>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(3))
{0: 3, 1: 3, 2: 3}

>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(4))
{0: 2, 1: 2, 2: 2, 3: 3}
```

**boundary()**

Return the integer coordinates of points on the boundary of `self`.

For the following description, picture the Ferrer's diagram of `self` using the French convention. Recall that the French convention puts the longest row on the bottom and the shortest row on the top. In addition, interpret the Ferrer's diagram as 1 x 1 cells in the Euclidean plane. So if `self` was the partition [3, 1], the lower-left vertices of the 1 x 1 cells in the Ferrer's diagram would be (0, 0), (1, 0), (2, 0), and (0, 1).

The boundary of a partition is the set \{NE(d) | \forall d diagonal\}. That is, for every diagonal line $y = x + b$ where $b \in \mathbb{Z}$, we find the northeasternmost (NE) point on that diagonal which is also in the Ferrer's diagram.

The boundary will go from bottom-right to top-left.

**EXAMPLES:**

Consider the partition (1) depicted as a square on a cartesian plane with vertices (0, 0), (1, 0), (1, 1), and (0, 1). Three of those vertices in the appropriate order form the boundary:

```python
sage: Partition([1]).boundary()
[(1, 0), (1, 1), (0, 1)]
```

```python
>>> from sage.all import *

>>> Partition([Integer(1)]).boundary()
[(1, 0), (1, 1), (0, 1)]
```

The partition (3, 1) can be visualized as three squares on a cartesian plane. The coordinates of the appropriate vertices form the boundary:

```python
sage: Partition([3, 1]).boundary()
[(3, 0), (3, 1), (2, 1), (1, 1), (1, 2), (0, 2)]
```
```python
>>> from sage.all import *

>>> Partition([Integer(3), Integer(1)]).boundary()
[(3, 0), (3, 1), (2, 1), (1, 1), (1, 2), (0, 2)]
```

See also:

`k_rim()`. You might have been looking for `k_boundary()` instead.

**cell_poset** *(orientation='SE')*

Return the Young diagram of `self` as a poset. The optional keyword variable `orientation` determines the order relation of the poset.

The poset always uses the set of cells of the Young diagram of `self` as its ground set. The order relation of the poset depends on the `orientation` variable (which defaults to "SE"). Concretely, `orientation` has to be specified to one of the strings "NW", "NE", "SW", and "SE", standing for “northwest”, “northeast”, “southwest” and “southeast”, respectively. If `orientation` is "SE", then the order relation of the poset is such that a cell `u` is greater or equal to a cell `v` in the poset if and only if `u` lies weakly southeast of `v` (this means that `u` can be reached from `v` by a sequence of south and east steps; the sequence is allowed to consist of south steps only, or of east steps only, or even be empty). Similarly the order relation is defined for the other three orientations. The Young diagram is supposed to be drawn in English notation.

The elements of the poset are the cells of the Young diagram of `self`, written as tuples of zero-based coordinates (so that `(3, 7)` stands for the 8-th cell of the 4-th row, etc.).

**EXAMPLES:**

```python
sage: # needs sage.graphs
dsage: p = Partition([3, 3, 1])
d sage: Q = p.cell_poset(); Q
Finite poset containing 7 elements
d sage: sorted(Q)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
d sage: sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
d sage: Q.minimal_elements()
[(0, 0)]
d sage: sorted(Q.upper_covers((1, 0)))
[(1, 1), (2, 0)]
d sage: Q.upper_covers((1, 1))
[(1, 2)]
```

```python
sage: # needs sage.graphs
sage: P = p.cell_poset(orientation="NW"); P
Finite poset containing 7 elements
sage: sorted(P)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: sorted(P.minimal_elements())
[(0, 0)]
sage: P.maximal_elements()
[(0, 0)]
sage: P.upper_covers((2, 0))
[(1, 0)]
sage: sorted(P.upper_covers((1, 2)))
[(0, 2), (1, 1)]
sage: sorted(P.upper_covers((1, 1)))
[(0, 1), (1, 0)]
sage: sorted([len(P.upper_covers(v)) for v in P])
[0, 1, 1, 1, 2, 2]
```

(continues on next page)
sage: # needs sage.graphs
sage: R = p.cell_poset(orientation="NE"); R
Finite poset containing 7 elements
sage: sorted(R)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
sage: R.maximal_elements()
[(0, 2)]
sage: R.minimal_elements()
[(2, 0)]
sage: sorted([len(R.upper_covers(v)) for v in R])
[0, 1, 1, 1, 1, 2, 2]
sage: R.is_isomorphic(P)
False
sage: R.is_isomorphic(P.dual())
False

>>> from sage.all import *
>>> # needs sage.graphs
>>> p = Partition([Integer(3),Integer(3),Integer(1)])
>>> Q = p.cell_poset(); Q
Finite poset containing 7 elements
>>> sorted(Q)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> sorted(Q.maximal_elements())
[(1, 2), (2, 0)]
>>> Q.minimal_elements()
[(0, 0)]
>>> sorted(Q.upper_covers((Integer(1), Integer(0))))
[(1, 1), (2, 0)]
>>> Q.upper_covers((Integer(1), Integer(1)))
[(1, 2)]

>>> # needs sage.graphs
>>> P = p.cell_poset(orientation="NW"); P
Finite poset containing 7 elements
>>> sorted(P)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]
>>> sorted(P.minimal_elements())
[(1, 2), (2, 0)]
>>> P.maximal_elements()
[(0, 0)]
>>> P.upper_covers((Integer(2), Integer(0)))
[(1, 0)]
>>> sorted(P.upper_covers((Integer(1), Integer(2))))
[(0, 2), (1, 1)]
>>> sorted(P.upper_covers((Integer(1), Integer(1))))
[(0, 1), (1, 0)]
>>> sorted([len(P.upper_covers(v)) for v in P])
[0, 1, 1, 1, 2, 2]

>>> # needs sage.graphs
>>> R = p.cell_poset(orientation="NE"); R
Finite poset containing 7 elements
>>> sorted(R)
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1), (1, 2), (2, 0)]

(continues on next page)
Linear extensions of \texttt{p.cell_poset()} are in 1-to-1 correspondence with standard Young tableaux of shape \( p \):

\begin{verbatim}
>>> all( len(p.cell_poset().linear_extensions()) == len(p.standard_tableaux()) for n in range(8) for p in Partitions(n) )
True
\end{verbatim}

This is not the case for northeast orientation:

\begin{verbatim}
>>> q = Partition([3, 1])
>>> q.cell_poset(orientation="NE").is_chain()
True
\end{verbatim}

\texttt{cells()}

Return the coordinates of the cells of \texttt{self}.

\textbf{EXAMPLES}:

\begin{verbatim}
>>> Partition([2,2]).cells()
[(0, 0), (0, 1), (1, 0), (1, 1)]

>>> Partition([3,2]).cells()
[(0, 0), (0, 1), (0, 2), (1, 0), (1, 1)]
\end{verbatim}
centralizer_size \((t=0, q=0)\)

Return the size of the centralizer of any permutation of cycle type \(\text{self}\).

If \(m_i\) is the multiplicity of \(i\) as a part of \(p\), this is given by

\[
\prod_i m_i!^i^{m_i}.
\]

Including the optional parameters \(t\) and \(q\) gives the \(q, t\) analog, which is the former product times

\[
\prod_{i=1}^{\text{length}(p)} \frac{1 - q^{p_i}}{1 - t^{p_i}}.
\]

See Section 1.3, p. 24, in [Ke1991].

EXAMPLES:

```python
sage: Partition([2, 2, 1]).centralizer_size()
8
sage: Partition([2, 2, 2]).centralizer_size()
48
sage: Partition([2, 2, 1]).centralizer_size(q=2, t=3)
9/16
sage: Partition([]).centralizer_size()
1
sage: Partition([]).centralizer_size(q=2, t=4)
1
```

```python
>>> from sage.all import *

>>> Partition([Integer(2), Integer(2), Integer(1)]).centralizer_size()
8
>>> Partition([Integer(2), Integer(2), Integer(2)]).centralizer_size()
48
>>> Partition([Integer(2), Integer(2), Integer(1)]).centralizer_size(q=Integer(2), t=Integer(3))
9/16
>>> Partition([]).centralizer_size()
1
>>> Partition([]).centralizer_size(q=Integer(2), t=Integer(4))
1
```

character_polynomial()

Return the character polynomial associated to the partition \(\text{self}\).

The character polynomial \(q_\mu\) associated to a partition \(\mu\) is defined by

\[
q_\mu(x_1, x_2, \ldots, x_k) = \downarrow \sum_{\alpha^\mu \leq k} \frac{\chi_\alpha^\mu}{1^{a_1!} 2^{a_2!} \cdots k^{a_k!} a_1! a_2! \cdots a_k!} \prod_{i=1}^{k} (ix_i - 1)^{a_i}
\]

where \(k\) is the size of \(\mu\), and \(a_i\) is the multiplicity of \(i\) in \(\alpha\).

It is computed in the following manner:

1. Expand the Schur function \(s_\mu\) in the power-sum basis,
2. Replace each \(p_i\) with \(ix_i - 1\),
3. Apply the umbral operator \(\downarrow\) to the resulting polynomial.

EXAMPLES:
**components()**

Return a list containing the shape of \texttt{self}.

This method exists only for compatibility with \texttt{PartitionTuples}.

EXAMPLES:

```python
sage: Partition([3,2]).components()
[[3, 2]]
```

**conjugacy_class_size()**

Return the size of the conjugacy class of the symmetric group indexed by \texttt{self}.

EXAMPLES:

```python
sage: Partition([2,2,2]).conjugacy_class_size()
15
sage: Partition([2,2,1]).conjugacy_class_size()
15
sage: Partition([2,1,1]).conjugacy_class_size()
6
```

**conjugate()**
Return the conjugate partition of the partition `self`. This is also called the associated partition or the transpose in the literature.

EXAMPLES:

```python
sage: Partition([2,2]).conjugate()
[2, 2]
sage: Partition([6,3,1]).conjugate()
[3, 2, 2, 1, 1, 1]
```

The conjugate partition is obtained by transposing the Ferrers diagram of the partition (see `ferrers_diagram()`):

```python
sage: print(Partition([6,3,1]).ferrers_diagram())
******
*** *
sage: print(Partition([6,3,1]).conjugate().ferrers_diagram())
***
** **
* *
*
```

`contains(x)`

Return `True` if `x` is a partition whose Ferrers diagram is contained in the Ferrers diagram of `self`.

EXAMPLES:

```python
sage: p = Partition([3,2,1])
sage: p.contains([2,1])
True
sage: all(p.contains(mu) for mu in Partitions(3))
True
sage: all(p.contains(mu) for mu in Partitions(4))
False
```
```python
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2),Integer(1)])
>>> p.contains([Integer(2),Integer(1)])
True
>>> all(p.contains(mu) for mu in Partitions(Integer(3)))
True
>>> all(p.contains(mu) for mu in Partitions(Integer(4)))
False
```

**content** 

$(r, c, multicharge=(0,))$

Return the content of the cell at row $r$ and column $c$.

The content of a cell is $c - r$.

For consistency with partition tuples there is also an optional `multicharge` argument which is an offset to the usual content. By setting the `multicharge` equal to the 0-element of the ring $\mathbb{Z}/e\mathbb{Z}$, the corresponding $e$-residue will be returned. This is the content modulo $e$.

The content (and residue) do not strictly depend on the partition, however, this method is included because it is often useful in the context of partitions.

**EXAMPLES:**

```python
sage: p = Partition([3,2])
sage: sum([p.content(*c) for c in p.cells()])
2
```

and now we return the 3-residue of a cell:

```python
sage: p = Partition([2,1])
sage: p.content(1,0, multicharge=IntegerModRing(3)(0))
2
```

**contents_tableau** 

$(multicharge=(0,))$

Return the tableau which has $(k, r, c)$-th cell equal to the content $multicharge[k] - r + c$ of the cell.

**EXAMPLES:**

```python
sage: p = Partition([2,1])
sage: p.contents_tableau()
[[0, 1], [-1]]
```

(continues on next page)
core (length)

Return the length-core of the partition – in the literature the core is commonly referred to as the $k$-core, $p$-core, $r$-core, ....

The $r$-core of a partition $\lambda$ can be obtained by repeatedly removing rim hooks of size $r$ from (the Young diagram of) $\lambda$ until this is no longer possible. The remaining partition is the core.

EXAMPLES:

```
sage: Partition([6,3,2,2]).core(3)
[2, 1, 1]
sage: Partition([]).core(3)
[]
sage: Partition([8,7,7,4,1,1,1,1,1]).core(3)
[2, 1, 1]
```

corners ()

Return a list of the corners of the partition self.

A corner of a partition $\lambda$ is a cell of the Young diagram of $\lambda$ which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form $(i, j)$, where $i$ and $j$ are the coordinates of the respective corner. The coordinates are counted from 0.
Note: This is referred to as an “inner corner” in [Sag2001].

EXAMPLES:

```sage
Partition([3, 2, 1]).corners()
[(0, 2), (1, 1), (2, 0)]
```

```sage
Partition([3, 3, 1]).corners()
[(1, 2), (2, 0)]
```

```sage
Partition([]).corners()
[]
```

```sage
>>> from sage.all import *
```

```sage
>>> Partition([Integer(3), Integer(2), Integer(1)]).corners()
[(0, 2), (1, 1), (2, 0)]
```

```sage
>>> Partition([Integer(3), Integer(3), Integer(1)]).corners()
[(1, 2), (2, 0)]
```

```sage
>>> Partition([]).corners()
[]
```

corners_residue(i, l)

Return a list of the corners of the partition `self` having `l`-residue `i`.

A corner of a partition `λ` is a cell of the Young diagram of `λ` which can be removed from the Young diagram while still leaving a straight shape behind. See residue() for the definition of the `l`-residue.

The entries of the list returned are pairs of the form `(i, j)`, where `i` and `j` are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```sage
Partition([3, 2, 1]).corners_residue(0, 3)
[[1, 1]]
```

```sage
Partition([3, 2, 1]).corners_residue(1, 3)
[[2, 0]]
```

```sage
Partition([3, 2, 1]).corners_residue(2, 3)
[[0, 2]]
```

```sage
>>> from sage.all import *
```

```sage
>>> Partition([Integer(3), Integer(2), Integer(1)]).corners_residue(Integer(0), Integer(3))
[[1, 1]]
```

```sage
>>> Partition([Integer(3), Integer(2), Integer(1)]).corners_residue(Integer(1), Integer(3))
[[2, 0]]
```

```sage
>>> Partition([Integer(3), Integer(2), Integer(1)]).corners_residue(Integer(2), Integer(3))
[[0, 2]]
```

crank()

Return the Dyson crank of `self`.

The Dyson crank of a partition `λ` is defined as follows: If `λ` contains at least one 1, then the crank is `μ(λ) − ω(λ)`, where `ω(λ)` is the number of `λ sin`'s, and `μ(λ)` is the number of parts of `λ` larger than `ω(λ)`. If `λ` contains no 1, then the crank is simply the largest part of `λ`.

REFERENCES:
• [AG1988]

EXAMPLES:

```
sage: Partition([]).crank()
sage: Partition([3,2,2]).crank()
sage: Partition([5,4,2,1,1]).crank()
sage: Partition([1,1,1]).crank()
sage: Partition([6,4,4,3]).crank()
sage: Partition([6,3,3,1,1]).crank()
sage: Partition([6]).crank()
sage: Partition([5,1]).crank()
sage: Partition([4,2]).crank()
sage: Partition([4,1,1]).crank()
sage: Partition([3,3]).crank()
sage: Partition([3,2,1]).crank()
sage: Partition([3,1,1,1]).crank()
sage: Partition([2,2,2]).crank()
sage: Partition([2,2,1,1]).crank()
sage: Partition([2,1,1,1,1]).crank()
sage: Partition([1,1,1,1,1,1]).crank()
```

```
>>> from sage.all import *
>>> Partition([]).crank()
>>> Partition([Integer(3),Integer(2),Integer(2)]).crank()
>>> Partition([Integer(5),Integer(4),Integer(2),Integer(1),Integer(1)]).crank()
>>> Partition([Integer(1),Integer(1),Integer(1)]).crank()
>>> Partition([Integer(6),Integer(4),Integer(4),Integer(3)]).crank()
>>> Partition([Integer(6),Integer(3),Integer(3),Integer(1),Integer(1)]).crank()
>>> Partition([Integer(6)]).crank()
>>> Partition([Integer(5),Integer(1)]).crank()
```

-4
Partition([Integer(1), Integer(1), Integer(1), Integer(1), Integer(1), Integer(1)]).crank()
-6

**defect** *(e, multicharge=(0,))*

Return the e-defect or the e-weight of self.

The $e$-defect is the number of (connected) $e$-rim hooks that can be removed from the partition.

The defect of a partition is given by

$$\text{defect}(\beta) = (\Lambda, \beta) - \frac{1}{2}(\beta, \beta),$$

where $\Lambda = \sum_r \lambda_r \kappa_r$ for the multicharge $(\kappa_1, \ldots, \kappa_\ell)$ and $\beta = \sum_{(r,c)} \alpha_{(c-r)} \mod e)$, with the sum being over the cells in the partition.

**INPUT:**

- $e$ – the quantum characteristic
- multicharge – the multicharge (default (0,))

**OUTPUT:**

- a non-negative integer, which is the defect of the block containing the partition self

**EXAMPLES:**

```python
sage: Partition([4, 3, 2]).defect(2)
3
sage: Partition([0]).defect(2)
0
sage: Partition([3]).defect(2)
1
sage: Partition([6]).defect(2)
3
sage: Partition([9]).defect(2)
4
sage: Partition([12]).defect(2)
6
sage: Partition([4, 3, 2]).defect(3)
3
```

(continues on next page)
degree \( (e) \)

Return the \( e \)-th degree of \( \text{self} \).

The \( e \)-th degree of a partition \( \lambda \) is the sum of the \( e \)-th degrees of the standard tableaux of shape \( \lambda \). The \( e \)-th degree is the exponent of \( \Phi_e(q) \) in the Gram determinant of the Specht module for a semisimple Iwahori-Hecke algebra of type \( A \) with parameter \( q \).

INPUT:

- \( e \) – an integer \( e > 1 \)

OUTPUT:

A non-negative integer.

EXAMPLES:

```python
sage: Partition([4, 3]).degree(2)
28
sage: Partition([4, 3]).degree(3)
15
```
Therefore, the Gram determinant of $S(5, 3)$ when the Hecke parameter $q$ is “generic” is

$$q^N \Phi_2(q)^{28} \Phi_3(q)^{15} \Phi_4(q)^8 \Phi_5(q)^{13}$$

for some integer $N$. Compare with `prime_degree()`.

**dimension (smaller=None, k=1)**

Return the number of paths from the `smaller` partition to the partition `self`, where each step consists of adding a $k$-ribbon while keeping a partition.

Note that a 1-ribbon is just a single cell, so this counts paths in the Young graph when $k = 1$.

Note also that the default case ($k = 1$ and `smaller = []`) gives the dimension of the irreducible representation of the symmetric group corresponding to `self`.

**INPUT:**

- `smaller` – a partition (default: an empty list `[]`)
- `k` – a positive integer (default: 1)

**OUTPUT:**

The number of such paths

**EXAMPLES:**

Looks at the number of ways of getting from $[5, 4]$ to the empty partition, removing one cell at a time:
Same, but removing one 3-ribbon at a time. Note that the 3-core of $\mu$ is empty:

```sage
definition: mu.dimension(k=3)
3
```

```python
>>> from sage.all import *
>>> mu.dimension(k=Integer(3))
3
```

The 2-core of $\mu$ is not the empty partition:

```sage
definition: mu.dimension(k=2)
0
```

```python
>>> from sage.all import *
>>> mu.dimension(k=Integer(2))
0
```

Indeed, the 2-core of $\mu$ is $[1]$:

```sage
definition: mu.dimension(Partition([1]),k=2)
2
```

```python
>>> from sage.all import *
>>> mu.dimension(Partition([Integer(1)]),k=Integer(2))
2
```

**ALGORITHM:**

Depending on the parameters given, different simplifications occur. When $k = 1$ and smaller is empty, this function uses the hook formula. When $k = 1$ and smaller is not empty, it uses a formula from [ORV].

When $k \neq 1$, we first check that both self and smaller have the same $k$-core, then use the $k$-quotients and the same algorithm on each of the $k$-quotients.

**AUTHORS:**

- Paul-Olivier Dehaye (2011-06-07)

**dominated_partitions** (*rows=None*)

Return a list of the partitions dominated by $n$. If $rows$ is specified, then it only returns the ones whose number of rows is at most $rows$.

**EXAMPLES:**

```sage
definition: Partition([3,2,1]).dominated_partitions()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1]]
```

```sage
definition: Partition([3,2,1]).dominated_partitions(rows=3)
[[3, 2, 1], [2, 2, 2]]
```

```python
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).dominated_partitions()
[[3, 2, 1], [3, 1, 1, 1], [2, 2, 2], [2, 2, 1, 1], [2, 1, 1, 1, 1], [1, 1, 1, 1, 1, 1]]
```

```python
>>> Partition([Integer(3),Integer(2),Integer(1)]).dominated_partitions(rows=Integer(3))
[[3, 2, 1], [2, 2, 2]]
```
**dominates** (*p2*)

Return True if self dominates the partition *p2*. Otherwise it returns False.

**EXAMPLES:**

```
sage: p = Partition([3,2])
sage: p.dominates([3,1])
True
sage: p.dominates([2,2])
True
sage: p.dominates([2,1,1])
True
sage: p.dominates([3,3])
False
sage: p.dominates([4])
False
sage: Partition([4]).dominates(p)
False
sage: Partition([]).dominates([1])
False
sage: Partition([]).dominates([])
True
sage: Partition([1]).dominates([])
True
```

**down ()**

Return a generator for partitions that can be obtained from self by removing a cell.

**EXAMPLES:**

```
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2)])
>>> p.dominates([Integer(3),Integer(1)])
True
>>> p.dominates([Integer(2),Integer(2)])
True
>>> p.dominates([Integer(2),Integer(1),Integer(1)])
True
>>> p.dominates([Integer(3),Integer(3)])
False
>>> Partition([Integer(4)]).dominates(p)
False
>>> Partition([]).dominates([Integer(1)])
False
>>> Partition([]).dominates([])
True
>>> Partition([Integer(1)]).dominates([])
True
```

---

**Combinatorics, Release 10.4**

---
down_list()

Return a list of the partitions that can be obtained from self by removing a cell.

EXAMPLES:

```
sage: Partition([2,1,1]).down_list()
[[1, 1, 1], [2, 1]]
sage: Partition([3,2]).down_list()
[[2, 2], [3, 1]]
sage: Partition([3,2,1]).down_list()
[[2, 2, 1], [3, 1, 1], [3, 2]]
sage: Partition([]).down_list()  # checks :issue:A11435A
[]
```

dual_equivalence_graph(directed=False, coloring=None)

Return the dual equivalence graph of self.

Two permutations \(p\) and \(q\) in the symmetric group \(S_n\) differ by an \(i\)-elementary dual equivalence (or dual Knuth) relation (where \(i\) is an integer with \(1 < i < n\)) when the following two conditions are satisfied:

- In the one-line notation of the permutation \(p\), the letter \(i\) does not appear in between \(i-1\) and \(i+1\).
- The permutation \(q\) is obtained from \(p\) by switching two of the three letters \(i-1, i, i+1\) (in its one-line notation) – namely, the leftmost and the rightmost one in order of their appearance in \(p\).

Notice that this is equivalent to the statement that the permutations \(p^{-1}\) and \(q^{-1}\) differ by an elementary Knuth equivalence at positions \(i-1, i, i+1\).

Two standard Young tableaux of shape \(\lambda\) differ by an \(i\)-elementary dual equivalence relation (of color \(i\)), if their reading words differ by an \(i\)-elementary dual equivalence relation.

The dual equivalence graph of the partition \(\lambda\) is the edge-colored graph whose vertices are the standard Young tableaux of shape \(\lambda\), and whose edges colored by \(i\) are given by the \(i\)-elementary dual equivalences.

INPUT:

- directed – (default: False) whether to have the dual equivalence graph be directed (where we have a directed edge \(S \rightarrow T\) if \(i\) appears to the left of \(i+1\) in the reading word of \(T\); otherwise we have the directed edge \(T \rightarrow S\))
- coloring – (optional) a function which sends each integer \(i > 1\) to a color (as a string, e.g., 'red' or 'black') to be used when visually representing the resulting graph using dot2tex; the default choice
is 2 -> 'red', 3 -> 'blue', 4 -> 'green', 5 -> 'purple', 6 -> 'brown',
7 -> 'orange', 8 -> 'yellow', anything greater than 8 -> 'black'.

REFERENCES:
• [As2008b]

EXAMPLES:

```
sage: # needs sage.graphs
sage: P = Partition([3,1,1])
sage: G = P.dual_equivalence_graph()
sage: G.edges(sort=True)
[([[1, 2, 3], [4], [5]], [[1, 2, 4], [3], [5]], 3),
 ([[1, 2, 4], [3], [5]], [[1, 2, 5], [3], [4]], 4),
 ([[1, 2, 4], [3], [5]], [[1, 3, 4], [2], [5]], 2),
 ([[1, 2, 5], [3], [4]], [[1, 3, 5], [2], [4]], 2),
 ([[1, 3, 4], [2], [5]], [[1, 2, 5], [3], [4]], 2),
 ([[1, 3, 5], [2], [4]], [[1, 3, 4], [2], [5]], 4),
 ([[1, 3, 5], [2], [4]], [[1, 4, 5], [2], [3]], 3)]
sage: G = P.dual_equivalence_graph(directed=True)
sage: G.edges(sort=True)
[([[1, 2, 4], [3], [5]], [[1, 2, 3], [4], [5]], 3),
 ([[1, 2, 5], [3], [4]], [[1, 3, 5], [2], [4]], 2),
 ([[1, 3, 4], [2], [5]], [[1, 2, 4], [3], [5]], 2),
 ([[1, 3, 5], [2], [4]], [[1, 3, 5], [2], [4]], 4),
 ([[1, 4, 5], [2], [3]], [[1, 3, 5], [2], [4]], 3)]
```

```Python
>>> from sage.all import *
>>> # needs sage.graphs
>>> P = Partition([Integer(3),Integer(1),Integer(1)])
>>> G = P.dual_equivalence_graph()
>>> G.edges(sort=True)
[([[1, 2, 3], [4], [5]], [[1, 2, 4], [3], [5]], 3),
 ([[1, 2, 4], [3], [5]], [[1, 2, 5], [3], [4]], 4),
 ([[1, 2, 4], [3], [5]], [[1, 3, 4], [2], [5]], 2),
 ([[1, 2, 5], [3], [4]], [[1, 3, 5], [2], [4]], 2),
 ([[1, 3, 4], [2], [5]], [[1, 2, 4], [3], [5]], 2),
 ([[1, 3, 5], [2], [4]], [[1, 3, 5], [2], [4]], 4),
 ([[1, 3, 5], [2], [4]], [[1, 4, 5], [2], [3]], 3)]
>>> G = P.dual_equivalence_graph(directed=True)
>>> G.edges(sort=True)
[([[1, 2, 4], [3], [5]], [[1, 2, 3], [4], [5]], 3),
 ([[1, 2, 5], [3], [4]], [[1, 3, 5], [2], [4]], 2),
 ([[1, 3, 4], [2], [5]], [[1, 2, 4], [3], [5]], 2),
 ([[1, 3, 5], [2], [4]], [[1, 3, 5], [2], [4]], 4),
 ([[1, 4, 5], [2], [3]], [[1, 3, 5], [2], [4]], 3)]
```
```
evaluation()

Return the evaluation of self.

The commutative evaluation, often shortened to evaluation, of a word (we think of a partition as a word in
\{1, 2, 3, \ldots\}) is its image in the free commutative monoid. In other words, this counts how many occurrences
there are of each letter.

This is also is known as Parikh vector and abelianization and has the same output as `to_exp()`.

EXAMPLES:
```
Partition([4, 3, 1, 1]).evaluation()
[2, 0, 1, 1]

>>> from sage.all import *
>>> Partition([Integer(4), Integer(3), Integer(1), Integer(1)]).evaluation()
[2, 0, 1, 1]

ferrers_diagram()
Return the Ferrers diagram of self.

EXAMPLES:

sage: mu = Partition([5, 5, 2, 1])
sage: Partitions.options(diagram_str='*', convention="english")
sage: print(mu.ferrers_diagram())
*****
*****
**
*
sage: Partitions.options(diagram_str='▉')
sage: print(mu.ferrers_diagram())
▉▉▉▉▉
▉▉▉▉▉
▉▉
▉

>>> Partitions.options.convention="french"
>>> print(mu.ferrers_diagram())
▉
▉▉
▉▉▉▉▉

sage: print(Partition([]).ferrers_diagram())
-

>>> Partitions.options(diagram_str='-/')
>>> print(Partition([]).ferrers_diagram())
(//)

sage: Partitions.options._reset()
frobenius_coordinates()  
Return a pair of sequences of Frobenius coordinates aka beta numbers of the partition. 
These are two strictly decreasing sequences of nonnegative integers of the same length. 

EXAMPLES:

```python
sage: Partition([]).frobenius_coordinates()
([], [])
sage: Partition([1]).frobenius_coordinates()
([0], [0])
sage: Partition([3,3,3]).frobenius_coordinates()
([2, 1, 0], [2, 1, 0])
sage: Partition([9,1,1,1,1,1]).frobenius_coordinates()
([8], [6])
```

frobenius_rank()  
Return the Frobenius rank of the partition self. 
The Frobenius rank of a partition \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \cdots) \) is defined to be the largest \( i \) such that \( \lambda_i \geq i \). In other words, it is the number of cells on the main diagonal of \( \lambda \). In yet other words, it is the size of the largest square fitting into the Young diagram of \( \lambda \). 

EXAMPLES:

```python
sage: Partition([]).frobenius_rank()
0
sage: Partition([1]).frobenius_rank()
1
sage: Partition([3,3,3]).frobenius_rank()
3
sage: Partition([9,1,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,1,1,1,1]).frobenius_rank()
1
sage: Partition([2,2,1,1,1]).frobenius_rank()
2
sage: Partition([3,2]).frobenius_rank()
```

(continues on next page)
from_kbounded_to_grassmannian(k)

Maps a $k$-bounded partition to a Grassmannian element in the affine Weyl group of type $A_k^{(1)}$.

For details, see the documentation of the method `from_kbounded_to_reduced_word()`.

EXAMPLES:

```python
sage: p = Partition([2,1,1])
sage: p.from_kbounded_to_grassmannian(2) # needs sage.modules
[-1 1 1]
[-2 2 1]
[-2 1 2]
sage: p = Partition([])
sage: p.from_kbounded_to_grassmannian(2) # needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
```
from sage.all import *
>>> p = Partition([Integer(2), Integer(1), Integer(1)])
>>> p.from_kbounded_to_grassmannian(Integer(2))  # needs sage.modules
[-1 1 1]
[-2 2 1]
[-2 1 2]
>>> p = Partition([])
>>> p.from_kbounded_to_grassmannian(Integer(2))  # needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]

from_kbounded_to_reduced_word(k)
Maps a $k$-bounded partition to a reduced word for an element in the affine permutation group.
This uses the fact that there is a bijection between $k$-bounded partitions and $(k+1)$-cores and an action of the affine nilCoxeter algebra of type $A_k^{(1)}$ on $(k+1)$-cores as described in [LM2006b].

EXAMPLES:

sage: p = Partition([2,1,1])
sage: p.from_kbounded_to_reduced_word(2)
[2, 1, 2, 0]
sage: p = Partition([3,1])
sage: p.from_kbounded_to_reduced_word(3)
[3, 2, 1, 0]
sage: p.from_kbounded_to_reduced_word(2)
Traceback (most recent call last):
  ... ValueError: the partition must be 2-bounded
sage: p = Partition([])
sage: p.from_kbounded_to_reduced_word(2)
[]

>>> from sage.all import *
>>> p = Partition([Integer(2), Integer(1), Integer(1)])
>>> p.from_kbounded_to_reduced_word(Integer(2))
[2, 1, 2, 0]
>>> p = Partition([Integer(3), Integer(1)])
>>> p.from_kbounded_to_reduced_word(Integer(3))
[3, 2, 1, 0]
>>> p.from_kbounded_to_reduced_word(Integer(2))
Traceback (most recent call last):
  ... ValueError: the partition must be 2-bounded
>>> p = Partition([])
>>> p.from_kbounded_to_reduced_word(Integer(2))
[]

garnir_tableau(*cell)
Return the Garnir tableau of shape $\text{self}$ corresponding to the cell $\text{cell}$. If $\text{cell} = (a, c)$ then $(a + 1, c)$ must belong to the diagram of $\text{self}$.
The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring.
The Garnir tableaux are the “first” non-standard tableaux which arise when you act by simple transpositions. If \((a, c)\) is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers \(1, 2, \ldots, n\) entered in order from left to right along the rows of the diagram up to the cell \((a, c - 1)\), then along the cells \((a + 1, 1)\) to \((a + 1, c)\), then \((a, c)\) until the end of row \(a\) and then continuing from left to right in the remaining positions. The examples below probably make this clearer!

**Note:** The function also sets \(g._\text{garnir\_cell}\), where \(g\) is the resulting Garnir tableau, equal to \(\text{cell}\) which is used by some other functions.

**EXAMPLES:**

```python
g = Partition([5, 3, 3, 2]).garnir_tableau((0, 2)); g.pp()
1 2 6 7 8
3 4 5
9 10 11
12 13

g.is_row_strict(); g.is_column_strict()
True
False
```

```python
g = Partition([5, 3, 3, 2]).garnir_tableau(0, 2).pp()
1 2 6 7 8
3 4 5
9 10 11
12 13
```

```python
g = Partition([5, 3, 3, 2]).garnir_tableau(2, 1).pp()
1 2 3 4 5
6 7 8
9 12 13
10 11
```

```python
g = Partition([5, 3, 3, 2]).garnir_tableau(2, 2).pp()
Traceback (most recent call last):
...
ValueError: (row+1, col) must be inside the diagram
```

```python
from sage.all import *
g = Partition([Integer(5), Integer(3), Integer(3), Integer(2)]).garnir_tableau((Integer(0), Integer(2))); g.pp()
1 2 6 7 8
3 4 5
9 10 11
12 13
```

```python
g.is_row_strict(); g.is_column_strict()
True
False
```

```python
Partition([Integer(5), Integer(3), Integer(3), Integer(2)]).garnir_tableau(Integer(0), Integer(2)).pp()
1 2 6 7 8
3 4 5
9 10 11
12 13
```

```python
Partition([Integer(5), Integer(3), Integer(3), Integer(2)]).garnir_tableau(Integer(2), Integer(1)).pp()
1 2 3 4 5
```
Partition([Integer(5), Integer(3), Integer(3), Integer(2)]).garnir_tableau(Integer(2), Integer(2)).pp()
Traceback (most recent call last):
... Value Error: (row+1, col) must be inside the diagram

See also:

- top_garnir_tableau()

garsia_procesi_module(base_ring=None)

Return the Garsia-Procesi module corresponding to self.

INPUT:

- base_ring – (default: QQ) the base ring

EXAMPLES:

```
sage: GP = Partition([3, 2, 1]).garsia_procesi_module(QQ); GP
Garsia-Procesi module of shape [3, 2, 1] over Rational Field
sage: GP.graded_frobenius_image()
q^4*s[3, 2, 1] + q^3*s[3, 3] + q^3*s[4, 1, 1] + (q^3+q^2)*s[4, 2] + (q^2+q)*s[5, 1] + s[6]
sage: Partition([3, 2, 1]).garsia_procesi_module(GF(3))
Garsia-Procesi module of shape [3, 2, 1] over Finite Field of size 3
```

```
>>> from sage.all import *

 Partition([3, 2, 1]).garsia_procesi_module(module(GF(3)))
Garsia-Procesi module of shape [3, 2, 1] over Finite Field of size 3
```

generalized_pochhammer_symbol(a, alpha)

Return the generalized Pochhammer symbol $a_{\text{self}}^{(\alpha)}$. This is the product over all cells $(i, j)$ in self of $a - (i - 1)/\alpha + j - 1$.

EXAMPLES:

```
sage: Partition([2, 2]).generalized_pochhammer_symbol(2, 1)
12
```

```
>>> from sage.all import *
>>> Partition([2, 2]).generalized_pochhammer_symbol(2, 1)
12
```
get_part \( (i, \text{default}=0) \)

Return the \( i \)th part of \( \text{self} \), or \( \text{default} \) if it does not exist.

EXAMPLES:

```python
sage: p = Partition([2, 1])
sage: p.get_part(0), p.get_part(1), p.get_part(2)
(2, 1, 0)
sage: p.get_part(10, -1)
-1
sage: Partition([]).get_part(0)
0
```

**glaisher_franklin\((s)\)**

Apply the Glaisher-Franklin bijection to \( \text{self} \).

The Franklin-Glaisher bijection, with parameter \( s \), returns a partition whose set of parts that are repeated at least \( s \) times equals the set of parts divisible by \( s \) in \( \text{self} \), after dividing each part by \( s \).

**INPUT:**

- \( s \) – positive integer

**EXAMPLES:**

```python
sage: Partition([4, 3, 2, 2, 1]).glaisher_franklin(2)
[3, 2, 2, 1, 1, 1, 1]
```

```python
>>> from sage.all import *
>>> p = Partition([Integer(4), Integer(3), Integer(2), Integer(2), Integer(1)]).glaisher_franklin(Integer(2))
>>> p
[3, 2, 2, 1, 1, 1, 1]
```

**glaisher_franklin_inverse\((s)\)**

Apply the inverse of the Glaisher-Franklin bijection to \( \text{self} \).

The inverse of the Franklin-Glaisher bijection, with parameter \( s \), returns a partition whose set of parts that are divisible by \( s \), after dividing each by \( s \), equals the equals the set of parts repeated at least \( s \) times in \( \text{self} \).

**INPUT:**

- \( s \) – positive integer

**EXAMPLES:**

```python
sage: Partition([4, 3, 2, 2, 1]).glaisher_franklin(2)
[3, 2, 2, 1, 1, 1, 1]
```

```python
sage: Partition([3, 2, 2, 1, 1, 1, 1]).glaisher_franklin_inverse(2)
[4, 3, 2, 2, 1]
```

5.1. Comprehensive Module List 2731
has_k_rectangle \(k\)
Return True if the Ferrer’s diagram of self contains \(k - i + 1\) rows (or more) of length \(i\) (exactly) for any \(i\) in \([1, k]\).

This is mainly a helper function for is_k_reducible() and is_k_irreducible(), the only difference between this function and is_k_reducible() being that this function allows any partition as input while is_k_reducible() requires the input to be \(k\)-bounded.

EXAMPLES:
The partition \([1, 1, 1]\) has at least 2 rows of length 1:

```
sage: Partition([1, 1, 1]).has_k_rectangle(2)
True
```

The partition \([1, 1, 1]\) does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```
sage: Partition([1, 1, 1]).has_k_rectangle(4)
False
```

See also:
is_k_irreducible(), is_k_reducible(), has_rectangle()

has_rectangle \((h, w)\)
Return True if the Ferrer’s diagram of self has \(h\) (or more) rows of length \(w\) (exactly).

INPUT:

- \(h\) – An integer \(h \geq 1\). The (minimum) height of the rectangle.
- \(w\) – An integer \(w \geq 1\). The width of the rectangle.

EXAMPLES:

```
sage: Partition([3, 3, 3, 3]).has_rectangle(2, 3)
True
sage: Partition([3, 3]).has_rectangle(2, 3)
True
sage: Partition([4, 3]).has_rectangle(2, 3)
```

(continues on next page)
False

\texttt{sage: Partition([3]).has_rectangle(2, 3)}
False

\begin{verbatim}
>>> from sage.all import *
>>> Partition([Integer(3), Integer(3), Integer(3), Integer(3)]).has_rectangle(Integer(2), Integer(3))
True
>>> Partition([Integer(3), Integer(3)]).has_rectangle(Integer(2), Integer(3))
True
>>> Partition([Integer(4), Integer(3)]).has_rectangle(Integer(2), Integer(3))
False
>>> Partition([Integer(3)]).has_rectangle(Integer(2), Integer(3))
False
\end{verbatim}

See also:

\texttt{has_k_rectangle()}

\textbf{hook_length}(i, j)

Return the length of the hook of cell \((i, j)\) in self.

The (length of the) hook of cell \((i, j)\) of a partition \(\lambda\) is

\[
\lambda_i + \lambda'_j - i - j + 1
\]

where \(\lambda'\) is the conjugate partition. In English convention, the hook length is the number of cells horizontally to the right and vertically below the cell \((i, j)\) (including that cell).

EXAMPLES:

\begin{verbatim}
\texttt{sage: p = Partition([2,2,1])
\texttt{sage: p.hook_length(0, 0)}
4
\texttt{sage: p.hook_length(0, 1)}
2
\texttt{sage: p.hook_length(2, 0)}
1
\texttt{sage: Partition([3,3]).hook_length(0, 0)}
4
\texttt{sage: cell = [0,0]; Partition([3,3]).hook_length(*cell)}
4
\end{verbatim}

\begin{verbatim}
\texttt{>>> from sage.all import *}
\texttt{>>> p = Partition([Integer(2),Integer(2),Integer(1)])}
\texttt{>>> p.hook_length(Integer(0), Integer(0))}
4
\texttt{>>> p.hook_length(Integer(0), Integer(1))}
2
\texttt{>>> p.hook_length(Integer(2), Integer(0))}
1
\texttt{>>> Partition([Integer(3),Integer(3)]).hook_length(Integer(0), Integer(0))}
4
\texttt{>>> cell = [Integer(0),Integer(0)]; Partition([Integer(3),Integer(3)]).hook_length(*cell)}
4
\end{verbatim}
**hook_lengths()**

Return a tableau of shape `self` with the cells filled in with the hook lengths.

In each cell, put the sum of one plus the number of cells horizontally to the right and vertically below the cell (the hook length).

For example, consider the partition `[3, 2, 1]` of 6 with Ferrers diagram:

```
# # #
# #
#
```

When we fill in the cells with the hook lengths, we obtain:

```
5 3 1
3 1
1
```

**EXAMPLES:**

```python
sage: Partition([2,2,1]).hook_lengths()
[[4, 2], [3, 1], [1]]
sage: Partition([3,3]).hook_lengths()
[[4, 3, 2], [3, 2, 1]]
sage: Partition([3,2,1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: Partition([2,2]).hook_lengths()
[[3, 2], [2, 1]]
sage: Partition([5]).hook_lengths()
[[5, 4, 3, 2, 1]]
```

```python
# >>> from sage.all import *
# >>> Partition([Integer(2),Integer(2),Integer(1)]).hook_lengths()
# [[4, 2], [3, 1], [1]]
# >>> Partition([Integer(3),Integer(3)]).hook_lengths()
# [[4, 3, 2], [3, 2, 1]]
# >>> Partition([Integer(3),Integer(2),Integer(1)]).hook_lengths()
# [[5, 3, 1], [3, 1], [1]]
# >>> Partition([Integer(2),Integer(2)]).hook_lengths()
# [[3, 2], [2, 1]]
# >>> Partition([Integer(5)]).hook_lengths()
# [[5, 4, 3, 2, 1]]
```

**REFERENCES:**

**hook_polynomial** `q, t`

Return the two-variable hook polynomial.

**EXAMPLES:**

```python
sage: R.<q,t> = PolynomialRing(QQ)
sage: a = Partition([2,2]).hook_polynomial(q,t)
sage: a == (1 - t)*(1 - q*t)*(1 - t^2)*(1 - q*t^2)
True
sage: a = Partition([3,2,1]).hook_polynomial(q,t)
sage: a == (1 - t)^3*(1 - q*t^2)^2*(1 - q^2*t^3)
True
```
>>> from sage.all import *
>>> R = PolynomialRing(QQ, names=('q', 't',)); (q, t,) = R._first_ngens(2)
>>> a = Partition([Integer(2),Integer(2)]).hook_polynomial(q,t)
>>> a == (Integer(1) - t)*(Integer(1) - q*t)*(Integer(1) - t**Integer(2))*(Integer(1) - q*t**Integer(2))
True
>>> a = Partition([Integer(3),Integer(2),Integer(1)]).hook_polynomial(q,t)
>>> a == (Integer(1) - t)**Integer(3)*(Integer(1) - q*t**Integer(2))**Integer(2)*(Integer(1) - q**Integer(2)*t**Integer(3))
True

**hook_product** \((a)\)

Return the Jack hook-product.

**EXAMPLES:**

```
sage: Partition([3,2,1]).hook_product(x)  # needs sage.symbolic
(2*x + 3)*(x + 2)^2
```

```
sage: Partition([2,2]).hook_product(x)  # needs sage.symbolic
2*(x + 2)*(x + 1)
```

```
>>> from sage.all import *

>>> Partition([Integer(3),Integer(2),Integer(1)]).hook_product(x)  # needs sage.symbolic
(2*x + 3)*(x + 2)^2
```

```
>>> Partition([Integer(2),Integer(2)]).hook_product(x)  # needs sage.symbolic
2*(x + 2)*(x + 1)
```

**hooks**

Return a sorted list of the hook lengths in \(self\).

**EXAMPLES:**

```
sage: Partition([3,2,1]).hooks()
[5, 3, 3, 1, 1, 1]
```

```
>>> from sage.all import *

>>> Partition([Integer(3),Integer(2),Integer(1)]).hooks()
[5, 3, 3, 1, 1, 1]
```

**horizontal_border_strip_cells** \((k)\)

Return a list of all the horizontal border strips of length \(k\) which can be added to \(self\), where each horizontal border strip is a generator of cells.

**EXAMPLES:**

```
sage: list(Partition([]).horizontal_border_strip_cells(0))
[]
```

```
sage: list(Partition([3,2,1]).horizontal_border_strip_cells(0))
[]
```

```
sage: list(Partition([]).horizontal_border_strip_cells(2))
[[[0, 0], (0, 1)]]
```

```
sage: list(Partition([2,2]).horizontal_border_strip_cells(2))
```

(continues on next page)
initial_column_tableau()

Return the initial column tableau of shape self.

The initial column tableau of shape self is the standard tableau that has the numbers 1 to n, where n is the size() of self, entered in order from top to bottom and then left to right down the columns of self.

EXAMPLES:

sage: Partition([3,2]).initial_column_tableau()
[[1, 3, 5], [2, 4]]

initial_tableau()

Return the standard tableau which has the numbers 1, 2, ..., n where n is the size() of self entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

sage: Partition([3,2,2]).initial_tableau()
[[1, 2, 3], [4, 5], [6, 7]]
inside_corners()

Return a list of the corners of the partition self.

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form \((i,j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** This is referred to as an “inner corner” in [Sag2001].

EXAMPLES:

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners()
[(1, 1)]
>>> Partition([Integer(3),Integer(3),Integer(1)]).corners()
[(2, 0)]
>>> Partition([]).corners()
[]

inside_corners_residue \((i, l)\)

Return a list of the corners of the partition self having \(l\)-residue \(i\).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind. See residue() for the definition of the \(l\)-residue.

The entries of the list returned are pairs of the form \((i,j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

```
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(0), \_

**is_core**\((k)\)

Return `True` if the Partition `self` is a \(k\)-core.

A partition is said to be a \(k\)-core if it has no hooks of length \(k\). Equivalently, a partition is said to be a \(k\)-core if it is its own \(k\)-core (where the latter is defined as in `core()`).

Visually, this can be checked by trying to remove border strips of size \(k\) from `self`. If this is not possible, then `self` is a \(k\)-core.

**EXAMPLES:**
In the partition \((2, 1)\), a hook length of 2 does not occur, but a hook length of 3 does:

```python
sage: p = Partition([2, 1])
sage: p.is_core(2)
True
sage: p.is_core(3)
False
sage: q = Partition([12, 8, 5, 2, 2, 1])
sage: q.is_core(4)
False
sage: q.is_core(5)
True
sage: q.is_core(0)
True
```

See also:
`core()`, `Core`

**is_empty()**

Return `True` if `self` is the empty partition.

**EXAMPLES:**

```python
sage: Partition([]).is_empty()
True
sage: Partition([2, 1, 1]).is_empty()
False
```

```python
>>> from sage.all import *

>>> Partition([]).is_empty()

(continues on next page)```
is_k_bounded\( (k) \)

Return True if the partition self is bounded by \( k \).

EXAMPLES:

```python
>>> Partition([4, 3, 1]).is_k_bounded(4)
True
>>> Partition([4, 3, 1]).is_k_bounded(7)
True
>>> Partition([4, 3, 1]).is_k_bounded(3)
False
```

is_k_irreducible\( (k) \)

Return True if the partition self is \( k \)-irreducible.

A \( k \)-bounded partition is \( k \)-irreducible if its Ferrer’s diagram does not contain \( k - i + 1 \) rows (or more) of length \( i \) (exactly) for every \( i \in [1, k] \).

(Also, a \( k \)-bounded partition is \( k \)-irreducible if and only if it is not \( k \)-reducible.)

EXAMPLES:

The partition \([1, 1, 1]\) has at least 2 rows of length 1:

```python
>>> from sage.all import *
>>> Partition([1, 1, 1]).is_k_irreducible(2)
False
```

The partition \([1, 1, 1]\) does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```python
>>> from sage.all import *
>>> Partition([1, 1, 1]).is_k_irreducible(4)
True
```

See also:

is_k_reducible(), has_k_rectangle()
**is_k_reducible** $(k)$
Return True if the partition self is $k$-reducible.

A $k$-bounded partition is $k$-reducible if its Ferrer's diagram contains $k - i + 1$ rows (or more) of length $i$ (exactly) for some $i \in [1,k]$.

(Also, a $k$-bounded partition is $k$-reducible if and only if it is not $k$-irreducible.)

**EXAMPLES:**
The partition $[1, 1, 1]$ has at least 2 rows of length 1:

```python
sage: Partition([1, 1, 1]).is_k_reducible(2)
True
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).is_k_reducible(Integer(2))
True
```

The partition $[1, 1, 1]$ does not have 4 rows of length 1, 3 rows of length 2, 2 rows of length 3, nor 1 row of length 4:

```python
sage: Partition([1, 1, 1]).is_k_reducible(4)
False
>>> from sage.all import *
>>> Partition([Integer(1), Integer(1), Integer(1)]).is_k_reducible(Integer(4))
False
```

**See also:**

`is_k_irreducible()`, `has_k_rectangle()`

**is_regular** $(e, \text{ multicharge}=(0,))$
Return True if this is an $e$-regular partition.

A partition is $e$-regular if it does not have $e$ equal non-zero parts.

**EXAMPLES:**

```python
sage: Partition([4,3,3,3]).is_regular(2)
False
sage: Partition([4,3,3,3]).is_regular(3)
False
sage: Partition([4,3,3,3]).is_regular(4)
True
>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(3)]).is_regular(Integer(2))
False
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(3)]).is_regular(Integer(3))
False
>>> Partition([Integer(4),Integer(3),Integer(3),Integer(3)]).is_regular(Integer(4))
True
```
**is_restricted** (*e, multicharge=*(0,))

Return True if this is an e-restricted partition.

An e-restricted partition is a partition such that the difference of consecutive parts is always strictly less than e, where partitions are considered to have an infinite number of 0 parts. I.e., the last part must be strictly less than e.

**EXAMPLES:**

```python
sage: Partition([4,3,3,2]).is_restricted(2)
False
sage: Partition([4,3,3,2]).is_restricted(3)
True
sage: Partition([4,3,3,2]).is_restricted(4)
True
sage: Partition([4]).is_restricted(4)
False
```

**is_symmetric()**

Return True if the partition self equals its own transpose.

**EXAMPLES:**

```python
sage: Partition([2, 1]).is_symmetric()
True
sage: Partition([3, 1]).is_symmetric()
False
```

**jacobi_trudi()**

Return the Jacobi-Trudi matrix of self thought of as a skew partition. See `SkewPartition.jacobi_trudi()`.

**EXAMPLES:**

```python
sage: # needs sage.modules
sage: part = Partition([3,2,1])
sage: jt = part.jacobi_trudi(); jt
```

(continues on next page)
\[
\begin{bmatrix}
\end{bmatrix}
\]

\textbf{sage:} s = SymmetricFunctions(QQ).schur()
\textbf{sage:} h = SymmetricFunctions(QQ).homogeneous()
\textbf{sage:} h(s(part))
\textbf{h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]}
\textbf{sage:} jt.det()
\textbf{h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]}

k\_atom\(k\)

Return a list of the standard tableaux of size self.size() whose k-atom is equal to self.

\begin{verbatim}
sage: p = Partition([3,2,1])
\textbf{sage:} p.k_atom(1)
[]
\textbf{sage:} p.k_atom(3)
[[[1, 1, 1, 2, 3], [2]],
 [[1, 1, 1, 3], [2, 2]],
 [[1, 1, 1, 2], [2, [3]],
 [[1, 1, 1], [2, 2], [3]]]
\textbf{sage:} p.k_atom(4)
[[[1, 1, 1, 3], [2, 2]], [[1, 1, 1], [2, 2], [3]]]
\end{verbatim}

k\_boundary\(k\)

Return the skew partition formed by removing the cells of the k-interior, see k\_interior().

\begin{verbatim}
>>> from sage.all import *
>>> # needs sage.modules
>>> part = Partition([Integer(3),Integer(2),Integer(1)])
>>> jt = part.jacobi_trudi(); jt
>>> s = SymmetricFunctions(QQ).schur()
>>> h = SymmetricFunctions(QQ).homogeneous()
>>> h(s(part))
\textbf{h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]}
>>> jt.det()
\textbf{h[3, 2, 1] - h[3, 3] - h[4, 1, 1] + h[5, 1]}
\end{verbatim}
```python
sage: p = Partition([3,2,1])
sage: p.k_boundary(2)
[3, 2, 1] / [2, 1]
sage: p.k_boundary(3)
[3, 2, 1] / [1]
sage: p = Partition([12,8,5,5,2,2,1])
sage: p.kBoundary(4)
[12, 8, 5, 5, 2, 2, 1] / [8, 5, 2]

>>> from sage.all import *

>>> p = Partition([Integer(3),Integer(2),Integer(1)])

>>> p.k_boundary(Integer(2))
[3, 2, 1] / [2, 1]

>>> p.k_boundary(Integer(3))
[3, 2, 1] / [1]

>>> p = Partition([Integer(12),Integer(8),Integer(5),Integer(5),Integer(2), Integer(2),Integer(1)])

>>> p.k_boundary(Integer(4))
[12, 8, 5, 5, 2, 2, 1] / [8, 5, 2]
```

**k_column_lengths** *(k)*

Return the k-column-shape of the partition self.

This is the 'column' analog of **k_row_lengths**.

**EXAMPLES:**

```python
sage: Partition([6,1]).k_column_lengths(2)
[1, 0, 0, 0, 1, 1]
sage: Partition([4,4,4,3,2]).k_column_lengths(2)
[1, 1, 1, 2]
```

```python
>>> from sage.all import *
>>> Partition([Integer(6), Integer(1)]).k_column_lengths(Integer(2))
[1, 0, 0, 0, 1, 1]

>>> Partition([Integer(4), Integer(4), Integer(4), Integer(3), Integer(2)]).k_column_lengths(Integer(2))
[1, 1, 1, 2]
```

See also:

**k_row_lengths**, **k_boundary**, **SkewPartition.row_lengths**, **SkewPartition.column_lengths**

**k_conjugate** *(k)*

Return the k-conjugate of self.

The k-conjugate is the partition that is given by the columns of the k-skew diagram of the partition.

We can also define the k-conjugate in the following way. Let \( P \) denote the bijection from \((k + 1)\)-cores to \(k\)-bounded partitions. The \(k\)-conjugate of a \((k + 1)\)-core \( \lambda \) is

\[
\lambda^{(k)} = \text{inv}((P(\lambda))').
\]

**EXAMPLES:**
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_conjugate(4)
[3, 2, 2, 1, 1, 1, 1, 1, 1]

>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(2),Integer(2),Integer(1),
→Integer(1)])
>>> p.k_conjugate(Integer(4))
[3, 2, 2, 1, 1, 1, 1, 1, 1]

\textbf{k\_interior}(k)

Return the partition consisting of the cells of \texttt{self} whose hook lengths are greater than \textit{k}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p = Partition([3,2,1])
sage: p.hook_lengths()
[[5, 3, 1], [3, 1], [1]]
sage: p.k_interior(2)
[2, 1]
sage: p.k_interior(3)
[1]
sage: p = Partition([])
sage: p.k_interior(3)
[]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> p = Partition([Integer(3),Integer(2),Integer(1)])
>>> p.hook_lengths()
[[5, 3, 1], [3, 1], [1]]
>>> p.k_interior(Integer(2))
[2, 1]
>>> p.k_interior(Integer(3))
[1]
>>> p = Partition([])
>>> p.k_interior(Integer(3))
[]
\end{verbatim}

\textbf{k\_irreducible}(k)

Return the partition with all \(r \times (k + 1 - r)\) rectangles removed.

If \texttt{self} is a \(k\)-bounded partition, then this method will return the partition where all rectangles of dimension \(r \times (k + 1 - r)\) for \(1 \leq r \leq k\) have been deleted.

If \texttt{self} is not a \(k\)-bounded partition then the method will raise an error.

\textbf{INPUT:}

- \textit{k} – a non-negative integer

\textbf{OUTPUT:}

- a partition

\textbf{EXAMPLES:}
Combinatorics, Release 10.4

\[sage: Partition([3,2,2,1,1,1]).k_irreducible(4)\]
\[[3, 2, 2, 1, 1, 1]\]
\[sage: Partition([3,2,2,1,1,1]).k_irreducible(3)\]
\[
\]
\[sage: Partition([3,3,2,2,2,1,1,1,1]).k_irreducible(3)\]
\[[2, 1]\]

```python
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1),Integer(1),
Integer(1)]).k_irreducible(Integer(4))
[3, 2, 1, 1, 1]
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1),Integer(1),
Integer(1)]).k_irreducible(Integer(3))
[]
>>> Partition([Integer(3),Integer(3),Integer(2),Integer(2),Integer(2),Integer(2),
Integer(1),Integer(1),Integer(1),Integer(1)]).k_irreducible(Integer(3))
[2, 1]
```

**k_rim**

Return the \(k\)-rim of `self` as a list of integer coordinates.

The \(k\)-rim of a partition is the “line between” (or “intersection of”) the \(k\)-boundary and the \(k\)-interior. (Section 2.3 of [HM2011])

It will be output as an ordered list of integer coordinates, where the origin is \((0, 0)\). It will start at the top-left of the \(k\)-rim (using French convention) and end at the bottom-right.

**EXAMPLES:**

Consider the partition \((3, 1)\) split up into its \(1\)-interior and \(1\)-boundary:

The line shown in bold is the \(1\)-rim, and that information is equivalent to the integer coordinates of the points that occur along that line:

```python
sage: Partition([3, 1]).k_rim(1)
[(3, 0), (2, 0), (2, 1), (1, 1), (0, 1), (0, 2)]
```

```python
>>> from sage.all import *
>>> Partition([Integer(3), Integer(1)]).k_rim(Integer(1))
[(3, 0), (2, 0), (2, 1), (1, 1), (0, 1), (0, 2)]
```

**See also:**

`k_interior()`, `k_boundary()`, `boundary()`
**k_row_lengths(k)**

Return the \(k\)-row-shape of the partition \(self\).

This is equivalent to taking the \(k\)-boundary of the partition and then returning the row-shape of that. We do *not* discard rows of length 0. (Section 2.2 of [LLMS2013])

**EXAMPLES:**

```python
sage: Partition([6, 1]).k_row_lengths(2)
[2, 1]
sage: Partition([4, 4, 4, 3, 2]).k_row_lengths(2)
[0, 1, 1, 2]
```

```python
>>> from sage.all import *

```> `[Integer(6), Integer(1)]`.k_row_lengths(Integer(2))
[2, 1]
```> `[Integer(4), Integer(4), Integer(4), Integer(3), Integer(2)]`.k_row_lengths(Integer(2))
[0, 1, 1, 2]

See also:

- \(k\_column\_lengths()\)
- \(k\_boundary()\)
- \(SkewPartition\_row\_lengths()\)
- \(SkewPartition\_column\_lengths()\)

**k_size(k)**

Given a partition \(self\) and a \(k\), return the size of the \(k\)-boundary.

This is the same as the length method \(sage.combinat.core.Core\_length()\) of the \(sage.combinat.core.Core\) object, with the exception that here we don’t require \(self\) to be a \(k + 1\)-core.

**EXAMPLES:**

```python
sage: Partition([2, 1, 1]).k_size(1)
2
sage: Partition([2, 1, 1]).k_size(2)
3
sage: Partition([2, 1, 1]).k_size(3)
3
sage: Partition([2, 1, 1]).k_size(4)
4
```

```python
>>> from sage.all import *

```> `[Integer(2), Integer(1), Integer(1)]`.k_size(Integer(1))
2
```> `[Integer(2), Integer(1), Integer(1)]`.k_size(Integer(2))
3
```> `[Integer(2), Integer(1), Integer(1)]`.k_size(Integer(3))
3
```> `[Integer(2), Integer(1), Integer(1)]`.k_size(Integer(4))
4

See also:

- \(k\_boundary()\)
- \(SkewPartition\_size()\)
\textbf{\texttt{k\_skew}(k)}

Return the $k$-skew partition.

The $k$-skew diagram of a $k$-bounded partition is the skew diagram denoted $\lambda/k$ satisfying the conditions:

1. row $i$ of $\lambda/k$ has length $\lambda_i$,
2. no cell in $\lambda/k$ has hook-length exceeding $k$,
3. every square above the diagram of $\lambda/k$ has hook length exceeding $k$.

\textbf{REFERENCES:}

- [LM2004]

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p = Partition([4,3,2,2,1,1])
sage: p.k_skew(4)
[9, 5, 3, 2, 1, 1] / [5, 2, 1]

>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(2),Integer(2),Integer(1),
                 Integer(1)])
>>> p.k_skew(Integer(4))
[9, 5, 3, 2, 1, 1] / [5, 2, 1]
\end{verbatim}

\textbf{\texttt{k\_split}(k)}

Return the $k$-split of self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Partition([4,3,2,1]).k_split(3)
[]
sage: Partition([4,3,2,1]).k_split(4)
[[4], [3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(5)
[[4, 3], [2, 1]]
sage: Partition([4,3,2,1]).k_split(6)
[[4, 3, 2], [1]]
sage: Partition([4,3,2,1]).k_split(7)
[[4, 3, 2, 1]]
sage: Partition([4,3,2,1]).k_split(8)
[[4, 3, 2, 1]]

>>> from sage.all import *
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_split(Integer(3))
[]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_split(Integer(4))
[[4], [3, 2], [1]]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_split(Integer(5))
[[4, 3], [2, 1]]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_split(Integer(6))
[[4, 3, 2], [1]]
>>> Partition([Integer(4),Integer(3),Integer(2),Integer(1)]).k_split(Integer(7))
[[4, 3, 2, 1]]
\end{verbatim}

(continues on next page)
ladder_tableau(e, ladder_lengths=False)

Return the ladder tableau of shape self.

The $e$-ladder tableau is the standard Young tableau obtained by reading the ladders, the set of cells $(i, j)$ that differ from $(i + e - 1, j - 1)$, of the partition $\lambda$ from left-to-right.

INPUT:

- $e$ – a nonnegative integer; 0 is considered as $\infty$ (analogous to the characteristic of a ring)
- ladder_sizes – (default: False) if True, also return the sizes of the ladders

See also:

ladders()

EXAMPLES:

sage: la = Partition([6, 5, 3, 1])
sage: ascii_art(la.ladder_tableau(3))

1  2  3  5  7  10
4  6  8  11 13
9 12 14
15

sage: la.ladder_tableau(3, ladder_lengths=True)[1]

[1, 1, 2, 2, 3, 3, 3]

sage: ascii_art(la.ladder_tableau(0))

1 2 3 4 5 6
7 8 9 10 11
12 13 14
15

sage: all(ll == 1 for ll in la.ladder_tableau(0, ladder_lengths=True)[1])
True
**ladders**\((e)\)
Return a dictionary containing the ladders in the diagram of \texttt{self}.
For \(e > 0\), a node \((i, j)\) in a partition belongs to the \(l\)-th \(e\)-ladder if \(l = (e - 1)r + c\).

**INPUT:**
- \(e\) – a nonnegative integer; if 0, then we set \(e = \text{self.size()} + 1\)

**EXAMPLES:**
```python
sage: Partition([3, 2]).ladders(3)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2), (1, 0)], 3: [(1, 1)]}
```
```python
>>> from sage.all import *
>>> Partition([Integer(3), Integer(2)]).ladders(Integer(3))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2), (1, 0)], 3: [(1, 1)]}
```

When \(e\) is 0, the cells are in bijection with the ladders, but the index of the ladder depends on the size of the partition:
```python
sage: Partition([3, 2]).ladders(0)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 6: [(1, 1)]}
sage: Partition([3, 2, 1]).ladders(0)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 6: [(1, 0)], 7: [(1, 1)], 12: [(2, 0)]}
sage: Partition([3, 1, 1]).ladders(0)
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 10: [(2, 0)]}
sage: Partition([1, 1, 1]).ladders(0)
{0: [(0, 0)], 3: [(1, 0)], 6: [(2, 0)]}
```
```python
>>> from sage.all import *
>>> Partition([Integer(3), Integer(2)]).ladders(Integer(0))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 6: [(1, 1)]}
>>> Partition([Integer(3), Integer(2), Integer(1)]).ladders(Integer(0))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 6: [(1, 0)], 7: [(1, 1)], 12: [(2, 0)]}
>>> Partition([Integer(3), Integer(1), Integer(1)]).ladders(Integer(0))
{0: [(0, 0)], 1: [(0, 1)], 2: [(0, 2)], 5: [(1, 0)], 10: [(2, 0)]}
>>> Partition([Integer(1), Integer(1), Integer(1)]).ladders(Integer(0))
{0: [(0, 0)], 3: [(1, 0)], 6: [(2, 0)]}
```

**larger_lex**\((rhs)\)
Return \texttt{True} if \texttt{self} is larger than \texttt{rhs} in lexicographic order. Otherwise return \texttt{False}.

**EXAMPLES:**
```python
sage: p = Partition([3, 2])
sage: p.larger_lex([3, 1])
True
sage: p.larger_lex([1, 4])
True
sage: p.larger_lex([3, 2, 1])
False
sage: p.larger_lex([3])
True
sage: p.larger_lex([5])
False
```
(continues on next page)
sage: p.larger_lex([3,1,1,1,1,1,1,1])
True

```python
>>> from sage.all import *

>>> p = Partition([Integer(3),Integer(2)])

>>> p.larger_lex([Integer(3),Integer(1)])
True

>>> p.larger_lex([Integer(1),Integer(4)])
True

>>> p.larger_lex([Integer(3),Integer(2),Integer(1)])
False

>>> p.larger_lex([Integer(3)])
True

>>> p.larger_lex([Integer(5)])
False

>>> p.larger_lex([Integer(3),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])
True
```

**leg_cells**(i, j)

Return the list of the cells of the leg of cell (i, j) in self.

The leg of cell \(c = (i, j)\) is defined to be the cells below \(c\) (in English convention).

The cell coordinates are zero-based, i.e., the northwesternmost cell is (0, 0).

**INPUT:**

- i, j – two integers

**OUTPUT:**

A list of pairs of integers

**EXAMPLES:**

```python
sage: Partition([4,4,3,1]).leg_cells(1,1)
[(2, 1)]

sage: Partition([4,4,3,1]).leg_cells(0,1)
[(1, 1), (2, 1)]

sage: Partition([]).leg_cells(0,0)
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```

```python
>>> from sage.all import *

>>> Partition([Integer(4),Integer(4),Integer(3),Integer(1)]).leg_cells(Integer(1),Integer(1))
[(2, 1)]

>>> Partition([Integer(4),Integer(4),Integer(3),Integer(1)]).leg_cells(Integer(0),Integer(1))
[(1, 1), (2, 1)]

>>> Partition([]).leg_cells(Integer(0),Integer(0))
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```
\textbf{leg_length} \((i, j)\)

Return the length of the leg of cell \((i, j)\) in \texttt{self}.

The leg of cell \(c = (i, j)\) is defined to be the cells below \(c\) (in English convention).

The cell coordinates are zero-based, i.e., the northwesternmost cell is \((0, 0)\).

\textbf{INPUT:}

\begin{itemize}
  \item \(i, j\) – two integers
\end{itemize}

\textbf{OUTPUT:}

An integer or a \texttt{ValueError}

\textbf{EXAMPLES:}

\begin{verbatim}
sage: p = Partition([2,2,1])
sage: p.leg_length(0, 0)
2
sage: p.leg_length(0,1)
1
sage: p.leg_length(2,0)
0
sage: Partition([3,3]).leg_length(0, 0)
1
sage: cell = [0,0]; Partition([3,3]).leg_length(*cell)
1

>>> from sage.all import *

>>> p = Partition([Integer(2),Integer(2),Integer(1)])

>>> p.leg_length(Integer(0), Integer(0))
2

>>> p.leg_length(Integer(0),Integer(1))
1

>>> p.leg_length(Integer(2),Integer(0))
0

>>> Partition([Integer(3),Integer(3)]).leg_length(Integer(0), Integer(0))
1

>>> cell = [Integer(0),Integer(0)]; Partition([Integer(3),Integer(3)]).leg_length(*cell)
1
\end{verbatim}

\textbf{leg_lengths} \((flat=False)\)

Return a tableau of shape \texttt{self} with each cell filled in with its leg length. The optional boolean parameter \texttt{flat} provides the option of returning a flat list.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Partition([2,2,1]).leg_lengths()
[[2, 1], [1, 0], [0]]

sage: Partition([2,2,1]).leg_lengths(flat=True)
[2, 1, 1, 0, 0]

sage: Partition([3,3]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]

sage: Partition([3,3]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
\end{verbatim}
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> Partition([Integer(2),Integer(2),Integer(1)]).leg_lengths()
[[2, 1], [1, 0], [0]]
>>> Partition([Integer(2),Integer(2),Integer(1)]).leg_lengths(flat=True)
[2, 1, 0, 0]
>>> Partition([Integer(3),Integer(3)]).leg_lengths()
[[1, 1, 1], [0, 0, 0]]
>>> Partition([Integer(3),Integer(3)]).leg_lengths(flat=True)
[1, 1, 1, 0, 0, 0]
```

length()
Return the number of parts in self.

EXAMPLES:

```python
sage: Partition([3,2]).length()
2
sage: Partition([2,2,1]).length()
3
sage: Partition([]).length()
0
```

level()
Return the level of self, which is always 1.

This method exists only for compatibility with PartitionTuples.

EXAMPLES:

```python
sage: Partition([4,3,2]).level()
1
```

lower_hook(i, j, alpha)
Return the lower hook length of the cell \((i, j)\) in self. When \(alpha = 1\), this is just the normal hook length.

The lower hook length of a cell \((i, j)\) in a partition \(\kappa\) is defined by

\[
\ell_{\kappa}(i, j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).
\]

EXAMPLES:

```python
sage: p = Partition([2,1])
sage: p.lower_hook(0,0,1)
3
```
```python
sage: p.hook_length(0,0)
3
sage: [ p.lower_hook(i,j,x) for i,j in p.cells() ]
[x + 2, 1, 1]
```

```python
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)])
>>> p.hook_length(Integer(0),Integer(0),Integer(0))
3
>>> [ p.lower_hook(i,j,x) for i,j in p.cells() ]
[x + 2, 1, 1]
```

**lower_hook_lengths**(alpha)

Return a tableau of shape self with the cells filled in with the lower hook lengths. When alpha = 1, these are just the normal hook lengths.

The lower hook length of a cell (i,j) in a partition $\kappa$ is defined by

$$h^\kappa(i,j) = \kappa'_j - i + 1 + \alpha(\kappa_i - j).$$

**EXAMPLES:**

```python
sage: Partition([3,2,1]).lower_hook_lengths(x)
[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
sage: Partition([3,2,1]).lower_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
```

```python
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).lower_hook_lengths(x)

[[2*x + 3, x + 2, 1], [x + 2, 1], [1]]
>>> Partition([Integer(3),Integer(2),Integer(1)]).lower_hook_lengths(Integer(1))

[[5, 3, 1], [3, 1], [1]]
```

**next**()

Return the partition that lexicographically follows self, of the same size. If self is the last partition, then return False.

**EXAMPLES:**

```python
sage: next(Partition([4]))
[3, 1]
sage: next(Partition([1,1,1,1]))
False
```
next_within_bounds (min=[], max=None, partition_type=None)

Get the next partition lexicographically that contains $\text{min}$ and is contained in $\text{max}$.

**INPUT:**

- **min** – (default [], the empty partition) The ‘minimum partition’ that \( \text{next}_\text{within}_\text{bounds}(\text{self}) \) must contain.
- **max** – (default None) The ‘maximum partition’ that \( \text{next}_\text{within}_\text{bounds}(\text{self}) \) must be contained in. If set to None, then there is no restriction.
- **partition_type** – (default None) The type of partitions allowed. For example, ‘strict’ for strictly decreasing partitions, or None to allow any valid partition.

**EXAMPLES:**

```python
sage: m = [1, 1]
sage: M = [3, 2, 1]
sage: Partition([1, 1]).next_within_bounds(min=m, max=M)
[1, 1, 1]
sage: Partition([1, 1, 1]).next_within_bounds(min=m, max=M)
[2, 1]
sage: Partition([2, 1]).next_within_bounds(min=m, max=M)
[2, 1, 1]
sage: Partition([2, 1, 1]).next_within_bounds(min=m, max=M)
[2, 2]
sage: Partition([2, 2]).next_within_bounds(min=m, max=M)
[2, 2, 1]
sage: Partition([2, 2, 1]).next_within_bounds(min=m, max=M)
[3, 1]
sage: Partition([3, 1]).next_within_bounds(min=m, max=M)
[3, 1, 1]
sage: Partition([3, 1, 1]).next_within_bounds(min=m, max=M)
[3, 2]
sage: Partition([3, 2]).next_within_bounds(min=m, max=M)
[3, 2, 1]
sage: Partition([3, 2, 1]).next_within_bounds(min=m, max=M) == None
True
```

```python
>>> from sage.all import *
>>> next (Partition([Integer(4)]))
[3, 1]
>>> next (Partition([Integer(1), Integer(1), Integer(1), Integer(1)]))
False
```

```python
>>> from sage.all import *
>>> m = [Integer(1), Integer(1)]
>>> M = [Integer(3), Integer(2), Integer(1)]
>>> Partition([Integer(1), Integer(1)]).next_within_bounds(min=m, max=M)
[1, 1, 1]
>>> Partition([Integer(1), Integer(1), Integer(1), Integer(1)]).next_within_bounds(min=m, max=M)
[2, 1]
>>> Partition([Integer(2), Integer(1)]).next_within_bounds(min=m, max=M)
[2, 1, 1]
>>> Partition([Integer(2), Integer(1), Integer(1)]).next_within_bounds(min=m, max=M)
[2, 2]
```
See also:

next ()

outer_rim()

Return the outer rim of self.

The outer rim of a partition \( \lambda \) is defined as the cells which do not belong to \( \lambda \) and which are adjacent to cells in \( \lambda \).

EXAMPLES:

The outer rim of the partition \([4,1]\) consists of the cells marked with \# below:

\[
****#
*####
##
\]

sage: Partition([4,1]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]

sage: Partition([2,2,1]).outer_rim()
[(3, 0), (3, 1), (2, 1), (2, 2), (1, 2), (0, 2)]

sage: Partition([2,2]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]

sage: Partition([6,3,3,1,1]).outer_rim()
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1, 5), (1, 6), (0, 6)]

sage: Partition([]).outer_rim()
[(0, 0)]

from sage.all import *

>>> Partition([Integer(4),Integer(1)]).outer_rim()
[(2, 0), (2, 1), (1, 1), (1, 2), (1, 3), (1, 4), (0, 4)]

>>> Partition([Integer(2),Integer(2),Integer(1)]).outer_rim()
[(3, 0), (3, 1), (2, 1), (2, 2), (1, 2), (0, 2)]

>>> Partition([Integer(2),Integer(2)]).outer_rim()
[(2, 0), (2, 1), (2, 2), (1, 2), (0, 2)]

>>> Partition([Integer(6),Integer(3),Integer(3),Integer(1),Integer(1)]).outer_rim()

(continues on next page)

\[
[(5, 0), (5, 1), (4, 1), (3, 1), (3, 2), (3, 3), (2, 3), (1, 3), (1, 4), (1, 5), (1, 6), (0, 6)]
\]

>>> Partition([]).outer_rim()

\[
[(0, 0)]
\]

**outline** (*variable=None*)

Return the outline of the partition \(self\).

This is a piecewise linear function, normalized so that the area under the partition \([1]\) is 2.

**INPUT:**

- `variable` - a variable (default: 'x' in the symbolic ring)

**EXAMPLES:**

```python
sage: # needs sage.symbolic
sage: [Partition([5,4]).outline()(x=i) for i in range(-10,11)]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]

sage: Partition([]).outline()

\[
abs(x)
\]

sage: Partition([1]).outline()

\[
abs(x + 1) + abs(x - 1) - abs(x)
\]

sage: y = SR.var("y")

sage: Partition([6,5,1]).outline(variable=y)

\[
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3) + abs(y - 1) - abs(y - 2) + abs(y - 3)
\]
```

\[
>>> from sage.all import *
\]

\[
>>> [Partition(Integer(5),Integer(4)).outline()(x=i) for i in range(-Integer(10),Integer(11))]
[10, 9, 8, 7, 6, 5, 6, 5, 6, 5, 4, 3, 2, 3, 4, 5, 6, 7, 8, 9, 10]
\]

\[
>>> Partition([]).outline()
\]

\[
abs(x)
\]

\[
>>> Partition(Integer(1)).outline()
\]

\[
abs(x + 1) + abs(x - 1) - abs(x)
\]

\[
>>> y = SR.var("y")
\]

\[
>>> Partition(Integer(6),Integer(5),Integer(1)).outline(variable=y)
\]

\[
abs(y + 6) - abs(y + 5) + abs(y + 4) - abs(y + 3) + abs(y - 1) - abs(y - 2) + abs(y - 3)
\]

**outside_corners**

Return a list of the outside corners of the partition \(self\).

An outside corner (also called a cocorner) of a partition \(\lambda\) is a cell on \(\mathbb{Z}^2\) which does not belong to the Young diagram of \(\lambda\) but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** These are called “outer corners” in [Sag2001].

**EXAMPLES:**
outside_corners_residue \((i, l)\)

Return a list of the outside corners of the partition \(\text{self}\) having \(l\)-residue \(i\).

An outside corner (also called a cocorner) of a partition \(\lambda\) is a cell on \(\mathbb{Z}^2\) which does not belong to the Young diagram of \(\lambda\) but can be added to this Young diagram to still form a straight-shape Young diagram. See \(\text{residue()}\) for the definition of the \(l\)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

EXAMPLES:

\[
\text{sage: Partition([3, 2, 1]).outside_corners_residue(0, 3)} \\
[(0, 3), (3, 0)]
\]

\[
\text{sage: Partition([3, 2, 1]).outside_corners_residue(1, 3)} \\
[(1, 2)]
\]

\[
\text{sage: Partition([3, 2, 1]).outside_corners_residue(2, 3)} \\
[(2, 1)]
\]

plancherel_measure()

Return the probability of \(\text{self}\) under the Plancherel probability measure on partitions of the same size.

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and \(\text{Partitions_n.random_element_plancherel()}\).

EXAMPLES:
Combinatorics, Release 10.4

sage: Partition([]).plancherel_measure()
1
sage: Partition([1]).plancherel_measure()
1
sage: Partition([2]).plancherel_measure()
1/2
sage: [mu.plancherel_measure() for mu in Partitions(3)]
[1/6, 2/3, 1/6]

sage: Partition([5,4]).plancherel_measure()
7/1440

>>> from sage.all import *

>>> Partition([]).plancherel_measure()
1

>>> Partition([Integer(1)]).plancherel_measure()
1

>>> Partition([Integer(2)]).plancherel_measure()
1/2

>>> [mu.plancherel_measure() for mu in Partitions(Integer(3))]
[1/6, 2/3, 1/6]

>>> Partition([Integer(5),Integer(4)]).plancherel_measure()
7/1440

\textbf{power} \( (k) \)

Return the cycle type of the \( k \)-th power of any permutation with cycle type \texttt{self} (thus describes the powermap of symmetric groups).

Equivalent to GAP's \texttt{PowerPartition}.

\textbf{EXAMPLES:}

sage: p = Partition([5,3])
sage: p.power(1)
[5, 3]
sage: p.power(2)
[5, 3]
sage: p.power(3)
[5, 1, 1, 1]
sage: p.power(4)
[5, 3]

>>> from sage.all import *

>>> p = Partition([Integer(5),Integer(3)])
>>> p.power(Integer(1))
[5, 3]

>>> p.power(Integer(2))
[5, 3]

>>> p.power(Integer(3))
[5, 1, 1, 1]

>>> p.power(Integer(4))
[5, 3]

Now let us compare this to the power map on \( S_8 \):

sage: # needs sage.groups
sage: G = SymmetricGroup(8)
sage: g = G([(1,2,3,4,5),(6,7,8)]); g

(continues on next page)
\begin{itemize}
\item \((1,2,3,4,5)\ (6,7,8)\)
\item \texttt{sage: g^2}
\item \((1,3,5,2,4)\ (6,8,7)\)
\item \texttt{sage: g^3}
\item \((1,4,2,5,3)\)
\item \texttt{sage: g^4}
\item \((1,5,4,3,2)\ (6,7,8)\)
\end{itemize}

\begin{verbatim}
>>> from sage.all import *
>>> # needs sage.groups
>>> G = SymmetricGroup(Integer(8))
>>> g = G([(Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)),
\rightarrow (Integer(6),Integer(7),Integer(8))]); g
(1,2,3,4,5) (6,7,8)
>>> g**Integer(2)
(1,3,5,2,4) (6,8,7)
>>> g**Integer(3)
(1,4,2,5,3)
>>> g**Integer(4)
(1,5,4,3,2) (6,7,8)
\end{verbatim}

\begin{verbatim}
\texttt{sage: Partition([3,2,1]).power(3)}
[2, 1, 1, 1, 1]
\end{verbatim}

\begin{verbatim}
\texttt{pp()}
\texttt{Print the Ferrers diagram.}
\texttt{See \texttt{ferrers_diagram()}} \texttt{for more on the Ferrers diagram.}
\texttt{EXAMPLES:}

\begin{verbatim}
\texttt{sage: Partition([5,5,2,1]).pp()}
*****
*****
** *
\texttt{sage: Partitions.options.convention='French'}
\texttt{sage: Partition([5,5,2,1]).pp()}
*
**
*****
*****
\texttt{sage: Partitions.options._reset()}
\end{verbatim}
\end{verbatim}

\begin{verbatim}
\texttt{>>> from sage.all import *}
\texttt{>>> Partition([Integer(5),Integer(5),Integer(2),Integer(1)]).pp()}
*****
*****
** *
\texttt{>>> Partitions.options.convention='French'}
\end{verbatim}

{
\texttt{(continues on next page)}
}
Partition([Integer(5), Integer(5), Integer(2), Integer(1)]).pp()  
*  
**  
*****  
*****  
Partition.options._reset()

prime_degree (p)

Return the prime degree for the prime integer p for self.

INPUT:

• p – a prime integer

OUTPUT:

A non-negative integer

The degree of a partition \( \lambda \) is the sum of the \( e \)-degree() of the standard tableaux of shape \( \lambda \), for \( e \) a power of the prime \( p \). The prime degree gives the exponent of \( p \) in the Gram determinant of the integral Specht module of the symmetric group.

EXAMPLES:

sage: Partition([4, 3]).prime_degree(2)
36
sage: Partition([4, 3]).prime_degree(3)
15
sage: Partition([4, 3]).prime_degree(5)
13
sage: Partition([4, 3]).prime_degree(7)
0

Therefore, the Gram determinant of \( S(5, 3) \) when \( q = 1 \) is \( 2^{36} 3^{15} 5^{13} \). Compare with degree().

quotient (length)

Return the quotient of the partition – in the literature the quotient is commonly referred to as the \( k \)-quotient, \( p \)-quotient, \( r \)-quotient, ….

The \( r \)-quotient of a partition \( \lambda \) is a list of \( r \) partitions (labelled from 0 to \( r - 1 \)), constructed in the following way. Label each cell in the Young diagram of \( \lambda \) with its content modulo \( r \). Let \( R_i \) be the set of rows ending in a cell labelled \( i \), and \( C_j \) be the set of columns ending in a cell labelled \( i \). Then the \( j \)-th component of the quotient of \( \lambda \) is the partition defined by intersecting \( R_j \) with \( C_{j+1} \). (See Theorem 2.7.37 in [JK1981].)

EXAMPLES:

sage: Partition([7, 7, 5, 3, 3, 1]).quotient(3)(([2], [1], [2, 2, 2]))
>>> from sage.all import *
>>> Partition([Integer(7), Integer(7), Integer(5), Integer(3), Integer(3),
            Integer(3), Integer(1)]).quotient(Integer(3))
([2], [1], [2, 2, 2])

**reading_tableau()**

Return the RSK recording tableau of the reading word of the (standard) tableau \( T \) labeled down (in English convention) each column to the shape of \( \text{self} \).

For an example of the tableau \( T \), consider the partition \( \lambda = (3, 2, 1) \), then we have:

```
1 4 6
2 5
3
```

For more, see \textit{RSK()}.  

**EXAMPLES:**

```
sage: Partition([3,2,1]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).reading_tableau()
[[1, 3, 6], [2, 5], [4]]
```

**removable_cells()**

Return a list of the corners of the partition \( \text{self} \).

A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** This is referred to as an “inner corner” in [Sag2001].

**EXAMPLES:**

```
sage: Partition([3,2,1]).corners()
[(0, 2), (1, 1), (2, 0)]
sage: Partition([3,3,1]).corners()
[(1, 2), (2, 0)]
sage: Partition([]).corners()
[]
```

```
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners()
[(0, 2), (1, 1), (2, 0)]
>>> Partition([Integer(3),Integer(3),Integer(1)]).corners()
[(1, 2), (2, 0)]
>>> Partition([]).corners()
[]
```

**removable_cells_residue**  
\((i, l)\)

Return a list of the corners of the partition \( \text{self} \) having \( l \)-residue \( i \).
A corner of a partition \( \lambda \) is a cell of the Young diagram of \( \lambda \) which can be removed from the Young diagram while still leaving a straight shape behind. See \( \text{residue()} \) for the definition of the \( l \)-residue.

The entries of the list returned are pairs of the form \((i, j)\), where \( i \) and \( j \) are the coordinates of the respective corner. The coordinates are counted from 0.

**EXAMPLES:**

```python
sage: Partition([3,2,1]).corners_residue(0, 3)
[(1, 1)]
sage: Partition([3,2,1]).corners_residue(1, 3)
[(2, 0)]
sage: Partition([3,2,1]).corners_residue(2, 3)
[(0, 2)]
```

```python
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(0), Integer(3))
[(1, 1)]
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(1), Integer(3))
[(2, 0)]
>>> Partition([Integer(3),Integer(2),Integer(1)]).corners_residue(Integer(2), Integer(3))
[(0, 2)]
```

**remove_cell**

Return the partition obtained by removing a cell at the end of row \( i \) of \( \text{self} \).

**EXAMPLES:**

```python
sage: Partition([2,2]).remove_cell(1)
[2, 1]
sage: Partition([2,2,1]).remove_cell(2)
[2, 2]
sage: #Partition([2,2]).remove_cell(0)
```

```python
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).remove_cell(Integer(1))
[2, 1]
>>> Partition([Integer(2),Integer(2),Integer(1)]).remove_cell(Integer(2))
[2, 2]
>>> #Partition([2,2]).remove_cell(0)
```

```python
sage: Partition([2,2]).remove_cell(1,1)
[2, 1]
sage: #Partition([2,2]).remove_cell(1,0)
```

```python
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).remove_cell(Integer(1),Integer(1))
[2, 1]
>>> #Partition([2,2]).remove_cell(1,0)
```

**remove_horizontal_border_strip**

Return the partitions obtained from \( \text{self} \) by removing an horizontal border strip of length \( k \).

**EXAMPLES:**
The result is returned as an instance of `Partitions_with_constraints`:

```python
sage: Partition([5, 3, 1]).remove_horizontal_border_strip(5)
```

The subpartitions of `[5, 3, 1]` obtained by removing a horizontal border strip of length 5

```python
>>> from sage.all import *

```
EXAMPLES:

```python
def
```
Zolotarev’s lemma states that the Legendre symbol \( \left( \frac{a}{p} \right) \) for an integer \( a \pmod{p} \) (\( p \) a prime number), can be computed as \( \text{sign}(p_a) \), where \( \text{sign} \) denotes the sign of a permutation and \( p_a \) the permutation of the residue classes \( \pmod{p} \) induced by modular multiplication by \( a \), provided \( p \) does not divide \( a \).

We verify this in some examples.

\[
\text{sage: } F = \text{GF}(11) \\
\text{# \texttt{needs sage.rings.finite_rings}}
\]

\[
\text{sage: } a = F.multiplicative_generator(); a \\
\text{# \texttt{needs sage.rings.finite_rings}}
\]

\[
2
\]

\[
\text{sage: } \text{plist} = \{\text{int}(a^F(x)) \text{ for } x \text{ in range(1,11)}\}; \text{plist} \\
\text{# \texttt{needs sage.rings.finite_rings}}
\]

\[
[2, 4, 6, 8, 10, 1, 3, 5, 7, 9]
\]

This corresponds to the permutation \((1, 2, 4, 8, 5, 10, 9, 7, 3, 6)\) (acting the set \(\{1, 2, \ldots, 10\}\)) and to the partition \([10]\).
Now replace 2 by 3:

```python
sage: plist = [int(F(3*x)) for x in range(1,11)]; plist
# needs sage.rings.finite_rings
[3, 6, 9, 1, 4, 7, 10, 2, 5, 8]
sage: list(range(1, 11))
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
sage: p = PermutationGroupElement('(3,4,8,7,9)')
# needs sage.groups
sage: p.sign()
# needs sage.groups
1
sage: kronecker_symbol(3,11)
1
```
needs sage.rings.finite_rings

sage: Partition([2,2,1]).simple_module_dimension(GF(3))  # needs sage.rings.finite_rings

sage: for la in Partitions(6, regular=3):
    ....: print(la, la.specht_module_dimension(), la.simple_module_dimension(GF(3)))

>>> from sage.all import *

>>> Partition((Integer(2),Integer(2),Integer(1))).simple_module_dimension()  # needs sage.rings.finite_rings

>>> Partition((Integer(2),Integer(2),Integer(1))).specht_module_dimension()  # needs sage.rings.finite_rings

>>> for la in Partitions(Integer(6), regular=Integer(3)):
    ....: print(la, la.specht_module_dimension(), la.simple_module_dimension(GF(Integer(3))))

size()

Return the size of self.

EXAMPLES:

sage: Partition([2,2]).size()
4
sage: Partition([3,2,1]).size()
6

>>> from sage.all import *

>>> Partition((Integer(2),Integer(2))).size()
4

>>> Partition((Integer(3),Integer(2),Integer(1))).size()
6

specht_module(base_ring=None)
Return the Specht module corresponding to self.

**EXAMPLES:**

```sage
sage: SM = Partition([2,2,1]).specht_module(QQ); SM
Specht module of [2, 2, 1] over Rational Field
sage: SM.frobenius_image()
```

```python
>>> from sage.all import *
>>> SM = Partition([Integer(2),Integer(2),Integer(1)]).specht_module(QQ); SM
Specht module of [2, 2, 1] over Rational Field
>>> SM.frobenius_image()
```

**specht_module_dimension** *(base_ring=None)*

Return the dimension of the Specht module corresponding to self.

This is equal to the number of standard tableaux of shape self when over a field of characteristic 0.

**INPUT:**

- base_ring – (default: Q) the base ring

**EXAMPLES:**

```sage
sage: Partition([2,2,1]).specht_module_dimension()
5
sage: Partition([2,2,1]).specht_module_dimension(GF(2))
# needs sage.rings.finite_rings
5
```

```python
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2),Integer(1)]).specht_module_dimension(GF(Integer(2)))
# needs sage.rings.finite_rings
5
```

**standard_tableaux()**

Return the standard tableaux of shape self.

**EXAMPLES:**

```sage
sage: Partition([3,2,2,1]).standard_tableaux()
Standard tableaux of shape [3, 2, 2, 1]
```

```python
>>> from sage.all import *
>>> Partition([Integer(3),Integer(2),Integer(2),Integer(1)]).standard_tableaux()
Standard tableaux of shape [3, 2, 2, 1]
```
**stretch** \((k)\)

Return the partition obtained by multiplying each part with the given number.

**EXAMPLES:**

```
sage: p = Partition([4,2,2,1,1])
sage: p.stretch(3)
[12, 6, 6, 3, 3]
```

**suter_diagonal_slide** \((n, \text{exp}=1)\)

Return the image of \texttt{self} in \(Y_n\) under Suter’s diagonal slide \(\sigma_n\), where the notations used are those defined in [Sut2002].

The set \(Y_n\) is defined as the set of all partitions \(\lambda\) such that the hook length of the \((0,0)\)-cell (i.e. the north-western most cell in English notation) of \(\lambda\) is less than \(n\), including the empty partition.

The map \(\sigma_n\) sends a partition (with non-zero entries) \((\lambda_1, \lambda_2, \ldots, \lambda_m) \in Y_n\) to the partition \((\lambda_2 + 1, \lambda_3 + 1, \ldots, \lambda_m + 1, 1, 1, \ldots, 1)\). In other words, it pads the partition with trailing zeroes until it has length \(n - \lambda_1\), then removes its first part, and finally adds 1 to each part.

By Theorem 2.1 of [Sut2002], the dihedral group \(D_n\) with \(2n\) elements acts on \(Y_n\) by letting the primitive rotation act as \(\sigma_n\) and the reflection act as conjugation of partitions (\texttt{conjugate()}). This action is faithful if \(n \geq 3\).

**INPUT:**

- \(n\) – nonnegative integer
- \(\text{exp}\) – (default: 1) how many times \(\sigma_n\) should be applied

**OUTPUT:**

The result of applying Suter’s diagonal slide \(\sigma_n\) to \texttt{self}, assuming that \texttt{self} lies in \(Y_n\). If the optional argument \(\text{exp}\) is set, then the slide \(\sigma_n\) is applied not just once, but \(\text{exp}\) times (note that \(\text{exp}\) is allowed to be negative, since the slide has finite order).

**EXAMPLES:**

```
sage: Partition([5,4,1]).suter_diagonal_slide(8)
[5, 2]
sage: Partition([5,4,1]).suter_diagonal_slide(9)
[5, 2, 1]
sage: Partition([]).suter_diagonal_slide(7)
[1, 1, 1, 1, 1, 1]
sage: Partition([]).suter_diagonal_slide(1)
[]
sage: Partition([]).suter_diagonal_slide(7, exp=-1)
[6]
sage: Partition([]).suter_diagonal_slide(1, exp=-1)
[]
sage: P7 = Partitions(7)
sage: all( p == p.suter_diagonal_slide(9, exp=-1).suter_diagonal_slide(9) 
       ....: for p in P7 )
True
```
Check of the assertion in [Sut2002] that $\sigma_n(\sigma_n(\lambda')) = \lambda$:

```
sage: all( p.suter_diagonal_slide(8).conjugate() == p.conjugate().suter_diagonal_slide(8, exp=-1) for p in P7 )
True
```
>>> from sage.all import *
>>> all( p.suter_diagonal_slide(Integer(8)).conjugate() == p.conjugate().suter_diagonal_slide(Integer(8), exp=Integer(-1)) for p in P7 )
True

Check of Claim 1 in [Sut2002]:

```python
sage: P5 = Partitions(5)
sage: all( all( (p.suter_diagonal_slide(Integer(6)) in q.suter_diagonal_slide(Integer(6)).down()) or (q.suter_diagonal_slide(Integer(6)) in p.suter_diagonal_slide(Integer(6)).down()) for p in q.down() ) for q in P5 )
True
```

```
t_completion(t)
Return the t-completion of the partition self.
```

If \( \lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots) \) is a partition and \( t \) is an integer greater or equal to \( |\lambda| + \lambda_1 \), then the \( t \)-completion of \( \lambda \) is defined as the partition \( (t - |\lambda|, \lambda_1, \lambda_2, \lambda_3, \ldots) \) of \( t \). This partition is denoted by \( \lambda[t] \) in [BOR2009], by \( \lambda[t] \) in [BdVO2012], and by \( \lambda(t) \) in [CO2010].

**EXAMPLES:**

```
sage: Partition([]).t_completion(0)
[]
sage: Partition([]).t_completion(1)
[1]
sage: Partition([]).t_completion(2)
[2]
sage: Partition([]).t_completion(3)
[3]
sage: Partition([2, 1]).t_completion(5)
[2, 2, 1]
sage: Partition([2, 1]).t_completion(6)
[3, 2, 1]
sage: Partition([2, 2, 1]).t_completion(13)
[4, 4, 2, 2, 1]
sage: Partition([2, 2, 1]).t_completion(19)
[10, 4, 2, 2, 1]
sage: Partition([2, 2, 1]).t_completion(10)
Traceback (most recent call last):
...
ValueError: 10-completion is not defined
```

(continues on next page)
Traceback (most recent call last):
...  
ValueError: 5-completion is not defined

>>> from sage.all import *
>>> Partition([]).t_completion(Integer(0))
[]
>>> Partition([]).t_completion(Integer(1))
[1]
>>> Partition([]).t_completion(Integer(2))
[2]
>>> Partition([]).t_completion(Integer(3))
[3]
>>> Partition([Integer(2), Integer(1)]).t_completion(Integer(5))
[2, 2, 1]
>>> Partition([Integer(2), Integer(1)]).t_completion(Integer(6))
[3, 2, 1]
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_completion(Integer(13))
[4, 4, 2, 2, 1]
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_completion(Integer(19))
[10, 4, 2, 2, 1]
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_completion(Integer(10))
Traceback (most recent call last):
...  
ValueError: 10-completion is not defined
>>> Partition([Integer(4), Integer(2), Integer(2), Integer(1)]).t_completion(Integer(5))
Traceback (most recent call last):
...  
ValueError: 5-completion is not defined

tabloid_module (base_ring=None)

Return the tabloid module corresponding to self.

EXAMPLES:

```sage
tm = Partition([2, 2, 1]).tabloid_module(QQ); tm
Tabloid module of [2, 2, 1] over Rational Field
tm.frobenius_image()
```

```sage
from sage.all import *
>>> TM = Partition([Integer(2), Integer(2), Integer(1)]).tabloid_module(QQ); TM
Tabloid module of [2, 2, 1] over Rational Field
>>> TM.frobenius_image()
```

to_core (k)

Maps the k-bounded partition self to its corresponding k + 1-core.

See also k_skew().

EXAMPLES:
```python
sage: p = Partition([4,3,2,2,1,1])
sage: c = p.to_core(4); c
[9, 5, 3, 2, 1, 1]
sage: type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: c.to_bounded_partition() == p
True
```

```python
>>> from sage.all import *
>>> p = Partition([Integer(4),Integer(3),Integer(2),Integer(2),Integer(1),
next,Integer(1)])
>>> c = p.to_core(Integer(4)); c
[9, 5, 3, 2, 1, 1]
>>> type(c)
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> c.to_bounded_partition() == p
True
```

to\_dyck\_word\(n=None\)

Return the \(n\)-Dyck word whose corresponding partition is \texttt{self} (or, if \(n\) is not specified, the \(n\)-Dyck word with smallest \(n\) to satisfy this property).

If \(w\) is an \(n\)-Dyck word (that is, a Dyck word with \(n\) open symbols and \(n\) close symbols), then the Dyck path corresponding to \(w\) can be regarded as a lattice path in the northeastern half of an \(n \times n\)-square. The region to the northeast of this Dyck path can be regarded as a partition. It is called the partition corresponding to the Dyck word \(w\). \(\text{See to\_partition()}\).

For every partition \(\lambda\) and every nonnegative integer \(n\), there exists at most one \(n\)-Dyck word \(w\) such that the partition corresponding to \(w\) is \(\lambda\) (in fact, such \(w\) exists if and only if \(\lambda_i + i \leq n\) for every \(i\), where \(\lambda\) is written in the form \((\lambda_1, \lambda_2, \ldots, \lambda_k)\) with \(\lambda_k > 0\)). This method computes this \(w\) for a given \(\lambda\) and \(n\). If \(n\) is not specified, this method computes the \(w\) for the smallest possible \(n\) for which such an \(w\) exists. (The minimality of \(n\) means that the partition demarcated by the Dyck path touches the diagonal.)

EXAMPLES:

```python
sage: Partition([2,2]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(4)
[1, 1, 0, 0, 1, 1, 0, 0]
sage: Partition([2,2]).to_dyck_word(5)
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: Partition([6,3,1]).to_dyck_word()
[1, 1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
sage: Partition([]).to_dyck_word()
[]
sage: Partition([]).to_dyck_word(3)
[1, 1, 1, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 0]
>>> Partition([Integer(2),Integer(2)]).to_dyck_word(Integer(4))
[1, 1, 0, 0, 1, 1, 0, 0]
>>> Partition([Integer(2),Integer(2)]).to_dyck_word(Integer(5))
[1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
>>> Partition([Integer(6),Integer(3),Integer(1)]).to_dyck_word()
[1, 1, 1, 0, 1, 0, 0, 1, 0, 0, 0, 1, 0]
```
(continues on next page)
The partition corresponding to self.dyck_word() is self indeed:

```python
sage: all( p.to_dyck_word().to_partition() == p
.....:     for p in Partitions(5) )
True
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> d[Integer(2)]
2
>>> d[Integer(1)]
1
>>> Integer(5) in d
False
```

**to_list()**

Return `self` as a list.

**EXAMPLES:**

```python
sage: p = Partition([2,1]).to_list(); p
[2, 1]
sage: type(p)
<class 'list'>
```

```python
>>> from sage.all import *

>>> p = Partition([Integer(2),Integer(1)]).to_list(); p
[2, 1]

>>> type(p)
<class 'list'>
```

**top_garnir_tableau** *(e, cell)*

Return the most dominant standard tableau which dominates the corresponding Garnir tableau and has the same e-residue.

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules. The top Garnir tableaux arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is cell = (r, c) and m and M are the entries in the cells (r, c) and (r+1, c), respectively, in the initial tableau then the top e-Garnir tableau is obtained by inserting the numbers m, m+1, ..., M in order from left to right first in the cells in row r+1 which are not in the e-Garnir belt, then in the cell in rows r and r+1 which are in the Garnir belt and then, finally, in the remaining cells in row r which are not in the Garnir belt. All other entries in the tableau remain unchanged.

If e = 0, or if there are no e-bricks in either row r or r+1, then the top Garnir tableau is the corresponding Garnir tableau.

**EXAMPLES:**

```python
sage: Partition([5,4,3,2]).top_garnir_tableau(2,(0,2)).pp()
  1  2  4  5  8
  3  6  7  9
 10 11 12
 13 14

sage: Partition([5,4,3,2]).top_garnir_tableau(3,(0,2)).pp()
  1  2  3  4  5
  6  7  8  9
 10 11 12
 13 14

sage: Partition([5,4,3,2]).top_garnir_tableau(4,(0,2)).pp()
  1  2  6  7  8
  3  4  5  9
```

(continues on next page)
sage: Partition([5,4,3,2]).top_garnir_tableau(0,(0,2)).pp()
1 2 6 7 8
3 4 5 9
10 11 12
13 14

sage: Partition([5,4,3,2]).top_garnir_tableau(2,(0,2)).pp()
1 2 4 5 8
3 6 7 9
10 11 12
13 14

REFERENCES:

• [KMR2012]

up()

Return a generator for partitions that can be obtained from self by adding a cell.

EXAMPLES:

sage: list(Partition([2,1,1]).up())
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: list(Partition([3,2]).up())
[[4, 2], [3, 3], [3, 2, 1]]
sage: [p for p in Partition([[]]).up()]
[[1]]
**up_list()**

Return a list of the partitions that can be formed from `self` by adding a cell.

**EXAMPLES:**

```python
sage: Partition([2,1,1]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
sage: Partition([3,2]).up_list()
[[4, 2], [3, 3], [3, 2, 1]]
```

```python
>>> from sage.all import *
>>> Partition([Integer(2),Integer(1),Integer(1)]).up_list()
[[3, 1, 1], [2, 2, 1], [2, 1, 1, 1]]
```

**upper_hook** *(i, j, alpha)*

Return the upper hook length of the cell *(i, j)* in `self`. When `alpha = 1`, this is just the normal hook length.

The upper hook length of a cell *(i, j)* in a partition κ is defined by

\[ h^*_\kappa(i, j) = \kappa'_j - i + \alpha(\kappa_i - j + 1). \]

**EXAMPLES:**

```python
sage: p = Partition([2,1])
sage: p.upper_hook(0,0,1)
3
```

```python
>>> p = Partition([Integer(2),Integer(1)])
```

```python
>>> p.upper_hook(0,0,1)
3
```

```python
sage: [ p.upper_hook(i,j,x) for i,j in p.cells() ]  # needs sage.symbolic
[2*x + 1, x, x]
```

```python
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)])
```

```python
>>> p.upper_hook(Integer(0),Integer(0),Integer(1))
3
```

```python
>>> [ p.upper_hook(i,j,x) for i,j in p.cells() ]  # needs sage.symbolic
[2*x + 1, x, x]
```

**upper_hook_lengths** *(alpha)*

Return a tableau of shape `self` with the cells filled in with the upper hook lengths. When `alpha = 1`, these are just the normal hook lengths.

The upper hook length of a cell *(i, j)* in a partition κ is defined by

\[ h^*_\kappa(i, j) = \kappa'_j - i + \alpha(\kappa_i - j + 1). \]

**EXAMPLES:**

```python
>>> from sage.all import *
>>> p = Partition([Integer(2),Integer(1)])
```

```python
>>> p.upper_hook_length(Integer(0),Integer(0))
3
```

```python
>>> [ p.upper_hook(i,j,x) for i,j in p.cells() ]  # needs sage.symbolic
[2*x + 1, x, x]
```
Partition([3, 2, 1]).upper_hook_lengths(x)  #
˓→needs sage.symbolic
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
Partition([3, 2, 1]).upper_hook_lengths(1)
[[5, 3, 1], [3, 1], [1]]
Partition([3, 2, 1]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]

>>> from sage.all import *
>>> Partition([Integer(3), Integer(2), Integer(1)]).upper_hook_lengths(x) ˓→ # needs sage.symbolic
[[3*x + 2, 2*x + 1, x], [2*x + 1, x], [x]]
Partition([Integer(3), Integer(2), Integer(1)]).upper_hook_˓→lengths(Integer(1))
[[5, 3, 1], [3, 1], [1]]
Partition([Integer(3), Integer(2), Integer(1)]).hook_lengths()
[[5, 3, 1], [3, 1], [1]]

vertical_border_strip_cells(k)
Return a list of all the vertical border strips of length k which can be added to self, where each horizontal border strip is a generator of cells.

EXAMPLES:

>>> from sage.all import *
>>> list(Partition([]).vertical_border_strip_cells(0))
[]
>>> list(Partition([3, 2, 1]).vertical_border_strip_cells(0))
[]
>>> list(Partition([]).vertical_border_strip_cells(2))
[[0, 0], [1, 0]]
>>> list(Partition([2, 2]).vertical_border_strip_cells(2))
[[0, 2], [1, 2]],
[[0, 2], [2, 0]],
[[2, 0], [3, 0]]
>>> list(Partition([3, 2, 2]).vertical_border_strip_cells(2))
[[0, 3], [1, 2]],
[[0, 3], [3, 0]],
[[1, 2], [2, 2]],
[[1, 2], [3, 0]],
[[3, 0], [4, 0]]

(continues on next page)
weighted_size()

Return the weighted size of self.

The weighted size of a partition \( \lambda \) is

\[
\sum_i i \cdot \lambda_i,
\]

where \( \lambda = (\lambda_0, \lambda_1, \lambda_2, \cdots) \).

This also the sum of the leg length of every cell in \( \lambda \), or

\[
\sum_i \left( \frac{\lambda_i'}{2} \right)
\]

where \( \lambda' \) is the conjugate partition of \( \lambda \).

EXAMPLES:

```python
sage: Partition([2,2]).weighted_size()
2
sage: Partition([3,3,3]).weighted_size()
9
sage: Partition([5,2]).weighted_size()
2
sage: Partition([]).weighted_size()
0
```

```python
>>> from sage.all import *
>>> Partition([Integer(2),Integer(2)]).weighted_size()
2
>>> Partition([Integer(3),Integer(3),Integer(3)]).weighted_size()
9
>>> Partition([Integer(5),Integer(2)]).weighted_size()
2
>>> Partition([]).weighted_size()
0
```

young_subgroup()

Return the corresponding Young, or parabolic, subgroup of the symmetric group.

The Young subgroup of a partition \( \lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k) \) of \( n \) is the group:

\[
S_{\lambda_1} \times S_{\lambda_2} \times \cdots \times S_{\lambda_k}
\]

embedded into \( S_n \) in the standard way (i.e., the \( S_{\lambda_i} \) factor acts on the numbers from \( \lambda_1 + \lambda_2 + \cdots + \lambda_{i-1} + 1 \) to \( \lambda_1 + \lambda_2 + \cdots + \lambda_i \)).

EXAMPLES:

```python
sage: Partition([4,2]).young_subgroup()  # needs sage.groups
Permutation Group with generators [(], (5,6), (3,4), (2,3), (1,2)]
```
from sage.all import *
Partition([Integer(4), Integer(2)]).young_subgroup()

## needs sage.groups
Permutation Group with generators [(), (5,6), (3,4), (2,3), (1,2)]

young_subgroup_generators()
Return an indexing set for the generators of the corresponding Young subgroup. Here the generators correspond to the simple adjacent transpositions $s_i = (i \ i + 1)$.

EXAMPLES:

sage: Partition([4,2]).young_subgroup_generators()
[1, 2, 3, 5]
sage: Partition([1,1,1]).young_subgroup_generators()
[]
sage: Partition([2,2]).young_subgroup_generators()
[1, 3]

See also:

young_subgroup()

zero_one_sequence()
Compute the finite $0 - 1$ sequence of the partition.

The full $0 - 1$ sequence is the sequence (infinite in both directions) indicating the steps taken when following the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.

Note that every full $0 - 1$ sequence starts with infinitely many 0’s and ends with infinitely many 1’s.

One place where these arise is in the affine symmetric group where one takes an affine permutation $w$ and every $i$ such that $w(i) \leq 0$ corresponds to a 1 and $w(i) > 0$ corresponds to a 0. See pages 24-25 of [LLMSSZ2013] for connections to affine Grassmannian elements (note there they use the French convention for their partitions).

These are also known as path sequences, Maya diagrams, plus-minus diagrams, Comet code [Sta-EC2], among others.

OUTPUT:

The finite $0 - 1$ sequence is obtained from the full $0 - 1$ sequence by omitting all heading 0’s and trailing 1’s. The output sequence is finite, starts with a 1 and ends with a 0 (unless it is empty, for the empty partition). Its length is the sum of the first part of the partition with the length of the partition.

EXAMPLES:

sage: Partition([5,4]).zero_one_sequence()
[1, 1, 1, 0, 1, 0]
sage: Partition([]).zero_one_sequence()
[]
### class sage.combinat.partition.Partitions

**Bases:** UniqueRepresentation, Parent

Partitions \(n, \text{ **kwargs} \) returns the combinatorial class of integer partitions of \( n \) subject to the constraints given by the keywords.

Valid keywords are: `starting`, `ending`, `min_part`, `max_part`, `max_length`, `min_length`, `length`, `max_slope`, `min_slope`, `inner`, `outer`, `parts_in`, `regular`, and `restricted`. They have the following meanings:

- `starting=p` specifies that the partitions should all be less than or equal to \( p \) in lex order. This argument cannot be combined with any other (see Issue #15467).
- `ending=p` specifies that the partitions should all be greater than or equal to \( p \) in lex order. This argument cannot be combined with any other (see Issue #15467).
- `length=k` specifies that the partitions have exactly \( k \) parts.
- `min_length=k` specifies that the partitions have at least \( k \) parts.
- `min_part=k` specifies that all parts of the partitions are at least \( k \).
- `inner=p` specifies that the partitions must contain the partition \( p \).
- `outer=p` specifies that the partitions be contained inside the partition \( p \).
- `min_slope=k` specifies that the partitions have slope at least \( k \); the slope at position \( i \) is the difference between the \((i+1)\)-th part and the \(i\)-th part.
- `parts_in=S` specifies that the partitions have parts in the set \( S \), which can be any sequence of pairwise distinct positive integers. This argument cannot be combined with any other (see Issue #15467).
- `regular=ell` specifies that the partitions are \( \ell \)-regular, and can only be combined with the `max_length` or `max_part`, but not both; keywords if \( n \) is not specified
- `restricted=ell` specifies that the partitions are \( \ell \)-restricted, and cannot be combined with any other keywords

The `max_*` versions, along with `inner` and `ending`, work analogously.

Right now, the `parts_in`, `starting`, `ending`, `regular`, and `restricted` keyword arguments are mutually exclusive, both of each other and of other keyword arguments. If you specify, say, `parts_in`, all other keyword arguments will be ignored; `starting`, `ending`, `regular`, and `restricted` work the same way.

**EXAMPLES:**

If no arguments are passed, then the combinatorial class of all integer partitions is returned:
If an integer \( n \) is passed, then the combinatorial class of integer partitions of \( n \) is returned:

```
sage: Partitions(3)
Partitions of the integer 3
sage: Partitions(3).list()
[[3], [2, 1], [1, 1, 1]]
```

If \( \text{starting}=p \) is passed, then the combinatorial class of partitions greater than or equal to \( p \) in lexicographic order is returned:

```
sage: Partitions(3, starting=[2,1])
Partitions of the integer 3 starting with [2, 1]
sage: Partitions(3, starting=[2,1]).list()
[[2, 1], [1, 1, 1]]
```

If \( \text{ending}=p \) is passed, then the combinatorial class of partitions at most \( p \) in lexicographic order is returned:

```
sage: Partitions(3, ending=[2,1])
Partitions of the integer 3 ending with [2, 1]
sage: Partitions(3, ending=[2,1]).list()
[[3], [2, 1]]
```

Using \( \text{max_slope}=-1 \) yields partitions into distinct parts – each part differs from the next by at least 1. Use a different \( \text{max_slope} \) to get parts that differ by, say, 2:

```
sage: Partitions(7, max_slope=-1).list()
[[7], [6, 1], [5, 2], [4, 3], [4, 2, 1]]
```
The number of partitions of $n$ into odd parts equals the number of partitions into distinct parts. Let's test that for $n$ from 10 to 20:

```python
sage: def test(n):
    ...:     return (Partitions(n, max_slope=-1).cardinality()
    ...:               == Partitions(n, parts_in=[1,3..n]).cardinality())
sage: all(test(n) for n in [10..20]) # needs sage.libs.gap
True
```

The number of partitions of $n$ into distinct parts that differ by at least 2 equals the number of partitions into parts that equal 1 or 4 modulo 5; this is one of the Rogers-Ramanujan identities:

```python
sage: def test(n):
    ...:     return (Partitions(n, max_slope=-2).cardinality()
    ...:               == Partitions(n, parts_in=(\[1,6..n\] + \[4,9..n\])).cardinality())
sage: all(test(n) for n in (ellipsis_range(Integer(10),Ellipsis,Integer(20)))) # needs sage.libs.gap
True
```

Here are some more examples illustrating `min_part`, `max_part`, and `length`:

```python
sage: Partitions(5, min_part=2)
Partitions of the integer 5 satisfying constraints min_part=2
sage: Partitions(5, min_part=2).list()
[[5], [3, 2]]
```
>>> from sage.all import *
>>> Partitions(Integer(5), min_part=Integer(2))
Partitions of the integer 5 satisfying constraints min_part=2
>>> Partitions(Integer(5), min_part=Integer(2)).list()
[[5], [3, 2]]

sage: Partitions(3, max_length=2).list()
[[3], [2, 1]]

>>> from sage.all import *
>>> Partitions(Integer(3), max_length=Integer(2)).list()
[[3], [2, 1]]

sage: Partitions(10, min_part=2, length=3).list()
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]

>>> from sage.all import *
>>> Partitions(Integer(10), min_part=Integer(2), length=Integer(3)).list()
[[6, 2, 2], [5, 3, 2], [4, 4, 2], [4, 3, 3]]

Some examples using the regular keyword:
sage: Partitions(regular=4)
4-Regular Partitions
sage: Partitions(regular=4, max_length=3)
4-Regular Partitions with max length 3
sage: Partitions(regular=4, max_part=3)
4-Regular 3-Bounded Partitions
sage: Partitions(3, regular=4)
4-Regular Partitions of the integer 3

>>> from sage.all import *
>>> Partitions(regular=Integer(4))
4-Regular Partitions
>>> Partitions(regular=Integer(4), max_length=Integer(3))
4-Regular Partitions with max length 3
>>> Partitions(regular=Integer(4), max_part=Integer(3))
4-Regular 3-Bounded Partitions
>>> Partitions(Integer(3), regular=Integer(4))
4-Regular Partitions of the integer 3

Some examples using the restricted keyword:
sage: Partitions(restricted=4)
4-Restricted Partitions
sage: Partitions(3, restricted=4)
4-Restricted Partitions of the integer 3

>>> from sage.all import *
>>> Partitions(restricted=Integer(4))
4-Restricted Partitions
>>> Partitions(Integer(3), restricted=Integer(4))
4-Restricted Partitions of the integer 3

Here are some further examples using various constraints:
sage: [x for x in Partitions(4)]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2)]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, max_length=2)]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(4, min_length=2, max_length=2)]
[[3, 1], [2, 2]]
sage: [x for x in Partitions(4, max_part=2)]
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(4, min_part=2)]
[[4], [2, 2]]
sage: [x for x in Partitions(4, outer=[3, 1, 1])]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(Integer(4), length=Integer(2))]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(Integer(4), min_length=Integer(2))]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(Integer(4), max_length=Integer(2))]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(Integer(4), min_length=Integer(2), max_length=Integer(2))]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(Integer(4), max_part=Integer(2))]
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(Integer(4), min_part=Integer(2))]
[[4], [2, 2]]
sage: [x for x in Partitions(Integer(4), outer=[Integer(3), Integer(1), Integer(1)])]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(Integer(4), outer=[infinity, Integer(1), Integer(1)])]
[[4], [3, 1], [2, 2]]
sage: [x for x in Partitions(Integer(4), inner=[Integer(1), Integer(1), Integer(1)])]
[[2, 1, 1], [1, 1, 1, 1]]
sage: [x for x in Partitions(Integer(4), max_slope=Integer(-1))]
[[4], [3, 1]]
sage: [x for x in Partitions(Integer(4), min_slope=Integer(-1))]
[[4], [2, 2], [2, 1, 1], [1, 1, 1, 1]]

>>> from sage.all import *

>>> [x for x in Partitions(Integer(4))]
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]

>>> [x for x in Partitions(Integer(4), length=Integer(2))]
[[3, 1], [2, 2]]

>>> [x for x in Partitions(Integer(4), min_length=Integer(2))]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]

>>> [x for x in Partitions(Integer(4), max_length=Integer(2))]
[[4], [3, 1], [2, 2]]

>>> [x for x in Partitions(Integer(4), min_length=Integer(2), max_length=Integer(2))]
[[4], [3, 1], [2, 2]]

>>> [x for x in Partitions(Integer(4), max_part=Integer(2))]
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]

>>> [x for x in Partitions(Integer(4), min_part=Integer(2))]
[[4], [2, 2]]

>>> [x for x in Partitions(Integer(4), outer=[Integer(3), Integer(1), Integer(1)])]
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]

>>> [x for x in Partitions(Integer(4), outer=[infinity, Integer(1), Integer(1)])]
[[4], [3, 1], [2, 2]]

>>> [x for x in Partitions(Integer(4), inner=[Integer(1), Integer(1), Integer(1)])]
[[2, 1, 1], [1, 1, 1, 1]]

>>> [x for x in Partitions(Integer(4), max_slope=Integer(-1))]
[[4], [3, 1]]

>>> [x for x in Partitions(Integer(4), min_slope=Integer(-1))]
[[4], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
Note that if you specify min_part=0, then it will treat the minimum part as being 1 (see Issue #13605):

```sage
[x for x in Partitions(4, length=3, min_part=0)]
```
```
[[2, 1, 1]]
```

```sage
[x for x in Partitions(4, min_length=3, min_part=0)]
```
```
[[2, 1, 1], [1, 1, 1, 1]]
```

Except for very special cases, counting is done by brute force iteration through all the partitions. However the iteration itself has a reasonable complexity (see `IntegerListsLex`), which allows for manipulating large partitions:

```sage
Partitions(1000, max_length=1).list()
```
```
[[1000]]
```

```sage
Partitions(Integer(1000), max_length=Integer(1)).list()
```
```
[[1000]]
```

In particular, getting the first element is also constant time:

```sage
Partitions(30, max_part=29).first()
```
```
[29, 1]
```

```sage
Partitions(Integer(30), max_part=Integer(29)).first()
```
```
[29, 1]
```

Element

alias of `Partition`

```python
options = Current options for Partitions - convention: English -
diagram_str: * - display: list - latex: young_diagram -
lalendar_diagram_str: \ast
```

subset (*args, **kwargs)

Return `self` if no arguments are given.

Otherwise, it raises a `ValueError`.

EXAMPLES:
sage: P = Partitions([5, starting=[3,1]]); P
Partitions of the integer 5 starting with [3, 1]
sage: P.subset()
Partitions of the integer 5 starting with [3, 1]
sage: P.subset(ending=[3,1])
Traceback (most recent call last):
...  
ValueError: invalid combination of arguments

>>> from sage.all import *
>>> P = Partitions(Integer(5), starting=[Integer(3),Integer(1)]); P
Partitions of the integer 5 starting with [3, 1]
>>> P.subset()
Partitions of the integer 5 starting with [3, 1]
>>> P.subset(ending=[Integer(3),Integer(1)])
Traceback (most recent call last):
...  
ValueError: invalid combination of arguments

class sage.combinat.partition.PartitionsGreatestEQ(n,k)
Bases: UniqueRepresentation, IntegerListsLex

The class of all (unordered) “restricted” partitions of the integer \( n \) having all its greatest parts equal to the integer \( k \).

EXAMPLES:

sage: PartitionsGreatestEQ(10, 2)
Partitions of 10 having greatest part equal to 2
sage: PartitionsGreatestEQ(10, 2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1]]

sage: [4,3,2,1] in PartitionsGreatestEQ(10, 2)
False
sage: [2,2,2,2,2] in PartitionsGreatestEQ(10, 2)
True

>>> from sage.all import *
>>> PartitionsGreatestEQ(Integer(10), Integer(2))
Partitions of 10 having greatest part equal to 2
>>> PartitionsGreatestEQ(Integer(10), Integer(2)).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1]]

>>> [Integer(4),Integer(3),Integer(2),Integer(1)] in...
PartitionsGreatestEQ(Integer(10), Integer(2))
False
>>> [Integer(2),Integer(2),Integer(2),Integer(2),Integer(2)] in...
PartitionsGreatestEQ(Integer(10), Integer(2))
True
The empty partition has no maximal part, but it is contained in the set of partitions with any specified maximal part:

```
sage: PartitionsGreatestEQ(0, 2).list()
[]
```

>>> from sage.all import *

```sage
>>> PartitionsGreatestEQ(Integer(0), Integer(2)).list()
[]
```

**Element**

alias of `Partition`

**cardinality()**

Return the cardinality of `self`.

**EXAMPLES:**

```
sage: PartitionsGreatestEQ(10, 2).cardinality()
5
```

```
>>> from sage.all import *

>>> PartitionsGreatestEQ(Integer(10), Integer(2)).cardinality()
5
```

```
options = Current options for Partitions - convention: English -
diagram_str: * - display: list - latex: young_diagram -
latex_diagram_str: \ast
```

**class** `sage.combinat.partition.PartitionsGreatestLE(n, k)`

**Bases:** `UniqueRepresentation`, `IntegerListsLex`

The class of all (unordered) “restricted” partitions of the integer `n` having parts less than or equal to the integer `k`.

**EXAMPLES:**

```
sage: PartitionsGreatestLE(10, 2)
Partitions of 10 having parts less than or equal to 2
sage: PartitionsGreatestLE(10, 2).list()
[[2, 2, 2, 2, 2],
 [2, 2, 2, 2, 1, 1],
 [2, 2, 2, 1, 1, 1, 1],
 [2, 2, 1, 1, 1, 1, 1, 1],
 [2, 1, 1, 1, 1, 1, 1, 1, 1],
 [1, 1, 1, 1, 1, 1, 1, 1, 1, 1]]
```

```
sage: [4,3,2,1] in PartitionsGreatestLE(10, 2)
False
sage: [2,2,2,2] in PartitionsGreatestLE(10, 2)
True
sage: PartitionsGreatestLE(10, 2).first().parent()
Partitions...
```

(continues on next page)
Element

alias of *Partition*

cardinality()

Return the cardinality of self.

EXAMPLES:

```
sage: PartitionsGreatestLE(9, 5).cardinality()  # needs sage.libs.gap
23
```

```
>>> from sage.all import *
>>> PartitionsGreatestLE(Integer(9), Integer(5)).cardinality()  # needs sage.libs.gap
23
```

dependencies = Current options for Partitions - convention: English -
diagram_str: * - display: list - latex: young_diagram -
latex_diagram_str: \ast

class sage.combinat.partition.PartitionsInBox(h, w)

Bases: *Partitions*

All partitions which fit in an \( h \times w \) box.

EXAMPLES:

```
sage: PartitionsInBox(2,2)
Integer partitions which fit in a 2 x 2 box
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
```

```
>>> from sage.all import *
>>> PartitionsInBox(Integer(2),Integer(2))
Integer partitions which fit in a 2 x 2 box
>>> PartitionsInBox(Integer(2),Integer(2)).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
```
**cardinality()**
Return the cardinality of self.

**EXAMPLES:**
```
sage: PartitionsInBox(2, 3).cardinality()
10
```

```
>>> from sage.all import *

>>> PartitionsInBox(Integer(2), Integer(3)).cardinality()
10
```

**list()**
Return a list of all the partitions inside a box of height \( h \) and width \( w \).

**EXAMPLES:**
```
sage: PartitionsInBox(2,2).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]
sage: PartitionsInBox(2,3).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```

```
>>> from sage.all import *

>>> PartitionsInBox(Integer(2),Integer(2)).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2]]

>>> PartitionsInBox(Integer(2),Integer(3)).list()
[[], [1], [1, 1], [2], [2, 1], [2, 2], [3], [3, 1], [3, 2], [3, 3]]
```

**class sage.combinat.partition.Partitions_all**

**Bases:** Partitions

Class of all partitions.

**from_beta_numbers** *(beta)*

Return a partition corresponding to a sequence of beta numbers.

A sequence of beta numbers is a strictly increasing sequence \( 0 \leq b_1 < \cdots < b_k \) of non-negative integers. The corresponding partition \( \mu = (\mu_k, \ldots, \mu_1) \) is given by \( \mu_i = [1, i] \setminus \{b_1, \ldots, b_i\} \). This gives a bijection from the set of partitions with at most \( k \) non-zero parts to the set of strictly increasing sequences of non-negative integers of length \( k \).

**EXAMPLES:**
```
sage: Partitions().from_beta_numbers([0,1,2,4,5,8])
[3, 1, 1]
sage: Partitions().from_beta_numbers([0,2,3,6])
[3, 1, 1]
```

```
>>> from sage.all import *

>>> Partitions().from_beta_numbers([Integer(0),Integer(1),Integer(2),
                                 Integer(4),Integer(5),Integer(8)])
[3, 1, 1]

>>> Partitions().from_beta_numbers([Integer(0),Integer(2),Integer(3),
                                 Integer(6)])
[3, 1, 1]
```
from_core_and_quotient (core, quotient)

Return a partition from its core and quotient.

Algorithm from mupad-combinat.

EXAMPLES:

```python
sage: Partitions().from_core_and_quotient([2,1], [[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
```

```python
>>> from sage.all import *
>>> Partitions().from_core_and_quotient([Integer(2),Integer(1)], [[Integer(2),
Integer(1)],[Integer(3)],[Integer(1),Integer(1),Integer(1)]])
[11, 5, 5, 3, 2, 2, 2]
```

from_exp (exp)

Return a partition from its list of multiplicities.

EXAMPLES:

```python
sage: Partitions().from_exp([2,2,1])
[3, 2, 2, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions().from_exp([Integer(2),Integer(2),Integer(1)])
[3, 2, 2, 1, 1]
```

from_frobenius_coordinates (frobenius_coordinates)

Return a partition from a pair of sequences of Frobenius coordinates.

EXAMPLES:

```python
sage: Partitions().from_frobenius_coordinates(([],[]))
[]
sage: Partitions().from_frobenius_coordinates(([0],[0]))
[1]
sage: Partitions().from_frobenius_coordinates(([1],[1]))
[2, 1]
sage: Partitions().from_frobenius_coordinates(([6,3,2],[4,1,0]))
[7, 5, 5, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions().from_frobenius_coordinates(([],[]))
[]
>>> Partitions().from_frobenius_coordinates((Integer(0),[Integer(0)]))
[1]
>>> Partitions().from_frobenius_coordinates((Integer(1),[Integer(1)]))
[2, 1]
>>> Partitions().from_frobenius_coordinates((Integer(6),Integer(3),
Integer(2)],[Integer(4),Integer(1),Integer(0)]))
[7, 5, 5, 1, 1]
```

from_zero_one (seq)

Return a partition from its 0 – 1 sequence.

The full 0 – 1 sequence is the sequence (infinite in both directions) indicating the steps taken when follow-
ing the outer rim of the diagram of the partition. We use the convention that in English convention, a 1 corresponds to an East step, and a 0 corresponds to a North step.
Note that every full 0—1 sequence starts with infinitely many 0's and ends with infinitely many 1's.

See also:

\[ \text{Partition.zero_one_sequence()} \]

INPUT:

The input should be a finite sequence of 0's and 1's. The heading 0's and trailing 1's will be discarded.

EXAMPLES:

```python
sage: Partitions().from_zero_one([])
[]
sage: Partitions().from_zero_one([1,0])
[1]
sage: Partitions().from_zero_one([1, 1, 1, 0, 1, 0])
[5, 4]
```

```python
>>> from sage.all import *

>>> Partitions().from_zero_one([])
[]

>>> Partitions().from_zero_one([Integer(1),Integer(0)])
[1]

>>> Partitions().from_zero_one([Integer(1), Integer(1), Integer(1), ...
\rightarrow Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)])
[5, 4]
```

Heading 0's and trailing 1's are correctly handled:

```python
sage: Partitions().from_zero_one([0,0,1,1,1,0,1,0,1,1,1])
[5, 4]

>>> from sage.all import *

>>> Partitions().from_zero_one([Integer(0),Integer(0),Integer(1),Integer(1), \n\leftrightarrow Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(1), \n\leftrightarrow Integer(1),Integer(1)])
[5, 4]
```

\[ \text{subset (size=None, **kwargs)} \]

Return the subset of partitions of a given size and additional keyword arguments.

EXAMPLES:

```python
sage: P = Partitions()

sage: P.subset(4)
Partitions of the integer 4

>>> from sage.all import *

>>> P = Partitions()

>>> P.subset(Integer(4))
Partitions of the integer 4
```

\[ \text{class sage.combinat.partition.Partitions_all_bounded(k)} \]

Bases: Partitions

\[ \text{class sage.combinat.partition.Partitions_constraints(*args, **kwds)} \]

Bases: IntegerListsLex \]
For unpickling old constrained Partitions_constraints objects created with sage <= 3.4.1. See Partitions.

```python
class sage.combinat.partition.Partitions_ending(n, ending_partition)
Bases: Partitions

All partitions with a given ending.

**first()**

Return the first partition in self.

**next(part)**

Return the next partition after part in self.

```python
class sage.combinat.partition.Partitions_n(n)
Bases: Partitions

Partitionsoftheinteger n.

**cardinality(algorithm='flint')**

Return thenumberofpartitionsofthespecifiedsize.

**INPUT:**

- `algorithm` – (default: 'flint')
  - 'flint' – use FLINT (currently the fastest)
  - 'gap' – use GAP (VERY slow)
  - 'pari' – use PARI. Speed seems the same as GAP until n is in the thousands, in which case PARI is faster.

It is possible to associate with every partition of the integer n a conjugacy class of permutations in the symmetric group on n points and vice versa. Therefore the number of partitions \( p_n \) is the number of conjugacy classes of the symmetric group on n points.

**EXAMPLES:**
sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: Partitions(5).cardinality(algorithm='gap')
# needs sage.libs.gap
7

sage: from sage.all import *
sage: v = Partitions(Integer(5)).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7
sage: Partitions(Integer(5)).cardinality(algorithm='gap')
# needs sage.libs.gap
7

sage: # needs sage.libs.flint
sage: Partitions(3).cardinality()
3
sage: number_of_partitions(5, algorithm='flint')
7
sage: Partitions(10).cardinality()
42
sage: Partitions(40).cardinality()
37338
sage: Partitions(100).cardinality()
1'90569292

sage: # needs sage.libs.flint
sage: from sage.all import *
sage: Partitions(Integer(3)).cardinality()
3
sage: number_of_partitions(Integer(5), algorithm='flint')
7
sage: Partitions(Integer(10)).cardinality()
42
sage: Partitions(Integer(40)).cardinality()
37338
sage: Partitions(Integer(100)).cardinality()
1'90569292

sage: # needs sage.libs.pari
sage: Partitions(3).cardinality(algorithm='pari')
3
sage: Partitions(5).cardinality(algorithm='pari')
7
sage: Partitions(10).cardinality(algorithm='pari')
42

sage: # needs sage.libs.pari
sage: from sage.all import *
sage: Partitions(Integer(3)).cardinality(algorithm='pari')
3
sage: Partitions(Integer(5)).cardinality(algorithm='pari')
7
(continues on next page)
A generating function for $p_n$ is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \frac{1}{1 - x^k}.$$ 

We use Sage to verify that the first several coefficients do indeed agree:

```sage
sage: q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()

sage: prod([(1-q^k)^(-1) for k in range(1,9)])  # partial product of 1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)

sage: [Partitions(k).cardinality() for k in range(2,10)]  # needs sage.libs.flint
[2, 3, 5, 7, 11, 15, 22, 30]
```

Another consistency test for $n$ up to 500:

```sage
sage: len([n for n in [1..500] if Partitions(n).cardinality() != Partitions(n).cardinality(algorithm='pari')])  # needs sage.libs.flint
0
```

For negative inputs, the result is zero (the algorithm is ignored):

```sage
sage: Partitions(-5).cardinality()
0
```

```sage
>>> from sage.all import *

>>> len((n for n in (ellipsis_range(Integer(1),Ellipsis,Integer(500))) if Partitions(n).cardinality() != Partitions(n).cardinality(algorithm='pari')))  # needs sage.libs.flint
0
```

REFERENCES:

- Wikipedia article Partition_(number_theory) first() Return the lexicographically first partition of a positive integer $n$. This is the partition $[n]$. 5.1. Comprehensive Module List 2795
EXAMPLES:

```
sage: Partitions(4).first()
[4]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).first()
[4]
```

**last()**

Return the lexicographically last partition of the positive integer $n$. This is the all-ones partition.

EXAMPLES:

```
sage: Partitions(4).last()
[1, 1, 1, 1]
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).last()
[1, 1, 1, 1]
```

**next(p)**

Return the lexicographically next partition after the partition $p$.

EXAMPLES:

```
sage: Partitions(4).next([4])
[3, 1]
```

```
sage: Partitions(4).next([1,1,1,1])
is None
```

```
True
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).next([Integer(4)])
[3, 1]
```

```
>>> Partitions(Integer(4)).next([Integer(1),Integer(1),Integer(1),
˓→Integer(1)])
is None
```

```
True
```

**prev(p)**

Return the lexicographically previous partition before partition $p$.

EXAMPLES:

```
sage: Partitions(4).prev([3, 1])
[4]
```

```
sage: Partitions(4).prev([4])
is None
```

```
True
```

```
>>> from sage.all import *
>>> Partitions(Integer(4)).prev([Integer(3), Integer(1)])
[4]
```

```
>>> Partitions(Integer(4)).prev([Integer(4)])
is None
```

```
True
```

**random_element**(measure='uniform')

Return a random partition of $n$ for the specified measure.

INPUT:
• measure='uniform' or 'Plancherel' (default: 'uniform')

See also:

• random_element_uniform()
• random_element_plancherel()

EXAMPLES:

```python
sage: Partitions(5).random_element() # random
[2, 1, 1, 1] # needs sage.libs.flint
dosage: Partitions(5).random_element(measure='Plancherel') # random
[2, 1, 1, 1] # needs sage.libs.flint

>>> from sage.all import *

Partitions(Integer(5)).random_element() # random
[2, 1, 1, 1]

Partitions(Integer(20)).random_element() # random
[9, 3, 3, 2, 2, 1]
```

random_element_plancherel()

Return a random partition of $n$ (for the Plancherel measure).

This probability distribution comes from the uniform distribution on permutations via the Robinson-Schensted correspondence.

See Wikipedia article Plancherel_measure and Partition.plancherel_measure().

EXAMPLES:

```python
sage: Partitions(5).random_element_plancherel() # random
[2, 1, 1, 1]

dosage: Partitions(20).random_element_plancherel() # random
[9, 3, 3, 2, 2, 1]

>>> from sage.all import *

>>> Partitions(Integer(5)).random_element_plancherel() # random
[2, 1, 1, 1]

>>> Partitions(Integer(20)).random_element_plancherel() # random
[9, 3, 3, 2, 2, 1]
```

ALGORITHM:

• insert by Robinson-Schensted a uniform random permutations of $n$ and returns the shape of the resulting tableau. The complexity is $O(n \ln(n))$ which is likely optimal. However, the implementation could be optimized.

AUTHOR:

• Florent Hivert (2009-11-23)

random_element_uniform()

Return a random partition of $n$ with uniform probability.

EXAMPLES:
ALGORITHM:

- It is a python Implementation of RANDPAR, see [NW1978]. The complexity is unknown, there may be better algorithms.

Todo: Check in Knuth AOCP4.

- There is also certainly a lot of room for optimizations, see comments in the code.

AUTHOR:

- Florent Hivert (2009-11-23)

subset (**kwargs)

Return a subset of self with the additional optional arguments.

EXAMPLES:

```python
sage: P = Partitions(5); P
Partitions of the integer 5
sage: P.subset(starting=[3,1])
Partitions of the integer 5 starting with [3, 1]
```

```python
>>> from sage.all import *
>>> P = Partitions(Integer(5)); P
Partitions of the integer 5
>>> P.subset(starting=[Integer(3),Integer(1)])
Partitions of the integer 5 starting with [3, 1]
```

class sage.combinat.partition.Partitions_nk(n, k)

Bases: Partitions

Partitions of the integer $n$ of length equal to $k$.

cardinality (algorithm='hybrid')

Return the number of partitions of the specified size with the specified length.

INPUT:

- algorithm – (default: 'hybrid') the algorithm to compute the cardinality and can be one of the following:
  - 'hybrid' – use a hybrid algorithm which uses heuristics to reduce the complexity
EXAMPLES:

```python
sage: v = Partitions(5, length=2).list(); v
[[4, 1], [3, 2]]
sage: len(v)
2
sage: Partitions(5, length=2).cardinality()
2

>>> from sage.all import *

>>> v = Partitions(Integer(5), length=Integer(2)).list(); v
[[4, 1], [3, 2]]
>>> len(v)
2
>>> Partitions(Integer(5), length=Integer(2)).cardinality()
2
```

More generally, the number of partitions of $n$ of length 2 is $\left\lfloor \frac{n}{2} \right\rfloor$:

```python
sage: all( Partitions(n, length=2).cardinality() == n // 2 for n in range(10) )
True

>>> from sage.all import *

>>> all( Partitions(n, length=Integer(2)).cardinality() == n // Integer(2) for n in range(Integer(10)) )
True
```

The number of partitions of $n$ of length 1 is 1 for $n$ positive:

```python
sage: all( Partitions(n, length=1).cardinality() == 1 for n in range(1, 10) )
True

>>> from sage.all import *

>>> all( Partitions(n, length=Integer(1)).cardinality() == Integer(1) for n in range(Integer(1), Integer(10)) )
True
```

Further examples:

```python
sage: # needs sage.libs.flint
sage: Partitions(5, length=3).cardinality()
2
sage: Partitions(6, length=3).cardinality()
3
sage: Partitions(8, length=4).cardinality()
5
sage: Partitions(8, length=5).cardinality()
3
sage: Partitions(15, length=6).cardinality()
26
sage: Partitions(0, length=0).cardinality()
1
sage: Partitions(0, length=1).cardinality()

(continues on next page)```
0

```sage
sage: Partitions(1, length=0).cardinality()
0
sage: Partitions(1, length=4).cardinality()
0
```

```python
>>> from sage.all import *
```

```python
# needs sage.libs.flint
```

```python
>>> Partitions(Integer(5), length=Integer(3)).cardinality()
2
>>> Partitions(Integer(6), length=Integer(3)).cardinality()
3
>>> Partitions(Integer(8), length=Integer(4)).cardinality()
5
>>> Partitions(Integer(8), length=Integer(5)).cardinality()
3
>>> Partitions(Integer(15), length=Integer(6)).cardinality()
26
>>> Partitions(Integer(0), length=Integer(0)).cardinality()
1
>>> Partitions(Integer(0), length=Integer(1)).cardinality()
0
>>> Partitions(Integer(1), length=Integer(0)).cardinality()
0
>>> Partitions(Integer(1), length=Integer(4)).cardinality()
0
```

subset (**kwargs)

Return a subset of self with the additional optional arguments.

EXAMPLES:

```sage
sage: P = Partitions(5, length=2); P
Partitions of the integer 5 of length 2
sage: P.subset(max_part=3)
Partitions of the integer 5 satisfying constraints length=2, max_part=3
```

```python
>>> from sage.all import *
```

```python
>>> P = Partitions(Integer(5), length=Integer(2)); P
Partitions of the integer 5 of length 2
>>> P.subset(max_part=Integer(3))
Partitions of the integer 5 satisfying constraints length=2, max_part=Integer(3)
```

class sage.combinat.partition.Partitions_parts_in(n, parts)

Bases: Partitions

Partitions of $n$ with parts in a given set $S$.

This is invoked indirectly when calling `Partitions(n, parts_in=parts)`, where `parts` is a list of pairwise distinct integers.

cardinality()

Return the number of partitions with parts in `self`. Wraps GAP's `NrRestrictedPartitions`.

EXAMPLES:
Combinatorics, Release 10.4

sage: Partitions(15, parts_in=[2,3,7]).cardinality()  # needs sage.libs.gap
5

If you can use all parts 1 through \( n \), we’d better get \( p(n) \):

sage: (Partitions(20, parts_in=[1..20]).cardinality()
  # needs sage.libs.gap
  ...: == Partitions(20).cardinality())
True

sage: (Partitions(Integer(20), parts_in=(ellipsis_range(Integer(1),Ellipsis,
  Integer(20))).cardinality()
  # needs sage.libs.gap
  ...: == Partitions(Integer(20)).cardinality())
True

**first()**

Return the lexicographically first partition of a positive integer \( n \) with the specified parts, or None if no such partition exists.

EXAMPLES:

sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]

sage: Partitions(9, parts_in=[3,4]).first()
[3, 3, 3]
sage: Partitions(6, parts_in=[1..6]).first()
[6]
sage: Partitions(30, parts_in=[4,7,8,10,11]).first()
[11, 11, 8]

**last()**

Return the lexicographically last partition of the positive integer \( n \) with the specified parts, or None if no such partition exists.

EXAMPLES:

sage: Partitions(15, parts_in=[2,3]).last()
[3, 2, 2, 2, 2, 2, 2]
sage: Partitions(30, parts_in=[4,7,8,10,11]).last()
[7, 7, 4, 4, 4, 4]
Combinatorics, Release 10.4

True

sage: Partitions(50, parts_in=[11, 12, 13]).last()
[13, 13, 12, 12]
sage: Partitions(30, parts_in=[4, 7, 8, 10, 11]).last()
[7, 7, 4, 4, 4, 4]

>>> from sage.all import *

>>> Partitions(Integer(15), parts_in=[Integer(2), Integer(3)]).last()
[3, 2, 2, 2, 2]
>>> Partitions(Integer(30), parts_in=[Integer(4), Integer(7), Integer(8), Integer(10), Integer(11)]).last()
[7, 7, 4, 4, 4, 4]
>>> Partitions(Integer(10), parts_in=[Integer(3), Integer(6)]).last() is None
True
>>> Partitions(Integer(10), parts_in=[Integer(3), Integer(6)]).last() is None
True

class sage.combinat.partition.Partitions_starting(n, starting_partition)

Bases: Partitions

All partitions with a given start.

first()

Return the first partition in self.

EXAMPLES:

sage: Partitions(3, starting=[2,1]).first()
[2, 1]
sage: Partitions(3, starting=[1,1,1]).first()
[1, 1, 1]
sage: Partitions(3, starting=[1,1]).first()
False
sage: Partitions(3, starting=[3,1]).first()
[3]
sage: Partitions(3, starting=[2,2]).first()
[2, 1]

next(part)

Return the next partition after part in self.
EXAMPLES:

```python
sage: Partitions(3, starting=[2,1]).next(Partition([2,1]))
[1, 1, 1]
```

```python
>>> from sage.all import *

>>> Partitions(Integer(3), starting=[Integer(2),Integer(1)]).next(Partition([Integer(2),Integer(1)]))
[1, 1, 1]
```

class sage.combinat.partition.Partitions_with_constraints(*args, **kwds)

Bases: IntegerListsLex

Partitions which satisfy a set of constraints.

EXAMPLES:

```python
sage: P = Partitions(6, inner=[1,1], max_slope=-1)
sage: list(P)
[[5, 1], [4, 2], [3, 2, 1]]
```

```python
>>> from sage.all import *

>>> P = Partitions(Integer(6), inner=[Integer(1),Integer(1)], max_slope=Integer(-1))

>>> list(P)
[[5, 1], [4, 2], [3, 2, 1]]
```

Element

alias of Partition

```python
options = Current options for Partitions - convention: English -
diagram_str: * - display: list - latex: young_diagram -
llatex_diagram_str: \ast
```

class sage.combinat.partition.RegularPartitions(ell, is_infinite=False)

Bases: Partitions

Base class for ℓ-regular partitions.

Let ℓ be a positive integer. A partition λ is ℓ-regular if \( m_i < \ell \) for all \( i \), where \( m_i \) is the multiplicity of \( i \) in \( \lambda \).

Note: This is conjugate to the notion of ℓ-restricted partitions, where the difference between any two consecutive parts is < \( \ell \).

INPUT:

- ell – the positive integer ℓ
- is_infinite – boolean; if the subset of ℓ-regular partitions is infinite

ell()

Return the value ℓ.

EXAMPLES:

```python
sage: P = Partitions(regular=2)
sage: P.ell()
2
```
class sage.combinat.partition.RegularPartitions_all(ell)
    Bases: RegularPartitions
    The class of all $\ell$-regular partitions.
    INPUT:
    • ell – the positive integer $\ell$
    See also:
    RegularPartitions

class sage.combinat.partition.RegularPartitions_bounded(ell, k)
    Bases: RegularPartitions
    The class of $\ell$-regular $k$-bounded partitions.
    INPUT:
    • ell – the integer $\ell$
    • k – integer; the value $k$
    See also:
    RegularPartitions

class sage.combinat.partition.RegularPartitions_n(n, ell)
    Bases: RegularPartitions, Partitions_n
    The class of $\ell$-regular partitions of $n$.
    INPUT:
    • n – the integer $n$ to partition
    • ell – the integer $\ell$
    See also:
    RegularPartitions

cardinality()
    Return the cardinality of self.

    EXAMPLES:

sage: P = Partitions(5, regular=3)
sage: P.cardinality()  # needs sage.libs.flint
5
sage: P = Partitions(5, regular=6)
sage: P.cardinality()  # needs sage.libs.flint
7
sage: P.cardinality() == Partitions(5).cardinality()  # needs sage.libs.flint
True
```python
>>> from sage.all import *
>>> P = Partitions(Integer(5), regular=Integer(3))
>>> P.cardinality()  # needs sage.libs.flint
5
>>> P = Partitions(Integer(5), regular=Integer(6))
>>> P.cardinality()  # needs sage.libs.flint
7
>>> P.cardinality() == Partitions(Integer(5)).cardinality()  # needs sage.libs.flint
True
```

```python
class sage.combinat.partition.RegularPartitions_truncated(ell, max_len)
Bases: RegularPartitions
The class of \( \ell \)-regular partitions with max length \( k \).

INPUT:

- \( \ell \) – the integer \( \ell \)
- \( \text{max} \_\text{len} \) – integer; the maximum length

See also:

RegularPartitions

max_length()

Return the maximum length of the partitions of \( \text{self} \).

EXAMPLES:

```python
sage: P = Partitions(regular=4, max_length=3)
sage: P.max_length()
3
```
```
```python
class sage.combinat.partition.RestrictedPartitions_all(ell)
Bases: RestrictedPartitions_generic
The class of all \( \ell \)-restricted partitions.

INPUT:

- \( \ell \) – the positive integer \( \ell \)

See also:

RestrictedPartitions_generic

class sage.combinat.partition.RestrictedPartitions_generic(ell, is_infinite=False)
Bases: Partitions
Base class for \( \ell \)-restricted partitions.

Let \( \ell \) be a positive integer. A partition \( \lambda \) is \( \ell \)-restricted if \( \lambda_i - \lambda_{i+1} < \ell \) for all \( i \), including rows of length 0.
```
**Note:** This is conjugate to the notion of $\ell$-regular partitions, where the multiplicity of any parts is at most $\ell$.

**INPUT:**
- $\ell$ – the positive integer $\ell$
- `is_infinite` – boolean; if the subset of $\ell$-restricted partitions is infinite

**ell()**
Return the value $\ell$.

**EXAMPLES:**

```
sage: P = Partitions(restricted=2)
sage: P.ell()
2
```

```
>>> from sage.all import *
>>> P = Partitions(restricted=Integer(2))
>>> P.ell()
2
```

**class** `sage.combinat.partition.RestrictedPartitions_n(n, ell)`

**Bases:** `RestrictedPartitions_generic`, `Partitions_n`

The class of $\ell$-restricted partitions of $n$.

**INPUT:**
- $n$ – the integer $n$ to partition
- $\ell$ – the integer $\ell$

**See also:**
`RestrictedPartitions_generic`

**cardinality()**
Return the cardinality of self.

**EXAMPLES:**

```
sage: P = Partitions(5, restricted=3)
sage: P.cardinality()
# needs sage.libs.flint
5
```

```
sage: P = Partitions(5, restricted=6)
sage: P.cardinality()
# needs sage.libs.flint
7
```

```
sage: P.cardinality() == Partitions(5).cardinality()
# needs sage.libs.flint
True
```

```
>>> from sage.all import *
>>> P = Partitions(Integer(5), restricted=Integer(3))
>>> P.cardinality()
# needs sage.libs.flint
5
```

(continues on next page)
sage.combinat.partition.number_of_partitions(n, algorithm='default')

Return the number of partitions of $n$ with, optionally, at most $k$ parts.

The options of number_of_partitions() are being deprecated Issue #13072 in favour of Partitions_n.cardinality() so that number_of_partitions() can become a stripped down version of the fastest algorithm available (currently this is using FLINT).

INPUT:

- $n$ – an integer
- algorithm – (default: ‘default’) [Will be deprecated except in Partition().cardinality() ]
  - 'default' – If $k$ is not None, then use Gap (very slow). If $k$ is None, use FLINT.
  - 'flint' – use FLINT

EXAMPLES:

sage: v = Partitions(5).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]
sage: len(v)
7

>>> from sage.all import *

>>> v = Partitions(Integer(5)).list(); v
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1], [2, 1, 1, 1], [1, 1, 1, 1, 1]]

>>> len(v)
7

The input must be a nonnegative integer or a ValueError is raised.

sage: number_of_partitions(-5)
Traceback (most recent call last):
  ...
ValueError: n (-5) must be a nonnegative integer

>>> from sage.all import *

>>> number_of_partitions(-Integer(5))
Traceback (most recent call last):
  ...
ValueError: n (-5) must be a nonnegative integer

sage: # needs sage.libs.flint
sage: number_of_partitions(10)
42
sage: number_of_partitions(3)
3
sage: number_of_partitions(10)
A generating function for the number of partitions $p_n$ is given by the reciprocal of Euler's function:

$$\sum_{n=0}^{\infty} p_n x^n = \prod_{k=1}^{\infty} \frac{1}{1-x^k}.$$ 

We use Sage to verify that the first several coefficients do indeed agree:

```sage
q = PowerSeriesRing(QQ, 'q', default_prec=9).gen()
sage: prod([(1-q^k)^(-1) for k in range(1,9)])
# partial product of
1 + q + 2*q^2 + 3*q^3 + 5*q^4 + 7*q^5 + 11*q^6 + 15*q^7 + 22*q^8 + O(q^9)
sage: [number_of_partitions(k) for k in range(2,10)]
# needs sage.libs.flint
[2, 3, 5, 7, 11, 15, 22, 30]
```

### 5.1.166 Partition/Diagram Algebras

```python
class sage.combinat.partition_algebra.PartitionAlgebraElement_ak
    Bases: PartitionAlgebraElement_generic
class sage.combinat.partition_algebra.PartitionAlgebraElement_bk
    Bases: PartitionAlgebraElement_generic
class sage.combinat.partition_algebra.PartitionAlgebraElement_generic
    Bases: IndexedFreeModuleElement
class sage.combinat.partition_algebra.PartitionAlgebraElement_pk
    Bases: PartitionAlgebraElement_generic
class sage.combinat.partition_algebra.PartitionAlgebraElement_prk
    Bases: PartitionAlgebraElement_generic
class sage.combinat.partition_algebra.PartitionAlgebraElement_rk
    Bases: PartitionAlgebraElement_generic
```
class sage.combinat.partition_algebra.PartitionAlgebraElement_sk
Bases: PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebraElement_tk
Bases: PartitionAlgebraElement_generic

class sage.combinat.partition_algebra.PartitionAlgebra_ak($R$, $k$, $n$, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_ak(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_ak(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.PartitionAlgebra_bk($R$, $k$, $n$, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_bk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_bk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.PartitionAlgebra_generic($R$, cclass, $n$, $k$, name=None, prefix=None)
Bases: CombinatorialFreeModule

EXAMPLES:

```
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(QQ, 3, 1)
sage: TestSuite(s).run()
sage: s == loads(dumps(s))
True
```

```
>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> s = PartitionAlgebra_sk(QQ, Integer(3), Integer(1))
>>> TestSuite(s).run()
>>> s == loads(dumps(s))
True
```
one_basis()
Return the basis index for the unit of the algebra.

EXAMPLES:

```python
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(ZZ, 3, 1)
sage: len(s.one().support())  # indirect doctest
1
```

product_on_basis(left, right)

EXAMPLES:

```python
sage: from sage.combinat.partition_algebra import *
sage: s = PartitionAlgebra_sk(QQ, 3, 1)
sage: t12 = s(Set([Set([1,-2]),Set([2,-1]),Set([3,-3])]))
sage: t12^2 == s(1)  # indirect doctest
True
```

class sage.combinat.partition_algebra.PartitionAlgebra_pk(R, k, n, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

```python
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_pk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```

class sage.combinat.partition_algebra.PartitionAlgebra_prk(R, k, n, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

```python
sage: from sage.combinat.partition_algebra import *
sage: p = PartitionAlgebra_prk(QQ, 3, 1)
sage: p == loads(dumps(p))
True
```
sage: p == loads(dumps(p))
True

>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_prk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_rk(R, k, n, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

sage: from sage.combinat.partition_algebra import *
    p = PartitionAlgebra_rk(QQ, 3, 1)
    p == loads(dumps(p))
True

>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_rk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_sk(R, k, n, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

sage: from sage.combinat.partition_algebra import *
    p = PartitionAlgebra_sk(QQ, 3, 1)
    p == loads(dumps(p))
True

>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_sk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True

class sage.combinat.partition_algebra.PartitionAlgebra_tk(R, k, n, name=None)
Bases: PartitionAlgebra_generic

EXAMPLES:

sage: from sage.combinat.partition_algebra import *
    p = PartitionAlgebra_tk(QQ, 3, 1)
    p == loads(dumps(p))
True

>>> from sage.all import *
>>> from sage.combinat.partition_algebra import *
>>> p = PartitionAlgebra_tk(QQ, Integer(3), Integer(1))
>>> p == loads(dumps(p))
True
sage.combinat.partition_algebra.SetPartitionsAk(k)

Return the combinatorial class of set partitions of type $A_k$.

EXAMPLES:

```python
sage: A3 = SetPartitionsAk(3); A3
Set partitions of {1, ..., 3, -1, ..., -3}
sage: A3.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
sage: A3.random_element() #random
{{1, 3, -3, -1}, {2, -2}}
sage: A3.cardinality()
203
sage: A2p5 = SetPartitionsAk(2.5); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
sage: A2p5.cardinality()
52
sage: A2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
sage: A2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
sage: A2p5.random_element() #random
{{-1}, {-2}, {3, -3}, {1, 2}}
```

```python
>>> from sage.all import *
>>> A3 = SetPartitionsAk(Integer(3)); A3
Set partitions of {1, ..., 3, -1, ..., -3}
>>> A3.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> A3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
>>> A3.random_element() #random
{{1, 3, -3, -1}, {2, -2}}
>>> A3.cardinality()
203
>>> A2p5 = SetPartitionsAk(RealNumber('2.5')); A2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block
>>> A2p5.cardinality()
52
>>> A2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> A2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
>>> A2p5.random_element() #random
{{-1}, {-2}, {3, -3}, {1, 2}}
```

class sage.combinat.partition_algebra.SetPartitionsAk_k(k)

Bases: SetPartitions_set
Element

alias of SetPartitionsXkElement

class sage.combinat.partition_algebra.SetPartitionsAkhalf_k(k)

Bases: SetPartitions_set

Element

alias of SetPartitionsXkElement

sage.combinat.partition_algebra.SetPartitionsBk(k)

Return the combinatorial class of set partitions of type \( B_k \).

These are the set partitions where every block has size 2.

EXAMPLES:

```python
sage: B3 = SetPartitionsBk(3); B3
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with block size 2

sage: B3.first()  #random
({2, -2}, {1, -3}, {3, -1})

sage: B3.last()  #random
({1, 2}, {3, -2}, {-3, -1})

sage: B3.random_element()  #random
({2, -1}, {1, -3}, {3, -2})

sage: B3.cardinality()
15

sage: B2p5 = SetPartitionsBk(2.5); B2p5
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with 3 and -3 in the same block and
\rightarrow with block size 2

sage: B2p5.first()  #random
({2, -1}, {3, -3}, {1, -2})

sage: B2p5.last()  #random
({1, 2}, {3, -3}, {-1, -2})

sage: B2p5.random_element()  #random
({2, -2}, {3, -3}, {1, -1})

sage: B2p5.cardinality()
3
```

```python
>>> from sage.all import *

>>> B3 = SetPartitionsBk(Integer(3)); B3
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with block size 2

>>> B3.first()  #random
({2, -2}, {1, -3}, {3, -1})

>>> B3.last()  #random
({1, 2}, {3, -2}, {-3, -1})

>>> B3.random_element()  #random
({2, -1}, {1, -3}, {3, -2})

>>> B3.cardinality()
15

>>> B2p5 = SetPartitionsBk(RealNumber('2.5')); B2p5
```

(continues on next page)
Set partitions of \{1, \ldots, 3, -1, \ldots, -3\} with 3 and -3 in the same block and with block size 2

```python
>>> B2p5.first()  # random
\{(2, -1), (3, -3), (1, -2)\}
>>> B2p5.last()  # random
\{(1, 2), (3, -3), (-1, -2)\}
>>> B2p5.random_element()  # random
\{(2, -2), (3, -3), (1, -1)\}
>>> B2p5.cardinality()
3
```

```python
class sage.combinat.partition_algebra.SetPartitionsBk_k(k)
Bases: SetPartitionsAk_k
cardinality()

Return the number of set partitions in \(B_k\) where \(k\) is an integer.
This is given by \((2k)!! = (2k-1)\cdot(2k-3)\cdot\ldots\cdot5\cdot3\cdot1\).

EXAMPLES:
```
sage: SetPartitionsBk(3).cardinality()
15
sage: SetPartitionsBk(2).cardinality()
3
sage: SetPartitionsBk(1).cardinality()
1
sage: SetPartitionsBk(4).cardinality()
105
sage: SetPartitionsBk(5).cardinality()
945
```
```
>>> from sage.all import *
```
```
>>> SetPartitionsBk(Integer(3)).cardinality()
15
>>> SetPartitionsBk(Integer(2)).cardinality()
3
>>> SetPartitionsBk(Integer(1)).cardinality()
1
>>> SetPartitionsBk(Integer(4)).cardinality()
105
```
```
>>> from sage.all import *
```
```
>>> SetPartitionsBkhalf_k(k)
Bases: SetPartitionsAkhalf_k
cardinality()

Return the combinatorial class of set partitions of type \(I_k\).
These are set partitions with a propagating number of less than \(k\). Note that the identity set partition \(\{\{1, -1\}, \ldots, \{k, -k\}\}\) is not in \(I_k\).

EXAMPLES:
```
sage.combinat.partition_algebra.SetPartitionsIk(k)
```
\texttt{sage}: I3 = SetPartitionsIk(3); I3
Set partitions of \{1, ..., 3, -1, ..., -3\} with propagating number < 3
\texttt{sage}: I3.cardinality()
197

\texttt{sage}: I3.first() \texttt{#random}
\{(1, 2, 3, -1, -3, -2)\}
\texttt{sage}: I3.last() \texttt{#random}
\{(-1), (-2), (3), (1), (-3), (2)\}
\texttt{sage}: I3.random_element() \texttt{#random}
\{(-1), (-3, -2), (2, 3), (1)\}

\texttt{sage}: I2p5 = SetPartitionsIk(2.5); I2p5
Set partitions of \{1, ..., 3, -1, ..., -3\} with 3 and -3 in the same block and...
→ propagating number < 3
\texttt{sage}: I2p5.cardinality()
50

\texttt{sage}: I2p5.first() \texttt{#random}
\{(1, 2, 3, -1, -3, -2)\}
\texttt{sage}: I2p5.last() \texttt{#random}
\{(-1), (-2), (2), (3, -3), (1)\}
\texttt{sage}: I2p5.random_element() \texttt{#random}
\{(-1), (-2), (1, 3, -3), (2)\}

\texttt{>>> from sage.all import *}
\texttt{>>> I3 = SetPartitionsIk(Integer(3)); I3}
Set partitions of \{1, ..., 3, -1, ..., -3\} with propagating number < 3
\texttt{>>> I3.cardinality()}
197

\texttt{>>> I3.first() \texttt{#random}}
\{1, 2, 3, -1, -3, -2\}
\texttt{>>> I3.last() \texttt{#random}}
\{(-1), (-2), (3), (1), (-3), (2)\}
\texttt{>>> I3.random_element() \texttt{#random}}
\{(-1), (-3, -2), (2, 3), (1)\}

\texttt{>>> I2p5 = SetPartitionsIk(RealNumber(\texttt{2.5})); I2p5}
Set partitions of \{1, ..., 3, -1, ..., -3\} with 3 and -3 in the same block and...
→ propagating number < 3
\texttt{>>> I2p5.cardinality()}
50

\texttt{>>> I2p5.first() \texttt{#random}}
\{1, 2, 3, -1, -3, -2\}
\texttt{>>> I2p5.last() \texttt{#random}}
\{(-1), (-2), (2), (3, -3), (1)\}
\texttt{>>> I2p5.random_element() \texttt{#random}}
\{(-1), (-2), (1, 3, -3), (2)\}
cardinality()

sage.combinat.partition_algebra.SetPartitionsPRk(k)

Return the combinatorial class of set partitions of type \( PR_k \).

EXAMPLES:

```python
sage: SetPartitionsPRk(3)
Set partitions of \( \{1, \ldots, 3, -1, \ldots, -3\} \) with at most 1 positive and negative entry in each block and that are planar

>>> from sage.all import *
>>> SetPartitionsPRk(Integer(3))
Set partitions of \( \{1, \ldots, 3, -1, \ldots, -3\} \) with at most 1 positive and negative entry in each block and that are planar
```

class sage.combinat.partition_algebra.SetPartitionsPRk_k(k)

Bases: SetPartitionsRk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsPRkhalf_k(k)

Bases: SetPartitionsRkhalf_k
cardinality()

sage.combinat.partition_algebra.SetPartitionsPk(k)

Return the combinatorial class of set partitions of type \( P_k \).

These are the planar set partitions.

EXAMPLES:

```python
sage: P3 = SetPartitionsPk(3); P3
Set partitions of \( \{1, \ldots, 3, -1, \ldots, -3\} \) that are planar
sage: P3.cardinality()
132

sage: P3.first() # random
\{\{1, 2, 3, -1, -3, -2\}\}

sage: P3.last() # random
\{\{-1\}, \{-2\}, \{3\}, \{1\}, \{-3\}, \{2\}\}

sage: P3.random_element() # random
\{\{1, 2, -1\}, \{-3\}, \{3, -2\}\}

sage: P2p5 = SetPartitionsPk(2.5); P2p5
Set partitions of \( \{1, \ldots, 3, -1, \ldots, -3\} \) with 3 and -3 in the same block and that are planar
sage: P2p5.cardinality()
42

sage: P2p5.first() # random
\{\{1, 2, 3, -1, -3, -2\}\}

sage: P2p5.last() # random
\{\{-1\}, \{-2\}, \{2\}, \{3, -3\}, \{1\}\}

sage: P2p5.random_element() # random
\{\{1, 2, 3, -3\}, \{-1, -2\}\}
```
```python
>>> from sage.all import *
>>> P3 = SetPartitionsPk(Integer(3)); P3
Set partitions of {1, ..., 3, -1, ..., -3} that are planar
>>> P3.cardinality()
132
>>> P3.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> P3.last() #random
{{-1}, {-2}, {3}, {1}, {-3}, {2}}
>>> P3.random_element() #random
{{1, 2, -1}, {-3}, {3, -2}}

>>>
```

```python
>>> P2p5 = SetPartitionsPk(RealNumber('2.5')); P2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and...
that are planar
>>> P2p5.cardinality()
42
>>> P2p5.first() #random
{{1, 2, 3, -1, -3, -2}}
>>> P2p5.last() #random
{{-1}, {-2}, {2}, {3, -3}, {1}}
>>> P2p5.random_element() #random
{{1, 2, 3, -3}, {-1, -2}}
```

```python
class sage.combinat.partition_algebra.SetPartitionsPk_k(k)
    Bases: SetPartitionsAk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsPkhalf_k(k)
    Bases: SetPartitionsAkhalf_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsRk_k(k)
    Return the combinatorial class of set partitions of type \( R_k \).
    EXAMPLES:

sage: SetPartitionsRk(3)
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
and negative entry in each block
```

```python
>>> from sage.all import *
>>> SetPartitionsRk(Integer(3))
Set partitions of {1, ..., 3, -1, ..., -3} with at most 1 positive
and negative entry in each block
```

```python
class sage.combinat.partition_algebra.SetPartitionsRk_k(k)
    Bases: SetPartitionsAk_k
cardinality()

class sage.combinat.partition_algebra.SetPartitionsRkhalf_k(k)
    Bases: SetPartitionsAkhalf_k
```
cardinality()

sage.combinat.partition_algebra.SetPartitionsSk(k)

Return the combinatorial class of set partitions of type $S_k$.

There is a bijection between these set partitions and the permutations of $1, \ldots, k$.

EXAMPLES:

```python
sage: S3 = SetPartitionsSk(3); S3
Set partitions of $\{1, \ldots, 3, -1, \ldots, -3\}$ with propagating number 3
sage: S3.cardinality()
6
sage: S3.list()  #random
[{{2, -2}, {3, -3}, {1, -1}},
 {{1, -1}, {2, -3}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}},
 {{1, -2}, {2, -3}, {3, -1}},
 {{1, -3}, {2, -1}, {3, -2}},
 {{1, -3}, {2, -2}, {3, -1}}]
sage: S3.first()  #random
({2, -2}, {3, -3}, {1, -1})
sage: S3.last()  #random
({1, -3}, {2, -2}, {3, -1})
sage: S3.random_element()  #random
({1, -3}, {2, -1}, {3, -2})
```

```python
sage: S3p5 = SetPartitionsSk(3.5); S3p5
Set partitions of $\{1, \ldots, 4, -1, \ldots, -4\}$ with 4 and -4 in the same block and propagating number 4
sage: S3p5.cardinality()
6
sage: S3p5.list()  #random
[{{2, -2}, {3, -3}, {1, -1}, {4, -4}},
 {{2, -3}, {1, -1}, {4, -4}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}, {4, -4}},
 {{2, -3}, {1, -2}, {4, -4}, {3, -1}},
 {{1, -3}, {4, -4}, {3, -1}}]
sage: S3p5.first()  #random
({2, -2}, {3, -3}, {1, -1}, {4, -4})
sage: S3p5.last()  #random
({1, -3}, {2, -2}, {4, -4}, {3, -1})
sage: S3p5.random_element()  #random
({1, -3}, {2, -2}, {4, -4}, {3, -1})
```

```python
>>> from sage.all import *
>>> S3 = SetPartitionsSk(Integer(3)); S3
Set partitions of $\{1, \ldots, 3, -1, \ldots, -3\}$ with propagating number 3
>>> S3.cardinality()
6
>>> S3.list()  #random
[{{2, -2}, {3, -3}, {1, -1}},
 {{1, -1}, {2, -3}, {3, -2}},
 {{2, -1}, {3, -3}, {1, -2}},
 {{1, -2}, {2, -3}, {3, -1}},
 {{1, -3}, {2, -1}, {3, -2}},
 {{1, -3}, {2, -2}, {3, -1}}]
```

(continues on next page)
{\{1, -2\}, \{2, -3\}, \{3, -1\}},
{\{1, -3\}, \{2, -1\}, \{3, -2\}},
{\{1, -3\}, \{2, -2\}, \{3, -1\}}

>>> S3.first() #random
{{2, -2}, \{3, -3\}, \{1, -1\}}

>>> S3.last() #random
{{1, -3}, \{2, -2\}, \{3, -1\}}

>>> S3.random_element() #random
{{1, -3}, \{2, -1\}, \{3, -2\}}

>>> S3p5 = SetPartitionsSk(RealNumber('3.5')); S3p5
Set partitions of \{1, ..., 4, -1, ..., -4\} with 4 and -4 in the same block and...→ propagating number 4

>>> S3p5.cardinality()
6

>>> S3p5.first() #random

class sage.combinat.partition_algebra.SetPartitionsSk_k

Bases:
SetPartitionsAk_k

cardinality()

Return k!.

class sage.combinat.partition_algebra.SetPartitionsSkhalf_k

Bases:
SetPartitionsAkhalf_k

cardinality

sage.combinat.partition_algebra.SetPartitionsTk_k

Return the combinatorial class of set partitions of type \(T_k\).

These are planar set partitions where every block is of size 2.

EXAMPLES:

sage: T3 = SetPartitionsTk(3); T3
Set partitions of \{1, ..., 3, -1, ..., -3\} with block size 2 and that are planar

sage: T3.cardinality()
5

sage: T3.first() #random
{{1, -3}, \{2, 3\}, \{-1, -2\}}

sage: T3.last() #random
{{1, 2}, \{3, -1\}, \{-3, -2\}}
sage: T3.random_element()  # random
{{1, -3}, {2, 3}, {-1, -2}}

sage: T2p5 = SetPartitionsTk(2.5); T2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and...
→ with block size 2 and that are planar
sage: T2p5.cardinality()
2

sage: T2p5.first()  # random
{{2, -2}, {3, -3}, {1, -1}}
sage: T2p5.last()  # random
{{1, 2}, {3, -3}, {-1, -2}}

>>> from sage.all import *
>>> T3 = SetPartitionsTk(Integer(3)); T3
Set partitions of {1, ..., 3, -1, ..., -3} with block size 2 and that are planar
>>> T3.cardinality()
5

>>> T3.first()  # random
{{1, -3}, {2, 3}, {-1, -2}}
>>> T3.last()  # random
{{1, 2}, {3, -1}, {-3, -2}}

>>> T3.random_element()  # random
{{1, -3}, {2, 3}, {-1, -2}}

>>> T2p5 = SetPartitionsTk(RealNumber('2.5')); T2p5
Set partitions of {1, ..., 3, -1, ..., -3} with 3 and -3 in the same block and...
→ with block size 2 and that are planar
>>> T2p5.cardinality()
2

>>> T2p5.first()  # random
{{2, -2}, {3, -3}, {1, -1}}
>>> T2p5.last()  # random
{{1, 2}, {3, -3}, {-1, -2}}
sage: A2p5 = SetPartitionsAk(2.5)
sage: x = A2p5.first(); x
{(-3, -2, -1, 1, 2, 3})
sage: x.check()
sage: y = A2p5.next(x); y
{(3, -1, 2), (-2, -1, 1, 2)},
sage: y.check()

>>> from sage.all import *
>>> A2p5 = SetPartitionsAk(RealNumber('2.5'))
>>> x = A2p5.first(); x
{(-3, -2, -1, 1, 2, 3})
>>> x.check()
>>> y = A2p5.next(x); y
{(3, -1, 2), (-2, -1, 1, 2)}
>>> y.check()

sage.combinat.partition_algebra.identity(k)

Return the identity set partition 1, -1, ..., k, -k

EXAMPLES:

sage: import sage.combinat.partition_algebra as pa
sage: pa.identity(2)
{(2, -2), (1, -1)}

>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> pa.identity(Integer(2))
{(2, -2), (1, -1)}

sage.combinat.partition_algebra.is_planar(sp)

Return True if the diagram corresponding to the set partition is planar; otherwise, it returns False.

EXAMPLES:

sage: import sage.combinat.partition_algebra as pa
sage: pa.is_planar( pa.to_set_partition([[1,-2],[2,-1]]))
False
sage: pa.is_planar( pa.to_set_partition([[1,-1],[2,-2]]))
True

>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> pa.is_planar( pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-
˓→Integer(1)]]))
False
>>> pa.is_planar( pa.to_set_partition([[Integer(1),-Integer(1)],[Integer(2),-
˓→Integer(2)]]))
True

sage.combinat.partition_algebra.pair_to_graph(sp1, sp2)

Return a graph consisting of the disjoint union of the graphs of set partitions sp1 and sp2 along with edges joining the bottom row (negative numbers) of sp1 to the top row (positive numbers) of sp2.

The vertices of the graph sp1 appear in the result as pairs (k, 1), whereas the vertices of the graph sp2 appear as pairs (k, 2).
EXAMPLES:

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])
sage: g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
```

```python
>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>>
sp1 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
sp2 = pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])
g = pa.pair_to_graph( sp1, sp2 ); g
Graph on 8 vertices
```

```python
sage: g.vertices(sort=False)  #random
[(-2, 1), (-2, 2), (-1, 1), (-1, 2), (1, 1), (1, 2), (2, 1), (2, 2)]
sage: g.edges(sort=False)  #random
[((-2, 1), (2, 2), None), ((-1, 1), (1, 1), None), ((-1, 1), (1, 2), None)]
```

```python
>>> from sage.all import *
>>>
sp3 = pa.to_set_partition([[Integer(1), -Integer(1)],[Integer(2)],[Integer(2)]])
sp4 = pa.to_set_partition([[Integer(1)],[-Integer(1)],[Integer(2)],[Integer(2)]])
g = pa.pair_to_graph( sp3, sp4 ); g
Graph on 8 vertices
```

```
(continues on next page)
```
sage.combinat.partition_algebra.propagating_number(sp)

Return the propagating number of the set partition \( sp \).

The propagating number is the number of blocks with both a positive and negative number.

EXAMPLES:

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,2],[-2,-1]])

sage: pa.propagating_number(sp1)
2
sage: pa.propagating_number(sp2)
0
```

sage.combinat.partition_algebra.set_partition_composition(sp1, sp2)

Return a tuple consisting of the composition of the set partitions \( sp1 \) and \( sp2 \) and the number of components removed from the middle rows of the graph.

EXAMPLES:

```python
sage: import sage.combinat.partition_algebra as pa
sage: sp1 = pa.to_set_partition([[1,-2],[2,-1]])
sage: sp2 = pa.to_set_partition([[1,-2],[2,-1]])

sage: pa.set_partition_composition(sp1, sp2) == (pa.identity(2), 0)
True
```

sage.combinat.partition_algebra.to_graph(sp)

Return a graph representing the set partition \( sp \).

EXAMPLES:
sage: import sage.combinat.partition_algebra as pa
sage: g = pa.to_graph( pa.to_set_partition([[1,-2],[2,-1]])); g
Graph on 4 vertices
sage: g.vertices(sort=False) #random
[1, 2, -2, -1]
sage: g.edges(sort=False) #random
[((1, -2, None), (2, -1, None))]

>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> g = pa.to_graph( pa.to_set_partition([[Integer(1),-Integer(2)],[Integer(2),-Integer(1)]])); g
Graph on 4 vertices
>>> g.vertices(sort=False) #random
[1, 2, -2, -1]
>>> g.edges(sort=False) #random
[((1, -2, None), (2, -1, None))]

sage.combinat.partition_algebra.to_set_partition(l, k=None)
Convert a list of a list of numbers to a set partitions.
Each list of numbers in the outer list specifies the numbers contained in one of the blocks in the set partition.
If k is specified, then the set partition will be a set partition of 1, ..., k, -1, ..., -k. Otherwise, k will default to the minimum number needed to contain all of the specified numbers.

EXAMPLES:

sage: import sage.combinat.partition_algebra as pa
sage: pa.to_set_partition([[1,-1],[2,-2]]) == pa.identity(2)
True

>>> from sage.all import *
>>> import sage.combinat.partition_algebra as pa
>>> pa.to_set_partition([[Integer(1),-Integer(1)],[Integer(2),-Integer(2)]]).is_identity() == True
True

5.1.167 Kleshchev partitions

A partition (tuple) \( \mu \) is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty \texttt{PartitionTuple} of the same \texttt{level()} and \texttt{multicharge}. In this way, the set of Kleshchev multipartitions becomes a realization of a Kashiwara crystal \texttt{sage.combinat.crystals.crystals} for an irreducible integral highest weight representation of \( U_q(\hat{\mathfrak{sl}}_e) \).

The Kleshchev multipartitions first appeared in the work of Ariki and Mathas [AM2000] where it was shown that they index the irreducible representations of the cyclotomic Hecke algebras of type \( A \) [AK1994]. Soon afterwards Ariki [Ariki2001] showed that the set of Kleshchev multipartitions naturally label the irreducible representations of these algebras. As a far reaching generalization of these ideas the Ariki-Brundan-Kleshchev categorification theorem [Ariki1996] [BK2009] says that these algebras categorify the irreducible integral highest weight representations of the quantum group \( U_q(\hat{\mathfrak{sl}}_e) \) of the affine special linear group. Under this categorification, \( q \) corresponds to the grading shift on the cyclotomic
Hecke algebras, where the grading from the Brundan-Kleshchev graded isomorphism theorem to the \textit{KLR algebras} of type \(A\) \cite{BK2009}.

The group algebras of the symmetric group in characteristic \(p\) are an important special case of the cyclotomic Hecke algebras of type \(A\). In this case, depending on your prefer convention, the set of Kleshchev partitions is the set of \(p\)-regular or \(p\)-restricted Partitions. In this case, Kleshchev \cite{Kle1995} proved that the modular branching rules were given by adding and removing \textit{good nodes}; see \texttt{good\_cells()}. Lascoux, Leclerc and Thibon \cite{LLT1996} noticed that Kleshchev's branching rules coincided with Kashiwara's crystal operators for the fundamental representation of \(L(\Lambda_0)\) of \(U_q(\mathfrak{sl}_p)\) and their celebrated \textit{LLT conjecture} said that decomposition matrices of the \texttt{sage.algebras.iwahori_hecke_algebra.IwahoriHeckeAlgebra} of the symmetric group should be computable using the canonical basis of \(L(\Lambda_0)\). This was proved and generalised to all cyclotomic Hecke algebras of type \(A\) by Ariki \cite{Ariki1996} and then further generalized to the graded setting by Brundan and Kleshchev \cite{BK2009}.

The main class for accessing Kleshchev partition (tuples) is \texttt{KleshchevPartitions}. Unfortunately, just as with the symmetric group, different authors use different conventions when defining Kleshchev partitions, which depends on whether you read components from left to right, or right to left, and whether you read the nodes in the partition in each component from top to bottom or bottom to top. The \texttt{KleshchevPartitions} class supports these four different conventions:

default, the \texttt{left restricted} convention is used. As a shorthand, \texttt{LG}, \texttt{LS}, \texttt{RG} and \texttt{RS}, respectively, can be used to specify the convention With the \texttt{left} convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the \texttt{right} convention the most dominant partition is on the right.

The \texttt{KleshchevPartitions} class can automatically convert between these four different conventions:

\begin{verbatim}
>>> from sage.all import *
>>> KPlg = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),
    convention='left regular')
>>> KPls = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),
    convention='left restricted')
>>> [KPlg(mu) for mu in KPls]  # indirect doc test
[[[1], [1]], [[2], []]]

>>> from sage.all import *
>>> KP1g = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
>>> KP1s = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
>>> [KP1g(mu) for mu in KP1s]  # indirect doc test
[[[1], [1]], [[2], []]]
\end{verbatim}

class sage.combinat.partition_kleshchev.KleshchevCrystalMixin

Bases: object

Mixin class for the crystal structure of a Kleshchev partition.

Epsilon()

Return $\varepsilon$ of self.

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.Epsilon()
3*Lambda[1]
```

Phi()

Return $\phi$ of self.

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.Phi()
3*Lambda[0] + 2*Lambda[1]
```

epsilon(i)

Return the Kashiwara crystal operator $\varepsilon_i$ applied to self.

INPUT:

- $i$ – an element of the index set

EXAMPLES:
phi(i)

Return the Kashiwara crystal operator $\varphi_i$ applied to self.

INPUT:

- i – an element of the index set

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: [x.phi(i) for i in C.index_set()]
[3, 2, 0]
```

weight()

Return the weight of self.

EXAMPLES:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.weight()
3*Lambda[0] - Lambda[1] - 5*delta
```

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right regular")
sage: y = C([[5,1,1],[4,2,2,1,1]])
sage: y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
```

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: y = C([[5,1,1],[4,2,2,1,1]])
sage: y.weight()
```

(continues on next page)
\begin{verbatim}
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],
   ←convention="left regular")
>>> x = C([[Integer(5),Integer(4),Integer(1)], [Integer(3),Integer(2),
   ←Integer(1),Integer(1)]]))
>>> x.weight()
3*Lambda[0] - Lambda[1] - 5*delta
>>> x.Phi() - x.Epsilon()
3*Lambda[0] - Lambda[1]
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],
   ←convention="right regular")
>>> y = C([[Integer(5),Integer(1),Integer(1)], [Integer(4),Integer(2),
   ←Integer(2),Integer(1),Integer(1)]]))
>>> y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
>>> y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],
   ←convention="left regular")
>>> y = C([[Integer(5),Integer(1),Integer(1)], [Integer(4),Integer(2),
   ←Integer(2),Integer(1),Integer(1)]]))
>>> y.weight()
6*Lambda[0] - 4*Lambda[1] - 4*delta
>>> y.Phi() - y.Epsilon()
6*Lambda[0] - 4*Lambda[1]

class sage.combinat.partition_kleshchev.KleshchevPartition (parent, mu)
    Bases: Partition
    Abstract base class for Kleshchev partitions. See KleshchevPartitions.
    cogood_cells (i=None)
    Return a list of the cells of self that are cogood.
    The cogood i-cell is the 'last' conormal i-cell. As with the conormal cells we can choose to read either up or
down the partition as specified by convention().
    INPUT:
    • i – (optional) a residue
    OUTPUT:
    If no residue i is specified then a dictionary of cogood cells is returned, which gives the cogood cells for 0
<= i < e.
    EXAMPLES:
    sage: KP = KleshchevPartitions(3, convention="regular")
    sage: KP([[5,4,4,3,2]]).cogood_cells()
    {0: (1, 4), 1: (4, 2)}
    sage: KP([[5,4,4,3,2]]).cogood_cells(0)
\end{verbatim}
conormal_cells\( (i=\texttt{None}) \)

Return a dictionary of the cells of \texttt{self} which are conormal.

Following [Kle1995], the conormal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \(e\)-residue \(i\) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable \(i\)-cells that remain at the end of this process are the conormal \(i\)-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting \texttt{convention} = \texttt{'RS'}.

INPUT:

- \(i\) – (optional) a residue

OUTPUT:

If no residue \(i\) is specified then a dictionary of conormal cells is returned, which gives the conormal cells for \(0 \leq i < e\).

EXAMPLES:

\begin{verbatim}
sage: KP = KleshchevPartitions(3, convention="regular")
sage: KP([5,4,4,3,2]).conormal_cells()
{(1, 4), (5, 0), (4, 2)}
\end{verbatim}
sage: KP([5,4,4,3,2]).conormal_cells(0)
[(1, 4)]
sage: KP([5,4,4,3,2]).conormal_cells(1)
[(5, 0), (4, 2)]
sage: KP = KleshchevPartitions(3, convention="restricted")
sage: KP([5,4,4,3,2]).conormal_cells()
{0: [(1, 4), (3, 3)], 2: [(0, 5)]}

>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention="regular")
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_cells(Integer(0))
[(1, 4)]
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_cells(Integer(1))
[(5, 0), (4, 2)]
>>> KP = KleshchevPartitions(Integer(3), convention="restricted")
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).conormal_cells()
{0: [(1, 4), (3, 3)], 2: [(0, 5)]}

good_cell_sequence()

Return a sequence of good nodes from the empty partition to self, or None if no such sequence exists.

EXAMPLES:

sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2),
 (3, 0), (2, 1), (1, 2), (3, 1), (0, 3), (1, 3),
 (2, 2), (3, 2), (4, 0), (4, 1), (0, 4), (2, 3)]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_cell_sequence()
[(0, 0), (0, 1), (1, 0), (0, 2), (1, 1), (2, 0),
 (0, 3), (2, 1), (1, 2), (1, 3), (3, 0), (3, 1),
 (2, 2), (4, 0), (2, 3), (3, 2), (0, 4), (4, 1)]

>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cell_sequence()
[(0, 0), (1, 0), (0, 1), (2, 0), (1, 1), (0, 2),
 (3, 0), (2, 1), (1, 2), (3, 1), (0, 3), (1, 3),
 (2, 2), (3, 2), (4, 0), (4, 1), (0, 4), (2, 3)]
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cell_sequence()
[(0, 0), (0, 1), (1, 0), (0, 2), (1, 1), (2, 0),
 (0, 3), (2, 1), (1, 2), (1, 3), (3, 0), (3, 1),
 (2, 2), (4, 0), (2, 3), (3, 2), (0, 4), (4, 1)]

good_cells (i=None)

Return a list of the cells of self that are good.
The good $i$-cell is the 'first' normal $i$-cell. As with the normal cells we can choose to read either up or down the partition as specified by convention().

**INPUT:**

- $i$ – (optional) a residue

**OUTPUT:**

If no residue $i$ is specified then a dictionary of good cells is returned, which gives the good cells for $0 \leq i < e$.

**EXAMPLES:**

```python
sage: KP3 = KleshchevPartitions(3, convention='regular')
sage: KP3([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP3([5,4,4,3,2]).good_cells(1)
(2, 3)
sage: KP4 = KleshchevPartitions(4, convention='restricted')
sage: KP4([5,4,4,3,2]).good_cells()
{1: (2, 3)}
sage: KP4([5,4,4,3,2]).good_cells(0)
’sage: KP4([5,4,4,3,2]).good_cells(1)
(2, 3)
```

```python
>>> from sage.all import *
```

```python
>>> KP3 = KleshchevPartitions(Integer(3), convention='regular')
>>> KP3([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells()  
{1: (2, 3)}
>>> KP3([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells(Integer(1))
(2, 3)
>>> KP4 = KleshchevPartitions(Integer(4), convention='restricted')
>>> KP4([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells()  
{1: (2, 3)}
>>> KP4([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells(Integer(0))
>>> KP4([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_cells(Integer(1))
```

**good_residue_sequence()**

Return a sequence of good nodes from the empty partition to self, or None if no such sequence exists.

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).good_residue_sequence()
[0, 2, 1, 1, 0, 2, 0, 2, 1, 1, 0, 2, 0, 2, 2, 0, 1, 1]
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).good_residue_sequence()
{0, 1, 2, 2, 0, 1, 0, 2, 1, 2, 0, 1, 0, 2, 1, 2, 1, 0]
```

```python
>>> from sage.all import *
```

```python
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).good_residue_sequence()
[0, 2, 1, 1, 0, 2, 0, 2, 1, 1, 0, 2, 0, 2, 2, 0, 1, 1]
```
is_regular()

Return True if self is a $\epsilon$-regular partition tuple.

A partition tuple is $\epsilon$-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction. Equivalently, all partitions are 0-regular and if $\epsilon > 0$ then a partition is $\epsilon$-regular if no $\epsilon$ non-zero parts of self are equal.

EXAMPLES:

```sage
sage: KP = KleshchevPartitions(2)
sage: KP([2,1,1]).is_regular()
False
sage: KP = KleshchevPartitions(3)
sage: KP([2,1,1]).is_regular()
True
sage: KP([]).is_regular()
True
```

is_restricted()

Return True if self is an $\epsilon$-restricted partition tuple.

A partition tuple is $\epsilon$-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction. Equivalently, all partitions are 0-restricted and if $\epsilon > 0$ then a partition is $\epsilon$-restricted if the difference of successive parts of self are always strictly less than $\epsilon$.

EXAMPLES:

```sage
sage: KP = KleshchevPartitions(2, convention='regular')
sage: KP([3,1]).is_restricted()
False
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([3,1]).is_restricted()
True
sage: KP([]).is_restricted()
True
```
mullineux_conjugate()

Return the partition tuple that is the Mullineux conjugate of self.

It follows from results in [BK2009], [Mat2015] that if \( \nu \) is the Mullineux conjugate of the Kleshchev partition tuple \( \mu \) then the simple module \( D^\nu = (D^\mu)^{sgn} \) is obtained from \( D^\mu \) by twisting by the \( sgn \)-automorphism with is the Iwahori-Hecke algebra analogue of tensoring with the one dimensional sign representation.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, convention='regular')
```
`KP([5,4,4,3,2]).mullineux_conjugate()`

```python
[9, 7, 1, 1]
```

```python
sage: KP = KleshchevPartitions(3, convention='restricted')
```
`KP([5,4,4,3,2]).mullineux_conjugate()`

```python
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
```

```python
sage: mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc
```

```python
[9, 7, 1, 1]
```

```python
mc.parent().multicharge()
```

```python
(1,)
```

```python
sage: KP = KleshchevPartitions(3, [2], convention='regular')
```
`KP([5,4,4,3,2]).mullineux_conjugate()`

```python
[9, 7, 1, 1]
```

```python
mc = KP([5,4,4,3,2]).mullineux_conjugate(); mc
```

```python
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
```

```python
mc.parent().multicharge()
```

```python
(1,)
```

```python
>>> from sage.all import *
```

```python
>>> KP = KleshchevPartitions(Integer(3), convention='regular')
```
`KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_conjugate()`

```python
[9, 7, 1, 1]
```

```python
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
```
`KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_conjugate()`

```python
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
```

```python
>>> mc = KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_conjugate(); mc
```

```python
[9, 7, 1, 1]
```

```python
mc.parent().multicharge()
```

```python
(1,)
```

```python
>>> KP = KleshchevPartitions(Integer(3), [Integer(2)], convention='restricted')
```
`KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_conjugate()`

```python
[3, 2, 2, 2, 2, 2, 2, 1, 1, 1]
```

```python
>>> mc = KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).mullineux_conjugate(); mc
```

```python
[9, 7, 1, 1]
```

```python
mc.parent().multicharge()
```

```python
(1,)
```

normal_cells (i=None)

Return a dictionary of the cells of the partition that are normal.
Following [Kle1995], the normal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of $e$-residue $i$ and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable $i$-cells that remain at the end of the this process are the normal $i$-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting convention = 'RS'.

INPUT:

- $i$ – (optional) a residue

OUTPUT:

If no residue $i$ is specified then a dictionary of normal cells is returned, which gives the normal cells for $0 \leq i < e$.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, convention='regular')
sage: KP([5,4,4,3,2]).normal_cells()
{1: [(2, 3), (0, 4)]}
sage: KP([5,4,4,3,2]).normal_cells(1)
{(2, 3), (0, 4)}
sage: KP = KleshchevPartitions(3, convention='restricted')
sage: KP([5,4,4,3,2]).normal_cells()
{0: [(4, 1)], 2: [(3, 2)]}
sage: KP([5,4,4,3,2]).normal_cells(2)
[(3, 2)]
```

```python
>>> from sage.all import *

>>> KP = KleshchevPartitions(Integer(3), convention='regular')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_cells()
{1: [(2, 3), (0, 4)]}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_cells(1)
[(2, 3), (0, 4)]
>>> KP = KleshchevPartitions(Integer(3), convention='restricted')
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_cells()
{0: [(4, 1)], 2: [(3, 2)]}
>>> KP([Integer(5),Integer(4),Integer(4),Integer(3),Integer(2)]).normal_cells(2)
[(3, 2)]
```

class `sage.combinat.partition_kleshchev.KleshchevPartitionCrystal` (parent, mu)

Kleshchev partition with the crystal structure.

$e(i)$

Return the action of $e_i$ on self.

INPUT:

- $i$ – an element of the index set

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.e(0)
sage: x.e(1)
[5, 4]
```

```python
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), convention="left regular")
>>> x = C([Integer(5),Integer(4),Integer(1)])
>>> x.e(Integer(0))
>>> x.e(Integer(1))
[5, 4]
```

\( f(i) \)

Return the action of \( f_i \) on \( \text{self} \).

**INPUT:**

- \( i \) – an element of the index set

**EXAMPLES:**

```python
sage: C = crystals.KleshchevPartitions(3, convention="left regular")
sage: x = C([5,4,1])
sage: x.f(0)
[5, 5, 1]
sage: x.f(1)
sage: x.f(2)
[5, 4, 2]
```

```python
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), convention="left regular")
>>> x = C([Integer(5),Integer(4),Integer(1)])
>>> x.f(Integer(0))
>>> x.f(Integer(1))
>>> x.f(Integer(2))
[5, 4, 2]
```

class \texttt{sage.combinat.partition_kleshchev.KleshchevPartitionTuple}(\texttt{parent}, \texttt{mu})

Bases: PartitionTuple

Abstract base class for Kleshchev partition tuples. See \texttt{KleshchevPartitions}.

\texttt{cogood_cells}(i=None)

Return a list of the cells of the partition that are cogood.

The cogood \( i \)-cell is the 'last' conormal \( i \)-cell. As with the conormal cells we can choose to read either up or down the partition as specified by \texttt{convention()}.

**INPUT:**

- \( i \) – (optional) a residue

**OUTPUT:**

If no residue \( i \) is specified then a dictionary of cogood cells is returned, which gives the cogood cells for \( 0 \leq i < e \).

**EXAMPLES:**
conormal_cells \(i=None\)

Return a dictionary of the cells of the partition that are conormal.

Following [Kle1995], the conormal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \(e\)-residue \(i\) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The addable \(i\)-cells that remain at the end of the this process are the conormal \(i\)-cells.

When computing conormal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting convention = 'RS'.

INPUT:

- \(i\) – (optional) a residue

OUTPUT:

If no residue \(i\) is specified then a dictionary of conormal cells is returned, which gives the conormal cells for \(0 \leq i < e\).

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.conormal_cells()
{0: (1, 2, 1), 1: (1, 3, 0)}
sage: pt.conormal_cells(0)
(1, 2, 1)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 1, 1]])
sage: pt.conormal_cells()
{1: (0, 0, 5), 2: (1, 3, 0)}
sage: pt.conormal_cells(0) is None
True
sage: pt.conormal_cells(1) is None
False
```

```python
>>> from sage.all import *

>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> pt = KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)])
>>> pt.conormal_cells()
{0: (1, 2, 1), 1: (1, 3, 0)}
>>> pt.conormal_cells(Integer(0))
(1, 2, 1)
>>> KP = KleshchevPartitions(Integer(4), [Integer(0),Integer(1)], convention="left regular")
>>> pt = KP([[Integer(5), Integer(2), Integer(2)], [Integer(6), Integer(1), ... Integer(1)])
>>> pt.conormal_cells()
{1: (0, 0, 5), 2: (1, 3, 0)}
>>> pt.conormal_cells(Integer(0)) is None
True
>>> pt.conormal_cells(Integer(1)) is None
False
```
{0: [(1, 2, 1), (1, 1, 3), (1, 0, 5)],
1: [(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]}
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(1)
[(1, 3, 0), (0, 2, 0), (0, 1, 2), (0, 0, 4)]
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(2)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="right restricted")
sage: KP([[4, 2], [5, 3, 1]]).conormal_cells(0)
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]

>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention="left regular")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).conormal_cells(Integer(0))
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]

**good_cell_sequence()**

Return a sequence of good nodes from the empty partition to self.

EXAMPLES:

```
sage: KP = KleshchevPartitions(3, [0,1])
sage: KP([[4, 2], [5, 3, 1]]).good_cell_sequence()
[(0, 0, 0), (1, 0, 0), (1, 0, 1), (0, 0, 1), (0, 0, 0), (1, 0, 0), (1, 0, 1), (1, 0, 2), (1, 0, 0), (0, 0, 0), (1, 1, 3), (1, 0, 3), (1, 1, 2), (1, 0, 4)]
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)], convention="right restricted")
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).good_cell_sequence()
[(1, 0, 5), (1, 1, 3), (1, 2, 1)]
```

**good_cells(i=None)**

Return a list of the cells of the partition tuple which are good.

The good $i$-cell is the ‘first’ normal $i$-cell. As with the normal cells we can choose to read either up or down the partition as specified by `convention()`.

**INPUT:**

- $i$ – (optional) a residue
OUTPUT:
If no residue \( i \) is specified then a dictionary of good cells is returned, which gives the good cells for \( 0 \leq i < e \).

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: pt = KP([[4, 2], [5, 3, 1]])
sage: pt.good_cells()
{2: (1, 0, 4)}
sage: pt.good_cells(2)
(1, 0, 4)
sage: KP = KleshchevPartitions(4, [0,1], convention="left regular")
sage: pt = KP([[5, 2, 2], [6, 2, 1]])
sage: pt.good_cells()
{0: (0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1)}
sage: pt.good_cells(1)  # is None
True
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> pt = KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]])
>>> pt.good_cells()
(1, 0, 4)
>>> KP = KleshchevPartitions(Integer(4), [Integer(0),Integer(1)], convention="left regular")
>>> pt = KP([[Integer(5), Integer(2), Integer(2)], [Integer(6), Integer(2), Integer(1)]])
>>> pt.good_cells()
(0, 0, 4), 2: (1, 0, 5), 3: (0, 2, 1))
>>> pt.good_cells(Integer(1))  # is None
True
```

**good_residue_sequence()**

Return a sequence of good nodes from the empty partition to self.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: KP([[4, 2], [5, 3, 1]]).good_residue_sequence()
[0, 1, 2, 1, 2, 0, 1, 0, 2, 2, 0, 1, 0, 2, 2]
```

```python
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])
>>> KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).good_residue_sequence()
[0, 1, 2, 1, 2, 0, 1, 0, 2, 2, 0, 1, 0, 2, 2]
```

**is_regular()**

Return True if self is a \( e \)-regular partition tuple.

A partition tuple is \( e \)-regular if we can get to the empty partition tuple by successively removing a sequence of good cells in the down direction.

EXAMPLES:
is_restricted()

Return True if self is an \(\epsilon\)-restricted partition tuple.

A partition tuple is \(\epsilon\)-restricted if we can get to the empty partition tuple by successively removing a sequence of good cells in the up direction.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(2, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()  # False

sage: KP = KleshchevPartitions(4, [0,2], convention="right restricted")
sage: KP([[3,2,1], [2,1,1]]).is_regular()  # True

sage: KP([[], []]).is_regular()  # True

>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(2), [Integer(0),Integer(2)], convention="left regular")
>>> KP([[Integer(3),Integer(2),Integer(1), [Integer(2),Integer(1), Integer(1)]].is_regular()  # False

>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(2)], convention="left regular")
>>> KP([[Integer(3),Integer(2),Integer(1), [Integer(2),Integer(1), Integer(1)]].is_regular()  # True

>>> KP([[], []]).is_regular()  # True
```

mullineux_conjugate()

Return the partition that is the Mullineux conjugate of self.

It follows from results in [Kle1996] [Bru1998] that if \(\nu\) is the Mullineux conjugate of the Kleshchev partition

```python
```
tuple \( \mu \) then the simple module \( D^\nu = (D^\mu)^{\text{sgn}} \) is obtained from \( D^\mu \) by twisting by the sgn-automorphism with is the Hecke algebra analogue of tensoring with the one dimensional sign representation.

EXAMPLES:

```python
sage: KP = KleshchevPartitions(3, [0,1])
sage: mc = KP([[4, 2], [5, 3, 1]]).mullineux_conjugate(); mc
([2, 2, 1, 1], [3, 2, 2, 1, 1])
sage: mc.parent()
Kleshchev partitions with e=3 and multicharge=(0,2)
```

```python
>>> from sage.all import *

>>> KP = KleshchevPartitions(Integer(3), [Integer(0),Integer(1)])

>>> mc = KP([[Integer(4), Integer(2)], [Integer(5), Integer(3), Integer(1)]]).mullineux_conjugate(); mc
([2, 2, 1, 1], [3, 2, 2, 1, 1])

>>> mc.parent()
Kleshchev partitions with e=3 and multicharge=(0,2)
```

**normal_cells** \((i=\text{None})\)

Return a dictionary of the removable cells of the partition that are normal.

Following [Kle1995], the normal cells are computed by reading up (or down) the rows of the partition and marking all of the addable and removable cells of \(e\)-residue \(i\) and then recursively removing all adjacent pairs of removable and addable cells (in that order) from this list. The removable \(i\)-cells that remain at the end of the this process are the normal \(i\)-cells.

When computing normal cells you can either read the cells in order from top to bottom (this corresponds to labeling the simple modules of the symmetric group by regular partitions) or from bottom to top (corresponding to labeling the simples by restricted partitions). By default we read down the partition but this can be changed by setting `convention = 'RS'`.

**INPUT:**

- \(i\) – (optional) a residue

**OUTPUT:**

If no residue \(i\) is specified then a dictionary of normal cells is returned, which gives the normal cells for \(0 \leq i < e\).

**EXAMPLES:**

```python
sage: KP = KleshchevPartitions(3, [0,1], convention="left restricted")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{2: [(1, 0, 4), (1, 1, 2), (1, 2, 0)]}
sage: KP([[4, 2], [5, 3, 1]]).normal_cells(1)
[]
sage: KP = KleshchevPartitions(3, [0,1], convention="left regular")
sage: KP([[4, 2], [5, 3, 1]]).normal_cells()
{0: [(0, 1, 1), (0, 0, 3)], 2: [(1, 2, 0), (1, 1, 2), (1, 0, 4)]}
```
class sage.combinat.partition_kleshchev.KleshchevPartitionTupleCrystal(parent, mu)

Kleshchev partition tuple with the crystal structure.

.. math::

   e(i)

Return the action of \(e_i\) on \(self\).

INPUT:

- \(i\) – an element of the index set

EXAMPLES:

.. code-block:: python

   sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
   sage: x = C([[5,4,1],[3,2,1,1]])
   sage: x.e(0)
   [[[5, 4, 1], [2, 2, 1, 1]]

\(f(i)\)

Return the action of \(f_i\) on \(self\).

INPUT:
• $i$ – an element of the index set

**EXAMPLES:**

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="left regular")
sage: x = C([[5,4,1],[3,2,1,1]])
sage: x.f(0)
([5, 5, 1], [3, 2, 1, 1])
sage: x.f(1)
([5, 4, 1], [3, 2, 2, 1])
sage: x.f(2)
```

```python
>>> from sage.all import *

>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0),Integer(2)],
   convention=left regular)

>>> x = C([[Integer(5),Integer(4),Integer(1)],[Integer(3),Integer(2),
   Integer(1)]]

>>> x.f(Integer(0))
([5, 5, 1], [3, 2, 1, 1])

>>> x.f(Integer(1))
([5, 4, 1], [3, 2, 2, 1])

>>> x.f(Integer(2))
```

**class** `sage.combinat.partition_kleshchev.KleshchevPartitions`  
**Bases:** `PartitionTuples`

Kleshchev partitions

A partition (tuple) $\mu$ is Kleshchev if it can be recursively obtained by adding a sequence of good nodes to the empty `PartitionTuple` of the same `level()` and multicharge.

There are four different conventions that are used in the literature for Kleshchev partitions, depending on whether we read partitions from top to bottom (regular) or bottom to top (restricted) and whether we read partition tuples from left to right or right to left. All of these conventions are supported:

```python
sage: KleshchevPartitions(2, [0,0], size=2, convention='left regular')[1]
[[[1], [1]], [[2], [1]]]

sage: KleshchevPartitions(2, [0,0], size=2, convention='left restricted')[1]
[[[1], [1]], [[], [1, 1]]]

sage: KleshchevPartitions(2, [0,0], size=2, convention='right regular')[1]
[[[1], [1]], [[], [2]]]

sage: KleshchevPartitions(2, [0,0], size=2, convention='right restricted')[1]
[[[1], [1]], [[1, 1], []]]
```

```python
>>> from sage.all import *

>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),
   convention='left regular')[1]
[[[1], [1]], [[2], [1]]]

>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),
   convention='left restricted')[1]
[[[1], [1]], [[], [1, 1]]]

>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),
   convention='right regular')[1]
[[[1], [1]], [[], [2]]]

>>> KleshchevPartitions(Integer(2), [Integer(0),Integer(0)], size=Integer(2),
   convention='right restricted')[1]
[[[1], [1]], [[1, 1], []]]
```
By default, the left restricted convention is used. As a shorthand, LG, LS, RG and RS, respectively, can be used to specify the convention. With the left convention the partition tuples should be ordered with the most dominant partitions in the partition tuple on the left and with the right convention the most dominant partition is on the right.

The KleshchevPartitions class will automatically convert between these four different conventions:

```
sage: KPlg = KleshchevPartitions(2, [0,0], size=2, convention='left regular')
sage: KPls = KleshchevPartitions(2, [0,0], size=2, convention='left restricted')
sage: [KPlg(mu) for mu in KPls]
[[([1], [1]), ([2], [])]]

>>> from sage.all import *

>>> KPlg = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)],
size=Integer(2), convention='left regular')

>>> KPls = KleshchevPartitions(Integer(2), [Integer(0),Integer(0)],
size=Integer(2), convention='left restricted')

>>> [KPlg(mu) for mu in KPls]
[[([1], [1]), ([2], [])]]
```

EXAMPLES:

```
sage: sorted(KleshchevPartitions(5,[3,2,1],1, convention='RS'))

[([], [], [1]), ([], [1], []), ([1], [], [])]

sage: sorted(KleshchevPartitions(5, [3,2,1], 1, convention='LS'))

[([], [], [1]), ([], [1], []), ([1], [], [])]

sage: sorted(KleshchevPartitions(5, [3,2,1], 3))

[([], [], [1, 1, 1]), ([], [1], [1, 1]), ([1], [1], [1]), ([1], [1, 1], []), ([1], [2], []), ([2], [1], []), ([3], [], [])]

sage: sorted(KleshchevPartitions(5, [3,2,1], 3, convention="left regular"))

[([], [], [1, 1, 1]), ([], [1], [1, 1]), ([1], [1], [1]), ([1], [1, 1], []), ([1], [2], []), ([2], [1], []), ([3], [], [])]
```

(continues on next page)
>>> from sage.all import *

>>> sorted(KleshchevPartitions(Integer(5), [Integer(3), Integer(2), Integer(1)],
                                         →Integer(1), convention='RS'))
[([], [], [1]), ([], [1], []), ([1], [], [])]

>>> sorted(KleshchevPartitions(Integer(5), [Integer(3), Integer(2), Integer(1)],
                                         →Integer(1), convention='LS'))
[([], [], [1]), ([], [1], []), ([1], [], [])]

>>> sorted(KleshchevPartitions(Integer(5), [Integer(3), Integer(2), Integer(1)],
                                         →Integer(3)))
[([], [], [1, 1, 1]), ([], [1], [1, 1]), ([], [1], [2]), ([], [1, 1], []),
 ([2], [], [1]), ([2], [1], []), ([3], [], [])]

>>> sorted(KleshchevPartitions(Integer(5), [Integer(3), Integer(2), Integer(1)],
                                         →Integer(3), convention="left regular")]
[([], [], [1, 1, 1]), ([], [1], [1, 1]), ([], [1], [2]),
 ([], [1, 1], []), ([1], [], [1, 1]), ([1], [], [2]), ([1], [], [3]),

convention()
Return the convention of self.
EXAMPLES:

```
sage: KP = KleshchevPartitions(4)
sage: KP.convention()
'restricted'
sage: KP = KleshchevPartitions(6, [4], 3, convention="right regular")
sage: KP.convention()
'regular'
sage: KP = KleshchevPartitions(5, [3,0,1], 1)
sage: KP.convention()
'left restricted'
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='right regular')
sage: KP.convention()
'right regular'
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(4))
>>> KP.convention()
'restricted'
>>> KP = KleshchevPartitions(Integer(6), [Integer(4)], Integer(3), convention="right regular")
>>> KP.convention()
'regular'
>>> KP = KleshchevPartitions(Integer(5), [Integer(3),Integer(0),Integer(1)],
"right regular")
>>> KP.convention()
'left restricted'
>>> KP = KleshchevPartitions(Integer(5), [Integer(3),Integer(0),Integer(1)],
"right regular")
>>> KP.convention()
'right regular'
```

```
multicharge()

Return the multicharge of self.

EXAMPLES:

```
sage: KP = KleshchevPartitions(6, [2])
sage: KP.multicharge()
(2,)
sage: KP = KleshchevPartitions(5, [3,0,1], 1, convention='LS')
sage: KP.multicharge()
(3, 0, 1)
```

```
>>> from sage.all import *
>>> KP = KleshchevPartitions(Integer(6), [Integer(2)])
>>> KP.multicharge()
(2,)
>>> KP = KleshchevPartitions(Integer(5), [Integer(3),Integer(0),Integer(1)],
"LS")
>>> KP.multicharge()
(3, 0, 1)
```

class sage.combinat.partition_kleshchev.KleshchevPartitions_all(e, multicharge, convention)

Bases: KleshchevPartitions

Class of all Kleshchev partitions.
**Crystal structure**

We consider type $A_{e-1}^{(1)}$ crystals, and let $r = (r_i | r_i \in \mathbb{Z}/e\mathbb{Z})$ be a finite sequence of length $k$, which is the *level*, and $\lambda = \sum_i r_i$. We will model the highest weight $U_q(\mathfrak{g})$-crystal $B(\lambda)$ by a particular subset of partition tuples of level $k$.

Consider a partition tuple $\mu$ with multicharge $r$. We define $e_i(\mu)$ as the partition tuple obtained after the deletion of the $i$-good cell to $\mu$ and 0 if there is no $i$-good cell. We define $f_i(\mu)$ as the partition tuple obtained by the addition of the $i$-cogood cell to $\mu$ and 0 if there is no $i$-good cell.

The crystal $B(\lambda)$ is the crystal generated by the empty partition tuple. We can compute the weight of an element $\mu$ by taking $\lambda - \sum_{i=0}^{n} c_i \alpha_i$ where $c_i$ is the number of cells of $n$-residue $i$ in $\mu$. Partition tuples in the crystal are known as *Kleshchev partitions*.

**Note:** We can describe normal (not restricted) Kleshchev partition tuples in $B(\lambda)$ as partition tuples $\mu$ such that $\mu_{r_i-r_i+1+x}^{(t)} < \mu_x^{(t+1)}$ for all $x \geq 1$ and $1 \leq t \leq k - 1$.

**INPUT:**
- $e$ – for type $A_{e-1}^{(1)}$ or 0
- multicharge – the multicharge sequence $r$
- convention – (default: 'LS') the reading convention

**EXAMPLES:**

We first do an example of a level 1 crystal:

```
sage: C = crystals.KleshchevPartitions(3, [0], convention="left restricted")
sage: C
Kleshchev partitions with e=3
sage: mg = C.highest_weight_vector()
sage: mg
[]
sage: mg.f(0)
[1]
sage: mg.f(1)
sage: mg.f(2)
sage: mg.f_string([0,2,1,0])
[1, 1, 1, 1]
sage: mg.f_string([0,1,2,0])
[2, 2]
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: B = crystals.LSPaths([A,2,1], [1,0,0])
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
True
```

```python
>>> from sage.all import *
>>> C = crystals.KleshchevPartitions(Integer(3), [Integer(0)], convention="left restricted")
>>> C
Kleshchev partitions with e=3
>>> mg = C.highest_weight_vector()
>>> mg
[]
```

(continues on next page)
Now a higher level crystal:

```python
sage: C = crystals.KleshchevPartitions(3, [0,2], convention="right restricted")
sage: mg = C.highest_weight_vector()
sage: mg
([], [])
sage: mg.f(0)
([1], [])
sage: mg.f(2)
([], [1])
sage: mg.f_string([0,1,2,0])
([2, 2], [])
sage: mg.f_string([0,2,1,0])
([1, 1, 1, 1], [])
sage: mg.f_string([2,0,1,0])
([], [2])
sage: GC = C.subcrystal(max_depth=5).digraph()
sage: B = crystals.LSPaths(['A',Integer(2),Integer(1)], [Integer(1),Integer(0), Integer(0)])
sage: GB = B.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GB, edge_labels=True)
```

True

```python
>>> from sage.all import *
```
The ordering of the residues gives a different representation of the higher level crystals (but it is still isomorphic):

```python
sage: C2 = crystals.KleshchevPartitions(3, [2,0], convention="right restricted")
sage: mg2 = C2.highest_weight_vector()
sage: mg2.f_string([0,1,2,0])
([2], [2])
sage: mg2.f_string([0,2,1,0])
([1, 1, 1], [1])
sage: mg2.f_string([2,0,1,0])
([2, 1], [1])
sage: GC2 = C2.subcrystal(max_depth=5).digraph()
sage: GC.is_isomorphic(GC2, edge_labels=True)
True
```

**class** `sage.combinat.partition_kleshchev.KleshchevPartitions_size(e, multicharge=(0,), size=0, convention='RS')`

**Bases:** `KleshchevPartitions`

Kleshchev partitions of a fixed size.

**Element**

alias of `KleshchevPartitionTuple`
5.1.168 Partition Shifting Algebras

This module contains families of operators that act on partitions or, more generally, integer sequences. In particular, this includes Young’s raising operators $R_{ij}$, which act on integer sequences by adding 1 to the $i$-th entry and subtracting 1 to the $j$-th entry. A special case is acting on partitions.

AUTHORS:

• Matthew Lancellotti, George H. Seelinger (2018): Initial version

```python
class sage.combinat.partition_shifting_algebras.ShiftingOperatorAlgebra(base_ring=Univariate Polynomial Ring in t over Rational Field, prefix='S')
```

**Bases:** CombinatorialFreeModule

An algebra of shifting operators.

Let $R$ be a commutative ring. The algebra of shifting operators is isomorphic as an $R$-algebra to the Laurent polynomial ring $R[x_1^\pm, x_2^\pm, x_3^\pm, \ldots]$. Moreover, the monomials of the shifting operator algebra act on any integer sequence $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ as follows. Let $S$ be our algebra of shifting operators. Then, for any monomial $s = x_1^{a_1}x_2^{a_2} \cdots x_r^{a_r} \in S$ where $a_i \in \mathbb{Z}$ and $r \geq \ell$, we get that $s.\lambda = (\lambda_1 + a_1, \lambda_2 + a_2, \ldots, \lambda_r + a_r)$ where we pad $\lambda$ with $r-\ell$ zeros. In particular, we can recover Young’s raising operator, $R_{ij}$, for $i < j$, acting on partitions by having $x_i^1$ act on a partition $\lambda$.

One can extend the action of these shifting operators to a basis of symmetric functions, but at the expense of no longer actually having a well-defined operator. Formally, to extend the action of the shifting operators on a symmetric function basis $B = \{b_\lambda\}_\lambda$, we define an $R$-module homomorphism $\phi : R[x_1^\pm, x_2^\pm, \ldots] \to B$. Then we compute $x_1^{a_1} \cdots x_r^{a_r}.b_\lambda$ by first computing $(x_1^{a_1} \cdots x_r^{a_r})x_1^{\lambda_1} \cdots x_\ell^{\lambda_\ell}$ and then applying $\phi$ to the result. For examples of what this looks like with specific bases, see below.

This implementation is consistent with how many references work formally with raising operators. For instance, see exposition surrounding [BMPS2018] Equation (4.1).

We follow the following convention for creating elements: $S(1, 0, -1, 2)$ is the shifting operator that raises the first part by 1, lowers the third part by 1, and raises the fourth part by 2.

In addition to acting on partitions (or any integer sequence), the shifting operators can also act on symmetric functions in a basis $B$ when a conversion to $B$ has been registered, preferably using `build_and_register_conversion()`.

For a definition of raising operators, see [BMPS2018] Definition 2.1. See `ij()` to create operators using the notation in [BMPS2018].

**INPUT:**

- `base_ring` – (default: `QQ['t']`) the base ring
- `prefix` – (default: "S") the label for the shifting operators

**EXAMPLES:**

```python
sage: S = ShiftingOperatorAlgebra()
sage: elm = S[1, -1, 2]; elm
```

(continues on next page)
The shifting operator monomials can act on a complete homogeneous symmetric function or a Schur function:

```python
from sage.all import *

S = ShiftingOperatorAlgebra()

elm = S[Integer(1), -Integer(1), Integer(2)]; elm
S(1, -1, 2)

elm([Integer(5), Integer(4)])
[[[6, 3, 2], 1]]
```

In fact, we can extend this action by linearity:

```python
elm = (1 - S[1,-1]) * (1 - S[4])
sage: elm == S([]) - S([1, -1]) - S([4]) + S([5, -1])
```

```python
elm(s[Integer(5), Integer(4)])
s[6, 3, 2]
```

```python
elm(h[Integer(5), Integer(4)])
h[6, 3, 2]
```

```python
S[Integer(1), -Integer(1)](s[Integer(5), Integer(4)])
s[6, 3]
```

```python
S[Integer(1), -Integer(1)](h[Integer(5), Integer(4)])
h[6, 3]
```
The algebra also comes equipped with homomorphisms to various symmetric function bases; these homomorphisms are how the action of $S$ on the specific symmetric function bases is implemented:

```
sage: elm = S([3,1,2]); elm
S(3, 1, 2)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
0
```

However, not all homomorphisms are equivalent, so the action is basis dependent:

```
sage: elm = S([3,2,1]); elm
S(3, 2, 1)
sage: h(elm)
h[3, 2, 1]
sage: s(elm)
s[3, 2, 1]
sage: s(elm) == s(h(elm))
False
```

We can also use raising operators to implement the Jacobi-Trudi identity:
Combinatorics, Release 10.4

```python
sage: op = (1-S[(1,-1)]) * (1-S[(1,0,-1)]) * (1-S[(0,1,-1)])
sage: s(op(h[3,2,1]))
s[3, 2, 1]
```

```python
>>> from sage.all import *

>>> op = (Integer(1)-S[(Integer(1),-Integer(1))]) * (Integer(1)-S[(Integer(1),-Integer(0),-Integer(1))]) * (Integer(1)-S[(Integer(0),Integer(1),-Integer(1))])

```sage``` op(h[Integer(3),Integer(2),Integer(1)])```s[3, 2, 1]

```python
class Element
Bases: IndexedFreeModuleElement

An element of a ShiftingOperatorAlgebra.

build_and_register_conversion(support_map, codomain)

Build a module homomorphism from a map sending integer sequences to codomain and registers the result into Sage’s conversion model.

The intended use is to define a morphism from self to a basis B of symmetric functions that will be used by ShiftingOperatorAlgebra to define the action of the operators on B.

Note: The actions on the complete homogeneous symmetric functions and on the Schur functions by morphisms are already registered.

Warning: Because ShiftingOperatorAlgebra inherits from UniqueRepresentation, once you register a conversion, this will apply to all instances of ShiftingOperatorAlgebra over the same base ring with the same prefix.

INPUT:

- `support_map` – a map from integer sequences to codomain
- `codomain` – the codomain of `support_map`, usually a basis of symmetric functions

EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: p = sym.p()
sage: zero_map = lambda part: p.zero()
sage: S.build_and_register_conversion(zero_map, p)
sage: p(2*S([1,0,-1]) + S([2,1,0]) - 3*S([0,1,3]))
0
sage: op = S((1, -1))
```

```python
True
```

```python
```
For a more illustrative example, we can implement a simple (but not mathematically justified!) conversion on the monomial basis:

```
sage: S = ShiftingOperatorAlgebra(QQ)
sage: sym = SymmetricFunctions(QQ)
sage: m = sym.m()
sage: def supp_map(gamma):
    ... gsort = sorted(gamma, reverse=True)
    ... return m(gsort) if gsort in Partitions() else m.zero()
sage: S.build_and_register_conversion(supp_map, m)
sage: op = S.ij(0, 1)
sage: op(2*m[4, 3] + 5*m[2, 2] + 7*m[2]) == 2*m[5, 2] + 5*m[3, 1]
True
```

```
ij (i, j)
Return the raising operator $R_{ij}$ as notated in [BMPS2018] Definition 2.1.
```

Shorthand element constructor that allows you to create raising operators using the familiar $R_{ij}$ notation found in [BMPS2018] Definition 2.1, with the exception that indices here are 0-based, not 1-based.

EXAMPLES:
Create the raising operator which raises part 0 and lowers part 2 (indices are 0-based):

```
sage: R = ShiftingOperatorAlgebra()
sage: R.ij(0, 2)
S(1, 0, -1)

>>> from sage.all import *
>>> R = ShiftingOperatorAlgebra()
>>> R.ij(Integer(0), Integer(2))
S(1, 0, -1)
```

```
one_basis ()
Return the index of the basis element for 1.
```
EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra()
sage: S.one_basis()
()
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra()
>>> S.one_basis()
()
```

**product_on_basis** (*x*, *y*)

Return the product of basis elements indexed by *x* and *y*.

EXAMPLES:

```python
sage: S = ShiftingOperatorAlgebra()
sage: S.product_on_basis((0, 5, 2), (3, -2, 5))
S(3, 7, 0, 5)
sage: S.product_on_basis((1, -2, 0, 3, -6), (-1, 2, 2))
S(0, 0, 2, 3, -6)
sage: S.product_on_basis((1, -2, -2), (-1, 2, 2))
S()
```

```python
>>> from sage.all import *
>>> S = ShiftingOperatorAlgebra()
>>> S.product_on_basis((Integer(0), Integer(5), Integer(2)), (Integer(3),-Integer(2), Integer(5)))
S(3, 7, 0, 5)
>>> S.product_on_basis((Integer(1), -Integer(2), Integer(0), Integer(3),-Integer(6)), (-Integer(1), Integer(2), Integer(2)))
S(0, 0, 2, 3, -6)
>>> S.product_on_basis((Integer(1), -Integer(2), -Integer(2)), (-Integer(1),-Integer(2), Integer(2)))
S()
```

```python
class sage.combinat.partition_shifting_algebras.ShiftingSequenceSpace

Bases: Singleton, Parent

A helper for ShiftingOperatorAlgebra that contains all tuples with entries in \( \mathbb{Z} \) of finite support with no trailing 0's.

EXAMPLES:

```python
sage: from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
sage: (1, -1) in S
True
sage: (1, -1, 0, 9) in S
True
sage: [1, -1] in S
False
sage: (0.5, 1) in S
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.partition_shifting_algebras import ShiftingSequenceSpace
```
Combinatorics, Release 10.4

>>> S = ShiftingSequenceSpace()
>>> (Integer(1), -Integer(1)) in S
True
>>> (Integer(1), -Integer(1), Integer(0), Integer(9)) in S
True
>>> [Integer(1), -Integer(1)] in S
False
>>> (RealNumber('0.5'), Integer(1)) in S
False

cHECK (seq)

Verify that seq is a valid shifting sequence.

If it is not, raise a ValueError.

EXAMPLES:

```
sage: from sage.combinat.partition_shifting_algebras import *
    → ShiftingSequenceSpace
sage: S = ShiftingSequenceSpace()
    → ShiftingSequenceSpace
sage: S.check((1, -1))
    → S.check((1, -1, 0, 9))
    → S.check([1, -1])
Traceback (most recent call last):
... ValueError: invalid index [1, -1]
sage: S.check((0.5, 1))
Traceback (most recent call last):
... ValueError: invalid index (0.500000000000000, 1)
```

```
>>> from sage.all import *
    → from sage.combinat.partition_shifting_algebras import *
    → ShiftingSequenceSpace
>>> S = ShiftingSequenceSpace()
    → S.check((Integer(1), -Integer(1)))
    → S.check((Integer(1), -Integer(1), Integer(0), Integer(9)))
    → S.check([Integer(1), -Integer(1)])
Traceback (most recent call last):
... ValueError: invalid index [1, -1]
>>> S.check((RealNumber('0.5'), Integer(1)))
Traceback (most recent call last):
... ValueError: invalid index (0.500000000000000, 1)
```
5.1.169 Partition tuples

A PartitionTuple is a tuple of partitions. That is, an ordered \(k\)-tuple of partitions \(\mu = (\mu^{(1)}, \mu^{(2)}, \ldots, \mu^{(k)})\). If

\[
 n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|
\]

then we say that \(\mu\) is a \(k\)-partition of \(n\).

In representation theory partition tuples arise as the natural indexing set for the ordinary irreducible representations of:

- the wreath products of cyclic groups with symmetric groups,
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type \(G(r, 1, n)\),
- the degenerate cyclotomic Hecke algebras of type \(G(r, 1, n)\).

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras, which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to partition tuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

A PartitionTuple belongs to PartitionTuples and its derived classes. PartitionTuples is the parent class for all partitions tuples. Four different classes of tuples of partitions are currently supported:

- PartitionTuples(level=k,size=n) are \(k\)-tuple of partitions of \(n\).
- PartitionTuples(level=k) are \(k\)-tuple of partitions.
- PartitionTuples(size=n) are tuples of partitions of \(n\).
- PartitionTuples() are tuples of partitions.

Note: As with Partitions, in sage the cells, or nodes, of partition tuples are 0-based. For example, the (lexicographically) first cell in any non-empty partition tuple is \([0, 0, 0]\).

EXAMPLES:

```sage
sage: PartitionTuple([[2,2],[1,1],[2]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0, 1)]

>>> from sage.all import *

>>> PartitionTuple([[Integer(2),Integer(2)],[Integer(1),Integer(1)],[Integer(2)]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (1, 0, 0), (1, 1, 0), (2, 0, 0), (2, 0, 1)]
```
Many \texttt{PartitionTuple} methods take the individual coordinates \((k, r, c)\) as their arguments, here \(k\) is the component, \(r\) is the row index and \(c\) is the column index. If your coordinates are in the form \((k, r, c)\) then use Python’s *-operator.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]

>>> from sage.all import *
>>> mu=PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),Integer(1)]]

>>> [ mu.arm_length(*c) for c in mu.cells()]
[0, 0, 1, 0, 1, 0, 0]
\end{verbatim}

\textbf{Warning:} In Sage, if \texttt{mu} is a partition tuple then \texttt{mu[k]} most naturally refers to the \(k\)-th component of \texttt{mu}, so we use the convention of the \((k, r, c)\)-th cell in a partition tuple refers to the cell in component \(k\), row \(r\), and column \(c\).

In the literature, the cells of a partition tuple are usually written in the form \((r, c, k)\), where \(r\) is the row index, \(c\) is the column index, and \(k\) is the component index.

\textbf{REFERENCES:}

- [DJM1998]
- [BK2009]

\textbf{AUTHORS:}

\textbf{EXAMPLES:}

First is a finite enumerated set and the remaining classes are infinite enumerated sets:

\begin{verbatim}
sage: PartitionTuples().an_element()
([1, 1, 1, 1], [2, 1, 1], [3, 1], [4])
sage: PartitionTuples(4).an_element()
([], [1], [2], [3])
sage: PartitionTuples(size=5).an_element()
([[1], [1], [1], [1], [1]])
sage: PartitionTuples(4,5).an_element()
([1], [], [], [4])
sage: PartitionTuples(3,2)

#needs sage.libs.flint

[[2], [], []],
([1], [], []),
([1], [], []),
([1], [1], []),
([1], [], []),
([1], [2], []),
([1], [1, 1], []),
([1], [1], []),
([1], [1], []),
([1], [1, 1], []),
([1], [1], [])]
sage: PartitionTuples(2,3).list()
#needs sage.libs.flint

(continues on next page)
One tuples of partitions are naturally in bijection with partitions and, as far as possible, partition tuples attempts to identify one tuples with partitions:

```python
sage: Partition([4,3]) == PartitionTuple([[4,3]])
True
sage: Partition([4,3]) == PartitionTuple([4,3])
True
sage: PartitionTuple([4,3])
[4, 3]
sage: Partition([4,3]) in PartitionTuples()
True
```
Partition tuples come equipped with many of the corresponding methods for partitions. For example, it is possible to add and remove cells, to conjugate partition tuples, to work with their diagrams, compare partition tuples in dominance and so:

```python
sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).pp()
   **** - ** ***
     * **
     *

sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).conjugate()
([1, 1, 1], [3, 2], [], [2, 1, 1, 1])

sage: PartitionTuple([[4,1],[],[2,2,1],[3]]).conjugate().pp()
   * *** - ** *
    * ** *
    * *

sage: lam = PartitionTuples(3)([[3,2],[],[1,1,1,1]]); lam
([3, 2], [], [1, 1, 1, 1])

sage: lam.level()

 (continues on next page)
Every partition tuple behaves every much like a tuple of partitions:

```python
sage: mu = PartitionTuple([[4,1],[],[2,2,1],[3]])
sage: [ nu for nu in mu ]
[[4, 1], [], [2, 2, 1], [3]]
sage: Set([ type(nu) for nu in mu ])
{<class 'sage.combinat.partition.Partitions_all_with_category.element_class'>}
sage: mu[2][2]
1
sage: mu[3]
[3]
sage: mu.components()
[[4, 1], [], [2, 2, 1], [3]]
sage: mu.components() == [ nu for nu in mu ]
True
sage: mu[0]
[4, 1]
sage: mu[1]
[]
sage: mu[2]
[2, 2, 1]
sage: mu[2][0]
2
sage: mu[2][1]
2
sage: mu.level()
4
sage: len(mu)
4
sage: mu.cells()
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 0, 3), (0, 1, 0), (2, 0, 0), (2, 0, 1), (2, 1, 0), (2, 1, 1), (2, 2, 0), (3, 0, 0), (3, 0, 1), (3, 0, 2)]
sage: mu.addable_cells()
[(0, 0, 4), (0, 1, 1), (0, 2, 0), (1, 0, 0), (2, 0, 2), (2, 2, 1), (2, 3, 0), (3, 0, 3), (3, 1, 0)]
sage: mu.removable_cells()
[(0, 0, 3), (0, 1, 0), (2, 1, 1), (2, 2, 0), (3, 0, 2)]
```

```plaintext
>>> from sage.all import *
```
Attached to a partition tuple is the corresponding Young, or parabolic, subgroup:

```python
sage: mu.young_subgroup()
Permutation Group with generators
[(), (12,13), (11,12), (8,9), (6,7), (3,4), (2,3), (1,2)]
```

```python
sage: mu.young_subgroup_generators()
[1, 2, 3, 6, 8, 11, 12]
```

```python
>>> from sage.all import *
>>> mu.young_subgroup()
Permutation Group with generators
[(), (12,13), (11,12), (8,9), (6,7), (3,4), (2,3), (1,2)]
>>> mu.young_subgroup_generators()
[1, 2, 3, 6, 8, 11, 12]
```

```python
class sage.combinat.partition_tuple.PartitionTuple(parent, mu)
    Bases: CombinatorialElement
```

5.1. Comprehensive Module List
A tuple of *Partition*.  
A tuple of partition comes equipped with many of methods available to partitions. The level of the PartitionTuple is the length of the tuple.

This is an ordered \( k \)-tuple of partitions \( \mu = (\mu^{(1)}, \mu^{(2)}, ..., \mu^{(k)}) \). If

\[
n = |\mu| = |\mu^{(1)}| + |\mu^{(2)}| + \cdots + |\mu^{(k)}|
\]

then \( \mu \) is a \( k \)-partition of \( n \).

In representation theory PartitionTuples arise as the natural indexing set for the ordinary irreducible representations of:
- the wreath products of cyclic groups with symmetric groups
- the Ariki-Koike algebras, or the cyclotomic Hecke algebras of the complex reflection groups of type \( G(r, 1, n) \)
- the degenerate cyclotomic Hecke algebras of type \( G(r, 1, n) \)

When these algebras are not semisimple, partition tuples index an important class of modules for the algebras which are generalisations of the Specht modules of the symmetric groups.

Tuples of partitions also index the standard basis of the higher level combinatorial Fock spaces. As a consequence, the combinatorics of partition tuples encapsulates the canonical bases of crystal graphs for the irreducible integrable highest weight modules of the (quantized) affine special linear groups and the (quantized) affine general linear groups. By the categorification theorems of Ariki, Varagnolo-Vasserot, Stroppel-Webster and others, in characteristic zero the degenerate and non-degenerate cyclotomic Hecke algebras, via their Khovanov-Lauda-Rouquier grading, categorify the canonical bases of the quantum affine special and general linear groups.

Partitions are naturally in bijection with 1-tuples of partitions. Most of the combinatorial operations defined on partitions extend to PartitionTuples in a meaningful way. For example, the semisimple branching rules for the Specht modules are described by adding and removing cells from partition tuples and the modular branching rules correspond to adding and removing good and cogood nodes, which is the underlying combinatorics for the associated crystal graphs.

**Warning:** In the literature, the cells of a partition tuple are usually written in the form \((r, c, k)\), where \( r \) is the row index, \( c \) is the column index, and \( k \) is the component index. In sage, if \( \mu \) is a partition tuple then \( \mu[k] \) most naturally refers to the \( k \)-th component of \( \mu \), so we use the convention of the \((k, r, c)\)-th cell in a partition tuple refers to the cell in component \( k \), row \( r \), and column \( c \).

**INPUT:**
Anything which can reasonably be interpreted as a tuple of partitions. That is, a list or tuple of partitions or valid input to *Partition*.

**EXAMPLES:**

```
sage: mu=PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]); mu
((3, 2), (2, 1), [], (1, 1, 1, 1))
sage: mu==nu
True
sage: mu is nu

True
```

See also:

- `PartitionTuples`
- `Partitions`

**Element**

- alias of `Partition`

**add_cell** 

带入 

This does not change `self`.

**EXAMPLES:**
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).add_cell(0,0,1)
([(2, 1), (4, 3), (2, 1, 1)])

>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(4),Integer(3)],

→[Integer(2),Integer(1),Integer(1)]]).add_cell(Integer(0),Integer(0),

→Integer(1))
([(2, 1), (4, 3), (2, 1, 1)])

addable_cells()
Return a list of the removable cells of this partition tuple.
All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

EXAMPLES:

sage: PartitionTuple([[1,1],[2],[2,1],[3]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]

sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1),

→(2, 3, 0)]

arm_length\((k, r, c)\)
Return the length of the arm of cell \((k, r, c)\) in self.

INPUT:
• \(k\) – The component
• \(r\) – The row
• \(c\) – The cell

OUTPUT:
• The arm length as an integer

The arm of cell \((k, r, c)\) is the number of cells in the \(k\)-th component which are to the right of the cell in row \(r\) and column \(c\).

EXAMPLES:

sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,0)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,0,1)
0
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).arm_length(2,2,0)
0
block \((e, \text{multicharge})\)

Return a dictionary \(\beta\) that determines the block associated to the partition \(\text{self}\) and the quantum characteristic() \(e\).

INPUT:

- \(e\) – the quantum characteristic
- \(\text{multicharge}\) – the multicharge (default \((0, 0)\))

OUTPUT:

- a dictionary giving the multiplicities of the residues in the partition tuple \(\text{self}\)

In more detail, the value \(\text{beta}[i]\) is equal to the number of nodes of residue \(i\). This corresponds to the positive root

\[
\sum_{i \in I} \beta_i \alpha_i \in Q^+,
\]

an element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a cyclotomic Hecke algebra of type \(A\) belong to the same block if and only if they correspond to same element \(\beta\) of the root lattice, given above.

We return a dictionary because when the quantum characteristic is \(0\), the Cartan type is \(A_\infty\), in which case the simple roots are indexed by the integers.

EXAMPLES:

\begin{verbatim}
sage: PartitionTuple([[2, 2], [2, 2]]).block(0, (0, 0))
(-1: 2, 0: 4, 1: 2)
sage: PartitionTuple([[2, 2], [2, 2]]).block(2, (0, 0))
(0: 4, 1: 4)
sage: PartitionTuple([[2, 2], [2, 2]]).block(2, (0, 1))
(0: 4, 1: 4)
sage: PartitionTuple([[2, 2], [2, 2]]).block(3, (0, 2))
(0: 3, 1: 2, 2: 3)
sage: PartitionTuple([[2, 2], [2, 2]]).block(3, (0, 2))
(0: 3, 1: 2, 2: 3)
sage: PartitionTuple([[2, 2], [2, 2]]).block(3, (3, 2))
(0: 3, 1: 2, 2: 3)
sage: PartitionTuple([[2, 2], [2, 2]]).block(4, (0, 0))
(0: 4, 1: 2, 3: 2)
\end{verbatim}
cells()
Return the coordinates of the cells of self. Coordinates are given as (component index, row index, column index) and are 0 based.

EXAMPLES:

sage: PartitionTuple([[2, 1], [1], [1, 1, 1]]).cells()
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0), (2, 1, 0), (2, 2, 0)]

components()
Return a list containing the shape of this partition.

This function exists in order to give a uniform way of iterating over the "components" of partition tuples of level 1 (partitions) and for higher levels.

EXAMPLES:

sage: for t in PartitionTuple([[2, 1], [3, 2], [3]]).components():
    print('\$%s\n' % t.ferrers_diagram())

*** *
***
***

sage: for t in PartitionTuple([3, 2]).components():
    print('\$%s\n' % t.ferrers_diagram())

*** **

5.1. Comprehensive Module List
Conjugate

Return the conjugate partition tuple of self.

The conjugate partition tuple is obtained by reversing the order of the components and then swapping the rows and columns in each component.

Examples:

```
sage: PartitionTuple([[2, 1], [1, 1], [1, 1, 1]]).conjugate()
([3], [1, 2, 1])
```

Contains (\(\mu\))

Return True if this partition tuple contains \(\mu\).

If \(\lambda = (\lambda^{(1)}, \ldots, \lambda^{(l)})\) and \(\mu = (\mu^{(1)}, \ldots, \mu^{(m)})\) are two partition tuples then \(\lambda\) contains \(\mu\) if \(m \leq l\) and \(\mu^{(i)} \leq \lambda^{(i)}\) for \(1 \leq i \leq m\) and \(r \geq 0\).

Examples:

```
sage: PartitionTuple([[1, 1], [2], [2, 1]]).contains( PartitionTuple([[1, 1], [2], [2, 1]]) )
True
```

Content \((k, r, c, \text{multicharge})\)

Return the content of the cell.

Let \(m_k = \text{multicharge}[k]\), then the content of a cell is \(m_k + c - r\).

If the \text{multicharge} is a list of integers then it simply offsets the values of the contents in each component. On the other hand, if the \text{multicharge} belongs to \(\mathbb{Z}/e\mathbb{Z}\) then the corresponding \(e\)-residue is returned (that
is, the content mod e).

As with the content method for partitions, the content of a cell does not technically depend on the partition tuple, but this method is included because it is often useful.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [0,0,0])
-1
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, [1,0,0])
0
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(2,1,0, [0,0,0])
-1
```

```python
>>> from sage.all import *

>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),Integer(1),Integer(1)]]).content(Integer(0),Integer(1),Integer(0), IntegerModRing(Integer(3))(c) for c in [Integer(0),Integer(0),Integer(0)])
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),Integer(1),Integer(1)]]).content(Integer(0),Integer(1),Integer(0), IntegerModRing(Integer(3))(c) for c in [Integer(0),Integer(1),Integer(0)])
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),Integer(1),Integer(1)]]).content(Integer(2),Integer(1),Integer(0), multicharge)
-1
```

and now we return the 3-residue of a cell:

```python
sage: multicharge = [IntegerModRing(3)(c) for c in [0,0,0]]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content(0,1,0, multicharge)
2
```

```python
>>> from sage.all import *

>>> multicharge = [IntegerModRing(Integer(3))(c) for c in [0,0,0]]

>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2)],[Integer(1),Integer(1),Integer(1)]]).content(Integer(0),Integer(1),Integer(0), multicharge)
2
```

**content_tableau (multicharge)**

Return the tableau which has (k, r, c)th entry equal to the content multicharge[k]−r+c of this cell.

