the ring of symmetric functions.

super_categories()

The super categories of self.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = FilteredSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of bases of Symmetric Functions over Rational Field,
 Category of commutative filtered Hopf algebras with basis over Rational␣
↪Field]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import FilteredSymmetricFunctionsBases
>>> Sym = SymmetricFunctions(QQ)
>>> bases = FilteredSymmetricFunctionsBases(Sym)
>>> bases.super_categories()
[Category of bases of Symmetric Functions over Rational Field,
 Category of commutative filtered Hopf algebras with basis over Rational␣
↪Field]
```

class sage.combinat.sf.sfa.**GradedSymmetricFunctionsBases**(*parent_with_realization*)

Bases: Category_realization_of_parent

The category of graded bases of the ring of symmetric functions.

These are further required to have the property that the basis element indexed by the empty partition is 1.

class ElementMethods

Bases: object

degree_negation()

Return the image of self under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

Calling degree_negation(self) is equivalent to calling self.parent().degree_negation(self).

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
sage: f.degree_negation()
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
sage: x = m.zero().degree_negation(); x
0
sage: parent(x) is m
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.monomial()
>>> f = Integer(2)*m[Integer(2),Integer(1)] + Integer(4)*m[Integer(1),
↪Integer(1)] - Integer(5)*m[Integer(1)] - Integer(3)*m[[]]
>>> f.degree_negation()
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
>>> x = m.zero().degree_negation(); x
0
>>> parent(x) is m
True
```

degree_zero_coefficient()

Return the degree zero coefficient of `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[[]]
sage: f.degree_zero_coefficient()
3
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.monomial()
>>> f = Integer(2)*m[Integer(2),Integer(1)] + Integer(3)*m[[]]
>>> f.degree_zero_coefficient()
3
```

is_unit()

Return whether this element is a unit in the ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(ZZ).monomial()
sage: (2*m[2,1] + m[[]]).is_unit()
False

sage: m = SymmetricFunctions(QQ).monomial()
sage: (3/2*m([])).is_unit()
True
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(ZZ).monomial()
>>> (Integer(2)*m[Integer(2),Integer(1)] + m[[]]).is_unit()
False

>>> m = SymmetricFunctions(QQ).monomial()
>>> (Integer(3)/Integer(2)*m([])).is_unit()
True
```

class ParentMethods

Bases: `object`

antipode_by_coercion(*element*)

The antipode of `element`.

INPUT:

- `element` – element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: p = Sym.p()
sage: s = Sym.s()
sage: e = Sym.e()
sage: h = Sym.h()
sage: (h([]) + h([1])).antipode() # indirect doctest
h[] - h[1]
sage: (s([]) + s([1]) + s[2]).antipode()
s[] - s[1] + s[1, 1]
sage: (p([2]) + p([3])).antipode()
-p[2] - p[3]
sage: (e([2]) + e([3])).antipode()
e[1, 1] - e[1, 1, 1] - e[2] + 2*e[2, 1] - e[3]
sage: f = Sym.f()
sage: f([3,2,1]).antipode()
-f[3, 2, 1] - 4*f[3, 3] - 2*f[4, 2] - 2*f[5, 1] - 6*f[6]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> p = Sym.p()
>>> s = Sym.s()
>>> e = Sym.e()
>>> h = Sym.h()
>>> (h([]) + h([Integer(1)])).antipode() # indirect doctest
h[] - h[1]
>>> (s([]) + s([Integer(1)]) + s[Integer(2)]).antipode()
s[] - s[1] + s[1, 1]
>>> (p([Integer(2)]) + p([Integer(3)])).antipode()
-p[2] - p[3]
>>> (e([Integer(2)]) + e([Integer(3)])).antipode()
e[1, 1] - e[1, 1, 1] - e[2] + 2*e[2, 1] - e[3]
>>> f = Sym.f()
>>> f([Integer(3),Integer(2),Integer(1)]).antipode()
-f[3, 2, 1] - 4*f[3, 3] - 2*f[4, 2] - 2*f[5, 1] - 6*f[6]
```

The antipode is an involution:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.s()
sage: all( s[u].antipode().antipode() == s[u] for u in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> s = Sym.s()
>>> all( s[u].antipode().antipode() == s[u] for u in␣
↪Partitions(Integer(4)) )
True
```

The antipode is an algebra homomorphism:

```
sage: Sym = SymmetricFunctions(FiniteField(23))
sage: h = Sym.h()
sage: all( all( (s[u] * s[v]).antipode() == s[u].antipode() * s[v].
↪antipode()
....:            for u in Partitions(3) )
....:       for v in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FiniteField(Integer(23)))
>>> h = Sym.h()
>>> all( all( (s[u] * s[v]).antipode() == s[u].antipode() * s[v].
↪antipode()
...            for u in Partitions(Integer(3)) )
...       for v in Partitions(Integer(3)) )
True
```

counit(*element*)

Return the counit of `element`.

The counit is the constant term of `element`.

INPUT:

- `element` – element in a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 3*m[[]]
sage: f.counit()
3
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.monomial()
>>> f = Integer(2)*m[Integer(2),Integer(1)] + Integer(3)*m[[]]
>>> f.counit()
3
```

degree_negation(*element*)

Return the image of `element` under the degree negation automorphism of the ring of symmetric functions.

The degree negation is the automorphism which scales every homogeneous element of degree k by $(-1)^k$ (for all k).

INPUT:

- `element` – symmetric function written in `self`

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.monomial()
sage: f = 2*m[2,1] + 4*m[1,1] - 5*m[1] - 3*m[[]]
sage: m.degree_negation(f)
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.monomial()
>>> f = Integer(2)*m[Integer(2),Integer(1)] + Integer(4)*m[Integer(1),
↪Integer(1)] - Integer(5)*m[Integer(1)] - Integer(3)*m[[]]
>>> m.degree_negation(f)
-3*m[] + 5*m[1] + 4*m[1, 1] - 2*m[2, 1]
```

super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import GradedSymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = GradedSymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of filtered bases of Symmetric Functions over Rational Field,
 Category of commutative graded Hopf algebras with basis over Rational Field]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import GradedSymmetricFunctionsBases
>>> Sym = SymmetricFunctions(QQ)
>>> bases = GradedSymmetricFunctionsBases(Sym)
>>> bases.super_categories()
[Category of filtered bases of Symmetric Functions over Rational Field,
 Category of commutative graded Hopf algebras with basis over Rational Field]
```

class sage.combinat.sf.sfa.**SymmetricFunctionAlgebra_generic**(*Sym*, *basis_name=None*, *prefix=None*, *graded=True*)

Bases: `CombinatorialFreeModule`

Abstract base class for symmetric function algebras.

Todo

Most of the methods in this class are generic (manipulations of morphisms, …) and should be generalized (or removed)

Element

alias of *SymmetricFunctionAlgebra_generic_Element*

basis_name()

Return the name of the basis of `self`.

This is used for output and, for the classical bases of symmetric functions, to connect this basis with Symmetrica.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: s.basis_name()
'Schur'
sage: p = Sym.p()
sage: p.basis_name()
'powersum'
sage: h = Sym.h()
sage: h.basis_name()
'homogeneous'
sage: e = Sym.e()
sage: e.basis_name()
'elementary'
sage: m = Sym.m()
sage: m.basis_name()
'monomial'
sage: f = Sym.f()
sage: f.basis_name()
'forgotten'
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> s.basis_name()
'Schur'
>>> p = Sym.p()
>>> p.basis_name()
'powersum'
>>> h = Sym.h()
>>> h.basis_name()
'homogeneous'
>>> e = Sym.e()
>>> e.basis_name()
'elementary'
>>> m = Sym.m()
>>> m.basis_name()
'monomial'
>>> f = Sym.f()
>>> f.basis_name()
```

(continues on next page)

(continued from previous page)

```
'forgotten'
```

change_ring(*R*)

Return the base change of `self` to R.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s.change_ring(QQ)
Symmetric Functions over Rational Field in the Schur basis
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> s.change_ring(QQ)
Symmetric Functions over Rational Field in the Schur basis
```

construction()

Return a pair `(F, R)`, where `F` is a *SymmetricFunctionsFunctor* and R is a ring, such that `F(R)` returns `self`.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Integer Ring)
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> s.construction()
(SymmetricFunctionsFunctor[Schur], Integer Ring)
```

coproduct_by_coercion(*elt*)

Return the coproduct of the element `elt` by coercion to the Schur basis.

INPUT:

- `elt` – an instance of this basis

OUTPUT:

- The image of `elt` under the comultiplication (=coproduct) of the coalgebra of symmetric functions. The result is an element of the tensor squared of the basis `self`.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: m[3,1,1].coproduct()
m[] # m[3, 1, 1] + m[1] # m[3, 1] + m[1, 1] # m[3] + m[3] # m[1, 1] + m[3, 1]
↪# m[1] + m[3, 1, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1])
m[] # m[2, 1] + m[1] # m[2] + m[2] # m[1] + m[2, 1] # m[]
sage: m.coproduct_by_coercion(m[2,1]) == m([2,1]).coproduct()
True
sage: McdH = SymmetricFunctions(QQ['q','t'].fraction_field()).macdonald().H()
sage: McdH[2,1].coproduct()
```

(continues on next page)

(continued from previous page)

```
McdH[] # McdH[2, 1] + ((q^2*t-1)/(q*t-1))*McdH[1] # McdH[1, 1] + ((q*t^2-1)/

f[] # f[3] + f[3] # f[]
>>> f[Integer(3),Integer(2),Integer(1)].coproduct()
f[] # f[3, 2, 1] + f[1] # f[3, 2] + f[2] # f[3, 1] + f[2, 1] # f[3] + f[3] #␣
↪f[2, 1] + f[3, 1] # f[2] + f[3, 2] # f[1] + f[3, 2, 1] # f[]
```

dual_basis(*scalar=None*, *scalar_name=''*, *basis_name=None*, *prefix=None*)

Return the dual basis of `self` with respect to the scalar product `scalar`.

INPUT:

- `scalar` – a function `zee` from partitions to the base ring which specifies the scalar product by $\langle p_\lambda, p_\lambda \rangle = \mathrm{zee}(\lambda)$. (Independently on the function chosen, the power sum basis will always be orthogonal; the function `scalar` only determines the norms of the basis elements.) If `scalar` is None, then the standard (Hall) scalar product is used.
- `scalar_name` – name of the scalar function
- `prefix` – prefix used to display the basis

EXAMPLES:

The duals of the elementary symmetric functions with respect to the Hall scalar product are the forgotten symmetric functions.

```
sage: e = SymmetricFunctions(QQ).e()
sage: f = e.dual_basis(prefix='f'); f
Dual basis to Symmetric Functions over Rational Field in the elementary basis␣
↪with respect to the Hall scalar product
sage: f([2,1])^2
4*f[2, 2, 1, 1] + 6*f[2, 2, 2] + 2*f[3, 2, 1] + 2*f[3, 3] + 2*f[4, 1, 1] +␣
↪f[4, 2]
sage: f([2,1]).scalar(e([2,1]))
1
sage: f([2,1]).scalar(e([1,1,1]))
0
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> f = e.dual_basis(prefix='f'); f
Dual basis to Symmetric Functions over Rational Field in the elementary basis␣
↪with respect to the Hall scalar product
>>> f([Integer(2),Integer(1)])**Integer(2)
4*f[2, 2, 1, 1] + 6*f[2, 2, 2] + 2*f[3, 2, 1] + 2*f[3, 3] + 2*f[4, 1, 1] +␣
↪f[4, 2]
>>> f([Integer(2),Integer(1)]).scalar(e([Integer(2),Integer(1)]))
1
>>> f([Integer(2),Integer(1)]).scalar(e([Integer(1),Integer(1),Integer(1)]))
0
```

Since the power-sum symmetric functions are orthogonal, their duals with respect to the Hall scalar product are scalar multiples of themselves.

```
sage: p = SymmetricFunctions(QQ).p()
sage: q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Functions over Rational Field in the powersum basis␣
↪with respect to the Hall scalar product
sage: q([2,1])^2
4*q[2, 2, 1, 1]
sage: p([2,1]).scalar(q([2,1]))
1
sage: p([2,1]).scalar(q([1,1,1]))
0
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> q = p.dual_basis(prefix='q'); q
Dual basis to Symmetric Functions over Rational Field in the powersum basis␣
↪with respect to the Hall scalar product
>>> q([Integer(2),Integer(1)])**Integer(2)
4*q[2, 2, 1, 1]
>>> p([Integer(2),Integer(1)]).scalar(q([Integer(2),Integer(1)]))
1
>>> p([Integer(2),Integer(1)]).scalar(q([Integer(1),Integer(1),Integer(1)]))
0
```

from_polynomial(*poly*, *check=True*)

Convert polynomial to a symmetric function in the monomial basis and then to the basis `self`.

INPUT:

- `poly` – a symmetric polynomial
- `check` – boolean (default: `True`); specifies whether the computation checks that the polynomial is indeed symmetric

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.homogeneous()
sage: f = (h([]) + h([2,1]) + h([3])).expand(3)
sage: h.from_polynomial(f)
h[] + h[2, 1] + h[3]
sage: s = Sym.s()
sage: g = (s([]) + s([2,1])).expand(3); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + 1
sage: s.from_polynomial(g)
s[] + s[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> h = Sym.homogeneous()
>>> f = (h([]) + h([Integer(2),Integer(1)]) + h([Integer(3)])).
↪expand(Integer(3))
>>> h.from_polynomial(f)
h[] + h[2, 1] + h[3]
>>> s = Sym.s()
>>> g = (s([]) + s([Integer(2),Integer(1)])).expand(Integer(3)); g
x0^2*x1 + x0*x1^2 + x0^2*x2 + 2*x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + 1
>>> s.from_polynomial(g)
s[] + s[2, 1]
```

get_print_style()

Return the value of the current print style for `self`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
```

(continues on next page)

(continued from previous page)

```
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.get_print_style()
'lex'
>>> s.set_print_style('length')
>>> s.get_print_style()
'length'
>>> s.set_print_style('lex')
```

prefix()

Return the prefix on the elements of `self`.

EXAMPLES:

```
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur([3,2,1])
s[3, 2, 1]
sage: schur.prefix()
's'
```

```
>>> from sage.all import *
>>> schur = SymmetricFunctions(QQ).schur()
>>> schur([Integer(3),Integer(2),Integer(1)])
s[3, 2, 1]
>>> schur.prefix()
's'
```

product_by_coercion(*left*, *right*)

Return the product of elements `left` and `right` by coercion to the Schur basis.

INPUT:

- `left`, `right` – instances of this basis

OUTPUT: the product of `left` and `right` expressed in the basis `self`

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: p.product_by_coercion(p[3,1,1], p[2,2])
p[3, 2, 2, 1, 1]
sage: m = SymmetricFunctions(QQ).m()
sage: m.product_by_coercion(m[2,1],m[1,1]) == m[2,1]*m[1,1]
True
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> p.product_by_coercion(p[Integer(3),Integer(1),Integer(1)], p[Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(2)])
p[3, 2, 2, 1, 1]
>>> m = SymmetricFunctions(QQ).m()
>>> m.product_by_coercion(m[Integer(2),Integer(1)],m[Integer(1),Integer(1)])␣
↪== m[Integer(2),Integer(1)]*m[Integer(1),Integer(1)]
True
```

set_print_style(*ps*)

Set the value of the current print style to `ps`.

INPUT:

- `ps` – string specifying the printing style

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.get_print_style()
'lex'
sage: s.set_print_style('length')
sage: s.get_print_style()
'length'
sage: s.set_print_style('lex')
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.get_print_style()
'lex'
>>> s.set_print_style('length')
>>> s.get_print_style()
'length'
>>> s.set_print_style('lex')
```

symmetric_function_ring()

Return the family of symmetric functions associated to the basis `self`.

OUTPUT: an instance of the ring of symmetric functions

EXAMPLES:

```
sage: schur = SymmetricFunctions(QQ).schur()
sage: schur.symmetric_function_ring()
Symmetric Functions over Rational Field
sage: power = SymmetricFunctions(QQ['t']).power()
sage: power.symmetric_function_ring()
Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> schur = SymmetricFunctions(QQ).schur()
>>> schur.symmetric_function_ring()
Symmetric Functions over Rational Field
>>> power = SymmetricFunctions(QQ['t']).power()
>>> power.symmetric_function_ring()
Symmetric Functions over Univariate Polynomial Ring in t over Rational Field
```

transition_matrix(*basis*, *n*)

Return the transition matrix between `self` and `basis` for the homogeneous component of degree `n`.

INPUT:

- `basis` – a basis of the ring of symmetric functions
- `n` – nonnegative integer

OUTPUT:

A matrix of coefficients giving the expansion of the homogeneous degree-n elements of `self` in the degree-n elements of `basis`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: m = SymmetricFunctions(QQ).m()
sage: s.transition_matrix(m,5)
[1 1 1 1 1 1 1]
[0 1 1 2 2 3 4]
[0 0 1 1 2 3 5]
[0 0 0 1 1 3 6]
[0 0 0 0 1 2 5]
[0 0 0 0 0 1 4]
[0 0 0 0 0 0 1]
sage: s.transition_matrix(m,1)
[1]
sage: s.transition_matrix(m,0)
[1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> m = SymmetricFunctions(QQ).m()
>>> s.transition_matrix(m,Integer(5))
[1 1 1 1 1 1 1]
[0 1 1 2 2 3 4]
[0 0 1 1 2 3 5]
[0 0 0 1 1 3 6]
[0 0 0 0 1 2 5]
[0 0 0 0 0 1 4]
[0 0 0 0 0 0 1]
>>> s.transition_matrix(m,Integer(1))
[1]
>>> s.transition_matrix(m,Integer(0))
[1]
```

```
sage: p = SymmetricFunctions(QQ).p()
sage: s.transition_matrix(p, 4)
[ 1/4  1/3  1/8  1/4 1/24]
[-1/4    0 -1/8  1/4  1/8]
[   0 -1/3  1/4    0 1/12]
[ 1/4    0 -1/8 -1/4  1/8]
[-1/4  1/3  1/8 -1/4 1/24]
sage: StoP = s.transition_matrix(p,4)
sage: a = s([3,1])+5*s([1,1,1,1])-s([4])
```

(continues on next page)

(continued from previous page)

```
sage: a
5*s[1, 1, 1, 1] + s[3, 1] - s[4]
sage: mon = sorted(a.support())
sage: coeffs = [a[i] for i in mon]
sage: coeffs
[5, 1, -1]
sage: mon

class sage.combinat.sf.sfa.**SymmetricFunctionAlgebra_generic_Element**

Bases: IndexedFreeModuleElement

Class of generic elements for the symmetric function algebra.

adams_operator(*n*)

Return the image of the symmetric function `self` under the n-th Adams operator.

The n-th Adams operator $\mathbf{f}_n$ is defined to be the map from the ring of symmetric functions to itself that sends every symmetric function $P(x_1, x_2, x_3, \ldots)$ to $P(x_1^n, x_2^n, x_3^n, \ldots)$. This operator $\mathbf{f}_n$ is a Hopf algebra endomorphism, and satisfies

$$\mathbf{f}_n m_{(\lambda_1,\lambda_2,\lambda_3,\dots)} = m_{(n\lambda_1,n\lambda_2,n\lambda_3,\dots)}$$

for every partition $(\lambda_1, \lambda_2, \lambda_3, \dots)$ (where m means the monomial basis). Moreover, $\mathbf{f}_n(p_r) = p_{nr}$ for every positive integer r (where p_k denotes the k-th powersum symmetric function).

The n-th Adams operator is also called the n-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n-th Adams operator is also the n-th Adams operator of the Λ-ring of symmetric functions over the integers.

The n-th Adams operator can also be described via plethysm: Every symmetric function P satisfies $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$, where p_n is the n-th powersum symmetric function, and $\circ$ denotes (outer) plethysm.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Adams operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].adams_operator(2)
-s[3, 3] + s[4, 2] - s[5, 1] + s[6]
sage: m[4,2,1].adams_operator(3)
m[12, 6, 3]
sage: p[4,2,1].adams_operator(3)
p[12, 6, 3]
sage: h[4].adams_operator(2)
h[4, 4] - 2*h[5, 3] + 2*h[6, 2] - 2*h[7, 1] + 2*h[8]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> h = Sym.h()
>>> s = Sym.s()
>>> m = Sym.m()
>>> s[Integer(3)].adams_operator(Integer(2))
-s[3, 3] + s[4, 2] - s[5, 1] + s[6]
>>> m[Integer(4),Integer(2),Integer(1)].adams_operator(Integer(3))
m[12, 6, 3]
>>> p[Integer(4),Integer(2),Integer(1)].adams_operator(Integer(3))
p[12, 6, 3]
>>> h[Integer(4)].adams_operator(Integer(2))
h[4, 4] - 2*h[5, 3] + 2*h[6, 2] - 2*h[7, 1] + 2*h[8]
```

The Adams endomorphisms are multiplicative:

```
sage: all( all( s(lam).adams_operator(3) * s(mu).adams_operator(3) # long time
....:           == (s(lam) * s(mu)).adams_operator(3)
....:           for mu in Partitions(3) )
....:      for lam in Partitions(3) )
True
sage: all( all( m(lam).adams_operator(2) * m(mu).adams_operator(2)
....:           == (m(lam) * m(mu)).adams_operator(2)
....:           for mu in Partitions(4) )
....:      for lam in Partitions(4) )
True
sage: all( all( p(lam).adams_operator(2) * p(mu).adams_operator(2)
....:           == (p(lam) * p(mu)).adams_operator(2)
....:           for mu in Partitions(3) )
....:      for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( s(lam).adams_operator(Integer(3)) * s(mu).adams_
↪operator(Integer(3)) # long time
...           == (s(lam) * s(mu)).adams_operator(Integer(3))
...           for mu in Partitions(Integer(3)) )
...      for lam in Partitions(Integer(3)) )
True
>>> all( all( m(lam).adams_operator(Integer(2)) * m(mu).adams_
↪operator(Integer(2))
...           == (m(lam) * m(mu)).adams_operator(Integer(2))
...           for mu in Partitions(Integer(4)) )
...      for lam in Partitions(Integer(4)) )
True
>>> all( all( p(lam).adams_operator(Integer(2)) * p(mu).adams_
↪operator(Integer(2))
...           == (p(lam) * p(mu)).adams_operator(Integer(2))
...           for mu in Partitions(Integer(3)) )
...      for lam in Partitions(Integer(4)) )
True
```

Being Hopf algebra endomorphisms, the Adams operators commute with the antipode:

```
sage: all( p(lam).adams_operator(4).antipode()
....:      == p(lam).antipode().adams_operator(4)
....:      for lam in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> all( p(lam).adams_operator(Integer(4)).antipode()
...      == p(lam).antipode().adams_operator(Integer(4))
...      for lam in Partitions(Integer(3)) )
True
```

Testing the $\mathbf{f}_n(P) = p_n \circ P = P \circ p_n$ equality (over $\mathbf{Q}$, since plethysm is currently not defined over $\mathbf{Z}$ in Sage):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( s(lam).adams_operator(3) == s(lam).plethysm(p[3])
....:      == s(p[3].plethysm(s(lam)))
....:      for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> p = Sym.p()
>>> all( s(lam).adams_operator(Integer(3)) == s(lam).plethysm(p[Integer(3)])
...      == s(p[Integer(3)].plethysm(s(lam)))
...      for lam in Partitions(Integer(4)) )
True
```

By Exercise 7.61 in Stanley's EC2 [STA] (see the errata on his website), $\mathbf{f}_n(h_m)$ is a linear combination of Schur polynomials (of straight shapes) using coefficients 0, 1 and -1 only; moreover, all partitions whose Schur polynomials occur with coefficient $\neq 0$ in this combination have empty n-cores. Let us check this on examples:

```
sage: all( all( all( (coeff == -1 or coeff == 1)
....:                and lam.core(n) == Partition([])
....:                for lam, coeff in s([m]).adams_operator(n) )
....:           for n in range(2, 4) )
....:      for m in range(4) )
True
```

```
>>> from sage.all import *
>>> all( all( all( (coeff == -Integer(1) or coeff == Integer(1))
...                and lam.core(n) == Partition([])
...                for lam, coeff in s([m]).adams_operator(n) )
...           for n in range(Integer(2), Integer(4)) )
...      for m in range(Integer(4)) )
True
```

See also:

plethysm()

Todo: This method is fast on the monomial and the powersum bases, while all other bases get converted to the monomial basis. For most bases, this is probably the quickest way to do, but at least the Schur basis should have a better option. (Quoting from Stanley's EC2 [STA]: "D. G. Duncan, J. London Math. Soc. 27 (1952), 235-236, or Y. M. Chen, A. M. Garsia, and J. B. Remmel, Contemp. Math. 34 (1984), 109-153".)

arithmetic_product(*x*)

Return the arithmetic product of `self` and `x` in the basis of `self`.

The arithmetic product is a binary operation $\boxdot$ on the ring of symmetric functions which is bilinear in its two arguments and satisfies

$$p_\lambda \boxdot p_\mu = \prod_{i \geq 1, j \geq 1} p_{\mathrm{lcm}(\lambda_i, \mu_j)}^{\mathrm{gcd}(\lambda_i, \mu_j)}$$

for any two partitions $\lambda = (\lambda_1, \lambda_2, \lambda_3, \dots)$ and $\mu = (\mu_1, \mu_2, \mu_3, \dots)$ (where p_ν denotes the power-sum symmetric function indexed by the partition ν, and p_i denotes the i-th power-sum symmetric function). This is enough to define the arithmetic product if the base ring is torsion-free as a **Z**-module; for all other cases the arithmetic product is uniquely determined by requiring it to be functorial in the base ring. See http://mathoverflow.net/questions/138148/ for a discussion of this arithmetic product.

If f and g are two symmetric functions which are homogeneous of degrees a and b, respectively, then $f \boxdot g$ is homogeneous of degree ab.

The arithmetic product is commutative and associative and has unity $e_1 = p_1 = h_1$.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

Arithmetic product of `self` with `x`; this is a symmetric function over the same base ring as `self`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2]).arithmetic_product(s([2]))
s[1, 1, 1, 1] + 2*s[2, 2] + s[4]
sage: s([2]).arithmetic_product(s([1,1]))
s[2, 1, 1] + s[3, 1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(2)]).arithmetic_product(s([Integer(2)]))
s[1, 1, 1, 1] + 2*s[2, 2] + s[4]
>>> s([Integer(2)]).arithmetic_product(s([Integer(1),Integer(1)]))
s[2, 1, 1] + s[3, 1]
```

The symmetric function `e[1]` is the unity for the arithmetic product:

```
sage: e = SymmetricFunctions(ZZ).e()
sage: all( e([1]).arithmetic_product(e(q)) == e(q) for q in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(ZZ).e()
>>> all( e([Integer(1)]).arithmetic_product(e(q)) == e(q) for q in␣
↪Partitions(Integer(4)) )
True
```

The arithmetic product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_
↪product(e(p))  # long time (26s on sage.math, 2013)
....:           for q in Partitions(4) )
....:       for p in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> all( all( e(p).arithmetic_product(m(q)) == m(q).arithmetic_product(e(p))
↪# long time (26s on sage.math, 2013)
...           for q in Partitions(Integer(4)) )
...       for p in Partitions(Integer(4)) )
True
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a **Q**-algebra (in which case the arithmetic product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the "corresponding" basis of the symmetric function algebra over **Q** (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

bernstein_creation_operator(*n*)

Return the image of `self` under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator $\mathbf{B}_n$ is defined as the endomorphism of the space Sym of symmetric functions which sends every f to

$$\sum_{i\geq 0}(-1)^i h_{n+i}e_i^\perp,$$

where usual notations are in place (h stands for the complete homogeneous symmetric functions, e for the elementary ones, and $e_i^\perp$ means skewing (*skew_by()*) by e_i).

This has been studied in [BBSSZ2012], section 2.2, where the following rule is given for computing $\mathbf{B}_n$ on a Schur function: If $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ is an n-tuple of integers (positive or not), then

$$\mathbf{B}_n s_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = s_{(n,\alpha_1,\alpha_2,\ldots,\alpha_n)}.$$

Here, $s_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ is the "Schur function" associated to the n-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_n)$, and defined by literally applying the Jacobi-Trudi identity, i.e., by

$$s_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = \det\left((h_{\alpha_i-i+j})_{i,j=1,2,\ldots,n}\right).$$

This notion of a Schur function clearly extends the classical notion of Schur function corresponding to a partition, but is easily reduced to the latter (in fact, for any n-tuple α of integers, one easily sees that s_α is either 0 or minus-plus a Schur function corresponding to a partition; and it is easy to determine which of these is the case and find the partition by a combinatorial algorithm).

EXAMPLES:

Let us check that what this method computes agrees with the definition:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: def bernstein_creation_by_def(n, f):
....:     # `n`-th Bernstein creation operator applied to `f`
....:     # computed according to its definition.
....:     res = f.parent().zero()
....:     if not f:
....:         return res
....:     max_degree = max(sum(m) for m, c in f)
....:     for i in range(max_degree + 1):
....:         if n + i >= 0:
....:             res += (-1) ** i * h[n + i] * f.skew_by(e[i])
....:     return res
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↪operator(n)
....:      for n in range(-2, 3) for l in Partitions(4) )
True
sage: all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↪operator(n)
....:      for n in range(-3, 4) for l in Partitions(3) )
True
sage: all( bernstein_creation_by_def(n, e[l]) == e[l].bernstein_creation_
↪operator(n)
....:      for n in range(-3, 4) for k in range(3) for l in Partitions(k) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> e = Sym.e()
>>> h = Sym.h()
>>> s = Sym.s()
>>> def bernstein_creation_by_def(n, f):
...     # `n`-th Bernstein creation operator applied to `f`
...     # computed according to its definition.
...     res = f.parent().zero()
...     if not f:
...         return res
...     max_degree = max(sum(m) for m, c in f)
...     for i in range(max_degree + Integer(1)):
...         if n + i >= Integer(0):
...             res += (-Integer(1)) ** i * h[n + i] * f.skew_by(e[i])
...     return res
>>> all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↪operator(n)
...      for n in range(-Integer(2), Integer(3)) for l in␣
↪Partitions(Integer(4)) )
True
>>> all( bernstein_creation_by_def(n, s[l]) == s[l].bernstein_creation_
↪operator(n)
...      for n in range(-Integer(3), Integer(4)) for l in␣
```

(continues on next page)

(continued from previous page)

```
↪Partitions(Integer(3)) )
True
>>> all( bernstein_creation_by_def(n, e[l]) == e[l].bernstein_creation_
↪operator(n)
...      for n in range(-Integer(3), Integer(4)) for k in range(Integer(3))␣
↪for l in Partitions(k) )
True
```

Some examples:

```
sage: s[3,2].bernstein_creation_operator(3)
s[3, 3, 2]
sage: s[3,2].bernstein_creation_operator(1)
-s[2, 2, 2]
sage: h[3,2].bernstein_creation_operator(-2)
h[2, 1]
sage: h[3,2].bernstein_creation_operator(-1)
h[2, 1, 1] - h[2, 2] - h[3, 1]
sage: h[3,2].bernstein_creation_operator(0)
-h[3, 1, 1] + h[3, 2]
sage: h[3,2].bernstein_creation_operator(1)
-h[2, 2, 2] + h[3, 2, 1]
sage: h[3,2].bernstein_creation_operator(2)
-h[3, 3, 1] + h[4, 2, 1]
```

```
>>> from sage.all import *
>>> s[Integer(3),Integer(2)].bernstein_creation_operator(Integer(3))
s[3, 3, 2]
>>> s[Integer(3),Integer(2)].bernstein_creation_operator(Integer(1))
-s[2, 2, 2]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(2))
h[2, 1]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(1))
h[2, 1, 1] - h[2, 2] - h[3, 1]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(Integer(0))
-h[3, 1, 1] + h[3, 2]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(Integer(1))
-h[2, 2, 2] + h[3, 2, 1]
>>> h[Integer(3),Integer(2)].bernstein_creation_operator(Integer(2))
-h[3, 3, 1] + h[4, 2, 1]
```

character_to_frobenius_image(n)

Interpret `self` as a GL_n character and then take the Frobenius image of this character of the permutation matrices S_n which naturally sit inside of GL_n.

To know the value of this character at a permutation of cycle structure ρ the symmetric function `self` is evaluated at the eigenvalues of a permutation of cycle structure ρ. The Frobenius image is then defined as $\sum_{\rho \vdash n} f[\Xi_\rho] p_\rho / z_\rho$.

See also

eval_at_permutation_roots()

INPUT:

- `n` – nonnegative integer to interpret `self` as a character of GL_n

OUTPUT: a symmetric function of degree `n`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([1,1]).character_to_frobenius_image(5)
s[3, 1, 1] + s[4, 1]
sage: s([2,1]).character_to_frobenius_image(5)
s[2, 2, 1] + 2*s[3, 1, 1] + 2*s[3, 2] + 3*s[4, 1] + s[5]
sage: s([2,2,2]).character_to_frobenius_image(3)
s[3]
sage: s([2,2,2]).character_to_frobenius_image(4)
s[2, 2] + 2*s[3, 1] + 2*s[4]
sage: s([2,2,2]).character_to_frobenius_image(5)
2*s[2, 2, 1] + s[3, 1, 1] + 4*s[3, 2] + 3*s[4, 1] + 2*s[5]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(1),Integer(1)]).character_to_frobenius_image(Integer(5))
s[3, 1, 1] + s[4, 1]
>>> s([Integer(2),Integer(1)]).character_to_frobenius_image(Integer(5))
s[2, 2, 1] + 2*s[3, 1, 1] + 2*s[3, 2] + 3*s[4, 1] + s[5]
>>> s([Integer(2),Integer(2),Integer(2)]).character_to_frobenius_
↪image(Integer(3))
s[3]
>>> s([Integer(2),Integer(2),Integer(2)]).character_to_frobenius_
↪image(Integer(4))
s[2, 2] + 2*s[3, 1] + 2*s[4]
>>> s([Integer(2),Integer(2),Integer(2)]).character_to_frobenius_
↪image(Integer(5))
2*s[2, 2, 1] + s[3, 1, 1] + 4*s[3, 2] + 3*s[4, 1] + 2*s[5]
```

degree()

Return the degree of `self` (which is defined to be 0 for the zero element).

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1]) + 3
sage: z.degree()
4
sage: s(1).degree()
0
sage: s(0).degree()
0
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> z = s([Integer(4)]) + s([Integer(2),Integer(1)]) + s([Integer(1),
↪Integer(1),Integer(1)]) + s([Integer(1)]) + Integer(3)
>>> z.degree()
```

(continues on next page)

(continued from previous page)

```
4
>>> s(Integer(1)).degree()
0
>>> s(Integer(0)).degree()
0
```

derivative_with_respect_to_p1(*n=1*)

Return the symmetric function obtained by taking the derivative of `self` with respect to the power-sum symmetric function p_1 when the expansion of `self` in the power-sum basis is considered as a polynomial in p_k's (with $k \geq 1$).

This is the same as skewing `self` by the first power-sum symmetric function p_1.

INPUT:

- `n` – (default: 1) nonnegative integer which determines which power of the derivative is taken

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ).p()
sage: a = p([1,1,1])
sage: a.derivative_with_respect_to_p1()
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(1)
3*p[1, 1]
sage: a.derivative_with_respect_to_p1(2)
6*p[1]
sage: a.derivative_with_respect_to_p1(3)
6*p[]
```

```
>>> from sage.all import *
>>> p = SymmetricFunctions(QQ).p()
>>> a = p([Integer(1),Integer(1),Integer(1)])
>>> a.derivative_with_respect_to_p1()
3*p[1, 1]
>>> a.derivative_with_respect_to_p1(Integer(1))
3*p[1, 1]
>>> a.derivative_with_respect_to_p1(Integer(2))
6*p[1]
>>> a.derivative_with_respect_to_p1(Integer(3))
6*p[]
```

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3]).derivative_with_respect_to_p1()
s[2]
sage: s([2,1]).derivative_with_respect_to_p1()
s[1, 1] + s[2]
sage: s([1,1,1]).derivative_with_respect_to_p1()
s[1, 1]
sage: s(0).derivative_with_respect_to_p1()
0
sage: s(1).derivative_with_respect_to_p1()
0
```

(continues on next page)

(continued from previous page)

```
sage: s([1]).derivative_with_respect_to_p1()
s[]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(3)]).derivative_with_respect_to_p1()
s[2]
>>> s([Integer(2),Integer(1)]).derivative_with_respect_to_p1()
s[1, 1] + s[2]
>>> s([Integer(1),Integer(1),Integer(1)]).derivative_with_respect_to_p1()
s[1, 1]
>>> s(Integer(0)).derivative_with_respect_to_p1()
0
>>> s(Integer(1)).derivative_with_respect_to_p1()
0
>>> s([Integer(1)]).derivative_with_respect_to_p1()
s[]
```

Let us check that taking the derivative with respect to `p[1]` is equivalent to skewing by `p[1]`:

```
sage: p1 = s([1])
sage: all( s(lam).derivative_with_respect_to_p1()
....:      == s(lam).skew_by(p1) for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> p1 = s([Integer(1)])
>>> all( s(lam).derivative_with_respect_to_p1()
...      == s(lam).skew_by(p1) for lam in Partitions(Integer(4)) )
True
```

eval_at_permutation_roots(*rho*)

Evaluate at eigenvalues of a permutation matrix.

Evaluate a symmetric function at the eigenvalues of a permutation matrix whose cycle structure is `rho`. This computation is computed by coercing to the power sum basis where the value may be computed on the generators.

This function evaluates an element at the roots of unity

$$\Xi_{\rho_1}, \Xi_{\rho_2}, \ldots, \Xi_{\rho_\ell}$$

where

$$\Xi_m = 1, \zeta_m, \zeta_m^2, \ldots, \zeta_m^{m-1}$$

and ζ_m is an m root of unity. These roots of unity represent the eigenvalues of permutation matrix with cycle structure ρ.

INPUT:

- `rho` – a partition or a list of nonnegative integers

OUTPUT: an element of the base ring

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,3]).eval_at_permutation_roots([6])
0
sage: s([3,3]).eval_at_permutation_roots([3])
1
sage: s([3,3]).eval_at_permutation_roots([1])
0
sage: s([3,3]).eval_at_permutation_roots([3,3])
4
sage: s([3,3]).eval_at_permutation_roots([1,1,1,1,1])
175
sage: (s[1]+s[2]+s[3]).eval_at_permutation_roots([3,2])
2
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(6)])
0
>>> s([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(3)])
1
>>> s([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(1)])
0
>>> s([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(3),
↪Integer(3)])
4
>>> s([Integer(3),Integer(3)]).eval_at_permutation_roots([Integer(1),
↪Integer(1),Integer(1),Integer(1),Integer(1)])
175
>>> (s[Integer(1)]+s[Integer(2)]+s[Integer(3)]).eval_at_permutation_
↪roots([Integer(3),Integer(2)])
2
```

expand(*n*, *alphabet='x'*)

Expand the symmetric function `self` as a symmetric polynomial in `n` variables.

INPUT:

- `n` – nonnegative integer
- `alphabet` – (default: `'x'`) a variable for the expansion

OUTPUT:

A monomial expansion of `self` in the n variables labelled `x0`, `x1`, …, `x{n-1}` (or just `x` if $n = 1$), where `x` is `alphabet`.

EXAMPLES:

```
sage: J = SymmetricFunctions(QQ).jack(t=2).J()
sage: J([2,1]).expand(3)
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 +␣
↪4*x1*x2^2
sage: (2*J([2])).expand(0)
0
sage: (3*J([])).expand(0)
3
```

```
>>> from sage.all import *
>>> J = SymmetricFunctions(QQ).jack(t=Integer(2)).J()
>>> J([Integer(2),Integer(1)]).expand(Integer(3))
4*x0^2*x1 + 4*x0*x1^2 + 4*x0^2*x2 + 6*x0*x1*x2 + 4*x1^2*x2 + 4*x0*x2^2 +
↪4*x1*x2^2
>>> (Integer(2)*J([Integer(2)])).expand(Integer(0))
0
>>> (Integer(3)*J([])).expand(Integer(0))
3
```

exponential_specialization(*t=None*, *q=1*)

Return the exponential specialization of a symmetric function (when $q = 1$), or the q-exponential specialization (when $q \neq 1$).

The *exponential specialization* ex at t is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R. It is defined whenever the base ring K is a **Q**-algebra and t is an element of R. The easiest way to define it is by specifying its values on the powersum symmetric functions to be $p_1 = t$ and $p_n = 0$ for $n > 1$. Equivalently, on the homogeneous functions it is given by $ex(h_n) = t^n/n!$; see Proposition 7.8.4 of [EnumComb2].

By analogy, the q-exponential specialization is a K-algebra homomorphism from the K-algebra of symmetric functions to another K-algebra R that depends on two elements t and q of R for which the elements $1 - q^i$ for all positive integers i are invertible. It can be defined by specifying its values on the complete homogeneous symmetric functions to be

$$ex_q(h_n) = t^n/[n]_q!,$$

where $[n]_q!$ is the q-factorial. Equivalently, for $q \neq 1$ and a homogeneous symmetric function f of degree n, we have

$$ex_q(f) = (1 - q)^n t^n ps_q(f),$$

where $ps_q(f)$ is the stable principal specialization of f (see `principal_specialization()`). (See (7.29) in [EnumComb2].)

The limit of ex_q as $q \to 1$ is ex.

INPUT:

- `t` – (default: `None`) the value to use for t; the default is to create a ring of polynomials in `t`
- `q` – (default: 1) the value to use for q. If `q` is `None`, then a ring (or fraction field) of polynomials in `q` is created.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: (m[2,1]+m[1,1]).exponential_specialization()
1/2*t^2
sage: (m[2,1]+m[1,1]).exponential_specialization(q=1)
1/2*t^2
sage: m[1,1].exponential_specialization(q=None)
(q/(q + 1))*t^2
sage: Qq = PolynomialRing(QQ, "q"); q = Qq.gen()
sage: m[1,1].exponential_specialization(q=q)
(q/(q + 1))*t^2
sage: Qt = PolynomialRing(QQ, "t"); t = Qt.gen()
```

(continues on next page)

(continued from previous page)

```
sage: m[1,1].exponential_specialization(t=t)
1/2*t^2
sage: Qqt = PolynomialRing(QQ, ["q", "t"]); q, t = Qqt.gens()
sage: m[1,1].exponential_specialization(q=q, t=t)
q*t^2/(q + 1)

sage: x = m[3]+m[2,1]+m[1,1,1]
sage: d = x.homogeneous_degree()
sage: var("q t")                                                        #␣
↪needs sage.symbolic
(q, t)
sage: factor((x.principal_specialization()*(1-q)^d*t^d))               #␣
↪needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
sage: factor(x.exponential_specialization(q=q, t=t))                   #␣
↪needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> (m[Integer(2),Integer(1)]+m[Integer(1),Integer(1)]).exponential_
↪specialization()
1/2*t^2
>>> (m[Integer(2),Integer(1)]+m[Integer(1),Integer(1)]).exponential_
↪specialization(q=Integer(1))
1/2*t^2
>>> m[Integer(1),Integer(1)].exponential_specialization(q=None)
(q/(q + 1))*t^2
>>> Qq = PolynomialRing(QQ, "q"); q = Qq.gen()
>>> m[Integer(1),Integer(1)].exponential_specialization(q=q)
(q/(q + 1))*t^2
>>> Qt = PolynomialRing(QQ, "t"); t = Qt.gen()
>>> m[Integer(1),Integer(1)].exponential_specialization(t=t)
1/2*t^2
>>> Qqt = PolynomialRing(QQ, ["q", "t"]); q, t = Qqt.gens()
>>> m[Integer(1),Integer(1)].exponential_specialization(q=q, t=t)
q*t^2/(q + 1)

>>> x = m[Integer(3)]+m[Integer(2),Integer(1)]+m[Integer(1),Integer(1),
↪Integer(1)]
>>> d = x.homogeneous_degree()
>>> var("q t")                                                        #␣
↪needs sage.symbolic
(q, t)
>>> factor((x.principal_specialization()*(Integer(1)-q)**d*t**d))     ␣
↪       # needs sage.symbolic

>>> factor(x.exponential_specialization(q=q, t=t))                   #␣
↪needs sage.symbolic
t^3/((q^2 + q + 1)*(q + 1))
```

factor()

Return the factorization of this symmetric function.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: factor((5*e[3] + e[2,1] + e[1])*(7*e[2] + e[5,1]))
(e[1] + e[2, 1] + 5*e[3]) * (7*e[2] + e[5, 1])

sage: R.<x, y> = QQ[]
sage: s = SymmetricFunctions(R.fraction_field()).s()
sage: factor((s[3] + x*s[2,1] + 1)*(3*y*s[2] + s[4,1] + x*y))
(-s[] - x*s[2, 1] - s[3]) * (-x*y*s[] - 3*y*s[2] - s[4, 1])
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> factor((Integer(5)*e[Integer(3)] + e[Integer(2),Integer(1)] +␣
↪e[Integer(1)])*(Integer(7)*e[Integer(2)] + e[Integer(5),Integer(1)]))
(e[1] + e[2, 1] + 5*e[3]) * (7*e[2] + e[5, 1])

>>> R = QQ['x, y']; (x, y,) = R._first_ngens(2)
>>> s = SymmetricFunctions(R.fraction_field()).s()
>>> factor((s[Integer(3)] + x*s[Integer(2),Integer(1)] +␣
↪Integer(1))*(Integer(3)*y*s[Integer(2)] + s[Integer(4),Integer(1)] + x*y))
(-s[] - x*s[2, 1] - s[3]) * (-x*y*s[] - 3*y*s[2] - s[4, 1])
```

frobenius(**args*, ***kwds*)

Deprecated: Use `adams_operator()` instead. See Issue #36396 for details.

gcd(*other*)

Return the greatest common divisor with `other`.

INPUT:

- `other` – the other symmetric function

EXAMPLES:

```
sage: e = SymmetricFunctions(ZZ).e()
sage: A = 5*e[3] + e[2,1] + e[1]
sage: B = 7*e[2] + e[5,1]
sage: C = 3*e[1,1] + e[2]
sage: gcd(A*B^2, B*C)
7*e[2] + e[5, 1]

sage: p = SymmetricFunctions(ZZ).p()
sage: gcd(e[2,1], p[1,1]-p[2])
e[2]
sage: gcd(p[2,1], p[3,2]-p[2,1])
p[2]
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(ZZ).e()
>>> A = Integer(5)*e[Integer(3)] + e[Integer(2),Integer(1)] + e[Integer(1)]
>>> B = Integer(7)*e[Integer(2)] + e[Integer(5),Integer(1)]
>>> C = Integer(3)*e[Integer(1),Integer(1)] + e[Integer(2)]
```

(continues on next page)

(continued from previous page)

```
>>> gcd(A*B**Integer(2), B*C)
7*e[2] + e[5, 1]

>>> p = SymmetricFunctions(ZZ).p()
>>> gcd(e[Integer(2),Integer(1)], p[Integer(1),Integer(1)]-p[Integer(2)])
e[2]
>>> gcd(p[Integer(2),Integer(1)], p[Integer(3),Integer(2)]-p[Integer(2),
↪Integer(1)])
p[2]
```

hl_creation_operator(*nu*, *t=None*)

This is the vertex operator that generalizes Jing's operator.

It is a linear operator that raises the degree by $|\nu|$. This creation operator is a t-analogue of multiplication by `s(nu)` .

See also

Proposition 5 in [SZ2001].

INPUT:

- `nu` – a partition or a list of integers
- `t` – (default: `None`, in which case `t` is used) an element of the base ring

REFERENCES:

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ['t']).s()
sage: s([2]).hl_creation_operator([3,2])
s[3, 2, 2] + t*s[3, 3, 1] + t*s[4, 2, 1] + t^2*s[4, 3] + t^2*s[5, 2]

sage: Sym = SymmetricFunctions(FractionField(QQ['t']))
sage: HLQp = Sym.hall_littlewood().Qp()
sage: s = Sym.s()

```

inner_plethysm(*x*)

Return the inner plethysm of `self` with `x`.

Whenever R is a $\mathbf{Q}$-algebra, and f and g are two symmetric functions over R such that the constant term of f is zero, the inner plethysm of f with g is a symmetric function over R, and the degree of this symmetric function is the same as the degree of g. We will denote the inner plethysm of f with g by $f\{g\}$ (in contrast to the notation of outer plethysm which is generally denoted $f[g]$); in Sage syntax, it is `f.inner_plethysm(g)`.

First we describe the axiomatic definition of the operation; see below for a representation-theoretic interpretation. In the following equations, we denote the outer product (i.e., the standard product on the ring of symmetric functions, `product()`) by $\cdot$ and the Kronecker product (`itensor()`) by $*$).

$$(f + g)\{h\} = f\{h\} + g\{h\}$$
$$(f \cdot g)\{h\} = (f\{h\}) * (g\{h\})$$
$$p_k\{f + g\} = p_k\{f\} + p_k\{g\}$$

where p_k is the k-th power-sum symmetric function for every $k > 0$.

Let σ be a permutation of cycle type μ and let μ^k be the cycle type of σ^k. Then,

$$p_k\{p_\mu/z_\mu\} = \sum_{\nu:\nu^k=\mu} p_\nu/z_\nu$$

Since $(p_\mu/z_\mu)_\mu$ is a basis for the symmetric functions, these four formulas define the symmetric function operation $f\{g\}$ for any symmetric functions f and g (where f has constant term 0) by expanding f in the power sum basis and g in the dual basis p_μ/z_μ.

See also

`itensor()`, `partition_power()`, `plethysm()`

This operation admits a representation-theoretic interpretation in the case where f is a Schur function s_λ and g is a homogeneous degree n symmetric function with nonnegative integral coefficients in the Schur basis. The symmetric function $f\{g\}$ is the Frobenius image of the S_n-representation constructed as follows.

The assumptions on g imply that g is the Frobenius image of a representation ρ of the symmetric group S_n:

$$\rho : S_n \to GL_N.$$

If the degree N of this representation is greater than or equal to the number of parts of λ, then f, which denotes s_λ, corresponds to the character of some irreducible GL_N-representation, say

$$\sigma : GL_N \to GL_M.$$

The composition $\sigma \circ \rho : S_n \to GL_M$ is a representation of S_n whose Frobenius image is precisely $f\{g\}$.

If N is less than the number of parts of λ, then $f\{g\}$ is 0 by definition.

When f is a symmetric function with constant term $\neq 0$, the inner plethysm $f\{g\}$ isn't well-defined in the ring of symmetric functions. Indeed, it is not clear how to define $1\{g\}$. The most sensible way to get around this probably is defining it as the infinite sum $h_0 + h_1 + h_2 + \cdots$ (where h_i means the i-th complete homogeneous symmetric function) in the completion of this ring with respect to its grading. This is how [SchaThi1994] defines $1\{g\}$. The present method, however, sets it to be the sum of h_i over all i for which the i-th homogeneous component of g is nonzero. This is rather a hack than a reasonable definition. Use with caution!

Note

If a symmetric function g is written in the form $g = g_0 + g_1 + g_2 + \cdots$ with each g_i homogeneous of degree i, then $f\{g\} = f\{g_0\} + f\{g_1\} + f\{g_2\} + \cdots$ for every f with constant term 0. But in general, inner plethysm is not linear in the second variable.

REFERENCES:

INPUT:

- x – element of the ring of symmetric functions over the same base ring as self

OUTPUT: an element of symmetric functions in the parent of self

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)

6*p[1, 1, 1] + 12*p[3]
```

inner_tensor(*x*)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!)\cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note: The internal product is sometimes referred to as "inner product" in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see *scalar()*).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods *itensor()*, *internal_product()*, *kronecker_product()*, *inner_tensor()* are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> b = s([Integer(3)])
>>> a.itensor(b)
s[2, 1]
>>> c = s([Integer(3),Integer(2),Integer(1)])
>>> c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n-th complete homogeneous symmetric function `h[n]` (a.k.a. `s[n]`) is f:

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(ZZ).h()
>>> all( h([Integer(5)]).itensor(h(p)) == h(p) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product of a Schur function s_λ with the n-th elementary symmetric function `e[n]`, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> F = CyclotomicField(Integer(12))
>>> s = SymmetricFunctions(F).s()
>>> e = SymmetricFunctions(F).e()
>>> all( e([Integer(5)]).itensor(s(p)) == s(p.conjugate()) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(4) )
....:      for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
....:           for r in Partitions(4) )
....:      for p in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(Integer(4)) )
...      for p in Partitions(Integer(4)) )
True

>>> F = FractionField(QQ['q','t'])
>>> mq = SymmetricFunctions(F).macdonald().Q()
>>> mh = SymmetricFunctions(F).macdonald().H()
>>> all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
...           for r in Partitions(Integer(4)) )
```

(continues on next page)

(continued from previous page)

```
...       for p in Partitions(Integer(3)) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, "Noncommutative symmetric functions", arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w))␣
↪with
....:                            # * meaning Kronecker product and \mu␣
↪meaning the
....:                            # usual multiplication.
....:     result = w.parent().zero()
....:     for partition_pair, coeff in w.coproduct():
....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])   # long time
....:                == (e[u] * s[v]).itensor(m[w])
....:                for w in Partitions(5) )
....:           for v in Partitions(2) )
....:      for u in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()
>>> def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w)) with
...                            # * meaning Kronecker product and \mu meaning␣
↪the
...                            # usual multiplication.
...     result = w.parent().zero()
...     for partition_pair, coeff in w.coproduct():
...         result += coeff * w.parent()(u).itensor(partition_
↪pair[Integer(0)]) * w.parent()(v).itensor(partition_pair[Integer(1)])
...     return result
>>> all( all( all( tensor_copr(e[u], s[v], m[w])   # long time
...                == (e[u] * s[v]).itensor(m[w])
...                for w in Partitions(Integer(5)) )
...           for v in Partitions(Integer(2)) )
...      for u in Partitions(Integer(3)) )
True
```

Some examples from Briand, Orellana, Rosas, "The stability of the Kronecker products of Schur functions." arXiv 0907.4652:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
```

(continues on next page)

(continued from previous page)

```
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
↪+ s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> s[Integer(2),Integer(2)].itensor(s[Integer(2),Integer(2)])
s[1, 1, 1, 1] + s[2, 2] + s[4]
>>> s[Integer(3),Integer(2)].itensor(s[Integer(3),Integer(2)])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
>>> s[Integer(4),Integer(2)].itensor(s[Integer(4),Integer(2)])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]
↪+ s[6]
```

An example from p. 220 of Thibon, “Hopf algebras of symmetric functions and tensor products of symmetric group representations”, International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQbar).s()
>>> s[Integer(2),Integer(1)].itensor(s[Integer(2),Integer(1)])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a $\mathbf{Q}$-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn’t. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the “corresponding” basis of the symmetric function algebra over $\mathbf{Q}$ (using the `corresponding_basis_over` hack) from the case when it isn’t (in which case it transforms everything into the Schur basis, which is slow).

internal_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means λ is a partition of n, and n is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer n. If the base ring is a $\mathbf{Q}$-algebra, it also satisfies

$$\Delta^{\times}(h_n) = \sum_{\lambda \vdash n} z_{\lambda}^{-1} p_{\lambda} \otimes p_{\lambda},$$

where

$$z_{\lambda} = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of i in λ (see `zee()`).

The method `kronecker_coproduct()` is a synonym of `internal_coproduct()`.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #
↪s[3] + s[3] # s[2, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> a = s([Integer(2),Integer(1)])
>>> a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #
↪s[3] + s[3] # s[2, 1]

>>> e = SymmetricFunctions(QQ).e()
>>> b = e([Integer(2)])
>>> b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions f, g and h satisfy $\langle f * g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle$, where we write $\Delta^{\times}(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \
↪left< g, h''_i \right>
....:     result = h.base_ring().zero()
....:     for partition_pair, coeff in h.internal_coproduct():
....:         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.
↪parent()(g).scalar(partition_pair[1])
....:     return result
sage: all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪scalar(m[w])  # long time (10s on sage.math, 2013)
```

(continues on next page)

(continued from previous page)

```
....:                 for w in Partitions(5) )
....:            for v in Partitions(2) )
....:       for u in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()
>>> def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \
↪left< g, h''_i \right>
...     result = h.base_ring().zero()
...     for partition_pair, coeff in h.internal_coproduct():
...         result += coeff * h.parent()(f).scalar(partition_
↪pair[Integer(0)]) * h.parent()(g).scalar(partition_pair[Integer(1)])
...     return result
>>> all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪scalar(m[w])  # long time (10s on sage.math, 2013)
...                 for w in Partitions(Integer(5)) )
...            for v in Partitions(Integer(2)) )
...       for u in Partitions(Integer(3)) )
True
```

Let us check the formulas for $\Delta^{\times}(h_n)$ and $\Delta^{\times}(p_n)$ given in the description of this method:

```
sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)])␣
↪for lam in Partitions(n)])
....:       for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))])␣
↪for lam in Partitions(n)])
....:       for n in range(6) )
True
sage: all( factorial(n) * h([n]).internal_coproduct()
....:       == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
....:               for lam in Partitions(n)])
....:       for n in range(6) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> p = SymmetricFunctions(QQ).p()
>>> h = SymmetricFunctions(QQ).h()
>>> s = SymmetricFunctions(QQ).s()
>>> all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)]) for␣
↪lam in Partitions(n)])
...       for n in range(Integer(6)) )
True
```

(continues on next page)

(continued from previous page)

```
>>> all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))]) for␣
↪lam in Partitions(n)])
...       for n in range(Integer(6)) )
True
>>> all( factorial(n) * h([n]).internal_coproduct()
...       == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
...               for lam in Partitions(n)])
...       for n in range(Integer(6)) )
True
```

internal_product(*x*)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note

The internal product is sometimes referred to as "inner product" in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
```

(continues on next page)

(continued from previous page)

```
>>> a = s([Integer(2),Integer(1)])
>>> b = s([Integer(3)])
>>> a.itensor(b)
s[2, 1]
>>> c = s([Integer(3),Integer(2),Integer(1)])
>>> c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n-th complete homogeneous symmetric function `h[n]` (a.k.a. `s[n]`) is f:

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(ZZ).h()
>>> all( h([Integer(5)]).itensor(h(p)) == h(p) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product of a Schur function s_λ with the n-th elementary symmetric function `e[n]`, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> F = CyclotomicField(Integer(12))
>>> s = SymmetricFunctions(F).s()
>>> e = SymmetricFunctions(F).e()
>>> all( e([Integer(5)]).itensor(s(p)) == s(p.conjugate()) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(4) )
....:      for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
```

(continues on next page)

(continued from previous page)

```
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
....:           for r in Partitions(4) )
....:       for p in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(Integer(4)) )
...       for p in Partitions(Integer(4)) )
True

>>> F = FractionField(QQ['q','t'])
>>> mq = SymmetricFunctions(F).macdonald().Q()
>>> mh = SymmetricFunctions(F).macdonald().H()
>>> all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
...           for r in Partitions(Integer(4)) )
...       for p in Partitions(Integer(3)) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Noncommutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w))␣
↪with
....:                            # * meaning Kronecker product and \mu␣
↪meaning the
....:                            # usual multiplication.
....:     result = w.parent().zero()
....:     for partition_pair, coeff in w.coproduct():
....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])    # long time
....:                == (e[u] * s[v]).itensor(m[w])
....:                for w in Partitions(5) )
....:           for v in Partitions(2) )
....:       for u in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()
>>> def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w)) with
...                            # * meaning Kronecker product and \mu meaning␣
```

(continues on next page)

(continued from previous page)

```
↪the
...                                 # usual multiplication.
...     result = w.parent().zero()
...     for partition_pair, coeff in w.coproduct():
...         result += coeff * w.parent()(u).itensor(partition_
↪pair[Integer(0)]) * w.parent()(v).itensor(partition_pair[Integer(1)])
...     return result
>>> all( all( all( tensor_copr(e[u], s[v], m[w])    # long time
...                  == (e[u] * s[v]).itensor(m[w])
...                  for w in Partitions(Integer(5)) )
...             for v in Partitions(Integer(2)) )
...        for u in Partitions(Integer(3)) )
True
```

Some examples from Briand, Orellana, Rosas, "The stability of the Kronecker products of Schur functions." arXiv 0907.4652:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]␣
↪+ s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> s[Integer(2),Integer(2)].itensor(s[Integer(2),Integer(2)])
s[1, 1, 1, 1] + s[2, 2] + s[4]
>>> s[Integer(3),Integer(2)].itensor(s[Integer(3),Integer(2)])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
>>> s[Integer(4),Integer(2)].itensor(s[Integer(4),Integer(2)])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]␣
↪+ s[6]
```

An example from p. 220 of Thibon, "Hopf algebras of symmetric functions and tensor products of symmetric group representations", International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQbar).s()
>>> s[Integer(2),Integer(1)].itensor(s[Integer(2),Integer(1)])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a **Q**-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the "corresponding" basis of the symmetric function algebra over **Q** (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

is_schur_positive()

Return `True` if and only if `self` is Schur positive.

If s is the space of Schur functions over `self`'s base ring, then this is the same as `self._is_positive(s)`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1]) + s([3])
sage: a.is_schur_positive()
True
sage: a = s([2,1]) - s([3])
sage: a.is_schur_positive()
False
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)]) + s([Integer(3)])
>>> a.is_schur_positive()
True
>>> a = s([Integer(2),Integer(1)]) - s([Integer(3)])
>>> a.is_schur_positive()
False
```

```
sage: QQx = QQ['x']
sage: s = SymmetricFunctions(QQx).s()
sage: x = QQx.gen()
sage: a = (1+x)*s([2,1])
sage: a.is_schur_positive()
True
sage: a = (1-x)*s([2,1])
sage: a.is_schur_positive()
False
sage: s(0).is_schur_positive()
True
sage: s(1+x).is_schur_positive()
True
```

```
>>> from sage.all import *
>>> QQx = QQ['x']
>>> s = SymmetricFunctions(QQx).s()
>>> x = QQx.gen()
>>> a = (Integer(1)+x)*s([Integer(2),Integer(1)])
>>> a.is_schur_positive()
True
>>> a = (Integer(1)-x)*s([Integer(2),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> a.is_schur_positive()
False
>>> s(Integer(0)).is_schur_positive()
True
>>> s(Integer(1)+x).is_schur_positive()
True
```

itensor(*x*)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note

The internal product is sometimes referred to as "inner product" in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> b = s([Integer(3)])
>>> a.itensor(b)
```

(continues on next page)

(continued from previous page)

```
s[2, 1]
>>> c = s([Integer(3),Integer(2),Integer(1)])
>>> c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n-th complete homogeneous symmetric function `h[n]` (a.k.a. `s[n]`) is f:

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(ZZ).h()
>>> all( h([Integer(5)]).itensor(h(p)) == h(p) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product of a Schur function s_λ with the n-th elementary symmetric function `e[n]`, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> F = CyclotomicField(Integer(12))
>>> s = SymmetricFunctions(F).s()
>>> e = SymmetricFunctions(F).e()
>>> all( e([Integer(5)]).itensor(s(p)) == s(p.conjugate()) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(4) )
....:       for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
```

(continues on next page)

(continued from previous page)

```
....:            for r in Partitions(4) )
....:       for p in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(Integer(4)) )
...       for p in Partitions(Integer(4)) )
True

>>> F = FractionField(QQ['q','t'])
>>> mq = SymmetricFunctions(F).macdonald().Q()
>>> mh = SymmetricFunctions(F).macdonald().H()
>>> all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
...            for r in Partitions(Integer(4)) )
...       for p in Partitions(Integer(3)) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, "Noncommutative symmetric functions", arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w))␣
↪with
....:                            # * meaning Kronecker product and \mu␣
↪meaning the
....:                            # usual multiplication.
....:     result = w.parent().zero()
....:     for partition_pair, coeff in w.coproduct():
....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
....:     return result
sage: all( all( all( tensor_copr(e[u], s[v], m[w])    # long time
....:                == (e[u] * s[v]).itensor(m[w])
....:                for w in Partitions(5) )
....:           for v in Partitions(2) )
....:      for u in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()
>>> def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w)) with
...                            # * meaning Kronecker product and \mu meaning␣
↪the
...                            # usual multiplication.
...     result = w.parent().zero()
```

(continues on next page)

(continued from previous page)

```
...     for partition_pair, coeff in w.coproduct():
...         result += coeff * w.parent()(u).itensor(partition_
↪pair[Integer(0)]) * w.parent()(v).itensor(partition_pair[Integer(1)])
...     return result
>>> all( all( all( tensor_copr(e[u], s[v], m[w])   # long time
...                == (e[u] * s[v]).itensor(m[w])
...                for w in Partitions(Integer(5)) )
...           for v in Partitions(Integer(2)) )
...      for u in Partitions(Integer(3)) )
True
```

Some examples from Briand, Orellana, Rosas, "The stability of the Kronecker products of Schur functions." arXiv 0907.4652:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: s[2,2].itensor(s[2,2])
s[1, 1, 1, 1] + s[2, 2] + s[4]
sage: s[3,2].itensor(s[3,2])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s[4,2].itensor(s[4,2])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]␣
↪+ s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> s[Integer(2),Integer(2)].itensor(s[Integer(2),Integer(2)])
s[1, 1, 1, 1] + s[2, 2] + s[4]
>>> s[Integer(3),Integer(2)].itensor(s[Integer(3),Integer(2)])
s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 1, 1] + s[3, 2] + s[4, 1] + s[5]
>>> s[Integer(4),Integer(2)].itensor(s[Integer(4),Integer(2)])
s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]␣
↪+ s[6]
```

An example from p. 220 of Thibon, "Hopf algebras of symmetric functions and tensor products of symmetric group representations", International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQbar).s()
>>> s[Integer(2),Integer(1)].itensor(s[Integer(2),Integer(1)])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a **Q**-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the "corresponding" basis of the symmetric function algebra over **Q** (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

kronecker_coproduct()

Return the inner coproduct of `self` in the basis of `self`.

The inner coproduct (also known as the Kronecker coproduct, as the internal coproduct, or as the second comultiplication on the ring of symmetric functions) is a ring homomorphism $\Delta^\times$ from the ring of symmetric functions to the tensor product (over the base ring) of this ring with itself. It is uniquely characterized by the formula

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda = \sum_{\lambda \vdash n} h_\lambda \otimes m_\lambda = \sum_{\lambda \vdash n} m_\lambda \otimes h_\lambda,$$

where $\lambda \vdash n$ means λ is a partition of n, and n is any nonnegative integer. It also satisfies

$$\Delta^\times(p_n) = p_n \otimes p_n$$

for any positive integer n. If the base ring is a **Q**-algebra, it also satisfies

$$\Delta^\times(h_n) = \sum_{\lambda \vdash n} z_\lambda^{-1} p_\lambda \otimes p_\lambda,$$

where

$$z_\lambda = \prod_{i=1}^{\infty} i^{m_i(\lambda)} m_i(\lambda)!$$

with $m_i(\lambda)$ meaning the number of appearances of i in λ (see *zee()*).

The method *kronecker_coproduct()* is a synonym of *internal_coproduct()*.

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: a = s([2,1])
sage: a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #␣
→s[3] + s[3] # s[2, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: b = e([2])
sage: b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> a = s([Integer(2),Integer(1)])
>>> a.internal_coproduct()
s[1, 1, 1] # s[2, 1] + s[2, 1] # s[1, 1, 1] + s[2, 1] # s[2, 1] + s[2, 1] #␣
→s[3] + s[3] # s[2, 1]

>>> e = SymmetricFunctions(QQ).e()
>>> b = e([Integer(2)])
>>> b.internal_coproduct()
e[1, 1] # e[2] + e[2] # e[1, 1] - 2*e[2] # e[2]
```

The internal coproduct is adjoint to the internal product with respect to the Hall inner product: Any three symmetric functions f, g and h satisfy $\langle f * g, h\rangle = \sum_i \langle f, h'_i\rangle \langle g, h''_i\rangle$, where we write $\Delta^{\times}(h)$ as $\sum_i h'_i \otimes h''_i$. Let us check this in degree 4:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \
↪left< g, h''_i \right>
....:     result = h.base_ring().zero()
....:     for partition_pair, coeff in h.internal_coproduct():
....:         result += coeff * h.parent()(f).scalar(partition_pair[0]) * h.
↪parent()(g).scalar(partition_pair[1])
....:     return result
sage: all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪scalar(m[w])  # long time (10s on sage.math, 2013)
....:                  for w in Partitions(5) )
....:            for v in Partitions(2) )
....:      for u in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(29))).e()
>>> s = SymmetricFunctions(FiniteField(Integer(29))).s()
>>> m = SymmetricFunctions(FiniteField(Integer(29))).m()
>>> def tensor_incopr(f, g, h):  # computes \sum_i \left< f, h'_i \right> \
↪left< g, h''_i \right>
...     result = h.base_ring().zero()
...     for partition_pair, coeff in h.internal_coproduct():
...         result += coeff * h.parent()(f).scalar(partition_
↪pair[Integer(0)]) * h.parent()(g).scalar(partition_pair[Integer(1)])
...     return result
>>> all( all( all( tensor_incopr(e[u], s[v], m[w]) == (e[u].itensor(s[v])).
↪scalar(m[w])  # long time (10s on sage.math, 2013)
...                  for w in Partitions(Integer(5)) )
...            for v in Partitions(Integer(2)) )
...      for u in Partitions(Integer(3)) )
True
```

Let us check the formulas for $\Delta^{\times}(h_n)$ and $\Delta^{\times}(p_n)$ given in the description of this method:

```
sage: e = SymmetricFunctions(QQ).e()
sage: p = SymmetricFunctions(QQ).p()
sage: h = SymmetricFunctions(QQ).h()
sage: s = SymmetricFunctions(QQ).s()
sage: all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)])␣
↪for lam in Partitions(n)])
....:      for n in range(6) )
True
sage: all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))])␣
↪for lam in Partitions(n)])
....:      for n in range(6) )
True
```

(continues on next page)

(continued from previous page)

```
sage: all( factorial(n) * h([n]).internal_coproduct()
....:      == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
....:              for lam in Partitions(n)])
....:      for n in range(6) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(QQ).e()
>>> p = SymmetricFunctions(QQ).p()
>>> h = SymmetricFunctions(QQ).h()
>>> s = SymmetricFunctions(QQ).s()
>>> all( s(h([n])).internal_coproduct() == sum([tensor([s(lam), s(lam)]) for␣
↪lam in Partitions(n)])
...      for n in range(Integer(6)) )
True
>>> all( h([n]).internal_coproduct() == sum([tensor([h(lam), h(m(lam))]) for␣
↪lam in Partitions(n)])
...      for n in range(Integer(6)) )
True
>>> all( factorial(n) * h([n]).internal_coproduct()
...      == sum([lam.conjugacy_class_size() * tensor([h(p(lam)), h(p(lam))])
...              for lam in Partitions(n)])
...      for n in range(Integer(6)) )
True
```

kronecker_product(*x*)

Return the internal (tensor) product of `self` and `x` in the basis of `self`.

The internal tensor product can be defined as the linear extension of the definition on power sums $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$, where $z_\lambda = (1^{r_1} r_1!)(2^{r_2} r_2!) \cdots$ for $\lambda = (1^{r_1} 2^{r_2} \cdots)$ and where $*$ denotes the internal tensor product. The internal tensor product is also known as the Kronecker product, or as the second multiplication on the ring of symmetric functions.

Note that the internal product of any two homogeneous symmetric functions of equal degrees is a homogeneous symmetric function of the same degree. On the other hand, the internal product of two homogeneous symmetric functions of distinct degrees is 0.

Note

The internal product is sometimes referred to as "inner product" in the literature, but unfortunately this name is shared by a different operation, namely the Hall inner product (see `scalar()`).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the internal product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

The methods `itensor()`, `internal_product()`, `kronecker_product()`, `inner_tensor()` are all synonyms.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: b = s([3])
sage: a.itensor(b)
s[2, 1]
sage: c = s([3,2,1])
sage: c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> b = s([Integer(3)])
>>> a.itensor(b)
s[2, 1]
>>> c = s([Integer(3),Integer(2),Integer(1)])
>>> c.itensor(c)
s[1, 1, 1, 1, 1, 1] + 2*s[2, 1, 1, 1, 1] + 3*s[2, 2, 1, 1] + 2*s[2, 2, 2]
 + 4*s[3, 1, 1, 1] + 5*s[3, 2, 1] + 2*s[3, 3] + 4*s[4, 1, 1]
 + 3*s[4, 2] + 2*s[5, 1] + s[6]
```

There are few quantitative results pertaining to Kronecker products in general, which makes their computation so difficult. Let us test a few of them in different bases.

The Kronecker product of any homogeneous symmetric function f of degree n with the n-th complete homogeneous symmetric function `h[n]` (a.k.a. `s[n]`) is f:

```
sage: h = SymmetricFunctions(ZZ).h()
sage: all( h([5]).itensor(h(p)) == h(p) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(ZZ).h()
>>> all( h([Integer(5)]).itensor(h(p)) == h(p) for p in␣
↪Partitions(Integer(5)) )
True
```

The Kronecker product of a Schur function s_λ with the n-th elementary symmetric function `e[n]`, where $n = |\lambda|$, is $s_{\lambda'}$ (where λ' is the conjugate partition of λ):

```
sage: F = CyclotomicField(12)
sage: s = SymmetricFunctions(F).s()
sage: e = SymmetricFunctions(F).e()
sage: all( e([5]).itensor(s(p)) == s(p.conjugate()) for p in Partitions(5) )
True
```

```
>>> from sage.all import *
>>> F = CyclotomicField(Integer(12))
>>> s = SymmetricFunctions(F).s()
>>> e = SymmetricFunctions(F).e()
>>> all( e([Integer(5)]).itensor(s(p)) == s(p.conjugate()) for p in␣
```

(continues on next page)

(continued from previous page)

```
↪Partitions(Integer(5)) )
True
```

The Kronecker product is commutative:

```
sage: e = SymmetricFunctions(FiniteField(19)).e()
sage: m = SymmetricFunctions(FiniteField(19)).m()
sage: all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(4) )
....:      for p in Partitions(4) )
True

sage: F = FractionField(QQ['q','t'])
sage: mq = SymmetricFunctions(F).macdonald().Q()
sage: mh = SymmetricFunctions(F).macdonald().H()
sage: all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
....:           for r in Partitions(4) )
....:      for p in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> e = SymmetricFunctions(FiniteField(Integer(19))).e()
>>> m = SymmetricFunctions(FiniteField(Integer(19))).m()
>>> all( all( e(p).itensor(m(q)) == m(q).itensor(e(p)) for q in␣
↪Partitions(Integer(4)) )
...      for p in Partitions(Integer(4)) )
True

>>> F = FractionField(QQ['q','t'])
>>> mq = SymmetricFunctions(F).macdonald().Q()
>>> mh = SymmetricFunctions(F).macdonald().H()
>>> all( all( mq(p).itensor(mh(r)) == mh(r).itensor(mq(p))    # long time
...           for r in Partitions(Integer(4)) )
...      for p in Partitions(Integer(3)) )
True
```

Let us check (on examples) Proposition 5.2 of Gelfand, Krob, Lascoux, Leclerc, Retakh, Thibon, “Noncommutative symmetric functions”, arXiv hep-th/9407124, for $r = 2$:

```
sage: e = SymmetricFunctions(FiniteField(29)).e()
sage: s = SymmetricFunctions(FiniteField(29)).s()
sage: m = SymmetricFunctions(FiniteField(29)).m()
sage: def tensor_copr(u, v, w):  # computes \mu ((u \otimes v) * \Delta(w))␣
↪with
....:                            # * meaning Kronecker product and \mu␣
↪meaning the
....:                            # usual multiplication.
....:     result = w.parent().zero()
....:     for partition_pair, coeff in w.coproduct():
....:         result += coeff * w.parent()(u).itensor(partition_pair[0]) * w.
↪parent()(v).itensor(partition_pair[1])
....:     return result
```

(continues on next page)

(continued from previous page)

```
sage: all( all( all( tensor_copr(e[u], s[v], m[w])   # long time
....:                == (e[u] * s[v]).itensor(m[w])
....:                for w in Partitions(5) )
....:           for v in Partitions(2) )
....:      for u in Partitions(3) )
True
```

```

s[2, 2, 2] + s[3, 1, 1, 1] + 2*s[3, 2, 1] + s[4, 1, 1] + 2*s[4, 2] + s[5, 1]␣
↪+ s[6]
```

An example from p. 220 of Thibon, "Hopf algebras of symmetric functions and tensor products of symmetric group representations", International Journal of Algebra and Computation, 1991:

```
sage: s = SymmetricFunctions(QQbar).s()
sage: s[2,1].itensor(s[2,1])
s[1, 1, 1] + s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQbar).s()
>>> s[Integer(2),Integer(1)].itensor(s[Integer(2),Integer(1)])
s[1, 1, 1] + s[2, 1] + s[3]
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a **Q**-algebra (in which case the Kronecker product can be easily computed using the power sum basis) from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the "corresponding" basis of the symmetric function algebra over **Q** (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

left_padded_kronecker_product(*x*)

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the Kronecker product (*itensor()*) on the space of symmetric functions. For any partitions α, β, γ, let $g^{\gamma}_{\alpha,\beta}$ denote the coefficient of the complete homogeneous symmetric function h_γ in the Kronecker product $h_\alpha * h_\beta$. For every partition $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the n-completion of λ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)$; see *t_completion()*). Then, for any partitions α and β and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $h_{\alpha[n]} * h_{\beta[n]}$ in the form

$$h_{\alpha[n]} * h_{\beta[n]} = \sum_{\gamma} g^{\gamma[n]}_{\alpha[n],\beta[n]} h_{\gamma[n]}$$

with γ ranging over all partitions. The coefficients $g^{\gamma[n]}_{\alpha[n],\beta[n]}$ are independent on n. These coefficients $g^{\gamma[n]}_{\alpha[n],\beta[n]}$ are denoted by $\overline{g}^{\gamma}_{\alpha,\beta}$, and the symmetric function

$$\sum_{\gamma} \overline{g}^{\gamma}_{\alpha,\beta} h_\gamma$$

is said to be the *left-padded Kronecker product* of h_α and h_β. By bilinearity, this extends to a definition of a left-padded Kronecker product of any two symmetric functions.

This notion of left-padded Kronecker product can be lifted to the non-commutative symmetric functions (*left_padded_kronecker_product()*).

Warning

Do not mistake this product for the reduced Kronecker product (*reduced_kronecker_product()*), which uses the Schur functions instead of the complete homogeneous functions in its definition.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the left-padded Kronecker product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: h = Sym.h()
sage: h[2,1].left_padded_kronecker_product(h[3])
h[1, 1, 1, 1] + h[2, 1] + h[2, 1, 1] + h[2, 1, 1, 1] + h[2, 2, 1] + h[3, 2, 1]
sage: h[2,1].left_padded_kronecker_product(h[1])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
sage: h[1].left_padded_kronecker_product(h[2,1])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
sage: h[1,1].left_padded_kronecker_product(h[2])
h[1, 1] + 2*h[1, 1, 1] + h[2, 1, 1]
sage: h[1].left_padded_kronecker_product(h[2,1,1])
h[1, 1, 1, 1] + 2*h[2, 1, 1] + h[2, 1, 1, 1]
sage: h[2].left_padded_kronecker_product(h[3])
h[2, 1] + h[2, 1, 1] + h[3, 2]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> h = Sym.h()
>>> h[Integer(2),Integer(1)].left_padded_kronecker_product(h[Integer(3)])
h[1, 1, 1, 1] + h[2, 1] + h[2, 1, 1] + h[2, 1, 1, 1] + h[2, 2, 1] + h[3, 2, 1]
>>> h[Integer(2),Integer(1)].left_padded_kronecker_product(h[Integer(1)])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
>>> h[Integer(1)].left_padded_kronecker_product(h[Integer(2),Integer(1)])
h[1, 1, 1] + h[2, 1] + h[2, 1, 1]
>>> h[Integer(1),Integer(1)].left_padded_kronecker_product(h[Integer(2)])
h[1, 1] + 2*h[1, 1, 1] + h[2, 1, 1]
>>> h[Integer(1)].left_padded_kronecker_product(h[Integer(2),Integer(1),
↪Integer(1)])
h[1, 1, 1, 1] + 2*h[2, 1, 1] + h[2, 1, 1, 1]
>>> h[Integer(2)].left_padded_kronecker_product(h[Integer(3)])
h[2, 1] + h[2, 1, 1] + h[3, 2]
```

Taking the left-padded Kronecker product with $1 = h_\emptyset$ is the identity map on the ring of symmetric functions:

```
sage: all( h[Partition([])].left_padded_kronecker_product(h[lam])
....:      == h[lam] for i in range(4)
....:      for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> all( h[Partition([])].left_padded_kronecker_product(h[lam])
...      == h[lam] for i in range(Integer(4))
...      for lam in Partitions(i) )
True
```

Here is a rule for the left-padded Kronecker product of h_1 (this is the same as $h_{(1)}$) with any complete homogeneous function: Let λ be a partition. Then, the left-padded Kronecker product of h_1 and h_λ is

$\sum_\mu a_\mu h_\mu$, where the sum runs over all partitions μ, and the coefficient a_μ is defined as the number of ways to obtain μ from λ by one of the following two operations:

- Insert a 1 into λ.
- Subtract 1 from one of the entries of λ (and remove the entry if it thus becomes 0), and insert a 1 into λ.

We check this for partitions of size ≤ 4:

```
sage: def mults1(I):
....:     # Left-padded Kronecker multiplication by h[1].
....:     res = h[I[:] + [1]]
....:     for k in range(len(I)):
....:         I2 = I[:]
....:         if I2[k] == 1:
....:             I2 = I2[:k] + I2[k+1:]
....:         else:
....:             I2[k] -= 1
....:         res += h[sorted(I2 + [1], reverse=True)]
....:     return res
sage: all( mults1(I) == h[1].left_padded_kronecker_product(h[I])
....:                == h[I].left_padded_kronecker_product(h[1])
....:       for i in range(5) for I in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> def mults1(I):
...     # Left-padded Kronecker multiplication by h[1].
...     res = h[I[:] + [Integer(1)]]
...     for k in range(len(I)):
...         I2 = I[:]
...         if I2[k] == Integer(1):
...             I2 = I2[:k] + I2[k+Integer(1):]
...         else:
...             I2[k] -= Integer(1)
...         res += h[sorted(I2 + [Integer(1)], reverse=True)]
...     return res
>>> all( mults1(I) == h[Integer(1)].left_padded_kronecker_product(h[I])
...                == h[I].left_padded_kronecker_product(h[Integer(1)])
...       for i in range(Integer(5)) for I in Partitions(i) )
True
```

The left-padded Kronecker product is commutative:

```
sage: all( h[lam].left_padded_kronecker_product(h[mu])
....:      == h[mu].left_padded_kronecker_product(h[lam])
....:      for lam in Partitions(3) for mu in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> all( h[lam].left_padded_kronecker_product(h[mu])
...      == h[mu].left_padded_kronecker_product(h[lam])
...      for lam in Partitions(Integer(3)) for mu in Partitions(Integer(3)) )
True
```

nabla(*q=None*, *t=None*, *power=1*)

Return the value of the nabla operator applied to `self`.

The eigenvectors of the nabla operator are the Macdonald polynomials in the Ht basis.

If the parameter `power` is an integer then it calculates nabla to that integer. The default value of `power` is 1.

INPUT:

- `q`, `t` – parameters (default: `None`, in which case `q` and `t` are used)
- `power` – (default: `1`) an integer indicating how many times to apply the operator ∇. Negative values of `power` indicate powers of ∇^{-1}.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: p = Sym.power()
sage: p([1,1]).nabla()
-(1/2*q*t-1/2*q-1/2*t-1/2)*p[1, 1] + (1/2*q*t-1/2*q-1/2*t+1/2)*p[2]
sage: p([2,1]).nabla(q=1)
-(t+1)*p[1, 1, 1] + t*p[2, 1]
sage: p([2]).nabla(q=1)*p([1]).nabla(q=1)
-(t+1)*p[1, 1, 1] + t*p[2, 1]
sage: s = Sym.schur()
sage: s([2,1]).nabla()
-(q^3*t+q^2*t^2+q*t^3)*s[1, 1, 1] - (q^2*t+q*t^2)*s[2, 1]
sage: s([1,1,1]).nabla()
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: s([1,1,1]).nabla(t=1)
(q^3+q^2+2*q+1)*s[1, 1, 1] + (q^2+2*q+2)*s[2, 1] + s[3]
sage: s(0).nabla()
0
sage: s(1).nabla()
s[]
sage: s([2,1]).nabla(power=-1)
-((q+t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(-q^3*t^3))*s[3]
sage: (s([2])+s([3])).nabla()
-q*t*s[1, 1] + (q^3*t^2+q^2*t^3)*s[1, 1, 1] + q^2*t^2*s[2, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> p = Sym.power()
>>> p([Integer(1),Integer(1)]).nabla()
-(1/2*q*t-1/2*q-1/2*t-1/2)*p[1, 1] + (1/2*q*t-1/2*q-1/2*t+1/2)*p[2]
>>> p([Integer(2),Integer(1)]).nabla(q=Integer(1))
-(t+1)*p[1, 1, 1] + t*p[2, 1]
>>> p([Integer(2)]).nabla(q=Integer(1))*p([Integer(1)]).nabla(q=Integer(1))
-(t+1)*p[1, 1, 1] + t*p[2, 1]
>>> s = Sym.schur()
>>> s([Integer(2),Integer(1)]).nabla()
-(q^3*t+q^2*t^2+q*t^3)*s[1, 1, 1] - (q^2*t+q*t^2)*s[2, 1]
>>> s([Integer(1),Integer(1),Integer(1)]).nabla()
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
>>> s([Integer(1),Integer(1),Integer(1)]).nabla(t=Integer(1))
(q^3+q^2+2*q+1)*s[1, 1, 1] + (q^2+2*q+2)*s[2, 1] + s[3]
```

(continues on next page)

(continued from previous page)

```
>>> s(Integer(0)).nabla()
0
>>> s(Integer(1)).nabla()
s[]
>>> s([Integer(2),Integer(1)]).nabla(power=-Integer(1))
-((q+t)/(q^2*t^2))*s[2, 1] + ((q^2+q*t+t^2)/(-q^3*t^3))*s[3]
>>> (s([Integer(2)])+s([Integer(3)])).nabla()
-q*t*s[1, 1] + (q^3*t^2+q^2*t^3)*s[1, 1, 1] + q^2*t^2*s[2, 1]
```

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]
```

```
>>> from sage.all import *
>>> J = SymmetricFunctions(QQ).jack(t=Integer(1)).P()
>>> a = J([Integer(2),Integer(1)]) + J([Integer(1),Integer(1),Integer(1)])
>>> a.omega()
JackP[2, 1] + JackP[3]
>>> J(Integer(0)).omega()
0
>>> J(Integer(1)).omega()
JackP[]
```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
```

(continues on next page)

(continued from previous page)

```
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.m()
>>> f = Sym.f()
>>> all( f(lam) == m(lam).omega() for lam in Partitions(Integer(3)) )
True
>>> all( m(lam) == f(lam).omega() for lam in Partitions(Integer(3)) )
True
```

omega_involution()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

The default implementation converts to the Schur basis, then performs the automorphism and changes back.

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: J = SymmetricFunctions(QQ).jack(t=1).P()
sage: a = J([2,1]) + J([1,1,1])
sage: a.omega()
JackP[2, 1] + JackP[3]
sage: J(0).omega()
0
sage: J(1).omega()
JackP[]
```

```
>>> from sage.all import *
>>> J = SymmetricFunctions(QQ).jack(t=Integer(1)).P()
>>> a = J([Integer(2),Integer(1)]) + J([Integer(1),Integer(1),Integer(1)])
>>> a.omega()
JackP[2, 1] + JackP[3]
>>> J(Integer(0)).omega()
0
```

(continues on next page)

(continued from previous page)

```
>>> J(Integer(1)).omega()
JackP[]
```

The forgotten symmetric functions are the images of the monomial symmetric functions under omega:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: m = Sym.m()
sage: f = Sym.f()
sage: all( f(lam) == m(lam).omega() for lam in Partitions(3) )
True
sage: all( m(lam) == f(lam).omega() for lam in Partitions(3) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> m = Sym.m()
>>> f = Sym.f()
>>> all( f(lam) == m(lam).omega() for lam in Partitions(Integer(3)) )
True
>>> all( m(lam) == f(lam).omega() for lam in Partitions(Integer(3)) )
True
```

omega_qt(*q=None*, *t=None*)

Return the image of `self` under the q,t-deformed omega automorphism which sends p_k to $(-1)^{k-1} \cdot \frac{1-q^k}{1-t^k} \cdot p_k$ for all positive integers k.

In general, this is well-defined outside of the powersum basis only if the base ring is a **Q**-algebra.

If $q = t$, then this is the omega automorphism (`omega()`).

INPUT:

- `q`, `t` – parameters (default: `None`, in which case `'q'` and `'t'` are used)

EXAMPLES:

```
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p[5].omega_qt()
-((q^5-1)/(-t^5+1))*p[5]
sage: p[5].omega_qt(q,t)
-((q^5-1)/(-t^5+1))*p[5]
sage: p([2]).omega_qt(q,t)
((q^2-1)/(-t^2+1))*p[2]
sage: p([2,1]).omega_qt(q,t)
-((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
sage: p([3,2]).omega_qt(5,q)
-(2976/(q^5-q^3-q^2+1))*p[3, 2]
sage: p(0).omega_qt()
0
sage: p(1).omega_qt()
p[]
sage: H = SymmetricFunctions(QQqt).macdonald().H()
```

(continues on next page)

(continued from previous page)

```
sage: H([1,1]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(q,t)
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
sage: H([1,1]).omega_qt(t,q)
-((t^3-t^2-t+1)/(-q^3+q^2+q-1))*McdH[2]
sage: Sym = SymmetricFunctions(FractionField(QQ['q','t']))
sage: S = Sym.macdonald().S()
sage: S([1,1]).omega_qt()
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] - ((q^2*t-q*t-q+1)/(-t^3+t^2+t-
↪1))*McdS[2]
sage: s = Sym.schur()
sage: s(S([1,1]).omega_qt())
s[2]
```

```
>>> from sage.all import *
>>> QQqt = QQ['q,t'].fraction_field()
>>> q,t = QQqt.gens()
>>> p = SymmetricFunctions(QQqt).p()
>>> p[Integer(5)].omega_qt()
-((q^5-1)/(-t^5+1))*p[5]
>>> p[Integer(5)].omega_qt(q,t)
-((q^5-1)/(-t^5+1))*p[5]
>>> p([Integer(2)]).omega_qt(q,t)
((q^2-1)/(-t^2+1))*p[2]
>>> p([Integer(2),Integer(1)]).omega_qt(q,t)
-((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
>>> p([Integer(3),Integer(2)]).omega_qt(Integer(5),q)
-(2976/(q^5-q^3-q^2+1))*p[3, 2]
>>> p(Integer(0)).omega_qt()
0
>>> p(Integer(1)).omega_qt()
p[]
>>> H = SymmetricFunctions(QQqt).macdonald().H()
>>> H([Integer(1),Integer(1)]).omega_qt()
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
>>> H([Integer(1),Integer(1)]).omega_qt(q,t)
((2*q^2-2*q*t-2*q+2*t)/(t^3-t^2-t+1))*McdH[1, 1] + ((q-1)/(t-1))*McdH[2]
>>> H([Integer(1),Integer(1)]).omega_qt(t,q)
-((t^3-t^2-t+1)/(-q^3+q^2+q-1))*McdH[2]
>>> Sym = SymmetricFunctions(FractionField(QQ['q','t']))
>>> S = Sym.macdonald().S()
>>> S([Integer(1),Integer(1)]).omega_qt()
((q^2-q*t-q+t)/(t^3-t^2-t+1))*McdS[1, 1] - ((q^2*t-q*t-q+1)/(-t^3+t^2+t-
↪1))*McdS[2]
>>> s = Sym.schur()
>>> s(S([Integer(1),Integer(1)]).omega_qt())
s[2]
```

plethysm(*x*, *include=None*, *exclude=None*)

Return the outer plethysm of `self` with `x`.

This is implemented only over base rings which are **Q**-algebras. (To compute outer plethysms over general binomial rings, change bases to the fraction field.)

The outer plethysm of f with g is commonly denoted by $f[g]$ or by $f \circ g$. It is an algebra map in f, but not (generally) in g.

By default, the degree one elements are taken to be the generators for the `self`'s base ring. This setting can be modified by specifying the `include` and `exclude` keywords.

INPUT:

- `x` – a symmetric function over the same base ring as `self`
- `include` – list of variables to be treated as degree one elements instead of the default degree one elements
- `exclude` – list of variables to be excluded from the default degree one elements

OUTPUT:

An element in the parent of `x` or the base ring R of `self` when `x` is in R.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: h = Sym.h()
sage: h3h2 = h[3](h[2]); h3h2
h[2, 2, 2] - 2*h[3, 2, 1] + h[3, 3] + h[4, 1, 1] - h[5, 1] + h[6]
sage: s(h3h2)
s[2, 2, 2] + s[4, 2] + s[6]
sage: p = Sym.p()
sage: p3s21 = p[3](s[2,1]); p3s21
s[2, 2, 2, 1, 1, 1] - s[2, 2, 2, 2, 1] - s[3, 2, 1, 1, 1, 1]
 + s[3, 2, 2, 2] + s[3, 3, 1, 1, 1] - s[3, 3, 2, 1] + 2*s[3, 3, 3]
 + s[4, 1, 1, 1, 1, 1] - s[4, 3, 2] + s[4, 4, 1] - s[5, 1, 1, 1, 1]
 + s[5, 2, 2] - s[5, 4] + s[6, 1, 1, 1] - s[6, 2, 1] + s[6, 3]
sage: p(p3s21)
1/3*p[3, 3, 3] - 1/3*p[9]
sage: e = Sym.e()
sage: e[3](e[2])
e[3, 3] + e[4, 1, 1] - 2*e[4, 2] - e[5, 1] + e[6]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> h = Sym.h()
>>> h3h2 = h[Integer(3)](h[Integer(2)]); h3h2
h[2, 2, 2] - 2*h[3, 2, 1] + h[3, 3] + h[4, 1, 1] - h[5, 1] + h[6]
>>> s(h3h2)
s[2, 2, 2] + s[4, 2] + s[6]
>>> p = Sym.p()
>>> p3s21 = p[Integer(3)](s[Integer(2),Integer(1)]); p3s21
s[2, 2, 2, 1, 1, 1] - s[2, 2, 2, 2, 1] - s[3, 2, 1, 1, 1, 1]
 + s[3, 2, 2, 2] + s[3, 3, 1, 1, 1] - s[3, 3, 2, 1] + 2*s[3, 3, 3]
 + s[4, 1, 1, 1, 1, 1] - s[4, 3, 2] + s[4, 4, 1] - s[5, 1, 1, 1, 1]
 + s[5, 2, 2] - s[5, 4] + s[6, 1, 1, 1] - s[6, 2, 1] + s[6, 3]
>>> p(p3s21)
1/3*p[3, 3, 3] - 1/3*p[9]
>>> e = Sym.e()
```

(continues on next page)

(continued from previous page)

```
>>> e[Integer(3)](e[Integer(2)])
e[3, 3] + e[4, 1, 1] - 2*e[4, 2] - e[5, 1] + e[6]
```

Note that the output is in the basis of the input `x`:

```
sage: s[2,1](h[3])
h[4, 3, 2] - h[4, 4, 1] - h[5, 2, 2] + h[5, 3, 1] + h[5, 4]
 + h[6, 2, 1] - 2*h[6, 3] - h[7, 1, 1] + h[7, 2] + h[8, 1] - h[9]

sage: h[2,1](s[3])
s[4, 3, 2] + s[4, 4, 1] + s[5, 2, 2] + s[5, 3, 1] + s[5, 4]
 + s[6, 2, 1] + 2*s[6, 3] + 2*s[7, 2] + s[8, 1] + s[9]
```

```
>>> from sage.all import *
>>> s[Integer(2),Integer(1)](h[Integer(3)])
h[4, 3, 2] - h[4, 4, 1] - h[5, 2, 2] + h[5, 3, 1] + h[5, 4]
 + h[6, 2, 1] - 2*h[6, 3] - h[7, 1, 1] + h[7, 2] + h[8, 1] - h[9]

>>> h[Integer(2),Integer(1)](s[Integer(3)])
s[4, 3, 2] + s[4, 4, 1] + s[5, 2, 2] + s[5, 3, 1] + s[5, 4]
 + s[6, 2, 1] + 2*s[6, 3] + 2*s[7, 2] + s[8, 1] + s[9]
```

Examples over a polynomial ring:

```
sage: R.<t> = QQ[]
sage: s = SymmetricFunctions(R).s()
sage: a = s([3])
sage: f = t * s([2])
sage: a(f)
t^3*s[2, 2, 2] + t^3*s[4, 2] + t^3*s[6]
sage: f(a)
t*s[4, 2] + t*s[6]
sage: s(0).plethysm(s[1])
0
sage: s(1).plethysm(s[1])
s[]
sage: s(1).plethysm(s(0))
s[]
```

```
>>> from sage.all import *
>>> R = QQ['t']; (t,) = R._first_ngens(1)
>>> s = SymmetricFunctions(R).s()
>>> a = s([Integer(3)])
>>> f = t * s([Integer(2)])
>>> a(f)
t^3*s[2, 2, 2] + t^3*s[4, 2] + t^3*s[6]
>>> f(a)
t*s[4, 2] + t*s[6]
>>> s(Integer(0)).plethysm(s[Integer(1)])
0
>>> s(Integer(1)).plethysm(s[Integer(1)])
s[]
```

(continues on next page)

(continued from previous page)

```
>>> s(Integer(1)).plethysm(s(Integer(0)))
s[]
```

When x is a constant, then it is returned as an element of the base ring:

```
sage: s[3](2).parent() is R
True
```

```
>>> from sage.all import *
>>> s[Integer(3)](Integer(2)).parent() is R
True
```

Sage also handles plethysm of tensor products of symmetric functions:

```
sage: s = SymmetricFunctions(QQ).s()
sage: X = tensor([s[1],s[[]]])
sage: Y = tensor([s[[]],s[1]])
sage: s[1,1,1](X+Y)
s[] # s[1, 1, 1] + s[1] # s[1, 1] + s[1, 1] # s[1] + s[1, 1, 1] # s[]
sage: s[1,1,1](X*Y)
s[1, 1, 1] # s[3] + s[2, 1] # s[2, 1] + s[3] # s[1, 1, 1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> X = tensor([s[Integer(1)],s[[]]])
>>> Y = tensor([s[[]],s[Integer(1)]])
>>> s[Integer(1),Integer(1),Integer(1)](X+Y)
s[] # s[1, 1, 1] + s[1] # s[1, 1] + s[1, 1] # s[1] + s[1, 1, 1] # s[]
>>> s[Integer(1),Integer(1),Integer(1)](X*Y)
s[1, 1, 1] # s[3] + s[2, 1] # s[2, 1] + s[3] # s[1, 1, 1]
```

One can use this to work with symmetric functions in two sets of commuting variables. For example, we verify the Cauchy identities (in degree 5):

```
sage: m = SymmetricFunctions(QQ).m()
sage: P5 = Partitions(5)
sage: sum(s[mu](X)*s[mu](Y) for mu in P5) == sum(m[mu](X)*h[mu](Y) for mu in␣
↪P5)
True
sage: sum(s[mu](X)*s[mu.conjugate()](Y) for mu in P5) ==␣
↪sum(m[mu](X)*e[mu](Y) for mu in P5)
True
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> P5 = Partitions(Integer(5))
>>> sum(s[mu](X)*s[mu](Y) for mu in P5) == sum(m[mu](X)*h[mu](Y) for mu in P5)
True
>>> sum(s[mu](X)*s[mu.conjugate()](Y) for mu in P5) == sum(m[mu](X)*e[mu](Y)␣
↪for mu in P5)
True
```

Sage can also do the plethysm with an element in the completion:

```
sage: s = SymmetricFunctions(QQ).s()
sage: L = LazySymmetricFunctions(s)
sage: f = s[2,1]
sage: g = L(s[1]) / (1 - L(s[1])); g
s[1] + (s[1,1]+s[2]) + (s[1,1,1]+2*s[2,1]+s[3])
 + (s[1,1,1,1]+3*s[2,1,1]+2*s[2,2]+3*s[3,1]+s[4])
 + (s[1,1,1,1,1]+4*s[2,1,1,1]+5*s[2,2,1]+6*s[3,1,1]+5*s[3,2]+4*s[4,1]+s[5])
 + ... + O^8
sage: fog = f(g)
sage: fog[:8]
[s[2, 1],
 s[1, 1, 1, 1] + 3*s[2, 1, 1] + 2*s[2, 2] + 3*s[3, 1] + s[4],
 2*s[1, 1, 1, 1, 1] + 8*s[2, 1, 1, 1] + 10*s[2, 2, 1]
 + 12*s[3, 1, 1] + 10*s[3, 2] + 8*s[4, 1] + 2*s[5],
 3*s[1, 1, 1, 1, 1, 1] + 17*s[2, 1, 1, 1, 1] + 30*s[2, 2, 1, 1]
 + 16*s[2, 2, 2] + 33*s[3, 1, 1, 1] + 54*s[3, 2, 1] + 16*s[3, 3]
 + 33*s[4, 1, 1] + 30*s[4, 2] + 17*s[5, 1] + 3*s[6],
 5*s[1, 1, 1, 1, 1, 1, 1] + 30*s[2, 1, 1, 1, 1, 1] + 70*s[2, 2, 1, 1, 1]
 + 70*s[2, 2, 2, 1] + 75*s[3, 1, 1, 1, 1] + 175*s[3, 2, 1, 1]
 + 105*s[3, 2, 2] + 105*s[3, 3, 1] + 100*s[4, 1, 1, 1] + 175*s[4, 2, 1]
 + 70*s[4, 3] + 75*s[5, 1, 1] + 70*s[5, 2] + 30*s[6, 1] + 5*s[7]]
sage: parent(fog)
Lazy completion of Symmetric Functions over Rational Field in the Schur basis

Todo

The implementation of plethysm in `sage.data_structures.stream.Stream_plethysm` seems to be faster. This should be investigated.

principal_specialization(*n=+Infinity*, *q=None*)

Return the principal specialization of a symmetric function.

The *principal specialization* of order n at q is the ring homomorphism $ps_{n,q}$ from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for $i \in \{1, \ldots, n\}$ and $x_i \mapsto 0$ for $i > n$. Here, q is a given element of R, and we assume that the variables of our symmetric functions are $x_1, x_2, x_3, \ldots$. (To be more precise, $ps_{n,q}$ is a K-algebra homomorphism, where K is the base ring.) See Section 7.8 of [EnumComb2].

The *stable principal specialization* at q is the ring homomorphism ps_q from the ring of symmetric functions to another commutative ring R given by $x_i \mapsto q^{i-1}$ for all i. This is well-defined only if the resulting infinite sums converge; thus, in particular, setting $q = 1$ in the stable principal specialization is an invalid operation.

INPUT:

- `n` – (default: `infinity`) a nonnegative integer or `infinity`, specifying whether to compute the principal specialization of order `n` or the stable principal specialization.
- `q` – (default: `None`) the value to use for q; the default is to create a ring of polynomials in `q` (or a field of rational functions in `q`) over the given coefficient ring.

EXAMPLES:

```
sage: m = SymmetricFunctions(QQ).m()
sage: x = m[1,1]
sage: x.principal_specialization(3)
q^3 + q^2 + q
```

```
>>> from sage.all import *
>>> m = SymmetricFunctions(QQ).m()
>>> x = m[Integer(1),Integer(1)]
>>> x.principal_specialization(Integer(3))
q^3 + q^2 + q
```

By default we return a rational function in `q`. Sometimes it is better to obtain an element of the symbolic ring:

```
sage: h = SymmetricFunctions(QQ).h()
sage: (h[3]+h[2]).principal_specialization(q=var("q"))                    #␣
↪needs sage.symbolic
1/((q^2 - 1)*(q - 1)) - 1/((q^3 - 1)*(q^2 - 1)*(q - 1))
```

```
>>> from sage.all import *
>>> h = SymmetricFunctions(QQ).h()
>>> (h[Integer(3)]+h[Integer(2)]).principal_specialization(q=var("q"))     ␣
↪              # needs sage.symbolic
1/((q^2 - 1)*(q - 1)) - 1/((q^3 - 1)*(q^2 - 1)*(q - 1))
```

In case `q` is in the base ring, it must be passed explicitly:

```
sage: R = QQ['q,t']
sage: Ht = SymmetricFunctions(R).macdonald().Ht()
sage: Ht[2].principal_specialization()
Traceback (most recent call last):
...
ValueError: the variable q is in the base ring, pass it explicitly

sage: Ht[2].principal_specialization(q=R("q"))
(q^2 + 1)/(q^3 - q^2 - q + 1)
```

```
>>> from sage.all import *
>>> R = QQ['q,t']
>>> Ht = SymmetricFunctions(R).macdonald().Ht()
>>> Ht[Integer(2)].principal_specialization()
Traceback (most recent call last):
...
ValueError: the variable q is in the base ring, pass it explicitly

>>> Ht[Integer(2)].principal_specialization(q=R("q"))
(q^2 + 1)/(q^3 - q^2 - q + 1)
```

Note that the principal specialization can be obtained as a plethysm:

```
sage: R = QQ['q'].fraction_field()
sage: s = SymmetricFunctions(R).s()
sage: one = s.one()
sage: q = R("q")
sage: f = s[3,2,2]
sage: f.principal_specialization(q=q) == f(one/(1-q)).coefficient([])
True
sage: f.principal_specialization(n=4, q=q) == f(one*(1-q^4)/(1-q)).
↪coefficient([])
True
```

```
>>> from sage.all import *
>>> R = QQ['q'].fraction_field()
>>> s = SymmetricFunctions(R).s()
>>> one = s.one()
>>> q = R("q")
>>> f = s[Integer(3),Integer(2),Integer(2)]
>>> f.principal_specialization(q=q) == f(one/(Integer(1)-q)).coefficient([])
True
>>> f.principal_specialization(n=Integer(4), q=q) == f(one*(Integer(1)-
↪q**Integer(4))/(Integer(1)-q)).coefficient([])
True
```

reduced_kronecker_product(*x*)

Return the reduced Kronecker product of `self` and `x` in the basis of `self`.

The reduced Kronecker product is a bilinear map mapping two symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $*$ denote the Kronecker product (*itensor()*) on the space of symmetric functions. For any partitions α, β, γ, let $g^{\gamma}_{\alpha,\beta}$ denote the coefficient of the Schur function s_γ in the Kronecker product $s_\alpha * s_\beta$ (this is called a Kronecker coefficient). For every partition

$\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$ and every integer $n > |\lambda| + \lambda_1$, let $\lambda[n]$ denote the n-completion of λ (this is the partition $(n - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots)$; see `t_completion()`). Then, Theorem 1.2 of [BOR2009] shows that for any partitions α and β and every integer $n \geq |\alpha| + |\beta| + \alpha_1 + \beta_1$, we can write the Kronecker product $s_{\alpha[n]} * s_{\beta[n]}$ in the form

$$s_{\alpha[n]} * s_{\beta[n]} = \sum_{\gamma} g_{\alpha[n],\beta[n]}^{\gamma[n]} s_{\gamma[n]}$$

with γ ranging over all partitions. The coefficients $g_{\alpha[n],\beta[n]}^{\gamma[n]}$ are independent on n. These coefficients $g_{\alpha[n],\beta[n]}^{\gamma[n]}$ are denoted by $\overline{g}_{\alpha,\beta}^{\gamma}$, and the symmetric function

$$\sum_{\gamma} \overline{g}_{\alpha,\beta}^{\gamma} s_{\gamma}$$

is said to be the *reduced Kronecker product* of s_α and s_β. By bilinearity, this extends to a definition of a reduced Kronecker product of any two symmetric functions.

The definition of the reduced Kronecker product goes back to Murnaghan, and has recently been studied in [BOR2009], [BdVO2012] and other places (our notation $\overline{g}_{\alpha,\beta}^{\gamma}$ appears in these two sources).

