(continues on next page)
Display a DyckWord as a lattice path in the $\mathbb{Z}^2$ grid.

If the type is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

If the type is “NE-SE”, then the path is simply printed as up steps and down steps.

**INPUT:**

- **type** – (default: None) can either be:
  - None to use the option default
  - “N-E” to show self as a path of north and east steps, or
  - “NE-SE” to show self as a path of north-east and south-east steps.

- **labelling** – (if type is “N-E”) a list of labels assigned to the up steps in self.

- **underpath** – (if type is “N-E”, default: True) If True, the labelling is shown under the path; otherwise, it is shown to the right of the path.
EXAMPLES:

```

returns_to_zero()

Return a list of positions where self has height 0, excluding the position 0.

EXAMPLES:

sage: DyckWord([]).returns_to_zero()
[1]
sage: DyckWord([1, 0]).returns_to_zero()
[2]
sage: DyckWord([1, 0, 1, 0]).returns_to_zero()
[2, 4]
sage: DyckWord([1, 1, 0, 0]).returns_to_zero()
[4]

sage: DyckWord([Integer(1), Integer(0)]).returns_to_zero()
[1]
sage: DyckWord([Integer(1), Integer(0)]).returns_to_zero()
[2]
sage: DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).returns_to_zero()
[2, 4]
sage: DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).returns_to_zero()
[4]
rise_composition()

The sequences of lengths of runs of 1's in self. Also equal to the sequence of lengths of vertical segments in the Dyck path.

EXAMPLES:

```sage
dyck = DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).pretty_print()

| x
|_______|
| x x x .
| x x ...
| x . . .
| x . . . .
| . . . . .

dyck = DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).rise_composition()
[2, 3, 2]
dyck = DyckWord([1, 0, 1, 0]).rise_composition()
[1, 1]
```

```python
>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),
                Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),
                Integer(1), Integer(0), Integer(0)]).pretty_print()

| x
|_______|
| x x x .
| x x ...
| x . . .
| x . . . .
| . . . . .

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),
                Integer(1), Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),
                Integer(1), Integer(0), Integer(0)]).rise_composition()
[2, 3, 2]

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).rise_composition()
[1, 1]
```

set_latex_options(D)

Set the latex options for use in the _latex_ function.

The default values are set in the __init__ function.

- **tikz_scale** – (default: 1) scale for use with the tikz package.
- **diagonal** – (default: False) boolean value to draw the diagonal or not.
- **line width** – (default: 2**“tikz_scale”) value representing the line width.
- **color** – (default: black) the line color.
- **bounce path** – (default: False) boolean value to indicate if the bounce path should be drawn.
- **peaks** – (default: False) boolean value to indicate if the peaks should be displayed.
• valleys – (default: False) boolean value to indicate if the valleys should be displayed.

INPUT:
• D – a dictionary with a list of latex parameters to change

EXAMPLES:

```sage
D = DyckWord([1,0,1,0,1,0])
D.set_latex_options({"tikz_scale":2})
D.set_latex_options({"valleys":True, "color":"blue"})
```

```sage
from sage.all import *
D = DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
           Integer(0)]
D.set_latex_options({"tikz_scale":Integer(2)})
D.set_latex_options({"valleys":True, "color":"blue"})
```

Todo: This should probably be merged into DyckWord.options.

tamari_interval (other)

Return the Tamari interval between self and other as a TamariIntervalPoset.

A “Tamari interval” means an interval in the Tamari order. The Tamari order on the set of Dyck words of size \( n \) is the partial order obtained from the Tamari order on the set of binary trees of size \( n \) (see `tamari_lequal()`) by means of the Tamari bijection between Dyck words and binary trees (`to_dyck_word_tamari()`).

INPUT:
• other – a Dyck word greater or equal to self in the Tamari order

EXAMPLES:

```sage
# needs sage.graphs
dw = DyckWord([1, 1, 0, 1, 0, 0, 1, 0])
ip = dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 1, 0, 0])); ip
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), ...
(2, 1)]
ip.lower_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]
ip.upper_dyck_word()
[1, 1, 1, 0, 0, 1, 0, 0]
ip.interval_cardinality()
4
ip.number_of_tamari_inversions()
2
dw.tamari_interval(DyckWord([1,1,0,0,1,1,0,0]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice
```
```python
>>> from sage.all import *
>>> # needs sage.graphs

>>> dw = DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)])

>>> ip = dw.tamari_interval(DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0), Integer(0)])); ip

The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)]

>>> ip.lower_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]

>>> ip.upper_dyck_word()
[1, 1, 1, 0, 0, 1, 0, 0]

>>> ip.interval_cardinality()
4

>>> ip.number_of_tamari_inversions()
2

>>> list(ip.dyck_words())
[[1, 1, 1, 0, 0, 1, 0, 0], [1, 1, 1, 0, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 0, 1, 0, 0, 1, 0]]

>>> dw.tamari_interval(DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice
```

to_area_sequence()

Return the area sequence of the Dyck word self.

The area sequence of a Dyck word \( w \) is defined as follows: Representing the Dyck word \( w \) as a Dyck path from \((0, 0)\) to \((n, n)\) using \( N \) and \( E \) steps (this involves padding \( w \) by \( E \) steps until \( w \) reaches the main diagonal if \( w \) is not already a complete Dyck path), the area sequence of \( w \) is the sequence \((a_1, a_2, \ldots, a_n)\), where \( a_i \) is the number of full cells in the \( i \)-th row of the rectangle \([0, n] \times [0, n]\) which lie completely above the diagonal. (The cells are the regions into which the rectangle is subdivided by the lines \( x = i \) with \( i \) integer and the lines \( y = j \) with \( j \) integer. The \( i \)-th row consists of all the cells between the lines \( y = i - 1 \) and \( y = i \).)

An alternative definition: Representing the Dyck word \( w \) as a Dyck path consisting of \( NE \) and \( SE \) steps, the area sequence is the sequence of ordinates of all lattice points on the path which are starting points of \( NE \) steps.

A list of integers \( l \) is the area sequence of some Dyck path if and only if it satisfies \( l_0 = 0 \) and \( 0 \leq l_{i+1} \leq l_i + 1 \) for \( i > 0 \).

EXAMPLES:

```python
sage: DyckWord([]).to_area_sequence()
[]
sage: DyckWord([1, 0]).to_area_sequence()
[0]
sage: DyckWord([1, 1, 0]).to_area_sequence()
[0, 1]
sage: DyckWord([1, 1, 0, 0]).to_area_sequence()
[0, 0]
sage: all(dw == ....: DyckWords().from_area_sequence(dw.to_area_sequence())
  ....:   for i in range(6) for dw in DyckWords(i))
```
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
DyckWord([1,0,1,0,1,0,1,0,1,0]).to_area_sequence()
[0, 0, 0, 0, 0]

DyckWord([1,1,1,1,0,0,0,0,0]).to_area_sequence()
[0, 1, 2, 3, 4]

DyckWord([1,1,1,1,0,1,0,0,0,0]).to_area_sequence()
[0, 1, 2, 3, 3]

DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_area_sequence()
[0, 1, 1, 0, 1, 1, 1]
```

```python
>>> from sage.all import *

DyckWord([]).to_area_sequence()
[]

DyckWord([Integer(1), Integer(0)]).to_area_sequence()
[0]

DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_area_sequence()
[0, 1]

DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0)]).to_area_sequence()
[0, 0]

all(dw == ...
... DyckWords().from_area_sequence(dw.to_area_sequence()) ...
... for i in range(Integer(6)) for dw in DyckWords(i))
True

DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(0)]).to_area_sequence()
[0, 0, 0, 0, 0, 0, 0, 0, 0]
```

```python
DyckWords().from_area_sequence().to_area_sequence()

DyckWords().from_area_sequence().to_area_sequence()
[0, 1, 2, 3, 3]

DyckWords().from_area_sequence().to_area_sequence()
[0, 1, 1, 0, 1, 1, 1]
```

```python
to_binary_tree(usemap='1L0R')
Return a binary tree recursively constructed from the Dyck path self by the map usemap. The default usemap is '1L0R' which means:

• an empty Dyck word is a leaf,
• a non empty Dyck word reads $1L0R$ where $L$ and $R$ correspond to respectively its left and right subtrees.

INPUT:
• usemap -- a string, either '1L0R', '1R0L', 'L1R0', or 'R1L0'

Other valid usemap are '1R0L', 'L1R0', and 'R1L0'. These correspond to different maps from Dyck paths to binary trees, whose recursive definitions are hopefully clear from the names.

EXAMPLES:
```
```
sage: dw.to_binary_tree()
[., .]
sage: dw = DyckWord([])
sage: dw.to_binary_tree()
.
sage: dw = DyckWord([1,0,1,1,0,0])
sage: dw.to_binary_tree()['LR']
[[., .], [., .]]
sage: dw = DyckWord([1,0,1,0,1,1,0,1,0,0,0])

to_binary_tree_tamari()  
Return the binary tree corresponding to self in a way which is consistent with the Tamari orders on the set of Dyck paths and on the set of binary trees.
This is the 'L1R0' map documented in to_binary_tree().

EXAMPLES:

```python
sage: DyckWord([1,0]).to_binary_tree_tamari()  # needs sage.graphs
[. , .]
sage: DyckWord([1,0,1,0,0]).to_binary_tree_tamari()  # needs sage.graphs
[[. , .], [. , .]]
sage: DyckWord([1,0,1,0,1,0]).to_binary_tree_tamari()  # needs sage.graphs
[[[. , .], .], .]
```

```
>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0)]).to_binary_tree_tamari()  # needs sage.graphs
[. , .]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(1), Integer(0), Integer(0)]).to_binary_tree_tamari()  # needs sage.graphs
[[[. , .], [. , .]], .]
```

to_path_string(unicode=False)
Return a path representation of the Dyck word consisting of steps / and \.

INPUT:

- unicode – boolean (default False) whether to use unicode

EXAMPLES:

```python
sage: print(DyckWord([1, 0, 1, 0]).to_path_string())
/\/
```

```python
sage: print(DyckWord([1, 1, 0, 0]).to_path_string())
/\  
```

```python
sage: print(DyckWord([1,1,0,1,1,0,0,1,0,1,0,0]).to_path_string())
/\  \  
```

```
>>> from sage.all import *

>>> print(DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_path_string())
/\  
```

```
>>> print(DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_path_string())
/\  
```

(continues on next page)
to_standard_tableau()

Return a standard tableau of shape \((a, b)\) where \(a\) is the number of open symbols and \(b\) is the number of close symbols in \(self\).

EXAMPLES:

```python
sage: DyckWord([]).to_standard_tableau()
[]
sage: DyckWord([1, 0]).to_standard_tableau()
[[1], [2]]
sage: DyckWord([1, 1, 0, 0]).to_standard_tableau()
[[1, 1], [3, 4]]
sage: DyckWord([1, 0, 1, 0]).to_standard_tableau()
[[1, 3], [2, 4]]
sage: DyckWord([1]).to_standard_tableau()
[[1]]
sage: DyckWord([1, 0, 1]).to_standard_tableau()
[[1, 3], [2]]
```

from sage.all import *

```python
>>> from sage.all import *

>>> DyckWord([]).to_standard_tableau()
[]

>>> DyckWord([Integer(1), Integer(0)]).to_standard_tableau()
[[1, 2], [3, 4]]

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0)]).to_standard_tableau()
[[1, 2, 3], [4, 5], [6]]
```

to_tamari_sorting_tuple()

Convert a Dyck word to a Tamari sorting tuple.

The result is a list of integers, one for every up-step from left to right. To each up-step is associated the distance to the corresponding down step in the Dyck word.

This is useful for a faster conversion to binary trees.

EXAMPLES:

```python
sage: DyckWord([]).to_tamari_sorting_tuple()
[]

sage: DyckWord([1, 0]).to_tamari_sorting_tuple()
[0]

sage: DyckWord([1, 1, 0, 0]).to_tamari_sorting_tuple()
[0, 1]
```

(continues on next page)
Combinatorics, Release 10.4

sage: DyckWord([1, 0, 1, 0]).to_tamari_sorting_tuple()
[0, 0]
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_tamari_sorting_tuple()
[2, 0, 0]

See also:
to_Catalan_code()

touch_composition()

Return a composition which indicates the positions where self returns to the diagonal.
This assumes self to be a complete Dyck word.

OUTPUT:
• a composition of length equal to the length of the Dyck word.

EXAMPLES:

sage: DyckWord([1, 0, 1, 0]).touch_composition()
[1, 1]
sage: DyckWord([1, 1, 0, 0]).touch_composition()
[2]

(continues on next page)
touch_points()

Return the abscissae (or, equivalently, ordinates) of the points where the Dyck path corresponding to self (comprising \(NE\) and \(SE\) steps) touches the main diagonal. This includes the last point (if it is on the main diagonal) but excludes the beginning point.

Note that these abscissae are precisely the entries of \(\text{return}_\text{to}_\text{zero()}\) divided by 2.

**OUTPUT:**

- a list of integers indicating where the path touches the diagonal

**EXAMPLES:**

```python
>>> DyckWord([1, 0, 1, 0]).touch_points()
[1, 2]
>>> DyckWord([1, 1, 0, 0]).touch_points()
[2]
>>> DyckWord([1, 1, 0, 0, 1, 0]).touch_points()
[2, 3]
>>> DyckWord([1, 0, 1, 1, 0, 0]).touch_points()
[1, 3]
```

valleys()

Return a list of the positions of the valleys of a Dyck word.

A valley is 0 followed by a 1.

**See also:**

peaks(), number_of_valleys()

**EXAMPLES:**

```python
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).valleys()
[1]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).valleys()
[2]
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0)]).valleys()
[1, 3]
```
class sage.combinat.dyck_word.DyckWordBacktracker(k1, k2)

Bases: GenericBacktracker

This class is an iterator for all Dyck words with \( n \) opening parentheses and \( n - k \) closing parentheses using the backtracker class. It is used by the DyckWords_size class.

This is not really meant to be called directly, partially because it fails in a couple corner cases: \( \text{DWB}(0) \) yields \([0]\), not the empty word, and \( \text{DWB}(k, k+1) \) yields something (it shouldn't yield anything). This could be fixed with a sanity check in \_rec(), but then we'd be doing the sanity check every time we generate new objects; instead, we do one sanity check in DyckWords and assume here that the sanity check has already been made.

AUTHOR:
- Dan Drake (2008-05-30)

class sage.combinat.dyck_word.DyckWord_complete (parent, l, latex_options={})

Bases: DyckWord

The class of complete Dyck words. A Dyck word is complete, if it contains as many closers as openers.

For further information on Dyck words, see DyckWords_class.

area()

Return the area for self corresponding to the area of the Dyck path.

One can view a balanced Dyck word as a lattice path from \((0, 0)\) to \((n, n)\) in the first quadrant by letting ‘1’s represent steps in the direction \((1, 0)\) and ‘0’s represent steps in the direction \((0, 1)\). The resulting path will remain weakly above the diagonal \(y = x\).

The area statistic is the number of complete squares in the integer lattice which are below the path and above the line \(y = x\). The ‘half-squares’ directly above the line \(y = x\) do not contribute to this statistic.

EXAMPLES:

```python
sage: dw = DyckWord([1,0,1,0])
sage: dw.area() # 2 half-squares, 0 complete squares
0

>>> from sage.all import *
>>> dw = DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)])
>>> dw.area() # 2 half-squares, 0 complete squares
0

sage: dw = DyckWord([1,1,1,0,1,1,0,0,0,1,0,0,1,0,0,0])
sage: dw.area()
19

>>> from sage.all import *
>>> dw = DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
```

(continues on next page)
```python
sage: DyckWord([1,1,1,1,0,0,0,0]).area()
6
sage: DyckWord([1,1,1,0,1,0,0,0]).area()
5
sage: DyckWord([1,1,1,0,0,1,0,0]).area()
4
sage: DyckWord([1,0,1,1,0,1,0,0]).area()
3
sage: DyckWord([1,1,0,1,1,0,0,0]).area()
2
sage: DyckWord([1,1,0,0,1,1,0,0]).area()
4
sage: DyckWord([1,0,1,1,1,0,0,0]).area()
3
sage: DyckWord([1,0,1,0,1,1,0,0]).area()
1
sage: DyckWord([1,0,1,1,0,0,1,0]).area()
1
sage: DyckWord([1,1,0,0,1,0,1,0]).area()
1
sage: DyckWord([1,1,0,1,0,0,1,0]).area()
2
sage: DyckWord([1,1,0,1,0,1,0,0]).area()
3
sage: DyckWord([1,0,1,0,1,0,1,0]).area()
0
```

```python
>>> from sage.all import *
```

```python
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(1),Integer(0),
        Integer(0),Integer(0),Integer(0)]).area()
6
```

```python
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),
        Integer(0),Integer(0),Integer(0)]).area()
5
```

```python
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
        Integer(0),Integer(1),Integer(0)]).area()
4
```

```python

        Integer(1),Integer(0),Integer(0)]).area()
4
```

```python
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(0),Integer(1),
        Integer(1),Integer(1),Integer(0),Integer(0)]).area()
```

(continues on next page)
area_dinv_to_bounce_area_map()

Return the image of self under the map which sends a Dyck word with area equal to r and dinv equal to s to a Dyck word with bounce equal to r and area equal to s.

The inverse of this map is bounce_area_to_area_dinv_map().

For a definition of this map, see [Hag2008] p. 50 where it is called \( \zeta \). However, this map differs from Haglund's map by an application of reverse() (as does the definition of the bounce() statistic).

EXAMPLES:

```
sage: DyckWord([[1,1,0,1,0,0,1,1,0,1,0,1,0,0]]).area_dinv_to_bounce_area_map()
[1, 0, 1, 0]
sage: DyckWord([[1,1,0,1,0,0,1,1,0,1,0,1,0,0]]).area()
5
sage: DyckWord([[1,1,0,1,0,0,1,1,0,1,0,1,0,0]]).dinv()
13
sage: DyckWord([[1,1,1,1,0,0,0,0,1,0,1,0,1,0]]).area()
13
sage: DyckWord([[1,1,1,1,0,0,0,0,1,0,1,0,1,0,0]]).bounce()
5
sage: DyckWord([[1,1,1,1,0,0,0,0,1,0,1,0,1,0,0]]).area_dinv_to_bounce_area_map()
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: DyckWord([[1,1,0,0]]).area_dinv_to_bounce_area_map()
[1, 1, 0, 0]
sage: DyckWord([[1,1,0,0,1,0,0,1,1,0,0,1,0,0]]).area_dinv_to_bounce_area_map()
[1, 1, 0, 0]
```

```python
from sage.all import *
```

```python
>>> DyckWord([[Integer(1),Integer(0),Integer(0),Integer(1),Integer(1),
Integer(0),Integer(0),Integer(1),Integer(1),Integer(1),Integer(0),
Integer(0),Integer(0)]].area_dinv_to_bounce_area_map()
>>> DyckWord([[Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),
Integer(0),Integer(0),Integer(1),Integer(0),Integer(0)]].area_dinv_to_bounce_area_map()
```

(continues on next page)
\textbf{bounce}()

Return the bounce statistic of \texttt{self} due to J. Haglund, see [Hag2008].

One can view a balanced Dyck word as a lattice path from \((0, 0)\) to \((n, n)\) in the first quadrant by letting ‘1’s represent steps in the direction \((0, 1)\) and ‘0’s represent steps in the direction \((1, 0)\). The resulting path will remain weakly above the diagonal \(y = x\).

We describe the bounce statistic of such a path in terms of what is known as the “bounce path”.

We can think of our bounce path as describing the trail of a billiard ball shot West from \((n, n)\), which “bounces” down whenever it encounters a vertical step and “bounces” left when it encounters the line \(y = x\).

The bouncing ball will strike the diagonal at the places

\[ (0, 0), (j_1, j_1), (j_2, j_2), \ldots, (j_{r} - 1, j_{r} - 1), (j_r, j_r) = (n, n). \]

We define the bounce to be the sum \(\sum_{i=1}^{r-1} j_i\).

\textbf{EXAMPLES:}

\begin{verbatim}
sage: DyckWord([1,1,1,0,1,1,1,0,0,0,1,1,0,0,1,0,0,0]).bounce() 7
sage: DyckWord([1,1,1,0,0,0,0]).bounce() 0
sage: DyckWord([1,1,0,1,0,0,0]).bounce() 1
sage: DyckWord([1,1,0,1,0,0,0]).bounce() 2
sage: DyckWord([1,1,0,1,0,0,0]).bounce() 3
sage: DyckWord([0,1,0,1,0,1,0,0]).bounce() 3
\end{verbatim}
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: DyckWord([1,1,0,0,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,1,0,0,1,1,0,0,0]).bounce()
2
sage: DyckWord([1,0,1,1,1,0,0,0]).bounce()
1
sage: DyckWord([1,0,1,1,0,0,1,0]).bounce()
4
sage: DyckWord([1,0,1,0,1,1,0,0]).bounce()
3
sage: DyckWord([1,0,1,0,0,1,0,1]).bounce()

-Integer(0),Integer(1),Integer(0),Integer(0)]).bounce()
5
```

(continues on next page)
bounce_area_to_area_dinv_map()

Return the image of the Dyck word under the map which sends a Dyck word with bounce equal to \( r \) and area equal to \( s \) to a Dyck word with area equal to \( r \) and \( \text{dinv} \) equal to \( s \).

This implementation uses a recursive method by saying that the last entry in the area sequence of the Dyck word \( \text{self} \) is equal to the number of touch points of the Dyck path minus 1 of the image of this map.

The inverse of this map is \( \text{area_dinv_to_bounce_area_map()} \).

For a definition of this map, see [Hag2008] p. 50 where it is called \( \zeta^{-1} \). However, this map differs from Haglund’s map by an application of \( \text{reverse()} \) (as does the definition of the bounce() statistic).

EXAMPLES:

```python
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0, 1, 1, 1, 1, 0, 0, 1, 0, 0]
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0]).area()
5
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0]).bounce()
9
sage: DyckWord([1,1,0,0,1,1,1,1,0,0,1,0,0]).dinv()
5
sage: all(D==D.bounce_area_to_area_dinv_map().area_dinv_to_bounce_area_map() for D in DyckWords(5))
True
sage: DyckWord([1,1,0,0]).bounce_area_to_area_dinv_map()
[1, 0, 1, 0]
sage: DyckWord([1,0,1,0]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0]
```

```python
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),Integer(1),Integer(0),
Integer(1),Integer(0),Integer(0)]).bounce_area_to_area_dinv_map()
[1, 1, 0, 0, 1, 1, 1, 1, 0, 0, 1, 0, 0, 0]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(1),Integer(0),Integer(0)]).area()
5
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(1),Integer(0),Integer(0)]).bounce()
9
```
DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), → Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), → Integer(0), Integer(0), Integer(0)]).area() 9

DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), → Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), → Integer(0), Integer(0), Integer(0)]).dinv() 5

all(D==D.bounce_area_to_area_dinv_map().area_dinv_to_bounce_area_map() → for D in DyckWords(Integer(6))) True

DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), → Integer(0)]).bounce_path() [1, 0, 1, 1, 0, 0]

DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).bounce_path() [1, 0, 1, 0, 1, 0]

DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), → Integer(0)]).bounce_path() [1, 0, 1, 0, 1, 0]

DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), → Integer(0), Integer(0), Integer(0)]).bounce_path() [1, 0, 1, 0, 1, 0]

characteristic_symmetric_function(q=None, R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field)

The characteristic function of self is the sum of \( q^{\text{dinv}(D,F)} Q_{\text{ides}(\text{read}(D,F))} \) over all permutation fillings of the Dyck path representing self, where \( \text{ides}(\text{read}(D,F)) \) is the descent composition of the inverse of the reading word of the filling.
INPUT:

• \(q\) – (default: \(q = R(q)\)) a parameter for the generating function power

• \(R\) – (default: \(R = \mathbb{Q}[q,t].fraction_field()\)) the base ring to do the calculations over

OUTPUT:

• an element of the symmetric functions over the ring \(R\) (in the Schur basis).

EXAMPLES:

```python
sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: f = sum(t**D.area() * D.characteristic_symmetric_function() #... for D in DyckWords(3)); f
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: f.nabla(power=-1) #... # needs sage.modules
s[1, 1, 1]
```

The `decomposition_reverse()` function returns the involution of \(self\) with a recursive definition.

If a Dyck word \(D\) decomposes as \(1D_10D_2\) where \(D_1\) and \(D_2\) are complete Dyck words then the decomposition reverse is \(1\phi(D_2)0\phi(D_1)\).

EXAMPLES:

```python
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0]).decomposition_reverse()
[1, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0]
sage: DyckWord([1, 1, 0, 1, 0, 1, 0, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0]).decomposition_reverse()
[1, 1, 0, 1, 0, 1, 0, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0, 1, 1, 0, 0, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,0]).decomposition_reverse()
[1, 0, 1, 0]
sage: DyckWord([1,0,1]).decomposition_reverse()
[1, 1, 0, 0]
```

(continues on next page)
dinv (labeling=None)

Return the dinv statistic of self due to M. Haiman, see [Hag2008].

If a labeling is provided then this function returns the dinv of the labeled Dyck word.

INPUT:

• labeling – an optional argument to be viewed as the labelings of the vertical edges of the Dyck path

OUTPUT:

• an integer representing the dinv statistic of the Dyck path or the labelled Dyck path.

EXAMPLES:

```python
sage: DyckWord([1,0,1,0,1,0,1,0,1,0]).dinv()
10
sage: DyckWord([1,1,1,1,1,0,0,0,0,0]).dinv()
0
sage: DyckWord([1,1,1,1,0,1,0,0,0,0]).dinv()
1
sage: DyckWord([1,1,0,1,0,1,0,1,0,1,0,1,0,0]).dinv()
13
sage: DyckWord([1,1,0,1,0,1,0,1,0,1,0,1,0,0]).dinv([1,2,3,4,5,6,7])
11
sage: DyckWord([1,1,0,1,0,1,0,1,0,1,0,1,0,0]).dinv([6,7,5,3,4,2,1])
2
```

```python
>>> from sage.all import *
```
first_return_decomposition()

Decompose a Dyck word into a pair of Dyck words (potentially empty) where the first word consists of the word after the first up step and the corresponding matching closing parenthesis.

EXAMPLES:

```python
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).first_return_decomposition()
([1, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0])
sage: DyckWord([1,1,0,0]).first_return_decomposition()
([1, 0], [])
sage: DyckWord([1,0,1,0]).first_return_decomposition()
([], [1, 0])
```

list_parking_functions()

Return all parking functions whose supporting Dyck path is self.

EXAMPLES:

```python
sage: DyckWord([1,1,0,0,1,0]).list_parking_functions()
[[1, 1, 3], [1, 3, 1], [3, 1, 1]]
```

major_index()

Return the major index of self.

The major index of a Dyck word $D$ is the sum of the positions of the valleys of $D$ (when started counting at position 1).

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).major_index()
2
sage: DyckWord([1, 1, 0, 0]).major_index()
0
sage: DyckWord([1, 1, 0, 1, 0]).major_index()
4
```
Combinatorics, Release 10.4

sage: DyckWord([1, 0, 1, 1, 0, 0]).major_index()
2

>>> from sage.all import *
>>> DyckWord([1, 0, 1, 1, 0, 0]).major_index()
2
>>> DyckWord([1, 1, 0, 0, 0]).major_index()
0
>>> DyckWord([1, 1, 0, 0, 1, 0]).major_index()
4
>>> DyckWord([1, 0, 1, 1, 0, 0]).major_index()
2

number_of_parking_functions()

Return the number of parking functions with self as the supporting Dyck path.

One representation of a parking function is as a pair consisting of a Dyck path and a permutation \( \pi \) such that if \([a_0, a_1, \ldots, a_{n-1}]\) is the area_sequence of the Dyck path (see to_area_sequence) then the permutation \( \pi \) satisfies \( \pi_i < \pi_{i+1} \) whenever \( a_i < a_{i+1} \). This function counts the number of permutations \( \pi \) which satisfy this condition.

EXAMPLES:

sage: DyckWord(area_sequence=[0,1,2]).number_of_parking_functions()
1
sage: DyckWord(area_sequence=[0,1,1]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,1,0]).number_of_parking_functions()
3
sage: DyckWord(area_sequence=[0,0,0]).number_of_parking_functions()
6

>>> from sage.all import *
>>> DyckWord(area_sequence=[0,1,2]).number_of_parking_functions()
1
>>> DyckWord(area_sequence=[0,1,1]).number_of_parking_functions()
3
>>> DyckWord(area_sequence=[0,1,0]).number_of_parking_functions()
3
>>> DyckWord(area_sequence=[0,0,0]).number_of_parking_functions()
6

number_of_tunnels (tunnel_type='centered')

Return the number of tunnels of self of type tunnel_type.

A tunnel is a pair \((a, b)\) where \(a\) is the position of an open parenthesis and \(b\) is the position of the matching close parenthesis. If \(a + b = n\) then the tunnel is called centered. If \(a + b < n\) then the tunnel is called left and if \(a + b > n\), then the tunnel is called right.

INPUT:
• **tunnel_type** – (default: 'centered') can be one of the following: 'left', 'right', 'centered', or 'all'.

**EXAMPLES:**

```python
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels()
0
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(˓→'left')
5
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(˓→'right')
2
sage: DyckWord([1, 1, 0, 1, 1, 1, 0, 0, 0, 0, 1, 1, 0, 0]).number_of_tunnels(˓→'all')
7
sage: DyckWord([1, 1, 0, 0]).number_of_tunnels('centered')
2
```

```python
>>> from sage.all import *

>>> DyckWord([1, 1, 0, 1, 0, 0]).number_of_tunnels('centered')
2
```

`parking_functions()`

Iterate over parking functions whose supporting Dyck path is `self`.

**EXAMPLES:**

```python
sage: list(DyckWord([1,1,0,1,0,0]).parking_functions())
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]
```

```python
>>> from sage.all import *

>>> list(DyckWord([1,1,0,1,0,0]).parking_functions())
[[1, 1, 2], [1, 2, 1], [2, 1, 1]]
```

`pyramid_weight()`

Return the pyramid weight of `self`.

A pyramid of `self` is a subsequence of the form $1^h 0^h$. A pyramid is maximal if it is neither preceded by a 1 nor followed by a 0.
The pyramid weight of a Dyck path is the sum of the lengths of the maximal pyramids and was defined in [DS1992].

**EXAMPLES:**

```python
sage: DyckWord([1,1,0,1,1,1,0,0,1,0,0,0,1,1,0,0]).pyramid_weight()
6
sage: DyckWord([1,1,1,0,0,0]).pyramid_weight()
3
sage: DyckWord([1,0,1,1,1,0]).pyramid_weight()
3
sage: DyckWord([1,1,0,1,0,0]).pyramid_weight()
2
```

```python
>>> from sage.all import *

>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),
            -> Integer(1),Integer(0),Integer(0),Integer(1),Integer(1),Integer(0),
            -> Integer(0),Integer(1),Integer(1),Integer(0),Integer(0)]).pyramid_weight()
6
```

```python
>>> DyckWord([Integer(1),Integer(1),Integer(1),Integer(0),Integer(0),
            -> Integer(0)]).pyramid_weight()
3
```

```python
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
            -> Integer(0)]).pyramid_weight()
3
>>> DyckWord([Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),
            -> Integer(0)]).pyramid_weight()
2
```

**reading_permutation()**

Return the reading permutation of `self`.

This is the permutation formed by taking the reading word of the Dyck path representing `self` (with $N$ and $E$ steps) if the vertical edges of the Dyck path are labeled from bottom to top with 1 through $n$ and the diagonals are read from top to bottom starting with the diagonal furthest from the main diagonal.

**EXAMPLES:**

```python
sage: DyckWord([1,0,1,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).reading_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,0]).reading_permutation()
[3, 2, 1]
sage: DyckWord([1,1,0,0,1,0]).reading_permutation()
[2, 3, 1]
sage: DyckWord([1,0,1,1,0,0,1,0]).reading_permutation()
[3, 4, 2, 1]
```

```python
>>> from sage.all import *

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).reading_permutation()
[2, 1]
```

```python
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).reading_permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(0)]).reading_permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
            -> Integer(0)]).reading_permutation()
```

(continues on next page)
reverse()

Return the reverse and complement of self.

This operation corresponds to flipping the Dyck path across the $y = -x$ line.

EXAMPLES:

```python
sage: DyckWord([1,1,0,0,1,0]).reverse()
[1, 0, 1, 1, 0, 0]
sage: DyckWord([1,1,1,0,0,0]).reverse()
[1, 1, 1, 0, 0, 0]
sage: len([D for D in DyckWords(5) if D.reverse() == D])
10
```

semilength()

Return the semilength of self.

The semilength of a complete Dyck word $d$ is the number of openers and the number of closers.

EXAMPLES:

```python
sage: DyckWord([1, 0, 1, 0]).semilength()
2

>>> from sage.all import *

>>> DyckWord([1, 1, 0, 1, 0, 0, 1, 1, 0, 1, 0, 1, 0, 0]).semilength()
2
```

to_132_avoiding_permutation()

Use the bijection by C. Krattenthaler in [Kra2001] to send self to a 132-avoiding permutation.

EXAMPLES:

```python
sage: DyckWord([1,1,0,0]).to_132_avoiding_permutation()
[1, 2]
sage: DyckWord([1,0,1,0]).to_132_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,1,0,1,0,1,0,1,0,1,0,0,1,0,1,0,0]).to_132_avoiding_permutation()
[6, 5, 4, 7, 2, 1, 3]
```
to_312_avoiding_permutation()

Convert self to a 312-avoiding permutation using the bijection by Bandlow and Killpatrick in [BK2001].

This sends the area to the inversion number.

EXAMPLES:

```
sage: DyckWord([1,1,0,0]).to_312_avoiding_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_312_avoiding_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_312_avoiding_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

```python
from sage.all import *

DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_312_avoiding_permutation()
[1, 2]
DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_312_avoiding_permutation()
[2, 1]
DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(0)]).to_312_avoiding_permutation()
[6, 5, 4, 7, 2, 1, 3]
```

to_321_avoiding_permutation()

Use the bijection (pp. 60-61 of [Knu1973] or section 3.1 of [CK2008]) to send self to a 321-avoiding permutation.

It is shown in [EP2004] that it sends the number of centered tunnels to the number of fixed points, the number of right tunnels to the number of exceedences, and the semilength plus the height of the middle point to 2 times the length of the longest increasing subsequence.