As with the content function, by setting the multicharge appropriately the tableau containing the residues is returned.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,0])
([[0, 1], [-1]], [[0, 1]], [[0], [-1], [-2]])
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau([0,0,1]).pp()
    0 1 0 1
  -1 0
  -1
```
as with the content function the multicharge can be used to return the tableau containing the residues of the

cells:

```python
sage: multicharge=[ IntegerModRing(3)(c) for c in [0,0,1] ]
sage: PartitionTuple([[2,1],[2],[1,1,1]]).content_tableau(multicharge).pp()
 0 1 0 1 1
 -1 0
 2
```

corners()

Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the

component.

EXAMPLES:

```python
sage: PartitionTuple([[1,1],[2],[2,1]]).removable_cells()
[(0, 1, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).removable_cells()
[(0, 1, 0), (1, 0, 3), (1, 1, 2), (2, 0, 1), (2, 2, 0)]
```

defect (\(e, \text{multicharge}\))

Return the \(e\)-defect or the \(e\)-weight \(self\).

The \(e\)-defect is the number of (connected) \(e\)-rim hooks that can be removed from the partition.

The defect of a partition tuple is given by

\[
defect(\beta) = (\Lambda, \beta) - \frac{1}{2}(\beta, \beta),
\]
where \( \Lambda = \sum \Lambda \kappa_r \) for the multicharge \((\kappa_1, \ldots, \kappa_\ell)\) and \( \beta = \sum_{(r,c)} \alpha_{(c-r)} \pmod{e} \), with the sum being over the cells in the partition.

INPUT:
- \( e \) – the quantum characteristic
- \( \text{multicharge} \) – the multicharge (default \((0,\))

OUTPUT:
- a non-negative integer, which is the defect of the block containing the partition tuple \( \text{self} \)

EXAMPLES:

```python
sage: PartitionTuple([[2,2],[2,2]]).defect(0,(0,0))
0
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,0))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(2,(0,1))
8
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(0,2))
5
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(0,2))
5
sage: PartitionTuple([[2,2],[2,2]]).defect(3,(3,2))
2
sage: PartitionTuple([[2,2],[2,2]]).defect(4,(0,0))
0
```

```python
>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(0),(Integer(0),Integer(0)))
0
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(2),(Integer(0),Integer(0)))
8
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(2),(Integer(0),Integer(1)))
8
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(3),(Integer(0),Integer(0)))
5
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(3),(Integer(0),Integer(2)))
5
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(3),(Integer(3),Integer(2)))
2
>>> PartitionTuple([[Integer(2),Integer(2)], [Integer(2),Integer(2)]]).
←defect(Integer(4),(Integer(0),Integer(0)))
0
```

degree \( (e) \)

Return the \( e \)-th degree of \( \text{self} \).

The \( e \)-th degree is the sum of the degrees of the standard tableaux of shape \( \lambda \). The \( e \)-th degree is the exponent of \( \Phi_e(q) \) in the Gram determinant of the Specht module for a semisimple cyclotomic Hecke algebra of type \( A \) with parameter \( q \).
For this calculation the multicharge \((\kappa_1, \ldots, \kappa_l)\) is chosen so that \(\kappa_{r+1} - \kappa_r > n\), where \(n\) is the \texttt{size()} of \(\lambda\) as this ensures that the Hecke algebra is semisimple.

**INPUT:**
- \(e\) – an integer \(e > 1\)

**OUTPUT:**
A non-negative integer.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[2,2]]).degree(2)
532
sage: PartitionTuple([[2,1],[2,2]]).degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).degree(4)
196
sage: PartitionTuple([[2,1],[2,2]]).degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(6)
105
sage: PartitionTuple([[2,1],[2,2]]).degree(7)
0
```

>>> from sage.all import *

```python
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
→ degree(Integer(2))
532
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
→ degree(Integer(3))
259
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
→ degree(Integer(4))
196
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
→ degree(Integer(5))
105
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
→ degree(Integer(6))
105
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(2),Integer(2)]]).
→ degree(Integer(7))
0
```

Therefore, the Gram determinant of \(S(2,1|2,2)\) when the Hecke parameter \(q\) is “generic” is

\[ q^N \Phi_2(q)^{532} \Phi_3(q)^{259} \Phi_4(q)^{196} \Phi_5(q)^{105} \Phi_6(q)^{105} \]

for some integer \(N\). Compare with \texttt{prime_degree()}.

**diagram()**

Return a string for the Ferrers diagram of \texttt{self}.

**EXAMPLES:**

```python
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
  ** *** 
  * ** * 
```

(continues on next page)
sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
*** ** - *
** * *
** *

sage: PartitionTuples.options(convention="french")

sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
*
** * *
*** ** - *

sage: PartitionTuples.options._reset()

>>> from sage.all import *

>>> print(PartitionTuple([[Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(1),Integer(1),Integer(1)]]).diagram())
** *** *
* ** *
*** ** _ *

>>> print(PartitionTuple([[Integer(3),Integer(2)],[Integer(2),Integer(1)],[Integer(1),Integer(1),Integer(1),Integer(1)]]).diagram())
*
** * *
*** ** _ *

>>> PartitionTuples.options(convention="french")

>>> print(PartitionTuple([[Integer(3),Integer(2)],[Integer(2),Integer(1)],[Integer(1),Integer(1),Integer(1),Integer(1)]]).diagram())
*
** * *
*** ** _ *

>>> PartitionTuples.options._reset()

dominates (mu)

Return True if the PartitionTuple dominates or equals \( \mu \) and False otherwise.

Given partition tuples \( \mu = (\mu^{(1)}, \ldots, \mu^{(m)}) \) and \( \nu = (\nu^{(1)}, \ldots, \nu^{(n)}) \) then \( \mu \) dominates \( \nu \) if

\[
\sum_{k=1}^{l-1} |\mu^{(k)}| + \sum_{r \geq 1} \mu^{(l)}(r) \geq \sum_{k=1}^{l-1} |\nu^{(k)}| + \sum_{r \geq 1} \nu^{(l)}(r)
\]

EXAMPLES:

sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: mu=PartitionTuple([[1,1],[1,1],[2,1]])
sage: mu.dominates(mu)
True
sage: mu.dominates(nu)
True
sage: nu.dominates(mu)
False
sage: tau=PartitionTuple([[],[2,1],[]])
sage: tau.dominates([2,1],[[],[]])
False

(continues on next page)
Combinatorics, Release 10.4

```python
sage: tau.dominates([[],[],[2,1]])
True

>>> from sage.all import *
>>> mu=PartitionTuple([[1,1],[],[2]])
>>> nu=PartitionTuple([[1,1],[1,1],[2,1]])
>>> mu.dominates(mu)
True
>>> mu.dominates(nu)
True
>>> nu.dominates(mu)
False
>>> tau=PartitionTuple([[],[2,1],[]])
>>> tau.dominates([[],[2,1],[]])
False
>>> tau.dominates([[],[],[2,1]])
True
```

down()

Generator (iterator) for the partition tuples that are obtained from self by removing a cell.

**EXAMPLES:**

```python
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).down()]
[([1], [2, 1], [1, 1]), ([1], [3, 1, 1]), ([1], [3, 1], [1])]

sage: [mu for mu in PartitionTuple([[],[],[]]).down()]
[
```

```python
>>> from sage.all import *
>>> [mu for mu in PartitionTuple([[],[3,1],[1,1]]).down()]
[([1], [2, 1], [1, 1]), ([1], [3, 1, 1]), ([1], [3, 1], [1])]

>>> [mu for mu in PartitionTuple([[],[],[]]).down()]
[
```

down_list()

Return a list of the partition tuples that can be formed from self by removing a cell.

**EXAMPLES:**

```python
sage: PartitionTuple([[],[3,1],[1,1]]).down_list()
[([1], [2, 1], [1, 1]), ([1], [3, 1, 1]), ([1], [3, 1], [1])]

sage: PartitionTuple([[],[],[]]).down_list()
[
```

```python
>>> from sage.all import *
>>> PartitionTuple([[],[3,1],[1,1]]).down_list()
[([1], [2, 1], [1, 1]), ([1], [3, 1, 1]), ([1], [3, 1], [1])]

>>> PartitionTuple([[],[],[]]).down_list()
[
```

ferrers_diagram()

Return a string for the Ferrers diagram of self.
EXAMPLES:

```python
sage: print(PartitionTuple([[2,1],[3,2],[1,1,1]]).diagram())
*** *
  *
  *
sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
*** ** - *
  ** *
  *
  *
sage: PartitionTuples.options(convention="french")
sage: print(PartitionTuple([[3,2],[2,1],[],[1,1,1,1]]).diagram())
  *
  *
  *
  *
sage: PartitionTuples.options._reset()
```

```python
>>> from sage.all import *
>>> print(PartitionTuple([[Integer(2),Integer(1)],[Integer(3),Integer(2)],
[Integer(1),Integer(1),Integer(1)]]).diagram())
*** *
  *
  *
sage: PartitionTuples.options._reset()
```

garnir_tableau(*cell)

Return the Garnir tableau of shape `self` corresponding to the cell `cell`.

If `cell = (k, a, c)` then `(k, a + 1, c)` must belong to the diagram of the `PartitionTuple`. If this is not the case then we return `False`.

**Note:** The function also sets `g._garnir_cell` equal to `cell` which is used by some other functions.

The Garnir tableaux play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring.

The Garnir tableau are the “first” non-standard tableaux which arise when you act by simple transpositions. If `(k, a, c)` is a cell in the Young diagram of a partition, which is not at the bottom of its column, then the corresponding Garnir tableau has the integers 1, 2, ..., `n` entered in order from left to right along the rows of the diagram up to the cell `(k, a, c - 1)`, then along the cells `(k, a + 1, c)` to `(k, a + 1, c)`, then `(k, a, c)` until the end of row `a` and then continuing from left to right in the remaining positions. The examples below probably make this clearer!
EXAMPLES:

```python
sage: PartitionTuple([[5, 3], [2, 2], [4, 3]]).garnir_tableau((0, 0, 2)).pp()
1 2 6 7 8 9 10 13 14 15 16
3 4 5

sage: PartitionTuple([[5, 3], [2, 2], [4, 3]]).garnir_tableau((0, 0, 2)).pp()
1 2 6 7 8 12 13 16 17 18 19
3 4 5 11 12 17 18 19

sage: PartitionTuple([[5, 3, 3], [2, 2], [4, 3]]).garnir_tableau((0, 1, 2)).pp()
1 2 3 4 5 12 13 16 17 18 19
6 7 11
8 9 10

sage: PartitionTuple([[5, 3, 3], [2, 2], [4, 3]]).garnir_tableau((1, 0, 0)).pp()
1 2 3 4 5 13 14 16 17 18 19
6 7 8 12 15 20 21 22
9 10 11

sage: PartitionTuple([[5, 3, 3], [2, 2], [4, 3]]).garnir_tableau((1, 0, 1)).pp()
1 2 3 4 5 12 15 16 17 18 19
6 7 8 13 14 20 21 22
9 10 11

sage: PartitionTuple([[5, 3, 3], [2, 2], [4, 3]]).garnir_tableau((2, 0, 1)).pp()
1 2 3 4 5 12 13 16 19 20 21
6 7 8 14 15 17 18 22
9 10 11

sage: PartitionTuple([[5, 3, 3], [2, 2], [4, 3]]).garnir_tableau((2, 1, 1)).pp()
1 2 3 4 5 13 14 16 17 18 19
6 7 8 12 15 20 21 22
9 10 11
```

```python
>>> from sage.all import *

>>> PartitionTuple([[Integer(5), Integer(3)], [Integer(2), Integer(2)],
    →[Integer(4), Integer(3)]].garnir_tableau((Integer(0), Integer(0),
    →Integer(2))).pp()
1 2 6 7 8 9 10 13 14 15 16
3 4 5

>>> PartitionTuple([[Integer(5), Integer(3), Integer(3)], [Integer(2),
    →Integer(2)], [Integer(4), Integer(3)]].garnir_tableau((Integer(0), Integer(0),
    →Integer(2))).pp()
1 2 6 7 8 12 13 16 17 18 19
3 4 5 11 12 17 18 19

>>> PartitionTuple([[Integer(5), Integer(3), Integer(3)], [Integer(2),
    →Integer(2)], [Integer(4), Integer(3)]].garnir_tableau((Integer(0), Integer(1),
    →Integer(2))).pp()
1 2 3 4 5 12 13 16 17 18 19
6 7 11
8 9 10

>>> PartitionTuple([[Integer(5), Integer(3), Integer(3)], [Integer(2),
    →Integer(2)], [Integer(4), Integer(3)]].garnir_tableau((Integer(1), Integer(0),
    →Integer(0))).pp()
1 2 3 4 5 13 14 16 17 18 19
6 7 8 12 15 20 21 22
9 10 11

>>> PartitionTuple([[Integer(5), Integer(3), Integer(3)], [Integer(2),
    →Integer(2)], [Integer(4), Integer(3)]].garnir_tableau((Integer(1), Integer(1),
    →Integer(1))).pp()
1 2 3 4 5 12 15 16 17 18 19
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
>>> PartitionTuple([[Integer(5),Integer(3),Integer(3)],
---Integer(2),
---Integer(2)],,[Integer(4),Integer(3)]]).garnir_tableau((Integer(2),Integer(0),
---Integer(1))).pp()
1 2 3 4 5 12 13 16 19 20 21
6 7 8 14 15 17 18 22
9 10 11
>>> PartitionTuple([[Integer(5),Integer(3),Integer(3)],,[Integer(2),
---Integer(2)],,[Integer(4),Integer(3)]]).garnir_tableau((Integer(2),Integer(1),
---Integer(1))).pp()
Traceback (most recent call last):
... ValueError: (comp, row+1, col) must be inside the diagram
```

See also:

- `top_garnir_tableau`

`hook_length(k, r, c)`

Return the length of the hook of cell \((k, r, c)\) in the partition.

The hook of cell \((k, r, c)\) is defined as the cells to the right or below (in the English convention). If your coordinates are in the form \((k, r, c)\), use Python’s `*`-operator.

**EXAMPLES:**

```
sage: mu=PartitionTuple([[1,1],[2],[2,1]])
sage: [ mu.hook_length(*c) for c in mu.cells() ]
[2, 1, 2, 1, 3, 1, 1]

>>> from sage.all import *
>>> mu=PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),
---Integer(1)]])
>>> [ mu.hook_length(*c) for c in mu.cells() ]
[2, 1, 2, 1, 3, 1, 1]
```

`initial_column_tableau()`

Return the initial column tableau of shape \(\lambda\).

The initial column tableau of shape \(\lambda\) is the standard tableau that has the numbers 1 to \(n\), where \(n\) is the `size()` of \(\lambda\), entered in order from top to bottom, and then left to right, down the columns of each component, starting from the rightmost component and working to the left.

**EXAMPLES:**

```
sage: PartitionTuple([ [3,1],[3,2] ]).initial_column_tableau()
([[6, 8, 9], [7]], [[1, 3, 5], [2, 4]])

>>> from sage.all import *
>>> PartitionTuple([ [Integer(3),Integer(1)],[Integer(3),Integer(2)] ]).
---initial_column_tableau()
([[6, 8, 9], [7]], [[1, 3, 5], [2, 4]])
```

`initial_tableau()`

Return the `StandardTableauTuple` which has the numbers 1, 2, ..., \(n\), where \(n\) is the `size()` of
self, entered in order from left to right along the rows of each component, where the components are ordered from left to right.

EXAMPLES:

```python
sage: PartitionTuple([[2,1],[3,2]]).initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
```

```python
>>> from sage.all import *

>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(3),Integer(2)]]).initial_tableau()
([[1, 2], [3]], [[4, 5, 6], [7, 8]])
```

### leg_length \((k, r, c)\)

Return the length of the leg of cell \((k, r, c)\) in \(self\).

**INPUT:**

- \(k\) – The component
- \(r\) – The row
- \(c\) – The cell

**OUTPUT:**

- The leg length as an integer

The leg of cell \((k, r, c)\) is the number of cells in the \(k\)-th component which are below the node in row \(r\) and column \(c\).  

**EXAMPLES:**

```python
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,0)
2
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,0,1)
1
sage: PartitionTuple([[],[2,1],[2,2,1],[3]]).leg_length(2,2,0)
0
```

```python
>>> from sage.all import *

>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),Integer(1)],[Integer(3)]]).leg_length(Integer(2),Integer(0),Integer(0))
2
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),Integer(1)],[Integer(3)]]).leg_length(Integer(2),Integer(0),Integer(1))
1
>>> PartitionTuple([[],[Integer(2),Integer(1)],[Integer(2),Integer(2),Integer(1)],[Integer(3)]]).leg_length(Integer(2),Integer(2),Integer(0))
0
```

### level()

Return the level of this partition tuple.

The level is the length of the tuple.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1,1,0],[2,1]]).level()
2
```
Combinatorics, Release 10.4

sage: PartitionTuple([],[],[2,1,1]).level()
3

>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1),Integer(1),Integer(0)],[Integer(2), →Integer(1)]]).level()
2
>>> PartitionTuple([[1,1],[[],[Integer(2),Integer(1),Integer(1)]]]).level()
3

**outside_corners()**

Return a list of the removable cells of this partition tuple.

All indices are of the form \((k, r, c)\), where \(r\) is the row-index, \(c\) is the column index and \(k\) is the component.

**EXAMPLES:**

sage: PartitionTuple([[1,1],[2],[2,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]

sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 4), (1, 1, 3), (1, 2, 0), (2, 0, 2), (2, 1, 1), →(2, 3, 0)]

>>> from sage.all import *
>>> PartitionTuple([[Integer(1),Integer(1)],[Integer(2)],[Integer(2),Integer(1)]]).addable_cells()
[(0, 0, 1), (0, 2, 0), (1, 0, 2), (1, 1, 0), (2, 0, 2), (2, 1, 1), (2, 2, 0)]

prime_degree \((p)\)

Return the \(p\)-th prime degree of self.

The degree of a partition \(\lambda\) is the sum of the \(e\)-degrees° of the standard tableaux of shape \(\lambda\) (see *degree*).
for $e$ a power of the prime $p$. The prime degree gives the exponent of $p$ in the Gram determinant of the integral Specht module of the symmetric group.

The $p$-th degree is the sum of the degrees of the standard tableaux of shape $\lambda$. The $p$-th degree is the exponent of $p$ in the Gram determinant of a semisimple cyclotomic Hecke algebra of type $A$ with parameter $q = 1$.

As with `degree()`, for this calculation the multicharge $(\kappa_1, \ldots, \kappa_l)$ is chosen so that $\kappa_{r+1} - \kappa_r > n$, where $n$ is the `size()` of $\lambda$ as this ensures that the Hecke algebra is semisimple.

**INPUT:**
- $e$ – an integer $e > 1$
- multicharge – an $l$-tuple of integers, where $l$ is the `level()` of self

**OUTPUT:**
A non-negative integer

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(2)
728
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(3)
259
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(5)
105
sage: PartitionTuple([[2,1],[2,2]]).prime_degree(7)
0
```

Therefore, the Gram determinant of $S(2,1|2,2)$ when $q = 1$ is $2^{728} \cdot 3^{259} \cdot 5^{105}$. Compare with `degree()`.

**removable_cells()**

Return a list of the removable cells of this partition tuple.

All indices are of the form $(k, r, c)$, where $r$ is the row-index, $c$ is the column index and $k$ is the component.

**EXAMPLES:**

```python
>>> from sage.all import *

sage: PartitionTuple([[2,1],[2,2]]).removable_cells()
[(0, 0, 1), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
sage: PartitionTuple([[1,1],[2,1],[2,1]]).removable_cells()
[(0, 0, 0), (1, 0, 1), (2, 0, 1), (2, 1, 0)]
```
remove_cell \(k, r, c\)
Return the partition tuple obtained by removing a cell in row \(r\), column \(c\), and component \(k\).
This does not change \(self\).

EXAMPLES:

```
sage: PartitionTuple([[1,1],[4,3],[2,1,1]]).remove_cell(0,1,0)
([1], [4, 3], [2, 1, 1])
```

row_standard_tableaux()
Return the row standard tableau tuples of shape \(self\).

EXAMPLES:

```
sage: PartitionTuple([[1],[3,2,2,1],[2,2,1],[3]]).row_standard_tableaux()
Row standard tableau tuples of shape ([1], [3, 2, 2, 1], [2, 2, 1], [3])
```

size()
Return the size of a partition tuple.

EXAMPLES:

```
sage: PartitionTuple([[2,1],[1],[2,2]]).size()
7
sage: PartitionTuple([[],[],[1],[3,2,1]]).size()
7
```

standard_tableaux()
Return the standard tableau tuples of shape \(self\).
EXAMPLES:

```python
sage: PartitionTuple([[], [3, 2, 1], [2, 1], [3]]).standard_tableaux()
Standard tableau tuples of shape ([], [3, 2, 1], [2, 1], [3])
```

```python
>>> from sage.all import *
```

```python
>>> PartitionTuple([[], [Integer(3), Integer(2), Integer(2), Integer(1)],
                   [Integer(2), Integer(2), Integer(1)], [Integer(3)]]).standard_tableaux()
Standard tableau tuples of shape ([], [3, 2, 1], [2, 1], [3])
```

to_exp \((k=0)\)

Return a tuple of the multiplicities of the parts of a partition.

Use the optional parameter \(k\) to get a return list of length at least \(k\).

EXAMPLES:

```python
sage: PartitionTuple([[1, 1], [2], [2, 1]]).to_exp()
([2], [0, 1], [1, 1])
```

```python
sage: PartitionTuple([[1, 1], [2, 2, 2], [2, 1]]).to_exp()
([2], [0, 4], [1, 1])
```

```python
>>> from sage.all import *
```

```python
>>> PartitionTuple([[Integer(1), Integer(1)], [Integer(2)],
                   [Integer(2), Integer(1)]]).to_exp()
([2], [0, 1], [1, 1])
```

```python
>>> PartitionTuple([[Integer(1), Integer(1)], [Integer(2), Integer(2), Integer(2),
                   Integer(1)]].to_exp()
([2], [0, 4], [1, 1])
```

to_list()

Return \(self\) as a list of lists.

EXAMPLES:

```python
sage: PartitionTuple([[1, 1], [4, 3], [2, 1, 1]]).to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

```python
>>> from sage.all import *
```

```python
>>> PartitionTuple([[Integer(1), Integer(1)], [Integer(4), Integer(3)],
                   [Integer(2), Integer(1)]].to_list()
[[1, 1], [4, 3], [2, 1, 1]]
```

top_garnir_tableau \((e, \text{cell})\)

Return the most dominant standard tableau which dominates the corresponding Garnir tableau and has the same residue that has shape \(self\) and is determined by \(e\) and \(\text{cell}\).

The Garnir tableau play an important role in integral and non-semisimple representation theory because they determine the “straightening” rules for the Specht modules over an arbitrary ring. The top Garnir tableaux arise in the graded representation theory of the symmetric groups and higher level Hecke algebras. They were introduced in [KMR2012].

If the Garnir node is \(\text{cell}=(k, r, c)\) and \(m\) and \(M\) are the entries in the cells \((k, r, c)\) and \((k, r+1, c)\), respectively, in the initial tableau then the top \(e\)-Garnir tableau is obtained by inserting the numbers \(m, m+1, \ldots, M\) in order from left to right first in the cells in row \(r+1\) which are not in the \(e\)-Garnir belt, then in the cell in rows \(r\) and \(r+1\) which are in the Garnir belt and then, finally, in the remaining cells in row \(r\) which are not in the Garnir belt. All other entries in the tableau remain unchanged.
If $e = 0$, or if there are no $e$-bricks in either row $r$ or $r+1$, then the top Garnir tableau is the corresponding Garnir tableau.

EXAMPLES:

```python
sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,2)).pp()
  1  2  3  9 10 12 13 16
  4  5  6 11 14 15 17
  7  8  18 19 20
  21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(2,(1,0,1)).pp()
  1  2  3  9 10 11 12 13
  4  5  6 14 15 16 17
  7  8  18 19 20
  21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(1,0,1)).pp()
  1  2  3  9 12 13 14 15
  4  5  6 10 11 16 17
  7  8  18 19 20
  21 22

sage: PartitionTuple([[3,3,2],[5,4,3,2]]).top_garnir_tableau(3,(3,0,1)).pp()
  Traceback (most recent call last):
    ... ValueError: (comp, row+1, col) must be inside the diagram
```

```python
>>> from sage.all import *

>>> PartitionTuple([[Integer(3),Integer(3),Integer(2)],[Integer(5),Integer(4), ...
→Integer(3),Integer(2)]]).top_garnir_tableau(Integer(2),(Integer(1), ...
→Integer(0),Integer(2))).pp()
  1  2  3  9 10 12 13 16
  4  5  6 11 14 15 17
  7  8  18 19 20
  21 22

>>> PartitionTuple([[Integer(3),Integer(3),Integer(2)],[Integer(5),Integer(4), ...
→Integer(3),Integer(2)]]).top_garnir_tableau(Integer(2),(Integer(1), ...
→Integer(0),Integer(1))).pp()
  1  2  3  9 10 11 12 13
  4  5  6 14 15 16 17
  7  8  18 19 20
  21 22

>>> PartitionTuple([[Integer(3),Integer(3),Integer(2)],[Integer(5),Integer(4), ...
→Integer(3),Integer(2)]]).top_garnir_tableau(Integer(3),(Integer(1), ...
→Integer(0),Integer(1))).pp()
  1  2  3  9 12 13 14 15
  4  5  6 10 11 16 17
  7  8  18 19 20
  21 22

>>> PartitionTuple([[Integer(3),Integer(3),Integer(2)],[Integer(5),Integer(4), ...
→Integer(3),Integer(2)]]).top_garnir_tableau(Integer(3),(Integer(3), ...
→Integer(0),Integer(1))).pp()
  Traceback (most recent call last):
    ... ValueError: (comp, row+1, col) must be inside the diagram
```

See also:
• garnir_tableau()

**up()**

Generator (iterator) for the partition tuples that are obtained from self by adding a cell.

**EXAMPLES:**

```python
sage: [mu for mu in PartitionTuple([[],[3,1],[1,1]]).up()]
[[[1], [3, 1], [1, 1]], ([[], [4, 1], [1, 1]], ([[], [3, 2], [1, 1]], ([[], [3, 1], [1, 1]], ([[], [3, 1], [2, 1]], ([[], [3, 1], [1, 1, 1]]))]
```

```python
sage: [mu for mu in PartitionTuple([[],[],[],[]]).up()]
[[[1], [], [], []]], ([[], [1], [], []]), ([[], [], [1], []]), ([[], [], [], [1]])
```

```python
>>> from sage.all import *

>>> [mu for mu in PartitionTuple([[Integer(2),Integer(1)],[Integer(4),Integer(2)], [Integer(1)]]).up_list()]
[[[1], [3, 1], [1, 1]], ([[], [4, 1], [1, 1]], ([[], [3, 2], [1, 1]], ([[], [3, 1], [1, 1]], ([[], [3, 1], [2, 1]], ([[], [3, 1], [1, 1, 1]]))]
```

**up_list()**

Return a list of the partition tuples that can be formed from self by adding a cell.

**EXAMPLES:**

```python
sage: PartitionTuple([[],[3,1],[1,1]]).up_list()
[[[1], [3, 1], [1, 1]], ([[], [4, 1], [1, 1]], ([[], [3, 2], [1, 1]], ([[], [3, 1], [1, 1]], ([[], [3, 1], [2, 1]], ([[], [3, 1], [1, 1, 1]]))]
```

```python
sage: PartitionTuple([[],[],[],[]]).up_list()
[[[1], [], [], []]], ([[], [1], [], []]), ([[], [], [1], []]), ([[], [], [], [1]])
```

**young_subgroup()**

Return the corresponding Young, or parabolic, subgroup of the symmetric group.

**EXAMPLES:**

```python
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup() # needs sage.groups
Permutation Group with generators [(), (8,9), (6,7), (5,6), (4,5), (1,2)]
```

```python
>>> from sage.all import *

>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(4),Integer(2)],[Integer(1)]]).young_subgroup() # needs sage.groups
Permutation Group with generators [(), (8,9), (6,7), (5,6), (4,5), (1,2)]
```

**young_subgroup_generators()**

Return an indexing set for the generators of the corresponding Young subgroup.

**EXAMPLES:**
sage: PartitionTuple([[2,1],[4,2],[1]]).young_subgroup_generators()
[1, 4, 5, 6, 8]

>>> from sage.all import *
>>> PartitionTuple([[Integer(2),Integer(1)],[Integer(4),Integer(2)],

/wp]->[Integer(1)]]).young_subgroup_generators()
[1, 4, 5, 6, 8]

class sage.combinat.partition_tuple.PartitionTuples
    Bases: UniqueRepresentation, Parent

Class of all partition tuples.

For more information about partition tuples, see PartitionTuple.

This is a factory class which returns the appropriate parent based on the values of level, size, and regular

INPUT:
• level – the length of the tuple
• size – the total number of cells
• regular – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an
  entry may have in a component plus 1

If a level \( k \) is specified and regular is a tuple of integers \( \ell_1, \ldots, \ell_k \), then this specifies partition tuples \( \mu \) such
that \( \mu_i = \ell_i \)-regular, where 0 here represents \( \infty \)-regular partitions (equivalently, partitions without restrictions). If
regular is an integer \( \ell \), then we set \( \ell_i = \ell \) for all \( i \).

Element
    alias of PartitionTuple

level()
    Return the level or None if it is not defined.

EXAMPLES:

sage: PartitionTuples().level() is None
True
sage: PartitionTuples(7).level()
7

>>> from sage.all import *
>>> PartitionTuples().level() is None
True
>>> PartitionTuples(Integer(7)).level()
7

options = Current options for Partitions - convention: English -
diagram_str: * - display: list - latex: young_diagram -
latex_diagram_str: \ast

size()
    Return the size or None if it is not defined.

EXAMPLES:
```python
sage: PartitionTuples().size() is None
True
sage: PartitionTuples(size=7).size()
7

>>> from sage.all import *
>>> PartitionTuples().size() is None
True
>>> PartitionTuples(size=Integer(7)).size()
7
```

```python
class sage.combinat.partition_tuple.PartitionTuples_all
    Bases: PartitionTuples
    
    Class of partition tuples of a arbitrary level and arbitrary sum.

class sage.combinat.partition_tuple.PartitionTuples_level
    (level, category=None)
    Bases: PartitionTuples
    
    Class of partition tuples of a fixed level, but summing to an arbitrary integer.

class sage.combinat.partition_tuple.PartitionTuples_level_size
    (level, size)
    Bases: PartitionTuples
    
    Class of partition tuples with a fixed level and a fixed size.

cardinality()
    
    Return the number of level-tuples of partitions of size n.
    
    Wraps a pari function call using pari:eta.
    
    EXAMPLES:

sage: PartitionTuples(2,3).cardinality()  # needs sage.libs.pari
10
sage: PartitionTuples(2,8).cardinality()  # needs sage.libs.pari
185

>>> from sage.all import *
>>> PartitionTuples(Integer(2),Integer(3)).cardinality()  # needs sage.libs.pari
10
>>> PartitionTuples(Integer(2),Integer(8)).cardinality()  # needs sage.libs.pari
185
```

class sage.combinat.partition_tuple.PartitionTuples_size
    (size)
    Bases: PartitionTuples
    
    Class of partition tuples of a fixed size, but arbitrary level.

class sage.combinat.partition_tuple.RegularPartitionTuples
    (regular, **kwds)
    Bases: PartitionTuples
    
    Abstract base class for ℓ-regular partition tuples.
class sage.combinat.partition_tuple.RegularPartitionTuples_all(regular)
Bases: RegularPartitionTuples
Class of \( \ell \)-regular partition tuples.

class sage.combinat.partition_tuple.RegularPartitionTuples_level(level, regular)
Bases: PartitionTuples_level
Regular Partition tuples of a fixed level.

INPUT:

- **level** – a non-negative Integer; the level
- **regular** – a positive integer or a tuple of non-negative integers; if an integer, the highest multiplicity an entry may have in a component plus 1 with 0 representing \( \infty \)-regular (equivalently, partitions without restrictions) regular is a tuple of integers \((\ell_1, \ldots, \ell_k)\) that specifies partition tuples \(\mu\) such that \(\mu_i\) is \(\ell_i\)-regular. If regular is an integer \(\ell\), then we set \(\ell_i = \ell\) for all \(i\).

EXAMPLES:

```python
sage: RPT = PartitionTuples(level=4, regular=(2,3,0,2))
```

```plaintext
[([], [], [], []), ([1], [], [], []), ([1], [], [1], []), ([1], [], [], [1]), ([2], [], [], []), ([1], [1], [], []), ([1], [], [1], []), ([1], [], [], [1]), ([1], [1], [], []), ([1], [], [], [1]), ([1], [1], [], []), ([1], [1], [1], []), ([1], [], [1], []), ([1], [1], [], []), ([1], [1], [], []), ([2], [1], [], []), ([1], [], [1], []), ([2], [1], [1], []), ([2], [1], [], []), ([2], [1], [1], []), ([2], [1], [1], []), ([1], [2], [1], []), ([1], [1], [1], [1]), ([1], [1], [], [1]), ([3], [1], [], []), ([2], [1], [1], []), ([2], [1], [], []), ([2], [1], [1], []), ([2], [1], [1], []), ([1], [2], [1], []), ([1], [1], [1], [1]), ([1], [1], [], [1])] in RPT
```

```python
sage: [[1,1],[3],[5,5,5],[7,2]] in RPT
False
```

```python
sage: [[3,1],[3],[5,5,5],[7,2]] in RPT
True
```

```python
sage: [[3,1],[3],[5,5,5]] in RPT
False
```

```python
>>> from sage.all import *
```

```python
>>> RPT = PartitionTuples(level=Integer(4), regular=(Integer(2),Integer(3), Integer(0),Integer(2)))
```

```python
>>> RPT[:Integer(24)]
```

class sage.combinat.partition_tuple.RegularPartitionTuples_size(size, regular)
Bases: RegularPartitionTuples

Class of \( \ell \)-regular partition tuples with a fixed size.
5.1.170 Iterators over the partitions of an integer

The iterators generate partitions in either increasing or decreasing lexicographic orders and a partition \( P \) is represented either in ascending \( (P_i \leq P_{i+1}) \) or descending \( (P_i \geq P_{i+1}) \) orders:

```
sage: from sage.combinat.partitions import ZS1_iterator
sage: for p in ZS1_iterator(4):
    ....:    print(p)
   [4]
   [3, 1]
   [2, 2]
   [2, 1, 1]
   [1, 1, 1, 1]
sage: from sage.combinat.partitions import AccelDesc_iterator
sage: for p in AccelDesc_iterator(4):
    ....:    print(p)
   [4]
   [3, 1]
   [2, 2]
   [2, 1, 1]
   [1, 1, 1, 1]
sage: from sage.combinat.partitions import ZS2_iterator
sage: for p in ZS2_iterator(4):
    ....:    print(p)
   [1, 1, 1, 1]
   [2, 1, 1]
   [2, 2]
   [3, 1]
   [4]
sage: from sage.combinat.partitions import AccelAsc_iterator
sage: for p in AccelAsc_iterator(4):
    ....:    print(p)
   [1, 1, 1, 1]
   [1, 1, 2]
   [1, 3]
   [2, 2]
   [4]
```

(continues on next page)
...    print(p)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
>>> from sage.combinat.partitions import AccelAsc_iterator
>>> for p in AccelAsc_iterator(Integer(4)):
...    print(p)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]

For each of these iterators, this module also provides a next method that takes a partition as input and return the next partition in the corresponding ordering:

```
sage: from sage.combinat.partitions import ZS1_next
sage: ZS1_next([2, 2])
[2, 1, 1]
sage: from sage.combinat.partitions import AccelDesc_next
sage: AccelDesc_next([2, 2])
[2, 1, 1]
sage: from sage.combinat.partitions import ZS2_next
sage: ZS2_next([2, 2])
[3, 1]
sage: from sage.combinat.partitions import AccelAsc_next
sage: AccelAsc_next([2, 2])
[4]
```

```
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_next
>>> ZS1_next([Integer(2), Integer(2)])
[2, 1, 1]
>>> from sage.combinat.partitions import AccelDesc_next
>>> AccelDesc_next([Integer(2), Integer(2)])
[2, 1, 1]
>>> from sage.combinat.partitions import ZS2_next
>>> ZS2_next([Integer(2), Integer(2)])
[3, 1]
>>> from sage.combinat.partitions import AccelAsc_next
>>> AccelAsc_next([Integer(2), Integer(2)])
[4]
```

It is also possible to iterate over the partitions of bounded length:

```
sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: for p in ZS1_iterator_nk(6, 3):
...    print(p)
[6]
[5, 1]
[4, 2]
[4, 1, 1]
[3, 3]
[3, 2, 1]
```

(continues on next page)
>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator_nk
>>> for p in ZS1_iterator_nk(Integer(6), Integer(3)):
...     print(p)
[6]
[5, 1]
[4, 2]
[4, 1, 1]
[3, 3]
[3, 2, 1]
[2, 2, 2]

AUTHOR:

• William Stein (2007-07-28): initial version
• Jonathan Bober (2007-07-28): wrote the program partitions_c.cc that does all the actual heavy lifting.
• David Coudert (2024-06-01): reshape method ZS1_iterator() to ease the implementation of ZS1_next() and add iterators and next methods based on ZS2, AccelAsc and AccelDesc from [ZS1998] and [KS2012].

sage.combinat.partitions.AccelAsc_iterator(n)
Return an iterator over the partitions of n.

The partitions are generated in the increasing lexicographic order and each partition is represented as a list in ascending order (i.e., \( p_i \leq p_{i+1} \)).

This is an implementation of the AccelAsc algorithm found in [KS2012].

See also:
sage.combinat.partitions.ZS1_iterator()

EXAMPLES:

sage: from sage.combinat.partitions import AccelAsc_iterator
sage: for p in AccelAsc_iterator(4):
    ....:     print(p)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
sage: next(AccelAsc_iterator(4))
[1, 1, 1, 1]
sage: type(_)
<class 'list'>

(continues on next page)
sage.combinat.partitions.AccelAsc_next(P)

Return the partition after P in the ordering of the AccelAsc algorithm.

INPUT:

• P – a list encoding a partition of an integer n in ascending order (i.e., $P_i \leq P_{i+1}$)

EXAMPLES:

```python
sage: from sage.combinat.partitions import AccelAsc_next
sage: P = [1, 1, 1, 1]
sage: while P:
....:     print(P)
....:     P = AccelAsc_next(P)
[1, 1, 1, 1]
[1, 1, 2]
[1, 3]
[2, 2]
[4]
```

sage.combinat.partitions.AccelDesc_iterator(n)

Return an iterator over the partitions of n.

The partitions are generated in the increasing lexicographic order and each partition is represented as a list in descending order (i.e., $p_i \geq p_{i+1}$).

This is an implementation of the AccelDesc algorithm found in [KS2012].

See also:

sage.combinat.partitions.ZS1_iterator()

EXAMPLES:

```python
sage: from sage.combinat.partitions import AccelDesc_iterator
sage: for p in AccelDesc_iterator(4):
....:     print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
```
sage: next(AccelDesc_iterator(4))
[4]
sage: type(_)
<class 'list'>

>>> from sage.all import *
>>> from sage.combinat.partitions import AccelDesc_iterator
>>> for p in AccelDesc_iterator(Integer(4)):
...    print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]

Check that ZS1_iterator() and AccelDesc_iterator() generate partitions in the same order:

sage: from sage.combinat.partitions import ZS1_iterator
sage: from sage.misc.prandom import randint
sage: n = randint(1, 50)
sage: all(p == q for p, q in zip(ZS1_iterator(n), AccelDesc_iterator(n)))  # long...
˓→time
True

>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator
>>> from sage.misc.prandom import randint
>>> n = randint(Integer(1), Integer(50))
>>> all(p == q for p, q in zip(ZS1_iterator(n), AccelDesc_iterator(n)))  # long...
˓→time
True

sage.combinat.partitions.AccelDesc_next(P)

Return the partition after P in the ordering of the AccelDesc algorithm.

INPUT:

• P – a list encoding a partition of an integer n in descending order (i.e., \(P_i \geq P_{i+1}\))

EXAMPLES:
sage: all(AccelDesc_next(p) == q for p, q in zip(A, A[1:]))
True

>>> from sage.all import *
>>> from sage.combinat.partitions import AccelDesc_iterator, AccelDesc_next
>>> while P:
...    print(P)
...    P = AccelDesc_next(P)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]

sage.combinat.partitions.ZS1_iterator(n)

Return an iterator over the partitions of n.

The partitions are generated in the decreasing lexicographic order and each partition is represented as a list P in descending order (i.e., $P_i \geq P_{i+1}$). The method yields lists and not objects of type Partition.

This is an implementation of the ZS1 algorithm found in [ZS1998].

See also:

• sage.combinat.partitions.ZS2_iterator()
• sage.combinat.partitions.AccelDesc_iterator()

EXAMPLES:

sage: from sage.combinat.partitions import ZS1_iterator
sage: for p in ZS1_iterator(4):
...    print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]

5.1. Comprehensive Module List
Combinatorics, Release 10.4

>>> next(ZS1_iterator(Integer(4)))
[4]
>>> type(_)
<class 'list'>

sage.combinat.partitions.ZS1_iterator_nk(n, k)
An iterator for the partitions of n of length at most k (in the decreasing lexicographic order) which returns lists and not objects of type Partition.

The algorithm is a mild variation on ZS1_iterator(); I would not vow for its speed.

EXAMPLES:

sage: from sage.combinat.partitions import ZS1_iterator_nk
sage: it = ZS1_iterator_nk(4, 3)
sage: next(it)
[4]
sage: type(_)
<class 'list'>

>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator_nk
>>> it = ZS1_iterator_nk(Integer(4), Integer(3))
>>> next(it)
[4]
>>> type(_)
<class 'list'>

sage.combinat.partitions.ZS1_next(P)
Return the partition after P in the ordering of the ZS1 algorithm.

INPUT:

• P – a list encoding a partition of an integer n in descending order (i.e., $P_i \geq P_{i+1}$)

EXAMPLES:

sage: from sage.combinat.partitions import ZS1_iterator, ZS1_next
sage: P = [4]
sage: while P:
...:     print(P)
...:     P = ZS1_next(P)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
sage: A = [list(p) for p in Partitions(7)]
sage: all(ZS1_next(p) == q for p, q in zip(A, A[1:]))
True

>>> from sage.all import *
>>> from sage.combinat.partitions import ZS1_iterator, ZS1_next
>>> P = [Integer(4)]
>>> while P:
...     print(P)
...     P = ZS1_next(P)
(continues on next page)
sage.combinat.partitions.ZS2_iterator(n)

Return an iterator over the partitions of n.

The partitions are generated in the increasing lexicographic order and each partition is represented as a list in descending order (i.e., $p_i \geq p_{i+1}$).

This is an implementation of the ZS2 algorithm found in [ZS1998].

See also:

sage.combinat.partitions.ZS1_iterator()

EXAMPLES:

```python
sage: from sage.combinat.partitions import ZS2_iterator
sage: for p in ZS2_iterator(4):
    ....:     print(p)
[1, 1, 1, 1]
[2, 1, 1]
[2, 2]
[3, 1]
[4]
sage: next(ZS2_iterator(4))
[1, 1, 1, 1]
sage: type(_)
<class 'list'>
```

sage.combinat.partitions.ZS2_next(P)

Return the partition after P in the ordering of the ZS2 algorithm.

INPUT:

- P – a list encoding a partition of an integer n in descending order (i.e., $p_i \geq p_{i+1}$)

EXAMPLES:
A perfect matching of a set $S$ is a partition into 2-element sets. If $S$ is the set \{1, ..., $n$\}, it is equivalent to fixpoint-free involutions. These simple combinatorial objects appear in different domains such as combinatorics of orthogonal polynomials and of the hyperoctaedral groups (see [MV], [McD] and also [CM]):

AUTHOR:

- Valentin Feray, 2010: initial version
- Martin Rubey, 2017: inherit from SetPartition, move crossings and nestings to SetPartition

EXAMPLES:

Create a perfect matching:

```sage
sage: m = PerfectMatching(\{(a, e), (b, c), (d, f)\}); m
[(a, e), (b, c), (d, f)]
```

Count its crossings, if the ground set is totally ordered:

```sage
sage: n = PerfectMatching([3, 8, 1, 7, 6, 5, 4, 2]); n
[(1, 3), (2, 8), (4, 7), (5, 6)]
sage: n.number_of_crossings()
1
```

(continues on next page)
List the perfect matchings of a given ground set:

```python
sage: PerfectMatchings(4).list()
[[[1, 2], [3, 4]], [[1, 3], [2, 4]], [[1, 4], [2, 3]]]
```

```python
>>> from sage.all import *
```

```python
>>>'n.parent()
```

The parent, which is the set of perfect matchings of the ground set, is automatically created:

```python
sage: n.parent()
```

If the ground set is ordered, one can, for example, ask if the matching is non-crossing:

```python
sage: PerfectMatching(((1, 4), (2, 3), (5, 6))).is_noncrossing()
```

```
(continues on next page)
```
Weingarten_function \((d, \text{other}=\text{None})\)
Return the Weingarten function of two pairings.

This function is the value of some integrals over the orthogonal groups \(O_N\). With the convention of [CM], the method returns \(Wg^{O_N}(d)(\text{other}, \text{self})\).

EXAMPLES:

```python
sage: m = PerfectMatching([(1,3),(2,4)])
sage: n = PerfectMatching([(1,2),(3,4)])
 sage: factor(m.Weingarten_function(N, n))
-1/((N + 2)*(N - 1)*N)
```

loop_type \((\text{other}=\text{None})\)
Return the loop type of \text{self}.

INPUT:

- \text{other} – a perfect matching of the same set of \text{self}. (if the second argument is empty, the method \text{an_element}() is called on the parent of the first)

OUTPUT:
If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the ordered list of the semi-length of these cycles (considered as a partition)

EXAMPLES:

```python
sage: m = PerfectMatching([(‘a’,’e’), (‘b’,’c’), (‘d’,’f’)])
 sage: n = PerfectMatching([(‘a’,’b’), (‘d’,’f’), (‘e’,’c’)])
 sage: m.loop_type(n)
[2, 1]
```
**loops** (*other=None*)

Return the loops of *self*.

**INPUT:**

- *other* – a perfect matching of the same set of *self*. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

**OUTPUT:**

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns the list of these cycles (each cycle is given as a list).

**EXAMPLES:**

```python
sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
sage: n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
sage: loops = m.loops(n)
sage: loops
[[a, e, c, b], [d, f]]
```

**loops_iterator** (*other=None*)

Iterate through the loops of *self*.

**INPUT:**

- *other* – a perfect matching of the same set of *self*. (if the second argument is empty, the method `an_element()` is called on the parent of the first)

**OUTPUT:**

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns an iterator for these cycles (each cycle is given as a list).

**EXAMPLES:**

```python
>>> from sage.all import *
>>> m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
>>> n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
>>> loops = m.loops(n)
>>> loops
[[a, e, c, b], [d, f]]
```

>>> from sage.all import *
>>> o = PerfectMatching(((Integer(1), Integer(7)), (Integer(2), Integer(4)),
                          (Integer(3), Integer(8)), (Integer(5), Integer(6))))
>>> p = PerfectMatching(((Integer(1), Integer(6)), (Integer(2), Integer(7)),
                          (Integer(3), Integer(4)), (Integer(5), Integer(8))))
>>> it = o.loops_iterator(p)
>>> next(it)
[1, 7, 2, 4, 3, 8, 5, 6]
>>> next(it)
Traceback (most recent call last):
...
StopIteration

number_of_loops (other=None)

Return the number of loops of self.

INPUT:

- other – a perfect matching of the same set of self. (if the second argument is empty, the method an_element() is called on the parent of the first)

OUTPUT:

If we draw the two perfect matchings simultaneously as edges of a graph, the graph obtained is a union of cycles of even lengths. The function returns their numbers.

EXAMPLES:

sage: m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
sage: n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
sage: m.number_of_loops(n)
2

>>> from sage.all import *
>>> m = PerfectMatching([('a', 'e'), ('b', 'c'), ('d', 'f')])
>>> n = PerfectMatching([('a', 'b'), ('d', 'f'), ('e', 'c')])
>>> m.number_of_loops(n)
2

partner (x)

Return the element in the same pair than x in the matching self.

EXAMPLES:

sage: m = PerfectMatching([(-3, 1), (2, 4), (-2, 7)])
sage: m.partner(4)
2
sage: n = PerfectMatching([('c', 'b'), ('d', 'f'), ('e', 'a')])
sage: n.partner('c')
'b'
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> m = PerfectMatching([(-Integer(3), Integer(1)), (Integer(2), Integer(4)),
   (-Integer(2), Integer(7))])

>>> m.partner(Integer(4))
2

>>> n = PerfectMatching([(c,b),(d,f),(e,a)])

>>> n.partner(c)
b
```

**standardization()**

Return the standardization of `self`.

See `SetPartition.standardization()` for details.

**EXAMPLES:**

```python
sage: n = PerfectMatching([(c,b),(d,f),(e,a)])
sage: n.standardization()
[(1, 5), (2, 3), (4, 6)]
```

**to_graph()**

Return the graph corresponding to the perfect matching.

**OUTPUT:**

The realization of `self` as a graph.

**EXAMPLES:**

```python
sage: PerfectMatching([[1,3], [4,2]]).to_graph().edges(sort=True, # needs sage.graphs
   labels=False)
[(1, 3), (2, 4)]
sage: PerfectMatching([[1,4], [3,2]]).to_graph().edges(sort=True, # needs sage.graphs
   labels=False)
[(1, 4), (2, 3)]
sage: PerfectMatching([]).to_graph().edges(sort=True, labels=False)  # needs sage.graphs
[]
```

5.1. Comprehensive Module List 2905
to_noncrossing_set_partition()

Return the noncrossing set partition (on half as many elements) corresponding to the perfect matching if the perfect matching is noncrossing, and otherwise gives an error.

OUTPUT:

The realization of self as a noncrossing set partition.

EXAMPLES:

```
sage: PerfectMatching([[1,3], [4,2]]).to_noncrossing_set_partition()
Traceback (most recent call last):
...
ValueError: matching must be non-crossing
sage: PerfectMatching([[1,4], [3,2]]).to_noncrossing_set_partition()
{(1, 2)}
sage: PerfectMatching([]).to_noncrossing_set_partition()
()
```

```python
>>> from sage.all import *

>>> PerfectMatching([[Integer(1),Integer(3)], [Integer(4),Integer(2)]]).to_noncrossing_set_partition()
Traceback (most recent call last):
...
ValueError: matching must be non-crossing
```

```python
>>> PerfectMatching([[Integer(1),Integer(4)], [Integer(3),Integer(2)]]).to_noncrossing_set_partition()
{(1, 2)}
```

```python
>>> PerfectMatching([]).to_noncrossing_set_partition()
()
```

class sage.combinat.perfect_matching.PerfectMatchings(s)

Bases: SetPartitions_set

Perfect matchings of a ground set.

INPUT:

• s – an iterable of hashable objects or an integer

EXAMPLES:

If the argument s is an integer n, it will be transformed into the set \{1,\ldots,n\}:

```
sage: M = PerfectMatchings(6); M
Perfect matchings of \{1, 2, 3, 4, 5, 6\}
sage: PerfectMatchings([-1, -3, 1, 2])
Perfect matchings of \{1, 2, -3, -1\}
```

```python
>>> from sage.all import *

>>> M = PerfectMatchings(Integer(6)); M
Perfect matchings of \{1, 2, 3, 4, 5, 6\}
```

```python
>>> M = PerfectMatchings(Integer(6)); M
Perfect matchings of \{1, 2, 3, 4, 5, 6\}
```

>>> PerfectMatchings([-Integer(1), -Integer(3), Integer(1), Integer(2)])
Perfect matchings of \{1, 2, -3, -1\}
```

One can ask for the list, the cardinality or an element of a set of perfect matching:

```
sage: PerfectMatchings(4).list()
[[[1, 2], (3, 4)], [[1, 3], (2, 4)], [(1, 4), (2, 3)]]
```

(continues on next page)
sage: PerfectMatchings(8).cardinality()
105
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.an_element()
sage: x # random
[(a, c), (b, e), (d, f)]

sage: all(PerfectMatchings(i).an_element() in PerfectMatchings(i) for i in range(2,11,2))
True

>>> from sage.all import *
>>> PerfectMatchings(Integer(4)).list()
[[[1, 2], [3, 4]], [[1, 3], [2, 4]], [[1, 4], [2, 3]]]
>>> M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
>>> x = M.an_element()
>>> x # random
[(a, c), (b, e), (d, f)]
>>> all(PerfectMatchings(i).an_element() in PerfectMatchings(i) for i in range(Integer(2),Integer(11),Integer(2)))
True

Element

alias of PerfectMatching

Weingarten_matrix(N)

Return the Weingarten matrix corresponding to the set of PerfectMatchings self.

It is a useful theoretical tool to compute polynomial integrals over the orthogonal group \(O_N\) (see [CM]).

EXAMPLES:

sage: M = PerfectMatchings(4).Weingarten_matrix(var('N'))
# needs sage.symbolic
sage: N*(N-1)*(N+2)*M.apply_map(factor)
[ N + 1 -1 -1]
[ -1 N + 1 -1]
[ -1 -1 N + 1]

>>> from sage.all import *
>>> M = PerfectMatchings(Integer(4)).Weingarten_matrix(var('N'))
# needs sage.symbolic
>>> N*(N-Integer(1))*(N+Integer(2))*M.apply_map(factor)
[ N + 1 -1 -1]
[ -1 N + 1 -1]
[ -1 -1 N + 1]

base_set()

Return the base set of self.

EXAMPLES:

sage: PerfectMatchings(3).base_set()
{1, 2, 3}
```python
>>> from sage.all import *
>>> PerfectMatchings(Integer(3)).base_set()
{1, 2, 3}
```

**base_set_cardinality()**

Return the cardinality of the base set of self.

**EXAMPLES:**

```python
sage: PerfectMatchings(3).base_set_cardinality()
3
```

```python
>>> from sage.all import *
>>> PerfectMatchings(Integer(3)).base_set_cardinality()
3
```

**cardinality()**

Return the cardinality of the set of perfect matchings self.

This is $1 \times 3 \times 5 \times \cdots \times (2n - 1)$, where $2n$ is the size of the ground set.

**EXAMPLES:**

```python
sage: PerfectMatchings(8).cardinality()
105
sage: PerfectMatchings([1, 2, 3, 4]).cardinality()
3
sage: PerfectMatchings(3).cardinality()
0
sage: PerfectMatchings([]).cardinality()
1
```

```python
>>> from sage.all import *
>>> PerfectMatchings(Integer(8)).cardinality()
105
>>> PerfectMatchings([Integer(1), Integer(2), Integer(3), Integer(4)]).cardinality()
3
>>> PerfectMatchings(Integer(3)).cardinality()
0
>>> PerfectMatchings([]).cardinality()
1
```

**random_element()**

Return a random element of self.

**EXAMPLES:**

```python
sage: M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
sage: x = M.random_element()
sage: x  # random
[('a', 'b'), ('c', 'd'), ('e', 'f')]
```

```python
>>> from sage.all import *
>>> M = PerfectMatchings(('a', 'e', 'b', 'f', 'c', 'd'))
>>> x = M.random_element()
```

(continues on next page)
>>> list # random
[('a', 'b'), ('c', 'd'), ('e', 'f')]

5.1.172 Permutations

The Permutations module. Use `Permutation?` to get information about the Permutation class, and `Permutations?` to get information about the combinatorial class of permutations.

**Warning:** This file defined `Permutation` which depends upon `CombinatorialElement` despite it being deprecated (see Issue #13742). This is dangerous. In particular, the `Permutation._left_to_right_multiply_on_right()` method (which can be called through multiplication) disables the input checks (see `Permutation()`). This should not happen. Do not trust the results.

What does this file define?

The main part of this file consists in the definition of permutation objects, i.e. the `Permutation()` method and the `Permutation` class. Global options for elements of the permutation class can be set through the `Permutations.options()` object.

Below are listed all methods and classes defined in this file.

**Methods of Permutations objects**

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>left_action_product()</code></td>
<td>Returns the product of <code>self</code> with another permutation, in which the other permutation is applied first.</td>
</tr>
<tr>
<td><code>right_action_product()</code></td>
<td>Returns the product of <code>self</code> with another permutation, in which <code>self</code> is applied first.</td>
</tr>
<tr>
<td><code>size()</code></td>
<td>Returns the size of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>cycle_string()</code></td>
<td>Returns the disjoint-cycles representation of <code>self</code> as string.</td>
</tr>
<tr>
<td><code>next()</code></td>
<td>Returns the permutation that follows <code>self</code> in lexicographic order (in the same symmetric group as <code>self</code>).</td>
</tr>
<tr>
<td><code>prev()</code></td>
<td>Returns the permutation that comes directly before <code>self</code> in lexicographic order (in the same symmetric group as <code>self</code>).</td>
</tr>
<tr>
<td><code>to_tableau_by_shape()</code></td>
<td>Returns a tableau of shape <code>shape</code> with the entries in <code>self</code>.</td>
</tr>
<tr>
<td><code>to_cycles()</code></td>
<td>Returns the permutation <code>self</code> as a list of disjoint cycles.</td>
</tr>
<tr>
<td><code>forget_cycles()</code></td>
<td>Return <code>self</code> under the forget cycle map.</td>
</tr>
<tr>
<td><code>to_permutation_group_element()</code></td>
<td>Returns a <code>PermutationGroupElement</code> equal to <code>self</code>.</td>
</tr>
<tr>
<td><code>signature()</code></td>
<td>Returns the signature of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>is_even()</code></td>
<td>Returns <code>True</code> if the permutation <code>self</code> is even, and <code>False</code> otherwise.</td>
</tr>
<tr>
<td><code>to_matrix()</code></td>
<td>Returns a matrix representing the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>rank()</code></td>
<td>Returns the rank of <code>self</code> in lexicographic ordering (on the symmetric group containing <code>self</code>).</td>
</tr>
<tr>
<td><code>to_inversion_vector()</code></td>
<td>Returns the inversion vector of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>inversions()</code></td>
<td>Returns a list of the inversions of permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>stack_sort()</code></td>
<td>Returns the permutation obtained by sorting <code>self</code> through one stack.</td>
</tr>
<tr>
<td><code>to_digraph()</code></td>
<td>Return a digraph representation of <code>self</code>.</td>
</tr>
<tr>
<td><code>show()</code></td>
<td>Displays the permutation as a drawing.</td>
</tr>
</tbody>
</table>

Table 3 – continued from previous page

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>number_of_inversions()</code></td>
<td>Returns the number of inversions in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>noninversions()</code></td>
<td>Returns the k-noninversions in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>number_of_noninversions()</code></td>
<td>Returns the number of k-noninversions in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>length()</code></td>
<td>Returns the Coxeter length of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>inverse()</code></td>
<td>Returns the inverse of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>ishift()</code></td>
<td>Returns the i-shift of <code>self</code>.</td>
</tr>
<tr>
<td><code>iswitch()</code></td>
<td>Returns the i-switch of <code>self</code>.</td>
</tr>
<tr>
<td><code>runs()</code></td>
<td>Returns a list of the runs in the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>longest_increasing_subsequences_length()</code></td>
<td>Returns the length of the longest increasing subsequences of <code>self</code>.</td>
</tr>
<tr>
<td><code>longest_increasing_subsequences()</code></td>
<td>Returns the list of the longest increasing subsequences of <code>self</code>.</td>
</tr>
<tr>
<td><code>longest_increasing_subsequences_number()</code></td>
<td>Returns the number of longest increasing subsequences</td>
</tr>
<tr>
<td><code>cycle_type()</code></td>
<td>Returns the cycle type of <code>self</code> as a partition of <code>len(self)</code>.</td>
</tr>
<tr>
<td><code>foata_bijection()</code></td>
<td>Returns the image of the permutation <code>self</code> under the Foata bijection $\phi$.</td>
</tr>
<tr>
<td><code>foata_bijection_inverse()</code></td>
<td>Returns the image of the permutation <code>self</code> under the inverse of the Foata bijection $\phi$.</td>
</tr>
<tr>
<td><code>fundamental_transformation()</code></td>
<td>Returns the image of the permutation <code>self</code> under the Renyi-Foata-Schuetzenberger fundamental transformation.</td>
</tr>
<tr>
<td><code>fundamental_transformation_inverse()</code></td>
<td>Returns the image of the permutation <code>self</code> under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.</td>
</tr>
<tr>
<td><code>destandardize()</code></td>
<td>Returns the destandardization of <code>self</code> with respect to weight and ordered alphabet.</td>
</tr>
<tr>
<td><code>to_lehmer_code()</code></td>
<td>Returns the Lehmer code of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>to_lehmer_cocode()</code></td>
<td>Returns the Lehmer cocode of <code>self</code>.</td>
</tr>
<tr>
<td><code>reduced_word()</code></td>
<td>Returns the reduced word of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>reduced_words()</code></td>
<td>Returns a list of the reduced words of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>reduced_words_iterator()</code></td>
<td>An iterator for the reduced words of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>reduced_word_lexmin()</code></td>
<td>Returns a lexicographically minimal reduced word of a permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>fixed_points()</code></td>
<td>Returns a list of the fixed points of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>is_derangement()</code></td>
<td>Returns True if the permutation <code>self</code> is a derangement, and False otherwise.</td>
</tr>
<tr>
<td><code>is_simple()</code></td>
<td>Returns True if the permutation <code>self</code> is simple, and False otherwise.</td>
</tr>
<tr>
<td><code>number_of_fixed_points()</code></td>
<td>Returns the number of fixed points of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>recoils()</code></td>
<td>Returns the list of the recoils of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>number_of_recoils()</code></td>
<td>Returns the number of recoils of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>recoils_composition()</code></td>
<td>Returns the composition corresponding to the recoils of <code>self</code>.</td>
</tr>
<tr>
<td><code>descents()</code></td>
<td>Returns the list of the descents of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>idescents()</code></td>
<td>Returns a list of the idescents of <code>self</code>.</td>
</tr>
<tr>
<td><code>idescents_signature()</code></td>
<td>Returns the list obtained by mapping each position in <code>self</code> to $-1$ if it is an idescent and 1 if it is not an idescent.</td>
</tr>
<tr>
<td><code>number_of_descents()</code></td>
<td>Returns the number of descents of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>number_of_idescents()</code></td>
<td>Returns the number of idescents of the permutation <code>self</code>.</td>
</tr>
<tr>
<td><code>descents_composition()</code></td>
<td>Returns the composition corresponding to the descents of <code>self</code>.</td>
</tr>
<tr>
<td><code>descent_polynomial()</code></td>
<td>Returns the descent polynomial of the permutation <code>self</code>.</td>
</tr>
</tbody>
</table>

<tr>
<td><strong>pattern_positions()</strong></td>
<td>Returns the list of positions where the pattern <code>patt</code> appears in <code>self</code>.</td>
</tr>
<tr>
<td><strong>reverse()</strong></td>
<td>Returns the permutation obtained by reversing the 1-line notation of <code>self</code>.</td>
</tr>
<tr>
<td><strong>complement()</strong></td>
<td>Returns the complement of the permutation which is obtained by replacing each value <code>x</code> in the 1-line notation of <code>self</code> with <code>n - x + 1</code>.</td>
</tr>
<tr>
<td><strong>permutation_poset()</strong></td>
<td>Returns the permutation poset of <code>self</code>.</td>
</tr>
<tr>
<td><strong>dict()</strong></td>
<td>Returns a dictionary corresponding to the permutation <code>self</code>.</td>
</tr>
<tr>
<td><strong>action()</strong></td>
<td>Returns the action of the permutation <code>self</code> on a list.</td>
</tr>
<tr>
<td><strong>robinson_schensted()</strong></td>
<td>Returns the pair of standard tableaux obtained by running the Robinson-Schensted Algorithm on <code>self</code>.</td>
</tr>
<tr>
<td><strong>left_tableau()</strong></td>
<td>Returns the left standard tableau after performing the RSK algorithm.</td>
</tr>
<tr>
<td><strong>right_tableau()</strong></td>
<td>Returns the right standard tableau after performing the RSK algorithm.</td>
</tr>
<tr>
<td><strong>increasing_tree()</strong></td>
<td>Returns the increasing tree of <code>self</code>.</td>
</tr>
<tr>
<td><strong>increasing_tree_shape()</strong></td>
<td>Returns the shape of the increasing tree of <code>self</code>.</td>
</tr>

</table>

**AUTHORS:**

- Mike Hansen
- Dan Drake (2008-04-07): allow Permutation() to take lists of tuples
- Sébastien Labbé (2009-03-17): added robinson_schensted_inverse
- Travis Scrimshaw:
  - (2012-08-16): to_standard() no longer modifies input
- Travis Scrimshaw (2014-02-05): Made StandardPermutations_n a finite Weyl group to make it more uniform with SymmetricGroup. Added ability to compute the conjugacy classes.
- Trevor K. Karn (2022-08-05): Add `Permutation.n_reduced_words()`
Classes and methods

class sage.combinat.permutation.Arrangements

Bases: Permutations

An arrangement of a multiset mset is an ordered selection without repetitions. It is represented by a list that contains only elements from mset, but maybe in a different order.

Arrangements returns the combinatorial class of arrangements of the multiset mset that contain k elements.

EXAMPLES:

```python
sage: mset = [1,1,2,3,4,4,5]
sage: Arrangements(mset, 2).list()  # needs sage.libs.gap
[[1, 1],
 [1, 2],
 [1, 3],
 [1, 4],
 [1, 5],
 [2, 1],
 [2, 3],
 [2, 4],
 [2, 5],
 [3, 1],
 [3, 2],
 [3, 4],
 [3, 5],
 [4, 1],
 [4, 2],
 [4, 3],
 [4, 4],
 [4, 5],
 [5, 1],
 [5, 2],
 [5, 3],
 [5, 4]]
sage: Arrangements(mset, 2).cardinality()  # needs sage.libs.gap
22
sage: Arrangements( ['c','a','t'], 2 ).list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]
sage: Arrangements( ['c','a','t'], 3 ).list()
[['c', 'a', 't'],
 ['c', 't', 'a'],
 ['a', 'c', 't'],
 ['a', 't', 'c'],
 ['t', 'c', 'a'],
 ['t', 'a', 'c']]```

```python
>>> from sage.all import *

>>> mset = [Integer(1),Integer(1),Integer(2),Integer(3),Integer(4),Integer(4),
 Integer(5)]

>>> Arrangements(mset, Integer(2)).list()  # needs sage.libs.gap
[[1, 1],
 [1, 2],
 [1, 3],
 ....
]```

(continues on next page)

```plaintext

[1, 4],
[1, 5],
[2, 1],
[2, 3],
[2, 4],
[2, 5],
[3, 1],
[3, 2],
[3, 4],
[3, 5],
[4, 1],
[4, 2],
[4, 3],
[4, 4],
[4, 5],
[5, 1],
[5, 2],
[5, 3],
[5, 4]

>>> Arrangements(mset, Integer(2)).cardinality()
    → # needs sage.libs.gap
22

>>> Arrangements(["c","a","t"], Integer(2)).list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]

>>> Arrangements(["c","a","t"], Integer(3)).list()
[['c', 'c', 't'],
['c', 't', 'c'],
['a', 'c', 't'],
['a', 't', 'c'],
['t', 'c', 'a'],
['t', 'a', 'c']]

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: A = Arrangements([1,1,2,3,4,4,5], 2)
sage: A.cardinality()
    → needs sage.libs.gap
22

>>> from sage.all import *
>>> A = Arrangements([Integer(1),Integer(1),Integer(2),Integer(3),Integer(4),
    → Integer(4),Integer(5)], Integer(2))
>>> A.cardinality()
    → needs sage.libs.gap
22

class sage.combinat.permutation.Arrangements_msetk(mset, k)

    Bases: Arrangements, Permutations_msetk

    Arrangements of length \(k\) of a multiset \(M\).

class sage.combinat.permutation.Arrangements_setk(s, k)

    Bases: Arrangements, Permutations_setk

    Arrangements of length \(k\) of a set \(S\).
```
class sage.combinat.permutation.CyclicPermutations(mset)

Bases: Permutations_mset

Return the class of all cyclic permutations of mset in cycle notation. These are the same as necklaces.

INPUT:

• mset – A multiset

EXAMPLES:

sage: CyclicPermutations(range(4)).list()  # needs sage.combinat
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
sage: CyclicPermutations([1,1,1]).list()  # needs sage.combinat
[[1, 1, 1]]
>>>
from sage.all import *

>>> CyclicPermutations(range(Integer(4))).list()  # needs sage.combinat
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]

>>> CyclicPermutations([Integer(1),Integer(1),Integer(1)]).list()  # needs sage.combinat
[[1, 1, 1], [1, 1, 1]]

iterator (distinct=False)

EXAMPLES:

sage: CyclicPermutations(range(4)).list()  # indirect doctest  # needs sage.combinat
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
sage: CyclicPermutations([1,1,1]).list()  # needs sage.combinat
[[1, 1, 1]]
sage: CyclicPermutations([1,1,1]).list(distinct=True)  # needs sage.combinat
[[1, 1, 1], [1, 1, 1]]

>>> from sage.all import *

>>> CyclicPermutations(range(Integer(4))).list()  # indirect doctest  # needs sage.combinat
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]

Combinatorics, Release 10.4

(continued from previous page)

```python
[0, 1, 3, 2],
[0, 2, 1, 3],
[0, 2, 3, 1],
[0, 3, 1, 2],
[0, 3, 2, 1]]

>>> CyclicPermutations([Integer(1),Integer(1),Integer(1)]).list()  # needs sage.combinat
[[1, 1, 1]]

>>> CyclicPermutations([Integer(1),Integer(1),Integer(1)]).
list(distinct=True)  # needs sage.combinat
[[1, 1, 1], [1, 1, 1]]

list (distinct=False)

EXAMPLES:

```python
sage: CyclicPermutations(range(4)).list()  # needs sage.combinat
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
```

```python
>>> from sage.all import *

>>> CyclicPermutations(range(Integer(4))).list()  # needs sage.combinat
[[0, 1, 2, 3],
 [0, 1, 3, 2],
 [0, 2, 1, 3],
 [0, 2, 3, 1],
 [0, 3, 1, 2],
 [0, 3, 2, 1]]
```

class sage.combinat.permutation.CyclicPermutationsOfPartition (partition)

Bases: Permutations

Combinations of cyclic permutations of each cell of a given partition.

This is the same as a Cartesian product of necklaces.

EXAMPLES:

```python
sage: CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]]).list()  # needs sage.combinat
[[[1, 2, 3, 4], [5, 6, 7]],
 [[1, 2, 4, 3], [5, 6, 7]],
 [[1, 3, 2, 4], [5, 6, 7]],
 [[1, 3, 4, 2], [5, 6, 7]],
 [[1, 4, 2, 3], [5, 6, 7]],
 [[1, 4, 3, 2], [5, 6, 7]],
 [[1, 2, 3, 4], [5, 7, 6]],
 [[1, 2, 4, 3], [5, 7, 6]],
 [[1, 3, 2, 4], [5, 7, 6]],
 [[1, 3, 4, 2], [5, 7, 6]],
 [[1, 4, 2, 3], [5, 7, 6]],
 [[1, 4, 3, 2], [5, 7, 6]]]
```
>>> from sage.all import *

>>> CyclicPermutationsOfPartition([[Integer(1),Integer(2),Integer(3),Integer(4)],
                                         [Integer(5),Integer(6),Integer(7)]]).list()  # needs sage.
-> combinat
[[[1, 2, 3, 4], [5, 6, 7]],
 [[[1, 2, 4, 3], [5, 6, 7]],
 [[[1, 3, 2, 4], [5, 6, 7]],
 [[[1, 3, 4, 2], [5, 6, 7]],

(continues on next page)
class Element
   Bases: ClonableArray

   A cyclic permutation of a partition.

   check()
   Check that self is a valid element.

   EXAMPLES:

   sage: CP = CyclicPermutationsOfPartition([[1,2,3,4],[5,6,7]])
   sage: elt = CP[0]
   # needs sage.combinat
   sage: elt.check()
   # needs sage.combinat

   >>> from sage.all import *
   >>> CP = CyclicPermutationsOfPartition([Integer(1),Integer(2),Integer(3),
   Integer(4)], [Integer(5),Integer(6),Integer(7)])
   >>> elt = CP[Integer(0)]
   # needs sage.combinat
   >>> elt.check()
   # needs sage.combinat

iterator (distinct=False)

AUTHORS:
   • Robert Miller

```

```python
>>> from sage.combinat.permutation import PatternAvoider
>>> P = Permutations(Integer(4))
>>> p = PatternAvoider(P, [[Integer(1),Integer(2),Integer(3)]]).
```

```python
class sage.combinat.permutation.PatternAvoider (parent, patterns)
    Bases: GenericBacktracker

    EXAMPLES:

    sage: from sage.combinat.permutation import PatternAvoider
    sage: P = Permutations(4)
    sage: p = PatternAvoider(P, [[1,2,3]])
    sage: loads(dumps(p))
    <sage.combinat.permutation.PatternAvoider object at 0x...>

    >>> from sage.all import *
    >>> from sage.combinat.permutation import PatternAvoider
    >>> P = Permutations(Integer(4))
    >>> p = PatternAvoider(P, [[Integer(1),Integer(2),Integer(3)]]).
```

```python
class sage.combinat.permutation.Permutation (parent, l, algorithm='lex', sjt=None, check=True)
    Bases: CombinatorialElement

    A permutation.

    Converts l to a permutation on \{1, 2, \ldots, n\}.

    INPUT:
• 1 – Can be any one of the following:
  – an instance of \textit{Permutation},
  – list of integers, viewed as one-line permutation notation. The construction checks that you give an acceptable entry. To avoid the check, use the \texttt{check} option.
  – string, expressing the permutation in cycle notation.
  – list of tuples of integers, expressing the permutation in cycle notation.
  – a \texttt{PermutationGroupElement}
  – a pair of two standard tableaux of the same shape. This yields the permutation obtained from the pair using the inverse of the Robinson-Schensted algorithm.

• \texttt{check} – boolean (default: \texttt{True}); whether to check that input is correct. Slows the function down, but ensures that nothing bad happens. This is set to \texttt{True} by default.

• \texttt{algorithm} – string (default: \texttt{lex}); the algorithm used to generate the permutations. Supported algorithms are:
  – \texttt{lex}: lexicographic order generation, this is the default algorithm.
  – \texttt{sjt}: Steinhaus-Johnson-Trotter algorithm to generate permutations using only transposition of two elements in the list. It is highly recommended to set \texttt{check=True} (default value).

• \texttt{sjt} – \texttt{SJT} (default: \texttt{None}); the \texttt{SJT} object holding the permutation internal state. This should only be specified when initializing with non-identity permutation.

\textbf{Warning:} Since Issue #13742 the input is checked for correctness: it is not accepted unless it actually is a permutation on \{1,\ldots,n\}. It means that some \texttt{Permutation()} objects cannot be created anymore without setting \texttt{check=False}, as there is no certainty that its functions can handle them, and this should be fixed in a much better way ASAP (the functions should be rewritten to handle those cases, and new tests be added).

\textbf{Warning:} There are two possible conventions for multiplying permutations, and the one currently enabled in Sage by default is the one which has \((pq)(i) = q(p(i))\) for any permutations \(p \in S_n\) and \(q \in S_n\) and any \(1 \leq i \leq n\). (This equation looks less strange when the action of permutations on numbers is written from the right: then it takes the form \(i^{pq} = (i^p)^q\), which is an associativity law). There is an alternative convention, which has \((pq)(i) = p(q(i))\) instead. The conventions can be switched at runtime using \texttt{sage.combinat.permutation.Permutations.options()}. It is best for code not to rely on this setting being set to a particular standard, but rather use the methods \texttt{left_action_product()} and \texttt{right_action_product()} for multiplying permutations (these methods don’t depend on the setting). See Issue #14885 for more details.

\textbf{Note:} The \texttt{bruhat*} methods refer to the strong Bruhat order. To use the \textit{weak} Bruhat order, look under \texttt{permutohedron*}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([2,1]) [2, 1]
sage: Permutation([2, 1, 4, 5, 3]) [2, 1, 4, 5, 3]
sage: Permutation('1,2')
\end{verbatim}

(continues on next page)
sage: Permutation((1,2)(3,4,5))  
[2, 1, 4, 5, 3]

sage: Permutation( ((1,2),(3,4,5)) )  
[2, 1, 4, 5, 3]

sage: Permutation( [(1,2),(3,4,5)] )  
[2, 1, 4, 5, 3]

sage: Permutation( ((1,2)) )  
[2, 1]

sage: Permutation( (1,2) )  
[2, 1]

sage: Permutation( ((1,2),) )  
[2, 1]

sage: Permutation( ((1,),) )  
[1]

sage: Permutation( (1,) )  
[1]

sage: Permutation( () )  
[]

sage: p = Permutation((1, 2, 5)); p  
[2, 5, 3, 4, 1]

sage: type(p)  
<class 'sage.combinat.permutation.StandardPermutations_n_with_category.element_class'>

>>> from sage.all import *

>>> Permutation([Integer(2),Integer(1)])  
[2, 1]

>>> Permutation([Integer(2), Integer(1), Integer(4), Integer(5), Integer(3)])  
[2, 1, 4, 5, 3]

>>> Permutation('1,2')  
[2, 1]

>>> Permutation('(1,2)(3,4,5)')  
[2, 1, 4, 5, 3]

>>> Permutation( ((Integer(1),Integer(2)),(Integer(3),Integer(4),Integer(5))) )  
[2, 1, 4, 5, 3]

>>> Permutation( [(Integer(1),Integer(2)),(Integer(3),Integer(4),Integer(5))] )  
[2, 1, 4, 5, 3]

>>> Permutation( ((Integer(1),Integer(2))) )  
[2, 1]

>>> Permutation( (Integer(1),Integer(2)) )  
[2, 1]

>>> Permutation( (Integer(1),Integer(2),) )  
[2, 1]

>>> Permutation( (Integer(1),),)  
[1]

>>> Permutation( () )  
[]

>>> p = Permutation((Integer(1), Integer(2), Integer(5))); p  
[2, 5, 3, 4, 1]
Generate permutations using the Steinhaus-Johnson Trotter algorithm. The output is not in lexicographic order:

```python
sage: p = Permutation([1, 2, 3, 4], algorithm='sjt'); p
[1, 2, 3, 4]

sage: p = p.next(); p
[1, 2, 4, 3]

sage: p = p.next(); p
[1, 4, 2, 3]

sage: p = Permutation([1, 2, 3], algorithm='sjt')

sage: for _ in range(6):
    ....:     p = p.next()

sage: p
False

sage: Permutation([1, 3, 2, 4], algorithm='sjt')
Traceback (most recent call last):
  ... ValueError: no internal state directions were given for non-identity starting permutation for Steinhaus-Johnson-Trotter algorithm

>>> from sage.all import *
```

Construction from a string in cycle notation:

```python
sage: p = Permutation( (4,5) ); p
[1, 2, 3, 5, 4]

>>> from sage.all import *
```

The size of the permutation is the maximum integer appearing; add a 1-cycle to increase this:
We construct a `Permutation` from a `PermutationGroupElement`:

```python
sage: g = PermutationGroupElement([2,1,3]) # needs sage.groups
sage: Permutation(g) # needs sage.groups
[2, 1, 3]
```

From a pair of tableaux of the same shape. This uses the inverse of the Robinson-Schensted algorithm:

```python
sage: # needs sage.combinat
sage: p = [[1, 4, 7], [2, 5], [3], [6]]
sage: q = [[1, 2, 5], [3, 6], [4], [7]]
sage: P = Tableau(p)
sage: Q = Tableau(q)
sage: Permutation( (p, q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [p, q] )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( (P, Q) )
[3, 6, 5, 2, 7, 4, 1]
sage: Permutation( [P, Q] )
[3, 6, 5, 2, 7, 4, 1]
```

(continues on next page)
RS_partition()

Return the shape of the tableaux obtained by applying the RSK algorithm to self.

EXAMPLES:

```
sage: Permutation([1,4,3,2]).RS_partition()  # needs sage.combinat
[2, 1, 1]
```

absolute_length()

Return the absolute length of self

The absolute length is the length of the shortest expression of the element as a product of reflections.

For permutations in the symmetric groups, the absolute length is the size minus the number of its disjoint cycles.

EXAMPLES:

```
sage: Permutation([4,2,3,1]).absolute_length()  # needs sage.combinat
1
```

action(a)

Return the action of the permutation self on a list a.

The action of a permutation \( p \in S_n \) on an \( n \)-element list \( (a_1, a_2, \ldots, a_n) \) is defined to be \( (a_{p(1)}, a_{p(2)}, \ldots, a_{p(n)}) \).

EXAMPLES:

```
sage: p = Permutation([2,1,3])
sage: a = list(range(3))
sage: p.action(a)
[1, 0, 2]
sage: b = [1,2,3,4]
sage: p.action(b)
Traceback (most recent call last):
...
ValueError: len(a) must equal len(self)
sage: q = Permutation([2,3,1])
```
sage: a = list(range(3))
sage: q.action(a)
[1, 2, 0]

>>> from sage.all import *

>>> p = Permutation([Integer(2), Integer(1), Integer(3)])
>>> a = list(range(Integer(3)))
>>> p.action(a)
[1, 0, 2]

>>> b = [Integer(1), Integer(2), Integer(3), Integer(4)]
>>> p.action(b)
Traceback (most recent call last):
...
ValueError: len(a) must equal len(self)

>>> q = Permutation([Integer(2), Integer(3), Integer(1)])
>>> a = list(range(Integer(3)))
>>> q.action(a)
[1, 2, 0]

avoid(patt)

Test whether the permutation self avoids the pattern patt.

EXAMPLES:

sage: Permutation([6,2,5,4,3,1]).avoids([4,2,3,1])  # needs sage.combinat
False

sage: Permutation([6,1,2,5,4,3]).avoids([4,2,3,1])  # needs sage.combinat
True

sage: Permutation([6,1,2,5,4,3]).avoids([3,4,1,2])  # needs sage.combinat
True

>>> from sage.all import *

>>> Permutation([Integer(6),Integer(2),Integer(5),Integer(4),Integer(3),
Integer(1)]).avoids([Integer(4),Integer(2),Integer(3),Integer(1)])  # needs sage.combinat
False

>>> Permutation([Integer(6),Integer(1),Integer(2),Integer(5),Integer(4),
Integer(3)]).avoids([Integer(4),Integer(2),Integer(3),Integer(1)])  # needs sage.combinat
True

>>> Permutation([Integer(6),Integer(1),Integer(2),Integer(5),Integer(4),
Integer(3)]).avoids([Integer(3),Integer(4),Integer(1),Integer(2)])  # needs sage.combinat
True

binary_search_tree(left_to_right=True)

Return the binary search tree associated to self.

If w is a word, then the binary search tree associated to w is defined as the result of starting with an empty binary tree, and then inserting the letters of w one by one into this tree. Here, the insertion is being done according to the method binary_search_insert(), and the word w is being traversed from left to right.
A permutation is regarded as a word (using one-line notation), and thus a binary search tree associated to a permutation is defined.

If the optional keyword variable `left_to_right` is set to `False`, the word $w$ is being traversed from right to left instead.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).binary_search_tree()  # needs sage.graphs
1[., 4[3[., .], .], .]
sage: Permutation([4,1,3,2]).binary_search_tree()  # needs sage.graphs
4[1[., 3[., .], .], .]
```

By passing the option `left_to_right=False` one can have the insertion going from right to left:

```python
sage: Permutation([1,4,3,2]).binary_search_tree(False)  # needs sage.graphs
2[1[., .], 3[., 4[., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree(False)  # needs sage.graphs
2[1[., .], 3[., 4[., .]]]
```

```python
>>> from sage.all import *

>>> Permutation([1,4,3,2]).binary_search_tree_shape()  # needs sage.graphs
[., [[[., .], .], .]]
```

**binary_search_tree_shape** (*left_to_right=True*)

Return the shape of the binary search tree of the permutation (a non labelled binary tree).

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).binary_search_tree_shape()  # needs sage.graphs
[., [[[., .], .], .]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape()  # needs sage.graphs
[[[., .], .], .]
```

```python
>>> from sage.all import *

>>> Permutation([1,4,3,2]).binary_search_tree_shape()  # needs sage.graphs
[., [[[., .], .], .]]
>>> Permutation([4,1,3,2]).binary_search_tree_shape()  # needs sage.graphs
[[[., .], .], .]
```

(continues on next page)
By passing the option `left_to_right=False` one can have the insertion going from right to left:

```python
sage: Permutation([1,4,3,2]).binary_search_tree_shape(False)  # needs sage.graphs
[[., .], [., [., .]]]
sage: Permutation([4,1,3,2]).binary_search_tree_shape(False)  # needs sage.graphs
[[., .], [., [., .]]]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).binary_search_tree_shape(False)  # needs sage.graphs
[[., .], [., [., .]]]
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).binary_search_tree_shape(False)  # needs sage.graphs
[[., .], [., [., .]]]
```

`bruhat_greater()`

Return the combinatorial class of permutations greater than or equal to `self` in the Bruhat order (on the symmetric group containing `self`).

See `bruhat_lequal()` for the definition of the Bruhat order.

EXAMPLES:

```python
sage: Permutation([4,1,2,3]).bruhat_greater().list()  # needs sage.graphs
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3)]).bruhat_greater().list()  # needs sage.graphs
[[4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```

`bruhat_inversions()`

Return the list of inversions of `self` such that the application of this inversion to `self` decreases its number of inversions by exactly 1.

Equivalently, it returns the list of pairs `(i, j)` such that `i < j`, such that `p(i) > p(j)` and such that there exists no `k` (strictly) between `i` and `j` satisfying `p(i) > p(k) > p(j)`.

EXAMPLES:

```python
sage: Permutation([4,1,2,3]).bruhat_inversions()  # needs sage.graphs
[[1, 2], [1, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```
sage: Permutation([5,2,3,4,1]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: Permutation([6,1,4,5,2,3]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]

>>> from sage.all import *
>>> Permutation([Integer(5),Integer(2),Integer(3),Integer(4),Integer(1)]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
>>> Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2),Integer(3)]).bruhat_inversions()
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]

bruhat_inversions_iterator()
Return the iterator for the inversions of self such that the application of this inversion to self decreases its number of inversions by exactly 1.

EXAMPLES:

sage: list(Permutation([5,2,3,4,1]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
sage: list(Permutation([6,1,4,5,2,3]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]

>>> from sage.all import *
>>> list(Permutation([Integer(5),Integer(2),Integer(3),Integer(4),Integer(1)]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [1, 4], [2, 4], [3, 4]]
>>> list(Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2),Integer(3)]).bruhat_inversions_iterator())
[[0, 1], [0, 2], [0, 3], [2, 4], [2, 5], [3, 4], [3, 5]]

bruhat_lequal(p2)
Return True if self is less or equal to p2 in the Bruhat order.

The Bruhat order (also called strong Bruhat order or Chevalley order) on the symmetric group \( S_n \) is the partial order on \( S_n \) determined by the following condition: If \( p \) is a permutation, and \( i \) and \( j \) are two indices satisfying \( p(i) > p(j) \) and \( i < j \) (that is, \((i, j)\) is an inversion of \( p \) with \( i < j \)), then \( p \circ (i, j) \) (the permutation obtained by first switching \( i \) with \( j \) and then applying \( p \)) is smaller than \( p \) in the Bruhat order.

One can show that a permutation \( p \in S_n \) is less or equal to a permutation \( q \in S_n \) in the Bruhat order if and only if for every \( i \in \{0,1,\ldots,n\} \) and \( j \in \{1,2,\ldots,n\} \), the number of the elements among \( p(1), p(2), \ldots, p(j) \) that are greater than \( i \) is \( \leq \) to the number of the elements among \( q(1), q(2), \ldots, q(j) \) that are greater than \( i \).

This method assumes that self and p2 are permutations of the same integer \( n \).

EXAMPLES:

sage: Permutation([2,4,3,1]).bruhat_lequal(Permutation([3,4,2,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([3,1,2]))
True
sage: Permutation([2,1,3]).bruhat_lequal(Permutation([1,2,3]))
(continues on next page)
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,1,3]))
False
sage: Permutation([1,3,2]).bruhat_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,3,1]).bruhat_lequal(Permutation([1,3,2]))
False
sage: sorted([len([b for b in Permutations(3) if a.bruhat_lequal(b)])
.... for a in Permutations(3)])
[1, 2, 2, 4, 4, 6]
sage: Permutation([]).bruhat_lequal(Permutation([]))
True

>>> from sage.all import *
>>> Permutation([Integer(2),Integer(4),Integer(3),Integer(1)]).bruhat_lequal(Permutation([Integer(3),Integer(4),Integer(2),Integer(1)]))
True
>>> Permutation([Integer(2),Integer(1),Integer(3)]).bruhat_lequal(Permutation([Integer(3),Integer(4),Integer(2),Integer(1)]))
True
>>> Permutation([Integer(2),Integer(1),Integer(3)]).bruhat_lequal(Permutation([Integer(1),Integer(2),Integer(3)]))
False
>>> Permutation([Integer(1),Integer(3),Integer(2)]).bruhat_lequal(Permutation([Integer(1),Integer(2),Integer(3)]))
False
>>> Permutation([Integer(1),Integer(3),Integer(2)]).bruhat_lequal(Permutation([Integer(1),Integer(2),Integer(3)]))
True
>>> Permutation([Integer(2),Integer(3),Integer(1)]).bruhat_lequal(Permutation([Integer(1),Integer(3),Integer(2)]))
False
>>> sorted([len([b for b in Permutations(Integer(3)) if a.bruhat_lequal(b)])
... for a in Permutations(Integer(3))])
[1, 2, 2, 4, 4, 6]
>>> Permutation([]).bruhat_lequal(Permutation([]))
True

bruhat_pred()

Return a list of the permutations strictly smaller than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See bruhat_lequal() for the definition of the Bruhat order.

EXAMPLES:
sage: Permutation([6,1,4,5,2,3]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],

(continues on next page)
\[ \{6, 1, 3, 5, 2, 4\}, \]
\[ \{6, 1, 4, 2, 5, 3\}, \]
\[ \{6, 1, 4, 3, 2, 5\} \]

```python
>>> from sage.all import *

>>> Permutation([Integer(6),Integer(1),Integer(4),Integer(5),Integer(2), Integer(3)]).bruhat_pred()
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

**bruhat_pred_iterator()**

An iterator for the permutations strictly smaller than self in the Bruhat order (on the symmetric group containing self) such that there is no permutation between one of those and self.

See **bruhat_lequal()** for the definition of the Bruhat order.

**EXAMPLES:**

```python
sage: [x for x in Permutation([6,1,4,5,2,3]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

```python
>>> from sage.all import *

>>> [x for x in Permutation([Integer(6),Integer(1),Integer(4),Integer(5), Integer(2), Integer(3)]).bruhat_pred_iterator()]
[[1, 6, 4, 5, 2, 3],
 [4, 1, 6, 5, 2, 3],
 [5, 1, 4, 6, 2, 3],
 [6, 1, 2, 5, 4, 3],
 [6, 1, 3, 5, 2, 4],
 [6, 1, 4, 2, 5, 3],
 [6, 1, 4, 3, 2, 5]]
```

**bruhat_smaller()**

Return the combinatorial class of permutations smaller than or equal to self in the Bruhat order (on the symmetric group containing self).

See **bruhat_lequal()** for the definition of the Bruhat order.

**EXAMPLES:**

```python
sage: Permutation([4,1,2,3]).bruhat_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [1, 4, 3, 2],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 3, 1, 4],
 [2, 3, 4, 1],
 [2, 4, 1, 3],
 [2, 4, 3, 1],
 [3, 1, 2, 4],
 [3, 1, 4, 2],
 [3, 2, 1, 4],
 [3, 2, 4, 1],
 [3, 4, 1, 2],
 [3, 4, 2, 1],
 [4, 1, 2, 3],
 [4, 1, 3, 2],
 [4, 2, 1, 3],
 [4, 2, 3, 1],
 [4, 3, 1, 2],
 [4, 3, 2, 1]]
```
Combinatorics, Release 10.4

(continued from previous page)

```
[2, 1, 3, 4],
[2, 1, 4, 3],
[3, 1, 2, 4],
[4, 1, 2, 3]]
```

```python
>>> from sage.all import *

Permutation([Integer(4), Integer(1), Integer(2), Integer(3)]).bruhat_succ_smaller().list()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 3, 2, 4],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [3, 1, 2, 4],
 [4, 1, 2, 3]]
```

**bruhat_succ()**

Return a list of the permutations strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See **bruhat_lequal()** for the definition of the Bruhat order.

**EXAMPLES:**

```
sage: Permutation([6, 1, 4, 5, 2, 3]).bruhat_succ()
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

```python
>>> from sage.all import *

Permutation([Integer(6), Integer(1), Integer(4), Integer(5), Integer(2), Integer(3)]).bruhat_suc
```

```
[6, 4, 1, 5, 2, 3],
[6, 2, 4, 5, 1, 3],
[6, 1, 5, 4, 2, 3],
[6, 1, 4, 5, 3, 2]]
```

**bruhat_succ_iterator()**

An iterator for the permutations that are strictly greater than `self` in the Bruhat order (on the symmetric group containing `self`) such that there is no permutation between one of those and `self`.

See **bruhat_lequal()** for the definition of the Bruhat order.

**EXAMPLES:**

```
sage: [x for x in Permutation([6, 1, 4, 5, 2, 3]).bruhat_succ_iterator()]
[[6, 4, 1, 5, 2, 3],
 [6, 2, 4, 5, 1, 3],
 [6, 1, 5, 4, 2, 3],
 [6, 1, 4, 5, 3, 2]]
```

```python
>>> from sage.all import *

[x for x in Permutation([Integer(6), Integer(1), Integer(4), Integer(5), Integer(2), Integer(3)]).bruhat_suc
```
complement()  
Return the complement of the permutation self.

The complement of a permutation $w \in S_n$ is defined as the permutation in $S_n$ sending each $i$ to $n+1-w(i)$.

EXAMPLES:

```
sage: Permutation([1,2,3]).complement()
[3, 2, 1]
sage: Permutation([1, 3, 2]).complement()
[3, 1, 2]
```

>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).complement()
[3, 2, 1]
>>> Permutation([Integer(1), Integer(3), Integer(2)]).complement()
[3, 1, 2]

cycle_string(singletons=False)

Return a string of the permutation in cycle notation.

If singletons=True, it includes 1-cycles in the string.

EXAMPLES:

```
sage: Permutation([1,2,3]).cycle_string() ''
sage: Permutation([2,1,3]).cycle_string() ''(1,2)''
sage: Permutation([2,3,1]).cycle_string() ''(1,2,3)''
sage: Permutation([2,1,3]).cycle_string(singletons=True) ''(1,2)(3)''
```

>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).cycle_string() ''
>>> Permutation([Integer(2),Integer(1),Integer(3)]).cycle_string() ''(1,2)''
>>> Permutation([Integer(2),Integer(1),Integer(3)]).cycle_string() ''(1,2,3)''
>>> Permutation([Integer(2),Integer(1),Integer(3)]).cycle_string() ''string(singletons=True)''
''(1,2)(3)''

cycle_tuples(singletons=True, use_min=True)

Return the permutation self as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If singletons=False is given, the list does not contain the singleton cycles.
If \texttt{use\_min=False} is given, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element.

**EXAMPLES:**

```python
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]
sage: Permutation([2,1,3,4]).to_cycles(use\_min=True)
[(1, 2), (3,), (4,)]
sage: Permutation([2,1,3,4]).to_cycles(use\_min=False)
[(4,), (3,), (2, 1)]
sage: Permutation([2,1,3,4]).to_cycles(singletons=False, use\_min=False)
[(2, 1)]
sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]
sage: Permutation([4,1,5,2,6,3]).to_cycles(use\_min=False)
[(6, 3, 5), (4, 2, 1)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles()
[(1, 6), (2, 4), (3, 5)]
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles(use\_min=False)
[(6, 1), (5, 3), (4, 2)]
```

The algorithm is of complexity \(O(n)\) where \(n\) is the size of the given permutation.

\texttt{cycle\_type()}
Return a partition of \( \text{len}(\text{self}) \) corresponding to the cycle type of \( \text{self} \).

This is a non-increasing sequence of the cycle lengths of \( \text{self} \).

**EXAMPLES:**

```python
sage: Permutation([3,1,2,4]).cycle_type() # needs sage.combinat
[3, 1]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(1),Integer(2),Integer(4)]).cycle_type() # needs sage.combinat
[3, 1]
```

decreasing_runs \((\text{as\_tuple} = \text{False})\)

Decreasing runs of the permutation.

**INPUT:**
- `as_tuple` – boolean (default: \text{False}) choice of output format

**OUTPUT:**
- a list of lists or a tuple of tuples

**See also:**
- `runs()`

**EXAMPLES:**

```python
sage: s = Permutation([2,8,3,9,6,4,5,1,7])
sage: s.decreasing_runs()
[[2], [8, 3], [9, 6, 4], [5, 1], [7]]
sage: s.decreasing_runs(as_tuple=True)
((2,), (8, 3), (9, 6, 4), (5, 1), (7,))
```

```python
>>> from sage.all import *
>>> s = Permutation([Integer(2),Integer(8),Integer(3),Integer(9),Integer(6), Integer(4),Integer(5),Integer(1),Integer(7)])
>>> s.decreasing_runs()([[2], [8, 3], [9, 6, 4], [5, 1], [7]])
>>> s.decreasing_runs(as_tuple=True)((2,), (8, 3), (9, 6, 4), (5, 1), (7,))
```

descent_polynomial()

Return the descent polynomial of the permutation \( \text{self} \).

The descent polynomial of a permutation \( p \) is the product of all the \( z[p(i)] \) where \( i \) ranges over the descents of \( p \).

A descent of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(i+1) \).

**REFERENCES:**
- [GS1984]

**EXAMPLES:**
Todo: This docstring needs to be fixed. First, the definition does not match the implementation (or the examples). Second, this doesn’t seem to be defined in [GS1984] (the descent monomial in their (7.23) is different).

**descents** *(final_descent=False, side='right', positive=False, from_zero=False, index_set=None)*

Return the list of the descents of *self*.

A descent of a permutation *p* is an integer *i* such that *p*(i) > *p*(i + 1).

**Warning:** By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword from_zero to True.

**INPUT:**

- final_descent – boolean (default False); if True, the last position of a non-empty permutation is also considered as a descent
- side – 'right' (default) or 'left'; if 'left', return the descents of the inverse permutation
- positive – boolean (default False); if True, return the positions that are not descents
- from_zero – boolean (default False); if True, return the positions starting from 0
- index_set – list (default: [1, ..., n-1] where *self* is a permutation of *n*); the index set to check for descents

**EXAMPLES:**

```python
sage: Permutation([3,1,2]).descents()
[1]
sage: Permutation([1,4,3,2]).descents()
[2, 3]
sage: Permutation([1,4,3,2]).descents(final_descent=True)
[2, 3, 4]
sage: Permutation([1,4,3,2]).descents(index_set=[1,2])
[2]
sage: Permutation([1,4,3,2]).descents(from_zero=True)
[1, 2]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(1),Integer(2)]).descents()
[1]
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).descents() # continues on next page
```
Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).descents(final_descent=True)
[2, 3, 4]
Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).descents(index_set=[Integer(1), Integer(2)])
[2]
Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).descents(from_zero=True)
[1, 2]

**descents_composition()**

Return the descent composition of self.

The descent composition of a permutation $p \in S_n$ is defined as the composition of $n$ whose descent set equals the descent set of $p$. Here, the descent set of $p$ is defined as the set of all $i \in \{1, 2, \ldots, n-1\}$ satisfying $p(i) > p(i+1)$. The descent set of a composition $c = (i_1, i_2, \ldots, i_k)$ is defined as the set $\{i_1, i_1 + i_2, i_1 + i_2 + i_3, \ldots, i_1 + i_2 + \cdots + i_{k-1}\}$.

**EXAMPLES:**

```
sage: Permutation([1,3,2,4]).descents_composition()
[2, 2]
sage: Permutation([4,1,6,7,2,3,8,5]).descents_composition()
[1, 3, 3, 1]
sage: Permutation([]).descents_composition()
[]
```

```python
from sage.all import *
```

```
Permutation([Integer(1), Integer(3), Integer(2), Integer(4)]).descents_composition()
[2, 2]
Permutation([Integer(4), Integer(1), Integer(6), Integer(7), Integer(2),
Integer(3), Integer(8), Integer(5)]).descents_composition()
[1, 3, 3, 1]
Permutation([]).descents_composition()
[]
```

destandardize(weight, ordered_alphabet=None)

Return destandardization of self with respect to weight and ordered_alphabet.

**INPUT:**

- weight – list or tuple of nonnegative integers that sum to $n$ if self is a permutation in $S_n$.
- ordered_alphabet – (default: None) a list or tuple specifying the ordered alphabet the destandardized word is over

**OUTPUT:** word over the ordered_alphabet which standardizes to self

Let $weight = (w_1, w_2, \ldots, w_d)$. Then this method looks for an increasing sequence of $1, 2, \ldots, w_1$ and labels all letters in it by 1, then an increasing sequence of $w_1 + 1, w_1 + 2, \ldots, w_1 + w_2$ and labels all these letters by 2, etc. If an increasing sequence for the specified weight does not exist, an error is returned. The output is a word $w$ over the specified ordered alphabet with evaluation $weight$ such that $w$.standard_permutation() is self.

**EXAMPLES:**
Combinatorics, Release 10.4

sage: p = Permutation([1,2,5,3,6,4])
sage: p.destandardize([3,1,2])  # needs sage.combinat
word: 113132
sage: p = Permutation([2,1,3])
sage: p.destandardize([2,1])
Traceback (most recent call last):
  ... ValueError: Standardization with weight [2, 1] is not possible!

>>> from sage.all import *
>>> p = Permutation([Integer(1),Integer(2),Integer(5),Integer(3),Integer(6), Integer(4)])
>>> p.destandardize([Integer(3),Integer(1),Integer(2)])  # needs sage.combinat
word: 113132
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> p.destandardize([Integer(2),Integer(1)])
Traceback (most recent call last):
  ... ValueError: Standardization with weight [2, 1] is not possible!

\textbf{dict}()\

Return a dictionary corresponding to the permutation.

\textbf{EXAMPLES:}

sage: p = Permutation([2,1,3])
sage: d = p.dict()
sage: d[1]
2
sage: d[2]
1
sage: d[3]
3

>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> d = p.dict()
>>> d[Integer(1)]
Integer(2)
>>> d[Integer(2)]
Integer(1)
>>> d[Integer(3)]
Integer(3)

\textbf{fixed_points}()\

Return a list of the fixed points of \texttt{self}.

\textbf{EXAMPLES:}

sage: Permutation([1,3,2,4]).fixed_points() [1, 4]
sage: Permutation([1,2,3,4]).fixed_points() [1, 2, 3, 4]
>>> from sage.all import *

>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4)]).fixed_points()
[1, 4]

>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4)]).fixed_points()
[1, 2, 3, 4]

**foata_bijection()**

Return the image of the permutation `self` under the Foata bijection \( \phi \).

The bijection shows that \( \text{maj} \) (the major index) and \( \text{inv} \) (the number of inversions) are equidistributed: if \( \phi(P) = Q \), then \( \text{maj}(P) = \text{inv}(Q) \).

The Foata bijection \( \phi \) is a bijection on the set of words with no two equal letters. It can be defined by induction on the size of the word: Given a word \( w_1w_2\cdots w_n \), start with \( \phi(w_1) = w_1 \). At the \( i \)-th step, if \( \phi(w_1w_2\cdots w_i) = v_1v_2\cdots v_i \), we define \( \phi(w_1w_2\cdots w_iw_{i+1}) \) by placing \( w_{i+1} \) on the end of the word \( v_1v_2\cdots v_i \) and breaking the word up into blocks as follows. If \( w_{i+1} > v_i \), place a vertical line to the right of each \( v_k \) for which \( w_{i+1} > v_k \). Otherwise, if \( w_{i+1} < v_i \), place a vertical line to the right of each \( v_k \) for which \( w_{i+1} < v_k \). In either case, place a vertical line at the start of the word as well. Now, within each block between vertical lines, cyclically shift the entries one place to the right.

For instance, to compute \( \phi([1, 4, 2, 5, 3]) \), the sequence of words is

- 1,
- \( |1\)4 \( \rightarrow \) 14,
- \( |4\)2 \( \rightarrow \) 412,
- \( |4\)125 \( \rightarrow \) 4125,
- \( |4\)1253 \( \rightarrow \) 45123.

So \( \phi([1, 4, 2, 5, 3]) = [4, 5, 1, 2, 3] \).

See section 2 of [FS1978], and the proof of Proposition 1.4.6 in [EnumComb1].

See also:

- **foata_bijection_inverse()** for the inverse map.

**EXAMPLES:**

```python
sage: Permutation([1,2,4,3]).foata_bijection()
[4, 1, 2, 3]

sage: Permutation([2,5,1,3,4]).foata_bijection()
[2, 1, 3, 5, 4]

sage: P = Permutation([2,5,1,3,4])

sage: P.major_index() == P.foata_bijection().number_of_inversions()
True

sage: all( P.major_index() == P.foata_bijection().number_of_inversions() 
    ....:     for P in Permutations(4) )
True
```

>>> from sage.all import *

>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4)]).foata_bijection()
[4, 1, 2, 3]

>>> Permutation([Integer(2),Integer(5),Integer(1),Integer(3),Integer(4)]).foata_bijection()
[2, 1, 3, 5, 4]
```

(continues on next page)
\[ [2, 1, 3, 5, 4] \]
\[
>>> P = \text{Permutation([Integer(2),Integer(5),Integer(1),Integer(3),Integer(4)])}
>>> P.major_index() == P.foata_bijection().number_of_inversions()
True
>>> all( P.major_index() == P.foata_bijection().number_of_inversions() ...
... for P in \text{Permutations(Integer(4))} )
True
\]

The example from [FS1978]:

\[
\text{sage: } \text{Permutation([7,4,9,2,6,1,5,8,3]).foata_bijection()}
[4, 7, 2, 6, 1, 9, 5, 8, 3]
\]
\[
>>> \text{from sage.all import *}
>>> \text{Permutation([Integer(7),Integer(4),Integer(9),Integer(2),Integer(6),}
\rightarrow \text{Integer(1),Integer(5),Integer(8),Integer(3)]).foata_bijection()}
[4, 7, 2, 6, 1, 9, 5, 8, 3]
\]

Border cases:

\[
\text{sage: } \text{Permutation([]).foata_bijection()}
[]
\text{sage: } \text{Permutation([1]).foata_bijection()}
[1]
\]
\[
>>> \text{from sage.all import *}
>>> \text{Permutation([]).foata_bijection()}
[]
>>> \text{Permutation([Integer(1)]).foata_bijection()}
[1]
\]

\text{foata_bijection_inverse()}

Return the image of the permutation \text{self} under the inverse of the Foata bijection \( \phi \).

See \text{foata_bijection()} for the definition of the Foata bijection.

\text{EXAMPLES:}

\[
\text{sage: } \text{Permutation([4, 1, 2, 3]).foata_bijection()}
[1, 2, 4, 3]
\]
\[
>>> \text{from sage.all import *}
>>> \text{Permutation([Integer(4), Integer(1), Integer(2), Integer(3)]).foata_}
\rightarrow \text{bijection()}
[1, 2, 4, 3]
\]

\text{forget_cycles()}

Return the image of \text{self} under the map which forgets cycles.

Consider a permutation \( \sigma \) written in standard cyclic form:

\[
\sigma = (a_{1,1}, \ldots, a_{1,k_1})(a_{2,1}, \ldots, a_{2,k_2}) \cdots (a_{m,1}, \ldots, a_{m,k_m}),
\]
where $a_{1,1} < a_{2,1} < \cdots < a_{m,1}$ and $a_{j,1} < a_{j,i}$ for all $1 \leq j \leq m$ and $2 \leq i \leq k_j$ where we include cycles of length 1 as well. The image of the forget cycle map $\phi$ is given by

$$\phi(\sigma) = [a_{1,1}, \ldots, a_{1,k_1}, a_{2,1}, \ldots, a_{2,k_2}, \ldots, a_{m,1}, \ldots, a_{m,k_m}]$$

considered as a permutation in 1-line notation.

See also:

* `fundamental_transformation()`, which is a similar map that is defined by instead taking $a_{j,1} > a_{j,i}$ and is bijective.

**EXAMPLES:**

```sage
sage: P = Permutations(5)
sage: x = P([1, 5, 3, 4, 2])
sage: x.forget_cycles()
[1, 2, 5, 3, 4]
```

```sage
>>> from sage.all import *
>>>
P = Permutations(Integer(5))
>>>
x = P([Integer(1), Integer(5), Integer(3), Integer(4), Integer(2)])
>>>
x.forget_cycles()
[1, 2, 5, 3, 4]
```

We select all permutations with a cycle composition of $[2, 3, 1]$ in $S_6$:

```sage
sage: P = Permutations(6)
sage: l = [p for p in P if [len(t) for t in p.to_cycles()] == [1,3,2]]
```

```sage
>>> from sage.all import *
>>>
P = Permutations(Integer(6))
>>>
l = [p for p in P if [len(t) for t in p.to_cycles()] == [Integer(1), Integer(3), Integer(2)]]
```

Next we apply $\phi$ and then take the inverse, and then view the results as a poset under the Bruhat order:

```sage
sage: B = Poset([[1, lambda x,y: x.bruhat_lequal(y)]])
```

```sage
# needs sage.combinat sage.graphs
sage: B.rank_function()(x) for x in B)
```

```sage
# needs sage.combinat sage.graphs
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
```

We check the statement in [CC2013] that the posets $C_{[1,3,1,1]}$ and $C_{[1,3,2]}$ are isomorphic:
fundamental_transformation()

Return the image of the permutation self under the Renyi-Foata-Schuetzenberger fundamental transformation.

The fundamental transformation is a bijection from the set of all permutations of \{1, 2, \ldots, n\} to itself, which transforms any such permutation \(w\) as follows: Write \(w\) in cycle form, with each cycle starting with its highest element, and the cycles being sorted in increasing order of their highest elements. Drop the parentheses in the resulting expression, thus reading it as a one-line notation of a new permutation \(u\). Then, \(u\) is the image of \(w\) under the fundamental transformation.

See [EnumComb1], Proposition 1.3.1.

See also:

fundamental_transformation_inverse() for the inverse map.

forget_cycles() for a similar (but non-bijective) map where each cycle is starting from its lowest element.

EXAMPLES:

```python
sage: Permutation([5, 1, 3, 4, 2]).fundamental_transformation()
[3, 4, 5, 2, 1]
sage: Permutations(5)([1, 5, 3, 4, 2]).fundamental_transformation()
[1, 3, 4, 5, 2]
sage: Permutation([8, 4, 7, 2, 9, 6, 5, 1, 3]).fundamental_transformation()
[4, 2, 6, 8, 1, 9, 3, 7, 5]
```
\[ \rightarrow \text{transformation}(\) [4, 2, 6, 8, 1, 9, 3, 7, 5] \]

Comparison with \textit{forget_cycles}():

\begin{verbatim}
sage: P = Permutation(((1,3,4),(2,5)))
sage: P
[3, 5, 4, 1, 2]
sage: P.forget_cycles()
[1, 3, 4, 2, 5]
sage: P.fundamental_transformation()
[4, 1, 3, 5, 2]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> P = Permutation((Integer(1),Integer(3),Integer(4)),(Integer(2), Integer(5)))
>>> P
[3, 5, 4, 1, 2]
>>> P.forget_cycles()
[1, 3, 4, 2, 5]
>>> P.fundamental_transformation()
[4, 1, 3, 5, 2]
\end{verbatim}

\textbf{fundamental_transformation\_inverse}()

Return the image of the permutation \texttt{self} under the inverse of the Renyi-Foata-Schuetzenberger fundamental transformation.

The inverse of the fundamental transformation is a bijection from the set of all permutations of \(\{1, 2, \ldots, n\}\) to itself, which transforms any such permutation \(w\) as follows: Let \(I = \{i_1 < i_2 < \cdots < i_k\}\) be the set of all left-to-right maxima of \(w\) (that is, of all indices \(j\) such that \(w(j)\) is bigger than each of \(w(1), w(2), \ldots, w(j-1)\)). The image of \(w\) under the inverse of the fundamental transformation is the permutation \(u\) that sends \(w(i-1)\) to \(w(i)\) for all \(i \not\in I\) (notice that this makes sense, since \(1 \in I\) whenever \(n > 0\), while sending each \(w(i_p - 1)\) (with \(p \geq 2\)) to \(w(i_{p-1})\). Here, we set \(i_{k+1} = n + 1\).

See [EnumComb1], Proposition 1.3.1.

See also: \textit{fundamental_transformation}() for the inverse map.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Permutation([3, 4, 5, 2, 1]).fundamental_transformation\_inverse()
[5, 1, 3, 4, 2]
sage: Permutation([4, 2, 6, 8, 1, 9, 3, 7, 5]).fundamental_transformation\_inverse()
[8, 4, 7, 2, 9, 6, 5, 1, 3]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> Permutation((Integer(3), Integer(4), Integer(5), Integer(2), Integer(1))).
>>> fundamental_transformation\_inverse()
[5, 1, 3, 4, 2]
>>> Permutation((Integer(4), Integer(2), Integer(6), Integer(8), Integer(1),
>>> Integer(9), Integer(3), Integer(7), Integer(5))).fundamental_transformation\_inverse()
[8, 4, 7, 2, 9, 6, 5, 1, 3]
\end{verbatim}
grade()

Return the size of self.

EXAMPLES:

```
sage: Permutation([3,4,1,2,5]).size()
5
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(4),Integer(1),Integer(2),Integer(5)]).size()
5
```

has_nth_root(n)

Check if self has n-th roots.

An n-th root of the permutation \(\sigma\) is a permutation \(\gamma\) such that \(\gamma^n = \sigma\).

Note that the number of \(n\)-th roots only depends on the cycle type of self.

EXAMPLES:

```
sage: # needs sage.combinat
sage: sigma = Permutations(5).identity()
sage: sigma.has_nth_root(3)
True
sage: sigma = Permutation('(1, 3)')
sage: sigma.has_nth_root(2)
False
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> sigma = Permutations(Integer(5)).identity()
>>> sigma.has_nth_root(Integer(3))
True
>>> sigma = Permutation('(1, 3)')
>>> sigma.has_nth_root(Integer(2))
False
```

See also:

- \texttt{nth_roots()}
- \texttt{number_of_nth_roots()}

has_pattern(patt)

Test whether the permutation self contains the pattern patt.

EXAMPLES:

```
sage: Permutation([3,5,1,4,6,2]).has_pattern([1,3,2])  # needs sage.combinat
True
```

```
>>> from sage.all import *
>>> Permutation([Integer(3),Integer(5),Integer(1),Integer(4),Integer(6), Integer(2)]).has_pattern([Integer(1),Integer(3),Integer(2)])
```

(continues on next page)
hypercuboctahedral_double_coset_type()

Return the coset-type of self as a partition.

self must be a permutation of even size 2n. The coset-type determines the double class of the permutation, that is its image in $H_n \backslash S_{2n} / H_n$, where $H_n$ is the n-th hyperoctahedral group.

The coset-type is determined as follows. Consider the perfect matching \{1, 2\}, \{3, 4\}, ..., \{2n - 1, 2n\} and its image by self, and draw them simultaneously as edges of a graph whose vertices are labeled by 1, 2, ..., 2n. The coset-type is the ordered sequence of the semi-lengths of the cycles of this graph (see Chapter VII of [Mac1995] for more details, particularly Section VII.2).

EXAMPLES:

sage: # needs sage.combinat
sage: p = Permutation([3, 4, 6, 1, 5, 7, 2, 8])

sage: p.hyperoctahedral_double_coset_type()
[3, 1]

sage: all(p.hyperoctahedral_double_coset_type() == ...
   ...: p.inverse().hyperoctahedral_double_coset_type()
   ...: for p in Permutations(4))
True

sage: Permutation([]).hyperoctahedral_double_coset_type()
[]

sage: Permutation([3, 1, 2]).hyperoctahedral_double_coset_type()
Traceback (most recent call last): ...
ValueError: [3, 1, 2] is a permutation of odd size and has no coset-type

idescents(final_descent=False, from_zero=False)

Return a list of the idescents of self, that is the list of the descents of self's inverse.

A descent of a permutation p is an integer i such that $p(i) > p(i+1)$.

**Warning:** By default, the descents are returned as elements in the index set, i.e., starting at 1. If you want them to start at 0, set the keyword `from_zero` to `True`.  

5.1. Comprehensive Module List

2947
INPUT:

- `final_descent` – boolean (default False); if True, the last position of a non-empty permutation is also considered as a descent
- `from_zero` – optional boolean (default False); if False, return the positions starting from 1

EXAMPLES:

```python
sage: Permutation([2, 3, 1]).idescents()
[1]
sage: Permutation([1, 4, 3, 2]).idescents()
[2, 3]
sage: Permutation([1, 4, 3, 2]).idescents(final_descent=True)
[2, 3, 4]
sage: Permutation([1, 4, 3, 2]).idescents(from_zero=True)
[1, 2]
```

```python
>>> from sage.all import *

>>> Permutation([Integer(2), Integer(3), Integer(1)]).idescents()
[1]
>>> Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).idescents()
[2, 3]
>>> Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).idescents(final_descent=True)
[2, 3, 4]
>>> Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).idescents(from_zero=True)
[1, 2]
```

**idescents_signature** (final_descent=False)

Return the list obtained as follows: Each position in `self` is mapped to −1 if it is an idescent and 1 if it is not an idescent.

See `idescents()` for a definition of idescents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:

```python
sage: Permutation([1, 4, 3, 2]).idescents()
[2, 3]
sage: Permutation([1, 4, 3, 2]).idescents_signature()
[1, -1, -1, 1]
```

```python
>>> from sage.all import *

>>> Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).idescents()
[2, 3]
>>> Permutation([Integer(1), Integer(4), Integer(3), Integer(2)]).idescents_signature()
[1, -1, -1, 1]
```

**imajor_index** (final_descent=False)

Return the inverse major index of the permutation `self`, which is the major index of the inverse of `self`.

The major index of a permutation $p$ is the sum of the descents of $p$. Since our permutation indices are 0-based, we need to add the number of descents.
With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**

```python
sage: Permutation([2,1,3]).imajor_index()
1
sage: Permutation([3,4,1,2]).imajor_index()
2
sage: Permutation([4,3,2,1]).imajor_index()
6
```

```python
>>> from sage.all import *

Permutation([Integer(2),Integer(1),Integer(3)]).imajor_index()
1
Permutation([Integer(3),Integer(4),Integer(1),Integer(2)]).imajor_index()
2
Permutation([Integer(4),Integer(3),Integer(2),Integer(1)]).imajor_index()
6
```

**increasing_tree** *(compare=\texttt{<\textit{builtin function min}>})*

Return the increasing tree associated to self.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).increasing_tree() # needs sage.graphs
1[., 2[3[4[., .], .], .], .]

sage: Permutation([4,1,3,2]).increasing_tree() # needs sage.graphs
1[4[., .], 2[3[., .], .]]
```

```python
>>> from sage.all import *

Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).increasing_tree() # needs sage.graphs
1[., 2[3[4[., .], .], .]]
Permutation([Integer(4),Integer(1),Integer(3),Integer(2)]).increasing_tree() # needs sage.graphs
1[4[., .], 2[3[., .], .]]
```

By passing the option compare=max one can have the decreasing tree instead:

```python
sage: Permutation([2,3,4,1]).increasing_tree(max) # needs sage.graphs
4[3[2[., .], .], 1[., .]]

sage: Permutation([2,3,1,4]).increasing_tree(max) # needs sage.graphs
4[3[2[., .], 1[., .]], .]
```

```python
>>> from sage.all import *

Permutation([Integer(2),Integer(3),Integer(4),Integer(1)]).increasing_tree(max) # needs sage.graphs
4[3[2[., .], .], 1[., .]]
Permutation([Integer(2),Integer(3),Integer(1),Integer(4)]).increasing_tree(max) # needs sage.graphs
4[3[2[., .], 1[., .]], .]
```
**increasing_tree_shape** *(compare=<built-in function min>)*

Return the shape of the increasing tree associated with the permutation.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).increasing_tree_shape()  # needs sage.graphs
[[., [[., .], .]], .]
sage: Permutation([4,1,3,2]).increasing_tree_shape()  # needs sage.graphs
[[., .], [[., .], .]]
```

By passing the option `compare=max` one can have the decreasing tree instead:

```python
sage: Permutation([2,3,4,1]).increasing_tree_shape(max)  # needs sage.graphs
[[[., .], .], [., .]]
sage: Permutation([2,3,1,4]).increasing_tree_shape(max)  # needs sage.graphs
[[[., .], [., .]], .]
```

**inverse()**

Return the inverse of self.

**EXAMPLES:**

```python
sage: Permutation([3,8,5,10,9,4,6,1,7,2]).inverse()  # 8, 10, 1, 6, 3, 7, 9, 2, 5, 4
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
sage: Permutation([2, 4, 1, 5, 3]).inverse()  # 3, 1, 5, 2, 4
[3, 1, 5, 2, 4]
```

```python
sage: ~Permutation([2, 4, 1, 5, 3])  # 3, 1, 5, 2, 4
[3, 1, 5, 2, 4]
```

```python
>>> from sage.all import *

>>> Permutation([Integer(3),Integer(8),Integer(5),Integer(10),Integer(9),
Integer(4),Integer(6),Integer(1),Integer(7),Integer(2)]).inverse()  # 8, 10, 1, 6, 3, 7, 9, 2, 5, 4
[8, 10, 1, 6, 3, 7, 9, 2, 5, 4]
```

```python
>>> Permutation([Integer(2), Integer(4), Integer(1), Integer(5), Integer(3)]).inverse()  # needs sage.graphs
[3, 1, 5, 2, 4]
```

(continues on next page)
inversions()
Return a list of the inversions of self.

An inversion of a permutation \( p \) is a pair \((i, j)\) such that \( i < j \) and \( p(i) > p(j) \).

EXAMPLES:
```python
sage: Permutation([3, 2, 4, 1, 5]).inversions()
[(1, 2), (1, 4), (2, 4), (3, 4)]
```

is_derangement()
Return whether self is a derangement.

A permutation \( \sigma \) is a derangement if \( \sigma \) has no fixed points.

EXAMPLES:
```python
sage: P = Permutation([1, 4, 2, 3])
sage: P.is_derangement()
False
sage: P = Permutation([2, 3, 1])
sage: P.is_derangement()
True
```

is_even()
Return True if the permutation self is even and False otherwise.

EXAMPLES:
```python
sage: Permutation([1, 2, 3]).is_even()
True
sage: Permutation([2, 1, 3]).is_even()
False
```

>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).is_even()
True
>>> Permutation([Integer(2),Integer(1),Integer(3)]).is_even()
False
**is_simple()**

Return whether `self` is simple.

A permutation is simple if it does not send any proper sub-interval to a sub-interval.

For instance, `[6, 1, 3, 5, 2, 4]` is not simple because it maps the interval `[3, 4, 5, 6]` to `[2, 3, 4, 5]`, whereas `[2, 6, 3, 5, 1, 4]` is simple.

See OEIS sequence A111111

**EXAMPLES:**

```python
sage: g = Permutation([4, 2, 3, 1])
sage: g.is_simple()
False

sage: g = Permutation([6, 1, 3, 5, 2, 4])
sage: g.is_simple()
False

sage: g = Permutation([2, 6, 3, 5, 1, 4])
sage: g.is_simple()
True

sage: [len([pi for pi in Permutations(n) if pi.is_simple()]) for n in range(6)]
[1, 1, 2, 0, 2, 6]
```

```python
>>> from sage.all import *

>>> g = Permutation([Integer(4), Integer(2), Integer(3), Integer(1)])
>>> g.is_simple()
False

>>> g = Permutation([Integer(6), Integer(1), Integer(3), Integer(5), Integer(2),
 -> Integer(4)])
>>> g.is_simple()
False

>>> g = Permutation([Integer(2), Integer(6), Integer(3), Integer(5), Integer(1),
 -> Integer(4)])
>>> g.is_simple()
True

>>> [len([pi for pi in Permutations(n) if pi.is_simple()]) for n in range(Integer(6))]
[1, 1, 2, 0, 2, 6]
```

**ishift(i)**

Return the `i`-shift of `self`. If an `i`-shift of `self` can't be performed, then `self` is returned.

An `i`-shift can be applied when `i` is not inbetween `i - 1` and `i + 1`. The `i`-shift moves `i` to the other side, and leaves the relative positions of `i - 1` and `i + 1` in place. All other entries of the permutations are also left in place.

**EXAMPLES:**

Here, `2` is to the left of both `1` and `3`. A `2`-shift can be applied which moves the `2` to the right and leaves `1` and `3` in their same relative order:
sage: Permutation([2,1,3]).ishift(2)
[1, 3, 2]

```python
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).ishift(Integer(2))
[1, 3, 2]
```

All entries other than \(i, i - 1\) and \(i + 1\) are unchanged:

```python
sage: Permutation([2,4,1,3]).ishift(2)
[1, 4, 3, 2]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(4),Integer(1),Integer(3)]).ishift(Integer(2))
[1, 4, 3, 2]
```

Since 2 is between 1 and 3 in \([1,2,3]\), a 2-shift cannot be applied to \([1,2,3]\)

```python
sage: Permutation([1,2,3]).ishift(2)
[1, 2, 3]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(1),Integer(2),Integer(3)]).ishift(Integer(2))
[1, 2, 3]
```

**iswitch\((i)\)**

Return the \(i\)-switch of \(self\). If an \(i\)-switch of \(self\) can’t be performed, then \(self\) is returned.

An \(i\)-switch can be applied when the subsequence of \(self\) formed by the entries \(i - 1\), \(i\) and \(i + 1\) is neither increasing nor decreasing. In this case, this subsequence is reversed (i.e., its leftmost element and its rightmost element switch places), while all other letters of \(self\) are kept in place.

**EXAMPLES:**

Here, 2 is to the left of both 1 and 3. A 2-switch can be applied which moves the 2 to the right and switches the relative order between 1 and 3:

```python
sage: Permutation([2,1,3]).iswitch(2)
[3, 1, 2]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(1),Integer(3)]).iswitch(Integer(2))
[3, 1, 2]
```

All entries other than \(i - 1\), \(i\) and \(i + 1\) are unchanged:

```python
sage: Permutation([2,4,1,3]).iswitch(2)
[3, 4, 1, 2]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(4),Integer(1),Integer(3)]).iswitch(Integer(2))
[3, 4, 1, 2]
```

Since 2 is between 1 and 3 in \([1,2,3]\), a 2-switch cannot be applied to \([1,2,3]\)
left_action_product (lp)

Return the permutation obtained by composing self with lp in such an order that lp is applied first and self is applied afterwards.

This is usually denoted by either self * lp or lp * self depending on the conventions used by the author. If the value of a permutation p ∈ Sn on an integer i ∈ {1, 2, ⋯, n} is denoted by p(i), then this should be denoted by self * lp in order to have associativity (i.e., in order to have (p · q)(i) = p(q(i)) for all p, q and i). If, on the other hand, the value of a permutation p ∈ Sn on an integer i ∈ {1, 2, ⋯, n} is denoted by i^p, then this should be denoted by lp * self in order to have associativity (i.e., in order to have i^{pq} = (i^p)^q for all p, q and i).

EXAMPLES:

```python
sage: p = Permutation([2, 1, 3])
sage: q = Permutation([3, 1, 2])
sage: p.left_action_product(q)
[3, 2, 1]
sage: q.left_action_product(p)
[1, 3, 2]
```

left_tableau ()

Return the left standard tableau after performing the RSK algorithm on self.

EXAMPLES:

```python
sage: Permutation([1, 4, 3, 2]).left_tableau() # needs sage.combinat
[[1, 2], [3], [4]]
```

length ()

Return the Coxeter length of self.

The length of a permutation p is given by the number of inversions of p.

EXAMPLES:
sage: Permutation([5, 1, 3, 4, 2]).length()
6

```python
>>> from sage.all import *
>>> Permutation([Integer(5), Integer(1), Integer(3), Integer(4), Integer(2)]).
˓→length()
6
```

**longest_increasing_subsequence_length()**

Return the length of the longest increasing subsequences of `self`.

**EXAMPLES:**

```python
sage: Permutation([2,3,1,4]).longest_increasing_subsequence_length()
3
sage: all(i.longest_increasing_subsequence_length() == len(RSK(i)[0][0])
˓→# needs sage.combinat ...
˓→for i in Permutations(5))
True
sage: Permutation([]).longest_increasing_subsequence_length()
0
```

```python
>>> from sage.all import *
>>> Permutation([Integer(2),Integer(3),Integer(4),Integer(1)]).longest_˓→increasing_subsequences()
# needs sage.graphs
[[2, 3, 4]]
>>> Permutation([Integer(5), Integer(7), Integer(1), Integer(2), Integer(6),␣˓→Integer(4), Integer(3)]).longest_increasing_subsequences()
# needs sage.
```

(continues on next page)
Note: This algorithm could be made faster using a balanced search tree for each column instead of sorted lists. See discussion on Issue #31451.

**longest_increasing_subsequences_number()**

Return the number of increasing subsequences of maximal length in `self`.

The list of longest increasing subsequences of a permutation is given by `longest_increasing_subsequences()`, and the length of these subsequences is given by `longest_increasing_subsequence_length()`.

The algorithm is similar to `longest_increasing_subsequences()`. Namely, the longest increasing subsequences are encoded as increasing sequences in a ranked poset from a smallest to a largest element. Their number can be obtained via dynamic programming: for each `v` in the poset we compute the number of paths from a smallest element to `v`.

**EXAMPLES:**

```python
sage: sum(p.longest_increasing_subsequences_number() for p in Permutations(8))
120770
sage: p = Permutations(50).random_element()
sage: (len(p.longest_increasing_subsequences()) ==
... needs sage.graphs...
... p.longest_increasing_subsequences_number())
True
```

**major_index** (*final_descent=False*)

Return the major index of `self`.

The major index of a permutation `p` is the sum of the descents of `p`. Since our permutation indices are 0-based, we need to add the number of descents.

With the `final_descent` option, the last position of a non-empty permutation is also considered as a descent.

**EXAMPLES:**

```python
sage: Permutation([2,1,3]).major_index()
1
sage: Permutation([3,4,1,2]).major_index()
```

(continues on next page)
sage: Permutation([4,3,2,1]).major_index()
6

>>> from sage.all import *

>>> Permutation([Integer(2),Integer(1),Integer(3)]).major_index()
1
>>> Permutation([Integer(3),Integer(4),Integer(1),Integer(2)]).major_index()
2
>>> Permutation([Integer(4),Integer(3),Integer(2),Integer(1)]).major_index()
6

\textbf{multi\_major\_index} (composition)

Return the multimajor index of this permutation with respect to \texttt{composition}.

\textsc{input:}

\begin{itemize}
    \item \texttt{composition} – a composition of the \texttt{size()} of this permutation
\end{itemize}

\textsc{examples:}

sage: p = Permutation([5, 6, 2, 1, 3, 7, 4])

sage: p.multi_major_index([3, 2, 2])
[2, 0, 1]

sage: p.multi_major_index([7]) == [p.major_index()]
True

sage: p.multi_major_index([1]*7)
[0, 0, 0, 0, 0, 0, 0]

sage: Permutation([]).multi_major_index([])
[]

REFERENCES:

\begin{itemize}
    \item [JS2000]
\end{itemize}

\textbf{next} ()

Return the permutation that follows \texttt{self} on the symmetric group containing \texttt{self}. If \texttt{self} is the last permutation, then \texttt{next} returns \texttt{False}. If the \texttt{algorithm} parameter is specified, the permutations will be generated according to it. Supported algorithms are:

\begin{itemize}
    \item \texttt{lex}: lexicographic order generation, this is the default algorithm.
    \item \texttt{sjt}: Steinhaus-Johnson-Trotter algorithm to generate permutations using only transposition of two elements in the list. It is highly recommended to set \texttt{check=True} (default value).
\end{itemize}

\textsc{examples:}
sage: p = Permutation([1, 3, 2])
sage: next(p)
[2, 1, 3]
sage: p = Permutation([4, 3, 2, 1])
sage: next(p)
False
sage: p = Permutation([1, 2, 3], algorithm='sjt')
sage: p = next(p); p
[1, 3, 2]
sage: p = next(p); p
[3, 1, 2]

>>> from sage.all import *
>>> p = Permutation([Integer(1), Integer(3), Integer(2)])
>>> p = next(p)
[2, 1, 3]
>>> p = Permutation([Integer(4), Integer(3), Integer(2), Integer(1)], algorithm='sjt')
>>> p = next(p); p
[1, 3, 2]

noninversions \( (k) \)

Return the list of all \( k \)-noninversions in \( self \).

If \( k \) is an integer and \( p \in S_n \) is a permutation, then a \( k \)-noninversion in \( p \) is defined as a strictly increasing sequence \( (i_1, i_2, \ldots, i_k) \) of elements of \( \{1, 2, \ldots, n\} \) satisfying \( p(i_1) < p(i_2) < \cdots < p(i_k) \). (In other words, a \( k \)-noninversion in \( p \) can be regarded as a \( k \)-element subset of \( \{1, 2, \ldots, n\} \) on which \( p \) restricts to an increasing map.)

EXAMPLES:

sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.noninversions(1)
[[3], [2], [4], [1], [5]]
sage: p.noninversions(2)
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
sage: p.noninversions(3)
[[3, 4, 5], [2, 4, 5]]
sage: p.noninversions(4)
[]
sage: p.noninversions(5)
[]

>>> from sage.all import *
>>> p = Permutation([Integer(3), Integer(2), Integer(4), Integer(1), Integer(5)])
>>> p.noninversions(Integer(1))
[[3], [2], [4], [1], [5]]
>>> p.noninversions(Integer(2))
[[3, 4], [3, 5], [2, 4], [2, 5], [4, 5], [1, 5]]
>>> p.noninversions(Integer(3))
[[3, 4, 5], [2, 4, 5]]
>>> p.noninversions(Integer(4))
nth_roots \( (n) \)

Return all \( n \)-th roots of \( \text{self} \) (as a generator).

An \( n \)-th root of the permutation \( \sigma \) is a permutation \( \gamma \) such that \( \gamma^n = \sigma \).

Note that the number of \( n \)-th roots only depends on the cycle type of \( \text{self} \).

EXAMPLES:

```python
sage: # needs sage.combinat
sage: sigma = Permutations(5).identity()
```
```python
sage: list(sigma.nth_roots(3))
```
```output
[[1, 4, 3, 5, 2], [1, 5, 3, 2, 4], [1, 2, 4, 5, 3], [1, 2, 5, 3, 4],
 [4, 2, 3, 5, 1], [5, 2, 3, 1, 4], [3, 2, 5, 4, 1], [5, 2, 1, 4, 3],
 [2, 5, 3, 4, 1], [5, 1, 3, 4, 2], [2, 3, 1, 4, 5], [3, 1, 2, 4, 5],
 [2, 4, 3, 1, 5], [4, 1, 3, 2, 5], [3, 2, 4, 1, 5], [4, 2, 1, 3, 5],
 [1, 3, 4, 2, 5], [1, 4, 2, 3, 5], [1, 3, 5, 4, 2], [1, 5, 2, 4, 3],
 [1, 2, 3, 4, 5]]
```
```python
sage: sigma = Permutation((1, 3))
```
```python
sage: list(sigma.nth_roots(2))
```
```output
[]
```

For \( n \geq 6 \), this algorithm begins to be more efficient than naive search (look at all permutations and test their \( n \)-th power).

See also:

- has_nth_root()
- number_of_nth_roots()

number_of_descents \( \text{(final_descent=False)} \)

Return the number of descents of \( \text{self} \).

With the final_descent option, the last position of a non-empty permutation is also considered as a descent.

EXAMPLES:
Number of descents

Return the number of descents of self.

EXAMPLES:

```python
sage: Permutation([1,4,3,2]).number_of_descents()
2
sage: Permutation([1,4,3,2]).number_of_descents(final_descent=True)
3
```
REFERENCES:

- http://mathworld.wolfram.com/PermutationInversion.html

EXAMPLES:

```python
sage: Permutation([3, 2, 4, 1, 5]).number_of_inversions()
4
sage: Permutation([1, 2, 6, 4, 7, 3, 5]).number_of_inversions()
6
```

```python
>>> from sage.all import *
>>> Permutation([Integer(3), Integer(2), Integer(4), Integer(1), Integer(5)]).number_of_inversions()
4
>>> Permutation([Integer(1), Integer(2), Integer(6), Integer(4), Integer(7), Integer(3), Integer(5)]).number_of_inversions()
6
```

**number_of_noninversions** *(k)*

Return the number of *k*-noninversions in `self`.

If *k* is an integer and \( p \in S_n \) is a permutation, then a \( k \)-noninversion in \( p \) is defined as a strictly increasing sequence \( (i_1, i_2, \ldots, i_k) \) of elements of \( \{1, 2, \ldots, n\} \) satisfying \( p(i_1) < p(i_2) < \cdots < p(i_k) \). (In other words, a \( k \)-noninversion in \( p \) can be regarded as a \( k \)-element subset of \( \{1, 2, \ldots, n\} \) on which \( p \) restricts to an increasing map.)

The number of \( k \)-noninversions in \( p \) has been denoted by \( \text{noninv}_k(p) \) in [RSW2011], where conjectures and results regarding this number have been stated.

**EXAMPLES**

```python
sage: p = Permutation([3, 2, 4, 1, 5])
sage: p.number_of_noninversions(1)
5
sage: p.number_of_noninversions(2)
6
sage: p.number_of_noninversions(3)
2
sage: p.number_of_noninversions(4)
0
sage: p.number_of_noninversions(5)
0
```

```python
>>> from sage.all import *
>>> p = Permutation([Integer(3), Integer(2), Integer(4), Integer(1), Integer(5)])
>>> p.number_of_noninversions(Integer(1))
5
>>> p.number_of_noninversions(Integer(2))
6
>>> p.number_of_noninversions(Integer(3))
2
>>> p.number_of_noninversions(Integer(4))
0
>>> p.number_of_noninversions(Integer(5))
0
```

The number of 2-noninversions of a permutation \( p \in S_n \) is \( \binom{n}{2} \) minus its number of inversions:
We also check some corner cases:

```python
sage: all( x.number_of_noninversions(1) == 5 for x in Permutations(5) )
True
sage: all( x.number_of_noninversions(0) == 1 for x in Permutations(5) )
True
sage: Permutation([]).number_of_noninversions(1)
0
sage: Permutation([]).number_of_noninversions(0)
1
sage: Permutation([2, 1]).number_of_noninversions(3)
0
```

### number_of_nth_roots(n)

Return the number of \( n \)-th roots of \( \sigma \).

An \( n \)-th root of the permutation \( \sigma \) is a permutation \( \gamma \) such that \( \gamma^n = \sigma \).

Note that the number of \( n \)-th roots only depends on the cycle type of \( \sigma \).

**EXAMPLES:**

```python
sage: Sigma = Permutations(5).identity()
sage: Sigma.number_of_nth_roots(3)
21
sage: Sigma = Permutation('(1, 3)')
sage: Sigma.number_of_nth_roots(2)
0
```
>>> from sage.all import *
>>> # needs sage.combinat
>>> Sigma = Permutations(Integer(5)).identity()
>>> Sigma.number_of_nth_roots(Integer(3))
21
>>> Sigma = Permutation('1, 3')
>>> Sigma.number_of_nth_roots(Integer(2))
0

See also:

  • nth_roots()
  • has_nth_root()

number_of_peaks()
Return the number of peaks of the permutation self.
A peak of a permutation \( p \) is an integer \( i \) such that \( p(i - 1) < p(i) \) and \( p(i) > p(i + 1) \).

EXAMPLES:

sage: Permutation([1,3,2,4,5]).number_of_peaks()
1
sage: Permutation([4,1,3,2,6,5]).number_of_peaks()
2

>>> from sage.all import *
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5)]).˓
-> number_of_peaks()
1
>>> Permutation([Integer(4),Integer(1),Integer(3),Integer(2),Integer(6),˓
-> Integer(5)]).number_of_peaks()
2

number_of_recoils()
Return the number of recoils of the permutation self.

EXAMPLES:

sage: Permutation([1,4,3,2]).number_of_recoils()
2

>>> from sage.all import *
>>> Permutation([Integer(1),Integer(4),Integer(3),Integer(2)]).number_of_˓
-> recoils()
2

number_of_reduced_words()
Return the number of reduced words of self without explicitly computing them all.

EXAMPLES:

sage: p = Permutation([6,4,2,5,1,8,3,7])
sage: len(p.reduced_words()) == p.number_of_reduced_words()  # Needs sage.combinat
True
```python
>>> from sage.all import *
>>> p = Permutation([Integer(6), Integer(4), Integer(2), Integer(5), Integer(1),
                   Integer(8), Integer(3), Integer(7)])
>>> len(p.reduced_words()) == p.number_of_reduced_words()  # needs sage.combinat
True
```

**number_of_saliances()**

Return the number of saliances of `self`.

A saliance of a permutation \( p \) is an integer \( i \) such that \( p(i) > p(j) \) for all \( j > i \).

**EXAMPLES:**

```python
sage: Permutation([2, 3, 1, 5, 4]).number_of_saliances()
2
sage: Permutation([5, 4, 3, 2, 1]).number_of_saliances()
5
```

```python
>>> from sage.all import *
>>> Permutation([Integer(2), Integer(3), Integer(1), Integer(5), Integer(4)]).number_of_saliances()
2
>>> Permutation([Integer(5), Integer(4), Integer(3), Integer(2), Integer(1)]).number_of_saliances()
5
```

**order()**

Return the order of `self`.

**EXAMPLES:**

```python
sage: sigma = Permutation([3, 4, 1, 2, 5])
sage: sigma.order()
2
sage: sigma * sigma
[1, 2, 3, 4, 5]
```

```python
>>> from sage.all import *
>>> sigma = Permutation([Integer(3), Integer(4), Integer(1), Integer(2), Integer(5)])
>>> sigma.order()
2
>>> sigma * sigma
[1, 2, 3, 4, 5]
```

**pattern_positions(patt)**

Return the list of positions where the pattern `patt` appears in the permutation `self`.

**EXAMPLES:**

```python
sage: Permutation([3, 5, 1, 4, 6, 2]).pattern_positions([1, 3, 2])  # needs sage.combinat
[[0, 1, 3], [2, 3, 5], [2, 4, 5]]
```
peaks()

Return a list of the peaks of the permutation self.

A peak of a permutation $p$ is an integer $i$ such that $p(i - 1) < p(i)$ and $p(i) > p(i + 1)$.

EXAMPLES:

sage: Permutation([1,3,2,4,5]).peaks()
[1]
sage: Permutation([4,1,3,2,6,5]).peaks()
[2, 4]
sage: Permutation([]).peaks()
[]

permutation_poset()

Return the permutation poset of self.

The permutation poset of a permutation $p$ is the poset with vertices $(i, p(i))$ for $i = 1, 2, \ldots, n$ (where $n$ is the size of $p$) and order inherited from $\mathbb{Z} \times \mathbb{Z}$.

EXAMPLES:

sage: # needs sage.combinat sage.graphs
sage: Permutation([3,1,5,4,2]).permutation_poset().cover_relations()
[[[2, 1], (5, 2)],
 [[2, 1], (3, 5)],
 [[2, 1], (4, 4)],
 [[1, 3], (3, 5)],
 [[1, 3], (4, 4)]]
sage: Permutation([]).permutation_poset().cover_relations()
[]
sage: Permutation([1,3,2]).permutation_poset().cover_relations()
[[[1, 1], (2, 3)], [[1, 1], (3, 2)]]
sage: Permutation([1,2]).permutation_poset().cover_relations()
[[[1, 1], (2, 2)]]
sage: P = Permutation([1,5,2,4,3])

(continues on next page)
This should hold for any $P$:

```python
sage: P.permutation_poset().greene_shape() == P.RS_partition()  # needs sage.combinat sage.graphs
True
```

```
>>> from sage.all import *
>>> P.permutation_poset().greene_shape() == P.RS_partition()  # needs sage.combinat sage.graphs
True
```

**permutohedron_greater**(side='right')

Return a list of permutations greater than or equal to self in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option `side='left'`, then they will be done in the left permutohedron.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

**EXAMPLES:**

```python
sage: Permutation([4,2,1,3]).permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
sage: Permutation([4,2,1,3]).permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_greater()
[[4, 2, 1, 3], [4, 2, 3, 1], [4, 3, 2, 1]]
```

```python
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_greater(side='left')
[[4, 2, 1, 3], [4, 3, 1, 2], [4, 3, 2, 1]]
```

**permutohedron_join**(other, side='right')

Return the join of the permutations `self` and `other` in the right permutohedron order (or, if side is set to 'left', in the left permutohedron order).

The permutohedron orders (see `permutohedron_lequal()`) are lattices; the join operation refers to this lattice structure. In more elementary terms, the join of two permutations $\pi$ and $\psi$ in the symmetric group $S_n$ is the permutation in $S_n$ whose set of inversion is the transitive closure of the union of the set of inversions of $\pi$ with the set of inversions of $\psi$. 

2966 Chapter 5. Comprehensive Module List
See also:

permutohedron_lequal(), permutohedron_meet().

ALGORITHM:

It is enough to construct the join of any two permutations \( \pi \) and \( \psi \) in \( S_n \) with respect to the right weak order. (The join of \( \pi \) and \( \psi \) with respect to the left weak order is the inverse of the join of \( \pi^{-1} \) and \( \psi^{-1} \) with respect to the right weak order.) Start with an empty list \( l \) (denoted \( \texttt{xs} \) in the actual code). For \( i = 1, 2, \ldots, n \) (in this order), we insert \( i \) into this list in the rightmost possible position such that any letter in \( \{1, 2, \ldots, i - 1\} \) which appears further right than \( i \) in either \( \pi \) or \( \psi \) (or both) must appear further right than \( i \) in the resulting list. After all numbers are inserted, we are left with a list which is precisely the join of \( \pi \) and \( \psi \) (in one-line notation). This algorithm is due to Markowsky, [Mar1994] (Theorem 1 (a)).

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q)
[3, 1, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p)
[3, 2, 1]
```

```python
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q = Permutation([Integer(1),Integer(3),Integer(2)])
>>> p.permutohedron_join(q)
[3, 1, 2]
>>> r = Permutation([Integer(2),Integer(1),Integer(3)])
>>> r.permutohedron_join(p)
[3, 2, 1]
```

```
sage: p = Permutation([3,2,4,1])
sage: q = Permutation([4,2,1,3])
sage: p.permutohedron_join(q)
[4, 3, 2, 1]
sage: r = Permutation([3,1,2,4])
sage: p.permutohedron_join(r)
[3, 2, 4, 1]
```

```python
>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(2),Integer(4),Integer(1)])
>>> q = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> p.permutohedron_join(q)
[4, 3, 2, 1]
>>> r = Permutation([Integer(3),Integer(1),Integer(2),Integer(4)])
>>> p.permutohedron_join(r)
[3, 2, 4, 1]
```

(continues on next page)
The universal property of the join operation is satisfied:

```
sage: def test_uni_join(p, q):
    ...:     j = p.permutohedron_join(q)
    ...:     if not p.permutohedron_lequal(j):
    ...:         return False
    ...:     if not q.permutohedron_lequal(j):
    ...:         return False
    ...:     for r in p.permutohedron_greater():
    ...:         if q.permutohedron_lequal(r) and not j.permutohedron_lequal(r):
    ...:             return False
    ...:     return True
sage: all( test_uni_join(p, q) for p in Permutations(3) for q in Permutations(3) )
True
sage: test_uni_join(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3, 1, 2, 5, 4, 6, 8]))
True
```

Border cases:

```
sage: p = Permutation([])
sage: p.permutohedron_join(p)
[]
sage: p = Permutation([1])
sage: p.permutohedron_join(p)
[1]
```

```
The left permutohedron:

```
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_join(q, side="left")
[3, 2, 1]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_join(p, side="left")
[3, 1, 2]
```

permutohedron_lequal \((p2, \text{side}=\text{\textquoteleft\textquoteright\textright}')\)

Return True if self is less or equal to \(p2\) in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option \text{side}=\text{\textquoteleft\textleft}'\textright\textquoteright', then they will be done in the left permutohedron.

For every nonnegative integer \(n\), the right (resp. left) permutohedron order (also called the right (resp. left) weak order, or the right (resp. left) weak Bruhat order) is a partial order on the symmetric group \(S_n\). It can be defined in various ways, including the following ones:

- Two permutations \(u\) and \(v\) in \(S_n\) satisfy \(u \leq v\) in the right (resp. left) permutohedron order if and only if the (Coxeter) length of the permutation \(v^{-1} \circ u\) (resp. of the permutation \(u \circ v^{-1}\)) equals the length of \(v\) minus the length of \(u\). Here, \(p \circ q\) means the permutation obtained by applying \(q\) first and then \(p\). (Recall that the Coxeter length of a permutation is its number of inversions.)

- Two permutations \(u\) and \(v\) in \(S_n\) satisfy \(u \leq v\) in the right (resp. left) permutohedron order if and only if every pair \((i, j)\) of elements of \(\{1, 2, \cdots, n\}\) such that \(i < j\) and \(u^{-1}(i) > u^{-1}(j)\) (resp. \(u(i) > u(j)\)) also satisfies \(v^{-1}(i) > v^{-1}(j)\) (resp. \(v(i) > v(j)\)).

- A permutation \(v \in S_n\) covers a permutation \(u \in S_n\) in the right (resp. left) permutohedron order if and only if we have \(v = u \circ (i, i + 1)\) (resp. \(v = (i, i + 1) \circ u\)) for some \(i \in \{1, 2, \cdots, n - 1\}\) satisfying \(u(i) < u(i + 1)\) (resp. \(u^{-1}(i) < u^{-1}(i + 1)\)). Here, again, \(p \circ q\) means the permutation obtained by applying \(q\) first and then \(p\).

The right and the left permutohedron order are mutually isomorphic, with the isomorphism being the map sending every permutation to its inverse. Each of these orders endows the symmetric group \(S_n\) with the structure of a graded poset (the rank function being the Coxeter length).

**Warning:** The permutohedron order is not to be mistaken for the strong Bruhat order \((\text{bruhat_lequal()}\)) , despite both orders being occasionally referred to as the Bruhat order.
EXAMPLES:

```python
sage: p = Permutation([3,2,1,4])
sage: p.permutohedron_lequal(Permutation([4,2,1,3]))
False
sage: p.permutohedron_lequal(Permutation([4,2,1,3]), side='left')
True
sage: p.permutohedron_lequal(p)
True

sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]))
True
sage: Permutation([2,1,3]).permutohedron_lequal(Permutation([2,3,1]), side='left')
False
sage: sorted([len([b for b in Permutations(3) if a.permutohedron_lequal(b)])
           for a in Permutations(3)])
[1, 2, 2, 3, 3, 6]

>>> from sage.all import *
>>> p = Permutation([Integer(3),Integer(2),Integer(1),Integer(4)])
>>> p.permutohedron_lequal(Permutation([Integer(4),Integer(2),Integer(1),
                                      Integer(3)]))
False
>>> p.permutohedron_lequal(Permutation([Integer(4),Integer(2),Integer(1),
                                      Integer(3)]), side='left')
True
>>> p.permutohedron_lequal(p)
True
```

(continues on next page)
permutohedron_meet (other, side='right')

Return the meet of the permutations self and other in the right permutohedron order (or, if side is set to 'left', in the left permutohedron order).

The permutohedron orders (see permutohedron_lequal()) are lattices; the meet operation refers to this lattice structure. It is connected to the join operation by the following simple symmetry property: If \( \pi \) and \( \psi \) are two permutations \( \pi \) and \( \psi \) in the symmetric group \( S_n \), and if \( w_0 \) denotes the permutation \((n, n - 1, \ldots, 1) \in S_n\), then

\[
\pi \land \psi = w_0 \circ ((w_0 \circ \pi) \lor (w_0 \circ \psi)) = ((\pi \circ w_0) \lor (\psi \circ w_0)) \circ w_0
\]

and

\[
\pi \lor \psi = w_0 \circ ((w_0 \circ \pi) \land (w_0 \circ \psi)) = ((\pi \circ w_0) \land (\psi \circ w_0)) \circ w_0,
\]

where \( \land \) means meet and \( \lor \) means join.

See also:
permutohedron_lequal(), permutohedron_join().

AUTHORS:

Viviane Pons and Darij Grinberg, 18 June 2014.

EXAMPLES:

```python
sage: p = Permutation([3,1,2])
sage: q = Permutation([1,3,2])
sage: p.permutohedron_meet(q)
[1, 3, 2]
sage: r = Permutation([2,1,3])
sage: r.permutohedron_meet(p)
[1, 2, 3]
```
The universal property of the meet operation is satisfied:

```python
def test_uni_meet(p, q):
    m = p.permutohedron_meet(q)
    if not m.permutohedron_lequal(p):
        return False
    if not m.permutohedron_lequal(q):
        return False
    for r in p.permutohedron_smaller():
        if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
            return False
    return True
```

```python
all( test_uni_meet(p, q) for p in Permutations(3) for q in Permutations(3) )
```

True

```python
test_uni_meet(Permutation([6, 4, 7, 3, 2, 5, 8, 1]), Permutation([7, 3, 2, 5, 4, 6, 8]))
```

True

```python
(continues on next page)
```
```python
>>> def test_uni_meet(p, q):
...     m = p.permutohedron_meet(q)
...     if not m.permutohedron_lequal(p):
...         return False
...     if not m.permutohedron_lequal(q):
...         return False
...     for r in p.permutohedron_smaller():
...         if r.permutohedron_lequal(q) and not r.permutohedron_lequal(m):
...             return False
...     return True

>>> all(test_uni_meet(p, q) for p in Permutations(Integer(3)) for q in Permutations(Integer(3)) )
True

>>> test_uni_meet(Permutation([Integer(6), Integer(4), Integer(7), Integer(3), Integer(2), Integer(5), Integer(8), Integer(1)]), Permutation([Integer(7), Integer(3), Integer(1), Integer(2), Integer(5), Integer(4), Integer(6), Integer(8)]))
True

Border cases:

```
Return a list of the permutations strictly smaller than \texttt{self} in the permutohedron order such that there is no permutation between any of those and \texttt{self}.

By default, the computations are done in the right permutohedron. If you pass the option \texttt{side='left'}, then they will be done in the left permutohedron.

See \texttt{permutohedron_lequal()} for the definition of the permutohedron orders.

EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
sage: p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

```
>>> from sage.all import *
>>> p = Permutation([Integer(4),Integer(2),Integer(1),Integer(3)])
>>> p.permutohedron_pred()
[[2, 4, 1, 3], [4, 1, 2, 3]]
>>> p.permutohedron_pred(side='left')
[[4, 1, 2, 3], [3, 2, 1, 4]]
```

\texttt{permutohedron_smaller(side='right')}

Return a list of permutations smaller than or equal to \texttt{self} in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option \texttt{side='left'}, then they will be done in the left permutohedron.

See \texttt{permutohedron_lequal()} for the definition of the permutohedron orders.

EXAMPLES:

```
sage: Permutation([4,2,1,3]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

```
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_smaller()
[[1, 2, 3, 4],
 [1, 2, 4, 3],
 [1, 4, 2, 3],
 [2, 1, 3, 4],
 [2, 1, 4, 3],
 [2, 4, 1, 3],
 [4, 1, 2, 3],
 [4, 2, 1, 3]]
```

```
sage: Permutation([4,2,1,3]).permutohedron_smaller(side='left')
[[1, 2, 3, 4],
 [1, 3, 2, 4],
  
```
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

>>> from sage.all import *

>>> Permutation([Integer(4),Integer(2),Integer(1),Integer(3)]).permutohedron_→ smaller(side='left')

[ [1, 2, 3, 4],
  [1, 3, 2, 4],
  [2, 1, 3, 4],
  [2, 3, 1, 4],
  [3, 1, 2, 4],
  [3, 2, 1, 4],
  [4, 1, 2, 3],
  [4, 2, 1, 3]]

permutohedron_succ (side='right')

Return a list of the permutations strictly greater than self in the permutohedron order such that there is no permutation between any of those and self.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

sage: p = Permutation([4,2,1,3])
sage: p.permutohedron_succ()

[[4, 2, 3, 1]]

sage: p.permutohedron_succ(side=left)

[[4, 3, 1, 2]]

prev ()

Return the permutation that comes directly before self in lexicographic order on the symmetric group containing self. If self is the first permutation, then it returns False. Does not support the Steinhaus-Johnson-Trotter algorithm for the moment.

EXAMPLES:

sage: p = Permutation([1,2,3])
sage: p.prev()
False
sage: p = Permutation([1,3,2])
sage: p.prev()

[1, 2, 3]
Todo: Implement the previous permutation for the Steinhaus-Johnson-Trotter algorithm.

rank()
Return the rank of self in the lexicographic ordering on the symmetric group to which self belongs.

EXAMPLES:

```
sage: Permutation([1,2,3]).rank()
0
sage: Permutation([1, 2, 4, 6, 3, 5]).rank()
10
sage: perms = Permutations(6).list()
sage: [p.rank() for p in perms] == list(range(factorial(6)))
True
```

recoils()
Return the list of the positions of the recoils of self.

A recoil of a permutation \( p \) is an integer \( i \) such that \( i + 1 \) appears to the left of \( i \) in \( p \). Here, the positions are being counted starting at 0. (Note that it is the positions, not the recoils themselves, which are being listed.)

EXAMPLES:

```
sage: Permutation([1,4,3,2]).recoils()
[2, 3]
sage: Permutation([]).recoils()
[]
```

recoils_composition()
Return the recoils composition of self.
The recoils composition of a permutation \( p \in S_n \) is the composition of \( n \) whose descent set is the set of the recoils of \( p \) (not their positions). In other words, this is the descents composition of \( p^{-1} \).

**EXAMPLES:**

```python
sage: Permutation([1,3,2,4]).recoils_composition()
[2, 2]
sage: Permutation([]).recoils_composition()
[]
```

```python
>>> from sage.all import *

>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4)]).recoils_composition()
[2, 2]
```

```
reduced_word()
```

Return a reduced word of the permutation `self`.

See `reduced_words()` for the definition of reduced words and a way to compute them all.

**Warning:** This does not respect the multiplication convention.

**EXAMPLES:**

```python
sage: Permutation([3,5,4,6,2,1]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]
```

```python
Permutation([1]).reduced_word_lexmin()
[]
```

```python
Permutation([]).reduced_word_lexmin()
[]
```

```python
>>> from sage.all import *
```

```python
>>> Permutation([Integer(3),Integer(5),Integer(4),Integer(6),Integer(2),Integer(1)]).reduced_word()
[2, 1, 4, 3, 2, 4, 3, 5, 4, 5]
```

```python
Permutation([1]).reduced_word_lexmin()
[]
```

```python
Permutation([]).reduced_word_lexmin()
[]
```

```
reduced_word_lexmin()
```

Return a lexicographically minimal reduced word of the permutation `self`.

See `reduced_words()` for the definition of reduced words and a way to compute them all.

**EXAMPLES:**

```python
sage: Permutation([3,4,2,1]).reduced_word_lexmin()
[1, 2, 1, 3, 2]
```

(continues on next page)
Permutation([]).reduced_word_lexmin()  
[]

>>> from sage.all import *

>>> Permutation([Integer(3), Integer(4), Integer(2), Integer(1)]).reduced_word_lexmin()
[1, 2, 1, 3, 2]

Permutation([1]).reduced_word_lexmin()
[]

Permutation([]).reduced_word_lexmin()
[]

reduced_words()

Return a list of the reduced words of self.

The notion of a reduced word is based on the well-known fact that every permutation can be written as a
product of adjacent transpositions. In more detail: If \( n \) is a nonnegative integer, we can define the transpositions \( s_i = (i, i+1) \in S_n \) for all \( i \in \{1, 2, \ldots, n-1\} \), and every \( p \in S_n \) can then be written as a product 
\( s_{i_1}s_{i_2}\cdots s_{i_k} \) for some sequence \( (i_1, i_2, \ldots, i_k) \) of elements of \( \{1, 2, \ldots, n-1\} \) here \( \{1, 2, \ldots, n-1\} \) denotes the empty set when \( n \leq 1 \). Fixing a \( p \), the sequences \( (i_1, i_2, \ldots, i_k) \) of smallest length satisfying 
\( p = s_{i_1}s_{i_2}\cdots s_{i_k} \) are called the reduced words of \( p \). (Their length is the Coxeter length of \( p \), and can be computed using length().)

Note that the product of permutations is defined here in such a way that \((pq)(i) = p(q(i)) \) for all permutations 
\( p \) and \( q \) and each \( i \in \{1, 2, \ldots, n\} \) (this is the same convention as in left_action_product(), but not the default semantics of the * operator on permutations in Sage). Thus, for instance, \( s_2s_1 \) is the permutation obtained by first transposing 1 with 2 and then transposing 2 with 3.

See also:
reduced_word(), reduced_word_lexmin()

EXAMPLES:

sage: Permutation([2, 1, 3]).reduced_words()
[[1]]
sage: Permutation([3, 1, 2]).reduced_words()
[[2, 1]]
sage: Permutation([3, 2, 1]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
sage: Permutation([3, 2, 4, 1]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]

Permutation([1]).reduced_words()
[]
Permutation([]).reduced_words()
[]

>>> from sage.all import *

>>> Permutation([Integer(2), Integer(1), Integer(3)]).reduced_words()
[[1]]

>>> Permutation([Integer(3), Integer(1), Integer(2)]).reduced_words()
[[2, 1]]

>>> Permutation([Integer(3), Integer(2), Integer(1)]).reduced_words()
[[1, 2, 1], [2, 1, 2]]
Permutation([Integer(3), Integer(2), Integer(4), Integer(1)]).reduced_words()
[[1, 2, 3, 1], [1, 2, 1, 3], [2, 1, 2, 3]]

Permutation([1]).reduced_words()
[[ ]]  
Permutation([]).reduced_words()
[[ ]]  

reduced_words_iterator()
Return an iterator for the reduced words of self.

EXAMPLES:

```sage:
next(Permutation([5, 2, 3, 4, 1]).reduced_words_iterator())
[1, 2, 3, 4, 3, 2, 1]
```

```sage:
from sage.all import *

next(Permutation([Integer(5), Integer(2), Integer(3), Integer(4), Integer(1)]).reduced_words_iterator())
[1, 2, 3, 4, 3, 2, 1]
```

remove_extra_fixed_points()
Return the permutation obtained by removing any fixed points at the end of self.

However, return [1] rather than [] if self is the identity permutation.

This is mostly a helper method for sage.combinat.schubert_polynomial, where it is used to normalize finitary permutations of \{1, 2, 3, \ldots \}.

EXAMPLES:

```sage:
Permutation([2, 1, 3]).remove_extra_fixed_points()

sage:
Permutation([1, 2, 3, 4]).remove_extra_fixed_points()

sage:
Permutation([2, 1]).remove_extra_fixed_points()

sage:
Permutation([]).remove_extra_fixed_points()
```

```sage:
from sage.all import *

Permutation([Integer(2), Integer(1), Integer(3)]).remove_extra_fixed_points()
[2, 1]

Permutation([Integer(1), Integer(2), Integer(3), Integer(4)]).remove_extra_fixed_points()
[1]

Permutation([Integer(2), Integer(1)]).remove_extra_fixed_points()
[2, 1]

Permutation([]).remove_extra_fixed_points()
[1]
```

See also:
retract_plain()
retract_direct_product \( (m) \)
Return the direct-product retract of the permutation \( \text{self} \in S_n \) to \( S_m \), where \( m \leq n \). If this retract is undefined, then None is returned.

If \( \nu \in S_n \) is a permutation, and \( m \) is a nonnegative integer less or equal to \( n \), then the direct-product retract of \( \nu \) to \( S_m \) is defined only if \( \nu([m]) = [m] \), where \( [m] \) denotes the interval \( \{1, 2, \ldots, m\} \). In this case, it is defined as the permutation written \( (\nu(1), \nu(2), \ldots, \nu(m)) \) in one-line notation.

EXAMPLES:

```python
sage: Permutation([4,1,2,3,5]).retract_direct_product(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_direct_product(3)
[4, 1, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(5)
[1, 4, 2, 3, 6, 5]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(4)
[1, 4, 2, 3, 6, 5]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(3)
[1, 4, 2, 3, 6, 5]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(2)
[1, 4, 2, 3, 6, 5]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_direct_product(0)
[]
sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True
```

See also:

retract_plain(), retract_okounkov_vershik()

retract_okounkov_vershik \( (m) \)
Return the Okounkov-Vershik retract of the permutation \( \text{self} \in S_n \) to \( S_m \), where \( m \leq n \).

If \( p \in S_n \) is a permutation, and \( m \) is a nonnegative integer less or equal to \( n \), then the Okounkov-Vershik retract of \( p \) to \( S_m \) is defined as the permutation in \( S_m \) which sends every \( i \in \{1, 2, \ldots, m\} \) to \( p^{k_i}(i) \), where \( k_i \) is the smallest positive integer \( k \) satisfying \( p^k(i) \leq m \).

In other words, the Okounkov-Vershik retract of \( p \) is the permutation whose disjoint cycle decomposition is obtained by removing all letters strictly greater than \( m \) from the decomposition of \( p \) into disjoint cycles (and removing all cycles which are emptied in the process).

When \( m = n - 1 \), the Okounkov-Vershik retract (as a map \( S_n \to S_{n-1} \)) is the map \( \tilde{p}_n \) introduced in Section 7 of [VO2005], and appears as (3.20) in [CST2010]. In the general case, the Okounkov-Vershik retract of a permutation in \( S_n \) to \( S_m \) can be obtained by first taking its Okounkov-Vershik retract to \( S_{n-1} \), then that of the resulting permutation to \( S_{n-2} \), etc. until arriving in \( S_m \).

**EXAMPLES:**

```python
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(3)
[3, 1, 2]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(2)
[2, 1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([4,1,2,3,5]).retract_okounkov_vershik(0)
[]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(5)
[1, 4, 2, 3, 5]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(4)
[1, 4, 2, 3]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(3)
[1, 3, 2]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(2)
[1, 2]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(1)
[1]
sage: Permutation([1,4,2,3,6,5]).retract_okounkov_vershik(0)
[]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(5)
[1, 5, 4, 3, 2]
sage: Permutation([6,5,4,3,2,1]).retract_okounkov_vershik(4)
[1, 2, 4, 3]
sage: Permutation([1,5,2,6,3,7,4,8]).retract_okounkov_vershik(4)
[1, 2, 4, 3]
sage: all( p.retract_direct_product(3) == p for p in Permutations(3) )
True
```

```python
>>> from sage.all import *
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).retract_okounkov_vershik(Integer(4))
[4, 1, 2, 3]
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).
(continues on next page)

Integer(7), Integer(4), Integer(8)]).retract_okounkov_vershik(Integer(4))
[1, 3, 2, 4]

>>> all( p.retract_direct_product(Integer(3)) == p for p in
Permutations(Integer(3)) )
True

See also:
retract_plain(), retract_direct_product()

retract_plain(m)
Return the plain retract of the permutation self in \(S_n\) to \(S_m\), where \(m \leq n\). If this retract is undefined, then None is returned.

If \(p \in S_n\) is a permutation, and \(m\) is a nonnegative integer less or equal to \(n\), then the plain retract of \(p\) to \(S_m\) is defined only if every \(i > m\) satisfies \(p(i) = i\). In this case, it is defined as the permutation written \((p(1), p(2), \ldots, p(m))\) in one-line notation.
EXAMPLES:

```python
sage: Permutation([4,1,2,3,5]).retract_plain(4)
[4, 1, 2, 3]
sage: Permutation([4,1,2,3,5]).retract_plain(3)
[4, 1, 2, 3, 5]
```

```python
sage: Permutation([1,3,2,4,5,6]).retract_plain(3)
[1, 3, 2]
sage: Permutation([1,3,2,4,5,6]).retract_plain(2)
[1, 3, 2, 4, 5, 6]
```

```python
sage: Permutation([1,2,3,4,5]).retract_plain(1)
[1]
sage: Permutation([1,2,3,4,5]).retract_plain(0)
[]
sage: all( p.retract_plain(3) == p for p in Permutations(3) )
True
```

```python
>>> from sage.all import *

```

```python
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).→
retract_plain(Integer(4))
[4, 1, 2, 3, 5]
>>> Permutation([Integer(4),Integer(1),Integer(2),Integer(3),Integer(5)]).→
retract_plain(Integer(3))
[4, 1, 2, 3, 5]
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5),→
Integer(6)]).retract_plain([Integer(3)])
[1, 3, 2]
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(4),Integer(5),→
Integer(6)]).retract_plain([Integer(2)])
[1, 3, 2, 4, 5, 6]
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]).→
retract_plain([Integer(1)])
[1]
>>> Permutation([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]).→
retract_plain([Integer(0)])
[]
>>> all( p.retract_plain(Integer(3)) == p for p in Permutations(Integer(3)) )
True
```

See also:

```python
retract_direct_product(), retract_okounkov_vershik(), remove_extra_fixed_points()
```

```python
reverse()
```

Return the permutation obtained by reversing the list.

EXAMPLES:

```python
sage: Permutation([3,4,1,2]).reverse()
[2, 1, 4, 3]
sage: Permutation([1,2,3,4,5]).reverse()
[5, 4, 3, 2, 1]
```

```python
from sage.all import *
```

```python
from sage.all import *
```

(continues on next page)
right_action_product (rp)

Return the permutation obtained by composing self with rp in such an order that self is applied first and rp is applied afterwards.

This is usually denoted by either self * rp or rp * self depending on the conventions used by the author. If the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \ldots, n\}$ is denoted by $p(i)$, then this should be denoted by $rp \cdot self$ in order to have associativity (i.e., in order to have $(p \cdot q)(i) = p(q(i))$ for all $p$, $q$ and $i$). If, on the other hand, the value of a permutation $p \in S_n$ on an integer $i \in \{1, 2, \ldots, n\}$ is denoted by $i^p$, then this should be denoted by $self \cdot rp$ in order to have associativity (i.e., in order to have $i^{p \cdot q} = (i^p)^q$ for all $p$, $q$ and $i$).

EXAMPLES:

```python
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: p.right_action_product(q)
[1, 3, 2]
sage: q.right_action_product(p)
[3, 2, 1]
```

right_permutohedron_interval (other)

Return the list of the permutations belonging to the right permutohedron interval where self is the minimal element and other the maximal element.

See permutohedron_lequal() for the definition of the permutohedron orders.

EXAMPLES:

```python
sage: p = Permutation([2, 1, 4, 5, 3]); q = Permutation([2, 5, 4, 1, 3])
sage: p.right_permutohedron_interval(q)  # needs sage.graphs sage.modules
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
```
**right_permutohedron_interval_iterator** (other)

Return an iterator on the permutations (represented as integer lists) belonging to the right permutohedron interval where `self` is the minimal element and `other` the maximal element.

See `permutohedron_lequal()` for the definition of the permutohedron orders.

**EXAMPLES:**

```python
sage: p = Permutation([2, 1, 4, 5, 3]); q = Permutation([2, 5, 4, 1, 3])
sage: p.right_permutohedron_interval(q)  # indirect doctest
[[2, 4, 5, 1, 3], [2, 4, 1, 5, 3], [2, 1, 4, 5, 3], [2, 1, 5, 4, 3], [2, 5, 1, 4, 3], [2, 5, 4, 1, 3]]
```

**right_tableau()**

Return the right standard tableau after performing the RSK algorithm on `self`.

**EXAMPLES:**

```python
sage: Permutation([1,4,3,2]).right_tableau()  # indirect doctest
[[1, 2], [3], [4]]
```

**robinson_schensted()**

Return the pair of standard tableaux obtained by running the Robinson-Schensted algorithm on `self`.

This can also be done by running `RSK()` on `self` (with the optional argument `check_standard=True` to return standard Young tableaux).

**EXAMPLES:**

```python
sage: Permutation([6,2,3,1,7,5,4]).robinson_schensted()  # indirect doctest
[[[1, 3, 4], [2, 5], [6, 7]], [[1, 3, 5], [2, 6], [4, 7]]]
```

**rothe_diagram()**

Return the Rothe diagram of `self`. 

---

5.1. Comprehensive Module List 2985
EXAMPLES:

```
sage: p = Permutation([4,2,1,3])
sage: D = p.rothe_diagram(); D  # needs sage.combinat
[(0, 0), (0, 1), (0, 2), (1, 0)]
sage: D.pp()  # needs sage.combinat
O O O .
O . . .
. . . .
. . . .
```

```python
>>> from sage.all import *
>>> p = Permutation([Integer(4), Integer(2), Integer(1), Integer(3)])
>>> D = p.rothe_diagram(); D  # needs sage.combinat
[(0, 0), (0, 1), (0, 2), (1, 0)]
>>> D.pp()  # needs sage.combinat
O O O .
O . . .
. . . .
. . . .
```

### runs (as_tuple=False)

Return a list of the runs in the nonempty permutation `self`.

A run in a permutation is defined to be a maximal (with respect to inclusion) nonempty increasing substring (i.e., contiguous subsequence). For instance, the runs in the permutation \([6,1,7,3,4,5,2]\) are \([6], [1,7], [3,4,5]\) and \([2]\).

Runs in an empty permutation are not defined.

**INPUT:**

- `as_tuple` — boolean (default: False) choice of output format

**OUTPUT:**

a list of lists or a tuple of tuples

**REFERENCES:**

- http://mathworld.wolfram.com/PermutationRun.html

**EXAMPLES:**

```
sage: Permutation([1,2,3,4]).runs()
[[1, 2, 3, 4]]
sage: Permutation([4,3,2,1]).runs()
[[4], [3], [2], [1]]
sage: Permutation([2,4,1,3]).runs()
[[2, 4], [1, 3]]
sage: Permutation([1]).runs()
[[1]]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(1), Integer(2), Integer(3), Integer(4)]).runs()
[[[1, 2, 3, 4]]]
```
Combinatorics, Release 10.4

The example from above:

```python
sage: Permutation([6, 1, 7, 3, 4, 5, 2]).runs()
[[6], [1, 7], [3, 4, 5], [2]]
sage: Permutation([6, 1, 7, 3, 4, 5, 2]).runs(as_tuple=True)
((6,), (1, 7), (3, 4, 5), (2,))
```

The number of runs in a nonempty permutation equals its number of descents plus 1:

```python
sage: all(len(p.runs()) == p.number_of_descents() + 1
.....:       for p in Permutations(6) )
True
```

Return a list of the saliances of the permutation `self`.

A saliance of a permutation `p` is an integer `i` such that `p(i) > p(j)` for all `j > i`.

EXAMPLES:

```python
sage: Permutation([2, 3, 1, 5, 4]).saliances()
[3, 4]
sage: Permutation([5, 4, 3, 2, 1]).saliances()
[0, 1, 2, 3, 4]
```

Return the right (or left) shifted concatenation of `self` with a permutation `other`. These operations are also known as the Loday-Ronco over and under operations.
INPUT:

• other—a permutation, a list, a tuple, or any iterable representing a permutation.
• side—(default: "right") the string “left” or “right”.

OUTPUT:
If side is "right", the method returns the permutation obtained by concatenating self with the letters of other incremented by the size of self. This is what is called side / other in [LR0102066], and denoted as the “over” operation. Otherwise, i.e., when side is "left", the method returns the permutation obtained by concatenating the letters of other incremented by the size of self with self. This is what is called side \ other in [LR0102066] (which seems to use the \((\sigma \pi)(i) = \pi(\sigma(i))\) convention for the product of permutations).

EXAMPLES:

```python
sage: from sage.all import *
sage: Permutation([1]).shifted_concatenation(Permutation([1]), "right")
[]
sage: Permutation([1]).shifted_concatenation(Permutation([1]), "left")
[]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]), "right")
[2, 4, 1, 3, 7, 5, 6]
sage: Permutation([2, 4, 1, 3]).shifted_concatenation(Permutation([3, 1, 2]), "left")
[7, 5, 6, 2, 4, 1, 3]
```

```python
>>> from sage.all import *
>>> Permutation([1]).shifted_concatenation(Permutation([1]), "right")
[]
>>> Permutation([1]).shifted_concatenation(Permutation([1]), "left")
[]
>>> Permutation([Integer(2), Integer(4), Integer(1), Integer(3)]).shifted_concatenation(Permutation([Integer(3), Integer(1), Integer(2)]), "right")
[2, 4, 1, 3, 7, 5, 6]
>>> Permutation([Integer(2), Integer(4), Integer(1), Integer(3)]).shifted_concatenation(Permutation([Integer(3), Integer(1), Integer(2)]), "left")
[7, 5, 6, 2, 4, 1, 3]
```

`shifted_shuffle` (other)
Return the shifted shuffle of two permutations self and other.

INPUT:

• other—a permutation, a list, a tuple, or any iterable representing a permutation.

OUTPUT:

The list of the permutations appearing in the shifted shuffle of the permutations self and other.

EXAMPLES:

```python
sage: # needs sage.graphs sage.modules
sage: Permutation([1]).shifted_shuffle(Permutation([1]))
[[1]]
sage: Permutation([1, 2, 3]).shifted_shuffle(Permutation([1]))
[[1, 2, 3], [1, 2, 3], [1, 2, 3], [1, 2, 3], [1, 2, 3]]
sage: Permutation([1, 2]).shifted_shuffle(Permutation([2, 1]))
[[1, 2], [4, 3, 1, 2], [1, 4, 3, 2], [4, 3, 1, 2], [1, 4, 3, 2]]
```

(continues on next page)
The shifted shuffle product is associative. We can test this on an admittedly toy example:

```
sage: a = Permutation([1, 2, 3])
sage: b = Permutation([2, 1, 3])
sage: c = Permutation([3, 1, 2])
sage: all(sorted(a.shifted_shuffle(b)).shifted_shuffle(c) == sorted(a.shifted_shuffle(b.shifted_shuffle(c))) for _ in range(10))
```

The `shifted_shuffle` method on permutations gives the same permutations as the `shifted_shuffle` method on words (but is faster):

```
sage: a = Word('abc')
sage: b = Word('def')
sage: all(sorted(a.shifted_shuffle(b)).shifted_shuffle(c) == sorted(a.shifted_shuffle(b.shifted_shuffle(c))) for _ in range(10))
```
for p2 in Permutations(3) )
    for p1 in Permutations(2) )
True

>>> from sage.all import *
>>> all( all( sorted(p1.shifted_shuffle(p2))
# needs sage.combinat sage.graphs sage.modules sage.rings.finite_rings
    == sorted([Permutation(p) for p in
    Word(p1).shifted_shuffle(Word(p2))])
    for p2 in Permutations(Integer(3)) )
    for p1 in Permutations(Integer(2)) )
True

show (representation='cycles', orientation='landscape', **args)
Display the permutation as a drawing.

INPUT:

* representation – different kinds of drawings are available

  – "cycles" (default) – the permutation is displayed as a collection of directed cycles
  – "braid" – the permutation is displayed as segments linking each element 1, ..., 𝑛 to its image on a parallel line.

    When using this drawing, it is also possible to display the permutation horizontally (orientation = "landscape", default option) or vertically (orientation = "portrait").

  – "chord-diagram" – the permutation is displayed as a directed graph, all of its vertices being located on a circle.

All additional arguments are forwarded to the show subcalls.

EXAMPLES:

sage: P20 = Permutations(20)
sage: P20.random_element().show(representation="cycles")
# needs sage.graphs sage.plot
sage: P20.random_element().show(representation="chord-diagram")
# needs sage.graphs sage.plot
sage: P20.random_element().show(representation="braid")
# needs sage.graphs sage.plot
sage: P20.random_element().show(representation="braid",
    orientation='portrait')
**sign()**

Return the signature of the permutation self. This is \((-1)^l\), where \(l\) is the number of inversions of self.

**Note:** \(\text{sign()}\) can be used as an alias for \(\text{signature()}\).

**EXAMPLES:**

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
sage: Permutation([1,3,2,5,4]).sign()
1
sage: Permutation([]).sign()
```

```
>>> from sage.all import *
```

```
>>> Permutation([Integer(4), Integer(2), Integer(3), Integer(1), Integer(5)]).→signature()
-1
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(5),Integer(4)]).→sign()
1
>>> Permutation([]).sign()
```

**signature()**

Return the signature of the permutation self. This is \((-1)^l\), where \(l\) is the number of inversions of self.

**Note:** \(\text{sign()}\) can be used as an alias for \(\text{signature()}\).

**EXAMPLES:**

```
sage: Permutation([4, 2, 3, 1, 5]).signature()
-1
sage: Permutation([1,3,2,5,4]).sign()
1
sage: Permutation([]).sign()
```

```
>>> from sage.all import *
```

```
>>> Permutation([Integer(4), Integer(2), Integer(3), Integer(1), Integer(5)]).→signature()
-1
>>> Permutation([Integer(1),Integer(3),Integer(2),Integer(5),Integer(4)]).→sign()
1
>>> Permutation([]).sign()
```

**simion_schmidt (avoid=[1, 2, 3])**

Implements the Simion-Schmidt map which sends an arbitrary permutation to a pattern avoiding permutation, where the permutation pattern is one of four length-three patterns. This method also implements the bijection between (for example) \([1,2,3]\)- and \([1,3,2]\)-avoiding permutations.

**INPUT:**

5.1. Comprehensive Module List 2991
• avoid one of the patterns [1, 2, 3], [1, 3, 2], [3, 1, 2], [3, 2, 1].

EXAMPLES:

```python
sage: P = Permutations(6)
sage: p = P([[4, 5, 1, 6, 3, 2]])
sage: pl = [ [1, 2, 3], [1, 3, 2], [3, 1, 2], [3, 2, 1] ]
sage: for q in pl:
    # needs sage.combinat....
    s = p.simion_schmidt(q)
    print("{} {}\n    ".format(s, s.has_pattern(q)))
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

```python
>>> from sage.all import *

>>> P = Permutations(Integer(6))

>>> p = P([Integer(4), Integer(5), Integer(1), Integer(6), Integer(3), Integer(2)])

>>> pl = [ [Integer(1), Integer(2), Integer(3)], [Integer(1), Integer(3), Integer(2)], 
                [Integer(2)], [Integer(3), Integer(1), Integer(2)], [Integer(3), Integer(2), 
                Integer(1)] ]

>>> for q in pl:
    # needs sage.combinat....
    s = p.simion_schmidt(q)
    print("{} {}\n    ".format(s, s.has_pattern(q)))
[4, 6, 1, 5, 3, 2] False
[4, 2, 1, 3, 5, 6] False
[4, 5, 3, 6, 2, 1] False
[4, 5, 1, 6, 2, 3] False
```

(size)

Return the size of self.

EXAMPLES:

```python
sage: Permutation([3, 4, 1, 2, 5]).size()
5
```

```python
>>> from sage.all import *

>>> Permutation([Integer(3), Integer(4), Integer(1), Integer(2), Integer(5)]).size()
5
```

(stack_sort)

Return the stack sort of a permutation.

This is another permutation obtained through the process of sorting using one stack. If the result is the identity permutation, the original permutation is stack-sortable.

See Wikipedia article Stack-sortable_permutation

EXAMPLES:

```python
sage: p = Permutation([2, 1, 5, 3, 4, 9, 7, 8, 6])
sage: p.stack_sort()
[1, 2, 3, 4, 5, 7, 6, 8, 9]
```

(continues on next page)
sage: S5 = Permutations(5)
sage: len([1 for s in S5 if s.stack_sort() == S5.one()])
42

>>> from sage.all import *
>>> p = Permutation([Integer(2), Integer(1), Integer(5), Integer(3), Integer(4),
                    Integer(9), Integer(7), Integer(8), Integer(6)])
>>> p.stack_sort()
[1, 2, 3, 4, 5, 7, 6, 8, 9]
>>> S5 = Permutations(Integer(5))
>>> len([Integer(1) for s in S5 if s.stack_sort() == S5.one()])
42

**sylvester_class** *(left_to_right=False)*

Iterate over the equivalence class of the permutation *self* under sylvester congruence.

Sylvester congruence is an equivalence relation on the set $S_n$ of all permutations of $n$. It is defined as the smallest equivalence relation such that every permutation of the form $uacbvw$ with $u$, $v$ and $w$ being words and $a$, $b$ and $c$ being letters satisfying $a \leq b < c$ is equivalent to the permutation $ucaebvw$. (Here, permutations are regarded as words by way of one-line notation.) This definition comes from [HNT2005], Definition 8, where it is more generally applied to arbitrary words.

The equivalence class of a permutation $p \in S_n$ under sylvester congruence is called the **sylvester class** of $p$. It is an interval in the right permutohedron order (see `permutohedron_lequal()`) on $S_n$.

This is related to the `sylvester_class()` method in that the equivalence class of a permutation $\pi$ under sylvester congruence is the sylvester class of the right-to-left binary search tree of $\pi$. However, the present method yields permutations, while the method on labelled binary trees yields plain lists.

If the variable `left_to_right` is set to True, the method instead iterates over the equivalence class of *self* with respect to the *left* sylvester congruence. The left sylvester congruence is easiest to define by saying that two permutations are equivalent under it if and only if their reverses (`reverse()`) are equivalent under (standard) sylvester congruence.

**EXAMPLES:**

The sylvester class of a permutation in $S_5$:

```
sage: p = Permutation([3, 5, 1, 2, 4])
sage: sorted(p.sylvester_class())
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```

```bash
>>> from sage.all import *
>>> p = Permutation([Integer(3), Integer(5), Integer(1), Integer(2),
                    Integer(4)])
>>> sorted(p.sylvester_class())
[[1, 3, 2, 5, 4],
 [1, 3, 5, 2, 4],
 [1, 5, 3, 2, 4],
 [3, 1, 2, 5, 4],
 [3, 1, 5, 2, 4],
 [3, 5, 1, 2, 4],
 [5, 1, 3, 2, 4],
 [5, 3, 1, 2, 4]]
```
The Sylvester class of a permutation $p$ contains $p$:

```
sage: all(p in p.sylvester_class() for p in Permutations(4))  # needs sage.combinat sage.graphs
True
```

Small cases:

```
sage: list(Permutation([]).sylvester_class())  # needs sage.combinat sage.graphs
[]
sage: list(Permutation([1]).sylvester_class())  # needs sage.combinat sage.graphs
[[1]]
```

The Sylvester classes in $S_3$:

```
sage: [sorted(p.sylvester_class()) for p in Permutations(3)]  # needs sage.combinat sage.graphs
[[[1, 2, 3]],
 [[1, 3, 2], [3, 1, 2]],
 [[2, 1, 3]],
 [[2, 3, 1]],
 [[1, 3, 2], [3, 1, 2]],
 [[3, 2, 1]]]
```

(continues on next page)
The left Sylvester classes in $S_3$:

```python
sage: sorted(p.sylvester_class(left_to_right=True))
```

```python
[[1, 2, 3],
 [1, 3, 2],
 [2, 1, 3],
 [2, 3, 1],
 [3, 1, 2],
 [3, 2, 1]]
```

A left Sylvester class in $S_5$:

```python
element = Permutation([4, 2, 1, 5, 3])
sage: sorted(element.sylvester_class(left_to_right=True))
```

```python
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 5, 1],
 [4, 2, 5, 1, 3],
 [4, 2, 5, 3, 1],
 [4, 5, 2, 1, 3],
 [4, 5, 2, 3, 1]]
```

```python
from sage.all import *
```

```python
from sage.all import *
```

```python
p = Permutation([Integer(4), Integer(2), Integer(1), Integer(5),
                 Integer(3)])
sage: sorted(p.sylvester_class(left_to_right=True))
```

```python
[[4, 2, 1, 3, 5],
 [4, 2, 1, 5, 3],
 [4, 2, 3, 1, 5],
 [4, 2, 3, 5, 1],
 [4, 2, 5, 1, 3],
 [4, 2, 5, 3, 1],
 [4, 5, 2, 1, 3],
 [4, 5, 2, 3, 1]]
```
Return a matrix representing the permutation in the `AlternatingSignMatrix` class.

**EXAMPLES:**

```python
sage: m = Permutation([1,2,3]).to_alternating_sign_matrix(); m
# needs sage.combinat sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
sage: parent(m)
# needs sage.combinat sage.modules
Alternating sign matrices of size 3
```

```
>>> from sage.all import *

>>> m = Permutation([Integer(1),Integer(2),Integer(3)]).to_alternating_sign_matrix(); m
# needs sage.combinat sage.modules
[1 0 0]
[0 1 0]
[0 0 1]

>>> parent(m)
# needs sage.combinat sage.modules
Alternating sign matrices of size 3
```

### to_cycles (singletons=True, use_min=True)

Return the permutation `self` as a list of disjoint cycles.

The cycles are returned in the order of increasing smallest elements, and each cycle is returned as a tuple which starts with its smallest element.

If `singletons=False` is given, the list does not contain the singleton cycles.

If `use_min=False` is given, the cycles are returned in the order of increasing largest (not smallest) elements, and each cycle starts with its largest element.

**EXAMPLES:**

```python
sage: Permutation([2,1,3,4]).to_cycles()
[(1, 2), (3,), (4,)]  
sage: Permutation([2,1,3,4]).to_cycles(singletons=False)
[(1, 2)]  
sage: Permutation([2,1,3,4]).to_cycles(use_min=True)
[(1, 2), (3,), (4,)]  
sage: Permutation([2,1,3,4]).to_cycles(use_min=False)
[(4,), (3,), (2, 1)]  
sage: Permutation([2,1,3,4]).to_cycles(singletons=False, use_min=False)
[(2, 1)]
```

```python
sage: Permutation([4,1,5,2,6,3]).to_cycles()
[(1, 4, 2), (3, 5, 6)]

sage: Permutation([4,1,5,2,6,3]).to_cycles(use_min=False)
[(6, 3, 5), (4, 2, 1)]
```

```python
sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles()
[(1, 6), (2, 4), (3, 5)]

sage: Permutation([6, 4, 5, 2, 3, 1]).to_cycles(use_min=False)
[(6, 1), (5, 3), (4, 2)]
```

```python
>>> from sage.all import *

>>> Permutation([Integer(2),Integer(1),Integer(3),Integer(4)]).to_cycles()
(continues on next page)```

The algorithm is of complexity $O(n)$ where $n$ is the size of the given permutation.

to_digraph()

Return a digraph representation of self.

EXAMPLES:

```python
sage: d = Permutation([3, 1, 2]).to_digraph()  # needs sage.graphs
sage: d.edges(sort=True, labels=False)  # needs sage.graphs
[(1, 3), (2, 1), (3, 2)]
```

```python
sage: P = Permutations(range(1, 10))

sage: d = Permutation(P.random_element()).to_digraph()  # needs sage.graphs
sage: all(c.is_cycle() for c in d.strongly_connected_components_subgraphs())
True
```

```python
sage: d = Permutation([1, 2, 3, 4]).to_digraph()  # needs sage.graphs
sage: d.edges(sort=True, labels=False)  # needs sage.graphs
[(1, 3), (2, 1), (3, 2)]
```

```python
>>> from sage.all import *

>>> d = Permutation([Integer(3), Integer(1), Integer(2)]).to_digraph()  # needs sage.graphs
>>> d.edges(sort=True, labels=False)  # needs sage.graphs
[(1, 3), (2, 1), (3, 2)]
```
to_inversion_vector()

Return the inversion vector of self.

The inversion vector of a permutation \( p \in S_n \) is defined as the vector \((v_1, v_2, \ldots, v_n)\), where \( v_i \) is the number of elements larger than \( i \) that appear to the left of \( i \) in the permutation \( p \).

The algorithm is of complexity \( O(n \log(n)) \) where \( n \) is the size of the given permutation.

EXAMPLES:

```
sage: Permutation([5,9,1,8,2,6,4,7,3]).to_inversion_vector()
[2, 3, 6, 4, 0, 2, 2, 1, 0]
sage: Permutation([8,7,2,1,9,4,6,5,10,3]).to_inversion_vector()
[3, 2, 7, 3, 4, 3, 1, 0, 0, 0]
sage: Permutation([3,2,4,1,5]).to_inversion_vector()
[3, 1, 0, 0, 0]
```

```
>>> from sage.all import *
```
to_lehmer_code()

Return the Lehmer code of the permutation self.

The Lehmer code of a permutation \( p \) is defined as the list \([c[1], c[2], ..., c[n]]\), where \( c[i] \) is the number of \( j > i \) such that \( p(j) < p(i) \).

EXAMPLES:

```python
sage: p = Permutation([2,1,3])
sage: p.to_lehmer_code()
[1, 0, 0]
sage: q = Permutation([3,1,2])
sage: q.to_lehmer_code()
[2, 0, 0]
sage: Permutation([1]).to_lehmer_code()
[0]
sage: Permutation([]).to_lehmer_code()
[]
```

```python
>>> from sage.all import *
>>> p = Permutation([Integer(2),Integer(1),Integer(3)])
>>> p.to_lehmer_code()
[1, 0, 0]
>>> q = Permutation([Integer(3),Integer(1),Integer(2)])
>>> q.to_lehmer_code()
[2, 0, 0]
>>> Permutation([Integer(1)]).to_lehmer_code()
[0]
>>> Permutation([]).to_lehmer_code()
[]
```

to_major_code(final_descent=False)

Return the major code of the permutation self.

The major code of a permutation \( p \) is defined as the sequence \((m_1 - m_2, m_2 - m_3, ..., m_n)\), where \( m_i \) is the major index of the permutation obtained by erasing all letters smaller than \( i \) from \( p \).

With the final_descent option, the last position of a non-empty permutation is also considered as a descent. This has an effect on the computation of major indices.

REFERENCES:

EXAMPLES:

```python
sage: Permutation([9,3,5,7,2,1,4,6,8]).to_major_code()
[5, 0, 1, 0, 1, 2, 0, 1, 0]
sage: Permutation([2,8,4,3,6,7,9,5,1]).to_major_code()
[8, 3, 3, 1, 4, 0, 1, 0, 0]
```

```python
>>> from sage.all import *
>>> Permutation([Integer(9),Integer(3),Integer(5),Integer(7),Integer(2),
(continues on next page)
to_matrix()

Return a matrix representing the permutation.

EXAMPLES:

```python
sage: Permutation([1,2,3]).to_matrix()
# needs sage.modules
[1 0 0]
[0 1 0]
[0 0 1]
```

Alternatively:

```python
sage: matrix(Permutation([1,3,2]))
# needs sage.modules
[1 0 0]
[0 0 1]
[0 1 0]
```

Notice that matrix multiplication corresponds to permutation multiplication only when the permutation option mult='r2l'.

```python
sage: Permutations.options.mult='r2l'
```

```python
sage: p = Permutation([2,1,3])
sage: q = Permutation([3,1,2])
sage: (p*q).to_matrix()
# needs sage.modules
[0 0 1]
[0 1 0]
[1 0 0]
sage: p.to_matrix()*q.to_matrix()
# needs sage.modules
[0 0 1]
[0 1 0]
[1 0 0]
```

```python
sage: Permutations.options.mult=l2r
```

(continues on next page)
### to_permutation_group_element()

Return a PermutationGroupElement equal to `self`.

**EXAMPLES:**

```python
sage: Permutation([3,4,1,2,5]).to_permutation_group_element()  #...
   ← needs sage.groups
(1,2)(3,4)
sage: Permutation([1,2,3]).to_permutation_group_element()  #...
   ← needs sage.groups
()
```

### to_tableau_by_shape(shape)

Return a tableau of shape `shape` with the entries in `self`. The tableau is such that the reading word (i.e., the word obtained by reading the tableau row by row, starting from the top row in English notation, with each row being read from left to right) is `self`.

**EXAMPLES:**

```python
sage: T = Permutation([3,4,1,2,5]).to_tableau_by_shape([3,2]); T  #...
   ← needs sage.combinat
```
weak_excedences()

Return all the numbers \( self[i] \) such that \( self[i] \geq i+1 \).

EXAMPLES:

sage: Permutation([1,4,3,2,5]).weak_excedences()
[1, 4, 3, 5]

class sage.combinat.permutation.Permutations

Bases: UniqueRepresentation, Parent

Permutations.

Permutations(\( n \)) returns the class of permutations of \( n \), if \( n \) is an integer, list, set, or string.

Permutations(\( n, \ k \)) returns the class of length-\( k \) partial permutations of \( n \) (where \( n \) is any of the above things); \( k \) must be a nonnegative integer. A length-\( k \) partial permutation of \( n \) is defined as a \( k \)-tuple of pairwise distinct elements of \( \{1, 2, \ldots, n\} \).

Valid keyword arguments are: 'descents', 'bruhat_smaller', 'bruhat_greater', 'recoils_finer', 'recoils_fatter', 'recoils', and 'avoiding'. With the exception of 'avoiding', you cannot specify \( n \) or \( k \) along with a keyword.

Permutations(descents=(list,n)) returns the class of permutations of \( n \) with descents in the positions specified by list. This uses the slightly nonstandard convention that the images of \( 1, 2, \ldots, n \) under the permutation are regarded as positions \( 0, 1, \ldots, n - 1 \), so for example the presence of \( 1 \) in list signifies that the permutations \( \pi \) should satisfy \( \pi(2) > \pi(3) \). Note that list is supposed to be a list of positions of the descents, not the descents composition. It does not return the class of permutations with descents composition list.

Permutations(bruhat_smaller=p) and Permutations(bruhat_greater=p) return the class of permutations smaller-or-equal or greater-or-equal, respectively, than the given permutation \( p \) in the Bruhat order. (The Bruhat order is defined in bruhat_lequal(). It is also referred to as the strong Bruhat order.)

Permutations(recoils=p) returns the class of permutations whose recoils composition is \( p \). Unlike the descents=(list, n) syntax, this actually takes a composition as input.

Permutations(recoils_fatter=p) and Permutations(recoils_finer=p) return the class of permutations whose recoils composition is fatter or finer, respectively, than the given composition \( p \).

Permutations(n, avoiding=P) returns the class of permutations of \( n \) avoiding \( P \). Here \( P \) may be a single permutation or a list of permutations; the returned class will avoid all patterns in \( P \).
EXAMPLES:

```python
sage: p = Permutations(3); p
Standard permutations of 3
sage: p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

>>> from sage.all import *

>>> p = Permutations(Integer(3)); p
Standard permutations of 3

>>> p.list()
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

sage: p = Permutations(3, 2); p
Permutations of {1,...,3} of length 2
sage: p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

>>> from sage.all import *

>>> p = Permutations(Integer(3), Integer(2)); p
Permutations of {1,...,3} of length 2

>>> p.list()
[[1, 2], [1, 3], [2, 1], [2, 3], [3, 1], [3, 2]]

sage: p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']

sage: p.list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]

>>> from sage.all import *

>>> p = Permutations(['c', 'a', 't']); p
Permutations of the set ['c', 'a', 't']

>>> p.list()
[['c', 'a', 't'], ['c', 't', 'a'], ['a', 'c', 't'], ['a', 't', 'c'], ['t', 'c', 'a'], ['t', 'a', 'c']]

sage: p = Permutations(['c', 'a', 't'], 2); p
Permutations of the set ['c', 'a', 't'] of length 2

sage: p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]

>>> from sage.all import *

>>> p = Permutations(['c', 'a', 't'], Integer(2)); p
Permutations of the set ['c', 'a', 't'] of length 2

>>> p.list()
[['c', 'a'], ['c', 't'], ['a', 'c'], ['a', 't'], ['t', 'c'], ['t', 'a']]
```

5.1. Comprehensive Module List
sage: p = Permutations([1,1,2]); p
Permutations of the multi-set [1, 1, 2]
sage: p.list()
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]

```python
>>> from sage.all import *

>>> p = Permutations([Integer(1),Integer(1),Integer(2)]); p
Permutations of the multi-set [1, 1, 2]
```
```
>>> p.list()
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]
```

```python
sage: p = Permutations([1,1,2], 2); p
Permutations of the multi-set [1, 1, 2] of length 2
```
```
sage: p.list()
# needs sage.libs.gap
[ [ 1, 1 ], [ 1, 2 ], [ 2, 1 ] ]

Element

alias of Permutation
options = Current options for Permutations - display: list -
generator_name: s - latex: list - latex_empty_str: 1 - mult: l2r

class sage.combinat.permutation.PermutationsNK(s, k)
    Bases: Permutations_setk

This exists solely for unpickling PermutationsNK objects created with Sage <= 6.3.

class sage.combinat.permutation.Permutations_mset(mset)
    Bases: Permutations

Permutations of a multiset $M$.

A permutation of a multiset $M$ is represented by a list that contains exactly the same elements as $M$ (with the same multiplicities), but possibly in different order. If $M$ is a proper set there are $|M|!$ such permutations. Otherwise, if the first element appears $k_1$ times, the second element appears $k_2$ times and so on, the number of permutations is $|M|!/(k_1!k_2!...)$, which is sometimes called a multinomial coefficient.

EXAMPLES:

```python
sage: mset = [1,1,2,2,2]
sage: from sage.combinat.permutation import Permutations_mset
sage: P = Permutations_mset(mset); P
Permutations of the multi-set [1, 1, 2, 2, 2]
sage: sorted(P)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [1, 2, 2, 2, 1],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 1, 2, 2, 1],
 [2, 2, 1, 1, 2],
 [2, 2, 1, 2, 1],
 [2, 2, 2, 1, 1]]

sage: # needs sage.modules
sage: MS = MatrixSpace(GF(2), 2, 2)
sage: A = MS([[0,1],[1,0]])
sage: rows = A.rows()
sage: rows[0].set_immutable()
sage: rows[1].set_immutable()
sage: P = Permutations_mset(rows); P
Permutations of the multi-set [(0, 1), (1, 0)]
sage: sorted(P)
[[[0, 1], [1, 0]], [[1, 0], [0, 1]]]

>>> from sage.all import *
>>> mset = [Integer(1),Integer(1),Integer(2),Integer(2),Integer(2)]
>>> from sage.combinat.permutation import Permutations_mset
>>> P = Permutations_mset(mset); P
Permutations of the multi-set [1, 1, 2, 2, 2]
>>> sorted(P)
[[1, 1, 2, 2, 2],
 [1, 2, 1, 2, 2],
 [1, 2, 2, 1, 2],
 [1, 2, 2, 2, 1],
 [2, 1, 1, 2, 2],
 [2, 1, 2, 1, 2],
 [2, 1, 2, 2, 1],
 [2, 2, 1, 1, 2],
 [2, 2, 1, 2, 1],
 [2, 2, 2, 1, 1],

[2, 1, 2, 1, 2],
[2, 1, 2, 1, 2],
[2, 2, 1, 1, 2],
[2, 2, 1, 2, 1],
[2, 2, 2, 1, 1]]

```python
# needs sage.modules
MS = MatrixSpace(GF(Integer(2)), Integer(2), Integer(2))
A = MS([Integer(1), Integer(0), Integer(1), Integer(1)])
rows = A.rows()
rows[Integer(0)].set_immutable()
rows[Integer(1)].set_immutable()
P = Permutations_mset(rows); P
Permutations of the multi-set [(1, 0), (1, 1)]
```

```python
>>> P
[[[1, 0), (1, 1)], [(1, 1), (1, 0)]]
```

class Element

    Bases: ClonableArray

    A permutation of an arbitrary multiset.

    check()  
    Verify that self is a valid permutation of the underlying multiset.

    EXAMPLES:

    ```python
    sage: S = Permutations(['c','a','c'])
sage: elt = S(['c','c','a'])
sage: elt.check()
    ```

    ```python
    >>> from sage.all import *
    >>> S = Permutations(['c','a','c'])
    >>> elt = S(['c','c','a'])
    >>> elt.check()
    ```

cardinality()  
Return the cardinality of the set.

    EXAMPLES:

    ```python
    sage: Permutations([1,2,2]).cardinality()
    3
    sage: Permutations([1,1,2,2,2]).cardinality()
    10
    ```

    ```python
    >>> from sage.all import *
    >>> Permutations([Integer(1), Integer(2), Integer(2)]).cardinality()
    3
    >>> Permutations([Integer(1), Integer(1), Integer(2), Integer(2), Integer(2)]).cardinality()
    10
    ```

rank(p)  
Return the rank of p in lexicographic order.

    INPUT:
• p – a permutation of M

ALGORITHM:
The algorithm uses the recurrence from the solution to exercise 4 in [Knu2011], Section 7.2.1.2:

\[
\text{rank}(p_1 \ldots p_n) = \text{rank}(p_2 \ldots p_n) + \frac{1}{n} \binom{n}{n_1, \ldots, n_t} \sum_{j=1}^{t} n_j [x_j < p_1],
\]

where \(x_j,n_j\) are the distinct elements of \(p\) with their multiplicities, \(n\) is the sum of \(n_1,\ldots,n_t\), \(\binom{n}{n_1,\ldots,n_t}\) is the multinomial coefficient, \(\sum_{j=1}^{t} n_j [x_j < p_1]\) means “the number of elements to the right of the first element that are less than the first element”.

EXAMPLES:

```
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.rank(list(sorted(mset)))
0
sage: p.rank(list(reversed(sorted(mset)))) == p.cardinality() - 1
True
sage: p.rank([3, 1, 4, 1, 5, 9, 2, 6, 5])
30991
```

```
>>> from sage.all import *
>>> mset = [Integer(1), Integer(1), Integer(2), Integer(3), Integer(4),
  ... Integer(5), Integer(5), Integer(6), Integer(9)]
>>> p = Permutations(mset)
>>> p.rank(list(sorted(mset)))
0
>>> p.rank(list(reversed(sorted(mset)))) == p.cardinality() - Integer(1)
True
>>> p.rank([Integer(3), Integer(1), Integer(4), Integer(1), Integer(5),
  ... Integer(9), Integer(2), Integer(6), Integer(5)])
30991
```

unrank \((r)\)

Return the permutation of \(M\) having lexicographic rank \(r\).

INPUT:

• \(r\) – an integer between 0 and self.cardinality() - 1 inclusive

ALGORITHM:
The algorithm is adapted from the solution to exercise 4 in [Knu2011], Section 7.2.1.2.

EXAMPLES:

```
sage: mset = [1, 1, 2, 3, 4, 5, 5, 6, 9]
sage: p = Permutations(mset)
sage: p.unrank(30991)
[3, 1, 4, 1, 5, 9, 2, 6, 5]
sage: p.rank(p.unrank(10))
10
sage: p.unrank(0) == list(sorted(mset))
True
sage: p.unrank(p.cardinality()-1) == list(reversed(sorted(mset)))
True
```
```python
>>> from sage.all import *
>>> mset = [Integer(1), Integer(1), Integer(2), Integer(3), Integer(4),
...         Integer(5), Integer(5), Integer(6), Integer(9)]
>>> p = Permutations(mset)
>>> p.unrank(Integer(30991))
[3, 1, 4, 1, 5, 9, 2, 6, 5]
>>> p.rank(p.unrank(Integer(10)))
10
>>> p.unrank(Integer(0)) == list(sorted(mset))
True
>>> p.unrank(p.cardinality()-Integer(1)) == list(reversed(sorted(mset)))
True
```

```python
class sage.combinat.permutation.Permutations_msetk(mset, k)
Bases: Permutations_mset

Length-\(k\) partial permutations of a multiset.

A length-\(k\) partial permutation of a multiset \(M\) is represented by a list of length \(k\) whose entries are elements of \(M\), appearing in the list with a multiplicity not higher than their respective multiplicity in \(M\).

cardinality()  
Return the cardinality of the set.

EXAMPLES:
```
sage: Permutations([1,2,2], 2).cardinality()  # needs sage.libs.gap
3
```

```python
>>> from sage.all import *

>>> Permutations([Integer(1),Integer(2),Integer(2)], Integer(2)).
_cardinality()  
3
```

```python
class sage.combinat.permutation.Permutations_nk(n, k)
Bases: Permutations

Length-\(k\) partial permutations of \(\{1, 2, \ldots, n\}\).

class Element

Bases: ClonableArray

A length-\(k\) partial permutation of \([n]\).

check()  
Verify that \(self\) is a valid length-\(k\) partial permutation of \([n]\).

EXAMPLES:
```
sage: S = Permutations(4, 2)
sage: elt = S([3, 1])
sage: elt.check()
```
```
```
cardinality()
EXAMPLES:

```python
sage: Permutations(3,0).cardinality()
1
sage: Permutations(3,1).cardinality()
3
sage: Permutations(3,2).cardinality()
6
sage: Permutations(3,3).cardinality()
6
sage: Permutations(3,4).cardinality()
0

>>> from sage.all import *
>>> Permutations(Integer(3),Integer(0)).cardinality()
1
>>> Permutations(Integer(3),Integer(1)).cardinality()
3
>>> Permutations(Integer(3),Integer(2)).cardinality()
6
>>> Permutations(Integer(3),Integer(3)).cardinality()
6
>>> Permutations(Integer(3),Integer(4)).cardinality()
0
```

random_element()
EXAMPLES:

```python
sage: s = Permutations(3,2).random_element()
sage: s in Permutations(3,2)
True

>>> from sage.all import *
>>> s = Permutations(Integer(3),Integer(2)).random_element()
>>> s in Permutations(Integer(3),Integer(2))
True
```

class sage.combinat.permutation.Permutations_set(s)
Bases: Permutations

Permutations of an arbitrary given finite set.
Here, a “permutation of a finite set $S$” means a list of the elements of $S$ in which every element of $S$ occurs exactly once. This is not to be confused with bijections from $S$ to $S$, which are also often called permutations in literature.

class Element
Bases: ClonableArray

A permutation of an arbitrary set.

check()
Verify that self is a valid permutation of the underlying set.

EXAMPLES:
```python
sage: S = Permutations(['c', 'a', 't'])
sage: elt = S(['t', 'c', 'a'])
sage: elt.check()

>>> from sage.all import *
>>> S = Permutations(['c', 'a', 't'])
>>> elt = S(['t', 'c', 'a'])
>>> elt.check()
```

**cardinality()**

Return the cardinality of the set.

**EXAMPLES:**

```python
sage: Permutations([1,2,3]).cardinality()
6

>>> from sage.all import *
>>> Permutations([Integer(1),Integer(2),Integer(3)]).cardinality()
6
```

**random_element()**

**EXAMPLES:**

```python
sage: s = Permutations([1,2,3]).random_element()
sage: s.parent() is Permutations([1,2,3])
True

>>> from sage.all import *
>>> s = Permutations([Integer(1),Integer(2),Integer(3)]).random_element()
>>> s.parent() is Permutations([Integer(1),Integer(2),Integer(3)])
True
```

**class sage.combinat.permutation.Permutations_setk(s, k)**

**Bases:** Permutations_set

Length-\( k \) partial permutations of an arbitrary given finite set.

Here, a “length-\( k \) partial permutation of a finite set \( S \)” means a list of length \( k \) whose entries are pairwise distinct and all belong to \( S \).

**random_element()**

**EXAMPLES:**

```python
sage: s = Permutations([1,2,4], 2).random_element()
sage: s in Permutations([1,2,4], 2)
True

>>> from sage.all import *
>>> s = Permutations([Integer(1),Integer(2),Integer(4)], Integer(2)).random_element()
>>> s in Permutations([Integer(1),Integer(2),Integer(4)], Integer(2))
True
```

**class sage.combinat.permutation.StandardPermutations_all**

**Bases:** Permutations

3012 Chapter 5. Comprehensive Module List
All standard permutations.

**graded_component** \((n)\)

Return the graded component.

**EXAMPLES:**

```python
sage: P = Permutations()
sage: P.graded_component(4) == Permutations(4)
True

>>> from sage.all import *
>>> P = Permutations()
>>> P.graded_component(Integer(4)) == Permutations(Integer(4))
True
```

class sage.combinat.permutation.StandardPermutations_all_avoiding \((a)\)

**Bases:** StandardPermutations_all

All standard permutations avoiding a set of patterns.

**patterns**

Return the patterns avoided by this class of permutations.

**EXAMPLES:**

```python
sage: P = Permutations(avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
([2, 1, 3], [1, 2, 3])

>>> from sage.all import *
>>> P = Permutations(avoiding=[[Integer(2),Integer(1),Integer(3)],[Integer(1),
→Integer(2),Integer(3)]])
>>> P.patterns()
([2, 1, 3], [1, 2, 3])
```

class sage.combinat.permutation.StandardPermutations_avoiding_12 \((n)\)

**Bases:** StandardPermutations_avoiding_generic

**cardinality**

Return the cardinality of self.

**EXAMPLES:**

```python
sage: P = Permutations(3, avoiding=[1, 2])
sage: P.cardinality()
1

>>> from sage.all import *
>>> P = Permutations(Integer(3), avoiding=[Integer(1), Integer(2)])
>>> P.cardinality()
1
```

class sage.combinat.permutation.StandardPermutations_avoiding_123 \((n)\)

**Bases:** StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[1, 2, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 2, 3]).list() )
42
```

```python
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(1), Integer(2), Integer(3)]).cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(1), Integer(2), Integer(3)]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_132(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[1, 3, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[1, 3, 2]).list() )
42
```

```python
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(1), Integer(3), Integer(2)]).cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(1), Integer(3), Integer(2)]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_21(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: P = Permutations(3, avoiding=[2, 1])
sage: P.cardinality()
1
```

```python
>>> from sage.all import *
>>> P = Permutations(Integer(3), avoiding=[Integer(2), Integer(1)])
>>> P.cardinality()
1
```

class sage.combinat.permutation.StandardPermutations_avoiding_213(n)

Bases: StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[2, 1, 3]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 1, 3]).list() )
42
```

```python
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(2), Integer(1), Integer(3)]).→cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(2), Integer(1),...
→Integer(3)]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_231(n)
Bases: StandardPermutations_avoiding_generic

cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[2, 3, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[2, 3, 1]).list() )
42
```

```python
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(2), Integer(3), Integer(1)]).→cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(2), Integer(3),...
→Integer(1)]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_312(n)
Bases: StandardPermutations_avoiding_generic

cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[3, 1, 2]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 1, 2]).list() )
42
```

```python
>>> from sage.all import *
>>> Permutations(Integer(5), avoiding=[Integer(3), Integer(1), Integer(2)]).→cardinality()
42
>>> len( Permutations(Integer(5), avoiding=[Integer(3), Integer(1),...
→Integer(2)]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_321(n)
Bases: StandardPermutations_avoiding_generic
cardinality()

EXAMPLES:

```python
sage: Permutations(5, avoiding=[3, 2, 1]).cardinality()
42
sage: len( Permutations(5, avoiding=[3, 2, 1]).list() )
42
```

```python
>>> from sage.all import *

>>> Permutations(Integer(5), avoiding=[Integer(3), Integer(2), Integer(1)]).cardinality()
42
```

```python
>>> len( Permutations(Integer(5), avoiding=[Integer(3), Integer(2), Integer(1)]).list() )
42
```

class sage.combinat.permutation.StandardPermutations_avoiding_generic(n, a)

Bases: StandardPermutations_n_abstract

Generic class for subset of permutations avoiding a set of patterns.

property a

self.a is deprecated; use patterns() instead.

cardinality()

Return the cardinality of self.

EXAMPLES:

```python
sage: P = Permutations(3, avoiding=[[2, 1, 3],[1,2,3]])
sage: P.cardinality()
# needs sage.combinat
4
```

```python
>>> from sage.all import *

>>> P = Permutations(Integer(3), avoiding=[[Integer(2), Integer(1),Integer(3)], [Integer(1),Integer(2),Integer(3)]])

>>> P.cardinality()
# needs sage.combinat
4
```

patterns()

Return the patterns avoided by this class of permutations.

EXAMPLES:

```python
sage: P = Permutations(3, avoiding=[[2,1,3],[1,2,3]])
sage: P.patterns()
(([2, 1, 3], [1, 2, 3])
```

```python
>>> from sage.all import *

>>> P = Permutations(Integer(3), avoiding=[[Integer(2),Integer(1),Integer(3)],
   ... [Integer(1),Integer(2),Integer(3)]])

>>> P.patterns()
(([2, 1, 3], [1, 2, 3])
```
class sage.combinat.permutation.StandardPermutations_bruhat_greater(p)

Bases: Permutations

Permutations of \(\{1, \ldots, n\}\) that are greater than or equal to a permutation \(p\) in the Bruhat order.

class sage.combinat.permutation.StandardPermutations_bruhat_smaller(p)

Bases: Permutations

Permutations of \(\{1, \ldots, n\}\) that are less than or equal to a permutation \(p\) in the Bruhat order.

class sage.combinat.permutation.StandardPermutations_descents(d, n)

Bases: StandardPermutations_n_abstract

Permutations of \(\{1, \ldots, n\}\) with a fixed set of descents.

cardinality()

Return the cardinality of \(\text{self}\).

ALGORITHM:
The algorithm described in [Vie1979] is implemented naively.

EXAMPLES:

```
sage: P = Permutations(descents=[[1,0,2], 5])
sage: P.cardinality()
4
```

```
>>> from sage.all import *

>>> P = Permutations(descents=[[Integer(1),Integer(0),Integer(2)],
    →Integer(5)])

>>> P.cardinality()
4
```

first()

Return the first permutation with descents \(d\).

EXAMPLES:

```
sage: Permutations(descents=[[1,0,4,8],12]).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

```
>>> from sage.all import *

>>> Permutations(descents=[[Integer(1),Integer(0),Integer(4),Integer(8)],
    →Integer(12)]).first()
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]
```

last()

Return the last permutation with descents \(d\).

EXAMPLES:

```
sage: Permutations(descents=[[1,0,4,8],12]).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```

```
>>> from sage.all import *

>>> Permutations(descents=[[Integer(1),Integer(0),Integer(4),Integer(8)],
    →Integer(12)]).last()
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]
```
class sage.combinat.permutation.StandardPermutations_n(n)
    Bases: StandardPermutations_n_abstract
    Permutations of the set \{1, 2, \ldots, n\}.
    These are also called permutations of size \(n\), or the elements of the \(n\)-th symmetric group.

Todo: Have a reduced_word() which works in both multiplication conventions.

class Element (parent, i, algorithm='lex', sjt=None, check=True)
    Bases: Permutation
    apply_simple_reflection_left(i)
        Return self multiplied by the simple reflection \(s[i]\) on the left.
        This acts by switching the entries in positions \(i\) and \(i + 1\).

        Warning: This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing reduced_word()).

    EXAMPLES:

    sage: W = Permutations(3)
    sage: w = W([2,3,1])
    sage: w.apply_simple_reflection_left(1)
    [1, 3, 2]
    sage: w.apply_simple_reflection_left(2)
    [3, 2, 1]

    >>> from sage.all import *
    >>> W = Permutations(Integer(3))
    >>> w = W([Integer(2),Integer(3),Integer(1)])
    >>> w.apply_simple_reflection_left(Integer(1))
    [1, 3, 2]
    >>> w.apply_simple_reflection_left(Integer(2))
    [3, 2, 1]

    apply_simple_reflection_right(i)
        Return self multiplied by the simple reflection \(s[i]\) on the right.
        This acts by switching the entries \(i\) and \(i + 1\).

        Warning: This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing reduced_word()).

    EXAMPLES:

    sage: W = Permutations(3)
    sage: w = W([2,3,1])
    sage: w.apply_simple_reflection_right(1)
    [3, 2, 1]
    sage: w.apply_simple_reflection_right(2)
    [2, 1, 3]
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> W = Permutations(Integer(3))

>>> w = W([Integer(2), Integer(3), Integer(1)])

>>> w.apply_simple_reflection_right(Integer(1))
[3, 2, 1]

>>> w.apply_simple_reflection_right(Integer(2))
[2, 1, 3]
```

**has_left_descent** (*i*, *mult=None*)
Check if *i* is a left descent of self.

A left descent of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n-1\}$ such that $s_i \circ \pi$ has smaller length than $\pi$. Thus, a left descent of $\pi$ is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi^{-1}(i) > \pi^{-1}(i+1)$.

**Warning**: The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.

**Warning**: This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing `reduced_word()`).

**EXAMPLES**:

```python
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: (~x).descents()
[1, 2]

sage: [i for i in P.index_set() if x.has_left_descent(i)]
[1, 2]
```

```python
>>> from sage.all import *

>>> P = Permutations(Integer(4))

>>> x = P([Integer(3), Integer(2), Integer(4), Integer(1)])

>>> (~x).descents()
[1, 2]

>>> [i for i in P.index_set() if x.has_left_descent(i)]
[1, 2]
```

**has_right_descent** (*i*, *mult=None*)
Check if *i* is a right descent of self.

A right descent of a permutation $\pi \in S_n$ means an index $i \in \{1, 2, \ldots, n-1\}$ such that $\pi \circ s_i$ has smaller length than $\pi$. Thus, a right descent of $\pi$ is an index $i \in \{1, 2, \ldots, n-1\}$ satisfying $\pi(i) > \pi(i+1)$.

**Warning**: The methods `descents()` and `idescents()` behave differently than their Weyl group counterparts. In particular, the indexing is 0-based. This could lead to errors. Instead, construct the descent set as in the example.
Warning: This ignores the multiplication convention in order to be consistent with other Coxeter operations in permutations (e.g., computing reduced_word()).

EXAMPLES:

```sage
sage: P = Permutations(4)
sage: x = P([3, 2, 4, 1])
sage: x.descents()
[1, 3]
sage: [i for i in P.index_set() if x.has_right_descent(i)]
[1, 3]
```

```python
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> x = P([Integer(3), Integer(2), Integer(4), Integer(1)])
>>> x.descents()
[1, 3]
>>> [i for i in P.index_set() if x.has_right_descent(i)]
[1, 3]
```

inverse()
Return the inverse of self.

EXAMPLES:

```sage
sage: P = Permutations(4)
sage: w0 = P([4, 3, 2, 1])
sage: w0.inverse() == w0
True
sage: w0.inverse().parent() is P
True
sage: P([3, 2, 4, 1]).inverse()
[4, 2, 1, 3]
```

```python
>>> from sage.all import *
>>> P = Permutations(Integer(4))
>>> w0 = P([Integer(4), Integer(3), Integer(2), Integer(1)])
>>> w0.inverse() == w0
True
>>> w0.inverse().parent() is P
True
>>> P([Integer(3), Integer(2), Integer(4), Integer(1)]).inverse()
[4, 2, 1, 3]
```

algebra(base_ring, category=None)
Return the symmetric group algebra associated to self.

INPUT:

- `base_ring`: a ring
- `category`: a category (default: the category of self)

EXAMPLES:
Combinatorics, Release 10.4

sage: # needs sage.groups sage.modules
sage: P = Permutations(4)

Symmetric group algebra of order 4 over Rational Field

sage: A = P.algebra(QQ); A
Join of Category of Coxeter group algebras over Rational Field
and Category of finite group algebras over Rational Field
and Category of finite dimensional cellular algebras
with basis over Rational Field

sage: A = P.algebra(QQ, category=Monoids())

Category of finite dimensional cellular monoid algebras over Rational Field

as_permutation_group()

Return self as a permutation group.

EXAMPLES:

sage: P = Permutations(4)

sage: PG = P.as_permutation_group(); PG
Symmetric group of order 4! as a permutation group

sage: G = SymmetricGroup(4)

sage: PG is G
True

>>> from sage.all import *
>>> # needs sage.groups sage.modules
>>> P = Permutations(Integer(4))

>>> PG = P.as_permutation_group(); PG
Symmetric group of order 4! as a permutation group

>>> G = SymmetricGroup(Integer(4))

>>> PG is G
True

cardinality()

Return the number of permutations of size $n$, which is $n!$.
EXAMPLES:

```python
sage: Permutations(0).cardinality()
1
sage: Permutations(3).cardinality()
6
sage: Permutations(4).cardinality()
24

>>> from sage.all import *
>>> Permutations(Integer(0)).cardinality()
1
>>> Permutations(Integer(3)).cardinality()
6
>>> Permutations(Integer(4)).cardinality()
24
```

cartan_type()

Return the Cartan type of self.

The symmetric group $S_n$ is a Coxeter group of type $A_{n-1}$.

EXAMPLES:

```python
sage: A = SymmetricGroup([2,3,7]); A.cartan_type()  # needs sage.combinat sage.groups
['A', 2]
sage: A = SymmetricGroup([]); A.cartan_type()      # needs sage.combinat sage.groups
['A', 0]

>>> from sage.all import *
>>> A = SymmetricGroup([Integer(2),Integer(3),Integer(7)]); A.cartan_type()  # needs sage.combinat sage.groups
['A', 2]
>>> A = SymmetricGroup([]); A.cartan_type()      # needs sage.combinat sage.groups
['A', 0]
```

codegrees()

Return the codegrees of self.

EXAMPLES:

```python
sage: Permutations(3).codegrees()
(0, 1)
sage: Permutations(7).codegrees()
(0, 1, 2, 3, 4, 5)

>>> from sage.all import *
>>> Permutations(Integer(3)).codegrees()
(0, 1)
>>> Permutations(Integer(7)).codegrees()
(0, 1, 2, 3, 4, 5)
```

conjugacy_class(g)

Return the conjugacy class of $g$ in self.
INPUT:

- \( g \) – a partition or an element of \( \text{self} \)

EXAMPLES:

```python
sage: G = Permutations(5)
sage: g = G([2,3,4,1,5])
sage: G.conjugacy_class(g)  # needs sage.combinat sage.graphs sage.groups
Conjugacy class of cycle type [4, 1] in Standard permutations of 5
```

```python
sage: G.conjugacy_class(Partition([2, 1, 1, 1]))  # needs sage.combinat sage.graphs sage.groups
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5
```

```python
>>> from sage.all import *

G = Permutations(Integer(5))

G.conjugacy_class(Partition([Integer(2), Integer(1), Integer(1), Integer(1)]))  # needs sage.combinat sage.graphs sage.groups
Conjugacy class of cycle type [2, 1, 1, 1] in Standard permutations of 5
```

### conjugacy_classes()

Return a list of the conjugacy classes of \( \text{self} \).

EXAMPLES:

```python
sage: G = Permutations(4)
sage: G.conjugacy_classes()  # needs sage.combinat sage.graphs sage.groups
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,
```

```python
>>> from sage.all import *

G = Permutations(Integer(4))

G.conjugacy_classes()  # needs sage.combinat sage.graphs sage.groups
[Conjugacy class of cycle type [1, 1, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 1, 1] in Standard permutations of 4,
 Conjugacy class of cycle type [2, 2] in Standard permutations of 4,
 Conjugacy class of cycle type [3, 1] in Standard permutations of 4,
```

### conjugacy_classes_iterator()

Iterate over the conjugacy classes of \( \text{self} \).

EXAMPLES:

```python
sage: G = Permutations(4)
sage: list(G.conjugacy_classes_iterator()) == G.conjugacy_classes()  # needs sage.combinat sage.graphs sage.groups
True
```
>>> from sage.all import *
>>> G = Permutations(Integer(4))
>>> list(G.conjugacy_classes_iterator()) == G.conjugacy_classes() #
->needs sage.combinat sage.graphs sage.groups
True

conjugacy_classes_representatives()

Return a complete list of representatives of conjugacy classes in self.

Let $S_n$ be the symmetric group on $n$ letters. The conjugacy classes are indexed by partitions $\lambda$ of $n$. The ordering of the conjugacy classes is reverse lexicographic order of the partitions.

EXAMPLES:

```sage
sage: G = Permutations(5)
sage: G.conjugacy_classes_representatives() #
->needs sage.combinat sage.libs.flint
[[1, 2, 3, 4, 5],
[2, 1, 3, 4, 5],
[2, 1, 4, 3, 5],
[2, 3, 1, 4, 5],
[2, 3, 1, 5, 4],
[2, 3, 4, 1, 5],
[2, 3, 4, 5, 1]]
```

```sage
>>> from sage.all import *
>>> G = Permutations(Integer(5))
>>> G.conjugacy_classes_representatives() #
->needs sage.combinat sage.libs.flint
[[1, 2, 3, 4, 5],
[2, 1, 3, 4, 5],
[2, 1, 4, 3, 5],
[2, 3, 1, 4, 5],
[2, 3, 1, 5, 4],
[2, 3, 4, 1, 5],
[2, 3, 4, 5, 1]]
```

degree()

Return the degree of self.

This is the cardinality $n$ of the set self acts on.

EXAMPLES:

```sage
sage: Permutations(0).degree()
0
sage: Permutations(1).degree()
1
sage: Permutations(5).degree()
5
```

```sage
>>> from sage.all import *
>>> Permutations(Integer(0)).degree()
0
>>> Permutations(Integer(1)).degree()
1
>>> Permutations(Integer(5)).degree()
5
```
degrees()

Return the degrees of self.

These are the degrees of the fundamental invariants of the ring of polynomial invariants.

EXAMPLES:

```python
sage: Permutations(3).degrees()
(2, 3)
sage: Permutations(7).degrees()
(2, 3, 4, 5, 6, 7)
```

>>> from sage.all import *
>>> Permutations(Integer(3)).degrees()
(2, 3)
>>> Permutations(Integer(7)).degrees()
(2, 3, 4, 5, 6, 7)

element_in_conjugacy_classes(nu)

Return a permutation with cycle type nu.

If the size of nu is smaller than the size of permutations in self, then some fixed points are added.

EXAMPLES:

```python
sage: PP = Permutations(5)
sage: PP.element_in_conjugacy_classes([2,2])
# needs sage.combinat
[2, 1, 4, 3, 5]
sage: PP.element_in_conjugacy_classes([5, 5])
# needs sage.combinat
Traceback (most recent call last):
... ValueError: the size of the partition (=10) should be at most the size of the...

>>> from sage.all import *
>>> PP = Permutations(Integer(5))
>>> PP.element_in_conjugacy_classes([Integer(2),Integer(2)])
# needs sage.combinat
[2, 1, 4, 3, 5]
>>> PP.element_in_conjugacy_classes([Integer(5), Integer(5)])
# needs sage.combinat
Traceback (most recent call last):
... ValueError: the size of the partition (=10) should be at most the size of the...
```

gens()

Return a set of generators for self as a group.

EXAMPLES:

```python
sage: P4 = Permutations(4)
sage: P4.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3])
```
```python
>>> from sage.all import *
>>> P4 = Permutations(Integer(4))
>>> P4.gens()
([2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3])
```

### identity()

Return the identity permutation of size $n$.

**EXAMPLES:**

```python
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

### index_set()

Return the index set for the descents of the symmetric group $\text{self}$.  
This is $\{1, 2, \ldots, n - 1\}$, where $\text{self}$ is $S_n$.

**EXAMPLES:**

```python
sage: P = Permutations(8)
sage: P.index_set()
(1, 2, 3, 4, 5, 6, 7)
```

### one()

Return the identity permutation of size $n$.

**EXAMPLES:**

```python
sage: Permutations(4).identity()
[1, 2, 3, 4]
sage: Permutations(0).identity()
[]
```

### random_element()

**EXAMPLES:**

```python
```
sage: s = Permutations(4).random_element(); s  # random
[1, 2, 4, 3]
sage: s in Permutations(4)
True

>>> from sage.all import *
>>> s = Permutations(Integer(4)).random_element(); s  # random
[1, 2, 4, 3]

**rank** *(p=None)*

Return the rank of self or p depending on input.

If a permutation p is given, return the rank of p in self. Otherwise return the dimension of the underlying vector space spanned by the (simple) roots.

**EXAMPLES:**

```
sage: P = Permutations(5)
sage: P.rank()
4
sage: SP3 = Permutations(3)
sage: list(map(SP3.rank, SP3))
[0, 1, 2, 3, 4, 5]
sage: SP0 = Permutations(0)
sage: list(map(SP0.rank, SP0))
[0]

>>> from sage.all import *
>>>
```

**simple_reflection** *(i)*

For i in the index set of self (that is, for i in \(\{1, 2, \ldots, n-1\}\), where self is \(S_n\)), this returns the elementary transposition \(s_i = (i, i+1)\).

**EXAMPLES:**

```
sage: P = Permutations(4)
sage: P.simple_reflection(2)
[1, 3, 2, 4]
sage: P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}

>>> from sage.all import *
>>> P = Permutations(Integer(4))
```
>>> P.simple_reflection(Integer(2))
[1, 3, 2, 4]
>>> P.simple_reflections()
Finite family {1: [2, 1, 3, 4], 2: [1, 3, 2, 4], 3: [1, 2, 4, 3]}

unrank(r)

EXAMPLES:

```python
sage: SP3 = Permutations(3)
sage: l = list(map(SP3.unrank, range(6)))
l == SP3.list()
True
sage: SP0 = Permutations(0)
sage: l = list(map(SP0.unrank, range(1)))
l == SP0.list()
True
```

```python
from sage.all import *
```

```python
SP3 = Permutations(Integer(3))
l = list(map(SP3.unrank, range(Integer(6))))
l == SP3.list()
True
SP0 = Permutations(Integer(0))
l = list(map(SP0.unrank, range(Integer(1))))
l == SP0.list()
True
```

class sage.combinat.permutation.StandardPermutations_n_abstract(n, category=None)

Bases: Permutations

Abstract base class for subsets of permutations of the set \{1, 2, \ldots, n\}.

Warning: Anything inheriting from this class should override the \_contains\_ method.

class sage.combinat.permutation.StandardPermutations_recoils(recoils)

Bases: Permutations

Permutations of \{1, \ldots, n\} with a fixed recoils composition.

class sage.combinat.permutation.StandardPermutations_recoilsfatter(recoils)

Bases: Permutations

class sage.combinat.permutation.StandardPermutations_recoilsfiner(recoils)

Bases: Permutations

sage.combinat.permutation.bistochastic_as_sum_of_permutations(M, check=True)

Return the positive sum of permutations corresponding to the bistochastic matrix \(M\).

A stochastic matrix is a matrix with nonnegative real entries such that the sum of the elements of any row is equal to 1. A bistochastic matrix is a stochastic matrix whose transpose matrix is also stochastic (there are conditions both on the rows and on the columns).

According to the Birkhoff-von Neumann Theorem, any bistochastic matrix can be written as a convex combination of permutation matrices, which also means that the polytope of bistochastic matrices is integer.
As a non-bistochastic matrix can obviously not be written as a convex combination of permutations, this theorem is an equivalence.