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

OUTPUT:

- the reduced Kronecker product of `self` with `x` (an element of the ring of symmetric functions in the same basis as `self`)

EXAMPLES:

The example from page 2 of [BOR2009]:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: s[2].reduced_kronecker_product(s[2])
s[] + s[1] + s[1, 1] + s[1, 1, 1] + 2*s[2] + 2*s[2, 1] + s[2, 2] + s[3] + s[3,
↪ 1] + s[4]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> s[Integer(2)].reduced_kronecker_product(s[Integer(2)])
s[] + s[1] + s[1, 1] + s[1, 1, 1] + 2*s[2] + 2*s[2, 1] + s[2, 2] + s[3] + s[3,
↪ 1] + s[4]
```

Taking the reduced Kronecker product with $1 = s_{\emptyset}$ is the identity map on the ring of symmetric functions:

```
sage: all( s[Partition([])].reduced_kronecker_product(s[lam])
....:      == s[lam] for i in range(4)
....:      for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> all( s[Partition([])].reduced_kronecker_product(s[lam])
...      == s[lam] for i in range(Integer(4))
...      for lam in Partitions(i) )
True
```

While reduced Kronecker products are hard to compute in general, there is a rule for taking reduced Kronecker products with s_1. Namely, for every partition λ, the reduced Kronecker product of s_λ with s_1 is $\sum_\mu a_\mu s_\mu$, where the sum runs over all partitions μ, and the coefficient a_μ is defined as the number of ways to obtain μ from λ by one of the following three operations:

- Add an addable cell (`addable_cells()`) to λ.
- Remove a removable cell (`removable_cells()`) from λ.
- First remove a removable cell from λ, then add an addable cell to the resulting Young diagram.

This is, in fact, Proposition 5.15 of [CO2010] in an elementary wording. We check this for partitions of size ≤ 4:

```
sage: def mults1(lam):
....:     # Reduced Kronecker multiplication by s[1], according
....:     # to [CO2010]_.
....:     res = s.zero()
....:     for mu in lam.up_list():
....:         res += s(mu)
....:     for mu in lam.down_list():
....:         res += s(mu)
....:         for nu in mu.up_list():
....:             res += s(nu)
....:     return res
sage: all( mults1(lam) == s[1].reduced_kronecker_product(s[lam])
....:      for i in range(5) for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> def mults1(lam):
...     # Reduced Kronecker multiplication by s[1], according
...     # to [CO2010]_.
...     res = s.zero()
...     for mu in lam.up_list():
...         res += s(mu)
...     for mu in lam.down_list():
...         res += s(mu)
...         for nu in mu.up_list():
...             res += s(nu)
...     return res
>>> all( mults1(lam) == s[Integer(1)].reduced_kronecker_product(s[lam])
...      for i in range(Integer(5)) for lam in Partitions(i) )
True
```

Here is the example on page 3 of Christian Gutschwager's arXiv 0912.4411v3:

```
sage: s[1,1].reduced_kronecker_product(s[2])
s[1] + 2*s[1, 1] + s[1, 1, 1] + s[2] + 2*s[2, 1] + s[2, 1, 1] + s[3] + s[3, 1]
```

```
>>> from sage.all import *
>>> s[Integer(1),Integer(1)].reduced_kronecker_product(s[Integer(2)])
s[1] + 2*s[1, 1] + s[1, 1, 1] + s[2] + 2*s[2, 1] + s[2, 1, 1] + s[3] + s[3, 1]
```

Example 39 from F. D. Murnaghan, "The analysis of the Kronecker product of irreducible representations of the symmetric group", American Journal of Mathematics, Vol. 60, No. 3, Jul. 1938:

```
sage: s[3].reduced_kronecker_product(s[2,1])
s[1] + 2*s[1, 1] + 2*s[1, 1, 1] + s[1, 1, 1, 1] + 2*s[2] + 5*s[2, 1] + 4*s[2,␣
↪1, 1]
+ s[2, 1, 1, 1] + 3*s[2, 2] + 2*s[2, 2, 1] + 2*s[3] + 5*s[3, 1] + 3*s[3, 1, 1]
+ 3*s[3, 2] + s[3, 2, 1] + 2*s[4] + 3*s[4, 1] + s[4, 1, 1] + s[4, 2] + s[5]
+ s[5, 1]
```

```
>>> from sage.all import *
>>> s[Integer(3)].reduced_kronecker_product(s[Integer(2),Integer(1)])
s[1] + 2*s[1, 1] + 2*s[1, 1, 1] + s[1, 1, 1, 1] + 2*s[2] + 5*s[2, 1] + 4*s[2,␣
↪1, 1]
+ s[2, 1, 1, 1] + 3*s[2, 2] + 2*s[2, 2, 1] + 2*s[3] + 5*s[3, 1] + 3*s[3, 1, 1]
+ 3*s[3, 2] + s[3, 2, 1] + 2*s[4] + 3*s[4, 1] + s[4, 1, 1] + s[4, 2] + s[5]
+ s[5, 1]
```

Todo

This implementation of the reduced Kronecker product is painfully slow.

restrict_degree(*d*, *exact=True*)

Return the degree `d` component of `self`.

INPUT:

- `d` – positive integer, degree of the terms to be returned
- `exact` – boolean, if `True`, returns the terms of degree exactly `d`, otherwise returns all terms of degree less than or equal to `d`

OUTPUT: the homogeneous component of `self` of degree `d`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_degree(2)
0
sage: z.restrict_degree(1)
s[1]
sage: z.restrict_degree(3)
s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(3, exact=False)
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_degree(0)
0
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> z = s([Integer(4)]) + s([Integer(2),Integer(1)]) + s([Integer(1),
↪Integer(1),Integer(1)]) + s([Integer(1)])
>>> z.restrict_degree(Integer(2))
0
>>> z.restrict_degree(Integer(1))
```

(continues on next page)

(continued from previous page)

```
s[1]
>>> z.restrict_degree(Integer(3))
s[1, 1, 1] + s[2, 1]
>>> z.restrict_degree(Integer(3), exact=False)
s[1] + s[1, 1, 1] + s[2, 1]
>>> z.restrict_degree(Integer(0))
0
```

restrict_partition_lengths(*l*, *exact=True*)

Return the terms of `self` labelled by partitions of length `l`.

INPUT:

- `l` – nonnegative integer
- `exact` – boolean, defaulting to `True`

OUTPUT:

- if `True`, returns the terms labelled by partitions of length precisely `l`; otherwise returns all terms labelled by partitions of length less than or equal to `l`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_partition_lengths(2)
s[2, 1]
sage: z.restrict_partition_lengths(0)
0
sage: z.restrict_partition_lengths(2, exact = False)
s[1] + s[2, 1] + s[4]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> z = s([Integer(4)]) + s([Integer(2),Integer(1)]) + s([Integer(1),
↪Integer(1),Integer(1)]) + s([Integer(1)])
>>> z.restrict_partition_lengths(Integer(2))
s[2, 1]
>>> z.restrict_partition_lengths(Integer(0))
0
>>> z.restrict_partition_lengths(Integer(2), exact = False)
s[1] + s[2, 1] + s[4]
```

restrict_parts(*n*)

Return the terms of `self` labelled by partitions λ with $\lambda_1 \leq n$.

INPUT:

- `n` – positive integer, to restrict the parts of the partitions of the terms to be returned

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: z = s([4]) + s([2,1]) + s([1,1,1]) + s([1])
sage: z.restrict_parts(2)
```

(continues on next page)

(continued from previous page)

```
s[1] + s[1, 1, 1] + s[2, 1]
sage: z.restrict_parts(1)
s[1] + s[1, 1, 1]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> z = s([Integer(4)]) + s([Integer(2),Integer(1)]) + s([Integer(1),
↪Integer(1),Integer(1)]) + s([Integer(1)])
>>> z.restrict_parts(Integer(2))
s[1] + s[1, 1, 1] + s[2, 1]
>>> z.restrict_parts(Integer(1))
s[1] + s[1, 1, 1]
```

scalar(*x*, *zee=None*)

Return the standard scalar product between `self` and `x`.

This is also known as the "Hall inner product" or the "Hall scalar product".

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `zee` – an optional function on partitions giving the value for the scalar product between p_μ and p_μ (default: the standard `zee()` function)

This is the default implementation that converts both `self` and `x` into either Schur functions (if `zee` is not specified) or power-sum functions (if `zee` is specified) and performs the scalar product in that basis.

EXAMPLES:

```
sage: e = SymmetricFunctions(QQ).e()
sage: h = SymmetricFunctions(QQ).h()
sage: m = SymmetricFunctions(QQ).m()
sage: p4 = Partitions(4)
sage: matrix([ [e(a).scalar(h(b)) for a in p4] for b in p4])
[ 0  0  0  0  1]
[ 0  0  0  1  4]
[ 0  0  1  2  6]
[ 0  1  2  5 12]
[ 1  4  6 12 24]
sage: matrix([ [h(a).scalar(e(b)) for a in p4] for b in p4])
[ 0  0  0  0  1]
[ 0  0  0  1  4]
[ 0  0  1  2  6]
[ 0  1  2  5 12]
[ 1  4  6 12 24]
sage: matrix([ [m(a).scalar(e(b)) for a in p4] for b in p4])
[-1  2  1 -3  1]
[ 0  1  0 -2  1]
[ 0  0  1 -2  1]
[ 0  0  0 -1  1]
[ 0  0  0  0  1]
sage: matrix([ [m(a).scalar(h(b)) for a in p4] for b in p4])
[1 0 0 0 0]
[0 1 0 0 0]
```

(continues on next page)

(continued from previous page)

```
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]

sage: p = SymmetricFunctions(QQ).p()
sage: m(p[3,2]).scalar(p[3,2], zee=lambda mu: 2**mu.length())
4
sage: m(p[3,2]).scalar(p[2,2,1], lambda mu: 1)
0
sage: m[3,2].scalar(h[3,2], zee=lambda mu: 2**mu.length())
2/3
```

```
>>> from sage.all import *

>>> m(p[Integer(3),Integer(2)]).scalar(p[Integer(2),Integer(2),Integer(1)],␣
↪lambda mu: Integer(1))
0
>>> m[Integer(3),Integer(2)].scalar(h[Integer(3),Integer(2)], zee=lambda mu:␣
↪Integer(2)**mu.length())
2/3
```

scalar_hl(*x*, *t=None*)

Return the t-deformed standard Hall-Littlewood scalar product of `self` and `x`.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `t` – parameter (default: `None`, in which case `t` is used)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
>>> sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

scalar_jack(*x*, *t=None*)

Return the Jack-scalar product between `self` and `x`.

This scalar product is defined so that the power sum elements p_μ are orthogonal and $\langle p_\mu, p_\mu \rangle = z_\mu t^{\ell(\mu)}$, where $\ell(\mu)$ denotes the length of μ.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `t` – an optional parameter (default: `None` in which case `t` is used)

EXAMPLES:

```
sage: p = SymmetricFunctions(QQ['t']).power()
sage: matrix([[p(mu).scalar_jack(p(nu)) for nu in Partitions(4)] for mu in␣
→Partitions(4)])
[   4*t       0       0       0       0]
[     0   3*t^2       0       0       0]
[     0       0   8*t^2       0       0]
[     0       0       0   4*t^3       0]
[     0       0       0       0 24*t^4]
sage: matrix([[p(mu).scalar_jack(p(nu),2) for nu in Partitions(4)] for mu in␣
→Partitions(4)])
[  8   0   0   0   0]
[  0  12   0   0   0]

↪+ 2*t)]
```

scalar_qt(*x*, *q=None*, *t=None*)

Return the q, t-deformed standard Hall-Littlewood scalar product of `self` and `x`.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `q`, `t` – parameters (default: `None` in which case `q` and `t` are used)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_qt(a); factor(sp)
(t - 1)^-3 * (q - 1) * (t^2 + t + 1)^-1 * (q^2*t^2 - q*t^2 + q^2 - 2*q*t + t^
↪2 - q + 1)
sage: sp.parent()
Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field
sage: a.scalar_qt(a,q=0)
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
```

(continues on next page)

↪2 - y + 1)
```

scalar_t(*x*, *t=None*)

Return the t-deformed standard Hall-Littlewood scalar product of `self` and `x`.

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`
- `t` – parameter (default: `None`, in which case `t` is used)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: a = s([2,1])
sage: sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
sage: sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> a = s([Integer(2),Integer(1)])
>>> sp = a.scalar_t(a); sp
(-t^2 - 1)/(t^5 - 2*t^4 + t^3 - t^2 + 2*t - 1)
>>> sp.parent()
Fraction Field of Univariate Polynomial Ring in t over Rational Field
```

skew_by(*x*)

Return the result of skewing `self` by `x`. (Skewing by `x` is the endomorphism (as additive group) of the ring of symmetric functions adjoint to multiplication by `x` with respect to the Hall inner product.)

INPUT:

- `x` – element of the ring of symmetric functions over the same base ring as `self`

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([3,2]).skew_by(s([2]))
s[2, 1] + s[3]
sage: s([3,2]).skew_by(s([1,1,1]))
0
sage: s([3,2,1]).skew_by(s([2,1]))
s[1, 1, 1] + 2*s[2, 1] + s[3]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s([Integer(3),Integer(2)]).skew_by(s([Integer(2)]))
s[2, 1] + s[3]
>>> s([Integer(3),Integer(2)]).skew_by(s([Integer(1),Integer(1),Integer(1)]))
0
>>> s([Integer(3),Integer(2),Integer(1)]).skew_by(s([Integer(2),Integer(1)]))
s[1, 1, 1] + 2*s[2, 1] + s[3]
```

```
sage: p = SymmetricFunctions(QQ).powersum()
sage: p([4,3,3,2,2,1]).skew_by(p([2,1]))
4*p[4, 3, 3, 2]
sage: zee = sage.combinat.sf.sfa.zee
sage: zee([4,3,3,2,2,1])/zee([4,3,3,2])
```

(continues on next page)

(continued from previous page)

s[]
>>> s([]).skew_by(s[Integer(1)])
0
```

theta(a)

Return the image of `self` under the theta endomorphism which sends p_k to $a \cdot p_k$ for every positive integer k.

In general, this is well-defined outside of the powersum basis only if the base ring is a **Q**-algebra.

INPUT:

- `a` – an element of the base ring

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s([2,1]).theta(2)
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
sage: p = SymmetricFunctions(QQ).p()
sage: p([2]).theta(2)
2*p[2]
sage: p(0).theta(2)
0
sage: p(1).theta(2)
p[]
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
```

(continues on next page)

(continued from previous page)

```
>>> s([Integer(2),Integer(1)]).theta(Integer(2))
2*s[1, 1, 1] + 6*s[2, 1] + 2*s[3]
>>> p = SymmetricFunctions(QQ).p()
>>> p([Integer(2)]).theta(Integer(2))
2*p[2]
>>> p(Integer(0)).theta(Integer(2))
0
>>> p(Integer(1)).theta(Integer(2))
p[]
```

theta_qt(*q=None*, *t=None*)

Return the image of `self` under the q,t-deformed theta endomorphism which sends p_k to $\frac{1-q^k}{1-t^k} \cdot p_k$ for all positive integers k.

In general, this is well-defined outside of the powersum basis only if the base ring is a **Q**-algebra.

INPUT:

- `q`, `t` – parameters (default: `None`, in which case 'q' and 't' are used)

EXAMPLES:

```
sage: QQqt = QQ['q,t'].fraction_field()
sage: q,t = QQqt.gens()
sage: p = SymmetricFunctions(QQqt).p()
sage: p([2]).theta_qt(q,t)
-((q^2-1)/(-t^2+1))*p[2]
sage: p([2,1]).theta_qt(q,t)
((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
sage: p(0).theta_qt(q=1,t=3)
0
sage: p([2,1]).theta_qt(q=2,t=3)
3/16*p[2, 1]
sage: s = p.realization_of().schur()
sage: s([3]).theta_qt(q=0)*(1-t)*(1-t^2)*(1-t^3)
t^3*s[1, 1, 1] + (t^2+t)*s[2, 1] + s[3]
sage: p(1).theta_qt()
p[]
```

```
>>> from sage.all import *
>>> QQqt = QQ['q,t'].fraction_field()
>>> q,t = QQqt.gens()
>>> p = SymmetricFunctions(QQqt).p()
>>> p([Integer(2)]).theta_qt(q,t)
-((q^2-1)/(-t^2+1))*p[2]
>>> p([Integer(2),Integer(1)]).theta_qt(q,t)
((q^3-q^2-q+1)/(t^3-t^2-t+1))*p[2, 1]
>>> p(Integer(0)).theta_qt(q=Integer(1),t=Integer(3))
0
>>> p([Integer(2),Integer(1)]).theta_qt(q=Integer(2),t=Integer(3))
3/16*p[2, 1]
>>> s = p.realization_of().schur()
>>> s([Integer(3)]).theta_qt(q=Integer(0))*(Integer(1)-t)*(Integer(1)-
```

(continues on next page)

(continued from previous page)

```
↪t**Integer(2))*(Integer(1)-t**Integer(3))
t^3*s[1, 1, 1] + (t^2+t)*s[2, 1] + s[3]
>>> p(Integer(1)).theta_qt()
p[]
```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n, and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n}e_{r/n}$$

(where h is the complete homogeneous basis, p is the powersum basis, and e is the elementary basis). For every nonnegative integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for "shift") endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Adams operator (see `adams_operator()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley's [STA].

Let λ be a partition. Let n be a positive integer. If the n-core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer s. (If n does not divide the length of λ, then this is achieved by adding trailing zeroes to λ.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n. Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi\prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the n-quotient of λ.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: p = Sym.p()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: s[3].verschiebung(2)
0
```

(continues on next page)

(continued from previous page)

```
sage: s[3].verschiebung(3)
s[1]
sage: p[3].verschiebung(3)
3*p[1]
sage: m[3,2,1].verschiebung(3)
-18*m[1, 1] - 3*m[2]
sage: p[3,2,1].verschiebung(3)
0
sage: h[4].verschiebung(2)
h[2]
sage: p[2].verschiebung(2)
2*p[1]
sage: m[3,2,1].verschiebung(6)
12*m[1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> p = Sym.p()
>>> h = Sym.h()
>>> s = Sym.s()
>>> m = Sym.m()
>>> s[Integer(3)].verschiebung(Integer(2))
0
>>> s[Integer(3)].verschiebung(Integer(3))
s[1]
>>> p[Integer(3)].verschiebung(Integer(3))
3*p[1]
>>> m[Integer(3),Integer(2),Integer(1)].verschiebung(Integer(3))
-18*m[1, 1] - 3*m[2]
>>> p[Integer(3),Integer(2),Integer(1)].verschiebung(Integer(3))
0
>>> h[Integer(4)].verschiebung(Integer(2))
h[2]
>>> p[Integer(2)].verschiebung(Integer(2))
2*p[1]
>>> m[Integer(3),Integer(2),Integer(1)].verschiebung(Integer(6))
12*m[1]
```

The Verschiebung endomorphisms are multiplicative:

```
sage: all( all( s(lam).verschiebung(2) * s(mu).verschiebung(2)
....:           == (s(lam) * s(mu)).verschiebung(2)
....:           for mu in Partitions(4) )
....:      for lam in Partitions(4) )
True
```

```
>>> from sage.all import *
>>> all( all( s(lam).verschiebung(Integer(2)) * s(mu).verschiebung(Integer(2))
...           == (s(lam) * s(mu)).verschiebung(Integer(2))
...           for mu in Partitions(Integer(4)) )
...      for lam in Partitions(Integer(4)) )
True
```

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

```
sage: all( p(lam).verschiebung(3).antipode()
....:      == p(lam).antipode().verschiebung(3)
....:      for lam in Partitions(6) )
True
```

```
>>> from sage.all import *
>>> all( p(lam).verschiebung(Integer(3)).antipode()
...      == p(lam).antipode().verschiebung(Integer(3))
...      for lam in Partitions(Integer(6)) )
True
```

Testing the adjointness between the Adams operators $\mathbf{f}_n$ and the Verschiebung operators $\mathbf{V}_n$:

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: p = Sym.p()
sage: all( all( s(lam).verschiebung(2).scalar(p(mu))
....:           == s(lam).scalar(p(mu).adams_operator(2))
....:           for mu in Partitions(3) )
....:      for lam in Partitions(6) )
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> p = Sym.p()
>>> all( all( s(lam).verschiebung(Integer(2)).scalar(p(mu))
...           == s(lam).scalar(p(mu).adams_operator(Integer(2)))
...           for mu in Partitions(Integer(3)) )
...      for lam in Partitions(Integer(6)) )
True
```

class sage.combinat.sf.sfa.**SymmetricFunctionsBases**(*parent_with_realization*)

Bases: `Category_realization_of_parent`

The category of bases of the ring of symmetric functions.

INPUT:

- `self` – a category of bases for the symmetric functions
- `base` – ring of symmetric functions

class ParentMethods

Bases: `object`

Eulerian(*n, j, k=None*)

Return the Eulerian symmetric function $Q_{n,j}$ (with n either an integer or a partition) or $Q_{n,j,k}$ (if the optional argument `k` is specified) in terms of the basis `self`.

It is known that the Eulerian quasisymmetric functions are in fact symmetric functions [SW2010]. For more information, see `QuasiSymmetricFunctions.Fundamental.Eulerian()`, which accepts the same syntax as this method.

INPUT:

- n – the nonnegative integer n or a partition
- j – the number of excedances
- k – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.m()
sage: m.Eulerian(3, 1)
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
sage: h = Sym.h()
sage: h.Eulerian(4, 2)
h[2, 2] + h[3, 1] + h[4]
sage: s = Sym.s()
sage: s.Eulerian(5, 2)
s[2, 2, 1] + s[3, 1, 1] + 5*s[3, 2] + 6*s[4, 1] + 6*s[5]
sage: s.Eulerian([2,2,1], 2)
s[2, 2, 1] + s[3, 2] + s[4, 1] + s[5]
sage: s.Eulerian(5, 2, 2)
s[3, 2] + s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.m()
>>> m.Eulerian(Integer(3), Integer(1))
4*m[1, 1, 1] + 3*m[2, 1] + 2*m[3]
>>> h = Sym.h()
>>> h.Eulerian(Integer(4), Integer(2))
h[2, 2] + h[3, 1] + h[4]
>>> s = Sym.s()
>>> s.Eulerian(Integer(5), Integer(2))
s[2, 2, 1] + s[3, 1, 1] + 5*s[3, 2] + 6*s[4, 1] + 6*s[5]
>>> s.Eulerian([Integer(2),Integer(2),Integer(1)], Integer(2))
s[2, 2, 1] + s[3, 2] + s[4, 1] + s[5]
>>> s.Eulerian(Integer(5), Integer(2), Integer(2))
s[3, 2] + s[4, 1] + s[5]
```

We check Equation (5.4) in [SW2010]:

```
sage: h.Eulerian([6], 3)
h[3, 2, 1] - h[4, 1, 1] + 2*h[4, 2] + h[5, 1]
sage: s.Eulerian([6], 3)
s[3, 2, 1] + s[3, 3] + 3*s[4, 2] + 3*s[5, 1] + 3*s[6]
```

```
>>> from sage.all import *
>>> h.Eulerian([Integer(6)], Integer(3))
h[3, 2, 1] - h[4, 1, 1] + 2*h[4, 2] + h[5, 1]
>>> s.Eulerian([Integer(6)], Integer(3))
s[3, 2, 1] + s[3, 3] + 3*s[4, 2] + 3*s[5, 1] + 3*s[6]
```

carlitz_shareshian_wachs(*n*, *d*, *s*, *comparison=None*)

Return the Carlitz-Shareshian-Wachs symmetric function $X_{n,d,s}$ (if comparison is None), or $U_{n,d,s}$ (if comparison is -1), or $V_{n,d,s}$ (if comparison is 0), or $W_{n,d,s}$ (if comparison is 1) written in the basis self. These functions are defined below.

The Carlitz-Shareshian-Wachs symmetric functions have been introduced in [GriRei18], Exercise 2.9.11, as refinements of a certain particular case of chromatic quasisymmetric functions defined by Shareshian and Wachs. Their definitions are as follows:

Let n, d and s be three nonnegative integers. Let $W(n,d,s)$ denote the set of all n-tuples $(w_1, w_2, \ldots, w_n)$ of positive integers having the property that there exist precisely d elements i of $\{1, 2, \ldots, n-1\}$ satisfying $w_i > w_{i+1}$, and precisely s elements i of $\{1, 2, \ldots, n-1\}$ satisfying $w_i = w_{i+1}$. For every $w = (w_1, w_2, \ldots, w_n) \in W(n,d,s)$, let x_w be the monomial $x_{w_1} x_{w_2} \cdots x_{w_n}$. We then define the power series $X_{n,d,s}$ by

$$X_{n,d,s} = \sum_{w \in W(n,d,s)} x_w.$$

This is a symmetric function (according to [GriRei18], Exercise 2.9.11(b)), and for $s = 0$ equals the t^d-coefficient of the descent enumerator of Smirnov words of length n (an example of a chromatic quasisymmetric function which happens to be symmetric – see [ShaWach2014], Example 2.5).

Assume that $n > 0$. Then, we can define three further power series as follows:

$$U_{n,d,s} = \sum_{w_1 < w_n} x_w; \qquad V_{n,d,s} = \sum_{w_1 = w_n} x_w; \qquad W_{n,d,s} = \sum_{w_1 > w_n} x_w,$$

where all three sums range over $w = (w_1, w_2, \ldots, w_n) \in W(n,d,s)$. These three power series $U_{n,d,s}$, $V_{n,d,s}$ and $W_{n,d,s}$ are symmetric functions as well ([GriRei18], Exercise 2.9.11(c)). Their sum is $X_{n,d,s}$.

REFERENCES:

INPUT:

- `n` – nonnegative integer
- `d` – nonnegative integer
- `s` – nonnegative integer
- `comparison` – (default: `None`) a variable which can take the forms `None`, `-1`, `0` and `1`

OUTPUT:

The Carlitz-Shareshian-Wachs symmetric function $X_{n,d,s}$ (if `comparison` is `None`), or $U_{n,d,s}$ (if `comparison` is `-1`), or $V_{n,d,s}$ (if `comparison` is `0`), or $W_{n,d,s}$ (if `comparison` is `1`) written in the basis `self`.

EXAMPLES:

>>> m.carlitz_shareshian_wachs(Integer(4), Integer(2), Integer(0),␣
↪comparison=Integer(1))
8*m[1, 1, 1, 1] + 2*m[2, 1, 1] + m[2, 2]
>>> m.carlitz_shareshian_wachs(Integer(1), Integer(0), Integer(0),␣
↪comparison=Integer(1))
0
```

corresponding_basis_over(R)

Return the realization of symmetric functions corresponding to `self` but over the base ring `R`. Only works when `self` is one of the classical bases, not one of the q,t-dependent ones. In the latter case, `None` is returned instead.

INPUT:

- `R` – a commutative ring

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: m = Sym.monomial()
sage: m.corresponding_basis_over(ZZ)
```

(continues on next page)

(continued from previous page)

```
doctest:warning
...
DeprecationWarning: S.corresponding_basis_over(R) is deprecated.
Use S.change_ring(R) instead.
See https://github.com/sagemath/sage/issues/37220 for details.
Symmetric Functions over Integer Ring in the monomial basis

sage: Sym = SymmetricFunctions(CyclotomicField())
sage: s = Sym.schur()
sage: s.corresponding_basis_over(Integers(13))
Symmetric Functions over Ring of integers modulo 13 in the Schur basis

sage: P = ZZ['q','t']
sage: Sym = SymmetricFunctions(P)
sage: mj = Sym.macdonald().J()
sage: mj.corresponding_basis_over(Integers(13)['q','t'])
Symmetric Functions over Multivariate Polynomial Ring in q, t over
 Ring of integers modulo 13 in the Macdonald J basis
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> m = Sym.monomial()
>>> m.corresponding_basis_over(ZZ)
doctest:warning
...
DeprecationWarning: S.corresponding_basis_over(R) is deprecated.
Use S.change_ring(R) instead.
See https://github.com/sagemath/sage/issues/37220 for details.
Symmetric Functions over Integer Ring in the monomial basis

>>> Sym = SymmetricFunctions(CyclotomicField())
>>> s = Sym.schur()
>>> s.corresponding_basis_over(Integers(Integer(13)))
Symmetric Functions over Ring of integers modulo 13 in the Schur basis

>>> P = ZZ['q','t']
>>> Sym = SymmetricFunctions(P)
>>> mj = Sym.macdonald().J()
>>> mj.corresponding_basis_over(Integers(Integer(13))['q','t'])
Symmetric Functions over Multivariate Polynomial Ring in q, t over
 Ring of integers modulo 13 in the Macdonald J basis
```

Todo

This function is an ugly hack using strings. It should be rewritten as soon as the bases of `SymmetricFunctions` are put on a more robust and systematic footing.

degree_on_basis(*b*)

Return the degree of the basis element indexed by `b`.

INPUT:

- `self` – a basis of the symmetric functions
- `b` – a partition

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['q,t'].fraction_field())
sage: m = Sym.monomial()
sage: m.degree_on_basis(Partition([3,2]))
5
sage: P = Sym.macdonald().P()
sage: P.degree_on_basis(Partition([]))
0
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['q,t'].fraction_field())
>>> m = Sym.monomial()
>>> m.degree_on_basis(Partition([Integer(3),Integer(2)]))
5
>>> P = Sym.macdonald().P()
>>> P.degree_on_basis(Partition([]))
0
```

formal_series_ring()

Return the completion of all formal linear combinations of `self` with finite linear combinations in each homogeneous degree (computed lazily).

EXAMPLES:

```
sage: s = SymmetricFunctions(ZZ).s()
sage: L = s.formal_series_ring()
sage: L
Lazy completion of Symmetric Functions over Integer Ring in the Schur
↪basis
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(ZZ).s()
>>> L = s.formal_series_ring()
>>> L
Lazy completion of Symmetric Functions over Integer Ring in the Schur
↪basis
```

fraction_field()

Return the fraction field of `self`.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.fraction_field()
Fraction Field of Symmetric Functions over Rational Field in the Schur
↪basis
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.fraction_field()
```

(continues on next page)

(continued from previous page)

```
Fraction Field of Symmetric Functions over Rational Field in the Schur␣
↪basis
```

gessel_reutenauer(*lam*)

Return the Gessel-Reutenauer symmetric function corresponding to the partition `lam` written in the basis `self`.

Let λ be a partition. The *Gessel-Reutenauer symmetric function* $\mathbf{GR}_\lambda$ corresponding to λ is the symmetric function denoted L_λ in [GR1993] and in Exercise 7.89 of [STA] and denoted $\mathbf{GR}_\lambda$ in Definition 6.6.34 of [GriRei18]. It is also called the *higher Lie character*, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials $\mathbf{x}_w$ over all words w over the alphabet $\{1, 2, 3, \ldots\}$ which have CFL type λ. Here, the monomial $\mathbf{x}_w$ for a word $w = (w_1, w_2, \ldots, w_k)$ is defined as $x_{w_1} x_{w_2} \cdots x_{w_k}$, and the *CFL type* of a word w is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization (`lyndon_factorization()`) of w. The fact that this power series $\mathbf{GR}_\lambda$ is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions $F_{\mathrm{Des}\,\sigma}$ over all permutations σ that have cycle type λ. See `sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental` for the definition of fundamental quasisymmetric functions, and `cycle_type()` for that of cycle type. For a permutation σ, we use $\mathrm{Des}\,\sigma$ to denote the descent composition (`descents_composition()`) of σ. Again, this definition does not make the symmetry of $\mathbf{GR}_\lambda$ obvious.
- For every positive integer n, we have

$$\mathbf{GR}_{(n)} = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},$$

  where p_d denotes the d-th power-sum symmetric function. This $\mathbf{GR}_{(n)}$ is also denoted by L_n, and is called the Lie character. Now, the higher Lie character $\mathbf{GR}_\lambda$ is defined as the product:

$$h_{m_1}[L_1] \cdot h_{m_2}[L_2] \cdot h_{m_3}[L_3] \cdots ,$$

  where m_i denotes the multiplicity of the part i in λ, and where the square brackets stand for plethysm (`plethysm()`). This definition makes the symmetry (but not the integrality!) of $\mathbf{GR}_\lambda$ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

$\mathbf{GR}_\lambda$ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree-n component $T_n(V)$ of $T(V)$ into $GL(V)$ representations indexed by partitions. The higher Lie characters are the symmetric group S_n characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, *Thrall's problem* (see e.g. [Sch2003b]) asks, for λ a partition of n, can we combinatorially interpret the coefficients α_μ^λ in the Schur-expansion of $\mathbf{GR}_\lambda$:

$$\mathbf{GR}_\lambda = \sum_{\mu \vdash n} \alpha_\mu^\lambda s_\mu.$$

INPUT:

- `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition `[lam]`)

OUTPUT:

The Gessel-Reutenauer symmetric function $\mathbf{GR}_\lambda$, where λ is `lam`, expanded in the basis `self`.

EXAMPLES:

The first few values of $\mathbf{GR}_{(n)} = L_n$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
 - 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
 - h[4, 2] - h[5, 1] + h[6]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
>>> h.gessel_reutenauer(Integer(1))
h[1]
>>> h.gessel_reutenauer(Integer(2))
h[1, 1] - h[2]
>>> h.gessel_reutenauer(Integer(3))
h[2, 1] - h[3]
>>> h.gessel_reutenauer(Integer(4))
h[2, 1, 1] - h[2, 2]
>>> h.gessel_reutenauer(Integer(5))
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
>>> h.gessel_reutenauer(Integer(6))
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
 - 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
 - h[4, 2] - h[5, 1] + h[6]
```

Gessel-Reutenauer functions indexed by partitions:

```
sage: h.gessel_reutenauer([2, 1])
h[1, 1, 1] - h[2, 1]
sage: h.gessel_reutenauer([2, 2])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]
```

```
>>> from sage.all import *
>>> h.gessel_reutenauer([Integer(2), Integer(1)])
h[1, 1, 1] - h[2, 1]
>>> h.gessel_reutenauer([Integer(2), Integer(2)])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]
```

The Gessel-Reutenauer functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: s.gessel_reutenauer([2, 2, 1])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]
```

```
>>> from sage.all import *
>>> s = Sym.s()
>>> s.gessel_reutenauer([Integer(2), Integer(1)])
s[1, 1, 1] + s[2, 1]
>>> s.gessel_reutenauer([Integer(2), Integer(2), Integer(1)])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]
```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```
sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True
```

```
>>> from sage.all import *
>>> s.gessel_reutenauer([Integer(4)]) == s.gessel_reutenauer([Integer(2),␣
→Integer(1), Integer(1)])
True
```

They also go by the name *higher Lie character*:

```
sage: s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1])
True
```

```
>>> from sage.all import *
>>> s.higher_lie_character([Integer(2), Integer(2), Integer(1)]) == s.
→gessel_reutenauer([Integer(2), Integer(2), Integer(1)])
True
```

Of the above three equivalent definitions of $\mathbf{GR}_\lambda$, we use the third one for computations. Let us check that the second one gives the same results:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam): # `\mathbf{GR}_\lambda`
....:     n = lam.size()
....:     r = F.sum_of_monomials([sigma.descents_composition()
....:                             for sigma in Permutations(n)
....:                             if sigma.cycle_type() == lam])
....:     return r.to_symmetric_function()
sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
....:      for n in range(5) for lam in Partitions(n) )
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F() # fundamental basis
>>> def GR_def2(lam): # `\mathbf{GR}_\lambda`
...     n = lam.size()
...     r = F.sum_of_monomials([sigma.descents_composition()
```

(continues on next page)

(continued from previous page)

```
...                             for sigma in Permutations(n)
...                             if sigma.cycle_type() == lam])
...     return r.to_symmetric_function()
>>> all( GR_def2(lam) == h.gessel_reutenauer(lam)
...      for n in range(Integer(5)) for lam in Partitions(n) )
True
```

And the first one, too (assuming symmetry):

```
sage: m = Sym.m()
sage: def GR_def1(lam): # `\mathbf{GR}_\lambda`
....:     n = lam.size()
....:     Permus_mset = sage.combinat.permutation.Permutations_mset
....:     def coeff_of_m_mu_in_result(mu):
....:         words_to_check = Permus_mset([i for (i, l) in enumerate(mu)
....:                                       for _ in range(l)])
....:         return sum((1 for w in words_to_check if
....:                     Partition(list(reversed(sorted([len(v) for v in␣
↪Word(w).lyndon_factorization()]))))
....:                     == lam))
....:     r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
....:                         for mu in Partitions(n)],
....:                        distinct=True)
....:     return r
sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
....:      for n in range(5) for lam in Partitions(n) )
True
```

```
>>> from sage.all import *
>>> m = Sym.m()
>>> def GR_def1(lam): # `\mathbf{GR}_\lambda`
...     n = lam.size()
...     Permus_mset = sage.combinat.permutation.Permutations_mset
...     def coeff_of_m_mu_in_result(mu):
...         words_to_check = Permus_mset([i for (i, l) in enumerate(mu)
...                                       for _ in range(l)])
...         return sum((Integer(1) for w in words_to_check if
...                     Partition(list(reversed(sorted([len(v) for v in␣
↪Word(w).lyndon_factorization()]))))
...                     == lam))
...     r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
...                         for mu in Partitions(n)],
...                        distinct=True)
...     return r
>>> all( GR_def1(lam) == h.gessel_reutenauer(lam)
...      for n in range(Integer(5)) for lam in Partitions(n) )
True
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a **Q**-algebra from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the "corresponding" basis of the symmetric function algebra over **Q** (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

higher_lie_character(*lam*)

Return the Gessel-Reutenauer symmetric function corresponding to the partition `lam` written in the basis `self`.

Let λ be a partition. The *Gessel-Reutenauer symmetric function* $\mathbf{GR}_\lambda$ corresponding to λ is the symmetric function denoted L_λ in [GR1993] and in Exercise 7.89 of [STA] and denoted $\mathbf{GR}_\lambda$ in Definition 6.6.34 of [GriRei18]. It is also called the *higher Lie character*, for instance in [Sch2003b]. It can be defined in several ways:

- It is the sum of the monomials $\mathbf{x}_w$ over all words w over the alphabet $\{1, 2, 3, \ldots\}$ which have CFL type λ. Here, the monomial $\mathbf{x}_w$ for a word $w = (w_1, w_2, \ldots, w_k)$ is defined as $x_{w_1} x_{w_2} \cdots x_{w_k}$, and the *CFL type* of a word w is defined as the partition obtained by sorting (in decreasing order) the lengths of the factors in the Lyndon factorization (`lyndon_factorization()`) of w. The fact that this power series $\mathbf{GR}_\lambda$ is symmetric is not obvious.
- It is the sum of the fundamental quasisymmetric functions $F_{\mathrm{Des}\,\sigma}$ over all permutations σ that have cycle type λ. See `sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions.Fundamental` for the definition of fundamental quasisymmetric functions, and `cycle_type()` for that of cycle type. For a permutation σ, we use $\mathrm{Des}\,\sigma$ to denote the descent composition (`descents_composition()`) of σ. Again, this definition does not make the symmetry of $\mathbf{GR}_\lambda$ obvious.
- For every positive integer n, we have

$$\mathbf{GR}_{(n)} = \frac{1}{n} \sum_{d|n} \mu(d) p_d^{n/d},$$

  where p_d denotes the d-th power-sum symmetric function. This $\mathbf{GR}_{(n)}$ is also denoted by L_n, and is called the Lie character. Now, the higher Lie character $\mathbf{GR}_\lambda$ is defined as the product:

$$h_{m_1}[L_1] \cdot h_{m_2}[L_2] \cdot h_{m_3}[L_3] \cdots ,$$

  where m_i denotes the multiplicity of the part i in λ, and where the square brackets stand for plethysm (`plethysm()`). This definition makes the symmetry (but not the integrality!) of $\mathbf{GR}_\lambda$ obvious.

The equivalences of these three definitions are proven in [GR1993] Sections 2-3. (See also [GriRei18] Subsection 6.6.2 for the equivalence of the first two definitions and further formulas.)

$\mathbf{GR}_\lambda$ has further significance in representations afforded by the tensor algebra $T(V)$ of a finite dimensional vector space. The Poincaré-Birkhoff-Witt theorem describes the universal enveloping algebra of a Lie algebra. It gives a decomposition of the degree-n component $T_n(V)$ of $T(V)$ into $GL(V)$ representations indexed by partitions. The higher Lie characters are the symmetric group S_n characters corresponding to this decomposition via Schur-Weyl duality.

Another important question, *Thrall's problem* (see e.g. [Sch2003b]) asks, for λ a partition of n, can we combinatorially interpret the coefficients α_μ^λ in the Schur-expansion of $\mathbf{GR}_\lambda$:

$$\mathbf{GR}_\lambda = \sum_{\mu \vdash n} \alpha_\mu^\lambda s_\mu.$$

INPUT:

- `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition `[lam]`)

OUTPUT:

The Gessel-Reutenauer symmetric function $\mathbf{GR}_\lambda$, where λ is `lam`, expanded in the basis `self`.

EXAMPLES:

The first few values of $\mathbf{GR}_{(n)} = L_n$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.gessel_reutenauer(1)
h[1]
sage: h.gessel_reutenauer(2)
h[1, 1] - h[2]
sage: h.gessel_reutenauer(3)
h[2, 1] - h[3]
sage: h.gessel_reutenauer(4)
h[2, 1, 1] - h[2, 2]
sage: h.gessel_reutenauer(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
sage: h.gessel_reutenauer(6)
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
 - 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
 - h[4, 2] - h[5, 1] + h[6]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
>>> h.gessel_reutenauer(Integer(1))
h[1]
>>> h.gessel_reutenauer(Integer(2))
h[1, 1] - h[2]
>>> h.gessel_reutenauer(Integer(3))
h[2, 1] - h[3]
>>> h.gessel_reutenauer(Integer(4))
h[2, 1, 1] - h[2, 2]
>>> h.gessel_reutenauer(Integer(5))
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
>>> h.gessel_reutenauer(Integer(6))
h[2, 1, 1, 1, 1] - h[2, 2, 1, 1] - h[2, 2, 2]
 - 2*h[3, 1, 1, 1] + 5*h[3, 2, 1] - 2*h[3, 3] + h[4, 1, 1]
 - h[4, 2] - h[5, 1] + h[6]
```

Gessel-Reutenauer functions indexed by partitions:

```
sage: h.gessel_reutenauer([2, 1])
h[1, 1, 1] - h[2, 1]
sage: h.gessel_reutenauer([2, 2])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]
```

```
>>> from sage.all import *
>>> h.gessel_reutenauer([Integer(2), Integer(1)])
h[1, 1, 1] - h[2, 1]
>>> h.gessel_reutenauer([Integer(2), Integer(2)])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 2*h[2, 2] + h[3, 1] - h[4]
```

The Gessel-Reutenauer functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.gessel_reutenauer([2, 1])
s[1, 1, 1] + s[2, 1]
sage: s.gessel_reutenauer([2, 2, 1])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]
```

```
>>> from sage.all import *
>>> s = Sym.s()
>>> s.gessel_reutenauer([Integer(2), Integer(1)])
s[1, 1, 1] + s[2, 1]
>>> s.gessel_reutenauer([Integer(2), Integer(2), Integer(1)])
s[1, 1, 1, 1, 1] + s[2, 1, 1, 1] + s[2, 2, 1] + s[3, 2]
```

They do not form a basis, as the following example (from [GR1993] p. 201) shows:

```
sage: s.gessel_reutenauer([4]) == s.gessel_reutenauer([2, 1, 1])
True
```

```
>>> from sage.all import *
>>> s.gessel_reutenauer([Integer(4)]) == s.gessel_reutenauer([Integer(2),␣
↪Integer(1), Integer(1)])
True
```

They also go by the name *higher Lie character*:

```
sage: s.higher_lie_character([2, 2, 1]) == s.gessel_reutenauer([2, 2, 1])
True
```

```
>>> from sage.all import *
>>> s.higher_lie_character([Integer(2), Integer(2), Integer(1)]) == s.
↪gessel_reutenauer([Integer(2), Integer(2), Integer(1)])
True
```

Of the above three equivalent definitions of $\mathbf{GR}_\lambda$, we use the third one for computations. Let us check that the second one gives the same results:

```
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F() # fundamental basis
sage: def GR_def2(lam): # `\mathbf{GR}_\lambda`
....:     n = lam.size()
....:     r = F.sum_of_monomials([sigma.descents_composition()
....:                            for sigma in Permutations(n)
....:                            if sigma.cycle_type() == lam])
....:     return r.to_symmetric_function()
sage: all( GR_def2(lam) == h.gessel_reutenauer(lam)
....:      for n in range(5) for lam in Partitions(n) )
True
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F() # fundamental basis
```

(continues on next page)

(continued from previous page)

```
>>> def GR_def2(lam): # `\mathbf{GR}_\lambda`
...     n = lam.size()
...     r = F.sum_of_monomials([sigma.descents_composition()
...                             for sigma in Permutations(n)
...                             if sigma.cycle_type() == lam])
...     return r.to_symmetric_function()
>>> all( GR_def2(lam) == h.gessel_reutenauer(lam)
...      for n in range(Integer(5)) for lam in Partitions(n) )
True
```

And the first one, too (assuming symmetry):

```
sage: m = Sym.m()
sage: def GR_def1(lam): # `\mathbf{GR}_\lambda`
....:     n = lam.size()
....:     Permus_mset = sage.combinat.permutation.Permutations_mset
....:     def coeff_of_m_mu_in_result(mu):
....:         words_to_check = Permus_mset([i for (i, l) in enumerate(mu)
....:                                       for _ in range(l)])
....:         return sum((1 for w in words_to_check if
....:                     Partition(list(reversed(sorted([len(v) for v in␣
↪Word(w).lyndon_factorization()]))))
....:                     == lam))
....:     r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
....:                         for mu in Partitions(n)],
....:                        distinct=True)
....:     return r
sage: all( GR_def1(lam) == h.gessel_reutenauer(lam)
....:      for n in range(5) for lam in Partitions(n) )
True
```

```
>>> from sage.all import *
>>> m = Sym.m()
>>> def GR_def1(lam): # `\mathbf{GR}_\lambda`
...     n = lam.size()
...     Permus_mset = sage.combinat.permutation.Permutations_mset
...     def coeff_of_m_mu_in_result(mu):
...         words_to_check = Permus_mset([i for (i, l) in enumerate(mu)
...                                       for _ in range(l)])
...         return sum((Integer(1) for w in words_to_check if
...                     Partition(list(reversed(sorted([len(v) for v in␣
↪Word(w).lyndon_factorization()]))))
...                     == lam))
...     r = m.sum_of_terms([(mu, coeff_of_m_mu_in_result(mu))
...                         for mu in Partitions(n)],
...                        distinct=True)
...     return r
>>> all( GR_def1(lam) == h.gessel_reutenauer(lam)
...      for n in range(Integer(5)) for lam in Partitions(n) )
True
```

Note

The currently existing implementation of this function is technically unsatisfactory. It distinguishes the case when the base ring is a **Q**-algebra from the case where it isn't. In the latter, it does a computation using universal coefficients, again distinguishing the case when it is able to compute the "corresponding" basis of the symmetric function algebra over **Q** (using the `corresponding_basis_over` hack) from the case when it isn't (in which case it transforms everything into the Schur basis, which is slow).

is_commutative()

Return whether this symmetric function algebra is commutative.

INPUT:

- `self` – a basis of the symmetric functions

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_commutative()
True
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.is_commutative()
True
```

is_field(*proof=True*)

Return whether `self` is a field. (It is not.)

INPUT:

- `self` – a basis of the symmetric functions
- `proof` – an optional argument (default: value: `True`)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_field()
False
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.is_field()
False
```

is_integral_domain(*proof=True*)

Return whether `self` is an integral domain. (It is if and only if the base ring is an integral domain.)

INPUT:

- `self` – a basis of the symmetric functions
- `proof` – an optional argument (default: value: `True`)

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.is_integral_domain()
True
```

(continues on next page)

(continued from previous page)

```
sage: s = SymmetricFunctions(Zmod(14)).s()
sage: s.is_integral_domain()
False
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.is_integral_domain()
True

>>> s = SymmetricFunctions(Zmod(Integer(14))).s()
>>> s.is_integral_domain()
False
```

lehrer_solomon(*lam*)

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition `lam` written in the basis `self`.

Let $\lambda \vdash n$ be a partition. The *Lehrer-Solomon symmetric function* $\mathbf{LS}_\lambda$ corresponding to λ is the Frobenius characteristic of the representation denoted $\mathrm{Ind}_{Z_\lambda}^{S_n}(\xi_\lambda)$ in Theorem 4.5 of [LS1986] or W_λ in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to λ (after reordering appropriately).

It can be computed using Sundaram's plethystic formula (see [Sun1994] Theorem 1.8):

$$\mathbf{LS}_\lambda = \prod_{\text{odd } j \geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j \geq 2} e_{m_j}[\pi_j],$$

where h_{m_j} are complete homogeneous symmetric functions, e_{m_j} are elementary symmetric functions, and π_j are the images of the Gessel-Reutenauer symmetric function $\mathbf{GR}_{(j)}$ (see `gessel_reutenauer()`) under the involution ω (i.e. `omega_involution()`):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(2)).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(1)).omega_involution()
sage: s.lehrer_solomon([2,1]) == pi_2 * pi_1 # since h_1, e_1 are␣
↪plethystic identities
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> pi_2 = (s.gessel_reutenauer(Integer(2))).omega_involution()
>>> pi_1 = (s.gessel_reutenauer(Integer(1))).omega_involution()
>>> s.lehrer_solomon([Integer(2),Integer(1)]) == pi_2 * pi_1 # since h_1,␣
↪e_1 are plethystic identities
True
```

Note that this also gives the S_n-equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type-A reflection arrangement).

The representation corresponding to $\mathbf{LS}_\lambda$ exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

INPUT:

- `lam` – a partition or a positive integer (in the latter case, it is understood to mean the partition `[lam]`)

OUTPUT:

The Lehrer-Solomon symmetric function $\mathbf{LS}_\lambda$, where λ is `lam`, expanded in the basis `self`.

EXAMPLES:

The first few values of $\mathbf{LS}_{(n)}$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
h[1]
sage: h.lehrer_solomon(2)
h[2]
sage: h.lehrer_solomon(3)
h[2, 1] - h[3]
sage: h.lehrer_solomon(4)
h[2, 1, 1] - h[2, 2]
sage: h.lehrer_solomon(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
>>> h.lehrer_solomon(Integer(1))
h[1]
>>> h.lehrer_solomon(Integer(2))
h[2]
>>> h.lehrer_solomon(Integer(3))
h[2, 1] - h[3]
>>> h.lehrer_solomon(Integer(4))
h[2, 1, 1] - h[2, 2]
>>> h.lehrer_solomon(Integer(5))
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
```

The *`whitney_homology_character()`* method is an alias:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2,␣
↪1])
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> s = Sym.schur()
>>> s.lehrer_solomon([Integer(2), Integer(2), Integer(1)]) == s.whitney_
↪homology_character([Integer(2), Integer(2), Integer(1)])
True
```

Lehrer-Solomon functions indexed by partitions:

```
sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])
h[3, 1] - h[4]
```

```
>>> from sage.all import *
>>> h.lehrer_solomon([Integer(2), Integer(1)])
h[2, 1]
>>> h.lehrer_solomon([Integer(2), Integer(2)])
h[3, 1] - h[4]
```

The Lehrer-Solomon functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

```
>>> from sage.all import *
>>> s = Sym.s()
>>> s.lehrer_solomon([Integer(2), Integer(1)])
s[2, 1] + s[3]
>>> s.lehrer_solomon([Integer(2), Integer(2), Integer(1)])
s[3, 1, 1] + s[3, 2] + s[4, 1]
>>> s.lehrer_solomon([Integer(4), Integer(1)])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

one_basis()

Return the empty partition, as per `AlgebrasWithBasis.ParentMethods.one_basis`.

INPUT:

- `self` – a basis of the ring of symmetric functions

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ['t'].fraction_field())
sage: s = Sym.s()
sage: s.one_basis()
[]
sage: Q = Sym.hall_littlewood().Q()
sage: Q.one_basis()
[]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ['t'].fraction_field())
>>> s = Sym.s()
>>> s.one_basis()
[]
>>> Q = Sym.hall_littlewood().Q()
>>> Q.one_basis()
[]
```

Todo

generalize to Modules.Graded.Connected.ParentMethods

skew_schur(*x*)

Return the skew Schur function indexed by `x` in `self`.

INPUT:

- `x` – a skew partition

EXAMPLES:

```
sage: sp = SkewPartition([[5,3,3,1], [3,2,1]])
sage: s = SymmetricFunctions(QQ).s()
sage: s.skew_schur(sp)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 3*s[3, 2, 1]
 + s[3, 3] + 2*s[4, 1, 1] + 2*s[4, 2] + s[5, 1]

sage: e = SymmetricFunctions(QQ).e()
sage: ess = e.skew_schur(sp); ess
e[2, 1, 1, 1, 1] - e[2, 2, 1, 1] - e[3, 1, 1, 1] + e[3, 2, 1]
sage: ess == e(s.skew_schur(sp))
True
```

```
>>> from sage.all import *
>>> sp = SkewPartition([[Integer(5),Integer(3),Integer(3),Integer(1)],␣
↪[Integer(3),Integer(2),Integer(1)]])
>>> s = SymmetricFunctions(QQ).s()
>>> s.skew_schur(sp)
s[2, 2, 1, 1] + s[2, 2, 2] + s[3, 1, 1, 1] + 3*s[3, 2, 1]
 + s[3, 3] + 2*s[4, 1, 1] + 2*s[4, 2] + s[5, 1]

>>> e = SymmetricFunctions(QQ).e()
>>> ess = e.skew_schur(sp); ess
e[2, 1, 1, 1, 1] - e[2, 2, 1, 1] - e[3, 1, 1, 1] + e[3, 2, 1]
>>> ess == e(s.skew_schur(sp))
True
```

whitney_homology_character(*lam*)

Return the Lehrer-Solomon symmetric function (also known as the Whitney homology character) corresponding to the partition `lam` written in the basis `self`.

Let $\lambda \vdash n$ be a partition. The *Lehrer-Solomon symmetric function* $\mathbf{LS}_\lambda$ corresponding to λ is the Frobenius characteristic of the representation denoted $\mathrm{Ind}_{Z_\lambda}^{S_n}(\xi_\lambda)$ in Theorem 4.5 of [LS1986] or W_λ in Theorem 2.7 of [HR2017]. It was first computed as a symmetric function in [Sun1994].

It is the symmetric group representation corresponding to a summand of the Whitney homology of the set partition lattice. The summand comes from the orbit of set partitions with block sizes corresponding to λ (after reordering appropriately).

It can be computed using Sundaram's plethystic formula (see [Sun1994] Theorem 1.8):

$$\mathbf{LS}_\lambda = \prod_{\text{odd } j\geq 1} h_{m_j}[\pi_j] \prod_{\text{even } j\geq 2} e_{m_j}[\pi_j],$$

where h_{m_j} are complete homogeneous symmetric functions, e_{m_j} are elementary symmetric functions, and π_j are the images of the Gessel-Reutenauer symmetric function $\mathbf{GR}_{(j)}$ (see gessel_reutenauer()) under the involution ω (i.e. omega_involution()):

```
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: pi_2 = (s.gessel_reutenauer(2)).omega_involution()
sage: pi_1 = (s.gessel_reutenauer(1)).omega_involution()
sage: s.lehrer_solomon([2,1]) == pi_2 * pi_1 # since h_1, e_1 are␣
↪plethystic identities
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> pi_2 = (s.gessel_reutenauer(Integer(2))).omega_involution()
>>> pi_1 = (s.gessel_reutenauer(Integer(1))).omega_involution()
>>> s.lehrer_solomon([Integer(2),Integer(1)]) == pi_2 * pi_1 # since h_1,␣
↪e_1 are plethystic identities
True
```

Note that this also gives the S_n-equivariant structure of the Orlik-Solomon algebra of the braid arrangement (also known as the type-A reflection arrangement).

The representation corresponding to $\mathbf{LS}_\lambda$ exhibits representation stability [Chu2012], and a sharp bound is given in [HR2017].

INPUT:

- lam – a partition or a positive integer (in the latter case, it is understood to mean the partition [lam])

OUTPUT:

The Lehrer-Solomon symmetric function $\mathbf{LS}_\lambda$, where λ is lam, expanded in the basis self.

EXAMPLES:

The first few values of $\mathbf{LS}_{(n)}$:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: h = Sym.h()
sage: h.lehrer_solomon(1)
h[1]
sage: h.lehrer_solomon(2)
h[2]
sage: h.lehrer_solomon(3)
h[2, 1] - h[3]
sage: h.lehrer_solomon(4)
h[2, 1, 1] - h[2, 2]
sage: h.lehrer_solomon(5)
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> h = Sym.h()
>>> h.lehrer_solomon(Integer(1))
h[1]
>>> h.lehrer_solomon(Integer(2))
```

(continues on next page)

(continued from previous page)

```
h[2]
>>> h.lehrer_solomon(Integer(3))
h[2, 1] - h[3]
>>> h.lehrer_solomon(Integer(4))
h[2, 1, 1] - h[2, 2]
>>> h.lehrer_solomon(Integer(5))
h[2, 1, 1, 1] - h[2, 2, 1] - h[3, 1, 1] + h[3, 2] + h[4, 1] - h[5]
```

The `whitney_homology_character()` method is an alias:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: s = Sym.schur()
sage: s.lehrer_solomon([2, 2, 1]) == s.whitney_homology_character([2, 2,␣
↪1])
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> s = Sym.schur()
>>> s.lehrer_solomon([Integer(2), Integer(2), Integer(1)]) == s.whitney_
↪homology_character([Integer(2), Integer(2), Integer(1)])
True
```

Lehrer-Solomon functions indexed by partitions:

```
sage: h.lehrer_solomon([2, 1])
h[2, 1]
sage: h.lehrer_solomon([2, 2])
h[3, 1] - h[4]
```

```
>>> from sage.all import *
>>> h.lehrer_solomon([Integer(2), Integer(1)])
h[2, 1]
>>> h.lehrer_solomon([Integer(2), Integer(2)])
h[3, 1] - h[4]
```

The Lehrer-Solomon functions are Schur-positive:

```
sage: s = Sym.s()
sage: s.lehrer_solomon([2, 1])
s[2, 1] + s[3]
sage: s.lehrer_solomon([2, 2, 1])
s[3, 1, 1] + s[3, 2] + s[4, 1]
sage: s.lehrer_solomon([4, 1])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

```
>>> from sage.all import *
>>> s = Sym.s()
>>> s.lehrer_solomon([Integer(2), Integer(1)])
s[2, 1] + s[3]
>>> s.lehrer_solomon([Integer(2), Integer(2), Integer(1)])
s[3, 1, 1] + s[3, 2] + s[4, 1]
```

(continues on next page)

(continued from previous page)

```
>>> s.lehrer_solomon([Integer(4), Integer(1)])
s[2, 1, 1, 1] + s[2, 2, 1] + 2*s[3, 1, 1] + s[3, 2] + s[4, 1]
```

super_categories()

The super categories of `self`.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import SymmetricFunctionsBases
sage: Sym = SymmetricFunctions(QQ)
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()
[Category of realizations of Symmetric Functions over Rational Field,
 Category of commutative Hopf algebras with basis over Rational Field,
 Join of Category of realizations of Hopf algebras over Rational Field
     and Category of graded algebras over Rational Field
     and Category of graded coalgebras over Rational Field,
 Category of unique factorization domains]

sage: Sym = SymmetricFunctions(ZZ["x"])
sage: bases = SymmetricFunctionsBases(Sym)
sage: bases.super_categories()

↪over Integer Ring]
```

class sage.combinat.sf.sfa.**SymmetricFunctionsFamilyFunctor**(*basis*, *family*, *name*, **args*)

Bases: *SymmetricFunctionsFunctor*

Initialize the functor.

INPUT:

- basis – the basis of the symmetric function algebra

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import SymmetricFunctionsFamilyFunctor
sage: R.<t> = ZZ[]
sage: basis = SymmetricFunctions(R).macdonald(q=1).H()
sage: family = sage.combinat.sf.macdonald.Macdonald
sage: name = basis.basis_name()
sage: SymmetricFunctionsFamilyFunctor(basis, family, name, 1, t)
SymmetricFunctionsFunctor[Macdonald H with q=1]
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import SymmetricFunctionsFamilyFunctor
>>> R = ZZ['t']; (t,) = R._first_ngens(1)
>>> basis = SymmetricFunctions(R).macdonald(q=Integer(1)).H()
>>> family = sage.combinat.sf.macdonald.Macdonald
>>> name = basis.basis_name()
>>> SymmetricFunctionsFamilyFunctor(basis, family, name, Integer(1), t)
SymmetricFunctionsFunctor[Macdonald H with q=1]
```

class sage.combinat.sf.sfa.**SymmetricFunctionsFunctor**(*basis*, *name*, **args*)

Bases: ConstructionFunctor

A constructor for algebras of symmetric functions.

EXAMPLES:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

```
>>> from sage.all import *
>>> s = SymmetricFunctions(QQ).s()
>>> s.construction()
(SymmetricFunctionsFunctor[Schur], Rational Field)
```

rank = 9

sage.combinat.sf.sfa.**is_SymmetricFunction**(*x*)

Check whether x is a symmetric function.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import is_SymmetricFunction
sage: s = SymmetricFunctions(QQ).s()
sage: is_SymmetricFunction(2)
doctest:warning...
DeprecationWarning: The function is_SymmetricFunction is deprecated;
use 'isinstance(..., SymmetricFunctionAlgebra_generic.Element)' instead.
See https://github.com/sagemath/sage/issues/38279 for details.
False
sage: is_SymmetricFunction(s(2))
True
sage: is_SymmetricFunction(s([2,1]))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import is_SymmetricFunction
>>> s = SymmetricFunctions(QQ).s()
>>> is_SymmetricFunction(Integer(2))
doctest:warning...
DeprecationWarning: The function is_SymmetricFunction is deprecated;
use 'isinstance(..., SymmetricFunctionAlgebra_generic.Element)' instead.
See https://github.com/sagemath/sage/issues/38279 for details.
False
>>> is_SymmetricFunction(s(Integer(2)))
True
>>> is_SymmetricFunction(s([Integer(2),Integer(1)]))
True
```

sage.combinat.sf.sfa.**is_SymmetricFunctionAlgebra**(*x*)

Check whether x is a symmetric function algebra.

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import is_SymmetricFunctionAlgebra
sage: is_SymmetricFunctionAlgebra(5)
doctest:warning...
DeprecationWarning: the function is_SymmetricFunctionAlgebra is deprecated;
use 'isinstance(..., SymmetricFunctionAlgebra_generic)' instead
See https://github.com/sagemath/sage/issues/37896 for details.
False
sage: is_SymmetricFunctionAlgebra(ZZ)
False
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(ZZ).schur())
True
sage: is_SymmetricFunctionAlgebra(SymmetricFunctions(QQ).e())
True

sage.combinat.sf.sfa.**zee**(*part*)

Return the size of the centralizer of any permutation of cycle type `part`.

Note that the size of the centralizer is the inner product between `p(part)` and itself, where p is the power-sum symmetric functions.

INPUT:

- `part` – integer partition (for example, `[2,1,1]`)

OUTPUT:

- the integer $\prod_i i^{m_i(part)} m_i(part)!$ where $m_i(part)$ is the number of parts in the partition `part` equal to i

EXAMPLES:

```
sage: from sage.combinat.sf.sfa import zee
sage: zee([2,1,1])
4
```

```
>>> from sage.all import *
>>> from sage.combinat.sf.sfa import zee
>>> zee([Integer(2),Integer(1),Integer(1)])
4
```

5.1.304 Witt symmetric functions

class sage.combinat.sf.witt.**SymmetricFunctionAlgebra_witt**(*Sym*)

Bases: *SymmetricFunctionAlgebra_multiplicative*

The Witt symmetric function basis (or Witt basis, to be short).

The Witt basis of the ring of symmetric functions is denoted by (x_λ) in [HazWitt1], section 9.63, and by (q_λ) in [DoranIV1996]. We will denote this basis by (w_λ) (which is precisely how it is denoted in [GriRei18], Exercise 2.9.3(d)). It is a multiplicative basis (meaning that $w_\emptyset = 1$ and that every partition λ satisfies $w_\lambda = w_{\lambda_1} w_{\lambda_2} w_{\lambda_3} \cdots$, where w_i means $w_{(i)}$ for every nonnegative integer i).

This basis can be defined in various ways. Probably the most well-known one is using the equation

$$\prod_{d=1}^{\infty} (1 - w_d t^d)^{-1} = \sum_{n=0}^{\infty} h_n t^n$$

where t is a formal variable and h_n are the complete homogeneous symmetric functions, extended to 0 by $h_0 = 1$. This equation allows one to uniquely determine the functions $w_1, w_2, w_3, \ldots$ by recursion; one consequently extends the definition to all w_λ by requiring multiplicativity.

A way to rewrite the above equation without power series is:

$$h_n = \sum_{\lambda \vdash n} w_\lambda$$

for all nonnegative integers n, where $\lambda \vdash n$ means that λ is a partition of n.

A similar equation (which is easily seen to be equivalent to the former) is

$$e_n = \sum_{\lambda} (-1)^{n - \ell(\lambda)} w_\lambda,$$

with the sum running only over *strict* partitions λ of n this time. This equation can also be used to recursively define the w_n. Furthermore, every positive integer n satisfies

$$p_n = \sum_{d \mid n} d w_d^{n/d},$$

and this can be used to define the w_n recursively over any ring which is torsion-free as a $\mathbf{Z}$-module. While these equations all yield easy formulas for classical bases of the ring of symmetric functions in terms of the Witt symmetric functions, it seems difficult to obtain explicit formulas in the other direction.

The Witt symmetric functions owe their name to the fact that the ring of symmetric functions can be viewed as the coordinate ring of the group scheme of Witt vectors, and the Witt symmetric functions are the functions that send a Witt vector to its components (whereas the powersum symmetric functions send a Witt vector to its ghost components). Details can be found in [HazWitt1] or section 3.2 of [BorWi2004].

INPUT:

- `Sym` – an instance of the ring of the symmetric functions

REFERENCES:

EXAMPLES:

Here are the first few Witt symmetric functions, in various bases:

```
sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: p = Sym.p()
sage: s = Sym.s()
sage: m = Sym.m()

sage: p(w([1]))
p[1]
```

(continues on next page)

(continued from previous page)

```
sage: m(w([1]))
m[1]
sage: e(w([1]))
e[1]
sage: h(w([1]))
h[1]
sage: s(w([1]))
s[1]

sage: p(w([2]))
-1/2*p[1, 1] + 1/2*p[2]
sage: m(w([2]))
-m[1, 1]
sage: e(w([2]))
-e[2]
sage: h(w([2]))
-h[1, 1] + h[2]
sage: s(w([2]))
-s[1, 1]

sage: p(w([3]))
-1/3*p[1, 1, 1] + 1/3*p[3]
sage: m(w([3]))
-2*m[1, 1, 1] - m[2, 1]
sage: e(w([3]))
-e[2, 1] + e[3]
sage: h(w([3]))
-h[2, 1] + h[3]
sage: s(w([3]))
-s[2, 1]

sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: e = Sym.e()
sage: h = Sym.h()
sage: s = Sym.s()
sage: m = Sym.m()
sage: p = Sym.p()
sage: m(w([4]))
-9*m[1, 1, 1, 1] - 4*m[2, 1, 1] - 2*m[2, 2] - m[3, 1]
sage: e(w([4]))
-e[2, 1, 1] + e[3, 1] - e[4]
sage: h(w([4]))
-h[1, 1, 1, 1] + 2*h[2, 1, 1] - h[2, 2] - h[3, 1] + h[4]
sage: s(w([4]))
-s[1, 1, 1, 1] - s[2, 1, 1] - s[2, 2] - s[3, 1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> w = Sym.w()
>>> e = Sym.e()
>>> h = Sym.h()
```

(continues on next page)

(continued from previous page)

```
>>> p = Sym.p()
>>> s = Sym.s()
>>> m = Sym.m()

>>> p(w([Integer(1)]))
p[1]
>>> m(w([Integer(1)]))
m[1]
>>> e(w([Integer(1)]))
e[1]
>>> h(w([Integer(1)]))
h[1]
>>> s(w([Integer(1)]))
s[1]

>>> p(w([Integer(2)]))
-1/2*p[1, 1] + 1/2*p[2]
>>> m(w([Integer(2)]))
-m[1, 1]
>>> e(w([Integer(2)]))
-e[2]
>>> h(w([Integer(2)]))
-h[1, 1] + h[2]
>>> s(w([Integer(2)]))
-s[1, 1]

>>> p(w([Integer(3)]))
-1/3*p[1, 1, 1] + 1/3*p[3]
>>> m(w([Integer(3)]))
-2*m[1, 1, 1] - m[2, 1]
>>> e(w([Integer(3)]))
-e[2, 1] + e[3]
>>> h(w([Integer(3)]))
-h[2, 1] + h[3]
>>> s(w([Integer(3)]))
-s[2, 1]

>>> Sym = SymmetricFunctions(ZZ)
>>> w = Sym.w()
>>> e = Sym.e()
>>> h = Sym.h()
>>> s = Sym.s()
>>> m = Sym.m()
>>> p = Sym.p()
>>> m(w([Integer(4)]))
-9*m[1, 1, 1, 1] - 4*m[2, 1, 1] - 2*m[2, 2] - m[3, 1]
>>> e(w([Integer(4)]))
-e[2, 1, 1] + e[3, 1] - e[4]
>>> h(w([Integer(4)]))
-h[1, 1, 1, 1] + 2*h[2, 1, 1] - h[2, 2] - h[3, 1] + h[4]
>>> s(w([Integer(4)]))
-s[1, 1, 1, 1] - s[2, 1, 1] - s[2, 2] - s[3, 1]
```

Some examples of conversions the other way:

```
sage: w(h[3])
w[1, 1, 1] + w[2, 1] + w[3]
sage: w(e[3])
-w[2, 1] + w[3]
sage: w(m[2,1])
2*w[2, 1] - 3*w[3]
sage: w(p[3])
w[1, 1, 1] + 3*w[3]
```

```
>>> from sage.all import *
>>> w(h[Integer(3)])
w[1, 1, 1] + w[2, 1] + w[3]
>>> w(e[Integer(3)])
-w[2, 1] + w[3]
>>> w(m[Integer(2),Integer(1)])
2*w[2, 1] - 3*w[3]
>>> w(p[Integer(3)])
w[1, 1, 1] + 3*w[3]
```

Antipodes:

```
sage: w([1]).antipode()
-w[1]
sage: w([2]).antipode()
-w[1, 1] - w[2]
```

```
>>> from sage.all import *
>>> w([Integer(1)]).antipode()
-w[1]
>>> w([Integer(2)]).antipode()
-w[1, 1] - w[2]
```

The following holds for all odd i and is easily proven by induction:

```
sage: all(w([i]).antipode() == -w([i]) for i in range(1, 10, 2))
True
```

```
>>> from sage.all import *
>>> all(w([i]).antipode() == -w([i]) for i in range(Integer(1), Integer(10),
↪Integer(2)))
True
```

The Witt basis does not allow for simple expressions for comultiplication and antipode in general (this is related to the fact that the sum of two Witt vectors isn't easily described in terms of the components). Therefore, a number of computations with Witt symmetric functions pass through the complete homogeneous symmetric functions by default.

class Element

Bases: *Element*

omega()

Return the image of `self` under the omega automorphism.

The *omega automorphism* is defined to be the unique algebra endomorphism ω of the ring of symmetric functions that satisfies $\omega(e_k) = h_k$ for all positive integers k (where e_k stands for the k-th elementary symmetric function, and h_k stands for the k-th complete homogeneous symmetric function). It furthermore is a Hopf algebra endomorphism and an involution, and it is also known as the *omega involution*. It sends the power-sum symmetric function p_k to $(-1)^{k-1} p_k$ for every positive integer k.

The images of some bases under the omega automorphism are given by

$$\omega(e_\lambda) = h_\lambda, \qquad \omega(h_\lambda) = e_\lambda, \qquad \omega(p_\lambda) = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda, \qquad \omega(s_\lambda) = s_{\lambda'},$$

where λ is any partition, where $\ell(\lambda)$ denotes the length (`length()`) of the partition λ, where λ' denotes the conjugate partition (`conjugate()`) of λ, and where the usual notations for bases are used (e = elementary, h = complete homogeneous, p = powersum, s = Schur).

`omega_involution()` is a synonym for the `omega()` method.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(QQ)
sage: w = Sym.w()
sage: a = w([4,3,1,1]); a
w[4, 3, 1, 1]
sage: a.omega()
-w[3, 1, 1, 1, 1, 1, 1] - w[3, 2, 1, 1, 1, 1]
 - w[3, 2, 2, 1, 1] - w[4, 3, 1, 1]

sage: h = Sym.h()
sage: all(w(h(w[la]).omega()) == w[la].omega()
....:     for n in range(6) for la in Partitions(n))
True
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(QQ)
>>> w = Sym.w()
>>> a = w([Integer(4),Integer(3),Integer(1),Integer(1)]); a
w[4, 3, 1, 1]
>>> a.omega()
-w[3, 1, 1, 1, 1, 1, 1] - w[3, 2, 1, 1, 1, 1]
 - w[3, 2, 2, 1, 1] - w[4, 3, 1, 1]

>>> h = Sym.h()
>>> all(w(h(w[la]).omega()) == w[la].omega()
...     for n in range(Integer(6)) for la in Partitions(n))
True
```

coproduct(*elt*)

Return the coproduct of the element `elt`.

INPUT:

- `elt` – a symmetric function written in this basis

OUTPUT:

The coproduct acting on `elt`; the result is an element of the tensor squared of the basis `self`.

EXAMPLES:

```
sage: w = SymmetricFunctions(QQ).w()
sage: w[2].coproduct()
w[] # w[2] - w[1] # w[1] + w[2] # w[]
sage: w.coproduct(w[2])
w[] # w[2] - w[1] # w[1] + w[2] # w[]
sage: w[2,1].coproduct()
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
→w[2, 1] # w[]
sage: w.coproduct(w[2,1])
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
→w[2, 1] # w[]
```

```
>>> from sage.all import *
>>> w = SymmetricFunctions(QQ).w()
>>> w[Integer(2)].coproduct()
w[] # w[2] - w[1] # w[1] + w[2] # w[]
>>> w.coproduct(w[Integer(2)])
w[] # w[2] - w[1] # w[1] + w[2] # w[]
>>> w[Integer(2),Integer(1)].coproduct()
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
→w[2, 1] # w[]
>>> w.coproduct(w[Integer(2),Integer(1)])
w[] # w[2, 1] - w[1] # w[1, 1] + w[1] # w[2] - w[1, 1] # w[1] + w[2] # w[1] +
→w[2, 1] # w[]
```

verschiebung(*n*)

Return the image of the symmetric function `self` under the n-th Verschiebung operator.

The n-th Verschiebung operator $\mathbf{V}_n$ is defined to be the unique algebra endomorphism V of the ring of symmetric functions that satisfies $V(h_r) = h_{r/n}$ for every positive integer r divisible by n, and satisfies $V(h_r) = 0$ for every positive integer r not divisible by n. This operator $\mathbf{V}_n$ is a Hopf algebra endomorphism. For every nonnegative integer r with $n \mid r$, it satisfies

$$\mathbf{V}_n(h_r) = h_{r/n}, \quad \mathbf{V}_n(p_r) = np_{r/n}, \quad \mathbf{V}_n(e_r) = (-1)^{r-r/n}e_{r/n}, \quad \mathbf{V}_n(w_r) = w_{r/n},$$

(where h is the complete homogeneous basis, p is the powersum basis, e is the elementary basis, and w is the Witt basis). For every nonnegative integer r with $n \nmid r$, it satisfes

$$\mathbf{V}_n(h_r) = \mathbf{V}_n(p_r) = \mathbf{V}_n(e_r) = \mathbf{V}_n(w_r) = 0.$$

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism. Its name derives from the Verschiebung (German for “shift”) endomorphism of the Witt vectors.

The n-th Verschiebung operator is adjoint to the n-th Frobenius operator (see `frobenius()` for its definition) with respect to the Hall scalar product (`scalar()`).

The action of the n-th Verschiebung operator on the Schur basis can also be computed explicitly. The following (probably clumsier than necessary) description can be obtained by solving exercise 7.61 in Stanley’s [STA].

Let λ be a partition. Let n be a positive integer. If the n-core of λ is nonempty, then $\mathbf{V}_n(s_\lambda) = 0$. Otherwise, the following method computes $\mathbf{V}_n(s_\lambda)$: Write the partition λ in the form $(\lambda_1, \lambda_2, \ldots, \lambda_{ns})$ for some nonnegative integer s. (If n does not divide the length of λ, then this is achieved by adding trailing zeroes to λ.) Set $\beta_i = \lambda_i + ns - i$ for every $s \in \{1, 2, \ldots, ns\}$. Then, $(\beta_1, \beta_2, \ldots, \beta_{ns})$ is a strictly decreasing sequence of nonnegative integers. Stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $-1 - \beta_i$ modulo n. Let ξ be the sign of the permutation that is used for this sorting. Let ψ be the sign of the permutation that is used to stably sort the list $(1, 2, \ldots, ns)$ in order of (weakly) increasing remainder of $i - 1$ modulo n. (Notice that $\psi = (-1)^{n(n-1)s(s-1)/4}$.) Then, $\mathbf{V}_n(s_\lambda) = \xi\psi \prod_{i=0}^{n-1} s_{\lambda^{(i)}}$, where $(\lambda^{(0)}, \lambda^{(1)}, \ldots, \lambda^{(n-1)})$ is the n-quotient of λ.

INPUT:

- `n` – positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of symmetric functions) to `self`.

EXAMPLES:

```
sage: Sym = SymmetricFunctions(ZZ)
sage: w = Sym.w()
sage: w[3].verschiebung(2)
0
sage: w[4].verschiebung(4)
w[1]
```

```
>>> from sage.all import *
>>> Sym = SymmetricFunctions(ZZ)
>>> w = Sym.w()
>>> w[Integer(3)].verschiebung(Integer(2))
0
>>> w[Integer(4)].verschiebung(Integer(4))
w[1]
```

5.1.305 Shard intersection order

This file builds a combinatorial version of the shard intersection order of type A (in the classification of finite Coxeter groups). This is a lattice on the set of permutations, closely related to noncrossing partitions and the weak order.

For technical reasons, the elements of the posets are not permutations, but can be easily converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

```
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([Integer(1),Integer(3),Integer(4),Integer(2)])
>>> e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
>>> Permutation(list(e0)) == p0
True
```

See also

A general implementation for all finite Coxeter groups is available as `shard_poset()`

REFERENCES:

`class sage.combinat.shard_order.ShardPosetElement(p)`

Bases: `tuple`

An element of the shard poset.

This is basically a permutation with extra stored arguments:

- `p` – the permutation itself as a tuple
- `runs` – the decreasing runs as a tuple of tuples
- `run_indices` – list; `integer -> index of the run`
- `dpg` – the transitive closure of the shard preorder graph
- `spg` – the transitive reduction of the shard preorder graph

These elements can easily be converted from and to permutations:

```
sage: from sage.combinat.shard_order import ShardPosetElement
sage: p0 = Permutation([1,3,4,2])
sage: e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
sage: Permutation(list(e0)) == p0
True
```

```
>>> from sage.all import *
>>> from sage.combinat.shard_order import ShardPosetElement
>>> p0 = Permutation([Integer(1),Integer(3),Integer(4),Integer(2)])
>>> e0 = ShardPosetElement(p0); e0
(1, 3, 4, 2)
>>> Permutation(list(e0)) == p0
True
```

`sage.combinat.shard_order.shard_poset(n)`

Return the shard intersection order on permutations of size n.

This is defined on the set of permutations. To every permutation, one can attach a pre-order, using the descending runs and their relative positions.

The shard intersection order is given by the implication (or refinement) order on the set of pre-orders defined from all permutations.

This can also be seen in a geometrical way. Every pre-order defines a cone in a vector space of dimension n. The shard poset is given by the inclusion of these cones.

See also

shard_preorder_graph()

EXAMPLES:

```
sage: P = posets.ShardPoset(4); P  # indirect doctest
Finite poset containing 24 elements
sage: P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
sage: P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
sage: P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
sage: P.is_self_dual()
False
```

```
>>> from sage.all import *
>>> P = posets.ShardPoset(Integer(4)); P  # indirect doctest
Finite poset containing 24 elements
>>> P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
>>> P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
>>> P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
>>> P.is_self_dual()
False
```

sage.combinat.shard_order.**shard_preorder_graph**(*runs*)

Return the preorder attached to a tuple of decreasing runs.

This is a directed graph, whose vertices correspond to the runs.

There is an edge from a run R to a run S if R is before S in the list of runs and the two intervals defined by the initial and final indices of R and S overlap.

This only depends on the initial and final indices of the runs. For this reason, this input can also be given in that shorten way.

INPUT:

- `runs` – either
  - a tuple of tuples, the runs of a permutation, or
  - a tuple of pairs (i, j), each one standing for a run from i to j

OUTPUT: a directed graph, with vertices labelled by integers

EXAMPLES:

```
sage: from sage.combinat.shard_order import shard_preorder_graph
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: def cut(lr):
....:     return tuple((r[0], r[-1]) for r in lr)
sage: shard_preorder_graph(cut(s.decreasing_runs()))
Digraph on 5 vertices
sage: s = Permutation([9,4,3,2,8,6,5,1,7])
sage: P = shard_preorder_graph(s.decreasing_runs())
sage: P.is_isomorphic(digraphs.TransitiveTournament(3))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.shard_order import shard_preorder_graph
>>> s = Permutation([Integer(2),Integer(8),Integer(3),Integer(9),Integer(6),
↪Integer(4),Integer(5),Integer(1),Integer(7)])
>>> def cut(lr):
...     return tuple((r[Integer(0)], r[-Integer(1)]) for r in lr)
>>> shard_preorder_graph(cut(s.decreasing_runs()))
Digraph on 5 vertices
>>> s = Permutation([Integer(9),Integer(4),Integer(3),Integer(2),Integer(8),
↪Integer(6),Integer(5),Integer(1),Integer(7)])
>>> P = shard_preorder_graph(s.decreasing_runs())
>>> P.is_isomorphic(digraphs.TransitiveTournament(Integer(3)))
True
```

5.1.306 Shifted primed tableaux

AUTHORS:

- Kirill Paramonov (2017-08-18): initial implementation
- Chaman Agrawal (2019-08-12): add parameter to allow primed diagonal entry

class sage.combinat.shifted_primed_tableau.**CrystalElementShiftedPrimedTableau**(*parent*, *T*, *skew=None*, *check=True*, *preprocessed=False*)

Bases: *ShiftedPrimedTableau*

Class for elements of `crystals.ShiftedPrimedTableau`.

e(*ind*)

Compute the action of the crystal operator e_i on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- `ind` – an element in the index set of the crystal

OUTPUT: primed tableau or `None`

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,'2p','3p'], [2,'3p',3,3],[3,4]])
sage: t.pp()
1  1  1  2' 3'
   2  3' 3  3
      3  4
sage: s = t.e(2)
sage: s.pp()
1  1  1  2' 3'
   2  2  3  3
      3  4
sage: t == s.f(2)
True
```

(continues on next page)

(continued from previous page)

```
sage: SPT = ShiftedPrimedTableaux([2,1])
sage: t = SPT([[2,'3p'],[3]])
sage: t.e(-1).pp()
1  3'
   3
sage: t.e(1).pp()
1  3'
   3
sage: t.e(2).pp()
2  2
   3

sage: r = SPT([[2, 2],[3]])
sage: r.e(-1).pp()
1  2
   3
sage: r.e(1).pp()
1  2
   3
sage: r.e(2) is None
True

sage: r = SPT([[1,'3p'],[3]])
sage: r.e(-1) is None
True
sage: r.e(1) is None
True
sage: r.e(2).pp()
1  2'
   3

f(*ind*)

Compute the action of the crystal operator f_i on a shifted primed tableau using cases from the papers [HPS2017] and [AO2018].

INPUT:

- `ind` – element in the index set of the crystal

OUTPUT: primed tableau or `None`

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([[1,1,1,1,'3p'],[2,2,2,'3p'],[3,3]])
sage: t.pp()
1  1  1  1  3'
   2  2  2  3'
      3  3
sage: s = t.f(2)
sage: s is None
True
```

(continues on next page)

(continued from previous page)

```
sage: t = SPT([[1,1,1,'2p','3p'],[2,2,3,3],[3,4]])

↪is None
True
```

is_highest_weight(*index_set=None*)

Return whether `self` is a highest weight element of the crystal.

An element is highest weight if it vanishes under all crystal operators e_i.

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([5,4,2])
sage: t = SPT([(1, 1, 1, 1, 1), (2, 2, 2, "3p"), (3, 3)])
sage: t.is_highest_weight()
True

sage: SPT = ShiftedPrimedTableaux([5,4])
sage: s = SPT([(1, 1, 1, 1, 1), (2, 2, "3p", 3)])
sage: s.is_highest_weight(index_set=[1])
True
```

```
>>> from sage.all import *
>>> SPT = ShiftedPrimedTableaux([Integer(5),Integer(4),Integer(2)])
>>> t = SPT([(Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)),␣
↪(Integer(2), Integer(2), Integer(2), "3p"), (Integer(3), Integer(3))])
>>> t.is_highest_weight()
True
```

(continues on next page)

(continued from previous page)

```
>>> SPT = ShiftedPrimedTableaux([Integer(5),Integer(4)])
>>> s = SPT([(Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)),
↪(Integer(2), Integer(2), "3p", Integer(3))])
>>> s.is_highest_weight(index_set=[Integer(1)])
True
```

reading_word()

Return the reading word of `self`.

The reading word of a shifted primed tableau is constructed as follows:

1. List all primed entries in the tableau, column by column, in decreasing order within each column, moving from the rightmost column to the left, and with all the primes removed (i.e. all entries are increased by half a unit).
2. Then list all unprimed entries, row by row, in increasing order within each row, moving from the bottommost row to the top.

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux([4,2])
sage: t = SPT([[1,'2p',2,2],[2,'3p']])
sage: t.reading_word()
[3, 2, 2, 1, 2, 2]
```

```
>>> from sage.all import *
>>> SPT = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> t = SPT([[Integer(1),'2p',Integer(2),Integer(2)],[Integer(2),'3p']])
>>> t.reading_word()
[3, 2, 2, 1, 2, 2]
```

weight()

Return the weight of `self`.

The weight of a shifted primed tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.weight()
(1, 4, 1)
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.weight()
(1, 4, 1)
```

class sage.combinat.shifted_primed_tableau.**PrimedEntry**(*entry=None*, *double=None*)

Bases: `SageObject`

The class of entries in shifted primed tableaux.

An entry in a shifted primed tableau is an element in the alphabet $\{1' < 1 < 2' < 2 < \cdots < n' < n\}$. The difference between two elements i and $i-1$ counts as a whole unit, whereas the difference between i and i' counts as half a unit. Internally, we represent an unprimed element x as $2x$ and the primed elements as the corresponding odd integer that respects the total order.

INPUT:

- `entry` – half integer or string of an integer possibly ending in `p` or `'`
- `double` – the doubled value

decrease_half()

Decrease `self` by half a unit.

decrease_one()

Decrease `self` by one unit.

increase_half()

Increase `self` by half a unit.

increase_one()

Increase `self` by one unit.

integer()

Return the corresponding integer i for primed entries of the form i or i'.

is_primed()

Check if `self` is a primed element.

is_unprimed()

Check if `self` is an unprimed element.

primed()

Prime `self` if it is an unprimed element.

unprimed()

Unprime `self` if it is a primed element.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableau**(*parent*, *T*, *skew=None*, *check=True*, *preprocessed=False*)

Bases: `ClonableArray`

A shifted primed tableau.

A primed tableau is a tableau of shifted shape in the alphabet $X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns;
2. a row cannot have two repeated primed elements, and a column cannot have two repeated non-primed elements;

Skew shape of the shifted primed tableaux is specified either with an optional argument `skew` or with `None` entries.

Primed entries in the main diagonal can be allowed with the optional boolean parameter `primed_diagonal`` (default: ``False`).

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: T([[1,"2'","3'",3],[2,"3'"]])[1]
(2, 3')
sage: t = ShiftedPrimedTableau([[1,"2p",2.5,3],[2,2.5]])
```

(continues on next page)

(continued from previous page)

```
sage: t[1]
(2, 3')
sage: ShiftedPrimedTableau([["2p",2,3],["2p","3p"],[2]], skew=[2,1])
[(None, None, 2', 2, 3), (None, 2', 3'), (2,)]
sage: ShiftedPrimedTableau([[None,None,"2p"],[None,"2p"]])
[(None, None, 2'), (None, 2')]
sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: T([[1,"2'","3'",3],["2'","3'"]])[1] # With primed diagonal entry
(2', 3')
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> T([[Integer(1),"2'","3'",Integer(3)],[Integer(2),"3'"]])[Integer(1)]
(2, 3')
>>> t = ShiftedPrimedTableau([[Integer(1),"2p",RealNumber('2.5'),Integer(3)],
→[Integer(2),RealNumber('2.5')]])
>>> t[Integer(1)]
(2, 3')
>>> ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p","3p"],[Integer(2)]],␣
→skew=[Integer(2),Integer(1)])
[(None, None, 2', 2, 3), (None, 2', 3'), (2,)]
>>> ShiftedPrimedTableau([[None,None,"2p"],[None,"2p"]])
[(None, None, 2'), (None, 2')]
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)], primed_diagonal=True)
>>> T([[Integer(1),"2'","3'",Integer(3)],["2'","3'"]])[Integer(1)] # With primed␣
→diagonal entry
(2', 3')
```

check()

Check that `self` is a valid primed tableau.

EXAMPLES:

```
sage: T = ShiftedPrimedTableaux([4,2])
sage: t = T([[1,'2p',2,2],[2,'3p']])
sage: t.check()
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"],[2]],skew=[2,1])
sage: s.check()
sage: t = T([['1p','2p',2,2],[2,'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '2p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2]

sage: T = ShiftedPrimedTableaux([4,2], primed_diagonal=True)
sage: t = T([['1p','2p',2,2],[2,'3p']])  # primed_diagonal allowed
sage: t.check()
sage: t = T([['1p','1p',2,2],[2,'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '1p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

```
>>> from sage.all import *
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)])
>>> t = T([[Integer(1),'2p',Integer(2),Integer(2)],[Integer(2),'3p']])
>>> t.check()
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"],
↪[Integer(2)]],skew=[Integer(2),Integer(1)])
>>> s.check()
>>> t = T([['1p','2p',Integer(2),Integer(2)],[Integer(2),'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '2p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2]

>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2)], primed_diagonal=True)
>>> t = T([['1p','2p',Integer(2),Integer(2)],[Integer(2),'3p']])   # primed_
↪diagonal allowed
>>> t.check()
>>> t = T([['1p','1p',Integer(2),Integer(2)],[Integer(2),'3p']])
Traceback (most recent call last):
...
ValueError: [['1p', '1p', 2, 2], [2, '3p']] is not an element of
 Shifted Primed Tableaux of shape [4, 2] and maximum entry 6
```

is_standard()

Return `True` if the entries of `self` are in bijection with positive primed integers $1', 1, 2', \ldots, n$.

EXAMPLES:

```
sage: ShiftedPrimedTableau([["1'", 1, "2'"], [2, "3'"]],
....:                      primed_diagonal=True).is_standard()
True
sage: ShiftedPrimedTableau([["1'", 1, 2], ["2'", "3'"]],
....:                      primed_diagonal=True).is_standard()
True
sage: ShiftedPrimedTableau([["1'", 1, 1], ["2'", 2]],
....:                      primed_diagonal=True).is_standard()
False
sage: ShiftedPrimedTableau([[1, "2'"], [2]]).is_standard()
False
sage: s = ShiftedPrimedTableau([[None, None,"1p","2p",2],[None,"1"]])
sage: s.is_standard()
True
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableau([["1'", Integer(1), "2'"], [Integer(2), "3'"]],
...                      primed_diagonal=True).is_standard()
True
>>> ShiftedPrimedTableau([["1'", Integer(1), Integer(2)], ["2'", "3'"]],
...                      primed_diagonal=True).is_standard()
True
>>> ShiftedPrimedTableau([["1'", Integer(1), Integer(1)], ["2'", Integer(2)]],
...                      primed_diagonal=True).is_standard()
False
```

(continues on next page)

(continued from previous page)

```
>>> ShiftedPrimedTableau([[Integer(1), "2'"], [Integer(2)]]).is_standard()
False
>>> s = ShiftedPrimedTableau([[None, None,"1p","2p",Integer(2)],[None,"1"]])
>>> s.is_standard()
True
```

max_entry()

Return the minimum unprimed letter $x > y$ for all y in `self`.

EXAMPLES:

```
sage: Tab = ShiftedPrimedTableau([(1,1,'2p','3p'),(2,2)])
sage: Tab.max_entry()
3
```

```
>>> from sage.all import *
>>> Tab = ShiftedPrimedTableau([(Integer(1),Integer(1),'2p','3p'),(Integer(2),
↪Integer(2))])
>>> Tab.max_entry()
3
```

pp()

Pretty print `self`.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.pp()
1  2' 2  2
   2  3'
sage: t = ShiftedPrimedTableau([[10,'11p',11,11],[11,'12']])
sage: t.pp()
10  11' 11  11
    11  12
sage: s = ShiftedPrimedTableau([['2p',2,3],['2p']],skew=[2,1])
sage: s.pp()
 .  .  2' 2  3
    .  2'
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.pp()
1  2' 2  2
   2  3'
>>> t = ShiftedPrimedTableau([[Integer(10),'11p',Integer(11),Integer(11)],
↪[Integer(11),'12']])
>>> t.pp()
10  11' 11  11
    11  12
>>> s = ShiftedPrimedTableau([['2p',Integer(2),Integer(3)],['2p']],
↪skew=[Integer(2),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> s.pp()
 .  .  2' 2  3
    .  2'
```

restrict(*n*)

Return the restriction of the shifted tableau to all the numbers less than or equal to n.

Note: If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method *restriction_outer_shape()* is preferred. Similarly if only the skew shape is needed, use *restriction_shape()*.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.restrict(2).pp()
1  2' 2  2
   2

sage: t.restrict("2p").pp()
1  2'

sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]], skew=[2,1])
sage: s.restrict(2).pp()
.  .  2' 2
   .  2'
sage: s.restrict(1.5).pp()
.  .  2'
   .  2'
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.restrict(Integer(2)).pp()
1  2' 2  2
   2

>>> t.restrict("2p").pp()
1  2'

>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],␣
↪skew=[Integer(2),Integer(1)])
>>> s.restrict(Integer(2)).pp()
.  .  2' 2
   .  2'
>>> s.restrict(RealNumber('1.5')).pp()
.  .  2'
   .  2'
```

restriction_outer_shape(*n*)

Return the outer shape of the restriction of the shifted tableau `self` to n.

If T is a (skew) shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the outer shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]], skew=[2,1])
sage: s.pp()
.  .  2' 2  3
   .  2'
sage: s.restriction_outer_shape(2)
[4, 2]
sage: s.restriction_outer_shape("2p")
[3, 2]
```

```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],
↪skew=[Integer(2),Integer(1)])
>>> s.pp()
.  .  2' 2  3
   .  2'
>>> s.restriction_outer_shape(Integer(2))
[4, 2]
>>> s.restriction_outer_shape("2p")
[3, 2]
```

restriction_shape(*n*)

Return the skew shape of the restriction of the skew tableau `self` to `n`.

If T is a shifted tableau and n is a half-integer, then the restriction of T to n is defined as the (skew) shifted tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the skew shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]], skew=[2,1])
sage: s.pp()
 .  .  2' 2  3
    .  2'

sage: s.restriction_shape(2)
[4, 2] / [2, 1]
```

```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],
↪skew=[Integer(2),Integer(1)])
>>> s.pp()
 .  .  2' 2  3
    .  2'

>>> s.restriction_shape(Integer(2))
[4, 2] / [2, 1]
```

shape()

Return the shape of the underlying partition of `self`.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([[1,'2p',2,2],[2,'3p']])
sage: t.shape()
[4, 2]
sage: s = ShiftedPrimedTableau([["2p",2,3],["2p"]],skew=[2,1])
sage: s.shape()
[5, 2] / [2, 1]
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([[Integer(1),'2p',Integer(2),Integer(2)],
↪[Integer(2),'3p']])
>>> t.shape()
[4, 2]
>>> s = ShiftedPrimedTableau([["2p",Integer(2),Integer(3)],["2p"]],
↪skew=[Integer(2),Integer(1)])
>>> s.shape()
[5, 2] / [2, 1]
```

to_chain()

Return the chain of partitions corresponding to the (skew) shifted tableau `self`, interlaced by one of the colours `1` is the added cell is on the diagonal, `2` if an ordinary entry is added and `3` if a primed entry is added.

EXAMPLES:

```
sage: s = ShiftedPrimedTableau([(1, 2, 3.5, 5, 6.5), (3, 5.5)])
sage: s.pp()
 1  2  4' 5  7'
    3  6'

sage: s.to_chain()
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

sage: s = ShiftedPrimedTableau([(1, 3.5), (2.5,), (6,)], skew=[2,1])
sage: s.pp()
 .  .  1  4'
    .  3'
       6

sage: s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```

```
>>> from sage.all import *
>>> s = ShiftedPrimedTableau([(Integer(1), Integer(2), RealNumber('3.5'),␣
↪Integer(5), RealNumber('6.5')), (Integer(3), RealNumber('5.5'))])
>>> s.pp()
 1  2  4' 5  7'
    3  6'

>>> s.to_chain()
```

(continues on next page)

(continued from previous page)

```
[[], 1, [1], 2, [2], 1, [2, 1], 3, [3, 1], 2, [4, 1], 3, [4, 2], 3, [5, 2]]

>>> s = ShiftedPrimedTableau([(Integer(1), RealNumber('3.5')), (RealNumber('2.
↪5'),), (Integer(6),)], skew=[Integer(2),Integer(1)])
>>> s.pp()
 .  .  1  4'
    .  3'
       6

>>> s.to_chain()
[[2, 1], 2, [3, 1], 0, [3, 1], 3, [3, 2], 3, [4, 2], 0, [4, 2], 1, [4, 2, 1]]
```

weight()

Return the weight of `self`.

The weight of a shifted primed tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau.

EXAMPLES:

```
sage: t = ShiftedPrimedTableau([['2p',2,2],[2,'3p']], skew=[1])
sage: t.weight()
(0, 4, 1)
```

```
>>> from sage.all import *
>>> t = ShiftedPrimedTableau([['2p',Integer(2),Integer(2)],[Integer(2),'3p']],
↪ skew=[Integer(1)])
>>> t.weight()
(0, 4, 1)
```

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux**(*skew=None*, *primed_diagonal=False*)

Bases: `UniqueRepresentation`, `Parent`

Return the combinatorial class of shifted primed tableaux subject to the constraints given by the arguments.

A primed tableau is a tableau of shifted shape on the alphabet $X' = \{1' < 1 < 2' < 2 < \cdots < n' < n\}$ such that

1. the entries are weakly increasing along rows and columns
2. a row cannot have two repeated primed entries, and a column cannot have two repeated non-primed entries

INPUT:

Valid optional keywords:

- `shape` – the (outer skew) shape of tableaux
- `weight` – the weight of tableaux
- `max_entry` – the maximum entry of tableaux
- `skew` – the inner skew shape of tableaux
- `primed_diagonal` – allow primed entries in main diagonal of tableaux

The weight of a tableau is defined to be the vector with i-th component equal to the number of entries i and i' in the tableau. The sum of the coordinates in the weight vector must be equal to the number of entries in the partition.

The shape and skew must be strictly decreasing partitions. The primed_diagonal is a boolean (default: False).

EXAMPLES:

```
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2]); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[(1, 2, 2), (3, 3)],
 [(1, 2', 3'), (2, 3)],
 [(1, 2', 3'), (2, 3')],
 [(1, 2', 2), (3, 3)]]
sage: SPT = ShiftedPrimedTableaux(weight=(1,2,2), shape=[3,2],
....:                              primed_diagonal=True); SPT
Shifted Primed Tableaux of weight (1, 2, 2) and shape [3, 2]
sage: SPT.list()
[[(1, 2, 2), (3, 3)],
 [(1, 2, 2), (3', 3)],
 [(1, 2', 3'), (2, 3)],
 [(1, 2', 3'), (2, 3')],
 [(1, 2', 3'), (2', 3)],
 [(1, 2', 3'), (2', 3')],
 [(1, 2', 2), (3, 3)],

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_all**(*skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

The class of all shifted primed tableaux.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_shape**(*shape*, *max_entry=None*, *skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

Shifted primed tableaux of a fixed shape.

Shifted primed tableaux admit a type A_n classical crystal structure with highest weights corresponding to a given shape.

The list of module generators consists of all elements of the crystal with nonincreasing weight entries.

The crystal is constructed following operations described in [HPS2017] and [AO2018].

The optional `primed_diagonal` allows primed entries in the main diagonal of all the Shifted primed tableaux of a fixed shape. If the `max_entry` is `None` then `max_entry` is set to the total number of entries in the tableau if `primed_diagonal` is `True`.

EXAMPLES:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4).cardinality()
384
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4))
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4)).cardinality()
384
```

We compute some of the crystal structure:

```
sage: SPTC = crystals.ShiftedPrimedTableaux([3,2], 3)
sage: T = SPTC.module_generators[-1]
sage: T
[(1, 1, 2'), (2, 3')]
sage: T.f(2)
[(1, 1, 3'), (2, 3')]
sage: len(SPTC.module_generators)
7
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
24
```

```
>>> from sage.all import *
>>> SPTC = crystals.ShiftedPrimedTableaux([Integer(3),Integer(2)], Integer(3))
>>> T = SPTC.module_generators[-Integer(1)]
>>> T
[(1, 1, 2'), (2, 3')]
>>> T.f(Integer(2))
[(1, 1, 3'), (2, 3')]
>>> len(SPTC.module_generators)
7
>>> SPTC[Integer(0)]
[(1, 1, 1), (2, 2)]
>>> SPTC.cardinality()
24
```

We compare this implementation with the $q(n)$-crystal on (tensor products) of letters:

```
sage: tableau_crystal = crystals.ShiftedPrimedTableaux([4,1], 3)
sage: tableau_digraph = tableau_crystal.digraph()
sage: c = crystals.Letters(['Q', 3])
sage: tensor_crystal = tensor([c]*5)
sage: u = tensor_crystal(c(1), c(1), c(1), c(2), c(1))
sage: subcrystal = tensor_crystal.subcrystal(generators=[u],
....:                                        index_set=[1,2,-1])
sage: tensor_digraph = subcrystal.digraph()
```

(continues on next page)

(continued from previous page)

```
sage: tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```

```
>>> from sage.all import *
>>> tableau_crystal = crystals.ShiftedPrimedTableaux([Integer(4),Integer(1)],␣
↪Integer(3))
>>> tableau_digraph = tableau_crystal.digraph()
>>> c = crystals.Letters(['Q', Integer(3)])
>>> tensor_crystal = tensor([c]*Integer(5))
>>> u = tensor_crystal(c(Integer(1)), c(Integer(1)), c(Integer(1)), c(Integer(2)),
↪ c(Integer(1)))
>>> subcrystal = tensor_crystal.subcrystal(generators=[u],
...                                        index_set=[Integer(1),Integer(2),-
↪Integer(1)])
>>> tensor_digraph = subcrystal.digraph()
>>> tensor_digraph.is_isomorphic(tableau_digraph, edge_labels=True)
True
```

If we allow primed entries in the main diagonal:

```
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
....:                       primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
sage: ShiftedPrimedTableaux([4,3,1], max_entry=4,
....:                      primed_diagonal=True).cardinality()
3072
sage: SPTC = ShiftedPrimedTableaux([3,2], max_entry=3,
....:                              primed_diagonal=True)
sage: T = SPTC[-1]
sage: T
[(1', 2', 2), (3', 3)]
sage: SPTC[0]
[(1, 1, 1), (2, 2)]
sage: SPTC.cardinality()
96
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4),
...                       primed_diagonal=True)
Shifted Primed Tableaux of shape [4, 3, 1] and maximum entry 4
>>> ShiftedPrimedTableaux([Integer(4),Integer(3),Integer(1)], max_
↪entry=Integer(4),
...                      primed_diagonal=True).cardinality()
3072
>>> SPTC = ShiftedPrimedTableaux([Integer(3),Integer(2)], max_entry=Integer(3),
...                              primed_diagonal=True)
>>> T = SPTC[-Integer(1)]
>>> T
[(1', 2', 2), (3', 3)]
>>> SPTC[Integer(0)]
[(1, 1, 1), (2, 2)]
```

(continues on next page)

(continued from previous page)

```
>>> SPTC.cardinality()
96
```

module_generators()

Return the generators of `self` as a crystal.

shape()

Return the shape of the shifted tableaux `self`.

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_weight**(*weight*, *skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

Shifted primed tableaux of fixed weight.

EXAMPLES:

```
sage: ShiftedPrimedTableaux(weight=(2,3,1))
Shifted Primed Tableaux of weight (2, 3, 1)
sage: ShiftedPrimedTableaux(weight=(2,3,1)).cardinality()
17
sage: SPT = ShiftedPrimedTableaux(weight=(2,3,1), primed_diagonal=True)
sage: SPT.cardinality()
64
sage: T = ShiftedPrimedTableaux(weight=(3,2), primed_diagonal=True)
sage: T[:5]
[[(1, 1, 1, 2, 2)],
 [(1, 1, 1, 2', 2)],
 [(1', 1, 1, 2, 2)],
 [(1', 1, 1, 2', 2)],
 [(1, 1, 1, 2), (2,)]]
sage: T.cardinality()
16
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1)))
Shifted Primed Tableaux of weight (2, 3, 1)
>>> ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1))).cardinality()
17
>>> SPT = ShiftedPrimedTableaux(weight=(Integer(2),Integer(3),Integer(1)), primed_
↪diagonal=True)
>>> SPT.cardinality()
64
>>> T = ShiftedPrimedTableaux(weight=(Integer(3),Integer(2)), primed_
↪diagonal=True)
>>> T[:Integer(5)]
[[(1, 1, 1, 2, 2)],
 [(1, 1, 1, 2', 2)],
 [(1', 1, 1, 2, 2)],
 [(1', 1, 1, 2', 2)],
 [(1, 1, 1, 2), (2,)]]
>>> T.cardinality()
16
```

class sage.combinat.shifted_primed_tableau.**ShiftedPrimedTableaux_weight_shape**(*weight*, *shape*, *skew=None*, *primed_diagonal=False*)

Bases: *ShiftedPrimedTableaux*

Shifted primed tableaux of the fixed weight and shape.

EXAMPLES:

```
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
sage: ShiftedPrimedTableaux([4,2,1], weight=(2,3,2)).cardinality()
4
sage: T = ShiftedPrimedTableaux([4,2,1], weight=(2,3,2),
....:                            primed_diagonal=True)
sage: T[:6]
[[(1, 1, 2, 2), (2, 3'), (3,)],
 [(1, 1, 2, 2), (2, 3'), (3',)],
 [(1, 1, 2, 2), (2', 3'), (3,)],
 [(1, 1, 2, 2), (2', 3'), (3',)],
 [(1, 1, 2', 3), (2, 2), (3,)],
 [(1, 1, 2', 3), (2, 2), (3',)]]
sage: T.cardinality()
32
```

```
>>> from sage.all import *
>>> ShiftedPrimedTableaux([Integer(4),Integer(2),Integer(1)], weight=(Integer(2),
↪Integer(3),Integer(2)))
Shifted Primed Tableaux of weight (2, 3, 2) and shape [4, 2, 1]
>>> ShiftedPrimedTableaux([Integer(4),Integer(2),Integer(1)], weight=(Integer(2),
↪Integer(3),Integer(2))).cardinality()
4
>>> T = ShiftedPrimedTableaux([Integer(4),Integer(2),Integer(1)],␣
↪weight=(Integer(2),Integer(3),Integer(2)),
...                           primed_diagonal=True)
>>> T[:Integer(6)]
[[(1, 1, 2, 2), (2, 3'), (3,)],
 [(1, 1, 2, 2), (2, 3'), (3',)],
 [(1, 1, 2, 2), (2', 3'), (3,)],
 [(1, 1, 2, 2), (2', 3'), (3',)],
 [(1, 1, 2', 3), (2, 2), (3,)],
 [(1, 1, 2', 3), (2, 2), (3',)]]
>>> T.cardinality()
32
```

5.1.307 Shuffle product of iterables

The shuffle product of two sequences of lengths m and n is a sum over the $\binom{m+n}{n}$ ways of interleaving the two sequences.

That could be defined inductively by:

$$(a_n)_{n\geqslant 0} \Cup (b_m)_{m\geqslant 0} = a_0 \cdot ((a_n)_{n\geqslant 1} \Cup (b_m)_{m\geqslant 0}) + b_0 \cdot ((a_n)_{n\geqslant 0} \Cup (b_m)_{m\geqslant 1})$$

with (a_n) and (b_m) two non-empty sequences and if one of them is empty then the product is equals to the other.