EXAMPLES:

```
sage: DyckWord([1,1,0,0,0,0,0,0]).to_321_avoiding_permutation()
[2, 1]
sage: DyckWord([1,0,1,0,1,0,0,0,0,0,1,0,0]).to_321_avoiding_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_321_avoiding_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

```python
from sage.all import *

DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_321_avoiding_permutation()
[2, 1]
DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_321_avoiding_permutation()
[1, 2]
DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(0)]).to_321_avoiding_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(1),Integer(0),Integer(0)]).area()
5
>>> p.length()
5
```
The `to_321_avoiding_permutation()` method returns a permutation that avoids the pattern 321. For example:

```python
sage: DyckWord([1,0,1,0]).to_321_avoiding_permutation()
[2, 1]
sage: DyckWord([1,1,0,0]).to_321_avoiding_permutation()
[1, 2]
```

A Dyck word can also be converted to a Catalan code using the `to_Catalan_code()` method. A Catalan code is a sequence of integers $(a_1, a_2, \ldots, a_n)$ of length $n$, such that:

- $0 \leq a_i \leq n - i$ for every $i$;

- if $i < j$ and $a_i > 0$ and $a_j > 0$ and $a_{i+1} = a_{i+2} = \cdots = a_{j-1} = 0$, then $a_i - a_j < j - i$.

It turns out that the Catalan codes of length $n$ are in bijection with Dyck words.

```python
>>> from sage.all import *
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_321_avoiding_permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_321_avoiding_permutation()
[1, 2]
>>> D = DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(0),Integer(0)])
>>> p = D.to_321_avoiding_permutation()
>>> p
[3, 5, 1, 6, 2, 7, 4]
>>> D.number_of_tunnels()
0
>>> p.number_of_fixed_points()
0
```
The Catalan code of a Dyck word is example (x) in Richard Stanley’s exercises on combinatorial interpretations for Catalan objects. The code in this example is the reverse of the description provided there. See [Sta-EC2] and [StaCat98].

EXAMPLES:

```
sage: DyckWord([]).to_Catalan_code()
[]
sage: DyckWord([1, 0]).to_Catalan_code()
[0]
sage: DyckWord([1, 1, 0, 0]).to_Catalan_code()
[0, 1]
sage: DyckWord([1, 0, 1, 0]).to_Catalan_code()
[0, 0]
sage: all(dw ==
   ....:   DyckWords().from_Catalan_code(dw.to_Catalan_code())
   ....:   for i in range(6) for dw in DyckWords(i))
True
```

See also:

- `to_tamari_sorting_tuple()`
- `to_alternating_sign_matrix()`

Return self as an alternating sign matrix.

This is an inclusion map from Dyck words of length $2n$ to certain $n \times n$ alternating sign matrices.

EXAMPLES:

```
sage: DyckWord([1,1,1,0,1,0,0,0]).to_alternating_sign_matrix()  
[ 0 0 1 0]
[ 1 0 -1 1]
[ 0 1 0 0]
[ 0 0 1 0]
```

```
sage: DyckWord([1,0,1,0,1,1,0,0]).to_alternating_sign_matrix()  
[ 0 0 0 1]
[ 0 1 0 0]
[ 0 0 1 0]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),
    Integer(0), Integer(0), Integer(0)]).to_alternating_sign_matrix()  # needs sage.modules
[0 0 1 0]
[1 0 -1 1]
[0 1 0 0]
[0 0 1 0]
>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1),
    Integer(1), Integer(0), Integer(0), Integer(0)]).to_alternating_sign_matrix()  # needs sage.modules
[1 0 0 0]
[0 1 0 0]
[0 0 0 1]
[0 0 1 0]
```

to_non_decreasing_parking_function()

Bijection to non-decreasing parking functions.

See there the method `to_dyck_word()` for more information.

EXAMPLES:

```python
sage: DyckWord([]).to_non_decreasing_parking_function() []
sage: DyckWord([1, 0]).to_non_decreasing_parking_function() [1]
sage: DyckWord([1, 1, 0, 0]).to_non_decreasing_parking_function() [1, 1]
sage: DyckWord([1, 0, 1, 0]).to_non_decreasing_parking_function() [1, 2]
sage: DyckWord([1, 0, 1, 0, 1, 0, 1, 0]).to_non_decreasing_parking_function() [1, 2, 2, 3, 5]
```

to_noncrossing_partition (bijection=None)

Bijection of Biane from self to a noncrossing partition.

There is an optional parameter bijection that indicates if a different bijection from Dyck words to non-crossing partitions should be used (since there are potentially many).

If the parameter bijection is “Stump” then the bijection used is from [Stu2008], see also the method `to_noncrossing_permutation()`.
Thanks to Mathieu Dutour for describing the bijection. See also from_noncrossing_partition().

EXAMPLES:

```
sage: DyckWord([]).to_noncrossing_partition()
{}
sage: DyckWord([1, 0]).to_noncrossing_partition()
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition()
{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition()
{{1, 2, 3}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition()
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition()
{{1, 3}, {2}}
sage: DyckWord([]).to_noncrossing_partition("Stump")
{}
sage: DyckWord([1, 0]).to_noncrossing_partition("Stump")
{{1}}
sage: DyckWord([1, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2}}
sage: DyckWord([1, 1, 1, 0, 0, 0]).to_noncrossing_partition("Stump")
{{1, 3}, {2}}
sage: DyckWord([1, 0, 1, 0, 1, 0]).to_noncrossing_partition("Stump")
{{1}, {2}, {3}}
sage: DyckWord([1, 1, 0, 1, 0, 0]).to_noncrossing_partition("Stump")
{{1, 2, 3}}
>> from sage.all import *
>> DyckWord([]).to_noncrossing_partition()
{}
>> DyckWord([Integer(1), Integer(0)]).to_noncrossing_partition()
{{1}}
>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_noncrossing_partition()
{{1, 2}}
>> DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]).to_noncrossing_partition()
{{1, 2, 3}}
>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0)]).to_noncrossing_partition()
{{1}, {2}, {3}}
>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0)]).to_noncrossing_partition("Stump")
{}
>> DyckWord([Integer(1), Integer(0)]).to_noncrossing_partition("Stump")
{{1}}
>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_noncrossing_partition("Stump")
{{1, 2}}
>> DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]).to_noncrossing_partition("Stump")
{{1, 2, 3}}
>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0)]).to_noncrossing_partition("Stump")
```

(continues on next page)
to_noncrossing_permutation()

Use the bijection by C. Stump in [Stu2008] to send self to a non-crossing permutation.

A non-crossing permutation when written in cyclic notation has cycles which are strictly increasing. Sends the area to the inversion number and self.major_index() to \( n(n-1) - maj(\sigma) - maj(\sigma^{-1}) \). Uses the function pealing().

EXAMPLES:

```python
sage: DyckWord([1,1,0,0]).to_noncrossing_permutation()
[2, 1]
sage: DyckWord([1,0,1,0]).to_noncrossing_permutation()
[1, 2]
sage: p = DyckWord([1,1,0,1,0,1,0,1,0,1,0,1,0,1,0,0]).to_noncrossing_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
sage: DyckWord([1,1,0,1,0,1,0,1,0,1,0,1,0,1,0,0]).area()
5
sage: p.length()
5
```

>>> from sage.all import *

```python
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_noncrossing_permutation()
[2, 1]
>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0)]).to_noncrossing_permutation()
[1, 2]
>>> p = DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),
Integer(1),Integer(0),Integer(0)]).to_noncrossing_permutation(); p
[2, 3, 1, 5, 6, 7, 4]
>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),
Integer(0),Integer(1),Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),Integer(0),
Integer(1),Integer(0),Integer(0)]).area()
5
>>> p.length()
5
```

to_ordered_tree()

Return the ordered tree corresponding to self where the depth of the tree is the maximal height of self.

EXAMPLES:

```python
sage: # needs sage.graphs
d = DyckWord([1,1,0,0])
sage: D.to_ordered_tree()
[[[]]]
sage: D = DyckWord([1,0,1,0])
sage: D.to_ordered_tree()
[[], []]
```
\begin{verbatim}
sage: D = DyckWord([1, 0, 1, 1, 0, 0])
sage: D.to_ordered_tree()
[[[]], [[]]]
sage: D = DyckWord([1, 0, 1, 0, 1, 0, 0, 1, 1, 0, 1, 1, 0, 0, 0])
sage: D.to_ordered_tree()
[[[[], []], []], [[[], []], [[]]]]

>>> from sage.all import *

>>> # needs sage.graphs

>>> D = DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)])

>>> D.to_ordered_tree()
[[[[], []]], []]

>>> D = DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)])

>>> D.to_ordered_tree()
[[[[], []]], []]

>>> D = DyckWord([Integer(1), Integer(0), Integer(1), Integer(1),
Integer(0), Integer(1), Integer(1), Integer(0), Integer(0),
Integer(0)])

>>> D.to_ordered_tree()
[[[[], []], []], [[[], []], [[]]]]

to_pair_of_standard_tableaux()

Convert \texttt{self} to a pair of standard tableaux of the same shape and of length less than or equal to two.

EXAMPLES:

\begin{verbatim}
sage: DyckWord([1,0,1,0]).to_pair_of_standard_tableaux()
(([[1], [2]]), ([[1], [2]])
sage: DyckWord([1,1,0,0]).to_pair_of_standard_tableaux()
(([[1, 2]], [[1, 2]]),)
sage: DyckWord([1,1,0,1,0,0,1,1,0,1,0,1,0,0]).to_pair_of_standard_tableaux()
(((1, 2, 4, 7), [3, 5, 6]), [[1, 2, 4, 6], [3, 5, 7]])

>>> from sage.all import *

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_pair_of_
standard_tableaux()
(((1, 2)], [[1, 2]]),

>>> DyckWord([Integer(1), Integer(0), Integer(1), Integer(0)]).to_pair_of_
standard_tableaux()
(((1, 2)], [[1, 2]]),

>>> DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),
Integer(0), Integer(1), Integer(1), Integer(0), Integer(0), Integer(1),
Integer(0), Integer(1), Integer(0), Integer(0)]).to_pair_of_standard_tableaux()
(((1, 2, 4, 7), [3, 5, 6]), [[1, 2, 4, 6], [3, 5, 7]])

to_partition()

Return the partition associated to \texttt{self}.

This partition is determined by thinking of \texttt{self} as a lattice path and considering the cells which are above
the path but within the $n \times n$ grid and the partition is formed by reading the sequence of the number of cells
in this collection in each row.

OUTPUT:
\end{verbatim}
\end{verbatim}
• a partition representing the rows of cells in the square lattice and above the path

EXAMPLES:

```python
sage: DyckWord([]).to_partition()
[]
sage: DyckWord([1,0]).to_partition()
[]
sage: DyckWord([1,1,0,0]).to_partition()
[]
sage: DyckWord([1,0,1,0]).to_partition()
[1]
sage: DyckWord([1,0,1,0,1,0]).to_partition()
[2, 1]
sage: DyckWord([1,1,0,0,1,0]).to_partition()
[2]
sage: DyckWord([1,0,1,1,0,0]).to_partition()
[1, 1]
```

```python
>>> from sage.all import *

>>> DyckWord([]).to_partition()
[]

>>> DyckWord([Integer(1),Integer(0)]).to_partition()
[]

>>> DyckWord([Integer(1),Integer(1),Integer(0),Integer(0)]).to_partition()
[]

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
            Integer(0)]).to_partition()
[2, 1]

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
            Integer(0),Integer(0)]).to_partition()
[2]

>>> DyckWord([Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),
            Integer(0),Integer(0)]).to_partition()
[1, 1]
```

to_permutation(map)

This is simply a method collecting all implemented maps from Dyck words to permutations.

INPUT:

• map – defines the map from Dyck words to permutations. These are currently:
  – Bandlow-Killpatrick: to_312_avoiding_permutation()
  – Knuth: to_321_avoiding_permutation()
  – Krattenthaler: to_132_avoiding_permutation()
  – Stump: to_noncrossing_permutation()

EXAMPLES:

```python
sage: D = DyckWord([1,1,1,0,1,0,0,0])
sage: D.pretty_print()
____
| x x
| x x
```
(continues on next page)
```python
>>> from sage.all import *

>>> D = DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),
    -Integer(0), Integer(0), Integer(0)])

>>> D.to_permutation(map="Bandlow-Killpatrick")
[3, 4, 2, 1]

>>> D.to_permutation(map="Stump")
[4, 2, 3, 1]

>>> D.to_permutation(map="Knuth")
[1, 2, 4, 3]

>>> D.to_permutation(map="Krattenthaler")
[2, 1, 3, 4]
```

```python
to_triangulation()

Map self to a triangulation.

The map from complete Dyck words of length 2n to triangulations of n + 2-gon given by this function is a bijection that can be described as follows.

Consider the Dyck word as a path from (0, 0) to (n, n) staying above the diagonal, where 1 is an up step and 0 is a right step. Then each horizontal step has a co-height (0 at the top and n - 1 at most at the bottom). One reads the Dyck word from left to right. At the beginning, all vertices from 0 to n + 1 are available. For each horizontal step, one creates an edge from the vertex indexed by the co-height to the next available vertex. This chops out a triangle from the polygon and one removes the middle vertex of this triangle from the list of available vertices.

This bijection has the property that the set of smallest vertices of the edges in a triangulation is an encoding of the co-heights, from which the Dyck word can be easily recovered.

OUTPUT:

a list of pairs (i, j) that are the edges of the triangulations.

EXAMPLES:

```python
sage: DyckWord([1, 1, 0, 0]).to_triangulation()
[(0, 2)]

sage: [t.to_triangulation() for t in DyckWords(3)]
```
from sage.all import *

DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)]).to_triangulation()

[t.to_triangulation() for t in DyckWords(Integer(3))]

REFERENCES:

• [Cha2005]

to_triangulation_as_graph() - Map self to a triangulation and return the result as a graph.

See to_triangulation() for the bijection used to map complete Dyck words to triangulations.

OUTPUT:

• A graph containing both the perimeter edges and the inner edges of a triangulation of a regular polygon.

EXAMPLES:

sage: g = DyckWord([1, 1, 0, 0, 1, 0]).to_triangulation_as_graph(); g
Graph on 5 vertices
sage: g.edges(sort=True, labels=False)
[(0, 1), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (3, 4)]

sage: g.show() # not tested

from sage.all import *

>>> g = DyckWord([Integer(1), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0)]).to_triangulation_as_graph(); g
Graph on 5 vertices
>>> g.edges(sort=True, labels=False)
[(0, 1), (0, 4), (1, 2), (1, 3), (1, 4), (2, 3), (3, 4)]
>>> g.show() # not tested

tunnels() - Return an iterator of ranges of the matching parentheses in the Dyck word self.

That is, if (a, b) is in self.tunnels(), then the matching parenthesis to self[a] is self[b-1].

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: list(DyckWord([1, 1, 0, 1, 1, 0, 0, 1, 0, 0]).tunnels())
[(0, 10), (1, 3), (3, 7), (4, 6), (7, 9)]
```

```python
>>> from sage.all import *
>>> list(DyckWord([Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),
→ Integer(0), Integer(0), Integer(1), Integer(0), Integer(0)]).tunnels())
[(0, 10), (1, 3), (3, 7), (4, 6), (7, 9)]
```

```python
class sage.combinat.dyck_word.DyckWords
    Bases: UniqueRepresentation, Parent

Dyck words.

A Dyck word is a sequence \((w_1, \ldots, w_n)\) consisting of 1 s and 0 s, with the property that for any \(i\) with \(1 \leq i \leq n\), the sequence \((w_1, \ldots, w_i)\) contains at least as many 1 s as 0 s.

A Dyck word is balanced if the total number of 1 s is equal to the total number of 0 s. The number of balanced Dyck words of length \(2k\) is given by the Catalan number \(C_k\).

EXAMPLES:

This class can be called with three keyword parameters \(k1, k2\) and complete.

If neither \(k1\) nor \(k2\) are specified, then `DyckWords` returns the combinatorial class of all balanced (=complete) Dyck words, unless the keyword complete is set to False (in which case it returns the class of all Dyck words).

```python
sage: DW = DyckWords(); DW
Complete Dyck words
sage: [] in DW
True
sage: [1, 0, 1, 0] in DW
True
sage: [1, 1, 0] in DW
False
sage: ADW = DyckWords(complete=False); ADW
Dyck words
sage: [] in ADW
True
sage: [1, 0, 1, 0] in ADW
True
sage: [1, 1, 0] in ADW
True
sage: [1, 0, 0] in ADW
False
```

```python
>>> from sage.all import *
>>> DW = DyckWords(); DW
Complete Dyck words
>>> [] in DW
True
>>> [Integer(1), Integer(0), Integer(1), Integer(0)] in DW
True
>>> [Integer(1), Integer(1), Integer(0)] in DW
False
>>> ADW = DyckWords(complete=False); ADW
Dyck words
>>> [] in ADW
True
```

(continues on next page)
If just $k_1$ is specified, then it returns the balanced Dyck words with $k_1$ opening parentheses and $k_1$ closing parentheses.

```python
sage: DW2 = DyckWords(2); DW2
Dyck words with 2 opening parentheses and 2 closing parentheses
sage: DW2.first()
[1, 0, 1, 0]
sage: DW2.last()
[1, 1, 0, 0]
sage: DW2.cardinality()
2
sage: DyckWords(100).cardinality() == catalan_number(100)
True
```

If $k_2$ is specified in addition to $k_1$, then it returns the Dyck words with $k_1$ opening parentheses and $k_2$ closing parentheses.

```python
sage: DW32 = DyckWords(3,2); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
sage: DW32.list()
[[1, 0, 1, 0, 1],
 [1, 0, 1, 1, 0],
 [1, 1, 0, 0, 1],
 [1, 1, 0, 1, 0],
 [1, 1, 1, 0, 0]]
```

```python
>>> from sage.all import *

>>> DW32 = DyckWords(Integer(3),Integer(2)); DW32
Dyck words with 3 opening parentheses and 2 closing parentheses
```

```python
>>> DW32.list()
[[1, 0, 1, 0, 1],
 [1, 0, 1, 1, 0],
 [1, 1, 0, 0, 1],
 [1, 1, 0, 1, 0],
 [1, 1, 1, 0, 0]]
```
alias of *DyckWord*

**from_heights** *(heights)*

Compute a Dyck word knowing its heights.

We view the Dyck word as a Dyck path from \((0, 0)\) to \((2n, 0)\) in the first quadrant by letting 1’s represent steps in the direction \((1, 1)\) and 0’s represent steps in the direction \((1, -1)\).

The \(\text{heights}()\) is the sequence of the \(y\)-coordinates of the \(2n + 1\) lattice points along this path.

**EXAMPLES:**

```python
sage: from sage.combinat.dyck_word import DyckWord
sage: D = DyckWords(complete=False)
sage: D.from_heights((0,))
[]
sage: D.from_heights((0, 1, 0))
[1, 0]
sage: D.from_heights((0, 1, 2, 1, 0))
[1, 1, 0, 0]
```

This also works for incomplete Dyck words:

```python
sage: D.from_heights((0, 1, 2, 1, 2, 1))
[1, 1, 0, 1, 0]
sage: D.from_heights((0, 1, 2, 1))
[1, 1, 0]
```

See also:

*heights()*, *min_from_heights()*

**min_from_heights** *(heights)*

Compute the smallest Dyck word which achieves or surpasses a given sequence of heights.

**INPUT:**

- `heights` – a nonempty list or iterable consisting of nonnegative integers, the first of which is 0

**OUTPUT:**
• The smallest Dyck word whose sequence of heights is componentwise higher-or-equal to heights. Here, “smaller” can be understood both in the sense of lexicographic order on the Dyck words, and in the sense of every vertex of the path having the smallest possible height.

See also:

• \texttt{heights()}
• \texttt{from\_heights()}

EXAMPLES:

```python
sage: D = DyckWords(complete=False)
sage: D.min_from_heights((0,))
[]
sage: D.min_from_heights((0, 1, 0))
[1, 0]
sage: D.min_from_heights((0, 0, 2, 0, 0))
[1, 1, 0, 0]
sage: D.min_from_heights((0, 0, 2, 0, 2, 0))
[1, 1, 0, 1, 0]
sage: D.min_from_heights((0, 0, 1, 0, 1, 0))
[1, 1, 0, 1, 0]
```

```python
>>> from sage.all import *
>>> D = DyckWords(complete=False)
>>> D.min_from_heights((Integer(0),))
[]
>>> D.min_from_heights((Integer(0), Integer(1), Integer(0)))
[1, 0]
>>> D.min_from_heights((Integer(0), Integer(0), Integer(2), Integer(0), Integer(2), Integer(0)))
[1, 1, 0, 1, 0]
>>> D.min_from_heights((Integer(0), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0)))
[1, 1, 0, 1, 0]
```

class sage.combinat.dyck_word.DyckWords_all

    Bases: DyckWords

All Dyck words.

class sage.combinat.dyck_word.DyckWords_size(k1,k2)

    Bases: DyckWords

    Dyck words with \(k_1\) openers and \(k_2\) closers.

    \texttt{cardinality()} 

    Return the number of Dyck words with \(k_1\) openers and \(k_2\) closers.
This number is
\[ \frac{k_1 - k_2 + 1}{k_1 + 1} \binom{k_1 + k_2}{k_2} = \binom{k_1 + k_2}{k_2} - \binom{k_1 + k_2}{k_2 - 1} \]
if \( k_2 \leq k_1 + 1 \), and 0 if \( k_2 > k_1 \) (these numbers are the same if \( k_2 = k_1 + 1 \)).

**EXAMPLES:**

```python
sage: DyckWords(3, 2).cardinality()
sage: all(all(DyckWords(p, q).cardinality() == len(DyckWords(p, q).list()) for q in range(p + 1)) for p in range(7))
True
```

```python
>>> from sage.all import *
>>> DyckWords(Integer(3), Integer(2)).cardinality()
5
>>> all(all(DyckWords(p, q).cardinality() == len(DyckWords(p, q).list()) for q in range(p + Integer(1))) for p in range(Integer(7)))
True
```

```python
sage.combinat.dyck_word.is_a(obj, k1=None, k2=None)
```
Tests if `obj` is a Dyck word with exactly `k1` open symbols and exactly `k2` close symbols.

If `k1` is not specified, then the number of open symbols can be arbitrary. If `k1` is specified but `k2` is not, then `k2` is set to be `k1`.

**EXAMPLES:**

```python
sage: from sage.combinat.dyck_word import is_a
sage: is_a([1,1,0,0])
True
sage: is_a([1,0,1,0])
True
sage: is_a([1,1,0,0], 2)
True
sage: is_a([1,1,0,0], 3)
False
sage: is_a([1,1,0,0], 3, 2)
False
sage: is_a([1,1,0])
True
sage: is_a([1,1,0])
False
sage: is_a([1,0,0])
False
sage: is_a([1,1,0,2,1])
True
sage: is_a([1,1,0], 2)
False
sage: is_a([1,1,0], 1, 1)
False
```

(continues on next page)
is_a([Integer(1),Integer(1),Integer(0),Integer(0)])
>>> True
>>> is_a([Integer(1),Integer(0),Integer(1),Integer(0)])
>>> True
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)], Integer(2))
>>> True
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)], Integer(3))
>>> False
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0)], Integer(3), Integer(2))
>>> False
>>> is_a([Integer(1),Integer(1),Integer(0)])
>>> True
>>> is_a([Integer(0),Integer(1),Integer(0)])
>>> False
>>> is_a([Integer(1),Integer(0),Integer(0)])
>>> False
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0),Integer(2),Integer(1)])
>>> True
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0),Integer(2)])
>>> False
>>> is_a([Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),Integer(1)])
>>> False

sage.combinat.dyck_word.is_area_sequence(seq)
Test if a sequence $l$ of integers satisfies $l_0 = 0$ and $0 \leq l_{i+1} \leq l_i + 1$ for $i > 0$.

EXAMPLES:

```python
sage: from sage.combinat.dyck_word import is_area_sequence
sage: is_area_sequence([0,2,0])
False
sage: is_area_sequence([1,2,3])
False
sage: is_area_sequence([0,1,0])
True
sage: is_area_sequence([0,1,2])
True
sage: is_area_sequence([])
True
```

```python
>> from sage.all import *
>> from sage.combinat.dyck_word import is_area_sequence
>> is_area_sequence([Integer(0),Integer(2),Integer(0)])
False
>> is_area_sequence([Integer(1),Integer(2),Integer(3)])
False
>> is_area_sequence([Integer(0),Integer(1),Integer(0)])
True
>> is_area_sequence([Integer(0),Integer(1),Integer(2)])
True
>> is_area_sequence([])
True
```

sage.combinat.dyck_word.pealing(D, return_touches=False)
A helper function for computing the bijection from a Dyck word to a 231-avoiding permutation using the bijection “Stump”. For details see [Stu2008].
See also:

\texttt{to\_noncrossing\_partition()}

**EXAMPLES:**

```
sage: from sage.combinat.dyck_word import pealing
sage: pealing(DyckWord([1,1,0,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1,0,1,0]))
[1, 0, 1, 0]
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]))
[1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
sage: pealing(DyckWord([1,1,0,0]),return\_touches=True)
([(1, 0, 1, 0), [(1, 2)]])
sage: pealing(DyckWord([1,0,1,0]),return\_touches=True)
([(1, 0, 1, 0), []])
sage: pealing(DyckWord([1, 1, 0, 0, 1, 1, 1, 0, 0, 0]),return\_touches=True)
([(1, 0, 1, 0, 1, 0, 1, 0, 1, 0), [(1, 2), [3, 5]]])
```

\texttt{sage.combinat.dyck_word.replace\_parens(x)}

A map sending \texttt{'} to \texttt{open\_symbol} and \texttt{'} to \texttt{close\_symbol}, and raising an error on any input other than \texttt{'} (and \texttt{'}). The values of the constants \texttt{open\_symbol} and \texttt{close\_symbol} are subject to change.

This is the inverse map of \texttt{replace\_symbols()}. 

**INPUT:**

- \texttt{x} – either an opening or closing parenthesis

**OUTPUT:**

- If \texttt{x} is an opening parenthesis, replace \texttt{x} with the constant \texttt{open\_symbol}.
- If \texttt{x} is a closing parenthesis, replace \texttt{x} with the constant \texttt{close\_symbol}.
- Raise a \texttt{ValueError} if \texttt{x} is neither an opening nor a closing parenthesis.

See also:

\texttt{replace\_symbols()}

5.1. Comprehensive Module List 1385
EXAMPLES:

```python
sage: from sage.combinat.dyck_word import replace_parens
sage: replace_parens('()')
1
sage: replace_parens('()')
0
sage: replace_parens(1)
Traceback (most recent call last):
...
ValueError
```

```python
>>> from sage.all import *
>>> from sage.combinat.dyck_word import replace_parens
>>> replace_parens('()')
1
>>> replace_parens('()')
0
>>> replace_parens(Integer(1))
Traceback (most recent call last):
...
ValueError
```

`sage.combinat.dyck_word.replace_symbols(x)`

A map sending `open_symbol` to `' ' and `close_symbol` to '}', and raising an error on any input other than `open_symbol` and `close_symbol`. The values of the constants `open_symbol` and `close_symbol` are subject to change.

This is the inverse map of `replace_parens()`.

INPUT:

- `x` - either `open_symbol` or `close_symbol`.

OUTPUT:

- If `x` is `open_symbol`, replace `x` with `' '.
- If `x` is `close_symbol`, replace `x` with '}'
- If `x` is neither `open_symbol` nor `close_symbol`, a `ValueError` is raised.

See also:

`replace_parens()`

EXAMPLES:

```python
sage: from sage.combinat.dyck_word import replace_symbols
sage: replace_symbols(1)
'(1
sage: replace_symbols(0)
')
sage: replace_symbols(3)
Traceback (most recent call last):
...
ValueError
```

```python
>>> from sage.all import *
>>> from sage.combinat.dyck_word import replace_symbols
(continues on next page)```
5.1.101 Substitutions over unit cube faces (Rauzy fractals)

This module implements the $E_1^*(\sigma)$ substitution associated with a one-dimensional substitution $\sigma$, that acts on unit faces of dimension $(d - 1)$ in $\mathbb{R}^d$.

This module defines the following classes and functions:

- **Face** – a class to model a face
- **Patch** – a class to model a finite set of faces
- **E1Star** – a class to model the $E_1^*(\sigma)$ application defined by the substitution $\sigma$

See the documentation of these objects for more information.

The convention for the choice of the unit faces and the definition of $E_1^*(\sigma)$ varies from article to article. Here, unit faces are defined by

\[
\begin{align*}
[x, 1]^* &= \{x + \lambda e_2 + \mu e_3 : \lambda, \mu \in [0, 1]\} \\
[x, 2]^* &= \{x + \lambda e_1 + \mu e_3 : \lambda, \mu \in [0, 1]\} \\
[x, 3]^* &= \{x + \lambda e_1 + \mu e_2 : \lambda, \mu \in [0, 1]\}
\end{align*}
\]

and the dual substitution $E_1^*(\sigma)$ is defined by

\[
E_1^*(\sigma)([x, i]^*) = \bigcup_{k=1,2,3} \bigcup_{s | \sigma(k) = pts} [M^{-1}(x + \ell(s)), k]^*,
\]

where $\ell(s)$ is the abelianized of $s$, and $M$ is the matrix of $\sigma$.

**AUTHORS:**

- Franco Saliola (2009): initial version
- Vincent Delecroix, Timo Jolivet, Stepan Starosta, Sebastien Labbe (2010-05): redesign
- Timo Jolivet (2010-08, 2010-09, 2011): redesign

**REFERENCES:**

**EXAMPLES:**

We start by drawing a simple three-face patch:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: x = [Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)]
sage: P = Patch(x)
sage: P
Patch: [[(0, 0, 0), 1]^*, [(0, 0, 0), 2]^*, [(0, 0, 0), 3]^*]
sage: P.plot()  # not tested
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch

>>> x = [Face((Integer(0),Integer(0),Integer(0)),Integer(1)), Face((Integer(0),
   -Integer(0),Integer(0)),Integer(2)), Face((Integer(0),Integer(0),Integer(0)),
   -Integer(3))]

>>> P = Patch(x)

>>> P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]

>>> P.plot()  #not tested
```

We apply a substitution to this patch, and draw the result:

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)

sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
   1), 1]*]

sage: E(P).plot()  #not tested
```

```python
>>> from sage.all import *

>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)], Integer(2):[Integer(1),
   -Integer(3)], Integer(3):[Integer(1)]})

>>> E = E1Star(sigma)

>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
   1), 1]*]

>>> E(P).plot()  #not tested
```

Note:

- The type of a face is given by an integer in \([1, \ldots, d]\) where \(d\) is the length of the vector of the face.
- The alphabet of the domain and the codomain of \(\sigma\) must be equal, and they must be of the form \([1, \ldots, d]\), where \(d\) is a positive integer corresponding to the length of the vectors of the faces on which \(E_1^*(\sigma)\) will act.

```python
sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2), Face((0,0,0),3)])

sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})

sage: E = E1Star(sigma)

sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
   1), 1]*]

>>> from sage.all import *

>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)), Face((Integer(0),
   -Integer(0),Integer(0)),Integer(2)), Face((Integer(0),Integer(0),Integer(0)),
   -Integer(3))])

>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)], Integer(2):[Integer(1),
   -Integer(3)], Integer(3):[Integer(1)]})

>>> E = E1Star(sigma)

>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, 0, -
   1), 1]*]
```

The application of an \(E_1^*\) substitution assigns to each new face the color of its preimage. The `repaint` method allows us to repaint the faces of a patch. A single color can also be assigned to every face, by specifying a list of a single color:
A list of colors allows us to color the faces sequentially:

```sage
from sage.all import *
P = Patch([Face((0,0,0), t) for t in [1,2,3]])
P = E(P, 5)
P.repaint(['red', 'yellow', 'green', 'blue', 'black'])
P = E(P, 3)
P.plot() #not tested
```

All the color schemes from `list(matplotlib.cm.datad)` can be used:

```sage
from sage.all import *
P = Patch([Face((0,0,0), t) for t in [1,2,3]])
P = E(P)
P.repaint(cmap='summer')
P = E(P, 3)
P.plot() #not tested
P.repaint(cmap='hsv')
P = E(P, 2)
P.plot() #not tested
```

It is also possible to specify a dictionary to color the faces according to their type:

```sage
P = Patch([Face((0,0,0), t) for t in [1,2,3]])
P = E(P, 5)
P.repaint({1:(0.7, 0.7, 0.7), 2:(0.5,0.5,0.5), 3:(0.3,0.3,0.3)})
P.plot() #not tested
P.repaint({1:'red', 2:'yellow', 3:'green'})
P.plot() #not tested
```
```python
>>> from sage.all import *

P = Patch([(Face((Integer(0), Integer(0), Integer(0)), t) for t in [Integer(1), ~Integer(2), Integer(3)])])
>>> P = E(P, Integer(5))
>>> P.repaint({Integer(1): (RealNumber(0.7), RealNumber(0.7), RealNumber(0.7)), ~Integer(2): (RealNumber(0.5), RealNumber(0.5), RealNumber(0.5)), ~Integer(3): (RealNumber(0.3), RealNumber(0.3), RealNumber(0.3))})
>>> P.plot()  # not tested
>>> P.plot()  # not tested
```

Let us look at a nice big patch in 3D:

```python
sage: sigma = WordMorphism({1: [1, 2], 2: [3], 3: [1]})
sage: E = E1Star(sigma)
sage: P = Patch([(Face((0, 0, 0), t) for t in [1, 2, 3])])
sage: P = P + P.translate([-1, 1, 0])
sage: P = E(P, 11)
sage: P.plot3d()  # not tested
```

Plotting with TikZ pictures is possible:

```python
sage: P = Patch([(Face((0, 0, 0), t) for t in [1, 2, 3])])
sage: s = P.plot_tikz()
sage: print(s)  # not tested
```

(continues on next page)
Plotting patches made of unit segments instead of unit faces:

```python
sage: P = Patch([Face([0,0], 1), Face([0,0], 2)])
sage: E = E1Star(WordMorphism({1:[1,2],2:[1]}))
sage: F = E1Star(WordMorphism({1:[1,1,2],2:[2,1]}))
sage: E(P,5).plot()  # needs sage.plot
Graphics object consisting of 21 graphics primitives
sage: F(P,3).plot()  # needs sage.plot
Graphics object consisting of 34 graphics primitives
```

Everything works in any dimension (except for the plotting features which only work in dimension two or three):

```python
>>> from sage.all import *
>>> P = Patch([Face((0,0,0,0),1), Face((0,0,0,0),4)])
>>> sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1),...
>>> from sage.all import *
>>> P = Patch([Face((0,0,0,0),1), Face((0,0,0,0),4)])
>>> sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1),...
```

5.1. Comprehensive Module List
Combinatorics, Release 10.4

```python
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1,5], 5:[1,6], 6:[1,7], 7:[1,8],
                          8:[1,9], 9:[1,10], 10:[1,11], 11:[1,12], 12:[1]})
sage: E = E1Star(sigma)
sage: E
E_1^*(1->12, 10->1, 11, 11->1, 12, 12->1, 2->13, 3->14, 4->15, 5->16, 6->17, 7->18, 8->
  9->1, 10)
sage: P = Patch([Face((0,0,0,0,0,0,0,0,0,0,0,0), t) for t in [1,2,3]])
sage: for x in sorted(E(P), key=lambda x: (x.vector(), x.type())):
    print(x)
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0), 1]*
[(0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0, 0), 2]*

```
INPUT:

- **\( \sigma \) – unimodular WordMorphism, i.e. such that its incidence matrix has determinant \( \pm 1 \).
- **method** – ‘prefix’ or ‘suffix’ (default: ‘suffix’) Enables to use an alternative definition \( E_1^*(\sigma) \) substitutions, where the abelianized of the prefix is used instead of the suffix.

**Note:** The alphabet of the domain and the codomain of \( \sigma \) must be equal, and they must be of the form \([1, \ldots, d]\), where \( d \) is a positive integer corresponding to the length of the vectors of the faces on which \( E_1^*(\sigma) \) will act.

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, -1, 0), 1]*]
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1), Integer(2),Integer(3)]])
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],... Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, -1, 0), 1]*]
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> P = Patch([Face((0,0,0),t) for t in [1,2,3]])
>>> sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
>>> E = E1Star(sigma, method=\'prefix\')
>>> E(P)
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*, [(0, 1, -1), 2]*, [(1, -1, 0), 1]*]
```

```python
sage: x = [Face((0,0,0,0),1), Face((0,0,0,0),4)]
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> P = Patch(x)
>>> sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1,4], 4:[1]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1), 2]*, [(1, 0, 0, -1), 1]*]
```
```python
>>> from sage.all import *
>>> x = [Face((Integer(0),Integer(0),Integer(0),Integer(0)),Integer(1)),
   Face((Integer(0),Integer(0),Integer(0),Integer(0)),Integer(4))]
>>> P = Patch(x)
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],
   Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1),Integer(4)],
   Integer(4):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E(P)
Patch: [[(0, 0, 0, 0), 3]*, [(0, 0, 0, 0), 4]*, [(0, 0, 1, -1), 3]*, [(0, 1, 0, -1), 2]*, [(1, 0, 0, -1), 1]*]
```

### `inverse_matrix()`

Return the inverse of the matrix associated with `self`.