This function, given a bistochastic matrix, returns the corresponding decomposition.

**INPUT:**
- **M** – A bistochastic matrix
- **check** (boolean) – set to True (default) to check that the matrix is indeed bistochastic

**OUTPUT:**
- An element of CombinatorialFreeModule, which is a free \( F \)-module (where \( F \) is the ground ring of the given matrix) whose basis is indexed by the permutations.

**Note:**
- In this function, we just assume 1 to be any constant: for us a matrix \( M \) is bistochastic if there exists \( c > 0 \) such that \( M/c \) is bistochastic.
- You can obtain a sequence of pairs \((\text{permutation}, \text{coeff})\), where \text{permutation} is a Sage Permutation instance, and \text{coeff} its corresponding coefficient from the result of this function by applying the list function.
- If you are interested in the matrix corresponding to a Permutation you will be glad to learn about the Permutation.to_matrix() method.
- The base ring of the matrix can be anything that can be coerced to RR.

**See also:**
- as_sum_of_permutations() to use this method through the Matrix class.

**EXAMPLES:**

We create a bistochastic matrix from a convex sum of permutations, then try to deduce the decomposition from the matrix:

```
sage: from sage.combinat.permutation import bistochastic_as_sum_of_permutations
dsage: # needs networkx sage.graphs sage.modules
dsage: L = []
dsage: L.append((9,Permutation([4, 1, 3, 5, 2])))
dsage: L.append((6,Permutation([5, 3, 4, 1, 2])))
dsage: L.append((3,Permutation([3, 1, 4, 2, 5])))
dsage: L.append((2,Permutation([1, 4, 2, 3, 5])))
dsage: M = sum([c * p.to_matrix() for (c,p) in L])
dsage: decomp = bistochastic_as_sum_of_permutations(M)
dsage: print(decomp)
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]]
+ 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, 1, 2]]
```
... L.append((Integer(6), Permutation([Integer(5), Integer(3), Integer(4),
          Integer(1), Integer(2)])))
>>> L.append((Integer(3), Permutation([Integer(3), Integer(1), Integer(4),
          Integer(2), Integer(5)])))
>>> L.append((Integer(2), Permutation([Integer(1), Integer(4), Integer(2),
          Integer(3), Integer(5)])))
>>> M = sum([c * p.to_matrix() for (c, p) in L])
>>> decomp = bistochastic_as_sum_of_permutations(M)
>>> print(decomp)
2*B[[1, 4, 2, 3, 5]] + 3*B[[3, 1, 4, 2, 5]]
+ 9*B[[4, 1, 3, 5, 2]] + 6*B[[5, 3, 4, 1, 2]]

An exception is raised when the matrix is not positive and bistochastic:

```
sage: # needs sage.modules
sage: M = Matrix([[2, 3], [2, 2]])
sage: decomp = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
  ... ValueError: The matrix is not bistochastic
sage: bistochastic_as_sum_of_permutations(Matrix(GF(7), 2, [2, 1, 1, 2]))
Traceback (most recent call last):
  ... ValueError: The base ring of the matrix must have a coercion map to RR
sage: bistochastic_as_sum_of_permutations(Matrix(ZZ, Integer(2), [Integer(2), -Integer(1), -Integer(1), Integer(2)]))
Traceback (most recent call last):
  ... ValueError: The matrix should have nonnegative entries
```

```
>>> from sage.all import *
>>> # needs sage.modules
>>> M = Matrix([[Integer(2), Integer(3)], [Integer(2), Integer(2)]])
>>> decomp = bistochastic_as_sum_of_permutations(M)
Traceback (most recent call last):
  ... ValueError: The matrix is not bistochastic
>>> bistochastic_as_sum_of_permutations(Matrix(GF(Integer(7)), Integer(2),
          [Integer(2), Integer(1), Integer(1), Integer(1)])
Traceback (most recent call last):
  ... ValueError: The base ring of the matrix must have a coercion map to RR
>>> bistochastic_as_sum_of_permutations(Matrix(ZZ, Integer(2), [Integer(2),
          -Integer(1), -Integer(1), Integer(2)])
Traceback (most recent call last):
  ... ValueError: The matrix should have nonnegative entries
```

sage.combinat.permutation.bounded_affine_permutation(A)

Return the bounded affine permutation of a matrix.

The bounded affine permutation of a matrix $A$ with entries in $R$ is a partial permutation of length $n$, where $n$ is the number of columns of $A$. The entry in position $i$ is the smallest value $j$ such that column $i$ is in the span of columns $i + 1, \ldots, j$, over $R$, where column indices are taken modulo $n$. If column $i$ is the zero vector, then the permutation has a fixed point at $i$.

INPUT:
• A – matrix with entries in a ring $R$

EXAMPLES:

```python
sage: from sage.combinat.permutation import bounded_affine_permutation
sage: A = Matrix(ZZ, [[1,0,0,0], [0,1,0,0]])  # needs sage.modules
sage: bounded_affine_permutation(A)  # needs sage.libs.flint sage.modules
[5, 6, 3, 4]
```

```python
sage: A = Matrix(ZZ, [[0,1,0,1,0], [0,0,1,1,0]])  # needs sage.modules
sage: bounded_affine_permutation(A)  # needs sage.libs.flint sage.modules
[1, 4, 7, 8, 5]
```

```python
sage: A = Matrix(ZZ, [[Integer(1),Integer(0),Integer(0),Integer(0)],
                  [Integer(0),Integer(1),Integer(0),Integer(0)]]).transpose()  # needs sage.libs.flint sage.modules
sage: bounded_affine_permutation(A)  # needs sage.libs.flint sage.modules
[5, 6, 3, 4]
```

```python
sage: A = Matrix(ZZ, [[Integer(0),Integer(1),Integer(0),Integer(1),Integer(0)],
                  [Integer(0),Integer(0),Integer(1),Integer(1),Integer(0)]]).transpose()  # needs sage.libs.flint sage.modules
sage: bounded_affine_permutation(A)  # needs sage.libs.flint sage.modules
[1, 4, 7, 8, 5]
```

REFERENCES:

• [KLS2013]

sage.combinat.permutation.bruhat_lequal(p1, p2)

Return True if $p1$ is less than $p2$ in the Bruhat order.

Algorithm from mupad-combinat.

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.bruhat_lequal([2,4,3,1],[3,4,2,1])
True
```

sage.combinat.permutation.descents_composition_first(dc)

Compute the smallest element of a descent class having a descent composition $dc$.

EXAMPLES:
sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_first([1,1,3,4,3])
[3, 2, 1, 4, 6, 5, 7, 8, 10, 9, 11, 12]

sage.combinat.permutation.descents_composition_last(dc)

Return the largest element of a descent class having a descent composition dc.

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_last([1,1,3,4,3])
[12, 11, 8, 9, 10, 4, 5, 6, 7, 1, 2, 3]

sage.combinat.permutation.descents_composition_list(dc)

Return a list of all the permutations that have the descent composition dc.

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.descents_composition_list([1,2,2])
# needs sage.graphs sage.modules
[[5, 2, 4, 1, 3],
 [5, 3, 4, 1, 2],
 [4, 3, 5, 1, 2],
 [4, 2, 5, 1, 3],
 [3, 2, 5, 1, 4],
 [2, 1, 5, 3, 4],
 [3, 1, 5, 2, 4],
 [4, 1, 5, 2, 3],
 [5, 1, 4, 2, 3],
 [5, 1, 3, 2, 4],
 [4, 1, 3, 2, 5],
 [3, 1, 4, 2, 5],
 [2, 1, 4, 3, 5],
 [3, 2, 4, 1, 5],
 [4, 2, 3, 1, 5],
 [5, 2, 3, 1, 4]]

>>> from sage.all import *
>>> import sage.combinat.permutation as permutation
>>>
permutation.descents_composition_list([Integer(1),Integer(2),Integer(2)])
# needs sage.graphs sage.modules
[[5, 2, 4, 1, 3],
 [5, 3, 4, 1, 2],
 [4, 3, 5, 1, 2],
 # (continues on next page)
sage.combinat.permutation.from_cycles(n, cycles, parent=None)

Return the permutation in the \( n \)-th symmetric group whose decomposition into disjoint cycles is cycles.

This function checks that its input is correct (i.e. that the cycles are disjoint and their elements integers among 1...\( n \)). It raises an exception otherwise.

**Warning:** It assumes that the elements are of int type.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_cycles(4, [[1,2]])
[2, 1, 3, 4]
sage: permutation.from_cycles(4, [[1,2,4]])
[2, 4, 3, 1]
sage: permutation.from_cycles(10, [[3,1],[4,5],[6,8,9]])
[3, 2, 1, 5, 4, 8, 7, 9, 6, 10]
sage: permutation.from_cycles(10, ((2, 5), (6, 1, 3)))
[3, 5, 6, 4, 2, 1, 7, 8, 9, 10]
sage: permutation.from_cycles(4, [])
[1, 2, 3, 4]
sage: permutation.from_cycles(4, [[]])
[1, 2, 3, 4]
sage: permutation.from_cycles(0, [])
[]
```

```python
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation

>>> permutation.from_cycles(Integer(4), [[Integer(1),Integer(2)]])
[2, 1, 3, 4]
```

(continues on next page)
Bad input (see Issue #13742):

```python
sage: Permutation("(-12,2)(3,4)"")
Traceback (most recent call last):
  ... ValueError: all elements should be strictly positive integers, but I found -12
sage: Permutation("(1,2)(2,4)"")
Traceback (most recent call last):
  ... ValueError: the element 2 appears more than once in the input
sage: permutation.from_cycles(4, [[1,18]])
Traceback (most recent call last):
  ... ValueError: you claimed that this is a permutation on 1...4, but it contains 18
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation

```

```
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 5, 2, 6, 4, 7, 3]
sage: permutation.from_inversion_vector([0])
[1]
sage: permutation.from_inversion_vector([])
[]
```

Return the permutation corresponding to inversion vector iv.

See `sage.combinat.permutation.Permutation.from_inverse_vector` for a definition of the inversion vector of a permutation.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_inversion_vector([3,1,0,0,0])
[3, 2, 4, 1, 5]
sage: permutation.from_inversion_vector([2,3,6,4,0,2,2,1,0])
[5, 9, 1, 5, 2, 6, 4, 7, 3]
sage: permutation.from_inversion_vector([0])
[1]
sage: permutation.from_inversion_vector([])
[]
```
sage.combinat.permutation.from_lehmer_cocode(lehmer, parent=Standard permutations)

Return the permutation with Lehmer code lehmer.

The Lehmer code of a permutation \( p \) is defined as the list \( (c_1, c_2, \ldots, c_n) \), where \( c_i \) is the number of \( j < i \) such that \( p(j) > p(i) \).

EXAMPLES:

```python
sage: import sage.combinat.permutation as permutation
sage: lcc = Permutation([2,1,5,4,3]).to_lehmer_cocode(); lcc
[0, 1, 0, 1, 2]
```

```python
sage: permutation.from_lehmer_cocode(lcc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.from_lehmer_code(lehmer, parent=None)

Return the permutation with Lehmer code lehmer.

EXAMPLES:

```python
sage: lcc = Permutation([2,1,5,4,3]).to_lehmer_code(); lcc
[1, 0, 2, 1, 0]
```

```python
sage: permutation.from_lehmer_code(lcc)
[2, 1, 5, 4, 3]
```

sage.combinat.permutation.from_major_code(mc, final_descent=False)

Return the permutation with major code mc.

The major code of a permutation is defined in \( \text{to_major_code()} \).
Warning: This function creates illegal permutations (i.e. Permutation([9])), and this is dangerous as the Permutation() class is only designed to handle permutations on 1...n. This will have to be changed when Sage permutations will be able to handle anything, but right now this should be fixed. Be careful with the results.

Warning: If mc is not a major index of a permutation, then the return value of this method can be anything. Garbage in, garbage out!

REFERENCES:

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: permutation.from_major_code([5, 0, 1, 0, 1, 2, 0, 1, 0])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
sage: permutation.from_major_code([8, 3, 3, 1, 4, 0, 1, 0, 0])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
sage: Permutation([2,1,6,4,7,3,5]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
sage: permutation.from_major_code([3, 2, 0, 2, 2, 0, 0])
[2, 1, 6, 4, 7, 3, 5]
```

```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation

>>> permutation.from_major_code([Integer(5), Integer(0), Integer(1), Integer(1),
                Integer(4), Integer(0), Integer(1), Integer(0)])
[9, 3, 5, 7, 2, 1, 4, 6, 8]
```

```
>>> permutation.from_major_code([Integer(8), Integer(3), Integer(3), Integer(1),
                Integer(4), Integer(0), Integer(1), Integer(0)])
[2, 8, 4, 3, 6, 7, 9, 5, 1]
```

```
>>> Permutation([Integer(2),Integer(1),Integer(6),Integer(4),Integer(7),
                Integer(2),Integer(0),Integer(0)]).to_major_code()
[3, 2, 0, 2, 2, 0, 0]
```

```
>>> permutation.from_major_code([Integer(3), Integer(2), Integer(0), Integer(2),
                Integer(2), Integer(0), Integer(0)])
[2, 1, 6, 4, 7, 3, 5]
```

```
```

sage.combinat.permutation.from_permutation_group_element(pge, parent=None)

Return a Permutation given a PermutationGroupElement pge.

EXAMPLES:

```
sage: import sage.combinat.permutation as permutation
sage: pge = PermutationGroupElement([(1,2),(3,4)])
#...
```

```
sage: permutation.from_permutation_group_element(pge) #...
[2, 1, 4, 3]
```

```
```
sage.combinat.permutation.from_rank(n, rank)

Return the permutation of the set \{1, ..., n\} with lexicographic rank \(\text{rank}\). This is the permutation whose Lehmer code is the factoradic representation of \(\text{rank}\). In particular, the permutation with \(\text{rank}\) 0 is the identity permutation.

The permutation is computed without iterating through all of the permutations with lower rank. This makes it efficient for large permutations.

**Note:** The variable \(\text{rank}\) is not checked for being in the interval from 0 to \(n! - 1\). When outside this interval, it acts as its residue modulo \(n!\).

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: Permutation([3, 6, 5, 4, 2, 1]).rank()
359
sage: [permutation.from_rank(3, i) for i in range(6)]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

```python
sage: Permutations(6)[10] [1, 2, 4, 6, 3, 5]
sage: permutation.from_rank(6,10) [1, 2, 4, 6, 3, 5]
```

```python
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation

>>> Permutation(Integer(3), Integer(6), Integer(5), Integer(4), Integer(2), Integer(1)).rank()
359
```

```python
>>> [permutation.from_rank(Integer(3), i) for i in range(Integer(6))]
[[1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
>>> Permutations(Integer(6))[Integer(10)] [1, 2, 4, 6, 3, 5]
```

```
>>> permutation.from_rank(Integer(6),Integer(10)) [1, 2, 4, 6, 3, 5]
```

sage.combinat.permutation.from_reduced_word(rw, parent=None)

Return the permutation corresponding to the reduced word \(\text{rw}\).

See `reduced_words()` for a definition of reduced words and the convention on the order of multiplication used.

**EXAMPLES:**

```python
sage: import sage.combinat.permutation as permutation
sage: permutation.from_reduced_word([3,2,3,1,2,3,1]) [3, 4, 2, 1]
```

```python
sage: permutation.from_reduced_word([])
[]
```
>>> from sage.all import *
>>> import sage.combinat.permutation as permutation

permutation.from_reduced_word([Integer(3), Integer(2), Integer(3), Integer(1),
→ Integer(2), Integer(3), Integer(1)])
[3, 4, 2, 1]

permutation.from_reduced_word([])
[]

sage.combinat.permutation.permutohedron_lequal(p1, p2, side='right')

Return True if p1 is less than or equal to p2 in the permutohedron order.

By default, the computations are done in the right permutohedron. If you pass the option side='left', then they will be done in the left permutohedron.

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,→3]))
False
sage: permutation.permutohedron_lequal(Permutation([3,2,1,4]),Permutation([4,2,1,→3]), side='left')
True

sage.combinat.permutation.to_standard(p, key=None)

Return a standard permutation corresponding to the iterable p.

INPUT:

• p – an iterable
• key – (optional) a comparison key for the element x of p

EXAMPLES:

sage: import sage.combinat.permutation as permutation
sage: permutation.to_standard([4,2,7])
[2, 1, 3]
sage: permutation.to_standard([1,2,3])
[1, 2, 3]
sage: permutation.to_standard([])
[]
sage: permutation.to_standard([1,2,3], key=λ x: -x)
[3, 2, 1]
>>> from sage.all import *
>>> # needs sage.combinat
>>> import sage.combinat.permutation as permutation

>>> permutation.to_standard([Integer(4),Integer(2),Integer(7)])
[2, 1, 3]

>>> permutation.to_standard([Integer(1),Integer(2),Integer(3)])
[1, 2, 3]

>>> permutation.to_standard([])
[]

>>> permutation.to_standard([Integer(1),Integer(2),Integer(3)], key=lambda x: -x)
[3, 2, 1]

>>> permutation.to_standard([Integer(5),Integer(8),Integer(2),Integer(5)],
→key=lambda x: -x)
[2, 1, 4, 3]

5.1.173 Permutations (Cython file)

This is a nearly-straightforward implementation of what Knuth calls “Algorithm P” in TAOCP 7.2.1.2. The intent is to be able to enumerate permutation by “plain changes”, or multiplication by adjacent transpositions, as a generator. This is useful when a class of objects is inherently enumerated by permutations, but it is faster to swap items in a permutation than construct the next object directly from the next permutation in a list. The backtracking algorithm in sage/graphs/genus.pyx is an example of this.

The lowest level is implemented as a struct with auxiliary methods. This is because Cython does not allow pointers to class instances, so a list of these objects is inherently slower than a list of structs. The author prefers ugly code to slow code.

For those willing to sacrifice a (very small) amount of speed, we provide a class that wraps our struct.

sage.combinat.permutation_cython.left_action_product (S, lp)

Return the permutation obtained by composing a permutation S with a permutation lp in such an order that lp is applied first and S is applied afterwards.

See also:

sage.combinat.permutation.Permutation.left_action_product ()

EXAMPLES:

sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import left_action_product
sage: left_action_product(p, q)
[3, 2, 1, 4]
sage: left_action_product(q, p)
[1, 3, 2, 4]
sage: q
[3, 1, 2]

(continues on next page)
sage.combinat.permutation_cython.left_action_same_n(S, lp)

Return the permutation obtained by composing a permutation S with a permutation lp in such an order that lp is applied first and S is applied afterwards and S and lp are of the same length.

See also:
sage.combinat.permutation.Permutation.left_action_product()

EXAMPLES:

```python
sage: p = [2, 1, 3]
sage: q = [3, 1, 2]
sage: from sage.combinat.permutation_cython import left_action_same_n
sage: left_action_same_n(p, q)
[3, 2, 1]
sage: left_action_same_n(q, p)
[1, 3, 2]
```

sage.combinat.permutation_cython.map_to_list(l, values, n)

Build a list by mapping the array l using values.

**Warning:** There is no check of the input data at any point. Using wrong types or values with wrong length is likely to result in a Sage crash.

**INPUT:**

- l – array of unsigned int (i.e., type 'I')
- values – tuple; the values of the permutation
- n – int; the length of the array l

**OUTPUT:**

A list representing the permutation.

**EXAMPLES:**

```python
sage: from array import array
sage: from sage.combinat.permutation_cython import map_to_list
sage: l = array('I', [0, 1, 0, 3, 3, 0, 1])
sage: map_to_list(l, ('a', 'b', 'c', 'd'), 7)
['a', 'b', 'a', 'd', 'd', 'a', 'b']
```
sage.combinat.permutation_cython.next_perm(l)

Obtain the next permutation under lex order of `l` by mutating `l`.

Algorithm based on: http://marknelson.us/2002/03/01/next-permutation/

**INPUT:**
- `l` – array of unsigned int (i.e., type 'I')

**Warning:** This method mutates the array `l`.

**OUTPUT:**
- boolean; whether another permutation was obtained

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from array import array
>>> L = array('I', [Integer(1), Integer(1), Integer(2), Integer(3)])
>>> while next_perm(L):
...    print(L)
array('I', [1, 1, 3, 2])
array('I', [1, 2, 1, 3])
array('I', [1, 2, 3, 1])
array('I', [1, 3, 1, 2])
array('I', [1, 3, 2, 1])
array('I', [2, 1, 1, 3])
array('I', [2, 1, 3, 1])
array('I', [2, 3, 1, 1])
array('I', [3, 1, 1, 2])
array('I', [3, 1, 2, 1])
array('I', [3, 2, 1, 1])
```

(continues on next page)
sage.combinat.permutation_cython.permutation_iterator_transposition_list(n)

Returns a list of transposition indices to enumerate the permutations on \( n \) letters by adjacent transpositions. Assumes zero-based lists. We artificially limit the argument to \( n < 12 \) to avoid overflowing 32-bit pointers. While the algorithm works for larger \( n \), the user is encouraged to avoid filling anything more than 4GB of memory with the output of this function.

EXAMPLES:

```python
sage: import sage.combinat.permutation_cython
sage: from sage.combinat.permutation_cython import permutation_iterator_transposition_list
sage: permutation_iterator_transposition_list(4)
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]
sage: permutation_iterator_transposition_list(200)
Traceback (most recent call last):
  ... ValueError: Cowardly refusing to enumerate the permutations on more than 12 letters.
sage: permutation_iterator_transposition_list(1)
[]
sage: # Generate the permutations of [1,2,3,4] fixing 4.
sage: Q = [1,2,3,4]
sage: L = [copy(Q)]
sage: for t in permutation_iterator_transposition_list(3):
    ...:     Q[t], Q[t+1] = Q[t+1], Q[t]
    ...:     L.append(copy(Q))
sage: print(L)
[[1, 2, 3, 4], [1, 3, 2, 4], [3, 1, 2, 4], [3, 2, 1, 4], [2, 3, 1, 4], [2, 1, 3, 4]]
```

```python
>>> from sage.all import *
>>> import sage.combinat.permutation_cython
>>> from sage.combinat.permutation_cython import permutation_iterator_transposition_list

>>> permutation_iterator_transposition_list(Integer(4))
[2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2, 0, 2, 1, 0, 2, 0, 1, 2]

>>> permutation_iterator_transposition_list(Integer(200))
Traceback (most recent call last):
  ... ValueError: Cowardly refusing to enumerate the permutations on more than 12 letters.

>>> permutation_iterator_transposition_list(Integer(1))
[]

>>> # Generate the permutations of [1,2,3,4] fixing 4.
>>> Q = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> L = [copy(Q)]
>>> for t in permutation_iterator_transposition_list(Integer(3)):
...     Q[t], Q[t+Integer(1)] = Q[t+Integer(1)], Q[t]
...     L.append(copy(Q))
>>> print(L)
[[1, 2, 3, 4], [1, 3, 2, 4], [3, 1, 2, 4], [3, 2, 1, 4], [2, 3, 1, 4], [2, 1, 3, 4]]
```
sage.combinat.permutation_cython.right_action_product($S, rp$)

Return the permutation obtained by composing a permutation $S$ with a permutation $rp$ in such an order that $S$ is applied first and $rp$ is applied afterwards.

See also:

`sage.combinat.permutation.Permutation.right_action_product()`

**EXAMPLES:**

```python
sage: p = [2,1,3,4]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_product
sage: right_action_product(p, q)
[1, 3, 2, 4]
sage: right_action_product(q, p)
[3, 2, 1, 4]
sage: q
[3, 1, 2]
```

sage.combinat.permutation_cython.right_action_same_n($S, rp$)

Return the permutation obtained by composing a permutation $S$ with a permutation $rp$ in such an order that $S$ is applied first and $rp$ is applied afterwards and $S$ and $rp$ are of the same length.

See also:

`sage.combinat.permutation.Permutation.right_action_product()`

**EXAMPLES:**

```python
sage: p = [2,1,3]
sage: q = [3,1,2]
sage: from sage.combinat.permutation_cython import right_action_same_n
sage: right_action_same_n(p, q)
[1, 3, 2]
sage: from sage.all import *
sage: p = [Integer(2),Integer(1),Integer(3)]
sage: q = [Integer(3),Integer(1),Integer(2)]
sage: from sage.combinat.permutation_cython import right_action_same_n
sage: right_action_same_n(p, q)
[1, 3, 2]
```
5.1.174 Posets

Common posets can be accessed through `posets.<tab>` and are listed in the posets catalog:

- Catalog of posets and lattices

Poset-related classes:

- Finite posets
- Finite lattices and semilattices
- Linear Extensions of Posets
- D-Complete Posets
- Forest Posets
- Mobile posets
- Incidence Algebras
- Cartesian products of Posets
- Möbius Algebras
- Generalized Tamari lattices
- Tamari Interval-posets
- Shard intersection order

If you are looking for Poset-related categories, see `Posets`, `FinitePosets`, `LatticePosets` and `FiniteLatticePosets`.

5.1.175 Cartesian products of Posets

AUTHORS:
- Daniel Krenn (2015)

```python
class sage.combinat.posets.cartesian_product.CartesianProductPoset (sets, category, order=None, **kwargs)
```

Bases: `CartesianProduct`

A class implementing Cartesian products of posets (and elements thereof). Compared to `CartesianProduct` you are able to specify an order for comparison of the elements.

INPUT:

- `sets` – a tuple of parents.
- `category` – a subcategory of `Sets().CartesianProducts()` & `Posets()`.
- `order` – a string or function specifying an order less or equal. It can be one of the following:
  - 'native' – elements are ordered by their native ordering, i.e., the order the wrapped elements (tuples) provide.

>>> right_action_same_n(q, p)
[3, 2, 1]
- 'lex' – elements are ordered lexicographically.
- 'product' – an element is less or equal to another element, if less or equal is true for all its components (Cartesian projections).
- A function which performs the comparison ≤. It takes two input arguments and outputs a boolean.

Other keyword arguments (kwargs) are passed to the constructor of CartesianProduct.

**EXAMPLES:**

```python
sage: P = Poset((srange(3), lambda left, right: left <= right))
...:
sage: Cl = cartesian_product((P, P), order='lex')
...:
sage: Cl((1, 1)) <= Cl((2, 0))
True
sage: Cp = cartesian_product((P, P), order='product')
...:
sage: Cp((1, 1)) <= Cp((2, 0))
False
sage: def le_sum(left, right):
....: return (sum(left) < sum(right) or
....: sum(left) == sum(right) and left[0] <= right[0])
...:
sage: Cs = cartesian_product((P, P), order=le_sum)
...:
sage: Cs((1, 1)) <= Cs((2, 0))
True

See also:
CartesianProduct
class Element
   Bases: Element
def le_sum(left, right):
   ...: return (sum(left) < sum(right) or
   ...: sum(left) == sum(right) and left[Integer(0)] <= right[Integer(0)])
>>> from sage.all import *
...:
>>> P = Poset((srange(Integer(3)), lambda left, right: left <= right))
...:
>>> Cl = cartesian_product((P, P), order='lex')
...:
>>> Cl((Integer(1), Integer(1))) <= Cl((Integer(2), Integer(0)))
True
>>> Cp = cartesian_product((P, P), order='product')
...:
>>> Cp((Integer(1), Integer(1))) <= Cp((Integer(2), Integer(0)))
False
>>> def le_sum(left, right):
...: return (sum(left) < sum(right) or
...: sum(left) == sum(right) and left[Integer(0)] <= right[Integer(0)])
...:
>>> Cs = cartesian_product((P, P), order=le_sum)
...:
>>> Cs((Integer(1), Integer(1))) <= Cs((Integer(2), Integer(0)))
True
```
Note: This method uses the order defined on creation of this Cartesian product. See `CartesianProductPoset`.

EXAMPLES:

```python
sage: P = posets.ChainPoset(10)
sage: def le_sum(left, right):
    ....:    return (sum(left) < sum(right) or
    ....:               sum(left) == sum(right) and left[0] <= right[0])
sage: C = cartesian_product((P, P), order=le_sum)
sage: C.le(C((1, 6)), C((6, 1)))
True
sage: C.le(C((6, 1)), C((1, 6)))
False
sage: C.le(C((1, 6)), C((6, 6)))
True
sage: C.le(C((6, 6)), C((1, 6)))
False
```

```python
>>> from sage.all import *

>>> P = posets.ChainPoset(Integer(10))

>>> def le_sum(left, right):
...    return (sum(left) < sum(right) or
...               sum(left) == sum(right) and left[Integer(0)] <= right[Integer(0)])

>>> C = cartesian_product((P, P), order=le_sum)

>>> C.le(C((Integer(1), Integer(6))), C((Integer(6), Integer(1))))
True
>>> C.le(C((Integer(6), Integer(1))), C((Integer(1), Integer(6))))
False
>>> C.le(C((Integer(1), Integer(6))), C((Integer(6), Integer(6))))
True
>>> C.le(C((Integer(6), Integer(6))), C((Integer(1), Integer(6))))
False
```

**le_lex** (left, right)

Test whether left is lexicographically smaller or equal to right.

**INPUT:**

• left – an element.
• right – an element.

**OUTPUT:**

A boolean.

**EXAMPLES:**

```python
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='lex')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
    ....:    for b in T:
    ....:        assert Q.le(a, b) == (a <= b)
    ....:        print('%%s <= %%s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True (continues on next page)
```

(continued from previous page)

P = Poset((srange(Integer(2)), lambda left, right: left <= right))
Q = cartesian_product((P, P), order='lex')
T = [Q((Integer(0), Integer(0))), Q((Integer(1), Integer(1))), Q((Integer(0), Integer(1))), Q((Integer(1), Integer(0)))]

for a in T:
    for b in T:
        assert Q.le(a, b) == (a <= b)
        print('%s <= %s = %s' % (a, b, a <= b))
```

**le_native** (*left*, *right*)

Test whether *left* is smaller or equal to *right* in the order provided by the elements themselves.

**INPUT:**

- *left* – an element.
- *right* – an element.

**OUTPUT:**

A boolean.

**EXAMPLES:**
```python
sage: P = Poset((srange(2), lambda left, right: left <= right))
sage: Q = cartesian_product((P, P), order='native')
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
sage: for a in T:
    for b in T:
        assert Q.le(a, b) == (a <= b)
        print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
>>> from sage.all import *
>>> P = Poset((srange(Integer(2)), lambda left, right: left <= right))
>>> Q = cartesian_product((P, P), order='native')
>>> T = [Q((Integer(0), Integer(0))), Q((Integer(1), Integer(1))), Q((Integer(0), Integer(1))), Q((Integer(1), Integer(0)))]
>>> for a in T:
...    for b in T:
...        assert Q.le(a, b) == (a <= b)
...        print('%s <= %s = %s' % (a, b, a <= b))
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = True
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

`le_product(left, right)`

Test whether `left` is component-wise smaller or equal to `right`.

**INPUT:**

- `left` – an element.
- `right` – an element.
OUTPUT:

A boolean.

The comparison is True if the result of the comparison in each component is True.

EXAMPLES:

```python
sage: P = Poset((srange(2), lambda left, right: left <= right))
```

```python
sage: Q = cartesian_product((P, P), order='product')
```

```python
sage: T = [Q((0, 0)), Q((1, 1)), Q((0, 1)), Q((1, 0))]
```

```python
sage: for a in T:
...     for b in T:
...         assert Q.le(a, b) == (a <= b)
...         print('%s <= %s = %s' % (a, b, a <= b))
```

```
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False
(0, 1) <= (1, 1) = True
(0, 1) <= (0, 1) = True
(0, 1) <= (1, 0) = False
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```

```python
>>> from sage.all import *
```

```python
>>> P = Poset((srange(Integer(2)), lambda left, right: left <= right))
```

```python
>>> Q = cartesian_product((P, P), order='product')
```

```python
>>> T = [Q((Integer(0), Integer(0))), Q((Integer(1), Integer(1))), Q((Integer(0), Integer(1))), Q((Integer(1), Integer(0)))]
```

```python
>>> for a in T:
...     for b in T:
...         assert Q.le(a, b) == (a <= b)
...         print('%s <= %s = %s' % (a, b, a <= b))
```

```
(0, 0) <= (0, 0) = True
(0, 0) <= (1, 1) = True
(0, 0) <= (0, 1) = True
(0, 0) <= (1, 0) = True
(1, 1) <= (0, 0) = False
(1, 1) <= (1, 1) = True
(1, 1) <= (0, 1) = False
(1, 1) <= (1, 0) = False
(0, 1) <= (0, 0) = False

(0, 1) <= (1, 0) = False
(1, 0) <= (0, 0) = False
(1, 0) <= (1, 1) = True
(1, 0) <= (0, 1) = False
(1, 0) <= (1, 0) = True
```
5.1.176 D-Complete Posets

AUTHORS:

• Stefan Grosser (06-2020): initial implementation

class sage.combinat.posets.d_complete.DCompletePoset (hasse_diagram, elements, category, facade, key)

Bases: FiniteJoinSemilattice

A d-complete poset.

D-complete posets are a class of posets introduced by Proctor in [Proc1999]. It includes common families such as shapes, shifted shapes, and rooted forests. Proctor showed in [PDynk1999] that d-complete posets have decompositions in irreducible posets, and showed in [Proc2014] that d-complete posets admit a hook-length formula (see Wikipedia article Hook_length_formula). A complete proof of the hook-length formula can be found in [KY2019].

EXAMPLES:

```python
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Posets.DoubleTailedDiamond(2)
sage: TestSuite(P).run()

sage: P = Posets.DoubleTailedDiamond(2)
sage: TestSuite(P).run()
```

get_hook (elm)

Return the hook length of the element elm.

EXAMPLES:

```python
sage: from sage.combinat.posets.d_complete import DCompletePoset
sage: P = DCompletePoset(DiGraph({0: [1], 1: [2]}))
sage: P.get_hook(1)
2
```

get_hooks ()

Return all the hook lengths as a dictionary.

EXAMPLES:

```python
sage: from sage.combinat.posets.d_complete import DCompletePoset
sage: P = DCompletePoset(DiGraph({0: [1, 2], 1: [3], 2: [3], 3: []}))
sage: P.get_hooks()
{0: 1, 1: 2, 2: 2, 3: 3}
```
>>> from sage.all import *
>>> from sage.combinat.posets.d_complete import DCompletePoset
>>> P = DCompletePoset(DiGraph({Integer(0): [Integer(1), Integer(2)],
    →Integer(1): [Integer(3)], Integer(2): [Integer(3)], Integer(3): []}))
>>> P.get_hooks()
{0: 1, 1: 2, 2: 2, 3: 3}
>>> from sage.combinat.posets.poset_examples import Posets
>>> YDP321 = Posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),
    →Integer(1)]))
>>> P = DCompletePoset(YDP321._hasse_diagram.reverse())
>>> P.get_hooks()
{0: 5, 1: 3, 2: 1, 3: 3, 4: 1, 5: 1}

hook_product()
Return the hook product for the poset.

5.1.177 Mobile posets

class sage.combinat.posets.mobile.MobilePoset (hasse_diagram, elements, category, facade, key,
ribbon=None, check=True)

Bases: FinitePoset

A mobile poset.

Mobile posets are an extension of d-complete posets which permit a determinant formula for counting linear ex-
tensions. They are formed by having a ribbon poset with d-complete posets ‘hanging’ below it and at most one
d-complete poset above it, known as the anchor. See [GGMM2020] for the definition.

EXAMPLES:

sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),
  # needs sage.combinat, sage.modules
....:
    {1: [posets.YoungDiagramPoset([3, 2], dual=True)],
     ....:
        3: [posets.DoubleTailedDiamond(Integer(6))]},
     ....:
        anchor=(Integer(4), Integer(2), posets.ChainPoset(Integer(6)))

sage: len(P._ribbon) # needs sage.combinat, sage.modules
8

sage: P._anchor # needs sage.combinat, sage.modules
(4, 5)

>>> from sage.all import *
>>> P = posets.MobilePoset(posets.RibbonPoset(Integer(7), [Integer(1),
  # needs sage.combinat, sage.modules
  →Integer(3)]),
    # needs sage.combinat, sage.modules
    ...:
      {Integer(1): [posets.YoungDiagramPoset([Integer(3),...
    →Integer(2)], dual=True)],
     ...:
        Integer(3): [posets.DoubleTailedDiamond(Integer(6))]},
     ...:
        anchor=(Integer(4), Integer(2), posets.
        ChainPoset(Integer(6)))
>>> len(P._ribbon) # needs sage.combinat, sage.modules
8

>>> P._anchor # needs sage.combinat, sage.modules
(4, 5)
This example is Example 5.9 in [GGMM2020]:

```python
sage: P1 = posets.MobilePoset(posets.RibbonPoset(8, [2,3,4]),
.....:   {4: [posets.ChainPoset(1)]},
.....:   anchor=(3, 0, posets.ChainPoset(1)))
sage: sorted([P1._element_to_vertex(i) for i in P1._ribbon])
[0, 1, 2, 6, 7, 9]
sage: P1._anchor
(3, 2)

sage: P2 = posets.MobilePoset(posets.RibbonPoset(15, [1,3,5,7,9,11,13]),
.....:   {}, anchor=(8, 0, posets.ChainPoset(1)))
sage: sorted(P2._ribbon)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13]
sage: P2._anchor
(8, (8, 0))
sage: P2.linear_extensions().cardinality()  #...
˓→needs sage.modules
21399440939

sage: EP = posets.MobilePoset(posets.ChainPoset(0), {})
Traceback (most recent call last):
...
ValueError: the empty poset is not a mobile poset
```

anchor()

Return the anchor of the mobile poset.

EXAMPLES:
ribbon()

Return the ribbon of the mobile poset.

EXAMPLES:

```sage
definition
>>> from sage.all import *
>>> from sage.combinat.posets.mobile import MobilePoset
>>> M2 = MobilePoset(Posets.RibbonPoset(5, [1,2]))
>>> M2.ancestor()
(4, 3)
```

5.1.178 Elements of posets, lattices, semilattices, etc.

```python
class sage.combinat.posets.elements.JoinSemilatticeElement (poset, element, vertex)
   Bases: PosetElement
class sage.combinat.posets.elements.LatticePosetElement (poset, element, vertex)
   Bases: MeetSemilatticeElement, JoinSemilatticeElement
class sage.combinat.posets.elements.MeetSemilatticeElement (poset, element, vertex)
   Bases: PosetElement
class sage.combinat.posets.elements.PosetElement (poset, element, vertex)
   Bases: Element
```

Establish the parent-child relationship between poset and element, where element is associated to the vertex of the Hasse diagram of the poset.

INPUT:

5.1. Comprehensive Module List 3053
Combinatorics, Release 10.4

• poset – a poset object
• element – any object
• vertex – a vertex of the Hasse diagram of the poset

5.1.179 Forest Posets

AUTHORS:

• Stefan Grosser (06-2020): initial implementation

class sage.combinat.posets.forest.ForestPoset (hasse_diagram, elements, category, facade, key)
    Bases: FinitePoset

A forest poset is a poset where the underlying Hasse diagram and is directed acyclic graph.

5.1.180 Hasse diagrams of posets

```
class sage.combinat.posets.hasse_diagram.HasseDiagram(data=None, pos=None, loops=None, format=None, weighted=None, data_structure='sparse', vertex_labels=True, name=None, multiedges=None, convert_empty_dict_labels_to_None=None, sparse=True, immutable=False, hash_labels=None)
```

**Bases:** DiGraph

The Hasse diagram of a poset. This is just a transitively-reduced, directed, acyclic graph without loops or multiple edges.

**Note:** We assume that `range(n)` is a linear extension of the poset. That is, `range(n)` is the vertex set and a topological sort of the digraph.

This should not be called directly, use Poset instead; all type checking happens there.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]}); H
Hasse diagram of a poset containing 4 elements
sage: TestSuite(H).run()
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[]}); H
```

(continues on next page)
antichains (element_class=<class 'list'>)

Return all antichains of self, organized as a prefix tree

**INPUT:**

- element_class – (default:list) an iterable type

**EXAMPLES:**

```python
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.antichains()
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
sage: A.cardinality()
8
sage: [1,3] in A
True
sage: [1,4] in A
False
```

antichains_iterator()

Return an iterator over the antichains of the poset.

**Note:** The algorithm is based on Freese-Jezek-Nation p. 226. It does a depth first search through the set of all antichains organized in a prefix tree.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> # needs sage.modules
>>> P = posets.PentagonPoset()
>>> H = P._hasse_diagram
>>> A = H.antichains()
>>> list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
>>> A.cardinality()
8
>>> [Integer(1),Integer(3)] in A
True
>>> [Integer(1),Integer(4)] in A
False
```
are_comparable\( (i,j) \)

Return whether \( i \) and \( j \) are comparable in the poset

**INPUT:**

- \( i, j \) – vertices of this Hasse diagram

**EXAMPLES:**

```python
sage: H = HasseDiagram({0:[1,2],1:[4],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]

sage: H = HasseDiagram({0:[],1:[],2:[],3:[4]})
sage: list(H.antichains_iterator())
[[], [2], [1], [1, 2], [0], [0, 2], [0, 1], [0, 1, 2]]

sage: H = HasseDiagram({0:[1,2],1:[2],2:[3],3:[4]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [0]]
```

```python
>>> from sage.all import *

# needs sage.modules

P = posets.PentagonPoset()
H = P._hasse_diagram
H.antichains_iterator()
<generator object ...antichains_iterator at ...>
list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]

>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
Integer(1):[Integer(4)],Integer(2):[Integer(3)],Integer(3):[Integer(4)]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [1, 3], [1, 2], [0]]

H = HasseDiagram({Integer(0):[]})
sage: list(H.antichains_iterator())
[[], [2], [1], [1, 2], [0], [0, 2], [0, 1], [0, 1, 2]]

H = HasseDiagram({Integer(0):[Integer(1),Integer(1):[Integer(2)],
Integer(2):[Integer(3)],Integer(3):[Integer(4)]})
sage: list(H.antichains_iterator())
[[], [4], [3], [2], [1], [0]]
```

```python
are_comparable(i,j)

Return whether \( i \) and \( j \) are comparable in the poset

**INPUT:**

- \( i, j \) – vertices of this Hasse diagram

**EXAMPLES:**

```python
sage: # needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: H.are_comparable(1,2)
False

sage: V = H.vertices(sort=True)
sage: [(i,j) for i in V for j in V if H.are_comparable(i,j)]
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (1, 0), (1, 1), (1, 4),
 (2, 0), (2, 2), (2, 3), (2, 4), (3, 0), (3, 2), (3, 3), (3, 4),
 (4, 0), (4, 1), (4, 2), (4, 3), (4, 4)]
```

```python
>>> from sage.all import *

# needs sage.modules

P = posets.PentagonPoset()
H = P._hasse_diagram
H.are_comparable(Integer(1),Integer(2))
False
```

(continues on next page)
V = H.vertices(sort=True)
[(0, 0), (0, 1), (0, 2), (0, 3), (0, 4), (1, 0), (1, 1), (1, 4),
 (2, 0), (2, 2), (2, 3), (2, 4), (3, 0), (3, 2), (3, 3), (3, 4),
 (4, 0), (4, 1), (4, 2), (4, 3), (4, 4)]

are_incomparable(i,j)
Return whether i and j are incomparable in the poset

INPUT:

• i, j – vertices of this Hasse diagram

EXAMPLES:

from sage.all import *
from sage.all import *
from sage.all import *

atoms_of_congruence_lattice()
Return atoms of the congruence lattice.

In other words, return “minimal non-trivial” congruences: A congruence is minimal if the only finer (as a partition of set of elements) congruence is the trivial congruence where every block contains only one element.

See also:
congruence()

OUTPUT:
List of congruences, every congruence as sage.combinat.set_partition.SetPartition

EXAMPLES:
ALGORITHM:

Every atom is a join-irreducible. Every join-irreducible of Con(L) is a principal congruence generated by a meet-irreducible element and the only element covering it (and also by a join-irreducible element and the only element covered by it). Hence we check those principal congruences to find the minimal ones.

bottom()

Return the bottom element of the poset, if it exists.

EXAMPLES:

```python
sage: P = Poset({0: [3], 1: [3], 2: [3], 3: [4], 4: [2]})
```

```python
sage: P.bottom() is None
True
```

```python
sage: Q = Poset({0: [1], 1: [2]})
```

```python
sage: Q.bottom() 0
```

bottom_moebius_function(j)

Return the value of the Möbius function of the poset on the elements zero and j, where zero is self. bottom(), the unique minimal element of the poset.

EXAMPLES:

```python
sage: P = Poset({0: [1, 2]})
```

```python
sage: hasse = P._hasse_diagram
sage: hasse.bottom_moebius_function(1)
-1
```

```python
sage: hasse.bottom_moebius_function(2)
-1
```

```python
sage: P = Poset({0: [1, 3], 1: [2], 2: [4], 3: [4]})
```

```python
sage: hasse = P._hasse_diagram
```

```python
sage: for i in range(5):
    ...:     print(hasse.bottom_moebius_function(i))
```

(continues on next page)
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1), Integer(2)]})
>>> hasse = P._hasse_diagram
>>> hasse.bottom_moebius_function(Integer(1))
-1
>>> hasse.bottom_moebius_function(Integer(2))
-1
>>> P = Poset({Integer(0): [Integer(1), Integer(3)], Integer(1): [Integer(2)],
Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> hasse = P._hasse_diagram
>>> for i in range(Integer(5)):
...     print(hasse.bottom_moebius_function(i))
1
-1
0
-1
1

cardinality()

Return the number of elements in the poset.

EXAMPLES:

sage: Poset([[1,2,3],[4],[4],[4]]).cardinality()
5

>>> from sage.all import *
>>> Poset([[Integer(1),Integer(2),Integer(3)], [Integer(4)], [Integer(4)],
[Integer(4)], [[]]).cardinality()
5

chains (element_class=<class 'list'>, exclude=None, conversion=None)

Return all chains of self, organized as a prefix tree.

INPUT:

- element_class – (default: list) an iterable type
- exclude – elements of the poset to be excluded (default: None)
- conversion – (default: None) used to pass
the list of elements of the poset in their fixed order

OUTPUT:

The enumerated set (with a forest structure given by prefix ordering) consisting of all chains of self, each of which is given as an element_class.

If conversion is given, then the chains are converted to chain of elements of this list.

EXAMPLES:
```sage
# needs sage.modules
sage: P = posets.PentagonPoset()
sage: H = P._hasse_diagram
sage: A = H.chains()
sage: list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]
sage: A.cardinality()
20
sage: [1,3] in A
False
sage: [1,4] in A
True
```

One can exclude some vertices:

```sage
# needs sage.modules
sage: list(H.chains(exclude=[4, 3]))
[[], [0], [0, 1], [0, 2], [1], [2]]
```

The `element_class` keyword determines how the chains are being returned:

```sage
P = Poset({1: [2, 3], 2: [4]})
sage: list(P._hasse_diagram.chains(element_class=tuple))
[(), (0,), (0, 1), (0, 1, 2), (0, 2), (0, 3), (1,), (1, 2), (2,), (3,)]
sage: list(P._hasse_diagram.chains())
[[], [0], [0, 1], [0, 2], [0, 3], [1], [1, 2], [2], [3]]
```

```sage
from sage.all import *
# needs sage.modules
from sage.all import *
```

```sage
P = Poset({1: [2, 3], 2: [4]})
```

```sage
>> from sage.all import *
>> # needs sage.modules
>> P = posets.PentagonPoset()
>> H = P._hasse_diagram
>> A = H.chains()
>> list(A)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]
>> A.cardinality()
20
>> [1,3] in A
False
>> [1,4] in A
True
```
(Note that taking the Hasse diagram has renamed the vertices.)

```python
sage: list(P._hasse_diagram.chains(element_class=tuple, exclude=[0]))
[(), (1,), (1, 2), (2,), (3,)]
```

```python
>>> from sage.all import *
>>> list(P._hasse_diagram.chains(element_class=tuple, exclude=[Integer(0)]))
[(), (1,), (1, 2), (2,), (3,)]
```

See also:

- `antichains()`
- `closed_interval(x, y)`

Return a list of the elements \( z \) of self such that \( x \leq z \leq y \).

The order is that induced by the ordering in self.linear_extension.

**INPUT:**

- \( x \) – any element of the poset
- \( y \) – any element of the poset

**Note:** The method `_precompute_intervals()` creates a cache which is used if available, making the function very fast.

See also:

- `interval_iterator()`

**EXAMPLES:**

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

```python
>>> from sage.all import *
>>> uc = [[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
→Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],
→[]]
>>> dag = DiGraph(dict(zip(range(len(uc)),uc)))
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram(dag)
>>> I = set([Integer(2),Integer(5),Integer(6),Integer(4),Integer(7)])
>>> I == set(H.interval(Integer(2),Integer(7)))
True
```

- `common_lower_covers(vertices)`

Return the list of all common lower covers of \( vertices \).

**EXAMPLES:**
common_upper_covers \( \text{vertices} \)

Return the list of all common upper covers of \text{vertices}.

EXAMPLES:
congruence (parts, start=None, stop_pairs=None)

Return the congruence start “extended” by parts.

start is assumed to be a valid congruence of the lattice, and this is not checked.

INPUT:

- parts – a list of lists; congruences to add
- start – a disjoint set; already computed congruence (or None)
- stop_pairs – a list of pairs; list of pairs for stopping computation

OUTPUT:

None, if the congruence generated by start and parts together contains a block that has elements a, b so that (a, b) is in the list stop_pairs. Otherwise the least congruence that contains a block whose subset is p for every p in parts or start, given as sage.sets.disjoint_set.DisjointSet_class.

ALGORITHM:

Use the quadrilateral argument from page 120 of [Dav1997].

Basically we take one block from todo-list, search quadrilateral blocks up and down against the block, and then complete them to closed intervals and add to todo-list.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})
sage: cong = H.congruence([[0, 1]]); cong
# needs sage.modules
{{0, 1, 3}, {2, 4}}
sage: H.congruence([[0, 2]], start=cong)
# needs sage.modules
{{0, 1, 2, 3, 4}}
sage: H.congruence([[0, 1]], stop_pairs=[[1, 3]]) is None
# needs sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):
... [Integer(3)], Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> cong = H.congruence([[Integer(0), Integer(1)]]); cong
... # needs sage.modules
{{0, 1, 3}, {2, 4}}
>>> H.congruence([[Integer(0), Integer(2)]], start=cong)
... # needs sage.modules
{{0, 1, 2, 3, 4}}
>>> H.congruence([[Integer(0), Integer(1)]], stop_pairs=[{Integer(1),
... Integer(3)}]) is None
# needs sage.modules
True
```

congruences_iterator()

Return an iterator over all congruences of the lattice.

EXAMPLES:
cover_relations()

Return the list of cover relations.

EXAMPLES:

```python
covers(x, y)

Return True if y covers x and False otherwise.

EXAMPLES:
```python
sage: Q = Poset([[1,5],[2,6],[3],[4],[6,3],[4]])
sage: Q.covers(Q(1),Q(6))
True
sage: Q.covers(Q(1),Q(4))
False
```

```python
>>> from sage.all import *
>>> Q = Poset([[Integer(1),Integer(5)],[Integer(2),Integer(6)],[Integer(3)],
            [Integer(4)],[[Integer(6),Integer(3)],[Integer(4)]]])
>>> Q.covers(Q(Integer(1)),Q(Integer(6)))
True
>>> Q.covers(Q(Integer(1)),Q(Integer(4)))
False
```

**coxeter_transformation** *(algorithm='cython')*

Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules.

INPUT:

- **algorithm** — optional, 'cython' (default) or 'matrix'

This uses either a specific matrix code in Cython, or generic matrices.

See also:

- `lequal_matrix()`, `moebius_function_matrix()`

EXAMPLES:

```python
sage: from sage.libs.flint sage.modules
sage: P = posets.PentagonPoset()._hasse_diagram
sage: M = P.coxeter_transformation(); M
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
sage: P.__dict__['coxeter_transformation'].clear_cache()
sage: P.coxeter_transformation(algorithm="matrix") == M
True
```

```python
>>> from sage.all import *
>>> # needs sage.libs.flint sage.modules
>>> P = posets.PentagonPoset()._hasse_diagram
>>> M = P.coxeter_transformation(); M
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
>>> P.__dict__['coxeter_transformation'].clear_cache()
>>> P.coxeter_transformation(algorithm="matrix") == M
True
```

**diamonds()**

Return the list of diamonds of *self*.

A diamond is the following subgraph of the Hasse diagram:
Thus each edge represents a cover relation in the Hasse diagram. We represent this as the tuple \((w, x, y, z)\).

**OUTPUT:**

A tuple with

- a list of all diamonds in the Hasse Diagram,
- a boolean checking that every \(w, x, y\) that form a \(\vee\), there is a unique element \(z\), which completes the diamond.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1,2], 1: [3], 2: [3], 3: []})
sage: H.diamonds()
((0, 1, 2, 3), True)

sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))
# needs sage.combinat sage.modules
sage: H = P._hasse_diagram
# needs sage.combinat sage.modules
sage: H.diamonds()
((0, 1, 3, 4), (3, 4, 5, 6), False)
```

**dual()**

Return a poset that is dual to the given poset.

This means that it has the same elements but opposite order. The elements are renumbered to ensure that `range(n)` is a linear extension.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram((Integer(0): [Integer(1),Integer(2)], Integer(1):...
                      [Integer(3)], Integer(2): [Integer(3)], Integer(3): []))
>>> H.diamonds()
((0, 1, 2, 3), True)

>>> P = posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),...
                      [Integer(2)])))
# needs sage.combinat sage.modules
>>> H = P._hasse_diagram
# needs sage.combinat sage.modules
>>> H.diamonds()
((0, 1, 3, 4), (3, 4, 5, 6), False)
```
Hasse diagram of a poset containing 5 elements
sage: H.dual()
˓→needs sage.combinat
Hasse diagram of a poset containing 5 elements

>>> from sage.all import *
>>> P = posets.IntegerPartitions(Integer(4))
˓→ # needs sage.combinat
>>> H = P._hasse_diagram; H
˓→needs sage.combinat
Hasse diagram of a poset containing 5 elements
>>> H.dual()
˓→needs sage.combinat
Hasse diagram of a poset containing 5 elements

**find_nonsemidistributive_elements** *(meet_or_join)*

Check if the lattice is semidistributive or not.

**INPUT:**

- `meet_or_join` - string 'meet' or 'join' to decide if to check for join-semidistributivity or meet-semidistributivity

**OUTPUT:**

- None if the lattice is semidistributive OR
- tuple \((u, e, x, y)\) such that \(u = e \lor x = e \lor y\) but \(u \neq e \lor (x \land y)\) if `meet_or_join`='join'
  and \(u = e \land x = e \land y\) but \(u \neq e \land (x \lor y)\) if `meet_or_join`='meet'

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6], ...: 4:[6], 5:[6]})
sage: H.find_nonsemidistributive_elements('join') is None
˓→needs sage.modules
False
sage: H.find_nonsemidistributive_elements('meet') is None
˓→needs sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2)], ...
˓→Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(4), Integer(5)], ...
˓→Integer(3):[Integer(6)], ...
˓→Integer(4):[Integer(6), Integer(5):[Integer(6)]]})
>>> H.find_nonsemidistributive_elements('join') is None
˓→needs sage.modules
False
>>> H.find_nonsemidistributive_elements('meet') is None
˓→needs sage.modules
True
```

**find_nonsemimodular_pair** *(upper)*

Return pair of elements showing the lattice is not modular.
INPUT:

- upper, a Boolean – if True, test whether the lattice is upper semimodular; otherwise test whether the lattice is lower semimodular.

OUTPUT:

None, if the lattice is semimodular. Pair \((a, b)\) violating semimodularity otherwise.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3, 4], 2:[4, 5], 3:[6], 4:[6], 5:[6]})
sage: H.find_nonsemimodular_pair(upper=True) is None
True
sage: H.find_nonsemimodular_pair(upper=False)
(5, 3)
sage: H_ = HasseDiagram(H.reverse().relabel(lambda x: 6-x, inplace=False))
sage: H_.find_nonsemimodular_pair(upper=True)
(3, 1)
sage: H_.find_nonsemimodular_pair(upper=False) is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2)], Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(4), Integer(5)], Integer(3):[Integer(6)], Integer(4):[Integer(6)], Integer(5):[Integer(6)]})
>>> H.find_nonsemimodular_pair(upper=True) is None
True
>>> H.find_nonsemimodular_pair(upper=False)
(5, 3)
>>> H_ = HasseDiagram(H.reverse().relabel(lambda x: Integer(6)-x, inplace=False))
>>> H_.find_nonsemimodular_pair(upper=True)
(3, 1)
>>> H_.find_nonsemimodular_pair(upper=False) is None
True
```

**find_nontrivial_congruence()**

Return a pair that generates non-trivial congruence or None if there is not any.

EXAMPLES:

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [5], 2: [3, 4], 3: [5], 4: [5]})

# needs sage.modules
sage: H.find_nontrivial_congruence()
({(0, 1), (2, 3, 4, 5)}

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})

# needs sage.modules
sage: H.find_nontrivial_congruence() is None
True
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
```

(continues on next page)
H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1): 
-> [Integer(5)], Integer(2): [Integer(3), Integer(4)], Integer(3): 
-> [Integer(5)], Integer(4): [Integer(5)]})

H.find_nontrivial_congruence()

H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)], 
-> Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3): 
-> [Integer(4)]})

H.find_nontrivial_congruence() is None

ALGORITHM:

See https://www.math.hawaii.edu/~ralph/Preprints/conlat.pdf:

If \( \Theta \) is a join irreducible element of a Con\((L)\), then there is at least one join-irreducible \( j \) and one meet-irreducible \( m \) such that \( \Theta \) is both the principal congruence generated by \((j^*, j)\), where \( j^* \) is the unique lower cover of \( j \), and the principal congruence generated by \((m, m^*)\), where \( m^* \) is the unique upper cover of \( m \).

So, we only check join irreducibles or meet irreducibles, whichever is a smaller set. To optimize more we stop computation whenever it finds a pair that we know to generate one-element congruence.

frattini_sublattice()

Return the list of elements of the Frattini sublattice of the lattice.

EXAMPLES:

```python
sage: H = posets.PentagonPoset()._hasse_diagram
sage: H.frattini_sublattice()
[0, 4]
```

```python
>>> from sage.all import *
>>> H = posets.PentagonPoset()._hasse_diagram
sage: H.frattini_sublattice()
[0, 4]
```

greedy_linear_extensions_iterator()

Return an iterator over greedy linear extensions of the Hasse diagram.

A linear extension \([e_1, e_2, \ldots, e_n]\) is greedy if for every \( i \) either \( e_{i+1} \) covers \( e_i \) or all upper covers of \( e_i \) have at least one lower cover that is not in \([e_1, e_2, \ldots, e_i]\).

Informally said a linear extension is greedy if it “always goes up when possible” and so has no unnecessary jumps.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 2: [3], 1: [4], 3: [4]})
sage: for l in N5.greedy_linear_extensions_iterator():
```
....:  print(l)
    [0, 1, 2, 3, 4]
    [0, 2, 3, 1, 4]

>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> N5 = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(2):
    → [Integer(3)], Integer(1): [Integer(4)], Integer(3): [Integer(4)])
>>> for l in N5.greedy_linear_extensions_iterator():
    ...  print(l)
    [0, 1, 2, 3, 4]
    [0, 2, 3, 1, 4]

has_bottom()

Return True if the poset has a unique minimal element.

EXAMPLES:

sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_bottom()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_bottom()
True

>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3),Integer(1):[Integer(3)],
    → Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})
>>> P.has_bottom()
False
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.has_bottom()
True

has_top()

Return True if the poset contains a unique maximal element, and False otherwise.

EXAMPLES:

sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[1],1:[]})
sage: Q.has_top()
True

>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3),Integer(1):[Integer(3)],
    → Integer(2):[Integer(3)],Integer(3):[Integer(4),Integer(5)],Integer(4):[],
    → Integer(5):[]})
>>> P.has_top()
False
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.has_top()
True
interval \((x, y)\)

Return a list of the elements \(z\) of \(\text{self}\) such that \(x \leq z \leq y\).

The order is that induced by the ordering in \(\text{self.linear_extension}\).

**INPUT:**

- \(x\) – any element of the poset
- \(y\) – any element of the poset

**Note:** The method \(\_\text{precompute_intervals}()\) creates a cache which is used if available, making the function very fast.

**See also:**

interval_iterator()

**EXAMPLES:**

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2,5,6,4,7])
sage: I == set(H.interval(2,7))
True
```

**interval_iterator** \((x, y)\)

Return an iterator of the elements \(z\) of \(\text{self}\) such that \(x \leq z \leq y\).

**INPUT:**

- \(x\) – any element of the poset
- \(y\) – any element of the poset

**See also:**

interval()

**Note:** This becomes much faster when first calling \(\_\text{leq_storage}()\), which precomputes the principal upper ideals.

**EXAMPLES:**
sage: uc = [[1, 3, 2], [4], [5, 6], [6], [7], [7], [7], []]
sage: dag = DiGraph(dict(zip(range(len(uc)), uc)))

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: I = set([2, 5, 6, 4, 7])

sage: I == set(H.interval_iterator(2, 7))
True

>>> from sage.all import *

>>> uc = [[Integer(1), Integer(3), Integer(2)],
       [Integer(4)],
       [Integer(4), Integer(5), Integer(6)],
       [Integer(6)],
       [Integer(7)],
       [Integer(7)],
       [Integer(7)], []]

>>> dag = DiGraph(dict(zip(range(len(uc)), uc)))

>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram(dag)

>>> I = set([Integer(2), Integer(5), Integer(6), Integer(4), Integer(7)])

>>> I == set(H.interval_iterator(Integer(2), Integer(7)))
True

is_antichain_of_poset(elms)

Return True if elms is an antichain of the Hasse diagram and False otherwise.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})

sage: H.is_antichain_of_poset([1, 2, 3])
True

sage: H.is_antichain_of_poset([0, 2, 3])
False

>>> from sage.all import *

>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],
                   Integer(1): [Integer(4)],
                   Integer(2): [Integer(4)],
                   Integer(3): [Integer(4)]})

>>> H.is_antichain_of_poset([Integer(1), Integer(2), Integer(3)])
True

>>> H.is_antichain_of_poset([Integer(0), Integer(2), Integer(3)])
False

is_bounded()

Return True if the poset contains a unique maximal element and a unique minimal element, and False otherwise.

EXAMPLES:

sage: P = Poset({0: [3], 1: [3], 2: [3], 3: [4, 5], 4: [], 5: []})

sage: P.is_bounded()
False

sage: Q = Poset({0: [1], 1: []})

sage: Q.is_bounded()
True

>>> from sage.all import *

>>> P = Poset({Integer(0): [Integer(3)], Integer(1): [Integer(3)],
             Integer(2): [Integer(3)]},
             (continues on next page)
is_chain()

Return True if the poset is totally ordered, and False otherwise.

EXAMPLES:

```python
sage: L = Poset({0:[1], 1:[2], 2:[3], 3:[4]})
sage: L.is_chain()
True
sage: V = Poset({0:[1,2]})
sage: V.is_chain()
False
```

is_complemented()

Return an element of the lattice that has no complement.

If the lattice is complemented, return None.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1, 2], 1:[3], 2:[3], 3:[4]})

# needs sage.modules
sage: H.is_complemented()
1

sage: H = HasseDiagram({0:[1, 2, 3], 1:[4], 2:[4], 3:[4]})

# needs sage.modules
sage: H.is_complemented() is None
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

# needs sage.modules
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2), Integer(3)],
˓→Integer(1):[Integer(4)], Integer(2):[Integer(4)], Integer(3):[Integer(4)]})
>>> H.is_complemented() is None
˓→needs sage.modules
True
```

**is_congruence_normal()**

Return True if the lattice can be constructed from the one-element lattice with Day doubling constructions of convex subsets.

Subsets to double does not need to be lower nor upper pseudo-intervals. On the other hand they must be convex, i.e. doubling a non-convex but municipal subset will give a lattice that returns False from this function.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H.is_congruence_normal()  # needs sage.combinat sage.modules
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram('1X7Q?AG?OG?W?O??')
>>> H.is_congruence_normal()  # needs sage.combinat sage.modules
True
```

The 5-element diamond is the smallest non-example:

```python
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
sage: H.is_congruence_normal()  # needs sage.combinat sage.modules
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})
>>> H.is_congruence_normal()  # needs sage.combinat sage.modules
False
```

This is done by doubling a non-convex subset:

```python
sage: H.is_congruence_normal()  # needs sage.combinat sage.modules
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram('0QC?a@CO?G?C?GA?O??_?@?BO?A_?G??C??_?@??')
>>> H.is_congruence_normal()  # needs sage.combinat sage.modules
False
```

(continues on next page)
ALGORITHM:
See http://www.math.hawaii.edu/~jb/inflation.pdf

is_convex_subset $S$
Return True if $S$ is a convex subset of the poset, and False otherwise.
A subset $S$ is *convex* in the poset if $b \in S$ whenever $a, c \in S$ and $a \leq b \leq c$.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: B3 = HasseDiagram({0: [1, 2, 4], 1: [3, 5], 2: [3, 6], ...
                      3: [7], 4: [5, 6], 5: [7], 6: [7]})
sage: B3.is_convex_subset([1, 3, 5, 4])  # Also connected
True
sage: B3.is_convex_subset([1, 3, 4])  # Not connected
True
sage: B3.is_convex_subset([0, 1, 2, 3, 6])  # No, 0 < 4 < 6
False
sage: B3.is_convex_subset([0, 1, 2, 7])  # No, 1 < 3 < 7.
False

>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> B3 = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(4)], ...
                      Integer(1): [Integer(3), Integer(5)], Integer(2): [Integer(3), Integer(6)], ...
                      Integer(3): [Integer(7)], Integer(4): [Integer(5), ...
                      Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> B3.is_convex_subset([Integer(1), Integer(3), Integer(5), Integer(4)])  # ...
                        Also connected
True
>>> B3.is_convex_subset([Integer(1), Integer(3), Integer(4)])  # Not connected
True
>>> B3.is_convex_subset([Integer(0), Integer(1), Integer(2), Integer(3), ...
                        Integer(6)])  # No, 0 < 4 < 6
False
>>> B3.is_convex_subset([Integer(0), Integer(1), Integer(2), Integer(7)])  # ...
                        No, 1 < 3 < 7.
False
```

is_gequal $x, y$
Return True if $x$ is greater than or equal to $y$, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: x, y, z = 0, 1, 4
sage: Q.is_gequal(x, y)
False
sage: Q.is_gequal(y, x)
```

(continues on next page)
False
sage: Q.is_gequal(x,z)
False
sage: Q.is_gequal(z,x)
True
sage: Q.is_gequal(z,y)
True
sage: Q.is_gequal(z,z)
True

is_greater_than(x,y)

Return True if x is greater than but not equal to y, and False otherwise.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: Q = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x, y, z = 0, 1, 4
sage: Q.is_greater_than(x,y)
False
sage: Q.is_greater_than(y,x)
False
sage: Q.is_greater_than(x,z)
False
sage: Q.is_greater_than(z,x)
True
sage: Q.is_greater_than(z,y)
True
sage: Q.is_greater_than(z,z)
False

(continues on next page)
>>> Q.is_greater_than(y,x)
False
>>> Q.is_greater_than(x,z)
False
>>> Q.is_greater_than(z,x)
True
>>> Q.is_greater_than(z,y)
True
>>> Q.is_greater_than(z,z)
False

is_join_semilattice()
Return True if self has a join operation, and False otherwise.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
   →7:[1]})
sage: H.is_join_semilattice()  # needs sage.modules
True
sage: H = HasseDiagram({0:[2,3],1:[2,3]})
sage: H.is_join_semilattice()  # needs sage.modules
False
sage: H = HasseDiagram({0:[2,3],1:[2,3],2:[4],3:[4]})
sage: H.is_join_semilattice()  # needs sage.modules
False

>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>>
H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
   →Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
   →Integer(3):[Integer(4),Integer(5),Integer(6),Integer(7)],Integer(4):[Integer(7)],
   →Integer(5):[Integer(7)],Integer(6):[Integer(7)],Integer(7):[]})
>>>
H.is_join_semilattice()  # needs sage.modules
True
>>>
H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],
   →Integer(1):[Integer(2),Integer(3)]})
>>>
H.is_join_semilattice()  # needs sage.modules
False
>>>
H = HasseDiagram({Integer(0):[Integer(2),Integer(3)],
   →Integer(1):[Integer(2),Integer(3)],Integer(2):[Integer(4)],
   →Integer(3):[Integer(4)]})
>>>
H.is_join_semilattice()  # needs sage.modules
False

is_lequal(i,j)
Return True if i is less than or equal to j in the poset, and False otherwise.

Note: If the lequal_matrix() has been computed, then this method is redefined to use the cached data
Combinatorics, Release 10.4

(see _alternate_is_lequal()).

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x, y, z = 0, 1, 4
sage: H.is_lequal(x, y)
False
sage: H.is_lequal(y, x)
False
sage: H.is_lequal(x, z)
True
sage: H.is_lequal(y, z)
True
sage: H.is_lequal(z, z)
True

>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(2)], Integer(1):[Integer(2)],
    Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> x, y, z = Integer(0), Integer(1), Integer(4)
>>> H.is_lequal(x, y)
False
>>> H.is_lequal(y, x)
False
>>> H.is_lequal(x, z)
True
>>> H.is_lequal(y, z)
True
>>> H.is_lequal(z, z)
True
```

_is_less_than_(x, y)

Return True if x is less than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: x, y, z = 0, 1, 4
sage: H.is_less_than(x, y)
False
sage: H.is_less_than(y, x)
False
sage: H.is_less_than(x, z)
True
sage: H.is_less_than(y, z)
True
sage: H.is_less_than(z, z)
False

>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(2)], Integer(1):[Integer(2)],
    Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> x, y, z = Integer(0), Integer(1), Integer(4)
>>> H.is_less_than(x, y)
False
>>> H.is_less_than(y, x)
False
>>> H.is_less_than(x, z)
True
>>> H.is_less_than(y, z)
True
>>> H.is_less_than(z, z)
False
```

(continues on next page)
Combinatorics, Release 10.4

is_linear_extension (lin_ext=None)

Test if an ordering is a linear extension.

EXAMPLES:

```python
codeachsage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_linear_extension(list(range(4)))
True
sage: H.is_linear_extension([3,2,1,0])
False
```

is_linear_interval (t_min, t_max)

Return whether the interval [t_min, t_max] is linear.
This means that this interval is a total order.

EXAMPLES:

```python
codeachsage: # needs sage.modules sage: P = posets.PentagonPoset() sage: H = P._hasse_diagram
sage: H.is_linear_interval(0, 4) False sage: H.is_linear_interval(0, 3) True sage: H.is_linear_interval(1, 3) False sage: H.is_linear_interval(1,1) True
```

is_meet_semilattice()

Return True if self has a meet operation, and False otherwise.

EXAMPLES:

```python
codeachsage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.is_meet_semilattice() False
```
is_ranked()

Return True if the poset is ranked, and False otherwise.

A poset is ranked if it admits a rank function. For more information about the rank function, see rank_function() and is_graded().

EXAMPLES:

```python
sage: P = Poset([[1],[2],[3],[4],[5]])

sage: P.is_ranked()
True

sage: Q = Poset([[1],[2,6],[3],[4],[5],[6,3],[4]])

sage: Q.is_ranked()
False
```
join_matrix()
Return the matrix of joins of self, when self is a join-semilattice; raise an error otherwise.

The \((x, y)\)-entry of this matrix is the join of \(x\) and \(y\) in self.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

**Note:** If self is a join-semilattice, then the return of this method is the same as _join(). Once the matrix has been computed, it is stored in _join(). Delete this attribute if you want to recompute the matrix.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: H.join_matrix()  # needs sage.modules
[0 1 2 3 4 5 6 7]
[1 1 4 7 4 7 7 7]
[2 4 2 6 4 5 6 7]
[3 7 6 3 7 7 6 7]
[4 4 4 7 4 7 7 7]
[5 7 5 7 7 5 7 7]
[6 7 6 6 7 7 6 7]
[7 7 7 7 7 7 7 7]
```
Define $\kappa(a)$ as the maximum element of $(\uparrow a_* \setminus \uparrow a)$, where $a_*$ is the element covered by $a$. It is always a meet-irreducible element, if it exists.

**Note:** Element $a$ is expected to be join-irreducible, and this is *not* checked.

**INPUT:**
- $a$ – a join-irreducible element of the lattice

**OUTPUT:**
The element $\kappa(a)$ or *None* if there is not a unique greatest element with given constraints.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4, 5], 3: [5], 4: [6], 5: [6]})
sage: H.kappa(1)
5
sage: H.kappa(2)
None

>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],
...                   Integer(1): [Integer(4)], Integer(2): [Integer(4), Integer(5)], Integer(3):
...                   [Integer(5)], Integer(4): [Integer(6)], Integer(5): [Integer(6)]})
>>> H.kappa(1)
5
>>> H.kappa(Integer(2))
None
```

$kappa\_dual(a)$

Return the minimum element smaller than the element covering $a$ but not smaller than $a$.

Define $\kappa^*(a)$ as the minimum element of $(\downarrow a_* \setminus \downarrow a)$, where $a_*$ is the element covering $a$. It is always a join-irreducible element, if it exists.

**Note:** Element $a$ is expected to be meet-irreducible, and this is *not* checked.

**INPUT:**
- $a$ – a join-irreducible element of the lattice

**OUTPUT:**
The element $\kappa^*(a)$ or *None* if there is not a unique smallest element with given constraints.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4, 5], 3: [6], 4: [6], 5: [6], 6: []})
sage: H.kappa_dual(3)
2
sage: H.kappa_dual(4)
None
```

3084 Chapter 5. Comprehensive Module List
>>> from sage.all import *

>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):
\rightarrow [Integer(3), Integer(4)], Integer(2): [Integer(4), Integer(5)], Integer(3):
\rightarrow [Integer(6)], Integer(4): [Integer(6)], Integer(5): [Integer(6)]})

>>> H.kappa_dual(Integer(3))
2

>>> H.kappa_dual(Integer(4))
is None

True

lequal_matrix (boolean=False)
Return a matrix whose \((i, j)\) entry is 1 if \(i\) is less than \(j\) in the poset, and 0 otherwise; and redefines __lt__ to use the boolean version of this matrix.

INPUT:

- boolean – optional flag (default False) telling whether to return a matrix with coefficients in \(F(2)\) or in \(Z\)

See also:

moebius_function_matrix(), coxeter_transformation()

EXAMPLES:

sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[[]])

sage: H = P._hasse_diagram

sage: M = H.lequal_matrix(); M

\[
\begin{pmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 1 & 1 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 1 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{pmatrix}
\]

sage: M.base_ring()

Integer Ring

sage: P = posets.DiamondPoset(6)

sage: H = P._hasse_diagram

sage: M = H.lequal_matrix(boolean=True)

\[
\begin{pmatrix}
1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 0 \\
\end{pmatrix}
\]

sage: M.base_ring()

Finite Field of size 2
linear_extension()

Return a linear extension

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})
sage: H.linear_extension()
[0, 1, 2, 3]

linear_extensions()

Return an iterator over all linear extensions.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2],1:[3],2:[3],3:[]})

lower_covers_iterator(element)

Return the list of elements that are covered by element.
EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],
                    6:[7],
                   7:[1]})
sage: list(H.lower_covers_iterator(0))
[]
sage: list(H.lower_covers_iterator(4))
[1, 2]
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
                   Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
                   Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
                   Integer(6):[Integer(7)],Integer(7):[]})

```  

```python
>>> list(H.lower_covers_iterator(Integer(0)))
[]
```

```python
>>> list(H.lower_covers_iterator(Integer(4)))
[1, 2]
```

### maximal_elements()

Return a list of the maximal elements of the poset.

EXAMPLES:

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[1]})
sage: P.maximal_elements()
[4]
```

```python
>>> from sage.all import *

```  

```python
L = posets.PentagonPoset() # needs sage.modules
ms = L._hasse_diagram.maximal_sublattices()
```

```python
sorted(ms, key=sorted)
```

```python
[(0, 1, 2, 4), {0, 1, 3, 4}, {0, 2, 3, 4}]
```

### maximal_sublattices()

Return maximal sublattices of the lattice.

EXAMPLES:

```python
sage: L = posets.PentagonPoset()
```

```python
>>>
```
```
**meet_matrix()**

Return the matrix of meets of `self`, when `self` is a meet-semilattice; raise an error otherwise.

The `(x, y)`-entry of this matrix is the meet of `x` and `y` in `self`.

This algorithm is modelled after the algorithm of Freese-Jezek-Nation (p217). It can also be found on page 140 of [Gec81].

**Note:** If `self` is a meet-semilattice, then the return of this method is the same as `_meet()`. Once the matrix has been computed, it is stored in `_meet()`. Delete this attribute if you want to recompute the matrix.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7], ˓→7:[]})
sage: H.meet_matrix()
# needs sage.modules
[0 0 0 0 0 0 0]
[0 1 0 1 0 1 0]
[0 0 2 0 2 2 2]
[0 0 0 3 0 0 3]
[0 1 2 0 4 2 4]
[0 0 2 0 2 5 2]
[0 0 2 3 2 6 6]
[0 1 2 3 4 5 6 7]
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)], ˓→Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)], ˓→Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)], ˓→Integer(6):[Integer(7)],Integer(7):[]})
>>> H.meet_matrix()
# needs sage.modules
[0 0 0 0 0 0 0]
[0 1 0 1 0 1 0]
[0 0 2 0 2 2 2]
[0 0 0 3 0 0 3]
[0 1 2 0 4 2 4]
[0 0 2 0 2 5 2]
[0 0 2 3 2 6 6]
[0 1 2 3 4 5 6 7]
```

**REFERENCE:**

**minimal_elements()**

Return a list of the minimal elements of the poset.

**EXAMPLES:**

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
```
sage: P(2) in P.minimal_elements()
True

>>> from sage.all import *

>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
            Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})

>>> P(Integer(0)) in P.minimal_elements()
True

>>> P(Integer(1)) in P.minimal_elements()
True

>>> P(Integer(2)) in P.minimal_elements()
True

moebius_function(i,j)
Return the value of the Möbius function of the poset on the elements i and j.

EXAMPLES:

sage: P = Poset([[1,2,3],[4],[4],[4],[]])
sage: H = P._hasse_diagram
sage: H.moebius_function(0,4)
2
sage: for u,v in P.cover_relations_iterator():
    if P.moebius_function(u,v) != -1:
        print("Bug in moebius_function!")

>>> from sage.all import *

>>> P = Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],[Integer(4)],[]])

>>> H = P._hasse_diagram

>>> H.moebius_function(Integer(0),Integer(4))
2

>>> for u,v in P.cover_relations_iterator():
    if P.moebius_function(u,v) != -Integer(1):
        print("Bug in moebius_function!")

moebius_function_matrix(algorithm='cython')
Return the matrix of the Möbius function of this poset.

This returns the matrix over $\mathbb{Z}$ whose $(x, y)$ entry is the value of the Möbius function of self evaluated on $x$ and $y$, and redefines moebius_function() to use it.

INPUT:

- algorithm -- optional, 'recursive', 'matrix' or 'cython' (default)

This uses either the recursive formula, a generic matrix inversion or a specific matrix inversion coded in Cython.

OUTPUT:

a dense matrix for the algorithm cython, a sparse matrix otherwise

Note: The result is cached in _moebius_function_matrix().
See also:

\texttt{lequal_matrix()}, \texttt{coxeter_transformation()}

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2], 1:[4], 2:[4,5,6], 3:[6], 4:[7], 5:[7], 6:[7], 7:[7]})
sage: H.moebius_function_matrix() #
needs sage.libs.flint sage.modules
[ 1 -1 -1 -1  1  0  1  0]
[ 0  1  0  0 -1  0  0  0]
[ 0  0  1  0 -1 -1  2]
[ 0  0  0  1  0  0 -1]
[ 0  0  0  0  1  0 -1]
[ 0  0  0  0  0  1 -1]
[ 0  0  0  0  0  0  1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(3), Integer(2)], Integer(1):[Integer(4)], Integer(2):[Integer(3)], Integer(3):[Integer(4), Integer(5)], Integer(4):[Integer(6)], Integer(5):[Integer(6)]})
>>> H.moebius_function_matrix() #
needs sage.libs.flint sage.modules
[ 1 -1 -1 -1  1  0  1  0]
[ 0  1  0  0 -1  0  0  0]
[ 0  0  1  0 -1 -1  2]
[ 0  0  0  1  0  0 -1]
[ 0  0  0  0  1  0 -1]
[ 0  0  0  0  0  1 -1]
[ 0  0  0  0  0  0  1]
```

\texttt{neutral_elements()}

Return the list of neutral elements of the lattice.

An element \(a\) in a lattice is neutral if the sublattice generated by \(a\), \(x\) and \(y\) is distributive for every \(x, y\) in the lattice.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4, 5], 4: [6], 5: [6]})
sage: sorted(H.neutral_elements()) #
needs sage.modules
[0, 4, 6]
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1), Integer(2)], Integer(1):[Integer(4)], Integer(2):[Integer(3)], Integer(3):[Integer(4), ... Integer(5)], ... Integer(4):[Integer(6)], Integer(5):[Integer(6)]})
```
ALGORITHM:

Basically we just check the distributivity against all element pairs $x, y$ to see if element $a$ is neutral or not.

If we found that $a, x, y$ is not a distributive triple, we add all three to the list of non-neutral elements. If we found $a$ to be neutral, we add it to the list of neutral elements. When testing we skip already found neutral elements, as they can’t be our $x$ or $y$.

We skip $a, x, y$ as trivial if it is a chain. We do that by letting $x$ to be a non-comparable to $a$; $y$ can be any element.

We first try to find $x$ and $y$ from elements not yet tested, so that we could get three birds with one stone.

And last, the top and bottom elements are always neutral and need not be tested.

**open_interval** $(x, y)$

Return a list of the elements $z$ of `self` such that $x < z < y$.

The order is that induced by the ordering in `self.linear_extension`.

**EXAMPLES:**

```python
sage: uc = [[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]]
sage: dag = DiGraph(dict(zip(range(len(uc)),uc)))
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram(dag)
sage: set([5,6,4]) == set(H.open_interval(2,7))
True
sage: H.open_interval(7,2)
[]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram

>>> H.order_filter([Integer(3), Integer(8)])
[3, 7, 8, 9, 10, 11, 12, 13, 14, 15]
```

**order_ideal (elements)**

Return the order ideal generated by a list of elements.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$.

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal([7,10])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

```python
>>> from sage.all import *

>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram

>>> H.order_ideal([Integer(7),Integer(10)])
[0, 1, 2, 3, 4, 5, 6, 7, 8, 10]
```

**order_ideal_cardinality (elements)**

Return the cardinality of the order ideal generated by `elements`.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$.

**EXAMPLES:**

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.order_ideal_cardinality([7,10])
10
```

```python
>>> from sage.all import *

>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram

>>> H.order_ideal_cardinality([Integer(7),Integer(10)])
10
```

**orthocomplementations_iterator ()**

Return an iterator over orthocomplementations of the lattice.

**OUTPUT:**

An iterator that gives plain list of integers.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,2], 1:[3,4], 3:[5], 4:[5], 2:[6,7],
                    6:[8], 7:[8], 5:[9], 8:[9]})

sage: list(H.orthocomplementations_iterator())
#˓→ needs sage.groups
[[9, 8, 5, 6, 7, 2, 3, 4, 1, 0], [9, 8, 5, 7, 6, 2, 4, 3, 1, 0]]
```

```python
>>> from sage.all import *

>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
                   Integer(1):[Integer(3),Integer(4)],
                   Integer(3):[Integer(5)]})

(continues on next page)```
ALGORITHM:

As $\text{DiamondPoset}(2n+2)$ has $(2n)!/(n!2^n)$ different orthocomplementations, the complexity of listing all of them is necessarily $O(n!)$.

An orthocomplemented lattice is self-dual, so that for example orthocomplement of an atom is a coatom. This function basically just computes list of possible orthocomplementations for every element (i.e. they must be complements and "duals"), and then tries to fit them all.

**prime_elements()**

Return the join-prime and meet-prime elements of the bounded poset.

An element $x$ of a poset $P$ is join-prime if the subposet induced by $\{y \in P \mid y \not\geq x\}$ has a top element. Meet-prime is defined dually.

**Note:** The poset is expected to be bounded, and this is not checked.

**OUTPUT:**

A pair $(j, m)$ where $j$ is a list of join-prime elements and $m$ is a list of meet-prime elements.

**EXAMPLES:**

\[
\begin{align*}
\text{sage: from sage.combinat.posets.hasse_diagram import HasseDiagram} \\
\text{sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})} \\
\text{sage: H.prime_elements()} \\
((1, 2), (2, 3))
\end{align*}
\]

\[
\begin{align*}
\text{>>> from sage.all import *} \\
\text{>>> from sage.combinat.posets.hasse_diagram import HasseDiagram} \\
\text{>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)], Integer(1):...} \\
\text{>>> H.prime_elements()} \\
([1, 2], [2, 3])
\end{align*}
\]

**principal_congruences_poset()**

Return the poset of join-irreducibles of the congruence lattice.

**OUTPUT:**

A pair $(P, D)$ where $P$ is a poset and $D$ is a dictionary.

Elements of $P$ are pairs $(x, y)$ such that $x$ is an element of the lattice and $y$ is an element covering it. In the poset $(a, b)$ is less than $(c, d)$ iff the principal congruence generated by $(a, b)$ is refinement of the principal congruence generated by $(c, d)$.

$D$ is a dictionary from pairs $(x, y)$ to the congruence (given as DisjointSet) generated by the pair.

**EXAMPLES:**

5.1. Comprehensive Module List
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: N5 = HasseDiagram({0: [1, 2], 1: [4], 2: [3], 3: [4]})

sage: P, D = N5.principal_congruences_poset()

# needs sage.combinat sage.modules

sage: P

# needs sage.combinat sage.modules

Finite poset containing 3 elements

sage: P.bottom()

# needs sage.combinat sage.modules

(2, 3)

sage: D[(2, 3)]

# needs sage.combinat sage.modules

{{0}, {1}, {2, 3}, {4}}

principal_order_filter(i)

Return the order filter generated by $i$.

EXAMPLES:

sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_filter(2)
[2, 3, 6, 7, 10, 11, 14, 15]

>>> from sage.all import *

>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram

>>> H.principal_order_filter(Integer(2))
[2, 3, 6, 7, 10, 11, 14, 15]

principal_order_ideal(i)

Return the order ideal generated by $i$.

EXAMPLES:

sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.principal_order_ideal(6)
[0, 2, 4, 6]

>>> from sage.all import *

>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram

>>> H.principal_order_ideal(Integer(6))
[0, 2, 4, 6]
**pseudocomplement** *(element)*

Return the pseudocomplement of element, if it exists.

The pseudocomplement is the greatest element whose meet with given element is the bottom element. It may not exist, and then the function returns None.

**INPUT:**

- *element* – an element of the lattice.

**OUTPUT:**

An element of the Hasse diagram, i.e. an integer, or None if the pseudocomplement does not exist.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [4], 3: [4]})

sage: H.pseudocomplement(2)
needs sage.modules
3

sage: H = HasseDiagram({0: [1, 2, 3], 1: [4], 2: [4], 3: [4]})

sage: H.pseudocomplement(2) is None
needs sage.modules
True
```

**rank** *(element=None)*

Return the rank of element, or the rank of the poset if element is None. (The rank of a poset is the length of the longest chain of elements of the poset.)

**EXAMPLES:**

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2), Integer(3)],
    Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3): [Integer(4)]})

>>> H.pseudocomplement(Integer(2))
# needs sage.modules
3

>>> H.pseudocomplement(Integer(2)) is None
# needs sage.modules
True
```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0):[Integer(1),Integer(3),Integer(2)],
                   →Integer(1):[Integer(4)],Integer(2):[Integer(4),Integer(5),Integer(6)],
                   →Integer(3):[Integer(6)],Integer(4):[Integer(7)],Integer(5):[Integer(7)],
                   →Integer(6):[Integer(7)],Integer(7):[]})
>>> H.rank(Integer(5))
2
>>> H.rank()
3
>>> Q = HasseDiagram({Integer(0):[Integer(1),Integer(2)],
                   →Integer(1):[Integer(3)],Integer(2):[],Integer(3):[]})
>>> Q.rank()
2
>>> Q.rank(Integer(1))
1

rank_function()

Return the (normalized) rank function of the poset, if it exists.

A rank function of a poset $P$ is a function $r$ that maps elements of $P$ to integers and satisfies: $r(x) = r(y) + 1$ if $x$ covers $y$. The function $r$ is normalized such that its minimum value on every connected component of the Hasse diagram of $P$ is 0. This determines the function $r$ uniquely (when it exists).

OUTPUT:

• a lambda function, if the poset admits a rank function
• None, if the poset does not admit a rank function

EXAMPLES:

sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[[]])
sage: P.rank_function() is not None
True
sage: P = Poset(((1,2,3,4),[[1,4],[2,3],[3,4]]), facade = True)

sage: P.rank_function() is not None
True
sage: P = Poset(((1,2,3,4,5),[[1,2],[2,3],[3,4],[1,5],[5,4]]), facade = True)

sage: P.rank_function() is not None
False
sage: P = Poset(((1,2,3,4,5,6,7,8),[[1,4],[2,3],[3,4],[5,7],[6,7]]), facade = True)

sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0

sage: P = Poset(((1,2,3,4),[[1,4],[2,3],[3,4]]), facade = True)

sage: P.rank_function() is not None
True
sage: P = Poset(((1,2,3,4),[[1,4],[2,3],[3,4]]), facade = True)

sage: P.rank_function() is not None
True
sage: P = Poset(((1,2,3,4),[[1,4],[2,3],[3,4]]), facade = True)

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> P.rank_function() is not None
True

>>> P = Poset(((Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)),
              [(Integer(1), Integer(2)), (Integer(2), Integer(3)), (Integer(3), Integer(4)),
               (Integer(1), Integer(5)), (Integer(5), Integer(4))]), facade = True)
>>> P.rank_function() is not None
False

>>> P = Poset(((Integer(1), Integer(2), Integer(3), Integer(4), Integer(5),
              Integer(6), Integer(7), Integer(8)), [(Integer(1), Integer(4)), (Integer(2),
              Integer(3)), (Integer(3), Integer(4)), (Integer(5), Integer(7)), (Integer(6),
              Integer(7))]), facade = True)
>>> f = P.rank_function(); f is not None
True

>>> f(Integer(5))
0

>>> f(Integer(2))
0
```

**skeleton()**

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented and non-empty.

The skeleton of the lattice is the subposet induced by those elements that are the pseudocomplement to at least one element.

**OUTPUT:**

List of elements such that the subposet induced by them is the skeleton of the lattice.

**EXAMPLES:**

```
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram

sage: H = HasseDiagram({0: [1, 2], 1: [3, 4], 2: [4],
                   ....: 3: [5], 4: [5]})
```

```python
sage: H.skeleton()  # needs sage.modules
[5, 2, 0, 3]
```

```
>>> from sage.all import *

>>> from sage.combinat.posets.hasse_diagram import HasseDiagram

>>> H = HasseDiagram((Integer(0): [Integer(1), Integer(2)], Integer(1):...
                   Integer(3), Integer(4)], Integer(2): [Integer(4)],
                   ... Integer(3): [Integer(5)], Integer(4): [Integer(5)])
```

```python
>>> H.skeleton()  # needs sage.modules
[5, 2, 0, 3]
```

**sublattices_iterator** *(elms, min_e)*

Return an iterator over sublattices of the Hasse diagram.

**INPUT:**

- elms – elements already in sublattice; use set() at start
- min_e – smallest new element to add for new sublattices

**OUTPUT:**
List of sublattices as sets of integers.

EXAMPLES:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 1: [3], 2: [3]})
sage: it = H.sublattices_iterator(set(), 0); it
<generator object ...sublattices_iterator at ...>
```

```
sage: next(it)
...
```

```
sage: next(it)
...
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)],
.... Integer(2): [Integer(3), Integer(4)]})
```

```
>>> it = H.sublattices_iterator(set(), Integer(0)); it
<generator object ...sublattices_iterator at ...>
```

```
>>> next(it)
...
```

```
>>> next(it)
...
```

supergreedy_linear_extensions_iterator()

Return an iterator over supergreedy linear extensions of the Hasse diagram.

A linear extension \([e_1, e_2, \ldots, e_n]\) is supergreedy if, for every \(i \geq j\), \(e_i\) covers \(e_j\) if for every \(i > k > j\) at least one lower cover of \(e_k\) is not in \([e_1, e_2, \ldots, e_k]\).

Informally said a linear extension is supergreedy if it “always goes as high possible, and withdraw so less as possible”. These are also called depth-first linear extensions.

EXAMPLES:

We show the difference between “only greedy” and supergreedy extensions:

```python
sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0: [1, 2], 2: [3, 4]})
sage: G_ext = list(H.greedy_linear_extensions_iterator())
sage: SG_ext = list(H.supergreedy_linear_extensions_iterator())
```

```
sage: [0, 2, 3, 1, 4] in G_ext
True
```

```
sage: [0, 2, 3, 1, 4] in SG_ext
False
```

```
sage: len(SG_ext)
4
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.hasse_diagram import HasseDiagram
>>> H = HasseDiagram({Integer(0): [Integer(1), Integer(2)],
.... Integer(2): [Integer(3), Integer(4)]})
```

```
>>> G_ext = list(H.greedy_linear_extensions_iterator())
```

(continues on next page)
Combinatorics, Release 10.4

>>> SG_ext = list(H.supergreedy_linear_extensions_iterator())
>>> [Integer(0), Integer(2), Integer(3), Integer(1), Integer(4)] in G_ext
True
>>> [Integer(0), Integer(2), Integer(3), Integer(1), Integer(4)] in SG_ext
False
>>> len(SG_ext)
4

top()
Return the top element of the poset, if it exists.

EXAMPLES:

sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top() is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1

upper_covers_iterator(element)
Return the list of elements that cover element.

EXAMPLES:

sage: from sage.combinat.posets.hasse_diagram import HasseDiagram
sage: H = HasseDiagram({0:[1,3,2],1:[4],2:[4,5,6],3:[6],4:[7],5:[7],6:[7],7:[]})
sage: list(H.upper_covers_iterator(0))
[1, 2, 3]
sage: list(H.upper_covers_iterator(7))
[]

vertical_decomposition(return_list=False)

5.1. Comprehensive Module List
Return vertical decomposition of the lattice.

This is the backend function for vertical decomposition functions of lattices.

The property of being vertically decomposable is defined for lattices. This is not checked, and the function works with any bounded poset.

INPUT:

• return_list, a boolean. If False (the default), return an element that is not the top neither the bottom element of the lattice, but is comparable to all elements of the lattice, if the lattice is vertically decomposable and None otherwise. If True, return list of decomposition elements.

EXAMPLES:

```python
sage: H = posets.BooleanLattice(4)._hasse_diagram
sage: H.vertical_decomposition() is None
True
sage: P = Poset( ([1,2,3,6,12,18,36], attrcall("divides")) )
sage: P._hasse_diagram.vertical_decomposition()
3
sage: P._hasse_diagram.vertical_decomposition(return_list=True)
[3]
```

```python
>>> from sage.all import *
>>> H = posets.BooleanLattice(Integer(4))._hasse_diagram
>>> H.vertical_decomposition() is None
True
>>> P = Poset( ([Integer(1),Integer(2),Integer(3),Integer(6),Integer(12),
    --Integer(18),Integer(36)], attrcall("divides")) )
>>> P._hasse_diagram.vertical_decomposition()
3
>>> P._hasse_diagram.vertical_decomposition(return_list=True)
[3]
```

exception sage.combinat.posets.hasse_diagram.LatticeError(fail, x, y)

Bases: ValueError

Helper exception class to forward elements without meet or join to upper level, so that the user will see “No meet for a and b” instead of “No meet for 1 and 2”.

5.1.181 Incidence Algebras

class sage.combinat.posets.incidence_algebras.IncidenceAlgebra(R, P, prefix='I')

Bases: CombinatorialFreeModule

The incidence algebra of a poset.

Let $P$ be a poset and $R$ be a commutative unital associative ring. The incidence algebra $I_P$ is the algebra of functions $\alpha: P \times P \to R$ such that $\alpha(x, y) = 0$ if $x \not\leq y$ where multiplication is given by convolution:

$$(\alpha \ast \beta)(x, y) = \sum_{x \leq k \leq y} \alpha(x, k)\beta(k, y).$$

This has a natural basis given by indicator functions for the interval $[a, b]$, i.e. $X_{a,b}(x, y) = \delta_{ax}\delta_{by}$. The incidence algebra is a unital algebra with the identity given by the Kronecker delta $\delta(x, y) = \delta_{xy}$. The M"obius function of $P$ is another element of $I_P$ whose inverse is the $\zeta$ function of the poset (so $\zeta(x, y) = 1$ for every interval $[x, y]$).
Todo: Implement the incidence coalgebra.

REFERENCES:

- Wikipedia article Incidence_algebra

class Element
   Bases: IndexedFreeModuleElement
   
   An element of an incidence algebra.

   is_unit()
   
   Return if self is a unit.

   EXAMPLES:

   sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: mu = I.moebius()
sage: mu.is_unit()
True
sage: zeta = I.zeta()
sage: zeta.is_unit()
True
sage: x = mu - I.zeta() + I[2,2]
sage: x.is_unit()
False
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
True

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> mu = I.moebius()
>>> mu.is_unit()
True
>>> zeta = I.zeta()
>>> zeta.is_unit()
True
>>> x = mu - I.zeta() + I[Integer(2),Integer(2)]
>>> x.is_unit()
False
>>> y = I.moebius() + I.zeta()
>>> y.is_unit()
True

This depends on the base ring:

sage: I = P.incidence_algebra(ZZ)
sage: y = I.moebius() + I.zeta()
sage: y.is_unit()
False

>>> from sage.all import *
>>> I = P.incidence_algebra(ZZ)
Combinatorics, Release 10.4

```python
>>> y = I.moebius() + I.zeta()
>>> y.is_unit()
False
```

to_matrix()

Return `self` as a matrix.

We define a matrix $M_{xy} = \alpha(x, y)$ for some element $\alpha \in I_P$ in the incidence algebra $I_P$ and we order the elements $x, y \in P$ by some linear extension of $P$. This defines an algebra (iso)morphism; in particular, multiplication in the incidence algebra goes to matrix multiplication.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius().to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
sage: I.zeta().to_matrix()
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

```python
>>> from sage.all import *
```

```python
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> I.moebius().to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
```

```python
>>> I.zeta().to_matrix()
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

delta()

Return the element 1 in `self` (which is the Kronecker delta $\delta(x, y)$).

EXAMPLES:

```python
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
```

```python
>>> from sage.all import *
```

```python
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.one()
```

(continues on next page)

\texttt{moebius()}

Return the Mobius function of self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: I.moebius()
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1] - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> I.moebius()
I[0, 0] - I[0, 1] - I[0, 2] + I[0, 3] + I[1, 1] - I[1, 3] + I[2, 2] - I[2, 3] + I[3, 3]
\end{verbatim}

\texttt{one()}

Return the element 1 in self (which is the Kronecker delta \(\delta(x, y)\)).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.one()
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.one()
\end{verbatim}

\texttt{poset()}

Return the defining poset of self.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.poset() Finite lattice containing 16 elements
sage: I.poset() == P
True
\end{verbatim}
```python
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.poset()
Finite lattice containing 16 elements
>>> I.poset() == P
True
```

**product_on_basis** \((A, B)\)

Return the product of basis elements indexed by \(A\) and \(B\).

**EXAMPLES:**

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.product_on_basis((1, 3), (3, 11))
I[1, 11]
sage: I.product_on_basis((1, 3), (2, 2))
0
```

```python
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.product_on_basis((Integer(1), Integer(3)), (Integer(3), Integer(11)))
I[1, 11]
>>> I.product_on_basis((Integer(1), Integer(3)), (Integer(2), Integer(2)))
0
```

**reduced_subalgebra** \((prefix='R')\)

Return the reduced incidence subalgebra.

**EXAMPLES:**

```
sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.reduced_subalgebra()
Reduced incidence algebra of Finite lattice containing 16 elements
over Rational Field
```

```python
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.reduced_subalgebra()
Reduced incidence algebra of Finite lattice containing 16 elements
over Rational Field
```

**some_elements** ()

Return a list of elements of self.

**EXAMPLES:**

```
sage: P = posets.BooleanLattice(1)
sage: I = P.incidence_algebra(QQ)
sage: Ielts = I.some_elements(); Ielts # random
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
 I[0, 0] - I[0, 1] + I[1, 1],
```

(continues on next page)
I[0, 0] + I[0, 1] + I[1, 1]
sage: [a in I for a in Ielts]
[True, True, True]

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(1))
>>> I = P.incidence_algebra(QQ)
>>> Ielts = I.some_elements(); Ielts # random
[2*I[0, 0] + 2*I[0, 1] + 3*I[1, 1],
I[0, 0] - I[0, 1] + I[1, 1],
I[0, 0] + I[0, 1] + I[1, 1]]
>>> [a in I for a in Ielts]
[True, True, True]

zeta()

Return the \(\zeta\) function in self.

The \(\zeta\) function on a poset \(P\) is given by

\[
\zeta(x, y) = \begin{cases} 
1 & x \leq y, \\
0 & x \nleq y.
\end{cases}
\]

EXAMPLES:

sage: P = posets.BooleanLattice(4)
sage: I = P.incidence_algebra(QQ)
sage: I.zeta() * I.moebius() == I.one()
True

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> I = P.incidence_algebra(QQ)
>>> I.zeta() * I.moebius() == I.one()
True

class sage.combinat.posets.incidence_algebras.ReducedIncidenceAlgebra

Bases: CombinatorialFreeModule

The reduced incidence algebra of a poset.

The reduced incidence algebra \(R_P\) is a subalgebra of the incidence algebra \(I_P\) where \(\alpha(x, y) = \alpha(x', y')\) when \([x, y]\) is isomorphic to \([x', y']\) as posets. Thus the delta, Möbius, and zeta functions are all elements of \(R_P\).

class Element

Bases: IndexedFreeModuleElement

An element of a reduced incidence algebra.

is_unit()

Return if self is a unit.

EXAMPLES:

sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: x = R.an_element()
sage: x.is_unit()
True

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> x = R.an_element()
>>> x.is_unit()
True

**lift()**

Return the lift of self to the ambient space.

**EXAMPLES:**

sage: P = posets.BooleanLattice(2)
sage: I = P.incidence_algebra(QQ)
sage: R = I.reduced_subalgebra()
sage: x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
sage: x.lift()

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> I = P.incidence_algebra(QQ)
>>> R = I.reduced_subalgebra()
>>> x = R.an_element(); x
2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]

**to_matrix()**

Return self as a matrix.

**EXAMPLES:**

sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: mu = R.moebius()
sage: mu.to_matrix()
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(2))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> mu = R.moebius()
>>> mu.to_matrix()
[ 1 -1 -1  1]

(continues on next page)
delta()

Return the Kronecker delta function in self.

EXAMPLES:

```sage
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.delta()
R[(0, 0)]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.delta()
R[(0, 0)]
```

lift()

Return the lift morphism from self to the ambient space.

EXAMPLES:

```sage
sage: P = posets.BooleanLattice(2)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.lift
Generic morphism:
  From: Reduced incidence algebra of Finite lattice containing 4 elements
      over Rational Field
  To:   Incidence algebra of Finite lattice containing 4 elements over
        Rational Field
sage: R.an_element() - R.one()
R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)]
```

```sage
c
```
EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.moebius()
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)]
```

```
one_basis()

Return the index of the element 1 in self.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.one_basis()
(0, 0)
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.one_basis()
(0, 0)
```

```
poset()

Return the defining poset of self.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.poset()
Finite lattice containing 16 elements
sage: R.poset() == P
True
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.poset()
Finite lattice containing 16 elements
>>> R.poset() == P
True
```

```
some_elements()

Return a list of elements of self.

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.some_elements()
```
(continues on next page)
(continued from previous page)

\[ 2\*R[(0, 0)] + 2\*R[(0, 1)] + 3\*R[(0, 3)], \\
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)], \\
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)] \]

```python
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(4))
>>> R = P.incidence_algebra(QQ).reduced_subalgebra()
>>> R.some_elements()
[2*R[(0, 0)] + 2*R[(0, 1)] + 3*R[(0, 3)],
R[(0, 0)] - R[(0, 1)] + R[(0, 3)] - R[(0, 7)] + R[(0, 15)],
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]]
```

**zeta()**

Return the \( \zeta \) function in self.

The \( \zeta \) function on a poset \( P \) is given by

\[
\zeta(x, y) = \begin{cases} 
1 & x \leq y, \\
0 & x \not\leq y. 
\end{cases}
\]

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(4)
sage: R = P.incidence_algebra(QQ).reduced_subalgebra()
sage: R.zeta()
R[(0, 0)] + R[(0, 1)] + R[(0, 3)] + R[(0, 7)] + R[(0, 15)]
```

### 5.1.182 Finite lattices and semilattices

This module implements finite (semi)lattices. It defines:

- **LatticePoset()**  
  Construct a lattice.
- **MeetSemilattice()**  
  Construct a meet semi-lattice.
- **JoinSemilattice()**  
  Construct a join semi-lattice.
- **FiniteLatticePoset**  
  A class for finite lattices.
- **FiniteMeetSemilattice**  
  A class for finite meet semilattices.
- **FiniteJoinSemilattice**  
  A class for finite join semilattices.
List of (semi)lattice methods

Meet and join

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>meet()</td>
<td>Return the meet of given elements.</td>
</tr>
<tr>
<td>join()</td>
<td>Return the join of given elements.</td>
</tr>
<tr>
<td>meet_matrix()</td>
<td>Return the matrix of meets of all elements of the meet semi-lattice.</td>
</tr>
<tr>
<td>join_matrix()</td>
<td>Return the matrix of joins of all elements of the join semi-lattice.</td>
</tr>
</tbody>
</table>

Properties of the lattice

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>is_distributive()</td>
<td>Return True if the lattice is distributive.</td>
</tr>
<tr>
<td>is_modular()</td>
<td>Return True if the lattice is modular.</td>
</tr>
<tr>
<td>is_lower_semimodular()</td>
<td>Return True if all elements with common upper cover have a common lower cover.</td>
</tr>
<tr>
<td>is_upper_semimodular()</td>
<td>Return True if all elements with common lower cover have a common upper cover.</td>
</tr>
<tr>
<td>is_semdistributive()</td>
<td>Return True if the lattice is both join- and meet-semidistributive.</td>
</tr>
<tr>
<td>is_join_semdistributive()</td>
<td>Return True if the lattice is join-semidistributive.</td>
</tr>
<tr>
<td>is_meet_semdistributive()</td>
<td>Return True if the lattice is meet-semidistributive.</td>
</tr>
<tr>
<td>is_meet_distributive()</td>
<td>Return True if the lattice is meet-distributive.</td>
</tr>
<tr>
<td>is_atom()</td>
<td>Return True if every element of the lattice can be written as a join of atoms.</td>
</tr>
<tr>
<td>is_coatom()</td>
<td>Return True if every element of the lattice can be written as a meet of coatoms.</td>
</tr>
<tr>
<td>is_geometric()</td>
<td>Return True if the lattice is atomic and upper semimodular.</td>
</tr>
<tr>
<td>is_extremal()</td>
<td>Return True if the lattice is extremal.</td>
</tr>
<tr>
<td>is_complemented()</td>
<td>Return True if every element of the lattice has at least one complement.</td>
</tr>
<tr>
<td>is_sectionally_complemented()</td>
<td>Return True if every interval from the bottom is complemented.</td>
</tr>
<tr>
<td>is_cosectionally_complemented()</td>
<td>Return True if every interval to the top is complemented.</td>
</tr>
<tr>
<td>is_relatively_complemented()</td>
<td>Return True if every interval of the lattice is complemented.</td>
</tr>
<tr>
<td>is_pseudocomplemented()</td>
<td>Return True if every element of the lattice has a (meet-)pseudocomplement.</td>
</tr>
<tr>
<td>is_join_pseudocomplemented()</td>
<td>Return True if every element of the lattice has a join-pseudocomplement.</td>
</tr>
<tr>
<td>is_orthocomplemented()</td>
<td>Return True if the lattice has an orthocomplementation.</td>
</tr>
<tr>
<td>is_supersolvable()</td>
<td>Return True if the lattice is supersolvable.</td>
</tr>
<tr>
<td>is_planar()</td>
<td>Return True if the lattice has an upward planar drawing.</td>
</tr>
<tr>
<td>is_dismantlable()</td>
<td>Return True if the lattice is dismantlable.</td>
</tr>
<tr>
<td>is_interval_dismantlable()</td>
<td>Return True if the lattice is interval dismantlable.</td>
</tr>
<tr>
<td>is_sublattice_dismantlable()</td>
<td>Return True if the lattice is sublattice dismantlable.</td>
</tr>
<tr>
<td>is_stone()</td>
<td>Return True if the lattice is a Stone lattice.</td>
</tr>
</tbody>
</table>

### Combinatorics

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>is_trim()</code></td>
<td>Return True if the lattice is a trim lattice.</td>
</tr>
<tr>
<td><code>is_vertically_decomposable()</code></td>
<td>Return True if the lattice is vertically decomposable.</td>
</tr>
<tr>
<td><code>is_simple()</code></td>
<td>Return True if the lattice has no nontrivial congruences.</td>
</tr>
<tr>
<td><code>is_isomorphic()</code></td>
<td>Return True if all congruences of the lattice consists of isoform blocks.</td>
</tr>
<tr>
<td><code>is_uniform()</code></td>
<td>Return True if all congruences of the lattice consists of equal-sized blocks.</td>
</tr>
<tr>
<td><code>is_regular()</code></td>
<td>Return True if all congruences of the lattice are determined by any of the congruence blocks.</td>
</tr>
<tr>
<td><code>is_subdirectly_reducible()</code></td>
<td>Return True if the lattice is a sublattice of the product of smaller lattices.</td>
</tr>
<tr>
<td><code>is_constructible_by_doublings()</code></td>
<td>Return True if the lattice is constructible by doublings from the one-element lattice.</td>
</tr>
<tr>
<td><code>breadth()</code></td>
<td>Return the breadth of the lattice.</td>
</tr>
</tbody>
</table>

### Specific elements

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>atoms()</code></td>
<td>Return elements covering the bottom element.</td>
</tr>
<tr>
<td><code>coatoms()</code></td>
<td>Return elements covered by the top element.</td>
</tr>
<tr>
<td><code>double_irreducibles()</code></td>
<td>Return double irreducible elements.</td>
</tr>
<tr>
<td><code>join_primes()</code></td>
<td>Return the join prime elements.</td>

<td>Return the list of complements of an element, or the dictionary of complements for all elements.</td>
</tr>
<tr>
<td><code>pseudocomplement()</code></td>
<td>Return the pseudocomplement of an element.</td>
</tr>
<tr>
<td><code>is_modular_element()</code></td>
<td>Return True if given element is modular in the lattice.</td>
</tr>
<tr>
<td><code>is_left_modular_element()</code></td>
<td>Return True if given element is left modular in the lattice.</td>
</tr>
<tr>
<td><code>neutral_elements()</code></td>
<td>Return neutral elements of the lattice.</td>
</tr>
<tr>
<td><code>canonical_joinands()</code></td>
<td>Return the canonical joinands of an element.</td>
</tr>
<tr>
<td><code>canonical_meetands()</code></td>
<td>Return the canonical meetands of an element.</td>
</tr>
</tbody>
</table>

### Sublattices

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>sublattice()</code></td>
<td>Return sublattice generated by list of elements.</td>
</tr>
<tr>
<td><code>submeetsemilattice()</code></td>
<td>Return meet-subsemilattice generated by list of elements.</td>
</tr>
<tr>
<td><code>subjoinsemilattice()</code></td>
<td>Return join-subsemilattice generated by list of elements.</td>
</tr>
<tr>
<td><code>is_sublattice()</code></td>
<td>Return True if the lattice is a sublattice of given lattice.</td>
</tr>
<tr>
<td><code>sublattices()</code></td>
<td>Return all sublattices of the lattice.</td>
</tr>
<tr>
<td><code>sublattices_lattice()</code></td>
<td>Return the lattice of sublattices.</td>
</tr>
<tr>
<td><code>isomorphic_sublattices_iterator()</code></td>
<td>Return an iterator over the sublattices isomorphic to given lattice.</td>
</tr>
<tr>
<td><code>maximal_sublattices()</code></td>
<td>Return maximal sublattices of the lattice.</td>
</tr>
<tr>
<td><code>frattini_sublattice()</code></td>
<td>Return the intersection of maximal sublattices of the lattice.</td>
</tr>
<tr>
<td><code>skeleton()</code></td>
<td>Return the skeleton of the lattice.</td>
</tr>
<tr>
<td><code>center()</code></td>
<td>Return the sublattice of complemented neutral elements.</td>
</tr>
<tr>
<td><code>vertical_decomposition()</code></td>
<td>Return the vertical decomposition of the lattice.</td>
</tr>
</tbody>
</table>

### Miscellaneous

5.1. Comprehensive Module List
moebius_algebra() Return the Möbius algebra of the lattice.
quantum_moebius_algebra() Return the quantum Möbius algebra of the lattice.
vertical_composition() Return ordinal sum of lattices with top/bottom element unified.
day_doubling() Return the lattice with Alan Day’s doubling construction of a subset.
adjunct() Return the adjunct with other lattice.
subdirect_decomposition() Return the subdirect decomposition of the lattice.
congruence() Return the congruence generated by lists of elements.
quotient() Return the quotient lattice by a congruence.
congruences_lattice() Return the lattice of congruences.

class sage.combinat.posets.lattices.FiniteJoinSemilattice (hasse_diagram, elements, category, facade, key)

Bases: FinitePoset

We assume that the argument passed to FiniteJoinSemilattice is the poset of a join-semilattice (i.e. a poset with least upper bound for each pair of elements).

Element

alias of JoinSemilatticeElement

cocatoms()

Return the list of co-atoms of this (semi)lattice.

A co-atom of a lattice is an element covered by the top element.

EXAMPLES:

    sage: L = posets.DivisorLattice(60)
    sage: sorted(L.cocatoms())
    [12, 20, 30]

    >>> from sage.all import *
    >>> L = posets.DivisorLattice(Integer(60))
    >>> sorted(L.cocatoms())
    [12, 20, 30]

See also:

- Dual function: atoms()

join(x, y=None)

Return the join of given elements in the lattice.

INPUT:

- x, y – two elements of the (semi)lattice OR
- x – a list or tuple of elements

EXAMPLES:
Combinatorics, Release 10.4

`sage:` D = posets.DiamondPoset(5)  
sage:` D.join(1, 2)  
4  
sage:` D.join(1, 1)  
1  
sage:` D.join(1, 4)  
4  
sage:` D.join(1, 0)  
1  

```python
>>> from sage.all import *  
>>> D = posets.DiamondPoset(Integer(5))  
>>> D.join(Integer(1), Integer(2))  
4  
>>> D.join(Integer(1), Integer(1))  
1  
>>> D.join(Integer(1), Integer(4))  
4  
>>> D.join(Integer(1), Integer(0))  
1  
```

Using list of elements as an argument. Join of empty list is the bottom element:

```python
sage:` B4=posets.BooleanLattice(4)  
sage:` B4.join([2,4,8])  
14  
sage:` B4.join([])  
0  

```python
>>> from sage.all import *  
>>> B4=posets.BooleanLattice(Integer(4))  
>>> B4.join([Integer(2),Integer(4),Integer(8)])  
14  
>>> B4.join([])  
0  
```

For non-facade lattices operator + works for join:

```python
sage:` L = posets.PentagonPoset(facade=False)  
sage:` L(1)+L(2)  
4  

```python
>>> from sage.all import *  
>>> L = posets.PentagonPoset(facade=False)  
>>> L(Integer(1))+L(Integer(2))  
4  
```

See also:

- Dual function: `meet()`

`join_matrix()`

Return a matrix whose \((i, j)\) entry is \(k\), where `self.linear_extension()[k]` is the join (least upper bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

EXAMPLES:
```
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade=False)
sage: J = P.join_matrix(); J
\[[0 1 2 3 4 5 6 7]
[1 1 3 7 7 7 7 7]
[2 3 2 4 6 6 6 6]
[3 3 3 3 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 5 6 7]
[6 7 6 7 6 6 6 7]
[7 7 7 7 7 7 7 7]
True
True
False
```

```
>>> from sage.all import *
>>> P = LatticePoset([[1,Integer(3),Integer(2)],[4],[4,Integer(5),Integer(6)],[6],[7],[7],[7],[7],[7]], facade=False)
>>> J = P.join_matrix(); J
\[[0 1 2 3 4 5 6 7]
[1 1 3 7 7 7 7 7]
[2 3 2 4 6 6 6 6]
[3 3 3 3 7 7 7 7]
[4 7 4 7 4 7 7 7]
[5 7 6 7 5 6 7]
[6 7 6 7 6 6 6 7]
[7 7 7 7 7 7 7 7]
```

```
>>> J[P(Integer(4)).vertex,P(Integer(3)).vertex] == P(Integer(7)).vertex
True
>>> J[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(5)).vertex
True
>>> J[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(2)).vertex
False
```

```
class sage.combinat.posets.lattices.FiniteLatticePoset (hasse_diagram, elements, category, facade, key)

Bases: FiniteMeetSemilattice, FiniteJoinSemilattice

We assume that the argument passed to FiniteLatticePoset is the poset of a lattice (i.e. a poset with greatest lower bound and least upper bound for each pair of elements).

Element

alias of LatticePosetElement

adjunct (other, a, b)

Return the adjunct of the lattice by other on the pair \((a, b)\).

It is assumed that \(a < b\) but \(b\) does not cover \(a\).

The adjunct of a lattice \(K\) to \(L\) with respect to pair \((a, b)\) of \(L\) is defined such that \(x < y\) if

- \(x, y \in K\) and \(x < y\) in \(K\),
- \(x, y \in L\) and \(x < y\) in \(L\),
```
Informally this can be seen as attaching the lattice $K$ to $L$ as a new block between $a$ and $b$. Dismantlable lattices are exactly those that can be created from chains with this function.

Mathematically, it is only defined when $L$ and $K$ have no common element; here we force that by giving them different names in the resulting lattice.

**EXAMPLES:**

```python
sage: Pnum = posets.PentagonPoset()
sage: Palp = Pnum.relabel(lambda x: chr(ord('a')+x))
sage: PP = Pnum.adjunct(Palp, 0, 3)
sage: PP.atoms()
[(0, 1), (0, 2), (1, 'a')]
sage: PP.coatoms()
[(0, 1), (0, 3)]
```

```python
>>> from sage.all import *

>>> Pnum = posets.PentagonPoset()

>>> Palp = Pnum.relabel(lambda x: chr(ord('a')+x))

>>> PP = Pnum.adjunct(Palp, Integer(0), Integer(3))

>>> PP.atoms()
[(0, 1), (0, 2), (1, 'a')]

>>> PP.coatoms()
[(0, 1), (0, 3)]
```

**breadth** *(certificate=False)*

Return the breadth of the lattice.

The breadth of a lattice is the largest integer $n$ such that any join of elements $x_1, x_2, \ldots, x_{n+1}$ is join of a proper subset of $x_i$.

This can be also characterized by subposets: a lattice of breadth at least $n$ contains a subposet isomorphic to the Boolean lattice of $2^n$ elements.

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return the pair $(b, a)$ where $b$ is the breadth and $a$ is an antichain such that the join of $a$ differs from the join of any proper subset of $a$. If certificate=False return just the breadth.

**EXAMPLES:**

```python
sage: D10 = posets.DiamondPoset(10)
sage: D10.breadth()
2

sage: B3 = posets.BooleanLattice(3)
sage: B3.breadth()
3

sage: B3.breadth(certificate=True)
(3, [1, 2, 4])
```
ALGORITHM:

For a lattice to have breadth at least \( n \), it must have an \( n \)-element antichain \( A \) with join \( j \). Element \( j \) must cover at least \( n \) elements. There must also be \( n - 2 \) levels of elements between \( A \) and \( j \). So we start by searching elements that could be our \( j \) and then just check possible antichains \( A \).

Note: Prior to version 8.1 this function returned just an antichain with \( certificate=True \).

canonical_joinands\( (e) \)

Return the canonical joinands of \( e \).

The canonical joinands of an element \( e \) in the lattice \( L \) is the subset \( S \subseteq L \) such that 1) the join of \( S \) is \( e \), and 2) if the join of some other subset \( S' \) of is also \( e \), then for every element \( s \in S \) there is an element \( s' \in S' \) such that \( s \leq s' \).

Informally said this is the set of lowest possible elements with given join. It exists for every element if and only if the lattice is join-semidistributive. Canonical joinands are always join-irreducibles.

INPUT:

• \( e \) – an element of the lattice

OUTPUT:

• canonical joinands as a list, if it exists; if not, None

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6],
...: 5: [7], 6: [7]})
sage: L.canonical_joinands(7)
[3, 4]
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6],
...: 5: [6]})
sage: L.canonical_joinands(6)
```

(continues on next page)
→[Integer(4), Integer(5)], Integer(3): [Integer(6)], Integer(4):...
→[Integer(6)],...
... Integer(5): [Integer(6)]]
>>> L.canonical_joinands(Integer(6)) is None
True

See also:

canonical_meetands()

canonical_meetands(e)

Return the canonical meetands of $e$.

The canonical meetands of an element $e$ in the lattice $L$ is the subset $S \subseteq L$ such that 1) the meet of $S$ is $e$, and 2) if the meet of some other subset $S'$ of is also $e$, then for every element $s \in S$ there is an element $s' \in S'$ such that $s \geq s'$.

Informally said this is the set of greatest possible elements with given meet. It exists for every element if and only if the lattice is meet-semidistributive. Canonical meetands are always meet-irreducibles.

INPUT:

- $e$ – an element of the lattice

OUTPUT:

- canonical meetands as a list, if it exists; if not, None

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5, 6], 4: [6], ....: 5: [7], 6: [7]})
sage: L.canonical_meetands(1)
[5, 4]
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6], ....: 5: [6]})
sage: L.canonical_meetands(1) is None
True
```

See also:

canonical_joinands()
center ()

Return the center of the lattice.

An element of a lattice is central if it is neutral and has a complement. The subposet induced by central elements is a center of the lattice. Actually it is a Boolean lattice.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [8, 9, 7],
...: 4: [5, 6], 5: [8, 10], 6: [10], 7: [13, 11],
...: 8: [13, 12], 9: [11, 12], 10: [13],
...: 11: [14], 12: [14], 13: [14]})

sage: C = L.center(); C
Finite lattice containing 4 elements

sage: C.cover_relations()
[[1, 2], [1, 12], [2, 14], [12, 14]]

sage: L = posets.DivisorLattice(60)
sage: sorted(L.center().list())
[1, 3, 4, 5, 12, 15, 20, 60]
```

See also:

neutral_elements(), complements()
Let us check that ‘a’ and ‘b’ are complements of each other:

```plaintext
sage: 'a' in C['b']
True
sage: 'b' in C['a']
True
```

Full list of complements:

```plaintext
sage: L.complements()  # random order
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}
```

```plaintext
sage: L = LatticePoset({0:[1,2],1:[3],2:[3],3:[4]})
sage: L.complements()  # random order
{0: [4], 4: [0]}
sage: L.complements(1)
[]
```

```plaintext
generate_congruence(S)  # random order
{0: [1], 1: [0], 'a': ['b', 'c'], 'b': ['c', 'a'], 'c': ['b', 'a']}
```

```plaintext
>>> L = LatticePoset((Integer(0):[Integer(1),Integer(2)],
        Integer(1):[Integer(3)],Integer(2):[Integer(3)],Integer(3):[Integer(4)]))
```

```plaintext
>>> L.complements()  # random order
{0: [4], 4: [0]}
```

```plaintext
L.complements(Integer(1))
[]
```

See also:

- `is_complemented()`

**congruence (S)**

Return the congruence generated by set of sets $S$.

A congruence of a lattice is an equivalence relation $\equiv$ that is compatible with meet and join; i.e. if $a_1 \equiv a_2$ and $b_1 \equiv b_2$, then $(a_1 
\vee b_1) \equiv (a_2 
\vee b_2)$ and $(a_1 \land b_1) \equiv (a_2 \land b_2)$.

By the congruence generated by set of sets $\{S_1, \ldots, S_n\}$ we mean the least congruence $\equiv$ such that for every $x, y \in S_i$ for some $i$ we have $x \equiv y$.

**INPUT:**

- $S$ – a list of lists; list of element blocks that the congruence will contain
OUTPUT:

Congruence of the lattice as a `sage.combinat.set_partition.SetPartition`.

EXAMPLES:

```python
sage: # needs sage.combinat
sage: L = posets.DivisorLattice(12)
sage: cong = L.congruence([[1, 3]])
sage: sorted(sorted(c) for c in cong)
[[[1, 3], [2, 6], [4, 12]]]
sage: L.congruence([[1, 2], [6, 12]])
{{1, 2, 4}, {3, 6, 12}}
```

```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.congruence([[1, 2]])
{{1, 2}, {3, 4}, {5}}
```

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 4: [5], 5: [7, 8],
                    6: [8], 3: [9], 7: [10], 8: [10], 9: [10]})
sage: cong = L.congruence([[1, 2]])
{{1, 2, 4}, {3, 6, 12}}
```

```python
>> from sage.all import *
>> L = posets.DivisorLattice(Integer(12))
>> cong = L.congruence([[Integer(1), Integer(3)]])
>> sorted(sorted(c) for c in cong)
[[[Integer(1, 3), [2, 6], [4, 12]]]
>> L.congruence([[Integer(1), Integer(2)], [Integer(6), Integer(12)]]))
{{1, 2, 4}, {3, 6, 12}}
```

```python
>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)],
                   Integer(2): ... [Integer(4), Integer(5)],
                   Integer(4): [Integer(5)]})
L.congruence([[Integer(1), Integer(2)]])

\[ \rightarrow \]

```python
>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)],
                   Integer(2): ... [Integer(4), Integer(5)],
                   Integer(4): [Integer(5)]})
\[ \rightarrow \]
```

```python
>> cong = L.congruence([[Integer(1), Integer(2)]])
>> cong[Integer(0)]
\[ \rightarrow \]
```

See also:

`quotient()`

`congruences_lattice(labels='congruence')`

Return the lattice of congruences.
A congruence of a lattice is a partition of elements to classes compatible with both meet- and join-operation; see `congruence()`. Elements of the congruence lattice are congruences ordered by refinement; i.e. if every class of a congruence $\Theta$ is contained in some class of $\Phi$, then $\Theta \leq \Phi$ in the congruence lattice.

**INPUT:**

- labels - a string; the type of elements in the resulting lattice

**OUTPUT:**

A distributive lattice.

- If `labels='congruence'`, then elements of the result will be congruences given as `sage.combinat.set_partition.SetPartition`.
- If `labels='integers'`, result is a lattice on integers isomorphic to the congruence lattice.

**EXAMPLES:**

```python
sage: # needs sage.combinat
sage: N5 = posets.PentagonPoset()
sage: CL = N5.congruences_lattice(); CL
Finite lattice containing 5 elements
sage: CL.atoms()

[{{0}, {1}, {2, 3}, {4}}]
sage: CL.coatoms()

[{{0, 1}, {2, 3, 4}}, {{0, 2, 3}, {1, 4}}]
sage: C4 = posets.ChainPoset(4)
sage: CL = C4.congruences_lattice(labels='integer')  # needs sage.combinat
sage: CL.is_isomorphic(posets.BooleanLattice(3))  # needs sage.combinat
True
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> N5 = posets.PentagonPoset()
>>> CL = N5.congruences_lattice(); CL
Finite lattice containing 5 elements
>>> CL.atoms()

[{{0}, {1}, {2, 3}, {4}}]
>>> CL.coatoms()

[{{0, 1}, {2, 3, 4}}, {{0, 2, 3}, {1, 4}}]

>>> C4 = posets.ChainPoset(Integer(4))
>>> CL = C4.congruences_lattice(labels='integer')  # needs sage.combinat
>>> CL.is_isomorphic(posets.BooleanLattice(Integer(3)))  # needs sage.combinat
True
```

day_doubling($S$)

Return the lattice with Alan Day's doubling construction of subset $S$.

The subset $S$ is assumed to be convex (i.e. if $a, c \in S$ and $a < b < c$ in the lattice, then $b \in S$) and connected (i.e. if $a, b \in S$ then there is a chain $a = e_1, e_2, \ldots, e_n = b$ such that $e_i$ either covers or is covered by $e_{i+1}$).
Alan Day’s doubling construction is a specific extension of the lattice. Here we formulate it in a format more suitable for computation.

Let $L$ be a lattice and $S$ a convex subset of it. The resulting lattice $L[S]$ has elements $(e, 0)$ for each $e \in L$ and $(e, 1)$ for each $e \in S$. If $x \leq y$ in $L$, then in the new lattice we have

- $(x, 0), (x, 1) \leq (y, 0), (y, 1)$
- $(x, 0) \leq (x, 1)$

**INPUT:**

- $S$ – a subset of the lattice

**EXAMPLES:**

```python
sage: L = LatticePoset({1: ['a', 'b', 2], 'a': ['c'], 'b': ['c', 'd'],
                      ....: 2: [3], 'c': [4], 'd': [4], 3: [4]})
sage: L2 = L.day_doubling(['a', 'b', 'c', 'd']); L2
Finite lattice containing 12 elements
sage: set(L2.upper_covers((1, 0))) == set([(2, 0), (a, 0), (b, 0)])
True
sage: set(L2.upper_covers((b, 0))) == set([(d, 0), (b, 1), (c, 0)])
True
```

```python
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): ['a', 'b', Integer(2)], 'a': ['c'], 'b': ['c ↦', 'd'],
                    ....: Integer(2): [Integer(3)], 'c': [Integer(4)], 'd':
                    →[Integer(4)], Integer(3): [Integer(4)]})
>>> L2 = L.day_doubling(['a', 'b', 'c', 'd']); L2
Finite lattice containing 12 elements
>>> set(L2.upper_covers((Integer(1), Integer(0)))) == set([(Integer(2),
                    →Integer(0)), (a, Integer(0)), (b, Integer(0))])
True
```

(continues on next page)
See also:

is_constructible_by_doublings()

double_irreducibles()

Return the list of double irreducible elements of this lattice.

A double irreducible element of a lattice is an element covering and covered by exactly one element. In other words it is neither a meet nor a join of any elements.

EXAMPLES:

```
sage: L = posets.DivisorLattice(12)
sage: sorted(L.double_irreducibles())
[3, 4]
sage: L = posets.BooleanLattice(3)
sage: L.double_irreducibles()
[]
```

See also:

meet_irreducibles(), join_irreducibles()

feichtner_yuzvinsky_ring (G, use_defining=False, base_ring=None)

Return the Feichtner-Yuzvinsky ring of self and G.

Let $R$ be a commutative ring, $L$ a lattice, and $G \subseteq L$. The Feichtner-Yuzvinsky ring is the quotient of the polynomial ring $R[h_g \mid g \in G]$ by the ideal generated by

- $h_a$ for every atom $a \in L \cap G$ and
- for every antichain $A$ of the subposet $G$ such that $g := \bigvee A \in G$ (with the join taken in $L$)
  \[ \prod_{a \in A} (h_g - h_a). \]

This was originally described for $G$ such that $(L, G)$ is a built lattice in the sense of [FY2004] (which has a geometric motivation), but this has been extended to $G$ being an arbitrary subset.

This is not the original definition, which uses the nested subsets of $G$ (see [FY2004] for the definition). However, the original construction, which we call the defining presentation and use the variables \{x_g \mid g \in G\}, can be recovered by setting $h_g = \sum_{g' \geq g} x_{g'}$ (where $g' \in G$).

INPUT:

- $G$ – a subset of elements of self
• use_defining – (default: False) whether or not to use the defining presentation in \(x_g\)

• base_ring – (default: \(\mathbb{Q}\)) the base ring

The order on the variables is equal to the ordering of the elements in \(G\).

**EXAMPLES:**

```sage
def FY = B2.feichtner_yuzvinsky_ring(B2[1:], use_defining=True)
FY
```

Quotient of Multivariate Polynomial Ring in \(x_0, x_1, x_2\) over Rational Field by the ideal \((x_0 + x_2, x_1 + x_2, x_0 \cdot x_1)\)

We reproduce the example from Section 5 of [Coron2023]:

```sage```
```python
# needs sage.geometry.polyhedron
H.<a,b,c,d> = HyperplaneArrangements(QQ)
Arr = H(a-b, b-c, c-d, d-a)
P = LatticePoset(Arr.intersection_poset())
FY = P.feichtner_yuzvinsky_ring([P.top(),5,1,2,3,4])
FY.defining_ideal().groebner_basis()
```

\[\{h_0^2 - h_0 \cdot h_1, h_1^2, h_2, h_3, h_4, h_5\}\]

**frattini_sublattice()**

Return the Frattini sublattice of the lattice.

The Frattini sublattice \(\Phi(L)\) is the intersection of all proper maximal sublattices of \(L\). It is also the set of “non-generators” - if the sublattice generated by set \(S\) of elements is whole lattice, then also \(S \setminus \Phi(L)\) generates
is_atomic (certificate=False)

Return **True** if the lattice is atomic, and **False** otherwise.

A lattice is atomic if every element can be written as a join of atoms.

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, e), where e is a join-irreducible element that is not an atom. If certificate=False return **True** or **False**.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 3], 3:[5], 4:[6], 5:[6]})
sage: L.is_atomic()
True
sage: L = LatticePoset({0: [1, 2], 1: [3], 2: [3], 3:[4]})
sage: L.is_atomic()
False
sage: L.is_atomic(certificate=True)
(False, 4)
```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],
    Integer(2): [Integer(5)], Integer(3): [Integer(5)], Integer(4): [Integer(6)],
    Integer(5): [Integer(6)]})
>>> L.is_atomic()
True

>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2)],
    Integer(1): [Integer(3)], Integer(2): [Integer(3)], Integer(3): [Integer(4)]})
>>> L.is_atomic()
False
>>> L.is_atomic(certificate=True)
(False, 4)

Note: See [EnumComb1], Section 3.3 for a discussion of atomic lattices.

See also:

• Dual property: is_coatomic()
• Stronger properties: is_sectionally_complemented()
• Mutually exclusive properties: is_vertically_decomposable()

is_coatomic(certificate=False)

Return True if the lattice is coatomic, and False otherwise.

A lattice is coatomic if every element can be written as a meet of coatoms; i.e. if the dual of the lattice is atomic.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, e), where e is a meet-irreducible element that is not a coatom. If certificate=False return True or False.

EXAMPLES:

sage: L = posets.BooleanLattice(3)
sage: L.is_coatomic()
True
sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4:[5]})
sage: L.is_coatomic()
False
sage: L.is_coatomic(certificate=True)
(False, 1)

>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(3))
>>> L.is_coatomic()
True

(continues on next page)
\[
\begin{align*}
\text{L} & = \text{LatticePoset}([0: [1, 2, 3], 1: [4], 2: [4], 3: [4]]) \\
\text{L} & .is_complemented() \\
& \text{True}
\end{align*}
\]

\[
\begin{align*}
\text{L} & = \text{LatticePoset}([1: [2, 3, 4], 2: [5, 6], 3: [5], 4: [6], \\
& \ldots: 5: [7], 6: [7]]) \\
\text{L} & .is_complemented() \\
& \text{False}
\end{align*}
\]

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3)],
& Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> L.is_complemented()
True
```

```
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],
& Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5)], Integer(4): [Integer(6)],
& \ldots: Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_complemented()
False
```

```
>>> L.is_complemented(certificate=True)
(False, 2)
```

See also:
• Stronger properties: is_sectionally_complemented(), is_cosectionally_complemented(), is_orthocomplemented()

• Other: complements()

is_constructible_by_doublings(type)

Return True if the lattice is constructible by doublings, and False otherwise.

We call a lattice doubling constructible if it can be constructed from the one element lattice by a sequence of Alan Day's doubling constructions.

Lattices constructible by interval doubling are also called bounded. Lattices constructible by lower and upper pseudo-interval are called lower bounded and upper bounded. Lattices constructible by any convex set doubling are called congruence normal.

INPUT:

• type – a string; can be one of the following:
  – 'interval' – allow only doublings of an interval
  – 'lower' – allow doublings of lower pseudo-interval; that is, a subset of the lattice with a unique minimal element
  – 'upper' – allow doublings of upper pseudo-interval; that is, a subset of the lattice with a unique maximal element
  – 'convex' – allow doubling of any convex set
  – 'any' – allow doubling of any set

EXAMPLES:

The pentagon can be constructed by doubling intervals; the 5-element diamond cannot be constructed by any doublings:

```sage
posets.PentagonPoset().is_constructible_by_doublings('interval')
True
```
```sage
posets.DiamondPoset(5).is_constructible_by_doublings('any')  # needs sage.combinat
False
```
```sage
>>> from sage.all import *
```
```sage
>>> posets.PentagonPoset().is_constructible_by_doublings('interval')
True
```
```sage
>>> posets.DiamondPoset(Integer(5)).is_constructible_by_doublings('any')  # needs sage.combinat
False
```

After doubling both upper and lower pseudo-interval a lattice is constructible by convex subset doubling:

```sage
L = posets.BooleanLattice(2)
sage: L = L.day_doubling([0, 1, 2])  # A lower pseudo-interval
sage: L.is_constructible_by_doublings('interval')
False
sage: L.is_constructible_by_doublings('lower')
True
sage: L = L.day_doubling([(3,0), (1,1), (2,1)])  # An upper pseudo-interval
sage: L.is_constructible_by_doublings('upper')
```

(continues on next page)
An example of a lattice that can be constructed by doublings of a non-convex subsets:

```python
sage: L = LatticePoset(DiGraph('OQC?a?@CO?G_C@?GA?O??_??@?BO?A_?G??C??_?@???
˓→')
```

```python
sage: L.is_constructible_by_doublings('convex')
False
```

```python
sage: L.is_constructible_by_doublings('any')
True
```

See also:

- Stronger properties: `is_distributive()` (doubling by interval), `is_join_semidistributive()` (doubling by lower pseudo-intervals), `is_meet_semidistributive()` (doubling by upper pseudo-intervals)
- Mutually exclusive properties: `is_simple()` (doubling by any set)
- Other: `day_doubling()`

ALGORITHM:

According to [HOLM2016] a lattice $L$ is lower bounded if and only if $|Ji(L)| = |Ji(Con L)|$, and so dually $|Mi(L)| = |Mi(Con L)|$ in upper bounded lattices. The same reference gives a test for being constructible by convex or by any subset.

`is_cosectionally_complemented(certificate=False)`

Return `True` if the lattice is cosectionally complemented, and `False` otherwise.
A lattice is *cosectionally complemented* if all intervals to the top element interpreted as sublattices are complemented.

**INPUT:**

- `certificate` – (default: `False`) Whether to return a certificate if the lattice is not cosectionally complemented.

**OUTPUT:**

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (b, e))`, where `b` is an element so that in the sublattice from `b` to the top element has no complement for element `e`.

**EXAMPLES:**

The smallest sectionally but not cosectionally complemented lattice:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6], 5: [6]})
sage: L.is_sectionally_complemented(), L.is_cosectionally_complemented()
(True, False)
```

A sectionally and cosectionally but not relatively complemented lattice:

```
sage: L = LatticePoset(DiGraph('MYiOP??D?OG@??O??CQ??O?W@??O??'))
sage: L.is_sectionally_complemented() and L.is_cosectionally_complemented()
True
sage: L.is_relatively_complemented()
False
```

Getting a certificate:

```
sage: L = LatticePoset(DiGraph('HW@D?Q?GE@G@??'))
sage: L.is_cosectionally_complemented(certificate=True)
(False, (2, 7))
```

**See also:**

- Dual property: `is_sectionally_complemented()`
• Weaker properties: \texttt{is\_complemented()}, \texttt{is\_coatomic()}, \texttt{is\_regular()}

• Stronger properties: \texttt{is\_relatively\_complemented()}

\texttt{is\_dismantlable}(\texttt{certificate=False})

Return True if the lattice is dismantlable, and False otherwise.

An $n$-element lattice $L_n$ is dismantlable if there is a sublattice chain $L_{n-1} \supset L_{n-2} \supset \cdots \supset L_0$ so that every $L_i$ is a sublattice of $L_{i+1}$ with one element less, and $L_0$ is the empty lattice. In other words, a dismantlable lattice can be reduced to empty lattice removing doubly irreducible element one by one.

INPUT:

• \texttt{certificate} (boolean) – Whether to return a certificate.
  - If \texttt{certificate = False} (default), returns True or False accordingly.
  - If \texttt{certificate = True}, returns:
    * (True, elms) when the lattice is dismantlable, where elms is elements listed in a possible removing order.
    * (False, crown) when the lattice is not dismantlable, where crown is a subposet of $2k$ elements $a_1, \ldots, a_k, b_1, \ldots, b_k$ with covering relations $a_i \lessdot b_i$ and $a_i \lessdot b_{i+1}$ for $i \in [1, \ldots, k-1]$, and $a_k \lessdot b_1$.

EXAMPLES:

\begin{verbatim}
sage: DL12 = LatticePoset((divisors(12), attrcall("divides")))
sage: DL12.is_dismantlable()
True
sage: DL12.is_dismantlable(certificate=True)
(True, [4, 2, 1, 3, 6, 12])
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_dismantlable()
False
sage: B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> DL12 = LatticePoset((divisors(Integer(12)), attrcall("divides")))
>>> DL12.is_dismantlable()
True
>>> DL12.is_dismantlable(certificate=True)
(True, [4, 2, 1, 3, 6, 12])
>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.is_dismantlable()
False
>>> B3.is_dismantlable(certificate=True)
(False, Finite poset containing 6 elements)
\end{verbatim}

Every planar lattice is dismantlable. Converse is not true:

\begin{verbatim}
sage: L = LatticePoset( [[[], [[0, 1], [0, 2], [0, 3], [0, 4]], ....: [1, 7], [2, 6], [3, 5], [4, 5]], ....: [4, 6], [4, 7], [5, 8], [6, 8]], ....: [7, 8]])
sage: L.is_dismantlable()
\end{verbatim}
True

```
sage: L.is_planar()
False
```

```python
>>> from sage.all import *

>>> L = LatticePoset( [
    [],
    [Integer(0), Integer(1)],
    [Integer(0), Integer(3)],
    ...].

>>> L.is_dismantlable()
True

>>> L.is_planar()
False
```

See also:

- Stronger properties: `is_planar()`
- Weaker properties: `is_sublattice_dismantlable()`

**is_distributive** *(certificate=False)*

Return True if the lattice is distributive, and False otherwise.

A lattice \((L, \lor, \land)\) is distributive if meet distributes over join: 
\(x \land (y \lor z) = (x \land y) \lor (x \land z)\) for every 
\(x, y, z \in L\) just like \(x \cdot (y + z) = x \cdot y + x \cdot z\) in normal arithmetic. For duality in lattices it follows that
then also join distributes over meet.

- **certificate** – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, (x, y, z)), where x, y and z are elements of the lattice such that 
\(x \land (y \lor z) \neq (x \land y) \lor (x \land z)\). If certificate=False return True or False.

**EXAMPLES:**

```
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [4], 4: [5]})
sage: L.is_distributive()
True

sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [6], 4: [6], 5: [6]})
sage: L.is_distributive()
False

sage: L.is_distributive(certificate=True)
(False, (5, 3, 2))
```

```python
>>> from sage.all import *

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):...)

>>> L.is_distributive()
True

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],...

>>> L.is_distributive()
True
```

(continues on next page)
is_distributive()
Returns True if the lattice is distributive, and False otherwise.

EXAMPLES:

Sage:
>>> L.is_distributive()
False
>>> L.is_distributive(certificate=True)
(False, (5, 3, 2))

See also:

• Weaker properties: is_modular(), is_semidistributive(), is_join_distributive(), is_meet_distributive(), is_subdirectly_reducible(), is_trim(), is_constructible_by_doublings() (by interval doubling), is_extremal()

• Stronger properties: is_stone()

is_extremal()
Returns True if the lattice is extremal, and False otherwise.

A lattice is extremal if the number of join-irreducibles is equal to the number of meet-irreducibles and to the number of cover relations in the longest chains.

EXAMPLES:

Sage:
>>> posets.PentagonPoset().is_extremal()
True
>>> P = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
>>> P.is_extremal()
False

See also:

• Stronger properties: is_distributive(), is_trim()

REFERENCES:

[Mark1992]

is_geometric()
Returns True if the lattice is geometric, and False otherwise.

A lattice is geometric if it is both atomic and upper semimodular.

EXAMPLES:

Canonical example is the lattice of partitions of finite set ordered by refinement:

Sage:
L = posets.SetPartitions(4)
# needs sage.combinat
>>> L.is_geometric()
True
Smallest example of geometric lattice that is not modular:

```python
sage: L = LatticePoset(DiGraph('K?@g@S?q?M?@?@?@?@?@??'))
sage: L.is_geometric()
True
sage: L.is_modular()
False
```

Two non-examples:

```python
sage: L = LatticePoset({1:[2, 3, 4], 2:[5, 6], 3:[5], 4:[6], 5:[7], 6:[7]})
sage: L.is_geometric()  # Graded, but not upper semimodular
False
sage: L = posets.ChainPoset(3)
sage: L.is_geometric()  # Modular, but not atomic
False
```

See also:

- Weaker properties: `is_upper_semimodular(), is_relatively_complemented()`

**is_interval_dismantlable** *(certificate=False)*

Return `True` if the lattice is interval dismantlable, and `False` otherwise.

An interval dismantling is a subdivision of a lattice to a principal upper set and a principal lower set. A lattice is *interval dismantlable* if it can be decomposed into 1-element lattices by consecutive interval dismantlings.

A lattice is *minimally interval non-dismantlable* if it is not interval dismantlable, but all of its sublattices are interval dismantlable.

**INPUT:**

- `certificate` — (default: `False`) whether to return a certificate
OUTPUT:

- if certificate=False, return only True or False
- if certificate=True, return either
  - (True, list) where list is a nested list showing the decomposition; for example
    list[1][0] is a lower part of upper part of the lattice when decomposed twice.
  - (False, M) where M is a minimally interval non-dismantlable sublattice of the lattice.

EXAMPLES:

```python
sage: L1 = LatticePoset({1: [2, 3], 3: [4, 5], 2: [6], 4: [6], 5: [6]})
sage: L1.is_interval_dismantlable()
True

sage: L2 = LatticePoset({1: [2, 3, 4, 5], 2: [6], 3: [6], 4: [6],
                      5: [6, 7], 6: [8], 7: [9, 10], 8:[10], 9:[10]})
sage: L2.is_interval_dismantlable()
False
```

To get certificates:

```python
sage: L1.is_interval_dismantlable(certificate=True)
(True, [[[1], [2]], [[[3], [5]], [[4], [6]]]])
sage: L2.is_interval_dismantlable(certificate=True)
(False, Finite lattice containing 5 elements)
```

See also:

- Stronger properties: `is_join_semidistributive()`, `is_meet_semidistributive()`
- Weaker properties: `is_sublattice_dismantlable()`

`is_isoform(certificate=False)`

Return True if the lattice is isoform and False otherwise.
A congruence is *isofrom* (or *isotype*) if all blocks are isomorphic sublattices. A lattice is isofrom if it has only isofrom congruences.

**INPUT:**

- `certificate` *(default: False)* whether to return a certificate if the lattice is not isofrom

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, C)` where `C` is a non-isoform congruence as a `sage.combinat.set_partition.SetPartition`. If `certificate=False` return True or False.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [6, 7],
        4: [7], 5: [8], 6: [8], 7: [8]})
sage: L.is_isoform()
True
```

```python
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],
    Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(6), Integer(7)],
    Integer(4): [Integer(7)], Integer(5): [Integer(8)],
    Integer(6): [Integer(8)], Integer(7): [Integer(8)]})
>>> L.is_isoform()
True
```

Every isofrom lattice is (trivially) uniform, but the converse is not true:

```python
sage: L = LatticePoset({1: [2, 3, 6], 2: [4, 5], 3: [5], 4: [9, 8],
        5: [7, 8], 6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_isoform(), L.is_uniform()
(False, True)
sage: L.is_isoform(certificate=True)
(False, {{1, 2, 4, 6, 9}, {3, 5, 7, 8, 10}})
```

```python
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(6)],
    Integer(2): [Integer(4), Integer(5)], Integer(3): [Integer(5)], Integer(4): [Integer(9), Integer(8)],
    Integer(5): [Integer(7)], Integer(6): [Integer(8)], Integer(7): [Integer(10)], Integer(8): [Integer(10)],
    Integer(9): [Integer(10)]})
>>> L.is_isoform(), L.is_uniform()
(False, True)
>>> L.is_isoform(certificate=True)
(False, {{1, 2, 4, 6, 9}, {3, 5, 7, 8, 10}})
```

See also:
• Weaker properties: \texttt{is\_uniform()}
• Stronger properties: \texttt{is\_simple(), is\_relatively\_complemented()}
• Other: \texttt{congruence()}

\texttt{is\_join\_distributive}(\texttt{certificate=False})

Return \texttt{True} if the lattice is join-distributive and \texttt{False} otherwise.

A lattice is \textit{join-distributive} if every interval from an element to the join of the element’s upper covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as \textit{Dilworth’s lattices} and \textit{upper locally distributive lattices}. They can be characterized in many other ways, see [Dil1940].

INPUT:

• \texttt{certificate} – (default: \texttt{False}) whether to return a certificate

OUTPUT:

• If \texttt{certificate=True} return either (\texttt{True}, \texttt{None}) or (\texttt{False}, \texttt{e}), where \texttt{e} is an element such that the interval from \texttt{e} to the meet of upper covers of \texttt{e} is not distributive. If \texttt{certificate=False} return \texttt{True} or \texttt{False}.

EXAMPLES:

\begin{verbatim}sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5, 7], ...
.....: 4: [6, 7], 5: [8, 9], 6: [9], 7: [9, 10], ...
.....: 8: [11], 9: [11], 10: [11]})
sage: L.is_join_distributive()
True
sage: L = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [6], ...
.....: 5: [7], 6: [7]})
sage: L.is_join_distributive()
False
sage: L.is_join_distributive(certificate=True)
(True, None)
\end{verbatim}

\begin{verbatim}>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)], ...
˓→Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5), Integer(7)], ...
˓→Integer(4): [Integer(6), Integer(7)], Integer(5): ...
˓→[Integer(8), Integer(9)], Integer(6): [Integer(9)], Integer(7): [Integer(9), ...
˓→Integer(10)], ...
˓→Integer(8): [Integer(11)], Integer(9): [Integer(11)], ...
˓→Integer(10): [Integer(11)]})
>>> L.is_join_distributive()
True
>>> L = LatticePoset({Integer(1): [Integer(2)], Integer(2): ...
˓→Integer(4)], Integer(3): [Integer(5)], Integer(4): [Integer(6)], ...
˓→Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_join_distributive()
False
>>> L.is_join_distributive(certificate=True)
(False, 2)
\end{verbatim}

See also:
• Dual property: `is_meet_distributive()`
• Weaker properties: `is_meet_semidistributive()`, `is_upper_semimodular()`
• Stronger properties: `is_distributive()`

`is_join_pseudocomplemented(certificate=False)`

Return True if the lattice is join-pseudocomplemented, and False otherwise.

A lattice is join-pseudocomplemented if every element $e$ has a join-pseudocomplement $e'$, i.e. the least element such that the join of $e$ and $e'$ is the top element.

INPUT:
• `certificate`—(default: False) whether to return a certificate

OUTPUT:
• If `certificate=True` return either (True, None) or (False, e), where e is an element without a join-pseudocomplement. If `certificate=False` return True or False.

EXAMPLES:

```sage
sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7],
....: 5: [6], 6: [7]})
sage: L.is_join_pseudocomplemented()
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7],
....: 5: [7], 6: [7]})
sage: L.is_join_pseudocomplemented()
False
sage: L.is_join_pseudocomplemented(certificate=True)
(False, 4)
```

```python
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(5)], Integer(2):
˓→[Integer(3), Integer(6)], Integer(3): [Integer(4)], Integer(4):
˓→[Integer(7)],
˓→... Integer(5): [Integer(6)], Integer(6): [Integer(7)]})
>>> L.is_join_pseudocomplemented()
True
```

```python
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):
˓→[Integer(4), Integer(5), Integer(6)], Integer(3): [Integer(6)], Integer(4):
˓→[Integer(7)],
˓→... Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_join_pseudocomplemented()
False
```

```python
>>> L.is_join_pseudocomplemented(certificate=True)
(False, 4)
```

See also:

• Dual property: `is_pseudocomplemented()`
• Stronger properties: `is_join_semidistributive()`
**is_join_semidistributive** *(certificate=False)*

Return True if the lattice is join-semidistributive, and False otherwise.

A lattice is join-semidistributive if for all elements $e, x, y$ in the lattice we have

$$ e \lor x = e \lor y \implies e \lor x = e \lor (x \land y) $$

**INPUT:**

- certificate – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, (e, x, y)) such that $e \lor x = e \lor y$ but $e \lor x \neq e \lor (x \land y)$. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: T4 = posets.TamariLattice(4)
sage: T4.is_join_semidistributive()
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], ...
                      4: [7], 5: [7], 6: [7]})
sage: L.is_join_semidistributive()
False
```

```python
>>> from sage.all import *
>>> T4 = posets.TamariLattice(Integer(4))
>>> T4.is_join_semidistributive()
True
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], ...
                      Integer(2): [Integer(4), Integer(5)], Integer(3): [Integer(5), Integer(6)], ...
                      Integer(4): [Integer(7)], Integer(5): [Integer(7)], ...
                      Integer(6): [Integer(7)]})
>>> L.is_join_semidistributive()
False
```

See also:

- Dual property: **is_meet_semidistributive()**
- Weaker properties: **is_join_pseudocomplemented(), is_interval_dismantlable()**
- Stronger properties: **is_semidistributive(), is_meet_distributive(), is_constructible_by_doublings()** (by lower pseudo-intervals)

**is_left_modular_element** *(x)*

Return True if x is a left modular element and False otherwise.

**INPUT:**

- x – an element of the lattice

An element $x$ in a lattice $L$ is left modular if

$$(y \lor x) \land z = y \lor (x \land z)$$
for every \( y \leq z \in L \).

It is enough to check this condition on all cover relations \( y < z \).

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: [i for i in P if P.is_left_modular_element(i)]
[0, 2, 3, 4]
```

See also:

- Stronger properties: `is_modular_element()`

**is_lower_semimodular** *(certificate=False)*

Return `True` if the lattice is lower semimodular and `False` otherwise.

A lattice is lower semimodular if any pair of elements with a common upper cover have also a common lower cover.

INPUT:

- `certificate` – (default: `False`) Whether to return a certificate if the lattice is not lower semimodular.

OUTPUT:

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (a, b))`, where \( a \) and \( b \) are covered by their join but do no cover their meet.

See Wikipedia article Semimodular_lattice

EXAMPLES:

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_lower_semimodular()
True
sage: L = posets.PentagonPoset()
sage: L.is_lower_semimodular()
False
sage: L = posets.ChainPoset(6)
sage: L.is_lower_semimodular()
True
sage: L = LatticePoset(DiGraph('IS?~AAOE_@?C?_@??'))
sage: L.is_lower_semimodular(certificate=True)
(False, (4, 2))
```

```python
>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
>>> L.is_lower_semimodular()
True
```
>>> L = posets.PentagonPoset()
>>> L.is_lower_semimodular()
False

>>> L = posets.ChainPoset(Integer(6))
>>> L.is_lower_semimodular()
True

>>> L = LatticePoset(DiGraph('IS?`AAOE_@?C?_@??'))
>>> L.is_lower_semimodular(certificate=True)
(False, (4, 2))

See also:

- Dual property: `is_upper_semimodular()`
- Weaker properties: `is_graded()`
- Stronger properties: `is_modular()`, `is_meet_distributive()`

**is_meet_distributive** *(certificate=False)*

Return True if the lattice is meet-distributive and False otherwise.

A lattice is *meet-distributive* if every interval to an element from the meet of the element's lower covers is a distributive lattice. Actually this distributive sublattice is then a Boolean lattice.

They are also called as *lower locally distributive lattices*. They can be characterized in many other ways, see [Dil1940].

**INPUT:**

- **certificate** – (default: False) whether to return a certificate

**OUTPUT:**

- If certificate=True return either (True, None) or (False, e), where e is an element such that the interval to e from the meet of lower covers of e is not distributive. If certificate=False return True or False.

**EXAMPLES:**

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5, 6, 7],
                        4: [7], 5: [9, 8], 6: [10, 8], 7:
                        [9, 10], 8: [11], 9: [11], 10: [11]})
sage: L.is_meet_distributive()
True
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6],
                        5: [6], 6: [7]})
sage: L.is_meet_distributive()
False
sage: L.is_meet_distributive(certificate=True)
(False, 6)
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

• Dual property: is_join_distributive()
• Weaker properties: is_join_semidistributive(), is_lower_semimodular()
• Stronger properties: is_distributive() is_meet_semidistributive (certificate=False)

Return True if the lattice is meet-semidistributive, and False otherwise.

A lattice is meet-semidistributive if for all elements e, x, y in the lattice we have

\[ e \land x = e \land y \implies e \land x = e \land (x \lor y) \]

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, (e, x, y)) such that
  \[ e \land x = e \land y \] but \[ e \land x \neq e \land (x \lor y) \]. If certificate=False return True or False.

EXAMPLES:

```python
sage: L = LatticePoset({1:[2, 3, 4], 2:[4, 5], 3:[5, 6], ...
4:[7], 5:[7], 6:[7]})
sage: L.is_meet_semidistributive()
True
dsage: L_ = L.dual()
sage: L_.is_meet_semidistributive()
False
dsage: L_.is_meet_semidistributive(certificate=True)
(False, (5, 4, 6))
```

- Weaker properties: `is_pseudocomplemented()`, `is_interval_dismantlable()`
- Stronger properties: `is_semidistributive()`, `is_join_distributive()`, `is_constructible_by_doublings()` (by upper pseudo-intervals)

**is_modular** *(L=None, certificate=False)*

Return `True` if the lattice is modular and `False` otherwise.

An element \( b \) of a lattice is modular if

\[
x \lor (a \land b) = (x \lor a) \land b
\]

for every element \( x \leq b \) and \( a \). A lattice is modular if every element is modular. There are other equivalent definitions, see Wikipedia article Modular_lattice.

With the parameter \( L \) this can be used to check that some subset of elements are all modular.

**INPUT:**

- \( L \) – (default: None) a list of elements to check being modular, if \( L \) is None, then this checks the entire lattice
- \( \text{certificate} \) – (default: False) whether to return a certificate

**OUTPUT:**

- If \( \text{certificate}=\text{True} \) return either `(True, None)` or `(False, (x, a, b))`, where \( a, b \) and \( x \) are elements of the lattice such that \( x < b \) but \( x \lor (a \land b) \neq (x \lor a) \land b \). If also \( L \) is given then \( b \) in the certificate will be an element of \( L \). If \( \text{certificate}=\text{False} \) return `True` or `False`.

**EXAMPLES:**

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_modular()
True

sage: L = posets.PentagonPoset()
sage: L.is_modular()
False

sage: L = LatticePoset({1:[2, 3], 2:[4, 5], 3:[5, 6], 4:[7], 5:[7], 6:[7]})
sage: L.is_modular(certificate=True)
(False, (2, 6, 4))
sage: [L.is_modular([x]) for x in L]
[True, True, False, True, True, False, True]

>>> from sage.all import *
>>> L = posets.DiamondPoset(Integer(5))
>>> L.is_modular()
```
True

L = posets.PentagonPoset()
L.is_modular()
False

L = LatticePoset({Integer(1):[Integer(2), Integer(3)],
                 Integer(2):[Integer(4), Integer(5)], Integer(3):[Integer(5), Integer(6)],
                 Integer(4):[Integer(7)], Integer(5):[Integer(7)], Integer(6):[Integer(7)]})
L.is_modular(certificate=True)
(False, (2, 6, 4))

[L.is_modular([x]) for x in L]
[True, True, False, True, True, False, True]

See also:

• Weaker properties: is_upper_semimodular(), is_lower_semimodular(), is_supersolvable()
• Stronger properties: is_distributive()
• Other: is_modular_element()

is_modular_element(x)

Return True if x is a modular element and False otherwise.

INPUT:

• x – an element of the lattice

An element x in a lattice L is modular if x ≤ b implies

\[ x \lor (a \land b) = (x \lor a) \land b \]

for every a, b ∈ L.

EXAMPLES:

sage: L = LatticePoset({1:[2,3], 2:[4,5], 3:[5,6], 4:[7], 5:[7], 6:[7]})
sage: L.is_modular()
False

sage: [L.is_modular_element(x) for x in L]
[True, True, False, True, True, False, True]

See also:

• Weaker properties: is_left_modular_element()
• Other: is_modular() to check modularity for the full lattice or some set of elements
**is_orthocomplemented** *(unique=False)*

Return True if the lattice admits an orthocomplementation, and False otherwise.

An orthocomplementation of a lattice is a function defined for every element \(e\) and marked as \(e^\perp\) such that
1) they are complements, i.e. \(e \lor e^\perp\) is the top element and \(e \land e^\perp\) is the bottom element,
2) it is involution, i.e. \((e^\perp)^\perp = e\), and
3) it is order-reversing, i.e. if \(a < b\) then \(b^\perp < a^\perp\).

**INPUT:**

- **unique**, a Boolean – If True, return True only if the lattice has exactly one orthocomplementation.
  If False (the default), return True when the lattice has at least one orthocomplementation.

**EXAMPLES:**

```python
sage: D5 = posets.DiamondPoset(5)
sage: D5.is_orthocomplemented()
False

sage: D6 = posets.DiamondPoset(6)
sage: D6.is_orthocomplemented()  # needs sage.groups
True

sage: D6.is_orthocomplemented(unique=True)  # needs sage.groups
False

sage: hexagon = LatticePoset({0: [1, 2], 1: [3], 2: [4], 3: [5], 4: [5]})
sage: hexagon.is_orthocomplemented(unique=True)  # needs sage.groups
True

>>> from sage.all import *
>>> D5 = posets.DiamondPoset(Integer(5))
>>> D5.is_orthocomplemented()  # needs sage.groups
False

>>> D6 = posets.DiamondPoset(Integer(6))
>>> D6.is_orthocomplemented()  # needs sage.groups
True

>>> D6.is_orthocompleted(unique=True)  # needs sage.groups
False

>>> hexagon = LatticePoset({Integer(0): [Integer(1), Integer(2)], Integer(1): [Integer(3)], Integer(2): [Integer(4)], Integer(3): [Integer(5)], Integer(4): [Integer(5)]})
>>> hexagon.is_orthocomplemented(unique=True)  # needs sage.groups
True
```

See also:

- Weaker properties: **is_complemented()**, **is_self_dual()**

**is_planar()**

Return True if the lattice is *upward* planar, and False otherwise.
A lattice is upward planar if its Hasse diagram has a planar drawing in the $\mathbb{R}^2$ plane, in such a way that $x$ is strictly below $y$ (on the vertical axis) whenever $x < y$ in the lattice.

Note that the scientific literature on posets often omits “upward” and shortens it to “planar lattice” (e.g. [GW2014]), which can cause confusion with the notion of graph planarity in graph theory.

**Note:** Not all lattices which are planar – in the sense of graph planarity – admit such a planar drawing (see example below).

**ALGORITHM:**

Using the result from [Platt1976], this method returns its result by testing that the Hasse diagram of the lattice is planar (in the sense of graph theory) when an edge is added between the top and bottom elements.

**EXAMPLES:**

The Boolean lattice of $2^3$ elements is not upward planar, even if its covering relations graph is planar:

```
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_planar()
False
sage: G = B3.cover_relations_graph()
sage: G.is_planar()
True
```

```
>>> from sage.all import *

>>> B3 = posets.BooleanLattice(Integer(3))
>>> B3.is_planar()
False
>>> G = B3.cover_relations_graph()
>>> G.is_planar()
True
```

Ordinal product of planar lattices is obviously planar. Same does not apply to Cartesian products:

```
sage: P = posets.PentagonPoset()
sage: Pc = P.product(P)
sage: Po = P.ordinal_product(P)
sage: Pc.is_planar()
False
sage: Po.is_planar()
True
```

```
>>> from sage.all import *

>>> P = posets.PentagonPoset()
>>> Pc = P.product(P)
>>> Po = P.ordinal_product(P)
>>> Pc.is_planar()
False
>>> Po.is_planar()
True
```

See also:

- Weaker properties: `is_dismantlable()`
is_pseudocomplemented (certificate=False)

Return True if the lattice is pseudocomplemented, and False otherwise.

A lattice is (meet-)pseudocomplemented if every element e has a pseudocomplement e^*, i.e. the greatest element such that the meet of e and e^* is the bottom element.

See Wikipedia article Pseudocomplement.

INPUT:

• certificate – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either (True, None) or (False, e), where e is an element without a pseudocomplement. If certificate=False return True or False.

EXAMPLES:

sage: L = LatticePoset({1: [2, 5], 2: [3, 6], 3: [4], 4: [7], ....: 5: [6], 6: [7]})
sage: L.is_pseudocomplemented()
True

sage: L = LatticePoset({1: [2, 3], 2: [4, 5, 6], 3: [6], 4: [7], ....: 5: [7], 6: [7]})
sage: L.is_pseudocomplemented()
False

sage: L.is_pseudocomplemented(certificate=True)
(False, 3)

>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(5)], Integer(2):...
→[Integer(3), Integer(6)], Integer(3): [Integer(4)], Integer(4):...
→[Integer(7)],
... Integer(5): [Integer(6)], Integer(6): [Integer(7)]})
>>> L.is_pseudocomplemented()
True

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):...
→[Integer(4), Integer(5), Integer(6)], Integer(3): [Integer(6)], Integer(4):...
→[Integer(7)],
... Integer(5): [Integer(7)], Integer(6): [Integer(7)]})
>>> L.is_pseudocomplemented()
False

>>> L.is_pseudocomplemented(certificate=True)
(False, 3)

See also:

• Dual property: is_join_pseudocomplemented()

• Stronger properties: is_meet_semidistributive()

• Other: pseudocomplement().

ALGORITHM:

According to [Cha92] a lattice is pseudocomplemented if and only if every atom has a pseudocomplement. So we only check those.
is_regular\(\text{(certificate=False)}\)

Return True if the lattice is regular and False otherwise.

A congruence of a lattice is regular if it is generated by any of its parts. A lattice is regular if it has only regular congruences.

INPUT:

• certificate – (default: False) whether to return a certificate if the lattice is not regular

OUTPUT:

• If certificate=True return either (True, None) or (False, (C, p)), where C is a non-regular congruence as a sage.combinat.set_partition.SetPartition and p is a congruence class of C such that the congruence generated by p is not C. If certificate=False return True or False.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [8, 7], 4: [6, 7],
                   ....:  5: [8], 6: [9], 7: [9], 8: [9]})
sage: L.is_regular()
needs sage.combinat
True

sage: N5 = posets.PentagonPoset()
sage: N5.is_regular()
needs sage.combinat
False

sage: N5.is_regular(certificate=True)
needs sage.combinat
(False, ({{0}, {1}, {2, 3}, {4}}, {0}))
```

```
>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],
                   ....:  Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(8), Integer(7)],
                   ....:  Integer(4): [Integer(6), Integer(7)],
                   ....:  Integer(5): [Integer(8)], Integer(6): [Integer(9)],
                   ....:  Integer(7): [Integer(9)], Integer(8): [Integer(9)]})
>>> L.is_regular()
needs sage.combinat
True

>>> N5 = posets.PentagonPoset()
>>> N5.is_regular()
needs sage.combinat
False

>>> N5.is_regular(certificate=True)
needs sage.combinat
(False, ({{0}, {1}, {2, 3}, {4}}, [0]))
```

See also:

• Stronger properties: is_uniform(), is_sectionally_complemented(), is_cosectionally_complemented()
• Mutually exclusive properties: is_vertically_decomposable()
• Other: congruence()
**is\_relatively\_complemented** *(certificate=False)*

Return True if the lattice is relatively complemented, and False otherwise.

A lattice is relatively complemented if every interval of it is a complemented lattice.

**INPUT:**

- certificate – (default: False) Whether to return a certificate if the lattice is not relatively complemented.

**OUTPUT:**

- If certificate=True return either (True, None) or (False, (a, b, c)), where b is the only element that covers a and is covered by c. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: L = LatticePoset({1: [2, 3, 4, 8], 2: [5, 6], 3: [5, 7],
....: 4: [6, 7], 5: [9], 6: [9], 7: [9], 8: [9]})
sage: L.is_relatively_complemented()
True
sage: L = posets.PentagonPoset()
sage: L.is_relatively_complemented()
False
```

Relatively complemented lattice must be both atomic and coatomic. Implication to other direction does not hold:

```python
sage: L = LatticePoset({0: [1, 2, 3, 4, 5], 1: [6, 7], 2: [6, 8],
....: 3: [7, 8, 9], 4: [9, 11], 5: [9, 10],
....: 6: [10, 11], 7: [12], 8: [12], 9: [12],
....: 10: [12], 11: [12]})
sage: L.is_atomic() and L.is_coatomic()
True
sage: L.is_relatively_complemented()
False
```

```python
>> from sage.all import *
>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3),
˓→Integer(4)],
˓→Integer(4), Integer(5)], Integer(1): [Integer(6), Integer(7)], Integer(2):...
˓→[Integer(6), Integer(8)],
˓→[Integer(3): [Integer(7), Integer(8), Integer(9)],
˓→Integer(4): [Integer(9), Integer(11)], Integer(5): [Integer(9),
˓→Integer(10)]},
(continues on next page)
```
We can also get a non-complemented 3-element interval:

```python
sage: L.is_relatively_complemented(certificate=True)
(False, (1, 6, 11))
```

See also:

- Weaker properties: `is_sectionally_complemented()`, `is_cosectionally_complemented()`, `is_isoform()`
- Stronger properties: `is_geometric()`

### is_sectionally_complemented(certificaté=False)

Return `True` if the lattice is sectionally complemented, and `False` otherwise.

A lattice is sectionally complemented if all intervals from the bottom element interpreted as sublattices are complemented lattices.

**INPUT:**

- `certificate` – (default: `False`) Whether to return a certificate if the lattice is not sectionally complemented.

**OUTPUT:**

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (t, e))`, where `t` is an element so that in the sublattice from the bottom element to `t` has no complement for element `e`.

**EXAMPLES:**

Smallest examples of a complemented but not sectionally complemented lattice and a sectionally complemented but not relatively complemented lattice:

```python
sage: L = posets.PentagonPoset()
sage: L.is_complemented()  # True
sage: L.is_sectionally_complemented()  # True
sage: L.is_relatively_complemented()  # False
```

```python
sage: L = LatticePoset({0: [1, 2, 3], 1: [4], 2: [4], 3: [5], 4: [5]})
sage: L.is_sectionally_complemented()  # True
sage: L.is_relatively_complemented()  # False
```
>>> from sage.all import *
>>> L = posets.PentagonPoset()
>>> L.is_complemented()
True
>>> L.is_sectionally_complemented()
False

>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3)],
→ Integer(1): [Integer(4)], Integer(2): [Integer(4)], Integer(3):
→ [Integer(5)], Integer(4): [Integer(5)]})
>>> L.is_sectionally_complemented()
True
>>> L.is_relatively_complemented()
False

Getting a certificate:

```
sage: L = LatticePoset(DiGraph('HYoGC?C@?C?G@??'))
sage: L.is_sectionally_complemented(certificate=True)
(False, (6, 1))
```

```
>>> from sage.all import *
>>> L = LatticePoset(DiGraph('HYoGC?C@?C?G@??'))
>>> L.is_sectionally_complemented(certificate=True)
(False, (6, 1))
```

See also:

- Dual property: `is_cosectionally_complemented()`
- Weaker properties: `is_complemented()`, `is_atomic()`, `is_regular()`
- Stronger properties: `is_relatively_complemented()`

**is_semidistributive()**

Return `True` if the lattice is both join- and meet-semidistributive, and `False` otherwise.

EXAMPLES:

Tamari lattices are typical examples of semidistributive but not distributive (and hence not modular) lattices:

```
sage: T4 = posets.TamariLattice(4)
sage: T4.is_semidistributive(), T4.is_distributive()
(True, False)
```

```
>>> from sage.all import *
>>> T4 = posets.TamariLattice(Integer(4))
>>> T4.is_semidistributive(), T4.is_distributive()
(True, False)
```

Smallest non-selfdual example:

```
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5], 4: [6], 5: [7], 6: [7]})
sage: L.is_semidistributive()
True
```

5.1. Comprehensive Module List
The diamond is not semidistributive:

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_semidistributive()
False
```

See also:

- Weaker properties: `is_join_semidistributive()`, `is_meet_semidistributive()`
- Stronger properties: `is_distributive()`

`is_simple()` (certificate=False)

Return True if the lattice is simple and False otherwise.

A lattice is simple if it has no nontrivial congruences; in other words, for every two distinct elements \(a\) and \(b\) the principal congruence generated by \((a, b)\) has only one component, i.e. the whole lattice.

**INPUT:**

- certificate – (default: False) whether to return a certificate if the lattice is not simple

**OUTPUT:**

- If certificate=True return either (True, None) or (False, c), where c is a non-trivial congruence as a `sage.combinat.set_partition.SetPartition`. If certificate=False return True or False.

**EXAMPLES:**

```python
sage: # needs sage.combinat
sage: posets.DiamondPoset(5).is_simple()  # Smallest nontrivial example
True
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6], 4: [6], 5: [6]})
sage: L.is_simple()
False
sage: L.is_simple(certificate=True)
(False, {(1, 3), {2, 4, 5, 6}})
```

```python
>>> from sage.all import *

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3)], Integer(2):
...
→[Integer(4), Integer(5)], Integer(3): [Integer(6)], Integer(4):
...
→[Integer(6)], Integer(5): [Integer(6)]})

True
```

(continues on next page)
Two more examples. First is a non-simple lattice without any 2-element congruences:

```python
sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5], 4: [6, 7],
    ....: 5: [8], 6: [8], 7: [8]})
sage: L.is_simple()
False
```

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [6, 7], 4: [8],
    ....: 5: [8], 6: [8], 7: [8]})
sage: L.is_simple()
True
```

See also:

- Weaker properties: `is_isofrom()`
- Mutually exclusive properties: `is_constructible_by_doublings()` (by any set)
- Other: `congruence()`

**is_stone** *(certificate=False)*

Return `True` if the lattice is a Stone lattice, and `False` otherwise.

The lattice is expected to be distributive (and hence pseudocomplemented).

A pseudocomplemented lattice is a Stone lattice if

\[ e^* \lor e^{**} = 1 \]

for every element \( e \) of the lattice, where \( * \) is the pseudocomplement and \( 1 \) is the top element of the lattice.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate
OUTPUT:

• If certificate=True return either (True, None) or (False, e) such that $e^* \lor e^{**} \neq \top$.

• If certificate=False return True or False.

EXAMPLES:

Divisor lattices are canonical example:

```sage
def is_stone(self, certificate=False):
    if certificate:
        return either (True, (K, L))
        or (False, (a, b)),
        where a and b are elements that are in the same congruence class for every nontrivial congruence of the lattice. Special case: If the lattice has zero or one element, return (False, None).

INPUT:
• certificate – (default: False) whether to return a certificate

OUTPUT:
• if certificate=False, return only True or False
• if certificate=True, return either
  – (True, (K, L)) such that the lattice is isomorphic to a sublattice of $K \times L$.
  – (False, (a, b)), where a and b are elements that are in the same congruence class for every nontrivial congruence of the lattice. Special case: If the lattice has zero or one element, return (False, None).

EXAMPLES:
```
sage: N5 = posets.PentagonPoset()
sage: N5.is_subdirectly_reducible()  # needs sage.combinat
False

sage: hex = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: hex.is_subdirectly_reducible()  # needs sage.combinat
True

sage: hex.is_subdirectly_reducible(certificate=True)  # needs sage.combinat
(True, (Finite lattice containing 5 elements, Finite lattice containing 5 elements))

sage: N5.is_subdirectly_reducible(certificate=True)  # needs sage.combinat
(False, (2, 3))

sage: res, cert = hex.is_subdirectly_reducible(certificate=True)  # needs sage.combinat
sage: cert[0].is_isomorphic(N5)  # needs sage.combinat
True

See also:

- Stronger properties: is_distributive(), is_vertically_decomposable()
- Other: subdirect_decomposition()
**is_sublattice**(other)

Return True if the lattice is a sublattice of other, and False otherwise.

Lattice $K$ is a sublattice of $L$ if $K$ is an (induced) subposet of $L$ and closed under meet and join of $L$.

**Note:** This method does not check whether the lattice is an isomorphic (i.e., up to relabeling) sublattice of other, but only if other directly contains the lattice as a sublattice.

**EXAMPLES:**

A pentagon sublattice in a non-modular lattice:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6: [7]})
sage: N5 = LatticePoset({1: [2, 6], 2: [4], 4: [7], 6: [7]})
sage: N5.is_sublattice(L)
True
```

This pentagon is a subposet but not closed under join, hence not a sublattice:

```python
sage: N5_ = LatticePoset({1: [2, 3], 2: [4], 3: [7], 4: [7]})
sage: N5_.is_induced_subposet(L)
True
sage: N5_.is_sublattice(L)
False
```

See also:

`isomorphic_sublattices_iterator()`

**is_sublattice_dismantlable**()

Return True if the lattice is sublattice dismantlable, and False otherwise.

A sublattice dismantling is a subdivision of a lattice into two non-empty sublattices. A lattice is sublattice dismantlable if it can be decomposed into 1-element lattices by consecutive sublattice dismantlings.

**EXAMPLES:**

The smallest non-example is this (and the dual):
Here we adjoin a (double-irreducible-)dismantlable lattice as a part to an interval-dismantlable lattice:

```python
sage: B3 = posets.BooleanLattice(3)
sage: N5 = posets.PentagonPoset()
sage: L = B3.adjunct(N5, Integer(1), Integer(7))
sage: L.is_dismantlable(), L.is_interval_dismantlable()
(False, False)
sage: L.is_sublattice_dismantlable()
True
```

See also:

- Stronger properties: `is_dismantlable()`, `is_interval_dismantlable()`

Todo: Add a certificate-option.

### is_supersolvable (certificate=False)

Return True if the lattice is supersolvable, and False otherwise.

A lattice $L$ is supersolvable if there exists a maximal chain $C$ such that every $x \in C$ is a modular element in $L$. Equivalent definition is that the sublattice generated by $C$ and any other chain is distributive.

INPUT:

- certificate – (default: False) whether to return a certificate

OUTPUT:

- If certificate=True return either (False, None) or (True, C), where C is a maximal chain of modular elements. If certificate=False return True or False.

EXAMPLES:
sage: L = posets.DiamondPoset(5)
sage: L.is_supersolvable()
True

sage: L = posets.PentagonPoset()
sage: L.is_supersolvable()
False

sage: L = LatticePoset({1:[2,3],2:[4,5],3:[5,6],4:[7],5:[7],6:[7]})
sage: L.is_supersolvable()
True
sage: L.is_supersolvable(certificate=True)
(True, [1, 2, 5, 7])
sage: L.is_modular()
False

sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [5, 6, 7],
                      2: [5, 8, 9], 3: [6, 8, 10], 4: [7, 9, 10],
                      5: [11], 6: [11], 7: [11], 8: [11],
                      9: [11], 10: [11]})

>>> from sage.all import *

>>> L = posets.DiamondPoset(Integer(5))

>>> L.is_supersolvable()
True

>>> L = posets.PentagonPoset()

>>> L.is_supersolvable()
False

>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3),
                                Integer(4), Integer(5), Integer(6), Integer(7)],
                                Integer(2): [Integer(4), Integer(5), Integer(6)],
                                Integer(4): [Integer(7)],
                                Integer(5): [Integer(7)], Integer(6): [Integer(7)]})

>>> L.is_supersolvable()
True

>>> L.is_supersolvable(certificate=True)
(True, [1, 2, 5, 7])

>>> L.is_modular()
False

>>> L = LatticePoset({Integer(0): [Integer(1), Integer(2), Integer(3),
                                Integer(4), Integer(5), Integer(6), Integer(7)],
                                Integer(1): [Integer(5), Integer(6), Integer(7)],
                                Integer(2): [Integer(5), Integer(8), Integer(9)],
                                Integer(3): [Integer(6), Integer(8), Integer(10)],
                                Integer(4): [Integer(7),
                                Integer(9), Integer(10)],
                                Integer(5): [Integer(11), Integer(6): [Integer(11)]},
                                Integer(7): [Integer(11)],
                                Integer(8): [Integer(11)],
                                Integer(9): [Integer(11)], Integer(10): [Integer(11)]})

>>> L.is_supersolvable()
False

See also:

- Weaker properties: `is_graded()`
- Stronger properties: `is_modular()`
is_trim\( (\text{certificate}=\text{False}) \)

Return whether a lattice is trim. A lattice is trim if it is extremal and left modular. This notion is defined in [Thom2006].

INPUT:

• certificate – boolean (default False) whether to return instead a maximum chain of left modular elements

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.is_trim()
True

sage: Q = LatticePoset(posets.SymmetricGroupWeakOrderPoset(3))
sage: Q.is_trim()
False
```

>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.is_trim()
True

>>> Q = LatticePoset(posets.SymmetricGroupWeakOrderPoset(Integer(3)))
>>> Q.is_trim()
False

See also:

• Weaker properties: is_extremal()
• Stronger properties: is_distributive()

REFERENCES:

is_uniform\( (\text{certificate}=\text{False}) \)

Return True if the lattice is uniform and False otherwise. A congruence is uniform if all blocks have equal number of elements. A lattice is uniform if it has only uniform congruences.

INPUT:

• certificate – (default: False) whether to return a certificate if the lattice is not uniform

OUTPUT:

• If certificate=True return either (True, None) or (False, C), where C is a non-uniform congruence as a sage.combinat.set_partition.SetPartition. If certificate=False return True or False.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [6, 7], 3: [5], 4: [5],
.....: 5: [8, 9], 6: [9], 7: [10], 8: [10], 9: [10]})
sage: L.is_uniform()
#...
```

(continues on next page)
Every uniform lattice is regular, but the converse is not true:

```
sage: N6 = LatticePoset({1: [2, 3, 5], 2: [4], 3: [4], 5: [6], 4: [6]})
sage: N6.is_uniform(), N6.is_regular()
(False, True)
sage: N6.is_uniform(certificate=True)
(False, {(1, 2, 3, 4), (5, 6)})
```

```
from sage.all import *

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],
                    Integer(2): [Integer(6), Integer(7)], Integer(3): [Integer(5)], Integer(4):
                    [Integer(5)],
                    ... Integer(5): [Integer(9), Integer(8)], Integer(6):
                    [Integer(9)], Integer(7): [Integer(10)], Integer(8): [Integer(10)],...
                    Integer(9): [Integer(10)]})
>>> L.is_uniform()
#-
needs sage.combinat
True
```

See also:

- Weaker properties: `is_regular()`
- Stronger properties: `is_isoform()`
- Other: `congruence()`

**is_upper_semimodular** *(certificate=False)*

Return `True` if the lattice is upper semimodular and `False` otherwise.

A lattice is upper semimodular if any pair of elements with a common lower cover have also a common upper cover.

INPUT:

- `certificate` – (default: `False`) Whether to return a certificate if the lattice is not upper semimodular.

OUTPUT:

- If `certificate=False` return `True` or `False`. If `certificate=True` return either `(True, None)` or `(False, (a, b))`, where `a` and `b` covers their meet but are not covered by their join.
See Wikipedia article Semimodular_lattice

EXAMPLES:

```python
sage: L = posets.DiamondPoset(5)
sage: L.is_upper_semimodular()
True

sage: L = posets.PentagonPoset()
sage: L.is_upper_semimodular()
False

sage: L = LatticePoset(posets.IntegerPartitions(4))
# needs sage.combinat
sage: L.is_upper_semimodular()
# needs sage.combinat
True

sage: L = LatticePoset({1:[2, 3, 4], 2:[5], 3:[5, 6], 4:[6], 5:[7], 6:[7]})
sage: L.is_upper_semimodular(certificate=True)
(False, (4, 2))
```

See also:

- Dual property: `is_lower_semimodular()`
- Weaker properties: `is_graded()`
- Stronger properties: `is_modular()`, `is_join_distributive()`, `is_geometric()`

`is_vertically_decomposable(certificate=False)`

Return `True` if the lattice is vertically decomposable, and `False` otherwise.

A lattice is vertically decomposable if it has an element that is comparable to all elements and is neither the bottom nor the top element.

Informally said, a lattice is vertically decomposable if it can be seen as two lattices “glued” by unifying the top element of first lattice to the bottom element of second one.
INPUT:
- certificate – (default: False) whether to return a certificate

OUTPUT:
- If certificate=True return either (False, None) or (True, e), where e is an element that is comparable to all other elements and is neither the bottom nor the top element. If certificate=False return True or False.

EXAMPLES:

```
sage: posets.TamariLattice(4).is_vertically_decomposable()
False
sage: L = LatticePoset( ([1, 2, 3, 6, 12, 18, 36],
.....: attrcall("divides")) )
```

```
sage: L.is_vertically_decomposable()
True
sage: L.is_vertically_decomposable(certificate=True)
(True, 6)
```

```
>>> from sage.all import *
>>> posets.TamariLattice(Integer(4)).is_vertically_decomposable()
False
>>> L = LatticePoset( ([Integer(1), Integer(2), Integer(3), Integer(6),
˓→Integer(12), Integer(18), Integer(36)],
...: attrcall("divides")) )
```

```
>>> L.is_vertically_decomposable()
True
>>> L.is_vertically_decomposable(certificate=True)
(True, 6)
```

See also:
- Weaker properties: is_subdirectly_reducible()
- Mutually exclusive properties: is_atomic(), is_coatomic(), is_regular()
- Other: vertical_decomposition()

**isomorphic_sublattices_iterator**(other)
Return an iterator over the sublattices of the lattice isomorphic to other.

INPUT:
- other – a finite lattice

EXAMPLES:
A non-modular lattice contains a pentagon sublattice:

```
sage: L = LatticePoset({1: [2, 3], 2: [4, 5], 3: [5, 6], 4: [7], 5: [7], 6:
˓→[7]})
```

```
sage: L.is_modular()
False
```

```
sage: N5 = posets.PentagonPoset()
sage: N5_in_L = next(L.isomorphic_sublattices_iterator(N5)); N5_in_L
Finite lattice containing 5 elements
```

```
sage: N5_in_L.list()
[1, 3, 6, 4, 7]
```
A divisor lattice is modular, hence does not contain the pentagon as sublattice, even if it has the pentagon subposet:

```
sage: D12 = posets.DivisorLattice(12)
sage: D12.has_isomorphic_subposet(N5)
True
sage: list(D12.isomorphic_sublattices_iterator(N5))
[]
```

Join-primes

Return the join-prime elements of the lattice.

An element $x$ of a lattice $L$ is join-prime if $x \leq a \lor b$ implies $x \leq a$ or $x \leq b$ for every $a, b \in L$.

These are also called coprime in some books. Every join-prime is join-irreducible; converse holds if and only if the lattice is distributive.

EXAMPLES:

```
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5],
....: 4: [6], 5: [7], 6: [7]})
sage: L.join_primes()
[3, 4]
sage: D12 = posets.DivisorLattice(12)  # Distributive lattice
sage: D12.join_irreducibles() == D12.join_primes()
True
```
\[
>>> \text{from sage.all import *}
\]
\[
>>> \text{L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],}
\]
\[
\rightarrow \text{Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5)],}
\]
\[
\rightarrow \text{Integer(4): [Integer(6)], Integer(5): [Integer(7)],}
\]
\[
\rightarrow \text{Integer(6): [Integer(7)]})}
\]
\[
>>> \text{L.join_primes()}
\]
\[
[3, 4]
\]
\[
>>> \text{D12 = posets.DivisorLattice(Integer(12))} \quad \# \text{Distributive lattice}
\]
\[
>>> \text{D12.join_irreducibles() == D12.join_primes()}
\]
\[
True
\]

See also:

- Dual function: \texttt{meet_primes()}
- Other: \texttt{join_irreducibles()}

\textbf{maximal_sublattices()}

Return maximal (proper) sublattices of the lattice.

\textbf{EXAMPLES:}

\[
\text{sage: L = LatticePoset(( [], [[1,2],[1,17],[1,8],[2,3],[2,22],}
\]
\[
\rightarrow \text{[2,5],[2,7],[17,22],[17,13],[8,7],}
\]
\[
\rightarrow \text{[8,13],[3,16],[3,9],[22,16],[22,18],}
\]
\[
\rightarrow \text{[22,10],[5,18],[5,14],[7,9],[7,14],}
\]
\[
\rightarrow \text{[7,10],[13,10],[16,6],[16,19],[9,19],}
\]
\[
\rightarrow \text{[18,6],[18,33],[14,33],[10,19],}
\]
\[
\rightarrow \text{[10,33],[6,4],[19,4],[33,4]]})}
\]
\[
\text{sage: maxs = L.maximal_sublattices()}
\]
\[
\text{sage: len(maxs)}
\]
\[
7
\]
\[
\text{sage: sorted(maxs[0].list())}
\]
\[
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 16, 18, 19, 22, 33]
\]
>>> sorted(maxs[Integer(0)].list())
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 14, 16, 18, 19, 22, 33]

\textbf{meet\_primes()}

Return the meet-prime elements of the lattice.

An element \( x \) of a lattice \( L \) is \textit{meet-prime} if \( x \geq a \land b \) implies \( x \geq a \) or \( x \geq b \) for every \( a, b \in L \).

These are also called just \textit{prime} in some books. Every meet-prime is meet-irreducible; converse holds if and only if the lattice is distributive.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: L = LatticePoset({1: [2, 3, 4], 2: [5, 6], 3: [5], ...
4: [6], 5: [7], 6: [7]})
sage: L.meet_primes()
[6, 5]
sage: D12 = posets.DivisorLattice(12)
sage: sorted(D12.meet_primes())
[3, 4, 6]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],...
˓→Integer(2): [Integer(5), Integer(6)], Integer(3): [Integer(5)],...
˓→Integer(4): [Integer(6)], Integer(5): [Integer(7)],...
˓→Integer(6): [Integer(7)]})

>>> L.meet_primes()
[6, 5]

>>> D12 = posets.DivisorLattice(Integer(12))

>>> sorted(D12.meet_primes())
[3, 4, 6]
\end{verbatim}

\textbf{See also:}

- Dual function: \textit{join\_primes()}
- Other: \textit{meet\_irreducibles()}

\textbf{moebius\_algebra} (\( R \))

Return the Möbius algebra of \textit{self} over \( R \).

\textbf{OUTPUT:}

An instance of \textit{sage.combinat.posets.moebius\_algebra.MoebiusAlgebra}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: L = posets.BooleanLattice(4)
sage: L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field

>>> from sage.all import *

>>> L = posets.BooleanLattice(Integer(4))

>>> L.moebius_algebra(QQ)
Moebius algebra of Finite lattice containing 16 elements over Rational Field
\end{verbatim}
neutral_elements()

Return the list of neutral elements of the lattice.

An element $e$ of the lattice $L$ is neutral if the sublattice generated by $e$, $x$ and $y$ is distributive for all $x, y \in L$. It can also be characterized as an element of intersection of maximal distributive sublattices.

EXAMPLES:

```python
sage: L = LatticePoset({1: [2, 3], 2: [6], 3: [4, 5, 6], 4: [8],
....: 5: [7], 6: [7], 7: [8, 9], 8: [10], 9: [10]})
```

```python
sage: L.neutral_elements()
[1, 3, 8, 10]
```

quantum_moebius_algebra ($q=None$)

Return the quantum Möbius algebra of self with parameter $q$.

INPUT:

- $q$ – (optional) the deformation parameter $q$

OUTPUT:

An instance of sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
```

```python
sage: L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements
with $q=q$ over Univariate Laurent Polynomial Ring in $q$ over Integer Ring
```

```python
>>> from sage.all import *
```n

```python
>>> L = posets.BooleanLattice(Integer(4))
```n
```python
>>> L.quantum_moebius_algebra()
Quantum Moebius algebra of Finite lattice containing 16 elements
with $q=q$ over Univariate Laurent Polynomial Ring in $q$ over Integer Ring
```

quotient ($congruence$, $labels='tuple'$)

Return the quotient lattice by $congruence$.

Let $L$ be a lattice and $\Theta$ be a congruence of $L$ with congruence classes $\Theta_1, \Theta_2, \ldots$. The quotient lattice $L/\Theta$ is the lattice with elements $\{\Theta_1, \Theta_2, \ldots\}$ and meet and join given by the original lattice. Explicitly, if $e_1 \in \Theta_1$ and $e_2 \in \Theta_2$, such that $e_1 \lor e_2 \in \Theta_3$ then $\Theta_1 \lor \Theta_2 = \Theta_3$ in $L/\Theta$ and similarly for meets.

INPUT:

- $congruence$ – list of lists; a congruence
- $labels$ – string; the elements of the resulting lattice and can be one of the following:
  - 'tuple' – elements are tuples of elements of the original lattice
- 'lattice' – elements are sublattices of the original lattice
- 'integer' – elements are labeled by integers

Warning: congruence is expected to be a valid congruence of the lattice. This is not checked.

EXAMPLES:

```
sage: # needs sage.combinat
sage: L = posets.PentagonPoset()
sage: c = L.congruence([[0, 1]])
sage: I = L.quotient(c); I
Finite lattice containing 2 elements
sage: I.top()
(2, 3, 4)
sage: I = L.quotient(c, labels='lattice')
sage: I.top()
Finite lattice containing 3 elements
```

```
sage: # needs sage.combinat
sage: B3 = posets.BooleanLattice(3)
sage: c = B3.congruence([[0,1]])
sage: B2 = B3.quotient(c, labels='integer')
sage: B2.is_isomorphic(posets.BooleanLattice(2))
True
```

>>> from sage.all import *
>>> # needs sage.combinat
>>> L = posets.PentagonPoset()
>>> c = L.congruence([[Integer(0), Integer(1)]])
>>> I = L.quotient(c); I
Finite lattice containing 2 elements
>>> I.top()
(2, 3, 4)
>>> I = L.quotient(c, labels='lattice')
>>> I.top()
Finite lattice containing 3 elements

>>> # needs sage.combinat
>>> B3 = posets.BooleanLattice(Integer(3))
>>> c = B3.congruence([[Integer(0), Integer(1)]])
>>> B2 = B3.quotient(c, labels='integer')
>>> B2.is_isomorphic(posets.BooleanLattice(Integer(2)))
True

See also:

congruence()
skeleton()

Return the skeleton of the lattice.

The lattice is expected to be pseudocomplemented.

The skeleton of a pseudocomplemented lattice \( L \), where * is the pseudocomplementation operation, is the subposet induced by \( \{ e^* \mid e \in L \} \). Actually this poset is a Boolean lattice.

EXAMPLES:
Combinatorics, Release 10.4

sage: D12 = posets.DivisorLattice(12)
sage: S = D12.skeleton(); S
Finite lattice containing 4 elements
sage: S.cover_relations()
[[1, 3], [1, 4], [3, 12], [4, 12]]

sage: T4 = posets.TamariLattice(4)
sage: T4.skeleton().is_isomorphic(posets.BooleanLattice(3))
True

See also:

sage.combinat.posets.lattices.FiniteMeetSemilattice.pseudocomplement()

subdirect_decomposition()
Return the subdirect decomposition of the lattice.

The subdirect decomposition of a lattice $L$ is the list of smaller lattices $L_1, \ldots, L_n$ such that $L$ is a sublattice of $L_1 \times \ldots \times L_n$, none of $L_i$ can be decomposed further and $L$ is not a sublattice of any $L_i$. (Except when the list has only one element, i.e. when the lattice is subdirectly irreducible.)

EXAMPLES:

sage: posets.ChainPoset(3).subdirect_decomposition() # needs sage.combinat
[Finite lattice containing 2 elements, Finite lattice containing 2 elements]

sage: L = LatticePoset({1: [2, 4], 2: [3], 3: [6, 7], 4: [5, 7],
5: [9, 8], 6: [9], 7: [9], 8: [10], 9: [10]})

sage: Ldecomp = L.subdirect_decomposition()

sage: [fac.cardinality() for fac in Ldecomp]
[2, 5, 7]

sage: Ldecomp[1].is_isomorphic(posets.PentagonPoset())
True

>>> from sage.all import *
>>> posets.ChainPoset(Integer(3)).subdirect_decomposition() # needs sage.combinat
[Finite lattice containing 2 elements, Finite lattice containing 2 elements]

>>> L = LatticePoset({Integer(1): [Integer(2), Integer(4)], Integer(2):
[Integer(3)], Integer(3): [Integer(6), Integer(7)], Integer(4): [Integer(5),
Integer(7)],
Integer(5): [Integer(9), Integer(8)], Integer(6):...} (continues on next page)
Combinatorics, Release 10.4

→[Integer(9)], Integer(7): [Integer(9)], Integer(8): [Integer(10)],...
→[Integer(9): [Integer(10)]]

>>> Ldecomp = L.subdirect_decomposition()
>>> [fac.cardinality() for fac in Ldecomp]

[2, 5, 7]

>>> Ldecomp[Integer(1)].is_isomorphic(posets.PentagonPoset())

True

sublattice (elms)

Return the smallest sublattice containing elements on the given list.

INPUT:

• elms – a list of elements of the lattice.

EXAMPLES:

sage: L = LatticePoset((([], [[1, 2], [1, 17], [1, 8], [2, 3], [2, 22], [2, 5], [2, 7], [17, 22], [17, 13], [8, 7], [8, 13], [3, 16], [3, 9], [22, 16], [22, 18], [22, 10], [5, 18], [5, 14], [7, 9], [7, 14], [7, 10], [13, 10], [16, 6], [16, 19], [9, 19], [18, 6], [18, 33], [14, 33], [10, 19], [10, 33], [6, 4], [19, 4], [33, 4]]))

sage: L.sublattice([14, 13, 22]).list()

[1, 2, 8, 7, 14, 17, 13, 22, 10, 33]

sage: L = posets.BooleanLattice(3)

sage: L.sublattice([3, 5, 6, 7])

Finite lattice containing 8 elements

sage: from sage.all import *

>>> L = LatticePoset((([], [[1, 2], [1, 17], [1, 8], [2, 3], [2, 22], [2, 5], [2, 7], [17, 22], [17, 13], [8, 7], [8, 13], [3, 16], [3, 9], [22, 16], [22, 18], [22, 10], [5, 18], [5, 14], [7, 9], [7, 14], [7, 10], [13, 10], [16, 6], [16, 19], [9, 19], [18, 6], [18, 33], [14, 33], [10, 19], [10, 33], [6, 4], [19, 4], [33, 4]]))

sage: L.sublattice([Integer(14), Integer(13), Integer(22)]).list()

[1, 2, 8, 7, 14, 17, 13, 22, 10, 33]

sage: L = posets.BooleanLattice(Integer(3))

sage: L.sublattice([Integer(3), Integer(5), Integer(6), Integer(7)])

Finite lattice containing 8 elements

sublattices ()

Return all sublattices of the lattice.

EXAMPLES:

sage: L = LatticePoset({1: [2, 3, 4], 2: [5], 3: [5, 6], 4: [6],
.....: 5: [7], 6: [7]})

sage: sublats = L.sublattices(); len(sublats)

54

(continues on next page)
sage: sublats[3]
Finite lattice containing 4 elements
sage: sublats[3].list()
[1, 2, 3, 5]

>>> from sage.all import *
>>> L = LatticePoset({Integer(1): [Integer(2), Integer(3), Integer(4)],
˓→Integer(2):[Integer(5)], Integer(3):[Integer(5), Integer(6)],
˓→Integer(4):[Integer(6)],
˓→Integer(5):[Integer(7)], Integer(6):[Integer(7)]})
>>> sublats = L.sublattices(); len(sublats)
54
>>> sublats[Integer(3)]
Finite lattice containing 4 elements
>>> sublats[Integer(3)].list()
[1, 2, 3, 5]

sublattices_lattice (labels='lattice')

Return the lattice of sublattices.

Every element of the returned lattice is a sublattice and they are ordered by containment; that is, atoms are one-element lattices, coatoms are maximal sublattices of the original lattice and so on.

INPUT:

- labels -- string; can be one of the following:
  - 'lattice' (default) elements of the lattice will be lattices that correspond to sublattices of the original lattice
  - 'tuple' -- elements are tuples of elements of the sublattices of the original lattice
  - 'integer' -- elements are plain integers

EXAMPLES:

sage: D4 = posets.DiamondPoset(4)
sage: sll = D4.sublattices_lattice(labels='tuple')
sage: sll.coatoms()  # = maximal sublattices of the original lattice
[(0, 1, 3), (0, 2, 3)]
sage: L = posets.DivisorLattice(12)
sage: sll = L.sublattices_lattice()
sage: L.is_dismantlable() == (len(sll.atoms()) == sll.rank())
True

>>> from sage.all import *
>>> D4 = posets.DiamondPoset(Integer(4))
>>> sll = D4.sublattices_lattice(labels='tuple')
>>> sll.coatoms()  # = maximal sublattices of the original lattice
[(0, 1, 3), (0, 2, 3)]
>>> L = posets.DivisorLattice(Integer(12))
>>> sll = L.sublattices_lattice()
>>> L.is_dismantlable() == (len(sll.atoms()) == sll.rank())
True
**vertical_composition**(other, labels='pairs')

Return the vertical composition of the lattice with other.

Let $L$ and $K$ be lattices and $b_K$ the bottom element of $K$. The vertical composition of $L$ and $K$ is the ordinal sum of $L$ and $K \setminus \{b_K\}$. Informally said this is lattices “glued” together with a common element.

Mathematically, it is only defined when $L$ and $K$ have no common element; here we force that by giving them different names in the resulting poset.

**INPUT:**

- other – a lattice
- labels – a string (default 'pairs'); can be one of the following:
  - 'pairs' – each element $v$ in this poset will be named $(0, v)$ and each element $u$ in other will be named $(1, u)$ in the result
  - 'integers' – the elements of the result will be relabeled with consecutive integers

**EXAMPLES:**

```python
sage: L = LatticePoset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d']})
sage: K = LatticePoset({'e': ['f', 'g'], 'f': ['h'], 'g': ['h']})
sage: M = L.vertical_composition(K)
sage: M.list()
[(0, 'a'), (0, 'b'), (0, 'c'), (0, 'd'), (1, 'f'), (1, 'g'), (1, 'h')]
sage: M.upper_covers((0, 'd'))
[(1, 'f'), (1, 'g')]
sage: C2 = posets.ChainPoset(2)
sage: M3 = posets.DiamondPoset(5)
sage: L = C2.vertical_composition(M3, labels='integers')
sage: L.cover_relations()
[[0, 1], [1, 2], [1, 3], [1, 4], [2, 5], [3, 5], [4, 5]]
```

See also:

**vertical_decomposition()**, **sage.combinat.posets.posets.FinitePoset.ordinal_sum()**

**vertical_decomposition**(elements_only=False)

Return sublattices from the vertical decomposition of the lattice.

Let $d_1, \ldots, d_n$ be elements (excluding the top and bottom elements) comparable to every element of the lattice. Let $b$ be the bottom element and $t$ be the top element. This function returns either a list $d_1, \ldots, d_n$,
or the list of intervals \([b, d_1], [d_1, d_2], \ldots, [d_{n-1}, d_n], [d_n, t]\) as lattices.

Informally said, this returns the lattice split into parts at every single-element “cutting point”.

**INPUT:**

- `elements_only` - if True, return the list of decomposing elements as defined above; if False (the default), return the list of sublattices so that the lattice is a vertical composition of them.

**EXAMPLES:**

Number 6 is divided by 1, 2, and 3, and it divides 12, 18 and 36:

```python
sage: L = LatticePoset( [[1, 2, 3, 6, 12, 18, 36], ...
....:       attrcall("divides"))

sage: parts = L.vertical_decomposition()

sage: [lat.list() for lat in parts]
[[1, 2, 3, 6], [6, 12, 18, 36]]

sage: L.vertical_decomposition(elements_only=True)
[6]
```

```python
>>> from sage.all import *

>>> L = LatticePoset( [Integer(1), Integer(2), Integer(3), Integer(6), ...
˓→Integer(12), Integer(18), Integer(36)], ...
....:       attrcall("divides"))

>>> parts = L.vertical_decomposition()

>>> [lat.list() for lat in parts]
[[1, 2, 3, 6], [6, 12, 18, 36]]

>>> L.vertical_decomposition(elements_only=True)
[6]
```

See also:

vertical_composition(), is_vertically_decomposable()
>>> from sage.all import *
>>> L = posets.DivisorLattice(Integer(60))
>>> sorted(L.atoms())
[2, 3, 5]

See also:

• Dual function: coatoms()

meet (x, y=None)

Return the meet of given elements in the lattice.

INPUT:

• x, y – two elements of the (semi)lattice OR
• x – a list or tuple of elements

EXAMPLES:

```
sage: D = posets.DiamondPoset(5)
sage: D.meet(1, 2)
0
sage: D.meet(1, 1)
1
sage: D.meet(1, 0)
0
sage: D.meet(1, 4)
1
```

Using list of elements as an argument. Meet of empty list is the bottom element:

```
sage: B4=posets.BooleanLattice(4)
sage: B4.meet([3,5,6])
0
sage: B4.meet([])
15
```

For non-facade lattices operator * works for meet:

```
```
```python
sage: L = posets.PentagonPoset(facade=False)
sage: L(1) * L(2)
0
```

```python
>>> from sage.all import *
>>> L = posets.PentagonPoset(facade=False)
>>> L(Integer(1)) * L(Integer(2))
0
```

See also:

- Dual function: `join()`

**meet_matrix()**

Return a matrix whose \((i, j)\) entry is \(k\), where `self.linear_extension()[k]` is the meet (greatest lower bound) of `self.linear_extension()[i]` and `self.linear_extension()[j]`.

** EXAMPLES:**

```python
sage: P = LatticePoset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade=False)
sage: M = P.meet_matrix(); M

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 2 & 2 & 0 & 2 & 2 & 2 \\
0 & 1 & 2 & 3 & 2 & 0 & 3 & 3 \\
0 & 0 & 2 & 2 & 4 & 0 & 4 & 4 \\
0 & 0 & 0 & 0 & 5 & 5 & 5 & 5 \\
0 & 0 & 2 & 2 & 5 & 6 & 6 & 6 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\
\end{bmatrix}
\]

True
True
False
```

```python
>>> from sage.all import *
>>> P = LatticePoset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],
[Integer(4),Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],
[Integer(7)],[]], facade=False)

>>> M = P.meet_matrix(); M

\[
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 1 & 0 & 0 & 1 & 1 \\
0 & 0 & 2 & 2 & 0 & 2 & 2 & 2 \\
0 & 1 & 2 & 3 & 2 & 0 & 3 & 3 \\
0 & 0 & 2 & 2 & 4 & 0 & 4 & 4 \\
0 & 0 & 0 & 0 & 5 & 5 & 5 & 5 \\
0 & 0 & 2 & 2 & 5 & 6 & 6 & 6 \\
0 & 1 & 2 & 3 & 4 & 5 & 6 & 7 \\
\end{bmatrix}
\]

>>> M[P(Integer(4)).vertex,P(Integer(3)).vertex] == P(Integer(0)).vertex
True
>>> M[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(2)).vertex
True
>>> M[P(Integer(5)).vertex,P(Integer(2)).vertex] == P(Integer(5)).vertex
False
```
**pseudocomplement** (*element*)

Return the pseudocomplement of *element*, if it exists.

The (meet-)pseudocomplement is the greatest element whose meet with given element is the bottom element. I.e. in a meet-semilattice with bottom element \( \emptyset \) the pseudocomplement of an element \( e \) is the element \( e^* \) such that \( e \land e^* = \emptyset \) and \( e' \leq e^* \) if \( e \land e' = \emptyset \).

See Wikipedia article Pseudocomplement.

**INPUT:**

- *element* – an element of the lattice.

**OUTPUT:**

An element of the lattice or None if the pseudocomplement does not exist.

**EXAMPLES:**

The pseudocomplement’s pseudocomplement is not always the original element:

```python
sage: L = LatticePoset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: L.pseudocomplement(2)
5
sage: L.pseudocomplement(5)
4
```

An element can have complements but no pseudocomplement, or vice versa:

```python
sage: L = LatticePoset({0: [1, 2], 1: [3, 4, 5], 2: [5], 3: [6],
....: 4: [6], 5: [6]})
sage: L.complements(1), L.pseudocomplement(1)
([], 2)
sage: L.complements(2), L.pseudocomplement(2)
([3, 4], None)
```

See also:

`is_pseudocomplemented()`
subjoinsemilattice \texttt{(elms)}

Return the smallest join-subsemilattice containing elements on the given list.

INPUT:

- \texttt{elms} – a list of elements of the lattice.

EXAMPLES:

\begin{verbatim}
sage: L = posets.DivisorLattice(1000)
sage: L_ = L.subjoinsemilattice([2, 25, 125]); L_
sFinite join-semilattice containing 5 elements
sage: sorted(L_.list())
[2, 25, 50, 125, 250]
\end{verbatim}

See also:

- Dual function: \texttt{submeetsemilattice()}

submeetsemilattice \texttt{(elms)}

Return the smallest meet-subsemilattice containing elements on the given list.

INPUT:

- \texttt{elms} – a list of elements of the lattice.

EXAMPLES:

\begin{verbatim}
sage: L = posets.DivisorLattice(1000)
sage: L_ = L.submeetsemilattice([200, 250, 125]); L_
sFinite meet-semilattice containing 5 elements
sage: L_.list()
[25, 50, 200, 125, 250]
\end{verbatim}

See also:

- Dual function: \texttt{subjoinsemilattice()}

sage.combinat.posets.lattices.JoinSemilattice \texttt{\texttt{(data=None, *args, **options)}}

Construct a join semi-lattice from various forms of input data.

INPUT:

- \texttt{data, *args, **options} – data and options that will be passed down to \texttt{Poset()} to construct a poset that is also a join semilattice
See also:

\begin{verbatim}
Poset(), MeetSemilattice(), LatticePoset()
\end{verbatim}

EXAMPLES:

Using data that defines a poset:

\begin{verbatim}
sage: JoinSemilattice([[1,2],[3],[3]])
Finite join-semilattice containing 3 elements

sage: JoinSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite join-semilattice containing 3 elements
\end{verbatim}

Using a previously constructed poset:

\begin{verbatim}
sage: P = Poset([[1,2],[3],[3]])
sage: J = JoinSemilattice(P); J
Finite join-semilattice containing 3 elements

sage: type(J)
<class 'sage.combinat.posets.lattices.FiniteJoinSemilattice_with_category'>
\end{verbatim}

If the data is not a lattice, then an error is raised:

\begin{verbatim}
sage: JoinSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
                      'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
... 
LatticeError: no join for b and c
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> JoinSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
                      'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
... 
LatticeError: no join for b and c
\end{verbatim}

sage.combinat.posets.lattices.LatticePoset (data=None, *args, **options)

Construct a lattice from various forms of input data.

INPUT:

\begin{itemize}
\item data,*args,**options – data and options that will be passed down to Poset() to construct a poset that is also a lattice.
\end{itemize}
OUTPUT:

An instance of `FiniteLatticePoset`.

See also:

`Posets`, `FiniteLatticePosets`, `JoinSemiLattice()`, `MeetSemiLattice()`

EXAMPLES:

Using data that defines a poset:

```
sage: LatticePoset([[1,2],[3],[3]])
Finite lattice containing 3 elements

sage: LatticePoset([[1,2],[3],[3]], cover_relations = True)
Finite lattice containing 3 elements
```

Using a previously constructed poset:

```
sage: P = Poset([[1,2],[3],[3]])
sage: L = LatticePoset(P); L
Finite lattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteLatticePoset_with_category'>
```

If the data is not a lattice, then an error is raised:

```
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: LatticePoset((elms, rels))
Traceback (most recent call last):
...
ValueError: not a meet-semilattice: no bottom element
```

```
```
Creating a facade lattice:

```python
sage: L = LatticePoset([[1,2],[3],[3]], facade = True)
sage: L.category()
Category of facade finite enumerated lattice posets
sage: parent(L[0])
Integer Ring
sage: TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

```python
>>> from sage.all import *

>>> L = LatticePoset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]], facade=True)

>>> L.category()
Category of facade finite enumerated lattice posets

>>> parent(L[Integer(0)])
Integer Ring

>>> TestSuite(L).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

`sage.combinat.posets.lattices.MeetSemilattice(data=None, *args, **options)`

Construct a meet semi-lattice from various forms of input data.

**INPUT:**

- `data, *args, **options` – data and options that will be passed down to `Poset()` to construct a poset that is also a meet semilattice.

**See also:**

`Poset(), JoinSemilattice(), LatticePoset()`

**EXAMPLES:**

Using data that defines a poset:

```python
sage: MeetSemilattice([[1,2],[3],[3]])
Finite meet-semilattice containing 3 elements

sage: MeetSemilattice([[1,2],[3],[3]], cover_relations = True)
Finite meet-semilattice containing 3 elements
```

```python
>>> from sage.all import *

>>> MeetSemilattice([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]])
Finite meet-semilattice containing 3 elements

>>> MeetSemilattice([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]], cover_relations = True)
Finite meet-semilattice containing 3 elements
```

Using a previously constructed poset:

```python
sage: P = Poset([[1,2],[3],[3]])
sage: L = MeetSemilattice(P); L
Finite meet-semilattice containing 3 elements
sage: type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```
```python
>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2)],[Integer(3)],[Integer(3)]]
Finite meet-semilattice containing 3 elements
>>> type(L)
<class 'sage.combinat.posets.lattices.FiniteMeetSemilattice_with_category'>
```

If the data is not a lattice, then an error is raised:

```python
sage: MeetSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....: 'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
... LatticeError: no meet for e and d
```

```
>>> from sage.all import *
>>> MeetSemilattice({'a': ['b', 'c'], 'b': ['d', 'e'],
....: 'c': ['d', 'e'], 'd': ['f'], 'e': ['f']})
Traceback (most recent call last):
... LatticeError: no meet for e and d
```

### 5.1.183 Linear Extensions of Posets

This module defines two classes:

- `LinearExtensionOfPoset`
- `LinearExtensionsOfPoset`
- `LinearExtensionsOfPosetWithHooks`
- `LinearExtensionsOfForest`

**Classes and methods**

```python
class sage.combinat.posets.linear_extensions.LinearExtensionOfPoset
    Bases: ClonableArray

A linear extension of a finite poset \( P \) of size \( n \) is a total ordering \( \pi := \pi_0\pi_1\ldots\pi_{n-1} \) of its elements such that \( i < j \) whenever \( \pi_i < \pi_j \) in the poset \( P \).

When the elements of \( P \) are indexed by \( \{1, 2, \ldots, n\} \), \( \pi \) denotes a permutation of the elements of \( P \) in one-line notation.

**INPUT:**

- `linear_extension` – a list of the elements of \( P \)
- `poset` – the underlying poset \( P \)

**See also:**

`Poset, LinearExtensionsOfPoset`

**EXAMPLES:**
sage: P = Poset(((1,2,3,4), [[1,3],[1,4],[2,3]]),
  linear_extension=True, facade=False)
sage: p = P.linear_extension([1,4,2,3]); p
[1, 4, 2, 3]
sage: p.parent()
The set of all linear extensions of
Finite poset containing 4 elements with distinguished linear extension
sage: p[0], p[1], p[2], p[3]
(1, 4, 2, 3)

Following Schützenberger and later Haiman and Malvenuto-Reutenauer, Stanley [Stan2009] defined a promotion
and evacuation operator on any finite poset \( P \) using operators \( \tau_i \) on the linear extensions of \( P \):

sage: p.promotion()
[1, 2, 3, 4]
sage: Q = p.promotion().to_poset()
sage: Q.cover_relations()
[[1, 3], [1, 4], [2, 3]]
sage: Q == P
True
sage: p.promotion(3)
[1, 4, 2, 3]
sage: Q = p.promotion(3).to_poset()
sage: Q == P
False
sage: Q.cover_relations()
[[1, 2], [1, 4], [3, 4]]
check ()

Checks whether self is indeed a linear extension of the underlying poset.

evacuation ()

Compute evacuation on the linear extension of a poset.

Evacuation on a linear extension $\pi$ of length $n$ is defined as $\pi(\tau_1 \cdots \tau_{n-1})(\tau_1 \cdots \tau_{n-2}) \cdots (\tau_1)$. For more details see [Stan2009].

See also:

tau (), promotion ()

EXAMPLES:

```python
sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: p = P.linear_extension([1,2,3,4,5,6,7])
sage: p.evacuation()
[1, 4, 2, 3, 7, 5, 6]
sage: p.evacuation().evacuation() == p
True
```

is_greedy ()

Return True if the linear extension is greedy.

A linear extension $[e_1, e_2, \ldots, e_n]$ is greedy if for every $i$ either $e_{i+1}$ covers $e_i$ or all upper covers of $e_i$ have at least one lower cover that is not in $[e_1, e_2, \ldots, e_i]$.

Informally said a linear extension is greedy if it “always goes up when possible” and so has no unnecessary jumps.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()  # needs sage.modules
sage: for l in P.linear_extensions():  # needs sage.modules
.....:     if not l.is_greedy():
.....:         print(l)
[0, 2, 1, 3, 4]
```

```python
>>> from sage.all import *
>>> P = posets.PentagonPoset()  # needs sage.modules
>>> for l in P.linear_extensions():  # needs sage.modules
.....:     if not l.is_greedy():
.....:         print(l)
[0, 2, 1, 3, 4]
```
is_supergreedy()

Return True if the linear extension is supergreedy.

A linear extension of a poset $P$ with elements $\{x_1, x_2, ..., x_t\}$ is super greedy, if it can be obtained using the following algorithm: choose $x_1$ to be a minimal element of $P$; suppose $X = \{x_1, ..., x_i\}$ have been chosen; let $M$ be the set of minimal elements of $P \setminus X$. If there is an element of $M$ which covers an element $x_j$ in $X$, then let $x_{i+1}$ be one of these such that $j$ is maximal; otherwise, choose $x_{i+1}$ to be any element of $M$.

Informally, a linear extension is supergreedy if it “always goes up and recedes the least”; in other words, supergreedy linear extensions are depth-first linear extensions. For more details see [KTZ1987].

EXAMPLES:

```python
sage: X = [0,1,2,3,4,5,6]
sage: Y = [[0,5],[1,4],[1,5],[3,6],[4,3],[5,6],[6,2]]
sage: P = Poset((X,Y), cover_relations=True, facade=False)
sage: for l in P.linear_extensions():
    if l.is_supergreedy():
        print(l)
[1, 4, 3, 0, 5, 6, 2]
[0, 1, 4, 3, 5, 6, 2]
[0, 1, 5, 4, 3, 6, 2]
```

```python
>>> from sage.all import *
>>> X = [Integer(0),Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
      Integer(6)]
>>> Y = [[Integer(0),Integer(5)],[Integer(1),Integer(4)],[Integer(1),
      Integer(5)],[Integer(3),Integer(6)],[Integer(4),Integer(3)],[Integer(5),
      Integer(6)],[Integer(6),Integer(2)]]
>>> P = Poset((X,Y), cover_relations=True, facade=False)
>>> for l in P.linear_extensions():
    if l.is_supergreedy():
        print(l)
[1, 4, 3, 0, 5, 6, 2]
[0, 1, 4, 3, 5, 6, 2]
[0, 1, 5, 4, 3, 6, 2]
```

```python
>>> Q = posets.PentagonPoset()  # needs sage.modules
>>> for l in Q.linear_extensions():
    if not l.is_supergreedy():
        print(l)
[0, 2, 1, 3, 4]
```

(continues on next page)
... print(l)
[0, 2, 1, 3, 4]

jump_count()

Return the number of jumps in the linear extension.

A jump in a linear extension \([e_1, e_2, \ldots, e_n]\) is a pair \((e_i, e_{i+1})\) such that \(e_{i+1}\) does not cover \(e_i\).

See also:

• sage.combinat.posets.posets.FinitePoset.jump_number()

EXAMPLES:

```
sage: B3 = posets.BooleanLattice(3)
sage: l1 = B3.linear_extension((0, 1, 2, 3, 4, 5, 6, 7))
sage: l1.jump_count()
3
sage: l2 = B3.linear_extension((0, 1, 2, 4, 3, 5, 6, 7))
sage: l2.jump_count()
5
```

poset()

Return the underlying original poset.

EXAMPLES:

```
sage: P = Poset(((1,2,3,4), [(1,2),[2,3],[1,4]]))
sage: p = P.linear_extension([1,2,4,3])
sage: p.poset()
Finite poset containing 4 elements
```

promotion(i=1)

Compute the (generalized) promotion on the linear extension of a poset.

INPUT:

• i – (default: 1) an integer between 1 and \(n - 1\), where \(n\) is the cardinality of the poset
The \( i \)-th generalized promotion operator \( \partial_i \) on a linear extension \( \pi \) is defined as \( \pi \tau_i \tau_{i+1} \cdots \tau_{n-1} \), where \( n \) is the size of the linear extension (or size of the underlying poset).

For more details see [Stan2009].

See also:

\( \tau() \), \( \text{evacuation()} \)

EXAMPLES:

\[
\begin{align*}
\text{sage: } P &= \text{Poset}(([1,2,3,4,5,6,7], [(1,2), (1,4), (2,3), (2,5), (3,6), (4,7), (5, 6)])) \\
\text{sage: } p &= P.\text{linear_extension}([1,2,3,4,5,6,7]) \\
\text{sage: } q &= p.\text{promotion}(4); q \quad [1, 2, 3, 5, 6, 4, 7] \\
\text{sage: } p.\text{to_poset}() == q.\text{to_poset}() \quad \text{False} \\
\text{sage: } p.\text{to_poset}().\text{is_isomorphic}(q.\text{to_poset}()) \quad \text{True}
\end{align*}
\]

3 [1, 2, 4, 3] [1, 2, 3, 4]

to_poset()  

Return the poset associated to the linear extension self.

This method returns the poset obtained from the original poset $P$ by relabelling the $i$-th element of self to the $i$-th element of the original poset, while keeping the linear extension of the original poset.

For a poset with default linear extension $1,...,n$, self can be interpreted as a permutation, and the relabelling is done according to the inverse of this permutation.

EXAMPLES:

sage: P = Poset(((1,2,3,4), ([1,2],[1,3],[3,4])), linear_extension=True,
... facade=False)
sage: p = P.linear_extension([1,3,4,2])
sage: Q = p.to_poset(); Q

(continues on next page)
Finite poset containing 4 elements with distinguished linear extension

\begin{verbatim}
sage: P == Q
False

>>> from sage.all import *
>>> P = Poset(((Integer(1),Integer(2),Integer(3),Integer(4)), [[Integer(1), Integer(2)], [Integer(1), Integer(3)], [Integer(3), Integer(4)]]), linear_extension=True, facade=False)
>>> Q = p.to_poset(); Q
Finite poset containing 4 elements with distinguished linear extension

>>> P == Q
False
\end{verbatim}

The default linear extension remains the same:

\begin{verbatim}
sage: list(P)
[1, 2, 3, 4]
sage: list(Q)
[1, 2, 3, 4]

>>> from sage.all import *
>>> list(P)
[1, 2, 3, 4]
>>> list(Q)
[1, 2, 3, 4]
\end{verbatim}

But the relabelling can be seen on cover relations:

\begin{verbatim}
sage: P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
sage: Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]

sage: p = P.linear_extension([1,2,3,4])
sage: Q = p.to_poset()
sage: P == Q
True

>>> from sage.all import *
>>> P.cover_relations()
[[1, 2], [1, 3], [3, 4]]
>>> Q.cover_relations()
[[1, 2], [1, 4], [2, 3]]

>>> p = P.linear_extension([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> Q = p.to_poset()
>>> P == Q
True
\end{verbatim}

\begin{verbatim}
class sage.combinat.posets.linear_extensions.LinearExtensionsOfForest(poset, facade)

Bases: LinearExtensionsOfPoset

Linear extensions such that the poset is a forest.
\end{verbatim}
Cardinality()

Use Atkinson’s algorithm to compute the number of linear extensions.

EXAMPLES:

```python
sage: from sage.combinat.posets.forest import ForestPoset
sage: from sage.combinat.posets.poset_examples import Posets
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
# needs sage.modules
4
sage: Q = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
# needs sage.modules
4
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.forest import ForestPoset
>>> from sage.combinat.posets.poset_examples import Posets
# needs sage.modules
4
# needs sage.modules
4
```

class sage.combinat.posets.linear_extensions.LinearExtensionsOfMobile (poset, facade)

Bases: LinearExtensionsOfPoset

Linear extensions for a mobile poset.

cardinality()

Return the number of linear extensions by using the determinant formula for counting linear extensions of mobiles.

EXAMPLES:

```python
sage: from sage.combinat.posets.mobile import MobilePoset
sage: M = MobilePoset(DiGraph([[0,1,2,3,4,5,6,7,8], [(1,0),(3,0),(2,1),(2,3),(4,3), (5,4),(5,6),(7,4),(7,8)]]))
# needs sage.modules
1098
sage: M1 = posets.RibbonPoset(6, [1,3])
# needs sage.modules
61
```
```
sage: P = posets.MobilePoset(posets.RibbonPoset(7, [1,3]),
                         dual=True),
....: (1: [posets.YoungDiagramPoset([3, 2]),
    ....: anchor=(4, 2, posets.ChainPoset(6)))
sage: P.linear_extensions().cardinality()    # needs sage.combinat sage.modules
361628701868606400
```

```
>>> from sage.all import *
>>> from sage.combinat.posets.mobile import MobilePoset
>>> M = MobilePoset(DiGraph([(Integer(0),Integer(1),Integer(2),Integer(3), Integer(4),Integer(5),Integer(6),Integer(7),Integer(8)], [(Integer(1), Integer(0)),(Integer(3),Integer(0)),(Integer(2),Integer(1)),(Integer(2), Integer(3)),(Integer(4),
... Integer(3)), (Integer(5),Integer(4)),(Integer(5),Integer(6)),(Integer(7),
... Integer(4), (Integer(7),Integer(8))]))
>>> M.linear_extensions().cardinality()    # needs sage.modules
1098
>>> M1 = posets.RibbonPoset(Integer(6), [Integer(1),Integer(3)]
>>> M1.linear_extensions().cardinality()    # needs sage.modules
61

>>> P = posets.MobilePoset(posets.RibbonPoset(Integer(7), [Integer(1),Integer(3)]),
                         # needs sage.combinat sage.modules
... (Integer(1): [posets.YoungDiagramPoset([Integer(3),
    ... Integer(2)], dual=True)],
    ... Integer(3): [posets.
      DoubleTailedDiamond(Integer(6))]),
    ... anchor=(Integer(4), Integer(2), posets.
      ChainPoset(Integer(6)))))
>>> P.linear_extensions().cardinality()    # needs sage.combinat sage.modules
361628701868606400
```

```
class sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset(poset, facade)

Bases: UniqueRepresentation, Parent

The set of all linear extensions of a finite poset

INPUT:

- poset – a poset $P$ of size $n$
- facade – a boolean (default: False)

See also:

- sage.combinat.posets.posets.FinitePoset.linear_extensions()

EXAMPLES:
```
sage: elms = [1, 2, 3, 4]
sage: rels = [[1, 3], [1, 4], [2, 3]]
sage: P = Poset((elms, rels), linear_extension=True)
sage: L = P.linear_extensions(); L
The set of all linear extensions of
Finite poset containing 4 elements with distinguished linear extension
sage: L.cardinality()
5
sage: L.list()
[[1, 2, 3, 4], [2, 1, 3, 4], [2, 1, 4, 3], [1, 4, 2, 3], [1, 2, 4, 3]]
sage: L.an_element()
[1, 2, 3, 4]
sage: L.poset()
Finite poset containing 4 elements with distinguished linear extension

>>> from sage.all import *
>>> elms = [Integer(1), Integer(2), Integer(3), Integer(4)]
>>> rels = [[Integer(1), Integer(3)], [Integer(1), Integer(4)], [Integer(2),
Integer(3)]]
>>> P = Poset((elms, rels), linear_extension=True)
>>> L = P.linear_extensions(); L
The set of all linear extensions of
Finite poset containing 4 elements with distinguished linear extension
>>> L.cardinality()
5
>>> L.list()
[[1, 2, 3, 4], [2, 1, 3, 4], [2, 1, 4, 3], [1, 4, 2, 3], [1, 2, 4, 3]]

Element

alias of LinearExtensionOfPoset
cardinality()

Return the number of linear extensions.

EXAMPLES:

sage: N = Poset({0: [2, 3], 1: [3]})
sage: N.linear_extensions().cardinality()
5

>>> from sage.all import *
>>> N = Poset({Integer(0): [Integer(2), Integer(3)], Integer(1): [Integer(3)]})

markov_chain_digraph(action='promotion', labeling='identity')

Return the digraph of the action of generalized promotion or tau on self

INPUT:

• action – ‘promotion’ or ‘tau’ (default: ‘promotion’)
• labeling – ‘identity’ or ‘source’ (default: ‘identity’)

Todo:
• generalize this feature by accepting a family of operators as input
• move up in some appropriate category

This method creates a graph with vertices being the linear extensions of a given finite poset and an edge from \( \pi \) to \( \pi' \) if \( \pi' = \pi \circ \partial_i \) where \( \partial_i \) is the promotion operator (see `promotion()`) if action is set to promotion and \( \partial_i \) (see `tau()`) if action is set to tau. The label of the edge is \( i \) (resp. \( \pi_i \)) if labeling is set to identity (resp. source).

EXAMPLES:

```python
sage: P = Poset(((1, 2, 3, 4), [[1, 3], [1, 4], [2, 3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: G = L.markov_chain_digraph(); G
Looped multi-digraph on 5 vertices
sage: G.vertices(sort=True, key=repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: G.edges(sort=True, key=repr)
[(([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 3, 4], [1, 4, 2, 3], 1), ([1, 2, 4, 3], [1, 2, 3, 4], 3), ([1, 2, 4, 3], [1, 4, 2, 3], 4), ([1, 4, 2, 3], [1, 2, 3, 4], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([1, 4, 2, 3], [2, 1, 3, 4], 1), ([1, 4, 2, 3], [2, 1, 4, 3], 2), ([2, 1, 3, 4], [1, 2, 4, 3], 3), ([2, 1, 3, 4], [1, 4, 2, 3], 1), ([2, 1, 3, 4], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [1, 2, 3, 4], 1), ([2, 1, 4, 3], [1, 4, 2, 3], 4), ([2, 1, 4, 3], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [2, 1, 4, 3], 4)]
```

```python
sage: G = L.markov_chain_digraph(labeling=source)
sage: G.vertices(sort=True, key=repr)
[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]
sage: G.edges(sort=True, key=repr)
[(([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 3, 4], [1, 4, 2, 3], 1), ([1, 2, 4, 3], [1, 2, 3, 4], 3), ([1, 2, 4, 3], [1, 4, 2, 3], 4), ([1, 4, 2, 3], [1, 2, 3, 4], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([1, 4, 2, 3], [2, 1, 3, 4], 1), ([1, 4, 2, 3], [2, 1, 4, 3], 2), ([2, 1, 3, 4], [1, 2, 4, 3], 3), ([2, 1, 3, 4], [1, 4, 2, 3], 1), ([2, 1, 3, 4], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [1, 2, 3, 4], 1), ([2, 1, 4, 3], [1, 4, 2, 3], 4), ([2, 1, 4, 3], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [2, 1, 4, 3], 4)]
```

>>> from sage.all import *
>>> P = Poset(((Integer(1), Integer(2), Integer(3), Integer(4)), [[Integer(1), Integer(2), Integer(3)]], [Integer(1), Integer(2), Integer(3)])), linear_extension=True)
(continues on next page)
\[\text{extension=True}\]

\[
\begin{align*}
L &= P.linear_extensions() \\
G &= L.markov_chain_digraph(); G \\
\text{Looped multi-digraph on 5 vertices} \\
G.vertices(sort=True, key=repr) \\
[[1, 2, 3, 4], [1, 2, 4, 3], [2, 1, 3, 4], [2, 1, 4, 3]] \\
G.edges(sort=True, key=repr) \\
[([1, 2, 3, 4], [1, 2, 3, 4], 4), ([1, 2, 3, 4], [1, 2, 4, 3], 2), ([1, 2, 3, 4], [1, 2, 4, 3], 3), ([1, 2, 3, 4], [1, 2, 4, 3], 4), ([1, 2, 3, 4], [1, 4, 2, 3], 3), ([1, 2, 3, 4], [2, 1, 4, 3], 2), ([1, 2, 3, 4], [2, 1, 4, 3], 3), ([1, 4, 2, 3], [1, 2, 3, 4], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([1, 4, 2, 3], [2, 1, 4, 3], 2), ([1, 4, 2, 3], [2, 1, 4, 3], 3), ([2, 1, 3, 4], [1, 2, 4, 3], 1), ([2, 1, 3, 4], [1, 4, 2, 3], 2), ([2, 1, 3, 4], [2, 1, 3, 4], 3), ([2, 1, 3, 4], [2, 1, 3, 4], 4), ([2, 1, 3, 4], [2, 1, 4, 3], 2), ([2, 1, 3, 4], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [1, 2, 3, 4], 1), ([2, 1, 4, 3], [1, 4, 2, 3], 2), ([2, 1, 4, 3], [2, 1, 3, 4], 1), ([2, 1, 4, 3], [2, 1, 4, 3], 3), ([2, 1, 4, 3], [2, 1, 4, 3], 4)]
\end{align*}
\]

The edges of the graph are by default colored using blue for edge 1, red for edge 2, green for edge 3, and yellow for edge 4:

\[
\text{sage: view(G)} \quad \# \text{optional - dot2tex graphviz, not tested (opens external window)}
\]

\[
\text{>>> from sage.all import *} \\
\text{>>> view(G)} \quad \# \text{optional - dot2tex graphviz, not tested (opens external window)}
\]

Alternatively, one may get the graph of the action of the \texttt{tau} operator:

\[
\text{sage: G = L.markov_chain_digraph(action=’tau’); G} \\
\text{Looped multi-digraph on 5 vertices} \\
\text{sage: G.vertices(sort=True, key=repr)} \\
[[1, 2, 3, 4], [1, 2, 4, 3], [2, 1, 3, 4], [2, 1, 4, 3]] \\
\text{sage: G.edges(sort=True, key=repr)} \\
[([1, 2, 3, 4], [1, 2, 3, 4], 2), ([1, 2, 3, 4], [1, 2, 4, 3], 3), ([1, 2, 3, 4], [1, 4, 2, 3], 2), ([1, 2, 3, 4], [2, 1, 4, 3], 2), ([1, 2, 4, 3], [1, 2, 3, 4], 2), ([1, 2, 4, 3], [1, 4, 2, 3], 3), ([1, 4, 2, 3], [1, 2, 3, 4], 2), ([1, 4, 2, 3], [1, 4, 2, 3], 3), ([2, 1, 3, 4], [1, 2, 4, 3], 1), ([2, 1, 3, 4], [2, 1, 4, 3], 2), ([2, 1, 4, 3], [1, 2, 3, 4], 1), ([2, 1, 4, 3], [1, 4, 2, 3], 2), ([2, 1, 4, 3], [2, 1, 3, 4], 1), ([2, 1, 4, 3], [2, 1, 4, 3], 3)]
\]

(continues on next page)
\[ \{ [1, 2, 3, 4], [1, 2, 4, 3], 1 \}, \{ [1, 2, 4, 3], [1, 4, 2, 3], 1 \}, \{ [1, 2, 4, 3], [1, 4, 2, 3], 2 \}, \{ [1, 2, 4, 3], [2, 1, 3, 4], 2 \}, \{ [1, 2, 4, 3], [2, 1, 3, 4], 3 \}, \{ [1, 2, 4, 3], [2, 1, 4, 3], 1 \}, \{ [1, 2, 4, 3], [2, 1, 4, 3], 2 \}, \{ [1, 2, 4, 3], [2, 1, 4, 3], 3 \}, \{ [1, 2, 3, 4], [1, 2, 4, 3], 1 \}, \{ [1, 2, 3, 4], [1, 2, 4, 3], 2 \}, \{ [1, 2, 3, 4], [1, 4, 2, 3], 2 \}, \{ [1, 2, 3, 4], [2, 1, 3, 4], 2 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 2 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 3 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 3 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 3 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 3 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 2 \}, \{ [1, 2, 3, 4], [2, 1, 4, 3], 1 \} \]

```
sage: view(G) # optional - dot2tex graphviz, not tested (opens external window)
```

```python
from sage.all import *

G = L.markov_chain_digraph(action=tau); G
Looped multi-digraph on 5 vertices

G.vertices(sort=True, key=repr)
[[[1, 2, 3, 4], [1, 2, 4, 3], [1, 4, 2, 3], [2, 1, 3, 4], [2, 1, 4, 3]]

G.edges(sort=True, key=repr)
[[[1, 2, 3, 4], [1, 2, 3, 4], 2], [[1, 2, 4, 3], [1, 4, 2, 3], 2], [[1, 2, 4, 3], [2, 1, 3, 4], 2], [[1, 2, 4, 3], [2, 1, 4, 3], 2], [[1, 2, 4, 3], [2, 1, 4, 3], 3], [[1, 2, 4, 3], [2, 1, 4, 3], 3], [[1, 2, 4, 3], [2, 1, 4, 3], 3], [[1, 2, 4, 3], [2, 1, 4, 3], 3]]

```

See also:

markov_chain_transition_matrix(), promotion(), tau()

markov_chain_transition_matrix (action='promotion', labeling='identity')

Return the transition matrix of the Markov chain for the action of generalized promotion or tau on self

INPUT:

- action - 'promotion' or 'tau' (default: 'promotion')
- labeling - 'identity' or 'source' (default: 'identity')

This method yields the transition matrix of the Markov chain defined by the action of the generalized promotion operator \( \partial_i \) (resp. \( \tau_i \)) on the set of linear extensions of a finite poset. Here the transition from the linear extension \( \pi \) to \( \pi' \), where \( \pi' = \pi \partial_i \) (resp. \( \pi' = \pi \tau_i \)) is counted with weight \( x_i \) (resp. \( x_{\pi,i} \) if labeling is set to 'source').

EXAMPLES:

```
sage: P = Poset(((1,2,3,4), [[1,3],[1,4],[2,3]]), linear_extension=True)
sage: L = P.linear_extensions()
sage: L.markov_chain_transition_matrix()

See also:

*markov_chain_digraph()*, *promotion()*, *tau()*

**poset()**

Return the underlying original poset.