The shuffle product has been introduced by S. Eilenberg and S. Mac Lane in 1953 [EilLan53].

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct([1,2], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'],
 ['a', 1, 2, 'b', 'c'],
 [1, 'a', 2, 'b', 'c'],
 ['a', 'b', 1, 2, 'c'],
 ['a', 1, 'b', 2, 'c'],
 [1, 'a', 'b', 2, 'c'],
 ['a', 'b', 'c', 1, 2],
 ['a', 'b', 1, 'c', 2],
 ['a', 1, 'b', 'c', 2],
 [1, 'a', 'b', 'c', 2]]
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct
>>> list(ShuffleProduct([Integer(1),Integer(2)], ["a", "b", "c"]))
[[1, 2, 'a', 'b', 'c'],
 ['a', 1, 2, 'b', 'c'],
 [1, 'a', 2, 'b', 'c'],
 ['a', 'b', 1, 2, 'c'],
 ['a', 1, 'b', 2, 'c'],
 [1, 'a', 'b', 2, 'c'],
 ['a', 'b', 'c', 1, 2],
 ['a', 'b', 1, 'c', 2],
 ['a', 1, 'b', 'c', 2],
 [1, 'a', 'b', 'c', 2]]
```

```

cardinality()

The cardinality is defined by the sum of the cardinality of all shuffles. That means by a sum of binomials.

class sage.combinat.shuffle.**ShuffleProduct**(*l1*, *l2*, *element_constructor=None*)

Bases: *ShuffleProduct_abstract*

Shuffle product of two iterables.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct
sage: list(ShuffleProduct("abc", "de", element_constructor="".join))
['abcde',
 'adbce',
 'dabce',
 'abdce',
 'adebc',
 'daebc',
 'deabc',
 'adbec',
 'dabec',
 'abdec']
sage: list(ShuffleProduct("", "de", element_constructor="".join))
['de']
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct
>>> list(ShuffleProduct("abc", "de", element_constructor="".join))
```

(continues on next page)

(continued from previous page)

```
['abcde',
 'adbce',
 'dabce',
 'abdce',
 'adebc',
 'daebc',
 'deabc',
 'adbec',
 'dabec',
 'abdec']
>>> list(ShuffleProduct("", "de", element_constructor="".join))
['de']
```

cardinality()

Return the number of shuffles of l_1 and l_2, respectively of lengths m and n, which is $\binom{m+n}{n}$.

class sage.combinat.shuffle.**ShuffleProduct_abstract**(*l1*, *l2*, *element_constructor=None*)

Bases: Parent

Abstract base class for shuffle products.

class sage.combinat.shuffle.**ShuffleProduct_overlapping**(*w1*, *w2*, *element_constructor=None*, *add=<built-in function add>*)

Bases: *ShuffleProduct_abstract*

The overlapping shuffle product of the two words w1 and w2.

If u and v are two words whose letters belong to an additive monoid or to another kind of alphabet on which addition is well-defined, then the *overlapping shuffle product* of u and v is a certain multiset of words defined as follows: Let a and b be the lengths of u and v, respectively. Let A be the set $\{(0,1),(0,2),\cdots,(0,a)\}$, and let B be the set $\{(1,1),(1,2),\cdots,(1,b)\}$. Notice that the sets A and B are disjoint. We can make A and B into posets by setting $(k,i)\leq(k,j)$ for all $k\in\{0,1\}$ and $i\leq j$. Then, $A\cup B$ becomes a poset by disjoint union (we don't set $(0,i)\leq(1,i)$). Let p be the map from $A\cup B$ to the set of all letters which sends every $(0,i)$ to the i-th letter of u, and every $(1,j)$ to the j-th letter of v. For every nonnegative integer c and every surjective map $f:A\cup B\to\{1,2,\cdots,c\}$ for which both restrictions $f\mid_A$ and $f\mid_B$ are strictly increasing, let $w(f)$ be the length-c word such that for every $1\leq k\leq c$, the k-th letter of $w(f)$ equals $\sum_{j\in f^{-1}(k)}p(j)$ (this sum always has either one or two addends). The overlapping shuffle product of u and v is then the multiset of all $w(f)$ with c ranging over all nonnegative integers and f ranging over the surjective maps $f:A\cup B\to\{1,2,\cdots,c\}$ for which both restrictions $f\mid_A$ and $f\mid_B$ are strictly increasing.

If one restricts c to a particular fixed nonnegative integer, then the multiset is instead called the *overlapping shuffle product with precisely `a + b - c` overlaps*. This is nonempty only if $\max\{a,b\}\leq c\leq a+b$.

If $c=a+b$, then the overlapping shuffle product with precisely $a+b-c$ overlaps is plainly the shuffle product (ShuffleProduct_w1w2).

INPUT:

- w1, w2 – iterables
- element_constructor – (default: the parent of w1) the function used to construct the output
- add – (default: +) the addition function

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping
sage: w, u = [[2, 9], [9, 1]]
sage: S = ShuffleProduct_overlapping(w, u)
sage: sorted(S)
[[2, 9, 1, 9],
 [2, 9, 9, 1],
 [2, 9, 9, 1],
 [2, 9, 10],
 [2, 18, 1],
 [9, 1, 2, 9],
 [9, 2, 1, 9],
 [9, 2, 9, 1],
 [9, 2, 10],
 [9, 3, 9],
 [11, 1, 9],
 [11, 9, 1],
 [11, 10]]
sage: A = [{1,2}, {3,4}]
sage: B = [{2,3}, {4,5,6}]
sage: S = ShuffleProduct_overlapping(A, B, add=lambda X,Y: X.union(Y))
sage: list(S)
[[{1, 2}, {3, 4}, {2, 3}, {4, 5, 6}],
 [{1, 2}, {2, 3}, {3, 4}, {4, 5, 6}],
 [{1, 2}, {2, 3}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {3, 4}, {4, 5, 6}],
 [{2, 3}, {1, 2}, {4, 5, 6}, {3, 4}],
 [{2, 3}, {4, 5, 6}, {1, 2}, {3, 4}],
 [{1, 2, 3}, {3, 4}, {4, 5, 6}],
 [{1, 2}, {2, 3, 4}, {4, 5, 6}],
 [{1, 2, 3}, {4, 5, 6}, {3, 4}],
 [{1, 2}, {2, 3}, {3, 4, 5, 6}],
 [{2, 3}, {1, 2, 4, 5, 6}, {3, 4}],
 [{2, 3}, {1, 2}, {3, 4, 5, 6}],
 [{1, 2, 3}, {3, 4, 5, 6}]]
```

```
>>> from sage.all import *

```

class sage.combinat.shuffle.**ShuffleProduct_overlapping_r**(*w1*, *w2*, *r*, *element_constructor=None*, *add=<built-in function add>*)

Bases: *ShuffleProduct_abstract*

The overlapping shuffle product of the two words `w1` and `w2` with precisely `r` overlaps.

See *ShuffleProduct_overlapping* for a definition.

EXAMPLES:

```
sage: from sage.combinat.shuffle import ShuffleProduct_overlapping_r
sage: w, u = map(Words(range(20)), [[2, 9], [9, 1]])
sage: S = ShuffleProduct_overlapping_r(w,u,1)
sage: list(S)
[word: 11,9,1,
 word: 2,18,1,
 word: 11,1,9,
 word: 2,9,10,
 word: 939,
 word: 9,2,10]
```

```
>>> from sage.all import *
>>> from sage.combinat.shuffle import ShuffleProduct_overlapping_r
>>> w, u = map(Words(range(Integer(20))), [[Integer(2), Integer(9)], [Integer(9),
↪Integer(1)]])
>>> S = ShuffleProduct_overlapping_r(w,u,Integer(1))
>>> list(S)
[word: 11,9,1,
 word: 2,18,1,
 word: 11,1,9,
 word: 2,9,10,
 word: 939,
 word: 9,2,10]
```

5.1.308 Sidon sets and their generalizations, Sidon g-sets

AUTHORS:

- Martin Raum (07-25-2011)

`sage.combinat.sidon_sets.`**`sidon_sets`**`(N, g=1)`

Return the set of all Sidon-g sets that have elements less than or equal to N.

A Sidon-g set is a set of positive integers $A \subset [1, N]$ such that any integer M can be obtain at most g times as sums of unordered pairs of elements of A (the two elements are not necessary distinct):

$$\#\{(a_i, a_j) | a_i, a_j \in A, a_i + a_j = M, a_i \leq a_j\} \leq g$$

INPUT:

- `N` – positive integer
- `g` – positive integer (default: 1)

OUTPUT: a Sage set with categories whose element are also set of integers

EXAMPLES:

```
sage: S = sidon_sets(3, 2)
sage: sorted(S, key=str)
[{1, 2, 3}, {1, 2}, {1, 3}, {1}, {2, 3}, {2}, {3}, {}]
sage: S.cardinality()
8
sage: S.category()
Category of finite enumerated sets
sage: sid = S.an_element()
sage: sid
{2}
sage: sid.category()
Category of finite enumerated sets
```

```
>>> from sage.all import *
>>> S = sidon_sets(Integer(3), Integer(2))
>>> sorted(S, key=str)
[{1, 2, 3}, {1, 2}, {1, 3}, {1}, {2, 3}, {2}, {3}, {}]
>>> S.cardinality()
8
>>> S.category()
Category of finite enumerated sets
>>> sid = S.an_element()
>>> sid
{2}
>>> sid.category()
Category of finite enumerated sets
```

`sage.combinat.sidon_sets.`**`sidon_sets_rec`**`(g=1)`

Return the set of all Sidon-g sets that have elements less than or equal to N without checking the arguments. This internal function should not be call directly by user.

5.1.309 Similarity class types of matrices with entries in a finite field

The notion of a matrix conjugacy class type was introduced by J. A. Green in [Green55], in the context of computing the irreducible characters of finite general linear groups. The class types are equivalence classes of similarity classes of square matrices with entries in a finite field which, roughly speaking, have the same qualitative properties.

For example, all similarity classes of the same class type have centralizers of the same cardinality and the same degrees of elementary divisors. Qualitative properties of similarity classes such as semisimplicity and regularity descend to class types.

The most important feature of similarity class types is that, for any n, the number of similarity class types of $n \times n$ matrices is independent of q. This makes it possible to perform many combinatorial calculations treating q as a formal variable.

In order to define similarity class types, recall that similarity classes of $n \times n$ matrices with entries in $\mathbf{F}_q$ correspond to functions

$$c : \mathrm{Irr}\mathbf{F}_{q[t]} \to \Lambda$$

such that

$$\sum_{f \in \mathrm{Irr}\mathbf{F}_{q[t]}} |c(f)| \deg f = n,$$

where we denote the set of irreducible monic polynomials in $\mathbf{F}_{q[t]}$ by $\mathrm{Irr}\mathbf{F}_{q[t]}$, the set of all partitions by Λ, and the size of $\lambda \in \Lambda$ by $|\lambda|$.

Similarity classes indexed by functions c_1 and c_2 as above are said to be of the same type if there exists a degree-preserving self-bijection σ of $\mathrm{Irr}\mathbf{F}_{q[t]}$ such that $c_2 = c_1 \circ \sigma$. Thus, the type of c remembers only the degrees of the polynomials (and not the polynomials themselves) for which c takes a certain value λ. Replacing each irreducible polynomial of degree d for which c takes a non-trivial value λ by the pair (d, λ), we obtain a multiset of such pairs. Clearly, c_1 and c_2 have the same type if and only if these multisets are equal. Thus a similarity class type may be viewed as a multiset of pairs of the form (d, λ).

For 2×2 matrices there are four types:

```
sage: for tau in SimilarityClassTypes(2):
....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

```
>>> from sage.all import *
>>> for tau in SimilarityClassTypes(Integer(2)):
...     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

These four types correspond to the regular split semisimple matrices, the non-semisimple matrices, the central matrices and the irreducible matrices respectively.

For any matrix A in a given similarity class type, it is possible to calculate the number elements in the similarity class of A, the dimension of the algebra of matrices in $M_n(A)$ that commute with A, and the cardinality of the subgroup of $GL_n(\mathbf{F}_q)$ that commute with A. For each similarity class type, it is also possible to compute the number of classes of that type (and hence, the total number of matrices of that type). All these calculations treat the cardinality q of the finite field as a formal variable:

```
sage: M = SimilarityClassType([[1, [1]], [1, [1]]])
sage: M.class_card()
q^2 + q
sage: M.centralizer_algebra_dim()
2
sage: M.centralizer_group_card()
q^2 - 2*q + 1
sage: M.number_of_classes()
1/2*q^2 - 1/2*q
sage: M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

```
>>> from sage.all import *
>>> M = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1), [Integer(1)]]])
>>> M.class_card()
q^2 + q
>>> M.centralizer_algebra_dim()
2
>>> M.centralizer_group_card()
q^2 - 2*q + 1
>>> M.number_of_classes()
1/2*q^2 - 1/2*q
>>> M.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

We now describe two applications of similarity class types.

We say that an $n \times n$ matrix has rational canonical form type λ for some partition λ of n if the diagonal blocks in the rational canonical form have sizes given by the parts of λ. Thus the matrices with rational canonical type (n) are the regular ones, while the matrices with rational canonical type (1^n) are the central ones.

Using similarity class types, it becomes easy to get a formula for the number of matrices with a given rational canonical type:

```
sage: def matrices_with_rcf(la):
....:     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.
↪rcf()==la, SimilarityClassTypes(la.size()))])
sage: matrices_with_rcf(Partition([2,1]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

```
>>> from sage.all import *
>>> def matrices_with_rcf(la):
...     return sum([tau.number_of_matrices() for tau in filter(lambda tau:tau.
↪rcf()==la, SimilarityClassTypes(la.size()))])
>>> matrices_with_rcf(Partition([Integer(2),Integer(1)]))
q^6 + q^5 + q^4 - q^3 - q^2 - q
```

Similarity class types can also be used to calculate the number of simultaneous similarity classes of k-tuples of $n \times n$ matrices with entries in $\mathbf{F}_q$ by using Burnside's lemma:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_group,␣
↪centralizer_algebra_dim
sage: q = ZZ['q'].gen()
```

(continues on next page)

(continued from previous page)

```
sage: def simultaneous_similarity_classes(n, k):
....:     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_
↪dim(la)), invertible = True)/order_of_general_linear_group(n)
sage: simultaneous_similarity_classes(3, 2)
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import order_of_general_linear_group,␣
↪centralizer_algebra_dim
>>> q = ZZ['q'].gen()
>>> def simultaneous_similarity_classes(n, k):
...     return SimilarityClassTypes(n).sum(lambda la: q**(k*centralizer_algebra_
↪dim(la)), invertible = True)/order_of_general_linear_group(n)
>>> simultaneous_similarity_classes(Integer(3), Integer(2))
q^10 + q^8 + 2*q^7 + 2*q^6 + 2*q^5 + q^4
```

Similarity class types can be used to compute the coefficients of generating functions coming from the cycle index type techniques of Kung and Stong (see Morrison [Morrison06]).

They can also be used to compute the number of invariant subspaces for a matrix over a finite field of any given dimension. For this we use the elegant recursive formula of Ramaré [R17] (see also [PR22]).

Along with the results of [PSS13], similarity class types can be used to calculate the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two with residue field of cardinality q with centralizer of any given cardinality up to $n = 4$. Among these, the classes which are selftranspose can also be counted:

```
sage: from sage.combinat.similarity_class_type import matrix_centralizer_
↪cardinalities_length_two
sage: list(matrix_centralizer_cardinalities_length_two(3))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
(q^6 - 2*q^5 + q^4, q^5 - q^4),
(q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
(q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
(q^6 - q^5, q^4),
(q^10 - 2*q^9 + q^8, q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^8 - q^7, q^3 + q^2),
(q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
(q^12 - 2*q^11 + q^10, q^3 - q^2),
(q^14 - 2*q^13 + 2*q^11 - q^10, q^3 - q^2),
(q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
(q^12 - q^11, q^2),
(q^14 - 2*q^13 + q^12, q^2),
(q^18 - q^17 - q^16 + q^14 + q^13 - q^12, q^2),
(q^12 - q^9, 1/3*q^4 - 1/3*q^2),
(q^6 - q^3, 1/3*q^6 - 1/3*q^4)]
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import matrix_centralizer_cardinalities_
↪length_two
```

(continues on next page)

(continued from previous page)

```
>>> list(matrix_centralizer_cardinalities_length_two(Integer(3)))
[(q^6 - 3*q^5 + 3*q^4 - q^3, 1/6*q^6 - 1/2*q^5 + 1/3*q^4),
(q^6 - 2*q^5 + q^4, q^5 - q^4),
(q^8 - 3*q^7 + 3*q^6 - q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^10 - 2*q^9 + 2*q^7 - q^6, q^4 - q^3),
(q^8 - q^7 - q^6 + q^5, 1/2*q^5 - q^4 + 1/2*q^3),
(q^6 - q^5 - q^4 + q^3, 1/2*q^6 - 1/2*q^5),
(q^6 - q^5, q^4),
(q^10 - 2*q^9 + q^8, q^3),
(q^8 - 2*q^7 + q^6, q^4 - q^3),
(q^8 - q^7, q^3 + q^2),
(q^12 - 3*q^11 + 3*q^10 - q^9, 1/6*q^4 - 1/2*q^3 + 1/3*q^2),
(q^12 - 2*q^11 + q^10, q^3 - q^2),
(q^14 - 2*q^13 + 2*q^11 - q^10, q^3 - q^2),
(q^12 - q^11 - q^10 + q^9, 1/2*q^4 - 1/2*q^3),
(q^12 - q^11, q^2),
(q^14 - 2*q^13 + q^12, q^2),
(q^18 - q^17 - q^16 + q^14 + q^13 - q^12, q^2),
(q^12 - q^9, 1/3*q^4 - 1/3*q^2),
(q^6 - q^3, 1/3*q^6 - 1/3*q^4)]
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassType**(*parent*, *deg*, *par*)

Bases: `Element`

A primary similarity class type is a pair consisting of a partition and a positive integer.

For a partition λ and a positive integer d, the primary similarity class type (d, λ) represents similarity classes of square matrices of order $|\lambda| \cdot d$ with entries in a finite field of order q which correspond to the $\mathbf{F}_{q[t]}$-module

$$\frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_1}} \oplus \frac{\mathbf{F}_{q[t]}}{p(t)^{\lambda_2}} \oplus \cdots$$

for some irreducible polynomial $p(t)$ of degree d.

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

For a partition (d, λ) this dimension is given by $d(\lambda_1 + 3\lambda_2 + 5\lambda_3 + \cdots)$.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.centralizer_algebra_dim()
28
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
↪Integer(1)])
>>> PT.centralizer_algebra_dim()
28
```

centralizer_group_card(*q=None*)

Return the cardinality of the centralizer group of a matrix of type `self` in a field of order `q`.

INPUT:

- `q` – integer or an indeterminate

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(1, [])
sage: PT.centralizer_group_card()
1
sage: PT = PrimarySimilarityClassType(2, [1, 1])
sage: PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(1), [])
>>> PT.centralizer_group_card()
1
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(1), Integer(1)])
>>> PT.centralizer_group_card()
q^8 - q^6 - q^4 + q^2
```

degree()

Return degree of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.degree()
2
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
↪Integer(1)])
>>> PT.degree()
2
```

invariant_subspace_generating_function(*q=None*, *t=None*)

Return the invariant subspace generating function of `self`.

INPUT:

- `q` – (optional) an integer or an inderminate
- `t` – (optional) an indeterminate

EXAMPLES:

```
sage: PrimarySimilarityClassType(1, [2, 2]).invariant_subspace_generating_
→function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

```
>>> from sage.all import *
>>> PrimarySimilarityClassType(Integer(1), [Integer(2), Integer(2)]).
→invariant_subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

partition()

Return partition corresponding to `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.partition()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
→Integer(1)])
>>> PT.partition()
[3, 2, 1]
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 2, 1])
sage: PT.size()
12
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(2),␣
→Integer(1)])
>>> PT.size()
12
```

statistic(*func*, *q=None*)

Return $n_\lambda(q^d)$ where n_λ is the value returned by `func` upon input λ, if `self` is (d, λ).

EXAMPLES:

```
sage: PT = PrimarySimilarityClassType(2, [3, 1])
sage: q = ZZ['q'].gen()
sage: PT.statistic(lambda la:q**la.size(), q = q)
q^8
```

```
>>> from sage.all import *
>>> PT = PrimarySimilarityClassType(Integer(2), [Integer(3), Integer(1)])
>>> q = ZZ['q'].gen()
```

(continues on next page)

(continued from previous page)

```
>>> PT.statistic(lambda la:q**la.size(), q = q)
q^8
```

class sage.combinat.similarity_class_type.**PrimarySimilarityClassTypes**(*n*, *min*)

Bases: UniqueRepresentation, Parent

All primary similarity class types of size n whose degree is greater than that of min or whose degree is that of min and whose partition is less than of min in lexicographic order.

A primary similarity class type of size n is a pair (λ, d) consisting of a partition λ and a positive integer d such that $|\lambda|d = n$.

INPUT:

- n – positive integer
- min – a primary matrix type of size n

EXAMPLES:

If min is not specified, then the class of all primary similarity class types of size n is created:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: for PT in PTC:
....:     print(PT)
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

```
>>> from sage.all import *
>>> PTC = PrimarySimilarityClassTypes(Integer(2))
>>> for PT in PTC:
...     print(PT)
[1, [2]]
[1, [1, 1]]
[2, [1]]
```

If min is specified, then the class consists of only those primary similarity class types whose degree is greater than that of min or whose degree is that of min and whose partition is less than of min in lexicographic order:

```
sage: PTC = PrimarySimilarityClassTypes(2, min = PrimarySimilarityClassType(1, [1,
↪ 1]))
sage: for PT in PTC:
....:     print(PT)
[1, [1, 1]]
[2, [1]]
```

```
>>> from sage.all import *
>>> PTC = PrimarySimilarityClassTypes(Integer(2), min =␣
↪PrimarySimilarityClassType(Integer(1), [Integer(1), Integer(1)]))
>>> for PT in PTC:
...     print(PT)
[1, [1, 1]]
[2, [1]]
```

Element

alias of *PrimarySimilarityClassType*

size()

Return size of elements of `self`.

The size of a primary similarity class type (d, λ) is $d|\lambda|$.

EXAMPLES:

```
sage: PTC = PrimarySimilarityClassTypes(2)
sage: PTC.size()
2
```

```
>>> from sage.all import *
>>> PTC = PrimarySimilarityClassTypes(Integer(2))
>>> PTC.size()
2
```

class sage.combinat.similarity_class_type.**SimilarityClassType**(*parent*, *tau*)

Bases: *CombinatorialElement*

A similarity class type.

A matrix type is a multiset of primary similarity class types.

INPUT:

- `tau` – list of primary similarity class types or a square matrix over a finite field

EXAMPLES:

```
sage: tau1 = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]

sage: SimilarityClassType(Matrix(GF(2), [[1,1],[0,1]]))
[[1, [2]]]
```

```
>>> from sage.all import *
>>> tau1 = SimilarityClassType([[Integer(3), [Integer(3), Integer(2),␣
↪Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]]); tau1
[[2, [2, 1]], [3, [3, 2, 1]]]

>>> SimilarityClassType(Matrix(GF(Integer(2)), [[Integer(1),Integer(1)],
↪[Integer(0),Integer(1)]]))
[[1, [2]]]
```

as_partition_dictionary()

Return a dictionary whose keys are the partitions of types occurring in `self` and the value at the key λ is the partition formed by sorting the degrees of primary types with partition λ.

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.as_partition_dictionary()
{[1]: [1, 1]}
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),
↪[Integer(1)]]])
>>> tau.as_partition_dictionary()
{[1]: [1, 1]}
```

centralizer_algebra_dim()

Return the dimension of the algebra of matrices which commute with a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_algebra_dim()
2
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),
↪[Integer(1)]]])
>>> tau.centralizer_algebra_dim()
2
```

centralizer_group_card(*q=None*)

Return the cardinality of the group of matrices in $GL_n(\mathbf{F}_q)$ which commute with a matrix of type `self`.

INPUT:

- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.centralizer_group_card()
q^2 - 2*q + 1
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),
↪[Integer(1)]]])
>>> tau.centralizer_group_card()
q^2 - 2*q + 1
```

class_card(*q=None*)

Return the number of matrices in each similarity class of type `self`.

INPUT:

- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1, 1, 1, 1]]])
sage: tau.class_card()
1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.class_card()
q^2 + q
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1), Integer(1),␣
↪Integer(1), Integer(1)]]])
>>> tau.class_card()
1
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.class_card()
q^2 + q
```

invariant_subspace_generating_function(*q=None*, *t=None*)

Return the invariant subspace generating function of `self`.

The invariant subspace generating function is the function is the polynomial

$$\sum_{j\geq 0} a_j(q)t^j,$$

where $a_j(q)$ denotes the number of j-dimensional invariant subspaces of dimensiona j for any matrix with the similarity class type `self` with entries in a field of order q.

EXAMPLES:

```
sage: SimilarityClassType([[1, [2, 2]]]).invariant_subspace_generating_
↪function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
sage: A = Matrix(GF(2),[(0, 1, 0, 0), (0, 1, 1, 1), (1, 0, 1, 0), (1, 1, 0,␣
↪0)])
sage: SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

```
>>> from sage.all import *
>>> SimilarityClassType([[Integer(1), [Integer(2), Integer(2)]]]).invariant_
↪subspace_generating_function()
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
>>> A = Matrix(GF(Integer(2)),[(Integer(0), Integer(1), Integer(0),␣
↪Integer(0)), (Integer(0), Integer(1), Integer(1), Integer(1)), (Integer(1),␣
↪Integer(0), Integer(1), Integer(0)), (Integer(1), Integer(1), Integer(0),␣
↪Integer(0))])
>>> SimilarityClassType(A).invariant_subspace_generating_function()
t^4 + 1
```

is_regular()

Return `True` if every primary type in `self` has partition with one part.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1]], [1, [3]]])
sage: tau.is_regular()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [3]]])
sage: tau.is_regular()
False
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1)]], [Integer(1),␣
↪[Integer(3)]]])
>>> tau.is_regular()
True
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]],␣
↪[Integer(1), [Integer(3)]]])
>>> tau.is_regular()
False
```

is_semisimple()

Return True if every primary similarity class type in self has all parts equal to 1.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [1]]])
sage: tau.is_semisimple()
True
sage: tau = SimilarityClassType([[2, [1, 1]], [1, [2]]])
sage: tau.is_semisimple()
False
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]],␣
↪[Integer(1), [Integer(1)]]])
>>> tau.is_semisimple()
True
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1)]],␣
↪[Integer(1), [Integer(2)]]])
>>> tau.is_semisimple()
False
```

number_of_classes(*invertible=False*, *q=None*)

Return the number of similarity classes of matrices of type self.

INPUT:

- invertible – boolean; return number of invertible classes if set to True
- q – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_classes()
1/2*q^2 - 1/2*q
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.number_of_classes()
1/2*q^2 - 1/2*q
```

number_of_matrices(*invertible=False*, *q=None*)

Return the number of matrices of type self.

INPUT:

- `invertible` – a boolean; return the number of invertible matrices if set

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]]])
sage: tau.number_of_matrices()
q
sage: tau.number_of_matrices(invertible = True)
q - 1
sage: tau = SimilarityClassType([[1, [1]], [1, [1]]])
sage: tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]]])
>>> tau.number_of_matrices()
q
>>> tau.number_of_matrices(invertible = True)
q - 1
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(1)]]])
>>> tau.number_of_matrices()
1/2*q^4 - 1/2*q^2
```

rcf()

Return the partition corresponding to the rational canonical form of a matrix of type `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[2, [1, 1, 1]], [1, [3, 2]]])
sage: tau.rcf()
[5, 4, 2]
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(2), [Integer(1), Integer(1),␣
↪Integer(1)]], [Integer(1), [Integer(3), Integer(2)]]])
>>> tau.rcf()
[5, 4, 2]
```

size()

Return the sum of the sizes of the primary parts of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.size()
24
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(3), [Integer(3), Integer(2),␣
↪Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]])
>>> tau.size()
24
```

statistic(*func*, *q=None*)

Return.

$$\prod_{(d,\lambda)\in\tau} n_\lambda(q^d)$$

where $n_\lambda(q)$ is the value returned by `func` on the input λ.

INPUT:

- `func` – a function that takes a partition to a polynomial in `q`
- `q` – integer or an indeterminate

EXAMPLES:

```
sage: tau = SimilarityClassType([[1, [1]], [1, [2, 1]], [2, [1, 1]]])
sage: from sage.combinat.similarity_class_type import fq
sage: tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
sage: q = ZZ['q'].gen()
sage: tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(1), [Integer(1)]], [Integer(1),␣
↪[Integer(2), Integer(1)]], [Integer(2), [Integer(1), Integer(1)]]])
>>> from sage.combinat.similarity_class_type import fq
>>> tau.statistic(lambda la: prod([fq(m) for m in la.to_exp()]))
(q^9 - 3*q^8 + 2*q^7 + 2*q^6 - 4*q^5 + 4*q^4 - 2*q^3 - 2*q^2 + 3*q - 1)/q^9
>>> q = ZZ['q'].gen()
>>> tau.statistic(lambda la: q**la.size(), q = q)
q^8
```

class sage.combinat.similarity_class_type.**SimilarityClassTypes**(*n*, *min*)

Bases: `UniqueRepresentation`, `Parent`

Class of all similarity class types of size `n` with all primary matrix types greater than or equal to the primary matrix type `min`.

A similarity class type is a multiset of primary matrix types.

INPUT:

- `n` – nonnegative integer
- `min` – a primary similarity class type

EXAMPLES:

If `min` is not specified, then the class of all matrix types of size `n` is constructed:

```
sage: M = SimilarityClassTypes(2)
sage: for tau in M:
....:     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

```
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2))
>>> for tau in M:
...     print(tau)
[[1, [1]], [1, [1]]]
[[1, [2]]]
[[1, [1, 1]]]
[[2, [1]]]
```

If `min` is specified, then the class consists of only those similarity class types which are multisets of primary matrix types which either have size greater than that of `min`, or if they have size equal to that of `min`, then they occur after `min` in the iterator for `PrimarySimilarityClassTypes(n)`, where `n` is the size of `min`:

```
sage: M = SimilarityClassTypes(2, min = [1, [1, 1]])
sage: for tau in M:
....:     print(tau)
[[1, [1, 1]]]
[[2, [1]]]
```

```
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2), min = [Integer(1), [Integer(1),
→Integer(1)]])
>>> for tau in M:
...     print(tau)
[[1, [1, 1]]]
[[2, [1]]]
```

Element

alias of *SimilarityClassType*

size()

Return size of `self`.

EXAMPLES:

```
sage: tau = SimilarityClassType([[3, [3, 2, 1]], [2, [2, 1]]])
sage: tau.parent().size()
24
```

```
>>> from sage.all import *
>>> tau = SimilarityClassType([[Integer(3), [Integer(3), Integer(2),
→Integer(1)]], [Integer(2), [Integer(2), Integer(1)]]])
>>> tau.parent().size()
24
```

sum(*stat*, *sumover='matrices'*, *invertible=False*, *q=None*)

Return the sum of a local statistic over all types.

Given a set of functions $n_\lambda(q)$ (these could be polynomials or rational functions in q, for each similarity class type τ define

$$n_\tau(q) = \prod_{(d,\lambda)\in\tau} n_\lambda(q^d).$$

This function returns

$$\sum n_{\tau(g)}(q)$$

where $\tau(g)$ denotes the type of a matrix g, and the sum is over all $n \times n$ matrices if `sumover` is set to `'matrices'`, is over all $n \times n$ similarity classes if `sumover` is set to `'classes'`, and over all $n \times n$ types if `sumover` is set to `'types'`. If `invertible` is set to `True`, then the sum is only over invertible matrices or classes.

INPUT:

- `stat` – a function which takes partitions and returns a function of `q`
- `sumover` – can be one of the following:
  - `'matrices'`
  - `'classes'`
  - `'types'`
- `q` – integer or an indeterminate

OUTPUT: a function of `q`

EXAMPLES:

```
sage: M = SimilarityClassTypes(2)
sage: M.sum(lambda la:1)
q^4
sage: M.sum(lambda la:1, invertible = True)
q^4 - q^3 - q^2 + q
sage: M.sum(lambda la:1, sumover = "classes")
q^2 + q
sage: M.sum(lambda la:1, sumover = "classes", invertible = True)
q^2 - 1
```

```
>>> from sage.all import *
>>> M = SimilarityClassTypes(Integer(2))
>>> M.sum(lambda la:Integer(1))
q^4
>>> M.sum(lambda la:Integer(1), invertible = True)
q^4 - q^3 - q^2 + q
>>> M.sum(lambda la:Integer(1), sumover = "classes")
q^2 + q
>>> M.sum(lambda la:Integer(1), sumover = "classes", invertible = True)
q^2 - 1
```

Burside's lemma can be used to calculate the number of similarity classes of matrices:

```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim,
↪ order_of_general_linear_group
sage: q = ZZ['q'].gen()
sage: M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/
↪order_of_general_linear_group(2)
q^2 + q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_algebra_dim,␣
↪order_of_general_linear_group
>>> q = ZZ['q'].gen()
>>> M.sum(lambda la:q**centralizer_algebra_dim(la), invertible = True)/order_
↪of_general_linear_group(Integer(2))
q^2 + q
```

sage.combinat.similarity_class_type.**centralizer_algebra_dim**()

Return the dimension of the centralizer algebra in $M_n(\mathbf{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by `la`.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import centralizer_algebra_dim
sage: centralizer_algebra_dim(Partition([2, 1]))
5
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_algebra_dim
>>> centralizer_algebra_dim(Partition([Integer(2), Integer(1)]))
5
```

Note

If it is a list, `la` is expected to be sorted in decreasing order.

sage.combinat.similarity_class_type.**centralizer_group_cardinality**(*q=None*)

Return the cardinality of the centralizer group in $GL_n(\mathbf{F}_q)$ of a nilpotent matrix whose Jordan blocks are given by `la`.

INPUT:

- `lambda` – a partition
- `q` – an integer or an indeterminate

OUTPUT: a polynomial function of `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import centralizer_group_
↪cardinality
sage: q = ZZ['q'].gen()
sage: centralizer_group_cardinality(Partition([2, 1]))
q^5 - 2*q^4 + q^3
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import centralizer_group_cardinality
>>> q = ZZ['q'].gen()
>>> centralizer_group_cardinality(Partition([Integer(2), Integer(1)]))
q^5 - 2*q^4 + q^3
```

sage.combinat.similarity_class_type.**dictionary_from_generator**(*gen*)

Given a generator for a list of pairs (c, f), construct a dictionary whose keys are the distinct values for c and whose value at c is the sum of f over all pairs of the form (c', f) such that $c = c'$.

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import dictionary_from_generator
sage: dictionary_from_generator(((x // 2, x) for x in range(10)))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import dictionary_from_generator
>>> dictionary_from_generator(((x // Integer(2), x) for x in range(Integer(10))))
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

It also works with lists:

```
sage: dictionary_from_generator([(x // 2, x) for x in range(10)])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

```
>>> from sage.all import *
>>> dictionary_from_generator([(x // Integer(2), x) for x in range(Integer(10))])
{0: 1, 1: 5, 2: 9, 3: 13, 4: 17}
```

Note

Since the generator is first converted to a list, memory usage could be high.

sage.combinat.similarity_class_type.**ext_orbit_centralizers**(*input_data*, *q=None*, *selftranspose=False*)

Generate pairs consisting of centralizer cardinalities of orbits in $\mathrm{Ext}^1(M, M)$ for the action of $\mathrm{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$-module constructed from `input` and their frequencies.

INPUT:

- `input_data` – input for *input_parsing()*
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – boolean (default: `False`); stating if we only want selftranspose type

sage.combinat.similarity_class_type.**ext_orbits**(*input_data*, *q=None*, *selftranspose=False*)

Return the number of orbits in $\mathrm{Ext}^1(M, M)$ for the action of $\mathrm{Aut}(M, M)$, where M is the $\mathbf{F}_{q[t]}$-module constructed from `input_data`.

INPUT:

- `input_data` – input for *input_parsing()*
- `q` – (default: q) an integer or an indeterminate
- `selftranspose` – boolean (default: `False`); stating if we only want selftranspose type

sage.combinat.similarity_class_type.**fq**(*q=None*)

Return $(1 - q^{-1})(1 - q^{-2}) \cdots (1 - q^{-n})$.

INPUT:

- `n` – nonnegative integer
- `q` – integer or an indeterminate

OUTPUT: a rational function in `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import fq
sage: fq(0)
1
sage: fq(3)
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import fq
>>> fq(Integer(0))
1
>>> fq(Integer(3))
(q^6 - q^5 - q^4 + q^2 + q - 1)/q^6
```

`sage.combinat.similarity_class_type.`**`input_parsing`**(*data*)

Recognize and return the intended type of `input`.

`sage.combinat.similarity_class_type.`**`invariant_subspace_generating_function`**(*la*, *q=None*, *t=None*)

Return the invariant subspace generating function of a nilpotent matrix with Jordan block sizes given by `la`.

INPUT:

- `la` – a partition
- `q` – (optional) an integer or an inderminate
- `t` – (optional) an indeterminate

OUTPUT: a polynomial in `t` whose coefficients are polynomials in `q`

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import invariant_subspace_
↪generating_function
sage: invariant_subspace_generating_function([2,2])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import invariant_subspace_generating_
↪function
>>> invariant_subspace_generating_function([Integer(2),Integer(2)])
t^4 + (q + 1)*t^3 + (q^2 + q + 1)*t^2 + (q + 1)*t + 1
```

`sage.combinat.similarity_class_type.`**`matrix_centralizer_cardinalities`**(*n*, *q=None*, *invertible=False*)

Generate pairs consisting of centralizer cardinalities of matrices over a finite field and their frequencies.

sage.combinat.similarity_class_type.**matrix_centralizer_cardinalities_length_two**(*n*, *q=None*, *selftranspose=False*, *invertible=False*)

Generate pairs consisting of centralizer cardinalities of matrices over a principal ideal local ring of length two with residue field of order q and their frequencies.

INPUT:

- n – the order
- q – (default: q) an integer or an indeterminate
- selftranspose – boolean (default: False); stating if we only want selftranspose type
- invertible – boolean (default: False); stating if we only want invertible type

sage.combinat.similarity_class_type.**matrix_similarity_classes**(*n*, *q=None*, *invertible=False*)

Return the number of matrix similarity classes over a finite field of order q.

sage.combinat.similarity_class_type.**matrix_similarity_classes_length_two**(*n*, *q=None*, *selftranspose=False*, *invertible=False*)

Return the number of similarity classes of matrices of order n with entries in a principal ideal local ring of length two.

INPUT:

- n – the order
- q – (default: q) an integer or an indeterminate
- selftranspose – boolean (default: False); stating if we only want selftranspose type
- invertible – boolean (default: False); stating if we only want invertible type

EXAMPLES:

We can generate Table 6 of [PSS13]:

```
sage: from sage.combinat.similarity_class_type import matrix_similarity_classes_
↪length_two
sage: matrix_similarity_classes_length_two(2)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, invertible = True)
q^4 - q
sage: matrix_similarity_classes_length_two(3)
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
sage: matrix_similarity_classes_length_two(3, invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
sage: matrix_similarity_classes_length_two(4)
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
sage: matrix_similarity_classes_length_two(4, invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import matrix_similarity_classes_
```

(continues on next page)

(continued from previous page)

```
↪length_two
>>> matrix_similarity_classes_length_two(Integer(2))
q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(2), invertible = True)
q^4 - q
>>> matrix_similarity_classes_length_two(Integer(3))
q^6 + q^5 + 2*q^4 + q^3 + 2*q^2
>>> matrix_similarity_classes_length_two(Integer(3), invertible = true)
q^6 - q^3 + 2*q^2 - 2*q
>>> matrix_similarity_classes_length_two(Integer(4))
q^8 + q^7 + 3*q^6 + 3*q^5 + 5*q^4 + 3*q^3 + 3*q^2
>>> matrix_similarity_classes_length_two(Integer(4), invertible = True)
q^8 + q^6 - q^5 + 2*q^4 - 2*q^3 + 2*q^2 - 3*q
```

And also Table 7:

```
sage: matrix_similarity_classes_length_two(2, selftranspose = True)
q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(2, selftranspose = True, invertible =␣
↪True)
q^4 - q
sage: matrix_similarity_classes_length_two(3, selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3
sage: matrix_similarity_classes_length_two(3, selftranspose = True, invertible =␣
↪True)
q^6 - q^3
sage: matrix_similarity_classes_length_two(4, selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
sage: matrix_similarity_classes_length_two(4, selftranspose = True, invertible =␣
↪True)
q^8 + q^6 - q^5 - q
```

```
>>> from sage.all import *
>>> matrix_similarity_classes_length_two(Integer(2), selftranspose = True)
q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(2), selftranspose = True,␣
↪invertible = True)
q^4 - q
>>> matrix_similarity_classes_length_two(Integer(3), selftranspose = True)
q^6 + q^5 + 2*q^4 + q^3
>>> matrix_similarity_classes_length_two(Integer(3), selftranspose = True,␣
↪invertible = True)
q^6 - q^3
>>> matrix_similarity_classes_length_two(Integer(4), selftranspose = True)
q^8 + q^7 + 3*q^6 + 3*q^5 + 3*q^4 + q^3 + q^2
>>> matrix_similarity_classes_length_two(Integer(4), selftranspose = True,␣
↪invertible = True)
q^8 + q^6 - q^5 - q
```

sage.combinat.similarity_class_type.**order_of_general_linear_group**(*q=None*)

Return the cardinality of the group of $n \times n$ invertible matrices with entries in a field of order q.

INPUT:

- n – nonnegative integer
- q – integer or an indeterminate

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import order_of_general_linear_
↪group
sage: order_of_general_linear_group(0)
1
sage: order_of_general_linear_group(2)
q^4 - q^3 - q^2 + q
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import order_of_general_linear_group
>>> order_of_general_linear_group(Integer(0))
1
>>> order_of_general_linear_group(Integer(2))
q^4 - q^3 - q^2 + q
```

sage.combinat.similarity_class_type.**primitives**(*invertible=False*, *q=None*)

Return the number of similarity classes of simple matrices of order n with entries in a finite field of order q. This is the same as the number of irreducible polynomials of degree d.

If invertible is True, then only the number of similarity classes of invertible matrices is returned.

Note

All primitive classes are invertible unless n is 1.

INPUT:

- n – positive integer
- invertible – boolean; if set, only number of nonzero classes is returned
- q – integer or an indeterminate

OUTPUT: a rational function of the variable q

EXAMPLES:

```
sage: from sage.combinat.similarity_class_type import primitives
sage: primitives(1)
q
sage: primitives(1, invertible = True)
q - 1
sage: primitives(4)
1/4*q^4 - 1/4*q^2
sage: primitives(4, invertible = True)
1/4*q^4 - 1/4*q^2
```

```
>>> from sage.all import *
>>> from sage.combinat.similarity_class_type import primitives
>>> primitives(Integer(1))
q
```

(continues on next page)

(continued from previous page)

```
>>> primitives(Integer(1), invertible = True)
q - 1
>>> primitives(Integer(4))
1/4*q^4 - 1/4*q^2
>>> primitives(Integer(4), invertible = True)
1/4*q^4 - 1/4*q^2
```

5.1.310 sine-Gordon Y-system plotter

This class builds the triangulations associated to sine-Gordon and reduced sine-Gordon Y-systems as constructed in [NS].

AUTHORS:

- Salvatore Stella (2014-07-18): initial version

EXAMPLES:

A reduced sine-Gordon example with 3 generations:

```
sage: Y = SineGordonYsystem('A',(6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.plot()      #not tested
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3))); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
>>> Y.plot()      #not tested
```

The same integer tuple but for the non-reduced case:

```
sage: Y = SineGordonYsystem('D',(6,4,3)); Y
A sine-Gordon Y-system of type D with defining integer tuple (6, 4, 3)
sage: Y.plot()      #not tested
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('D',(Integer(6),Integer(4),Integer(3))); Y
A sine-Gordon Y-system of type D with defining integer tuple (6, 4, 3)
>>> Y.plot()      #not tested
```

Todo

The code for plotting is extremely slow.

REFERENCES:

class sage.combinat.sine_gordon.**SineGordonYsystem**(X, na)

Bases: SageObject

A class to model a (reduced) sine-Gordon Y-system.

Note that the generations, together with all integer tuples, in this implementation are numbered from 0 while in [NS] they are numbered from 1

INPUT:

- `X` – the type of the Y-system to construct (either 'A' or 'D')
- `na` – the tuple of positive integers defining the Y-system with `na[0] > 2`

See [NS]

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3)); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
sage: Y.intervals()
(((0, 0, 'R'),),
 ((0, 17, 'L'),
  (17, 34, 'L'),
...
  (104, 105, 'R'),
  (105, 0, 'R')))
sage: Y.triangulation()
((17, 89),
 (17, 72),
 (34, 72),
...
 (102, 105),
 (103, 105))
sage: Y.plot()      #not tested
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3))); Y
A sine-Gordon Y-system of type A with defining integer tuple (6, 4, 3)
>>> Y.intervals()
(((0, 0, 'R'),),
 ((0, 17, 'L'),
  (17, 34, 'L'),
...
  (104, 105, 'R'),
  (105, 0, 'R')))
>>> Y.triangulation()
((17, 89),
 (17, 72),
 (34, 72),
...
 (102, 105),
 (103, 105))
>>> Y.plot()      #not tested
```

F()

Return the number of generations in `self`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.F()
3
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.F()
3
```

intervals()

Return, divided by generation, the list of intervals used to construct the initial triangulation.

Each such interval is a triple `(p, q, X)` where `p` and `q` are the two extremal vertices of the interval and `X` is the type of the interval (one of 'L', 'R', 'NL', 'NR').

ALGORITHM:

The algorithm used here is the one described in section 5.1 of [NS]. The only difference is that we get rid of the special case of the first generation by treating the whole disk as a type 'R' interval.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.intervals()
(((0, 0, 'R'),),
 ((0, 17, 'L'),
  (17, 34, 'L'),
...
  (104, 105, 'R'),
  (105, 0, 'R')))
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.intervals()
(((0, 0, 'R'),),
 ((0, 17, 'L'),
  (17, 34, 'L'),
...
  (104, 105, 'R'),
  (105, 0, 'R')))
```

na()

Return the sequence of the integers n_a defining `self`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.na()
(6, 4, 3)
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.na()
(6, 4, 3)
```

pa()

Return the sequence of integers `p_a`, i.e. the total number of intervals of types 'NL' and 'NR' in the `(a+1)`-th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.pa()
(1, 6, 25)
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.pa()
(1, 6, 25)
```

plot(***kwds*)

Plot the initial triangulation associated to `self`.

INPUT:

- `radius` – the radius of the disk; by default the length of the circle is the number of vertices
- `points_color` – the color of the vertices; default 'black'
- `points_size` – the size of the vertices; default 7
- `triangulation_color` – the color of the arcs; default 'black'
- `triangulation_thickness` – the thickness of the arcs; default 0.5
- `shading_color` – the color of the shading used on neuter intervals; default 'lightgray'
- `reflections_color` – the color of the reflection axes; default 'blue'
- `reflections_thickness` – the thickness of the reflection axes; default 1

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.plot()                          # long time (2s)                        #␣
↪needs sage.plot
Graphics object consisting of 219 graphics primitives
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.plot()                          # long time (2s)                        #␣
↪needs sage.plot
Graphics object consisting of 219 graphics primitives
```

qa()

Return the sequence of integers `q_a`, i.e. the total number of intervals of types 'L' and 'R' in the `(a+1)`-th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.qa()
(6, 25, 81)
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.qa()
(6, 25, 81)
```

r()

Return the number of vertices in the polygon realizing self.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.r()
106
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.r()
106
```

rk()

Return the sequence of integers r^{(k)}, i.e. the width of an interval of type 'L' or 'R' in the k-th generation.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.rk()
(106, 17, 4)
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.rk()
(106, 17, 4)
```

triangulation()

Return the initial triangulation of the polygon realizing self as a tuple of pairs of vertices.

Warning

In type 'D' the returned triangulation does NOT contain the two radii.

ALGORITHM:

We implement the four cases described by Figure 14 in [NS].

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.triangulation()
((17, 89),
 (17, 72),
...
 (102, 105),
 (103, 105))
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.triangulation()
((17, 89),
```

(continues on next page)

(continued from previous page)

```
 (17, 72),
...
 (102, 105),
 (103, 105))
```

type()

Return the type of `self`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.type()
'A'
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.type()
'A'
```

vertices()

Return the vertices of the polygon realizing `self` as the ring of integers modulo `self.r()`.

EXAMPLES:

```
sage: Y = SineGordonYsystem('A',(6,4,3))
sage: Y.vertices()
Ring of integers modulo 106
```

```
>>> from sage.all import *
>>> Y = SineGordonYsystem('A',(Integer(6),Integer(4),Integer(3)))
>>> Y.vertices()
Ring of integers modulo 106
```

5.1.311 Six Vertex Model

class sage.combinat.six_vertex_model.**SixVertexConfiguration**

Bases: `ClonableArray`

A configuration in the six vertex model.

check()

Check if `self` is a valid 6 vertex configuration.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M[0].check()
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> M[Integer(0)].check()
```

energy(*epsilon*)

Return the energy of the configuration.

The energy of a configuration ν is defined as

$$E(\nu) = n_0\epsilon_0 + n_1\epsilon_1 + \cdots + n_5\epsilon_5$$

where n_i is the number of vertices of type i and ϵ_i is the i-th energy constant.

Note

We number our configurations as:

0. LR
1. LU
2. LD
3. UD
4. UR
5. RD

which differs from Wikipedia article Ice-type_model.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: nu = M[2]; nu
    ^    ^    ^
    |    |    |
--> # -> # <- # <--
    ^    |    ^
    |    V    |
--> # <- # -> # <--
    |    ^    |
    V    |    V
--> # -> # <- # <--
    |    |    |
    V    V    V
sage: nu.energy([1,2,1,2,1,2])
15
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> nu = M[Integer(2)]; nu
    ^    ^    ^
    |    |    |
--> # -> # <- # <--
    ^    |    ^
    |    V    |
--> # <- # -> # <--
    |    ^    |
    V    |    V
```

(continues on next page)

(continued from previous page)

```
--> # -> # <- # <--
    |    |    |
    V    V    V
>>> nu.energy([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1),
↪Integer(2)])
15
```

A KDP energy:

```
sage: nu.energy([1,1,0,1,0,1])
7
```

```
>>> from sage.all import *
>>> nu.energy([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
↪Integer(1)])
7
```

A Rys F energy:

```
sage: nu.energy([0,1,1,0,1,1])
4
```

```
>>> from sage.all import *
>>> nu.energy([Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),
↪Integer(1)])
4
```

The zero field assumption:

```
sage: nu.energy([1,2,3,1,3,2])
15
```

```
>>> from sage.all import *
>>> nu.energy([Integer(1),Integer(2),Integer(3),Integer(1),Integer(3),
↪Integer(2)])
15
```

plot(*color='sign'*)

Return a plot of `self`.

INPUT:

- `color` – can be any of the following:
  - `4` – use 4 colors: black, red, blue, and green with each corresponding to up, right, down, and left respectively
  - `2` – use 2 colors: red for horizontal, blue for vertical arrows
  - `'sign'` – use red for right and down arrows, blue for left and up arrows
  - a list of 4 colors for each direction
  - a function which takes a direction and a boolean corresponding to the sign

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: print(M[0].plot().description())                                  #␣
↪needs sage.plot
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), boundary_conditions='ice')
>>> print(M[Integer(0)].plot().description())                          ␣
↪     # needs sage.plot
Arrow from (-1.0,0.0) to (0.0,0.0)
Arrow from (-1.0,1.0) to (0.0,1.0)
Arrow from (0.0,0.0) to (0.0,-1.0)
Arrow from (0.0,0.0) to (1.0,0.0)
Arrow from (0.0,1.0) to (0.0,0.0)
Arrow from (0.0,1.0) to (0.0,2.0)
Arrow from (1.0,0.0) to (1.0,-1.0)
Arrow from (1.0,0.0) to (1.0,1.0)
Arrow from (1.0,1.0) to (0.0,1.0)
Arrow from (1.0,1.0) to (1.0,2.0)
Arrow from (2.0,0.0) to (1.0,0.0)
Arrow from (2.0,1.0) to (1.0,1.0)
```

to_signed_matrix()

Return the signed matrix of `self`.

The signed matrix corresponding to a six vertex configuration is given by 0 if there is a cross flow, a 1 if the outward arrows are vertical and -1 if the outward arrows are horizontal.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: [x.to_signed_matrix() for x in M]                                 #␣
↪needs sage.modules
[
[1 0 0]  [1 0 0]  [ 0  1  0]  [0 1 0]  [0 1 0]  [0 0 1]  [0 0 1]
[0 1 0]  [0 0 1]  [ 1 -1  1]  [1 0 0]  [0 0 1]  [1 0 0]  [0 1 0]
[0 0 1], [0 1 0], [ 0  1  0], [0 0 1], [1 0 0], [0 1 0], [1 0 0]
]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> [x.to_signed_matrix() for x in M]                                 #␣
```

class sage.combinat.six_vertex_model.**SixVertexModel**(*n*, *m*, *boundary_conditions*)

Bases: `UniqueRepresentation`, `Parent`

The six vertex model.

We model a configuration by indicating which configuration by the following six configurations which are determined by the two outgoing arrows in the Up, Right, Down, Left directions:

1. LR:

```
     |
     V
<-- # -->
     ^
     |
```

2. LU:

```
     ^
     |
<-- # <--
     ^
     |
```

3. LD:

```
     |
     V
<-- # <--
     |
     V
```

4. UD:

```
     ^
     |
--> # <--
     |
     V
```

5. UR:

```
     ^
     |
--> # -->
     ^
     |
```

6. RD:

```
     |
     V
--> # -->
     |
     V
```

INPUT:

- n – the number of rows
- m – (optional) the number of columns, if not specified, then the number of columns is the number of rows
- boundary_conditions – (optional) a quadruple of tuples whose entries are either:
  - True for an inward arrow,
  - False for an outward arrow, or
  - None for no boundary condition.

  There are also the following predefined boundary conditions:
  - 'ice' – the top and bottom boundary conditions are outward and the left and right boundary conditions are inward; this gives the square ice model. Also called domain wall boundary conditions.
  - 'domain wall' – same as 'ice'.
  - 'alternating' – the boundary conditions alternate between inward and outward.
  - 'free' – there are no boundary conditions.

EXAMPLES:

Here are the six types of vertices that can be created:

```
sage: M = SixVertexModel(1)
sage: list(M)
[
    |             ^             |             ^             ^             |
    V             |             V             |             |             V
<-- # -->     <-- # <--     <-- # <--     --> # <--     --> # -->     --> # -->
    ^             ^             |             |             ^             |
    |     ,       |     ,       V     ,       V     ,       |     ,       V
]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(1))
>>> list(M)
[
    |             ^             |             ^             ^             |
    V             |             V             |             |             V
<-- # -->     <-- # <--     <-- # <--     --> # <--     --> # -->     --> # -->
    ^             ^             |             |             ^             |
    |     ,       |     ,       V     ,       V     ,       |     ,       V
]
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = SixVertexModel(1, boundary_conditions='ice')
sage: len(M)
1
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: len(M)
42
sage: all(len(SixVertexModel(n, boundary_conditions='ice'))                  #␣
↪needs sage.modules
....:     == AlternatingSignMatrices(n).cardinality() for n in range(1, 7))
True
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(1), boundary_conditions='ice')
>>> len(M)
1
>>> M = SixVertexModel(Integer(4), boundary_conditions='ice')
>>> len(M)
42
>>> all(len(SixVertexModel(n, boundary_conditions='ice'))                  #␣
↪needs sage.modules
...     == AlternatingSignMatrices(n).cardinality() for n in range(Integer(1),␣
↪Integer(7)))
True
```

An example with a specified non-standard boundary condition and non-rectangular shape:

```
sage: M = SixVertexModel(2, 1, [[None], [True,True], [None], [None,None]])
sage: list(M)
[
    ^           ^           |           ^
    |           |           V           |
<-- # <--   <-- # <--   <-- # <--   --> # <--
    ^           ^           |           |
    |           |           V           V
<-- # <--   --> # <--   <-- # <--   <-- # <--
    ^           |           |           |
    |     ,     V     ,     V     ,     V
]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), Integer(1), [[None], [True,True], [None],␣
↪[None,None]])
>>> list(M)
[
    ^           ^           |           ^
    |           |           V           |
<-- # <--   <-- # <--   <-- # <--   --> # <--
    ^           ^           |           |
    |           |           V           V
<-- # <--   --> # <--   <-- # <--   <-- # <--
    ^           |           |           |
    |     ,     V     ,     V     ,     V
]
```

- Wikipedia article Ice-type_model

Element

alias of *SixVertexConfiguration*

boundary_conditions()

Return the boundary conditions of `self`.

EXAMPLES:

```
sage: M = SixVertexModel(2, boundary_conditions='ice')
sage: M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(2), boundary_conditions='ice')
>>> M.boundary_conditions()
((False, False), (True, True), (False, False), (True, True))
```

partition_function(*beta*, *epsilon*)

Return the partition function of `self`.

The partition function of a 6 vertex model is defined by:

$$Z = \sum_{\nu} e^{-\beta E(\nu)}$$

where we sum over all configurations and E is the energy function. The constant β is known as the *inverse temperature* and is equal to $1/k_B T$ where k_B is Boltzmann's constant and T is the system's temperature.

INPUT:

- `beta` – the inverse temperature constant β
- `epsilon` – the energy constants, see *energy()*

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: M.partition_function(2, [1,2,1,2,1,2])                                    #␣
↪needs sage.symbolic
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> M.partition_function(Integer(2), [Integer(1),Integer(2),Integer(1),
↪Integer(2),Integer(1),Integer(2)])                                # needs␣
↪sage.symbolic
e^(-24) + 2*e^(-28) + e^(-30) + 2*e^(-32) + e^(-36)
```

Wikipedia article Partition_function_(statistical_mechanics)

class sage.combinat.six_vertex_model.**SquareIceModel**(*n*)

Bases: *SixVertexModel*

The square ice model.

The square ice model is a 6 vertex model on an $n \times n$ grid with the boundary conditions that the top and bottom boundaries are pointing outward and the left and right boundaries are pointing inward. These boundary conditions are also called domain wall boundary conditions.

Configurations of the 6 vertex model with domain wall boundary conditions are in bijection with alternating sign matrices.

class Element

Bases: *SixVertexConfiguration*

An element in the square ice model.

to_alternating_sign_matrix()

Return an alternating sign matrix of `self`.

See also

to_signed_matrix()

EXAMPLES:

```
sage: M = SixVertexModel(4, boundary_conditions='ice')
sage: M[6].to_alternating_sign_matrix()                                  #␣
↪needs sage.modules
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
sage: M[7].to_alternating_sign_matrix()                                  #␣
↪needs sage.modules
[ 0  1  0  0]
[ 1 -1  1  0]
[ 0  1 -1  1]
[ 0  0  1  0]
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(4), boundary_conditions='ice')
>>> M[Integer(6)].to_alternating_sign_matrix()                             ␣
↪     # needs sage.modules
[1 0 0 0]
[0 0 0 1]
[0 0 1 0]
[0 1 0 0]
>>> M[Integer(7)].to_alternating_sign_matrix()                             ␣
↪     # needs sage.modules
[ 0  1  0  0]
[ 1 -1  1  0]
[ 0  1 -1  1]
[ 0  0  1  0]
```

from_alternating_sign_matrix(*asm*)

Return a configuration from the alternating sign matrix asm.

EXAMPLES:

```
sage: M = SixVertexModel(3, boundary_conditions='ice')
sage: asm = AlternatingSignMatrix([[0,1,0],[1,-1,1],[0,1,0]])                #␣
↪needs sage.modules
sage: M.from_alternating_sign_matrix(asm)                                    #␣
↪needs sage.modules
    ^    ^    ^
    |    |    |
--> # -> # <- # <--
    ^    |    ^
    |    V    |
--> # <- # -> # <--
    |    ^    |
    V    |    V
--> # -> # <- # <--
    |    |    |
    V    V    V
```

```
>>> from sage.all import *
>>> M = SixVertexModel(Integer(3), boundary_conditions='ice')
>>> asm = AlternatingSignMatrix([[Integer(0),Integer(1),Integer(0)],
↪[Integer(1),-Integer(1),Integer(1)],[Integer(0),Integer(1),Integer(0)]])   ␣
↪           # needs sage.modules
>>> M.from_alternating_sign_matrix(asm)                                    #␣
↪needs sage.modules
    ^    ^    ^
    |    |    |
--> # -> # <- # <--
    ^    |    ^
    |    V    |
--> # <- # -> # <--
    |    ^    |
    V    |    V
--> # -> # <- # <--
    |    |    |
    V    V    V
```

5.1.312 Skew Partitions

A skew partition skp of size n is a pair of partitions $[p_1, p_2]$ where p_1 is a partition of the integer n_1, p_2 is a partition of the integer n_2, p_2 is an inner partition of p_1, and $n = n_1 - n_2$. We say that p_1 and p_2 are respectively the *inner* and *outer* partitions of skp.

A skew partition can be depicted by a diagram made of rows of cells, in the same way as a partition. Only the cells of the outer partition p_1 which are not in the inner partition p_2 appear in the picture. For example, this is the diagram of the skew partition [[5,4,3,1],[3,3,1]].

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).diagram())
   **
   *
```

(continues on next page)

(continued from previous page)

```
 **
*
```

```
>>> from sage.all import *
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).diagram())
   **
   *
 **
*
```

A skew partition can be *connected*, which can easily be described in graphic terms: for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge. This is the diagram of the connected skew partition `[[5,4,3,1],[3,1]]`:

```
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
   **
 ***
***
*
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

```
>>> from sage.all import *
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).diagram())
   **
 ***
***
*
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).is_connected()
True
```

The first example of a skew partition is not a connected one.

Applying a reflection with respect to the main diagonal yields the diagram of the *conjugate skew partition*, here `[[4,3,3,2,1],[3,2,2]]`:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).conjugate().diagram())
   *
  *
  *
**
*
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).conjugate()
[4, 3, 3, 2, 1] / [3, 2, 2]
```

(continues on next page)

(continued from previous page)

```
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).conjugate().diagram())
   *
  *
  *
**
*
```

The *outer corners* of a skew partition are the corners of its outer partition. The *inner corners* are the internal corners of the outer partition when the inner partition is taken off. Shown below are the coordinates of the inner and outer corners.

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
sage: SkewPartition([[5,4,3,1],[3,3,1]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).outer_corners()
[(0, 4), (1, 3), (2, 2), (3, 0)]
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).inner_corners()
[(0, 3), (2, 1), (3, 0)]
```

EXAMPLES:

There are 9 skew partitions of size 3, with no empty row nor empty column:

```
sage: SkewPartitions(3).cardinality()
9
sage: SkewPartitions(3).list()
[[3] / [],
 [2, 1] / [],
 [3, 1] / [1],
 [2, 2] / [1],
 [3, 2] / [2],
 [1, 1, 1] / [],
 [2, 2, 1] / [1, 1],
 [2, 1, 1] / [1],
 [3, 2, 1] / [2, 1]]
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(3)).cardinality()
9
>>> SkewPartitions(Integer(3)).list()
[[3] / [],
 [2, 1] / [],
 [3, 1] / [1],
 [2, 2] / [1],
 [3, 2] / [2],
 [1, 1, 1] / [],
 [2, 2, 1] / [1, 1],
```

(continues on next page)

(continued from previous page)

```
[2, 1, 1] / [1],
[3, 2, 1] / [2, 1]]
```

There are 4 connected skew partitions of size 3:

```
sage: SkewPartitions(3, overlap=1).cardinality()
4
sage: SkewPartitions(3, overlap=1).list()
[[3] / [], [2, 1] / [], [2, 2] / [1], [1, 1, 1] / []]
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(3), overlap=Integer(1)).cardinality()
4
>>> SkewPartitions(Integer(3), overlap=Integer(1)).list()
[[3] / [], [2, 1] / [], [2, 2] / [1], [1, 1, 1] / []]
```

This is the conjugate of the skew partition `[[4,3,1], [2]]`

```
sage: SkewPartition([[4,3,1], [2]]).conjugate()
[3, 2, 2, 1] / [1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)], [Integer(2)]]).conjugate()
[3, 2, 2, 1] / [1, 1]
```

Geometrically, we just applied a reflection with respect to the main diagonal on the diagram of the partition. Of course, this operation is an involution:

```
sage: SkewPartition([[4,3,1],[2]]).conjugate().conjugate()
[4, 3, 1] / [2]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).conjugate().
↪conjugate()
[4, 3, 1] / [2]
```

The `jacobi_trudi()` method computes the Jacobi-Trudi matrix. See [Mac1995] for a definition and discussion.

```
sage: SkewPartition([[4,3,1],[2]]).jacobi_trudi()                          #␣
↪needs sage.modules
[h[2]  h[]    0]
[h[5] h[3]  h[]]
[h[6] h[4] h[1]]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).jacobi_trudi()  ␣
↪                                  # needs sage.modules
[h[2]  h[]    0]
[h[5] h[3]  h[]]
[h[6] h[4] h[1]]
```

This example shows how to compute the corners of a skew partition.

```
sage: SkewPartition([[4,3,1],[2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4,3,1],[2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).inner_corners()
[(0, 2), (1, 0)]
>>> SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

class `sage.combinat.skew_partition.`**`SkewPartition`**(*parent*, *skp*)

Bases: *CombinatorialElement*

A skew partition.

A skew partition of shape λ/μ is the Young diagram from the partition λ and removing the partition μ from the upper-left corner in English convention.

`cell_poset`(*orientation='SE'*)

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to `'SE'`). Concretely, `orientation` has to be specified to one of the strings `'NW'`, `'NE'`, `'SW'`, and `'SE'`, standing for "northwest", "northeast", "southwest" and "southeast", respectively. If `orientation` is `'SE'`, then the order relation of the poset is such that a cell u is greater or equal to a cell v in the poset if and only if u lies weakly southeast of v (this means that u can be reached from v by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that $(3, 7)$ stands for the 8-th cell of the 4-th row, etc.).

EXAMPLES:

```
sage: # needs sage.graphs
sage: p = SkewPartition([[3,3,1], [2,1]])
sage: Q = p.cell_poset(); Q
Finite poset containing 4 elements
sage: sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
sage: sorted(Q.minimal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(Q.upper_covers((1, 1)))
[(1, 2)]
```

(continues on next page)

(continued from previous page)

```
sage: sorted(Q.upper_covers((0, 2)))
[(1, 2)]

sage: # needs sage.graphs
sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 4 elements
sage: sorted(P)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(1, 2), (2, 0)]
sage: sorted(P.maximal_elements())
[(0, 2), (1, 1), (2, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]

sage: # needs sage.graphs
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 4 elements
sage: sorted(R)
[(0, 2), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: R.upper_covers((2, 0))
[(1, 1)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> p = SkewPartition([[Integer(3),Integer(3),Integer(1)], [Integer(2),
↪Integer(1)]])
>>> Q = p.cell_poset(); Q
Finite poset containing 4 elements
>>> sorted(Q)
[(0, 2), (1, 1), (1, 2), (2, 0)]
>>> sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
>>> sorted(Q.minimal_elements())

[(1, 1)]
>>> sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1]
```

cells()

Return the coordinates of the cells of `self`. Coordinates are given as `(row-index, column-index)` and are 0 based.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[4, 3, 1], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: SkewPartition([[2], []]).cells()
[(0, 0), (0, 1)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).
→cells()
[(0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], []]).cells()
[(0, 0), (0, 1), (0, 2), (0, 3), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> SkewPartition([[Integer(2)], []]).cells()
[(0, 0), (0, 1)]
```

column_lengths()

Return the column lengths of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).column_lengths()
[1, 2, 1]
sage: SkewPartition([[5,2,2,2],[2,1]]).column_lengths()
[2, 3, 1, 1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).column_lengths()
[1, 2, 1]
>>> SkewPartition([[Integer(5),Integer(2),Integer(2),Integer(2)],[Integer(2),
↪Integer(1)]]).column_lengths()
[2, 3, 1, 1, 1]
```

columns_intersection_set()

Return the set of cells in the columns of the outer shape of `self` which columns intersect the skew diagram of `self`.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([ (0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.columns_intersection_set() == cells
True
```

```
>>> from sage.all import *
>>> skp = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> cells = Set([ (Integer(0),Integer(0)), (Integer(0), Integer(1)),␣
↪(Integer(0),Integer(2)), (Integer(1), Integer(0)), (Integer(1), Integer(1)),
↪ (Integer(2), Integer(0))])
>>> skp.columns_intersection_set() == cells
True
```

conjugate()

Return the conjugate of the skew partition skp.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2]]).conjugate()
[3, 2, 1] / [1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2)]]).
↪conjugate()
[3, 2, 1] / [1, 1]
```

diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
   **
   *
 **
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
   **
```

*
>>> SkewPartitions.options(diagram_str='#', convention='French')
>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
↪[Integer(3),Integer(1)]]).diagram())
#
###
 ###
   ##
>>> SkewPartitions.options._reset()
```

ferrers_diagram()

Return the Ferrers diagram of `self`.

EXAMPLES:

```
sage: print(SkewPartition([[5,4,3,1],[3,3,1]]).ferrers_diagram())
   **
   *
 **
*
sage: print(SkewPartition([[5,4,3,1],[3,1]]).diagram())
   **
 ***
***
*
sage: SkewPartitions.options(diagram_str='#', convention='French')

>>> print(SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],
↪[Integer(3),Integer(1)]]).diagram())
#
###
 ###
   ##
>>> SkewPartitions.options._reset()
```

frobenius_rank()

Return the Frobenius rank of the skew partition `self`.

The Frobenius rank of a skew partition λ/μ can be defined in various ways. The quickest one is probably the following: Writing λ as $(\lambda_1, \lambda_2, \cdots, \lambda_N)$, and writing μ as $(\mu_1, \mu_2, \cdots, \mu_N)$, we define the Frobenius rank of λ/μ to be the number of all $1 \leq i \leq N$ such that

$$\lambda_i - i \not\in \{\mu_1 - 1, \mu_2 - 2, \cdots, \mu_N - N\}.$$

In other words, the Frobenius rank of λ/μ is the number of rows in the Jacobi-Trudi matrix of λ/μ which don't contain h_0. Further definitions have been considered in [Sta2002] (where Frobenius rank is just being called rank).

If μ is the empty shape, then the Frobenius rank of λ/μ is just the usual Frobenius rank of the partition λ (see *frobenius_rank()*).

EXAMPLES:

```
sage: SkewPartition([[8,8,7,4], [4,1,1]]).frobenius_rank()
4
sage: SkewPartition([[2,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1]]).frobenius_rank()
2
sage: SkewPartition([[2,1,1], [1,1]]).frobenius_rank()
2
sage: SkewPartition([[5,4,3,2], [2,1,1]]).frobenius_rank()
```

(continues on next page)

(continued from previous page)

```
3
sage: SkewPartition([[4,2,1], [3,1,1]]).frobenius_rank()
2
sage: SkewPartition([[4,2,1], [3,2,1]]).frobenius_rank()
1
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(8),Integer(8),Integer(7),Integer(4)], [Integer(4),
↪Integer(1),Integer(1)]]).frobenius_rank()
4
>>> SkewPartition([[Integer(2),Integer(1)], [Integer(1)]]).frobenius_rank()
2
>>> SkewPartition([[Integer(2),Integer(1),Integer(1)], [Integer(1)]]).
↪frobenius_rank()
2
>>> SkewPartition([[Integer(2),Integer(1),Integer(1)], [Integer(1),
↪Integer(1)]]).frobenius_rank()
2
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(2)], [Integer(2),
↪Integer(1),Integer(1)]]).frobenius_rank()
3
>>> SkewPartition([[Integer(4),Integer(2),Integer(1)], [Integer(3),Integer(1),
↪Integer(1)]]).frobenius_rank()
2
>>> SkewPartition([[Integer(4),Integer(2),Integer(1)], [Integer(3),Integer(2),
↪Integer(1)]]).frobenius_rank()
1
```

If the inner shape is empty, then the Frobenius rank of the skew partition is just the standard Frobenius rank of the partition:

```
sage: all( SkewPartition([lam, Partition([])]).frobenius_rank()
....:      == lam.frobenius_rank() for i in range(6)
....:      for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> all( SkewPartition([lam, Partition([])]).frobenius_rank()
...      == lam.frobenius_rank() for i in range(Integer(6))
...      for lam in Partitions(i) )
True
```

If the inner and outer shapes are equal, then the Frobenius rank is zero:

```
sage: all( SkewPartition([lam, lam]).frobenius_rank() == 0
....:      for i in range(6) for lam in Partitions(i) )
True
```

```
>>> from sage.all import *
>>> all( SkewPartition([lam, lam]).frobenius_rank() == Integer(0)
...      for i in range(Integer(6)) for lam in Partitions(i) )
True
```

inner()

Return the inner partition of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).inner()
[1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).inner()
[1, 1]
```

inner_corners()

Return a list of the inner corners of `self`.

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).inner_corners()
[(0, 2), (1, 0)]
sage: SkewPartition([[4, 3, 1], []]).inner_corners()
[(0, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).inner_
↪corners()
[(0, 2), (1, 0)]
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], []]).inner_corners()
[(0, 0)]
```

is_connected()

Return `True` if `self` is a connected skew partition.

A skew partition is said to be *connected* if for each pair of consecutive rows, there are at least two cells (one in each row) which have a common edge.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).is_connected()
False
sage: SkewPartition([[5,4,3,1],[3,1]]).is_connected()
True
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).is_connected()
False
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).is_connected()
True
```

is_overlap(*n*)

Return `True` if the overlap of `self` is at most `n`.

> **See also**
>
> *overlap()*

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,1]]).is_overlap(1)
True
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]]).is_overlap(Integer(1))
True
```

is_ribbon()

Return `True` if and only if `self` is a ribbon.

This means that if it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q.

EXAMPLES:

```
sage: P = SkewPartition([[4,4,3,3],[3,2,2]])
sage: P.pp()
   *
  **
  *
***
sage: P.is_ribbon()
True

sage: P = SkewPartition([[4,3,3],[1,1]])
sage: P.pp()
 ***
 **
***
sage: P.is_ribbon()
False

sage: P = SkewPartition([[4,4,3,2],[3,2,2]])
sage: P.pp()
   *
  **
  *
**
sage: P.is_ribbon()

***
sage: P.is_ribbon()
True

sage: SkewPartition([[2,2,1],[2,2,1]]).is_ribbon()
True
```

```
>>> from sage.all import *
>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
↪[Integer(3),Integer(2),Integer(2)]])
>>> P.pp()
   *
  **
  *
***
>>> P.is_ribbon()
True

>>> P = SkewPartition([[Integer(4),Integer(3),Integer(3)],[Integer(1),
↪Integer(1)]])
>>> P.pp()
 ***
 **
***
>>> P.is_ribbon()
False

>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(2)],
↪[Integer(3),Integer(2),Integer(2)]])
>>> P.pp()
   *
  **
  *
**
>>> P.is_ribbon()
False

>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
↪[Integer(4),Integer(2),Integer(2),Integer(1)]])
>>> P.pp()
<BLANKLINE>
  **
  *
 **
```

(continues on next page)

(continued from previous page)

```
>>> P.is_ribbon()
True

>>> P = SkewPartition([[Integer(4),Integer(4),Integer(3),Integer(3)],
↪[Integer(4),Integer(2),Integer(2)]])
>>> P.pp()
<BLANKLINE>
  **
  *
***
>>> P.is_ribbon()
True

>>> SkewPartition([[Integer(2),Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).is_ribbon()
True
```

jacobi_trudi()

Return the Jacobi-Trudi matrix of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).jacobi_trudi()                          #␣
↪needs sage.modules
[h[1]    0    0]
[h[3] h[1]    0]
[h[5] h[3] h[1]]
sage: SkewPartition([[4,3,2],[2,1]]).jacobi_trudi()                          #␣
↪needs sage.modules
[h[2]  h[]    0]
[h[4] h[2]  h[]]
[h[6] h[4] h[2]]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).jacobi_trudi()                          # needs sage.modules
[h[1]    0    0]
[h[3] h[1]    0]
[h[5] h[3] h[1]]
>>> SkewPartition([[Integer(4),Integer(3),Integer(2)],[Integer(2),
↪Integer(1)]]).jacobi_trudi()                          # needs sage.modules
[h[2]  h[]    0]
[h[4] h[2]  h[]]
[h[6] h[4] h[2]]
```

k_conjugate(k)

Return the k-conjugate of the skew partition.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(3)
[2, 1, 1, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(4)
```

(continues on next page)

(continued from previous page)

```
[2, 2, 1, 1] / [2, 1]
sage: SkewPartition([[3,2,1],[2,1]]).k_conjugate(5)
[3, 2, 1] / [2, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).k_conjugate(Integer(3))
[2, 1, 1, 1, 1] / [2, 1]
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).k_conjugate(Integer(4))
[2, 2, 1, 1] / [2, 1]
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).k_conjugate(Integer(5))
[3, 2, 1] / [2, 1]
```

outer()

Return the outer partition of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).outer()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).outer()
[3, 2, 1]
```

outer_corners()

Return a list of the outer corners of `self`.

These are corners that are contained inside of the shape. For the corners which are outside of the shape, use *outside_corners()*.

Warning

In the case that `self` is an honest (rather than skew) partition, these are the *corners()* of the outer partition. In the language of [Sag2001] these would be the "inner corners" of the outer partition.

See also

- *sage.combinat.skew_partition.SkewPartition.outside_corners()*
- *sage.combinat.partition.Partition.outside_corners()*

EXAMPLES:

```
sage: SkewPartition([[4, 3, 1], [2]]).outer_corners()
[(0, 3), (1, 2), (2, 0)]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(4), Integer(3), Integer(1)], [Integer(2)]]).outer_
↪corners()
[(0, 3), (1, 2), (2, 0)]
```

outside_corners()

Return the outside corners of `self`.

The outside corners are corners which are outside of the shape. This should not be confused with *outer_corners()* which consists of corners inside the shape. It returns a result analogous to the . `outside_corners()` method on (non-skew) `Partitions`.

See also

- *sage.combinat.skew_partition.SkewPartition.outer_corners()*
- *sage.combinat.partition.Partition.outside_corners()*

EXAMPLES:

```
sage: mu = SkewPartition([[3,2,1],[2,1]])
sage: mu.pp()
  *
 *
*
sage: mu.outside_corners()
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> mu.pp()
  *
 *
*
>>> mu.outside_corners()
[(0, 3), (1, 2), (2, 1), (3, 0)]
```

overlap()

Return the overlap of `self`.

The overlap of two consecutive rows in a skew partition is the number of pairs of cells (one in each row) that share a common edge. This number can be positive, zero, or negative.

The overlap of a skew partition is the minimum of the overlap of the consecutive rows, or infinity in the case of at most one row. If the overlap is positive, then the skew partition is called *connected*.

EXAMPLES:

```
sage: SkewPartition([[],[]]).overlap()
+Infinity
sage: SkewPartition([[1],[]]).overlap()
+Infinity
```

(continues on next page)

(continued from previous page)

```
sage: SkewPartition([[10],[]]).overlap()
+Infinity
sage: SkewPartition([[10],[2]]).overlap()
+Infinity
sage: SkewPartition([[10,1],[2]]).overlap()
-1
sage: SkewPartition([[10,10],[1]]).overlap()
9
```

```
>>> from sage.all import *
>>> SkewPartition([[],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(1)],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(10)],[]]).overlap()
+Infinity
>>> SkewPartition([[Integer(10)],[Integer(2)]]).overlap()
+Infinity
>>> SkewPartition([[Integer(10),Integer(1)],[Integer(2)]]).overlap()
-1
>>> SkewPartition([[Integer(10),Integer(10)],[Integer(1)]]).overlap()
9
```

pieri_macdonald_coeffs()

Computation of the coefficients which appear in the Pieri formula for Macdonald polynomials given in his book (Chapter 6.6 formula 6.24(ii))

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[2,1]]).pieri_macdonald_coeffs()
1
sage: SkewPartition([[3,2,1],[2,2]]).pieri_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)
sage: SkewPartition([[3,2,1],[2,2,1]]).pieri_macdonald_coeffs()
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^
↪3*t^4 + q*t^5 - q^3*t^2 + q^2*t^3 - q*t^3 - q^2*t - t^2 + 1)/(q^6*t^8 - q^
↪5*t^7 - q^5*t^6 - q^4*t^6 + q^3*t^5 + 2*q^3*t^4 + q^3*t^3 - q^2*t^2 - q*t^2␣
↪- q*t + 1)
sage: SkewPartition([[3,3,2,2],[3,2,2,1]]).pieri_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^3*t^3 - q^2*t^
↪4 + q^3*t^2 + q^2*t^3 - q*t^4 + q*t^3 + q*t - q + t - 1)/(q^5*t^6 - q^4*t^5␣
↪- q^3*t^4 - q^3*t^3 + q^2*t^3 + q^2*t^2 + q*t - 1)
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]]).pieri_macdonald_coeffs()
1
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(2)]]).pieri_macdonald_coeffs()
(q^2*t^3 - q^2*t - t^2 + 1)/(q^2*t^3 - q*t^2 - q*t + 1)
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).pieri_macdonald_coeffs()
```

(continues on next page)

(continued from previous page)

```
(q^6*t^8 - q^6*t^6 - q^4*t^7 - q^5*t^5 + q^4*t^5 - q^3*t^6 + q^5*t^3 + 2*q^
↪3*t^4 + q*t^5 - q^3*t^2 + q^2*t^3 - q*t^3 - q^2*t - t^2 + 1)/(q^6*t^8 - q^

↪- q*t + 1)
>>> SkewPartition([[Integer(3),Integer(3),Integer(2),Integer(2)],[Integer(3),
↪Integer(2),Integer(2),Integer(1)]]).pieri_macdonald_coeffs()
(q^5*t^6 - q^5*t^5 + q^4*t^6 - q^4*t^5 - q^4*t^3 + q^4*t^2 - q^3*t^3 - q^2*t^
↪4 + q^3*t^2 + q^2*t^3 - q*t^4 + q*t^3 + q*t - q + t - 1)/(q^5*t^6 - q^4*t^5␣
↪- q^3*t^4 - q^3*t^3 + q^2*t^3 + q^2*t^2 + q*t - 1)
```

pp()

Pretty-print `self`.

EXAMPLES:

```
sage: SkewPartition([[5,4,3,1],[3,3,1]]).pp()
   **
   *
 **
*
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]]).pp()
   **
   *
 **
*
```

quotient(k)

The quotient map extended to skew partitions.

EXAMPLES:

```
sage: SkewPartition([[3, 3, 2, 1], [2, 1]]).quotient(2)
[[3] / [], [] / []]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3), Integer(3), Integer(2), Integer(1)],␣
↪[Integer(2), Integer(1)]]).quotient(Integer(2))
[[3] / [], [] / []]
```

row_lengths()

Return the row lengths of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).row_lengths()
[2, 1, 1]
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)]]).row_lengths()
[2, 1, 1]
```

rows_intersection_set()

Return the set of cells in the rows of the outer shape of `self` which rows intersect the skew diagram of `self`.

EXAMPLES:

```
sage: skp = SkewPartition([[3,2,1],[2,1]])
sage: cells = Set([ (0,0), (0, 1), (0,2), (1, 0), (1, 1), (2, 0)])
sage: skp.rows_intersection_set() == cells
True
```

```
>>> from sage.all import *
>>> skp = SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
↪Integer(1)]])
>>> cells = Set([ (Integer(0),Integer(0)), (Integer(0), Integer(1)),␣
↪(Integer(0),Integer(2)), (Integer(1), Integer(0)), (Integer(1), Integer(1)),
↪ (Integer(2), Integer(0))])
>>> skp.rows_intersection_set() == cells
True
```

size()

Return the size of `self`.

EXAMPLES:

```
sage: SkewPartition([[3,2,1],[1,1]]).size()
4
```

```
>>> from sage.all import *
>>> SkewPartition([[Integer(3),Integer(2),Integer(1)],[Integer(1),
↪Integer(1)]]).size()
4
```

specht_module(*base_ring=None*)

Return the Specht module corresponding to `self`.

EXAMPLES:

```
sage: mu = SkewPartition([[3,2,1], [2]])
sage: SM = mu.specht_module(QQ)                                         #␣
↪needs sage.modules
sage: s = SymmetricFunctions(QQ).s()                                    #␣
↪needs sage.modules
sage: s(SM.frobenius_image())                                           #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)], [Integer(2)]])
>>> SM = mu.specht_module(QQ)                                           #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules
>>> s = SymmetricFunctions(QQ).s()                                    #␣
↪needs sage.modules
>>> s(SM.frobenius_image())                                           #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

We verify that the Frobenius image is the corresponding skew Schur function:

```
sage: s[3,2,1].skew_by(s[2])                                            #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
>>> from sage.all import *
>>> s[Integer(3),Integer(2),Integer(1)].skew_by(s[Integer(2)])          ␣
↪                               # needs sage.modules
s[2, 1, 1] + s[2, 2] + s[3, 1]
```

```
sage: mu = SkewPartition([[4,2,1], [2,1]])
sage: SM = mu.specht_module(QQ)                                         #␣
↪needs sage.modules
sage: s(SM.frobenius_image())                                           #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
sage: s(mu)                                                             #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(4),Integer(2),Integer(1)], [Integer(2),
↪Integer(1)]])
>>> SM = mu.specht_module(QQ)                                         #␣
↪needs sage.modules
>>> s(SM.frobenius_image())                                           #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
>>> s(mu)                                                             #␣
↪needs sage.modules
s[2, 1, 1] + s[2, 2] + 2*s[3, 1] + s[4]
```

specht_module_dimension(*base_ring=None*)

Return the dimension of the Specht module corresponding to `self`.

This is equal to the number of standard (skew) tableaux of shape `self`.

EXAMPLES:

```
sage: mu = SkewPartition([[3,2,1], [2]])
sage: mu.specht_module_dimension()                                      #␣
↪needs sage.modules
8
sage: mu.specht_module_dimension(GF(2))                                 #␣
```

(continues on next page)

(continued from previous page)

```
↪needs sage.modules sage.rings.finite_rings
8
```

```
>>> from sage.all import *
>>> mu = SkewPartition([[Integer(3),Integer(2),Integer(1)], [Integer(2)]])
>>> mu.specht_module_dimension()                                          #␣
↪needs sage.modules
8
>>> mu.specht_module_dimension(GF(Integer(2)))                            ␣
↪     # needs sage.modules sage.rings.finite_rings
8
```

to_dag(*format='string'*)

Return a directed acyclic graph corresponding to the skew partition `self`.

The directed acyclic graph corresponding to a skew partition p is the digraph whose vertices are the cells of p, and whose edges go from each cell to its lower and right neighbors (in English notation).

INPUT:

- `format` – either `'string'` or `'tuple'` (default: `'string'`); determines whether the vertices of the resulting dag will be strings or 2-tuples of coordinates

EXAMPLES:

```
sage: # needs sage.graphs
sage: dag = SkewPartition([[3, 3, 1], [1, 1]]).to_dag()
sage: dag.edges(sort=True)
[('0,1', '0,2', None),
('0,1', '1,1', None),
('0,2', '1,2', None),
('1,1', '1,2', None)]
sage: dag.vertices(sort=True)
['0,1', '0,2', '1,1', '1,2', '2,0']
sage: dag = SkewPartition([[3, 2, 1], [1, 1]]).to_dag(format='tuple')
sage: dag.edges(sort=True)
[((0, 1), (0, 2), None), ((0, 1), (1, 1), None)]
sage: dag.vertices(sort=True)
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> dag = SkewPartition([[Integer(3), Integer(3), Integer(1)], [Integer(1),␣
↪Integer(1)]]).to_dag()
>>> dag.edges(sort=True)
[('0,1', '0,2', None),
('0,1', '1,1', None),
('0,2', '1,2', None),
('1,1', '1,2', None)]
>>> dag.vertices(sort=True)
['0,1', '0,2', '1,1', '1,2', '2,0']
>>> dag = SkewPartition([[Integer(3), Integer(2), Integer(1)], [Integer(1),␣
↪Integer(1)]]).to_dag(format='tuple')
```

(continues on next page)

(continued from previous page)

```
>>> dag.edges(sort=True)
[((0, 1), (0, 2), None), ((0, 1), (1, 1), None)]
>>> dag.vertices(sort=True)
[(0, 1), (0, 2), (1, 1), (2, 0)]
```

to_list()

Return `self` as a list of lists.

EXAMPLES:

```
sage: s = SkewPartition([[4,3,1],[2]])
sage: s.to_list()
[[4, 3, 1], [2]]
sage: type(s.to_list())
<class 'list'>
```

```
>>> from sage.all import *
>>> s = SkewPartition([[Integer(4),Integer(3),Integer(1)],[Integer(2)]])
>>> s.to_list()
[[4, 3, 1], [2]]
>>> type(s.to_list())
<class 'list'>
```

class sage.combinat.skew_partition.**SkewPartitions**(*is_infinite=False*)

Bases: `UniqueRepresentation`, `Parent`

Skew partitions.

Warning

The iterator of this class only yields skew partitions which are reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column.

EXAMPLES:

```
sage: SkewPartitions(4)
Skew partitions of 4
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(row_lengths=[2,1,2])
Skew partitions with row lengths [2, 1, 2]
sage: SkewPartitions(4, overlap=2)
Skew partitions of 4 with a minimum overlap of 2
sage: SkewPartitions(4, overlap=2).list()
[[4] / [], [2, 2] / []]
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(4))
Skew partitions of 4
>>> SkewPartitions(Integer(4)).cardinality()
28
```

(continues on next page)

(continued from previous page)

```
>>> SkewPartitions(row_lengths=[Integer(2),Integer(1),Integer(2)])
Skew partitions with row lengths [2, 1, 2]
>>> SkewPartitions(Integer(4), overlap=Integer(2))
Skew partitions of 4 with a minimum overlap of 2
>>> SkewPartitions(Integer(4), overlap=Integer(2)).list()
[[4] / [], [2, 2] / []]
```

Element

alias of *SkewPartition*

from_row_and_column_length(*rowL*, *colL*)

Construct a partition from its row lengths and column lengths.

INPUT:

- rowL – a composition or a list of positive integers
- colL – a composition or a list of positive integers

OUTPUT:

- If it exists the unique skew-partitions with row lengths rowL and column lengths colL.
- Raise a ValueError if rowL and colL are not compatible.

EXAMPLES:

```
sage: S = SkewPartitions()
sage: print(S.from_row_and_column_length([3,1,2,2],[2,3,1,1,1]).diagram())
  ***
 *
**
**
sage: S.from_row_and_column_length([],[])
[] / []
sage: S.from_row_and_column_length([1],[1])
[1] / []
sage: S.from_row_and_column_length([2,1],[2,1])
[2, 1] / []
sage: S.from_row_and_column_length([1,2],[1,2])
[2, 2] / [1]
sage: S.from_row_and_column_length([1,2],[1,3])
Traceback (most recent call last):
...
ValueError: sum mismatch: [1, 2] and [1, 3]
sage: S.from_row_and_column_length([3,2,1,2],[2,3,1,1,1])
Traceback (most recent call last):
...
ValueError: incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1,
↪ 1]
```

```
>>> from sage.all import *
>>> S = SkewPartitions()
>>> print(S.from_row_and_column_length([Integer(3),Integer(1),Integer(2),
↪Integer(2)],[Integer(2),Integer(3),Integer(1),Integer(1),Integer(1)]).
```

(continues on next page)

(continued from previous page)

```
↪diagram())
  ***
 *
**
**
>>> S.from_row_and_column_length([],[])
[] / []
>>> S.from_row_and_column_length([Integer(1)],[Integer(1)])
[1] / []
>>> S.from_row_and_column_length([Integer(2),Integer(1)],[Integer(2),
↪Integer(1)])
[2, 1] / []
>>> S.from_row_and_column_length([Integer(1),Integer(2)],[Integer(1),
↪Integer(2)])
[2, 2] / [1]
>>> S.from_row_and_column_length([Integer(1),Integer(2)],[Integer(1),
↪Integer(3)])
Traceback (most recent call last):
...
ValueError: sum mismatch: [1, 2] and [1, 3]
>>> S.from_row_and_column_length([Integer(3),Integer(2),Integer(1),
↪Integer(2)],[Integer(2),Integer(3),Integer(1),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: incompatible row and column length : [3, 2, 1, 2] and [2, 3, 1, 1,
↪ 1]
```

Warning: If some rows and columns have length zero, there is no way to retrieve unambiguously the skew partition. We therefore raise a `ValueError`. For examples here are two skew partitions with the same row and column lengths:

```
sage: skp1 = SkewPartition([[2,2],[2,2]])
sage: skp2 = SkewPartition([[2,1],[2,1]])
sage: skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
sage: skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
sage: SkewPartitions().from_row_and_column_length([0,0], [0,0])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```

```
>>> from sage.all import *
>>> skp1 = SkewPartition([[Integer(2),Integer(2)],[Integer(2),Integer(2)]])
>>> skp2 = SkewPartition([[Integer(2),Integer(1)],[Integer(2),Integer(1)]])
>>> skp1.row_lengths(), skp1.column_lengths()
([0, 0], [0, 0])
>>> skp2.row_lengths(), skp2.column_lengths()
([0, 0], [0, 0])
>>> SkewPartitions().from_row_and_column_length([Integer(0),Integer(0)],␣
↪[Integer(0),Integer(0)])
Traceback (most recent call last):
...
ValueError: row and column length must be positive
```

options = Current options for SkewPartitions - convention: English - diagram_str: * - display: quotient - latex: young_diagram - latex_diagram_str: \ast - latex_marking_str: X

class sage.combinat.skew_partition.**SkewPartitions_all**

Bases: *SkewPartitions*

Class of all skew partitions.

class sage.combinat.skew_partition.**SkewPartitions_n**(*n*, *overlap*)

Bases: *SkewPartitions*

The set of skew partitions of `n` with overlap at least `overlap` and no empty row.

INPUT:

- `n` – nonnegative integer
- `overlap` – integer (default: 0)

Caveat: this set is stable under conjugation only for `overlap` equal to 0 or 1. What exactly happens for negative overlaps is not yet well specified and subject to change (we may want to introduce vertical overlap constraints as well).

Todo

As is, this set is essentially the composition of `Compositions(n)` (which give the row lengths) and `SkewPartition(n, row_lengths=...)`, and one would want to "inherit" list and cardinality from this composition.

cardinality()

Return the number of skew partitions of the integer n (with given overlap, if specified; and with no empty rows before the last row).

EXAMPLES:

```
sage: SkewPartitions(0).cardinality()
1
sage: SkewPartitions(4).cardinality()
28
sage: SkewPartitions(5).cardinality()
87
sage: SkewPartitions(4, overlap=1).cardinality()
9
sage: SkewPartitions(5, overlap=1).cardinality()
20
sage: s = SkewPartitions(5, overlap=-1)
sage: s.cardinality() == len(s.list())
True
```

```
>>> from sage.all import *
>>> SkewPartitions(Integer(0)).cardinality()
1
```

(continues on next page)

(continued from previous page)

```
>>> SkewPartitions(Integer(4)).cardinality()
28
>>> SkewPartitions(Integer(5)).cardinality()
87
>>> SkewPartitions(Integer(4), overlap=Integer(1)).cardinality()
9
>>> SkewPartitions(Integer(5), overlap=Integer(1)).cardinality()
20
>>> s = SkewPartitions(Integer(5), overlap=-Integer(1))
>>> s.cardinality() == len(s.list())
True
```

class sage.combinat.skew_partition.**SkewPartitions_rowlengths**(*co*, *overlap*)

Bases: *SkewPartitions*

All skew partitions with given row lengths.

sage.combinat.skew_partition.**row_lengths_aux**(*skp*)

EXAMPLES:

```
sage: from sage.combinat.skew_partition import row_lengths_aux
sage: row_lengths_aux([[5,4,3,1],[3,3,1]])
[2, 1, 2]
sage: row_lengths_aux([[5,4,3,1],[3,1]])
[2, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.skew_partition import row_lengths_aux
>>> row_lengths_aux([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(3),Integer(1)]])
[2, 1, 2]
>>> row_lengths_aux([[Integer(5),Integer(4),Integer(3),Integer(1)],[Integer(3),
↪Integer(1)]])
[2, 3]
```

5.1.313 Skew Tableaux

AUTHORS:

- Mike Hansen: Initial version
- Travis Scrimshaw, Arthur Lubovsky (2013-02-11): Factored out `CombinatorialClass`
- Trevor K. Karn (2022-08-03): added `backward_slide`

class sage.combinat.skew_tableau.**SemistandardSkewTableaux**(*category=None*)

Bases: *SkewTableaux*

Semistandard skew tableaux.

This class can be initialized with several optional variables: the size of the skew tableaux (as a nameless integer variable), their shape (as a nameless skew partition variable), their weight (*weight()*, as a nameless second variable after either the size or the shape) and their maximum entry (as an optional keyword variable called `max_entry`, unless the weight has been specified). If neither the weight nor the maximum entry is specified, the maximum entry defaults to the size of the tableau.

Note that "maximum entry" does not literally mean the highest entry; instead it is just an upper bound that no entry is allowed to surpass.

EXAMPLES:

The (infinite) class of all semistandard skew tableaux:

```
sage: SemistandardSkewTableaux()
Semistandard skew tableaux
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux()
Semistandard skew tableaux
```

The (still infinite) class of all semistandard skew tableaux with maximum entry 2:

```
sage: SemistandardSkewTableaux(max_entry=2)
Semistandard skew tableaux with maximum entry 2
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(max_entry=Integer(2))
Semistandard skew tableaux with maximum entry 2
```

The class of all semistandard skew tableaux of given size 3 and maximum entry 3:

```
sage: SemistandardSkewTableaux(3)
Semistandard skew tableaux of size 3 and maximum entry 3
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3))
Semistandard skew tableaux of size 3 and maximum entry 3
```

To set a different maximum entry:

```
sage: SemistandardSkewTableaux(3, max_entry = 7)
Semistandard skew tableaux of size 3 and maximum entry 7
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3), max_entry = Integer(7))
Semistandard skew tableaux of size 3 and maximum entry 7
```

Specifying a shape:

```
sage: SemistandardSkewTableaux([[2,1],[]])
Semistandard skew tableaux of shape [2, 1] / [] and maximum entry 3
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]])
Semistandard skew tableaux of shape [2, 1] / [] and maximum entry 3
```

Specifying both a shape and a maximum entry:

```
sage: S = SemistandardSkewTableaux([[2,1],[1]], max_entry = 3); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
```

(continues on next page)

(continued from previous page)

```
sage: S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
 [[None, 1], [3]],
 [[None, 2], [2]],
 [[None, 3], [2]],
 [[None, 2], [3]],
 [[None, 3], [3]]]

sage: for n in range(5):
....:     print("{} {}".format(n, len(SemistandardSkewTableaux([[2,2,1],[1]], max_
↪entry = n))))
0 0
1 0
2 1
3 9
4 35
```

```
>>> from sage.all import *
>>> S = SemistandardSkewTableaux([[Integer(2),Integer(1)],[Integer(1)]], max_
↪entry = Integer(3)); S
Semistandard skew tableaux of shape [2, 1] / [1] and maximum entry 3
>>> S.list()
[[[None, 1], [1]],
 [[None, 2], [1]],
 [[None, 1], [2]],
 [[None, 3], [1]],
 [[None, 1], [3]],
 [[None, 2], [2]],
 [[None, 3], [2]],
 [[None, 2], [3]],
 [[None, 3], [3]]]

>>> for n in range(Integer(5)):
...     print("{} {}".format(n, len(SemistandardSkewTableaux([[Integer(2),
↪Integer(2),Integer(1)],[Integer(1)]], max_entry = n))))
0 0
1 0
2 1
3 9
4 35
```

Specifying a shape and a weight:

```
sage: SemistandardSkewTableaux([[2,1],[]],[2,1])
Semistandard skew tableaux of shape [2, 1] / [] and weight [2, 1]
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]],[Integer(2),Integer(1)])
Semistandard skew tableaux of shape [2, 1] / [] and weight [2, 1]
```

(the maximum entry is redundant in this case and thus is ignored).

Specifying a size and a weight:

```
sage: SemistandardSkewTableaux(3, [2,1])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(3), [Integer(2),Integer(1)])
Semistandard skew tableaux of size 3 and weight [2, 1]
```

Warning

If the shape is not specified, the iterator of this class yields only skew tableaux whose shape is reduced, in the sense that there are no empty rows before the last nonempty row, and there are no empty columns before the last nonempty column. (Otherwise it would go on indefinitely.)

Warning

This class acts as a factory. The resulting classes are mainly useful for iteration. Do not rely on their containment tests, as they are not correct, e. g.:

```
sage: SkewTableau([[None]]) in SemistandardSkewTableaux(2)
True
```

```
>>> from sage.all import *
>>> SkewTableau([[None]]) in SemistandardSkewTableaux(Integer(2))
True
```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_all**(*max_entry*)

Bases: *SemistandardSkewTableaux*

Class of all semistandard skew tableaux, possibly with a given maximum entry.

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_shape**(*p*, *max_entry*)

Bases: *SemistandardSkewTableaux*

Class of semistandard skew tableaux of a fixed skew shape λ/μ with a given max entry.

A semistandard skew tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

INPUT:

- p – a skew partition
- max_entry – the max entry; defaults to the size of p

Warning

Input is not checked; please use *SemistandardSkewTableaux* to ensure the options are properly parsed.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux([[2,1],[]]).cardinality()
8
sage: SemistandardSkewTableaux([[2,1],[]], max_entry=2).cardinality()
2
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]]).cardinality()
8
>>> SemistandardSkewTableaux([[Integer(2),Integer(1)],[]], max_
↪entry=Integer(2)).cardinality()
2
```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_shape_weight**(*p*, *mu*)

Bases: *SemistandardSkewTableaux*

Class of semistandard skew tableaux of a fixed skew shape λ/ν and weight μ.

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_size**(*n*, *max_entry*)

Bases: *SemistandardSkewTableaux*

Class of all semistandard skew tableaux of a fixed size n, possibly with a given maximum entry.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2).cardinality()
8
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(2)).cardinality()
8
```

class sage.combinat.skew_tableau.**SemistandardSkewTableaux_size_weight**(*n*, *mu*)

Bases: *SemistandardSkewTableaux*

Class of semistandard tableaux of a fixed size n and weight μ.

cardinality()

EXAMPLES:

```
sage: SemistandardSkewTableaux(2,[1,1]).cardinality()
4
```

```
>>> from sage.all import *
>>> SemistandardSkewTableaux(Integer(2),[Integer(1),Integer(1)]).cardinality()
4
```

class sage.combinat.skew_tableau.**SkewTableau**(*parent*, *st*)

Bases: ClonableList

A skew tableau.

Note that Sage by default uses the English convention for partitions and tableaux. To change this, see `Tableaux.options()`.

EXAMPLES:

```
sage: st = SkewTableau([[None, 1],[2,3]]); st
[[None, 1], [2, 3]]
sage: st.inner_shape()
[1]
sage: st.outer_shape()
[2, 2]
```

```
>>> from sage.all import *
>>> st = SkewTableau([[None, Integer(1)],[Integer(2),Integer(3)]]); st
[[None, 1], [2, 3]]
>>> st.inner_shape()
[1]
>>> st.outer_shape()
[2, 2]
```

The `expr` form of a skew tableau consists of the inner partition followed by a list of the entries in each row from bottom to top:

```
sage: SkewTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> SkewTableau(expr=[[Integer(1),Integer(1)],[[Integer(5)],[Integer(3),
↪Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

The `chain` form of a skew tableau consists of a list of partitions $\lambda_1, \lambda_2, \ldots,$, such that all cells in λ_{i+1} that are not in λ_i have entry i:

```
sage: SkewTableau(chain=[[2], [2, 1], [3, 1], [4, 3, 2, 1]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

```
>>> from sage.all import *
>>> SkewTableau(chain=[[Integer(2)], [Integer(2), Integer(1)], [Integer(3),␣
↪Integer(1)], [Integer(4), Integer(3), Integer(2), Integer(1)]])
[[None, None, 2, 3], [1, 3, 3], [3, 3], [3]]
```

backward_slide(*corner=None*)

Apply a backward jeu de taquin slide on the specified outside `corner` of `self`.

Backward jeu de taquin slides are defined in Section 3.7 of [Sag2001].

> **Warning**
>
> The `inner_corners()` and `outer_corners()` are the `sage.combinat.partition.Partition.corners()` of the inner and outer partitions of the skew shape. They are different from the inner/outer corners defined in [Sag2001].

The "inner corners" of [Sag2001] may be found by calling `outer_corners()`. The "outer corners" of [Sag2001] may be found by calling `self.outer_shape().outside_corners()`.

EXAMPLES:

```
sage: T = SkewTableaux()([[2, 2], [4, 4], [5]])
sage: Tableaux.options.display='array'
sage: Q = T.backward_slide(); Q
. 2 2
4 4
5
sage: Q.backward_slide((1, 2))
. 2 2
. 4 4
5
sage: Q.reverse_slide((1, 2)) == Q.backward_slide((1, 2))
True

sage: T = SkewTableaux()([[1, 3],[3],[5]]); T
1 3
3
5
sage: T.reverse_slide((1,1))
. 1
3 3
5
```

```
>>> from sage.all import *
>>> T = SkewTableaux()([[Integer(2), Integer(2)], [Integer(4), Integer(4)],␣
↪[Integer(5)]])
>>> Tableaux.options.display='array'
>>> Q = T.backward_slide(); Q
. 2 2
4 4
5
>>> Q.backward_slide((Integer(1), Integer(2)))
. 2 2
. 4 4
5
>>> Q.reverse_slide((Integer(1), Integer(2))) == Q.backward_slide((Integer(1),
↪ Integer(2)))
True

>>> T = SkewTableaux()([[Integer(1), Integer(3)],[Integer(3)],[Integer(5)]]);␣
↪T
1 3
3
5
>>> T.reverse_slide((Integer(1),Integer(1)))
. 1
3 3
5
```

bender_knuth_involution(*k*, *rows=None*, *check=True*)

Return the image of `self` under the k-th Bender–Knuth involution, assuming `self` is a skew semistandard tableau.

Let T be a tableau, then a *lower free `k` in `T`* means a cell of T which is filled with the integer k and whose direct lower neighbor is not filled with the integer $k + 1$ (in particular, this lower neighbor might not exist at all). Let an *upper free `k + 1` in `T`* mean a cell of T which is filled with the integer $k + 1$ and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T, the lower free k's and the upper free $k + 1$'s in r together form a contiguous interval or r.

The *`k`-th Bender–Knuth switch at row `i`* changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of $k + 1$, it will now have b entries of k and a entries of $k + 1$. For fixed k, the k-th Bender–Knuth switches for different i commute. The composition of the k-th Bender–Knuth switches for all rows is called the *`k`-th Bender–Knuth involution*. This is used to show that the Schur functions defined by semistandard (skew) tableaux are symmetric functions.

INPUT:

- `k` – integer
- `rows` – (default: `None`) when set to `None`, the method computes the k-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k-th Bender–Knuth switches at row i over all i in `rows`. When set to an integer i, the method computes the k-th Bender–Knuth switch at row i. Note the indexing of the rows starts with 1.
- `check` – (default: `True`) check to make sure `self` is semistandard; set to `False` to avoid this check

OUTPUT:

The image of `self` under either the k-th Bender–Knuth involution, the k-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = SkewTableau([[None,None,None,4,4,5,6,7],[None,2,4,6,7,7,7],
....:                  [None,4,5,8,8,9],[None,6,7,10],[None,8,8,11],[None],
↪[4]])
sage: t
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(1)
[[None, None, None, 4, 4, 5, 6, 7], [None, 1, 4, 6, 7, 7, 7],

sage: t.bender_knuth_involution(4)
[[None, None, None, 4, 5, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [5]]
sage: t.bender_knuth_involution(5)
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 5, 7, 7, 7],
 [None, 4, 6, 8, 8, 9], [None, 5, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(6)
[[None, None, None, 4, 4, 5, 6, 6], [None, 2, 4, 6, 6, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
```

(continues on next page)

(continued from previous page)

```
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,None,None,Integer(4),Integer(4),Integer(5),
↪Integer(6),Integer(7)],[None,Integer(2),Integer(4),Integer(6),Integer(7),
↪Integer(7),Integer(7)],
...                     [None,Integer(4),Integer(5),Integer(8),Integer(8),
↪Integer(9)],[None,Integer(6),Integer(7),Integer(10)],[None,Integer(8),
↪Integer(8),Integer(11)],[None],[Integer(4)]])
>>> t
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
>>> t.bender_knuth_involution(Integer(1))
[[None, None, None, 4, 4, 5, 6, 7], [None, 1, 4, 6, 7, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
>>> t.bender_knuth_involution(Integer(4))
[[None, None, None, 4, 5, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [5]]
>>> t.bender_knuth_involution(Integer(5))
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 5, 7, 7, 7],
 [None, 4, 6, 8, 8, 9], [None, 5, 7, 10], [None, 8, 8, 11], [None], [4]]
>>> t.bender_knuth_involution(Integer(6))
[[None, None, None, 4, 4, 5, 6, 6], [None, 2, 4, 6, 6, 7, 7],
 [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
>>> t.bender_knuth_involution(Integer(666)) == t
True
>>> t.bender_knuth_involution(Integer(4), Integer(2)) == t
True
>>> t.bender_knuth_involution(Integer(4), Integer(3))
[[None, None, None, 4, 4, 5, 6, 7], [None, 2, 4, 6, 7, 7, 7],
 [None, 5, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], [None], [4]]
```

The Bender–Knuth involution is an involution:

```
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k)
....:     == t for k in range(1,4))
True
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(3),Integer(4),Integer(4)],[None,Integer(6),
↪Integer(10)],[Integer(7),Integer(7),Integer(11)],[Integer(18)]])
>>> all(t.bender_knuth_involution(k).bender_knuth_involution(k)
...     == t for k in range(Integer(1),Integer(4)))
True
```

The same for the single switches:

```
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j)
....:     == t for k in range(1,5) for j in range(1, 5))
True
```

```
>>> from sage.all import *
>>> all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j)
...     == t for k in range(Integer(1),Integer(5)) for j in range(Integer(1),
→Integer(5)))
True
```

Locality of the Bender–Knuth involutions:

```
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l)
....:     == t.bender_knuth_involution(l).bender_knuth_involution(k)
....:     for k in range(1,5) for l in range(1,5) if abs(k - l) > 1)
True
```

```
>>> from sage.all import *
>>> all(t.bender_knuth_involution(k).bender_knuth_involution(l)
...     == t.bender_knuth_involution(l).bender_knuth_involution(k)
...     for k in range(Integer(1),Integer(5)) for l in range(Integer(1),
→Integer(5)) if abs(k - l) > Integer(1))
True
```

AUTHORS:

- Darij Grinberg (2013-05-14)

cells()

Return the cells in `self`.

EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3],[6]])
sage: s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3)],[Integer(6)]])
>>> s.cells()
[(0, 1), (0, 2), (1, 0), (2, 0)]
```

cells_by_content(*c*)

Return the coordinates of the cells in `self` with content `c`.

EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.cells_by_content(0)
[(1, 1)]
sage: s.cells_by_content(1)
[(0, 1), (1, 2)]
sage: s.cells_by_content(2)
[(0, 2)]
sage: s.cells_by_content(-1)
[(1, 0)]
sage: s.cells_by_content(-2)
[(2, 0)]
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3),Integer(4),
↪Integer(5)],[Integer(6)]])
>>> s.cells_by_content(Integer(0))
[(1, 1)]
>>> s.cells_by_content(Integer(1))
[(0, 1), (1, 2)]
>>> s.cells_by_content(Integer(2))
[(0, 2)]
>>> s.cells_by_content(-Integer(1))
[(1, 0)]
>>> s.cells_by_content(-Integer(2))
[(2, 0)]
```

cells_containing(*i*)

Return the list of cells in which the letter `i` appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (a, b), where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = SkewTableau([[None,None,3],[None,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(2)
[]

sage: t = SkewTableau([[None,None,None,None],[None,4,5],[None,5,6],[None,9],
↪[None]])
sage: t.cells_containing(2)
[]
sage: t.cells_containing(4)
[(1, 1)]
sage: t.cells_containing(5)
[(2, 1), (1, 2)]

sage: SkewTableau([]).cells_containing(3)
[]

sage: SkewTableau([[None,None],[None]]).cells_containing(3)
[]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,None,Integer(3)],[None,Integer(3),Integer(5)],
↪[Integer(4),Integer(5)]])
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]
>>> t.cells_containing(Integer(4))
[(2, 0)]
```

(continues on next page)

(continued from previous page)

```
>>> t.cells_containing(Integer(2))
[]

>>> t = SkewTableau([[None,None,None,None],[None,Integer(4),Integer(5)],[None,
↪Integer(5),Integer(6)],[None,Integer(9)],[None]])
>>> t.cells_containing(Integer(2))
[]
>>> t.cells_containing(Integer(4))
[(1, 1)]
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]

>>> SkewTableau([]).cells_containing(Integer(3))
[]

>>> SkewTableau([[None,None],[None]]).cells_containing(Integer(3))
[]
```

check()

Check that `self` is a valid skew tableau. This is currently far too liberal, and only checks some trivial things.

EXAMPLES:

```
sage: t = SkewTableau([[None,1,1],[2]])
sage: t.check()

sage: t = SkewTableau([[None, None, 1], [2, 4], [], [3, 4, 5]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

sage: s = SkewTableau([[1, None, None],[2, None],[3]])
Traceback (most recent call last):
...
TypeError: not a valid skew tableau
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(1),Integer(1)],[Integer(2)]])
>>> t.check()

>>> t = SkewTableau([[None, None, Integer(1)], [Integer(2), Integer(4)], [],␣
↪[Integer(3), Integer(4), Integer(5)]])
Traceback (most recent call last):
...
TypeError: a skew tableau cannot have an empty list for a row

>>> s = SkewTableau([[Integer(1), None, None],[Integer(2), None],
↪[Integer(3)]])
Traceback (most recent call last):
...
TypeError: not a valid skew tableau
```

column_stabilizer()

Return the `PermutationGroup()` corresponding to the column stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: cs = SkewTableau([[None,2,3],[1,5],[4]]).column_stabilizer()
sage: cs.order() == factorial(2) * factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> cs = SkewTableau([[None,Integer(2),Integer(3)],[Integer(1),Integer(5)],
↪[Integer(4)]]).column_stabilizer()
>>> cs.order() == factorial(Integer(2)) * factorial(Integer(2))
True
>>> PermutationGroupElement([(Integer(1),Integer(3),Integer(2)),(Integer(4),
↪Integer(5))]) in cs
False
>>> PermutationGroupElement([(Integer(1),Integer(4))]) in cs
True
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).conjugate()
[[None, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]]).conjugate()
[[None, 2], [1, 3]]
```

entries_by_content(*c*)

Return the entries in `self` with content `c`.

EXAMPLES:

```
sage: s = SkewTableau([[None,1,2],[3,4,5],[6]])
sage: s.entries_by_content(0)
[4]
sage: s.entries_by_content(1)
[1, 5]
sage: s.entries_by_content(2)
[2]
sage: s.entries_by_content(-1)
[3]
```

(continues on next page)

(continued from previous page)

```
sage: s.entries_by_content(-2)
[6]
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3),Integer(4),
↪Integer(5)],[Integer(6)]])
>>> s.entries_by_content(Integer(0))
[4]
>>> s.entries_by_content(Integer(1))
[1, 5]
>>> s.entries_by_content(Integer(2))
[2]
>>> s.entries_by_content(-Integer(1))
[3]
>>> s.entries_by_content(-Integer(2))
[6]
```

evaluation()

Return the weight (aka evaluation) of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau T is the sequence $(a_1, a_2, a_3, \ldots)$, where a_k is the number of entries of T equal to k. This sequence contains only finitely many nonzero entries.

The weight of a skew tableau T is the same as the weight of the reading word of T, for any reading order.

evaluation() is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None,2],[None,4],[None,5],[None]]).weight()
[0, 1, 0, 1, 1]

sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None,None,None],[None]]).weight()
[]

sage: SkewTableau([[None,3,4],[None,6,7],[4,8],[5,13],[6],[7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).weight()
[1, 1, 1, 1]

>>> SkewTableau([[None,Integer(2)],[None,Integer(4)],[None,Integer(5)],
↪[None]]).weight()
[0, 1, 0, 1, 1]

>>> SkewTableau([]).weight()
```

(continues on next page)

(continued from previous page)

```
[]

>>> SkewTableau([[None,None,None],[None]]).weight()
[]

>>> SkewTableau([[None,Integer(3),Integer(4)],[None,Integer(6),Integer(7)],
↪[Integer(4),Integer(8)],[Integer(5),Integer(13)],[Integer(6)],
↪[Integer(7)]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

filling()

Return a list of the non-empty entries in `self`.

EXAMPLES:

```
sage: t = SkewTableau([[None,1],[2,3]])
sage: t.filling()
[[1], [2, 3]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> t.filling()
[[1], [2, 3]]
```

inner_shape()

Return the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).inner_shape()
[1, 1]
sage: SkewTableau([[1,2],[3,4],[7]]).inner_shape()
[]
sage: SkewTableau([[None,None,None,2,3],[None,1],[None],[2]]).inner_shape()
[3, 1, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(2)],[None,Integer(3)],
↪[Integer(4)]]).inner_shape()
[1, 1]
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)],
↪[Integer(7)]]).inner_shape()
[]
>>> SkewTableau([[None,None,None,Integer(2),Integer(3)],[None,Integer(1)],
↪[None],[Integer(2)]]).inner_shape()
[3, 1, 1]
```

inner_size()

Return the size of the inner shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).inner_size()
2
sage: SkewTableau([[None, 2], [1, 3]]).inner_size()
1
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]]).inner_size()
2
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).inner_size()
1
```

is_k_tableau(*k*)

Check whether `self` is a valid skew weak k-tableau.

EXAMPLES:

```
sage: t = SkewTableau([[None,2,3],[2,3],[3]])
sage: t.is_k_tableau(3)
True
sage: t = SkewTableau([[None,1,3],[2,2],[3]])
sage: t.is_k_tableau(3)
False
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(2),Integer(3)],[Integer(2),Integer(3)],
↪[Integer(3)]])
>>> t.is_k_tableau(Integer(3))
True
>>> t = SkewTableau([[None,Integer(1),Integer(3)],[Integer(2),Integer(2)],
↪[Integer(3)]])
>>> t.is_k_tableau(Integer(3))
False
```

is_ribbon()

Return `True` if and only if the shape of `self` is a ribbon.

This means that it has exactly one cell in each of q consecutive diagonals for some nonnegative integer q.

EXAMPLES:

```
sage: S = SkewTableau([[None, None, 1, 2],[None, None, 3],[1, 3, 4]])
sage: S.pp()
  .  .  1  2
  .  .  3
  1  3  4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, 1, 1, 2],[None, 2, 3],[1, 3, 4]])
sage: S.pp()
  .  1  1  2
  .  2  3
  1  3  4
```

(continues on next page)

(continued from previous page)

```
sage: S.is_ribbon()
False

sage: S = SkewTableau([[None, None, 1, 2],[None, None, 3],[1]])
sage: S.pp()
  .   .   1   2
  .   .   3
  1
sage: S.is_ribbon()
False

sage: S = SkewTableau([[None, None, None, None],[None, None, 3],[1, 2, 4]])
sage: S.pp()
  .   .   .   .
  .   .   3
  1   2   4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, None, None, None],[None, None, 3],[None, 2, 4]])
sage: S.pp()
  .   .   .   .
  .   .   3
  .   2   4
sage: S.is_ribbon()
True

sage: S = SkewTableau([[None, None],[None]])
sage: S.pp()
  .   .
  .
sage: S.is_ribbon()
True
```

```
>>> from sage.all import *
>>> S = SkewTableau([[None, None, Integer(1), Integer(2)],[None, None,␣
↪Integer(3)],[Integer(1), Integer(3), Integer(4)]])
>>> S.pp()
  .   .   1   2
  .   .   3
  1   3   4
>>> S.is_ribbon()
True

>>> S = SkewTableau([[None, Integer(1), Integer(1), Integer(2)],[None,␣
↪Integer(2), Integer(3)],[Integer(1), Integer(3), Integer(4)]])
>>> S.pp()
  .   1   1   2
  .   2   3
  1   3   4
>>> S.is_ribbon()
False
```

(continues on next page)

(continued from previous page)

```
>>> S = SkewTableau([[None, None, Integer(1), Integer(2)],[None, None,␣
↪Integer(3)],[Integer(1)]])
>>> S.pp()
  .  .  1  2
  .  .  3
  1
>>> S.is_ribbon()
False

>>> S = SkewTableau([[None, None, None, None],[None, None, Integer(3)],
↪[Integer(1), Integer(2), Integer(4)]])
>>> S.pp()
  .  .  .  .
  .  .  3
  1  2  4
>>> S.is_ribbon()
True

>>> S = SkewTableau([[None, None, None, None],[None, None, Integer(3)],[None,␣
↪Integer(2), Integer(4)]])
>>> S.pp()
  .  .  .  .
  .  .  3
  .  2  4
>>> S.is_ribbon()
True

>>> S = SkewTableau([[None, None],[None]])
>>> S.pp()
  .  .
  .
>>> S.is_ribbon()
True
```

is_semistandard()

Return `True` if `self` is a semistandard skew tableau and `False` otherwise.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 2], [1, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 3], [2, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3]]).is_semistandard()
True
sage: SkewTableau([[None, 3, 2]]).is_semistandard()
False
```

(continues on next page)

(continued from previous page)

```
sage: SkewTableau([[None, 2, 3], [1, 4]]).is_semistandard()
True
sage: SkewTableau([[None, 2, 3], [1, 2]]).is_semistandard()
False
sage: SkewTableau([[None, 2, 3], [None, None, 4]]).is_semistandard()
False
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(2)], [Integer(1), Integer(3)]]).
→is_semistandard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_
→semistandard()
True
>>> SkewTableau([[None, Integer(3)], [Integer(2), Integer(4)]]).is_
→semistandard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(2)]]).is_
→semistandard()
False
>>> SkewTableau([[None, Integer(2), Integer(3)]]).is_semistandard()
True
>>> SkewTableau([[None, Integer(3), Integer(2)]]).is_semistandard()
False
>>> SkewTableau([[None, Integer(2), Integer(3)], [Integer(1), Integer(4)]]).
→is_semistandard()
True
>>> SkewTableau([[None, Integer(2), Integer(3)], [Integer(1), Integer(2)]]).
→is_semistandard()
False
>>> SkewTableau([[None, Integer(2), Integer(3)], [None, None, Integer(4)]]).
→is_semistandard()
False
```

is_standard()

Return `True` if `self` is a standard skew tableau and `False` otherwise.

EXAMPLES:

```
sage: SkewTableau([[None, 2], [1, 3]]).is_standard()
True
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 3], [2, 4]]).is_standard()
False
sage: SkewTableau([[None, 2], [2, 4]]).is_standard()
False
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).is_standard()
True
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_standard()
```

(continues on next page)

(continued from previous page)

```
False
>>> SkewTableau([[None, Integer(3)], [Integer(2), Integer(4)]]).is_standard()
False
>>> SkewTableau([[None, Integer(2)], [Integer(2), Integer(4)]]).is_standard()
False
```

outer_shape()

Return the outer shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).outer_shape()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(2)],[None,Integer(3)],
↪[Integer(4)]]).outer_shape()
[3, 2, 1]
```

outer_size()

Return the size of the outer shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).outer_size()
6
sage: SkewTableau([[None, 2], [1, 3]]).outer_size()
4
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]]).outer_size()
6
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).outer_size()
4
```

pp()

Return a pretty print string of the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,2,3],[None,4],[5]]).pp()
  .  2  3
  .  4
  5
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(2),Integer(3)],[None,Integer(4)],
↪[Integer(5)]]).pp()
  .  2  3
  .  4
  5
```

rectify(*algorithm=None*)

Return a *StandardTableau*, *SemistandardTableau*, or just *Tableau* formed by applying the jeu de taquin process to `self`.

See page 15 of [Ful1997].

INPUT:

- `algorithm` – (optional) if set to `'jdt'`, rectifies by jeu de taquin; if set to `'schensted'`, rectifies by Schensted insertion of the reading word. Otherwise, guesses which will be faster.

EXAMPLES:

```
sage: S = SkewTableau([[None,1],[2,3]])
sage: S.rectify()
[[1, 3], [2]]
sage: T = SkewTableau([[None, None, None, 4],[None,None,1,6],[None,None,5],[2,
↪3]])
sage: T.rectify()
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
sage: T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

```
>>> from sage.all import *
>>> S = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> S.rectify()
[[1, 3], [2]]
>>> T = SkewTableau([[None, None, None, Integer(4)],[None,None,Integer(1),
↪Integer(6)],[None,None,Integer(5)],[Integer(2),Integer(3)]])
>>> T.rectify()
[[1, 3, 4, 6], [2, 5]]
>>> T.rectify(algorithm='jdt')
[[1, 3, 4, 6], [2, 5]]
>>> T.rectify(algorithm='schensted')
[[1, 3, 4, 6], [2, 5]]
>>> T.rectify(algorithm='spaghetti')
Traceback (most recent call last):
...
ValueError: algorithm must be 'jdt', 'schensted', or None
```

restrict(*n*)

Return the restriction of the (semi)standard skew tableau to all the numbers less than or equal to `n`.

Note

If only the outer shape of the restriction, rather than the whole restriction, is needed, then the faster method *restriction_outer_shape()* is preferred. Similarly if only the skew shape is needed, use *restriction_shape()*.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).restrict(2)
[[None, 1], [2]]
sage: SkewTableau([[None,1],[2],[3]]).restrict(1)
[[None, 1]]
sage: SkewTableau([[None,1],[1],[2]]).restrict(1)
[[None, 1], [1]]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).
↪restrict(Integer(2))
[[None, 1], [2]]
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).
↪restrict(Integer(1))
[[None, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).
↪restrict(Integer(1))
[[None, 1], [1]]
```

restriction_outer_shape(n)

Return the outer shape of the restriction of the semistandard skew tableau `self` to n.

If T is a semistandard skew tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the outer shape of the restriction. For the restriction itself, use *restrict()*.

EXAMPLES:

```
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_outer_shape(3)
[2, 2, 1]
sage: SkewTableau([[None,2],[None],[4],[5]]).restriction_outer_shape(2)
[2, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_outer_shape(0)
[2, 1]
sage: T.restriction_outer_shape(2)
[2, 1]
sage: T.restriction_outer_shape(3)
[3, 1]
sage: T.restriction_outer_shape(4)
[3, 3]
sage: T.restriction_outer_shape(19)
[4, 3, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,None],[Integer(2),Integer(3)],[Integer(3),
↪Integer(4)]]).restriction_outer_shape(Integer(3))
[2, 2, 1]
>>> SkewTableau([[None,Integer(2)],[None],[Integer(4)],[Integer(5)]]).
↪restriction_outer_shape(Integer(2))
[2, 1]
>>> T = SkewTableau([[None,None,Integer(3),Integer(5)],[None,Integer(4),
```

(continues on next page)

(continued from previous page)

```
↪Integer(4)],[Integer(17)]])
>>> T.restriction_outer_shape(Integer(0))
[2, 1]
>>> T.restriction_outer_shape(Integer(2))
[2, 1]
>>> T.restriction_outer_shape(Integer(3))
[3, 1]
>>> T.restriction_outer_shape(Integer(4))
[3, 3]
>>> T.restriction_outer_shape(Integer(19))
[4, 3, 1]
```

restriction_shape(n)

Return the skew shape of the restriction of the semistandard skew tableau `self` to `n`.

If T is a semistandard skew tableau and n is a nonnegative integer, then the restriction of T to n is defined as the (semistandard) skew tableau obtained by removing all cells filled with entries greater than n from T.

This method computes merely the skew shape of the restriction. For the restriction itself, use `restrict()`.

EXAMPLES:

```
sage: SkewTableau([[None,None],[2,3],[3,4]]).restriction_shape(3)
[2, 2, 1] / [2]
sage: SkewTableau([[None,2],[None],[4],[5]]).restriction_shape(2)
[2, 1] / [1, 1]
sage: T = SkewTableau([[None,None,3,5],[None,4,4],[17]])
sage: T.restriction_shape(0)
[2, 1] / [2, 1]
sage: T.restriction_shape(2)
[2, 1] / [2, 1]
sage: T.restriction_shape(3)
[3, 1] / [2, 1]
sage: T.restriction_shape(4)
[3, 3] / [2, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,None],[Integer(2),Integer(3)],[Integer(3),
↪Integer(4)]]).restriction_shape(Integer(3))
[2, 2, 1] / [2]
>>> SkewTableau([[None,Integer(2)],[None],[Integer(4)],[Integer(5)]]).
↪restriction_shape(Integer(2))
[2, 1] / [1, 1]
>>> T = SkewTableau([[None,None,Integer(3),Integer(5)],[None,Integer(4),
↪Integer(4)],[Integer(17)]])
>>> T.restriction_shape(Integer(0))
[2, 1] / [2, 1]
>>> T.restriction_shape(Integer(2))
[2, 1] / [2, 1]
>>> T.restriction_shape(Integer(3))
[3, 1] / [2, 1]
>>> T.restriction_shape(Integer(4))
[3, 3] / [2, 1]
```

reverse_slide(*corner=None*)

Apply a backward jeu de taquin slide on the specified outside `corner` of `self`.

Backward jeu de taquin slides are defined in Section 3.7 of [Sag2001].

> **Warning**
>
> The `inner_corners()` and `outer_corners()` are the *sage.combinat.partition.Partition.corners()* of the inner and outer partitions of the skew shape. They are different from the inner/outer corners defined in [Sag2001].
>
> The "inner corners" of [Sag2001] may be found by calling `outer_corners()`. The "outer corners" of [Sag2001] may be found by calling `self.outer_shape().outside_corners()`.

EXAMPLES:

```
sage: T = SkewTableaux()([[2, 2], [4, 4], [5]])
sage: Tableaux.options.display='array'
sage: Q = T.backward_slide(); Q
. 2 2
4 4
5
sage: Q.backward_slide((1, 2))
. 2 2
. 4 4
5
sage: Q.reverse_slide((1, 2)) == Q.backward_slide((1, 2))
True

sage: T = SkewTableaux()([[1, 3],[3],[5]]); T
1 3
3
5
sage: T.reverse_slide((1,1))
. 1
3 3
5
```

```
>>> from sage.all import *
>>> T = SkewTableaux()([[Integer(2), Integer(2)], [Integer(4), Integer(4)],␣
→[Integer(5)]])
>>> Tableaux.options.display='array'
>>> Q = T.backward_slide(); Q
. 2 2
4 4
5
>>> Q.backward_slide((Integer(1), Integer(2)))
. 2 2
. 4 4
5
>>> Q.reverse_slide((Integer(1), Integer(2))) == Q.backward_slide((Integer(1),
→ Integer(2)))
True
```

(continues on next page)

(continued from previous page)

```
>>> T = SkewTableaux()([[Integer(1), Integer(3)],[Integer(3)],[Integer(5)]]);␣
↪T
1 3
3
5
>>> T.reverse_slide((Integer(1),Integer(1)))
. 1
3 3
5
```

row_stabilizer()

Return the PermutationGroup() corresponding to the row stabilizer of self.

This assumes that every integer from 1 to the size of self appears exactly once in self.

EXAMPLES:

```
sage: # needs sage.groups
sage: rs = SkewTableau([[None,1,2,3],[4,5]]).row_stabilizer()
sage: rs.order() == factorial(3) * factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in rs
True
sage: PermutationGroupElement([(1,4)]) in rs
False
sage: rs = SkewTableau([[None,1,2],[3]]).row_stabilizer()
sage: PermutationGroupElement([(1,2),(3,)]) in rs
True
sage: rs.one().domain()
[1, 2, 3]
sage: rs = SkewTableau([[None,None,1],[None,2],[3]]).row_stabilizer()
sage: rs.order()
1
sage: rs = SkewTableau([[None,None,2,4,5],[1,3]]).row_stabilizer()
sage: rs.order()
12
sage: rs = SkewTableau([]).row_stabilizer()
sage: rs.order()
1
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> rs = SkewTableau([[None,Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5)]]).row_stabilizer()
>>> rs.order() == factorial(Integer(3)) * factorial(Integer(2))
True
>>> PermutationGroupElement([(Integer(1),Integer(3),Integer(2)),(Integer(4),
↪Integer(5))]) in rs
True
>>> PermutationGroupElement([(Integer(1),Integer(4))]) in rs
False
>>> rs = SkewTableau([[None,Integer(1),Integer(2)],[Integer(3)]]).row_
```

(continues on next page)

(continued from previous page)

```
↪stabilizer()
>>> PermutationGroupElement([(Integer(1),Integer(2)),(Integer(3),)]) in rs
True
>>> rs.one().domain()
[1, 2, 3]
>>> rs = SkewTableau([[None,None,Integer(1)],[None,Integer(2)],[Integer(3)]]).
↪row_stabilizer()
>>> rs.order()
1
>>> rs = SkewTableau([[None,None,Integer(2),Integer(4),Integer(5)],
↪[Integer(1),Integer(3)]]).row_stabilizer()
>>> rs.order()
12
>>> rs = SkewTableau([]).row_stabilizer()
>>> rs.order()
1
```

shape()

Return the shape of `self`.

EXAMPLES:

```
sage: SkewTableau([[None,1,2],[None,3],[4]]).shape()
[3, 2, 1] / [1, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(2)],[None,Integer(3)],
↪[Integer(4)]]).shape()
[3, 2, 1] / [1, 1]
```

shuffle(*t2*)

Shuffle the standard tableaux `self` and `t2`.

Let `t1 = self`. The shape of `t2` must extend the shape of `t1`, that is, `self.outer_shape() == t2.inner_shape()`. Then this function computes the pair of tableaux `(t2_new, t1_new)` obtained by using jeu de taquin slides to move the boxes of `t2` behind the boxes of `self`.

The entries of `t2_new` are obtained by performing successive inwards jeu de taquin slides on `t2` in the order indicated by the entries of `t1`, from largest to smallest. The entries of `t1` then slide outwards one by one and land in the squares vacated successively by `t2`, forming `t1_new`.

Note

Equivalently, the entries of `t1_new` are obtained by performing outer jeu de taquin slides on `t1` in the order indicated by the entries of `t2`, from smallest to largest. In this case the entries of `t2` slide backwards and fill the squares successively vacated by `t1` and so form `t2_new`. (This is not how the algorithm is implemented.)

INPUT:

- `self`, `t2` – a pair of standard SkewTableaux with `self.outer_shape() == t2.inner_shape()`

OUTPUT:

- `t2_new, t1_new` – a pair of standard *SkewTableaux* with `t2_new.outer_shape() == t1_new.inner_shape()`

EXAMPLES:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: (t2_new, t1_new) = t1.shuffle(t2)
sage: t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
sage: t2_new
[[None, 2, 3], [1, 4], [5]]
sage: t1_new.outer_shape() == t2.outer_shape()
True
sage: t2_new.inner_shape() == t1.inner_shape()
True
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(3),
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,
↪Integer(4)], [Integer(1), Integer(2), Integer(5)]])
>>> (t2_new, t1_new) = t1.shuffle(t2)
>>> t1_new
[[None, None, None, 2], [None, None, 1], [None, 3, 4]]
>>> t2_new
[[None, 2, 3], [1, 4], [5]]
>>> t1_new.outer_shape() == t2.outer_shape()
True
>>> t2_new.inner_shape() == t1.inner_shape()
True
```

Shuffling is an involution:

```
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: sh = lambda x,y : x.shuffle(y)
sage: (t1, t2) == sh(*sh(t1, t2))
True
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(3),
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,
↪Integer(4)], [Integer(1), Integer(2), Integer(5)]])
>>> sh = lambda x,y : x.shuffle(y)
>>> (t1, t2) == sh(*sh(t1, t2))
True
```

Both tableaux must be standard:

```
sage: t1 = SkewTableau([[None, 1, 2], [2, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 5]])
sage: t1.shuffle(t2)
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
sage: t1 = SkewTableau([[None, 1, 2], [3, 4]])
sage: t2 = SkewTableau([[None, None, None, 3], [None, None, 4], [1, 2, 6]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...

↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,␣
↪Integer(4)], [Integer(1), Integer(2), Integer(5)]])
>>> t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
>>> t1 = SkewTableau([[None, Integer(1), Integer(2)], [Integer(3),␣
↪Integer(4)]])
>>> t2 = SkewTableau([[None, None, None, Integer(3)], [None, None,␣
↪Integer(4)], [Integer(1), Integer(2), Integer(6)]])
>>> t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the tableaux must be standard
```

The shapes (not just the nonempty cells) must be adjacent:

```
sage: t1 = SkewTableau([[None, None, None], [1]])
sage: t2 = SkewTableau([[None], [None], [1]])
sage: t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the shapes must be adjacent
```

```
>>> from sage.all import *
>>> t1 = SkewTableau([[None, None, None], [Integer(1)]])
>>> t2 = SkewTableau([[None], [None], [Integer(1)]])
>>> t1.shuffle(t2)
Traceback (most recent call last):
...
ValueError: the shapes must be adjacent
```

size()

Return the number of cells in `self`.

EXAMPLES:

```
sage: SkewTableau([[None, 2, 4], [None, 3], [1]]).size()
4
```

(continues on next page)

(continued from previous page)

```
sage: SkewTableau([[None, 2], [1, 3]]).size()
3
```

```
>>> from sage.all import *
>>> SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],␣
↪[Integer(1)]]).size()
4
>>> SkewTableau([[None, Integer(2)], [Integer(1), Integer(3)]]).size()
3
```

slide(*corner=None*, *return_vacated=False*)

Apply a jeu de taquin slide to `self` on the specified inner corner and return the resulting tableau.

If no corner is given, the topmost inner corner is chosen.

The optional parameter `return_vacated=True` causes the output to be the pair `(t, (i, j))` where `t` is the new tableau and `(i, j)` are the coordinates of the vacated square.

See [Ful1997] p12-13.

EXAMPLES:

```
sage: st = SkewTableau([[None, None, None, None, 2], [None, None, None, None,␣
↪6], [None, 2, 4, 4], [2, 3, 6], [5, 5]])
sage: st.slide((2, 0))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3,␣
↪5, 6], [5]]
sage: st2 = SkewTableau([[None, None, 3], [None, 2, 4], [1, 5]])
sage: st2.slide((1, 0), True)
([[None, None, 3], [1, 2, 4], [5]], (2, 1))
```

```
>>> from sage.all import *
>>> st = SkewTableau([[None, None, None, None, Integer(2)], [None, None, None,
↪ None, Integer(6)], [None, Integer(2), Integer(4), Integer(4)], [Integer(2),
↪ Integer(3), Integer(6)], [Integer(5), Integer(5)]])
>>> st.slide((Integer(2), Integer(0)))
[[None, None, None, None, 2], [None, None, None, None, 6], [2, 2, 4, 4], [3,␣
↪5, 6], [5]]
>>> st2 = SkewTableau([[None, None, Integer(3)], [None, Integer(2),␣
↪Integer(4)], [Integer(1), Integer(5)]])
>>> st2.slide((Integer(1), Integer(0)), True)
([[None, None, 3], [1, 2, 4], [5]], (2, 1))
```

standardization(*check=True*)

Return the standardization of `self`, assuming `self` is a semistandard skew tableau.

The standardization of a semistandard skew tableau T is the standard skew tableau st(T) of the same shape as T whose reversed reading word is the standardization of the reversed reading word of T.

The standardization of a word w can be formed by replacing all 1's in w by $1, 2, \ldots, k_1$ from left to right, all 2's in w by $k_1 + 1, k_1 + 2, \ldots, k_2$, and repeating for all letters that appear in w. See also `Word.standard_permutation()`.

INPUT:

- `check` – (default: `True`) check to make sure `self` is semistandard; set to `False` to avoid this check

EXAMPLES:

```
sage: t = SkewTableau([[None,None,3,4,7,19],[None,4,4,8],[None,5,16,17],
↪[None],[2],[3]])
sage: t.standardization()
[[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1],␣
↪[2]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,None,Integer(3),Integer(4),Integer(7),Integer(19)],
↪[None,Integer(4),Integer(4),Integer(8)],[None,Integer(5),Integer(16),
↪Integer(17)],[None],[Integer(2)],[Integer(3)]])
>>> t.standardization()
[[None, None, 3, 6, 8, 12], [None, 4, 5, 9], [None, 7, 10, 11], [None], [1],␣
↪[2]]
```

Standard skew tableaux are fixed under standardization:

```
sage: p = Partition([4,3,3,2])
sage: q = Partitions(3).random_element()                                    #␣
↪needs sage.libs.flint
sage: all(t == t.standardization()                                          #␣
↪needs sage.libs.flint
....:     for t in StandardSkewTableaux([p, q]))
True
```

```
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(3),Integer(2)])
>>> q = Partitions(Integer(3)).random_element()                              ␣
↪     # needs sage.libs.flint
>>> all(t == t.standardization()                                          #␣
↪needs sage.libs.flint
...     for t in StandardSkewTableaux([p, q]))
True
```

The reading word of the standardization is the standardization of the reading word:

```
sage: t = SkewTableau([[None,3,4,4],[None,6,10],[7,7,11],[18]])
sage: t.to_word().standard_permutation() == t.standardization().to_
↪permutation()
True
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None,Integer(3),Integer(4),Integer(4)],[None,Integer(6),
↪Integer(10)],[Integer(7),Integer(7),Integer(11)],[Integer(18)]])
>>> t.to_word().standard_permutation() == t.standardization().to_permutation()
True
```

to_chain(*max_entry=None*)

Return the chain of partitions corresponding to the (semi)standard skew tableau `self`.

The optional keyword parameter `max_entry` can be used to customize the length of the chain. Specifically, if this parameter is set to a nonnegative integer `n`, then the chain is constructed from the positions of the letters $1, 2, \ldots, n$ in the tableau.

EXAMPLES:

```
sage: SkewTableau([[None,1],[2],[3]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=2)
[[1], [2, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=3)
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
sage: SkewTableau([[None,1],[1],[2]]).to_chain(max_entry=1)
[[1], [2, 1]]
sage: SkewTableau([[None,None,2],[None,3],[None,5]]).to_chain(max_entry=6)
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
sage: SkewTableau([]).to_chain()
[[]]
sage: SkewTableau([]).to_chain(max_entry=1)
[[], []]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2)],[Integer(3)]]).to_chain()
[[1], [2], [2, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain()
[[1], [2, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_
↪entry=Integer(2))
[[1], [2, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_
↪entry=Integer(3))
[[1], [2, 1], [2, 1, 1], [2, 1, 1]]
>>> SkewTableau([[None,Integer(1)],[Integer(1)],[Integer(2)]]).to_chain(max_
↪entry=Integer(1))
[[1], [2, 1]]
>>> SkewTableau([[None,None,Integer(2)],[None,Integer(3)],[None,Integer(5)]]).
↪to_chain(max_entry=Integer(6))
[[2, 1, 1], [2, 1, 1], [3, 1, 1], [3, 2, 1], [3, 2, 1], [3, 2, 2], [3, 2, 2]]
>>> SkewTableau([]).to_chain()
[[]]
>>> SkewTableau([]).to_chain(max_entry=Integer(1))
[[], []]
```

to_expr()

The first list in a result corresponds to the inner partition of the skew shape. The second list is a list of the rows in the skew tableau read from the bottom up.

Provided for compatibility with MuPAD-Combinat. In MuPAD-Combinat, if `t` is a skew tableau, then to_expr gives the same result as `expr(t)` would give in MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableau([[None,1,1,3],[None,2,2],[1]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
sage: SkewTableau([]).to_expr()
[[], []]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1),Integer(1),Integer(3)],[None,Integer(2),
↪Integer(2)],[Integer(1)]]).to_expr()
[[1, 1], [[1], [2, 2], [1, 1, 3]]]
>>> SkewTableau([]).to_expr()
[[], []]
```

to_list()

Return a (mutable) list representation of `self`.

EXAMPLES:

```
sage: stlist = [[None, None, 3], [None, 1, 3], [2, 2]]
sage: st = SkewTableau(stlist)
sage: st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
sage: st.to_list() == stlist
True
```

```
>>> from sage.all import *
>>> stlist = [[None, None, Integer(3)], [None, Integer(1), Integer(3)],␣
↪[Integer(2), Integer(2)]]
>>> st = SkewTableau(stlist)
>>> st.to_list()
[[None, None, 3], [None, 1, 3], [2, 2]]
>>> st.to_list() == stlist
True
```

to_permutation()

Return a permutation with the entries of `self` obtained by reading `self` row by row, from the bottommost to the topmost row, with each row being read from left to right, in English convention. See *to_word_by_row()*.

EXAMPLES:

```
sage: SkewTableau([[None,2],[3,4],[None],[1]]).to_permutation()
[1, 3, 4, 2]
sage: SkewTableau([[None,2],[None,4],[1],[3]]).to_permutation()
[3, 1, 4, 2]
sage: SkewTableau([[None]]).to_permutation()
[]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(2)],[Integer(3),Integer(4)],[None],
↪[Integer(1)]]).to_permutation()
[1, 3, 4, 2]
>>> SkewTableau([[None,Integer(2)],[None,Integer(4)],[Integer(1)],
↪[Integer(3)]]).to_permutation()
[3, 1, 4, 2]
>>> SkewTableau([[None]]).to_permutation()
[]
```

to_ribbon(*check_input=True*)

Return `self` as a ribbon-shaped tableau (*RibbonShapedTableau*), provided that the shape of `self` is a ribbon.

INPUT:

- `check_input` – boolean (default: `True`); whether or not to check that `self` indeed has ribbon shape

EXAMPLES:

```
sage: SkewTableau([[None,1],[2,3]]).to_ribbon()
[[None, 1], [2, 3]]
```

```
>>> from sage.all import *
>>> SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]]).to_ribbon()
[[None, 1], [2, 3]]
```

to_tableau()

Return a tableau with the same filling. This only works if the inner shape of the skew tableau has size zero.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).to_tableau()
[[1, 2], [3, 4]]
```

```
>>> from sage.all import *
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).to_
↪tableau()
[[1, 2], [3, 4]]
```

to_word()

Return a word obtained from a row reading of `self`.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
  .  2  4
  .  3
  1
sage: s.to_word_by_row()
word: 1324
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> s.pp()
  .  1
  2  3
```

(continues on next page)

(continued from previous page)

```
>>> s.to_word_by_row()
word: 231
>>> s = SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],
↪[Integer(1)]])
>>> s.pp()
  .  2  4
  .  3
  1
>>> s.to_word_by_row()
word: 1324
```

to_word_by_column()

Return the word obtained from a column reading of the skew tableau.

This is the word obtained by concatenating the columns from the rightmost one (in English notation) to the leftmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
sage: s.to_word_by_column()
word: 132
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> s.pp()
  .  1
  2  3
>>> s.to_word_by_column()
word: 132
```

```
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
.  2  4
.  3
1
sage: s.to_word_by_column()
word: 4231
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],
↪[Integer(1)]])
>>> s.pp()
.  2  4
.  3
1
>>> s.to_word_by_column()
word: 4231
```

to_word_by_row()

Return a word obtained from a row reading of `self`.

This is the word obtained by concatenating the rows from the bottommost one (in English notation) to the topmost one.

EXAMPLES:

```
sage: s = SkewTableau([[None,1],[2,3]])
sage: s.pp()
  .  1
  2  3
sage: s.to_word_by_row()
word: 231
sage: s = SkewTableau([[None, 2, 4], [None, 3], [1]])
sage: s.pp()
  .  2  4
  .  3
  1
sage: s.to_word_by_row()
word: 1324
```

```
>>> from sage.all import *
>>> s = SkewTableau([[None,Integer(1)],[Integer(2),Integer(3)]])
>>> s.pp()
  .  1
  2  3
>>> s.to_word_by_row()
word: 231
>>> s = SkewTableau([[None, Integer(2), Integer(4)], [None, Integer(3)],
↪[Integer(1)]])
>>> s.pp()
  .  2  4
  .  3
  1
>>> s.to_word_by_row()
word: 1324
```

weight()

Return the weight (aka evaluation) of the tableau `self`. Trailing zeroes are omitted when returning the weight.

The weight of a skew tableau T is the sequence $(a_1, a_2, a_3, \ldots)$, where a_k is the number of entries of T equal to k. This sequence contains only finitely many nonzero entries.

The weight of a skew tableau T is the same as the weight of the reading word of T, for any reading order.

evaluation() is a synonym for this method.

EXAMPLES:

```
sage: SkewTableau([[1,2],[3,4]]).weight()
[1, 1, 1, 1]

sage: SkewTableau([[None,2],[None,4],[None,5],[None]]).weight()
[0, 1, 0, 1, 1]
```

(continues on next page)

(continued from previous page)

```
sage: SkewTableau([]).weight()
[]

sage: SkewTableau([[None,None,None], [None]]).weight()
[]

sage: SkewTableau([[None,3,4],[None,6,7],[4,8],[5,13],[6],[7]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

```
>>> from sage.all import *
>>> SkewTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).weight()
[1, 1, 1, 1]

>>> SkewTableau([[None,Integer(2)],[None,Integer(4)],[None,Integer(5)],
↪[None]]).weight()
[0, 1, 0, 1, 1]

>>> SkewTableau([]).weight()
[]

>>> SkewTableau([[None,None,None], [None]]).weight()
[]

>>> SkewTableau([[None,Integer(3),Integer(4)],[None,Integer(6),Integer(7)],
↪[Integer(4),Integer(8)],[Integer(5),Integer(13)],[Integer(6)],
↪[Integer(7)]]).weight()
[0, 0, 1, 2, 1, 2, 2, 1, 0, 0, 0, 0, 1]
```

class sage.combinat.skew_tableau.**SkewTableau_class**(*parent*, *st*)

Bases: *SkewTableau*

This exists solely for unpickling `SkewTableau_class` objects.

class sage.combinat.skew_tableau.**SkewTableaux**(*category=None*)

Bases: `UniqueRepresentation`, `Parent`

Class of all skew tableaux.

Element

alias of *SkewTableau*

from_chain(*chain*)

Return the tableau corresponding to the chain of partitions.

EXAMPLES:

```
sage: SkewTableaux().from_chain([[1,1],[2,1],[3,1],[3,2],[3,3],[3,3,1]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> SkewTableaux().from_chain([[Integer(1),Integer(1)],[Integer(2),
↪Integer(1)],[Integer(3),Integer(1)],[Integer(3),Integer(2)],[Integer(3),
↪Integer(3)],[Integer(3),Integer(3),Integer(1)]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_expr(*expr*)

Return a *SkewTableau* from a MuPAD-Combinat expr for a skew tableau.

The first list in `expr` is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

```
sage: SkewTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```
>>> from sage.all import *
>>> SkewTableaux().from_expr([[Integer(1),Integer(1)],[[Integer(5)],
→[Integer(3),Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

from_shape_and_word(*shape*, *word*)

Return the skew tableau corresponding to the skew partition `shape` and the word `word` obtained from the row reading.

EXAMPLES:

```
sage: t = SkewTableau([[None, 1, 3], [None, 2], [4]])
sage: shape = t.shape()
sage: word  = t.to_word()
sage: SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

```
>>> from sage.all import *
>>> t = SkewTableau([[None, Integer(1), Integer(3)], [None, Integer(2)],␣
→[Integer(4)]])
>>> shape = t.shape()
>>> word  = t.to_word()
>>> SkewTableaux().from_shape_and_word(shape, word)
[[None, 1, 3], [None, 2], [4]]
```

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.skew_tableau.**StandardSkewTableaux**(*category=None*)

Bases: *SkewTableaux*

Standard skew tableaux.

EXAMPLES:

```
sage: S = StandardSkewTableaux(); S
Standard skew tableaux
sage: S.cardinality()
+Infinity
```

```
>>> from sage.all import *
>>> S = StandardSkewTableaux(); S
```

(continues on next page)

(continued from previous page)

```
Standard skew tableaux
>>> S.cardinality()
+Infinity
```

```
sage: S = StandardSkewTableaux(2); S
Standard skew tableaux of size 2
sage: S.cardinality()                                                           #␣
↪needs sage.modules
4
```

```
>>> from sage.all import *
>>> S = StandardSkewTableaux(Integer(2)); S
Standard skew tableaux of size 2
>>> S.cardinality()                                                         #␣
↪needs sage.modules
4
```

```
sage: # needs sage.graphs sage.modules
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).list()
[[[None, 2, 3], [None, 4], [1]],
 [[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 2, 4], [None, 3], [1]]]
```

```
>>> from sage.all import *
>>> # needs sage.graphs sage.modules
>>> StandardSkewTableaux([[Integer(3), Integer(2), Integer(1)], [Integer(1),␣
↪Integer(1)]]).list()
[[[None, 2, 3], [None, 4], [1]],
 [[None, 1, 2], [None, 3], [4]],
 [[None, 1, 2], [None, 4], [3]],
 [[None, 1, 3], [None, 4], [2]],
 [[None, 1, 4], [None, 3], [2]],
 [[None, 1, 4], [None, 2], [3]],
 [[None, 1, 3], [None, 2], [4]],
 [[None, 2, 4], [None, 3], [1]]]
```

class sage.combinat.skew_tableau.**StandardSkewTableaux_all**

Bases: *StandardSkewTableaux*

Class of all standard skew tableaux.

class sage.combinat.skew_tableau.**StandardSkewTableaux_shape**(*skp*)

Bases: *StandardSkewTableaux*

Standard skew tableaux of a fixed skew shape λ/μ.

cardinality()

Return the number of standard skew tableaux with shape of the skew partition skp. This uses a formula due to Aitken (see Cor. 7.16.3 of [Sta-EC2]).

EXAMPLES:

```
sage: StandardSkewTableaux([[3, 2, 1], [1, 1]]).cardinality()              #␣
↪needs sage.modules
8
```

```
>>> from sage.all import *
>>> StandardSkewTableaux([[Integer(3), Integer(2), Integer(1)], [Integer(1),␣
↪Integer(1)]]).cardinality()              # needs sage.modules
8
```

class sage.combinat.skew_tableau.**StandardSkewTableaux_size**(*n*)

Bases: *StandardSkewTableaux*

Standard skew tableaux of a fixed size n.

cardinality()

EXAMPLES:

```
sage: # needs sage.modules
sage: StandardSkewTableaux(1).cardinality()
1
sage: StandardSkewTableaux(2).cardinality()
4
sage: StandardSkewTableaux(3).cardinality()
24
sage: StandardSkewTableaux(4).cardinality()
194
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> StandardSkewTableaux(Integer(1)).cardinality()
1
>>> StandardSkewTableaux(Integer(2)).cardinality()
4
>>> StandardSkewTableaux(Integer(3)).cardinality()
24
>>> StandardSkewTableaux(Integer(4)).cardinality()
194
```

5.1.314 Functions that compute some of the sequences in Sloane's tables

EXAMPLES:

Type `sloane.[tab]` to see a list of the sequences that are defined.

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a(1)
1
sage: a(6)
4
```

(continues on next page)

(continued from previous page)

```
sage: a(100)
9
```

```
>>> from sage.all import *
>>> a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
>>> a(Integer(1))
1
>>> a(Integer(6))
4
>>> a(Integer(100))
9
```

Type `d._eval??` to see how the function that computes an individual term of the sequence is implemented.

The input must be a positive integer:

```
sage: a(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

```
>>> from sage.all import *
>>> a(Integer(0))
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
>>> a(Integer(1)/Integer(3))
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

You can also change how a sequence prints:

```
sage: a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
sage: a.rename('(..., tau(n), ...)')
sage: a
(..., tau(n), ...)
sage: a.reset_name()
sage: a
The integer sequence tau(n), which is the number of divisors of n.
```

```
>>> from sage.all import *
>>> a = sloane.A000005; a
The integer sequence tau(n), which is the number of divisors of n.
>>> a.rename('(..., tau(n), ...)')
>>> a
```

(continues on next page)

(continued from previous page)

```
(..., tau(n), ...)
>>> a.reset_name()
>>> a
The integer sequence tau(n), which is the number of divisors of n.
```

See also:

- If you want to get more informations relative to a sequence (references, links, examples, programs, …), you can use the On-Line Encyclopedia of Integer Sequences provided by the `OEIS` module.
- If you plan to do a lot of automatic searches for subsequences, you should consider installing `SloaneEncyclopedia`, a local partial copy of the OEIS.

class sage.combinat.sloane_functions.**A000005**

Bases: *SloaneSequence*

The sequence $tau(n)$, which is the number of divisors of n.

This sequence is also denoted $d(n)$ (also called $\tau(n)$ or $\sigma_0(n)$), the number of divisors of n.

INPUT:

- n – positive integer

EXAMPLES:

```
sage: d = sloane.A000005; d
The integer sequence tau(n), which is the number of divisors of n.
sage: d(1)
1
sage: d(6)
4
sage: d(51)
4
sage: d(100)
9
sage: d(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
sage: d.list(10)
[1, 2, 2, 3, 2, 4, 2, 4, 3, 4]
```

```
>>> from sage.all import *
>>> d = sloane.A000005; d
The integer sequence tau(n), which is the number of divisors of n.
>>> d(Integer(1))
1
>>> d(Integer(6))
4
>>> d(Integer(51))
4
>>> d(Integer(100))
9
>>> d(Integer(0))
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
>>> d.list(Integer(10))
[1, 2, 2, 3, 2, 4, 2, 4, 3, 4]
```

- Jaap Spies (2007-01-30)

cf()

EXAMPLES:

```
sage: it = sloane.A000009.cf()
sage: [next(it) for i in range(14)]
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

```
>>> from sage.all import *
>>> it = sloane.A000009.cf()
>>> [next(it) for i in range(Integer(14))]
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

list(n)

EXAMPLES:

```
sage: sloane.A000009.list(14)
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

```
>>> from sage.all import *
>>> sloane.A000009.list(Integer(14))
[1, 1, 1, 2, 2, 3, 4, 5, 6, 8, 10, 12, 15, 18]
```

class sage.combinat.sloane_functions.**A000010**

Bases: *SloaneSequence*

The integer sequence A000010 is Euler's totient function.

Number of positive integers $i < n$ that are relative prime to n. Number of totatives of n.

Euler totient function $\phi(n)$: count numbers n and prime to n. `euler_phi` is a standard Sage function implemented in PARI.

INPUT:

- `n` – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A000010; a
Euler's totient function
sage: a(1)
1
sage: a(0)
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
sage: a(11)
10
sage: a.list(12)
[1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 4]
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

```
>>> from sage.all import *
>>> a = sloane.A000010; a
Euler's totient function
>>> a(Integer(1))
1
>>> a(Integer(0))
Traceback (most recent call last):
...
ValueError: input n (=0) must be a positive integer
>>> a(Integer(11))
10
>>> a.list(Integer(12))
[1, 1, 2, 2, 4, 2, 6, 4, 6, 4, 10, 4]
>>> a(Integer(1)/Integer(3))
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

ValueError: input n (=0) must be a positive integer
```

AUTHORS:

- Jaap Spies (2007-01-18)

class sage.combinat.sloane_functions.**A000016**

Bases: *SloaneSequence*

Sloane's A000016.

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A000016; a
Sloane's A000016.
sage: a(1)
1
sage: a(0)
1
sage: a(8)
16
sage: a(75)
251859545753048193000
sage: a(-4)
Traceback (most recent call last):
...
ValueError: input n (=-4) must be an integer >= 0
sage: a.list(12)
[1, 1, 1, 2, 2, 4, 6, 10, 16, 30, 52, 94]
```

```
>>> from sage.all import *
>>> a = sloane.A000016; a
Sloane's A000016.
>>> a(Integer(1))
1
>>> a(Integer(0))
1
>>> a(Integer(8))
16
>>> a(Integer(75))
251859545753048193000

Traceback (most recent call last):
...
ValueError: input n (=-4) must be an integer >= 0
>>> a.list(Integer(12))
[1, 1, 1, 2, 2, 4, 6, 10, 16, 30, 52, 94]
```

AUTHORS:

- Jaap Spies (2007-01-18)

class sage.combinat.sloane_functions.**A000027**

Bases: *SloaneSequence*

The natural numbers. Also called the whole numbers, the counting numbers or the positive integers.

The following examples are tests of SloaneSequence more than A000027.

EXAMPLES:

```
sage: s = sloane.A000027; s
The natural numbers.
sage: s(10)
10
```

```
>>> from sage.all import *
>>> s = sloane.A000027; s
The natural numbers.
>>> s(Integer(10))
10
```

Index n is interpreted as _eval(n):

```
sage: s[10]
10
```

```
>>> from sage.all import *
>>> s[Integer(10)]
10
```

Slices are interpreted with absolute offsets, so the following returns the terms of the sequence up to but not including the third term:

```
sage: s[:3]
[1, 2]
sage: s[3:6]
[3, 4, 5]
sage: s.list(5)
[1, 2, 3, 4, 5]
```

```
>>> from sage.all import *
>>> s[:Integer(3)]
[1, 2]
>>> s[Integer(3):Integer(6)]
[3, 4, 5]
>>> s.list(Integer(5))
[1, 2, 3, 4, 5]
```

class sage.combinat.sloane_functions.**A000043**

Bases: *SloaneSequence*

Primes p such that $2^p - 1$ is prime. $2^p - 1$ is then called a Mersenne prime.

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A000043;a
Primes p such that 2^p - 1 is prime. 2^p - 1 is then called a Mersenne prime.
sage: a(1)
2
sage: a(2)
3
sage: a(39)
13466917
sage: a(40)
Traceback (most recent call last):
...
IndexError: list index out of range
sage: a.list(12)
[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127]
```

```
>>> from sage.all import *
>>> a = sloane.A000043;a
Primes p such that 2^p - 1 is prime. 2^p - 1 is then called a Mersenne prime.
>>> a(Integer(1))
2
>>> a(Integer(2))
3
>>> a(Integer(39))
13466917
>>> a(Integer(40))
Traceback (most recent call last):
...
IndexError: list index out of range
>>> a.list(Integer(12))
[2, 3, 5, 7, 13, 17, 19, 31, 61, 89, 107, 127]
```

AUTHORS:

- Jaap Spies (2007-01-26)

class sage.combinat.sloane_functions.**A000045**

Bases: *SloaneSequence*

Sequence of Fibonacci numbers, offset 0,4.

REFERENCES:

- S. Plouffe, Project Gutenberg, The First 1001 Fibonacci Numbers, http://ibiblio.org/pub/docs/books/gutenberg/etext01/fbncc10.txt

We have one more. Our first Fibonacci number is 0.

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A000045; a
Fibonacci numbers with index n >= 0
sage: a(0)
0
sage: a(1)
1
sage: a.list(12)
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

```
>>> from sage.all import *
>>> a = sloane.A000045; a
Fibonacci numbers with index n >= 0
>>> a(Integer(0))
0
>>> a(Integer(1))
1
>>> a.list(Integer(12))
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34, 55, 89]
>>> a(Integer(1)/Integer(3))
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

AUTHORS:

- Jaap Spies (2007-01-13)

fib()

Return a generator over all Fibonacci numbers, starting with 0.

EXAMPLES:

```
sage: it = sloane.A000045.fib()
sage: [next(it) for i in range(10)]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

```
>>> from sage.all import *
>>> it = sloane.A000045.fib()
>>> [next(it) for i in range(Integer(10))]
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

list(*n*)

EXAMPLES:

```
sage: sloane.A000045.list(10)
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

```
>>> from sage.all import *
>>> sloane.A000045.list(Integer(10))
[0, 1, 1, 2, 3, 5, 8, 13, 21, 34]
```

class sage.combinat.sloane_functions.**A000069**

Bases: *SloaneSequence*

Odious numbers: odd number of 1s in binary expansion.

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A000069; a
Odious numbers: odd number of 1s in binary expansion.
sage: a(0)
1
sage: a(2)
4
sage: a.list(9)
[1, 2, 4, 7, 8, 11, 13, 14, 16]
```

```
>>> from sage.all import *
>>> a = sloane.A000069; a
Odious numbers: odd number of 1s in binary expansion.
>>> a(Integer(0))
1

Bases: *ExtremesOfPermanentsSequence*

$a(n) = n * a(n-1) + (n-4) * a(n-2)$, with $a(2) = 0$, $a(3) = 1$.

With offset 1, permanent of (0,1)-matrix of size $n \times (n+d)$ with $d = 4$ and n zeros not on a line. This is a special case of Theorem 2.3 of Seok-Zun Song et al. Extremes of permanents of (0,1)-matrices, p. 201-202.

Seok-Zun Song et al., Extremes of permanents of (0,1)-matrices, Lin. Algebra and its Applic. 373 (2003), p. 197-210.

INPUT:

- n – positive integer >= 2

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A001909;a
a(n) = n*a(n-1) + (n-4)*a(n-2), a(2) = 0, a(3) = 1.
sage: a(1)

class sage.combinat.sloane_functions.**A083105**

Bases: *RecurrenceSequence2*

Second-order linear recurrence sequence with $a(n) = a(n-1) + a(n-2)$.

$a(0) = 62638280004239857$, $a(1) = 49463435743205655$. This is the second-order linear recurrence sequence with $a(0)$ and $a(1)$ co-prime. It was found by Donald Knuth in 1990.

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A083105;a
Second-order linear recurrence sequence with a(n) = a(n-1) + a(n-2).
sage: a(1)

class sage.combinat.sloane_functions.**A109814**

Bases: *SloaneSequence*

The n th term of the sequence $a(n)$ is the largest k such that n can be written as sum of k consecutive integers.

By definition, n is the sum of at most $a(n)$ consecutive positive integers. Suppose n is to be written as sum of k consecutive integers starting with m, then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor d of n there is a unique corresponding $k = min(d, 2n/d)$. $a(n)$ can be alternatively defined as the largest among those k .

```

AUTHORS:

- Jaap Spies (2007-01-13)

is_number_of_the_third_kind(n)

Return `True` if and only if n is a number of the third kind.

A number is of the third kind if it can be written as a sum of at least three consecutive positive integers. Odd primes can only be written as a sum of two consecutive integers. Powers of 2 do not have a representation as a sum of k consecutive integers (other than the trivial $n = n$ for $k = 1$).

See: http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf

INPUT:

- `n` – positive integer

OUTPUT: `True` if n is not prime and not a power of 2

EXAMPLES:

```
sage: a = sloane.A111774
sage: a.is_number_of_the_third_kind(6)
True
sage: a.is_number_of_the_third_kind(100)
True
sage: a.is_number_of_the_third_kind(16)
False
sage: a.is_number_of_the_third_kind(97)
False
```

```
>>> from sage.all import *
>>> a = sloane.A111774
>>> a.is_number_of_the_third_kind(Integer(6))
True
>>> a.is_number_of_the_third_kind(Integer(100))
True
>>> a.is_number_of_the_third_kind(Integer(16))

>>> a.is_number_of_the_third_kind(Integer(97))
False
```

AUTHORS:

- Jaap Spies (2006-12-09)

list(n)

EXAMPLES:

```
sage: sloane.A111774.list(12)
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
```

```
>>> from sage.all import *
>>> sloane.A111774.list(Integer(12))
[6, 9, 10, 12, 14, 15, 18, 20, 21, 22, 24, 25]
```

class sage.combinat.sloane_functions.**A111775**

Bases: *SloaneSequence*

Number of ways n can be written as a sum of at least three consecutive integers.

Powers of 2 and (odd) primes can not be written as a sum of at least three consecutive integers. $a(n)$ strongly depends on the number of odd divisors of n (A001227): Suppose n is to be written as sum of k consecutive integers starting with m, then $2n = k(2m + k - 1)$. Only one of the factors is odd. For each odd divisor of n there is a unique corresponding k, $k = 1$ and $k = 2$ must be excluded.

See: http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A111775; a
Number of ways n can be written as a sum of at least three consecutive integers.
```

```
>>> from sage.all import *
>>> a = sloane.A111775; a
Number of ways n can be written as a sum of at least three consecutive integers.
```

```
sage: a(1)
0
sage: a(0)
0
```

```
>>> from sage.all import *
>>> a(Integer(1))
0
>>> a(Integer(0))
0
```

We have a(15)=2 because 15 = 4+5+6 and 15 = 1+2+3+4+5. The number of odd divisors of 15 is 4.

```
sage: a(15)
2
```

```
>>> from sage.all import *
>>> a(Integer(15))
2
```

```
sage: a(100)
2
sage: a(256)
0
```

(continues on next page)

(continued from previous page)

```
sage: a(29)
0
sage: a.list(20)
[0, 0, 0, 0, 0, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 2, 0, 0, 2, 0]
sage: a(1/3)
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

```
>>> from sage.all import *
>>> a(Integer(100))
2
>>> a(Integer(256))
0
>>> a(Integer(29))
0
>>> a.list(Integer(20))
[0, 0, 0, 0, 0, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 2, 0, 0, 2, 0]
>>> a(Integer(1)/Integer(3))
Traceback (most recent call last):
...
TypeError: input must be an int or Integer
```

class sage.combinat.sloane_functions.**A111787**

Bases: *SloaneSequence*

This function returns the n-th number of Sloane's sequence A111787

$a(n) = 0$ if n is an odd prime or a power of 2. For numbers of the third kind (see A111774) we proceed as follows: suppose n is to be written as sum of k consecutive integers starting with m, then $2n = k(2m + k - 1)$. Let p be the smallest odd prime divisor of n then $a(n) = min(p, 2n/p)$.

See: http://www.jaapspies.nl/mathfiles/problem2005-2C.pdf

INPUT:

- n – nonnegative integer

OUTPUT: integer; function value

EXAMPLES:

```
sage: a = sloane.A111787; a
a(n) is the least k >= 3 such that n can be written as sum of k consecutive␣
↪integers. a(n)=0 if such a k does not exist.
sage: a.offset

class sage.combinat.sloane_functions.**ExponentialNumbers**(*a*)

Bases: *SloaneSequence*

A sequence of Exponential numbers.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import ExponentialNumbers
sage: ExponentialNumbers(0)
Sequence of Exponential numbers around 0
```

```
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import ExponentialNumbers
>>> ExponentialNumbers(Integer(0))
Sequence of Exponential numbers around 0
```

class sage.combinat.sloane_functions.**ExtremesOfPermanentsSequence**(*offset=1*)

Bases: *SloaneSequence*

gen(*a0*, *a1*, *d*)

EXAMPLES:

```
sage: it = sloane.A000153.gen(0,1,2)
sage: [next(it) for i in range(5)]
[0, 1, 2, 7, 32]
```

```
>>> from sage.all import *
>>> it = sloane.A000153.gen(Integer(0),Integer(1),Integer(2))
>>> [next(it) for i in range(Integer(5))]
[0, 1, 2, 7, 32]
```

list(*n*)

EXAMPLES:

```
sage: sloane.A000153.list(8)
[0, 1, 2, 7, 32, 181, 1214, 9403]
```

```
>>> from sage.all import *
>>> sloane.A000153.list(Integer(8))
[0, 1, 2, 7, 32, 181, 1214, 9403]
```

class sage.combinat.sloane_functions.**ExtremesOfPermanentsSequence2**(*offset=1*)

Bases: *ExtremesOfPermanentsSequence*

gen(*a0*, *a1*, *d*)

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
sage: e = ExtremesOfPermanentsSequence2()
sage: it = e.gen(6,43,6)
sage: [next(it) for i in range(5)]
[6, 43, 307, 2542, 23799]
```

```
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import ExtremesOfPermanentsSequence2
>>> e = ExtremesOfPermanentsSequence2()
>>> it = e.gen(Integer(6),Integer(43),Integer(6))
>>> [next(it) for i in range(Integer(5))]
[6, 43, 307, 2542, 23799]
```

class sage.combinat.sloane_functions.**RecurrenceSequence**(*offset=1*)

Bases: *SloaneSequence*

list(*n*)

EXAMPLES:

```
sage: sloane.A001110.list(8)
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

```
>>> from sage.all import *
>>> sloane.A001110.list(Integer(8))
[0, 1, 36, 1225, 41616, 1413721, 48024900, 1631432881]
```

class sage.combinat.sloane_functions.**RecurrenceSequence2**(*offset=1*)

Bases: *SloaneSequence*

list(*n*)

EXAMPLES:

```
sage: sloane.A001906.list(10)
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]
```

```
>>> from sage.all import *
>>> sloane.A001906.list(Integer(10))
[0, 1, 3, 8, 21, 55, 144, 377, 987, 2584]
```

class sage.combinat.sloane_functions.**Sloane**

Bases: SageObject

A collection of Sloane generating functions.

This class inspects sage.combinat.sloane_functions, accumulating all the SloaneSequence classes starting with 'A'. These are listed for tab completion, but not instantiated until requested.

EXAMPLES:

Ensure we have lots of entries:

```
sage: len(sloane.__dir__()) > 100
True
```

```
>>> from sage.all import *
>>> len(sloane.__dir__()) > Integer(100)
True
```

Ensure none are being incorrectly returned:

```
sage: [ None for n in sloane.__dir__() if not n.startswith('A') ]
[]
```

```
>>> from sage.all import *
>>> [ None for n in sloane.__dir__() if not n.startswith('A') ]
[]
```

Ensure we can access dynamic constructions and cache correctly:

```
sage: s = sloane.A000587
sage: s is sloane.A000587
True
```

```
>>> from sage.all import *
>>> s = sloane.A000587
>>> s is sloane.A000587
True
```

Ensure that we can access other functions in parent classes:

```
sage: sloane.__class__
<class 'sage.combinat.sloane_functions.Sloane'>
```

```
>>> from sage.all import *
>>> sloane.__class__
<class 'sage.combinat.sloane_functions.Sloane'>
```

AUTHORS:

- Nick Alexander

class sage.combinat.sloane_functions.**SloaneSequence**(*offset=1*)

Bases: SageObject

Base class for a Sloane integer sequence.

list(*n*)

Return n terms of the sequence:

```
sequence[offset], sequence[offset+1], ..., sequence[offset+n-1].
```

EXAMPLES:

```
sage: sloane.A000012.list(4)
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> sloane.A000012.list(Integer(4))
[1, 1, 1, 1]
```

sage.combinat.sloane_functions.**perm_mh**(*m*, *h*)

This functions calculates $f(g, h)$ from Sloane's sequences A079908-A079928

INPUT:

- m – positive integer
- h – nonnegative integer

OUTPUT: permanent of the $m \times (m + h)$ matrix, etc.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import perm_mh
sage: perm_mh(3,3)
```

(continues on next page)

(continued from previous page)

```
36
sage: perm_mh(3,4)
76
```

```
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import perm_mh
>>> perm_mh(Integer(3),Integer(3))
36
>>> perm_mh(Integer(3),Integer(4))
76
```

AUTHORS:

- Jaap Spies (2006)

sage.combinat.sloane_functions.**recur_gen2**(*a0*, *a1*, *a2*, *a3*)

Homogeneous general second-order linear recurrence generator with fixed coefficients.

a(0) = a0, a(1) = a1, a(n) = a2*a(n-1) + a3*a(n-2)

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2
sage: it = recur_gen2(1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

```
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import recur_gen2
>>> it = recur_gen2(Integer(1),Integer(1),Integer(1),Integer(1))
>>> [next(it) for i in range(Integer(10))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

sage.combinat.sloane_functions.**recur_gen2b**(*a0*, *a1*, *a2*, *a3*, *b*)

Inhomogeneous second-order linear recurrence generator with fixed coefficients and $b = f(n)$

$a(0) = a0$, $a(1) = a1$, $a(n) = a2 * a(n-1) + a3 * a(n-2) + f(n)$.

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen2b
sage: it = recur_gen2b(1,1,1,1, lambda n: 0)
sage: [next(it) for i in range(10)]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

```
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import recur_gen2b
>>> it = recur_gen2b(Integer(1),Integer(1),Integer(1),Integer(1), lambda n:␣
→Integer(0))
>>> [next(it) for i in range(Integer(10))]
[1, 1, 2, 3, 5, 8, 13, 21, 34, 55]
```

sage.combinat.sloane_functions.**recur_gen3**(*a0*, *a1*, *a2*, *a3*, *a4*, *a5*)

Homogeneous general third-order linear recurrence generator with fixed coefficients a(0) = a0, a(1) = a1, a(2) = a2, a(n) = a3*a(n-1) + a4*a(n-2) + a5*a(n-3)

EXAMPLES:

```
sage: from sage.combinat.sloane_functions import recur_gen3
sage: it = recur_gen3(1,1,1,1,1,1)
sage: [next(it) for i in range(10)]
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

```
>>> from sage.all import *
>>> from sage.combinat.sloane_functions import recur_gen3
>>> it = recur_gen3(Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1))
>>> [next(it) for i in range(Integer(10))]
[1, 1, 1, 3, 5, 9, 17, 31, 57, 105]
```

5.1.315 Combinatorial species

Todo

Short blurb about species

Todo

Proofread / point to the main classes rather than the modules?

Introductory material

5.1.316 Characteristic Species

class sage.combinat.species.characteristic_species.**CharacteristicSpecies**(*n*, *min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the characteristic species of order n.

This species has exactly one structure on a set of size n and no structures on sets of any other size.

EXAMPLES:

```
sage: X = species.CharacteristicSpecies(1)
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series()[0:4]
[0, 1, 0, 0]
sage: X.isotype_generating_series()[0:4]
[0, 1, 0, 0]
sage: X.cycle_index_series()[0:4]                                    #␣
↪needs sage.modules
[0, p[1], 0, 0]

sage: F = species.CharacteristicSpecies(3)
sage: c = F.generating_series()[0:4]
sage: F._check()
True
sage: F == loads(dumps(F))
True
```

```
>>> from sage.all import *
>>> X = species.CharacteristicSpecies(Integer(1))
>>> X.structures([Integer(1)]).list()
[1]
>>> X.structures([Integer(1),Integer(2)]).list()
[]
>>> X.generating_series()[Integer(0):Integer(4)]
[0, 1, 0, 0]
```

(continues on next page)

(continued from previous page)

```
>>> X.isotype_generating_series()[Integer(0):Integer(4)]
[0, 1, 0, 0]
>>> X.cycle_index_series()[Integer(0):Integer(4)]                                   ␣
↪           # needs sage.modules
[0, p[1], 0, 0]

>>> F = species.CharacteristicSpecies(Integer(3))
>>> c = F.generating_series()[Integer(0):Integer(4)]
>>> F._check()
True
>>> F == loads(dumps(F))
True
```

class sage.combinat.species.characteristic_species.**CharacteristicSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

automorphism_group()

Return the group of permutations whose action on this structure leave it fixed. For the characteristic species, there is only one structure, so every permutation is in its automorphism group.

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()                                                        #␣
↪needs sage.groups
Symmetric group of order 3! as a permutation group
```

```
>>> from sage.all import *
>>> F = species.CharacteristicSpecies(Integer(3))
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> a.automorphism_group()                                                          #␣
↪needs sage.groups
Symmetric group of order 3! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```

```
>>> from sage.all import *
>>> F = species.CharacteristicSpecies(Integer(3))
>>> a = F.structures(["a", "b", "c"]).random_element(); a
```

(continues on next page)

(continued from previous page)

```
{'a', 'b', 'c'}
>>> a.canonical_label()
{'a', 'b', 'c'}
```

transport(*perm*)

Return the transport of this structure along the permutation `perm`.

EXAMPLES:

```
sage: F = species.CharacteristicSpecies(3)
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))                                    #␣
↪needs sage.groups
sage: a.transport(p)                                                        #␣
↪needs sage.groups
{'a', 'b', 'c'}
```

```
>>> from sage.all import *
>>> F = species.CharacteristicSpecies(Integer(3))
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> p = PermutationGroupElement((Integer(1),Integer(2)))                     ␣
↪              # needs sage.groups
>>> a.transport(p)                                                         #␣
↪needs sage.groups
{'a', 'b', 'c'}
```

sage.combinat.species.characteristic_species.**CharacteristicSpecies_class**

alias of *CharacteristicSpecies*

class sage.combinat.species.characteristic_species.**EmptySetSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *CharacteristicSpecies*

Return the empty set species.

This species has exactly one structure on the empty set. It is the same (and is implemented) as `CharacteristicSpecies(0)`.

EXAMPLES:

```
sage: X = species.EmptySetSpecies()
sage: X.structures([]).list()
[{}]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series()[0:4]
[1, 0, 0, 0]
sage: X.isotype_generating_series()[0:4]
[1, 0, 0, 0]
sage: X.cycle_index_series()[0:4]                                         #␣
↪needs sage.modules
[p[], 0, 0, 0]
```

```
>>> from sage.all import *
>>> X = species.EmptySetSpecies()
>>> X.structures([]).list()
[{}]
>>> X.structures([Integer(1),Integer(2)]).list()
[]
>>> X.generating_series()[Integer(0):Integer(4)]
[1, 0, 0, 0]
>>> X.isotype_generating_series()[Integer(0):Integer(4)]
[1, 0, 0, 0]
>>> X.cycle_index_series()[Integer(0):Integer(4)]                              ␣
↪          # needs sage.modules
[p[], 0, 0, 0]
```

sage.combinat.species.characteristic_species.**EmptySetSpecies_class**

alias of *EmptySetSpecies*

class sage.combinat.species.characteristic_species.**SingletonSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *CharacteristicSpecies*

Return the species of singletons.

This species has exactly one structure on a set of size 1. It is the same (and is implemented) as `CharacteristicSpecies(1)`.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: X.structures([1]).list()
[1]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series()[0:4]
[0, 1, 0, 0]
sage: X.isotype_generating_series()[0:4]
[0, 1, 0, 0]
sage: X.cycle_index_series()[0:4]                                          #␣
↪needs sage.modules
[0, p[1], 0, 0]
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> X.structures([Integer(1)]).list()
[1]
>>> X.structures([Integer(1),Integer(2)]).list()
[]
>>> X.generating_series()[Integer(0):Integer(4)]
[0, 1, 0, 0]
>>> X.isotype_generating_series()[Integer(0):Integer(4)]
[0, 1, 0, 0]
>>> X.cycle_index_series()[Integer(0):Integer(4)]                              ␣
↪          # needs sage.modules
[0, p[1], 0, 0]
```

sage.combinat.species.characteristic_species.**SingletonSpecies_class**

alias of *SingletonSpecies*

5.1.317 Composition species

class sage.combinat.species.composition_species.**CompositionSpecies**(*F*, *G*, *min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the composition of two species.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: C = species.CycleSpecies()
sage: S = E(C)
sage: S.generating_series()[:5]
[1, 1, 1, 1, 1]
sage: E(C) is S
True
```

```
>>> from sage.all import *
>>> E = species.SetSpecies()
>>> C = species.CycleSpecies()
>>> S = E(C)
>>> S.generating_series()[:Integer(5)]
[1, 1, 1, 1, 1]
>>> E(C) is S
True
```

weight_ring()

Return the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: L.weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> E = species.SetSpecies(); C = species.CycleSpecies()
>>> L = E(C)
>>> L.weight_ring()
Rational Field
```

class sage.combinat.species.composition_species.**CompositionSpeciesStructure**(*parent*, *labels*, *pi*, *f*, *gs*)

Bases: *GenericSpeciesStructure*

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- `labels` – list of labels

OUTPUT:

A structure with the i-th label of `self` replaced with the i-th label of the list.

EXAMPLES:

```
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()                               #␣
↪needs sage.libs.flint
sage: a = S[2]; a                                                          #␣
↪needs sage.libs.flint
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.change_labels([1,2,3])                                             #␣
↪needs sage.libs.flint
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]
```

```
>>> from sage.all import *
>>> E = species.SetSpecies(); C = species.CycleSpecies()
>>> L = E(C)
>>> S = L.structures(['a','b','c']).list()                               #␣
↪needs sage.libs.flint
>>> a = S[Integer(2)]; a                                                  ␣
↪     # needs sage.libs.flint
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
>>> a.change_labels([Integer(1),Integer(2),Integer(3)])                   ␣
↪                         # needs sage.libs.flint
F-structure: {{1, 3}, {2}}; G-structures: [(1, 3), (2)]
```

transport(*perm*)

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))                                   #␣
↪needs sage.groups
sage: E = species.SetSpecies(); C = species.CycleSpecies()
sage: L = E(C)
sage: S = L.structures(['a','b','c']).list()                               #␣
↪needs sage.libs.flint
sage: a = S[2]; a                                                          #␣
↪needs sage.libs.flint
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
sage: a.transport(p)                                                       #␣
↪needs sage.groups sage.libs.flint
F-structure: {{'a', 'b'}, {'c'}}; G-structures: (('a', 'c'), ('b'))
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement((Integer(2),Integer(3)))                  ␣
↪                # needs sage.groups
>>> E = species.SetSpecies(); C = species.CycleSpecies()
>>> L = E(C)
>>> S = L.structures(['a','b','c']).list()                               #␣
↪needs sage.libs.flint
```

(continues on next page)

(continued from previous page)

```
>>> a = S[Integer(2)]; a                                                        ␣
↪     # needs sage.libs.flint
F-structure: {{'a', 'c'}, {'b'}}; G-structures: (('a', 'c'), ('b'))
>>> a.transport(p)                                                            #␣
↪needs sage.groups sage.libs.flint
F-structure: {{'a', 'b'}, {'c'}}; G-structures: (('a', 'c'), ('b'))
```

sage.combinat.species.composition_species.**CompositionSpecies_class**

alias of *CompositionSpecies*

5.1.318 Cycle Species

class sage.combinat.species.cycle_species.**CycleSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the species of cycles.

EXAMPLES:

```
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.structures([1,2,3,4]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]
```

```
>>> from sage.all import *
>>> C = species.CycleSpecies(); C
Cyclic permutation species
>>> C.structures([Integer(1),Integer(2),Integer(3),Integer(4)]).list()
[(1, 2, 3, 4),
 (1, 2, 4, 3),
 (1, 3, 2, 4),
 (1, 3, 4, 2),
 (1, 4, 2, 3),
 (1, 4, 3, 2)]
```

class sage.combinat.species.cycle_species.**CycleSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

automorphism_group()

Return the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: a = P.structures([1, 2, 3, 4])[0]; a
(1, 2, 3, 4)
sage: a.automorphism_group()                                                  #␣
↪needs sage.groups
Permutation Group with generators [(1,2,3,4)]
```

```
>>> from sage.all import *
>>> P = species.CycleSpecies()
>>> a = P.structures([Integer(1), Integer(2), Integer(3),␣
↪Integer(4)])[Integer(0)]; a
(1, 2, 3, 4)
>>> a.automorphism_group()                                          #␣
↪needs sage.groups
Permutation Group with generators [(1,2,3,4)]
```

```
sage: [a.transport(perm) for perm in a.automorphism_group()]         #␣
↪needs sage.groups
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]
```

```
>>> from sage.all import *
>>> [a.transport(perm) for perm in a.automorphism_group()]          #␣
↪needs sage.groups
[(1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4), (1, 2, 3, 4)]
```

canonical_label()

EXAMPLES:

```
sage: P = species.CycleSpecies()
sage: P.structures(["a","b","c"]).random_element().canonical_label()
('a', 'b', 'c')
```

```
>>> from sage.all import *
>>> P = species.CycleSpecies()
>>> P.structures(["a","b","c"]).random_element().canonical_label()
('a', 'b', 'c')
```

permutation_group_element()

Return this cycle as a permutation group element.

EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: a.permutation_group_element()                                  #␣
↪needs sage.groups
(1,2,3)
```

```
>>> from sage.all import *
>>> F = species.CycleSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(0)]; a
('a', 'b', 'c')
>>> a.permutation_group_element()                                   #␣
↪needs sage.groups
(1,2,3)
```

transport(*perm*)

Return the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.CycleSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
('a', 'b', 'c')
sage: p = PermutationGroupElement((1,2))                                    #␣
↪needs sage.groups
sage: a.transport(p)                                                        #␣
↪needs sage.groups
('a', 'c', 'b')
```

```
>>> from sage.all import *
>>> F = species.CycleSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(0)]; a
('a', 'b', 'c')
>>> p = PermutationGroupElement((Integer(1),Integer(2)))                    ␣
↪              # needs sage.groups
>>> a.transport(p)                                                        #␣
↪needs sage.groups
('a', 'c', 'b')
```

sage.combinat.species.cycle_species.**CycleSpecies_class**

alias of *CycleSpecies*

5.1.319 Empty Species

class sage.combinat.species.empty_species.**EmptySpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the empty species. This species has no structure at all. It is the zero of the semi-ring of species.

EXAMPLES:

```
sage: X = species.EmptySpecies(); X
Empty species
sage: X.structures([]).list()
[]
sage: X.structures([1]).list()
[]
sage: X.structures([1,2]).list()
[]
sage: X.generating_series()[0:4]
[0, 0, 0, 0]
sage: X.isotype_generating_series()[0:4]
[0, 0, 0, 0]
sage: X.cycle_index_series()[0:4]                                          #␣
↪needs sage.modules
[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> X = species.EmptySpecies(); X
Empty species
>>> X.structures([]).list()
```

(continues on next page)

(continued from previous page)

```
[]
>>> X.structures([Integer(1)]).list()
[]
>>> X.structures([Integer(1),Integer(2)]).list()
[]
>>> X.generating_series()[Integer(0):Integer(4)]
[0, 0, 0, 0]
>>> X.isotype_generating_series()[Integer(0):Integer(4)]
[0, 0, 0, 0]
>>> X.cycle_index_series()[Integer(0):Integer(4)]                          ␣
↪              # needs sage.modules
[0, 0, 0, 0]
```

The empty species is the zero of the semi-ring of species. The following tests that it is neutral with respect to addition:

```
sage: Empt  = species.EmptySpecies()
sage: S = species.CharacteristicSpecies(2)
sage: X = S + Empt
sage: X == S     # TODO: Not Implemented
True
sage: (X.generating_series()[0:4] ==
....:  S.generating_series()[0:4])
True
sage: (X.isotype_generating_series()[0:4] ==
....:  S.isotype_generating_series()[0:4])
True
sage: (X.cycle_index_series()[0:4] ==                                      #␣
↪needs sage.modules
....:  S.cycle_index_series()[0:4])
True
```

```
>>> from sage.all import *
>>> Empt  = species.EmptySpecies()
>>> S = species.CharacteristicSpecies(Integer(2))
>>> X = S + Empt
>>> X == S     # TODO: Not Implemented
True
>>> (X.generating_series()[Integer(0):Integer(4)] ==
...  S.generating_series()[Integer(0):Integer(4)])
True
>>> (X.isotype_generating_series()[Integer(0):Integer(4)] ==
...  S.isotype_generating_series()[Integer(0):Integer(4)])
True
>>> (X.cycle_index_series()[Integer(0):Integer(4)] ==                      ␣
↪              # needs sage.modules
...  S.cycle_index_series()[Integer(0):Integer(4)])
True
```

The following tests that it is the zero element with respect to multiplication:

```
sage: Y = Empt*S
```

(continues on next page)

(continued from previous page)

```
sage: Y == Empt    # TODO: Not Implemented
True
sage: Y.generating_series()[0:4]
[0, 0, 0, 0]
sage: Y.isotype_generating_series()[0:4]
[0, 0, 0, 0]
sage: Y.cycle_index_series()[0:4]                                        #␣
↪needs sage.modules
[0, 0, 0, 0]
```

```
>>> from sage.all import *
>>> Y = Empt*S
>>> Y == Empt    # TODO: Not Implemented
True
>>> Y.generating_series()[Integer(0):Integer(4)]
[0, 0, 0, 0]
>>> Y.isotype_generating_series()[Integer(0):Integer(4)]
[0, 0, 0, 0]
>>> Y.cycle_index_series()[Integer(0):Integer(4)]                        ␣
↪               # needs sage.modules
[0, 0, 0, 0]
```

sage.combinat.species.empty_species.**EmptySpecies_class**

alias of *EmptySpecies*

5.1.320 Functorial composition species

class sage.combinat.species.functorial_composition_species.**FunctorialCompositionSpecies**(*F*, *G*, *min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*

Return the functorial composition of two species.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = species.SetSpecies(size=2)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series()[0:5]                             #␣
↪needs sage.modules
[1, 1, 2, 4, 11]

sage: G = species.SimpleGraphSpecies()
sage: c = G.generating_series()[0:2]
sage: type(G)
<class 'sage.combinat.species.functorial_composition_species.
↪FunctorialCompositionSpecies'>
```

(continues on next page)

(continued from previous page)

```
sage: G == loads(dumps(G))
True
sage: G._check()   # False due to isomorphism types not being implemented    #␣
↪needs sage.modules
False
```

```
>>> from sage.all import *
>>> E = species.SetSpecies()
>>> E2 = species.SetSpecies(size=Integer(2))
>>> WP = species.SubsetSpecies()
>>> P2 = E2*E
>>> G = WP.functorial_composition(P2)
>>> G.isotype_generating_series()[Integer(0):Integer(5)]                     ␣
↪          # needs sage.modules
[1, 1, 2, 4, 11]

>>> G = species.SimpleGraphSpecies()
>>> c = G.generating_series()[Integer(0):Integer(2)]
>>> type(G)
<class 'sage.combinat.species.functorial_composition_species.
↪FunctorialCompositionSpecies'>
>>> G == loads(dumps(G))
True
>>> G._check()   # False due to isomorphism types not being implemented    # needs␣
↪sage.modules
False
```

weight_ring()

Return the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: G.weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> G = species.SimpleGraphSpecies()
>>> G.weight_ring()
Rational Field
```

sage.combinat.species.functorial_composition_species.**FunctorialCompositionSpecies_class**

alias of *FunctorialCompositionSpecies*

class sage.combinat.species.functorial_composition_species.**FunctorialCompositionStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

5.1.321 Generating Series

This file makes a number of extensions to lazy power series by endowing them with some semantic content for how they're to be interpreted.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse10.html. One notable difference is that we use power-sum symmetric functions as the coefficients of our cycle index series.

class sage.combinat.species.generating_series.**CycleIndexSeries**(*parent*, *coeff_stream*)

Bases: LazySymmetricFunction

coefficient_cycle_type(*t*)

Return the coefficient of a cycle type `t` in `self`.

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]),3*p([2,1])])
sage: f.coefficient_cycle_type([1])
1
sage: f.coefficient_cycle_type([1,1])
2
sage: f.coefficient_cycle_type([2,1])
3
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> from sage.combinat.species.generating_series import CycleIndexSeriesRing
>>> p = SymmetricFunctions(QQ).power()
>>> CIS = CycleIndexSeriesRing(QQ)
>>> f = CIS([Integer(0), p([Integer(1)]), Integer(2)*p([Integer(1),
↪Integer(1)]),Integer(3)*p([Integer(2),Integer(1)])])
>>> f.coefficient_cycle_type([Integer(1)])
1
>>> f.coefficient_cycle_type([Integer(1),Integer(1)])
2
>>> f.coefficient_cycle_type([Integer(2),Integer(1)])
3
```

count(*t*)

Return the number of structures corresponding to a certain cycle type `t`.

EXAMPLES:

```
sage: # needs sage.modules
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: p = SymmetricFunctions(QQ).power()
sage: CIS = CycleIndexSeriesRing(QQ)
sage: f = CIS([0, p([1]), 2*p([1,1]), 3*p([2,1])])
sage: f.count([1])
1
```

(continues on next page)

(continued from previous page)

```
sage: f.count([1,1])
4
sage: f.count([2,1])
6
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> from sage.combinat.species.generating_series import CycleIndexSeriesRing
>>> p = SymmetricFunctions(QQ).power()
>>> CIS = CycleIndexSeriesRing(QQ)
>>> f = CIS([Integer(0), p([Integer(1)]), Integer(2)*p([Integer(1),
↪Integer(1)]), Integer(3)*p([Integer(2),Integer(1)])])
>>> f.count([Integer(1)])
1
>>> f.count([Integer(1),Integer(1)])
4
>>> f.count([Integer(2),Integer(1)])
6
```

derivative(*n=1*)

Return the species-theoretic n-th derivative of `self`.

For a cycle index series $F(p_1, p_2, p_3, \ldots)$, its derivative is the cycle index series $F' = D_{p_1} F$ (that is, the formal derivative of F with respect to the variable p_1).

If F is the cycle index series of a species S then F' is the cycle index series of an associated species S' of S-structures with a "hole".

EXAMPLES:

The species E of sets satisfies the relationship $E' = E$:

```
sage: E = species.SetSpecies().cycle_index_series()                          #␣
↪needs sage.modules
sage: E[:8] == E.derivative()[:8]                                            #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> E = species.SetSpecies().cycle_index_series()                          #␣
↪needs sage.modules
>>> E[:Integer(8)] == E.derivative()[:Integer(8)]                            ␣
↪               # needs sage.modules
True
```

The species C of cyclic orderings and the species L of linear orderings satisfy the relationship $C' = L$:

```
sage: C = species.CycleSpecies().cycle_index_series()                        #␣
↪needs sage.modules
sage: L = species.LinearOrderSpecies().cycle_index_series()                  #␣
↪needs sage.modules
sage: L[:8] == C.derivative()[:8]                                            #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> C = species.CycleSpecies().cycle_index_series()                    #␣
↪needs sage.modules
>>> L = species.LinearOrderSpecies().cycle_index_series()              #␣
↪needs sage.modules
>>> L[:Integer(8)] == C.derivative()[:Integer(8)]                      ␣
↪                # needs sage.modules
True
```

exponential()

Return the species-theoretic exponential of `self`.

For a cycle index Z_F of a species F, its exponential is the cycle index series $Z_E \circ Z_F$, where Z_E is the *ExponentialCycleIndexSeries()*.

The exponential $Z_E \circ Z_F$ is then the cycle index series of the species $E \circ F$ of "sets of F-structures".

EXAMPLES:

Let BT be the species of binary trees, BF the species of binary forests, and E the species of sets. Then we have $BF = E \circ BT$:

```
sage: BT = species.BinaryTreeSpecies().cycle_index_series()              #␣
↪needs sage.modules
sage: BF = species.BinaryForestSpecies().cycle_index_series()            #␣
↪needs sage.modules
sage: BT.exponential().isotype_generating_series()[:8] == BF.isotype_
↪generating_series()[:8]                # needs sage.modules
True
```

```
>>> from sage.all import *
>>> BT = species.BinaryTreeSpecies().cycle_index_series()              #␣
↪needs sage.modules
>>> BF = species.BinaryForestSpecies().cycle_index_series()            #␣
↪needs sage.modules
>>> BT.exponential().isotype_generating_series()[:Integer(8)] == BF.isotype_
↪generating_series()[:Integer(8)]                # needs sage.modules
True
```

generating_series()

Return the generating series of `self`.

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: cis = P.cycle_index_series()                                       #␣
↪needs sage.modules
sage: f = cis.generating_series()                                        #␣
↪needs sage.modules
sage: f[:5]                                                              #␣
↪needs sage.modules
[1, 1, 1, 5/6, 5/8]
```

```
>>> from sage.all import *
>>> P = species.PartitionSpecies()
```

(continues on next page)

(continued from previous page)

```
>>> cis = P.cycle_index_series()                                    #␣
↪needs sage.modules
>>> f = cis.generating_series()                                     #␣
↪needs sage.modules
>>> f[:Integer(5)]                                                    ␣
↪      # needs sage.modules
[1, 1, 1, 5/6, 5/8]
```

isotype_generating_series()

Return the isotype generating series of `self`.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: cis = P.cycle_index_series()                                    #␣
↪needs sage.modules
sage: f = cis.isotype_generating_series()                             #␣
↪needs sage.modules
sage: f[:10]                                                          #␣
↪needs sage.modules
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> cis = P.cycle_index_series()                                    #␣
↪needs sage.modules
>>> f = cis.isotype_generating_series()                             #␣
↪needs sage.modules
>>> f[:Integer(10)]                                                   ␣
↪      # needs sage.modules
[1, 1, 2, 3, 5, 7, 11, 15, 22, 30]
```

logarithm()

Return the combinatorial logarithm of `self`.

For a cycle index Z_F of a species F, its logarithm is the cycle index series $Z_\Omega \circ Z_F$, where Z_Ω is the *LogarithmCycleIndexSeries()*.

The logarithm $Z_\Omega \circ Z_F$ is then the cycle index series of the (virtual) species $\Omega \circ F$ of "connected F-structures". In particular, if $F = E^+ \circ G$ for E^+ the species of nonempty sets and G some other species, then $\Omega \circ F = G$.

EXAMPLES:

Let G be the species of nonempty graphs and CG be the species of nonempty connected graphs. Then $G = E^+ \circ CG$, so $CG = \Omega \circ G$:

```
sage: G = species.SimpleGraphSpecies().cycle_index_series() - 1       #␣
↪needs sage.modules
sage: from sage.combinat.species.generating_series import␣
↪LogarithmCycleIndexSeries
sage: CG = LogarithmCycleIndexSeries()(G)                             #␣
↪needs sage.modules
sage: CG.isotype_generating_series()[0:8]                             #␣
↪needs sage.modules
[0, 1, 1, 2, 6, 21, 112, 853]
```

```
>>> from sage.all import *
>>> G = species.SimpleGraphSpecies().cycle_index_series() - Integer(1)      ␣
↪     # needs sage.modules
>>> from sage.combinat.species.generating_series import␣
↪LogarithmCycleIndexSeries
>>> CG = LogarithmCycleIndexSeries()(G)                                    #␣
↪needs sage.modules
>>> CG.isotype_generating_series()[Integer(0):Integer(8)]                  ␣
↪              # needs sage.modules
[0, 1, 1, 2, 6, 21, 112, 853]
```

pointing()

Return the species-theoretic pointing of `self`.

For a cycle index F, its pointing is the cycle index series $F^\bullet = p_1 \cdot F'$.

If F is the cycle index series of a species S then $F^\bullet$ is the cycle index series of an associated species $S^\bullet$ of S-structures with a marked "root".

EXAMPLES:

The species $E^\bullet$ of "pointed sets" satisfies $E^\bullet = X \cdot E$:

```
sage: E = species.SetSpecies().cycle_index_series()                          #␣
↪needs sage.modules
sage: X = species.SingletonSpecies().cycle_index_series()                    #␣
↪needs sage.modules
sage: E.pointing()[:8] == (X*E)[:8]                                          #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> E = species.SetSpecies().cycle_index_series()                          #␣
↪needs sage.modules
>>> X = species.SingletonSpecies().cycle_index_series()                    #␣
↪needs sage.modules
>>> E.pointing()[:Integer(8)] == (X*E)[:Integer(8)]                          ␣
↪              # needs sage.modules
True
```

class sage.combinat.species.generating_series.**CycleIndexSeriesRing**(*base_ring*, *sparse=True*)

Bases: `LazySymmetricFunctions`

Return the ring of cycle index series over `R`.

This is the ring of formal power series $\Lambda[x]$, where Λ is the ring of symmetric functions over `R` in the p-basis. Its purpose is to house the cycle index series of species (in a somewhat nonstandard notation tailored to Sage): If F is a species, then the *cycle index series* of F is defined to be the formal power series

$$\sum_{n \geq 0} \frac{1}{n!} \Big(\sum_{\sigma \in S_n} \operatorname{fix} F[\sigma] \prod_{z \text{ is a cycle of } \sigma} p_{\text{length of } z} \Big) x^n \in \Lambda_{\mathbf{Q}}[x],$$

where $\operatorname{fix} F[\sigma]$ denotes the number of fixed points of the permutation $F[\sigma]$ of $F[n]$. We notice that this power series is "equigraded" (meaning that its x^n-coefficient is homogeneous of degree n). A more standard convention in combinatorics would be to use x_i instead of p_i, and drop the x (that is, evaluate the above power series at $x = 1$);

but this would be more difficult to implement in Sage, as it would be an element of a power series ring in infinitely many variables.

Note that it is just a `LazyPowerSeriesRing` (whose base ring is Λ) whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import CycleIndexSeriesRing
sage: R = CycleIndexSeriesRing(QQ); R                                          #␣
↪needs sage.modules
Cycle Index Series Ring over Rational Field
sage: p = SymmetricFunctions(QQ).p()                                           #␣
↪needs sage.modules
sage: R(lambda n: p[n])                                                        #␣
↪needs sage.modules
p[] + p[1] + p[2] + p[3] + p[4] + p[5] + p[6] + O^7
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import CycleIndexSeriesRing
>>> R = CycleIndexSeriesRing(QQ); R                                          #␣
↪needs sage.modules
Cycle Index Series Ring over Rational Field
>>> p = SymmetricFunctions(QQ).p()                                           #␣
↪needs sage.modules
>>> R(lambda n: p[n])                                                        #␣
↪needs sage.modules
p[] + p[1] + p[2] + p[3] + p[4] + p[5] + p[6] + O^7
```

Element

alias of `CycleIndexSeries`

sage.combinat.species.generating_series.**ExponentialCycleIndexSeries**()

Return the cycle index series of the species E of sets.

This cycle index satisfies

$$Z_E = \sum_{n \geq 0} \sum_{\lambda \vdash n} \frac{p_\lambda}{z_\lambda}.$$

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪ExponentialCycleIndexSeries
sage: ExponentialCycleIndexSeries()[:5]                                        #␣
↪needs sage.modules
[p[], p[1], 1/2*p[1, 1] + 1/2*p[2], 1/6*p[1, 1, 1] + 1/2*p[2, 1]
 + 1/3*p[3], 1/24*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] + 1/8*p[2, 2]
 + 1/3*p[3, 1] + 1/4*p[4]]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪ExponentialCycleIndexSeries
>>> ExponentialCycleIndexSeries()[:Integer(5)]                                 ␣
↪     # needs sage.modules
[p[], p[1], 1/2*p[1, 1] + 1/2*p[2], 1/6*p[1, 1, 1] + 1/2*p[2, 1]
```

(continues on next page)

(continued from previous page)

```
+ 1/3*p[3], 1/24*p[1, 1, 1, 1] + 1/4*p[2, 1, 1] + 1/8*p[2, 2]
+ 1/3*p[3, 1] + 1/4*p[4]]
```

class sage.combinat.species.generating_series.**ExponentialGeneratingSeries**(*parent*, *coeff_stream*)

Bases: LazyPowerSeries

A class for ordinary generating series.

Note that it is just a LazyPowerSeries whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(lambda n: n)
sage: f
z + 2*z^2 + 3*z^3 + 4*z^4 + 5*z^5 + 6*z^6 + O(z^7)
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(lambda n: n)
>>> f
z + 2*z^2 + 3*z^3 + 4*z^4 + 5*z^5 + 6*z^6 + O(z^7)
```

count(*n*)

Return the number of structures of size n.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(lambda n: 1)
sage: [f.count(i) for i in range(7)]
[1, 1, 2, 6, 24, 120, 720]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪ExponentialGeneratingSeriesRing
>>> R = ExponentialGeneratingSeriesRing(QQ)
>>> f = R(lambda n: Integer(1))
>>> [f.count(i) for i in range(Integer(7))]
[1, 1, 2, 6, 24, 120, 720]
```

counts(*n*)

Return the number of structures on a set for size i for each i in range(n).

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(5)
[0, 1, 4, 18, 96]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪ExponentialGeneratingSeriesRing
>>> R = ExponentialGeneratingSeriesRing(QQ)
>>> f = R(range(Integer(20)))
>>> f.counts(Integer(5))
[0, 1, 4, 18, 96]
```

functorial_composition(*y*)

Return the exponential generating series which is the functorial composition of `self` with `y`.

If $f = \sum_{n=0}^{\infty} f_n \frac{x^n}{n!}$ and $g = \sum_{n=0}^{\infty} g_n \frac{x^n}{n!}$, then functorial composition $f \Box g$ is defined as

$$f \Box g = \sum_{n=0}^{\infty} f_{g_n} \frac{x^n}{n!}.$$

REFERENCES:

- Section 2.2 of [BLL1998].

EXAMPLES:

```
sage: G = species.SimpleGraphSpecies()
sage: g = G.generating_series()
sage: [g.coefficient(i) for i in range(10)]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]

sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: g1 = WP.generating_series()
sage: g2 = P2.generating_series()
sage: g1.functorial_composition(g2)[:10]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

```
>>> from sage.all import *
>>> G = species.SimpleGraphSpecies()
>>> g = G.generating_series()
>>> [g.coefficient(i) for i in range(Integer(10))]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]

>>> E = species.SetSpecies()
>>> E2 = E.restricted(min=Integer(2), max=Integer(3))
>>> WP = species.SubsetSpecies()
>>> P2 = E2*E
>>> g1 = WP.generating_series()
```

(continues on next page)

(continued from previous page)

```
>>> g2 = P2.generating_series()
>>> g1.functorial_composition(g2)[:Integer(10)]
[1, 1, 1, 4/3, 8/3, 128/15, 2048/45, 131072/315, 2097152/315, 536870912/2835]
```

class sage.combinat.species.generating_series.**ExponentialGeneratingSeriesRing**(*base_ring*)

Bases: LazyPowerSeriesRing

Return the ring of exponential generating series over R.

Note that it is just a LazyPowerSeriesRing whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪ExponentialGeneratingSeriesRing
sage: R = ExponentialGeneratingSeriesRing(QQ); R
Lazy Taylor Series Ring in z over Rational Field
sage: [R(lambda n: 1).coefficient(i) for i in range(4)]
[1, 1, 1, 1]
sage: R(lambda n: 1).counts(4)
[1, 1, 2, 6]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪ExponentialGeneratingSeriesRing
>>> R = ExponentialGeneratingSeriesRing(QQ); R
Lazy Taylor Series Ring in z over Rational Field
>>> [R(lambda n: Integer(1)).coefficient(i) for i in range(Integer(4))]
[1, 1, 1, 1]
>>> R(lambda n: Integer(1)).counts(Integer(4))
[1, 1, 2, 6]
```

Element

alias of *ExponentialGeneratingSeries*

sage.combinat.species.generating_series.**LogarithmCycleIndexSeries**()

Return the cycle index series of the virtual species Ω, the compositional inverse of the species E^+ of nonempty sets.

The notion of virtual species is treated thoroughly in [BLL1998]. The specific algorithm used here to compute the cycle index of Ω is found in [Labelle2008].

EXAMPLES:

The virtual species Ω is 'properly virtual', in the sense that its cycle index has negative coefficients:

```
sage: from sage.combinat.species.generating_series import␣
↪LogarithmCycleIndexSeries
sage: LogarithmCycleIndexSeries()[0:4]                                     #␣
↪needs sage.modules
[0, p[1], -1/2*p[1, 1] - 1/2*p[2], 1/3*p[1, 1, 1] - 1/3*p[3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import LogarithmCycleIndexSeries
>>> LogarithmCycleIndexSeries()[Integer(0):Integer(4)]                    ␣
```

(continues on next page)

(continued from previous page)

```
↪               # needs sage.modules
[0, p[1], -1/2*p[1, 1] - 1/2*p[2], 1/3*p[1, 1, 1] - 1/3*p[3]]
```

Its defining property is that $\Omega \circ E^{+} = E^{+} \circ \Omega = X$ (that is, that composition with E^{+} in both directions yields the multiplicative identity X):

```
sage: Eplus = sage.combinat.species.set_species.SetSpecies(min=1).cycle_index_
↪series()       # needs sage.modules
sage: LogarithmCycleIndexSeries()(Eplus)[0:4]                              #␣
↪needs sage.modules
[0, p[1], 0, 0]
```

```
>>> from sage.all import *
>>> Eplus = sage.combinat.species.set_species.SetSpecies(min=Integer(1)).cycle_
↪index_series()       # needs sage.modules
>>> LogarithmCycleIndexSeries()(Eplus)[Integer(0):Integer(4)]              ␣
↪               # needs sage.modules
[0, p[1], 0, 0]
```

class sage.combinat.species.generating_series.**OrdinaryGeneratingSeries**(*parent*, *coeff_stream*)

Bases: LazyPowerSeries

A class for ordinary generating series.

Note that it is just a LazyPowerSeries whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(lambda n: n)
sage: f
z + 2*z^2 + 3*z^3 + 4*z^4 + 5*z^5 + 6*z^6 + O(z^7)
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(lambda n: n)
>>> f
z + 2*z^2 + 3*z^3 + 4*z^4 + 5*z^5 + 6*z^6 + O(z^7)
```

count(*n*)

Return the number of structures on a set of size n.

INPUT:

- n – the size of the set

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
```

(continues on next page)

(continued from previous page)

```
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.count(10)
10
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(range(Integer(20)))
>>> f.count(Integer(10))
10
```

counts(*n*)

Return the number of structures on a set for size `i` for each `i` in `range(n)`.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ)
sage: f = R(range(20))
sage: f.counts(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ)
>>> f = R(range(Integer(20)))
>>> f.counts(Integer(10))
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

class `sage.combinat.species.generating_series.`**OrdinaryGeneratingSeriesRing**(*base_ring*)

Bases: `LazyPowerSeriesRing`

Return the ring of ordinary generating series over `R`.

Note that it is just a `LazyPowerSeriesRing` whose elements have some extra methods.

EXAMPLES:

```
sage: from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
sage: R = OrdinaryGeneratingSeriesRing(QQ); R
Lazy Taylor Series Ring in z over Rational Field
sage: [R(lambda n: 1).coefficient(i) for i in range(4)]
[1, 1, 1, 1]
sage: R(lambda n: 1).counts(4)
[1, 1, 1, 1]
sage: R == loads(dumps(R))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.species.generating_series import␣
↪OrdinaryGeneratingSeriesRing
>>> R = OrdinaryGeneratingSeriesRing(QQ); R
Lazy Taylor Series Ring in z over Rational Field
>>> [R(lambda n: Integer(1)).coefficient(i) for i in range(Integer(4))]
[1, 1, 1, 1]
>>> R(lambda n: Integer(1)).counts(Integer(4))
[1, 1, 1, 1]
>>> R == loads(dumps(R))
True
```

Element

alias of *OrdinaryGeneratingSeries*

5.1.322 Examples of Combinatorial Species

sage.combinat.species.library.**BinaryForestSpecies**()

Return the species of binary forests.

Binary forests are defined as sets of binary trees.

EXAMPLES:

```
sage: F = species.BinaryForestSpecies()
sage: F.generating_series().counts(10)
[1, 1, 3, 19, 193, 2721, 49171, 1084483, 28245729, 848456353]
sage: F.isotype_generating_series().counts(10)                              #␣
↪needs sage.modules
[1, 1, 2, 4, 10, 26, 77, 235, 758, 2504]
sage: F.cycle_index_series()[:7]                                            #␣
↪needs sage.modules
[p[],
 p[1],
 3/2*p[1, 1] + 1/2*p[2],
 19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
 193/24*p[1, 1, 1, 1] + 3/4*p[2, 1, 1] + 5/8*p[2, 2] + 1/3*p[3, 1] + 1/4*p[4],

[p[],
```

(continues on next page)

(continued from previous page)

```
p[1],
3/2*p[1, 1] + 1/2*p[2],
19/6*p[1, 1, 1] + 1/2*p[2, 1] + 1/3*p[3],
193/24*p[1, 1, 1, 1] + 3/4*p[2, 1, 1] + 5/8*p[2, 2] + 1/3*p[3, 1] + 1/4*p[4],
907/40*p[1, 1, 1, 1, 1] + 19/12*p[2, 1, 1, 1] + 5/8*p[2, 2, 1] + 1/2*p[3, 1, 1]␣
↪+ 1/6*p[3, 2] + 1/4*p[4, 1] + 1/5*p[5],
49171/720*p[1, 1, 1, 1, 1, 1] + 193/48*p[2, 1, 1, 1, 1] + 15/16*p[2, 2, 1, 1] +␣
↪61/48*p[2, 2, 2] + 19/18*p[3, 1, 1, 1] + 1/6*p[3, 2, 1] + 7/18*p[3, 3] + 3/
↪8*p[4, 1, 1] + 1/8*p[4, 2] + 1/5*p[5, 1] + 1/6*p[6]]
```

sage.combinat.species.library.**BinaryTreeSpecies**()

Return the species of binary trees on n leaves.