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.inverse_matrix()
[ 0 1 0]
[ 0 0 1]
[ 1 -1 -1]
```

### `matrix()`

Return the matrix associated with `self`.

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.matrix()
[1 1 1]
[1 0 0]
[0 1 0]
```

\texttt{sigma()}

Return the \texttt{WordMorphism} associated with \texttt{self}.

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: E.sigma()
WordMorphism: 1->12, 2->13, 3->1
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],
  Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> E.sigma()
WordMorphism: 1->12, 2->13, 3->1
\end{verbatim}

\texttt{class \texttt{sage.combinat.e_one_star.F}ace\texttt{}(v, t, color=None)}

\texttt{Bases: sageObject}

A class to model a unit face of arbitrary dimension.

A unit face in dimension $d$ is represented by a $d$-dimensional vector $v$ and a type $t$ in \{1, \ldots, $d$\}. The type of the face corresponds to the canonical unit vector to which the face is orthogonal. The optional \texttt{color} argument is used in plotting functions.

**INPUT:**

- \texttt{v} – tuple of integers
- \texttt{t} – integer in \{1, \ldots, \text{len}(v)\}, type of the face. The face of type $i$ is orthogonal to the canonical vector $e_i$.
- \texttt{color} – color (default: \texttt{None}) color of the face, used for plotting only. If \texttt{None}, its value is guessed from the face type.

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
sage: f.type()
3
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.vector()
(0, 2, 0)
>>> f.type()
3
\end{verbatim}

\begin{verbatim}
sage: f = Face((0,2,0), 3, color=(0.5, 0.5, 0.5))
sage: f.color()
RGB color (0.5, 0.5, 0.5)
\end{verbatim}
>>> from sage.all import *
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3), color=(RealNumber('0.5'), RealNumber('0.5'), RealNumber('0.5')))
>>> f.color()
RGB color (0.5, 0.5, 0.5)

color\colorNone

Return or change the color of the face.

INPUT:

- color – string, rgb tuple, color (default: None) the new color to assign to the face. If None, it returns the color of the face.

OUTPUT:

color or None

EXAMPLES:

sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.color()
RGB color (0.0, 0.0, 1.0)
sage: f.color('red')
sage: f.color()
RGB color (1.0, 0.0, 0.0)

>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.color()
RGB color (0.0, 0.0, 1.0)
>>> f.color('red')
>>> f.color()
RGB color (1.0, 0.0, 0.0)

type()

Return the type of the face.

EXAMPLES:

sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.type()
3

>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.type()
3

sage: f = Face((0,2,0), 3)
sage: f.type()
3
```python
>>> from sage.all import *
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.type()
3
```

**vector()**

Return the vector of the face.

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face
sage: f = Face((0,2,0), 3)
sage: f.vector()
(0, 2, 0)
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face
>>>
>>> f = Face((Integer(0),Integer(2),Integer(0)), Integer(3))
>>> f.vector()
(0, 2, 0)
```

```python
class sage.combinat.e_one_star.Patch(faces, face_contour=None)
Bases: SageObject
A class to model a collection of faces. A patch is represented by an immutable set of Faces.

**Note:** The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

**Note:** Since version 4.7.1, Patches are immutable, except for the colors of the faces, which are not taken into account for equality tests and hash functions.

**INPUT:**

- faces – finite iterable of faces
- face_contour – dict (default:None) maps the face type to vectors describing the contour of unit faces. If None, defaults contour are assumed for faces of type 1, 2, 3 or 1, 2, 3. Used in plotting methods only.

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>>
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1), Integer(2),Integer(3)]]))
>>> P
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*]
```
sage: face_contour = {}
sage: face_contour[1] = map(vector, [(0,0,0),(0,1,0),(0,1,1),(0,0,1)])
sage: face_contour[2] = map(vector, [(0,0,0),(0,0,1),(1,0,1),(1,0,0)])
sage: face_contour[3] = map(vector, [(0,0,0),(1,0,0),(1,1,0),(0,1,0)])
sage: Patch([Face((0,0,0),t) for t in [1,2,3]], face_contour=face_contour)
"Patch: \([(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(0, 0, 0), 3]*\]"

difference (other)
Return the difference of self and other.

INPUT:

- other - a finite iterable of faces or a single face

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.difference(Face([0,0,0],2))
"Patch: \([(0, 0, 0), 1]*, [(0, 0, 0), 3]*\]"
sage: P.difference(P)
"Patch: []"
```

dimension ()
Return the dimension of the vectors of the faces of self

It returns None if self is the empty patch.

The dimension of a patch is the length of the vectors of the faces in the patch, which is assumed to be the same for every face in the patch.

EXAMPLES:
```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P.dimension() # 3
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)), t) for t in [Integer(1),Integer(2),Integer(3)]])
>>> P.dimension() # 3
```

### faces_of_color(color)

Return a list of the faces that have the given color.

**INPUT:**

- **color** – color

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1, red), Face((1,2,0),3, blue), Face((1,2,0),1, red)])
sage: sorted(P.faces_of_color(red))
[[[0, 0, 0], 1]*, [[[1, 2, 0], 1]*]
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1), red),
             Face((Integer(1),Integer(2),Integer(0)),Integer(3), blue),
             Face((Integer(1),Integer(2),Integer(0)),Integer(1), red)])
>>> sorted(P.faces_of_color(red))
[[[0, 0, 0], 1]*, [[[1, 2, 0], 1]*]
```

### faces_of_type(t)

Return a list of the faces that have type \(t\).

**INPUT:**

- **t** – integer or any other type

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_type(1))
[[[0, 0, 0], 1]*, [[[1, 2, 0], 1]*]
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),
             Face((Integer(1),Integer(2),Integer(0)),Integer(3)),
             Face((Integer(1),Integer(2),Integer(0)),Integer(1))])
>>> sorted(P.faces_of_type(Integer(1)))
[[[0, 0, 0], 1]*, [[[1, 2, 0], 1]*]
```
faces_of_vector(v)

Return a list of the faces whose vector is v.

INPUT:

• v – a vector

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: sorted(P.faces_of_vector([1,2,0]))
[[[1, 2, 0], 1]*, [[1, 2, 0], 3]*]
```

occurrences_of(other)

Return all positions at which other appears in self, that is, all vectors v such that set(other.translate(v)) <= set(self).

INPUT:

• other – a Patch

OUTPUT:

a list of vectors

EXAMPLES:

```
sage: from sage.combinat.e_one_star import Face, Patch, E1Star
sage: P = Patch([Face([0,0,0], 1), Face([0,0,0], 2), Face([0,0,0], 3)])
sage: Q = Patch([Face([0,0,0], 1), Face([0,0,0], 2)])
sage: P.occurrences_of(Q)
[(0, 0, 0)]
sage: Q = Q.translate([1,2,3])
sage: P.occurrences_of(Q)
[(-1, -2, -3)]
```

>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>>
>>> P = Patch([[Face(Integer(0), Integer(0), Integer(0)), Integer(1)],
    →Face((Integer(1), Integer(2), Integer(0)), Integer(3)), Face((Integer(1),
    →Integer(2), Integer(0)), Integer(1))])
>>>
>>> sorted(P.faces_of_vector([Integer(1),Integer(2),Integer(0)]))
[[[1, 2, 0], 1]*, [[1, 2, 0], 3]*]
sage: E = E1Star(WordMorphism({1:[1,2], 2:[1,3], 3:[1]}))
sage: P = Patch([[Face((0,0,0), 1), Face((0,0,0), 2), Face((0,0,0), 3)])
sage: P = E(P,4)
sage: Q = Patch([[Face((0,0,0), 1), Face((0,0,0), 2)])
sage: L = P.occurrences_of(Q)
sage: sorted(L)
[(0, 0, 0), (0, 0, 1), (0, 1, -1), (1, 0, -1), (1, 1, -3), (1, 1, -2)]

plot (projmat=None, opacity=0.75)

Return a 2D graphic object depicting the patch.

INPUT:

- projmat – matrix (default: None) the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If None, the isometric projection is used by default.
- opacity – float between 0 and 1 (default: 0.75) opacity of the face

Warning: Plotting is implemented only for patches in two or three dimensions.

EXAMPLES:

sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([[Face((0,0,0),t) for t in [1,2,3]])
sage: P.plot()  # needs sage.plot
Graphics object consisting of 3 graphics primitives

sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([[Face((0,0,0),t) for t in [1,2,3]])
sage: P = E(P, 5)
sage: P.plot()  # needs sage.plot (continues on next page)
needs sage.plot
Graphics object consisting of 57 graphics primitives

```python
>>> from sage.all import *
>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],
                        Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),t) for t in [Integer(1),Integer(2),Integer(3)]])
>>> P = E(P, Integer(5))
>>> P.plot()  #...
```

Plot with a different projection matrix:

```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: M = matrix(2, 3, [1,0,-1,0.3,1,-3])
sage: P = E(P, 3)
sage: P.plot(projmat=M)  #...
```

Plot patches made of unit segments:

```
sage: P = Patch([Face([0,0], 1), Face([0,0], 2)])
sage: E = E1Star(WordMorphism({1:[1,2],2:[1]}))
sage: F = E1Star(WordMorphism({1:[1,1,2],2:[2,1]}))
sage: E(P,5).plot()  #...
```

(continues on previous page)
plot3d()
Return a 3D graphics object depicting the patch.

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([[Face((0,0,0),t) for t in [1,2,3]]])
sage: P.plot3d()  # not tested
```
• **projmat** – matrix (default: None) the projection matrix. Its number of lines must be two. Its number of columns must equal the dimension of the ambient space of the faces. If None, the isometric projection is used by default.

• **print_tikz_env** – bool (default: True) if True, the tikzpicture environment are printed

• **edgecolor** – string (default: 'black') either 'black' or 'facecolor' (color of unit face edges)

• **scale** – real number (default: 0.25) scaling constant for the whole figure

• **drawzero** – bool (default: False) if True, mark the origin by a black dot

• **extra_code_before** – string (default: '') extra code to include in the tikz picture

• **extra_code_after** – string (default: '') extra code to include in the tikz picture

**EXAMPLES:**

```python
sage: from sage.combinat.e_one_star import E1Star, Face, Patch
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
```

```python
sage: s = P.plot_tikz()
sage: len(s)
602
```

```python
sage: print(s)  # not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm, \rightarrow 0.250000cm)}]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```

```python
>>> from sage.all import *
>>> from sage.combinat.e_one_star import E1Star, Face, Patch
>>> P = Patch([Face(Integer(0),Integer(0),Integer(0)),t) for t in ...
# [Integer(1),Integer(2),Integer(3)]]
>>> s = P.plot_tikz()
```

```python
>>> len(s)
602
```

```python
>>> print(s)  # not tested
\begin{tikzpicture}
[x={(-0.216506cm,-0.125000cm)}, y={(0.216506cm,-0.125000cm)}, z={(0.000000cm, \rightarrow 0.250000cm)}]
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}]
(0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\end{tikzpicture}
```
sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])
sage: P = E(P, 4)
sage: from sage.misc.latex import latex
sage: latex.add_to_preamble('\usepackage{tikz}')

>>> from sage.all import *

>>> sigma = WordMorphism({Integer(1):[Integer(1),Integer(2)],
˓→Integer(2):[Integer(1),Integer(3)], Integer(3):[Integer(1)]})
>>> E = E1Star(sigma)
>>> P = Patch([Face((0,0,0), Integer(0), Integer(0), t) for t in...
˓→[Integer(1),Integer(2),Integer(3)]])
>>> P = E(P, Integer(4))

Plot using shades of gray (useful for article figures):

sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: E = E1Star(sigma)
sage: P = Patch([Face((0,0,0), t) for t in [1,2,3]])

sage: P.repaint([(0.9, 0.9, 0.9), (0.65,0.65,0.65), (0.4,0.4,0.4)])

sage: P = E(P, 4)
sage: s = P.plot_tikz()

Plotting with various options:

sage: sigma = WordMorphism({1:[1,2], 2:[1,3], 3:[1]})
sage: M = matrix(2,3,[float(u) for u in [1,0,-0.7071,0,1,-0.7071]])

sage: P = E(P, 3)
sage: s = P.plot_tikz(projmat=M, edgecolor=facecolor, scale=0.6,...
˓→drawzero=True)
Adding X, Y, Z axes using the extra code feature:

```python
sage: length = 1.5
sage: space = 0.3
sage: axes = ''
sage: axes += '\draw[->, thick, black] (0,0,0) -- (%s, 0, 0)\n' % length
sage: axes += '\draw[->, thick, black] (0,0,0) -- (0, %s, 0)\n' % length
sage: axes += '\node at (%s,0,0) {$x$}\n' % (length + space)
sage: axes += '\node at (0,%s,0) {$y$}\n' % (length + space)
sage: axes += '\node at (0,0,%s) {$z$}\n' % (length + space)
sage: axes += '\draw[->, thick, black] (0,0,0) -- (0, 0, %s)\n' % length
```

From the code snippet, we can see the following:

- `M = matrix(Integer(2), Integer(3), [float(u) for u in [Integer(1), Integer(0), -RealNumber('0.7071'), Integer(0), Integer(1), -RealNumber('0.7071')]])` defines a matrix `M` using symbolic computation.
- `P = E(P, Integer(3))` appears to be a call to a function `E` with `P` and `Integer(3)` as arguments, possibly indicating a step in some algorithm.
- `s = P.plot_tikz(projmat=M, edgecolor='facecolor', scale=RealNumber('0.6'), drawzero=True)` plots a graph using TikZ and the `projmat` parameter.

The code snippet also includes the definition of `length` and `space` variables and uses them to draw axes and a cube. The `vector` and `draw` commands are used to draw the axes, and `facecolor` and `shift` are used to fill the cube faces and marks the zero point. The `options` dictionary is used to customize the plot further.

```python
from sage.all import *
length = RealNumber('1.5')
space = RealNumber('0.3')
axes = ''
axes += '\draw[->, thick, black] (0,0,0) -- (%s, 0, 0)\n' % length
axes += '\draw[->, thick, black] (0,0,0) -- (0, %s, 0)\n' % length
axes += '\node at (%s,0,0) {$x$}\n' % (length + space)
axes += '\node at (0,%s,0) {$y$}\n' % (length + space)
axes += '\node at (0,0,%s) {$z$}\n' % (length + space)
axes += '\draw[->, thick, black] (0,0,0) -- (0, 0, %s)\n' % length
```

(continues on next page)
cube = Patch([Face((Integer(0), Integer(0), Integer(0)), Integer(1)),
    Face((Integer(0), Integer(0), Integer(0)), Integer(2)),
    Face((Integer(0), Integer(0), Integer(0)), Integer(3))])

options = dict(scale=RealNumber('0.5'), drawzero=True, extra_code_ before=axes)

s = cube.plot_tikz(**options)

print(s)  # not tested

\begin{tikzpicture}
\[x={(-0.433013cm,-0.250000cm)}, y={(0.433013cm,-0.250000cm)}, z={(0.000000cm, 0.500000cm)}\]
\draw[->, thick, black] (0,0,0) -- (1.50000000000000, 0, 0);
\draw[->, thick, black] (0,0,0) -- (0, 1.50000000000000, 0);
\node at (1.80000000000000,0,0) {$x$};
\node at (0,1.80000000000000,0) {$y$};
\node at (0,0,1.80000000000000) {$z$};
\draw[->, thick, black] (0,0,0) -- (0, 0, 1.50000000000000);
\definecolor{facecolor}{rgb}{0.000,1.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}] (0, 0, 0) -- (0, 0, 1) -- (1, 0, 1) -- (1, 0, 0) -- cycle;
\definecolor{facecolor}{rgb}{1.000,0.000,0.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}] (0, 0, 0) -- (0, 1, 0) -- (0, 1, 1) -- (0, 0, 1) -- cycle;
\definecolor{facecolor}{rgb}{0.000,0.000,1.000}
\fill[fill=facecolor, draw=black, shift={(0,0,0)}] (0, 0, 0) -- (1, 0, 0) -- (1, 1, 0) -- (0, 1, 0) -- cycle;
\node[circle,fill=black,draw=black,minimum size=1.5mm,inner sep=0pt] at (0,0,0) {};
\end{tikzpicture}

\textbf{repaint} \textit{(cmap='Set1')}

Repaint all the faces of self from the given color map.

This only changes the colors of the faces of self.

\textbf{INPUT:}

- \texttt{cmap} – color map (default: 'Set1'). It can be one of the following:
  - string – A coloring map. For available coloring map names type: \texttt{sorted(colormaps)}
  - list – a list of colors to assign cyclically to the faces. A list of a single color colors all the faces with the same color.
  - dict – a dict of face types mapped to colors, to color the faces according to their type.
  - \texttt{()}, the empty dict – shortcut for \{1:'red', 2:'green', 3:'blue'\}.

\textbf{EXAMPLES:}

Using a color map:

\begin{verbatim}
sage: from sage.combinat.e_one_star import Face, Patch
sage: color = (0, 0, 0)
\end{verbatim}

5.1. Comprehensive Module List 1407
Using a list of colors:

```
sage: P = Patch([Face((0,0,0),t,color) for t in [1,2,3]])
sage: P.repaint([(0.9, 0.9, 0.9), (0.65, 0.65, 0.65), (0.4, 0.4, 0.4)])
sage: for f in P: f.color()
```

```
RGB color (0.9, 0.9, 0.9)
RGB color (0.65, 0.65, 0.65)
RGB color (0.4, 0.4, 0.4)
```

Using a dictionary to color faces according to their type:

```
sage: P = Patch([Face((0,0,0),t) for t in [1,2,3]])
sage: P.repaint({1:'black', 2:'yellow', 3:'green'})
sage: P.plot()  #not tested
sage: P.repaint({})
sage: P.plot()  #not tested
```

```
translate(ν)

Return a translated copy of self by vector ν.
```
INPUT:

• $v$ – vector or tuple

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((1,2,0),3), Face((1,2,0),1)])
sage: P.translate([-1,-2,0])
Patch: [[(-1, -2, 0), 1]*, [(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),
              Face((Integer(1),Integer(2),Integer(0)),Integer(3)), Face((Integer(1),
              Integer(2),Integer(0)),Integer(1))])
>>> P.translate([-Integer(1),-Integer(2),Integer(0)])
Patch: [[(-1, -2, 0), 1]*, [(0, 0, 0), 1]*, [(0, 0, 0), 3]*]
```

union (other)

Return a Patch consisting of the union of self and other.

INPUT:

• other – a Patch or a Face or a finite iterable of faces

EXAMPLES:

```python
sage: from sage.combinat.e_one_star import Face, Patch
sage: P = Patch([Face((0,0,0),1), Face((0,0,0),2)])
sage: P.union(Face((1,2,3), 3))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*]
sage: P.union([Face((1,2,3), 3), Face((2,3,3), 2)])
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*, [(2, 3, 3), 2]*]
```

```
>>> from sage.all import *
>>> from sage.combinat.e_one_star import Face, Patch
>>> P = Patch([Face((Integer(0),Integer(0),Integer(0)),Integer(1)),
              Face((Integer(0),Integer(0),Integer(0)),Integer(2))])
>>> P.union(Face((Integer(1),Integer(2),Integer(3)), Integer(3)))
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*]
>>> P.union([Face((Integer(1),Integer(2),Integer(3)), Integer(3)),
            Face((Integer(2),Integer(3),Integer(2)), Integer(2))])
Patch: [[(0, 0, 0), 1]*, [(0, 0, 0), 2]*, [(1, 2, 3), 3]*, [(2, 3, 3), 2]*]
```

5.1.102 Enumerated sets and combinatorial objects

Todo: Proofread / point to the main classes rather than the modules

5.1.103 Tools for enumeration modulo the action of a permutation group

sage.combinat.enumeration_mod_permgroup.all_children(v, max_part)

Returns all the children of an integer vector (ClonableIntArray) v in the tree of enumeration by lexicographic order. The children of an integer vector v whose entries have the sum n are all integer vectors of sum n + 1 which follow v in the lexicographic order.

That means this function adds 1 on the last non zero entries and the following ones. For an integer vector v such that

\[ v = [\ldots, a, 0, 0] \text{ with } a \neq 0, \]

then, the list of children is

\[ [\ldots, a + 1, 0, 0], [\ldots, a, 1, 0], [\ldots, a, 0, 1]]. \]

EXAMPLES:

```python
sage: from sage.combinat.enumeration_mod_permgroup import all_children
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: v = IncreasingIntArrays([1,2,3,4])
sage: all_children(v, -1)
[[1, 2, 3, 5]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import all_children
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> v = IncreasingIntArrays([Integer(1),Integer(2),Integer(3),Integer(4)])
>>> all_children(v, -Integer(1))
[[1, 2, 3, 5]]
```

sage.combinat.enumeration_mod_permgroup.canonical_children(sgs, v, max_part)

Returns the canonical children of the integer vector v. This function computes all children of the integer vector v via the function `all_children()` and returns from this list only those which are canonicals identified via the function `is_canonical()`.

EXAMPLES:

```python
sage: from sage.combinat.enumeration_mod_permgroup import canonical_children
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: sgs = G.strong_generating_system()
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
```

(continues on next page)
sage: canonical_children(sgs, IA([1,2,3,5]), -1)
[]

>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import canonical_children
>>> G = PermutationGroup([[1,2,3,4]])
>>> sgs = G.strong_generating_system()
>>> IA = IncreasingIntArrays()
>>> canonical_children(sgs, IA([1,2,3,5]), -1)
[]

sage.combinat.enumeration_mod_permgroup.canonical_representative_of_orbit_of(sgs, v)

Returns the maximal vector for the lexicographic order living in the orbit of \( v \) under the action of the permutation group whose strong generating system is \( sgs \). The maximal vector is also called "canonical". Hence, this method returns the canonical vector inside the orbit of \( v \). If \( v \) is already canonical, the method returns \( v \).

Let \( G \) be the permutation group which admits \( sgs \) as a strong generating system. An integer vector \( v \) is said to be canonical under the action of \( G \) if and only if:

\[
v = \max_{\text{lex order}} \{g \cdot v | g \in G\}
\]

EXAMPLES:

sage: from sage.combinat.enumeration_mod_permgroup import canonical_representative_of_orbit_of
sage: G = PermutationGroup([[1,2,3,4]])
sage: sgs = G.strong_generating_system()
>>> IA = IncreasingIntArrays()
>>> canonical_representative_of_orbit_of(sgs, IA([1,2,3,5]))
[5, 1, 2, 3]

sage.combinat.enumeration_mod_permgroup.is_canonical(sgs, v)

Returns \( True \) if the integer vector \( v \) is maximal with respect to the lexicographic order in its orbit under the action of the permutation group whose strong generating system is \( sgs \). Such vectors are said to be canonical.

Let \( G \) be the permutation group which admit \( sgs \) as a strong generating system. An integer vector \( v \) is said to be canonical under the action of \( G \) if and only if:

\[
v = \max_{\text{lex order}} \{g \cdot v | g \in G\}
\]

EXAMPLES:
```python
sage: from sage.combinat.enumeration_mod_permgroup import is_canonical
sage: G = PermutationGroup([[(1,2,3,4)]])
sage: sgs = G.strong_generating_system()
sage: from sage.structure.list_clone_demo import IncreasingIntArrays
sage: IA = IncreasingIntArrays()
sage: is_canonical(sgs, IA([1,2,3,6]))
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.enumeration_mod_permgroup import is_canonical
>>> G = PermutationGroup([[(Integer(1),Integer(2),Integer(3),Integer(4))]])
>>> sgs = G.strong_generating_system()
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> is_canonical(sgs, IA([Integer(1),Integer(2),Integer(3),Integer(6)]))
False
```

`sage.combinat.enumeration_mod_permgroup. lex_cmp(v1, v2)

Lexicographic comparison of `ClonableIntArray`

 INPUT:

Two instances `v1`, `v2` of `ClonableIntArray`

 OUTPUT:

`-1, 0, 1`, depending on whether `v1` is lexicographically smaller, equal, or greater than `v2`.

 EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(SymmetricGroup(5),5)
sage: I = IntegerVectorsModPermutationGroup(SymmetricGroup(5))
sage: J = IntegerVectorsModPermutationGroup(SymmetricGroup(6))
sage: v1 = I([2,3,1,2,3], check=False)
sage: v2 = I([2,3,2,3,2], check=False)
sage: v3 = J([2,3,1,2,3,1], check=False)
sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp
sage: lex_cmp(v1, v1)
0
sage: lex_cmp(v1, v2)
-1
sage: lex_cmp(v2, v1)
1
sage: lex_cmp(v1, v3)
-1
sage: lex_cmp(v3, v1)
1
```

```python
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(SymmetricGroup(Integer(5)),Integer(5))
>>> I = IntegerVectorsModPermutationGroup(SymmetricGroup(Integer(5)))
>>> J = IntegerVectorsModPermutationGroup(SymmetricGroup(Integer(6)))
>>> v1 = I([Integer(2),Integer(3),Integer(1),Integer(2),Integer(3)], check=False)
>>> v2 = I([Integer(2),Integer(3),Integer(2),Integer(3),Integer(2)], check=False)
>>> v3 = J([Integer(2),Integer(3),Integer(1),Integer(2),Integer(3),Integer(1)], check=False)
>>> from sage.combinat.enumeration_mod_permgroup import lex_cmp
>>> lex_cmp(v1, v1)
(continues on next page)
```
Combinatorics, Release 10.4

sage.combinat.enumeration_mod_permgroup.\texttt{lex\_cmp\_partial}(v_1, v_2, \texttt{step})

Partial comparison of the two lists according the lexicographic order. It compares the \texttt{step}-th first entries.

\textbf{EXAMPLES:}

```
sage: from sage.combinat.enumeration_mod_permgroup import lex_cmp_partial
sage: IA = IncreasingIntArrays()
```  
```
sage: lex_cmp_partial(IA([0,1,2,3]), IA([0,1,2,4]), 3)
0
sage: lex_cmp_partial(IA([0,1,2,3]), IA([0,1,2,4]), 4)
-1
```

sage.combinat.enumeration_mod_permgroup.\texttt{orbit}(sgs, v)

Returns the orbit of the integer vector \texttt{v} under the action of the permutation group whose strong generating system is \texttt{sgs}.

\textbf{NOTE:}

The returned orbit is a set. In the doctests, we convert it into a sorted list.

\textbf{EXAMPLES:}

```
sage: from sage.combinat.enumeration_mod_permgroup import orbit
sage: G = PermutationGroup([[1, 2, 3, 4]])
```  
```
sage: sgs = G.strong_generating_system()
sage: IA = IncreasingIntArrays()
sage: sorted(orbit(sgs, IA([1, 2, 3, 4])))
[[1, 2, 3, 4], [2, 3, 4, 1], [3, 4, 1, 2], [4, 1, 2, 3]]
```
>>> from sage.structure.list_clone_demo import IncreasingIntArrays
>>> IA = IncreasingIntArrays()
>>> sorted(orbit(sgs, IA([Integer(1), Integer(2), Integer(3), Integer(4)])))
[[1, 2, 3, 4], [2, 3, 4, 1], [3, 4, 1, 2], [4, 1, 2, 3]]

5.1.104 Compute Bell and Uppuluri-Carpenter numbers

AUTHORS:
  • Nick Alexander

sage.combinat.expnums.expnums(n, aa)
  Compute the first $n$ exponential numbers around $aa$, starting with the zero-th.

INPUT:
  • $n$ – C machine int
  • $aa$ – C machine int

OUTPUT: A list of length $n$.

ALGORITHM: We use the same integer addition algorithm as GAP. This is an extension of Bell's triangle to the general case of exponential numbers. The recursion performs $O(n^2)$ additions, but the running time is dominated by the cost of the last integer addition, because the growth of the integer results of partial computations is exponential in $n$. The algorithm stores $O(n)$ integers, but each is exponential in $n$.

EXAMPLES:

sage: expnums(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]

>>> from sage.all import *
>>> expnums(Integer(10), Integer(1))
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]

sage: expnums(10, -1)
[1, -1, 0, 1, 1, -2, -9, -9, 50, 267]

>>> from sage.all import *
>>> expnums(Integer(10), -Integer(1))
[1, -1, 0, 1, 1, -2, -9, -9, 50, 267]

sage: expnums(1, 1)
[1]
sage: expnums(0, 1)
[]
sage: expnums(-1, 0)
[]

>>> from sage.all import *
>>> expnums(Integer(1), Integer(1))
[1]
>>> expnums(Integer(0), Integer(1))
[]
AUTHORS:

• Nick Alexander

\texttt{sage.combinat.expnums.expnums2(n, aa)}

A vanilla python (but compiled via Cython) implementation of expnums.

We Compute the first $n$ exponential numbers around $aa$, starting with the zero-th.

EXAMPLES:

\begin{verbatim}
>>> from sage.combinat.expnums import expnums2
>>> expnums2(10, 1)
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.expnums import expnums2
>>> expnums2(Integer(10), Integer(1))
[1, 1, 2, 5, 15, 52, 203, 877, 4140, 21147]
\end{verbatim}

5.1.105 Families

This is a backward compatibility stub. Use \texttt{sage.sets.family} instead.

5.1.106 Brent Yorgey's fast algorithm for integer vector (multiset) partitions.

ALGORITHM:

https://wiki.haskell.org/The_Monad.Reader/Previous_issues

AUTHORS:

• D. K. Sunko (2020-02-19): initial version
• F. Chapoton (2020-02-22): conversion to iterators and shorter doctests and doc tweaks
• T. Scrimshaw (2020-03-06): Cython optimizations and doc tweaks

\texttt{sage.combinat.fast_vector_partitions.fast_vector_partitions(v, min_vals=None)}

Brent Yorgey's fast algorithm for integer vector (multiset) partitions.

INPUT:

• $v$ – list of non-negative integers, understood as the vector to be partitioned
• $\text{min_vals}$ – optional list of non-negative integers, of same length as $v$

OUTPUT:

A list of lists, each representing a vector partition of $v$.

If $\text{min_vals}$ is given, only partitions with parts $p \geq \text{min_vals}$ in the lexicographic ordering will appear.

If $\text{min_vals}$ is given and $\text{len(min_vals)} \neq \text{len(v)}$, an error is raised.
EXAMPLES:

The older the computer, the more impressive the comparison:

```
sage: from sage.combinat.fast_vector_partitions import fast_vector_partitions
sage: fastvparts = list(fast_vector_partitions([3, 3, 3]))
sage: vparts = list(VectorPartitions([3, 3, 3]))
sage: vparts == fastvparts[::-1]
True
sage: len(fastvparts)
686
sage: list(fast_vector_partitions([1, 2, 3], min_vals=[0, 1, 1]))
[[[1, 2, 3]],
 [[0, 2, 3], [1, 0, 0]],
 [[0, 2, 2], [1, 0, 1]],
 [[0, 2, 1], [1, 0, 2]],
 [[0, 2, 0], [1, 0, 3]],
 [[0, 1, 3], [1, 1, 0]],
 [[0, 1, 2], [1, 1, 1]],
 [[0, 1, 1], [1, 1, 2]],
 [[0, 1, 1], [0, 1, 2], [1, 0, 0]],
 [[0, 1, 1], [0, 1, 1], [1, 0, 1]]]
sage: L1 = list(fast_vector_partitions([5, 7, 6], min_vals=[1, 3, 2]))
sage: L1 == list(VectorPartitions([5, 7, 6], min=[1, 3, 2]))[::-1]
True
```

Note: The partitions are returned as an iterator.

In this documentation, $a <\!\!=\!\! b$ means $a[i] \leq b[i]$ for all $i$ (notation following B. Yorgey’s paper). It is the monomial partial ordering in Dickson’s lemma: $a <\!\!=\!\! b$ iff $x^a$ divides $x^b$ as monomials.
Warning: The ordering of the partitions is reversed with respect to the output of Sage class `VectorPartitions`.

`sage.combinat.fast_vector_partitions.recursive_vector_partitions(v, vL)`

Iterate over a lexicographically ordered list of lists, each list representing a vector partition of `v`, such that no part of any partition is lexicographically smaller than `vL`.

Internal part of `fast_vector_partitions()`.

**INPUT:**

- `v` – list of non-negative integers, understood as a vector
- `vL` – list of non-negative integers, understood as a vector

**EXAMPLES:**

```python
sage: from sage.combinat.fast_vector_partitions import recursive_vector_partitions
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 1]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]]]
```

```python
sage: list(recursive_vector_partitions([2, 2, 2],[1, 1, 0]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]]]
```

```python
sage: list(recursive_vector_partitions([2, 2, 2],[1, 0, 1]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]], [[1, 0, 2], [1, 2, 0]], [[1, 0, 1], [1, 2, 1]]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import recursive_vector_partitions

>>> list(recursive_vector_partitions([Integer(2), Integer(2), Integer(2)],
                                 => [Integer(1), Integer(1), Integer(1)]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]]]
```

```python
>>> list(recursive_vector_partitions([Integer(2), Integer(2), Integer(2)],
                                 => [Integer(1), Integer(1), Integer(0)]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]]]
```

```python
>>> list(recursive_vector_partitions([Integer(2), Integer(2), Integer(2)],
                                 => [Integer(1), Integer(0), Integer(1)]))
[[[2, 2, 2]], [[1, 1, 1], [1, 1, 1]], [[1, 1, 0], [1, 1, 2]], [[1, 0, 2], [1, 2, 0]], [[1, 0, 1], [1, 2, 1]]]
```

`sage.combinat.fast_vector_partitions.recursive_within_from_to(m, s, e, useS, useE)`

Iterate over a lexicographically ordered list of lists `v` satisfying `e <= v <= s` and `v <|= m` as vectors.

Internal part of `fast_vector_partitions()`.

**INPUT:**

- `m` – list of non-negative integers, understood as a vector
- `s` – list of non-negative integers, understood as a vector
- `e` – list of non-negative integers, understood as a vector
- `useS` – boolean
- `useE` – boolean
• useE – boolean

EXAMPLES:

```python
sage: from sage.combinat.fast_vector_partitions import recursive_within_from_to
sage: list(recursive_within_from_to([1, 2, 3], [1, 2, 2], [1, 1, 1], True, True))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import recursive_within_from_to
>>> list(recursive_within_from_to(Integer(1), Integer(2), Integer(3),
     →Integer(1), Integer(2), Integer(2), [Integer(1), Integer(1), Integer(1)], True, →True))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

**Note:** The flags `useS` and `useE` are used to implement the condition efficiently. Because testing it loops over the vector, re-testing at each step as the vector is parsed is inefficient: all but the last comparison have been done cumulatively already. This code tests only for the last one, using the flags to accumulate information from previous calls.