**EXAMPLES:**

```python
sage: P = Poset(((1,2,3,4), ((1,2), (2,3), (1,4))))
sage: L = P.linear_extensions()
sage: L.poset()
Finite poset containing 4 elements
```

```python
>>> from sage.all import *

>>> from sage.combinat.posets.poset_examples import Posets

>>> P = Posets.YoungDiagramPoset(Partition([3,2]), dual=True)
>>> L = P.linear_extensions()
>>> L.poset()
Finite poset containing 4 elements
```

**class** *sage.combinat.posets.linear_extensions.LinearExtensionsOfPosetWithHooks (poset, facade)*

**Bases:** *LinearExtensionsOfPoset*

Linear extensions such that the poset has well-defined hook lengths (i.e., d-complete).

**cardinality()**

Count the number of linear extensions using a hook-length formula.

**EXAMPLES:**

```python
sage: from sage.combinat.posets.poset_examples import Posets

sage: P = Posets.YoungDiagramPoset(Partition([3,2]), dual=True)
# needs sage.combinat sage.modules
sage: P.linear_extensions().cardinality()
# needs sage.combinat sage.modules

>>> P.linear_extensions().cardinality()  # needs sage.combinat sage.modules
5
```
5.1.184 Möbius Algebras

class sage.combinat.posets.moebius_algebra.BasisAbstract (R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)

Bases: CombinatorialFreeModule, BindableClass

Abstract base class for a basis.

class sage.combinat.posets.moebius_algebra.MoebiusAlgebra (R, L)

Bases: Parent, UniqueRepresentation

The Möbius algebra of a lattice.

Let \( L \) be a lattice. The Möbius algebra \( M_L \) was originally constructed by Solomon [Solomon67] and has a natural basis \( \{ E_x \mid x \in L \} \) with multiplication given by \( E_x \cdot E_y = E_{x \lor y} \). Moreover this has a basis given by orthogonal idempotents \( \{ I_x \mid x \in L \} \) (so \( I_x I_y = \delta_{xy} I_x \) where \( \delta \) is the Kronecker delta) related to the natural basis by

\[
I_x = \sum_{x \leq y} \mu_L(x, y) E_y,
\]

where \( \mu_L \) is the Möbius function of \( L \).

**Note:** We use the join \( \lor \) for our multiplication, whereas [Greene73] and [Etienne98] define the Möbius algebra using the meet \( \land \). This is done for compatibility with QuantumMoebiusAlgebra.

REFERENCES:

class E (M, prefix=None)

Bases: BasisAbstract

The natural basis of a Möbius algebra.

Let \( E_x \) and \( E_y \) be basis elements of \( M_L \) for some lattice \( L \). Multiplication is given by \( E_x E_y = E_{x \lor y} \).

one ()

Return the element 1 of self.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.moebius_algebra(QQ).E()
sage: E.one()
```

```python
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> E = L.moebius_algebra(QQ).E()
>>> E.one()
```

product_on_basis (x, y)

Return the product of basis elements indexed by \( x \) and \( y \).

EXAMPLES:
class I(M, prefix='I')

Bases: BasisAbstract

The (orthogonal) idempotent basis of a Möbius algebra.

Let $I_x$ and $I_y$ be basis elements of $M_L$ for some lattice $L$. Multiplication is given by $I_x I_y = \delta_{xy} I_x$ where $\delta_{xy}$ is the Kronecker delta.

one()

Return the element 1 of self.

EXAMPLES:

>>> from sage.all import *

>>> L = posets.BooleanLattice(Integer(4))

>>> I = L.moebius_algebra(QQ).I()

>>> I.one()

product_on_basis(x, y)

Return the product of basis elements indexed by $x$ and $y$.

EXAMPLES:

>>> from sage.all import *

>>> L = posets.BooleanLattice(Integer(4))

>>> I = L.moebius_algebra(QQ).I()

>>> I.product_on_basis(Integer(5), Integer(14))

(continues on next page)
a_realization()

Return a particular realization of self (the $B$-basis).

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.a_realization()
Moebius algebra of Finite lattice containing 16 elements
over Rational Field in the natural basis
```

idempotent

alias of $I$

lattice()

Return the defining lattice of self.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: M = L.moebius_algebra(QQ)
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

natural

alias of $E$

class sage.combinat.posets.moebius_algebra.MoebiusAlgebraBases(parent_with_realization)

Bases: Category_realization_of_parent

The category of bases of a Möbius algebra.

INPUT:

- `base` – a Möbius algebra
class ElementMethods
    Bases: object

class ParentMethods
    Bases: object

    one()
    Return the element 1 of self.
    EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: all(C.one() * b == b for b in C.basis())
True
```

    product_on_basis(x, y)
    Return the product of basis elements indexed by x and y.
    EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: C = L.quantum_moebius_algebra().C()
sage: C.product_on_basis(5, 14)
q^3*C[15]
sage: C.product_on_basis(2, 8)
q^4*C[10]
```

    super_categories()
    The super categories of self.
    EXAMPLES:

```
sage: from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
sage: M = posets.BooleanLattice(4).moebius_algebra(QQ)
sage: bases = MoebiusAlgebraBases(M)
sage: bases.super_categories()
[Category of finite dimensional commutative algebras with basis over Rational Field,
 Category of realizations of Moebius algebra of Finite lattice containing 16 elements over Rational Field]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.posets.moebius_algebra import MoebiusAlgebraBases
>>> M = posets.BooleanLattice(Integer(4)).moebius_algebra(QQ)
>>> bases = MoebiusAlgebraBases(M)
>>> bases.super_categories()
[Category of finite dimensional commutative algebras with basis over Rational Field,
 Category of realizations of Moebius algebra of Finite lattice containing 16 elements over Rational Field]
```

class sage.combinat.posets.moebius_algebra.QuantumMoebiusAlgebra(L, q=None)

Bases: Parent, UniqueRepresentation

The quantum Möbius algebra of a lattice.

Let \( L \) be a lattice, and we define the quantum Möbius algebra \( M_L(q) \) as the algebra with basis \( \{ E_x \mid x \in L \} \) with multiplication given by

\[
E_x E_y = \sum_{z \geq a \geq x \lor y} \mu_L(a, z) q^{\text{crk} a} E_z,
\]

where \( \mu_L \) is the Möbius function of \( L \) and \( \text{crk} \) is the corank function (i.e., \( \text{crk} a = \text{rank} L - \text{rank} a \)). At \( q = 1 \), this reduces to the multiplication formula originally given by Solomon.

class C(M, prefix='C')

Bases: BasisAbstract

The characteristic basis of a quantum Möbius algebra.

The characteristic basis \( \{ C_x \mid x \in L \} \) of \( M_L \) for some lattice \( L \) is defined by

\[
C_x = \sum_{a \geq x} P(F^x(q)) E_a,
\]

where \( F^x = \{ y \in L \mid y \geq x \} \) is the principal order filter of \( x \) and \( P(F^x(q)) \) is the characteristic polynomial of the (sub)poset \( F^x \).

class E(M, prefix='E')

Bases: BasisAbstract

The natural basis of a quantum Möbius algebra.

Let \( E_x \) and \( E_y \) be basis elements of \( M_L \) for some lattice \( L \). Multiplication is given by

\[
E_x E_y = \sum_{z \geq a \geq x \lor y} \mu_L(a, z) q^{\text{crk} a} E_z,
\]

where \( \mu_L \) is the Möbius function of \( L \) and \( \text{crk} \) is the corank function (i.e., \( \text{crk} a = \text{rank} L - \text{rank} a \)).

one()

Return the element 1 of self.

EXAMPLES:

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: all(E.one() * b == b for b in E.basis())
True
```
```python
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(4))
>>> E = L.quantum_moebius_algebra().E()
>>> all(E.one() * b == b for b in E.basis())
True
```

**product_on_basis** *(x, y)*

Return the product of basis elements indexed by *x* and *y*.

**EXAMPLES:**

```python
sage: L = posets.BooleanLattice(4)
sage: E = L.quantum_moebius_algebra().E()
sage: E.product_on_basis(5, 14)
E[15]
sage: E.product_on_basis(2, 8)
```

### class KL *(M, prefix='KL')*

Bases: `BasisAbstract`

The Kazhdan-Lusztig basis of a quantum Möbius algebra.

The Kazhdan-Lusztig basis \( \{B_x \mid x \in L\} \) of \( M_L \) for some lattice \( L \) is defined by

\[
B_x = \sum_{y \geq x} P_{x,y}(q) E_a,
\]

where \( P_{x,y}(q) \) is the Kazhdan–Lusztig polynomial of \( L \), following the definition given in [EPW14].

**EXAMPLES:**

We construct some examples of Proposition 4.5 of [EPW14]:

```python
sage: M = posets.BooleanLattice(4).quantum_moebius_algebra()
sage: KL = M.KL()
(q^2+q^3)*KL[5] + (q+2*q^2+q^3)*KL[7] + (q+2*q^2+q^3)*KL[13] + (1+3*q+3*q^2+q^3)*KL[15]
(1+3*q+3*q^2+q^3)*KL[15]
(q+3*q^2+3*q^3+q^4)*KL[14] + (1+4*q+6*q^2+4*q^3+q^4)*KL[15]
```
a_realization()

Return a particular realization of self (the $B$-basis).

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.a_realization()
Quantum Moebius algebra of Finite lattice containing 16 elements
with $q=q$ over Univariate Laurent Polynomial Ring in $q$
over Integer Ring in the natural basis
```

characteristic_basis

alias of $C$

kazhdan_lusztig

alias of $KL$

lattice()

Return the defining lattice of self.

EXAMPLES:

```
sage: L = posets.BooleanLattice(4)
sage: M = L.quantum_moebius_algebra()
sage: M.lattice()
Finite lattice containing 16 elements
sage: M.lattice() == L
True
```

natural

alias of $E$
5.1.185 Catalog of posets and lattices

Some common posets can be accessed through the `posets.<tab>` object:

```
sage: posets.PentagonPoset()
Finite lattice containing 5 elements
```

Moreover, the set of all posets of order $n$ is represented by `Posets(n)`:

```
sage: Posets(5)
Posets containing 5 elements
```

The infinite set of all posets can be used to find minimal examples:

```
sage: for P in Posets():
    ....:    if not P.is_series_parallel():
    ....:        break
sage: P
Finite poset containing 4 elements
```

Catalog of common posets:

**Constructions**

```python
class sage.combinat.posets.poset_examples.Posets
    Bases: object
    A collection of posets and lattices.

EXAMPLES:
```

<sage: posets.BooleanLattice(3)
Finite lattice containing 8 elements
```sage: posets.ChainPoset(3)`
Finite lattice containing 3 elements
sage: posets.RandomPoset(17,.15)
Finite poset containing 17 elements

>>> from sage.all import *
>>> posets.BooleanLattice(Integer(3))
Finite lattice containing 8 elements
>>> posets.ChainPoset(Integer(3))
Finite lattice containing 3 elements
>>> posets.RandomPoset(Integer(17),RealNumber('15'))
Finite poset containing 17 elements

The category of all posets:
sage: Posets()
Category of posets

>>> from sage.all import *
>>> Posets()
Category of posets

The enumerated set of all posets on 3 elements, up to an isomorphism:
sage: Posets(3)
Posets containing 3 elements

>>> from sage.all import *
>>> Posets(Integer(3))
Posets containing 3 elements

See also:
Posets, FinitePosets, Poset()

static AntichainPoset (n, facade=None)
Return an antichain (a poset with no comparable elements) containing \( n \) elements.

INPUT:

- \( n \) (an integer) – number of elements
- facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:
sage: A = posets.AntichainPoset(6); A
Finite poset containing 6 elements

>>> from sage.all import *
>>> A = posets.AntichainPoset(Integer(6)); A
Finite poset containing 6 elements

static BooleanLattice (n, facade=None, use_subsets=False)
Return the Boolean lattice containing \( 2^n \) elements.

- \( n \) – integer; number of elements will be \( 2^n \)
Combinatorics, Release 10.4

- facade – boolean; whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

- use_subsets – boolean (default: False); if True, then label the elements by subsets of \{1, 2, \ldots, n\}; otherwise label the elements by 0, 1, 2, \ldots, 2^n – 1

EXAMPLES:

```
sage: posets.BooleanLattice(5)
Finite lattice containing 32 elements

sage: sorted(posets.BooleanLattice(2))
[0, 1, 2, 3]

sage: sorted(posets.BooleanLattice(2, use_subsets=True), key=list)
[{}, {1}, {1, 2}, {2}]
```

```
>>> from sage.all import *

>>> posets.BooleanLattice(Integer(5))
Finite lattice containing 32 elements

>>> posets.BooleanLattice(Integer(2))
[0, 1, 2, 3]

>>> posets.BooleanLattice(Integer(2), use_subsets=True), key=list)
[{}, {1}, {1, 2}, {2}]
```

static ChainPoset(n, facade=None)

Return a chain (a totally ordered poset) containing n elements.

- n (an integer) – number of elements.
- facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

EXAMPLES:

```
sage: C = posets.ChainPoset(6); C
Finite lattice containing 6 elements

sage: C.linear_extension()
[0, 1, 2, 3, 4, 5]
```

```
>>> from sage.all import *

>>> C = posets.ChainPoset(Integer(6)); C
Finite lattice containing 6 elements

>>> C.linear_extension()
[0, 1, 2, 3, 4, 5]
```

static CoxeterGroupAbsoluteOrderPoset(W, use_reduced_words=True)

Return the poset of elements of a Coxeter group with respect to absolute order.

INPUT:

- W – a Coxeter group
- use_reduced_words – boolean (default: True); if True, then the elements are labeled by their lexicographically minimal reduced word

EXAMPLES:
```
sage: W = CoxeterGroup(['B', 3])  # needs sage.groups
sage: posets.CoxeterGroupAbsoluteOrderPoset(W)  # needs sage.groups
Finite poset containing 48 elements

sage: W = WeylGroup(['B', 2], prefix='s')  # needs sage.groups
sage: posets.CoxeterGroupAbsoluteOrderPoset(W, False)  # needs sage.groups
Finite poset containing 8 elements
```

```
>>> from sage.all import *

>>> W = CoxeterGroup(['B', Integer(3)])  # needs sage.groups
>>> posets.CoxeterGroupAbsoluteOrderPoset(W)  # needs sage.groups
Finite poset containing 48 elements

>>> W = WeylGroup(['B', Integer(2)], prefix='s')  # needs sage.groups
>>> posets.CoxeterGroupAbsoluteOrderPoset(W, False)  # needs sage.groups
Finite poset containing 8 elements
```

**static Crown** (n, facade=None)

Return the crown poset of 2n elements.

In this poset every element i for 0 ≤ i ≤ n – 1 is covered by elements i + n and i + n + 1, except that n – 1 is covered by n and n + 1.

**INPUT:**

• n – number of elements, an integer at least 2

• facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

**EXAMPLES:**

```
sage: posets.Crown(3)
Finite poset containing 6 elements
```

```
>>> from sage.all import *

>>> posets.Crown(Integer(3))
Finite poset containing 6 elements
```

**static DexterSemilattice** (n)

Return the n-th Dexter meet-semilattice.

**INPUT:**

• n – a nonnegative integer (the index)

**OUTPUT:**

a finite meet-semilattice

The elements of the semilattice are *Dyck paths* in the \((n + 1 \times n)\)-rectangle.

**EXAMPLES:**
```python
sage: posets.DexterSemilattice(3)
Finite meet-semilattice containing 5 elements

sage: P = posets.DexterSemilattice(4); P
Finite meet-semilattice containing 14 elements

sage: len(P.maximal_chains())
15

sage: len(P.maximal_elements())
4

sage: P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1

>>> from sage.all import *

>>> posets.DexterSemilattice(Integer(3))
Finite meet-semilattice containing 5 elements

>>> P = posets.DexterSemilattice(Integer(4)); P
Finite meet-semilattice containing 14 elements

>>> len(P.maximal_chains())
15

>>> len(P.maximal_elements())
4

>>> P.chain_polynomial()
q^5 + 19*q^4 + 47*q^3 + 42*q^2 + 14*q + 1
```

REFERENCES:

- [Cha18]

**static DiamondPoset** (*n*, facade=None)

Return the lattice of rank two containing *n* elements.

**INPUT:**

- *n* – number of elements, an integer at least 3

  - facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

**EXAMPLES:**

```python
sage: posets.DiamondPoset(7)
Finite lattice containing 7 elements

>>> from sage.all import *

>>> posets.DiamondPoset(Integer(7))
Finite lattice containing 7 elements
```

**static DivisorLattice** (*n*, facade=None)

Return the divisor lattice of an integer.

Elements of the lattice are divisors of *n* and *x < y* in the lattice if *x* divides *y*.

**INPUT:**

- *n* – an integer

  - facade (boolean) – whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor
EXAMPLES:

```
sage: P = posets.DivisorLattice(12)
sage: sorted(P.cover_relations())
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]

sage: P = posets.DivisorLattice(10, facade=False)
sage: P(2) < P(5)
False
```

```
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(12))
>>> sorted(P.cover_relations())
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]

>>> P = posets.DivisorLattice(Integer(10), facade=False)
>>> P(Integer(2)) < P(Integer(5))
False
```

**static DoubleTailedDiamond(n)**

Return a double-tailed diamond of $2n + 2$ elements.

**INPUT:**

- `n` – a positive integer

**EXAMPLES:**

```
sage: P = posets.DoubleTailedDiamond(2); P
Finite d-complete poset containing 6 elements
sage: P.cover_relations()
[[1, 2], [2, 3], [2, 4], [3, 5], [4, 5], [5, 6]]
```

```
>>> from sage.all import *
>>> P = posets.DoubleTailedDiamond(Integer(2)); P
Finite d-complete poset containing 6 elements
>>> P.cover_relations()
[[1, 2], [2, 3], [2, 4], [3, 5], [4, 5], [5, 6]]
```

**static IntegerCompositions(n)**

Return the poset of integer compositions of the integer $n$.

A composition of a positive integer $n$ is a list of positive integers that sum to $n$. The order is reverse refinement: $[p_1, p_2, ..., p_l] < [q_1, q_2, ..., q_m]$ if $q$ consists of an integer composition of $p_1$, followed by an integer composition of $p_2$, and so on.

**EXAMPLES:**

```
sage: P = posets.IntegerCompositions(7); P
Finite poset containing 64 elements
sage: len(P.cover_relations())
192
```

```
>>> from sage.all import *
>>> P = posets.IntegerCompositions(Integer(7)); P
Finite poset containing 64 elements
>>> len(P.cover_relations())
192
```
**static IntegerPartitions(n)**

Return the poset of integer partitions on the integer n.

A partition of a positive integer n is a non-increasing list of positive integers that sum to n. If p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two parts of p (and sorting, if necessary).

**EXAMPLES:**

```sage
sage: P = posets.IntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
28
```

```python
>>> from sage.all import *
>>> P = posets.IntegerPartitions(Integer(7)); P
Finite poset containing 15 elements
>>> len(P.cover_relations())
28
```

**static IntegerPartitionsDominanceOrder(n)**

Return the lattice of integer partitions on the integer n ordered by dominance.

That is, if p = (p₁,...,pᵢ) and q = (q₁,...,qⱼ) are integer partitions of n, then p is greater than q if and only if p₁ + ... + pₖ > q₁ + ... + qₖ for all k.

**INPUT:**

- n – a positive integer

**EXAMPLES:**

```sage
sage: P = posets.IntegerPartitionsDominanceOrder(6); P
Finite lattice containing 11 elements
sage: P.cover_relations()
[[[1, 1, 1, 1, 1, 1], [2, 1, 1, 1, 1]],
 [[2, 1, 1, 1, 1], [2, 2, 1, 1]],
 [[2, 2, 1, 1], [2, 2, 2]],
 [[2, 2, 1, 1], [3, 1, 1, 1]],
 [[2, 2, 2], [3, 1, 1]],
 [[3, 3, 1, 1], [3, 2, 1]],
 [[3, 2, 1], [3, 3]],
 [[3, 2, 1], [4, 1, 1]],
 [[3, 3], [4, 2]],
 [[4, 1, 1], [4, 2]],
 [[4, 2], [5, 1]],
 [[5, 1], [6]]]
```

```python
>>> from sage.all import *
>>> P = posets.IntegerPartitionsDominanceOrder(Integer(6)); P
Finite lattice containing 11 elements
>>> P.cover_relations()
[[[1, 1, 1, 1, 1, 1], [2, 1, 1, 1, 1]],
 [[2, 1, 1, 1, 1], [2, 2, 1, 1]],
 [[2, 2, 1, 1], [2, 2, 2]],
 [[2, 2, 1, 1], [3, 1, 1, 1]],
 [[2, 2, 2], [3, 1, 1]],
 [[3, 3, 1, 1], [3, 2, 1]],
 [[3, 2, 1], [3, 3]],
 [[3, 2, 1], [4, 1, 1]],
 [[3, 3], [4, 2]],
 [[4, 1, 1], [4, 2]],
 [[4, 2], [5, 1]],
 [[5, 1], [6]]]
```

static MobilePoset (ribbon, hangers, anchor=None)

Return a mobile poset with the ribbon `ribbon` and with hanging d-complete posets specified in `hangers` and a d-complete poset attached above, specified in `anchor`.

**INPUT:**

- `ribbon` – a finite poset that is a ribbon
- `hangers` – a dictionary mapping an element on the ribbon to a list of d-complete posets that it covers
- `anchor` – (optional) a tuple (ribbon_elmt, anchor_elmt, anchor_poset), where anchor_elmt covers ribbon_elmt, and anchor_elmt is an acyclic element of anchor_poset

**EXAMPLES:**

```python
sage: R = Posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
sage: M = Posets.MobilePoset(R, {3: [H]})
sage: len(M.cover_relations())
7
```

```python
sage: P = posets.MobilePoset(posets.RibbonPoset(Integer(7), [Integer(1), Integer(3)]),
....: {1: [posets.YoungDiagramPoset([Integer(3), Integer(2)], dual=True)],
....: 3: [posets.DoubleTailedDiamond(Integer(6))],
....: anchor=(Integer(4), Integer(2), posets.ChainPoset(Integer(6)))
}sage: len(P.cover_relations())
33
```

**static NoncrossingPartitions** (W)

Return the lattice of noncrossing partitions.

**INPUT:**

- `W` – a finite Coxeter group or a Weyl group
EXAMPLES:

```python
sage: W = CoxeterGroup(['A', 3])  # needs sage.groups
sage: posets.NoncrossingPartitions(W)  # needs sage.groups
Finite lattice containing 14 elements
sage: W = WeylGroup(['B', 2], prefix='s')  # needs sage.groups
sage: posets.NoncrossingPartitions(W)  # needs sage.groups
Finite lattice containing 6 elements
```

```python
>>> from sage.all import *
>>> W = CoxeterGroup(['A', Integer(3)])  # needs sage.groups
>>> posets.NoncrossingPartitions(W)  # needs sage.groups
Finite lattice containing 14 elements
>>> W = WeylGroup(['B', Integer(2)], prefix='s')  # needs sage.groups
>>> posets.NoncrossingPartitions(W)  # needs sage.groups
Finite lattice containing 6 elements
```

static `PentagonPoset`(facade=None)

Return the Pentagon poset.

INPUT:

- facade (boolean) – whether to make the returned poset a facade poset (see `sage.categories.facade_sets`); the default behaviour is the same as the default behaviour of the `Poset()` constructor

EXAMPLES:

```python
sage: P = posets.PentagonPoset(); P
Finite lattice containing 5 elements
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```

```python
>>> from sage.all import *
>>> P = posets.PentagonPoset(); P
Finite lattice containing 5 elements
>>> P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
```

static `PermutationPattern`(n)

Return the poset of permutations under pattern containment up to rank $n$.

INPUT:

- n – a positive integer

A permutation $u = u_1 \cdots u_n$ contains the pattern $v = v_1 \cdots v_m$ if there is a (not necessarily consecutive) subsequence of $u$ of length $m$ whose entries have the same relative order as $v$.

See Wikipedia article Permutation_pattern.
EXAMPLES:

```python
sage: P4 = posets.PermutationPattern(4); P4
Finite poset containing 33 elements
sage: sorted(P4.lower_covers(Permutation([2,4,1,3])))
[[[1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

```python
>>> from sage.all import *
>>> P4 = posets.PermutationPattern(Integer(4)); P4
>>> sorted(P4.lower_covers(Permutation([Integer(2),Integer(4),Integer(1),
       ←Integer(3)])))
[[[1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2]]
```

See also:

`has_pattern()`

**static PermutationPatternInterval**(bottom, top)

Return the poset consisting of an interval in the poset of permutations under pattern containment between bottom and top.

**INPUT:**

- bottom, top – permutations where top contains bottom as a pattern

A permutation $u = u_1 \cdots u_n$ contains the pattern $v = v_1 \cdots v_m$ if there is a (not necessarily consecutive) subsequence of $u$ of length $m$ whose entries have the same relative order as $v$.

See Wikipedia article Permutation_pattern.

**EXAMPLES:**

```python
sage: t = Permutation([2,3,1])
sage: b = Permutation([4,6,2,3,5,1])
sage: R = posets.PermutationPatternInterval(t, b); R
Finite poset containing 14 elements
sage: R.moebius_function(R.bottom(),R.top())
-4
```

```python
>>> from sage.all import *
>>> t = Permutation([Integer(2),Integer(3),Integer(1)])
>>> b = Permutation([Integer(4),Integer(6),Integer(2),Integer(3),Integer(5),
       ←Integer(1)])
>>> R = posets.PermutationPatternInterval(t, b); R
Finite poset containing 14 elements
>>> R.moebius_function(R.bottom(),R.top())
-4
```

See also:

`has_pattern()`, `PermutationPattern()`

**static PermutationPatternOccurrenceInterval**(bottom, top, pos)

Return the poset consisting of an interval in the poset of permutations under pattern containment between bottom and top, where a specified instance of bottom in top must be maintained.

**INPUT:**

- bottom, top – permutations where top contains bottom as a pattern
• **pos** – a list of indices indicating a distinguished copy of
  bottom inside top (indexed starting at 0)

For further information (and picture illustrating included example), see [ST2010].

See Wikipedia article Permutation_pattern.

**EXAMPLES:**

```python
sage: t = Permutation([3,2,1])
sage: b = Permutation([6,3,4,5,2,1])
sage: A = posets.PermutationPatternOccurrenceInterval(t, b, (0,2,4)); A
Finite poset containing 8 elements
```

```python
>>> from sage.all import *

>>> t = Permutation([Integer(3),Integer(2),Integer(1)])

>>> b = Permutation([Integer(6),Integer(3),Integer(4),Integer(5),Integer(2),
  Integer(1)])

>>> A = posets.PermutationPatternOccurrenceInterval(t, b, (Integer(0),
  Integer(2),Integer(4))); A
Finite poset containing 8 elements
```

See also:

* has_pattern(), PermutationPattern(), PermutationPatternInterval()*

**static PowerPoset** (*n*)

Return the power poset on *n* element posets.

Elements of the power poset are all posets on the set \{0, 1, \ldots, n - 1\} ordered by extension. That is, the antichain of *n* elements is the bottom and \( P_a \leq P_b \) in the power poset if \( P_b \) is an extension of \( P_a \).

These were studied in [Bru1994].

**EXAMPLES:**

```python
sage: P3 = posets.PowerPoset(3); P3
Finite meet-semilattice containing 19 elements

sage: all(P.is_chain() for P in P3.maximal_elements())
True
```

```python
>>> from sage.all import *

>>> P3 = posets.PowerPoset(Integer(3)); P3
Finite meet-semilattice containing 19 elements

>>> all(P.is_chain() for P in P3.maximal_elements())
True
```

**static ProductOfChains** (*chain_lengths, facade=None*)

Return a product of chains.

• **chain_lengths** – A list of nonnegative integers; number of elements in each chain.

• **facade** – boolean; whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

**EXAMPLES:**

```python
sage: P = posets.ProductOfChains([2, 2]); P
Finite lattice containing 4 elements

sage: P.linear_extension()
```

(continues on next page)
static RandomLattice(n, p, properties=None)

Return a random lattice on \( n \) elements.

INPUT:

- \( n \) – number of elements, a non-negative integer
- \( p \) – a probability, a positive real number less than one
- properties – a list of properties for the lattice. Currently implemented:
  - None, no restrictions for lattices to create
  - ‘planar’, the lattice has an upward planar drawing
  - ‘dismantlable’ (implicated by ‘planar’)
  - ‘distributive’ (implicated by ‘stone’)
  - ‘stone’

OUTPUT:

A lattice on \( n \) elements. When properties is None, the probability \( p \) roughly measures number of covering relations of the lattice. To create interesting examples, make the probability a little below one, for example 0.9.

Currently parameter \( p \) has no effect only when properties is not None.

**Note:** Results are reproducible in same Sage version only. Underlying algorithm may change in future versions.

**EXAMPLES:**

```python
sage: set_random_seed(0)  # Results are reproducible
sage: L = posets.RandomLattice(8, 0.995); L
Finite lattice containing 8 elements
sage: L.cover_relations()
[[7, 6], [7, 3], [7, 1], ..., [5, 4], [2, 4], [1, 4], [0, 4]]
```
```python
>>> from sage.all import *
>>> set_random_seed(Integer(0)) # Results are reproducible
>>> L = posets.RandomLattice(Integer(8), RealNumber('0.995')); L
Finite lattice containing 8 elements
>>> L.cover_relations()
[[7, 6], [7, 3], [7, 1], ..., [5, 4], [2, 4], [1, 4], [0, 4]]
>>> L = posets.RandomLattice(Integer(10), Integer(0), properties=['dismantlable'])
>>> L.is_dismantlable()
True
```

See also:

`RandomPoset()`

```python
static RandomPoset (n, p)
Generate a random poset on n elements according to a probability p.
```

**INPUT:**

- n – number of elements, a non-negative integer
- p – a probability, a real number between 0 and 1 (inclusive)

**OUTPUT:**

A poset on n elements. The probability p roughly measures width/height of the output: p = 0 always generates an antichain, p = 1 will return a chain. To create interesting examples, keep the probability small, perhaps on the order of 1/n.

**EXAMPLES:**

```python
sage: set_random_seed(0) # Results are reproducible
sage: P = posets.RandomPoset(5, 0.3)
sage: P.cover_relations()
[[5, 4], [4, 2], [1, 2]]
```

```python
>>> from sage.all import *
>>> set_random_seed(Integer(0)) # Results are reproducible
>>> P = posets.RandomPoset(Integer(5), RealNumber('0.3'))
>>> P.cover_relations()
[[5, 4], [4, 2], [1, 2]]
```

See also:

`RandomLattice()`

```python
static RestrictedIntegerPartitions (n)
Return the poset of integer partitions on the integer n ordered by restricted refinement.

That is, if p and q are integer partitions of n, then p covers q if and only if q is obtained from p by joining two distinct parts of p (and sorting, if necessary).

**EXAMPLES:**

```python
sage: P = posets.RestrictedIntegerPartitions(7); P
Finite poset containing 15 elements
sage: len(P.cover_relations())
17
```
static RibbonPoset \((n, \text{descents})\)
Return a ribbon poset on \(n\) vertices with descents at \text{descents}.

INPUT:
- \(n\) – the number of vertices
- \text{descents} – an iterable; the indices on the ribbon where \(y > x\)

EXAMPLES:
```python
sage: R = Posets.RibbonPoset(5, [1,2])
sage: sorted(R.cover_relations())
[[0, 1], [2, 1], [3, 2], [3, 4]]
```

static SSTPoset \((s, f=None)\)
The lattice poset on semistandard tableaux of shape \(s\) and largest entry \(f\) that is ordered by componentwise comparison of the entries.

INPUT:
- \(s\) – shape of the tableaux
- \(f\) – integer (default: None); the maximum fill number. By default (None), the method uses the number of cells in the shape.

Note: This is a basic implementation and most certainly not the most efficient.

EXAMPLES:
```python
sage: posets.SSTPoset([2,1])
Finite lattice containing 8 elements
sage: posets.SSTPoset([2,1],4)
Finite lattice containing 20 elements
sage: posets.SSTPoset([2,1,2]).cover_relations()
[[[[[1, 1], [2]], [[1, 2], [2]]]]]
sage: posets.SSTPoset([3,2]).bottom()    # long time (6s on sage.math, →2012)
[[1, 1, 1], [2, 2]]
sage: posets.SSTPoset([3,2,4]).maximal_elements()
[[[3, 3, 4], [4, 4]]]
static SetPartitions\((n)\)

Return the lattice of set partitions of the set \(\{1, \ldots, n\}\) ordered by refinement.

**INPUT:**

- \(n\) – a positive integer

**EXAMPLES:**

```
sage: posets.SetPartitions(4)
Finite lattice containing 15 elements
```
sage: P.is_self_dual()
False

>>> from sage.all import *
>>> P = posets.ShardPoset(Integer(4)); P  # indirect doctest
Finite poset containing 24 elements
>>> P.chain_polynomial()
34*q^4 + 90*q^3 + 79*q^2 + 24*q + 1
>>> P.characteristic_polynomial()
q^3 - 11*q^2 + 23*q - 13
>>> P.zeta_polynomial()
17/3*q^3 - 6*q^2 + 4/3*q
>>> P.is_self_dual()
False

static StandardExample(n, facade=None)
Return the partially ordered set on 2n elements with dimension n.

Let $P$ be the poset on \{0, 1, 2, \ldots, 2n − 1\} whose defining relations are that $i < j$ for every $0 \leq i < n \leq j < 2n$ except when $i + n = j$. The poset $P$ is the so-called standard example of a poset with dimension $n$.

INPUT:

• $n$ – an integer $\geq 2$, dimension of the constructed poset
• $facade$ – boolean; whether to make the returned poset a facade poset (see sage.categories.facade_sets); the default behaviour is the same as the default behaviour of the Poset() constructor

OUTPUT:

The standard example of a poset of dimension $n$.

EXAMPLES:

sage: A = posets.StandardExample(3);
A
Finite poset containing 6 elements
sage: A.dimension()
# needs networkx
3

REFERENCES:

• [Gar2015]
• [Ros1999]

static SymmetricGroupAbsoluteOrderPoset(n, labels='permutations')
Return the poset of permutations with respect to absolute order.

INPUT:

• $n$ – a positive integer
• label – (default: 'permutations') a label for the elements of the poset returned by the function; the options are
  - 'permutations' – labels the elements by their one-line notation
  - 'reduced_words' – labels the elements by the lexicographically minimal reduced word
  - 'cycles' – labels the elements by their expression as a product of cycles

**EXAMPLES:**

```python
sage: posets.SymmetricGroupAbsoluteOrderPoset(4) # needs sage.groups
Finite poset containing 24 elements
sage: posets.SymmetricGroupAbsoluteOrderPoset(3, labels="cycles") # needs sage.groups
Finite poset containing 6 elements
sage: posets.SymmetricGroupAbsoluteOrderPoset(3, labels="reduced_words") # needs sage.groups
Finite poset containing 6 elements
```

```python
>>> from sage.all import *
>>> posets.SymmetricGroupAbsoluteOrderPoset(Integer(4)) # needs sage.groups
Finite poset containing 24 elements
>>> posets.SymmetricGroupAbsoluteOrderPoset(Integer(3), labels="cycles") # needs sage.groups
Finite poset containing 6 elements
>>> posets.SymmetricGroupAbsoluteOrderPoset(Integer(3), labels="reduced_words") # needs sage.groups
Finite poset containing 6 elements
```

### static SymmetricGroupBruhatIntervalPoset (start, end)

The poset of permutations with respect to Bruhat order.

**INPUT:**

- start – list permutation
- end – list permutation (same n, of course)

**Note:** Must have start <= end.

**EXAMPLES:**

Any interval is rank symmetric if and only if it avoids these permutations:

```python
sage: P1 = posets.SymmetricGroupBruhatIntervalPoset([[1,2,3,4], [3,4,1,2]])
sage: P2 = posets.SymmetricGroupBruhatIntervalPoset([[1,2,3,4], [4,2,3,1]])
sage: ranks1 = [P1.rank(v) for v in P1]
sage: ranks2 = [P2.rank(v) for v in P2]
sage: [ranks1.count(i) for i in sorted(set(ranks1))]  
[1, 3, 5, 4, 1]
sage: [ranks2.count(i) for i in sorted(set(ranks2))]  
[1, 3, 5, 6, 4, 1]
```

```python
>>> from sage.all import *
>>> P1 = posets.SymmetricGroupBruhatIntervalPoset([Integer(1),Integer(2)],  
(continues on next page)
```
static SymmetricGroupBruhatOrderPoset\( (n) \)

The poset of permutations with respect to Bruhat order.

EXAMPLES:

```python
sage: posets.SymmetricGroupBruhatOrderPoset(4)
Finite poset containing 24 elements
```

```python
>>> from sage.all import *
>>> posets.SymmetricGroupBruhatOrderPoset(Integer(4))
Finite poset containing 24 elements
```

static SymmetricGroupWeakOrderPoset\( (n, \text{labels='permutations', side='right'}) \)

The poset of permutations of \( \{1, 2, \ldots, n\} \) with respect to the weak order (also known as the permutahedron order, cf. permutohedron_lequal()).

The optional variable \text{labels} (default: "permutations") determines the labelling of the elements if \( n < 10 \). The optional variable \text{side} (default: "right") determines whether the right or the left permutahedron order is to be used.

EXAMPLES:

```python
sage: posets.SymmetricGroupWeakOrderPoset(4)
Finite poset containing 24 elements
```

```python
>>> from sage.all import *
>>> posets.SymmetricGroupWeakOrderPoset(Integer(4))
Finite poset containing 24 elements
```

static TamariLattice\( (n, m=1) \)

Return the \( n \)-th Tamari lattice.

Using the slope parameter \( m \), one can also get the \( m \)-Tamari lattices.

INPUT:

- \( n \) – a nonnegative integer (the index)
- \( m \) – an optional nonnegative integer (the slope, default to 1)

OUTPUT:

a finite lattice

In the usual case, the elements of the lattice are \textit{Dyck paths} in the \((n + 1 \times n)\)-rectangle. For a general slope \( m \), the elements are Dyck paths in the \((mn + 1 \times n)\)-rectangle.

See Tamari lattice for mathematical background.

EXAMPLES:

- [BMFPR2011]

**static TetrahedralPoset** (*n*, *colors*, **labels*)

Return the tetrahedral poset based on the input colors.

This method will return the tetrahedral poset with \( n - 1 \) layers and covering relations based on the input colors of 'green', 'red', 'orange', 'silver', 'yellow' and 'blue' as defined in [Striker2011]. For particular color choices, the order ideals of the resulting tetrahedral poset will be isomorphic to known combinatorial objects.

For example, for the colors 'blue', 'yellow', 'orange', and 'green', the order ideals will be in bijection with alternating sign matrices. For the colors 'yellow', 'orange', and 'green', the order ideals will be in bijection with semistandard Young tableaux of staircase shape. For the colors 'red', 'orange', 'green', and optionally 'yellow', the order ideals will be in bijection with totally symmetric self-complementary plane partitions in a \( 2n \times 2n \times 2n \) box.

**INPUT:**

- `n` – Defines the number \( n - 1 \) of layers in the poset.
- `colors` – The colors that define the covering relations of the poset. Colors used are 'green', 'red', 'yellow', 'orange', 'silver', and 'blue'.
- `labels` – Keyword variable used to determine whether the poset is labeled with integers or tuples. To label with integers, the method should be called with `labels='integers'`. Otherwise, the labeling will default to tuples.

**EXAMPLES:**

```python
sage: posets.TetrahedralPoset(4, 'green', 'red', 'yellow', 'silver', 'blue', 'orange')
Finite poset containing 10 elements
sage: posets.TetrahedralPoset(4, 'green', 'red', 'yellow', 'silver', 'blue', 'orange',
....: labels='integers')
Finite poset containing 10 elements
```

```python
sage: A = AlternatingSignMatrices(3)
sage: p = A.lattice()
sage: ji = p.join_irreducibles_poset()
sage: tet = posets.TetrahedralPoset(3, 'green', 'yellow', 'blue', 'orange')
sage: ji.is_isomorphic(tet)
True
```
static UpDownPoset\((n, m=1)\)

Return the up-down poset on \(n\) elements where every \((m+1)\) step is down and the rest are up.

The case where \(m = 1\) is sometimes referred to as the zig-zag poset or the fence.

**INPUT:**

- \(n\) – nonnegative integer, number of elements in the poset
- \(m\) – nonnegative integer (default 1), how frequently down steps occur

**OUTPUT:**

The partially ordered set on \(\{0, 1, \ldots, n - 1\}\) where \(i\) covers \(i + 1\) if \(m\) divides \(i + 1\), and \(i + 1\) covers \(i\) otherwise.

**EXAMPLES:**

```python
sage: P = posets.UpDownPoset(7, 2); P
Finite poset containing 7 elements
sage: sorted(P.cover_relations())
[[0, 1], [1, 2], [3, 2], [3, 4], [4, 5], [6, 5]]
```

Fibonacci numbers as the number of antichains of a poset:

```python
sage: [len(posets.UpDownPoset(n).antichains().list()) for n in range(6)]
[1, 2, 3, 5, 8, 13]
```

```python
sage: [len(posets.UpDownPoset(n).antichains().list()) for n in range(6)]
[1, 2, 3, 5, 8, 13]
```
INPUT:

- `lam` – a partition
- `dual` – (default: `False`) determines the orientation of the poset; if `True`, then it is a join semilattice, otherwise it is a meet semilattice

EXAMPLES:

```sage
P = posets.YoungDiagramPoset(Partition([2, 2])); P
Finite meet-semilattice containing 4 elements

sage: sorted(P.cover_relations())
[[[0, 0], [0, 1]], [[0, 0], [1, 0]], [[0, 1], [1, 1]], [[1, 0], [1, 1]]]
```

```sage
posets.YoungDiagramPoset([3, 2], dual=True)
Finite join-semilattice containing 5 elements
```

```sage
from sage.all import *
```

```sage
P = posets.YoungDiagramPoset(Partition([Integer(2), Integer(2)])); P
Finite meet-semilattice containing 4 elements

sage: sorted(P.cover_relations())
[[[0, 0], [0, 1]], [[0, 0], [1, 0]], [[0, 1], [1, 1]], [[1, 0], [1, 1]]]
```

```sage
posets.YoungDiagramPoset([Integer(3), Integer(2)], dual=True)
Finite join-semilattice containing 5 elements
```

**static YoungFibonacci** (`n`)  
Return the Young-Fibonacci lattice up to rank `n`.  
Elements of the (infinite) lattice are words with letters ‘1’ and ‘2’. The covers of a word are the words with another ‘1’ added somewhere not after the first occurrence of an existing ‘1’ and, additionally, the words where the first ‘1’ is replaced by a ‘2’. The lattice is truncated to have rank `n`.  
See Wikipedia article Young-Fibonacci lattice.

EXAMPLES:

```sage
Y5 = posets.YoungFibonacci(5); Y5
Finite meet-semilattice containing 20 elements

sage: sorted(Y5.upper_covers(Word('211')))
[word: 1211, word: 2111, word: 221]
```

```sage
from sage.all import *
```

```sage
Y5 = posets.YoungFibonacci(Integer(5)); Y5
Finite meet-semilattice containing 20 elements

sage: sorted(Y5.upper_covers(Word('211')))
[word: 1211, word: 2111, word: 221]
```

**static YoungsLattice** (`n`)  
Return Young’s Lattice up to rank `n`.  
In other words, the poset of partitions of size less than or equal to `n` ordered by inclusion.

INPUT:

- `n` – a positive integer

EXAMPLES:
```
sage: P = posets.YoungsLattice(3); P
Finite meet-semilattice containing 7 elements
sage: P.cover_relations()
[[[], [1]],
 [ [1], [1, 1]],
 [ [1], [2]],
 [ [1, 1], [1, 1, 1]],
 [ [1, 1], [2, 1]],
 [ [2], [2, 1]],
 [ [2], [3]]]

>>> from sage.all import *
>>> P = posets.YoungsLattice(Integer(3)); P
Finite meet-semilattice containing 7 elements
>>> P.cover_relations()
[[[], [1]],
 [ [1], [1, 1]],
 [ [1], [2]],
 [ [1, 1], [1, 1, 1]],
 [ [1, 1], [2, 1]],
 [ [2], [2, 1]],
 [ [2], [3]]]
```

**static YoungsLatticePrincipalOrderIdeal** (lam)

Return the principal order ideal of the partition lam in Young’s Lattice.

**INPUT:**
- lam – a partition

**EXAMPLES:**
```
sage: P = posets.YoungsLatticePrincipalOrderIdeal(Partition([2,2]))
sage: P
Finite lattice containing 6 elements
sage: P.cover_relations()
[[[], [1]],
 [ [1], [1, 1]],
 [ [1], [2]],
 [ [1, 1], [1, 2]],
 [ [2], [2, 1]],
 [ [2, 1], [2, 2]]]
```

```
>>> from sage.all import *
>>> P = posets.YoungsLatticePrincipalOrderIdeal(Partition([Integer(2),
˓→Integer(2)]))
>>> P
Finite lattice containing 6 elements
>>> P.cover_relations()
[[[], [1]],
 [ [1], [1, 1]],
 [ [1], [2]],
 [ [1, 1], [1, 2]],
 [ [2], [2, 1]],
 [ [2, 1], [2, 2]]]
```

```
sage = <module 'sage' (˓→_frozen_importlib_external._NamespaceLoader object)>]
```

5.1. Comprehensive Module List 3225
Combinatorics, Release 10.4

sage.combinat.posets.poset_examples.check_int(n, minimum=0)

Check that \( n \) is an integer at least equal to \( \text{minimum} \).

This is a boilerplate function ensuring input safety.

INPUT:

- \( n \) – anything
- \( \text{minimum} \) – an optional integer (default: 0)

EXAMPLES:

```python
sage: from sage.combinat.posets.poset_examples import check_int
sage: check_int(6, 3)
6
sage: check_int(6)
6

sage: check_int(-1)
Traceback (most recent call last):
... ValueError: number of elements must be a non-negative integer, not -1
sage: check_int(1, 3)
Traceback (most recent call last):
... ValueError: number of elements must be an integer at least 3, not 1
sage: check_int('junk')
Traceback (most recent call last):
... ValueError: number of elements must be a non-negative integer, not junk
```

```python
>>> from sage.all import *
>>> from sage.combinat.posets.poset_examples import check_int
>>> check_int(Integer(6), Integer(3))
6
>>> check_int(Integer(6))
6

>>> check_int(-Integer(1))
Traceback (most recent call last):
... ValueError: number of elements must be a non-negative integer, not -1
>>> check_int(Integer(1), Integer(3))
Traceback (most recent call last):
... ValueError: number of elements must be an integer at least 3, not 1
>>> check_int('junk')
Traceback (most recent call last):
... ValueError: number of elements must be a non-negative integer, not junk
```

alias of Posets
5.1.186 Finite posets

This module implements finite partially ordered sets. It defines:

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>FinitePoset</code></td>
<td>A class for finite posets</td>
</tr>
<tr>
<td><code>FinitePosets_n</code></td>
<td>A class for finite posets up to isomorphism (i.e. unlabeled posets)</td>
</tr>
<tr>
<td><code>Poset()</code></td>
<td>Construct a finite poset from various forms of input data.</td>
</tr>
<tr>
<td><code>is_poset()</code></td>
<td>Return <code>True</code> if a directed graph is acyclic and transitively reduced.</td>
</tr>
</tbody>
</table>

List of Poset methods

Comparing, intervals and relations

<table>
<thead>
<tr>
<th>Method</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>is_less_than()</code></td>
<td>Return <code>True</code> if <code>x</code> is strictly less than <code>y</code> in the poset.</td>

<tr>
<td><code>common_lower_covers()</code></td>
<td>Return the list of all common lower covers of the given elements.</td>
</tr>
<tr>
<td><code>meet()</code></td>
<td>Return the meet of given elements if it exists; <code>None</code> otherwise.</td>
</tr>
<tr>
<td><code>join()</code></td>
<td>Return the join of given elements if it exists; <code>None</code> otherwise.</td>
</tr>
</tbody>
</table>

Properties of the poset
cardinality() Return the number of elements in the poset.
height() Return the number of elements in a longest chain of the poset.
width() Return the number of elements in a longest antichain of the poset.
relations_number() Return the number of relations in the poset.
dimension() Return the dimension of the poset.
jump_number() Return the jump number of the poset.
magnitude() Return the magnitude of the poset.
has_bottom() Return True if the poset has a unique minimal element.
has_top() Return True if the poset has a unique maximal element.
is_bounded() Return True if the poset has both unique minimal and unique maximal element.
is_chain() Return True if the poset is totally ordered.
is_connected() Return True if the poset is connected.
is_graded() Return True if all maximal chains of the poset have same length.
is_ranked() Return True if the poset has a rank function.
is_rank_symmetric() Return True if the poset is rank symmetric.
is_series_parallel() Return True if the poset can be built by ordinal sums and disjoint unions.
is_greedy() Return True if all greedy linear extensions have equal number of jumps.
is_jump_critical() Return True if removal of any element reduces the jump number.
is_eulerian() Return True if the poset is Eulerian.
is_incomparable_chain_free() Return True if the poset is (m+n)-free.
is_slender() Return True if the poset is slender.
is_sperner() Return True if the poset is Sperner.
is_join_semilattice() Return True if the poset has a join operation.
is_meet_semilattice() Return True if the poset has a meet operation.

Minimal and maximal elements

bottom() Return the bottom element of the poset, if it exists.
top() Return the top element of the poset, if it exists.
maximal_elements() Return the list of the maximal elements of the poset.
minimal_elements() Return the list of the minimal elements of the poset.

New posets from old ones
disjoint_union() Return the disjoint union of the poset with other poset.
ordinal_sum() Return the ordinal sum of the poset with other poset.
product() Return the Cartesian product of the poset with other poset.
ordinal_product() Return the ordinal product of the poset with other poset.
rees_product() Return the Rees product of the poset with other poset.
lexicographic_sum() Return the lexicographic sum of posets.
star_product() Return the star product of the poset with other poset.
with_bounds() Return the poset with bottom and top element adjoined.
without_bounds() Return the poset with bottom and top element removed.
dual() Return the dual of the poset.
completion_by_cuts() Return the Dedekind-MacNeille completion of the poset.
intervals_poset() Return the poset of intervals of the poset.
connected_components() Return the connected components of the poset as subposets.
factor() Return the decomposition of the poset as a Cartesian product.
ordinal_summands() Return the ordinal summands of the poset.
subposet() Return the subposet containing elements with partial order induced by this poset.
random_subposet() Return a random subposet that contains each element with given probability.
relabel() Return a copy of this poset with its elements relabelled.
canonical_label() Return copy of the poset canonically (re)labelled to integers.
slant_sum() Return the slant sum poset of two posets.

Chains, antichains & linear intervals

is_chain_of_poset() Return True if elements in the given list are comparable.
is_an_antichain_of_poset() Return True if elements in the given list are incomparable.
is_linear_interval() Return whether the given interval is a total order.
chains() Return the chains of the poset.
antichains() Return the antichains of the poset.
maximal_chains() Return the maximal chains of the poset.
maximal_antichains() Return the maximal antichains of the poset.
maximal_chains_iterator() Return an iterator over the maximal chains of the poset.
maximal_chain_length() Return the maximum length of maximal chains of the poset.
antichains_iterator() Return an iterator over the antichains of the poset.
random_maximal_chain() Return a random maximal chain.
random_maximal_antichain() Return a random maximal antichain.
linear_intervals_count() Return the enumeration of linear intervals in the poset.

Drawing

show() Display the Hasse diagram of the poset.
plot() Return a Graphic object corresponding the Hasse diagram of the poset.
graphviz_string() Return a representation in the DOT language, ready to render in graphviz.

Comparing posets

5.1. Comprehensive Module List
### Combinatorics, Release 10.4

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>is_isomorphic()</code></td>
<td>Return True if both posets are isomorphic.</td>
</tr>
<tr>
<td><code>is_induced_subposet()</code></td>
<td>Return True if given poset is an induced subposet of this poset.</td>
</tr>
</tbody>
</table>

#### Polynomials

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>chain_polynomial()</code></td>
<td>Return the chain polynomial of the poset.</td>
</tr>
<tr>
<td><code>characteristic_polynomial()</code></td>
<td>Return the characteristic polynomial of the poset.</td>
</tr>
<tr>
<td><code>f_polynomial()</code></td>
<td>Return the f-polynomial of the poset.</td>
</tr>
<tr>
<td><code>flag_f_polynomial()</code></td>
<td>Return the flag f-polynomial of the poset.</td>

<td>Return the zeta polynomial of the poset.</td>
</tr>
<tr>
<td><code>M_triangle()</code></td>
<td>Return the M-triangle of the poset.</td>
</tr>
<tr>
<td><code>kazhdan_lusztig_polynomial()</code></td>
<td>Return the Kazhdan-Lusztig polynomial of the poset.</td>
</tr>
<tr>
<td><code>coxeter_polynomial()</code></td>
<td>Return the characteristic polynomial of the Coxeter transformation.</td>
</tr>
<tr>
<td><code>degree_polynomial()</code></td>
<td>Return the generating polynomial of degrees of vertices in the Hasse diagram.</td>
</tr>
<tr>
<td><code>p_partition Enumerator()</code></td>
<td>Return a P-partition enumerator of the poset.</td>
</tr>
</tbody>
</table>

#### Polytopes

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><code>chain_polytope()</code></td>
<td>Return the chain polytope of the poset.</td>

<tr>
<td>moebius_function()</td>
<td>Return the value of Möbius function of given elements in the poset.</td>
</tr>
<tr>
<td>moebius_function_matrix()</td>
<td>Return a matrix whose (i,j) entry is the value of the Möbius function evaluated at self.linear_extension()[i] and self.linear_extension()[j].</td>
</tr>
<tr>
<td>coxeter_transformation()</td>
<td>Return the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules.</td>
</tr>
<tr>
<td>coxeter_smith_form()</td>
<td>Return the Smith form of the Coxeter transformation.</td>
</tr>
</tbody>
</table>

### Miscellaneous

5.1. Comprehensive Module List
sorted()  Return given list sorted by the poset.

isomorphic_subposets()  Return all subposets isomorphic to another poset.

isomorphic_subposets_iterator()  Return an iterator over the subposets isomorphic to another poset.

has_isomorphic_subposet()  Return True if the poset contains a subposet isomorphic to another poset.

list()  List the elements of the poset.

cuts()  Return the cuts of the given poset.

dilworth_decomposition()  Return a partition of the points into the minimal number of chains.

greene_shape()  Computes the Greene-Kleitman partition aka Greeneshape of the poset self.

incidence_algebra()  Return the incidence algebra of self.

is_EL_labelling()  Return whether f is an EL labelling of the poset.

isomorphic_subposets_iterator()  Return an iterator over the subposets isomorphic to another poset.

isomorphic_subposets()  Return all subposets isomorphic to another poset.

level_sets()  Return elements grouped by maximal number of cover relations from a minimal element.

order_complex()  Return the order complex associated to this poset.

random_order_ideal()  Return a random order ideal of self with uniform probability.

rank()  Return the rank of an element, or the rank of the poset.

rank_function()  Return a rank function of the poset, if it exists.

unwrap()  Unwraps an element of this poset.

atkinson()  Return the a-spectrum of a poset whose undirected Hasse diagram is a forest.

spectrum()  Return the a-spectrum of this poset.

Classes and functions

class sage.combinat.posets.posets.FinitePoset (hasse_diagram, elements, category, facade, key)

Bases: UniqueRepresentation, Parent

A (finite) n-element poset constructed from a directed acyclic graph.

INPUT:

- hasse_diagram – an instance of FinitePoset, or a DiGraph that is transitivity-reduced, acyclic, loop-free, and multiedge-free.
- elements – an optional list of elements, with element[i] corresponding to vertex i. If elements is None, then it is set to be the vertex set of the digraph. Note that if this option is set, then elements is considered as a specified linear extension of the poset and the linear_extension attribute is set.
- category – FinitePosets, or a subcategory thereof.
- facade – a boolean or None (default); whether the FinitePoset’s elements should be wrapped to make them aware of the Poset they belong to.
  - If facade = True, the FinitePoset’s elements are exactly those given as input.
  - If facade = False, the FinitePoset’s elements will become PosetElement objects.
  - If facade = None (default) the expected behaviour is the behaviour of facade = True, unless the opposite can be deduced from the context (i.e. for instance if a FinitePoset is built from another FinitePoset, itself built with facade = False)
• key – any hashable value (default: None).

EXAMPLES:

```
sage: uc = [[2, 3], [], [1], [1], [1], [3, 4]]
sage: from sage.combinat.posets.posets import FinitePoset
sage: P = FinitePoset(DiGraph(dict([(i,uc[i]) for i in range(len(uc))])), facade=False); P
Finite poset containing 6 elements
sage: P.cover_relations()
[[5, 4], [5, 3], [4, 1], [0, 2], [0, 3], [2, 1], [3, 1]]
sage: TestSuite(P).run()
sage: P.category()
Category of finite enumerated posets
sage: P.__class__
<class 'sage.combinat.posets.posets.FinitePoset_with_category'>

sage: Q = sage.combinat.posets.posets.FinitePoset(P, facade = False); Q
Finite poset containing 6 elements
sage: Q is P
True
```

```>>> from sage.all import *
>>> uc = [[Integer(2),Integer(3)], [], [Integer(1)], [Integer(1)], [Integer(1)], [Integer(3),Integer(4)]]
>>> from sage.combinat.posets.posets import FinitePoset
>>> P = FinitePoset(DiGraph(dict([(i,uc[i]) for i in range(len(uc))]))), facade=False); P
Finite poset containing 6 elements
>>> P.cover_relations()
[[5, 4], [5, 3], [4, 1], [0, 2], [0, 3], [2, 1], [3, 1]]
>>> TestSuite(P).run()
>>> P.category()
Category of finite enumerated posets
>>> P.__class__
<class 'sage.combinat.posets.posets.FinitePoset_with_category'>

>>> Q = sage.combinat.posets.posets.FinitePoset(P, facade = False); Q
Finite poset containing 6 elements
>>> Q is P
True
```

We keep the same underlying Hasse diagram, but change the elements:

```
sage: Q = sage.combinat.posets.posets.FinitePoset(P, elements=[1,2,3,4,5,6], facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]
```

```>>> from sage.all import *
>>> Q = sage.combinat.posets.posets.FinitePoset(P, elements=[Integer(1), Integer(2),Integer(3),Integer(4),Integer(5),Integer(6)], facade=False); Q
Finite poset containing 6 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 5], [2, 6], [3, 4], [3, 5], [4, 6], [5, 6]]
```
We test the facade argument:

```python
sage: P = Poset(DiGraph({'a':['b'], 'b':['c'], 'c':['d']}), facade=False)
sage: P.category()
Category of finite enumerated posets
sage: parent(P[0]) is P
True

sage: Q = Poset(DiGraph({'a':['b'], 'b':['c'], 'c':['d']}), facade=True)
sage: Q.category()
Category of facade finite enumerated posets
sage: parent(Q[0]) is str
True
sage: TestSuite(Q).run(skip = ['_test_an_element']) # is_parent_of is not yet implemented
```

Changing a non facade poset to a facade poset:

```python
sage: PQ = Poset(P, facade=True)
sage: PQ.category()
Category of facade finite enumerated posets
sage: parent(PQ[0]) is str
True
sage: PQ is Q
True
```

Changing a facade poset to a non facade poset:

```python
sage: QP = Poset(Q, facade=False)
sage: QP.category()
Category of finite enumerated posets
sage: parent(QP[0]) is QP
True
```
Conversion to some other software is possible:

```python
>>> from sage.all import *
>>> QP = Poset(Q, facade = False)
>>> QP.category()
Category of finite enumerated posets
>>> parent(QP[Integer(0)]) is QP
True
```

Note: A class that inherits from this class needs to define Element. This is the class of the elements that the inheriting class contains. For example, for this class, FinitePoset, Element is PosetElement. It can also define _dual_class which is the class of dual posets of this class. E.g. FiniteMeetSemilattice. _dual_class is FiniteJoinSemilattice.

**Element**

alias of PosetElement

**M_triangle()**

Return the M-triangle of the poset.

The poset is expected to be graded.

OUTPUT:

an M_triangle

The M-triangle is the generating polynomial of the Möbius numbers

\[ M(x, y) = \sum_{a \leq b} \mu(a, b)x^{|a|}y^{|b|}. \]

**EXAMPLES:**
antichains($element\_constructor=None$)

Return the antichains of the poset.

An antichain of a poset is a set of elements of the poset that are pairwise incomparable.

INPUT:

- element\_constructor -- a function taking an iterable as argument (default: list)

OUTPUT:

The enumerated set (of type $PairwiseCompatibleSubsets$) of all antichains of the poset, each of which is given as an element\_constructor.

EXAMPLES:

```python
sage: A = posets.PentagonPoset().antichains(); A
Set of antichains of Finite lattice containing 5 elements
sage: list(A)
[[], [0], [1], [1, 2], [1, 3], [2], [3], [4]]
```

To get the antichains as, say, sets, one may use the element\_constructor option:

```python
sage: list(posets.ChainPoset(3).antichains(element\_constructor=set))
[set(), {0}, {1}, {2}]
```

To get the antichains of a given size one can currently use:
sage: list(A.elements_of_depth_iterator(2))
[[1, 2], [1, 3]]

```
>>> from sage.all import *
```

```
>>> list(A.elements_of_depth_iterator(Integer(2)))
[[1, 2], [1, 3]]
```

Eventually the following syntax will be accepted:

```
sage: A.subset(size=2)  # not implemented
```

```
>>> from sage.all import *
```

```
>>> A.subset(size=Integer(2))  # not implemented
```

Note: Internally, this uses `sage.combinat.subsets_pairwise.PairwiseCompatibleSubsets` and `RecursivelyEnumeratedSet_forest`. At this point, iterating through this set is about twice slower than using `antichains_iterator()` (tested on `posets.AntichainPoset(15)`). The algorithm is the same (depth first search through the tree), but `antichains_iterator()` manually inlines things which apparently avoids some infrastructure overhead.

On the other hand, this returns a full featured enumerated set, with containment testing, etc.

See also:

`maximal_antichains()`, `chains()`

`antichains_iterator()`

Return an iterator over the antichains of the poset.

EXAMPLES:

```
sage: it = posets.PentagonPoset().antichains_iterator(); it
<generator object ...antichains_iterator at ...

sage: next(it), next(it)
([], [4])
```

```
>>> from sage.all import *
```

```
>>> it = posets.PentagonPoset().antichains_iterator(); it
<generator object ...antichains_iterator at ...

>>> next(it), next(it)
([], [4])
```

See also:

`antichains()`

`atkinson(a)`

Return the $a$-spectrum of a poset whose Hasse diagram is cycle-free as an undirected graph.

Given an element $a$ in a poset $P$, the $a$-spectrum is the list of integers whose $i$-th term contains the number of linear extensions of $P$ with element $a$ located in the $i$-th position.

INPUT:

- `self` – a poset whose Hasse diagram is a forest
• a – an element of the poset

OUTPUT:

The $a$-spectrum of this poset, returned as a list.

EXAMPLES:

```python
sage: P = Poset({0: [2], 1: [2], 2: [3, 4], 3: [], 4: []})
sage: P.atkinson(0)
[2, 2, 0, 0, 0]

sage: P = Poset({0: [1], 1: [2, 3], 2: [], 3: [], 4: [5, 6], 5: [], 6: []})
sage: P.atkinson(5)
[0, 10, 18, 24, 28, 30, 30]

sage: P = posets.AntichainPoset(10)
sage: P.atkinson(0)
[362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880]

>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],
            Integer(2): [Integer(3), Integer(4)], Integer(3): [], Integer(4): []})
>>> P.atkinson(Integer(0))
[2, 2, 0, 0, 0]

>>> P = Poset({Integer(0): [Integer(1)], Integer(1): [Integer(2), Integer(3)],
            Integer(2): [], Integer(3): [], Integer(4): [Integer(5), Integer(6)],
            Integer(5): [], Integer(6): []})
>>> P.atkinson(Integer(5))
[0, 10, 18, 24, 28, 30, 30]

>>> P = posets.AntichainPoset(Integer(10))
>>> P.atkinson(Integer(0))
[362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880, 362880]
```

Note: This function is the implementation of the algorithm from [At1990].

bottom()

Return the unique minimal element of the poset, if it exists.

EXAMPLES:

```python
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: P.bottom() is None
True

sage: Q = Poset({0:[1], 1:[]})
sage: Q.bottom()
0

>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],
            Integer(2):[Integer(3)], Integer(3):[Integer(4), Integer(4):[]}]
>>> P.bottom() is None
```

(continues on next page)
True

```python
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.bottom()
0
```

See also:

has_bottom(), top()

canonical_label (algorithm=None)

Return the unique poset on the labels {0, ..., n − 1} (where n is the number of elements in the poset) that is isomorphic to this poset and invariant in the isomorphism class.

INPUT:

- algorithm – string (optional); a parameter forwarded to underlying graph function to select the algorithm to use

EXAMPLES:

```python
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: Q = P.canonical_label()
sage: sorted(Q.list())
[0, 1, 2, 3, 4, 5]
sage: Q.is_isomorphic(P)
True
```

Canonical labeling of (semi)lattice returns (semi)lattice:

```python
sage: D = DiGraph({"a":["b","c"]})
sage: P = Poset(D)
sage: ML = MeetSemilattice(D)
sage: P.canonical_label()
Finite poset containing 3 elements
sage: ML.canonical_label()
Finite meet-semilattice containing 3 elements
```

```python
>>> from sage.all import *

>>> D = DiGraph({"a":["b","c"]})
>>> P = Poset(D)
>>> ML = MeetSemilattice(D)
>>> P.canonical_label()
Finite poset containing 3 elements
>>> ML.canonical_label()
Finite meet-semilattice containing 3 elements
```
See also:

- Canonical labeling of directed graphs: `canonical_label()`

**cardinality()**

Return the number of elements in the poset.

**EXAMPLES:**

```
sage: Poset([[1,2,3],[4],[4],[4],[]]).cardinality()
5

>>> from sage.all import *
>>> Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],
        →[Integer(4)],[]]).cardinality()
5
```

See also:

- `degree_polynomial()` for a more refined invariant

**chain_polynomial()**

Return the chain polynomial of the poset.

The coefficient of $q^k$ is the number of chains of $k$ elements in the poset. List of coefficients of this polynomial is also called a *f*-vector of the poset.

**Note:** This is not what has been called the chain polynomial in [St1986]. The latter is identical with the order polynomial in SageMath (`order_polynomial()`).

See also:

- `f_polynomial()`, `order_polynomial()`

**EXAMPLES:**

```
sage: P = posets.ChainPoset(3)
sage: t = P.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
sage: t(1) == len(list(P.chains()))
True

sage: P = posets.BooleanLattice(3)
sage: P.chain_polynomial()
6*q^4 + 18*q^3 + 19*q^2 + 8*q + 1

sage: P = posets.AntichainPoset(5)
sage: P.chain_polynomial()
5*q + 1

>>> from sage.all import *
>>> P = posets.ChainPoset(Integer(3))
>>> t = P.chain_polynomial(); t
q^3 + 3*q^2 + 3*q + 1
>>> t(Integer(1)) == len(list(P.chains()))
True
```
chain_polytope()
Return the chain polytope of the poset self.

The chain polytope of a finite poset \( P \) is defined as the subset of \( \mathbb{R}^P \) consisting of all maps \( x: P \to \mathbb{R} \) satisfying

\[
x(p) \geq 0 \text{ for all } p \in P,
\]

and

\[
x(p_1) + x(p_2) + \ldots + x(p_k) \leq 1 \text{ for all chains } p_1 < p_2 < \ldots < p_k \text{ in } P.
\]

This polytope was defined and studied in [St1986].

EXAMPLES:

```python
sage: P = posets.AntichainPoset(3)
sage: Q = P.chain_polytope(); Q
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices

sage: P = posets.PentagonPoset()
sage: Q = P.chain_polytope(); Q
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
```

chains(element_constructor=None, exclude=None)
Return the chains of the poset.

A chain of a poset is an increasing sequence of distinct elements of the poset.

INPUT:

- element_constructor – a function taking an iterable as argument (default: list)
- exclude – elements of the poset to be excluded (default: None)

OUTPUT:

The enumerated set (of type PairwiseCompatibleSubsets) of all chains of the poset, each of which is given as an element_constructor.
sage: C = posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
sage: list(C)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]

>>> from sage.all import *
>>> C = posets.PentagonPoset().chains(); C
Set of chains of Finite lattice containing 5 elements
>>> list(C)
[[], [0], [0, 1], [0, 1, 4], [0, 2], [0, 2, 3], [0, 2, 3, 4], [0, 2, 4],
 [0, 3], [0, 3, 4], [0, 4], [1], [1, 4], [2], [2, 3], [2, 3, 4], [2, 4],
 [3], [3, 4], [4]]

Exclusion of elements, tuple (instead of list) as constructor:

sage: P = Poset({1: [2, 3], 2: [4], 3: [4, 5]})
sage: list(P.chains(element_constructor=tuple, exclude=[3]))
[(), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,)]

>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
→ Integer(3): [Integer(4), Integer(5)]})
>>> list(P.chains(element_constructor=tuple, exclude=[Integer(3)]))
[(), (1,), (1, 2), (1, 2, 4), (1, 4), (1, 5), (2,), (2, 4), (4,), (5,)]

To get the chains of a given size one can currently use:

sage: list(C.elements_of_depth_iterator(2))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]

>>> from sage.all import *
>>> list(C.elements_of_depth_iterator(Integer(2)))
[[0, 1], [0, 2], [0, 3], [0, 4], [1, 4], [2, 3], [2, 4], [3, 4]]

Eventually the following syntax will be accepted:

sage: C.subset(size=2)  # not implemented

>>> from sage.all import *
>>> C.subset(size=Integer(2))  # not implemented

See also:

maximal_chains(), antichains()

characteristic_polynomial()

Return the characteristic polynomial of the poset.

The poset is expected to be graded and have a bottom element.

If $P$ is a graded poset with rank $n$ and a unique minimal element $\hat{0}$, then the characteristic polynomial of $P$ is defined to be

$$\sum_{x \in P} \mu(\hat{0}, x) q^{n-r(x)} \in \mathbb{Z}[q],$$
where $\rho$ is the rank function, and $\mu$ is the Möbius function of $P$.

See section 3.10 of [EnumComb1].

EXAMPLES:

```sage
P = posets.DiamondPoset(5)
sage: P.characteristic_polynomial()
q^2 - 3*q + 2
P = posets.DiamondPoset(5)
sage: P.characteristic_polynomial()
q^2 - 3*q + 2
```

```sage
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
>>> P.characteristic_polynomial()
q^2 - 3*q + 2
```

```
closed_interval $(x, y)$

Return the list of elements $z$ such that $x \leq z \leq y$ in the poset.

EXAMPLES:

```sage
P = Poset((divisors(1000), attrcall("divides")))
sage: P.closed_interval(2, 100)
[2, 4, 10, 20, 50, 100]
```

```sage
>>> from sage.all import *
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.closed_interval(Integer(2), Integer(100))
[2, 4, 10, 20, 50, 100]
```

See also:

open_interval()

common_lower_covers $(elmts)$

Return all of the common lower covers of the elements $elmts$.

EXAMPLES:

```sage
P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.common_lower_covers([1, 2])
[0]
```

```sage
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1),Integer(2)], Integer(1): [Integer(3)],...
   \rightarrow Integer(2): [Integer(3)], Integer(3): []})
>>> P.common_lower_covers([Integer(1), Integer(2)])
[0]
```
common_upper_covers (elmts)

Return all of the common upper covers of the elements elmts.

EXAMPLES:

```
sage: P = Poset({0: [1, 2], 1: [3], 2: [3], 3: []})
sage: P.common_upper_covers([1, 2])
[3]
```

comparability_graph()

Return the comparability graph of the poset.

The comparability graph is an undirected graph where vertices are the elements of the poset and there is an edge between two vertices if they are comparable in the poset.

See Wikipedia article Comparability_graph

EXAMPLES:

```
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.comparability_graph(); g
Comparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
True
```

See also:

incomparability_graph(), sage.graphs.comparability

compare_elements (x, y)

Compare x and y in the poset.

• If \( x < y \), return \(-1\).
• If \( x = y \), return \(0\).
• If \( x > y \), return \(1\).
• If \( x \) and \( y \) are not comparable, return \(None\).

EXAMPLES:
sage: P = Poset([[1, 2], [4], [3], [4], []])
sage: P.compare_elements(0, 0)
0
sage: P.compare_elements(0, 4)
-1
sage: P.compare_elements(4, 0)
1
sage: P.compare_elements(1, 2) is None
True

>>> from sage.all import *

>>> P = Poset([[Integer(1), Integer(2)], [Integer(4)], [Integer(3)], [Integer(4)], []])

>>> P.compare_elements(Integer(0), Integer(0))
0

>>> P.compare_elements(Integer(0), Integer(4))
-1

>>> P.compare_elements(Integer(4), Integer(0))
1

>>> P.compare_elements(Integer(1), Integer(2)) is None
True

completion_by_cuts()

Return the completion by cuts of self.

This is the smallest lattice containing the poset. This is also called the Dedekind-MacNeille completion.

See the Wikipedia article Dedekind-MacNeille completion.

OUTPUT:

• a finite lattice

EXAMPLES:

sage: P = posets.PentagonPoset()
sage: P.completion_by_cuts().is_isomorphic(P)
True

sage: Y = Poset({1: [2], 2: [3, 4]})
sage: trafficsign = LatticePoset({1: [2], 2: [3, 4], 3: [5], 4: [5]})
sage: L = Y.completion_by_cuts()
sage: L.is_isomorphic(trafficsign)
True

sage: P = posets.SymmetricGroupBruhatOrderPoset(3)
sage: Q = P.completion_by_cuts(); Q
Finite lattice containing 7 elements

>>> from sage.all import *

>>> P = posets.PentagonPoset()

>>> P.completion_by_cuts().is_isomorphic(P)
True

>>> Y = Poset({Integer(1): [Integer(2)], Integer(2): [Integer(3), Integer(4)]})

>>> trafficsign = LatticePoset({Integer(1): [Integer(2)], Integer(2):...

(continues on next page)
See also:

cuts(), irreducibles_poset()

connected_components()

Return the connected components of the poset as subposets.

EXAMPLES:

sage: P = Poset({1: [2, 3], 3: [4, 5], 6: [7, 8]})
sage: parts = sorted(P.connected_components(), key=len); parts
[Finite poset containing 3 elements,
 Finite poset containing 5 elements]
sage: parts[0].cover_relations()
[[6, 7], [6, 8]]

See also:

disjoint_union(), is_connected()

cover_relations()

Return the list of pairs \([x, y]\) of elements of the poset such that \(y\) covers \(x\).

EXAMPLES:

sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: P.cover_relations()
[[1, 2], [0, 2], [2, 3], [3, 4]]

See also:

disjoint_union(), is_connected()

cover_relations_graph()

Return the (undirected) graph of cover relations.

EXAMPLES:
```python
type: sage: P = Poset({0: [1, 2], 1: [3], 2: [3]})
sage: G = P.cover_relations_graph(); G
Graph on 4 vertices
sage: G.has_edge(3, 1), G.has_edge(3, 0)
(True, False)

>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1), Integer(2)],
            Integer(1): [Integer(3)],
            Integer(2): [Integer(3)]})
>>> G = P.cover_relations_graph(); G
Graph on 4 vertices
>>> G.has_edge(Integer(3), Integer(1)), G.has_edge(Integer(3), Integer(0))
(True, False)
```

See also:

- `hasse_diagram()`
- `cover_relations_iterator()`

Return an iterator over the cover relations of the poset.

**EXAMPLES:**

```python
type: sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: type(P.cover_relations_iterator())
<class 'generator'>
sage: [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

```python
type: sage: P = Poset({Integer(0): [Integer(1), Integer(2)],
            Integer(1): [Integer(2)],
            Integer(2): [Integer(3)],
            Integer(3): [Integer(4)],
            Integer(4): []})
>>> type(P.cover_relations_iterator())
<class 'generator'>
>>> [z for z in P.cover_relations_iterator()]
[[1, 2], [0, 2], [2, 3], [3, 4]]
```

covers `(x, y)`

Return `True` if `y` covers `x` and `False` otherwise.

Element `y` covers `x` if `x < y` and there is no `z` such that `x < z < y`.

**EXAMPLES:**

```python
type: sage: P = Poset([[1, 5], [2, 6], [3], [4], [], [6, 3], [4]])
sage: P.covers(1, 6)
True
sage: P.covers(1, 4)
False
sage: P.covers(1, 5)
False
```

```python
type: sage: P = Poset([[Integer(1), Integer(5)], [Integer(2), Integer(6)],
            [Integer(3)],
            [Integer(4)], [1, [Integer(6), Integer(3), Integer(4)]])
>>> P.covers(Integer(1), Integer(6))
True
```
coxeter_polynomial()

Return the Coxeter polynomial of the poset.

OUTPUT:

a polynomial in one variable

The output is the characteristic polynomial of the Coxeter transformation. This polynomial only depends on
the derived category of modules on the poset.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.coxeter_polynomial()  # needs sage.libs.flint
x^5 + x^4 + x + 1

sage: p = posets.SymmetricGroupWeakOrderPoset(3)  # needs sage.groups
sage: p.coxeter_polynomial()  # needs sage.groups sage.libs.flint
x^6 + x^5 - x^3 + x + 1
```

See also:

- `coxeter_transformation()`, `coxeter_smith_form()`

coxeter_smith_form(algorithm='singular')

Return the Smith normal form of $x$ minus the Coxeter transformation matrix.

INPUT:

- **algorithm** = optional (default 'singular'), possible values are 'singular', 'sage',
  'gap', 'pari', 'maple', 'magma', 'fricas'

Beware that speed depends very much on the choice of algorithm. Sage is rather slow, Singular is faster and
Pari is fast at least for small sizes.

OUTPUT:

- list of polynomials in one variable, each one dividing the next one
The output list is a refinement of the characteristic polynomial of the Coxeter transformation, which is its product. This list of polynomials only depends on the derived category of modules on the poset.

EXAMPLES:

```python
sage: P = posets.PentagonPoset()
sage: P.coxeter_smith_form()
[1, 1, 1, 1, x^5 + x^4 + x + 1]
sage: P = posets.DiamondPoset(7)
sage: prod(P.coxeter_smith_form()) == P.coxeter_polynomial()
True
```

See also:

- `coxeter_transformation()`, `coxeter_matrix()`

### `coxeter_transformation()`

Return the Coxeter transformation of the poset.

**OUTPUT:**

a square matrix with integer coefficients

The output is the matrix of the Auslander-Reiten translation acting on the Grothendieck group of the derived category of modules on the poset, in the basis of simple modules. This matrix is usually called the Coxeter transformation.

**EXAMPLES:**

```python
sage: posets.PentagonPoset().coxeter_transformation()
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
```

```python
>>> from sage.all import *
>>> posets.PentagonPoset().coxeter_transformation()
[ 0 0 0 0 -1]
[ 0 0 0 1 -1]
[ 0 1 0 0 -1]
[-1 1 1 0 -1]
[-1 1 0 1 -1]
```
See also:

coxeter_polynomial(), coxeter_smith_form()

cuts()

Return the list of cuts of the poset self.

A cut is a subset $A$ of self such that the set of lower bounds of the set of upper bounds of $A$ is exactly $A$.

The cuts are computed here using the maximal independent sets in the auxiliary graph defined as $P \times [0, 1]$ with an edge from $(x, 0)$ to $(y, 1)$ if and only if $x \npreceq_P y$. See the end of section 4 in [JRJ94].

EXAMPLES:

```sage
sage: P = posets.AntichainPoset(3)
sage: Pc = P.cuts()
sage: Pc # random
[frozenset({0}),
 frozenset(),
 frozenset({0, 1, 2}),
 frozenset({2}),
 frozenset({1})]
sage: sorted(list(c) for c in Pc)
[[], [0], [0, 1, 2], [1], [2]]
```

See also:

completion_by_cuts()

degree_polynomial()

Return the generating polynomial of degrees of vertices in self.

This is the sum

$$\sum_{v \in P} x^{\text{in}(v)} y^{\text{out}(v)},$$

where $\text{in}(v)$ and $\text{out}(v)$ are the number of incoming and outgoing edges at vertex $v$ in the Hasse diagram of $P$.

Because this polynomial is multiplicative for Cartesian product of posets, it is useful to help see if the poset can be isomorphic to a Cartesian product.

EXAMPLES:

```sage
sage: P = posets.PentagonPoset()
sage: P.deegree_polynomial()
x^2 + 3*x*y + y^2
```

(continues on next page)
sage: P = posets.BooleanLattice(4)
sage: P.degree_polynomial().factor()
(x + y)^4

>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> P.degree_polynomial()
x^2 + 3*x*y + y^2

>>> P = posets.BooleanLattice(Integer(4))
>>> P.degree_polynomial().factor()
(x + y)^4

See also:

cardinality() for the value at (x, y) = (1, 1)

diamonds()

Return the list of diamonds of self.

A diamond is the following subgraph of the Hasse diagram:

```
   z
  / \
x  /  
y /    
w
```

Thus each edge represents a cover relation in the Hasse diagram. We represent this as the tuple (w, x, y, z).

OUTPUT:

A tuple with

- a list of all diamonds in the Hasse Diagram,
- a boolean checking that every w, x, y that form a V, there is a unique element z, which completes the diamond.

EXAMPLES:

sage: P = Poset({0: [1,2], 1: [3], 2: [3], 3: []})
sage: P.diamonds()
([(0, 1, 2, 3)], True)

sage: P = posets.YoungDiagramPoset(Partition([3, 2, 2]))  # needs sage.combinat
sage: P.diamonds()  # needs sage.combinat
([([(0, 0), (0, 1), (1, 0), (1, 1)], False])

>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1),Integer(2)], Integer(1): [Integer(3)],
            Integer(2): [Integer(3)], Integer(3): []})
>>> P.diamonds()
([(0, 1, 2, 3)], True)

>>> P = posets.YoungDiagramPoset(Partition([Integer(3), Integer(2),
                                         Integer(5), Integer(1)]))
(continues on next page)
dilworth_decomposition()

Return a partition of the points into the minimal number of chains.

According to Dilworth’s theorem, the points of a poset can be partitioned into \( \alpha \) chains, where \( \alpha \) is the cardinality of its largest antichain. This method returns such a partition.

See Wikipedia article Dilworth’s theorem.

ALGORITHM:

We build a bipartite graph in which a vertex \( v \) of the poset is represented by two vertices \( v^- \), \( v^+ \). For any two \( u, v \) such that \( u < v \) in the poset we add an edge \( v^+u^- \).

A matching in this graph is equivalent to a partition of the poset into chains: indeed, a chain \( v_1 \ldots v_k \) gives rise to the matching \( v_1^+v_2^-, v_2^+v_3^-, \ldots \), and from a matching one can build the union of chains.

According to Dilworth’s theorem, the number of chains is equal to \( \alpha \) (the posets’ width).

EXAMPLES:

```
sage: p = posets.BooleanLattice(4)
sage: p.width()  # needs networkx
6
sage: p.dilworth_decomposition()  # random  # needs networkx
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

```
>>> from sage.all import *
>>> p = posets.BooleanLattice(Integer(4))
>>> p.width()  # needs networkx
6
>>> p.dilworth_decomposition()  # random  # needs networkx
[[7, 6, 4], [11, 3], [12, 8, 0], [13, 9, 1], [14, 10, 2], [15, 5]]
```

See also:

level_sets() to return elements grouped to antichains.

dimension (**certificate**, **solver**, **integrality_tolerance=False**)  

Return the dimension of the Poset.

The (Dushnik-Miller) dimension of a poset is the minimal number of total orders so that the poset is their “intersection”. More precisely, the dimension of a poset defined on a set \( X \) of points is the smallest integer \( n \) such that there exist linear extensions \( P_1, \ldots, P_n \) of \( P \) satisfying:

\[
u \leq_P v \text{ if and only if } \forall i, u \leq_{P_i} v\]

For more information, see the Wikipedia article Order_dimension.

INPUT:
- `certificate` (boolean; default: False) – whether to return an integer (the dimension) or a certificate, i.e. a smallest set of linear extensions.

- `solver` – (default: None) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to None, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.

- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**Note:** The speed of this function greatly improves when more efficient MILP solvers (e.g. Gurobi, CPLEX) are installed. See `MixedIntegerLinearProgram` for more information.

**Note:** Prior to version 8.3 this returned only realizer with `certificate=True`. Now it returns a pair having a realizer as the second element. See Issue #25588 for details.

**ALGORITHM:**

As explained [FT00], the dimension of a poset is equal to the (weak) chromatic number of a hypergraph. More precisely:

Let $inc(P)$ be the set of (ordered) pairs of incomparable elements of $P$, i.e. all $uv$ and $vu$ such that $u \not\leq_P v$ and $v \not\leq_P u$. Any linear extension of $P$ is a total order on $X$ that can be seen as the union of relations from $P$ along with some relations from $inc(P)$. Thus, the dimension of $P$ is the smallest number of linear extensions of $P$ which cover all points of $inc(P)$.

Consequently, $dim(P)$ is equal to the chromatic number of the hypergraph $\mathcal{H}_{inc}$, where $\mathcal{H}_{inc}$ is the hypergraph defined on $inc(P)$ whose sets are all $S \subseteq inc(P)$ such that $P \cup S$ is not acyclic.

We solve this problem through a `Mixed Integer Linear Program`.

The problem is known to be NP-complete.

**EXAMPLES:**

We create a poset, compute a set of linear extensions and check that we get back the poset from them:

```python
sage: P = Poset([[1, 4], [3], [4, 5, 3], [6], [], [6], []])
sage: P.dimension()  # needs networkx
3
sage: dim, L = P.dimension(certificate=True)  # needs sage.numerical.mip
sage: L  # random -- architecture-dependent  # needs sage.numerical.mip
[[0, 2, 4, 5, 1, 3, 6], [2, 5, 0, 1, 3, 4, 6], [0, 1, 2, 3, 5, 6, 4]]
sage: Poset((L[0], lambda x, y: all(l.index(x) < l.index(y) for l in L)))  # needs sage.numerical.mip
True
```

```python
>>> from sage.all import *

>>> P = Poset([[1, 4], [1, 4], [3], [4, 5, 3], [6], [], [6], []])
>>> P.dimension()  # needs networkx
3
>>> dim, L = P.dimension(certificate=True)  # needs sage.numerical.mip
```

(continues on next page)
According to Schnyder’s theorem, the incidence poset (of height 2) of a graph has dimension \( \leq 3 \) if and only if the graph is planar:

```python
sage: G = graphs.CompleteGraph(4)
sage: P = Poset(DiGraph({(u,v):[u,v] for u,v, in G.edges(sort=True)}))
```

```
# not tested (around 4s with CPLEX)
```

```python
sage: P.dimension() # not tested (around 4s with CPLEX)
3
```

```python
>> from sage.all import *
```

```python
>>> G = graphs.CompleteBipartiteGraph(3,3)
```

```python
>>> P = Poset(DiGraph({(u,v):[u,v] for u,v, in G.edges(sort=True)}))
```

```python
>>> P.dimension() # not tested (around 4s with CPLEX)
4
```

**disjoint_union** (*other, labels='pairs')

Return a poset isomorphic to disjoint union (also called direct sum) of the poset with *other*. The disjoint union of \( P \) and \( Q \) is a poset that contains every element and relation from both \( P \) and \( Q \), and where every element of \( P \) is incomparable to every element of \( Q \).

Mathematically, it is only defined when \( P \) and \( Q \) have no common element; here we force that by giving them different names in the resulting poset.

**INPUT:**

- **other**, a poset.
- **labels** – (defaults to ‘pairs’) If set to ‘pairs’, each element \( v \) in this poset will be named \( (0,v) \) and each element \( u \) in *other* will be named \( (1,u) \) in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

**EXAMPLES:**

```python
sage: P1 = Poset({'a': 'b'})
sage: P2 = Poset({'c': 'd'})
sage: P = P1.disjoint_union(P2); P
```

```
Finite poset containing 4 elements
```

```python
sage: sorted(P.cover_relations())
```

(continues on next page)
We show how to get literally direct sum with elements untouched:

\[
\begin{align*}
\text{sage: } & \quad P = P1\text{.disjoint_union}(P2)\text{.relabel}(\lambda x: x[1]) \\
\text{sage: } & \quad \text{sorted}(P\text{.cover_relations}()) \\
& \quad [\{(0, 'a'), (0, 'b')\}, \{(1, 'c'), (1, 'd')\}] \\
\end{align*}
\]

See also:

c\text{connected_components}()
d\text{ual}()

Return the dual poset of the given poset.

In the dual of a poset \( P \) we have \( x \leq y \) iff \( y \leq x \) in \( P \).

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \quad P = \text{Poset}({1: [2, 3], 3: [4]}) \\
\text{sage: } & \quad P\text{.cover_relations}() \\
& \quad [[1, 2], [1, 3], [3, 4]] \\
\text{sage: } & \quad Q = P\text{.dual}() \\
\text{sage: } & \quad Q\text{.cover_relations}() \\
& \quad [[4, 3], [3, 1], [2, 1]] \\
\end{align*}
\]

(continues on next page)
P.cover_relations()
[[1, 2], [1, 3], [3, 4]]

Q = P.dual()
Q.cover_relations()
[[4, 3], [3, 1], [2, 1]]

Dual of a lattice is a lattice; dual of a meet-semilattice is join-semilattice and vice versa. Also the dual of a (non-)facade poset is again (non-)facade:

sage: V = MeetSemilattice({1: [2, 3]}, facade=False)
sage: A = V.dual(); A
Finite join-semilattice containing 3 elements
sage: A(2) < A(1)
True

See also:

is_self_dual()
evacuation()

Compute evacuation on the linear extension associated to the poset self.

OUTPUT:

• an isomorphic poset, with the same default linear extension

Evacuation is defined on a poset self of size n by applying the evacuation operator \((\tau_1 \cdots \tau_{n-1})\tau_1 \cdots \tau_{n-2} \cdots \tau_1\), to the default linear extension \(\pi\) of self (see evacuation()), and relabeling self accordingly. For more details see [Stan2009].

EXAMPLES:

sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.evacuation()
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]), linear_extension=True, facade=False)
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]]
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> P.evacuation()
Finite poset containing 2 elements with distinguished linear extension
>>> P.evacuation() == P
True

>>> P = Poset(((Integer(1), Integer(2), Integer(3), Integer(4), Integer(5),
              Integer(6), Integer(7)), [[Integer(1), Integer(2)], [Integer(1), Integer(4)],
              [Integer(2), Integer(3)], [Integer(2), Integer(5)], [Integer(3), Integer(6)],
              [Integer(4), Integer(7)], [Integer(5), Integer(6)]), linear_extension=True,
              facade=False)
>>> P.list()
[1, 2, 3, 4, 5, 6, 7]

>>> Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 3], [2, 5], [3, 4], [3, 6], [4, 7], [6, 7]]
```

Note that the results depend on the linear extension associated to the poset:

```python
sage: P = Poset(((1,2,3,4,5,6,7), [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]

sage: Q = P.evacuation(); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 5], [2, 3], [5, 6], [5, 4], [6, 7], [4, 7]]
```

```python
>>> from sage.all import *

sage: P = Poset((divisors(15), attrcall("divides")), linear_extension=True)

sage: P.list()
[1, 3, 5, 15]

sage: Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]
```

Here is an example of a poset where the elements are not labelled by \( \{1, 2, \ldots, n\} \):

```python
sage: P = Poset((divisors(15), attrcall("divides")), linear_extension = True)

sage: P.list()
[1, 3, 5, 15]

sage: Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]
```

(continues on next page)
Q = P.evacuation(); Q
Finite poset containing 4 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 3], [1, 5], [3, 15], [5, 15]]

AUTHOR:

- Anne Schilling (2012-02-18)

*f_polynomial*

Return the $f$-polynomial of the poset.

The poset is expected to be bounded.

This is the $f$-polynomial of the order complex of the poset minus its bounds.

The coefficient of $q^i$ is the number of chains of $i + 1$ elements containing both bounds of the poset.

**Note:** This is slightly different from the `fPolynomial` method in Macaulay2.

**EXAMPLES:**

```python
sage: P = posets.DiamondPoset(5)
sage: P.f_polynomial()
3*q^2 + q
sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [7], 6: [7]})
sage: P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q
```

```python
>>> from sage.all import *
>>> P = posets.DiamondPoset(Integer(5))
>>> P.f_polynomial()
3*q^2 + q
```

```python
>>> P.f_polynomial()
q^4 + 4*q^3 + 5*q^2 + q
```

See also:

`is_bounded()`, `h_polynomial()`, `order_complex()`, `sage.topology.cell_complex.GenericCellComplex.f_vector()`
factor()
Factor the poset as a Cartesian product of smaller posets.

This only works for connected posets for the moment.

The decomposition of a connected poset as a Cartesian product of posets (prime in the sense that they cannot be written as Cartesian products) is unique up to reordering and isomorphism.

OUTPUT:

a list of posets

EXAMPLES:

```sage
sage: P = posets.PentagonPoset()
sage: Q = P * P
sage: Q.factor()  # Output: [Finite poset containing 5 elements, Finite poset containing 5 elements]
sage: P1 = posets.ChainPoset(3)
sage: P2 = posets.ChainPoset(7)
sage: P1.factor()  # Output: [Finite lattice containing 3 elements]
sage: (P1 * P2).factor()  # Output: [Finite poset containing 7 elements, Finite poset containing 3 elements]
sage: P = posets.TamariLattice(4)
sage: (P * P).factor()  # Output: [Finite poset containing 14 elements, Finite poset containing 14 elements]
```

See also:

product()

REFERENCES:

flag_f_polynomial()
Return the flag $f$-polynomial of the poset.
The poset is expected to be bounded and ranked.

This is the sum, over all chains containing both bounds, of a monomial encoding the ranks of the elements of the chain.

More precisely, if $P$ is a bounded ranked poset, then the flag $f$-polynomial of $P$ is defined as the polynomial

$$
\sum_{p_0 < p_1 < \cdots < p_k, \ p_0 = \text{min } P, \ p_k = \text{max } P} x_{\rho(p_1)}x_{\rho(p_2)}\cdots x_{\rho(p_k)} \in \mathbb{Z}[x_1, x_2, \cdots, x_n],
$$

where $\text{min } P$ and $\text{max } P$ are (respectively) the minimum and the maximum of $P$, where $\rho$ is the rank function of $P$ (normalized to satisfy $\rho(\text{min } P) = 0$), and where $n$ is the rank of $\text{max } P$. (Note that the indeterminate $x_0$ does not actually appear in the polynomial.)

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbb{Z}[x_0, x_1, x_2, \cdots, x_{n+1}]$ by this method.

See Wikipedia article h-vector.

**EXAMPLES:**

```python
sage: P = posets.DiamondPoset(5)
sage: P.flag_f_polynomial()
3*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: P.flag_f_polynomial()
2*x1*x2*x3 + 2*x1*x3 + 2*x2*x3 + x3

sage: q = polygen(ZZ,'q')
sage: P.flag_f_polynomial(q,q,q) == P.f_polynomial()
True

sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_f_polynomial()
3*x1*x2*x3 + 3*x1*x3 + x2*x3 + x3
```

See also:

`is_bounded()`, `flag_h_polynomial()`
flag_h_polynomial()

Return the flag $h$-polynomial of the poset.

The poset is expected to be bounded and ranked.

If $P$ is a bounded ranked poset whose maximal element has rank $n$ (where the minimal element is set to have rank 0), then the flag $h$-polynomial of $P$ is defined as the polynomial

$$
\prod_{k=1}^{n} (1 - x_k) \cdot f \left( \frac{x_1}{1 - x_1}, \frac{x_2}{1 - x_2}, \ldots, \frac{x_n}{1 - x_n} \right) \in \mathbb{Z}[x_1, x_2, \ldots, x_n],
$$

where $f$ is the flag $f$-polynomial of $P$ (see flag_f_polynomial()).

For technical reasons, the polynomial is returned in the slightly larger ring $\mathbb{Q}[x_0, x_1, x_2, \ldots, x_{n+1}]$ by this method.

See Wikipedia article $h$-vector.

EXAMPLES:

```python
sage: P = posets.DiamondPoset(5)
sage: P.flag_h_polynomial()
2*x1*x2 + x2

sage: P = Poset({1: [2, 3], 2: [4], 3: [5], 4: [6], 5: [6]})
sage: f1 = P.flag_h_polynomial(); f1
-x1*x2*x3 + x1*x3 + x2*x3 + x3
sage: q = polygen(ZZ, 'q')
sage: f1(q,q,q,q) == P.h_polynomial()
True

sage: P = Poset({1: [2, 3, 4], 2: [5], 3: [5], 4: [5], 5: [6]})
sage: P.flag_h_polynomial()
2*x1*x3 + x3
```

```python
>>> from sage.all import *

>>> P = posets.DiamondPoset(Integer(5))

>>> P.flag_h_polynomial()
2*x1*x2 + x2

>>> P = Poset({Integer(1): [Integer(2), Integer(3)], Integer(2): [Integer(4)],
             Integer(3): [Integer(5)], Integer(4): [Integer(6)], Integer(5):...,
             Integer(6):...})

>>> f1 = P.flag_h_polynomial(); f1

>>> q = polygen(ZZ, 'q')

>>> f1(q,q,q,q) == P.h_polynomial()

True
```

(continues on next page)
P = posets.ChainPoset(Integer(4))
P.flag_h_polynomial()
x3

See also:
is_bounded(), flag_f_polynomial()

frank_network()

Return Frank’s network of the poset.

This is defined in Section 8 of [BF1999].

OUTPUT:

A pair \((G, e)\), where \(G\) is Frank’s network of \(P\) encoded as a DiGraph, and \(e\) is the cost function on its edges encoded as a dictionary (indexed by these edges, which in turn are encoded as tuples of 2 vertices).

Note: Frank’s network of \(P\) is a certain directed graph with \(2|P| + 2\) vertices, defined in Section 8 of [BF1999]. Its set of vertices consists of two vertices \((0, p)\) and \((1, p)\) for each element \(p\) of \(P\), as well as two vertices \((-1, 0)\) and \((2, 0)\). (These notations are not the ones used in [BF1999]; see the table below for their relation.) The edges are:

- for each \(p\) in \(P\), an edge from \((-1, 0)\) to \((0, p)\);
- for each \(p\) in \(P\), an edge from \((1, p)\) to \((2, 0)\);
- for each \(p\) and \(q\) in \(P\) such that \(p \geq q\), an edge from \((0, p)\) to \((1, q)\).

We make this digraph into a network in the sense of flow theory as follows: The vertex \((-1, 0)\) is considered as the source of this network, and the vertex \((2, 0)\) as the sink. The cost function is defined to be 1 on the edge from \((0, p)\) to \((1, p)\) for each \(p \in P\), and to be 0 on every other edge. The capacity is 1 on each edge. Here is how to translate this notations into that used in [BF1999]:

<table>
<thead>
<tr>
<th>our notations</th>
<th>[BF1999]</th>
</tr>
</thead>
<tbody>
<tr>
<td>(-1, 0)</td>
<td>s</td>
</tr>
<tr>
<td>(0, p)</td>

AUTHOR:

- Darij Grinberg (2013-05-09)

\textbf{ge} (x, y)

Return \textbf{True} if $x$ is greater than or equal to $y$ in the poset, and \textbf{False} otherwise.

\textbf{EXAMPLES:}

```
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

See also:

\textbf{is_greater_than()}, \textbf{is_lequal()}.

\textbf{graphviz_string} (\textit{graph_string}='graph', \textit{edge_string}='--')

Return a representation in the DOT language, ready to render in graphviz.

\textbf{EXAMPLES:}

```
sage: P = Poset({'a':['b'], 'b':['d'], 'c':['d'], 'd':['f'], 'e':['f'], 'f':[]})
sage: print(P.graphviz_string())
graph {
  "f"--"d";"b"--"a";"c"--"e";
  "e"--"a";"d"--"c";"b"--"e";"d"--"b";"f"--"d";
}
```
```
>>> from sage.all import *

>>> P = Poset({"a": ["b"], "b": ["d"], "c": ["d"], "d": ["f"], "e": ["f"], "f": []})

>>> print(P.graphviz_string())
graph {
  "f"--"e"; "d"--"c"; "b"--"a"; "d"--"b"; "f"--"d";
}
```

greene_shape()  

Return the Greene-Kleitman partition of self.

The Greene-Kleitman partition of a finite poset $P$ is the partition $(c_1 - c_0, c_2 - c_1, c_3 - c_2, \ldots)$, where $c_k$ is the maximum cardinality of a union of $k$ chains of $P$. Equivalently, this is the conjugate of the partition $(a_1 - a_0, a_2 - a_1, a_3 - a_2, \ldots)$, where $a_k$ is the maximum cardinality of a union of $k$ antichains of $P$.

See many sources, e.g., [BF1999], for proofs of this equivalence.

EXAMPLES:

```
sage: # needs sage.combinat
sage: P = Poset([[3,2,1], [[3,1], [2,1]]])
sage: P.greene_shape()
[2, 1]
sage: P = Poset([[1,2,3,4], [[1,4], [2,4], [4,3]]])
sage: P.greene_shape()
[3, 1]
sage: P = Poset([[1,2,3,4,5,6,7,8,9,10,11,12,13,14,15,16,17,18,19,20,21,22], ...
  ...: [[1,4], [2,4], [4,3]]])
sage: P.greene_shape()
[3, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: P = Poset([[1,1]])
sage: P.greene_shape()
[]
```

```
>>> from sage.all import *

>>> # needs sage.combinat

>>> P = Poset([[Integer(3),Integer(2),Integer(1)], [[Integer(3), Integer(1)], ...
  ...: [Integer(2), Integer(1)]]])

>>> P.greene_shape()
[2, 1]

>>> P = Poset([[Integer(1),Integer(2),Integer(3),Integer(4)], [[Integer(1), ...
  ...: Integer(4)], [Integer(2), Integer(4)], [Integer(4), Integer(3)]]])

>>> P.greene_shape()
[3, 1]

>>> P = Poset([[Integer(1),Integer(2),Integer(3),Integer(4),Integer(5), ...
  ...: Integer(6), Integer(7), Integer(8), Integer(9), Integer(10), Integer(11), ...
  ...: Integer(12), Integer(13), Integer(14), Integer(15), Integer(16), Integer(17), ...
  ...: Integer(18), Integer(19), Integer(20), Integer(21), Integer(22)], ...
  ...: [[Integer(1), Integer(4)], [Integer(2), Integer(4)], [Integer(4), ...
  ...: Integer(3)]]])

>>> P.greene_shape()
[3, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1]

>>> P = Poset([[1,1]])

>>> P.greene_shape()
[]
```

AUTHOR:

- Darij Grinberg (2013-05-09)
\textbf{gt} (x, y)

Return True if \( x \) is greater than but not equal to \( y \) in the poset, and False otherwise.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True
sage: P.is_greater_than(1, 2)
False
sage: P.is_greater_than(3, 3)
False
sage: P.is_greater_than(0, 1)
False
\end{verbatim}

For non-facade posets also > works:

\begin{verbatim}
sage: P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],
Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
sage: P.is_greater_than(Integer(3), Integer(1))
True
\end{verbatim}

See also:
\texttt{is_geq\_equal()}, \texttt{is_less\_than()}.

\textbf{h\_polynomial}()

Return the \( h \)-polynomial of a bounded poset \texttt{self}.

This is the \( h \)-polynomial of the order complex of the poset minus its bounds.

This is related to the \( f \)-polynomial by a simple change of variables:

\[ h(q) = (1 - q)^{\deg f} f \left( \frac{q}{1 - q} \right), \]

where \( f \) and \( h \) denote the \( f \)-polynomial and the \( h \)-polynomial, respectively.

See Wikipedia article h-vector.

\textbf{Warning:} This is slightly different from the \texttt{hPolynomial} method in Macaulay2.
### EXAMPLES:

```python
sage: P = posets.AntichainPoset(3).order_ideals_lattice()
sage: P.h_polynomial()
q^3 + 4*q^2 + q
sage: P = posets.DiamondPoset(5)
sage: P.h_polynomial()
2*q^2 + q
sage: P = Poset({1: []})
sage: P.h_polynomial()
1
```

```python
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3)).order_ideals_lattice()
>>> P.h_polynomial()
q^3 + 4*q^2 + q
>>> P = posets.DiamondPoset(Integer(5))
>>> P.h_polynomial()
2*q^2 + q
>>> P = Poset({Integer(1): []})
>>> P.h_polynomial()
1
```

See also:

- `is_bounded()`, `f_polynomial()`, `order_complex()`, `sage.topology.simplicial_complex.SimplicialComplex.h_vector()`

### has_bottom()

Return `True` if the poset has a unique minimal element, and `False` otherwise.

#### EXAMPLES:

```python
sage: P = Poset({0: [3], 1: [3], 2: [3], 3: [4], 4: []})
sage: P.has_bottom()
False
sage: Q = Poset({0: [1], 1: []})
sage: Q.has_bottom()
True
```

```python
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(3)], Integer(1): [Integer(3)],...
   ...: Integer(2): [Integer(3)], Integer(3): [Integer(4)], Integer(4): [()]})
>>> P.has_bottom()
False
>>> Q = Poset({Integer(0): [Integer(1)], Integer(1): []})
>>> Q.has_bottom()
True
```

See also:

- Dual Property: `has_top()`
- Stronger properties: `is_bounded()`
- Other: `bottom()`
has_isomorphic_subposet \( (other) \)

Return True if the poset contains a subposet isomorphic to other.

By subposet we mean that there exist a set \( X \) of elements such that self.subposet \( (X) \) is isomorphic to other.

INPUT:

* other – a finite poset

EXAMPLES:

```
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: T = Poset({1:[2,3], 2:[4,5], 3:[6,7]})
sage: N5 = posets.PentagonPoset()
sage: N5.has_isomorphic_subposet(T)
False
sage: N5.has_isomorphic_subposet(D)
True
sage: len([P for P in Posets(5) if P.has_isomorphic_subposet(D)])
11
```

```
>>> from sage.all import *
>>> D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)],
˓→Integer(3):[Integer(4)]})
>>> T = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4),
˓→Integer(5)], Integer(3):[Integer(6),Integer(7)]})
>>> N5 = posets.PentagonPoset()
>>> N5.has_isomorphic_subposet(T)
False
>>> N5.has_isomorphic_subposet(D)
True
>>> len([P for P in Posets(Integer(5)) if P.has_isomorphic_subposet(D)])
11
```

has_top()

Return True if the poset has a unique maximal element, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.has_top()
False
sage: Q = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: Q.has_top()
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],...
˓→Integer(2):[Integer(3)], Integer(3):[Integer(4), Integer(5)], Integer(4):[],
˓→Integer(5):[]})
>>> P.has_top()
False
>>> Q = Poset({Integer(0):[Integer(3)], Integer(1):[Integer(3)],...
˓→(continues on next page)
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> Q = Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[])
>>> Q.has_top()
True
```

See also:

- Dual Property: `has_bottom()`
- Stronger properties: `is_bounded()`
- Other: `top()`

`hasse_diagram()`

Return the Hasse diagram of the poset as a Sage `DiGraph`.

The Hasse diagram is a directed graph where vertices are the elements of the poset and there is an edge from \( u \) to \( v \) whenever \( v \) covers \( u \) in the poset.

If `dot2tex` is installed, then this sets the Hasse diagram’s latex options to use the `dot2tex` formatting.

**EXAMPLES:**

```python
sage: P = posets.DivisorLattice(12)
sage: H = P.hasse_diagram(); H
Digraph on 6 vertices
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: H.edges(sort=True, labels=False)
[(1, 2), (1, 3), (2, 4), (2, 6), (3, 6), (4, 12), (6, 12)]
```

```python
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(12))
>>> H = P.hasse_diagram(); H
Digraph on 6 vertices
>>> P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
>>> H.edges(sort=True, labels=False)
[(1, 2), (1, 3), (2, 4), (2, 6), (3, 6), (4, 12), (6, 12)]
```

`height (certificate=False)`

Return the height (number of elements in a longest chain) of the poset.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return \((h, c)\), where \( h \) is the height and \( c \) is a chain of maximum cardinality. If `certificate=False` return only the height.

**EXAMPLES:**

```python
sage: P = Poset({0: [1], 2: [3, 4], 4: [5, 6]})
sage: P.height()
3
sage: posets.PentagonPoset().height(certificate=True)
(4, [0, 2, 3, 4])
```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(1)], Integer(2): [Integer(3), Integer(4)],
   Integer(4): [Integer(5), Integer(6)]})
>>> P.height()
3
>>> posets.PentagonPoset().height(certificate=True)
(4, [0, 2, 3, 4])

incidence_algebra \( (R, \text{prefix}=T) \)

Return the incidence algebra of \( \text{self} \) over \( R \).

OUTPUT:

An instance of \( \text{sage.combinat.posets.incidence_algebras.IncidenceAlgebra} \).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements
over Rational Field
```

```
>>> from sage.all import *
>>>
P = posets.BooleanLattice(Integer(4))
>>> P.incidence_algebra(QQ)
Incidence algebra of Finite lattice containing 16 elements
over Rational Field
```

incomparability_graph()

Return the incomparability graph of the poset.

This is the complement of the comparability graph, i.e. an undirected graph where vertices are the elements of the poset and there is an edge between vertices if they are not comparable in the poset.

EXAMPLES:

```
sage: Y = Poset({1: [2], 2: [3, 4]})
sage: g = Y.incomparability_graph(); g
Incomparability graph on 4 vertices
sage: Y.compare_elements(1, 3) is not None
True
sage: g.has_edge(1, 3)
False
```

```
>>> from sage.all import *
>>>
Y = Poset({Integer(1): [Integer(2)], Integer(2): [Integer(3), Integer(4)]})
>>> g = Y.incomparability_graph(); g
Incomparability graph on 4 vertices
>>> Y.compare_elements(Integer(1), Integer(3)) is not None
True
>>> g.has_edge(Integer(1), Integer(3))
False
```

See also:

comparability_graph()
**interval** \((x, y)\)

Return a list of the elements \(z\) such that \(x \leq z \leq y\).

**INPUT:**

- \(x\) – any element of the poset
- \(y\) – any element of the poset

**EXAMPLES:**

```python
sage: uc = [[1, 3, 2], [4], [4, 5, 6], [6], [7], [7], [7], []]
sage: dag = DiGraph(dict(zip(range(len(uc)), uc)))
sage: P = Poset(dag)
sage: I = set(map(P, [2, 5, 6, 4, 7]))
sage: I == set(P.interval(2, 7))
True
```

```python
>>> from sage.all import *
>>> uc = [[Integer(1), Integer(3), Integer(2)], [Integer(4)], [Integer(4), ...
    ➔ Integer(5), Integer(6)], [Integer(6)], [Integer(7)], [Integer(7)], ...
    ➔ []]
>>> dag = DiGraph(dict(zip(range(len(uc)), uc)))
>>> P = Poset(dag)
>>> I = set(map(P, [Integer(2), Integer(5), Integer(6), Integer(4), Integer(7)]))
>>> I == set(P.interval(Integer(2), Integer(7)))
True
```

```python
sage: dg = DiGraph({"a": ["b","c"], "b": ["d"], "c": ["d"]})
sage: P = Poset(dg, facade = False)
sage: P.interval("a", "d")
[a, b, c, d]
```

```python
>>> from sage.all import *
>>> dg = DiGraph({"a": ["b","c"], "b": ["d"], "c": ["d"]})
>>> P = Poset(dg, facade = False)
>>> P.interval("a", "d")
[a, b, c, d]
```

**intervals_number()**

Return the number of relations in the poset.

A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: P.relations_number()
13
```

```python
sage: posets.TamariLattice(4).relations_number()
68
```
Combinatorics, Release 10.4

>>> posets.TamariLattice(Integer(4)).relations_number()
68

See also:

relations_iterator(), relations()

intervals_poset()

Return the natural partial order on the set of intervals of the poset.

OUTPUT:

a finite poset

The poset of intervals of a poset \( P \) has the set of intervals \([x, y]\) in \( P \) as elements, endowed with the order relation defined by \([x_1, y_1] \leq [x_2, y_2]\) if and only if \( x_1 \leq x_2 \) and \( y_1 \leq y_2 \).

This is also called \( P \) to the power 2, meaning the poset of poset-morphisms from the 2-chain to \( P \).

If \( P \) is a lattice, the result is also a lattice.

EXAMPLES:

sage: P = Poset({0:[1]})
sage: P.intervals_poset()
Finite poset containing 3 elements

sage: P = posets.PentagonPoset()
sage: P.intervals_poset()
Finite lattice containing 13 elements

>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(1)]})
>>> P.intervals_poset()
Finite poset containing 3 elements

>>> P = posets.PentagonPoset()
>>> P.intervals_poset()
Finite lattice containing 13 elements

is_EL_labelling (f, return_raising_chains=False)

Return True if \( f \) is an EL labelling of self.

A labelling \( f \) of the edges of the Hasse diagram of a poset is called an EL labelling (edge lexicographic labelling) if for any two elements \( u \) and \( v \) with \( u \leq v \),

- there is a unique \( f \)-raising chain from \( u \) to \( v \) in the Hasse diagram, and this chain is lexicographically first among all chains from \( u \) to \( v \).

For more details, see [Bj1980].

INPUT:

- \( f \) – a function taking two elements a and b in self such that b covers a and returning elements in a totally ordered set.
- return_raising_chains (optional; default:False) if True, returns the set of all raising chains in self, if possible.
EXAMPLES:

Let us consider a Boolean poset:

```python
sage: P = Poset([[0, 0], [0, 1], [1, 0], [1, 1]], [[0, 0], [0, 1], [1, 0], [1, 1]], facade=True)
sage: label = lambda a, b: min( i for i in [0, 1] if a[i] != b[i] )
sage: P.is_EL_labelling(label)
True
sage: P.is_EL_labelling(label, return_raising_chains=True)
{(0, 0), (0, 1)): [1],
 (0, 0), (1, 0)): [0],
 (0, 0), (1, 1)): [0, 1],
 (0, 1), (1, 1)): [0],
 (1, 0), (1, 1)): [1]}
```

```
>>> from sage.all import *
>>> P = Poset([[0, 0], [0, 1], [1, 0], [1, 1]], [[0, 0], [0, 1], [1, 0], [1, 1]], facade=True)
>>> label = lambda a, b: min( i for i in [Integer(0), Integer(1)] if a[i] != b[i] )
>>> P.is_EL_labelling(label)
True
>>> P.is_EL_labelling(label, return_raising_chains=True)
{(0, 0), (0, 1)): [1],
 (0, 0), (1, 0)): [0],
 (0, 0), (1, 1)): [0, 1],
 (0, 1), (1, 1)): [0],
 (1, 0), (1, 1)): [1]}
```

`is_antichain_of_poset (elms)`

Return True if elms is an antichain of the poset and False otherwise.

Set of elements are an antichain of a poset if they are pairwise incomparable.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(5)
sage: P.is_antichain_of_poset([3, 5, 7])
False
sage: P.is_antichain_of_poset([3, 5, 14])
True
```

```python
>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(5))
>>> P.is_antichain_of_poset([Integer(3), Integer(5), Integer(14)])
True
```

`is_bounded()`

Return True if the poset is bounded, and False otherwise.

A poset is bounded if it contains both a unique maximal element and a unique minimal element.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4, 5], 4:[], 5:[]})
sage: P.is_bounded()
False
sage: Q = posets.DiamondPoset(5)
sage: Q.is_bounded()
True
```

See also:

- Weaker properties: `has_bottom()`, `has_top()`
- Other: `with_bounds()`, `without_bounds()`

**is_chain()**

Return True if the poset is totally ordered ("chain"), and False otherwise.

**EXAMPLES:**

```python
sage: I = Poset({0:[1], 1:[2], 2:[3], 3:[4]})
sage: I.is_chain()
True
sage: II = Poset({0:[1], 2:[3]})
sage: II.is_chain()
False
sage: V = Poset({0:[1, 2]})
sage: V.is_chain()
False
```

```python
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(1)], Integer(1):[Integer(2)],...
˓→Integer(2):[Integer(3)], Integer(3):[Integer(4), Integer(5), Integer(4):[],
˓→ Integer(5):[])})
>>> P.is_bounded()
False
>>> Q = posets.DiamondPoset(Integer(5))
>>> Q.is_bounded()
True
```

**is_chain_of_poset()**

Return True if `elms` is a chain of the poset, and False otherwise.

```python
>>> from sage.all import *
>>> I = Poset({Integer(0):[Integer(1)], Integer(1):[Integer(2)],...
˓→Integer(2):[Integer(3)], Integer(3):[Integer(4)]})
>>> I.is_chain()
True
```

```python
>>> II = Poset({Integer(0):[Integer(1)], Integer(2):[Integer(3)]})
>>> II.is_chain()
False
```

```python
>>> V = Poset({Integer(0):[Integer(1), Integer(2)]})
>>> V.is_chain()
False
```

```python
>>> V = Poset({Integer(0):[Integer(1), Integer(2)]})
>>> V.is_chain()
False
```

**is_chain_of_poset()**

Return True if `elms` is a chain of the poset, and False otherwise.
Set of elements are a *chain* of a poset if they are comparable to each other.

**INPUT:**

- `elms` – a list or other iterable containing some elements of the poset
- `ordered` – a Boolean. If `True`, then return `True` only if elements in `elms` are strictly increasing in the poset; this makes no sense if `elms` is a set. If `False` (the default), then elements can be repeated and be in any order.

**EXAMPLES:**

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: sorted(P.list())
[1, 2, 3, 4, 6, 12]
sage: P.is_chain_of_poset([12, 3])
True
sage: P.is_chain_of_poset([3, 4, 12])
False
sage: P.is_chain_of_poset([12, 3], ordered=True)
False
sage: P.is_chain_of_poset([1, 1, 3], ordered=True)
False
sage: P.is_chain_of_poset([1, 3], ordered=True)
True
```

```python
>>> from sage.all import *
>>> P = Poset((divisors(Integer(12)), attrcall("divides")))
>>> sorted(P.list())
[1, 2, 3, 4, 6, 12]
>>> P.is_chain_of_poset([Integer(12), Integer(3)])
True
>>> P.is_chain_of_poset([Integer(3), Integer(4), Integer(12)])
False
>>> P.is_chain_of_poset([Integer(12), Integer(3)], ordered=True)
False
>>> P.is_chain_of_poset([Integer(1), Integer(1), Integer(3)], ordered=True)
True
>>> P.is_chain_of_poset([Integer(1), Integer(1), Integer(3)], ordered=True)
False
```

**is_connected()**

Return `True` if the poset is connected, and `False` otherwise.

A poset is connected if its Hasse diagram is connected.

If a poset is not connected, then it can be divided to parts $S_1$ and $S_2$ so that every element of $S_1$ is incomparable to every element of $S_2$.

**EXAMPLES:**

```
sage: P = Poset({1:[2, 3], 3:[4, 5]})
sage: P.is_connected()
True
```

```
sage: P = Poset({1:[2, 3], 3:[4, 5], 6:[7, 8]})
```
sage: P.is_connected()
False

>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(2), Integer(3)], Integer(3):[Integer(4),
˓→ Integer(5)]})
>>> P.is_connected()
True

>>> P = Poset({Integer(1):[Integer(2), Integer(3)], Integer(3):[Integer(4),
˓→ Integer(5)], Integer(6):[Integer(7), Integer(8)]})
>>> P.is_connected()
False

See also:

connected_components()

is_d_complete()

Return True if a poset is d-complete and False otherwise.

See also:

• d_complete

EXAMPLES:

sage: from sage.combinat.posets.posets import FinitePoset
sage: A = Poset({0: [1,2]})

sage: A.is_d_complete()
False

sage: from sage.combinat.posets.poset_examples import Posets
sage: B = Posets.DoubleTailedDiamond(3)

sage: B.is_d_complete()
True

sage: C = Poset({0: [2], 1: [2], 2: [3, 4], 3: [5], 4: [5], 5: [6]})

sage: C.is_d_complete()
False

sage: D = Poset({0: [1, 2], 1: [4], 2: [4], 3: [4]})

sage: D.is_d_complete()
False

sage: P = Posets.YoungDiagramPoset(Partition([3, 2, 2]), dual=True)  #...
˓→ needs sage.combinat

sage: P.is_d_complete()
#...
˓→ needs sage.combinat

True

>>> from sage.all import *
>>> from sage.combinat.posets.posets import FinitePoset
>>> A = Poset({0: [Integer(1),Integer(2)]})

>>> A.is_d_complete()
False
>>> from sage.combinat.posets.poset_examples import Posets
>>> B = Posets.DoubleTailedDiamond(Integer(3))
>>> B.is_d_complete()
True

>>> C = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],
            Integer(2): [Integer(3), Integer(4)], Integer(3): [Integer(5)], Integer(4): [Integer(5)], Integer(5): [Integer(6)]})
>>> C.is_d_complete()
False

>>> D = Poset({Integer(0): [Integer(1), Integer(2)], Integer(1): [Integer(4)],
            Integer(2): [Integer(4)], Integer(3): [Integer(4)]})
>>> D.is_d_complete()
False

>>> P = Posets.YoungDiagramPoset(Partition([Integer(3), Integer(2)]), dual=True)  # needs sage.combinat
>>> P.is_d_complete()  # needs sage.combinat
True

is_eulerian (k=None, certificate=False)

Return True if the poset is Eulerian, and False otherwise.

The poset is expected to be graded and bounded.

A poset is Eulerian if every non-trivial interval has the same number of elements of even rank as of odd rank.
A poset is k-eulerian if every non-trivial interval up to rank k is Eulerian.

See Wikipedia article Eulerian_poset.

INPUT:

• k, an integer – only check if the poset is k-eulerian. If None (the default), check if the poset is Eulerian.

• certificate, a Boolean – (default: False) whether to return a certificate

OUTPUT:

• If certificate=True return either True, None or False, (a, b), where the interval (a, b) is not Eulerian. If certificate=False return True or False.

EXAMPLES:

sage: P = Poset({0: [1, 2, 3], 1: [4, 5], 2: [4, 6], 3: [5, 6],
            ....: 4: [7, 8], 5: [7, 8], 6: [7, 8], 7: [9], 8: [9]})

sage: P.is_eulerian()  # needs sage.libs.flint
True

sage: P = Poset({0: [1, 2, 3], 1: [4, 5, 6], 2: [4, 6], 3: [4, 5],
            ....: 4: [7], 5: [7], 6: [7]})

sage: P.is_eulerian()  # needs sage.libs.flint
False

>>> from sage.all import *

>>> P = Poset({Integer(0): [Integer(1), Integer(2), Integer(3)]}, Integer(1):...
(continued from previous page)

>>> P.is_eulerian()
   # needs sage.libs.flint
True

>>> P = Poset({Integer(0): [Integer(1), Integer(2), Integer(3)], Integer(1):
   # needs sage.geometry.polyhedron sage.libs.flint
   True

>>> from sage.all import *

>>> P = Poset(DiGraph('MWW@_?W?@_?W??@??O@_?W?@_?W?@??O??')); P
Finite poset containing 14 elements
sage: P.is_eulerian(k=Integer(3))   # needs sage.libs.flint
True

>>> from sage.all import *

>>> P = Poset(DiGraph('MWW@?W?@_?W??@??O@_?W?@_?W?@??O??')); P
Finite poset containing 14 elements
sage: P.is_eulerian(k=integer(3))  # needs sage.libs.flint
True

sage: P.is_eulerian(k=integer(4))  # needs sage.libs.flint
False

Getting an interval that is not Eulerian:

Canonical examples of Eulerian posets are the face lattices of convex polytopes:

sage: P = polytopes.cube().face_lattice()

A poset that is 3- but not 4-eulerian:

sage: P = Poset(DiGraph('MWW@?W?@_?W??@??O@_?W?@_?W?@??O??'))

sage: P = Poset(DiGraph('MWW@?W?@_?W??@??O@_?W?@_?W?@??O??'))
Combinatorics, Release 10.4

```
sage: P = posets.DivisorLattice(12)
sage: P.is_eulerian(certificate=True)  # needs sage.libs.flint
(False, (1, 4))
```

```python
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(12))
>>> P.is_eulerian(certificate=True)  # needs sage.libs.flint
(False, (1, 4))
```

### is_gequal(x, y)

Return True if \(x\) is greater than or equal to \(y\) in the poset, and False otherwise.

**EXAMPLES:**

```
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: [ ]})
sage: P.is_gequal(3, 1)
True
sage: P.is_gequal(2, 2)
True
sage: P.is_gequal(0, 1)
False
```

```python
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],
            Integer(2): [Integer(3)], Integer(3): [Integer(4)], Integer(4): [ ]})
>>> P.is_gequal(Integer(3), Integer(1))
True
>>> P.is_gequal(Integer(2), Integer(2))
True
>>> P.is_gequal(Integer(0), Integer(1))
False
```

See also:

`is_greater_than()`, `is_lequal()`.

### is_graded()

Return True if the poset is graded, and False otherwise.

A poset is graded if all its maximal chains have the same length.

There are various competing definitions for graded posets (see Wikipedia article Graded_poset). This definition is from section 3.1 of Richard Stanley’s *Enumerative Combinatorics, Vol. 1* [EnumComb1]. Some sources call these posets *tiered*.

Every graded poset is ranked. The converse is true for bounded posets, including lattices.

**EXAMPLES:**

```
sage: P = posets.PentagonPoset()  # Not even ranked
sage: P.is_graded()
False
```

```
sage: P = Poset({1: [2, 3], 3: [4]})  # Ranked, but not graded
sage: P.is_graded()
False
```

(continues on next page)
sage: P = Poset({1:[3, 4], 2:[3, 4], 5:[6]})
sage: P.is_graded()
True

sage: P = Poset([1, [2], [], [4], []])
sage: P.is_graded()
False

>>> from sage.all import *
>>> P = posets.PentagonPoset()  # Not even ranked
>>> P.is_graded()
False

>>> P = Poset({Integer(1):[Integer(2), Integer(3)], Integer(3):[Integer(4)]})
# Ranked, but not graded
>>> P.is_graded()
True

>>> P = Poset([Integer(1), [Integer(2)], [], [Integer(4)], []])
>>> P.is_graded()
False

See also:

is_ranked(), level_sets()

is_greater_than(x, y)

Return True if x is greater than but not equal to y in the poset, and False otherwise.

EXAMPLES:

sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_greater_than(3, 1)
True

sage: P.is_greater_than(1, 2)
False

sage: P.is_greater_than(3, 3)
False

sage: P.is_greater_than(0, 1)
False

>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],
... Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> P.is_greater_than(Integer(3), Integer(1))
True

>>> P.is_greater_than(Integer(1), Integer(2))
False

>>> P.is_greater_than(Integer(3), Integer(3))
False

(continues on next page)
For non-facade posets also > works:

```python
sage: P = Poset({3: [1, 2]}, facade=False)
sage: P(2) > P(3)
True
```

See also:

* `is_gequal()`, `is_less_than()`.

**is_greedy** *(certificate=False)*

Return True if the poset is greedy, and False otherwise.

A poset is greedy if every greedy linear extension has the same number of jumps.

**INPUT:**

* certificate – (default: False) whether to return a certificate

**OUTPUT:**

* If certificate=True return either (True, None) or (False, (A, B)) where A and B are greedy linear extensions so that B has more jumps. If certificate=False return True or False.

**EXAMPLES:**

This is not a self-dual property:

```python
sage: W = Poset({1: [3, 4], 2: [4, 5]})
sage: M = W.dual()
sage: W.is_greedy()
True
sage: M.is_greedy()
False
```

Getting a certificate:

```python
sage: N = Poset({1: [3], 2: [3, 4]})
sage: N.is_greedy(certificate=True)
(False, (([1, 2, 4, 3], [2, 4, 1, 3]))
```
is_incomparable_chain_free \((m, n=\text{None})\)

Return True if the poset is \((m + n)\)-free, and False otherwise.

A poset is \((m + n)\)-free if there is no incomparable chains of lengths \(m\) and \(n\). Three cases have special name (see [EnumComb1], exercise 3.15):

- “interval order” is \((2 + 2)\)-free
- “semiorder” (or “unit interval order”) is \((1 + 3)\)-free and \((2 + 2)\)-free
- “weak order” is \((1 + 2)\)-free.

INPUT:

- \(m, n\) – positive integers

It is also possible to give a list of integer pairs as argument. See below for an example.

EXAMPLES:

```python
sage: B3 = posets.BooleanLattice(3)
sage: B3.is_incomparable_chain_free(1, 3)
True
sage: B3.is_incomparable_chain_free(2, 2)
False
sage: IP6 = posets.IntegerPartitions(6)  # needs sage.combinat
sage: IP6.is_incomparable_chain_free(1, 3)  # needs sage.combinat
False
sage: IP6.is_incomparable_chain_free(2, 2)  # needs sage.combinat
True
```

A list of pairs as an argument:
We show how to get an incomparable chain pair:

```python
sage: P = posets.PentagonPoset()
sage: chains_1_2 = Poset({0:[], 1:[2]})
sage: incomps = P.isomorphic_subposets(chains_1_2)[0]
sage: sorted(incomps.list()), incomps.cover_relations()
(([1, 2, 3], [[2, 3]])
```

```
>>> from sage.all import *
>>> P = posets.PentagonPoset()
>>> chains_1_2 = Poset({Integer(0):[], Integer(1):[Integer(2)]})
>>> incomps = P.isomorphic_subposets(chains_1_2)[Integer(0)]
>>> sorted(incomps.list()), incomps.cover_relations()
(([1, 2, 3], [[2, 3]])
```

AUTHOR:

• Eric Rowland (2013-05-28)

**is_induced_subposet** *(other)*

Return True if the poset is an induced subposet of other, and False otherwise.

A poset $P$ is an induced subposet of $Q$ if every element of $P$ is an element of $Q$, and $x \leq_P y$ iff $x \leq_Q y$. Note that “induced” here has somewhat different meaning compared to that of graphs.

INPUT:

• other, a poset.

Note: This method does not check whether the poset is a isomorphic (i.e., up to relabeling) subposet of other, but only if other directly contains the poset as an induced subposet. For isomorphic subposets see has_isomorphic_subposet().

**EXAMPLES:**

```python
sage: P = Poset({1:[2, 3]})
sage: Q = Poset({1:[2, 4], 2:[3]})
sage: P.is_induced_subposet(Q)
False
sage: R = Poset({0:[1], 1:[3, 4], 3:[5], 4:[2]})
sage: P.is_induced_subposet(R)
True
```

```
>>> from sage.all import *
>>> P = Poset({Integer(1):[Integer(2), Integer(3)]})
>>> Q = Poset({Integer(1):[Integer(2), Integer(4)], Integer(2):[Integer(3)]})
>>> P.is_induced_subposet(Q)
False
```
is_isomorphic

Return True if both posets are isomorphic.

EXAMPLES:

sage: P = Poset(([1,2,3], [[1,3],[2,3]]))
sage: Q = Poset(([4,5,6], [[4,6],[5,6]]))
sage: P.is_isomorphic(Q)
True

is_join_semilattice

Return True if the poset has a join operation, and False otherwise.

A join is the least upper bound for given elements, if it exists.

INPUT:

- certificate – (default: False) whether to return a certificate

OUTPUT:

- If certificate=True return either (True, None) or (False, (a, b)) where elements a and b have no least upper bound. If certificate=False return True or False.

EXAMPLES:

sage: P = Poset(([1,3,2], [4], [4,5,6], [6], [7], [7], [7], []))
sage: P.is_join_semilattice()
True

sage: P = Poset({1:[3, 4], 2:[3, 4], 3:[5], 4:[5]})
sage: P.is_join_semilattice()
False
sage: P.is_join_semilattice(certificate=True)
(False, (2, 1))
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> P.is_join_semilattice()
False
>>> P.is_join_semilattice(certificate=True)
(False, (2, 1))
```

See also:

- Dual property: `is_meet_semilattice()`
- Stronger properties: `is_lattice()`

**is_jump_critical (certificate=False)**

Return `True` if the poset is jump-critical, and `False` otherwise.

A poset $P$ is *jump-critical* if every proper subposet has smaller jump number.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, e)` so that removing element $e$ from the poset does not decrease the jump number. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```python
sage: P = Poset({1: [3, 6], 2: [3, 4, 5], 4: [6, 7], 5: [7]})
sage: P.is_jump_critical()
True

sage: P = posets.PentagonPoset()
sage: P.is_jump_critical()
False

sage: P.is_jump_critical(certificate=True)
(False, 3)
```

```python
>>> from sage.all import *
>>> P = Poset({Integer(1): [Integer(3), Integer(6)], Integer(2): [Integer(3),
                           Integer(4), Integer(5)], Integer(4): [Integer(6), Integer(7)],
                           Integer(5): [Integer(7)]})
>>> P.is_jump_critical()
True

>>> P = posets.PentagonPoset()
>>> P.is_jump_critical()
False

>>> P.is_jump_critical(certificate=True)
(False, 3)
```

See also:

- `jump_number()`

**is_lequal (x, y)**

Return `True` if $x$ is less than or equal to $y$ in the poset, and `False` otherwise.
EXAMPLES:

```python
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
```

```python
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False
```

```python
>>> from sage.all import *
```

```python
>>> P = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],
            Integer(2): [Integer(3)], Integer(3): [Integer(4)],
            Integer(4): []})
```

```python
>>> P.is_lequal(Integer(2), Integer(4))
True
>>> P.is_lequal(Integer(2), Integer(2))
True
>>> P.is_lequal(Integer(0), Integer(1))
False
>>> P.is_lequal(Integer(3), Integer(2))
False
```

See also:

`is_less_than()`, `is_gequal()`.

`is_less_than(x, y)`

Return `True` if `x` is less than but not equal to `y` in the poset, and `False` otherwise.

EXAMPLES:

```python
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
```

```python
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
sage: P.is_less_than(2, 2)
False
```

```python
>>> from sage.all import *
```

```python
>>> P = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],
            -> Integer(2): [Integer(3)], Integer(3): [Integer(4)], Integer(4): []})
```

```python
>>> P.is_less_than(Integer(1), Integer(3))
True
>>> P.is_less_than(Integer(0), Integer(1))
False
>>> P.is_less_than(Integer(2), Integer(2))
False
```

For non-facade posets also `<` works:

```python
sage: P = Poset({3: [1, 2], facade=False})
```

```python
sage: P(1) < P(2)
False
```
```python
>>> from sage.all import *
>>> P = Poset({Integer(3): [Integer(1), Integer(2)]}, facade=False)
>>> P(Integer(1)) < P(Integer(2))
False
See also:

is_lequal(), is_greater_than().

is_linear_extension(l)

Return whether l is a linear extension of self.

INPUT:

- l – a list (or iterable) containing all of the elements of self exactly once

EXAMPLES:

```python
sage: P = Poset((divisors(12), attrcall("divides")), facade=True, linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.is_linear_extension([1, 2, 4, 3, 6, 12])
True
sage: P.is_linear_extension([1, 2, 4, 6, 3, 12])
False
sage: [p for p in Permutations(list(P)) if P.is_linear_extension(p)]
[[1, 2, 3, 4, 6, 12],
 [1, 2, 3, 6, 4, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 2, 4, 6, 3, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12]]
```

(continues on next page)
```python
>>> list(P.linear_extensions())
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```

**Note:** This is used and systematically tested in `LinearExtensionsOfPosets`

See also:

`linear_extension()`, `linear_extensions()`

`is_linear_interval(x, y)`

Return whether the interval $[x, y]$ is linear.

This means that this interval is a total order.

**EXAMPLES:**

```python
sage: P = posets.PentagonPoset()
sage: P.is_linear_interval(0, 4)
False
sage: P.is_linear_interval(0, 3)
True
sage: P.is_linear_interval(1, 3)
False
```

```python
>>> from sage.all import *
```

```python
>>> P = posets.PentagonPoset()
```

```python
>>> P.is_linear_interval(Integer(0), Integer(4))
False
>>> P.is_linear_interval(Integer(0), Integer(3))
True
>>> P.is_linear_interval(Integer(1), Integer(3))
False
```

`is_meet_semilattice(certificate=False)`

Return `True` if the poset has a meet operation, and `False` otherwise.

A meet is the greatest lower bound for given elements, if it exists.

**INPUT:**

- `certificate` – (default: `False`) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either `(True, None)` or `(False, (a, b))` where elements $a$ and $b$ have no greatest lower bound. If `certificate=False` return `True` or `False`.

**EXAMPLES:**

```python
sage: P = Poset({1:[2, 3, 4], 2:[5, 6], 3:[6], 4:[6, 7]})
sage: P.is_meet_semilattice()
True
```
**sage:** Q = P.dual()
**sage:** Q.is_meet_semilattice()
False

**sage:** V = posets.IntegerPartitions(5)  
# needs sage.combinat
**sage:** V.is_meet_semilattice(certificate=True)  
# needs sage.combinat
(False, ((2, 2, 1), (3, 1, 1)))

```python
>>> from sage.all import *
>>> P.is_meet_semilattice()
True

>>> Q = P.dual()
>>> Q.is_meet_semilattice()
False

>>> V = posets.IntegerPartitions(Integer(5))  
# needs sage.combinat
>>> V.is_meet_semilattice(certificate=True)  
# needs sage.combinat
(False, ((2, 2, 1), (3, 1, 1)))
```

See also:

- Dual property: `is_join_semilattice()`
- Stronger properties: `is_lattice()`

`is_parent_of(x)`

Return `True` if `x` is an element of the poset.

`is_rank_symmetric()`

Return `True` if the poset is rank symmetric, and `False` otherwise.

The poset is expected to be graded and connected.

A poset of rank `h` (maximal chains have `h + 1` elements) is rank symmetric if the number of elements are equal in ranks `i` and `h - i` for every `i` in `0, 1, ..., h`.

**EXAMPLES:**

```python
sage: P = Poset({1:[3, 4, 5], 2:[3, 4, 5], 3:[6], 4:[7], 5:[7]})
sage: P.is_rank_symmetric()
True
sage: P = Poset({1:[2], 2:[3, 4], 3:[5], 4:[5]})
Sage: P.is_rank_symmetric()
False
```

```python
>>> from sage.all import *
```
is_ranked()

Return True if the poset is ranked, and False otherwise.

A poset is ranked if there is a function \( r \) from poset elements to integers so that \( r(x) = r(y) + 1 \) when \( x \) covers \( y \).

Informally said a ranked poset can be “levelized”: every element is on a “level”, and every cover relation goes only one level up.

EXAMPLES:

```python
sage: P = Poset( ([1, 2, 3, 4], [[1, 2], [2, 4], [3, 4]] )
sage: P.is_ranked()
True
sage: P = Poset( [[1, 5], [2, 6], [3, 4], [], [6, 3], [4]]
sage: P.is_ranked()
False
```

>>> from sage.all import *

```python
sage: P = Poset( ([Integer(1), Integer(2), Integer(3), Integer(4)],
              [[Integer(1), Integer(2)], [Integer(2), Integer(4)], [Integer(3),
              Integer(4)]])

sage: P.is_ranked()
True

sage: P = Poset( [[Integer(1), Integer(5)], [Integer(2), Integer(6)],
               [Integer(3)], [Integer(4)], [Integer(6), Integer(3)],
               [Integer(4)]])

sage: P.is_ranked()
False
```

See also:

`rank_function()`, `rank()`, `is_graded()`

is_series_parallel()

Return True if the poset is series-parallel, and False otherwise.

A poset is series-parallel if it can be built up from one-element posets using the operations of disjoint union and ordinal sum. This is also called \( N \)-free property: every poset that is not series-parallel contains a subposet isomorphic to the 4-element N-shaped poset where \( a > c, d \) and \( b > d \).

Note: Some papers use the term N-free for posets having no N-shaped poset as a cover-preserving subposet. This definition is not used here.

See Wikipedia article Series-parallel partial order.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: VA = Poset({1: [2, 3], 4: [5], 6: [5]})
sage: VA.is_series_parallel()
True
sage: big_N = Poset({1: [2, 4], 2: [3], 4:[7], 5:[6], 6:[7]})
sage: big_N.is_series_parallel()
False
```

```python
>>> from sage.all import *
>>> VA = Poset({Integer(1): [Integer(2), Integer(3)], Integer(4):...
˓→[Integer(5)], Integer(6): [Integer(5)]})
>>> VA.is_series_parallel()
True
>>> big_N = Poset({Integer(1): [Integer(2), Integer(4)], Integer(2):...
˓→[Integer(3)], Integer(4):[Integer(7)], Integer(5):[Integer(6)],...
˓→Integer(6):[Integer(7)]})
>>> big_N.is_series_parallel()
False
```

**is_slender** *(certificate=False)*

Return True if the poset is slender, and False otherwise.

A finite graded poset is slender if every rank 2 interval contains three or four elements, as defined in [Stan2009]. (This notion of “slender” is unrelated to the eponymous notion defined by Graetzer and Kelly in “The Free m-Lattice on the Poset H”, Order 1 (1984), 47–65.)

This function does not check if the poset is graded or not. Instead it just returns True if the poset does not contain 5 distinct elements \(x, y, a, b\) and \(c\) such that \(x \leq a, b, c \leq y\) where \(\leq\) is the covering relation.

**INPUT:**

- `certificate` – (default: False) whether to return a certificate

**OUTPUT:**

- If `certificate=True` return either (True, None) or (False, (a, b)) so that the interval \([a, b]\) has at least five elements. If `certificate=False` return True or False.

**EXAMPLES:**

```python
sage: P = Poset(((1, 2, 3, 4), [[1, 2], [1, 3], [2, 4], [3, 4]]))
sage: P.is_slender()
True
sage: P = Poset(((1,2,3,4,5),[[1,2],[1,3],[1,4],[2,5],[3,5],[4,5]]))
sage: P.is_slender()
False
```

```python
sage: # needs sage.groups
sage: W = WeylGroup(['A', 2])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: W = WeylGroup(['A', 3])
sage: G = W.bruhat_poset()
sage: G.is_slender()
True
sage: P = posets.IntegerPartitions(6) # needs sage.combinat
sage: P.is_slender(certificate=True) #...
```

(continues on next page)
is_sperner()

Return True if the poset is Sperner, and False otherwise.

The poset is expected to be ranked.

A poset is Sperner, if no antichain is larger than the largest rank level (one of the sets of elements of the same rank) in the poset.

See Wikipedia article Sperner_property_of_a_partially_ordered_set

See also:

width(), dilworth_decomposition()

EXAMPLES:

```python
sage: posets.SetPartitions(3).is_sperner()  # needs sage.combinat
True
sage: P = Poset({0: [3,4,5], 1: [5], 2: [5]})
sage: P.is_sperner()  # needs networkx
False
```

```python
>>> from sage.all import *
>>> posets.SetPartitions(Integer(3)).is_sperner()  # needs sage.combinat
(...)
```

(continues on next page)

### isomorphic_subposets

**isomorphic_subposets**(*other*)

Return a list of subposets of `self` isomorphic to `other`.

By subposet we mean `self.subposet(X)` which is isomorphic to `other` and where `X` is a subset of elements of `self`.

**INPUT:**

- `other` – a finite poset

**EXAMPLES:**

```python
sage: C2 = Poset({0:[1]})
sage: C3 = Poset({'a':['b'], 'b':['c']})
sage: L = sorted(x.cover_relations() for x in C3.isomorphic_subposets(C2))
```

```python
>>> from sage.all import *
```

```python
sage: D = Poset({Integer(1):[Integer(2),Integer(3)], Integer(2):[Integer(4)], Integer(3):[Integer(4)]})
>>> len(D.isomorphic_subposets_iterator())
```

**Note:** If this function takes too much time, try using `isomorphic_subposets_iterator()`.

### isomorphic_subposets_iterator

**isomorphic_subposets_iterator**(*other*)

Return an iterator over the subposets of `self` isomorphic to `other`.

By subposet we mean `self.subposet(X)` which is isomorphic to `other` and where `X` is a subset of elements of `self`. 

```python
from sage.all import *
```

```python
C2 = Poset({Integer(0): [Integer(1)]})
C3 = Poset({a:[b], b:[c]})
L = sorted(x.cover_relations() for x in C3.isomorphic_subposets_iterator(C2))
```
INPUT:

- \texttt{other} – a finite poset

EXAMPLES:

```python
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: N5 = posets.PentagonPoset()
sage: for P in N5.isomorphic_subposets_iterator(D):
....:     print(P.cover_relations())
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
[[0, 1], [0, 2], [1, 4], [2, 4]]
[[0, 1], [0, 3], [1, 4], [3, 4]]
```

Warning: This function will return same subposet as many times as there are automorphism on it. This is due to \texttt{subgraph_search_iterator()} returning labelled subgraphs. On the other hand, this function does not eat memory like \texttt{isomorphic_subposets()} does.

See also:

\begin{verbatim}
sage.combinat.posets.lattices.FiniteLatticePoset.
isomorphic_sublattices_iterator().
\end{verbatim}

\texttt{join(x, y)}

Return the join of two elements $x$, $y$ in the poset if the join exists; and \texttt{None} otherwise.

EXAMPLES:

```python
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: D.join(2, 3)
4
sage: P = Poset({'e':['b'], 'f':['b', 'c', 'd'], 'g':['c', 'd'],
....:     'b':['a'], 'c':['a']})
sage: P.join('a', 'b')
'a'
sage: P.join('e', 'a')
'a'
sage: P.join('c', 'b')
'a'
sage: P.join('e', 'f')
'b'
sage: P.join('e', 'g')
'a'
sage: P.join('c', 'd') \texttt{is None}
True
```

(continues on next page)
jump_number (certificate=False)

Return the jump number of the poset.

A jump in a linear extension \([e_1, \ldots, e_n]\) of a poset \(P\) is a pair \((e_i, e_{i+1})\) so that \(e_{i+1}\) does not cover \(e_i\) in \(P\). The jump number of a poset is the minimal number of jumps in linear extensions of a poset.

**INPUT:**

- certificate – (default: False) Whether to return a certificate

**OUTPUT:**

- If certificate=True return a pair \((n, l)\) where \(n\) is the jump number and \(l\) is a linear extension with \(n\) jumps. If certificate=False return only the jump number.

**EXAMPLES:**

sage: B3 = posets.BooleanLattice(3)
sage: B3.jump_number()
3

sage: N = Poset({1: [3, 4], 2: [3]})
sage: N.jump_number(certificate=True)
(1, [1, 4, 2, 3])

from sage.all import *
B3 = posets.BooleanLattice(Integer(3))
B3.jump_number()
3

N = Poset({Integer(1): [Integer(3), Integer(4)], Integer(2): [Integer(3)]})
N
ALGORITHM:

It is known that every poset has a greedy linear extension – an extension $[e_1, e_2, \ldots, e_n]$ where every $e_{i+1}$ is an upper cover of $e_i$ if that is possible – with the smallest possible number of jumps; see [Sys1987]. Hence it suffices to test only those. We do that by backtracking. The problem is proven to be NP-complete.

See also:

\texttt{is\_jump\_critical()}

\texttt{kazhdan\_lusztig\_polynomial}(x=\texttt{None}, y=\texttt{None}, q=\texttt{None}, canonical\_labels=\texttt{None})

Return the Kazhdan-Lusztig polynomial $P_{x,y}(q)$ of the poset.

The poset is expected to be ranked.

We follow the definition given in [EPW14]. Let $G$ denote a graded poset with unique minimal and maximal elements and $\chi_G$ denote the characteristic polynomial of $G$. Let $I_x$ and $P_x$ denote the principal order ideal and filter of $x$ respectively. Define the \textit{Kazhdan-Lusztig polynomial} of $G$ as the unique polynomial $P_G(q)$ satisfying the following:

1. If rank $G = 0$, then $P_G(q) = 1$.
2. If rank $G > 0$, then deg $P_G(q) < \frac{1}{2}$ rank $G$.
3. We have

$$q^{\text{rank } G}P_G(q^{-1}) = \sum_{x \in G} \chi_{I_x}(q)P_{P_x}(q).$$

We then extend this to $P_{x,y}(q)$ by considering the subposet corresponding to the (closed) interval $[x, y]$. We also define $P_\emptyset(q) = 0$ (so if $x \not\leq y$, then $P_{x,y}(q) = 0$).

INPUT:

- $q$ – (default: $q \in \mathbb{Z}[q]$) the indeterminate $q$
- $x$ – (default: the minimal element) the element $x$
- $y$ – (default: the maximal element) the element $y$
- $\text{canonical\_labels}$ – (optional) for subposets, use the canonical labeling (this can limit recursive calls for posets with large amounts of symmetry, but producing the labeling takes time); if not specified, this is True if $x$ and $y$ are both not specified and False otherwise

EXAMPLES:

```python
>>> from sage.all import *
>>> L = posets.BooleanLattice(Integer(3))
>>> L.kazhdan_lusztig_polynomial()
1
```
AUTHORS:

- Travis Scrimshaw (27-12-2014)

\( \text{le}(x, y) \)

Return True if \( x \) is less than or equal to \( y \) in the poset, and False otherwise.

EXAMPLES:

```
sage: P = Poset({0: [2], 1: [2], 2: [3], 3: [4], 4: []})
sage: P.is_lequal(2, 4)
True
sage: P.is_lequal(2, 2)
True
sage: P.is_lequal(0, 1)
False
sage: P.is_lequal(3, 2)
False
```

```
>>> from sage.all import *
>>> P = Poset({Integer(0): [Integer(2)], Integer(1): [Integer(2)],
             Integer(2): [Integer(3)], Integer(3): [Integer(4)], Integer(4): []}))
>>> P.is_lequal(Integer(2), Integer(4))
True
>>> P.is_lequal(Integer(2), Integer(2))
True
>>> P.is_lequal(Integer(0), Integer(1))
False
>>> P.is_lequal(Integer(3), Integer(2))
False
```

See also:

\( is_less_than() \), \( is_gequal() \).
**lequal_matrix** *(ring=Integer Ring, sparse=False)*

Compute the matrix whose \((i,j)\) entry is 1 if \(\text{self.linear_extension()[i]} < \text{self.linear_extension()[j]}\) and 0 otherwise.

**INPUT:**

- **ring** – the ring of coefficients (default: \(\mathbb{Z}\))
- **sparse** – whether the returned matrix is sparse or not (default: True)

**EXAMPLES:**

```
sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[[]], facade=False)
sage: LEQM = P.lequal_matrix(); LEQM
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 0 1 1 1]
[0 0 0 1 0 0 1 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]
sage: LEQM[1,3]
1
sage: P.linear_extension()[1] < P.linear_extension()[3]
True
sage: LEQM[2,5]
0
False
```

```python
>>> from sage.all import *

>>> P = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4), →Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)], →[]], facade=False)

>>> LEQM = P.lequal_matrix(); LEQM
[1 1 1 1 1 1 1 1]
[0 1 0 1 0 0 0 1]
[0 0 1 1 0 1 1 1]
[0 0 0 1 0 0 1 1]
[0 0 0 0 1 0 0 1]
[0 0 0 0 0 1 1 1]
[0 0 0 0 0 0 1 1]
[0 0 0 0 0 0 0 1]

>>> LEQM[Integer(1),Integer(3)]
1
>>> P.linear_extension()[Integer(1)] < P.linear_extension()[Integer(3)]
True
>>> LEQM[Integer(2),Integer(5)]
0
>>> P.linear_extension()[Integer(2)] < P.linear_extension()[Integer(5)]
False
```

We now demonstrate the usage of the optional parameters:

```
sage: P.lequal_matrix(ring=QQ, sparse=False).parent()  #...
                 ←needs sage.libs.flint
Full MatrixSpace of 8 by 8 dense matrices over Rational Field
```
level_sets()

Return elements grouped by maximal number of cover relations from a minimal element.

This returns a list of lists \( l \) such that \( l[i] \) is the set of minimal elements of the poset obtained by removing the elements in \( l[0], l[1], \ldots, l[i-1] \). (In particular, \( l[0] \) is the set of minimal elements of \( self \).)

Every level is an antichain of the poset.

EXAMPLES:

```python
sage: P = Poset({0:[1,2], 1:[3], 2:[3], 3:[]})
sage: P.level_sets()
[[0], [1, 2], [3]]
```

```python
sage: Q = Poset({0:[1,2], 1:[3], 2:[4], 3:[4]})
sage: Q.level_sets()
[[0], [1, 2], [3], [4]]
```

See also:

- dilworth_decomposition() to return elements grouped to chains.

lexicographic_sum(\( P \))

Return the lexicographic sum using this poset as index.

In the lexicographic sum of posets \( P_t \) by index poset \( T \) we have \( x \leq y \) if either \( x \leq y \) in \( P_t \) for some \( t \in T \), or \( x \in P_i \), \( y \in P_j \) and \( i \leq j \) in \( T \).

Informally said we substitute every element of \( T \) by corresponding poset \( P_t \).

Mathematically, it is only defined when all \( P_t \) have no common element; here we force that by giving them different names in the resulting poset.

disjoint_union() and ordinal_sum() are special cases of lexicographic sum where the index poset is an (anti)chain. ordinal_product() is a special case where every \( P_t \) is same poset.

INPUT:

- \( P \) – dictionary whose keys are elements of this poset, values are posets

EXAMPLES:
Combinatorics, Release 10.4

```sage
N = Poset({1: [3, 4], 2: [4]})
P = {1: posets.PentagonPoset(), 2: N,
NP = N.lexicographic_sum(P); NP
Finite poset containing 16 elements
sorted(NP.minimal_elements())
[(1, 0), (2, 1), (2, 2)]
```

```sage
>>> from sage.all import *
>>> N = Poset({Integer(1): [Integer(3), Integer(4)], Integer(2): [Integer(4)]})
>>> P = {Integer(1): posets.PentagonPoset(), Integer(2): N,
>>> NP = N.lexicographic_sum(P); NP
Finite poset containing 16 elements
>>> sorted(NP.minimal_elements())
[(1, 0), (2, 1), (2, 2)]
```

**linear_extension** *(linear_extension=None, check=True)*

Return a linear extension of this poset.

A linear extension of a finite poset \( P \) of size \( n \) is a total ordering \( \pi := \pi_0 \pi_1 \ldots \pi_{n-1} \) of its elements such that \( i < j \) whenever \( \pi_i < \pi_j \) in the poset \( P \).

**INPUT:**

- **linear_extension** – (default: None) a list of the elements of self
- **check** – a boolean (default: True); whether to check that linear_extension is indeed a linear extension of self.

**EXAMPLES:**

```sage
P = Poset((divisors(15), attrcall("divides")), facade=True)
```

```sage
>>> from sage.all import *
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)
```

Without optional argument, the default linear extension of the poset is returned, as a plain list:

```sage
P.linear_extension()
[1, 3, 5, 15]
```

```sage
>>> from sage.all import *
>>> P.linear_extension()
[1, 3, 5, 15]
```

Otherwise, a full-featured linear extension is constructed as an element of \( P \).linear_extensions():

```sage
l = P.linear_extension([1,5,3,15]); l
[1, 5, 3, 15]
sage: type(l)
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category.element_class'>
sage: l.parent()
The set of all linear extensions of Finite poset containing 4 elements
```

5.1. Comprehensive Module List
>>> from sage.all import *
>>> l = P.linear_extension([Integer(1), Integer(5), Integer(3), Integer(15)]); l
[1, 5, 3, 15]

By default, the linear extension is checked for correctness:

sage: l = P.linear_extension([1,3,15,5])
Traceback (most recent call last):
  ...
ValueError: [1, 3, 15, 5] is not a linear extension of Finite poset containing 4 elements

This can be disabled (at your own risks!) with:

sage: P.linear_extension([1,3,15,5], check=False)
[1, 3, 15, 5]

See also:

is_linear_extension(), linear_extensions()

Todo:

• Is it acceptable to have those two features for a single method?
• In particular, we miss a short idiom to get the default linear extension

linear_extensions (facade=False)
Return the enumerated set of all the linear extensions of this poset.

INPUT:

• facade – a boolean (default: False); whether to return the linear extensions as plain lists

Warning: The facade option is not yet fully functional:

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)  
sage: L = P.linear_extensions(facade=True); L
The set of all linear extensions of
Finite poset containing 6 elements with distinguished linear extension

```
sage: L([1, 2, 3, 4, 6, 12])
Traceback (most recent call last):
...
TypeError: Cannot convert list to sage.structure.element.Element
```

```
>>> from sage.all import *

>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_extension=True)
>>> L = P.linear_extensions(facade=True); L
The set of all linear extensions of
Finite poset containing 6 elements with distinguished linear extension

```
```
>>> L([Integer(1), Integer(2), Integer(3), Integer(4), Integer(6), Integer(12)])
Traceback (most recent call last):
...
TypeError: Cannot convert list to sage.structure.element.Element
```

EXAMPLES:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: L = P.linear_extensions(); L
The set of all linear extensions of
Finite poset containing 6 elements with distinguished linear extension

```
```
sage: l = L.an_element(); l
[1, 2, 3, 4, 6, 12]
>>>
```
```
sage: L.cardinality()
5
```
```
sage: L.list()
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
```
```
```
>>> from sage.all import *

>>> P = Poset((divisors(Integer(12)), attrcall("divides")), linear_extension=True)

```
```
>>> P.list()
[1, 2, 3, 4, 6, 12]
```
```
>>> L = P.linear_extensions(); L
The set of all linear extensions of
Finite poset containing 6 elements with distinguished linear extension

```
```
>>> l = L.an_element(); l
[1, 2, 3, 4, 6, 12]
>>>
```
```
>>> L.cardinality()
5
```
```
>>> L.list()
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]

```
```
Each element is aware that it is a linear extension of $P$:

```
sage: type(l.parent())
<class 'sage.combinat.posets.linear_extensions.LinearExtensionsOfPoset_with_category'>
```

With `facade=True`, the elements of $L$ are plain lists instead:

```
sage: L = P.linear_extensions(facade=True)
sage: l = L.an_element()
sage: type(l)
<class 'list'>
```

**Warning:** In Sage <= 4.8, this function used to return a plain list of lists. To recover the previous functionality, please use:

```
sage: L = list(P.linear_extensions(facade=True)); L
[[1, 2, 3, 4, 6, 12],
 [1, 2, 4, 3, 6, 12],
 [1, 3, 2, 4, 6, 12],
 [1, 3, 2, 6, 4, 12],
 [1, 2, 3, 6, 4, 12]]
sage: type(L[0])
<class 'list'>
```

See also:

- `linear_extension()`, `is_linear_extension()`
- `linear_extensions_graph()`

Return the linear extensions graph of the poset.

Vertices of the graph are linear extensions of the poset. Two vertices are connected by an edge if the linear extensions differ by only one adjacent transposition.
sage: N = Poset({1: [3, 4], 2: [4]})
sage: G = N.linear_extensions_graph(); G
Graph on 5 vertices
sage: G.neighbors(N.linear_extension([1, 2, 3, 4]))
[[2, 1, 3, 4], [1, 3, 2, 4], [1, 2, 4, 3]]
sage: chevron = Poset({1: [2, 6], 2: [3], 4: [3, 5], 6: [5]})
sage: G = chevron.linear_extensions_graph(); G
Graph on 22 vertices
sage: G.size()
36

linear_intervals_count()

Return the enumeration of linear intervals w.r.t. their cardinality.

An interval is linear if it is a total order.

OUTPUT: list of integers

See also:

is_linear_interval()

EXAMPLES:

sage: P = posets.PentagonPoset()
sage: P.linear_intervals_count()
[5, 5, 2]
sage: P = posets.TamariLattice(4)
sage: P.linear_intervals_count()
[14, 21, 12, 2]

list()

List the elements of the poset. This just returns the result of linear_extension().
EXAMPLES:

```sage
d = Poset({ 0:[1,2], 1:[3], 2:[3,4] }, facade = False)
d.list()
[0, 1, 2, 3, 4]
type(d.list()[0])
<class 'sage.combinat.posets.posets.FinitePoset_with_category.element_class'>
```

```sage>
from sage.all import *

>>> d = Poset({ Integer(0):[Integer(1),Integer(2)], Integer(1):[Integer(3)],...
Integer(2):[Integer(3),Integer(4)] }, facade = False)
>>> d.list()
[0, 1, 2, 3, 4]
>>> type(d.list()[Integer(0)])
<class 'sage.combinat.posets.posets.FinitePoset_with_category.element_class'>
```

```
lower_covers(x)
```

Return the list of lower covers of the element `x`.

A lower cover of `x` is an element `y` such that `y < x` and there is no element `z` so that `y < z < x`.

EXAMPLES:

```sage
P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
P.lower_covers(3)
[2, 5]
P.lower_covers(0)
[]
```

```sage>
from sage.all import *

>>> P = Poset({Integer(1):[Integer(5)], Integer(2):[Integer(6)],...
Integer(3):[], Integer(4):[Integer(4)]})
>>> P.lower_covers(Integer(3))
[2, 5]
>>> P.lower_covers(Integer(0))
[]
```

See also:

```
upper_covers()
```

```
lower_covers_iterator(x)
```

Return an iterator over the lower covers of the element `x`.

EXAMPLES:

```sage
P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
10 = P.lower_covers_iterator(3)
type(10)
<class 'generator'>
next(10)
2
```

```sage>
from sage.all import *

>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],...
Integer(2):[Integer(3), Integer(3):[]])
>>> 10 = P.lower_covers_iterator(Integer(3))
type(10)
```

(continues on next page)
lt (x, y)

Return True if x is less than but not equal to y in the poset, and False otherwise.

EXAMPLES:

```python
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.is_less_than(1, 3)
True
sage: P.is_less_than(0, 1)
False
sage: P.is_less_than(2, 2)
False
```

For non-facade posets also < works:

```python
sage: P = Poset({3: [1, 2], facade=False})
sage: P(1) < P(2)
False
```

See also:

- `is_lequal()`, `is_greater_than()`.
- `magnitude()`

Return the magnitude of self.

The magnitude is an integer defined as the sum of all Möbius numbers, and can be seen as some kind of Euler characteristic of the poset. It is additive under disjoint union and multiplicative under Cartesian product.

REFERENCES:

- https://golem.ph.utexas.edu/category/2011/06/the_magnitude_of_an_enriched_c.html

EXAMPLES:
sage: # needs sage.groups sage.libs.flint
sage: P = posets.PentagonPoset()
sage: P.magnitude()
1
sage: W = SymmetricGroup(4)
sage: P = W.noncrossing_partition_lattice().without_bounds()
sage: P.magnitude()
-4
sage: P = posets.TamariLattice(4).without_bounds()
sage: P.magnitude()
0

See also:

order_complex()

maximal_antichains()

Return the maximal antichains of the poset.

An antichain \( a \) of poset \( P \) is \textit{maximal} if there is no element \( e \in P \setminus a \) such that \( a \cup \{e\} \) is an antichain.

EXAMPLES:

sage: P = Poset({'a': ['b', 'c'], 'b': ['d', 'e']})

sage: [sorted(anti) for anti in P.maximal_antichains()]
[[['a'], ['b', 'c'], ['c', 'd', 'e']]]

sage: posets.PentagonPoset().maximal_antichains()
[[0], [1, 2], [1, 3], [4]]

See also:

antichains(), maximal_chains()

maximal_chain_length()

Return the maximum length of a maximal chain in the poset.

The length here is the number of vertices.
EXAMPLES:

```python
sage: P = posets.TamariLattice(5)
sage: P.maximal_chain_length()
11
```

```python
>>> from sage.all import *

>>> P = posets.TamariLattice(Integer(5))

>>> P.maximal_chain_length()
11
```

See also:

`maximal_chains()`, `maximal_chains_iterator()`

**maximal_chains** *(partial=None)*

Return all maximal chains of this poset.

Each chain is listed in increasing order.

**INPUT:**

- `partial` – list (optional); if given, the list `partial` is assumed to be the start of a maximal chain, and the function will find all maximal chains starting with the elements in `partial`

This is used in constructing the order complex for the poset.

**EXAMPLES:**

```python
sage: P = posets.BooleanLattice(3)
sage: P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7], [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7]]

sage: P.maximal_chains(partial=[0,2])
[[0, 2, 3, 7], [0, 2, 6, 7]]

sage: Q = posets.ChainPoset(6)
sage: Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

```python
>>> from sage.all import *

>>> P = posets.BooleanLattice(Integer(3))

>>> P.maximal_chains()
[[0, 1, 3, 7], [0, 1, 5, 7], [0, 2, 3, 7], [0, 2, 6, 7], [0, 4, 5, 7], [0, 4, 6, 7]]

>>> P.maximal_chains(partial=[Integer(0),Integer(2)])
[[0, 2, 3, 7], [0, 2, 6, 7]]

>>> Q = posets.ChainPoset(Integer(6))

>>> Q.maximal_chains()
[[0, 1, 2, 3, 4, 5]]
```

See also:

`maximal_antichains()`, `chains()`

**maximal_chains_iterator** *(partial=None)*

Return an iterator over maximal chains.

Each chain is listed in increasing order.

**INPUT:**

---

5.1. Comprehensive Module List 3309

Combinatorics, Release 10.4
• partial – list (optional); if given, the list partial is assumed to be the start of a maximal chain, and the function will yield all maximal chains starting with the elements in partial

EXAMPLES:

```python
sage: P = posets.BooleanLattice(3)
sage: it = P.maximal_chains_iterator()
sage: next(it)
[0, 1, 3, 7]
```

```python
>>> from sage.all import *

>>> P = posets.BooleanLattice(Integer(3))

>>> it = P.maximal_chains_iterator()

>>> next(it)
[0, 1, 3, 7]
```

See also:

antichains_iterator()  

maximal_elements()  

Return the list of the maximal elements of the poset.

EXAMPLES:

```python
sage: P = Poset({0:[3],1:[3],2:[3],3:[4],4:[]})
sage: P.maximal_elements()
[4]
```

```python
>>> from sage.all import *

>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
Integer(2):[Integer(3)],Integer(3):[Integer(4)],Integer(4):[]})

>>> P.maximal_elements()
[4]
```

See also:

minimal_elements().  

meet(x, y)  

Return the meet of two elements x, y in the poset if the meet exists; and None otherwise.

EXAMPLES:

```python
sage: D = Poset({1:[2,3], 2:[4], 3:[4]})
sage: D.meet(2, 3)
1
sage: P = Poset({'a':['b', 'c'], 'b':['e', 'f'], 'c':['f', 'g'],
 'd':['f', 'g']})

sage: P.meet('a', 'b')
'a'
sage: P.meet('e', 'a')
'a'
sage: P.meet('c', 'b')
'a'
sage: P.meet('e', 'f')
'b'
sage: P.meet('e', 'g')
'a'
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: P.meet('c', 'd') is None
True
sage: P.meet('g', 'f') is None
True
```

```python
>>> from sage.all import *

D = Poset({Integer(1):[Integer(2), Integer(3)], Integer(2):[Integer(4)], ...
           Integer(3):[Integer(4)]})
>>> D.meet(Integer(2), Integer(3))
1
>>> P = Poset({'a': ['b', 'c'], 'b': ['e', 'f'], 'c': ['f', 'g'], ...
             'd': ['f', 'g']})
>>> P.meet('a', 'b')
'a'
>>> P.meet('e', 'a')
'a'
>>> P.meet('c', 'b')
'a'
>>> P.meet('e', 'f')
'b'
>>> P.meet('e', 'g')
'a'
>>> P.meet('c', 'd') is None
True
>>> P.meet('g', 'f') is None
True
```

```
minimal_elements()

Return the list of the minimal elements of the poset.

EXAMPLES:

```python
sage: P = Poset({0:[3], 1:[3], 2:[3], 3:[4], 4:[]})
sage: P(0) in P.minimal_elements()
True
sage: P(1) in P.minimal_elements()
True
sage: P(2) in P.minimal_elements()
True
```
sage: P = Poset([[1,2,3],[4],[4],[4],[[]])
sage: P.moebius_function(P(0),P(4))
2
sage: sum(P.moebius_function(P(0),v) for v in P)
0
sage: sum(abs(P.moebius_function(P(0),v)) for v in P)
6
sage: for u,v in P.cover_relations_iterator():
    if P.moebius_function(u,v) != -1:
        print("Bug in moebius_function!")

>>> from sage.all import *
>>> P = Poset([[Integer(1),Integer(2),Integer(3)],[Integer(4)],[Integer(4)],
    \[Integer(4)],[[]])
>>> P.moebius_function(P(Integer(0)),P(Integer(4)))
2
>>> sum(P.moebius_function(P(Integer(0)),v) for v in P)
0
>>> sum(abs(P.moebius_function(P(Integer(0)),v)) for v in P)
6
>>> for u,v in P.cover_relations_iterator():
    if P.moebius_function(u,v) != Integer(1):
        print("Bug in moebius_function!")

sage: Q = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[[]])
sage: Q.moebius_function(Q(0),Q(7))
0
sage: Q.moebius_function(Q(0),Q(5))
0
sage: Q.moebius_function(Q(2),Q(7))
2
sage: Q.moebius_function(Q(3),Q(3))
1
sage: sum([Q.moebius_function(Q(0),v) for v in Q])
0

>>> from sage.all import *
>>> Q = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
    \[Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],[Integer(7)],[
    \[[]])
>>> Q.moebius_function(Q(Integer(0)),Q(Integer(7)))
0
>>> Q.moebius_function(Q(Integer(0)),Q(Integer(5)))
0
>>> Q.moebius_function(Q(Integer(2)),Q(Integer(7)))
2
>>> Q.moebius_function(Q(Integer(3)),Q(Integer(3)))
1
>>> sum([Q.moebius_function(Q(Integer(0)),v) for v in Q])
0

moebius_function_matrix(ring=Integer Ring, sparse=False)

Return a matrix whose (i,j) entry is the value of the Möbius function evaluated at self.linear_extension()[i] and self.linear_extension()[j].
INPUT:

- `ring` – the ring of coefficients (default: \(\mathbb{Z}\))
- `sparse` – whether the returned matrix is sparse or not (default: True)

EXAMPLES:

```
from sage.all import *

P = Poset([[4,2,3],[1],[1],[1],[]])

x, y = (P.linear_extension()[0], P.linear_extension()[1])

P.moebius_function(x, y)
-1

M = P.moebius_function_matrix(ring=QQ, sparse=False)
M.parent()
Full MatrixSpace of 5 by 5 dense matrices over Rational Field

open_interval(x, y)
Return the list of elements \(z\) such that \(x < z < y\) in the poset.
EXAMPLES:

```sage
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.open_interval(2, 100)
[4, 10, 20, 50]
```

```python
>>> from sage.all import *

>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))

>>> P.open_interval(Integer(2), Integer(100))
[4, 10, 20, 50]
```

See also:

`closed_interval()`

**order_complex**(on_ints=False)

Return the order complex associated to this poset.

The order complex is the simplicial complex with vertices equal to the elements of the poset, and faces given by the chains.

**INPUT:**

- on_ints -- a boolean (default: False)

**OUTPUT:**

an order complex of type `SimplicialComplex`

**EXAMPLES:**

```sage
sage: P = posets.BooleanLattice(3)
sage: S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets

sage: S.f_vector()
[1, 8, 19, 18, 6]

sage: S.homology()  # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}

sage: Q = P.subposet([1,2,3,4,5,6])

sage: Q.order_complex().homology()  # a circle
{0: 0, 1: Z}
```

```python
>>> from sage.all import *

>>> P = posets.BooleanLattice(Integer(3))

>>> S = P.order_complex(); S
Simplicial complex with vertex set (0, 1, 2, 3, 4, 5, 6, 7) and 6 facets

>>> S.f_vector()
[1, 8, 19, 18, 6]

>>> S.homology()  # S is contractible
{0: 0, 1: 0, 2: 0, 3: 0}

>>> Q = P.subposet([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),
                  Integer(6)])

>>> Q.order_complex().homology()  # a circle
{0: 0, 1: Z}
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)
>>> P.order_complex()
Simplicial complex with vertex set (1, 3, 5, 15) and
facets {(1, 3, 15), (1, 5, 15)}
```

If `on_ints`, then the elements of the poset are labelled 0, 1, ... in the chain complex:

```python
sage: P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and
facets {(0, 1, 3), (0, 2, 3)}
```

```python
>>> from sage.all import *
>>> P.order_complex(on_ints=True)
Simplicial complex with vertex set (0, 1, 2, 3) and
facets {(0, 1, 3), (0, 2, 3)}
```

**order_filter** *(elements)*

Return the order filter generated by the elements of an iterable `elements`.

$I$ is an order filter if, for any $x$ in $I$ and $y$ such that $y \geq x$, then $y$ is in $I$. This is also called upper set or upset.

**EXAMPLES:**

```python
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_filter([20, 25])
[20, 40, 25, 50, 100, 200, 125, 250, 500, 1000]
```

```python
>>> from sage.all import *
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.order_filter([Integer(20), Integer(25)])
[20, 40, 25, 50, 100, 200, 125, 250, 500, 1000]
```

See also:

`order_ideal()`, `principal_order_filter()`.

**order_ideal** *(elements)*

Return the order ideal generated by the elements of an iterable `elements`.

$I$ is an order ideal if, for any $x$ in $I$ and $y$ such that $y \leq x$, then $y$ is in $I$. This is also called lower set or downset.

**EXAMPLES:**

```python
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal([20, 25])
[1, 2, 4, 5, 10, 20, 25]
```

```python
>>> from sage.all import *
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.order_ideal([Integer(20), Integer(25)])
[1, 2, 4, 5, 10, 20, 25]
```

See also:

`order_filter()`, `principal_order_ideal()`.

5.1. Comprehensive Module List
order_ideal_cardinality(elements)
Return the cardinality of the order ideal generated by elements.

The elements \( I \) is an order ideal if, for any \( x \in I \) and \( y \) such that \( y \leq x \), then \( y \in I \).

EXAMPLES:

```
sage: P = posets.BooleanLattice(4)
sage: P.order_ideal_cardinality([7,10])
10
```

```
>>> from sage.all import *
>>> P = posets.BooleanLattice=Integer(4))
>>> P.order_ideal_cardinality=[[Integer(7),Integer(10)]
10
```

order_ideal_plot(elements)
Return a plot of the order ideal generated by the elements of an iterable elements.

\( I \) is an order ideal if, for any \( x \) in \( I \) and \( y \) such that \( y \leq x \), then \( y \) is in \( I \). This is also called lower set or downset.

EXAMPLES:

```
sage: # needs sage.plot
sage: P = Poset((divisors(1000), attrcall("divides")))
sage: P.order_ideal_plot([20, 25])
Graphics object consisting of 41 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot
>>> P = Poset((divisors(Integer(1000)), attrcall("divides")))
>>> P.order_ideal_plot([Integer(20), Integer(25)])
Graphics object consisting of 41 graphics primitives
```

order_polynomial()
Return the order polynomial of the poset.

The order polynomial \( \Omega_P(q) \) of a poset \( P \) is defined as the unique polynomial \( S \) such that for each integer \( m \geq 1 \), \( S(m) \) is the number of order-preserving maps from \( P \) to \( \{1, \ldots, m\} \).

See sections 3.12 and 3.15 of [EnumComb1], and also [St1986].

EXAMPLES:

```
sage: P = posets.AntichainPoset(3)
sage: P.order_polynomial()
q^3
```

```
sage: P = posets.ChainPoset(3)
sage: f = P.order_polynomial(); f
1/6*q^3 + 1/2*q^2 + 1/3*q
sage: [f(i) for i in range(4)]
[0, 1, 4, 10]
```

```
>>> from sage.all import *
>>> P = posets.AntichainPoset(Integer(3))
>>> P.order_polynomial()
```
(continues on next page)
q^3

```python
>>> P = posets.ChainPoset(Integer(3))
```

```python
>>> f = P.order_polynomial(); f
1/6*q^3 + 1/2*q^2 + 1/3*q
```

```python
>>> [f(i) for i in range(Integer(4))]
[0, 1, 4, 10]
```

See also:

*order_polytope()*

**order_polytope()**

Return the order polytope of the poset self.

The order polytope of a finite poset \( P \) is defined as the subset of \( \mathbb{R}^P \) consisting of all maps \( x : P \to \mathbb{R} \) satisfying

\[
0 \leq x(p) \leq 1 \text{ for all } p \in P,
\]

and

\[
x(p) \leq x(q) \text{ for all } p, q \in P \text{ satisfying } p < q.
\]

This polytope was defined and studied in [St1986].

**EXAMPLES:**

```python
sage: P = posets.AntichainPoset(3)
sage: Q = P.order_polytope(); Q
A 3-dimensional polyhedron in ZZ^3 defined as the convex hull of 8 vertices
```

```python
sage: P = posets.PentagonPoset()
sage: Q = P.order_polytope(); Q
A 5-dimensional polyhedron in ZZ^5 defined as the convex hull of 8 vertices
```

```python
sage: P = Poset([[1,2,3],[[1,2],[1,3]]])
sage: Q = P.order_polytope()
```

```python
sage: Q.contains((1,0,0))
False
```

```python
sage: Q.contains((0,1,1))
True
```

```python
>>> from sage.all import *
```

```python
>>> P = posets.AntichainPoset(Integer(3))
```

```python
>>> Q = P.order_polytope(); Q
```

```python
>>> P = posets.PentagonPoset()
```

```python
>>> Q = P.order_polytope(); Q
```

```python
>>> from sage.all import *
```

(continues on next page)
ordinal_product (other, labels='pairs')

Return the ordinal product of self and other.

The ordinal product of two posets $P$ and $Q$ is a partial order on the Cartesian product of the underlying sets of $P$ and $Q$, defined as follows (see [EnumComb1], p. 284).

In the ordinal product, $(p, q) \leq (p', q')$ if either $p \leq p'$ or $p = p'$ and $q \leq q'$.

This construction is not symmetric in $P$ and $Q$. Informally said we put a copy of $Q$ in place of every element of $P$.

INPUT:

- other -- a poset
- labels -- either 'integers' or 'pairs' (default); how the resulting poset will be labeled

EXAMPLES:

```python
sage: P1 = Poset(((\text{'a'}, \text{'b'}), [\text{('a'), \text{'b'}]}))
sage: P2 = Poset(((\text{'c'}, \text{'d'}), [\text{('c'), \text{'d'}]}))
sage: P = P1.ordinal_product(P2); P
Finite poset containing 4 elements
sage: sorted(P.cover_relations())
[[\text{('a'), \text{'c'}}, \text{('a'), \text{'d'}}], [\text{('a'), \text{'d'}}, \text{('b'), \text{'c'}}], [\text{('b'), \text{'c'}}, \text{('b'), \text{'d'}}]]
```

See also:

- product(), ordinal_sum()

ordinal_sum (other, labels='pairs')

Return a poset or (semi)lattice isomorphic to ordinal sum of the poset with other.

The ordinal sum of $P$ and $Q$ is a poset that contains every element and relation from both $P$ and $Q$, and where every element of $P$ is smaller than any element of $Q$.

Mathematically, it is only defined when $P$ and $Q$ have no common element; here we force that by giving them different names in the resulting poset.
The ordinal sum on lattices is a lattice; resp. for meet- and join-semilattices.

**INPUT:**

- `other`, a poset.
- `labels` – (defaults to ‘pairs’) If set to ‘pairs’, each element \( v \) in this poset will be named \((0, v)\) and each element \( u \) in other will be named \((1, u)\) in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

**EXAMPLES:**

```python
sage: P1 = Poset( ([1, 2, 3, 4], [[1, 2], [1, 3], [1, 4]]) )
sage: P2 = Poset( ([1, 2, 3,], [[2,1], [3,1]]) )
sage: P3 = P1.ordinal_sum(P2); P3
Finite poset containing 7 elements
sage: len(P1.maximal_elements())*len(P2.minimal_elements())
6
sage: len(P1.cover_relations()+P2.cover_relations())
5
sage: len(P3.cover_relations())  # Every element of P2 is greater than elements of P1.
11
sage: P3.list()  # random
[(0, 1), (0, 2), (0, 4), (0, 3), (1, 2), (1, 3), (1, 1)]
sage: P4 = P1.ordinal_sum(P2, labels='integers')
sage: P4.list()  # random
[0, 1, 2, 3, 5, 6, 4]
```

Return type depends on input types:

```python
>>> from sage.all import *
>>> P1 = Poset({1:[2]}); P
Finite poset containing 2 elements
>>> JL = JoinSemilattice({1:[2]}); JL
Finite join-semilattice containing 2 elements
>>> P3 = P1.ordinal_sum(P2); P3
```

(continues on next page)
Finite poset containing 4 elements
\texttt{sage}: \texttt{L.ordinal_sum(JL)}

Finite join-semilattice containing 4 elements
\texttt{sage}: \texttt{L.ordinal_sum(L)}

Finite lattice containing 4 elements
\texttt{from sage.all import *}
\texttt{P = Poset({Integer(1):
\texttt{[Integer(2)]}})); P}

Finite lattice containing 2 elements
\texttt{P.ordinal_sum(L)}

Finite poset containing 4 elements
\texttt{L.ordinal_sum(JL)}

Finite join-semilattice containing 4 elements
\texttt{L.ordinal_sum(L)}

See also:
\texttt{ordinal_summands()}, \texttt{disjoint_union()}, \texttt{sage.combinat.posets.lattices.FiniteLatticePoset.vertical_composition()}

\textbf{ordinal_summands()}

Return the ordinal summands of the poset as subposets.

The ordinal summands of a poset $P$ is the longest list of non-empty subposets $P_1, \ldots, P_n$ whose ordinal sum is $P$. This decomposition is unique.

\textbf{EXAMPLES}:

\begin{verbatim}
\texttt{sage: P = Poset({
\texttt{"a": [\texttt{\textquoteleft c\textquoteright, \textquoteleft d\textquoteright}},
\texttt{\textquoteright b\textquoteright: [\textquoteleft d\textquoteright]},
\texttt{\textquoteright c\textquoteright: [\textquoteleft x\textquoteright, \textquoteleft y\textquoteright]},
\texttt{\ldots: \textquoteleft d\textquoteright: [\textquoteleft x\textquoteright, \textquoteleft y\textquoteright]}\})
\texttt{sage: parts = P.ordinal_summands(); parts}
[Finite poset containing 4 elements, Finite poset containing 2 elements]
\texttt{sage: sorted(parts[0])}
[\textquoteleft a\textquoteright, \textquoteleft b\textquoteright, \textquoteleft c\textquoteright, \textquoteleft d\textquoteright]
\texttt{sage: Q = parts[0].ordinal_sum(parts[1])}
\texttt{Q.is_isomorphic(P)}
True
\end{verbatim}

\begin{verbatim}
\texttt{from sage.all import *}
\texttt{P = Poset({

\texttt{\textquoteright b\textquoteright: [\textquoteleft d\textquoteright]},
\texttt{\textquoteright c\textquoteright: [\textquoteleft x\textquoteright, \textquoteleft y\textquoteright]},
\texttt{\ldots: \textquoteleft d\textquoteright: [\textquoteleft x\textquoteright, \textquoteleft y\textquoteright]}\})
\texttt{parts = P.ordinal_summands(); parts}
[Finite poset containing 4 elements, Finite poset containing 2 elements]
\texttt{sorted(parts[Integer(0)])}
[\textquoteleft a\textquoteright, \textquoteleft b\textquoteright, \textquoteleft c\textquoteright, \textquoteleft d\textquoteright]
\texttt{Q = parts[Integer(0)].ordinal_sum(parts[Integer(1)])}
\texttt{Q.is_isomorphic(P)}
True
\end{verbatim}

See also:
\texttt{ordinal_sum()}

}\textbf{ordinal_sum()}
ALGORITHM:
Suppose that a poset \( P \) is the ordinal sum of posets \( L \) and \( U \). Then \( P \) contains maximal antichains \( l \) and \( u \) such that every element of \( u \) covers every element of \( l \); they correspond to maximal elements of \( L \) and minimal elements of \( U \).

We consider a linear extension \( x_1, \ldots, x_n \) of the poset’s elements.

We keep track of the maximal elements of subposet induced by elements \( 0, \ldots, x_i \) and minimal elements of subposet induced by elements \( x_{i+1}, \ldots, x_n \), incrementing \( i \) one by one. We then check if \( l \) and \( u \) fit the previous description.

\[
p_{\text{partition enumerator}}(\text{tup}, R, \text{weights} = \text{None}, \text{check} = \text{False})
\]

Return a \( P \)-partition enumerator of \( self \).

Given a total order \( \prec \) on the elements of a finite poset \( P \) (the order of \( P \) and the total order \( \prec \) can be unrelated; in particular, the latter does not have to extend the former), a \( P \)-partition enumerator is the quasisymmetric function \( \sum_f \prod_{p \in P} x_{f(p)} \), where the first sum is taken over all \( P \)-partitions \( f \).

A \( P \)-partition is a function \( f : P \rightarrow \{1, 2, 3, \ldots\} \) satisfying the following properties for any two elements \( i \) and \( j \) of \( P \) satisfying \( i \prec_P j \):

- if \( i \prec j \) then \( f(i) \leq f(j) \),
- if \( j \prec i \) then \( f(i) < f(j) \).

The optional argument \( \text{weights} \) allows constructing a generalized ("weighted") version of the \( P \)-partition enumerator. Namely, \( \text{weights} \) should be a dictionary whose keys are the elements of \( P \). Then, the generalized \( P \)-partition enumerator corresponding to weights \( \text{weights} \) is \( \sum_f \prod_{p \in P} w_{p}^{f(p)} \), where the sum is again over all \( P \)-partitions \( f \). Here, \( w(p) \) is \( \text{weights}[p] \). The classical \( P \)-partition enumerator is the particular case obtained when all \( p \) satisfy \( w(p) = 1 \).

In the language of [Grinb2016a], the generalized \( P \)-partition enumerator is the quasisymmetric function \( \Gamma(E, w) \), where \( E \) is the special double poset \( (P, <_P, \prec) \), and where \( w \) is the dictionary \( \text{weights} \) (regarded as a function from \( P \) to the positive integers).

INPUT:
- \( \text{tup} \) – the tuple containing all elements of \( P \) (each of them exactly once), in the order dictated by the total order \( \prec \)
- \( R \) – a commutative ring
- \( \text{weights} \) – (optional) a dictionary of positive integers, indexed by elements of \( P \); any missing item will be understood as 1

OUTPUT:
The \( P \)-partition enumerator of \( self \) according to \( \text{tup} \) in the algebra \( QSym \) of quasisymmetric functions over the base ring \( R \).

EXAMPLES:

```python
sage: # needs sage.combinat
sage: P = Poset(((1, 2, 3, 4), [(1, 4), (2, 4), (4, 3)]))
'sage: FP = P.p_partition Enumerator((3, 1, 0, 4), QQ, check=True); FP
'sage: expansion = FP.expand(5)
'sage: xs = expansion.parent().gens()
'sage: expansion == sum(xs[a]*xs[b]*xs[c]*xs[d]
   for a in range(5) for b in range(5)
   for c in range(5) for d in range(5)
```
if a <= b and c <= b and b < d)

sage: P = Poset([[1],[2]])
sage: FP = P.p_partition_enumerator((1, 2), QQ, check=True); FP
\#....: needs sage.combinat
M[]

>>> from sage.all import *

>>> P = Poset([[1,2,3,4], [1,4], [2,4], [4,3]])
>>> FP = P.p_partition_enumerator((3,1,2,4), QQ, check=True); FP

>>> P = Poset([[1,2,3,4], [2,4], [4,3]])
>>> FP = P.p_partition_enumerator((3,1,2,4), QQ, check=True); FP

With the weights parameter:

sage: P = Poset([[1,2,3,4], [1,4], [2,4], [4,3]])

sage: FP = P.p_partition_enumerator((3,1,2,4), QQ, check=True); FP

       weights={'a': Integer(3), 'b': Integer(5), 'c': Integer(7)}, check=True); FP

```

```
plot (label_elements=True, element_labels=None, layout='acyclic', cover_labels=None, **kwds)

Return a Graphic object for the Hasse diagram of the poset.

If the poset is ranked, the plot uses the rank function for the heights of the elements.

INPUT:

- Options to change element look:
  - element_colors – a dictionary where keys are colors and values are lists of elements
  - element_color – a color for elements not set in element_colors
  - element_shape – the shape of elements, like 's' for square; see https://matplotlib.org/api/markers_api.html for the list
  - element_size (default: 200) - the size of elements
  - label_elements (default: True) - whether to display element labels
  - element_labels (default: None) - a dictionary where keys are elements and values are labels to show

- Options to change cover relation look:
  - cover_colors – a dictionary where keys are colors and values are lists of cover relations given as pairs of elements
  - cover_color – a color for elements not set in cover_colors
```
- **cover_style** — style for cover relations: 'solid', 'dashed', 'dotted' or 'dashdot'
- **cover_labels** — a dictionary, list or function representing labels of the covers of the poset. When set to None (default) no label is displayed on the edges of the Hasse Diagram.
- **cover_labels_background** — a background color for cover relations. The default is “white”. To achieve a transparent background use “transparent”.

• Options to change overall look:
  - **figsize** (default: 8) - size of the whole plot
  - **title** — a title for the plot
  - **fontsize** — fontsize for the title
  - **border** (default: False) - whether to draw a border over the plot

**Note:** All options of GenericGraph.plot are also available through this function.

**EXAMPLES:**

This function can be used without any parameters:

```python
sage: # needs sage.plot
sage: D12 = posets.DivisorLattice(12)
sage: D12.plot()
Graphics object consisting of 14 graphics primitives
```

Just the abstract form of the poset; examples of relabeling:

```python
sage: # needs sage.plot
sage: D12.plot(label_elements=False)
Graphics object consisting of 8 graphics primitives
```
Some settings for coverings:

```python
sage: # needs sage.plot
dsage:D12.plot(cover_labels=d, cover_color='gray', cover_style='dotted')
```

To emphasize some elements and show some options:

```python
sage: L = LatticePoset({0: [1, 2, 3, 4], 1: [12], 2: [6, 7],
                   ...: 3: [5, 9], 4: [5, 6, 10, 11], 5: [13],
                   ...: 6: [12], 7: [12, 8, 9], 8: [13], 9: [13],
                   ...: 10: [12], 11: [12], 12: [13]})
sage: F = L.frattini_sublattice()
sage: F_internal = [c for c in F.cover_relations()
                   ...: if c in L.cover_relations()]
sage: L.plot(figsize=Integer(12), border=True, element_shape='s',
                   ...: element_size=Integer(400), element_color='white',
                   ...: element_colors=('blue': F, 'green': L.double_irreducibles(),
                   ...: cover_color='lightgray', cover_colors=('black': F_internal),
                   ...: title='The Frattini sublattice in blue', fontsize=Integer(10))
```

Return the Cartesian product of the poset with other.

The Cartesian (or ‘direct’) product of $P$ and $Q$ is defined by $(p, q) \leq (p', q')$ iff $p \leq p'$ in $P$ and $q \leq q'$ in $Q$. Product of (semi)lattices are returned as a (semi)lattice.
EXAMPLES:

```python
sage: P = posets.ChainPoset(3)
sage: Q = posets.ChainPoset(4)
sage: PQ = P.product(Q) ; PQ
Finite lattice containing 12 elements
sage: len(PQ.cover_relations())
17
sage: Q.product(P).is_isomorphic(PQ)
True
sage: P = posets.BooleanLattice(2)
sage: Q = P.product(P)
sage: Q.is_isomorphic(posets.BooleanLattice(4))
True
```

```python
>>> from sage.all import *
```

```python
>>> P = posets.ChainPoset(Integer(3))
```

```python
>>> Q = posets.ChainPoset(Integer(4))
```

```python
>>> P*Q
Finite lattice containing 6 elements
```

One can also simply use `*`:

```python
sage: P = posets.ChainPoset(2)
sage: Q = posets.ChainPoset(3)
sage: P*Q
Finite lattice containing 6 elements
```

See also:

`CartesianProductPoset`, `factor()`

`promotion(i=1)`

Compute the (extended) promotion on the linear extension of the poset `self`.

**INPUT:**

- `i` – an integer between 1 and `n` (default: 1)

**OUTPUT:**

- an isomorphic poset, with the same default linear extension
The extended promotion is defined on a poset \( \text{self} \) of size \( n \) by applying the promotion operator \( \tau_i \tau_{i+1} \cdots \tau_{n-1} \) to the default linear extension \( \pi \) of \( \text{self} \) (see \texttt{promotion()}), and relabeling \( \text{self} \) accordingly. For more details see [Stan2009].

When the elements of the poset \( \text{self} \) are labelled by \( \{1, 2, \ldots, n\} \), the linear extension is the identity, and \( i = 1 \), the above algorithm corresponds to the promotion operator on posets defined by Schützenberger as follows. Remove 1 from \( \text{self} \) and replace it by the minimum \( j \) of all labels covering 1 in the poset. Then, remove \( j \) and replace it by the minimum of all labels covering \( j \), and so on. This process ends when a label is a local maximum. Place the label \( n + 1 \) at this vertex. Finally, decrease all labels by 1.

**EXAMPLES:**

```
sage: P = Poset(([1,2], [[1,2]]), linear_extension=True, facade=False)
sage: P.promotion()
Finite poset containing 2 elements with distinguished linear extension
sage: P == P.promotion()
True

sage: P = Poset(([1,2,3,4,5,6,7], [[1,2],[1,4],[2,3],[2,5],[3,6],[4,7],[5,6]]))
sage: P.list()
[1, 2, 3, 5, 6, 4, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```

```from sage.all import *
>>> P = Poset(([Integer(1),Integer(2)], [[Integer(1),Integer(2)]]), linear_extension=True, facade=False)
>>> P.promotion()
Finite poset containing 2 elements with distinguished linear extension
>>> P == P.promotion()
True

>>> P = Poset(([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5), Integer(6),Integer(7)], [[Integer(1),Integer(2)],[Integer(1),Integer(4)], [Integer(2),Integer(3)],[Integer(2),Integer(5)],[Integer(3),Integer(6)], [Integer(4),Integer(7)], [Integer(5),Integer(6)]]))
>>> P.list()
[1, 2, 3, 5, 6, 4, 7]
>>> Q = P.promotion(Integer(4)); Q
Finite poset containing 7 elements with distinguished linear extension
>>> Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 5], [3, 7], [5, 7], [6, 4]]
```

Note that if one wants to obtain the promotion defined by Schützenberger's algorithm directly on the poset, one needs to make sure the linear extension is the identity:

```
sage: P = P.with_linear_extension([1,2,3,4,5,6,7])
sage: P.list()
[1, 2, 3, 4, 5, 6, 7]
sage: Q = P.promotion(4); Q
Finite poset containing 7 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 6], [2, 3], [2, 4], [3, 5], [4, 5], [6, 7]]
sage: Q = P.promotion()
sage: Q.cover_relations()
```

(continues on next page)
Here is an example for a poset not labelled by \{1, 2, \ldots, n\}:

```
sage: P = Poset((divisors(30), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 5, 6, 10, 15, 30]
sage: P.cover_relations()
[[1, 2], [1, 3], [1, 5], [2, 6], [2, 10], [3, 6], [3, 15],
 [5, 10], [5, 15], [6, 30], [10, 30], [15, 30]]
sage: Q = P.promotion(4); Q
Finite poset containing 8 elements with distinguished linear extension
sage: Q.cover_relations()
[[1, 2], [1, 3], [1, 6], [2, 5], [2, 15], [3, 5], [3, 10],
 [5, 30], [6, 10], [6, 15], [10, 30], [15, 30]]
```

AUTHOR:

- Anne Schilling (2012-02-18)
random_linear_extension()

Return a random linear extension of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_linear_extension()
[0, 4, 1, 2, 3, 8, 10, 5, 12, 9, 13, 11, 6, 14, 7, 15]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # results are reproduceable
>>> P = posets.BooleanLattice(Integer(4))
>>> P.random_linear_extension()
[0, 4, 1, 2, 3, 8, 10, 5, 12, 9, 13, 11, 6, 14, 7, 15]
```

random_maximal_antichain()

Return a random maximal antichain of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_antichain()
[1, 8, 2, 4]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # results are reproduceable
>>> P = posets.BooleanLattice(Integer(4))
>>> P.random_maximal_antichain()
[1, 8, 2, 4]
```

random_maximal_chain()

Return a random maximal chain of the poset.

The distribution is not uniform.

EXAMPLES:

```
sage: set_random_seed(0)  # results are reproduceable
sage: P = posets.BooleanLattice(4)
sage: P.random_maximal_chain()
[0, 4, 5, 7, 15]
```

```
>>> from sage.all import *
>>> set_random_seed(Integer(0))  # results are reproduceable
>>> P = posets.BooleanLattice(Integer(4))
>>> P.random_maximal_chain()
[0, 4, 5, 7, 15]
```

random_order_ideal(direction='down')

Return a random order ideal with uniform probability.

INPUT:
• direction – 'up', 'down' or 'antichain' (default: 'down')

OUTPUT:

A randomly selected order ideal (or order filter if direction='up', or antichain if direction='antichain') where all order ideals have equal probability of occurring.

ALGORITHM:

Uses the coupling from the past algorithm described in [Propp1997].

EXAMPLES:

```python
sage: P = posets.BooleanLattice(3)
sage: P.random_order_ideal()  # random
[0, 1, 2, 3, 4, 5, 6]
sage: P.random_order_ideal(direction='up')  # random
[6, 7]
sage: P.random_order_ideal(direction='antichain')  # random
[1, 2]
sage: P = posets.TamariLattice(5)
sage: a = P.random_order_ideal('antichain')
sage: P.is_antichain_of_poset(a)
True
sage: a = P.random_order_ideal('up')
sage: P.is_order_filter(a)
True
sage: a = P.random_order_ideal('down')
sage: P.is_order_ideal(a)
True
```

>>> from sage.all import *

```python
>> P = posets.BooleanLattice(Integer(3))
>> P.random_order_ideal()  # random
[0, 1, 2, 3, 4, 5, 6]
>>> P.random_order_ideal(direction='up')  # random
[6, 7]
>>> P.random_order_ideal(direction='antichain')  # random
[1, 2]
>>> P = posets.TamariLattice(Integer(5))
>>> a = P.random_order_ideal('antichain')
>>> P.is_antichain_of_poset(a)
True
>>> a = P.random_order_ideal('up')
>>> P.is_order_filter(a)
True
>>> a = P.random_order_ideal('down')
>>> P.is_order_ideal(a)
True
```

`random_subposet (p)`

Return a random subposet that contains each element with probability p.

EXAMPLES:

```python
sage: P = posets.BooleanLattice(3)
sage: set_random_seed(0)  # Results are reproducible
```

(continues on next page)
sage: Q = P.random_subposet(0.5)
sage: Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]

>>> from sage.all import *
>>> P = posets.BooleanLattice(Integer(3))
>>> set_random_seed(Integer(0))  # Results are reproducible
>>> Q = P.random_subposet(RealNumber('0.5'))
>>> Q.cover_relations()
[[0, 2], [0, 5], [2, 3], [3, 7], [5, 7]]

rank (element=None)

Return the rank of an element element in the poset self, or the rank of the poset if element is None.

(The rank of a poset is the length of the longest chain of elements of the poset. This is sometimes called the length of a poset.)

EXAMPLES:

sage: P = Poset([[1,3,2],[4],[4,5,6],[6],[7],[7],[7],[]], facade = False)
sage: P.rank(5)
2
sage: P.rank()
3
sage: Q = Poset([[1,2],[3],[],[]])

sage: P = posets.SymmetricGroupBruhatOrderPoset(4)

sage: [(v,P.rank(v)) for v in P]
[(1234, 0),
 (1243, 1),
 ...
 (4312, 5),
 (4321, 6)]

>>> from sage.all import *

>>> P = Poset([[Integer(1),Integer(3),Integer(2)],[Integer(4)],[Integer(4),
 →Integer(5),Integer(6)],[Integer(6)],[Integer(7)],[Integer(7)],
 →[]], facade = False)

>>> P.rank(Integer(5))
2

>>> P.rank()
3

>>> Q = Poset([[Integer(1),Integer(2)],[Integer(3)],[1],[1]])

>>> P = posets.SymmetricGroupBruhatOrderPoset(Integer(4))

>>> [(v,P.rank(v)) for v in P]
[(1234', 0),
 (1243', 1),
 ...
 (4312', 5),
 (4321', 6)]

rank_function()

Return the (normalized) rank function of the poset, if it exists.

A rank function of a poset $P$ is a function $r$ that maps elements of $P$ to integers and satisfies: $r(x) = r(y) + 1$ if $x$ covers $y$. The function $r$ is normalized such that its minimum value on every connected component of
the Hasse diagram of \( P \) is 0. This determines the function \( r \) uniquely (when it exists).

**OUTPUT:**

- a lambda function, if the poset admits a rank function
- None, if the poset does not admit a rank function

**EXAMPLES:**

```python
sage: P = Poset(((1, 2, 3, 4), [(1,4), (2,3), (3,4)]), facade=True)
sage: P.rank_function() is not None
True
sage: P = Poset(((1, 2, 3, 4, 5), [(1,4), (2,3), (3,4), (1,5), (5,4)]), facade=True)
sage: P.rank_function() is not None
False
sage: P = Poset(((1, 2, 3, 4, 5, 6, 7, 8), [(1,4), (2,3), (3,4), (5,7), (6,7)]), facade=True)
sage: f = P.rank_function(); f is not None
True
sage: f(5)
0
sage: f(2)
0
```

```bash
>>> from sage.all import *
```

```python
>>> P = Poset(((Integer(1), Integer(2), Integer(3), Integer(4), [Integer(1), Integer(4), Integer(5)]), [(Integer(1), Integer(2), Integer(3), Integer(4), [Integer(5), Integer(4)]), facade=True)
>>> P.rank_function() is not None
True
```

```python
>>> P = Poset(((Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(6), Integer(7), Integer(8), [Integer(1), Integer(4), Integer(5), Integer(4), Integer(5), [Integer(6), Integer(7)]), facade=True)
>>> f = P.rank_function(); f is not None
True
```

```python
>>> f(Integer(5))
0
```

```python
>>> f(Integer(2))
0
```

**rees_product (other)**

Return the Rees product of \( self \) and \( other \).

This is only defined if both posets are graded.

The underlying set is the set of pairs \((p, q)\) in the Cartesian product such that \(rk(p) \geq rk(q)\).

This operation was defined by Björner and Welker in [BjWe2005]. Other references are [MBRe2011] and [LSW2012].

**EXAMPLES:**

```python
sage: B3 = posets.BooleanLattice(3)
sage: B3t = B3.subposet(list(range(1, 8)))
```

(continues on next page)
sage: C3 = posets.ChainPoset(3)
sage: D = B3t.rees_product(C3); D
Finite poset containing 12 elements
sage: sorted(D.minimal_elements())
[(1, 0), (2, 0), (4, 0)]
sage: sorted(D.maximal_elements())
[(7, 0), (7, 1), (7, 2)]
sage: D.with_bounds().moebius_function('bottom','top')
2

See also:

product(), ordinal_product(), star_product()

relabel (relabeling=None)
Return a copy of this poset with its elements relabeled.

INPUT:

• relabeling – a function, dictionary, list or tuple

The given function or dictionary must map each (non-wrapped) element of self to some distinct object. The given list or tuple must be made of distinct objects.

When the input is a list or a tuple, the relabeling uses the total ordering of the elements of the poset given by list(self).

If no relabeling is given, the poset is relabeled by integers from 0 to n – 1 according to one of its linear extensions. This means that i < j as integers whenever i < j in the relabeled poset.

EXAMPLES:

Relabeling using a function:

sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: Q = P.relabel(lambda x: x+1)
sage: Q.list()
[2, 3, 4, 5, 7, 13]
sage: Q.cover_relations()
[[2, 3], [2, 4], [3, 5], [3, 7], [4, 7], [5, 13], [7, 13]]
Mind the `c.element`; this is because the relabeling is applied to the elements of the poset without the wrapping. Thanks to this convention, the same relabeling function can be used both for facade or non facade posets.

Relabeling using a list:

```
sage: P = posets.PentagonPoset()
sage: list(P)
[0, 1, 2, 3, 4]
sage: P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
sage: Q = P.relabel(list(abcde))
sage: Q.cover_relations()
[['a', 'b'], ['a', 'c'], ['b', 'e'], ['c', 'd'], ['d', 'e']]
```
\begin{verbatim}
>>> P.cover_relations()
[[0, 1], [0, 2], [1, 4], [2, 3], [3, 4]]
>>> Q = P.relabel(list('abcde'))
>>> Q.cover_relations()
[['a', 'b'], ['a', 'c'], ['b', 'e'], ['c', 'd'], ['d', 'e']]

Default behaviour is increasing relabeling:

sage: a2 = posets.ChainPoset(2)
sage: P = a2 * a2
sage: Q = P.relabel()
sage: Q.cover_relations()
[[0, 1], [0, 2], [1, 3], [2, 3]]

Relabeling a (semi)lattice gives a (semi)lattice:

sage: P = JoinSemilattice({0: [1]})
sage: P.relabel(lambda n: n + 1)
Finite join-semilattice containing 2 elements

Note: As can be seen in the above examples, the default linear extension of \( Q \) is that of \( P \) after relabeling. In particular, \( P \) and \( Q \) share the same internal Hasse diagram.
\end{verbatim}

\textbf{relations()}

Return the list of all relations of the poset.

A relation is a pair of elements \( x \) and \( y \) such that \( x \leq y \) in the poset.

The number of relations is the dimension of the incidence algebra.

\textbf{OUTPUT:}

A list of pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: P.relations()
[[[1, 1], [1, 2], [1, 3], [1, 4], [0, 0], [0, 2], [0, 3],
  [0, 4], [2, 2], [2, 3], [2, 4], [3, 3], [3, 4], [4, 4]]

>>> from sage.all import *

>>>
\end{verbatim}
See also:

relations_number(), relations_iterator()

AUTHOR:

• Rob Beezer (2011-05-04)

relations_iterator (strict=False)

Return an iterator for all the relations of the poset.

A relation is a pair of elements \(x\) and \(y\) such that \(x \leq y\) in the poset.

INPUT:

• \(\text{strict}\) – a boolean (default False) if True, returns an iterator over relations \(x < y\), excluding all relations \(x \leq x\).

OUTPUT:

A generator that produces pairs (each pair is a list), where the first element of the pair is less than or equal to the second element.

EXAMPLES:

```sage
sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[4], 4:[]})
sage: it = P.relations_iterator()
sage: type(it)
<class 'generator'>
sage: next(it), next(it)
([1, 1], [1, 2])
sage: P = posets.PentagonPoset()
sage: list(P.relations_iterator(strict=True))
[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```

```python
>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(2)], Integer(1):[Integer(2)],
-Integer(2):[Integer(3)], Integer(3):[Integer(4)], Integer(4):[]})
>>> it = P.relations_iterator()
>>> type(it)
<class 'generator'>
>>> next(it), next(it)
([1, 1], [1, 2])
```

```sage
>>> P = posets.PentagonPoset()
>>> list(P.relations_iterator(strict=True))
[[0, 1], [0, 2], [0, 4], [0, 3], [1, 4], [2, 3], [2, 4], [3, 4]]
```
relations_number()

Return the number of relations in the poset.

A relation is a pair of elements $x$ and $y$ such that $x \leq y$ in the poset.

Relations are also often called intervals. The number of intervals is the dimension of the incidence algebra.

EXAMPLES:

```
sage: P = posets.PentagonPoset()
sage: P.relations_number()
13

sage: posets.TamariLattice(4).relations_number()
68
```

See also:

relations_iterator(), relations()

show (label_elements=True, element_labels=None, cover_labels=None, **kwds)

Displays the Hasse diagram of the poset.

INPUT:

- label_elements (default: True) – whether to display element labels
- element_labels (default: None) – a dictionary of element labels
- cover_labels – a dictionary, list or function representing labels of the covers of self. When set to None (default) no label is displayed on the edges of the Hasse Diagram.

Note: This method also accepts:

- All options of GenericGraph.plot
- All options of Graphics.show

EXAMPLES:

```
sage: D = Poset({ 0:[1,2], 1:[3], 2:[3,4] })
sage: D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
sage: D.show()

sage: elm_labs = {0:'a', 1:'b', 2:'c', 3:'d', 4:'e'}
sage: D.show(element_labels=elm_labs)
```

>> from sage.all import *
>> P = posets.PentagonPoset()
>> P.relations_number()
13
>> posets.TamariLattice(Integer(4)).relations_number()
68

```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> D.plot(label_elements=False)
Graphics object consisting of 6 graphics primitives
>>> D.show()
>>> elm_labs = {Integer(0):'a', Integer(1):'b', Integer(2):'c', Integer(3):'d', Integer(4):'e')
>>> D.show(element_labels=elm_labs)
```

One more example with cover labels:

```python
sage: # needs sage.plot
sage: P = posets.PentagonPoset()
sage: P.show(cover_labels=lambda a, b: a - b)
```

```python
>>> from sage.all import *
>>> # needs sage.plot
>>> P = posets.PentagonPoset()
>>> P.show(cover_labels=lambda a, b: a - b)
```

**slant_sum** *(p, element, p_element)*

Return the slant sum poset of posets self and p by connecting them with a cover relation *(p_element, element)*.

**Note:** The element names of self and p must be distinct.

**INPUT:**

- `p` – the poset used for the slant sum
- `element` – the element of self that is the top of the new cover relation
- `p_element` – the element of p that is the bottom of the new cover relation

**EXAMPLES:**

```python
sage: R = posets.RibbonPoset(5, [1,2])
sage: H = Poset([[5, 6, 7], [(5, 6), (6,7)]])
sage: SS = R.slant_sum(H, 3, 7)
sage: all(cr in SS.cover_relations() for cr in R.cover_relations())
True
sage: all(cr in SS.cover_relations() for cr in H.cover_relations())
True
sage: SS.covers(Integer(7), Integer(3))
True
```

```python
>>> from sage.all import *
>>> R = posets.RibbonPoset(Integer(5), [Integer(1),Integer(2)])
>>> H = Poset([[Integer(5), Integer(6), Integer(7)], [Integer(5),... Integer(6)], (Integer(6),Integer(7))]])
>>> SS = R.slant_sum(H, Integer(3), Integer(7))
>>> all(cr in SS.cover_relations() for cr in R.cover_relations())
True
>>> all(cr in SS.cover_relations() for cr in H.cover_relations())
True
>>> SS.covers(Integer(7), Integer(3))
True
```
sorted(l, allow_incomparable=True, remove_duplicates=False)

Return the list \( l \) sorted by the poset.

**INPUT:**

- \( l \) – a list of elements of the poset
- \( \text{allow_incomparable} \) – a Boolean. If True (the default), return incomparable elements in some order; if False, raise an error if \( l \) is not a chain of the poset.
- \( \text{remove_duplicates} \) – a Boolean. If True, remove duplicates from the output list.

**EXAMPLES:**

```python
sage: P = posets.DivisorLattice(36)
sage: P.sorted([1, 4, 1, 6, 2, 12])  # Random order for 4 and 6
[1, 1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], remove_duplicates=True)
[1, 2, 4, 6, 12]
sage: P.sorted([1, 4, 1, 6, 2, 12], allow_incomparable=False)
Traceback (most recent call last):
... ValueError: the list contains incomparable elements
```

```python
sage: P = Poset({7:[1, 5], 1:[2, 6], 5:[3], 6:[3, 4]})
sage: P.sorted([4, 1, 4, 5, 7])  # Random order for 1 and 5
[7, 1, 5, 4, 4]
sage: P.sorted([4, 1, 4, 5, 7], remove_duplicates=True)
[7, 1, 4]
sage: P.sorted([4, 1, 4, 5, 7], allow_incomparable=False)
Traceback (most recent call last):
... ValueError: the list contains incomparable elements
```

```python
>>> from sage.all import *
>>> P = posets.DivisorLattice(Integer(36))
>>> P.sorted([Integer(1), Integer(4), Integer(1), Integer(6), Integer(2),
Integer(12)])  # Random order for 4 and 6
[1, 1, 2, 4, 6, 12]
>>> P.sorted([Integer(1), Integer(4), Integer(1), Integer(6), Integer(2),
Integer(12)], remove_duplicates=True)
[1, 2, 4, 6, 12]
>>> P.sorted([Integer(1), Integer(4), Integer(1), Integer(6), Integer(2),
Integer(12)], allow_incomparable=False)
Traceback (most recent call last):
... ValueError: the list contains incomparable elements
```

```python
>>> P = Poset({Integer(7):[Integer(1), Integer(5), Integer(1):[Integer(2),
Integer(6), Integer(2),
Integer(12)]},
Integer(4), Integer(1), Integer(4), Integer(5), Integer(7))  # Random order for 1 and 5
[7, 1, 5, 4, 4]
>>> P.sorted([Integer(1), Integer(4), Integer(4), Integer(7)], remove_duplicates=True)
[7, 1, 4]
>>> P.sorted([Integer(4), Integer(1), Integer(4), Integer(5), Integer(7)],
allow_incomparable=False)
Traceback (most recent call last):
... ValueError: the list contains incomparable elements
```

(continues on next page)
ValueError: the list contains incomparable elements

spectrum \((a)\)
Return the \(a\)-spectrum of this poset.

The \(a\)-spectrum in a poset \(P\) is the list of integers whose \(i\)-th position contains the number of linear extensions of \(P\) that have \(a\) in the \(i\)-th location.

INPUT:
• \(a\) – an element of this poset

OUTPUT:
The \(a\)-spectrum of this poset, returned as a list.

EXAMPLES:

```python
sage: P = posets.ChainPoset(5)
sage: P.spectrum(2)
[0, 0, 1, 0, 0]

sage: P = posets.BooleanLattice(3)
sage: P.spectrum(5)
[0, 0, 0, 12, 16, 16, 0]

sage: P = posets.YoungDiagramPoset(Partition([3,2,1]))
# needs sage.combinat
sage: P.spectrum((0,1))
[0, 8, 6, 2, 0, 0]

sage: P = posets.AntichainPoset(4)
sage: P.spectrum(3)
[6, 6, 6, 6]
```

```python
>>> from sage.all import *

>>> P = posets.ChainPoset(Integer(5))
>>> P.spectrum(Integer(2))
[0, 0, 1, 0, 0]

>>> P = posets.BooleanLattice(Integer(3))
>>> P.spectrum(Integer(5))
[0, 0, 0, 12, 16, 16, 0]

>>> P = posets.YoungDiagramPoset(Partition([Integer(3),Integer(2), Integer(1)]))
# needs sage.combinat
>>> P.spectrum((Integer(0),Integer(1)))
[0, 8, 6, 2, 0, 0]

>>> P = posets.AntichainPoset(Integer(4))
>>> P.spectrum(Integer(3))
[6, 6, 6, 6]
```

star_product \((other, labels='pairs')\)
Return a poset isomorphic to the star product of the poset with \(other\).
Both this poset and other are expected to be bounded and have at least two elements.

Let $P$ be a poset with top element $\top_P$ and $Q$ be a poset with bottom element $\bot_Q$. The star product of $P$ and $Q$ is the ordinal sum of $P \setminus \top_P$ and $Q \setminus \bot_Q$.

Mathematically, it is only defined when $P$ and $Q$ have no common elements; here we force that by giving them different names in the resulting poset.

**INPUT:**

- **other** – a poset.
- **labels** – (defaults to ‘pairs’) If set to ‘pairs’, each element $v$ in this poset will be named $(0, v)$ and each element $u$ in other will be named $(1, u)$ in the result. If set to ‘integers’, the elements of the result will be relabeled with consecutive integers.

**EXAMPLES:**

This is mostly used to combine two Eulerian posets to third one, and makes sense for graded posets only:

```
sage: B2 = posets.BooleanLattice(2)
sage: B3 = posets.BooleanLattice(3)
sage: P = B2.star_product(B3); P
Finite poset containing 10 elements
sage: P.is_eulerian()  # needs sage.libs.flint
True
```

```
>>> from sage.all import *
>>> B2 = posets.BooleanLattice(Integer(2))
>>> B3 = posets.BooleanLattice(Integer(3))
>>> P = B2.star_product(B3); P
Finite poset containing 10 elements
>>> P.is_eulerian()  # needs sage.libs.flint
True
```

We can get elements as pairs or as integers:

```
sage: ABC = Poset({'a': ['b'], 'b': ['c']})
sage: XYZ = Poset({'x': ['y'], 'y': ['z']})
sage: ABC.star_product(XYZ).list()
[(0, 'a'), (0, 'b'), (1, 'y'), (1, 'z')]
sage: sorted(ABC.star_product(XYZ, labels='integers'))
[0, 1, 2, 3]
```

```
>>> from sage.all import *
>>> ABC = Poset({'a': ['b'], 'b': ['c']})
>>> XYZ = Poset({'x': ['y'], 'y': ['z']})
>>> ABC.star_product(XYZ).list()
[(0, 'a'), (0, 'b'), (1, 'y'), (1, 'z')]
>>> sorted(ABC.star_product(XYZ, labels='integers'))
[0, 1, 2, 3]
```

**subposet (elements)**

Return the poset containing given elements with partial order induced by this poset.

**EXAMPLES:**
sage: P = Poset({'a': ['c', 'd'], 'b': ['d', 'e'], 'c': ['f'],
            'd': ['f'], 'e': ['f']})
sage: Q = P.subposet(['a', 'b', 'f']); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[['b', 'f'], ['a', 'f']]

>>> from sage.all import *
>>> P = Poset({'a': ['c', 'd'], 'b': ['d', 'e'], 'c': ['f'],
             'd': ['f'], 'e': ['f']})
>>> Q = P.subposet(['a', 'b', 'f']); Q
Finite poset containing 3 elements
>>> Q.cover_relations()
[['b', 'f'], ['a', 'f']]

A subposet of a non-facade poset is again a non-facade poset:

sage: P = posets.PentagonPoset(facade=False)
sage: Q = P.subposet([Integer(0), Integer(1), Integer(2), Integer(4)])
sage: Q(Integer(1)) < Q(Integer(2))
False

>>> from sage.all import *
>>> P = posets.PentagonPoset(facade=False)
>>> Q = P.subposet([Integer(0), Integer(1), Integer(2), Integer(4)])
>>> Q(Integer(1)) < Q(Integer(2))
False

top()
Return the unique maximal element of the poset, if it exists.

EXAMPLES:

sage: P = Poset({0:[3],1:[3],2:[3],3:[4,5],4:[],5:[]})
sage: P.top()  is None
True
sage: Q = Poset({0:[1],1:[]})
sage: Q.top()
1

>>> from sage.all import *
>>> P = Poset({Integer(0):[Integer(3)],Integer(1):[Integer(3)],
             Integer(2):[Integer(3)],Integer(3):[Integer(4),Integer(5)],Integer(4):[],
             Integer(5):[]})
>>> P.top()  is None
True
>>> Q = Poset({Integer(0):[Integer(1)],Integer(1):[]})
>>> Q.top()
1

See also:
has_top(), bottom()
unwrap(element)
Return the element element of the poset self in unwrapped form.

INPUT:
• element — an element of self

EXAMPLES:

```python
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: x = P.an_element(); x
1
sage: x.parent()
Finite poset containing 4 elements
sage: P.unwrap(x)
1
sage: P.unwrap(x).parent()
Integer Ring
```

```python
>>> from sage.all import *

>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade = False)

>>> x = P.an_element(); x
1

>>> x.parent()
Finite poset containing 4 elements

>>> P.unwrap(x)
1

>>> P.unwrap(x).parent()
Integer Ring
```

For a non facade poset, this is equivalent to using the `.element` attribute:

```python
sage: P.unwrap(x) is x.element
True
```

```python
>>> from sage.all import *

>>> P.unwrap(x) is x.element
True
```

For a facade poset, this does nothing:

```python
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: x = P.an_element()
sage: P.unwrap(x) is x
True
```

```python
>>> from sage.all import *

>>> P = Poset((divisors(Integer(15)), attrcall("divides")), facade=True)

>>> x = P.an_element()

>>> P.unwrap(x) is x
True
```

This method is useful in code where we do not know if P is a facade poset or not.

```python
upper_covers(x)
```

Return the list of upper covers of the element `x`.

An upper cover of `x` is an element `y` such that `x < y` and there is no element `z` so that `x < z < y`.

EXAMPLES:
sage: P = Poset([[1,5], [2,6], [3], [4], [], [6,3], [4]])
sage: P.upper_covers(1)
[2, 6]

See also:

\texttt{lower_covers()}

\texttt{upper_covers_iterator}(x)

Return an iterator over the upper covers of the element \( x \).

EXAMPLES:

sage: P = Poset({0:[2], 1:[2], 2:[3], 3:[]})
sage: type(P.upper_covers_iterator(0))
<class 'generator'>

width (\texttt{certificate=False})

Return the width of the poset (the size of its longest antichain).

It is computed through a matching in a bipartite graph; see Wikipedia article Dilworth%27s_theorem for more information. The width is also called Dilworth number.

INPUT:

- \texttt{certificate} – (default: \texttt{False}) whether to return a certificate

OUTPUT:

- If \texttt{certificate=True} return \((w, a)\), where \( w \) is the width of a poset and \( a \) is an antichain of maximum cardinality. If \texttt{certificate=False} return only width of the poset.

EXAMPLES:

sage: P = posets.BooleanLattice(4)
sage: P.width() #... 6

sage: w, max_achain = P.width(certificate=True)
sage: sorted(max_achain)
[3, 5, 6, 9, 10, 12]

>>> from sage.all import *

>>> P = posets.BooleanLattice(Integer(4))

>>> P.width() #...

(continues on next page)
needs networkx

```python
w, max_achain = P.width(certificate=True)
sorted(max_achain)
[3, 5, 6, 9, 10, 12]
```

with_bounds (labels=('bottom', 'top'))

Return the poset with bottom and top elements adjoined.

This function adds top and bottom elements to the poset. It will always add elements, it does not check if the poset already has a bottom or a top element.

For lattices and semilattices this function returns a lattice.

**INPUT:**

- `labels` – A pair of elements to use as a bottom and top element of the poset. Default is strings 'bottom' and 'top'. Either of them can be None, and then a new bottom or top element will not be added.

**EXAMPLES:**

```python
sage: V = Poset({0: [1, 2]})
sage: trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements
sage: trafficsign.list()
['bottom', 0, 1, 2, 'top']
sage: trafficsign = V.with_bounds(labels=(-1, -2))
sage: trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]
sage: Y = V.with_bounds(labels=(-1, None))
sage: Y.cover_relations()
[[-1, 0], [0, 1], [0, 2]]
sage: P = posets.PentagonPoset()  # A lattice
sage: P.with_bounds()
Finite lattice containing 7 elements
sage: P = posets.PentagonPoset(facade=False)
sage: P.with_bounds()
Finite lattice containing 7 elements
```

```python
>>> from sage.all import *

>>> V = Poset({Integer(0): [Integer(1), Integer(2)]})

>>> trafficsign = V.with_bounds(); trafficsign
Finite poset containing 5 elements

>>> trafficsign.list()
['bottom', 0, 1, 2, 'top']

>>> trafficsign = V.with_bounds(labels=(-Integer(1), -Integer(2)))

>>> trafficsign.cover_relations()
[[-1, 0], [0, 1], [0, 2], [1, -2], [2, -2]]

>>> Y = V.with_bounds(labels=(-Integer(1), None))

>>> Y.cover_relations()
[[-1, 0], [0, 1], [0, 2]]
```
>>> P = posets.PentagonPoset()  # A lattice
>>> P.with_bounds()
Finite lattice containing 7 elements

>>> P = posets.PentagonPoset(facade=False)
>>> P.with_bounds()
Finite lattice containing 7 elements

See also:

`without_bounds()` for the reverse operation

**with_linear_extension** *(linear_extension)*

Return a copy of `self` with a different default linear extension.

**EXAMPLES:**

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: list(P)
[1, 2, 3, 4, 6, 12]
sage: Q = P.with_linear_extension([1, 3, 2, 6, 4, 12])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

```
>>> from sage.all import *
```

```
sage: P = Poset((divisors(Integer(12)), attrcall("divides")), linear_extension=True)
sage: P.cover_relations()
[[1, 2], [1, 3], [2, 4], [2, 6], [3, 6], [4, 12], [6, 12]]
sage: list(P)
[1, 2, 3, 4, 6, 12]
sage: Q = P.with_linear_extension([Integer(1), Integer(3), Integer(2), Integer(6), Integer(4), Integer(12)])
sage: list(Q)
[1, 3, 2, 6, 4, 12]
sage: Q.cover_relations()
[[1, 3], [1, 2], [3, 6], [2, 6], [2, 4], [6, 12], [4, 12]]
```

**Note:** With the current implementation, this requires relabeling the internal `DiGraph` which is $O(n+m)$, where $n$ is the number of elements and $m$ the number of cover relations.

**without_bounds()**

Return the poset without its top and bottom elements.

This is useful as an input for the method `order_complex()`.

If there is either no top or no bottom element, this raises a `TypeError`.

**EXAMPLES:**
sage: P = posets.PentagonPoset()
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[[2, 3]]

sage: P = posets.DiamondPoset(5)
sage: Q = P.without_bounds(); Q
Finite poset containing 3 elements
sage: Q.cover_relations()
[]

See also:

with_bounds() for the reverse operation

zeta_polynomial()

Return the zeta polynomial of the poset.

The zeta polynomial of a poset is the unique polynomial \( Z(q) \) such that for every integer \( m > 1 \), \( Z(m) \) is the number of weakly increasing sequences \( x_1 \leq x_2 \leq \cdots \leq x_{m-1} \) of elements of the poset.

The polynomial \( Z(q) \) is integral-valued, but generally does not have integer coefficients. It can be computed as

\[
Z(q) = \sum_{k \geq 1} \binom{q - 2}{k - 1} c_k,
\]

where \( c_k \) is the number of all chains of length \( k \) in the poset.

For more information, see section 3.12 of [EnumComb1].

In particular, \( Z(2) \) is the number of vertices and \( Z(3) \) is the number of intervals.

EXAMPLES:

sage: P = posets.PentagonPoset()
sage: P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q
sage: P = posets.DiamondPoset(5)

(continues on next page)
sage: P.zeta_polynomial()
3/2*q^2 - 1/2*q

>>> from sage.all import *
>>> posets.ChainPoset(Integer(2)).zeta_polynomial()
q
>>> posets.ChainPoset(Integer(3)).zeta_polynomial()
1/2*q^2 + 1/2*q
>>> P = posets.PentagonPoset()
>>> P.zeta_polynomial()
1/6*q^3 + q^2 - 1/6*q
>>> P = posets.DiamondPoset(Integer(5))
>>> P.zeta_polynomial()
3/2*q^2 - 1/2*q

class sage.combinat.posets.posets.FinitePosets_n(n)
Bases: UniqueRepresentation, Parent

The finite enumerated set of all posets on \( n \) elements, up to an isomorphism.

EXAMPLES:

sage: P = Posets(3)
sage: P.cardinality()
5
sage: for p in P: print(p.cover_relations())
[]
[[1, 2]]
[[0, 1], [0, 2]]
[[0, 1], [1, 2]]
[[1, 2], [0, 2]]

>>> from sage.all import *
>>> P = Posets(Integer(3))
>>> P.cardinality()
5
>>> for p in P: print(p.cover_relations())
[]
[[1, 2]]
[[0, 1], [0, 2]]
[[0, 1], [1, 2]]
[[1, 2], [0, 2]]

cardinality (from_iterator=False)

Return the cardinality of this object.

Note: By default, this returns pre-computed values obtained from the On-Line Encyclopedia of Integer Sequences (OEIS sequence A000112). To override this, pass the argument from_iterator=True.

EXAMPLES:
sage: P = Posets(3)
sage: P.cardinality()
5
sage: P.cardinality(from_iterator=True)
5

>>> from sage.all import *
>>> P = Posets(Integer(3))
>>> P.cardinality()
5
>>> P.cardinality(from_iterator=True)
5

sage.combinat.posets.posets.Poset(data=None, element_labels=None, cover_relations=False, linear_extension=False, category=None, facade=None, key=None)

Construct a finite poset from various forms of input data.

INPUT:

• data – different input are accepted by this constructor:
  1. A two-element list or tuple \((E, R)\), where \(E\) is a collection of elements of the poset and \(R\) is a collection of relations \(x \leq y\), each represented as a two-element list/tuple/iterable such as \([x, y]\). The poset is then the transitive closure of the provided relations. If \(\text{cover_relations=True}\), then \(R\) is assumed to contain exactly the cover relations of the poset. If \(E\) is empty, then \(E\) is taken to be the set of elements appearing in the relations \(R\).
  2. A two-element list or tuple \((E, f)\), where \(E\) is the set of elements of the poset and \(f\) is a function such that, for any pair \(x, y\) of elements of \(E\), \(f(x, y)\) returns whether \(x \leq y\). If \(\text{cover_relations=True}\), then \(f(x, y)\) should instead return whether \(x\) is covered by \(y\).
  3. A dictionary of upper covers: \(data[x]\) is a list of the elements that cover the element \(x\) in the poset.
  4. A list or tuple of upper covers: \(data[x]\) is a list of the elements that cover the element \(x\) in the poset. If the set of elements is not a set of consecutive integers starting from zero, then:
    – every element must appear in the data, for example in its own entry.
    – \(data\) must be ordered in the same way as sorted elements.

Warning: If data is a list or tuple of length 2, then it is handled by the case 2 above.

  5. An acyclic, loop-free and multi-edge free DiGraph. If \(\text{cover_relations=True}\), then the edges of the digraph are assumed to correspond to the cover relations of the poset. Otherwise, the cover relations are computed.
  6. A previously constructed poset (the poset itself is returned).

• element_labels – (default: None); an optional list or dictionary of objects that label the poset elements.
• cover_relations – a boolean (default: False); whether the data can be assumed to describe a directed acyclic graph whose arrows are cover relations; otherwise, the cover relations are first computed.
• linear_extension – a boolean (default: False); whether to use the provided list of elements as default linear extension for the poset; otherwise a linear extension is computed. If the data is given as the pair \((E, f)\), then \(E\) is taken to be the linear extension.
• facade – a boolean or None (default); whether the Poset()’s elements should be wrapped to make them aware of the Poset they belong to.

  – If facade = True, the Poset()’s elements are exactly those given as input.
  – If facade = False, the Poset()’s elements will become PosetElement objects.
  – If facade = None (default) the expected behaviour is the behaviour of facade = True, unless the opposite can be deduced from the context (i.e. for instance if a Poset() is built from another Poset(), itself built with facade = False)

OUTPUT:

FinitePoset – an instance of the FinitePoset class.

If category is specified, then the poset is created in this category instead of FinitePosets.

See also:

Posets, Posets, FinitePosets

EXAMPLES:

1. Elements and cover relations:

```python
sage: elms = [1,2,3,4,5,6,7]
sage: rels = [[1,2],[3,4],[4,5],[2,5]]
sage: Poset((elms, rels), cover_relations = True, facade = False)
Finite poset containing 7 elements
```

2. Elements and function: the standard permutations of [1, 2, 3, 4] with the Bruhat order:

```python
sage: elms = [1,2,3,4]
sage: rels = [[1,2],[1,3],[1,4],[2,3],[2,4],[3,4]]
sage: P = Poset( [elms,rels] ,cover_relations=False); P
Finite poset containing 4 elements
```

```python
>>> from sage.all import *
>>> elms = [Integer(1),Integer(2),Integer(3),Integer(4)]
>>> rels = [[Integer(1),Integer(2)],[Integer(1),Integer(3)],[Integer(1),Integer(4)],[Integer(3),Integer(4)]]
>>> P = Poset( [elms,rels] ,cover_relations=False); P
Finite poset containing 4 elements
```

```python
>>> P.cover_relations()
[[[1, 2], [2, 3], [3, 4]]
```
Combinatorics, Release 10.4

sage: elms = Permutations(4)
sage: fcn = lambda p, q : p.bruhat_lequal(q)
sage: Poset((elms, fcn))
Finite poset containing 24 elements

>>> from sage.all import *

>>> elms = Permutations(Integer(4))

>>> fcn = lambda p, q : p.bruhat_lequal(q)

>>> Poset((elms, fcn))
Finite poset containing 24 elements

With a function that identifies the cover relations: the set partitions of \{1, 2, 3\} ordered by refinement:

sage: # needs sage.combinat
sage: elms = SetPartitions(3)
sage: def fcn(A, B):
    ....:     if len(A) != len(B)+1:
    ....:         return False
    ....:     for a in A:
    ....:         if not any(set(a).issubset(b) for b in B):
    ....:             return False
    ....:     return True

sage: Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements

>>> from sage.all import *

>>> # needs sage.combinat

>>> elms = SetPartitions(Integer(3))

>>> def fcn(A, B):
    ...     if len(A) != len(B)+Integer(1):
    ...         return False
    ...     for a in A:
    ...         if not any(set(a).issubset(b) for b in B):
    ...             return False
    ...     return True

>>> Poset((elms, fcn), cover_relations=True)
Finite poset containing 5 elements

3. A dictionary of upper covers:

sage: Poset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d'], 'd': []})
Fastest poset containing 4 elements

>>> from sage.all import *

>>> Poset({'a': ['b', 'c'], 'b': ['d'], 'c': ['d'], 'd': []})
Fastest poset containing 4 elements

4. A list of upper covers, with range(5) as set of vertices:

sage: Poset([[1, 2], [4], [3], [4], []])
Fastest poset containing 5 elements

>>> from sage.all import *

>>> Poset([[1, 2], [4], [3], [4], []])
Fastest poset containing 5 elements

A list of upper covers, with letters as vertices:

5.1. Comprehensive Module List 3351
Sage:
```
Poset([['a', 'b'], ['b', 'c'], ['c']])
Finite poset containing 3 elements
```

```python
>>> from sage.all import *

>>> Poset([['a', 'b'], ['b', 'c'], ['c']])
Finite poset containing 3 elements
```

A list of upper covers and a dictionary of labels:

```
sage: elm_labs = {0:"a", 1:"b", 2:"c", 3:"d", 4:"e"}
sage: P = Poset([[1,2],[4],[3],[4],[[]], elm_labs, facade=False)
sage: P.list()
[a, b, c, d, e]
```

```python
>>> from sage.all import *

>>> elm_labs = {Integer(0):"a", Integer(1):"b", Integer(2):"c", Integer(3):"d", Integer(4):"e"}

>>> P = Poset([[Integer(1),Integer(2)],[Integer(4)],[Integer(3)],[Integer(4)],[], elm_labs, facade=False])

>>> P.list()
[a, b, c, d, e]
```

**Warning:** The special case where the argument data is a list or tuple of length 2 is handled by the case 2. So you cannot use this method to input a 2-element poset.

5. An acyclic DiGraph.