The species of binary trees B is defined by $B = X + B \cdot B$, where X is the singleton species.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.generating_series().counts(10)
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
sage: B.isotype_generating_series().counts(10)
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
sage: B._check()
True
```

```
>>> from sage.all import *
>>> B = species.BinaryTreeSpecies()
>>> B.generating_series().counts(Integer(10))
[0, 1, 2, 12, 120, 1680, 30240, 665280, 17297280, 518918400]
>>> B.isotype_generating_series().counts(Integer(10))
[0, 1, 1, 2, 5, 14, 42, 132, 429, 1430]
>>> B._check()
True
```

```
sage: B = species.BinaryTreeSpecies()
sage: a = B.structures([1,2,3,4,5])[187]; a
2*((5*3)*(4*1))
sage: a.automorphism_group()                                                    #␣
↪needs sage.groups
Permutation Group with generators [()]
```

```
>>> from sage.all import *
>>> B = species.BinaryTreeSpecies()
>>> a = B.structures([Integer(1),Integer(2),Integer(3),Integer(4),
↪Integer(5)])[Integer(187)]; a
2*((5*3)*(4*1))
>>> a.automorphism_group()                                                    #␣
↪needs sage.groups
Permutation Group with generators [()]
```

sage.combinat.species.library.**SimpleGraphSpecies**()

Return the species of simple graphs.

EXAMPLES:

```
sage: S = species.SimpleGraphSpecies()
sage: S.generating_series().counts(10)
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]
sage: S.cycle_index_series()[:5]                                    #␣
↪needs sage.modules
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
sage: S.isotype_generating_series()[:6]                              #␣
↪needs sage.modules
[1, 1, 2, 4, 11, 34]
```

```
>>> from sage.all import *
>>> S = species.SimpleGraphSpecies()
>>> S.generating_series().counts(Integer(10))
[1, 1, 2, 8, 64, 1024, 32768, 2097152, 268435456, 68719476736]
>>> S.cycle_index_series()[:Integer(5)]                               ␣
↪    # needs sage.modules
[p[],
 p[1],
 p[1, 1] + p[2],
 4/3*p[1, 1, 1] + 2*p[2, 1] + 2/3*p[3],
 8/3*p[1, 1, 1, 1] + 4*p[2, 1, 1] + 2*p[2, 2] + 4/3*p[3, 1] + p[4]]
>>> S.isotype_generating_series()[:Integer(6)]                        ␣
↪    # needs sage.modules
[1, 1, 2, 4, 11, 34]
```

5.1.323 Linear-order Species

class sage.combinat.species.linear_order_species.**LinearOrderSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the species of linear orders.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series()[0:5]
[1, 1, 1, 1, 1]

sage: L = species.LinearOrderSpecies()
sage: L._check()
True
sage: L == loads(dumps(L))
True
```

```
>>> from sage.all import *
>>> L = species.LinearOrderSpecies()
```

(continues on next page)

(continued from previous page)

```
>>> L.generating_series()[Integer(0):Integer(5)]
[1, 1, 1, 1, 1]

>>> L = species.LinearOrderSpecies()
>>> L._check()
True
>>> L == loads(dumps(L))
True
```

class sage.combinat.species.linear_order_species.**LinearOrderSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

automorphism_group()

Return the group of permutations whose action on this structure leave it fixed. For the species of linear orders, there is no non-trivial automorphism.

EXAMPLES:

```
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
['a', 'b', 'c']
sage: a.automorphism_group()                                          #␣
↪needs sage.groups
Symmetric group of order 1! as a permutation group
```

```
>>> from sage.all import *
>>> F = species.LinearOrderSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(0)]; a
['a', 'b', 'c']
>>> a.automorphism_group()                                            #␣
↪needs sage.groups
Symmetric group of order 1! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: P = species.LinearOrderSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.canonical_label()
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> P = species.LinearOrderSpecies()
>>> s = P.structures(["a", "b", "c"]).random_element()
>>> s.canonical_label()
['a', 'b', 'c']
```

transport(*perm*)

Return the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: F = species.LinearOrderSpecies()
sage: a = F.structures(["a", "b", "c"])[0]; a
['a', 'b', 'c']
sage: p = PermutationGroupElement((1,2))                                      #␣
↪needs sage.groups
sage: a.transport(p)                                                          #␣
↪needs sage.groups
['b', 'a', 'c']
```

```
>>> from sage.all import *
>>> F = species.LinearOrderSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(0)]; a
['a', 'b', 'c']
>>> p = PermutationGroupElement((Integer(1),Integer(2)))                       ␣
↪             # needs sage.groups
>>> a.transport(p)                                                           #␣
↪needs sage.groups
['b', 'a', 'c']
```

sage.combinat.species.linear_order_species.**LinearOrderSpecies_class**

alias of *LinearOrderSpecies*

5.1.324 Miscellaneous Functions

sage.combinat.species.misc.**accept_size**(*f*)

The purpose of this decorator is to change calls like species.SetSpecies(size=1) to species.SetSpecies(min=1, max=2). This is to make caching species easier and to restrict the number of parameters that the lower level code needs to know about.

EXAMPLES:

```
sage: from sage.combinat.species.misc import accept_size
sage: def f(*args, **kwds):
....:     print("{} {}".format(args, sorted(kwds.items())))
sage: f = accept_size(f)
sage: f(min=1)
() [('min', 1)]
sage: f(size=2)
() [('max', 3), ('min', 2)]
```

```
>>> from sage.all import *
>>> from sage.combinat.species.misc import accept_size
>>> def f(*args, **kwds):
...     print("{} {}".format(args, sorted(kwds.items())))
>>> f = accept_size(f)
>>> f(min=Integer(1))
() [('min', 1)]
>>> f(size=Integer(2))
() [('max', 3), ('min', 2)]
```

sage.combinat.species.misc.**change_support**(*perm*, *support*, *change_perm=None*)

Changes the support of a permutation defined on [1, …, n] to support.

EXAMPLES:

```
sage: from sage.combinat.species.misc import change_support
sage: p = PermutationGroupElement((1,2,3)); p
(1,2,3)
sage: change_support(p, [3,4,5])
(3,4,5)
```

```
>>> from sage.all import *
>>> from sage.combinat.species.misc import change_support
>>> p = PermutationGroupElement((Integer(1),Integer(2),Integer(3))); p
(1,2,3)
>>> change_support(p, [Integer(3),Integer(4),Integer(5)])
(3,4,5)
```

5.1.325 Partition Species

class sage.combinat.species.partition_species.**PartitionSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*

Return the species of partitions.

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: P.generating_series()[0:5]
[1, 1, 1, 5/6, 5/8]
sage: P.isotype_generating_series()[0:5]
[1, 1, 2, 3, 5]

sage: P = species.PartitionSpecies()
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

```
>>> from sage.all import *
>>> P = species.PartitionSpecies()
>>> P.generating_series()[Integer(0):Integer(5)]
[1, 1, 1, 5/6, 5/8]
>>> P.isotype_generating_series()[Integer(0):Integer(5)]
[1, 1, 2, 3, 5]

>>> P = species.PartitionSpecies()
>>> P._check()
True
>>> P == loads(dumps(P))
True
```

class sage.combinat.species.partition_species.**PartitionSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

EXAMPLES:

```
sage: from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
sage: P = species.PartitionSpecies()
sage: s = PartitionSpeciesStructure(P, ['a','b','c'], [[1,2],[3]]); s
{{'a', 'b'}, {'c'}}
sage: s == loads(dumps(s))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.species.partition_species import PartitionSpeciesStructure
>>> P = species.PartitionSpecies()
>>> s = PartitionSpeciesStructure(P, ['a','b','c'], [[Integer(1),Integer(2)],
↪[Integer(3)]]); s
{{'a', 'b'}, {'c'}}
>>> s == loads(dumps(s))
True
```

automorphism_group()

Return the group of permutations whose action on this set partition leave it fixed.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.automorphism_group()
Permutation Group with generators [(1,2)]
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement((Integer(2),Integer(3)))
>>> from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
>>> a = PartitionSpeciesStructure(None, [Integer(2),Integer(3),Integer(4)],␣
↪[[Integer(1),Integer(2)],[Integer(3)]]); a
{{2, 3}, {4}}
>>> a.automorphism_group()
Permutation Group with generators [(1,2)]
```

canonical_label()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a'}, {'b'}, {'c'}}]
```

```
>>> from sage.all import *
>>> P = species.PartitionSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.canonical_label() for s in S]
[{{'a', 'b', 'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a', 'b'}, {'c'}},
 {{'a'}, {'b'}, {'c'}}]
```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- `labels` – list of labels

OUTPUT:

A structure with the i-th label of `self` replaced with the i-th label of the list.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.change_labels([1,2,3])
{{1, 2}, {3}}
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement((Integer(2),Integer(3)))
>>> from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
>>> a = PartitionSpeciesStructure(None, [Integer(2),Integer(3),Integer(4)],␣
↪[[Integer(1),Integer(2)],[Integer(3)]]); a
{{2, 3}, {4}}
>>> a.change_labels([Integer(1),Integer(2),Integer(3)])
{{1, 2}, {3}}
```

transport(*perm*)

Return the transport of this set partition along the permutation perm. For set partitions, this is the direct product of the automorphism groups for each of the blocks.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3))
sage: from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
sage: a = PartitionSpeciesStructure(None, [2,3,4], [[1,2],[3]]); a
{{2, 3}, {4}}
sage: a.transport(p)
{{2, 4}, {3}}
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement((Integer(2),Integer(3)))
>>> from sage.combinat.species.partition_species import␣
↪PartitionSpeciesStructure
>>> a = PartitionSpeciesStructure(None, [Integer(2),Integer(3),Integer(4)],␣
↪[[Integer(1),Integer(2)],[Integer(3)]]); a
{{2, 3}, {4}}
>>> a.transport(p)
{{2, 4}, {3}}
```

sage.combinat.species.partition_species.**PartitionSpecies_class**

alias of *PartitionSpecies*

5.1.326 Permutation species

class sage.combinat.species.permutation_species.**PermutationSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the species of permutations.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: P.generating_series()[0:5]
[1, 1, 1, 1, 1]
sage: P.isotype_generating_series()[0:5]
[1, 1, 2, 3, 5]

sage: P = species.PermutationSpecies()
sage: c = P.generating_series()[0:3]
sage: P._check()
True
sage: P == loads(dumps(P))
True
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> P.generating_series()[Integer(0):Integer(5)]
[1, 1, 1, 1, 1]
>>> P.isotype_generating_series()[Integer(0):Integer(5)]
[1, 1, 2, 3, 5]

>>> P = species.PermutationSpecies()
>>> c = P.generating_series()[Integer(0):Integer(3)]
>>> P._check()
True
>>> P == loads(dumps(P))
True
```

class sage.combinat.species.permutation_species.**PermutationSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

automorphism_group()

Return the group of permutations whose action on this structure leave it fixed.

EXAMPLES:

```
sage: set_random_seed(0)
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))
>>> p = PermutationGroupElement((Integer(2),Integer(3),Integer(4)))
>>> P = species.PermutationSpecies()
>>> a = P.structures(["a", "b", "c", "d"])[Integer(2)]; a
['a', 'c', 'b', 'd']
>>> a.automorphism_group()
Permutation Group with generators [(2,3), (1,4)]
```

```
sage: [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd']]
```

```
>>> from sage.all import *
>>> [a.transport(perm) for perm in a.automorphism_group()]
[['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd'],
 ['a', 'c', 'b', 'd']]
```

canonical_label()

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[['a', 'b', 'c'],
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'c', 'a'],
 ['b', 'c', 'a'],
 ['b', 'a', 'c']]
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.canonical_label() for s in S]
[['a', 'b', 'c'],
```

(continues on next page)

(continued from previous page)

```
 ['b', 'a', 'c'],
 ['b', 'a', 'c'],
 ['b', 'c', 'a'],
 ['b', 'c', 'a'],
 ['b', 'a', 'c']]
```

permutation_group_element()

Return `self` as a permutation group element.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.permutation_group_element()
(2,3)
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement((Integer(2),Integer(3),Integer(4)))
>>> P = species.PermutationSpecies()
>>> a = P.structures(["a", "b", "c", "d"])[Integer(2)]; a
['a', 'c', 'b', 'd']
>>> a.permutation_group_element()
(2,3)
```

transport(*perm*)

Return the transport of this structure along the permutation perm.

EXAMPLES:

```
sage: p = PermutationGroupElement((2,3,4))
sage: P = species.PermutationSpecies()
sage: a = P.structures(["a", "b", "c", "d"])[2]; a
['a', 'c', 'b', 'd']
sage: a.transport(p)
['a', 'd', 'c', 'b']
```

```
>>> from sage.all import *
>>> p = PermutationGroupElement((Integer(2),Integer(3),Integer(4)))
>>> P = species.PermutationSpecies()
>>> a = P.structures(["a", "b", "c", "d"])[Integer(2)]; a
['a', 'c', 'b', 'd']
>>> a.transport(p)
['a', 'd', 'c', 'b']
```

sage.combinat.species.permutation_species.**PermutationSpecies_class**

alias of *PermutationSpecies*

5.1.327 Product species

class sage.combinat.species.product_species.**ProductSpecies**(*F*, *G*, *min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: A = X*X
sage: A.generating_series()[0:4]
[0, 0, 1, 0]

sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
sage: F == loads(dumps(F))
True
sage: F._check()                                                    #␣
↪needs sage.libs.flint
True
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> A = X*X
>>> A.generating_series()[Integer(0):Integer(4)]
[0, 0, 1, 0]

>>> P = species.PermutationSpecies()
>>> F = P * P; F
Product of (Permutation species) and (Permutation species)
>>> F == loads(dumps(F))
True
>>> F._check()                                                 # needs␣
↪sage.libs.flint
True
```

left_factor()

Return the left factor of this product.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
sage: F.left_factor()
Permutation species
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> X = species.SingletonSpecies()
>>> F = P*X
>>> F.left_factor()
Permutation species
```

right_factor()

Return the right factor of this product.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: X = species.SingletonSpecies()
sage: F = P*X
sage: F.right_factor()
Singleton species
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> X = species.SingletonSpecies()
>>> F = P*X
>>> F.right_factor()
Singleton species
```

weight_ring()

Return the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you multiply (and add) elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S*S
sage: C.weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> C = S*S
>>> C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S*S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> S = species.SetSpecies(weight=QQ['t'].gen())
>>> C = S*S
>>> C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```
sage: S = species.SetSpecies()
sage: C = (S*S).weighted(QQ['t'].gen())
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
```

(continues on next page)

(continued from previous page)

```
>>> C = (S*S).weighted(QQ['t'].gen())
>>> C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

class sage.combinat.species.product_species.**ProductSpeciesStructure**(*parent*, *labels*, *subset*, *left*, *right*)

Bases: *GenericSpeciesStructure*

automorphism_group()

EXAMPLES:

```
sage: # needs sage.groups
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures([1,2,3,4])[1]; a
{1}*{2, 3, 4}
sage: a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> p = PermutationGroupElement((Integer(2),Integer(3)))
>>> S = species.SetSpecies()
>>> F = S * S
>>> a = F.structures([Integer(1),Integer(2),Integer(3),
↪Integer(4)])[Integer(1)]; a
{1}*{2, 3, 4}
>>> a.automorphism_group()
Permutation Group with generators [(2,3), (2,3,4)]
```

```
sage: [a.transport(g) for g in a.automorphism_group()]                    #␣
↪needs sage.groups
[{1}*{2, 3, 4},
 {1}*{2, 3, 4},

↪needs sage.groups
[{2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}, {2, 3}*{1, 4}]
```

canonical_label()

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: S = F.structures(['a','b','c']).list(); S
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'b'}*{'a', 'c'},
 {'c'}*{'a', 'b'},
 {'a', 'b'}*{'c'},
 {'a', 'c'}*{'b'},
 {'b', 'c'}*{'a'},
 {'a', 'b', 'c'}*{}]
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> F = S * S
>>> S = F.structures(['a','b','c']).list(); S
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'b'}*{'a', 'c'},
 {'c'}*{'a', 'b'},
 {'a', 'b'}*{'c'},
 {'a', 'c'}*{'b'},
 {'b', 'c'}*{'a'},
 {'a', 'b', 'c'}*{}]
```

```
sage: F.isotypes(['a','b','c']).cardinality()
4
sage: [s.canonical_label() for s in S]
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a', 'b'}*{'c'},
```

(continues on next page)

(continued from previous page)

```
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b', 'c'}*{}]
```

```
>>> from sage.all import *
>>> F.isotypes(['a','b','c']).cardinality()
4
>>> [s.canonical_label() for s in S]
[{}*{'a', 'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a'}*{'b', 'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b'}*{'c'},
 {'a', 'b', 'c'}*{}]
```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- `labels` – list of labels

OUTPUT:

A structure with the i-th label of `self` replaced with the i-th label of the list.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[0]; a
{}*{'a', 'b', 'c'}
sage: a.change_labels([1,2,3])
{}*{1, 2, 3}
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> F = S * S
>>> a = F.structures(['a','b','c'])[Integer(0)]; a
{}*{'a', 'b', 'c'}
>>> a.change_labels([Integer(1),Integer(2),Integer(3)])
{}*{1, 2, 3}
```

transport(*perm*)

EXAMPLES:

```
sage: # needs sage.groups
sage: p = PermutationGroupElement((2,3))
sage: S = species.SetSpecies()
sage: F = S * S
sage: a = F.structures(['a','b','c'])[4]; a
{'a', 'b'}*{'c'}
```

(continues on next page)

(continued from previous page)

```
sage: a.transport(p)
{'a', 'c'}*{'b'}
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> p = PermutationGroupElement((Integer(2),Integer(3)))
>>> S = species.SetSpecies()
>>> F = S * S
>>> a = F.structures(['a','b','c'])[Integer(4)]; a
{'a', 'b'}*{'c'}
>>> a.transport(p)
{'a', 'c'}*{'b'}
```

sage.combinat.species.product_species.**ProductSpecies_class**

alias of *ProductSpecies*

5.1.328 Recursive Species

class sage.combinat.species.recursive_species.**CombinatorialSpecies**(*min=None*)

Bases: *GenericCombinatorialSpecies*

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: loads(dumps(F))
Combinatorial species
```

```
>>> from sage.all import *
>>> F = CombinatorialSpecies()
>>> loads(dumps(F))
Combinatorial species
```

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series()[0:4]
[1, 1, 1, 1]
sage: LL = loads(dumps(L))
sage: LL.generating_series()[0:4]
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> E = species.EmptySetSpecies()
>>> L = CombinatorialSpecies()
>>> L.define(E+X*L)
>>> L.generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]
>>> LL = loads(dumps(L))
>>> LL.generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]
```

define(*x*)

Define `self` to be equal to the combinatorial species `x`.

This is used to define combinatorial species recursively. All of the real work is done by calling the `.set()` method for each of the series associated to `self`.

EXAMPLES: The species of linear orders L can be recursively defined by $L = 1 + X * L$ where 1 represents the empty set species and X represents the singleton species:

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.generating_series()[0:4]
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[1*(2*(3*{})),
 1*(3*(2*{})),
 2*(1*(3*{})),
 2*(3*(1*{})),
 3*(1*(2*{})),
 3*(2*(1*{}))]
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> E = species.EmptySetSpecies()
>>> L = CombinatorialSpecies()
>>> L.define(E+X*L)
>>> L.generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]
>>> L.structures([Integer(1),Integer(2),Integer(3)]).cardinality()
6
>>> L.structures([Integer(1),Integer(2),Integer(3)]).list()
[1*(2*(3*{})),
 1*(3*(2*{})),
 2*(1*(3*{})),
 2*(3*(1*{})),
 3*(1*(2*{})),
 3*(2*(1*{}))]
```

```
sage: L = species.LinearOrderSpecies()
sage: L.generating_series()[0:4]
[1, 1, 1, 1]
sage: L.structures([1,2,3]).cardinality()
6
sage: L.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```
>>> from sage.all import *
>>> L = species.LinearOrderSpecies()
>>> L.generating_series()[Integer(0):Integer(4)]
```

(continues on next page)

(continued from previous page)

```
[1, 1, 1, 1]
>>> L.structures([Integer(1),Integer(2),Integer(3)]).cardinality()
6
>>> L.structures([Integer(1),Integer(2),Integer(3)]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

weight_ring()

EXAMPLES:

```
sage: F = species.CombinatorialSpecies()
sage: F.weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> F = species.CombinatorialSpecies()
>>> F.weight_ring()
Rational Field
```

```
sage: X = species.SingletonSpecies()
sage: E = species.EmptySetSpecies()
sage: L = CombinatorialSpecies()
sage: L.define(E+X*L)
sage: L.weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> E = species.EmptySetSpecies()
>>> L = CombinatorialSpecies()
>>> L.define(E+X*L)
>>> L.weight_ring()
Rational Field
```

class sage.combinat.species.recursive_species.**CombinatorialSpeciesStructure**(*parent*, *s*, ***options*)

Bases: *SpeciesStructureWrapper*

5.1.329 Set Species

class sage.combinat.species.set_species.**SetSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the species of sets.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E.structures([1,2,3]).list()
[{1, 2, 3}]
sage: E.isotype_generating_series()[0:4]
[1, 1, 1, 1]
```

(continues on next page)

(continued from previous page)

```
sage: S = species.SetSpecies()
sage: c = S.generating_series()[0:3]
sage: S._check()
True
sage: S == loads(dumps(S))
True
```

```
>>> from sage.all import *
>>> E = species.SetSpecies()
>>> E.structures([Integer(1),Integer(2),Integer(3)]).list()
[{1, 2, 3}]
>>> E.isotype_generating_series()[Integer(0):Integer(4)]
[1, 1, 1, 1]

>>> S = species.SetSpecies()
>>> c = S.generating_series()[Integer(0):Integer(3)]
>>> S._check()
True
>>> S == loads(dumps(S))
True
```

class sage.combinat.species.set_species.**SetSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

automorphism_group()

Return the group of permutations whose action on this set leave it fixed. For the species of sets, there is only one isomorphism class, so every permutation is in its automorphism group.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.automorphism_group()                                          #␣
↪needs sage.groups
Symmetric group of order 3! as a permutation group
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> a.automorphism_group()                                            #␣
↪needs sage.groups
Symmetric group of order 3! as a permutation group
```

canonical_label()

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures(["a","b","c"]).random_element(); a
{'a', 'b', 'c'}
sage: a.canonical_label()
{'a', 'b', 'c'}
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> a = S.structures(["a","b","c"]).random_element(); a
{'a', 'b', 'c'}
>>> a.canonical_label()
{'a', 'b', 'c'}
```

transport (*perm*)

Return the transport of this set along the permutation perm.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
sage: p = PermutationGroupElement((1,2))                                    #␣
↪needs sage.groups
sage: a.transport(p)                                                        #␣
↪needs sage.groups
{'a', 'b', 'c'}
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> a = F.structures(["a", "b", "c"]).random_element(); a
{'a', 'b', 'c'}
>>> p = PermutationGroupElement((Integer(1),Integer(2)))                    ␣
↪             # needs sage.groups
>>> a.transport(p)                                                        #␣
↪needs sage.groups
{'a', 'b', 'c'}
```

sage.combinat.species.set_species.**SetSpecies_class**

alias of *SetSpecies*

5.1.330 Combinatorial Species

This file defines the main classes for working with combinatorial species, operations on them, as well as some implementations of basic species required for other constructions.

This code is based on the work of Ralf Hemmecke and Martin Rubey's Aldor-Combinat, which can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/aldor/combinat/index.html. In particular, the relevant section for this file can be found at http://www.risc.uni-linz.ac.at/people/hemmecke/AldorCombinat/combinatse8.html.

Weighted Species:

As a first application of weighted species, we count unlabeled ordered trees by total number of nodes and number of internal nodes. To achieve this, we assign a weight of 1 to the leaves and of q to internal nodes:

```
sage: q = QQ['q'].gen()
sage: leaf = species.SingletonSpecies()
sage: internal_node = species.SingletonSpecies(weight=q)
sage: L = species.LinearOrderSpecies(min=1)
sage: T = species.CombinatorialSpecies(min=1)
sage: T.define(leaf + internal_node*L(T))
```

(continues on next page)

(continued from previous page)

```
sage: T.isotype_generating_series()[0:6]                                  #␣
↪needs sage.modules
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

```
>>> from sage.all import *
>>> q = QQ['q'].gen()
>>> leaf = species.SingletonSpecies()
>>> internal_node = species.SingletonSpecies(weight=q)
>>> L = species.LinearOrderSpecies(min=Integer(1))
>>> T = species.CombinatorialSpecies(min=Integer(1))
>>> T.define(leaf + internal_node*L(T))
>>> T.isotype_generating_series()[Integer(0):Integer(6)]                   ␣
↪              # needs sage.modules
[0, 1, q, q^2 + q, q^3 + 3*q^2 + q, q^4 + 6*q^3 + 6*q^2 + q]
```

Consider the following:

```
sage: T.isotype_generating_series().coefficient(4)                        #␣
↪needs sage.modules
q^3 + 3*q^2 + q
```

```
>>> from sage.all import *
>>> T.isotype_generating_series().coefficient(Integer(4))                  ␣
↪     # needs sage.modules
q^3 + 3*q^2 + q
```

This means that, among the trees on 4 nodes, one has a single internal node, three have two internal nodes, and one has three internal nodes.

class sage.combinat.species.species.**GenericCombinatorialSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: SageObject

algebraic_equation_system()

Return a system of algebraic equations satisfied by this species.

The nodes are numbered in the order that they appear as vertices of the associated digraph.

EXAMPLES:

```
sage: B = species.BinaryTreeSpecies()
sage: B.algebraic_equation_system()                                      #␣
↪needs sage.graphs
[-node3^2 + node1, -node1 + node3 + (-z)]
```

```
>>> from sage.all import *
>>> B = species.BinaryTreeSpecies()
>>> B.algebraic_equation_system()                                      #␣
↪needs sage.graphs
[-node3^2 + node1, -node1 + node3 + (-z)]
```

```
sage: sorted(B.digraph().vertex_iterator(), key=str)                     #␣
↪needs sage.graphs
```

(continues on next page)

(continued from previous page)

```
[Combinatorial species with min=1,
 Product of (Combinatorial species with min=1)
        and (Combinatorial species with min=1),
 Singleton species,
 Sum of (Singleton species)
    and (Product of (Combinatorial species with min=1)
    and (Combinatorial species with min=1))]
```

```
>>> from sage.all import *
>>> sorted(B.digraph().vertex_iterator(), key=str)                          #␣
↪needs sage.graphs
[Combinatorial species with min=1,
 Product of (Combinatorial species with min=1)
        and (Combinatorial species with min=1),
 Singleton species,
 Sum of (Singleton species)
    and (Product of (Combinatorial species with min=1)
    and (Combinatorial species with min=1))]
```

```
sage: B.algebraic_equation_system()[0].parent()                              #␣
↪needs sage.graphs
Multivariate Polynomial Ring in node0, node1, node2, node3 over
 Fraction Field of Univariate Polynomial Ring in z over Rational Field
```

```
>>> from sage.all import *
>>> B.algebraic_equation_system()[Integer(0)].parent()                        ␣
↪     # needs sage.graphs
Multivariate Polynomial Ring in node0, node1, node2, node3 over
 Fraction Field of Univariate Polynomial Ring in z over Rational Field
```

composition(*g*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: S(S)
Composition of (Set species) and (Set species)
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> S(S)
Composition of (Set species) and (Set species)
```

cycle_index_series(*base_ring=None*)

Return the cycle index series for this species.

The cycle index series is a sequence of symmetric functions.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.cycle_index_series()                                             #␣
↪needs sage.modules
```

(continues on next page)

(continued from previous page)

```
sage: g[0:4]                                                            #␣
↪needs sage.modules
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> g = P.cycle_index_series()                                        #␣
↪needs sage.modules
>>> g[Integer(0):Integer(4)]                                            ␣
↪              # needs sage.modules
[p[], p[1], p[1, 1] + p[2], p[1, 1, 1] + p[2, 1] + p[3]]
```

digraph()

Return a directed graph where the vertices are the individual species that make up this one.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: B = species.CombinatorialSpecies()
sage: B.define(X+B*B)
sage: g = B.digraph(); g                                                #␣
↪needs sage.graphs
Multi-digraph on 4 vertices

sage: sorted(g, key=str)                                                #␣
↪needs sage.graphs
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
 Singleton species,
 Sum of (Singleton species) and
  (Product of (Combinatorial species) and (Combinatorial species))]

sage: d = {sp: i for i, sp in enumerate(g)}                             #␣
↪needs sage.graphs
sage: g.relabel(d)                                                      #␣
↪needs sage.graphs
sage: g.canonical_label().edges(sort=True)                              #␣
↪needs sage.graphs
[(0, 3, None), (2, 0, None), (2, 0, None), (3, 1, None), (3, 2, None)]
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> B = species.CombinatorialSpecies()
>>> B.define(X+B*B)
>>> g = B.digraph(); g                                                #␣
↪needs sage.graphs
Multi-digraph on 4 vertices

>>> sorted(g, key=str)                                                #␣
↪needs sage.graphs
[Combinatorial species,
 Product of (Combinatorial species) and (Combinatorial species),
```

(continues on next page)

(continued from previous page)

```
 Singleton species,
 Sum of (Singleton species) and
  (Product of (Combinatorial species) and (Combinatorial species))]

>>> d = {sp: i for i, sp in enumerate(g)}                                   #␣
↪needs sage.graphs
>>> g.relabel(d)                                                            #␣
↪needs sage.graphs
>>> g.canonical_label().edges(sort=True)                                    #␣
↪needs sage.graphs
[(0, 3, None), (2, 0, None), (2, 0, None), (3, 1, None), (3, 2, None)]
```

functorial_composition(*g*)

Return the functorial composition of `self` with `g`.

EXAMPLES:

```
sage: E = species.SetSpecies()
sage: E2 = E.restricted(min=2, max=3)
sage: WP = species.SubsetSpecies()
sage: P2 = E2*E
sage: G = WP.functorial_composition(P2)
sage: G.isotype_generating_series()[0:5]                                    #␣
↪needs sage.modules
[1, 1, 2, 4, 11]
```

```
>>> from sage.all import *
>>> E = species.SetSpecies()
>>> E2 = E.restricted(min=Integer(2), max=Integer(3))
>>> WP = species.SubsetSpecies()
>>> P2 = E2*E
>>> G = WP.functorial_composition(P2)
>>> G.isotype_generating_series()[Integer(0):Integer(5)]                    ␣
↪             # needs sage.modules
[1, 1, 2, 4, 11]
```

generating_series(*base_ring=None*)

Return the generating series for this species.

This is an exponential generating series so the n-th coefficient of the series corresponds to the number of labeled structures with n labels divided by $n!$.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.generating_series()
sage: g[:4]
[1, 1, 1, 1]
sage: g.counts(4)
[1, 1, 2, 6]
sage: P.structures([1,2,3]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
sage: len(_)
6
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> g = P.generating_series()
>>> g[:Integer(4)]
[1, 1, 1, 1]
>>> g.counts(Integer(4))
[1, 1, 2, 6]
>>> P.structures([Integer(1),Integer(2),Integer(3)]).list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
>>> len(_)
6
```

is_weighted()

Return True if this species has a nontrivial weighting associated with it.

EXAMPLES:

```
sage: C = species.CycleSpecies()
sage: C.is_weighted()
False
```

```
>>> from sage.all import *
>>> C = species.CycleSpecies()
>>> C.is_weighted()
False
```

isotype_generating_series(*base_ring=None*)

Return the isotype generating series for this species.

The n-th coefficient of this series corresponds to the number of isomorphism types for the structures on n labels.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: g = P.isotype_generating_series()
sage: g[0:4]                                                            #␣
↪needs sage.libs.flint
[1, 1, 2, 3]
sage: g.counts(4)                                                       #␣
↪needs sage.libs.flint
[1, 1, 2, 3]
sage: P.isotypes([1,2,3]).list()                                        #␣
↪needs sage.libs.flint
[[2, 3, 1], [2, 1, 3], [1, 2, 3]]
sage: len(_)                                                            #␣
↪needs sage.libs.flint
3
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> g = P.isotype_generating_series()
>>> g[Integer(0):Integer(4)]                                            ␣
↪              # needs sage.libs.flint
```

(continues on next page)

(continued from previous page)

```
[1, 1, 2, 3]
>>> g.counts(Integer(4))                                                    ␣
↪     # needs sage.libs.flint
[1, 1, 2, 3]
>>> P.isotypes([Integer(1),Integer(2),Integer(3)]).list()                   ␣
↪                         # needs sage.libs.flint
[[2, 3, 1], [2, 1, 3], [1, 2, 3]]
>>> len(_)                                                                 #␣
↪needs sage.libs.flint
3
```

isotypes(*labels*, *structure_class=None*)

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: F.isotypes([1,2,3]).list()
Traceback (most recent call last):
...
ValueError: Stream is not yet defined
```

```
>>> from sage.all import *
>>> F = CombinatorialSpecies()
>>> F.isotypes([Integer(1),Integer(2),Integer(3)]).list()
Traceback (most recent call last):
...
ValueError: Stream is not yet defined
```

product(*g*)

Return the product of `self` and `g`.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P * P; F
Product of (Permutation species) and (Permutation species)
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> F = P * P; F
Product of (Permutation species) and (Permutation species)
```

restricted(**args*, ***kwds*)

Return the restriction of the species.

INPUT:

- `min` – (optional) integer
- `max` – (optional) integer

EXAMPLES:

```
sage: S = species.SetSpecies().restricted(min=3); S
Set species with min=3
```

(continues on next page)

(continued from previous page)

```
sage: S.structures([1,2]).list()
[]
sage: S.generating_series()[0:5]
[0, 0, 0, 1/6, 1/24]
```

```
>>> from sage.all import *
>>> S = species.SetSpecies().restricted(min=Integer(3)); S
Set species with min=3
>>> S.structures([Integer(1),Integer(2)]).list()
[]
>>> S.generating_series()[Integer(0):Integer(5)]
[0, 0, 0, 1/6, 1/24]
```

structures(*labels*, *structure_class=None*)

EXAMPLES:

```
sage: F = CombinatorialSpecies()
sage: F.structures([1,2,3]).list()
Traceback (most recent call last):
...
ValueError: Stream is not yet defined
```

```
>>> from sage.all import *
>>> F = CombinatorialSpecies()
>>> F.structures([Integer(1),Integer(2),Integer(3)]).list()
Traceback (most recent call last):
...
ValueError: Stream is not yet defined
```

sum(*g*)

Return the sum of `self` and `g`.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P; F
Sum of (Permutation species) and (Permutation species)
sage: F.structures([1,2]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> F = P + P; F
Sum of (Permutation species) and (Permutation species)
>>> F.structures([Integer(1),Integer(2)]).list()
[[1, 2], [2, 1], [1, 2], [2, 1]]
```

weight_ring()

Return the ring in which the weights of this species occur.

By default, this is just the field of rational numbers.

EXAMPLES:

```
sage: species.SetSpecies().weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> species.SetSpecies().weight_ring()
Rational Field
```

weighted(*weight*)

Return a version of this species with the specified weight.

EXAMPLES:

```
sage: t = ZZ['t'].gen()
sage: C = species.CycleSpecies(); C
Cyclic permutation species
sage: C.weighted(t)
Cyclic permutation species with weight=t
```

```
>>> from sage.all import *
>>> t = ZZ['t'].gen()
>>> C = species.CycleSpecies(); C
Cyclic permutation species
>>> C.weighted(t)
Cyclic permutation species with weight=t
```

5.1.331 Species structures

We will illustrate the use of the structure classes using the "balls and bars" model for integer compositions. An integer composition of 6 such as [2, 1, 3] can be represented in this model as 'oooooo' where the 6 o's correspond to the balls and the 2 's correspond to the bars. If BB is our species for this model, the it satisfies the following recursive definition:

BB = o + o*BB + o*|*BB

Here we define this species using the default structures:

```
sage: ball = species.SingletonSpecies()
sage: bar = species.EmptySetSpecies()
sage: BB = CombinatorialSpecies()
sage: BB.define(ball + ball*BB + ball*bar*BB)
sage: o = var('o')                                                          #␣
↪needs sage.symbolic
sage: BB.isotypes([o]*3).list()                                             #␣
↪needs sage.symbolic
[o*(o*o), o*((o*{})*o), (o*{})*(o*o), (o*{})*((o*{})*o)]
```

```
>>> from sage.all import *
>>> ball = species.SingletonSpecies()
>>> bar = species.EmptySetSpecies()
>>> BB = CombinatorialSpecies()
>>> BB.define(ball + ball*BB + ball*bar*BB)
>>> o = var('o')                                                        #␣
↪needs sage.symbolic
>>> BB.isotypes([o]*Integer(3)).list()                                    ␣
```

(continues on next page)

(continued from previous page)

```
↪     # needs sage.symbolic
[o*(o*o), o*((o*{})*o), (o*{})*(o*o), (o*{})*((o*{})*o)]
```

If we ignore the parentheses, we can read off that the integer compositions are [3], [2, 1], [1, 2], and [1, 1, 1].

class sage.combinat.species.structure.**GenericSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *CombinatorialObject*

This is a base class from which the classes for the structures inherit.

EXAMPLES:

```
sage: from sage.combinat.species.structure import GenericSpeciesStructure
sage: a = GenericSpeciesStructure(None, [2,3,4], [1,2,3])
sage: a
[2, 3, 4]
sage: a.parent() is None
True
sage: a == loads(dumps(a))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.species.structure import GenericSpeciesStructure
>>> a = GenericSpeciesStructure(None, [Integer(2),Integer(3),Integer(4)],␣
↪[Integer(1),Integer(2),Integer(3)])
>>> a
[2, 3, 4]
>>> a.parent() is None
True
>>> a == loads(dumps(a))
True
```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- labels – list of labels

OUTPUT:

A structure with the i-th label of self replaced with the i-th label of the list.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.change_labels([1,2,3]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

```
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.change_labels([Integer(1),Integer(2),Integer(3)]) for s in S]
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

is_isomorphic(*x*)

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: a = S.structures([1,2,3]).random_element(); a
{1, 2, 3}
sage: b = S.structures(['a','b','c']).random_element(); b
{'a', 'b', 'c'}
sage: a.is_isomorphic(b)
True
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> a = S.structures([Integer(1),Integer(2),Integer(3)]).random_element(); a
{1, 2, 3}
>>> b = S.structures(['a','b','c']).random_element(); b
{'a', 'b', 'c'}
>>> a.is_isomorphic(b)
True
```

labels()

Return the labels used for this structure.

Note

This includes labels which may not "appear" in this particular structure.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: s = P.structures(["a", "b", "c"]).random_element()
sage: s.labels()
['a', 'b', 'c']
```

```
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> s = P.structures(["a", "b", "c"]).random_element()
>>> s.labels()
['a', 'b', 'c']
```

parent()

Return the species that this structure is associated with.

EXAMPLES:

```
sage: L = species.LinearOrderSpecies()
sage: a,b = L.structures([1,2])
sage: a.parent()
Linear order species
```

```
>>> from sage.all import *
>>> L = species.LinearOrderSpecies()
```

(continues on next page)

(continued from previous page)

```
>>> a,b = L.structures([Integer(1),Integer(2)])
>>> a.parent()
Linear order species
```

class sage.combinat.species.structure.**IsotypesWrapper**(*species*, *labels*, *structure_class*)

Bases: *SpeciesWrapper*

A base class for the set of isotypes of a species with given set of labels. An object of this type is returned when you call the `isotypes()` method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.isotypes([1,2,3])
sage: S == loads(dumps(S))
True
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.isotypes([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True
```

class sage.combinat.species.structure.**SimpleIsotypesWrapper**(*species*, *labels*, *structure_class*)

Bases: *SpeciesWrapper*

> **Warning**
>
> This is deprecated and currently not used for anything.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.structures([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True
```

class sage.combinat.species.structure.**SimpleStructuresWrapper**(*species*, *labels*, *structure_class*)

Bases: *SpeciesWrapper*

> **Warning**
>
> This is deprecated and currently not used for anything.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.structures([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True
```

sage.combinat.species.structure.**SpeciesStructure**

alias of *GenericSpeciesStructure*

class sage.combinat.species.structure.**SpeciesStructureWrapper**(*parent*, *s*, ***options*)

Bases: *GenericSpeciesStructure*

This is a class for the structures of species such as the sum species that do not provide "additional" structure. For example, if you have the sum C of species A and B, then a structure of C will either be either something from A or B. Instead of just returning one of these directly, a "wrapper" is put around them so that they have their parent is C rather than A or B:

```
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.parent()
Sum of (Singleton species) and (Singleton species)
sage: from sage.combinat.species.structure import SpeciesStructureWrapper
sage: issubclass(type(s), SpeciesStructureWrapper)
True
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> X2 = X+X
>>> s = X2.structures([Integer(1)]).random_element(); s
1
>>> s.parent()
Sum of (Singleton species) and (Singleton species)
>>> from sage.combinat.species.structure import SpeciesStructureWrapper
>>> issubclass(type(s), SpeciesStructureWrapper)
True
```

EXAMPLES:

```
sage: E = species.SetSpecies(); B = E+E
sage: s = B.structures([1,2,3]).random_element()
sage: s.parent()
Sum of (Set species) and (Set species)
sage: s == loads(dumps(s))
True
```

```
>>> from sage.all import *
>>> E = species.SetSpecies(); B = E+E
>>> s = B.structures([Integer(1),Integer(2),Integer(3)]).random_element()
>>> s.parent()
Sum of (Set species) and (Set species)
>>> s == loads(dumps(s))
True
```

canonical_label()

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3])[1]; s                               #␣
↪needs sage.libs.flint
{{1, 3}, {2}}
sage: s.canonical_label()                                                #␣
↪needs sage.libs.flint
{{1, 2}, {3}}
```

```
>>> from sage.all import *
>>> P = species.PartitionSpecies()
>>> s = (P+P).structures([Integer(1),Integer(2),Integer(3)])[Integer(1)]; s  ␣
↪                               # needs sage.libs.flint
{{1, 3}, {2}}
>>> s.canonical_label()                                                #␣
↪needs sage.libs.flint
{{1, 2}, {3}}
```

change_labels(*labels*)

Return a relabelled structure.

INPUT:

- `labels` – list of labels

OUTPUT:

A structure with the i-th label of `self` replaced with the i-th label of the list.

EXAMPLES:

```
sage: X = species.SingletonSpecies()
sage: X2 = X+X
sage: s = X2.structures([1]).random_element(); s
1
sage: s.change_labels(['a'])
'a'
```

```
>>> from sage.all import *
>>> X = species.SingletonSpecies()
>>> X2 = X+X
>>> s = X2.structures([Integer(1)]).random_element(); s
1
>>> s.change_labels(['a'])
'a'
```

transport(*perm*)

EXAMPLES:

```
sage: P = species.PartitionSpecies()
sage: s = (P+P).structures([1,2,3])[1]; s                                    #␣
↪needs sage.libs.flint
{{1, 3}, {2}}
sage: s.transport(PermutationGroupElement((2,3)))                            #␣
↪needs sage.groups sage.libs.flint
{{1, 2}, {3}}
```

```
>>> from sage.all import *
>>> P = species.PartitionSpecies()
>>> s = (P+P).structures([Integer(1),Integer(2),Integer(3)])[Integer(1)]; s  ␣
↪                                 # needs sage.libs.flint
{{1, 3}, {2}}
>>> s.transport(PermutationGroupElement((Integer(2),Integer(3))))           ␣
↪                  # needs sage.groups sage.libs.flint
{{1, 2}, {3}}
```

class sage.combinat.species.structure.**SpeciesWrapper**(*species*, *labels*, *iterator*, *generating_series*, *name*, *structure_class*)

Bases: `Parent`

This is a abstract base class for the set of structures of a species as well as the set of isotypes of the species.

Note: One typically does not use *SpeciesWrapper* directly, but instead instantiates one of its subclasses: *StructuresWrapper* or *IsotypesWrapper*.

EXAMPLES:

```
sage: from sage.combinat.species.structure import SpeciesWrapper
sage: F = species.SetSpecies()
sage: S = SpeciesWrapper(F, [1,2,3], "_structures", "generating_series",
↪'Structures', None)
sage: S
Structures for Set species with labels [1, 2, 3]
sage: S.list()
[{1, 2, 3}]
sage: S.cardinality()
1
```

```
>>> from sage.all import *
>>> from sage.combinat.species.structure import SpeciesWrapper
>>> F = species.SetSpecies()
>>> S = SpeciesWrapper(F, [Integer(1),Integer(2),Integer(3)], "_structures",
↪"generating_series", 'Structures', None)
>>> S
Structures for Set species with labels [1, 2, 3]
>>> S.list()
```

(continues on next page)

(continued from previous page)

```
[{1, 2, 3}]
>>> S.cardinality()
1
```

cardinality()

Return the number of structures in this set.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).cardinality()
1
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> F.structures([Integer(1),Integer(2),Integer(3)]).cardinality()
1
```

labels()

Return the labels used on these structures. If X is the species, then *labels()* returns the preimage of these structures under the functor X.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: F.structures([1,2,3]).labels()
[1, 2, 3]
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> F.structures([Integer(1),Integer(2),Integer(3)]).labels()
[1, 2, 3]
```

class sage.combinat.species.structure.**StructuresWrapper**(*species*, *labels*, *structure_class*)

Bases: *SpeciesWrapper*

A base class for the set of structures of a species with given set of labels. An object of this type is returned when you call the `structures()` method of a species.

EXAMPLES:

```
sage: F = species.SetSpecies()
sage: S = F.structures([1,2,3])
sage: S == loads(dumps(S))
True
```

```
>>> from sage.all import *
>>> F = species.SetSpecies()
>>> S = F.structures([Integer(1),Integer(2),Integer(3)])
>>> S == loads(dumps(S))
True
```

5.1.332 Subset Species

class sage.combinat.species.subset_species.**SubsetSpecies**(*min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the species of subsets.

EXAMPLES:

```
sage: S = species.SubsetSpecies()
sage: S.generating_series()[0:5]
[1, 2, 2, 4/3, 2/3]
sage: S.isotype_generating_series()[0:5]
[1, 2, 3, 4, 5]

sage: S = species.SubsetSpecies()
sage: c = S.generating_series()[0:3]
sage: S._check()
True
sage: S == loads(dumps(S))
True
```

```
>>> from sage.all import *
>>> S = species.SubsetSpecies()
>>> S.generating_series()[Integer(0):Integer(5)]
[1, 2, 2, 4/3, 2/3]
>>> S.isotype_generating_series()[Integer(0):Integer(5)]
[1, 2, 3, 4, 5]

>>> S = species.SubsetSpecies()
>>> c = S.generating_series()[Integer(0):Integer(3)]
>>> S._check()
True
>>> S == loads(dumps(S))
True
```

class sage.combinat.species.subset_species.**SubsetSpeciesStructure**(*parent*, *labels*, *list*)

Bases: *GenericSpeciesStructure*

automorphism_group()

Return the group of permutations whose action on this subset leave it fixed.

EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures([1,2,3,4])[6]; a
{1, 3}
sage: a.automorphism_group()                                                    #␣
↪needs sage.groups
Permutation Group with generators [(2,4), (1,3)]
```

```
>>> from sage.all import *
>>> F = species.SubsetSpecies()
>>> a = F.structures([Integer(1),Integer(2),Integer(3),
↪Integer(4)])[Integer(6)]; a
```

(continues on next page)

(continued from previous page)

```
{1, 3}
>>> a.automorphism_group()                                                   #␣
↪needs sage.groups
Permutation Group with generators [(2,4), (1,3)]
```

```
sage: [a.transport(g) for g in a.automorphism_group()]                          #␣
↪needs sage.groups
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]
```

```
>>> from sage.all import *
>>> [a.transport(g) for g in a.automorphism_group()]                        #␣
↪needs sage.groups
[{1, 3}, {1, 3}, {1, 3}, {1, 3}]
```

canonical_label()

Return the canonical label of `self`.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.canonical_label() for s in S]
[{}, {'a'}, {'a'}, {'a'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b', 'c'}]
```

```
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.canonical_label() for s in S]
[{}, {'a'}, {'a'}, {'a'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b'}, {'a', 'b', 'c'}]
```

complement()

Return the complement of `self`.

EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: a.complement()
{'b'}
```

```
>>> from sage.all import *
>>> F = species.SubsetSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(5)]; a
{'a', 'c'}
>>> a.complement()
{'b'}
```

label_subset()

Return a subset of the labels that “appear” in this structure.

EXAMPLES:

```
sage: P = species.SubsetSpecies()
sage: S = P.structures(["a", "b", "c"])
sage: [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

```
>>> from sage.all import *
>>> P = species.SubsetSpecies()
>>> S = P.structures(["a", "b", "c"])
>>> [s.label_subset() for s in S]
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

transport(*perm*)

Return the transport of this subset along the permutation perm.

EXAMPLES:

```
sage: F = species.SubsetSpecies()
sage: a = F.structures(["a", "b", "c"])[5]; a
{'a', 'c'}
sage: p = PermutationGroupElement((1,2))                                    #␣
↪needs sage.groups
sage: a.transport(p)                                                        #␣
↪needs sage.groups
{'b', 'c'}
sage: p = PermutationGroupElement((1,3))                                    #␣
↪needs sage.groups
sage: a.transport(p)                                                        #␣
↪needs sage.groups
{'a', 'c'}
```

```
>>> from sage.all import *
>>> F = species.SubsetSpecies()
>>> a = F.structures(["a", "b", "c"])[Integer(5)]; a
{'a', 'c'}
>>> p = PermutationGroupElement((Integer(1),Integer(2)))                    ␣
↪               # needs sage.groups
>>> a.transport(p)                                                        #␣
↪needs sage.groups
{'b', 'c'}
>>> p = PermutationGroupElement((Integer(1),Integer(3)))                    ␣
↪               # needs sage.groups
>>> a.transport(p)                                                        #␣
↪needs sage.groups
{'a', 'c'}
```

sage.combinat.species.subset_species.**SubsetSpecies_class**

alias of `SubsetSpecies`

5.1.333 Sum species

class sage.combinat.species.sum_species.**SumSpecies**(*F*, *G*, *min=None*, *max=None*, *weight=None*)

Bases: *GenericCombinatorialSpecies*, UniqueRepresentation

Return the sum of two species.

EXAMPLES:

```
sage: S = species.PermutationSpecies()
sage: A = S+S
sage: A.generating_series()[:5]
[2, 2, 2, 2, 2]

sage: P = species.PermutationSpecies()
sage: F = P + P
sage: F._check()                                                    #␣
↪needs sage.libs.flint
True
sage: F == loads(dumps(F))
True
```

```
>>> from sage.all import *
>>> S = species.PermutationSpecies()
>>> A = S+S
>>> A.generating_series()[:Integer(5)]
[2, 2, 2, 2, 2]

>>> P = species.PermutationSpecies()
>>> F = P + P
>>> F._check()                                                  # needs␣
↪sage.libs.flint
True
>>> F == loads(dumps(F))
True
```

left_summand()

Return the left summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.left_summand()
Permutation species
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> F = P + P*P
>>> F.left_summand()
Permutation species
```

right_summand()

Return the right summand of this species.

EXAMPLES:

```
sage: P = species.PermutationSpecies()
sage: F = P + P*P
sage: F.right_summand()
Product of (Permutation species) and (Permutation species)
```

```
>>> from sage.all import *
>>> P = species.PermutationSpecies()
>>> F = P + P*P
>>> F.right_summand()
Product of (Permutation species) and (Permutation species)
```

weight_ring()

Return the weight ring for this species. This is determined by asking Sage's coercion model what the result is when you add elements of the weight rings for each of the operands.

EXAMPLES:

```
sage: S = species.SetSpecies()
sage: C = S+S
sage: C.weight_ring()
Rational Field
```

```
>>> from sage.all import *
>>> S = species.SetSpecies()
>>> C = S+S
>>> C.weight_ring()
Rational Field
```

```
sage: S = species.SetSpecies(weight=QQ['t'].gen())
sage: C = S + S
sage: C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

```
>>> from sage.all import *
>>> S = species.SetSpecies(weight=QQ['t'].gen())
>>> C = S + S
>>> C.weight_ring()
Univariate Polynomial Ring in t over Rational Field
```

class sage.combinat.species.sum_species.**SumSpeciesStructure**(*parent*, *s*, ***options*)

Bases: *SpeciesStructureWrapper*

sage.combinat.species.sum_species.**SumSpecies_class**

alias of *SumSpecies*

5.1.334 Specht Modules

AUTHORS:

- Travis Scrimshaw (2023-1-22): initial version
- Travis Scrimshaw (2023-11-23): added simple modules based on code from Sacha Goldman

Todo

Integrate this with the implementations in `sage.modules.with_basis.representation`.

class `sage.combinat.specht_module.`**`MaximalSpechtSubmodule`**(*specht_module*)

Bases: *SymmetricGroupRepresentation*, `SubmoduleWithBasis`

The maximal submodule U^λ of the Specht module S^λ.

ALGORITHM:

We construct U^λ as the intersection $S \cap S^\perp$, where $S^\perp$ is the orthogonal complement of the Specht module S inside of the tabloid module T (with respect to the natural bilinear form on T).

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: U = SM.maximal_submodule()
sage: u = U.an_element(); u
2*U[0] + 2*U[1]
sage: [p * u for p in list(SGA.basis())[:4]]
[2*U[0] + 2*U[1], 2*U[2] + 2*U[3], 2*U[0] + 2*U[1], U[0] + 2*U[2]]
sage: sum(SGA.basis()) * u
0
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> U = SM.maximal_submodule()
>>> u = U.an_element(); u
2*U[0] + 2*U[1]
>>> [p * u for p in list(SGA.basis())[:Integer(4)]]
[2*U[0] + 2*U[1], 2*U[2] + 2*U[3], 2*U[0] + 2*U[1], U[0] + 2*U[2]]
>>> sum(SGA.basis()) * u
0
```

`Element`

alias of *Element*

class `sage.combinat.specht_module.`**`SimpleModule`**(*specht_module*)

Bases: *SymmetricGroupRepresentation*, `QuotientModuleWithBasis`

The simple S_n-module associated with a partition λ.

The simple module D^λ is the quotient of the Specht module S^λ by its *maximal submodule* U^λ.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,1,1])
sage: D = SM.simple_module()
sage: v = D.an_element(); v
2*D[[[1, 3, 5], [2], [4]]] + 2*D[[[1, 4, 5], [2], [3]]]
sage: SGA.an_element() * v
2*D[[[1, 2, 4], [3], [5]]] + 2*D[[[1, 3, 5], [2], [4]]]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(1),Integer(1)])
>>> D = SM.simple_module()
>>> v = D.an_element(); v
2*D[[[1, 3, 5], [2], [4]]] + 2*D[[[1, 4, 5], [2], [3]]]
>>> SGA.an_element() * v
2*D[[[1, 2, 4], [3], [5]]] + 2*D[[[1, 3, 5], [2], [4]]]
```

We give an example on how to construct the decomposition matrix (the Specht modules are a complete set of irreducible projective modules) and the Cartan matrix of a symmetric group algebra:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: BM = matrix(SGA.simple_module(la).brauer_character()
....:               for la in Partitions(4, regular=3))
sage: SBT = matrix(SGA.specht_module(la).brauer_character()
....:                for la in Partitions(4))
sage: D = SBT * ~BM; D
[1 0 0 0]
[0 1 0 0]
[1 0 1 0]
[0 0 0 1]
[0 0 1 0]
sage: D.transpose() * D
[2 0 1 0]
[0 1 0 0]
[1 0 2 0]
[0 0 0 1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> BM = matrix(SGA.simple_module(la).brauer_character()
...               for la in Partitions(Integer(4), regular=Integer(3)))
>>> SBT = matrix(SGA.specht_module(la).brauer_character()
...                for la in Partitions(Integer(4)))
>>> D = SBT * ~BM; D
[1 0 0 0]
[0 1 0 0]
[1 0 1 0]
[0 0 0 1]
[0 0 1 0]
>>> D.transpose() * D
[2 0 1 0]
[0 1 0 0]
[1 0 2 0]
[0 0 0 1]
```

We verify this against the direct computation (up to reindexing the rows and columns):

```
sage: SGA.cartan_invariants_matrix()  # long time
[1 0 0 0]
[0 1 0 0]
[0 0 2 1]
```

(continues on next page)

(continued from previous page)

```
[0 0 1 2]
```

```
>>> from sage.all import *
>>> SGA.cartan_invariants_matrix()  # long time
[1 0 0 0]
[0 1 0 0]
[0 0 2 1]
[0 0 1 2]
```

Element

alias of `Element`

class sage.combinat.specht_module.**SpechtModule**(*SGA*, *D*)

Bases: `SymmetricGroupRepresentation`, `SubmoduleWithBasis`

A Specht module.

Let S_n be the symmetric group on n letters and R be a commutative ring. The *Specht module* S^D for a diagram D is an S_n-module defined as follows. Let

$$R(D) := \sum_{w \in R_D} w, \qquad C(D) := \sum_{w \in C_D} (-1)^w w,$$

where R_D (resp. C_D) is the row (resp. column) stabilizer of D. Then, we construct the Specht module S^D as the left ideal

$$S^D = R[S_n]C(D)R(D),$$

where $R[S_n]$ is the group algebra of S_n over R.

INPUT:

- `SGA` – a symmetric group algebra
- `D` – a diagram

EXAMPLES:

We begin by constructing all irreducible Specht modules for the symmetric group S_4 and show that they give a full set of irreducible representations both by having distinct Frobenius characters and the sum of the square of their dimensions is equal to $4!$:

```
sage: SP = [la.specht_module(QQ) for la in Partitions(4)]
sage: s = SymmetricFunctions(QQ).s()
sage: [s(S.frobenius_image()) for S in SP]
[s[4], s[3, 1], s[2, 2], s[2, 1, 1], s[1, 1, 1, 1]]
sage: sum(S.dimension()^2 for S in SP)
24
```

```
>>> from sage.all import *
>>> SP = [la.specht_module(QQ) for la in Partitions(Integer(4))]
>>> s = SymmetricFunctions(QQ).s()
>>> [s(S.frobenius_image()) for S in SP]
[s[4], s[3, 1], s[2, 2], s[2, 1, 1], s[1, 1, 1, 1]]
>>> sum(S.dimension()**Integer(2) for S in SP)
24
```

Next, we compute the Specht module for a more general diagram for S_5 and compute its irreducible decomposition by using its Frobenius character:

```
sage: D = [(0,0), (0,1), (1,1), (1,2), (0,3)]
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module(D)
sage: SM.dimension()
9
sage: s(SM.frobenius_image())
s[3, 2] + s[4, 1]
```

```
>>> from sage.all import *
>>> D = [(Integer(0),Integer(0)), (Integer(0),Integer(1)), (Integer(1),
↪Integer(1)), (Integer(1),Integer(2)), (Integer(0),Integer(3))]
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module(D)
>>> SM.dimension()
9
>>> s(SM.frobenius_image())
s[3, 2] + s[4, 1]
```

This carries a natural (left) action of the symmetric group (algebra):

```
sage: S5 = SGA.group()
sage: v = SM.an_element(); v
2*S[0] + 2*S[1] + 3*S[2]
sage: S5([2,1,5,3,4]) * v
3*S[0] + 2*S[1] + 2*S[2]
sage: x = SGA.an_element(); x
[1, 2, 3, 4, 5] + 2*[1, 2, 3, 5, 4] + 3*[1, 2, 4, 3, 5] + [5, 1, 2, 3, 4]
sage: x * v
15*S[0] + 14*S[1] + 16*S[2] - 7*S[5] + 2*S[6] + 2*S[7]
```

```
>>> from sage.all import *
>>> S5 = SGA.group()
>>> v = SM.an_element(); v
2*S[0] + 2*S[1] + 3*S[2]
>>> S5([Integer(2),Integer(1),Integer(5),Integer(3),Integer(4)]) * v
3*S[0] + 2*S[1] + 2*S[2]
>>> x = SGA.an_element(); x
[1, 2, 3, 4, 5] + 2*[1, 2, 3, 5, 4] + 3*[1, 2, 4, 3, 5] + [5, 1, 2, 3, 4]
>>> x * v
15*S[0] + 14*S[1] + 16*S[2] - 7*S[5] + 2*S[6] + 2*S[7]
```

See also

SpechtRepresentation for an implementation of the representation by matrices.

class Element

Bases: IndexedFreeModuleElement

class sage.combinat.specht_module.**SpechtModuleTableauxBasis**(*ambient*)

Bases: *SpechtModule*

A Specht module of a partition in the classical standard tableau basis.

This is constructed as a S_n-submodule of the `TabloidModule` (also referred to as the standard module).

See also:

- `SpechtModule` for the generic diagram implementation constructed as a left ideal of the group algebra
- `SpechtRepresentation` for an implementation of the representation by matrices.

bilinear_form(*u*, *v*)

Return the natural bilinear form of `self` applied to `u` and `v`.

The natural bilinear form is given by the pullback of the natural bilinear form on the tabloid module (where the tabloid basis is an orthonormal basis).

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([2,2,1])
sage: u = SM.an_element(); u
3*S[[1, 2], [3, 5], [4]] + 2*S[[1, 3], [2, 5], [4]] + 2*S[[1, 4], [2, 5], [3]]
sage: v = sum(SM.basis())
sage: SM.bilinear_form(u, v)
140
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(2),Integer(2),Integer(1)])
>>> u = SM.an_element(); u
3*S[[1, 2], [3, 5], [4]] + 2*S[[1, 3], [2, 5], [4]] + 2*S[[1, 4], [2, 5], [3]]
>>> v = sum(SM.basis())
>>> SM.bilinear_form(u, v)
140
```

gram_matrix()

Return the Gram matrix of the natural bilinear form of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([2,2,1])
sage: M = SM.gram_matrix(); M
[12  4 -4 -4  4]
[ 4 12  4  4  4]
[-4  4 12  4  4]
[-4  4  4 12  4]
[ 4  4  4  4 12]
sage: M.det() != 0
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(2),Integer(2),Integer(1)])
```

(continues on next page)

(continued from previous page)

```
>>> M = SM.gram_matrix(); M
[12  4 -4 -4  4]
[ 4 12  4  4  4]
[-4  4 12  4  4]
[-4  4  4 12  4]
[ 4  4  4  4 12]
>>> M.det() != Integer(0)
True
```

intrinsic_arrangement(*base_ring=None*)

Return the intrinsic arrangement of `self`.

Consider the Specht module S^λ with λ a (integer) partition of n (i.e., S^λ is an S_n-module). The *intrinsic arrangement* of S^λ is the central hyperplane arrangement in S^λ given by the hyperplanes H_α, indexed by a set partition α of $\{1, \ldots, n\}$ of size λ, defined by

$$H_\alpha := \bigoplus_{\tau \in T_\alpha} (S^\lambda)^\tau,$$

where T_α is some set of generating transpositions of the Young subgroup S_α and V^τ denotes the τ-invariant subspace of V. (These hyperplanes do not depend on the choice of T_α.)

This was introduced in [TVY2020] as a generalization of the braid arrangement, which is the case when $\lambda = (n-1, 1)$ (equivalently, for the irreducible representation of S_n given by the type A_{n-1} root system).

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: SM = SGA.specht_module([2, 1, 1])
sage: A = SM.intrinsic_arrangement()
sage: A.hyperplanes()
(Hyperplane T0 - T1 - 3*T2 + 0,
 Hyperplane T0 - T1 + T2 + 0,
 Hyperplane T0 + 3*T1 + T2 + 0,
 Hyperplane 3*T0 + T1 - T2 + 0)
sage: A.is_free()
False
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> SM = SGA.specht_module([Integer(2), Integer(1), Integer(1)])
>>> A = SM.intrinsic_arrangement()
>>> A.hyperplanes()
(Hyperplane T0 - T1 - 3*T2 + 0,
 Hyperplane T0 - T1 + T2 + 0,
 Hyperplane T0 + 3*T1 + T2 + 0,
 Hyperplane 3*T0 + T1 - T2 + 0)
>>> A.is_free()
False
```

We reproduce Example 3 of [TVY2020]:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(5):
```

(continues on next page)

(continued from previous page)

```
....:     SM = SGA.specht_module(la)
....:     A = SM.intrinsic_arrangement()
....:     print(la, A.characteristic_polynomial())
[5] 1
[4, 1] x^4 - 10*x^3 + 35*x^2 - 50*x + 24
[3, 2] x^5 - 15*x^4 + 90*x^3 - 260*x^2 + 350*x - 166
[3, 1, 1] x^6 - 10*x^5 + 45*x^4 - 115*x^3 + 175*x^2 - 147*x + 51
[2, 2, 1] x^5 - 10*x^4 + 45*x^3 - 105*x^2 + 120*x - 51
[2, 1, 1, 1] x^4 - 5*x^3 + 10*x^2 - 10*x + 4
[1, 1, 1, 1, 1] 1

sage: A = SGA.specht_module([4, 1]).intrinsic_arrangement()
sage: A.characteristic_polynomial().factor()
(x - 4) * (x - 3) * (x - 2) * (x - 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> for la in Partitions(Integer(5)):
...     SM = SGA.specht_module(la)
...     A = SM.intrinsic_arrangement()
...     print(la, A.characteristic_polynomial())
[5] 1
[4, 1] x^4 - 10*x^3 + 35*x^2 - 50*x + 24
[3, 2] x^5 - 15*x^4 + 90*x^3 - 260*x^2 + 350*x - 166
[3, 1, 1] x^6 - 10*x^5 + 45*x^4 - 115*x^3 + 175*x^2 - 147*x + 51
[2, 2, 1] x^5 - 10*x^4 + 45*x^3 - 105*x^2 + 120*x - 51
[2, 1, 1, 1] x^4 - 5*x^3 + 10*x^2 - 10*x + 4
[1, 1, 1, 1, 1] 1

>>> A = SGA.specht_module([Integer(4), Integer(1)]).intrinsic_arrangement()
>>> A.characteristic_polynomial().factor()
(x - 4) * (x - 3) * (x - 2) * (x - 1)
```

lift()

The lift (embedding) map from `self` to the ambient space.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([3, 1, 1])
sage: SM.lift
Generic morphism:
  From: Specht module of [3, 1, 1] over Rational Field
  To:   Tabloid module of [3, 1, 1] over Rational Field
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(3), Integer(1), Integer(1)])
>>> SM.lift
Generic morphism:
  From: Specht module of [3, 1, 1] over Rational Field
  To:   Tabloid module of [3, 1, 1] over Rational Field
```

maximal_submodule()

Return the maximal submodule of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: U = SM.maximal_submodule()
sage: U.dimension()
4
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> U = SM.maximal_submodule()
>>> U.dimension()
4
```

retract()

The retract map from the ambient space.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: X = SGA.tabloid_module([2,2,1])
sage: Y = X.specht_module()
sage: Y.retract
Generic morphism:
  From: Tabloid module of [2, 2, 1] over Rational Field
  To:   Specht module of [2, 2, 1] over Rational Field
sage: all(Y.retract(u.lift()) == u for u in Y.basis())
True

sage: Y.retract(X.zero())
0
sage: Y.retract(sum(X.basis()))
Traceback (most recent call last):
...
ValueError: ... is not in the image
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> X = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> Y = X.specht_module()
>>> Y.retract
Generic morphism:
  From: Tabloid module of [2, 2, 1] over Rational Field
  To:   Specht module of [2, 2, 1] over Rational Field
>>> all(Y.retract(u.lift()) == u for u in Y.basis())
True

>>> Y.retract(X.zero())
0
>>> Y.retract(sum(X.basis()))
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: ... is not in the image
```

simple_module()

Return the simple (or irreducible) S_n-submodule of `self`.

See also

SimpleModule

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: SM = SGA.specht_module([3,2])
sage: L = SM.simple_module()
sage: L.dimension()
1

sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module([3,2])
sage: SM.simple_module() is SM
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> L = SM.simple_module()
>>> L.dimension()
1

>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module([Integer(3),Integer(2)])
>>> SM.simple_module() is SM
True
```

class sage.combinat.specht_module.**SymmetricGroupRepresentation**(*SGA*)

Bases: `Representation_abstract`

Mixin class for symmetric group (algebra) representations.

frobenius_image()

Return the Frobenius image of `self`.

The Frobenius map is defined as the map to symmetric functions

$$F(\chi) = \frac{1}{n!} \sum_{w \in S_n} \chi(w) p_{\rho(w)},$$

where χ is the character of the S_n-module `self`, p_λ is the powersum symmetric function basis element indexed by λ, and $\rho(w)$ is the cycle type of w as a partition. Specifically, this map takes irreducible representations indexed by λ to the Schur function s_λ.

EXAMPLES:

```
sage: SM = Partition([2,2,1]).specht_module(QQ)
sage: SM.frobenius_image()
s[2, 2, 1]
sage: SM = Partition([4,1]).specht_module(CyclotomicField(5))
sage: SM.frobenius_image()
s[4, 1]
```

```
>>> from sage.all import *
>>> SM = Partition([Integer(2),Integer(2),Integer(1)]).specht_module(QQ)
>>> SM.frobenius_image()
s[2, 2, 1]
>>> SM = Partition([Integer(4),Integer(1)]).specht_
↪module(CyclotomicField(Integer(5)))
>>> SM.frobenius_image()
s[4, 1]
```

We verify the regular representation:

```
sage: from sage.combinat.diagram import Diagram
sage: D = Diagram([(0,0), (1,1), (2,2), (3,3), (4,4)])
sage: F = D.specht_module(QQ).frobenius_image(); F
s[1, 1, 1, 1, 1] + 4*s[2, 1, 1, 1] + 5*s[2, 2, 1]
 + 6*s[3, 1, 1] + 5*s[3, 2] + 4*s[4, 1] + s[5]
sage: s = SymmetricFunctions(QQ).s()
sage: F == sum(StandardTableaux(la).cardinality() * s[la]
....:          for la in Partitions(5))
True
sage: all(s[la] == la.specht_module(QQ).frobenius_image()
....:     for n in range(1, 5) for la in Partitions(n))
True

sage: D = Diagram([(0,0), (1,1), (1,2), (2,3), (2,4)])
sage: SM = D.specht_module(QQ)
sage: SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> from sage.combinat.diagram import Diagram
>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2)), (Integer(3),Integer(3)), (Integer(4),Integer(4))])
>>> F = D.specht_module(QQ).frobenius_image(); F
s[1, 1, 1, 1, 1] + 4*s[2, 1, 1, 1] + 5*s[2, 2, 1]
 + 6*s[3, 1, 1] + 5*s[3, 2] + 4*s[4, 1] + s[5]
>>> s = SymmetricFunctions(QQ).s()
>>> F == sum(StandardTableaux(la).cardinality() * s[la]
...          for la in Partitions(Integer(5)))
True
>>> all(s[la] == la.specht_module(QQ).frobenius_image()
...     for n in range(Integer(1), Integer(5)) for la in Partitions(n))
True

>>> D = Diagram([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
```

(continues on next page)

(continued from previous page)

```
↪(Integer(1),Integer(2)), (Integer(2),Integer(3)), (Integer(2),Integer(4))])
>>> SM = D.specht_module(QQ)
>>> SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

An example using the tabloid module:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2, 2, 1])
sage: TM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2), Integer(2), Integer(1)])
>>> TM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + 2*s[3, 2] + 2*s[4, 1] + s[5]
```

class sage.combinat.specht_module.**TabloidModule**(*SGA*, *shape*)

Bases: *SymmetricGroupRepresentation*, *CombinatorialFreeModule*

The vector space of all tabloids of a fixed shape with the natural symmetric group action.

A *tabloid* is an *OrderedSetPartition* whose underlying set is $\{1, \ldots, n\}$. The symmetric group acts by permuting the entries of the set. Hence, this is a representation of the symmetric group defined over any field.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: TM = SGA.tabloid_module([2, 2, 1])
sage: TM.dimension()
30
sage: TM.brauer_character()
(30, 6, 2, 0, 0)
sage: IM = TM.invariant_module()
sage: IM.dimension()
1
sage: IM.basis()[0].lift() == sum(TM.basis())
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> TM = SGA.tabloid_module([Integer(2), Integer(2), Integer(1)])
>>> TM.dimension()
30
>>> TM.brauer_character()
(30, 6, 2, 0, 0)
>>> IM = TM.invariant_module()
>>> IM.dimension()
1
>>> IM.basis()[Integer(0)].lift() == sum(TM.basis())
True
```

class Element

Bases: IndexedFreeModuleElement

bilinear_form(*u*, *v*)

Return the natural bilinear form of `self` applied to `u` and `v`.

The natural bilinear form is given by defining the tabloid basis to be orthonormal.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2,2,1])
sage: u = TM.an_element(); u
2*T[{1, 2}, {3, 4}, {5}] + 2*T[{1, 2}, {3, 5}, {4}] + 3*T[{1, 2}, {4, 5}, {3}]
sage: v = sum(TM.basis())
sage: TM.bilinear_form(u, v)
7
sage: TM.bilinear_form(u, TM.zero())
0
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> u = TM.an_element(); u
2*T[{1, 2}, {3, 4}, {5}] + 2*T[{1, 2}, {3, 5}, {4}] + 3*T[{1, 2}, {4, 5}, {3}]
>>> v = sum(TM.basis())
>>> TM.bilinear_form(u, v)
7
>>> TM.bilinear_form(u, TM.zero())
0
```

specht_module()

Return the Specht submodule of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module([2,2,1])
sage: TM.specht_module() is SGA.specht_module([2,2,1])
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module([Integer(2),Integer(2),Integer(1)])
>>> TM.specht_module() is SGA.specht_module([Integer(2),Integer(2),
↪Integer(1)])
True
```

sage.combinat.specht_module.**polytabloid**(T)

Compute the polytabloid element associated to a tableau `T`.

For a tableau T, the polytabloid associated to T is

$$e_T = \sum_{\sigma \in C_T} (-1)^\sigma \{\sigma T\},$$

where $\{\}$ is the row-equivalence class, i.e. a tabloid, and C_T is the column stabilizer of T. The sum takes place in the module spanned by tabloids $\{T\}$.

OUTPUT:

A `dict` whose keys are tabloids represented by tuples of frozensets and whose values are the coefficient.

EXAMPLES:

```
sage: from sage.combinat.specht_module import polytabloid
sage: T = StandardTableau([[1,3,4],[2,5]])
sage: polytabloid(T)
{(frozenset({1, 3, 4}), frozenset({2, 5})): 1,
 (frozenset({1, 4, 5}), frozenset({2, 3})): -1,
 (frozenset({2, 3, 4}), frozenset({1, 5})): -1,
 (frozenset({2, 4, 5}), frozenset({1, 3})): 1}
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import polytabloid
>>> T = StandardTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(5)]])
>>> polytabloid(T)
{(frozenset({1, 3, 4}), frozenset({2, 5})): 1,
 (frozenset({1, 4, 5}), frozenset({2, 3})): -1,
 (frozenset({2, 3, 4}), frozenset({1, 5})): -1,
 (frozenset({2, 4, 5}), frozenset({1, 3})): 1}
```

`sage.combinat.specht_module.`**`simple_module_rank`**(*la*, *base_ring*)

Return the rank of the simple S_n-module corresponding to the partition `la` of size n over `base_ring`.

EXAMPLES:

```
sage: from sage.combinat.specht_module import simple_module_rank
sage: simple_module_rank([3,2,1,1], GF(3))
13
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import simple_module_rank
>>> simple_module_rank([Integer(3),Integer(2),Integer(1),Integer(1)],␣
↪GF(Integer(3)))
13
```

`sage.combinat.specht_module.`**`specht_module_rank`**(*D*, *base_ring=None*)

Return the rank of the Specht module of diagram `D`.

EXAMPLES:

```
sage: from sage.combinat.specht_module import specht_module_rank
sage: specht_module_rank([(0,0), (1,1), (2,2)])
6
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import specht_module_rank
>>> specht_module_rank([(Integer(0),Integer(0)), (Integer(1),Integer(1)),␣
↪(Integer(2),Integer(2))])
6
```

sage.combinat.specht_module.**specht_module_spanning_set**(*D*, *SGA=None*)

Return a spanning set of the Specht module of diagram D.

INPUT:

- D – list of cells (r,c) for row r and column c
- SGA – (optional) a symmetric group algebra

EXAMPLES:

```
sage: from sage.combinat.specht_module import specht_module_spanning_set
sage: specht_module_spanning_set([(0,0), (1,1), (2,2)])
([1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1])
sage: specht_module_spanning_set([(0,0), (1,1), (2,1)])
([1, 2, 3] - [1, 3, 2], -[1, 2, 3] + [1, 3, 2], [2, 1, 3] - [3, 1, 2],
 [2, 3, 1] - [3, 2, 1], -[2, 1, 3] + [3, 1, 2], -[2, 3, 1] + [3, 2, 1])

sage: SGA = SymmetricGroup(3).algebra(QQ)
sage: specht_module_spanning_set([(0,0), (1,1), (2,1)], SGA)
(() - (2,3), -(1,2) + (1,3,2), (1,2,3) - (1,3),
 -() + (2,3), -(1,2,3) + (1,3), (1,2) - (1,3,2))
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import specht_module_spanning_set
>>> specht_module_spanning_set([(Integer(0),Integer(0)), (Integer(1),Integer(1)),
↪(Integer(2),Integer(2))])
([1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1])
>>> specht_module_spanning_set([(Integer(0),Integer(0)), (Integer(1),Integer(1)),
↪(Integer(2),Integer(1))])
([1, 2, 3] - [1, 3, 2], -[1, 2, 3] + [1, 3, 2], [2, 1, 3] - [3, 1, 2],
 [2, 3, 1] - [3, 2, 1], -[2, 1, 3] + [3, 1, 2], -[2, 3, 1] + [3, 2, 1])

>>> SGA = SymmetricGroup(Integer(3)).algebra(QQ)
>>> specht_module_spanning_set([(Integer(0),Integer(0)), (Integer(1),Integer(1)),
↪(Integer(2),Integer(1))], SGA)
(() - (2,3), -(1,2) + (1,3,2), (1,2,3) - (1,3),
 -() + (2,3), -(1,2,3) + (1,3), (1,2) - (1,3,2))
```

sage.combinat.specht_module.**tabloid_gram_matrix**(*la*, *base_ring*)

Compute the Gram matrix of the bilinear form of a Specht module pulled back from the tabloid module.

For the module spanned by all tabloids, we define an bilinear form by having the tabloids be an orthonormal basis. We then pull this bilinear form back across the natural injection of the Specht module into the tabloid module.

EXAMPLES:

```
sage: from sage.combinat.specht_module import tabloid_gram_matrix
sage: tabloid_gram_matrix([3,2], GF(5))
[4 2 2 1 4]
[2 4 1 2 1]
[2 1 4 2 1]
[1 2 2 4 2]
[4 1 1 2 4]
```

```
>>> from sage.all import *
>>> from sage.combinat.specht_module import tabloid_gram_matrix
>>> tabloid_gram_matrix([Integer(3),Integer(2)], GF(Integer(5)))
[4 2 2 1 4]
[2 4 1 2 1]
[2 1 4 2 1]
[1 2 2 4 2]
[4 1 1 2 4]
```

5.1.335 Subsets

The set of subsets of a finite set. The set can be given as a list or a `Set` or else as an integer n which encodes the set $\{1, 2, ..., n\}$. See *Subsets* for more information and examples.

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods

class sage.combinat.subset.**SubMultiset_s**(*s*)

Bases: `Parent`

The combinatorial class of the sub multisets of `s`.

EXAMPLES:

```
sage: S = Subsets([1,2,2,3], submultiset=True)
sage: S.cardinality()
12
sage: S.list()
[[],
 [1],
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
sage: S.first()
[]
sage: S.last()
[1, 2, 2, 3]
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3)], submultiset=True)
>>> S.cardinality()
12
>>> S.list()
[[],
 [1],
```

(continues on next page)

(continued from previous page)

```
 [2],
 [3],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [1, 2, 2],
 [1, 2, 3],
 [2, 2, 3],
 [1, 2, 2, 3]]
>>> S.first()
[]
>>> S.last()
[1, 2, 2, 3]
```

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: S = Subsets([1,1,2,3],submultiset=True)
sage: S.cardinality()
12
sage: len(S.list())
12

sage: S = Subsets([1,1,2,2,3],submultiset=True)
sage: S.cardinality()
18
sage: len(S.list())
18

sage: S = Subsets([1,1,1,2,2,3],submultiset=True)
sage: S.cardinality()
24
sage: len(S.list())
24
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],
↪submultiset=True)
>>> S.cardinality()
12
>>> len(S.list())
12

>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(2),Integer(3)],
↪submultiset=True)
>>> S.cardinality()
18
>>> len(S.list())
18
```

(continues on next page)

(continued from previous page)

```
>>> S = Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3)],submultiset=True)
>>> S.cardinality()
24
>>> len(S.list())
24
```

element_class

alias of `list`

generating_serie(*variable='x'*)

Return the polynomial associated to the counting of the elements of `self` weighted by the number of element they contain.

EXAMPLES:

```
sage: Subsets([1,1],submultiset=True).generating_serie()
x^2 + x + 1
sage: Subsets([1,1,2,3],submultiset=True).generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
sage: Subsets([1,1,1,2,2,3,3,4],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1

sage: S = Subsets([1,1,1,2,2,3,3,4],submultiset=True)
sage: S.cardinality()
72
sage: sum(S.generating_serie())
72
```

```
>>> from sage.all import *
>>> Subsets([Integer(1),Integer(1)],submultiset=True).generating_serie()
x^2 + x + 1
>>> Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],submultiset=True).
↪generating_serie()
x^4 + 3*x^3 + 4*x^2 + 3*x + 1
>>> Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3),Integer(4)],submultiset=True).generating_serie()
x^8 + 4*x^7 + 9*x^6 + 14*x^5 + 16*x^4 + 14*x^3 + 9*x^2 + 4*x + 1

>>> S = Subsets([Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3),Integer(3),Integer(4)],submultiset=True)
>>> S.cardinality()
72
>>> sum(S.generating_serie())
72
```

random_element()

Return a random element of `self` with uniform law.

EXAMPLES:

```
sage: S = Subsets([1,1,2,3], submultiset=True)
sage: s = S.random_element()
sage: s in S
True
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(1),Integer(2),Integer(3)],␣
↪submultiset=True)
>>> s = S.random_element()
>>> s in S
True
```

class sage.combinat.subset.**SubMultiset_sk**(*s*, *k*)

Bases: *SubMultiset_s*

The combinatorial class of the subsets of size k of a multiset s. Note that each subset is represented by a list of the elements rather than a set since we can have multiplicities (no multiset data structure yet in sage).

EXAMPLES:

```
sage: S = Subsets([1,2,3,3],2,submultiset=True)
sage: S._k
2
sage: S.cardinality()
4
sage: S.first()
[1, 2]
sage: S.last()
[3, 3]
sage: [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(3),Integer(3)],Integer(2),
↪submultiset=True)
>>> S._k
2
>>> S.cardinality()
4
>>> S.first()
[1, 2]
>>> S.last()
[3, 3]
>>> [sub for sub in S]
[[1, 2], [1, 3], [2, 3], [3, 3]]
```

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: S = Subsets([1,2,2,3,3,3],4,submultiset=True)
sage: S.cardinality()
5
```

(continues on next page)

(continued from previous page)

```
sage: len(list(S))
5

sage: S = Subsets([1,2,2,3,3,3],3,submultiset=True)
sage: S.cardinality()
6
sage: len(list(S))
6
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
↪Integer(3)],Integer(4),submultiset=True)
>>> S.cardinality()
5
>>> len(list(S))
5

>>> S = Subsets([Integer(1),Integer(2),Integer(2),Integer(3),Integer(3),
↪Integer(3)],Integer(3),submultiset=True)
>>> S.cardinality()
6
>>> len(list(S))
6
```

generating_serie(*variable='x'*)

Return the polynomial associated to the counting of the elements of `self` weighted by the number of elements they contains

EXAMPLES:

```
sage: x = ZZ['x'].gen()
sage: l = [1,1,1,1,2,2,3]
sage: for k in range(len(l)):
....:     S = Subsets(l,k,submultiset=True)
....:     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
True
True
True
True
True
```

```
>>> from sage.all import *
>>> x = ZZ['x'].gen()
>>> l = [Integer(1),Integer(1),Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(3)]
>>> for k in range(len(l)):
...     S = Subsets(l,k,submultiset=True)
...     print(S.generating_serie('x') == S.cardinality()*x**k)
True
True
```

(continues on next page)

(continued from previous page)

```
True
True
True
True
True
```

random_element()

Return a random submultiset of given length.

EXAMPLES:

```
sage: s = Subsets(7,3).random_element()
sage: s in Subsets(7,3)
True

sage: s = Subsets(7,5).random_element()
sage: s in Subsets(7,5)
True
```

```
>>> from sage.all import *
>>> s = Subsets(Integer(7),Integer(3)).random_element()
>>> s in Subsets(Integer(7),Integer(3))
True

>>> s = Subsets(Integer(7),Integer(5)).random_element()
>>> s in Subsets(Integer(7),Integer(5))
True
```

sage.combinat.subset.**Subsets**(*s*, *k=None*, *submultiset=False*)

Return the combinatorial class of the subsets of the finite set `s`. The set can be given as a list, Set or any iterable convertible to a set. Alternatively, a nonnegative integer n can be provided in place of `s`; in this case, the result is the combinatorial class of the subsets of the set $\{1, 2, \dots, n\}$ (i.e. of the Sage `range(1,n+1)`).

A second optional parameter `k` can be given. In this case, `Subsets` returns the combinatorial class of subsets of `s` of size `k`.

> **Warning**
>
> The subsets are returned as Sets. Do not assume that these Sets are ordered; they often are not! (E.g., `Subsets(10).list()[619]` returns `{10, 4, 5, 6, 7}` on my system.) See *SubsetsSorted* for a similar class which returns the subsets as sorted tuples.

Finally the option `submultiset` allows one to deal with sets with repeated elements, usually called multisets. The method then returns the class of all multisets in which every element is contained at most as often as it is contained in `s`. These multisets are encoded as lists.

EXAMPLES:

```
sage: S = Subsets([1, 2, 3]); S
Subsets of {1, 2, 3}
sage: S.cardinality()
8
```

(continues on next page)

(continued from previous page)

```
sage: S.first()
{}
sage: S.last()
{1, 2, 3}
sage: S.random_element() in S
True
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(1), Integer(2), Integer(3)]); S
Subsets of {1, 2, 3}
>>> S.cardinality()
8
>>> S.first()
{}
>>> S.last()
{1, 2, 3}
>>> S.random_element() in S
True
>>> S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

Here is the same example where the set is given as an integer:

```
sage: S = Subsets(3)
sage: S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

```
>>> from sage.all import *
>>> S = Subsets(Integer(3))
>>> S.list()
[{}, {1}, {2}, {3}, {1, 2}, {1, 3}, {2, 3}, {1, 2, 3}]
```

We demonstrate various the effect of the various options:

```
sage: S = Subsets(3, 2); S
Subsets of {1, 2, 3} of size 2
sage: S.list()
[{1, 2}, {1, 3}, {2, 3}]

sage: S = Subsets([1, 2, 2], submultiset=True); S
SubMultiset of [1, 2, 2]
sage: S.list()
[[], [1], [2], [1, 2], [2, 2], [1, 2, 2]]

sage: S = Subsets([1, 2, 2, 3], 3, submultiset=True); S
SubMultiset of [1, 2, 2, 3] of size 3
sage: S.list()
[[1, 2, 2], [1, 2, 3], [2, 2, 3]]

sage: S = Subsets(['a','b','a','b'], 2, submultiset=True); S.list()
```

(continues on next page)

(continued from previous page)

```
[['a', 'a'], ['a', 'b'], ['b', 'b']]
```

```
>>> from sage.all import *
>>> S = Subsets(Integer(3), Integer(2)); S
Subsets of {1, 2, 3} of size 2
>>> S.list()
[{1, 2}, {1, 3}, {2, 3}]

>>> S = Subsets([Integer(1), Integer(2), Integer(2)], submultiset=True); S
SubMultiset of [1, 2, 2]
>>> S.list()
[[], [1], [2], [1, 2], [2, 2], [1, 2, 2]]

>>> S = Subsets([Integer(1), Integer(2), Integer(2), Integer(3)], Integer(3),␣
→submultiset=True); S
SubMultiset of [1, 2, 2, 3] of size 3
>>> S.list()
[[1, 2, 2], [1, 2, 3], [2, 2, 3]]

>>> S = Subsets(['a','b','a','b'], Integer(2), submultiset=True); S.list()
[['a', 'a'], ['a', 'b'], ['b', 'b']]
```

And it is possible to play with subsets of subsets:

```
sage: S = Subsets(3)
sage: S2 = Subsets(S); S2
Subsets of Subsets of {1, 2, 3}
sage: S2.cardinality()
256
sage: it = iter(S2)
sage: [next(it) for _ in range(8)]
[{}, {{}}, {{1}}, {{2}}, {{3}}, {{1, 2}},  {{1, 3}}, {{2, 3}}]
sage: S2.random_element()     # random
{{2}, {1, 2, 3}, {}}
sage: [S2.unrank(k) for k in range(256)] == S2.list()
True

sage: S3 = Subsets(S2)
sage: S3.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S3.unrank(14123091480)  # random
{{{2}, {1, 2, 3}, {1, 2}, {3}, {}},
 {{1, 2, 3}, {2}, {1}, {1, 3}},
 {{}, {2}, {2, 3}, {1, 2}},
 {{}, {2}, {1, 2, 3}, {1, 2}},
 {},
 {{}, {1}, {1, 2, 3}}}

sage: T = Subsets(S2, 10)
sage: T.cardinality()
278826214642518400
sage: T.unrank(1441231049)  # random
```

(continues on next page)

(continued from previous page)

```
{{{1, 2, 3}, {2}, {2, 3}}, {{3}, {1, 3}, ..., {3}, {1}, {}, {1, 3}}}
```

```
>>> from sage.all import *
>>> S = Subsets(Integer(3))
>>> S2 = Subsets(S); S2
Subsets of Subsets of {1, 2, 3}
>>> S2.cardinality()
256
>>> it = iter(S2)
>>> [next(it) for _ in range(Integer(8))]
[{}, {{}}, {{1}}, {{2}}, {{3}}, {{1, 2}},  {{1, 3}}, {{2, 3}}]
>>> S2.random_element()     # random
{{2}, {1, 2, 3}, {}}
>>> [S2.unrank(k) for k in range(Integer(256))] == S2.list()
True

>>> S3 = Subsets(S2)
>>> S3.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
>>> S3.unrank(Integer(14123091480))  # random
{{{2}, {1, 2, 3}, {1, 2}, {3}, {}},
 {{1, 2, 3}, {2}, {1}, {1, 3}},
 {{}, {2}, {2, 3}, {1, 2}},
 {{}, {2}, {1, 2, 3}, {1, 2}},
 {},
 {{}, {1}, {1, 2, 3}}}

>>> T = Subsets(S2, Integer(10))
>>> T.cardinality()
278826214642518400
>>> T.unrank(Integer(1441231049))  # random
{{{1, 2, 3}, {2}, {2, 3}}, {{3}, {1, 3}, ..., {3}, {1}, {}, {1, 3}}}
```

class sage.combinat.subset.**SubsetsSorted**(s)

Bases: *Subsets_s*

Lightweight class of all subsets of some set S, with each subset being encoded as a sorted tuple.

Used to model indices of algebras given by subsets (so we don't have to explicitly build all 2^n subsets in memory). For example, CliffordAlgebra.

element_class

alias of tuple

first()

Return the first element of self.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.first()
()
```

```
>>> from sage.all import *
>>> from sage.combinat.subset import SubsetsSorted
>>> S = SubsetsSorted(range(Integer(3)))
>>> S.first()
()
```

last()

Return the last element of `self`.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.last()
(0, 1, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.subset import SubsetsSorted
>>> S = SubsetsSorted(range(Integer(3)))
>>> S.last()
(0, 1, 2)
```

random_element()

Return a random element of `self`.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: isinstance(S.random_element(), tuple)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.subset import SubsetsSorted
>>> S = SubsetsSorted(range(Integer(3)))
>>> isinstance(S.random_element(), tuple)
True
```

unrank(*r*)

Return the subset which has rank `r`.

EXAMPLES:

```
sage: from sage.combinat.subset import SubsetsSorted
sage: S = SubsetsSorted(range(3))
sage: S.unrank(4)
(0, 1)
```

```
>>> from sage.all import *
>>> from sage.combinat.subset import SubsetsSorted
>>> S = SubsetsSorted(range(Integer(3)))
>>> S.unrank(Integer(4))
(0, 1)
```

class sage.combinat.subset.**Subsets_s**(*s*)

Bases: Parent

Subsets of a given set.

EXAMPLES:

```
sage: S = Subsets(4); S
Subsets of {1, 2, 3, 4}
sage: S.cardinality()
16
sage: Subsets(4).list()
[{}, {1}, {2}, {3}, {4},
 {1, 2}, {1, 3}, {1, 4}, {2, 3}, {2, 4}, {3, 4},
 {1, 2, 3}, {1, 2, 4}, {1, 3, 4}, {2, 3, 4},
 {1, 2, 3, 4}]

sage: S = Subsets(Subsets(Subsets(GF(3)))); S
Subsets of Subsets of Subsets of Finite Field of size 3
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: S.unrank(3149254230)  # random
{{{1}, {0, 2}}, {{0, 1, 2}, {0, 1}, {1}, {1, 2}},
 {{2}, {1, 2}, {0, 1, 2}, {0, 2}, {1}, {}},
 {{1, 2}, {0}},
 {{0, 1, 2}, {0, 1}, {0, 2}, {1, 2}}}
```

```
>>> from sage.all import *
>>> S = Subsets(Integer(4)); S
Subsets of {1, 2, 3, 4}
>>> S.cardinality()
16
>>> Subsets(Integer(4)).list()
[{}, {1}, {2}, {3}, {4},
 {1, 2}, {1, 3}, {1, 4}, {2, 3}, {2, 4}, {3, 4},
 {1, 2, 3}, {1, 2, 4}, {1, 3, 4}, {2, 3, 4},
 {1, 2, 3, 4}]

>>> S = Subsets(Subsets(Subsets(GF(Integer(3))))); S
Subsets of Subsets of Subsets of Finite Field of size 3
>>> S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
>>> S.unrank(Integer(3149254230))  # random
{{{1}, {0, 2}}, {{0, 1, 2}, {0, 1}, {1}, {1, 2}},
 {{2}, {1, 2}, {0, 1, 2}, {0, 2}, {1}, {}},
 {{1, 2}, {0}},
 {{0, 1, 2}, {0, 1}, {0, 2}, {1, 2}}}
```

cardinality()

Return the number of subsets of the set `s`.

This is given by $2^{|s|}$.

EXAMPLES:

```
sage: Subsets(Set([1,2,3])).cardinality()
8
sage: Subsets([1,2,3,3]).cardinality()
8
sage: Subsets(3).cardinality()
8
```

```
>>> from sage.all import *
>>> Subsets(Set([Integer(1),Integer(2),Integer(3)])).cardinality()
8
>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)]).cardinality()
8
>>> Subsets(Integer(3)).cardinality()
8
```

element_class

alias of `Set_object_enumerated`

first()

Return the first subset of `s`. Since we aren't restricted to subsets of a certain size, this is always the empty set.

EXAMPLES:

```
sage: Subsets([1,2,3]).first()
{}
sage: Subsets(3).first()
{}
```

```
>>> from sage.all import *
>>> Subsets([Integer(1),Integer(2),Integer(3)]).first()
{}
>>> Subsets(Integer(3)).first()
{}
```

last()

Return the last subset of `s`. Since we aren't restricted to subsets of a certain size, this is always the set `s` itself.

EXAMPLES:

```
sage: Subsets([1,2,3]).last()
{1, 2, 3}
sage: Subsets(3).last()
{1, 2, 3}
```

```
>>> from sage.all import *
>>> Subsets([Integer(1),Integer(2),Integer(3)]).last()
{1, 2, 3}
>>> Subsets(Integer(3)).last()
{1, 2, 3}
```

lattice()

Return the lattice of subsets ordered by containment.

EXAMPLES:

```
sage: X = Subsets([7,8,9])
sage: X.lattice()                                                        #␣
↪needs sage.combinat sage.graphs
Finite lattice containing 8 elements
sage: Y = Subsets(0)
sage: Y.lattice()                                                        #␣
↪needs sage.combinat sage.graphs
Finite lattice containing 1 elements
```

```
>>> from sage.all import *
>>> X = Subsets([Integer(7),Integer(8),Integer(9)])
>>> X.lattice()                                                          #␣
↪needs sage.combinat sage.graphs
Finite lattice containing 8 elements
>>> Y = Subsets(Integer(0))
>>> Y.lattice()                                                          #␣
↪needs sage.combinat sage.graphs
Finite lattice containing 1 elements
```

random_element()

Return a random element of the class of subsets of s (in other words, a random subset of s).

EXAMPLES:

```
sage: Subsets(3).random_element()           # random
{2}
sage: Subsets([4,5,6]).random_element()     # random
{5}

sage: S = Subsets(Subsets(Subsets([0,1,2])))
sage: S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
sage: s = S.random_element()
sage: s     # random
{{{1, 2}, {2}, {0}, {1}}, {{1, 2}, {0, 1, 2}, {0, 2}, {0}, {0, 1}}, ..., {{1,␣
↪2}, {2}, {1}}, {{2}, {0, 2}, {}, {1}}}
sage: s in S
True
```

```
>>> from sage.all import *
>>> Subsets(Integer(3)).random_element()           # random
{2}
>>> Subsets([Integer(4),Integer(5),Integer(6)]).random_element()     # random
{5}

>>> S = Subsets(Subsets(Subsets([Integer(0),Integer(1),Integer(2)])))
>>> S.cardinality()
115792089237316195423570985008687907853269984665640564039457584007913129639936
>>> s = S.random_element()
>>> s     # random
{{{1, 2}, {2}, {0}, {1}}, {{1, 2}, {0, 1, 2}, {0, 2}, {0}, {0, 1}}, ..., {{1,␣
↪2}, {2}, {1}}, {{2}, {0, 2}, {}, {1}}}
>>> s in S
```

(continues on next page)

(continued from previous page)

```
True
```

rank(*sub*)

Return the rank of `sub` as a subset of `s`.

EXAMPLES:

```
sage: Subsets(3).rank([])
0
sage: Subsets(3).rank([1,2])
4
sage: Subsets(3).rank([1,2,3])
7
sage: Subsets(3).rank([2,3,4])
Traceback (most recent call last):
...
ValueError: {2, 3, 4} is not a subset of {1, 2, 3}
```

```
>>> from sage.all import *
>>> Subsets(Integer(3)).rank([])
0
>>> Subsets(Integer(3)).rank([Integer(1),Integer(2)])
4
>>> Subsets(Integer(3)).rank([Integer(1),Integer(2),Integer(3)])
7
>>> Subsets(Integer(3)).rank([Integer(2),Integer(3),Integer(4)])
Traceback (most recent call last):
...
ValueError: {2, 3, 4} is not a subset of {1, 2, 3}
```

underlying_set()

Return the set of elements.

EXAMPLES:

```
sage: Subsets(GF(13)).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}
```

```
>>> from sage.all import *
>>> Subsets(GF(Integer(13))).underlying_set()
{0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12}
```

unrank(*r*)

Return the subset of `s` that has rank `k`.

EXAMPLES:

```
sage: Subsets(3).unrank(0)
{}
sage: Subsets([2,4,5]).unrank(1)
{2}
sage: Subsets([1,2,3]).unrank(257)
Traceback (most recent call last):
```

(continues on next page)

(continued from previous page)

```
...
IndexError: index out of range
```

```
>>> from sage.all import *
>>> Subsets(Integer(3)).unrank(Integer(0))
{}
>>> Subsets([Integer(2),Integer(4),Integer(5)]).unrank(Integer(1))
{2}
>>> Subsets([Integer(1),Integer(2),Integer(3)]).unrank(Integer(257))
Traceback (most recent call last):
...
IndexError: index out of range
```

class sage.combinat.subset.**Subsets_sk**(*s*, *k*)

Bases: *Subsets_s*

Subsets of fixed size of a set.

EXAMPLES:

```
sage: S = Subsets([0,1,2,5,7], 3); S
Subsets of {0, 1, 2, 5, 7} of size 3
sage: S.cardinality()
10
sage: S.first(), S.last()
({0, 1, 2}, {2, 5, 7})
sage: S.random_element()  # random
{0, 5, 7}
sage: S([0,2,7])
{0, 2, 7}
sage: S([0,3,5])
Traceback (most recent call last):
...
ValueError: {0, 3, 5} not in Subsets of {0, 1, 2, 5, 7} of size 3
sage: S([0])
Traceback (most recent call last):
...
ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3
```

```
>>> from sage.all import *
>>> S = Subsets([Integer(0),Integer(1),Integer(2),Integer(5),Integer(7)],␣
↪Integer(3)); S
Subsets of {0, 1, 2, 5, 7} of size 3
>>> S.cardinality()
10
>>> S.first(), S.last()
({0, 1, 2}, {2, 5, 7})
>>> S.random_element()  # random
{0, 5, 7}
>>> S([Integer(0),Integer(2),Integer(7)])
{0, 2, 7}
>>> S([Integer(0),Integer(3),Integer(5)])
```

(continues on next page)

(continued from previous page)

```
Traceback (most recent call last):
...
ValueError: {0, 3, 5} not in Subsets of {0, 1, 2, 5, 7} of size 3
>>> S([Integer(0)])
Traceback (most recent call last):
...
ValueError: {0} not in Subsets of {0, 1, 2, 5, 7} of size 3
```

an_element()

Return an example of subset.

EXAMPLES:

```
sage: Subsets(0,0).an_element()
{}
sage: Subsets(3,2).an_element()
{1, 3}
sage: Subsets([2,4,5],2).an_element()
{2, 5}
```

```
>>> from sage.all import *
>>> Subsets(Integer(0),Integer(0)).an_element()
{}
>>> Subsets(Integer(3),Integer(2)).an_element()
{1, 3}
>>> Subsets([Integer(2),Integer(4),Integer(5)],Integer(2)).an_element()
{2, 5}
```

cardinality()

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).cardinality()
3
sage: Subsets([1,2,3,3], 2).cardinality()
3
sage: Subsets([1,2,3], 1).cardinality()
3
sage: Subsets([1,2,3], 3).cardinality()
1
sage: Subsets([1,2,3], 0).cardinality()
1
sage: Subsets([1,2,3], 4).cardinality()
0
sage: Subsets(3,2).cardinality()
3
sage: Subsets(3,4).cardinality()
0
```

```
>>> from sage.all import *
>>> Subsets(Set([Integer(1),Integer(2),Integer(3)]), Integer(2)).cardinality()
3
>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)], Integer(2)).
```

(continues on next page)

(continued from previous page)

```
↪cardinality()
3
>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(1)).cardinality()
3
>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(3)).cardinality()
1
>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(0)).cardinality()
1
>>> Subsets([Integer(1),Integer(2),Integer(3)], Integer(4)).cardinality()
0
>>> Subsets(Integer(3),Integer(2)).cardinality()
3
>>> Subsets(Integer(3),Integer(4)).cardinality()
0
```

first()

Return the first subset of s of size k.