**Warning:** Expects to be called with `s <= m`. Expects to be called first with `useS == useE == True`.

`sage.combinat.fast_vector_partitions.within_from_to(m, s, e)`

Iterate over a lexicographically ordered list of lists `v` satisfying `e <= v <= s` and `v <= m` as vectors.

**Internal part of** `fast_vector_partitions()`.

**INPUT:**

• *m* – list of non-negative integers, understood as a vector
• *s* – list of non-negative integers, understood as a vector
• *e* – list of non-negative integers, understood as a vector

**EXAMPLES:**

```
sage: from sage.combinat.fast_vector_partitions import within_from_to
sage: list(within_from_to([1, 2, 3], [1, 2, 2], [1, 1, 1]))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

```
>>> from sage.all import *
>>> from sage.combinat.fast_vector_partitions import within_from_to
>>> list(within_from_to(Integer(1), Integer(2), Integer(3),
     →Integer(1), Integer(2), Integer(2), [Integer(1), Integer(1), Integer(1)]))
[[1, 2, 2], [1, 2, 1], [1, 2, 0], [1, 1, 3], [1, 1, 2], [1, 1, 1]]
```

**Note:** The input `s` will be “clipped” internally if it does not satisfy the condition `s <= m`.

To understand the input check, some line art is helpful. Assume that `(a, b)` are the two least significant coordinates of some vector. Say:
\[ e = (2,3), \ s = (7,6), \ m = (9,8). \]

In the figure, these values are denoted by \( E, S, \) and \( M, \) while the letter \( X \) stands for all other allowed values of \( v = (a, b): \)

If \( S \) moves horizontally, the full-height columns fill the box in until \( S \) reaches \( M, \) at which point it remains the limit in the b-direction as it moves out of the box, while \( M \) takes over as the limit in the a-direction, so the \( M \)-column remains filled only up to \( S, \) no matter how much \( S \) moves further to the right.

If \( S \) moves vertically, its column will be filled to the top of the box, but it remains the relevant limit in the a-direction, while \( M \) takes over in the b-direction as \( S \) goes out of the box upwards.

Both behaviors are captured by using the smaller coordinate of \( S \) and \( M, \) whenever \( S \) is outside the box defined by \( M. \) The input will be “clipped” accordingly in that case.

**Warning:** The “clipping” behavior is transparent to the user, but may be puzzling when comparing outputs with the function `recursive_within_from_to()` which has no input protection.

### 5.1.107 Fully commutative elements of Coxeter groups

An element \( w \) in a Coxeter system \( (W, S) \) is fully commutative (FC) if every two reduced words of \( w \) can be related by a sequence of only commutation relations, i.e., relations of the form \( st = ts \) where \( s, t \) are commuting generators in \( S. \) See [Ste1996].

**Authors:**

- Chase Meadors, Tianyuan Xu (2020): Initial version
Acknowledgements

A draft of this code was written during an REU project at University of Colorado Boulder. We thank Rachel Castro, Joel Courtney, Thomas Magnuson and Natalie Schoenhals for their contribution to the project and the code.

```python
class sage.combinat.fully_commutative_elements.FullyCommutativeElement
    Bases: NormalizedClonableList

    A fully commutative (FC) element in a Coxeter system.

    An element \( w \) in a Coxeter system \((W,S)\) is fully commutative (FC) if every two reduced word of \( w \) can be related by a sequence of only commutation relations, i.e., relations of the form \( st = ts \) where \( s, t \) are commuting generators in \( S \).

    Every FC element has a canonical reduced word called its Cartier–Foata form. See [Gre2006]. We will normalize each FC element to this form.

    `check()`
    Called automatically when an element is created.

    EXAMPLES:

    >>> from sage.all import *
    >>> CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()([Integer(1), Integer(2)]) # indirect doctest
    [1, 2]
    >>> CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()([Integer(1), Integer(2), Integer(1)]) # indirect doctest
    Traceback (most recent call last):
    ...,
    ValueError: the input is not a reduced word of a fully commutative element

    `coset_decomposition(J, side='left')`
    Return the coset decomposition of `self` with respect to the parabolic subgroup generated by \( J \).

    INPUT:

    - \( J \) – subset of the generating set \( S \) of the Coxeter system
    - `side` – string (default: 'left'); if the value is set to 'right', then the function returns the tuple \((w_j', w_j)\) from the coset decomposition \( w = w_j' \cdot w_j \) of \( w \) with respect to \( J \)

    OUTPUT:

    The tuple of elements \((w_j, w_j')\) such that \( w = w_j \cdot w_j' \) is generated by the elements in \( J \), and \( w_j' \) has no left descent from \( J \). This tuple is unique and satisfies the equation \( \ell(w) = \ell(w_j) + \ell(w_j') \), where \( \ell \) denotes Coxeter length, by general theory; see Proposition 2.4.4 of [BB2005].

    EXAMPLES:
```

5.1. Comprehensive Module List 1423
Note: The factor $w_J$ of the coset decomposition $w = w_J \cdot w^J$ can be obtained by greedily “pulling left descents of $w$ that are in $J$ to the left”; see the proof of [BB2005]. This greedy algorithm works for all elements in Coxeter group, but it becomes especially simple for FC elements because descents are easier to find for FC elements.

descents (side='left')

Obtain the set of descents on the appropriate side of self.

INPUT:

- side – string (default: 'left'); if set to 'right', find the right descents

A generator $s$ is called a left or right descent of an element $w$ if $l(sw)$ or $l(ws)$ is smaller than $l(w)$, respectively. If $w$ is FC, then $s$ is a left descent of $w$ if and only if $s$ appears to in the word and every generator to the left of the leftmost $s$ in the word commutes with $s$. A similar characterization exists for right descents of FC elements.

EXAMPLES:

```python
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1})
([1], [6, 2, 5, 4, 6, 5])
sage: w.coset_decomposition({1}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [1])
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

```python
>>> from sage.all import *

```

```python
>>> FC = CoxeterGroup(['B', Integer(6)]).fully_commutative_elements()

```

```python
>>> w = FC([Integer(1), Integer(6), Integer(2), Integer(5), Integer(4),
   ... Integer(6), Integer(5)])

```

```python
>>> w.coset_decomposition({Integer(1)})
([1], [6, 2, 5, 4, 6, 5])

```

`descents (side='right')`

Obtain the set of descents on the appropriate side of self.

INPUT:

- side – string (default: 'left'); if set to 'right', find the right descents

A generator $s$ is called a left or right descent of an element $w$ if $l(sw)$ or $l(ws)$ is smaller than $l(w)$, respectively. If $w$ is FC, then $s$ is a left descent of $w$ if and only if $s$ appears to in the word and every generator to the left of the leftmost $s$ in the word commutes with $s$. A similar characterization exists for right descents of FC elements.

EXAMPLES:

```python
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: sorted(w.descents())
[1, 4]

```

```python
>>> from sage.all import *

```

```python
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()

```

```python
>>> w = FC([Integer(1), Integer(6), Integer(2), Integer(5), Integer(4),
   ... Integer(6), Integer(5)])

```

```python
>>> w.coset_decomposition({Integer(1)})
([1], [6, 2, 5, 4, 6, 5])

```

```python
>>> w.coset_decomposition({Integer(1)}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [1])

```

```python
>>> w.coset_decomposition({Integer(5), Integer(6)})
([6, 5, 6], [1, 2, 4, 5])

```

```python
>>> w.coset_decomposition({Integer(5), Integer(6)}, side='right')
([1, 6, 2, 5, 4], [6, 5])

```

```python
>>> from sage.all import *

```

```python
>>> FC = CoxeterGroup(['B', Integer(6)]).fully_commutative_elements()

```

```python
>>> w = FC([Integer(1), Integer(6), Integer(2), Integer(5), Integer(4),
   ... Integer(6), Integer(5)])

```

```python
>>> w.coset_decomposition({Integer(1)})
([1], [6, 2, 5, 4, 6, 5])

```

```python
>>> w.coset_decomposition({Integer(1)}, side = 'right')
([1, 6, 2, 5, 4, 6, 5], [1])

```

```python
>>> w.coset_decomposition({Integer(5), Integer(6)})
([6, 5, 6], [1, 2, 4, 5])

```

```python
>>> w.coset_decomposition({Integer(5), Integer(6)}, side='right')
([1, 6, 2, 5, 4], [6, 5])

```
Combinatorics, Release 10.4

```python
>>> w = FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),
   ...   Integer(4), Integer(3)])
>>> sorted(w.descents())
[1, 4]
>>> w.descents(side='right')
{3}
>>> FC = CoxeterGroup(['A', Integer(5)]).fully_commutative_elements()
>>> sorted(FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),
   ...   Integer(4), Integer(3)]).descents())
[1, 4]
```

See also:

`find_descent()`

`find_descent(s, side='left')`

Check if \( s \) is a descent of \( \text{self} \) and find its position if so.

A generator \( s \) is called a left or right descent of an element \( w \) if \( l(sw) \) or \( l(ws) \) is smaller than \( l(w) \), respectively. If \( w \) is FC, then \( s \) is a left descent of \( w \) if and only if \( s \) appears to the left of the leftmost \( s \) in the word and every generator to the left of the leftmost \( s \) in the word commutes with \( s \). A similar characterization exists for right descents of FC elements.

**INPUT:**

- \( s \) – integer representing a generator of the Coxeter system
- \( \text{side} \) – string (default: 'left'); if the argument is set to 'right', the function checks if \( s \) is a right descent of \( \text{self} \) and finds the index of the rightmost occurrence of \( s \) if so

**OUTPUT:**

Determine if the generator \( s \) is a left descent of \( \text{self} \); return the index of the leftmost occurrence of \( s \) in \( \text{self} \) if so and return None if not.

**EXAMPLES:**

```python
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.find_descent(1)
0
sage: w.find_descent(1, side='right')

sage: w.find_descent(4)
1
sage: w.find_descent(4, side='right')

sage: w.find_descent(3)
```

```python
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> w = FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),
   ...   Integer(4), Integer(3)])
>>> w.find_descent(Integer(1))
0
>>> w.find_descent(Integer(1), side='right')
<BLANKLINE>
```

(continues on next page)
Combinatorics, Release 10.4

>>> w.find_descent(Integer(4), side='right')
>>> w.find_descent(Integer(3))

**group_element()**

Get the actual element of the Coxeter group associated with \texttt{self.parent()} corresponding to \texttt{self}.

**EXAMPLES:**

```
sage: W = CoxeterGroup(['A', 3])
sage: FC = W.fully_commutative_elements()
sage: x = FC([1, 2])
sage: x.group_element()
[ 0 -1 1]
[ 1 -1 1]
[ 0 0 1]
sage: x.group_element() in W
True
```

```python
from sage.all import *
```

```
>>> W = CoxeterGroup(['A', Integer(3)])
```  
```
>>> FC = W.fully_commutative_elements()
```

```
>>> x = FC([Integer(1), Integer(2)])
```  
```
>>> x.group_element() in W
True
```

**has_descent \((s, side='left')\)**

Determine if \(s\) is a descent on the appropriate side of \(self\).

**INPUT:**

- \texttt{side} – string (default: 'left'); if set to 'right', determine if \texttt{self} has \(s\) as a right descent

**OUTPUT:** a boolean value

**EXAMPLES:**

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: w = FC([1, 4, 3, 5, 2, 4, 3])
sage: w.has_descent(1)
True
sage: w.has_descent(1, side='right')
False
sage: w.has_descent(4)
True
sage: w.has_descent(4, side='right')
False
```

```python
from sage.all import *
```

```
>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
```  
```
>>> w = FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),
˓→Integer(4), Integer(3)])
```  
```
(continues on next page)```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> w.has_descent(Integer(1))
True
>>> w.has_descent(Integer(1), side='right')
False
>>> w.has_descent(Integer(4))
True
>>> w.has_descent(Integer(4), side='right')
False
```

`find_descent()`

`heap (**kwargs)`
Create the heap poset of `self`.

The heap of an FC element `w` is a labeled poset that can be defined from any reduced word of `w`. Different reduced words yield isomorphic labeled posets, so the heap is well defined.

Heaps are very useful for visualizing and studying FC elements; see, for example, [Ste1996] and [GX2020].

**INPUT:**

- `self` – list, a reduced word `w = s_0...s_{k-1}` of an FC element
- `one_index` – boolean (default: False). Setting the value to True will change the underlying set of the poset to `{1,2,...,n}`
- `display_labeling` – boolean (default: False). Setting the value to True will display the label `s_i` for each element `i` of the poset

**OUTPUT:**

A labeled poset where the underlying set is `{0,1,...,k-1}` and where each element `i` carries `s_i` as its label. The partial order `<` on the poset is defined by declaring `i < j` if `i < j` and `m(s_i, s_j) ≠ 2`.

**EXAMPLES:**

```python
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4]).heap().cover_relations()
[[[1, 2], [1, 3], [2, 5], [2, 4], [3, 5], [0, 4]]
```

```python
>>> from sage.all import *
>>> FC = CoxeterGroup(['A', Integer(5)]).fully_commutative_elements()
>>> FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2),Integer(4)]).heap().cover_relations()
[[[1, 2], [1, 3], [2, 5], [2, 4], [3, 5], [0, 4]]
```

is_fully_commutative()
Check if `self` is the reduced word of an FC element.

To check if `self` is FC, we use the well-known characterization that an element `w` in a Coxeter system `(W, S)` is FC if and only if for every pair of generators `s, t ∈ S` for which `m(s, t) > 2`, no reduced word of `w` contains the ‘braid’ word `sts...` of length `m(s, t)` as a contiguous subword. See [Ste1996].

5.1. Comprehensive Module List 1427
**check()** is an alias of this method, and is called automatically when an element is created.

**EXAMPLES:**

```python
sage: FC = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: x = FC([1, 2]); x.is_fully_commutative()
True
sage: x = FC.element_class(FC, [1, 2, 1], check=False); x.is_fully_commutative()
False
```

```python
>>> from sage.all import *

>>> FC = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> x = FC([Integer(1), Integer(2)]); x.is_fully_commutative()
True
>>> x = FC.element_class(FC, [Integer(1), Integer(2), Integer(1)],
check=False); x.is_fully_commutative()
False
```

**n_value()**

Calculate the n-value of self.

The n-value of a fully commutative element is the width (length of any longest antichain) of its heap. The n-value is important as it coincides with Lusztig’s a-value for FC elements in all Weyl and affine Weyl groups as well as so-called star-reducible groups; see [GX2020].

**EXAMPLES:**

```python
sage: FC = CoxeterGroup(['A', 5]).fully_commutative_elements()
sage: FC([1,3]).n_value()
2
sage: FC([1,2,3]).n_value()
1
sage: FC([1,3,2]).n_value()
2
sage: FC([1,3,2,5]).n_value()
3
```

```python
>>> from sage.all import *

>>> FC = CoxeterGroup(['A', Integer(5)]).fully_commutative_elements()

>>> FC([Integer(1),Integer(3)]).n_value()
2

>>> FC([Integer(1),Integer(2),Integer(3)]).n_value()
1

>>> FC([Integer(1),Integer(3),Integer(2)]).n_value()
2

>>> FC([Integer(1),Integer(3),Integer(2),Integer(5)]).n_value()
3
```

**normalize()**

Mutate self into Cartier-Foata normal form.

**EXAMPLES:**

The following reduced words express the same FC elements in $B_5$:

```python
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([1, 4, 3, 5, 2, 4, 3]) # indirect doctest
```
sage: FC([4, 1, 3, 5, 2, 4, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
sage: FC([4, 3, 1, 5, 4, 2, 3]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]

```
>>> from sage.all import *

>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
>>> FC([Integer(1), Integer(4), Integer(3), Integer(5), Integer(2), ...
→ Integer(4), Integer(3)]) # indirect doctest
[1, 4, 3, 5, 2, 4, 3]
```

Note: The Cartier–Foata form of a reduced word of an FC element $w$ can be found recursively by repeatedly moving left descents of elements to the left and ordering the left descents from small to large. In the above example, the left descents of the element are 4 and 1, therefore the Cartier–Foata form of the element is the concatenation of [1,4] with the Cartier–Foata form of the remaining part of the word. See [Gre2006].

See also:

descents()

plot_heap()

Display the Hasse diagram of the heap of self.

The Hasse diagram is rendered in the lattice $S \times \mathbb{N}$, with every element $i$ in the poset drawn as a point labelled by its label $s_i$. Every point is placed in the column for its label at a certain level. The levels start at 0 and the level $k$ of an element $i$ is the maximal number $k$ such that the heap contains a chain $i_0 \prec i_1 \prec ... \prec i_k$ where $i_k = i$. See [Ste1996] and [GX2020].

OUTPUT: GraphicsObject

EXAMPLES:

```
sage: FC = CoxeterGroup(['B', 5]).fully_commutative_elements()
sage: FC([3,2,4,3,1]).plot_heap() # needs sage.plot
```

```
>>> from sage.all import *

>>> FC = CoxeterGroup(['B', Integer(5)]).fully_commutative_elements()
```

```
>>> FC([Integer(3),Integer(2),Integer(4),Integer(3),Integer(1)]).plot_heap() # needs sage.plot
```

star_operation($J$, direction, side='left')

Apply a star operation on self relative to two noncommuting generators.

Star operations were first defined on elements of Coxeter groups by Kazhdan and Lusztig in [KL1979] with respect to pair of generators $s, t$ such that $m(s, t) = 3$. Later, Lusztig generalized the definition in
via coset decompositions, to allow star operations with respect to any pair of generators \( s, t \) such that \( m(s, t) \geq 3 \). Given such a pair, we can potentially perform four types of star operations corresponding to all combinations of a 'direction' and a 'side': upper left, lower left, upper right and lower right; see [Gre2006].

Let \( w \) be an element in \( W \) and let \( J \) be any pair \( \{ s, t \} \) of noncommuting generators in \( S \). Consider the coset decomposition \( w = w_J \cdot J \cdot w \) of \( w \) relative to \( J \). Then an upper left star operation is defined on \( w \) if and only if \( 1 \leq l(w_J) \leq m(s, t) - 2 \); when this is the case, the operation returns \( x \cdot w_J \cdot w \) where \( x \) is the letter \( J \) different from the leftmost letter of \( w_J \). A lower left star operation is defined on \( w \) if and only if \( 2 \leq l(w_J) \leq m(s, t) - 1 \); when this is the case, the operation removes the leftmost letter of \( w_J \) from \( w \). Similar facts hold for right star operations. See [Gre2006].

The facts of the previous paragraph hold in general, even if \( w \) is not FC. Note that if \( f \) is a star operation of any kind, then for every element \( w \in W \), the elements \( w \) and \( f(w) \) are either both FC or both not FC.

**INPUT:**

- \( J \) – a set of two integers representing two noncommuting generators of the Coxeter system
- \( \text{direction} \) – string, 'upper' or 'lower': the function performs an upper or lower star operation according to \( \text{direction} \)
- \( \text{side} \) – string (default: 'left'): if this is set to 'right', the function performs a right star operation

**OUTPUT:**

The Cartier–Foata form of the result of the star operation if the operation is defined on \( \text{self}, \text{None} \) otherwise.

**EXAMPLES:**

We will compute all star operations on the following FC element in type \( B_6 \) relative to \( J = \{5, 6\} \):

```
sage: FC = CoxeterGroup(['B', 6]).fully_commutative_elements()
sage: w = FC([1, 6, 2, 5, 4, 6, 5])
```

```python
>>> from sage.all import *
>>> FC = CoxeterGroup(['B', Integer(6)]).fully_commutative_elements()
(continues on next page)```
Whether and how a left star operations can be applied depend on the coset decomposition $w = w_J \cdot w'$:

```
sage: w.coset_decomposition({5, 6})
([6, 5, 6], [1, 2, 4, 5])
```

```
>>> from sage.all import *
```  

```
>>> w.coset_decomposition({Integer(5), Integer(6)})
([6, 5, 6], [1, 2, 4, 5])
```

Only the lower star operation is defined on the left on $w$:

```
sage: w.star_operation({5, 6}, 'upper')
sage: w.star_operation({5, 6}, 'lower')
[1, 5, 2, 4, 6, 5]
```

Whether and how a right star operations can be applied depend on the coset decomposition $w = w_J \cdot w'$:

```
sage: w.coset_decomposition({5, 6}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

```
>>> from sage.all import *
```  

```
>>> w.coset_decomposition({Integer(5), Integer(6)}, side='right')
([1, 6, 2, 5, 4], [6, 5])
```

Both types of right star operations on defined for this example:

```
sage: w.star_operation({5, 6}, 'upper', side='right')
sage: w.star_operation({5, 6}, 'lower', side='right')
[1, 6, 2, 5, 4, 6, 5]
```

```
>>> from sage.all import *
```  

```
>>> w.star_operation(Integer(5), Integer(6), 'upper', side='right')
[1, 6, 2, 5, 4, 6, 5]
```  

```
>>> w.star_operation(Integer(5), Integer(6), 'lower', side='right')
[1, 6, 2, 5, 4, 6]
```

```class sage.combinat.fully_commutative_elements.FullyCommutativeElements(CoxeterGroup)
Bases: UniqueRepresentation, Parent

Class for the set of fully commutative (FC) elements of a Coxeter system.
```
Coxeter systems with finitely many FC elements, or \textit{FC-finite} Coxeter systems, are classified by Stembridge in [Ste1996]. They fall into seven families, namely the groups of types $A_n$, $B_n$, $D_n$, $E_n$, $F_n$, $H_n$, and $I_2(m)$.

**INPUT:**

- \(\text{data} \) – CoxeterMatrix, CartanType, or the usual datum that can is taken in the constructors for these classes (see \texttt{sage.combinat.root_system.coxeter_group.CoxeterGroup()})

**OUTPUT:**

The class of fully commutative elements in the Coxeter group constructed from \(\text{data}\). This will belong to the category of enumerated sets. If the Coxeter data corresponds to a Cartan type, the category is further refined to either finite enumerated sets or infinite enumerated sets depending on whether the Coxeter group is FC-finite; the refinement is not carried out if \(\text{data}\) is a Coxeter matrix not corresponding to a Cartan type.

**Todo:** It would be ideal to implement the aforementioned refinement to finite and infinite enumerated sets for all possible \(\text{data}\), regardless of whether it corresponds to a Cartan type. Doing so requires determining if an arbitrary Coxeter matrix corresponds to a Cartan type. It may be best to address this issue in \texttt{sage.combinat.root_system}. On the other hand, the refinement in the general case may be unnecessary in light of the fact that Stembridge’s classification of FC-finite groups contains a very small number of easily-recognizable families.

**EXAMPLES:**

Create the enumerate set of fully commutative elements in $B_3$:

\[
\text{FC} = \text{CoxeterGroup}([\text{B}, 3]).\text{fully.commumutative_elements}(); \text{FC}
\]

Fully commutative elements of Finite Coxeter group over Number Field in \(a\) with defining polynomial \(x^2 - 2\) with \(a = 1.414213562373095?\) with Coxeter matrix:

\[
\begin{bmatrix}
1 & 3 & 2 \\
3 & 1 & 4 \\
2 & 4 & 1
\end{bmatrix}
\]

Construct elements:

\[
\text{FC([])}
\]

\[
[1, 2]
\]

\[
\text{FC([1, 2])}
\]

\[
[2, 3, 2]
\]

\[
\text{FC([1, 3, 2])}
\]

\[
[2, 4, 1]
\]

\[
\text{FC([1, 2, 3])}
\]

\[
[3, 2, 3]
\]

\[
\text{FC([1, 2, 3])}
\]

\[
[3, 2, 3]
\]
Elements are normalized to Cartier–Foata normal form upon construction:

```
sage: FC([3,1])
[1, 3]
sage: FC([2,3,1])
[2, 1, 3]
sage: FC([1,3]) == FC([3,1])
True
```

Attempting to create an element from an input that is not the reduced word of a fully commutative element throws a ValueError:

```
sage: FC([1,2,1])
Traceback (most recent call last):
... ValueError: the input is not a reduced word of a fully commutative element
```

Enumerate the FC elements in $A_3$:

```
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.category()
Category of finite enumerated sets
sage: FCA3.list()
[[],
 [1],
 [2],
 [3],
 [2, 1],
 [1, 3],
 [1, 2],
```

(continues on next page)
[3, 2],
[2, 3],
[3, 2, 1],
[2, 1, 3],
[1, 3, 2],
[1, 2, 3],
[2, 1, 3, 2]]

>>> from sage.all import *
>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> FCA3.category()
Category of finite enumerated sets
>>> FCA3.list()
[[],
[1],
[2],
[3],
[2, 1],
[1, 3],
[1, 2],
[3, 2],
[2, 3],
[3, 2, 1],
[2, 1, 3],
[1, 3, 2],
[1, 2, 3],
[2, 1, 3, 2]]

Count the FC elements in $B_8$:

```
sage: FCB8 = CoxeterGroup(['B', 8]).fully_commutative_elements()
sage: len(FCB8)  # long time (7 seconds)
14299
```

```
>>> from sage.all import *
>>> FCB8 = CoxeterGroup(['B', Integer(8)]).fully_commutative_elements()
>>> len(FCB8)  # long time (7 seconds)
14299
```

Iterate through the FC elements of length up to 2 in the non-FC-finite group affine $A_2$:

```
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(2))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2]]
```

```
>>> from sage.all import *
>>> FCAffineA2 = CoxeterGroup(['A', Integer(2), Integer(1)]).fully_commutative_elements()
>>> FCAffineA2.category()
Category of infinite enumerated sets
>>> list(FCAffineA2.iterate_to_length(Integer(2)))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2]]
```

The cardinality of the set is determined from the classification of FC-finite Coxeter groups:
sage: CoxeterGroup('A2').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B7').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('A3~').fully_commutative_elements().category()
Category of infinite enumerated sets
sage: CoxeterGroup('F4~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('E8~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('F4~x8~').fully_commutative_elements().category()
Category of finite enumerated sets
sage: CoxeterGroup('B4~x8~').fully_commutative_elements().category()
Category of infinite enumerated sets

>>> from sage.all import *
>>> CoxeterGroup('A2').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('B7').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('A3~').fully_commutative_elements().category()
Category of infinite enumerated sets
>>> CoxeterGroup('F4~').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('E8~').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('F4~x8~').fully_commutative_elements().category()
Category of finite enumerated sets
>>> CoxeterGroup('B4~x8~').fully_commutative_elements().category()
Category of infinite enumerated sets

Element
    alias of FullyCommutativeElement

coxeter_group()
    Obtain the Coxeter group associated with self.

    EXAMPLES:

sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: FCA3.coxeter_group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2]
[3 1 3]
[2 3 1]

>>> from sage.all import *
>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()
>>> FCA3.coxeter_group()
Finite Coxeter group over Integer Ring with Coxeter matrix:
[1 3 2]
[3 1 3]
[2 3 1]

iterate_to_length(length)
    Iterate through the elements of this class up to a maximum length.

    INPUT:
• length — integer; maximum length of element to generate

OUTPUT: generator for elements of self of length up to length

EXAMPLES:
The following example produces all FC elements of length up to 2 in the group $A_3$:

```python
sage: FCA3 = CoxeterGroup(['A', 3]).fully_commutative_elements()
sage: list(FCA3.iterate_to_length(2))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3]]
```

```python
>>> from sage.all import *

>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()

>>> list(FCA3.iterate_to_length(Integer(2)))
[[], [1], [2], [3], [2, 1], [1, 3], [1, 2], [3, 2], [2, 3]]
```

The lists for length 4 and 5 are the same since 4 is the maximum length of an FC element in $A_3$:

```python
sage: list(FCA3.iterate_to_length(4)) == list(FCA3)
True
```

```python
>>> from sage.all import *

>>> FCA3 = CoxeterGroup(['A', Integer(3)]).fully_commutative_elements()

>>> list(FCA3.iterate_to_length(Integer(4))) == list(FCA3)
True
```

The following example produces all FC elements of length up to 4 in the affine Weyl group $\tilde{A}_2$:

```python
sage: FCAffineA2 = CoxeterGroup(['A', 2, 1]).fully_commutative_elements()
sage: FCAffineA2.category()
Category of infinite enumerated sets
sage: list(FCAffineA2.iterate_to_length(4))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2, 0], [2, 1, 0], [0, 1, 2], [1, 0, 2], [0, 2, 1], [2, 0, 1], [1, 0, 2], [1, 2, 0], [2, 1, 0], [0, 1, 2, 0], [1, 2, 0, 1], [2, 1, 0, 2], [0, 2, 1, 0], [1, 0, 2, 1], [2, 0, 1, 2]]
```

```python
>>> from sage.all import *

>>> FCAffineA2 = CoxeterGroup(['A', Integer(2), Integer(1)]).fully_commutative_elements()

>>> FCAffineA2.category()
Category of infinite enumerated sets

>>> list(FCAffineA2.iterate_to_length(Integer(4)))
[[], [0], [1], [2], [1, 0], [2, 0], [0, 1], [2, 1], [0, 2], [1, 2, 0], [2, 1, 0], [0, 1, 2], [1, 0, 2], [0, 2, 1], [2, 0, 1], [1, 0, 2], [1, 2, 0], [2, 1, 0], [0, 1, 2, 0], [1, 2, 0, 1], [2, 1, 0, 2], [0, 2, 1, 0], [1, 0, 2, 1], [2, 0, 1, 2]]
```

(continues on next page)
5.1.108 Finite state machines, automata, transducers

This module adds support for finite state machines, automata and transducers.

For creating automata and transducers you can use classes

- `Automaton` and `Transducer` (or the more general class `FiniteStateMachine`)

or the generators

- `automata` and `transducers`

which contain preconstructed and commonly used automata and transducers. See also the examples below.

Contents

**FiniteStateMachine and derived classes** `Transducer` and `Automaton`

**Examples**

We start with a general `FiniteStateMachine`. Later there will be also an `Automaton` and a `Transducer`.

**A simple finite state machine**

We can easily create a finite state machine by

```python
sage: fsm = FiniteStateMachine()
sage: fsm
Empty finite state machine
```

```python
>>> from sage.all import *
>>> fsm = FiniteStateMachine()
>>> fsm
Empty finite state machine
```

By default this is the empty finite state machine, so not very interesting. Let’s create and add some states and transitions:

```python
sage: day = fsm.add_state('day')
sage: night = fsm.add_state('night')
sage: sunrise = fsm.add_transition(night, day)
sage: sunset = fsm.add_transition(day, night)
```
Let us look at sunset more closely:

```python
sunset
```

Transition from 'day' to 'night': -|--

Note that could also have created and added the transitions directly by:

```python
fsm.add_transition('day', 'night')
```

Transition from 'day' to 'night': -|--

This would have had added the states automatically, since they are present in the transitions.

Anyhow, we got the following finite state machine:

```python
fsm
```

Finite state machine with 2 states

We can also obtain the underlying directed graph by

```python
fsm.graph()
```

Looped multi-digraph on 2 vertices

To visualize a finite state machine, we can use latex() and run the result through LaTeX, see the section on LaTeX output below.

Alternatively, we could have created the finite state machine above simply by

```python
FiniteStateMachine({('night', 'day'), ('day', 'night'))
```

Finite state machine with 2 states

See FiniteStateMachine for a lot of possibilities to create finite state machines.

5.1. Comprehensive Module List 1443
A simple Automaton (recognizing NAFs)

We want to build an automaton which recognizes non-adjacent forms (NAFs), i.e., sequences which have no adjacent non-zeros. We use 0, 1, and −1 as digits:

```python
sage: NAF = Automaton(
    {'A': [('A', 0), ('B', 1), ('B', -1)], 'B': [('A', 0)]})
sage: NAF.state('A').is_initial = True
sage: NAF.state('A').is_final = True
sage: NAF.state('B').is_final = True
sage: NAF
Automaton with 2 states
```

Of course, we could have specified the initial and final states directly in the definition of `NAF` by `initial_states=['A']` and `final_states=['A', 'B']`.

So let's test the automaton with some input:

```python
sage: NAF([0])
True
sage: NAF([0, 1])
True
sage: NAF([1, -1])
False
sage: NAF([0, -1, 0, 1])
True
sage: NAF([0, -1, -1, -1, 0])
False
sage: NAF([-1, 0, 0, 1, 1])
False
```

Alternatively, we could call that by

```python
>>> from sage.all import *
>>> NAF = Automaton(
    ...    {'A': [('A', Integer(0)), ('B', Integer(1)), ('B', -Integer(1))], 'B': [('A', -Integer(0))])
>>> NAF.state('A').is_initial = True
>>> NAF.state('A').is_final = True
>>> NAF.state('B').is_final = True
>>> NAF
Automaton with 2 states
```
Recognizing NAFs via Automata Operations

Alternatively, we can use automata operations to recognize NAFs; for simplicity, we only use the input alphabet \([0, 1]\). On the one hand, we can construct such an automaton by forbidding the word \(11\):

\[
\text{sage: } \text{forbidden = automata.ContainsWord([1, 1], input_alphabet=[0, 1])}
\]
\[
\text{sage: } \text{NAF_negative = forbidden.complement()}
\]
\[
\text{sage: } \text{NAF_negative([1, 1, 0, 1])}
\]
\[
\text{False}
\]
\[
\text{sage: } \text{NAF_negative([1, 0, 1, 0, 1])}
\]
\[
\text{True}
\]

On the other hand, we can write this as a regular expression and translate that into automata operations:

\[
\text{sage: } \text{zero = automata.Word([0])}
\]
\[
\text{sage: } \text{one = automata.Word([1])}
\]
\[
\text{sage: } \text{epsilon = automata.EmptyWord(input_alphabet=[0, 1])}
\]
\[
\text{sage: } \text{NAF_positive = (zero + one*zero).kleene_star() * (epsilon + one)}
\]
We check that the two approaches are equivalent:

```
>>> from sage.all import *
>>> NAF_negative.is_equivalent(NAF_positive)
True
```

```
>>> from sage.all import *
>>> NAF_negative.is_equivalent(NAF_positive)
True
```

See also:

ContainsWord(), Word(), complement(), kleene_star(), EmptyWord(), is_equivalent().

**LaTeX output**

We can visualize a finite state machine by converting it to LaTeX by using the usual function \texttt{latex()}. Within LaTeX, TikZ is used for typesetting the graphics, see the Wikipedia article PGF/TikZ.