```
sage: dag = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: Poset(dag)
Finite poset containing 6 elements
```

```python
>>> from sage.all import *

>>> dag = DiGraph({Integer(0):[Integer(2),Integer(3)], Integer(1):[Integer(3), Integer(4)], Integer(2):[Integer(5)], Integer(3):[Integer(5)], Integer(4):[Integer(5)]})

>>> Poset(dag)
Finite poset containing 6 elements
```

Any directed acyclic graph without loops or multiple edges, as long as `cover_relations=False`:

```
sage: dig = DiGraph({0:[2,3], 1:[3,4,5], 2:[5], 3:[5], 4:[5]})
sage: dig.allows_multiple_edges()
False
sage: dig.allows_loops()
False
sage: dig.transitive_reduction() == dig
False
sage: Poset(dig, cover_relations=False)
Finite poset containing 6 elements
```

```
sage: Poset(dig, cover_relations=True)
Traceback (most recent call last):
...
ValueError: Hasse diagram is not transitively reduced
```

3352 Chapter 5. Comprehensive Module List
>>> from sage.all import *
>>> dig = DiGraph({Integer(0):[Integer(2),Integer(3)], Integer(1):[Integer(3),
    Integer(4),Integer(5)], Integer(2):[Integer(5)], Integer(3):[Integer(5)],
    Integer(4):[Integer(5)]})
>>> dig.allows_multiple_edges()
False
>>> dig.allows_loops()
False
>>> dig.transitive_reduction() == dig
False
>>> Poset(dig, cover_relations=False)
Finite poset containing 6 elements
>>> Poset(dig, cover_relations=True)
Traceback (most recent call last):
  ... ValueError: Hasse diagram is not transitively reduced

**Default Linear extension**

Every poset $P$ obtained with `Poset` comes equipped with a default linear extension, which is also used for enumerating its elements. By default, this linear extension is computed, and has no particular significance:

```
sage: P = Poset((divisors(12), attrcall("divides")))
sage: P.list()
[1, 2, 4, 3, 6, 12]
sage: P.linear_extension()
[1, 2, 4, 3, 6, 12]
```

You may enforce a specific linear extension using the `linear_extension` option:

```
sage: P = Poset((divisors(12), attrcall("divides")), linear_extension=True)
sage: P.list()
[1, 2, 3, 4, 6, 12]
sage: P.linear_extension()
[1, 2, 3, 4, 6, 12]
```

Depending on popular request, `Poset` might eventually get modified to always use the provided list of elements as default linear extension, when it is one.

See also:

* `FinitePoset.linear_extensions()`
**Facade posets**

When `facade = False`, the elements of a poset are wrapped so as to make them aware that they belong to that poset:

```
sage: P = Poset(DiGraph({d:[c,b], c:[a], b:[a]}), facade = False)
sage: d,c,b,a = list(P)
sage: a.parent() is P
True
```

This allows for comparing elements according to $P$:

```
sage: c < a
True
```

However, this may have surprising effects:

```
sage: my_elements = ['a','b','c','d']
sage: any(x in my_elements for x in P)
False
```

and can be annoying when one wants to manipulate the elements of the poset:

```
sage: a + b
Traceback (most recent call last):
  ...TypeError: unsupported operand parent(s) for +: 'Finite poset containing 4 elements' and 'Finite poset containing 4 elements'
sage: a.element + b.element
'ab'
```

By default, facade posets are constructed instead:
In this example, the elements of the poset remain plain strings:

```
sage: P = Poset(DiGraph({'d': ['c', 'b'], 'c': ['a'], 'b': ['a']}))
```

```
>>> from sage.all import *

>>> P = Poset(DiGraph({'d': ['c', 'b'], 'c': ['a'], 'b': ['a']}))
```

Of course, those strings are not aware of $P$. So to compare two such strings, one needs to query $P$:

```
sage: d, c, b, a = list(P)
sage: type(a)
<class 'str'>
```

```
>>> from sage.all import *

>>> d, c, b, a = list(P)

>>> type(a)
<class 'str'>
```

which models the usual mathematical notation $a < P b$.

Most operations seem to still work, but at this point there is no guarantee whatsoever:

```
sage: a < b
True
sage: P.lt(a,b)
False
```

```
>>> from sage.all import *

>>> a < b
True

>>> P.lt(a,b)
False
```

```
sage: P.list()
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('a')
['d', 'c', 'b', 'a']
sage: P.principal_order_ideal('b')
['d', 'b']
sage: P.principal_order_ideal('d')
['d']
sage: TestSuite(P).run()
```

```
>>> from sage.all import *

>>> P.list()
['d', 'c', 'b', 'a']

>>> P.principal_order_ideal('a')
['d', 'c', 'b', 'a']

>>> P.principal_order_ideal('b')
['d', 'b']

>>> P.principal_order_ideal('d')
['d']

>>> TestSuite(P).run()
```
Warning: `DiGraph` is used to construct the poset, and the vertices of a `DiGraph` are converted to plain Python `int`'s if they are `Integer`'s:

```python
sage: G = DiGraph({0:[2,3], 1:[3,4], 2:[5], 3:[5], 4:[5]})
sage: type(G.vertices(sort=True)[0])
<class 'int'>
```

This is worked around by systematically converting back the vertices of a poset to `Integer`'s if they are `int`'s:

```python
sage: P = Poset((divisors(15), attrcall("divides")), facade = False)
sage: type(P.an_element().element)
<class 'sage.rings.integer.Integer'>
sage: P = Poset((divisors(15), attrcall("divides")), facade=True)
sage: type(P.an_element())
<class 'sage.rings.integer.Integer'>
```

This may be abusive:

```python
sage: P = Poset((range(5), operator.le), facade = True)
sage: P.an_element().parent()
Integer Ring
```

Unique representation

As most parents, `Poset` have unique representation (see `UniqueRepresentation`). Namely if two posets are created from two equal data, then they are not only equal but actually identical:

```python
sage: data1 = [[1,2],[3],[3]]
sage: data2 = [[1,2],[3],[3]]
sage: P1 = Poset(data1)
sage: P2 = Poset(data2)
sage: P1 == P2
True
sage: P1 is P2
True
```
In situations where this behaviour is not desired, one can use the `key` option:

```python
sage: P1 = Poset(data1, key = "foo")
sage: P2 = Poset(data2, key = "bar")
sage: P1 is P2
False
sage: P1 == P2
False
```

key can be any hashable value and is passed down to `UniqueRepresentation`. It is otherwise ignored by the poset constructor.

`sage.combinat.posets.posets.is_poset(dig)`

Return `True` if a directed graph is acyclic and transitively reduced, and `False` otherwise.

EXAMPLES:

```python
sage: from sage.combinat.posets.posets import is_poset
sage: dig = DiGraph({0:[3], 1:[3, 4, 5], 2:[5], 3:[5], 4:[5]})
sage: is_poset(dig)
False
sage: is_poset(dig.transitive_reduction())
True
```

```python
sage: from sage.all import *
sage: P1 = Poset(data1, key = "foo")
sage: P2 = Poset(data2, key = "bar")
sage: P1 is P2
False
sage: P1 == P2
False
```
### 5.1.187 $q$-Analogues

`sage.combinat.q_analogues.gaussian_binomial(n, k, q=None, algorithm='auto')`

This is an alias of `q_binomial()`.

See `q_binomial()` for the full documentation.

**EXAMPLES:**

```python
sage: gaussian_binomial(4, 2)
q^4 + q^3 + 2*q^2 + q + 1
```

```python
>>> from sage.all import *
>>> gaussian_binomial(Integer(4), Integer(2))
q^4 + q^3 + 2*q^2 + q + 1
```

`sage.combinat.q_analogues.gaussian_multinomial(seq, q=None, binomial_algorithm='auto')`

Return the $q$-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

\[
\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q![k_2]_q! \cdots [k_m]_q!}
\]

where $n = k_1 + k_2 + \cdots + k_m$.

If $q$ is unspecified, then the variable is the generator $q$ for a univariate polynomial ring over the integers.

**INPUT:**

- `seq` – an iterable of the values $k_1$ to $k_m$ defined above
- `q` – (default: None) the variable $q$; if None, then use a default variable in $\mathbb{Z}[q]$
- `binomial_algorithm` – (default: 'auto') the algorithm to use in `q_binomial()`; see possible values there

**ALGORITHM:**

We use the equivalent formula

\[
\binom{k_1 + \cdots + k_m}{k_1, \ldots, k_m}_q = \prod_{i=1}^{m} \binom{\sum_{j=1}^{i} k_j}{k_i}_q.
\]

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1, 2, 1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial([1, 2, 1], q=1) == multinomial([1, 2, 1])
True
sage: q_multinomial((3, 2)) == q_binomial(5, 3)
True
sage: q_multinomial([])
1
```

```python
>>> from sage.all import *
>>> from sage.combinat.q_analogues import q_multinomial
>>> q_multinomial([Integer(1), Integer(2), Integer(1)])
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
>>> q_multinomial([Integer(1),Integer(2),Integer(1)], q=Integer(1)) ==
   multinomial([Integer(1),Integer(2),Integer(1)])
True
>>> q_multinomial((Integer(3),Integer(2))) == q_binomial(Integer(5),Integer(3))
True
>>> q_multinomial([])
1
```

sage.combinat.q_analogues.number_of_irreducible_polynomials(n, q=None, m=1)

Return the number of monic irreducible polynomials of degree \(n\) in \(m\) variables over the finite field with \(q\) elements.

If \(q\) is not given, the result is returned as an integer-valued polynomial in \(\mathbb{Q}[q]\).

INPUT:
- \(n\) – positive integer
- \(q\) – None (default) or a prime power
- \(m\) – positive integer (default 1)

OUTPUT: integer or integer-valued polynomial over \(\mathbb{Q}\)

EXAMPLES:
```
sage: number_of_irreducible_polynomials(8, q=2)
30
sage: number_of_irreducible_polynomials(9, q=9)
43046640
sage: number_of_irreducible_polynomials(5, q=11, m=3)
2079650567184059145647246367401741345157369643207055703168
```

```
>>> from sage.all import *
```

```
>>> number_of_irreducible_polynomials(Integer(8), q=Integer(2))
30
>>> number_of_irreducible_polynomials(Integer(9), q=Integer(9))
43046640
>>> number_of_irreducible_polynomials(Integer(5), q=Integer(11), m=Integer(3))
2079650567184059145647246367401741345157369643207055703168
```

```
sage: poly = number_of_irreducible_polynomials(12); poly
1/12*q^12 - 1/12*q^6 - 1/12*q^4 + 1/12*q^2
sage: poly(5) == number_of_irreducible_polynomials(12, q=5)
True
```

```
sage: poly = number_of_irreducible_polynomials(5, m=3); poly
q^55 + q^54 + q^53 + q^52 + q^51 + q^50 + ... + 1/5*q^5 - 1/5*q^3 - 1/5*q^2 - 1/5*q
sage: poly(11) == number_of_irreducible_polynomials(5, q=11, m=3)
True
```

```
>>> from sage.all import *
```

```
>>> poly = number_of_irreducible_polynomials(Integer(12)); poly
1/12*q^12 - 1/12*q^6 - 1/12*q^4 + 1/12*q^2
>>> poly(Integer(5)) == number_of_irreducible_polynomials(Integer(12),q=Integer(5))
True
>>> poly = number_of_irreducible_polynomials(Integer(5), m=Integer(3)); poly
```

(continues on next page)
This function is \textit{much} faster than enumerating the polynomials:

\begin{verbatim}
sage: num = number_of_irreducible_polynomials(99, q=101)
sage: num.bit_length()
653
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> num = number_of_irreducible_polynomials(Integer(99), q=Integer(101))
>>> num.bit_length()
653
\end{verbatim}

\section*{ALGORITHM:}

In the univariate case, classical formula \( \frac{1}{n} \sum_{d|n} \mu(n/d)q^d \) using the M"obius function \( \mu \); see \texttt{moebius()}. In the multivariate case, formula from \cite{Bodin2007}, independently \cite{Alekseyev2006}.

\begin{verbatim}
sage.combinat.q_analogues.q_binomial (n, k, q=None, algorithm='auto')
\end{verbatim}

Return the \( q \)-binomial coefficient.

This is also known as the Gaussian binomial coefficient, and is defined by

\[
\binom{n}{k}_q = \frac{(1 - q^n)(1 - q^{n-1}) \cdots (1 - q^{n-k+1})}{(1 - q)(1 - q^2) \cdots (1 - q^k)}.
\]

See \texttt{Wikipedia} article \texttt{Gaussian\_binomial\_coefficient}.

If \( q \) is unspecified, then the variable is the generator \( q \) for a univariate polynomial ring over the integers.

\section*{INPUT:}

- \( n, k \) – the values \( n \) and \( k \) defined above
- \( q \) – (default: \texttt{None}) the variable \( q \); if \texttt{None}, then use a default variable in \( \mathbb{Z}[q] \)
- \texttt{algorithm} – (default: \texttt{'auto'}) the algorithm to use and can be one of the following:
  - \texttt{'auto'} – automatically choose the algorithm; see the algorithm section below
  - \texttt{'naive'} – use the naive algorithm
  - \texttt{'cyclotomic'} – use cyclotomic algorithm

\section*{ALGORITHM:}

The naive algorithm uses the product formula. The cyclotomic algorithm uses a product of cyclotomic polynomials (cf. \cite{CH2006}).

When the algorithm is set to \texttt{'auto'}, we choose according to the following rules:

- If \( q \) is a polynomial:
  
  When \( n \) is small or \( k \) is small with respect to \( n \), one uses the naive algorithm. When both \( n \) and \( k \) are big, one uses the cyclotomic algorithm.
  
  If \( q \) is in the symbolic ring (or a symbolic subring), one uses the cyclotomic algorithm.
• Otherwise one uses the naive algorithm, unless $q$ is a root of unity, then one uses the cyclotomic algorithm.

EXAMPLES:

By default, the variable is the generator of $\mathbb{Z}[q]$:

```python
sage: from sage.combinat.q_analogues import q_binomial
sage: g = q_binomial(5,1); g
q^4 + q^3 + q^2 + q + 1
sage: g.parent()
Univariate Polynomial Ring in q over Integer Ring
```

```python
>>> from sage.all import *
>>> from sage.combinat.q_analogues import q_binomial
>>> g = q_binomial(Integer(5),Integer(1)); g
q^4 + q^3 + q^2 + q + 1
>>> g.parent()
Univariate Polynomial Ring in q over Integer Ring
```

For $n \geq 0$, the $q$-binomial coefficient vanishes unless $0 \leq k \leq n$:

```python
sage: q_binomial(4,5)
0
sage: q_binomial(5,-1)
0
```

```python
>>> from sage.all import *
>>> q_binomial(Integer(4),Integer(1))
0
>>> q_binomial(Integer(5),-Integer(1))
0
```

For $k \geq 0$, the $q$-binomial coefficient is extended as a polynomial in $n$:

```python
sage: q_binomial(-4,1)
-q^-4 - q^-3 - q^-2 - q^-1
sage: q_binomial(-2,3)
-q^-9 - q^-8 - q^-7 - q^-6
```

```python
>>> from sage.all import *
>>> q_binomial(-Integer(4),Integer(1))
-q^-4 - q^-3 - q^-2 - q^-1
>>> q_binomial(-Integer(2),Integer(3))
-q^-9 - q^-8 - q^-7 - q^-6
```

Other variables can be used, given as third parameter:

```python
sage: p = ZZ['p'].gen()
sage: q_binomial(4,2,p)
p^4 + p^3 + 2*p^2 + p + 1
```

```python
>>> from sage.all import *
>>> p = ZZ['p'].gen()
>>> q_binomial(Integer(4),Integer(2),p)
p^4 + p^3 + 2*p^2 + p + 1
```

The third parameter can also be arbitrary values:
Combinatorics, Release 10.4

sage: q_binomial(5,1,2) == g.subs(q=2)
True
sage: q_binomial(5,1,1)
5
sage: q_binomial(4,2,-1)
2
sage: q_binomial(4,2,1.14)
152.030056160000
sage: R = GF((5, 2), t)
sage: t = R.gen(0)
sage: q_binomial(6, 3, t)
2*t + 3

>>> from sage.all import *
>>> q_binomial(Integer(5),Integer(1),Integer(2)) == g.subs(q=Integer(2))
True
>>> q_binomial(Integer(5),Integer(1),Integer(1))
5
>>> q_binomial(Integer(4),Integer(2),-Integer(1))
2
>>> q_binomial(Integer(4),Integer(2),RealNumber('1.14'))
152.030056160000
>>> R = GF((Integer(5), Integer(2)), 't')
>>> t = R.gen(0)
>>> q_binomial(Integer(6), Integer(3), t)
2*t + 3

We can also do this for more complicated objects such as matrices or symmetric functions:

sage: q_binomial(4,2,matrix([[2,1],[-1,3]]))
[ -6 84]
[-84 78]
sage: Sym = SymmetricFunctions(QQ)
sage: s = Sym.schur()
sage: q_binomial(4,1, s[2]+s[1])

>>> from sage.all import *
>>> q_binomial(Integer(4),Integer(2),matrix([[Integer(2),Integer(1)],[Integer(-1),Integer(3)]]))
[ -6 84]
[-84 78]
>>> Sym = SymmetricFunctions(QQ)
>>> s = Sym.schur()
>>> q_binomial(Integer(4),Integer(1), s[2]+s[1])

REFERENCES:

AUTHORS:

- Frédéric Chapoton, David Joyner and William Stein
sage.combinat.q_analogues.q_catalan_number($n, q=None, m=1$)

Return the $q$-Catalan number of index $n$.

INPUT:

- $q$ – optional variable
- $m$ – (optional integer) to get instead the $m$-Fuss-Catalan numbers

If $q$ is unspecified, then it defaults to using the generator $q$ for a univariate polynomial ring over the integers.

There are several $q$-Catalan numbers. This procedure returns the one which can be written using the $q$-binomial coefficients.

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_catalan_number
sage: q_catalan_number(4)
$q^12 + q^10 + q^9 + 2*q^8 + q^7 + 2*q^6 + q^5 + 2*q^4 + q^3 + q^2 + 1$

sage: p = ZZ['p'].gen(0)
sage: q_catalan_number(4, p)
p^12 + p^10 + p^9 + 2*p^8 + p^7 + 2*p^6 + p^5 + 2*p^4 + p^3 + p^2 + 1

sage: q_catalan_number(3, m=2)
$q^12 + q^10 + q^9 + q^8 + q^7 + 2*q^6 + q^5 + q^4 + q^3 + q^2 + 1$

>>> from sage.all import *
>>> from sage.combinat.q_analogues import q_catalan_number
>>> q_catalan_number(Integer(4))
$q^12 + q^10 + q^9 + 2*q^8 + q^7 + 2*q^6 + q^5 + 2*q^4 + q^3 + q^2 + 1$

>>> p = ZZ['p'].gen(0)
>>> q_catalan_number(Integer(4), p)
p^12 + p^10 + p^9 + 2*p^8 + p^7 + 2*p^6 + p^5 + 2*p^4 + p^3 + p^2 + 1

>>> q_catalan_number(Integer(3), m=Integer(2))
$q^12 + q^10 + q^9 + q^8 + q^7 + 2*q^6 + q^5 + q^4 + q^3 + q^2 + 1$
```

sage.combinat.q_analogues.q_factorial($n, q=None$)

Return the $q$-analogue of the factorial $n!$.

This is the product

$$[1]_q [2]_q \cdots [n]_q = 1 \cdot (1 + q) \cdot (1 + q + q^2) \cdots (1 + q + q^2 + \cdots + q^{n-1}).$$

If $q$ is unspecified, then this function defaults to using the generator $q$ for a univariate polynomial ring over the integers.

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_factorial
sage: q_factorial(3)
$q^3 + 2*q^2 + 2*q + 1$

sage: p = ZZ['p'].gen(0)
sage: q_factorial(3, p)
p^3 + 2*p^2 + 2*p + 1
```
The $q$-analog of $n!$ is only defined for $n$ a non-negative integer (Issue #11411):

```python
sage: q_factorial(-2)
Traceback (most recent call last):
  ...  
ValueError: argument (-2) must be a nonnegative integer
```

```
>>> from sage.all import *
>>> from sage.combinat.q_analogues import q_factorial
>>> q_factorial(Integer(-2))
Traceback (most recent call last):
  ...  
ValueError: argument (-2) must be a nonnegative integer
```

`sage.combinat.q_analogues.q_int(n, q=None)`

Return the $q$-analogue of the integer $n$.

The $q$-analogue of the integer $n$ is given by

$$[n]_q = \begin{cases} 
1 + q + \cdots + q^{n-1}, & \text{if } n \geq 0, \\
-q^{-n}[-n]_q, & \text{if } n \leq 0.
\end{cases}$$

Consequently, if $q = 1$ then $[n]_1 = n$ and if $q \neq 1$ then $[n]_q = (q^n - 1)/(q - 1)$.

If the argument $q$ is not specified then it defaults to the generator $q$ of the univariate polynomial ring over the integers.

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_int
sage: q_int(3)
q^2 + q + 1
sage: q_int(-3)
-q^-3 - q^-2 - q^-1
sage: p = ZZ['p'].gen(0)
```

(continues on next page)
sage.combinat.q_analogues.q_jordan(q=None)

Return the $q$-Jordan number of $t$.

If $q$ is the power of a prime number, the output is the number of complete flags in $F_N^q$ (where $N$ is the size of $t$) stable under a linear nilpotent endomorphism $f_t$ whose Jordan type is given by $t$, i.e. such that for all $i$:

$$\dim(\ker f_t^i) = t[0] + \cdots + t[i-1]$$

If $q$ is unspecified, then it defaults to using the generator $q$ for a univariate polynomial ring over the integers.

The result is cached.

INPUT:

- $t$ – an integer partition, or an argument accepted by Partition
- $q$ – (default: None) the variable $q$; if None, then use a default variable in $\mathbb{Z}[q]$

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_jordan
sage: [q_jordan(mu, 2) for mu in Partitions(5)]
[9765, 1029, 213, 93, 29, 9, 1]
sage: [q_jordan(mu, 2) for mu in Partitions(6)]
[615195, 40635, 5643, 2331, 1491, 515, 147, 87, 47, 11, 1]
sage: q_jordan([3,2,1])
16*q^4 + 24*q^3 + 14*q^2 + 5*q + 1
sage: q_jordan([2,1], x)
# needs sage.symbolic
2*x + 1
```

If the partition is trivial (i.e. has only one part), we get the $q$-factorial (in this case, the nilpotent endomorphism is necessarily $0$):

```python
sage: from sage.combinat.q_analogues import q_factorial
sage: q_jordan([5]) == q_factorial(5)
True
sage: q_jordan([11], 5) == q_factorial(11, 5)
True
```
AUTHOR:

- Xavier Caruso (2012-06-29)

sage.combinat.q_analogues.q_multinomial(seq=q=None, binomial_algorithm='auto')

Return the $q$-multinomial coefficient.

This is also known as the Gaussian multinomial coefficient, and is defined by

$$\binom{n}{k_1, k_2, \ldots, k_m}_q = \frac{[n]_q!}{[k_1]_q! [k_2]_q! \cdots [k_m]_q!}$$

where $n = k_1 + k_2 + \cdots + k_m$.

If $q$ is unspecified, then the variable is the generator $q$ for a univariate polynomial ring over the integers.

INPUT:

- seq – an iterable of the values $k_1$ to $k_m$ defined above
- q – (default: None) the variable $q$; if None, then use a default variable in $\mathbb{Z}[q]$
- binomial_algorithm – (default: 'auto') the algorithm to use in $q\_binomial();$ see possible values there

ALGORITHM:

We use the equivalent formula

$$\binom{k_1 + \cdots + k_m}{k_1, k_2, \ldots, k_m}_q = \prod_{i=1}^{m} \binom{\sum_{j=1}^{i} k_j}{k_i}_q.$$

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_multinomial
sage: q_multinomial([1, 2, 1])
q^5 + 2*q^4 + 3*q^3 + 3*q^2 + 2*q + 1
sage: q_multinomial(3, 2) == q_binomial(5, 3)
True
sage: q_multinomial([])
1
```
sage.combinat.q_analogues.q_pochhammer(n, a, q=None)

Return the \(q\)-Pochhammer \((a; q)_n\).

The \(q\)-Pochhammer symbol is defined by

\[
(a; q)_n = \prod_{k=0}^{n-1} (1 - aq^k)
\]

with \((a; q)_0 = 1\) for all \(a, q\) and \(n \in \mathbb{N}\). By using the identity

\[
(a; q)_n = \frac{(a; q)_\infty}{(aq^n; q)_\infty},
\]

we can extend the definition to \(n < 0\) by

\[
(a; q)_n = \frac{1}{(aq^n; q)_{-n}} = \prod_{k=1}^{-n} \frac{1}{1 - a/q^k}.
\]

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import q_pochhammer
sage: q_pochhammer(3, 1/7)
6/343*q^3 - 6/49*q^2 - 6/49*q + 6/7
sage: q_pochhammer(3, 3)
-18*q^3 + 6*q^2 + 6*q - 2
sage: q_pochhammer(3, 1)
0
sage: R.<q> = ZZ[]
0
sage: q_pochhammer(4, q)
q^10 - q^9 - q^8 + 2*q^5 - q^2 - q + 1
sage: q_pochhammer(4, q^2)
q^14 - q^12 - q^11 - q^10 + q^8 + 2*q^7 + q^6 - q^4 - q^3 - q^2 + 1
sage: q_pochhammer(-3, q)
1/(-q^9 + q^7 + q^6 + q^5 - q^4 - q^3 - q^2 + 1)
```
sage.combinat.q_analogues.q_stirling_number1 \( (k, q=\text{None}) \)

Return the (unsigned) \( q \)-Stirling number of the first kind.

This is a \( q \)-analogue of \( \text{sage.combinat.combinat.stirling_number1()} \).

**INPUT:**
- \( n, k \) – integers with \( 1 \leq k \leq n \)
- \( q \) – optional variable (default \( q \))

**OUTPUT:** a polynomial in the variable \( q \)

These polynomials satisfy the recurrence
\[
s_{n,k} = s_{n-1,k-1} + [n-1]_q s_{n-1,k}.
\]

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_stirling_number1
sage: q_stirling_number1(4,2)
q^3 + 3*q^2 + 4*q + 3

sage: all(stirling_number1(6,k) == q_stirling_number1(6,k)(1)  
     for k in range(1,6))
True

sage: x = polygen(QQ['q'],'x')
sage: S = sum(q_stirling_number1(5,k)*x**k for k in range(1,6))
sage: factor(S)
x * (x + 1) * (x + q + 1) * (x + q^2 + q + 1) * (x + q^3 + q^2 + q + 1)
```

**REFERENCES:**
- [Ca1948]
- [Ca1954]
This is a \( q \)-analogue of `sage.combinat.combinat.stirling_number2()`.

**INPUT:**
- \( n, k \) – integers with \( 1 \leq k \leq n \)
- \( q \) – optional variable (default \( q \))

**OUTPUT:** a polynomial in the variable \( q \)

These polynomials satisfy the recurrence

\[
S_{n,k} = q^{k-1}S_{n-1,k-1} + [k]qS_{n-1,k}.
\]

**EXAMPLES:**

```python
sage: from sage.combinat.q_analogues import q_stirling_number2
sage: q_stirling_number2(4,2)
q^3 + 3*q^2 + 3*q

sage: all(stirling_number2(6,k) == q_stirling_number2(6,k)(1)
....: for k in range(7))
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.q_analogues import q_stirling_number2

>>> q_stirling_number2(Integer(4),Integer(2))
q^3 + 3*q^2 + 3*q

>>> all(stirling_number2(Integer(6),k) == q_stirling_number2(Integer(6),
˓→k)(Integer(1))
... for k in range(Integer(7)))
True
```

**REFERENCES:**
- [Mil1978]

`sage.combinat.q_analogues.q_subgroups_of_abelian_group` `la, mu, q=None, algorithm='birkhoff')`

Return the \( q \)-number of subgroups of type \( \mu \) in a finite abelian group of type \( \lambda \).

**INPUT:**
- \( \lambda \) – type of the ambient group as a `Partition`
- \( \mu \) – type of the subgroup as a `Partition`
- \( q \) – (default: \( \text{None} \)) an indeterminate or a prime number; if \( \text{None} \), this defaults to \( q \in \mathbb{Z}_q \)
- `algorithm` – (default: 'birkhoff') the algorithm to use can be one of the following:
  - 'birkhoff' – use the Birkhoff formula from [Bu87]
  - 'delsarte' – use the formula from [Delsarte48]

**OUTPUT:**
The number of subgroups of type \( \mu \) in a group of type \( \lambda \) as a polynomial in \( q \).

**ALGORITHM:**
Let $q$ be a prime number and $\lambda = (\lambda_1, \ldots, \lambda_l)$ be a partition. A finite abelian $q$-group is of type $\lambda$ if it is isomorphic to

$$\mathbb{Z}/q^{\lambda_1}\mathbb{Z} \times \cdots \times \mathbb{Z}/q^{\lambda_l}\mathbb{Z}.$$ 

The formula from [Bu87] works as follows: Let $\lambda$ and $\mu$ be partitions. Let $\lambda'$ and $\mu'$ denote the conjugate partitions to $\lambda$ and $\mu$, respectively. Then the number of subgroups of type $\mu$ in a group of type $\lambda$ is given by

$$\prod_{i=1}^{l} q^{\mu'_i+1}(\lambda'_i-\mu'_i)\left(\frac{\lambda'_i-\mu'_i+1}{q}\right).$$

The formula from [Delsarte48] works as follows: Let $\lambda$ and $\mu$ be partitions. Let $(s_1, s_2, \ldots, s_l)$ and $(r_1, r_2, \ldots, r_k)$ denote the parts of the partitions conjugate to $\lambda$ and $\mu$, respectively. Let

$$\mathfrak{F}(\xi_1, \ldots, \xi_k) = \xi_1^{r_2} \xi_2^{r_3} \cdots \xi_k^{r_k} \prod_{i=1}^{l} (\xi_1 - q^{s_1}) \prod_{i=2}^{l} (\xi_2 - q^{s_2}) \cdots \prod_{i=k}^{l} (\xi_k - q^{-s_k}).$$

Then the number of subgroups of type $\mu$ in a group of type $\lambda$ is given by

$$\frac{\mathfrak{F}(q^{s_1}, q^{s_2}, \ldots, q^{s_k})}{\mathfrak{F}(q^{r_1}, q^{r_2}, \ldots, q^{r_k})}.$$

• Tomer Bauer (2013, 2018): Implemented the Birkhoff algorithm and refactoring

```python
sage.combinat.q_analogues.qt_catalan_number(n)
```

Return the $q, t$-Catalan number of index $n$.

EXAMPLES:

```python
sage: from sage.combinat.q_analogues import qt_catalan_number
sage: qt_catalan_number(1)
1
sage: qt_catalan_number(2)
q + t
sage: qt_catalan_number(3)
q^3 + q^2*t + q^2*t^2 + t^3 + q*t
sage: qt_catalan_number(4)
q^6 + q^5*t + q^4*t^2 + q^3*t^3 + q^2*t^4 + q*t^5 + t^6 + q^4*t + q^3*t^2 + q^2*t^3 + q^2*t + q^3*t + q^2*t^2 + q*t^3
```

The $q, t$-Catalan number of index $n$ is only defined for $n$ a nonnegative integer (Issue #11411):

```python
sage: qt_catalan_number(-2)
Traceback (most recent call last):
  ...
ValueError: argument (-2) must be a nonnegative integer
```
5.1.188 \(q\)-Bernoulli Numbers and Polynomials

sage.combinat.q_bernoulli.q_bernoulli \((p=\text{None})\)

Compute Carlitz's \(q\)-analogue of the Bernoulli numbers.

For every nonnegative integer \(m\), the \(q\)-Bernoulli number \(\beta_m\) is a rational function of the indeterminate \(q\) whose value at \(q = 1\) is the usual Bernoulli number \(B_m\).

INPUT:

- \(m\) – a nonnegative integer
- \(p\) (default: \(\text{None}\)) – an optional value for \(q\)

OUTPUT:

A rational function of the indeterminate \(q\) (if \(p\) is \(\text{None}\))

Otherwise, the rational function is evaluated at \(p\).

EXAMPLES:

```python
sage: from sage.combinat.q_bernoulli import q_bernoulli
sage: q_bernoulli(0)
1
sage: q_bernoulli(1)
-1/(q + 1)
```

On one can evaluate the rational function by giving a second argument:

```python
sage: x = PolynomialRing(GF(2),'x').gen()
sage: q_bernoulli(5,x)
x/(x^6 + x^5 + x + 1)
```
The function does not accept negative arguments:

```python
sage: q_bernoulli(-1)
Traceback (most recent call last):
  ... ValueError: the argument must be a nonnegative integer
```

REFERENCES:
sage.combinat.q_bernoulli.q_bernoulli_polynomial()

Compute Carlitz's $q$-analogue of the Bernoulli polynomials.

For every nonnegative integer $m$, the $q$-Bernoulli polynomial is a polynomial in one variable $x$ with coefficients in $\mathbb{Q}(q)$ whose value at $q = 1$ is the usual Bernoulli polynomial $B_m(x)$.

The original $q$-Bernoulli polynomials introduced by Carlitz were polynomials in $q^y$ with coefficients in $\mathbb{Q}(q)$. This function returns these polynomials but expressed in the variable $x = (q^y - 1)/(q - 1)$. This allows to let $q = 1$ to recover the classical Bernoulli polynomials.

INPUT:

* $m$ – a nonnegative integer

OUTPUT:

A polynomial in one variable $x$.

EXAMPLES:

```python
sage: from sage.combinat.q_bernoulli import q_bernoulli_polynomial
sage: q_bernoulli_polynomial(0)
1
sage: q_bernoulli_polynomial(1)
(2/(q + 1))*x - 1/(q + 1)

sage: x = q_bernoulli_polynomial(1).parent().gen()
sage: all(q_bernoulli_polynomial(i)(q=1) == bernoulli_polynomial(x,i) # needs sage.libs.flint
    ....:     for i in range(12))
True
sage: all(q_bernoulli_polynomial(i)(x=0) == q_bernoulli(i)
    ....:     for i in range(12))
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.q_bernoulli import q_bernoulli_polynomial, q_bernoulli

sage: q_bernoulli_polynomial(0)
1
sage: q_bernoulli_polynomial(1)
```

(continues on next page)
\[(2/(q + 1)) \cdot x - 1/(q + 1)\]

```python
>>> x = q_bernoulli_polynomial(Integer(1)).parent().gen()
>>> all(q_bernoulli_polynomial(i)(q=Integer(1)) == bernoulli_polynomial(x,i)
˓→ # needs sage.libs.flint
... for i in range(Integer(12)))
True

>>> all(q_bernoulli_polynomial(i)(x=Integer(0)) == q_bernoulli(i)
˓→ for i in range(Integer(12)))
True
```

The function does not accept negative arguments:

```python
sage: q_bernoulli_polynomial(-1)
Traceback (most recent call last):
... ValueError: the argument must be a nonnegative integer
```

```python
>>> from sage.all import *

>>> q_bernoulli_polynomial(-Integer(1))
Traceback (most recent call last):
... ValueError: the argument must be a nonnegative integer
```

5.1.190 Rankers

\text{sage.combinat.ranker.from_list}(l)

Returns a ranker from the list \(l\).

\text{INPUT:}

\begin{itemize}
    \item \text{l} – a list
\end{itemize}

\text{OUTPUT:}

\begin{itemize}
    \item \text{[rank, unrank]} – functions
\end{itemize}
EXAMPLES:

```python
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]
sage: r, u = ranker.from_list(l)
sage: r(1)
0
sage: r(3)
2
sage: u(2)
3
sage: u(0)
1
```

```python
>>> from sage.all import *
>>> import sage.combinat.ranker as ranker

>>> l = [Integer(1),Integer(2),Integer(3)]

>>> r, u = ranker.from_list(l)

>>> r(Integer(1))
0

>>> r(Integer(3))
2

>>> u(Integer(2))
3

>>> u(Integer(0))
1
```

`sage.combinat.ranker.on_fly()`

Returns a pair of enumeration functions rank / unrank.

rank assigns on the fly an integer, starting from 0, to any object passed as argument. The object should be hashable.

unrank is the inverse function; it returns None for indices that have not yet been assigned.

EXAMPLES:

```python
sage: [rank, unrank] = sage.combinat.ranker.on_fly()
sage: rank('a')
0
sage: rank('b')
1
sage: rank('c')
2
sage: rank('a')
0
sage: unrank(2)
'c'

sage: unrank(3)
'd'

sage: unrank(3)
'd'
```

```python
>>> from sage.all import *
```

```python
>>> [rank, unrank] = sage.combinat.ranker.on_fly()

>>> rank('a')
0

>>> rank('b')
1
```

(continues on next page)
Todo: add tests as in combinat::rankers

sage.combinat.ranker.rank_from_list(l)
Return a rank function for the elements of l.

INPUT:

• l – a duplicate free list (or iterable) of hashable objects

OUTPUT:

• a function from the elements of l to 0, ..., len(l)

EXAMPLES:

>>> sage: import sage.combinat.ranker as ranker
given l = ['a', 'b', 'c']
given r = ranker.rank_from_list(l)
given r('a')
given 0
given r('c')
given 2

For non elements a ValueError is raised, as with the usual index method of lists:

sage: r('blah')
Traceback (most recent call last):
...
ValueError: 'blah' is not in dict

>>> from sage.all import *
>>> sage: import sage.combinat.ranker as ranker
>>> l = ['a', 'b', 'c']
>>> r = ranker.rank_from_list(l)
>>> r('a')
0
>>> r('c')
2
Currently, the rank function is a `CallableDict`; but this is an implementation detail:

```python
sage: type(r)
<class 'sage.misc.callable_dict.CallableDict'>
sage: r
{'a': 0, 'b': 1, 'c': 2}
```

```python
>>> from sage.all import *
>>> type(r)
<class 'sage.misc.callable_dict.CallableDict'>
```  
With the current implementation, no error is issued in case of duplicate value in `l`. Instead, the rank function returns the position of some of the duplicates:

```python
sage: r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
sage: r('a')
2
```

```python
>>> from sage.all import *
>>> r = ranker.rank_from_list(['a', 'b', 'a', 'c'])
>>> r('a')
2
```

Constructing the rank function itself is of complexity $O(|l|)$. Then, each call to the rank function consists of an essentially constant time dictionary lookup.

```
sage.combinat.ranker.unrank(L, i)
```

Return the $i$-th element of $L$.

**INPUT:**

- $L$ – a list, tuple, finite enumerated set, ...
- $i$ – an int or `Integer`

The purpose of this utility is to give a uniform idiom to recover the $i$-th element of an object $L$, whether $L$ is a list, tuple (or more generally a `collections.abc.Sequence`), an enumerated set, some old parent of Sage still implementing unranking in the method `__getitem__`, or an iterable (see `collections.abc.Iterable`). See Issue #15919.

**EXAMPLES:**

Lists, tuples, and other sequences:

```python
sage: from sage.combinat.ranker import unrank
sage: unrank(['a','b','c'], 2)
'c'
sage: unrank(['a','b','c'], 1)
'b'
sage: unrank(range(3,13,2), 1)
5
```

```python
>>> from sage.all import *
>>> from sage.combinat.ranker import unrank
>>> unrank(['a','b','c'], Integer(2))
'c'
```  
(continues on next page)
>>> unrank(('a', 'b', 'c'), Integer(1))
'b'
>>> unrank(range(Integer(3), Integer(13), Integer(2)), Integer(1))
5

Enumerated sets:

sage: unrank(GF(7), 2)
2
sage: unrank(IntegerModRing(29), 10)
10

>>> from sage.all import *

>>> unrank(GF(Integer(7)), Integer(2))
2

>>> unrank(IntegerModRing(Integer(29)), Integer(10))
10

An iterable:

sage: unrank(NN, 4)
4

>>> from sage.all import *

>>> unrank(NN, Integer(4))
4

An iterator:

sage: unrank(('a{}'.format(i) for i in range(20)), 0)
'a0'
sage: unrank(('a{}'.format(i) for i in range(20)), 2)
'a2'

>>> from sage.all import *

>>> unrank(('a{}'.format(i) for i in range(Integer(20))), Integer(0))
'a0'

>>> unrank(('a{}'.format(i) for i in range(Integer(20))), Integer(2))
'a2'

**Warning:** When unranking an iterator, it returns the \textit{i}-th element beyond where it is currently at:

sage: from sage.combinat.ranker import unrank
sage: it = iter(range(20))
sage: unrank(it, 2)
2
sage: unrank(it, 2)
5

>>> from sage.all import *

>>> from sage.combinat.ranker import unrank
>>> it = iter(range(Integer(20)))
>>> unrank(it, Integer(2))
2

>>> unrank(it, Integer(2))
5
sage.combinat.ranker.unrank_from_list(l)

Returns an unrank function from a list.

EXAMPLES:

```python
sage: import sage.combinat.ranker as ranker
sage: l = [1,2,3]

sage: u = ranker.unrank_from_list(l)
sage: u(2)
3
sage: u(0)
1
```

```python
>>> from sage.all import *
>>> import sage.combinat.ranker as ranker

>>> l = [Integer(1),Integer(2),Integer(3)]

>>> u = ranker.unrank_from_list(l)

>>> u(Integer(2))
3

>>> u(Integer(0))
1
```

### 5.1.191 Recognizable Series

Let $A$ be an alphabet and $K$ a semiring. Then a formal series $S$ with coefficients in $K$ and indices in the words $A^*$ is called recognizable if it has a linear representation, i.e., there exists

- a nonnegative integer $n$

and there exist

- two vectors $\text{left}$ and $\text{right}$ of dimension $n$ and

- a morphism of monoids $\mu$ from $A^*$ to $n \times n$ matrices over $K$

such that the coefficient corresponding to a word $w \in A^*$ equals

$$\text{left} \ \mu(w) \ \text{right}.$$  

**Note:** Whenever a minimization ($\text{minimized()}$) of a series needs to be computed, it is required that $K$ is a field. In particular, minimization is called before checking if a series is nonzero.
Classes and Methods

```python
class sage.combinat.recognizable_series.PrefixClosedSet(words)
    Bases: object
    A prefix-closed set.
    Creation of this prefix-closed set is interactive iteratively.
    INPUT:
    • words – a class of words (instance of Words)
    EXAMPLES:

    sage: from sage.combinat.recognizable_series import PrefixClosedSet
    sage: P = PrefixClosedSet(Words([0, 1], infinite=False)); P
    [word: ]
    sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
    [word: ]

    >>> from sage.all import *
    >>> from sage.combinat.recognizable_series import PrefixClosedSet
    >>> P = PrefixClosedSet(Words([Integer(0), Integer(1)], infinite=False)); P
    [word: ]
    >>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]); P
    [word: ]

    See iterate_possible_additions() for further examples.
    ```

add(w, check=True)
    Add a word to this prefix-closed set.
    INPUT:
    • w – a word
    • check – boolean (default: True). If set, then it is verified whether all proper prefixes of w are already in this prefix-closed set.
    OUTPUT:
    Nothing, but a RuntimeError is raised if the check fails.
    EXAMPLES:
Combinatorics, Release 10.4

```python
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1])
sage: W = P.words
sage: P.add(W([0])); P
[word: , word: 0]
sage: P.add(W([0, 1])); P
[word: , word: 0, word: 01]
sage: P.add(W([1, 1]))
Traceback (most recent call last):
  ... ValueError: cannot add as not all prefixes of 11 are included yet
```
print('{}' .format(p))
if n in (0, 2, 3, 5):
    P.add(p)
    print('...added')

from sage.all import *
from sage.combinat.recognizable_series import PrefixClosedSet
P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]);

for n, p in enumerate(P.iterate_possible_additions()):
    print('{}' .format(p))
    if n in (Integer(0), Integer(2), Integer(3), Integer(5)):
        P.add(p)
        print('...added')

sage: P.elements
[word: , word: 0, word: 00, word: 01, word: 001]

Calling the iterator once more, returns all elements:

sage: list(P.iterate_possible_additions())
[word: 0, word: 1, word: 00, word: 01, word: 000, word: 001, ...]
word: 010,
word: 011,
word: 0010,
word: 0011]

```python
>>> from sage.all import *

```

```python
>>>
list(P.iterate_possible_additions())
[word: 0,
word: 1,
word: 00,
word: 01,
word: 000,
word: 001,
word: 010,
word: 011,
word: 0010,
word: 0011]
```

The method `iterate_possible_additions()` is roughly equivalent to

```python
sage: list(p + a
.....:   for p in P.elements
.....:   for a in P.words.iterate_by_length(1))
[word: 0,
word: 1,
word: 00,
word: 01,
word: 000,
word: 001,
word: 010,
word: 011,
word: 0010,
word: 0011]
```

```python
>>> from sage.all import *

```

```python
>>>
list(p + a
... for p in P.elements
... for a in P.words.iterate_by_length(Integer(1)))
[word: 0,
word: 1,
word: 00,
word: 01,
word: 000,
word: 001,
word: 010,
word: 011,
word: 0010,
word: 0011]
```

```python
>>> from sage.all import *

```

```python
>>>
list(p + a
... for p in P.elements
... for a in P.words.iterate_by_length(Integer(1)))
[word: 0,
word: 1,
word: 00,
word: 01,
word: 000,
word: 001,
word: 010,
word: 011,
word: 0010,
word: 0011]
```

However, the above does not allow to add elements during iteration, whereas `iterate_possible_additions()` does.

`prefix_set()`

Return the set of minimal (with respect to prefix ordering) elements of the complement of this prefix closed set.

See also Proposition 2.3.1 of [BR2010a].
OUTPUT:

A list

EXAMPLES:

```python
sage: from sage.combinat.recognizable_series import PrefixClosedSet
sage: P = PrefixClosedSet.create_by_alphabet([0, 1]); P
[...]
sage: for n, p in enumerate(P.iterate_possible_additions()):
    if n in (0, 1, 2, 4, 6):
        P.add(p)
sage: P
[...]
```

```python
>>> from sage.all import *
>>> from sage.combinat.recognizable_series import PrefixClosedSet
>>> P = PrefixClosedSet.create_by_alphabet([Integer(0), Integer(1)]); P
[...]
```

```python
class sage.combinat.recognizable_series.RecognizableSeries (parent, mu, left, right)
Bases: ModuleElement

A recognizable series.

- **parent** – an instance of RecognizableSeriesSpace
- **mu** – a family of square matrices, all of which have the same dimension. The indices of this family are the elements of the alphabet. mu may be a list or tuple of the same cardinality as the alphabet as well. See also **mu**.
- **left** – a vector. When evaluating a coefficient, this vector is multiplied from the left to the matrix obtained from **mu** applying on a word. See also **left**.
- **right** – a vector. When evaluating a coefficient, this vector is multiplied from the right to the matrix obtained from **mu** applying on a word. See also **right**.

When created via the parent RecognizableSeriesSpace, then the following option is available.

EXAMPLES:

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
     ...:    vector([0, 1]), vector([1, 0])).transposed(); S
[1] + 3*[01] + [10] + 5*[11] + 9*[001] + 3*[010] + ...
```

```python
>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> S = Rec((Matrix([[Integer(3), Integer(6)], [Integer(0), Integer(1)]])),
```

(continues on next page)
We can access coefficients by

```python
sage: W = Rec.indices()
sage: S[W([0, 0, 1])]
```

See also:

- recognizable series, RecognizableSeriesSpace.

**coefficient_of_word** *(w, multiply_left=True, multiply_right=True)*

Return the coefficient to word *w* of this series.

**INPUT:**

- *w* – a word over the parent’s `alphabet()`
- `multiply_left` – (default: `True`) a boolean. If `False`, then multiplication by *left* is skipped.
- `multiply_right` – (default: `True`) a boolean. If `False`, then multiplication by *right* is skipped.

**OUTPUT:**

An element in the parent’s `coefficient_ring()`

**EXAMPLES:**

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: W = Rec.indices()
sage: S = Rec((Matrix([[1, 0], [0, 1]]), Matrix([[0, -1], [1, 2]])),
....:    left=vector([0, 1]), right=vector([1, 0]))
sage: S[W(7.digits(2))] # indirect doctest
```

```python
>>> from sage.all import *
```  

```python
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
```  

```python
>>> W = Rec.indices()
```  

```python
>>> S = Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),
....:    left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),
....:    Integer(0)]))
```  

```python
>>> S[W(Integer(7).digits(Integer(2)))] # indirect doctest
```

dimension()

Return the dimension of this recognizable series.

**EXAMPLES:**
Combinatorics, Release 10.4

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
....: left=vector([0, 1]), right=vector([1, 0])).dimension()
2

>>> from sage.all import *
>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]],
....: Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),
....: left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),
....: Integer(0)]))).dimension()
2

hadamard_product(*args, **kwds)

Return the Hadamard product of this recognizable series and the other recognizable series, i.e., multiply the two series coefficient-wise.

**INPUT:**

- other - a RecognizableSeries with the same parent as this recognizable series
- minimize - (default: None) a boolean or None. If True, then minimized() is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s minimize_results is used.

**OUTPUT:**

A RecognizableSeries

**EXAMPLES:**

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
....: vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

sage: O = Seq2((Matrix([[0, 0], [0, 1]]), Matrix([[0, 1], [0, 1]])),
....: vector([1, 0]), vector([0, 1]))
sage: O
2-regular sequence 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, ...

sage: C = Seq2((Matrix([[2, 0], [0, 1]]), Matrix([[0, 1], [-2, 3]])),
....: vector([1, 0]), vector([0, 1]))
sage: C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)

```
>>> O = Seq2((Matrix([[Integer(0), Integer(0)], [Integer(0), Integer(1)]]),
    Matrix([[Integer(0), Integer(1)], [Integer(0), Integer(1)]])),
    vector([Integer(1), Integer(0)]), vector([Integer(0),
    Integer(1)]))
>>> O
2-regular sequence 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, ...

>>> C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(2), Integer(1)]]),
    Matrix([[Integer(0), Integer(1)], [-Integer(2), Integer(3)]])),
    vector([Integer(1), Integer(0)]), vector([Integer(0),
    Integer(1)]))
>>> C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

sage: CE = C.hadamard_product(E)
sage: CE
2-regular sequence 0, 0, 2, 0, 4, 0, 6, 0, 8, 0, ...

sage: CE.linear_representation()
((1, 0, 0),
 Finite family {0: [0 1 0]
 [0 2 0]
 [0 2 1],
 1: [ 0 0 0]
 [ 0 0 1]
 [ 0 -2 3]},
 (0, 0, 2))

sage: Z = E.hadamard_product(O)
sage: Z
2-regular sequence 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, ...

sage: Z.linear_representation()
(()
 Finite family {0: []},
 1: []),
())

>>> from sage.all import *

sage: CE = C.hadamard_product(E)

sage: CE
2-regular sequence 0, 0, 2, 0, 4, 0, 6, 0, 8, 0, ...

sage: CE.linear_representation()
((1, 0, 0),
 Finite family {0: [0 1 0]
 [0 2 0]
 [0 2 1],
 1: [ 0 0 0]
 [ 0 0 1]
 [ 0 -2 3]},
 (0, 0, 2))

sage: Z = E.hadamard_product(O)

sage: Z
2-regular sequence 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, ...

sage: Z.linear_representation()
(()
 Finite family {0: []},
 1: []),
())

(continues on next page)
is_trivial_zero()

Return whether this recognizable series is trivially equal to zero (without any minimization).

EXAMPLES:

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])

sage: Rec((Matrix([[0, 1], [0, 0]]), Matrix([[1, 0], [0, 1]])),
      ....: left=vector([0, 1]), right=vector([1, 0])).is_trivial_zero()
False

sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
      ....: left=vector([0, 0]), right=vector([1, 0])).is_trivial_zero()
True

sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [0, 1]])),
      ....: left=vector([0, 1]), right=vector([0, 0])).is_trivial_zero()
True
```

The following two differ in the coefficient of the empty word:

```python
sage: Rec((Matrix([[0, 0], [0, 0]]), Matrix([[0, 0], [0, 0]])),
      ....: left=vector([0, 1]), right=vector([1, 0])).is_trivial_zero()
False

sage: Rec((Matrix([[0, 0], [0, 0]]), Matrix([[0, 0], [0, 0]])),
      ....: left=vector([1, 1]), right=vector([1, 0])).is_trivial_zero()
True
```
property left

When evaluating a coefficient, this vector is multiplied from the left to the matrix obtained from \( \mu \) applied on a word.

linear_representation()

Return the linear representation of this series.

OUTPUT:

A triple \((\text{left}, \mu, \text{right})\) containing the vectors \text{left} and \text{right}, and the family of matrices \( \mu \).

EXAMPLES:

```sage
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]]), ....:     vector([0, 1]), vector([1, 0]) ....: ).transposed().linear_representation()
((1, 0),
 Finite family {0: [3 0]
[6 1],
 1: [ 0 1]
[-6 5]},
(0, 1))
```

minimized()

Return a recognizable series equivalent to this series, but with a minimized linear representation.

The coefficients of the involved matrices need be in a field. If this is not the case, then the coefficients are automatically coerced to their fraction field.

OUTPUT:

A \text{RecognizableSeries}

ALGORITHM:

This method implements the minimization algorithm presented in Chapter 2 of [BR2010a].

**Note:** Due to the algorithm, the left vector of the result is always \((1, 0, \ldots, 0)\), i.e., the first vector of the standard basis.

EXAMPLES:
```python
sage: from itertools import islice
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])

sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
          ..., vector([0, 1]), vector([1, 0])).transposed()

sage: S
    + 15*[011] + [100] + 11*[101] + 5*[110] + ...

sage: M = S.minimized()

sage: M.mu[0], M.mu[1], M.left, M.right
([3 0]
 [6 1], [-6 5], (1, 0), (0, 1))

sage: all(c == d and v == w
....:   for (c, v), (d, w) in islice(zip(iter(S), iter(M)), 20))
True

sage: S = Rec((Matrix([[2, 0], [1, 1]]),
            ..., vector([1, 0]), vector([1, 0])))

sage: S
[] + 2*[0] + 2*[1] + 4*[00] + 4*[01] + 4*[10] + 4*[11]
    + 8*[000] + 8*[001] + 8*[010] + ...

sage: M = S.minimized()

sage: M.mu[0], M.mu[1], M.left, M.right
([2], [2], (1), (1))

sage: all(c == d and v == w
....:   for (c, v), (d, w) in islice(zip(iter(S), iter(M)), 20))
True
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
... vector([Integer(1), Integer(0)]), vector([Integer(1),
    Integer(1)]))
>>> S
  + 8*[000] + 8*[001] + 8*[010] + ...
>>> M = S.minimized()
>>> M.mu[Integer(0)], M.mu[Integer(1)], M.left, M.right
([2], [2], (1), (1))
>>> all(c == d and v == w
... for (c, v), (d, w) in islice(zip(iter(S), iter(M)), Integer(20)))
True
```

property **mu**

When evaluating a coefficient, this is applied on each letter of a word; the result is a matrix. This extends **mu** to words over the parent’s alphabet().

property **right**

When evaluating a coefficient, this vector is multiplied from the right to the matrix obtained from **mu** applied on a word.

**transposed()**

Return the transposed series.

**OUTPUT:**

A RecognizableSeries

Each of the matrices in **mu** is transposed. Additionally the vectors left and right are switched.

**EXAMPLES:**

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: S = Rec((Matrix([[3, 6], [0, 1]]), Matrix([[0, -6], [1, 5]])),
    ....: vector([0, 1]), vector([1, 0])).transposed()
sage: S
  + 15*[011] + [100] + 11*[101] + 5*[110] + ...
sage: S.mu[0], S.mu[1], S.left, S.right
([3 0] [ 0 1]
[6 1], [-6 5], (1, 0), (0, 1))
sage: T = S.transposed()
sage: T
[1] + [01] + 3*[10] + 5*[11] + [001] + 3*[010]
  + 5*[011] + 9*[100] + 11*[101] + 15*[110] + ...
sage: T.mu[0], T.mu[1], T.left, T.right
([3 6] [ 0 -6]
[0 1], [ 1 5], (0, 1), (1, 0))
```

```python
>>> from sage.all import *

>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> S = Rec((Matrix([[Integer(3), Integer(6)],
    ... [Integer(0), Integer(1)]]),
    ... vector([Integer(0), Integer(1)]), vector([Integer(1)]))
```

(continues on next page)

The space of recognizable series on the given alphabet and with the given coefficients.

INPUT:

- coefficient_ring – a (semi-)ring
- alphabet – a tuple, list or TotallyOrderedFiniteSet. If specified, then the indices are the finite words over this alphabet. alphabet and indices cannot be specified at the same time.
- indices – a SageMath-parent of finite words over an alphabet. alphabet and indices cannot be specified at the same time.
- category – (default: None) the category of this space

EXAMPLES:

We create a recognizable series that counts the number of ones in each word:

```
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec
Space of recognizable series on {0, 1} with coefficients in Integer Ring
```

```
sage: Rec((Matrix([[1, 0], [0, 1]]), Matrix([[1, 1], [0, 1]])),
      vector([1, 0]), vector([0, 1]))
[1] + [01] + [10] + 2*[11] + [001] + [010] + 2*[011] + [100] + 2*[101] + 2*[110]
˓→ ...
```

```python
>>> from sage.all import *

>>> Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
>>> Rec
Space of recognizable series on {0, 1} with coefficients in Integer Ring
```

```
>>> Rec((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),
          vector([Integer(1), Integer(1)]),
          vector([Integer(0), Integer(1)])))
[1] + [01] + [10] + 2*[11] + [001] + [010] + 2*[011] + [100] + 2*[101] + 2*[110]
˓→ ...
```
All of the following examples create the same space:

```python
sage: Rec1 = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec1
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec2 = RecognizableSeriesSpace(coefficient_ring=ZZ, alphabet=[0, 1])
sage: Rec2
Space of recognizable series on {0, 1} with coefficients in Integer Ring
sage: Rec3 = RecognizableSeriesSpace(ZZ, indices=Words([0, 1], infinite=False))
sage: Rec3
Space of recognizable series on {0, 1} with coefficients in Integer Ring
```

See also:

recognizable series, RecognizableSeries.

Element

alias of RecognizableSeries

alphabet()

Return the alphabet of this recognizable series space.

OUTPUT:

A totally ordered set

EXAMPLES:

```python
sage: RecognizableSeriesSpace(ZZ, [0, 1]).alphabet()
{0, 1}
```

coefficient_ring()

Return the coefficients of this recognizable series space.

OUTPUT:

A (semi-)ring

EXAMPLES:

```python
sage: RecognizableSeriesSpace(ZZ, [0, 1]).coefficient_ring()
Integer Ring
```
indices()

Return the indices of the recognizable series.

OUTPUT:
The set of finite words over the alphabet

EXAMPLES:

```python
sage: RecognizableSeriesSpace(ZZ, [0, 1]).indices()
Finite words over {0, 1}
```

**property minimize_results**

A boolean indicating whether `RecognizableSeries.minimized()` is automatically called after performing operations.

one()

Return the one element of this `RecognizableSeriesSpace`, i.e. the embedding of the one of the coefficient ring into this `RecognizableSeriesSpace`.

EXAMPLES:

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: O = Rec.one(); O
[] + ...
sage: O.linear_representation()
(((1), Finite family {0: [0], 1: [0]}), (1))
```

one_hadamard()

Return the identity with respect to the `hadamard_product()`, i.e. the coefficient-wise multiplication.

OUTPUT:
A `RecognizableSeries`

EXAMPLES:

```python
sage: Rec = RecognizableSeriesSpace(ZZ, [0, 1])
sage: Rec.one_hadamard()
[] + [0] + [1] + [00] + [01] + [10] + [11] + [000] + [001] + [010] + ...
```
```python
>>> from sage.all import *

Rec = RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)])
Rec.one_hadamard()

[] + [0] + [1] + [00] + [01] + [01] + [00]
+ [11] + [000] + [001] + [010] + ...

some_elements(**kwds)

Return some elements of this recognizable series space.

See TestSuite for a typical use case.

INPUT:

• kwds are passed on to the element constructor

OUTPUT:

An iterator

EXAMPLES:

sage: tuple(RecognizableSeriesSpace(ZZ, [0, 1]).some_elements())
(([1] + [01] + [10] + 2*[11] + [001] + [010]
  + 2*[011] + [100] + 2*[101] + 2*[110] + ...,
 [ ] + [1] + [11] + [111] + [1111] + [11111] + [111111] + ...,
 [ ] + [0] + [1] + [00] + [10] + [11]
  + [000] - 1*[001] + [100] + [110] + ...,
 2*[1] - 1*[1] + 2*[10] - 1*[101]
  + 2*[1010] - 1*[10101] + 2*[101010] + ...,
 [ ] + [1] + 6*[00] + [11] - 39*[000] + 5*[001] + 6*[100] + [111]
  + 288*[0000] - 33*[0001] + ...,
 210*[1] + ..., ...,
 2210*[1] - 170*[0] + 170*[1] + ...),
```

```
>>> from sage.all import *

>>>

tuple(RecognizableSeriesSpace(ZZ, [Integer(0), Integer(1)]).some_elements())
(([1] + [01] + [10] + 2*[11] + [001] + [010]
  + 2*[011] + [100] + 2*[101] + 2*[110] + ...,
 [ ] + [1] + [11] + [111] + [1111] + [11111] + [111111] + ...,
 [ ] + [0] + [1] + [00] + [10] + [11]
  + [000] - 1*[001] + [100] + [110] + ...,
 2*[1] - 1*[1] + 2*[10] - 1*[101]
  + 2*[1010] - 1*[10101] + 2*[101010] + ...,
 [ ] + [1] + 6*[00] + [11] - 39*[000] + 5*[001] + 6*[100] + [111]
  + 288*[0000] - 33*[0001] + ...,
 210*[1] + ..., ...,
 2210*[1] - 170*[0] + 170*[1] + ...))
```

sage.combinat.recognizable_series.minimize_result(operation)

A decorator for operations that enables control of automatic minimization on the result.

INPUT:

• operation—a method
A method with the following additional argument:

- `minimize` *(default: None)* a boolean or `None`. If `True`, then `minimized()` is called after the operation, if `False`, then not. If this argument is `None`, then the default specified by the parent’s `minimize_results` is used.

**Note:** If the result of operation is `self`, then minimization is not applied unless `minimize=True` is explicitly set, in particular, independent of the parent’s `minimize_results`.

### 5.1.192 $k$-regular sequences

An introduction and formal definition of $k$-regular sequences can be found, for example, on the Wikipedia article [k-regular_sequence](https://en.wikipedia.org/wiki/k-regular_sequence) or in [AS2003].

```python
sage: import logging
```

```python
>>> from sage.all import *
>>> import logging
>>> logging.basicConfig()
```

**Examples**

#### Binary sum of digits

The binary sum of digits $S(n)$ of a nonnegative integer $n$ satisfies $S(2n) = S(n)$ and $S(2n+1) = S(n)+1$. We model this by the following:

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: S = Seq2((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [1, 1]])),
...     left=vector([0, 1]), right=vector([1, 0]))
sage: S
2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...
sage: all(S[n] == sum(n.digits(2)) for n in srange(10))
True
```

```python
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> S = Seq2((Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]],
...     left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),
...     Integer(0)])))
>>> S
2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...
>>> all(S[n] == sum(n.digits(Integer(2))) for n in srange(Integer(10)))
True
```
Number of odd entries in Pascal’s triangle

Let us consider the number of odd entries in the first $n$ rows of Pascal's triangle:

```python
sage: @cached_function
....: def u(n):
....:     if n <= 1:
....:         return n
....:     return 2 * u(n // 2) + u((n+1) // 2)
sage: tuple(u(n) for n in srange(10))
(0, 1, 3, 5, 9, 11, 15, 19, 27, 29)
```

There is a 2-regular sequence describing the numbers above as well:

```python
>>> from sage.all import *

>>> @cached_function
... def u(n):
...     if n <= Integer(1):
...         return n
...     return Integer(2) * u(n // Integer(2)) + u((n+Integer(1)) // Integer(2))

>>> tuple(u(n) for n in srange(Integer(10)))
(0, 1, 3, 5, 9, 11, 15, 19, 27, 29)
```

Classes and Methods

**exception** sage.combinat.regular_sequence.DegeneratedSequenceError

Bases: RuntimeError

Exception raised if a degenerated sequence (see `is_degenerated()`) is detected.

**EXAMPLES:**

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: Seq2((Matrix([2]), Matrix([3])), vector([1]), vector([1]))
Traceback (most recent call last):
  ...  
DegeneratedSequenceError: degenerated sequence: mu[0]*right != right.
Using such a sequence might lead to wrong results.
You can use 'allow_degenerated_sequence=True' followed
by a call of method .regenerated() for correcting this.
```

```python
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> Seq2((Matrix([Integer(2)]), Matrix([Integer(3)])), vector([Integer(1)]), vector([Integer(1)]))
Traceback (most recent call last):
  ...  
DegeneratedSequenceError: degenerated sequence: mu[0]*right != right.
Using such a sequence might lead to wrong results.
You can use 'allow_degenerated_sequence=True' followed
by a call of method .regenerated() for correcting this.
```

class sage.combinat.regular_sequence.RecurrenceParser(k, coefficient_ring)

Bases: object

A parser for recurrence relations that allow the construction of a $k$-linear representation for the sequence satisfying these recurrence relations.

This is used by `RegularSequenceRing.from_recurrence()` to construct a `RegularSequence`.

**ind** ($M, m, ll, uu$)

Determine the index operator corresponding to the recursive sequence as defined in [HKL2022].

**INPUT:**

- $M, m$ – parameters of the recursive sequences, see [HKL2022], Definition 3.1
- $ll, uu$ – parameters of the resulting linear representation, see [HKL2022], Theorem A

**OUTPUT:**

A dictionary which maps both row numbers to subsequence parameters and vice versa, i.e.,

- $\text{ind}[i]$ – a pair $(j, d)$ representing the sequence $x(k^j n + d)$ in the $i$-th component (0-based) of the resulting linear representation,
- $\text{ind}[(j, d)]$ – the (0-based) row number of the sequence $x(k^j n + d)$ in the linear representation.

**EXAMPLES:**

```python
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: RP.ind(3, 1, -3, 3)
{(0, 0): 0, (1, -1): 3, (1, -2): 2, (1, -3): 1,
(continues on next page)
See also:

RegularSequenceRing.from_recurrence()

left (recurrence_rules)

Construct the vector left of the linear representation of recursive sequences.

INPUT:

• recurrence_rules – a namedtuple generated by parameters(); it only needs to contain a field dim (a positive integer)

OUTPUT: a vector

EXAMPLES:

```python
sage: from collections import namedtuple
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)

sage: recurrence_rules = {'dim': 5, 'inhomogeneities': {}}

sage: RP.left(recurrence_rules)
(1, 0, 0, 0, 0)
```

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)

sage: recurrence_rules = {'M': 'M', 'm': 'm', 'll': 'll', 'uu': 'uu', 'dim': 'dim', 'inhomogeneities': 'inhomogeneities'}

sage: RP.left(recurrence_rules)
(1, 0, 0, 0, 0)
```
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: recurrence_rules = RRD(M=Integer(3), m=Integer(2), ll=Integer(0),
                        uu=Integer(9), dim=Integer(5),
                        inhomogeneities={Integer(0): Seq2.one_hadamard()})
sage: RP.left(recurrence_rules)
(1, 0, 0, 0, 0, 0, 0, 0)
```

```python
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> RRD = namedtuple('recurrence_rules_dim',
                   ['M', 'm', 'll', 'uu', 'dim', 'inhomogeneities'])
>>> recurrence_rules = RRD(M=Integer(3), m=Integer(2), ll=Integer(0),
                          uu=Integer(9), dim=Integer(5),
                          inhomogeneities={Integer(0): Seq2.one_hadamard()})
>>> RP.left(recurrence_rules)
(1, 0, 0, 0, 0, 0, 0, 0)
```

See also:

`RegularSequenceRing.from_recurrence()`

**matrix** *(recurrence_rules, rem, correct_offset=True)*

Construct the matrix for remainder `rem` of the linear representation of the sequence represented by `recurrence_rules`.

**INPUT:**

- `recurrence_rules` – a named tuple generated by `parameters()`
- `rem` – an integer between 0 and `k - 1`
- `correct_offset` – (default: True) a boolean. If True, then the resulting linear representation has no offset. See [HKL2022] for more information.

**OUTPUT:** a matrix

**EXAMPLES:**

The following example illustrates how the coefficients in the right-hand sides of the recurrence relations correspond to the entries of the matrices.

```python
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: var('n')
n
sage: function('f')
f

`RegularSequenceRing.from_recurrence()`

**parameters** `(M, m, coeffs, initial_values, offset=0, inhomogeneities={})`

Determine parameters from recurrence relations as admissible in `RegularSequenceRing.from_recurrence()`.

**INPUT:**

All parameters are explained in the high-level method `RegularSequenceRing.from_recurrence()`.

**OUTPUT:** a namedtuple `recurrence_rules` consisting of

- `M, m, l, u, offset` — parameters of the recursive sequences, see [HKL2022], Definition 3.1
- `ll, uu, n1, dim` — parameters and dimension of the resulting linear representation, see [HKL2022], Theorem A
- `coeffs` — a dictionary mapping `(r, j)` to the coefficients $c_{r,j}$, as given in [HKL2022], Equation (3.1). If `coeffs[{(r, j)]` is not given for some `r` and `j`, then it is assumed to be zero.
- `initial_values` — a dictionary mapping integers `n` to the `n`-th value of the sequence
- `inhomogeneities` — a dictionary mapping integers `r` to the inhomogeneity $g_r$ as given in [HKL2022], Corollary D.
EXAMPLES:

```python
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: RP.parameters(2, 1,
....: (0, -2): 3, (0, 0): 1, (0, 1): 2, (1, -2): 6, (1, 0): 4,
....: (1, 1): 5, (2, -2): 9, (2, 0): 7, (2, 1): 8, (3, -2): 12,
....: (3, 0): 10, (3, 1): 11, (0: 1, 1: 2, 2: 1, 3: 4), 0, {0: 1})
recurrence_rules(M=2, m=1, l=-2, u=1, ll=-6, uu=3, dim=14,
coeffs={(0, -2): 3, (0, 0): 1, (0, 1): 2, (1, -2): 6, (1, 0): 4,
(1, 1): 5, (2, -2): 9, (2, 0): 7, (2, 1): 8, (3, -2): 12,
(3, 0): 10, (3, 1): 11}, initial_values={0: 1, 1: 2, 2: 1, 3: 4,

RegularSequenceRing.from_recurrence()

parse_direct_arguments \( (M, m, \text{coeffs, initial\_values}) \)

Check whether the direct arguments as admissible in RegularSequenceRing.

from\_recurrence() are valid.

INPUT:

All parameters are explained in the high-level method RegularSequenceRing.

from\_recurrence().

OUTPUT: a tuple consisting of the input parameters

EXAMPLES:

```python
>>> from sage.all import *
>>> from sage.combinat.regular_sequence import RecurrenceParser
>>> RP = RecurrenceParser(Integer(2), ZZ)
>>> RP.parameters(Integer(2), Integer(1),

```

See also:

`RegularSequenceRing.from_recurrence()`

`parse_recurrence(equations, function, var)`

Parse recurrence relations as admissible in `RegularSequenceRing.from_recurrence()`.

INPUT:

All parameters are explained in the high-level method `RegularSequenceRing.from_recurrence()`.

OUTPUT: a tuple consisting of
• \( M, m \) – see `RegularSequenceRing.from_recurrence()`

• `coeffs` – see `RegularSequenceRing.from_recurrence()`

• `initial_values` – see `RegularSequenceRing.from_recurrence()`

EXAMPLES:

```python
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
```

```python
sage: var('n')
```

```python
sage: function(f)
```

```python
sage: RP.parse_recurrence([  
...:     f(4*n) == f(2*n) + 2*f(2*n + 1) + 3*f(2*n - 2),  
...:     f(4*n + 1) == 4*f(2*n) + 5*f(2*n + 1) + 6*f(2*n - 2),  
...:     f(4*n + 2) == 7*f(2*n) + 8*f(2*n + 1) + 9*f(2*n - 2),  
...:     f(4*n + 3) == 10*f(2*n) + 11*f(2*n + 1) + 12*f(2*n - 2),  
...:     f(0) == 1, f(1) == 2, f(2) == 1, f(n)
...                 ], f, n)
```

```python
(2, 1, {(0, -2): 3, (0, 0): 1, (0, 1): 2, (1, -2): 6, (1, 0): 4,  
(1, 1): 5, (2, -2): 9, (2, 0): 7, (2, 1): 8, (3, -2): 12, (3, 0): 10,  
(3, 1): 11}, {0: 1, 1: 2, 2: 1})
```

Stern–Brocot Sequence:

```python
sage: RP.parse_recurrence([  
...:     f(2*n) == f(n), f(2*n + 1) == f(n) + f(n + 1),  
...:     f(0) == 0, f(1) == 1, f(n)
...                 ], f, n)
```

```python
(1, 0, {(0, 0): 1, (1, 0): 1, (1, 1): 1}, {0: 0, 1: 1})
```

Stern–Brocot Sequence:

```python
sage: RP.parse_recurrence([

... f(Integer(0)) == Integer(0), f(Integer(1)) == Integer(1)), f, n)
(1, 0, {(0, 0): 1, (1, 0): 1, (1, 1): 1}, {0: 0, 1: 1})

See also:

RegularSequenceRing.from_recurrence()

right(recurrence_rules)

Construct the vector right of the linear representation of the sequence induced by recurrence_rules.

INPUT:

- recurrence_rules – a namedtuple generated by parameters()

OUTPUT: a vector

See also:

RegularSequenceRing.from_recurrence()

shifted_inhomogeneities(recurrence_rules)

Return a dictionary of all needed shifted inhomogeneities as described in the proof of Corollary D in [HKL2022].

INPUT:

- recurrence_rules – a namedtuple generated by parameters()

OUTPUT:

A dictionary mapping $r$ to the regular sequence $\sum_{i} g_r(n + i)$ for $g_r$ as given in [HKL2022], Corollary D, and $i$ between $\lceil \ell' / k^M \rceil$ and $\lceil (k^M - k^m + u') / k^M \rceil + 1$; see [HKL2022], proof of Corollary D. The first blocks of the corresponding vector-valued sequence (obtained from its linear representation) correspond to the sequences $g_r(n + i)$ where $i$ is as in the sum above; the remaining blocks consist of other shifts which are required for the regular sequence.

EXAMPLES:

```python
sage: from collections import namedtuple
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: Seq2 = RegularSequenceRing(2, ZZ)

sage: S = Seq2((Matrix([[1, 0], [0, 1]]), Matrix([[1, 0], [1, 1]])),
  left=vector([0, 1]), right=vector([1, 0]))

sage: S
2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...

sage: RR = namedtuple(recurrence_rules, 
  ['M', 'm', 'll', 'uu', 'inhomogeneities'])

sage: recurrence_rules = RR(M=3, m=0, ll=-14, uu=14,
  inhomogeneities={0: S, 1: S})

sage: SI = RP.shifted_inhomogeneities(recurrence_rules)

sage: SI
{0: 2-regular sequence 4, 5, 7, 9, 11, 11, 11, 12, 13, 13, ...,
  1: 2-regular sequence 4, 5, 7, 9, 11, 11, 12, 13, 13, ...}
```

```bash
>>> from sage.all import *
>>> from collections import namedtuple
>>> from sage.combinat.regular_sequence import RecurrenceParser
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> RP = RecurrenceParser(Integer(2), ZZ)
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> S = Seq2([Matrix([[Integer(1), Integer(0)], [Integer(0), Integer(1)]]),
            Matrix([[Integer(1), Integer(0)], [Integer(1), Integer(1)]]),
            left=vector([Integer(0), Integer(1)]), right=vector([Integer(1),
            Integer(0)]))
>>> S
2-regular sequence 0, 1, 1, 2, 1, 2, 3, 1, 2, ...
>>> RR = namedtuple(recurrence_rules,
                  ['M', 'm', 'll', 'uu', 'inhomogeneities'])
>>> recurrence_rules = RR(M=Integer(3), m=Integer(0), ll=Integer(-14),
                        uu=Integer(14),
                        inhomogeneities={Integer(0): S, Integer(1): S})
>>> SI = RP.shifted_inhomogeneities(recurrence_rules)
>>> SI
{0: 2-regular sequence 4, 5, 7, 9, 11, 11, 11, 12, 13, 13, ...
1: 2-regular sequence 4, 5, 7, 9, 11, 11, 12, 13, 13, ...}
```

The first blocks of the corresponding vector-valued sequence correspond to the corresponding shifts of the inhomogeneity. In this particular case, there are no other blocks:

```python
sage: lower = -2
sage: upper = 3
sage: SI[0].dimension() == S.dimension() * (upper - lower + 1)
True
sage: all(
    Seq2(
        SI[0].mu,
        vector((i - lower)*[0, 0] + list(S.left) + (upper - i)*[0, 0]),
        SI[0].right)
    == S.subsequence(1, i)
    for i in range(lower, upper+1))
True
```

```python
>>> from sage.all import *
>>> lower = -Integer(2)
>>> upper = Integer(3)
>>> SI[Integer(0)].dimension() == S.dimension() * (upper - lower + Integer(1))
True
>>> all(
    Seq2(
        SI[Integer(0)].mu,
        vector((i - lower)*[Integer(0), Integer(0)] + list(S.left) +
            (upper - i)*[Integer(0), Integer(0)]),
        SI[Integer(0)].right)
    == S.subsequence(Integer(1), i)
    for i in range(lower, upper+Integer(1)))
True
```

See also:

- `RegularSequenceRing.from_recurrence()`
- `v_eval_n(recurrence_rules, n)`

Return the vector $v(n)$ as given in [HKL2022], Theorem A.

INPUT:
• recurrence_rules – a named tuple generated by parameters()
• n – an integer

OUTPUT: a vector

EXAMPLES:

Stern–Brocot Sequence:

```python
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
```
```
sage: SB_rules = RP.parameters(
    1, 0, {(0, 0): 1, (1, 0): 1, (1, 1): 1},
    {0: 0, 1: 1, 2: 1}, 0)
```
```
sage: RP.v_eval_n(SB_rules, 0)
```
```
(0, 1, 1)
```

See also:

RegularSequenceRing.from_recurrence()

values (M, m, l, u, ll, coeffs, initial_values, last_value_needed, offset, inhomogeneities)

Determine enough values of the corresponding recursive sequence by applying the recurrence relations given in RegularSequenceRing.from_recurrence() to the values given in initial_values.

INPUT:

• M, m, l, u, offset – parameters of the recursive sequences, see [HKL2022], Definition 3.1
• ll – parameter of the resulting linear representation, see [HKL2022], Theorem A
• coeffs – a dictionary where coeffs[(r, j)] is the coefficient \(c_{r,j}\) as given in RegularSequenceRing.from_recurrence(). If coeffs[(r, j)] is not given for some \(r\) and \(j\), then it is assumed to be zero.
• initial_values – a dictionary mapping integers \(n\) to the \(n\)-th value of the sequence
• last_value_needed – last initial value which is needed to determine the linear representation
• inhomogeneities – a dictionary mapping integers \(r\) to the inhomogeneity \(g_r\) as given in [HKL2022], Corollary D.

OUTPUT:

A dictionary mapping integers \(n\) to the \(n\)-th value of the sequence for all \(n\) up to last_value_needed.

EXAMPLES:

Stern–Brocot Sequence:
```python
sage: from sage.combinat.regular_sequence import RecurrenceParser
sage: RP = RecurrenceParser(2, ZZ)
sage: RP.values(M=1, m=0, l=0, u=1, ll=0,
....: coeffs={(0, 0): 1, (1, 0): 1, (1, 1): 1},
....: initial_values={0: 0, 1: 1, 2: 1}, last_value_needed=20,
....: offset=0, inhomogeneities={})
{0: 0, 1: 1, 2: 1, 3: 2, 4: 1, 5: 3, 6: 2, 7: 3, 8: 1, 9: 4, 10: 3,
```

See also:

RegularSequenceRing.from_recurrence()

class sage.combinat.regular_sequence.RegularSequence (parent, mu, left=None, right=None)
Bases: RecognizableSeries

A $k$-regular sequence.

INPUT:

* parent – an instance of RegularSequenceRing
* mu – a family of square matrices, all of which have the same dimension. The indices of this family are $0, ..., k-1$. $\mu$ may be a list or tuple of cardinality $k$ as well. See also $\mu()$.
* left – (default: None) a vector. When evaluating the sequence, this vector is multiplied from the left to the matrix product. If None, then this multiplication is skipped.
* right – (default: None) a vector. When evaluating the sequence, this vector is multiplied from the right to the matrix product. If None, then this multiplication is skipped.

When created via the parent RegularSequenceRing, then the following option is available.

* allow_degenerated_sequence – (default: False) a boolean. If set, then there will be no check if the input is a degenerated sequence (see $is\_degenerated()$). Otherwise the input is checked and a DegeneratedSequenceError is raised if such a sequence is detected.

EXAMPLES:

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: S = Seq2((Matrix([[3, 0], [6, 1]]), Matrix([[0, 1], [-6, 5]])),
....: vector([1, 0]), vector([0, 1])); S
2-regular sequence 0, 1, 3, 5, 9, 11, 15, 19, 27, 29, ...
```

```python
>>> from sage.all import *
>>> from sage.combinat.regular_sequence import RecurrenceParser
>>> RP = RecurrenceParser(Integer(2), ZZ)
>>> RP.values(M=Integer(1), m=Integer(0), l=Integer(0), u=Integer(1),
˓→ll=Integer(0),
....: coeffs={(Integer(0), Integer(0)): Integer(1), (Integer(1),
˓→Integer(0)): Integer(1), (Integer(1), Integer(1)): Integer(1)},
....: initial_values={Integer(0): Integer(0), Integer(1): Integer(1),
˓→Integer(2): Integer(1)}, last_value_needed=Integer(20),
....: offset=Integer(0), inhomogeneities={})
{0: 0, 1: 1, 2: 1, 3: 2, 4: 1, 5: 3, 6: 2, 7: 3, 8: 1, 9: 4, 10: 3,
```
We can access the coefficients of a sequence by

```python
sage: S[5]
11
```

or iterating over the first, say 10, by

```python
sage: from itertools import islice
sage: list(islice(S, 10))
[0, 1, 3, 5, 9, 11, 15, 19, 27, 29]
```

See also:

- `k-regular sequence`, `RegularSequenceRing`
- `backward_differences` (**kwds**)

Return the sequence of backward differences of this \( k \)-regular sequence.

**INPUT:**

- `minimize` – (default: `None`) a boolean or `None`. If `True`, then `minimized()` is called after the operation, if `False`, then not. If this argument is `None`, then the default specified by the parent’s `minimize_results` is used.

**OUTPUT:**

A `RegularSequence`

**Note:** The coefficient to the index \(-1\) is 0.

**EXAMPLES:**

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: C = Seq2((Matrix([[0, 1], [-6, 5]]), vector([1, 0]), vector([0, 1])), ...
  vector([[1, 1], [0, 1]]));
  ...
  2-regular sequence 0, 1, 3, 5, 9, 11, 15, 19, 27, 29, ...

sage: C.backward_differences()
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
```
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(2), Integer(1)]]), ...
→Matrix([[Integer(0), Integer(1)], [-Integer(2), Integer(3)]])), ...
→vector([Integer(1), Integer(0)]), vector([Integer(0),...
→Integer(1)]))
>>> C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
>>> C.backward_differences()
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...

sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])), ...
....:
→vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

sage: E.backward_differences()
2-regular sequence 1, -1, 1, -1, 1, -1, 1, -1, 1, -1, ...

sage: S = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, -1], [1, 2]])), ...
....:
→vector([0, 1]), right=vector([1, 0]))
sage: S[7]
3

This is equivalent to:

sage: S.coefficient_of_n(7)
3

5.1. Comprehensive Module List
**convolution** (*args, **kwds*)

Return the product of this \(k\)-regular sequence with \(\text{other}\), where the multiplication is convolution of power series.

The operator \(*\) is mapped to \texttt{convolution()}.

**INPUT:**

- \(\text{other} - \text{a RegularSequence}\)
- \(\text{minimize} - \text{(default: None)} \) a boolean or None. If True, then \texttt{minimized()} is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s \texttt{minimize_results} is used.

**OUTPUT:**

A \texttt{RegularSequence}

**ALGORITHM:**

See pdf attached to github pull request \#35894 which contains a draft describing the details of the used algorithm.

**EXAMPLES:**

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
          ....: vector([1, 0]), vector([1, 1]))
sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...
```

We can build the convolution (in the sense of power-series) of \(E\) by itself via:

```python
sage: E.convolution(E)
2-regular sequence 1, 0, 2, 0, 3, 0, 4, 0, 5, 0, ...
```

This is the same as using multiplication operator:

```python
sage: E * E
2-regular sequence 1, 0, 2, 0, 3, 0, 4, 0, 5, 0, ...
```
>>> from sage.all import *

2-regular sequence 1, 0, 2, 0, 3, 0, 4, 0, 5, 0, ...

Building `partial_sums()` can also be seen as a convolution:

```
sage: o = Seq2.one_hadamard()
sage: E * o
2-regular sequence 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, ...

sage: E * o == E.partial_sums(include_n=True)
True
```

```
>>> from sage.all import *

>>> o = Seq2.one_hadamard()

>>> E * o
2-regular sequence 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, ...

>>> E * o == E.partial_sums(include_n=True)
True
```

`forward_differences(**kws)`

Return the sequence of forward differences of this $k$-regular sequence.

**INPUT:**

- `minimize` – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's `minimize_results` is used.

**OUTPUT:**

A `RegularSequence`

**EXAMPLES:**

```
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
.....: vector([1, 0]), vector([0, 1]))

sage: C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

sage: C.forward_differences()
2-regular sequence 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
```

```
>>> from sage.all import *

>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)

>>> C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(2), Integer(1)]]),
.....: Matrix([[Integer(0), Integer(1)], [-Integer(2), Integer(3)]])),
.....: vector([Integer(1), Integer(0)]), vector([Integer(0), Integer(1)]))

>>> C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

>>> C.forward_differences()
2-regular sequence 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
```

```
sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
.....: vector([1, 0]), vector([1, 1]))

sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...
```

(continues on next page)
\textbf{is\_degenerated()}

Return whether this $k$-regular sequence is degenerated, i.e., whether this $k$-regular sequence does not satisfy $\mu[0]*\text{right} = \text{right}$.

\textbf{EXAMPLES:}

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: Seq2((Matrix([2]), Matrix([3])), vector([1]), vector([1]))
# indirect doctest
Traceback (most recent call last):
... DegeneratedSequenceError: degenerated sequence: mu[0]*right != right.
Using such a sequence might lead to wrong results.
You can use 'allow\_degenerated\_sequence=True' followed
by a call of method .regenerated() for correcting this.
sage: S = Seq2((Matrix([2]), Matrix([3])), vector([1]), vector([1]),
.....:     allow\_degenerated\_sequence=True)
sage: S
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
sage: S.is\_degenerated()
True
```

```python
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> Seq2((Matrix([Integer(2)]), Matrix([Integer(3)])), vector([Integer(1)]),
.....:     allow\_degenerated\_sequence=True)
>>> S
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
>>> S.is\_degenerated()
True
```

```python
sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
.....:     vector([1, 0]), vector([0, 1]))
```

(continues on next page)
sage: C.is_degenerated()
False

partial_sums(*args, **kwds)

Return the sequence of partial sums of this $k$-regular sequence. That is, the $n$-th entry of the result is the sum of the first $n$ entries in the original sequence.

INPUT:

- include_n – (default: False) a boolean. If set, then the $n$-th entry of the result is the sum of the entries up to index $n$ (included).

- minimize – (default: None) a boolean or None. If True, then minimized() is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's minimize_results is used.

OUTPUT:

A RegularSequence

EXAMPLES:

sage: Seq2 = RegularSequenceRing(2, ZZ)

sage: E = Seq2((Matrix([[0, 1], [0, 1]]), Matrix([[0, 0], [0, 1]])),
             vector([1, 0]), vector([1, 1]))

sage: E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

sage: E.partial_sums()
2-regular sequence 0, 1, 1, 2, 2, 3, 3, 4, 4, 5, ...

sage: E.partial_sums(include_n=True)
2-regular sequence 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, ...

>>> from sage.all import *

>>> E = Seq2((Matrix([[Integer(0), Integer(1)], [Integer(0), Integer(1)]]),
             vector([Integer(1), Integer(0)]), vector([Integer(1), Integer(1)])))

>>> E
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...

>>> E.partial_sums()
2-regular sequence 0, 1, 1, 2, 2, 3, 3, 4, 4, 5, ...

>>> E.partial_sums(include_n=True)
2-regular sequence 1, 1, 2, 2, 3, 3, 4, 4, 5, 5, ...

sage: C = Seq2((Matrix([[2, 0], [2, 1]]), Matrix([[0, 1], [-2, 3]])),
             vector([1, 0]), vector([0, 1]))

(continues on next page)
Combinatorics, Release 10.4

sage: C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
sage: C.partial_sums()
2-regular sequence 0, 0, 1, 3, 6, 10, 15, 21, 28, 36, ...
sage: C.partial_sums(include_n=True)
2-regular sequence 0, 1, 3, 6, 10, 15, 21, 28, 36, 45, ...

```python
>>> from sage.all import *
>>> C = Seq2((Matrix([[Integer(2), Integer(0)]],
                  [Integer(2), Integer(1)]),
              Matrix([[Integer(0), Integer(1)]],
                      [-Integer(2), Integer(3)])),
            vector([Integer(1), Integer(0)]), vector([Integer(0),
                      Integer(1)]))
>>> C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
>>> C.partial_sums()
2-regular sequence 0, 0, 1, 3, 6, 10, 15, 21, 28, 36, ...
>>> C.partial_sums(include_n=True)
2-regular sequence 0, 1, 3, 6, 10, 15, 21, 28, 36, 45, ...
```

The following linear representation of $S$ is chosen badly (is degenerated, see `is_degenerated()`), as $\mu(0)$ applied on right does not equal right:

```python
sage: S = Seq2((Matrix([2]), Matrix([3])), vector([1]), vector([1]),
            allow_degenerated_sequence=True)
```

```python
sage: S
2-regular sequence 1, 3, 6, 9, 12, 18, 27, 24, 36, ...
```

```python
>>> from sage.all import *
```

```python
>>> S = Seq2((Matrix([Integer(2)]), Matrix([Integer(3)])),
          vector([Integer(1)]), vector([Integer(1)]),
          allow_degenerated_sequence=True)
```

```python
>>> S
2-regular sequence 1, 3, 6, 9, 12, 18, 27, 24, 36, ...
```

Therefore, building partial sums produces a wrong result:

```python
sage: H = S.partial_sums(include_n=True, minimize=False)
sage: H
2-regular sequence 1, 5, 16, 25, 62, 80, 98, 125, 274, 310, ...
```

```python
sage: H = S.partial_sums(minimize=False)
```

```python
sage: H
2-regular sequence 0, 2, 10, 16, 50, 62, 80, 98, 250, 274, ...
```

```python
>>> from sage.all import *
```

```python
>>> H = S.partial_sums(include_n=True, minimize=False)
```

```python
>>> H
2-regular sequence 1, 5, 16, 25, 62, 80, 98, 125, 274, 310, ...
```

```python
>>> H = S.partial_sums(minimize=False)
```

```python
>>> H
2-regular sequence 0, 2, 10, 16, 50, 62, 80, 98, 250, 274, ...
```

We can `guess()` the correct representation:

```python
sage: from itertools import islice
```
for s in islice(S, 110):
    ps += s
    L.append(ps)

G = Seq2.guess(lambda n: L[n])

G

2-regular sequence 1, 4, 10, 19, 31, 49, 67, 94, 118, 154, ...

G.linear_representation()

((1, 0, 0, 0),
 Finite family {0: [ 0 1 0 0]
 [ 0 0 0 1]
 [-5 5 1 0]
 [10 -17 0 8],
 1: [ 0 0 1 0]
 [-5 3 3 0]
 [-5 0 6 0]
 [-30 21 10 0]),
 (1, 1, 4, 1))

G.minimized().dimension() == G.dimension()

True

Or we regenerate the sequence $S$ first:

S.regenerated().partial_sums(include_n=True, minimize=False)

2-regular sequence 1, 4, 10, 19, 31, 49, 67, 94, 118, 154, ...

S.regenerated().partial_sums(minimize=False)

2-regular sequence 0, 1, 4, 10, 19, 31, 49, 67, 94, 118, ...

from sage.all import *
from itertools import islice

S.regenerated().partial_sums(include_n=True, minimize=False)

2-regular sequence 1, 4, 10, 19, 31, 49, 67, 94, 118, 154, ...

S.regenerated().partial_sums(minimize=False)

2-regular sequence 0, 1, 4, 10, 19, 31, 49, 67, 94, 118, ...

regenerated(*args, **kwds)
Return a $k$-regular sequence that satisfies $\mu(0) = \text{right}$ with the same values as this sequence.

**INPUT:**

- minimize – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's `minimize_results` is used.

**OUTPUT:**

A `RegularSequence`

**ALGORITHM:**

Theorem B of [HKL2022] with $n_0 = 1$.

**EXAMPLES:**

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
```

```python
>>> from sage.all import *

>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
```

The following linear representation of $S$ is chosen badly (is degenerated, see `is_degenerated()`), as $\mu(0)$ applied on `right` does not equal `right`:

```python
sage: S = Seq2((Matrix([2]), Matrix([3])), vector([1]), vector([1]),...
         allow_degenerated_sequence=True)
```

```python
sage: S
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
```

```python
sage: S.is_degenerated()
True
```

```python
>>> from sage.all import *

>>> S = Seq2((Matrix([Integer(2)]), Matrix([Integer(3)])),...
         vector([Integer(1)]), vector([Integer(1)]),...
         allow_degenerated_sequence=True)

>>> S
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
```

```python
>>> S.is_degenerated()
True
```

However, we can regenerate the sequence $S$:

```python
sage: H = S.regenerated()
```

```python
sage: H
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
```

```python
sage: H.linear_representation()
((1, 0),
 Finite family {0: [ 0 1]
   [-2 3],
   1: [3 0]
   [6 0]},
 (1, 1))
```

```python
sage: H.is_degenerated()
False
```
**shift_left** \((b=l, **kwds)\)

Return the sequence obtained by shifting this \(k\)-regular sequence \(b\) steps to the left.

**INPUT:**
- \(b\) – an integer
- `minimize` – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's `minimize_results` is used.

**OUTPUT:**
A `RegularSequence`

**Note:** If \(b\) is negative (i.e., actually a right-shift), then the coefficients when accessing negative indices are 0.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> H = S.regenerated()
>>> H
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
>>> H.linear_representation()
((1, 0),
 Finite family {0: [ 0 1]
 [-2 3],
 1: [3 0]
 [6 0]},
 (1, 1))
>>> H.is_degenerated()
False
```

```python
shift_left (b=l, **kwds)
```

Return the sequence obtained by shifting this \(k\)-regular sequence \(b\) steps to the left.

**INPUT:**
- \(b\) – an integer
- `minimize` – (default: None) a boolean or None. If True, then `minimized()` is called after the operation, if False, then not. If this argument is None, then the default specified by the parent's `minimize_results` is used.

**OUTPUT:**
A `RegularSequence`

**Note:** If \(b\) is negative (i.e., actually a right-shift), then the coefficients when accessing negative indices are 0.

**EXAMPLES:**

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: C = Seq2((Matrix([[2, 0], [0, 1]]), Matrix([[2, 1], [0, 1]]),
 ... : vector([1, 0]), vector([0, 1])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```

```python
sage: C.shift_left()
2-regular sequence 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
```

```python
sage: C.shift_left(3)
2-regular sequence 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, ...
```

```python
sage: C.shift_left(-2)
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 5, 6, 7, ...
```

```python
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(0), Integer(1)]],
 ... : vector([Integer(1), Integer(0)]), vector([Integer(0),
 ... : Integer(1)]))); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```

```python
>>> C.shift_left()
2-regular sequence 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, ...
```

```python
>>> C.shift_left(Integer(3))
2-regular sequence 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, ...
```

(continues on next page)
Combinatorics, Release 10.4

>>> C.shift_left(-Integer(2))
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 5, 6, 7, ...

shift_right \(b=1, \**kwds\)

Return the sequence obtained by shifting this \(k\)-regular sequence \(b\) steps to the right.

INPUT:

- \(b\) – an integer
- minimize – (default: None) a boolean or None. If True, then minimized() is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s minimize_results is used.

OUTPUT:

A RegularSequence

Note: If \(b\) is positive (i.e., indeed a right-shift), then the coefficients when accessing negative indices are 0.

EXAMPLES:

```sage
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: C = Seq2((Matrix([[2, 0], [0, 1]]), Matrix([[2, 1], [0, 1]]),
....: vector([1, 0]), vector([0, 1])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

sage: C.shift_right()
2-regular sequence 0, 0, 1, 2, 3, 4, 5, 6, 7, 8, ...

sage: C.shift_right(3)
2-regular sequence 0, 0, 0, 0, 1, 2, 3, 4, 5, 6, ...

sage: C.shift_right(-2)
2-regular sequence 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, ...
```

```python
>>> from sage.all import *

Seq2 = RegularSequenceRing(Integer(2), ZZ)

C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(0), Integer(1)]]),
....: vector([Integer(1), Integer(0)]), vector([Integer(0), Integer(1)]))); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

C.shift_right()
2-regular sequence 0, 0, 1, 2, 3, 4, 5, 6, 7, 8, ...

C.shift_right(Integer(3))
2-regular sequence 0, 0, 0, 0, 1, 2, 3, 4, 5, 6, ...

C.shift_right(-Integer(2))
2-regular sequence 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, ...
```

subsequence \(*args, **kwds\)

Return the subsequence with indices \(an + b\) of this \(k\)-regular sequence.

INPUT:

- \(a\) – a nonnegative integer
- \(b\) – an integer
Alternatively, this is allowed to be a dictionary \( b_j \mapsto c_j \). If so and applied on \( f(n) \), the result will be the sum of all \( c_j \cdot f(an + b_j) \).

- \texttt{minimize} – (default: None) a boolean or None. If True, then \texttt{minimized()} is called after the operation, if False, then not. If this argument is None, then the default specified by the parent’s \texttt{minimize_results} is used.

\textbf{OUTPUT:}

A \texttt{RegularSequence}

\textbf{Note:} If \( b \) is negative (i.e., right-shift), then the coefficients when accessing negative indices are 0.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: Seq2 = RegularSequenceRing(2, ZZ)

>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)

We consider the sequence \( C \) with \( C(n) = n \) and the following linear representation corresponding to the vector \((n,1)\):

\begin{verbatim}
sage: C = Seq2((Matrix([[2, 0], [0, 1]]), Matrix([[2, 1], [0, 1]])),
....: vector([1, 0]), vector([0, 1])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...

>>> from sage.all import *
>>> C = Seq2((Matrix([[Integer(2), Integer(0)], [Integer(0), Integer(1)]]),
...          Matrix([[Integer(2), Integer(1)], [Integer(0), Integer(1)]])),
...         vector([Integer(1), Integer(0)]), vector([Integer(0), Integer(1)])); C
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
\end{verbatim}

We now extract various subsequences of \( C \):

\begin{verbatim}
sage: C.subsequence(2, 0)
2-regular sequence 0, 2, 4, 6, 8, 10, 12, 14, 16, 18, ...

sage: S31 = C.subsequence(3, 1); S31
2-regular sequence 1, 4, 7, 10, 13, 16, 19, 22, 25, 28, ...

sage: S31.linear_representation()
((1, 0),
 Finite family {0: 
[ 0 1]
[-2 3],
 1: 
[ 6 -2]
[10 -3]},
(1, 1))

sage: C.subsequence(3, 2)
2-regular sequence 2, 5, 8, 11, 14, 17, 20, 23, 26, 29, ...

>>> from sage.all import *
>>> C.subsequence(Integer(2), Integer(0))
2-regular sequence 0, 2, 4, 6, 8, 10, 12, 14, 16, 18, ...
\end{verbatim}

(continues on next page)
S31 = C.subsequence(Integer(3), Integer(1)); S31
2-regular sequence 1, 4, 7, 10, 13, 16, 19, 22, 25, 28, ...

S31.linear_representation()
((1, 0),
 Finite family {0: [ 0  1]
               [-2  3],
               1: [ 6 -2]
               [10 -3]},
(1, 1))

C.subsequence(Integer(3), Integer(2))
2-regular sequence 2, 5, 8, 11, 14, 17, 20, 23, 26, 29, ...

Srs = C.subsequence(1, -1); Srs
2-regular sequence 0, 0, 1, 2, 3, 4, 5, 6, 7, 8, ...

Srs.linear_representation()
((1, 0, 0),
 Finite family {0: [ 0  1  0]
               [-2  3  0]
               [-4  4  1],
               1: [ -2  2  0]
               [ 0  0  1]
               [ 12 -12  5]},
(0, 0, 1))

We can build backward_differences() manually by passing a dictionary for the parameter b:

Sbd = C.subsequence(1, {0: 1, -1: -1}); Sbd
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...

Sbd = C.subsequence(Integer(1), {Integer(0): Integer(1), -Integer(1): -Integer(1)}); Sbd
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...

transposed(allow_degenerated_sequence=False)
Return the transposed sequence.

INPUT:

• allow_degenerated_sequence—(default: False) a boolean. If set, then there will be no check
  if the transposed sequence is a degenerated sequence (see is_degenerated()). Otherwise the
  transposed sequence is checked and a DegeneratedSequenceError is raised if such a sequence
is detected.

OUTPUT:

A **RegularSequence**

Each of the matrices in \( \mu \) is transposed. Additionally the vectors \( \text{left} \) and \( \text{right} \) are switched.

EXAMPLES:

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: U = Seq2((Matrix([[3, 2], [0, 1]]), Matrix([[2, 0], [1, 3]])),
....:     left=vector([0, 1]), right=vector([1, 0]),
....:     allow_degenerated_sequence=True)
sage: U.is_degenerated()
True
sage: Ut = U.transposed()
sage: Ut.linear_representation()
((1, 0),
 Finite family {0: [3 0]
  [2 1],
 1: [2 1]
  [0 3]},
 (0, 1))
sage: Ut.is_degenerated()
False
sage: Ut.transposed()
Traceback (most recent call last):
 ...  
DegeneratedSequenceError: degenerated sequence: \( \mu[0]\)!right != right.
Using such a sequence might lead to wrong results.  
You can use 'allow_degenerated_sequence=True' followed 
by a call of method .regenerated() for correcting this.
sage: Utt = Ut.transposed(allow_degenerated_sequence=True)
sage: Utt.is_degenerated()
True
```
Traceback (most recent call last):
...
DegeneratedSequenceError: degenerated sequence: mu[0]*right != right.
Using such a sequence might lead to wrong results.
You can use 'allow_degenerated_sequence=True' followed
by a call of method .regenerated() for correcting this.
>>> Utt = Ut.transposed(allow_degenerated_sequence=True)
>>> Utt.is_degenerated()
True

See also:

RecognizableSeries.transposed

class sage.combinat.regular_sequence.RegularSequenceRing(k, *args, **kwds)
Bases: RecognizableSeriesSpace

The space of $k$-regular Sequences over the given coefficient_ring.

INPUT:

- $k$ – an integer at least 2 specifying the base
- coefficient_ring – a (semi-)ring

- category – (default: None) the category of this space

EXAMPLES:

sage: RegularSequenceRing(2, ZZ)
Space of 2-regular sequences over Integer Ring
sage: RegularSequenceRing(3, ZZ)
Space of 3-regular sequences over Integer Ring

>>> from sage.all import *
>>> RegularSequenceRing(Integer(2), ZZ)
Space of 2-regular sequences over Integer Ring
>>> RegularSequenceRing(Integer(3), ZZ)
Space of 3-regular sequences over Integer Ring

See also:

$k$-regular sequence, RegularSequence.

Element

alias of RegularSequence

from_recurrence(*args, **kwds)

Construct the unique $k$-regular sequence which fulfills the given recurrence relations and initial values. The
recurrence relations have to have the specific shape of $k$-recursive sequences as described in [HKL2022], and
are either given as symbolic equations, e.g.,

sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: var('n')
n
sage: function('f')
f
sage: Seq2.from_recurrence(
....:     f(2*n) == 2*f(n), f(2*n + 1) == 3*f(n) + 4*f(n - 1),
)
Combinatorics, Release 10.4

(continued from previous page)

....:  f(0) == 0, f(1) == 1, f, n)
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 10, 6, 17, ...

```python
>>> from sage.all import *
>>> Seq2 = RegularSequenceRing(Integer(2), ZZ)
>>> var('n')
>>> function('f')
>>> Seq2.from_recurrence(
    ...  f(Integer(2)*n) == Integer(2)*f(n), f(Integer(2)*n + Integer(1)) ==
    ...  Integer(3)*f(n) + Integer(4)*f(n - Integer(1)),
    ...  f(Integer(0)) == Integer(0), f(Integer(1)) == Integer(1)), f, n)
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 10, 6, 17, ...
```

or via the parameters of the $k$-recursive sequence as described in the input block below:

```python
sage: Seq2.from_recurrence(M=Integer(1), m=Integer(0),
    ...  coeffs={(Integer(0), Integer(0)): Integer(2), (Integer(1),
    ...  Integer(0)): Integer(3), (Integer(1), -Integer(1)): Integer(4)},
    ...  initial_values={Integer(0): Integer(0), Integer(1): Integer(1)})
2-regular sequence 0, 0, 0, 1, 2, 3, 4, 10, 6, 17, ...
```

INPUT:

Positional arguments:

If the recurrence relations are represented by symbolic equations, then the following arguments are required:

- **equations** – A list of equations where the elements have either the form
  
  \[- f(k^M n + r) = c_r f(k^m n + l) + c_{r+1} f(k^m n + l + 1) + \ldots + c_u f(k^m n + u) \]
  
  for some integers $0 \leq r < k^M$, $M > m \geq 0$ and $l \leq u$, and some coefficients $c_{r,j}$ from the (semi)ring $\text{coefficient\_ring}$ of the corresponding $\text{RegularSequenceRing}$, valid for all integers $n \geq$ offset for some integer offset $\geq \max(-l/k^m, 0)$ (default: 0), and there is an equation of this form (with the same parameters $M$ and $m$) for all $r$
  
  or the form
  
  \[- f(k) == t \]

  for some integer $k$ and some $t$ from the (semi)ring $\text{coefficient\_ring}$.

The recurrence relations above uniquely determine a $k$-regular sequence; see [HKL2022] for further information.

- **function** – symbolic function $f$ occurring in the equations

- **var** – symbolic variable ($n$ in the above description of equations)

The following second representation of the recurrence relations is particularly useful for cases where $\text{coefficient\_ring}$ is not compatible with $\text{sage.symbolic.ring.SymbolicRing}$. Then the following arguments are required:

- **M** – parameter of the recursive sequences, see [HKL2022], Definition 3.1, as well as in the description of equations above
• \(m\) – parameter of the recursive sequences, see [HKL2022], Definition 3.1, as well as in the description of equations above

• \(\text{coeffs}\) – a dictionary where \(\text{coeffs}\[(r, \ j)\] \) is the coefficient \(c_{r,j}\) as given in the description of equations above. If \(\text{coeffs}\[(r, \ j)\] \) is not given for some \(r\) and \(j\), then it is assumed to be zero.

• \(\text{initial\_values}\) – a dictionary mapping integers \(n\) to the \(n\)-th value of the sequence

Optional keyword-only argument:

• \(\text{offset}\) – (default: 0) an integer. See explanation of equations above.

• \(\text{inhomogeneities}\) – (default: \(\{}\)) a dictionary mapping integers \(r\) to the inhomogeneity \(g_r\) as given in [HKL2022], Corollary D. All inhomogeneities have to be regular sequences from \(\text{self}\) or elements of \(\text{coefficient\_ring}\).

OUTPUT: a \texttt{RegularSequence}

EXAMPLES:

Stern–Brocot Sequence:

\[
\begin{align*}
\text{sage: } & \text{Seq2 = RegularSequenceRing}(2, \ \text{ZZ}) \\
\text{sage: } & \text{var}(\text{\'n\'}) \\
\text{sage: } & \text{f} \\
\text{sage: } & \text{SB = Seq2.from\_recurrence(} \\
\text{\quad} & \text{\[} \\
\text{\quad} & \quad f(2^n) == f(n), \ f(2^n + 1) == f(n) + f(n + 1), \\
\text{\quad} & \quad f(0) == 0, \ f(1) == 1], \ f, \ n) \\
\text{sage: } & \text{SB} \\
\text{\quad} & \text{2-regular sequence \ 0, \ 1, \ 1, \ 2, \ 1, \ 3, \ 2, \ 3, \ 1, \ 4, \ \ldots}
\end{align*}
\]

Number of Odd Entries in Pascal's Triangle:

\[
\begin{align*}
\text{sage: } & \text{Seq2.from\_recurrence(} \\
\text{\quad} & \text{\[} \\
\text{\quad} & \quad f(2^n) == 3*f(n), \ f(2^n + 1) == 2*f(n) + f(n + 1), \\
\text{\quad} & \quad f(0) == 0, \ f(1) == 1], \ f, \ n) \\
\text{sage: } & \text{SB} \\
\text{\quad} & \text{2-regular sequence \ 0, \ 1, \ 3, \ 5, \ 9, \ 11, \ 15, \ 19, \ 27, \ 29, \ \ldots}
\end{align*}
\]
Number of Unbordered Factors in the Thue–Morse Sequence:

\[
\text{sage: } UB = \text{Seq2.from_recurrence}([\]
....:  f(8*n) == 2*f(4*n),
....:  f(8*n + 1) == f(4*n + 1),
....:  f(8*n + 2) == f(4*n + 1) + f(4*n + 3),
....:  f(8*n + 3) == -f(4*n + 1) + f(4*n + 2),
....:  f(8*n + 4) == 2*f(4*n + 2),
....:  f(8*n + 5) == f(4*n + 3),
....:  f(8*n + 6) == -f(4*n + 1) + f(4*n + 2) + f(4*n + 3),
....:  f(8*n + 7) == 2*f(4*n + 1) + f(4*n + 3),
....:  f(0) == 1, f(1) == 2, f(2) == 2, f(3) == 4, f(4) == 2,
....:  f(5) == 4, f(6) == 6, f(7) == 0, f(8) == 4, f(9) == 4,
....:  f(10) == 4, f(11) == 4, f(12) == 12, f(13) == 0, f(14) == 4,
....:  f(15) == 4, f(16) == 8, f(17) == 4, f(18) == 8, f(19) == 0,
....:  f(20) == 8, f(21) == 4, f(22) == 4, f(23) == 8], f, n, offset=3)
\]
\[
\text{sage: } UB
\]
2-regular sequence 1, 2, 2, 4, 2, 4, 6, 0, 4, 4, ...

\[
\text{Binary sum of digits } S(n), \text{ characterized by the recurrence relations } S(4n) = S(2n), S(4n+1) = S(2n+1), S(4n+2) = S(2n+1) \text{ and } S(4n+3) = -S(2n) + 2S(2n+1):
\]

\[
\text{sage: } S = \text{Seq2.from_recurrence}([\]
....:  f(4*n) == f(2*n),
....:  f(4*n + 1) == f(2*n + 1),
\]
(continues on next page)
Combinatorics, Release 10.4

\[ f(4n + 2) = f(2n + 1), \]
\[ f(4n + 3) = -f(2n) + 2f(2n + 1), \]
\[ f(0) = 0, f(1) = 1, \]
\[ \text{sage: } S \]

\[ \text{2-regular sequence 0, 1, 1, 2, 1, 2, 2, 3, 1, 2, ...} \]

\[ \text{sage: } S2 = \text{Seq2}((\text{Matrix([[1, 0], [0, 1]])), \text{Matrix([[1, 0], [1, 1]]))}), \]
\[ \text{left=vector([0, 1]), right=vector([1, 0]))} \]

\[ \text{sage: } (S - S2).is_trivial_zero() \]

\[ \text{True} \]

\[ \text{sage: } S3 = \text{Seq2}((\text{M=Integer(1), m=Integer(0),}} \)
\[ \text{coeffs={(Integer(0), Integer(0)): Integer(1), (Integer(1), Integer(0)): Integer(1)},}} \]
\[ \text{initial_values={Integer(0): Integer(0), Integer(1): Integer(1)},}} \]
\[ \text{inhomogeneities={Integer(1): Integer(1)})} \]

\[ \text{sage: } (S3 - S2).is_trivial_zero() \]

\[ \text{True} \]

Alternatively, we can also use the simpler but inhomogeneous recurrence relations \( S(2n) = S(n) \) and \( S(2n + 1) = S(n) + 1 \) via direct parameters:

\[ \text{sage: } S3 = \text{Seq2.from_recurrence(M=Integer(1), m=Integer(0),}} \]
\[ \text{coeffs={(Integer(0), Integer(0)): Integer(1), (Integer(1), Integer(0)): Integer(1),}} \]
\[ \text{initial_values={Integer(0): Integer(0), Integer(1): Integer(1)},}} \]
\[ \text{inhomogeneities={Integer(1): Integer(1)})} \]

\[ \text{sage: } (S3 - S2).is_trivial_zero() \]

\[ \text{True} \]
Number of Non-Zero Elements in the Generalized Pascal’s Triangle (see [LRS2017]):

```python
sage: Seq2 = RegularSequenceRing(2, QQ)
sage: P = Seq2.from_recurrence([  
        ...: f(4*n) == 5/3*f(2*n) - 1/3*f(2*n + 1),
        ...: f(4*n + 1) == 4/3*f(2*n) + 1/3*f(2*n + 1),
        ...: f(4*n + 2) == 1/3*f(2*n) + 4/3*f(2*n + 1),
        ...: f(4*n + 3) == -1/3*f(2*n) + 5/3*f(2*n + 1),
        ...: f(0) == 1, f(1) == 2], f, n)
sage: P
2-regular sequence 1, 2, 3, 3, 4, 5, 5, 4, 5, 7, ...
```

Finally, the same sequence can also be obtained via direct parameters without symbolic equations:

```python
sage: Seq2.from_recurrence(M=2, m=1,  
        ...: coeffs={(0, 0): 5/3, (0, 1): -1/3,  
        ...: (1, 0): 4/3, (1, 1): 1/3,  
        ...: (2, 0): 1/3, (2, 1): 4/3,  
        ...: (3, 0): -1/3, (3, 1): 5/3},  
        ...: initial_values={0: 1, 1: 2})
2-regular sequence 1, 2, 3, 3, 4, 5, 5, 4, 5, 7, ...
```

```
guess (f, n_verify=100, max_exponent=10, sequence=None)
```

Guess a k-regular sequence whose first terms coincide with \((f(n))_{n \geq 0}\).
INPUT:

- \( f \) – a function (callable) which determines the sequence. It takes nonnegative integers as an input
- \( n_{\text{verify}} \) – (default: 100) a positive integer. The resulting \( k \)-regular sequence coincides with \( f \) on the first \( n_{\text{verify}} \) terms.
- \( \text{max\_exponent} \) – (default: 10) a positive integer specifying the maximum exponent of \( k \) which is tried when guessing the sequence, i.e., relations between \( f(k^t n + r) \) are used for \( 0 \leq t \leq \text{max\_exponent} \) and \( 0 \leq r < k^t \)
- \( \text{sequence} \) – (default: None) a \( k \)-regular sequence used for bootstrapping the guessing by adding information of the linear representation of \( \text{sequence} \) to the guessed representation

OUTPUT:

A RegularSequence

ALGORITHM:

For the purposes of this description, the right vector valued sequence associated with a regular sequence consists of the corresponding matrix product multiplied by the right vector, but without the left vector of the regular sequence.

The algorithm maintains a right vector valued sequence consisting of the right vector valued sequence of the argument \( \text{sequence} \) (replaced by an empty tuple if \( \text{sequence} \) is None) plus several components of the shape \( m \mapsto f(k^t \cdot m + r) \) for suitable \( t \) and \( r \).

Implicitly, the algorithm also maintains a \( d \times n_{\text{verify}} \) matrix \( A \) (where \( d \) is the dimension of the right vector valued sequence) whose columns are the current right vector valued sequence evaluated at the non-negative integers less than \( n_{\text{verify}} \) and ensures that this matrix has full row rank.

EXAMPLES:

Binary sum of digits:

\[
\text{sage: } \text{Seq2} = \text{RegularSequenceRing}(2, \mathbb{Z}_2) \\
\text{sage: } \text{import logging} \quad \text{(continues on next page)}
\]

Let us guess a 2-linear representation for \( s(n) \):

\[
\text{sage: } \text{Seq2} = \text{RegularSequenceRing}(2, \mathbb{Z}_2) \\
\text{sage: } \text{import logging} \quad \text{(continues on next page)}
\]
The `INFO` messages mean that the right vector valued sequence is the sequence \((s(n), s(2n+1))^\top\).

We guess again, but this time, we use a constant sequence for bootstrapping the guessing process:

```python
sage: C = Seq2.one_hadamard(); C
2-regular sequence 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
sage: S2 = Seq2.guess(s, sequence=C); S2
INFO:...:including 2-regular sequence 1, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
INFO:...:including f_{1*m+0}
2-regular sequence 0, 1, 1, 1, 1, 1, 1, 1, 1, 1, ...
sage: S2.linear_representation()
((0, 1),
 Finite family {0: [1 0]
               [0 1],
               1: [ 0 1]
               [-1 2]},
(1, 0))
sage: S1 == S2
True
```
>>> S2.linear_representation()
((0, 1),
 Finite family {0: [1 0]
                   [0 1],
               1: [1 0]
                   [1 1]},
(1, 0))
>>> S1 == S2
True

The sequence of all natural numbers:

```sage```
S = Seq2.guess(lambda n: n); S
INFO:...:including f_{1*m+0}
INFO:...:including f_{2*m+1}
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```sage```
S.linear_representation()
((1, 0),
 Finite family {0: [2 0]
               [2 1],
           1: [ 0 1]
               [-2 3]},
(0, 1))

```sage```
from sage.all import *
```sage```
S = Seq2.guess(lambda n: n); S
INFO:...:including f_{1*m+0}
INFO:...:including f_{2*m+1}
2-regular sequence 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, ...
```sage```
S.linear_representation()
((1, 0),
 Finite family {0: [2 0]
               [2 1],
           1: [ 0 1]
               [-2 3]},
(0, 1))

The indicator function of the even integers:

```sage```
S = Seq2.guess(lambda n: ZZ(is_even(n))); S
INFO:...:including f_{1*m+0}
INFO:...:including f_{2*m+0}
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...
```sage```
S.linear_representation()
((1, 0),
 Finite family {0: [0 1]
               [0 1],
           1: [0 0]
               [0 1]},
(1, 1))

```sage```
from sage.all import *
```sage```
S = Seq2.guess(lambda n: ZZ(is_even(n))); S
INFO:...:including f_{1*m+0}
INFO:...:including f_{2*m+0}
2-regular sequence 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, ...
```sage```
(continues on next page)
The indicator function of the odd integers:

```python
sage: S = Seq2.guess(lambda n: ZZ(is_odd(n))); S
INFO:...:including f_{1*m+0}
INFO:...:including f_{2*m+1}
2-regular sequence 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, ...
sage: S.linear_representation()
((1, 0),
 Finite family {0: [0 0]
 [0 1],
 1: [0 1]
 [0 1]},
(0, 1))
sage: logging.getLogger().setLevel(logging.WARN)
```

The following linear representation of $S$ is chosen badly (is degenerated, see `is_degenerated()`), as $\mu(0)$ applied on right does not equal right:

```python
sage: S = Seq2((Matrix([2]), Matrix([3])), vector([1]), vector([1]),
 ....: allow_degenerated_sequence=True)
sage: S
2-regular sequence 1, 3, 6, 9, 12, 18, 18, 27, 24, 36, ...
sage: S.is_degenerated()
True
```

However, we can `guess()` a 2-regular sequence of dimension 2:

```python
>>> S.linear_representation()
((1, 0),
 Finite family {0: [0 0]
 [0 1],
 1: [0 1]
 [0 1]},
(1, 1))
```
one()

Return the one element of this RegularSequenceRing, i.e. the unique neutral element for * and also the embedding of the one of the coefficient ring into this RegularSequenceRing.

EXAMPLES:

```python
sage: Seq2 = RegularSequenceRing(2, ZZ)
sage: O = Seq2.one(); O
2-regular sequence 1, 0, 0, 0, 0, 0, 0, 0, 0, 0, ...
sage: O.linear_representation()
((1), Finite family {0: [1], 1: [0]}, (1))
```

some_elements()

Return some elements of this k-regular sequence.

See TestSuite for a typical use case.

OUTPUT:

An iterator

EXAMPLES:
sage: tuple(RegularSequenceRing(2, ZZ).some_elements())
(2-regular sequence 0, 1, 2, 1, 2, 2, 3, 1, 2, ...,
  2-regular sequence 1, 0, 1, 0, 1, 0, 0, 1, 0, ...,
  2-regular sequence 1, 0, 1, -1, 0, 0, 1, -2, -1, ...,
  2-regular sequence 2, -1, 0, 0, -1, 0, 0, 0, 0, ...,
  2-regular sequence 1, 0, 1, 5, 0, 0, 1, -33, 5, ...,
  2-regular sequence -5, 0, 0, 0, 0, 0, 0, 0, 0, ...,
  2-regular sequence -59, -20, 0, -20, 0, 0, -20, 0, 0, ...,
  ...
  2-regular sequence 2210, 170, 0, 0, 0, 0, 0, 0, 0, ...)

>>> from sage.all import *
>>> tuple(RegularSequenceRing(Integer(2), ZZ).some_elements())
(2-regular sequence 0, 1, 2, 1, 2, 2, 3, 1, 2, ...,
  2-regular sequence 1, 0, 1, 0, 1, 0, 0, 1, 0, ...,
  2-regular sequence 1, 0, 1, -1, 0, 0, 1, -2, -1, ...,
  2-regular sequence 2, -1, 0, 0, -1, 0, 0, 0, 0, ...,
  2-regular sequence 1, 0, 1, 5, 0, 0, 1, -33, 5, ...,
  2-regular sequence -5, 0, 0, 0, 0, 0, 0, 0, 0, ...,
  2-regular sequence -59, -20, 0, -20, 0, 0, -20, 0, 0, ...,
  ...
  2-regular sequence 2210, 170, 0, 0, 0, 0, 0, 0, 0, ...)

sage.combinat.regular_sequence.pad_right(T, length, zero=0)
Pad T to the right by using zero to have at least the given length.

INPUT:

- T – A tuple, list or other iterable
- length – a nonnegative integer
- zero – (default: 0) the elements to pad with

OUTPUT:

An object of the same type as T

EXAMPLES:

sage: from sage.combinat.regular_sequence import pad_right
sage: pad_right((1, 2, 3), 10)
(1, 2, 3, 0, 0, 0, 0, 0, 0, 0)
sage: pad_right((1, 2, 3), 2)
(1, 2, 3)
sage: pad_right([[1, 2], [3, 4]], [0, 0])
[(1, 2), (3, 4), (0, 0), (0, 0)]

>>> from sage.all import *
>>> from sage.combinat.regular_sequence import pad_right
>>> pad_right((Integer(1), Integer(2), Integer(3)), Integer(10))
(1, 2, 3, 0, 0, 0, 0, 0, 0, 0)
>>> pad_right((Integer(1), Integer(2), Integer(3)), Integer(2))
(1, 2, 3)
>>> pad_right([[Integer(1), Integer(2)], [Integer(3), Integer(4)]], Integer(4),
            pad_right([Integer(0), Integer(0)]))
[(1, 2), (3, 4), (0, 0), (0, 0)]
sage.combinat.regular_sequence.value(D, k)

Return the value of the expansion with digits D in base k, i.e.

\[
\sum_{0 \leq j < \text{len } D} D[j]k^j.
\]

INPUT:
- D – a tuple or other iterable
- k – the base

OUTPUT:
An element in the common parent of the base k and of the entries of D

EXAMPLES:

```
sage: from sage.combinat.regular_sequence import value
sage: value(42.digits(7), 7)
42
```

```
>>> from sage.combinat.regular_sequence import value
>>> value(Integer(42).digits(Integer(7)), Integer(7))
42
```

## 5.1.193 Restricted growth arrays

These combinatorial objects are in bijection with set partitions.

```
class sage.combinat.restricted_growth.RestrictedGrowthArrays(n)

Bases: UniqueRepresentation, Parent

EXAMPLES:
```

```
sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(3)
sage: R == loads(dumps(R))
True
```

```
>>> from sage.combinat.restricted_growth import RestrictedGrowthArrays
>>> R = RestrictedGrowthArrays(Integer(3))
>>> R == loads(dumps(R))
True
```

```
cardinality()

EXAMPLES:
```

sage: from sage.combinat.restricted_growth import RestrictedGrowthArrays
sage: R = RestrictedGrowthArrays(6)
sage: R.cardinality() # needs sage.libs.flint
203

>>> from sage.all import *
>>> from sage.combinat.restricted_growth import RestrictedGrowthArrays
>>> R = RestrictedGrowthArrays(Integer(6))
>>> R.cardinality() # needs sage.libs.flint
203

5.1.194 Ribbons

5.1.195 Ribbon Shaped Tableaux

class sage.combinat.ribbon_shaped_tableau.RibbonShapedTableau(parent, t)
    Bases: SkewTableau

A ribbon shaped tableau.

For the purposes of this class, a ribbon shaped tableau is a skew tableau whose shape is a skew partition which:

- has at least one cell in row 1;
- has at least one cell in column 1;
- has exactly one cell in each of \( q \) consecutive diagonals, for some nonnegative integer \( q \).

A ribbon is given by a list of the rows from top to bottom.

EXAMPLES:

sage: x = RibbonShapedTableau([[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]])
x
[[None, None, None, 2, 3], [None, 1, 4, 5], [3, 2]]
sage: x.pp()
. . . 2 3
  1 4 5
  3 2
sage: x.shape()
[5, 4, 2] / [3, 1]

>>> x = RibbonShapedTableau([[None, None, None, Integer(2), Integer(3)], [None, None, Integer(1), Integer(4), Integer(5)], [Integer(3), Integer(2)]])
x
[[None, None, None, Integer(2), Integer(3)], [None, None, Integer(1), Integer(4), Integer(5)], [Integer(3), Integer(2)]]
>>> x.pp()
. . . 2 3
  1 4 5
  3 2
>>> x.shape()
[5, 4, 2] / [3, 1]

The entries labeled by \texttt{None} correspond to the inner partition. Using \texttt{None} is optional; the entries will be shifted accordingly.
```python
sage: x = RibbonShapedTableau([[2,3],[1,4,5],[3,2]]); x.pp()
 . . . 2 3
 . . . 1 4 5
 . . . 3 2
```

```
>>> from sage.all import *
>>> x = RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
→Integer(5)],[Integer(3),Integer(2)]]); x.pp()
 . . . 2 3
 . . . 1 4 5
 . . . 3 2
```

**height()**

Return the height of `self`.

The height is given by the number of rows in the outer partition.

EXAMPLES:

```python
sage: RibbonShapedTableau([[2,3],[1,4,5]]).height()
2
```

```
>>> from sage.all import *
>>> RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
→Integer(5)]]).height()
2
```

**spin()**

Return the spin of `self`.

EXAMPLES:

```python
sage: RibbonShapedTableau([[2,3],[1,4,5]]).spin()
1/2
```

```
>>> from sage.all import *
>>> RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
→Integer(5)]]).spin()
1/2
```

**width()**

Return the width of the ribbon.

This is given by the length of the longest row in the outer partition.

EXAMPLES:

```python
sage: RibbonShapedTableau([[2,3],[1,4,5]]).width()
4
sage: RibbonShapedTableau([]).width()
0
```

```
>>> from sage.all import *
>>> RibbonShapedTableau([[Integer(2),Integer(3)],[Integer(1),Integer(4),
→Integer(5)]]).width()
4
```

(continues on next page)
class sage.combinat.ribbon_shaped_tableau.RibbonShapedTableaux(category=None)

Bases: SkewTableaux

The set of all ribbon shaped tableaux.

Element

alias of RibbonShapedTableau

def from_shape_and_word(shape, word)

Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

sage: RibbonShapedTableaux().from_shape_and_word([1,3],[1,3,3,7])
[[None, None, 1], [3, 3, 7]]

options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

class sage.combinat.ribbon_shaped_tableau.Ribbon_class(parent, t)

Bases: RibbonShapedTableau

This exists solely for unpickling Ribbon_class objects.

class sage.combinat.ribbon_shaped_tableau.StandardRibbonShapedTableaux(category=None)

Bases: StandardSkewTableaux

The set of all standard ribbon shaped tableaux.

INPUT:

• shape – (optional) the composition shape of the rows

Element

alias of RibbonShapedTableau

def from_permutation(p)

Return a standard ribbon of size len(p) from a permutation p. The lengths of each row are given by the distance between the descents of the permutation p.

EXAMPLES:

sage: import sage.combinat.ribbon_shaped_tableau as rst
sage: [StandardRibbonShapedTableaux().from_permutation(p) for p in Permutations(3)]
[[[1, 2, 3]],
 [[None, 2], [1, 3]],
 [[1, 3], [2]],
 [[None, 1], [2, 3]],
...]
(continues on next page)
from sage.all import *  
from sage.combinat.ribbon_shaped_tableau as rst

for p in Permutations(Integer(3))
    print(StandardRibbonShapedTableaux().from_permutation(p))

from_shape_and_word(shape, word)
Return the ribbon corresponding to the given ribbon shape and word.

EXAMPLES:

>>> from sage.all import *
>>> StandardRibbonShapedTableaux().from_shape_and_word([Integer(2)], [Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)])
[[None, None, 1, 2], [3, 4, 5]]
```python
>>> from sage.all import *

StandardRibbonShapedTableaux([Integer(2),Integer(2)])
Standard ribbon shaped tableaux of shape [2, 2]

StandardRibbonShapedTableaux([Integer(2),Integer(2)]).first()
[[None, 2, 4], [1, 3]]

StandardRibbonShapedTableaux([Integer(2),Integer(2)]).last()
[[None, 1, 2], [3, 4]]

# needs sage.graphs sage.modules

StandardRibbonShapedTableaux([Integer(2),Integer(2)]).cardinality()
5

StandardRibbonShapedTableaux([Integer(2),Integer(2)]).list()
[[[None, 1, 3], [2, 4]],
 [[None, 1, 2], [3, 4]],
 [[None, 2, 3], [1, 4]],
 [[None, 2, 4], [1, 3]],
 [[None, 1, 4], [2, 3]]]

StandardRibbonShapedTableaux([Integer(3),Integer(2),Integer(2)]).cardinality()
155
```

```python
5.1.196 Ribbon Tableaux

class sage.combinat.ribbon_tableau.MultiSkewTableau(parent, *args, **kwds)

Bases: CombinatorialElement

A multi skew tableau which is a tuple of skew tableaux.

EXAMPLES:

sage: s = MultiSkewTableau([ [[None,1],[2,3]], [[1,2],[2]] ])  
sage: s.size()
```

(continues on next page)
Combinatorics, Release 10.4

>>> from sage.all import *

>>> s = MultiSkewTableau( [ [[[None, Integer(1)], [Integer(2), Integer(3)]],
                          [ [Integer(1), Integer(2)], [Integer(2)]]] )

>>> s.size()
6

>>> s.weight()
[2, 3, 1]

>>> s.shape()
[[2, 2] / [1], [2, 1] / []]

inversion_pairs()
Return a list of the inversion pairs of self.

EXAMPLES:

sage: s = MultiSkewTableau([ [[2,3],[5,5]], [[1,1],[3,3]], [[2],[6]] ])

sage: s.inversion_pairs()
[((0, (0, 0)), (1, (0, 0))),
 ((0, (1, 0)), (1, (0, 1))),
 ((0, (0, 1)), (1, (1, 0))),
 ((0, (1, 1)), (1, (1, 1))),
 ((0, (1, 1)), (2, (0, 0))),
 ((1, (0, 1)), (2, (0, 0))),
 ((1, (1, 1)), (2, (0, 0))))

sage: s = MultiSkewTableau([ [Integer(2),Integer(3)], [Integer(5),Integer(5)],
                          [ [Integer(1), Integer(1)], [Integer(3), Integer(3)], [Integer(2)],
                          [Integer(6)] ]])

sage: s.inversion_pairs()
[((0, (0, 0)), (1, (0, 0))),
 ((0, (1, 0)), (1, (0, 1))),
 ((0, (0, 1)), (1, (1, 0))),
 ((0, (1, 1)), (1, (1, 1))),
 ((0, (1, 1)), (2, (0, 0))),
 ((1, (0, 1)), (2, (0, 0))),
 ((1, (1, 1)), (2, (0, 0))))

inversions()
Return the number of inversion pairs of self.

EXAMPLES:

sage: t1 = SkewTableau([[1]])

sage: t2 = SkewTableau([[2]])

sage: MultiSkewTableau([t1,t1]).inversions()
0

sage: MultiSkewTableau([t1,t2]).inversions()
0

sage: MultiSkewTableau([t2,t2]).inversions()
shape()

Return the shape of self.

EXAMPLES:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.shape()
[[2, 2] / [1], [2, 2] / [1], [2, 2] / [1]]
```

size()

Return the size of self.

This is the sum of the sizes of the skew tableaux in self.

EXAMPLES:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.size()
9
```
Weight

Return the weight of self.

Examples:

```python
sage: s = SemistandardSkewTableaux([[2,2],[1]]).list()
sage: a = MultiSkewTableau([s[0],s[1],s[2]])
sage: a.weight()
[5, 3, 1]
```

Class `sage.combinat.ribbon_tableau.MultiSkewTableaux(category=None)`

Bases: `UniqueRepresentation`, `Parent`

Multiskew tableaux.

Element

alias of `MultiSkewTableau`

Class `sage.combinat.ribbon_tableau.RibbonTableau(parent, st)`

Bases: `SkewTableau`

A ribbon tableau.

A ribbon is a connected skew shape which does not contain any 2 × 2 boxes. A ribbon tableau is a skew tableau whose shape is partitioned into ribbons, each of which is filled with identical entries.

Examples:

```python
sage: rt = RibbonTableau([[None, 1],[2,3]]); rt
[[None, 1], [2, 3]]
sage: rt.inner_shape()
[1]
sage: rt.outer_shape()
[2, 2]
sage: rt = RibbonTableau([[None, None, 0, 0, 0], [None, 0, 0, 2], [1, 0, 1]]); rt.pp()
 . 0 0 0
 . 0 0 2
 1 0 1
```

```python
>>> from sage.all import *
>>> rt = RibbonTableau([[None, Integer(1)],[Integer(2),Integer(3)]]); rt
[[None, 1], [2, 3]]
>>> rt.inner_shape()
[1]
```
In the previous example, each ribbon is uniquely determined by a non-zero entry. The 0 entries are used to fill in the rest of the skew shape.

**Note:** Sanity checks are not performed; lists can contain any object.

```python
sage: RibbonTableau(expr=[[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

```python
>>> from sage.all import *

>>> RibbonTableau(expr=[[Integer(1),Integer(1)],[[Integer(5)],[Integer(3),Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]
```

**length()**

Return the length of the ribbons into a ribbon tableau.

**EXAMPLES:**

```python
sage: RibbonTableau([[None, 1],[2,3]]).length()
1
sage: RibbonTableau([[1,0],[2,0]]).length()
2
```

```python
>>> from sage.all import *

>>> RibbonTableau([[None, Integer(1)],[Integer(2),Integer(3)]]).length()
1
>>> RibbonTableau([[Integer(1),Integer(0)],[Integer(2),Integer(0)]]).length()
2
```

**to_word()**

Return a word obtained from a row reading of `self`.

**Warning:** Unlike the `to_word` method on skew tableaux (which are a superclass of this), this method does not filter out None entries.

**EXAMPLES:**

```python
sage: R = RibbonTableau([[0, 0, 3, 0], [1, 1, 0], [2, 0, 4]])
sage: R.to_word()
word: 2041100030
```
```python
from sage.all import *

R = RibbonTableau([[Integer(0), Integer(0), Integer(3), Integer(0)],
                   [Integer(1), Integer(1), Integer(0)],
                   [Integer(2), Integer(0), Integer(4)]])

R.to_word()
word: 2041100030
```

class sage.combinat.ribbon_tableau.RibbonTableau_class (parent, st)

Bases: RibbonTableau

This exists solely for unpickling RibbonTableau_class objects.

class sage.combinat.ribbon_tableau.RibbonTableaux

Bases: UniqueRepresentation, Parent

Ribbon tableaux.

A ribbon tableau is a skew tableau whose skew shape \textit{shape} is tiled by ribbons of length \textit{length}. The weight \textit{weight} is calculated from the labels on the ribbons.

**Note:** Here we impose the condition that the ribbon tableaux are semistandard.

**INPUT(Optional):**

- \textit{shape} – skew shape as a list of lists or an object of type SkewPartition
- \textit{length} – integer, \textit{shape} is partitioned into ribbons of length \textit{length}
- \textit{weight} – list of integers, computed from the values of non-zero entries labeling the ribbons

**EXAMPLES:**

```python
sage: RibbonTableaux([[2,1],[]], [1,1,1], 1)
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons

sage: R = RibbonTableaux([[5,4,3],[2,1]], [2,1], 3)
sage: for i in R: i.pp(); print("\n")

. . 0 0 0
. 0 0 2
1 0 1
. . 1 0 0
. 0 0 0
1 0 2
. . 0 0 0
. 1 0 1
2 0 0
```

```python
>>> from sage.all import *

>>> RibbonTableaux([[Integer(2),Integer(1)],[]], [Integer(1),Integer(1),
Integer(1)], Integer(1))
Ribbon tableaux of shape [2, 1] / [] and weight [1, 1, 1] with 1-ribbons

>>> R = RibbonTableaux([[Integer(5),Integer(4),Integer(3)],[Integer(2),
Integer(1)],[Integer(2),Integer(1)], Integer(3))

>>> for i in R: i.pp(); print("\n")

. . 0 0 0
. 0 0 2
```

(continues on next page)
REFERENCES:

Element

alias of RibbonTableau

from_expr(l)

Return a RibbonTableau from a MuPAD-Combinat expr for a skew tableau. The first list in expr is the inner shape of the skew tableau. The second list are the entries in the rows of the skew tableau from bottom to top.

Provided primarily for compatibility with MuPAD-Combinat.

EXAMPLES:

sage: RibbonTableaux().from_expr([[1,1],[[5],[3,4],[1,2]]])
[[None, 1, 2], [None, 3, 4], [5]]

>>> from sage.all import *
>>> RibbonTableaux().from_expr([[Integer(1),Integer(1)],[[Integer(5)],
                                      [Integer(3),Integer(4)],[Integer(1),Integer(2)]]])
[[None, 1, 2], [None, 3, 4], [5]]

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: RibbonTableaux([[2,1],[]],[1,1,1],1).cardinality()
2
sage: RibbonTableaux([[2,2],[]],[1,1,2]).cardinality()
2
sage: RibbonTableaux([[4,3],[]],[2,1,1,1],2).cardinality()
5

options = Current options for Tableaux - ascii_art: repr - convention:

   English - display: list - latex: diagram

class sage.combinat.ribbon_tableau.RibbonTableaux_shape_weight_length

   shape, weight, length)

   Bases: RibbonTableaux

   Ribbon tableaux of a given shape, weight, and length.

cardinality()

   Return the cardinality of self.

   EXAMPLES:
class sage.combinat.ribbon_tableau.SemistandardMultiSkewTableaux(shape, weight)

Semistandard multi skew tableaux.

A multi skew tableau is a $k$-tuple of skew tableaux of given shape with a specified total weight.

EXAMPLES:

```
sage: S = SemistandardMultiSkewTableaux([[[2,1],[1]], [[2,2],[1]]], [2,2,2]); S
Semistandard multi skew tableaux of shape [[2, 1] / [], [2, 2] / [1]] and weight...

```

sage.combinat.ribbon_tableau.cospin_polynomial(part, weight, length)

Return the cospin polynomial associated to part, weight, and length.

EXAMPLES:
sage: from sage.combinat.ribbon_tableau import cospin_polynomial
sage: cospin_polynomial([6,6,6],[4,2],3)
t^4 + t^3 + 2*t^2 + t + 1
sage: cospin_polynomial([3,3,3,2,1], [3,1], 3)
1
sage: cospin_polynomial([3,3,3,2,1], [2,2], 3)
t + 1
sage: cospin_polynomial([3,3,3,2,1], [2,1,1], 3)
t^2 + 2*t + 2
sage: cospin_polynomial([3,3,3,2,1], [1,1,1,1], 3)
t^3 + 3*t^2 + 5*t + 3
sage: cospin_polynomial([[6]*6, [3,3]], [4,4,2], 3)
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3

>>> from sage.all import *
>>> from sage.combinat.ribbon_tableau import cospin_polynomial
>>> cospin_polynomial([Integer(6),Integer(6),Integer(6)], [Integer(4),Integer(2)], Integer(3))
t^4 + t^3 + 2*t^2 + t + 1
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)], [Integer(3),Integer(1)], Integer(3))
1
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)], [Integer(2),Integer(2)], Integer(3))
t + 1
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)], [Integer(2),Integer(1),Integer(1)], Integer(3))
t^2 + 2*t + 2
>>> cospin_polynomial([Integer(3),Integer(3),Integer(3),Integer(2),Integer(1)], [Integer(1),Integer(1),Integer(1),Integer(1)], Integer(3))
t^3 + 3*t^2 + 5*t + 3
>>> cospin_polynomial([Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)], [Integer(1),Integer(1)], [Integer(2),Integer(2),Integer(1),Integer(1)], Integer(3))
2*t^2 + 6*t + 2
>>> cospin_polynomial([[Integer(6)]*Integer(6), [Integer(3),Integer(3)]], [Integer(4),Integer(4),Integer(4),Integer(2),Integer(1)], Integer(3))
3*t^4 + 6*t^3 + 9*t^2 + 5*t + 3

sage.combinat.ribbon_tableau.count_rec(nexts, current, part, weight, length)

INPUT:
- nexts, current, part - skew partitions
- weight - non-negative integer list
- length - integer

sage.combinat.ribbon_tableau.graph_implementation_rec(skp, weight, length, function)

sage.combinat.ribbon_tableau.insertion_tableau(skp, perm, evaluation, tableau, length)

INPUT:
- skp - skew partitions
- perm, evaluation - non-negative integers
- tableau - skew tableau

5.1. Comprehensive Module List
• length – integer

`sage.combinat.ribbon_tableau.list_rec(nexts, current, part, weight, length)`

INPUT:

• nexts, current, part – skew partitions
• weight – non-negative integer list
• length – integer

`sage.combinat.ribbon_tableau.spin_polynomial(part, weight, length)`

Returns the spin polynomial associated to part, weight, and length.

EXAMPLES:

```python
sage: # needs sage.symbolic
sage: from sage.combinat.ribbon_tableau import spin_polynomial
sage: spin_polynomial([6,6,6],[4,2],3)
t^6 + t^5 + 2*t^4 + t^3 + t^2
sage: spin_polynomial([6,6,6],[4,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([3,3,3,2,1],[2,2],3)
t^(7/2) + t^(5/2)
sage: spin_polynomial([3,3,3,2,1],[2,1,1],3)
t^6 + 2*t^5 + 3*t^4 + 2*t^3 + t^2
sage: spin_polynomial([3,3,3,2,1],[1,1,1,1],3)
2*t^(7/2) + 6*t^(5/2) + 2*t^(3/2)
sage: spin_polynomial([6]*6,[4,4,2],3)
3*t^9 + 5*t^8 + 9*t^7 + 6*t^6 + 3*t^5
```

`sage.combinat.ribbon_tableau.spin_polynomial_square(part, weight, length)`

Returns the spin polynomial associated with part, weight, and length, with the substitution $t \rightarrow t^2$ made.
EXAMPLES:

```
sage: from sage.combinat.ribbon_tableau import spin_polynomial_square
sage: spin_polynomial_square([6,6,6],[4,2],3)
t^12 + t^10 + 2*t^8 + t^6 + t^4
sage: spin_polynomial_square([6,6,6],[4,1,1],3)
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
sage: spin_polynomial_square([3,3,3,2,1], [2,2], 3)
t^7 + t^5
sage: spin_polynomial_square([3,3,3,2,1], [2,1,1], 3)
2*t^7 + 2*t^5 + t^3
sage: spin_polynomial_square([3,3,3,2,1], [1,1,1,1], 3)
3*t^7 + 5*t^5 + 3*t^3 + t
sage: spin_polynomial_square([5,4,3,2,1,1], [2,2,1], 3)
2*t^9 + 6*t^7 + 2*t^5
sage: spin_polynomial_square([[6]*6, [3,3]], [4,4,2], 3)
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```

```
>>> from sage.all import *
>>> from sage.combinat.ribbon_tableau import spin_polynomial_square
>>> spin_polynomial_square([Integer(6),Integer(6),Integer(6)], [Integer(4), Integer(2)], Integer(3))
t^12 + t^10 + 2*t^8 + t^6 + t^4
>>> spin_polynomial_square([Integer(6),Integer(6),Integer(6)], [Integer(4), Integer(1),Integer(1)], Integer(3))
t^12 + 2*t^10 + 3*t^8 + 2*t^6 + t^4
>>> spin_polynomial_square([Integer(3),Integer(3),Integer(3),Integer(2), Integer(1)], [Integer(2),Integer(2)], Integer(3))
t^7 + t^5
>>> spin_polynomial_square([Integer(3),Integer(3),Integer(3),Integer(2), Integer(1)], [Integer(2),Integer(1),Integer(1)], Integer(3))
2*t^7 + 2*t^5 + t^3
>>> spin_polynomial_square([Integer(3),Integer(3),Integer(3),Integer(2), Integer(1)], [Integer(1),Integer(1),Integer(1)], Integer(3))
3*t^7 + 5*t^5 + 3*t^3 + t
>>> spin_polynomial_square([Integer(5),Integer(4),Integer(3),Integer(2), Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(2),Integer(1)], Integer(3))
2*t^9 + 6*t^7 + 2*t^5
>>> spin_polynomial_square([[Integer(6)]*Integer(6), [Integer(3),Integer(3)]], [Integer(4),Integer(4),Integer(2)], Integer(3))
3*t^18 + 5*t^16 + 9*t^14 + 6*t^12 + 3*t^10
```
sage: spin_rec(t, [], [[], [3, 3]], sp([[2, 2, 2], []], [2, 3])

[2*t^7 + 2*t^5 + t^3]
5.1.197 Rigged configurations

Todo: Proofread / point to the main classes rather than the modules?

- Crystal of Rigged Configurations
- Rigged Configurations of \mathcal{B}(\infty)
- Rigged Configurations
- Rigged Configuration Elements
- Tensor Product of Kirillov-Reshetikhin Tableaux
- Tensor Product of Kirillov-Reshetikhin Tableaux Elements
- Kirillov-Reshetikhin Tableaux
- Kleber Trees
- Rigged Partitions

Bijectons

- Bijection between rigged configurations and KR tableaux
- Abstract classes for the rigged configuration bijections
- Bijection classes for type $A_n^{(1)}$
- Bijection classes for type $B_n^{(1)}$
- Bijection classes for type $C_n^{(1)}$
- Bijection classes for type $D_n^{(1)}$
- Bijection classes for type $A_{2n-1}^{(2)}$
- Bijection classes for type $A_{2n}^{(2)}$
- Bijection classes for type $A_{2n}^{(2)\dagger}$
- Bijection classes for type $D_{n+1}^{(2)}$
- Bijection classes for type $D_4^{(3)}$
- Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux

5.1.198 Abstract classes for the rigged configuration bijections

This file contains two sets of classes, one for the bijection from KR tableaux to rigged configurations and the other for the reverse bijection. We do this for two reasons, one is because we can store a state in the bijection locally, so we do not have to constantly pass it around between functions. The other is because it makes the code easier to read in the *_element.py files.

These classes are not meant to be used by the user and are only supposed to be used internally to perform the bijections between TensorProductOfKirillovReshetikhinTableaux and RiggedConfigurations.

AUTHORS:

class sage.combinat.rigged_configurations.bij_abstract_class.KRTToRCBijectionAbstract(tp_krt)
    Bases: object

    Root abstract class for the bijection from KR tableaux to rigged configurations.
    This class holds the state of the bijection and generates the next state. This class should
    never be created directly.

    next_state(val)
        Build the next state in the bijection.
        INPUT:
            • val – The value we are adding

    run(verbos=False)
        Run the bijection from a tensor product of KR tableaux to a rigged configuration.
        INPUT:
            • tp_krt – A tensor product of KR tableaux
            • verbose – (Default: False) Display each step in the bijection

    EXAMPLES:

    sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1],
            [[2, 1]])
    sage: from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
    sage: KRTToRCBijectionTypeA(KRT(pathlist=[[5, 2]]).run()
    -1[-]1
    1[ ]1
    0[ ]0
    -1[-]1

    >>> from sage.all import *
    >>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',
            4, 1], [[2, 1]])
    >>> from sage.combinat.rigged_configurations.bij_type_A import KRTToRCBijectionTypeA
    >>> KRTToRCBijectionTypeA(KRT(pathlist=[[5, 2]])).run()
    -1[-]1
    1[ ]1
    0[ ]0
    -1[-]1

class sage.combinat.rigged_configurations.bij_abstract_class.RCToKRTBijectionAbstract(RC_element)
    Bases: object

    Root abstract class for the bijection from rigged configurations to tensor product of Kirillov-Reshetikhin tableaux.
This class holds the state of the bijection and generates the next state. This class should never be created directly.

`next_state` *(height)*

Build the next state in the bijection.

`run` *(verbose=False, build_graph=False)*

Run the bijection from rigged configurations to tensor product of KR tableaux.

**INPUT:**

- `verbose` — (default: False) display each step in the bijection
- `build_graph` — (default: False) build the graph of each step of the bijection

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1],[1],[1],[1]])
sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
sage: RCToKRTBijectionTypeA(x).run()
[[2], [5]]
sage: bij = RCToKRTBijectionTypeA(x)
sage: bij.run(build_graph=True)
[[2], [5]]
sage: bij._graph
Digraph on 3 vertices
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2),
˓→Integer(1)]]
>>> x = RC(partition_list=[[Integer(1)],[Integer(1)],[Integer(1)],
˓→[Integer(1)]]))
>>> from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
>>> RCToKRTBijectionTypeA(x).run()
[[2], [5]]
>>> bij = RCToKRTBijectionTypeA(x)
>>> bij.run(build_graph=True)
[[2], [5]]
>>> bij._graph
Digraph on 3 vertices
```

### 5.1.199 Bijection between rigged configurations for $B(\infty)$ and marginally large tableaux

**AUTHORS:**

- Travis Scrimshaw (2015-07-01): Initial version

**REFERENCES:**

**class** `sage.combinat.rigged_configurations.bij_infinity.FromRCIsomorphism`

Bases: `Morphism`

Crystal isomorphism of $B(\infty)$ in the rigged configuration model to the tableau model.
class sage.combinat.rigged_configurations.bij_infinity.FromTableauIsomorphism
    Bases: Morphism

    Crystal isomorphism of $B(\infty)$ in the tableau model to the rigged configuration model.

class sage.combinat.rigged_configurations.bij_infinity.MLTToRCBijectionTypeB(tp_krt)
    Bases: KRTToRCBijectionTypeB

    run()
    
    Run the bijection from a marginally large tableaux to a rigged configuration.

    EXAMPLES:

    sage: vct = CartanType(['B',4]).as_folding()
    sage: RC = crystals.infinity.RiggedConfigurations(vct)
    sage: T = crystals.infinity.Tableaux(['B',4])
    sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_→generators[0]})
    sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
    sage: all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest
    True

    >>> from sage.all import *
    >>> vct = CartanType(['B',Integer(4)]).as_folding()
    >>> RC = crystals.infinity.RiggedConfigurations(vct)
    >>> T = crystals.infinity.Tableaux(['B',Integer(4)])
    >>> Psi = T.crystal_morphism({T.module_generators[Integer(0)]: RC.module_→generators[Integer(0)]})
    >>> TS = [x.value for x in T.subcrystal(max_depth=Integer(4))]  
    >>> all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest 
    True

class sage.combinat.rigged_configurations.bij_infinity.MLTToRCBijectionTypeD(tp_krt)
    Bases: KRTToRCBijectionTypeD

    run()
    
    Run the bijection from a marginally large tableaux to a rigged configuration.

    EXAMPLES:

    sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
    sage: T = crystals.infinity.Tableaux(['D',4])
    sage: Psi = T.crystal_morphism({T.module_generators[0]: RC.module_→generators[0]})
    sage: TS = [x.value for x in T.subcrystal(max_depth=4)]
    sage: all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest
    True

    >>> from sage.all import *
    >>> RC = crystals.infinity.RiggedConfigurations(['D',Integer(4)])
    >>> T = crystals.infinity.Tableaux(['D',Integer(4)])
    >>> Psi = T.crystal_morphism({T.module_generators[Integer(0)]: RC.module_→generators[Integer(0)]})
    >>> TS = [x.value for x in T.subcrystal(max_depth=Integer(4))] 
    >>> all(Psi(b) == RC(b) for b in TS) # long time # indirect doctest 
    True
class sage.combinat.rigged_configurations.bij_infinity.RCToMLTBijectionTypeB

Bases: RCToKRTBijectionTypeB

run()

Run the bijection from rigged configurations to a marginally large tableau.

EXAMPLES:

```python
sage: vct = CartanType(['B',4]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: T = crystals.infinity.Tableaux(['B',4])
sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
sage: all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
True
```

```python
>>> from sage.all import *
>>> vct = CartanType(['B',Integer(4)]).as_folding()
>>> RC = crystals.infinity.RiggedConfigurations(vct)
>>> T = crystals.infinity.Tableaux(['B',Integer(4)])
>>> Psi = RC.crystal_morphism({RC.module_generators[Integer(0)]: T.module_generators[Integer(0)]})
>>> RCS = [x.value for x in RC.subcrystal(max_depth=Integer(4))]  
>>> all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
True
```

class sage.combinat.rigged_configurations.bij_infinity.RCToMLTBijectionTypeD

Bases: RCToKRTBijectionTypeD

run()

Run the bijection from rigged configurations to a marginally large tableau.

EXAMPLES:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['D',4])
sage: T = crystals.infinity.Tableaux(['D',4])
sage: Psi = RC.crystal_morphism({RC.module_generators[0]: T.module_generators[0]})
sage: RCS = [x.value for x in RC.subcrystal(max_depth=4)]
sage: all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
True
```

```python
>>> from sage.all import *
>>> RC = crystals.infinity.RiggedConfigurations(['D',Integer(4)])
>>> T = crystals.infinity.Tableaux(['D',Integer(4)])
>>> Psi = RC.crystal_morphism({RC.module_generators[Integer(0)]: T.module_generators[Integer(0)]})
>>> RCS = [x.value for x in RC.subcrystal(max_depth=Integer(4))]  
>>> all(Psi(nu) == T(nu) for nu in RCS) # long time # indirect doctest
True
```
5.1.200 Bijection classes for type $A_n^{(1)}$

Part of the (internal) classes which run the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux of type $A_n^{(1)}$.

AUTHORS:

```python
class sage.combinat.rigged_configurations.bij_type_A.KRToRCBijectionTypeA(tp_krt):
    Bases: KRTToRCBijectionAbstract
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_n^{(1)}$.

    next_state(val)
    Build the next state for type $A_n^{(1)}$.

    EXAMPLES:

    sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([A, 4, 1], [[[2, 1]]])
    sage: from sage.combinat.rigged_configurations.bij_type_A import KRToRCBijectionTypeA
    sage: bijection = KRToRCBijectionTypeA(KRT(pathlist=[[4, 3]]))
    sage: bijection.next_state(3)

>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([A, Integer(4), Integer(1)], [[Integer(2), Integer(1)]]),
>>> from sage.combinat.rigged_configurations.bij_type_A import KRToRCBijectionTypeA
>>> bijection = KRToRCBijectionTypeA(KRT(pathlist=[Integer(4), Integer(3)]))
>>> bijection.next_state(Integer(3))
```

class sage.combinat.rigged_configurations.bij_type_A.RCToKRTBijectionTypeA(RC_element):
    Bases: RCToKRTBijectionAbstract
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_n^{(1)}$.

    next_state(height)
    Build the next state for type $A_n^{(1)}$.

    EXAMPLES:

    sage: RC = RiggedConfigurations([A, 4, 1], [[2, 1]])
    sage: from sage.combinat.rigged_configurations.bij_type_A import RCToKRTBijectionTypeA
    sage: bijection = RCToKRTBijectionTypeA(RC(partition_list=[[1], [1], [1], [1]]))
```

(continues on next page)
5.1.201 Bijection classes for type $A_{2n}^{(2)\dagger}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)\dagger}$.

AUTHORS:
- Travis Scrimshaw (2012-12-21): Initial version

```python
class sage.combinat.rigged_configurations.bij_type_A2_dual.KRTToRCBijectionTypeA2Dual(tp_krt):
    Bases: KRTToRCBijectionTypeC
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)\dagger}$.
    This inherits from type $C_n^{(1)}$ because we use the same methods in some places.
    next_state(val)
        Build the next state for type $A_{2n}^{(2)\dagger}$.

class sage.combinat.rigged_configurations.bij_type_A2_dual.RCToKRTBijectionTypeA2Dual(RC_element):
    Bases: RCToKRTBijectionTypeC
    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)\dagger}$.
    next_state(height)
        Build the next state for type $A_{2n}^{(2)\dagger}$.
```

5.1.202 Bijection classes for type $A_{2n}^{(2)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $A_{2n}^{(2)}$.

AUTHORS:
- Travis Scrimshaw (2012-12-21): Initial version

```python
class sage.combinat.rigged_configurations.bij_type_A2_even.KRTToRCBijectionTypeA2Even(tp_krt):
    Bases: KRTToRCBijectionTypeC
    Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n}^{(2)}$.
```
This inherits from type $C_n(1)$ because we use the same methods in some places.

```python
next_state(val)
```

Build the next state for type $A_{2n}^{(2)}$.

class sage.combinat.rigged_configurations.bij_type_A2_even.RCToKRTBijectionTypeA2Even(RC_element)

Bases: RCToKRTBijectionTypeC

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n}^{(2)}$.

```python
next_state(height)
```

Build the next state for type $A_{2n}^{(2)}$.

### 5.1.203 Bijection classes for type $A_{2n-1}^{(2)}$

Part of the (internal) classes which run the bijection between rigged configurations and KR tableaux of type $A_{2n-1}^{(2)}$.

AUTHORS:
- Travis Scrimshaw (2012-12-21): Initial version

class sage.combinat.rigged_configurations.bij_type_A2_odd.KRTToRCBijectionTypeA2Odd(tp_krt)

Bases: KRTToRCBijectionTypeA

Specific implementation of the bijection from KR tableaux to rigged configurations for type $A_{2n-1}^{(2)}$.

This inherits from type $A_n(1)$ because we use the same methods in some places.

```python
next_state(val)
```

Build the next state for type $A_{2n-1}^{(2)}$.

class sage.combinat.rigged_configurations.bij_type_A2_odd.RCToKRTBijectionTypeA2Odd(RC_element)

Bases: RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $A_{2n-1}^{(2)}$.

```python
next_state(height)
```

Build the next state for type $A_{2n-1}^{(2)}$.

### 5.1.204 Bijection classes for type $B_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $B_n^{(1)}$.

AUTHORS:
- Travis Scrimshaw (2012-12-21): Initial version
class sage.combinat.rigged_configurations.bij_type_B.KRTToRCBijectionTypeB(tp_krt)
Bases: KRTToRCBijectionTypeC

Specific implementation of the bijection from KR tableaux to rigged configurations for type $B_n^{(1)}$.

next_state (val)
Build the next state for type $B_n^{(1)}$.

other_outcome (rc, pos_val, width_n)
Do the other case $(QS)$ possibility.
This arises from the ambiguity when we found a singular string at the max width in $\nu^{(n)}$. We had first attempted case $(S)$, and if that resulted in an invalid rigged configuration, we now finish the bijection using case $(QS)$.

EXAMPLES:

```
sage: RC = RiggedConfigurations(['B', 3, 1], [[2, 1], [1, 2]])
sage: rc = RC(partition_list=[[2, 1], [1, 2]])
sage: t = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux()
sage: t.to_rigged_configuration() == rc  # indirect doctest
True
```

```python
>> from sage.all import *
>> RC = RiggedConfigurations(['B', Integer(3), Integer(1)], [[Integer(2), Integer(1)],[Integer(1), Integer(2)]]
>> rc = RC(partition_list=[[Integer(2), Integer(1)],[Integer(1), Integer(2)]]
>> t = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux()
>> t.to_rigged_configuration() == rc  # indirect doctest
True
```

run (verbose=False)
Run the bijection from a tensor product of KR tableaux to a rigged configuration.

INPUT:

- tp_krt – A tensor product of KR tableaux
- verbose – (Default: False) Display each step in the bijection

EXAMPLES:

```
sage: from sage.combinat.rigged_configurations.bij_type_B import KRTToRCBijectionTypeB
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['B', 3, 1],
              [[2, 1]])
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.bij_type_B import KRTToRCBijectionTypeB

[[1], [3], [-2]]
>>> bij._graph
Digraph on 6 vertices
```

```python
>>> from sage.combinat.rigged_configurations.bij_type_C import RCToKRTBijectionTypeC

```
Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $C_n^{(1)}$.

next_state (height)

Build the next state for type $C_n^{(1)}$.

5.1.206 Bijection classes for type $D_n^{(1)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_n^{(1)}$.

AUTHORS:

```python
class sage.combinat.rigged_configurations.bij_type_D.KRTToRCBijectionTypeD(tp_krt)
    Bases: KRTToRCBijectionTypeA

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_n^{(1)}$.
    This inherits from type $A_n^{(1)}$ because we use the same methods in some places.

doubling_map ()
    Perform the doubling map of the rigged configuration at the current state of the bijection.
    This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map ()
    Perform the halving map of the rigged configuration at the current state of the bijection.
    This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

next_state (val)
    Build the next state for type $D_n^{(1)}$.

run (verbose=False)
    Run the bijection from a tensor product of KR tableaux to a rigged configuration for type $D_n^{(1)}$.

    INPUT:
    • tp_krt – A tensor product of KR tableaux
    • verbose – (Default: False) Display each step in the bijection

    EXAMPLES:
```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(["D", 4, 1],...
    \rightarrow[[2,1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import...
    \rightarrowKRTToRCBijectionTypeD
sage: KRTToRCBijectionTypeD(KRT(pathlist=[[[-3,2]]])).run()

2[ ]2
-1[ ]-1
```

(continues on next page)
from sage.all import *

crystals = import *

KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([D, 4, 1], [[2, 1]])

KRTToRCBijectionTypeD(KRT(pathlist=[[-3, 2]])).run()

class sage.combinat.rigged_configurations.bij_type_D.RCToKRTBijectionTypeD (RC_el-

Bases: RCToKRTBijectionTypeA

Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D^{(1)}_n$.

doubling_map()

Perform the doubling map of the rigged configuration at the current state of the bijection.

This is the map $B(\Lambda) \mapsto B(2\Lambda)$ which doubles each of the rigged partitions and updates the vacancy numbers accordingly.

halving_map()

Perform the halving map of the rigged configuration at the current state of the bijection.

This is the inverse map to $B(\Lambda) \mapsto B(2\Lambda)$ which halves each of the rigged partitions and updates the vacancy numbers accordingly.

next_state(height)

Build the next state for type $D^{(1)}_n$.

run(verbos=False, build_graph=False)

Run the bijection from rigged configurations to tensor product of KR tableaux for type $D^{(1)}_n$.

INPUT:

• verbose=True (default: False) display each step in the bijection

• build_graph=True (default: False) build the graph of each step of the bijection

EXAMPLES:
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: x = RC(partition_list=[[1], [1], [1], [1]])
sage: from sage.combinat.rigged_configurations.bij_type_D import ..

(continues on next page)
5.1.207 Bijection classes for type $D_{n+1}^{(2)}$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D_{n+1}^{(2)}$.

**AUTHORS:**

```python
class sage.combinat.rigged_configurations.bij_type_D_twisted.KRTToRCBijectionTypeDTwisted(tp_krt):
    Bases: KRTToRCBijectionTypeD, KRTToRCBijectionTypeA2Even

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $D_{n+1}^{(2)}$.

    This inherits from type $C_{n}^{(1)}$ and $D_{n}^{(1)}$ because we use the same methods in some places.

    next_state(val)
        Build the next state for type $D_{n+1}^{(2)}$.

    run(verbos=False)
        Run the bijection from a tensor product of KR tableaux to a rigged configuration for type $D_{n+1}^{(2)}$.

        INPUT:

        - tp_krt -- A tensor product of KR tableaux
        - verbose -- (Default: False) Display each step in the bijection

        EXAMPLES:
```

```python
>>> from sage.all import *

    Digraph on 6 vertices
5.1.208 Bijection classes for type $D^{(3)}_4$

Part of the (internal) classes which runs the bijection between rigged configurations and KR tableaux of type $D^{(3)}_4$.

AUTHORS:

- Travis Scrimshaw (2014-09-10): Initial version

```python
class sage.combinat.rigged_configurations.bij_type_D_tri.KRTToRCBijectionTypeDTri(tp_krt):
    Bases: KRTToRCBijectionTypeA

    Specific implementation of the bijection from KR tableaux to rigged configurations for type $D^{(3)}_4$.
    This inherits from type $A^{(1)}_n$ because we use the same methods in some places.

    next_state(val)
        Build the next state for $D^{(3)}_4$.

class sage.combinat.rigged_configurations.bij_type_D_tri.RCToKRTBijectionTypeDTri(RC_element):
    Bases: RCToKRTBijectionTypeA

    Specific implementation of the bijection from rigged configurations to tensor products of KR tableaux for type $D^{(3)}_4$.

    next_state(height)
        Build the next state for $D^{(3)}_4$.
```

5.1.209 Bijection between rigged configurations and KR tableaux

Functions which are big switch statements to create the bijection class of the correct type.

AUTHORS:

- Travis Scrimshaw (2012-12-21): Added all non-exceptional bijection types
- Travis Scrimshaw (2014-09-10): Added type $D^{(3)}_4$
sage.combinat.rigged_configurations.bijection.KRTToRCBijection(tp_krt)

Return the correct KR tableaux to rigged configuration bijection helper class.

sage.combinat.rigged_configurations.bijection.RCToKRTBijection(rigged_configuration_elt)

Return the correct rigged configuration to KR tableaux bijection helper class.

## 5.1.210 Kleber Trees

A Kleber tree is a tree of weights generated by Kleber’s algorithm [Kleber1]. The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots of the difference.

**AUTHORS:**

- Travis Scrimshaw (2011-05-03): Initial version
- Travis Scrimshaw (2013-02-13): Added support for virtual trees and improved \LaTeX output

**EXAMPLES:**

```
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
Kleber tree of Cartan type ['A', 3, 1] and B = ((3, 2), (2, 1), (1, 1), (1, 1))
sage: KleberTree(['D', 4, 1], [[2,2]])
Kleber tree of Cartan type ['D', 4, 1] and B = ((2, 2),)
```

```
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import KleberTree

>>> KleberTree(['A', Integer(3), Integer(1)], [[Integer(3),Integer(2)], [Integer(1),Integer(1)], [Integer(1),Integer(1)]])
Kleber tree of Cartan type ['A', 3, 1] and B = ((3, 2), (2, 1), (1, 1), (1, 1))
>>> KleberTree(['D', Integer(4), Integer(1)], [[Integer(2),Integer(2)]])
Kleber tree of Cartan type ['D', 4, 1] and B = ((2, 2),)
```

```python
class sage.combinat.rigged_configurations.kleber_tree.KleberTree(cartan_type, B, classical_ct)

Bases: UniqueRepresentation, Parent

The tree that is generated by Kleber’s algorithm.

A Kleber tree is a tree of weights generated by Kleber's algorithm [Kleber1]. It is used to generate the set of all admissible rigged configurations for the simply-laced affine types $A_n^{(1)}$, $D_n^{(1)}$, $E_6^{(1)}$, $E_7^{(1)}$, and $E_8^{(1)}$.

**See also:**

There is a modified version for non-simply-laced affine types at `VirtualKleberTree`.

The nodes correspond to the weights in the positive Weyl chamber obtained by subtracting a (non-zero) positive root. The edges are labeled by the coefficients of the roots, and $X$ is a child of $Y$ if $Y$ is the root else if the edge label of $Y$ to its parent $Z$ is greater (in every component) than the label from $X$ to $Y$.

For a Kleber tree, one needs to specify an affine (simply-laced) Cartan type and a sequence of pairs $(r, s)$, where $s$ is any positive integer and $r$ is a node in the Dynkin diagram. Each $(r, s)$ can be viewed as a rectangle of width $s$ and height $r$.

**INPUT:**

- `cartan_type` – an affine simply-laced Cartan type
• \( \mathbf{B} \) – a list of dimensions of rectangles by \([r, c]\) where \( r \) is the number of rows and \( c \) is the number of columns

REFERENCES:

EXAMPLES:

Simply-laced example:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[3,2], [1,1]])
sage: KT.list()
[Kleber tree node with weight [1, 0, 2] and upwards edge root [0, 0, 0],
Kleber tree node with weight [0, 0, 1] and upwards edge root [1, 1, 1]]
sage: KT = KleberTree(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]])
sage: KT.cardinality()
10
sage: KT = KleberTree(['D', 4, 1], [[2,2]])
sage: KT.cardinality()
3
sage: KT = KleberTree(['D', 4, 1], [[4,5]])
sage: KT.cardinality()
1
```

From [Kleber2]:

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import KleberTree
>>> KT = KleberTree(['E', 6, 1], [[4, 2]]) # long time (9s on sage.math, 2012)
>>> KT.cardinality() # long time
12
```

We check that relabelled types work (Issue #16876):

```python
sage: ct = CartanType(['A',3,1]).relabel(lambda x: x+2)
sage: kt = KleberTree(ct, [[3,1],[5,1]])
sage: list(kt)
(continues on next page)
```
from sage.all import *
c
ct = CartanType(['A', Integer(3), Integer(1)]).relabel(lambda x: x+Integer(2))
c
t = KleberTree(ct, [[Integer(3), Integer(1)], [Integer(3), Integer(1)]])
c
list(t)

Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 0, 0],
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 1, 1]
c
cartan_type()

Return the Cartan type of this Kleber tree.

EXAMPLES:

sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]

5.1. Comprehensive Module List
```python
sage: KT.cartan_type()
['A', 3, 1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import KleberTree
>>> KT = KleberTree(['A', Integer(3), Integer(1)], [[Integer(1),Integer(1)]])
```

```python
>>> KT.cartan_type()
['A', 3, 1]
```

**depth_first_iter()**

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['A', 3, 1], [[2, 2], [2, 3]])
```

```python
for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import KleberTree
>>>
```

```python
KT = KleberTree(['A', Integer(3), Integer(1)], [[Integer(2), Integer(2)], [Integer(2), Integer(3)]])
```

```python
for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 5, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 3, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 3, 0] and upwards edge root [1, 2, 1]
Kleber tree node with weight [1, 1, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 2, 1]
```

**digraph()**

Return a DiGraph representation of this Kleber tree.

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
```

```python
KT.digraph()
Digraph on 3 vertices
```

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import KleberTree
>>> KT = KleberTree(['D', Integer(4), Integer(1)], [[Integer(2), Integer(2)],[Integer(2), Integer(3)]])
```

```python
KT.digraph()
Digraph on 3 vertices
```

**latex_options(****options**)**

Return the current latex options if no arguments are passed, otherwise set the corresponding latex option.

**OPTIONS:**
Combinatorics, Release 10.4

- `hspace` – (default: 2.5) the horizontal spacing of the tree nodes
- `vspace` – (default: \(x\)) the vertical spacing of the tree nodes, here \(x\) is the minimum of \(-2.5\) or \(-0.75n\) where \(n\) is the rank of the classical type
- `edge_labels` – (default: True) display edge labels
- `use_vector_notation` – (default: False) display edge labels using vector notation instead of a linear combination

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 3, 1], [[2,1], [2,1]])
```

```python
sage: KT.latex_options(vspace=-4, use_vector_notation=True)
```

```python
sage: sorted(KT.latex_options().items())
```

```python
[(edge_labels, True), (hspace, 2.5), (use_vector_notation, True), ('vspace', -4)]
```

```python
plot(**options)
```

Return the plot of self as a directed graph.

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree(['D', 4, 1], [[2, 2]])
```

```python
sage: print(KT.plot())
```

```python
Graphics object consisting of 8 graphics primitives
```

```python
class sage.combinat.rigged_configurations.kleber_tree.KleberTreeNode (parent_obj, node_weight, dominant_root, parent_node=None)
```

**Bases:** `Element`

A node in the Kleber tree.

This class is meant to be used internally by the Kleber tree class and should not be created directly by the user.

For more on the Kleber tree and the nodes, see `KleberTree`.  

5.1. Comprehensive Module List 3479
The dominating root is the up_root which is the difference between the parent node’s weight and this node’s weight.

INPUT:

- parent_obj – The parent object of this element
- node_weight – The weight of this node
- dominant_root – The dominating root
- parent_node – (default:None) The parent node of this node

depth()

Return the depth of this node in the tree.

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: RS = RootSystem(['A', 2])
sage: WS = RS.weight_lattice()
sage: R = RS.root_lattice()
sage: KT = KleberTree(['A', 2, 1], [[1,1]])
sage: n = KT(WS.sum_of_terms(([1,5], (2,2))), R.zero())
sage: n.depth
0
sage: n2 = KT(WS.sum_of_terms(([1,5], (2,2))), R.zero(), n)
sage: n2.depth
1
```

multiplicity()

Return the multiplicity of self.

The multiplicity of a node $x$ of depth $d$ weight $\lambda$ in a simply-laced Kleber tree is equal to:

$$
\prod_{i>0} \prod_{a \in T} \left( \frac{p_i^{(a)} + m_i^{(a)}}{p_i^{(a)}} \right)
$$

Recall that

$$
m_i^{(a)} = \left( \lambda^{(i-1)} - 2\lambda^{(i)} + \lambda^{(i+1)} \mid \Lambda \right),
$$

$$
p_i^{(a)} = (\alpha_a \mid \lambda^{(i)}) - \sum_{j>i} (j-i) \Lambda_j^{(a)},
$$
where $\lambda^{(i)}$ is the weight node at depth $i$ in the path to $x$ from the root and we set $\lambda^{(j)} = \lambda$ for all $j \geq d$.

Note that $m_i^{(a)} = 0$ for all $i > d$.

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import KleberTree
sage: KT = KleberTree([['A', 3, 1], [[3, 2], [2, 1], [1, 1], [1, 1]]])
sage: for x in KT: x, x.multiplicity()
(Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 0, 0], 1)
(Kleber tree node with weight [3, 0, 1] and upwards edge root [0, 1, 1], 1)
(Kleber tree node with weight [0, 2, 2] and upwards edge root [1, 0, 0], 1)
(Kleber tree node with weight [1, 0, 3] and upwards edge root [1, 1, 0], 2)
(Kleber tree node with weight [1, 1, 1] and upwards edge root [1, 1, 1], 4)
(Kleber tree node with weight [0, 0, 2] and upwards edge root [2, 2, 1], 2)
(Kleber tree node with weight [2, 0, 0] and upwards edge root [0, 1, 1], 2)
(Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 1, 0], 1)
(Kleber tree node with weight [0, 1, 0] and upwards edge root [0, 0, 1], 1)

>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import KleberTree
>>> KT = KleberTree([['A', Integer(3), Integer(1)], [[Integer(3), Integer(2)],
    [Integer(2), Integer(1)], [Integer(1), Integer(1)], [Integer(1), Integer(1)]]])
>>> for x in KT: x, x.multiplicity()
(Kleber tree node with weight [2, 1, 2] and upwards edge root [0, 0, 0], 1)
(Kleber tree node with weight [3, 0, 1] and upwards edge root [0, 1, 1], 1)
(Kleber tree node with weight [0, 2, 2] and upwards edge root [1, 0, 0], 1)
(Kleber tree node with weight [1, 0, 3] and upwards edge root [1, 1, 0], 2)
(Kleber tree node with weight [1, 1, 1] and upwards edge root [1, 1, 1], 4)
(Kleber tree node with weight [0, 0, 2] and upwards edge root [2, 2, 1], 2)
(Kleber tree node with weight [2, 0, 0] and upwards edge root [0, 1, 1], 2)
(Kleber tree node with weight [0, 1, 0] and upwards edge root [1, 1, 0], 1)
(Kleber tree node with weight [0, 1, 0] and upwards edge root [0, 0, 1], 1)
```

```
Bases: VirtualKleberTree

Kleber tree for types $A_{2n}^{(2)}$ and $A_{2n}^{(2)\dagger}$.

Note that here for $A_{2n}^{(2)}$ we use $\tilde{\gamma}_a$ in place of $\gamma_a$ in constructing the virtual Kleber tree, and so we end up selecting all nodes since $\tilde{\gamma}_a = 1$ for all $a \in T$. For type $A_{2n}^{(2)\dagger}$, we have $\gamma_a = 1$ for all $a \in T$.

See also:

VirtualKleberTree

`breadth_first_iter` (all_nodes=False)

Iterate over all nodes in the tree following a breadth-first traversal.

INPUT:

- `all_nodes` – (default: False) if True, output all nodes in the tree

EXAMPLES:
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in KT.breadth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]

**depth_first_iter**(all_nodes=False)
Iterate (recursively) over the nodes in the tree following a depth-first traversal.

**INPUT:**

- all_nodes – (default: False) if True, output all nodes in the tree

**EXAMPLES:**

sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['A', 4, 2], [[2,1]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
sage: for x in KT.depth_first_iter(True): x
Kleber tree node with weight [0, 2, 0] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
Kleber tree node with weight [0, 0, 0] and upwards edge root [1, 2, 1]
class sage.combinat.rigged_configurations.kleber_tree.VirtualKleberTree(cartan_type, B)

Bases: KleberTree

A virtual Kleber tree.

We can use a modified version of the Kleber algorithm called the virtual Kleber algorithm [OSS03] to compute all admissible rigged configurations for non-simply-laced types. This uses the following embeddings into the simply-laced types:

\[ C^{(1)}_n, A^{(2)}_{2n}, A^{(2)}_{2n+1} \hookrightarrow A^{(1)}_{2n-1} \]

\[ A^{(2)}_{2n-1}, B^{(1)}_n \hookrightarrow D^{(1)}_{n+1} \]

\[ E^{(2)}_6, F^{(4)}_4 \hookrightarrow E^{(1)}_6 \]

\[ D^{(3)}_4, G^{(1)}_2 \hookrightarrow D^{(1)}_4 \]

One then selects the subset of admissible nodes which are translates of the virtual requirements. In the graph, the selected nodes are indicated by brackets [\[\]].

**Note:** Because these are virtual nodes, all information is given in the corresponding simply-laced type.

**See also:**

For more on the Kleber algorithm, see *KleberTree*.

**REFERENCES:**

**INPUT:**

- cartan_type – an affine non-simply-laced Cartan type
- B – a list of dimensions of rectangles by \([r, c]\) where \(r\) is the number of rows and \(c\) is the number of columns

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import *

sage: KT = VirtualKleberTree(['C', 4, 1], [[2,2]])
sage: KT.cardinality()
3
sage: KT.base_tree().cardinality()
6
sage: KT = VirtualKleberTree(['C', 4, 1], [[4,5]])
sage: KT.cardinality()
1
sage: KT = VirtualKleberTree(['D', 5, 2], [[2,1], [1,1]])
sage: KT.cardinality()
8
sage: KT = VirtualKleberTree(CartanType(['A', 4, 2]).dual(), [[1,1], [2,2]])
sage: KT.cardinality()
15
```
```python
from sage.all import *
from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree

KT = VirtualKleberTree(['C', Integer(4), Integer(1)], [[Integer(2), Integer(2)]]
KT.cardinality()
3
KT.base_tree().cardinality()
6
KT = VirtualKleberTree(['C', Integer(4), Integer(1)], [[Integer(4), Integer(5)]]
KT.cardinality()
1
KT = VirtualKleberTree(['D', Integer(5), Integer(2)], [[Integer(2), Integer(1)], [Integer(1), Integer(1)]]
KT.cardinality()
8
KT = VirtualKleberTree(CartanType(['A', Integer(4), Integer(2)]).dual(),
[[Integer(1), Integer(1)], [Integer(2), Integer(2)]]
KT.cardinality()
15
```

**base_tree()**

Return the underlying virtual Kleber tree associated to self.

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[2,2]])
sage: KT.base_tree()
Kleber tree of Cartan type ['A', 7, 1] and B = ((2, 2), (6, 2))
```

```python
sage: from sage.all import *
from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
>>> KT = VirtualKleberTree(['C', Integer(4), Integer(1)], [[Integer(2), Integer(2)]]
>>> KT.base_tree()
Kleber tree of Cartan type ['A', 7, 1] and B = ((2, 2), (6, 2))
```

**breadth_first_iter**(all_nodes=False)

Iterate over all nodes in the tree following a breadth-first traversal.

**INPUT:**

- all_nodes – (default: False) if True, output all nodes in the tree

**EXAMPLES:**

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[2,1]])
sage: for x in KT.breadth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```

```python
sage: for x in KT.breadth_first_iter(True):
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
```

Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
>>> KT = VirtualKleberTree(['C', Integer(2), Integer(1)], [[Integer(1), Integer(1)], [Integer(2),Integer(1)]])
>>> for x in KT.breadth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
>>> for x in KT.breadth_first_iter(True): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```

```
depth_first_iter (all_nodes=False)

Iterate (recursively) over the nodes in the tree following a depth-first traversal.

INPUT:

- all_nodes – (default: False) if True, output all nodes in the tree

EXAMPLES:

```python
sage: from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
sage: KT = VirtualKleberTree(['C', 2, 1], [[1,1], [2,1]])
sage: for x in KT.depth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.rigged_configurations.kleber_tree import VirtualKleberTree
>>> KT = VirtualKleberTree(['C', Integer(2), Integer(1)], [[Integer(1), Integer(1)], [Integer(2),Integer(1)]])
>>> for x in KT.depth_first_iter(): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
>>> for x in KT.depth_first_iter(True): x
Kleber tree node with weight [1, 2, 1] and upwards edge root [0, 0, 0]
Kleber tree node with weight [0, 2, 0] and upwards edge root [1, 1, 1]
Kleber tree node with weight [1, 0, 1] and upwards edge root [0, 1, 0]
```
5.1.211 Kirillov-Reshetikhin Tableaux

Kirillov-Reshetikhin tableaux are rectangular tableaux with $r$ rows and $s$ columns that naturally arise under the bijection between rigged configurations and tableaux [RigConBijection]. They are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{r,s}$ under the (inverse) filling map [OSS13] [SS2015]. They do not have to satisfy the semistandard row or column restrictions. These tensor products are the result from the bijection from rigged configurations [RigConBijection].

For more information, see KirillovReshetikhinTableaux and TensorProductOfKirillovReshetikhinTableaux.

AUTHORS:

- Travis Scrimshaw (2012-01-03): Initial version

REFERENCES:

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxBn(cartan_type, r, s)

    Bases: KRTableauxTypeHorizontal

    Kirillov-Reshetikhin tableaux $B^{n,s}$ of type $B_n^{(1)}$.

    Element

    alias of KRTableauxSpinElement from_kirillov_reshetikhin_crystal(krc)

    Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

    EXAMPLES:

    sage: C = crystals.KirillovReshetikhin(['B',3,1], 3, 3, model='KN')
    sage: krc = C.module_generators[1].f_string([3,2,3,1,3,3]); krc
    [++, [[2], [0], [-3]]]
    sage: KR.from_kirillov_reshetikhin_crystal(krc)
    [[1, 1, 2], [2, 2, -3], [-3, -3, -1]]

    >>> from sage.all import *
    >>> KR = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)], Integer(3),
                                        model='KR')
    >>> C = crystals.KirillovReshetikhin(['B',Integer(3),Integer(1)], Integer(3),
                                         model='KN')
    >>> krc = C.module_generators[Integer(1)].f_string([Integer(3),Integer(2),
                                                   Integer(3),Integer(1),Integer(3),Integer(3)]); krc
    [++, [2], [0], [-3]]
    >>> KR.from_kirillov_reshetikhin_crystal(krc)
    [[1, 1, 2], [2, 2, -3], [-3, -3, -1]]

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxDTwistedSpin(cartan_type, r, s)

    Bases: KRTableauxRectangle

    Kirillov-Reshetikhin tableaux $B^{r,s}$ of type $D_n^{(2)}$ with $r = n$.

    EXAMPLES:
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 2], 1, 1, model='KR')
sage: KRT.cardinality()
8
t sage: KRC = crystals.KirillovReshetikhin(['D', 4, 2], 1, 1, model='KN')
sage: KRT.cardinality() == KRC.cardinality()
True

---

Element

alias ofKRTableauxSpinElement
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxRectangle(car-
tan_type, 
r, s)

Bases:KirillovReshetikhinTableaux

Kirillov-Reshetkhintableaux $B_{r,s}$ whose module generator is a single $r \times s$ rectangle.

These are Kirillov-Reshetkhin tableaux $B_{r,s}$ of type:

• $A_n^{(1)}$ for all $1 \leq r \leq n$,
• $C_n^{(1)}$ when $r = n$.

from_kirillov_reshetikhin_crystal(krc)

Construct aKirillovReshetikhinTableauxElement.

EXAMPLES:
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: C = crystals.KirillovReshetikhin(['A',4,1], 2, 1, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3], [4]]

---

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxSpin(car-
tan_type, 
r, s)

Bases:KRTableauxRectangle

5.1. Comprehensive Module List

3487
Kirillov-Reshetikhin tableaux $B^{r,s}$ of type $D^{(1)}_n$ with $r = n, n - 1$.

Element

alias of `KirillovReshetikhinTableauxSpinElement`

```
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxSpinElement(parent, list, **options)
```

Bases: `KirillovReshetikhinTableauxElement`

Kirillov-Reshetikhin tableau for spinors.

Here we are in the embedding $B(\Lambda_n) \hookrightarrow B(2\Lambda_n)$, so $e_i$ and $f_i$ act by $e_i^2$ and $f_i^2$ respectively for all $i \neq 0$. We do this so our columns are full width (as opposed to half width and/or uses a $\pm$ representation).

classical_weight()

Return the classical weight of self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1, model='KR')
sage: KRT.module_generators[0].classical_weight()
(1/2, 1/2, 1/2, 1/2)
```

```
>>> from sage.all import *

>>> KRT = crystals.KirillovReshetikhin(['D', Integer(4), Integer(1)],
   -> Integer(4), Integer(1), model='KR')

>>> KRT.module_generators[Integer(0)].classical_weight()
(1/2, 1/2, 1/2, 1/2)
```

e(i)

Calculate the action of $e_i$ on self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).e(1)
[[1], [3], [-4], [-2]]
sage: KRT(-1, -4, 3, 2).e(3)
```

```
>>> from sage.all import *

>>> KRT = crystals.KirillovReshetikhin(['D', Integer(4), Integer(1)],
   -> Integer(4), Integer(1), model='KR')

>>> KRT(-Integer(1), -Integer(4), Integer(3), Integer(2)).e(Integer(1))
[[1], [3], [-4], [-2]]

>>> KRT(-Integer(1), -Integer(4), Integer(3), Integer(2)).e(Integer(3))
```

epsilon(i)

Compute $\varepsilon_i$ of self.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).epsilon(1)
1
```

(continues on next page)
Calculating the action of $f_i$ on $self$.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1, model='KR')
sage: KRT(-1, -4, 3, 2).f(1)
sage: KRT(-1, -4, 3, 2).f(3)
[[2], [4], [-3], [-1]]
```

Return the image of $self$ under the left column splitting map.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')
sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1); elt.pp()
1 1 1
2 2 3
-4 -4 -4
-3 -3 -2
sage: elt.left_split().pp()
1 (X) 1 1
2 2 3
-4 -4 -4
-3 -3 -2
```

(continues on next page)
elt.left_split().pp()

1 (X) 1 1
2 2 3
-4 -4 -4
-3 -3 -2

\( \phi(i) \)

Compute \( \varphi_i \) of self.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 4, 1, model='KR')

sage: KRT(-1, -4, 3, 2).phi(1)
0

sage: KRT(-1, -4, 3, 2).phi(3)
1
```

```python
>>> from sage.all import *

>>> KRT = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],...
˓→Integer(4), Integer(3), model='KR')

```

```python
>>> KRT(-Integer(1), -Integer(4), Integer(3), Integer(2)).phi(Integer(1))
0

>>> KRT(-Integer(1), -Integer(4), Integer(3), Integer(2)).phi(Integer(3))
1
```

**to_array** (rows=True)

Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is \([2, 1, 4, 3]\), so as a \(2 \times 2\) tableau:

```
1 3
2 4
```

we output \([[[1, 3], [2, 4]]]\).

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be \([[[2, 1], [4, 3]]]\).

**INPUT:**

- **rows** – (Default: True) Set to True if the resulting array is by row, otherwise it is by column.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 4, 3, model='KR')

sage: elt = KRT(-3,-4,2,1,-3,-4,2,1,-2,-4,3,1)

sage: elt.to_array()
[[[1, 1, 1], [2, 2, 3], [-4, -4, -4], [-3, -3, -2]]

sage: elt.to_array(False)
[[[-3, -4, 2, 1], [-3, -4, 2, 1], [-2, -4, 3, 1]]

```

```python
>>> from sage.all import *

>>> KRT = crystals.KirillovReshetikhin(['D', Integer(4), Integer(1)],...
˓→Integer(4), Integer(3), model='KR')

```

(continues on next page)
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeBox

Bases: KRTableauxTypeVertical

Kirillov-Reshetikhin tableaux $B^{r,s}$ of type:

- $A_n^{(2)}$ for all $r \leq n$,
- $D_{n+1}^{(2)}$ for all $r < n$,
- $D_4^{(3)}$ for $r = 1$.

class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeFromRC

Bases: KirillovReshetikhinTableaux

Kirillov-Reshetikhin tableaux $B^{r,s}$ constructed from rigged configurations under the bijection $\Phi$.

Warning: The Kashiwara-Nakashima version is not implemented due to the non-trivial multiplicities of classical components, so classical_decomposition() does not work.

Element

alias of KRTableauxTypeFromRCElement

module_generators()

The module generators of self.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(['D', 4, 3], 2, 1, model='KR')
sage: KRT.module_generators
(([1], [2]), ([1], [0]), ([1], [E]), [[E], [E]])

>>> from sage.all import *
>>> KRT = crystals.KirillovReshetikhin(['D', Integer(4), Integer(3)],
     -Integer(2), Integer(1), model='KR')
>>> KRT.module_generators
(([1], [2]), ([1], [0]), ([1], [E]), [[E], [E]])

5.1. Comprehensive Module List
**Bases: KirillovReshetikhinTableauxElement**

A Kirillov-Reshetikhin tableau constructed from rigged configurations under the bijection $\Phi$.

$e_i(i)$

Perform the action of $e_i$ on `self`.

**Todo:** Implement a direct action of $e_0$ without moving to rigged configurations.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators[0].e(0)
[[2], [E]]
```

$\epsilon_i(i)$

Compute $\epsilon_i$ of `self`.

**Todo:** Implement a direct action of $\epsilon_0$ without moving to KR crystals.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
6
```

$f_i(i)$

Perform the action of $f_i$ on `self`.

**Todo:** Implement a direct action of $f_0$ without moving to rigged configurations.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 1, model='KR')
sage: KRT.module_generators[0].f(0)
sage: KRT.module_generators[3].f(0)
[[1], [0]]
```
phi(i)

Compute $\varphi_i$ of self.

Todo: Compute $\varphi_0$ without moving to KR crystals.

EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 2, model='KR')
```

```python
sage: KRT.module_generators[0].phi(0)
```

0

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,3], 2, 3, model='KR')
```

```python
sage: C = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KN')
```

```python
sage: krc = C(4,3); krc
[[3], [4]]
```

```python
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
```

[[3, -2, 1], [4, -1, 2]]

```python
sage: KRT = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KR')
```

```python
sage: C = crystals.KirillovReshetikhin(['C',4,1], 2, 3, model='KN')
```

```python
sage: krc = C(4,3); krc
[[3], [4]]
```

```python
```

(continues on next page)
class sage.combinat.rigged_configurations.kr_tableaux.KRTableauxTypeVertical(car-
tan_type, r, s)

Bases: KirillovReshetikhinTableaux

Kirillov-Reshetikhin tableaux $B_{r,s}$ of type:

- $D_n^{(1)}$ for all $1 \leq r < n - 1$,
- $B_n^{(1)}$ for all $1 \leq r < n$,
- $A_{2n-1}^{(2)}$ for all $1 \leq r \leq n$.

from_kirillov_reshetikhin_crystal (krc)

Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

EXAMPLES:

```
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: C = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KN')
sage: krc = C(4,3); krc
[[3], [4]]
sage: KRT.from_kirillov_reshetikhin_crystal(krc)
[[3, -2, 1], [4, -1, 2]]
```

>>> from sage.all import *
```
• type \( A_{2n-1}^{(2)} \) for all \( r \),

the filling map is defined in [OSS2011].

For the spinor cases in type \( D_n^{(1)} \), the crystal \( B^{k,s} \) where \( k = n - 1, n \), is isomorphic as a classical crystal to \( B(s\Lambda_k) \), and here we consider the Kirillov-Reshetikhin tableaux as living in \( B(2s\Lambda_k) \) under the natural doubling map. In this case, the crystal operators \( e_i \) and \( f_i \) act as \( e_i^2 \) and \( f_i^2 \) respectively. See [BijectionDn].

For the spinor cases in type \( B_n^{(1)} \), the crystal \( B^{n,s} \), we consider the images under the natural doubling map into \( B^{n,2s} \). The classical components of this crystal are now given by removing \( 2 \times 2 \) boxes. The filling map is the same as below (see the non-spin type \( C_n^{(1)} \)).

For \( B^{r,s} \) in:

• type \( C_n^{(1)} \) when \( r < n \),
• type \( A_{2n}^{(2)\dagger} \) for all \( r \),

the filling map is given as follows. Suppose we are considering the (classically) highest weight element in the classical component \( B(\lambda) \). Then we fill it in with the horizontal dominoes \( [\bar{i}, i] \) in the \( i \)-th row from the top (in English notation) and reordering the columns so that they are increasing. Recall from above that \( B^{n,s} \cong B(s\Lambda_n) \) in type \( C_n^{(1)} \).

For \( B^{r,s} \) in:

• type \( A_{2n}^{(2)} \) for all \( r \),
• type \( D_{n+1}^{(2)} \) when \( r < n \),
• type \( D_4^{(3)} \) when \( r = 1 \),

the filling map is the same as given in [OSS2011] except for the rightmost column which is given by the column \([1, 2, \ldots, k, \emptyset, \ldots, \emptyset]\) where \( k = (r + x - 1)/2 \) in Step 3 of [OSS2011].

For the spinor case in type \( D_n^{(2)} \), the crystal \( B^{n,s} \), we define the filling map in the same way as in type \( D_n^{(1)} \).

Note: The filling map and classical decompositions in non-spinor cases can be classified by how the special node 0 connects with the corresponding classical diagram.

The classical crystal structure is given by the usual Kashiwara-Nakashima tableaux rules. That is to embed this into \( B(\Lambda_1^{\otimes ns}) \) by using the reading word and then applying the classical crystal operator. The affine crystal structure is given by converting to the corresponding KR crystal element, performing the affine crystal operator, and pulling back to a KR tableau.

For more information about the bijection between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux, see TensorProductOfKirillovReshetikhinTableaux.

Note: The tableaux for all non-simply-laced types are provably correct if the bijection with rigged configurations holds. Therefore this is currently only proven for \( B^{r-1} \) or \( B^{1,s} \) and in general for types \( A_n^{(1)} \) and \( D_n^{(1)} \).

INPUT:

• cartan_type – the Cartan type
• r – the Dynkin diagram index (typically the number of rows)
• s – the number of columns

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
sage: elt = KRT(4, 3); elt
[[3], [4]]

sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 1, model='KR')
sage: elt = KRT(-1, 1); elt
[[1], [-1]]
```

We can create highest weight crystals from a given shape or weight:

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
```

We can go between `KashiwaraNakashimaTableaux()` and `KirillovReshetikhinTableaux` elements:

```python
sage: KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN')
sage: KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: elt = KRCrys(3, 2); elt
[[2], [3]]
```
We check that the classical weights in the classical decompositions agree in a few different type:

```python
from sage.all import *

KRCrys = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KN')
KRTab = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)  # True

KRCrys = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KN')
KRTab = crystals.KirillovReshetikhin(['B', 3, 1], 2, 2, model='KR')
all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)  # True

KRCrys = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KN')
KRTab = crystals.KirillovReshetikhin(['C', 3, 1], 2, 2, model='KR')
all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)  # True

KRCrys = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KN')
KRTab = crystals.KirillovReshetikhin(['D', 4, 2], 2, 2, model='KR')
all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)  # True

KRCrys = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KN')
KRTab = crystals.KirillovReshetikhin(['A', 4, 2], 2, 2, model='KR')
all(t.classical_weight() == KRCrys(t).classical_weight() for t in KRTab)  # True
```

(continues on next page)
Element

alias of KirillovReshetikhinTableauxElement

classical_decomposition()

Return the classical crystal decomposition of self.

EXAMPLES:

 sage: crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR').classical_decomposition()
  The crystal of tableaux of type ['D', 4] and shape(s) [[], [1, 1], [2, 2]]

 from_kirillov_reshetikhin_crystal (krc)

Construct an element of self from the Kirillov-Reshetikhin crystal element krc.

EXAMPLES:

 sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
 sage: C = crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KN')
 sage: krc = C(4,3); krc
  [[3], [4]]
 sage: KRT.from_kirillov_reshetikhin_crystal(krc)
  [[3], [4]]

 kirillov_reshetikhin_crystal()
Return the corresponding KR crystal in the *Kashiwara-Nakashima model*.

**EXAMPLES:**

```python
sage: crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR').kirillov_reshetikhin_crystal()
Kirillov-Reshetikhin crystal of type ['A', 4, 1] with (r,s)=(2,1)
```

```python
>>> from sage.all import *

>>> crystals.KirillovReshetikhin(['A', Integer(4), Integer(1)], Integer(2), Integer(1), model='KR').kirillov_reshetikhin_crystal()
Kirillov-Reshetikhin crystal of type ['A', 4, 1] with (r,s)=(2,1)
```

`module_generator` (*i=None, **options*)

Return the specified module generator.

**INPUT:**

- `i` – the index of the module generator

We can also get a module generator by using one of the following optional arguments:

- `shape` – the associated shape
- `column_shape` – the shape given as columns (a column of length \(k\) correspond to a classical weight \(\omega_k\))
- `weight` – the weight
- `classical_weight` – the classical weight

If no arguments are specified, then return the unique module generator of classical weight \(s\Lambda_r\).

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 2, model='KR')
sage: KRT.module_generator(1)
[[1, 1], [2, -1]]
sage: KRT.module_generator(shape=[1,1])
[[1, 1], [2, -1]]
sage: KRT.module_generator(column_shape=[2])
[[1, 1], [2, -1]]
sage: WS = RootSystem(['D',4,1]).weight_space()
sage: KRT.module_generator(weight=WS.sum_of_terms([[0,-2],[2,1]]))
[[1, 1], [2, -1]]
sage: WSC = RootSystem(['D',4]).weight_space()
sage: KRT.module_generator(classical_weight=WSC.fundamental_weight(2))
[[1, 1], [2, -1]]
sage: KRT.module_generator()
[[1, 1], [2, 2]]
```

```python
>>> from sage.all import *

>>> KRT = crystals.KirillovReshetikhin(['D', Integer(4), Integer(1)], Integer(2), Integer(2), model='KR')

>>> KRT.module_generator(Integer(1))
```

(continues on next page)
[[[1, 1], [2, -1]]

>>> KRT.module_generator(shape=[Integer(1), Integer(1)])
[[1, 1], [2, -1]]

>>> KRT.module_generator(column_shape=[Integer(2)])
[[1, 1], [2, -1]]

>>> WS = RootSystem(['D', Integer(4), Integer(1)]).weight_space()
>>> KRT.module_generator(weight=WS.sum_of_terms([[Integer(0), -Integer(2)],
                                                    [Integer(2), Integer(1)]]))
[[1, 1], [2, -1]]

>>> WSC = RootSystem(['D', Integer(4)]).weight_space()
>>> KRT.module_generator(classical_weight=WSC.fundamental_weight(Integer(2)))
[[1, 1], [2, -1]]

r()

Return the value $r$ for this tableaux class which corresponds to the number of rows.

EXAMPLES:

```sage
crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
```

s()

Return the value $s$ for this tableaux class which corresponds to the number of columns.

EXAMPLES:

```sage
crystals.KirillovReshetikhin(['A', 4, 1], 2, 1, model='KR')
```

tensor(*crystals, **options)

Return the tensor product of self with crystals.

If crystals is a list of (a tensor product of) KR tableaux, this returns a `TensorProductOfKirillovReshetikhinTableaux`.

EXAMPLES:
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
                                                           [[1, 3], [3, 1]])
sage: K.tensor(TP, K)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
and factor(s) ((2, 2), (1, 3), (3, 1), (2, 2))
sage: C = crystals.KirillovReshetikhin(['A', 3, 1], 3, 1, model='KN')
sage: K.tensor(K, C)
Full tensor product of the crystals
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)

>>> from sage.all import *
>>> K = crystals.KirillovReshetikhin(['A', Integer(3), Integer(1)],
                                   Integer(2), Integer(2), model='KR')
>>> TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', Integer(3),
                                                            Integer(1)],
                                                           [[Integer(1),Integer(3)], [Integer(3),Integer(1)]])
>>> K.tensor(TP, K)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1]
and factor(s) ((2, 2), (1, 3), (3, 1), (2, 2))
>>> C = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(3),
                                    Integer(1), model='KN')
>>> K.tensor(K, C)
Full tensor product of the crystals
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)

class sage.combinat.rigged_configurations.kr_tableaux.KirillovReshetikhinTableauxElement

Bases: TensorProductOfRegularCrystalsElement

A Kirillov-Reshetikhin tableau.

For more information, see KirillovReshetikhinTableaux and TensorProductOfKirillovReshetikhinTableaux.

classical_weight()

Return the classical weight of self.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)

>>> from sage.all import *
>>> KRT = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],
                                       Integer(2), Integer(2), model='KR')

(continues on next page)
elt = KRT(Integer(3), Integer(2), -Integer(1), Integer(1)); elt
[[2, 1], [3, -1]]
elt.classical_weight()
(0, 1, 1, 0)

\[ 2 \]

**e** \( (i) \)

Perform the action of \( e_i \) on self.

**Todo:** Implement a direct action of \( e_0 \) without moving to KR crystals.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].e(0)
[[2, 1], [3, -1]]
```

```python
from sage.all import *
KRT = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],... →Integer(2), Integer(2), model='KR')
KRT.module_generators[Integer(0)].e(Integer(0))
[[2, 1], [3, -1]]
```

**epsilon** \( (i) \)

Compute \( \varepsilon_i \) of self.

**Todo:** Implement a direct action of \( \varepsilon_0 \) without moving to KR crystals.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].epsilon(0)
2
```

```python
from sage.all import *
KRT = crystals.KirillovReshetikhin(['D',Integer(4),Integer(1)],... →Integer(2), Integer(2), model='KR')
KRT.module_generators[Integer(0)].epsilon(Integer(0))
2
```

**f** \( (i) \)

Perform the action of \( f_i \) on self.

**Todo:** Implement a direct action of \( f_0 \) without moving to KR crystals.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].f(0)
[[1, 1], [2, -1]]
```
left_split()
Return the image of self under the left column splitting map.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
  1  -2  1
  2  -1  2
sage: ls = mg.left_split(); ls.pp()
  1  (X)  -2  1
  2  -1  2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and...
  →factor(s) ((2, 1), (2, 2))

phi(i)
Compute \( \phi_i \) of self.

Todo: Compute \( \phi_0 \) without moving to KR crystals.

EXAMPLES:

sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KRT.module_generators[0].phi(0)
  2

pp()
Pretty print self.

EXAMPLES:
**right_split()**

Return the image of self under the right column splitting map.

Let $*$ denote the Lusztig involution, and $ls$ as the left splitting map. The right splitting map is defined as $rs := * \circ ls \circ *$.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['D', 4, 1], 2, 3, model='KR')
sage: mg = KRT.module_generators[1]; mg.pp()
1 -2 1
 2 -1 2
sage: ls = mg.right_split(); ls.pp()
-2 1 (X) 1
-1 2 2
sage: ls.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and
factor(s) ((2, 2), (2, 1))
```

**to_array** *(rows=True)*

Return a 2-dimensional array representation of this Kirillov-Reshetikhin element.

If the output is in rows, then it outputs the top row first (in the English convention) from left to right.

For example: if the reading word is $[2, 1, 4, 3]$, so as a $2 \times 2$ tableau:

```
1 3
2 4
```
we output \([1, 3], [2, 4]\).

If the output is in columns, then it outputs the leftmost column first with the bottom element first. In other words this parses the reading word into its columns.

Continuing with the previous example, the output would be \([2, 1], [4, 3]\).

**INPUT:**

- **rows** – (Default: True) Set to True if the resulting array is by row, otherwise it is by column.

**EXAMPLES:**

```python
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3)
sage: elt.to_array()
[[1, 3], [2, 4]]
sage: elt.to_array(False)
[[2, 1], [4, 3]]
```

**to_classical_highest_weight** *(index_set=None)*

Return the classical highest weight element corresponding to self.

**INPUT:**

- **index_set** – (Default: None) Return the highest weight with respect to the index set. If None is passed in, then this uses the classical index set.

**OUTPUT:**

A pair \([H, f\_str]\) where \(H\) is the highest weight element and \(f\_str\) is a list of \(a_i\) of \(f_{a_i}\) needed to reach \(H\).

**EXAMPLES:**

```python
sage: KRTab = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRTab(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_classical_highest_weight()
[[[1, 1], [2, -1]], [1, 2]]
```

**to_kirillov_reshetikhin_crystal**

Construct a KashiwaraNakashimaTableaux() element from self.
We construct the Kirillov-Reshetikhin crystal element as follows:

1. Determine the shape $\lambda$ of the KR crystal from the weight.
2. Determine a path $e_{i_1} e_{i_2} \cdots e_{i_k}$ to the highest weight.
3. Apply $f_{i_k} \cdots f_{i_2} f_{i_1}$ to a highest weight KR crystal of shape $\lambda$.

EXAMPLES:

```sage
sage: KRT = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: elt = KRT(3,2,-1,1); elt
[[2, 1], [3, -1]]
sage: elt.to_kirillov_reshetikhin_crystal()
[[2], [3]]
```

```
>>> from sage.all import *
>>> KRT = crystals.KirillovReshetikhin(['D','Integer(4)','Integer(1)]), Integer(2), Integer(2), model='KR')
>>> elt = KRT(Integer(3),Integer(2),-Integer(1),Integer(1)); elt
[[2, 1], [3, -1]]
>>> elt.to_kirillov_reshetikhin_crystal()
[[2], [3]]
```

`to_tableau()`

Return a `Tableau` object of self.

EXAMPLES:

```sage
sage: KRT = crystals.KirillovReshetikhin(['A', 4, 1], 2, 2, model='KR')
sage: elt = KRT(2, 1, 4, 3); elt
[[1, 3], [2, 4]]
sage: t = elt.to_tableau(); t
[[1, 3], [2, 4]]
sage: type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

```sage
>>> from sage.all import *
>>> KRT = crystals.KirillovReshetikhin(['A','Integer(4)','Integer(1)]), Integer(2), Integer(2), model='KR')
>>> elt = KRT(Integer(2),Integer(1), Integer(4), Integer(3)); elt
[[1, 3], [2, 4]]
>>> t = elt.to_tableau(); t
[[1, 3], [2, 4]]
>>> type(t)
<class 'sage.combinat.tableau.Tableaux_all_with_category.element_class'>
```

`weight()`

Return the weight of self.

EXAMPLES:

```sage
sage: KR = crystals.KirillovReshetikhin(['D',4,1], 2, 2, model='KR')
sage: KR.module_generators[1].weight()
-2*Lambda[0] + Lambda[2]
```

```sage
>>> from sage.all import *
>>> KR.module_generators[1].weight()
-2*Lambda[0] + Lambda[2]
```

(continues on next page)
5.1.212 Crystal of Rigged Configurations

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

We only consider the highest weight crystal structure, not the Kirillov-Reshetikhin structure, and we extend this to symmetric types.

```python
from sage.all import *
```

```python
La = RootSystem(['C', Integer(3)]).weight_lattice().fundamental_weights()
vct = CartanType(['C', Integer(3)]).as_folding()
RC = crystals.RiggedConfigurations(vct, La[Integer(2)])
elt = RC(partition_list=[[Integer(0)], [Integer(1)], [Integer(1)]])
to_virtual(rc)
```

INPUT:

- `rc` – a rigged configuration element

EXAMPLES:

```python
>>> from sage.all import *
```
```
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[2])
sage: elt = RC(partition_list=[[], [1], [1]]); elt
(0[ ]0
-1[ ]-1
)

sage: RC.to_virtual(elt)
(0[ ]0
-2[ ][-2
0[ ]0
)
```

```
>>> from sage.all import *

from sage.all import *
>>> La = RootSystem(['C', Integer(3)]).weight_lattice().fundamental_weights()
>>> vct = CartanType(['C', Integer(3)]).as_folding()
>>> RC = crystals.RiggedConfigurations(vct, La[Integer(2)])
>>> elt = RC(partition_list=[[[]], [Integer(1)], [Integer(1)]]); elt
(0[ ]0
-1[ ]-1
)

>>> RC.to_virtual(elt)
(0[ ]0
-2[ ][-2
0[ ]0
)
```

```virtual()
Return the corresponding virtual crystal.

EXAMPLES:
```
Crystal of rigged configurations of type ['C', 2, 1] and weight Lambda[0]

```python
>>> from sage.all import *
>>> La = RootSystem(['C', Integer(2), Integer(1)]).weight_lattice().fundamental_weights()
>>> vct = CartanType(['C', Integer(2), Integer(1)]).as_folding()
>>> RC = crystals.RiggedConfigurations(vct, La[Integer(0)])
>>> RC
Crystal of rigged configurations of type ['C', 2, 1] and weight Lambda[0]
```

Crystal of rigged configurations of type ['A', 3, 1] and weight 2*Lambda[0]

```python
class sage.combinat.rigged_configurations.rc_crystal.CrystalOfRiggedConfigurations(wt, WLR)

Bases: UniqueRepresentation, Parent

A highest weight crystal of rigged configurations.

The crystal structure for finite simply-laced types is given in [CrysStructSchilling06]. These were then shown to be the crystal operators in all finite types in [SS2015], all simply-laced and a large class of unfoldings of simply-laced types in [SS2015II], and all symmetrizable types (uniformly) in [SS2017].

INPUT:

- `cartan_type` – (optional) a Cartan type or a Cartan type given as a folding
- `wt` – the highest weight vector in the weight lattice

EXAMPLES:

For simplicity, we display the rigged configurations horizontally:

```python
sage: RiggedConfigurations.options.display='horizontal'
```

We start with a simply-laced finite type:

```python
sage: La = RootSystem(['A', 2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1] + La[2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2])
0[ ] 0[ ] -1
sage: mg.f_string([1,2,2])
0[ ] 0[ ] -2[ ] -2
sage: mg.f_string([1,2,2,2])
-1[ ] -1[ ] -1[ ]
sage: RC.cardinality()
8
sage: T = crystals.Tableaux(['A', 2], shape=[2,1])
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
True
```
We construct a non-simply-laced affine type:

```python
sage: La = RootSystem(['C', 3]).weight_lattice().fundamental_weights()
```

```python
sage: RC = crystals.RiggedConfigurations(La[2])
```

```python
sage: mg = RC.highest_weight_vector()
```

```python
sage: mg.f_string([2, 3])
```

```python
sage: T = crystals.Tableaux(['C', 3], shape=[1, 1])
```

```python
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
```

```python
True
```

We can construct rigged configurations using a diagram folding of a simply-laced type. This yields an equivalent but distinct crystal:

```python
sage: vct = CartanType(['C', 3]).as_folding()
```

```python
sage: RC = crystals.RiggedConfigurations(vct, La[2])
```

```python
sage: mg = RC.highest_weight_vector()
```

```python
sage: mg.f_string([2, 3])
```

```python
sage: T = crystals.Tableaux(['C', 3], shape=[1, 1])
```

```python
sage: RC.digraph().is_isomorphic(T.digraph(), edge_labels=True)
```

```python
True
```
We reset the global options:

```python
sage: RiggedConfigurations.options._reset()

>>> from sage.all import *
```

REFERENCES:

- [SS2015]
- [SS2015II]
- [SS2017]

**Element**

alias of `RCHighestWeightElement`

```python
options = current options for RiggedConfigurations - convention: English - display: vertical - element_ascii_art: True - half_width_boxes_type_B: True
```

**weight_lattice_realization()**

Return the weight lattice realization used to express the weights of elements in `self`.

**EXAMPLES:**

```python
sage: La = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[0])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

```python
>>> from sage.all import *

>>> La = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice(extended=True).fundamental_weights()

>>> RC = crystals.RiggedConfigurations(La[Integer(0)])

>>> RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]
```

### 5.1.213 Rigged Configurations of $B(\infty)$

**AUTHORS:**

- Travis Scrimshaw (2013-04-16): Initial version

```python
class sage.combinat.rigged_configurations.rc_infinity.InfinityCrystalOfNonSimplyLacedRC(wt):
    Bases: InfinityCrystalOfRiggedConfigurations

    Rigged configurations for $B(\infty)$ in non-simply-laced types.
```
class Element (parent, rigged_partitions=[], **options)

Bases: RCNonSimplyLacedElement

A rigged configuration in $B(\infty)$ in non-simply-laced types.

weight()

Return the weight of self.

EXAMPLES:

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[1],[1,1],[1]], rigging_list=[[0],[-1,-1],
- [0]])
sage: elt.weight()
(-1, -1, 0)

sage: vct = CartanType(['F', 4, 1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,0,3,4,2,2]); ascii_art(elt)
-1[ ]-1 0[ ]1 -2[ ][ ]-2 0[ ]1 -1[ ]-1
sage: wt = elt.weight(); wt
sage: al = RC.weight_lattice_realization().simple_roots()
True
```

from_virtual (vrc)

Convert vrc in the virtual crystal into a rigged configuration of the original Cartan type.

INPUT:

- vrc – a virtual rigged configuration

EXAMPLES:
```python
sage: vct = CartanType(['C', 2]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[3],[2]], rigging_list=[[-2],[0]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret
-3[ ][ ][ ]-2
-1[ ][ ]0
sage: ret == elt
True
```

```python
>>> from sage.all import *
>>> vct = CartanType(['C', Integer(2)]).as_folding()
>>> RC = crystals.infinity.RiggedConfigurations(vct)
>>> elt = RC(partition_list=[[Integer(3)],[Integer(2)]], rigging_list=[[Integer(-2)],[Integer(0)]]))
>>> vrc_elt = RC.to_virtual(elt)
>>> ret = RC.from_virtual(vrc_elt); ret
-3[ ][ ][ ]-2
-1[ ][ ]0
```

**to_virtual** *(rc)*

Convert `rc` into a rigged configuration in the virtual crystal.

**INPUT:**

- `rc` – a rigged configuration element

**EXAMPLES:**

```python
sage: vct = CartanType(['C', 2]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: mg = RC.highest_weight_vector()
sage: elt = mg.f_string([1,2,2,1,1]); elt
-3[ ][ ][ ]-2
-1[ ][ ]0
sage: velt = RC.to_virtual(elt); velt
-3[ ][ ][ ]-2
-2[ ][ ][ ]0
-3[ ][ ][ ]-2
```

```python
sage: velt.parent()
The infinity crystal of rigged configurations of type ['A', 3]
```
```python
>>> from sage.all import *
>>> vct = CartanType(['C', Integer(2)]).as_folding()
>>> RC = crystals.infinity.RiggedConfigurations(vct)
>>> mg = RC.highest_weight_vector()
>>> elt = mg.f_string([Integer(1), Integer(2), Integer(2), Integer(1),
   -> Integer(1)]); elt
-3[ ][ ][ ]-2
-1[ ][ ]0
>>> velt = RC.to_virtual(elt); velt
-3[ ][ ][ ]-2
-2[ ][ ][ ]0
-3[ ][ ][ ]-2
>>> velt.parent()
The infinity crystal of rigged configurations of type ['A', 3]
```

`virtual()`

Return the corresponding virtual crystal.

**EXAMPLES:**

```python
sage: vct = CartanType(['C', 3]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: RC
The infinity crystal of rigged configurations of type ['C', 3]
sage: RC.virtual
The infinity crystal of rigged configurations of type ['A', 5]
```

**class** `sage.combinat.rigged_configurations.rc_infinity.InfinityCrystalOfRiggedConfigurations`

**Bases:** `UniqueRepresentation, Parent`

Rigged configuration model for $\mathcal{B}(\infty)$.

The crystal is generated by the empty rigged configuration with the same crystal structure given by the highest weight model except we remove the condition that the resulting rigged configuration needs to be valid when applying $f_a$.

**INPUT:**

- `cartan_type` — a Cartan type

**EXAMPLES:**

For simplicity, we display all of the rigged configurations horizontally:
We begin with a simply-laced finite type:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3]); RC
The infinity crystal of rigged configurations of type ['A', 3]
sage: RC.options(display='horizontal')

sage: mg = RC.highest_weight_vector(); mg
(/) (/) (/)

sage: elt = mg.f_string([2,1,3,2]); elt
0[ ]0 -2[ ]-1 0[ ]0
   -2[ ]-1
sage: elt.e(1)
```

```python
sage: elt.e(3)
```

```python
sage: mg.f_string([2,1,3,2]).e(2)
-1[ ]-1 0[ ]1 -1[ ]-1
```

Next we consider a non-simply-laced finite type:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['C', 3])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([2,1,3,2])
0[ ]0 -1[ ]0 0[ ]0
   -1[ ]-1
sage: mg.f_string([2,3,2,1,3,2])
0[ ]-1 -1[ ]1 -1[ ]-1
```

5.1. Comprehensive Module List 3515
We can construct rigged configurations using a diagram folding of a simply-laced type. This yields an equivalent but distinct crystal:

```python
>>> vct = CartanType(['C', 3]).as_folding()
>>> VRC = crystals.infinity.RiggedConfigurations(vct)
>>> mg = VRC.highest_weight_vector()
>>> mg.f_string([2, 1, 3, 2])
0[ ]0 -2[ ]-1 0[ ]0
-2[ ]-1
>>> mg.f_string([2, 3, 2, 1, 3, 2])
-1[ ]-1 -2[ ][ ][ ]-1 -1[ ][ ]0
>>> G = RC.subcrystal(max_depth=5).digraph()
>>> VG = VRC.subcrystal(max_depth=5).digraph()
>>> G.is_isomorphic(VG, edge_labels=True)
True
```

We can also construct $B(\infty)$ using rigged configurations in affine types:

```python
>>> RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
>>> mg = RC.highest_weight_vector()
>>> mg.f_string([0, 1, 2, 3, 0, 1, 3])
-1[ ]0 -1[ ]-1 1[ ]1 -1[ ][ ]-1
-1[ ]0 -1[ ]-1
>>> RC = crystals.infinity.RiggedConfigurations(['C', 3, 1])
>>> mg = RC.highest_weight_vector()
>>> mg.f_string([1, 2, 3, 0, 1, 2, 3, 3, 0])
-2[ ][ ]-1 0[ ]1 0[ ]0 -4[ ][ ][ ]-2
```

(continues on next page)
sage: RC = crystals.infinity.RiggedConfigurations(['A', 6, 2])
sage: mg = RC.highest_weight_vector()
sage: mg.f_string([1,2,3,0,1,2,3,0])
0[ ]-1 0[ ]1 0[ ]0 -4[ ][ ][ ]-2
0[ ]-1 0[ ]1 0[ ]-1

>>> from sage.all import *

```python
>>> RC = crystals.infinity.RiggedConfigurations(['A', Integer(3), Integer(1)])
>>> mg = RC.highest_weight_vector()
>>> mg.f_string([Integer(0),Integer(1),Integer(2),Integer(3),Integer(0),
                Integer(1),Integer(3)])
-1[ ]0 -1[ ]-1 1[ ]1 -1[ ][ ][ ]-1
-1[ ]0 -1[ ]-1
```

```python
>>> RC = crystals.infinity.RiggedConfigurations(['C', Integer(3), Integer(1)])
>>> mg = RC.highest_weight_vector()
>>> mg.f_string([Integer(1),Integer(2),Integer(3),Integer(0),Integer(1),
                Integer(2),Integer(3),Integer(3),Integer(0)])
-2[ ][ ]-1 0[ ]1 0[ ]0 -4[ ][ ][ ]-2
0[ ]0 0[ ]-1
```

```python
>>> RC = crystals.infinity.RiggedConfigurations(['A', Integer(6), Integer(2)])
>>> mg = RC.highest_weight_vector()
>>> mg.f_string([Integer(1),Integer(2),Integer(3),Integer(0),Integer(1),
                Integer(2),Integer(3),Integer(3),Integer(0)])
0[ ]-1 0[ ]1 0[ ]0 -4[ ][ ][ ]-2
0[ ]-1 0[ ]1 0[ ]-1
```

We reset the global options:

```python
sage: RiggedConfigurations.options._reset()
```

```python
>>> from sage.all import *
```

```python
>>> RiggedConfigurations.options._reset()
```

```python
class Element (
    parent,
    rigged_partitions=[], **options)
```

```python
Bases: RiggedConfigurationElement
```

A rigged configuration in \( B(\infty) \) in simply-laced types.

```python
weight ()
```

Return the weight of self.

EXAMPLES:

```python
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3, 1])
sage: elt = RC(partition_list=[[1,1]]*4, rigging_list=[[1,1], [0,0], [0,
                -0], [-1,-1]])
sage: elt.weight()
-2*delta
```

```python
>>> from sage.all import *
```

```python
>>> RC = crystals.infinity.RiggedConfigurations(['A', Integer(3),
                Integer(1)])
```

```python
>>> elt = RC(partition_list=[[Integer(1),Integer(1)]]*Integer(4), rigging_
options = Current options for RiggedConfigurations - convention: English -
display: vertical - element_ascii_art: True - half_width_boxes_type_B: True

weight_lattice_realization()
Return the weight lattice realization used to express the weights of elements in self.

EXAMPLES:

sage: RC = crystals.infinity.RiggedConfigurations(['A', 2, 1])
sage: RC.weight_lattice_realization()
Extended weight lattice of the Root system of type ['A', 2, 1]

5.1.214 Rigged Configuration Elements

A rigged configuration element is a sequence of RiggedPartition objects.

AUTHORS:
• Travis Scrimshaw (2010-09-26): Initial version
• Travis Scrimshaw (2012-10-25): Added virtual rigged configurations

class sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement,

Bases: KRRiggedConfigurationElement, RCNonSimplyLacedElement

\mathcal{U}_q'(g) rigged configurations in non-simply-laced types.

cc()
Compute the cocharge statistic.

Computes the cocharge statistic \text{[OSS03]} on this rigged configuration \((\nu, J)\) by computing the cocharge as a virtual rigged configuration \((\hat{\nu}, \hat{J})\) and then using the identity \(cc(\hat{\nu}, \hat{J}) = \gamma_0 cc(\nu, J)\).

EXAMPLES:

sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1],[2,1],[1,1]]).cocharge()
1
**cocharge()**

Compute the cocharge statistic.

Computes the cocharge statistic [OSS03] on this rigged configuration \((\nu, J)\) by computing the cocharge as a virtual rigged configuration \((\tilde{\nu}, \tilde{J})\) and then using the identity \(cc(\tilde{\nu}, \tilde{J}) = \gamma_0 cc(\nu, J)\).

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[2,1], [1,1]])
sage: RC(partition_list=[[1,1], [2,1], [1,1]]).cocharge()
1
```

**e(a)**

Return the action of \(e_a\) on self.

This works by lifting into the virtual configuration, then applying

\[
e_a^\nu = \prod_{j \in \iota(a)} \tilde{e}_j^\gamma_j
\]

and pulling back.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 6, 2], [[1,]*7])
sage: elt = RC(partition_list=[[1]*5, [2,1,1], [3,2]])
sage: elt.e(3)
```

(continues on next page)
\( \mathfrak{f}(a) \)

Return the action of \( \mathfrak{f}_a \) on \( \text{self} \).

This works by lifting into the virtual configuration, then applying

\[
\mathfrak{f}_a'' = \prod_{j \in i(a)} \mathfrak{f}_j^j
\]

and pulling back.

**EXAMPLES:**

```python
from sage.all import *
RC = RiggedConfigurations(['A', 6, 2], [[1, 1]*7])
elt = RC(partition_list=[[1]*5, [2, 1, 1], [2, 1]], rigging_list=[[0]*5, [0, 1, 1, 1], [1, 0]])
elt.f(3)
```

```python
elt.e(Integer(3))
```

```python
elt.e(Integer(3))
```
class sage.combinat.rigged_configurations.rigged_configuration_element.KRRCSimplyLacedElement

Bases: KRRiggedConfigurationElement

\(U_q(\mathfrak{g})\) rigged configurations in simply-laced types.

\texttt{cc()}

Compute the cocharge statistic of \texttt{self}.

Computes the cocharge statistic \cite{CrysStructSchilling06} on this rigged configuration \((\nu, J)\). The cocharge statistic is defined as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a,b \in I_0} \sum_{j,k > 0} (\alpha_a \mid \alpha_b) \min(j, k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i > 0} \left| J(a, i) \right|
\]

EXAMPLES:

\begin{verbatim}sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2,1], [1,1]]) sage: RC(partition_list=[[1], [1], []]).cocharge() 1
\end{verbatim}

\begin{verbatim}>>> from sage.all import * >>> RC = RiggedConfigurations(['A', Integer(3), Integer(1)], [[Integer(3), Integer(2)], [Integer(2),Integer(1)], [Integer(1),Integer(1)]]) >>> RC(partition_list=[[Integer(1)], [Integer(1)], []]).cocharge() 1
\end{verbatim}

\texttt{charge()}

Compute the charge statistic of \texttt{self}.

Let \(B\) denote a set of rigged configurations. The charge \(c\) of a rigged configuration \(b\) is computed as

\[
c(b) = \max(\text{cc}(b) \mid b \in B) - \text{cc}(b).
\]

EXAMPLES:
cocharge()

Compute the cocharge statistic of self.

Computes the cocharge statistic [CrysStructSchilling06] on this rigged configuration \((\nu, J)\). The cocharge statistic is defined as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a, b \in I_0} \sum_{j, k > 0} (\alpha_a | \alpha_b) \min(j, k) m_j^{(a)} m_k^{(b)} + \sum_{a \in I} \sum_{i > 0} \left| J^{(a, i)}(a) \right|
\]

EXAMPLES:

```sage
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [2, 1], [1, 1]])
sage: RC(partition_list=[[1], [1], []]).cocharge()
1
```
cocharge()

Compute the cocharge statistic.
Computes the cocharge statistic [RigConBijection] on this rigged configuration \((\nu, J)\). The cocharge statistic is computed as:

\[
cc(\nu, J) = \frac{1}{2} \sum_{a \in I_0} \sum_{i>0} t^a_i \epsilon_a \left( \sum_{j>0} \min(i, j) L_j^{(a)} - p_i^{(a)} \right) + \sum_{a \in I} t^a \sum_{i>0} |J^{(a, i)}|.
\]

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1, 1], [2, 2]])
sage: sc = RC.cartan_type().as_folding().scaling_factors()
sage: all(mg.cocharge() * sc[0] == mg.to_virtual_configuration().cocharge()
      ... for mg in RC.module_generators)
True
```

```python
>> from sage.all import *
>> RC = RiggedConfigurations(CartanType(['A', Integer(4), Integer(2)]).dual(),
                        [[Integer(1), Integer(1)], [Integer(2), Integer(2)]])
>> sc = RC.cartan_type().as_folding().scaling_factors()
>> all(mg.cocharge() * sc[Integer(0)] == mg.to_virtual_configuration().cocharge()
      ... for mg in RC.module_generators)
True
```

epsilon\(a\)

Return the value of \(\epsilon_a\) of self.
Here we need to modify the usual definition by \(\epsilon'_n := 2\epsilon_n\).

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1, 1], [2, 2]])
sage: def epsilon(x, i):
    ... x = x.e(i)
    ... eps = 0
    ... while x is not None:
        ... x = x.e(i)
        ... eps = eps + 1
    ... return eps
```

(continues on next page)
sage: all(epsilon(rc, 2) == rc.epsilon(2) for rc in RC)
True

>>> from sage.all import *
>>> RC = RiggedConfigurations(CartanType(['A', Integer(4), Integer(2)]).dual(),
                            [[Integer(1), Integer(1)], [Integer(2), Integer(2)]])
>>> def epsilon(x, i):
...     x = x.e(i)
...     eps = Integer(0)
...     while x is not None:
...         x = x.e(i)
...         eps = eps + Integer(1)
...     return eps
>>> all(epsilon(rc, Integer(2)) == rc.epsilon(Integer(2)) for rc in RC)
True

phi \(a\)

Return the value of \(\varphi_a\) of self.

Here we need to modify the usual definition by \(\varphi'_n := 2\varphi_n\).

EXAMPLES:

sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1, 1], [2, 2]])

sage: def phi(x, i):
...     x = x.f(i)
...     ph = Integer(0)
...     while x is not None:
...         x = x.f(i)
...         ph = ph + 1
...     return ph

sage: all(phi(rc, 2) == rc.phi(2) for rc in RC)
True

>>> from sage.all import *
>>> RC = RiggedConfigurations(CartanType(['A', Integer(4), Integer(2)]).dual(),
                            [[Integer(1), Integer(1)], [Integer(2), Integer(2)]])
>>> def phi(x, i):
...     x = x.f(i)
...     ph = Integer(0)
...     while x is not None:
...         x = x.f(i)
...         ph = ph + Integer(1)
...     return ph
>>> all(phi(rc, Integer(2)) == rc.phi(Integer(2)) for rc in RC)
True

class sage.combinat.rigged_configurations.rigged_configuration_element.KRRiggedConfigurationElement

Bases: RiggedConfigurationElement

\(U'_q(g)\) rigged configurations.
EXAMPLES:

We can go between rigged configurations and tensor products of tensor products of KR tableaux:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[1,1], [2,1]])
sage: rc_elt = RC(partition_list=[[1], [1,1], [1], [1]])
sage: tp_krtab = rc_elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krtab
[[[-2]]  (X)  [[1], [2]]
sage: tp_krcrys = rc_elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krcrys
[[[-2]], [[1], [2]]]
sage: tp_krcrys == tp_krtab.to_tensor_product_of_kirillov_reshetikhin_crystals()
True
sage: RC(tp_krcrys) == rc_elt
True
sage: RC(tp_krtab) == rc_elt
True
sage: tp_krtab.to_rigged_configuration() == rc_elt
True
```

check()

Make sure all of the riggings are less than or equal to the vacancy number.

classical_weight()

Return the classical weight of self.

The classical weight \( \Lambda \) of a rigged configuration is

\[
\Lambda = \sum_{\alpha \in \mathcal{I}} \sum_{i > 0} L_i^{(\alpha)} \Lambda_{\alpha} - \sum_{a \in \mathcal{I}} \sum_{i > 0} i m_i^{(\alpha)} \alpha_{\alpha}.
\]

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[1,1], [2,1]])
sage: elt = RC(partition_list=[[2], [2,1], [1], [1]])
sage: elt.classical_weight()
(0, 1, 1, 0)
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> RC = RiggedConfigurations(['D', Integer(4), Integer(1)], [[Integer(2), ¬Integer(2)]]

>>> elt = RC(partition_list=[[Integer(2)], [Integer(2), Integer(1)], ¬[Integer(1)], [Integer(1)]])

>>> elt.classical_weight()
(0, 1, 1, 0)

This agrees with the corresponding classical weight as KR tableaux:

```
sage: krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); krt
[[2, 1], [3, -1]]
sage: krt.classical_weight() == elt.classical_weight()
True
```

```
>>> from sage.all import *

>>> krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); krt
[[2, 1], [3, -1]]

>>> krt.classical_weight() == elt.classical_weight()
True
```

\texttt{complement\_rigging} (\texttt{reverse\_factors=False})

Apply the complement rigging morphism $\theta$ to self.

Consider a highest weight rigged configuration $(\nu, J)$, the complement rigging morphism $\theta : RC(L) \to RC(L)$ is given by sending $(\nu, J) \mapsto (\nu, J')$, where $J'$ is obtained by taking the coriggings $x' = p_i^{(a)} - x$, and then extending as a crystal morphism. (The name comes from taking the complement partition for the riggings in a $m_i^{(a)} \times p_i^{(a)}$ box.)

**INPUT:**

- \texttt{reverse\_factors} – (default: False) if True, then this returns an element in $RC(B')$ where $B'$ is the tensor factors of self in reverse order

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['D', 4, 1], [[1, 1], [2, 2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
1[ ][ ][ ]1 0[ ][ ][ ]0 0[ ][ ][ ]0
0[ ][ ][ ]0

sage: ascii_art(mg.complement_rigging())
1[ ]0 0[ ][ ][ ]0 0[ ][ ][ ]0
0[ ][ ][ ]0

sage: lw = mg.to_lowest_weight([1, 2, 3, 4])

sage: ascii_art(lw)
-1[ ]0 0[ ][ ][ ]0
0[ ][ ][ ]0
-1[ ]-1 0[ ][ ][ ]0
0[ ][ ][ ]0

sage: ascii_art(lw.complement_rigging())
-1[ ]0 0[ ][ ][ ]0
0[ ][ ][ ]0
-1[ ]-1 0[ ][ ][ ]0
0[ ][ ][ ]0

sage: lw.complement_rigging() == mg.complement_rigging().to_lowest_weight([1, ¬2, 3, 4])
True
```

(continues on next page)
Combinatorics, Release 10.4

We check that the Lusztig involution (under the modification of also mapping to the highest weight element) intertwines with the complement map $\theta$ (that reverses the tensor factors) under the bijection $\Phi$:

\begin{verbatim}
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2], [2, 1], [1, 2]])
sage: for mg in RC.module_generators: # long time
    y = mg.to_tensor_product_of_kirillov_reshetikhin_tableaux()
    hw = y.lusztig_involution().to_highest_weight([1, 2, 3, 4])[0]
    c = mg.complement_rigging(True)
    hwc = c.to_tensor_product_of_kirillov_reshetikhin_tableaux()
    assert hw == hwc
\end{verbatim}

**delta**

Return the image of self under the left box removal map $\delta$.
The map \( \delta : RC(B^{r,1} \otimes B) \rightarrow RC(B^{r-1,1} \otimes B) \) (if \( r = 1 \), then we remove the left-most factor) is the basic map in the bijection \( \Phi \) between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see `to_tensor_product_of_kirillov_reshetikhin_tableaux()`. We can extend \( \delta \) when the left-most factor is not a single column by precomposing with `left_split()`.

**Note:** Due to the special nature of the bijection for the spinor cases in types \( D_n^{(1)} \), \( B_n^{(1)} \), and \( A_{2n-1}^{(2)} \), this map is not defined in these cases.

**INPUT:**
- `return_b` – (default: `False`) whether to return the resulting letter from \( \delta \)

**OUTPUT:**
The resulting rigged configuration or if `return_b` is `True`, then a tuple of the resulting rigged configuration and the letter.

**EXAMPLES:**

```python
def example():
    RC = RiggedConfigurations(['C',4,1], [[3,2]])
    mg = RC.module_generators[-1]
    ascii_art(mg)
    ascii_art(mg.left_box(True))
    x,b = mg.left_box(True)
    b
    b.parent()

def another_example():
    from sage.all import *
    RC = RiggedConfigurations(['C',4,1], [[3,2]])
    mg = RC.module_generators[-1]
    ascii_art(mg)
    ascii_art(mg.left_box(True))
    x,b = mg.left_box(True)
    b
    b.parent()
```

**Return the action of the crystal operator \( e_a \) on self.**

For the classical operators, this implements the method defined in [CrysStructSchilling06]. For \( e_0 \), this converts the class to a tensor product of KR tableaux and does the corresponding \( e_0 \) and pulls back.
Todo: Implement $e_0$ without appealing to tensor product of KR tableaux.

**INPUT:**
- $a$ – the index of the partition to remove a box

**OUTPUT:**
The resulting rigged configuration element.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
sage: elt.e(1)

(0 [ ] 0)
0 [ ] 0
-1 [ ] -1
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), Integer(1)]])
>>> elt = RC(partition_list=[[Integer(1)], [Integer(1)], [Integer(1)], [Integer(1)]])
>>> elt.e(Integer(3))
>>> elt.e(Integer(1))

(0 [ ] 0)
0 [ ] 0
-1 [ ] -1
```

$\epsilon(a)$

Return $\epsilon_0$ of self.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: I = RC.index_set()
sage: matrix([[mg.epsilon(i) for i in I] for mg in RC.module_generators])

[4 0 0 0 0]
[3 0 0 0 0]
[2 0 0 0 0]
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['D', Integer(4), Integer(1)], [[Integer(2), Integer(2)]])
```

(continues on next page)
\begin{verbatim}
>>> I = RC.index_set()
>>> matrix([[mg.epsilon(i) for i in I] for mg in RC.module_generators])
[[4 0 0 0 0]
 [3 0 0 0 0]
 [2 0 0 0 0]]
\end{verbatim}

\textbf{f} (a)

Return the action of the crystal operator $f_a$ on self.

For the classical operators, this implements the method defined in \cite{CrysStructSchilling06}. For $f_0$, this converts the class to a tensor product of KR tableaux and does the corresponding $f_0$ and pulls back.

\textbf{Todo:} Implement $f_0$ without appealing to tensor product of KR tableaux.

\textbf{INPUT:}

- \texttt{a} – the index of the partition to add a box

\textbf{OUTPUT:}

The resulting rigged configuration element.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RC = RiggedConfigurations(['A', 4, 1], [[2,1]])
sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.f(1)
sage: elt.f(2)

0[ ][ ]0
-1[ ][ ]-1
-1[ ][ ]-1
1[ ][ ]1
-1[ ][ ]-1

>>> from sage.all import *

>>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), -Integer(1)]]))

>>> elt = RC(partition_list=[[Integer(1), [1], [1], [1]])

>>> elt.f(Integer(1))

>>> elt.f(Integer(2))

<BLANKLINE>
\end{verbatim}
**left_box**(return_b=False)

Return the image of self under the left box removal map $\delta$.

The map $\delta : RC(B_r^{1,1} \otimes B) \to RC(B_r^{1,1} \otimes B)$ (if $r = 1$, then we remove the left-most factor) is the basic map in the bijection $\Phi$ between rigged configurations and tensor products of Kirillov-Reshetikhin tableaux. For more information, see `to_tensor_product_of_kirillov_reshetikhin_tableaux()`.

We can extend $\delta$ when the left-most factor is not a single column by precomposing with a `left_split()`.

**Note:** Due to the special nature of the bijection for the spinor cases in types $D_n^{(1)}$, $B_n^{(1)}$, and $A_{2n-1}^{(2)}$, this map is not defined in these cases.

**INPUT:**

* return_b = (default: False) whether to return the resulting letter from $\delta$

**OUTPUT:**

The resulting rigged configuration or if return_b is True, then a tuple of the resulting rigged configuration and the letter.