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).first()
{1, 2}
sage: Subsets([1,2,3,3], 2).first()
{1, 2}
sage: Subsets(3,2).first()
{1, 2}
sage: Subsets(3,4).first()
Traceback (most recent call last):
...
EmptySetError
```

```
>>> from sage.all import *
>>> Subsets(Set([Integer(1),Integer(2),Integer(3)]), Integer(2)).first()
{1, 2}
>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)], Integer(2)).first()
{1, 2}
>>> Subsets(Integer(3),Integer(2)).first()
{1, 2}
>>> Subsets(Integer(3),Integer(4)).first()
Traceback (most recent call last):
...
EmptySetError
```

last()

Return the last subset of s of size k.

EXAMPLES:

```
sage: Subsets(Set([1,2,3]), 2).last()
{2, 3}
sage: Subsets([1,2,3,3], 2).last()
{2, 3}
sage: Subsets(3,2).last()
```

(continues on next page)

(continued from previous page)

```
{2, 3}
sage: Subsets(3,4).last()
Traceback (most recent call last):
...
EmptySetError
```

```
>>> from sage.all import *
>>> Subsets(Set([Integer(1),Integer(2),Integer(3)]), Integer(2)).last()
{2, 3}
>>> Subsets([Integer(1),Integer(2),Integer(3),Integer(3)], Integer(2)).last()
{2, 3}
>>> Subsets(Integer(3),Integer(2)).last()
{2, 3}
>>> Subsets(Integer(3),Integer(4)).last()
Traceback (most recent call last):
...
EmptySetError
```

random_element()

Return a random element of the class of subsets of `s` of size `k` (in other words, a random subset of `s` of size `k`).

EXAMPLES:

```
sage: s = Subsets(3, 2).random_element()
sage: s in Subsets(3, 2)
True

sage: Subsets(3,4).random_element()
Traceback (most recent call last):
...
EmptySetError
```

```
>>> from sage.all import *
>>> s = Subsets(Integer(3), Integer(2)).random_element()
>>> s in Subsets(Integer(3), Integer(2))
True

>>> Subsets(Integer(3),Integer(4)).random_element()
Traceback (most recent call last):
...
EmptySetError
```

rank(*sub*)

Return the rank of `sub` as a subset of `s` of size `k`.

EXAMPLES:

```
sage: Subsets(3,2).rank([1,2])
0
sage: Subsets([2,3,4],2).rank([3,4])
2
```

(continues on next page)

(continued from previous page)

```
sage: Subsets([2,3,4],2).rank([2])
Traceback (most recent call last):
...
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
sage: Subsets([2,3,4],4).rank([2,3,4,5])
Traceback (most recent call last):
...
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}
```

```
>>> from sage.all import *
>>> Subsets(Integer(3),Integer(2)).rank([Integer(1),Integer(2)])
0
>>> Subsets([Integer(2),Integer(3),Integer(4)],Integer(2)).rank([Integer(3),
↪Integer(4)])
2
>>> Subsets([Integer(2),Integer(3),Integer(4)],Integer(2)).rank([Integer(2)])
Traceback (most recent call last):
...
ValueError: {2} is not a subset of length 2 of {2, 3, 4}
>>> Subsets([Integer(2),Integer(3),Integer(4)],Integer(4)).rank([Integer(2),
↪Integer(3),Integer(4),Integer(5)])
Traceback (most recent call last):
...
ValueError: {2, 3, 4, 5} is not a subset of length 4 of {2, 3, 4}
```

unrank(*r*)

Return the subset of `s` of size `k` that has rank `r`.

EXAMPLES:

```
sage: Subsets(3,2).unrank(0)
{1, 2}
sage: Subsets([2,4,5],2).unrank(0)
{2, 4}
sage: Subsets([1,2,8],3).unrank(42)
Traceback (most recent call last):
...
IndexError: index out of range
```

```
>>> from sage.all import *
>>> Subsets(Integer(3),Integer(2)).unrank(Integer(0))
{1, 2}
>>> Subsets([Integer(2),Integer(4),Integer(5)],Integer(2)).unrank(Integer(0))
{2, 4}
>>> Subsets([Integer(1),Integer(2),Integer(8)],Integer(3)).unrank(Integer(42))
Traceback (most recent call last):
...
IndexError: index out of range
```

`sage.combinat.subset.`**dict_to_list**(*d*)

Return a list whose elements are the elements of `i` of `d` repeated with multiplicity `d[i]`.

EXAMPLES:

```
sage: from sage.combinat.subset import dict_to_list
sage: dict_to_list({'a':1, 'b':3})
['a', 'b', 'b', 'b']
```

```
>>> from sage.all import *
>>> from sage.combinat.subset import dict_to_list
>>> dict_to_list({'a':Integer(1), 'b':Integer(3)})
['a', 'b', 'b', 'b']
```

sage.combinat.subset.**list_to_dict**(*l*)

Return a dictionary of multiplicities and the list of its keys.

INPUT:

- l – list with possibly repeated elements

The keys are the elements of l (in the same order in which they appear) and values are the multiplicities of each element in l.

EXAMPLES:

```
sage: from sage.combinat.subset import list_to_dict
sage: list_to_dict(['a', 'b', 'b', 'b'])
({'a': 1, 'b': 3}, ['a', 'b'])
```

```
>>> from sage.all import *
>>> from sage.combinat.subset import list_to_dict
>>> list_to_dict(['a', 'b', 'b', 'b'])
({'a': 1, 'b': 3}, ['a', 'b'])
```

sage.combinat.subset.**powerset**(*X*)

Iterator over the *list* of all subsets of the iterable X, in no particular order. Each list appears exactly once, up to order.

INPUT:

- X – an iterable

OUTPUT: iterator of lists

EXAMPLES:

```
sage: list(powerset([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
sage: [z for z in powerset([0,[1,2]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

```
>>> from sage.all import *
>>> list(powerset([Integer(1),Integer(2),Integer(3)]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
>>> [z for z in powerset([Integer(0),[Integer(1),Integer(2)]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

Iterating over the power set of an infinite set is also allowed:

```
sage: i = 0
sage: L = []
sage: for x in powerset(ZZ):
....:     if i > 10:
....:         break
....:     else:
....:         i += 1
....:     L.append(x)
sage: print(" ".join(str(x) for x in L))
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

```
>>> from sage.all import *
>>> i = Integer(0)
>>> L = []
>>> for x in powerset(ZZ):
...     if i > Integer(10):
...         break
...     else:
...         i += Integer(1)
...     L.append(x)
>>> print(" ".join(str(x) for x in L))
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

You may also use subsets as an alias for powerset:

```
sage: subsets([1,2,3])
<generator object ...powerset at 0x...>
sage: list(subsets([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of
sets must be hashable and many structures on which one wants the
powerset consist of non-hashable objects.
```

```
>>> from sage.all import *
>>> subsets([Integer(1),Integer(2),Integer(3)])
<generator object ...powerset at 0x...>
>>> list(subsets([Integer(1),Integer(2),Integer(3)]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of
sets must be hashable and many structures on which one wants the
powerset consist of non-hashable objects.
```

AUTHORS:

- William Stein
- Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects X.

`sage.combinat.subset.`**`subsets`**`(X)`

Iterator over the *list* of all subsets of the iterable `X`, in no particular order. Each list appears exactly once, up to order.

INPUT:

- x – an iterable

OUTPUT: iterator of lists

EXAMPLES:

```
sage: list(powerset([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
sage: [z for z in powerset([0,[1,2]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

```
>>> from sage.all import *
>>> list(powerset([Integer(1),Integer(2),Integer(3)]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]
>>> [z for z in powerset([Integer(0),[Integer(1),Integer(2)]])]
[[], [0], [[1, 2]], [0, [1, 2]]]
```

Iterating over the power set of an infinite set is also allowed:

```
sage: i = 0
sage: L = []
sage: for x in powerset(ZZ):
....:     if i > 10:
....:         break
....:     else:
....:         i += 1
....:     L.append(x)
sage: print(" ".join(str(x) for x in L))
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

```
>>> from sage.all import *
>>> i = Integer(0)
>>> L = []
>>> for x in powerset(ZZ):
...     if i > Integer(10):
...         break
...     else:
...         i += Integer(1)
...     L.append(x)
>>> print(" ".join(str(x) for x in L))
[] [0] [1] [0, 1] [-1] [0, -1] [1, -1] [0, 1, -1] [2] [0, 2] [1, 2]
```

You may also use subsets as an alias for powerset:

```
sage: subsets([1,2,3])
<generator object ...powerset at 0x...>
sage: list(subsets([1,2,3]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of
sets must be hashable and many structures on which one wants the
powerset consist of non-hashable objects.
```

```
>>> from sage.all import *
>>> subsets([Integer(1),Integer(2),Integer(3)])
<generator object ...powerset at 0x...>
>>> list(subsets([Integer(1),Integer(2),Integer(3)]))
[[], [1], [2], [1, 2], [3], [1, 3], [2, 3], [1, 2, 3]]

The reason we return lists instead of sets is that the elements of
sets must be hashable and many structures on which one wants the
powerset consist of non-hashable objects.
```

AUTHORS:

- William Stein
- Nils Bruin (2006-12-19): rewrite to work for not-necessarily finite objects X.

sage.combinat.subset.**uniq**(*L*)

Iterate over the elements of `L`, yielding every element at most once: keep only the first occurrence of any item.

The items must be hashable.

INPUT:

- `L` – iterable

EXAMPLES:

```
sage: L = [1, 1, 8, -5, 3, -5, 'a', 'x', 'a']
sage: it = uniq(L); it
<generator object uniq at ...>
sage: list(it)
[1, 8, -5, 3, 'a', 'x']
```

```
>>> from sage.all import *
>>> L = [Integer(1), Integer(1), Integer(8), -Integer(5), Integer(3), -Integer(5),
↪ 'a', 'x', 'a']
>>> it = uniq(L); it
<generator object uniq at ...>
>>> list(it)
[1, 8, -5, 3, 'a', 'x']
```

5.1.336 Subsets satisfying a hereditary property

sage.combinat.subsets_hereditary.**subsets_with_hereditary_property**(*f*, *X*, *max_obstruction_size=None*, *ncpus=1*)

Return all subsets S of X such that $f(S)$ is true.

The boolean function f must be decreasing, i.e. $f(S) \Rightarrow f(S')$ if $S' \subseteq S$.

This function is implemented to call f as few times as possible. More precisely, f will be called on all sets S such that $f(S)$ is true, as well as on all inclusionwise minimal sets S such that $f(S)$ is false.

The problem that this function answers is also known as the learning problem on monotone boolean functions, or as computing the set of winning coalitions in a simple game.

INPUT:

- f – boolean function which takes as input a list of elements from X
- X – list/iterable
- max_obstruction_size – integer; if you know that there is a k such that $f(S)$ is true if and only if $f(S')$ is true for all $S' \subseteq S$ with $S' \leq k$, set max_obstruction_size=k. It may dramatically decrease the number of calls to f. Set to None by default, meaning $k = |X|$.
- ncpus – number of cpus to use for this computation. Note that changing the value from 1 (default) to anything different *enables* parallel computations which can have a cost by itself, so it is not necessarily a good move. In some cases, however, it is a *great* move. Set to None to automatically detect and use the maximum number of cpus available.

> **Note**
>
> Parallel computations are performed through the parallel() decorator. See its documentation for more information, in particular with respect to the memory context.

EXAMPLES:

Sets whose elements all have the same remainder mod 2:

```
sage: from sage.combinat.subsets_hereditary import subsets_with_hereditary_
↪property
sage: def f(x):
....:     return (not x) or all(xx % 2 == x[0] % 2 for xx in x)
sage: list(subsets_with_hereditary_property(f, range(4)))
[[], [0], [1], [2], [3], [0, 2], [1, 3]]
```

```
>>> from sage.all import *
>>> from sage.combinat.subsets_hereditary import subsets_with_hereditary_property
>>> def f(x):
...     return (not x) or all(xx % Integer(2) == x[Integer(0)] % Integer(2) for␣
↪xx in x)
>>> list(subsets_with_hereditary_property(f, range(Integer(4))))
[[], [0], [1], [2], [3], [0, 2], [1, 3]]
```

Same, on two threads:

```
sage: sorted(subsets_with_hereditary_property(f, range(4), ncpus=2))
[[], [0], [0, 2], [1], [1, 3], [2], [3]]
```

```
>>> from sage.all import *
>>> sorted(subsets_with_hereditary_property(f, range(Integer(4)),␣
↪ncpus=Integer(2)))
[[], [0], [0, 2], [1], [1, 3], [2], [3]]
```

One can use this function to compute the independent sets of a graph. We know, however, that in this case the maximum obstructions are the edges, and have size 2. We can thus set max_obstruction_size=2, which reduces the number of calls to f from 91 to 56:

```
sage: # needs sage.graphs
sage: num_calls = 0
sage: g = graphs.PetersenGraph()
```

(continues on next page)

(continued from previous page)

```
sage: def is_independent_set(S):
....:     global num_calls
....:     num_calls += 1
....:     return g.subgraph(S).size() == 0
sage: l1 = list(subsets_with_hereditary_property(is_independent_set,
....:                                              g.vertices(sort=False)))
sage: num_calls
91
sage: num_calls = 0
sage: l2 = list(subsets_with_hereditary_property(is_independent_set,
....:                                              g.vertices(sort=False),
....:                                              max_obstruction_size=2))
sage: num_calls
56
sage: l1 == l2
True
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> num_calls = Integer(0)
>>> g = graphs.PetersenGraph()
>>> def is_independent_set(S):
...     global num_calls
...     num_calls += Integer(1)
...     return g.subgraph(S).size() == Integer(0)
>>> l1 = list(subsets_with_hereditary_property(is_independent_set,
...                                              g.vertices(sort=False)))
>>> num_calls
91
>>> num_calls = Integer(0)
>>> l2 = list(subsets_with_hereditary_property(is_independent_set,
...                                              g.vertices(sort=False),
...                                              max_obstruction_size=Integer(2)))
>>> num_calls
56
>>> l1 == l2
True
```

5.1.337 Subsets whose elements satisfy a predicate pairwise

class sage.combinat.subsets_pairwise.**PairwiseCompatibleSubsets**(*ambient*, *predicate*, *maximal=False*, *element_class=<class 'sage.sets.set.Set_object_enumerated'>*)

Bases: `RecursivelyEnumeratedSet_forest`

The set of all subsets of `ambient` whose elements satisfy `predicate` pairwise

INPUT:

- `ambient` – set (or iterable)
- `predicate` – a binary predicate

Assumptions: `predicate` is symmetric (`predicate(x,y) == predicate(y,x)`) and reflexive (`predicate(x,x) == True`).

Note

in fact, `predicate(x,x)` is never called.

Warning

The current name is suboptimal and is subject to change. Suggestions for a good name, and a good user entry point are welcome. Maybe `Subsets(..., independent = predicate)`.

EXAMPLES:

We construct the set of all subsets of $\{4,5,6,8,9\}$ whose elements are pairwise relatively prime:

```
sage: from sage.combinat.subsets_pairwise import PairwiseCompatibleSubsets
sage: def predicate(x, y): return gcd(x, y) == 1
sage: P = PairwiseCompatibleSubsets( [4,5,6,8,9], predicate); P
An enumerated set with a forest structure
sage: P.list()
[{}, {4}, {4, 5}, {9, 4, 5}, {9, 4}, {5}, {5, 6}, {8, 5}, {8, 9, 5}, {9, 5}, {6},
→{8}, {8, 9}, {9}]
sage: P.cardinality()
14
sage: P.category()
Category of finite enumerated sets
```

```
>>> from sage.all import *
>>> from sage.combinat.subsets_pairwise import PairwiseCompatibleSubsets
>>> def predicate(x, y): return gcd(x, y) == Integer(1)
>>> P = PairwiseCompatibleSubsets( [Integer(4),Integer(5),Integer(6),Integer(8),
→Integer(9)], predicate); P
An enumerated set with a forest structure
>>> P.list()
[{}, {4}, {4, 5}, {9, 4, 5}, {9, 4}, {5}, {5, 6}, {8, 5}, {8, 9, 5}, {9, 5}, {6},
→{8}, {8, 9}, {9}]
>>> P.cardinality()
14
>>> P.category()
Category of finite enumerated sets
```

Here we consider only those subsets which are maximal for inclusion (not yet implemented):

```
sage: P = PairwiseCompatibleSubsets( [4,5,6,8,9], predicate, maximal = True); P
An enumerated set with a forest structure
sage: P.list()              # todo: not implemented
[{9, 4, 5}, {5, 6}, {8, 9, 5}]
sage: P.cardinality()       # todo: not implemented
14
sage: P.category()
Category of finite enumerated sets
```

```
>>> from sage.all import *
>>> P = PairwiseCompatibleSubsets( [Integer(4),Integer(5),Integer(6),Integer(8),
↪Integer(9)], predicate, maximal = True); P
An enumerated set with a forest structure
>>> P.list()                    # todo: not implemented
[{9, 4, 5}, {5, 6}, {8, 9, 5}]
>>> P.cardinality()             # todo: not implemented
14
>>> P.category()
Category of finite enumerated sets
```

Algorithm

In the following, we order the elements of the ambient set by order of apparition. The elements of `self` are generated by organizing them in a search tree. Each node of this tree is of the form `(subset, rest)`, where:

- `subset` represents an element of `self`, represented by an increasing tuple
- `rest` is the set of all y's such that y appears after x in the ambient set and `predicate(x,y)` holds, represented by a decreasing tuple

The root of this tree is `( (), ambient )`. All the other elements are generated by recursive depth first search, which gives lexicographic order.

children(*subset_rest*)

Return the children of a node in the tree.

post_process(*subset_rest*)

5.1.338 Subwords

A subword of a word w is a word obtained by deleting the letters at some (non necessarily adjacent) positions in w. It is not to be confused with the notion of factor where one keeps adjacent positions in w. Sometimes it is useful to allow repeated uses of the same letter of w in a "generalized" subword. We call this a subword with repetitions.

For example:

- "bnjr" is a subword of the word "bonjour" but not a factor;
- "njo" is both a factor and a subword of the word "bonjour";
- "nr" is a subword of "bonjour";
- "rn" is not a subword of "bonjour";
- "nnu" is not a subword of "bonjour";
- "nnu" is a subword with repetitions of "bonjour";

A word can be given either as a string, as a list or as a tuple.

As repetition can occur in the initial word, in general subwords of a given word form an enumerated multiset rather than a set!

Todo

- implement subwords with repetitions

- implement the category of `EnumeratedMultiset` and inheritate from it when needed (i.e. the initial word has repeated letters)

AUTHORS:

- Mike Hansen: initial version
- Florent Hivert (2009/02/06): doc improvements + new methods + bug fixes

`sage.combinat.subword.`**`Subwords`**`(`*w*, *k=None*, *element_constructor=None*`)`

Return the set of subwords of `w`.

INPUT:

- `w` – a word (can be a list, a string, a tuple or a word)
- `k` – an optional integer to specify the length of subwords
- `element_constructor` – an optional function that will be used to build the subwords

EXAMPLES:

```
sage: S = Subwords(['a','b','c']); S
Subwords of ['a', 'b', 'c']
sage: S.first()
[]
sage: S.last()
['a', 'b', 'c']
sage: S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

```
>>> from sage.all import *
>>> S = Subwords(['a','b','c']); S
Subwords of ['a', 'b', 'c']
>>> S.first()
[]
>>> S.last()
['a', 'b', 'c']
>>> S.list()
[[], ['a'], ['b'], ['c'], ['a', 'b'], ['a', 'c'], ['b', 'c'], ['a', 'b', 'c']]
```

The same example using string, tuple or a word:

```
sage: S = Subwords('abc'); S
Subwords of 'abc'
sage: S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']

sage: S = Subwords((1,2,3)); S
Subwords of (1, 2, 3)
sage: S.list()
[(), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3)]

sage: w = Word([1,2,3])
sage: S = Subwords(w); S
Subwords of word: 123
```

(continues on next page)

(continued from previous page)

```
sage: S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]
```

```
>>> from sage.all import *
>>> S = Subwords('abc'); S
Subwords of 'abc'
>>> S.list()
['', 'a', 'b', 'c', 'ab', 'ac', 'bc', 'abc']

>>> S = Subwords((Integer(1),Integer(2),Integer(3))); S
Subwords of (1, 2, 3)
>>> S.list()
[(), (1,), (2,), (3,), (1, 2), (1, 3), (2, 3), (1, 2, 3)]

>>> w = Word([Integer(1),Integer(2),Integer(3)])
>>> S = Subwords(w); S
Subwords of word: 123
>>> S.list()
[word: , word: 1, word: 2, word: 3, word: 12, word: 13, word: 23, word: 123]
```

Using word with specified length:

```
sage: S = Subwords(['a','b','c'], 2); S
Subwords of ['a', 'b', 'c'] of length 2
sage: S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]
```

```
>>> from sage.all import *
>>> S = Subwords(['a','b','c'], Integer(2)); S
Subwords of ['a', 'b', 'c'] of length 2
>>> S.list()
[['a', 'b'], ['a', 'c'], ['b', 'c']]
```

An example that uses the `element_constructor` argument:

```
sage: p = Permutation([3,2,1])
sage: Subwords(p, element_constructor=tuple).list()
[(), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1)]
sage: Subwords(p, 2, element_constructor=tuple).list()
[(3, 2), (3, 1), (2, 1)]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(2),Integer(1)])
>>> Subwords(p, element_constructor=tuple).list()
[(), (3,), (2,), (1,), (3, 2), (3, 1), (2, 1), (3, 2, 1)]
>>> Subwords(p, Integer(2), element_constructor=tuple).list()
[(3, 2), (3, 1), (2, 1)]
```

class sage.combinat.subword.**Subwords_w**(*w*, *element_constructor*)

Bases: `Parent`

Subwords of a given word.

cardinality()

EXAMPLES:

```
sage: Subwords([1,2,3]).cardinality()
8
```

```
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)]).cardinality()
8
```

first()

EXAMPLES:

```
sage: Subwords([1,2,3]).first()
[]
sage: Subwords((1,2,3)).first()
()
sage: Subwords('123').first()
''
```

```
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)]).first()
[]
>>> Subwords((Integer(1),Integer(2),Integer(3))).first()
()
>>> Subwords('123').first()
''
```

last()

EXAMPLES:

```
sage: Subwords([1,2,3]).last()
[1, 2, 3]
sage: Subwords((1,2,3)).last()
(1, 2, 3)
sage: Subwords('123').last()
'123'
```

```
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)]).last()
[1, 2, 3]
>>> Subwords((Integer(1),Integer(2),Integer(3))).last()
(1, 2, 3)
>>> Subwords('123').last()
'123'
```

random_element()

Return a random subword with uniform law.

EXAMPLES:

```
sage: S1 = Subwords([1,2,3,2,1,3])
sage: S2 = Subwords([4,6,6,6,7,4,5,5])
```

(continues on next page)

(continued from previous page)

```
sage: for i in range(100):
....:     w = S1.random_element()
....:     if w in S2:
....:         assert not w
sage: for i in range(100):
....:     w = S2.random_element()
....:     if w in S1:
....:         assert not w
```

```
>>> from sage.all import *
>>> S1 = Subwords([Integer(1),Integer(2),Integer(3),Integer(2),Integer(1),
↪Integer(3)])
>>> S2 = Subwords([Integer(4),Integer(6),Integer(6),Integer(6),Integer(7),
↪Integer(4),Integer(5),Integer(5)])
>>> for i in range(Integer(100)):
...     w = S1.random_element()
...     if w in S2:
...         assert not w
>>> for i in range(Integer(100)):
...     w = S2.random_element()
...     if w in S1:
...         assert not w
```

class sage.combinat.subword.**Subwords_wk**(*w*, *k*, *element_constructor*)

Bases: *Subwords_w*

Subwords with fixed length of a given word.

cardinality()

Return the number of subwords of w of length k.

EXAMPLES:

```
sage: Subwords([1,2,3], 2).cardinality()
3
```

```
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)], Integer(2)).cardinality()
3
```

first()

EXAMPLES:

```
sage: Subwords([1,2,3],2).first()
[1, 2]
sage: Subwords([1,2,3],0).first()
[]
sage: Subwords((1,2,3),2).first()
(1, 2)
sage: Subwords((1,2,3),0).first()
()
sage: Subwords('123',2).first()
'12'
```

(continues on next page)

(continued from previous page)

```
sage: Subwords('123',0).first()
''
```

```
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)],Integer(2)).first()
[1, 2]
>>> Subwords([Integer(1),Integer(2),Integer(3)],Integer(0)).first()
[]
>>> Subwords((Integer(1),Integer(2),Integer(3)),Integer(2)).first()
(1, 2)
>>> Subwords((Integer(1),Integer(2),Integer(3)),Integer(0)).first()
()
>>> Subwords('123',Integer(2)).first()
'12'
>>> Subwords('123',Integer(0)).first()
''
```

last()

EXAMPLES:

```
sage: Subwords([1,2,3],2).last()
[2, 3]
sage: Subwords([1,2,3],0).last()
[]
sage: Subwords((1,2,3),2).last()
(2, 3)
sage: Subwords((1,2,3),0).last()
()
sage: Subwords('123',2).last()
'23'
sage: Subwords('123',0).last()
''
```

```
>>> from sage.all import *
>>> Subwords([Integer(1),Integer(2),Integer(3)],Integer(2)).last()
[2, 3]
>>> Subwords([Integer(1),Integer(2),Integer(3)],Integer(0)).last()
[]
>>> Subwords((Integer(1),Integer(2),Integer(3)),Integer(2)).last()
(2, 3)
>>> Subwords((Integer(1),Integer(2),Integer(3)),Integer(0)).last()
()
>>> Subwords('123',Integer(2)).last()
'23'
>>> Subwords('123',Integer(0)).last()
''
```

random_element()

Return a random subword of given length with uniform law.

EXAMPLES:

```
sage: S1 = Subwords([1,2,3,2,1],3)
sage: S2 = Subwords([4,4,5,5,4,5,4,4],3)
sage: for i in range(100):
....:   w = S1.random_element()
....:   if w in S2:
....:       assert not w
sage: for i in range(100):
....:   w = S2.random_element()
....:   if w in S1:
....:       assert not w
```

```
>>> from sage.all import *
>>> S1 = Subwords([Integer(1),Integer(2),Integer(3),Integer(2),Integer(1)],
↪Integer(3))
>>> S2 = Subwords([Integer(4),Integer(4),Integer(5),Integer(5),Integer(4),
↪Integer(5),Integer(4),Integer(4)],Integer(3))
>>> for i in range(Integer(100)):
...   w = S1.random_element()
...   if w in S2:
...       assert not w
>>> for i in range(Integer(100)):
...   w = S2.random_element()
...   if w in S1:
...       assert not w
```

sage.combinat.subword.**smallest_positions**(*word*, *subword*, *pos=0*)

Return the smallest positions for which `subword` appears as a subword of `word`.

If `pos` is specified, then it returns the positions of the first appearance of subword starting at `pos`.

If `subword` is not found in `word`, then return `False`.

EXAMPLES:

```
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,4,4], [2,4])
[1, 3]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4])
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],2)
[2, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,3,4,4], [3,4],3)
[3, 4]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [2,3])
[1, 2]
sage: sage.combinat.subword.smallest_positions([1,2,3,4], [5,5])
False
sage: sage.combinat.subword.smallest_positions([1,3,3,4,5],[3,5])
[1, 4]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5],[3,5,3])
[1, 3, 6]
sage: sage.combinat.subword.smallest_positions([1,3,3,5,4,5,3,5],[3,5,3],2)
[2, 3, 6]
```

(continues on next page)

(continued from previous page)

↪Integer(4),Integer(3),Integer(4),Integer(4)],[Integer(2),Integer(3),Integer(3),
↪Integer(1)])
False
>>> sage.combinat.subword.smallest_positions([Integer(1),Integer(3),Integer(3),
↪Integer(5),Integer(4),Integer(5),Integer(3),Integer(5)],[Integer(3),Integer(5),
↪Integer(3)],Integer(3))
False
```

5.1.339 Subword complex

Fix a Coxeter system (W, S). The subword complex $\mathcal{SC}(Q, w)$ associated to a word $Q \in S^*$ and an element $w \in W$ is the simplicial complex whose ground set is the set of positions in Q and whose facets are complements of sets of positions defining a reduced expression for w.

A subword complex is a shellable sphere if and only if the Demazure product of Q equals w, otherwise it is a shellable ball.

The code is optimized to be used with `ReflectionGroup`, it works as well with `CoxeterGroup`, but many methods fail for `WeylGroup`.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',3]); I = list(W.index_set())          # optional - gap3
sage: Q = I + W.w0.coxeter_sorting_word(I); Q                        # optional - gap3
[1, 2, 3, 1, 2, 3, 1, 2, 1]

sage: S = SubwordComplex(Q,W.w0)                                     # optional - gap3
sage: for F in S: print("{} {}".format(F, F.root_configuration()))            #␣
↪optional - gap3
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(3)]); I = list(W.index_set())        # optional␣
↪- gap3
>>> Q = I + W.w0.coxeter_sorting_word(I); Q                          # optional - gap3
[1, 2, 3, 1, 2, 3, 1, 2, 1]

>>> S = SubwordComplex(Q,W.w0)                                       # optional - gap3
>>> for F in S: print("{} {}".format(F, F.root_configuration()))              #␣
↪optional - gap3
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
```

(continues on next page)

(continued from previous page)

```
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

Testing that the implementation also works with CoxeterGroup:

```
sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I); Q
[1, 2, 3, 1, 2, 3, 1, 2, 1]
sage: S = SubwordComplex(Q,W.w0); S
Subword complex of type ['A', 3] for Q = (1, 2, 3, 1, 2, 3, 1, 2, 1) and pi = [1, 2,␣
↪3, 1, 2, 1]
sage: P = S.increasing_flip_poset(); P; len(P.cover_relations())
Finite poset containing 14 elements
21
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['A',Integer(3)]); I = list(W.index_set())
>>> Q = I + W.w0.coxeter_sorting_word(I); Q
[1, 2, 3, 1, 2, 3, 1, 2, 1]
>>> S = SubwordComplex(Q,W.w0); S
Subword complex of type ['A', 3] for Q = (1, 2, 3, 1, 2, 3, 1, 2, 1) and pi = [1, 2,␣
↪3, 1, 2, 1]
>>> P = S.increasing_flip_poset(); P; len(P.cover_relations())
Finite poset containing 14 elements
21
```

The root configuration works:

```
sage: for F in S: print("{} {}".format(F, F.root_configuration()))
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

```
>>> from sage.all import *
>>> for F in S: print("{} {}".format(F, F.root_configuration()))
(0, 1, 2) [(1, 0, 0), (0, 1, 0), (0, 0, 1)]
(0, 1, 8) [(1, 0, 0), (0, 1, 0), (0, 0, -1)]
(0, 2, 6) [(1, 0, 0), (0, 1, 1), (0, -1, 0)]
(0, 6, 7) [(1, 0, 0), (0, 0, 1), (0, -1, -1)]
```

(continues on next page)

(continued from previous page)

```
(0, 7, 8) [(1, 0, 0), (0, -1, 0), (0, 0, -1)]
(1, 2, 3) [(1, 1, 0), (0, 0, 1), (-1, 0, 0)]
(1, 3, 8) [(1, 1, 0), (-1, 0, 0), (0, 0, -1)]
(2, 3, 4) [(1, 1, 1), (0, 1, 0), (-1, -1, 0)]
(2, 4, 6) [(1, 1, 1), (-1, 0, 0), (0, -1, 0)]
(3, 4, 5) [(0, 1, 0), (0, 0, 1), (-1, -1, -1)]
(3, 5, 8) [(0, 1, 0), (-1, -1, 0), (0, 0, -1)]
(4, 5, 6) [(0, 1, 1), (-1, -1, -1), (0, -1, 0)]
(5, 6, 7) [(-1, 0, 0), (0, 0, 1), (0, -1, -1)]
(5, 7, 8) [(-1, 0, 0), (0, -1, 0), (0, 0, -1)]
```

And the weight configuration also works:

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)])
>>> F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
>>> F.extended_weight_configuration(coefficients=(Integer(1),Integer(2)))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

One finally can compute the brick polytope, using all functionality on weight configurations, though it does not realize to live in real space:

```
sage: W = CoxeterGroup(['A',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q,W.w0)
sage: S.brick_polytope()                                                    #␣
↪needs sage.geometry.polyhedron
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 14 vertices

sage: W = CoxeterGroup(['H',3]); I = list(W.index_set())
sage: Q = I + W.w0.coxeter_sorting_word(I)
sage: S = SubwordComplex(Q,W.w0)
sage: S.brick_polytope()                                                    #␣
↪needs sage.geometry.polyhedron
doctest:...: RuntimeWarning: the polytope is built with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices
```

```
>>> from sage.all import *
>>> W = CoxeterGroup(['A',Integer(3)]); I = list(W.index_set())
```

(continues on next page)

(continued from previous page)

```
>>> Q = I + W.w0.coxeter_sorting_word(I)
>>> S = SubwordComplex(Q,W.w0)
>>> S.brick_polytope()                                                    #␣
↪needs sage.geometry.polyhedron

> This implementation only works for groups build using `CoxeterGroup`, and does not work with groups build using `WeylGroup`.

EXAMPLES:

As an example, dual associahedra are subword complexes in type A_{n-1} given by the word $[1, \dots, n, 1, \dots, n, 1, \dots, n-1, \dots, 1, 2, 1]$ and the permutation w_0.

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
```

(continues on next page)

(continued from previous page)

```
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],
↪w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
>>> SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],
↪w); SC
Subword complex of type ['A', 2] for Q = (1, 2, 1, 2, 1) and pi = [1, 2, 1]
>>> SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

REFERENCES: [KnuMil], [PilStu]

Element

alias of *SubwordComplexFacet*

barycenter()

Return the barycenter of the brick polytope of `self`.

> **See also**
>
> *brick_polytope()*

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                          # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                # optional - gap3
sage: SC.barycenter()                                       # optional - gap3
(2/3, 4/3)

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.barycenter()
(4/3, 8/3)
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                              # optional
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                 # optional - gap3
>>> SC.barycenter()                                             # optional - gap3
```

(continues on next page)

(continued from previous page)

```
(2/3, 4/3)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.barycenter()
(4/3, 8/3)
```

brick_fan()

Return the brick fan of `self`.

It is the normal fan of the brick polytope of `self`. It is formed by the cones generated by the weight configurations of the facets of `self`.

See also

weight_cone

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.brick_fan()
Rational polyhedral fan in 2-d lattice N
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.brick_fan()
Rational polyhedral fan in 2-d lattice N

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.brick_fan()
Rational polyhedral fan in 2-d lattice N
```

brick_polytope(*coefficients=None*)

Return the brick polytope of `self`.

This polytope is the convex hull of the brick vectors of `self`.

INPUT:

- `coefficients` – (optional) a list of coefficients used to scale the fundamental weights

See also:

`brick_vectors()`

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                           # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                 # optional - gap3
sage: X = SC.brick_polytope(); X                             # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: Y = SC.brick_polytope(coefficients=[1,2]); Y           # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: X == Y                                                 # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

sage: # optional - gap3
sage: W = ReflectionGroup(['H',3])
sage: c = W.index_set(); Q = c + tuple(W.w0.coxeter_sorting_word(c))
sage: SC = SubwordComplex(Q,W.w0)
sage: SC.brick_polytope()
doctest:...:
RuntimeWarning: the polytope is built with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                            # optional␣
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                   # optional - gap3
>>> X = SC.brick_polytope(); X                             # optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

>>> Y = SC.brick_polytope(coefficients=[Integer(1),Integer(2)]); Y          #␣
↪optional - gap3
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

>>> X == Y                                                 # optional - gap3
False

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
```

(continues on next page)

(continued from previous page)

```
>>> X = SC.brick_polytope(); X
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 5 vertices

>>> # optional - gap3
>>> W = ReflectionGroup(['H',Integer(3)])
>>> c = W.index_set(); Q = c + tuple(W.w0.coxeter_sorting_word(c))
>>> SC = SubwordComplex(Q,W.w0)
>>> SC.brick_polytope()
doctest:...:
RuntimeWarning: the polytope is built with rational vertices
A 3-dimensional polyhedron in QQ^3 defined as the convex hull of 32 vertices
```

brick_vectors(*coefficients=None*)

Return the list of all brick vectors of facets of `self`.

INPUT:

- `coefficients` – (optional) a list of coefficients used to scale the fundamental weights

See also

brick_vector

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.brick_vectors()
[(5/3, 7/3), (5/3, 1/3), (2/3, 7/3), (-1/3, 4/3), (-1/3, 1/3)]
sage: SC.brick_vectors(coefficients=(1,2))
[(7/3, 11/3), (7/3, 2/3), (4/3, 11/3), (-2/3, 5/3), (-2/3, 2/3)]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.brick_vectors()
[(10/3, 14/3), (10/3, 2/3), (4/3, 14/3), (-2/3, 8/3), (-2/3, 2/3)]
sage: SC.brick_vectors(coefficients=(1,2))
[(14/3, 22/3), (14/3, 4/3), (8/3, 22/3), (-4/3, 10/3), (-4/3, 4/3)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.brick_vectors()
[(5/3, 7/3), (5/3, 1/3), (2/3, 7/3), (-1/3, 4/3), (-1/3, 1/3)]
>>> SC.brick_vectors(coefficients=(Integer(1),Integer(2)))
[(7/3, 11/3), (7/3, 2/3), (4/3, 11/3), (-2/3, 5/3), (-2/3, 2/3)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)], W.w0)
>>> SC.brick_vectors()
[(10/3, 14/3), (10/3, 2/3), (4/3, 14/3), (-2/3, 8/3), (-2/3, 2/3)]
>>> SC.brick_vectors(coefficients=(Integer(1),Integer(2)))
[(14/3, 22/3), (14/3, 4/3), (8/3, 22/3), (-4/3, 10/3), (-4/3, 4/3)]
```

cartan_type()

Return the Cartan type of `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.cartan_type()
['A', 2]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.cartan_type()
['A', 2]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.cartan_type()
['A', 2]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.cartan_type()
['A', 2]
```

cover_relations(*label=False*)

Return the set of cover relations in the associated poset.

INPUT:

- `label` – boolean (default: `False`); whether or not to label the cover relations by the position of flip

OUTPUT: list of pairs of facets

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                          # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                # optional - gap3
sage: sorted(SC.cover_relations())                          # optional - gap3
```

(continues on next page)

(continued from previous page)

```
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: sorted(SC.cover_relations())
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                             # optional␣
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                     # optional - gap3
>>> sorted(SC.cover_relations())                           # optional - gap3
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> sorted(SC.cover_relations())
[((0, 1), (0, 4)),
 ((0, 1), (1, 2)),
 ((0, 4), (3, 4)),
 ((1, 2), (2, 3)),
 ((2, 3), (3, 4))]
```

dimension()

Return the dimension of `self`.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                         # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)               # optional - gap3
sage: SC.dimension()                                       # optional - gap3
1

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.dimension()
1
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                          # optional␣
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                    # optional - gap3
>>> SC.dimension()                                          # optional - gap3
1

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.dimension()
1
```

facets()

Return all facets of `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.facets()
[(0, 1), (0, 4), (1, 2), (2, 3), (3, 4)]
```

greedy_facet(*side='positive'*)

Return the negative (or positive) greedy facet of `self`.

This is the lexicographically last (or first) facet of `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.greedy_facet(side='positive')
(0, 1)
sage: SC.greedy_facet(side='negative')
(3, 4)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.greedy_facet(side='positive')
(0, 1)
sage: SC.greedy_facet(side='negative')
(3, 4)
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.greedy_facet(side='positive')
(0, 1)
>>> SC.greedy_facet(side='negative')
(3, 4)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.greedy_facet(side='positive')
(0, 1)
>>> SC.greedy_facet(side='negative')
(3, 4)
```

group()

Return the group associated to `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.group()
Irreducible real reflection group of rank 2 and type A2

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.group()
```

(continues on next page)

(continued from previous page)

```
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.group()
Irreducible real reflection group of rank 2 and type A2

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]
```

increasing_flip_graph(*label=True*)

Return the increasing flip graph of the subword complex.

OUTPUT: a directed graph

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                          # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                # optional - gap3
sage: SC.increasing_flip_graph()                            # optional - gap3
Digraph on 5 vertices

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.increasing_flip_graph()
Digraph on 5 vertices
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                          # optional␣
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                # optional - gap3
>>> SC.increasing_flip_graph()                            # optional - gap3
Digraph on 5 vertices

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.increasing_flip_graph()
Digraph on 5 vertices
```

increasing_flip_poset()

Return the increasing flip poset of the subword complex.

OUTPUT: a poset

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                          # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                # optional - gap3
sage: SC.increasing_flip_poset()                            # optional - gap3
Finite poset containing 5 elements

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.increasing_flip_poset()
Finite poset containing 5 elements
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                          # optional␣
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                # optional - gap3
>>> SC.increasing_flip_poset()                            # optional - gap3
Finite poset containing 5 elements

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.increasing_flip_poset()
Finite poset containing 5 elements
```

interval(*I*, *J*)

Return the interval [I,J] in the increasing flip graph subword complex.

INPUT:

- I, J – two facets

OUTPUT: a set of facets

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: F = SC([1,2])
sage: SC.interval(F, F)
{(1, 2)}

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: F = SC([1,2])
sage: SC.interval(F, F)
{(1, 2)}
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> F = SC([Integer(1),Integer(2)])
>>> SC.interval(F, F)
{(1, 2)}

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> F = SC([Integer(1),Integer(2)])
>>> SC.interval(F, F)
{(1, 2)}
```

is_ball()

Return `True` if the subword complex `self` is a ball.

This is the case if and only if it is not a sphere.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_ball()
False

sage: SC = SubwordComplex([3,2,1,3,2,3], w)                    # optional - gap3
sage: SC.is_ball()                                              # optional - gap3
True

sage: W = CoxeterGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_ball()
False
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
↪Integer(3)], w)
>>> SC.is_ball()
False

>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)], w)                    # optional - gap3
>>> SC.is_ball()                                        # optional - gap3
True
```

(continues on next page)

(continued from previous page)

```
>>> W = CoxeterGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
↪Integer(3)], w)
>>> SC.is_ball()
False
```

is_double_root_free()

Return `True` if `self` is double-root-free.

This means that the root configurations of all facets do not contain a root twice.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.is_double_root_free()
True

sage: SC = SubwordComplex([1,1,2,2,1,1], w)                    # optional - gap3
sage: SC.is_double_root_free()                                 # optional - gap3
True

sage: SC = SubwordComplex([1,2,1,2,1,2], w)                    # optional - gap3
sage: SC.is_double_root_free()                                 # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.is_double_root_free()
True
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.is_double_root_free()
True

>>> SC = SubwordComplex([Integer(1),Integer(1),Integer(2),Integer(2),
↪Integer(1),Integer(1)], w)                    # optional - gap3
>>> SC.is_double_root_free()                                # optional - gap3
True

>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1),Integer(2)], w)                    # optional - gap3
>>> SC.is_double_root_free()                                # optional - gap3
```

(continues on next page)

(continued from previous page)

```
False

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.is_double_root_free()
True
```

is_pure()

Return `True` since all subword complexes are pure.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_pure()
True

sage: W = CoxeterGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_pure()
True
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
↪Integer(3)], w)
>>> SC.is_pure()
True

>>> W = CoxeterGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
↪Integer(3)], w)
>>> SC.is_pure()
True
```

is_root_independent()

Return `True` if `self` is root-independent.

This means that the root configuration of any (or equivalently all) facets is linearly independent.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                              # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                    # optional - gap3
sage: SC.is_root_independent()                                  # optional - gap3
```

(continues on next page)

(continued from previous page)

```
True

sage: SC = SubwordComplex([1,2,1,2,1,2], W.w0)               # optional - gap3
sage: SC.is_root_independent()                               # optional - gap3
False

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.is_root_independent()
True
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                          # optional␣
↪- gap3
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                   # optional - gap3
>>> SC.is_root_independent()                              # optional - gap3
True

>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1),Integer(2)], W.w0)             # optional - gap3
>>> SC.is_root_independent()                              # optional - gap3
False

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.is_root_independent()
True
```

is_sphere()

Return `True` if the subword complex `self` is a sphere.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_sphere()
True

sage: SC = SubwordComplex([3,2,1,3,2,3], w)                  # optional - gap3
sage: SC.is_sphere()                                         # optional - gap3
False

sage: W = CoxeterGroup(['A',3])
sage: w = W.from_reduced_word([2,3,2])
sage: SC = SubwordComplex([3,2,3,2,3], w)
sage: SC.is_sphere()
True
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
↪Integer(3)], w)
>>> SC.is_sphere()
True

>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(1),Integer(3),
↪Integer(2),Integer(3)], w)                    # optional - gap3
>>> SC.is_sphere()                                         # optional - gap3
False

>>> W = CoxeterGroup(['A',Integer(3)])
>>> w = W.from_reduced_word([Integer(2),Integer(3),Integer(2)])
>>> SC = SubwordComplex([Integer(3),Integer(2),Integer(3),Integer(2),
↪Integer(3)], w)
>>> SC.is_sphere()
True
```

kappa_preimages()

Return a dictionary containing facets of `self` as keys, and list of elements of `self.group()` as values.

See also

kappa_preimage

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: kappa = SC.kappa_preimages()
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in␣
↪kappa[F]]))
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: kappa = SC.kappa_preimages()
sage: for F in SC: print("{} {}".format(F, [w.reduced_word() for w in␣
↪kappa[F]]))
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
```

(continues on next page)

(continued from previous page)

```
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> kappa = SC.kappa_preimages()
>>> for F in SC: print("{} {}".format(F, [w.reduced_word() for w in␣
↪kappa[F]]))
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> kappa = SC.kappa_preimages()
>>> for F in SC: print("{} {}".format(F, [w.reduced_word() for w in␣
↪kappa[F]]))
(0, 1) [[]]
(0, 4) [[2], [2, 1]]
(1, 2) [[1]]
(2, 3) [[1, 2]]
(3, 4) [[1, 2, 1]]
```

minkowski_summand(i)

Return the i th Minkowski summand of `self`.

INPUT:

- `i` – an integer defining a position in the word Q

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                          # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)                # optional - gap3
sage: SC.minkowski_summand(1)                               # optional - gap3
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

sage: W = CoxeterGroup(['A',2])
sage: SC = SubwordComplex([1,2,1,2,1], W.w0)
sage: SC.minkowski_summand(1)
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])                              # optional␣
↪- gap3
```

(continues on next page)

(continued from previous page)

```
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)                    # optional - gap3
>>> SC.minkowski_summand(Integer(1))                              # optional␣
↪- gap3
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex

>>> W = CoxeterGroup(['A',Integer(2)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], W.w0)
>>> SC.minkowski_summand(Integer(1))
A 0-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex
```

pi()

Return the element in the Coxeter group associated to `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.pi().reduced_word()
[1, 2, 1]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.pi().reduced_word()
[1, 2, 1]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.pi().reduced_word()
[1, 2, 1]
```

word()

Return the word in the simple generators associated to `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
```

(continues on next page)

(continued from previous page)

```
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.word()
(1, 2, 1, 2, 1)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: SC.word()
(1, 2, 1, 2, 1)
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.word()
(1, 2, 1, 2, 1)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)], w)
>>> SC.word()
(1, 2, 1, 2, 1)
```

class sage.combinat.subword_complex.**SubwordComplexFacet**(*parent*, *positions*, *facet_test=True*)

Bases: `Simplex`, `Element`

A facet of a subword complex.

Facets of the subword complex $\mathcal{SC}(Q, w)$ are complements of sets of positions in Q defining a reduced expression for w.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC[0]; F
(0, 1)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1], w)
sage: F = SC[0]; F
(0, 1)
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
```

(continues on next page)

(continued from previous page)

```
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],␣
↪w)
>>> F = SC[Integer(0)]; F
(0, 1)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),Integer(1)],␣
↪w)
>>> F = SC[Integer(0)]; F
(0, 1)
```

brick_vector(*coefficients=None*)

Return the brick vector of `self`.

This is the sum of the weight vectors in the extended weight configuration.

INPUT:

- `coefficients` – (optional) a list of coefficients used to scale the fundamental weights

See also

extended_weight_configuration()

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_weight_configuration()
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.brick_vector()
(2/3, 7/3)
sage: F.brick_vector(coefficients=[1,2])
(4/3, 11/3)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2])
sage: F.brick_vector()
(4/3, 14/3)
sage: F.brick_vector(coefficients=[1,2])
(8/3, 22/3)
```

```
>>> from sage.all import *
>>> # optional - gap3
```

(continues on next page)

(continued from previous page)

```
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.extended_weight_configuration()
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
>>> F.brick_vector()
(2/3, 7/3)
>>> F.brick_vector(coefficients=[Integer(1),Integer(2)])
(4/3, 11/3)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)])
>>> F.brick_vector()
(4/3, 14/3)
>>> F.brick_vector(coefficients=[Integer(1),Integer(2)])
(8/3, 22/3)
```

extended_root_configuration()

Return the extended root configuration of `self`.

Let $Q = q_1 \ldots q_m \in S^*$ and $w \in W$. The extended root configuration of a facet I of $\mathcal{SC}(Q,w)$ is the sequence $\mathsf{r}(I,1),\ldots,\mathsf{r}(I,m)$ of roots defined by $\mathsf{r}(I,k) = \Pi Q_{[k-1]\setminus I}(\alpha_{q_k})$, where $\Pi Q_{[k-1]\setminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \setminus I$ in this order.

The extended root configuration is used to perform flips efficiently.

See also

flip()

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
```

(continues on next page)

(continued from previous page)

```
sage: F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.extended_root_configuration()
[(1, 0), (1, 1), (-1, 0), (1, 1), (0, 1)]
```

extended_weight_configuration(*coefficients=None*)

Return the extended weight configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The extended weight configuration of a facet I of $\mathcal{SC}(Q, w)$ is the sequence $\mathsf{w}(I, 1), \dots, \mathsf{w}(I, m)$ of weights defined by $\mathsf{w}(I, k) = \Pi Q_{[k-1] \smallsetminus I}(\omega_{q_k})$, where $\Pi Q_{[k-1] \smallsetminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \smallsetminus I$ in this order.

The extended weight configuration is used to compute the brick vector.

INPUT:

- `coefficients` – (optional) a list of coefficients used to scale the fundamental weights

See also

brick_vector()

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(2/3, 1/3), (2/3, 4/3), (-1/3, 1/3), (2/3, 4/3), (-1/3, 1/3)]

sage: W = CoxeterGroup(['A',2])
```

(continues on next page)

(continued from previous page)

```
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2])
sage: F.extended_weight_configuration()
[(4/3, 2/3), (2/3, 4/3), (-2/3, 2/3), (2/3, 4/3), (-2/3, 2/3)]
sage: F.extended_weight_configuration(coefficients=(1,2))
[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)])
>>> F.extended_weight_configuration()
[(2/3, 1/3), (1/3, 2/3), (-1/3, 1/3), (1/3, 2/3), (-1/3, 1/3)]
>>> F.extended_weight_configuration(coefficients=(Integer(1),Integer(2)))
[(2/3, 1/3), (2/3, 4/3), (-1/3, 1/3), (2/3, 4/3), (-1/3, 1/3)]

>>> W = CoxeterGroup(['A',Integer(2)])

[(4/3, 2/3), (4/3, 8/3), (-2/3, 2/3), (4/3, 8/3), (-2/3, 2/3)]
```

flip(*i*, *return_position=False*)

Return the facet obtained after flipping position `i` in `self`.

INPUT:

- `i` – integer; position in the word Q
- `return_position` – boolean (default: `False`); tells whether the new position should be returned as well

OUTPUT:

- The new subword complex facet.
- The new position if `return_position` is `True`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.flip(1)
```

(continues on next page)

(continued from previous page)

```
(2, 3)
sage: F.flip(1, return_position=True)
((2, 3), 3)

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.flip(1)
(2, 3)
sage: F.flip(1, return_position=True)
((2, 3), 3)
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.flip(Integer(1))
(2, 3)
>>> F.flip(Integer(1), return_position=True)
((2, 3), 3)

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.flip(Integer(1))
(2, 3)
>>> F.flip(Integer(1), return_position=True)
((2, 3), 3)
```

is_vertex()

Return `True` if `self` is a vertex of the brick polytope of `self.parent`.

A facet is a vertex of the brick polytope if its root cone is pointed. Note that this property is always satisfied for root-independent subword complexes.

```

(continues on next page)

(continued from previous page)

```
False
```

kappa_preimage()

Return the fiber of `self` under the κ map.

The κ map sends an element $w \in W$ to the unique facet of $I \in \mathcal{SC}(Q, w)$ such that the root configuration of I is contained in $w(\Phi^+)$. In other words, w is in the preimage of `self` under κ if and only if w^{-1} sends every root in the root configuration to a positive root.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])                              # optional - gap3
sage: w = W.from_reduced_word([1,2,1])                          # optional - gap3
sage: SC = SubwordComplex([1,2,1,2,1],w)                        # optional - gap3

sage: F = SC([1,2]); F                                          # optional - gap3
(1, 2)

```

plot (*list_colors=None*, *labels=[]*, *thickness=3*, *fontsize=14*, *shift=(0, 0)*, *compact=False*, *roots=True*, ***args*)

In type A or B, plot a pseudoline arrangement representing the facet `self`.

Pseudoline arrangements are graphical representations of facets of types A or B subword complexes.

INPUT:

- `list_colors` – list (default: `[]`); to change the colors of the pseudolines
- `labels` – list (default: `[]`); to change the labels of the pseudolines
- `thickness` – integer (default: 3); for the thickness of the pseudolines
- `fontsize` – integer (default: 14); for the size of the font used for labels
- `shift` – couple of coordinates (default: `(0,0)`) to change the origin
- `compact` – boolean (default: `False`); to require a more compact representation
- `roots` – boolean (default: `True`); whether to print the extended root configuration

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)

REFERENCES: [PilStu]

root_cone()

Return the polyhedral cone generated by the root configuration of `self`.

See also:

root_configuration()

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',1])
sage: w = W.from_reduced_word([1])
sage: SC = SubwordComplex([1,1,1],w)
sage: F = SC([0,2]); F.root_cone()
1-d cone in 1-d lattice N

sage: W = CoxeterGroup(['A',1])
sage: w = W.from_reduced_word([1])
sage: SC = SubwordComplex([1,1,1],w)
sage: F = SC([0,2]); F.root_cone()
1-d cone in 1-d lattice N
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(1)])
>>> w = W.from_reduced_word([Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(1),Integer(1)],w)
>>> F = SC([Integer(0),Integer(2)]); F.root_cone()
1-d cone in 1-d lattice N

>>> W = CoxeterGroup(['A',Integer(1)])
>>> w = W.from_reduced_word([Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(1),Integer(1)],w)
>>> F = SC([Integer(0),Integer(2)]); F.root_cone()
1-d cone in 1-d lattice N
```

root_configuration()

Return the root configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The root configuration of a facet $I = [i_1, \dots, i_n]$ of $\mathcal{SC}(Q, w)$ is the sequence $\mathsf{r}(I, i_1), \dots, \mathsf{r}(I, i_n)$ of roots defined by $\mathsf{r}(I, k) = \Pi Q_{[k-1] \smallsetminus I}(\alpha_{q_k})$, where $\Pi Q_{[k-1] \smallsetminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \smallsetminus I$ in this order.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.root_configuration()
[(1, 1), (-1, 0)]
```

(continues on next page)

(continued from previous page)

```
sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.root_configuration()                                    # optional - gap3
[(1, 1), (-1, 0)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.root_configuration()
[(1, 1), (-1, 0)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.root_configuration()                                    # optional - gap3
[(1, 1), (-1, 0)]
```

show (**kwds*, ***args*)

Show the facet `self`.

See also

plot()

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F.show()
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
```

(continues on next page)

(continued from previous page)

```
>>> F = SC([Integer(1),Integer(2)]); F.show()
<BLANKLINE>
```

upper_root_configuration()

Return the positive roots of the root configuration of `self`.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.root_configuration()
[(1, 1), (-1, 0)]
sage: F.upper_root_configuration()
[(1, 0)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.upper_root_configuration()
[(1, 0)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.root_configuration()
[(1, 1), (-1, 0)]
>>> F.upper_root_configuration()
[(1, 0)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.upper_root_configuration()
[(1, 0)]
```

weight_cone()

Return the polyhedral cone generated by the weight configuration of `self`.

See also

weight_configuration()

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: WC = F.weight_cone(); WC
2-d cone in 2-d lattice N
sage: WC.rays()
N( 1, 2),
N(-1, 1)
in 2-d lattice N

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: WC = F.weight_cone(); WC
2-d cone in 2-d lattice N
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> WC = F.weight_cone(); WC
2-d cone in 2-d lattice N
>>> WC.rays()
N( 1, 2),
N(-1, 1)
in 2-d lattice N

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> WC = F.weight_cone(); WC
2-d cone in 2-d lattice N
```

weight_configuration()

Return the weight configuration of `self`.

Let $Q = q_1 \dots q_m \in S^*$ and $w \in W$. The weight configuration of a facet $I = [i_1, \dots, i_n]$ of $\mathcal{SC}(Q, w)$ is the sequence $\mathsf{w}(I, i_1), \dots, \mathsf{w}(I, i_n)$ of weights defined by $\mathsf{w}(I, k) = \Pi Q_{[k-1] \smallsetminus I}(\omega_{q_k})$, where $\Pi Q_{[k-1] \smallsetminus I}$ is the product of the simple reflections q_i for $i \in [k-1] \smallsetminus I$ in this order.

EXAMPLES:

```
sage: # optional - gap3
sage: W = ReflectionGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.weight_configuration()
[(1/3, 2/3), (-1/3, 1/3)]

sage: W = CoxeterGroup(['A',2])
sage: w = W.from_reduced_word([1,2,1])
sage: SC = SubwordComplex([1,2,1,2,1],w)
sage: F = SC([1,2]); F
(1, 2)
sage: F.weight_configuration()
[(2/3, 4/3), (-2/3, 2/3)]
```

```
>>> from sage.all import *
>>> # optional - gap3
>>> W = ReflectionGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.weight_configuration()
[(1/3, 2/3), (-1/3, 1/3)]

>>> W = CoxeterGroup(['A',Integer(2)])
>>> w = W.from_reduced_word([Integer(1),Integer(2),Integer(1)])
>>> SC = SubwordComplex([Integer(1),Integer(2),Integer(1),Integer(2),
↪Integer(1)],w)
>>> F = SC([Integer(1),Integer(2)]); F
(1, 2)
>>> F.weight_configuration()
[(2/3, 4/3), (-2/3, 2/3)]
```

5.1.340 Super Tableaux

AUTHORS:

- Matthew Lancellotti (2007): initial version
- Chaman Agrawal (2019-07-23): Modify standard and semistandard tableaux for super tableaux.

class sage.combinat.super_tableau.**SemistandardSuperTableau**(*parent*, *t*, *check=True*, *preprocessed=False*)

Bases: *Tableau*

A semistandard super tableau.

A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of oddd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

INPUT:

- `t` – a tableau, a list of iterables, or an empty list

EXAMPLES:

```
sage: t = SemistandardSuperTableau([['1p',2,"3'"],[2,3]]); t
[[1', 2, 3'], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1' 2 3'
2 3
sage: t = Tableau([["1p",2],[2]])
sage: s = SemistandardSuperTableau(t); s
[[1', 2], [2]]
sage: SemistandardSuperTableau([]) # The empty tableau
[]
```

```
>>> from sage.all import *
>>> t = SemistandardSuperTableau([['1p',Integer(2),"3'"],[Integer(2),
↪Integer(3)]]); t
[[1', 2, 3'], [2, 3]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
1' 2 3'
2 3
>>> t = Tableau([["1p",Integer(2)],[Integer(2)]])
>>> s = SemistandardSuperTableau(t); s
[[1', 2], [2]]
>>> SemistandardSuperTableau([]) # The empty tableau
[]
```

check()

Check that `self` is a valid semistandard super tableau.

class sage.combinat.super_tableau.**SemistandardSuperTableaux**(***kwds*)

Bases: *SemistandardTableaux*

The set of semistandard super tableaux.

A semistandard super tableau is a tableau with primed positive integer entries. As defined in [Muth2019], a semistandard super tableau weakly increases along the rows and down the columns. Also, the letters of even parity (unprimed) strictly increases down the columns, and letters of oddd parity (primed) strictly increases along the rows. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: SST = SemistandardSuperTableaux(); SST
Semistandard super tableaux
```

```
>>> from sage.all import *
>>> SST = SemistandardSuperTableaux(); SST
Semistandard super tableaux
```

Element

alias of *SemistandardSuperTableau*

class sage.combinat.super_tableau.**SemistandardSuperTableaux_all**

Bases: *SemistandardSuperTableaux*

All semistandard super tableaux.

class sage.combinat.super_tableau.**StandardSuperTableau**(*parent*, *t*, *check=True*, *preprocessed=False*)

Bases: *SemistandardSuperTableau*

A standard super tableau.

A standard super tableau is a semistandard super tableau whose entries are in bijection with positive primed integers $1', 1, 2' \ldots n$.

For more information refer [Muth2019].

INPUT:

- t – a Tableau, a list of iterables, or an empty list

EXAMPLES:

```
sage: t = StandardSuperTableau([["1'",1,"2'",2,"3'"],[3,"4'"]]); t
[[1', 1, 2', 2, 3'], [3, 4']]
sage: t.shape()
[5, 2]
sage: t.pp() # pretty printing
1' 1 2' 2 3'
3 4'
sage: t.is_standard()
True
sage: StandardSuperTableau([]) # The empty tableau
[]
```

```
>>> from sage.all import *
>>> t = StandardSuperTableau([["1'",Integer(1),"2'",Integer(2),"3'"],[Integer(3),
↪"4'"]]); t
[[1', 1, 2', 2, 3'], [3, 4']]
>>> t.shape()
[5, 2]
>>> t.pp() # pretty printing
1' 1 2' 2 3'
3 4'
>>> t.is_standard()
True
>>> StandardSuperTableau([]) # The empty tableau
[]
```

check()

Check that self is a standard tableau.

is_standard()

Return `True` since `self` is a standard super tableau.

EXAMPLES:

```
sage: StandardSuperTableau([['1p', 1], ['2p', 2]]).is_standard()
True
```

```
>>> from sage.all import *
>>> StandardSuperTableau([['1p', Integer(1)], ['2p', Integer(2)]]).is_
↪standard()
True
```

class sage.combinat.super_tableau.**StandardSuperTableaux**(***kwds*)

Bases: *SemistandardSuperTableaux*, `Parent`

The set of standard super tableaux.

A standard super tableau is a tableau whose entries are primed positive integers, which are strictly increasing in rows and down columns and contains each letters from 1',1,2'…n exactly once.

For more information refer [Muth2019].

INPUT:

- `n` – a nonnegative integer or a partition

EXAMPLES:

```
sage: SST = StandardSuperTableaux()
sage: SST
Standard super tableaux
sage: SST([["1'",1,"2'",2,"3'"],[3,"4'"]])
[[1', 1, 2', 2, 3'], [3, 4']]
sage: SST = StandardSuperTableaux(3)
sage: SST
Standard super tableaux of size 3
sage: SST.first()
[[1', 1, 2']]
sage: SST.last()
[[1'], [1], [2']]
sage: SST.cardinality()
4
sage: SST.list()
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
sage: SST = StandardSuperTableaux([3,2])
sage: SST
Standard super tableaux of shape [3, 2]
```

```
>>> from sage.all import *
>>> SST = StandardSuperTableaux()
>>> SST
Standard super tableaux
>>> SST([["1'",Integer(1),"2'",Integer(2),"3'"],[Integer(3),"4'"]])
[[1', 1, 2', 2, 3'], [3, 4']]
>>> SST = StandardSuperTableaux(Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> SST
Standard super tableaux of size 3
>>> SST.first()
[[1', 1, 2']]
>>> SST.last()
[[1'], [1], [2']]
>>> SST.cardinality()
4
>>> SST.list()
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
>>> SST = StandardSuperTableaux([Integer(3),Integer(2)])
>>> SST
Standard super tableaux of shape [3, 2]
```

Element

alias of *StandardSuperTableau*

class sage.combinat.super_tableau.**StandardSuperTableaux_all**

Bases: *StandardSuperTableaux*, DisjointUnionEnumeratedSets

All standard super tableaux.

class sage.combinat.super_tableau.**StandardSuperTableaux_shape**(*p*)

Bases: *StandardSuperTableaux*

Standard super tableaux of a fixed shape p.

cardinality()

Return the number of standard super tableaux of given shape.

The standard super tableaux of a fixed shape p are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer *sage.combinat.tableau.StandardTableaux_shape* for more details.

EXAMPLES:

```
sage: StandardSuperTableaux([3,2,1]).cardinality()
16
sage: StandardSuperTableaux([2,2]).cardinality()
2
sage: StandardSuperTableaux([5]).cardinality()
1
sage: StandardSuperTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardSuperTableaux([]).cardinality()
1
```

```
>>> from sage.all import *
>>> StandardSuperTableaux([Integer(3),Integer(2),Integer(1)]).cardinality()
16
>>> StandardSuperTableaux([Integer(2),Integer(2)]).cardinality()
2
>>> StandardSuperTableaux([Integer(5)]).cardinality()
1
```

(continues on next page)

(continued from previous page)

```
>>> StandardSuperTableaux([Integer(6),Integer(5),Integer(5),Integer(3)]).
↪cardinality()
6651216
>>> StandardSuperTableaux([]).cardinality()
1
```

class sage.combinat.super_tableau.**StandardSuperTableaux_size**(*n*)

Bases: *StandardSuperTableaux*, DisjointUnionEnumeratedSets

Standard super tableaux of fixed size n.

EXAMPLES:

```
sage: [ t for t in StandardSuperTableaux(1) ]
[[[1']]]
sage: [ t for t in StandardSuperTableaux(2) ]
[[[1', 1]], [[1'], [1]]]
sage: [ t for t in StandardSuperTableaux(3) ]
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
sage: StandardSuperTableaux(4)[:]
[[[1', 1, 2', 2]],
 [[1', 2', 2], [1]],
 [[1', 1, 2], [2']],
 [[1', 1, 2'], [2]],
 [[1', 2'], [1, 2]],
 [[1', 1], [2', 2]],
 [[1', 2], [1], [2']],
 [[1', 2'], [1], [2]],
 [[1', 1], [2'], [2]],
 [[1'], [1], [2'], [2]]]
```

```
>>> from sage.all import *
>>> [ t for t in StandardSuperTableaux(Integer(1)) ]
[[[1']]]
>>> [ t for t in StandardSuperTableaux(Integer(2)) ]
[[[1', 1]], [[1'], [1]]]
>>> [ t for t in StandardSuperTableaux(Integer(3)) ]
[[[1', 1, 2']], [[1', 2'], [1]], [[1', 1], [2']], [[1'], [1], [2']]]
>>> StandardSuperTableaux(Integer(4))[:]
[[[1', 1, 2', 2]],
 [[1', 2', 2], [1]],
 [[1', 1, 2], [2']],
 [[1', 1, 2'], [2]],
 [[1', 2'], [1, 2]],
 [[1', 1], [2', 2]],
 [[1', 2], [1], [2']],
 [[1', 2'], [1], [2]],
 [[1', 1], [2'], [2]],
 [[1'], [1], [2'], [2]]]
```

cardinality()

Return the number of all standard super tableaux of size n.

The standard super tableaux of size n are in bijection with the corresponding standard tableaux (under the alphabet relabeling). Refer *sage.combinat.tableau.StandardTableaux_size* for more details.

EXAMPLES:

```
sage: StandardSuperTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardSuperTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
sage: StandardSuperTableaux(50).cardinality()   # long time
27886995605342342839104615869259776
```

```
>>> from sage.all import *
>>> StandardSuperTableaux(Integer(3)).cardinality()
4
>>> ns = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(6)]
>>> sts = [StandardSuperTableaux(n) for n in ns]
>>> all(st.cardinality() == len(st.list()) for st in sts)
True
>>> StandardSuperTableaux(Integer(50)).cardinality()   # long time
27886995605342342839104615869259776
```

5.1.341 Super Partitions

AUTHORS:

- Mike Zabrocki

A super partition of size n and fermionic sector m is a pair consisting of a strict partition of some integer r of length m (that may end in a 0) and an integer partition of $n - r$.

This module provides tools for manipulating super partitions.

Super partitions are the indexing set for symmetric functions in super space.

Super partitions may be input in two different formats: one as a pair consisting of fermionic (strict partition) and a bosonic (partition) part and the other as a list of integer values where the negative entries come first and are listed in strict order followed by the positive values in weak order.

A super partition is displayed as two partitions separated by a semicolon as a default. Super partitions may also be displayed as a weakly increasing sequence of integers that are strict if the numbers are not positive.

These combinatorial objects index the space of symmetric polynomials in two sets of variables, one commuting and one anti-commuting, and they are known as symmetric functions in super space (hence the origin of the name super partitions).

EXAMPLES:

```
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
```

(continues on next page)

(continued from previous page)

```
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
sage: [-2, 0, 1, 1] in SuperPartitions(4,2)
True
sage: [-1, 0, 1, 1] in SuperPartitions(4,2)
False
sage: [-2, -2, 2, 1] in SuperPartitions(7,2)
False
```

```
>>> from sage.all import *
>>> SuperPartitions()
Super Partitions
>>> SuperPartitions(Integer(2))
Super Partitions of 2
>>> SuperPartitions(Integer(2)).cardinality()
8
>>> SuperPartitions(Integer(4),Integer(2))
Super Partitions of 4 and of fermionic sector 2
>>> [[Integer(2),Integer(0)],[Integer(1),Integer(1)]] in SuperPartitions(Integer(4),
↪Integer(2))
True
>>> [[Integer(1),Integer(0)],[Integer(1),Integer(1)]] in SuperPartitions(Integer(4),
↪Integer(2))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(1)]] in SuperPartitions(Integer(4))
True
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(2),Integer(1)]] in␣
↪SuperPartitions(Integer(4))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(1)]] in SuperPartitions()
True
>>> [[Integer(1),Integer(1)],[Integer(2),Integer(1)]] in SuperPartitions()
False
>>> [-Integer(2), Integer(0), Integer(1), Integer(1)] in SuperPartitions(Integer(4),
↪Integer(2))
True
>>> [-Integer(1), Integer(0), Integer(1), Integer(1)] in SuperPartitions(Integer(4),
↪Integer(2))
False
>>> [-Integer(2), -Integer(2), Integer(2), Integer(1)] in SuperPartitions(Integer(7),
↪Integer(2))
False
```

REFERENCES:

- [JL2016]

class sage.combinat.superpartition.**SuperPartition**(*parent*, *lst*, *check=True*, *immutable=True*)

Bases: ClonableArray

A super partition.

A *super partition* of size n and fermionic sector m is a pair consisting of a strict partition of some integer r of length m (that may end in a 0) and an integer partition of $n - r$.

EXAMPLES:

```
sage: sp = SuperPartition([[1,0],[2,2,1]]); sp
[1, 0; 2, 2, 1]
sage: sp[0]
(1, 0)
sage: sp[1]
(2, 2, 1)
sage: sp.fermionic_degree()
2
sage: sp.bosonic_degree()
6
sage: sp.length()
5
sage: sp.conjugate()
[4, 2; ]
```

```
>>> from sage.all import *
>>> sp = SuperPartition([[Integer(1),Integer(0)],[Integer(2),Integer(2),
↪Integer(1)]]); sp
[1, 0; 2, 2, 1]
>>> sp[Integer(0)]
(1, 0)
>>> sp[Integer(1)]
(2, 2, 1)
>>> sp.fermionic_degree()
2
>>> sp.bosonic_degree()
6
>>> sp.length()
5
>>> sp.conjugate()
[4, 2; ]
```

a_part()

The antisymmetric part as a list of strictly decreasing integers.

OUTPUT: list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).antisymmetric_part()
[3, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).antisymmetric_part()
[2, 1, 0]
```

add_horizontal_border_strip_star(*h*)

Return a list of super partitions that differ from `self` by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star basis of symmetric functions in super space (see Theorem 7 from [JL2016]).

INPUT:

- `h` – number of cells in the horizontal strip

OUTPUT: list of super partitions

EXAMPLES:

```
sage: SuperPartition([[4,1],[3]]).add_horizontal_border_strip_star(3)
[[3, 1; 7],
 [4, 1; 6],
 [3, 0; 6, 2],
 [3, 1; 6, 1],
 [4, 0; 5, 2],
 [4, 1; 5, 1],
 [3, 0; 5, 3],
 [3, 1; 5, 2],
 [4, 0; 4, 3],
 [4, 1; 4, 2],
 [4, 1; 3, 3]]
sage: SuperPartition([[2,1],[3]]).add_horizontal_border_strip_star(2)
[[2, 1; 5], [2, 0; 4, 2], [2, 1; 4, 1], [2, 0; 3, 3], [2, 1; 3, 2]]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(4),Integer(1)],[Integer(3)]]).add_horizontal_
↪border_strip_star(Integer(3))
[[3, 1; 7],
 [4, 1; 6],
 [3, 0; 6, 2],
 [3, 1; 6, 1],
 [4, 0; 5, 2],
 [4, 1; 5, 1],
 [3, 0; 5, 3],
 [3, 1; 5, 2],
 [4, 0; 4, 3],
 [4, 1; 4, 2],
 [4, 1; 3, 3]]
>>> SuperPartition([[Integer(2),Integer(1)],[Integer(3)]]).add_horizontal_
↪border_strip_star(Integer(2))
[[2, 1; 5], [2, 0; 4, 2], [2, 1; 4, 1], [2, 0; 3, 3], [2, 1; 3, 2]]
```

add_horizontal_border_strip_star_bar(*h*)

List super partitions that differ from `self` by a horizontal strip.

The notion of horizontal strip comes from the Pieri rule for the Schur-star-bar basis of symmetric functions in super space (see Theorem 10 from [JL2016]).

INPUT:

- `h` – number of cells in the horizontal strip

OUTPUT: list of super partitions

EXAMPLES:

```
sage: SuperPartition([[4,1],[5,4]]).add_horizontal_border_strip_star_bar(3)
[[4, 1; 8, 4],
 [4, 1; 7, 5],
 [4, 2; 7, 4],
 [4, 1; 7, 4, 1],
 [4, 2; 6, 5],
 [4, 1; 6, 5, 1],
 [4, 3; 6, 4],
 [4, 2; 6, 4, 1],
 [4, 1; 6, 4, 2],
 [4, 3; 5, 5],
 [4, 2; 5, 5, 1],
 [4, 1; 5, 5, 2],
 [4, 3; 5, 4, 1],
 [4, 1; 5, 4, 3]]
sage: SuperPartition([[3,1],[5]]).add_horizontal_border_strip_star_bar(2)
[[3, 1; 7],
 [4, 1; 6],
 [3, 2; 6],
 [3, 1; 6, 1],
 [4, 2; 5],
 [4, 1; 5, 1],
 [3, 2; 5, 1],
 [3, 1; 5, 2]]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(4),Integer(1)],[Integer(5),Integer(4)]]).add_
↪horizontal_border_strip_star_bar(Integer(3))
[[4, 1; 8, 4],
 [4, 1; 7, 5],
 [4, 2; 7, 4],
 [4, 1; 7, 4, 1],
 [4, 2; 6, 5],
 [4, 1; 6, 5, 1],
 [4, 3; 6, 4],
 [4, 2; 6, 4, 1],
 [4, 1; 6, 4, 2],
 [4, 3; 5, 5],
 [4, 2; 5, 5, 1],
 [4, 1; 5, 5, 2],
 [4, 3; 5, 4, 1],
```

(continues on next page)

(continued from previous page)

```
 [4, 1; 5, 4, 3]]
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(5)]]).add_horizontal_
↪border_strip_star_bar(Integer(2))
[[3, 1; 7],
 [4, 1; 6],
 [3, 2; 6],
 [3, 1; 6, 1],
 [4, 2; 5],
 [4, 1; 5, 1],
 [3, 2; 5, 1],
 [3, 1; 5, 2]]
```

antisymmetric_part()

The antisymmetric part as a list of strictly decreasing integers.

OUTPUT: list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).antisymmetric_part()
[3, 1]
sage: SuperPartition([[2,1,0],[3,3]]).antisymmetric_part()
[2, 1, 0]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).antisymmetric_part()
[3, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).antisymmetric_part()
[2, 1, 0]
```

bi_degree()

Return the bidegree of `self`, which is a pair consisting of the bosonic and fermionic degree.

OUTPUT: a tuple of two integers

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bi_degree()
(9, 2)
sage: SuperPartition([[2,1,0],[3,3]]).bi_degree()
(9, 3)
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).bi_degree()
(9, 2)
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).bi_degree()
(9, 3)
```

bosonic_degree()

Return the bosonic degree of `self`.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

OUTPUT: integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_degree()
9
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_degree()
9
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).bosonic_degree()
9
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).bosonic_degree()
9
```

bosonic_length()

Return the length of the partition of the symmetric part.

OUTPUT: integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_length()
3
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_length()
2
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).bosonic_length()
3
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).bosonic_length()
2
```

check()

Check that `self` is a valid super partition.

EXAMPLES:

```
sage: SP = SuperPartition([[1],[1]])
sage: SP.check()
```

```
>>> from sage.all import *
>>> SP = SuperPartition([[Integer(1)],[Integer(1)]])
>>> SP.check()
```

conjugate()

Conjugate of a super partition.

The *conjugate* of a super partition is defined by conjugating the circled diagram.

OUTPUT: a *SuperPartition*

EXAMPLES:

```
sage: SuperPartition([[3, 1, 0], [4, 3, 2, 1]]).conjugate()
[6, 4, 1; 3]
sage: all(sp == sp.conjugate().conjugate() for sp in SuperPartitions(4))
True
sage: all(sp.conjugate() in SuperPartitions(3,2) for sp in SuperPartitions(3,
↪2))
True
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3), Integer(1), Integer(0)], [Integer(4),␣
↪Integer(3), Integer(2), Integer(1)]]).conjugate()
[6, 4, 1; 3]
>>> all(sp == sp.conjugate().conjugate() for sp in␣
↪SuperPartitions(Integer(4)))
True
>>> all(sp.conjugate() in SuperPartitions(Integer(3),Integer(2)) for sp in␣
↪SuperPartitions(Integer(3),Integer(2)))
True
```

degree()

Return the bosonic degree of `self`.

The *bosonic degree* is the sum of the sizes of the antisymmetric and symmetric parts.

OUTPUT: integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).bosonic_degree()
9
sage: SuperPartition([[2,1,0],[3,3]]).bosonic_degree()
9
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).bosonic_degree()
9
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).bosonic_degree()
9
```

dominates(*other*)

Return `True` if and only if `self` dominates `other`.

If the symmetric and anti-symmetric parts of `self` and `other` are not the same size then the result is `False`.

EXAMPLES:

```
sage: LA = SuperPartition([[2,1],[2,1,1]])
sage: LA.dominates([[2,1],[3,1]])
False
sage: LA.dominates([[2,1],[1,1,1,1]])
True
```

(continues on next page)

(continued from previous page)

```
sage: LA.dominates([[3],[2,1,1]])
False
sage: LA.dominates([[1],[1]*6])
False
```

```
>>> from sage.all import *
>>> LA = SuperPartition([[Integer(2),Integer(1)],[Integer(2),Integer(1),
↪Integer(1)]])
>>> LA.dominates([[Integer(2),Integer(1)],[Integer(3),Integer(1)]])
False
>>> LA.dominates([[Integer(2),Integer(1)],[Integer(1),Integer(1),Integer(1),
↪Integer(1)]])
True
>>> LA.dominates([[Integer(3)],[Integer(2),Integer(1),Integer(1)]])
False
>>> LA.dominates([[Integer(1)],[Integer(1)]*Integer(6)])
False
```

fermionic_degree()

Return the fermionic degree of `self`.

The *fermionic degree* is the length of the antisymmetric part.

OUTPUT: integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).fermionic_degree()
2
sage: SuperPartition([[2,1,0],[3,3]]).fermionic_degree()
3
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).fermionic_degree()
2
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).fermionic_degree()
3
```

fermionic_sector()

Return the fermionic degree of `self`.

The *fermionic degree* is the length of the antisymmetric part.

OUTPUT: integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).fermionic_degree()
2
sage: SuperPartition([[2,1,0],[3,3]]).fermionic_degree()
3
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).fermionic_degree()
2
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).fermionic_degree()
3
```

static from_circled_diagram(*shape*, *corners*)

Construct a super partition from a circled diagram.

A circled diagram consists of a partition of the concatenation of the antisymmetric and symmetric parts and a list of addable cells of the partition which indicate the location of the circled cells.

INPUT:

- `shape` – a partition or list of integers
- `corners` – list of removable cells of `shape`

OUTPUT: a *SuperPartition*

EXAMPLES:

```
sage: SuperPartition.from_circled_diagram([3, 2, 2, 1, 1], [(0, 3), (3, 1)])
[3, 1; 2, 2, 1]
sage: SuperPartition.from_circled_diagram([3, 3, 2, 1], [(2, 2), (3, 1), (4,␣
↪0)])
[2, 1, 0; 3, 3]
sage: from_cd = SuperPartition.from_circled_diagram
sage: all(sp == from_cd(*sp.to_circled_diagram()) for sp in␣
↪SuperPartitions(4))
True
```

```
>>> from sage.all import *
>>> SuperPartition.from_circled_diagram([Integer(3), Integer(2), Integer(2),␣
↪Integer(1), Integer(1)], [(Integer(0), Integer(3)), (Integer(3),␣
↪Integer(1))])
[3, 1; 2, 2, 1]
>>> SuperPartition.from_circled_diagram([Integer(3), Integer(3), Integer(2),␣
↪Integer(1)], [(Integer(2), Integer(2)), (Integer(3), Integer(1)),␣
↪(Integer(4), Integer(0))])
[2, 1, 0; 3, 3]
>>> from_cd = SuperPartition.from_circled_diagram
>>> all(sp == from_cd(*sp.to_circled_diagram()) for sp in␣
↪SuperPartitions(Integer(4)))
True
```

length()

Return the length of `self`, which is the sum of the lengths of the antisymmetric and symmetric part.

OUTPUT: integer

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).length()
5
sage: SuperPartition([[2,1,0],[3,3]]).length()
5
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
→Integer(1)]]).length()
5
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
→Integer(3)]]).length()
5
```

s_part()

The symmetric part as a list of weakly decreasing integers.

OUTPUT: list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
→Integer(1)]]).symmetric_part()
[2, 2, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
→Integer(3)]]).symmetric_part()
[3, 3]
```

shape_circled_diagram()

A concatenated partition with an extra cell for each antisymmetric part

OUTPUT: a partition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).shape_circled_diagram()
[4, 2, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).shape_circled_diagram()
[3, 3, 3, 2, 1]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
→Integer(1)]]).shape_circled_diagram()
[4, 2, 2, 2, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
→Integer(3)]]).shape_circled_diagram()
[3, 3, 3, 2, 1]
```

sign()

Return the sign of a permutation of cycle type the symmetric part of `self`.

OUTPUT: either 1 or -1

EXAMPLES:

```
sage: SuperPartition([[1,0],[3,1,1]]).sign()
-1
sage: SuperPartition([[1,0],[3,2,1]]).sign()
1
sage: sum(sp.sign()/sp.zee() for sp in SuperPartitions(6,0))
0
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(1),Integer(0)],[Integer(3),Integer(1),
↪Integer(1)]]).sign()
-1
>>> SuperPartition([[Integer(1),Integer(0)],[Integer(3),Integer(2),
↪Integer(1)]]).sign()
1
>>> sum(sp.sign()/sp.zee() for sp in SuperPartitions(Integer(6),Integer(0)))
0
```

symmetric_part()

The symmetric part as a list of weakly decreasing integers.

OUTPUT: list

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).symmetric_part()
[2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).symmetric_part()
[3, 3]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).symmetric_part()
[2, 2, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).symmetric_part()
[3, 3]
```

to_circled_diagram()

The shape of the circled diagram and a list of addable cells

A circled diagram consists of a partition for the outer shape and a list of removable cells of the partition indicating the location of the circled cells

OUTPUT: list consisting of a partition and a list of pairs of integers

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).to_circled_diagram()
[[3, 2, 2, 1, 1], [(0, 3), (3, 1)]]
```

(continues on next page)

(continued from previous page)

```
sage: SuperPartition([[2,1,0],[3,3]]).to_circled_diagram()
[[3, 3, 2, 1], [(2, 2), (3, 1), (4, 0)]]
sage: from_cd = SuperPartition.from_circled_diagram
sage: all(sp == from_cd(*sp.to_circled_diagram()) for sp in␣
↪SuperPartitions(4))
True
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).to_circled_diagram()
[[3, 2, 2, 1, 1], [(0, 3), (3, 1)]]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).to_circled_diagram()
[[3, 3, 2, 1], [(2, 2), (3, 1), (4, 0)]]
>>> from_cd = SuperPartition.from_circled_diagram
>>> all(sp == from_cd(*sp.to_circled_diagram()) for sp in␣
↪SuperPartitions(Integer(4)))
True
```

to_composition()

Concatenate the antisymmetric and symmetric parts to a composition.

OUTPUT:

- a (possibly weak) composition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).to_composition()
[3, 1, 2, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition()
[2, 1, 0, 3, 3]
sage: SuperPartition([[2,1,0],[3,3]]).to_composition().parent()
Compositions of nonnegative integers
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).to_composition()
[3, 1, 2, 2, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).to_composition()
[2, 1, 0, 3, 3]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).to_composition().parent()
Compositions of nonnegative integers
```

to_list()

The list of two lists with the antisymmetric and symmetric parts.

EXAMPLES:

```
sage: SuperPartition([[1],[1]]).to_list()
[[1], [1]]
```

(continues on next page)

(continued from previous page)

```
sage: SuperPartition([[],[1]]).to_list()
[[], [1]]
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(1)],[Integer(1)]]).to_list()
[[1], [1]]
>>> SuperPartition([[],[Integer(1)]]).to_list()
[[], [1]]
```

to_partition()

Concatenate and sort the antisymmetric and symmetric parts to a partition.

OUTPUT: a partition

EXAMPLES:

```
sage: SuperPartition([[3,1],[2,2,1]]).to_partition()
[3, 2, 2, 1, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition()
[3, 3, 2, 1]
sage: SuperPartition([[2,1,0],[3,3]]).to_partition().parent()
Partitions
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(3),Integer(1)],[Integer(2),Integer(2),
↪Integer(1)]]).to_partition()
[3, 2, 2, 1, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).to_partition()
[3, 3, 2, 1]
>>> SuperPartition([[Integer(2),Integer(1),Integer(0)],[Integer(3),
↪Integer(3)]]).to_partition().parent()
Partitions
```

zee()

Return the centralizer size of a permutation of cycle type symmetric part of `self`.

OUTPUT: a positive integer

EXAMPLES:

```
sage: SuperPartition([[1,0],[3,1,1]]).zee()
6
sage: SuperPartition([[1],[2,2,1]]).zee()
8
sage: sum(1/sp.zee() for sp in SuperPartitions(6,0))
1
```

```
>>> from sage.all import *
>>> SuperPartition([[Integer(1),Integer(0)],[Integer(3),Integer(1),
↪Integer(1)]]).zee()
6
>>> SuperPartition([[Integer(1)],[Integer(2),Integer(2),Integer(1)]]).zee()
```

(continues on next page)

(continued from previous page)

```
8
>>> sum(Integer(1)/sp.zee() for sp in SuperPartitions(Integer(6),Integer(0)))
1
```

class sage.combinat.superpartition.**SuperPartitions**(*is_infinite=False*)

Bases: UniqueRepresentation, Parent

Super partitions.

A super partition of size n and fermionic sector m is a pair consisting of a strict partition of some integer r of length m (that may end in a 0) and an integer partition of $n - r$.

INPUT:

- n – integer (default: None)
- m – if n is specified, an integer (optional: default None)

Super partitions are the indexing set for symmetric functions in super space.

EXAMPLES:

```
sage: SuperPartitions()
Super Partitions
sage: SuperPartitions(2)
Super Partitions of 2
sage: SuperPartitions(2).cardinality()
8
sage: SuperPartitions(4,2)
Super Partitions of 4 and of fermionic sector 2
sage: [[2,0],[1,1]] in SuperPartitions(4,2)
True
sage: [[1,0],[1,1]] in SuperPartitions(4,2)
False
sage: [[1,0],[2,1]] in SuperPartitions(4)
True
sage: [[1,0],[2,2,1]] in SuperPartitions(4)
False
sage: [[1,0],[2,1]] in SuperPartitions()
True
sage: [[1,1],[2,1]] in SuperPartitions()
False
```

```
>>> from sage.all import *
>>> SuperPartitions()
Super Partitions
>>> SuperPartitions(Integer(2))
Super Partitions of 2
>>> SuperPartitions(Integer(2)).cardinality()
8
>>> SuperPartitions(Integer(4),Integer(2))
Super Partitions of 4 and of fermionic sector 2
>>> [[Integer(2),Integer(0)],[Integer(1),Integer(1)]] in␣
↪SuperPartitions(Integer(4),Integer(2))
True
```

(continues on next page)

(continued from previous page)

```
>>> [[Integer(1),Integer(0)],[Integer(1),Integer(1)]] in␣
↪SuperPartitions(Integer(4),Integer(2))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(1)]] in␣
↪SuperPartitions(Integer(4))
True
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(2),Integer(1)]] in␣
↪SuperPartitions(Integer(4))
False
>>> [[Integer(1),Integer(0)],[Integer(2),Integer(1)]] in SuperPartitions()
True
>>> [[Integer(1),Integer(1)],[Integer(2),Integer(1)]] in SuperPartitions()
False
```

Element

alias of `SuperPartition`

options = Current options for SuperPartition - display: default

class sage.combinat.superpartition.**SuperPartitions_all**

Bases: `SuperPartitions`

Initialize `self`.

class sage.combinat.superpartition.**SuperPartitions_n**(*n*)

Bases: `SuperPartitions`

Initialize `self`.

class sage.combinat.superpartition.**SuperPartitions_n_m**(*n*, *m*)

Bases: `SuperPartitions`

Initialize `self`.

5.1.342 Symmetric Group Algebra

sage.combinat.symmetric_group_algebra.**HeckeAlgebraSymmetricGroupT**(*R*, *n*, *q=None*)

Return the Hecke algebra of the symmetric group S_n on the T-basis with quantum parameter `q` over the ring R.

If R is a commutative ring and q is an invertible element of R, and if n is a nonnegative integer, then the Hecke algebra of the symmetric group S_n over R with quantum parameter q is defined as the algebra generated by the generators $T_1, T_2, \ldots, T_{n-1}$ with relations

$$T_i T_{i+1} T_i = T_{i+1} T_i T_{i+1}$$

for all $i < n-1$ ("braid relations"),

$$T_i T_j = T_j T_i$$

for all i and j such that $|i-j| > 1$ ("locality relations"), and

$$T_i^2 = q + (q-1) T_i$$

for all i (the "quadratic relations", also known in the form $(T_i+1)(T_i-q) = 0$). (This is only one of several existing definitions in literature, not all of which are fully equivalent. We are following the conventions of [Go1993].) For any permutation $w \in S_n$, we can define an element T_w of this Hecke algebra by setting $T_w = T_{i_1} T_{i_2} \cdots T_{i_k}$, where $w = s_{i_1} s_{i_2} \cdots s_{i_k}$ is a reduced word for w (with s_i meaning the transposition $(i, i+1)$, and the product of permutations being evaluated by first applying s_{i_k}, then $s_{i_{k-1}}$, etc.). This element is independent of the choice of the reduced decomposition, and can be computed in Sage by calling `H[w]` where `H` is the Hecke algebra and `w` is the permutation.

The Hecke algebra of the symmetric group S_n with quantum parameter q over R can be seen as a deformation of the group algebra RS_n; indeed, it becomes RS_n when $q = 1$.

Warning: The multiplication on the Hecke algebra of the symmetric group does *not* follow the global option `mult` of the `Permutations` class (see `options()`). It is always as defined above. It does not match the default option (`mult=l2r`) of the symmetric group algebra!

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3)
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate␣
↪Polynomial Ring in q over Rational Field
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
Hecke algebra of the symmetric group of order 3 on the T basis over Univariate␣
↪Polynomial Ring in q over Rational Field
```

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2)
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over␣
↪Rational Field
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(2))
Hecke algebra of the symmetric group of order 3 with q=2 on the T basis over␣
↪Rational Field
```

The multiplication on the Hecke algebra follows a different convention than the one on the symmetric group algebra does by default:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3([1,3,2]) * H3([2,1,3])
T[3, 1, 2]
sage: S3 = SymmetricGroupAlgebra(QQ, 3)
sage: S3([1,3,2]) * S3([2,1,3])
[2, 3, 1]

sage: TestSuite(H3).run()
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> H3([Integer(1),Integer(3),Integer(2)]) * H3([Integer(2),Integer(1),
↪Integer(3)])
T[3, 1, 2]
>>> S3 = SymmetricGroupAlgebra(QQ, Integer(3))
```

(continues on next page)

(continued from previous page)

```
>>> S3([Integer(1),Integer(3),Integer(2)]) * S3([Integer(2),Integer(1),
↪Integer(3)])
[2, 3, 1]

>>> TestSuite(H3).run()
```

Note

IwahoriHeckeAlgebra gives a different implementation of the Iwahori-Hecke algebras of a Coxeter system (W, S). This includes the Hecke algebras of the symmetric group as special case.

class sage.combinat.symmetric_group_algebra.**HeckeAlgebraSymmetricGroup_generic**(*R*, *n*, *q=None*)

Bases: *CombinatorialFreeModule*

one_basis()

Return the identity permutation.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).one()  # indirect doctest
T[1, 2, 3]
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3)).one()  # indirect doctest
T[1, 2, 3]
```

q()

Return the variable or parameter q.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ, 3).q()
q
sage: HeckeAlgebraSymmetricGroupT(QQ, 3, 2).q()
2
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3)).q()
q
>>> HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(2)).q()
2
```

class sage.combinat.symmetric_group_algebra.**HeckeAlgebraSymmetricGroup_t**(*R*, *n*, *q=None*)

Bases: *HeckeAlgebraSymmetricGroup_generic*

algebra_generators()

Return the generators of the algebra.

EXAMPLES:

```
sage: HeckeAlgebraSymmetricGroupT(QQ,3).algebra_generators()
[T[2, 1, 3], T[1, 3, 2]]
```

```
>>> from sage.all import *
>>> HeckeAlgebraSymmetricGroupT(QQ,Integer(3)).algebra_generators()
[T[2, 1, 3], T[1, 3, 2]]
```

jucys_murphy(*k*)

Return the Jucys-Murphy element J_k of the Hecke algebra.

These Jucys-Murphy elements are defined by

$$J_k = (T_{k-1}T_{k-2}\cdots T_1)(T_1T_2\cdots T_{k-1}).$$

More explicitly,

$$J_k = q^{k-1} + \sum_{l=1}^{k-1}(q^l - q^{l-1})T_{(l,k)}.$$

For generic q, the J_k generate a maximal commutative sub-algebra of the Hecke algebra.

Warning

The specialization $q = 1$ does *not* map these elements J_k to the Young-Jucys-Murphy elements of the group algebra RS_n. (Instead, it maps the "reduced" Jucys-Murphy elements $(J_k - q^{k-1})/(q-1)$ to the Young-Jucys-Murphy elements of RS_n.)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ,3)
sage: j2 = H3.jucys_murphy(2); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: j3 = H3.jucys_murphy(3); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
sage: j2*j3 == j3*j2
True
sage: j0 = H3.jucys_murphy(1); j0 == H3.one()
True
sage: H3.jucys_murphy(0)
Traceback (most recent call last):
...
ValueError: k (= 0) must be between 1 and n (= 3)
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ,Integer(3))
>>> j2 = H3.jucys_murphy(Integer(2)); j2
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
>>> j3 = H3.jucys_murphy(Integer(3)); j3
q^2*T[1, 2, 3] + (q^2-q)*T[1, 3, 2] + (q-1)*T[3, 2, 1]
>>> j2*j3 == j3*j2
True
>>> j0 = H3.jucys_murphy(Integer(1)); j0 == H3.one()
```

(continues on next page)

(continued from previous page)

```
True
>>> H3.jucys_murphy(Integer(0))
Traceback (most recent call last):
...
ValueError: k (= 0) must be between 1 and n (= 3)
```

product_on_basis(*perm1*, *perm2*)

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: a = H3([2,1,3])+2*H3([1,2,3])-H3([3,2,1])
sage: a^2 #indirect doctest
6*T[1, 2, 3] + 4*T[2, 1, 3] - T[2, 3, 1]
- T[3, 1, 2] - 4*T[3, 2, 1]
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(1))
>>> a = H3([Integer(2),Integer(1),Integer(3)])+Integer(2)*H3([Integer(1),
↪Integer(2),Integer(3)])-H3([Integer(3),Integer(2),Integer(1)])
>>> a**Integer(2) #indirect doctest
6*T[1, 2, 3] + 4*T[2, 1, 3] - T[2, 3, 1]
- T[3, 1, 2] - 4*T[3, 2, 1]
```

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3([2,1,3])+2*QS3([1,2,3])-QS3([3,2,1])
sage: a^2
6*[1, 2, 3] + 4*[2, 1, 3] - [2, 3, 1] - [3, 1, 2] - 4*[3, 2, 1]
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> a = QS3([Integer(2),Integer(1),Integer(3)])+Integer(2)*QS3([Integer(1),
↪Integer(2),Integer(3)])-QS3([Integer(3),Integer(2),Integer(1)])
>>> a**Integer(2)
6*[1, 2, 3] + 4*[2, 1, 3] - [2, 3, 1] - [3, 1, 2] - 4*[3, 2, 1]
```

t(*i*)

Return the element T_i of the Hecke algebra `self`.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ,3)
sage: H3.t(1)
T[2, 1, 3]
sage: H3.t(2)
T[1, 3, 2]
sage: H3.t(0)
Traceback (most recent call last):
...
ValueError: i (= 0) must be between 1 and n-1 (= 2)
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ,Integer(3))
>>> H3.t(Integer(1))
T[2, 1, 3]
>>> H3.t(Integer(2))
T[1, 3, 2]
>>> H3.t(Integer(0))
Traceback (most recent call last):
...
ValueError: i (= 0) must be between 1 and n-1 (= 2)
```

t_action(*a*, *i*)

Return the product $T_i \cdot a$.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: a = H3([2,1,3])+2*H3([1,2,3])
sage: H3.t_action(a, 1)
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
sage: H3.t(1)*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> a = H3([Integer(2),Integer(1),Integer(3)])+Integer(2)*H3([Integer(1),
↪Integer(2),Integer(3)])
>>> H3.t_action(a, Integer(1))
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
>>> H3.t(Integer(1))*a
q*T[1, 2, 3] + (q+1)*T[2, 1, 3]
```

t_action_on_basis(*perm*, *i*)

Return the product $T_i \cdot T_{perm}$, where `perm` is a permutation in the symmetric group S_n.

EXAMPLES:

```
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
sage: H3.t_action_on_basis(Permutation([1,2,3]), 1)
T[2, 1, 3]
sage: H3 = HeckeAlgebraSymmetricGroupT(QQ, 3, 1)
sage: H3.t_action_on_basis(Permutation([2,1,3]), 1)
T[1, 2, 3]
sage: H3.t_action_on_basis(Permutation([1,3,2]), 2)
T[1, 2, 3]
```

```
>>> from sage.all import *
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3))
>>> H3.t_action_on_basis(Permutation([Integer(2),Integer(1),Integer(3)]),␣
↪Integer(1))
q*T[1, 2, 3] + (q-1)*T[2, 1, 3]
```

(continues on next page)

(continued from previous page)

```
>>> H3.t_action_on_basis(Permutation([Integer(1),Integer(2),Integer(3)]),␣
↪Integer(1))
T[2, 1, 3]
>>> H3 = HeckeAlgebraSymmetricGroupT(QQ, Integer(3), Integer(1))
>>> H3.t_action_on_basis(Permutation([Integer(2),Integer(1),Integer(3)]),␣
↪Integer(1))
T[1, 2, 3]
>>> H3.t_action_on_basis(Permutation([Integer(1),Integer(3),Integer(2)]),␣
↪Integer(2))
T[1, 2, 3]
```

class sage.combinat.symmetric_group_algebra.**KLCellularBasis**(*SGA*)

Bases: *SGACellularBasis*

The Kazhdan-Lusztig C' basis (at $q = 1$) of the symmetric group algebra realized as a `cellular basis`

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: KL = SGA.kazhdan_lusztig_cellular_basis()
sage: for la in KL.simple_module_parameterization():
....:     CM = KL.cell_module(la)
....:     print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> KL = SGA.kazhdan_lusztig_cellular_basis()
>>> for la in KL.simple_module_parameterization():
...     CM = KL.cell_module(la)
...     print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1
```

class sage.combinat.symmetric_group_algebra.**MurphyBasis**(*SGA*)

Bases: *SGACellularBasis*

The Murphy basis of a symmetric group algebra.

Let R be a commutative ring, and let $A = R[S_n]$ denote the group algebra (over R) of S_n. The *Murphy basis* is the basis of A defined as follows. Let S, T be standard tableaux of shape λ. Define T^λ as the standard tableau of shape λ with the first row filled with $1, \dots, \lambda_1$, the second row $\lambda_1 + 1, \dots, \lambda_1 + \lambda_2$, and so on. Let $d(S)$ be the unique permutation such that $S = T^\lambda d(S)$ under the natural action. Then the Murphy basis element indexed by S and T is

$$M_{S'T'} = d(S)^{-1} R_\lambda d(T),$$

where S' denotes the conjugate tableau. The Murphy basis is a `cellular basis` of A.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: M = SGA.murphy_basis()
sage: for la in M.simple_module_parameterization():
....:     CM = M.cell_module(la)
....:     print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> M = SGA.murphy_basis()
>>> for la in M.simple_module_parameterization():
...     CM = M.cell_module(la)
...     print(la, CM.dimension(), CM.simple_module().dimension())
[2, 2, 1] 5 4
[3, 1, 1] 6 6
[3, 2] 5 1
[4, 1] 4 4
[5] 1 1
```

REFERENCES:

- [DJM1998]
- [Mathas2004]

class sage.combinat.symmetric_group_algebra.**SGACellularBasis**(*SGA*)

Bases: `CellularBasis`

A cellular basis of the symmetric group algebra.

one()

Return the element 1 in `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: M = SGA.murphy_basis()
sage: M.one()
C([4], [[1, 2, 3, 4]], [[1, 2, 3, 4]])
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> M = SGA.murphy_basis()
>>> M.one()
C([4], [[1, 2, 3, 4]], [[1, 2, 3, 4]])
```

one_basis()

Return the index of the basis element for the multiplicative identity.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: M = SGA.murphy_basis()
sage: M.one_basis()
([4], [[1, 2, 3, 4]], [[1, 2, 3, 4]])
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> M = SGA.murphy_basis()
>>> M.one_basis()
([4], [[1, 2, 3, 4]], [[1, 2, 3, 4]])
```

sage.combinat.symmetric_group_algebra.**SymmetricGroupAlgebra**(*R*, *W*, *category=None*)

Return the symmetric group algebra of order `W` over the ring `R`.

INPUT:

- `W` – a symmetric group; alternatively an integer n can be provided, as shorthand for `Permutations(n)`.
- `R` – a base ring
- `category` – a category (default: the category of `W`)

This supports several implementations of the symmetric group. At this point this has been tested with `W=Permutations(n)` and `W=SymmetricGroup(n)`.

Warning

Some features are failing in the latter case, in particular if the domain of the symmetric group is not $1, \ldots, n$.

Note

The brave can also try setting `W=WeylGroup(['A',n-1])`, but little support for this currently exists.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3); QS3
Symmetric group algebra of order 3 over Rational Field
sage: QS3(1)
[1, 2, 3]
sage: QS3(2)
2*[1, 2, 3]
sage: basis = [QS3(p) for p in Permutations(3)]
sage: a = sum(basis); a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: a^2
6*[1, 2, 3] + 6*[1, 3, 2] + 6*[2, 1, 3] + 6*[2, 3, 1]
+ 6*[3, 1, 2] + 6*[3, 2, 1]
sage: a^2 == 6*a
True
sage: b = QS3([3, 1, 2])
sage: b
[3, 1, 2]
```

(continues on next page)

(continued from previous page)

```
sage: b*a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: b*a == a
True
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3)); QS3
Symmetric group algebra of order 3 over Rational Field
>>> QS3(Integer(1))
[1, 2, 3]
>>> QS3(Integer(2))
2*[1, 2, 3]
>>> basis = [QS3(p) for p in Permutations(Integer(3))]
>>> a = sum(basis); a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> a**Integer(2)
6*[1, 2, 3] + 6*[1, 3, 2] + 6*[2, 1, 3] + 6*[2, 3, 1]
+ 6*[3, 1, 2] + 6*[3, 2, 1]
>>> a**Integer(2) == Integer(6)*a
True
>>> b = QS3([Integer(3), Integer(1), Integer(2)])
>>> b
[3, 1, 2]
>>> b*a
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> b*a == a
True
```

We now construct the symmetric group algebra by providing explicitly the underlying group:

```
sage: SGA = SymmetricGroupAlgebra(QQ, Permutations(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Standard permutations of 4
sage: SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]

sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(4)); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Symmetric group of order 4! as a permutation group
sage: SGA.an_element()
() + (2,3,4) + 2*(1,3)(2,4) + 3*(1,4)(2,3)

sage: SGA = SymmetricGroupAlgebra(QQ, WeylGroup(["A",3], prefix='s')); SGA
Symmetric group algebra of order 4 over Rational Field
sage: SGA.group()
Weyl Group of type ['A', 3] (as a matrix group acting
on the ambient space)
sage: SGA.an_element()
s1*s2*s3 + 3*s2*s3*s1*s2 + 2*s3*s1 + 1
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Permutations(Integer(4))); SGA
Symmetric group algebra of order 4 over Rational Field
>>> SGA.group()
Standard permutations of 4
>>> SGA.an_element()
[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 3*[1, 3, 2, 4] + [4, 1, 2, 3]

>>> SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(Integer(4))); SGA
Symmetric group algebra of order 4 over Rational Field
>>> SGA.group()
Symmetric group of order 4! as a permutation group
>>> SGA.an_element()
() + (2,3,4) + 2*(1,3)(2,4) + 3*(1,4)(2,3)

>>> SGA = SymmetricGroupAlgebra(QQ, WeylGroup(["A",Integer(3)], prefix='s')); SGA
Symmetric group algebra of order 4 over Rational Field
>>> SGA.group()
Weyl Group of type ['A', 3] (as a matrix group acting
on the ambient space)
>>> SGA.an_element()
s1*s2*s3 + 3*s2*s3*s1*s2 + 2*s3*s1 + 1
```

The preferred way to construct the symmetric group algebra is to go through the usual `algebra` method:

```
sage: SGA = Permutations(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
sage: SGA.group()
Standard permutations of 3

sage: SGA = SymmetricGroup(3).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
sage: SGA.group()
Symmetric group of order 3! as a permutation group
```

```
>>> from sage.all import *
>>> SGA = Permutations(Integer(3)).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
>>> SGA.group()
Standard permutations of 3

>>> SGA = SymmetricGroup(Integer(3)).algebra(QQ); SGA
Symmetric group algebra of order 3 over Rational Field
>>> SGA.group()
Symmetric group of order 3! as a permutation group
```

The canonical embedding from the symmetric group algebra of order n to the symmetric group algebra of order $p > n$ is available as a coercion:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.coerce_map_from(QS3)
Generic morphism:
```

(continues on next page)

(continued from previous page)

```
  From: Symmetric group algebra of order 3 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: x3  = QS3([3,1,2]) + 2 * QS3([2,3,1]); x3
2*[2, 3, 1] + [3, 1, 2]
sage: QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> QS4.coerce_map_from(QS3)
Generic morphism:
  From: Symmetric group algebra of order 3 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

>>> x3  = QS3([Integer(3),Integer(1),Integer(2)]) + Integer(2) * QS3([Integer(2),
↪Integer(3),Integer(1)]); x3
2*[2, 3, 1] + [3, 1, 2]
>>> QS4(x3)
2*[2, 3, 1, 4] + [3, 1, 2, 4]
```

This allows for mixed expressions:

```
sage: x4  = 3 * QS4([3, 1, 4, 2])
sage: x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]

sage: QS0 = SymmetricGroupAlgebra(QQ, 0)
sage: QS1 = SymmetricGroupAlgebra(QQ, 1)
sage: x0 = QS0([])
sage: x1 = QS1([1])
sage: x0 * x1
[1]
sage: x3 - (2*x0 + x1) - x4
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

```
>>> from sage.all import *
>>> x4  = Integer(3) * QS4([Integer(3), Integer(1), Integer(4), Integer(2)])
>>> x3 + x4
2*[2, 3, 1, 4] + [3, 1, 2, 4] + 3*[3, 1, 4, 2]

>>> QS0 = SymmetricGroupAlgebra(QQ, Integer(0))
>>> QS1 = SymmetricGroupAlgebra(QQ, Integer(1))
>>> x0 = QS0([])
>>> x1 = QS1([Integer(1)])
>>> x0 * x1
[1]
>>> x3 - (Integer(2)*x0 + x1) - x4
-3*[1, 2, 3, 4] + 2*[2, 3, 1, 4] + [3, 1, 2, 4] - 3*[3, 1, 4, 2]
```

Caveat: to achieve this, constructing `SymmetricGroupAlgebra(QQ, 10)` currently triggers the construction of all symmetric group algebras of smaller order. Is this a feature we really want to have?

> **Warning**
>
> The semantics of multiplication in symmetric group algebras with index set `Permutations(n)` is determined by the order in which permutations are multiplied, which currently defaults to "in such a way that multiplication is associative with permutations acting on integers from the right", but can be changed to the opposite order at runtime by setting the global variable `Permutations.options['mult']` (see `sage.combinat.permutation.Permutations.options()`). On the other hand, the semantics of multiplication in symmetric group algebras with index set `SymmetricGroup(n)` does not depend on this global variable. (This has the awkward consequence that the coercions between these two sorts of symmetric group algebras do not respect multiplication when this global variable is set to `'r2l'`.) In view of this, it is recommended that code not rely on the usual multiplication function, but rather use the methods `left_action_product()` and `right_action_product()` for multiplying permutations (these methods don't depend on the setting). See Issue #14885 for more information.

We conclude by constructing the algebra of the symmetric group as a monoid algebra:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3, category=Monoids())
sage: QS3.category()
Category of finite dimensional cellular monoid algebras
over Rational Field
sage: TestSuite(QS3).run(skip=['_test_construction'])
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3), category=Monoids())
>>> QS3.category()
Category of finite dimensional cellular monoid algebras
over Rational Field
>>> TestSuite(QS3).run(skip=['_test_construction'])
```

class `sage.combinat.symmetric_group_algebra.`**`SymmetricGroupAlgebra_n`**(*R*, *W*, *category*)

Bases: `GroupAlgebra_class`

`algebra_generators`()

Return generators of this group algebra (as algebra) as a list of permutations.

The generators used for the group algebra of S_n are the transposition $(2,1)$ and the n-cycle $(1,2,\ldots,n)$, unless $n \leq 1$ (in which case no generators are needed).

EXAMPLES:

```
sage: SymmetricGroupAlgebra(ZZ,5).algebra_generators()
Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])

sage: SymmetricGroupAlgebra(QQ,0).algebra_generators()
Family ()

sage: SymmetricGroupAlgebra(QQ,1).algebra_generators()
Family ()
```

```
>>> from sage.all import *
>>> SymmetricGroupAlgebra(ZZ,Integer(5)).algebra_generators()
```

(continues on next page)

(continued from previous page)

```
Family ([2, 1, 3, 4, 5], [2, 3, 4, 5, 1])

>>> SymmetricGroupAlgebra(QQ,Integer(0)).algebra_generators()
Family ()

>>> SymmetricGroupAlgebra(QQ,Integer(1)).algebra_generators()
Family ()
```

antipode(*x*)

Return the image of the element `x` of `self` under the antipode of the Hopf algebra `self` (where the comultiplication is the usual one on a group algebra).

Explicitly, this is obtained by replacing each permutation σ by σ^{-1} in `x` while keeping all coefficients as they are.

EXAMPLES:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.antipode(2 * QS4([1, 3, 4, 2]) - 1/2 * QS4([1, 4, 2, 3]))
-1/2*[1, 3, 4, 2] + 2*[1, 4, 2, 3]
sage: all( QS4.antipode(QS4(p)) == QS4(p.inverse())
....:      for p in Permutations(4) )
True

sage: ZS3 = SymmetricGroupAlgebra(ZZ, 3)
sage: ZS3.antipode(ZS3.zero())
0
sage: ZS3.antipode(-ZS3(Permutation([2, 3, 1])))
-[3, 1, 2]
```

```
>>> from sage.all import *
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> QS4.antipode(Integer(2) * QS4([Integer(1), Integer(3), Integer(4),␣
↪Integer(2)]) - Integer(1)/Integer(2) * QS4([Integer(1), Integer(4),␣
↪Integer(2), Integer(3)]))
-1/2*[1, 3, 4, 2] + 2*[1, 4, 2, 3]
>>> all( QS4.antipode(QS4(p)) == QS4(p.inverse())
...      for p in Permutations(Integer(4)) )
True

>>> ZS3 = SymmetricGroupAlgebra(ZZ, Integer(3))
>>> ZS3.antipode(ZS3.zero())
0
>>> ZS3.antipode(-ZS3(Permutation([Integer(2), Integer(3), Integer(1)])))
-[3, 1, 2]
```

binary_unshuffle_sum(*k*)

Return the k-th binary unshuffle sum in the group algebra `self`.

The k-th binary unshuffle sum in the symmetric group algebra RS_n over a ring R is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \cdots < \sigma(k)$ and $\sigma(k+1) < \sigma(k+2) < \cdots < \sigma(n)$.

This element has the property that, if it is denoted by t_k, and if the k-th semi-RSW element (see *semi_rsw_element()*) is denoted by s_k, then $s_k S(t_k)$ and $t_k S(s_k)$ both equal the k-th

Reiner-Saliola-Welker shuffling element of RS_n (see `rsw_shuffling_element()`).

The k-th binary unshuffle sum is the image of the complete non-commutative symmetric function $S^{(k,n-k)}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The binary unshuffle sums on $\mathbf{Q}S_3$:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.binary_unshuffle_sum(0)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(1)
[1, 2, 3] + [2, 1, 3] + [3, 1, 2]
sage: QS3.binary_unshuffle_sum(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.binary_unshuffle_sum(3)
[1, 2, 3]
sage: QS3.binary_unshuffle_sum(4)
0
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS3.binary_unshuffle_sum(Integer(0))
[1, 2, 3]
>>> QS3.binary_unshuffle_sum(Integer(1))
[1, 2, 3] + [2, 1, 3] + [3, 1, 2]
>>> QS3.binary_unshuffle_sum(Integer(2))
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
>>> QS3.binary_unshuffle_sum(Integer(3))
[1, 2, 3]
>>> QS3.binary_unshuffle_sum(Integer(4))
0
```

Let us check the relation with the k-th Reiner-Saliola-Welker shuffling element stated in the docstring:

```
sage: def test_rsw(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     for k in range(1, n):
....:         a = ZSn.semi_rsw_element(k)
....:         b = ZSn.binary_unshuffle_sum(k)
....:         c = ZSn.left_action_product(a, ZSn.antipode(b))
....:         d = ZSn.left_action_product(b, ZSn.antipode(a))
....:         e = ZSn.rsw_shuffling_element(k)
....:         if c != e or d != e:
....:             return False
....:     return True
sage: test_rsw(3)
True
sage: test_rsw(4)  # long time
True
sage: test_rsw(5)  # long time
True
```

```
>>> from sage.all import *
>>> def test_rsw(n):
...     ZSn = SymmetricGroupAlgebra(ZZ, n)
...     for k in range(Integer(1), n):
...         a = ZSn.semi_rsw_element(k)
...         b = ZSn.binary_unshuffle_sum(k)
...         c = ZSn.left_action_product(a, ZSn.antipode(b))
...         d = ZSn.left_action_product(b, ZSn.antipode(a))
...         e = ZSn.rsw_shuffling_element(k)
...         if c != e or d != e:
...             return False
...     return True
>>> test_rsw(Integer(3))
True
>>> test_rsw(Integer(4))  # long time
True
>>> test_rsw(Integer(5))  # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```
sage: def test_rsw_ncsf(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     NSym = NonCommutativeSymmetricFunctions(ZZ)
....:     S = NSym.S()
....:     for k in range(1, n):
....:         a = S(Composition([k, n-k])).to_symmetric_group_algebra()
....:         if a != ZSn.binary_unshuffle_sum(k):
....:             return False
....:     return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
True
sage: test_rsw_ncsf(5)  # long time
True
```

```
>>> from sage.all import *
>>> def test_rsw_ncsf(n):
...     ZSn = SymmetricGroupAlgebra(ZZ, n)
...     NSym = NonCommutativeSymmetricFunctions(ZZ)
...     S = NSym.S()
...     for k in range(Integer(1), n):
...         a = S(Composition([k, n-k])).to_symmetric_group_algebra()
...         if a != ZSn.binary_unshuffle_sum(k):
...             return False
...     return True
>>> test_rsw_ncsf(Integer(3))
True
>>> test_rsw_ncsf(Integer(4))
True
>>> test_rsw_ncsf(Integer(5))  # long time
True
```

canonical_embedding(*other*)

Return the canonical coercion of `self` into a symmetric group algebra `other`.