```
>>> from sage.all import *
>>>latex(NAF)
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state, accepting, initial] (v0) at (3.000000, 0.000000) {$\text{	exttt{A}}$};
\node[state, accepting] (v1) at (-3.000000, 0.000000) {$\text{	exttt{B}}$};
\path[->] (v0) edge[loop above] node {$0$} ();
\path[->] (v0.185.00) edge node[rotate=360.00, anchor=north] {$1, -1$} (v1.355.00);
\path[->] (v1.5.00) edge node[rotate=0.00, anchor=south] {$0$} (v0.175.00);
\end{tikzpicture}
```

We can turn this into a graphical representation.

```
>>> from sage.all import *
>>> view(NAF)
```

To actually see this, use the live documentation in the Sage notebook and execute the cells in this and the previous section.

Several options can be set to customize the output, see \texttt{latex_options()} for details. In particular, we use \texttt{format_letter_negative()} to format $-1$ as $\overline{1}$.
To use the output of `latex()` in your own \LaTeX file, you have to include

```
\usepackage{tikz}
\usetikzlibrary{automata}
```

into the preamble of your file.
A simple transducer (binary inverter)

Let's build a simple transducer, which rewrites a binary word by inverting each bit:

```python
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:   initial_states=['A'], final_states=['A'])
```

```python
>>> from sage.all import *
>>> inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A', Integer(1),
˓→Integer(0))]},
...   initial_states=['A'], final_states=['A'])
```

We can look at the states and transitions:

```python
sage: inverter.states()
['A']

sage: for t in inverter.transitions():
....:   print(t)
Transition from 'A' to 'A': 0|1
Transition from 'A' to 'A': 1|0
```

```python
>>> from sage.all import *
>>> inverter.states()
['A']
>>> for t in inverter.transitions():
...
Transition from 'A' to 'A': 0|1
Transition from 'A' to 'A': 1|0
```

Now we apply a word to it and see what the transducer does:

```python
sage: inverter([0, 1, 0, 1, 0, 0, 1, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> inverter([Integer(0), Integer(1), Integer(0), Integer(1),
˓→Integer(0), Integer(0), Integer(1), Integer(1), Integer(1)])
[1, 0, 1, 1, 0, 0, 1, 1, 1, 0, 0, 0]
```

True means, that we landed in a final state, that state is labeled 'A', and we also got an output.

Transducers and (in)finite Words

A transducer can also act on everything iterable, in particular, on Sage's words.

```python
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
```

```python
>>> from sage.all import *
>>> W = Words([Integer(0), Integer(1)]); W
Finite and infinite words over {0, 1}
```

Let us take the inverter from the previous section and feed some finite word into it:
We see that the output is again a word (this is a consequence of calling `process()` with `automatic_output_type`).

We can even input something infinite like an infinite word:

```sage
tm = words.ThueMorseWord(); tm
word: 0110100110010110100101100110100110010110...
```

```sage
inverter(tm)
word: 1001011001101001011010011001011001101001...
```

A transducer which performs division by 3 in binary

Now we build a transducer, which divides a binary number by 3. The labels of the states are the remainder of the division. The transition function is

```sage
def f(state_from, read):
    if state_from + read <= 1:
        state_to = 2*state_from + read
        write = 0
    else:
        state_to = 2*state_from + read - 3
        write = 1
    return (state_to, write)
```

which assumes reading a binary number from left to right. We get the transducer with

```sage:D = Transducer(f, initial_states=[0], final_states=[0],
        input_alphabet=[0, 1])
```
Let us try to divide 12 by 3:

```python
sage: D([1, 1, 0, 0])
[0, 1, 0, 0]
```

Now we want to divide 13 by 3:

```python
sage: D([1, 1, 0, 1])
Traceback (most recent call last):
  ... ValueError: Invalid input sequence.
```

The raised `ValueError` means 13 is not divisible by 3.

## Gray Code

The Gray code is a binary numeral system where two successive values differ in only one bit, cf. the Wikipedia article [Gray code](https://en.wikipedia.org/wiki/Gray_code). The Gray code of an integer \( n \) is obtained by a bitwise xor between the binary expansion of \( n \) and the binary expansion of \( \lfloor n/2 \rfloor \); the latter corresponds to a shift by one position in binary.

The purpose of this example is to construct a transducer converting the standard binary expansion to the Gray code by translating this construction into operations with transducers.

For this construction, the least significant digit is at the left-most position. Note that it is easier to shift everything to the right first, i.e., multiply by 2 instead of building \( \lfloor n/2 \rfloor \). Then, we take the input xor with the right shift of the input and forget the first letter.

We first construct a transducer shifting the binary expansion to the right. This requires storing the previously read digit in a state.

```python
sage: def shift_right_transition(state, digit):
    ...:     if state == 'I':
    ...:         return (digit, None)
    ...:     else:
    ...:         return (digit, state)
sage: shift_right_transducer = Transducer(
    ...:     shift_right_transition,
    ...:     initial_states=['I'],
    ...:     input_alphabet=[0, 1],
    ...:     final_states=[0])
sage: shift_right_transducer.transitions()
```

(continues on next page)
Transition from I to 0: 0|-, Transition from I to 1: 1|-,
Transition from 0 to 0: 0|0, Transition from 0 to 1: 1|0,
Transition from 1 to 0: 0|1, Transition from 1 to 1: 1|1

```python
sage: shift_right_transducer([0, 1, 1, 0])
[0, 1, 1]
sage: shift_right_transducer([1, 0, 0])
[1, 0]
```

```python
>>> from sage.all import *

>>> def shift_right_transition(state, digit):
...     if state == 'I':
...         return (digit, None)
...     else:
...         return (digit, state)

>>> shift_right_transducer = Transducer(
...     shift_right_transition,
...     initial_states=['I'],
...     input_alphabet=[Integer(0), Integer(1)],
...     final_states=[Integer(0)])

>>> shift_right_transducer.transitions()
[Transition from 'I' to 0: 0|-, Transition from 'I' to 1: 1|-, Transition from 0 to 0: 0|0, Transition from 0 to 1: 1|0, Transition from 1 to 0: 0|1, Transition from 1 to 1: 1|1]

>>> shift_right_transducer([Integer(0), Integer(1), Integer(1), Integer(0)])
[0, 1, 1]
>>> shift_right_transducer([Integer(1), Integer(0), Integer(0)])
Traceback (most recent call last):
  ...
ValueError: Invalid input sequence.
```

The output of the shifts above look a bit weird (from a right-shift transducer, we would expect, for example, that [1, 0, 0] was mapped to [0, 1, 0]), since we write `None` instead of the zero at the left. Further, note that only 0 is listed as a final state as we have to enforce that a most significant zero is read as the last input letter in order to flush the last digit:

```python
sage: shift_right_transducer([0, 1, 0, 1])
Traceback (most recent call last):
  ...
ValueError: Invalid input sequence.
```

Next, we construct the transducer performing the xor operation. We also have to take `None` into account as our `shift_right_transducer` waits one iteration until it starts writing output. This corresponds with our intention to forget the first letter.

```python
sage: def xor_transition(state, digits):
... (continues on next page)
```
The transducer computing the Gray code is then constructed as a Cartesian product between the shifted version and the original input (represented here by the shift_right_transducer and the identity transducer, respectively). This Cartesian product is then fed into the xor_transducer as a composition of transducers.
sage: product_transducer = shift_right_transducer.cartesian_product(transducers.˓→Identity([0, 1]))
sage: Gray_transducer = xor_transducer(product_transducer)

>>> from sage.all import *
>>> product_transducer = shift_right_transducer.cartesian_product(transducers.˓→Identity([Integer(0), Integer(1)]))
>>> Gray_transducer = xor_transducer(product_transducer)

We use construct_final_word_out() to make sure that all output is written; otherwise, we would have to make sure that a sufficient number of trailing zeros is read.

sage: Gray_transducer.construct_final_word_out([0])
sage: Gray_transducer.transitions()
[Transition from ((I', 0), 0) to ((0, 0), 0): 0|-,
 Transition from ((I', 0), 0) to ((1, 0), 0): 1|-,
 Transition from ((0, 0), 0) to ((0, 0), 0): 0|0,
 Transition from ((0, 0), 0) to ((1, 0), 0): 1|1,
 Transition from ((1, 0), 0) to ((0, 0), 0): 0|1,
 Transition from ((1, 0), 0) to ((1, 0), 0): 1|0]

>>> from sage.all import *
>>> Gray_transducer.construct_final_word_out([Integer(0)])
>>> Gray_transducer.transitions()
[Transition from ((I', 0), 0) to ((0, 0), 0): 0|-,
 Transition from ((I', 0), 0) to ((1, 0), 0): 1|-,
 Transition from ((0, 0), 0) to ((0, 0), 0): 0|0,
 Transition from ((0, 0), 0) to ((1, 0), 0): 1|1,
 Transition from ((1, 0), 0) to ((0, 0), 0): 0|1,
 Transition from ((1, 0), 0) to ((1, 0), 0): 1|0]

There is a prepackaged transducer for Gray code, let’s see whether they agree. We have to use relabeled() to relabel our states with integers.

sage: constructed = Gray_transducer.relabeled()
sage: packaged = transducers.GrayCode()
sage: constructed == packaged
True

>>> from sage.all import *
>>> constructed = Gray_transducer.relabeled()
>>> packaged = transducers.GrayCode()
>>> constructed == packaged
True

Finally, we check that this indeed computes the Gray code of the first 10 non-negative integers.

sage: for n in srange(10):
   ....:     Gray_transducer(n.bits())
[]
[1]
[1, 1]
[0, 1]
[0, 1, 1]
[1, 1, 1]
[1, 0, 1]

(continues on next page)
Using the hook-functions

Let's use the previous example “division by 3” to demonstrate the optional state and transition parameters hook.

First, we define what those functions should do. In our case, this is just saying in which state we are and which transition we take.

```sage
def state_hook(process, state, output):
    print("We are now in State %s." % (state.label(),))

def transition_hook(transition, process):
    print("Currently we go from %s to %s, "
          "reading %s and writing %s." % (
            transition.from_state, transition.to_state,
            FSMWordSymbol(transition.word_in),
            FSMWordSymbol(transition.word_out)))
```

Now, let's add these hook-functions to the existing transducer:

```sage
for s in D.iter_states():
    s.hook = state_hook

for t in D.iter_transitions():
    t.hook = transition_hook
```
>>> from sage.all import *
>>> for s in D.iter_states():
...    s.hook = state_hook

>>> for t in D.iter_transitions():
...    t.hook = transition_hook

Rerunning the process again now gives the following output:

```
sage: D.process([1, 1, 0, 1], check_epsilon_transitions=False)
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
Currently we go from 1 to 0, reading 1 and writing 1.
We are now in State 0.
Currently we go from 0 to 0, reading 0 and writing 0.
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
(False, 1, [0, 1, 0, 0])
```

```
>>> from sage.all import *

>>> D.process([Integer(1), Integer(1), Integer(0), Integer(1)], check_epsilon_transitions=False)
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
Currently we go from 1 to 0, reading 1 and writing 1.
We are now in State 0.
Currently we go from 0 to 0, reading 0 and writing 0.
We are now in State 0.
Currently we go from 0 to 1, reading 1 and writing 0.
We are now in State 1.
(False, 1, [0, 1, 0, 0])
```

The example above just explains the basic idea of using hook-functions. In the following, we will use those hooks more seriously.

**Warning:** The hooks of the states are also called while exploring the epsilon successors of a state (during processing). In the example above, we used `check_epsilon_transitions=False` to avoid this (and also therefore got a cleaner output).

**Warning:** The arguments used when calling a hook have changed in Issue #16538 from `hook(state, process)` to `hook(process, state, output).`
Detecting sequences with same number of 0 and 1

Suppose we have a binary input and want to accept all sequences with the same number of 0 and 1. This cannot be done with a finite automaton. Anyhow, we can make usage of the hook functions to extend our finite automaton by a counter:

```python
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: C = FiniteStateMachine()
```

```python
def update_counter(process, state, output):
    try:
        l = process.preview_word()
    except RuntimeError:
        raise StopIteration
    process.fsm.counter += 1 if l == 1 else -1
    if process.fsm.counter > 0:
        next_state = 'positive'
    elif process.fsm.counter < 0:
        next_state = 'negative'
    else:
        next_state = 'zero'
    return FSMTransition(state, process.fsm.state(next_state), l, process.fsm.counter)
```

```python
sage: C.add_state(FSMState('zero', hook=update_counter, is_initial=True, is_final=True))
'zero'
sage: C.add_state(FSMState('positive', hook=update_counter))
'positive'
sage: C.add_state(FSMState('negative', hook=update_counter))
'negative'
```

Now, let's input some sequence:

```python
sage: C.counter = 0; C([1, 1, 1, 1, 0, 0])
```
The result is False, since there are four 1 but only two 0. We land in the state positive and we can also see the values of the counter in each step.

Let's try some other examples:

```python
sage: C.counter = 0; C([1, 1, 0, 0])
(True, 'zero', [1, 2, 1, 0])
sage: C.counter = 0; C([0, 1, 0, 0])
(False, 'negative', [-1, 0, -1, -2])
```

  - docstring of `FiniteStateMachine` rewritten, `Automaton` and `Transducer` inherited from `FiniteStateMachine`
Methods

\texttt{sage.combinat.finite_state_machine.Automaton(*args, **kwargs)}

Bases: \texttt{FiniteStateMachine}

This creates an automaton, which is a finite state machine, whose transitions have input labels. An automaton has additional features like creating a deterministic and a minimized automaton. See class \texttt{FiniteStateMachine} for more information.

**EXAMPLES:**

We can create an automaton recognizing even numbers (given in binary and read from left to right) in the following way:

\begin{verbatim}
\texttt{sage: A = Automaton([('P', 'Q', 0), ('P', 'P', 1),}
\texttt{......: ('Q', 'P', 1), ('Q', 'Q', 0)],}
\texttt{......: initial_states=["P"], final_states=["Q"]})}
\texttt{sage: A}
Automaton with 2 states
\texttt{sage: A([0])}
True
\texttt{sage: A([1, 1, 0])}
True
\texttt{sage: A([1, 0, 1])}
False
\end{verbatim}

```python
>>> from sage.all import *
>>> A = Automaton([('P', 'Q', Integer(0)), ('P', 'P', Integer(1)),
... ('Q', 'P', Integer(1)), ('Q', 'Q', Integer(0))],
... initial_states=['P'], final_states=['Q'])
>>> A
Automaton with 2 states
>>> A([Integer(0)])
True
>>> A([Integer(1), Integer(1), Integer(0)])
True
>>> A([Integer(1), Integer(0), Integer(1)])
False
```
Note that the full output of the commands can be obtained by calling `process()` and looks like this:

```
sage: A.process([[1, 0, 1])
(False, 'P')
```

```
>>> from sage.all import *

>>> A.process([[Integer(1), Integer(0), Integer(1)])
(False, 'P')
```

cartesian_product (other, only_accessible_components=True)

Return a new automaton which accepts an input if it is accepted by both given automata.

**INPUT:**

- `other` – an automaton
- `only_accessible_components` – If True (default), then the result is piped through `accessible_components()`. If no `new_input_alphabet` is given, it is determined by `determine_alphabets()`.

**OUTPUT:**

A new automaton which computes the intersection (see below) of the languages of `self` and `other`.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition `((A, B), (C, D), a)` in the new automaton if there are transitions `(A, C, a)` and `(B, D, a)` in the old automata.

The methods `intersection()` and `cartesian_product()` are the same (for automata).

**EXAMPLES:**

```
sage: aut1 = Automaton([('1', '2', 1),
....: ('2', '2', 1),
....: ('2', '2', 0),
....: initial_states=['1'],
....: final_states=['2'],
....: determine_alphabets=True)

sage: aut2 = Automaton([('A', 'A', 1),
....: ('A', 'B', 0),
....: ('B', 'B', 0),
....: ('B', 'A', 1),
....: initial_states=['A'],
....: final_states=['B'],
....: determine_alphabets=True)

sage: res = aut1.intersection(aut2)

sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)

sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)

sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-
, Transition from ('2', 'A') to ('2', 'B'): 0|-
, Transition from ('2', 'A') to ('2', 'A'): 1|-
, Transition from ('2', 'B') to ('2', 'B'): 0|-
, Transition from ('2', 'B') to ('2', 'A'): 1|-
]```

(continues on next page)
For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by remove_epsilon_transitions().

```
sage: a1 = Automaton([[0, 0, 0],
                  ....:                 (0, 1, None),
                  ....:                 (1, 1, 1),
                  ....:                 (1, 2, 1)],
                  ....:                 initial_states=[0],
                  ....:                 final_states=[1],
                  ....:                 determine_alphabets=True)
sage: a2 = Automaton([[0, 0, 0], (0, 1, 1), (1, 1, 1)],
                  ....:                 initial_states=[0],
                  ....:                 final_states=[1],
                  ....:                 determine_alphabets=True)
sage: a1.intersection(a2)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input) was found.
sage: a1.remove_epsilon_transitions()  # not tested (since not implemented yet)
sage: a1.intersection(a2)  # not tested
```

(continues on next page)
...  
>>> a2 = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(1), Integer(1)), (Integer(1), Integer(1), Integer(1))], initial_states=[Integer(0)], final_states=[Integer(1)], determine_alphabets=True)  
>>> a1.intersection(a2)  
Traceback (most recent call last):  
...
ValueError: An epsilon-transition (with empty input) was found.  
>>> a1.remove_epsilon_transitions()  
# not tested (since not implemented yet)  
>>> a1.intersection(a2)  
# not tested

complement()  
Return the complement of this automaton.  

OUTPUT:  
An Automaton.  
If this automaton recognizes language \( \mathcal{L} \) over an input alphabet \( \mathcal{A} \), then the complement recognizes \( \mathcal{A} \setminus \mathcal{L} \).  

EXAMPLES:

sage: A = automata.Word([0, 1])  
sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1]) if A(w)]  
[[0, 1]]  
sage: Ac = A.complement()  
sage: Ac.transitions()  
[Transition from 0 to 1: 0|-,
 Transition from 0 to 3: 1|-,
 Transition from 2 to 3: 0|-,
 Transition from 2 to 3: 1|-,
 Transition from 1 to 2: 1|-,
 Transition from 1 to 3: 0|-,
 Transition from 3 to 3: 0|-,
 Transition from 3 to 3: 1|-]

sage: [w for w in ([], [0], [1], [0, 0], [0, 1], [1, 0], [1, 1]) if Ac(w)]  
[[], [0], [1], [0, 0], [1, 0], [1, 1]]

>>> from sage.all import *  
>>> A = automata.Word([Integer(0), Integer(1)])  
>>> [w for w in ([], [Integer(0)], [Integer(1)], [Integer(0), Integer(0)], ...) if A(w)]  
[[0, 1]]  
>>> Ac = A.complement()  
>>> Ac.transitions()  
[Transition from 0 to 1: 0|-,
 Transition from 0 to 3: 1|-,
 Transition from 2 to 3: 0|-,
 Transition from 2 to 3: 1|-,
 Transition from 1 to 2: 1|-,
The automaton must be deterministic:

```python
sage: A = automata.Word([Integer(0)]) * automata.Word([Integer(1)])
sage: A.complement()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.
sage: Ac = A.determinisation().complement()
```

```python
>>> from sage.all import *

sage: A = automata.Word([Integer(0)]) * automata.Word([Integer(1)])
>>> A.complement()
Traceback (most recent call last):
...
ValueError: The finite state machine must be deterministic.

```
>>> from sage.all import *
>>> aut = Automaton(((A, 'A', Integer(0)), ('A', 'B', Integer(1)), ('B', 'B ↦', Integer(1))),
                ... initial_states=['A'], final_states=['B'])
>>> aut.determinisation().transitions()
[Transition from frozenset({'A'}) to frozenset({'A'}): 0|-,
 Transition from frozenset({'A'}) to frozenset({'B'}): 1|-,
 Transition from frozenset({'B'}) to frozenset(): 0|-,
 Transition from frozenset({'B'}) to frozenset({'B'}): 1|-,
 Transition from frozenset() to frozenset(): 0|-,
 Transition from frozenset() to frozenset(): 1|-]

sage: A = Automaton(((A, 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
                 .... ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)),
                 .... initial_states=['A'], final_states=['C'])
sage: A.determinisation().states()
[frozenset({'A'}),
 frozenset({'A', 'B'}),
 frozenset({'A', 'C'}),
 frozenset({'A', 'B', 'C'})]

>>> from sage.all import *
>>> A = Automaton(((0, 1, 1), (0, 2, [1, 1]), (0, 3, [1, 1, 1]),
                .... (1, 0, -1), (2, 0, -2), (3, 0, -3)),
                .... initial_states=[0], final_states=[0, 1, 2, 3])
>>> B = A.determinisation().relabeled().coaccessible_components()
sage: sorted(B.transitions())
[Transition from 0 to 1: 1|-,
 Transition from 1 to 0: -1|-,
 Transition from 1 to 3: 1|-,
 Transition from 3 to 0: -2|-,
 Transition from 3 to 4: 1|-,
 Transition from 4 to 0: -3|-]
Transition from 1 to 0: -1|-
Transition from 1 to 3: 1|--
Transition from 3 to 0: -2|--
Transition from 3 to 4: 1|--
Transition from 4 to 0: -3|--

Note that colors of states have to be hashable:

```
sage: A = Automaton([[0, 0, 0]], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
  ...
TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()
Automaton with 1 state
```

```
>>> from sage.all import *
>>>
>>> A = Automaton([[Integer(0), Integer(0), Integer(0)]], initial_ ˓→states=[Integer(0)])
>>> A.state(Integer(0)).color = []
>>> A.determinisation()
Traceback (most recent call last):
  ...
TypeError: unhashable type: 'list'
>>>
>>> A.state(Integer(0)).color = ()
>>> A.determinisation()  
Automaton with 1 state
```

If the colors of all constituent states are None, the resulting color is None, too (Issue #19199):

```
sage: A = Automaton([(0, 0, 0)], initial_states=[0],  
                  final_states=[0])
```

```
>>> [s.color for s in A.determinisation().iter_states()]
[None]
```

```
>>> from sage.all import *

>>> A = Automaton([(Integer(0), Integer(0), Integer(0))],  
                 initial_states=[Integer(0)],  
                 final_states=[Integer(0)])
```

```
>>> [s.color for s in A.determinisation().iter_states()]
[None]
```

**intersection** *(other, only_accessible_components=True)*

Return a new automaton which accepts an input if it is accepted by both given automata.

**INPUT:**

- `other` — an automaton
- `only_accessible_components` — If True (default), then the result is piped through `accessible_components()`. If no new_input_alphabet is given, it is determined by `determine_alphabets()`.

**OUTPUT:**
A new automaton which computes the intersection (see below) of the languages of self and other.

The set of states of the new automaton is the Cartesian product of the set of states of both given automata. There is a transition \((A, B), (C, D), a\) in the new automaton if there are transitions \((A, C)\) and \((B, D)\) in the old automata.

The methods intersection() and cartesian_product() are the same (for automata).

EXAMPLES:

```
sage: aut1 = Automaton([('1', '2', 1),
                   ('2', '2', 1),
                   ('2', '2', 0)],
                   initial_states=['1'],
                   final_states=['2'],
                   determine_alphabets=True)

sage: aut2 = Automaton([('A', 'A', 1),
                   ('A', 'B', 0),
                   ('B', 'B', 0),
                   ('B', 'A', 1)],
                   initial_states=['A'],
                   final_states=['B'],
                   determine_alphabets=True)

sage: res = aut1.intersection(aut2)
sage: (aut1([1, 1]), aut2([1, 1]), res([1, 1]))
(True, False, False)

sage: (aut1([1, 0]), aut2([1, 0]), res([1, 0]))
(True, True, True)

sage: res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'B') to ('2', 'B'): 0|-,
 Transition from ('2', 'B') to ('2', 'A'): 1|-]
```

```
>>> from sage.all import *
>>> aut1 = Automaton([('1', '2', Integer(1)),
                   ('2', '2', Integer(1)),
                   ('2', '2', Integer(0))],
                   initial_states=['1'],
                   final_states=['2'],
                   determine_alphabets=True)

>>> aut2 = Automaton([('A', 'A', Integer(1)),
                   ('A', 'B', Integer(0)),
                   ('B', 'B', Integer(0)),
                   ('B', 'A', Integer(1))],
                   initial_states=['A'],
                   final_states=['B'],
                   determine_alphabets=True)

>>> res = aut1.intersection(aut2)

>>> (aut1([Integer(1), Integer(1)]), aut2([Integer(1), Integer(1)]),
   res([Integer(1), Integer(1)]))
(True, False, False)

>>> (aut1([Integer(1), Integer(0)]), aut2([Integer(1), Integer(0)]),
   res([Integer(1), Integer(0)]))
(True, True, True)

>>> res.transitions()
[Transition from ('1', 'A') to ('2', 'A'): 1|-,
 Transition from ('2', 'A') to ('2', 'B'): 0|-,
 Transition from ('2', 'A') to ('2', 'A'): 1|-]
```

(continues on next page)
Transition from ('2', 'A') to ('2', 'A'): 1|-,
Transition from ('2', 'B') to ('2', 'B'): 0|-,
Transition from ('2', 'B') to ('2', 'A'): 1|-

For automata with epsilon-transitions, intersection is not well defined. But for any finite state machine, epsilon-transitions can be removed by `remove_epsilon_transitions()`.

```
sage: a1 = Automaton([[(0, 0, 0),
                        (0, 1, None),
                        (1, 1, 1),
                        (1, 2, 1)],
                     initial_states=[0],
                     final_states=[1],
                     determine_alphabets=True)
sage: a2 = Automaton([[(0, 0, 0), (0, 1, 1), (1, 1, 1)],
                        initial_states=[0],
                        final_states=[1],
                        determine_alphabets=True)
sage: a1.intersection(a2)
Traceback (most recent call last):
... ValueError: An epsilon-transition (with empty input) was found.
sage: a1.remove_epsilon_transitions()  # not tested (since not implemented yet)
sage: a1.intersection(a2)  # not tested
```

```
>>> from sage.all import *
>>> a1 = Automaton([[(Integer(0), Integer(0), Integer(0)),
                   (Integer(0), Integer(1), None),
                   (Integer(1), Integer(1), Integer(1)),
                   (Integer(1), Integer(2), Integer(1))],
                 initial_states=[Integer(0)],
                 final_states=[Integer(1)],
                 determine_alphabets=True)
>>> a2 = Automaton([[(Integer(0), Integer(0), Integer(0)),
                   (Integer(0), Integer(1), Integer(1)),
                   (Integer(1), Integer(1), Integer(1))],
                 initial_states=[Integer(0)],
                 final_states=[Integer(1)],
                 determine_alphabets=True)
```

```
>>> a1.intersection(a2)
Traceback (most recent call last):
... ValueError: An epsilon-transition (with empty input) was found.
>>> a1.remove_epsilon_transitions()  # not tested (since not implemented yet)
>>> a1.intersection(a2)  # not tested
```

**is_equivalent**(other)

Test whether two automata are equivalent, i.e., accept the same language.

**INPUT:**

- other an `Automaton`.

**EXAMPLES:**
sage: A = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 1)],
.....: initial_states=[0],
.....: final_states=[0])
sage: B = Automaton([(a, a, 0), (a, b, 1), (b, a, 1)],
.....: initial_states=['a'],
.....: final_states=['a'])
sage: A.is_equivalent(B)
True
sage: B.add_transition('b', 'a', 0)
Transition from 'b' to 'a': 0|--
sage: A.is_equivalent(B)
False

```python
>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(1), Integer(1)), (Integer(1), Integer(0), Integer(1))],
... initial_states=[Integer(0)],
... final_states=[Integer(0)])
>>> B = Automaton([(a, a, Integer(0)), (a, b, Integer(1)), (b, a, Integer(1))],
... initial_states=['a'],
... final_states=['a'])
>>> A.is_equivalent(B)
True
>>> B.add_transition('b', 'a', Integer(0))
Transition from 'b' to 'a': 0|--
>>> A.is_equivalent(B)
False
```

**language** (*max_length=None, **kwargs*)

Return all words accepted by this automaton.

**INPUT:**

- **max_length** – an integer or None (default). Only inputs of length at most max_length will be considered. If None, then this iterates over all possible words without length restrictions.

- **kwargs** – will be passed on to the process iterator. See *process()* for a description.

**OUTPUT:**

An iterator.

**EXAMPLES:**

```python
sage: NAF = Automaton(
.....: {A: [('A', 0), ('B', 1), ('B', -1)],
.....: 'B': [('A', 0)]},
.....: initial_states=['A'], final_states=['A', 'B'])
sage: list(NAF.language(3))
[[], [0], [-1], [1],
 [-1, 0], [0, 0], [1, 0], [0, -1], [0, 1],
 [-1, 0, 0], [0, -1, 0], [0, 0, 0], [0, 1, 0], [1, 0, 0],
 [-1, 0, -1], [-1, 0, 1], [0, 0, -1],
 [0, 0, 1], [1, 0, -1], [1, 0, 1]]
```
>>> from sage.all import *
>>> NAF = Automaton(
...     {'A': [('A', Integer(0)), ('B', Integer(1)), ('B', -Integer(1))],
...     'B': [('A', Integer(0))]},
...     initial_states=['A'], final_states=['A', 'B'])
>>> list(NAF.language(Integer(3))
[[],
 [0], [-1], [1],
 [-1, 0], {0, 0}, [1, 0], [0, -1], [0, 1],
 [-1, 0, 0], {0, -1, 0}, {0, 0, 0}, [0, 1, 0], [1, 0, 0],
 [-1, 0, -1], [-1, 0, 1], {0, 0, -1},
 [0, 0, 1], {1, 0, -1}, {1, 0, 1}]

See also:

FiniteStateMachine.language().process().

minimization(algorithm=None)

Return the minimization of the input automaton as a new automaton.

INPUT:

- algorithm – Either Moore’s algorithm (by algorithm='Moore' or as default for deterministic automata) or Brzozowski’s algorithm (when algorithm='Brzozowski' or when the automaton is not deterministic) is used.

OUTPUT:

A new automaton.

The resulting automaton is deterministic and has a minimal number of states.

EXAMPLES:

sage: A = Automaton([('A', 'A', 1), ('A', 'A', 0), ('A', 'B', 1),
.....: ('B', 'C', 0), ('C', 'C', 1), ('C', 'C', 0)],

process (*args, **kwargs)

Return whether the automaton accepts the input and the state where the computation stops.

INPUT:

- **input_tape** – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.

- **initial_state** or **initial_states** – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.

- **list_of_outputs** – (default: None) a boolean or None. If True, then the outputs are given in list form (even if we have no or only one single output). If False, then the result is never a list (an exception is raised if the result cannot be returned). If `list_of_outputs=None` the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).

- **only_accepted** – (default: False) a boolean. If set, then the first argument in the output is guaranteed to be True (if the output is a list, then the first argument of each element will be True).

- **full_output** – (default: True) a boolean. If set, then the full output is given, otherwise only whether the sequence is accepted or not (the first entry below only).

- **always_include_output** – if set (not by default), always return a triple containing the (non-existing) output. This is in order to obtain output compatible with that of `FiniteStateMachine.process()`. If this parameter is set, `full_output` has no effect.

- **format_output** – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.

- **check_epsilon_transitions** – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.

- **write_final_word_out** – (default: True) a boolean specifying whether the final output words should be written or not.

- **use_multitape_input** – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.

- **process_all_prefixes_of_input** – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

- **process_iterator_class** – (default: None) a class inherited from `FSMProcessIterator`. If None, then `FSMProcessIterator` is taken. An instance of this class is created and is used during the processing.
OUTPUT:

The full output is a pair (or a list of pairs, cf. parameter list_of_outputs), where

- the first entry is True if the input string is accepted and
- the second gives the state reached after processing the input tape (This is a state with label None if the input could not be processed, i.e., if at one point no transition to go on could be found.).

If full_output is False, then only the first entry is returned.

If always_include_output is set, an additional third entry [] is included.

Note that in the case the automaton is not deterministic, all possible paths are taken into account. You can use determinisation() to get a deterministic automaton machine.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see __call__() for a version of process() with shortened output.

Internally this function creates and works with an instance of FSMProcessIterator. This iterator can also be obtained with iter_process().