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['C',4,1], [[3,2]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
sage: ascii_art(mg.left_box())
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
sage: x,b = mg.left_box(True)
sage: b
-1
sage: b.parent()
The crystal of letters for type ['C', 4]
```

```
>>> from sage.all import *
>>> RC = RiggedConfigurations(['C',Integer(4),Integer(1)], [[Integer(3),˓→Integer(2)]]
>>> mg = RC.module_generators[-Integer(1)]
>>> ascii_art(mg)
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
>>> ascii_art(mg.left_box())
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
0[ ][ ]0 0[ ][ ]0 0[ ][ ]0
>>> x,b = mg.left_box(True)
>>> b
-1
>>> b.parent()
The crystal of letters for type ['C', 4]
```

**left_column_box()**

Return the image of self under the left column box splitting map $\gamma$.

5.1. Comprehensive Module List 3531
Consider the map $\gamma : RC(B^{-1} \otimes B) \to RC(B^{1,1} \otimes B^{r-1,1} \otimes B)$ for $r > 1$, which is a natural strict classical crystal injection. On rigged configurations, the map $\gamma$ adds a singular string of length 1 to $\nu^{(n)}$.

We can extend $\gamma$ when the left-most factor is not a single column by precomposing with a \texttt{left_split()}. EXAMPLES:

```plaintext
sage: RC = RiggedConfigurations(['C',3,1], [[3,1], [2,1]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ]0 0[ ]0 0[ ]0
     0[ ]0 0[ ]0
sage: ascii_art(mg.left_column_box())
0[ ]0 0[ ]0 0[ ]0
     0[ ]0 0[ ]0
sage: RC = RiggedConfigurations(['C',3,1], [[2,1], [1,1], [3,1]])
sage: mg = RC.module_generators[-7]
sage: ascii_art(mg)
1[ ]1 0[ ]0 0[ ]0
     0[ ]0 0[ ]0
sage: ascii_art(mg.left_column_box())
1[ ]1 1[ ]0 0[ ]0
     1[ ]0 0[ ]0
```

\texttt{left_split()}

Return the image of \texttt{self} under the left column splitting map $\beta$.

Consider the map $\beta : RC(B^{-s} \otimes B) \to RC(B^{1,1} \otimes B^{s-1,1} \otimes B)$ for $s > 1$ which is a natural classical crystal injection. On rigged configurations, the map $\beta$ does nothing (except possibly changing the vacancy numbers).

EXAMPLES:

```plaintext
class: RC = RiggedConfigurations(['C',4,1], [[3,3]])
class: mg = RC.module_generators[-1]
```

(continues on next page)
sage: ascii_art(mg)
\[
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{array}
\]

sage: ascii_art(mg.left_split())
\[
\begin{array}{cccc}
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 \\
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
\end{array}
\]

>>> from sage.all import *

>>> RC = RiggedConfigurations(['C', Integer(4), Integer(1)], [[Integer(3), Integer(3)]]

>>> mg = RC.module_generators[-Integer(1)]

>>> ascii_art(mg)
\[
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
\end{array}
\]

>>> ascii_art(mg.left_split())
\[
\begin{array}{cccc}
0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 \\
1 & 0 & 0 & 0 \\
1 & 0 & 0 & 0 \\
\end{array}
\]

\[\phi(a)\]

Return \(\varphi_a\) of self.

EXAMPLES:

sage: RC = RiggedConfigurations(['D', 4, 1], [[2], [2]])

sage: I = RC.index_set()

sage: matrix([[mg.phi(i) for i in I] for mg in RC.module_generators])
\[
\begin{bmatrix}
0 & 2 & 0 & 0 \\
1 & 0 & 1 & 0 \\
2 & 0 & 0 & 0 \\
\end{bmatrix}
\]

right_column_box()

Return the image of self under the right column box splitting map \(\gamma^*\).

Consider the map \(\gamma^* : RC(B \otimes B^{r-1,1}) \to RC(B \otimes B^{r-1,1} \otimes B^{1,1})\) for \(r > 1\), which is a natural strict classical crystal injection. On rigged configurations, the map \(\gamma\) adds a string of length 1 with rigging 0 to \(\nu(\alpha)\) for all \(\alpha < r\) to a classically highest weight element and extended as a classical crystal morphism.

We can extend \(\gamma^*\) when the right-most factor is not a single column by precomposing with a right_split().

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[2, 1], [1, 1], [3, 1]])
sage: mg = RC.module_generators[7]
sage: ascii_art(mg)
1[ ]0 0[ ][ ]0 0[ ]0
0[ ]0 0[ ]0
sage: ascii_art(mg.right_column_box())
1[ ]0 0[ ][ ]0 0[ ]0
1[ ]0 0[ ]0 0[ ]0
0[ ]0
```

```python
>>> from sage.all import *

RC = RiggedConfigurations(['C', Integer(3), Integer(1)], [[Integer(2), Integer(1)], [Integer(1), Integer(1)], [Integer(3), Integer(1)]])
mg = RC.module_generators[Integer(7)]
>>> ascii_art(mg)
1[ ]0 0[ ][ ]0 0[ ]0
0[ ]0 0[ ]0
>>> ascii_art(mg.right_column_box())
1[ ]0 0[ ][ ]0 0[ ]0
1[ ]0 0[ ]0 0[ ]0
0[ ]0
```

```python
right_split()
```

Return the image of self under the right column splitting map $\beta^\ast$.

Let $\theta$ denote the complement rigging map which reverses the tensor factors and $\beta$ denote the left splitting map, we define the right splitting map by $\beta^\ast := \theta \circ \beta \circ \theta$.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C', 4, 1], [[3, 3]])
sage: mg = RC.module_generators[-1]
sage: ascii_art(mg)
0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0
0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0
0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]0
sage: ascii_art(mg.right_split())
0[ ][ ][ ][ ]0 0[ ][ ][ ][ ]1 0[ ]0
0[ ][ ][ ][ ]0 1[ ][ ][ ][ ]1 0[ ]0
0[ ][ ][ ][ ]0 1[ ][ ][ ][ ]1 0[ ]0
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2], [1, 2]])
sage: elt = RC(partition_list=[[3, 1], [2, 2, 1], [2, 1], [2]])
sage: ascii_art(elt)
-1[ ][ ][ ]-1 0[ ][ ]0 -1[ ][ ][ ]-1 1[ ][ ][ ]1
0[ ]0 0[ ][ ]0 -1[ ][ ]-1
0[ ]0
sage: ascii_art(elt.right_split())
-1[ ][ ][ ]-1 0[ ][ ]0 -1[ ][ ][ ]-1 1[ ][ ][ ]1
1[ ]0 0[ ][ ]0 -1[ ][ ]-1
0[ ]0
```

```python
>>> from sage.all import *

RC = RiggedConfigurations(['C', Integer(4), Integer(1)], [[Integer(3), Integer(3)]]])
mg = RC.module_generators[-Integer(1)]
>>> ascii_art(mg)
(continues on next page)
```
We check that the bijection commutes with the right splitting map:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[1, 1], [2, 2]])
sage: all(rc.right_split().to_tensor_product_of_kirillov_reshetikhin_tableaux() == rc.to_tensor_product_of_kirillov_reshetikhin_tableaux().right_split() for rc in RC)
True
```

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

This is a composition of the map to a tensor product of KR tableaux, and then to a tensor product of KR crystals.

### INPUT:

- **display_steps** *(default: False)* boolean which indicates if we want to print each step in the algorithm
- **build_graph** *(default: False)* boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of $\delta$ or the doubling/halving map

### EXAMPLES:
sage: RC = RiggedConfigurations(["D", 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); krc
[[[2, 3], [3, -2]]]

We can recover the rigged configuration:

sage: ret = RC(krc); ret
0[ ]0
-2[ ]-2
-2[ ]-2
0[ ]0
0[ ]0
sage: elt == ret
True

We can also construct and display a graph of the bijection as follows:

sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(build_graph=True)
sage: view(G) # not tested

To_tensor_product_of_kirillov_reshetikhin_tableaux(display_steps=False, build_graph=False)
Perform the bijection from this rigged configuration to a tensor product of Kirillov-Reshetikhin tableaux given in [RigConBijection] for single boxes and with [BijectionLRT] and [BijectionDn] for multiple columns and rows.

**Note:** This is only proven to be a bijection in types $A_{1}^{(1)}$ and $D_{1}^{(1)}$, as well as $\otimes_{i} B_{\nu_{i}}$ and $\otimes_{i} B_{\nu_{i}}^{1, s_{i}}$ for general affine types.

**INPUT:**
- `display_steps` - (default: False) boolean which indicates if we want to print each step in the algorithm
- `build_graph` - (default: False) boolean which indicates if we want to construct and return a graph of the bijection whose vertices are rigged configurations obtained at each step and edges are labeled by either the return value of $\delta$ or the doubling/halving map

**OUTPUT:**
- The tensor product of KR tableaux element corresponding to this rigged configuration.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).to_tensor_product_of_kirillov_reshetikhin_tableaux()
[[[3, 3], [5, 5]]

sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[2], [2,2], [1], [1]])
sage: tp_krt = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); tp_krt
[[2, 3], [3, -2]]
```

This is invertible by calling `to_rigged_configuration()`:

```python
sage: ret = tp_krt.to_rigged_configuration(); ret
[[0], [0]]
-2[ ][ -2]
-2[ ][ -2]
```

(continues on next page)
sage: elt == ret
True

>>> from sage.all import *
>>> ret = tp_krt.to_rigged_configuration(); ret

0[ ]0

-2[ ][ ]-2
-2[ ][ ]-2

0[ ]0

>>> elt == ret
True

To view the steps of the bijection in the output, run with the display_steps=True option:

sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(True)

0[ ]0

-2[ ][ ]-2

0[ ]0

0[ ]0

0[ ]0

[[3, 2]]

[[2, 3], [3, -2]]

sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(True)

0[ ]0

-2[ ][ ]-2

0[ ]0

0[ ]0

0[ ]0

(continues on next page)
We can also construct and display a graph of the bijection as follows:

```
sage: ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(build_→graph=True)
sage: view(G)  # not tested
```

```
from sage.all import *

ret, G = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(build_→graph=True)
view(G)  # not tested
```

`weight()`

Return the weight of `self`.

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['E', 6, 1], [[2, 2]])
sage: [x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[2], -2*Lambda[0] + Lambda[2], 0]
sage: KR = crystals.KirillovReshetikhin(['E', 6, 1], 2, 2)
sage: [x.weight() for x in KR.module_generators]  # long time
[0, -2*Lambda[0] + Lambda[2], -4*Lambda[0] + 2*Lambda[2]]
sage: RC = RiggedConfigurations(['D', 6, 1], [[4, 2]])
sage: [x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[4], -4*Lambda[0] + Lambda[2] + Lambda[4],
-2*Lambda[0] + Lambda[4], -4*Lambda[0] + 2*Lambda[2],
-2*Lambda[0] + Lambda[2], 0]
```

```
from sage.all import *

RC = RiggedConfigurations(['E', Integer(6), Integer(1)], [[2, 2]])
[x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[2], -2*Lambda[0] + Lambda[2], 0]
KR = crystals.KirillovReshetikhin(['E', Integer(6), Integer(1)], Integer(2),
Integer(2))
[x.weight() for x in KR.module_generators]  # long time
[0, -2*Lambda[0] + Lambda[2], -4*Lambda[0] + 2*Lambda[2]]
RC = RiggedConfigurations(['D', Integer(6), Integer(1)], [[4, 2]])
[x.weight() for x in RC.module_generators]
[-4*Lambda[0] + 2*Lambda[4], -4*Lambda[0] + Lambda[2] + Lambda[4],
-2*Lambda[0] + Lambda[4], -4*Lambda[0] + 2*Lambda[2],
-2*Lambda[0] + Lambda[2], 0]
```
class sage.combinat.rigged_configurations.rigged_configuration_element.RCHWNonSimplyLacedElement

Bases: RCNonSimplyLacedElement

Rigged configurations in highest weight crystals.

check()

Make sure all of the riggings are less than or equal to the vacancy number.

f(a)

Return the action of \( f_a \) on self.

This works by lifting into the virtual configuration, then applying

\[
f^v = \prod_{j \in (a)} \hat{f}_j^\gamma_j
\]

and pulling back.

EXAMPLES:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.RiggedConfigurations(vct, La[0])
sage: elt = RC(partition_list=[[1,1],[2],[2]])

sage: elt.f(0)
0[ ][ ]0 -1[ ][ ]-1
0[ ][ ]-1[ ][ ]-1

sage: ascii_art(elt.f(1))
0[ ]0 0[ ][ ]0 -1[ ][ ]-1
0[ ]0 -1[ ][ ]-1
```

>>> from sage.all import *

```python
>>> La = RootSystem(['C',Integer(2),Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> vct = CartanType(['C',Integer(2),Integer(1)]).as_folding()
>>> RC = crystals.RiggedConfigurations(vct, La[Integer(0)])
>>> elt = RC(partition_list=[[Integer(1),Integer(1)],[Integer(2)],[Integer(2)]]),

>>> elt.f(Integer(0))
>>> ascii_art(elt.f(Integer(1)))
0[ ][ ]0 0[ ][ ]0 -1[ ][ ]-1
0[ ][ ]-1[ ][ ]-1
>>> elt.f(Integer(2))
```

weight()

Return the weight of self.

EXAMPLES:

```
sage: La = RootSystem(['C',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: vct = CartanType(['C',2,1]).as_folding()
```
class sage.combinat.rigged_configurations.rigged_configuration_element.RCHighestWeightElement

Bases: RiggedConfigurationElement

Rigged configurations in highest weight crystals.

check ()

Make sure all of the riggings are less than or equal to the vacancy number.

f (a)

Return the action of the crystal operator $f_a$ on self.

This implements the method defined in [CrysStructSchilling06] which finds the value $k$ which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length $k$ in the $a$-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label $-1$. If any of the resulting vacancy numbers are larger than the labels (i.e. it is an invalid rigged configuration), then $f_a$ is undefined.

INPUT:

• a – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```python
sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: RC = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: elt = RC(partition_list=[[1,1],[1],[2]])
sage: elt.f(0)
-2[ ][ ]
-1[ ]
1[ ]
```
Combinatorics, Release 10.4

(continued from previous page)

>>> from sage.all import *
>>> La = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> RC = crystals.RiggedConfigurations(['A',Integer(2),Integer(1)],
                     La[Int(0)])
>>> elt = RC(partition_list=[Int(1),Int(1),Int(1)],
                     [Int(2)]))
>>> elt.f(Int(0))
<BLANKLINE>
-2[ ]-2
-1[ ]-1
<BLANKLINE>
1[ ]1
<BLANKLINE>
0[ ][ ]0
<BLANKLINE>
>>> elt.f(Int(1))
<BLANKLINE>
0[ ]0
0[ ]0
<BLANKLINE>
-1[ ]-1
-1[ ]-1
<BLANKLINE>
0[ ][ ]0
<BLANKLINE>
>>> elt.f(Int(2))

weight()

Return the weight of self.

EXAMPLES:

sage: La = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
sage: B = crystals.RiggedConfigurations(['A',2,1], La[0])
sage: mg = B.module_generators[0]
sage: mg.f_string([0,1,2,0]).weight()
```python
>>> from sage.all import *
>>> La = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> B = crystals.RiggedConfigurations(['A', Integer(2), Integer(1)],-La[Integer(0)])
>>> mg = B.module_generators[Integer(0)]
>>> mg.f_string([Integer(0), Integer(1), Integer(2), Integer(0)]).weight()
```
Return the action of $f_a$ on self.

This works by lifting into the virtual configuration, then applying

$$f_a' = \prod_{j \in \pi(a)} f_j^{\gamma_j}$$

and pulling back.

EXAMPLES:

```python
sage: vct = CartanType(['C',2,1]).as_folding()
sage: RC = crystals.infinity.RiggedConfigurations(vct)
sage: elt = RC(partition_list=[[2],[1,1],[2]], rigging_list=[[1],[-1,-1],[-1]])
sage: ascii_art(elt.f(0))
-4[ ] [ ] [ ]-1 -2[ ]-1 -2[ ]-1
-2[ ]-1

sage: ascii_art(elt.f(1))
-1[ ] [ ]-1 -2[ ]-1 -1[ ] [ ]-1
-2[ ]-1

sage: ascii_art(elt.f(2))
-2[ ] [ ]-1 -2[ ]-1 -2[ ]-1
-2[ ]-1
```

>>> from sage.all import *
>>> vct = CartanType(['C',Integer(2),Integer(1)]).as_folding()
>>> RC = crystals.infinity.RiggedConfigurations(vct)
>>> elt = RC(partition_list=[[Integer(2)],[1,1],[2]],
       rigging_list=[[1],[1],[1]])
>>> ascii_art(elt.f(0))
-4[ ] [ ] [ ]-1 -2[ ]-1 -2[ ]-1
-2[ ]-1

>>> ascii_art(elt.f(1))
-1[ ] [ ]-1 -2[ ]-1 -1[ ] [ ]-1
-2[ ]-1

>>> ascii_art(elt.f(2))
-2[ ] [ ]-1 -2[ ]-1 -2[ ]-1
-2[ ]-1
```

to_virtual_configuration()

Return the corresponding rigged configuration in the virtual crystal.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt

0[ ][ ] [ ] [ ]

sage: elt.to_virtual_configuration()
```

(continues on next page)
```python
>>> from sage.all import *

>>> RC = RiggedConfigurations([C,Integer(2),Integer(1)],
    [[Integer(1), Integer(2)],[Integer(1),Integer(1)],[Integer(2),Integer(1)]]

>>> elt = RC(partition_list=[[Integer(3)],[Integer(2)]]); elt

>>> elt.to_virtual_configuration()
```

class sage.combinat.rigged_configurations.rigged_configuration_element.RiggedConfigurationElement

Bases: ClonableArray

A rigged configuration for simply-laced types.

For more information on rigged configurations, see `RiggedConfigurations`. For rigged configurations for non-simply-laced types, use `RCNonSimplyLacedElement`.

Typically to create a specific rigged configuration, the user will pass in the optional argument `partition_list` and if the user wants to specify the rigging values, give the optional argument `rigging_list` as well. If `rigging_list` is not passed, the rigging values are set to the corresponding vacancy numbers.

**INPUT:**
- `parent` – the parent of this element
- `rigged_partitions` – a list of rigged partitions

There are two optional arguments to explicitly construct a rigged configuration. The first is `partition_list` which gives a list of partitions, and the second is `rigging_list` which is a list of corresponding lists of riggings. If only `partition_list` is specified, then it sets the rigging equal to the calculated vacancy numbers.

If we are constructing a rigged configuration from a rigged configuration (say of another type) and we don’t want to recompute the vacancy numbers, we can use the `use_vacancy_numbers` to avoid the recomputation.

**EXAMPLES:**
Type $A_n^{(1)}$ examples:
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])

sage: RC(partition_list=[[2], [2, 2], [2], [2]])

\[
\begin{array}{ccc}
0 & [ & ] & 0 \\
-2 & [ & ] & -2 \\
-2 & [ & ] & -2 \\
2 & [ & ] & 2 \\
-2 & [ & ] & -2
\end{array}
\]

sage: RC = RiggedConfigurations(['A', 4, 1], [[1, 1], [1, 1]])

sage: RC(partition_list=[[], [], [], []])

Type $D_{n}^{(1)}$ examples:

sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 2]])

sage: RC(partition_list=[[3], [3, 2], [4], [3]])

(continues on next page)
sage: RC = RiggedConfigurations(['D', 4, 1], [[1, 1], [2, 1]])
sage: RC(partition_list=[[1], [1,1], [1], [1]])

<BLANKLINE>
-1
1
<BLANKLINE>
1
<BLANKLINE>
Combinatorics, Release 10.4

(continued from previous page)

```python
RC = RiggedConfigurations(['D', Integer(4), Integer(1)], [[Integer(1), ...
RC(partition_list=[[Integer(1)], [Integer(1),Integer(1)], [Integer(1),...
RC(partition_list=[[Integer(1)], [Integer(1),Integer(1)], [Integer(1),...
RC(partition_list=[[Integer(1)], [Integer(1),Integer(1)], [Integer(1),...
RC(partition_list=[[Integer(1)], [Integer(1),Integer(1)], [Integer(1),...
RC2 = RiggedConfigurations(['D', Integer(5), Integer(1)], [[Integer(2),...
RC2 = RiggedConfigurations(['D', Integer(5), Integer(1)], [[Integer(2),...
RC2 = RiggedConfigurations(['D', Integer(5), Integer(1)], [[Integer(2),...
RC2 = RiggedConfigurations(['D', Integer(5), Integer(1)], [[Integer(2),...
```

```
check()
Check the rigged configuration is properly defined.
There is nothing to check here.

EXAMPLES:
sage: RC = crystals.infinity.RiggedConfigurations(['A', 4])
sage: b = RC.module_generators[0].f_string([[1,2,1,1,2,4,2,3,3,2]])
sage: b.check()
```
Return the action of the crystal operator $e_a$ on self.

This implements the method defined in [CrysStructSchilling06] which finds the value $k$ which is the length of the string with the smallest negative rigging of smallest length. Then it removes a box from a string of length $k$ in the $a$-th rigged partition, keeping all colabels fixed and increasing the new label by one. If no such string exists, then $e_a$ is undefined.

This method can also be used when the underlying Cartan matrix is a Borcherds-Cartan matrix. In this case, then method of [SS2018] is used, where the new label is increased by half of the $a$-th diagonal entry of the underlying Borcherds-Cartan matrix. This method will also return None if $a$ is imaginary and the smallest rigging in the $a$-th rigged partition is not exactly half of the $a$-th diagonal entry of the Borcherds-Cartan matrix.

INPUT:

- $a$ – the index of the partition to remove a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```python
def e(a):
    from sage.all import *
    RC = crystals.infinity.RiggedConfigurations(['A', Integer(4)])
    b = RC.module_generators[Integer(0)].f_string([Integer(1), Integer(2),
                                                    Integer(1), Integer(1), Integer(2), Integer(4), Integer(2), Integer(3),
                                                    Integer(3), Integer(2)])
    b.check()

sage: elt = RC(partition_list=[[1], [1], [1], [1]])
sage: elt.e(3)
\[
\begin{array}{cccc}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
-1 & -1 & -1 & -1 \\
\end{array}
\]

sage: A = CartanMatrix([[-2,-1],[-1,-2]], borcherds=True)
```

```python
def e(a):
    from sage.all import *
    RC = crystals.infinity.RiggedConfigurations(A)
    nu0 = RC(partition_list=[[[]]])
    nu = nu0.f_string([1,0,0,0])
    ascii_art(nu.e(0))

sage: A = CartanMatrix([[-2,-1],[-1,-2]], borcherds=True)
```
epsilon \(a\)

Return \(\epsilon_a\) of self.

Let \(x_\ell\) be the smallest string of \(\nu^{(a)}\) or 0 if \(\nu^{(a)} = \emptyset\), then we have \(\epsilon_a = -\min(0, x_\ell)\).

EXAMPLES:

```python
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.epsilon(i) for i in I] for rc in RC[:4]])
```

\[
\begin{bmatrix}
0 & 0 \\
1 & 0 \\
0 & 1 \\
0 & 2 \\
\end{bmatrix}
\]

\(f(a)\)

Return the action of the crystal operator \(f_a\) on self.

This implements the method defined in [CrysStructSchilling06] which finds the value \(k\) which is the length of the string with the smallest nonpositive rigging of largest length. Then it adds a box from a string of length \(k\) in the \(a\)-th rigged partition, keeping all colabels fixed and decreasing the new label by one. If no such string exists, then it adds a new string of length 1 with label \(-1\). However we need to modify the definition to work for \(B(\infty)\) by removing the condition that the resulting rigged configuration is valid.

This method can also be used when the underlying Cartan matrix is a Borcherds-Cartan matrix. In this case,
then method of [SS2018] is used, where the new label is decreased by half of the \(a\)-th diagonal entry of the underlying Borcherds-Cartan matrix.

INPUT:

• \(a\) – the index of the partition to add a box

OUTPUT:

The resulting rigged configuration element.

EXAMPLES:

```sage
sage: RC = crystals.infinity.RiggedConfigurations(['A', 3])
sage: nu0 = RC.module_generators[0]
sage: nu0.f(2)

(/)
-2[ ]-1
(/)
```

```sage
sage: A = CartanMatrix([[-2, -1], [-1, -2]], borcherds=True)
sage: RC = crystals.infinity.RiggedConfigurations(A)
sage: nu0 = RC(partition_list=[[], []])
sage: nu = nu0.f_string([1, 0, 0, 0])
sage: ascii_art(nu.f(0))
```

```
9[ ]7 6[ ]5
9[ ]5
9[ ]3
9[ ]1
```

```sage
>>> from sage.all import *
```

```sage
>>> RC = crystals.infinity.RiggedConfigurations(['A', Integer(3)])
>>> nu0 = RC.module_generators[Integer(0)]
```

```sage
>>> nu0.f(Integer(2))

(/)
-2[ ]-1
(/)
```

```sage
>>> A = CartanMatrix([[Integer(-2), Integer(-1)], [Integer(-1), Integer(-2)]], 
                   borcherds=True)
>>> RC = crystals.infinity.RiggedConfigurations(A)
>>> nu0 = RC(partition_list=[[[]]])
>>> nu = nu0.f_string([Integer(1), Integer(0), Integer(0), Integer(0)])
>>> ascii_art(nu.f(Integer(0)))
```

```
9[ ]7 6[ ]5
9[ ]5
9[ ]3
9[ ]1
```

```sage
nu()
```

Return the list \(\nu\) of rigged partitions of this rigged configuration element.
The $\nu$ array as a list.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RC(partition_list=[[2], [2,2], [2], [2]]).nu()

\[
\begin{array}{|c|c|}
\hline
0 & 0 \\
-2 & -2 \\
-2 & -2 \\
2 & 2 \\
-2 & -2 \\
\hline
\end{array}
\]
```

```python
from sage.all import *

RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), Integer(2)]]).

RC(partition_list=[[Integer(2)], [Integer(2), Integer(2)], [Integer(2)], [Integer(2)]]).nu()

\[
\begin{array}{|c|c|}
\hline
0 & 0 \\
-2 & -2 \\
-2 & -2 \\
2 & 2 \\
-2 & -2 \\
\hline
\end{array}
\]
```

**partition_rigging_lists()**

Return the list of partitions and the associated list of riggings of `self`.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[1,2],[2,2]])
sage: rc = RC(partition_list=[[2],[1],[1]], rigging_list=[[-1],[0],[-1]]); rc

-1[ ][ ]-1
1[ ]0
-1[ ]-1

sage: rc.partition_rigging_lists()

[[[2], [1], [1]], [[-1], [0], [-1]]]
```

```python
from sage.all import *

RC = RiggedConfigurations(['A', Integer(3), Integer(1)], [[Integer(1), Integer(2)], [Integer(2), Integer(2)]]).

rc = RC(partition_list=[[Integer(2)], [Integer(1)], [Integer(1)]], rigging_list=[[-Integer(1)], [Integer(0)], [-Integer(1)]]); rc

-1[ ][ ]-1
1[ ]0
-1[ ]-1

rc.partition_rigging_lists()

[[[2], [1], [1]], [[-1], [0], [-1]]]
```
\( \phi(a) \)

Return \( \varphi_a \) of \( \text{self} \).

Let \( x_\ell \) be the smallest string of \( \nu(a) \) or 0 if \( \nu(a) = \emptyset \), then we have \( \varepsilon_a = p^{(a)}_\infty - \min(0, x_\ell) \).

EXAMPLES:

```
sage: La = RootSystem(['B',2]).weight_lattice().fundamental_weights()
sage: RC = crystals.RiggedConfigurations(La[1]+La[2])
sage: I = RC.index_set()
sage: matrix([[rc.phi(i) for i in I] for rc in RC[:4]])
[1 1]
[0 3]
[0 2]
[1 1]
```

\( \text{vacancy_number}(a, i) \)

Return the vacancy number \( p^{(a)}_i \).

INPUT:

- \( a \) – the index of the rigged partition
- \( i \) – the row of the rigged partition

EXAMPLES:

```
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: elt = RC(partition_list=[[1], [2,1], [1], []])
sage: elt.vacancy_number(2, 3)
-2
sage: elt.vacancy_number(2, 2)
-2
sage: elt.vacancy_number(2, 1)
-1
```

```bash
>>> from sage.all import *
... >>> La = RootSystem(['B', Integer(2)]).weight_lattice().fundamental_weights()
... >>> RC = crystals.RiggedConfigurations(La[Integer(1)]+La[Integer(2)])
... >>> I = RC.index_set()
... >>> matrix([[rc.phi(i) for i in I] for rc in RC[:Integer(4)]]))
[1 1]
[0 3]
[0 2]
[1 1]
```

```bash
>>> from sage.all import *
... >>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), Integer(4), Integer(1)], [Integer(2), Integer(4), Integer(1)]),
... ... >>> elt = RC(partition_list=[[Integer(1)], [Integer(2),Integer(1)], ...
... ... (continues on next page)
```

5.1. Comprehensive Module List 3553
5.1.215 Rigged Configurations

AUTHORS:
  • Travis Scrimshaw (2010-09-26): Initial version

Return the KR crystal $B^{n,s}$ using rigged configurations.

This is the rigged configuration $RC(B^{n,s})$ or $RC(L)$ with $L = (L_i^{(a)})$ and $L_i^{(a)} = \delta_{a,r}\delta_{i,s}$.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> K1 = crystals.kirillov_reshetikhin.RiggedConfigurations(['A',6,2], 2, 1)
>>> K2 = crystals.kirillov_reshetikhin.LSPaths(['A',6,2], 2, 1)
>>> K1.digraph().is_isomorphic(K2.digraph(), edge_labels=True)
True
```

```python
>>> K1 = crystals.kirillov_reshetikhin.RiggedConfigurations(['A',Integer(6), Integer(2)], Integer(2), Integer(1))
>>> K2 = crystals.kirillov_reshetikhin.LSPaths(['A',Integer(6),Integer(2)], Integer(2), Integer(1))
>>> K1.digraph().is_isomorphic(K2.digraph(), edge_labels=True)
True
```

**class** `sage.combinat.rigged_configurations.rigged_configurations.RCNonSimplyLaced(`
carton_type, `dim`)

Bases: `RiggedConfigurations`

Rigged configurations in non-simply-laced types.

These are rigged configurations which lift to virtual rigged configurations in a simply-laced type.
For more on rigged configurations, see \textit{RiggedConfigurations}.

\textbf{Element} \newline
alias of \texttt{KRRCNonSimplyLacedElement}

\textbf{from\_virtual} (\texttt{vrc}) \newline
Convert \texttt{vrc} in the virtual crystal into a rigged configuration of the original Cartan type. \newline
\textbf{INPUT}: \newline
\begin{itemize}
  \item \texttt{vrc} – a virtual rigged configuration
\end{itemize}
\textbf{EXAMPLES}:

\begin{verbatim}
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]])
sage: vrc_elt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(vrc_elt); ret
0[ ][ ][ 0]
0[ ][ ]0
sage: ret == elt
True

>>> from sage.all import *

>>> RC = RiggedConfigurations(['C',Integer(2),Integer(1)],
                                 [[Integer(1),Integer(2)],[Integer(1),Integer(1)],[Integer(2),Integer(1)]])
>>> elt = RC(partition_list=[[Integer(3)],[Integer(2)]])
>>> vrc_elt = RC.to_virtual(elt)
>>> ret = RC.from_virtual(vrc_elt); ret
<BLANKLINE>
0[ ][ ][ 0]
0[ ][ ]0
>>> ret == elt
True
\end{verbatim}

\textbf{kleber\_tree} () \newline
Return the underlying (virtual) Kleber tree used to generate all highest weight rigged configurations. \newline
\textbf{EXAMPLES}:

\begin{verbatim}
sage: RC = RiggedConfigurations(['C',3,1], [[1,1],[2,1]])
sage: RC.kleber_tree()
Virtual Kleber tree of Cartan type ['C', 3, 1] and B = ((1, 1), (2, 1))

>>> from sage.all import *

>>> RC = RiggedConfigurations(['C',Integer(3),Integer(1)],
                                 [[Integer(1),Integer(1)],[Integer(2),Integer(1)]])
>>> RC.kleber_tree()
Virtual Kleber tree of Cartan type ['C', 3, 1] and B = ((1, 1), (2, 1))
\end{verbatim}

\textbf{module\_generators} () \newline
Module generators for this set of rigged configurations. \newline
Iterate over the highest weight rigged configurations by moving through the \texttt{KleberTree} and then setting appropriate values of the partitions. \newline
\textbf{EXAMPLES}:
\begin{verbatim}
from sage.all import *
RC = RiggedConfigurations(['C', 3, 1], [[1,2]])

RC.module_generators

0[ ]0
0[ ]0
0[ ]0

RC = RiggedConfigurations(['D',4,3], [[1,1]])

RC.module_generators

0[ ]0
0[ ]0
0[ ]0

RC = RiggedConfigurations(['C', Integer(3), Integer(1)], [[Integer(1), Integer(2)]]

RC = RiggedConfigurations(['D', Integer(4), Integer(3)], [[Integer(1), Integer(1)]]

RC.module_generators

0[ ]0
0[ ]0
0[ ]0

RC = RiggedConfigurations(['D',Integer(4),Integer(3)], [[Integer(1), Integer(1)]]

RC.module_generators

0[ ]0
0[ ]0
0[ ]0
\end{verbatim}
to_virtual(rc)

Convert rc into a rigged configuration in the virtual crystal.

INPUT:

• rc – a rigged configuration element

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt
0[ ][ ]0
0[ ][ ]0
sage: velt = RC.to_virtual(elt); velt
0[ ][ ][ ]0
0[ ][ ][ ]0
0[ ][ ][ ]0
0[ ][ ][ ]0
sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 2))
```

virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['C',2,1], [[1,2],[1,1],[2,1]])
sage: elt = RC(partition_list=[[3],[2]]); elt
0[ ][ ]0
0[ ][ ]0
>>> velt = RC.to_virtual(elt); velt
0[ ][ ][ ]0
0[ ][ ][ ]0
0[ ][ ][ ]0
0[ ][ ][ ]0
>>> velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 2))
```
Rigged configurations of type \([\Lambda', 3, 1]\) and factor(s) \([(1, 2), (3, 2), (1, \rightarrow 1), (3, 1), (2, 2)]\)

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['C', Integer(2), Integer(1)], [[Integer(1), Integer(2), Integer(1)], [Integer(1), Integer(1), Integer(1)], [Integer(2), Integer(1)]])
>>> RC
Rigged configurations of type ['C', 2, 1] and factor(s) ((1, 2), (1, 1), (2, \rightarrow 1))
>>> RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 1), (2, 1))
```

```python
class sage.combinat.rigged_configurations.rigged_configurations.RCTypeA2Dual(car
tan_type, dims)

Bases: RCTypeA2Even

Rigged configurations of type \(A_{2n}^{(2)}\).

For more on rigged configurations, see `RiggedConfigurations`.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,2],[1,1],[2,1]])
sage: RC
Rigged configurations of type ['BC', 2, 2]^* and factor(s) ((1, 2), (1, 1), (2, \rightarrow 1))
sage: RC.cardinality()
750
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 1), (2, 1))
```

```python
sage: RC = RiggedConfigurations(CartanType(['A',2,2]).dual(), [[1,1]])
sage: RC.cardinality()
3
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[Integer(1),Integer(2)],[Integer(1),Integer(1)],[Integer(2),Integer(1)]]).
dual(), [[1,2],[1,1],[2,1]])
sage: TestSuite(RC).run() # long time
sage: TestSuite(RC).run() # long time
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(CartanType(['A',Integer(4),Integer(2)]).dual(), [[Integer(1),Integer(2)],[Integer(1),Integer(1)], [Integer(2),Integer(1)]]))
>>> RC
Rigged configurations of type ['BC', 2, 2]^* and factor(s) ((1, 2), (1, 1), (2, \rightarrow 1))
>>> RC.cardinality()
750
>>> RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 1), (2, 1))
>>> RC = RiggedConfigurations(CartanType(['A',Integer(2),Integer(2)]).dual(), [[Integer(1),Integer(1)]])
>>> RC.cardinality()
3
```
from sage.all import *

RC = RiggedConfigurations(CartanType(['A', Integer(4), Integer(2)]).dual(), [[Integer(2), Integer(2)]])
elt = RC(partition_list=[[Integer(1), Integer(1)]]
velt = RC.to_virtual(elt)
ret = RC.from_virtual(velt); ret
-1[ ]-1
1[ ]1

ret == elt
True

module_generators()
Module generators for rigged configurations of type $A^{(2)\dagger}_{2n}$.
Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions. This also skips rigged configurations where $P_{i}^{(n)} < 1$ when $i$ is odd.

EXAMPLES:

sage: RC = RiggedConfigurations(CartanType(['A', 4, 2]).dual(), [[1, 1]])
sage: for x in RC.module_generators: x

(continues on next page)
```
>>> from sage.all import *
>>> RC = RiggedConfigurations(CartanType(['A', Integer(4), Integer(2)]).dual(), [[Integer(1), Integer(1)]]
>>> for x in RC.module_generators: x
(1)
(1)
(1)

\textbf{to\_virtual} (rc)
\begin{quote}
Convert $rc$ into a rigged configuration in the virtual crystal.
\end{quote}
\begin{flushleft}
\textbf{INPUT:}
\begin{itemize}
\item $rc$ – a rigged configuration element
\end{itemize}
\textbf{EXAMPLES:}
\begin{Verbatim}
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt
-1[ ]-1
1[ ]1
sage: velt = RC.to_virtual(elt); velt
-1[ ]-1
2[ ]2
-1[ ]-1
sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 2), (2, 2))
\end{Verbatim}
\end{flushleft}
```
class sage.combinat.rigged_configurations.rigged_configurations.RCTypeA2Even(car-
ten_type, dims)

Bases: RCNonSimplyLaced

Rigged configurations for type $A_{2n}^{(2)}$.

For more on rigged configurations, see RiggedConfigurations.

EXAMPLES:

sage: RC = RiggedConfigurations(['A',4,2], [[2,1], [1,2]])
150
sage: RC.cardinality()

sage: RC = RiggedConfigurations(['A',2,2], [[1,1]])
3
sage: RC.cardinality()

sage: TestSuite(RC).run() # long time

sage: RC = RiggedConfigurations(['A',4,2], [[2,1]])

sage: TestSuite(RC).run() # long time

from sage.all import *

RC = RiggedConfigurations(['A',Integer(4),Integer(2)], [[Integer(2),
→Integer(1)], [Integer(1),Integer(2)]])

RC.cardinality() # long time

RC = RiggedConfigurations(['A',Integer(2),Integer(2)], [[Integer(1),
→Integer(1)]])

RC.cardinality() # long time

RC = RiggedConfigurations(['A',Integer(4),Integer(2)], [[Integer(2),
→Integer(1)]])

TestSuite(RC).run() # long time

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: RC = RiggedConfigurations(['A',4,2], [[1,1], [2,2]])

sage: RC.cardinality() 250

from sage.all import *

RC = RiggedConfigurations(['A',Integer(4),Integer(2)], [[Integer(1),
→Integer(1)], [Integer(2),Integer(2)]]))

RC.cardinality() 250
**from_virtual** *(vrc)*

Convert *vrc* in the virtual crystal into a rigged configuration of the original Cartan type.

**INPUT:**

- *vrc* – a virtual rigged configuration element

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['A',4,2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]])
sage: velt = RC.to_virtual(elt)
sage: ret = RC.from_virtual(velt); ret

-1[ ]-1
1[ ]1

sage: ret == elt
True
```

```python
>>> from sage.all import *

>>> RC = RiggedConfigurations(['A',Integer(4),Integer(2)], [[Integer(2),
˓→Integer(2)]]

>>> elt = RC(partition_list=[[Integer(1)],[Integer(1)]]

>>> velt = RC.to_virtual(elt)

>>> ret = RC.from_virtual(velt); ret

-1[ ]-1
1[ ]1
```

**to_virtual** *(rc)*

Convert *rc* into a rigged configuration in the virtual crystal.

**INPUT:**

- *rc* – a rigged configuration element

**EXAMPLES:**

```
sage: RC = RiggedConfigurations(['A',4,2], [[2,2]])
sage: elt = RC(partition_list=[[1],[1]]); elt

-1[ ]-1
1[ ]1

sage: velt = RC.to_virtual(elt); velt

-1[ ]-1
2[ ]2
-1[ ]-1
```

(continues on next page)
```python
sage: velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 2), (2, 2))

>>> from sage.all import *
>>> RC = RiggedConfigurations(['A',Integer(4),Integer(2)], [[Integer(2), →Integer(2)]])
>>> elt = RC(partition_list=[[Integer(1)], [Integer(1)]]); elt
-1[ ]-1
1[ ]1
>>> velt = RC.to_virtual(elt); velt
-1[ ]-1
2[ ]2
-1[ ]-1
>>> velt.parent()
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 2), (2, 2))
```

```python
virtual()

Return the corresponding virtual crystal.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 4, 2], [[1, 2], [1, 1], [2, 1]])
sage: RC
Rigged configurations of type ['BC', 2, 2] and factor(s) ((1, 2), (1, 1), (2, 1))
sage: RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 1), (2, 1))
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['A',Integer(4),Integer(2)], [[Integer(1), →Integer(2)],[Integer(1),Integer(1)], [Integer(2),Integer(1)]]))
>>> RC
Rigged configurations of type ['BC', 2, 2] and factor(s) ((1, 2), (1, 1), (2, 1))
>>> RC.virtual
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 2), (3, 2), (1, 1), (3, 1), (2, 1), (2, 1))
```

```python
class sage.combinat.rigged_configurations.rigged_configurations.RiggedConfigurations(car-
tan_type, B)

Bases: UniqueRepresentation, Parent

Rigged configurations as \(U_q'(g)\)-crystals.

Let \(\bar{T}\) denote the classical index set associated to the Cartan type of the rigged configurations. A rigged configuration
of multiplicity array $L_i^{(a)}$ and dominant weight $\Lambda$ is a sequence of partitions $\{\nu^{(a)} | a \in T\}$ such that

$$\sum_{T \times \mathbb{Z}^+} im_i^{(a)} \alpha_a = \sum_{T \times \mathbb{Z}^+} iL_i^{(a)} \Lambda_a - \Lambda$$

where $\alpha_a$ is a simple root, $\Lambda_a$ is a fundamental weight, and $m_i^{(a)}$ is the number of rows of length $i$ in the partition $\nu^{(a)}$.

Each partition $\nu^{(a)}$, in the sequence also comes with a sequence of statistics $p_i^{(a)}$ called *vacancy numbers* and a weakly decreasing sequence $J_i^{(a)}$ of length $m_i^{(a)}$ called *riggings*. Vacancy numbers are computed based upon the partitions and $L_i^{(a)}$, and the riggings must satisfy $\max J_i^{(a)} \leq p_i^{(a)}$. We call such a partition a *rigged partition*. For more, see [RigConBijection] [CrysStructSchilling06] [BijectionLRT].

Rigged configurations form combinatorial objects first introduced by Kerov, Kirillov and Reshetikhin that arose from studies of statistical mechanical models using the Bethe Ansatz. They are sequences of rigged partitions. A rigged partition is a partition together with a label associated to each part that satisfy certain constraints. The labels are also called riggings.

Rigged configurations exist for all affine Kac-Moody Lie algebras. See for example [HKOTT2002]. In Sage they are specified by providing a Cartan type and a list of rectangular shapes $B$. The list of all (highest weight) rigged configurations for given $B$ is computed via the (virtual) Kleber algorithm (see also KleberTree and VirtualKleberTree).

Rigged configurations in simply-laced types all admit a classical crystal structure [CrysStructSchilling06]. For non-simply-laced types, the crystal is given by using virtual rigged configurations [OSS03]. The highest weight rigged configurations are those where all riggings are nonnegative. The list of all rigged configurations is computed from the highest weight ones using the crystal operators.

Rigged configurations are conjecturally in bijection with TensorProductOfKirillovReshetikhinTableaux of non-exceptional affine types where the list $B$ corresponds to the tensor factors $B^{r \times s}$. The bijection has been proven in types $A_n^{(1)}$ and $D_n^{(1)}$ and when the only non-zero entries of $L_i^{(a)}$ are either only $L_i^{(a)}$ or only $L_i^{(1)}$ (corresponding to single columns or rows respectively) [RigConBijection], [BijectionLRT], [BijectionDn].

KR crystals are implemented in Sage, see KirillovReshetikhinCrystal(), however, in the bijection with rigged configurations a different realization of the elements in the crystal are obtained, which are coined KR tableaux, see KirillovReshetikhinTableaux. For more details see [OSS2011].

**Note:** All non-simply-laced rigged configurations have not been proven to give rise to aligned virtual crystals (i.e. have the correct crystal structure or isomorphic as affine crystals to the tensor product of KR tableaux).

**INPUT:**

- cartan_type – a Cartan type
- $B$ – a list of positive integer tuples $(r, s)$ corresponding to the tensor factors in the bijection with tensor product of Kirillov-Reshetikhin tableaux or equivalently the sequence of width $s$ and height $r$ rectangles

**REFERENCES:**

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[[3, 2], [1, 2], [1, 1]]])
sage: RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (1, 2), (1, 1))
sage: RC = RiggedConfigurations(['A', 3, 1], [[2,1]]); RC
(continues on next page)
```
Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1),)
sage: RC.cardinality()
6
sage: len(RC.list()) == RC.cardinality()
True
sage: RC.list() # random
[
       0[ ]0
   (/) (/) (/) -1[ ]-1 -1[ ]-1

   (/) (/) -1[ ]-1 (/) -1[ ]-1 0[ ]0
   , , , , ,
]

>>> from sage.all import *

>>> RC = RiggedConfigurations(['A', Integer(3), Integer(1)], [[Integer(3), Integer(2)], [Integer(1), Integer(2)], [Integer(1), Integer(1)]]);

A rigged configuration element with all riggings equal to the vacancy numbers can be created as follows:

sage: RC = RiggedConfigurations(['A', 3, 1], [[3,2], [2,1], [1,1], [1,1]]); RC
Rigged configurations of type ['A', 3, 1] and factor(s) ((3, 2), (2, 1), (1, 1),)
sage: elt = RC(partition_list=[[1],[],[]]); elt
0[ ]0
(/)
(/)
If on the other hand we also want to specify the riggings, this can be achieved as follows:

```
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2], [1, 1]])
sage: RC(partition_list=[[2], [2], [2]])
```

```
1[ ][ ]1
0[ ][ ]0
0[ ][ ]0
```

```
sage: RC(partition_list=[[2], [2], [2]], rigging_list=[[0], [0], [0]])
```

```
1[ ][ ]0
0[ ][ ]0
0[ ][ ]0
```

A larger example:

```
sage: RC = RiggedConfigurations(['D', 7, 1], [[3, 3], [5, 2], [4, 3], [2, 3], [4, 4], [3, 1],
    [1, 4], [2, 2]])
sage: elt = RC(partition_list=[[2], [3, 2, 1], [2, 2, 1, 1, 1], [2, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1],
    [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1], [3, 2, 1, 1, 1, 1]],
```

>>> elt
<BLANKLINE>
3[ ][ ]2
<BLANKLINE>
To obtain the KR tableau under the bijection between rigged configurations and KR tableaux, we can type the following. This example was checked against Reiho Sakamoto’s Mathematica program on rigged configurations:

```sage
sage: output = elt.to_tensor_product_of_kirillov_reshetikhin_tableaux(); output
[[1, 1, 1], [2, 3, 3], [3, 4, -5]] (X) [[1, 1], [2, 2], [3, 3], [5, -6], [6, -5]]
→ (X)
[[1, 1, 2], [2, 2, 3], [3, 3, 7], [4, 4, -7]] (X) [[1, 1, 1], [2, 2, 2]] (X)
[[1, 1, 1, 3], [2, 2, 3, 4], [3, 3, 4, 5], [4, 4, 5, 6]] (X) [[1], [2], [3]] (X)
→ [[1, 1, 1, 1]] (X) [[1, 1], [2, 2]]
sage: elt.to_tensor_product_of_kirillov_reshetikhin_tableaux().to_rigged_configuration() == elt
True
sage: output.to_rigged_configuration().to_tensor_product_of_kirillov_reshetikhin_tableaux() == output
True
```

```python
>>> from sage.all import *
```
We can also convert between rigged configurations and tensor products of KR crystals:

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[2, 1]])
sage: elt = RC(partition_list=[[1],[1,1],[1],[1]])
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[]]]
sage: ret = RC(tp_krc)
sage: ret == elt
True
```

```python
>>> from sage.all import *

sage: RC = RiggedConfigurations(['D', 4, 1], [[4,1], [3,3]])
sage: KR1 = crystals.KirillovReshetikhin(['D', 4, 1], 4, 1)
sage: KR2 = crystals.KirillovReshetikhin(['D', 4, 1], 3, 3)
sage: T = crystals.TensorProduct(KR1, KR2)
sage: t = T[1]; t
[[++++, []], [+---, [[1], [2], [4], [-4]]]]
sage: ret = RC(t)
sage: ret.to_tensor_product_of_kirillov_reshetikhin_crystals()
[[++++, []], [+---, [[1], [2], [4], [-4]]]]
```

Element

alias of `KRRCSimplyLacedElement`

```python
classically_highest_weight_vectors()
```

Return the classically highest weight elements of `self`. 

5.1. Comprehensive Module List
fermionic_formula \( (q=\text{None}, \text{only}_\text{highest}_\text{weight}=\text{False}, \text{weight}=\text{None}) \)

Return the fermionic formula associated to self.

Given a set of rigged configurations \( RC(\lambda, L) \), the fermionic formula is defined as:

\[
M(\lambda, L; q) = \sum_{(\nu, J)} q^{cc(\nu, J)}
\]

where we sum over all (classically highest weight) rigged configurations of weight \( \lambda \) where \( cc \) is the cocharge statistic. This is known to reduce to

\[
M(\lambda, L; q) = \sum_{\nu} q^{cc(\nu)} \prod_{(a, i) \in I \times Z} \left[ p_i^{(a)} + m_i^{(a)} \right]_q
\]

The generating function of \( M(\lambda, L; q) \) in the weight algebra subsumes all fermionic formulas:

\[
M(L; q) = \sum_{\lambda \in P} M(\lambda, L; q) \lambda.
\]

This is conjecturally equal to the one dimensional configuration sum of the corresponding tensor product of Kirillov-Reshetikhin crystals, see [HKOTT2002]. This has been proven in general for type \( A_n^{(1)} \) [BijectionLRT], single factors \( B^{r,s} \) in type \( D_n^{(1)} \) [OSS2011] with the result from [Sakamoto13], as well as for a tensor product of single columns [OSS2003], [BijectionDn] or a tensor product of single rows [OSS03] for all non-exceptional types.

**INPUT:**

- \( q \) – the variable \( q \)
- \( \text{only}_\text{highest}_\text{weight} \) – use only the classically highest weight rigged configurations
- \( \text{weight} \) – return the fermionic formula \( M(\lambda, L; q) \) where \( \lambda \) is the classical weight weight

**REFERENCES:**

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 2, 1], [[1,1], [1,1]])
sage: RC.fermionic_formula()
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
+ B[-2*Lambda[2]] + (q+1)*B[Lambda[2]]
```

```python
t = QQ[t].gen(0)
sage: RC.fermionic_formula(t)
B[-2*Lambda[1] + 2*Lambda[2]] + (t+1)*B[-Lambda[1]]
+ B[-2*Lambda[2]] + (t+1)*B[Lambda[2]]
```

```python
sage: La = RC.weight_lattice_realization().classical().fundamental_weights()
sage: RC.fermionic_formula(weight=La[2])
q + 1
sage: RC.fermionic_formula(only_highest_weight=True, weight=La[2])
q
```

```python
>>> from sage.all import *
```

```python
>>> RC = RiggedConfigurations(['A', Integer(2), Integer(1)], [[Integer(1), ←Integer(1)], [Integer(1),Integer(1)]]])
>>> RC.fermionic_formula()
B[-2*Lambda[1] + 2*Lambda[2]] + (q+1)*B[-Lambda[1]]
```

(continues on next page)
\[ B[-2*\Lambda[1] + 2*\Lambda[2]] + (t+1)*B[-\Lambda[1]] \]
\[ + (t+1)*B[\Lambda[1] - \Lambda[2]] + B[2*\Lambda[1]] \]
\[ + B[-2*\Lambda[2]] + (t+1)*B[\Lambda[2]] \]

\[ t = QQ['t'].gen(Integer(0)) \]
\[ RC.fermionic_formula(t) \]
\[ B[-2*\Lambda[1] + 2*\Lambda[2]] + (t+1)*B[-\Lambda[1]] \]
\[ + (t+1)*B[\Lambda[1] - \Lambda[2]] + B[2*\Lambda[1]] \]
\[ + B[-2*\Lambda[2]] + (t+1)*B[\Lambda[2]] \]

\[ La = RC.weight_lattice_realization().classical().fundamental_weights() \]
\[ RC.fermionic_formula(weight=La[Integer(2)]) \]
\[ q + 1 \]
\[ RC.fermionic_formula(only_highest_weight=True, weight=La[Integer(2)]) \]
\[ q \]

Only using the highest weight elements on other types:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
q*B[0] + q*B[lambda[2]] + B[2*lambda[2]]
```

```python
sage: RC = RiggedConfigurations(['B', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)  # long time
```

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)  # long time
(q^2+q)^2*B[lambda[1] + lambda[2]] + (q^2+q)*B[lambda[1] + 2*lambda[2]]
```

```python
sage: RC = RiggedConfigurations(['D', 4, 1], [[3,1], [4,1], [2,1]])
sage: RC.fermionic_formula(only_highest_weight=True)
(q^4+q^3+q^2)*B[lambda[1]] + (q^2+q)*B[lambda[1] + lambda[2]]
```

```python
sage: RC = RiggedConfigurations(['E', 6, 1], [[2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
q^2*B[0] + q*B[lambda[2]] + B[2*lambda[2]]
```

```python
sage: RC = RiggedConfigurations(['B', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
# long time
```

```python
sage: RC = RiggedConfigurations(['C', 3, 1], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)  # long time
(q^2+q)^2*B[lambda[1] + lambda[2]] + (q^2+q)*B[lambda[1] + 2*lambda[2]]
```

```python
sage: RC = RiggedConfigurations(['D', 4, 2], [[3,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)  # long time
```

```python
sage: RC = RiggedConfigurations(CartanType(['A',4,2]).dual(), [[1,1], [2,2]])
sage: RC.fermionic_formula(only_highest_weight=True)
(q^2+q)*B[lambda[1] + 2*lambda[2]] + (q^5+2*q^4+q^3)*B[lambda[1] + lambda[2]]
```

```python
>>> from sage.all import *  
```
Combinatorics, Release 10.4

kleber_tree()

Return the underlying Kleber tree used to generate all highest weight rigged configurations.

EXAMPLES:

sage: RC = RiggedConfigurations(['A',3,1], [[1,1], [2,1]])
sage: RC.kleber_tree()
Kleber tree of Cartan type ['A', 3, 1] and B = ((1, 1), (2, 1))

module_generators()

Module generators for this set of rigged configurations.

Iterate over the highest weight rigged configurations by moving through the KleberTree and then setting appropriate values of the partitions.

EXAMPLES:

sage: RC = RiggedConfigurations(['A',3,1], [[1,1], [2,1]]) sage: for x in RC.module_generators: x

(continues on next page)
>>> from sage.all import *

>>> RC = RiggedConfigurations(['D', Integer(4), Integer(1)], [[Integer(2),
˓→Integer(1)]]

>>> for x in RC.module_generators: x

options = Current options for RiggedConfigurations - convention: English -
display: vertical - element_ascii_art: True - half_width_boxes_type_B: True

tensor (*crystals, **options)

Return the tensor product of self with crystals.

If crystals is a list of rigged configurations of the same Cartan type, then this returns a new Rigged-
Configurations.

EXAMPLES:
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: RC2 = RiggedConfigurations(['A', 3, 1], [[1,1], [3,3]])
sage: RC.tensor(RC2, RC2)
Rigged configurations of type ['A', 3, 1]
and factor(s) ((2, 1), (1, 3), (1, 1), (3, 3), (1, 1), (3, 3))
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: RC.tensor(K)
Full tensor product of the crystals
[Rigged configurations of type ['A', 3, 1] and factor(s) ((2, 1), (1, 3)),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2)]
```

tensor_product_of_kirillov_reshetikhin_crystals()

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3,1], [2,2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_crystals()
Full tensor product of the crystals
[Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(2,2)]
```

tensor_product_of_kirillov_reshetikhin_tableaux()

Return the corresponding tensor product of Kirillov-Reshetikhin tableaux.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 3, 1], [[3, 2], [1, 2]])
sage: RC.tensor_product_of_kirillov_reshetikhin_tableaux()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and
factor(s) ((3, 2), (1, 2))
```
5.1.216 Rigged Partitions

Class and methods of the rigged partition which are used by the rigged configuration class. This is an internal class used by the rigged configurations and KR tableaux during the bijection, and is not to be used by the end-user.

We hold the partitions as a 1-dim array of positive integers where each value corresponds to the length of the row. This is the shape of the partition which can be accessed by the regular index.

The data for the vacancy number is also stored in a 1-dim array which each entry corresponds to the row of the tableau, and similarly for the partition values.

AUTHORS:

• Travis Scrimshaw (2010-09-26): Initial version

Todo: Convert this to using multiplicities \( m_i \) (perhaps with a dictionary)?

```python
class sage.combinat.rigged_configurations.rigged_partition.RiggedPartition
Bases: sage_object

The RiggedPartition class which is the data structure of a rigged (i.e. marked or decorated) Young diagram of a partition.

Note that this class as a stand-alone object does not make sense since the vacancy numbers are calculated using the entire rigged configuration. For more, see RiggedConfigurations.

EXAMPLES:

```
• $t$ – The scaling factor

OUTPUT:

• The number of cells

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])
sage: RP.get_num_cells_to_column(1)
2
sage: RP.get_num_cells_to_column(2)
3
sage: RP.get_num_cells_to_column(3)
3
sage: RP.get_num_cells_to_column(3, 2)
5
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), Integer(2)]])
>>> RP = RC(partition_list=[Integer(2),[Integer(2),Integer(2)],[Integer(2), Integer(1)],[Integer(2)]])(Integer(2))
>>> RP.get_num_cells_to_column(Integer(1))
2
>>> RP.get_num_cells_to_column(Integer(2))
3
>>> RP.get_num_cells_to_column(Integer(3))
3
>>> RP.get_num_cells_to_column(Integer(3), Integer(2))
5
```

**insert_cell** *(max_width)*

Insert a cell given at a singular value as long as its less than the specified width.

Note that *insert_cell()* does not update riggings or vacancy numbers, but it does prepare the space for them. Returns the width of the row we inserted at.

INPUT:

• max_width – The maximum width (i.e. row length) that we can insert the cell at

OUTPUT:

• The width of the row we inserted at.

EXAMPLES:

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2],[2,2],[2,1],[2]])
sage: RP.insert_cell(2)
2
sage: RP
0[ ][ ][ ]None
-1[ ]-1
```

```python
>>> from sage.all import *
>>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), Integer(2)]]))
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> RP = RC(partition_list=[[Integer(2)], [Integer(2), Integer(2)], [Integer(2), Integer(1)], [Integer(2)]])
>>> RP.insert_cell(Integer(2))
2
>>> RP
0[ ][ ][ ]None
-1[ ]-1
```

**remove_cell (row, num_cells=1)**

Removes a cell at the specified row.

Note that `remove_cell()` does not set/update the vacancy numbers or the riggings, but guarantees that the location has been allocated in the returned index.

**INPUT:**

- **row** – the row to remove the cell from
- **num_cells** – (default: 1) the number of cells to remove

**OUTPUT:**

- The location of the newly constructed row or `None` if unable to remove row or if deleted a row.

**EXAMPLES:**

```python
sage: RC = RiggedConfigurations(['A', 4, 1], [[2, 2]])
sage: RP = RC(partition_list=[[2], [2, 2], [2, 1], [2]])[2]
sage: RP.remove_cell(0)
0
sage: RP
None[ ]None
-1[ ]-1
```

```python
>>> from sage.all import *
```

```python
>>> RC = RiggedConfigurations(['A', Integer(4), Integer(1)], [[Integer(2), Integer(2)])
```

```python
>>> RP = RC(partition_list=[[Integer(2)], [Integer(2), Integer(2)], [Integer(2), Integer(1)], [Integer(2)]])
>>> RP.remove_cell(Integer(0))
0
>>> RP
None[ ]None
-1[ ]-1
```

**rigging**

**vacancy_numbers**

**class**

sage.combinat.rigged_configurations.rigged_partition.RiggedPartitionTypeB

Bases: RiggedPartition

Rigged partitions for type $B_n^{(1)}$ which have special printing rules which comes from the fact that the $n$-th partition can have columns of width $\frac{n}{2}$.
5.1.217 Tensor Product of Kirillov-Reshetikhin Tableaux

A tensor product of KirillovReshetikhinTableaux which are tableaux of $r$ rows and $s$ columns which naturally arise in the bijection between rigged configurations and tableaux and which are in bijection with the elements of the Kirillov-Reshetikhin crystal $B^{-\infty}$, see KirillovReshetikhinCrystal().

AUTHORS:

- Travis Scrimshaw (2010-09-26): Initial version

EXAMPLES:

Type $A_n^{(1)}$ examples:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2, 1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) (((3, → 1), (2, 1)))
sage: KRT.cardinality()
24
```

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[1,1], [3,1]])
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) (((1, → 1), (3, 1)))
sage: len(KRT.module_generators)
5
```

Type $D_n^{(1)}$ examples:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D',4,1], [[1,1], [1,1], [2, 1]])
```

(continues on next page)
sage: KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and factor(s) ((1, → 1), (2, 1), (1, 1))
sage: T = KRT(pathlist=[[1], [-2, 2], [1]])
sage: T
[[1]] (X) [[2], [-2]] (X) [[1]]
sage: T2 = KRT(pathlist=[[1], [2, -2], [1]])
sage: T2
[[1]] (X) [[-2, [2]] (X) [[1]]
sage: T == T2
False

>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', Integer(4), → Integer(1)], [[Integer(1), Integer(1)], [Integer(2), Integer(1)], [Integer(1), → Integer(1)]])
>>> KRT
Tensor product of Kirillov-Reshetikhin tableaux of type ['D', 4, 1] and factor(s) ((1, → 1), (2, 1), (1, 1))
>>> T = KRT(pathlist=[[Integer(1)], [-Integer(2), Integer(2)], [Integer(1)]])
>>> T
[[1]] (X) [[2], [-2]] (X) [[1]]
>>> T2 = KRT(pathlist=[[Integer(1)], [Integer(2), -Integer(2)], [Integer(1)]])
>>> T2
[[1]] (X) [[-2, [2]] (X) [[1]]
>>> T == T2
False

class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.HighestWeightTensorKRT:
Bases: UniqueRepresentation

Class so we do not have to build the module generators for TensorProductOfKirillovReshetikhinTableaux at initialization.

Warning: This class is for internal use only!

cardinality()

Return the cardinality of self, which is the number of highest weight elements.

EXAMPLES:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], → [[2, 2]])
sage: from sage.combinat.rigged_configurations.tensor_product_kr_tableaux import HighestWeightTensorKRT
sage: HW = HighestWeightTensorKRT(KRT)
sage: HW.cardinality()
3
sage: len(HW)
3
sage: len(KRT.module_generators)
3
```python
>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', Integer(4),
... Integer(1)], [[Integer(2), Integer(2)]])
>>> from sage.combinat.rigged_configurations.tensor_product_kr_tableaux.
... import HighestWeightTensorKRT
>>> HW = HighestWeightTensorKRT(KRT)
>>> HW.cardinality()
3
>>> len(HW)
3
>>> len(KRT.module_generators)
3
```

```python
class sage.combinat.rigged_configurations.tensor_product_kr_tableaux.TensorProductOfKirillovReshetikhinTableaux
classes: FullTensorProductOfRegularCrystals

A tensor product of KirillovReshetikhinTableaux.

Through the bijection with rigged configurations, the tableaux that are produced in all nonexceptional types are all
of rectangular shapes and do not necessarily obey the usual strict increase in columns and weak increase in rows.
The relation between the elements of the Kirillov-Reshetikhin crystal, given by the Kashiwara-Nakashima tableaux,
and the Kirillov-Reshetikhin tableaux is given by a filling map.

Note: The tableaux for all non-simply-laced types are provably correct if the bijection with rigged configu-
```
(continues on next page)
We can get the highest weight elements by using the attribute `module_generators`:

```sage
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2,1]])
sage: list(KRT.module_generators)
[[[1], [2], [3]] (X) [[1], [2]], [[1], [3], [4]] (X) [[1], [2]]]
```

```sage
>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A',3,1], [[3,1], [2,1]])
```

```sage
>>> list(KRT.module_generators)
[[[1], [2], [3]] (X) [[1], [2]], [[1], [3], [4]] (X) [[1], [2]]]
```
To create elements directly (i.e., not passing in KR tableaux elements), there is the `pathlist` option will receive a list of lists which contain the reversed far-eastern reading word of the tableau. That is to say, in English notation, the word obtain from reading bottom-to-top, left-to-right.

One can still create elements in the same way as tensor product of crystals:

```
>>> from sage.all import *

>>> K1 = crystals.KirillovReshetikhin(['A',3,1], 3, 2, model='KR')
>>> K2 = crystals.KirillovReshetikhin(['A',3,1], 1, 2, model='KR')
>>> K3 = crystals.KirillovReshetikhin(['A',3,1], 2, 1, model='KR')

>>> eltlong = KRT(K1(Integer(3), Integer(2), Integer(1), Integer(4), Integer(2), Integer(1)), K2(Integer(1), Integer(3)), K3(Integer(3), Integer(1)))
```

Element

```
Element alias of TensorProductOfKirillovReshetikhinTableauxElement
generated_configurations()

    Return the corresponding set of rigged configurations.

    EXAMPLES:
```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
            [[1, 3], [2, 1]])
sage: KRT.rigged_configurations()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 3), (2, 1))

>>> from sage.all import *

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', Integer(3),
            Integer(1)], [[Integer(1),Integer(3)], [Integer(2),Integer(1)]]

sage: KRT.rigged_configurations()
Rigged configurations of type ['A', 3, 1] and factor(s) ((1, 3), (2, 1))

tensor(*crystals, **options)

Return the tensor product of self with crystals.

If crystals is a list of (a tensor product of) KR tableaux, this returns a TensorProductOfKirillovReshetikhinTableaux.

EXAMPLES:

sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
            [[1,3],[3,1]])
sage: K = crystals.KirillovReshetikhin(['A', 3, 1], 2, 2, model='KR')
sage: TP.tensor(K, TP)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 3), (3, 1), (2, 2), (1, 3), (3, 1))

sage: C = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(3),
            Integer(1), model='KN')
sage: TP.tensor(K, C)
Full tensor product of the crystals
[Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (1, 3),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (3, 1),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]

>>> from sage.all import *

sage: TP = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', Integer(3),
            Integer(1)], [[Integer(1),Integer(3)], [Integer(3),Integer(1)]])

sage: K = crystals.KirillovReshetikhin(['A', Integer(3), Integer(1)],
            Integer(2), Integer(2), model='KR')
sage: TP.tensor(K, TP)
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 3), (3, 1), (2, 2), (1, 3), (3, 1))

sage: C = crystals.KirillovReshetikhin(['A',Integer(3),Integer(1)], Integer(3),
            Integer(1), model='KN')

sage: TP.tensor(K, C)
Full tensor product of the crystals
[Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (1, 3),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (3, 1),
Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and shape (2, 2),
Kirillov-Reshetikhin crystal of type ['A', 3, 1] with (r,s)=(3,1)]

tensor_product_of_kirillov_reshetikhin_crystals()

Return the corresponding tensor product of Kirillov-Reshetikhin crystals.

EXAMPLES:
5.1.218 Tensor Product of Kirillov-Reshetikhin Tableaux Elements

A tensor product of KirillovReshetikhinTableauxElement.

AUTHORS:

• Travis Scrimshaw (2010-09-26): Initial version

`class sage.combinat.rigged_configurations.tensor_product_kr_tableaux_element.TensorProductOfKirillovReshetikhinTableauxElement`

Bases: `TensorProductOfRegularCrystalsElement`

An element in a tensor product of Kirillov-Reshetikhin tableaux.

For more on tensor product of Kirillov-Reshetikhin tableaux, see TensorProductOfKirillovReshetikhinTableaux.

The most common way to construct an element is to specify the option pathlist which is a list of lists which will be used to generate the individual factors of `KirillovReshetikhinTableauxElement`.

EXAMPLES:

Type $A_3^{(1)}$ examples:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], 
               [[1, 1], [2,1], [2,1], [2,1], [2,1]])
sage: T = KRT(pathlist=[[2], [4,1], [3], [4,2], [3,1], [2,1]])
sage: T
[[2]] (X) [[1], [4]] (X) [[3]] (X) [[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()
0[ ][ ]0
1[ ]1
1[ ][ ]0
1[ ]0
1[ ]0
0[ ][ ]0
```

(continues on next page)
sage: T = KRT(pathlist=[[1], [2,1], [1], [4,1], [3,1], [2,1]])
sage: T
[[1]] (X) [[1], [2]] (X) [[1], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()

>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', Integer(3), →Integer(1)], [[Integer(1), Integer(1)], [Integer(2), Integer(1)], [Integer(1), →Integer(1)], [Integer(2), Integer(1)], [Integer(2), Integer(1)], [Integer(2), →Integer(1)]])
>>> T = KRT(pathlist=[[Integer(2)], [Integer(4),Integer(1)], [Integer(3),Integer(1)], [Integer(4),Integer(2)], [Integer(3),Integer(1)], [Integer(2),Integer(1)]])
>>> T
[[2]] (X) [[1], [4]] (X) [[3]] (X) [[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
>>> T.to_rigged_configuration()

>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[1, →1], [1,1], [1,1], [1,1]])
>>> T = KRT(pathlist=[[-1], [-1], [1], [1]])
>>> T
[[-1]] (X) [[-1]] (X) [[1]] (X) [[1]]
>>> T.to_rigged_configuration()

Type $D_{n}^{(1)}$ examples:

sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], [[1, →1], [1,1], [1,1], [1,1]])
>>> T
[[1]] (X) [[4]] (X) [[1], [4]] (X) [[1], [3]] (X) [[1], [2]]

\end{verbatim}

\texttt{classical_weight}()

Return the classical weight of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([D,4,1],
\rightarrow [[2,2]])
sage: elt = KRT(pathlist=[[3,2,-1,1]]); elt
[[2, 1], [3, -1]]
sage: elt.classical_weight()
(0, 1, 1, 0)
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([A,3,1],
\rightarrow [[2,2],[1,3]])
sage: elt = KRT(pathlist=[[2,1,3,2],[1,4,4]]); elt
[[1, 2], [2, 3]] (X) [[1, 4, 4]]
sage: elt.classical_weight()
(2, 2, 1, 2)
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([D,Integer(4),
\rightarrow Integer(1)], [[Integer(2),Integer(2)]]))
>>> elt = KRT(pathlist=[[Integer(3),Integer(2),-Integer(1),Integer(1)]]); elt
[[2, 1], [3, -1]]
>>> elt.classical_weight()
(0, 1, 1, 0)
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux([A,Integer(3),
\rightarrow Integer(1)], [[Integer(2),Integer(2)], [Integer(1),Integer(3)]]))
>>> elt = KRT(pathlist=[[Integer(2),Integer(1),Integer(3),Integer(2)],
\rightarrow [Integer(1),Integer(4),Integer(4)]]); elt
[[1, 2], [2, 3]] (X) [[1, 4, 4]]
>>> elt.classical_weight()
(2, 2, 1, 2)
\end{verbatim}

\texttt{left_split}()

Return the image of \texttt{self} under the left column splitting map.

5.1. Comprehensive Module List 3587
EXAMPLES:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
               [[2, 2], [1, 3]])
sage: elt = KRT(pathlist=[[2, 1, 3, 2], [1, 4, 4]]); elt.pp()
 1 2 (X) 1 4 4
 2 3
```

```python
sage: elt.left_split().pp()
 1 (X) 2 (X) 1 4 4
 2 3
```

```python
>>> from sage.all import *
```

```python
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', Integer(3),
               Integer(1)], [[Integer(2), Integer(2)], [Integer(1), Integer(3)]]);
```

```python
>>> elt = KRT(pathlist=[[Integer(2), Integer(1), Integer(3), Integer(2)],
               [Integer(1), Integer(4), Integer(4)]]); elt.pp()
 1 2 (X) 1 4 4
 2 3
```

```python
>>> elt.left_split().pp()
 1 (X) 2 (X) 1 4 4
 2 3
```

`lusztig_involution()`

Return the result of the classical Lusztig involution on `self`.

EXAMPLES:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1],
               [[2, 2], [1, 3]])
sage: elt = KRT(pathlist=[[2, 1, 3, 2], [1, 4, 4]])
sage: li = elt.lusztig_involution(); li
[[1, 1, 4]] (X) [[2, 3], [3, 4]]
sage: li.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 3), (2, 2))
```

```python
>>> from sage.all import *
```

```python
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', Integer(3),
               Integer(1)], [[Integer(2), Integer(2)], [Integer(1), Integer(3)]]);
```

```python
>>> elt = KRT(pathlist=[[Integer(2), Integer(1), Integer(3), Integer(2)],
               [Integer(1), Integer(4), Integer(4)]]); elt.lusztig_involution()
[[1, 1, 4]] (X) [[2, 3], [3, 4]]
```

```python
>>> li.parent()
Tensor product of Kirillov-Reshetikhin tableaux of type ['A', 3, 1] and factor(s) ((1, 3), (2, 2))
```

`pp()`

Pretty print `self`.

EXAMPLES:

```python
sage: TPKRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 4, 1],
               [[2, 2], [3, 1], [3, 3]])
sage: TPKRT.module_generators[0].pp()
 1 1 (X) 1 (X) 1 1 1
 2 2 2 2 2 2
 3 3 3 3
```
right_split()
Return the image of self under the right column splitting map.

EXAMPLES:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], [[2, 2], [1, 4]])
sage: elt = KRT(pathlist=[[2, 1, 3, 2], [1, 4, 4]]); elt.pp()
1 2 (X) 1 4 4
2 3
sage: elt.right_split().pp()
1 2 (X) 1 4 (X) 4
2 3
```

Let \(*\) denote the Lusztig involution, we check that \(* \circ L \circ * = r\):

```python
sage: all(x.lusztig_involution().left_split().lusztig_involution() == x.right_split() for x in KRT)
True
```

to_rigged_configuration(display_steps=False)
Perform the bijection from self to a rigged configuration which is described in [RigConBijection], [BijectionLRT], and [BijectionDn].

**Note:** This is only proven to be a bijection in types $A^{(1)}_n$ and $D^{(1)}_n$, as well as $\otimes_i B'^{1,1}$ and $\otimes_i B^{1,1}$, for general affine types.

**INPUT:**
- `display_steps` (default: False) Boolean which indicates if we want to output each step in the algorithm.
OUTPUT:

The rigged configuration corresponding to self.

EXAMPLES:

Type $A_{n}^{(1)}$ example:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', 3, 1], →[[[2,1], [2,1], [2,1]]])
sage: T = KRT(pathlist=[[4, 2], [3, 1], [2, 1]])
sage: T
[[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
sage: T.to_rigged_configuration()

0[ ]0
1[ ]1
1[ ]0
0[ ]0
```

```
>>> from sage.all import *
>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['A', →Integer(3), Integer(1)], [[Integer(2),Integer(1)], [Integer(2),Integer(1)], →[Integer(2),Integer(1)]])
>>> T = KRT(pathlist=[[Integer(4), Integer(2)], [Integer(3), Integer(1)], →[Integer(2), Integer(1)]])
>>> T
[[2], [4]] (X) [[1], [3]] (X) [[1], [2]]
>>> T.to_rigged_configuration()
<BLANKLINE>0[ ]0
<BLANKLINE>1[ ]1
1[ ]0
<BLANKLINE>0[ ]0
<BLANKLINE>
```

Type $D_{n}^{(1)}$ example:

```
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1], →[[[2,2]]])
sage: T = KRT(pathlist=[[2,1,4,3]])
sage: T
[[1, 3], [2, 4]]
sage: T.to_rigged_configuration()

0[ ]0
-1[ ]-1
-1[ ]-1
0[ ]0
```

(/>
>>> from sage.all import *

>>> KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', Integer(4), Integer(1)], [[Integer(2), Integer(2)]]

>>> T = KRT(pathlist=[[Integer(2), Integer(1), Integer(4), Integer(3)]]

>>> T

[[1, 3], [2, 4]]

>>> T.to_rigged_configuration()

0[ ]0
-1[ ]-1
-1[ ]-1
0[ ]0

Type $D^{(1)}$ spinor example:

```python
sage: CP = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 5, 1],
    [[5,1],[2,1],[1,1],[1,1],[1,1]])

sage: elt = CP(pathlist=[[-2,-5,4,3,1],[-1,2],[1],[1],[1]])

sage: elt

[[1], [3], [4], [-5], [-2]] (X) [[2], [-1]] (X) [[1]] (X) [[1]] (X) [[1]]

sage: elt.to_rigged_configuration()

2[ ]1
0[ ]0
0[ ]0
0[ ]0
0[ ]0
0[ ]0
```

(continues on next page)
This is invertible by calling `to_tensor_product_of_kirillov_reshetikhin_tableaux()`:

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1],
                   [[2, 2]])
sage: T = KRT(pathlist=[[2, 1, 4, 3]])
sage: rc = T.to_rigged_configuration()
sage: ret = rc.to_tensor_product_of_kirillov_reshetikhin_tableaux(); ret
[[[1, 3], [2, 4]]]
sage: ret == T
True
```

### `to_tensor_product_of_kirillov_reshetikhin_crystals()`

Returns a tensor product of Kirillov-Reshetikhin crystals corresponding to `self`.

This works by performing the filling map on each individual factor. For more on the filling map, see `KirillovReshetikhinTableaux`.

**EXAMPLES:**

```python
sage: KRT = crystals.TensorProductOfKirillovReshetikhinTableaux(['D', 4, 1],
                   [[1, 1], [2, 2]])
sage: elt = KRT(pathlist=[[-1], [-1, 2, -1, 1]]); elt
[[[-1]], [[2, 1], [-1, -1]]]
sage: tp_krc = elt.to_tensor_product_of_kirillov_reshetikhin_crystals(); tp_krc
[[[-1]], [[2], [-1]]]
```

We can recover the original tensor product of KR tableaux:

```python
sage: ret = KRT(tp_krc); ret
[[[-1]], [[2], [-1]]]
sage: ret == elt
True
```

5.1.220 Ambient lattices and ambient spaces

class sage.combinat.root_system.ambient_space.AmbientSpace(root_system, base_ring, index_set=None)

Bases: CombinatorialFreeModule

Abstract class for ambient spaces

All subclasses should implement a class method smallest_base_ring taking a Cartan type as input, and a method dimension working on a partially initialized instance with just root_system as attribute. There is no safe default implementation for the later, so none is provided.

EXAMPLES:

```
sage: AL = RootSystem(['A',2]).ambient_lattice()

>>> from sage.all import *

>>> AL = RootSystem(['A',Integer(2)]).ambient_lattice()
```

Note: This is only used so far for finite root systems.

Caveat: Most of the ambient spaces currently have a basis indexed by 0,...,n, unlike the usual mathematical convention:

```
sage: e = AL.basis()
sage: e[0], e[1], e[2]
((1, 0, 0), (0, 1, 0), (0, 0, 1))
```

This will be cleaned up!

- sage.combinat.root_system.type_dual.AmbientSpace
- sage.combinat.root_system.type_affine.AmbientSpace

Element

alias of AmbientSpaceElement
coroot_lattice()

EXAMPLES:

```python
sage: e = RootSystem(["A", 3]).ambient_lattice()
sage: e.coroot_lattice()
Ambient lattice of the Root system of type ["A", 3]
```

```
>>> from sage.all import *
>>> e = RootSystem(["A", Integer(3)]).ambient_lattice()
>>> e.coroot_lattice()
Ambient lattice of the Root system of type ["A", 3]
```

dimension()

Return the dimension of this ambient space.

EXAMPLES:

```python
sage: from sage.combinat.root_system.ambient_space import AmbientSpace
sage: e = RootSystem([F,4]).ambient_space()
sage: AmbientSpace.dimension(e)
Traceback (most recent call last):
... NotImplementedError
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.ambient_space import AmbientSpace
>>> e = RootSystem([F,Integer(4)]).ambient_space()
>>> AmbientSpace.dimension(e)
Traceback (most recent call last):
... NotImplementedError
```

from_vector_notation(weight, style='lattice')

INPUT:

- weight—a vector or tuple representing a weight

Returns an element of self. If the weight lattice is not of full rank, it coerces it into the weight lattice, or its ambient space by orthogonal projection. This arises in two cases: for SL(r+1), the weight lattice is contained in a hyperplane of codimension one in the ambient space, and for types E6 and E7, the weight lattice is contained in a subspace of codimensions 2 or 3, respectively.

If style="coroots" and the data is a tuple of integers, it is assumed that the data represent a linear combination of fundamental weights. If style="coroots", and the root lattice is not of full rank in the ambient space, it is projected into the subspace corresponding to the semisimple derived group. This arises with Cartan type A, E6 and E7.

EXAMPLES:

```python
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0,0))
(1, 0, 0)
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0,0))
(1, 0, 0)
sage: RootSystem("A2").ambient_space().from_vector_notation((1,0),style="coroots")
(2/3, -1/3, -1/3)
```
```python
>>> from sage.all import *
>>> RootSystem("A2").ambient_space().from_vector_notation((Integer(1),
         Integer(0),Integer(0)))
(1, 0, 0)
>>> RootSystem("A2").ambient_space().from_vector_notation((Integer(1),
         Integer(0),Integer(0)))
(1, 0, 0)
>>> RootSystem("A2").ambient_space().from_vector_notation((Integer(1),
         Integer(0),Integer(0)), style="coroots")
(2/3, -1/3, -1/3)
```

**fundamental_weight** (*i*)

Returns the fundamental weight \( \Lambda_i \) in self

In several of the ambient spaces, it is more convenient to construct all fundamental weights at once. To support this, we provide this default implementation of `fundamental_weight` using the method `fundamental_weights`. Beware that this will cause a loop if neither `fundamental_weight` nor `fundamental_weights` is implemented.

**EXAMPLES:**

```python
sage: e = RootSystem(["F", 4]).ambient_space()
sage: e.fundamental_weight(3)
(3/2, 1/2, 1/2, 1/2)
sage: e = RootSystem(["G", 2]).ambient_space()
sage: e.fundamental_weight(1)
(1, 0, -1)
sage: e = RootSystem(["E", 6]).ambient_space()
sage: e.fundamental_weight(3)
(-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6)
```

```python
>>> from sage.all import *
>>> e = RootSystem(["F", Integer(4)]).ambient_space()
>>> e.fundamental_weight(Integer(3))
(3/2, 1/2, 1/2, 1/2)
>>> e = RootSystem(["G", Integer(2)]).ambient_space()
>>> e.fundamental_weight(Integer(1))
(1, 0, -1)
>>> e = RootSystem(["E", Integer(6)]).ambient_space()
>>> e.fundamental_weight(Integer(3))
(-1/2, 1/2, 1/2, 1/2, 1/2, -5/6, -5/6, 5/6)
```

**reflection** (*root, coroot=None*)

**EXAMPLES:**

```python
sage: e = RootSystem(["A", 3]).ambient_lattice()
sage: a = e.simple_root(0); a
(-1, 0, 0, 0)
sage: b = e.simple_root(1); b
(1, -1, 0, 0)
sage: s_a = e.reflection(a)
sage: s_a(b)
(0, -1, 0, 0)
```
```python
>>> from sage.all import *

>>> e = RootSystem(["A", Integer(3)]).ambient_lattice()

>>> a = e.simple_root(Integer(0)); a
(-1, 0, 0, 0)

>>> b = e.simple_root(Integer(1)); b
(1, -1, 0, 0)

>>> s_a = e.reflection(a)

>>> s_a(b)
(0, -1, 0, 0)
```

**simple_coroot** (*i*)

Returns the *i*-th simple coroot, as an element of this space.

**EXAMPLES:**

```python
sage: R = RootSystem(["A",3])
sage: L = R.ambient_lattice()
sage: L.simple_coroot(1)
(1, -1, 0, 0)
sage: L.simple_coroot(2)
(0, 1, -1, 0)
sage: L.simple_coroot(3)
(0, 0, 1, -1)
```

```python
>>> from sage.all import *

>>> R = RootSystem(["A",Integer(3)])

>>> L = R.ambient_lattice()

>>> L.simple_coroot(Integer(1))
(1, -1, 0, 0)

>>> L.simple_coroot(Integer(2))
(0, 1, -1, 0)

>>> L.simple_coroot(Integer(3))
(0, 0, 1, -1)
```

**classmethod smallest_base_ring**(cartan_type=None)

Return the smallest ground ring over which the ambient space can be realized.

This class method will get called with the Cartan type as input. This default implementation returns \( \mathbb{Q} \); subclasses should override it as appropriate.

**EXAMPLES:**

```python
sage: e = RootSystem(["F",4]).ambient_space()
sage: e.smallest_base_ring()
Rational Field
```

```python
>>> from sage.all import *

>>> e = RootSystem(["F",Integer(4)]).ambient_space()

>>> e.smallest_base_ring()
Rational Field
```

**to_ambient_space_morphism**( )

Return the identity map on self.

This is present for uniformity of use; the corresponding method for abstract root and weight lattices/spaces, is not trivial.

**EXAMPLES:**

```
```
```python
sage: P = RootSystem(['A', 2]).ambient_space()
sage: f = P.to_ambient_space_morphism()
sage: p = P.an_element()
sage: p
(2, 2, 3)
sage: f(p)
(2, 2, 3)
sage: f(p)==p
True

>>> from sage.all import *

>>> P = RootSystem(['A', Integer(2)]).ambient_space()

>>> f = P.to_ambient_space_morphism()

>>> p = P.an_element()

>>> p
(2, 2, 3)

>>> f(p)
(2, 2, 3)

>>> f(p)==p
True
```

class sage.combinat.root_system.ambient_space.AmbientSpaceElement

Bases: IndexedFreeModuleElement

associated_coroot()

EXAMPLES:
```python
sage: e = RootSystem(['F', 4]).ambient_space()
sage: a = e.simple_root(0); a
(1/2, -1/2, -1/2, -1/2)
sage: a.associated_coroot()
(1, -1, -1, -1)

>>> from sage.all import *

>>> e = RootSystem(['F', Integer(4)]).ambient_space()

>>> a = e.simple_root(Integer(0)); a
(1/2, -1/2, -1/2, -1/2)

>>> a.associated_coroot()
(1, -1, -1, -1)
```

coerce_to_e6()

For type E7 or E8, orthogonally projects an element of the root lattice into the E6 root lattice. This operation on weights corresponds to intersection with the semisimple subgroup E6.

EXAMPLES:
```python
sage: [b.coerce_to_e6() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0), (0, 0, 1, 0, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3)]

>>> from sage.all import *

>>> [b.coerce_to_e6() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0), (0, 0, 1, 0, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0, 0), (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3), (0, 0, 0, 0, 0, 1/3, 1/3, -1/3), (0, 0, 0, 0, 0, -1/3, -1/3, 1/3)]
```
coerce_to_e7()

For type E8, this orthogonally projects the given element of the E8 root lattice into the E7 root lattice. This operation on weights corresponds to intersection with the semisimple subgroup E7.

EXAMPLES:

```python
sage: [b.coerce_to_e7() for b in RootSystem("E8").ambient_space().basis()]
[(1, 0, 0, 0, 0, 0, 0, 0), (0, 1, 0, 0, 0, 0, 0, 0),
 (0, 0, 1, 0, 0, 0, 0, 0), (0, 0, 0, 1, 0, 0, 0, 0),
 (0, 0, 0, 0, 1, 0, 0, 0), (0, 0, 0, 0, 0, 1, 0, 0),
 (0, 0, 0, 0, 0, 0, 1/2, -1/2), (0, 0, 0, 0, 0, 0, -1/2, 1/2)]
```

coerce_to_sl()

For type ['A',r], this coerces the element of the ambient space into the root space by orthogonal projection. The root space has codimension one and corresponds to the Lie algebra of SL(r+1,CC), whereas the full weight space corresponds to the Lie algebra of GL(r+1,CC). So this operation corresponds to multiplication by a (possibly fractional) power of the determinant to give a weight determinant one.

EXAMPLES:

```python
sage: L = RootSystem("A2xA3").ambient_space()
sage: L([Integer(1),Integer(2),Integer(3),Integer(4),Integer(5),Integer(0),
    ->Integer(0)]).coerce_to_sl()
(-1, 0, 1, 7/4, 11/4, -9/4, -9/4)
```

dot_product (lambdacheck)

The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

```python
sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
```
>>> from sage.all import *
>>> e = RootSystem(['A',Integer(2)]).ambient_space()
>>> a = e.simple_root(Integer(0)); a
(-1, 0, 0)
>>> a.inner_product(a)
2

inner_product (lambdacheck)
The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2

is_positive_root()
EXAMPLES:

sage: R = RootSystem(['A',3]).ambient_space()
sage: r=R.simple_root(1)+R.simple_root(2)
sage: r.is_positive_root()
True
sage: r=R.simple_root(1)-R.simple_root(2)
sage: r.is_positive_root()
False

sage: e = RootSystem(['A',Integer(3)]).ambient_space()
>>> r=R.simple_root(Integer(1))+R.simple_root(Integer(2))
>>> r.is_positive_root()
True
>>> r=R.simple_root(Integer(1))-R.simple_root(Integer(2))
>>> r.is_positive_root()
False

scalar (lambdacheck)
The scalar product with elements of the coroot lattice embedded in the ambient space.

EXAMPLES:

sage: e = RootSystem(['A',2]).ambient_space()
sage: a = e.simple_root(0); a
(-1, 0, 0)
sage: a.inner_product(a)
2
to_ambient()

Map self to the ambient space.

This exists for uniformity. Its analogue for root and weight lattice realizations, is not trivial.

EXAMPLES:

```
sage: v = CartanType(['C',3]).root_system().ambient_space().an_element(); v
(2, 2, 3)
sage: v.to_ambient()
(2, 2, 3)
```

### 5.1.221 Associahedron

**Todo:**

- fix adjacency matrix
- edit graph method to get proper vertex labellings
- UniqueRepresentation?

**AUTHORS:**

- Christian Stump

```python
class sage.combinat.root_system.associahedron.Associahedra (base_ring, ambient_dim, backend='ppl')
```

Construct a parent class of Associahedra according to backend.

**See also:**

Associahedra_base.

**class** sage.combinat.root_system.associahedron.Associahedra_base

Bases: object

Base class of parent of Associahedra of specified dimension

**EXAMPLES:**
sage: from sage.combinat.root_system.associahedron import Associahedra
sage: parent = Associahedra(QQ,2,'ppl'); parent
Polyhedra in QQ^2
sage: type(parent)
<class 'sage.combinat.root_system.associahedron.Associahedra_ppl_with_category'>
sage: parent(['A',2])
Generalized associahedron of type ['A', 2] with 5 vertices

>>> from sage.all import *
>>> from sage.combinat.root_system.associahedron import Associahedra
>>> parent = Associahedra(QQ,Integer(2),'ppl'); parent
Polyhedra in QQ^2
>>> type(parent)
<class 'sage.combinat.root_system.associahedron.Associahedra_ppl_with_category'>
>>> parent(['A','2'])
Generalized associahedron of type ['A', 2] with 5 vertices

Importantly, the parent knows the dimension of the ambient space. If you try to construct an associahedron of a
different dimension, a ValueError is raised:

sage: parent(['A',3])
Traceback (most recent call last):
  ...
ValueError: V-representation data requires a list of length ambient_dim

>>> from sage.all import *
>>> parent(['A','Integer(3)'])
Traceback (most recent call last):
  ...
ValueError: V-representation data requires a list of length ambient_dim

class sage.combinat.root_system.associahedron.Associahedra_cdd(base_ring, ambient_dim, backend)
Bases: Associahedra_base, Polyhedra_QQ_cdd
Element
  alias of Associahedron_class_cdd
class sage.combinat.root_system.associahedron.Associahedra_field(base_ring, ambient_dim, backend)
Bases: Associahedra_base, Polyhedra_field
Element
  alias of Associahedron_class_field
class sage.combinat.root_system.associahedron.Associahedra_normaliz(base_ring, ambient_dim, backend)
Bases: Associahedra_base, Polyhedra_QQ_normaliz
Element
  alias of Associahedron_class_normaliz
Combinatorics, Release 10.4

class sage.combinat.root_system.associahedron.Asciahedra_polymake(base_ring,
    ambient_dim,
    backend)

    Bases: Associahedra_base, Polyhedra_polymake

    Element
    alias of Associahedron_class_polymake

class sage.combinat.root_system.associahedron.Asciahedra_ppl(base_ring,
    ambient_dim,
    backend)

    Bases: Associahedra_base, Polyhedra_QQ_ppl

    Element
    alias of Associahedron_class_ppl
```

```python
class sage.combinat.root_system.associahedron.Asciahedron(cartan_type, backend='ppl')

    Construct an associahedron.

    The generalized associahedron is a polytopal complex with vertices in one-to-one correspondence with clusters
    in the cluster complex, and with edges between two vertices if and only if the associated two clusters intersect in
codimension 1.

    The associahedron of type $A_n$ is one way to realize the classical associahedron as defined in the
Wikipedia article Associahedron.

    A polytopal realization of the associahedron can be found in [CFZ2002]. The implementation is based on
[CFZ2002], Theorem 1.5, Remark 1.6, and Corollary 1.9.

    INPUT:
    - cartan_type -- a cartan type according to
      sage.combinat.root_system.cartan_type.CartanTypeFactory
    - backend -- string ('ppl'); the backend to use; see
      sage.geometry.polyhedron.constructor.Polyhedron()

    EXAMPLES:
```

```
sage: Asso = polytopes.associahedron(['A',2]); Asso
    Generalized associahedron of type ['A', 2] with 5 vertices

sage: sorted(Asso.Hrepresentation(), key=repr)
[An inequality (-1, 0) x + 1 >= 0,
  An inequality (0, -1) x + 1 >= 0,
  An inequality (0, 1) x + 1 >= 0,
  An inequality (1, 0) x + 1 >= 0,
  An inequality (1, 1) x + 1 >= 0]

sage: Asso.Vrepresentation()
(A vertex at (1, -1), A vertex at (1, 1), A vertex at (-1, 1),
  A vertex at (-1, 0), A vertex at (0, -1))

sage: polytopes.associahedron(['B',2])
    Generalized associahedron of type ['B', 2] with 6 vertices
```

```python
>>> from sage.all import *

>>> Asso = polytopes.associahedron(['A',Integer(2)]); Asso
    Generalized associahedron of type ['A', 2] with 5 vertices
```

(continues on next page)
>>> sorted(Asso.Hrepresentation(), key=repr)
[An inequality (-1, 0) x + 1 >= 0,
 An inequality (0, -1) x + 1 >= 0,
 An inequality (0, 1) x + 1 >= 0,
 An inequality (1, 0) x + 1 >= 0,
 An inequality (1, 1) x + 1 >= 0]

>>> Asso.Vrepresentation()
(A vertex at (1, -1), A vertex at (1, 1), A vertex at (-1, 1),
 A vertex at (-1, 0), A vertex at (0, -1))

>>> polytopes.associahedron(['B',Integer(2)])
Generalized associahedron of type ['B', 2] with 6 vertices

The two pictures of [CFZ2002] can be recovered with:

```python
sage: Asso = polytopes.associahedron(['A',3]); Asso
Generalized associahedron of type ['A', 3] with 14 vertices
sage: Asso.plot()  # long time
Graphics3d Object

sage: Asso = polytopes.associahedron(['B',3]); Asso
Generalized associahedron of type ['B', 3] with 20 vertices
sage: Asso.plot()  # long time
Graphics3d Object
```

```python
>>> from sage.all import *
```

```python
class sage.combinat.root_system.associahedron.Associahedron_class_base(par-
ent=None, Vrep=None, Hrep=None, car-
tan_type=None, **kwds)

Bases: object

The base class of the Python class of an associahedron

You should use the Associahedron() convenience function to construct associahedra from the Cartan type.

cartan_type()
    Return the Cartan type of self.

EXAMPLES:
```
vertices_in_root_space()

Return the vertices of self as elements in the root space.

EXAMPLES:

```python
sage: Asso = polytopes.associahedron(['A',2])
sage: Asso.vertices()
(A vertex at (1, -1), A vertex at (1, 1),
 A vertex at (-1, 1), A vertex at (-1, 0),
 A vertex at (0, -1))
sage: Asso.vertices_in_root_space()
 -alpha[1], -alpha[2])
```
class sage.combinat.root_system.associahedron.Associahedron_class_normaliz(parent=None, Vrep=None, Hrep=None, cartan_type=None, **kwds)

Bases: Associahedron_class_base, Polyhedron_QQ_normaliz

class sage.combinat.root_system.associahedron.Associahedron_class_polymake(parent=None, Vrep=None, Hrep=None, cartan_type=None, **kwds)

Bases: Associahedron_class_base, Polyhedron_polymake

class sage.combinat.root_system.associahedron.Associahedron_class_ppl(parent=None, Vrep=None, Hrep=None, cartan_type=None, **kwds)

Bases: Associahedron_class_base, Polyhedron_QQ_ppl

5.1.222 Braid Move Calculator

AUTHORS:

• Dinakar Muthiah (2014-06-03): initial version

class sage.combinat.root_system.braid_move_calculator.BraidMoveCalculator(coxeter_group)

Bases: object

Helper class to compute braid moves.

chain_of_reduced_words(start_word, end_word)

Compute the chain of reduced words from start_word to end_word.

INPUT:

• start_word, end_word – two reduced expressions for the long word

EXAMPLES:

sage: from sage.combinat.root_system.braid_move_calculator import *
˓→BraidMoveCalculator
sage: W = CoxeterGroup(['A', 5])
sage: B = BraidMoveCalculator(W)
sage: B.chain_of_reduced_words((1,2,1,3,2,1,4,3,2,1,5,4,3,2,1), # not tested
   ....: (5,4,5,3,4,5,2,3,4,5,1,2,3,4,5))
>>> from sage.all import *
>>> from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
>>> W = CoxeterGroup(['A',Integer(5)])
>>> B = BraidMoveCalculator(W)

>>> B.chain_of_reduced_words((Integer(1),Integer(2),Integer(1),Integer(3),
   Integer(2),Integer(1),Integer(4),Integer(3),Integer(2),Integer(1),
   Integer(5),Integer(4),Integer(3),Integer(2),Integer(1)), # not tested
   ... (Integer(5),Integer(4),Integer(5),Integer(3),
   Integer(4),Integer(5),Integer(2),Integer(3),Integer(4),Integer(5),
   Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)))

put_in_front (k, input_word)
Return a list of reduced words starting with input_word and ending with a reduced word whose first letter is k.

There still remains an issue with 0 indices.

EXAMPLES:

```
sage: from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
sage: W = CoxeterGroup(['C',3])

sage: B = BraidMoveCalculator(W)

sage: B.put_in_front(2, (3, 2, 3, 1, 2, 3, 1, 2, 1))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 3, 1, 2, 1, 3, 2, 1),
 (3, 2, 3, 2, 1, 2, 3, 1, 2),
 (2, 3, 2, 3, 1, 2, 3, 1, 2))

sage: B.put_in_front(1, (3, 2, 3, 1, 2, 3, 1, 2, 1))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 1, 3, 2, 3, 1, 2, 1),
 (3, 2, 1, 3, 2, 3, 2, 1, 2),
 (3, 1, 2, 1, 3, 2, 3, 1, 2),
 (1, 3, 2, 1, 3, 2, 3, 1, 2))

sage: B.put_in_front(2, (3, 2, 3, 1, 2, 3, 1, 2, 1))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 3, 1, 2, 1, 3, 2, 1),
 (3, 2, 3, 2, 1, 2, 3, 1, 2),
 (2, 3, 2, 3, 1, 2, 3, 1, 2))
```

```
>>> from sage.all import *
>>> from sage.combinat.root_system.braid_move_calculator import BraidMoveCalculator
>>> W = CoxeterGroup(['C',Integer(3)])

>>> B = BraidMoveCalculator(W)

>>> B.put_in_front(Integer(2), (Integer(3), Integer(2), Integer(3),
   Integer(1), Integer(2), Integer(3), Integer(1), Integer(2), Integer(1)))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 3, 1, 2, 1, 3, 2, 1),
 (3, 2, 3, 2, 1, 2, 3, 1, 2),
 (2, 3, 2, 3, 1, 2, 3, 1, 2))

>>> B.put_in_front(Integer(2), (Integer(3), Integer(2), Integer(3),
   Integer(1), Integer(2), Integer(3), Integer(1), Integer(2), Integer(1)))
((3, 2, 3, 1, 2, 3, 1, 2, 1),
 (3, 2, 3, 1, 2, 1, 3, 2, 1),
 (3, 2, 3, 2, 1, 2, 3, 1, 2),
 (2, 3, 2, 3, 1, 2, 3, 1, 2))
```
(continues on next page)
(continued from previous page)

```python
B.put_in_front(Integer(1), (Integer(1), Integer(3), Integer(2), Integer(3), Integer(2), Integer(1), Integer(2), Integer(3), Integer(2)))
((1, 3, 2, 3, 2, 1, 2, 3),)
```

### 5.1.223 Braid Orbit

Cython function to compute the orbit of the braid moves on a reduced word.

```python
sage.combinat.root_system.braid_orbit.BraidOrbit(word, rels)

Return the orbit of `word` by all replacements given by `rels`.

**INPUT:**

- `word` – list of integers
- `rels` – list of pairs `(A, B)`, where A and B are lists of integers the same length

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.braid_orbit import BraidOrbit
sage: word = [1, 2, 1, 3, 2, 1]

sage: rels = [[[2, 1, 2], [1, 2, 1]], [[3, 1], [1, 3]], [[3, 2, 3], [2, 3, 2]]]

sage: sorted(BraidOrbit(word, rels))
[(1, 2, 1, 3, 2, 1),
 (1, 2, 3, 1, 2, 1),
 (1, 2, 3, 2, 1, 2),
 (1, 3, 2, 1, 3, 2),
 (1, 3, 2, 3, 1, 2),
 (2, 1, 2, 3, 2, 1),
 (2, 1, 3, 2, 1, 3),
 (2, 1, 3, 2, 3, 1),
 (2, 3, 1, 2, 1, 3),
 (2, 3, 1, 2, 3, 1),
 (2, 3, 2, 1, 2, 3),
 (3, 1, 2, 1, 3, 2),
 (3, 1, 2, 3, 1, 2),
 (3, 2, 1, 2, 3, 2),
 (3, 2, 1, 3, 2, 3),
 (3, 2, 3, 1, 2, 3)]

sage: len(_)
16
```

```python
>>> from sage.all import *

>>> from sage.combinat.root_system.braid_orbit import BraidOrbit

>>> word = [Integer(1), Integer(2), Integer(1), Integer(3), Integer(2), Integer(1)]

>>> rels = [[Integer(2), Integer(1), Integer(2)], [Integer(1), Integer(3)], [Integer(3), Integer(2), Integer(1)]

>>> sorted(BraidOrbit(word, rels))
[(1, 2, 1, 3, 2, 1),
 (1, 2, 3, 1, 2, 1),
 (1, 2, 3, 2, 1, 2),
 (1, 3, 2, 1, 3, 2),
 (1, 3, 2, 3, 1, 2),
 (2, 1, 2, 3, 2, 1),
 (2, 1, 3, 2, 1, 3),
 (2, 1, 3, 2, 3, 1),
 (2, 3, 1, 2, 1, 3),
 (2, 3, 1, 2, 3, 1),
 (2, 3, 2, 1, 2, 3),
 (3, 1, 2, 1, 3, 2),
 (3, 1, 2, 3, 1, 2),
 (3, 2, 1, 2, 3, 2),
 (3, 2, 1, 3, 2, 3),
 (3, 2, 3, 1, 2, 3)]
```

(continues on next page)
sage.combinat.root_system.braid_orbit.is_fully_commutative(word, rels)

Check if the braid orbit of word is using a braid relation.

**INPUT:**
- word – list of integers
- rels – list of pairs (A, B), where A and B are lists of integers the same length

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.braid_orbit import is_fully_commutative
sage: rels = [[[2, 1, 2], [1, 2, 1]], [[3, 1], [1, 3]], [[3, 2, 3], [2, 3, 2]]]
sage: word = [1, 2, 1, 3, 2, 1]
```

```python
sage: is_fully_commutative(word, rels)
False
```

```python
sage: word = [1, 2, 3]
```

```python
sage: is_fully_commutative(word, rels)
True
```

5.1.224 Branching Rules

class sage.combinat.root_system.branching_rules.BranchingRule(R, S, f, name='default',
intermediate_types=[],
intermediate_names=[])

**Bases:** SageObject

A class for branching rules.
Rtype()
In a branching rule R => S, returns the Cartan Type of the ambient group R.

EXAMPLES:

```
sage: branching_rule("A3","A2","levi").Rtype()
['A', 3]
```

Sage: from sage.all import *

Sage: branching_rule("A3","A2","levi").Rtype()
['A', 3]

Stype()
In a branching rule R => S, returns the Cartan Type of the subgroup S.

EXAMPLES:

```
sage: branching_rule("A3","A2","levi").Stype()
['A', 2]
```

Sage: from sage.all import *

Sage: branching_rule("A3","A2","levi").Stype()
['A', 2]

branch(chi, style=None)

INPUT:

- chi – A character of the WeylCharacterRing with Cartan type self.Rtype().

Returns the branched character.

EXAMPLES:

```
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: chi=G2(1,1); chi.degree()
64
sage: b=G2.maximal_subgroup("A2"); b
extended branching rule G2 => A2
sage: b.branch(chi)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
sage: A2=WeylCharacterRing("A2",style="coroots"); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients
sage: chi.branch(A2,rule=b)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
```

Sage: from sage.all import *

Sage: G2=WeylCharacterRing("G2",style="coroots")

Sage: chi=G2(Integer(1),Integer(1)); chi.degree()
64

Sage: b=G2.maximal_subgroup("A2"); b
extended branching rule G2 => A2

Sage: b.branch(chi)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)

Sage: A2=WeylCharacterRing("A2",style="coroots"); A2
The Weyl Character Ring of Type A2 with Integer Ring coefficients

Sage: chi.branch(A2,rule=b)
A2(0,1) + A2(1,0) + A2(0,2) + 2*A2(1,1) + A2(2,0) + A2(1,2) + A2(2,1)
**describe** (verbose=False, debug=False, no_r=False)

Describes how extended roots restrict under self.

**EXAMPLES:**

```python
sage: branching_rule("G2","A2","extended").describe()
3
0=<=O---O
1 2 0
G2~

root restrictions G2 => A2:

O---O
1 2
A2

0 => 2
2 => 1

For more detailed information use verbose=True
```

```python
>>> from sage.all import *

>>> branching_rule("G2","A2","extended").describe()
3
0=<=O---O
1 2 0
G2~

root restrictions G2 => A2:

O---O
1 2
A2

0 => 2
2 => 1

For more detailed information use verbose=True
```

In this example, 0 is the affine root, that is, the negative of the highest root, for "G2". If \( i = j \) is printed, this means that the \( i \)-th simple (or affine) root of the ambient group restricts to the \( j \)-th simple root of the subgroup. For reference the Dynkin diagrams are also printed. The extended Dynkin diagram of the ambient group is printed if the affine root restricts to a simple root. More information is printed if the parameter `verbose` is true.

```python
sage.combinat.root_system.branching_rules.branch_weyl_character(chi, R, S, rule='default')
```

INPUT:

- $\chi$ – a character of $G$
- $R$ – the Weyl Character Ring of $G$
- $S$ – the Weyl Character Ring of $H$
- rule – an element of the BranchingRule class or one (most usually) a keyword such as:
  - "levi"
  - "automorphic"
  - "symmetric"
  - "extended"
  - "orthogonal_sum"
  - "tensor"
  - "triality"
  - "miscellaneous"

The BranchingRule class is a wrapper for functions from the weight lattice of $G$ to the weight lattice of $H$. An instance of this class encodes an embedding of $H$ into $G$. The usual way to specify an embedding is to supply a keyword, which tells Sage to use one of the built-in rules. We will discuss these first.

To explain the predefined rules, we survey the most important branching rules. These may be classified into several cases, and once this is understood, the detailed classification can be read off from the Dynkin diagrams. Dynkin classified the maximal subgroups of Lie groups in Mat. Sbornik N.S. 30(72):349-462 (1952).

We will list give predefined rules that cover most cases where the branching rule is to a maximal subgroup. For convenience, we also give some branching rules to subgroups that are not maximal. For example, a Levi subgroup may or may not be maximal.

For example, there is a “levi” branching rule defined from $SL(5)$ (with Cartan type $A_4$) to $SL(4)$ (with Cartan type $A_3$), so we may compute the branching rule as follows:

**EXAMPLES:**

```python
sage: A3=WeylCharacterRing("A3",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: [A3(fw).branch(A2,rule="levi") for fw in A3.fundamental_weights()]
```

```python
[A2(0,0) + A2(1,0), A2(0,1) + A2(1,0), A2(0,0) + A2(0,1)]
```

In this case the Levi branching rule is the default branching rule so we may omit the specification rule="levi".

If a subgroup is not maximal, you may specify a branching rule by finding a chain of intermediate subgroups. For this purpose, branching rules may be multiplied as in the following example.

**EXAMPLES:**

```python
sage: A4=WeylCharacterRing("A4",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
>>> from sage.all import *
>>> A3=WeylCharacterRing("A3",style="coroots")
>>> [A3(fw).branch(A2,rule="levi") for fw in A3.fundamental_weights()]
[A2(0,0) + A2(1,0), A2(0,1) + A2(1,0), A2(0,0) + A2(0,1)]
```

(continues on next page)
Continued from previous page

```python
sage: A4(1,0,0,0).branch(A2, rule=br)
2*A2(0,0) + A2(1,0)
```

```python
>>> from sage.all import *
```

```python
>>> A4=WeylCharacterRing("A4",style="coroots")
```

```python
>>> A2=WeylCharacterRing("A2",style="coroots")
```

```python
>>> br=branching_rule("A4","A3")*branching_rule("A3","A2")
```

```python
>>> A4(Integer(1),Integer(0),Integer(0),Integer(0)).branch(A2,rule=br)
2*A2(0,0) + A2(1,0)
```

You may try omitting the rule if it is “obvious”. Default rules are provided for the following cases:

\[ A_{2s} \Rightarrow B_s, \]
\[ A_{2s-1} \Rightarrow C_s, \]
\[ A_{2s+1} \Rightarrow D_s. \]

The above default rules correspond to embedding the group \( SO(2s+1) \), \( Sp(2s) \) or \( SO(2s) \) into the corresponding general or special linear group by the standard representation. Default rules are also specified for the following cases:

\[ B_{s+1} \Rightarrow D_s, \]
\[ D_s \Rightarrow B_s. \]

These correspond to the embedding of \( O(n) \) into \( O(n+1) \) where \( n = 2s \) or \( 2s + 1 \). Finally, the branching rule for the embedding of a Levi subgroup is also implemented as a default rule.

**EXAMPLES:**

```python
sage: A1 = WeylCharacterRing("A1", style="coroots")
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: D4 = WeylCharacterRing("D4", style="coroots")
sage: B3 = WeylCharacterRing("B3", style="coroots")
sage: B4 = WeylCharacterRing("B4", style="coroots")
sage: A6 = WeylCharacterRing("A6", style="coroots")
sage: A7 = WeylCharacterRing("A7", style="coroots")
sage: def try_default_rule(R,S):
    return [R(f).branch(S) for f in R.fundamental_weights()]
sage: try_default_rule(A2,A1)
[A1(0) + A1(1), A1(0) + A1(1)]
sage: try_default_rule(D4,B3)
[B3(0,0,0) + B3(1,0,0), B3(1,0,0) + B3(0,1,0), B3(0,0,1), B3(0,0,1)]
sage: try_default_rule(B4,D4)
[D4(0,0,0,0) + D4(1,0,0,0), D4(1,0,0,0) + D4(0,1,0,0),
 D4(0,1,0,0) + D4(0,0,1,1), D4(0,0,1,1) + D4(0,0,0,1)]
sage: try_default_rule(A7,D4)
[D4(1,0,0,0), D4(0,1,0,0), D4(0,0,1,1), D4(0,0,2,0) + D4(0,0,0,2),
 D4(0,0,1,1), D4(0,1,0,0), D4(1,0,0,0)]
sage: try_default_rule(A6,B3)
[B3(1,0,0), B3(0,1,0), B3(0,0,2), B3(0,0,2), B3(0,1,0), B3(1,0,0)]
```

```python
>>> from sage.all import *
```

```python
>>> A1 = WeylCharacterRing("A1", style="coroots")
```

```python
>>> A2 = WeylCharacterRing("A2", style="coroots")
```

```python
>>> D4 = WeylCharacterRing("D4", style="coroots")
```

(continues on next page)
>>> B3 = WeylCharacterRing("B3", style="coroots")
>>> B4 = WeylCharacterRing("B4", style="coroots")
>>> A6 = WeylCharacterRing("A6", style="coroots")
>>> A7 = WeylCharacterRing("A7", style="coroots")

```python
>>> def try_default_rule(R,S):
    return [R(f).branch(S) for f in R.fundamental_weights()]
```

```python
>>> try_default_rule(A2,A1)
[A1(0) + A1(1), A1(0) + A1(1)]
```

```python
>>> try_default_rule(D4,B3)
[B3(0,0,0) + B3(1,0,0), B3(0,0,0) + B3(0,1,0), B3(0,0,0), B3(0,0,1), B3(0,0,1)]
```

```python
>>> try_default_rule(B4,D4)
[D4(0,0,0,0) + D4(1,0,0,0), D4(1,0,0,0) + D4(0,1,0,0), D4(0,1,0,0) + D4(0,0,1,1), D4(0,0,1,0) + D4(0,0,0,1)]
```

```python
>>> try_default_rule(A7,D4)
[D4(1,0,0,0), D4(0,1,0,0), D4(0,0,1,1), D4(0,0,2,0) + D4(0,0,0,2), D4(0,0,1,1), D4(1,0,0,0)]
```

```python
>>> try_default_rule(A6,B3)
[B3(1,0,0), B3(0,1,0), B3(0,0,2), B3(0,0,2), B3(0,1,0), B3(1,0,0)]
```

If a default rule is not known, you may cue Sage as to what the Lie group embedding is by supplying a rule from the list of predefined rules. We will treat these next.

**Levi Type**

These can be read off from the Dynkin diagram. If removing a node from the Dynkin diagram produces another Dynkin diagram, there is a branching rule. A Levi subgroup may or may not be maximal. If it is maximal, there may or may not be a built-in branching rule for but you may obtain the Levi branching rule by first branching to a suitable maximal subgroup. For these rules use the option rule="levi":

\[
\begin{align*}
A_r & \Rightarrow A_{r-1} \\
B_r & \Rightarrow A_{r-1} \\
B_r & \Rightarrow B_{r-1} \\
C_r & \Rightarrow A_{r-1} \\
C_r & \Rightarrow C_{r-1} \\
D_r & \Rightarrow A_{r-1} \\
D_r & \Rightarrow D_{r-1} \\
E_r & \Rightarrow A_{r-1} \quad r = 7, 8 \\
E_r & \Rightarrow D_{r-1} \quad r = 6, 7, 8 \\
E_r & \Rightarrow E_{r-1} \\
F_4 & \Rightarrow B_3 \\
F_4 & \Rightarrow C_3 \\
G_2 & \Rightarrow A_1(\text{short root})
\end{align*}
\]

Not all Levi subgroups are maximal subgroups. If the Levi is not maximal there may or may not be a pre-programmed rule="levi" for it. If there is not, the branching rule may still be obtained by going through an intermediate subgroup that is maximal using rule="extended". Thus the other Levi branching rule from \(G_2 \Rightarrow A_1\) corresponding to the long root is available by first branching \(G_2 \Rightarrow A_2\) then \(A_2 \Rightarrow A_1\). Similarly the branching rules to the Levi subgroup:

\[
E_r \Rightarrow A_{r-1} \quad r = 6, 7, 8
\]
may be obtained by first branching $E_6 \Rightarrow A_5 \times A_1$, $E_7 \Rightarrow A_7$ or $E_8 \Rightarrow A_8$.

EXAMPLES:

```python
sage: A1 = WeylCharacterRing("A1")
sage: A2 = WeylCharacterRing("A2")
sage: A3 = WeylCharacterRing("A3")
sage: A4 = WeylCharacterRing("A4")
sage: A5 = WeylCharacterRing("A5")
sage: B2 = WeylCharacterRing("B2")
sage: B3 = WeylCharacterRing("B3")
sage: B4 = WeylCharacterRing("B4")
sage: C2 = WeylCharacterRing("C2")
sage: C3 = WeylCharacterRing("C3")
sage: D3 = WeylCharacterRing("D3")
sage: D4 = WeylCharacterRing("D4")
sage: E6=WeylCharacterRing("E6",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: D5=WeylCharacterRing("D5",style="coroots")
sage: D6=WeylCharacterRing("D6",style="coroots")
sage: [B3(w).branch(A2,rule="levi") for w in B3.fundamental_weights()]

```

```python
[A2(0,0,0) + A2(1,0,0) + A2(0,0,-1),
A2(0,0,0) + A2(1,0,0) + A2(1,1,0) + A2(1,0,-1) + A2(0,-1,-1) + A2(0,0,-1),
A2(-1/2,-1/2,-1/2) + A2(1/2,-1/2,-1/2) + A2(1/2,1/2,-1/2) + A2(1/2,1/2,1/2)]
```

The last example must be understood as follows. The representation of $B_3$ being branched is spin, which is not a representation of $SO(7)$ but of its double cover $\tilde{SO}(7)$, the group $A_2$ is really $GL(3)$ and the double cover of $SO(7)$ induces a cover of $GL(3)$ that is trivial over $SL(3)$ but not over the center of $GL(3)$. The weight lattice for this $GL(3)$ consists of triples $(a, b, c)$ of half integers such that $a - b$ and $b - c$ are in $\mathbb{Z}$, and this is reflected in the last decomposition.

\[ \text{A1xB1}(1,1) + 2\text{A1xB1}(0,1) + 2\text{A1xB1}(1,0) \]
Automorphic Type

If the Dynkin diagram has a symmetry, then there is an automorphism that is a special case of a branching rule. There is also an exotic “triality” automorphism of $D_4$ having order 3. Use `rule=\"automorphic\"` (or for $D_4$ `rule=\"triality\"`):

\[
egin{align*}
A_r & \Rightarrow A_r \\
D_r & \Rightarrow D_r \\
E_6 & \Rightarrow E_6
\end{align*}
\]

EXAMPLES:

```
sage: [A3(chi).branch(A3,rule=\"automorphic\") for chi in A3.fundamental_weights()]
[A3(0,0,0,-1), A3(0,0,-1,-1), A3(0,-1,-1,-1)]
sage: [D4(chi).branch(D4,rule=\"automorphic\") for chi in D4.fundamental_weights()]
[D4(1,0,0,0), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2)]
```

Here is an example with $D_4$ triality:

```
sage: [D4(chi).branch(D4,rule=\"triality\") for chi in D4.fundamental_weights()]
[D4(1/2,1/2,1/2,1/2), D4(1,1,0,0), D4(1/2,1/2,1/2,1/2), D4(1/2,1/2,1/2,-1/2)]
```

Symmetric Type

Related to the automorphic type, when $G$ admits an outer automorphism (usually of degree 2) we may consider the branching rule to the isotropy subgroup $H$. Outer automorphisms correspond to symmetries of the Dynkin diagram. For such isotropy subgroups use `rule=\"symmetric\"`. We may thus obtain the following branching rules.

\[
egin{align*}
A_2r & \Rightarrow B_r \\
A_{2r-1} & \Rightarrow C_r \\
A_{2r-1} & \Rightarrow D_r \\
D_r & \Rightarrow B_{r-1} \\
E_6 & \Rightarrow F_4 \\
E_6 & \Rightarrow C_4 \\
D_4 & \Rightarrow G_2
\end{align*}
\]

The last branching rule, $D_4 \Rightarrow G_2$ is not to a maximal subgroup since $D_4 \Rightarrow B_3 \Rightarrow G_2$, but it is included for convenience.

In some cases, two outer automorphisms that differ by an inner automorphism may have different fixed subgroups. Thus, while the Dynkin diagram of $E_6$ has a single involutory automorphism, there are two involutions of the group (differing by an inner automorphism) with fixed subgroups $F_4$ and $C_4$. Similarly $SL(2r)$, of Cartan type $A_{2r-1}$,
has subgroups $SO(2r)$ and $Sp(2r)$, both fixed subgroups of outer automorphisms that differ from each other by an inner automorphism.

In many cases the Dynkin diagram of $H$ can be obtained by folding the Dynkin diagram of $G$.

EXAMPLES:

```python
sage: [w.branch(B2,rule="symmetric") for w in [A4(1,0,0,0,0),A4(1,1,0,0,0),A4(1,1,\rightarrow 1,0,0),A4(2,0,0,0,0)]
[B2(1,0), B2(1,1), B2(1,1), B2(0,0) + B2(2,0)]

sage: [A5(w).branch(C3,rule="symmetric") for w in A5.fundamental_weights()]
[C3(1,0,0), C3(0,0,0) + C3(1,1,0), C3(1,0,0) + C3(1,1,1), C3(0,0,0) + C3(1,1,0),...→ C3(1,0,0)]

>>> [E6(fw).branch(F4,rule="symmetric") for fw in E6.fundamental_weights()] #...

```

```python
(continues on next page)
```
Extended Type

If removing a node from the extended Dynkin diagram results in a Dynkin diagram, then there is a branching rule. Use rule="extended" for these. We will also use this classification for some rules that are not of this type, mainly involving type $B$, such as $D_6 \Rightarrow B_3 \times B_3$.

Here is the extended Dynkin diagram for $D_6$:

```
0  6
|   |
|   |
0---0---0---0---0---0
1  2  3  4  6
```

Removing the node 3 results in an embedding $D_3 \times D_3 \Rightarrow D_6$. This corresponds to the embedding $SO(6) \times SO(6) \Rightarrow SO(12)$, and is of extended type. On the other hand the embedding $SO(5) \times SO(7) \Rightarrow SO(12)$ (e.g. $B_2 \times B_3 \Rightarrow D_6$) cannot be explained this way but for uniformity is implemented under rule="extended".

The following rules are implemented as special cases of rule="extended":

- $E_6 \Rightarrow A_5 \times A_1, A_2 \times A_2 \times A_2$
- $E_7 \Rightarrow A_7, D_6 \times A_1, A_3 \times A_3 \times A_1$
- $E_8 \Rightarrow A_8, D_8, E_7 \times A_1, A_4 \times A_4, D_5 \times A_3, E_6 \times A_2$
- $F_4 \Rightarrow B_4, C_3 \times A_1, A_2 \times A_2, A_3 \times A_1$
- $G_2 \Rightarrow A_1 \times A_1$

Note that $E_8$ has only a limited number of representations of reasonably low degree.

**EXAMPLES:**

```
sage: [B3(x).branch(D3,rule="extended") for x in B3.fundamental_weights()]
[D3(0,0,0) + D3(1,0,0),
D3(1,0,0) + D3(1,1,0),
D3(1/2,1/2,-1/2) + D3(1/2,1/2,1/2)]
sage: [G2(w).branch(A2, rule="extended") for w in G2.fundamental_weights()]

We get D4 => A1xA1xA1xA1  
by remembering that A1xA1 = D2.  
[D4(fw).branch(D2xD2, rule="extended") for fw in D4.fundamental_weights()]

Orthogonal Sum

Using rule="orthogonal_sum", for \( n = a + b + c + \cdots \), you can get any branching rule:

\[
 SO(n) \Rightarrow SO(a) \times SO(b) \times SO(c) \times \cdots,  
 Sp(2n) \Rightarrow Sp(2a) \times Sp(2b) \times Sp(2c) \times \cdots,
\]

where \( O(a) \) is type \( D_r \) for \( a = 2r \) or \( B_r \) for \( a = 2r + 1 \) and \( Sp(2r) \) is type \( C_r \). In some cases these are also of extended type, as in the case \( D_3 \times D_3 \Rightarrow D_6 \) discussed above. But in other cases, for example \( B_3 \times B_3 \Rightarrow D_7 \), they are not of extended type.

Tensor

There are branching rules:

\[
 A_{r-1} \Rightarrow A_{r-1} \times A_{s-1},  
 B_{2r+s+r+s} \Rightarrow B_r \times B_s,  
 D_{2r+s+s} \Rightarrow B_r \times D_s,  
 D_{2r+s} \Rightarrow D_r \times D_s,  
 D_{2r+s} \Rightarrow C_r \times C_s,  
 C_{2r+s+s} \Rightarrow B_r \times C_s,  
 C_{2r+s} \Rightarrow C_r \times D_s,  
\]

corresponding to the tensor product homomorphism. For type \( A \), the homomorphism is \( GL(r) \times GL(s) \Rightarrow GL(rs) \). For the classical types, the relevant fact is that if \( V, W \) are orthogonal or symplectic spaces, that is, spaces endowed with symmetric or skew-symmetric bilinear forms, then \( V \otimes W \) is also an orthogonal space (if \( V \) and \( W \) are both orthogonal or both symplectic) or symplectic (if one of \( V \) and \( W \) is orthogonal and the other symplectic).

The corresponding branching rules are obtained using rule="tensor".

EXAMPLES:

```python
sage: A5=WeylCharacterRing("A5", style="coroots")
sage: A2xA1=WeylCharacterRing("A2xA1", style="coroots")
sage: [A5(hwv).branch(A2xA1, rule="tensor") for hwv in A5.fundamental_weights()]

C2xC1(0,1,2) + C2xC1(2,0,0) + C2xC1(0,0,2),
C2xC1(1,0,1),
C2xC1(0,1,0) + C2xC1(0,0,2)]

>>> C3=WeylCharacterRing("C3",style="coroots")
>>> B1xC1=WeylCharacterRing("B1xC1",style="coroots")
>>> [C3(f).branch(B1xC1,rule="tensor") for f in C3.fundamental_weights()]
[B1xC1(2,1), B1xC1(2,2) + B1xC1(4,0), B1xC1(4,1) + B1xC1(0,3)]
Symmetric Power

The $k$-th symmetric and exterior power homomorphisms map

$$GL(n) \Rightarrow GL\left(\binom{n+k-1}{k}\right) \times GL\left(\binom{n}{k}\right).$$

The corresponding branching rules are not implemented but a special case is. The $k$-th symmetric power homomorphism $SL(2) \Rightarrow GL(k+1)$ has its image inside of $SO(2r+1)$ if $k = 2r$ and inside of $Sp(2r)$ if $k = 2r - 1$. Hence there are branching rules:

$$B_r \Rightarrow A_1$$

$$C_r \Rightarrow A_1$$

and these may be obtained using the rule “symmetric_power”.

EXAMPLES:

```sage
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: B3=WeylCharacterRing("B3",style="coroots")
sage: C3=WeylCharacterRing("C3",style="coroots")
sage: [B3(fw).branch(A1,rule="symmetric_power") for fw in B3.fundamental_weights()]
[A1(6), A1(2) + A1(6) + A1(10), A1(0) + A1(6)]
sage: [C3(fw).branch(A1,rule="symmetric_power") for fw in C3.fundamental_weights()]
```

```
>>> from sage.all import *
>>> A1=WeylCharacterRing("A1",style="coroots")
>>> B3=WeylCharacterRing("B3",style="coroots")
>>> C3=WeylCharacterRing("C3",style="coroots")
>>> [B3(fw).branch(A1,rule="symmetric_power") for fw in B3.fundamental_weights()]
[A1(6), A1(2) + A1(6) + A1(10), A1(0) + A1(6)]
>>> [C3(fw).branch(A1,rule="symmetric_power") for fw in C3.fundamental_weights()]
```

Miscellaneous

Use rule="miscellaneous" for the following embeddings of maximal subgroups, all involving exceptional groups.

$$B_3 \Rightarrow G_2,$$

$$E_6 \Rightarrow G_2,$$

$$E_7 \Rightarrow A_2,$$

$$F_4 \Rightarrow G_2 \times A_1,$$

$$E_6 \Rightarrow G_2 \times A_2,$$

$$E_7 \Rightarrow G_2 \times C_3,$$

$$E_7 \Rightarrow F_4 \times A_1,$$

$$E_7 \Rightarrow A_1 \times A_1,$$

$$E_7 \Rightarrow G_2 \times A_1,$$

$$E_8 \Rightarrow G_2 \times F_4,$$

$$E_8 \Rightarrow A_2 \times A_1,$$

$$E_8 \Rightarrow B_2.$$
Except for those embeddings available by `rule="extended"`, these are the only embeddings of these groups as maximal subgroups. There may be other embeddings besides these. For example, there are other more obvious embeddings of $A_2$ and $G_2$ into $E_6$. However the embeddings in this table are characterized as embeddings as maximal subgroups. Regarding the embeddings of $A_2$ and $G_2$ in $E_6$, the embeddings in question may be characterized by the condition that the 27-dimensional representations of $E_6$ restrict irreducibly to $A_2$ or $G_2$. Since $G_2$ has a subgroup isomorphic to $A_2$, it is worth mentioning that the composite branching rules:

```
branching_rule("E6","G2","miscellaneous")*branching_rule("G2","A2","extended")
branching_rule("E6","A2","miscellaneous")
```

are distinct.

These embeddings are described more completely (with references to the literature) in the thematic tutorial at:

EXAMPLES:

```sage
sage: G2 = WeylCharacterRing("G2")
sage: [fw1, fw2, fw3] = B3.fundamental_weights()

A1 maximal subgroups of exceptional groups

There are seven cases where the exceptional group $G_2$, $F_4$, $E_7$ or $E_8$ contains a maximal subgroup of type $A_1$. These are tabulated in Theorem 1 of Testerman, The construction of the maximal $A_1$’s in the exceptional algebraic groups, Proc. Amer. Math. Soc. 116 (1992), no. 3, 635-644. The names of these branching rules are roman numerals referring to the seven cases of her Theorem 1. Use these branching rules as in the following examples.

EXAMPLES:

```
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: F4=WeylCharacterRing("F4",style="coroots")
sage: E7=WeylCharacterRing("E7",style="coroots")
sage: E8=WeylCharacterRing("E8",style="coroots")
sage: [G2(f).branch(A1,rule="i") for f in G2.fundamental_weights()]
[A1(6), A1(2) + A1(10)]
sage: F4(1,0,0,0).branch(A1,rule="ii")
A1(2) + A1(10) + A1(14) + A1(22)
sage: E7(0,0,0,0,0,0,1).branch(A1,rule="iii")
A1(9) + A1(17) + A1(27)
sage: E7(0,0,0,0,0,0,1).branch(A1,rule="iv")
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="v") # long time (0.6s)
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="vi") # long time (0.6s)
    A1(46)
sage: E8(0,0,0,0,0,0,0,1).branch(A1,rule="vii") # long time (0.6s)
    A1(34) + A1(38)
```
Branching Rules From Plethysms

Nearly all branching rules $G \Rightarrow H$ where $G$ is of type $A$, $B$, $C$ or $D$ are covered by the preceding rules. The function `branching_rule_from_plethysm()` covers the remaining cases.

This is a general rule that includes any branching rule from types $A$, $B$, $C$, or $D$ as a special case. Thus it could be used in place of the above rules and would give the same results. However it is most useful when branching from $G$ to a maximal subgroup $H$ such that rank$(H) < \text{rank}(G) - 1$.

We consider a homomorphism $H \Rightarrow G$ where $G$ is one of $SL(r+1)$, $SO(2r+1)$, $Sp(2r)$ or $SO(2r)$. The function `branching_rule_from_plethysm()` produces the corresponding branching rule. The main ingredient is the character $\chi$ of the representation of $H$ that is the homomorphism to $GL(r+1)$, $GL(2r+1)$ or $GL(2r)$.

This rule is so powerful that it contains the other rules implemented above as special cases. First let us consider the symmetric fifth power representation of $SL(2)$.

```python
sage: A1=WeylCharacterRing("A1",style="coroots")
sage: chi=A1([Integer(5)])
sage: chi.degree()
6
sage: chi.frobenius_schur_indicator()
-1
```

(continues on next page)
This confirms that the character has degree 6 and is symplectic, so it corresponds to a homomorphism $SL(2) \to Sp(6)$, and there is a corresponding branching rule $C_3 \to A_1$.

```
>>> chi.frobenius_schur_indicator()
-1
```

This is identical to the results we would obtain using rule="symmetric_power". The next example gives a branching not available by other standard rules.

```
>>> from sage.all import *

>>> C3 = WeylCharacterRing("C3",style="coroots")
>>> sym5rule = branching_rule_from_plethysm(chi,"C3")
>>> [C3(hwv).branch(A1,rule=sym5rule) for hwv in C3.fundamental_weights()]
```

We have confirmed that the adjoint representation of $G_2$ gives a homomorphism into $SO(14)$, and that the pullback of the one of the two 64 dimensional spin representations to $SO(14)$ is an irreducible representation of $G_2$.

We do not actually have to create the character or its parent WeylCharacterRing to create the branching rule:

```
>>> b = branching_rule("C7","C3(0,0,1)","plethysm"); b
plethysm (along C3(0,0,1)) branching rule C7 => C3
```

5.1. Comprehensive Module List
**Isomorphic Type**

Although not usually referred to as a branching rule, the effects of the accidental isomorphisms may be handled using rule="isomorphic":

\[
\begin{align*}
B_2 & \Rightarrow C_2 \\
C_2 & \Rightarrow B_2 \\
A_3 & \Rightarrow D_3 \\
D_3 & \Rightarrow A_3 \\
D_2 & \Rightarrow A_1 \\
B_1 & \Rightarrow A_1 \\
C_1 & \Rightarrow A_1
\end{align*}
\]

**EXAMPLES:**

```python
sage: B2 = WeylCharacterRing("B2")
sage: C2 = WeylCharacterRing("C2")
sage: [B2(x).branch(C2, rule="isomorphic") for x in B2.fundamental_weights()]

[[C2(1,1), C2(1,0)]
```

```python
sage: [C2(x).branch(B2, rule="isomorphic") for x in C2.fundamental_weights()]

[[B2(1/2,1/2), B2(1,0)]
```

```python
sage: D3 = WeylCharacterRing("D3")
sage: A3 = WeylCharacterRing("A3")
sage: [A3(x).branch(D3,rule="isomorphic") for x in A3.fundamental_weights()]

[[D3(1/2,1/2,1/2), D3(1,0,0), D3(1/2,1/2,-1/2)]
```

```python
sage: [D3(x).branch(A3,rule="isomorphic") for x in D3.fundamental_weights()]

[[A3(1/2,1/2,-1/2,-1/2), A3(1/4,1/4,1/4,-3/4), A3(3/4,-1/4,-1/4,-1/4)]
```

Here \(A_3(x, y, z, w)\) can be understood as a representation of \(SL(4)\). The weights \(x, y, z, w\) and \(x + t, y + t, z + t, w + t\) represent the same representation of \(SL(4)\) - though not of \(GL(4)\) - since \(A_3(x + t, y + t, z + t, w + t)\) is the same as \(A_3(x, y, z, w)\) tensored with \(\det^t\). So as a representation of \(SL(4)\), \(A_3(1/4, 1/4, 1/4, -3/4)\) is the same as \(A_3(1, 1, 1, 0)\). The exterior square representation \(SL(4) \Rightarrow GL(6)\) admits an invariant symmetric bilinear form, so is a representation \(SL(4) \Rightarrow SO(6)\) that lifts to an isomorphism \(SL(4) \Rightarrow \text{Spin}(6)\). Conversely, there are two isomorphisms \(SO(6) \Rightarrow SL(4)\), of which we’ve selected one.

In cases like this you might prefer style="coroots":

```python
sage: A3 = WeylCharacterRing("A3", style="coroots")
sage: D3 = WeylCharacterRing("D3", style="coroots")
sage: [D3(fw) for fw in D3.fundamental_weights()]

[[D3(1,0,0), D3(0,1,0), D3(0,0,1)]
```

(continues on next page)
sage: [D3(fw).branch(A3,rule="isomorphic") for fw in D3.fundamental_weights()]
[A3(0,1,0), A3(0,0,1), A3(1,0,0)]
sage: D2 = WeylCharacterRing("D2", style="coroots")
sage: A1xA1 = WeylCharacterRing("A1xA1", style="coroots")
sage: [D2(fw).branch(A1xA1,rule="isomorphic") for fw in D2.fundamental_weights()]
[A1xA1(1,0), A1xA1(0,1)]

Branching From a Reducible WeylCharacterRing

If the Cartan Type of R is reducible, we may project a character onto any of the components, or any combination of components. The rule to project on the first component is specified by the string "proj1", the rule to project on the second component is "proj2". To project on the first and third components, use "proj13" and so on.

EXAMPLES:

sage: A2xG2=WeylCharacterRing("A2xG2",style="coroots")
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: A2xG2(1,0,1,0).branch(A2,rule="proj1")
7*A2(1,0)
sage: A2xG2(1,0,1,0).branch(G2,rule="proj2")
3*G2(1,0)
sage: A2xA2xG2=WeylCharacterRing("A2xA2xG2",style="coroots")
sage: A2xA2xG2(0,1,1,1,0,1).branch(A2xG2,rule="proj13")
8*A2xG2(0,1,0,1)

A more general way of specifying a branching rule from a reducible type is to supply a list of rules, one component rule for each component type in the root system. In the following example, we branch the fundamental representations of $D_4$ down to $A_1 \times A_1 \times A_1 \times A_1$ through the intermediate group $D_2 \times D_2$. We use multiplicative
notation to compose the branching rules. There is no need to construct the intermediate WeylCharacterRing with type \(D_2 \times D_2\).

**EXAMPLES:**

```python
sage: D4 = WeylCharacterRing("D4",style="coroots")
sage: A1xA1xA1xA1 = WeylCharacterRing("A1xA1xA1",style="coroots")
sage: b = branching_rule("D2","A1xA1","isomorphic")
sage: br = branching_rule("D4","D2xD2","extended")*branching_rule("D2xD2", "A1xA1xA1", [b,b])
sage: [D4(fw).branch(A1xA1xA1xA1,rule=br) for fw in D4.fundamental_weights()]
```

In the list of rules to be supplied in branching from a reducible root system, we may use two key words “omit” and “identity”. The term “omit” means that we omit one factor, projecting onto the remaining factors. The term “identity” is supplied when the irreducible factor Cartan Types of both the target and the source are the same, and the component branching rule is to be the identity map. For example, we have projection maps from \(A_3 \times A_2\) to \(A_3\) and \(A_2\), and the corresponding branching may be accomplished as follows. In this example the same could be accomplished using rule="proj2".

**EXAMPLES:**

```python
sage: A3xA2=WeylCharacterRing("A3xA2",style="coroots")
sage: A3=WeylCharacterRing("A3",style="coroots")
sage: chi = A3xA2(0,1,0,1,0)
sage: chi.branch(A3,rule=["identity","omit"]) 3*A3(0,1,0)
sage: A2=WeylCharacterRing("A2",style="coroots")
sage: chi.branch(A2,rule=["omit","identity"]) 6*A2(1,0)
```
Yet another way of branching from a reducible root system with repeated Cartan types is to embed along the diagonal. The branching rule is equivalent to the tensor product, as the example shows:

```python
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2xG2=WeylCharacterRing("G2xG2",style="coroots")
sage: G2=WeylCharacterRing("G2",style="coroots")
sage: G2xG2(1,0,0,1).branch(G2,rule="diagonal")
G2(1,0) + G2(2,0) + G2(1,1)
sage: G2xG2(1,0,0,1).branch(G2,rule="diagonal") == G2(1,0)*G2(0,1)
True
```

Writing Your Own (Branching) Rules

Suppose you want to branch from a group $G$ to a subgroup $H$. Arrange the embedding so that a Cartan subalgebra $U$ of $H$ is contained in a Cartan subalgebra $T$ of $G$. There is thus a mapping from the weight spaces $\text{Lie}(T)^* \to \text{Lie}(U)^*$. Two embeddings will produce identical branching rules if they differ by an element of the Weyl group of $H$.

The rule is this map $\text{Lie}(T)^*$, which is $G.\text{space}()$, to $\text{Lie}(U)^*$, which is $H.\text{space}()$, which you may implement as a function. As an example, let us consider how to implement the branching rule $A_3 \Rightarrow C_2$. Here $H = C_2 = Sp(4)$ embedded as a subgroup in $A_3 = GL(4)$. The Cartan subalgebra $U$ consists of diagonal matrices with eigenvalues $u_1, u_2, -u_2, -u_1$. The $C_2.\text{space}()$ is the two dimensional vector spaces consisting of the linear functionals $u_1$ and $u_2$ on $U$. On the other hand $\text{Lie}(T)$ is $\mathbb{R}^4$. A convenient way to see the restriction is to think of it as the adjoint of the map $(u_1, u_2) \mapsto (u_1, u_2, -u_2, -u_1)$, that is, $(x_0, x_1, x_2, x_3) \mapsto (x_0 - x_3, x_1 - x_2)$. Hence we may encode the rule as follows:

```python
def rule(x):
    return [x[0]-x[3],x[1]-x[2]]
```
or simply:

```
rule = lambda x: [x[0]-x[3],x[1]-x[2]]
```

We may now make and use the branching rule as follows.

**EXAMPLES:**

```python
sage: br = BranchingRule("A3", "C2", lambda x: [x[0]-x[3],x[1]-x[2]], "homemade");
```

**Output:**

```
homemade branching rule A3 => C2
```

```python
sage: [A3,C2]=[WeylCharacterRing(x,style="coroots") for x in ["A3","C2"]]
sage: A3(0,1,0).branch(C2,rule=br)
C2(0,0) + C2(0,1)
```
>>> from sage.all import *

br = BranchingRule("A3", "C2", lambda x: [x[Integer(0)]-x[Integer(3)], -x[Integer(1)]-x[Integer(2)]], "homemade"); br
homemade branching rule A3 => C2
>>> [A3,C2]=[WeylCharacterRing(x,style="coroots") for x in ["A3","C2"]]

A3(Integer(0),Integer(1),Integer(0)).branch(C2,rule=br)
C2(0,0) + C2(0,1)

sage.combinat.root_system.branching_rules.branching_rule (Rtype, Stype, rule='default')

Creates a branching rule.

INPUT:

• R – the Weyl Character Ring of G
• S – the Weyl Character Ring of H
• rule – a string describing the branching rule as a map from the weight space of S to the weight space of R.

If the rule parameter is omitted, in some cases, a default rule is supplied. See branch_weyl_character().

EXAMPLES:

sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")
sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
[[1, 0], [1, 1], [1, 0]]

sage.combinat.root_system.branching_rules.branching_rule_from_plethysm (chi, cartan_type, return_matrix=False)

Create the branching rule of a plethysm.

INPUT:

• chi – the character of an irreducible representation π of a group G
• cartan_type – a classical Cartan type (A, B, C or D).

It is assumed that the image of the irreducible representation πi naturally has its image in the group G.

Returns a branching rule for this plethysm.

EXAMPLES:

The adjoint representation SL(3) → GL(8) factors through SO(8). The branching rule in question will describe how representations of SO(8) composed with this homomorphism decompose into irreducible characters of SL(3):

sage: A2 = WeylCharacterRing("A2")
sage: A2 = WeylCharacterRing("A2", style="coroots")
sage: ad = A2.adjoint_representation(); ad
A2(1,1)
sage: ad.degree()
This confirms that \(\mathfrak{ad}\) has degree 8 and is orthogonal, hence factors through \(SO(8)\) which is type \(D_4\):

\[
\text{sage: br = branching_rule_from_plethysm(ad,"D4")}
\]

\[
\text{sage: D4 = WeylCharacterRing("D4")}
\]

\[
\text{sage: [D4(f).branch(A2,rule = br) for f in D4.fundamental_weights()]
}\]

\[
[A2(1,1), A2(0,3) + A2(1,1) + A2(3,0), A2(1,1), A2(1,1)]
\]

sage.combinat.root_system.branching_rules.get_branching_rule(Rtype, Stype, rule='default')

Creates a branching rule.

INPUT:

- \(R\) – the Weyl Character Ring of \(G\)
- \(S\) – the Weyl Character Ring of \(H\)
- \(\text{rule}\) – a string describing the branching rule as a map from the weight space of \(S\) to the weight space of \(R\).

If the rule parameter is omitted, in some cases, a default rule is supplied. See \texttt{branch_weyl_character}().

EXAMPLES:

\[
\text{sage: rule = branching_rule(CartanType("A3"),CartanType("C2"),"symmetric")}
\]

\[
\text{sage: [rule(x) for x in WeylCharacterRing("A3").fundamental_weights()]
}\]

\[
[[1, 0], [1, 1], [1, 0]]
\]

sage.combinat.root_system.branching_rules.maximal_subgroups(ct, mode='print_rules')

Given a classical Cartan type (of rank less than or equal to 8) this prints the Cartan types of maximal subgroups, with a method of obtaining the branching rule. The string to the right of the colon in the output is a command to create a branching rule.

INPUT:
• ct – a classical irreducible Cartan type

Returns a list of maximal subgroups of ct.

EXAMPLES:

```python
sage: from sage.combinat.root_system.branching_rules import maximal_subgroups
sage: maximal_subgroups("D4")
B3:branching_rule("D4","B3","symmetric")
A2:branching_rule("D4","A2(1,1)","plethysm")
A1xC2:branching_rule("D4","C1xC2","tensor")*branching_rule("C1xC2","A1xC2", ->[branching_rule("C1","A1","isomorphic"),"identity"])
```

maximal_subgroups()

### 5.1.225 Cartan matrices

AUTHORS:

**class** `sage.combinat.root_system.cartan_matrix.CartanMatrix`

**Bases:** `Matrix_integer_sparse, CartanType_abstract`

A (generalized) Cartan matrix.

A matrix $A = (a_{ij})_{i,j \in I}$ for some index set $I$ is a generalized Cartan matrix if it satisfies the following properties:

- $a_{ii} = 2$ for all $i$,
- $a_{ij} \leq 0$ for all $i \neq j$,
- $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

Additionally some reference assume that a Cartan matrix is *symmetrizable* (see `is_symmetrizable()`). However following Kac, we do not make that assumption here.

An even, integral Borcherds–Cartan matrix is an integral matrix $A = (a_{ij})_{i,j \in I}$ for some countable index set $I$ which satisfies the following properties:

- $a_{ii} \in \{2\} \cup 2\mathbb{Z}_{>0}$ for all $i$, ...
• $a_{ij} \leq 0$ for all $i \neq j$,
• $a_{ij} = 0$ if and only if $a_{ji} = 0$ for all $i \neq j$.

**INPUT:**

Can be anything which is accepted by CartanType or a matrix.

If given a matrix, one can also use the keyword `cartan_type` when giving a matrix to explicitly state the type. Otherwise this will try to check the input matrix against possible standard types of Cartan matrices. To disable this check, use the keyword `cartan_type_check = False`.

If one wants to initialize a Borcherds-Cartan matrix using matrix data, use the keyword `borcherds=True`. To specify the diagonal entries of corresponding to a Cartan type (a Cartan matrix is treated as matrix data), use `borcherds` with a list of the diagonal entries.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: CartanMatrix(['A', 4])
[ 2 -1 0 0 ]
[-1 2 -1 0]
[ 0 -1 2 -1 ]
[ 0 0 -1 2 ]
sage: CartanMatrix(['B', 6])
[ 2 -1 0 0 0 0 ]
[-1 2 -1 0 0 0]
[ 0 -1 2 -1 0 0 ]

Examples of Borcherds-Cartan matrices:

sage: CartanMatrix([[2,-1],[-1,-2]], borcherds=True) # needs sage.graphs
[ 2 -1]
[-1 -2]
sage: CartanMatrix('B3', borcherds=[-4,-6,2]) # needs sage.graphs
[-4 -1 0]
[-1 -6 -1]
[ 0 -2 2]

>>> from sage.all import *
>>> CartanMatrix([[Integer(2),-Integer(1)],[Integer(1),-Integer(2)]]),
borcherds=True) # needs sage.graphs
[ 2 -1]
[-1 -2]
>>> CartanMatrix('B3', borcherds=[-Integer(4),-Integer(6),Integer(2)]) # needs sage.graphs
[-4 -1 0]
[-1 -6 -1]
[ 0 -2 2]

5.1. Comprehensive Module List
**Note:** Since this is a matrix, `row()` and `column()` will return the standard row and column respectively. To get the row with the indices as in Dynkin diagrams/Cartan types, use `row_with_indices()` and `column_with_indices()` respectively.

### cartan_matrix()

Return the Cartan matrix of `self`.

**EXAMPLES:**

```python
sage: CartanMatrix(['C',3]).cartan_matrix()  # needs sage.graphs
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

```python
>>> from sage.all import *

>>> CartanMatrix(['C',Integer(3)]).cartan_matrix()  # needs sage.graphs
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

### cartan_type()

Return the Cartan type of `self` or `self` if unknown.

**EXAMPLES:**

```python
sage: C = CartanMatrix(['A',4,1])  # needs sage.graphs
sage: C.cartan_type()  # needs sage.graphs
['A', 4, 1]
```

```python
>>> from sage.all import *

>>> C = CartanMatrix(['A',Integer(4),Integer(1)])  # needs sage.graphs
>>> C.cartan_type()  # needs sage.graphs
['A', 4, 1]
```

If the Cartan type is unknown:

```python
sage: C = CartanMatrix([[2,-1,-2], [-1,2,-1], [-2,-1,2]])  # needs sage.graphs
sage: C.cartan_type()  # needs sage.graphs
[ 2 -1 -2]
[-1  2 -1]
[-2 -1  2]
```

```python
>>> from sage.all import *

>>> C = CartanMatrix([[Integer(2),-Integer(1),-Integer(2)], [-Integer(1), Integer(2),-Integer(1)], [-Integer(2),-Integer(1),Integer(2)]])  # needs sage.graphs
>>> C.cartan_type()  # needs sage.graphs
```

(continues on next page)
column_with_indices(j)

Return the \( j^{th} \) column \((a_{i,j})_i\) of self as a container (or iterator) of tuples \((i, a_{i,j})\)

EXAMPLES:

```python
sage: M = CartanMatrix(['B',4])
# needs sage.graphs
sage: [ (i,a) for (i,a) in M.column_with_indices(3) ]
# needs sage.graphs
[(3, 2), (2, -1), (4, -2)]
```

coxeter_diagram()

Construct the Coxeter diagram of self.

See also:

`CartanType_abstract.coxeter_diagram()`

EXAMPLES:

```python
sage: cm = CartanMatrix([[2,-5,0],
                      [-2,2,-1],
                      [0,-1,2]])
```

```python
sage: G = cm.coxeter_diagram(); G
Graph on 3 vertices
```

```python
sage: G.edges(sort=True)
[[0, 1, +Infinity], (1, 2, 3)]
```

```python
sage: ct = CartanType(['A',2,2], ['B',3])
```

```python
sage: ct.coxeter_diagram()
Graph on 5 vertices
```

```python
carton_matrix().coxeter_diagram() == ct.coxeter_diagram()
True
```
coxeter_matrix()

Return the Coxeter matrix for self.

See also:
CartanType_abstract.coxeter_matrix()

EXAMPLES:

sage: # needs sage.graphs
sage: cm = CartanMatrix([[2, -5, 0], [-2, 2, -1], [0, -1, 2]])
sage: cm.coxeter_matrix()
[ 1 -1  2]
[-1  1  3]
[ 2  3  1]
sage: ct = CartanType([['A', 2, 2], ['B', 3]])
sage: ct.coxeter_matrix()
[ 1 -1  2  2  2]
[-1  1  2  2  2]
[ 2  2  3  1  4]
[ 2  2  2  4  1]
sage: ct.cartan_matrix().coxeter_matrix() == ct.coxeter_matrix()
True

dual()

Return the dual Cartan matrix of self, which is obtained by taking the transpose.

EXAMPLES:

sage: # needs sage.graphs
sage: ct = CartanType(['C', 3])
sage: M = CartanMatrix(ct); M
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
sage: M.dual()
[ 2 -1  0]
[-1  2 -1]
[ 0 -2  2]

(continues on next page)
sage: M.dual() == CartanMatrix(ct.dual())
True
sage: M.dual().cartan_type() == ct.dual()
True

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> ct = CartanType(['C',Integer(3)])
>>> M = CartanMatrix(ct); M
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
>>> M.dual()
[ 2 -1  0]
[-1  2 -1]
[ 0 -2  2]
>>> M.dual() == CartanMatrix(ct.dual())
True
>>> M.dual().cartan_type() == ct.dual()
True
```

An example with arbitrary Cartan matrices:

```python
sage: # needs sage.graphs
sage: cm = CartanMatrix([[2,-5], [-2, 2]]); cm
[ 2 -5]
[-2  2]
sage: cm.dual()
[ 2 -2]
[-5  2]
sage: cm.dual() == CartanMatrix(cm.transpose())
True
sage: cm.dual().dual() == cm
True
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> cm = CartanMatrix([[Integer(2),-Integer(5)], [-Integer(2), Integer(2)]]); cm
[ 2 -5]
[-2  2]
>>> cm.dual()
[ 2 -2]
[-5  2]
>>> cm.dual() == CartanMatrix(cm.transpose())
True
>>> cm.dual().dual() == cm
True
```

dynkin_diagram()

Return the Dynkin diagram corresponding to self.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: C = CartanMatrix(['A',2])
```
sage: C = CartanMatrix(['F',4,1])
sage: C.dynkin_diagram()
O---O---O=>=O---O
0 1 2 3 4
F4~
sage: C = CartanMatrix([[2,-4],[-4,2]])
sage: C.dynkin_diagram()
Dynkin diagram of rank 2

>>> from sage.all import *
>>> # needs sage.graphs
>>> C = CartanMatrix(['A',Integer(2)])
>>> C.dynkin_diagram()
O---O
1 2
A2
>>> C = CartanMatrix(['F',Integer(4),Integer(1)])
>>> C.dynkin_diagram()
O---O---O=>=O---O
0 1 2 3 4
F4~
>>> C = CartanMatrix([[Integer(2),-Integer(4)],[Integer(4),-Integer(4),Integer(2)]])
>>> C.dynkin_diagram()
Dynkin diagram of rank 2

indecomposable_blocks()

Return a tuple of all indecomposable blocks of self.

EXAMPLES:

sage: # needs sage.graphs
sage: M = CartanMatrix(['A',2])
sage: M.indecomposable_blocks()
([ 2 -1
  [-1 2]
],)
sage: M = CartanMatrix(['A',2,1],['A',3,1])
sage: M.indecomposable_blocks()
([ 2 -1 0 -1
  [-1 2 -1 0] [ 2 -1 -1]
  [ 0 -1 2 -1] [-1 2 -1]
  [-1 0 -1 2], [-1 -1 2]
])

>>> from sage.all import *
>>> # needs sage.graphs
>>> M = CartanMatrix(['A',Integer(2)])
>>> M.indecomposable_blocks()
([ 2 -1
  [ 2 -1]
],)

(continues on next page)
Combinatorics, Release 10.4

[-1 2]

```python
>>> M = CartanMatrix([[A, Integer(2), Integer(1)], [A, Integer(3),
˓→ Integer(1)]])
```

```python
>>> M.indecomposable_blocks()
```

```python
[
[ 2 -1 0 -1]
[-1 2 -1 0] [ 2 -1 -1]
[ 0 -1 2 -1] [-1 2 -1]
[-1 0 -1 2], [-1 -1 2]
]
```

### index_set()

Return the index set of self.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: C = CartanMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CartanMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```

```python
>>> from sage.all import *
```

```python
>>> # needs sage.graphs
```

```python
C = CartanMatrix(['A',Integer(1),Integer(1)])
```

```python
C.index_set()
```

```python
(0, 1)
```

```python
C = CartanMatrix(['E',Integer(6)])
```

```python
C.index_set()
```

```python
(1, 2, 3, 4, 5, 6)
```

### is_affine()

Return True if self is an affine type or False otherwise.

A generalized Cartan matrix is affine if all of its indecomposable blocks are either finite (see is_finite()) or have zero determinant with all proper principal minors positive.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: M = CartanMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CartanMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_affine()
False
```

```python
>>> from sage.all import *
```

```python
>>> # needs sage.graphs
```

```python
M = CartanMatrix(['C',Integer(4)])
```

(continues on next page)
Combinatorics, Release 10.4

>>> M.is_affine()
False
>>> M = CartanMatrix([['D', Integer(4), Integer(1)]])
>>> M.is_affine()
True
>>> M = CartanMatrix([[Integer(2), -Integer(4)], [-Integer(3), Integer(2)]]))
>>> M.is_affine()
False

is_crystallographic()
Implements CartanType_abstract.is_crystallographic().

A Cartan matrix is crystallographic if it is symmetrizable.

EXAMPLES:

sage: CartanMatrix([['F', 4]]).is_crystallographic()  
˓→ # needs sage.graphs
True

>>> from sage.all import *

is_finite()
Return True if self is a finite type or False otherwise.

A generalized Cartan matrix is finite if the determinant of all its principal submatrices (see principal_submatrices()) is positive. Such matrices have a positive definite symmetrized matrix. Note that a finite matrix may consist of multiple blocks of Cartan matrices each having finite Cartan type.

EXAMPLES:

sage: # needs sage.graphs
sage: M = CartanMatrix([['C', 4]])
sage: M.is_finite()
True
sage: M = CartanMatrix([['D', 4, 1]])
sage: M.is_finite()
False
sage: M = CartanMatrix([[2, -4], [-3, 2]])
sage: M.is_finite()
False

>>> from sage.all import *

˓→ # needs sage.graphs
**is_hyperbolic** (*compact=False*)

Return if `True` if `self` is a (compact) hyperbolic type or `False` otherwise.

An indecomposable generalized Cartan matrix is hyperbolic if it has negative determinant and if any proper connected subdiagram of its Dynkin diagram is of finite or affine type. It is compact hyperbolic if any proper connected subdiagram has finite type.

**INPUT:**

- `compact` — if `True`, check if matrix is compact hyperbolic

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: M = CartanMatrix([[2,-2,0],[-2,2,-1],[0,-1,2]])
sage: M.is_hyperbolic()
True
sage: M.is_hyperbolic(compact=True)
False

sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_hyperbolic()
True
sage: M = CartanMatrix(['C',4])
sage: M.is_hyperbolic()
False
```

```python
>>> from sage.all import *

>>> # needs sage.graphs

>>> M = CartanMatrix([[Integer(2),-Integer(2),Integer(0)],[Integer(0),-Integer(1),Integer(2)],[Integer(0),-Integer(1),Integer(2)]])

>>> M.is_hyperbolic()
True
>>> M.is_hyperbolic(compact=True)
False

>>> M = CartanMatrix([[Integer(2),-Integer(3)],[Integer(0),-Integer(1),Integer(2)]])

>>> M.is_hyperbolic()
True
>>> M = CartanMatrix(['C',Integer(4)])

>>> M.is_hyperbolic()
False
```

**is_indecomposable**

Return if `self` is an indecomposable matrix or `False` otherwise.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: M = CartanMatrix(['A',5])
sage: M.is_indecomposable()
True
sage: M = CartanMatrix([[2,-1,0],[-1,2,0],[0,0,2]])

sage: M.is_indecomposable()
False
```

```python
>>> from sage.all import *

>>> # needs sage.graphs

>>> M = CartanMatrix(['A',Integer(5)])

>>> M.is_indecomposable()
True
```

(continues on next page)
is_indefinite()
Return if self is an indefinite type or False otherwise.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_indefinite()
True
sage: M = CartanMatrix("A2")
sage: M.is_indefinite()
False
```

is_lorentzian()
Return True if self is a Lorentzian type or False otherwise.

A generalized Cartan matrix is Lorentzian if it has negative determinant and exactly one negative eigenvalue.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: M = CartanMatrix([[2,-3],[-3,2]])
sage: M.is_lorentzian()
True
sage: M = CartanMatrix([[2,-1],[-1,2]])
sage: M.is_lorentzian()
False
```

is_simply_laced()
Implements CartanType_abstract.is_simply_laced().

A Cartan matrix is simply-laced if all non diagonal entries are 0 or -1.

EXAMPLES:
```python
sage: cm = CartanMatrix([[2, -1, -1, -1], [-1, 2, -1, -1], [-1, -1, 2, -1], [-1, -1, -1, 2]])
```
```
False
```
```
```python
from sage.all import *
```
Combinatorics, Release 10.4

```python
sage: M = CartanMatrix(['A',2])  # needs sage.graphs
sage: M.principal_submatrices()  # needs sage.graphs
[]

M.principal_submatrices(proper=True)  # needs sage.graphs
[]
```

```python
>>> from sage.all import *
>>> M = CartanMatrix(['A',Integer(2)])  # needs sage.graphs
>>> M.principal_submatrices()  # needs sage.graphs
[]
```

```python
rank()
Return the rank of self.

EXAMPLES:
```n
```python
sage: CartanMatrix(['C',3]).rank()  # needs sage.graphs
3
sage: CartanMatrix(['A2','B2','F4']).rank()  # needs sage.graphs
8
```

```python
>>> from sage.all import *
>>> CartanMatrix(['C',Integer(3)]).rank()  # needs sage.graphs
3
>>> CartanMatrix(['A2','B2','F4']).rank()  # needs sage.graphs
8
```

```python
reflection_group(type='matrix')
Return the reflection group corresponding to self.

EXAMPLES:
```n
```python
sage: C = CartanMatrix(['A',3])  # needs sage.graphs
sage: C.reflection_group()  # needs sage.graphs sage.libs.gap
Weyl Group of type ['A', 3] (as a matrix group acting on the root space)
```
```python
>>> from sage.all import *
>>> C = CartanMatrix(['A',Integer(3)])
   # needs sage.graphs
>>> C.reflection_group()  # needs sage.graphs sage.libs.gap
Weyl Group of type ['A', 3] (as a matrix group acting on the root space)

relabel (relabelling)
Return the relabelled Cartan matrix.

EXAMPLES:
```}
```python
sage: # needs sage.graphs
cm = CartanMatrix(['A',3])
sage: R = cm.relabel({1:0, 2:4, 3:1}); R
[ 2 0 -1]
[ 0 2 -1]
[-1 -2 2]
sage: R.index_set()
(0, 1, 4)
sage: cm
[ 2 -1 0]
[-1 2 -2]
[ 0 -1 2]
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> cm = CartanMatrix(['A',Integer(3)])
>>> R = cm.relabel({Integer(1):Integer(0), Integer(2):Integer(4),
   Integer(3):Integer(1)}); R
[ 2 0 -1]
[ 0 2 -1]
[-1 -2 2]
>>> R.index_set()
(0, 1, 4)
>>> cm
[ 2 -1 0]
[-1 2 -2]
[ 0 -1 2]
```

root_space()
Return the root space corresponding to self.

EXAMPLES:
```python
sage: C = CartanMatrix(['A',3])  # needs sage.graphs
sage: C.root_space()  # needs sage.graphs
Root space over the Rational Field of the Root system of type ['A', 3]
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> C = CartanMatrix(['A',Integer(3)])
   # needs sage.graphs
>>> C.root_space()  # needs sage.graphs
Root space over the Rational Field of the Root system of type ['A', 3]
```
**root_system()**

Return the root system corresponding to self.

**EXAMPLES:**

```
sage: C = CartanMatrix(['A',3])  # needs sage.graphs
sage: C.root_system()             # needs sage.graphs
Root system of type ['A', 3]
```

```
>>> from sage.all import *
>>> C = CartanMatrix(['A',Integer(3)])
# needs sage.graphs
>>> C.root_system()             # needs sage.graphs
Root system of type ['A', 3]
```

**row_with_indices(i)**

Return the \(i\)th row \((a_{i,j})\) of self as a container (or iterator) of tuples \((j, a_{i,j})\)

**EXAMPLES:**

```
sage: M = CartanMatrix(['C',4])
# needs sage.graphs
sage: [ (i,a) for (i,a) in M.row_with_indices(3) ]  # needs sage.graphs
[(3, 2), (2, -1), (4, -2)]
```

```
>>> from sage.all import *
# needs sage.graphs
>>> M = CartanMatrix(['C',Integer(4)])
# needs sage.graphs
>>> [ (i,a) for (i,a) in M.row_with_indices(Integer(3)) ]
[(3, 2), (2, -1), (4, -2)]
```

**subtype(index_set)**

Return a subtype of self given by index_set.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of self by index_set.

**EXAMPLES:**

```
sage: C = CartanMatrix(['F',4])
# needs sage.graphs
sage: S = C.subtype([1,2,3])
```

```
>>> from sage.all import *
# needs sage.graphs
>>> C = CartanMatrix(['F',Integer(4)])
# needs sage.graphs
```
Combinatorics, Release 10.4

sage: S = C.subtype([Integer(1), Integer(2), Integer(3)])

sage: S
[2 -1 0]
[-1 2 -1]
[0 -2 2]

sage: S.index_set()
(1, 2, 3)

**symmetrized_matrix()**

Return the symmetrized matrix of self if symmetrizable.

**EXAMPLES:**

```python
sage: cm = CartanMatrix(['B', 4, 1])  # needs sage.graphs
sage: cm.symmetrized_matrix()
[ 4 0 -2 0 0]
[ 0 4 -2 0 0]
[-2 -2 4 -2 0]
[ 0 0 -2 4 -2]
[ 0 0 0 -2 2]
```

```python
>>> from sage.all import *
>>> cm = CartanMatrix(['B', Integer(4), Integer(1)])  # needs sage.graphs
>>> cm.symmetrized_matrix()
[ 4 0 -2 0 0]
[ 0 4 -2 0 0]
[-2 -2 4 -2 0]
[ 0 0 -2 4 -2]
[ 0 0 0 -2 2]
```

**symmetrizer()**

Return the symmetrizer of self.

**EXAMPLES:**

```python
sage: cm = CartanMatrix([[2, -5], [-2, 2]])  # needs sage.graphs
sage: cm.symmetrizer()
Finite family {0: 2, 1: 5}
```

```python
>>> from sage.all import *
>>> cm = CartanMatrix([[Integer(2), -Integer(5)], [-Integer(2), Integer(2)]])  # needs sage.graphs
>>> cm.symmetrizer()
Finite family {0: 2, 1: 5}
```

sage.combinat.root_system.cartan_matrix.find_cartan_type_from_matrix\( (CM) \)

Find a Cartan type by direct comparison of Dynkin diagrams given from the generalized Cartan matrix CM and return None if not found.

**INPUT:**

5.1. Comprehensive Module List
• CM – a generalized Cartan matrix

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: from sage.combinat.root_system.cartan_matrix import find_cartan_type_from_matrix
sage: CM = CartanMatrix([[2, -1, -1], [-1, 2, -1], [-1, -1, 2]])
sage: find_cartan_type_from_matrix(CM)
['A', 2, 1]

sage: CM = CartanMatrix([[2, -1, 0], [-1, 2, -2], [0, -1, 2]])
sage: find_cartan_type_from_matrix(CM)
['C', 3] relabelled by {1: 0, 2: 1, 3: 2}

sage: CM = CartanMatrix([[2, -1, -2], [-1, 2, -1], [-2, -1, 2]])
sage: find_cartan_type_from_matrix(CM)

Warning

sage.combinat.root_system.cartan_matrix.is_borcherds_cartan_matrix(M)
Return True if M is an even, integral Borcherds-Cartan matrix. For a definition of such a matrix, see Cartan Matrix.

**EXAMPLES:**

```python
sage: from sage.all import *

sage: M = Matrix([[2, -1], [-1, 2]])

sage: is_borcherds_cartan_matrix(M)  # doctest: +NORMALIZE_WHITESPACE
True

sage: N = Matrix([[2, -1], [-1, 0]])

sage: is_borcherds_cartan_matrix(N)  # doctest: +NORMALIZE_WHITESPACE
False

sage: O = Matrix([[2, -1], [-1, -2]])

sage: is_borcherds_cartan_matrix(O)  # doctest: +NORMALIZE_WHITESPACE
True

sage: O = Matrix([[2, -1], [-1, -3]])

sage: is_borcherds_cartan_matrix(O)  # doctest: +NORMALIZE_WHITESPACE
False
```

(continues on next page)
Combinatorics, Release 10.4

sage.combinat.root_system.cartan_matrix.is_generalized_cartan_matrix(M)

Return True if \( M \) is a generalized Cartan matrix. For a definition of a generalized Cartan matrix, see Cartan Matrix.

EXAMPLES:

```python
sage: from sage.combinat.root_system.cartan_matrix import is_generalized_cartan_matrix
sage: M = matrix([[2, -1, -2], [-1, 2, -1], [-2, -1, 2]])
sage: is_generalized_cartan_matrix(M)
True
sage: M = matrix([[2, -1, -2], [-1, 2, -1], [0, -1, 2]])
sage: is_generalized_cartan_matrix(M)
False
sage: M = matrix([[1, -1, -2], [-1, 2, -1], [-2, -1, 2]])
sage: is_generalized_cartan_matrix(M)
False
```

A non-symmetrizable example:

```python
sage: M = matrix([[2, -1, -2], [-1, 2, -1], [-1, -1, 2]])
sage: is_generalized_cartan_matrix(M)
True
```
5.1.226 Cartan types

Todo: Why does sphinx complain if I use sections here?

Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. Cartan types are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type $A_4$:

\begin{verbatim}
sage: T = CartanType(['A', 4]); T
['A', 4]
\end{verbatim}

It is the name of the following Dynkin diagram:

\begin{verbatim}
sage: DynkinDiagram(T) \#-- needs sage.graphs
O---O---O---O
1 2 3 4
A4
\end{verbatim}

Note: For convenience, the following shortcuts are available:

\begin{verbatim}
sage: DynkinDiagram(['A',4]) \#--

sage: DynkinDiagram('A4') \#--

sage: T.dynkin_diagram() \#--
\end{verbatim}

(continues on next page)
See `DynkinDiagram` for how to further manipulate Dynkin diagrams.

From this data (the Cartan datum), one can construct the associated root system:

```
sage: RootSystem(T)
Root system of type ['A', 4]
```

```
>>> from sage.all import *

>>> RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of $A_n$ is the symmetric $S_{n+1}$:

```
sage: W = WeylGroup(T); W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
sage: W.cardinality()
120
```

```
>>> from sage.all import *

>>> W = WeylGroup(T); W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
>>> W.cardinality()
120
```

while the Lie algebra is $sl_{n+1}$, and the Lie group $SL_{n+1}$ (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

```
sage: C = crystals.Letters(T); C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]
```

```
sage: C = crystals.Tableaux(T, shape=[2]); C
```

(continues on next page)
The crystal of tableaux of type ['A', 4] and shape(s) [[2]]
sage: C.cardinality()

15

The crystal of letters for type ['A', 4]

[1, 2, 3, 4, 5]

The crystal of tableaux of type ['A', 4] and shape(s) [[2]]

15

Here is a sample of all the finite irreducible crystallographic Cartan types:

sage: CartanType.samples(finite=True, crystallographic=True)

[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5],
['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2],

A_{1}^{(1)}, A_{5}^{(1)}, B_{1}^{(1)}, B_{5}^{(1)},
C_{1}^{(1)}, C_{5}^{(1)}, D_{3}^{(1)}, D_{5}^{(1)},
E_6^{(1)}, E_7^{(1)}, E_8^{(1)}, F_4^{(1)}, G_2^{(1)},
BC_{1}^{(2)}, BC_{5}^{(2)},\]

B_{5}^{(1)\vee}, C_{4}^{(1)\vee}, F_4^{(1)\vee},
G_2^{(1)\vee}, BC_{1}^{(2)\vee}, BC_{5}^{(2)\vee}]

One can also get latex representations of the crystallographic Cartan types and their corresponding Dynkin diagrams:

sage: [latex(ct) for ct in CartanType.samples(crystallographic=True)]

[A_{1}, A_{5}, B_{1}, B_{5}, C_{1}, C_{5}, D_{2}, D_{3}, D_{5},
E_{6}, E_{7}, E_{8}, F_4, G_2,
A_{1}^{(1)}, A_{5}^{(1)}, B_{1}^{(1)}, B_{5}^{(1)},
C_{1}^{(1)}, C_{5}^{(1)}, D_{3}^{(1)}, D_{5}^{(1)},
E_{6}^{(1)}, E_{7}^{(1)}, E_{8}^{(1)}, F_4^{(1)}, G_2^{(1)},
BC_{1}^{(2)}, BC_{5}^{(2)},
B_{5}^{(1)\vee}, C_{4}^{(1)\vee}, F_4^{(1)\vee},
G_2^{(1)\vee}, BC_{1}^{(2)\vee}, BC_{5}^{(2)\vee}]

(sage: view([DynkinDiagram(ct) for ct in CartanType.samples(crystallographic=True)]))

not tested
Non-crystallographic Cartan types are also partially supported:

```python
sage: CartanType.samples(finite=True, crystallographic=False)
[['I', 5], ['H', 3], ['H', 4]]
```

In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. `sage.combinat.root_system.type_A`). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root_system), and further mathematical properties:

```python
sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)
```

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3540426509. For example:

```python
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)  # needs sage.graphs
O 4
  |  |
O---O---O
1 2 3
D4

sage: E6 = CartanType(['E',6])
sage: DynkinDiagram(E6)  # needs sage.graphs
O 2
  |
O---O---O---O---O
1 3 4 5 6
E6
```
Note: The direction of the arrows is the opposite (i.e. the transpose) of Bourbaki's convention, but agrees with Kac's. For example, in type $C_2$, we have:

```python
sage: C2 = DynkinDiagram(['C',2]); C2

sage: C2.cartan_matrix()  # needs sage.graphs
\begin{bmatrix}
 2 & -2 \\
-1 & 2
\end{bmatrix}
```

However Bourbaki would have the Cartan matrix as:

$$
\begin{bmatrix}
 2 & -1 \\
-2 & 2
\end{bmatrix}.
$$

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type $E_6$ can be obtained via:

```python
sage: E6.relabel({1:1,2:6,3:2,4:3,5:4,6:5}).dynkin_diagram()  # needs sage.graphs
```

(continues on next page)
Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()
    # needs sage.graphs
sage: g.add_vertices([1,2,3])
    # needs sage.graphs
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()
    # needs sage.graphs
[2 0 0]
[0 2 0]
[0 0 2]
```

Then we add a couple edges:

```
sage: g.add_edge(1,2,2)
    # needs sage.graphs
sage: g.add_edge(1,3)
    # needs sage.graphs
```

(continues on next page)
and we get the desired Cartan matrix:

```python
sage: g.cartan_matrix()
# needs sage.graphs
[2 0 0]
[0 2 0]
[0 0 2]
```

Oops, the Cartan matrix did not change! This is because it is cached for efficiency (see `cached_method`). In general, a Dynkin diagram should not be modified after having been used.

**Warning:** this is not checked currently

**Todo:** add a method `set_mutable()` as, say, for matrices

Here, we can work around this by clearing the cache:

```python
sage: delattr(g, 'cartan_matrix')
# needs sage.graphs
```

Now we get the desired Cartan matrix:

```python
sage: g.cartan_matrix()
# needs sage.graphs
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]
```
>>> from sage.all import *
>>> g.cartan_matrix()
\[ \begin{array}{ccc}
 2 & -1 & -1 \\
-2 & 2 & -1 \\
-1 & -1 & 2 \\
\end{array} \]

Note that backward edges have been automatically added:

```sage
sage: g.edges(sort=True)
\[ (1, 2, 2), (1, 3, 1), (2, 1, 1), (2, 3, 1), (3, 1, 1), (3, 2, 1) \]
```

Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```sage
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```

or using the following short hand notation:

```sage
sage: CartanType("A2xB2")
A2xB2
sage: CartanType("A2","B2") == CartanType("A2xB2")
True
```

5.1. Comprehensive Module List
Degenerate cases

When possible, type $I_n$ is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```python
sage: CartanType(['I',1])
A1xA1
sage: CartanType(['I',3])
['A', 2]
sage: CartanType(['I',4])
['C', 2]
sage: CartanType(['I',6])
['G', 2]
```

```python
>>> from sage.all import *
```

```python
>> CartanType(['I',Integer(1)])
A1xA1
>>> CartanType(['I',Integer(3)])
['A', 2]
>>> CartanType(['I',Integer(4)])
['C', 2]
>>> CartanType(['I',Integer(6)])
['G', 2]
```

The Dynkin diagrams for types $B_1$, $C_1$, $D_2$, and $D_3$ are isomorphic to that for $A_1$, $A_1$, $A_1 \times A_1$, and $A_3$, respectively. However, their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

```python
sage: CartanType(['B',1])
['B', 1]
sage: CartanType(['C',1])
['C', 1]
sage: CartanType(['D',2])
['D', 2]
sage: CartanType(['D',3])
['D', 3]
```

```python
>>> from sage.all import *
```

```python
>> CartanType(['B',Integer(1)])
['B', 1]
>>> CartanType(['C',Integer(1)])
['C', 1]
>>> CartanType(['D',Integer(2)])
['D', 2]
>>> CartanType(['D',Integer(3)])
['D', 3]
```
Affine Cartan types

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):

```python
sage: CartanType(['A', 4, 1]).dynkin_diagram()  # needs sage.graphs
0
O----O------O
|      |
|      |
O----O----O
1 2 3 4
A4~
sage: CartanType(['B', 4, 1]).dynkin_diagram()  # needs sage.graphs
0
O---O---O=>=O
|      |
|      |
0---O---O
1 2 3 4
B4~
```

or dual thereof:

```python
>>> from sage.all import *

>>> CartanType(['A', Integer(4), Integer(1)]).dynkin_diagram()  # needs sage.graphs
0
O----O------O
|      |
|      |
O----O----O
1 2 3 4
A4~

>>> CartanType(['B', Integer(4), Integer(1)]).dynkin_diagram()  # needs sage.graphs
0
O---O---O<=<=O
|      |
|      |
0---O----O
1 2 3 4
B4~*
```

(continues on next page)
or is of type $\tilde{BC}_n$ (which yields an irreducible, but nonreduced root system):

```sage
sage: CartanType(["BC", 4, 2]).dynkin_diagram()

# needs sage.graphs
O=<=O---O---O=<=O
0 1 2 3 4
BC4~
```

This includes the two degenerate cases:

```sage
sage: CartanType(["A", 1, 1]).dynkin_diagram()

# needs sage.graphs
O<=>O
0 1
A1~

sage: CartanType(["BC", 1, 2]).dynkin_diagram()

# needs sage.graphs
4
O=<=O
0 1
BC1~
```

For the user convenience, Kac's notations for twisted affine types are automatically translated into the previous ones:

```sage
sage: CartanType(["A", 9, 2])
["B", 5, 1]^*

sage: CartanType(["A", 9, 2]).dynkin_diagram()

O 0
| |
```

(continues on next page)
Combinatorics, Release 10.4

| O---O---O---O<=O  1 2 3 4 5 |
| B5- |

**sage:** CartanType(["A", 10, 2]).dynkin_diagram()
O<=O---O---O<=O  0 1 2 3 4 5

**BC5-**

**sage:** CartanType(["D", 5, 2]).dynkin_diagram()
O<=O---O---O=>=O  0 1 2 3 4

C4- *

**sage:** CartanType(["D", 4, 3]).dynkin_diagram()
3
O=>=O---O  2 1 0

G2-* relabelled by {0: 0, 1: 2, 2: 1}

**sage:** CartanType(["E", 6, 2]).dynkin_diagram()
O---O---O=<=O---O  0 1 2 3 4

Additionally one can set the notation option to use Kac’s notation:

**sage:** # needs sage.graphs
**sage:** CartanType(["A", 9, 2]).dynkin_diagram()

5.1. Comprehensive Module List
Combinatorics, Release 10.4

Infinite Cartan types

There are minimal implementations of the Cartan types $A_\infty$ and $A_{+\infty}$. In sage oo is the same as $+\text{Infinity}$, so NN and ZZ are used to differentiate between the $A_{+\infty}$ and $A_\infty$ root systems:

```python
sage: CartanType(['A', NN])
['A', NN]
sage: print(CartanType(['A', NN]).ascii_art())
O---O---O---O---O---O---...
0 1 2 3 4 5 6
sage: CartanType(['A', ZZ])
['A', ZZ]
sage: print(CartanType(['A', ZZ]).ascii_art())
..---O---O---O---O---O---O---...
-3 -2 -1 0 1 2 3
```

There are also the following shorthands:

```python
sage: CartanType("Aoo")
['A', ZZ]
sage: CartanType("A+oo")
['A', NN]
```

Abstract classes for Cartan types

- CartanType_abstract
- CartanType_crystallographic
- CartanType_simply_laced
- CartanType_simple
- CartanType_finite
- CartanType_affine (see also Root system data for affine Cartan types)

Cartan types

Todo: Why does sphinx complain if I use sections here?
Introduction

Loosely speaking, Dynkin diagrams (or equivalently Cartan matrices) are graphs which are used to classify root systems, Coxeter and Weyl groups, Lie algebras, Lie groups, crystals, etc. up to an isomorphism. Cartan types are a standard set of names for those Dynkin diagrams (see Wikipedia article Dynkin_diagram).

Let us consider, for example, the Cartan type $A_4$:

```
sage: T = CartanType(['A', 4]); T
['A', 4]
```

```
>>> from sage.all import *

>>> T = CartanType(['A', Integer(4)]); T
['A', 4]
```

It is the name of the following Dynkin diagram:

```
sage: DynkinDiagram(T)

O---O---O---O
1 2 3 4
A4
```

```
>>> from sage.all import *

>>> DynkinDiagram(T)

O---O---O---O
1 2 3 4
A4
```

**Note:** For convenience, the following shortcuts are available:

```
sage: DynkinDiagram(['A',4])

O---O---O---O
1 2 3 4
A4
```

```
sage: DynkinDiagram('A4')

O---O---O---O
1 2 3 4
A4
```

```
sage: T.dynkin_diagram()

O---O---O---O
1 2 3 4
A4
```

```
>>> from sage.all import *

>>> DynkinDiagram(['A',Integer(4)])

O---O---O---O
1 2 3 4
A4
```

```
>>> DynkinDiagram('A4')

O---O---O---O
1 2 3 4
A4
```

(continues on next page)
See `DynkinDiagram` for how to further manipulate Dynkin diagrams.

From this data (the Cartan datum), one can construct the associated root system:

```sage
sage: RootSystem(T)
Root system of type ['A', 4]
```

The associated Weyl group of $A_n$ is the symmetric group $S_{n+1}$:

```sage
sage: W = WeylGroup(T); W
Weyl Group of type ['A', 4] (as a matrix group acting on the ambient space)
```

while the Lie algebra is $sl_{n+1}$, and the Lie group $SL_{n+1}$ (TODO: illustrate this once this is implemented).

One may also construct crystals associated to various Dynkin diagrams. For example:

```sage
sage: C = crystals.Letters(T); C
The crystal of letters for type ['A', 4]
sage: C.list()
[1, 2, 3, 4, 5]
sage: C = crystals.Tableaux(T, shape=[2]); C
The crystal of tableaux of type ['A', 4] and shape(s) [[2]]
sage: C.cardinality()
15
```
Here is a sample of all the finite irreducible crystallographic Cartan types:

```python
crystals.Tableaux(T, shape=[Integer(2)]); C
```

Their corresponding Dynkin diagrams:

```python
crystals.Letters(T); C
```

Non-crystallographic Cartan types are also partially supported:
In Sage, a Cartan type is used as a database of type-specific information and algorithms (see e.g. `sage.combinat.root_system.type_A`). This database includes how to construct the Dynkin diagram, the ambient space for the root system (see Wikipedia article Root_system), and further mathematical properties:

```python
sage: T.is_finite(), T.is_simply_laced(), T.is_affine(), T.is_crystallographic()
(True, True, False, True)
```

In particular, a Sage Cartan type is endowed with a fixed choice of labels for the nodes of the Dynkin diagram. This choice follows the conventions of Nicolas Bourbaki, Lie Groups and Lie Algebras: Chapter 4-6, Elements of Mathematics, Springer (2002). ISBN 978-3540426509. For example:

```python
sage: T = CartanType(['D', 4])
sage: DynkinDiagram(T)
˓→ # needs sage.graphs
0 4
|   
0---O--O--O
1 2 3
D4
```

```python
sage: E6 = CartanType(['E', 6])
sage: DynkinDiagram(E6)
˓→ # needs sage.graphs
0 2
|   
0---O---O---O---O---O
1 3 4 5 6
E6
```

(continues on next page)
Note: The direction of the arrows is the opposite (i.e. the transpose) of Bourbaki's convention, but agrees with Kac's.

For example, in type $C_2$, we have:

```sage
sage: C2 = DynkinDiagram(['C',2]); C2
O=<=O
1 2
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]
```

However Bourbaki would have the Cartan matrix as:

\[
\begin{bmatrix}
2 & -1 \\
-2 & 2
\end{bmatrix}
\]

If desired, other node labelling conventions can be achieved. For example the Kac labelling for type $E_6$ can be obtained via:

```sage
sage: E6.relabel({1:1,2:6,3:2,4:3,5:4,6:5}).dynkin_diagram()
O 6
| |
O---O---O---O---O
1 2 3 4 5
E6 relabelled by {1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5}
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

E6 relabelled by \((1: 1, 2: 6, 3: 2, 4: 3, 5: 4, 6: 5)\)

Contributions implementing other conventions are very welcome.

Another option is to build from scratch a new Dynkin diagram. The architecture has been designed to make it fairly easy to add other labelling conventions. In particular, we strived at choosing type free algorithms whenever possible, so in principle most features should remain available even with custom Cartan types. This has not been used much yet, so some rough corners certainly remain.

Here, we construct the hyperbolic example of Exercise 4.9 p. 57 of Kac, Infinite Dimensional Lie Algebras. We start with an empty Dynkin diagram, and add a couple nodes:

```
sage: g = DynkinDiagram()
   # needs sage.graphs
sage: g.add_vertices([1,2,3])
   # needs sage.graphs
```

Note that the diagonal of the Cartan matrix is already initialized:

```
sage: g.cartan_matrix()  # needs sage.graphs
[2 0 0]
[0 2 0]
[0 0 2]
```

Then we add a couple edges:

```
sage: g.add_edge(1,2,2)  # needs sage.graphs
sage: g.add_edge(1,3)  # needs sage.graphs
sage: g.add_edge(2,3)  # needs sage.graphs
```

(continues on next page)
and we get the desired Cartan matrix:

```
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]
```

Note that backward edges have been automatically added:
Reducible Cartan types

Reducible Cartan types can be specified by passing a sequence or list of irreducible Cartan types:

```
sage: CartanType(['A',2],['B',2])
A2xB2
sage: CartanType([['A',2],['B',2]])
A2xB2
sage: CartanType(['A',2],['B',2]).is_reducible()
True
```

or using the following short hand notation:

```
sage: CartanType("A2xB2")
A2xB2
sage: CartanType("A2","B2") == CartanType("A2xB2")
True
```

Degenerate cases

When possible, type $I_n$ is automatically converted to the isomorphic crystallographic Cartan types (any reason not to do so?):

```
sage: CartanType(['I',1])
A1xA1
sage: CartanType(['I',3])
["A", 2]
sage: CartanType(['I',4])
["C", 2]
```

(continues on next page)
The Dynkin diagrams for types $B_1$, $C_1$, $D_2$, and $D_3$ are isomorphic to that for $A_1$, $A_1$, $A_1 \times A_1$, and $A_3$, respectively. However their natural ambient space realizations (stemming from the corresponding infinite families of Lie groups) are different. Therefore, the Cartan types are considered as distinct:

**Affine Cartan types**

For affine types, we use the usual conventions for affine Coxeter groups: each affine type is either untwisted (that is arise from the natural affinisation of a finite Cartan type):
from sage.all import *

CartanType(["A", Integer(4), Integer(1)]).dynkin_diagram()  # needs sage.graphs

CartanType(["B", Integer(4), Integer(1)]).dynkin_diagram()  # needs sage.graphs

CartanType(["B", 4, 1]).dual().dynkin_diagram()  # needs sage.graphs

CartanType(["BC", 4, 2]).dynkin_diagram()  # needs sage.graphs

CartanType(["BC", Integer(4), Integer(2)]).dynkin_diagram()  (continues on next page)
This includes the two degenerate cases:

```python
sage: CartanType(['A', 1, 1]).dynkin_diagram()  # needs sage.graphs
O<>O
0 1
A1~
```

```python
sage: CartanType(['BC', 1, 2]).dynkin_diagram()  # needs sage.graphs
4
O<>O
0 1
BC1~
```

For the user convenience, Kac’s notations for twisted affine types are automatically translated into the previous ones:

```python
>>> from sage.all import *

>>> CartanType(['A', 9, 2]).dynkin_diagram()  # needs sage.graphs
A9~
```

```python
sage: CartanType(['A', 9, 2]).dynkin_diagram()
0 0
| |
0---O---O---O---O=<=O
1 2 3 4 5
B5~*

sage: CartanType(['A', 10, 2]).dynkin_diagram()
0=<=O---O---O---O=<=O
0 1 2 3 4 5
BC5~

sage: CartanType(['D', 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0 1 2 3 4
C4~*

sage: CartanType(['D', 4, 3]).dynkin_diagram()
3
O=>=O---O
5
```

(continues on next page)
G2~* relabelled by {0: 0, 1: 2, 2: 1}
```
sage: CartanType(['E', 6, 2]).dynkin_diagram()
O---O---O=<=O---O
0 1 2 3 4
F4~*
```

```python
>>> from sage.all import *

>>> # needs sage.graphs

>>> CartanType(['A', Integer(9), Integer(2)]
['B', 5, 1]^*

>>> CartanType(['A', Integer(9), Integer(2)]).dynkin_diagram()
O 0
| |
O---O---O---O=<=O
1 2 3 4 5
B5~*

>>> CartanType(['A', Integer(10), Integer(2)]).dynkin_diagram()
O=<=O---O---O---O=<=O
0 1 2 3 4 5
BC5~

>>> CartanType(['D', Integer(5), Integer(2)]).dynkin_diagram()
O=<=O---O---O=>=O
0 1 2 3 4
C4~*

>>> CartanType(['D', Integer(4), Integer(3)]).dynkin_diagram()
3
O=>=O---O
2 1 0
G2~* relabelled by {0: 0, 1: 2, 2: 1}

>>> CartanType(['E', Integer(6), Integer(2)]).dynkin_diagram()
O---O---O=<=O---O
0 1 2 3 4
F4~*
```

Additionally one can set the notation option to use Kac's notation:

```
sage: # needs sage.graphs
sage: CartanType.options['notation'] = 'Kac'
```
```python
sage: CartanType(['A', 9, 2])
['A', 9, 2]
sage: CartanType(['A', 9, 2]).dynkin_diagram()
O 0
| |
O---O---O---O=<=O
1 2 3 4 5
A9^2
```
```python
sage: CartanType(['A', 10, 2]).dynkin_diagram()
O=<=O---O---O---O=<=O
0 1 2 3 4 5
A10^2
```
```python
sage: CartanType(['D', 5, 2]).dynkin_diagram()
O=<=O---O---O=>=O
0 1 2 3 4
```
```python
sage: CartanType(['D', 4, 3]).dynkin_diagram()
3
O=>=O---O
2 1 0
```
```python
G2~* relabelled by {0: 0, 1: 2, 2: 1}
```
```python
>>> CartanType(['E', Integer(6), Integer(2)]).dynkin_diagram()
O---O---O=<=O---O
0 1 2 3 4
F4~*
```
```
(continues on next page)
D5^2
 sage: CartanType(["D", 4, 3]).dynkin_diagram()
 3
O=>=O---O
 2 1 0
D4^3
 sage: CartanType(["E", 6, 2]).dynkin_diagram()
O---O---O=<=O---O
 0 1 2 3 4
E6^2
 sage: CartanType.options['notation'] = 'BC'

>>> from sage.all import *
>>> # needs sage.graphs
>>> CartanType.options['notation'] = 'Kac'

Infinite Cartan types

There are minimal implementations of the Cartan types $A_{\infty}$ and $A_{+\infty}$. In sage oo is the same as $+Infinity$, so $NN$ and $ZZ$ are used to differentiate between the $A_{+\infty}$ and $A_{\infty}$ root systems:

 sage: CartanType(['A', NN])
 ['A', NN]
sage: print(CartanType(['A', NN]).ascii_art())
O---O---O---O---O---O---O---O---...
 0 1 2 3 4 5 6
 sage: CartanType(['A', ZZ])
 ['A', ZZ]

(continues on next page)
Combinatorics, Release 10.4

sage: print(CartanType(['A', ZZ]).ascii_art())
..---O---O---O---O---O---O---..  
-3 -2 -1 0 1 2 3

>>> from sage.all import *

>>> CartanType(['A', NN])
['A', NN]

>>> print(CartanType(['A', NN]).ascii_art())
O---O---O---O---O---O---O---..  
0 1 2 3 4 5 6

[97x594]>>> CartanType(['A', ZZ])
['A', ZZ]

>>> print(CartanType(['A', ZZ]).ascii_art())
..---O---O---O---O---O---O---..  
-3 -2 -1 0 1 2 3

There are also the following shorthands:

sage: CartanType("Aoo")
['A', ZZ]

sage: CartanType("A+oo")
['A', NN]

>>> from sage.all import *

>>> CartanType("Aoo")
['A', ZZ]

>>> CartanType("A+oo")
['A', NN]

Abstract classes for Cartan types

- CartanType_abstract
- CartanType_crystallographic
- CartanType_simply_laced
- CartanType_simple
- CartanType_finite
- CartanType_affine (see also Root system data for affine Cartan types)
- sage.combinat.root_system.cartan_type.CartonType
- Root system data for dual Cartan types
- Root system data for reducible Cartan types
- Root system data for relabelled Cartan types

Concrete classes for Cartan types

- CartanType_standard
- CartanType_standard_finite
- CartanType_standard_affine
- CartanType_standard_untwisted_affine

Type specific data

The data essentially consists of a description of the Dynkin/Coxeter diagram and, when relevant, of the natural embedding of the root system in an Euclidean space. Everything else is reconstructed from this data.

- Root system data for type A
- Root system data for type B
- Root system data for type C
- Root system data for type D
- Root system data for type E
- Root system data for type F
- Root system data for type G
- Root system data for type H
- Root system data for type I
- Root system data for super type A
- Root system data for type Q
- Root system data for (untwisted) type A affine
- Root system data for (untwisted) type B affine
- Root system data for (untwisted) type C affine
- Root system data for (untwisted) type D affine
- Root system data for (untwisted) type E affine
- Root system data for (untwisted) type F affine
- Root system data for (untwisted) type G affine
- Root system data for type BC affine
- Root system data for type A infinity

Todo: Should those indexes come before the introduction?

class sage.combinat.root_system.cartan_type.CartanTypeFactory
    Bases: SageObject

    classmethod color(i)
        Default color scheme for the vertices of a Dynkin diagram (and associated objects)

        EXAMPLES:

        sage: CartanType.color(1)
         'blue'
        sage: CartanType.color(2)
        'red'
        sage: CartanType.color(3)
        'green'
>>> from sage.all import *
>>> CartanType.color(Integer(1))
'blue'
>>> CartanType.color(Integer(2))
'red'
>>> CartanType.color(Integer(3))
'green'

The default color is black:

sage: CartanType.color(0)
'black'

>>> from sage.all import *
>>> CartanType.color(Integer(0))
'black'

Negative indices get the same color as their positive counterparts:

sage: CartanType.color(-1)
'blue'
sage: CartanType.color(-2)
'red'
sage: CartanType.color(-3)
'green'

>>> from sage.all import *
>>> CartanType.color(-Integer(1))
'blue'
>>> CartanType.color(-Integer(2))
'red'
>>> CartanType.color(-Integer(3))
'green'

options = Current options for CartanType - dual_latex: \vee - dual_str: * - latex_marked: True - latex_relabel: True - mark_special_node: none - marked_node_str: X - notation: Stembridge - special_node_str: @

samples (finite=None, affine=None, crystallographic=None)

Return a sample of the available Cartan types.

INPUT:

- finite – a boolean or None (default: None)
- affine – a boolean or None (default: None)
- crystallographic – a boolean or None (default: None)

The sample contains all the exceptional finite and affine Cartan types, as well as typical representatives of the infinite families.

EXAMPLES:

sage: CartanType.samples()
[[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5], ['D', 2], ['D', 3], ['D', 5], ['E', 6], ['E', 7], ['E', 8], ['F', 4], ['G', 2], ['I', 5], ['H', 3], ['H', 4]]]
The finite, affine and crystallographic options allow respectively for restricting to (non)finite, (non)affine, and (non)crystallographic Cartan types:

```python
>>> from sage.all import *
>>> CartanType.samples(finite=True)
[[[A', 1], [A', 5], [B', 1], [B', 5], [C', 1], [C', 5], [D', 2], [D', 3], [D'], 5],
 [E', 6], [E', 7], [E', 8], [F', 4], [G', 2], [I', 5], [H', 3], [H', 4]]

>>> CartanType.samples(affine=True)
[[[A', 1, 1], [A', 5, 1], [B', 1, 1], [B', 5, 1],
 [C', 1, 1], [C', 5, 1], [D', 3, 1], [D'], 5, 1],
 [E', 6, 1], [E', 7, 1], [E', 8, 1], [F', 4, 1], [G', 2, 1], [BC', 1, 2], [BC', 5, 2],

>>> CartanType.samples(crystallographic=True)
[[[A', 1], [A', 5], [B', 1], [B', 5], [C', 1], [C', 5], [D', 2], [D', 3], [D'], 5],
 [E', 6], [E', 7], [E', 8], [F', 4], [G', 2], [I', 5], [H', 3], [H', 4]]

>>> CartanType.samples(crystallographic=False)
[[[I', 5], [H', 3], [H', 4]]
```

(continues on next page)
>>> CartanType.samples(affine=True)
[[[A, 1, 1], [[A], 5, 1], [[B], 1, 1], [[B], 5, 1],
 [C], 1, 1], [[C], 5, 1], [[D], 3, 1], [[D], 5, 1],
 [E], 6, 1], [[E], 7, 1], [[E], 8, 1], [[F], 4, 1], [[G], 2, 1], [[HC], 1, 1-
 2], [[H], 5, 2],
[[B], 5, 1]^*, [[C], 4, 1]^*, [[F], 4, 1]^*, [[G], 2, 1]^*, [[HC], 1, 2]^*, [
 ˓→[H], 5, 2]^*]

Todo: add some reducible Cartan types (suggestions?)

class sage.combinat.root_system.cartan_type.CartanType_abstract
Bases: object

Abstract class for Cartan types

Subclasses should implement:

• dynkin_diagram()
• cartan_matrix()
• is_finite()
• is_affine()
• is_irreducible()

as_folding (folding_of=None, sigma=None)

Return self realized as a folded Cartan type.

For finite and affine types, this is realized by the Dynkin diagram foldings:

\[
\begin{align*}
C_n & \leftrightarrow A_{2n-1}^{(2)}, A_{2n}^{(2)}, D_{n+1}^{(2)} \\
A^{(2)}_{2n-1} & \leftrightarrow D_{n+1}^{(1)} \\
E_6^{(2)} & \leftrightarrow E_6^{(1)} \\
D_4^{(3)} & \leftrightarrow D_4^{(1)} \\
C_n & \leftrightarrow A_{2n-1} \\
B_n & \leftrightarrow D_{n+1} \\
F_4 & \leftrightarrow E_6 \\
G_2 & \leftrightarrow D_4.
\end{align*}
\]
For general types, this returns self as a folded type of self with \( \sigma \) as the identity map.

For more information on these foldings and folded Cartan types, see \texttt{sage.combinat.root_system.type_folded.CartanTypeFolded}.

If the optional inputs \texttt{folding_of} and \texttt{sigma} are specified, then this returns the folded Cartan type of \texttt{self} in \texttt{folding_of} given by the automorphism \texttt{sigma}.

**EXAMPLES:**

```python
sage: CartanType(['B', 3, 1]).as_folding()
['B', 3, 1] as a folding of ['D', 4, 1]
sage: CartanType(['F', 4]).as_folding()
['F', 4] as a folding of ['E', 6]
sage: CartanType(['BC', 3, 2]).as_folding()
['BC', 3, 2] as a folding of ['A', 5, 1]
sage: CartanType(['D', 4, 3]).as_folding()
['G', 2, 1]^* relabelled by {0: 0, 1: 2, 2: 1} as a folding of ['D', 4, 1]
```

**coxeter_diagram()**

Return the Coxeter diagram for \texttt{self}.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: CartanType(['B',3]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A',3]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 3)]
```

```python
>>> from sage.all import *

>>>

sage: CartanType(['B',Integer(3)]).coxeter_diagram()
Graph on 3 vertices
sage: CartanType(['A',Integer(3)]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 3)]
```
**coxeter_matrix()**

Return the Coxeter matrix for `self`.

**EXAMPLES:**

```python
sage: CartanType(['A', 4]).coxeter_matrix()  # needs sage.graphs
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(4)]).coxeter_matrix()  # needs sage.graphs
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

**coxeter_type()**

Return the Coxeter type for `self`.

**EXAMPLES:**

```python
sage: CartanType(['A', 4]).coxeter_type()
Coxeter type of ['A', 4]
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(4)]).coxeter_type()
Coxeter type of ['A', 4]
```

**dual()**

Return the dual Cartan type, possibly just as a formal dual.

**EXAMPLES:**

```python
sage: CartanType(['A',3]).dual()
['A', 3]
sage: CartanType(['B', 3]).dual()
['C', 3]
sage: CartanType(['C',2]).dual()
['B', 2]
sage: CartanType(['D',4]).dual()
['D', 4]
sage: CartanType(['E',8]).dual()
['E', 8]
sage: CartanType(['F',4]).dual()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

```python
>>> from sage.all import *
>>> CartanType(['A',Integer(3)]).dual()
['A', 3]
>>> CartanType(['B', Integer(3)]).dual()
['C', 3]
>>> CartanType(['C',Integer(2)]).dual()
['B', 2]
```
index_set()

Return the index set for self.

This is the list of the nodes of the associated Coxeter or Dynkin diagram.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', 4]).index_set()  
(1, 2, 3, 4)
sage: CartanType(['A', 7, 2]).index_set()  
(0, 1, 2, 3, 4)
sage: CartanType(['A', 6, 2]).index_set()  
(0, 1, 2, 3)
sage: CartanType(['D', 6, 2]).index_set()  
(0, 1, 2, 3, 4, 5)
sage: CartanType(['E', 6, 1]).index_set()  
(0, 1, 2, 3, 4, 5, 6)
sage: CartanType(['E', 6, 2]).index_set()  
(0, 1, 2, 3)
sage: CartanType(['A', 2, 2]).index_set()  
(0, 1)
sage: CartanType(['G', 2, 1]).index_set()  
(0, 1, 2)
sage: CartanType(['F', 4, 1]).index_set()  
(0, 1, 2, 3, 4)
```

```python
>>> from sage.all import *
```

```python
sage: CartanType(['A', Integer(3), Integer(1)]).index_set()
(0, 1, 2, 3)
sage: CartanType(['D', Integer(4)]).index_set()  
(1, 2, 3, 4)
sage: CartanType(['A', Integer(7), Integer(2)]).index_set()  
(0, 1, 2, 3, 4)
sage: CartanType(['A', Integer(6), Integer(2)]).index_set()  
(0, 1, 2, 3)
sage: CartanType(['D', Integer(6), Integer(2)]).index_set()  
(0, 1, 2, 3, 4, 5)
sage: CartanType(['E', Integer(6), Integer(1)]).index_set()  
(0, 1, 2, 3, 4, 5, 6)
sage: CartanType(['E', Integer(6), Integer(2)]).index_set()  
(0, 1, 2, 3)
sage: CartanType(['A', Integer(2), Integer(2)]).index_set()  
(0, 1)
sage: CartanType(['G', Integer(2), Integer(1)]).index_set()  
(0, 1, 2)
```
is_affine()

Return whether self is affine.

EXAMPLES:

```
sage: CartanType(['A', 3]).is_affine()
False
sage: CartanType(['A', 3, 1]).is_affine()
True
```

is_atomic()

This method is usually equivalent to is_reducible(), except for the Cartan type $D_2$.

$D_2$ is not a standard Cartan type. It is equivalent to type $A_1 \times A_1$ which is reducible; however the isomorphism from its ambient space (for the orthogonal group of degree 4) to that of $A_1 \times A_1$ is non trivial, and it is useful to have it.

From a programming point of view its implementation is more similar to the irreducible types, and so the method is_atomic() is supplied.

EXAMPLES:

```
sage: CartanType("D2").is_atomic()
True
sage: CartanType("D2").is_irreducible()
False
```

is_compound()

A short hand for not is_atomic().

is_crystallographic()

Return whether this Cartan type is crystallographic.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

```
sage: [[t, t.is_crystallographic()] for t in CartanType.
samples(finite=True)]
[['['A', 1], True], ['['A', 5], True],
['['B', 1], True], ['['B', 5], True],
```
is_finite()  
Return whether this Cartan type is finite.

EXAMPLES:

```python
sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.is_finite()
Traceback (most recent call last):
...  
NotImplementedError: <abstract method is_finite at ...>
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.cartan_type import CartanType_abstract
>>>
C = CartanType_abstract()
>>> C.is_finite()
Traceback (most recent call last):
...  
NotImplementedError: <abstract method is_finite at ...>
```

```python
sage: CartanType(['A',4]).is_finite()
True
sage: CartanType(['A',4, 1]).is_finite()
False
```

isImplemented()  
Check whether the Cartan datum for self is actually implemented.

EXAMPLES:

```python
>>> from sage.all import *
>>> CartanType(['A',4]).is_finite()
True
>>> CartanType(['A',Integer(4)]).is_finite()
False
```

```python
sage: CartanType(['A',4,1]).is_finite()  
# needs sage.graphs
True
```

(continues on next page)
Combinatorics, Release 10.4

sage: CartanType(['H',3]).is_implemented()
True

>>> from sage.all import *
>>> CartanType(['A',Integer(4),Integer(1)]).is_implemented()
# needs sage.graphs
True
>>> CartanType(['H',Integer(3)]).is_implemented()
True

is_irreducible()

Report whether this Cartan type is irreducible (i.e. simple). This should be overridden in any subclass.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
>>> C.is_irreducible()
False

is_reducible()

Report whether the root system is reducible (i.e. not simple), that is whether it can be factored as a product of root systems.

EXAMPLES:

sage: CartanType("A2xB3").is_reducible()
True

is_simply_laced()

Return whether this Cartan type is simply laced.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

sage: [ [t, t.is_simply_laced() ] for t in CartanType.samples() ]
[['A', 1], ['A', 5], ['B', 1], ['B', 5], ['C', 1], ['C', 5],
]
Combinatorics, Release 10.4

>>> from sage.all import *

>>> [ [t, t.is_simply_laced() for t in CartanType.samples() ]
   for [D, 2], True], [D, 3], True], [[D, 5], True],
   [[E, 6], True], [[E, 7], True], [[E, 8], True],
   [[F', 2], False], [[G', 2], False], [[I', 5], False],
   [[H', 3], False], [[H', 4], False],
   [[A', 1, 1], False], [[A', 5, 1], True],
   [[B', 1, 1], False], [[B', 5, 1], False],
   [[C', 1, 1], False], [[C', 5, 1], False],
   [[D', 3, 1], True], [[D', 5, 1], True],
   [[E', 6, 1], True], [[E', 7, 1], True], [[E', 8, 1], True],
   [[E', 4, 1], False], [[G', 2, 1], False],
   [[BC', 1, 2], False], [[BC', 5, 2], False],
   [[B', 5, 1]^*, False], [[C', 4, 1]^*, False],
   [[F', 4, 1]^*, False], [[G', 2, 1]^*, False],
   [[BC', 1, 2]^*, False], [[BC', 5, 2]^*, False]]

marked_nodes

Return a Cartan type with the nodes marked_nodes marked.

INPUT:

• marked_nodes – a list of nodes to mark

EXAMPLES:

sage: CartanType(['F', 4]).marked_nodes([1, 3]).dynkin_diagram()          # needs sage.graphs
X---O=>=X---O
1 2 3 4
F4 with nodes (1, 3) marked

sage: CartanType(['F', Integer(4)]).marked_nodes([Integer(1), Integer(3)]).
   dynkin_diagram()          # needs sage.graphs
X---O=>=X---O
1 2 3 4
F4 with nodes (1, 3) marked
options = Current options for CartanType - dual_latex: \vee - dual_str: * - latex_marked: True - latex_relabel: True - mark_special_node: none - marked_node_str: X - notation: Stembridge - special_node_str: @

rank()

Return the rank of self.

This is the number of nodes of the associated Coxeter or Dynkin diagram.

EXAMPLES:

```
sage: CartanType(['A', 4]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['I', 8]).rank()
2
```

relabel(relabelling)

Return a relabelled copy of this Cartan type.

INPUT:

- relabelling - a function (or a list or dictionary)

OUTPUT:

an isomorphic Cartan type obtained by relabelling the nodes of the Dynkin diagram. Namely, the node with label \( i \) is relabelled \( f(i) \) (or, by \( f[i] \) if \( f \) is a list or dictionary).

EXAMPLES:

```
sage: CartanType(['F',4]).relabel({ 1:4, 2:3, 3:2, 4:1 }).dynkin_diagram()
# needs sage.graphs
O---O=>=O---O
\( 4 \ 3 \ 2 \ 1 \)
F4 relabelled by \{1: 4, 2: 3, 3: 2, 4: 1\}
```

```
>>> from sage.all import *

# needs sage.graphs
O---O=>=O---O
\( 4 \ 3 \ 2 \ 1 \)
F4 relabelled by \{1: 4, 2: 3, 3: 2, 4: 1\}
```

root_system()

Return the root system associated to self.

EXAMPLES:
sage: CartanType(['A',4]).root_system()
Root system of type ['A', 4]

>>> from sage.all import *
>>> CartanType(['A',Integer(4)]).root_system()
Root system of type ['A', 4]

subtype(index_set)

Return a subtype of self given by index_set.

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of self by index_set.

EXAMPLES:

sage: ct = CartanType(['A',6,2])
sage: ct.dynkin_diagram()
# needs sage.graphs
O=<=O---O=<=O
0 1 2 3
BC3~
sage: ctsubtype([1,2,3])
# needs sage.graphs
['C', 3]

>>> from sage.all import *
>>> ct = CartanType(['A',Integer(6),Integer(2)])
>>> ct.dynkin_diagram()
# needs sage.graphs
O=<=O---O=<=O
0 1 2 3
BC3~
>>> ctsubtype([Integer(1),Integer(2),Integer(3)])
# needs sage.graphs
['C', 3]

type()

Return the type of self, or None if unknown.

This method should be overridden in any subclass.

EXAMPLES:

sage: from sage.combinat.root_system.cartan_type import CartanType_abstract
sage: C = CartanType_abstract()
sage: C.type() is None
True

>>> from sage.all import *
>>> from sage.combinat.root_system.cartan_type import CartanType_abstract
>>> C = CartanType_abstract()
>>> C.type() is None
True

class sage.combinat.root_system.cartan_type.CartanType_affine

Bases: CartanType_simple, CartanType_crystallographic

An abstract class for simple affine Cartan types
AmbientSpace

alias of AmbientSpace

a()

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by $[0, 1, \ldots]$, in the same order as the index set.

EXAMPLES:

```
sage: # needs sage.graphs
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 2, 3: 4, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> RootSystem(['C',Integer(2),Integer(1)]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
>>> RootSystem(['D',Integer(4),Integer(1)]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
>>> RootSystem(['F',Integer(4),Integer(1)]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 2, 3: 4, 4: 2}
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

้า is a shortcut for col_annihilator:

```
sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator()   # needs sage.graphs
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().col_annihilator()   # needs sage.graphs
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}
```

acheck ($m$=None)

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument $m$ is for internal use only.

EXAMPLES:
```python
sage: # needs sage.graphs
sage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 1}
sage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

```python
>>> from sage.all import *

sage: RootSystem(['C',Integer(2),Integer(1)]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}

sage: RootSystem(['D',Integer(4),Integer(1)]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}

sage: RootSystem(['F',Integer(4),Integer(1)]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 1}

sage: RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

```python
acheck is a shortcut for row_annihilator:

sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()  # needs sage.graphs
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

```python
>>> from sage.all import *

sage: RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().row_annihilator()  # needs sage.graphs
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

FIXME:

- The current implementation assumes that the Cartan matrix is indexed by $[0, 1, ...]$, in the same order as the index set.
- This really should be a method of `CartanMatrix`

**basic_untwisted()**

Return the basic untwisted Cartan type associated with this affine Cartan type.

Given an affine type $X_n^{(r)}$, the basic untwisted type is $X_n$. In other words, it is the classical Cartan type that is twisted to obtain self.

**EXAMPLES:**

```python
sage: CartanType(['A', 1, 1]).basic_untwisted()
['A', 1]
sage: CartanType(['A', 3, 1]).basic_untwisted()
['A', 3]
sage: CartanType(['B', 3, 1]).basic_untwisted()
['B', 3]
sage: CartanType(['E', 6, 1]).basic_untwisted()
['E', 6]
sage: CartanType(['G', 2, 1]).basic_untwisted()
['G', 2]
```

(continues on next page)
Returns the family \((c_i)_i\) of integer coefficients defined by 

\[
c_i = \max(1, a_i/a^e e_i)
\]

(see e.g. [FSS07] p. 3)

FIXME: the current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

EXAMPLES:

\[
\begin{align*}
sage: & \text{# needs} \ \text{sage.graphs} \\
sage: & \text{RootSystem}(['C', 2, 1]).cartan_type().c() \\
& \text{Finite family} \{0: 1, 1: 2, 2: 1\} \\
sage: & \text{RootSystem}(['D', 4, 1]).cartan_type().c() \\
& \text{Finite family} \{0: 1, 1: 3, 2: 1, 3: 1, 4: 1\} \\
sage: & \text{RootSystem}(['F', 4, 1]).cartan_type().c() \\
& \text{Finite family} \{0: 1, 1: 3, 2: 1, 3: 2, 4: 2\}
\end{align*}
\]
>>> from sage.all import *
>>> # needs sage.graphs
>>> RootSystem(['C',Integer(2),Integer(1)]).cartan_type().c()
Finite family {0: 1, 1: 2, 2: 1}
>>> RootSystem(['D',Integer(4),Integer(1)]).cartan_type().c()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
>>> RootSystem(['F',Integer(4),Integer(1)]).cartan_type().c()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().c()
Finite family {0: 2, 1: 1, 2: 1, 3: 1, 4: 1}

REFERENCES:
classical()

Return the classical Cartan type associated with this affine Cartan type.

EXAMPLES:

```python
sage: CartanType(['A', 1, 1]).classical()
['A', 1]
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
sage: CartanType(['A', 2, 2]).classical()
['C', 1]
sage: CartanType(['BC', 1, 2]).classical()
['C', 1]
sage: CartanType(['A', 10, 2]).classical()
['C', 5]
sage: CartanType(['BC', 5, 2]).classical()
['C', 5]
sage: CartanType(['D', 5, 2]).classical()
['B', 4]
sage: CartanType(['E', 6, 1]).classical()
['E', 6]
sage: CartanType(['G', 2, 1]).classical()
['G', 2]
sage: CartanType(['E', 6, 2]).classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
sage: CartanType(['D', 4, 3]).classical()
['G', 2]
```
CartanType(["A", Integer(2), Integer(2)]).classical()
['C', 1]
CartanType(["BC", Integer(1), Integer(2)]).classical()
['C', 1]
CartanType(["A", Integer(4), Integer(2)]).classical()
['C', 2]
CartanType(["BC", Integer(2), Integer(2)]).classical()
['C', 2]
CartanType(["A", Integer(10), Integer(2)]).classical()
['C', 5]
CartanType(["BC", Integer(5), Integer(2)]).classical()
['C', 5]
CartanType(["D", Integer(5), Integer(2)]).classical()
['B', 4]
CartanType(["E", Integer(6), Integer(1)]).classical()
['E', 6]
CartanType(["G", Integer(2), Integer(1)]).classical()
['C', 2]
CartanType(["E", Integer(6), Integer(2)]).classical()
['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
CartanType(["D", Integer(4), Integer(3)]).classical()
['G', 2]

We check that classical(), sage.combinat.root_system.cartan_type.
CartanType_crystallographic.dynkin_diagram(), and special_node() are con-
sistent:

```python
sage: for ct in CartanType.samples(affine=True):
    g1 = ct.classical().dynkin_diagram()
    g2 = ct.dynkin_diagram()
    g2.delete_vertex(ct.special_node())
    assert g1.vertices(sort=True) == g2.vertices(sort=True)
    assert g1.edges(sort=True) == g2.edges(sort=True)

>>> from sage.all import *
>>> for ct in CartanType.samples(affine=True):
    g1 = ct.classical().dynkin_diagram()
    g2 = ct.dynkin_diagram()
    g2.delete_vertex(ct.special_node())
    assert g1.vertices(sort=True) == g2.vertices(sort=True)
    assert g1.edges(sort=True) == g2.edges(sort=True)
```

col_annihilator()

Return the unique minimal non trivial annihilating linear combination of \(\alpha_0^\vee, \alpha_1^\vee, \ldots, \alpha_r^\vee\) with nonnegative coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the columns of the Cartan matrix with non-negative coefficients).

Throw an error if the existence or uniqueness does not hold

FIXME: the current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

EXAMPLES:
sage: RootSystem(['C',2,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
sage: RootSystem(['D',4,1]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
sage: RootSystem(['F',4,1]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
sage: RootSystem(['BC',4,2]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}

>>> from sage.all import *
>>> RootSystem(['C',Integer(2),Integer(1)]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 1}
>>> RootSystem(['D',Integer(4),Integer(1)]).cartan_type().a()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
>>> RootSystem(['F',Integer(4),Integer(1)]).cartan_type().a()
Finite family {0: 1, 1: 2, 2: 3, 3: 4, 4: 2}
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().a()
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}

a is a shortcut for col_annihilator:

sage: RootSystem(['BC',4,2]).cartan_type().col_annihilator() # needs sage.graphs
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}

>>> from sage.all import *
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().col_annihilator()  # needs sage.graphs
Finite family {0: 2, 1: 2, 2: 2, 3: 2, 4: 1}

is_affine()  
EXAMPLES:

sage: CartanType(['A', 3, 1]).is_affine()
True

>>> from sage.all import *
>>> CartanType(['A', Integer(3), Integer(1)]).is_affine()
True

is_finite()  
EXAMPLES:

sage: CartanType(['A', 3, 1]).is_finite()
False

>>> from sage.all import *
>>> CartanType(['A', Integer(3), Integer(1)]).is_finite()
False

is_untwisted_affine()  
Return whether self is untwisted affine
A Cartan type is untwisted affine if it is the canonical affine extension of some finite type. Every affine type
is either untwisted affine, dual thereof, or of type $BC$.

**EXAMPLES:**

```python
sage: CartanType(['A', 3, 1]).is_untwisted_affine()
True
sage: CartanType(['A', 3, 1]).dual().is_untwisted_affine()  # this one is...
    -> self dual!
True
sage: CartanType(['B', 3, 1]).is_untwisted_affine()
False
sage: CartanType(['BC', 3, 2]).is_untwisted_affine()
False
```

```python
>>> from sage.all import *

>>> CartanType(['A', Integer(3), Integer(1)]).is_untwisted_affine()
True
>>> CartanType(['A', Integer(3), Integer(1)]).dual().is_untwisted_affine()  #...
    -> this one is self dual!
True
>>> CartanType(['B', Integer(3), Integer(1)]).is_untwisted_affine()
False
>>> CartanType(['BC', Integer(3), Integer(2)]).is_untwisted_affine()
False
```

**other_affinization()**

Return the other affinization of the same classical type.

**EXAMPLES:**

```python
sage: CartanType(['A', 3, 1]).other_affinization()
['A', 3, 1]
sage: CartanType(['B', 3, 1]).other_affinization()
['C', 3, 1]`
sage: CartanType(['C', 3, 1]).dual().other_affinization()
['B', 3, 1]
```

```python
>>> from sage.all import *

>>> CartanType(['A', Integer(3), Integer(1)]).other_affinization()
['A', 3, 1]
>>> CartanType(['B', Integer(3), Integer(1)]).other_affinization()
['C', 3, 1]`
>>> CartanType(['C', Integer(3), Integer(1)]).dual().other_affinization()
['B', 3, 1]
```

Is this what we want?:

```python
sage: CartanType(['BC', 3, 2]).dual().other_affinization()
['B', 3, 1]
```

```python
>>> from sage.all import *

>>> CartanType(['BC', Integer(3), Integer(2)]).dual().other_affinization()
['B', 3, 1]
```

**row_annihilator**(m=None)

Return the unique minimal non trivial annihilating linear combination of $\alpha_0, \alpha_1, \ldots, \alpha_n$ with nonnegative
coefficients (or alternatively, the unique minimal non trivial annihilating linear combination of the rows of the Cartan matrix with non-negative coefficients).

Throw an error if the existence of uniqueness does not hold

The optional argument \( m \) is for internal use only.

**EXAMPLES:**

```python
tsage: # needs sage.graphs
tsage: RootSystem(['C',2,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
tsage: RootSystem(['D',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
tsage: RootSystem(['F',4,1]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
tsage: RootSystem(['BC',4,2]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> RootSystem(['C',Integer(2),Integer(1)]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 1}
>>> RootSystem(['D',Integer(4),Integer(1)]).cartan_type().acheck()
Finite family {0: 1, 1: 1, 2: 2, 3: 1, 4: 1}
>>> RootSystem(['F',Integer(4),Integer(1)]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 3, 3: 2, 4: 1}
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().acheck()
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

```python
sage: RootSystem(['BC',4,2]).cartan_type().row_annihilator()  # needs sage.graphs
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> RootSystem(['BC',Integer(4),Integer(2)]).cartan_type().row_annihilator()  # needs sage.graphs
Finite family {0: 1, 1: 2, 2: 2, 3: 2, 4: 2}
```

**FIXME:**

- The current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.
- This really should be a method of `CartanMatrix`.

### special_node()

Return a special node of the Dynkin diagram.

A *special* node is a node of the Dynkin diagram such that pruning it yields a Dynkin diagram for the associated classical type (see `classical()`).

This method returns the label of some special node. This is usually 0 in the standard conventions.

**EXAMPLES:**

```python
sage: CartanType(['A', 3, 1]).special_node()
0
```
>>> from sage.all import *
>>> CartanType(['A', Integer(3), Integer(1)]).special_node()
0

The choice is guaranteed to be consistent with the indexing of the nodes of the classical Dynkin diagram:

```
sage: CartanType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CartanType(['A', 3, 1]).classical().index_set()
(1, 2, 3)
```

**special_nodes()**

Return the set of special nodes of the affine Dynkin diagram.

**EXAMPLES:**

```
sage: # needs sage.graphs sage.groups
sage: CartanType(['A',3,1]).special_nodes()
(0, 1, 2, 3)
sage: CartanType(['C',2,1]).special_nodes()
(0, 2)
sage: CartanType(['D',4,1]).special_nodes()
(0, 1, 3, 4)
sage: CartanType(['E',6,1]).special_nodes()
(0, 1, 6)
sage: CartanType(['D',3,2]).special_nodes()
(0, 2)
sage: CartanType(['A',4,2]).special_nodes()
(0,)
```

**translation_factors()**

Return the translation factors for self.

Those are the smallest factors $t_i$ such that the translation by $t_i \alpha_i$ maps the fundamental polygon to another polygon in the alcove picture.

**OUTPUT:**
a dictionary from `self.index_set()` to \( \mathbb{Z} \) (or \( \mathbb{Q} \) for affine type \( BC \))

Those coefficients are all 1 for dual untwisted, and in particular for simply laced. They coincide with the usual \( c_i \) coefficients (see `c()` for untwisted and dual thereof. See the discussion below for affine type \( BC \).

**Note:** One usually realizes the alcove picture in the coweight lattice, with translations by coroots; in that case, one will use the translation factors for the dual Cartan type.

FIXME: the current implementation assumes that the Cartan matrix is indexed by \([0, 1, \ldots]\), in the same order as the index set.

EXAMPLES:

```
sage: CartanType(['C',2,1]).translation_factors()
Finite family {0: 1, 1: 2, 2: 1}
sage: CartanType(['C',2,1]).dual().translation_factors()
Finite family {0: 1, 1: 1, 2: 1}
sage: CartanType(['D',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['F',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
sage: CartanType(['BC',4,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1/2}
```

We proceed with systematic tests taken from MuPAD-Combinat’s testsuite:

```
sage: CartanType(['C',2,1]).translation_factors()
Finite family {0: 1, 1: 2, 2: 1}
sage: CartanType(['C',2,1]).dual().translation_factors()
Finite family {0: 1, 1: 1, 2: 1}
sage: CartanType(['D',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1}
sage: CartanType(['F',4,1]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 2, 4: 2}
sage: CartanType(['BC',4,2]).translation_factors()
Finite family {0: 1, 1: 1, 2: 1, 3: 1, 4: 1/2}
```

5.1. Comprehensive Module List
sage: list(CartanType(['F', 4, 1]).translation_factors())
[1, 1, 1, 2, 2]
sage: list(CartanType(['G', 2, 1]).translation_factors())
[1, 3, 1]
sage: list(CartanType(['A', 2, 2]).translation_factors())
[1, 1/2]

[1, 1, 1, 1, 1, 1, 1, 1]
>>> list(CartanType(['F', Integer(4), Integer(1)]).translation_factors())
[1, 1, 1, 2, 2]
We conclude with a discussion of the appropriate value for affine type $BC$. Let us consider the alcove picture realized in the weight lattice. It is obtained by taking the level-1 affine hyperplane in the weight lattice, and projecting it along $\Lambda_0$:

```
sage: R = RootSystem(["BC",2,2])
sage: alpha = R.weight_space().simple_roots()  # needs sage.graphs
sage: alphacheck = R.coroot_space().simple_roots()
```

Here are the levels of the fundamental weights:

```
sage: Lambda[0].level(), Lambda[1].level(), Lambda[2].level()
(1, 2, 2)
```

So the “center” of the fundamental polygon at level 1 is:

```
sage: O = Lambda[0]
sage: O.level()  # needs sage.graphs
1
```

We take the projection $\omega_1$ at level 0 of $\Lambda_1$ as unit vector on the $x$-axis, and the projection $\omega_2$ at level 0 of $\Lambda_2$ as unit vector of the $y$-axis:

```
sage: omega1 = Lambda[1] - 2*Lambda[0]
sage: omega1.level(), omega2.level()
(0, 0)
```
The projections of the simple roots can be read off:

\[
\begin{align*}
\text{sage: } & \alpha[0] \quad \# \text{ needs sage.graphs} \\
& 2\cdot \Lambda[0] - \Lambda[1] \\
\text{sage: } & \alpha[1] \quad \# \text{ needs sage.graphs} \\
& -2\cdot \Lambda[0] + 2\cdot \Lambda[1] - \Lambda[2] \\
\text{sage: } & \alpha[2] \quad \# \text{ needs sage.graphs} \\
& -2\cdot \Lambda[1] + 2\cdot \Lambda[2]
\end{align*}
\]

Namely \( \alpha_0 = -\omega_1, \alpha_1 = 2\omega_1 - \omega_2 \) and \( \alpha_2 = -2\omega_1 + 2\omega_2 \).

The reflection hyperplane defined by \( \alpha_0^\vee \) goes through the points \( O + 1/2\omega_1 \) and \( O + 1/2\omega_2 \):

\[
\begin{align*}
\text{sage: } & \quad (O+(1/2)\cdot \omega_1).scalar(\alpha_0) \quad 0 \\
\text{sage: } & \quad (O+(1/2)\cdot \omega_2).scalar(\alpha_0) \quad 0
\end{align*}
\]

Hence, the fundamental alcove is the triangle \( (O, O + 1/2\omega_1, O + 1/2\omega_2) \). By successive reflections, one can tile the full plane. This induces a tiling of the full plane by translates of the fundamental polygon.

**Todo:** Add the picture here, once root system plots in the weight lattice will be implemented. In the mean time, the reader may look up the dual picture on Figure 2 of [HST09] which was produced by MuPAD-Combinat.

From this picture, one can read that translations by \( \omega_0, \alpha_1, \) and \( 1/2\omega_2 \) map the fundamental polygon to translates of it in the alcove picture, and are smallest with this property. Hence, the translation factors for affine type \( BC \) are \( t_0 = 1, t_1 = 1, t_2 = 1/2 \):
```python
sage: CartanType(['BC',2,2]).translation_factors()  # needs sage.graphs
Finite family {0: 1, 1: 1, 2: 1/2}

>>> from sage.all import *

>>> CartanType(['BC',Integer(2),Integer(2)]).translation_factors()  
# needs sage.graphs
 Finite family {0: 1, 1: 1, 2: 1/2}
```

REFERENCES:

```python
class sage.combinat.root_system.cartan_type.CartanType_crystallographic
    Bases: CartanType_abstract

    An abstract class for crystallographic Cartan types.

    ascii_art (label=lambda x: x', node=None)
        Return an ascii art representation of the Dynkin diagram.

        INPUT:
        • label -- (default: the identity) a relabeling function for the nodes
        • node -- (optional) a function which returns the character for a node

        EXAMPLES:

sage: cartan_type = CartanType(['B',5,1])
sage: print(cartan_type.ascii_art())

O 0
| |
O---O---O---O=>=O
1 2 3 4 5

>>> from sage.all import *

>>> cartan_type = CartanType(['B',Integer(5),Integer(1)])

>>> print(cartan_type.ascii_art())

O 0
| |
O---O---O---O=>=O
1 2 3 4 5
```

The label option is useful to visualize various statistics on the nodes of the Dynkin diagram:

```python
sage: a = cartan_type.col_annihilator(); a  # needs sage.graphs
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 2, 5: 2}
sage: print(CartanType(['B',5,1]).ascii_art(label=a.__getitem__))  
# needs sage.graphs
 O 1
 | |
O---O---O---O=>=O
1 2 2 2 2
```

5.1. Comprehensive Module List
To use the function `cartan_matrix()`, you can import `cartan_type` and create a Cartan type object. Then, you can call `cartan_matrix()` on that object to get the associated Cartan matrix.

Here's an example:

```python
>>> from sage.all import *
>>> a = cartan_type.col_annihilator(); a
# needs sage.graphs
Finite family {0: 1, 1: 1, 2: 2, 3: 2, 4: 2, 5: 2}
```

To print the Cartan type:

```python
>>> print(CartanType(['B',Integer(5),Integer(1)]).ascii_art(label=a.__getitem__()))
0 1
|`
O---O---O---O=>=O
1 2 2 2 2
```

The `cartan_matrix()` function returns the Cartan matrix associated with the Cartan type.

```python
sage: CartanType(['A',4]).cartan_matrix() # needs sage.graphs
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

The `coxeter_diagram()` function returns the Coxeter diagram for the Cartan type.

```python
>>> from sage.all import *
>>> CartanType(['A',Integer(4)]).cartan_matrix() # needs sage.graphs
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

To see the Coxeter diagram:

```python
cartan_matrix() Return the Cartan matrix associated with self.

EXAMPLES:

sage: CartanType(['A',3]).cartan_matrix() # needs sage.graphs
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

```python
coxeter_diagram() Return the Coxeter diagram for self.

This implementation constructs it from the Dynkin diagram.

See also:

CartanType_abstract.coxeter_diagram()

EXAMPLES:

sage: # needs sage.graphs
cartan_matrix()
```

```python
cartan_matrix()
```

```python
coxeter_diagram()
```

```python
coxeter_diagram()
```

```python
coxeter_diagram()
```

```python
coxeter_diagram()
```
```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> CartanType(['A',Integer(3)]).coxeter_diagram()
Graph on 3 vertices
>>> CartanType(['A',Integer(3)]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 3)]
>>> CartanType(['B',Integer(3)]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4)]
>>> CartanType(['G',Integer(2)]).coxeter_diagram().edges(sort=True)
[(1, 2, 6)]
>>> CartanType(['F',Integer(4)]).coxeter_diagram().edges(sort=True)
[(1, 2, 3), (2, 3, 4), (3, 4, 3)]
>>> CartanType(['A',Integer(2),Integer(2)]).coxeter_diagram().edges(sort=True)
[(0, 1, +Infinity)]
```

dynkin_diagram()

Return the Dynkin diagram associated with self.

EXAMPLES:

```python
sage: CartanType(['A',4]).dynkin_diagram()  # needs sage.graphs
O---O---O---O
1 2 3 4
A4
```

Note: Derived subclasses should typically implement this as a cached method.

index_set_bipartition()

Return a bipartition \{L, R\} of the vertices of the Dynkin diagram.

For i and j both in L (or both in R), the simple reflections \(s_i\) and \(s_j\) commute.

Of course, the Dynkin diagram should be bipartite. This is always the case for all finite types.

EXAMPLES:

```python
sage: CartanType(['A',5]).index_set_bipartition()  # needs sage.graphs
({1, 3, 5}, {2, 4})
sage: CartanType(['A',2,1]).index_set_bipartition()  # needs sage.graphs
Traceback (most recent call last):
  ... ValueError: the Dynkin diagram must be bipartite
```
>>> from sage.all import *
>>> CartanType(['A', Integer(5)]).index_set_bipartition()
... # needs sage.graphs
{(1, 3, 5), (2, 4)}

>>> CartanType(['A', Integer(2), Integer(1)]).index_set_bipartition()
... # needs sage.graphs
Traceback (most recent call last):
  ... ValueError: the Dynkin diagram must be bipartite

is_crystallographic()

Implements CartanType_abstract.is_crystallographic() by returning True.

EXAMPLES:

sage: CartanType(['A', 3, 1]).is_crystallographic()
True

sage: CartanType(['A', Integer(3), Integer(1)]).is_crystallographic()
True

symmetrizer()

Return the symmetrizer of the Cartan matrix of self.

A Cartan matrix $M$ is symmetrizable if there exists a non trivial diagonal matrix $D$ such that $DM$ is a symmetric matrix, that is $DM = M^t D$. In that case, $D$ is unique, up to a scalar factor for each connected component of the Dynkin diagram.

This method computes the unique minimal such $D$ with positive integral coefficients. If $D$ exists, it is returned as a family. Otherwise None is returned.

The coefficients are coerced to base_ring.

EXAMPLES:

sage: CartanType(['B', 5]).symmetrizer()
# needs sage.graphs
Finite family {1: 2, 2: 2, 3: 2, 4: 2, 5: 1}

sage: CartanType(['BC', 5, 2]).symmetrizer()
# needs sage.graphs
Finite family {1: 2, 2: 2, 3: 2, 4: 2, 5: 1}

Here is a neat trick to visualize it better:

sage: T = CartanType(['B', 5])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
# needs sage.graphs
O---O---O---O=>=O
  2 2 2 2 1

sage: T = CartanType(['BC', 5, 2])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
# needs sage.graphs
(continues on next page)
O<=O---O---O---O=<=O
1 2 2 2 2 4

>>> from sage.all import *
>>> T = CartanType(\["B",Integer(5)\])
>>> print(T.ascii_art(T.symmetrizer().__getitem__))
#---
˓→ needs sage.graphs
O---O---O---O=>=O
2 2 2 2 1

Here is the symmetrizer of some reducible Cartan types:

sage: T = CartanType(\["D", 2\])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
#---
˓→ needs sage.graphs
O O
1 1

sage: T = CartanType(\["B",5\],\["BC",5, 2\])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
#---
˓→ needs sage.graphs
O=<=O---O---O---O=<=O
1 2 2 2 2 4

>>> from sage.all import *
>>> T = CartanType(\["D", Integer(2)\])
>>> print(T.ascii_art(T.symmetrizer().__getitem__))
#---
˓→ needs sage.graphs
O O
1 1

>>> T = CartanType(\["B",Integer(5)\],\["BC",Integer(5), Integer(2)\])
>>> print(T.ascii_art(T.symmetrizer().__getitem__))
#---
˓→ needs sage.graphs
O=<=O---O---O---O=<=O
1 2 2 2 2 4

Property: up to an overall scalar factor, this gives the norm of the simple roots in the ambient space:

sage: T = CartanType(\["C",5\])
sage: print(T.ascii_art(T.symmetrizer().__getitem__))
#---
˓→ needs sage.graphs
O---O---O---O<==O
2 2 2 2 1

sage: alpha = RootSystem(T).ambient_space().simple_roots()

(continues on next page)
```python
from sage.all import *
T = CartanType(['C', Integer(5)])
print(T.ascii_art(T.symmetrizer().__getitem__))
```

```
O---O---O---O=<=O
2 2 2 2 4
```

```python
alpha = RootSystem(T).ambient_space().simple_roots()
print(T.ascii_art(lambda i: alpha[i].scalar(alpha[i])))
```

```python
class sage.combinat.root_system.cartan_type.CartanType_decorator:
    def index_set(self):
        EXAMPLES:
```
```python
ct = CartanType(['F', 4, 1]).dual()
sage: ct.index_set()
(0, 1, 2, 3, 4)
```

```python
ct = CartanType(['F', Integer(4), Integer(1)]).dual()
sage: ct.index_set()
(0, 1, 2, 3, 4)
```

```python
def is_affine(self):
    EXAMPLES:
```
```python
ct = CartanType(['G', 2]).relabel({1:2,2:1})
sage: ct.is_affine()
False
```

```python
ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
Integer(2):Integer(1)})
sage: ct.is_affine()
False
```

```python
def is_crystallographic(self):
    EXAMPLES:
```
```python
ct = CartanType(['G', 2]).dual()
sage: ct.is_crystallographic()
False
```
>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
   →Integer(2):Integer(1)})
>>> ct.is_crystallographic()
True

is_finite()
EXAMPLES:

sage: ct = CartanType(['G', 2]).relabel({1:2, 2:1})
sage: ct.is_finite()
True

>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
   →Integer(2):Integer(1)})
>>> ct.is_finite()
True

is_irreducible()
EXAMPLES:

sage: ct = CartanType(['G', 2]).relabel({1:2, 2:1})
sage: ct.is_irreducible()
True

>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
   →Integer(2):Integer(1)})
>>> ct.is_irreducible()
True

rank()
EXAMPLES:

sage: ct = CartanType(['G', 2]).relabel({1:2, 2:1})
sage: ct.rank()
2

>>> from sage.all import *
>>> ct = CartanType(['G', Integer(2)]).relabel({Integer(1):Integer(2),
   →Integer(2):Integer(1)})
>>> ct.rank()
2

class sage.combinat.root_system.cartan_type.CartonType_finite
Bases: CartanType_abstract
An abstract class for simple affine Cartan types.

is_affine()
EXAMPLES:

sage: CartanType(['A', 3]).is_affine()
False
```python
>>> from sage.all import *
>>> CartanType(['A', Integer(3)]).is_affine()
False

is_finite()

EXAMPLES:

```

```python
sage: CartanType(['A', 3]).is_finite()
True
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(3)]).is_finite()
True
```

class sage.combinat.root_system.cartan_type.CartanType_simple

Bases: CartanType_abstract

An abstract class for simple Cartan types.

is_irreducible()

Return whether self is irreducible, which is True.

EXAMPLES:

```

```python
sage: CartanType(['A', 3]).is_irreducible()
True
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(3)]).is_irreducible()
True
```

class sage.combinat.root_system.cartan_type.CartanType_simple_finite

Bases: object

class sage.combinat.root_system.cartan_type.CartanType_simply_laced

Bases: CartanType_crystallographic

An abstract class for simply laced Cartan types.

dual()

Simply laced Cartan types are self-dual, so return self.