INPUT:

- `other` – a symmetric group algebra with order p satisfying $p \geq n$, where n is the order of `self`, over a ground ring into which the ground ring of `self` coerces.

EXAMPLES:

```
sage: QS2 = SymmetricGroupAlgebra(QQ, 2)
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: phi = QS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: x = QS2([2,1]) + 2 * QS2([1,2])
sage: phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]

sage: loads(dumps(phi))
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

sage: ZS2 = SymmetricGroupAlgebra(ZZ, 2)
sage: phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 4 over Rational Field

sage: phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 2 over Rational Field

sage: QS4.canonical_embedding(QS2)
Traceback (most recent call last):
...
ValueError: There is no canonical embedding from Symmetric group
 algebra of order 2 over Rational Field to Symmetric group
 algebra of order 4 over Rational Field

sage: QS4g = SymmetricGroup(4).algebra(QQ)
sage: QS4.canonical_embedding(QS4g)(QS4([1,3,2,4]))
(2,3)
sage: QS4g.canonical_embedding(QS4)(QS4g((2,3)))
[1, 3, 2, 4]
sage: ZS2.canonical_embedding(QS4g)(ZS2([2,1]))
(1,2)
sage: ZS2g = SymmetricGroup(2).algebra(ZZ)
sage: ZS2g.canonical_embedding(QS4)(ZS2g((1,2)))
[2, 1, 3, 4]
```

```
>>> from sage.all import *
>>> QS2 = SymmetricGroupAlgebra(QQ, Integer(2))
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> phi = QS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

>>> x = QS2([Integer(2),Integer(1)]) + Integer(2) * QS2([Integer(1),
↪Integer(2)])
>>> phi(x)
2*[1, 2, 3, 4] + [2, 1, 3, 4]

>>> loads(dumps(phi))
Generic morphism:
  From: Symmetric group algebra of order 2 over Rational Field
  To:   Symmetric group algebra of order 4 over Rational Field

>>> ZS2 = SymmetricGroupAlgebra(ZZ, Integer(2))
>>> phi = ZS2.canonical_embedding(QS4); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 4 over Rational Field

>>> phi = ZS2.canonical_embedding(QS2); phi
Generic morphism:
  From: Symmetric group algebra of order 2 over Integer Ring
  To:   Symmetric group algebra of order 2 over Rational Field

>>> QS4.canonical_embedding(QS2)
Traceback (most recent call last):
...
ValueError: There is no canonical embedding from Symmetric group
 algebra of order 2 over Rational Field to Symmetric group
 algebra of order 4 over Rational Field

>>> QS4g = SymmetricGroup(Integer(4)).algebra(QQ)
>>> QS4.canonical_embedding(QS4g)(QS4([Integer(1),Integer(3),Integer(2),
↪Integer(4)]))
(2,3)
>>> QS4g.canonical_embedding(QS4)(QS4g((Integer(2),Integer(3))))
[1, 3, 2, 4]
>>> ZS2.canonical_embedding(QS4g)(ZS2([Integer(2),Integer(1)]))
(1,2)
>>> ZS2g = SymmetricGroup(Integer(2)).algebra(ZZ)
>>> ZS2g.canonical_embedding(QS4)(ZS2g((Integer(1),Integer(2))))
[2, 1, 3, 4]
```

cell_module(*la*, ***kwds*)

Return the cell module indexed by `la`.

EXAMPLES:

```
sage: S = SymmetricGroupAlgebra(QQ, 3)
sage: M = S.cell_module(Partition([2,1])); M
Cell module indexed by [2, 1] of Cellular basis of
 Symmetric group algebra of order 3 over Rational Field
```

```
>>> from sage.all import *
>>> S = SymmetricGroupAlgebra(QQ, Integer(3))
>>> M = S.cell_module(Partition([Integer(2),Integer(1)])); M
Cell module indexed by [2, 1] of Cellular basis of
 Symmetric group algebra of order 3 over Rational Field
```

We check that the input `la` is standardized:

```
sage: N = S.cell_module([2,1])
sage: M is N
True
```

```
>>> from sage.all import *
>>> N = S.cell_module([Integer(2),Integer(1)])
>>> M is N
True
```

cell_module_indices(*la*)

Return the indices of the cell module of `self` indexed by `la` .

This is the finite set $M(\lambda)$.

EXAMPLES:

```
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_module_indices([3,1])
Standard tableaux of shape [3, 1]
```

```
>>> from sage.all import *
>>> S = SymmetricGroupAlgebra(QQ, Integer(4))
>>> S.cell_module_indices([Integer(3),Integer(1)])
Standard tableaux of shape [3, 1]
```

cell_poset()

Return the cell poset of `self`.

EXAMPLES:

```
sage: S = SymmetricGroupAlgebra(QQ, 4)
sage: S.cell_poset()
Finite poset containing 5 elements
```

```
>>> from sage.all import *
>>> S = SymmetricGroupAlgebra(QQ, Integer(4))
>>> S.cell_poset()
Finite poset containing 5 elements
```

central_orthogonal_idempotent(*la*, *block=True*)

Return the central idempotent for the symmetric group of order n corresponding to the indecomposable block to which the partition `la` is associated.

If `self.base_ring()` contains $\mathbf{Q}$, this corresponds to the classical central idempotent corresponding to the irreducible representation indexed by `la`.

Alternatively, if `self.base_ring()` has characteristic $p > 0$, then Theorem 2.8 in [Mur1983] provides that `la` is associated to an idempotent f_μ, where μ is the p-core of `la`. This f_μ is a sum of classical idempotents,

$$f_\mu = \sum_{c(\lambda)=\mu} e_\lambda,$$

where the sum ranges over the partitions λ of n with p-core equal to μ.

INPUT:

- `la` – a partition of `self.n` or a `self.base_ring().characteristic()`-core of such a partition
- `block` – boolean (default: `True`); when `False`, this returns the classical idempotent associated to `la` (defined over $\mathbf{Q}$)

OUTPUT:

If `block=False` and the corresponding coefficients are not defined over `self.base_ring()`, then return `None`. Otherwise return an element of `self`.

EXAMPLES:

Asking for block idempotents in any characteristic, by passing a partition of `self.n`:

```
sage: S0 = SymmetricGroup(4).algebra(QQ)
sage: S2 = SymmetricGroup(4).algebra(GF(2))
sage: S3 = SymmetricGroup(4).algebra(GF(3))
sage: S0.central_orthogonal_idempotent([2,1,1])
3/8*() - 1/8*(3,4) - 1/8*(2,3) - 1/8*(2,4) - 1/8*(1,2)
 - 1/8*(1,2)(3,4) + 1/8*(1,2,3,4) + 1/8*(1,2,4,3)
 + 1/8*(1,3,4,2) - 1/8*(1,3) - 1/8*(1,3)(2,4)
 + 1/8*(1,3,2,4) + 1/8*(1,4,3,2) - 1/8*(1,4)
 + 1/8*(1,4,2,3) - 1/8*(1,4)(2,3)
sage: S2.central_orthogonal_idempotent([2,1,1])
()
sage: idem = S3.central_orthogonal_idempotent([4]); idem
 () + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: idem == S3.central_orthogonal_idempotent([1,1,1,1])
True
sage: S3.central_orthogonal_idempotent([2,2])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

```
>>> from sage.all import *
>>> S0 = SymmetricGroup(Integer(4)).algebra(QQ)
>>> S2 = SymmetricGroup(Integer(4)).algebra(GF(Integer(2)))
>>> S3 = SymmetricGroup(Integer(4)).algebra(GF(Integer(3)))
>>> S0.central_orthogonal_idempotent([Integer(2),Integer(1),Integer(1)])
3/8*() - 1/8*(3,4) - 1/8*(2,3) - 1/8*(2,4) - 1/8*(1,2)
 - 1/8*(1,2)(3,4) + 1/8*(1,2,3,4) + 1/8*(1,2,4,3)
 + 1/8*(1,3,4,2) - 1/8*(1,3) - 1/8*(1,3)(2,4)
 + 1/8*(1,3,2,4) + 1/8*(1,4,3,2) - 1/8*(1,4)
```

(continues on next page)

(continued from previous page)

```
 + 1/8*(1,4,2,3) - 1/8*(1,4)(2,3)
>>> S2.central_orthogonal_idempotent([Integer(2),Integer(1),Integer(1)])
()
>>> idem = S3.central_orthogonal_idempotent([Integer(4)]); idem
 () + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
>>> idem == S3.central_orthogonal_idempotent([Integer(1),Integer(1),
↪Integer(1),Integer(1)])
True
>>> S3.central_orthogonal_idempotent([Integer(2),Integer(2)])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for block idempotents in any characteristic, by passing p-cores:

```
sage: S0.central_orthogonal_idempotent([1,1])
Traceback (most recent call last):
...
ValueError: [1, 1] is not a partition of integer 4
sage: S2.central_orthogonal_idempotent([])
()
sage: S2.central_orthogonal_idempotent([1])
Traceback (most recent call last):
...
ValueError: the 2-core of [1] is not a 2-core of a partition of 4
sage: S3.central_orthogonal_idempotent([1])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
sage: S3.central_orthogonal_idempotent([7])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

```
>>> from sage.all import *
>>> S0.central_orthogonal_idempotent([Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: [1, 1] is not a partition of integer 4
>>> S2.central_orthogonal_idempotent([])
()
>>> S2.central_orthogonal_idempotent([Integer(1)])
Traceback (most recent call last):
...
ValueError: the 2-core of [1] is not a 2-core of a partition of 4
>>> S3.central_orthogonal_idempotent([Integer(1)])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
>>> S3.central_orthogonal_idempotent([Integer(7)])
() + (1,2)(3,4) + (1,3)(2,4) + (1,4)(2,3)
```

Asking for classical idempotents:

```
sage: S3.central_orthogonal_idempotent([2,2], block=False) is None
True
sage: S3.central_orthogonal_idempotent([2,1,1], block=False)
(3,4) + (2,3) + (2,4) + (1,2) + (1,2)(3,4) + 2*(1,2,3,4)
 + 2*(1,2,4,3) + 2*(1,3,4,2) + (1,3) + (1,3)(2,4)
 + 2*(1,3,2,4) + 2*(1,4,3,2) + (1,4) + 2*(1,4,2,3)
```

(continues on next page)

(continued from previous page)

```
 + (1,4)(2,3)
```

```
>>> from sage.all import *
>>> S3.central_orthogonal_idempotent([Integer(2),Integer(2)], block=False) is␣
↪None
True
>>> S3.central_orthogonal_idempotent([Integer(2),Integer(1),Integer(1)],␣
↪block=False)
(3,4) + (2,3) + (2,4) + (1,2) + (1,2)(3,4) + 2*(1,2,3,4)
 + 2*(1,2,4,3) + 2*(1,3,4,2) + (1,3) + (1,3)(2,4)
 + 2*(1,3,2,4) + 2*(1,4,3,2) + (1,4) + 2*(1,4,2,3)
 + (1,4)(2,3)
```

See also:

- *sage.combinat.partition.Partition.core()*

central_orthogonal_idempotents()

Return a maximal list of central orthogonal idempotents for `self`.

This method does not require that `self` be semisimple, relying on Nakayama's Conjecture whenever `self.base_ring()` has positive characteristic.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: a = QS3.central_orthogonal_idempotents()
sage: a[0]  # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1]
 + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
sage: a[1]  # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ,Integer(3))
>>> a = QS3.central_orthogonal_idempotents()
>>> a[Integer(0)]  # [3]
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1]
 + 1/6*[3, 1, 2] + 1/6*[3, 2, 1]
>>> a[Integer(1)]  # [2, 1]
2/3*[1, 2, 3] - 1/3*[2, 3, 1] - 1/3*[3, 1, 2]
```

See also:

- *central_orthogonal_idempotent()*

dft(*form=None*, *mult='l2r'*)

Return the discrete Fourier transform for `self`.

See [Mur1983] for the construction of central primitive orthogonal idempotents. For each idempotent e_i we have a homomorphic projection $v \mapsto ve_i$. Choose a basis for each submodule spanned by $\{\sigma e_i | \sigma \in S_n\}$. The change-of-basis from the standard basis $\{\sigma\}_\sigma$ is returned.

INPUT:

- `mult` – string (default: $l2r$); if set to $r2l$, this causes the method to use the antipodes (`antipode()`) of the seminormal basis instead of the seminormal basis.
- `form` – string (default: `"modular"` if $p|n!$ else `"seminormal"`); one of the following:
  - `"seminormal"` – use the seminormal basis
  - `"modular"` – use the modular DFT, which uses the Peirce decomposition of the group algebra into blocks with central orthogonal idempotents
  - `"unitary"` – use the unitary DFT, which computes the extended Cholesky decomposition of an S_n-invariant symmetric bilinear form as a change-of-basis matrix (for positive characteristics, it must be a finite field of square order)

EXAMPLES:

The default is the seminormal DFT when the characteristic does not divide the group order:

```
sage: QQ_S3 = SymmetricGroupAlgebra(QQ, 3)
sage: QQ_S3.dft()
[   1    1    1    1    1    1]
[   1  1/2   -1 -1/2 -1/2  1/2]
[   0  3/4    0  3/4 -3/4 -3/4]
[   0    1    0   -1    1   -1]
[   1 -1/2    1 -1/2 -1/2 -1/2]
[   1   -1   -1    1    1   -1]
```

```
>>> from sage.all import *
>>> QQ_S3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QQ_S3.dft()
[   1    1    1    1    1    1]
[   1  1/2   -1 -1/2 -1/2  1/2]
[   0  3/4    0  3/4 -3/4 -3/4]
[   0    1    0   -1    1   -1]
[   1 -1/2    1 -1/2 -1/2 -1/2]
[   1   -1   -1    1    1   -1]
```

The unitary form works in characteristic zero:

```
sage: U = QQ_S3.dft(form='unitary'); U
[-1/6*sqrt3*sqrt2 -1/6*sqrt3*sqrt2 -1/6*sqrt3*sqrt2 -1/6*sqrt3*sqrt2 -1/
↪6*sqrt3*sqrt2 -1/6*sqrt3*sqrt2]
[       1/3*sqrt3        1/6*sqrt3       -1/3*sqrt3       -1/6*sqrt3       -1/
↪6*sqrt3        1/6*sqrt3]
[               0              1/2                0              1/2              ␣
↪    -1/2             -1/2]
[               0              1/2                0             -1/2              ␣
↪     1/2             -1/2]

↪   -1/2             -1/2]
[               0              1/2                0             -1/2          ␣
↪    1/2             -1/2]
[       1/3*sqrt3       -1/6*sqrt3        1/3*sqrt3       -1/6*sqrt3       -1/
↪6*sqrt3       -1/6*sqrt3]
[-1/6*sqrt3*sqrt2  1/6*sqrt3*sqrt2  1/6*sqrt3*sqrt2 -1/6*sqrt3*sqrt2 -1/
↪6*sqrt3*sqrt2  1/6*sqrt3*sqrt2]
>>> U*U.H == Integer(1)
True
```

Over finite fields of square order with characteristic $p > n$, we can perform the unitary DFT:

```
sage: GF25_S3 = SymmetricGroupAlgebra(GF(5**2), 3)
sage: U = GF25_S3.dft(form='unitary'); U
[       1        1        1        1        1        1]
[2*z2 + 4   z2 + 2 3*z2 + 1 4*z2 + 3 4*z2 + 3   z2 + 2]
[       0        2        0        2        3        3]
[       0   z2 + 1        0 4*z2 + 4   z2 + 1 4*z2 + 4]
[2*z2 + 4 4*z2 + 3 2*z2 + 4 4*z2 + 3 4*z2 + 3 4*z2 + 3]
[       1        4        4        1        1        4]
sage: U*U.H == 1
True
```

```
>>> from sage.all import *
>>> GF25_S3 = SymmetricGroupAlgebra(GF(Integer(5)**Integer(2)), Integer(3))
>>> U = GF25_S3.dft(form='unitary'); U
[       1        1        1        1        1        1]
[2*z2 + 4   z2 + 2 3*z2 + 1 4*z2 + 3 4*z2 + 3   z2 + 2]
[       0        2        0        2        3        3]
[       0   z2 + 1        0 4*z2 + 4   z2 + 1 4*z2 + 4]
[2*z2 + 4 4*z2 + 3 2*z2 + 4 4*z2 + 3 4*z2 + 3 4*z2 + 3]
[       1        4        4        1        1        4]
>>> U*U.H == Integer(1)
True
```

Over fields of characteristic $p > 0$ such that $p|n!$, we use the modular Fourier transform (Issue #37751):

```
sage: GF2_S3 = SymmetricGroupAlgebra(GF(2), 3)
sage: GF2_S3.dft()
[1 0 0 0 1 0]
[0 1 0 0 0 1]
```

(continues on next page)

(continued from previous page)

```
[0 0 1 0 0 1]
[0 0 0 1 1 0]
[1 0 0 1 1 0]
[0 1 1 0 0 1]
```

```
>>> from sage.all import *
>>> GF2_S3 = SymmetricGroupAlgebra(GF(Integer(2)), Integer(3))
>>> GF2_S3.dft()
[1 0 0 0 1 0]
[0 1 0 0 0 1]
[0 0 1 0 0 1]
[0 0 0 1 1 0]
[1 0 0 1 1 0]
[0 1 1 0 0 1]
```

epsilon_ik(*itab*, *ktab*, *star=0*, *mult='l2r'*)

Return the seminormal basis element of `self` corresponding to the pair of tableaux `itab` and `ktab` (or restrictions of these tableaux, if the optional variable `star` is set).

INPUT:

- `itab`, `ktab` – two standard tableaux of size n
- `star` – integer (default: 0)
- `mult` – string (default: $l2r$); if set to $r2l$, this causes the method to return the antipode (`antipode()`) of $\epsilon(I, K)$ instead of $\epsilon(I, K)$ itself.

OUTPUT:

The element $\epsilon(I, K)$, where I and K are the tableaux obtained by removing all entries higher than $n - \mathrm{star}$ from `itab` and `ktab`, respectively. Here, we are using the notations from `seminormal_basis()`.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: a = QS3.epsilon_ik([[1,2,3]], [[1,2,3]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]␣
↪+ 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
sage: a = QS3.epsilon_ik([[1,2],[3]], [[1,2],[3]]); a
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]␣
↪- 1/6*[3, 2, 1]
sage: QS3.dft()*vector(a)
(0, 0, 0, 0, 1, 0)
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> a = QS3.epsilon_ik([[Integer(1),Integer(2),Integer(3)]], [[Integer(1),
↪Integer(2),Integer(3)]]); a
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]␣
↪+ 1/6*[3, 2, 1]
>>> QS3.dft()*vector(a)
(1, 0, 0, 0, 0, 0)
```

(continues on next page)

(continued from previous page)

```
>>> a = QS3.epsilon_ik([[Integer(1),Integer(2)],[Integer(3)]], [[Integer(1),
↪Integer(2)],[Integer(3)]]); a
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]␣
↪- 1/6*[3, 2, 1]
>>> QS3.dft()*vector(a)
(0, 0, 0, 0, 1, 0)
```

Let us take some properties of the seminormal basis listed in the docstring of `seminormal_basis()`, and verify them on the situation of S_3.

First, check the formula

$$\epsilon(T) = \frac{1}{\kappa_{\mathrm{sh}(T)}} \epsilon(\overline{T}) e(T) \epsilon(\overline{T}).$$

In fact:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn1(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
....:     for T in StandardTableaux(n):
....:         TT = T.restrict(n-1)
....:         eTT = QSn1.epsilon_ik(TT, TT)
....:         eT = QSn.epsilon_ik(T, T)
....:         kT = prod(T.shape().hooks())
....:         if kT * eT != eTT * e(T) * eTT:
....:             return False
....:     return True
sage: test_sn1(3)
True
sage: test_sn1(4)    # long time
True
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e
>>> def test_sn1(n):
...     QSn = SymmetricGroupAlgebra(QQ, n)
...     QSn1 = SymmetricGroupAlgebra(QQ, n - Integer(1))
...     for T in StandardTableaux(n):
...         TT = T.restrict(n-Integer(1))
...         eTT = QSn1.epsilon_ik(TT, TT)
...         eT = QSn.epsilon_ik(T, T)
...         kT = prod(T.shape().hooks())
...         if kT * eT != eTT * e(T) * eTT:
...             return False
...     return True
>>> test_sn1(Integer(3))
True
>>> test_sn1(Integer(4))    # long time
True
```

Next, we check the identity

$$\epsilon(T,S) = \frac{1}{\kappa_{\mathrm{sh}(T)}}\epsilon(\overline{S})\pi_{T,S}e(T)\epsilon(\overline{T})$$

which we used to define $\epsilon(T,S)$. In fact:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: def test_sn2(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     mul = QSn.left_action_product
....:     QSn1 = SymmetricGroupAlgebra(QQ, n - 1)
....:     for lam in Partitions(n):
....:         k = prod(lam.hooks())
....:         for T in StandardTableaux(lam):
....:             for S in StandardTableaux(lam):
....:                 TT = T.restrict(n-1)
....:                 SS = S.restrict(n-1)
....:                 eTT = QSn1.epsilon_ik(TT, TT)
....:                 eSS = QSn1.epsilon_ik(SS, SS)
....:                 eTS = QSn.epsilon_ik(T, S)
....:                 piTS = [0] * n
....:                 for (i, j) in T.cells():
....:                     piTS[T[i][j] - 1] = S[i][j]
....:                 piTS = QSn(Permutation(piTS))
....:                 if k * eTS != mul(mul(eSS, piTS), mul(e(T), eTT)):
....:                     return False
....:     return True
sage: test_sn2(3)
True
sage: test_sn2(4)    # long time
True
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e
>>> def test_sn2(n):
...     QSn = SymmetricGroupAlgebra(QQ, n)
...     mul = QSn.left_action_product
...     QSn1 = SymmetricGroupAlgebra(QQ, n - Integer(1))
...     for lam in Partitions(n):
...         k = prod(lam.hooks())
...         for T in StandardTableaux(lam):
...             for S in StandardTableaux(lam):
...                 TT = T.restrict(n-Integer(1))
...                 SS = S.restrict(n-Integer(1))
...                 eTT = QSn1.epsilon_ik(TT, TT)
...                 eSS = QSn1.epsilon_ik(SS, SS)
...                 eTS = QSn.epsilon_ik(T, S)
...                 piTS = [Integer(0)] * n
...                 for (i, j) in T.cells():
...                     piTS[T[i][j] - Integer(1)] = S[i][j]
...                 piTS = QSn(Permutation(piTS))
...                 if k * eTS != mul(mul(eSS, piTS), mul(e(T), eTT)):
...                     return False
```

(continues on next page)

(continued from previous page)

```
...     return True
>>> test_sn2(Integer(3))
True
>>> test_sn2(Integer(4))    # long time
True
```

Let us finally check the identity

$$\epsilon(T,S)\epsilon(U,V) = \delta_{T,V}\epsilon(U,S)$$

In fact:

```
sage: def test_sn3(lam):
....:     n = lam.size()
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     mul = QSn.left_action_product
....:     for T in StandardTableaux(lam):
....:         for S in StandardTableaux(lam):
....:             for U in StandardTableaux(lam):
....:                 for V in StandardTableaux(lam):
....:                     lhs = mul(QSn.epsilon_ik(T, S), QSn.epsilon_ik(U,␣
↪V))
....:                     if T == V:
....:                         rhs = QSn.epsilon_ik(U, S)
....:                     else:
....:                         rhs = QSn.zero()
....:                     if rhs != lhs:
....:                         return False
....:     return True
sage: all( test_sn3(lam) for lam in Partitions(3) )
True
sage: all( test_sn3(lam) for lam in Partitions(4) )    # long time
True
```

```
>>> from sage.all import *
>>> def test_sn3(lam):
...     n = lam.size()
...     QSn = SymmetricGroupAlgebra(QQ, n)
...     mul = QSn.left_action_product
...     for T in StandardTableaux(lam):
...         for S in StandardTableaux(lam):
...             for U in StandardTableaux(lam):
...                 for V in StandardTableaux(lam):
...                     lhs = mul(QSn.epsilon_ik(T, S), QSn.epsilon_ik(U, V))
...                     if T == V:
...                         rhs = QSn.epsilon_ik(U, S)
...                     else:
...                         rhs = QSn.zero()
...                     if rhs != lhs:
...                         return False
...     return True
>>> all( test_sn3(lam) for lam in Partitions(Integer(3)) )
```

(continues on next page)

(continued from previous page)

```
True
>>> all( test_sn3(lam) for lam in Partitions(Integer(4)) )    # long time
True
```

garsia_procesi_module(*la*)

Return the *Garsia-Procesi module* of self indexed by la.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 6)
sage: SGA.garsia_procesi_module(Partition([2,2,1,1]))
Garsia-Procesi module of shape [2, 2, 1, 1] over Finite Field of size 2
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(6))
>>> SGA.garsia_procesi_module(Partition([Integer(2),Integer(2),Integer(1),
↪Integer(1)]))
Garsia-Procesi module of shape [2, 2, 1, 1] over Finite Field of size 2
```

jucys_murphy(*k*)

Return the Jucys-Murphy element J_k (also known as a Young-Jucys-Murphy element) for the symmetric group algebra self.

The Jucys-Murphy element J_k in the symmetric group algebra RS_n is defined for every $k \in \{1, 2, \ldots, n\}$ by

$$J_k = (1, k) + (2, k) + \cdots + (k - 1, k) \in RS_n,$$

where the addends are transpositions in S_n (regarded as elements of RS_n). We note that there is not a dependence on n, so it is often suppressed in the notation.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.jucys_murphy(1)
0
sage: QS3.jucys_murphy(2)
[2, 1, 3]
sage: QS3.jucys_murphy(3)
[1, 3, 2] + [3, 2, 1]

sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: j3 = QS4.jucys_murphy(3); j3
[1, 3, 2, 4] + [3, 2, 1, 4]
sage: j4 = QS4.jucys_murphy(4); j4
[1, 2, 4, 3] + [1, 4, 3, 2] + [4, 2, 3, 1]
sage: j3*j4 == j4*j3
True

sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.jucys_murphy(4)
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS3.jucys_murphy(Integer(1))
0
>>> QS3.jucys_murphy(Integer(2))
[2, 1, 3]
>>> QS3.jucys_murphy(Integer(3))
[1, 3, 2] + [3, 2, 1]

>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> j3 = QS4.jucys_murphy(Integer(3)); j3
[1, 3, 2, 4] + [3, 2, 1, 4]
>>> j4 = QS4.jucys_murphy(Integer(4)); j4
[1, 2, 4, 3] + [1, 4, 3, 2] + [4, 2, 3, 1]
>>> j3*j4 == j4*j3
True

>>> QS5 = SymmetricGroupAlgebra(QQ, Integer(5))
>>> QS5.jucys_murphy(Integer(4))
[1, 2, 4, 3, 5] + [1, 4, 3, 2, 5] + [4, 2, 3, 1, 5]
```

kazhdan_lusztig_basis_element(*w*)

Return the Kazhdan-Lusztig C'_w basis element at $q = 1$.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: for w in SGA.group():
....:     print(w, SGA.kazhdan_lusztig_basis_element(w))
[1, 2, 3] [1, 2, 3]
[1, 3, 2] [1, 2, 3] + [1, 3, 2]
[2, 1, 3] [1, 2, 3] + [2, 1, 3]
[2, 3, 1] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1]
[3, 1, 2] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [3, 1, 2]
[3, 2, 1] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 
→1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(3))
>>> for w in SGA.group():
...     print(w, SGA.kazhdan_lusztig_basis_element(w))
[1, 2, 3] [1, 2, 3]
[1, 3, 2] [1, 2, 3] + [1, 3, 2]
[2, 1, 3] [1, 2, 3] + [2, 1, 3]
[2, 3, 1] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1]
[3, 1, 2] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [3, 1, 2]
[3, 2, 1] [1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 
→1]
```

kazhdan_lusztig_cellular_basis()

Return the Kazhdan-Lusztig basis (at $q = 1$) of `self` as a cellular basis.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: KL = SGA.kazhdan_lusztig_cellular_basis()
sage: KL(SGA.an_element())
C([2, 1], [[1, 2], [3]], [[1, 2], [3]])
 + C([2, 1], [[1, 3], [2]], [[1, 2], [3]])
 + 2*C([2, 1], [[1, 3], [2]], [[1, 3], [2]])
 - 3*C([3], [[1, 2, 3]], [[1, 2, 3]])
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(3))
>>> KL = SGA.kazhdan_lusztig_cellular_basis()
>>> KL(SGA.an_element())
C([2, 1], [[1, 2], [3]], [[1, 2], [3]])
 + C([2, 1], [[1, 3], [2]], [[1, 2], [3]])
 + 2*C([2, 1], [[1, 3], [2]], [[1, 3], [2]])
 - 3*C([3], [[1, 2, 3]], [[1, 2, 3]])
```

ladder_idempotent(*la*)

Return the ladder idempotent of `self`.

Let F be a field of characteristic p. The *ladder idempotent* of shape λ is the idempotent of $F[S_n]$ defined as follows. Let T be the *ladder tableau* of shape λ. Let $[T]$ be the set of standard tableaux whose residue sequence is the same as for T. Let α be the sizes of the ladders of λ. Then the ladder idempotent is constructed as

$$\widetilde{e}_\lambda := \frac{1}{\alpha!}\left(\sum_{\sigma\in S_\alpha}\sigma\right)\left(\overline{\sum_{U\in[T]} E_U}\right),$$

where E_{UU} is the `seminormal_basis()` element over $\mathbf{Q}$ and we project the sum to F, S_α is the Young subgroup corresponding to α, and $\alpha! = \alpha_1!\cdots\alpha_k!$.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: for la in Partitions(SGA.n):
....:     idem = SGA.ladder_idempotent(la)
....:     print(la)
....:     print(idem)
....:     assert idem^2 == idem
[4]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[3, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + [3, 4, 1, 2] + [3, 4, 2, 1] + [4, 3, 1, 2] + [4, 3, 2, 1]
[2, 2]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[2, 1, 1]
2*[1, 2, 3, 4] + [1, 2, 4, 3] + 2*[1, 3, 2, 4] + [1, 3, 4, 2]
 + [1, 4, 2, 3] + 2*[1, 4, 3, 2] + 2*[2, 1, 3, 4] + [2, 1, 4, 3]
 + 2*[2, 3, 1, 4] + [2, 3, 4, 1] + [2, 4, 1, 3] + 2*[2, 4, 3, 1]
 + 2*[3, 1, 2, 4] + [3, 1, 4, 2] + 2*[3, 2, 1, 4] + [3, 2, 4, 1]
```

(continues on next page)

(continued from previous page)

```
 + [4, 1, 2, 3] + 2*[4, 1, 3, 2] + [4, 2, 1, 3] + 2*[4, 2, 3, 1]
[1, 1, 1, 1]
2*[1, 2, 3, 4] + [1, 2, 4, 3] + [2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + [3, 4, 2, 1] + [4, 3, 1, 2] + 2*[4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> for la in Partitions(SGA.n):
...     idem = SGA.ladder_idempotent(la)
...     print(la)
...     print(idem)
...     assert idem**Integer(2) == idem
[4]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[3, 1]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + [3, 4, 1, 2] + [3, 4, 2, 1] + [4, 3, 1, 2] + [4, 3, 2, 1]
[2, 2]
2*[1, 2, 3, 4] + 2*[1, 2, 4, 3] + 2*[2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + 2*[3, 4, 2, 1] + 2*[4, 3, 1, 2] + 2*[4, 3, 2, 1]
[2, 1, 1]
2*[1, 2, 3, 4] + [1, 2, 4, 3] + 2*[1, 3, 2, 4] + [1, 3, 4, 2]
 + [1, 4, 2, 3] + 2*[1, 4, 3, 2] + 2*[2, 1, 3, 4] + [2, 1, 4, 3]
 + 2*[2, 3, 1, 4] + [2, 3, 4, 1] + [2, 4, 1, 3] + 2*[2, 4, 3, 1]
 + 2*[3, 1, 2, 4] + [3, 1, 4, 2] + 2*[3, 2, 1, 4] + [3, 2, 4, 1]
 + [4, 1, 2, 3] + 2*[4, 1, 3, 2] + [4, 2, 1, 3] + 2*[4, 2, 3, 1]
[1, 1, 1, 1]
2*[1, 2, 3, 4] + [1, 2, 4, 3] + [2, 1, 3, 4] + 2*[2, 1, 4, 3]
 + 2*[3, 4, 1, 2] + [3, 4, 2, 1] + [4, 3, 1, 2] + 2*[4, 3, 2, 1]
```

When $p = 0$, these idempotents will generate all of the simple modules (which are the *Specht modules* and also projective modules):

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(SGA.n):
....:     idem = SGA.ladder_idempotent(la)
....:     assert idem^2 == idem
....:     print(la, SGA.principal_ideal(idem).dimension())
[5] 1
[4, 1] 4
[3, 2] 5
[3, 1, 1] 6
[2, 2, 1] 5
[2, 1, 1, 1] 4
[1, 1, 1, 1, 1] 1
sage: [StandardTableaux(la).cardinality() for la in Partitions(SGA.n)]
[1, 4, 5, 6, 5, 4, 1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> for la in Partitions(SGA.n):
```

(continues on next page)

(continued from previous page)

```
...     idem = SGA.ladder_idempotent(la)
...     assert idem**Integer(2) == idem
...     print(la, SGA.principal_ideal(idem).dimension())
[5] 1
[4, 1] 4
[3, 2] 5
[3, 1, 1] 6
[2, 2, 1] 5
[2, 1, 1, 1] 4
[1, 1, 1, 1, 1] 1
>>> [StandardTableaux(la).cardinality() for la in Partitions(SGA.n)]
[1, 4, 5, 6, 5, 4, 1]
```

left_action_product (*left*, *right*)

Return the product of two elements `left` and `right` of `self`, where multiplication is defined in such a way that for two permutations p and q, the product pq is the permutation obtained by first applying q and then applying p. This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the left.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.left_action_product(QS3(p1), QS3(p2))
[3, 2, 1]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
sage: QS3.left_action_product(0, x)
0
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> p1 = Permutation([Integer(2), Integer(1), Integer(3)])
>>> p2 = Permutation([Integer(3), Integer(1), Integer(2)])
>>> QS3.left_action_product(QS3(p1), QS3(p2))
[3, 2, 1]
>>> x = QS3([Integer(1), Integer(2), Integer(3)]) -␣
↪Integer(2)*QS3([Integer(1), Integer(3), Integer(2)])
>>> y = Integer(1)/Integer(2) * QS3([Integer(3), Integer(1), Integer(2)]) +␣
↪Integer(3)*QS3([Integer(1), Integer(2), Integer(3)])
>>> QS3.left_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] - [2, 1, 3] + 1/2*[3, 1, 2]
>>> QS3.left_action_product(Integer(0), x)
0
```

The method coerces its input into the algebra `self`:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.left_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.left_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]
```

```
>>> from sage.all import *
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> QS4.left_action_product(QS3([Integer(1), Integer(2), Integer(3)]),␣
→QS3([Integer(2), Integer(1), Integer(3)]))
[2, 1, 3, 4]
>>> QS4.left_action_product(Integer(1), Permutation([Integer(4), Integer(1),␣
→Integer(2), Integer(3)]))
[4, 1, 2, 3]
```

Warning

Note that coercion presently works from permutations of `n` into the `n`-th symmetric group algebra, and also from all smaller symmetric group algebras into the `n`-th symmetric group algebra, but not from permutations of integers smaller than `n` into the `n`-th symmetric group algebra.

monomial_from_smaller_permutation(*permutation*)

Convert `permutation` into a permutation, possibly extending it to the appropriate size, and return the corresponding basis element of `self`.

EXAMPLES:

```
sage: QS5 = SymmetricGroupAlgebra(QQ, 5)
sage: QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
sage: QS5.monomial_from_smaller_permutation(Permutation([3,1,2]))
[3, 1, 2, 4, 5]
sage: QS5.monomial_from_smaller_permutation([5,3,4,1,2])
[5, 3, 4, 1, 2]
sage: QS5.monomial_from_smaller_permutation(SymmetricGroup(2)((1,2)))
[2, 1, 3, 4, 5]

sage: QS5g = SymmetricGroup(5).algebra(QQ)
sage: QS5g.monomial_from_smaller_permutation([2,1])
(1,2)
```

```
>>> from sage.all import *
>>> QS5 = SymmetricGroupAlgebra(QQ, Integer(5))
>>> QS5.monomial_from_smaller_permutation([])
[1, 2, 3, 4, 5]
>>> QS5.monomial_from_smaller_permutation(Permutation([Integer(3),Integer(1),
→Integer(2)]))
[3, 1, 2, 4, 5]
>>> QS5.monomial_from_smaller_permutation([Integer(5),Integer(3),Integer(4),
→Integer(1),Integer(2)])
[5, 3, 4, 1, 2]
```

(continues on next page)

(continued from previous page)

```
>>> QS5.monomial_from_smaller_
↪permutation(SymmetricGroup(Integer(2))((Integer(1),Integer(2))))
[2, 1, 3, 4, 5]

>>> QS5g = SymmetricGroup(Integer(5)).algebra(QQ)
>>> QS5g.monomial_from_smaller_permutation([Integer(2),Integer(1)])
(1,2)
```

murphy_basis()

Return the *Murphy basis* of self.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: M = SGA.murphy_basis()
sage: M(SGA.an_element())
-C([1, 1, 1], [[1], [2], [3]], [[1], [2], [3]])
 + C([2, 1], [[1, 2], [3]], [[1, 2], [3]])
 + C([2, 1], [[1, 2], [3]], [[1, 3], [2]])
 + 2*C([2, 1], [[1, 3], [2]], [[1, 2], [3]])
 + 4*C([2, 1], [[1, 3], [2]], [[1, 3], [2]])
 - 3*C([3], [[1, 2, 3]], [[1, 2, 3]])
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(3))
>>> M = SGA.murphy_basis()
>>> M(SGA.an_element())
-C([1, 1, 1], [[1], [2], [3]], [[1], [2], [3]])
 + C([2, 1], [[1, 2], [3]], [[1, 2], [3]])
 + C([2, 1], [[1, 2], [3]], [[1, 3], [2]])
 + 2*C([2, 1], [[1, 3], [2]], [[1, 2], [3]])
 + 4*C([2, 1], [[1, 3], [2]], [[1, 3], [2]])
 - 3*C([3], [[1, 2, 3]], [[1, 2, 3]])
```

murphy_basis_element(S, T)

Return the Murphy basis element indexed by S and T.

See also

MurphyBasis

EXAMPLES:

```
sage: import itertools
sage: SGA = SymmetricGroupAlgebra(QQ, 3)
sage: for S, T in itertools.product(StandardTableaux([2,1]), repeat=2):
....:     print(S, T, SGA.murphy_basis_element(S, T))
[[1, 3], [2]] [[1, 3], [2]] [1, 2, 3] + [2, 1, 3]
[[1, 3], [2]] [[1, 2], [3]] [1, 3, 2] + [3, 1, 2]
[[1, 2], [3]] [[1, 3], [2]] [1, 3, 2] + [2, 3, 1]
[[1, 2], [3]] [[1, 2], [3]] [1, 2, 3] + [3, 2, 1]
```

```
>>> from sage.all import *
>>> import itertools
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(3))
>>> for S, T in itertools.product(StandardTableaux([Integer(2),Integer(1)]),␣
↪repeat=Integer(2)):
...     print(S, T, SGA.murphy_basis_element(S, T))
[[1, 3], [2]] [[1, 3], [2]] [1, 2, 3] + [2, 1, 3]
[[1, 3], [2]] [[1, 2], [3]] [1, 3, 2] + [3, 1, 2]
[[1, 2], [3]] [[1, 3], [2]] [1, 3, 2] + [2, 3, 1]
[[1, 2], [3]] [[1, 2], [3]] [1, 2, 3] + [3, 2, 1]
```

retract_direct_product (f, m)

Return the direct-product retract of the element $f \in RS_n$ to RS_m, where $m \leq n$ (and where RS_n is `self`).

If m is a nonnegative integer less or equal to n, then the direct-product retract from S_n to S_m is defined as an R-linear map $S_n \to S_m$ which sends every permutation $p \in S_n$ to

$$\begin{cases} \mathrm{dret}(p) & \text{if } \mathrm{dret}(p) \text{ is defined;} \\ 0 & \text{otherwise} \end{cases}.$$

Here $\mathrm{dret}(p)$ denotes the direct-product retract of the permutation p to S_m, which is defined in *retract_direct_product()*.

EXAMPLES:

```
sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_direct_product(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) +␣
↪7*SGA3([1,3,2]), 2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_direct_product(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0

sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +␣
↪11*SGA5([3,2,1,4,5]), 4)
11*[3, 2, 1, 4]
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +␣
↪11*SGA5([3,2,1,4,5]), 3)
-6*[1, 3, 2] + 11*[3, 2, 1]
sage: SGA5.retract_direct_product(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +␣

retract_plain(), *retract_direct_product()*

retract_plain(f, m)

Return the plain retract of the element $f \in RS_n$ to RS_m, where $m \leq n$ (and where RS_n is `self`).

If m is a nonnegative integer less or equal to n, then the plain retract from S_n to S_m is defined as an R-linear map $S_n \to S_m$ which sends every permutation $p \in S_n$ to

$$\begin{cases} \mathrm{pret}(p) & \text{if } \mathrm{pret}(p) \text{ is defined;} \\ 0 & \text{otherwise} \end{cases}.$$

Here $\mathrm{pret}(p)$ denotes the plain retract of the permutation p to S_m, which is defined in *retract_plain()*.

EXAMPLES:

```
sage: SGA3 = SymmetricGroupAlgebra(QQ, 3)
sage: SGA3.retract_plain(2*SGA3([1,2,3]) - 4*SGA3([2,1,3]) + 7*SGA3([1,3,2]),␣
↪2)
2*[1, 2] - 4*[2, 1]
sage: SGA3.retract_plain(2*SGA3([1,3,2]) - 5*SGA3([2,3,1]), 2)
0

sage: SGA5 = SymmetricGroupAlgebra(QQ, 5)
sage: SGA5.retract_plain(8*SGA5([1,4,2,5,3]) - 6*SGA5([1,3,2,5,4]) +␣
↪11*SGA5([3,2,1,4,5]), 4)
11*[3, 2, 1, 4]

↪Integer(4),Integer(5)]), Integer(0))
8*[]
```

See also

retract_direct_product(), *retract_okounkov_vershik()*

right_action_product(*left*, *right*)

Return the product of two elements `left` and `right` of `self`, where multiplication is defined in such a way that for two permutations p and q, the product pq is the permutation obtained by first applying p and then applying q. This definition of multiplication is tailored to make multiplication of permutations associative with their action on numbers if permutations are to act on numbers from the right.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: p1 = Permutation([2, 1, 3])
sage: p2 = Permutation([3, 1, 2])
sage: QS3.right_action_product(QS3(p1), QS3(p2))
[1, 3, 2]
sage: x = QS3([1, 2, 3]) - 2*QS3([1, 3, 2])
sage: y = 1/2 * QS3([3, 1, 2]) + 3*QS3([1, 2, 3])
sage: QS3.right_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] + 1/2*[3, 1, 2] - [3, 2, 1]
sage: QS3.right_action_product(0, x)
0
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> p1 = Permutation([Integer(2), Integer(1), Integer(3)])
>>> p2 = Permutation([Integer(3), Integer(1), Integer(2)])
>>> QS3.right_action_product(QS3(p1), QS3(p2))
[1, 3, 2]
```

(continues on next page)

(continued from previous page)

```
>>> x = QS3([Integer(1), Integer(2), Integer(3)]) -␣
↪Integer(2)*QS3([Integer(1), Integer(3), Integer(2)])
>>> y = Integer(1)/Integer(2) * QS3([Integer(3), Integer(1), Integer(2)]) +␣
↪Integer(3)*QS3([Integer(1), Integer(2), Integer(3)])
>>> QS3.right_action_product(x, y)
3*[1, 2, 3] - 6*[1, 3, 2] + 1/2*[3, 1, 2] - [3, 2, 1]
>>> QS3.right_action_product(Integer(0), x)
0
```

The method coerces its input into the algebra `self`:

```
sage: QS4 = SymmetricGroupAlgebra(QQ, 4)
sage: QS4.right_action_product(QS3([1, 2, 3]), QS3([2, 1, 3]))
[2, 1, 3, 4]
sage: QS4.right_action_product(1, Permutation([4, 1, 2, 3]))
[4, 1, 2, 3]
```

```
>>> from sage.all import *
>>> QS4 = SymmetricGroupAlgebra(QQ, Integer(4))
>>> QS4.right_action_product(QS3([Integer(1), Integer(2), Integer(3)]),␣
↪QS3([Integer(2), Integer(1), Integer(3)]))
[2, 1, 3, 4]
>>> QS4.right_action_product(Integer(1), Permutation([Integer(4), Integer(1),␣
↪Integer(2), Integer(3)]))
[4, 1, 2, 3]
```

Warning

Note that coercion presently works from permutations of `n` into the `n`-th symmetric group algebra, and also from all smaller symmetric group algebras into the `n`-th symmetric group algebra, but not from permutations of integers smaller than `n` into the `n`-th symmetric group algebra.

rsw_shuffling_element(k)

Return the k-th Reiner-Saliola-Welker shuffling element in the group algebra `self`.

The k-th Reiner-Saliola-Welker shuffling element in the symmetric group algebra RS_n over a ring R is defined as the sum $\sum_{\sigma \in S_n} \mathrm{noninv}_k(\sigma) \cdot \sigma$, where for every permutation σ, the number $\mathrm{noninv}_k(\sigma)$ is the number of all k-noninversions of σ (that is, the number of all k-element subsets of $\{1, 2, \ldots, n\}$ on which σ restricts to a strictly increasing map). See `sage.combinat.permutation.number_of_noninversions()` for the noninv map.

This element is more or less the operator $\nu_{k,1^{n-k}}$ introduced in [RSW2011]; more precisely, $\nu_{k,1^{n-k}}$ is the left multiplication by this element.

It is a nontrivial theorem (Theorem 1.1 in [RSW2011]) that the operators $\nu_{k,1^{n-k}}$ (for fixed n and varying k) pairwise commute. It is a conjecture (Conjecture 1.2 in [RSW2011]) that all their eigenvalues are integers (which, in light of their commutativity and easily established symmetry, yields that they can be simultaneously diagonalized over $\mathbf{Q}$ with only integer eigenvalues).

EXAMPLES:

The Reiner-Saliola-Welker shuffling elements on $\mathbf{Q}S_3$:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.rsw_shuffling_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.rsw_shuffling_element(1)
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2,
↪ 1]
sage: QS3.rsw_shuffling_element(2)
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + [2, 3, 1] + [3, 1, 2]
sage: QS3.rsw_shuffling_element(3)
[1, 2, 3]
sage: QS3.rsw_shuffling_element(4)
0
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS3.rsw_shuffling_element(Integer(0))
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> QS3.rsw_shuffling_element(Integer(1))
3*[1, 2, 3] + 3*[1, 3, 2] + 3*[2, 1, 3] + 3*[2, 3, 1] + 3*[3, 1, 2] + 3*[3, 2,
↪ 1]
>>> QS3.rsw_shuffling_element(Integer(2))
3*[1, 2, 3] + 2*[1, 3, 2] + 2*[2, 1, 3] + [2, 3, 1] + [3, 1, 2]
>>> QS3.rsw_shuffling_element(Integer(3))
[1, 2, 3]
>>> QS3.rsw_shuffling_element(Integer(4))
0
```

Checking the commutativity of Reiner-Saliola-Welker shuffling elements (we leave out the ones for which it is trivial):

```
sage: def test_rsw_comm(n):
....:     QSn = SymmetricGroupAlgebra(QQ, n)
....:     rsws = [QSn.rsw_shuffling_element(k) for k in range(2, n)]
....:     return all(ri * rsws[j] == rsws[j] * ri
....:                for i, ri in enumerate(rsws) for j in range(i))
sage: test_rsw_comm(3)
True
sage: test_rsw_comm(4)    # long time
True
sage: test_rsw_comm(5)    # not tested
True
```

```
>>> from sage.all import *
>>> def test_rsw_comm(n):
...     QSn = SymmetricGroupAlgebra(QQ, n)
...     rsws = [QSn.rsw_shuffling_element(k) for k in range(Integer(2), n)]
...     return all(ri * rsws[j] == rsws[j] * ri
...                for i, ri in enumerate(rsws) for j in range(i))
>>> test_rsw_comm(Integer(3))
True
>>> test_rsw_comm(Integer(4))    # long time
True
```

(continues on next page)

(continued from previous page)

```
>>> test_rsw_comm(Integer(5))    # not tested
True
```

Note: For large k (relative to n), it might be faster to call `QSn.left_action_product(QSn.semi_rsw_element(k), QSn.antipode(binary_unshuffle_sum(k)))` than `QSn.rsw_shuffling_element(n)`.

See also:

`semi_rsw_element()`, `binary_unshuffle_sum()`

semi_rsw_element(k)

Return the k-th semi-RSW element in the group algebra `self`.

The k-th semi-RSW element in the symmetric group algebra RS_n over a ring R is defined as the sum of all permutations $\sigma \in S_n$ satisfying $\sigma(1) < \sigma(2) < \cdots < \sigma(k)$.

This element has the property that, if it is denoted by s_k, then $s_k S(s_k)$ is $(n-k)!$ times the k-th Reiner-Saliola-Welker shuffling element of RS_n (see `rsw_shuffling_element()`). Here, S denotes the antipode of the group algebra RS_n.

The k-th semi-RSW element is the image of the complete non-commutative symmetric function $S^{(k,1^{n-k})}$ in the ring of non-commutative symmetric functions under the canonical projection on the symmetric group algebra (through the descent algebra).

EXAMPLES:

The semi-RSW elements on $\mathbf{Q}S_3$:

```
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: QS3.semi_rsw_element(0)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(1)
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: QS3.semi_rsw_element(2)
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
sage: QS3.semi_rsw_element(3)
[1, 2, 3]
sage: QS3.semi_rsw_element(4)
0
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))
>>> QS3.semi_rsw_element(Integer(0))
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> QS3.semi_rsw_element(Integer(1))
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> QS3.semi_rsw_element(Integer(2))
[1, 2, 3] + [1, 3, 2] + [2, 3, 1]
```

(continues on next page)

(continued from previous page)

```
>>> QS3.semi_rsw_element(Integer(3))
[1, 2, 3]
>>> QS3.semi_rsw_element(Integer(4))
0
```

Let us check the relation with the k-th Reiner-Saliola-Welker shuffling element stated in the docstring:

```
sage: def test_rsw(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     for k in range(1, n):
....:         a = ZSn.semi_rsw_element(k)
....:         b = ZSn.left_action_product(a, ZSn.antipode(a))
....:         if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
....:             return False
....:     return True
sage: test_rsw(3)
True
sage: test_rsw(4)
True
sage: test_rsw(5)  # long time
True
```

```
>>> from sage.all import *
>>> def test_rsw(n):
...     ZSn = SymmetricGroupAlgebra(ZZ, n)
...     for k in range(Integer(1), n):
...         a = ZSn.semi_rsw_element(k)
...         b = ZSn.left_action_product(a, ZSn.antipode(a))
...         if factorial(n-k) * ZSn.rsw_shuffling_element(k) != b:
...             return False
...     return True
>>> test_rsw(Integer(3))
True
>>> test_rsw(Integer(4))
True
>>> test_rsw(Integer(5))  # long time
True
```

Let us also check the statement about the complete non-commutative symmetric function:

```
sage: def test_rsw_ncsf(n):
....:     ZSn = SymmetricGroupAlgebra(ZZ, n)
....:     NSym = NonCommutativeSymmetricFunctions(ZZ)
....:     S = NSym.S()
....:     for k in range(1, n):
....:         a = S(Composition([k] + [1]*(n-k))).to_symmetric_group_algebra()
....:         if a != ZSn.semi_rsw_element(k):
....:             return False
....:     return True
sage: test_rsw_ncsf(3)
True
sage: test_rsw_ncsf(4)
```

(continues on next page)

(continued from previous page)

```
True
sage: test_rsw_ncsf(5)  # long time
True
```

```
>>> from sage.all import *
>>> def test_rsw_ncsf(n):
...     ZSn = SymmetricGroupAlgebra(ZZ, n)
...     NSym = NonCommutativeSymmetricFunctions(ZZ)
...     S = NSym.S()
...     for k in range(Integer(1), n):
...         a = S(Composition([k] + [Integer(1)]*(n-k))).to_symmetric_group_
↪algebra()
...         if a != ZSn.semi_rsw_element(k):
...             return False
...     return True
>>> test_rsw_ncsf(Integer(3))
True
>>> test_rsw_ncsf(Integer(4))
True
>>> test_rsw_ncsf(Integer(5))  # long time
True
```

seminormal_basis(*mult='l2r'*)

Return a list of the seminormal basis elements of `self`.

The seminormal basis of a symmetric group algebra is defined as follows:

Let n be a nonnegative integer. Let R be a $\mathbf{Q}$-algebra. In the following, we will use the "left action" convention for multiplying permutations. This means that for all permutations p and q in S_n, the product pq is defined in such a way that $(pq)(i) = p(q(i))$ for each $i \in \{1, 2, \ldots, n\}$ (this is the same convention as in `left_action_product()`, but not the default semantics of the $*$ operator on permutations in Sage). Thus, for instance, $s_2 s_1$ is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3 (where $s_i = (i, i+1)$).

For every partition λ of n, let

$$\kappa_\lambda = \frac{n!}{f^\lambda}$$

where f^λ is the number of standard Young tableaux of shape λ. Note that κ_λ is an integer, namely the product of all hook lengths of λ (by the hook length formula). In Sage, this integer can be computed by using `sage.combinat.symmetric_group_algebra.kappa()`.

Let T be a standard tableau of size n.

Let $a(T)$ denote the formal sum (in RS_n) of all permutations in S_n which stabilize the rows of T (as sets), i. e., which map each entry i of T to an entry in the same row as i. (See `sage.combinat.symmetric_group_algebra.a()` for an implementation of this.)

Let $b(T)$ denote the signed formal sum (in RS_n) of all permutations in S_n which stabilize the columns of T (as sets). Here, "signed" means that each permutation is multiplied with its sign. (This is implemented in `sage.combinat.symmetric_group_algebra.b()`.)

Define an element $e(T)$ of RS_n to be $a(T)b(T)$. (This is implemented in `sage.combinat.symmetric_group_algebra.e()` for $R = \mathbf{Q}$.)

Let $\mathrm{sh}(T)$ denote the shape of T. (See `shape()`.)

Let $\overline{T}$ denote the standard tableau of size $n-1$ obtained by removing the letter n (along with its cell) from T (if $n \geq 1$).

Now, we define an element $\epsilon(T)$ of RS_n. We define it by induction on the size n of T, so we set $\epsilon(\emptyset) = 1$ and only need to define $\epsilon(T)$ for $n \geq 1$, assuming that $\epsilon(\overline{T})$ is already defined. We do this by setting

$$\epsilon(T) = \frac{1}{\kappa_{\mathrm{sh}(T)}} \epsilon(\overline{T}) e(T) \epsilon(\overline{T}).$$

This element $\epsilon(T)$ is implemented as `sage.combinat.symmetric_group_algebra.epsilon()` for $R = \mathbf{Q}$, but it is also a particular case of the elements $\epsilon(T, S)$ defined below.

Now let S be a further tableau of the same shape as T (possibly equal to T). Let $\pi_{T,S}$ denote the permutation in S_n such that applying this permutation to the entries of T yields the tableau S. Define an element $\epsilon(T, S)$ of RS_n by

$$\epsilon(T, S) = \frac{1}{\kappa_{\mathrm{sh}(T)}} \epsilon(\overline{S}) \pi_{T,S} e(T) \epsilon(\overline{T}) = \frac{1}{\kappa_{\mathrm{sh}(T)}} \epsilon(\overline{S}) a(S) \pi_{T,S} b(T) \epsilon(\overline{T}).$$

This element $\epsilon(T, S)$ is called *Young's seminormal unit corresponding to the bitableau `(T, S)`*, and is the return value of `epsilon_ik()` applied to `T` and `S`. Note that $\epsilon(T, T) = \epsilon(T)$.

If we let λ run through all partitions of n, and (T, S) run through all pairs of tableaux of shape λ, then the elements $\epsilon(T, S)$ form a basis of RS_n. This basis is called *Young's seminormal basis* and has the properties that

$$\epsilon(T, S) \epsilon(U, V) = \delta_{T,V} \epsilon(U, S)$$

(where δ stands for the Kronecker delta).

Warning: Because of our convention, we are multiplying our elements in reverse of those given in some papers, for example [Ram1997]. Using the other convention of multiplying permutations, we would instead have $\epsilon(U, V) \epsilon(T, S) = \delta_{T,V} \epsilon(U, S)$.

In other words, Young's seminormal basis consists of the matrix units in a (particular) Artin-Wedderburn decomposition of RS_n into a direct product of matrix algebras over $\mathbf{Q}$.

The output of `seminormal_basis()` is a list of all elements of the seminormal basis of `self`.

INPUT:

- `mult` – string (default: `'l2r'`); if set to `'r2l'`, this causes the method to return the list of the antipodes (`antipode()`) of all $\epsilon(T, S)$ instead of the $\epsilon(T, S)$ themselves.

EXAMPLES:

```
sage: QS3 = SymmetricGroupAlgebra(QQ,3)
sage: QS3.seminormal_basis()
[1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1,␣
↪2] + 1/6*[3, 2, 1],
1/3*[1, 2, 3] + 1/6*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]␣
↪+ 1/6*[3, 2, 1],
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1],
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1],
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]␣
```

(continues on next page)

(continued from previous page)

```
↪- 1/6*[3, 2, 1],
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]␣
↪- 1/6*[3, 2, 1]]
```

```
>>> from sage.all import *
>>> QS3 = SymmetricGroupAlgebra(QQ,Integer(3))
>>> QS3.seminormal_basis()
[1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1,␣
↪2] + 1/6*[3, 2, 1],
1/3*[1, 2, 3] + 1/6*[1, 3, 2] - 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]␣
↪+ 1/6*[3, 2, 1],
1/3*[1, 3, 2] + 1/3*[2, 3, 1] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1],
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1],
1/3*[1, 2, 3] - 1/6*[1, 3, 2] + 1/3*[2, 1, 3] - 1/6*[2, 3, 1] - 1/6*[3, 1, 2]␣
↪- 1/6*[3, 2, 1],
1/6*[1, 2, 3] - 1/6*[1, 3, 2] - 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2]␣
↪- 1/6*[3, 2, 1]]
```

simple_module(*la*)

Return the simple module of `self` indexed by the partition `la`.

Over a field of characteristic 0, this simply returns the Specht module.

See also

sage.combinat.specht_module.SimpleModule

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 5)
sage: D = SGA.simple_module(Partition([3,1,1]))
sage: D
Simple module of [3, 1, 1] over Finite Field of size 3
sage: D.brauer_character()
(6, 0, -2, 0, 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(5))
>>> D = SGA.simple_module(Partition([Integer(3),Integer(1),Integer(1)]))
>>> D
Simple module of [3, 1, 1] over Finite Field of size 3
>>> D.brauer_character()
(6, 0, -2, 0, 1)
```

simple_module_dimension(*la*)

Return the dimension of the simple module of `self` indexed by the partition `la`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(5), 6)
sage: SGA.simple_module_dimension(Partition([4,1,1]))
10
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(5)), Integer(6))
>>> SGA.simple_module_dimension(Partition([Integer(4),Integer(1),Integer(1)]))
10
```

simple_module_parameterization()

Return a parameterization of the simple modules of `self`.

The symmetric group algebra of S_n over a field of characteristic p has its simple modules indexed by all p-regular partitions of n.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 6)
sage: SGA.simple_module_parameterization()
Partitions of the integer 6

sage: SGA = SymmetricGroupAlgebra(GF(2), 6)
sage: SGA.simple_module_parameterization()
2-Regular Partitions of the integer 6
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(6))
>>> SGA.simple_module_parameterization()
Partitions of the integer 6

>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(6))
>>> SGA.simple_module_parameterization()
2-Regular Partitions of the integer 6
```

specht_module(D)

Return the Specht module of `self` indexed by the diagram `D`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SM = SGA.specht_module(Partition([3,1,1]))
sage: SM
Specht module of [3, 1, 1] over Rational Field
sage: SM.frobenius_image()
s[3, 1, 1]

sage: SM = SGA.specht_module([(1,1),(1,3),(2,2),(3,1),(3,2)])
sage: SM
Specht module of [(1, 1), (1, 3), (2, 2), (3, 1), (3, 2)] over Rational Field
sage: SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SM = SGA.specht_module(Partition([Integer(3),Integer(1),Integer(1)]))
>>> SM
Specht module of [3, 1, 1] over Rational Field
>>> SM.frobenius_image()
```

(continues on next page)

(continued from previous page)

```
s[3, 1, 1]

>>> SM = SGA.specht_module([(Integer(1),Integer(1)),(Integer(1),Integer(3)),
↪(Integer(2),Integer(2)),(Integer(3),Integer(1)),(Integer(3),Integer(2))])
>>> SM
Specht module of [(1, 1), (1, 3), (2, 2), (3, 1), (3, 2)] over Rational Field
>>> SM.frobenius_image()
s[2, 2, 1] + s[3, 1, 1] + s[3, 2]
```

specht_module_dimension(*D*)

Return the dimension of the Specht module of `self` indexed by `D`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: SGA.specht_module_dimension(Partition([3,1,1]))
6
sage: SGA.specht_module_dimension([(1,1),(1,3),(2,2),(3,1),(3,2)])
16
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> SGA.specht_module_dimension(Partition([Integer(3),Integer(1),Integer(1)]))
6
>>> SGA.specht_module_dimension([(Integer(1),Integer(1)),(Integer(1),
↪Integer(3)),(Integer(2),Integer(2)),(Integer(3),Integer(1)),(Integer(3),
↪Integer(2))])
16
```

tabloid_module(*D*)

Return the module of tabloids with the natural action of `self`.

See also

TabloidModule

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: TM = SGA.tabloid_module(Partition([3,1,1]))
sage: TM
Tabloid module of [3, 1, 1] over Rational Field
sage: s = SymmetricFunctions(QQ).s()
sage: s(TM.frobenius_image())
s[3, 1, 1] + s[3, 2] + 2*s[4, 1] + s[5]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> TM = SGA.tabloid_module(Partition([Integer(3),Integer(1),Integer(1)]))
>>> TM
Tabloid module of [3, 1, 1] over Rational Field
```

(continues on next page)

(continued from previous page)

```
>>> s = SymmetricFunctions(QQ).s()
>>> s(TM.frobenius_image())
s[3, 1, 1] + s[3, 2] + 2*s[4, 1] + s[5]
```

young_symmetrizer(*la*)

Return the Young symmetrizer of shape `la` of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(3))
sage: SGA.young_symmetrizer([2,1])
() + (1,2) - (1,3,2) - (1,3)
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: SGA.young_symmetrizer([2,1,1])
[1, 2, 3, 4] - [1, 2, 4, 3] + [2, 1, 3, 4] - [2, 1, 4, 3]
 - [3, 1, 2, 4] + [3, 1, 4, 2] - [3, 2, 1, 4] + [3, 2, 4, 1]
 + [4, 1, 2, 3] - [4, 1, 3, 2] + [4, 2, 1, 3] - [4, 2, 3, 1]
sage: SGA.young_symmetrizer([5,1,1])
Traceback (most recent call last):
...
ValueError: the partition [5, 1, 1] is not of size 4
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, SymmetricGroup(Integer(3)))
>>> SGA.young_symmetrizer([Integer(2),Integer(1)])
() + (1,2) - (1,3,2) - (1,3)
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> SGA.young_symmetrizer([Integer(2),Integer(1),Integer(1)])
[1, 2, 3, 4] - [1, 2, 4, 3] + [2, 1, 3, 4] - [2, 1, 4, 3]
 - [3, 1, 2, 4] + [3, 1, 4, 2] - [3, 2, 1, 4] + [3, 2, 4, 1]
 + [4, 1, 2, 3] - [4, 1, 3, 2] + [4, 2, 1, 3] - [4, 2, 3, 1]
>>> SGA.young_symmetrizer([Integer(5),Integer(1),Integer(1)])
Traceback (most recent call last):
...
ValueError: the partition [5, 1, 1] is not of size 4
```

`sage.combinat.symmetric_group_algebra.`**a**(*tableau*, *star=0*, *base_ring=Rational Field*)

The row projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the sum (in the group algebra of the relevant symmetric group over **Q**) of all the permutations which preserve the rows of `tableau`. It is called a_{tableau} in [EGHLSVY], Section 4.2.

INPUT:

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once
- `star` – nonnegative integer (default: 0); when this optional variable is set, the method computes not the row projection operator of `tableau`, but the row projection operator of the restriction of `tableau` to the entries `1, 2, ..., tableau.size() - star` instead.
- `base_ring` – commutative ring (default: `QQ`); when this optional variable is set, the row projection operator is computed over a user-determined base ring instead of **Q**. (Note that symmetric group algebras currently don't preserve coercion, so e. g. a symmetric group algebra over **Z** does not coerce into the corresponding one over **Q**; so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import a
sage: a([[1,2]])
[1, 2] + [2, 1]
sage: a([[1],[2]])
[1, 2]
sage: a([])
[]
sage: a([[1, 5], [2, 3], [4]])
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: a([[1,4], [2,3]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import a
>>> a([[Integer(1),Integer(2)]])
[1, 2] + [2, 1]
>>> a([[Integer(1)],[Integer(2)]])
[1, 2]
>>> a([])
[]
>>> a([[Integer(1), Integer(5)], [Integer(2), Integer(3)], [Integer(4)]])
[1, 2, 3, 4, 5] + [1, 3, 2, 4, 5] + [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
>>> a([[Integer(1),Integer(4)], [Integer(2),Integer(3)]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

The same with a skew tableau:

```
sage: a([[None,1,4], [2,3]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

```
>>> from sage.all import *
>>> a([[None,Integer(1),Integer(4)], [Integer(2),Integer(3)]], base_ring=ZZ)
[1, 2, 3, 4] + [1, 3, 2, 4] + [4, 2, 3, 1] + [4, 3, 2, 1]
```

`sage.combinat.symmetric_group_algebra.`**b**(*tableau*, *star=0*, *base_ring=Rational Field*)

The column projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

This is the signed sum (in the group algebra of the relevant symmetric group over $\mathbf{Q}$) of all the permutations which preserve the column of `tableau` (where the signs are the usual signs of the permutations). It is called b_{tableau} in [EGHLSVY], Section 4.2.

INPUT:

- `tableau` – Young tableau which contains every integer from 1 to its size precisely once
- `star` – nonnegative integer (default: 0). When this optional variable is set, the method computes not the column projection operator of `tableau`, but the column projection operator of the restriction of `tableau` to the entries `1, 2, ..., tableau.size() - star` instead.
- `base_ring` – commutative ring (default: `QQ`). When this optional variable is set, the column projection operator is computed over a user-determined base ring instead of $\mathbf{Q}$. (Note that symmetric group algebras currently don't preserve coercion, so e. g. a symmetric group algebra over $\mathbf{Z}$ does not coerce into the corresponding one over $\mathbf{Q}$; so convert manually or choose your base rings wisely!)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import b
sage: b([[1,2]])
[1, 2]
sage: b([[1],[2]])
[1, 2] - [2, 1]
sage: b([])
[]
sage: b([[1, 2, 4], [5, 3]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
sage: b([[1, 4], [2, 3]], base_ring=ZZ)
[1, 2, 3, 4] - [1, 2, 4, 3] - [2, 1, 3, 4] + [2, 1, 4, 3]
sage: b([[1, 4], [2, 3]], base_ring=Integers(5))
[1, 2, 3, 4] + 4*[1, 2, 4, 3] + 4*[2, 1, 3, 4] + [2, 1, 4, 3]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import b
>>> b([[Integer(1),Integer(2)]])
[1, 2]
>>> b([[Integer(1)],[Integer(2)]])
[1, 2] - [2, 1]
>>> b([])
[]
>>> b([[Integer(1), Integer(2), Integer(4)], [Integer(5), Integer(3)]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
>>> b([[Integer(1), Integer(4)], [Integer(2), Integer(3)]], base_ring=ZZ)
[1, 2, 3, 4] - [1, 2, 4, 3] - [2, 1, 3, 4] + [2, 1, 4, 3]
>>> b([[Integer(1), Integer(4)], [Integer(2), Integer(3)]], base_
↪ring=Integers(Integer(5)))
[1, 2, 3, 4] + 4*[1, 2, 4, 3] + 4*[2, 1, 3, 4] + [2, 1, 4, 3]
```

The same with a skew tableau:

```
sage: b([[None, 2, 4], [1, 3], [5]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
```

```
>>> from sage.all import *
>>> b([[None, Integer(2), Integer(4)], [Integer(1), Integer(3)], [Integer(5)]])
[1, 2, 3, 4, 5] - [1, 3, 2, 4, 5] - [5, 2, 3, 4, 1] + [5, 3, 2, 4, 1]
```

With the `l2r` setting for multiplication, the unnormalized Young symmetrizer `e(tableau)` should be the product `b(tableau) * a(tableau)` for every `tableau`. Let us check this on the standard tableaux of size 5:

```
sage: from sage.combinat.symmetric_group_algebra import a, b, e
sage: all( e(t) == b(t) * a(t) for t in StandardTableaux(5) )
True
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import a, b, e
>>> all( e(t) == b(t) * a(t) for t in StandardTableaux(Integer(5)) )
True
```

`sage.combinat.symmetric_group_algebra.`**`e`**`(`*tableau*, *star=0*`)`

The unnormalized Young projection operator corresponding to the Young tableau `tableau` (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard).

If n is a nonnegative integer, and T is a Young tableau containing every integer from 1 to n exactly once, then the unnormalized Young projection operator $e(T)$ is defined by

$$e(T) = a(T)b(T) \in \mathbf{Q}S_n,$$

where $a(T) \in \mathbf{Q}S_n$ is the sum of all permutations in S_n which fix the rows of T (as sets), and $b(T) \in \mathbf{Q}S_n$ is the signed sum of all permutations in S_n which fix the columns of T (as sets). Here, "signed" means that each permutation is multiplied with its sign; and the product on the group S_n is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations p and q and any $1 \leq i \leq n$.

Note that the definition of $e(T)$ is not uniform across literature. Others define it as $b(T)a(T)$ instead, or include certain scalar factors (we do not, whence "unnormalized").

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e
sage: e([[1,2]])
[1, 2] + [2, 1]
sage: e([[1],[2]])
[1, 2] - [2, 1]
sage: e([])
[]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e
>>> e([[Integer(1),Integer(2)]])
[1, 2] + [2, 1]
>>> e([[Integer(1)],[Integer(2)]])
[1, 2] - [2, 1]
>>> e([])
[]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e([[1,2],[3]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

```
>>> from sage.all import *
>>> e([[Integer(1),Integer(2)],[Integer(3)]])
[1, 2, 3] + [2, 1, 3] - [3, 1, 2] - [3, 2, 1]
```

To obtain the product $b(T)a(T)$, one has to take the antipode of this:

```
sage: QS3 = parent(e([[1,2],[3]]))
sage: QS3.antipode(e([[1,2],[3]]))
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

```
>>> from sage.all import *
>>> QS3 = parent(e([[Integer(1),Integer(2)],[Integer(3)]]))
>>> QS3.antipode(e([[Integer(1),Integer(2)],[Integer(3)]]))
[1, 2, 3] + [2, 1, 3] - [2, 3, 1] - [3, 2, 1]
```

And here is an example for a skew tableau:

```
sage: e([[None, 2, 1], [4, 3]])
[1, 2, 3, 4] + [1, 2, 4, 3] - [1, 3, 2, 4] - [1, 4, 2, 3]
 + [2, 1, 3, 4] + [2, 1, 4, 3] - [2, 3, 1, 4] - [2, 4, 1, 3]
```

```
>>> from sage.all import *
>>> e([[None, Integer(2), Integer(1)], [Integer(4), Integer(3)]])
[1, 2, 3, 4] + [1, 2, 4, 3] - [1, 3, 2, 4] - [1, 4, 2, 3]
 + [2, 1, 3, 4] + [2, 1, 4, 3] - [2, 3, 1, 4] - [2, 4, 1, 3]
```

See also

e_hat()

sage.combinat.symmetric_group_algebra.**e_hat**(*tab*, *star=0*)

The Young projection operator corresponding to the Young tableau tab (which is supposed to contain every integer from 1 to its size precisely once, but may and may not be standard). This is an idempotent in the rational group algebra.

If n is a nonnegative integer, and T is a Young tableau containing every integer from 1 to n exactly once, then the Young projection operator $\widehat{e}(T)$ is defined by

$$\widehat{e}(T) = \frac{1}{\kappa_\lambda} a(T) b(T) \in \mathbf{Q} S_n,$$

where λ is the shape of T, where κ_λ is $n!$ divided by the number of standard tableaux of shape λ, where $a(T) \in \mathbf{Q} S_n$ is the sum of all permutations in S_n which fix the rows of T (as sets), and where $b(T) \in \mathbf{Q} S_n$ is the signed sum of all permutations in S_n which fix the columns of T (as sets). Here, "signed" means that each permutation is multiplied with its sign; and the product on the group S_n is defined in such a way that $(pq)(i) = p(q(i))$ for any permutations p and q and any $1 \leq i \leq n$.

Note that the definition of $\widehat{e}(T)$ is not uniform across literature. Others define it as $\frac{1}{\kappa_\lambda} b(T) a(T)$ instead.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_hat
sage: e_hat([[1,2,3]])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/
↪6*[3, 2, 1]
sage: e_hat([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e_hat
>>> e_hat([[Integer(1),Integer(2),Integer(3)]])
1/6*[1, 2, 3] + 1/6*[1, 3, 2] + 1/6*[2, 1, 3] + 1/6*[2, 3, 1] + 1/6*[3, 1, 2] + 1/
↪6*[3, 2, 1]
>>> e_hat([[Integer(1)],[Integer(2)]])
1/2*[1, 2] - 1/2*[2, 1]
```

There are differing conventions for the order of the symmetrizers and antisymmetrizers. This example illustrates our conventions:

```
sage: e_hat([[1,2],[3]])
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
```

```
>>> from sage.all import *
>>> e_hat([[Integer(1),Integer(2)],[Integer(3)]])
1/3*[1, 2, 3] + 1/3*[2, 1, 3] - 1/3*[3, 1, 2] - 1/3*[3, 2, 1]
```

See also

e()

sage.combinat.symmetric_group_algebra.**e_ik**(*itab*, *ktab*, *star=0*)

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import e_ik
sage: e_ik([[1,2,3]], [[1,2,3]])
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
sage: e_ik([[1,2,3]], [[1,2,3]], star=1)
[1, 2] + [2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import e_ik
>>> e_ik([[Integer(1),Integer(2),Integer(3)]], [[Integer(1),Integer(2),
→Integer(3)]])
[1, 2, 3] + [1, 3, 2] + [2, 1, 3] + [2, 3, 1] + [3, 1, 2] + [3, 2, 1]
>>> e_ik([[Integer(1),Integer(2),Integer(3)]], [[Integer(1),Integer(2),
→Integer(3)]], star=Integer(1))
[1, 2] + [2, 1]
```

sage.combinat.symmetric_group_algebra.**epsilon**(*tab*, *star=0*)

The (T, T)-th element of the seminormal basis of the group algebra $\mathbf{Q}[S_n]$, where T is the tableau `tab` (with its `star` highest entries removed if the optional variable `star` is set).

See the docstring of *seminormal_basis()* for the notation used herein.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon
sage: epsilon([[1,2]])
1/2*[1, 2] + 1/2*[2, 1]
sage: epsilon([[1],[2]])
1/2*[1, 2] - 1/2*[2, 1]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import epsilon
>>> epsilon([[Integer(1),Integer(2)]])
1/2*[1, 2] + 1/2*[2, 1]
>>> epsilon([[Integer(1)],[Integer(2)]])
1/2*[1, 2] - 1/2*[2, 1]
```

sage.combinat.symmetric_group_algebra.**epsilon_ik**(*itab*, *ktab*, *star=0*)

Return the seminormal basis element of the symmetric group algebra $\mathbf{Q}S_n$ corresponding to the pair of tableaux itab and ktab (or restrictions of these tableaux, if the optional variable star is set).

INPUT:

- itab, ktab – two standard tableaux of same size
- star – integer (default: 0)

OUTPUT:

The element $\epsilon(I, K) \in \mathbf{Q}S_n$, where I and K are the tableaux obtained by removing all entries higher than $n -$ star from itab and ktab, respectively (where n is the size of itab and ktab). Here, we are using the notations from *seminormal_basis()*.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import epsilon_ik
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]])
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
sage: epsilon_ik([[1,2],[3]], [[1,3],[2]], star=1)
Traceback (most recent call last):
...
ValueError: the two tableaux must be of the same shape
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import epsilon_ik
>>> epsilon_ik([[Integer(1),Integer(2)],[Integer(3)]], [[Integer(1),Integer(3)],
↪[Integer(2)]])
1/4*[1, 3, 2] - 1/4*[2, 3, 1] + 1/4*[3, 1, 2] - 1/4*[3, 2, 1]
>>> epsilon_ik([[Integer(1),Integer(2)],[Integer(3)]], [[Integer(1),Integer(3)],
↪[Integer(2)]], star=Integer(1))
Traceback (most recent call last):
...
ValueError: the two tableaux must be of the same shape
```

sage.combinat.symmetric_group_algebra.**kappa**(*alpha*)

Return κ_α, which is $n!$ divided by the number of standard tableaux of shape α (where α is a partition of n).

INPUT:

- alpha – integer partition (can be encoded as a list)

OUTPUT:

The factorial of the size of alpha, divided by the number of standard tableaux of shape alpha. Equivalently, the product of all hook lengths of alpha.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import kappa
sage: kappa(Partition([2,1]))
3
sage: kappa([2,1])
3
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import kappa
>>> kappa(Partition([Integer(2),Integer(1)]))
```

(continues on next page)

(continued from previous page)

```
3
>>> kappa([Integer(2),Integer(1)])
3
```

sage.combinat.symmetric_group_algebra.**pi_ik**(*itab*, *ktab*)

Return the permutation p which sends every entry of the tableau `itab` to the respective entry of the tableau `ktab`, as an element of the corresponding symmetric group algebra.

This assumes that `itab` and `ktab` are tableaux (possibly given just as lists of lists) of the same shape. Both tableaux are allowed to be skew.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[1,3],[2]], [[1,2],[3]])
[1, 3, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import pi_ik
>>> pi_ik([[Integer(1),Integer(3)],[Integer(2)]], [[Integer(1),Integer(2)],
↪[Integer(3)]])
[1, 3, 2]
```

The same with skew tableaux:

```
sage: from sage.combinat.symmetric_group_algebra import pi_ik
sage: pi_ik([[None,1,3],[2]], [[None,1,2],[3]])
[1, 3, 2]
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import pi_ik
>>> pi_ik([[None,Integer(1),Integer(3)],[Integer(2)]], [[None,Integer(1),
↪Integer(2)],[Integer(3)]])
[1, 3, 2]
```

sage.combinat.symmetric_group_algebra.**seminormal_test**(*n*)

Run a variety of tests to verify that the construction of the seminormal basis works as desired. The numbers appearing are results in James and Kerber's 'Representation Theory of the Symmetric Group' [JK1981].

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_algebra import seminormal_test
sage: seminormal_test(3)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_algebra import seminormal_test
>>> seminormal_test(Integer(3))
True
```

5.1.343 Representations of the Symmetric Group

Todo

- construct the product of two irreducible representations.
- implement Induction/Restriction of representations.

Warning

This code uses a different convention than in Sagan's book "The Symmetric Group"

class sage.combinat.symmetric_group_representations.**GarsiaProcesiModule**(*SGA*, *shape*)

Bases: UniqueRepresentation, QuotientRing_generic, *SymmetricGroupRepresentation*

A Garsia-Procesi module.

Let λ be a partition of n and R be a commutative ring. The *Garsia-Procesi module* is defined by $R_\lambda := R[x_1, \ldots, x_n]/I_\lambda$, where

$$I_\lambda := \langle e_r(x_{i_1}, \ldots, x_{i_k}) \mid \{i_1, \ldots, i_k\} \subseteq [n] \text{ and } k \geq r > k - d_k(\lambda) \rangle,$$

with e_r being the r-the elementary symmetric function and $d_k(\lambda) = \lambda'_n + \cdots + \lambda'_{n+1-k}$, is the *Tanisaki ideal*.

If we consider $R = \mathbf{Q}$, then the Garsia-Procesi module has the following interpretation. Let $\mathcal{F}_n = GL_n/B$ denote the (complex type A) flag variety. Consider the Springer fiber $F_\lambda \subseteq \mathcal{F}_n$ associated to a nilpotent matrix with Jordan blocks sizes λ. Springer showed that the cohomology ring $H^*(F_\lambda)$ admits a graded S_n-action that agrees with the induced representation of the sign representation of the Young subgroup S_λ. From work of De Concini and Procesi, this S_n-representation is isomorphic to R_λ. Moreover, the graded Frobenius image is known to be a modified Hall-Littlewood polynomial.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 7)
sage: GP421 = SGA.garsia_procesi_module([4, 2, 1])
sage: GP421.dimension()
105
sage: v = GP421.an_element(); v
-gp1 - gp2 - gp3 - gp4 - gp5 - gp6
sage: SGA.an_element() * v
-6*gp1 - 6*gp2 - 6*gp3 - 6*gp4 - 6*gp5 - 5*gp6
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(7))
>>> GP421 = SGA.garsia_procesi_module([Integer(4), Integer(2), Integer(1)])
>>> GP421.dimension()
105
>>> v = GP421.an_element(); v
-gp1 - gp2 - gp3 - gp4 - gp5 - gp6
>>> SGA.an_element() * v
-6*gp1 - 6*gp2 - 6*gp3 - 6*gp4 - 6*gp5 - 5*gp6
```

We verify the result is a modified Hall-Littlewood polynomial by using the Q' Hall-Littlewood polynomials, replacing $q \mapsto q^{-1}$ and multiplying by the smallest power of q so the coefficients are again polynomials:

```
sage: GP421.graded_frobenius_image()
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
sage: R.<q> = QQ[]
sage: Sym = SymmetricFunctions(R)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(q).Qp()
sage: mHL = s(Qp[4,2,1]); mHL
s[4, 2, 1] + q*s[4, 3] + q*s[5, 1, 1] + (q^2+q)*s[5, 2]
 + (q^3+q^2)*s[6, 1] + q^4*s[7]
sage: mHL.map_coefficients(lambda c: R(q^4*c(q^-1)))
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
```

```
>>> from sage.all import *
>>> GP421.graded_frobenius_image()
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> Sym = SymmetricFunctions(R)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(q).Qp()
>>> mHL = s(Qp[Integer(4),Integer(2),Integer(1)]); mHL
s[4, 2, 1] + q*s[4, 3] + q*s[5, 1, 1] + (q^2+q)*s[5, 2]
 + (q^3+q^2)*s[6, 1] + q^4*s[7]
>>> mHL.map_coefficients(lambda c: R(q**Integer(4)*c(q**-Integer(1))))
q^4*s[4, 2, 1] + q^3*s[4, 3] + q^3*s[5, 1, 1] + (q^3+q^2)*s[5, 2]
 + (q^2+q)*s[6, 1] + s[7]
```

We show that the maximal degree component corresponds to the Yamanouchi words of content λ:

```
sage: B = GP421.graded_decomposition(4).basis()
sage: top_deg = [Word([i+1 for i in b.lift().lift().exponents()[0]]) for b in B]
sage: yamanouchi = [P.to_packed_word() for P in OrderedSetPartitions(range(7), [4,
↪ 2, 1])
....:                 if P.to_packed_word().reversal().is_yamanouchi()]
sage: set(top_deg) == set(yamanouchi)
True
```

```
>>> from sage.all import *
>>> B = GP421.graded_decomposition(Integer(4)).basis()
>>> top_deg = [Word([i+Integer(1) for i in b.lift().lift().
↪exponents()[Integer(0)]]) for b in B]
>>> yamanouchi = [P.to_packed_word() for P in␣
↪OrderedSetPartitions(range(Integer(7)), [Integer(4), Integer(2), Integer(1)])
...                 if P.to_packed_word().reversal().is_yamanouchi()]
>>> set(top_deg) == set(yamanouchi)
True
```

class Element(*parent*, *rep*, *reduce=True*)

Bases: `QuotientRingElement`

degree()

Return the degree of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP22 = SGA.garsia_procesi_module([2, 2])
sage: for b in GP22.basis():
....:     print(b, b.degree())
gp2*gp3 2
gp1*gp3 2
gp3 1
gp2 1
gp1 1
1 0
sage: v = sum(GP22.basis())
sage: v.degree()
2
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> GP22 = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> for b in GP22.basis():
...     print(b, b.degree())
gp2*gp3 2
gp1*gp3 2
gp3 1
gp2 1
gp1 1
1 0
>>> v = sum(GP22.basis())
>>> v.degree()
2
```

homogeneous_degree()

Return the (homogeneous) degree of `self` if homogeneous otherwise raise an error.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 4)
sage: GP31 = SGA.garsia_procesi_module([3, 1])
sage: for b in GP31.basis():
....:     print(b, b.homogeneous_degree())
gp3 1
gp2 1
gp1 1
1 0
sage: v = sum(GP31.basis()); v
gp1 + gp2 + gp3 + 1
sage: v.homogeneous_degree()
Traceback (most recent call last):
...
ValueError: element is not homogeneous
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(4))
>>> GP31 = SGA.garsia_procesi_module([Integer(3), Integer(1)])
>>> for b in GP31.basis():
...     print(b, b.homogeneous_degree())
gp3 1
gp2 1
gp1 1
1 0
>>> v = sum(GP31.basis()); v
gp1 + gp2 + gp3 + 1
>>> v.homogeneous_degree()
Traceback (most recent call last):
...
ValueError: element is not homogeneous
```

monomial_coefficients(*copy=None*)

Return the monomial coefficients of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP31 = SGA.garsia_procesi_module([3, 1])
sage: v = GP31.an_element(); v
-gp1 - gp2 - gp3
sage: v.monomial_coefficients()
{0: 2, 1: 2, 2: 2, 3: 0}
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> GP31 = SGA.garsia_procesi_module([Integer(3), Integer(1)])
>>> v = GP31.an_element(); v
-gp1 - gp2 - gp3
>>> v.monomial_coefficients()
{0: 2, 1: 2, 2: 2, 3: 0}
```

to_vector(*order=None*)

Return `self` as a (dense) free module vector.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 4)
sage: GP22 = SGA.garsia_procesi_module([2, 2])
sage: v = GP22.an_element(); v
-gp1 - gp2 - gp3
sage: v.to_vector()
(0, 0, 2, 2, 2, 0)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(4))
>>> GP22 = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> v = GP22.an_element(); v
-gp1 - gp2 - gp3
```

(continues on next page)

(continued from previous page)

```
>>> v.to_vector()
(0, 0, 2, 2, 2, 0)
```

basis()

Return a basis of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.basis()
Family (gp2*gp3, gp1*gp3, gp3, gp2, gp1, 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.basis()
Family (gp2*gp3, gp1*gp3, gp3, gp2, gp1, 1)
```

dimension()

Return the dimension of `self`.

The graded Frobenius character of the Garsia-Procesi module R_λ is given by the modified Hall-Littlewood polynomial $\widetilde{H}_{\lambda'}(x; q)$.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(1).Qp()
sage: for la in Partitions(5):
....:     print(SGA.garsia_procesi_module(la).dimension(),
....:           sum(c * StandardTableaux(la).cardinality()
....:               for la, c in s(Qp[la])))
1 1
5 5
10 10
20 20
30 30
60 60
120 120
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(Integer(1)).Qp()
>>> for la in Partitions(Integer(5)):
...     print(SGA.garsia_procesi_module(la).dimension(),
...           sum(c * StandardTableaux(la).cardinality()
...               for la, c in s(Qp[la])))
1 1
```

(continues on next page)

(continued from previous page)

```
5 5
10 10
20 20
30 30
60 60
120 120
```

get_order()

Return the order of the elements in the basis.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.get_order()
(0, 1, 2, 3, 4, 5)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.get_order()
(0, 1, 2, 3, 4, 5)
```

graded_brauer_character()

Return the graded Brauer character of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 5)
sage: GP311 = SGA.garsia_procesi_module([3, 1, 1])
sage: GP311.graded_brauer_character()
(6*q^3 + 9*q^2 + 4*q + 1, q + 1, q^3 - q^2 - q + 1)
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(5))
>>> GP311 = SGA.garsia_procesi_module([Integer(3), Integer(1), Integer(1)])
>>> GP311.graded_brauer_character()
(6*q^3 + 9*q^2 + 4*q + 1, q + 1, q^3 - q^2 - q + 1)
```

graded_character()

Return the graded character of `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: GP = SGA.garsia_procesi_module([2, 2, 1])
sage: gchi = GP.graded_character(); gchi
(5*q^4 + 11*q^3 + 9*q^2 + 4*q + 1, -q^4 + q^3 + 3*q^2 + 2*q + 1,
 q^4 - q^3 + q^2 + 1, -q^4 - q^3 + q + 1, -q^4 + q^3 - q + 1,
 q^4 - q^3 - q^2 + 1, q^3 - q^2 - q + 1)
sage: R.<q> = QQ[]
sage: gchi == sum(q^d * D.character()
```

(continues on next page)

(continued from previous page)

```
....:               for d, D in GP.graded_decomposition().items())
True
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2), Integer(1)])
>>> gchi = GP.graded_character(); gchi
(5*q^4 + 11*q^3 + 9*q^2 + 4*q + 1, -q^4 + q^3 + 3*q^2 + 2*q + 1,
 q^4 - q^3 + q^2 + 1, -q^4 - q^3 + q + 1, -q^4 + q^3 - q + 1,
 q^4 - q^3 - q^2 + 1, q^3 - q^2 - q + 1)
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> gchi == sum(q**d * D.character()
...             for d, D in GP.graded_decomposition().items())
True
```

graded_decomposition(*k=None*)

Return the decomposition of `self` as a direct sum of representations given by a fixed grading.

INPUT:

- `k` – (optional) integer; if given, return the k-th graded part

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(2), 5)
sage: GP32 = SGA.garsia_procesi_module([3, 2])
sage: decomp = GP32.graded_decomposition(); decomp
{0: Subrepresentation with basis {0} of Garsia-Procesi ...,
 1: Subrepresentation with basis {0, 1, 2, 3} of Garsia-Procesi ...,
 2: Subrepresentation with basis {0, 1, 2, 3, 4} of Garsia-Procesi ...}
sage: decomp[2] is GP32.graded_decomposition(2)
True
sage: GP32.graded_decomposition(10)
Subrepresentation with basis {} of Garsia-Procesi module
 of shape [3, 2] over Finite Field of size 2
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(2)), Integer(5))
>>> GP32 = SGA.garsia_procesi_module([Integer(3), Integer(2)])
>>> decomp = GP32.graded_decomposition(); decomp
{0: Subrepresentation with basis {0} of Garsia-Procesi ...,
 1: Subrepresentation with basis {0, 1, 2, 3} of Garsia-Procesi ...,
 2: Subrepresentation with basis {0, 1, 2, 3, 4} of Garsia-Procesi ...}
>>> decomp[Integer(2)] is GP32.graded_decomposition(Integer(2))
True
>>> GP32.graded_decomposition(Integer(10))
Subrepresentation with basis {} of Garsia-Procesi module
 of shape [3, 2] over Finite Field of size 2
```

graded_frobenius_image()

Return the graded Frobenius image of `self`.

The graded Frobenius image is the sum of the `frobenius_image()` of each graded component, which is known to result in the modified Hall-Littlewood polynomial $\widetilde{H}_\lambda(x; q)$.

EXAMPLES:

We verify that the result is the modified Hall-Littlewood polynomial for $n = 5$:

```
sage: R.<q> = QQ[]
sage: Sym = SymmetricFunctions(R)
sage: s = Sym.s()
sage: Qp = Sym.hall_littlewood(q).Qp()
sage: SGA = SymmetricGroupAlgebra(QQ, 5)
sage: for la in Partitions(5):
....:     f = SGA.garsia_procesi_module(la).graded_frobenius_image()
....:     d = f[la].degree()
....:     assert f.map_coefficients(lambda c: R(c(~q)*q^d)) == s(Qp[la])
```

```
>>> from sage.all import *
>>> R = QQ['q']; (q,) = R._first_ngens(1)
>>> Sym = SymmetricFunctions(R)
>>> s = Sym.s()
>>> Qp = Sym.hall_littlewood(q).Qp()
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(5))
>>> for la in Partitions(Integer(5)):
...     f = SGA.garsia_procesi_module(la).graded_frobenius_image()
...     d = f[la].degree()
...     assert f.map_coefficients(lambda c: R(c(~q)*q**d)) == s(Qp[la])
```

graded_representation_matrix(*elt*, *q=None*)

Return the matrix corresponding to the left action of the symmetric group (algebra) element `elt` on `self`.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(GF(3), 3)
sage: GP = SGA.garsia_procesi_module([1, 1, 1])
sage: elt = SGA.an_element(); elt
[1, 2, 3] + 2*[1, 3, 2] + [3, 1, 2]
sage: X = GP.graded_representation_matrix(elt); X
[  0   0   0   0   0   0]
[  0 q^2   0   0   0   0]
[  0 q^2   0   0   0   0]
[  0   0   0   q   0   0]
[  0   0   0   q   0   0]
[  0   0   0   0   0   1]
sage: X.parent()
Full MatrixSpace of 6 by 6 dense matrices over
 Univariate Polynomial Ring in q over Finite Field of size 3
sage: R.<q> = GF(3)[]
sage: t = R.quotient([q^2+2*q+1]).gen()
sage: GP.graded_representation_matrix(elt, t)
[       0        0        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0        0        0        1]
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(GF(Integer(3)), Integer(3))
>>> GP = SGA.garsia_procesi_module([Integer(1), Integer(1), Integer(1)])
>>> elt = SGA.an_element(); elt
[1, 2, 3] + 2*[1, 3, 2] + [3, 1, 2]
>>> X = GP.graded_representation_matrix(elt); X
[  0    0    0    0    0    0]
[  0 q^2    0    0    0    0]
[  0 q^2    0    0    0    0]
[  0    0    0    q    0    0]
[  0    0    0    q    0    0]
[  0    0    0    0    0    1]
>>> X.parent()
Full MatrixSpace of 6 by 6 dense matrices over
 Univariate Polynomial Ring in q over Finite Field of size 3
>>> R = GF(Integer(3))['q'];  (q,) = R._first_ngens(1)
>>> t = R.quotient([q**Integer(2)+Integer(2)*q+Integer(1)]).gen()
>>> GP.graded_representation_matrix(elt, t)
[       0        0        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0 qbar + 2        0        0        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0     qbar        0        0]
[       0        0        0        0        0        1]
```

one_basis()

Return the index of the basis element 1.

EXAMPLES:

```
sage: SGA = SymmetricGroupAlgebra(QQ, 4)
sage: GP = SGA.garsia_procesi_module([2, 2])
sage: GP.one_basis()
5
```

```
>>> from sage.all import *
>>> SGA = SymmetricGroupAlgebra(QQ, Integer(4))
>>> GP = SGA.garsia_procesi_module([Integer(2), Integer(2)])
>>> GP.one_basis()
5
```

class sage.combinat.symmetric_group_representations.**SpechtRepresentation**(*parent*, *partition*)

Bases: `SymmetricGroupRepresentation_generic_class`

representation_matrix(*permutation*)

Return the matrix representing the `permutation` in this irreducible representation.

Note

This method caches the results.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.representation_matrix(Permutation([2,1,3,4]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
sage: spc.representation_matrix(Permutation([3,2,1,4]))
[0 0 1]
[0 1 0]
[1 0 0]
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(1)], 'specht')
>>> spc.representation_matrix(Permutation([Integer(2),Integer(1),Integer(3),
↪Integer(4)]))
[ 0 -1  0]
[-1  0  0]
[ 0  0  1]
>>> spc.representation_matrix(Permutation([Integer(3),Integer(2),Integer(1),
↪Integer(4)]))
[0 0 1]
[0 1 0]
[1 0 0]
```

scalar_product (*u*, *v*)

Return `0` if `u+v` is not a permutation, and the signature of the permutation otherwise.

This is the scalar product of a vertex `u` of the underlying Yang-Baxter graph with the vertex `v` in the 'dual' Yang-Baxter graph.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,2], 'specht')
sage: spc.scalar_product((1,0,2,1,0),(0,3,0,3,0))
-1
sage: spc.scalar_product((1,0,2,1,0),(3,0,0,3,0))
0
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], 'specht')
>>> spc.scalar_product((Integer(1),Integer(0),Integer(2),Integer(1),
↪Integer(0)),(Integer(0),Integer(3),Integer(0),Integer(3),Integer(0)))
-1
>>> spc.scalar_product((Integer(1),Integer(0),Integer(2),Integer(1),
↪Integer(0)),(Integer(3),Integer(0),Integer(0),Integer(3),Integer(0)))
0
```

scalar_product_matrix (*permutation=None*)

Return the scalar product matrix corresponding to `permutation`.

The entries are given by the scalar products of `u` and `permutation.action(v)`, where `u` is a vertex in the underlying Yang-Baxter graph and `v` is a vertex in the dual graph.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([3,1], 'specht')
sage: spc.scalar_product_matrix()
[ 1  0  0]
[ 0 -1  0]
[ 0  0  1]

class sage.combinat.symmetric_group_representations.**SpechtRepresentations**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *SpechtRepresentation*

sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentation**(*partition*, *implementation='specht'*, *ring=None*, *cache_matrices=True*)

The irreducible representation of the symmetric group corresponding to `partition`.

INPUT:

- `partition` – a partition of a positive integer
- `implementation` – string (default: `'specht'`); one of:
  - `'seminormal'` – for Young's seminormal representation
  - `'orthogonal'` – for Young's orthogonal representation
  - `'specht'` – for Specht's representation
  - `'unitary'` – for the unitary representation
- `ring` – the ring over which the representation is defined
- `cache_matrices` – boolean (default: `True`); if `True`, then any representation matrices that are computed are cached

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal"); orth          #␣
↪needs sage.symbolic
Orthogonal representation of the symmetric group corresponding to [2, 1]
sage: all(a*a.transpose() == a.parent().identity_matrix() for a in orth)      #␣
↪needs sage.symbolic
True
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentation([Integer(2),Integer(1)], "orthogonal");
↪orth              # needs sage.symbolic
Orthogonal representation of the symmetric group corresponding to [2, 1]
>>> all(a*a.transpose() == a.parent().identity_matrix() for a in orth)        #
↪needs sage.symbolic
True
```

```
sage: # needs sage.symbolic
sage: orth = SymmetricGroupRepresentation([3,2], "orthogonal"); orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
sage: orth([2,1,3,4,5])
[ 1  0  0  0  0]
[ 0  1  0  0  0]
[ 0  0 -1  0  0]
[ 0  0  0  1  0]
[ 0  0  0  0 -1]
sage: orth([1,3,2,4,5])
[           1            0            0            0            0]
[           0         -1/2 1/2*sqrt(3)            0            0]
[           0 1/2*sqrt(3)          1/2            0            0]
[           0            0            0         -1/2 1/2*sqrt(3)]
[           0            0            0 1/2*sqrt(3)          1/2]
sage: orth([1,2,4,3,5])
[       -1/3 2/3*sqrt(2)            0            0            0]
[2/3*sqrt(2)          1/3            0            0            0]
[           0            0            1            0            0]
[           0            0            0            1            0]
[           0            0            0            0           -1]
```

```
>>> from sage.all import *
>>> # needs sage.symbolic
>>> orth = SymmetricGroupRepresentation([Integer(3),Integer(2)], "orthogonal");
↪orth
Orthogonal representation of the symmetric group corresponding to [3, 2]
>>> orth([Integer(2),Integer(1),Integer(3),Integer(4),Integer(5)])
[ 1  0  0  0  0]
[ 0  1  0  0  0]

[           0            0            0         -1/2 1/2*sqrt(3)]
[           0            0            0 1/2*sqrt(3)          1/2]
>>> orth([Integer(1),Integer(2),Integer(4),Integer(3),Integer(5)])
[       -1/3 2/3*sqrt(2)            0            0            0]
[2/3*sqrt(2)          1/3            0            0            0]
[           0            0            1            0            0]
[           0            0            0            1            0]
```

(continues on next page)

(continued from previous page)

```
[          0           0           0           0          -1]
```

The Specht representation:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc.scalar_product_matrix(Permutation([1,2,3,4,5]))
[ 1  0  0  0  0]
[ 0 -1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[-1  0  0  0 -1]
sage: spc.scalar_product_matrix(Permutation([5,4,3,2,1]))
[ 1 -1  0  1  0]
[ 0  0  1  0 -1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[-1  0  0  0 -1]
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc.verify_representation()
True
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht")
>>> spc.scalar_product_matrix(Permutation([Integer(1),Integer(2),Integer(3),
↪Integer(4),Integer(5)]))
[ 1  0  0  0  0]
[ 0 -1  0  0  0]
[ 0  0  1  0  0]
[ 0  0  0  1  0]
[-1  0  0  0 -1]
>>> spc.scalar_product_matrix(Permutation([Integer(5),Integer(4),Integer(3),
↪Integer(2),Integer(1)]))
[ 1 -1  0  1  0]
[ 0  0  1  0 -1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[-1  0  0  0 -1]
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
>>> spc.verify_representation()
True
```

The unitary representation:

```
sage: unitary = SymmetricGroupRepresentation([3,1], "unitary"); unitary
Unitary representation of the symmetric group corresponding to [3, 1]
sage: unitary_GF49 = SymmetricGroupRepresentation([3,1], "unitary",␣
↪ring=GF(7**2)); unitary_GF49
Unitary representation of the symmetric group corresponding to [3, 1]
sage: unitary_GF49([2,1,3,4])
[6 0 0]
[0 1 0]
[0 0 1]
sage: unitary_GF49([3,2,1,4])
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
sage: unitary_GF49.verify_representation()
True
```

```
>>> from sage.all import *
>>> unitary = SymmetricGroupRepresentation([Integer(3),Integer(1)], "unitary");␣
↪unitary
Unitary representation of the symmetric group corresponding to [3, 1]
>>> unitary_GF49 = SymmetricGroupRepresentation([Integer(3),Integer(1)], "unitary
↪", ring=GF(Integer(7)**Integer(2))); unitary_GF49
Unitary representation of the symmetric group corresponding to [3, 1]
>>> unitary_GF49([Integer(2),Integer(1),Integer(3),Integer(4)])
[6 0 0]
[0 1 0]
[0 0 1]
>>> unitary_GF49([Integer(3),Integer(2),Integer(1),Integer(4)])
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
>>> unitary_GF49.verify_representation()
True
```

By default, any representation matrices that are computed are cached:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht")
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: spc._cache__representation_matrix
{(([5, 4, 3, 2, 1],), ()): [ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]}
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht")
```

(continues on next page)

(continued from previous page)

```
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
>>> spc._cache__representation_matrix
{(([5, 4, 3, 2, 1],), ()): [ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]}
```

This can be turned off with the keyword `cache_matrices`:

```
sage: spc = SymmetricGroupRepresentation([3,2], "specht", cache_matrices=False)
sage: spc([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
sage: hasattr(spc, '_cache__representation_matrix')
False
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(3),Integer(2)], "specht", cache_
↪matrices=False)
>>> spc([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
>>> hasattr(spc, '_cache__representation_matrix')
False
```

Note

The implementation is based on the paper [Las].

`class sage.combinat.symmetric_group_representations.SymmetricGroupRepresentation_generic_class`(*parent*, *partition*)

Bases: `Element`

Generic methods for a representation of the symmetric group.

to_character()

Return the character of the representation.

EXAMPLES:

The trivial character:

```
sage: rho = SymmetricGroupRepresentation([3])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, 1, 1]
sage: all(chi(g) == 1 for g in SymmetricGroup(3))
True
```

```
>>> from sage.all import *
>>> rho = SymmetricGroupRepresentation([Integer(3)])
>>> chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
>>> chi.values()
[1, 1, 1]
>>> all(chi(g) == Integer(1) for g in SymmetricGroup(Integer(3)))
True
```

The sign character:

```
sage: rho = SymmetricGroupRepresentation([1,1,1])
sage: chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
sage: chi.values()
[1, -1, 1]
sage: all(chi(g) == g.sign() for g in SymmetricGroup(3))
True
```

```
>>> from sage.all import *
>>> rho = SymmetricGroupRepresentation([Integer(1),Integer(1),Integer(1)])
>>> chi = rho.to_character(); chi
Character of Symmetric group of order 3! as a permutation group
>>> chi.values()
[1, -1, 1]
>>> all(chi(g) == g.sign() for g in SymmetricGroup(Integer(3)))
True
```

The defining representation:

```
sage: triv = SymmetricGroupRepresentation([4])
sage: hook = SymmetricGroupRepresentation([3,1])
sage: def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
sage: list(map(def_rep, Permutations(4)))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

(continues on next page)

(continued from previous page)

```
sage: [p.to_matrix().trace() for p in Permutations(4)]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

```
>>> from sage.all import *
>>> triv = SymmetricGroupRepresentation([Integer(4)])
>>> hook = SymmetricGroupRepresentation([Integer(3),Integer(1)])
>>> def_rep = lambda p : triv(p).block_sum(hook(p)).trace()
>>> list(map(def_rep, Permutations(Integer(4))))
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
>>> [p.to_matrix().trace() for p in Permutations(Integer(4))]
[4, 2, 2, 1, 1, 2, 2, 0, 1, 0, 0, 1, 1, 0, 2, 1, 0, 0, 0, 1, 1, 2, 0, 0]
```

verify_representation()

Verify the representation.

This tests that the images of the simple transpositions are involutions and tests that the braid relations hold.

EXAMPLES:

```
sage: spc = SymmetricGroupRepresentation([1,1,1])
sage: spc.verify_representation()
True
sage: spc = SymmetricGroupRepresentation([4,2,1])
sage: spc.verify_representation()
True
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentation([Integer(1),Integer(1),Integer(1)])
>>> spc.verify_representation()
True
>>> spc = SymmetricGroupRepresentation([Integer(4),Integer(2),Integer(1)])
>>> spc.verify_representation()
True
```

sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentations**(*n*, *implementation='specht'*, *ring=None*, *cache_matrices=True*)

Irreducible representations of the symmetric group.

INPUT:

- `n` – positive integer
- `implementation` – string (default: `'specht'`); one of:
  - `'seminormal'` – for Young's seminormal representation
  - `'orthogonal'` – for Young's orthogonal representation
  - `'specht'` – for Specht's representation
  - `'unitary'` – for the unitary representation
- `ring` – the ring over which the representation is defined

- `cache_matrices` – boolean (default: `True`); if `True`, then any representation matrices that are computed are cached

EXAMPLES:

Young's orthogonal representation: the matrices are orthogonal.