If working with multi-tape finite state machines, all input words of transitions are words of $k$-tuples of letters. Moreover, the input tape has to consist of $k$ tracks, i.e., be a list or tuple of $k$ iterators, one for each track.

**Warning:** Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:

In the following examples, we construct an automaton which accepts non-adjacent forms (see also the example on non-adjacent forms in the documentation of the module Finite state machines, automata, transducers) and then test it by feeding it with several binary digit expansions.

```sage
NAF = Automaton(
    {':': [('_', 0), ('1', 1)], '1': [('_', 0)]},
    initial_states=['_'], final_states=['_', '1'])

[NAF.process(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
    [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]]
```

```sage
[(True, '_'), (True, '1'), (False, None),
(True, '1'), (False, None), (False, None)]
```

```python
>>> from sage.all import *
>>> NAF = Automaton(
...    {':': [('_', Integer(0)), ('1', Integer(1))], '1': [('_',
...        Integer(0))]},
...    initial_states=['_'], final_states=['_', '1'])

>>>
```
If we just want a condensed output, we use:

```
sage: [NAF.process(w, full_output=False)
    ....: for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
    ....: [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]
[True, True, False, True, False, False]
```

It is equivalent to:

```
sage: [NAF(w) for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
    ....: [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]
[True, True, False, True, False, False]
```

The following example illustrates the difference between non-existing paths and reaching a non-final state:

```
sage: NAF.process([2])
(False, None)
sage: NAF.add_transition(('\_', 's', 2))
Transition from '\_' to 's': 2|--
sage: NAF.process([2])
(False, 's')
```

```
>>> from sage.all import *
>>> [NAF(w) for w in [[Integer(0)], [Integer(0), Integer(1)], [Integer(1),
    ....: Integer(1)], [Integer(0), Integer(1), Integer(0), Integer(1)],
    ....: [Integer(0), Integer(0), Integer(1), Integer(1),
    ....: Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)]]]
[True, True, False, True, False, False]
```

A simple example of a (non-deterministic) multi-tape automaton is the following: It checks whether the two input tapes have the same number of ones:

```
sage: NAF.process([[Integer(2)]]
(False, None)
>>> NAF.add_transition(('\_', 's', Integer(2)))
Transition from '\_' to 's': 2|--
>>> NAF.process([[Integer(2)]]
(False, 's')
```
Combinatorics, Release 10.4

```
sage: M = Automaton([(=, =, (1, 1)),
        ...
        (=, =, (None, 0)),
        ...
        (=, '<', (0, None)),
        ...
        ('<', '<', (None, 1)),
        ...
        ('<', '<', (None, 0)),
        ...
        ('>', '>', (1, None)),
        ...
        ('>', '>', (0, None))],
        initial_states=[=],
        final_states=[=])
sage: M.process(([1, 0, 1], [1, 0]), use_multitape_input=True)
(False, >)
sage: M.process(([0, 1, 0], [0, 1, 1]), use_multitape_input=True)
(False, <)
sage: M.process(([1, 1, 0, 1], [0, 0, 1, 0, 1, 1]), use_multitape_input=True)
(True, =)
```

Alternatively, we can use the following (non-deterministic) multi-tape automaton for the same check:

```
sage: N = Automaton([(=, =, (0, 0)),
        ...
        (=, '<', (None, 1)),
        ...
        ('<', '<', (0, None)),
        ...
        ('<', '=', (1, None)),
        ...
        ('>', '>', (1, None)),
        ...
        ('>', '>', (0, None))],
        initial_states=[=],
        final_states=[=])
sage: N.process(([1, 0, 1], [1, 0]), use_multitape_input=True)
(False, >)
sage: N.process(([0, 1, 0], [0, 1, 1]), use_multitape_input=True)
(False, <)
```

(continues on next page)
sage: N.process([[1, 1, 0, 1], [0, 0, 1, 0, 1, 1]],
...       use_multitape_input=True)
(True, '=')

>>> from sage.all import *

>>> N = Automaton([('=', '=', (Integer(0), Integer(0))),
...       ('=', '<', (None, Integer(1))),
...       ('<', '<', (Integer(0), None)),
...       ('<', '>', (Integer(1), None)),
...       ('>', '=', (None, Integer(0))),
...       ('>', '>', (None, Integer(1))],
...       initial_states=['='],
...       final_states=['='])

>>> N.process([[Integer(1), Integer(0), Integer(1)], [Integer(1),
...       -> Integer(0)]), use_multitape_input=True)
(False, '>')

>>> N.process([[Integer(0), Integer(1), Integer(0)], [Integer(0),
...       -> Integer(1)]), use_multitape_input=True)
(False, '<')

>>> N.process([[Integer(1), Integer(1), Integer(0), Integer(1)], [Integer(0),
...       -> Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)]],
...       use_multitape_input=True)
(True, '=')

**shannon_parry_markov_chain()**

Compute a time homogeneous Markov chain such that all words of a given length recognized by the original
automaton occur as the output with the same weight; the transition probabilities correspond to the Parry
measure.

**OUTPUT:**

A Markov chain. Its input labels are the transition probabilities, the output labels the labels of the original
automaton. In order to obtain equal weight for all words of the same length, an “exit weight” is needed. It is
stored in the attribute color of the states of the Markov chain. The weights of the words of the same length
sum up to one up to an exponentially small error.

The stationary distribution of this Markov chain is saved as the initial probabilities of the states.

The transition probabilities correspond to the Parry measure (see [S1948] and [P1964]).

The automaton is assumed to be deterministic, irreducible and aperiodic. All states must be final.

**EXAMPLES:**

```python
sage: NAF = Automaton([(0, 0, 0), (0, 1, 1), (0, 1, -1),
...       (1, 0, 0)], initial_states=[0],
...       final_states=[0, 1])
sage: P_NAF = NAF.shannon_parry_markov_chain()  # needs sage.symbolic
sage: P_NAF.transitions()  # needs sage.symbolic
[Transition from 0 to 0: 1/2|0,
... ```
Transition from 0 to 1: 1/4|1,
Transition from 0 to 1: 1/4|-1,
Transition from 1 to 0: 1|0

```
sage: for s in P_NAF.iter_states():
    print(s.color)
3/4
3/2
```

```
>>> from sage.all import *
>>> NAF = Automaton(((Integer(0), Integer(0), Integer(0)), (Integer(0),-Integer(1), Integer(1)), (Integer(0), Integer(1), Integer(0)), (Integer(1), Integer(1), Integer(0))), initial_states=[Integer(0)], final_states=[Integer(0), Integer(1)])
>>> P_NAF = NAF.shannon_parry_markov_chain()
>>> P_NAF.transitions()
[Transition from 0 to 0: 1/2|0,
Transition from 0 to 1: 1/4|1,
Transition from 0 to 1: 1/4|-1,
Transition from 1 to 0: 1|0]
>>> for s in P_NAF.iter_states():
    print(s.color)
3/4
3/2
```

The stationary distribution is also computed and saved as the initial probabilities of the returned Markov chain:

```
sage: for s in P_NAF.states():
    print("{} {}".format(s, s.initial_probability))
0 2/3
1 1/3
```

```
>>> from sage.all import *
>>> for s in P_NAF.states():
    print("{} {}".format(s, s.initial_probability))
0 2/3
1 1/3
```

The automaton is assumed to be deterministic, irreducible and aperiodic:

```
sage: A = Automaton(((0, 0, 0), (0, 1, 1), (1, 1, 1), (1, 1, 0)),
                 initial_states=[0])
sage: A.shannon_parry_markov_chain()
Traceback (most recent call last):
    ...

NotImplementedError: Automaton must be deterministic.

```python
>>> A = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(1),Integer(0), Integer(0))],
                initial_states=[Integer(0)])

>>> A.shannon_parry_markov_chain()
```

Traceback (most recent call last):
...
NotImplementedError: Automaton must be aperiodic.

All states must be final:

```python
code: A = Automaton([(0, 1, 0), (0, 0, 1), (1, 0, 0)],
                   initial_states=[0])
code: A.shannon_parry_markov_chain()
```

Traceback (most recent call last):
...
NotImplementedError: All states must be final.

```python
>>> from sage.all import *

>>> A = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(0),
                  Integer(0), Integer(0)), (Integer(1), Integer(0), Integer(0))],
                 initial_states=[Integer(0)])

>>> A.shannon_parry_markov_chain()
```

Traceback (most recent call last):
...
NotImplementedError: All states must be final.

**ALGORITHM:**

See [HKP2015a], Lemma 4.1.

**REFERENCES:**
with_output (word_out_function=None)

Construct a transducer out of this automaton.

**INPUT:**

- `word_out_function` – (default: None) a function. It transforms a transition to the output word for this transition.

  If this is `None`, then the output word will be equal to the input word of each transition.

**OUTPUT:**

A transducer.

**EXAMPLES:**

```python
sage: A = Automaton([(0, 0, 'A'), (0, 1, 'B'), (1, 2, 'C')])
sage: T = A.with_output(); T
    Transducer with 3 states
sage: T.transitions()
    [Transition from 0 to 0: 'A'|'A',
    Transition from 0 to 1: 'B'|'B',
    Transition from 1 to 2: 'C'|'C']
```

This result is in contrast to:

```python
sage: Transducer(A).transitions()
    [Transition from 0 to 0: 'A'|-,
    Transition from 0 to 1: 'B'|-,
    Transition from 1 to 2: 'C'|-]
```

where no output labels are created.

Here is another example:

```python
sage: T2 = A.with_output(lambda t: [c.lower() for c in t.word_in])
sage: T2.transitions()
    [Transition from 0 to 0: 'A'|'a',
    Transition from 0 to 1: 'B'|'b',
    Transition from 1 to 2: 'C'|'c']
```

```python
>>> from sage.all import *

>>> A = Automaton([(Integer(0), Integer(0), 'A'), (Integer(0), Integer(1), 'B →'), (Integer(1), Integer(2), 'C')])

>>> T = A.with_output(); T
    Transducer with 3 states

>>> T.transitions()
    [Transition from 0 to 0: 'A'|'A',
    Transition from 0 to 1: 'B'|'B',
    Transition from 1 to 2: 'C'|'C']
```

This result is in contrast to:

```python
>>> from sage.all import *

>>> Transducer(A).transitions()
    [Transition from 0 to 0: 'A'|-',
    Transition from 0 to 1: 'B'|-',
    Transition from 1 to 2: 'C'|-]
```

(continues on next page)
We can obtain the same result by composing two transducers. As inner transducer of the composition, we use `with_output()` without the optional argument `word_out_function` (which makes the output of each transition equal to its input); as outer transducer we use a `map-transducer` (for converting to lower case). This gives

```python
sage: L = transducers.map(lambda x: x.lower(), ['A', 'B', 'C'])
sage: L.composition(A.with_output()).relabeled().transitions()
[Transition from 0 to 0: A|'a',
 Transition from 0 to 1: B|'b',
 Transition from 1 to 2: C|'c']
```

See also:

`input_projection()`, `output_projection()`, `Transducer`, `transducers.map()`.

```
sage.combinat.finite_state_machine.FSMLetterSymbol(letter)
```

Return a string associated to the input letter.

**INPUT:**

- `letter` – the input letter or `None` (representing the empty word).

**OUTPUT:**

If `letter` is `None` the symbol for the empty word `FSMEmptyWordSymbol` is returned, otherwise the string associated to the letter.

**EXAMPLES:**

```
sage: from sage.combinat.finite_state_machine import FSMLetterSymbol
sage: FSMLetterSymbol(0)  
'0'
sage: FSMLetterSymbol(None)  
'_'
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMLetterSymbol
>>> FSMLetterSymbol(Integer(0))  
'0'
>>> FSMLetterSymbol(None)  
'_'
```
class sage.combinat.finite_state_machine.FSMProcessIterator (fsm, input_tape=None, initial_state=None, initial_states=[], use_multitape_input=False, check_epsilon_transitions=True, write_final_word_out=True, format_output=None, process_all_prefixes_of_input=False, **kwargs)

Bases: sage_object, Iterator

This class takes an input, feeds it into a finite state machine (automaton or transducer, in particular), tests whether this was successful and calculates the written output.

INPUT:

- **fsm** – the finite state machine on which the input should be processed.
- **input_tape** – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter `use_multitape_input` and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.
- **initial_state** or **initial_states** – the initial state(s) in which the machine starts. Either specify a single one with `initial_state` or a list of them with `initial_states`. If both are given, `initial_state` will be appended to `initial_states`. If neither is specified, the initial states of the finite state machine are taken.
- **format_output** – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.
- **check_epsilon_transitions** – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.
- **write_final_word_out** – (default: True) a boolean specifying whether the final output words should be written or not.
- **use_multitape_input** – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.
- **process_all_prefixes_of_input** – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

OUTPUT:

An iterator.

In its simplest form, it behaves like an iterator which, in each step, goes from one state to another. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the process iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read. When the process stops, a `StopIteration` exception is thrown.
An instance of this class is generated when `FiniteStateMachine.process()` or `FiniteStateMachine.iter_process()` of a finite state machine, an automaton, or a transducer is invoked.

When working with multi-tape finite state machines, all input words of transitions are words of $k$-tuples of letters. Moreover, the input tape has to consist of $k$ tracks, i.e., be a list or tuple of $k$ iterators, one for each track.

**Warning:** Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

**EXAMPLES:**

The following transducer reads binary words and outputs a word, where blocks of ones are replaced by just a single one. Further only words that end with a zero are accepted.

```sage
t = Transducer({'A': [('A', 0, 0), ('B', 1, None)],
    'B': [('B', 1, None), ('A', 0, [1, 0])],
    initial_states=['A'], final_states=['A'])
t.process(input) # Output: (True, 'A', [1, 0, 0, 1, 0, 1, 0, 1, 0, 1, 0])
```

The function `FiniteStateMachine.process()` (internally) uses a `FSMProcessIterator`. We can do that manually, too, and get full access to the iteration process:

```sage
t = Transducer({'A': [('A', Integer(0), Integer(0)), ('B', Integer(1), None)],
    'B': [('B', Integer(1), None), ('A', Integer(0), [Integer(1), ...
    Integer(0)])],
    initial_states=['A'], final_states=['A'])
t.process(input) # Output: (True, 'A', [1, 0, 0, 1, 0, 1, 0, 1, 0])
```

(continues on next page)
+ at state 'B'

`FiniteStateMachine.process()`, `Automaton.process()`, `Transducer.process()`,
`FiniteStateMachine.iter_process()`, `FiniteStateMachine.__call__()`, `next()`.

```python
class Current
    Bases: dict

This class stores the branches which have to be processed during iteration and provides a nicer formatting of them.

This class is derived from `dict`. It is returned by the `next`-function during iteration.

EXAMPLES:

In the following example you can see the `dict` directly and then the nicer output provided by this class:

```python
sage: from sage.combinat.finite_state_machine import FSMProcessIterator
sage: inverter = Transducer({A: [(A, 0, 1), (A, 1, 0)]},
...: initial_states=['A'], final_states=['A'])
```

```python
sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
```

```python
sage: for current in it:
...:     print(dict(current))
...:     print(current)
{(1, 0),: {'A': Branch(tape_cache=tape at 1, outputs=[[1]])}}
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]
{(2, 0),: {'A': Branch(tape_cache=tape at 2, outputs=[[1, 0]])}}
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]
{
process (0 branches)
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMProcessIterator
```

```python
>>> inverter = Transducer({A: [(A, Integer(0), Integer(1)), (A, Integer(1), Integer(0))],
...: initial_states=['A'], final_states=['A'])
```

```python
>>> it = FSMProcessIterator(inverter, input_tape=[Integer(0), Integer(1)])
```

```python
>>> for current in it:
...     print(dict(current))
...     print(current)
{(1, 0),: {'A': Branch(tape_cache=tape at 1, outputs=[[1]])}}
process (1 branch)
```

(continues on next page)

5.1. Comprehensive Module List 1483
class FinishedBranch (accept, state, output)

Bases: tuple

A named tuple representing the attributes of a branch, once it is fully processed.

accept
   Alias for field number 0

output
   Alias for field number 2

state
   Alias for field number 1

next ()

Makes one step in processing the input tape.

INPUT:
   Nothing.

OUTPUT:
   It returns the current status of the iterator (see below). A StopIteration exception is thrown when there is/was nothing to do (i.e. all branches ended with previous call of next ()).

   The current status is a dictionary (encapsulated into an instance of Current). The keys are positions on the tape. The value corresponding to such a position is again a dictionary, where each entry represents a branch of the process. This dictionary maps the current state of a branch to a pair consisting of a tape cache and a list of output words, which were written during reaching this current state.

   EXAMPLES:

   sage: from sage.combinat.finite_state_machine import FSMProcessIterator
   sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
   ....:   initial_states=['A'], final_states=['A'])
   sage: it = FSMProcessIterator(inverter, input_tape=[0, 1])
   sage: next(it)
   process (1 branch)
   + at state 'A'
   +++ tape at 1, [[1]]
   sage: next(it)
   process (1 branch)
   + at state 'A'
   +++ tape at 2, [[1, 0]]
from sage.all import *
from sage.combinat.finite_state_machine import FSMProcessIterator

inverter = Transducer({A: [(A, Integer(0), Integer(1)), (A, _
→ Integer(1), Integer(0))]},
... initial_states=['A'], final_states=['A'])

it = FSMProcessIterator(inverter, input_tape=[Integer(0), Integer(1)])

next(it)
process (1 branch)
+ at state 'A'
+-- tape at 1, [[1]]

next(it)
process (1 branch)
+ at state 'A'
+-- tape at 2, [[1, 0]]

next(it)
process (0 branches)

next(it)
Traceback (most recent call last):
...
StopIteration

See also:

FiniteStateMachine.process(), Automaton.process(), Transducer.process(),
FiniteStateMachine.iter_process(),FiniteStateMachine.__call__(),FSMPro-
cessIterator.

preview_word(track_number=None, length=1, return_word=False)
Read a word from the input tape.

INPUT:

• track_number – an integer or None. If None, then a tuple of words (one from each track) is
  returned.
• length – (default: 1) the length of the word(s).
• return_word – (default: False) a boolean. If set, then a word is returned, otherwise a single letter
  (in which case length has to be 1).

OUTPUT:

A single letter or a word.

An exception StopIteration is thrown if the tape (at least one track) has reached its end.

Typically, this method is called from a hook-function of a state.

EXAMPLES:

sage: inverter = Transducer({'A': [('A', 0, 'one'),
... : ('A', 1, 'zero')],
... : initial_states=['A'], final_states=['A'])
sage: def state_hook(process, state, output):
... : print("We are now in state "$s." % (state.label(),))
... : try:
result (format_output=None)

Return the already finished branches during process.

INPUT:

• format_output – a function converting the output from list form to something more readable (default: output the list directly).

OUTPUT:

A list of triples (accepted, state, output).
See also the parameter format_output of \texttt{FSMProcessIterator}.

**EXAMPLES:**

```python
sage: inverter = Transducer({'A': [('A', 0, 'one'), ('A', 1, 'zero')]},
    initial_states=['A'], final_states=['A'])
sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for _ in it:
    pass
sage: it.result()
[[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]]
```

```python
>>> from sage.all import *
>>> inverter = Transducer({'A': [('A', Integer(0), 'one'), ('A', Integer(1), 'zero')]},
    initial_states=['A'], final_states=['A'])
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1), Integer(1)])
>>> for _ in it:
    pass
>>> it.result()
[[Branch(accept=True, state='A', output=['one', 'zero', 'zero'])]]
```

Using both the parameter format_output of \texttt{FSMProcessIterator} and the parameter format_output of \texttt{result()} leads to concatenation of the two functions:

```python
sage: it = inverter.iter_process(input_tape=[0, 1, 1],
    format_output=lambda L: ','.join(L))
sage: for _ in it:
    pass
sage: it.result()
[[Branch(accept=True, state='A', output=one, zero, zero)]]
```

```python
>>> from sage.all import *
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1), Integer(1)],
    format_output=lambda L: ','.join(L))
>>> for _ in it:
    pass
>>> it.result()
[[Branch(accept=True, state='A', output=one, zero, zero)]]
```

```python
class sage.combinat.finite_state_machine.FSMState

Bases: SageObject
```

Class for a state of a finite state machine.
INPUT:

- **label** – the label of the state.
- **word_out** – (default: None) a word that is written when the state is reached.
- **is_initial** – (default: False)
- **is_final** – (default: False)
- **final_word_out** – (default: None) a word that is written when the state is reached as the last state of some input; only for final states.
- **initial_probability** – (default: None) The probability of starting in this state if it is a state of a Markov chain.
- **hook** – (default: None) A function which is called when the state is reached during processing input. It takes two input parameters: the first is the current state (to allow using the same hook for several states), the second is the current process iterator object (to have full access to everything; e.g. the next letter from the input tape can be read in). It can output the next transition, i.e. the transition to take next. If it returns None the process iterator chooses. Moreover, this function can raise a StopIteration exception to stop processing of a finite state machine the input immediately. See also the example below.
- **color** – (default: None) In order to distinguish states, they can be given an arbitrary “color” (an arbitrary object). This is used in FiniteStateMachine.equivalence_classes(): states of different colors are never considered to be equivalent. Note that Automaton.determinisation() requires that color is hashable.
- **allow_label_None** – (default: False) If True allows also None as label. Note that a state with label None is used in FSMProcessIterator.

OUTPUT:

A state of a finite state machine.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state 1', word_out=0, is_initial=True)
sage: A
'state 1'
sage: A.label()
'state 1'
sage: B = FSMState('state 2')
sage: A == B
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('state 1', word_out=Integer(0), is_initial=True)
>>> A
'state 1'
>>> A.label()
'state 1'
>>> B = FSMState('state 2')
>>> A == B
False
```

We can also define a final output word of a final state which is used if the input of a transducer leads to this state. Such final output words are used in subsequential transducers.
The final output word can be a single letter, None or a list of letters:

```
sage: A = FSMState('A')
sage: A.is_final = True
sage: A.final_word_out = 2
sage: A.final_word_out
[2]
sage: A.final_word_out = [2, 3]
sage: A.final_word_out
[2, 3]
```

Only final states can have a final output word which is not None:

```
sage: B = FSMState('B')
sage: B.final_word_out is None
True
sage: B.final_word_out = 2
Traceback (most recent call last):
... ValueError: Only final states can have a final output word, but state B is not final.
```

Setting the final_word_out of a final state to None is the same as setting it to [] and is also the default for a final state:

```
sage: C = FSMState('C', is_final=True)
sage: C.final_word_out
['end']
```
It is not allowed to use `None` as a label:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: FSMState(None)
Traceback (most recent call last):
  ... ValueError: Label None reserved for a special state, choose another label.
```

This can be overridden by:

```python
sage: FSMState(None, allow_label_None=True)
None
```

Note that `Automaton.determinisation()` requires that `color` is hashable:

```python
sage: A = Automaton([[0, 0, 0], [0], [0]], initial_states=[0])
sage: A.state(0).color = []
sage: A.determinisation()
Traceback (most recent call last):
  ... TypeError: unhashable type: 'list'
sage: A.state(0).color = ()
sage: A.determinisation()
Automaton with 1 state
```
We can use a hook function of a state to stop processing. This is done by raising a `StopIteration` exception. The following code demonstrates this:

```python
>>> from sage.all import *
>>> A = Automaton([[Integer(0), Integer(0), Integer(0)]], initial_
    →states=[Integer(0)])
>>> A.state(Integer(0)).color = []
>>> A.determinisation()
Traceback (most recent call last):
... TypeError: unhashable type: 'list'
>>> A.state(Integer(0)).color = ()
>>> A.determinisation()
Automaton with 1 state
```

`copy()`

Return a (shallow) copy of the state.

INPUT:

Nothing.

OUTPUT:

A new state.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: A.is_initial = True
sage: A.is_final = True
sage: A.final_word_out = [1]
```
sage: B = copy(A)

sage: B.fully_equal(A)
True

sage: A.is_initial is B.is_initial
True

sage: A.is_final is B.is_final
True

sage: A.final_word_out is B.final_word_out
True

sage: A.color is B.color
True

sage: A.initial_probability is B.initial_probability
True

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState((1, 3), color=[1, 2], is_final=True, final_word_out=3,

deepcopy (memo=None)

Return a deep copy of the state.

INPUT:

• memo – (default: None) a dictionary storing already processed elements.

OUTPUT:

A new state.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState((1, 3), color=[1, 2], is_final=True, final_word_out=3,
....: initial_probability=1/3
sage: B = deepcopy(A)
sage: B
(1, 3)
sage: B.label() == A.label()
True
sage: B.label is A.label
False
sage: B.color == A.color
True
sage: B.color is A.color
False
sage: B.is_final == A.is_final
True
sage: B.is_final is A.is_final
True
sage: B.final_word_out == A.final_word_out
True
sage: B.final_word_out is A.final_word_out
False
sage: B.initial_probability == A.initial_probability
True

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState((Integer(1), Integer(3)), color=[Integer(1), Integer(2)], ...
...   is_final=True, final_word_out=Integer(3), ...
...   initial_probability=Integer(1)/Integer(3))
>>> B = deepcopy(A)
>>> B
(1, 3)
>>> B.label() == A.label()
True
>>> B.label is A.label
False
>>> B.color == A.color
True
>>> B.color is A.color
False
>>> B.is_final == A.is_final
True
>>> B.is_final is A.is_final
True
>>> B.final_word_out == A.final_word_out
True
>>> B.final_word_out is A.final_word_out
False
>>> B.initial_probability == A.initial_probability
True
```

**property final_word_out**

The final output word of a final state which is written if the state is reached as the last state of the input of the finite state machine. For a non-final state, the value is `None`.

`final_word_out` can be a single letter, a list or `None`, but for a final-state, it is always saved as a list.

**EXAMPLES:**
A non-final state cannot have a final output word:

```python
sage: B.final_word_out = [3, 4]
Traceback (most recent call last):
  ... ValueError: Only final states can have a final output word, but state B is not final.
```

**fully_equal**(other, compare_color=True)

Check whether two states are fully equal, i.e., including all attributes except `hook`.

**INPUT:**

- self – a state.
- other – a state.
**compare_color** – If True (default) colors are compared as well, otherwise not.

OUTPUT:

True or False.

Note that usual comparison by == does only compare the labels.

EXAMPLES:

```python
def from sage.combinat.finite_state_machine import FSMState
def A = FSMState('A')
def B = FSMState('A', is_initial=True)
def A.fully_equal(B)  # False
def A == B  # True
```

```python
A.is_initial = True; A.color = 'green'
A.fully_equal(B)  # False
```

```python
A.fully_equal(B, compare_color=False)  # True
```

---

**initial_probability** = None

**property is_final**

Describes whether the state is final or not.

True if the state is final and False otherwise.

EXAMPLES:

```python
def from sage.combinat.finite_state_machine import FSMState
A = FSMState('A', is_final=True, final_word_out=3)
A.is_final  # True
```

```python
A.is_final = False
Traceback (most recent call last):
...
ValueError: State A cannot be non-final, because it has a final output word. Only final states can have a final output word.
```

```python
A.final_word_out = None
A.is_final = False
A.is_final  # False
```

---

5.1. Comprehensive Module List
```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_final=True, final_word_out=Integer(3))
>>> A.is_final
True
>>> A.is_final = False
Traceback (most recent call last):
  ... ValueError: State A cannot be non-final, because it has a final output word. Only final states can have a final output word.
>>> A.final_word_out = None
>>> A.is_final = False
>>> A.is_final
False

is_initial = False

label()
Return the label of the state.

INPUT:
Nothing.

OUTPUT:
The label of the state.

EXAMPLES:
```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('state')
```
```
sage: A.label() 'state'
```

relabeled (label, memo=None)
Return a deep copy of the state with a new label.

INPUT:

• label – the label of new state.
• memo – (default: None) a dictionary storing already processed elements.

OUTPUT:
A new state.

EXAMPLES:
```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: A.relabeled('B')
'B'
```
```
class sage.combinat.finite_state_machine.FSMTransition(from_state, to_state, word_in=None, word_out=None, hook=None)

Bases: SageObject

Class for a transition of a finite state machine.

INPUT:

- from_state – state from which transition starts.
- to_state – state in which transition ends.
- word_in – the input word of the transitions (when the finite state machine is used as automaton)
- word_out – the output word of the transitions (when the finite state machine is used as transducer)

OUTPUT:

A transition of a finite state machine.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
sage: B = FSMState('B')
sage: S = FSMTransition(A, B, 0, 1)
sage: T = FSMTransition('A', 'B', 0, 1)

sage: T == S
True

sage: U = FSMTransition('A', 'B', 0)

sage: U == T
False

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState

>>> A = FSMState('A')

>>> A.relabeled('B')

'B'
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: copy(t)
Transition from 'A' to 'B': 0|--

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition

>>> t = FSMTransition('A', 'B', Integer(0))

>>> copy(t)
Transition from 'A' to 'B': 0|--
```

deepcopy (memo=None)

Return a deep copy of the transition.

**INPUT:**

- memo – (default: None) a dictionary storing already processed elements.

**OUTPUT:**

A new transition.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: deepcopy(t)
Transition from 'A' to 'B': 0|--
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition

>>> t = FSMTransition('A', 'B', Integer(0))

>>> deepcopy(t)
Transition from 'A' to 'B': 0|--
```

```python
from_state = None
```

State from which the transition starts. Read-only.

```python
to_state = None
```

State in which the transition ends. Read-only.

```python
word_in = None
```

Input word of the transition. Read-only.

```python
word_out = None
```

Output word of the transition. Read-only.

```python
sage.combinat.finite_state_machine.FSMWordSymbol(word)
```

Return a string of `word`. It may return the symbol of the empty word `FSMEemptyWordSymbol`.

**INPUT:**

- `word` – the input word.

**OUTPUT:**

A string of `word`.

**EXAMPLES:**
class sage.combinat.finite_state_machine.FiniteStateMachine(
    data=None,
    initial_states=None,
    final_states=None,
    input_alphabet=None,
    output_alphabet=None,
    determine_alphabets=None,
    with_final_word_out=None,
    store_states_dict=True,
    on_duplicate_transition=None
)

Bases: SageObject

Class for a finite state machine.

A finite state machine is a finite set of states connected by transitions.

INPUT:

- **data** – can be any of the following:
  1. a dictionary of dictionaries (of transitions),
  2. a dictionary of lists (of states or transitions),
  3. a list (of transitions),
  4. a function (transition function),
  5. an other instance of a finite state machine.

- **initial_states** and **final_states** – the initial and final states of this machine

- **input_alphabet** and **output_alphabet** – the input and output alphabets of this machine

- **determine_alphabets** – If True, then the function determine_alphabets() is called after data was read and processed, if False, then not. If it is None, then it is decided during the construction of the finite state machine whether determine_alphabets() should be called.

- **with_final_word_out** – If given (not None), then the function with_final_word_out() (more precisely, its inplace pendant construct_final_word_out()) is called with input letters=with_final_word_out at the end of the creation process.

- **store_states_dict** – If True, then additionally the states are stored in an internal dictionary for speed up.

- **on_duplicate_transition** – A function which is called when a transition is inserted into self which already existed (same from_state, same to_state, same word_in, same word_out).

This function is assumed to take two arguments, the first being the already existing transition, the second being the new transition (as an FSMTransition). The function must return the (possibly modified) original transition.
By default, we have `on_duplicate_transition=None`, which is interpreted as `on_duplicate_transition=duplicate_transition_ignore`, where `duplicate_transition_ignore` is a predefined function ignoring the occurrence. Other such predefined functions are `duplicate_transition_raise_error` and `duplicate_transition_add_input`.

OUTPUT:

A finite state machine.

The object creation of `Automaton` and `Transducer` is the same as the one described here (i.e. just replace the word `FiniteStateMachine` by `Automaton` or `Transducer`).

Each transition of an automaton has an input label. Automata can, for example, be determinised (see `Automaton.determinisation()`) and minimized (see `Automaton.minimization()`). Each transition of a transducer has an input and an output label. Transducers can, for example, be simplified (see `Transducer.simplification()`).

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState, FSMTransition

See documentation for more examples.

We illustrate the different input formats:

1. The input-data can be a dictionary of dictionaries, where
   - the keys of the outer dictionary are state-labels (from-states of transitions),
   - the keys of the inner dictionaries are state-labels (to-states of transitions),
   - the values of the inner dictionaries specify the transition more precisely.

The easiest is to use a tuple consisting of an input and an output word:

```
sage: FiniteStateMachine({a:{b:{word_in:0, word_out:1}, c:{word_in:1, word_out:1}}})
Finite state machine with 3 states
```

Instead of the tuple anything iterable (e.g. a list) can be used as well.

If you want to use the arguments of `FSMTransition` directly, you can use a dictionary:

```
sage: FiniteStateMachine({'a':{b:{'word_in':0, 'word_out':1}, ...., 'c':{word_in:1, 'word_out':1}}})
Finite state machine with 3 states
```

```
In the case you already have instances of `FSMTransition`, it is possible to use them directly:

```python
sage: FiniteStateMachine({'a': {'b': FSMTransition('a', 'b', 0, 1),
                                            ....
                                            'c': FSMTransition('a', 'c', 1, 1)})
Finite state machine with 3 states
```

2. The input-data can be a dictionary of lists, where the keys are states or label of states. The list-elements can be states:

```python
sage: a = FSMState('a')
sage: b = FSMState('b')
sage: c = FSMState('c')
sage: FiniteStateMachine({'a': [b, c]})
Finite state machine with 3 states
```

Or the list-elements can simply be labels of states:

```python
sage: FiniteStateMachine({'a': ['b', 'c']})
Finite state machine with 3 states
```

The list-elements can also be transitions:

```python
sage: FiniteStateMachine({'a': [FSMTransition('a', 'b', 0, 1),
                                            ....
                                            FSMTransition('a', 'c', 1, 1)]})
Finite state machine with 3 states
```

Or they can be tuples of a label, an input word and an output word specifying a transition:

```python
sage: FiniteStateMachine({'a': [('b', 0, 1), ('c', 1, 1)]})
Finite state machine with 3 states
```
>>> from sage.all import *
>>>FiniteStateMachine({"a":[("b", Integer(0), Integer(1)), ("c", Integer(1),
→Integer(1))])
Finite state machine with 3 states

3. The input-data can be a list, where its elements specify transitions:

sage: FiniteStateMachine([FSMTransition('a', 'b', 0, 1),
FSMTransition('a', 'c', 1, 1)])
Finite state machine with 3 states

It is possible to skip FSMTransition in the example above:

sage: FiniteStateMachine(["a", 'b', 0, 1], ('a', 'c', 1, 1)])
Finite state machine with 3 states

The parameters of the transition are given in tuples. Anyhow, anything iterable (e.g. a list) is possible. You can also name the parameters of the transition. For this purpose you take a dictionary:

sage: FiniteStateMachine([('from_state':'a', 'to_state':'b',
'word_in':0, 'word_out':1),
('from_state':'a', 'to_state':'c',
'word_in':1, 'word_out':1)])
Finite state machine with 3 states

Other arguments, which FSMTransition accepts, can be added, too.