EXAMPLES:

```

```python
sage: CartanType(['A', 3]).dual() ['A', 3]
```

```python
sage: CartanType(['A', 3, 1]).dual() ['A', 3, 1]
```

```python
sage: CartanType(['D', 3]).dual() ['D', 3]
```

```python
sage: CartanType(['D', 4, 1]).dual() ['D', 4, 1]
```

```python
sage: CartanType(['E', 6]).dual() ['E', 6]
```

```python
sage: CartanType(['E', 6, 1]).dual() ['E', 6, 1]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> CartanType(['A', 3]).dual()
['A', 3]
>>> CartanType(['A', Integer(3), Integer(1)]).dual()
['A', 3, 1]
>>> CartanType(['D', Integer(3)]).dual()
['D', 3]
>>> CartanType(['D', Integer(4), Integer(1)]).dual()
['D', 4, 1]
>>> CartanType(['E', Integer(6)]).dual()
['E', 6]
>>> CartanType(['E', Integer(6), Integer(1)]).dual()
['E', 6, 1]
```

```python
is_simply_laced()
```

Return whether `self` is simply laced, which is True.

**EXAMPLES:**

```python
sage: CartanType(['A', 3, 1]).is_simply_laced()
True
sage: CartanType(['A', 2]).is_simply_laced()
True
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(3), Integer(1)]).is_simply_laced()
True
>>> CartanType(['A', Integer(2)]).is_simply_laced()
True
```

class sage.combinat.root_system.cartan_type.CartanType_standard

Bases: UniqueRepresentation, SageObject

A concrete class for affine simple Cartan types.

```python
index_set()
```

Implements `CartanType_abstract.index_set()`.

The index set for all standard affine Cartan types is of the form \{0, \ldots, n\}.

**EXAMPLES:**

```python
sage: CartanType(['A', 5, 1]).index_set()
(0, 1, 2, 3, 4, 5)
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(5), Integer(1)]).index_set()
(0, 1, 2, 3, 4, 5)
```

```python
rank()
```

Return the rank of `self` which for type $X_n^{(1)}$ is $n + 1$.

**EXAMPLES:**
sage: CartanType(['A', 4, 1]).rank()
5
sage: CartanType(['B', 4, 1]).rank()
5
carte: CartanType(['C', 3, 1]).rank()
4
sage: CartanType(['D', 4, 1]).rank()
5
sage: CartanType(['E', 6, 1]).rank()
7
sage: CartanType(['E', 7, 1]).rank()
8
sage: CartanType(['F', 4, 1]).rank()
5
sage: CartanType(['G', 2, 1]).rank()
3
sage: CartanType(['A', 2, 2]).rank()
2
sage: CartanType(['A', 6, 2]).rank()
4
sage: CartanType(['A', 7, 2]).rank()
5
sage: CartanType(['D', 5, 2]).rank()
5
sage: CartanType(['E', 6, 2]).rank()
5
sage: CartanType(['D', 4, 3]).rank()
3

>>> from sage.all import *
... CartanType(['A', Integer(4), Integer(1)]).rank()
5
... CartanType(['B', Integer(4), Integer(1)]).rank()
5
... CartanType(['C', Integer(3), Integer(1)]).rank()
4
... CartanType(['D', Integer(4), Integer(1)]).rank()
5
... CartanType(['E', Integer(6), Integer(1)]).rank()
7
... CartanType(['E', Integer(7), Integer(1)]).rank()
8
... CartanType(['F', Integer(4), Integer(1)]).rank()
5
... CartanType(['G', Integer(2), Integer(1)]).rank()
3
... CartanType(['A', Integer(2), Integer(1)]).rank()
2
... CartanType(['A', Integer(6), Integer(2)]).rank()
4
... CartanType(['A', Integer(7), Integer(2)]).rank()
5
... CartanType(['D', Integer(5), Integer(2)]).rank()
5
... CartanType(['E', Integer(6), Integer(2)]).rank()
5
... CartanType(['D', Integer(4), Integer(3)]).rank()
3

(continues on next page)
special_node()

Implement CartanType_abstract.special_node().

With the standard labelling conventions, 0 is always a special node.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).special_node()
0
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(3), Integer(1)]).special_node()
0
```

type()

Return the type of self.

EXAMPLES:

```python
sage: CartanType(['A', 4, 1]).type()
'A'
```

```python
>>> from sage.all import *
>>> CartanType(['A', Integer(4), Integer(1)]).type()
'A'
```

class sage.combinat.root_system.cartan_type.CartanType_standard_finite(letter, n)

Bases: CartanType_standard, CartanType_finite

A concrete base class for the finite standard Cartan types.

This includes for example $A_3$, $D_4$, or $E_8$.

affine()

Return the corresponding untwisted affine Cartan type.

EXAMPLES:

```python
sage: CartanType(['A',3]).affine()
['A', 3, 1]
```

```python
>>> from sage.all import *
>>> CartanType(['A',Integer(3)]).affine()
['A', 3, 1]
```

coxeter_number()

Return the Coxeter number associated with self.

The Coxeter number is the order of a Coxeter element of the corresponding Weyl group.

See Bourbaki, Lie Groups and Lie Algebras V.6.1 or Wikipedia article Coxeter_element for more information.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: CartanType(['A',4]).coxeter_number()
5
sage: CartanType(['B',4]).coxeter_number()
8
sage: CartanType(['C',4]).coxeter_number()
8
```
EXAMPLES:

```python
sage: ct = CartanType(['A', 5])
sage: ct.opposition_automorphism()
# needs sage.libs.gap
Finite family {1: 5, 2: 4, 3: 3, 4: 2, 5: 1}
```

```python
sage: ct = CartanType(['D', 4])
sage: ct.opposition_automorphism()
# needs sage.libs.gap
Finite family {1: 1, 2: 2, 3: 3, 4: 4}
```

```python
sage: ct = CartanType(['D', 5])
sage: ct.opposition_automorphism()
# needs sage.libs.gap
Finite family {1: 1, 2: 2, 3: 3, 4: 5, 5: 4}
```

```python
sage: ct = CartanType(['C', 4])
sage: ct.opposition_automorphism()
# needs sage.libs.gap
Finite family {1: 1, 2: 2, 3: 3, 4: 4}
```

```python
>>> from sage.all import *
>>> ct = CartanType(['A', Integer(5)])
>>> ct.opposition_automorphism()
# needs sage/libs/gap
Finite family {1: 5, 2: 4, 3: 3, 4: 2, 5: 1}
```

```python
>>> ct = CartanType(['D', Integer(4)])
>>> ct.opposition_automorphism()
# needs sage/libs/gap
Finite family {1: 1, 2: 2, 3: 3, 4: 4}
```

```python
>>> ct = CartanType(['D', Integer(5)])
>>> ct.opposition_automorphism()
# needs sage/libs/gap
Finite family {1: 1, 2: 2, 3: 3, 4: 5, 5: 4}
```

```python
>>> ct = CartanType(['C', Integer(4)])
>>> ct.opposition_automorphism()
# needs sage/libs/gap
Finite family {1: 1, 2: 2, 3: 3, 4: 4}
```

```
rank()
```
Return the rank of self which for type $X_n$ is $n$.

EXAMPLES:

```python
sage: CartanType(['A', 3]).rank()
3
sage: CartanType(['B', 3]).rank()
3
sage: CartanType(['C', 3]).rank()
3
sage: CartanType(['D', 4]).rank()
4
sage: CartanType(['E', 6]).rank()
6
```
from sage.all import *

CartanType(['A', Integer(3)]).rank()
3
CartanType(['B', Integer(3)]).rank()
3
CartanType(['C', Integer(3)]).rank()
3
CartanType(['D', Integer(4)]).rank()
4
CartanType(['E', Integer(6)]).rank()
6

CartanType(['A', Integer(3)]).rank()
3
CartanType(['B', Integer(3)]).rank()
3
CartanType(['C', Integer(3)]).rank()
3
CartanType(['D', Integer(4)]).rank()
4
CartanType(['E', Integer(6)]).rank()
6

CartanType(['A', Integer(1), Integer(1)]).basic_untwisted()
['A', 1, 1]
CartanType(['B', Integer(1)]).basic_untwisted()
['B', 1]
CartanType(['C', Integer(1)]).basic_untwisted()
['C', 1]
CartanType(['D', Integer(1)]).basic_untwisted()
['D', 1]
CartanType(['E', Integer(1)]).basic_untwisted()
['E', 1]
CartanType(['F', Integer(1)]).basic_untwisted()
['F', 1]
CartanType(['G', Integer(1)]).basic_untwisted()
['G', 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1]
CartanType(['C', Integer(1), Integer(1)]).basic_untwisted()
['C', 1, 1]
CartanType(['D', Integer(1), Integer(1)]).basic_untwisted()
['D', 1, 1]
CartanType(['E', Integer(1), Integer(1)]).basic_untwisted()
['E', 1, 1]
CartanType(['F', Integer(1), Integer(1)]).basic_untwisted()
['F', 1, 1]
CartanType(['G', Integer(1), Integer(1)]).basic_untwisted()
['G', 1, 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)], ['C', Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1, 'C', 1]
CartanType(['D', Integer(1), Integer(1)], ['E', Integer(1)]).basic_untwisted()
['D', 1, 1, 'E', 1]
CartanType(['F', Integer(1), Integer(1)], ['G', Integer(1)]).basic_untwisted()
['F', 1, 1, 'G', 1]

['A', 1, 1, 'B', 1, 'C', 1, 'D', 1]
CartanType(['E', Integer(1), Integer(1)], ['F', Integer(1), Integer(1)]).basic_untwisted()
['E', 1, 1, 'F', 1, 1]
CartanType(['G', Integer(1), Integer(1)], ['H', Integer(1), Integer(1)]).basic_untwisted()
['G', 1, 1, 'H', 1, 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)], ['C', Integer(1)], ['D', Integer(1)], ['E', Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1, 'C', 1, 'D', 1, 'E', 1]
CartanType(['F', Integer(1), Integer(1)], ['G', Integer(1), Integer(1)]).basic_untwisted()
['F', 1, 1, 'G', 1, 1]
CartanType(['H', Integer(1), Integer(1)], ['I', Integer(1), Integer(1)]).basic_untwisted()
['H', 1, 1, 'I', 1, 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)], ['C', Integer(1)], ['D', Integer(1)], ['E', Integer(1)], ['F', Integer(1), Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1, 'C', 1, 'D', 1, 'E', 1, 'F', 1, 1]
CartanType(['G', Integer(1), Integer(1)], ['H', Integer(1), Integer(1)], ['I', Integer(1), Integer(1)]).basic_untwisted()
['G', 1, 1, 'H', 1, 1, 'I', 1, 1]
CartanType(['J', Integer(1), Integer(1)], ['K', Integer(1), Integer(1)]).basic_untwisted()
['J', 1, 1, 'K', 1, 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)], ['C', Integer(1)], ['D', Integer(1)], ['E', Integer(1)], ['F', Integer(1), Integer(1)], ['G', Integer(1), Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1, 'C', 1, 'D', 1, 'E', 1, 'F', 1, 1, 'G', 1, 1]
CartanType(['H', Integer(1), Integer(1)], ['I', Integer(1), Integer(1)], ['J', Integer(1), Integer(1)]).basic_untwisted()
['H', 1, 1, 'I', 1, 1, 'J', 1, 1]
CartanType(['K', Integer(1), Integer(1)], ['L', Integer(1), Integer(1)]).basic_untwisted()
['K', 1, 1, 'L', 1, 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)], ['C', Integer(1)], ['D', Integer(1)], ['E', Integer(1)], ['F', Integer(1), Integer(1)], ['G', Integer(1), Integer(1)], ['H', Integer(1), Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1, 'C', 1, 'D', 1, 'E', 1, 'F', 1, 1, 'G', 1, 1, 'H', 1, 1]
CartanType(['I', Integer(1), Integer(1)], ['J', Integer(1), Integer(1)], ['K', Integer(1), Integer(1)]).basic_untwisted()
['I', 1, 1, 'J', 1, 1, 'K', 1, 1]
CartanType(['L', Integer(1), Integer(1)], ['M', Integer(1), Integer(1)]).basic_untwisted()
['L', 1, 1, 'M', 1, 1]

CartanType(['A', Integer(1), Integer(1)], ['B', Integer(1)], ['C', Integer(1)], ['D', Integer(1)], ['E', Integer(1)], ['F', Integer(1), Integer(1)], ['G', Integer(1), Integer(1)], ['H', Integer(1), Integer(1)], ['I', Integer(1), Integer(1)]).basic_untwisted()
['A', 1, 1, 'B', 1, 'C', 1, 'D', 1, 'E', 1, 'F', 1, 1, 'G', 1, 1, 'H', 1, 1, 'I', 1, 1]
CartanType(['J', Integer(1), Integer(1)], ['K', Integer(1), Integer(1)], ['L', Integer(1), Integer(1)]).basic_untwisted()
['J', 1, 1, 'K', 1, 1, 'L', 1, 1]
CartanType(['M', Integer(1), Integer(1)], ['N', Integer(1), Integer(1)]).basic_untwisted()
['M', 1, 1, 'N', 1, 1]
classical()

Return the classical Cartan type associated with self.

EXAMPLES:

```python
sage: CartanType(['A', 3, 1]).classical()
['A', 3]
sage: CartanType(['B', 3, 1]).classical()
['B', 3]
sage: CartanType(['C', 3, 1]).classical()
['C', 3]
sage: CartanType(['D', 4, 1]).classical()
['D', 4]
sage: CartanType(['E', 6, 1]).classical()
['E', 6]
sage: CartanType(['F', 4, 1]).classical()
['F', 4]
sage: CartanType(['G', 2, 1]).classical()
['G', 2]
```

is_untwisted_affine()

Implement `CartanType_affine.is_untwisted_affine()` by returning True.

EXAMPLES:

```python
sage: CartanType(['B', 3, 1]).is_untwisted_affine()
True
```

```python
>>> from sage.all import *
```
class sage.combinat.root_system.cartan_type.SuperCartanType_standard
Bases: UniqueRepresentation, SageObject

options = Current options for CartanType - dual_latex: \vee - dual_str: * - latex_marked: True - latex_relabel: True - mark_special_node: none - marked_node_str: X - notation: Stembridge - special_node_str: @

5.1.227 Coxeter Groups

sage.combinat.root_system.coxeter_group.CoxeterGroup(data, implementation='reflection', base_ring=None, index_set=None)

Return an implementation of the Coxeter group given by data.

INPUT:

- data – a Cartan type (or coercible into; see CartanType) or a Coxeter matrix or graph
- implementation – (default: 'reflection') can be one of the following:
  - 'permutation' – as a permutation representation
  - 'matrix' – as a Weyl group (as a matrix group acting on the root space); if this is not implemented, this uses the "reflection" implementation
  - 'coxeter3' – using the coxeter3 package
  - 'reflection' – as elements in the reflection representation; see CoxeterMatrixGroup
- base_ring – (optional) the base ring for the 'reflection' implementation
- index_set – (optional) the index set for the 'reflection' implementation

EXAMPLES:

Now assume that data represents a Cartan type. If implementation is not specified, the reflection representation is returned:

sage: W = CoxeterGroup(['A',2]); W
#...

\needs sage.libs.gap
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3]
[3 1]

sage: W = CoxeterGroup(['A',3,1]); W
#...

\needs sage.libs.gap
Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]

sage: W = CoxeterGroup(['H',3]); W
#...

\needs sage.libs.gap
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5
with a = 2.236067977499790? with Coxeter matrix:
[1 3 2]

(continues on next page)
We now use the `implementation` option:

```python
sage: W = CoxeterGroup(["A",2], implementation="permutation"); W # optional -
   → gap3
Permutation Group with generators [(1,4)(2,3)(5,6), (1,3)(2,5)(4,6)]
sage: W.category() # optional -
   → gap3
Join of Category of finite enumerated permutation groups
    and Category of finite Weyl groups
    and Category of well generated finite irreducible complex reflection groups
sage: W = CoxeterGroup(["A",2], implementation="matrix"); W # needs sage.libs.gap
Weyl Group of type ['A', 2] (as a matrix group acting on the ambient space)
sage: W = CoxeterGroup(["H",3], implementation="matrix"); W # needs sage.libs.gap sage.rings.number_field
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5
    with a = 2.236067977499790? with Coxeter matrix:
    [1 3 2]
    [3 1 5]
    [2 5 1]
sage: W = CoxeterGroup(["H",3], implementation="reflection"); W # needs sage.libs.gap sage.rings.number_field
Finite Coxeter group over Number Field in a with defining polynomial x^2 - 5
    with a = 2.236067977499790? with Coxeter matrix:
    [1 3 2]
    [3 1 5]
    [2 5 1]
```

(continues on next page)
We use the different options for the “reflection” implementation:

```python
sage: W = CoxeterGroup(\["H",3\], implementation="reflection", base_ring=RR); W  
# optional - gap3
Finite Coxeter group over Real Field with 53 bits of precision with Coxeter
```

(continues on next page)
5.1.228 Coxeter Matrices

class sage.combinat.root_system.coxeter_matrix.CoxeterMatrix (parent, data, coxeter_type, index_set)

Bases: CoxeterType

A Coxeter matrix.

A Coxeter matrix \( M = (m_{ij})_{i,j \in I} \) is a matrix encoding a Coxeter system \((W, S)\), where the relations are given by \((s_i s_j)^{m_{ij}}\). Thus \( M \) is symmetric and has entries in \{1, 2, 3, \ldots, \infty\} with \( m_{ij} = 1 \) if and only if \( i = j \).

We represent \( m_{ij} = \infty \) by any number \( m_{ij} \leq -1 \). In particular, we can construct a bilinear form \( B = (b_{ij})_{i,j \in I} \) from \( M \) by

\[
    b_{ij} = \begin{cases} 
        m_{ij} & \text{if } m_{ij} < 0 \text{ (i.e., } m_{ij} = \infty \text{)}, \\
        -\cos \left( \frac{\pi}{m_{ij}} \right) & \text{otherwise}.
    \end{cases}
\]

EXAMPLES:

\[
sage: W = CoxeterGroup(['A', 4])
[1 3 2 2]
[3 1 2 2]
[2 3 1 3]
[2 2 3 1]
sage: W = CoxeterGroup(['B', 4])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
\]
\[
\begin{array}{cccc}
2 & 2 & 4 & 1 \\
sage: CoxeterMatrix(['C', 4]) \\
[1 & 3 & 2 & 2] \\
[3 & 1 & 3 & 2] \\
[2 & 3 & 1 & 4] \\
[2 & 2 & 4 & 1] \\
sage: CoxeterMatrix(['D', 4]) \\
[1 & 3 & 2 & 2] \\
[3 & 1 & 3 & 3] \\
[2 & 3 & 1 & 2] \\
[2 & 3 & 2 & 1] \\
sage: CoxeterMatrix(['E', 6]) \\
[1 & 2 & 3 & 2 & 2 & 2] \\
[2 & 1 & 2 & 3 & 2 & 2] \\
[3 & 2 & 1 & 3 & 2 & 2] \\
[2 & 3 & 3 & 1 & 3 & 2] \\
[2 & 2 & 2 & 3 & 1 & 3] \\
[2 & 2 & 2 & 2 & 3 & 1] \\
sage: CoxeterMatrix(['F', 4]) \\
[1 & 3 & 2 & 2] \\
[3 & 1 & 4 & 2] \\
[2 & 4 & 1 & 3] \\
[2 & 2 & 3 & 1] \\
sage: CoxeterMatrix(['G', 2]) \\
[1 & 6] \\
[6 & 1] \\
\end{array}
\]

```
>>> from sage.all import *

>>> CoxeterMatrix(['A', Integer(4)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]  
>>> CoxeterMatrix(['B', Integer(4)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]  
>>> CoxeterMatrix(['C', Integer(4)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 4]
[2 2 4 1]  
>>> CoxeterMatrix(['D', Integer(4)])
[1 3 2 2]
[3 1 3 3]
[2 3 1 2]
[2 3 2 1]  
>>> CoxeterMatrix(['E', Integer(6)])
[1 2 3 2 2 2]
[2 1 2 3 2 2]
[2 3 1 3 2 2]
```
Combinatorics, Release 10.4

\[
\begin{bmatrix}
2 & 3 & 1 & 3 & 2 \\
2 & 2 & 3 & 1 & 3 \\
2 & 2 & 2 & 3 & 1 \\
\end{bmatrix}
\]

```python
>>> CoxeterMatrix(['F', Integer(4)])
[1 3 2 2]
[3 1 4 2]
[2 4 1 3]
[2 2 3 1]

>>> CoxeterMatrix(['G', Integer(2)])
[1 6]
[6 1]
```

By default, entries representing $\infty$ are given by $-1$ in the Coxeter matrix:

```python
sage: G = Graph(((0, 1, None), (1, 2, 4), (0, 2, oo)))
sage: CoxeterMatrix(G)
[ 1 3 -1]
[ 3 1 4]
[-1 4 1]
```

```python
>>> from sage.all import *

>>> G = Graph(((Integer(0), Integer(1), None), (Integer(1), Integer(2), Integer(4)), (Integer(0), Integer(2), oo)))

>>> CoxeterMatrix(G)
[ 1 3 -1]
[ 3 1 4]
[-1 4 1]
```

It is possible to give a number $\leq -1$ to represent an infinite label:

```python
sage: CoxeterMatrix([[1, -1], [-1, 1]])
[ 1 -1]
[ -1 1]

sage: CoxeterMatrix([[1, -3/2], [-3/2, 1]])
[ 1 -3/2]
[-3/2 1]
```

```python
>>> from sage.all import *

>>> CoxeterMatrix([[Integer(1), -Integer(1)], [-Integer(1), Integer(1)]]))
[ 1 -1]
[ -1 1]

>>> CoxeterMatrix([[Integer(1), -Integer(3)/Integer(2)], [-Integer(3)/Integer(2), Integer(1)]]))
[ 1 -3/2]
[-3/2 1]
```

def \texttt{bilinear\_form}(R=None)

Return the bilinear form of \texttt{self}.

EXAMPLES:

```python
sage: # needs sage.libs.gap
sage: CoxeterType(['A', 2, 1]).bilinear_form()
[ 1 -1/2 -1/2]
```

(continues on next page)
\[
\begin{bmatrix}
-1/2 & 1 & -1/2 \\
-1/2 & -1/2 & 1 \\
\end{bmatrix}
\]

```python
sage: CoxeterType(['H', 3]).bilinear_form()
\[
\begin{bmatrix}
1 & -1/2 & 0 \\
-1/2 & 1 & 1/2*E(5)^2 + 1/2*E(5)^3 \\
0 & 1/2*E(5)^2 + 1/2*E(5)^3 & 1 \\
\end{bmatrix}
\]
```
```python
sage: CoxeterMatrix(['C',3]).coxeter_matrix()
[1 3 2]
[3 1 4]
[2 4 1]

>>> from sage.all import *
>>> CoxeterMatrix(['C',Integer(3)]).coxeter_matrix()
[1 3 2]
[3 1 4]
[2 4 1]
```

**coxeter_type()**

Return the Coxeter type of `self` or `self` if unknown.

**EXAMPLES:**

```python
sage: C = CoxeterMatrix(['A',4,1])
sage: C.coxeter_type()
Coxeter type of ['A', 4, 1]
```

If the Coxeter type is unknown:

```python
sage: C = CoxeterMatrix([[1,3,4], [3,1,-1], [4,-1,1]])
sage: C.coxeter_type()
[ 1 3 4]
[ 3 1 -1]
[ 4 -1 1]
```

**index_set()**

Return the index set of `self`.

**EXAMPLES:**

```python
sage: C = CoxeterMatrix(['A',1,1])
sage: C.index_set()
(0, 1)
sage: C = CoxeterMatrix(['E',6])
sage: C.index_set()
(1, 2, 3, 4, 5, 6)
```
is_affine()

Return if self is an affine type or False if unknown.

EXAMPLES:

```
sage: M = CoxeterMatrix(['C',4])
sage: M.is_affine()
False
sage: M = CoxeterMatrix(['D',4,1])
sage: M.is_affine()
True
sage: M = CoxeterMatrix([[1, 3], [3, 1]])
sage: M.is_affine()
False
sage: M = CoxeterMatrix([[1, -1, 7], [-1, 1, 3], [7, 3, 1]])
sage: M.is_affine()
False
```

is_crystallographic()

Return whether self is crystallographic.

A Coxeter matrix is crystallographic if all non-diagonal entries are either 2, 3, 4, or 6.

EXAMPLES:

```
sage: CoxeterMatrix(['F',4]).is_crystallographic()
True
sage: CoxeterMatrix(['H',3]).is_crystallographic()
False
```

```
>>> from sage.all import *

>>> M = CoxeterMatrix(['C',Integer(4)])
>>> M.is_affine()
False
>>> M = CoxeterMatrix(['D',Integer(4),Integer(1)])
>>> M.is_affine()
True
>>> M = CoxeterMatrix([[Integer(1), Integer(3)], [Integer(3), Integer(1)]])
>>> M.is_affine()
False
>>> M = CoxeterMatrix([[Integer(1), -Integer(1), Integer(7)], [-Integer(1), Integer(7), Integer(3)]])
>>> M.is_affine()
False
```
is_finite()
Return if self is a finite type or False if unknown.

EXAMPLES:

```python
sage: M = CoxeterMatrix(['C', 4])
sage: M.is_finite()
True
sage: M = CoxeterMatrix(['D', 4, 1])
sage: M.is_finite()
False
sage: M = CoxeterMatrix([[1, -1], [-1, 1]])
sage: M.is_finite()
False
```

```python
>>> from sage.all import *
>>> M = CoxeterMatrix(['C', Integer(4)])
>>> M.is_finite()
True
>>> M = CoxeterMatrix(['D', Integer(4), Integer(1)])
>>> M.is_finite()
False
>>> M = CoxeterMatrix([[Integer(1), -Integer(1)], [-Integer(1), Integer(1)]])
>>> M.is_finite()
False
```

is_irreducible()
Return whether self is irreducible.

A Coxeter matrix is irreducible if the Coxeter graph is connected.

EXAMPLES:

```python
sage: CoxeterMatrix([[F,4], [A,1]]).is_irreducible()
False
sage: CoxeterMatrix(['H',3]).is_irreducible()
True
```

```python
>>> from sage.all import *
>>> CoxeterMatrix([[F,Integer(4)], [A,Integer(1)]]).is_irreducible()
False
>>> CoxeterMatrix(['H',Integer(3)]).is_irreducible()
True
```

is_simply_laced()
Return if self is simply-laced.

A Coxeter matrix is simply-laced if all non-diagonal entries are either 2 or 3.

EXAMPLES:

```python
sage: cm = CoxeterMatrix([[1,3,3,3], [3,1,3,3], [3,3,1,3], [3,3,3,1]])
sage: cm.is_simply_laced()
True
```

```python
>>> from sage.all import *
>>> cm = CoxeterMatrix([[Integer(1),Integer(3),Integer(3),Integer(3)]],
(continues on next page)```
rank()

Return the rank of self.

EXAMPLES:

```
sage: CoxeterMatrix(['C', 3]).rank()
3
sage: CoxeterMatrix(['A2', 'B2', 'F4']).rank()
8
```

relabel(relabelling)

Return a relabelled copy of this Coxeter matrix.

INPUT:

- relabelling – a function (or dictionary)

OUTPUT:

an isomorphic Coxeter type obtained by relabelling the nodes of the Coxeter graph. Namely, the node with label \( i \) is relabelled \( f(i) \) (or, by \( f[i] \) if \( f \) is a dictionary).

EXAMPLES:

```
sage: CoxeterMatrix(['F', 4]).relabel({ 1:2, 2:3, 3:4, 4:1})
[1 4 2 3]
[4 1 3 2]
[2 3 1 2]
[3 2 2 1]
sage: CoxeterMatrix(['F', 4]).relabel(lambda x: x+1 if x<4 else 1)
[1 4 2 3]
[4 1 3 2]
[2 3 1 2]
[3 2 2 1]
```

```python
>>> from sage.all import *
>>> CoxeterMatrix(['F', Integer(4)]).relabel({ Integer(1):Integer(2),
→ Integer(2):Integer(3), Integer(3):Integer(4), Integer(4):Integer(1)})
[1 4 2 3]
[4 1 3 2]
[2 3 1 2]
[3 2 2 1]
>>> CoxeterMatrix(['F', Integer(4)]).relabel(lambda x: x+Integer(1) if x
→<Integer(4) else Integer(1))
[1 4 2 3]
[4 1 3 2]
```
class method samples

Return a sample of the available Coxeter types.

**INPUT:**

- **finite** (default: None) a boolean or None
- **affine** (default: None) a boolean or None
- **crystallographic** (default: None) a boolean or None
- **higher_rank** (default: None) a boolean or None

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families. Here the higher_rank term denotes non-finite, non-affine, Coxeter groups (including hyperbolic types).

**Todo:** Implement the hyperbolic and compact hyperbolic in the samples.

**EXAMPLES:**

```
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples()]
('B', 2, 1), ('D', 3, 1), ('E', 6, 1), ('E', 7, 1), ('F', 4, 1),

[1 -1 -1]
[1 -2 3 2]
[2 1 7]
[3 7 1], (-1 1 1),
]```
\[
\begin{align*}
\text{Coxeter type of } ['A', 1], \text{Coxeter type of } ['A', 5], \\
\text{Coxeter type of } ['B', 5], \text{Coxeter type of } ['D', 4], \\
\text{Coxeter type of } ['D', 5], \text{Coxeter type of } ['E', 6], \\
\text{Coxeter type of } ['E', 7], \text{Coxeter type of } ['E', 8], \\
\text{Coxeter type of } ['F', 4], \text{Coxeter type of } ['H', 3], \\
\text{Coxeter type of } ['H', 4], \text{Coxeter type of } ['I', 10], \\
\text{Coxeter type of } ['A', 2, 1], \text{Coxeter type of } ['B', 5, 1], \\
\text{Coxeter type of } ['C', 5, 1], \text{Coxeter type of } ['D', 5, 1], \\
\text{Coxeter type of } ['E', 6, 1], \text{Coxeter type of } ['F', 4, 1], \\
\text{Coxeter type of } ['G', 2, 1], \text{Coxeter type of } ['A', 1, 1], \text{[[-1 -1 1]} \\
\end{align*}
\]

The finite, affine and crystallographic options allow respectively for restricting to (non) finite, (non) affine, and (non) crystallographic Cartan types:

\begin{verbatim}
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(finite=True)]
[\text{Coxeter type of } ['A', 1], \text{Coxeter type of } ['A', 5], \\
\text{Coxeter type of } ['B', 5], \text{Coxeter type of } ['D', 4], \\
\text{Coxeter type of } ['D', 5], \text{Coxeter type of } ['E', 6], \\
\text{Coxeter type of } ['E', 7], \text{Coxeter type of } ['E', 8], \\
\text{Coxeter type of } ['F', 4], \text{Coxeter type of } ['H', 3], \\
\text{Coxeter type of } ['H', 4], \text{Coxeter type of } ['I', 10]]
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(affine=True)]
[\text{Coxeter type of } ['A', 2, 1], \text{Coxeter type of } ['B', 5, 1], \\
\text{Coxeter type of } ['C', 5, 1], \text{Coxeter type of } ['D', 5, 1], \\
\text{Coxeter type of } ['E', 6, 1], \text{Coxeter type of } ['F', 4, 1], \\
\text{Coxeter type of } ['G', 2, 1], \text{Coxeter type of } ['A', 1, 1]]
sage: [CM.coxeter_type() for CM in CoxeterMatrix.samples(crystallographic=True)]
[\text{Coxeter type of } ['A', 1], \text{Coxeter type of } ['A', 5], \\
\text{Coxeter type of } ['B', 5], \text{Coxeter type of } ['D', 4], \\
\text{Coxeter type of } ['D', 5], \text{Coxeter type of } ['E', 6], \\
\text{Coxeter type of } ['E', 7], \text{Coxeter type of } ['E', 8], \\
\text{Coxeter type of } ['F', 4, 1], \text{Coxeter type of } ['H', 3], \\
\text{Coxeter type of } ['H', 4], \text{Coxeter type of } ['I', 10]]
\end{verbatim}
Combinatorics, Release 10.4

Coxeter type of ['F', 4], Coxeter type of ['A', 2, 1],
Coxeter type of ['B', 5, 1], Coxeter type of ['C', 5, 1],
Coxeter type of ['D', 5, 1], Coxeter type of ['E', 6, 1],
Coxeter type of ['E', 7, 1], Coxeter type of ['E', 8, 1],
Coxeter type of ['F', 4, 1], Coxeter type of ['G', 2, 1])

sage: CoxeterMatrix.samples(crystallographic=False)

[ [1 3 2 2] [1 3 2]
 [3 1 5] [2 3 1 5]
 [2 5 1], [2 2 5 1], [10 1], [-2 1 -3 1]]

 [3 1 5] [2 3 1 5]
 [2 5 1], [2 2 5 1], [10 1], [-2 1 -3 1]]

(continues on next page)
Todo: add some reducible Coxeter types (suggestions?)

\[ \begin{bmatrix} 2 & 3 & -8 & 1 \\ \end{bmatrix} \]

`sage.combinat.root_system.coxeter_matrix.check_coxeter_matrix(m)`

Check if \( m \) represents a generalized Coxeter matrix and raise and error if not.

**EXAMPLES:**

```
sage: from sage.combinat.root_system.coxeter_matrix import check_coxeter_matrix
sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)

sage: m = matrix([[1,3],[3,1],[-2,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: not a square matrix

sage: m = matrix([[1,3,2],[3,1,-1],[2,-1,2]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: the matrix diagonal is not all 1

sage: m = matrix([[1,3,3],[3,1,-1],[2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: the matrix is not symmetric

sage: m = matrix([[1,3,1/2],[3,1,-1],[1/2,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: invalid Coxeter label 1/2

sage: m = matrix([[1,3,1],[3,1,-1],[1,-1,1]])
sage: check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: invalid Coxeter label 1
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.coxeter_matrix import check_coxeter_matrix

>>> m = matrix([[Integer(1),Integer(3),Integer(2)],[Integer(3),Integer(1),-Integer(1)],[Integer(2),-Integer(1),Integer(1)]]))

>>> check_coxeter_matrix(m)

>>> m = matrix([[Integer(1),Integer(3)],[Integer(3),Integer(1)],[Integer(2),-Integer(1)]])

>>> check_coxeter_matrix(m)
Traceback (most recent call last):
... ValueError: invalid Coxeter label 1
```
```python
ValueError: not a square matrix

>>> m = matrix([[Integer(1),Integer(3),Integer(2)],[Integer(3),Integer(1),-Integer(1)],[Integer(2),-Integer(1),Integer(2)]]
>>> check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: the matrix diagonal is not all 1

>>> m = matrix([[Integer(1),Integer(3),Integer(3)],[Integer(3),Integer(1),-Integer(1)],[Integer(2),-Integer(1),Integer(1)]]
>>> check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: the matrix is not symmetric

>>> m = matrix([[Integer(1),Integer(3),Integer(1)/Integer(2)],[Integer(3),-Integer(1),-Integer(1)],[Integer(1)/Integer(2),-Integer(1),Integer(1)]]
>>> check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: invalid Coxeter label 1/2

>>> m = matrix([[Integer(1),Integer(3),Integer(1)],[Integer(3),Integer(1),-Integer(1)],[Integer(1),-Integer(1),Integer(1)]]
>>> check_coxeter_matrix(m)
Traceback (most recent call last):
...
ValueError: invalid Coxeter label 1
```

```
sage.combinat.root_system.coxeter_matrix.coxeter_matrix_as_function(t)

Return the Coxeter matrix, as a function.

INPUT:

• t – a Cartan type

EXAMPLES:

```python
sage: from sage.combinat.root_system.coxeter_matrix import coxeter_matrix_as_function
sage: f = coxeter_matrix_as_function(['A',4])
sage: matrix([[f(i,j) for j in range(1,5)] for i in range(1,5)])
[1 3 2 2]
[3 1 3 2]
[2 3 1 3]
[2 2 3 1]
```

```
```
sage.combinat.root_system.coxeter_matrix.recog

nize_coxeter_type_from_matrix(coxeter_matrix,
index_set)

Return the Coxeter type of coxeter_matrix if known, otherwise return None.

EXAMPLES:

Some infinite ones:

sage: C = CoxeterMatrix([[1,3,2],[3,1,-1],[2,-1,1]])
sage: C.is_finite()  # indirect doctest
False

sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.is_finite()  # indirect doctest
False

Some finite ones:

sage: m = matrix(CoxeterMatrix([D, 4]))
sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True

sage: m = matrix(CoxeterMatrix([H, 4]))
sage: CoxeterMatrix(m).is_finite()  # indirect doctest
True

sage: CoxeterMatrix(CoxeterType([A,10]).coxeter_graph()).coxeter_type()
Coxeter type of [A, 10]

sage: CoxeterMatrix(CoxeterType([B,10]).coxeter_graph()).coxeter_type()
Coxeter type of [B, 10]

sage: CoxeterMatrix(CoxeterType([C,10]).coxeter_graph()).coxeter_type()
Coxeter type of [C, 10]

sage: CoxeterMatrix(CoxeterType([D,10]).coxeter_graph()).coxeter_type()
Coxeter type of [D, 10]

sage: CoxeterMatrix(CoxeterType([E,6]).coxeter_graph()).coxeter_type()
Coxeter type of [E, 6]

sage: CoxeterMatrix(CoxeterType([E,7]).coxeter_graph()).coxeter_type()
Coxeter type of [E, 7]

sage: CoxeterMatrix(CoxeterType([E,8]).coxeter_graph()).coxeter_type()
Coxeter type of [E, 8]

sage: CoxeterMatrix(CoxeterType([F,4]).coxeter_graph()).coxeter_type()
Coxeter type of [F, 4]

sage: CoxeterMatrix(CoxeterType([G,2]).coxeter_graph()).coxeter_type()

(continues on next page)
Coxeter type of ['G', 2]
sage: CoxeterMatrix(CoxeterType(['H', 3]).coxeter_graph()).coxeter_type()

Coxeter type of ['H', 3]
sage: CoxeterMatrix(CoxeterType(['H', 4]).coxeter_graph()).coxeter_type()

Coxeter type of ['H', 4]
sage: CoxeterMatrix(CoxeterType(['I', 100]).coxeter_graph()).coxeter_type()

Coxeter type of ['I', 100]

>>> from sage.all import *
>>> m = matrix(CoxeterMatrix(['D', Integer(4)]))
>>> CoxeterMatrix(m).is_finite() # indirect doctest
True
>>> m = matrix(CoxeterMatrix(['H', Integer(4)]))
>>> CoxeterMatrix(m).is_finite() # indirect doctest
True

>>> CoxeterMatrix(CoxeterType(['A', Integer(10)]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10]
>>> CoxeterMatrix(CoxeterType(['B', Integer(10)]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10]
>>> CoxeterMatrix(CoxeterType(['C', Integer(10)]).coxeter_graph()).coxeter_type()
Coxeter type of ['C', 10]
>>> CoxeterMatrix(CoxeterType(['D', Integer(10)]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10]
>>> CoxeterMatrix(CoxeterType(['E', Integer(6)]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6]
>>> CoxeterMatrix(CoxeterType(['E', Integer(7)]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 7]
>>> CoxeterMatrix(CoxeterType(['E', Integer(8)]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 8]
>>> CoxeterMatrix(CoxeterType(['F', Integer(4)]).coxeter_graph()).coxeter_type()
Coxeter type of ['F', 4]
>>> CoxeterMatrix(CoxeterType(['G', Integer(2)]).coxeter_graph()).coxeter_type()
Coxeter type of ['G', 2]
>>> CoxeterMatrix(CoxeterType(['H', Integer(3)]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 3]
>>> CoxeterMatrix(CoxeterType(['H', Integer(4)]).coxeter_graph()).coxeter_type()
Coxeter type of ['H', 4]
>>> CoxeterMatrix(CoxeterType(['I', Integer(100)]).coxeter_graph()).coxeter_type()
Coxeter type of ['I', 100]

Some affine graphs:

sage: CoxeterMatrix(CoxeterType(['A', 1, 1]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 1, 1]
sage: CoxeterMatrix(CoxeterType(['A', 10, 1]).coxeter_graph()).coxeter_type()
Coxeter type of ['A', 10, 1]
sage: CoxeterMatrix(CoxeterType(['B', 10, 1]).coxeter_graph()).coxeter_type()
Coxeter type of ['B', 10, 1]
sage: CoxeterMatrix(CoxeterType(['C', 10, 1]).coxeter_graph()).coxeter_type()
Coxeter type of ['C', 10, 1]
sage: CoxeterMatrix(CoxeterType(['D', 10, 1]).coxeter_graph()).coxeter_type()
Coxeter type of ['D', 10, 1]
sage: CoxeterMatrix(CoxeterType(['E', 6, 1]).coxeter_graph()).coxeter_type()
Coxeter type of ['E', 6, 1]
sage: CoxeterMatrix(CoxeterType(['E', 7, 1]).coxeter_graph()).coxeter_type()
5.1.229 Coxeter Types

class sage.combinat.root_system.coxeter_type.CoxeterType
    
    Bases: SageObject
    
    Abstract class for Coxeter types.

    bilinear_form(R=None)
    
    Return the bilinear form over R associated to self.

    INPUT:
    
    - R – (default: universal cyclotomic field) a ring used to compute the bilinear form

    EXAMPLES:
sage: # needs sage.graphs sage.libs.gap
sage: CoxeterType(['A', 2, 1]).bilinear_form()
[ 1  -1/2  -1/2]
[-1/2  1  -1/2]
[-1/2  -1/2  1]
sage: CoxeterType(['H', 3]).bilinear_form()
[ 1  -1/2  0]
[-1/2  1  1/2*E(5)^2 + 1/2*E(5)^3]
[ 0  1/2*E(5)^2 + 1/2*E(5)^3  1]
sage: C = CoxeterMatrix([[1,-1,-1],[-1,1,-1],[-1,-1,1]])
sage: C.bilinear_form()
[ 1  -1  -1]
[-1  1  -1]
[-1  -1  1]

>>> from sage.all import *
>>> # needs sage.graphs sage.libs.gap
>>> CoxeterType(['A', Integer(2), Integer(1)]).bilinear_form()
[ 1  -1/2  -1/2]
[-1/2  1  -1/2]
[-1/2  -1/2  1]
>>> CoxeterType(['H', Integer(3)]).bilinear_form()
[ 1  -1/2  0]
[-1/2  1  1/2*E(5)^2 + 1/2*E(5)^3]
[ 0  1/2*E(5)^2 + 1/2*E(5)^3  1]
>>> C = CoxeterMatrix([[Integer(1),-Integer(1),-Integer(1)],[Integer(1),-Integer(1),-Integer(1)],[Integer(1),-Integer(1),Integer(1)]])
>>> C.bilinear_form()
[ 1  -1  -1]
[-1  1  -1]
[-1  -1  1]

coxeter_graph()

Return the Coxeter graph associated to self.

EXAMPLES:

sage: CoxeterType(['A', 3]).coxeter_graph()
# needs sage.graphs
Graph on 3 vertices
sage: CoxeterType(['A', 3, 1]).coxeter_graph()  # needs sage.graphs
Graph on 4 vertices

>>> from sage.all import *
>>> # needs sage.graphs
>>> CoxeterType(['A', Integer(3)]).coxeter_graph()  # needs sage.graphs
Graph on 3 vertices
>>> CoxeterType(['A', Integer(3), Integer(1)]).coxeter_graph()  # needs sage.graphs
Graph on 4 vertices

coxeter_matrix()

Return the Coxeter matrix associated to self.

EXAMPLES:
Combinatorics, Release 10.4

```
sage: CoxeterType(['A', 3]).coxeter_matrix()  # needs sage.graphs
[1 3 2]
[3 1 3]
[2 3 1]
sage: CoxeterType(['A', 3, 1]).coxeter_matrix()  # needs sage.graphs
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]
```

```
>>> from sage.all import *
>>> CoxeterType(['A', Integer(3)]).coxeter_matrix()  # needs sage.graphs
[1 3 2]
[3 1 3]
[2 3 1]
>>> CoxeterType(['A', Integer(3), Integer(1)]).coxeter_matrix()  # needs sage.graphs
[1 3 2 3]
[3 1 3 2]
[2 3 1 3]
[3 2 3 1]
```

```
index_set()

Return the index set for self.

This is the list of the nodes of the associated Coxeter graph.

EXAMPLES:

```
sage: CoxeterType(['A', 3, 1]).index_set()
(0, 1, 2, 3)
sage: CoxeterType(['D', 4]).index_set()
(1, 2, 3, 4)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 7, 2]).index_set()
(0, 1, 2, 3, 4)
sage: CoxeterType(['A', 6, 2]).index_set()
(0, 1, 2)
sage: CoxeterType(['G', 2, 1]).index_set()
(0, 1, 2)
sage: CoxeterType(['F', 4, 1]).index_set()
(0, 1, 2, 3, 4)
```

```
>>> from sage.all import *
>>> CoxeterType(['A', Integer(3), Integer(1)]).index_set()
```

(continues on next page)
is_affine()

Return whether self is affine.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{CoxeterType(['A', 3]).is_affine()} \\
& \text{False} \\
\text{sage: } & \text{CoxeterType(['A', 3, 1]).is_affine()} \\
& \text{True}
\end{align*}
\]

\[
\begin{align*}
\text{from sage.all import * } \\
\text{CoxeterType(['A', Integer(3)]).is_affine()} \\
& \text{False} \\
\text{CoxeterType(['A', Integer(3), Integer(1)]).is_affine()} \\
& \text{True}
\end{align*}
\]

is_crystallographic()

Return whether self is crystallographic.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{[ [t, t.is_crystallographic()] for t in CartanType.} \\
& \text{samples(finite=True) ]} \\
& \text{[['A', 1], True], [['A', 5], True],} \\
& [['B', 1], True], [['B', 5], True],} \\
& [['C', 1], True], [['C', 5], True],} \\
& [['D', 2], True], [['D', 3], True], [['D', 5], True],} \\
& [['E', 6], True], [['E', 7], True], [['E', 8], True],} \\
& [['F', 4], True], [['G', 2], True],} \\
& [['I', 5], False], [['H', 3], False], [['H', 4], False]]
\end{align*}
\]
is_finite()
Return whether self is finite.

EXAMPLES:

sage: CoxeterType(['A',4]).is_finite()
True
sage: CoxeterType(['A',4,1]).is_finite()
False

is_simply_laced()
Return whether self is simply laced.

This returns False by default. Derived class should override this appropriately.

EXAMPLES:

sage: [ [t, t.is_simply_laced()] for t in CartanType.samples() ]
[['[A', 1], True], ['[A', 5], True],
 ['[B', 1], True], ['[B', 5], False],
 ['[C', 1], False], ['[C', 5], False],
 ['[D', 2], True], ['[D', 3], True], ['[D', 5], True],
 ['[E', 6], True], ['[E', 7], True], ['[E', 8], True],
 ['[F', 4], True], ['[G', 2], True],
 ['[I', 5], True], ['[H', 3], False], ['[H', 4], False]]
rank()

Return the rank of self.

This is the number of nodes of the associated Coxeter graph.

EXAMPLES:

```
sage: CoxeterType(['A', 4]).rank()
4
sage: CoxeterType(['A', 7, 2]).rank()
5
sage: CoxeterType(['I', 8]).rank()
2
```

```python
>>> from sage.all import *
>>> CoxeterType(['A', Integer(4)]).rank()
4
>>> CoxeterType(['A', Integer(7), Integer(2)]).rank()
5
>>> CoxeterType(['I', Integer(8)]).rank()
2
```

classmethod samples (finite=None, affine=None, crystallographic=None)

Return a sample of the available Coxeter types.

INPUT:

- **finite** – a boolean or None (default: None)
- **affine** – a boolean or None (default: None)
- **crystallographic** – a boolean or None (default: None)

The sample contains all the exceptional finite and affine Coxeter types, as well as typical representatives of the infinite families.

EXAMPLES:

```
sage: CoxeterType.samples()
[Coxeter type of ['A', 1], Coxeter type of ['A', 5],
 Coxeter type of ['B', 1], Coxeter type of ['B', 5],
 Coxeter type of ['C', 1], Coxeter type of ['C', 5],
 Coxeter type of ['D', 4], Coxeter type of ['D', 5],
 Coxeter type of ['E', 6], Coxeter type of ['E', 7],
 Coxeter type of ['E', 8],
 Coxeter type of ['F', 4],
 Coxeter type of ['G', 2],
 Coxeter type of ['H', 3],
 Coxeter type of ['H', 4],
 Coxeter type of ['I', 5],
 Coxeter type of ['A', 1, 1],
 Coxeter type of ['A', 5, 1],
 Coxeter type of ['B', 1, 1],
 Coxeter type of ['B', 5, 1],
 Coxeter type of ['C', 1, 1],
 Coxeter type of ['C', 5, 1],
 Coxeter type of ['D', 3, 1],
 Coxeter type of ['D', 5, 1],
 Coxeter type of ['E', 6, 1],
 Coxeter type of ['E', 7, 1],
 Coxeter type of ['E', 8, 1],
 Coxeter type of ['F', 4, 1],
 Coxeter type of ['G', 2, 1],
 Coxeter type of ['BC', 1, 2],

Todo: add some reducible Coxeter types (suggestions?)

class sage.combinat.root_system.coxeter_type.CoxeterTypeFromCartanType(carta-
tan_type)
Bases: UniqueRepresentation, CoxeterType

A Coxeter type associated to a Cartan type.

cartan_type()

Return the Cartan type used to construct self.

EXAMPLES:

```python
sage: C = CoxeterType(['C', 3])
sage: C.cartan_type()
['C', 3]
```

```python
>>> from sage.all import *
>>> C = CoxeterType(['C', Integer(3)])
>>> C.cartan_type()
['C', 3]
```

**component_types()**

A list of Coxeter types making up the reducible type.

EXAMPLES:

```python
sage: CoxeterType(['A', 2], ['B', 2]).component_types()
[Coxeter type of ['A', 2], Coxeter type of ['B', 2]]

sage: CoxeterType('A4xB3').component_types()
[Coxeter type of ['A', 4], Coxeter type of ['B', 3]]

sage: CoxeterType(['A', 2]).component_types()
Traceback (most recent call last):
  ... ValueError: component types only defined for reducible types
```

```python
>>> from sage.all import *
>>> CoxeterType(['A', Integer(2)], ['B', Integer(2)]).component_types()
[Coxeter type of ['A', 2], Coxeter type of ['B', 2]]

>>> CoxeterType('A4xB3').component_types()
[Coxeter type of ['A', 4], Coxeter type of ['B', 3]]

>>> CoxeterType(['A', Integer(2)]).component_types()
Traceback (most recent call last):
  ... ValueError: component types only defined for reducible types
```

**coxeter_graph()**

Return the Coxeter graph of self.

EXAMPLES:

```python
sage: C = CoxeterType(['H', 3])
sage: C.coxeter_graph().edges(sort=True)  # needs sage.graphs
[(1, 2, 3), (2, 3, 5)]
```

```python
>>> from sage.all import *
>>> C = CoxeterType(['H', Integer(3)])
>>> C.coxeter_graph().edges(sort=True)  # needs sage.graphs
[(1, 2, 3), (2, 3, 5)]
```

**coxeter_matrix()**

Return the Coxeter matrix associated to self.

EXAMPLES:
sage: C = CoxeterType(['H',3])
sage: C.coxeter_matrix()  # needs sage.graphs
[1 3 2]
[3 1 5]
[2 5 1]

>>> from sage.all import *
>>> C = CoxeterType(['H',Integer(3)])
>>> C.coxeter_matrix()  # needs sage.graphs
[1 3 2]
[3 1 5]
[2 5 1]

index_set()
Return the index set of self.

EXAMPLES:

sage: C = CoxeterType(['A', 4])
sage: C.index_set()
(1, 2, 3, 4)

>>> from sage.all import *
>>> C = CoxeterType(['A', Integer(4)])
>>> C.index_set()
(1, 2, 3, 4)

is_affine()
Return if self is an affine type.

EXAMPLES:

sage: C = CoxeterType(['F', 4, 1])
sage: C.is_affine()
True

>>> from sage.all import *
>>> C = CoxeterType(['F', Integer(4), Integer(1)])
>>> C.is_affine()
True

is_crystallographic()
Return if self is crystallographic.

EXAMPLES:

sage: C = CoxeterType(['C', 3])
sage: C.is_crystallographic()
True

sage: C = CoxeterType(['H', 3])
sage: C.is_crystallographic()
False
```python
>>> from sage.all import *
>>> C = CoxeterType(['C', Integer(3)])
>>> C.is_crystallographic()
True

>>> C = CoxeterType(['H', Integer(3)])
>>> C.is_crystallographic()
False

is_finite()
Return if self is a finite type.

EXAMPLES:

sage: C = CoxeterType(['E', 6])
sage: C.is_finite()
True

>>> from sage.all import *
>>> C = CoxeterType(['E', Integer(6)])
>>> C.is_finite()
True

is_irreducible()
Return if self is irreducible.

EXAMPLES:

sage: C = CoxeterType(['A', 5])
sage: C.is_irreducible()
True

sage: C = CoxeterType('B3xB3')
sage: C.is_irreducible()
False

>>> from sage.all import *
>>> C = CoxeterType(['A', Integer(5)])
>>> C.is_irreducible()
True

>>> C = CoxeterType('B3xB3')
>>> C.is_irreducible()
False

is_reducible()
Return if self is reducible.

EXAMPLES:

sage: C = CoxeterType(['A', 5])
sage: C.is_reducible()
False

sage: C = CoxeterType('A2xA2')
sage: C.is_reducible()
True
```
```python
>>> from sage.all import *

>>> C = CoxeterType(['A', Integer(5)])
>>> C.is_reducible()
False

>>> C = CoxeterType('A2xA2')
>>> C.is_reducible()
True
```

**is_simply_laced()**

Return if self is simply-laced.

**EXAMPLES:**

```python
sage: C = CoxeterType(['A', 5])
sage: C.is_simply_laced()
True

sage: C = CoxeterType(['B', 3])
sage: C.is_simply_laced()
False
```

```python
>>> from sage.all import *

>>> C = CoxeterType(['A', Integer(5)])
>>> C.is_simply_laced()
True

>>> C = CoxeterType(['B', Integer(3)])
>>> C.is_simply_laced()
False
```

**rank()**

Return the rank of self.

**EXAMPLES:**

```python
sage: C = CoxeterType(['I', 16])

sage: C.rank()
2
```

```python
>>> from sage.all import *

>>> C = CoxeterType(['I', Integer(16)])

>>> C.rank()
2
```

**relabel (relabelling)**

Return a relabelled copy of self.

**EXAMPLES:**

```python
sage: ct = CoxeterType(['A',2])

sage: ct.relabel({1:-1, 2:-2})
Coxeter type of ['A', 2] relabelled by {1: -1, 2: -2}
```

```python
>>> from sage.all import *

>>> ct = CoxeterType(['A',Integer(2)])
```

(continues on next page)
type()

Return the type of self.

EXAMPLES:

```python
sage: C = CoxeterType(['A', 4])
sage: C.type()
'A'
```

```
from sage.all import *
C = CoxeterType(['A', Integer(4)])
C.type()
'A'
```

## 5.1.230 Dynkin diagrams

AUTHORS:

`sage.combinat.root_system.dynkin_diagram.DynkinDiagram(*args, **kwds)`

Return the Dynkin diagram corresponding to the input.

INPUT:

The input can be one of the following:

- empty to obtain an empty Dynkin diagram
- a Cartan type
- a Cartan matrix
- a Cartan matrix and an indexing set

One can also input an indexing set by passing a tuple using the optional argument `index_set`.

The edge multiplicities are encoded as edge labels. For the corresponding Cartan matrices, this uses the convention in Hong and Kang, Kac, Fulton and Harris, and crystals. This is the opposite convention in Bourbaki and Wikipedia’s Dynkin diagram (Wikpedia article Dynkin_diagram). That is for $i \neq j$:

```python
i <-k-- j <=k a_ij = -k
<=k -scalar(coroot[i], root[j]) = k
<=k multiple arrows point from the longer root
to the shorter one
```

For example, in type $C_2$, we have:
sage: C2 = DynkinDiagram(['C',2]); C2
O<=O
1 2
C2
sage: C2.cartan_matrix()
[ 2 -2]
[-1  2]

>>> from sage.all import *

>>> C2 = DynkinDiagram(['C',Integer(2)]); C2
O<=O
1 2
C2

>>> C2.cartan_matrix()
[ 2 -2]
[-1  2]

However Bourbaki would have the Cartan matrix as:
\[
\begin{bmatrix}
2 & -1 \\
-2 & 2
\end{bmatrix}.
\]

EXAMPLES:

sage: DynkinDiagram(['A', 4])
O---O---O---O
1 2 3 4
A4

sage: DynkinDiagram(['A',1],['A',1])
O
1
O
2
A1xA1

sage: R = RootSystem("A2xB2xF4")
sage: DynkinDiagram(R)

`CartanType()` for a general discussion on Cartan types and in particular node labeling conventions.

class sage.combinat.root_system.dynkin_diagram.DynkinDiagram_class(t=None,
    index_set=None,
    odd_isotropic_roots=[],
    **options)

Bases: DiGraph, CartanType_abstract
A Dynkin diagram.

See also:

\texttt{DynkinDiagram()}

**INPUT:**

- \( t \) – a Cartan type, Cartan matrix, or None

**EXAMPLES:**

```python
sage: DynkinDiagram(['A', 3])
O---O---O
 1 2 3
A3
sage: C = CartanMatrix([[2, -3], [-4, 2]])
sage: DynkinDiagram(C)
Dynkin diagram of rank 2
sage: C.dynkin_diagram().cartan_matrix() == C
True
```

```python
>>> from sage.all import *

>>> from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class

>>> d = DynkinDiagram_class(CartanType(['A',3]))

>>> sorted(d.edges(sort=True))
[]

>>> d.add_edge(2, 3)

>>> sorted(d.edges(sort=True))
[(2, 3, 1), (3, 2, 1)]
```

**add_edge** \((i, j, label=1)\)

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class

sage: d = DynkinDiagram_class(CartanType(['A',3]))

sage: sorted(d.edges(sort=True))
[]

sage: d.add_edge(2, 3)

sage: sorted(d.edges(sort=True))
[(2, 3, 1), (3, 2, 1)]
```

**static an_instance()**

Returns an example of Dynkin diagram

**EXAMPLES:**

```python
```
```python
sage: from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
sage: g = DynkinDiagram_class.an_instance()
sage: g
Dynkin diagram of rank 3
sage: g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.dynkin_diagram import DynkinDiagram_class
>>> g = DynkinDiagram_class.an_instance()
>>> g
Dynkin diagram of rank 3
>>> g.cartan_matrix()
[ 2 -1 -1]
[-2 2 -1]
[-1 -1 2]
```

cartan_matrix()

Returns the Cartan matrix for this Dynkin diagram

EXAMPLES:

```python
sage: DynkinDiagram(['C',3]).cartan_matrix()
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

```python
>>> from sage.all import *

>>> DynkinDiagram(['C',Integer(3)]).cartan_matrix()
[ 2 -1  0]
[-1  2 -2]
[ 0 -1  2]
```

cartan_type()

EXAMPLES:

```python
sage: DynkinDiagram("A2","B2","F4").cartan_type()
A2xB2xF4
```

```python
>>> from sage.all import *

>>> DynkinDiagram("A2","B2","F4").cartan_type()
A2xB2xF4
```

column(j)

Returns the $j^{th}$ column $(a_{ij})_i$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples $(i,a_{ij})$

EXAMPLES:

```python
sage: g = DynkinDiagram("B",4)
sage: [ (i,a) for (i,a) in g.column(3) ]
[(3, 2), (2, -1), (4, -2)]
```
```python
>>> from sage.all import *
>>> g = DynkinDiagram("B", 4)
>>> [(i,a) for (i,a) in g.column(3)]
[(3, 2), (2, -1), (4, -2)]
```

**coxeter_diagram()**

Construct the Coxeter diagram of self.

See also:

*CartanType_abstract.coxeter_diagram()*

**EXAMPLES:**

```python
sage: cm = CartanMatrix([[2, -5, 0], [-2, 2, -1], [0, -1, 2]])
sage: D = cm.dynkin_diagram()
sage: G = D.coxeter_diagram(); G
Graph on 3 vertices
[(0, 1, +Infinity), (1, 2, 3)]
sage: ct = CartanType(['A', 2, 2], ['B', 3])
sage: ct.coxeter_diagram()
Graph on 5 vertices
sage: ct.dynkin_diagram().coxeter_diagram() == ct.coxeter_diagram()
True
```

**dual()**

Returns the dual Dynkin diagram, obtained by reversing all edges.

**EXAMPLES:**

```python
sage: D = DynkinDiagram(['C', 3])
sage: D.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
sage: D.dual()
O---O=>=O
1 2 3
B3
tsage: D.dual().edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
sage: D.dual() == DynkinDiagram(['B', 3])
True
```
>>> from sage.all import *
>>> D = DynkinDiagram(["C",Integer(3)])
>>> D.edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 1), (3, 2, 2)]
>>> D.dual()
O---O=>=O
1 2 3
B3
>>> D.dual().edges(sort=True)
[(1, 2, 1), (2, 1, 1), (2, 3, 2), (3, 2, 1)]
>>> D.dual() == DynkinDiagram(["B",Integer(3)])
True

dynkin_diagram()
EXAMPLES:

sage: DynkinDiagram(["C",3]).dynkin_diagram()
O---O=<=O
1 2 3
C3

index_set()
EXAMPLES:

sage: DynkinDiagram(["C",3]).index_set()
(1, 2, 3)
sage: DynkinDiagram("A2","B2","F4").index_set()
(1, 2, 3, 4, 5, 6, 7, 8)

is_affine()
Check if self corresponds to an affine root system.

EXAMPLES:

sage: CartanType(["F",4]).dynkin_diagram().is_affine()
False
sage: D = DynkinDiagram(CartanMatrix([[2, -4], [-3, 2]]))
sage: D.is_affine()
False

(continues on next page)
is_crystallographic()

Implements CartanType_abstract.is_crystallographic()

A Dynkin diagram always corresponds to a crystallographic root system.

EXAMPLES:

```python
sage: CartanType(['F', 4]).dynkin_diagram().is_crystallographic()
True
```

```python
>>> from sage.all import *
```
True
>>> CM = CartanMatrix([[Integer(2),-Integer(6)],[Integer(4),Integer(2)]])
>>> CM.dynkin_diagram().is_irreducible()
True
>>> CartanType("A2xB3").dynkin_diagram().is_irreducible()
False
>>> CM = CartanMatrix([[Integer(2),-Integer(6),Integer(0)],[Integer(4),Integer(2),Integer(0)],[Integer(0),Integer(0),Integer(2)]])
>>> CM.dynkin_diagram().is_irreducible()
False

odd_isotropic_roots()

Return the odd isotropic roots of self.

EXAMPLES:

```python
sage: g = DynkinDiagram(['A',4])
sage: g.odd_isotropic_roots()
()  # empty set
sage: g = DynkinDiagram(['A',4,3])
sage: g.odd_isotropic_roots()
(0,)
```

```python
>>> from sage.all import *
```

```python
>>> g = DynkinDiagram(['A',Integer(4)])
>>> g.odd_isotropic_roots()
()  # empty set
>>> g = DynkinDiagram(['A',Integer(4),Integer(3)])
>>> g.odd_isotropic_roots()
(0,)
```

rank()

Returns the index set for this Dynkin diagram

EXAMPLES:

```python
sage: DynkinDiagram(['C',3]).rank()
3
sage: DynkinDiagram("A2","B2","F4").rank()
8
```

```python
>>> from sage.all import *
```

```python
>>> DynkinDiagram(['C',Integer(3)]).rank()
3
>>> DynkinDiagram("A2","B2","F4").rank()
8
```

relabel(*args, **kwds)

Return the relabelled Dynkin diagram of self.

INPUT: see relabel()

There is one difference: the default value for inplace is False instead of True.

EXAMPLES:
sage: D = DynkinDiagram(['C',3])
sage: D.relabel({1:0, 2:4, 3:1})
O---O<=O
  0 4  1
C3 relabelled by {1: 0, 2: 4, 3: 1}
sage: D
O---O<=O
  1 2  3
C3

sage: _ = D.relabel({1:0, 2:4, 3:1}, inplace=True)
sage: D
O---O<=O
  0 4  1
C3 relabelled by {1: 0, 2: 4, 3: 1}

sage: D = DynkinDiagram(['A', [1,2]])
sage: Dp = D.relabel({-1:4, 0:-3, 1:3, 2:2})
sage: Dp
O---X---O---O
  4 -3 3  2
A1|2 relabelled by {-1: 4, 0: -3, 1: 3, 2: 2}
sage: Dp.odd_isotropic_roots()
(-3,)

sage: D = DynkinDiagram(['D', 5])
sage: G, perm = D.relabel(range(5), return_map=True)
sage: G
O 4
|
O---O---O---O
  0 1 2  3
D5 relabelled by {1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
sage: perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}

sage: perm = D.relabel(range(5), return_map=True, inplace=True)
sage: D
O 4
|
O---O---O---O
  0 1 2  3
D5 relabelled by {1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
sage: perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}

>>> from sage.all import *
>>> D = DynkinDiagram(['C', Integer(3)])
>>> D.relabel({Integer(1):Integer(0), Integer(2):Integer(4),...
   Integer(3):Integer(1)})
O---O<=O
  0 4  1
C3 relabelled by {1: 0, 2: 4, 3: 1}
>>> D
O---O<=O
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
1 2 3
C3

>>> _ = D.relabel({Integer(1):Integer(0), Integer(2):Integer(4),
                Integer(3):Integer(1)}, inplace=True)
>>> D
 0---0<=0
0 4 1
C3 relabelled by {1: 0, 2: 4, 3: 1}

>>> D = DynkinDiagram(["A", [Integer(1),Integer(2)]]
>>> Dp = D.relabel({-Integer(1):Integer(4), Integer(0):-Integer(3),
                 Integer(1):Integer(3), Integer(2):Integer(2)})
>>> Dp
 0---X---O---O
4 -3 3 2
A1|2 relabelled by {-1: 4, 0: -3, 1: 3, 2: 2}

>>> Dp.odd_isotropic_roots()
(-3,)

>>> D = DynkinDiagram(["D", Integer(5)])
>>> G, perm = D.relabel(range(Integer(5)), return_map=True)
>>> G
O 4 |
 0---O---O---O
0 1 2 3
D5 relabelled by {1: 0, 2: 1, 3: 2, 4: 3, 5: 4}

>>> perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}

>>> perm = D.relabel(range(Integer(5)), return_map=True, inplace=True)
>>> D
O 4 |
 0---O---O---O
0 1 2 3
D5 relabelled by {1: 0, 2: 1, 3: 2, 4: 3, 5: 4}

>>> perm
{1: 0, 2: 1, 3: 2, 4: 3, 5: 4}
```

row(i)

Returns the $i^{th}$ row $(a_{i,j})$ of the Cartan matrix corresponding to this Dynkin diagram, as a container (or iterator) of tuples $(j, a_{i,j})$

EXAMPLES:

```python
sage: g = DynkinDiagram("C",4)

sage: [(i,a) for (i,a) in g.row(3) ]
[(3, 2), (2, -1), (4, -2)]

>>> from sage.all import *
>>> g = DynkinDiagram("C",Integer(4))
>>> [(i,a) for (i,a) in g.row(Integer(3)) ]
```
subtype \((\text{index\_set})\)

Return a subtype of \(\text{self}\) given by \(\text{index\_set}\).

A subtype can be considered the Dynkin diagram induced from the Dynkin diagram of \(\text{self}\) by \(\text{index\_set}\).

**EXAMPLES:**

```python
sage: D = DynkinDiagram(['A',6,2]); D
O=<=O---O=<=O
0 1 2 3
BC3~
sage: D.subtype([1,2,3])
Dynkin diagram of rank 3
```

**symmetrizer()**

Return the symmetrizer of the corresponding Cartan matrix.

**EXAMPLES:**

```python
sage: d = DynkinDiagram()
sage: d.add_edge(1,2,3)
sage: d.add_edge(2,3)
sage: d.add_edge(3,4,3)
sage: d.symmetrizer()
Finite family {1: 9, 2: 3, 3: 3, 4: 1}
```

```python
>>> from sage.all import *

>>> D = DynkinDiagram(['A',Integer(6),Integer(2)]); D
O=<=O---O=<=O
0 1 2 3
BC3~
>>> D.subtype([Integer(1),Integer(2),Integer(3)])
Dynkin diagram of rank 3
```

```python
sage: from sage.combinat.root_system.dynkin_diagram import precheck

sage: ct = CartanType(['A',4])
sage: precheck(ct, letter='C')
Traceback (most recent call last):
  ...
ValueError: t[0] must be = 'C'
sage: precheck(ct, affine=1)
```

(continues on next page)
>>> from sage.all import *
>>> from sage.combinat.root_system.dynkin_diagram import precheck
>>> ct = CartanType(['A', Integer(4)])
>>> precheck(ct, letter='C')
Traceback (most recent call last):
  ... ValueError: t[0] must be = 'C'
>>> precheck(ct, affine=Integer(1))
Traceback (most recent call last):
  ... ValueError: t[2] must be = 1
>>> precheck(ct, length=Integer(3))
Traceback (most recent call last):
  ... ValueError: len(t) must be = 3
>>> precheck(ct, n=Integer(3))
Traceback (most recent call last):
  ... ValueError: t[1] must be = 3
>>> precheck(ct, n_ge=Integer(5))
Traceback (most recent call last):
  ... ValueError: t[1] must be >= 5

5.1.231 Hecke algebra representations

class sage.combinat.root_system.hecke_algebra_representation.CherednikOperatorsEigenvectors:

    Bases: UniqueRepresentation, SageObject

    A class for the family of eigenvectors of the $Y$ Cherednik operators for a module over a (Double) Affine Hecke algebra

    INPUT:

    - $T$ – a family $(T_i)_{i \in I}$ implementing the action of the generators of an affine Hecke algebra on $self$. The
intertwiner operators are built from these.

- \( T_Y \) – a family \((T^Y_i)_{i \in I}\) implementing the action of the generators of an affine Hecke algebra on \( \text{self} \). By default, this is \( T \). But this can be used to get the action of the full Double Affine Hecke Algebra. The \( Y \) operators are built from the \( T_Y \).

This returns a function \( \mu \mapsto E_\mu \) which uses intertwining operators to calculate recursively eigenvectors \( E_\mu \) for the action of the torus of the affine Hecke algebra with eigenvalue given by \( f \). Namely:

\[
E_\mu . Y^{\lambda^\vee} = f(\lambda^\vee, \mu) E_\mu
\]

Assumptions:

- \( \text{seed}(\mu) \) initializes the recurrence by returning an appropriate eigenvector \( E_\mu \) for \( \mu \) trivial enough. For example, for nonsymmetric Macdonald polynomials \( \text{seed}(\mu) \) returns the monomial \( X^\mu \) for a minuscule weight \( \mu \).
- \( f \) is almost equivariant. Namely, \( f(\lambda^\vee, \mu) = f(\lambda^\vee s_i, \text{twist}(\mu, i)) \) whenever \( i \) is a descent of \( \mu \).
- \( \text{twist}(\mu, i) \) maps \( \mu \) closer to the dominant chamber whenever \( i \) is a descent of \( \mu \).

Todo: Add tests for the above assumptions, and also that the classical operators \( T_1, \ldots, T_n \) from \( T \) and \( T_Y \) coincide.

\( Y() \)

Return the Cherednik operators.

**EXAMPLES:**

```python
sage: W = WeylGroup(['B',2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.Y()
Lazy family (...)_{i in Coroot lattice of the Root system of type ['B', 2, 1]}
```

**affine_lift(\( \mu \))**

Lift the index \( \mu \) to a space admitting an action of the affine Weyl group.

**INPUT:**

- \( \mu \) – an element \( \mu \) of the indexing set

In this space, one should have \( \text{first_descent} \) and \( \text{apply_simple_reflection} \) act properly.

**EXAMPLES:**
sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_=lambda x: ".join(str(i) for i in x.reduced_word())
sage: K = QQ["q1,q2"]
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_lift(w)
121

>>> from sage.all import *

>>> W = WeylGroup(["A",Integer(3)])
>>> W.element_class._repr_=lambda x: ".join(str(i) for i in x.reduced_word())
>>> K = QQ["q1,q2"]
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> E = KW.demazure_lusztig_eigenvectors(q1, q2)
>>> w = W.an_element(); w
123
>>> E.affine_lift(w)
121

affine_retract(\( \mu \))
Retract \( \mu \) from a space admitting an action of the affine Weyl group.

EXAMPLES:

sage: W = WeylGroup(["A",3])
sage: W.element_class._repr_=lambda x: ".join(str(i) for i in x.reduced_word())
sage: K = QQ["q1,q2"]
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w = W.an_element(); w
123
sage: E.affine_retract(E.affine_lift(w)) == w
True

>>> from sage.all import *

>>> W = WeylGroup(["A",Integer(3)])
>>> W.element_class._repr_=lambda x: ".join(str(i) for i in x.reduced_word())
>>> K = QQ["q1,q2"]
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> E = KW.demazure_lusztig_eigenvectors(q1, q2)
>>> w = W.an_element(); w
123
>>> E.affine_retract(E.affine_lift(w)) == w
True

cartan_type()
Return Cartan type of self.

EXAMPLES:
domain()

The module on which the affine Hecke algebra acts.

EXAMPLES:

```
sage: W = WeylGroup("B", 3)
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: E.domain()  
Algebra of Weyl Group of type [B, 3]  
(as a matrix group acting on the ambient space)  
over Multivariate Polynomial Ring in q1, q2 over Rational Field
```

```
>>> from sage.all import *
>>> W = WeylGroup("B", Integer(3))
>>> K = QQ['q1,q2']
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> E = KW.demazure_lusztig_eigenvectors(q1, q2)
>>> E.domain()  
Algebra of Weyl Group of type ['B', 3]  
(as a matrix group acting on the ambient space)  
over Multivariate Polynomial Ring in q1, q2 over Rational Field
```

eigenvalue(\(\mu, l\))

Return the eigenvalue of \(Y_\lambda^\nu\) on \(E_\mu\) computed by applying \(Y_\lambda^\nu\) on \(E_\mu\).

INPUT:

- \(\mu\) – the index \(\mu\) of an eigenvector, or a tentative eigenvector
• $l$ – the index $\lambda^Y$ of a Cherednik operator in \texttt{self.Y_index_set()}

This default implementation applies explicitly $Y_\mu$ to $E_\lambda$.

EXAMPLES:

```python
sage: W = WeylGroup("B",2)
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: Y = E.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: E.eigenvalue(w0, alphacheck[1])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[2])
q1/(-q2)
sage: E.eigenvalue(w0, alphacheck[0])
q2^2/q1^2
```

The following checks that all $E_w$ are eigenvectors, with eigenvalue given by Lemma 7.5 of \cite{HST2008} (checked for $A_2, A_3$):

```python
sage: Pcheck = Y.keys()
sage: Wcheck = Pcheck.weyl_group()
sage: P0check = Pcheck.classical()
sage: def height(root):
.....    return sum(P0check(root).coefficients())
sage: def eigenvalue(w, mu):
.....    return (-q2/q1)**height(Wcheck.from_reduced_word(w.reduced_word()).
->action(mu))
sage: all(E.eigenvalue(w, a) == eigenvalue(w, a) \texttt{for w in E.keys()} \texttt{for a in Y.}
->keys().simple_roots()) # long time (2.5s)
True
```

```python
>>> from sage.all import *
>>> W = WeylGroup("B",Integer(2))
>>> K = QQ['q1,q2'].fraction_field()
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> E = KW.demazure_lusztig_eigenvectors(q1, q2)
>>> w0 = W.long_element()
>>> Y = E.Y()
>>> alphacheck = Y.keys().simple_roots()
>>> E.eigenvalue(w0, alphacheck[Integer(1)])
q1/(-q2)
>>> E.eigenvalue(w0, alphacheck[Integer(2)])
q1/(-q2)
>>> E.eigenvalue(w0, alphacheck[Integer(0)])
q2^2/q1^2
```

(continues on next page)
**eigenvalues** \((\mu)\)

Return the eigenvalues of \(Y_{\alpha_0}, \ldots, Y_{\alpha_n}\) on \(E_{\mu}\).

**INPUT:**

- \(\mu\) – the index \(\mu\) of an eigenvector or a tentative eigenvector

**EXAMPLES:**

```python
sage: W = WeylGroup(["B",2])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: E.eigenvalues(w0)
[q2^2/q1^2, q1/(-q2), q1/(-q2)]
```

```python
>>> from sage.all import *
```

```python
sage: W = WeylGroup(["B",Integer(2)])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)
sage: w0 = W.long_element()
sage: E.eigenvalues(w0)
[q2^2/q1^2, q1/(-q2), q1/(-q2)]
```

**hecke_parameters** \((i)\)

Return the Hecke parameters for index \(i\).

**EXAMPLES:**

```python
sage: W = WeylGroup(["B",3])
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: E.hecke_parameters(1)
(q1, q2)
sage: E.hecke_parameters(2)
(q1, q2)
```

(continues on next page)
sage: E.hecke_parameters(0)
(q1, q2)

>>> from sage.all import *

>>> W = WeylGroup(['B', Integer(3)])
>>> K = QQ['q1,q2']
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> T = KW.demazure_lusztig_operators(q1, q2, affine=True)
>>> E = T.Y_eigenvectors()
>>> E.hecke_parameters(Integer(1))
(q1, q2)
>>> E.hecke_parameters(Integer(2))
(q1, q2)
>>> E.hecke_parameters(Integer(0))
(q1, q2)

keys()

The index set for the eigenvectors.

By default, this assumes that the eigenvectors span the full affine Hecke algebra module and that the eigenvectors have the same indexing as the basis of this module.

EXAMPLES:

```sage
W = WeylGroup(['A', 3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
KW = W.algebra(K)
E = KW.demazure_lusztig_eigenvectors(q1, q2)
E.keys()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
```

recession($\mu$)

Return the indices used in the recursion.

INPUT:

- $\mu$ – the index $\mu$ of an eigenvector

EXAMPLES:

```sage
W = WeylGroup(['A', 3])
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
KW = W.algebra(K)
E = KW.demazure_lusztig_eigenvectors(q1, q2)
E.recession()
Weyl Group of type ['A', 3] (as a matrix group acting on the ambient space)
```
seed \( (\mu) \)

Return the eigenvector for \( \mu \) minuscule.

**INPUT:**

- \( \mu \) – an element \( \mu \) of the indexing set

**OUTPUT:** an element of \( T.\text{domain()} \)

This default implementation returns the monomial indexed by \( \mu \).

**EXAMPLES:**

```python
sage: W = WeylGroup(['A',3])

sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())

sage: K = QQ[q1,q2].fraction_field()

sage: q1, q2 = K.gens()

sage: KW = W.algebra(K)

sage: E = KW.demazure_lusztig_eigenvectors(q1, q2)

sage: E.seed(W.long_element())
[1, 2, 1]
```
**twist** *(\(\mu, i\))*

Act by \(s_i\) on \(\mu\).

By default, this calls the method `apply_simple_reflection`.

**EXAMPLES:**

```python
sage: W = WeylGroup(['B',3])
sage: W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ[ 'q1', 'q2' ]
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: T = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = T.Y_eigenvectors()
sage: w = W.an_element(); w
123
sage: E.twist(w,1)
1231
```

```python
>>> from sage.all import *
>>> W = WeylGroup(['B',Integer(3)])
>>> W.element_class._repr_=lambda x: ''.join(str(i) for i in x.reduced_word())
>>> K = QQ[ 'q1', 'q2' ]
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> T = KW.demazure_lusztig_operators(q1, q2, affine=True)
>>> E = T.Y_eigenvectors()
>>> w = W.an_element(); w
123
>>> E.twist(w,Integer(1))
1231
```
- `cartan_type` – The Cartan type of the Hecke algebra
- `q1, q2` – The eigenvalues of the generators $T$ of the Hecke algebra
- `side` – “left” or “right” (default: “right”) whether this is a left or right representation

**EXAMPLES:**

```python
sage: K = QQ[\{'q1',\'q2\}].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup([\"A\",3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2); H
A representation of the \((q_1, q_2)\)-Hecke algebra of type [\"A\", 3, 1] on Algebra of Weyl Group of type [\"A\", 3]
(as a matrix group acting on the ambient space) over Rational Field
```

Among other things, it implements the $T_{w}$ operators, their inverses and compositions thereof:

```python
>>> from sage.all import *
>>> K = QQ[\{'q1',\'q2\}].fraction_field()
>>> q1, q2 = K.gens()
>>> KW = WeylGroup([\"A\",Integer(3)]).algebra(QQ)
>>> H = KW.demazure_lusztig_operators(q1,q2); H
A representation of the \((q_1, q_2)\)-Hecke algebra of type [\"A\", 3, 1] on Algebra of Weyl Group of type [\"A\", 3]
(as a matrix group acting on the ambient space) over Rational Field
```

and the Cherednik operators $Y_{\nu}$:

```python
sage: H.Y()
```

```python
>>> from sage.all import *
>>> H.Y()
```

**REFERENCES:**

- [HST2008]

**`Ti_inverse_on_basis`(x, i)**

The $T_{i}^{-1}$ operators, on basis elements

**INPUT:**

- `x` – the index of a basis element
- `i` – the index of a generator
EXAMPLES:

```python
sage: W = WeylGroup("A3")
```
```python
sage: W.element_class._repr_ = lambda x: 
"".join(str(i) for i in x.reduced_word())
```
```python
sage: K = QQ['q1, q2'].fraction_field()
```
```python
sage: q1, q2 = K.gens()
```
```python
sage: KW = W.algebra(K)
```
```python
sage: rho = KW.demazure_lusztig_operators(q1,q2)
```
```python
sage: w = W.an_element()
```
```python
sage: rho.Ti_inverse_on_basis(w, 1)
```
```python
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
```

```python
>>> from sage.all import *
```
```python
>>> W = WeylGroup("A3")
```
```python
>>> W.element_class._repr_ = lambda x: 
"".join(str(i) for i in x.reduced_word())
```
```python
>>> K = QQ['q1, q2'].fraction_field()
```
```python
>>> q1, q2 = K.gens()
```
```python
>>> KW = W.algebra(K)
```
```python
>>> rho = KW.demazure_lusztig_operators(q1,q2)
```
```python
>>> w = W.an_element()
```
```python
>>> rho.Ti_inverse_on_basis(w, Integer(1))
```
```python
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
```

`Ti_on_basis` *(x, i)*

The $T_i$ operators, on basis elements.

**INPUT:**

- x – the index of a basis element
- i – the index of a generator

**EXAMPLES:**

```python
sage: W = WeylGroup("A3")
```
```python
sage: W.element_class._repr_ = lambda x: 
"".join(str(i) for i in x.reduced_word())
```
```python
sage: K = QQ['q1, q2'].fraction_field()
```
```python
sage: q1, q2 = K.gens()
```
```python
sage: KW = W.algebra(K)
```
```python
sage: rho = KW.demazure_lusztig_operators(q1,q2)
```
```python
sage: w = W.an_element()
```
```python
sage: rho.Ti_on_basis(w,1)
```
```python
q1*1231
```

```python
>>> from sage.all import *
```
```python
>>> W = WeylGroup("A3")
```
```python
>>> W.element_class._repr_ = lambda x: 
"".join(str(i) for i in x.reduced_word())
```
```python
>>> K = QQ['q1, q2'].fraction_field()
```
```python
>>> q1, q2 = K.gens()
```
```python
>>> KW = W.algebra(K)
```
```python
>>> rho = KW.demazure_lusztig_operators(q1,q2)
```
```python
>>> w = W.an_element()
```
```python
>>> rho.Ti_on_basis(w,Integer(1))
```
```python
q1*1231
```

`Tw` *(word, signs=None, scalar=None)*

Return $T_w$.  

5.1. Comprehensive Module List
INPUT:

- **word** — a word $i_1, \ldots, i_k$ for some element $w$ of the Weyl group. See `straighten_word()` for how this word can be specified.
- **signs** — a list $\epsilon_1, \ldots, \epsilon_k$ of the same length as word with $\epsilon_i = \pm 1$ or None for $1, \ldots, 1$ (default: None)
- **scalar** — an element $c$ of the base ring or None for 1 (default: None)

OUTPUT:

a module morphism implementing

$$T_w = T_{i_k} \circ \cdots \circ T_{i_1}$$

in left action notation; that is $T_{i_1}$ is applied first, then $T_{i_2}$, etc.

More generally, if **scalar** or **signs** is specified, the morphism implements

$$cT_{i_k}^{\epsilon_k} \circ \cdots \circ T_{i_1}^{\epsilon_1}.$$
>>> from sage.all import *
>>> T[Integer(2)](T[Integer(1)](KW.one()))
q1^2*12
>>> T[Integer(1)](T[Integer(2)](KW.one()))
q1^2*21
>>> T12(x) == T[Integer(2)](T[Integer(1)](x))
True

Now with signs and scalar coefficient we construct $3T_2 \circ T_1^{-1}$:

```
sage: phi = T.Tw((1,2), (-1,1), 3)
sage: phi(KW.one())
((-3*q1)/q2)*12 + ((3*q1+3*q2)/q2)*2
sage: phi(T[1](x)) == 3*T[2](x)
True
```

```
>>> from sage.all import *
>>> phi = T.Tw((Integer(1),Integer(2)), (-Integer(1),Integer(1)), Integer(3))
>>> phi(KW.one())
((-3*q1)/q2)*12 + ((3*q1+3*q2)/q2)*2
>>> phi(T[Integer(1)](x)) == Integer(3)*T[Integer(2)](x)
True
```

For debugging purposes, one can recover the input data:

```
sage: phi.word
(1, 2)
sage: phi.signs
(-1, 1)
sage: phi.scalar
3
```

```
>>> from sage.all import *
>>> phi.word
(1, 2)
>>> phi.signs
(-1, 1)
>>> phi.scalar
3
```

Tw_inverse(word)

Return $T_w^{-1}$.

This is essentially a shorthand for $Tw()$ with all minus signs.

Todo: Add an example where $T_i \neq T_i^{-1}$

EXAMPLES:

```
sage: W = WeylGroup("A", 3)
sage: W.element_class._repr_ = lambda x: "".join(str(i) for i in x.reduced_word())
sage: KW = W.algebra(QQ)
sage: rho = KW.demazure_lusztig_operators(1, -1)
sage: x = KW.monomial(W.an_element()); x
```

(continues on next page)
sage: word = [1, 2]
sage: rho.Tw(word)(x)
sage: rho.Tw_inverse(word)(x)

sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2)
sage: x = KW.monomial(W.an_element()); x
123

sage: rho.Tw_inverse(word)(x)
1/q2^2*12321 + ((-q1-q2)/(q1*q2^2))*1231 + ((-q1-q2)/(q1*q2^2))*1232
+ ((q1^2+2*q1*q2+q2^2)/(q1^2*q2^2))*123

sage: rho.Tw(word)(_)
123

```python
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(3)])
>>> W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
>>> KW = W.algebra(QQ)
>>> rho = KW.demazure_lusztig_operators(Integer(1), -Integer(1))
>>> x = KW.monomial(W.an_element()); x
123
>>> word = [Integer(1),Integer(2)]
>>> rho.Tw(word)(x)
12312
>>> rho.Tw_inverse(word)(x)
12321

Y (base_ring=Integer Ring)

Return the Cherednik operators $Y$ for this representation of an affine Hecke algebra.

INPUT:

- self -- a representation of an affine Hecke algebra
- base_ring -- the base ring of the coroot lattice

This is a family of operators indexed by the coroot lattice for this Cartan type. In practice this is currently indexed instead by the affine coroot lattice, even if this indexing is not one to one, in order to allow for $Y[\alpha_i^\vee]$.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: W = WeylGroup(["A",3])
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: Y = rho.Y(); Y
Lazy family (...(i))_{i in Coroot lattice of the Root system of type [\'A\', 3,\rightarrow 1]}  
>>> from sage.all import *
>>> W = WeylGroup(["A",Integer(3)])
>>> K = QQ['q1,q2'].fraction_field()
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> rho = KW.demazure_lusztig_operators(q2, q1)
>>> Y = rho.Y(); Y
Lazy family (...(i))_{i in Coroot lattice of the Root system of type [\'A\', 3,\rightarrow 1]}
```

**Y_eigenvectors()**

Return the family of eigenvectors for the Cherednik operators $Y$ of this representation of an affine Hecke algebra.

**INPUT:**

- `self` – a representation of an affine Hecke algebra
- `base_ring` – the base ring of the coroot lattice

**EXAMPLES:**

```python
sage: W = WeylGroup(["B",2])
sage: W.element_class._repr_ = lambda x: "".join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1, q2, affine=True)
sage: E = rho.Y_eigenvectors()
sage: E.keys()
Weyl Group of type [\'B\', 2] (as a matrix group acting on the ambient space)
sage: w0 = W.long_element()
```

```python
>>> from sage.all import *
>>> W = WeylGroup(["B",Integer(2)])
>>> W.element_class._repr_ = lambda x: "".join(str(i) for i in x.reduced_word())
>>> K = QQ['q1,q2'].fraction_field()
>>> q1, q2 = K.gens()
>>> KW = W.algebra(K)
>>> rho = KW.demazure_lusztig_operators(q1, q2, affine=True)
>>> E = rho.Y_eigenvectors()
>>> E.keys()
Weyl Group of type [\'B\', 2] (as a matrix group acting on the ambient space)
>>> w0 = W.long_element()
```

To set the recurrence up properly, one often needs to customize the `CherednikOperatorsEigenvectors.affine_lift()` and `CherednikOperatorsEigenvectors.affine_retract()` methods. This would usually...
be done by subclassing \texttt{CherednikOperatorsEigenvectors}; here we just override the methods directly.

In this particular case, we multiply by \( w_0 \) to take into account that \( w_0 \) is the seed for the recursion:

\begin{verbatim}
sage: E.affine_lift = w0._mul_
sage: E.affine_retract = w0._mul_
sage: E[w0] 2121 sage: E.eigenvalues(E[w0]) [q2^2/q1^2, q1/(-q2), q1/(-q2)]
\end{verbatim}

This step is taken care of automatically if one instead calls the specialization \texttt{sage.coxeter_groups.CoxeterGroups.Algebras.demazure_lusztig_eigenvectors()}. Now we can compute all eigenvectors:

\begin{verbatim}
sage: [E[w] for w in W] [2121 - 121 - 212 + 12 + 21 - 1 - 2 + , -2121 + 212, (q2/(q1-q2))*2121 + (q2/(-q1+q2))*121 + (q2/(-q1+q2))*212 - 12 + ((-q2)/(-q1+q2))*21 + 2, ((-q2^2)/(q1^2-q1*q2+q2^2))*2121 - 121 + (q2^2/(-q1^2+q1*q2-q2^2))*212 + 21, ((-q1^2-q2^2)/(q1^2-q1*q2+q2^2))*2121 + ((-q1^2-q2^2)/(-q1^2+q1*q2-q2^2))*121 + ((-q2^2)/(-q1^2-q2^2))*212 - 12 + ((-q2^2)/(-q1^2-q2^2))*121 + ((-q2^2)/(-q1^2-q2^2))*121 - 21 + ,
˓→1, 2121, (q2/(-q1+q2))*2121 + ((-q2)/(-q1+q2))*121 - 212 + 12, -2121 + 1212]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> [E[w] for w in W] [2121 - 121 - 212 + 12 + 21 - 1 - 2 + , -2121 + 212, (q2/(q1-q2))*2121 + (q2/(-q1+q2))*121 + (q2/(-q1+q2))*212 - 12 + ((-q2)/(-q1+q2))*21 + 2, ((-q2^2)/(q1^2-q1*q2+q2^2))*2121 - 121 + (q2^2/(-q1^2+q1*q2-q2^2))*212 + 21, ((-q1^2-q2^2)/(q1^2-q1*q2+q2^2))*2121 + ((-q1^2-q2^2)/(-q1^2+q1*q2-q2^2))*121 + ((-q2^2)/(-q1^2-q2^2))*212 - 12 + ((-q2^2)/(-q1^2-q2^2))*121 + ((-q2^2)/(-q1^2-q2^2))*121 - 21 + ,
˓→1, 2121, (q2/(-q1+q2))*2121 + ((-q2)/(-q1+q2))*121 - 212 + 12, -2121 + 1212]
\end{verbatim}

\texttt{Y_lambdacheck (lambdacheck)}

Return the Cherednik operators \( Y^\lambda \) for this representation of an affine Hecke algebra.

INPUT:
• **lambdacheck** – an element of the coroot lattice for this Cartan type

**EXAMPLES:**

```
sage: N = WeylGroup(['B',2])
sage: N.element_class._repr_lambdacheck x: '

   join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
```  

We take $q_2$ and $q_1$ as eigenvalues to match with the notations of [HST2008]

```
sage: rho = KW.demazure_lusztig_operators(q2, q1)
sage: L = rho.Y().keys()
sage: alpha = L.simple_roots()
sage: Y0 = rho.Y_lambdacheck(alpha[0])
sage: Y1 = rho.Y_lambdacheck(alpha[1])
sage: Y2 = rho.Y_lambdacheck(alpha[2])
```

```
sage: x = KW.monomial(W.an_element()); x
12
sage: Y1(x)
((-q1^2-2*q1*q2-q2^2)/(-q2^2))*2121
+ ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1*q2^2))*121
+ ((q1^2+q1*q2)/(-q2^2))*212 + ((-q1^2)/(-q2^2))*12
```

```
sage: Y2(x)
((-q1^4-q1^3*q2-q1*q2^3-q2^4)/(-q1^3*q2))*2121
+ ((q1^3+q1^2*q2+q1*q2^2+q2^3)/(-q1^2*q2))*121 + (q2^3/(-q1^3))*12
```

(continues on next page)
The $Y$ operators commute:

```python
sage: Y0(Y1(x)) - Y1(Y0(x))
0
sage: Y2(Y1(x)) - Y1(Y2(x))
0
```

In the classical root lattice, $\alpha_0 + \alpha_1 + \alpha_2 = 0$:

```python
sage: Y0(Y1(Y2(x)))
12
```

Lemma 7.2 of [HST2008]:

```python
sage: w0 = KW.monomial(W.long_element())
sage: rho.Tw(0)(w0)
q2
sage: rho.Tw_inverse(1)(w0)
1/q2*212
sage: rho.Tw_inverse(2)(w0)
1/q2*121
```

Lemma 7.5 of [HST2008]:

```python
sage: Y0(w0)
q1^2/q2^2*2121
sage: Y1(w0)
(q2/(-q1))*2121
sage: Y2(w0)
(q2/(-q1))*2121
```
Todo: Add more tests

Add tests in type BC affine where the null coroot $\delta^\vee$ can have non trivial coefficient in term of $\alpha_0$

See also:

- [HST2008] for the formula in terms of $q_1, q_2$

**cartan_type()**

Return the Cartan type of self.

**EXAMPLES:**

```sage
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation
sage: KW = SymmetricGroup(3).algebra(QQ)
sage: action = lambda x,i: KW.monomial(x.apply_simple_reflection(i, side='right'))
sage: H = HeckeAlgebraRepresentation(KW, action, CartanType(['A',2]), 1, -1)
sage: H.cartan_type()
['A', 2]
sage: H = WeylGroup(['A',3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.cartan_type()
['A', 3, 1]
```

**domain()**

Return the domain of self.

**EXAMPLES:**

```sage
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation
sage: KW = SymmetricGroup(Integer(3)).algebra(QQ)
sage: action = lambda x,i: KW.monomial(x.apply_simple_reflection(i, side='right'))
sage: H = HeckeAlgebraRepresentation(KW, action, CartanType(['A',Integer(2)]), -Integer(1), Integer(1))
sage: H.cartan_type()
['A', 2]
sage: H = WeylGroup(['A',Integer(3)]).algebra(QQ).demazure_lusztig_operators(-Integer(1),Integer(1))
sage: H.cartan_type()
['A', 3, 1]
```
```python
sage: H = WeylGroup(['A', 3]).algebra(QQ).demazure_lusztig_operators(-1,1)
sage: H.domain()
Algebra of Weyl Group of type ['A', 3] (as a matrix group
acting on the ambient space) over Rational Field

>>> from sage.all import *
>>> H = WeylGroup(['A', Integer(3)]).algebra(QQ).demazure_lusztig_operators(-Integer(1),Integer(1))
>>> H.domain()
Algebra of Weyl Group of type ['A', 3] (as a matrix group
acting on the ambient space) over Rational Field
```

```python
on_basis(x, word, signs=None, scalar=None)

Action of product of $T_i$ and $T_i^{-1}$ on $x$.

INPUT:

- $x$ – the index of a basis element
- $word$ – word of indices of generators
- $signs$ – (default: None) sequence of signs of same length as $word$; determines which operators are supposed to be taken as inverses.
- $scalar$ – (default: None) scalar to multiply the answer by

EXAMPLES:
```
sage: from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation

sage: W = SymmetricGroup(3)
sage: domain = W.algebra(QQ)
sage: action = lambda x,i: domain.monomial(x.apply_simple_reflection(i, side='right'))
sage: rho = HeckeAlgebraRepresentation(domain, action, CartanType(['A',2]), 1, -1)
sage: rho.on_basis(W.one(), (1,2,1))
(1,3)
sage: word = (1,2)
sage: u = W.from_reduced_word(word)
sage: for w in W:
    assert rho.on_basis(w, word) == domain.monomial(w*u)
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.hecke_algebra_representation import HeckeAlgebraRepresentation

>>> W = SymmetricGroup(Integer(3))
>>> domain = W.algebra(QQ)
>>> action = lambda x,i: domain.monomial(x.apply_simple_reflection(i, side='right'))
>>> rho = HeckeAlgebraRepresentation(domain, action, CartanType(['A', Integer(2)]), Integer(1), -Integer(1))

>>> rho.on_basis(W.one(), (Integer(1),Integer(2),Integer(1)))
(1,3)

>>> word = (Integer(1),Integer(2))
```
(continues on next page)
The next example tests the signs:

```python
sage: W = WeylGroup("A3")
sage: W.element_class._repr_ = lambda x: ''.join(str(i) for i in x.reduced_word())
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = W.algebra(K)
sage: rho = KW.demazure_lusztig_operators(q1,q2)
sage: w = W.an_element(); w
123
sage: rho.on_basis(w, (1,), signs=(-1,))
-1/q2*1231 + ((q1+q2)/(q1*q2))*123
sage: rho.on_basis(w, (1,), signs=(1,))
q1*1231
sage: rho.on_basis(w, (1,1), signs=(1,-1))
123
sage: rho.on_basis(w, (1,1), signs=(-1,1))
123
```

**parameters (i)**

Return $q_1, q_2$ such that $(T_i - q_1)(T_i - q_2) = 0$.

**EXAMPLES:**

```python
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KW = WeylGroup(['A',3]).algebra(QQ)
sage: H = KW.demazure_lusztig_operators(q1,q2)
sage: H.parameters(1)
(1, q2)
sage: H = KW.demazure_lusztig_operators(1,-1)
sage: H.parameters(1)
(1, -1)
```
Todo: At this point, this method is constant. It’s meant as a starting point for implementing parameters depending on the node $i$ of the Dynkin diagram.

**straighten_word** *(word)*
Return a tuple of indices of generators after some straightening.

**INPUT:**
- *word* – a list/tuple of indices of generators, the index of a generator, or an object with a reduced word method

**OUTPUT:** a tuple of indices of generators

**EXAMPLES:**

```python
sage: W = WeylGroup("A", 3)
sage: H = W.algebra(QQ).demazure_lusztig_operators(-1, 1)
sage: H.straighten_word(1)
(1,)
sage: H.straighten_word((2, 1))
(2, 1)
sage: H.straighten_word([2, 1])
(2, 1)
sage: H.straighten_word(W.an_element())
(1, 2, 3)
```
5.1.232 Integrable Representations of Affine Lie Algebras

class sage.combinat.root_system.integrable_representations.IntegrableRepresentation(Lam)

Bases: UniqueRepresentation, CategoryObject

An irreducible integrable highest weight representation of an affine Lie algebra.

INPUT:

- Lam – a dominant weight in an extended weight lattice of affine type

REFERENCES:

- [Ka1990]

If \( \Lambda \) is a dominant integral weight for an affine root system, there exists a unique integrable representation \( V = V_\Lambda \) of highest weight \( \Lambda \). If \( \mu \) is another weight, let \( m(\mu) \) denote the multiplicity of the weight \( \mu \) in this representation. The set \( \text{supp}(V) \) of \( \mu \) such that \( m(\mu) > 0 \) is contained in the paraboloid

\[
(L + \rho|L + \rho) - (\mu + \rho|\mu + \rho) \geq 0
\]

where \( (\cdot|\cdot) \) is the invariant inner product on the weight lattice and \( \rho \) is the Weyl vector. Moreover if \( m(\mu) > 0 \) then \( \mu \in \text{supp}(V) \) differs from \( \Lambda \) by an element of the root lattice ([Ka1990], Propositions 11.3 and 11.4).

Let \( \delta \) be the nullroot, which is the lowest positive imaginary root. Then by [Ka1990], Proposition 11.3 or Corollary 11.9, for fixed \( \mu \) the function \( m(\mu - k\delta) \) is a monotone increasing function of \( k \). It is useful to take \( \mu \) to be such that this function is nonzero if and only if \( k \geq 0 \). Therefore we make the following definition. If \( \mu \) is such that \( m(\mu) \neq 0 \) but \( m(\mu + \delta) = 0 \) then \( \mu \) is called maximal.

Since \( \delta \) is fixed under the action of the affine Weyl group, and since the weight multiplicities are Weyl group invariant, the function \( k \mapsto m(\mu - k\delta) \) is unchanged if \( \mu \) is replaced by an equivalent weight. Therefore in tabulating these functions, we may assume that \( \mu \) is dominant. There are only a finite number of dominant maximal weights.

Since every nonzero weight multiplicity appears in the string \( \mu - k\delta \) for one of the finite number of dominant maximal weights \( \mu \), it is important to be able to compute these. We may do this as follows.

EXAMPLES:

```python
sage: Lambda = RootSystem(['A',3,1]).weight_lattice(extended=True).fundamental_weights()
2*Lambda[0] + Lambda[2]: 4 31 161 665 2381 63121 166085 417295 1007601
\rightarrow 2349655
Lambda[0] + 2*Lambda[1]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884
\rightarrow 1779570
Lambda[0] + 2*Lambda[3]: 2 18 99 430 1593 5274 16005 45324 121200 308829 754884
\rightarrow 1779570
\rightarrow 56390 1343178
3*Lambda[2] - delta: 3 21 107 450 1638 5367 16194 45687 121876 310056 757056
\rightarrow 178324
sage: Lambda = RootSystem(['D',4,1]).weight_lattice(extended=True).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+Lambda[1]).print_strings()...
\rightarrow # long time
Lambda[0] + Lambda[1]: 1 10 62 293 1165 4097 13120 38997 109036 289575 735870
\rightarrow 1799620
\rightarrow 1155717 2777795
```
In this example, we construct the extended weight lattice of Cartan type $A_3^{(1)}$, then define $\Lambda$ to be the fundamental weights $(\Lambda_i)_{i \in I}$. We find there are 5 maximal dominant weights in irreducible representation of highest weight $\Lambda_1 + \Lambda_2 + \Lambda_3$, and we determine their strings.

It was shown in [KacPeterson] that each string is the set of Fourier coefficients of a modular form. Every weight $\mu$ such that the weight multiplicity $m(\mu)$ is nonzero has the form

$$\Lambda - n_0 \alpha_0 - n_1 \alpha_1 - \cdots,$$

where the $n_i$ are nonnegative integers. This is represented internally as a tuple $(n_0, n_1, n_2, \ldots)$. If you want an individual multiplicity you use the method $m()$ and supply it with this tuple:

```
sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0]); V
Integrable representation of [C, 2, 1] with highest weight 2*Lambda[0]
sage: V.m((3,5,3))
18
```

The `IntegrableRepresentation` class has methods `to_weight()` and `from_weight()` to convert between this internal representation and the weight lattice:

```
```
sage: delta = V.weight_lattice().null_root()
sage: V.to_weight((4,3,2))
(4, 3, 2)

To get more values, use the depth parameter:

sage: L0 = RootSystem(['A',1,1]).weight_lattice(extended=true).fundamental_weight(0); L0
Lambda[0]
sage: IntegrableRepresentation(4*L0).print_strings(depth=20)
4*Lambda[0]: 1 1 3 6 13 23 44 75 131 215 354 561 889 1368 2097 3153 4712 6936 10151 14677

An example in type $C_2^{(1)}$:.

sage: Lambda = RootSystem(['C',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.print_strings()  # long time
2*Lambda[0]: 1 2 9 26 77 194 477 1084 2387 5010 10227 20198
Lambda[0] + Lambda[2] - delta: 1 5 18 55 149 372 922 2367 5010 10191 20198

(continues on next page)
Examples for twisted affine types:

```python
sage: Lambda = RootSystem(['A',2,2]).weight_lattice(extended=True).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]).strings()  
{Lambda[0]: [1, 1, 2, 3, 5, 7, 11, 15, 22, 30, 42, 56]}

sage: Lambda = RootSystem(['G',2,1]).dual.weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0]+Lambda[1]+Lambda[2])
sage: V.print_strings()  
# long time
6*Lambdacheck[0]: 4 28 100 320 944 2460 6064 14300 31968 69020 144676 293916

```

```python
>>> from sage.all import *
```
branch \(i=None,\) \(\text{weyl\_character\_ring=None, sequence=None, depth=5}\)

Return the branching rule on \(self\).

Removing any node from the extended Dynkin diagram of the affine Lie algebra results in the Dynkin diagram of a classical Lie algebra, which is therefore a Lie subalgebra. For example removing the 0 node from the Dynkin diagram of type \([X, r, 1]\) produces the classical Dynkin diagram of \([X, r]\).

Thus for each \(i\) in the index set, we may restrict \(self\) to the corresponding classical subalgebra. Of course \(self\) is an infinite dimensional representation, but each weight \(\mu\) is assigned a grading by the number of times the simple root \(\alpha_i\) appears in \(\Lambda - \mu\). Thus the branched representation is graded and we get sequence of finite-dimensional representations which this method is able to compute.

OPTIONAL:

\begin{itemize}
  \item \(i\) – (default: 0) an element of the index set
  \item \(\text{weyl\_character\_ring}\) – a WeylCharacterRing
  \item \(\text{sequence}\) – a dictionary
  \item \(\text{depth}\) – (default: 5) an upper bound for \(k\) determining how many terms to give
\end{itemize}

In the default case where \(i = 0\), you do not need to specify anything else, though you may want to increase the depth if you need more terms.

EXAMPLES:

\begin{verbatim}
\sage\: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=True).fundamental_weights()
\sage\: V = IntegrableRepresentation(2*Lambda[0])
\sage\: b = V.branch(); b
\end{verbatim}
needs sage.libs.gap
[A2(0,0),
A2(1,1),
A2(0,0) + 2*A2(1,1) + A2(2,2),
2*A2(0,0) + 2*A2(2,0) + 4*A2(1,1) + 2*A2(3,0) + 2*A2(2,2),
4*A2(0,0) + 3*A2(0,3) + 10*A2(1,1) + 3*A2(3,0) + A2(1,4) + 6*A2(2,2) + A2(4, 1),
6*A2(0,0) + 9*A2(0,3) + 20*A2(1,1) + 9*A2(3,0) + 3*A2(1,4) + 12*A2(2,2) + 3*A2(4, 1) + A2(3,3)]

If the parameter weyl_character_ring is omitted, the ring may be recovered as the parent of one of the branched coefficients:
sage: A2 = b[0].parent(); A2
# needs sage.libs.gap
The Weyl Character Ring of Type A2 with Integer Ring coefficients

If $i$ is not zero then you should specify the WeylCharacterRing that you are branching to. This is determined by the Dynkin diagram:
sage: Lambda = RootSystem(['B',3,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type().dynkin_diagram()
O 0
| |
O---O=>=O
1 2 3
B3~

>>> from sage.all import *
>>> Lambda = RootSystem(['B',Integer(3),Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> V = IntegrableRepresentation(Lambda[Integer(0)])
In this example, we observe that removing the $i = 2$ node from the Dynkin diagram produces a reducible diagram of type $A_1 \times A_1 \times A_1$. Thus we have a branching to $\text{sl}(2) \times \text{sl}(2) \times \text{sl}(2)$:

```
\.\sage: A1xA1xA1 = WeylCharacterRing("A1xA1xA1",style="coroots")  # needs sage.libs.gap
\.\sage: V.branch(i=2,weyl_character_ring=A1xA1xA1)  # needs sage.libs.gap
[\text{A1xA1xA1}(1,0,0),
\text{A1xA1xA1}(1,1,2),
\text{A1xA1xA1}(1,0,0) + \text{A1xA1xA1}(1,2,0) + \text{A1xA1xA1}(1,0,2),
\text{A1xA1xA1}(2,1,2) + \text{A1xA1xA1}(0,1,0) + 2*\text{A1xA1xA1}(0,1,2),
3*A1xA1xA1(1,0,0) + 2*A1xA1xA1(1,2,0) + A1xA1xA1(1,2,2) + 2*A1xA1xA1(1,0,2)→
+ A1xA1xA1(1,0,4) + A1xA1xA1(3,0,0),
A1xA1xA1(2,1,0) + 3*A1xA1xA1(2,1,2) + 2*A1xA1xA1(0,1,0) + 5*A1xA1xA1(0,1,2)→
+ A1xA1xA1(0,1,4) + A1xA1xA1(0,3,2)]
```

If the nodes of the two Dynkin diagrams are not in the same order, you must specify an additional parameter, sequence which gives a dictionary to the affine Dynkin diagram to the classical one.

**EXAMPLES:**

```
\.\sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()
\.\sage: V = IntegrableRepresentation(Lambda[0])
\.\sage: V.cartan_type().dynkin_diagram()
O---O---O=>=O---O
0 1 2 3 4
F4~
\.\sage: A1xC3=WeylCharacterRing("A1xC3",style="coroots")
\.\sage: A1xC3.dynkin_diagram()
O
1
O---O<=O
2 3 4
A1xC3
```
Observe that removing the \( i = 1 \) node from the \( \tilde{F}_4 \) Dynkin diagram gives the \( A_1 \times C_3 \) diagram, but the roots are in a different order. The nodes 0, 2, 3, 4 of \( \tilde{F}_4 \) correspond to 1, 4, 3, 2 of \( A_1 \times C_3 \) and so we encode this in a dictionary:

\[
\text{sage: V.branch(i=1, weyl_character_ring=A1xC3, sequence={0:1,2:4,3:3,4:2})}
\]

\[
\text{# long time}
\]
\[
[A1xC3(1,0,0,0),
A1xC3(0,0,0,1),
A1xC3(1,0,0,0) + A1xC3(1,2,0,0),
A1xC3(2,0,0,1) + A1xC3(0,0,0,1) + A1xC3(0,1,1,0),
2*A1xC3(1,0,0,0) + A1xC3(1,0,1,0) + 2*A1xC3(1,2,0,0) + A1xC3(1,0,2,0) +
A1xC3(3,0,0,0),
2*A1xC3(2,0,0,1) + A1xC3(2,1,1,0) + A1xC3(0,1,0,0) + 3*A1xC3(0,0,0,1) +
2*A1xC3(0,1,1,0) + A1xC3(0,2,0,1)]
\]

The branch method gives a way of computing the graded dimension of the integrable representation:

\[
\text{sage: Lambda = RootSystem("A1~").weight_lattice(extended=true).fundamental_weights()}
\]
\[
\text{sage: V=IntegrableRepresentation(Lambda[0])}
\]
\[
\text{sage: r = [x.degree() for x in V.branch(depth=15)]; r}
\]
\[
[1, 3, 4, 7, 13, 19, 29, 43, 62, 90, 126, 174, 239, 325, 435, 580]
\]
\[
\text{sage: oeis(r)}
\]
\[
\text{# optional -- internet}
\]
\[
0: A029552: Expansion of phi(x) / f(-x) in powers of x where phi(), f() are Ramanujan theta functions.
\]
>>> from sage.all import *

>>> Lambda = RootSystem("A1~").weight_lattice(extended=true).fundamental_weights()

>>> V=IntegrableRepresentation(Lambda[Integer(0)])

>>> r = [x.degree() for x in V.branch(depth=Integer(15))]; r
[1, 3, 4, 7, 13, 19, 29, 43, 62, 90, 126, 174, 239, 325, 435, 580]

>>> oeis(r) # optional

--- 

0: A029552: Expansion of phi(x) / f(-x) in powers of x where phi(), f() are Ramanujan theta functions.

\textbf{cartan_type}()

Return the Cartan type of self.

**EXAMPLES:**

```
sage: Lambda = RootSystem([F,4,1]).weight_lattice(extended=true).
fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.cartan_type()
['F', 4, 1]
```

\textbf{coxeter_number}()

Return the Coxeter number of the Cartan type of self.

The Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted $h$.

**EXAMPLES:**

```
sage: Lambda = RootSystem([F,4,1]).weight_lattice(extended=true).
fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.coxeter_number()
12
```

\textbf{dominant_maximal_weights}()

Return the dominant maximal weights of self.

A weight $\mu$ is \textit{maximal} if it has nonzero multiplicity but $\mu + \delta$ has multiplicity zero. There are a finite number of dominant maximal weights. Indeed, [Ka1990] Proposition 12.6 shows that the dominant maximal weights are in bijection with the classical weights in $k \cdot F$ where $F$ is the fundamental alcove and $k$ is the level. The construction used in this method is based on that Proposition.

**EXAMPLES:**
sage: Lambda = RootSystem(['C',3,1]).weight_lattice(extended=true).
     → fundamental_weights()
sage: IntegrableRepresentation(2*Lambda[0]).dominant_maximal_weights()
(2*Lambda[0],
 Lambda[0] + Lambda[2] - delta,
2*Lambda[1] - delta,
Lambda[1] + Lambda[3] - 2*delta,
2*Lambda[2] - 2*delta,
2*Lambda[3] - 3*delta)

>>> from sage.all import *
>>> Lambda = RootSystem(['C',Integer(3),Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> IntegrableRepresentation(Integer(2)*Lambda[Integer(0)]).dominant_maximal_weights()
(2*Lambda[0],
 Lambda[0] + Lambda[2] - delta,
2*Lambda[1] - delta,
Lambda[1] + Lambda[3] - 2*delta,
2*Lambda[2] - 2*delta,
2*Lambda[3] - 3*delta)

dual_coxeter_number()
Return the dual Coxeter number of the Cartan type of self.
The dual Coxeter number is defined in [Ka1990] Chapter 6, and commonly denoted $h^\vee$.
EXAMPLES:

sage: Lambda = RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.dual_coxeter_number()
9

>>> from sage.all import *
>>> Lambda = RootSystem(['F',Integer(4),Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> V = IntegrableRepresentation(Lambda[Integer(0)])
>>> V.dual_coxeter_number()
9

from_weight($\mu$)
Return the tuple $(n_0, n_1, ...)$ such that $\mu$ equals $\Lambda - \sum_{i \in I} n_i \alpha_i$ in self, where $\Lambda$ is the highest weight of self.
EXAMPLES:

sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
     → fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
sage: delta = V.weight_lattice().null_root()
(1, 0, 0)
>> from sage.all import *
>>> Lambda = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> V = IntegrableRepresentation(Integer(2)*Lambda[Integer(2)])
>>> V.to_weight((Integer(1),Integer(0),Integer(0)))
>>> delta = V.weight_lattice().null_root()
>>> V.from_weight(-Integer(2)*Lambda[Integer(0)] + Lambda[Integer(1)] + Integer(3)*Lambda[Integer(2)] - delta)
(1, 0, 0)

highest_weight()

Returns the highest weight of self.

EXAMPLES:

```sage
Lambda = RootSystem(['D',4,1]).weight_lattice(extended=true).fundamental_weights()
sage: IntegrableRepresentation(Lambda[0]+2*Lambda[2]).highest_weight()
Lambda[0] + 2*Lambda[2]
```

level()

Return the level of self.

The level of a highest weight representation $V_{\Lambda}$ is defined as $(\Lambda|\delta)$ See [Ka1990] section 12.4.

EXAMPLES:

```sage
Lambda = RootSystem(['G',2,1]).weight_lattice(extended=true).fundamental_weights()
sage: [IntegrableRepresentation(Lambda[i]).level() for i in [0,1,2]]
[1, 1, 2]
```

m(n)

Return the multiplicity of the weight $\mu$ in self, where $\mu = \Lambda - \sum n_i \alpha_i$.

INPUT:

- n – a tuple representing a weight $\mu$.

EXAMPLES:
Combinatorics, Release 10.4

```
sage: Lambda = RootSystem(['E', 6, 1]).weight_lattice(extended=true).
    fundamental_weights()
sage: V = IntegrableRepresentation(Lambda[0])
sage: u = V.highest_weight() - V.weight_lattice().null_root()
sage: V.from_weight(u)
(1, 1, 2, 2, 3, 2, 1)
sage: V.m(V.from_weight(u))
6
```

```
>>> from sage.all import *
>>> Lambda = RootSystem(['E', Integer(6), Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> V = IntegrableRepresentation(Lambda[Integer(0)])
>>> u = V.highest_weight() - V.weight_lattice().null_root()
>>> V.from_weight(u)
(1, 1, 2, 2, 3, 2, 1)
>>> V.m(V.from_weight(u))
6
```

modular_characteristic (mu=None)

Return the modular characteristic of self.

The modular characteristic is a rational number introduced by Kac and Peterson [KacPeterson], required to interpret the string functions as Fourier coefficients of modular forms. See [Ka1990] Section 12.7. Let $k$ be the level, and let $h^\vee$ be the dual Coxeter number. Then

$$m_\Lambda = \frac{|\Lambda + \rho|^2}{2(k + h^\vee)} - \frac{|\rho|^2}{2h^\vee}$$

If $\mu$ is a weight, then

$$m_{\Lambda, \mu} = m_\Lambda - \frac{|\mu|^2}{2k}$$

OPTIONAL:
- `mu` – a weight; or alternatively:
- `n` – a tuple representing a weight $\mu$.

If no optional parameter is specified, this returns $m_\Lambda$. If `mu` is specified, it returns $m_{\Lambda, \mu}$. You may use the tuple $n$ to specify $\mu$. If you do this, $\mu$ is $\Lambda - \sum n_i \alpha_i$.

EXAMPLES:

```
sage: Lambda = RootSystem(['A', 1, 1]).weight_lattice(extended=true).
    fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0]+2*Lambda[1])
sage: [V.modular_characteristic(x) for x in V.dominant_maximal_weights()]
[11/56, -1/280, 111/280]
```

```
>>> from sage.all import *
>>> Lambda = RootSystem(['A', Integer(1), Integer(1)]).weight_lattice(extended=true).
    fundamental_weights()
>>> V = IntegrableRepresentation(3*Lambda[Integer(0)]+2*Lambda[Integer(1)])
>>> [V.modular_characteristic(x) for x in V.dominant_maximal_weights()]
[11/56, -1/280, 111/280]
```
mult (\(\mu\))

Return the weight multiplicity of \(\mu\).

INPUT:

- \(\mu\) – an element of the weight lattice

EXAMPLES:

```python
sage: # needs sage.libs.gap
sage: L = RootSystem("B3-").weight_lattice(extended=True)
sage: Lambda = L.fundamental_weights()
sage: delta = L.null_root()
sage: W = L.weyl_group(prefix="s")
sage: [s0,s1,s2,s3] = W.simple_reflections()
sage: V = IntegrableRepresentation(Lambda[0])
sage: V.mult(Lambda[2] - 2*delta)
3
sage: V.mult(Lambda[2] - Lambda[1])
0
sage: weights = [w.action(Lambda[1] - 4*delta) for w in [s1,s2,s0*s1*s2*s3]]
sage: weights
[-Lambda[1] + Lambda[2] - 4*delta,
 Lambda[1] - 4*delta,
sage: [V.mult(mu) for mu in weights]
[35, 35, 35]
```

```python
>>> from sage.all import *
>>> # needs sage.libs.gap
>>> L = RootSystem("B3-").weight_lattice(extended=True)
>>> Lambda = L.fundamental_weights()
>>> delta = L.null_root()
>>> W = L.weyl_group(prefix="s")
>>> [s0,s1,s2,s3] = W.simple_reflections()
>>> V = IntegrableRepresentation(Lambda[Integer(0)])
>>> V.mult(Lambda[Integer(2)] - Integer(2)*delta)
3
>>> V.mult(Lambda[Integer(2)] - Lambda[Integer(1)])
0
>>> weights = [w.action(Lambda[Integer(1)] - Integer(4)*delta) for w in [s1,
... s2,s0*s1*s2*s3]]
>>> weights
[-Lambda[1] + Lambda[2] - 4*delta,
 Lambda[1] - 4*delta,
>>> [V.mult(mu) for mu in weights]
[35, 35, 35]
```

print_strings (\(depth=12\))

Print the strings of self.

See also:

strings()

EXAMPLES:
sage: Lambda = RootSystem(['A',1,1]).weight_lattice(extended=true).
˓→fundamental_weights()

sage: V = IntegrableRepresentation(2*Lambda[0])

sage: V.print_strings(depth=25)

2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 →
˓→2741 3740 5096 6868 9233 12306 16357

2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687 →
˓→2331 3206 4368 5922 7967 10670 14193 18803

**root_lattice()**

Return the root lattice associated to self.

**EXAMPLES:**

```
sage: V=IntegrableRepresentation(RootSystem(['F',4,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: V.root_lattice()
Root lattice of the Root system of type ['F', 4, 1]
```

```
>>> from sage.all import *

>>> V=IntegrableRepresentation(RootSystem(['F',Integer(4),Integer(1)]).weight_lattice(extended=true).fundamental_weight(Integer(0)))

>>> V.root_lattice()
Root lattice of the Root system of type ['F', 4, 1]
```

**s**(n, i)

Return the action of the i-th simple reflection on the internal representation of weights by tuples n in self.

**EXAMPLES:**

```
sage: V = IntegrableRepresentation(RootSystem(['A',2,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: [V.s((0,0,0),i) for i in V._index_set]
[(1, 0, 0), (0, 0, 0), (0, 0, 0)]
```

```
>>> from sage.all import *

>>> V = IntegrableRepresentation(RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true).fundamental_weight(Integer(0)))

>>> [V.s((Integer(0),Integer(0),Integer(0)),i) for i in V._index_set]
[(1, 0, 0), (0, 0, 0), (0, 0, 0)]
```

**string**(max_weight, depth=12)

Return the list of multiplicities \(m(\Lambda - k\delta)\) in self, where \(\Lambda\) is max_weight and \(k\) runs from 0 to depth.

**INPUT:**

- max_weight – a dominant maximal weight
• depth – (default: 12) the maximum value of \( k \)

**EXAMPLES:**

```python
sage: Lambda = RootSystem(['A', 2, 1]).weight_lattice(extended=True).fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[0])
sage: V.string(2*Lambda[0])
[1, 2, 8, 20, 52, 116, 256, 522, 1045, 1996, 3736, 6780]
sage: V.string(Lambda[1] + Lambda[2])
[0, 1, 4, 12, 32, 77, 172, 365, 740, 1445, 2736, 5041]
```

**strings (depth=12)**

Return the set of dominant maximal weights of `self`, together with the string coefficients for each.

**OPTIONAL:**

• depth – (default: 12) a parameter indicating how far to push computations

**EXAMPLES:**

```python
>>> from sage.all import *
>>> Lambda = RootSystem(['A', Integer(2), Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> V = IntegrableRepresentation(Integer(2)*Lambda[Integer(0)])
>>> V.string(Integer(2)*Lambda[Integer(0)])
[1, 2, 8, 20, 52, 116, 256, 522, 1045, 1996, 3736, 6780]
>>> V.string(Lambda[Integer(1)] + Lambda[Integer(2)])
[0, 1, 4, 12, 32, 77, 172, 365, 740, 1445, 2736, 5041]
```

**to_dominant**

Return the dominant weight in `self` equivalent to `n` under the affine Weyl group.

**EXAMPLES:**

```python
>>> from sage.all import *
>>> Lambda = RootSystem(['A', Integer(1), Integer(1)]).weight_lattice(extended=True).fundamental_weights()
>>> V = IntegrableRepresentation(Integer(2)*Lambda[Integer(0)])
>>> S = V.strings(depth=Integer(25))
>>> for k in S:
...    print("", format(k, ' ').join(str(x) for x in S[k]))
2*Lambda[0]: 1 1 3 5 10 16 28 43 70 105 161 236 350 501 722 1016 1431 1981 2741 3740 5096 6868 9233 12306 16357 2331 3206 4368 5922 7967 10670 14193 18803
2*Lambda[1] - delta: 1 2 4 7 13 21 35 55 86 130 196 287 420 602 858 1206 1687 2331 3206 4368 5922 7967 10670 14193 18803
```
Combinatorics, Release 10.4

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
    fundamental_weights()
sage: V = IntegrableRepresentation(3*Lambda[0])
sage: n = V.to_dominant((13,11,7)); n
(4, 3, 3)
sage: V.to_weight(n)
```

```
>>> from sage.all import *
>>> Lambda = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> V = IntegrableRepresentation(Integer(3)*Lambda[Integer(0)])
>>> n = V.to_dominant((Integer(13),Integer(11),Integer(7))); n
(4, 3, 3)
>>> V.to_weight(n)
```

`to_weight(n)`

Return the weight associated to the tuple `n` in `self`.

If `n` is the tuple `(n_1, n_2, ...),` then the associated weight is $\Lambda - \sum_i n_i \alpha_i$, where $\Lambda$ is the weight of the representation.

**INPUT:**

* `n` – a tuple representing a weight

**EXAMPLES:**

```
sage: Lambda = RootSystem(['A',2,1]).weight_lattice(extended=true).
    fundamental_weights()
sage: V = IntegrableRepresentation(2*Lambda[2])
sage: V.to_weight((1,0,0))
```

```
>>> from sage.all import *
>>> Lambda = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=true).fundamental_weights()
>>> V = IntegrableRepresentation(Integer(2)*Lambda[Integer(2)])
>>> V.to_weight((Integer(1),Integer(0),Integer(0)))
```

`weight_lattice()`

Return the weight lattice associated to `self`.

**EXAMPLES:**

```
sage: V=IntegrableRepresentation(RootSystem(['E',6,1]).weight_lattice(extended=true).fundamental_weight(0))
sage: V.weight_lattice()
Extended weight lattice of the Root system of type ['E', 6, 1]
```

```
>>> from sage.all import *
>>> V=IntegrableRepresentation(RootSystem(['E',Integer(6),Integer(1)]).weight_lattice(extended=true).fundamental_weight(Integer(0)))
>>> V.weight_lattice()
Extended weight lattice of the Root system of type ['E', 6, 1]
```
5.1.233 Nonsymmetric Macdonald polynomials

AUTHORS:
• Anne Schilling and Nicolas M. Thiéry (2013): initial version

ACKNOWLEDGEMENTS:
The initial version of this code (together with root_lattice_realization_algebras.Algebras and
hecke_algebra_representation.HeckeAlgebraRepresentation) was written by Anne Schilling and
Nicolas M. Thiery during the ICERM Semester Program on “Automorphic Forms, Combinatorial Representation Theory
and Multiple Dirichlet Series” (January 28, 2013 - May 3, 2013) with the help of Dan Bump, Ben Brubaker, Bogdan Ion,
Dan Orr, Arun Ram, Siddhartha Sahi, and Mark Shimozono. Special thanks go to Bogdan Ion and Mark Shimozono for
their patient explanations and hand computations to check the code.

class sage.combinat.root_system.non_symmetric_macdonald_polynomials.NonSymmetricMacdonaldPolynomials

Bases: CherednikOperatorsEigenvectors

Nonsymmetric Macdonald polynomials

INPUT:
• KL – an affine Cartan type or the group algebra of a realization of the affine weight lattice
• q, q1, q2 – parameters in the base ring of the group algebra (default: q, q1, q2)
• normalized – a boolean (default: True) whether to normalize the result to have leading coefficient 1

This implementation covers all reduced affine root systems. The polynomials are constructed recursively by the
application of intertwining operators.

Todo:
• Non-reduced case (Koornwinder polynomials).
• Non-equal parameters for the affine Hecke algebra.
• Choice of convention (dominant/anti-dominant, ...).
• More uniform implementation of the $T'_0$ operator.
• Optimizations, in particular in the calculation of the eigenvalues for the recursion.

EXAMPLES:
We construct the family of nonsymmetric Macdonald polynomials in three variables in type $A$:
sage: E = NonSymmetricMacdonaldPolynomials(["A",2,1])

They are constructed as elements of the group algebra of the classical weight lattice $L_0$ (or one of its realizations,
such as the ambient space, which is used here) and indexed by elements of $L_0$:
Combinatorics, Release 10.4

>>> from sage.all import *
>>> L0 = E.keys(); L0
Ambient space of the Root system of type ['A', 2]

Here is the nonsymmetric Macdonald polynomial with leading term \( [2, 0, 1] \):

```python
sage: E[L0([2,0,1])]
# needs sage.libs.gap
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 1, 1)]
+ ((-q1-q2)/(-q*q1-q2))*B[(2, 1, 0)] + B[(2, 0, 1)]
```

It can be seen as a polynomial (or in general a Laurent polynomial) by interpreting each term as an exponent vector.

The parameter \( q \) is the exponential of the null (co)root, whereas \( q_1 \) and \( q_2 \) are the two eigenvalues of each generator \( T_i \) of the affine Hecke algebra (see the background section for details).

By setting \( q_1 = t, q_2 = -1 \) and using the \texttt{root_lattice_realization_algebras.Algebras.ElementMethods.expand()} method, we recover the nonsymmetric Macdonald polynomial as computed by [HHL06]'s combinatorial formula:

```python
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['A',2,1], q=q, q1=t, q2=-1)
sage: vars = K['x0,x1,x2'].gens()
sage: E[L0([2,0,1])].expand(vars)
# needs sage.libs.gap
(t - 1)/(q*t - 1)*x0^2*x1 + x0^2*x2 + (q*t - q)/(q*t - 1)*x0*x1*x2
```

```python
>>> from sage.all import *
>>> K = QQ['q,t'].fraction_field()
>>> q,t = K.gens()
>>> E = NonSymmetricMacdonaldPolynomials(['A',Integer(2),Integer(1)], q=q, q1=t, q2=-Integer(1))
>>> vars = K['x0,x1,x2'].gens()
>>> E[L0([Integer(2),Integer(0),Integer(1)])].expand(vars)
# needs sage.libs.gap
(t - 1)/(q*t - 1)*x0^2*x1 + x0^2*x2 + (q*t - q)/(q*t - 1)*x0*x1*x2
```
Here is a type $G_2^{(1)}$ nonsymmetric Macdonald polynomial:

```python
sage: E = NonSymmetricMacdonaldPolynomials(['G',2,1])
sage: L0 = E.keys()
sage: omega = L0.fundamental_weights()
((-q*q1^3*q2-q*q1^2*q2^2)/(q*q1^4-q2^4))*B[(0, 0, 0)]
+ B[(1, -1, 0)] + ((-q1*q2^3-q2^4)/(q*q1^4-q2^4))*B[(1, 0, -1)]
```

Many more examples are given after the background section.

- `SymmetricFunctions.macdonald`

**Background**

**The polynomial module**

The nonsymmetric Macdonald polynomials are a distinguished basis of the “polynomial” module of the affine Hecke algebra. Given:

- a ground ring `K`, which contains the input parameters `q, q_1, q_2`
- an affine root system, specified by a Cartan type `C`
- a realization `L` of the weight lattice of type `C`

the polynomial module is the group algebra $K[L_0]$ of the classical weight lattice $L_0$ with coefficients in $K$. It is isomorphic to the Laurent polynomial ring over $K$ generated by the formal exponentials of any basis of $L_0$.

In our running example $L$ is the ambient space of type $G_2^{(1)}$:

```python
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q, q1, q2 = K.gens()
sage: C = CartanType(['C',2,1])
sage: L = RootSystem(C).ambient_space(); L
Ambient space of the Root system of type ['C', 2, 1]
sage: L.simple_roots()
Finite family {0: -2*e[0] + e['delta'], 1: e[0] - e[1], 2: 2*e[1]}
sage: omega = L.fundamental_weights(); omega
Finite family {0: e['deltacheck'], 1: e[0] + e['deltacheck'], 2: e[0] + e[1] + e['deltacheck']}
sage: L0 = L.classical(); L0
Ambient space of the Root system of type ['C', 2]
sage: KL0 = L0.algebra(K); KL0
```

(continues on next page)
Affine Hecke algebra

The affine Hecke algebra is generated by elements $T_i$ for $i$ in the set of affine Dynkin nodes. They satisfy the same braid relations as the simple reflections $s_i$ of the affine Weyl group. The $T_i$ satisfy the quadratic relation

$$(T_i - q_1)(T_i - q_2) = 0,$$

where $q_1$ and $q_2$ are the input parameters. Some of the representation theory requires that $q_1$ and $q_2$ satisfy additional relations; typically one uses the specializations $q_1 = u$ and $q_2 = -1/u$ or $q_1 = t$ and $q_2 = -1$). This can be achieved by constructing an appropriate field and passing $q_1$ and $q_2$ appropriately; see the examples. In principle, the parameter(s) could further depend on $i$; this is not yet implemented but the code has been designed in such a way that this feature is easy to add.

Demazure-Lusztig operators

The $i$-th Demazure-Lusztig operator is an operator on $K[L]$ which interpolates between the reflection $s_i$ and the Demazure operator $\pi_i$ (see root_lattice_realization.RootLatticeRealization.Algebras.ParentMethods.demazure_lusztig_operators()).

```python
sage: KL = L.algebra(K); KL
Algebra of the Ambient space of the Root system of type ['C', 2, 1] over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational
˓→Field
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: x = KL.monomial(omega[1]); x
B[e[0] + e['deltacheck']]
sage: T[2](x)
q1*B[e[0] + e['deltacheck']]
```
The affine Hecke algebra acts on $K[L]$ by letting the generators $T_i$ act by the Demazure-Lusztig operators. The class `sage.combinat.root_system.hecke_algebra_representation.HeckeAlgebraRepresentation` implements some simple generic features for representations of affine Hecke algebras defined by the action of their $T$-generators:

```python
sage: T
A representation of the $(q_1, q_2)$-Hecke algebra of type ['C', 2, 1] on Algebra of the Ambient space of the Root system of type ['C', 2, 1] over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

Here we construct the operator $q_1 T_2^{-1} o T_1^{-1} T_0$ from a signed reduced word:

```python
sage: T.Tw([0,1,2],[1,-1,-1], q1^2)
Generic endomorphism of Algebra of the Ambient space of the Root system of type ['C', 2, 1] over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over Rational Field
```

(continues on next page)
Generic endomorphism of Algebra of the Ambient space of the Root system of type $[\rightarrow C', 2, 1]$ 
over Fraction Field of Multivariate Polynomial Ring in $q$, $q_1$, $q_2$ over Rational Field

(note the reversal of the word). Inverses are computed using the quadratic relation.

**Cherednik operators**

The affine Hecke algebra contains elements $Y_{\lambda}$ indexed by the coroot lattice. Their action on $K[L]$ is implemented in Sage:

```sage
sage: Y = T.Y(); Y
Lazy family (...)_{i in Coroot lattice of the Root system of type ['C', 2, 1]}

sage: alphacheck = Y.keys().simple_roots()

sage: Y1 = Y[alphacheck[Integer(1)]]

sage: Y1(x)
((q1^2+2*q1*q2+q2^2)/(-q1*q2))*B[e[0] + e['deltacheck']]
+ ((-q1^2-2*q1*q2-q2^2)/(-q2^2))*B[-e[1] + e['deltacheck']]
+ ((-q1^2-q1*q2)/(-q2^2))*B[2*e[0] - e[1] - e['delta']
+ e['deltacheck']]
+ ((q1^3+q1^2*q2)/(q2^3))*B[e[0] - e['delta'] + e['deltacheck']]
+ e['deltacheck']]
+ ((q1^3+2*q1^2*q2+q1*q2^2)/(q2^3))*B[-e[1] - e['delta'] + e['deltacheck']]
+ ((-q1^3-2*q1^2*q2-q1*q2^2)/(q2^3))*B[e[0] - 2*e[1] - e['delta']
+ e['deltacheck']]
+ ((-q1^3-q1^2*q2)/(-q2^3))*B[3*e[0] - 3*e['delta'] + e['deltacheck']]
+ ((q1^3+q1^2*q2)/(-q2^3))*B[3*e[0] - 2*e[1] - 3*e['delta'] + e['deltacheck']]
```
(viewed multiplicatively). In practice, $Y_\lambda$ is constructed by computing combinatorially its signed reduced word (and an overall scalar factor) using the periodic orientation of the alcove model in the coweight lattice (see `hecke_algebra_representation.HeckeAlgebraRepresentation.Y_lambdacheck()`):

```python
sage: Lcheck = L.root_system.coweight_lattice()
sage: w = Lcheck.reduced_word_of_translation(Lcheck(alphacheck[1])); w
[0, 2, 1, 0, 2, 1]
sage: Lcheck.signs_of_alcovewalk(w)
[1, -1, 1, -1, 1, 1]
```

### Level zero representation of the affine Hecke algebra

The action of the affine Hecke algebra on $K[L]$ induces an action on $K[L_0]$: the action of $T_i$ on $X_\lambda$ for $\lambda$ a classical weight in $L_0$ is obtained by embedding the weight at level zero in the affine weight lattice (see `weight_lattice_realizations.WeightLatticeRealizations.ParentMethods.embed_at_level()`) applying the Demazure-Lusztig operator there, and projecting from $K[L] \to K[L_0]$ mapping the exponential of $\delta$ to $q$ (see `root_lattice_realization_algebras.Algebras.ParentMethods.q_project()`).

This is implemented in `root_lattice_realization_algebras.Algebras.ParentMethods.demazure_lusztig_operators_on_classical()`:

```python
sage: T = KL.demazure_lusztig_operators_on_classical(q, q1,q2)
sage: omega = L0.fundamental_weights()
sage: x = KL0.monomial(omega[1])
sage: T[0](x)
(-q*q2)*B[(-1, 0)]
```

For classical nodes these are the usual Demazure-Lusztig operators:

```python
sage: T[1](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]
```

```python
>>> from sage.all import *
>>>
>>> T = KL.demazure_lusztig_operators_on_classical(q, q1,q2)
>>>
>>> omega = L0.fundamental_weights()
>>> x = KL0.monomial(omega[Integer(1)])
>>> T[Integer(0)](x)
(-q*q2)*B[(-1, 0)]
```

```python
>>> from sage.all import *
>>>
>>> T[Integer(1)](x)
(q1+q2)*B[(1, 0)] + q1*B[(0, 1)]
```
Nonsymmetric Macdonald polynomials

We can now finally define the nonsymmetric Macdonald polynomials. Because the Cherednik operators commute (and there is no radical), they can be simultaneously diagonalized; namely, $K[L_0]$ admits a $K$-basis of joint eigenvectors for the $Y_\lambda$. For $\mu \in L_0$, the nonsymmetric Macdonald polynomial $E_\mu$ is the unique eigenvector of the family of Cherednik operators $Y_\lambda$ having $\mu$ as leading term:

```python
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2); E
The family of the Macdonald polynomials of type ['C', 2, 1] with parameters q, q1, q2
```

Or for short:

```python
sage: E = NonSymmetricMacdonaldPolynomials(C)
```

Recursive construction of the nonsymmetric Macdonald polynomials

The generators $T_i$ of the affine Hecke algebra almost skew commute with the Cherednik operators. More precisely, one can deform them into the so-called intertwining operators:

$$
\tau_i = T_i - (q_1 + q_2) \frac{Y_i^{a_i-1}}{1 - Y_i^a}.
$$

(where $a = 1$ except for $i = 0$ in type $BC$ where $a = a_0 = 2$) which satisfy the following skew commutation relations:

$$
\tau_i Y_\lambda = \tau_i Y_{s_i \lambda}.
$$

If $s_i \mu \neq \mu$, applying $\tau_i$ on an eigenvector $E_\mu$ produces a new eigenvector (essentially $E_{s_i \mu}$) with a distinct eigenvalue. It follows that the eigenvectors indexed by an affine Weyl orbit of weights, may be recursively computed from a single weight in the orbit.

In the case at hand, there is a little complication: namely, the simple reflections $s_i$ acting at level 0 do not act transitively on classical weights; in fact the orbits for the classical Weyl group and for the affine Weyl group are the same. Thus, one can construct the nonsymmetric Macdonald polynomials for all weights from those for the classical dominant weights, but one is lacking a creation operator to construct the nonsymmetric Macdonald polynomials for dominant weights.
Twisted Demazure-Lusztig operators

To compensate for this, one needs to consider another affinization of the action of the classical Demazure-Lusztig operators $T_1,...,T_n$, which gives rise to the double affine Hecke algebra. Following Cherednik, one adds another operator $T_0^\vee$ implemented in: `root_lattice_realization_algebras.Algebras.ParentMethods.T0_check_on_basis()`. See also: `root_lattice_realization_algebras.Algebras.ParentMethods.twisted_demazure_lusztig_operators()`.

Depending on the type (untwisted or not), this is a representation of the affine Hecke algebra for another affinization of the classical Cartan type. The corresponding action of the affine Weyl group – which is used to compute the recursion on $\mu$ – occurs in the corresponding weight lattice realization:

```sage
sage: E.L()
Ambient space of the Root system of type ['C', 2, 1]
sage: E.L_prime()
Coambient space of the Root system of type ['B', 2, 1]
sage: E.L_prime().classical()
Ambient space of the Root system of type ['C', 2]
```

See `L_prime()` and `cartan_type.CartanType_affine.other_affinization()`.

REFERENCES:

More examples

We show how to create the nonsymmetric Macdonald polynomials in two different ways and check that they are the same:

```sage
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['D',3,1], q, u, -1/u)
sage: omega = E.keys().fundamental_weights()
((-q*u^2+q)/(-q*u^4+1))*B[(1/2, -1/2, 1/2)]
+ ((-q*u^2+q)/(-q*u^4+1))*B[(1/2, 1/2, -1/2)] + B[(3/2, 1/2, 1/2)]
sage: KL = RootSystem(['D',3,1]).ambient_space().algebra(K)
sage: P = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
True
```

(continues on next page)
In type $A$, there is also a combinatorial implementation of the non symmetric Macdonald polynomials in terms of augmented diagram fillings as in [HHL06]. See `sage.combinat.sf.ns_macdonald.E()`. First we check that these polynomials are indeed eigenvectors of the Cherednik operators:

```
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t; q2 = -1
sage: KL = RootSystem("A",2,1).ambient_space().algebra(K)
sage: KL0 = KL.classical()
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2)
sage: omega = E.keys().fundamental_weights()
sage: w = omega[1]
sage: # needs sage.combinat sage.groups
sage: import sage.combinat.sf.ns_macdonald as NS
sage: def eig(l):
    return E.eigenvalues(KL0.from_polynomial(NS.E(l)))
sage: eig([1,0,0])
[t, (-1)/(-q*t^2), t]
sage: eig([2,0,0])
[q*t, (-1)/(-q^2*t^2), t]
sage: eig([3,0,0])
[q^2*t, (1)/(-q^3*t^2), q^4*t^2]
```
Combinatorics, Release 10.4

>>> w = omega[Integer(1)]

>>> # needs sage.combinat sage.groups
>>> import sage.combinat.sf.ns_macdonald as NS
>>> p = NS.E([Integer(1), Integer(0), Integer(0)]); p
x0

>>> pp = KL0.from_polynomial(p)
>>> E.eigenvalues(KL0.from_polynomial(p))
[t, (-1)/(-q*t^2), t]

>>> def eig(l):
    return
    E.eigenvalues(KL0.from_polynomial(NS.E(l)))

>>> # needs sage.combinat sage.groups

>>> eig([Integer(1), Integer(0), Integer(0)])
[t, (-1)/(-q*t^2), t]

>>> eig([Integer(2), Integer(0), Integer(0)])
[q^2*t, (-1)/(-q^2*t^2), t]

>>> eig([Integer(3), Integer(0), Integer(0)])
[q^3*t, (-1)/(-q^3*t^2), t]

>>> eig([Integer(2), Integer(0), Integer(4)])
[(-1)/(-q^4*t), 1/(q^3*t), q^4*t^2]

Next we check explicitly that they agree with the current implementation:

sage: K = QQ['q', 't'].fraction_field()
sage: q,t = K.gens()
sage: KL = RootSystem(["A",1,1]).ambient_lattice().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, t, -1)
sage: L0 = E.keys()
sage: KL0 = KL.classical()
sage: P = K['x0,x1']
sage: def EE(weight):
    return
    E[L0(weight)].expand(P.gens())

sage: # needs sage.combinat
sage: import sage.combinat.sf.ns_macdonald as NS

sage: EE([0,0])
1
sage: NS.E([0,0])
1

sage: EE([1,0])
x0
sage: NS.E([1,0])
x0

sage: EE([0,1])
(t - 1)/(q*t - 1)*x0 + x1
sage: NS.E([0,1])
(t - 1)/(q*t - 1)*x0 + x1

sage: EE([2,0])
x0^2 + (q*t - q)/(q*t - 1)*x0*x1
sage: NS.E([2,0])
x0^2 + (q*t - q)/(q*t - 1)*x0*x1

5.1. Comprehensive Module List

NS.E([Integer(1), Integer(1)])  # needs sage.combinat
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]

sage: E[L0([Integer(2), Integer(0)])]
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]

sage: E[L0([Integer(1), Integer(1)])]
((-q*t+q)/(-q*t+1))*B[(0, 0)] + B[(1, -1)]

sage: E[L0([Integer(0), Integer(2)])]
((-q*t+q)/(-q*t+1))*B[(-1, -1)] + B[(0, -2)]

Systematic checks with Sage’s implementation of [HHL06]:

sage: from sage.all import *

sage: E[L0([Integer(2), Integer(0)])]
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]

sage: E[L0([Integer(1), Integer(1)])]
((-q*t+q)/(-q*t+1))*B[(0, 0)] + B[(1, -1)]

sage: E[L0([Integer(0), Integer(2)])]
((-q*t+q)/(-q*t+1))*B[(-1, -1)] + B[(0, -2)]

The same, directly in the ambient lattice with several shifts:

sage: E[L0([2, 0])]
((-q*t+q)/(-q*t+1))*B[(1, 1)] + B[(2, 0)]

sage: E[L0([1, -1])]
((-q*t+q)/(-q*t+1))*B[(0, 0)] + B[(1, -1)]

sage: E[L0([0, -2])]
((-q*t+q)/(-q*t+1))*B[(-1, -1)] + B[(0, -2)]
With the current implementation, we can compute nonsymmetric Macdonald polynomials for any type, for example for type $E_6^{(1)}$:

```
sage: K = QQ['q,u'].fraction_field()
sage: q, u = K.gens()

case: KL = RootSystem("E", Integer(6)).weight_space(extended=True).algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q,u,-Integer(1)/u)
sage: L0 = E.keys()

case: E[L0.fundamental_weight(Integer(1)).weyl_action([Integer(2),Integer(4),Integer(3),Integer(2),Integer(1)])]

(continues on next page)
```
((-u^2+1)/(-q*u^16+1))*B[-Lambda[1] + Lambda[3]]
+ ((-u^2+1)/(-q*u^16+1))*B[Lambda[1]]
+ B[-Lambda[2] + Lambda[5]]
+ ((-u^2+1)/(-q*u^16+1))*B[-Lambda[3] + Lambda[4]]

>>> E[L0.fundamental_weight(Integer(2)].weyl_action((Integer(2),Integer(5),
                                            Integer(3),Integer(4),Integer(2)))]  # long time (6s)
((-q^2*u^20+q^2*u^18+q*u^2-q)/(-q^2*u^32+2*q*u^16-1))*B[0]
+ ((-q*u^20+q*u^18+u^2-1)/(-q^2*u^32+2*q*u^16-1))*B[-Lambda[2] + Lambda[4]]
+ ((-q*u^20+q*u^18+u^2-1)/(-q^2*u^32+2*q*u^16-1))*B[Lambda[2]]

>>> E[L0.fundamental_weight(Integer(1))+L0.fundamental_weight(Integer(6))]  # ... # long time (13s)
((q^2*u^10-q^2*u^8-q*u^6+q*u^4+q*u^2+u^2-q-1)/(-q^3*u^12+q^2*u^8+q*u^4-1))*B[(0,0,0)]
+ ((-u^2+1)/(-q^2*u^8+1))*B[(0,1,-1)] + ((-u^2+1)/(-q^2*u^8+1))*B[(0,1,1)]

We test various other types:

    sage: K = QQ['q,u'].fraction_field()
    sage: q, u = K.gens()
    sage: KL = RootSystem(["A",5,2]).ambient_space().algebra(K)
    sage: E = NonSymmetricMacdonaldPolynomials(KL, q, u, -1/u)
    sage: L0 = E.keys()
    sage: E[L0.fundamental_weight(4)]  # long time (5s)
    ((-q^3*u^20+q^3*u^18+q^2*u^2-q^2)/(-q^3*u^28+q^2*u^22+q*u^6-1))*B[(0,0,0,0)]
    + ((-q*u^2+q)/(-q*u^6+1))*B[(1/2,1/2,-1/2,-1/2)]
    + ((-q*u^2+q)/(-q*u^6+1))*B[(1/2,1/2,1/2,-1/2)]
    + ((-q*u^2+q)/(-q*u^6+1))*B[(1/2,1/2,-1/2,1/2)]
    + ((-q*u^2+q)/(-q*u^6+1))*B[(1/2,1/2,1/2,1/2)]
}(continues on next page)

Systematic checks with Sage’s implementation of [HHL06]:

```python
sage: import sage.combinat.sf.ns_macdonald as NS  # needs sage.combinat
sage: assert all(EE([x,y,z]) == NS.E([x,y,z]) for d in range(5)) # long time (9s), needs sage.combinat
......: for x,y,z in IntegerVectors(d,3))
```
```python
>>> q, q1, q2 = K.gens()
>>> KL = RootSystem("A", Integer(2), Integer(1)).ambient_space().algebra(K)
>>> E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2)
>>> L0 = E.keys()
>>> omega = L0.fundamental_weights()
>>> E[Integer(2)*omega[Integer(2)]]
((-q*q1-q*q2)/(-q*q1-q2))*B[(1, 2, 1)] + ((-q*q1-q*q2)/(-q*q1-q2))*B[(2, 1, 1)] +
B[(2, 2, 0)]
```

```python
for d in range(Integer(4)):
    for weight in IntegerVectors(d, Integer(3)).map(list).map(L0):
        eigenvalues = E.eigenvalues(E[L0(weight)])
```

Some type $C$ calculations:

```python
sage: E[-omega[1]]
# consistent with before refactoring
B[(0, 0)] + ((-t+1)/(-q*t+1))*B[(1, 0)] + ((-t+1)/(-q*t+1))*B[(0, -1)] + (((-t+1)/(q*t-1))*B[(0, 1)]
```

```python
sage: E[-omega[1]].map_coefficients(lambda c: c.subs(t=0))
# checking against crystals
```

```python
sage: E[-omega[2]]
((-q^2*t^4+q^2*t^3+2*q*t^2-2*q*t+t-1)/(-q^3*t^4+q^2*t^3+q*t-1))*B[(0, 0)]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

\[
+ ((-q^3*t^2+q^3*t)/(-q^3*t^3+1))*B[(-1, -1)]
+ ((-q^3*t^3+2*q^3*t^2-q^3*t)/(-q^4*t^4+q^3*t^3+q*t-1))*B[(1, -1)]
+ ((-q^4*t^4+q^4*t^3-3*q^3*t^3+3*q^2*t^2+q^3*t^2-q^2*t^2-q^2*t+q*t-q)/(-q^4*t^4+q^3*t^3+q*t-1))*B[(1, 1)]
+ ((q*t-q)/(q*t-1))*B[(2, 0)] + B[(2, 2)] + ((-q*t+q)/(-q*t+1))*B[(0, 2)]
\]

\text{ sage: E.eigenvalues(_)} # not checked

[\{q^3*t^3, t, (-1)/(q^2*t^2)\]
The following computations were calculated by hand:

```python
sage: E11 = KL0.sum_of_terms([[L0([1,1]), 1], [L0([0,0]), (-q*t^2 + q*t)/(1-q*t^3)]])
```

```python
true
```

```python
sage: E1m1 = KL0.sum_of_terms([[L0([1,-1]), 1], [L0([1,1]), (1-t)/(1-q*t^2)]])
```

```python
true
```

Now we present an example for a twisted affine root system. The results are eigenvectors:

```python
sage: K = QQ['q', 't'].fraction_field()
sage: q, t = K.gens()
sage: KL = RootSystem("C2~*").ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, t, -1)
sage: E[0*omega[1]]
```

```python
B[(0, 0)]
```

```python
sage: E[omega[1]]
```

```python
((-q*t+q)/(-q*t^2+1))*B[(0, 0)] + B[(1, 0)]
```

```python
sage: E.eigenvalues(_)
```

```python
[1/(q*t^2), t, t]
```

```python
sage: E[omega[1]]

    epsilon[Integer(1)], epsilon[Integer(0)], epsilon[Integer(1)]]:
    ...     x = KL.monomial(x)
    ...     assert q**Integer(2) * Y0(Y1(Y2(Y2(start)))) == start

KL0()

Return the group algebra where the nonsymmetric Macdonald polynomials live.

EXAMPLES:

sage: NonSymmetricMacdonaldPolynomials("B2~").KL0()
Algebra of the Ambient space of the Root system of type ['B', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over...
    Rational Field
sage: NonSymmetricMacdonaldPolynomials("B2~*").KL0()
Algebra of the Ambient space of the Root system of type ['C', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over...
    Rational Field

>>> from sage.all import *

>>> NonSymmetricMacdonaldPolynomials("B2~").KL0()
Algebra of the Ambient space of the Root system of type ['B', 2]
over Fraction Field of Multivariate Polynomial Ring in q, q1, q2 over...
    Rational Field

L()

Return the affinization of the classical weight space.

EXAMPLES:

sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L()
Ambient space of the Root system of type ['B', 2, 1]

>>> from sage.all import *

>>> NonSymmetricMacdonaldPolynomials(["B", Integer(2), Integer(1)]).L()
Ambient space of the Root system of type ['B', 2, 1]

L0()

Return the space indexing the monomials of the nonsymmetric Macdonald polynomials.

EXAMPLES:
sage: NonSymmetricMacdonaldPolynomials("B2--").L0()
Ambient space of the Root system of type ['B', 2]
sage: NonSymmetricMacdonaldPolynomials("B2--").L0()
Ambient space of the Root system of type ['C', 2]

>>> from sage.all import *
>>> NonSymmetricMacdonaldPolynomials("B2--").L0()
Ambient space of the Root system of type ['B', 2]
>>> NonSymmetricMacdonaldPolynomials("B2--").L0()
Ambient space of the Root system of type ['C', 2]

$L\_\text{check}()$

Return the other affinization of the classical weight space.

Todo: should this just return $L$ in the simply laced case?

EXAMPLES:

sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L_check()
Coambient space of the Root system of type ['C', 2, 1]
sage: NonSymmetricMacdonaldPolynomials(["B", 2, 1]).L_check().classical()
Ambient space of the Root system of type ['B', 2]

>>> from sage.all import *
>>> NonSymmetricMacdonaldPolynomials(["B", Integer(2), Integer(1)]).L_check()
Coambient space of the Root system of type ['C', 2, 1]
>>> NonSymmetricMacdonaldPolynomials(["B", Integer(2), Integer(1)]).L_check().classical()
Ambient space of the Root system of type ['B', 2]

$L\_\text{prime}()$

The affine space where classical weights are lifted for the recursion.

Also the parent of $\rho'$.

EXAMPLES:

In the twisted case, this is the affinization of the classical ambient space:

sage: NonSymmetricMacdonaldPolynomials("B2--").L()
Ambient space of the Root system of type ['B', 2, 1]**
sage: NonSymmetricMacdonaldPolynomials("B2--").L().classical()
Ambient space of the Root system of type ['C', 2]
sage: NonSymmetricMacdonaldPolynomials("B2--").L_prime()
Ambient space of the Root system of type ['B', 2, 1]**
sage: NonSymmetricMacdonaldPolynomials("B2--").L_prime().classical()
Ambient space of the Root system of type ['C', 2]

>>> from sage.all import *
>>> NonSymmetricMacdonaldPolynomials("B2--").L()
Ambient space of the Root system of type ['B', 2, 1]**
>>> NonSymmetricMacdonaldPolynomials("B2--").L().classical()
Ambient space of the Root system of type ['C', 2]

(continues on next page)
NonSymmetricMacdonaldPolynomials("B2~*").L_prime()
Ambient space of the Root system of type ['B', 2, 1]^*

NonSymmetricMacdonaldPolynomials("B2~*").L_prime().classical()
Ambient space of the Root system of type ['C', 2]

In the untwisted case, this is the other affinization of the classical ambient space:

from sage.all import *

NonSymmetricMacdonaldPolynomials("B2~") .L()
Ambient space of the Root system of type ['B', 2, 1]
NonSymmetricMacdonaldPolynomials("B2~") .L().classical()
Ambient space of the Root system of type ['B', 2]

NonSymmetricMacdonaldPolynomials("B2~") .L_prime()
Coambient space of the Root system of type ['C', 2, 1]
NonSymmetricMacdonaldPolynomials("B2~") .L_prime().classical()
Ambient space of the Root system of type ['B', 2]

For simply laced, the two affinizations coincide:

NonSymmetricMacdonaldPolynomials("A2~") .L()
Ambient space of the Root system of type ['A', 2, 1]
NonSymmetricMacdonaldPolynomials("A2~") .L().classical()
Ambient space of the Root system of type ['A', 2]

NonSymmetricMacdonaldPolynomials("A2~") .L_prime()
Coambient space of the Root system of type ['A', 2, 1]
NonSymmetricMacdonaldPolynomials("A2~") .L_prime().classical()
Ambient space of the Root system of type ['A', 2]

from sage.all import *

NonSymmetricMacdonaldPolynomials("A2~") .L()
Ambient space of the Root system of type ['A', 2, 1]
NonSymmetricMacdonaldPolynomials("A2~") .L().classical()
Ambient space of the Root system of type ['A', 2]

NonSymmetricMacdonaldPolynomials("A2~") .L_prime()
Coambient space of the Root system of type ['A', 2, 1]
NonSymmetricMacdonaldPolynomials("A2~") .L_prime().classical()
Ambient space of the Root system of type ['A', 2]

Note: do we want the coambient space of type $A_2^{(1)}$ instead?

For type BC:
```python
sage: NonSymmetricMacdonaldPolynomials(["BC",3,2]).L_prime()
Ambient space of the Root system of type ['BC', 3, 2]
```

```python
>>> from sage.all import *
>>> NonSymmetricMacdonaldPolynomials(["BC",Integer(3),Integer(2)]).L_prime()
Ambient space of the Root system of type ['BC', 3, 2]
```

### Q_to_Qcheck()

The reindexing of the index set of the Y’s by the coroot lattice.

**EXAMPLES:**

```python
sage: E = NonSymmetricMacdonaldPolynomials("C2~")
sage: alphacheck = E.Y().keys().simple_roots()
sage: E.Q_to_Qcheck(alphacheck[0])
alphacheck[0] - alphacheck[2]
sage: E.Q_to_Qcheck(alphacheck[1])
alphacheck[1]
sage: E.Q_to_Qcheck(alphacheck[2])
alphacheck[2]
sage: x.parent()
Root lattice of the Root system of type ['B', 2, 1]
sage: E.Q_to_Qcheck(x)
sage: _.parent()
Coroot lattice of the Root system of type ['C', 2, 1]
```

### Y()

Return the family of Y operators whose eigenvectors are the nonsymmetric Macdonald polynomials.

**EXAMPLES:**

```python
sage: NonSymmetricMacdonaldPolynomials("C2~").Y()
Lazy family (<lambda>(i))_{i in Root lattice of the Root system of type ['B', 2, 1]}  
sage: _.keys().classical()
Root lattice of the Root system of type ['B', 2]
```

(continues on next page)
affine_lift(\mu)

Return the affinization of \mu in L'.

INPUT:

- \mu -- a classical weight \mu

See also:

- hecke_algebra_representation.CherednikOperatorsEigenvectors
  .affine_lift()
- affine_retract()
- L_prime()

EXAMPLES:

In the untwisted case, this is the other affinization at level 1:

```
sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e[\delta]
sage: E.affine_lift(omega[1]).parent()
Coambient space of the Root system of type ['C', 2, 1]
```
In the twisted case, this is the usual affinization at level 1:

```python
from sage.all import *
E = NonSymmetricMacdonaldPolynomials("B2~")
L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
omega = L0.fundamental_weights()
E.affine_lift(omega[1])
e[0] + e['deltacheck']
E.affine_lift(omega[1]).parent()
Coambient space of the Root system of type ['C', 2, 1]^*
```

affine_retract \( \mu \)

Retract the affine weight \( \mu \) into a classical weight.

**INPUT:**

- \( \mu \) – an affine weight \( \mu \) in \( L' \)

**See also:**

- `hecke_algebra_representation.HeckeAlgebraRepresentation.affine_retract()`
- `affine_lift()`
- `L_prime()`

**EXAMPLES:**

```python
sage: E = NonSymmetricMacdonaldPolynomials("B2~")
sage: L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
sage: omega = L0.fundamental_weights()
sage: E.affine_lift(omega[1])
e[0] + e['deltacheck']
sage: E.affine_lift(omega[1]).parent()
Ambient space of the Root system of type ['C', 2, 1]^*
```
```python
>>> from sage.all import *
>>> E = NonSymmetricMacdonaldPolynomials("B2~")
>>> L0 = E.keys(); L0
Ambient space of the Root system of type ['B', 2]
>>> omega = L0.fundamental_weights()
>>> E.affine_lift(omega[Integer(1)])
e[0] + e['deltacheck']
>>> E.affine_retract(E.affine_lift(omega[Integer(1)]))
(1, 0)
```

```python
cartan_type()

Return Cartan type of self.

EXAMPLES:

```python
sage: NonSymmetricMacdonaldPolynomials(['B', 2, 1]).cartan_type()
['B', 2, 1]
```
```
```python
eigenvalue_experimental(mu, l)

Return the eigenvalue of $Y^{λ∨}$ acting on the macdonald polynomial $E_{μ}$.

INPUT:

- `mu` – the index $μ$ of an eigenvector
- `l` – an index $λ∨$ of some $Y$

Note:

- This method is currently not used; most tests below even test the naive method. They are left here as a basis for a future implementation.
- This is actually equivariant, as long as $s_i$ does not fix $λ$.
- This method is only really needed for $λ∨ = α_i^∨$ with $i = 0, ..., n$.

See Corollary 6.11 of [Haiman06].

EXAMPLES:

```python
sage: K = QQ['q,t'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = RootSystem(['A',1,1]).ambient_space().algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL, q, q1, q2)
sage: L0 = E.keys()
sage: E.eigenvalues(L0([0,0])) # Checked by hand by Mark and Arun  # needs sage.libs.gap
[1/(q*t), t]
sage: alpha = E.Y().keys().simple_roots()
sage: E.eigenvalue_experimental(L0([0,0]), alpha[0]) # todo: not implemented
```
```
Some examples of eigenvalues (not mathematically checked!!!):

\[
1/(q*t) \\
sage: \text{E.eigenvalue}_\text{experimental}(L0([0,0]), alpha[1])
\]

\[
t \\
\]

\[
>>> \text{from sage.all import } * \\
>>> K = QQ[\{'q,t\'}].fraction_field() \\
>>> q,t = K.gens() \\
>>> q1 = t \\
>>> q2 = -Integer(1) \\
>>> KL = RootSystem(["A",Integer(1),Integer(1)]).ambient_space().algebra(K) \\
>>> E = \text{NonSymmetricMacdonaldPolynomials}(KL, q, q1, q2) \\
>>> L0 = E.keys() \\
>>> E.eigenvalues(L0([Integer(0),Integer(0)])) \quad \# \text{Checked by hand by Mark and Arun} \\
\]

\[
[1/(q*t), t] \\
\]

\[
>>> \text{alpha} = E.Y().keys().simple_roots() \\
>>> \text{E.eigenvalue}_\text{experimental}(L0([Integer(0),Integer(0)]), alpha[Integer(0)]) \\
\rightarrow \# \text{todo: not implemented} \\
1/(q^2*t) \\
>>> E.eigenvalues(L0([Integer(0),Integer(0)]), alpha[Integer(1)]) \\
\]

\[
t \\
\]

\[
>>> \text{from sage.all import } * \\
>>> \# \text{needs sage.libs.gap} \\
>>> \text{sage: E.eigenvalues}(L0([1,0])) \\
[t, 1/(q^2*t)] \\
>>> \text{sage: E.eigenvalues}(L0([0,1])) \\
[1/(q^2*t), q^2*t] \\
>>> \text{sage: E.eigenvalues}(L0([1,1])) \\
[1/(q*t), t] \\
>>> \text{sage: E.eigenvalues}(L0([2,1])) \\
[t, 1/(q^2*t)] \\
>>> \text{sage: E.eigenvalues}(L0([-1,1])) \\
[(-1)/(-q^3*t), q^2*t] \\
>>> \text{sage: E.eigenvalues}(L0([-2,1])) \\
[(-1)/(-q^4*t), q^3*t] \\
>>> \text{sage: E.eigenvalues}(L0([-2,0])) \\
[(-1)/(-q^3*t), q^2*t] \\
\]

\[
>>> \text{from sage.all import } * \\
>>> \# \text{needs sage.libs.gap} \\
>>> \text{sage: E.eigenvalues}(L0([Integer(1),Integer(0)])) \\
[t, 1/(q^2*t)] \\
>>> \text{sage: E.eigenvalues}(L0([Integer(0),Integer(1)])) \\
[1/(q^2*t), q^2*t] \\
>>> \text{sage: E.eigenvalues}(L0([Integer(1),Integer(1)])) \\
[1/(q^2*t), t] \\
>>> \text{sage: E.eigenvalues}(L0([Integer(2),Integer(1)])) \\
[t, 1/(q^2*t)] \\
>>> \text{sage: E.eigenvalues}(L0([-Integer(1),Integer(1)])) \\
[(-1)/(-q^3*t), q^2*t] \\
>>> \text{sage: E.eigenvalues}(L0([-Integer(2),Integer(1)])) \\
[(-1)/(-q^4*t), q^3*t] \\
>>> \text{sage: E.eigenvalues}(L0([-Integer(2),Integer(0)])) \\
[(-1)/(-q^3*t), q^2*t] \\
\]
Some type $B$ examples:

```python
sage: K = QQ[\,'q,t\'].fraction_field()
sage: q,t = K.gens()
sage: q1 = t
sage: q2 = -1
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()

sage: # not tested
sage: E.eigenvalue(L0((0,0)), alpha[0])  # not checked
q/t
sage: E.eigenvalue(L0((1,0)), alpha[1])  # What Mark got by hand
q
sage: E.eigenvalue(L0((1,0)), alpha[2])  # not checked
t
sage: E.eigenvalue(L0((1,0)), alpha[0])  # not checked
1

sage: L = RootSystem("B2~*").ambient_space()
sage: KL = L.algebra(K)
sage: E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
sage: L0 = E.keys()
sage: alpha = L.simple_coroots()

sage: E.eigenvalue(L0((0,0)), alpha[0])  # assuming Mark's calculation is correct, one should get
# not tested
1/(q*t^2)
```

```python
>>> from sage.all import *
>>> K = QQ[\,'q,t\'].fraction_field()
>>> q,t = K.gens()
>>> q1 = t
>>> q2 = -Integer(1)
>>> L = RootSystem(["B",Integer(2),Integer(1)]).ambient_space()
>>> KL = L.algebra(K)
>>> E = NonSymmetricMacdonaldPolynomials(KL,q, q1, q2)
>>> L0 = E.keys()
>>> alpha = L.simple_coroots()

>>> E.eigenvalue(L0((Integer(0),Integer(0))), alpha[Integer(0)])  # not checked
q/t
>>> E.eigenvalue(L0((Integer(1),Integer(0))), alpha[Integer(1)])  # What Mark got by hand
q
>>> E.eigenvalue(L0((Integer(1),Integer(0))), alpha[Integer(2)])  # not checked
t
>>> E.eigenvalue(L0((Integer(1),Integer(0))), alpha[Integer(0)])  # not checked
1

>>> L = RootSystem("B2~*").ambient_space()
>>> KL = L.algebra(K)
```
The expected value can more or less be read off from equation (37), Corollary 6.15 of [Haiman06]

Todo:
- Use proposition 6.9 of [Haiman06] to check the action of the \( Y \)'s on monomials.
- Generalize to any \( q_1, q_2 \).
- Check claim by Mark: all scalar products should occur in the finite weight lattice, with \( \alpha_0 \) being the appropriate projection of the affine \( \alpha_0 \). Question: can this be emulated by being at level 0?

\[ \text{rho\_prime()} \]
Return the level 0 sum of the classical fundamental weights in \( L' \).

See also:
\[ \text{L\_prime()} \]

EXAMPLES:
Untwisted case:

\[ \text{sage: NonSymmetricMacdonaldPolynomials("B2~").rho\_prime()} \ # \text{CHECKME} \]
\[ 3/2*e[0] + 1/2*e[1] \]
\[ \text{sage: NonSymmetricMacdonaldPolynomials("B2~").rho\_prime().parent()} \]
\[ \text{Coambient space of the Root system of type ['C', 2, 1]} \]

\[ \text{from sage.all import *} \]
\[ \text{NonSymmetricMacdonaldPolynomials("B2~").rho\_prime()} \ # \text{CHECKME} \]
\[ 3/2*e[0] + 1/2*e[1] \]
\[ \text{NonSymmetricMacdonaldPolynomials("B2~").rho\_prime().parent()} \]
\[ \text{Coambient space of the Root system of type ['C', 2, 1]} \]

Twisted case:

\[ \text{sage: NonSymmetricMacdonaldPolynomials("B2~*").rho\_prime()} \ # \text{CHECKME} \]
\[ 2*e[0] + e[1] \]
\[ \text{sage: NonSymmetricMacdonaldPolynomials("B2~*").rho\_prime().parent()} \]
\[ \text{Ambient space of the Root system of type ['B', 2, 1]^*} \]

\[ \text{from sage.all import *} \]
\[ \text{NonSymmetricMacdonaldPolynomials("B2~*").rho\_prime()} \ # \text{CHECKME} \]
\[ 2*e[0] + e[1] \]
\[ \text{NonSymmetricMacdonaldPolynomials("B2~*").rho\_prime().parent()} \]
\[ \text{Ambient space of the Root system of type ['B', 2, 1]^*} \]

\[ \text{seed(\mu)} \]
Return \( E_\mu \) for \( \mu \) minuscule, i.e. in the fundamental alcove.

INPUT:
• \( \mu \) – the index \( \mu \) of an eigenvector

**EXAMPLES:**

```
sage: E = NonSymmetricMacdonaldPolynomials(['A',2,1])
sage: omega = E.keys().fundamental_weights()
sage: E.seed(omega[1])
B[(1, 0, 0)]
```

```python
from sage.all import *
E = NonSymmetricMacdonaldPolynomials(['A',Integer(2),Integer(1)])
omega = E.keys().fundamental_weights()
E.seed(omega[Integer(1)])
B[(1, 0, 0)]
```

**symmetric_macdonald_polynomial** (\( \mu \))

Return the symmetric Macdonald polynomial indexed by \( \mu \).

**INPUT:**

• \( \mu \) – a dominant weight \( \mu \)

**Warning:** The result is Weyl-symmetric only for Hecke parameters of the form \( q_1 = v \) and \( q_2 = -1/v \). In general the value of \( v \) below, should be the square root of \(-q_1/q_2\), but the use of \( q_1 = t \) and \( q_2 = -1 \) results in nonintegral powers of \( t \).

**EXAMPLES:**

```
sage: K = QQ['q,v,t'].fraction_field()
sage: q,v,t = K.gens()
sage: E = NonSymmetricMacdonaldPolynomials(['A',2,1], q, v, -1/v)
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[2])
# needs sage.libs.gap
B[(1, 1, 0)] + B[(1, 0, 1)] + B[(0, 1, 1)]
sage: E.symmetric_macdonald_polynomial(2*om[1])
# needs sage.libs.gap
((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 1, 0)] + ((q*v^2+v^2-q-1)/(q*v^2-1))*B[(1, 0, 1)] + B[(2, 0, 0)] + ((q*v^2+v^2-q-1)/(q*v^2-1))*B[(0, 1, 1)] + B[(0, 2, 0)] + B[(0, 0, 2)]
sage: f = E.symmetric_macdonald_polynomial(E.L0()((2,1,0))); f
# needs sage.libs.gap
((2*q*v^4+v^4-4*q*v^2+v^2-2-q-1)/(q*v^4-1))*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, 1)] + B[(0, 1, 2)] + B[(0, 2, 1)]
```

```python
K = QQ['q,v,t'].fraction_field()
q,v,t = K.gens()
E = NonSymmetricMacdonaldPolynomials(['A',Integer(2),Integer(1)], q, v, -Integer(1)/v)
om = E.L0().fundamental_weights()
E.symmetric_macdonald_polynomial(om[Integer(2)])
# needs sage.libs.gap
B[(1, 1, 0)] + B[(1, 0, 1)] + B[(0, 1, 1)]
E.symmetric_macdonald_polynomial(Integer(2)*om[Integer(1)])
# needs sage.libs.gap
(continues on next page)```
We compare with the type $A$ Macdonald polynomials coming from symmetric functions:

```python
sage: E = NonSymmetricMacdonaldPolynomials(['C',3,1], q, v, -1/v)
```

```python
sage: om = E.L0().fundamental_weights()
sage: E.symmetric_macdonald_polynomial(om[1]+om[2])
```

```latex
\begin{align*}
B[(-2, -1, 0)] + B[(-2, 1, 0)] + B[(-2, 0, -1)] + B[(-2, 0, 1)] + \frac{(4q^3v^{14} + 2q^2v^{14} - 2q^3v^{12} + 2q^2v^{12} - 2q^3v^{10} + qv^{10} - 5q^2v^{10} - 5qv^4 + q^2v^2 - 2v^4 + 2qv^2 - 2v^2 + 2q + 4)}{(q^3v^{14} - q^2v^{10} - qv^4 + 1)}*B[(0, 0, -1)] + \frac{(-4q^3v^{14} + 2q^2v^{14} - 2q^3v^{12} + 2q^2v^{12} - 2q^3v^{10} + qv^{10} - 5q^2v^{10} - 5qv^4 + q^2v^2 - 2v^4 + 2qv^2 - 2v^2 + 2q + 4)}{(q^3v^{14} - q^2v^{10} - qv^4 + 1)}*B[(0, 0, 1)]
\end{align*}
```
\[
\begin{align*}

\[
-2^2 q^3 v^2 + 2 q^2 v + 2 q + 2)/(q^4 v^12 - q^3 v^10 - q v^2 + 1) \ast B[-1, 0, 1] + ((-q v^2 - v^2 + q + 1)/(-q v^2 + 1)) \ast B[1, -1, 0] + ((q^4 v^12 - q^3 v^10 - q v^2 + 1)/(q^4 v^12 - q^3 v^10 - q v^2 + 1)) \ast B[1, 0, -1] + B[2, -2, 0] + ((q^4 v^12 - q^3 v^10 - q v^2 + 1)/(q^4 v^12 - q^3 v^10 - q v^2 + 1)) \ast B[0, 0, 0].
\]

\[ \text{twist}(\mu, i) \]

Act by \(s_i\) on the affine weight \(\mu\).

This calls simple_reflection; which is semantically the same as the default implementation.

EXAMPLES:

\[
\text{sage: } \text{# needs sage.libs.gap} \\
\text{sage: } W = \text{WeylGroup(["B",3])} \\
\text{sage: } W.\text{element_class._repr_} = \lambda x: \text{""}.join(str(i))
\]

(continues on next page)
....: for i in x.reduced_word()

sage: K = QQ['q1,q2']

sage: w = W.an_element(); w

sage: E.twist(w,1)

5.1.234 Pieri Factors

class sage.combinat.root_system.pieri_factors.PieriFactors

    Bases: UniqueRepresentation, Parent

    An abstract class for sets of Pieri factors, used for constructing Stanley symmetric functions. The set of Pieri factors for a given type can be realized as an order ideal of the Bruhat order poset generated by a certain set of maximal elements.

    See also:

    • WeylGroups.ParentMethods.pieri_factors()

    • WeylGroups.ElementMethods.stanley_symmetric_function()

    EXAMPLES:

sage: W = WeylGroup(['A',4])

sage: PF = W.pieri_factors()

sage: PF.an_element().reduced_word()

[4, 3, 2, 1]

sage: Waff = WeylGroup(['A',4,1])

sage: PFaff = Waff.pieri_factors()

sage: Waff.from_reduced_word(PF.an_element().reduced_word()) in PFaff

True

sage: W = WeylGroup(['B',3,1])

sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,2]) in PF.elements()
True
sage: PF.cardinality()
47

sage: W = WeylGroup(['C',3,1])
sage: PF = W.pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
sage: sorted(w.reduced_word() for w in PF if w.length() == 2)
[[0, 1], [1, 0], [1, 2], [2, 0], [2, 1],
 [2, 3], [3, 0], [3, 1], [3, 2]]

>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)])
>>> PF = W.pieri_factors()
>>> PF.an_element().reduced_word()
[4, 3, 2, 1]
>>> Waff = WeylGroup(['A','A',Integer(1)])
>>> PFaff = Waff.pieri_factors()
>>> Waff.from_reduced_word(PF.an_element().reduced_word()) in PFaff
True

>>> W = WeylGroup(['B',Integer(3),Integer(1)])
>>> PF = W.pieri_factors()
>>> W.from_reduced_word([Integer(2),Integer(3),Integer(2)]) in PF.elements()
True
sage: PF.cardinality()
47

REFERENCES:
• [FoSta1994]
• [BH1994]
• [Lam1996]
• [Lam2008]
• [LSS2009]
• [Pon2010]
default_weight()
Return the function \( i \mapsto z^i \), where \( z \) is the generator of \( \mathbb{Q}[z] \).

EXAMPLES:
sage: W = WeylGroup(['A', 3, 1])
sage: weight = W.pieri_factors().default_weight()
from sage.all import *
W = WeylGroup(["A", Integer(3), Integer(1)])
weight = W.pieri_factors().default_weight()
weight(Integer(1))
z
weight(Integer(5))

\textbf{elements()} \\
Return the elements of self. Those are constructed as the elements below the maximal elements of self in Bruhat order. 

\textbf{OUTPUT:} a RecursivelyEnumeratedSet\_generic object 

\textbf{EXAMPLES:}

\begin{verbatim}
sage: PF = WeylGroup(['A',3]).pieri_factors()
sage: sorted(w.reduced_word() for w in PF.elements()) 
[[], [1], [2], [2, 1], [3], [3, 1], [3, 2], [3, 2, 1]]
\end{verbatim}

\textbf{See also:}
maximal_elements()

\textbf{Todo:} Possibly remove this method and instead have this class inherit from RecursivelyEnumeratedSet\_generic.

\textbf{generating\_series}(weight=None)
Return a length generating series for the elements of self. 

\textbf{EXAMPLES:}

\begin{verbatim}
sage: PF = WeylGroup(['C',3,1]).pieri_factors()
sage: PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
sage: PF = WeylGroup(['B',4]).pieri_factors()
sage: PF.generating_series()
z^7 + 6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> PF = WeylGroup(['C',Integer(3),Integer(1)]).pieri_factors()
>>> PF.generating_series()
6*z^6 + 14*z^5 + 18*z^4 + 15*z^3 + 9*z^2 + 4*z + 1
\end{verbatim}
\[
\text{PF} = \text{WeylGroup(['B',Integer(4)])}.\text{pieri_factors()}
\]
\[
\text{PF}.\text{generating_series()}
\]
\[
z^7 + 6z^6 + 14z^5 + 18z^4 + 15z^3 + 9z^2 + 4z + 1
\]

\textbf{max_length()}

Return the maximal length of a Pieri factor.

\textbf{EXAMPLES:}

In type A and A affine, this is \(n\):

\[
\text{sage: WeylGroup(['A',5]).pieri_factors().max_length()}
5
\]
\[
\text{sage: WeylGroup(['A',5,1]).pieri_factors().max_length()}
5
\]

\[
\text{from sage.all import *}
\]
\[
\text{sage: WeylGroup(['A',Integer(5),Integer(1)]).pieri_factors().max_length()}
5
\]
\[
\text{sage: WeylGroup(['A',Integer(5)]).pieri_factors().max_length()}
5
\]

In type B and B affine, this is \(2n - 1\):

\[
\text{sage: WeylGroup(['B',5,1]).pieri_factors().max_length()}
9
\]
\[
\text{sage: WeylGroup(['B',5]).pieri_factors().max_length()}
9
\]

\[
\text{from sage.all import *}
\]
\[
\text{sage: WeylGroup(['B',Integer(5),Integer(1)]).pieri_factors().max_length()}
9
\]
\[
\text{sage: WeylGroup(['B',Integer(5)]).pieri_factors().max_length()}
9
\]

In type C affine this is \(2n\):

\[
\text{sage: WeylGroup(['C',5,1]).pieri_factors().max_length()}
10
\]

\[
\text{from sage.all import *}
\]
\[
\text{sage: WeylGroup(['C',Integer(5),Integer(1)]).pieri_factors().max_length()}
10
\]

In type D affine this is \(2n - 2\):

\[
\text{sage: WeylGroup(['D',5,1]).pieri_factors().max_length()}
8
\]

\[
\text{from sage.all import *}
\]
\[
\text{sage: WeylGroup(['D',Integer(5),Integer(1)]).pieri_factors().max_length()}
8
\]
maximal_elements()

Return the maximal elements of self with respect to Bruhat order.

The current implementation is via a conjectural type-free formula. Use maximal_elements_combinatorial() for proven type-specific implementations. To compare type-free and type-specific (combinatorial) implementations, use method _test_maximal_elements().

EXAMPLES:

```python
sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 4, 3, 2], [1, 0, 4, 3], [2, 1, 0, 4], [3, 2, 1, 0], [4, 3, 2, 1]]

sage: W = WeylGroup(RootSystem(['C',3,1]).weight_space())
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
 [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]

sage: W = WeylGroup(['B',3,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 2, 3, 2, 0], [1, 0, 2, 3, 2], [1, 2, 3, 2, 1],
 [2, 1, 0, 2, 3], [2, 3, 2, 1, 0], [3, 2, 1, 0, 2]]

sage: W = WeylGroup(['D',4,1])
sage: PF = W.pieri_factors()
sage: sorted([w.reduced_word() for w in PF.maximal_elements()], key=str)
[[0, 2, 4, 3, 2, 0], [1, 0, 2, 4, 3, 2], [1, 2, 4, 3, 2, 1],
 [2, 1, 0, 2, 4, 3], [2, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3],
 [4, 2, 1, 0, 2, 4], [4, 3, 2, 1, 0, 2]]
```
Bases: :class:`PieriFactors`

The Pieri factors of finite type A are the restriction of the Pieri factors of affine type A to finite permutations (under the canonical embedding of finite type A into the affine Weyl group), and the Pieri factors of finite type B are the restriction of the Pieri factors of affine type C. The finite type D Pieri factors are (weakly) conjectured to be the restriction of the Pieri factors of affine type D.

.. method:: maximal_elements()

   The current algorithm uses the fact that the maximal Pieri factors of affine type A, B, C, or D either contain a finite Weyl group element, or contain an affine Weyl group element whose reflection by \( s_0 \) gets a finite Weyl group element, and that either of these finite group elements will serve as a maximal element for finite Pieri factors. A better algorithm is desirable.

.. literalinclude:: sage/combinat/root_system/pieri_factors.py
   :language: python
   :caption: Examples:

```python
sage: W = WeylGroup(['A',5]).pieri_factors()
sage: [v.reduced_word() for v in W.maximal_elements()]
[[5, 4, 3, 2, 1]]

sage: W = WeylGroup(['B',4]).pieri_factors().maximal_elements()
[
[-1 0 0 0]
[ 0 1 0 0]
[ 0 0 1 0]
[ 0 0 0 1]]
```

.. class:: sage.combinat.root_system.pieri_factors.PieriFactors_type_A(W)

   Bases: :class:`PieriFactors_finite_type`

   The set of Pieri factors for finite type A.

   This is the set of elements of the Weyl group that have a reduced word that is strictly decreasing. This may also be viewed as the restriction of affine type A Pieri factors to finite Weyl group elements.

   .. method:: maximal_elements_combinatorial()

      Return the maximal Pieri factors, using the type A combinatorial description.

      .. literalinclude:: sage/combinat/root_system/pieri_factors.py
         :language: python
         :caption: Examples:

```python
sage: W = WeylGroup(['A',5])
sage: PF = W.pieri_factors()
sage: [v.reduced_word() for v in PF.maximal_elements_combinatorial()]
[[5, 4, 3, 2, 1]]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)])
>>> PF = W.pieri_factors()
>>> PF.maximal_elements_combinatorial()[Integer(0)].reduced_word()
[4, 3, 2, 1]
```

**stanley_symm_poly_weight**(*w*)

EXAMPLES:

```python
sage: W = WeylGroup(['A',4])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,1]))
0
```

```python
>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4)])
>>> PF = W.pieri_factors()
>>> PF.stanley_symm_poly_weight(W.from_reduced_word([Integer(3),Integer(1)]))
0
```

**class** *sage.combinat.root_system.pieri_factors.PieriFactors_type_A_affine*(*W, min_length, max_length, min_support, max_support*)

Bases: *PieriFactors_affine_type*

The set of Pieri factors for type A affine, that is the set of elements of the Weyl Group which are cyclically decreasing.

Those are used for constructing (affine) Stanley symmetric functions.

The Pieri factors are in bijection with the proper subsets of the index set. The bijection is given by the support. Namely, let *f* be a Pieri factor, and *red* a reduced word for *f*. No simple reflection appears twice in red, and the support *S* of *red* (that is the *i* such that *s* *i* appears in *red*) does not depend on the reduced word.

**cardinality**()

Return the cardinality of *self*.

EXAMPLES:

```python
sage: WeylGroup(['A', 3, 1]).pieri_factors().cardinality()
15
```

```python
>>> from sage.all import *
>>> WeylGroup(['A', Integer(3), Integer(1)]).pieri_factors().cardinality()
15
```

**generating_series**(weight=None)

Return a length generating series for the elements of *self*.

EXAMPLES:
sage: W = WeylGroup(['A', 3, 1])
sage: W.pieri_factors().cardinality()
15
sage: W.pieri_factors().generating_series()
4*z^3 + 6*z^2 + 4*z + 1

>>> from sage.all import *
>>> W = WeylGroup(['A', Integer(3), Integer(1)])
>>> W.pieri_factors().cardinality()
15
>>> W.pieri_factors().generating_series()
4*z^3 + 6*z^2 + 4*z + 1

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the affine type A combinatorial description.

EXAMPLES:

sage: W = WeylGroup(['A',4,1])
sage: PF = W.pieri_factors()
sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[3, 2, 1, 0], [2, 1, 0, 4], [1, 0, 4, 3], [0, 4, 3, 2], [4, 3, 2, 1]]

>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(4),Integer(1)])
>>> PF = W.pieri_factors()
>>> [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
[[3, 2, 1, 0], [2, 1, 0, 4], [1, 0, 4, 3], [0, 4, 3, 2], [4, 3, 2, 1]]

stanley_symm_poly_weight(w)

Weight used in computing (affine) Stanley symmetric polynomials for affine type A.

EXAMPLES:

sage: W = WeylGroup(['A',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.one())
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5,4,2,1,0]))
0

>>> from sage.all import *
>>> W = WeylGroup(['A',Integer(5),Integer(1)])
>>> PF = W.pieri_factors()
>>> PF.stanley_symm_poly_weight(W.one())
0
>>> PF.stanley_symm_poly_weight(W.from_reduced_word([Integer(5),Integer(4),
˓→Integer(2),Integer(1),Integer(0)]))
0

subset (length)

Return the subset of the elements of self of length length.

INPUT:

- length – a non-negative integer

EXAMPLES:
sage: PF = WeylGroup(['A', 3, 1]).pieri_factors(); PF
Pieri factors for Weyl Group of type ['A', 3, 1] (as a matrix group acting on...
  the root space)
sage: PF3 = PF.subset(length = 2)
sage: PF3.cardinality()
6

>> from sage.all import *
>> PF = WeylGroup(['A', Integer(3), Integer(1)]).pieri_factors(); PF
Pieri factors for Weyl Group of type ['A', 3, 1] (as a matrix group acting on...
  the root space)
>> PF3 = PF.subset(length = Integer(2))
>> PF3.cardinality()
6

class sage.combinat.root_system.pieri_factors.PieriFactors_type_B(W)

Bases: PieriFactors_finite_type

The type B finite Pieri factors are realized as the set of elements that have a reduced word that is a subword of 12...12(n−1)...21. They are the restriction of the type C affine Pieri factors to the set of finite Weyl group elements under the usual embedding.

maximal_elements_combinatorial()

Return the maximal Pieri factors, using the type B combinatorial description.

EXAMPLES:

sage: PF = WeylGroup([B,4]).pieri_factors()
sage: PF.maximal_elements_combinatorial()[0].reduced_word()
[1, 2, 3, 4, 3, 2, 1]

>>> from sage.all import *

>>> PF = WeylGroup([B,Integer(4)]).pieri_factors()

>>> PF.maximal_elements_combinatorial()[Integer(0)].reduced_word()
[1, 2, 3, 4, 3, 2, 1]

stanley_symm_poly_weight(w)

Weight used in computing Stanley symmetric polynomials of type $B$.

The weight for finite type B is the number of components of the support of an element minus the number of occurrences of $n$ in a reduced word.

EXAMPLES:

sage: W = WeylGroup(['B',5])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,1,5]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([3,4,5]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([1,2,3,4,5,4]))
0

>>> from sage.all import *

>>> W = WeylGroup(['B',Integer(5)])

>>> PF = W.pieri_factors()

>>> PF.stanley_symm_poly_weight(W.from_reduced_word([Integer(3),Integer(1),
(continues on next page)
class sage.combinat.root_system.pieri_factors.PieriFactors_type_B_affine(W)

Bases: PieriFactors_affine_type

The type B affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:

- cyclic rotations of the element with reduced word $234... (n-1)n(n-1)...3210$, except for $123...n...320$ and $023...n...321$.
- $123... (n-1)n(n-1)...321$
- $023... (n-1)n(n-1)...320$

EXAMPLES:

```python
sage: W = WeylGroup(['B',4,1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([2,3,4,3,2,1,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,1]) in PF.maximal_elements()
False
sage: W.from_reduced_word([1,0,2,3,4,3,2]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,3,4,3,2,0]) in PF.maximal_elements()
True
sage: W.from_reduced_word([0,2,0]) in PF
True

sage: PF.stanley_symm_poly_weight(W.from_reduced_word([Integer(3), Integer(4), Integer(5)]))
2
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(4)]))
0
```

maximal_elements_combinatorial()  
Return the maximal Pieri factors, using the affine type B combinatorial description.

EXAMPLES:
sage: W = WeylGroup(['B',4,1])
sage: [u.reduced_word() for u in W.pieri_factors().maximal_elements_
˓→combinatorial()]
[[1, 0, 2, 3, 4, 3, 2], [2, 1, 0, 2, 3, 4, 3], [3, 2, 1, 0, 2, 3, 4], [4, 3,…
˓→2, 1, 0, 2, 3], [3, 4, 3, 2, 1, 0, 2], [2, 3, 4, 3, 2, 1, 0], [1, 2, 3, 4,…
˓→3, 2, 1], [0, 2, 3, 4, 3, 2, 0]]

>>> from sage.all import *
>>> W = WeylGroup(['B',Integer(4),Integer(1)])
>>> [u.reduced_word() for u in W.pieri_factors().maximal_elements_
˓→combinatorial()]
[[1, 0, 2, 3, 4, 3, 2], [2, 1, 0, 2, 3, 4, 3], [3, 2, 1, 0, 2, 3, 4], [4, 3,…
˓→2, 1, 0, 2, 3], [3, 4, 3, 2, 1, 0, 2], [2, 3, 4, 3, 2, 1, 0], [1, 2, 3, 4,…
˓→3, 2, 1], [0, 2, 3, 4, 3, 2, 0]]

stanley_symm_poly_weight(w)

Return the weight of a Pieri factor to be used in the definition of Stanley symmetric functions.

For type B, this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. We also consider 0 and 1 to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type C). Let n be the rank of the affine Weyl group in question (if type ['B',k,1] then we have n = k+1). Let \( \chi(\text{v}.\text{length}() < n-1) \) be the indicator function that is 1 if the length of v is smaller than n-1, and 0 if the length of v is greater than or equal to n-1. If we call \( c'(v) \) the number of components of the complement of the support of v, then the type B weight is given by weight = \( c'(v) - \chi(\text{v}.\text{length}() < n-1) \).

EXAMPLES:

sage: W = WeylGroup(['B',5,1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([0,1,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,3]))
1
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([2,3,4,5]))
0

class sage.combinat.root_system.pieri_factors.PieriFactors_type_C_affine(W):
    Bases: PieriFactors_affine_type

    The type C affine Pieri factors are realized as the order ideal (in Bruhat order) generated by cyclic rotations of the element with unique reduced word 123... (n-1)n(n-1)3210.

    EXAMPLES:

    sage: W = WeylGroup(['C',3,1])
    sage: PF = W.pieri_factors()
    sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
    [[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
     [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]

    >>> from sage.all import *
    >>> W = WeylGroup(['C',Integer(3),Integer(1)])
    >>> PF = W.pieri_factors()
    >>> sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
    [[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
     [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]
```

```python
maximal_elements_combinatorial()

    Return the maximal Pieri factors, using the affine type C combinatorial description.

    EXAMPLES:

    sage: PF = WeylGroup(['C','3','1']).pieri_factors()
    sage: [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
    [[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
     [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]

    >>> from sage.all import *
    >>> PF = WeylGroup(['C','3','1']).pieri_factors()
    >>> [w.reduced_word() for w in PF.maximal_elements_combinatorial()]
    [[0, 1, 2, 3, 2, 1], [1, 0, 1, 2, 3, 2], [1, 2, 3, 2, 1, 0],
     [2, 1, 0, 1, 2, 3], [2, 3, 2, 1, 0, 1], [3, 2, 1, 0, 1, 2]]
```

```python
stanley_symm_poly_weight(w)

    Return the weight of a Pieri factor to be used in the definition of Stanley symmetric functions.

    For type C, this weight is the number of connected components of the support (the indices appearing in a reduced word) of an element.

    EXAMPLES:
```

3888 Chapter 5. Comprehensive Module List

class sage.combinat.root_system.pieri_factors.PieriFactors_type_D_affine(W):
    Bases: PieriFactors_affine_type

    The type D affine Pieri factors are realized as the order ideal (in Bruhat order) generated by the following elements:
    
    • cyclic rotations of the element with reduced word 234...\(n-2\)\(n-1\)(n-2)...3210 such that 1 and 0 are always adjacent and (n-1) and n are always adjacent.
    
    • 123...(n-2)n(n-1)(n-2)...321
    
    • 023...(n-2)n(n-1)(n-2)...320
    
    • n(n-2)...2102...(n-2)n
    
    • (n-1)(n-2)...2102...(n-2)(n-1)

    EXAMPLES:

sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: W.from_reduced_word([3, 2, 1, 0]) in PF
True
sage: W.from_reduced_word([0, 3, 2, 1]) in PF
False
sage: W.from_reduced_word([0, 1, 3, 2]) in PF
True
sage: W.from_reduced_word([2, 0, 1, 3]) in PF
True
sage: sorted([u.reduced_word() for u in PF.maximal_elements()], key=str)
[[0, 2, 3, 5, 4, 3, 2, 0], [1, 0, 2, 3, 5, 4, 3, 2], [1, 2, 3, 5, 4, 3, 2, 1],
 [2, 1, 0, 2, 3, 5, 4, 3], [2, 3, 5, 4, 3, 2, 1, 0], [3, 2, 1, 0, 2, 3, 5, 4],
 [3, 5, 4, 3, 2, 1, 0, 2], [4, 3, 2, 1, 0, 2, 3, 4], [5, 3, 2, 1, 0, 2, 3, 5],
 [5, 4, 3, 2, 1, 0, 2, 3]]
```python
from sage.all import *

W = WeylGroup(['D', Integer(5), Integer(1)])
PF = W.pieri_factors()
W.from_reduced_word([Integer(3), Integer(2), Integer(1), Integer(0)]) in PF
# True
W.from_reduced_word([Integer(0), Integer(3), Integer(2), Integer(1)]) in PF
# False
W.from_reduced_word([Integer(0), Integer(1), Integer(3), Integer(2)]) in PF
# True
W.from_reduced_word([Integer(2), Integer(0), Integer(1), Integer(3)]) in PF
# True

PF.maximal_elements()

PF.maximal_elements_combinatorial()

Return the maximal Pieri factors, using the affine type D combinatorial description.

EXAMPLES:

sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: set(PF.maximal_elements_combinatorial()) == set(PF.maximal_elements())
# True

from sage.all import *

W = WeylGroup(['D', Integer(5), Integer(1)])
PF = W.pieri_factors()
set(PF.maximal_elements_combinatorial()) == set(PF.maximal_elements())
# True

PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2]))
0
PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2, 1]))
0
PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2, 1, 0]))
0
PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2]))

stanley_symm_poly_weight(w)

Return the weight of \( w \), to be used in the definition of Stanley symmetric functions.

INPUT:

- \( w \) – a Pieri factor for this type

For type \( D \), this weight involves the number of components of the complement of the support of an element, where we consider 0 and 1 to be one node – if 1 is in the support, then we pretend 0 in the support, and vice versa. Similarly with \( n-1 \) and \( n \). We also consider 0 and 1, \( n-1 \) and \( n \) to be one node for the purpose of counting components of the complement (as if the Dynkin diagram were that of type \( C \)).

Type D Stanley symmetric polynomial weights are still conjectural. The given weight comes from conditions on elements of the affine Fomin-Stanley subalgebra, but work is needed to show this weight is correct for affine Stanley symmetric functions – see [LSS2009, Pon2010] for details.

EXAMPLES:

sage: W = WeylGroup(['D', 5, 1])
sage: PF = W.pieri_factors()
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2, 1]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2, 1, 0]))
0
sage: PF.stanley_symm_poly_weight(W.from_reduced_word([5, 2]))
```

(continues on next page)
5.1.235 Tutorial: visualizing root systems

Root systems encode the positions of collections of hyperplanes in space, and form the fundamental combinatorial data underlying Coxeter and Weyl groups, Lie algebras and groups, etc. The theory can be a bit intimidating at first because of the many technical gadgets (roots, coroots, weights, ...). Visualizing them goes a long way toward building a geometric intuition.

This tutorial starts from simple plots and guides you all the way to advanced plots with your own combinatorial data drawn on top of it.

See also:

- Root systems – An overview of root systems in Sage
- RootLatticeRealizations.ParentMethods.plot() – the main plotting function, with pointers to all the subroutines
First plots

In this first plot, we draw the root system for type $A_2$ in the ambient space. It is generated from two hyperplanes at a 120 degree angle:

```python
sage: L = RootSystem(["A",2]).ambient_space()
sage: L.plot()
Graphics object consisting of 13 graphics primitives
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(2)]).ambient_space()
>>> L.plot()
Graphics object consisting of 13 graphics primitives
```

Each of those hyperplane $H_{\alpha^\vee}$ is described by a linear form $\alpha^\vee$ called simple coroot. To each such hyperplane corresponds a reflection along a vector called root. In this picture, the reflections are orthogonal and the two simple roots $\alpha_1$ and $\alpha_2$ are vectors which are normal to the reflection hyperplanes. The same color code is used uniformly: blue for 1, red for 2, green for 3, ... (see `CartanType.color()`). The fundamental weights, $\Lambda_1$ and $\Lambda_2$ form the dual basis of the coroots.

The two reflections generate a group of order six which is nothing but the usual symmetric group $S_3$, in its natural action by permutations of the coordinates of the ambient space. Wait, but the ambient space should be of dimension 3 then? That’s perfectly right. Here is the full picture in 3D:

```python
sage: L = RootSystem(["A",2]).ambient_space()
sage: L.plot(projection=False)
Graphics3d Object
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(2)]).ambient_space()
>>> L.plot(projection=False)
Graphics3d Object
```

However in this space, the line $(1, 1, 1)$ is fixed by the action of the group. Therefore, the so called barycentric projection orthogonal to $(1, 1, 1)$ gives a convenient 2D picture which contains all the essential information. The same projection is used by default in type $G_2$:

```python
sage: L = RootSystem(["G",2]).ambient_space()
sage: L.plot(reflection_hyperplanes="all")
Graphics object consisting of 21 graphics primitives
```
The group is now the dihedral group of order 12, generated by the two reflections $s_1$ and $s_2$. The picture displays the hyperplanes for all 12 reflections of the group. Those reflections delimit 12 chambers which are in one to one correspondence with the elements of the group. The fundamental chamber, which is grayed out, is associated with the identity of the group.

**Warning:** The fundamental chamber is currently plotted as the cone generated by the fundamental weights. As can be seen on the previous 3D picture this is not quite correct if the fundamental weights do not span the space.

Another caveat is that some plotting features may require manipulating elements with rational coordinates which will fail if one is working in, say, the weight lattice. It is therefore recommended to use the root, weight, or ambient spaces for plotting purposes rather than their lattice counterparts.

Coming back to the symmetric group, here is the picture in the weight space, with all roots and all reflection hyperplanes; remark that, unlike in the ambient space, a root is not necessarily orthogonal to its corresponding reflection hyperplane:
One can further customize which roots to display, as in the following example showing the positive roots in the weight space for type ['G',2], labelled by their coordinates in the root lattice:

```python
sage: Q = RootSystem(['G',2]).root_space()
sage: L = RootSystem(['G',2]).ambient_space()
sage: L.plot(roots=list(Q.positive_roots()), fundamental_weights=False)
```

Graphics object consisting of 17 graphics primitives

One can also customize the projection by specifying a function. Here, we display all the roots for type $E_8$ using the
projection from its eight dimensional ambient space onto 3D described on Wikipedia’s E8 3D picture:

```python
sage: M = matrix([[0.0, -0.556793440452, 0.19694925177, -0.19694925177, 0.0805477263944, -0.385290876171, 0., 0.385290876171],
               ...: [0.180913155536, 0., 0.160212955043, 0.160212955043, 0., 0.0990170516545, 0.766360424875, 0.0990170516545],
               ...: [0.338261212718, 0, 0, -0.338261212718, 0.672816364803, 0.0., 0.672816364803, 0.0.],
               ...: [0.171502564281, 0, -0.171502564281]])

sage: L = RootSystem(['E', 8]).ambient_space()
sage: L.dimension()
8
sage: L.plot(roots='all', reflection_hyperplanes=False, # long time
         projection=lambda v: M*vector(v), labels=False)
Graphics3d Object
```

The projection function should be linear or affine, and return a vector with rational coordinates. The rationale for the later constraint is to allow for using the PPL exact library for manipulating polytopes. Indeed exact calculations give cleaner pictures (adjacent objects, intersection with the bounding box, …). Besides the interface to PPL is indeed currently faster than that for CDD, and it is likely to become even more so.

**Exercise**

Draw all finite root systems in 2D, using the canonical projection onto their Coxeter plane. See Stembridge’s page.
Alcoves and chambers

We now draw the root system for type $G_2$, with its alcoves (in finite type, those really are the chambers) and the corresponding elements of the Weyl group. We enlarge a bit the bounding box to make sure everything fits in the picture:

```
sage: RootSystem(["G",2]).ambient_space().plot(alcoves=True,
    ....: alcove_labels=True, bounding_box=5)
Graphics object consisting of 37 graphics primitives
```

The same picture in 3D, for type $B_3$:

```
sage: RootSystem(["B",3]).ambient_space().plot(alcoves=True, alcove_labels=True)
Graphics3d Object
```

Exercise

Can you spot the fundamental chamber? The fundamental weights? The simple roots? The longest element of the Weyl group?
Alcove pictures for affine types

We now draw the usual alcove picture for affine type $A_2^{(1)}$:

```sage
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot() # long time
Graphics object consisting of 160 graphics primitives
```

```python
>>> from sage.all import *

>>> L = RootSystem(["A",Integer(2),Integer(1)]).ambient_space()

>>> L.plot() # long time
Graphics object consisting of 160 graphics primitives
```

This picture is convenient because it is low dimensional and contains most of the relevant information. Beside, by choosing the ambient space, the elements of the Weyl group act as orthogonal affine maps. In particular, reflections are usual (affine) orthogonal reflections. However this is in fact only a slice of the real picture: the Weyl group actually acts by linear maps on the full ambient space. Those maps stabilize the so-called level $l$ hyperplanes, and we are visualizing here what's happening at level 1. Here is the full picture in 3D:

```sage
sage: L.plot(bounding_box=[[-3,3],[-3,3],[-1,1]], affine=False) # long time
Graphics3d Object
```
In fact, in type $A$, this really is a picture in 4D, but as usual the barycentric projection kills the boring extra dimension for us.

It's usually more readable to only draw the intersection of the reflection hyperplanes with the level 1 hyperplane:

```
sage: L.plot(affine=False, level=1) # long time
Graphics3d Object
```

Such 3D pictures are useful to better understand technicalities, like the fact that the fundamental weights do not necessarily all live at level 1:

```
sage: L = RootSystem(["G",2,1]).ambient_space()
sage: L.plot(affine=False, level=1)
Graphics3d Object
```
>>> from sage.all import *
>>> L = RootSystem(\"G\",Integer(2),Integer(1)).ambient_space()
>>> L.plot(affine=False, level=Integer(1))
Graphics3d Object

Note: Such pictures may tend to be a bit flat, and it may be helpful to play with the aspect_ratio and more generally with the various options of the show() method:

sage: p = L.plot(affine=False, level=1)
sage: p.show(aspect_ratio=[1,1,2], frame=False)

Even 2D pictures of the rank $1+1$ cases can give some food for thought. Here, we draw the root lattice, with the positive roots of small height in the root poset:

sage: L = RootSystem(\"C\",2,1).ambient_space()
sage: L.plot(coroots="simple", alcove_labels=True)
Graphics object consisting of 216 graphics primitives

As for finite root systems, the alcoves are indexed by the elements of the Weyl group $W$. Two alcoves indexed by $u$ and $v$ respectively share a wall if $u$ and $v$ are neighbors in the right Cayley graph: $u = v s_i$; the color of that wall is given by $i$:

Exercise

Draw the alcove picture at level 1, and compare the position of the fundamental weights and the vertices of the fundamental alcove.
Exercises

1. Use the same trick to draw the reflection hyperplanes in the weight lattice for the coroots of small height. Add
Here is a polished solution for the first exercise:

```python
sage: L = RootSystem(\["A",1,1\]).weight_space()
sage: seed = L.simple_coroots()
sage: succ = attrcall("pred")
sage: positive_coroots = RecursivelyEnumeratedSet(seed, succ, structure='graded')
sage: it = iter(positive_coroots)
sage: first_positive_coroots = [next(it) for i in range(20)]
sage: p = L.plot(fundamental_chamber=True,
            reflection_hyperplanes=first_positive_coroots,
            affine=False, alcove_labels=1,
            bounding_box=[[-9,9],[-1,2]],
            projection=lambda x: matrix([[1,-1],[1,1]])*vector(x))
sage: p.show(figsize=20)
```

Higher dimension affine pictures

We now do some plots for rank 4 affine types, at level 1. The space is tiled by the alcoves, each of which is a 3D simplex:

```python
sage: L = RootSystem(\["A",3,1\]).ambient_space()
sage: L.plot(reflection_hyperplanes=False, bounding_box=85/100)  # long time
```

It is recommended to use a small bounding box here, for otherwise the number of simplices grows quicker than what Sage can handle smoothly. It can help to specify explicitly which alcoves to visualize. Here is the fundamental alcove, specified by an element of the Weyl group:
Combinatorics, Release 10.4

```python
sage: W = L.weyl_group()
```

```python
sage: L.plot(reflection_hyperplanes=False, alcoves=[W.one()], bounding_box=2)
```

```
>>> from sage.all import *

>>> W = L.weyl_group()

>>> L.plot(reflection_hyperplanes=False, alcoves=[W.one()], bounding_box=Integer(2))
```

```
and the fundamental polygon, specified by the coordinates of its center in the root lattice:

```python
sage: W = L.weyl_group()
```

```python
sage: L.plot(reflection_hyperplanes=False, alcoves=[[0,0]], bounding_box=2)
```

```
>>> from sage.all import *

>>> W = L.weyl_group()

>>> L.plot(reflection_hyperplanes=False, alcoves=[[Integer(0),Integer(0)]], bounding_box=Integer(2))
```

Finally, we draw the alcoves in the classical fundamental chambers, using that those are indexed by the elements of the Weyl group having no other left descent than 0. In order to see the inner structure, we only draw the wireframe of the
facets of the alcoves. Specifying the wireframe option requires a more flexible syntax for plots which will be explained later on in this tutorial:

```
>>> from sage.all import *
>>> L = RootSystem(['B', Integer(3), Integer(1)]).ambient_space()
>>> W = L.weyl_group()
>>> alcoves = [-w for d in range(12) for w in W.affine_grassmannian_elements_of_given_length(d)]
>>> p = L.plot_fundamental_chamber("classical")
>>> p += L.plot_alcoves(alcoves=alcoves, wireframe=True)
>>> p += L.plot_fundamental_weights()
>>> p.show(frame=False)
```
Exercises

1. Draw the fundamental alcove in the ambient space, just by itself (no reflection hyperplane, root, ...). The automorphism group of the Dynkin diagram for $A_3^{(1)}$ (a cycle of length 4) is the dihedral group. Visualize the corresponding symmetries of the fundamental alcove.

2. Draw the fundamental alcoves for the other rank 4 affine types, and recover the automorphism groups of their Dynkin diagram from the pictures.

Drawing on top of a root system plot

The root system plots have been designed to be used as wallpaper on top of which to draw more information. In the following example, we draw an alcove walk, specified by a word of indices of simple reflections, on top of the weight lattice in affine type $A_{2,1}$:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,0,2,0,1,2,0]
sage: L.plot(alcove_walk=w1, bounding_box=6) # long time
Graphics object consisting of 535 graphics primitives
```

```
>>> from sage.all import *

>>> L = RootSystem(["A",Integer(2),Integer(1)]).ambient_space()

>>> w1 = [Integer(0),Integer(2),Integer(1),Integer(2),Integer(0),Integer(2),Integer(1),Integer(0),Integer(2),Integer(1),Integer(2),Integer(0)]

>>> L.plot(alcove_walk=w1, bounding_box=Integer(6)) # long time
Graphics object consisting of 535 graphics primitives
```

Now, what about drawing several alcove walks, and specifying some colors? A single do-it-all plot method would be cumbersome; so instead, it is actually built on top of many methods (see the list below) that can be called independently and combined at will:

```
sage: L.plot_roots() + L.plot_reflection_hyperplanes()
Graphics object consisting of 12 graphics primitives
```

```
>>> from sage.all import *

>>> L.plot_roots() + L.plot_reflection_hyperplanes()
Graphics object consisting of 12 graphics primitives
```
Note: By default the axes are disabled in root system plots since they tend to pollute the picture. Annoyingly they come back when combining them. Here is a workaround:

```
sage: p = L.plot_roots() + L.plot_reflection_hyperplanes()
sage: p.axes(False)
sage: p
Graphics object consisting of 12 graphics primitives
```

```
>>> from sage.all import *
>>> p = L.plot_roots() + L.plot_reflection_hyperplanes()
>>> p.axes(False)
>>> p
Graphics object consisting of 12 graphics primitives
```

In order to specify common information for all the pieces of a root system plot (choice of projection, bounding box, color code for the index set, ...), the easiest is to create an option object using `plot_parse_options()`, and pass it down to each piece. We use this to plot our two walks:

```
sage: # long time
sage: plot_options = L.plot_parse_options(bounding_box=[[-2,5],[-2,6]])
```

(continues on next page)
sage: w2 = [2,1,2,0,2,0,2,1,2,0,1,2,0,2,0,1,2,0,2]
sage: p = L.plot alcoves(plot_options=plot_options)
sage: p += L.plot alcove_walk(w1, color="green",
....: plot_options=plot_options)
sage: p += L.plot alcove_walk(w2, color="orange",
....: plot_options=plot_options)
sage: p
Graphics object consisting of ... graphics primitives

And another with some foldings:

sage: p += L.plot alcove_walk([0,1,2,0,2,0,1,2,0,1],
....: foldings=[False, False, True, False, False,
....: False, True, False, True, False],
....: color="purple")
sage: p.axes(False)
sage: p.show(figsize=20)
Here we show a weight at level 0 and the reduced word implementing the translation by this weight:

```python
sage: # long time
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: P = RootSystem(['A',2,1]).weight_space(extended=True)
sage: Lambda = P.fundamental_weights()
sage: walk = L.reduced_word_of_translation(L(t))
sage: plot_options = L.plot_parse_options(bounding_box=[[-2,5],[-2,5]])
sage: p = L.plot(plot_options=plot_options)
sage: p += L.plot_alcove_walk(walk, color="green",
                           plot_options=plot_options)
```

```python
sage: p += plot_options.family_of_vectors({t: L(t)})
```

```python
sage: p
```

Here is the output of the code:

```
5.1. Comprehensive Module List  3907
```

```python
>>> from sage.all import *
```

```python
>>> L = RootSystem(['A',2,1]).ambient_space()
```

```python
>>> P = RootSystem(['A',2,1]).weight_space(extended=True)
```

```python
>>> Lambda = P.fundamental_weights()
```

```python
>>> t = Integer(6)*Lambda[Integer(1)] - Integer(2)*Lambda[Integer(2)] - Integer(4)*Lambda[Integer(0)]
```

```python
>>> walk = L.reduced_word_of_translation(L(t))
```

```python
>>> plot_options = L.plot_parse_options(bounding_box=[[-Integer(2),Integer(5)],[Integer(2),Integer(5)]]])
```

```python
>>> p = L.plot(plot_options=plot_options)
```

```python
>>> p += L.plot_alcove_walk(walk, color="green",
                           plot_options=plot_options)
```

```python
>>> p += plot_options.family_of_vectors({t: L(t)})
```

```python
>>> plot_options.finalize(p)
```

```python
>>> p
```

```
Graphics object consisting of ... graphics primitives
```

```
Graphics object consisting of ... graphics primitives
```
Note that the coloring of the translated alcove does not match with that of the fundamental alcove: the translation actually lives in the extended Weyl group and is the composition of the simple reflections indexed by the alcove walk together with a rotation implementing an automorphism of the Dynkin diagram.

We conclude with a rank $3 + 1$ alcove walk:

```
sage: L = RootSystem(["B",3,1]).ambient_space()
sage: w3 = [0,2,1,3,2,0,2,1,0,2,3,1,2,1,3,2,0,2,0,1,2,0]
sage: (L.plot_fundamental_weights()
    ..:    + L.plot_reflection_hyperplanes(bounding_box=2) + L.plot_alcove_walk(w3))
Graphics3d Object
```

```
>>> from sage.all import *
>>> L = RootSystem(["B",Integer(3),Integer(1)]).ambient_space()
>>> w3 = [Integer(0),Integer(2),Integer(1),Integer(3),Integer(2),Integer(0),
    ..:    Integer(2),Integer(1),Integer(0),Integer(2),Integer(3),Integer(1),Integer(2),
    ..:    Integer(1),Integer(3),Integer(2),Integer(0),Integer(2),Integer(0),Integer(1),
    ..:    Integer(2),Integer(0)]
>>> (L.plot_fundamental_weights()
    ..:    + L.plot_reflection_hyperplanes(bounding_box=Integer(2)) + L.plot_alcove_
    ..:    walk(w3))
Graphics3d Object
```
Exercise

1. Draw the tiling of 3D space by the fundamental polygons for types A, B, C, D. Hints: use the **wireframe** option of `RootLatticeRealizations.ParentMethods.plot_alcoves()` and the **color** option of `plot()` to only draw the alcove facets indexed by 0.

Solution

```python
sage: L = RootSystem(['A',3,1]).ambient_space()
sage: alcoves = cartesian_product([[0,1],[0,1],[0,1]])
sage: color = lambda i: "black" if i==0 else None
sage: L.plot_alcoves(alcoves=alcoves, color=color, # long time
.....: bounding_box=10, wireframe=True).show(frame=False)
```

```python
>>> from sage.all import *

L = RootSystem(['A',Integer(3),Integer(1)]).ambient_space()

>>> alcoves = cartesian_product([[Integer(0),Integer(1)],[Integer(0),Integer(1)],[Integer(0),Integer(1)])

>>> color = lambda i: "black" if i==Integer(0) else None

>>> L.plot_alcoves(alcoves=alcoves, color=color, # long time
.....: bounding_box=Integer(10), wireframe=True).show(frame=False)
```

Hand drawing on top of a root system plot (aka Coxeter graph paper)

Taken from John Stembridge’s excellent data archive:

“If you’ve ever worked with affine reflection groups, you’ve probably wasted lots of time drawing the reflecting hyperplanes of the rank 2 groups on scraps of paper. You may also have wished you had pads of graph paper with these lines drawn in for you. If so, you’ve come to the right place. Behold! Coxeter graph paper!”.

Now you can create your own customized color Coxeter graph paper:

```python
sage: L = RootSystem(['C',2,1]).ambient_space()

sage: p = L.plot(bounding_box=[[-8,9],[-5,7]], # long time (10 s)
.....: coroots="simple"

sage: p # long time
Graphics object consisting of ... graphics primitives
```
By default Sage’s plot are bitmap pictures which would come out ugly if printed on paper. Instead, we recommend saving the picture in postscript or svg before printing it:

```
sage: p.save("C21paper.eps") # not tested
```

Note: Drawing pictures with a large number of alcoves is currently somewhat ridiculously slow. This is due to the use of generic code that works uniformly in all dimension rather than taylor-made code for 2D. Things should improve with the fast interface to the PPL library (see e.g. Issue #12553).

### Drawing custom objects on top of a root system plot

So far so good. Now, what if one wants to draw, on top of a root system plot, some object for which there is no preexisting plot method? Again, the `plot_options` object come in handy, as it can be used to compute appropriate coordinates.

Here we draw the permutohedron, that is the Cayley graph of the symmetric group $W$, by positioning each element $w$ at $w(\rho)$, where $\rho$ is in the fundamental alcove:

```
sage: L = RootSystem(["A",2]).ambient_space()  
sage: rho = L.rho()  
sage: plot_options = L.plot_parse_options()  
sage: W = L.weyl_group()  
sage: g = W.cayley_graph(side="right")  
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}  
sage: p = L.plot_alcoves()  
sage: p += g.plot(pos=positions, vertex_size=0,  
....:       color_by_label=plot_options.color)
```

(continues on next page)
Todo: Could we have nice \LaTeX{} labels in this graph?

The same picture for $A_3$ gives a nice 3D permutohedron:

```python
sage: L = RootSystem(['A',3]).ambient_space()
sage: rho = L.rho()
sage: plot_options = L.plot_parse_options()
sage: W = L.weyl_group()
sage: g = W.cayley_graph(side="right")
sage: positions = {w: plot_options.projection(w.action(rho)) for w in W}
sage: p = L.plot_roots()
sage: p += g.plot3d(pos3d=positions, color_by_label=plot_options.color)
sage: p
Graphics3d Object
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(3)]).ambient_space()
>>> rho = L.rho()
>>> plot_options = L.plot_parse_options()
```
Combinatorics, Release 10.4

```python
>>> W = L.weyl_group()
>>> g = W.cayley_graph(side="right")
>>> positions = {w: plot_options.projection(w.action(rho)) for w in W}
>>> p = L.plot_roots()
>>> p += g.plot3d(pos3d=positions, color_by_label=plot_options.color)
>>> p
Graphics3d Object
```

**Exercises**

1. Locate the identity element of $W$ in the previous picture
2. Rotate the picture appropriately to highlight the various symmetries of the permutohedron.
3. Make a function out of the previous example, and explore the Cayley graphs of all rank 2 and 3 Weyl groups.
4. Draw the root poset for type $B_2$ and $B_3$
5. Draw the root poset for type $E_8$ to recover the picture from [Wikipedia article File:E8_3D.png](#).

Similarly, we display a crystal graph by positioning each element according to its weight:

```python
sage: C = crystals.Tableaux(['A',2], shape=[4,2])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()
sage: g = C.digraph()
sage: positions = {x: plot_options.projection(x.weight()) for x in C}
sage: p = L.plot()
sage: p += g.plot(pos=positions, color_by_label=plot_options.color, vertex_size=0)
sage: p.axes(False)
sage: p.show(figsize=15)
```

```python
>>> from sage.all import *
>>> C = crystals.Tableaux(['A',Integer(2)], shape=[Integer(4),Integer(2)])
>>> L = C.weight_lattice_realization()
>>> plot_options = L.plot_parse_options()
```
Note: In the above picture, many pairs of tableaux have the same weight and are thus superposed (look for example near the center). Some more layout logic would be needed to separate those nodes properly, but the foundations are laid firmly and uniformly across all types of root systems for writing such extensions.

Here is an analogue picture in 3D:

```python
sage: C = crystals.Tableaux(['A', 3], shape=[3, 2, 1])
sage: L = C.weight_lattice_realization()
sage: plot_options = L.plot_parse_options()
sage: g = C.digraph()
sage: positions = {x: plot_options.projection(x.weight()) for x in C}
sage: p = L.plot(reflection_hyperplanes=False, fundamental_weights=False)
sage: p += g.plot3d(pos3d=positions, vertex_labels=True,
... color_by_label=plot_options.color, edge_labels=True)
sage: p
Graphics3d Object
```

```
>>> from sage.all import *
```
Exercise

Explore the previous picture and notice how the edges of the crystal graph are parallel to the simple roots.

Enjoy and please post your best pictures on the Sage-Combinat wiki.

class sage.combinat.root_system.plot.PlotOptions (space, projection=True, bounding_box=3, color=<bound method CartanTypeFactory.color of <class 'sage.combinat.root_system.cartan_type.CartonTypeFactory'>>, labels=True, level=None, affine=None, arrowsize=5)

Bases: object

A class for plotting options for root lattice realizations.

See also:

• RootLatticeRealizations.ParentMethods.plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

color (i)

Return the color to be used for objects indexed by i.

INPUT:

• i – an index

See also:

index_of_object ()

EXAMPLES:

sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.color(1) 'blue'
sage: options.color(2) 'red'
sage: for alpha in L.roots():
....: print("{} {}\n".format(alpha, options.color(alpha)))
alpha[1] blue
alpha[2] red
-alpha[1] black
-alpha[2] black

>>> from sage.all import *
>>> L = RootSystem(['A',Integer(2)]).root_lattice()
>>> options = L.plot_parse_options(labels=False)
>>> alpha = L.simple_roots()
>>> options.color(Integer(1)) 'blue'
>>> options.color(Integer(2))
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> for alpha in L.roots():
...     print("{} {}".format(alpha, options.color(alpha)))
alpha[1] blue
alpha[2] red
-alpha[1] black
-alpha[2] black
```

cone (rays=[], lines=[], color='black', thickness=1, alpha=1, wireframe=False, label=None, draw_degenerate=True, as_polyhedron=False)

Return the cone generated by the given rays and lines.

INPUT:

- rays, lines – lists of elements of the root lattice realization (default: [])
- color – a color (default: "black")
- alpha – a number in the interval [0, 1] (default: 1) the desired transparency
- label – an object to be used as the label for this cone. The label itself will be constructed by calling latex() or repr() on the object depending on the graphics backend.
- draw_degenerate – a boolean (default: True) whether to draw cones with a degenerate intersection with the bounding box
- as_polyhedron – a boolean (default: False) whether to return the result as a polyhedron, without clipping it to the bounding box, and without making a plot out of it (for testing purposes)

OUTPUT:

A graphic object, a polyhedron, or 0.

EXAMPLES:

sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2); p
Graphics object consisting of 2 graphics primitives
```

sage: list(p)
[Polygon defined by 4 points,
   Text '$2$' at the point (3.15...,3.15...)]
```

sage: options.cone(rays=[alpha[1]], lines=[alpha[2]], color='green', label=2, as_polyhedron=True)
A 2-dimensional polyhedron in ZZ^2 defined as the convex hull of 1 vertex, 1 ray, 1 line
```

5.1. Comprehensive Module List 3915

(continues on next page)
An empty result, being outside of the bounding box:

```
sage: options = L.plot_parse_options(labels=True,
.....: bounding_box=[[-10,-9]]^2)
sage: options.cone(rays=[alpha[1]], lines=[alpha[2]],
.....: color='green', label=2)
```

Test that the options are properly passed down:

```
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
.....: color='green', label=2, thickness=4, alpha=.5)
sage: list(p)
[Line defined by 2 points, Text '$2$' at the point (3.15...,3.15...)]
sage: sorted(p[0].options().items())
[('alpha', 0.500000000000000), ('legend_color', None),
('legend_label', None), ('rgbcolor', 'green'), ('thickness', 4),
('zorder', 1)]
```

This method is tested indirectly but extensively by the various plot methods of root lattice realizations.

\texttt{empty (**args)}

Return an empty plot.

\textbf{EXAMPLES:}
```python
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options(labels=True)
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(2)]).root_lattice()
>>> options = L.plot_parse_options(labels=True)
```

This currently returns `int(0)`:

```python
sage: options.empty()
0
```

```python
>>> from sage.all import *
>>> options.empty()
0
```

This is not a plot, so may cause some corner cases. On the other hand, 0 behaves as a fast neutral element, which is important given the typical idioms used in the plotting code:

```python
sage: p = point([0,0])
sage: p + options.empty() is p
True
```

```python
>>> from sage.all import *
>>> p = point([Integer(0),Integer(0)])
>>> p + options.empty() is p
True
```

**family_of_vectors**(vectors)

Return a plot of a family of vectors.

**INPUT:**

- vectors – family or vectors in self

The vectors are labelled by their index.

**EXAMPLES:**

```python
sage: L = RootSystem(["A",2]).root_lattice()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: p = options.family_of_vectors(alpha); p
Graphics object consisting of 4 graphics primitives
sage: list(p)
[Arrow from (0.0,0.0) to (1.0,0.0),
 Text '$1$' at the point (1.05,0.0),
 Arrow from (0.0,0.0) to (0.0,1.0),
 Text '$2$' at the point (0.0,1.05)]
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(2)]).root_lattice()
>>> options = L.plot_parse_options()
>>> alpha = L.simple_roots()
>>> p = options.family_of_vectors(alpha); p
Graphics object consisting of 4 graphics primitives
```

(continues on next page)
Handling of colors and labels:

```python
def color(i):
    return "purple" if i==1 else None
```

```python
options = L.plot_parse_options(labels=False, color=color)
p = options.family_of_vectors(alpha)
list(p)
p[0].options()['rgbcolor']
```

```python
>>> from sage.all import *
>>> def color(i):
... return "purple" if i==Integer(1) else None
>>> options = L.plot_parse_options(labels=False, color=color)
>>> p = options.family_of_vectors(alpha)
>>> list(p)
p[Integer(0)].options()['rgbcolor']
```

Matplotlib emits a warning for arrows of length 0 and draws nothing anyway. So we do not draw them at all:

```python
L = RootSystem(['A',2,1]).ambient_space()
options = L.plot_parse_options()
Lambda = L.fundamental_weights()
p = options.family_of_vectors(Lambda); p
list(p)
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(2),Integer(1)]).ambient_space()
>>> options = L.plot_parse_options()
>>> Lambda = L.fundamental_weights()
>>> p = options.family_of_vectors(Lambda); p
```

```python
finalize(G)
```

Finalize a root system plot.

INPUT:
• **G** – a root system plot or 0

This sets the aspect ratio to 1 and remove the axes. This should be called by all the user-level plotting methods of root systems. This will become mostly obsolete when customization options won’t be lost anymore upon addition of graphics objects and there will be a proper empty object for 2D and 3D plots.

**EXAMPLES:**

```
sage: L = RootSystem(["B",2,1]).ambient_space()
sage: options = L.plot_parse_options()
sage: p = L.plot_roots(plot_options=options)
sage: p += L.plot_coroots(plot_options=options)
sage: p.axes()
True
sage: p = options.finalize(p)
sage: p.axes()
False
sage: p.aspect_ratio()
1.0
```

```
sage: options = L.plot_parse_options(affine=False)
sage: p = L.plot_roots(plot_options=options)
sage: p += point([[1,1,0]])
sage: p = options.finalize(p)
sage: p.aspect_ratio()
[1.0, 1.0, 1.0]
```

```
>>> from sage.all import *
>>> L = RootSystem(["B",Integer(2),Integer(1)]).ambient_space()
>>> options = L.plot_parse_options()
>>> p = L.plot_roots(plot_options=options)
>>> p += L.plot_coroots(plot_options=options)
>>> p.axes()
True
>>> p = options.finalize(p)
>>> p.axes()
False
>>> p.aspect_ratio()
1.0
```

```
>>> options = L.plot_parse_options(affine=False)
>>> p = L.plot_roots(plot_options=options)
>>> p += point([Integer(1),Integer(1),Integer(0)])
>>> p = options.finalize(p)
>>> p.aspect_ratio()
[1.0, 1.0, 1.0]
```

If the input is 0, this returns an empty graphics object:

```
sage: type(options.finalize(0))
<class 'sage.plot.plot3d.base.Graphics3dGroup'>
sage: options = L.plot_parse_options()
sage: type(options.finalize(0))
<class 'sage.plot.graphics.Graphics'>
sage: list(options.finalize(0))
[]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> type(options.finalize(Integer(0)))
<class 'sage.plot.plot3d.base.Graphics3dGroup'>

>>> options = L.plot_parse_options()
>>> type(options.finalize(Integer(0)))
<class 'sage.plot.graphics.Graphics'>

>>> list(options.finalize(Integer(0)))
[]
```

**in_bounding_box** *(x)*

Return whether `x` is in the bounding box.

**INPUT:**

- `x` – an element of the root lattice realization

This method is currently one of the bottlenecks, and therefore cached.

**EXAMPLES:**

```python
sage: L = RootSystem("A",2,1).ambient_space()
sage: options = L.plot_parse_options()
sage: alpha = L.simple_roots()
sage: options.in_bounding_box(alpha[1])
True
sage: options.in_bounding_box(3*alpha[1])
False
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(2),Integer(1)]).ambient_space()
>>> options = L.plot_parse_options()
>>> alpha = L.simple_roots()
>>> options.in_bounding_box(alpha[Integer(1)])
True
>>> options.in_bounding_box(Integer(3)*alpha[Integer(1)])
False
```

**index_of_object** *(i)*

Try to return the node of the Dynkin diagram indexing the object `i`.

**OUTPUT:** a node of the Dynkin diagram or None

**EXAMPLES:**

```python
sage: L = RootSystem("A",3).root_lattice()
sage: alpha = L.simple_roots()
sage: omega = RootSystem("A",3).weight_lattice().fundamental_weights()
sage: options = L.plot_parse_options(labels=False)
sage: options.index_of_object(3)
3
sage: options.index_of_object(alpha[1])
1
sage: options.index_of_object(omega[2])
2
30
sage: options.index_of_object("bla")
```

Chapter 5. Comprehensive Module List
intersection_at_level_1(x)

Return $x$ scaled at the appropriate level, if level is set; otherwise return $x$.

INPUT:

• $x$ – an element of the root lattice realization

EXAMPLES:

```python
sage: L = RootSystem(['A',2,1]).weight_space()
sage: options = L.plot_parse_options()
sage: options.intersection_at_level_1(L.rho())
sage: options = L.plot_parse_options(affine=False, level=2)
sage: options.intersection_at_level_1(L.rho())
```

When level is not set, $x$ is returned:

```python
sage: options = L.plot_parse_options(affine=False)
sage: options.intersection_at_level_1(L.rho())
Lambda[0] + Lambda[1] + Lambda[2]
```

projection(v)

Return the projection of $v$. 
INPUT:

- \( x \) – an element of the root lattice realization

OUTPUT:

An immutable vector with integer or rational coefficients.

EXAMPLES:

```python
sage: L = RootSystem(['A', 2, 1]).ambient_space()
sage: options = L.plot_parse_options()
```

```python
sage: options.projection(L.rho())
(0, 989/571)
```

```python
sage: options = L.plot_parse_options(projection=False)
```

```python
sage: options.projection(L.rho())
(2, 1, 0)
```

```python
reflection_hyperplane(coroot, as_polyhedron=False)
```

Return a plot of the reflection hyperplane indexed by this coroot.

- \( \text{coroot} \) – a coroot

EXAMPLES:

```python
sage: L = RootSystem(['B', 2]).weight_space()
sage: alphacheck = L.simple_coroots()
```

```python
sage: options = L.plot_parse_options()
```

```python
sage: H = options.reflection_hyperplane(alphacheck[1]); H
```

```python
Graphics object consisting of 2 graphics primitives
```

```python
>>> from sage.all import *
>>> L = RootSystem(['B', Integer(2)]).weight_space()
```

```python
>>> alphacheck = L.simple_coroots()
```

```python
>>> options = L.plot_parse_options()
```

```python
>>> H = options.reflection_hyperplane(alphacheck[Integer(1)]); H
```

```python
Graphics object consisting of 2 graphics primitives
```

Todo: Display the periodic orientation by adding a + and a - sign close to the label. Typically by using the associated root to shift a bit from the vertex upon which the hyperplane label is attached.

```python
text(label, position, rgbcolor=(0, 0, 0))
```

Return text widget with label \( \text{label} \) at position \( \text{position} \)

INPUT:

- \( \text{label} \) – a string, or a Sage object upon which latex will be called
- position – a position
- rgbcolor – the color as an RGB tuple

**EXAMPLES:**

```python
sage: L = RootSystem(['A',2]).root_lattice()
sage: options = L.plot_parse_options()
sage: list(options.text("coucou", [0,1]))
[Text 'coucou' at the point (0.0,1.0)]
sage: list(options.text(L.simple_root(1), [0,1]))
[Text '\alpha_1' at the point (0.0,1.0)]
sage: list(options.text(L.simple_root(2), [1,0], rgbcolor=(1,0.5,0)))
[Text '\alpha_2' at the point (1.0,0.0)]
sage: options = L.plot_parse_options(labels=False)
sage: options.text("coucou", [0,1])
0
```

```python
sage: options = RootSystem(['B',3]).root_lattice().plot_parse_options()
sage: print(options.text("coucou", [0,1,2]).x3d_str())
<Transform translation='0 1 2'>
<Shape><Text string=coucou solid='true'/><Appearance><Material diffuseColor='0.0 0.0 0.0' shininess='1.0' specularColor='0.0 0.0 0.0'/></Appearance></Shape>
</Transform>
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(2)]).root_lattice()
>>> options = L.plot_parse_options()
>>> list(options.text("coucou", [Integer(0),Integer(1)]))
[Text 'coucou' at the point (0.0,1.0)]
>>> list(options.text(L.simple_root(Integer(1)), [Integer(0),Integer(1)]))
[Text '\alpha_1' at the point (0.0,1.0)]
>>> list(options.text(L.simple_root(Integer(2)), [Integer(1),Integer(0)], rgbcolor=(Integer(1),RealNumber('0.5'),Integer(0))))
[Text '\alpha_2' at the point (1.0,0.0)]
>>> options = L.plot_parse_options(labels=False)
>>> options.text("coucou", [Integer(0),Integer(1)])
0

>>> options = RootSystem(['B',Integer(3)]).root_lattice().plot_parse_options()
>>> print(options.text("coucou", [Integer(0),Integer(1),Integer(2)]).x3d_str())
<Transform translation='0 1 2'>
<Shape><Text string=coucou solid='true'/><Appearance><Material diffuseColor='0.0 0.0 0.0' shininess='1.0' specularColor='0.0 0.0 0.0'/></Appearance></Shape>
</Transform>
```

**thickness** *(i)*

Return the thickness to be used for lines indexed by *i*.

**INPUT:**

- *i* – an index
See also:

```
index_of_object()
```

EXAMPLES:

```
sage: L = RootSystem(["A",2,1]).root_lattice()
sage: options = L.plot_parse_options(labels=False)
sage: alpha = L.simple_roots()
sage: options.thickness(0)
2
sage: options.thickness(1)
1
sage: options.thickness(2)
1
sage: for alpha in L.simple_roots():
    ....:     print("{} {}").format(alpha, options.thickness(alpha))
alpha[0] 2
alpha[1] 1
alpha[2] 1
```

```text
>>> from sage.all import *
>>>
>>> L = RootSystem(["A",Integer(2),Integer(1)]).root_lattice()
>>> options = L.plot_parse_options(labels=False)
>>> alpha = L.simple_roots()
>>> options.thickness(Integer(0))
2
>>> options.thickness(Integer(1))
1
>>> options.thickness(Integer(2))
1
>>> for alpha in L.simple_roots():
    ...     print("{} {}").format(alpha, options.thickness(alpha))
alpha[0] 2
alpha[1] 1
alpha[2] 1
```

```
sage.combinat.root_system.plot.barycentric_projection_matrix(angle=0)
```

Return a family of $n+1$ vectors evenly spaced in a real vector space of dimension $n$.