```
sage: orth = SymmetricGroupRepresentations(3, "orthogonal"); orth              #␣
↪needs sage.symbolic
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
sage: orth.list()                                                              #␣
↪needs sage.symbolic
[Orthogonal representation of the symmetric group corresponding to [3],
 Orthogonal representation of the symmetric group corresponding to [2, 1],
 Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
sage: orth([2,1])([1,2,3])                                                     #␣
↪needs sage.symbolic
[1 0]
[0 1]
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentations(Integer(3), "orthogonal"); orth       ␣
↪     # needs sage.symbolic
Orthogonal representations of the symmetric group of order 3! over Symbolic Ring
>>> orth.list()                                                              #␣
↪needs sage.symbolic
[Orthogonal representation of the symmetric group corresponding to [3],
 Orthogonal representation of the symmetric group corresponding to [2, 1],
 Orthogonal representation of the symmetric group corresponding to [1, 1, 1]]
>>> orth([Integer(2),Integer(1)])([Integer(1),Integer(2),Integer(3)])          ␣
↪                                          # needs sage.symbolic
[1 0]
[0 1]
```

Young's seminormal representation.

```
sage: snorm = SymmetricGroupRepresentations(3, "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
sage: sgn = snorm([1,1,1]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
sage: list(map(sgn, Permutations(3)))
[[1], [-1], [-1], [1], [1], [-1]]
```

```
>>> from sage.all import *
>>> snorm = SymmetricGroupRepresentations(Integer(3), "seminormal"); snorm
Seminormal representations of the symmetric group of order 3! over Rational Field
>>> sgn = snorm([Integer(1),Integer(1),Integer(1)]); sgn
Seminormal representation of the symmetric group corresponding to [1, 1, 1]
>>> list(map(sgn, Permutations(Integer(3))))
[[1], [-1], [-1], [1], [1], [-1]]
```

The Specht Representation.

```
sage: spc = SymmetricGroupRepresentations(5, "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
sage: spc([3,2])([5,4,3,2,1])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
```

```
>>> from sage.all import *
>>> spc = SymmetricGroupRepresentations(Integer(5), "specht"); spc
Specht representations of the symmetric group of order 5! over Integer Ring
>>> spc([Integer(3),Integer(2)])([Integer(5),Integer(4),Integer(3),Integer(2),
↪Integer(1)])
[ 1 -1  0  1  0]
[ 0  0 -1  0  1]
[ 0  0  0 -1  1]
[ 0  1 -1 -1  1]
[ 0  1  0 -1  1]
```

The unitary representation.

```
sage: unitary = SymmetricGroupRepresentations(3, "unitary"); unitary
Unitary representations of the symmetric group of order 3! over Symbolic Ring
sage: unitary_GF49 = SymmetricGroupRepresentations(4, "unitary", ring=GF(7**2));␣
↪unitary_GF49
Unitary representations of the symmetric group of order 4! over Finite Field in␣
↪z2 of size 7^2
sage: unitary_GF49([3,1])([2,1,3,4])
[6 0 0]
[0 1 0]
[0 0 1]
sage: unitary_GF49([3,1])([3,2,1,4])
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
```

```
>>> from sage.all import *
>>> unitary = SymmetricGroupRepresentations(Integer(3), "unitary"); unitary
Unitary representations of the symmetric group of order 3! over Symbolic Ring
>>> unitary_GF49 = SymmetricGroupRepresentations(Integer(4), "unitary",␣
↪ring=GF(Integer(7)**Integer(2))); unitary_GF49
Unitary representations of the symmetric group of order 4! over Finite Field in␣
↪z2 of size 7^2
>>> unitary_GF49([Integer(3),Integer(1)])([Integer(2),Integer(1),Integer(3),
↪Integer(4)])
[6 0 0]
[0 1 0]
[0 0 1]
>>> unitary_GF49([Integer(3),Integer(1)])([Integer(3),Integer(2),Integer(1),
↪Integer(4)])
[       4 2*z2 + 3        0]
```

(continues on next page)

(continued from previous page)

```
[5*z2 + 5         3         0]
[        0        0         1]
```

Note: The implementation is based on the paper [Las].

class sage.combinat.symmetric_group_representations.**SymmetricGroupRepresentations_class**(*n*, *ring=None*, *cache_matrices=True*)

Bases: UniqueRepresentation, Parent

Generic methods for the CombinatorialClass of irreducible representations of the symmetric group.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: sp = SymmetricGroupRepresentations(4, "specht")
sage: sp.cardinality()
5
```

```
>>> from sage.all import *
>>> sp = SymmetricGroupRepresentations(Integer(4), "specht")
>>> sp.cardinality()
5
```

class sage.combinat.symmetric_group_representations.**UnitaryRepresentation**(*parent*, *partition*)

Bases: *SymmetricGroupRepresentation_generic_class*

A unitary representation of the symmetric group.

In characteristic zero, this is the same as the orthogonal representation since they are defined over the reals. In positive characteristic, we are able to construct representations when the field is finite, has square order, and the characteristic does not divide the order of the group. In this case, we construct the representation by first constructing the orthogonal representation ρ and then taking the extended Cholesky decomposition of the unique solution U to the equation $\rho(g)^T U \rho(g) = U$ for all g in G.

representation_matrix(*permutation*)

Return the matrix representing the `permutation` in this irreducible representation.

Note: This method caches the results.

EXAMPLES:

```
sage: unitary_specht = SymmetricGroupRepresentation([3,1], 'unitary',␣
↪ring=GF(7**2))
sage: unitary_specht.representation_matrix(Permutation([2,1,3,4]))
[6 0 0]
[0 1 0]
[0 0 1]
sage: unitary_specht.representation_matrix(Permutation([3,2,1,4]))
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
sage: all(A * A.H == 1 for A in [unitary_specht.representation_matrix(g)
....:                            for g in Permutations(4)])
True
```

```
>>> from sage.all import *
>>> unitary_specht = SymmetricGroupRepresentation([Integer(3),Integer(1)],
↪'unitary', ring=GF(Integer(7)**Integer(2)))
>>> unitary_specht.representation_matrix(Permutation([Integer(2),Integer(1),
↪Integer(3),Integer(4)]))
[6 0 0]
[0 1 0]
[0 0 1]
>>> unitary_specht.representation_matrix(Permutation([Integer(3),Integer(2),
↪Integer(1),Integer(4)]))
[       4 2*z2 + 3        0]
[5*z2 + 5        3        0]
[       0        0        1]
>>> all(A * A.H == Integer(1) for A in [unitary_specht.representation_
↪matrix(g)
...                            for g in Permutations(Integer(4))])
True
```

class sage.combinat.symmetric_group_representations.**UnitaryRepresentations**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *UnitaryRepresentation*

class sage.combinat.symmetric_group_representations.**YoungRepresentation_Orthogonal**(*parent*, *partition*)

Bases: *YoungRepresentation_generic*

class sage.combinat.symmetric_group_representations.**YoungRepresentation_Seminormal**(*parent*, *partition*)

Bases: *YoungRepresentation_generic*

class sage.combinat.symmetric_group_representations.**YoungRepresentation_generic**(*parent*, *partition*)

Bases: *SymmetricGroupRepresentation_generic_class*

Generic methods for Young's representations of the symmetric group.

representation_matrix(*permutation*)

Return the matrix representing permutation.

EXAMPLES:

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")              #␣
↪needs sage.symbolic
sage: orth.representation_matrix(Permutation([2,1,3]))                      #␣
↪needs sage.symbolic
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix(Permutation([1,3,2]))                      #␣
↪needs sage.symbolic
[       -1/2 1/2*sqrt(3)]
[1/2*sqrt(3)         1/2]
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentation([Integer(2),Integer(1)], "orthogonal
↪")              # needs sage.symbolic
>>> orth.representation_matrix(Permutation([Integer(2),Integer(1),
↪Integer(3)]))                    # needs sage.symbolic
[ 1  0]
[ 0 -1]
>>> orth.representation_matrix(Permutation([Integer(1),Integer(3),
↪Integer(2)]))                    # needs sage.symbolic
[       -1/2 1/2*sqrt(3)]
[1/2*sqrt(3)         1/2]
```

```
sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: p = PermutationGroupElement([2,1,3])
sage: norm.representation_matrix(p)
[ 1  0]
[ 0 -1]
sage: p = PermutationGroupElement([1,3,2])
sage: norm.representation_matrix(p)
[-1/2  3/2]
[ 1/2  1/2]
```

```
>>> from sage.all import *
>>> norm = SymmetricGroupRepresentation([Integer(2),Integer(1)], "seminormal")
>>> p = PermutationGroupElement([Integer(2),Integer(1),Integer(3)])
>>> norm.representation_matrix(p)
[ 1  0]
[ 0 -1]
>>> p = PermutationGroupElement([Integer(1),Integer(3),Integer(2)])
>>> norm.representation_matrix(p)
[-1/2  3/2]
[ 1/2  1/2]
```

representation_matrix_for_simple_transposition(*i*)

Return the matrix representing the transposition that swaps `i` and `i+1`.

EXAMPLES:

```
sage: orth = SymmetricGroupRepresentation([2,1], "orthogonal")              #␣
↪needs sage.symbolic
sage: orth.representation_matrix_for_simple_transposition(1)                #␣
↪needs sage.symbolic
[ 1  0]
[ 0 -1]
sage: orth.representation_matrix_for_simple_transposition(2)                #␣
↪needs sage.symbolic
[       -1/2 1/2*sqrt(3)]
[1/2*sqrt(3)         1/2]

sage: norm = SymmetricGroupRepresentation([2,1], "seminormal")
sage: norm.representation_matrix_for_simple_transposition(1)
[ 1  0]
[ 0 -1]
sage: norm.representation_matrix_for_simple_transposition(2)
[-1/2  3/2]
[ 1/2  1/2]
```

```
>>> from sage.all import *
>>> orth = SymmetricGroupRepresentation([Integer(2),Integer(1)], "orthogonal
↪")                # needs sage.symbolic
>>> orth.representation_matrix_for_simple_transposition(Integer(1))        ␣
↪      # needs sage.symbolic
[ 1  0]
[ 0 -1]
>>> orth.representation_matrix_for_simple_transposition(Integer(2))        ␣
↪      # needs sage.symbolic
[       -1/2 1/2*sqrt(3)]
[1/2*sqrt(3)         1/2]

>>> norm = SymmetricGroupRepresentation([Integer(2),Integer(1)], "seminormal")
>>> norm.representation_matrix_for_simple_transposition(Integer(1))
[ 1  0]
[ 0 -1]
>>> norm.representation_matrix_for_simple_transposition(Integer(2))
[-1/2  3/2]
[ 1/2  1/2]
```

class sage.combinat.symmetric_group_representations.**YoungRepresentations_Orthogonal**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *YoungRepresentation_Orthogonal*

class sage.combinat.symmetric_group_representations.**YoungRepresentations_Seminormal**(*n*, *ring=None*, *cache_matrices=True*)

Bases: *SymmetricGroupRepresentations_class*

Element

alias of *YoungRepresentation_Seminormal*

sage.combinat.symmetric_group_representations.**partition_to_vector_of_contents**(*partition*, *reverse=False*)

Return the "vector of contents" associated to partition.

EXAMPLES:

```
sage: from sage.combinat.symmetric_group_representations import partition_to_
↪vector_of_contents
sage: partition_to_vector_of_contents([3,2])
(0, 1, 2, -1, 0)
```

```
>>> from sage.all import *
>>> from sage.combinat.symmetric_group_representations import partition_to_vector_
↪of_contents
>>> partition_to_vector_of_contents([Integer(3),Integer(2)])
(0, 1, 2, -1, 0)
```

5.1.344 T-sequences

T-sequences are tuples of four (-1, 0, 1) sequences of length t where for every i exactly one sequence has a nonzero entry at index i and for which the nonperiodic autocorrelation function is equal to zero (i.e. they are complementary). See Definition 7.5 of [Seb2017].

These can be constructed from Turyn sequences. In particular, if Turyn sequences of length l exists, there will be T-sequences of length $4l - 1$ and $2l - 1$.

Turyn sequences are tuples of four (-1, +1) sequences X, U, Y, V of length $l, l, l-1, l-1$ with nonperiodic autocorrelation equal to zero and the additional constraints that:

- the first element of X is 1
- the last element of X is -1
- the last element of U is 1

The nonperiodic autocorrelation of a familiy of sequences $X = \{A_1, A_2, ..., A_n\}$ is defined as (see Definition 7.2 of [Seb2017]):

$$N_X(j) = \sum_{i=1}^{n-j}(a_{1,i}a_{1,i+j} + a_{2,i}a_{2,i+j} + ... + a_{n,i}a_{n,i+j})$$

AUTHORS:

- Matteo Cati (2022-11-16): initial version

sage.combinat.t_sequences.**T_sequences_construction_from_base_sequences**(*base_sequences*, *check=True*)

Construct T-sequences of length $2n + p$ from base sequences of length $n + p, n + p, n, n$.

Given base sequences A, B, C, D, the T-sequences are constructed as described in [KTR2005]:

$$T_1 = \frac{1}{2}(A + B); 0_n$$
$$T_2 = \frac{1}{2}(A - B); 0_n$$
$$T_3 = 0_{n+p} + \frac{1}{2}(C + D)$$
$$T_4 = 0_{n+p} + \frac{1}{2}(C - D)$$

INPUT:

- `base_sequences` – the base sequences that should be used to construct the T-sequences
- `check` – boolean (default: `True`); check that the sequences created are T-sequences before returning them

EXAMPLES:

```
sage: from sage.combinat.t_sequences import turyn_sequences_smallcases, T_
↪sequences_construction_from_base_sequences
sage: seqs = turyn_sequences_smallcases(4)
sage: T_sequences_construction_from_base_sequences(seqs)
[[1, 1, -1, 0, 0, 0, 0],
[0, 0, 0, -1, 0, 0, 0],
[0, 0, 0, 0, 1, 0, 1],
[0, 0, 0, 0, 0, 1, 0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import turyn_sequences_smallcases, T_sequences_
↪construction_from_base_sequences
>>> seqs = turyn_sequences_smallcases(Integer(4))
>>> T_sequences_construction_from_base_sequences(seqs)
[[1, 1, -1, 0, 0, 0, 0],
[0, 0, 0, -1, 0, 0, 0],
[0, 0, 0, 0, 1, 0, 1],
[0, 0, 0, 0, 0, 1, 0]]
```

sage.combinat.t_sequences.**T_sequences_construction_from_turyn_sequences**(*turyn_sequences*, *check=True*)

Construct T-sequences of length $4l - 1$ from Turyn sequences of length l.

Given Turyn sequences X, U, Y, V, the T-sequences are constructed as described in theorem 7.7 of [Seb2017]:

$$T_1 = 1; 0_{4l-2}$$
$$T_2 = 0; X/Y; 0_{2l-1}$$
$$T_3 = 0_{2l}; U/0_{l-2}$$
$$T_4 = 0_{2l} + 0_l/V$$

INPUT:

- `turyn_sequences` – the Turyn sequences that should be used to construct the T-sequences
- `check` – boolean (default: `True`); check that the sequences created are T-sequences before returning them

EXAMPLES:

```
sage: from sage.combinat.t_sequences import turyn_sequences_smallcases, T_
↪sequences_construction_from_turyn_sequences, is_T_sequences_set
sage: seqs = turyn_sequences_smallcases(4)
sage: T_sequences_construction_from_turyn_sequences(seqs)
[[1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
[0, 1, 1, 1, 1, -1, 1, -1, 0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1, 0, -1, 0, 1],
[0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, -1, 0, 1, 0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import turyn_sequences_smallcases, T_sequences_
↪construction_from_turyn_sequences, is_T_sequences_set
>>> seqs = turyn_sequences_smallcases(Integer(4))
>>> T_sequences_construction_from_turyn_sequences(seqs)
[[1, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0],
[0, 1, 1, 1, 1, -1, 1, -1, 0, 0, 0, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 0, 0, 0, 1, 0, 1, 0, -1, 0, 1],
[0, 0, 0, 0, 0, 0, 0, 0, 0, 1, 0, -1, 0, 1, 0]]
```

sage.combinat.t_sequences.**T_sequences_smallcases**(*t*, *existence=False*, *check=True*)

Construct T-sequences for some small values of t.

This method will try to use the constructions defined in *T_sequences_construction_from_base_sequences()* and *T_sequences_construction_from_turyn_sequences()* together with the Turyn sequences stored in *turyn_sequences_smallcases()*, or base sequences created by *base_sequences_smallcases()*.

This function contains also some T-sequences taken directly from [CRSKKY1989].

INPUT:

- `t` – integer; the length of the T-sequences to construct
- `existence` – boolean (default: `False`); if `True`, this method only returns whether a T-sequences of the given size can be constructed
- `check` – boolean (default: `True`); check that the sequences are T-sequences before returning them

EXAMPLES:

By default, this method returns the four T-sequences

```
sage: from sage.combinat.t_sequences import T_sequences_smallcases, is_T_
↪sequences_set
sage: T_sequences_smallcases(9)
[[1, 1, 0, 1, 0, 0, 0, 0, 0],
[0, 0, -1, 0, 1, 0, 0, 0, 0],
[0, 0, 0, 0, 0, 1, 0, 0, -1],
[0, 0, 0, 0, 0, 0, 1, -1, 0]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import T_sequences_smallcases, is_T_sequences_
↪set
>>> T_sequences_smallcases(Integer(9))
[[1, 1, 0, 1, 0, 0, 0, 0, 0],
[0, 0, -1, 0, 1, 0, 0, 0, 0],
```

(continues on next page)

(continued from previous page)

```
[0, 0, 0, 0, 0, 1, 0, 0, -1],
[0, 0, 0, 0, 0, 0, 1, -1, 0]]
```

If the existence flag is passed, the method returns a boolean

```
sage: T_sequences_smallcases(9, existence=True)
True
```

```
>>> from sage.all import *
>>> T_sequences_smallcases(Integer(9), existence=True)
True
```

sage.combinat.t_sequences.**base_sequences_construction**(*turyn_type_seqs*, *check=True*)

Construct base sequences of length $2n-1, 2n-1, n, n$ from Turyn type sequences of length $n, n, n, n-1$.

Given Turyn type sequences X, Y, Z, W of length $n, n, n, n-1$, Theorem 1 of [KTR2005] shows that the following are base sequences of length $2n-1, 2n-1, n, n$:

$$\begin{aligned}A &= Z; W \\ B &= Z; -W \\ C &= X \\ D &= Y\end{aligned}$$

INPUT:

- `turyn_type_seqs` – the list of 4 Turyn type sequences that should be used to construct the base sequences
- `check` – boolean (default: `True`); check that the resulting sequences are base sequences before returning them

OUTPUT: list containing the four base sequences

EXAMPLES:

```
sage: from sage.combinat.t_sequences import base_sequences_construction
sage: X = [1,1,-1,1,-1,1,-1,1]
sage: Y = [1,-1,-1,-1,-1,-1,-1,1]
sage: Z = [1,-1,-1,1,1,1,1,-1]
sage: W = [1,1,1,-1,1,1,-1]
sage: base_sequences_construction([X, Y, Z, W])
[[1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1],
[1, -1, -1, 1, 1, 1, 1, -1, -1, -1, -1, 1, -1, -1, 1],
[1, 1, -1, 1, -1, 1, -1, 1],
[1, -1, -1, -1, -1, -1, -1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import base_sequences_construction
>>> X = [Integer(1),Integer(1),-Integer(1),Integer(1),-Integer(1),Integer(1),-
↪Integer(1),Integer(1)]
>>> Y = [Integer(1),-Integer(1),-Integer(1),-Integer(1),-Integer(1),-Integer(1),-
↪Integer(1),Integer(1)]
>>> Z = [Integer(1),-Integer(1),-Integer(1),Integer(1),Integer(1),Integer(1),
↪Integer(1),-Integer(1)]
>>> W = [Integer(1),Integer(1),Integer(1),-Integer(1),Integer(1),Integer(1),-
```

(continues on next page)

(continued from previous page)

```
↪Integer(1)]
>>> base_sequences_construction([X, Y, Z, W])
[[1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1],
[1, -1, -1, 1, 1, 1, 1, -1, -1, -1, -1, 1, -1, -1, 1],
[1, 1, -1, 1, -1, 1, -1, 1],
[1, -1, -1, -1, -1, -1, -1, 1]]
```

See also

is_base_sequences_tuple()

sage.combinat.t_sequences.**base_sequences_smallcases**(*n*, *p*, *existence=False*, *check=True*)

Construct base sequences of length $n+p, n+p, n, n$ from available data.

The function uses the construction *base_sequences_construction()*, together with Turyn type sequences from *turyn_type_sequences_smallcases()* to construct base sequences with $p = n - 1$.

Furthermore, this function uses also Turyn sequences (i.e. base sequences with $p = 1$) from *turyn_sequences_smallcases()*.

INPUT:

- n – integer; the length of the last two base sequences
- p – integer; $n + p$ will be the length of the first two base sequences
- existence – boolean (default: False); if True, the function will only check whether the base sequences can be constructed
- check – boolean (default: True); check that the resulting sequences are base sequences before returning them

OUTPUT:

If existence is False, the function returns a list containing the four base sequences, or raises an error if the base sequences cannot be constructed. If existence is True, the function returns a boolean, which is True if the base sequences can be constructed and False otherwise.

EXAMPLES:

```
sage: from sage.combinat.t_sequences import base_sequences_smallcases
sage: base_sequences_smallcases(8, 7)
[[1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1],
[1, -1, -1, 1, 1, 1, 1, -1, -1, -1, -1, 1, -1, -1, 1],
[1, 1, -1, 1, -1, 1, -1, 1],
[1, -1, -1, -1, -1, -1, -1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import base_sequences_smallcases
>>> base_sequences_smallcases(Integer(8), Integer(7))
[[1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1],
[1, -1, -1, 1, 1, 1, 1, -1, -1, -1, -1, 1, -1, -1, 1],
[1, 1, -1, 1, -1, 1, -1, 1],
[1, -1, -1, -1, -1, -1, -1, 1]]
```

If existence is True, the function returns a boolean

```
sage: base_sequences_smallcases(8, 7, existence=True)
True
sage: base_sequences_smallcases(7, 5, existence=True)
False
```

```
>>> from sage.all import *
>>> base_sequences_smallcases(Integer(8), Integer(7), existence=True)
True
>>> base_sequences_smallcases(Integer(7), Integer(5), existence=True)
False
```

sage.combinat.t_sequences.**is_T_sequences_set**(*sequences*, *verbose=False*)

Check if a family of sequences is composed of T-sequences.

Given 4 (-1, 0, +1) sequences, they will be T-sequences if (Definition 7.4 of [Seb2017]):

- they have all the same length t
- for each index i, exactly one sequence is nonzero at i
- the nonperiodic autocorrelation is equal to 0

INPUT:

- `sequences` – list of four sequences
- `verbose` – boolean (default: `False`); if `True` the function will be verbose when the sequences do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.t_sequences import is_T_sequences_set
sage: seqs = [[1, 1, 0, 0, 0], [0, 0, 1, 0, 0], [0, 0, 0, 1, -1], [0, 0, 0, 0, 0]]
sage: is_T_sequences_set(seqs)
True
sage: seqs = [[1, 1, 0, 1, 0], [0, 0, 1, 0, 0], [0, 0, 0, 1, -1], [0, 0, 0, 0, 0]]
sage: is_T_sequences_set(seqs, verbose=True)
There should be exactly a nonzero element at every index, found 2 such
 elements at index 3
False
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_T_sequences_set
>>> seqs = [[Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)],
↪[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)], [Integer(0),
↪Integer(0), Integer(0), Integer(1), -Integer(1)], [Integer(0), Integer(0),
↪Integer(0), Integer(0), Integer(0)]]
>>> is_T_sequences_set(seqs)
True
>>> seqs = [[Integer(1), Integer(1), Integer(0), Integer(1), Integer(0)],
↪[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)], [Integer(0),
↪Integer(0), Integer(0), Integer(1), -Integer(1)], [Integer(0), Integer(0),
↪Integer(0), Integer(0), Integer(0)]]
>>> is_T_sequences_set(seqs, verbose=True)
There should be exactly a nonzero element at every index, found 2 such
```

(continues on next page)

(continued from previous page)

```
 elements at index 3
False
```

sage.combinat.t_sequences.**is_base_sequences_tuple**(*base_sequences*, *verbose=False*)

Check if the given sequences are base sequences.

Four (-1, +1) sequences A, B, C, D of length $n + p, n + p, n, n$ are called base sequences if for all $j \geq 1$:

$$N_A(j) + N_B(j) + N_C(j) + N_D(j) = 0$$

where $N_X(j)$ is the nonperiodic autocorrelation (See definition in [KTR2005]).

INPUT:

- `base_sequences` – the list of 4 sequences that should be checked
- `verbose` – boolean (default: `False`); if `True` the function will be verbose when the sequences do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.t_sequences import is_base_sequences_tuple
sage: seqs = [[1, -1, -1, 1, 1, 1, 1, -1, 1, 1, 1, -1, 1, 1, -1],[1, -1, -1, 1, 1,
↪ 1, 1, -1, -1, -1, -1, 1, -1, -1, 1],[1, 1, -1, 1, -1, 1, -1, 1],[1, -1, -1, -1,
↪ -1, -1, -1, 1]]
sage: is_base_sequences_tuple(seqs)
True
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_base_sequences_tuple
>>> seqs = [[Integer(1), -Integer(1), -Integer(1), Integer(1), Integer(1),␣
↪Integer(1), Integer(1), -Integer(1), Integer(1), Integer(1), Integer(1), -
↪Integer(1), Integer(1), Integer(1), -Integer(1)],[Integer(1), -Integer(1), -
↪Integer(1), Integer(1), Integer(1), Integer(1), Integer(1), -Integer(1), -
↪Integer(1), -Integer(1), -Integer(1), Integer(1), -Integer(1), -Integer(1),␣
↪Integer(1)],[Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1),␣
↪Integer(1), -Integer(1), Integer(1)],[Integer(1), -Integer(1), -Integer(1), -
↪Integer(1), -Integer(1), -Integer(1), -Integer(1), Integer(1)]]
>>> is_base_sequences_tuple(seqs)
True
```

If verbose is true, the function will be verbose

```
sage: seqs = [[1, -1], [1, 1], [-1], [2]]
sage: is_base_sequences_tuple(seqs, verbose=True)
Base sequences should only contain -1, +1, found 2
False
```

```
>>> from sage.all import *
>>> seqs = [[Integer(1), -Integer(1)], [Integer(1), Integer(1)], [-Integer(1)],␣
↪[Integer(2)]]
>>> is_base_sequences_tuple(seqs, verbose=True)
Base sequences should only contain -1, +1, found 2
False
```

See also

base_sequences_construction()

sage.combinat.t_sequences.**is_skew**(*seq*, *verbose=False*)

Check if the given sequence is skew.

A sequence $X = \{x_1, x_2, ..., x_n\}$ is defined skew (according to Definition 7.4 of [Seb2017]) if n is even and $x_i = -x_{n-i+1}$.

INPUT:

- `seq` – the sequence that should be checked
- `verbose` – boolean (default: `False`); if `True` the function will be verbose when the sequences do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.t_sequences import is_skew
sage: is_skew([1, -1, 1, -1, 1, -1])
True
sage: is_skew([1, -1, -1, -1], verbose=True)
Constraint not satisfied at index 1
False
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_skew
>>> is_skew([Integer(1), -Integer(1), Integer(1), -Integer(1), Integer(1), -
↪Integer(1)])
True
>>> is_skew([Integer(1), -Integer(1), -Integer(1), -Integer(1)], verbose=True)
Constraint not satisfied at index 1
False
```

sage.combinat.t_sequences.**is_symmetric**(*seq*, *verbose=False*)

Check if the given sequence is symmetric.

A sequence $X = \{x_1, x_2, ..., x_n\}$ is defined symmetric (according to Definition 7.4 of [Seb2017]) if n is odd and $x_i = x_{n-i+1}$.

INPUT:

- `seq` – the sequence that should be checked
- `verbose` – boolean (default: `False`); if `True` the function will be verbose when the sequences do not satisfy the constraints

EXAMPLES:

```
sage: from sage.combinat.t_sequences import is_symmetric
sage: is_symmetric([1, -1, 1, -1, 1])
True
sage: is_symmetric([1, -1, 1, 1, 1], verbose=True)
Constraint not satisfied at index 1
False
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import is_symmetric
>>> is_symmetric([Integer(1), -Integer(1), Integer(1), -Integer(1), Integer(1)])
True
>>> is_symmetric([Integer(1), -Integer(1), Integer(1), Integer(1), Integer(1)],␣
↪verbose=True)
Constraint not satisfied at index 1
False
```

sage.combinat.t_sequences.**turyn_sequences_smallcases**(*l*, *existence=False*)

Construction of Turyn sequences for small values of l.

The data is taken from [Seb2017] and [CRSKKY1989].

INPUT:

- `l` – integer; the length of the Turyn sequences
- `existence` – boolean (default: `False`); if `True`, only return whether the Turyn sequences are available for the given length

EXAMPLES:

By default, this method returns the four Turyn sequences

```
sage: from sage.combinat.t_sequences import turyn_sequences_smallcases
sage: turyn_sequences_smallcases(4)
[[1, 1, -1, -1], [1, 1, -1, 1], [1, 1, 1], [1, -1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import turyn_sequences_smallcases
>>> turyn_sequences_smallcases(Integer(4))
[[1, 1, -1, -1], [1, 1, -1, 1], [1, 1, 1], [1, -1, 1]]
```

If we pass the `existence` flag, the method will return a boolean

```
sage: turyn_sequences_smallcases(4, existence=True)
True
```

```
>>> from sage.all import *
>>> turyn_sequences_smallcases(Integer(4), existence=True)
True
```

sage.combinat.t_sequences.**turyn_type_sequences_smallcases**(*n*, *existence=False*)

Construction of Turyn type sequences for small values of n.

The data is taken from [KTR2005] for $n = 36$, and from [BDKR2013] for $n \leq 32$.

INPUT:

- `n` – integer; the length of the Turyn type sequences
- `existence` – boolean (default: `False`); if `True`, only return whether the Turyn type sequences are available for the given length

EXAMPLES:

By default, this method returns the four Turyn type sequences

```
sage: from sage.combinat.t_sequences import turyn_type_sequences_smallcases
sage: turyn_type_sequences_smallcases(4)
[[1, 1, 1, 1], [1, 1, -1, 1], [1, 1, -1, -1], [1, -1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.t_sequences import turyn_type_sequences_smallcases
>>> turyn_type_sequences_smallcases(Integer(4))
[[1, 1, 1, 1], [1, 1, -1, 1], [1, 1, -1, -1], [1, -1, 1]]
```

If we pass the `existence` flag, the method will return a boolean

```
sage: turyn_type_sequences_smallcases(4, existence=True)
True
```

```
>>> from sage.all import *
>>> turyn_type_sequences_smallcases(Integer(4), existence=True)
True
```

ALGORITHM:

The Turyn type sequences are stored in hexadecimal format. Given n hexadecimal digits $h_1, h_2, ..., h_n$, it is possible to get the Turyn type sequences by converting each h_i $(1 \leq i \leq n-1)$ into a four digits binary number. Then, the j-th binary digit is 0 if the i-th number in the j-th sequence is 1, and it is 1 if the number in the sequence is -1.

For the n-th digit, it should be converted to a 3 digits binary number, and then the same mapping as before can be used (see also [BDKR2013]).

5.1.345 Tableaux

AUTHORS:

- Mike Hansen (2007): initial version
- Jason Bandlow (2011): updated to use Parent/Element model, and many minor fixes
- Andrew Mathas (2012-13): completed the transition to the parent/element model begun by Jason Bandlow
- Travis Scrimshaw (11-22-2012): Added tuple options, changed `*katabolism*` to `*catabolism*`. Cleaned up documentation.
- Andrew Mathas (2016-08-11): Row standard tableaux added
- Oliver Pechenik (2018): Added increasing tableaux.

This file consists of the following major classes:

Element classes:

- *Tableau*
- *SemistandardTableau*
- *StandardTableau*
- *RowStandardTableau*
- *IncreasingTableau*

Factory classes:

- *Tableaux*

- *SemistandardTableaux*
- *StandardTableaux*
- *RowStandardTableaux*
- *IncreasingTableaux*

Parent classes:

- *Tableaux_all*
- *Tableaux_size*
- *SemistandardTableaux_all* (facade class)
- *SemistandardTableaux_size*
- *SemistandardTableaux_size_inf*
- *SemistandardTableaux_size_weight*
- *SemistandardTableaux_shape*
- *SemistandardTableaux_shape_inf*
- *SemistandardTableaux_shape_weight*
- *StandardTableaux_all* (facade class)
- *StandardTableaux_size*
- *StandardTableaux_shape*
- *IncreasingTableaux_all* (facade class)
- *IncreasingTableaux_size*
- *IncreasingTableaux_size_inf*
- *IncreasingTableaux_size_weight*
- *IncreasingTableaux_shape*
- *IncreasingTableaux_shape_inf*
- *IncreasingTableaux_shape_weight*
- *RowStandardTableaux_all* (facade class)
- *RowStandardTableaux_size*
- *RowStandardTableaux_shape*

For display options, see *Tableaux.options()*.

Todo

- Move methods that only apply to semistandard tableaux from tableau to semistandard tableau
- Copy/move functionality to skew tableaux
- Add a class for tableaux of a given shape (eg Tableaux_shape)

class sage.combinat.tableau.**IncreasingTableau**(*parent*, *t*, *check=True*)

Bases: *Tableau*

A class to model an increasing tableau.

INPUT:

- t – a tableau, a list of iterables, or an empty list

An *increasing tableau* is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = IncreasingTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = IncreasingTableau(t); s
[[1, 2], [2]]
sage: IncreasingTableau([]) # The empty tableau
[]
```

```
>>> from sage.all import *
>>> t = IncreasingTableau([[Integer(1),Integer(2),Integer(3)],[Integer(2),
↪Integer(3)]]); t
[[1, 2, 3], [2, 3]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
1 2 3
2 3
>>> t = Tableau([[Integer(1),Integer(2)],[Integer(2)]])
>>> s = IncreasingTableau(t); s
[[1, 2], [2]]
>>> IncreasingTableau([]) # The empty tableau
[]
```

You can also construct an *IncreasingTableau* from the appropriate Parent object:

```
sage: IT = IncreasingTableaux()
sage: IT([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> IT = IncreasingTableaux()
>>> IT([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]])
[[1, 2, 3], [4, 5]]
```

See also

- *SemistandardTableau*
- *StandardTableaux*
- *StandardTableau*
- *IncreasingTableaux*

K_bender_knuth(*i*)

Return the i-th K-Bender-Knuth operator (as defined in [DPS2017]) applied to self.

The i-th K-Bender-Knuth operator swaps the letters i and $i + 1$ everywhere where doing so would not break increasingness.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_bender_knuth(2)
[[1, 2, 4], [3, 4, 5]]
sage: T.K_bender_knuth(3)
[[1, 3, 4], [2, 4, 5]]
```

```
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(4),Integer(5)]])
>>> T.K_bender_knuth(Integer(2))
[[1, 2, 4], [3, 4, 5]]
>>> T.K_bender_knuth(Integer(3))
[[1, 3, 4], [2, 4, 5]]
```

K_evacuation(*ceiling=None*)

Return the K-evacuation involution from [TY2009] to self.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

```
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(4),Integer(5)]])
>>> T.K_evacuation()
[[1, 2, 4], [2, 3, 5]]
>>> T.K_evacuation(Integer(6))
```

(continues on next page)

(continued from previous page)

```
[[2, 3, 5], [3, 4, 6]]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),
↪Integer(4),Integer(5)],[Integer(5)]])
>>> U.K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

K_promotion(*ceiling=None*)

Return the K-promotion operator from [Pec2014] applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion()
[[1, 2, 3], [3, 4, 5]]
sage: T.K_promotion(6)
[[1, 2, 3], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion()
[[2, 3, 4], [3, 4, 5], [4]]
```

```
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(4),Integer(5)]])
>>> T.K_promotion()
[[1, 2, 3], [3, 4, 5]]
>>> T.K_promotion(Integer(6))
[[1, 2, 3], [3, 4, 6]]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),
↪Integer(4),Integer(5)],[Integer(5)]])
>>> U.K_promotion()
[[2, 3, 4], [3, 4, 5], [4]]
```

K_promotion_inverse(*ceiling=None*)

Return the inverse of K-promotion operator applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.K_promotion_inverse()
[[1, 2, 4], [3, 4, 5]]
sage: T.K_promotion_inverse(6)
[[2, 4, 5], [3, 5, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.K_promotion_inverse()
[[1, 2, 4], [2, 4, 5], [4]]
```

```
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(4),Integer(5)]])
>>> T.K_promotion_inverse()
[[1, 2, 4], [3, 4, 5]]
>>> T.K_promotion_inverse(Integer(6))
```

(continues on next page)

(continued from previous page)

```
[[2, 4, 5], [3, 5, 6]]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),
↪Integer(4),Integer(5)],[Integer(5)]])
>>> U.K_promotion_inverse()
[[1, 2, 4], [2, 4, 5], [4]]
```

check()

Check that `self` is a valid increasing tableau.

descent_set()

Compute the descents of the increasing tableau `self` as defined in [DPS2017].

The number i is a *descent* of an increasing tableau if some instance of $i+1$ appears in a lower row than some instance of i.

> **Note**
>
> This notion is close to the notion of descent for a standard tableau but is unrelated to the notion for semistandard tableaux.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,2,4],[3,5,6]])
sage: T.descent_set()
[2, 4]
sage: U = IncreasingTableau([[1,3,4],[2,4,5]])
sage: U.descent_set()
[1, 3, 4]
sage: V = IncreasingTableau([[1,3,4],[3,4,5],[4,5]])
sage: V.descent_set()
[3, 4]
```

```
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(2),Integer(4)],[Integer(3),
↪Integer(5),Integer(6)]])
>>> T.descent_set()
[2, 4]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(4),Integer(5)]])
>>> U.descent_set()
[1, 3, 4]
>>> V = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),
↪Integer(4),Integer(5)],[Integer(4),Integer(5)]])
>>> V.descent_set()
[3, 4]
```

dual_K_evacuation(*ceiling=None*)

Return the dual K-evacuation involution applied to `self`.

EXAMPLES:

```
sage: T = IncreasingTableau([[1,3,4],[2,4,5]])
sage: T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
sage: T.dual_K_evacuation(6)
[[2, 3, 5], [3, 4, 6]]
sage: U = IncreasingTableau([[1,3,4],[3,4,5],[5]])
sage: U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

```
>>> from sage.all import *
>>> T = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(4),Integer(5)]])
>>> T.dual_K_evacuation()
[[1, 2, 4], [2, 3, 5]]
>>> T.dual_K_evacuation(Integer(6))
[[2, 3, 5], [3, 4, 6]]
>>> U = IncreasingTableau([[Integer(1),Integer(3),Integer(4)],[Integer(3),
↪Integer(4),Integer(5)],[Integer(5)]])
>>> U.dual_K_evacuation()
[[1, 2, 3], [2, 3, 5], [3]]
```

class sage.combinat.tableau.**IncreasingTableaux**(***kwds*)

Bases: `Tableaux`

A factory class for the various classes of increasing tableaux.

An *increasing tableau* is a tableau whose entries are positive integers that are strictly increasing across rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

INPUT:

Keyword arguments:

- `size` – the size of the tableaux
- `shape` – the shape of the tableaux
- `eval` – the weight (also called binary content) of the tableaux, where values can be either 0 or 1 with position i being 1 if and only if i can appear in the tableaux
- `max_entry` – positive integer or infinity (`oo`); the maximum entry for the tableaux; if `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`

Positional arguments:

- the first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition
- the second keyword argument will always be interpreted as `eval`

Warning

The `eval` is not the usual notion of `eval` or `weight`, where the i-th entry counts how many i's appear in the tableau.

EXAMPLES:

```
sage: IT = IncreasingTableaux([2,1]); IT
Increasing tableaux of shape [2, 1] and maximum entry 3
sage: IT.list()
[[[1, 3], [2]], [[1, 2], [3]], [[1, 2], [2]], [[1, 3], [3]], [[2, 3], [3]]]

sage: IT = IncreasingTableaux(3); IT
Increasing tableaux of size 3 and maximum entry 3
sage: IT.list()
[[[1, 2, 3]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 2], [2]],
 [[1, 3], [3]],
 [[2, 3], [3]],
 [[1], [2], [3]]]

sage: IT = IncreasingTableaux(3, max_entry=2); IT
Increasing tableaux of size 3 and maximum entry 2
sage: IT.list()
[[[1, 2], [2]]]

sage: IT = IncreasingTableaux(3, max_entry=4); IT
Increasing tableaux of size 3 and maximum entry 4
sage: IT.list()
[[[1, 2, 3]],
 [[1, 2, 4]],
 [[1, 3, 4]],
 [[2, 3, 4]],
 [[1, 3], [2]],
 [[1, 2], [3]],
 [[1, 4], [2]],
 [[1, 2], [4]],
 [[1, 2], [2]],
 [[1, 4], [3]],
 [[1, 3], [4]],
 [[1, 3], [3]],
 [[1, 4], [4]],
 [[2, 4], [3]],
 [[2, 3], [4]],
 [[2, 3], [3]],
 [[2, 4], [4]],
 [[3, 4], [4]],
 [[1], [2], [3]],
 [[1], [2], [4]],
 [[1], [3], [4]],
 [[2], [3], [4]]]

sage: IT = IncreasingTableaux(3, max_entry=oo); IT
Increasing tableaux of size 3
sage: IT[123]
[[5, 7], [6]]

sage: IT = IncreasingTableaux(max_entry=2)
```

(continues on next page)

(continued from previous page)

```
sage: list(IT)
[[], [[1]], [[2]], [[1, 2]], [[1], [2]]]
sage: IT[4]
[[1], [2]]

sage: IncreasingTableaux()[0]
[]
```

```
>>> from sage.all import *

 [[2, 3], [3]],
 [[1], [2], [3]]]
```

class sage.combinat.tableau.**IncreasingTableaux_shape**(*p*, *max_entry=None*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed shape p with a given max entry.

An increasing tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

INPUT:

- p – a partition
- max_entry – the max entry; defaults to the size of p

class sage.combinat.tableau.**IncreasingTableaux_shape_inf**(*p*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed shape p and no maximum entry.

class sage.combinat.tableau.**IncreasingTableaux_shape_weight**(*p*, *wt*)

Bases: *IncreasingTableaux_shape*

Increasing tableaux of fixed shape p and binary weight wt.

class sage.combinat.tableau.**IncreasingTableaux_size**(*n*, *max_entry=None*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed size n.

class sage.combinat.tableau.**IncreasingTableaux_size_inf**(*n*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed size n with no maximum entry.

class sage.combinat.tableau.**IncreasingTableaux_size_weight**(*n*, *wt*)

Bases: *IncreasingTableaux*

Increasing tableaux of fixed size n and weight wt.

class sage.combinat.tableau.**RowStandardTableau**(*parent*, *t*, *check=True*)

Bases: *Tableau*

A class to model a row standard tableau.

A row standard tableau is a tableau whose entries are positive integers from 1 to m that increase along rows.

INPUT:

- t – a Tableau, a list of iterables, or an empty list

EXAMPLES:

```
sage: t = RowStandardTableau([[3,4,5],[1,2]]); t
[[3, 4, 5], [1, 2]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
3  4  5
1  2
sage: t.is_standard()
False
sage: RowStandardTableau([]) # The empty tableau
[]
sage: RowStandardTableau([[3,4,5],[1,2]]) in StandardTableaux()
False
sage: RowStandardTableau([[1,2,5],[3,4]]) in StandardTableaux()
True
```

```
>>> from sage.all import *
>>> t = RowStandardTableau([[Integer(3),Integer(4),Integer(5)],[Integer(1),
↪Integer(2)]]); t
[[3, 4, 5], [1, 2]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
3  4  5
```

(continues on next page)

(continued from previous page)

```
1  2
>>> t.is_standard()
False
>>> RowStandardTableau([]) # The empty tableau
[]
>>> RowStandardTableau([[Integer(3),Integer(4),Integer(5)],[Integer(1),
↪Integer(2)]]) in StandardTableaux()
False
>>> RowStandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),
↪Integer(4)]]) in StandardTableaux()
True
```

When using code that will generate a lot of tableaux, it is more efficient to construct a `RowStandardTableau` from the appropriate `Parent` object:

```
sage: ST = RowStandardTableaux()
sage: ST([[3, 4, 5], [1, 2]])
[[3, 4, 5], [1, 2]]
```

```
>>> from sage.all import *
>>> ST = RowStandardTableaux()
>>> ST([[Integer(3), Integer(4), Integer(5)], [Integer(1), Integer(2)]])
[[3, 4, 5], [1, 2]]
```

check()

Check that `self` is a valid row standard tableau.

class sage.combinat.tableau.**RowStandardTableaux**

Bases: `Tableaux`

A factory for the various classes of row standard tableaux.

INPUT:

- either a nonnegative integer (possibly specified with the keyword `n`) or a partition

OUTPUT: with no argument, the class of all standard tableaux

- with a nonnegative integer argument, `n`, the class of all standard tableaux of size `n`
- with a partition argument, the class of all standard tableaux of that shape

A row standard tableau is a tableau that contains each of the entries from 1 to n exactly once and is increasing along rows.

All classes of row standard tableaux are iterable.

EXAMPLES:

```
sage: ST = RowStandardTableaux(3); ST
Row standard tableaux of size 3
sage: ST.first()                                                            #␣
↪needs sage.graphs
[[1, 2, 3]]
sage: ST.last()                                                             #␣
↪needs sage.graphs sage.modules
[[3], [1], [2]]
sage: ST.cardinality()                                                      #␣
↪needs sage.graphs sage.modules
10
sage: ST.list()                                                             #␣

Element

alias of *RowStandardTableau*

class sage.combinat.tableau.**RowStandardTableaux_all**

Bases: *RowStandardTableaux*, DisjointUnionEnumeratedSets

All row standard tableaux.

class sage.combinat.tableau.**RowStandardTableaux_shape**(*p*)

Bases: *RowStandardTableaux*

Row Standard tableaux of a fixed shape p.

cardinality()

Return the number of row standard tableaux of this shape.

This is just the index of the corresponding Young subgroup in the full symmetric group.

EXAMPLES:

```
sage: RowStandardTableaux([3,2,1]).cardinality()
60
sage: RowStandardTableaux([2,2]).cardinality()
6
sage: RowStandardTableaux([5]).cardinality()
1
sage: RowStandardTableaux([6,5,5,3]).cardinality()
1955457504
sage: RowStandardTableaux([]).cardinality()
1
```

```
>>> from sage.all import *
>>> RowStandardTableaux([Integer(3),Integer(2),Integer(1)]).cardinality()
60
>>> RowStandardTableaux([Integer(2),Integer(2)]).cardinality()
6
>>> RowStandardTableaux([Integer(5)]).cardinality()
1
>>> RowStandardTableaux([Integer(6),Integer(5),Integer(5),Integer(3)]).
```

(continues on next page)

(continued from previous page)

```
↪cardinality()
1955457504
>>> RowStandardTableaux([]).cardinality()
1
```

class sage.combinat.tableau.**RowStandardTableaux_size**(*n*)

Bases: *RowStandardTableaux*, DisjointUnionEnumeratedSets

Row standard tableaux of fixed size n.

EXAMPLES:

```
sage: [t for t in RowStandardTableaux(1)]                                   #␣
↪needs sage.graphs
[[[1]]]
sage: [t for t in RowStandardTableaux(2)]                                   #␣
↪needs sage.graphs
[[[1, 2]], [[2], [1]], [[1], [2]]]
sage: list(RowStandardTableaux(3))                                          #␣
↪needs sage.graphs
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

```
>>> from sage.all import *
>>> [t for t in RowStandardTableaux(Integer(1))]                            ␣
↪     # needs sage.graphs
[[[1]]]
>>> [t for t in RowStandardTableaux(Integer(2))]                            ␣
↪     # needs sage.graphs
[[[1, 2]], [[2], [1]], [[1], [2]]]
>>> list(RowStandardTableaux(Integer(3)))                                   ␣
↪     # needs sage.graphs
[[[1, 2, 3]],
 [[2, 3], [1]],
 [[1, 2], [3]],
 [[1, 3], [2]],
 [[3], [2], [1]],
 [[2], [3], [1]],
 [[1], [3], [2]],
 [[1], [2], [3]],
 [[2], [1], [3]],
 [[3], [1], [2]]]
```

an_element()

Return a particular element of the class.

EXAMPLES:

```
sage: RowStandardTableaux(4).an_element()
[[1, 2, 3, 4]]
```

```
>>> from sage.all import *
>>> RowStandardTableaux(Integer(4)).an_element()
[[1, 2, 3, 4]]
```

class sage.combinat.tableau.**SemistandardTableau**(*parent*, *t*, *check=True*)

Bases: *Tableau*

A class to model a semistandard tableau.

INPUT:

- t – a tableau, a list of iterables, or an empty list

OUTPUT: a SemistandardTableau object constructed from t

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns.

EXAMPLES:

```
sage: t = SemistandardTableau([[1,2,3],[2,3]]); t
[[1, 2, 3], [2, 3]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
2 3
sage: t = Tableau([[1,2],[2]])
sage: s = SemistandardTableau(t); s
[[1, 2], [2]]
sage: SemistandardTableau([]) # The empty tableau
[]
```

```
>>> from sage.all import *
>>> t = SemistandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(2),
→Integer(3)]]); t
[[1, 2, 3], [2, 3]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
1 2 3
2 3
>>> t = Tableau([[Integer(1),Integer(2)],[Integer(2)]])
>>> s = SemistandardTableau(t); s
[[1, 2], [2]]
>>> SemistandardTableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a SemistandardTableau from the appropriate Parent object:

```
sage: SST = SemistandardTableaux()
sage: SST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> SST = SemistandardTableaux()
>>> SST([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]])
[[1, 2, 3], [4, 5]]
```

See also

- *Tableaux*

- *SemistandardTableaux*
- *StandardTableaux*
- *StandardTableau*

check()

Check that `self` is a valid semistandard tableau.

class sage.combinat.tableau.**SemistandardTableaux**(***kwds*)

Bases: *Tableaux*

A factory class for the various classes of semistandard tableaux.

INPUT:

Keyword arguments:

- `size` – the size of the tableaux
- `shape` – the shape of the tableaux
- `eval` – the weight (also called content or evaluation) of the tableaux
- `max_entry` – a maximum entry for the tableaux. This can be a positive integer or infinity (`oo`). If `size` or `shape` are specified, `max_entry` defaults to be `size` or the size of `shape`.

Positional arguments:

- The first argument is interpreted as either `size` or `shape` according to whether it is an integer or a partition
- The second keyword argument will always be interpreted as `eval`

OUTPUT:

- The appropriate class, after checking basic consistency tests. (For example, specifying `eval` implies a value for `max_entry`).

A semistandard tableau is a tableau whose entries are positive integers, which are weakly increasing in rows and strictly increasing down columns. Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

Classes of semistandard tableaux can be iterated over if and only if there is some restriction.

EXAMPLES:

```
sage: SST = SemistandardTableaux([2,1]); SST
Semistandard tableaux of shape [2, 1] and maximum entry 3
sage: SST.list()                                                          #␣

- *StandardTableau*

Element

alias of *SemistandardTableau*

class sage.combinat.tableau.**SemistandardTableaux_all**(*max_entry=None*)

Bases: *SemistandardTableaux*, DisjointUnionEnumeratedSets

All semistandard tableaux.

list()

class sage.combinat.tableau.**SemistandardTableaux_shape**(*p*, *max_entry=None*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed shape p with a given max entry.

A semistandard tableau with max entry i is required to have all its entries less or equal to i. It is not required to actually contain an entry i.

INPUT:

- `p` – a partition
- `max_entry` – the max entry; defaults to the size of p

cardinality(*algorithm='hook'*)

Return the cardinality of `self`.

INPUT:

- `algorithm` – (default: `'hook'`) any one of the following:
  - `'hook'` – use Stanley's hook length formula
  - `'sum'` – sum over the compositions of `max_entry` the number of semistandard tableau with `shape` and given weight vector

This is computed using *Stanley's hook length formula*:

$$f_{\lambda} = \prod_{u \in \lambda} \frac{n + c(u)}{h(u)}.$$

where n is the `max_entry`, $c(u)$ is the content of u, and $h(u)$ is the hook length of u. See [Sta-EC2] Corollary 7.21.4.

EXAMPLES:

>>> ssts = [SemistandardTableaux(p, max_entry=Integer(6)) for p in␣
↪Partitions(Integer(5))]
>>> all(sst.cardinality() == sst.cardinality(algorithm='sum')          #␣
↪needs sage.modules
...     for sst in ssts)
True
```

random_element()

Return a uniformly distributed random tableau of the given `shape` and `max_entry`.

Uses the algorithm from [Kra1999] based on the Novelli-Pak-Stoyanovskii bijection
http://www.sciencedirect.com/science/article/pii/0012365X9290368P

EXAMPLES:

```
sage: S = SemistandardTableaux([2, 2, 1, 1])
sage: S.random_element() in S
True
sage: S = SemistandardTableaux([2, 2, 1, 1], max_entry=7)
sage: S.random_element() in S
True
```

```
>>> from sage.all import *
>>> S = SemistandardTableaux([Integer(2), Integer(2), Integer(1), Integer(1)])
>>> S.random_element() in S
True
>>> S = SemistandardTableaux([Integer(2), Integer(2), Integer(1), Integer(1)],
↪ max_entry=Integer(7))
>>> S.random_element() in S
True
```

class sage.combinat.tableau.**SemistandardTableaux_shape_inf**(*p*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed shape p and no maximum entry.

class sage.combinat.tableau.**SemistandardTableaux_shape_weight**(*p*, *mu*)

Bases: *SemistandardTableaux_shape*

Semistandard tableaux of fixed shape p and weight μ.

cardinality()

Return the number of semistandard tableaux of the given shape and weight, as computed by `kostka_number` function of `symmetrica`.

EXAMPLES:

```
sage: # needs sage.modules
sage: SemistandardTableaux([2,2], [2, 1, 1]).cardinality()
```

(continues on next page)

(continued from previous page)

```
1
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).cardinality()
1
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).cardinality()
1
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).cardinality()
2
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> SemistandardTableaux([Integer(2),Integer(2)], [Integer(2), Integer(1),
↪Integer(1)]).cardinality()
1
>>> SemistandardTableaux([Integer(2),Integer(2),Integer(2)], [Integer(2),
↪Integer(2), Integer(1),Integer(1)]).cardinality()
1
>>> SemistandardTableaux([Integer(2),Integer(2),Integer(2)], [Integer(2),
↪Integer(2), Integer(2)]).cardinality()
1
>>> SemistandardTableaux([Integer(3),Integer(2),Integer(1)], [Integer(2),
↪Integer(2), Integer(2)]).cardinality()
2
```

list()

Return a list of all semistandard tableaux in `self` generated by symmetrica.

EXAMPLES:

```
sage: # needs sage.modules
sage: SemistandardTableaux([2,2], [2, 1, 1]).list()
[[[1, 1], [2, 3]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 1,1]).list()
[[[1, 1], [2, 2], [3, 4]]]
sage: SemistandardTableaux([2,2,2], [2, 2, 2]).list()
[[[1, 1], [2, 2], [3, 3]]]
sage: SemistandardTableaux([3,2,1], [2, 2, 2]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> SemistandardTableaux([Integer(2),Integer(2)], [Integer(2), Integer(1),
↪Integer(1)]).list()
[[[1, 1], [2, 3]]]
>>> SemistandardTableaux([Integer(2),Integer(2),Integer(2)], [Integer(2),
↪Integer(2), Integer(1),Integer(1)]).list()
[[[1, 1], [2, 2], [3, 4]]]
>>> SemistandardTableaux([Integer(2),Integer(2),Integer(2)], [Integer(2),
↪Integer(2), Integer(2)]).list()
[[[1, 1], [2, 2], [3, 3]]]
>>> SemistandardTableaux([Integer(3),Integer(2),Integer(1)], [Integer(2),
↪Integer(2), Integer(2)]).list()
[[[1, 1, 2], [2, 3], [3]], [[1, 1, 3], [2, 2], [3]]]
```

class sage.combinat.tableau.**SemistandardTableaux_size**(*n*, *max_entry=None*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed size n.

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: SemistandardTableaux(3).cardinality()
19
sage: SemistandardTableaux(4).cardinality()
116
sage: SemistandardTableaux(4, max_entry=2).cardinality()
9
sage: SemistandardTableaux(4, max_entry=10).cardinality()
4225
sage: ns = list(range(1, 6))
sage: ssts = [ SemistandardTableaux(n) for n in ns ]
sage: all(sst.cardinality() == len(sst.list()) for sst in ssts)              #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> SemistandardTableaux(Integer(3)).cardinality()
19
>>> SemistandardTableaux(Integer(4)).cardinality()
116
>>> SemistandardTableaux(Integer(4), max_entry=Integer(2)).cardinality()
9
>>> SemistandardTableaux(Integer(4), max_entry=Integer(10)).cardinality()
4225
>>> ns = list(range(Integer(1), Integer(6)))
>>> ssts = [ SemistandardTableaux(n) for n in ns ]
>>> all(sst.cardinality() == len(sst.list()) for sst in ssts)              #␣
↪needs sage.modules
True
```

random_element()

Generate a random *SemistandardTableau* with uniform probability.

The RSK algorithm gives a bijection between symmetric $k \times k$ matrices of nonnegative integers that sum to n and semistandard tableaux with size n and maximum entry k.

The number of $k \times k$ symmetric matrices of nonnegative integers having sum of elements on the diagonal i and sum of elements above the diagonal j is $\binom{k+i-1}{k-1}\binom{\binom{k}{2}+j-1}{\binom{k}{2}-1}$. We first choose the sum of the elements on the diagonal randomly weighted by the number of matrices having that trace. We then create random integer vectors of length k having that sum and use them to generate a $k \times k$ diagonal matrix. Then we take a random integer vector of length $\binom{k}{2}$ summing to half the remainder and distribute it symmetrically to the remainder of the matrix.

Applying RSK to the random symmetric matrix gives us a pair of identical *SemistandardTableau* of which we choose the first.

EXAMPLES:

```
sage: SemistandardTableaux(6).random_element()   # random                     #␣
↪needs sage.modules
[[1, 1, 2], [3, 5, 5]]
sage: SemistandardTableaux(6, max_entry=7).random_element()   # random        #␣
↪needs sage.modules
[[2, 4, 4, 6, 6, 6]]
```

```
>>> from sage.all import *
>>> SemistandardTableaux(Integer(6)).random_element()   # random              ␣
↪     # needs sage.modules
[[1, 1, 2], [3, 5, 5]]
>>> SemistandardTableaux(Integer(6), max_entry=Integer(7)).random_element()
↪# random       # needs sage.modules
[[2, 4, 4, 6, 6, 6]]
```

class sage.combinat.tableau.**SemistandardTableaux_size_inf**(*n*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed size n with no maximum entry.

list()

class sage.combinat.tableau.**SemistandardTableaux_size_weight**(*n*, *mu*)

Bases: *SemistandardTableaux*

Semistandard tableaux of fixed size n and weight μ.

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
sage: SemistandardTableaux(3, [2,1]).cardinality()                            #␣
↪needs sage.modules
2
sage: SemistandardTableaux(4, [2,2]).cardinality()                            #␣
↪needs sage.modules
3
```

```
>>> from sage.all import *
>>> SemistandardTableaux(Integer(3), [Integer(2),Integer(1)]).cardinality()  ␣
↪                       # needs sage.modules
2
>>> SemistandardTableaux(Integer(4), [Integer(2),Integer(2)]).cardinality()  ␣
↪                       # needs sage.modules
3
```

class sage.combinat.tableau.**StandardTableau**(*parent*, *t*, *check=True*)

Bases: *SemistandardTableau*

A class to model a standard tableau.

INPUT:

- `t` – a Tableau, a list of iterables, or an empty list

A standard tableau is a semistandard tableau whose entries are exactly the positive integers from 1 to n, where n is the size of the tableau.

EXAMPLES:

```
sage: t = StandardTableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
sage: t.is_standard()
True
sage: StandardTableau([]) # The empty tableau
[]
sage: StandardTableau([[1,2,3],[4,5]]) in RowStandardTableaux()
True
```

```
>>> from sage.all import *
>>> t = StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5)]]); t
[[1, 2, 3], [4, 5]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
1 2 3
4 5
>>> t.is_standard()
True
>>> StandardTableau([]) # The empty tableau
[]
>>> StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]])␣
↪in RowStandardTableaux()
True
```

When using code that will generate a lot of tableaux, it is more efficient to construct a StandardTableau from the appropriate `Parent` object:

```
sage: ST = StandardTableaux()
sage: ST([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> ST = StandardTableaux()
>>> ST([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]])
[[1, 2, 3], [4, 5]]
```

See also

- *Tableaux*
- *Tableau*

- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableaux*

check()

Check that `self` is a standard tableau.

dominates(*t*)

Return `True` if `self` dominates the tableau `t`.

That is, if the shape of the tableau restricted to k dominates the shape of `t` restricted to k, for $k = 1, 2, \ldots, n$.

When the two tableaux have the same shape, then this ordering coincides with the Bruhat ordering for the corresponding permutations.

INPUT:

- `t` – a tableau

EXAMPLES:

```
sage: s = StandardTableau([[1,2,3],[4,5]])
sage: t = StandardTableau([[1,2],[3,5],[4]])
sage: s.dominates(t)
True
sage: t.dominates(s)
False
sage: all(StandardTableau(s).dominates(t) for t in StandardTableaux([3,2]))
True
sage: s.dominates([[1,2,3,4,5]])
False
```

```
>>> from sage.all import *
>>> s = StandardTableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5)]])
>>> t = StandardTableau([[Integer(1),Integer(2)],[Integer(3),Integer(5)],
↪[Integer(4)]])
>>> s.dominates(t)
True
>>> t.dominates(s)
False
>>> all(StandardTableau(s).dominates(t) for t in StandardTableaux([Integer(3),
↪Integer(2)]))
True
>>> s.dominates([[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]])
False
```

down()

An iterator for all the standard tableaux that can be obtained from `self` by removing a cell. Note that this iterates just over a single tableau (or nothing if `self` is empty).

EXAMPLES:

```
sage: t = StandardTableau([[1,2],[3]])
sage: [x for x in t.down()]
[[[1, 2]]]
sage: t = StandardTableau([])
sage: [x for x in t.down()]
[]
```

```
>>> from sage.all import *
>>> t = StandardTableau([[Integer(1),Integer(2)],[Integer(3)]])
>>> [x for x in t.down()]
[[[1, 2]]]
>>> t = StandardTableau([])
>>> [x for x in t.down()]
[]
```

down_list()

Return a list of all the standard tableaux that can be obtained from `self` by removing a cell. Note that this is just a singleton list if `self` is nonempty, and an empty list otherwise.

EXAMPLES:

```
sage: t = StandardTableau([[1,2],[3]])
sage: t.down_list()
[[[1, 2]]]
sage: t = StandardTableau([])
sage: t.down_list()
[]
```

```
>>> from sage.all import *
>>> t = StandardTableau([[Integer(1),Integer(2)],[Integer(3)]])
>>> t.down_list()
[[[1, 2]]]
>>> t = StandardTableau([])
>>> t.down_list()
[]
```

is_standard()

Return `True` since `self` is a standard tableau.

EXAMPLES:

```
sage: StandardTableau([[1, 3], [2, 4]]).is_standard()
True
```

```
>>> from sage.all import *
>>> StandardTableau([[Integer(1), Integer(3)], [Integer(2), Integer(4)]]).is_
↪standard()
True
```

promotion(*n=None*)

Return the image of `self` under the promotion operator.

The promotion operator, applied to a standard tableau t, does the following:

Remove the letter n from t, thus leaving a hole where it used to be. Apply jeu de taquin to move this hole southwest (in French notation) until it reaches the inner boundary of t. Fill 0 into the hole once jeu de taquin has completed. Finally, add 1 to each letter in the tableau. The resulting standard tableau is the image of t under the promotion operator.

This definition of promotion is precisely the one given in [Hai1992] (p. 90). It is the inverse of the maps called "promotion" in [Sag2011] (p. 23) and in [Stan2009].

See the `promotion()` method for a more general operator.

EXAMPLES:

```
sage: ST = StandardTableaux(7)
sage: all( st.promotion().promotion_inverse() == st for st in ST ) # long time
True
sage: all( st.promotion_inverse().promotion() == st for st in ST ) # long time
True
sage: st = StandardTableau([[1,2,5],[3,4]])
sage: parent(st.promotion())
Standard tableaux
```

```
>>> from sage.all import *
>>> ST = StandardTableaux(Integer(7))
>>> all( st.promotion().promotion_inverse() == st for st in ST ) # long time
True
>>> all( st.promotion_inverse().promotion() == st for st in ST ) # long time
True
>>> st = StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),
↪Integer(4)]])
>>> parent(st.promotion())
Standard tableaux
```

promotion_inverse(*n=None*)

Return the image of `self` under the inverse promotion operator. The optional variable m should be set to the size of `self` minus 1 for a minimal speedup; otherwise, it defaults to this number.

The inverse promotion operator, applied to a standard tableau t, does the following:

Remove the letter 1 from t, thus leaving a hole where it used to be. Apply jeu de taquin to move this hole northeast (in French notation) until it reaches the outer boundary of t. Fill $n + 1$ into this hole, where n is the size of t. Finally, subtract 1 from each letter in the tableau. This yields a new standard tableau.

This definition of inverse promotion is the map called "promotion" in [Sag2011] (p. 23) and in [Stan2009], and is the inverse of the map called "promotion" in [Hai1992] (p. 90).

See the `promotion_inverse()` method for a more general operator.

EXAMPLES:

```
sage: t = StandardTableau([[1,3],[2,4]])
sage: t.promotion_inverse()
[[1, 2], [3, 4]]
```

```
>>> from sage.all import *
>>> t = StandardTableau([[Integer(1),Integer(3)],[Integer(2),Integer(4)]])
>>> t.promotion_inverse()
[[1, 2], [3, 4]]
```

We check the equivalence of two definitions of inverse promotion on standard tableaux:

```
sage: ST = StandardTableaux(7)
sage: def bk_promotion_inverse7(st):
....:     st2 = st
....:     for i in range(1, 7):
....:         st2 = st2.bender_knuth_involution(i, check=False)
....:     return st2
sage: all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST )
↪# long time
True
```

```
>>> from sage.all import *
>>> ST = StandardTableaux(Integer(7))
>>> def bk_promotion_inverse7(st):
...     st2 = st
...     for i in range(Integer(1), Integer(7)):
...         st2 = st2.bender_knuth_involution(i, check=False)
...     return st2
>>> all( bk_promotion_inverse7(st) == st.promotion_inverse() for st in ST ) #␣
↪long time
True
```

standard_descents()

Return a list of the integers i such that i appears strictly further north than $i + 1$ in `self` (this is not to say that i and $i + 1$ must be in the same column). The list is sorted in increasing order.

EXAMPLES:

```
sage: StandardTableau( [[1,3,4],[2,5]] ).standard_descents()
[1, 4]
sage: StandardTableau( [[1,2],[3,4]] ).standard_descents()
[2]
sage: StandardTableau( [[1,2,5],[3,4],[6,7],[8],[9]] ).standard_descents()
[2, 5, 7, 8]
sage: StandardTableau( [] ).standard_descents()
[]
```

```
>>> from sage.all import *
>>> StandardTableau( [[Integer(1),Integer(3),Integer(4)],[Integer(2),
↪Integer(5)]] ).standard_descents()
[1, 4]
>>> StandardTableau( [[Integer(1),Integer(2)],[Integer(3),Integer(4)]] ).
↪standard_descents()
[2]
>>> StandardTableau( [[Integer(1),Integer(2),Integer(5)],[Integer(3),
↪Integer(4)],[Integer(6),Integer(7)],[Integer(8)],[Integer(9)]] ).standard_
↪descents()
[2, 5, 7, 8]
>>> StandardTableau( [] ).standard_descents()
[]
```

standard_major_index()

Return the major index of the standard tableau `self` in the standard meaning of the word. The major index is defined to be the sum of the descents of `self` (see *standard_descents()* for their definition).

EXAMPLES:

```
sage: StandardTableau( [[1,4,5],[2,6],[3]] ).standard_major_index()
8
sage: StandardTableau( [[1,2],[3,4]] ).standard_major_index()
2
sage: StandardTableau( [[1,2,3],[4,5]] ).standard_major_index()
3
```

```
>>> from sage.all import *
>>> StandardTableau( [[Integer(1),Integer(4),Integer(5)],[Integer(2),
↪Integer(6)],[Integer(3)]] ).standard_major_index()
8
>>> StandardTableau( [[Integer(1),Integer(2)],[Integer(3),Integer(4)]] ).
↪standard_major_index()
2
>>> StandardTableau( [[Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5)]] ).standard_major_index()
3
```

standard_number_of_descents()

Return the number of all integers i such that i appears strictly further north than $i + 1$ in `self` (this is not to say that i and $i + 1$ must be in the same column). A list of these integers can be obtained using the *standard_descents()* method.

EXAMPLES:

```
sage: StandardTableau( [[1,2],[3,4],[5]] ).standard_number_of_descents()
2
sage: StandardTableau( [] ).standard_number_of_descents()
0
sage: tabs = StandardTableaux(5)
sage: all( t.standard_number_of_descents() == t.schuetzenberger_involution().
↪standard_number_of_descents() for t in tabs )
True
```

```
>>> from sage.all import *
>>> StandardTableau( [[Integer(1),Integer(2)],[Integer(3),Integer(4)],
↪[Integer(5)]] ).standard_number_of_descents()
2
>>> StandardTableau( [] ).standard_number_of_descents()
0
>>> tabs = StandardTableaux(Integer(5))
>>> all( t.standard_number_of_descents() == t.schuetzenberger_involution().
↪standard_number_of_descents() for t in tabs )
True
```

up()

An iterator for all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

```
>>> from sage.all import *
>>> t = StandardTableau([[Integer(1),Integer(2)]])
>>> [x for x in t.up()]
[[[1, 2, 3]], [[1, 2], [3]]]
```

up_list()

Return a list of all the standard tableaux that can be obtained from `self` by adding a cell.

EXAMPLES:

```
sage: t = StandardTableau([[1,2]])
sage: t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

```
>>> from sage.all import *
>>> t = StandardTableau([[Integer(1),Integer(2)]])
>>> t.up_list()
[[[1, 2, 3]], [[1, 2], [3]]]
```

class sage.combinat.tableau.**StandardTableaux**(***kwds*)

Bases: *SemistandardTableaux*

A factory for the various classes of standard tableaux.

INPUT:

- Either a nonnegative integer (possibly specified with the keyword `n`) or a partition.

OUTPUT: with no argument, the class of all standard tableaux

- With a nonnegative integer argument, `n`, the class of all standard tableaux of size `n`
- With a partition argument, the class of all standard tableaux of that shape.

A standard tableau is a semistandard tableaux which contains each of the entries from 1 to `n` exactly once.

All classes of standard tableaux are iterable.

EXAMPLES:

```
sage: ST = StandardTableaux(3); ST
Standard tableaux of size 3
sage: ST.first()
[[1, 2, 3]]
sage: ST.last()
[[1], [2], [3]]
sage: ST.cardinality()
4
sage: ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
```

```
>>> from sage.all import *
>>> ST = StandardTableaux(Integer(3)); ST
Standard tableaux of size 3
>>> ST.first()
[[1, 2, 3]]
>>> ST.last()
[[1], [2], [3]]
>>> ST.cardinality()
4
>>> ST.list()
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
```

See also:

- *Tableaux*
- *Tableau*
- *SemistandardTableaux*
- *SemistandardTableau*
- *StandardTableau*
- *StandardSkewTableaux*

Element

alias of *StandardTableau*

class sage.combinat.tableau.**StandardTableaux_all**

Bases: *StandardTableaux*, DisjointUnionEnumeratedSets

All standard tableaux.

class sage.combinat.tableau.**StandardTableaux_shape**(*p*)

Bases: *StandardTableaux*

Semistandard tableaux of a fixed shape p.

cardinality()

Return the number of standard Young tableaux of this shape.

This method uses the so-called *hook length formula*, a formula for the number of Young tableaux associated with a given partition. The formula says the following: Let λ be a partition. For each cell c of the Young diagram of λ, let the *hook length* of c be defined as 1 plus the number of cells horizontally to the right of c plus the number of cells vertically below c. The number of standard Young tableaux of shape λ is then $n!$ divided by the product of the hook lengths of the shape of λ, where $n = |\lambda|$.

For example, consider the partition `[3,2,1]` of `6` with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with their respective hook lengths, we obtain:

```
5 3 1
3 1
1
```

The hook length formula returns

$$\frac{6!}{5 \cdot 3 \cdot 1 \cdot 3 \cdot 1 \cdot 1} = 16.$$

EXAMPLES:

```
sage: StandardTableaux([3,2,1]).cardinality()
16
sage: StandardTableaux([2,2]).cardinality()
2
sage: StandardTableaux([5]).cardinality()
1
sage: StandardTableaux([6,5,5,3]).cardinality()
6651216
sage: StandardTableaux([]).cardinality()
1
```

```
>>> from sage.all import *
>>> StandardTableaux([Integer(3),Integer(2),Integer(1)]).cardinality()
16
>>> StandardTableaux([Integer(2),Integer(2)]).cardinality()
2
>>> StandardTableaux([Integer(5)]).cardinality()
1
>>> StandardTableaux([Integer(6),Integer(5),Integer(5),Integer(3)]).
↪cardinality()
6651216
>>> StandardTableaux([]).cardinality()
1
```

REFERENCES:

- http://mathworld.wolfram.com/HookLengthFormula.html

list()

Return a list of the standard Young tableaux of the specified shape.

EXAMPLES:

```
sage: StandardTableaux([2,2]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
sage: StandardTableaux([5]).list()
[[[1, 2, 3, 4, 5]]]
sage: StandardTableaux([3,2,1]).list()
[[[1, 4, 6], [2, 5], [3]],
 [[1, 3, 6], [2, 5], [4]],
 [[1, 2, 6], [3, 5], [4]],
 [[1, 3, 6], [2, 4], [5]],
 [[1, 2, 6], [3, 4], [5]],
 [[1, 4, 5], [2, 6], [3]],
```

(continues on next page)

(continued from previous page)

```
 [[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 3, 4], [2, 6], [5]],
 [[1, 2, 4], [3, 6], [5]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 3, 5], [2, 4], [6]],
 [[1, 2, 5], [3, 4], [6]],
 [[1, 3, 4], [2, 5], [6]],
 [[1, 2, 4], [3, 5], [6]],
 [[1, 2, 3], [4, 5], [6]]
```

```
>>> from sage.all import *
>>> StandardTableaux([Integer(2),Integer(2)]).list()
[[[1, 3], [2, 4]], [[1, 2], [3, 4]]]
>>> StandardTableaux([Integer(5)]).list()
[[[1, 2, 3, 4, 5]]]
>>> StandardTableaux([Integer(3),Integer(2),Integer(1)]).list()
[[[1, 4, 6], [2, 5], [3]],
 [[1, 3, 6], [2, 5], [4]],
 [[1, 2, 6], [3, 5], [4]],
 [[1, 3, 6], [2, 4], [5]],
 [[1, 2, 6], [3, 4], [5]],

 [[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 3, 4], [2, 6], [5]],
 [[1, 2, 4], [3, 6], [5]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 3, 5], [2, 4], [6]],
 [[1, 2, 5], [3, 4], [6]],
 [[1, 3, 4], [2, 5], [6]],
 [[1, 2, 4], [3, 5], [6]],
 [[1, 2, 3], [4, 5], [6]]]
```

random_element()

Return a random standard tableau of the given shape using the Greene-Nijenhuis-Wilf Algorithm.

EXAMPLES:

```
sage: t = StandardTableaux([2,2]).random_element()
sage: t.shape()
[2, 2]
sage: StandardTableaux([]).random_element()
[]
```

```
>>> from sage.all import *
>>> t = StandardTableaux([Integer(2),Integer(2)]).random_element()
>>> t.shape()
[2, 2]
>>> StandardTableaux([]).random_element()
[]
```

class sage.combinat.tableau.**StandardTableaux_size**(*n*)

Bases: `StandardTableaux`, `DisjointUnionEnumeratedSets`

Standard tableaux of fixed size n.

EXAMPLES:

```
sage: [ t for t in StandardTableaux(1) ]
[[[1]]]
sage: [ t for t in StandardTableaux(2) ]
[[[1, 2]], [[1], [2]]]
sage: [ t for t in StandardTableaux(3) ]
[[[1, 2, 3]], [[1, 3], [2]], [[1, 2], [3]], [[1], [2], [3]]]
sage: StandardTableaux(4)[:]
[[[1, 2, 3, 4]],
 [[1, 3, 4], [2]],
 [[1, 2, 4], [3]],
 [[1, 2, 3], [4]],
 [[1, 3], [2, 4]],
 [[1, 2], [3, 4]],
 [[1, 4], [2], [3]],
 [[1, 3], [2], [4]],
 [[1, 2], [3], [4]],
 [[1], [2], [3], [4]]]
```

```
>>> from sage.all import *
>>> [ t for t in StandardTableaux(Integer(1)) ]
[[[1]]]
>>> [ t for t in StandardTableaux(Integer(2)) ]
[[[1, 2]], [[1], [2]]]
>>> [ t for t in StandardTableaux(Integer(3)) ]

```

cardinality()

Return the number of all standard tableaux of size `n`.

The number of standard tableaux of size n is equal to the number of involutions in the symmetric group S_n. This is a consequence of the symmetry of the RSK correspondence, that if $\sigma \mapsto (P, Q)$, then $\sigma^{-1} \mapsto (Q, P)$. For more information, see Wikipedia article Robinson-Schensted-Knuth_correspondence#Symmetry.

ALGORITHM:

The algorithm uses the fact that standard tableaux of size `n` are in bijection with the involutions of size `n`, (see page 41 in section 4.1 of [Ful1997]). For each number of fixed points, you count the number of ways to choose those fixed points multiplied by the number of perfect matchings on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(3).cardinality()
4
sage: ns = [1,2,3,4,5,6]
sage: sts = [StandardTableaux(n) for n in ns]
sage: all(st.cardinality() == len(st.list()) for st in sts)
True
```

```
>>> from sage.all import *
>>> StandardTableaux(Integer(3)).cardinality()
4
>>> ns = [Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(6)]
>>> sts = [StandardTableaux(n) for n in ns]
>>> all(st.cardinality() == len(st.list()) for st in sts)
True
```

The cardinality can be computed without constructing all elements in this set, so this computation is fast (see also Issue #28273):

```
sage: StandardTableaux(500).cardinality()
423107565308608549951551753690...221285999236657443927937253376
```

```
>>> from sage.all import *
>>> StandardTableaux(Integer(500)).cardinality()
423107565308608549951551753690...221285999236657443927937253376
```

random_element()

Return a random StandardTableau with uniform probability.

This algorithm uses the fact that the Robinson-Schensted correspondence returns a pair of identical standard Young tableaux (SYTs) if and only if the permutation was an involution. Thus, generating a random SYT is equivalent to generating a random involution.

To generate an involution, we first need to choose its number of fixed points k (if the size of the involution is even, the number of fixed points will be even, and if the size is odd, the number of fixed points will be odd). To do this, we choose a random integer r between 0 and the number N of all involutions of size n. We then decompose the interval $\{1, 2, \ldots, N\}$ into subintervals whose lengths are the numbers of involutions of size n with respectively 0, 1, $\ldots$, $\lfloor N/2 \rfloor$ fixed points. The interval in which our random integer r lies then decides how many fixed points our random involution will have. We then place those fixed points randomly and then compute a perfect matching (an involution without fixed points) on the remaining values.

EXAMPLES:

```
sage: StandardTableaux(10).random_element() # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
sage: StandardTableaux(0).random_element()
[]
sage: StandardTableaux(1).random_element()
[[1]]
```

```
>>> from sage.all import *
>>> StandardTableaux(Integer(10)).random_element() # random
[[1, 3, 6], [2, 5, 7], [4, 8], [9], [10]]
```

(continues on next page)

(continued from previous page)

```
>>> StandardTableaux(Integer(0)).random_element()
[]
>>> StandardTableaux(Integer(1)).random_element()
[[1]]
```

class sage.combinat.tableau.**Tableau**(*parent*, *t*, *check=True*)

Bases: ClonableList

A class to model a tableau.

INPUT:

- t – a Tableau, a list of iterables, or an empty list

OUTPUT: a Tableau object constructed from t

A tableau is abstractly a mapping from the cells in a partition to arbitrary objects (called entries). It is often represented as a finite list of nonempty lists (or, more generally an iterator of iterables) of weakly decreasing lengths. This list, in particular, can be empty, representing the empty tableau.

Note that Sage uses the English convention for partitions and tableaux; the longer rows are displayed on top.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.shape()
[3, 2]
sage: t.pp() # pretty printing
1 2 3
4 5
sage: t.is_standard()
True

sage: Tableau([['a','c','b'],[],(2,1)]])
[['a', 'c', 'b'], [], (2, 1)]]
sage: Tableau([]) # The empty tableau
[]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]); t
[[1, 2, 3], [4, 5]]
>>> t.shape()
[3, 2]
>>> t.pp() # pretty printing
1 2 3
4 5
>>> t.is_standard()
True

>>> Tableau([['a','c','b'],[],(Integer(2),Integer(1))]])
[['a', 'c', 'b'], [], (2, 1)]]
>>> Tableau([]) # The empty tableau
[]
```

When using code that will generate a lot of tableaux, it is slightly more efficient to construct a Tableau from the appropriate Parent object:

```
sage: T = Tableaux()
sage: T([[1, 2, 3], [4, 5]])
[[1, 2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> T = Tableaux()
>>> T([[Integer(1), Integer(2), Integer(3)], [Integer(4), Integer(5)]])
[[1, 2, 3], [4, 5]]
```

- *StandardTableau*

add_entry(*cell*, *m*)

Return the result of setting the entry in cell `cell` equal to `m` in the tableau `self`.

This tableau has larger size than `self` if `cell` does not belong to the shape of `self`; otherwise, the tableau has the same shape as `self` and has the appropriate entry replaced.

INPUT:

- `cell` – a pair of nonnegative integers

OUTPUT:

The tableau `self` with the entry in cell `cell` set to `m`. This entry overwrites an existing entry if `cell` already belongs to `self`, or is added to the tableau if `cell` is a cocorner of the shape `self`. (Either way, the input is not modified.)

Note

Both coordinates of `cell` are interpreted as starting at 0. So, `cell == (0, 0)` corresponds to the northwesternmost cell.

EXAMPLES:

```
sage: s = StandardTableau([[1,2,5],[3,4]]); s.pp()
  1  2  5
  3  4
sage: t = s.add_entry( (1,2), 6); t.pp()
  1  2  5
  3  4  6
sage: t.category()
Category of elements of Standard tableaux
```

(continues on next page)

(continued from previous page)

```
sage: s.add_entry( (2,0), 6).pp()
  1  2  5
  3  4
  6
sage: u = s.add_entry( (1,2), 3); u.pp()
  1  2  5
  3  4  3
sage: u.category()
Category of elements of Tableaux
sage: s.add_entry( (2,2),3)
Traceback (most recent call last):
...
IndexError: (2, 2) is not an addable cell of the tableau
```

```
>>> from sage.all import *
>>> s = StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),
↪Integer(4)]]); s.pp()
  1  2  5
  3  4
>>> t = s.add_entry( (Integer(1),Integer(2)), Integer(6)); t.pp()
  1  2  5
  3  4  6
>>> t.category()
Category of elements of Standard tableaux
>>> s.add_entry( (Integer(2),Integer(0)), Integer(6)).pp()
  1  2  5
  3  4
  6
>>> u = s.add_entry( (Integer(1),Integer(2)), Integer(3)); u.pp()
  1  2  5
  3  4  3
>>> u.category()
Category of elements of Tableaux
>>> s.add_entry( (Integer(2),Integer(2)),Integer(3))
Traceback (most recent call last):
...
IndexError: (2, 2) is not an addable cell of the tableau
```

anti_restrict(*n*)

Return the skew tableau formed by removing all of the cells from `self` that are filled with a number at most n.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]]); t
[[1, 2, 3], [4, 5]]
sage: t.anti_restrict(1)
[[None, 2, 3], [4, 5]]
sage: t.anti_restrict(2)
[[None, None, 3], [4, 5]]
sage: t.anti_restrict(3)
[[None, None, None], [4, 5]]
```

(continues on next page)

(continued from previous page)

```
sage: t.anti_restrict(4)
[[None, None, None], [None, 5]]
sage: t.anti_restrict(5)
[[None, None, None], [None, None]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]]);
↪ t
[[1, 2, 3], [4, 5]]
>>> t.anti_restrict(Integer(1))
[[None, 2, 3], [4, 5]]
>>> t.anti_restrict(Integer(2))
[[None, None, 3], [4, 5]]
>>> t.anti_restrict(Integer(3))
[[None, None, None], [4, 5]]
>>> t.anti_restrict(Integer(4))
[[None, None, None], [None, 5]]
>>> t.anti_restrict(Integer(5))
[[None, None, None], [None, None]]
```

atom()

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).atom()
[2, 2]
sage: Tableau([[1,2,3],[4,5],[6]]).atom()
[3, 2, 1]
```

```
>>> from sage.all import *
>>> Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).atom()
[2, 2]
>>> Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)],
↪[Integer(6)]]).atom()
[3, 2, 1]
```

bender_knuth_involution(*k*, *rows=None*, *check=True*)

Return the image of `self` under the k-th Bender–Knuth involution, assuming `self` is a semistandard tableau.

Let T be a tableau, then a *lower free `k` in `T`* means a cell of T which is filled with the integer k and whose direct lower neighbor is not filled with the integer $k+1$ (in particular, this lower neighbor might not exist at all). Let an *upper free `k + 1` in `T`* mean a cell of T which is filled with the integer $k+1$ and whose direct upper neighbor is not filled with the integer k (in particular, this neighbor might not exist at all). It is clear that for any row r of T, the lower free k's and the upper free $k+1$'s in r together form a contiguous interval or r.

The *`k`-th Bender–Knuth switch at row `i`* changes the entries of the cells in this interval in such a way that if it used to have a entries of k and b entries of $k+1$, it will now have b entries of k and a entries of $k+1$. For fixed k, the k-th Bender–Knuth switches for different i commute. The composition of the k-th Bender–Knuth switches for all rows is called the *`k`-th Bender-Knuth involution*. This is used to show that the Schur functions defined by semistandard tableaux are symmetric functions.

INPUT:

- `k` – integer

- `rows` – (default: `None`) when set to `None`, the method computes the k-th Bender–Knuth involution as defined above. When an iterable, this computes the composition of the k-th Bender–Knuth switches at row i over all i in `rows`. When set to an integer i, the method computes the k-th Bender–Knuth switch at row i. Note the indexing of the rows starts with 1.
- `check` – (default: `True`) check to make sure `self` is semistandard; Set to `False` to avoid this check

OUTPUT:

The image of `self` under either the k-th Bender–Knuth involution, the k-th Bender–Knuth switch at a certain row, or the composition of such switches, as detailed in the INPUT section.

EXAMPLES:

```
sage: t = Tableau([[1,1,3,4,4,5,6,7],[2,2,4,6,7,7,7],[3,4,5,8,8,9],[6,6,7,10],
↪[7,8,8,11],[8]])
sage: t.bender_knuth_involution(1) == t
True
sage: t.bender_knuth_involution(2)
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(3)
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(4)
[[1, 1, 3, 4, 5, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(5)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 5, 7, 7, 7], [3, 4, 6, 8, 8, 9], [5, 5,␣
↪7, 10], [7, 8, 8, 11], [8]]
sage: t.bender_knuth_involution(666) == t
True
sage: t.bender_knuth_involution(4, 2) == t
True
sage: t.bender_knuth_involution(4, 3)
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(1),Integer(3),Integer(4),Integer(4),
↪Integer(5),Integer(6),Integer(7)],[Integer(2),Integer(2),Integer(4),
↪Integer(6),Integer(7),Integer(7),Integer(7)],[Integer(3),Integer(4),
↪Integer(5),Integer(8),Integer(8),Integer(9)],[Integer(6),Integer(6),
↪Integer(7),Integer(10)],[Integer(7),Integer(8),Integer(8),Integer(11)],
↪[Integer(8)]])
>>> t.bender_knuth_involution(Integer(1)) == t
True
>>> t.bender_knuth_involution(Integer(2))
[[1, 1, 2, 4, 4, 5, 6, 7], [2, 3, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
>>> t.bender_knuth_involution(Integer(3))
[[1, 1, 3, 3, 3, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 4, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
>>> t.bender_knuth_involution(Integer(4))
[[1, 1, 3, 4, 5, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6,␣
```

(continues on next page)

(continued from previous page)

```
↪7, 10], [7, 8, 8, 11], [8]]
>>> t.bender_knuth_involution(Integer(5))
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 5, 7, 7, 7], [3, 4, 6, 8, 8, 9], [5, 5,␣
↪7, 10], [7, 8, 8, 11], [8]]
>>> t.bender_knuth_involution(Integer(666)) == t
True
>>> t.bender_knuth_involution(Integer(4), Integer(2)) == t
True
>>> t.bender_knuth_involution(Integer(4), Integer(3))
[[1, 1, 3, 4, 4, 5, 6, 7], [2, 2, 4, 6, 7, 7, 7], [3, 5, 5, 8, 8, 9], [6, 6,␣
↪7, 10], [7, 8, 8, 11], [8]]
```

The `rows` keyword can be an iterator:

```
sage: t.bender_knuth_involution(6, iter([1,2])) == t
False
sage: t.bender_knuth_involution(6, iter([3,4])) == t
True
```

```
>>> from sage.all import *
>>> t.bender_knuth_involution(Integer(6), iter([Integer(1),Integer(2)])) == t
False
>>> t.bender_knuth_involution(Integer(6), iter([Integer(3),Integer(4)])) == t
True
```

The Bender–Knuth involution is an involution:

```
sage: T = SemistandardTableaux(shape=[3,1,1], max_entry=4)
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t       #␣
↪needs sage.modules
....:     for k in range(1, 5) for t in T)
True
```

```
>>> from sage.all import *
>>> T = SemistandardTableaux(shape=[Integer(3),Integer(1),Integer(1)], max_
↪entry=Integer(4))
>>> all(t.bender_knuth_involution(k).bender_knuth_involution(k) == t       #␣
↪needs sage.modules
...     for k in range(Integer(1), Integer(5)) for t in T)
True
```

The same holds for the single switches:

```
sage: all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t ␣
↪          # needs sage.modules
....:     for k in range(1, 5) for j in range(1, 5) for t in T)
True
```

```
>>> from sage.all import *
>>> all(t.bender_knuth_involution(k, j).bender_knuth_involution(k, j) == t   ␣
↪         # needs sage.modules
...     for k in range(Integer(1), Integer(5)) for j in range(Integer(1),␣
```

(continues on next page)

(continued from previous page)

```
↪Integer(5)) for t in T)
True
```

Locality of the Bender–Knuth involutions:

```
sage: all(t.bender_knuth_involution(k).bender_knuth_involution(l)              #␣
↪needs sage.modules
....:        == t.bender_knuth_involution(l).bender_knuth_involution(k)
....:     for k in range(1, 5) for l in range(1, 5) if abs(k - l) > 1
....:     for t in T)
True
```

```
>>> from sage.all import *
>>> all(t.bender_knuth_involution(k).bender_knuth_involution(l)              #␣
↪needs sage.modules
...        == t.bender_knuth_involution(l).bender_knuth_involution(k)
...     for k in range(Integer(1), Integer(5)) for l in range(Integer(1),␣
↪Integer(5)) if abs(k - l) > Integer(1)
...     for t in T)
True
```

Berenstein and Kirillov [KB1995] have shown that $(s_1 s_2)^6 = id$ (for tableaux of straight shape):

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k␣
↪+ 1)
sage: all(p(p(p(p(p(p(t,1),1),1),1),1),1) == t for t in T)                     #␣
↪needs sage.modules
True
```

```
>>> from sage.all import *
>>> p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k +␣
↪Integer(1))
>>> all(p(p(p(p(p(p(t,Integer(1)),Integer(1)),Integer(1)),Integer(1)),
↪Integer(1)),Integer(1)) == t for t in T)                     # needs sage.
↪modules
True
```

However, $(s_2 s_3)^6 = id$ is false:

```
sage: p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k␣
↪+ 1)
sage: t = Tableau([[1,2,2],[3,4]])
sage: x = t
sage: for i in range(6): x = p(x, 2)
sage: x
[[1, 2, 3], [2, 4]]
sage: x == t
False
```

```
>>> from sage.all import *
>>> p = lambda t, k: t.bender_knuth_involution(k).bender_knuth_involution(k +␣
↪Integer(1))
```

(continues on next page)

(continued from previous page)

```
>>> t = Tableau([[Integer(1),Integer(2),Integer(2)],[Integer(3),Integer(4)]])
>>> x = t
>>> for i in range(Integer(6)): x = p(x, Integer(2))
>>> x
[[1, 2, 3], [2, 4]]
>>> x == t
False
```

bump(*x*)

Insert `x` into `self` using Schensted's row-bumping (or row-insertion) algorithm.

EXAMPLES:

```
sage: t = Tableau([[1,2],[3]])
sage: t.bump(1)
[[1, 1], [2], [3]]
sage: t
[[1, 2], [3]]
sage: t.bump(2)
[[1, 2, 2], [3]]
sage: t.bump(3)
[[1, 2, 3], [3]]
sage: t
[[1, 2], [3]]
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t.bump(2)
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
sage: t.bump(1)
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2)],[Integer(3)]])
>>> t.bump(Integer(1))
[[1, 1], [2], [3]]
>>> t
[[1, 2], [3]]
>>> t.bump(Integer(2))
[[1, 2, 2], [3]]
>>> t.bump(Integer(3))
[[1, 2, 3], [3]]
>>> t
[[1, 2], [3]]
>>> t = Tableau([[Integer(1),Integer(2),Integer(2),Integer(3)],[Integer(2),
↪Integer(3),Integer(5),Integer(5)],[Integer(4),Integer(4),Integer(6)],
↪[Integer(5),Integer(6)]])
>>> t.bump(Integer(2))
[[1, 2, 2, 2], [2, 3, 3, 5], [4, 4, 5], [5, 6, 6]]
>>> t.bump(Integer(1))
[[1, 1, 2, 3], [2, 2, 5, 5], [3, 4, 6], [4, 6], [5]]
```

bump_multiply(*other*)

Multiply two tableaux using Schensted's bump.

This product makes the set of semistandard tableaux into an associative monoid. The empty tableau is the unit in this monoid. See pp. 11-12 of [Ful1997].

The same product operation is implemented in a different way in *slide_multiply()*.

EXAMPLES:

```
sage: t = Tableau([[1,2,2,3],[2,3,5,5],[4,4,6],[5,6]])
sage: t2 = Tableau([[1,2],[3]])
sage: t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2),Integer(2),Integer(3)],[Integer(2),
→Integer(3),Integer(5),Integer(5)],[Integer(4),Integer(4),Integer(6)],
→[Integer(5),Integer(6)]])
>>> t2 = Tableau([[Integer(1),Integer(2)],[Integer(3)]])
>>> t.bump_multiply(t2)
[[1, 1, 2, 2, 3], [2, 2, 3, 5], [3, 4, 5], [4, 6, 6], [5]]
```

catabolism()

Remove the top row of `self` and insert it back in using column Schensted insertion (starting with the largest letter).

EXAMPLES:

```
sage: Tableau([]).catabolism()
[]
sage: Tableau([[1,2,3,4,5]]).catabolism()
[[1, 2, 3, 4, 5]]
sage: Tableau([[1,1,3,3],[2,3],[3]]).catabolism()
[[1, 1, 2, 3, 3, 3], [3]]
sage: Tableau([[1, 1, 2, 3, 3, 3], [3]]).catabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

```
>>> from sage.all import *
>>> Tableau([]).catabolism()
[]
>>> Tableau([[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]]).
→catabolism()
[[1, 2, 3, 4, 5]]
>>> Tableau([[Integer(1),Integer(1),Integer(3),Integer(3)],[Integer(2),
→Integer(3)],[Integer(3)]]).catabolism()
[[1, 1, 2, 3, 3, 3], [3]]
>>> Tableau([[Integer(1), Integer(1), Integer(2), Integer(3), Integer(3),␣
→Integer(3)], [Integer(3)]]).catabolism()
[[1, 1, 2, 3, 3, 3, 3]]
```

catabolism_projector(*parts*)

EXAMPLES:

```
sage: t = Tableau([[1,1,3,3],[2,3],[3]])
sage: t.catabolism_projector([[4,2,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

(continues on next page)

(continued from previous page)

```
sage: t.catabolism_projector([[1]])
[]
sage: t.catabolism_projector([[2,1],[1]])
[]
sage: t.catabolism_projector([[1,1],[4,1]])
[[1, 1, 3, 3], [2, 3], [3]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(1),Integer(3),Integer(3)],[Integer(2),
→Integer(3)],[Integer(3)]])
>>> t.catabolism_projector([[Integer(4),Integer(2),Integer(1)]])
[[1, 1, 3, 3], [2, 3], [3]]
>>> t.catabolism_projector([[Integer(1)]])
[]
>>> t.catabolism_projector([[Integer(2),Integer(1)],[Integer(1)]])
[]
>>> t.catabolism_projector([[Integer(1),Integer(1)],[Integer(4),Integer(1)]])
[[1, 1, 3, 3], [2, 3], [3]]
```

catabolism_sequence()

Perform *catabolism()* on `self` until it returns a tableau consisting of a single row.

EXAMPLES:

```
sage: t = Tableau([[1,2,3,4,5,6,8],[7,9]])
sage: t.catabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
sage: Tableau([]).catabolism_sequence()
[[]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
→Integer(6),Integer(8)],[Integer(7),Integer(9)]])
>>> t.catabolism_sequence()
[[[1, 2, 3, 4, 5, 6, 8], [7, 9]],
 [[1, 2, 3, 4, 5, 6, 7, 9], [8]],
 [[1, 2, 3, 4, 5, 6, 7, 8], [9]],
 [[1, 2, 3, 4, 5, 6, 7, 8, 9]]]
>>> Tableau([]).catabolism_sequence()
[[]]
```

cells()

Return a list of the coordinates of the cells of `self`.

Coordinates start at 0, so the northwesternmost cell (in English notation) has coordinates $(0, 0)$.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

```
>>> from sage.all import *
>>> Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]
```

cells_containing(*i*)

Return the list of cells in which the letter i appears in the tableau `self`. The list is ordered with cells appearing from left to right.

Cells are given as pairs of coordinates (a, b), where both rows and columns are counted from 0 (so $a = 0$ means the cell lies in the leftmost column of the tableau, etc.).

EXAMPLES:

```
sage: t = Tableau([[1,1,3],[2,3,5],[4,5]])
sage: t.cells_containing(5)
[(2, 1), (1, 2)]
sage: t.cells_containing(4)
[(2, 0)]
sage: t.cells_containing(6)
[]

sage: t = Tableau([[1,1,2,4],[2,4,4],[4]])
sage: t.cells_containing(4)
[(2, 0), (1, 1), (1, 2), (0, 3)]

sage: t = Tableau([[1,1,2,8,9],[2,5,6,11],[3,7,7,13],[4,8,9],[5],[13],[14]])
sage: t.cells_containing(8)
[(3, 1), (0, 3)]

sage: Tableau([]).cells_containing(3)
[]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(1),Integer(3)],[Integer(2),Integer(3),
↪Integer(5)],[Integer(4),Integer(5)]])
>>> t.cells_containing(Integer(5))
[(2, 1), (1, 2)]
>>> t.cells_containing(Integer(4))
[(2, 0)]
>>> t.cells_containing(Integer(6))
[]

>>> t = Tableau([[Integer(1),Integer(1),Integer(2),Integer(4)],[Integer(2),
↪Integer(4),Integer(4)],[Integer(4)]])
>>> t.cells_containing(Integer(4))
[(2, 0), (1, 1), (1, 2), (0, 3)]

>>> t = Tableau([[Integer(1),Integer(1),Integer(2),Integer(8),Integer(9)],
↪[Integer(2),Integer(5),Integer(6),Integer(11)],[Integer(3),Integer(7),
↪Integer(7),Integer(13)],[Integer(4),Integer(8),Integer(9)],[Integer(5)],
↪[Integer(13)],[Integer(14)]])
>>> t.cells_containing(Integer(8))
[(3, 1), (0, 3)]
```

(continues on next page)

(continued from previous page)

```
>>> Tableau([]).cells_containing(Integer(3))
[]
```

charge()

Return the charge of the reading word of `self`. See `charge()` for more information.

EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]).charge()
0
sage: Tableau([[1,1,3],[2,2]]).charge()
1
sage: Tableau([[1,1,2],[2],[3]]).charge()
1
sage: Tableau([[1,1,2],[2,3]]).charge()
2
sage: Tableau([[1,1,2,3],[2]]).charge()
2
sage: Tableau([[1,1,2,2],[3]]).charge()
3
sage: Tableau([[1,1,2,2,3]]).charge()
4
```

```
>>> from sage.all import *
>>> Tableau([[Integer(1),Integer(1)],[Integer(2),Integer(2)],[Integer(3)]]).
↪charge()
0
>>> Tableau([[Integer(1),Integer(1),Integer(3)],[Integer(2),Integer(2)]]).
↪charge()
1
>>> Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2)],[Integer(3)]]).
↪charge()
1
>>> Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)]]).
↪charge()
2
>>> Tableau([[Integer(1),Integer(1),Integer(2),Integer(3)],[Integer(2)]]).
↪charge()
2
>>> Tableau([[Integer(1),Integer(1),Integer(2),Integer(2)],[Integer(3)]]).
↪charge()
3
>>> Tableau([[Integer(1),Integer(1),Integer(2),Integer(2),Integer(3)]]).
↪charge()
4
```

check()

Check that `self` is a valid straight-shape tableau.

EXAMPLES:

```
sage: t = Tableau([[1,1],[2]])
sage: t.check()

sage: t = Tableau([[None, None, 1], [2, 4], [3, 4, 5]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: a tableau must be a list of iterables of weakly decreasing length
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(1)],[Integer(2)]])
>>> t.check()

>>> t = Tableau([[None, None, Integer(1)], [Integer(2), Integer(4)],␣
↪[Integer(3), Integer(4), Integer(5)]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: a tableau must be a list of iterables of weakly decreasing length
```

cocharge()

Return the cocharge of the reading word of `self`. See *cocharge()* for more information.

EXAMPLES:

```
sage: Tableau([[1,1],[2,2],[3]]).cocharge()
4
sage: Tableau([[1,1,3],[2,2]]).cocharge()
3
sage: Tableau([[1,1,2],[2],[3]]).cocharge()
3
sage: Tableau([[1,1,2],[2,3]]).cocharge()
2
sage: Tableau([[1,1,2,3],[2]]).cocharge()
2
sage: Tableau([[1,1,2,2],[3]]).cocharge()
1
sage: Tableau([[1,1,2,2,3]]).cocharge()
0
```

```
>>> from sage.all import *
>>> Tableau([[Integer(1),Integer(1)],[Integer(2),Integer(2)],[Integer(3)]]).
↪cocharge()
4
>>> Tableau([[Integer(1),Integer(1),Integer(3)],[Integer(2),Integer(2)]]).
↪cocharge()
3
>>> Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2)],[Integer(3)]]).
↪cocharge()
3
>>> Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)]]).
↪cocharge()
2
>>> Tableau([[Integer(1),Integer(1),Integer(2),Integer(3)],[Integer(2)]]).
↪cocharge()
```

(continues on next page)

(continued from previous page)

```
2
>>> Tableau([[Integer(1),Integer(1),Integer(2),Integer(2)],[Integer(3)]]).
↪cocharge()
1
>>> Tableau([[Integer(1),Integer(1),Integer(2),Integer(2),Integer(3)]]).
↪cocharge()
0
```

codegree(*e*, *multicharge=(0,)*)

Return the Brundan-Kleshchev-Wang [BKW2011] codegree of the standard tableau `self`.

The *codegree* of a tableau is an integer that is defined recursively by successively stripping off the number k, for $k = n, n-1, \ldots, 1$ and at stage adding the number of addable cell of the same residue minus the number of removable cells of the same residue as k and are above k in the diagram.

The codegree of the tableau T gives the degree of "dual" homogeneous basis element of the Graded Specht module that is indexed by T.

INPUT:

- `e` – the *quantum characteristic*
- `multicharge` – (default: `[0]`) the multicharge

OUTPUT: the codegree of the tableau `self`, which is an integer

EXAMPLES:

```
sage: StandardTableau([[1,3,5],[2,4]]).codegree(3)                          #␣
↪needs sage.groups
0
sage: StandardTableau([[1,2,5],[3,4]]).codegree(3)                          #␣
↪needs sage.groups
1
sage: StandardTableau([[1,2,5],[3,4]]).codegree(4)                          #␣
↪needs sage.groups
0
```

```
>>> from sage.all import *
>>> StandardTableau([[Integer(1),Integer(3),Integer(5)],[Integer(2),
↪Integer(4)]]).codegree(Integer(3))                          # needs sage.
↪groups
0
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),
↪Integer(4)]]).codegree(Integer(3))                          # needs sage.
↪groups
1
>>> StandardTableau([[Integer(1),Integer(2),Integer(5)],[Integer(3),
↪Integer(4)]]).codegree(Integer(4))                          # needs sage.
↪groups
0
```

column_stabilizer()

Return the PermutationGroup corresponding to the column stabilizer of `self`.

This assumes that every integer from 1 to the size of `self` appears exactly once in `self`.

EXAMPLES:

```
sage: # needs sage.groups
sage: cs = Tableau([[1,2,3],[4,5]]).column_stabilizer()
sage: cs.order() == factorial(2)*factorial(2)
True
sage: PermutationGroupElement([(1,3,2),(4,5)]) in cs
False
sage: PermutationGroupElement([(1,4)]) in cs
True
```

```
>>> from sage.all import *
>>> # needs sage.groups
>>> cs = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),
↪Integer(5)]]).column_stabilizer()
>>> cs.order() == factorial(Integer(2))*factorial(Integer(2))
True
>>> PermutationGroupElement([(Integer(1),Integer(3),Integer(2)),(Integer(4),
↪Integer(5))]) in cs
False
>>> PermutationGroupElement([(Integer(1),Integer(4))]) in cs
True
```

components()

This function returns a list containing itself. It exists mainly for compatibility with *TableauTuple* as it allows constructions like the example below.

EXAMPLES:

```
sage: t = Tableau([[1,2,3],[4,5]])
sage: for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

```
>>> from sage.all import *
>>> t = Tableau([[Integer(1),Integer(2),Integer(3)],[Integer(4),Integer(5)]])
>>> for s in t.components(): print(s.to_list())
[[1, 2, 3], [4, 5]]
```

conjugate()

Return the conjugate of `self`.

EXAMPLES:

```
sage: Tableau([[1,2],[3,4]]).conjugate()
[[1, 3], [2, 4]]
sage: c = StandardTableau([[1,2],[3,4]]).conjugate()
sage: c.parent()
Standard tableaux
```

```
>>> from sage.all import *
>>> Tableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).conjugate()
[[1, 3], [2, 4]]
>>> c = StandardTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).
```

(continues on next page)

(continued from previous page)

```
↪conjugate()
>>> c.parent()
Standard tableaux
```

content (*k*, *multicharge=[0]*)

Return the content of `k` in the standard tableau `self`.

The content of k is $c - r$ if k appears in row r and column c of the tableau.

The `multicharge` is a list of length 1 which gives an offset for all of the contents. It is included mainly for compatibility with *sage.combinat.tableau_tuple.TableauTuple()*.

EXAMPLES:

```
sage: StandardTableau([[1,2],[3,4]]).content(3)
-1

sage: StandardTableau([[1,2],[3,4]]).content(6)
Traceback (most recent call last):
...
ValueError: 6 does not appear in tableau
```

```
>>> from sage.all import *
>>> StandardTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).
↪content(Integer(3))
-1

>>> StandardTableau([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).
↪content(Integer(6))