4. The input-data can also be function acting as transition function:

This function has two input arguments:

1. a label of a state (from which the transition starts),
2. a letter of the (input-)alphabet (as input-label of the transition).

It returns a tuple with the following entries:

1. a label of a state (to which state the transition goes),
2. a letter of or a word over the (output-)alphabet (as output-label of the transition).
It may also output a list of such tuples if several transitions from the from-state and the input letter exist (this means that the finite state machine is non-deterministic).

If the transition does not exist, the function should raise a LookupError or return an empty list.

When constructing a finite state machine in this way, some initial states and an input alphabet have to be specified.

```python
sage: def f(state_from, read):
    ... if int(state_from) + read <= 2:
    ...     state_to = 2*int(state_from)+read
    ...     write = 0
    ...     return (str(state_to), write)
    ...
    ... else:
    ...     state_to = 2*int(state_from) + read - 5
    ...     write = 1
    ...     return (str(state_to), write)

sage: F = FiniteStateMachine(f, input_alphabet=[0, 1],
    ...     initial_states=[0],
    ...     final_states=[0])

sage: F([1, 0, 1])
(True, 0, [0, 0, 1])
```

5. The input-data can be an other instance of a finite state machine:

```python
>>> from sage.all import *

>>> def f(state_from, read):
...     if int(state_from) + read <= Integer(2):
...         state_to = Integer(2)*int(state_from)+read
...         write = Integer(0)
...         return (str(state_to), write)
...     ...
...     state_to = Integer(2)*int(state_from) + read - Integer(5)
...     write = Integer(1)
...     return (str(state_to), write)

>>> F = FiniteStateMachine(f, input_alphabet=[Integer(0), Integer(1)],
...    ...     initial_states=['0'],
...    ...     final_states=['0'])

>>> F([Integer(1), Integer(0), Integer(1)])
(True, '0', [0, 0, 1])
```

The other parameters cannot be specified in that case. If you want to change these, use the attributes FSMState.is_initial, FSMState.is_final, input_alphabet, output_alphabet, on_duplicate_transition and methods determine_alphabets(), construct_final_word_out() on the new machine, respectively.

The following examples demonstrate the use of on_duplicate_transition:
Use `duplicate_transition_add_input` to emulate a Markov chain, the input labels are considered as transition probabilities:

```
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: F = FiniteStateMachine([['a', 'a', 1/2], ['a', 'a', 1/2]],
                         on_duplicate_transition=duplicate_transition_add_input)
sage: F.transitions()
[Transition from 'a' to 'a': 1|-
```

Use `with_final_word_out` to construct final output:

```
sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 0)],
                  initial_states=[0],
                  final_states=[0],
                  with_final_word_out=0)
sage: for s in T.iter_final_states():
```
Combinatorics, Release 10.4

(continued from previous page)

```python
....:    print("\{\} \{\}").format(s, s.final_word_out))
0 [ ]
1 [0]
```

```python
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(0)), (Integer(1),
....:        Integer(0), Integer(0), Integer(0))],
....:        initial_states=[Integer(0)],
....:        final_states=[Integer(0)],
....:        with_final_word_out=Integer(0))
>>> for s in T.iter_final_states():
....:    print("\{\} \{\}").format(s, s.final_word_out))
0 [ ]
1 [0]
```

```python
__call__(*args, **kwargs)
```

Call either method `composition()` or `process()` (with `full_output=False`). If the input is not finite (`is_finite` of input is `False`), then `iter_process()` (with `iterator_type='simple'`) is called. Moreover, the flag `automatic_output_type` is set (unless `format_output` is specified). See the documentation of these functions for possible parameters.

EXAMPLES:

The following code performs a `composition()`:

```python
sage: F = Transducer((['A', 'B', 1, 0), ('B', 'B', 1, 1),
....:        ('B', 'B', 0, 0)],
....:        initial_states=['A'], final_states=['B'])
sage: G = Transducer((1, 1, 0, 0), (1, 2, 1, 0),
....:        (2, 2, 0, 1), (2, 1, 1, 1)],
....:        initial_states=[1], final_states=[1])
>>> H = G(F)
```

An automaton or transducer can also act on an input (a list or other iterable of letters):

```python
sage: binary_inverter = Transducer({A: [(A, 0, 1), (A, 1, 0)]},
....:        initial_states=['A'], final_states=['A'])
```

5.1. Comprehensive Module List 1505
>>> from sage.all import *
>>> binary_inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A',...
→ Integer(1), Integer(0))],
... initial_states=['A'], final_states=['A'])
>>> binary_inverter((Integer(0), Integer(1), Integer(0), Integer(0),...
→ Integer(1), Integer(1))
[1, 0, 1, 0, 0]

We can also let them act on words:

sage: # needs sage.combinat
sage: W = Words([0, 1]); W
Finite and infinite words over {0, 1}
sage: binary_inverter(W([0, 1, 1, 0, 1, 1]))
word: 100100

Infinite words work as well:

sage: # needs sage.combinat
sage: words.FibonacciWord()
word: 0100101001001010010100100101001001010010...
sage: binary_inverter(words.FibonacciWord())
word: 1011010110110101101011011010110110101101...

When only one successful path is found in a non-deterministic transducer, the result of that path is returned.

sage: T = Transducer([(0, 1, 0, 1), (0, 2, 0, 2)],
... initial_states=[0], final_states=[1])
sage: T.process([0])
[(False, 2, [2]), (True, 1, [1])]
sage: T([0])
[1]

>>> from sage.all import *
>>> # needs sage.combinat
>>> W = Words([Integer(0), Integer(1)]); W
Finite and infinite words over {0, 1}
>>> binary_inverter(W([Integer(0), Integer(1), Integer(1), Integer(0),...
→ Integer(1), Integer(1)]))
word: 100100

>>> from sage.all import *
>>> # needs sage.combinat
>>> W = Words([Integer(0), Integer(1)]); W
Finite and infinite words over {0, 1}
>>> binary_inverter(W([Integer(0), Integer(1), Integer(1), Integer(0),...
→ Integer(1), Integer(1)]))
word: 100100
See also:

composition(), process(), iter_process(), Automaton.process(), Transducer.process().

accessible_components()

Return a new finite state machine with the accessible states of self and all transitions between those states.

INPUT:

Nothing.

OUTPUT:

A finite state machine with the accessible states of self and all transitions between those states.

A state is accessible if there is a directed path from an initial state to the state. If self has no initial states then a copy of the finite state machine self is returned.

EXAMPLES:

```
sage: F = Automaton([(0, 0, 0), (0, 1, 1), (1, 1, 0), (1, 0, 1)],
....:             initial_states=[0])
sage: F.accessible_components()
Automaton with 2 states
```

```
>>> from sage.all import *

>>> F = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),
˓→ Integer(1), Integer(1)), (Integer(1), Integer(1), Integer(0)), (Integer(1),
˓→ Integer(0), Integer(1))],
....:             initial_states=[Integer(0)])

>>> F.accessible_components()
Automaton with 2 states
```

```
sage: F = Automaton([(0, 0, 1), (0, 0, 1), (1, 1, 0), (1, 0, 1)],
....:             initial_states=[0])
sage: F.accessible_components()
Automaton with 1 state
```

```
>>> from sage.all import *

>>> F = Automaton([(Integer(0), Integer(0), Integer(1)), (Integer(0),
˓→ Integer(0), Integer(1)), (Integer(1), Integer(1), Integer(0)), (Integer(1),
˓→ Integer(0), Integer(1))],
....:             initial_states=[Integer(0)])

>>> F.accessible_components()
Automaton with 1 state
```

See also:

collection_components()

add_from_transition_function (function, initial_states=None, explore_existing_states=True)

Constructs a finite state machine from a transition function.

INPUT:

- function may return a tuple (new_state, output_word) or a list of such tuples.
- initial_states – If no initial states are given, the already existing initial states of self are taken.
- If explore_existing_states is True (default), then already existing states in self (e.g. already given final states) will also be processed if they are reachable from the initial states.
OUTPUT:
Nothing.

EXAMPLES:

```python
sage: F = FiniteStateMachine(initial_states=['A'],
                           input_alphabet=[0, 1])
sage: def f(state, input):
    return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f)
sage: F.transitions()
[Transition from 'A' to 'A': 0|0,
 Transition from 'A' to 'B': 0|1,
 Transition from 'A' to 'A': 1|1,
 Transition from 'A' to 'B': 1|0,
 Transition from 'B' to 'A': 0|0,
 Transition from 'B' to 'B': 0|1,
 Transition from 'B' to 'A': 1|1,
 Transition from 'B' to 'B': 1|0]
```

```python
>>> from sage.all import *
>>> F = FiniteStateMachine(initial_states=['A'],
                          input_alphabet=[Integer(0), Integer(1)])
>>> def f(state, input):
    return [('A', input), ('B', Integer(1)-input)]
>>> F.add_from_transition_function(f)
>>> F.transitions()
[Transition from 'A' to 'A': 0|0,
 Transition from 'A' to 'B': 0|1,
 Transition from 'A' to 'A': 1|1,
 Transition from 'A' to 'B': 1|0,
 Transition from 'B' to 'A': 0|0,
 Transition from 'B' to 'B': 0|1,
 Transition from 'B' to 'A': 1|1,
 Transition from 'B' to 'B': 1|0]
```

Initial states can also be given as a parameter:

```python
sage: F = FiniteStateMachine(input_alphabet=[0,1])
sage: def f(state, input):
    return [('A', input), ('B', 1-input)]
sage: F.add_from_transition_function(f, initial_states=['A'])
sage: F.initial_states()
['A']
```

```python
>>> from sage.all import *
>>> F = FiniteStateMachine(input_alphabet=[Integer(0), Integer(1)])
>>> def f(state, input):
    return [('A', input), ('B', Integer(1)-input)]
>>> F.add_from_transition_function(f, initial_states=['A'])
>>> F.initial_states()
['A']
```

Already existing states in the finite state machine (the final states in the example below) are also explored:

```python
sage: F = FiniteStateMachine(initial_states=[0],
                           final_states=[1],
                           input_alphabet=[0, 1])
```

(continues on next page)
input_alphabet=[0])

sage: def transition_function(state, letter):
... return 1 - state, []

sage: F.add_from_transition_function(transition_function)

sage: F.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-

>>> from sage.all import *

>>> F = FiniteStateMachine(initial_states=[Integer(0)],
... final_states=[Integer(1)],
... input_alphabet=[Integer(0)])

>>> def transition_function(state, letter):
... return Integer(1) - state, []

>>> F.add_from_transition_function(transition_function)

>>> F.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 1 to 0: 0|-

If explore_existing_states=False, however, this behavior is turned off, i.e., already existing states are not explored:

sage: F = FiniteStateMachine(initial_states=[0],
... final_states=[1],
... input_alphabet=[0])

sage: def transition_function(state, letter):
... return 1 - state, []

sage: F.add_from_transition_function(transition_function,
... exploreExistingStates=False)

sage: F.transitions()
[Transition from 0 to 1: 0|-

add_state (state)

Adds a state to the finite state machine and returns the new state. If the state already exists, that existing state is returned.

INPUT:

• state is either an instance of FSMState or, otherwise, a label of a state.

OUTPUT:

The new or existing state.

EXAMPLES:
sage: from sage.combinat.finite_state_machine import FSMState
sage: F = FiniteStateMachine()
sage: A = FSMState('A', is_initial=True)
sage: F.add_state(A)
'A'

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> F = FiniteStateMachine()
>>> A = FSMState('A', is_initial=True)
>>> F.add_state(A)
'A'

add_states (states)

Adds several states. See add_state for more information.

INPUT:

  • states — a list of states or iterator over states.

OUTPUT:

Nothing.

EXAMPLES:

sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B'])
sage: F.states()
['A', 'B']

>>> from sage.all import *
>>> F = FiniteStateMachine()
>>> F.add_states(['A', 'B'])
>>> F.states()
['A', 'B']

add_transition (*args, **kwargs)

Adds a transition to the finite state machine and returns the new transition.

If the transition already exists, the return value of self.on_duplicate_transition is returned. See the documentation of FiniteStateMachine.

INPUT:

The following forms are all accepted:

sage: from sage.combinat.finite_state_machine import FSMState, FSMTransition
sage: A = FSMState('A')
sage: B = FSMState('B')

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(FSMTransition(A, B, 0, 1))
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(A, B, 0, 1)
Transition from 'A' to 'B': 0|1

(continues on next page)
Combinatorics, Release 10.4

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(A, B, word_in=0, word_out=1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition('A', 'B', {'word_in': 0, 'word_out': 1})
Transition from 'A' to 'B': {'word_in': 0, 'word_out': 1}|

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition(from_state=A, to_state=B,
...:       word_in=0, word_out=1)
Transition from 'A' to 'B': 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition((A, B, 0, 1))
Transition from A to B: 0|1

sage: FSM = FiniteStateMachine()
sage: FSM.add_transition([A, B, 0, 1])
Transition from A to B: 0|1

>>> from sage.all import *

>>> from sage.combinat.finite_state_machine import FSMState, FSMTransition
>>> A = FSMState('A')
>>> B = FSMState('B')

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(FSMTransition(A, B, Integer(0), Integer(1)))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(A, B, Integer(0), Integer(1))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(A, B, word_in=Integer(0), word_out=Integer(1))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition('A', 'B', {'word_in': Integer(0), 'word_out': Integer(1)})
Transition from 'A' to 'B': {'word_in': 0, 'word_out': 1}|

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(from_state=A, to_state=B,
...:       word_in=Integer(0), word_out=Integer(1))
Transition from 'A' to 'B': 0|1

>>> FSM = FiniteStateMachine()
>>> FSM.add_transition({'from_state': A, 'to_state': B,
...:       'word_in': Integer(0), 'word_out': Integer(1)})

5.1. Comprehensive Module List 1511
Transition from 'A' to 'B': 0|1
>>> FSM = FiniteStateMachine()
>>> FSM.add_transition(('A', 'B', Integer(0), Integer(1)))

Transition from 'A' to 'B': 0|1
>>> FSM = FiniteStateMachine()
>>> FSM.add_transition([('A', 'B', Integer(0), Integer(1)])

Transition from 'A' to 'B': 0|1

If the states A and B are not instances of `FSMState`, then it is assumed that they are labels of states.

OUTPUT:
The new transition.

`add_transitions_from_function`(function, labels_as_input=True)

Adds one or more transitions if function(state, state) says that there are some.

INPUT:

- function – a transition function. Given two states from_state and to_state (or their labels if label_as_input is true), this function shall return a tuple (word_in, word_out) to add a transition from from_state to to_state with input and output labels word_in and word_out, respectively. If no such addition is to be added, the transition function shall return None. The transition function may also return a list of such tuples in order to add multiple transitions between the pair of states.

- label_as_input – (default: True)

OUTPUT:
Nothing.

EXAMPLES:
sage: F = FiniteStateMachine()
sage: F.add_states(['A', 'B', 'C'])
sage: def f(state1, state2):
... if state1 == 'C':
... return None
... return (Integer(0), Integer(1))
sage: F.add_transitions_from_function(f)
sage: len(F.transitions())
6

Multiple transitions are also possible:
Combinatorics, Release 10.4

```python
sage: F = FiniteStateMachine()
sage: F.add_states([0, 1])
sage: def f(state1, state2):
    ...:     if state1 != state2:
    ...:         return [(0, 1), (1, 0)]
    ...:     else:
    ...:         return None
sage: F.add_transitions_from_function(f)
sage: F.transitions()
[Transition from 0 to 1: 0|1,
 Transition from 0 to 1: 1|0,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```
\[
\begin{bmatrix}
0 & 0 & 0 & 1 \\
0 & x & x & 0 \\
0 & 0 & 0 & x \\
\end{bmatrix}
\]

```python
>>> from sage.all import *

>>> B = FiniteStateMachine({0:{0:([0,0], [0,0]),
    'a':([1,0], [0,0]),
    2:{0:([1,0], [0,0]),
       'b':([0,0], [0,0]),
       4:{0:([1,0], [0,0]),
          'c':([0,0], [0,0])}},
    initial_states=[0])})

>>> B.adjacency_matrix()

\[
\begin{bmatrix}
1 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 1 & 0 \\
x & 0 & 0 & 0 & 1 \\
0 & x & x & 0 & 0 \\
0 & 0 & 0 & x & x \\
\end{bmatrix}
\]
```

This is equivalent to:

```python
sage: matrix(B)

\[
\begin{bmatrix}
1 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 1 & 0 \\
x & 0 & 0 & 0 & 1 \\
0 & x & x & 0 & 0 \\
0 & 0 & 0 & x & x \\
\end{bmatrix}
\]
```

It is also possible to use other entries in the adjacency matrix:

```python
sage: B.adjacency_matrix(entry=(lambda transition: 1))

\[
\begin{bmatrix}
1 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 1 & 0 \\
x & 0 & 0 & 0 & 1 \\
0 & x & x & 0 & 0 \\
0 & 0 & 0 & x & x \\
\end{bmatrix}
\]
```

```python
sage: var('t')

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 1 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 1 \\
\end{bmatrix}
\]
```

(continues on next page)
(continued from previous page)

sage: a = Automaton([(0, 1, 0),
.....: (1, 2, 0),
.....: (2, 0, 1),
.....: (2, 1, 0)],
.....: initial_states=[0],
.....: final_states=[0])
sage: a.adjacency_matrix()  # needs sage.symbolic
\[
\begin{bmatrix}
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
e^{\text{i}*t} & 0 & 0 & 0 & 0 \\
0 & 0 & e^{\text{i}*t} & 0 & 0 \\
0 & 0 & 0 & 0 & e^{\text{i}*t}
\end{bmatrix}
\]

asymptotic_moments (variable=None)

Return the main terms of expectation and variance of the sum of output labels and its covariance with the sum of input labels.

INPUT:

* variable – a symbol denoting the length of the input, by default $n$.

OUTPUT:
A dictionary consisting of

- \( \text{expectation} - en + \text{Order}(1) \),
- \( \text{variance} - vn + \text{Order}(1) \),
- \( \text{covariance} - cn + \text{Order}(1) \)

for suitable constants \( e, v \) and \( c \).

Assume that all input and output labels are numbers and that \( \text{self} \) is complete and has only one final component. Assume further that this final component is aperiodic. Furthermore, assume that there is exactly one initial state and that all states are final.

Denote by \( X_n \) the sum of output labels written by the finite state machine when reading a random input word of length \( n \) over the input alphabet (assuming equidistribution).

Then the expectation of \( X_n \) is \( en + O(1) \), the variance of \( X_n \) is \( vn + O(1) \) and the covariance of \( X_n \) and the sum of input labels is \( cn + O(1) \), cf. [HKW2015], Theorem 3.9.

In the case of non-integer input or output labels, performance degrades significantly. For rational input and output labels, consider rescaling to integers. This limitation comes from the fact that determinants over polynomial rings can be computed much more efficiently than over the symbolic ring. In fact, we compute (parts) of a trivariate generating function where the input and output labels are exponents of some indeterminates, see [HKW2015], Theorem 3.9 for details. If those exponents are integers, we can use a polynomial ring.

**EXAMPLES:**

1. A trivial example: write the negative of the input:

```python
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, -1)], initial_states=[0], final_states=[0])
sage: T([0, 1, 1])
[0, -1, -1]
sage: # needs sage.symbolic
sage: moments = T.asymptotic_moments()
sage: moments['expectation']
-1/2*n + Order(1)
sage: moments['variance']
1/4*n + Order(1)
sage: moments['covariance']
-1/4*n + Order(1)
```

```python
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(0), Integer(1), -Integer(1))], initial_states=[Integer(0)], final_states=[Integer(0)])
>>> T([Integer(0), Integer(1), Integer(1)])
[0, -1, -1]
>>> # needs sage.symbolic
>>> moments = T.asymptotic_moments()
>>> moments['expectation']
-1/2*n + Order(1)
>>> moments['variance']
1/4*n + Order(1)
>>> moments['covariance']
-1/4*n + Order(1)
```
2. For the case of the Hamming weight of the non-adjacent-form (NAF) of integers, cf. the Wikipedia article Non-adjacent_form and the example on recognizing NAFs, the following agrees with the results in [HP2007].

We first use the transducer to convert the standard binary expansion to the NAF given in [HP2007]. We use the parameter with_final_word_out such that we do not have to add sufficiently many trailing zeros:

```python
sage: NAF = Transducer([(0, 0, 0, 0),
........:     (0, '.1', 1, None),
........:     ('.1', 0, 0, [1, 0]),
........:     ('.1', 1, 1, [-1, 0]),
........:     (1, 1, 1, 0),
........:     (1, '.1', 0, None),
........:     initial_states=[0],
........:     final_states=[0],
........:     with_final_word_out=[0])
```

As an example, we compute the NAF of 27 by this transducer.

```python
sage: binary_27 = 27.bits()
sage: binary_27
[1, 1, 0, 1, 1]
sage: NAF_27 = NAF(binary_27)
sage: NAF_27
[-1, 0, -1, 0, 0, 1, 0]
sage: ZZ(NAF_27, base=2)
27
```

Next, we are only interested in the Hamming weight:

```python
sage: def weight(state, input):
........:     if input is None:
........:         result = 0
........:     ```
Now, we actually compute the asymptotic moments:

```python
sage: # needs sage.symbolic
sage: moments = NAFweight.asymptotic_moments()
sage: moments['expectation']
1/3*n + Order(1)
sage: moments['variance']
2/27*n + Order(1)
sage: moments['covariance']
Order(1)
```

```python
>>> from sage.all import *
>>> # needs sage.symbolic
>>> moments = NAFweight.asymptotic_moments()
```
3. This is Example 3.16 in [HKW2015], where a transducer with variable output labels is given. There, the aim was to choose the output labels of this very simple transducer such that the input and output sum are asymptotically independent, i.e., the constant $c$ vanishes.

```python
sage: # needs sage.symbolic
sage: var('a_1, a_2, a_3, a_4')
(a_1, a_2, a_3, a_4)
sage: T = Transducer([[0, 0, 0, a_1], [0, 1, 1, a_3],
                  [1, 0, 0, a_4], [1, 1, 1, a_2]],
                  initial_states=[0], final_states=[0, 1])
sage: moments = T.asymptotic_moments()
verbose 0 (...) Non-integer output weights lead to significant performance degradation.
```

Therefore, the asymptotic covariance vanishes if and only if $a_2 = a_1$.

4. This is Example 4.3 in [HKW2015], dealing with the transducer converting the binary expansion of an integer into Gray code (cf. the Wikipedia article Gray_code and the example on Gray code):

```python
sage: # needs sage.symbolic
sage: moments = transducers.GrayCode().asymptotic_moments()
sage: moments['expectation']
1/2*n + Order(1)
sage: moments['variance']
1/4*n + Order(1)
sage: moments['covariance']
Order(1)
```

5.1. Comprehensive Module List
5. This is the first part of Example 4.4 in [HKW2015], counting the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```python
sage: block10 = transducers.CountSubblockOccurrences(
    ...: [1, 0],
    ...: input_alphabet=[0, 1])
sage: sorted(block10.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]
sage: # needs sage.symbolic
sage: moments = block10.asymptotic_moments()
sage: moments['expectation']
1/4*n + Order(1)
sage: moments['variance']
1/16*n + Order(1)
sage: moments['covariance']
Order(1)

6. This is the second part of Example 4.4 in [HKW2015], counting the number of 11 blocks in the standard binary expansion. The least significant digit is at the left-most position:

```python
sage: block10 = transducers.CountSubblockOccurrences(
    ...: [1, 1],
    ...: input_alphabet=[0, 1])
sage: sorted(block10.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]
sage: # needs sage.symbolic
sage: moments = block10.asymptotic_moments()
sage: moments['expectation']
1/4*n + Order(1)
sage: moments['variance']
1/16*n + Order(1)
sage: moments['covariance']
Order(1)
```
Combinatorics, Release 10.4

(continued from previous page)

Transition from () to (): 0|0,
Transition from () to (1,): 1|0,
Transition from (1,) to (): 0|0,
Transition from (1,) to (1,): 1|1

sage: # needs sage.symbolic
sage: var('N')
N
sage: moments = block11.asymptotic_moments(N)
1/4*N + Order(1)
sage: moments['variance']
5/16*N + Order(1)
sage: correlation = (moments['covariance'].coefficient(N) /
....: (1/2 * sqrt(moments['variance'].coefficient(N))))
sage: correlation
2/5*sqrt(5)

7. This is Example 4.5 in [HKW2015], counting the number of 01 blocks minus the number of 10 blocks in the standard binary expansion. The least significant digit is at the left-most position:

sage: block01 = transducers.CountSubblockOccurrences(
....: [0, 1],
....: input_alphabet=[0, 1])
sage: product_01x10 = block01.cartesian_product(block10)
sage: block_difference = transducers.sub([0, 1])(product_01x10)
sage: T = block_difference.simplification().relabel()
sage: T.transitions()
[Transition from 0 to 2: 0|1,
Transition from 0 to 0: 1|1,
Transition from 1 to 2: 0|0,
Transition from 1 to 0: 1|0,
(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
Transition from 2 to 2: 0|0,
Transition from 2 to 0: 1|1
```

```
sage: # needs sage.symbolic
sage: moments = T.asymptotic_moments()
Order(1)
sage: moments['expectation']
Order(1)
sage: moments['variance']
Order(1)
sage: moments['covariance']
Order(1)
```

```>>> from sage.all import *
>>> block01 = transducers.CountSubblockOccurrences(...
   ... [Integer(0), Integer(1)],
   ... input_alphabet=[Integer(0), Integer(1)])
>>> product_01x10 = block01.cartesian_product(block10)
>>> block_difference = transducers.sub([Integer(0), Integer(1)])(product_→01x10)
>>> T = block_difference.simplification().relabelled()
>>> T.transitions()
[Transition from 0 to 2: 0|-1,
 Transition from 0 to 0: 1|0,
 Transition from 1 to 2: 0|0,
 Transition from 1 to 0: 1|0,
 Transition from 2 to 2: 0|0,
 Transition from 2 to 0: 1|1]
```

```>>> # needs sage.symbolic
>>> moments = T.asymptotic_moments()
>>> moments['expectation']
Order(1)
>>> moments['variance']
Order(1)
>>> moments['covariance']
Order(1)
```

8. The finite state machine must have a unique final component:

```
sage: T = Transducer([(0, -1, -1, -1), (0, 1, 1, 1), ...
   ... (-1, -1, -1, -1), (-1, -1, 1, -1), ...
   ... (1, 1, -1, 1), (1, 1, 1, 1)],
   ... initial_states=[0],
   ... final_states=[0, 1, -1])
sage: T.asymptotic_moments()
Traceback (most recent call last):
...
NotImplementedError: asymptotic_moments is only implemented for finite state machines with one final component.
```

```>>> from sage.all import *
>>> T = Transducer([(Integer(0), -Integer(1), -Integer(1), -Integer(1),...
   ... (Integer(0), Integer(1), Integer(1), Integer(1)),
   ... (-Integer(1), -Integer(1), -Integer(1), -Integer(1)),...
   ... (-Integer(1), -Integer(1), Integer(1), -Integer(1)),
   ... (-Integer(1), -Integer(1), Integer(1), -Integer(1)),...
   ... (-Integer(1), -Integer(1), Integer(1), -Integer(1)),...
   ... (-Integer(1), -Integer(1), -Integer(1), -Integer(1)),...
   ... (-Integer(1), -Integer(1), -Integer(1), -Integer(1)),...
   ...
   ... final_states=[0, 1, -1])```
... (Integer(1), Integer(1), -Integer(1), Integer(1)), ...
→ (Integer(1), Integer(1), Integer(1), Integer(1)), ...
... initial_states=[Integer(0)], ...
... final_states=[Integer(0), Integer(1), -Integer(1)])

>>> T.asymptotic_moments()
Traceback (most recent call last):
...
NotImplementedError: asymptotic_moments is only implemented for finite state machines with one final component.

In this particular example, the first letter of the input decides whether we reach the loop at $-1$ or the loop at $1$. In the first case, we have $X_n = -n$, while we have $X_n = n$ in the second case. Therefore, the expectation $E(X_n)$ of $X_n$ is $E(X_n) = 0$. We get $(X_n - E(X_n))^2 = n^2$ in all cases, which results in a variance of $n^2$.

So this example shows that the variance may be non-linear if there is more than one final component.

ALGORITHM:
See [HKW2015], Theorem 3.9.

REFERENCES:

coop accessible_components()
Return the sub-machine induced by the coaccessible states of this finite state machine.

OUTPUT:
A finite state machine of the same type as this finite state machine.

EXAMPLES:

```
sage: A = automata.ContainsWord([1, 1], ...
....:     input_alphabet=[0, 1]).complement().minimization().relabeled()
sage: A.transitions()
[Transition from 0 to 0: 0|-,
 Transition from 0 to 0: 1|-,
 Transition from 1 to 2: 0|-,
 Transition from 1 to 0: 1|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 1: 1|-]
sage: A.initial_states()
[2]
sage: A.final_states()
[1, 2]
sage: C = A.coaccessible_components()
sage: C.transitions()
[Transition from 1 to 2: 0|-,
 Transition from 2 to 2: 0|-,
 Transition from 2 to 1: 1|-]
```
Transition from 0 to 0: 1|-,
Transition from 1 to 2: 0|-,
Transition from 1 to 0: 1|-,
Transition from 2 to 2: 0|-,
Transition from 2 to 1: 1|-

>>> A.final_states()
[1, 2]

>>> C = A.coaccessible_components()

>>> C.transitions()

See also:

accessible_components(), induced_sub_finite_state_machine()

completion (sink=None)

Return a completion of this finite state machine.

INPUT:

• sink – either an instance of FSMState or a label for the sink (default: None). If None, the least available non-zero integer is used.

OUTPUT:

A FiniteStateMachine of the same type as this finite state machine.

The resulting finite state machine is a complete version of this finite state machine. A finite state machine is considered to be complete if each transition has an input label of length one and for each pair \((q, a)\) where \(q\) is a state and \(a\) is an element of the input alphabet, there is exactly one transition from \(q\) with input label \(a\).

If this finite state machine is already complete, a deep copy is returned. Otherwise, a new non-final state (usually called a sink) is created and transitions to this sink are introduced as appropriate.

EXAMPLES:

sage: F = FiniteStateMachine([(0, 0, 0, 0),
....:   (0, 1, 1, 1),
....:   (1, 1, 0, 0)])

sage: F.is_complete()
False

sage: G1 = F.completion()

sage: G1.is_complete()
True

sage: G1.transitions()

(continues on next page)

 Transition from 1 to 'Sink': 1|-,
 Transition from 'Sink' to 'Sink': 0|-,
 Transition from 'Sink' to 'Sink': 1|-]

>>> F.completion(Integer(1))
Traceback (most recent call last):
...
ValueError: The finite state machine already contains a state '1'.

An input alphabet must be given:

sage: F = FiniteStateMachine([(0, 0, 0, 0),
...                          (0, 1, 1, 1),
...                          (1, 1, 0, 0)],
...                          determine_alphabets=False)
sage: F.is_complete()
Traceback (most recent call last):
...
ValueError: No input alphabet is given. Try calling determine_alphabets().

5.1. Comprehensive Module List
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> F = FiniteStateMachine([(Integer(0), Integer(0), Integer(0), Integer(0)),
...                         (Integer(0), Integer(1), Integer(1), Integer(1)),
...                         (Integer(1), Integer(1), Integer(0), Integer(0))],
...                         determine_alphabets=False)
>>> F.is_complete()
Traceback (most recent call last):
... ValueError: No input alphabet is given. Try calling determine_alphabets().
```

Non-deterministic machines are not allowed.

```python
sage: F = FiniteStateMachine([(0, 0, 0, 0), (0, 1, 0, 0)])
sage: F.is_complete()
False
sage: F.completion()
Traceback (most recent call last):
... ValueError: The finite state machine must be deterministic.
```

```python
>>> from sage.all import *
>>> F = FiniteStateMachine([(Integer(0), Integer(0), Integer(0), Integer(0)),
...                         (Integer(0), Integer(1), Integer(1), Integer(1)),
...                         (Integer(1), Integer(1), Integer(0), Integer(0))])
>>> F.is_complete()
False
>>> F.completion()
Traceback (most recent call last):
... ValueError: The finite state machine must be deterministic.
```

See also:

- `is_complete()`, `split_transitions()`, `determine_alphabets()`, `is_deterministic()`.
- `composition(other, algorithm=None, only_accessible_components=True)`
  
  Return a new transducer which is the composition of `self` and `other`.

INPUT:

- `other` – a transducer
- `algorithm` – can be one of the following
– **direct** – The composition is calculated directly.

There can be arbitrarily many initial and final states, but the input and output labels must have length 1.

**Warning:** The output of other is fed into self.

– **explorative** – An explorative algorithm is used.

The input alphabet of self has to be specified.

**Warning:** The output of other is fed into self.

If algorithm is *None*, then the algorithm is chosen automatically (at the moment always direct, except when there are output words of other or input words of self of length greater than 1).

**OUTPUT:**

A new transducer.

The labels of the new finite state machine are pairs of states of the original finite state machines. The color of a new state is the tuple of colors of the constituent states.

**EXAMPLES:**

```
sage: F = Transducer([('A', 'B', 1, 0), ('B', 'A', 0, 1)],
                   initial_states=['A', 'B'], final_states=['B'],
                   determine_alphabets=True)

sage: G = Transducer([(1, 1, 1, 0), (1, 2, 0, 1),
                   (2, 2, 1, 1), (2, 2, 0, 0)],
                   initial_states=[1], final_states=[2],
                   determine_alphabets=True)

sage: Hd = F.composition(G, algorithm='direct')

sage: Hd.initial_states()
[(1, B), (1, A)]

sage: Hd.transitions()
[Transition from (1, B) to (1, A): 1|1,
 Transition from (1, A) to (2, B): 0|0,
 Transition from (2, B) to (2, A): 0|1,
 Transition from (2, A) to (2, B): 1|0]

sage: He = F.composition(G, algorithm='explorative')

sage: He.initial_states()
[(1, 'A'), (1, 'B')]

sage: He.transitions()
[Transition from (1, 'A') to (2, 'B'): 0|0,
 Transition from (1, 'B') to (1, 'A'): 1|1,
 Transition from (2, 'B') to (2, 'A'): 0|1,
 Transition from (2, 'A') to (2, 'B'): 1|0]

sage: Hd == He
True
```

```python
>>> from sage.all import *

>>> F = Transducer([('A', 'B', Integer(1), Integer(0)), ('B', 'A', Integer(0),
                   Integer(1))],
                   initial_states=['A', 'B'], final_states=['B'],
                   determine_alphabets=True)
```

(continues on next page)
The following example has output of length > 1, so the explorative algorithm has to be used (and is selected automatically).