Those vectors are of norm 1, the scalar product between any two vector is $1/n$, thus the distance between two tips is constant.

The family is built recursively and uniquely determined by the following property: the last vector is $(0, \ldots, 0,-1)$, and the projection of the first $n$ vectors in dimension $n-1$, after appropriate rescaling to norm 1, retrieves the family for $n-1$.

OUTPUT:

A matrix with $n+1$ columns of height $n$ with rational or symbolic coefficients.

EXAMPLES:

One vector in dimension 0:

```
sage: from sage.combinat.root_system.root_lattice_realizations import barycentric_
    →projection_matrix
sage: m = barycentric_projection_matrix(0); m
[]
sage: matrix(QQ,0,1).nrows()
```
Combinatorics, Release 10.4

(continued from previous page)

```python
0
 sage: matrix(QQ,0,1).ncols()
1

```  

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.root_lattice_realizations import barycentric_projection_matrix
>>> m = barycentric_projection_matrix(Integer(0)); m
[]
>>> matrix(QQ,Integer(0),Integer(1)).nrows()
0
>>> matrix(QQ,Integer(0),Integer(1)).ncols()
1
```

Two vectors in dimension 1:

```python
sage: barycentric_projection_matrix(1)
[ 1 -1]

```  

```python
>>> from sage.all import *
>>> barycentric_projection_matrix(Integer(1))
[ 1 -1]
```

Three vectors in dimension 2:

```python
sage: barycentric_projection_matrix(2)
[ 1/2*sqrt(3) -1/2*sqrt(3) 0]
[ 1/2 1/2 -1]

```  

```python
>>> from sage.all import *
>>> barycentric_projection_matrix(Integer(2))
[ 1/2*sqrt(3) -1/2*sqrt(3) 0]
[ 1/2 1/2 -1]
```

Four vectors in dimension 3:

```python
sage: m = barycentric_projection_matrix(3); m
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2) 0 → 0]
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2) 0 → 0]
[ 1/3*sqrt(2) 1/3*sqrt(2) -2/3*sqrt(2) → 0]
[ 1/3 1/3 1/3 → -1]

```  

```python
>>> from sage.all import *
>>> m = barycentric_projection_matrix(Integer(3)); m
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2) 0 → 0]
[ 1/3*sqrt(3)*sqrt(2) -1/3*sqrt(3)*sqrt(2) 0 → 0]
[ 1/3*sqrt(2) 1/3*sqrt(2) -2/3*sqrt(2) → 0]
[ 1/3 1/3 1/3 → -1]
```

The columns give four vectors that sum up to zero:
Combinatorics, Release 10.4

```python
sage: sum(m.columns())
(0, 0, 0)
```

```python
>>> from sage.all import *

>>> sum(m.columns())
(0, 0, 0)
```

and have regular mutual angles:

```python
sage: m.transpose()*m
[ 1 -1/3 -1/3 -1/3]
[-1/3 1 -1/3 -1/3]
[-1/3 -1/3 1 -1/3]
[-1/3 -1/3 -1/3 1]
```

```python
>>> from sage.all import *

>>> m.transpose()*m
[ 1 -1/3 -1/3 -1/3]
[-1/3 1 -1/3 -1/3]
[-1/3 -1/3 1 -1/3]
[-1/3 -1/3 -1/3 1]
```

Here is a plot of them:

```python
sage: sum(arrow((0,0,0),x) for x in m.columns())
Graphics3d Object
```

```python
>>> from sage.all import *

>>> sum(arrow((Integer(0),Integer(0),Integer(0)),x) for x in m.columns())
Graphics3d Object
```

For 2D drawings of root systems, it is desirable to rotate the result to match with the usual conventions:

```python
sage: barycentric_projection_matrix(2, angle=2*pi/3)
[ 1/2 -1 1/2]
[1/2*sqrt(3) 0 -1/2*sqrt(3)]
```

```python
>>> from sage.all import *

>>> barycentric_projection_matrix(Integer(2), angle=Integer(2)*pi/Integer(3))
[ 1/2 -1 1/2]
[1/2*sqrt(3) 0 -1/2*sqrt(3)]
```

### 5.1.236 Finite complex reflection groups

Let $V$ be a finite-dimensional complex vector space. A reflection of $V$ is an operator $r \in \text{GL}(V)$ that has finite order and fixes pointwise a hyperplane in $V$.

For more definitions and classification types of finite complex reflection groups, see Wikipedia article Complex_reflection_group.

The point of entry to work with reflection groups is `ReflectionGroup()` which can be used with finite Cartan-Killing types:
sage: ReflectionGroup(['A',2])
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(['F',4])
Irreducible real reflection group of rank 4 and type F4
sage: ReflectionGroup(['H',3])
Irreducible real reflection group of rank 3 and type H3

>>> from sage.all import *
>>> ReflectionGroup(['A',Integer(2)])
Irreducible real reflection group of rank 2 and type A2
>>> ReflectionGroup(['F',Integer(4)])
Irreducible real reflection group of rank 4 and type F4
>>> ReflectionGroup(['H',Integer(3)])
Irreducible real reflection group of rank 3 and type H3

or with Shephard-Todd types:

sage: ReflectionGroup((1,1,3))
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup((2,1,3))
Irreducible real reflection group of rank 3 and type B3
sage: ReflectionGroup((3,1,3))
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: ReflectionGroup((4,2,3))
Irreducible complex reflection group of rank 3 and type G(4,2,3)
sage: ReflectionGroup(4)
Irreducible complex reflection group of rank 2 and type ST4
sage: ReflectionGroup(31)
Irreducible complex reflection group of rank 4 and type ST31

>>> from sage.all import *
>>> ReflectionGroup((Integer(1),Integer(1),Integer(3)))
Irreducible real reflection group of rank 2 and type A2
>>> ReflectionGroup((Integer(2),Integer(1),Integer(3)))
Irreducible real reflection group of rank 3 and type B3
>>> ReflectionGroup((Integer(3),Integer(1),Integer(3)))
Irreducible complex reflection group of rank 3 and type G(3,1,3)
>>> ReflectionGroup((Integer(4),Integer(2),Integer(3)))
Irreducible complex reflection group of rank 3 and type G(4,2,3)
>>> ReflectionGroup(Integer(4))
Irreducible complex reflection group of rank 2 and type ST4
>>> ReflectionGroup(Integer(31))
Irreducible complex reflection group of rank 4 and type ST31

Also reducible types are allowed using concatenation:

sage: ReflectionGroup(['A',3],(4,2,3))
Reducible complex reflection group of rank 6 and type A3 x G(4,2,3)

>>> from sage.all import *
>>> ReflectionGroup(['A',Integer(3)],(Integer(4),Integer(2),Integer(3)))
Reducible complex reflection group of rank 6 and type A3 x G(4,2,3)

Some special cases also occur, among them are:
A guided tour

We start with the example type $B_2$:

```
sage: W = ReflectionGroup(['B',2]); W
Irreducible real reflection group of rank 2 and type B2
```

Most importantly, observe that the group elements are usually represented by permutations of the roots:

```
sage: for w in W: print(w)
()
(1,3) (2,6) (5,7)
(1,5) (2,4) (6,8)
(1,7,5,3) (2,4,6,8)
(1,3,5,7) (2,8,6,4)
(2,8) (3,7) (4,6)
(1,7) (3,5) (4,8)
(1,5) (2,6) (3,7) (4,8)
```

This has the drawback that one can hardly see anything. Usually, one would look at elements with either of the following methods:

```
sage: for w in W: w.reduced_word()
[]
```

(continues on next page)
[2]
[1]
[1, 2]
[2, 1]
[2, 1, 2]
[1, 2, 1]
[1, 2, 1, 2]

sage: for w in W: w.reduced_word_in_reflections()
[]
[2]
[1]
[1, 2]
[1, 4]
[3]
[4]
[1, 3]

sage: for w in W: w.reduced_word(); w.to_matrix(); print("")
[]
[1 0]
[0 1]

[2]
[ 1 1]
[ 0 -1]

[1]
[-1 0]
[ 2 1]

[1, 2]
[-1 -1]
[ 2 1]

[2, 1]
[ 1 1]
[-2 -1]

[2, 1, 2]
[ 1 0]
[-2 -1]

[1, 2, 1]
[-1 -1]
[ 0 1]

[1, 2, 1, 2]
[-1 0]
[ 0 -1]

>>> from sage.all import *

>>> for w in W: w.reduced_word()
[]
[2]
[1]
The standard references for actions of complex reflection groups have the matrices acting on the right, so:

```
sage: W.simple_reflection(1).to_matrix()
[-1  0]
[ 2  1]
```
from sage.all import *

W.simple_reflection(Integer(1)).to_matrix()

\[
\begin{bmatrix}
-1 & 0 \\
2 & 1
\end{bmatrix}
\]

sends the simple root \(\alpha_0\), or \((1, 0)\) in vector notation, to its negative, while sending \(\alpha_1\) to \(2\alpha_0 + \alpha_1\).

Todo:

- properly provide root systems for real reflection groups
- element class should be unique to be able to work with large groups without creating elements multiple times
- \texttt{is_shephard_group, is_generalized_coxeter_group}
- exponents and coexponents
- coinvariant ring:
  - fake degrees from Torsten Hoge
  - operation of linear characters on all characters
  - harmonic polynomials
- linear forms for hyperplanes
- field of definition
- intersection lattice and characteristic polynomial:

\[
X = [ \alpha(t) \text{ for } t \text{ in } W.distinguished_reflections() ]
\]

\[
X = \text{Matrix}(\mathbb{Q}, X).\text{transpose()}
\]

\[
Y = \text{Matroid}(X)
\]

- linear characters
- permutation \(\pi\) on irreducibles
- hyperplane orbits (76.13 in Gap Manual)
- improve invariant form with a code similar to the one in \texttt{reflection_group_real.py}
- add a method \texttt{reflection_to_root} or \texttt{distinguished_reflection_to_positive_root}
- diagrams in ASCII-art (76.15)
- standard (BMR) presentations
- character table directly from Chevie
  - \texttt{GenericOrder (76.20), TorusOrder (76.21)}
- correct fundamental invariants for \(G_34\), check the others
- copy hardcoded data (degrees, invariants, braid relations…) into sage
- add other hardcoded data from the tables in chevie (location is \texttt{SAGEDIR/local/gap3/gap-jm5-2015-02-01/gap3/pkg/chevie/tbl}): basic derivations, discriminant, …
- transfer code for \texttt{reduced_word_in_reflections} into Gap4 or Sage
- list of reduced words for an element
- list of reduced words in reflections for an element
- Hurwitz action?

5.1. Comprehensive Module List
• is_crystallographic() should be hardcoded

AUTHORS:
• Christian Stump (2015): initial version

class sage.combinat.root_system.reflection_group_complex.ComplexReflectionGroup(W_types, index_set=None, hyperplane_index_set=None, reflection_index_set=None):

    Bases: UniqueRepresentation, PermutationGroup_generic

    A complex reflection group given as a permutation group.

    See also:
    ReflectionGroup()

class Element

    Bases: ComplexReflectionGroupElement

    conjugacy_class()

        Return the conjugacy class of self.

        EXAMPLES:

        sage: W = ReflectionGroup((1,1,3))
        sage: for w in W: sorted(w.conjugacy_class())
        [()]
        [(1,3) (2,5) (4,6), (1,4) (2,3) (5,6), (1,5) (2,4) (3,6)]
        [(1,3) (2,5) (4,6), (1,4) (2,3) (5,6), (1,5) (2,4) (3,6)]
        [(1,2,6) (3,4,5), (1,6,2) (3,5,4)]
        [(1,2,6) (3,4,5), (1,6,2) (3,5,4)]
        [(1,3) (2,5) (4,6), (1,4) (2,3) (5,6), (1,5) (2,4) (3,6)]

    conjugacy_class_representative()

        Return a representative of the conjugacy class of self.

        EXAMPLES:
```python
sage: W = ReflectionGroup((1,1,3))
sage: for w in W:
    ....:     print('%s %s (%s, %s)' % (w.reduced_word(), w.conjugacy_class_.representative().reduced_word(),))
[[] []
[2] [1]
[1] [1]
[1, 2] [1, 2]
[2, 1] [1, 2]
[1, 2, 1] [1]

>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> for w in W:
    ...     print('%s %s (%s, %s)' % (w.reduced_word(), w.conjugacy_class_.representative().reduced_word(),))
[[] []
[2] [1]
[1] [1]
[1, 2] [1, 2]
[2, 1] [1, 2]
[1, 2, 1] [1]

reflection_length\(\text{\textit{in\_unitary\_group}}=\text{\textit{False}}\)

Return the reflection length of self.

This is the minimal numbers of reflections needed to obtain self.

INPUT:

- \text{\textit{in\_unitary\_group}} - (\text{\textit{default: False}}) if True, the reflection length is computed in the unitary group which is the dimension of the move space of self

EXAMPLES:

```
apply_vector_field \( f, vf=None \)

Returns a rational function obtained by applying the vector field \( vf \) to the rational function \( f \).

If \( vf \) is not given, the primitive vector field is used.

**EXAMPLES:**

```
sage: W = ReflectionGroup(['A',2])
sage: for x in W.primitive_vector_field()[0].parent().gens():
    ...:     print(W.apply_vector_field(x))
3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
1/(6*x0^2 - 6*x0*x1 - 12*x1^2)
```

braid_relations()

Return the braid relations of \( \text{self} \).

**EXAMPLES:**

```
sage: W = ReflectionGroup((1,1,3))
sage: W.braid_relations()
[[[1, 2, 1], [2, 1, 2]]]

sage: W = ReflectionGroup((2,1,3))
sage: W.braid_relations()
[[[1, 2, 1, 2], [2, 1, 2, 1]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]
```

(continues on next page)
>>> W.braid_relations()

[[[1, 2, 1], [2, 1, 2]], [[1, 3], [3, 1]], [[2, 3, 2], [3, 2, 3]]]

\textbf{cartan\_matrix()}

Return the Cartan matrix associated with \texttt{self}.

If \texttt{self} is crystallographic, the returned Cartan matrix is an instance of \texttt{CartanMatrix}, and a normal matrix otherwise.

Let $s_1, \ldots, s_n$ be a set of reflections which generate \texttt{self} with associated simple roots $s_1, \ldots, s_n$ and simple coroots $s_i^\vee$. Then the Cartan matrix $C = (c_{ij})$ is given by $s_i^\vee(s_j)$. The Cartan matrix completely determines the reflection representation if the $s_i$ are linearly independent.

\textbf{EXAMPLES:}

\begin{verbatim}
>>> from sage.all import *

>>> ReflectionGroup(['A',4]).cartan_matrix()

[ 2 -1  0  0]
[-1  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]

>>> ReflectionGroup(['H',4]).cartan_matrix()

[ 2 E(5)^2 + E(5)^3  0  0]
[E(5)^2 + E(5)^3  2 -1  0]
[ 0 -1  2 -1]
[ 0  0 -1  2]

>>> ReflectionGroup(4).cartan_matrix()

[-2*E(3) - E(3)^2 E(3)^2]
[-E(3)^2 -2*E(3) - E(3)^2]

>>> ReflectionGroup((4,2,2)).cartan_matrix()

[ 2 -2*E(4) -2]
[E(4)  2  1 - E(4)]
[-1  1 + E(4)  2]
\end{verbatim}

\section{Comprehensive Module List}

\позицияроно, 10.4
codegrees()

Return the codegrees of self ordered within each irreducible component of self.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,4))
sage: W.codegrees()
(2, 1, 0)

sage: W = ReflectionGroup((2,1,4))
sage: W.codegrees()
(6, 4, 2, 0)

sage: W = ReflectionGroup((4,1,4))
sage: W.codegrees()
(12, 8, 4, 0)

sage: W = ReflectionGroup((4,2,4))
sage: W.codegrees()
(12, 8, 4, 0)

sage: W = ReflectionGroup((4,4,4))
sage: W.codegrees()
(8, 8, 4, 0)

sage: W = ReflectionGroup((1,1,4), (3,1,2))
sage: W.codegrees()
(2, 1, 0, 3, 0)

sage: W = ReflectionGroup((1,1,4), (6,1,12), 23)
sage: W.codegrees()
(2, 1, 0, 66, 60, 54, 48, 42, 36, 30, 24, 18, 12, 6, 0, 8, 4, 0)
```

>>> from sage.all import *

```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)))
>>> W.codegrees()
(2, 1, 0)

>>> W = ReflectionGroup((Integer(2),Integer(1),Integer(4)))
>>> W.codegrees()
(6, 4, 2, 0)

>>> W = ReflectionGroup((Integer(4),Integer(1),Integer(4)))
>>> W.codegrees()
(12, 8, 4, 0)

>>> W = ReflectionGroup((Integer(4),Integer(2),Integer(4)))
>>> W.codegrees()
(12, 8, 4, 0)

>>> W = ReflectionGroup((Integer(4),Integer(4),Integer(4)))
>>> W.codegrees()
(8, 8, 4, 0)

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(3),
                          Integer(1),Integer(1),Integer(2)))
>>> W.codegrees()
(2, 1, 0, 3, 0)
```

(continues on next page)
```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(6),
→Integer(1),Integer(12)), Integer(23))
>>> W.codegrees()
(2, 1, 0, 66, 60, 54, 48, 42, 36, 30, 24, 18, 12, 6, 0, 8, 4, 0)
```

**conjugacy_classes()**

Return the conjugacy classes of self.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))
sage: for C in W.conjugacy_classes(): sorted(C)
[[]]
[(1,3) (2,5) (4,6), (1,4) (2,3) (5,6), (1,5) (2,4) (3,6)]
[(1,2,6) (3,4,5), (1,6,2) (3,5,4)]

sage: W = ReflectionGroup((1,1,4))
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality()
True

sage: W = ReflectionGroup((3,1,2))
sage: sum(len(C) for C in W.conjugacy_classes()) == W.cardinality()
True

sage: W = ReflectionGroup(23)
```

```python
>>> from sage.all import *
```

```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> for C in W.conjugacy_classes(): sorted(C)
[[]]
[(1,3) (2,5) (4,6), (1,4) (2,3) (5,6), (1,5) (2,4) (3,6)]
[(1,2,6) (3,4,5), (1,6,2) (3,5,4)]
```

```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)))
>>> sum(len(C) for C in W.conjugacy_classes()) == W.cardinality()
True

>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(2)))
>>> sum(len(C) for C in W.conjugacy_classes()) == W.cardinality()
True

>>> W = ReflectionGroup(Integer(23))
```

```python
>>> sum(len(C) for C in W.conjugacy_classes()) == W.cardinality()
True
```

**conjugacy_classes_representatives()**

Return the shortest representatives of the conjugacy classes of self.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))
sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 2]]
```

(continues on next page)
sage: W = ReflectionGroup((1,1,4))

sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 3], [1, 2], [1, 3, 2]]

sage: W = ReflectionGroup((3,1,2))

sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 1], [2, 1, 2, 1], [2, 1, 2, 1, 1],
 [2, 1, 1, 2, 1, 1], [2], [1, 2], [1, 1, 2]]

sage: W = ReflectionGroup(23)

sage: [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 2],
 [1, 3],
 [2, 3],
 [1, 2, 3],
 [1, 2, 1, 2],
 [1, 2, 1, 2, 3],
 [1, 2, 1, 2, 3, 2, 1, 2, 3],
 [1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]]

>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))

>>> [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 2]]

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)))

>>> [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 3], [1, 2], [1, 3, 2]]

>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(2)))

>>> [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 1], [2, 1, 2, 1], [2, 1, 2, 1, 1],
 [2, 1, 1, 2, 1, 1], [2], [1, 2], [1, 1, 2]]

>>> W = ReflectionGroup(Integer(23))

>>> [w.reduced_word() for w in W.conjugacy_classes_representatives()]
[[], [1], [1, 2],
 [1, 3],
 [2, 3],
 [1, 2, 3],
 [1, 2, 1, 2],
 [1, 2, 1, 2, 3],
 [1, 2, 1, 2, 3, 2, 1, 2, 3],
 [1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]]

coxeter_number (chi=None)

Return the Coxeter number associated to the irreducible character chi of the reflection group self.

The Coxeter number of a complex reflection group $W$ is the trace in a character $\chi$ of $\sum_t (Id - t)$, where $t$ runs over all reflections. The result is always an integer.

When $\chi$ is the reflection representation, the Coxeter number is equal to $\frac{N + N^*}{n}$ where $N$ is the number of
reflections, \( N^* \) is the number of reflection hyperplanes, and \( n \) is the rank of \( W \). If \( W \) is further well-generated, the Coxeter number is equal to the highest degree \( d_n \) and to the order of a Coxeter element \( c \) of \( W \).

**EXAMPLES:**

```python
sage: W = ReflectionGroup("H",4)
sage: W.coxeter_number()
30
sage: all(W.coxeter_number(chi).is_integer() 
....: for chi in W.irreducible_characters())
True
sage: W = ReflectionGroup(14)
sage: W.coxeter_number()
24
```

```python
>>> from sage.all import *
>>> W = ReflectionGroup("H",Integer(4))
>>> W.coxeter_number()
30
>>> all(W.coxeter_number(chi).is_integer() 
... for chi in W.irreducible_characters())
True
>>> W = ReflectionGroup(Integer(14))
>>> W.coxeter_number()
24
```

degrees()

Return the degrees of \( \text{self} \) ordered within each irreducible component of \( \text{self} \).

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,4))
sage: W.degrees()
(2, 3, 4)
sage: W = ReflectionGroup((2,1,4))
sage: W.degrees()
(2, 4, 6, 8)
sage: W = ReflectionGroup((4,1,4))
sage: W.degrees()
(4, 8, 12, 16)
sage: W = ReflectionGroup((4,2,4))
sage: W.degrees()
(4, 8, 8, 12)
sage: W = ReflectionGroup((4,4,4))
sage: W.degrees()
(4, 4, 8, 12)
```

```python
>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)))
>>> W.degrees()
(2, 3, 4)
>>> W = ReflectionGroup((Integer(2),Integer(1),Integer(4)))
>>> W.degrees()
(continues on next page)
```
Examples of reducible types:

```python
sage: W = ReflectionGroup((1,1,4), (3,1,2)); W
Reducible complex reflection group of rank 5 and type A3 x G(3,1,2)
sage: W.degrees()
(2, 3, 4, 3, 6)
sage: W = ReflectionGroup((1,1,4), (6,1,12), 23)
sage: W.degrees()
(2, 3, 4, 6, 12, 24, 30, 36, 42, 48, 54, 60, 66, 72, 2, 6, 10)
```

```
>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(3), →Integer(1),Integer(2))); W
Reducible complex reflection group of rank 5 and type A3 x G(3,1,2)
>>> W.degrees()
(2, 3, 4, 3, 6)

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(6), →Integer(1),Integer(12)), Integer(23))
>>> W.degrees()
(2, 3, 4, 6, 12, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 2, 6, 10)
```

**discriminant()**

Return the discriminant of `self` in the polynomial ring on which the group acts.

This is the product

\[ \prod_H \alpha_H^{e_H}, \]

where \( \alpha_H \) is the linear form of the hyperplane \( H \) and \( e_H \) is its stabilizer order.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',2])
sage: W.discriminant()
x0^6 - 3*x0^5*x1 - 3/4*x0^4*x1^2 + 13/2*x0^3*x1^3
- 3/4*x0^2*x1^4 - 3*x0*x1^5 + x1^6

sage: W = ReflectionGroup(['B',2])
sage: W.discriminant()
x0^6*x1^2 - 6*x0^5*x1^3 + 13*x0^4*x1^4 - 12*x0^3*x1^5 + 4*x0^2*x1^6
```
```python
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])
>>> W.discriminant()
x0^6 - 3*x0^5*x1 - 3/4*x0^4*x1^2 + 13/2*x0^3*x1^3
- 3/4*x0^2*x1^4 - 3*x0*x1^5 + x1^6

>>> W = ReflectionGroup(['B',Integer(2)])
>>> W.discriminant()
x0^6*x1^2 - 6*x0^5*x1^3 + 13*x0^4*x1^4 - 12*x0^3*x1^5 + 4*x0^2*x1^6
```

**discriminant_in_invariant_ring (invariants=None)**

Return the discriminant of self in the invariant ring.

This is the function \( f \) in the invariants such that \( f(F_1(x), \ldots, F_n(x)) \) is the discriminant.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',3])
sage: W.discriminant_in_invariant_ring()
6*t0^3*t1^2 - 18*t0^4*t2 + 9*t1^4 - 36*t0*t1^2*t2 + 24*t0^2*t2^2 - 8*t2^3

sage: W = ReflectionGroup(['B',3])
sage: W.discriminant_in_invariant_ring()
- t0^2*t1^2*t2 + 16*t0^3*t2^2 + 2*t1^3*t2 - 36*t0*t1*t2^2 + 108*t2^3

sage: W = ReflectionGroup(['H',3])
sage: W.discriminant_in_invariant_ring()  # long time
(-829*E(5) - 1658*E(5)^2 - 1658*E(5)^3 - 829*E(5)^4)*t0^15
+ (213700*E(5) + 427400*E(5)^2 + 427400*E(5)^3 + 213700*E(5)^4)*t0^12*t1
+ (-22233750*E(5) - 44467500*E(5)^2 - 44467500*E(5)^3 - 22233750*E(5)^4)*t0^9*t1^2
+ (438750*E(5) + 877500*E(5)^2 + 877500*E(5)^3 + 438750*E(5)^4)*t0^6*t1^3
+ (-74250000*E(5) - 148500000*E(5)^2 - 148500000*E(5)^3 - 74250000*E(5)^4)*t0^4*t1*t2
+ (-9*1796875*E(5) + 2383593750*E(5)^2 + 2383593750*E(5)^3 + 1191796875*E(5)^4)*t0^3*t2^2
+ (39550781250*E(5) + 79101562500*E(5)^2 + 79101562500*E(5)^3 + 39550781250*E(5)^4)*t1^5
+ (131835937500*E(5) + 263671875000*E(5)^2 + 263671875000*E(5)^3 + 131835937500*E(5)^4)*t0^2*t1*t2^2
+ (395507812500*E(5) + 791015625000*E(5)^2 + 791015625000*E(5)^3 + 395507812500*E(5)^4)*t2^3
```

```python
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(3)])
>>> W.discriminant_in_invariant_ring()
6*t0^3*t1^2 - 18*t0^4*t2 + 9*t1^4 - 36*t0*t1^2*t2 + 24*t0^2*t2^2 - 8*t2^3

>>> W = ReflectionGroup(['B',Integer(3)])
>>> W.discriminant_in_invariant_ring()
```

(continues on next page)

5.1. Comprehensive Module List 3941
distinguished_reflection(i)

Return the i-th distinguished reflection of self.

These are the reflections in self acting on the complement of the fixed hyperplane \( H \) as \( \exp(2\pi i/n) \), where \( n \) is the order of the reflection subgroup fixing \( H \).

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
sage: W.distinguished_reflection(1)
(1,4)(2,3)(5,6)
sage: W.distinguished_reflection(2)
(1,3)(2,5)(4,6)
sage: W.distinguished_reflection(3)
(1,5)(2,4)(3,6)
sage: W = ReflectionGroup((3,1,1),hyperplane_index_set=['a'])
sage: W.distinguished_reflection('a')
(1,2,3)
sage: W = ReflectionGroup((1,1,3),(3,1,2))
sage: for i in range(W.number_of_reflection_hyperplanes()):
    ...:     W.distinguished_reflection(i+1)
(1,6)(2,5)(7,8)
(1,5)(2,7)(6,8)
(3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30)
30)
```

(continues from next page)
distinguished_reflections()

Return a finite family containing the distinguished reflections of self indexed by hyperplane_index_set().

These are the reflections in self acting on the complement of the fixed hyperplane $H$ as $\exp(2\pi i/n)$, where $n$ is the order of the reflection subgroup fixing $H$.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
sage: W.distinguished_reflections()
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}
```

```
sage: W = ReflectionGroup((1,1,3),hyperplane_index_set=['a','b','c'])
sage: W.distinguished_reflections()
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}
```

```
sage: W = ReflectionGroup((3,1,1))
sage: W.distinguished_reflections()
```
sage: W = ReflectionGroup((1,1,3),(3,1,2))
sage: W.distinguished_reflections()
Finite family {1: (1,6)(2,5)(7,8), 2: (1,5)(2,7)(6,8),
3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30),
5: (1,7)(2,6)(5,8),
7: (4,21,27)(10,22,28)(11,13,19)(12,14,20)(16,26,30)(17,18,25)(23,24,29),

>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> W.distinguished_reflections()
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6),
3: (1,5)(2,4)(3,6)}

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)), hyperplane_index_set=[a,b,c])
>>> W.distinguished_reflections()
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}

>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(1)))
>>> W.distinguished_reflections()
Finite family {1: (1,2,3)}

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)), (Integer(3), Integer(2)))
>>> W.distinguished_reflections()
Finite family {1: (1,6)(2,5)(7,8), 2: (1,5)(2,7)(6,8),
3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,26)(27,28,30),
5: (1,7)(2,6)(5,8),
7: (4,21,27)(10,22,28)(11,13,19)(12,14,20)(16,26,30)(17,18,25)(23,24,29),

fake_degrees()

Return the list of the fake degrees associated to self.

The fake degrees are $q$-versions of the degree of the character. In particular, they sum to Hilbert series of the coinvariant algebra of self.

**Note:** The ordering follows the one in Chevie and is not compatible with the current implementation of irreducible_characters().

**EXAMPLES:**
sage: W = ReflectionGroup(12)
sage: W.fake_degrees()
[1, q^12, q^11 + q, q^8 + q^4, q^7 + q^5, q^6 + q^4 + q^2,
 q^10 + q^8 + q^6, q^9 + q^7 + q^5 + q^3]
sage: W = ReflectionGroup(['H',4])
sage: W.cardinality()
14400
sage: sum(fdeg.subs(q=1)**2 for fdeg in W.fake_degrees())
14400

fundamental_invariants()
Return the fundamental invariants of self.
EXAMPLES:
sage: W = ReflectionGroup((1,1,3))
sage: W.fundamental_invariants()
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)
sage: W = ReflectionGroup((3,1,2))
sage: W.fundamental_invariants()
(x0^3 + x1^3, x0^3*x1^3)

hyperplane_index_set()
Return the index set of the hyperplanes of self.
EXAMPLES:
**independent_roots()**

Return a collection of simple roots generating the underlying vector space of self.

For well-generated groups, these are all simple roots. Otherwise, a linearly independent subset of the simple roots is chosen.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))
sage: W.independent_roots()
Finite family {1: (1, 0), 2: (0, 1)}

sage: W = ReflectionGroup((4,2,3))
sage: W.simple_roots()
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 3: (-1, 1, 0), 4: (0, -1, 1)}

sage: W.independent_roots()
Finite family {1: (1, 0, 0), 2: (-E(4), 1, 0), 4: (0, -1, 1)}
```

**index_set()**

Return the index set of the simple reflections of self.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,4))
sage: W.index_set()
(1, 2, 3)

sage: W = ReflectionGroup((1,1,4), index_set=[1,3,'asdf'])
sage: W.index_set()
(1, 3, 'asdf')
```
invariant_form(brute_force=False)

Return the form that is invariant under the action of self.

This is unique only up to a global scalar on the irreducible components.

INPUT:

- brute_force – if True, the computation is done by applying the Reynolds operator; this is, the invariant form of $e_i$ and $e_j$ is computed as the sum $\langle w(e_i), w(e_j) \rangle$, where $\langle \cdot, \cdot \rangle$ is the standard scalar product

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])
sage: F = W.invariant_form(); F
[ 1 -1/2 0]
[-1/2 1 -1/2]
[ 0 -1/2 1]
```

To check that this is indeed the invariant form, see:

```python
sage: S = W.simple_reflections()
sage: all( F == S[i].matrix()*F*S[i].matrix().transpose() for i in W.index_set() )
True
```

```python
sage: W = ReflectionGroup(['B',3])
sage: F = W.invariant_form(); F
[ 1 -1 0]
[-1 2 -1]
[ 0 -1 2]
sage: w = W.an_element().to_matrix()
```

(continues on next page)
It also worked for badly generated groups:

```
sage: W = ReflectionGroup(7)
sage: W.is_well_generated()
False
sage: F = W.invariant_form(); F
[1 0]
[0 1]
```
Combinatorics, Release 10.4

\[
\begin{bmatrix}
0 & 1 \\
\end{bmatrix}
\]

```
sage: S = W.simple_reflections()
sage: all(F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set())
True
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(Integer(7))
>>> W.is_well_generated()
False
>>> F = W.invariant_form(); F
[1 0]
[0 1]
>>> S = W.simple_reflections()
>>> all(F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set())
True
```

And also for reducible types:

```
sage: W = ReflectionGroup(['B',3],(4,2,3),4,7); W
Reducible complex reflection group of rank 10 and type B3 x G(4,2,3) x ST4 x \rightarrow ST7
sage: F = W.invariant_form(); S = W.simple_reflections()
sage: all(F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set())
True
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['B',Integer(3)],(Integer(4),Integer(2),Integer(3)),
(Integer(4),Integer(7)));
Reducible complex reflection group of rank 10 and type B3 x G(4,2,3) x ST4 x \rightarrow ST7
>>> F = W.invariant_form(); S = W.simple_reflections()
>>> all(F == S[i].matrix()*F*S[i].matrix().transpose().conjugate() for i in W.index_set())
True
```

```
invvariant_form_standardization()
```

Return the transformation of the space that turns the invariant form of `self` into the standard scalar product.

Let \( I \) be the invariant form of a complex reflection group, and let \( A \) be the Hermitian matrix such that \( A^2 = I \). The matrix \( A \) defines a change of basis such that the identity matrix is the invariant form. Indeed, we have

\[
(A^{-1}xIA)^* = A^{-1}x^*y^*A^{-1} = A^{-1}IA^{-1} = I,
\]

where \( I \) is the identity matrix.

**EXAMPLES:**

```
sage: W = ReflectionGroup((4,2,5))
sage: I = W.invariant_form()
sage: A = W.invariant_form_standardization()
sage: A^2 == I
True
```
>>> from sage.all import *
>>> W = ReflectionGroup((Integer(4),Integer(2),Integer(5)))
>>> I = W.invariant_form()
>>> A = W.invariant_form_standardization()
>>> A**Integer(2) == I
True

irreducible_components()

Return a list containing the irreducible components of self as finite reflection groups.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
sage: W.irreducible_components()
[Irreducible real reflection group of rank 2 and type A2]
sage: W = ReflectionGroup((1,1,3),(2,1,3))
sage: W.irreducible_components()
[Irreducible real reflection group of rank 2 and type A2,
Irreducible real reflection group of rank 3 and type B3]

>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> W.irreducible_components()
[Irreducible real reflection group of rank 2 and type A2]
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)),(Integer(2),
Integer(1),Integer(3)))
>>> W.irreducible_components()
[Irreducible real reflection group of rank 2 and type A2,
Irreducible real reflection group of rank 3 and type B3]

is_crystallographic()

Return True if self is crystallographic.

This is, if the field of definition is the rational field.

Todo: Make this more robust and do not use the matrix representation of the simple reflections.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3)); W
Irreducible real reflection group of rank 2 and type A2
sage: W.is_crystallographic()
True

sage: W = ReflectionGroup((2,1,3)); W
Irreducible real reflection group of rank 3 and type B3
sage: W.is_crystallographic()
True

sage: W = ReflectionGroup(23); W
Irreducible real reflection group of rank 3 and type H3
sage: W.is_crystallographic()
False

(continues on next page)
sage: W = ReflectionGroup((3,1,3)); W
Irreducible complex reflection group of rank 3 and type G(3,1,3)
sage: W.is_crystallographic()
False

sage: W = ReflectionGroup((4,2,2)); W
Irreducible complex reflection group of rank 2 and type G(4,2,2)
sage: W.is_crystallographic()
False

>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3))); W
Irreducible real reflection group of rank 2 and type A2
>>> W.is_crystallographic()
True

>>> W = ReflectionGroup((Integer(2),Integer(1),Integer(3))); W
Irreducible real reflection group of rank 3 and type B3
>>> W.is_crystallographic()
True

>>> W = ReflectionGroup(Integer(23)); W
Irreducible real reflection group of rank 3 and type H3
>>> W.is_crystallographic()
False

>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(3))); W
Irreducible complex reflection group of rank 3 and type G(3,1,3)
>>> W.is_crystallographic()
False

iteration_tracking_words()
Return an iterator going through all elements in self that tracks the reduced expressions.
This can be much slower than using the iteration as a permutation group with strong generating set.
EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
sage: for w in W.iteration_tracking_words(): w
()
(1,4) (2,3) (5,6)
(1,3) (2,5) (4,6)
(1,6,2) (3,5,4)
(1,2,6) (3,4,5)
(1,5) (2,4) (3,6)

>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> for w in W.iteration_tracking_words(): w

jacobian_of_fundamental_invariants (invs=None)

Return the matrix $\left[ \frac{\partial}{\partial x_i} F_j \right]$, where invs are any polynomials $F_1, \ldots, F_n$ in $x_1, \ldots, x_n$.

INPUT:

- invs -- (default: the fundamental invariants) the polynomials $F_1, \ldots, F_n$

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])
sage: W.fundamental_invariants()
(-2*x0^2 + 2*x0*x1 - 2*x1^2, 6*x0^2*x1 - 6*x0*x1^2)
sage: W.jacobian_of_fundamental_invariants()
[ -4*x0 + 2*x1 2*x0 - 4*x1]
[12*x0*x1 - 6*x1^2 6*x0^2 - 12*x0*x1]
```

number_of_irreducible_components()

Return the number of irreducible components of self.

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
sage: W.number_of_irreducible_components()
1
sage: W = ReflectionGroup((1,1,3),(2,1,3))
sage: W.number_of_irreducible_components()
2
```

```
**primitive_vector_field** (*invs=None*)

Return the primitive vector field of *self* is irreducible and well-generated.

The primitive vector field is given as the coefficients (being rational functions) in the basis $\partial_{x_1}, \ldots, \partial_{x_n}$.

This is the partial derivation along the unique invariant of degree given by the Coxeter number. It can be computed as the row of the inverse of the Jacobian given by the highest degree.

**EXAMPLES:**

```
sage: W = ReflectionGroup(['A',2])
sage: W.primitive_vector_field()
(3*x1/(6*x0^2 - 6*x0*x1 - 12*x1^2), 1/(6*x0^2 - 6*x0*x1 - 12*x1^2))
```

**rank**

Return the rank of *self*.

This is the dimension of the underlying vector space.

**EXAMPLES:**

```
sage: W = ReflectionGroup((1,1,3))
sage: W.rank()
2
sage: W = ReflectionGroup((2,1,3))
sage: W.rank()
3
sage: W = ReflectionGroup((4,1,3))
sage: W.rank()
3
sage: W = ReflectionGroup((4,2,3))
sage: W.rank()
3
```

**reflection** (*i*)

Return the *i*-th reflection of *self*.

**EXAMPLES:**

```
sage: W = ReflectionGroup((1,1,3))
sage: W.reflection(1)
(1,4)(2,3)(5,6)
sage: W.reflection(2)
(1,3)(2,5)(4,6)
sage: W.reflection(3)
(1,5)(2,4)(3,6)

sage: W = ReflectionGroup((3,1,1),reflection_index_set=['a','b'])
sage: W.reflection('a')
(1,2,3)
sage: W.reflection('b')
(1,3,2)

>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> W.reflection(Integer(1))
(1,4)(2,3)(5,6)
>>> W.reflection(Integer(2))
(1,3)(2,5)(4,6)
>>> W.reflection(Integer(3))
(1,5)(2,4)(3,6)

>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(1)),reflection_index_set=['a','b'])
>>> W.reflection('a')
(1,2,3)
>>> W.reflection('b')
(1,3,2)

reflection_character()
Return the reflection characters of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
sage: W.reflection_character()
[2, 0, -1]

reflection_eigenvalues(w, is_class_representative=False)
Return the reflection eigenvalue of w in self.

INPUT:

- is_class_representative – boolean (default True) whether to compute instead on the conjugacy class representative.

See also:

reflection_eigenvalues_family()

EXAMPLES:
sage: W = ReflectionGroup((1,1,3))
sage: for w in W:
    ....:     print('%s %s' % (w.reduced_word(), W.reflection_eigenvalues(w)))

[] [0, 0]
[2] [1/2, 0]
[1] [1/2, 0]
[1, 2] [1/3, 2/3]
[2, 1] [1/3, 2/3]
[1, 2, 1] [1/2, 0]

>> from sage.all import *
>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>> for w in W:
...     print('%s %s' % (w.reduced_word(), W.reflection_eigenvalues(w)))

[] [0, 0]
[2] [1/2, 0]
[1] [1/2, 0]
[1, 2] [1/3, 2/3]
[2, 1] [1/3, 2/3]
[1, 2, 1] [1/2, 0]

reflection_eigenvalues_family()

Return the reflection eigenvalues of self as a finite family indexed by the class representatives of self.

OUTPUT:

• list with entries $k/n$ representing the eigenvalue $e^k_n$.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
sage: W.reflection_eigenvalues_family()
Finite family {(): [0, 0], (1,4)(2,3)(5,6): [1/2, 0], (1,6,2)(3,5,4): [1/3, 2/3]}

sage: W = ReflectionGroup((3,1,2))
sage: reflection_eigenvalues = W.reflection_eigenvalues_family()
sage: for elt in sorted(reflection_eigenvalues.keys()):
    ....:     print('%s %s' % (elt, reflection_eigenvalues[elt]))

() [0, 0, 0]

reflection_hyperplane \( (i, \text{as\_linear\_functional=}\text{False, with\_order=}\text{False}) \)

Return the \( i \)-th reflection hyperplane of \( \text{self} \).

The \( i \)-th reflection hyperplane corresponds to the \( i \) distinguished reflection.

INPUT:

- \( i \) – an index in the index set
- \text{as\_linear\_functionals} – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:

```python
sage: W = ReflectionGroup((2,1,2))
sage: W.reflection_hyperplane(3)
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 0]
```

One can ask for the result as a linear form:

```python
sage: W.reflection_hyperplane(3, True)
(0, 1)
```

reflection_hyperplanes (\text{as\_linear\_functionals=}\text{False, with\_order=}\text{False})

Return the list of all reflection hyperplanes of \( \text{self} \), either as a codimension 1 space, or as its linear functional.

INPUT:

- \text{as\_linear\_functionals} – (default:False) flag whether to return the hyperplane or its linear functional in the basis dual to the given root basis

EXAMPLES:
```
sage: W = ReflectionGroup((1,1,3))
sage: for H in W.reflection_hyperplanes(): H
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 1/2]
Vector space of degree 2 and dimension 1 over Rational Field
Basis matrix:
[1 -1]

((1, -1), 2)
((1, -2), 2)
((0, 1), 2)
((1, 0), 2)

reflection_index_set()
Return the index set of the reflections of self.

EXAMPLES:

sage: W = ReflectionGroup((1, 1, 4))
sage: W.reflection_index_set()
(1, 2, 3, 4, 5, 6)
sage: W = ReflectionGroup((1, 1, 4), reflection_index_set=[1, 3, 'asdf', 7, 9, 11])
sage: W.reflection_index_set()
(1, 3, 'asdf', 7, 9, 11)
sage: W = ReflectionGroup((1, 1, 4), reflection_index_set=('a', 'b', 'c', 'd', 'e', 'f'))
sage: W.reflection_index_set()
('a', 'b', 'c', 'd', 'e', 'f')

from sage.all import *
W = ReflectionGroup((Integer(1), Integer(1), Integer(4)))
W.reflection_index_set()
reflections()

Return a finite family containing the reflections of self, indexed by self.
reflection_index_set().

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
sage: W.reflections()
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}
```

```python
sage: W = ReflectionGroup((1,1,3), reflection_index_set=['a', 'b', 'c'])
sage: W.reflections()
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}
```

```python
sage: W = ReflectionGroup((3,1,1))
sage: W.reflections()
Finite family {1: (1,2,3), 2: (1,3,2)}
```

```python
sage: W = ReflectionGroup((1,1,3), (3,1,2))
sage: W.reflections()
```

```python
>>> from sage.all import *
>>> W = ReflectionGroup((1,1,3))
>>> W.reflections()
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6), 3: (1,5)(2,4)(3,6)}
```

```python
>>> W = ReflectionGroup((1,1,3), reflection_index_set=['a', 'b', 'c'])
>>> W.reflections()
Finite family {'a': (1,4)(2,3)(5,6), 'b': (1,3)(2,5)(4,6), 'c': (1,5)(2,4)(3,6)}
```
Combinatorics, Release 10.4

>>> W = ReflectionGroup((Integer(3), Integer(1), Integer(1)))
>>> W.reflections()
Finite family {1: (1,2,3), 2: (1,3,2)}

>>> W = ReflectionGroup((Integer(1), Integer(1), Integer(3)), (Integer(3), Integer(1), Integer(2)))
>>> W.reflections()
Finite family {1: (1,6)(2,5)(7,8), 2: (1,5)(2,7)(6,8),
    3: (3,9,15)(4,10,16)(12,17,23)(14,18,24)(20,25,29)(21,22,

    18)(23,29,24)}

roots()
Return all roots corresponding to all reflections of self.

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
sage: W.roots()
[(1, 0), (0, 1), (1, 1), (-1, 0), (0, -1), (-1, -1)]

sage: W = ReflectionGroup((3,1,2))
sage: W.roots()
[(1, 0), (-1, 1), (E(3), 0), (-E(3), 1), (0, 1), (1, -1),
(0, E(3)), (1, -E(3)), (E(3)^2, 0), (-E(3)^2, 1),
(E(3), -1), (E(3), -E(3)), (0, E(3)^2), (1, -E(3)^2),
(-1, E(3)), (-E(3), E(3)), (E(3)^2, -1), (E(3)^2, -E(3)),
(E(3), -E(3)^2), (-E(3)^2, E(3)), (-1, E(3)^2),
(-E(3), E(3)^2), (E(3)^2, -E(3)^2), (-E(3)^2, E(3)^2)]

sage: W = ReflectionGroup((4,2,2))
sage: W.roots()
[(1, 0), (-E(4), 1), (-1, 1), (-1, 0), (E(4), 1), (1, 1),
(0, -E(4)), (E(4), -1), (E(4), E(4)), (0, E(4)),
(E(4), -E(4)), (0, 1), (1, -E(4)), (1, -1), (0, -1),
(1, E(4)), (-E(4), 0), (-1, E(4)), (E(4), 0), (-E(4), E(4)),
(-E(4), -1), (-E(4), -E(4)), (-1, -E(4)), (-1, -1)]

sage: W = ReflectionGroup((1,1,4), (3,1,2))
sage: W.roots()
[(1, 0, 0, 0, 0), (0, 1, 0, 0, 0), (0, 0, 1, 0, 0),
(0, 0, 0, 1, 0), (0, 0, 0, -1, 1), (1, 1, 0, 0, 0),
(0, 1, 1, 0, 0), (1, 1, 1, 0, 0), (-1, 0, 0, 0),
(continues on next page)
>>> from sage.all import *

series()

Return the series of the classification type to which self belongs.

For real reflection groups, these are the Cartan-Killing classification types
"A", "B", "C", "D", "E", "F", "G", "H", "I", and for complex non-real reflection groups these are the
Shephard-Todd classification type “ST”.

EXAMPIES:

```python
sage: ReflectionGroup((1,1,3)).series()
['A']
sage: ReflectionGroup((3,1,3)).series()
['ST']
```

```python
>>> from sage.all import *

>>> ReflectionGroup((Integer(1),Integer(1),Integer(3))).series()
['A']

>>> ReflectionGroup((Integer(3),Integer(1),Integer(3))).series()
['ST']
```

**set_reflection_representation**(refl_repr=None)

Set the reflection representation of self.

INPUT:

- `refl_repr` – a dictionary representing the matrices of the generators of self with keys given by the index set, or None to reset to the default reflection representation

EXAMPIES:

```python
sage: W = ReflectionGroup((1,1,3))
sage: for w in W: w.to_matrix(); print("-----")

>>> W.set_reflection_representation()
\end{verbatim}

**simple_coroot** \((i)\)

Return the simple root with index \(i\).

**EXAMPLES:**

\begin{verbatim}
sage: W = ReflectionGroup(['A',3])
sage: W.simple_coroot(1)
(2, -1, 0)
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> W = ReflectionGroup(['A',Integer(3)])

>>> W.simple_coroot(Integer(1))
(2, -1, 0)
\end{verbatim}

**simple_coroots()**

Return the simple coroots of \(self\).

These are the coroots corresponding to the simple reflections.

**EXAMPLES:**

\begin{verbatim}
sage: W = ReflectionGroup((1,1,3))
sage: W.simple_coroots()  # Finite family {1: (2, -1), 2: (-1, 2)}

sage: W = ReflectionGroup((1,1,4), (2,1,2))
sage: W.simple_coroots()  # Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0), 3: (0, -1, 2, 0, 0), 4: (0, 0, 0, -1, 2), 5: (0, 0, 0, 0, -1, 2)}

sage: W = ReflectionGroup((3,1,2))
sage: W.simple_coroots()  # Finite family {1: (-2*E(3) - E(3)^2, 0), 2: (-1, 1)}

sage: W = ReflectionGroup((1,1,4), (3,1,2))
sage: W.simple_coroots()  # Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0), 3: (0, -1, 2, 0, 0), 4: (0, 0, 0, -2*E(3) - E(3)^2, 0), 5: (0, 0, 0, 0, -1, 1)}
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))

\end{verbatim}

(continues on next page)
Finite family {1: (2, -1), 2: (-1, 2)}

```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(2),
   → Integer(1),Integer(2)))
>>> W.simple_coroots()
Finite family {1: (2, -1, 0, 0, 0), 2: (-1, 2, -1, 0, 0),
   → 4: (0, 0, 0, 2, -2), 5: (0, 0, 0, -1, 2)}
```

```python
>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(2)))
>>> W.simple_coroots()
```

```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(3),
   → Integer(1),Integer(2)))
>>> W.simple_coroots()
```

**simple_reflection** (*i*)

Return the *i*-th simple reflection of `self`.

**EXAMPLES:**

```python
sage: W = ReflectionGroup((1,1,3))
sage: W.simple_reflection(1)
(1,4)(2,3)(5,6)
sage: W.simple_reflections()
Finite family {1: (1,4)(2,3)(5,6), 2: (1,3)(2,5)(4,6)}
```

```python
>>> from sage.all import *
```

```python
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> W.simple_reflection(Integer(1))
(1,4)(2,3)(5,6)
```

**simple_root** (*i*)

Return the simple root with index *i*.

**EXAMPLES:**

```python
sage: W = ReflectionGroup(['A',3])
sage: W.simple_root(1)
(1, 0, 0)
sage: W.simple_root(2)
(0, 1, 0)
sage: W.simple_root(3)
(0, 0, 1)
```

```python
>>> from sage.all import *
```

```python
>>> W = ReflectionGroup(['A',Integer(3)])
>>> W.simple_root(Integer(1))
(1, 0, 0)
```

(continues on next page)
simple_roots()

Return the simple roots of self.

These are the roots corresponding to the simple reflections.

EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
sage: W.simple_roots()
Finite family {1: (1, 0), 2: (0, 1)}

sage: W = ReflectionGroup((1,1,4), (2,1,2))
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: (0, 0, 0, 1, 0), 5: (0, 0, 0, 0, 1)}

sage: W = ReflectionGroup((3,1,2))
sage: W.simple_roots()
Finite family {1: (1, 0), 2: (-1, 1)}

sage: W = ReflectionGroup((1,1,4), (3,1,2))
sage: W.simple_roots()
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: (0, 0, 0, 1, 0), 5: (0, 0, 0, -1, 1)}
```

```python
>>> from sage.all import *

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> W.simple_roots()
Finite family {1: (1, 0), 2: (0, 1)}

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(2), Integer(1),Integer(2)))
>>> W.simple_roots()
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: (0, 0, 0, 1, 0), 5: (0, 0, 0, 0, 1)}

>>> W = ReflectionGroup((Integer(3),Integer(1),Integer(2)))
>>> W.simple_roots()
Finite family {1: (1, 0), 2: (-1, 1)}

>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4)), (Integer(3), Integer(1),Integer(2)))
>>> W.simple_roots()
Finite family {1: (1, 0, 0, 0, 0), 2: (0, 1, 0, 0, 0), 3: (0, 0, 1, 0, 0), 4: (0, 0, 0, 1, 0), 5: (0, 0, 0, -1, 1)}
```
class sage.combinat.root_system.reflection_group_complex.IrreducibleComplexReflectionGroup

Bases: ComplexReflectionGroup
class Element
Bases: Element

is_coxeter_element (which_primitive=1, is_class_representative=False)
Return True if self is a Coxeter element.
This is, whether self has an eigenvalue that is a primitive $h$-th root of unity.

INPUT:
• whichPrimitive – (default:1) for which power of the first primitive $h$-th root of unity to look
  as a reflection eigenvalue for a regular element
• is_class_representative – boolean (default True) whether to compute instead on the
  conjugacy class representative

See also:
coxeter_element () coxeter_elements ()

EXAMPLES:

sage: W = ReflectionGroup((1,1,3))
sage: for w in W:
    ....:     print('%s %s' % (w.reduced_word(), w.is_coxeter_element()))
[ ] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False

>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
>>> for w in W:
...    print('%s %s' % (w.reduced_word(), w.is_coxeter_element()))
[] False
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False

is_h_regular (is_class_representative=False)
Return whether self is regular.
This is if self has an eigenvector with eigenvalue $h$ and which does not lie in any reflection hyperplane.
Here, $h$ denotes the Coxeter number.
EXAMPLES:

```python
sage: W = ReflectionGroup((1,1,3))
```
```
sage: for w in W:
    ....:     print('%s %s' % (w.reduced_word(), w.is_h_regular()))
```
```
[1, 2] True
[2, 1] True
[1, 2, 1] False
```
```
>>> from sage.all import *
```
```
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(3)))
```
```
>>> for w in W:
    ....:     print('%s %s' % (w.reduced_word(), w.is_h_regular()))
```
```
[2] False
[1] False
[1, 2] True
[2, 1] True
[1, 2, 1] False
```

is_regular(h, is_class_represerentative=False)

Return whether self is regular.

This is, if self has an eigenvector with eigenvalue of order h and which does not lie in any reflection hyperplane.

INPUT:

• h – the order of the eigenvalue
• is_class_represerentative – boolean (default True) whether to compute instead on the conjugacy class representative

EXAMPLES:

```
sage: W = ReflectionGroup((1,1,3))
sage: h = W.coxeter_number()
sage: for w in W:
    ....:     print("{} \n".format(w.reduced_word(), w.is_regular(h)))
```
```
[1, 2, 3]
[2, 1, 3]
[1, 3, 2]
[3, 2, 1]
[2, 1, 2, 3, 2]
[2, 3, 2, 1, 2]
[1, 2, 1, 2, 3, 2, 1]
[1, 2, 3, 2, 1, 2, 1]
```
```
sage: W = ReflectionGroup(23); h = W.coxeter_number()
sage: for w in W:
    ....:     if w.is_regular(h):
        ....:         w.reduced_word()
```
```
[1, 2, 3]
[2, 1, 3]
[1, 3, 2]
[3, 2, 1]
[2, 1, 2, 3, 2]
[2, 3, 2, 1, 2]
[1, 2, 1, 2, 3, 2, 1]
[1, 2, 3, 2, 1, 2, 1]
```
>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1), Integer(1), Integer(3)))
>>> h = W.coxeter_number()
>>> for w in W:
...     print("{} {}".format(w.reduced_word(), w.is_regular(h)))
[1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]

>>> W = ReflectionGroup(Integer(23)); h = W.coxeter_number()
>>> for w in W:
...     if w.is_regular(h):
...         print(w.reduced_word())
[1, 2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 2, 1, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
[1, 2, 1, 2, 3, 2, 1, 2, 1, 3, 2, 1, 2, 3]
Check that Issue #25478 is fixed:

```python
sage: W = ReflectionGroup(['A', 5])
sage: w = W.from_reduced_word([1, 2, 3, 5])
sage: w.is_regular(4)
False
sage: W = ReflectionGroup(['A', 3])
sage: len([w for w in W if w.is_regular(w.order())])
18
```

```python
>>> from sage.all import *
>>> W = ReflectionGroup(['A', Integer(5)])
>>> w = W.from_reduced_word([Integer(1), Integer(2), Integer(3), Integer(5)])
>>> w.is_regular(Integer(4))
False
>>> W = ReflectionGroup(['A', Integer(3)])
>>> len([w for w in W if w.is_regular(w.order())])
18
```

`sage.combinat.root_system.reflection_group_complex.multi_partitions(n, S, i=None)`

Return all vectors as lists of the same length as $S$ whose standard inner product with $S$ equals $n$.

**EXAMPLES:**

```python
sage: from sage.combinat.root_system.reflection_group_complex import multi_partitions
sage: multi_partitions(10, [2, 3, 3, 4])
[[5, 0, 0, 0],
 [3, 0, 0, 1],
 [2, 2, 0, 0],
 [2, 1, 1, 0],
 [2, 0, 2, 0],
 [1, 0, 0, 2],
 [0, 2, 0, 1],
 [0, 1, 1, 1],
 [0, 0, 2, 1]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.root_system.reflection_group_complex import multi_partitions
>>> multi_partitions(Integer(10), [Integer(2), Integer(3), Integer(3), Integer(4)])
[[5, 0, 0, 0],
 [3, 0, 0, 1],
 [2, 2, 0, 0],
 [2, 1, 1, 0],
 [2, 0, 2, 0],
 [1, 0, 0, 2],
 [0, 2, 0, 1],
 [0, 1, 1, 1],
 [0, 0, 2, 1]]
```

`sage.combinat.root_system.reflection_group_complex.power(k)`

Return $f^k$ and caching all intermediate results.

Speeds the computation if one has to compute $f^k$'s for many values of $k$.

**EXAMPLES:**

5.1. Comprehensive Module List
sage: P.<x,y,z> = PolynomialRing(QQ)
sage: f = -2*x^2 + 2*x*y - 2*y^2 + 2*y*z - 2*z^2
sage: all( f^k == power(f,k) for k in range(20) )
True

>>> from sage.all import *

>>> P = PolynomialRing(QQ, names=('x', 'y', 'z',)); (x, y, z,) = P._first_ngens(3)
>>> f = -Integer(2)*x**Integer(2) + Integer(2)*x*y - Integer(2)*y**Integer(2) +
    Integer(2)*y*z - Integer(2)*z**Integer(2)
>>> all( f**k == power(f,k) for k in range(Integer(20)) )
True

5.1.237 Finite real reflection groups

Let $V$ be a finite-dimensional real vector space. A reflection of $V$ is an operator $r \in \text{GL}(V)$ that has order 2 and fixes pointwise a hyperplane in $V$. In the present implementation, finite real reflection groups are tied with a root system.

Finite real reflection groups with root systems have been classified according to finite Cartan-Killing types. For more definitions and classification types of finite complex reflection groups, see Wikipedia article Complex_reflection_group.

The point of entry to work with reflection groups is `ReflectionGroup()` which can be used with finite Cartan-Killing types:

sage: ReflectionGroup(['A',2])
Irreducible real reflection group of rank 2 and type A2
sage: ReflectionGroup(['F',4])
Irreducible real reflection group of rank 4 and type F4
sage: ReflectionGroup(['H',3])
Irreducible real reflection group of rank 3 and type H3

>>> from sage.all import *

>>> ReflectionGroup(['A',Integer(2)])
Irreducible real reflection group of rank 2 and type A2
>>> ReflectionGroup(['F',Integer(4)])
Irreducible real reflection group of rank 4 and type F4
>>> ReflectionGroup(['H',Integer(3)])
Irreducible real reflection group of rank 3 and type H3

class sage.combinat.root_system.reflection_group_real.RealReflectionGroup(W_types, index_set=None, hyperplane_index_set=None, reflection_index_set=None):

    Bases: ComplexReflectionGroup

A real reflection group given as a permutation group.

See also:

ReflectionGroup()

class Element

    Bases: RealReflectionGroupElement, Element

left_coset_representatives()

    Return the left coset representatives of self.

    See also:

right_coset_representatives()

EXAMPLES:

    sage: W = ReflectionGroup(["A",2])
    sage: for w in W:
    ....:     lcr = w.left_coset_representatives()
    ....:     print("%s %s"%(w.reduced_word(),
    ....:                       [v.reduced_word() for v in lcr]))
    [] [[], [2], [1], [1, 2], [2, 1], [1, 2, 1]]
    [2] [[], [2], [1]]
    [1] [[], [1], [2, 1]]
    [1, 2] [[]]
    [2, 1] [[]]
    [1, 2, 1] [[], [2], [1, 2]]
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])
>>> for w in W:
...     lcr = w.left_coset_representatives()
...     print("%s %s

...     [v.reduced_word() for v in lcr])
...     
[]  
[2]  
[1]  
[1, 2]  
[2, 1]  
[1, 2, 1]  

right_coset_representatives()

Return the right coset representatives of self.

EXAMPLES:

sage: W = ReflectionGroup(['A',2])
sage: for w in W:
....:     rcr = w.right_coset_representatives()
....:     print("%s %s
....:     [v.reduced_word() for v in rcr])
...
[]  
[2]  
[1]  
[1, 2]  
[2, 1]  
[1, 2, 1]  

almost_positive_roots()

Return the almost positive roots of self.

EXAMPLES:

sage: W = ReflectionGroup(['A',3], ['B',2])
sage: W.almost_positive_roots()
[(-1, 0, 0, 0, 0),
 (0, -1, 0, 0, 0),
 (0, 0, -1, 0, 0),
 (0, 0, 0, -1, 0),
 (0, 0, 0, 0, -1),
 (1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
(continues on next page)
```python
(0, 0, 1, 0, 0),
(0, 0, 0, 1, 0),
(0, 0, 0, 0, 1),
(1, 1, 0, 0, 0),
(0, 1, 1, 0, 0),
(0, 0, 0, 1, 1),
(1, 1, 1, 0, 0),
(0, 0, 0, 2, 1)]

sage: W = ReflectionGroup(['A',3])
sage: W.almost_positive_roots()
[(-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (1, 1, 1)]

>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(3)], ['B',Integer(2)])
>>> W.almost_positive_roots()
[(-1, 0, 0, 0, 0),
 (0, -1, 0, 0, 0),
 (0, 0, -1, 0, 0),
 (0, 0, 0, -1, 0),
 (0, 0, 0, 0, -1),
 (1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 (0, 0, 0, 1, 0),
 (0, 0, 0, 0, 1),
 (1, 1, 0, 0, 0),
 (0, 1, 1, 0, 0),
 (1, 1, 1, 0, 0),
 (0, 0, 0, 2, 1)]

>>> W = ReflectionGroup(['A',Integer(3)])
>>> W.almost_positive_roots()
[(-1, 0, 0),
 (0, -1, 0),
 (0, 0, -1),
 (1, 0, 0),
 (0, 1, 0),
 (0, 0, 1),
 (1, 1, 0),
 (0, 1, 1),
 (1, 1, 1)]
```

`bipartite_index_set()`

Return the bipartite index set of a real reflection group.

**EXAMPLES:**
sage: W = ReflectionGroup("A", 5)
sage: W.bipartite_index_set()
[[1, 3, 5], [2, 4]]

sage: W = ReflectionGroup("A", 5, index_set=['a', 'b', 'c', 'd', 'e'])
sage: W.bipartite_index_set()
[['a', 'c', 'e'], ['b', 'd']]

bruhat_cone \((x, y, \text{side}='\text{upper}', \text{backend}='\text{cdd}')\)

Return the (upper or lower) Bruhat cone associated to the interval \([x, y]\).

To a cover relation \(v < w\) in strong Bruhat order you can assign a positive root \(\beta\) given by the unique reflection \(s_{\beta}\) such that \(s_{\beta}v = w\).

The upper Bruhat cone of the interval \([x, y]\) is the non-empty, polyhedral cone generated by the roots corresponding to \(x < a\) for all atoms \(a\) in the interval. The lower Bruhat cone of the interval \([x, y]\) is the non-empty, polyhedral cone generated by the roots corresponding to \(c < y\) for all coatoms \(c\) in the interval.

INPUT:

- \(x\) – an element in the group \(W\)
- \(y\) – an element in the group \(W\)
- \(\text{side}\) (default: 'upper') – must be one of the following:
  - 'upper' – return the upper Bruhat cone of the interval \([x, y]\)
  - 'lower' – return the lower Bruhat cone of the interval \([x, y]\)
- \(\text{backend}\) – string (default: 'cdd'); the backend to use to create the polyhedron

EXAMPLES:

sage: W = ReflectionGroup(['A', 2])
sage: x = W.from_reduced_word([1])
sage: y = W.w0
sage: W.bruhat_cone(x, y)
A 2-dimensional polyhedron in QQ^2 defined as the convex hull of 1 vertex and 2 rays

sage: W = ReflectionGroup(['E', 6])
sage: x = W.one()
sage: y = W.w0
sage: W.bruhat_cone(x, y, side='lower')
A 6-dimensional polyhedron in QQ^6 defined as the convex hull of 1 vertex and 6 rays

>> from sage.all import *

>> W = ReflectionGroup(['A', Integer(2)])
\[>>> x = W.\text{from\_reduced\_word}(\text{[Integer(1)]})\\ y = W.w0\\ W.\text{bruhat\_cone}(x, y)\]

A 2-dimensional polyhedron in \(\mathbb{Q}^2\) defined as the convex hull of 1 vertex and 2 rays

\[>>> W = \text{ReflectionGroup(\text{[\text{'E'}, Integer(6)]})}\\ x = W.\text{one()}\\ y = W.w0\\ W.\text{bruhat\_cone}(x, y, \text{side='lower'})\]

A 6-dimensional polyhedron in \(\mathbb{Q}^6\) defined as the convex hull of 1 vertex and 6 rays

\[\text{REFERENCES:}\]

- [Dy1994]
- [JS2021]

\[\text{cartan\_type()}\]

Return the Cartan type of \text{self}.

\[\text{EXAMPLES:}\]

\[\text{sage: } W = \text{ReflectionGroup(\text{[\text{'A'}, 3]})}\\ \text{sage: } W.\text{cartan\_type()}\\ \text{[\text{'A'}, 3]}\\ \text{sage: } W = \text{ReflectionGroup(\text{[\text{'A'}, 3]}, \text{[\text{'B'}, 3]})}\\ \text{sage: } W.\text{cartan\_type()}\\ \text{A3xB3 relabelled by \{1: 3, 2: 2, 3: 1\}}\]

\[\text{coxeter\_diagram()}\]

Return the Coxeter diagram associated to \text{self}.

\[\text{EXAMPLES:}\]

\[\text{sage: } G = \text{ReflectionGroup(\text{[\text{'B'}, 3]})}\\ \text{sage: } G.\text{coxeter\_diagram().edges(labels=True, sort=True)}\\ \text{[(1, 2, 4), (2, 3, 3)]}\]

\[\text{coxeter\_matrix()}\]

Return the Coxeter matrix associated to \text{self}.
Combinatorics, Release 10.4

EXAMPLES:

```python
sage: G = ReflectionGroup(['A',3])
sage: G.coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
```

```python
>>> from sage.all import *

>>> G = ReflectionGroup(['A',Integer(3)])

>>> G.coxeter_matrix()
[1 3 2]
[3 1 3]
[2 3 1]
```

**fundamental_weight**(i)

Return the fundamental weight with index i.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3])

sage: [ W.fundamental_weight(i) for i in W.index_set() ]

[(3/4, 1/2, 1/4), (1/2, 1, 1/2), (1/4, 1/2, 3/4)]
```

```python
>>> from sage.all import *

>>> W = ReflectionGroup(['A',Integer(3)])

>>> [ W.fundamental_weight(i) for i in W.index_set() ]

[(3/4, 1/2, 1/4), (1/2, 1, 1/2), (1/4, 1/2, 3/4)]
```

**fundamental_weights**()

Return the fundamental weights of self in terms of the simple roots.

The fundamental weights are defined by $s_j(\omega_i) = \omega_i - \delta_{i,j}\alpha_j$ for the simple reflection $s_j$ with corresponding simple roots $\alpha_j$.

In other words, the transpose Cartan matrix sends the weight basis to the root basis. Observe again that the action here is defined as a right action, see the example below.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',3], ['B',2])

sage: W.fundamental_weights()
Finite family {1: (3/4, 1/2, 1/4, 0, 0), 2: (1/2, 1, 1/2, 0, 0), 3: (1/4, 1/2, 3/4, 0, 0), 4: (0, 0, 0, 1, 1/2), 5: (0, 0, 0, 1, 1)}
```

```python
sage: W = ReflectionGroup(['A',3])

sage: W.fundamental_weights()
Finite family {1: (3/4, 1/2, 1/4), 2: (1/2, 1, 1/2), 3: (1/4, 1/2, 3/4)}
```

```python
sage: W = ReflectionGroup(['A',3])

sage: S = W.simple_reflections()

sage: N = W.fundamental_weights()

sage: for i in W.index_set():
    ....:     for j in W.index_set():
    ....:         print("{} {} {} {}\n".format(i, j, N[i], N[i]*S[j].to_matrix()))

1 1 (3/4, 1/2, 1/4) (-1/4, 1/2, 1/4)
1 2 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
1 3 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
```

(continues on next page)
\[ \begin{array}{cccc}
21 & \left( \frac{1}{2}, 1, 1/2 \right) & \left( \frac{1}{2}, 1, 1/2 \right) \\
22 & \left( \frac{1}{2}, 1, 1/2 \right) & \left( \frac{1}{2}, 0, 1/2 \right) \\
23 & \left( \frac{1}{2}, 1, 1/2 \right) & \left( \frac{1}{2}, 1, 1/2 \right) \\
31 & \left( 1/4, 1/2, 3/4 \right) & \left( 1/4, 1/2, 3/4 \right) \\
32 & \left( 1/4, 1/2, 3/4 \right) & \left( 1/4, 1/2, 3/4 \right) \\
33 & \left( 1/4, 1/2, 3/4 \right) & \left( 1/4, 1/2, -1/4 \right)
\end{array} \]

```python
>>> from sage.all import *

>>> W = ReflectionGroup(['A', Integer(3)], ['B', Integer(2)])

>>> W.fundamental_weights()
Finite family {1: (3/4, 1/2, 1/4, 0, 0), 2: (1/2, 1, 1/2, 0, 0), 3: (1/4, 1/2, 
\rightarrow 3/4, 0, 0), 4: (0, 0, 0, 1, 1/2), 5: (0, 0, 0, 1, 1)}

>>> W = ReflectionGroup(['A', Integer(3)])

>>> W.fundamental_weights()
Finite family {1: (3/4, 1/2, 1/4), 2: (1/2, 1, 1/2), 3: (1/4, 1/2, 3/4)}

>>> W = ReflectionGroup(['A', Integer(3)])

>>> S = W.simple_reflections()

>>> N = W.fundamental_weights()

>>> for i in W.index_set():
...   for j in W.index_set():
...     print("\%3d \%3d \%s \%s")
...     .format(i, j, N[i], N[i]*S[j].to_matrix())

1 1 (3/4, 1/2, 1/4) (-1/4, 1/2, 1/4)
1 2 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
1 3 (3/4, 1/2, 1/4) (3/4, 1/2, 1/4)
2 1 (1/2, 1, 1/2) (1/2, 1, 1/2)
2 2 (1/2, 1, 1/2) (1/2, 0, 1/2)
2 3 (1/2, 1, 1/2) (1/2, 1, 1/2)
3 1 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 2 (1/4, 1/2, 3/4) (1/4, 1/2, 3/4)
3 3 (1/4, 1/2, 3/4) (1/4, 1/2, -1/4)
```

**iteration (algorithm='breadth', tracking_words=True)**

Return an iterator going through all elements in `self`.

**INPUT:**

- **algorithm** (default: 'breadth') – must be one of the following:
  - 'breadth' – iterate over in a linear extension of the weak order
  - 'depth' – iterate by a depth-first-search
  - 'parabolic' – iterate by using parabolic subgroups
- **tracking_words** (default: True) – whether or not to keep track of the reduced words and store them in `_reduced_word`

**Note:** The fastest iteration is the parabolic iteration and the depth first algorithm without tracking words is second. In particular, 'depth' is ~1.5x faster than 'breadth'.

**Note:** The 'parabolic' iteration does not track words and requires keeping the subgroup corresponding to \( I \setminus \{ i \} \) in memory (for each \( i \) individually).
EXAMPLES:

```python
sage: W = ReflectionGroup(['B', 2])

sage: for w in W.iteration("breadth", True):
....:    print("%s %s\n%sw._reduced_word")
() []
(1,3) (2,6) (5,7) [1]
(1,5) (2,4) (6,8) [0]
(1,7,5,3) (2,4,6,8) [0, 1]
(1,3,5,7) (2,8,6,4) [1, 0]
(2,8) (3,7) (4,6) [1, 0, 1]
(1,7) (3,5) (4,8) [0, 1, 0]
(1,5) (2,6) (3,7) (4,8) [0, 1, 0, 1]

sage: for w in W.iteration("depth", False):
...
```

positive_roots()

Return the positive roots of self.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A', 3], ['B', 2])
sage: W.positive_roots()
[(1, 0, 0, 0, 0),
 (0, 1, 0, 0, 0),
 (0, 0, 1, 0, 0),
 ...]
```

(continues on next page)
reflection_to_positive_root(r)

Return the positive root orthogonal to the given reflection.

EXAMPLES:

```python
sage: W = ReflectionGroup(['A',2])
sage: for r in W.reflections():
    print(W.reflection_to_positive_root(r))
(1, 0)
(0, 1)
(1, 1)
```

right_coset_representatives(J)

Return the right coset representatives of self for the parabolic subgroup generated by the simple reflections in J.

EXAMPLES:
sage: W = ReflectionGroup("A",3)
sage: for J in Subsets([1,2,3]): W.right_coset_representatives(J)

[(), (2,5)(3,9)(4,6)(8,11)(10,12), (1,4)(2,8)(3,5)(7,10)(9,11),

 (1,3,7,9)(2,11,6,10)(4,8,5,12), (1,9,7,3)(2,10,6,11)(4,12,5,8),
]
root_to_reflection(root)

Return the reflection along the given root.

EXAMPLES:

```
sage: W = ReflectionGroup(['A',2])
sage: for beta in W.roots(): W.root_to_reflection(beta)
(1,4)(2,3)(5,6)
(1,3)(2,5)(4,6)
(1,5)(2,4)(3,6)
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)])
>>> for beta in W.roots(): W.root_to_reflection(beta)
(1,4)(2,3)(5,6)
(1,3)(2,5)(4,6)
(1,5)(2,4)(3,6)
```

simple_root_index(i)

Return the index of the simple root \(\alpha_i\).

This is the position of \(\alpha_i\) in the list of simple roots.
EXAMPLES:

```
sage: W = ReflectionGroup(['A',3])
sage: [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(3)])
>>> [W.simple_root_index(i) for i in W.index_set()]
[0, 1, 2]
```

```
sage.combinat.root_system.reflection_group_real.ReflexionGroup(*args, **kwds)
```

Construct a finite (complex or real) reflection group as a Sage permutation group by fetching the permutation representation of the generators from chevie’s database.

**INPUT:**

Can be one or multiple of the following:

- A triple \((r, p, n)\) with \(p\) divides \(r\), which denotes the group \(G(r, p, n)\)
- An integer between 4 and 37, which denotes an exceptional irreducible complex reflection group
- A finite Cartan-Killing type

**EXAMPLES:**

Finite reflection groups can be constructed from

Cartan-Killing classification types:

```
sage: W = ReflectionGroup(['A',3]); W
Irreducible real reflection group of rank 3 and type A3
sage: W = ReflectionGroup(['H',4]); W
Irreducible real reflection group of rank 4 and type H4
sage: W = ReflectionGroup(['I',5]); W
Irreducible real reflection group of rank 2 and type I2(5)
```

```
>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(3)]); W
Irreducible real reflection group of rank 3 and type A3
>>> W = ReflectionGroup(['H',Integer(4)]); W
Irreducible real reflection group of rank 4 and type H4
>>> W = ReflectionGroup(['I',Integer(5)]); W
Irreducible real reflection group of rank 2 and type I2(5)
```

The complex infinite family \(G(r, p, n)\) with \(p\) divides \(r\):

```
sage: W = ReflectionGroup((1,1,4)); W
Irreducible real reflection group of rank 3 and type A3
sage: W = ReflectionGroup((2,1,3)); W
Irreducible real reflection group of rank 3 and type B3
```
>>> from sage.all import *
>>> W = ReflectionGroup((Integer(1),Integer(1),Integer(4))); W
Irreducible real reflection group of rank 3 and type A3

>>> W = ReflectionGroup((Integer(2),Integer(1),Integer(3))); W
Irreducible real reflection group of rank 3 and type B3

Chevalley-Shepard-Todd exceptional classification types:

sage: W = ReflectionGroup(23); W
Irreducible real reflection group of rank 3 and type H3

>>> from sage.all import *
>>> W = ReflectionGroup(Integer(23)); W
Irreducible real reflection group of rank 3 and type H3

Cartan types and matrices:

sage: ReflectionGroup(CartanType(['A',2]))
Irreducible real reflection group of rank 2 and type A2

sage: ReflectionGroup(CartanType((['A',2],['A',2])))
Reducible real reflection group of rank 4 and type A2 x A2

sage: C = CartanMatrix(['A',2])
sage: ReflectionGroup(C)
Irreducible real reflection group of rank 2 and type A2

>>> from sage.all import *
>>> ReflectionGroup(CartanType(['A',Integer(2)]))
Irreducible real reflection group of rank 2 and type A2

>>> ReflectionGroup(CartanType((['A',Integer(2)],[A',Integer(2)])))
Reducible real reflection group of rank 4 and type A2 x A2

>>> C = CartanMatrix(['A',Integer(2)])
>>> ReflectionGroup(C)
Irreducible real reflection group of rank 2 and type A2

multiples of the above:

sage: W = ReflectionGroup(['A',2],['B',2]); W
Reducible real reflection group of rank 4 and type A2 x B2

sage: W = ReflectionGroup(['A',2],4); W
Reducible complex reflection group of rank 4 and type A2 x ST4

sage: W = ReflectionGroup((4,2,2),4); W
Reducible complex reflection group of rank 4 and type G(4,2,2) x ST4

>>> from sage.all import *
>>> W = ReflectionGroup(['A',Integer(2)],[B',Integer(2)]); W
Reducible real reflection group of rank 4 and type A2 x B2

>>> W = ReflectionGroup(['A',Integer(2)],Integer(4)); W
Reducible complex reflection group of rank 4 and type A2 x ST4

(continues on next page)
sage.combinat.root_system.reflection_group_real.is_chevie_available()
Test whether the GAP3 Chevie package is available.

EXAMPLES:

```python
sage: # needs sage.groups
sage: from sage.combinat.root_system.reflection_group_real import is_chevie_available
sage: is_chevie_available() # random
False
sage: is_chevie_available() in [True, False]
True
```

5.1.238 Group algebras of root lattice realizations

```python
class sage.combinat.root_system.root_lattice_realization_algebras.Algebras(
category, *args)

Bases: AlgebrasCategory
The category of group algebras of root lattice realizations.
This includes typically weight rings (group algebras of weight lattices).
```
\[ B[(0, 0, 0, 0)] + 2* B[(2, 2, 3, 0)] + B[(4, 4, 6, 0)] \]

\[
\text{sage: } w = W.an_element(); w.reduced_word() \quad \# _{-} \\
\text{sage: } m.acted_upon(w) \quad \# _{-}
\]

\[ B[(0, 0, 0, 0)] + 2* B[(2, 2, 3, 0)] + B[(4, 4, 6, 0)] \]

\[ \text{sage: } \text{from sage.all import *} \text{ from sage.libs.gap} \text{ from sage.libs.gap} \]

\[ \text{L = RootSystem(["A",Integer(3)])}.ambient_space() \]

\[ \text{W = L.ambient_lattice()} \text{ M = L.algebra(QQ[q,t])} \text{ m = M.an_element(); m} \text{ \# TODO: investigate why we don't get something more interesting} \]

\[ \text{w = W.an_element(); w.reduced_word()} \text{ m.acted_upon(w)} \text{ \# TODO: investigate why we don't get something more interesting} \]

\[ \text{sage: } \text{expand}(\text{alphabet}) \]

Expand self into variables in the alphabet.

**INPUT:**

- `alphabet` – a non-empty list/tuple of (invertible) variables in a ring to expand in

**EXAMPLES:**

\[ \text{sage: } \text{F = LaurentPolynomialRing(QQ, 'x,y,z')} \text{ p.expand(F.gens())} \]

\[ 2*x^2*y^2*z^3 + x*y + x + y*z^-1 + x*y^-1 \]

\[ \text{sage: } \text{from sage.all import *} \text{ from sage.libs.gap} \text{ from sage.libs.gap} \]

\[ \text{L = RootSystem(["A",Integer(2)])}.ambient_lattice() \]

\[ \text{KL = L.algebra(QQ)} \text{ p = KL.an_element() + KL.sum_of_monomials(L.some_elements())); p} \text{ B[(1, 0, 0)] + B[(1, -1, 0)] + B[(1, 1, 0)] + 2*B[(2, 2, 3)] + B[(0, 1, -1)]} \text{ F = LaurentPolynomialRing(QQ, 'x,y,z')} \text{ p.expand(F.gens())} \]

\[ 2*x^2*y^2*z^3 + x*y + x + y*z^-1 + x*y^-1 \]

**class** `ParentMethods`

Bases: `object`

\[ \text{T0_check_on_basis}(q1, q2, convention='antidominant') \]

Return the $T_0^\vee$ operator acting on the basis.

\[ 5.1. \text{Comprehensive Module List} \]
This implements the formula for $T_{0'}$ in Section 6.12 of [Haiman06].

REFERENCES:

Warning: The current implementation probably returns just nonsense, if the convention is not "dominant".

EXAMPLES:

```python
sage: K = QQ['q1,q2'].fraction_field()
sage: q1,q2 = K.gens()

sage: L = RootSystem(["A",1,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L.fundamental_weights()  # needs sage.graphs
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")  # needs sage.graphs
sage: f(L0.zero())  # needs sage.graphs
(q1+q2)*B[(0, 0)] + q1*B[(1, -1)]

sage: L = RootSystem(["A",3,1]).ambient_space()
sage: L0 = L.classical()
sage: KL = L.algebra(K)
sage: some_weights = L0.fundamental_weights()  # needs sage.graphs
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant")  # needs sage.graphs
sage: f(L0.zero())  # not checked  # needs sage.graphs
(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]
```

```python
>>> from sage.all import *

>>> K = QQ['q1,q2'].fraction_field()

>>> q1,q2 = K.gens()

>>> L = RootSystem(["A",1,1]).ambient_space()

>>> L0 = L.classical()

>>> KL = L.algebra(K)

>>> some_weights = L.fundamental_weights()  # needs sage.graphs

>>> f = KL.T0_check_on_basis(q1,q2, convention="dominant")  # needs sage.graphs

>>> f(L0.zero())  # not checked  # needs sage.graphs

(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]

>>> L = RootSystem(["A",3,1]).ambient_space()

>>> L0 = L.classical()

>>> KL = L.algebra(K)

>>> some_weights = L0.fundamental_weights()  # needs sage.graphs

>>> f = KL.T0_check_on_basis(q1,q2, convention="dominant")  # needs sage.graphs

>>> f(L0.zero())  # not checked  # needs sage.graphs

(q1+q2)*B[(0, 0, 0, 0)] + q1^3/q2^2*B[(1, 0, 0, -1)]
```
The following results have not been checked:

```python
sage: for x in some_weights:
    #→ needs sage.graphs
....:     print("{}/{}".format(x, f(x)))
(1, 0, 0, 0) : q1*B[(1, 0, 0, 0)]
(1, 1, 0, 0) : q1*B[(1, 1, 0, 0)]
(1, 1, 1, 0) : q1*B[(1, 1, 1, 0)]
```

Some examples for type $B_2^{(1)}$ dual:

```python
sage: L = RootSystem("B2-~*").ambient_space()
sage: L0 = L.classical()
sage: e = L.basis()
sage: K = QQ["q,u"].fraction_field()
sage: q,u = K.gens()
sage: q1 = u
sage: q2 = -1/u
sage: KL = L.algebra(K)
sage: KL0 = KL.classical()
sage: f = KL.T0_check_on_basis(q1,q2, convention="dominant") #→ needs sage.graphs
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention="dominant")
```

Direct calculation:

```python
sage: T.Tw(0)(KL0.monomial(L0([0,0]))) #→ needs sage.graphs
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
sage: KL.T0_check_on_basis(q1,q2, convention="dominant")(L0([0,0])) #→ needs sage.graphs
((u^2-1)/u)*B[(0, 0)] + u^3*B[(1, 1)]
```
Step by step calculation, comparing by hand with Mark Shimozono:

```
sage: res = T.Tw(2)(KL0.monomial(L0([0,0]))); res
u*B([0, 0])
sage: res = res * KL0.monomial(L0([-1,1])); res
u*B([-1, 1])
sage: res = T.Tw_inverse(1)(res); res
((u^2-1)/u)*B([0, 0]) + u^2*B([1, -1])
sage: res = T.Tw_inverse(2)(res); res
((u^2-1)/u)*B([0, 0]) + u^3*B([1, 1])
```

```
>>> from sage.all import *

>>> res = T.Tw(Integer(2))(KL0.monomial(L0([0,0]))); res
u*B([0, 0])
>>> res = res * KL0.monomial(L0([-1,1])); res
u*B([-1, 1])
>>> res = T.Tw_inverse(Integer(1))(res); res
((u^2-1)/u)*B([0, 0]) + u^2*B([1, -1])
>>> res = T.Tw_inverse(Integer(2))(res); res
((u^2-1)/u)*B([0, 0]) + u^3*B([1, 1])
```

cartan_type()

Return the Cartan type of self.

EXAMPLES:

```
sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.cartan_type()
['A', 2, 1]
sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
sage: A.cartan_type()
['B', 2]
```

classical()

Return the group algebra of the corresponding classical lattice.

EXAMPLES:

```
>>> from sage.all import *

>>> A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
>>> A.cartan_type()
['A', 2, 1]
>>> A = RootSystem(["B",2]).weight_space().algebra(QQ)
>>> A.cartan_type()
['B', 2]
```
Algebra of the Ambient space of the Root system of type ['A', 2] over Rational Field

```python
>>> from sage.all import *

>>> KL = RootSystem(['A',Integer(2),Integer(1)]).ambient_space().algebra(QQ)

>>> KL.classical()
Algebra of the Ambient space of the Root system of type ['A', 2] over Rational Field

demazure_lusztig_operator_on_basis(weight, i, q1, q2, convention='antidominant')

Return the result of applying the i-th Demazure-Lusztig operator on weight.

INPUT:

• weight – an element $\lambda$ of the weight lattice
• i – an element of the index set
• q1, q2 – two elements of the ground ring
• convention – "antidominant", "bar", or "dominant" (default: "antidominant")

See demazure_lusztig_operators() for the details.

EXAMPLES:

```python
sage: L = RootSystem(['A',1]).ambient_space()
sage: K = QQ[q1,q2]

sage: q1, q2 = K.gens()

sage: KL = L.algebra(K)

sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, q1, q2)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(3, 0)]
```

At $q_1 = 1$ and $q_2 = 0$ we recover the action of the isobaric divided differences $\pi_i$:

```python
sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0)
B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0)
B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]
sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0)
-B[(1, 2)] - B[(2, 1)]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> KL.demazure_lusztig_operator_on_basis(L((Integer(2),Integer(2))),
    → Integer(1), Integer(1), Integer(0))
B[(2, 2)]

>>> KL.demazure_lusztig_operator_on_basis(L((Integer(3),Integer(0))),
    → Integer(1), Integer(1), Integer(0))
B[(1, 2)] + B[(2, 1)] + B[(0, 3)] + B[(0, 3)]

>>> KL.demazure_lusztig_operator_on_basis(L((Integer(0),Integer(3))),
    → Integer(1), Integer(1), Integer(0))
-B[(1, 2)] - B[(2, 1)]

Or $1 - \pi_i$ for bar=True:

sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, 0, convention=
    → "bar")
0
sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, 0, convention=
    → "bar")
-B[(1, 2)] - B[(2, 1)] - B[(0, 3)]

sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, 0, convention=
    → "bar")
B[(1, 2)] + B[(2, 1)] + B[(0, 3)]

At $q_1 = 1$ and $q_2 = -1$ we recover the action of the simple reflection $s_i$:

sage: KL.demazure_lusztig_operator_on_basis(L((2,2)), 1, 1, -1)
B[(2, 2)]

sage: KL.demazure_lusztig_operator_on_basis(L((3,0)), 1, 1, -1)
B[(0, 3)]

sage: KL.demazure_lusztig_operator_on_basis(L((0,3)), 1, 1, -1)
B[(3, 0)]

>>> from sage.all import *

>>> KL.demazure_lusztig_operator_on_basis(L((Integer(2),Integer(2))),
    → Integer(1), Integer(1), -Integer(1))
B[(2, 2)]

>>> KL.demazure_lusztig_operator_on_basis(L((Integer(3),Integer(0))),
    → Integer(1), Integer(1), -Integer(1))
B[(0, 3)]

>>> KL.demazure_lusztig_operator_on_basis(L((Integer(0),Integer(3))),
    → Integer(1), Integer(1), -Integer(1))
B[(3, 0)]

demazure_lusztig_operator_on_classical_on_basis(weight, i, q, ql, q2,
    convention='antidominant')

Return the result of applying the $i$-th Demazure-Lusztig operator on the classical weight `weight` em-
```
bedded at level 0.

INPUT:
- weight – a classical weight $\lambda$
- i – an element of the index set
- $q_1, q_2$ – two elements of the ground ring
- convention – "antidominant", "bar", or "dominant" (default: "antidominant")

See :meth:`demazure_lusztig_operators()` for the details.

Todo:
- Optimize the code to only do the embedding/projection for $T_0$
- Add an option to specify at which level one wants to work. Currently this is level 0.

**EXAMPLES:**

```python
sage: L = RootSystem(["A",1,1]).ambient_space()
sage: L0 = L.classical()
sage: K = QQ["q,q1,q2"]
sage: q, q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: KL0 = L0.algebra(K)
```

These operators coincide with the usual Demazure-Lusztig operators:

```python
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((2,2)), 
          # needs sage.graphs
         ....:
         1, q, q1, q2)
q1*B[(2, 2)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((2,2)), 1, q1, q2)
q1*B[(2, 2)]
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((3,0)), 
          # needs sage.graphs
         ....:
         1, q, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: KL0.demazure_lusztig_operator_on_basis(L0((3,0)), 1, q1, q2)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(1),Integer(1)]).ambient_space()
>>> L0 = L.classical()
>>> K = QQ["q,q1,q2"]
>>> q, q1, q2 = K.gens()
>>> KL = L.algebra(K)
>>> KL0 = L0.algebra(K)
```

```python
sage: KL.demazure_lusztig_operator_on_classical_on_basis(L0((Integer(2), 
         # needs sage.graphs
         ....: Integer(2))), Integer(1), q, q1,-
         -q2)
q1*B[(2, 2)]
```

```python
>>> from sage.all import *
>>> KL.demazure_lusztig_operator_on_classical_on_basis(L0((Integer(2),Integer(2))),...
         -Integer(1), q1, q2)
q1*B[(2, 2)]
```

(continues on next page)
The Demazure-Lusztig operators give the usual representation of the operator $T_i$ of the (affine) Hecke algebra with eigenvalues $q_1$ and $q_2$ associated to the Weyl group.

Several variants are available to match with various conventions used in the literature:

- “bar” replaces $\pi_i$ in the formula above by $\pi_i = (1 - \pi_i)$.
- “dominant” conjugates the operator by $x^\lambda \mapsto x^{-\lambda}$.

The names dominant and antidominant for the conventions were chosen with regards to the nonsymmetric Macdonald polynomials. The $Y$ operators for the Macdonald polynomials in the “dominant” convention satisfy $Y_\lambda = T_{i_\lambda}$ for $\lambda$ dominant. This is also the convention used in [Haiman06]. For the “antidominant” convention, $Y_\lambda = T_{i_\lambda}$ with $\lambda$ antidominant.

• `demazure_lusztig_operator_on_basis()`.
• `NonSymmetricMacdonaldPolynomials`.

REFERENCES:

EXAMPLES:

```python
sage: L = RootSystem(“A”, 1).ambient_space()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: T = KL.demazure_lusztig_operators(q1, q2)
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2, 
       convention="dominant")
sage: x = KL.monomial(L((3, 0)))
sage: T[1](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
sage: Tbar[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q1-2*q2)*B[(0, 3)]
sage: Tbar[1](x) + T[1](x)
(q1+q2)*B[(3, 0)] + (-2*q2)*B[(0, 3)]
sage: Tdominant[1](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(0, 3)]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[(0, 0)] - 1/q2*B[(1, -1)]
```

We repeat similar computation in the affine setting:

```python
>>> from sage.all import *
>>> L = RootSystem(“A”, Integer(1)).ambient_space()
>>> K = QQ['q1,q2'].fraction_field()
>>> q1, q2 = K.gens()
>>> KL = L.algebra(K)
>>> T = KL.demazure_lusztig_operators(q1, q2)
>>> Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
>>> Tdominant = KL.demazure_lusztig_operators(q1, q2, 
       convention="dominant")
>>> x = KL.monomial(L((Integer(3),Integer(0))))
>>> T[Integer(1)](x)
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
>>> Tbar[Integer(1)](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q1-2*q2)*B[(0, 3)]
>>> Tbar[Integer(1)](x) + T[Integer(1)](x)
(q1+q2)*B[(3, 0)] + (-2*q2)*B[(0, 3)]
>>> Tdominant[Integer(1)](x)
(-q1-q2)*B[(1, 2)] + (-q1-q2)*B[(2, 1)] + (-q2)*B[(0, 3)]
>>> Tdominant.Tw_inverse(Integer(1))(KL.monomial(-L.simple_ 
       root(Integer(1))))
((-q1-q2)/(q1*q2))*B[(0, 0)] - 1/q2*B[(1, -1)]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: Tbar = KL.demazure_lusztig_operators(q1, q2, convention="bar")
sage: Tdominant = KL.demazure_lusztig_operators(q1, q2,
....:                                          convention="dominant")
sage: e = L.basis()
sage: x = KL.monomial(3*e[0])
sage: T[1](x)
(q1+q2)*B[e[0] + 2*e[1]] + (q1+q2)*B[2*e[0] + e[1]]
   + (q1+q2)*B[3*e[0]] + q1*B[3*e[1]]
sage: Tbar[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]]
   + (-q1-2*q2)*B[3*e[1]]
sage: Tdominant[1](x)
(-q1-q2)*B[e[0] + 2*e[1]] + (-q1-q2)*B[2*e[0] + e[1]]
   + (-q2)*B[3*e[1]]
sage: Tdominant.Tw_inverse(1)(KL.monomial(-L.simple_root(1)))
((-q1-q2)/(q1*q2))*B[0] - 1/q2*B[e[0] - e[1]]
```

One can obtain iterated operators by passing a reduced word or an element of the Weyl group:

```python
sage: T[1,2](x)
(q1^2+2*q1*q2+q2^2)*B[e[0] + e[1] + e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[e[0] + 2*e[1]]
  + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + 2*e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + e[1]]
  + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + 2*e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[3*e[0] + e[1]]
  + (q1^2+2*q1*q2+q2^2)*B[3*e[0] + 2*e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[3*e[0] + 3*e[2]]
```

```python
>>> from sage.all import *
>>> T[Integer(1), Integer(2)](x)
(q1^2+2*q1*q2+q2^2)*B[e[0] + e[1] + e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[e[0] + 2*e[1]]
  + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + 2*e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + e[1]]
  + (q1^2+2*q1*q2+q2^2)*B[2*e[0] + 2*e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[3*e[0] + e[1]]
  + (q1^2+2*q1*q2+q2^2)*B[3*e[0] + 2*e[2]]
  + (q1^2+2*q1*q2+q2^2)*B[3*e[0] + 3*e[2]]
```

(continues on next page)
and use that to check, for example, the braid relations:

```python
sage: T[1,2,1](x) - T[2,1,2](x)
0
```

>>> from sage.all import *

```python
>>> T[Integer(1),Integer(2),Integer(1)](x) - T[Integer(2),Integer(1),
˓→Integer(2)](x)
0
```

The operators satisfy the relations of the affine Hecke algebra with parameters $q_1, q_2$:

```python
sage: T._test_relations()
sage: Tdominant._test_relations()
sage: Tbar._test_relations() # -q2, q1+2*q2  # todo: not implemented: set...
˓→the appropriate eigenvalues!
```

And the $\bar{T}$ are basically the inverses of the $T$'s:

```python
sage: Tinv = KL.demazure_lusztig_operators(2/q1 + 1/q2, -1/q1,
˓→q1, q2)  # needs sage.graphs
0, 0, 0, 0, 0, 0, 0)
```

We check that $\Lambda_1 - \Lambda_0$ is an eigenvector for the $Y$'s in affine type:

```python
sage: K = QQ['q,q1,q2'].fraction_field()
sage: q,q1,q2 = K.gens()
sage: L = RootSystem(['A','2','1']).ambient_space()
sage: L0 = L.classical()
sage: Lambda = L.fundamental_weights()  # needs sage.graphs
sage: alphacheck = L0.simple_coroots()
sage: KL = L.algebra(K)
```
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: T = KL.demazure_lusztig_operators(q1, q2, convention="dominant")
sage: Y = T.Y()
```

```python
# alpha of coroot lattice is alphacheck

alphacheck = Y.keys().alpha()

```

```python
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
```

```python
sage: x = KL.monomial(Lambda[1] - Lambda[0]); x

# needs sage.graphs

B[e[0]]
```

In fact it is not exactly an eigenvector, but the extra 'delta' term is to be interpreted as a $q$ parameter:

```python
sage: # needs sage.graphs
```

```python
sage: Y[alphacheck[0]](KL.one())

q2^2/q1^2*B[0]
```

```python
((-q2^2)/(-q1^2))*B[e[0] - e['delta']]
```

```python
sage: Y[alphacheck[2]](x)

(q1/(q2))*B[e[0]]
```

```python
((-q2^2)/(-q1^2))*B[(1, 0, 0)]
```

```python
sage: KL.q_project(Y[alphacheck[1]](x), q)

((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]
```

```python
sage: KL.q_project(Y[alphacheck[0]](x), q)

((-q*q1)/q2)*B[(1, 0, 0)]
```

```python
sage: KL.q_project(Y[alphacheck[1]](x), q)

((-q2^2)/(-q*q1^2))*B[(1, 0, 0)]
```

```python
sage: KL.q_project(Y[alphacheck[2]](x), q)

(q1/(-q2))*B[(1, 0, 0)]
```

>>> from sage.all import *

>>> K = QQ[‘q,q1,q2’].fraction_field()

>>> q,q1,q2 = K.gens()

>>> L = RootSystem(["A",Integer(2),Integer(1)]).ambient_space()

>>> L0 = L.classical()

>>> Lambda = L.fundamental_weights()

>>> alphacheck = L0.simple_coroots()

>>> KL = L.algebra(K)

>>> T = KL.demazure_lusztig_operators(q1, q2, convention="dominant")

>>> Y = T.Y()

>>> alphacheck = Y.keys().alpha()  # alpha of coroot lattice is alphacheck

>>> alphacheck

Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}

>>> x = KL.monomial(Lambda[1] - Lambda[0]); x  # needs sage.graphs

B[e[0]]
```

(continues on next page)
We now check systematically that the Demazure-Lusztig operators satisfy the relations of the Iwahori-Hecke algebra:

```
sage: K = QQ['q1,q2']
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(crystallographic=True): # long
time 12s
    L = RootSystem(cartan_type).root_lattice()
    KL = L.algebra(K)
    T = KL.demazure_lusztig_operators(q1,q2)
    T._test_relations()
```

Recall that the Demazure-Lusztig operators are only defined when all monomials belong to the weight lattice. Thus, in the group algebra of the ambient space, we need to specify explicitly the elements on which to run the tests:

```
sage: for cartan_type in CartanType.samples(crystallographic=True): # long
time 12s
    L = RootSystem(cartan_type).weight_lattice()
    KL = L.algebra(K)
    T = KL.demazure_lusztig_operators(q1,q2)
    T._test_relations()
```
demazure_lusztig_operators_on_classical (q, q1, q2, convention='antidominant')

Return the Demazure-Lusztig operators acting at level 1 on self.classical().

INPUT:

- q, q1, q2 – three elements of the ground ring
- convention - "antidominant", "bar", or "dominant" (default: "antidominant")

Let $K_L$ be the group algebra of an affine weight lattice realization $L$. The Demazure-Lusztig operators for $K_L$ act on the group algebra of the corresponding classical weight lattice by embedding it at level 1, and projecting back.

See also:

- demazure_lusztig_operators().
- demazure_lusztig_operator_on_classical_on_basis().
- q_project()
>>> KL = L.algebra(K)
>>> KL0 = KL.classical()
>>> L0 = KL0.basis().keys()
>>> T = KL.demazure_lusztig_operators_on_classical(q, q1, q2)  
    # needs sage.graphs

>>> x = KL0.monomial(L0((Integer(3), Integer(0)))); x
B[(3, 0)]

For $T_1, \ldots$ we recover the usual Demazure-Lusztig operators:

```
sage: T[1](x)  
    # needs sage.graphs
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

```
>>> from sage.all import *

>>> T[Integer(1)](x)  
    # needs sage.graphs
(q1+q2)*B[(1, 2)] + (q1+q2)*B[(2, 1)] + (q1+q2)*B[(3, 0)] + q1*B[(0, 3)]
```

For $T_0$, we can note that, in the projection, $\delta$ is mapped to $q$:

```
sage: T[0](x)  
    # needs sage.graphs
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]
```

```
>>> from sage.all import *

>>> T[Integer(0)](x)  
    # needs sage.graphs
(-q^2*q1-q^2*q2)*B[(1, 2)] + (-q*q1-q*q2)*B[(2, 1)] + (-q^3*q2)*B[(0, 3)]
```

Note that there is no translation part, and in particular 1 is an eigenvector for all $T_i$'s:

```
sage: # needs sage.graphs
sage: T[0](KL0.one())
q1*B[(0, 0)]
sage: T[1](KL0.one())
q1*B[(0, 0)]
sage: Y = T.Y()
sage: alphacheck = Y.keys().simple_roots()
sage: Y[alphacheck[Integer(0)]](KL0.one())
((-q2)/(q*q1))*B[(0, 0)]
```

```
>>> from sage.all import *

>>> # needs sage.graphs

>>> T[Integer(0)](KL0.one())
q1*B[(0, 0)]
>>> T[Integer(1)](KL0.one())
q1*B[(0, 0)]
>>> Y = T.Y()
>>> alphacheck = Y.keys().simple_roots()
>>> Y[alphacheck[Integer(0)]](KL0.one())
((-q2)/(q*q1))*B[(0, 0)]
```

Matching with Ion Bogdan’s hand calculations from 3/15/2013:
sage: \text{L = RootSystem(["A",1,1]).weight_space(extended=True)}

sage: \text{K = QQ[\"q,u\"].fraction_field()}

sage: \text{q, u = K.gens()}

sage: \text{KL = L.algebra(K)}

sage: \text{KL0 = KL.classical()}

sage: \text{L0 = KL0.basis().keys()}

sage: \text{omega = L0.fundamental_weights()}

sage: \text{# needs sage.graphs}

sage: \text{T = KL.demazure_lusztig_operators_on_classical(q, u, -1/u, ....: convention="dominant \text{ means} ")}

sage: \text{Y = T.Y()}

sage: \text{alphacheck = Y.keys().simple_roots()}

sage: \text{Ydelta = Y[Y.keys().null_root()]}  \text{# This is } T_0 T_1 (T_1 \text{ acts first, then } T_0); \text{ Ion gets } T_1 T_0 \text{ } ((1, 0), (1, 1), 1)

sage: \text{Y0 = Y[alphacheck[0]]}  \text{# This is } 1/q T_1^{-1} T_0^{-1} \text{ } ((0, 1), (-1, -1), 1/q)

Note that the following computations use the “dominant” convention:

sage: \text{# needs sage.graphs}

sage: \text{T0 = T.Tw(0)}

sage: \text{q*u*B[-Lambda[1]] + ((u^2-1)/u)*B[Lambda[1]]}

(continues on next page)
demazure_operators()

Return the Demazure operators acting on self.

The $i$-th Demazure operator is defined by:

$$\pi_i = \frac{1 - e^{-\alpha_i} s_i}{1 - e^{-\alpha_i}}$$

It acts on $e^\lambda$, for $\lambda$ a weight, by:

$$\pi_i e^\lambda = \frac{e^\lambda - e^{-\alpha_i + s_i \lambda}}{1 - e^{-\alpha_i}}$$

This matches with Lascoux’ definition [Lascoux2003] of $\pi_i$, and with the $i$-th Demazure operator of [Kumar1987], which also works for general Kac-Moody types.

REFERENCES:

EXAMPLES:

We compute some Schur functions, as images of dominant monomials under the action of the maximal isobaric divided difference $\Delta_{w_0}$:

```python
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: w0 = tuple(L.weyl_group().long_element().reduced_word())  # needs sage.libs.gap
sage: pi = KL.demazure_operators()
sage: pi0 = pi[w0]  # needs sage.libs.gap
sage: pi0(KL.monomial(L((2,1))))
2*B[(1, 1, 1)] + B[(1, 2, 0)] + B[(1, 0, 2)] + B[(2, 1, 0)] + B[(2, 0, 1)] + B[(0, 1, 2)] + B[(0, 2, 1)]
```

```python
>>> from sage.all import *

>>> L = RootSystem(['A',Integer(2)]).ambient_lattice()

>>> KL = L.algebra(QQ)
```
Let us make the result into an actual polynomial:

```
sage: P = QQ['x,y,z']
sage: pi0(KL.monomial(L((2,1))).expand(P.gens()))
```

```
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

This is indeed a Schur function:

```
sage: s = SymmetricFunctions(QQ).s()
sage: s[2,1].expand(3, P.variable_names())
```

```
x^2*y + x*y^2 + x^2*z + 2*x*y*z + y^2*z + x*z^2 + y*z^2
```

Let us check this systematically on Schur functions of degree 6:

```
sage: for p in Partitions(6, max_length=3).list():
    assert (s.monomial(p).expand(3, P.variable_names())
    == pi0(KL.monomial(L(tuple(p)))).expand(P.gens()))
```

We check systematically that these operators satisfy the Iwahori-Hecke algebra relations:
....: L = RootSystem(cartan_type).weight_lattice()
....: KL = L.algebra(QQ)
....: T = KL.demazure_operators()
....: T._test_relations()

sage: L = RootSystem(['A',1,1]).weight_lattice()
sage: KL = L.algebra(QQ)
sage: T = KL.demazure_operators()
sage: T._test_relations()

>>> from sage.all import *
>>> for cartan_type in CartanType.samples(crystallographic=True): # long...
|_time (12s)
... L = RootSystem(cartan_type).weight_lattice()
... KL = L.algebra(QQ)
... T = KL.demazure_operators()
... T._test_relations()

>>> L = RootSystem(['A',1,1]).weight_lattice()
>>> KL = L.algebra(QQ)
>>> T = KL.demazure_operators()
>>> T._test_relations()

Warning: The Demazure operators are only defined if all the elements in the support have integral
scalar products with the coroots (basically, they are in the weight lattice). Otherwise an error is raised:

sage: L = RootSystem(CartanType(['G',2]).dual()).ambient_space()
sage: KL = L.algebra(QQ)
sage: pi = KL.demazure_operators()
sage: pi[1](KL.monomial(L([[0,0,1]])))
Traceback (most recent call last):
...
ValueError: the weight does not have an integral scalar product with␣
→the coroot

>>> from sage.all import *
>>> L = RootSystem(CartanType(['G',2]).dual()).ambient_space()
>>> KL = L.algebra(QQ)
>>> pi = KL.demazure_operators()
>>> pi[1](KL.monomial(L([[0,0,1]],)))
Traceback (most recent call last):
...
ValueError: the weight does not have an integral scalar product with␣
→the coroot

divided_difference_on_basis(weight, i)

Return the result of applying the i-th divided difference on weight.

INPUT:

• weight – a weight
• i – an element of the index set

Todo: type free definition (Viviane’s definition uses that we are in the ambient space)
EXAMPLES:

```python
sage: L = RootSystem(['A',1]).ambient_space()
sage: KL = L.algebra(QQ)
sage: KL.divided_difference_on_basis(L((2,2)), 1) # todo: not implemented
0
sage: KL.divided_difference_on_basis(L((3,0)), 1) # todo: not implemented
B[(2, 0)] + B[(1, 1)] + B[(0, 2)]
sage: KL.divided_difference_on_basis(L((0,3)), 1) # todo: not implemented
-B[(2, 0)] - B[(1, 1)] - B[(0, 2)]
```

In type $A$ and in the ambient lattice, we recover the usual action of divided differences polynomials:

```python
sage: x,y = QQ['x,y'].gens()
sage: d = lambda p: (p - p(y,x)) / (x-y)
sage: d(x^2*y^2)
0
sage: d(x^3)
x^2 + x*y + y^2
sage: d(y^3)
-x^2 - x*y - y^2
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(1)]).ambient_space()
>>> KL = L.algebra(QQ)
>>> KL.divided_difference_on_basis(L((Integer(2),Integer(2))), Integer(1)) # todo: not implemented
0
>>> KL.divided_difference_on_basis(L((Integer(3),Integer(0))), Integer(1)) # todo: not implemented
B[(2, 0)] + B[(1, 1)] + B[(0, 2)]
>>> KL.divided_difference_on_basis(L((Integer(0),Integer(3))), Integer(1)) # todo: not implemented
-B[(2, 0)] - B[(1, 1)] - B[(0, 2)]
```

```python
from polynomial (p)

Construct an element of self from a polynomial $p$.

INPUT:

• $p$—a polynomial

EXAMPLES:

```python
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: KL = L.algebra(QQ)
sage: x,y,z = QQ['x,y,z'].gens()
sage: KL.from_polynomial(x)
B[(1, 0, 0)]
```

(continues on next page)
Todo: make this work for Laurent polynomials too

\texttt{sage: KL.from_polynomial(x^2*y + 2*y - z)}
\texttt{B[(2, 1, 0)] + 2*B[(0, 1, 0)] - B[(0, 0, 1)]}

\texttt{>>> from sage.all import *}
\texttt{>>> L = RootSystem(["A",Integer(2)]).ambient_lattice()}
\texttt{>>> KL = L.algebra(QQ)}
\texttt{>>> x,y,z = QQ["x,y,z"].gens()}
\texttt{>>> KL.from_polynomial(x)}
\texttt{B[(1, 0, 0)]}
\texttt{>>> KL.from_polynomial(x**Integer(2)*y + Integer(2)*y - z)}
\texttt{B[(2, 1, 0)] + 2*B[(0, 1, 0)] - B[(0, 0, 1)]}

\textbf{Todo:} make this work for Laurent polynomials too

\texttt{isobaric_divided_difference_on_basis(weight, i)}

Return the result of applying the \textit{i}-th isobaric divided difference on \textit{weight}.

\textbf{INPUT:}

\begin{itemize}
\item weight—a weight
\item i—an element of the index set
\end{itemize}

\textbf{See also:}

\texttt{demazure_operators()}

\textbf{EXAMPLES:}

\texttt{>>> L = RootSystem(["A",1]).ambient_space()}
\texttt{>>> KL = L.algebra(QQ)}
\texttt{>>> KL.isobaric_divided_difference_on_basis(L((2,2)), 1)}
\texttt{B[(2, 2)]}
\texttt{>>> KL.isobaric_divided_difference_on_basis(L((3,0)), 1)}
\texttt{B[(1, 2)] + B[(2, 1)] + B[(3, 0)] + B[(0, 3)]}
\texttt{>>> KL.isobaric_divided_difference_on_basis(L((0,3)), 1)}
\texttt{-B[(1, 2)] - B[(2, 1)]}

In type $A$ and in the ambient lattice, we recover the usual action of divided differences on polynomials:

\texttt{>>> from sage.all import *}
\texttt{>>> L = RootSystem(["A",1]).ambient_space()}
\texttt{>>> KL = L.algebra(QQ)}
\texttt{>>> KL.isobaric_divided_difference_on_basis(L((Integer(2),Integer(2))), Integer(1))}
\texttt{B[(2, 2)]}
\texttt{>>> KL.isobaric_divided_difference_on_basis(L((Integer(3),Integer(0))), Integer(1))}
\texttt{-B[(1, 2)] - B[(2, 1)]}

In type $A$ and in the ambient lattice, we recover the usual action of divided differences on polynomials:

\texttt{sage: x,y = QQ['x,y'].gens()}
\texttt{sage: d = lambda p: (x*p - (x*p)(y,x)) / (x-y)}
\texttt{sage: d(x^2*y^2)}
\texttt{x^2*y^2}
sage: d(x^3)  
\(x^3 + x^2y + xy^2 + y^3\)

sage: d(y^3)  
\(-x^2y - xy^2\)

```python
>>> from sage.all import *

>>> x, y = QQ['x, y'].gens()

>>> d = lambda p: (x*p - (x*p)(y, x)) / (x-y)

>>> d(x**Integer(2)*y**Integer(2))  
x^2*y^2

>>> d(x**Integer(3))  
x^3 + x^2*y + xy^2 + y^3

>>> d(y**Integer(3))  
-x^2*y - xy^2
```

REFERENCES:

$q$-project

Implement the $q$-projection morphism from self to the group algebra of the classical space.

**INPUT:**
- $x$ – an element of the group algebra of self
- $q$ – an element of the ground ring

This is an algebra morphism mapping $\delta$ to $q$ and $X^b$ to its classical counterpart for the other elements $b$ of the basis of the realization.

**EXAMPLES:**

```python
sage: K = QQ['q'\].fraction_field()

sage: q = K.gen()

sage: KL = RootSystem("A",2,1).ambient_space().algebra(K)

sage: L = KL.basis().keys()

sage: e = L.basis()

sage: x = (KL.an_element() + KL.monomial(4*e[1] + 3*e[2]) + e["deltacheck"] - 2*e["delta"])); x

sage: KL.q_project(x, q)

B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

```python
>>> from sage.all import *

>>> K = QQ['q'\].fraction_field()

>>> q = K.gen()

>>> KL = RootSystem("BC",3,2).ambient_space().algebra(K)

>>> L = KL.basis().keys()

>>> e = L.basis()

>>> x = (KL.an_element() + KL.monomial(4*e[1] + 3*e[2]) + e["deltacheck"] - 2*e["delta"])); x

sage: KL.q_project(x, q)

B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> L = KL.basis().keys()
>>> e = L.basis()
>>> x = (KL.an_element() + KL.monomial(Integer(4)*e[Integer(1)] + Integer(3)*e[Integer(2)]) + e['deltacheck'] - Integer(2)*e['delta'])); x
```

```
>>> KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

```
>>> KL = RootSystem(['BC',Integer(3),Integer(2)]).ambient_space().algebra(K)
>>> L = KL.basis().keys()
>>> e = L.basis()
>>> x = (KL.an_element() + KL.monomial(Integer(4)*e[Integer(1)] + Integer(3)*e[Integer(2)]) + e['deltacheck'] - Integer(2)*e['delta'])); x
```

```
>>> KL.q_project(x, q)
B[(2, 2, 3)] + 1/q^2*B[(0, 4, 3)]
```

Warning: Recall that the null root, usually denoted δ, is in fact a[0]\delta in Sage’s notation, in order to avoid half integer coefficients (this only makes a difference in type BC). Similarly, what’s usually denoted q is in fact q^a[0] in Sage’s notations, to avoid manipulating square roots:

```python
sage: KL.q_project(KL.monomial(L.null_root()), q)  # needs sage.graphs
q^2*B[(0, 0, 0)]
```

```python
from sage.all import *
```

```
>>> KL.q_project(KL.monomial(L.null_root()), q)  # needs sage.graphs
q^2*B[(0, 0, 0)]
```

**q_project_on_basis**(*l*, *q*)

Return the monomial *c* *cl(l)* in the group algebra of the classical lattice.

**INPUT:**

- *l* – an element of the root lattice realization
- *q* – an element of the ground ring

Here, *cl(l)* is the projection of *l* in the classical lattice, and *c* is the coefficient of *l* in δ.

**See also:**

**q_project_on_basis()**

**EXAMPLES:**

```python
sage: K = QQ['q'].fraction_field()
sage: q = K.gen()
sage: KL = RootSystem(['A',2,1]).ambient_space().algebra(K)
```

(continues on next page)
sage: L = KL.basis().keys()
sage: e = L.basis()
sage: KL.q_project_on_basis(4*e[1] + 3*e[2] + e['deltacheck'] - 2*e['delta'], q)
1/q^2*B[(0, 4, 3)]

```python
>>> from sage.all import *
>>> K = QQ['q'].fraction_field()
>>> q = K.gen()
>>> KL = RootSystem(["A",Integer(2),Integer(1)]).ambient_space().algebra(K)
>>> L = KL.basis().keys()
>>> e = L.basis()
>>> KL.q_project_on_basis(Integer(4)*e[Integer(1)] + Integer(3)*e[Integer(2)]
  + e['deltacheck'] - Integer(2)*e['delta'], q)
1/q^2*B[(0, 4, 3)]
```

**some_elements()**

Return some elements of the algebra self.

**EXAMPLES:**

```python
sage: A = RootSystem(["A",2,1]).ambient_space().algebra(QQ)
sage: A.some_elements()

sage: A.some_elements()  # needs sage.graphs
 B[-e[0] + e[2] + e['delta']],
 B[e[1] - e[2]],
 B[e['deltacheck']]],
 B[e[0] + e['deltacheck']],
 B[e[0] + e[1] + e['deltacheck']]]
```

```python
sage: A = RootSystem(["B",2]).weight_space().algebra(QQ)
sage: A.some_elements()

sage: A.some_elements()  # needs sage.graphs
 B[Lambda[1]], B[Lambda[2]]]
```

```python
>>> from sage.all import *
>>> A = RootSystem(["A",Integer(2),Integer(1)]).ambient_space().algebra(QQ)
>>> A.some_elements()

>>> A.some_elements()  # needs sage.graphs
 B[-e[0] + e[2] + e['delta']],
 B[Lambda[1]],
 B[Lambda[2]]]
```

(continues on next page)
Combinatorics, Release 10.4

(B[e[0] - e[1]],
B[e[1] - e[2]],
B[e['deltacheck']],
B[e[0] + e['deltacheck']],
B[e[0] + e[1] + e['deltacheck']])

```python
>>> A = RootSystem(["B",Integer(2)]).weight_space().algebra(QQ)
>>> A.some_elements()
```

```python
#needs sage.graphs
B[-Lambda[1] + 2*Lambda[2]],
B[2*Lambda[2]],
```

**twisted_demazure_lusztig_operator_on_basis** *(weight, i, q1, q2, convention='antidominant')*

Return the twisted Demazure-Lusztig operator acting on the basis.

**INPUT:**
- `weight` – an element $\lambda$ of the weight lattice
- `i` – an element of the index set
- `q1, q2` – two elements of the ground ring
- `convention` – "antidominant", "bar", or "dominant" (default: "antidominant")

**See also:**
- `twisted_demazure_lusztig_operators()`

**EXAMPLES:**

```python
sage: L = RootSystem(["A",3,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: KL = L.algebra(K)
sage: Lambda = L.classical().fundamental_weights()
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1] + 2*Lambda[2], 1, q1, q2, convention="dominant")
(-q2)*B[(2, 3, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1] + 2*Lambda[2], 2, q1, q2, convention="dominant")
(-q1-q2)*B[(3, 1, 1, 0)] + (-q2)*B[(3, 0, 2, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1] + 2*Lambda[2], 3, q1, q2, convention="dominant")
q1*B[(3, 2, 0, 0)]
sage: KL.twisted_demazure_lusztig_operator_on_basis(Lambda[1]+2*Lambda[2], 0, q1, q2, convention="dominant")
((q1*q2+q2^2)/q1)*B[(1, 2, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(1, 2, 2, 0)] +
q2^2/q1*B[(1, 2, 0, 2)] + ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 1, 1)]
+ ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 1, 0, 2)]
+ ((q1^2+2*q1*q2+q2^2)/q1)*B[(2, 2, 1, 0)]
+ ((q1*q2+q2^2)/q1)*B[(2, 2, 0, 1)]
```

5.1. Comprehensive Module List 4011
```python
>>> from sage.all import *

>>> L = RootSystem(["A",3,1]).ambient_space()
>>> e = L.basis()
>>> K = QQ['q1,q2'].fraction_field()
>>> q1, q2 = K.gens()
>>> KL = L.algebra(K)
>>> Lambda = L.classical().fundamental_weights()

>>> KL.twisted_demazure_lusztig_operator_on_basis(...
  ... Lambda[Integer(1)] + Integer(2)*Lambda[Integer(2)], Integer(1),...
  ... q1, q2, convention="dominant")
(-q2)*B[(2, 3, 0, 0)]

>>> KL.twisted_demazure_lusztig_operator_on_basis(...
  ... Lambda[Integer(1)] + Integer(2)*Lambda[Integer(2)], Integer(2),...
  ... q1, q2, convention="dominant")
(-q1-q2)*B[(3, 1, 1, 0)] + (-q2)*B[(3, 0, 2, 0)]

>>> KL.twisted_demazure_lusztig_operator_on_basis(...
  ... Lambda[Integer(1)] + Integer(2)*Lambda[Integer(2)], Integer(3),...
  ... q1, q2, convention="dominant")
q1*B[(3, 2, 0, 0)]

>>> KL.twisted_demazure_lusztig_operator_on_basis(...
  ... Lambda[Integer(1)] + Integer(2)*Lambda[Integer(2)], Integer(0), q1,...
  ... q2, convention="dominant")
((q1*q2+q2^2)/q1)*B[(1, 2, 1, 1)] + ((q1*q2+q2^2)/q1)*B[(1, 2, 2, 0)]
+ q2^2/ql*B[(1, 2, 0, 2)] + ((q1^2+2*q1*q2+q2^2)/ql)*B[(2, 1, 1, 1)]
+ ((q1^2+2*q1*q2+q2^2)/ql)*B[(2, 1, 2, 0)]
+ ((q1^2+2*q1*q2+q2^2)/ql)*B[(2, 2, 1, 0)]
+ ((q1*q2+q2^2)/ql)*B[(2, 1, 0, 2)]
+ ((q1*q2+q2^2)/ql)*B[(2, 2, 0, 1)]
```

**twisted_demazure_lusztig_operators** *(q1, q2, convention='antidominant')*

Return the twisted Demazure-Lusztig operators acting on self.

**INPUT:**

- q1, q2 – two elements of the ground ring
- convention – "antidominant", "bar", or "dominant" (default: "antidominant")

**Warning:**

- the code is currently only tested for q1q2 = -1
- only the "dominant" convention is functional for i = 0

For $T_1, \ldots, T_n$, these operators are the usual Demazure-Lusztig operators. On the other hand, the operator $T_0$ is twisted:
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> L = RootSystem(["A", Integer(3), Integer(1)]).ambient_space()
>>> e = L.basis()
>>> K = QQ['q1,q2'].fraction_field()
>>> q1, q2 = K.gens()
>>> KL = L.algebra(K)
>>> T = KL.twisted_demazure_lusztig_operators(q1, q2, convention=\"dominant\")
>>> T._test_relations()
```

Todo: Choose a good set of Cartan Type to run on. Rank >4 is too big. But $C_1$ and $B_1$ are boring.

We now check systematically that those operators satisfy the relations of the Iwahori-Hecke algebra:

```python
sage: K = QQ['q1,q2'].fraction_field()
sage: q1, q2 = K.gens()
sage: for cartan_type in CartanType.samples(affine=True,...
crystallographic=True): # long time 12s
    ....: if cartan_type.rank() > 4: continue
    ....: if cartan_type.type() == 'BC': continue
    ....: KL = RootSystem(cartan_type).weight_lattice().algebra(K)
    ....: T = KL.twisted_demazure_lusztig_operators(q1, q2, convention=\"dominant\")
    ....: T._test_relations()
```

Todo: Investigate why $T_0^\vee$ currently does not satisfy the quadratic relation in type $BC$. This should hopefully be fixed when $T_0^\vee$ will have a more uniform implementation:

```python
sage: cartan_type = CartanType([\"BC\",1,2])
sage: KL = RootSystem(cartan_type).weight_lattice().algebra(K)
sage: T = KL.twisted_demazure_lusztig_operators(q1,q2, convention=\"dominant\")
sage: T._test_relations() # needs sage.graphs
Traceback (most recent call last):
  ... tester.assertTrue(Ti(Ti(x,i,-q2),i,-q1).is_zero()) ...
AssertionError: False is not true
```

```python
>>> from sage.all import *

>>> cartan_type = CartanType([\"BC\",Integer(1),Integer(2)])
>>> KL = RootSystem(cartan_type).weight_lattice().algebra(K)
>>> T = KL.twisted_demazure_lusztig_operators(q1,q2, convention=\"dominant\")
```

(continues on next page)
Comparison with T0:

```
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: e = L.basis()
sage: K = QQ["t,q'\].fraction_field()
sage: t,q = K.gens()
sage: q1 = t
sage: q2 = -1
sage: KL = L.algebra(K)
sage: L0 = L.classical()
sage: T = KL.demazure_lusztig_operators(q1,q2, convention="dominant")
sage: def T0(*l0): return KL.q_project(T[0].on_basis()(L.embed_at_level(L0(l0), 1)), q)
sage: T0_check_on_basis = KL.T0_check_on_basis(q1, q2,
                                          # needs sage.graphs
                                          ....:  convention="dominant")
sage: def T0c(*l0): return T0_check_on_basis(L0(l0))
sage: T0(Integer(0),Integer(0),Integer(1))
    # not double checked # needs sage.graphs
    ((-t+1)/q)*B[(1, 0, 0)] + 1/q^2*B[(2, 0, -1)]
```

```python
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(2),Integer(1)]).ambient_space()
>>> e = L.basis()
>>> K = QQ["t,q'\].fraction_field()
>>> t,q = K.gens()
>>> q1 = t
>>> q2 = -Integer(1)
>>> KL = L.algebra(K)
>>> L0 = L.classical()
>>> T = KL.demazure_lusztig_operators(q1,q2, convention="dominant")
>>> def T0(*l0): return KL.q_project(T[Integer(0)].on_basis()(L.embed_at_level(L0(l0), Integer(1))), q)
>>> T0_check_on_basis = KL.T0_check_on_basis(q1, q2,
                                          # needs sage.graphs
                                          ....:  convention="dominant")
>>> def T0c(*l0): return T0_check_on_basis(L0(l0))
>>> T0(Integer(0),Integer(0),Integer(1))
    # not double checked # needs sage.graphs
    ((-t+1)/q)*B[(1, 0, 0)] + 1/q^2*B[(2, 0, -1)]
```
5.1.239 Root lattice realizations

```python
class sage.combinat.root_system.root_lattice_realizations.RootLatticeRealizations(base, name=None):
    Bases: Category_over_base_ring
    The category of root lattice realizations over a given base ring
    A root lattice realization \( L \) over a base ring \( R \) is a free module (or vector space if \( R \) is a field) endowed with an embedding of the root lattice of some root system.
    Typical root lattice realizations over \( \mathbb{Z} \) include the root lattice, weight lattice, and ambient lattice. Typical root lattice realizations over \( \mathbb{Q} \) include the root space, weight space, and ambient space.
    To describe the embedding, a root lattice realization must implement a method `simple_root()` returning for each \( i \) in the index set the image of the simple root \( \alpha_i \) under the embedding.
    A root lattice realization must further implement a method on elements `scalar()`, computing the scalar product with elements of the coroot lattice or coroot space.
    Using those, this category provides tools for reflections, roots, the Weyl group and its action, …
    See also:
    • RootSystem
    • WeightLatticeRealizations
    • RootSpace
    • WeightSpace
    • AmbientSpace
    EXAMPLES:
    Here, we consider the root system of type \( A_7 \), and embed the root lattice element \( x = \alpha_2 + 2\alpha_6 \) in several root lattice realizations:
```

```
sage: R = RootSystem(["A", 7])
sage: alpha = R.root_lattice().simple_roots()
sage: L = R.root_space()
sage: L(x)
sage: L = R.weight_lattice()
sage: L(x)
# needs sage.graphs
sage: L = R.ambient_space()
sage: L(x)
(0, 1, -1, 0, 2, -2, 0, 0)
```
We embed the root space element $x = \alpha_2 + 1/2\alpha_6$ in several root lattice realizations:

```python
sage: alpha = R.root_space().simple_roots()
sage: L = R.weight_space()
sage: L(x)
#→ needs sage.graphs
```

Of course, one can’t embed the root space in the weight lattice:

```python
sage: L = R.weight_lattice()
sage: L(x)
Traceback (most recent call last):
  ...
TypeError: do not know how to make x (= alpha[2] + 1/2*alpha[5]) an element of self (=Weight lattice of the Root system of type ['A', 7])
```
If $K_1$ is a subring of $K_2$, then one could in theory have an embedding from the root space over $K_1$ to any root lattice realization over $K_2$; this is not implemented:

```python
sage: K1 = QQ
sage: K2 = QQ['q']
sage: L = R.weight_space(K2)

sage: alpha = R.root_space(K2).simple_roots()

sage: L(alpha[1])  # needs sage.graphs

sage: alpha = R.root_space(K1).simple_roots()

sage: L(alpha[1])
Traceback (most recent call last):
  ... TypeError: do not know how to make x (= alpha[1]) an element of self (=Weight space over the Univariate Polynomial Ring in q over Rational Field of the Root system of type ['A', 7])
```

By a slight abuse, the embedding of the root lattice is not actually required to be faithful. Typically for an affine root system, the null root of the root lattice is killed in the non extended weight lattice:

```python
>>> from sage.all import *

>>> R = RootSystem(['A', 3, 1])

>>> delta = R.root_lattice().null_root()  # needs sage.graphs

>>> L = R.weight_lattice()

>>> L(delta)  # needs sage.graphs
0
```

```python
>>> from sage.all import *

>>> R = RootSystem(['A', Integer(3), Integer(1)])
```

(continues on next page)
>>> delta = R.root_lattice().null_root()  
→ needs sage.graphs
>>> L = R.weight_lattice()  
>>> L(delta)  
→ needs sage.graphs
0

Algebras
alias of Algebras

class ElementMethods

Bases: object

affine_orbit()

The orbit of self under the dot or affine action of the Weyl group.

EXAMPLES:

```python
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())  # the output order is not specified  
needs sage.graphs
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2),  
(2, 1, 0), (0, -1, 4), (0, 3, 0)]

sage: L = RootSystem(['B', 2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit())  # the output order is not specified  
needs sage.graphs
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],  
Lambda[1], Lambda[1] - 6*Lambda[2],  
```

We compare the dot action orbit to the regular orbit:

```python
>>> from sage.all import *  
>>> L = RootSystem(['A', Integer(2)]).ambient_lattice()
>>> sorted(L.rho().dot_orbit())  # the output order is not specified  
needs sage.graphs
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2),  
(2, 1, 0), (0, -1, 4), (0, 3, 0)]

>>> L = RootSystem(['B', Integer(2)]).weight_lattice()
>>> sorted(L.fundamental_weights()[Integer(1)].dot_orbit())  # the output order is not specified  
needs sage.graphs
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],  
Lambda[1], Lambda[1] - 6*Lambda[2],  
```

Wecomparethedotactionorbittotheregularorbit:

```python
sage: # needs sage.graphs
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())  # the output order is not specified  
24
sage: len((-L.rho()).dot_orbit())  # the output order is not specified  
1
sage: La = L.fundamental_weights()
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho() + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho() + La[2]).dot_orbit())
6
```

```python
>>> from sage.all import *
# needs sage.graphs
>>> L = RootSystem(['A', Integer(3)]).weight_lattice()
>>> len(L.rho().dot_orbit())
24
>>> len((-L.rho()).dot_orbit())
1
>>> La = L.fundamental_weights()
>>> len(La[Integer(1)].dot_orbit())
24
>>> len(La[Integer(1)].orbit())
4
>>> len((-L.rho() + La[Integer(1)]).dot_orbit())
4
>>> len(La[Integer(2)].dot_orbit())
24
>>> len(La[Integer(2)].orbit())
6
>>> len((-L.rho() + La[Integer(2)]).dot_orbit())
6
```

**associated_coroot()**

Return the coroot associated to this root.

EXAMPLES:

```
sage: alpha = RootSystem(['A', 3]).root_space().simple_roots()
sage: alpha[1].associated_coroot()  # needs sage.graphs
alphacheck[1]
```

**associated_reflection()**

Given a positive root `self`, return a reduced word for the reflection orthogonal to `self`. Since the answer is cached, it is a tuple instead of a list.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: C3_rl = RootSystem(['C',3]).root_lattice()  # needs sage.graphs
sage: C3_rl.simple_root(3).weyl_action([1,2]).associated_reflection()  # needs sage.graphs
(1, 2, 3, 2, 1)
sage: C3_rl.simple_root(2).associated_reflection()  # needs sage.graphs
(2,)
```

```python
>>> from sage.all import *
>>> C3_rl = RootSystem(['C',Integer(3)]).root_lattice()  # needs sage.graphs
>>> C3_rl.simple_root(Integer(3)).weyl_action([Integer(1),Integer(2)]).associated_reflection()  # needs sage.graphs
(1, 2, 3, 2, 1)
>>> C3_rl.simple_root(Integer(2)).associated_reflection()  # needs sage.graphs
(2,)
```

**descents** *(index_set=None, positive=False)*

Return the descents of pt

```python
sage: space=RootSystem(['A',5]).weight_space()
sage: alpha = space.simple_roots()  # needs sage.graphs
[3, 5]
```

```python
>>> from sage.all import *
>>> space=RootSystem(['A',Integer(5)]).weight_space()
>>> alpha = space.simple_roots()  # needs sage.graphs
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).descents()  # needs sage.graphs
[3, 5]
```

**dot_action** *(w, inverse=False)*

Act on self by w using the dot or affine action.

Let $w$ be an element of the Weyl group. The dot action or affine action is given by:

$$w \cdot \lambda = w(\lambda + \rho) - \rho,$$

where $\rho$ is the sum of the fundamental weights.

**INPUT:**

- $w$ – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
- `inverse` – a boolean (default: `False`); whether to act by the inverse element

**EXAMPLES:**

```python
sage: P = RootSystem(['B',3]).weight_lattice()
sage: La = P.fundamental_weights()
```
Combinatorics, Release 10.4

(continued from previous page)

sage: mu.dot_action([1])  # needs sage.graphs
sage: mu.dot_action([3])  # needs sage.graphs
Lambda[1] + Lambda[3]
sage: mu.dot_action([1,2,3])  # needs sage.graphs

>>> from sage.all import *

>>> P = RootSystem(['B',Integer(3)]).weight_lattice()

>>> La = P.fundamental_weights()

>>> mu = La[Integer(1)] + Integer(2)*La[Integer(2)]

>>> mu.dot_action([Integer(1)])  # needs sage.graphs

>>> mu.dot_action([Integer(3)])  # needs sage.graphs
Lambda[1] + Lambda[3]

>>> mu.dot_action([Integer(1),Integer(2),Integer(3)])  # needs sage.graphs

We check that the origin of this action is at \(-\rho\):

```sage
all((-P.rho()).dot_action([i]) == -P.rho()  # needs sage.graphs
     for i in P.index_set())
True
```

REFERENCES:
- Wikipedia article Affine_action

\textbf{dot_orbit()}

The orbit of \texttt{self} under the dot or affine action of the Weyl group.

EXAMPLES:

```sage
sage: L = RootSystem(['A', 2]).ambient_lattice()
sage: sorted(L.rho().dot_orbit())  # the output order is not specified # needs sage.graphs
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2), (2, 1, 0), (0, -1, 4), (0, 3, 0)]
```

```sage
sage: L = RootSystem(['B',2]).weight_lattice()
sage: sorted(L.fundamental_weights()[1].dot_orbit())  # the output order is not specified # needs sage.graphs
```

(continues on next page)
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],
Lambda[1], Lambda[1] - 6*Lambda[2],

```python
>>> from sage.all import *
>>> L = RootSystem(['A', Integer(2)]).ambient_lattice()
>>> sorted(L.rho().dot_orbit())
# the output order is not specified
# needs sage.graphs
[(-2, 1, 4), (-2, 3, 2), (2, -1, 2),
(2, 1, 0), (0, -1, 4), (0, 3, 0)]
```

We compare the dot action orbit to the regular orbit:

```python
sage: # needs sage.graphs
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: len(L.rho().dot_orbit())
24
sage: len((-L.rho()).dot_orbit())
1
sage: La = L.fundamental_weights()
sage: len(La[1].dot_orbit())
24
sage: len(La[1].orbit())
4
sage: len((-L.rho() + La[1]).dot_orbit())
4
sage: len(La[2].dot_orbit())
24
sage: len(La[2].orbit())
6
sage: len((-L.rho() + La[2]).dot_orbit())
6
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> L = RootSystem(['B',Integer(2)]).weight_lattice()
>>> sorted(L.fundamental_weights()[Integer(1)].dot_orbit())
# the output order is not specified
# needs sage.graphs
[-4*Lambda[1], -4*Lambda[1] + 4*Lambda[2],
Lambda[1], Lambda[1] - 6*Lambda[2],
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> L = RootSystem(['A', Integer(3)]).weight_lattice()
>>> len(L.rho().dot_orbit())
24
>>> len((-L.rho()).dot_orbit())
1
>>> La = L.fundamental_weights()
>>> len(La[Integer(1)].dot_orbit())
24
>>> len(La[Integer(1)].orbit())
4
>>> len((-L.rho() + La[Integer(1)]).dot_orbit())
4
```
```python
>>> len(La[Integer(2)].dot_orbit())
24
>>> len(La[Integer(2)].orbit())
6
>>> len((-L.rho() + La[Integer(2)]).dot_orbit())
6
```

**extraspecial_pair()**

Return the extraspecial pair of `self` under the ordering defined by `positive_roots_by_height()`.

The **extraspecial pair** of a positive root $\gamma$ with some total ordering $<$ of the root lattice that respects height is the pair of positive roots $(\alpha, \beta)$ such that $\gamma = \alpha + \beta$ and $\alpha$ is as small as possible.

**EXAMPLES:**

```python
sage: Q = RootSystem(["G", 2]).root_lattice()
sage: Q.highest_root().extraspecial_pair()  # needs sage.graphs
(alpha[2], 3*alpha[1] + alpha[2])
```

```python
>>> from sage.all import *

```

```python
>>> Q = RootSystem(["G", Integer(2)]).root_lattice()
>>> Q.highest_root().extraspecial_pair()  # needs sage.graphs
(alpha[2], 3*alpha[1] + alpha[2])
```

**first_descent** `(index_set=None, positive=False)`

Return the first descent of `pt`.

One can use the `index_set` option to restrict to the parabolic subgroup indexed by `index_set`.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: space = RootSystem(["A",5]).weight_space()
sage: alpha = space.simple_roots()
3
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5])
5
sage: (alpha[1]+alpha[2]+alpha[4]).first_descent([1,2,5,3,4])
5
```

```python
>>> from sage.all import *

```

```python
>>> space = RootSystem(["A",Integer(5)]).weight_space()
>>> alpha = space.simple_roots()
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).first_descent()
3
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).first_descent([[Integer(1),Integer(2),Integer(5)]]
5
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).first_descent([[Integer(1),Integer(2),Integer(5),Integer(3),Integer(4)]]
5
```

5.1. Comprehensive Module List
greater()

Return the elements in the orbit of self which are greater than self in the weak order.

EXAMPLES:

```
sage: L = RootSystem(['A', 3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].greater()
[(0, 0, 1, 0), (0, 0, 0, 1)]
sage: len(L.rho().greater())
24
sage: len((-L.rho()).greater())
1
sage: sorted([len(x.greater()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, ...
  → 24]
```

has_descent(i, positive=False)

Test if self has a descent at position i, that is, if self is on the strict negative side of the i-th simple reflection hyperplane.

If positive is True, tests if it is on the strict positive side instead.

EXAMPLES:

```
sage: # needs sage.graphs
sage: space = RootSystem(['A', 5]).weight_space()
sage: alpha = RootSystem(['A', 5]).weight_space().simple_roots()
sage: [alpha[i].has_descent(1) for i in space.index_set()]
[False, True, False, False, False]
sage: [(-alpha[i]).has_descent(1) for i in space.index_set()]
[True, False, False, False, False]
sage: [alpha[i].has_descent(1, True) for i in space.index_set()]
[True, False, False, False, False]
sage: [(-alpha[i]).has_descent(1, True) for i in space.index_set()]
[False, True, False, False, False]
True
False
sage: (alpha[1]+alpha[2]+alpha[4]).has_descent(1, True)
True
```

(continues on next page)
```python
>>> space = RootSystem(['A', Integer(5)]).weight_space()
>>> alpha = RootSystem(['A', Integer(5)]).weight_space().simple_roots()
>>> [alpha[i].has_descent(Integer(1)) for i in space.index_set()]
[False, True, False, False, False]
>>> [(-alpha[i]).has_descent(Integer(1)) for i in space.index_set()]
[True, False, False, False, False]
>>> [alpha[i].has_descent(Integer(1), True) for i in space.index_set()]
[True, False, False, False, False]
>>> [(-alpha[i]).has_descent(Integer(1), True) for i in space.index_set()]
[False, True, False, False, False]
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).has_descent(Integer(3))
True
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).has_descent(Integer(1))
False
>>> (alpha[Integer(1)]+alpha[Integer(2)]+alpha[Integer(4)]).has_descent(Integer(1), True)
True
```

**height ()**

Return the height of self.

The height of a root \( \alpha = \sum_i a_i \alpha_i \) is defined to be \( h(\alpha) := \sum_i a_i \).

**EXAMPLES:**

```python
sage: Q = RootSystem(['G', 2]).root_lattice()
sage: Q.highest_root().height()
# needs sage.graphs
5
```

```python
>>> from sage.all import *
>>> Q = RootSystem(['G', Integer(2)]).root_lattice()
>>> Q.highest_root().height()
# needs sage.graphs
5
```

**is_dominant (index_set=None, positive=True)**

Return whether self is dominant.

This is done with respect to the sub–root system indicated by the subset of Dynkin nodes `index_set`.

If `index_set` is `None`, then the entire Dynkin node set is used. If `positive` is `False`, then the dominance condition is replaced by antidominance.

**EXAMPLES:**

```python
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: [x.is_dominant(positive=False) for x in Lambda]
[False, False]
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
sage: (Lambda[1]-Lambda[2]).is_dominant([1])
True
sage: (Lambda[1]-Lambda[2]).is_dominant([2])
False
sage: [x.is_dominant() for x in L.roots()]
[False, True, False, False, False, False]
sage: [x.is_dominant(positive=False) for x in L.roots()]
[False, False, False, False, True, False]
```

is_dominant_weight()
Test whether self is a dominant element of the weight lattice.

EXAMPLES:

```
sage: L = RootSystem(['A',2]).ambient_lattice()
sage: Lambda = L.fundamental_weights()
sage: [x.is_dominant() for x in Lambda]
[True, True]
sage: (3*Lambda[1]+Lambda[2]).is_dominant()
True
sage: (Lambda[1]-Lambda[2]).is_dominant()
False
sage: (-Lambda[1]+Lambda[2]).is_dominant()
False
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(2)]).ambient_lattice()
>>> Lambda = L.fundamental_weights()
>>> [x.is_dominant() for x in Lambda]
[True, True]
>>> (Integer(3)*Lambda[Integer(1)]+Lambda[Integer(2)]).is_dominant()
True
>>> (Lambda[Integer(1)]-Lambda[Integer(2)]).is_dominant()
False
>>> (-Lambda[Integer(1)]+Lambda[Integer(2)]).is_dominant()
False
```
Tests that the scalar products with the coroots are all nonnegative integers. For example, if \( x \) is the sum of a dominant element of the weight lattice plus some other element orthogonal to all coroots, then the implementation correctly reports \( x \) to be a dominant weight:

```sage
sage: x = Lambda[1] + L([-1,-1,-1])
sage: x.is_dominant_weight()
True
```

```python
>>> from sage.all import *
>>> x = Lambda[Integer(1)] + L([-Integer(1),-Integer(1),-Integer(1)])
>>> x.is_dominant_weight()
True
```

**is_imaginary_root()**

Return True if self is an imaginary root.

A root \( \alpha \) is imaginary if it is not \( W \)-conjugate to a simple root where \( W \) is the corresponding Weyl group.

**EXAMPLES:**

```sage
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_imaginary_root()  # needs sage.graphs
False
sage: elt.is_imaginary_root()  # needs sage.graphs
True
```

```python
>>> from sage.all import *
>>> Q = RootSystem(['B',Integer(2),Integer(1)]).root_lattice()
>>> alpha = Q.simple_roots()
>>> alpha[Integer(0)].is_imaginary_root()  # needs sage.graphs
False
>>> elt = alpha[Integer(0)] + alpha[Integer(1)] +... Integer(2)*alpha[Integer(2)]
>>> elt.is_imaginary_root()  # needs sage.graphs
True
```

**is_long_root()**

Return True if self is a long (real) root.

**EXAMPLES:**

```sage
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_long_root()  # needs sage.graphs
True
sage: alpha[1].is_long_root()  # needs sage.graphs
True
sage: alpha[2].is_long_root()  # needs sage.graphs
True
```

(continues on next page)
is_parabolic_root (index_set)
Return whether root is in the parabolic subsystem with Dynkin nodes index_set.
This assumes that self is a root.

INPUT:
• index_set – the Dynkin node set of the parabolic subsystem.

Todo: This implementation is only valid in the root or weight lattice

EXAMPLES:
sage: alpha = RootSystem(['A', 3]).root_lattice().from_vector(vector([1, 1, 0]))
sage: alpha.is_parabolic_root([1, 3])
False
sage: alpha.is_parabolic_root([1, 2])
True
sage: alpha.is_parabolic_root([2])
False

is_real_root()
Return True if self is a real root.
A root \(\alpha\) is real if it is \(W\)-conjugate to a simple root where \(W\) is the corresponding Weyl group.

EXAMPLES:
sage: Q = RootSystem(['B', 2, 1]).root_lattice()
sage: alpha = Q.simple_roots()
```python
 sage: alpha[0].is_real_root()  # needs sage.graphs
 True
 sage: elt.is_real_root()  # needs sage.graphs
 False
```

```python
>>> from sage.all import *
>>> Q = RootSystem(["B",Integer(2),Integer(1)]).root_lattice()
>>> alpha = Q.simple_roots()
>>> alpha[Integer(0)].is_real_root()  # needs sage.graphs
 True
>>> elt = alpha[Integer(0)] + alpha[Integer(1)] + Integer(2)*alpha[Integer(2)]
>>> elt.is_real_root()  # needs sage.graphs
 False
```

**is_short_root()**

Return True if self is a short (real) root.

Returns False unless the parent is an irreducible root system of finite type having two root lengths and self is of the shorter length. There is no check of whether self is actually a root.

**EXAMPLES:**

```python
 sage: # needs sage.graphs
 sage: Q = RootSystem(["C",2]).root_lattice()
 sage: al = Q.simple_root(1).weyl_action([1,2]); al
 sage: al.is_short_root()
 True
 sage: bt = Q.simple_root(2).weyl_action([2,1,2]); bt
 sage: bt.is_short_root()
 False
 sage: RootSystem(["A",2]).root_lattice().simple_root(1).is_short_root()
 False
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> Q = RootSystem(["C",Integer(2)]).root_lattice()
>>> al = Q.simple_root(Integer(1)).weyl_action([Integer(1),Integer(2)]);
 al
>>> al.is_short_root()
 True
>>> bt = Q.simple_root(Integer(2)).weyl_action([Integer(2),Integer(1),
 Integer(2)]); bt
>>> bt.is_short_root()
 False
>>> RootSystem(["A",Integer(2)]).root_lattice().simple_root(Integer(1)).
 is_short_root()
 False
```
An example in affine type:

```python
sage: # needs sage.graphs
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[0].is_short_root()
False
sage: alpha[1].is_short_root()
False
sage: alpha[2].is_short_root()
True
```

```python
>>> from sage.all import *

```

```python
>>> Q = RootSystem(['B',Integer(2),Integer(1)]).root_lattice()

```

```python
>>> alpha[Integer(0)].is_short_root()
False
>>> alpha[Integer(1)].is_short_root()
False
>>> alpha[Integer(2)].is_short_root()
True
```

level()

EXAMPLES:

```python
sage: L = RootSystem(['A',2,1]).weight_lattice()
sage: L.rho().level() #˓→needs sage.graphs
3
```

```python
>>> from sage.all import *

```

```python
>>> L = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice()

```

```python
>>> L.rho().level() #˓→needs sage.graphs
3
```

norm_squared()

Return the norm squared of self with respect to the symmetric form.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].norm_squared()
4
sage: alpha[2].norm_squared()
2
sage: elt.norm_squared()
50
sage: elt.norm_squared()
0
```

```python
sage: Q = RootSystem(CartanType(['A',4,2]).dual()).root_lattice()

```

(continues on next page)
orbit()

The orbit of self under the action of the Weyl group.

EXAMPLES:

\( \rho \) is a regular element whose orbit is in bijection with the Weyl group. In particular, it has 6 elements for the symmetric group \( S_3 \):

\[ \text{sage: } L = \text{RootSystem}("A", 2).ambient_lattice() \]
\[ \text{sage: } \text{sorted}(L.\text{rho()}.\text{orbit()}) \]
(2, 0, 1), (0, 1, 2), (0, 2, 1)]

sage: L = RootSystem("A", 3).weight_lattice()

sage: len(L.rho().orbit())
24

sage: len(L.fundamental_weights()[1].orbit())
4

sage: len(L.fundamental_weights()[2].orbit())
6

>> from sage.all import *

>>> L = RootSystem("A", Integer(2)).ambient_lattice()

>>> sorted(L.rho().orbit())
# the output order is not specified
[(1, 2, 0), (1, 0, 2), (2, 1, 0),
 (2, 0, 1), (0, 1, 2), (0, 2, 1)]

>>> L = RootSystem("A", Integer(3)).weight_lattice()

>>> len(L.rho().orbit())
24

>>> len(L.fundamental_weights()[Integer(1)].orbit())  # needs sage.graphs
4

>>> len(L.fundamental_weights()[Integer(2)].orbit())  # needs sage.graphs
6

\textbf{pred}(\texttt{index\_set=None})

Return the immediate predecessors of \texttt{self} for the weak order.

\textbf{INPUT:}

• \texttt{index\_set} – a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: None for all of them)

If \texttt{index\_set} is specified, the successors for the corresponding parabolic subsystem are returned.

\textbf{EXAMPLES:}

sage: L = RootSystem(['A',3]).weight_lattice()

sage: Lambda = L.fundamental_weights()

sage: Lambda[1].pred()
[]

sage: L.rho().pred()
[]

sage: (-L.rho()).pred()  # needs sage.graphs

sage: (-L.rho()).pred(index\_set=[1])  # needs sage.graphs
```
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(3)]).weight_lattice()
>>> Lambda = L.fundamental_weights()
>>> Lambda[Integer(1)].pred()
[]
>>> L.rho().pred()
[]
>>> (-L.rho()).pred()  
needs sage.graphs
>>> (-L.rho()).pred(index_set=[Integer(1)])  
needs sage.graphs
```

**reduced_word**(index_set=None, positive=True)

Return a reduced word for the inverse of the shortest Weyl group element that sends the vector `self` into the dominant chamber.

With the `index_set` optional parameter, this is done with respect to the corresponding parabolic subgroup.

If `positive` is `False`, use the antidominant chamber instead.

**EXAMPLES:**

```
sage: space = RootSystem(['A',5]).weight_space()  
sage: alpha = RootSystem(['A',5]).weight_space().simple_roots()  
needs sage.graphs
sage: alpha[1].reduced_word()  
needs sage.graphs
[2, 3, 4, 5]
```

```
>>> from sage.all import *
>>> space = RootSystem(['A',Integer(5)]).weight_space()  
>>> alpha = RootSystem(['A',Integer(5)]).weight_space().simple_roots()  
needs sage.graphs
>>> alpha[Integer(1)].reduced_word()  
needs sage.graphs
[2, 3, 4, 5]
```

**reflection**(root, use_coroot=False)

Reflect `self` across the hyperplane orthogonal to `root`.

If `use_coroot` is `True`, `root` is interpreted as a coroot.

**EXAMPLES:**

```
sage: R = RootSystem(['C',4])
sage: weight_lattice = R.weight_lattice()
sage: mu = weight_lattice.from_vector(vector([0,0,1,2]))
```

(continues on next page)
Implement the natural pairing with the coroot lattice.

INPUT:

• self – an element of a root lattice realization
• lambdacheck – an element of the coroot lattice or coroot space

OUTPUT: the scalar product of self and lambdacheck

EXAMPLES:

\[ a_i \cdot a_j = \begin{cases} 2 & \text{if } i = j \\ -1 & \text{if } i \neq j \end{cases} \]
```python
>>> from sage.all import *
>>> L = RootSystem(['A', Integer(4)]).root_lattice()
>>> alpha = L.simple_roots()
>>> alphacheck = L.simple_coroots()
>>> alpha[Integer(1)].scalar(alphacheck[Integer(1)])
˓→ # needs sage.graphs
2
>>> alpha[Integer(1)].scalar(alphacheck[Integer(2)])
˓→ # needs sage.graphs
-1
>>> matrix([[ alpha[i].scalar(alphacheck[j]) # ...
˓→ needs sage.graphs
... for i in L.index_set() ]
... for j in L.index_set() ])
[ 2 -1 0 0]
[-1 2 -1 0]
[ 0 -1 2 -1]
[ 0 0 -1 2]
```

**simple_reflection**(i)

Return the image of self by the i-th simple reflection.

**EXAMPLES:**

```python
sage: alpha = RootSystem(['A', 3]).root_lattice().alpha()
sage: alpha[1].simple_reflection(2) #...
˓→ needs sage.graphs

sage: Q = RootSystem(['A', 3, 1]).weight_lattice(extended=True)
sage: Lambda = Q.fundamental_weights() #...
˓→ needs sage.graphs
˓→ needs sage.graphs
-Lambda[0] + Lambda[1] + Lambda[3]
```

**simple_reflections()**

The images of self by all the simple reflections

**EXAMPLES:**
Combinatorics, Release 10.4

```python
sage: alpha = RootSystem(['A', 3]).root_lattice().alpha()
sage: alpha[1].simple_reflections()  # needs sage.graphs
[-alpha[1], alpha[1] + alpha[2], alpha[1]]
```

```python
>>> from sage.all import *

```

```python
>>>

```

`smaller()`

Return the elements in the orbit of `self` which are smaller than `self` in the weak order.

**EXAMPLES:**

```python
sage: L = RootSystem(['A', 3]).ambient_lattice()
sage: e = L.basis()
sage: e[2].smaller()
[(0, 0, 1, 0), (0, 1, 0, 0), (1, 0, 0, 0)]
sage: len(L.rho().smaller())
1
sage: len((-L.rho()).smaller())
24
sage: sorted([len(x.smaller()) for x in L.rho().orbit()])
[1, 2, 2, 2, 3, 3, 3, 3, 4, 4, 4, 5, 5, 6, 6, 6, 8, 8, 8, 8, 12, 12, 12, 24]

```

```python
>>> from sage.all import *

```

```python
>>> L = RootSystem(['A', Integer(3)]).ambient_lattice()

```

```python
>>>

```

` succ(index_set=None)`

Return the immediate successors of `self` for the weak order.

**INPUT:**

- `index_set` – a subset (as a list or iterable) of the nodes of the Dynkin diagram; (default: None for all of them)

If `index_set` is specified, the successors for the corresponding parabolic subsystem are returned.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: L = RootSystem(['A', 3]).weight_lattice()
sage: Lambda = L.fundamental_weights()
sage: Lambda[1].succ()
[-Lambda[1] + Lambda[2]]
sage: L.rho().succ()  # (continues on next page)
```

(continues on next page)
\[-\Lambda[1] + 2\Lambda[2] + \Lambda[3],
2\Lambda[1] - \Lambda[2] + 2\Lambda[3],
\Lambda[1] + 2\Lambda[2] - \Lambda[3]\]

```
sage: (-L.rho()).succ()
[]
```

```
sage: L.rho().succ(index_set=[1])
[-\Lambda[1] + 2\Lambda[2] + \Lambda[3]]
```

```
sage: L.rho().succ(index_set=[2])
```

```
>>> from sage.all import *
```

```
# needs sage.graphs
```

```
>>> L = RootSystem(['A',Integer(3)]).weight_lattice()
```

```
>>> Lambda = L.fundamental_weights()
```

```
>>> Lambda[Integer(1)].succ()
[-\Lambda[1] + \Lambda[2]]
```

```
>>> L.rho().succ()
[-\Lambda[1] + 2\Lambda[2] + \Lambda[3],
2\Lambda[1] - \Lambda[2] + 2\Lambda[3],
\Lambda[1] + 2\Lambda[2] - \Lambda[3]]
```

```
>>> (-L.rho()).succ()
[]
```

```
>>> L.rho().succ(index_set=[Integer(1)])
[-\Lambda[1] + 2\Lambda[2] + \Lambda[3]]
```

```
>>> L.rho().succ(index_set=[Integer(2)])
```

\textbf{symmetric\_form}(\textit{alpha})

Return the symmetric form of self with alpha.

Consider the simple roots $\alpha_i$ and let $(b_{ij})_{ij}$ denote the symmetrized Cartan matrix $(a_{ij})_{ij}$, we have

$$(\alpha_i | \alpha_j) = b_{ij}$$

and extended bilinearly. See Chapter 6 in Kac, Infinite Dimensional Lie Algebras for more details.

\textbf{EXAMPLES}:

```
sage: # needs sage.graphs
sage: Q = RootSystem(['B',2,1]).root_lattice()
sage: alpha = Q.simple_roots()
sage: alpha[1].symmetric_form(alpha[0])
0
sage: alpha[1].symmetric_form(alpha[1])
4
sage: elt.symmetric_form(alpha[1])
-14
sage: elt.symmetric_form(alpha[0]+2*alpha[2])
14
```

```
sage: Qc = RootSystem(['A',4,2]).coroot_lattice()
sage: alpha = Q.simple_roots()
sage: alphac = Qc.simple_roots()
```

(continues on next page)
from sage.all import *

# needs sage.graphs
Q = RootSystem(['B', 4]).root_lattice()
alpha = Q.simple_roots()
alpha[1].symmetric_form(alpha[0])

elt.symmetric_form(alpha[1])

eltc.symmetric_form(alphac[1])

to_ambient()

Map self to the ambient space.

EXAMPLES:

sage: B4_rs = CartanType(['B', 4]).root_system()
sage: alpha = B4_rs.root_lattice().an_element(); alpha
sage: alpha.to_ambient()
(2, 0, 1, -3)
sage: mu = B4_rs.weight_lattice().an_element(); mu
sage: mu.to_ambient()
(7, 5, 3, 0)
sage: v = B4_rs.ambient_space().an_element(); v
(2, 2, 3, 0)
sage: v.to_ambient()
(2, 2, 3, 0)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: alphavee = B4_rs.coroot_lattice().an_element(); alphavee
sage: alphavee.to_ambient()
(2, 0, 1, -3)
```

```python
>>> from sage.all import *
>>> B4_rs = CartanType(['B',Integer(4)]).root_system()
>>> alpha = B4_rs.root_lattice().an_element(); alpha
>>> alpha.to_ambient()
(2, 0, 1, -3)
>>> mu = B4_rs.weight_lattice().an_element(); mu
>>> mu.to_ambient()
(7, 5, 3, 0)
>>> v = B4_rs.ambient_space().an_element(); v
(2, 2, 3, 0)
>>> v.to_ambient()
(2, 2, 3, 0)
>>> alphavee = B4_rs.coroot_lattice().an_element(); alphavee
>>> alphavee.to_ambient()
(2, 0, 1, -3)
```

to_classical()

Map self to the classical lattice/space.

Only makes sense for affine type.

EXAMPLES:

```python
sage: R = CartanType(['A',3,1]).root_system()
sage: alpha = R.root_lattice().an_element(); alpha
sage: alb = alpha.to_classical(); alb
# needs sage.graphs
sage: alb.parent()
# needs sage.graphs
Root lattice of the Root system of type ['A', 3]
sage: v = R.ambient_space().an_element(); v
2*e[0] + 2*e[1] + 3*e[2]
sage: v.to_classical()
# needs sage.graphs
(2, 2, 3, 0)
```

```python
>>> from sage.all import *
>>> R = CartanType(['A',Integer(3),Integer(1)]).root_system()
>>> alpha = R.root_lattice().an_element(); alpha
>>> alb = alpha.to_classical(); alb
# needs sage.graphs
>>> alb.parent()
# needs sage.graphs
Root lattice of the Root system of type ['A', 3]
```
to\_dominant\_chamber \(\text{(index\_set=None, positive=True, reduced\_word=False)}\)

Return the unique dominant element in the Weyl group orbit of the vector \(\text{self}\).

If \(\text{positive}\) is \(\text{False}\), returns the antidominant orbit element.

With the \(\text{index\_set}\) optional parameter, this is done with respect to the corresponding parabolic subgroup.

If \(\text{reduced\_word}\) is \(\text{True}\), returns the 2-tuple \((\text{weight}, \text{direction})\) where \(\text{weight}\) is the (anti)dominant orbit element and \(\text{direction}\) is a reduced word for the Weyl group element sending \(\text{weight}\) to \(\text{self}\).

**Warning:** In infinite type, an orbit may not contain a dominant element. In this case the function may go into an infinite loop.

For affine root systems, errors are generated if the orbit does not contain the requested kind of representative. If the input vector is of positive (resp. negative) level, then there is a dominant (resp. antidominant) element in its orbit but not an antidominant (resp. dominant) one. If the vector is of level zero, then there are neither dominant nor antidominant orbit representatives, except for multiples of the null root, which are themselves both dominant and antidominant orbit representatives.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: space = RootSystem(['A',5]).weight_space()
sage: alpha = RootSystem(['A',5]).weight_space().simple_roots()

sage: alpha[1].to_dominant_chamber()
\Lambda[1] + \Lambda[5]

sage: alpha[1].to_dominant_chamber([1,2])

sage: Wl = RootSystem(['A',2,1]).weight_lattice(extended=True)

sage: mu = Wl.from_vector(vector([1,-3,0]))

sage: mu.to_dominant_chamber(positive=False, reduced_word=True)
(-\Lambda[1] - \Lambda[2] - \delta, [0, 2])

sage: # needs sage.graphs

sage: R = RootSystem(['A',1,1])

sage: r1 = R.root_lattice()

sage: nu = r1.zero()

sage: nu.to_dominant_chamber()
0

sage: nu.to_dominant_chamber(positive=False)
0

sage: mu = r1.from_vector(vector([0,1]))

sage: mu.to_dominant_chamber()
Traceback (most recent call last):
...
ValueError: alpha[1] is not in the orbit of the fundamental chamber

sage: mu.to_dominant_chamber(positive=False)
```

(continues on next page)
Traceback (most recent call last):
... 
ValueError: alpha[1] is not in the orbit of the negative of the
  fundamental chamber

>>> from sage.all import *
>>> # needs sage.graphs
>>> space = RootSystem(['A',Integer(5)]).weight_space()
>>> alpha = RootSystem(['A',Integer(5)]).weight_space().simple_roots()
>>> alpha[Integer(1)].to_dominant_chamber()
>>> alpha[Integer(1)].to_dominant_chamber([Integer(1),Integer(2)])
>>> wl = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True)
>>> mu = wl.from_vector(vector([Integer(1),-Integer(3),Integer(0)]))
>>> mu.to_dominant_chamber(positive=False, reduced_word=True)
(-Lambda[1] - Lambda[2] - delta, [0, 2])

>>> # needs sage.graphs
>>> R = RootSystem(['A',Integer(1),Integer(1)])
>>> rl = R.root_lattice()
>>> nu = rl.zero()
>>> nu.to_dominant_chamber()
0
>>> nu.to_dominant_chamber(positive=False)
0
>>> mu = rl.from_vector(vector([Integer(0),Integer(1)]))
>>> mu.to_dominant_chamber()
Traceback (most recent call last):
... 
ValueError: alpha[1] is not in the orbit of the fundamental chamber
>>> mu.to_dominant_chamber(positive=False)
Traceback (most recent call last):
... 
ValueError: alpha[1] is not in the orbit of the negative of the
  fundamental chamber

to_dual_type_cospace()

Map self to the dual type cospace.

For example, if self is in the root lattice of type ['B', 2], send it to the coroot lattice of type ['C', 2].

EXAMPLES:

sage: v = CartanType(['C',3]).root_system().weight_lattice().an_element(); v
sage: w = v.to_dual_type_cospace(); w
sage: w.parent()
Coweight lattice of the Root system of type ['B', 3]

>>> from sage.all import *
>>> v = CartanType(['C',Integer(3)]).root_system().weight_lattice().an_element(); v
(continues on next page)
\[
>>> w = v.to_dual_type_cospace(); w
\]
\[ 2\Lambda\check[1] + 2\Lambda\check[2] + 3\Lambda\check[3] \]
\[
>>> w.parent()
\]
Coweight lattice of the Root system of type ['B', 3]

**to_simple_root** *(reduced_word=False)*

Return (the index of) a simple root in the orbit of the positive root `self`.

**INPUT:**

- `self` – a positive root
- `reduced_word` – a boolean (default: False)

**OUTPUT:**

- The index \( i \) of a simple root \( \alpha_i \). If `reduced_word` is True, this returns instead a pair \((i, \text{word})\), where `word` is a sequence of reflections mapping \( \alpha_i \) up the root poset to `self`.

**EXAMPLES:**

```
sage: L = RootSystem(['A',3]).root_lattice()
sage: positive_roots = L.positive_roots()
sage: for alpha in sorted(positive_roots):
    # needs sage.graphs
    ....:     print("{} {}").format(alpha, alpha.to_simple_root())
alpha[1] 1
alpha[2] 2
alpha[3] 3
sage: for alpha in sorted(positive_roots):
    # needs sage.graphs
    ....:     print("{} {}").format(alpha, alpha.to_simple_root(reduced_word=True))
alpha[1] (1, ())
alpha[2] (2, ())
alpha[3] (3, ())
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(3)]).root_lattice()
>>> positive_roots = L.positive_roots()
>>> for alpha in sorted(positive_roots):
    # needs sage.graphs
    ....:     print("{} {}").format(alpha, alpha.to_simple_root())
alpha[1] 1
alpha[2] 2
alpha[3] 3
>>> for alpha in sorted(positive_roots):
    # needs sage.graphs
    ....:     print("{} {}").format(alpha, alpha.to_simple_root(reduced_word=True))
alpha[1] (1, ())
```
ALGORITHM:
This method walks from self down to the antidominant chamber by applying successively the simple reflection given by the first descent. Since self is a positive root, each step goes down the root poset, and one must eventually cross a simple root $\alpha_i$.

See also:
• first_descent()
• to_dominant_chamber()

Warning: The behavior is not specified if the input is not a positive root. For a finite root system, this is currently caught (albeit with a not perfect message):

```
sage: alpha = L.simple_roots()  # needs sage.graphs
sage: (2*alpha[1]).to_simple_root()  # needs sage.graphs
Traceback (most recent call last):
...
```

For an infinite root system, this method may run into an infinite recursion if the input is not a positive root.

**translation**($x$)
Return $x$ translated by $t$, that is, $x + \text{level}(x)t$.

INPUT:
• self -- an element $t$ at level 0
• $x$ -- an element of the same space

EXAMPLES:
```
sage: L = RootSystem(['A', 2, 1]).weight_lattice()  # needs sage.graphs
sage: alpha = L.simple_roots()  # needs sage.graphs
sage: Lambda = L.fundamental_weights()  # needs sage.graphs
sage: t = alpha[2]  # needs sage.graphs
```
Let us look at the translation of an element of level 1:

```
sage: Lambda[1].level()  # needs sage.graphs
1
sage: t.translation(Lambda[1])  # needs sage.graphs
-Lambda[0] + 2*Lambda[2]
sage: Lambda[1] + t  # needs sage.graphs
-Lambda[0] + 2*Lambda[2]
```

and of an element of level 0:

```
sage: alpha[1].level()  # needs sage.graphs
0
sage: t.translation(alpha[1])  # needs sage.graphs
sage: alpha[1] + 0*t  # needs sage.graphs
```

The arguments are given in this seemingly unnatural order to make it easy to construct the translation function:
weyl_action (element, inverse=False)

Act on self by an element of the Coxeter or Weyl group.

INPUT:
• element – an element of a Coxeter or Weyl group of the same Cartan type, or a tuple or a list (such as a reduced word) of elements from the index set
• inverse – a boolean (default: False): whether to act by the inverse element

EXAMPLES:

sage: wl = RootSystem(['A',3]).weight_lattice()
sage: mu = wl.from_vector(vector([1,0,-2]))
sage: mu
sage: mudom, rw = mu.to_dominant_chamber(positive=False, reduced_word=True)

...:
sage: mudom, rw
(-Lambda[2] - Lambda[3], [1, 2])

Acting by a (reduced) word:

sage: mudom.weyl_action(rw)
(-Lambda[2] - Lambda[3], [1, 2])

sage: mu.weyl_action(rw, inverse=True)
Acting by an element of the Coxeter or Weyl group on a vector in its own lattice of definition (implemented by matrix multiplication on a vector):

```python
sage: w = wl.weyl_group().from_reduced_word([1, 2])
#--
# needs sage.graphs sage.libs.gap
sage: mudom.weyl_action(w)
#--
# needs sage.graphs sage.libs.gap
```

Acting by an element of an isomorphic Coxeter or Weyl group (implemented by the action of a corresponding reduced word):

```python
sage: W = WeylGroup(["A",3], prefix="s")
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

(continued from previous page)

```python
needs sage.graphs
[0, 1, 2]
sage: wl = RootSystem(['A',4]).weight_lattice()
sage: mu = wl.from_vector(vector([1,1,0,0]))
sage: mu.weyl_stabilizer()
[3, 4]
sage: mu.weyl_stabilizer(index_set = [1,2,3])
[3]
```

```python
>>> from sage.all import *

>>> wl = RootSystem(['A',Integer(2),Integer(1)]).weight_lattice(extended=True)

>>> al = wl.null_root()  #...

>>> al.weyl_stabilizer()  #...

```

```python
>>> wl = RootSystem(['A',Integer(4)]).weight_lattice()

>>> mu = wl.from_vector(vector([Integer(1),Integer(1),Integer(0),Integer(0)]))

>>> mu.weyl_stabilizer()
[3, 4]

>>> mu.weyl_stabilizer(index_set = [Integer(1),Integer(2),Integer(3)])
[3]
```

```python

class ParentMethods

    Bases: object

    a_long_simple_root()

        Return a long simple root, corresponding to the highest outgoing edge in the Dynkin diagram.

        Warning: This may be broken in affine type $A_{2n}^{(2)}$

        Is it meaningful/broken for non irreducible?

Todo: implement CartanType.nodes_by_length as in MuPAD-Combinat (using CartanType.symmetrizer), and use it here.

    almost_positive_roots()

        Return the almost positive roots of self.

        These are the positive roots together with the simple negative roots.

        See also:

        almost_positive_root_decomposition(), tau_plus_minus()

    EXAMPLES:

    sage: L = RootSystem(['A',2]).root_lattice()
    sage: L.almost_positive_roots()

```

5.1. Comprehensive Module List 4047
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(2)]).root_lattice()
>>> L.almost_positive_roots()  # needs sage.graphs
[-alpha[1], alpha[1], alpha[1] + alpha[2], -alpha[2], alpha[2]]

almost_positive_roots_decomposition()

Return the decomposition of the almost positive roots of self.

This is the list of the orbits of the almost positive roots under the action of the dihedral group generated by the operators $\tau_+$ and $\tau_-.$

See also:

- almost_positive_roots()
- tau_plus_minus()

EXAMPLES:

sage: RootSystem(['A',2]).root_lattice().almost_positive_roots_decomposition()  # needs sage.graphs sage.libs.gap
\[-alpha[1], alpha[1], alpha[1] + alpha[2], alpha[2], -alpha[2]\]

sage: RootSystem(['B',2]).root_lattice().almost_positive_roots_decomposition()  # needs sage.graphs sage.libs.gap
\[-alpha[1], alpha[1], alpha[1] + 2*alpha[2],
-\alpha[2], alpha[2], alpha[1] + alpha[2]\]

sage: RootSystem(['D',4]).root_lattice().almost_positive_roots_decomposition()  # needs sage.graphs sage.libs.gap

(continues on next page)
alpha ()

Return the family \((\alpha_i)_{i \in I}\) of the simple roots, with the extra feature that, for simple irreducible root systems, \(\alpha_0\) yields the opposite of the highest root.

EXAMPLES:

```
sage: alpha = RootSystem(['A',2]).root_lattice().alpha()
sage: alpha[1]
alpha[1]
sage: alpha[0]  # needs sage.graphs
```

alphacheck ()

Return the family \((\alpha_i^\vee)_{i \in I}\) of the simple coroots, with the extra feature that, for simple irreducible root systems, \(\alpha_0^\vee\) yields the coroot associated to the opposite of the highest root (caveat: for non-simply-laced root systems, this is not the opposite of the highest coroot!).

EXAMPLES:

```
sage: alphacheck = RootSystem(['A',2]).ambient_space().alphacheck()
sage: alphacheck
Finite family {1: (1, -1, 0), 2: (0, 1, -1)}
```

Here is now \(\alpha_0^\vee\):

\((-1, 0, 1)\)

Todo: add a non simply laced example

Finally, here is an affine example:

```
sage: RootSystem(['A',2,1]).weight_space().alphacheck()
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}
sage: RootSystem(['A',3]).ambient_space().alphacheck()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}
```
from sage.all import *

RootSystem(['A', Integer(2), Integer(1)]).weight_space().alphacheck()
Finite family {0: alphacheck[0], 1: alphacheck[1], 2: alphacheck[2]}

RootSystem(['A', Integer(3)]).ambient_space().alphacheck()
Finite family {1: (1, -1, 0, 0), 2: (0, 1, -1, 0), 3: (0, 0, 1, -1)}

basic_imaginary_roots()

Return the basic imaginary roots of self.

The basic imaginary roots $\delta$ are the set of imaginary roots in $-C^\vee$ where $C$ is the dominant chamber (i.e., $\langle \beta, \alpha_i^\vee \rangle \leq 0$ for all $i \in I$). All imaginary roots are $W$-conjugate to a simple imaginary root.

EXAMPLES:

sage: Q = RootSystem(['A', 2, 1]).root_lattice()
sage: Q.basic_imaginary_roots()

>>> from sage.all import *
>>> Q = RootSystem(['A', Integer(2), Integer(1)]).root_lattice()
>>> Q.basic_imaginary_roots()

>>> from sage.all import *
>>> Q = RootSystem(['A', Integer(2), Integer(1)]).root_lattice()
>>> Q.basic_imaginary_roots()

cartan_type()

EXAMPLES:

sage: r = RootSystem(['A', 4]).root_space()
sage: r.cartan_type()
['A', 4]

classical()

Return the corresponding root/weight/ambient lattice/space.
EXAMPLES:

```
sage: RootSystem(["A",4,1]).root_lattice().classical()
Root lattice of the Root system of type ['A', 4]
sage: RootSystem(["A",4,1]).weight_lattice().classical()
Weight lattice of the Root system of type ['A', 4]
sage: RootSystem(["A",4,1]).ambient_space().classical()
Ambient space of the Root system of type ['A', 4]
```

```from sage.all import *
from sage.all import *
RootSystem(["A",Integer(4),Integer(1)]).root_lattice().classical()
Root lattice of the Root system of type ['A', 4]
RootSystem(["A",Integer(4),Integer(1)]).weight_lattice().classical()
Weight lattice of the Root system of type ['A', 4]
RootSystem(["A",Integer(4),Integer(1)]).ambient_space().classical()
Ambient space of the Root system of type ['A', 4]
```

cohighest_root()

Return the associated coroot of the highest root.

**Note:** this is usually not the highest coroot.

EXAMPLES:

```
sage: RootSystem(['A', 3]).ambient_space().cohighest_root()
(1, 0, 0, -1)
```

```from sage.all import *
from sage.all import *
RootSystem(['A', Integer(3)]).ambient_space().cohighest_root()
(1, 0, 0, -1)
```

coroot_lattice()

Return the coroot lattice.

EXAMPLES:

```
sage: RootSystem(["A",2]).root_lattice().coroot_lattice()
Coroot lattice of the Root system of type ['A', 2]
```

```from sage.all import *
from sage.all import *
RootSystem(["A", Integer(2)]).root_lattice().coroot_lattice()
Coroot lattice of the Root system of type ['A', 2]
```

coroot_space(base_ring=Rational Field)

Return the coroot space over base_ring.

**INPUT:**

- base_ring – a ring (default: Q)

**EXAMPLES:**

```
sage: RootSystem(["A",2]).root_lattice().coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 2]
sage: RootSystem(["A",2]).root_lattice().coroot_space(QQ['q'])
```

(continues on next page)
Coroot space over the Univariate Polynomial Ring in q over Rational Field of the Root system of type ['A', 2]

```python
>>> from sage.all import *

from sage.all import *

RootSystem(["A",Integer(2)]).root_lattice().coroot_space()
Coroot space over the Rational Field of the Root system of type ['A', 2]

RootSystem(["A",Integer(2)]).root_lattice().coroot_space(QQ["q"])
Coroot space over the Univariate Polynomial Ring in q over Rational Field of the Root system of type ['A', 2]
```

**dual_type_cospace()**

Return the cospace of dual type.

For example, if invoked on the root lattice of type ['B', 2], returns the coroot lattice of type ['C', 2].

**Warning:** Not implemented for ambient spaces.

**EXAMPLES:**

```python
sage: CartanType(['B',2]).root_system().root_lattice().dual_type_cospace()
Coroot lattice of the Root system of type ['C', 2]

sage: CartanType(['F',4]).root_system().coweight_lattice().dual_type_cospace()
Weight lattice of the Root system of type ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

```python
>>> from sage.all import *

from sage.all import *

CartanType(['B',Integer(2)]).root_system().root_lattice().dual_type_cospace()
Coroot lattice of the Root system of type ['C', 2]

CartanType(['F',Integer(4)]).root_system().coweight_lattice().dual_type_cospace()
Weight lattice of the Root system of type ['F', 4] relabelled by {1: 4, 2: 3, 3: 2, 4: 1}
```

**dynkin_diagram()**

**EXAMPLES:**

```python
sage: r = RootSystem(["A",4]).root_space()
sage: r.dynkin_diagram()
# needs sage.graphs

O---O---O---O
1 2 3 4
A4
```

```python
>>> from sage.all import *

from sage.all import *

r = RootSystem(["A",Integer(4)]).root_space()
r.dynkin_diagram()
# needs sage.graphs

O---O---O---O
1 2 3 4
A4
```
fundamental_weights_from_simple_roots()

Return the fundamental weights.

This is computed from the simple roots by using the inverse of the Cartan matrix. This method is therefore only valid for finite types and if this realization of the root lattice is large enough to contain them.

EXAMPLES:

In the root space, we retrieve the inverse of the Cartan matrix:

```python
sage: L = RootSystem(['B',3]).root_space()
sage: L.fundamental_weights_from_simple_roots()  # needs sage.graphs
sage: ~L.cartan_type().cartan_matrix()  # needs sage.graphs
[ 1 1 1/2]
[ 1 2 1]
[ 1 2 3/2]
```

In the weight lattice and the ambient space, we retrieve the fundamental weights:

```python
sage: L = RootSystem(['B',3]).weight_lattice()
sage: L.fundamental_weights_from_simple_roots()  # needs sage.graphs
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
sage: L = RootSystem(['B',3]).ambient_space()
sage: L.fundamental_weights()  # needs sage.graphs
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
sage: L.fundamental_weights_from_simple_roots()  # needs sage.graphs
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```

```python
>>> from sage.all import *
>>> L = RootSystem(['B',Integer(3)]).root_space()
>>> L.fundamental_weights_from_simple_roots()  # needs sage.graphs
```

```python
>>> L = RootSystem(['B',Integer(3)]).weight_lattice()
>>> L.fundamental_weights_from_simple_roots()  # needs sage.graphs
Finite family {1: Lambda[1], 2: Lambda[2], 3: Lambda[3]}
```

```python
>>> L = RootSystem(['B',Integer(3)]).ambient_space()
>>> L.fundamental_weights()  # needs sage.graphs
Finite family {1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)}
```
Finite family \{1: (1, 0, 0), 2: (1, 1, 0), 3: (1/2, 1/2, 1/2)\}

However the fundamental weights do not belong to the root lattice:

```python
sage: L = RootSystem(["B",3]).root_lattice()
sage: L.fundamental_weights_from_simple_roots()
# needs sage.graphs
Traceback (most recent call last):
...  ValueError: The fundamental weights do not live in this realization
of the root lattice
```

```python
>>> from sage.all import *

>>> L = RootSystem(["B",Integer(3)]).root_lattice()
>>> L.fundamental_weights_from_simple_roots()
# needs sage.graphs
Traceback (most recent call last):
...  ValueError: The fundamental weights do not live in this realization
of the root lattice
```

Beware of the usual $GL_n$ vs $SL_n$ catch in type $A$:

```python
sage: L = RootSystem(["A",3]).ambient_space()
sage: L.fundamental_weights()
Finite family \{1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)\}

sage: L.fundamental_weights_from_simple_roots()
# needs sage.graphs
Finite family \{1: (3/4, -1/4, -1/4, -1/4),
2: (1/2, 1/2, -1/2, -1/2),
3: (1/4, 1/4, 1/4, -3/4)\}

sage: L = RootSystem(["A",3]).ambient_lattice()
sage: L.fundamental_weights_from_simple_roots()
# needs sage.graphs
Traceback (most recent call last):
...  ValueError: The fundamental weights do not live in this realization
of the root lattice
```

```python
>>> from sage.all import *

>>> L = RootSystem(["A",Integer(3)]).ambient_space()

>>> L.fundamental_weights()
Finite family \{1: (1, 0, 0, 0), 2: (1, 1, 0, 0), 3: (1, 1, 1, 0)\}

>>> L.fundamental_weights_from_simple_roots()
# needs sage.graphs
Finite family \{1: (3/4, -1/4, -1/4, -1/4),
2: (1/2, 1/2, -1/2, -1/2),
3: (1/4, 1/4, 1/4, -3/4)\}
```

```python
>>> L = RootSystem(["A",Integer(3)]).ambient_lattice()

>>> L.fundamental_weights_from_simple_roots()
# needs sage.graphs
```
generalized_nonnesting_partition_lattice \((m, \text{facade}=False)\)
Return the lattice of \(m\)-nonnesting partitions.
This has been defined by Athanasiadis, see chapter 5 of [Arm06].

INPUT:
• \(m\) – integer

See also:
nonnesting_partition_lattice()

EXAMPLES:

```python
sage: R = RootSystem(['A', 2])
sage: RS = R.root_lattice()
sage: P = RS.generalized_nonnesting_partition_lattice(2); P  # needs sage.graphs
Finite lattice containing 12 elements
sage: P.coxeter_transformation()**20 == 1  # needs sage.graphs sage.libs.flint
True
```

highest_root()
Return the highest root (for an irreducible finite root system).

EXAMPLES:

```python
sage: RootSystem(['A', 4]).ambient_space().highest_root()
(1, 0, 0, 0, -1)
sage: RootSystem(['E', 6]).weight_space().highest_root()  # needs sage.graphs
Lambda[2]
```

>>> from sage.all import *
>>> R = RootSystem(['A', Integer(2)])
>>> RS = R.root_lattice()
>>> P = RS.generalized_nonnesting_partition_lattice(Integer(2)); P  # needs sage.graphs
Finite lattice containing 12 elements
>>> P.coxeter_transformation()**Integer(20) == Integer(1)  # needs sage.graphs sage.libs.flint
True
```
```plaintext
index_set()

EXAMPLES:

sage: r = RootSystem(['A', 4]).root_space()
sage: r.index_set()
(1, 2, 3, 4)

>>> from sage.all import *
>>> r = RootSystem(['A', Integer(4)]).root_space()
>>> r.index_set()
(1, 2, 3, 4)

long_roots()

Return a list of the long roots of self.

EXAMPLES:

sage: L = RootSystem(['B', 3]).root_lattice()
sage: sorted(L.long_roots())

# needs sage.graphs
 alpha[1], alpha[1] + alpha[2],

>>> from sage.all import *
>>> L = RootSystem(['B', Integer(3)]).root_lattice()
>>> sorted(L.long_roots())

# needs sage.graphs
 alpha[1], alpha[1] + alpha[2],

negative_roots()

Return the negative roots of self.

EXAMPLES:

sage: L = RootSystem(['A', 2]).weight_lattice()
sage: sorted(L.negative_roots())

# needs sage.graphs

>>> from sage.all import *
>>> L = RootSystem(['A', Integer(2)]).weight_lattice()
>>> sorted(L.negative_roots())

# needs sage.graphs

Algorithm: negate the positive roots
```

Chapter 5. Comprehensive Module List
nonnesting_partition_lattice (facade=False)

Return the lattice of nonnesting partitions.

This is the lattice of order ideals of the root poset.

This has been defined by Postnikov, see Remark 2 in [Reiner97].

See also:

generalized_nonnesting_partition_lattice(), root_poset()

EXAMPLES:

```python
sage: R = RootSystem(['A', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 14 elements
sage: P.coxeter_transformation()**10 == 1
True

sage: R = RootSystem(['B', 3])
sage: RS = R.root_lattice()
sage: P = RS.nonnesting_partition_lattice(); P
Finite lattice containing 20 elements
sage: P.coxeter_transformation()**7 == 1
True
```

REFERENCES:

nonparabolic_positive_root_sum (index_set=None)

Return the sum of positive roots not in a parabolic subsystem.

The conventions for index_set are as in nonparabolic_positive_roots().

EXAMPLES:
sage: Q = RootSystem(['A',3]).root_lattice()
sage: Q.nonparabolic_positive_root_sum((1,2)) #-
needs sage.graphs
sage: Q.nonparabolic_positive_root_sum()
#-
needs sage.graphs
0
sage: Q.nonparabolic_positive_root_sum(())
#-
needs sage.graphs

>>> from sage.all import *
>>> Q = RootSystem(['A',Integer(3)]).root_lattice()
>>> Q.nonparabolic_positive_root_sum((Integer(1),Integer(2))) #-
needs sage.graphs
>>> Q.nonparabolic_positive_root_sum()
needs sage.graphs
0
>>> Q.nonparabolic_positive_root_sum(())
needs sage.graphs

nonparabolic_positive_roots(index_set=None)

Return the positive roots of self that are not in the parabolic subsystem indicated by index_set.

If index_set is None, as in positive_roots() it is assumed to be the entire Dynkin node set.
Then the parabolic subsystem consists of all positive roots and the empty list is returned.

EXAMPLES:

sage: L = RootSystem(['A',3]).root_lattice()
sage: L.nonparabolic_positive_roots()
#-
needs sage.graphs
[]
sage: sorted(L.nonparabolic_positive_roots((1,2))) #-
needs sage.graphs
sage: sorted(L.nonparabolic_positive_roots(()))
#-
needs sage.graphs

>>> from sage.all import *
>>> L = RootSystem(['A',Integer(3)]).root_lattice()
>>> L.nonparabolic_positive_roots()
#-
needs sage.graphs
[]
>>> sorted(L.nonparabolic_positive_roots((Integer(1),Integer(2)))) #-
needs sage.graphs
>>> sorted(L.nonparabolic_positive_roots(()))
#-
needs sage.graphs

null_coroot()
Return the null coroot of \texttt{self}.

The null coroot is the smallest non trivial positive coroot which is orthogonal to all simple roots. It exists for any affine root system.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RootSystem(['C',2,1]).root_lattice().null_coroot() # needs sage.graphs
sage: RootSystem(['D',4,1]).root_lattice().null_coroot() # needs sage.graphs
sage: RootSystem(['F',4,1]).root_lattice().null_coroot() # needs sage.graphs
\end{verbatim}

\texttt{null_root}()

Return the null root of \texttt{self}.

The null root is the smallest non trivial positive root which is orthogonal to all simple coroots. It exists for any affine root system.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: RootSystem(['C',2,1]).root_lattice().null_root() # needs sage.graphs
sage: RootSystem(['D',4,1]).root_lattice().null_root() # needs sage.graphs
sage: RootSystem(['F',4,1]).root_lattice().null_root() # needs sage.graphs
\end{verbatim}

\texttt{from sage.all import *}

\begin{verbatim}
>> RootSystem(['C',Integer(2),Integer(1)]).root_lattice().null_root() # needs sage.graphs
>> RootSystem(['D',Integer(4),Integer(1)]).root_lattice().null_root() # needs sage.graphs
>> RootSystem(['F',Integer(4),Integer(1)]).root_lattice().null_root() # needs sage.graphs
\end{verbatim}

(continues on next page)
RootSystem(['F', Integer(4), Integer(1)]).root_lattice().null_root() ˓→ # needs sage.graphs

plot (roots='simple', coroots=False, reflection_hyperplanes='simple', fundamental_weights=None, fundamental_chamber=None, alcoves=None, alcove_labels=False, alcove_walk=None, **options)

Return a picture of this root lattice realization.

INPUT:
- **roots** – which roots to display, if any. Can be one of the following:
  - "simple" – The simple roots (the default)
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of roots
  - False
- **coroots** – which coroots to display, if any. Can be one of the following:
  - "simple" – The simple coroots (the default)
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of coroots
  - False
- **fundamental_weights** – a boolean or None (default: None) whether to display the fundamental weights. If None, the fundamental weights are drawn if available.
- **reflection_hyperplanes** – which reflection hyperplanes to display, if any. Can be one of the following:
  - "simple" – The simple roots
  - "classical" – Not yet implemented
  - "all" – Only works in the finite case
  - A list or tuple of roots
  - False (the default)
- **fundamental_chamber** – whether and how to draw the fundamental chamber. Can be one of the following:
  - A boolean – Set to True to draw the fundamental chamber
  - "classical" – Draw the classical fundamental chamber
  - None – (the default) The fundamental chamber is drawn except in the root lattice where this is not yet implemented. For affine types the classical fundamental chamber is drawn instead.
- **alcoves** – one of the following (default: True):
  - A boolean – Whether to display the alcoves
  - A list of alcoves – The alcoves to be drawn. Each alcove is specified by the coordinates of its center in the root lattice. Otherwise the alcoves that intersect the bounding box are drawn.
- **alcove_labels** – one of the following (default: False):
  - A boolean – Whether to display the elements of the Weyl group indexing the alcoves. This currently requires to also set the alcoves option.
  - A number / – The label is drawn at level l (affine type only), which only makes sense if affine is False.
- **bounding_box** – a rational number or a list of pairs thereof (default: 3)

Specifies a bounding box, in the coordinate system for this plot, in which to plot alcoves and other infinite objects. If the bounding box is a number a, then the bounding box is of the form [−a, a] in all directions. Beware that there can be some border effects and the returned graphic is not necessarily strictly contained in the bounding box.
- **alcove_walk** – an alcove walk or None (default: None)
The alcove walk is described by a list (or iterable) of vertices of the Dynkin diagram which specifies which wall is crossed at each step, starting from the fundamental alcove.

**projection** – one of the following (default: True):
- True – The default projection for the root lattice realization is used.
- False – No projection is used.
- barycentric – A barycentric projection is used.
- A function – If a function is specified, it should implement a linear (or affine) map taking as input an element of this root lattice realization and returning its desired coordinates in the plot, as a vector with rational coordinates.

**color** – a function mapping vertices of the Dynkin diagram to colors (default: "black" for 0, "blue" for 1, "red" for 2, "green" for 3)

This is used to set the color for the simple roots, fundamental weights, reflection hyperplanes, alcove facets, etc. If the color is None, the object is not drawn.

**labels** – a boolean (default: True) whether to display labels on the simple roots, fundamental weights, etc.

**EXAMPLES:**

```python
sage: L = RootSystem(['A',2,1]).ambient_space().plot()  # long time, needs sage.plot sage.symbolic
```

```python
from sage.all import *

L = RootSystem(['A',2,1]).ambient_space().plot()  # long time, needs sage.plot sage.symbolic
```

See also:
- `plot_parse_options()`
- `plot_roots()`, `plot_coroots()`
- `plot_fundamental_weights()`
- `plot_fundamental_chamber()`
- `plot_reflection_hyperplanes()`
- `plot_alcoves()`
- `plot_alcove_walk()`
- `plot_ls_paths()`
- `plot_mv_polytope()`
- `plot_crystal()`

`plot_alcove_walk(word, start=None, foldings=None, color='orange', **options)`

Plot an alcove walk.

**INPUT:**
- `word` – a list of elements of the index set
- `foldings` – a list of booleans or None (default: None)
- `start` – an element of this space (default: None for $\rho$)
- **options** – plotting options

**EXAMPLES:**

An alcove walk of type $A_2^{(1)}$:

```python
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: w1 = [0,2,1,2,0,2,1,0,2,1,2,1,2,0,2,0,1,2,0]
```
sage: p = L.plot_alcoves(bounding_box=5)  # long time (5s)  
˓→ needs sage.plot sage.symbolic 
sage: p += L.plot_alcove_walk(w1)  # long time  
˓→ needs sage.plot sage.symbolic 
sage: p  # long time  
˓→ needs sage.plot sage.symbolic 
Graphics object consisting of 375 graphics primitives

The same plot with another alcove walk:

sage: w2 = [2,1,2,0,2,0,2,1,2,1,2,1,0,1,2,0,2,0,1,2,0,2]  
sage: p += L.plot_alcove_walk(w2, color="orange")  # long time, 
˓→ needs sage.plot sage.symbolic 

And another with some foldings:

sage: pic = L.plot_alcoves(bounding_box=3)  # long time, 
˓→ needs sage.plot sage.symbolic 
sage: pic += L.plot_alcove_walk([0,1,2,0,2,0,1,2,0,1],  # long time (3s), 
˓→ needs sage.plot sage.symbolic 
˓→ foldings=[False, False, True, False, False, 
˓→ False, True, False, True, False], 
˓→ color="green"); pic 
Graphics object consisting of 155 graphics primitives

(continues on previous page)
... False, True, False, True, False],
... color="green"); pic
Graphics object consisting of 155 graphics primitives

plot_alcoves (alcoves=True, alcove_labels=False, wireframe=False, **options)
Plot the alcoves and optionally their labels.

INPUT:
• alcoves – a list of alcoves or True (default: True)
• alcove_labels – a boolean or a number specifying at which level to put the label (default: False)
• **options – Plotting options

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting, and in particular how the alcoves can be specified.

EXAMPLES:
2D plots:
sage: RootSystem("B",2,1).ambient_space().plot_alcoves()  # long time (3s), needs sage.plot sage.symbolic
Graphics object consisting of 228 graphics primitives

3D plots:
sage: RootSystem("A",2,1).weight_space().plot_alcoves(affine=False)  # long time (3s), needs sage.plot sage.symbolic
Graphics3d Object
sage: RootSystem("G",2,1).ambient_space().plot_alcoves(affine=False, level=1)  # long time (3s), needs sage.plot sage.symbolic
Graphics3d Object

Here we plot a single alcove:
sage: L = RootSystem("A",3,1).ambient_space()
sage: W = L.weyl_group()  # needs sage.libs.gap
sage: L.plot(alcoves=[W.one()], reflection_hyperplanes=False, bounding_box=2)  # needs sage.libs.gap sage.plot sage.symbolic
Graphics3d Object
>>> from sage.all import *
>>> L = RootSystem(["A",Integer(3),Integer(1)]).ambient_space()
>>> W = L.weyl_group()  # needs sage.libs.gap
>>> L.plot(alcoves=[W.one()], reflection_hyperplanes=False, bounding_box=Integer(2))  # needs sage.libs.gap sage.plot sage.symbolic
Graphics3d Object

plot_bounding_box(**options)
Plot the bounding box.

INPUT:
• **options – Plotting options
  This is mostly for testing purposes.

See also:
• plot() for a description of the plotting options
  • Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
sage: L = RootSystem(["A",2,1]).ambient_space()
sage: L.plot_bounding_box()  # needs sage.plot sage.symbolic
Graphics object consisting of 1 graphics primitive

>>> from sage.all import *
>>> L = RootSystem(["B",Integer(3),Integer(1)]).ambient_space()
>>> L.plot_bounding_box()  # needs sage.plot sage.symbolic
Graphics object consisting of 1 graphics primitive

plot_coroots(collection='simple', **options)
Plot the (simple/classical) coroots of this root lattice.

INPUT:
• collection – which coroots to display. Can be one of the following:
  – "simple" (the default)
  – "classical"
  – "all"
• **options – Plotting options

See also:
• plot() for a description of the plotting options
  • Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:
sage: RootSystem(["B",3]).ambient_space().plot_coroots()  # needs sage.plot sage.symbolic
Graphics3d Object

>>> from sage.all import *
>>> RootSystem(["B",Integer(3)]).ambient_space().plot_coroots()  # needs sage.plot sage.symbolic
Graphics3d Object
**plot_crystal** *(crystal, plot_labels=True, label_color='black', edge_labels=False, circle_size=0.06, circle_thickness=1.6, **options)*

Plot a finite crystal.

**INPUT:**
- **crystal** – the finite crystal to plot
- **plot_labels** – (default: True) can be one of the following:
  - **True** – use the latex labels
  - 'circles' – use circles for multiplicity up to 4; if the multiplicity is larger, then it uses the multiplicity
  - 'multiplicities' – use the multiplicities
- **label_color** – (default: 'black') the color of the labels
- **edge_labels** – (default: False) if True, then draw in the edge label
- **circle_size** – (default: 0.06) the size of the circles
- **circle_thickness** – (default: 1.6) the thickness of the extra rings of circles
- ****options** – plotting options

**See also:**
- **plot()** for a description of the plotting options
- **Tutorial: visualizing root systems** for a tutorial on root system plotting

**EXAMPLES:**

```
sage: # needs sage.combinat sage.plot sage.symbolic
sage: L = RootSystem(['A',2]).ambient_space()
sage: C = crystals.Tableaux(['A',2], shape=[2,1])
sage: L.plot_crystal(C, plot_labels='multiplicities')
Graphics object consisting of 15 graphics primitives
sage: C = crystals.Tableaux(['A',2], shape=[8,4])
```

A 3-dimensional example:

```
sage: L = RootSystem(['B',3]).ambient_space()  # needs sage.combinat
sage: C = crystals.Tableaux(['B',3], shape=[2,1])  # needs sage.combinat
sage: L.plot_crystal(C, plot_labels='circles', edge_labels=True)  # long time
Graphics3d Object
```

(continues on next page)
plot_fundamental_chamber (style='normal', **options)

Plot the (classical) fundamental chamber.

INPUT:
- style = "normal" or "classical" (default: "normal")
- **options – Plotting options

See also:
- plot() for a description of the plotting options
- Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

2D plots:

```python
definition
plot_fundamental_chamber(style='normal', **options)
```

3D plots:

```python
definition
plot_fundamental_chamber(style='normal', **options)
```
This feature is currently not available in the root lattice/space:

```python
sage: list(RootSystem(["A",2]).root_lattice().plot_fundamental_chamber())
˓→ # needs sage.plot
Traceback (most recent call last):
... TypeError: classical fundamental chamber not yet available in the root...
˓→lattice
```

```python
>>> from sage.all import *
>>> list(RootSystem(["A",Integer(2)]).root_lattice().plot_fundamental_˓→chamber())
# needs sage.plot
Traceback (most recent call last):
... TypeError: classical fundamental chamber not yet available in the root...
˓→lattice
```

```
plot_fundamental_weights(**options)
Plot the fundamental weights of this root lattice.

INPUT:
  • **options – Plotting options

See also:
  • `plot()` for a description of the plotting options
  • `Tutorial: visualizing root systems` for a tutorial on root system plotting

EXAMPLES:

```python
sage: RootSystem(["B",3]).ambient_space().plot_fundamental_weights()  #˓→needs sage.plot
Graphics3d Object
```

```python
>>> from sage.all import *
>>> RootSystem(["B",Integer(3)]).ambient_space().plot_fundamental_˓→weights()  # needs sage.plot
Graphics3d Object
```

```
plot_hedron(**options)
Plot the polyhedron whose vertices are given by the orbit of \( \rho \).

In type \(A\), this is the usual permutohedron.

See also:
  • `plot()` for a description of the plotting options
  • `Tutorial: visualizing root systems` for a tutorial on root system plotting

EXAMPLES:

```python
sage: # needs sage.plot sage.symbolic
sage: RootSystem(["A",2]).ambient_space().plot_hedron()
Graphics object consisting of 8 graphics primitives
sage: RootSystem(["A",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["B",3]).ambient_space().plot_hedron()
Graphics3d Object
sage: RootSystem(["C",3]).ambient_space().plot_hedron()
Graphics3d Object
```

(continues on next page)
sage: RootSystem(['D',3]).ambient_space().plot_hedron()
Graphics3d Object

>>> from sage.all import *
>>> # needs sage.plot sage.symbolic
>>> RootSystem(['A',Integer(2)]).ambient_space().plot_hedron()
Graphics object consisting of 8 graphics primitives

>>> RootSystem(['A',Integer(3)]).ambient_space().plot_hedron()
Graphics3d Object

>>> RootSystem(['B',Integer(3)]).ambient_space().plot_hedron()
Graphics3d Object

>>> RootSystem(['C',Integer(3)]).ambient_space().plot_hedron()
Graphics3d Object

>>> RootSystem(['D',Integer(3)]).ambient_space().plot_hedron()
Graphics3d Object

Surprise: polyhedra of large dimension know how to project themselves nicely:

sage: RootSystem(['F',4]).ambient_space().plot_hedron()
# long time, needs sage.plot sage.symbolic
Graphics3d Object

>>> from sage.all import *

plot_ls_paths (paths, plot_labels=None, colored_labels=True, **options)
Plot LS paths.

INPUT:
• paths – a finite crystal or list of LS paths
• plot_labels – (default: None) the distance to plot the LS labels from the endpoint of the path; set to None to not display the labels
• colored_labels – (default: True) if True, then color the labels the same color as the LS path
• **options – plotting options

See also:
• plot() for a description of the plotting options
• Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

sage: B = crystals.LSPaths(['A',2], [1,1])
# needs sage.combinat
sage: L = RootSystem(['A',2]).ambient_space()
sage: L.plot_fundamental_weights() + L.plot_ls_paths(B)
# needs sage.combinat sage.plot sage.symbolic
Graphics object consisting of 14 graphics primitives

>>> from sage.all import *
>>> B = crystals.LSPaths(['A',Integer(2)], [Integer(1),Integer(1)])
# needs sage.combinat
>>> L = RootSystem(['A',Integer(2)]).ambient_space()
>>> L.plot_fundamental_weights() + L.plot_ls_paths(B)
(continues on next page)
needs sage.combinat sage.plot sage.symbolic
Graphics object consisting of 14 graphics primitives

This also works in 3 dimensions:

```python
sage: B = crystals.LSPaths(['B',3], [2,0,0])
# needs sage.combinat
sage: L = RootSystem(['B',3]).ambient_space()
# needs sage.combinat
sage: L.plot_ls_paths(B)
# needs sage.combinat sage.plot sage.symbolic
Graphics3d Object
```

```python
>>> from sage.all import *
```
```python
>>> B = crystals.LSPaths(['B',Integer(3)], [Integer(2),Integer(0),
# needs sage.combinat
>>> L = RootSystem(['B',Integer(3)]).ambient_space()
# needs sage.combinat
>>> L.plot_ls_paths(B)
# needs sage.combinat sage.plot sage.symbolic
Graphics3d Object
```

```
plot_mv_polytope (mv_polytope, mark_endpoints=True, circle_size=0.06, circle_thickness=1.6,
wireframe='blue', fill='green', alpha=1, **options)
```

Plot an MV polytope.

INPUT:

- `mv_polytope` -- an MV polytope
- `mark_endpoints` -- (default: True) mark the endpoints of the MV polytope
- `circle_size` -- (default: 0.06) the size of the circles
- `circle_thickness` -- (default: 1.6) the thickness of the extra rings of circles
- `wireframe` -- (default: 'blue') color to draw the wireframe of the polytope with
- `fill` -- (default: 'green') color to fill the polytope with
- `alpha` -- (default: 1) the alpha value (opacity) of the fill
- `**options` -- plotting options

See also:

- `plot()` for a description of the plotting options
- Tutorial: visualizing root systems for a tutorial on root system plotting

EXAMPLES:

```python
sage: B = crystals.infinity.MVPolytopes(['C',2])
# needs sage.combinat
sage: L = RootSystem(['C',2]).ambient_space()
# needs sage.combinat
sage: p = B.highest_weight_vector().f_string([1,2,1,2])
# needs sage.combinat
sage: L.plot_fundamental_weights() + L.plot_mv_polytope(p)
# needs sage.combinat sage.geometry.polyhedron sage.plot sage.symbolic
Graphics object consisting of 14 graphics primitives
```

```python
>>> from sage.all import *
```
```python
>>> B = crystals.infinity.MVPolytopes(['C',Integer(2)])
# needs sage.combinat
>>> L = RootSystem(['C',Integer(2)]).ambient_space()
>>> p = B.highest_weight_vector().f_string([Integer(1),Integer(2),
Integer(1),Integer(2)])
# needs sage.combinat
```

(continues on next page)
This also works in 3 dimensions:

```python
sage: B = crystals.infinity.MVPolytopes(['A',3])  # needs sage.combinat
sage: L = RootSystem(['A',3]).ambient_space()
sage: p = B.highest_weight_vector().f_string([2,1,3,2])  # needs sage.combinat
sage: L.plot_mv_polytope(p)  # needs sage.combinat sage.geometry.polyhedron sage.plot sage.symbolic
```

```
Graphics3d Object
```

```
plot_parse_options(**args)
```
Return an option object to be used for root system plotting.

EXAMPLES:

```python
sage: L = RootSystem(['A',2,1]).ambient_space()
sage: options = L.plot_parse_options(); options  # needs sage.combinat
<sage.combinat.root_system.plot.PlotOptions object at ...>
```

```python
>>> from sage.all import *
```

```python
>>> B = crystals.infinity.MVPolytopes(['A',Integer(3)])  # needs sage.combinat
>>> L = RootSystem(['A',Integer(3)]).ambient_space()
>>> p = B.highest_weight_vector().f_string([Integer(2),Integer(1),
Integer(3),Integer(2)])  # needs sage.combinat
>>> L.plot_mv_polytope(p)  # needs sage.combinat sage.geometry.polyhedron sage.plot sage.symbolic
```

```
Graphics3d Object
```

See also:

- `plot()` for a description of the plotting options
- `Tutorial: visualizing root systems` for a tutorial on root system plotting

```
plot_reflection_hyperplanes(collection='simple', **options)
```
Plot the simple reflection hyperplanes.

INPUT:

- `collection` – which reflection hyperplanes to display. Can be one of the following:
  - "simple" (the default)
  - "classical"
  - "all"
- **options – Plotting options

See also:
• `plot()` for a description of the plotting options
• *Tutorial: visualizing root systems* for a tutorial on root system plotting

EXAMPLES:

```python
sage: # needs sage.plot sage.symbolic
sage: RootSystem(['A',2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(['G',2,1]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
sage: RootSystem(['A',3]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['B',3]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['A',3,1]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['B',3,1]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
sage: RootSystem(['A',2,1]).weight_space().plot_reflection_hyperplanes(affine=False, level=1)
Graphics3d Object
sage: RootSystem(['A',2]).root_lattice().plot_reflection_hyperplanes()
Graphics object consisting of 4 graphics primitives
```

```
>>> from sage.all import *
>>> # needs sage.plot sage.symbolic
>>> RootSystem(['A',Integer(2),Integer(1)]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
>>> RootSystem(['G',Integer(2),Integer(1)]).ambient_space().plot_reflection_hyperplanes()
Graphics object consisting of 6 graphics primitives
>>> RootSystem(['A',Integer(3)]).weight_space().plot_reflection_hyperplanes()
Graphics3d Object
>>> RootSystem(['B',Integer(3)]).ambient_space().plot_reflection_hyperplanes()
Graphics3d Object
>>> RootSystem(['A',Integer(3),Integer(1)]).weight_space().plot_reflection_hyperplanes(affine=False, level=Integer(1))
Graphics3d Object
>>> RootSystem(['A',Integer(2),Integer(1)]).root_lattice().plot_reflection_hyperplanes()
Graphics object consisting of 4 graphics primitives
```

**Todo:** Provide an option for transparency?

```python
plot_roots(collection='simple', **options)
```
Plot the (simple/classical) roots of this root lattice.

**INPUT:**
• collection – which roots to display can be one of the following:
  – "simple" (the default)
  – "classical"
  – "all"
• **options** – Plotting options

See also:
  • `plot()` for a description of the plotting options
  • `Tutorial: visualizing root systems` for a tutorial on root system plotting

EXAMPLES:

```python
sage: RootSystem(['B',3]).ambient_space().plot_roots()  # needs sage.plot
Graphics3d Object
sage: RootSystem(['B',3]).ambient_space().plot_roots("all")  # needs sage.plot
Graphics3d Object
```

```python
>>> from sage.all import *
>>> L = RootSystem(['A',3]).root_lattice()
>>> L.positive_imaginary_roots()  
```

```python
positive_imaginary_roots()

Return the positive imaginary roots of self.

EXAMPLES:

```python
sage: L = RootSystem(['A',3]).root_lattice()

sage: L.positive_imaginary_roots()
()  
```

```python
sage: L = RootSystem(['A',3,1]).root_lattice()

sage: PIR = L.positive_imaginary_roots(); PIR  
```

```python
>>> from sage.all import *

>>> L = RootSystem(['A',Integer(3)]).root_lattice()

>>> L.positive_imaginary_roots()  
```

```python
>>> L = RootSystem(['A',Integer(3),Integer(1)]).root_lattice()

>>> PIR = L.positive_imaginary_roots(); PIR  
```

(continues on next page)
positive_real_roots()

Return the positive real roots of self.

EXAMPLES:

```python
sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_real_roots()) # needs sage.graphs
 alpha[2], alpha[2] + alpha[3], alpha[3]]

sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PRR = L.positive_real_roots(); PRR
Positive real roots of type ['A', 3, 1]

sage: [PRR.unrank(i) for i in range(10)] # needs sage.graphs
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],

sage: Q = RootSystem(['A',4,2]).root_lattice()
sage: PR = Q.positive_roots() # needs sage.graphs

sage: [PR.unrank(i) for i in range(5)] # needs sage.graphs
[alpha[1],
 alpha[2],
 alpha[1] + alpha[2],
 2*alpha[1] + alpha[2],
 alpha[0] + alpha[1] + alpha[2]]

sage: Q = RootSystem(['D',3,2]).root_lattice()
sage: PR = Q.positive_roots() # needs sage.graphs

sage: [PR.unrank(i) for i in range(5)] # needs sage.graphs
[alpha[1],
 alpha[2],
 alpha[1] + 2*alpha[2],
 alpha[1] + alpha[2],
 alpha[0] + alpha[1] + 2*alpha[2]]
```
>>> from sage.all import *
>>> L = RootSystem(['A',Integer(3)]).root_lattice()
>>> sorted(L.positive_real_roots())
# needs sage.graphs
 alpha[2], alpha[2] + alpha[3], alpha[3]]

>>> L = RootSystem(['A',Integer(3),Integer(1)]).root_lattice()
>>> PRR = L.positive_real_roots(); PRR
# needs sage.graphs
Positive real roots of type ['A', 3, 1]
>>> [PRR.unrank(i) for i in range(Integer(10))]
# needs sage.graphs
[alpha[1], alpha[2], alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],

>>> Q = RootSystem(['A',Integer(4),Integer(2)]).root_lattice()
>>> PR = Q.positive_roots()
# needs sage.graphs
>>> [PR.unrank(i) for i in range(Integer(5))]
# needs sage.graphs
[alpha[1], alpha[2],
 alpha[1] + alpha[2],
 2*alpha[1] + alpha[2],
 alpha[0] + alpha[1] + alpha[2]]

>>> Q = RootSystem(['D',Integer(3),Integer(2)]).root_lattice()
>>> PR = Q.positive_roots()
# needs sage.graphs
>>> [PR.unrank(i) for i in range(Integer(5))]
# needs sage.graphs
[alpha[1], alpha[2],
 alpha[1] + 2*alpha[2],
 alpha[1] + alpha[2],
 alpha[0] + alpha[1] + 2*alpha[2]]

**positive_roots** (*index_set=None*)

Return the positive roots of self.

If *index_set* is not None, returns the positive roots of the parabolic subsystem with simple roots in *index_set*.

Algorithm for finite type: generate them from the simple roots by applying successive reflections toward the positive chamber.

**EXAMPLES:**
```python
sage: L = RootSystem(['A',3]).root_lattice()
sage: sorted(L.positive_roots())  # needs sage.graphs
[alpha[1], alpha[1] + alpha[2],
 alpha[2] + alpha[3], alpha[3]]
sage: sorted(L.positive_roots((1,2)))  # needs sage.graphs
[alpha[1], alpha[1] + alpha[2], alpha[2]]
sage: sorted(L.positive_roots(()))  # needs sage.graphs
[]
sage: L = RootSystem(['A',3,1]).root_lattice()
sage: PR = L.positive_roots(); PR  # needs sage.graphs
Disjoint union of Family (Positive real roots of type ['A', 3, 1],
 Positive imaginary roots of type ['A', 3, 1])
sage: [PR.unrank(i) for i in range(10)]  # needs sage.graphs
[alpha[1],
 alpha[2],
 alpha[3],
 alpha[1] + alpha[2],
 alpha[2] + alpha[3],
```
Combinatorics, Release 10.4

(continued from previous page)

\[
\begin{align*}
\alpha[1] + \alpha[2] + \alpha[3], \\
\alpha[0] + 2*\alpha[1] + \alpha[2] + \alpha[3], \\
\alpha[0] + \alpha[1] + 2*\alpha[2] + \alpha[3], \\
\alpha[0] + \alpha[1] + \alpha[2] + 2*\alpha[3], \\
\alpha[0] + 2*\alpha[1] + 2*\alpha[2] + \alpha[3]
\end{align*}
\]

**positive_roots_by_height** *(increasing=True)*

Return a list of positive roots in increasing order by height.

If `increasing` is False, returns them in decreasing order.

**Warning:** Raise an error if the Cartan type is not finite.

EXAMPLES:

```python
sage: L = RootSystem(['C',2]).root_lattice()
sage: L.positive_roots_by_height()  # needs sage.graphs
[\alpha[2], \alpha[1], \alpha[1] + \alpha[2], 2*\alpha[1] + \alpha[2]]
sage: L.positive_roots_by_height(increasing=False)  # needs sage.graphs
[2*\alpha[1] + \alpha[2], \alpha[1] + \alpha[2], \alpha[2], \alpha[1]]
```

```python
sage: L = RootSystem(['A',2,1]).root_lattice()
sage: L.positive_roots_by_height()  # needs sage.graphs
Traceback (most recent call last):
  ...
NotImplementedError: Only implemented for finite Cartan type
```

```python
>>> from sage.all import *
>>> L = RootSystem(['C',Integer(2)]).root_lattice()
>>> L.positive_roots_by_height()  # needs sage.graphs
[\alpha[2], \alpha[1], \alpha[1] + \alpha[2], 2*\alpha[1] + \alpha[2]]
>>> L.positive_roots_by_height(increasing=False)  # needs sage.graphs
[2*\alpha[1] + \alpha[2], \alpha[1] + \alpha[2], \alpha[2], \alpha[1]]
```

```python
>>> L = RootSystem(['A',Integer(2),Integer(1)]).root_lattice()
>>> L.positive_roots_by_height()  # needs sage.graphs
Traceback (most recent call last):
  ...
NotImplementedError: Only implemented for finite Cartan type
```

**positive_roots_nonparabolic** *(index_set=None)*

Return the set of positive roots outside the parabolic subsystem with Dynkin node set `index_set`.

**INPUT:**

- `index_set` – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set.

**EXAMPLES:**
sage: # needs sage.graphs
sage: lattice = RootSystem(['A', 3]).root_lattice()
sage: sorted(lattice.positive_roots_nonparabolic((1, 3)), key=str)
sage: sorted(lattice.positive_roots_nonparabolic((2, 3)), key=str)
sage: lattice.positive_roots_nonparabolic()
[]
sage: lattice.positive_roots_nonparabolic((1, 2, 3))
[]

>>> from sage.all import *
>>> # needs sage.graphs
>>> lattice = RootSystem(['A', Integer(3)]).root_lattice()
>>> sorted(lattice.positive_roots_nonparabolic((Integer(1), Integer(3)),
  →key=str)
>>> sorted(lattice.positive_roots_nonparabolic((Integer(2), Integer(3)),
  →key=str)
>>> lattice.positive_roots_nonparabolic()
[]
>>> lattice.positive_roots_nonparabolic((Integer(1), Integer(2),
  →Integer(3)))
[]

Warning: This returns an error if the Cartan type is not finite.

positive_roots_nonparabolic_sum(index_set=None)

Return the sum of positive roots outside the parabolic subsystem with Dynkin node set index_set.

INPUT:
• index_set – (default: None) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set

EXAMPLES:

sage: # needs sage.graphs
sage: lattice = RootSystem(['A', 3]).root_lattice()
sage: lattice.positive_roots_nonparabolic_sum((1, 3))
sage: lattice.positive_roots_nonparabolic_sum((2, 3))
sage: lattice.positive_roots_nonparabolic_sum((1, 2, 3))
0

>>> from sage.all import *
>>> # needs sage.graphs
>>> lattice = RootSystem(['A', Integer(3)]).root_lattice()
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> lattice.positive_roots_nonparabolic_sum((Integer(1),Integer(3)))
>>> lattice.positive_roots_nonparabolic_sum((Integer(2),Integer(3)))
>>> lattice.positive_roots_nonparabolic_sum(()
>>> lattice.positive_roots_nonparabolic_sum()
0
```

**Warning:** This returns an error if the Cartan type is not finite.

### positive_roots_parabolic(index_set=None)

Return the set of positive roots for the parabolic subsystem with Dynkin node set `index_set`.

**INPUT:**
- `index_set` – (default: `None`) the Dynkin node set of the parabolic subsystem. It should be a tuple. The default value implies the entire Dynkin node set.

**EXAMPLES:**

```python
sage: lattice = RootSystem(['A',3]).root_lattice()
sage: sorted(lattice.positive_roots_parabolic((1,3)), key=str)  # needs sage.graphs
[alpha[1], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic((2,3)), key=str)  # needs sage.graphs
[alpha[2], alpha[2] + alpha[3], alpha[3]]
sage: sorted(lattice.positive_roots_parabolic(), key=str)  # needs sage.graphs
 alpha[2], alpha[2] + alpha[3], alpha[3]]
```

**Warning:** This returns an error if the Cartan type is not finite.

### projection(root, coroot=None, to_negative=True)

Return the projection along the `root`, and across the hyperplane defined by `coroot`, as a function $\pi$ from `self` to `self`.

```python
>>> from sage.all import *
>>> lattice = RootSystem(['A',3]).root_lattice()
>>> sorted(lattice.positive_roots_parabolic((Integer(1),Integer(3))),
   key=str)  # needs sage.graphs
[alpha[1], alpha[3]]
>>> sorted(lattice.positive_roots_parabolic((Integer(2),Integer(3))),
   key=str)  # needs sage.graphs
[alpha[2], alpha[2] + alpha[3], alpha[3]]
>>> sorted(lattice.positive_roots_parabolic(), key=str)  # needs sage.graphs
 alpha[2], alpha[2] + alpha[3], alpha[3]]
```
\( \pi \) is a half-linear map which stabilizes the negative half space and acts by reflection on the positive half space.

If `to_negative` is `False`, then project onto the positive half space instead.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: y = space.simple_coroots()[1]
sage: pi = space.projection(x,y)
sage: x
sage: pi(x)
sage: pi(-x)
sage: pi = space.projection(x,y,
False)
sage: pi(-x)
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> space = RootSystem(['A',Integer(2)]).weight_lattice()
>>> x = space.simple_roots()[Integer(1)]
>>> y = space.simple_coroots()[Integer(1)]
>>> pi = space.projection(x,y)
>>> x
>>> pi(x)
>>> pi(-x)
>>> pi = space.projection(x,y, False)
>>> pi(-x)
```

`reflection(root, coroot=None)`

Return the reflection along the `root`, and across the hyperplane defined by `coroot`, as a function from `self` to `self`.

**EXAMPLES:**

```python
sage: # needs sage.graphs
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: y = space.simple_coroots()[1]
sage: s = space.reflection(x,y)
sage: x
sage: s(x)
sage: s(-x)
```

```python
>>> from sage.all import *
>>> # needs sage.graphs
>>> space = RootSystem(['A',Integer(2)]).weight_lattice()
>>> x = space.simple_roots()[Integer(1)]
>>> y = space.simple_coroots()[Integer(1)]
>>> s = space.reflection(x,y)
>>> x
>>> s(x)
>>> s(-x)
```

(continues on next page)
>> space = RootSystem(['A', Integer(2)]).weight_lattice()
>> x = space.simple_roots()[Integer(1)]
>> y = space.simple_coroots()[Integer(1)]
>> s = space.reflection(x, y)
>> x
>> s(x)
>> s(-x)

root_poset (restricted=False, facade=False)

Return the (restricted) root poset associated to self.
The elements are given by the positive roots (resp. non-simple, positive roots), and \( \alpha \leq \beta \) iff \( \beta - \alpha \) is a non-negative linear combination of simple roots.

INPUT:
- restricted – (default: False) if True, only non-simple roots are considered.
- facade – (default: False) passes facade option to the poset generator.

EXAMPLES:

```python
sage: # needs sage.graphs
sage: Phi = RootSystem(['A',1]).root_poset(); Phi
Finite poset containing 1 elements
sage: Phi.cover_relations()
[]
```

\[
[[\alpha_1 + \alpha_2, \alpha_1 + \alpha_2 + \alpha_3],
[\alpha_2 + \alpha_3, \alpha_1 + \alpha_2 + \alpha_3]]
\]

\[
>>> \text{Phi} = \text{RootSystem('B',Integer(2)).root_poset(); Phi}
\]

Finite poset containing 4 elements

\[
>>> \text{sorted(Phi.cover_relations(), key=str)}
[[\alpha_1 + \alpha_2, \alpha_1 + 2\alpha_2],
[\alpha_1, \alpha_1 + \alpha_2],
[\alpha_2, \alpha_1 + \alpha_2]]
\]

roots()

Return the roots of self.

EXAMPLES:

\[
\text{sage: RootSystem(['A',2]).ambient_lattice().roots()}
[(1, -1, 0), (1, 0, -1), (0, 1, -1), (-1, 1, 0), (-1, 0, 1), (0, -1, 1)]
\]

This matches with Wikipedia article Root_systems:

\[
\text{sage: for T in CartanType.samples(finite=True, crystallographic=True): #...}
\]

\[
\text{print("%s %3s %3s"%(T, len(RootSystem(T).root_lattice().roots()), len(RootSystem(T).weight_lattice().roots())))}
\]

\[
[A, 1] 2 2
[A, 5] 30 30
[B, 1] 2 2
[B, 5] 50 50
[C, 1] 2 2
[C, 5] 50 50
[D, 2] 4 4
[D, 3] 12 12
[D, 5] 40 40
[E, 6] 72 72
[E, 7] 126 126
[E, 8] 240 240
[F, 4] 48 48
[G, 2] 12 12
\]

(continues on next page)
Todo: The result should be an enumerated set, and handle infinite root systems.

\( s() \)

Return the family \((s_i)_{i \in I}\) of the simple reflections of this root system.

**EXAMPLES:**

```python
sage: r = RootSystem(['A', 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) )  # needs sage.graphs
-alpha[1]
```

\( \text{short_roots}() \)

Return a list of the short roots of \( \text{self} \).

**EXAMPLES:**

```python
sage: L = RootSystem(['B',3]).root_lattice()
sage: sorted(L.short_roots())  # needs sage.graphs
-alpha[2] - alpha[3],
 alpha[2] + alpha[3],
-alpha[3],
 alpha[3]]
```

```python
>>> from sage.all import *
>>> r = RootSystem(['B', Integer(3)]).root_lattice()
>>> sorted(r.short_roots())  # needs sage.graphs
-alpha[2] - alpha[3],
 alpha[2] + alpha[3],
-alpha[3],
 alpha[3]]
```
simple_coroot($i$)
Returns the $i^{th}$ simple coroot.
EXAMPLES:

```
sage: RootSystem(['A',2]).root_lattice().simple_coroot(1)
alphacheck[1]
```

```
>>> from sage.all import *
>>> RootSystem(['A',Integer(2)]).root_lattice().simple_coroot(Integer(1))
alphacheck[1]
```

simple_coroots()
Returns the family $(\alpha_i^\vee)_{i \in I}$ of the simple coroots.
EXAMPLES:

```
sage: alphacheck = RootSystem(['A',3]).root_lattice().simple_coroots()
sage: [alphacheck[i] for i in [1, 2, 3]]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

```
>>> from sage.all import *
>>> alphacheck = RootSystem(['A',Integer(3)]).root_lattice().simple_coroots()
>>> [alphacheck[i] for i in [Integer(1), Integer(2), Integer(3)]
[alphacheck[1], alphacheck[2], alphacheck[3]]
```

simple_projection($i$, to_negative=True)
Return the projection along the $i$-th simple root, and across the hyperplane define by the $i$-th simple coroot, as a function from self to self.

INPUT:
• $i$ - an element of the index set of self

EXAMPLES:

```
sage: # needs sage.graphs
sage: space = RootSystem(['A',2]).weight_lattice()
sage: x = space.simple_roots()[1]
sage: pi = space.simple_projection(1)
sage: x
sage: pi(x)
sage: pi(-x)
sage: pi = space.simple_projection(1,False)
sage: pi(-x)
```

```
>>> from sage.all import *
>>> # needs sage.graphs
>>> space = RootSystem(['A',Integer(2)]).weight_lattice()
>>> x = space.simple_roots()[Integer(1)]
>>> pi = space.simple_projection(Integer(1))
>>> x
```

(continues on next page)
Combinatorics, Release 10.4

>>> pi(x)
>>> pi(-x)
>>> pi = space.simple_projection(Integer(1),False)
>>> pi(-x)

**simple_projections**(to_negative=True)

Return the family \((s_i)_{i \in I}\) of the simple projections of this root system.

EXAMPLES:

```
sage: space = RootSystem(['A',2]).weight_lattice()
sage: pi = space.simple_projections()  # needs sage.graphs
sage: x = space.simple_roots()  # needs sage.graphs
sage: pi[1](x[2])  # needs sage.graphs
```

>>> from sage.all import *
>>> space = RootSystem(['A',Integer(2)]).weight_lattice()
>>> pi = space.simple_projections()  # needs sage.graphs
>>> x = space.simple_roots()  # needs sage.graphs
>>> pi[Integer(1)](x[Integer(2)])  # needs sage.graphs

**simple_reflection**(i)

Return the \(i\)-th simple reflection, as a function from \(self\) to \(self\).

INPUT:

- \(i\) – an element of the index set of \(self\)

EXAMPLES:

```
sage: space = RootSystem(['A',2]).ambient_lattice()
sage: s = space.simple_reflection(1)
sage: x = space.simple_roots()[1]; x
(1, -1, 0)
sage: s(x)
(-1, 1, 0)
```

>>> from sage.all import *
>>> space = RootSystem(['A',Integer(2)]).ambient_lattice()
>>> s = space.simple_reflection(Integer(1))
>>> x = space.simple_roots()[Integer(1)]; x
(1, -1, 0)
>>> s(x)
(-1, 1, 0)

**simple_reflections**(()

Return the family \((s_i)_{i \in I}\) of the simple reflections of this root system.
EXAMPLES:

```python
sage: r = RootSystem(['A', 2]).root_lattice()
sage: s = r.simple_reflections()
sage: s[1]( r.simple_root(1) ) # needs sage.graphs
-\alpha[1]
```

```python
from sage.all import *
>> r = RootSystem(['A', Integer(2)]).root_lattice()
>> s = r.simple_reflections()
>> s[Integer(1)]( r.simple_root(Integer(1)) ) # needs sage.graphs
-\alpha[1]
```

**simple_root**(i)

Return the i-th simple root.

This should be overridden by any subclass, and typically implemented as a cached method for efficiency.

EXAMPLES:

```python
sage: r = RootSystem(['A',3]).root_lattice()
sage: r.simple_root(1)
alpha[1]
```

```python
from sage.all import *
>> r = RootSystem(['A',Integer(3)]).root_lattice()
>> r.simple_root(Integer(1))
alpha[1]
```

**simple_roots()**

Return the family $\left(\alpha_i\right)_{i \in I}$ of the simple roots.

EXAMPLES:

```python
sage: alpha = RootSystem(['A',3]).root_lattice().simple_roots()
sage: [alpha[i] for i in [1,2,3]]
[alpha[1], alpha[2], alpha[3]]
```

```python
from sage.all import *
>> alpha = RootSystem(['A',Integer(3)]).root_lattice().simple_roots()
>> [alpha[i] for i in [Integer(1), Integer(2), Integer(3)]]
[alpha[1], alpha[2], alpha[3]]
```

**simple_roots_tilde()**

Return the family $\left(\hat{\alpha}_i\right)_{i \in I}$ of the simple roots.

**INPUT:**

- `self` -- an affine root lattice realization

The $\hat{\alpha}_i$ give the embedding of the root lattice of the other affinization of the same classical root lattice into this root lattice (space?).

This uses the fact that $\alpha_i = \hat{\alpha}_i$ for $i$ not a special node, and that

$$
\delta = \sum a_i \alpha_i = \sum b_i \hat{\alpha}_i
$$

EXAMPLES:
In simply laced cases, this is boring:

```
sage: RootSystem(["A",3, 1]).root_lattice().simple_roots_tilde()  # needs sage.graphs
Finite family {0: alpha[0], 1: alpha[1], 2: alpha[2], 3: alpha[3]}
```

This was checked by hand:

```
sage: RootSystem(["C",2,1]).coroot_lattice().simple_roots_tilde()  # needs sage.graphs
Finite family {0: alphacheck[0] - alphacheck[2],
    1: alphacheck[1],
    2: alphacheck[2]}
sage: RootSystem(["B",2,1]).coroot_lattice().simple_roots_tilde()  # needs sage.graphs
Finite family {0: alphacheck[0] - alphacheck[1],
    1: alphacheck[1],
    2: alphacheck[2]}
```

What about type BC?

```
some_elements()
```

Return some elements of this root lattice realization.

EXAMPLES:

```
sage: L = RootSystem(["A",2]).weight_lattice()
sage: L.some_elements()  # needs sage.graphs
    -Lambda[1] + 2*Lambda[2], Lambda[1], Lambda[2]]
sage: L = RootSystem(["A",2]).root_lattice()
sage: L.some_elements()
```

```
tau_epsilon_operator_on_almost_positive_roots(J)

The $\tau_\epsilon$ operator on almost positive roots.

Given a subset $J$ of non adjacent vertices of the Dynkin diagram, this constructs the operator on the almost positive roots which fixes the negative simple roots $\alpha_i$ for $i$ not in $J$, and acts otherwise by:

$$\tau_+(\beta) = \prod_{i \in J} s_i(\beta)$$

See Equation (1.2) of [CFZ2002].

EXAMPLES:

```python
sage: L = RootSystem(['A',4]).root_lattice()
sage: tau = L.tau_epsilon_operator_on_almost_positive_roots([1,3])  # needs sage.libs.gap
sage: alpha = L.simple_roots()  # needs sage.graphs
```

The action on a negative simple root not in $J$:

```python
sage: tau(-alpha[2])  # needs sage.graphs sage.libs.gap
-alpha[2]
```

```python
>>> from sage.all import *
```

The action on a negative simple root in $J$:

```python
sage: tau(-alpha[1])  # needs sage.graphs sage.libs.gap
alpha[1]
```

The action on all almost positive roots:

```python
>>> from sage.all import *
```

5.1. Comprehensive Module List 4087
This method works on any root lattice realization:
See also:

tau_plus_minus()

tau_plus_minus()

Return the $\tau^+$ and $\tau^-$ piecewise linear operators on self.

Those operators are induced by the bipartition $\{L, R\}$ of the simple roots of self, and stabilize the almost positive roots. Namely, $\tau^+$ fixes the negative simple roots $\alpha_i$ for $i \in R$, and acts otherwise by:

$$
\tau^+(\beta) = \prod_{s_i \in L} s_i(\beta)
$$

$\tau^-$ acts analogously, with $L$ and $R$ interchanged.

Those operators are used to construct the associahedron, a polytopal realization of the cluster complex (see Associahedron).

See also:

tau_epsilon_operator_on_almost_positive_roots()

EXAMPLES:

We explore the example of [CFZ2002] Eq.(1.3):

```python
sage: S = RootSystem(['A',2]).root_lattice()
sage: taup, taum = S.tau_plus_minus()  # needs sage.graphs sage.libs.gap
sage: for beta in S.almost_positive_roots():  # needs sage.graphs sage.libs.gap
....:     print("{}", "{}", "{}").format(beta, taup(beta), taum(beta))
```

See also:

tau_plus_minus()
\(-\alpha[1], \alpha[1], -\alpha[1]\)
\(\alpha[1], -\alpha[1], \alpha[1] + \alpha[2]\)
\(\alpha[1] + \alpha[2], \alpha[2], \alpha[1]\)
\(-\alpha[2], -\alpha[2], \alpha[2]\)
\(\alpha[2], \alpha[1] + \alpha[2], -\alpha[2]\)

```python
>>> from sage.all import *
>>> S = RootSystem(['A',Integer(2)]).root_lattice()
>>> taup, taum = S.tau_plus_minus()
...
for beta in S.almost_positive_roots():
...
    print("{}", {}, {}".format(beta, taup(beta), taum(beta)))
```

**to_ambient_space_morphism()**

Return the morphism to the ambient space.

**EXAMPLES:**

```python
sage: B2rs = CartanType(['B',2]).root_system()
sage: B2rs.root_lattice().to_ambient_space_morphism()
Generic morphism:
    From: Root lattice of the Root system of type ['B', 2]
    To: Ambient space of the Root system of type ['B', 2]
sage: B2rs.coroot_lattice().to_ambient_space_morphism()
Generic morphism:
    From: Coroot lattice of the Root system of type ['B', 2]
    To: Ambient space of the Root system of type ['B', 2]
sage: B2rs.weight_lattice().to_ambient_space_morphism()
Generic morphism:
    From: Weight lattice of the Root system of type ['B', 2]
    To: Ambient space of the Root system of type ['B', 2]
```

```python
>>> from sage.all import *
>>> B2rs = CartanType(['B',Integer(2)]).root_system()
>>> B2rs.root_lattice().to_ambient_space_morphism()
Generic morphism:
    From: Root lattice of the Root system of type ['B', 2]
    To: Ambient space of the Root system of type ['B', 2]
>>> B2rs.coroot_lattice().to_ambient_space_morphism()
Generic morphism:
    From: Coroot lattice of the Root system of type ['B', 2]
    To: Ambient space of the Root system of type ['B', 2]
>>> B2rs.weight_lattice().to_ambient_space_morphism()
Generic morphism:
    From: Weight lattice of the Root system of type ['B', 2]
    To: Ambient space of the Root system of type ['B', 2]
```

**weyl_group** *(prefix=None)*

Return the Weyl group associated to self.

**EXAMPLES:**
sage: RootSystem(['F',4]).ambient_space().weyl_group()  # needs sage.libs.gap
Weyl Group of type ['F', 4] (as a matrix group acting on the ambient space)
sage: RootSystem(['F',4]).root_space().weyl_group()  # needs sage.libs.gap
Weyl Group of type ['F', 4] (as a matrix group acting on the root space)

>>> from sage.all import *
>>> RootSystem(['F',Integer(4)]).ambient_space().weyl_group()  # needs sage.libs.gap
Weyl Group of type ['F', 4] (as a matrix group acting on the ambient space)
>>> RootSystem(['F',Integer(4)]).root_space().weyl_group()  # needs sage.libs.gap
Weyl Group of type ['F', 4] (as a matrix group acting on the root space)

super_categories()

EXAMPLES:

sage: from sage.combinat.root_system.root_lattice_realizations import RootLatticeRealizations
sage: RootLatticeRealizations(QQ).super_categories()
[Category of vector spaces with basis over Rational Field]

>>> from sage.all import *
>>> from sage.combinat.root_system.root_lattice_realizations import RootLatticeRealizations
>>> RootLatticeRealizations(QQ).super_categories()
[Category of vector spaces with basis over Rational Field]

5.1.240 Root lattices and root spaces

class sage.combinat.root_system.root_space.RootSpace(root_system, base_ring)

Bases: CombinatorialFreeModule

The root space of a root system over a given base ring

INPUT:

• root_system — a root system
• base_ring: a ring \( R \)

The root space (or lattice if base_ring is \( \mathbb{Z} \)) of a root system is the formal free module \( \bigoplus_{i \in I} R \alpha_i \) generated by the simple roots \( \{\alpha_i\}_{i \in I} \) of the root system.

This class is also used for coroot spaces (or lattices).

See also:

• RootSystem()
• RootSystem.root_lattice() and RootSystem.root_space()
• RootLatticeRealizations()

Todo: standardize the variable used for the root space in the examples (P?)
Element

alias of \textit{RootSpaceElement}

\texttt{simple\_root}()

Return the basis element indexed by \texttt{i}.

\textbf{INPUT}:

- \texttt{i} – an element of the index set

\textbf{EXAMPLES}:

```python
sage: F = CombinatorialFreeModule(QQ, [\texttt{a}, \texttt{b}, \texttt{c}])
sage: F.monomial(\texttt{a})
B[\texttt{a}]
```

\texttt{F.monomial} is in fact (almost) a map:

```python
sage: F.monomial