```python
sage: F = Transducer([('A', 'B', 1, [1, 0]), ('B', 'B', 1, 1),
                     ....: ('B', 'B', 0, 0)],
                     ....: initial_states=['A'], final_states=['B'])
sage: G = Transducer([(1, 1, 0, 0), (1, 2, 1, 0),
                      ....: (2, 2, 0, 1), (2, 1, 1, 1)],
                      ....: initial_states=[1], final_states=[1])
sage: He = G.composition(F, algorithm='explorative')
sage: He.transitions()
[(Transition from ('A', 1) to ('B', 2): 1|0,1,
  Transition from ('B', 2) to ('B', 2): 0|1,
  Transition from ('B', 2) to ('B', 1): 1|1,
  Transition from ('B', 1) to ('B', 1): 0|0,
  Transition from ('B', 1) to ('B', 2): 1|0]
sage: Ha = G.composition(F)
sage: Ha == He
True

>> from sage.all import *
>> F = Transducer([('A', 'B', Integer(1), [Integer(1), Integer(0)]), ('B', 'B',
                   ....: Integer(1), Integer(1)),
                   ....: ('B', 'B', Integer(0), Integer(0))],
                   ....: initial_states=['A'], final_states=['B'])
>> G = Transducer([(Integer(1), Integer(1), Integer(0), Integer(0)),
                   ....: (Integer(2), Integer(2), Integer(0), Integer(0))],
                   ....: initial_states=[Integer(1)], final_states=[Integer(1)])
>> He = G.composition(F, algorithm='explorative')
```
Combinatorics, Release 10.4

>>> He.transitions()
[Transition from ('A', 1) to ('B', 2): 1|0,1,
 Transition from ('B', 2) to ('B', 2): 0|1,
 Transition from ('B', 2) to ('B', 1): 1|1,
 Transition from ('B', 1) to ('B', 1): 0|0,
 Transition from ('B', 1) to ('B', 2): 1|0]

>>> Ha = G.composition(F)

>>> Ha == He
True

Final output words are also considered:

```
sage: F = Transducer([(A, B, 1, 0), (B, A, 0, 1)],
                   initial_states=[A, B],
                   final_states=[A, B])
sage: F.state(A).final_word_out = 0
sage: F.state(B).final_word_out = 1
sage: G = Transducer([(1, 1, 1, 0), (1, 2, 0, 1),
                   (2, 2, 1, 1), (2, 2, 0, 0)],
                   initial_states=[1], final_states=[2])
sage: G.state(2).final_word_out = 0

>>> from sage.all import *

>>> Hd = F.composition(G, algorithm='direct')
>>> Hd.final_states()
[(2, 'B')]

```

Note that (2, 'A') is not final, as the final output 0 of state 2 of G cannot be processed in state 'A' of F.

```
sage: [s.final_word_out for s in Hd.final_states()]
[[1, 0]]

```

```
sage: He = F.composition(G, algorithm='explorative')
```

```
sage: [s.final_word_out for s in He.final_states()]
[[1, 0]]
sage: Hd == He
True
```
Here is a non-deterministic example with intermediate output length > 1.

```python
sage: F = Transducer([(1, 1, 1, ['a', 'a']), (1, 2, 1, 'b'),
                  (2, 1, 2, 'a'), (2, 2, 2, 'b')],
                  initial_states=[1, 2])

sage: G = Transducer([('A', 'A', 'a', 'i'),
                  ('A', 'B', 'a', 'l'),
                  ('B', 'B', 'b', 'e')],
                  initial_states=['A', 'B'])

sage: G(F).transitions()
[Transition from (1, A) to (1, A): 1|i,i,
 Transition from (1, A) to (1, B): 1|i,l,
 Transition from (1, B) to (2, B): 1|e,
 Transition from (2, A) to (1, A): 2|i,
 Transition from (2, A) to (1, B): 2|l,
 Transition from (2, B) to (2, B): 2|e]
```

Be aware that after composition, different transitions may share the same output label (same python object):

```python
sage: F = Transducer([(A,B,0,0), (B,A,0,0)],
                  initial_states=[A],
                  final_states=[A])

sage: F.transitions()[0].word_out is F.transitions()[1].word_out
False

sage: G = Transducer([(C,C,0,1)],
                  initial_states=[C],
                  final_states=[C])

sage: H = G.composition(F)

sage: H.transitions()[0].word_out is H.transitions()[1].word_out
True
```
concatenation (other)

Concatenate this finite state machine with another finite state machine.

INPUT:

• other—a FiniteStateMachine.

OUTPUT:

A FiniteStateMachine of the same type as this finite state machine.

Assume that both finite state machines are automata. If \( \mathcal{L}_1 \) is the language accepted by this automaton and \( \mathcal{L}_2 \) is the language accepted by the other automaton, then the language accepted by the concatenated automaton is \( \{ w_1 w_2 \mid w_1 \in \mathcal{L}_1, w_2 \in \mathcal{L}_2 \} \) where \( w_1 w_2 \) denotes the concatenation of the words \( w_1 \) and \( w_2 \).

Assume that both finite state machines are transducers and that this transducer maps words \( w_1 \in \mathcal{L}_1 \) to words \( f_1(w_1) \) and that the other transducer maps words \( w_2 \in \mathcal{L}_2 \) to words \( f_2(w_2) \). Then the concatenated transducer maps words \( w_1 w_2 \) with \( w_1 \in \mathcal{L}_1 \) and \( w_2 \in \mathcal{L}_2 \) to \( f_1(w_1) f_2(w_2) \). Here, \( w_1 w_2 \) and \( f_1(w_1) f_2(w_2) \) again denote concatenation of words.

The input alphabet is the union of the input alphabets (if possible) and None otherwise. In the latter case, try calling determine_alphabets().

Instead of \( A \concatenation B \), the notation \( A \ast B \) can be used.

EXAMPLES:

Concatenation of two automata:

```python
sage: A = automata.Word([0])
sage: B = automata.Word([1])
sage: C = A.concatenation(B)
sage: C.transitions()
[(Transition from (0, 0) to (0, 1): 0|-,
  Transition from (0, 1) to (1, 0): -|-
  Transition from (1, 0) to (1, 1): 1|-
  Transition from (1, 1) to (1, 2): 2|--)]
sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|--,
  Transition from (0, 1) to (1, 0): -|--,
  Transition from (1, 0) to (1, 1): 1|--]
sage: C.transitions()
[(0, 0) -> (0, 1), (0, 1) -> (1, 0), (1, 0) -> (1, 1), (1, 1) -> (1, 2)]
```

```python
>>> F = Transducer([('A', 'B', Integer(0), Integer(0)), ('B', 'A', Integer(0), Integer(0))],
...    initial_states=['A'],
...    final_states=['A'])
>>> F.transitions()[Integer(0)].word_out is F.transitions()[Integer(1)].word_out
False
>>> G = Transducer([(C, C, Integer(0), Integer(1))],
...    initial_states=[C],
...    final_states=[C])
>>> H = G.composition(F)
>>> H.transitions()[Integer(0)].word_out is H.transitions()[Integer(1)].word_out
True
```
Combinatorics, Release 10.4

>>> from sage.all import *
>>> A = automata.Word([Integer(0)])
>>> B = automata.Word([Integer(1)])
>>> C = A.concatenation(B)
>>> C.transitions()
[Transition from (0, 0) to (0, 1): 0|-, Transition from (0, 1) to (1, 0): -|-, Transition from (1, 0) to (1, 1): 1|-]

>>> w = [Integer(0), Integer(0)], [Integer(0), Integer(1)], ...
... for w in ([Integer(0), Integer(0)], [Integer(0), Integer(1)], ...
... if C(w)
[[0, 1]]

>>> from sage.combinat.finite_state_machine import (...
... Automaton, Transducer)
>>> isinstance(C, Automaton)
True

Concatenation of two transducers:

>>> A = Transducer([(0, 1, 0, 1), (0, 1, 1, 2)], initial_states=[0], final_states=[1])
>>> B = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)], initial_states=[0], final_states=[1])
>>> C = A.concatenation(B)
>>> C.transitions()
[Transition from (0, 0) to (0, 1): 0|1, Transition from (0, 0) to (0, 1): 1|2, Transition from (0, 1) to (1, 0): -|-, Transition from (1, 0) to (1, 1): 0|1, Transition from (1, 0) to (1, 1): 1|0]

sage: C.transitions()
[Transition from (0, 0) to (0, 1): 0|1, Transition from (0, 0) to (0, 1): 1|2, Transition from (0, 1) to (1, 0): -|-, Transition from (1, 0) to (1, 1): 0|1, Transition from (1, 0) to (1, 1): 1|0]

(continues on next page)
Alternative notation as multiplication:

```python
sage: C == A * B
True
```

Final output words are taken into account:

```python
sage: A = Transducer([(0, 1, 0, 1)],
                   initial_states=[0],
                   final_states=[1])
sage: A.state(1).final_word_out = 2
sage: B = Transducer([(0, 1, 0, 3)],
                   initial_states=[0],
                   final_states=[1])
sage: B.state(1).final_word_out = 4
sage: C = A * B
sage: C([Integer(0), Integer(0)])
[1, 2, 3, 4]
```

Handling of the input alphabet:

```python
sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [0, 0])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
```

(continues on next page)
True
sage: D.input_alphabet
[[0, 0]]
sage: (A * B).input_alphabet
[0, 1, 2]
sage: (A * C).input_alphabet is None
True
sage: (A * D).input_alphabet is None
True

>>> from sage.all import *

>>> A = Automaton([(Integer(0), Integer(0), Integer(0))])

>>> B = Automaton([(Integer(0), Integer(0), Integer(1))], input_alphabet=[Integer(1), Integer(2)])

>>> C = Automaton([(Integer(0), Integer(0), Integer(2))], determine_alphabets=False)

>>> D = Automaton([(Integer(0), Integer(0), [Integer(0), Integer(0)])], input_alphabet=[Integer(0), Integer(0)])

>>> A.input_alphabet
[0]

>>> B.input_alphabet
[1, 2]

>>> C.input_alphabet is None
True

>>> D.input_alphabet
[[0, 0]]

>>> (A * B).input_alphabet
[0, 1, 2]

>>> (A * C).input_alphabet is None
True

>>> (A * D).input_alphabet is None
True

See also:

\texttt{disjoint_union()}, \texttt{determine_alphabets()}.

\textbf{construct\_final\_word\_out} \texttt{(letters, allow\_non\_final=True)}

This is an inplace version of \texttt{with\_final\_word\_out()}. See \texttt{with\_final\_word\_out()} for documentation and examples.

\textbf{copy}()

Return a (shallow) copy of the finite state machine.

OUTPUT:

A new finite state machine.

\textbf{deepcopy} \texttt{(memo=None)}

Return a deep copy of the finite state machine.

INPUT:

\begin{itemize}
  \item memo -- (default: None) a dictionary storing already processed elements.
\end{itemize}

OUTPUT:

A new finite state machine.

EXAMPLES:
sage: F = FiniteStateMachine([(('A', 'A', 0, 1), ('A', 'A', 1, 0))])
sage: deepcopy(F)
Finite state machine with 1 state

>>> from sage.all import *

>>> F = FiniteStateMachine([(('A', 'A', Integer(0), Integer(1)), ('A', 'A', Integer(1), Integer(0)))])

>>> deepcopy(F)
Finite state machine with 1 state

default_format_letter = <sage.misc.latex.Latex object>

default_format_transition_label(word)

Default formatting of words in transition labels for LaTeX output.

INPUT:

• word – list of letters

OUTPUT:

String representation of word suitable to be typeset in mathematical mode.

• For a non-empty word: Concatenation of the letters, piped through self.format_letter and separated by blanks.

• For an empty word: sage.combinat.finite_state_machine.EmptyWordLaTeX.

There is also a variant format_transition_label_reversed() writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

sage: T = Transducer()
sage: print(T.default_format_transition_label({
....: [('a', 'alpha', 'a_1', '0', 0, (0, 1))])
\text{\texttt{a}} \text{\texttt{alpha}} \text{\texttt{a\_1}} 0 0 \left(0, 1\right)

2. In the example above, 'a' and 'alpha' should perhaps be symbols:

sage: var('a alpha a_1')
# needs sage.symbolic
(a, alpha, a_1)
sage: print(T.default_format_transition_label([a, alpha, a_1]))
# needs sage.symbolic
a \alpha a_1

(continues on next page)
3. Example of an empty word:

```python
sage: print(T.default_format_transition_label([]))
\varepsilon
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```python
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
```

```python
>>> from sage.all import *

>>> T.default_format_transition_label([])
''
```

Finally, we restore the default value:

```python
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```python
sage: A = Automaton([(0, 1, 0)])
```

```python
def custom_format_transition_label(word):
    return "t"
```

```python
sage: A.latex_options(format_transition_label=custom_format_transition_label)
```

```python
>>> from sage.all import *

>>> A = Automaton([(Integer(0), Integer(1), Integer(0))])
```

```python
>>> def custom_format_transition_label(word):
...    return "t"

>>> A.latex_options(format_transition_label=custom_format_transition_label)
```

(continues on next page)
delete_state(s)

Deletes a state and all transitions coming or going to this state.

INPUT:

- s – a label of a state or an FSMState.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t1 = FSMTransition('A', 'B', 0)
sage: t2 = FSMTransition('B', 'B', 1)
sage: F = FiniteStateMachine([t1, t2])
sage: F.delete_state('A')
sage: F.transitions()
[Transition from B to B: 1|-
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t1 = FSMTransition('A', 'B', Integer(0))
>>> t2 = FSMTransition('B', 'B', Integer(1))
>>> F = FiniteStateMachine([t1, t2])
>>> F.delete_state('A')
>>> F.transitions()
[Transition from B to B: 1|-
```

delete_transition(t)

Deletes a transition by removing it from the list of transitions of the state, where the transition starts.

INPUT:

- t – a transition.

OUTPUT:

Nothing.

EXAMPLES:

```
sage: F = FiniteStateMachine([('A', 'B', 0), ('B', 'A', 1)])
sage: F.delete_transition(('A', 'B', 0))
sage: F.transitions()
[Transition from B to A: 1|-
```

```
>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'B', Integer(0)), ('B', 'A', Integer(1))])
>>> F.delete_transition(('A', 'B', Integer(0)))
```
determine_alphabets \((\texttt{reset}=\text{True})\)

Determine the input and output alphabet according to the transitions in this finite state machine.

**INPUT:**

- \(\texttt{reset} - \) If \(\texttt{reset}\) is \(\text{True}\), then the existing input and output alphabets are erased, otherwise new letters are appended to the existing alphabets.

**OUTPUT:**

Nothing.

After this operation the input alphabet and the output alphabet of this finite state machine are a list of letters.

**Todo:** At the moment, the letters of the alphabets need to be hashable.

**EXAMPLES:**

```sage
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
   ....: (2, 2, 1, 1), (2, 2, 0, 0)],
   ....: final_states=[1],
   ....: determine_alphabets=False)

sage: T.state(1).final_word_out = [1, 4]

sage: (T.input_alphabet, T.output_alphabet)
(None, None)

sage: T.determine_alphabets()

sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], [0, 1, 4])
```

See also:

determine_input_alphabet\((\text{reset}=\text{True})\)

determine_output_alphabet\((\text{reset}=\text{True})\)

**determine_input_alphabet \((\texttt{reset}=\text{True})\)**

Determine the input alphabet according to the transitions of this finite state machine.

**INPUT:**

- \(\texttt{reset} - \) a boolean (default: \(\text{True}\)). If \(\text{True}\), then the existing input alphabet is erased, otherwise new letters are appended to the existing alphabet.
OUTPUT:
Nothing.
After this operation the input alphabet of this finite state machine is a list of letters.

Todo: At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```sage
sage: T = Transducer([(1, 1, 1, 0), (1, 2, 2, 1),
                   (2, 2, 1, 1), (2, 2, 0, 0)],
                   final_states=[1],
                   determine_alphabets=False)

sage: (T.input_alphabet, T.output_alphabet)
(None, None)

sage: T.determine_input_alphabet()

sage: (T.input_alphabet, T.output_alphabet)
([0, 1, 2], None)
```

See also:

determine_output_alphabet(), determine_alphabets().

determine_output_alphabet (reset=True)

Determine the output alphabet according to the transitions of this finite state machine.

INPUT:

- reset – a boolean (default: True). If True, then the existing output alphabet is erased, otherwise new letters are appended to the existing alphabet.

OUTPUT:

Nothing.
After this operation the output alphabet of this finite state machine is a list of letters.

Todo: At the moment, the letters of the alphabet need to be hashable.

EXAMPLES:

```sage
>>> from sage.all import *

>>> T = Transducer([(Integer(1), Integer(1), Integer(1), Integer(0)),
                  (Integer(1), Integer(2), Integer(2), Integer(1)),
                  (Integer(2), Integer(2), Integer(1), Integer(1)),
                  (Integer(2), Integer(2), Integer(0), Integer(0))],
                  final_states=[Integer(1)],
                  determine_alphabets=False)

>>> (T.input_alphabet, T.output_alphabet)
(None, None)

>>> T.determine_input_alphabet()

>>> (T.input_alphabet, T.output_alphabet)
([0, 1, 2], None)
```
....: final_states=[1],
....: determine_alphabets=False)
sage: T.state(1).final_word_out = [1, 4]
sage: (T.input_alphabet, T.output_alphabet)
(Non...}

See also:
determine_input_alphabet(), determine_alphabets().
digraph (edge_labels='words_in_out')
Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- edge_label: (default: 'words_in_out') can be
  - 'words_in_out' (labels will be strings 'i|o')
  - a function with which takes as input a transition and outputs (returns) the label

OUTPUT:
A directed graph.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A) 'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1)) Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
See also:

DiGraph

disjoint_union(other)

Return the disjoint union of this and another finite state machine.

INPUT:

• other—a FiniteStateMachine.

OUTPUT:

An finite state machine of the same type as this finite state machine.

In general, the disjoint union of two finite state machines is non-deterministic. In the case of a automata, the language accepted by the disjoint union is the union of the languages accepted by the constituent automata. In the case of transducer, for each successful path in one of the constituent transducers, there will be one successful path with the same input and output labels in the disjoint union.

The labels of the states of the disjoint union are pairs \((i, s)\): for each state \(s\) of this finite state machine, there is a state \((0, s)\) in the disjoint union; for each state \(s\) of the other finite state machine, there is a state \((1, s)\) in the disjoint union.

The input alphabet is the union of the input alphabets (if possible) and None otherwise. In the latter case, try calling determine_alphabets().

The disjoint union can also be written as \(A + B\) or \(A | B\).

EXAMPLES:

```python
def A = Automaton([(0, 1, 0), (1, 0, 1)], initial_states=[0], final_states=[0])
sage: A.disjoint_union(B)
True
sage: B = Automaton([(0, 1, 0), (1, 2, 0), (2, 0, 1)], initial_states=[0], final_states=[0])
sage: B.disjoint_union(A)
True
sage: C = A.disjoint_union(B)
sage: C
Automaton with 5 states
sage: C.transitions()
(continues on next page)```
Transition from (0, 0) to (0, 1): 0|-,
Transition from (0, 1) to (0, 0): 1|-,
Transition from (1, 0) to (1, 1): 0|-,
Transition from (1, 1) to (1, 2): 0|-,
Transition from (1, 2) to (1, 0): 1|-]
sage: C([0, 0, 1])
True
sage: C([0, 1, 0, 1])
True
sage: C([1])
False
sage: C.initial_states()
[(0, 0), (1, 0)]

Instead of .disjoint_union, alternative notations are available:
sage: C1 = A + B
sage: C1 == C
True
sage: C2 = A | B
sage: C2 == C
True

>>> from sage.all import *
>>> A = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(1),
    Integer(0), Integer(1))],
    ... initial_states=[Integer(0)],
    ... final_states=[Integer(0)])
>>> A([Integer(0), Integer(1), Integer(0), Integer(1)])
True
>>> B = Automaton([(Integer(0), Integer(1), Integer(0)), (Integer(1),
    Integer(2), Integer(0)), (Integer(2), Integer(0), Integer(1))],
    ... initial_states=[Integer(0)],
    ... final_states=[Integer(0)])
>>> B([Integer(0), Integer(0), Integer(1)])
True
>>> C = A.disjoint_union(B)
>>> C
Automaton with 5 states
>>> C.transitions()
[Transition from (0, 0) to (0, 1): 0|-,
Transition from (0, 1) to (0, 0): 1|-,
Transition from (1, 0) to (1, 1): 0|-,
Transition from (1, 1) to (1, 2): 0|-,
Transition from (1, 2) to (1, 0): 1|-]
>>> C([Integer(0), Integer(0), Integer(1)])
True
>>> C([Integer(0), Integer(1), Integer(0), Integer(1)])
True
>>> C([Integer(1)])
False
>>> C.initial_states()
[(0, 0), (1, 0)]

(continues on next page)
In general, the disjoint union is not deterministic.:

```python
sage: C.is_deterministic()
False
sage: D = C.determinisation().minimization()
```

Disjoint union of transducers:

```python
sage: T1 = Transducer([(0, 0, 0, 1)],
                   initial_states=[0],
                   final_states=[0])
```

```python
sage: T2 = Transducer([(0, 0, 0, 2)],
                   initial_states=[0],
                   final_states=[0])
```

```python
sage: T = T1.disjoint_union(T2)
```

Traceback (most recent call last):

Handling of the input alphabet (see Issue #18989):

sage: A = Automaton([(0, 0, 0)])
sage: B = Automaton([(0, 0, 1)], input_alphabet=[1, 2])
sage: C = Automaton([(0, 0, 2)], determine_alphabets=False)
sage: D = Automaton([(0, 0, [0, 0])], input_alphabet=[[0, 0]])
sage: A.input_alphabet
[0]
sage: B.input_alphabet
[1, 2]
sage: C.input_alphabet is None
True
sage: D.input_alphabet
[[0, 0]]
sage: (A + B).input_alphabet
[0, 1, 2]
sage: (A + C).input_alphabet is None
True
sage: (A + D).input_alphabet is None
True

>>> from sage.all import *

>>> A = Automaton([(Integer(0), Integer(0), Integer(0))])
>>> B = Automaton([(Integer(0), Integer(0), Integer(1))], input_alphabet=[1, 2])
>>> C = Automaton([(Integer(0), Integer(0), Integer(2))], determine_alphabets=False)
>>> D = Automaton([(Integer(0), Integer(0), [Integer(0), Integer(0)])],
  input_alphabet=[[Integer(0), Integer(0)]])
>>> A.input_alphabet
[0]
>>> B.input_alphabet
([0, 1, 2])
[1, 2]
>>> C.input_alphabet is None
True
>>> D.input_alphabet
[[0, 0]]
>>> (A + B).input_alphabet
[0, 1, 2]
>>> (A + C).input_alphabet is None
True
>>> (A + D).input_alphabet is None
True

See also:
Automaton.intersection(), Transducer.intersection(), determine_alphabet().

empty_copy (memo=None, new_class=None)
Return an empty deep copy of the finite state machine, i.e., input_alphabet, output_alphabet, on_duplicate_transition are preserved, but states and transitions are not.

INPUT:

• memo – a dictionary storing already processed elements.
• new_class – a class for the copy. By default (None), the class of self is used.

OUTPUT:
A new finite state machine.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_error
sage: F = FiniteStateMachine([('A', 'A', 0, 2), ('A', 'A', 1, 3)],
....:     input_alphabet=[0, 1],
....:     output_alphabet=[2, 3],
....:     on_duplicate_transition=duplicate_transition_raise_error)

sage: FE = F.empty_copy(); FE
Empty finite state machine
sage: FE.input_alphabet
[0, 1]
sage: FE.output_alphabet
[2, 3]
sage: FE.on_duplicate_transition == duplicate_transition_raise_error
True

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_raise_error
>>> F = FiniteStateMachine([('A', 'A', Integer(0), Integer(2)), ('A', 'A',
....: Integer(1), Integer(3))],
....:     input_alphabet=[Integer(0), Integer(1)],
....:     output_alphabet=[Integer(2), Integer(3)],
....:     on_duplicate_transition=duplicate_transition_raise_error)
>>> FE = F.empty_copy(); FE
Empty finite state machine

(continues on next page)
Combinatorics, Release 10.4

Empty finite state machine
>>> FE.input_alphabet
[0, 1]
>>> FE.output_alphabet
[2, 3]
>>> FE.on_duplicate_transition == duplicate_transition_raise_error
True

epsilon_successors (state)
Return the dictionary with states reachable from state without reading anything from an input tape as keys. The values are lists of outputs.

INPUT:
- state – the state whose epsilon successors should be determined.

OUTPUT:
A dictionary mapping states to a list of output words.

The states in the output are the epsilon successors of state. Each word of the list of output words is a word written when taking a path from state to the corresponding state.

EXAMPLES:

```sage
t = Transducer([(0, 1, None, 'a'), (1, 2, None, 'b')])
t.epsilon_successors(0)
{1: [['a']], 2: [['a', 'b']])
t.epsilon_successors(1)
{2: [['b']])
t.epsilon_successors(2)
{}
```

If there is a cycle with only epsilon transitions, then this cycle is only processed once and there is no infinite loop:

```sage
s = Transducer([(0, 1, None, 'a'), (1, 0, None, 'b')])
s.epsilon_successors(0)
{0: [['a', 'b']], 1: [['a']])
s.epsilon_successors(1)
{0: [['b']], 1: [['b', 'a']])
```

(continues on next page)
equivalence_classes()

Return a list of equivalence classes of states.

OUTPUT:

A list of equivalence classes of states.

Two states $a$ and $b$ are equivalent if and only if there is a bijection $\varphi$ between paths starting at $a$ and paths starting at $b$ with the following properties: Let $p_a$ be a path from $a$ to $a'$ and $p_b$ a path from $b$ to $b'$ such that $\varphi(p_a) = p_b$, then

- $p_a\.word_{\text{in}} = p_b\.word_{\text{in}}$,
- $p_a\.word_{\text{out}} = p_b\.word_{\text{out}}$,
- $a'$ and $b'$ have the same output label, and
- $a'$ and $b'$ are both final or both non-final and have the same final output word.

The function equivalence_classes() returns a list of the equivalence classes to this equivalence relation.

This is one step of Moore's minimization algorithm.

See also:

minimization()

EXAMPLES:

```python
sage: fsm = FiniteStateMachine([\('A', 'B', 0, 1\), \('A', 'B', 1, 0\),
\('B', 'C', 0, 0\), \('B', 'C', 1, 1\),
\('C', 'D', 0, 1\), \('C', 'D', 1, 0\),
\('D', 'A', 0, 0\), \('D', 'A', 1, 1\)]

sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]

sage: fsm.state('A').is_final = True
sage: sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]

sage: fsm.state('C').is_final = True
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]

sage: fsm.state('A').final_word_out = 1
sage: sorted(fsm.equivalence_classes())
[['A'], ['B'], ['C'], ['D']]

sage: fsm.state('C').final_word_out = 1
sage: sorted(fsm.equivalence_classes())
[['A', 'C'], ['B', 'D']]
```

```python
>>> from sage.all import *
```

```python
>>> fsm = FiniteStateMachine([\('A', 'B', Integer(0), Integer(1)\), \('A', 'B', Integer(1), Integer(0)\),
\('B', 'C', Integer(0), Integer(0)\), \('B', 'C', Integer(1), Integer(1)\),
\('C', 'D', Integer(0), Integer(1)\), \('C', 'D', Integer(1), Integer(0)\),
\('D', 'A', Integer(0), Integer(0)\), \('D', 'A', Integer(1), Integer(1)\)]
```

(continues on next page)
final_components()

Return the final components of a finite state machine as finite state machines.

OUTPUT:

A list of finite state machines, each representing a final component of self.

A final component of a transducer \( T \) is a strongly connected component \( C \) such that there are no transitions of \( T \) leaving \( C \).

The final components are the only parts of a transducer which influence the main terms of the asymptotic behaviour of the sum of output labels of a transducer, see [HKP2015] and [HKW2015].

EXAMPLES:

sage: T = Transducer(
    [ ['A', 'B', 0, 0], ['B', 'C', 0, 1],
      ['C', 'B', 0, 1], ['A', 'D', 1, 0],
      ['D', 'D', 0, 0], ['D', 'B', 1, 0],
      ['A', 'E', 2, 0], ['E', 'E', 0, 0]]
)

sage: FC = T.final_components()

sage: sorted(FC[0].transitions())
[Transition from B to C: 0|1,
 Transition from C to B: 0|1]

sage: FC[1].transitions()
[Transition from E to E: 0|0]

>>> from sage.all import *

>>> T = Transducer(
    [ ['A', 'B', Integer(0), Integer(0)], ['B', 'C', Integer(0),
      Integer(1)],
      ['C', 'B', Integer(0), Integer(1)], ['A', 'D', Integer(1),
      Integer(0)],
      ['D', 'D', Integer(0), Integer(0)], ['D', 'B', Integer(1),
      Integer(0)],
      ['A', 'E', Integer(2), Integer(0)], ['E', 'E', Integer(0),
      Integer(0)]
    )

>>> FC = T.final_components()

>>> sorted(FC[Integer(0)].transitions())
[Transition from 'B' to 'C': 0|1,
 Transition from 'C' to 'B': 0|1]

>>> FC[Integer(1)].transitions()
[Transition from 'E' to 'E': 0|0]
Another example (cycle of length 2):

```python
sage: T = Automaton([[0, 1, 0], [1, 0, 0]])
sage: len(T.final_components()) == 1
True
sage: T.final_components()[0].transitions()
[Transition from 0 to 1: 0|--,
 Transition from 1 to 0: 0|--]

```
format_transition_label(word)

Default formatting of words in transition labels for LaTeX output.

INPUT:

- word – list of letters

OUTPUT:

String representation of word suitable to be typeset in mathematical mode.

- For a non-empty word: Concatenation of the letters, piped through self.format_letter and separated by blanks.
- For an empty word: sage.combinat.finite_state_machine.EmptyWordLaTeX.

There is also a variant format_transition_label_reversed() writing the words in reversed order.

EXAMPLES:

1. Example of a non-empty word:

```python
sage: T = Transducer()
sage: print(T.default_format_transition_label(
........ ['a', 'alpha', 'a_i', '0', 0, (0, 1)])
\text{\texttt{a}} \text{\texttt{alpha}} \text{\texttt{a_i}} 0 0 \left(0, 1\right)
```

2. In the example above, 'a' and 'alpha' should perhaps be symbols:
3. Example of an empty word:

```python
>>> from sage.all import *

>>> var('a alpha a_1')

# needs sage.symbolic
(a, alpha, a_1)

>>> print(T.default_format_transition_label([a, alpha, a_1]))

# needs sage.symbolic
a \alpha a_{1}
```

We can change this by setting `sage.combinat.finite_state_machine.EmptyWordLaTeX`:

```python
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = ''
sage: T.default_format_transition_label([[]])

'\varepsilon'
```

Finally, we restore the default value:

```python
sage: sage.combinat.finite_state_machine.EmptyWordLaTeX = r'\varepsilon'
```

4. This method is the default value for `FiniteStateMachine.format_transition_label`. That can be changed to be any other function:

```python
sage: A = Automaton([(0, 1, 0)])
sage: def custom_format_transition_label(word):
    ...:    return "t"

sage: A.latex_options(format_transition_label=custom_format_transition_label)

sage: print(latex(A))

\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\node[state] (v1) at (-3.000000, 0.000000) {$1$};
\end{tikzpicture}
```

(continues on next page)
format_transition_label_reversed(word)

Format words in transition labels in reversed order.

INPUT:

• word – list of letters.

OUTPUT:

String representation of word suitable to be typeset in mathematical mode, letters are written in reversed order.

This is the reversed version of default_format_transition_label().

In digit expansions, digits are frequently processed from the least significant to the most significant position, but it is customary to write the least significant digit at the right-most position. Therefore, the labels have to be reversed.

EXAMPLES:

```python
sage: T = Transducer([(0, 0, 0, [1, 2, 3])])
sage: T.format_transition_label_reversed([1, 2, 3])
'3 2 1'
sage: T.latex_options(format_transition_label=T.format_transition_label_reversed)
sage: print(latex(T))
\begin{tikzpicture}[auto, initial text=, >=latex]
\node[state] (v0) at (3.000000, 0.000000) {$0$};
\path[->] (v0) edge[loop above] node {$0|\mid 3 2 1$} ();
\end{tikzpicture}
```
graph (edge_labels='words_in_out')

Return the graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

- **edge_label**: (default: `'words_in_out'`) can be
  - `'words_in_out'` (labels will be strings `'i'|'o'')
  - a function with which takes as input a transition and outputs (returns) the label

OUTPUT:

A directed graph.

EXAMPLES:

```
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: T = Transducer()
sage: T.graph()
Looped multi-digraph on 0 vertices
sage: T.add_state(A)
'A'
sage: T.graph()
Looped multi-digraph on 1 vertex
sage: T.add_transition(('A', 'A', 0, 1))
Transition from 'A' to 'A': 0|1
sage: T.graph()
Looped multi-digraph on 1 vertex
```

```
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A')
>>> T = Transducer()
>>> T.graph()
Looped multi-digraph on 0 vertices
>>> T.add_state(A)
'A'
>>> T.graph()
Looped multi-digraph on 1 vertex
>>> T.add_transition(('A', 'A', Integer(0), Integer(1)))
Transition from 'A' to 'A': 0|1
>>> T.graph()
Looped multi-digraph on 1 vertex
```

See also:

DiGraph

has_final_state (state)

Return whether state is one of the final states of the finite state machine.

INPUT:

- **state** can be a FSMState or a label.
OUTPUT:
True or False.

EXAMPLES:

```sage
FiniteStateMachine(final_states=['A']).has_final_state('A')
True

>>> from sage.all import *
>>> FiniteStateMachine(final_states=['A']).has_final_state('A')
True
```

**has_final_states()**

Return whether the finite state machine has a final state.

OUTPUT:
True or False.

EXAMPLES:

```sage
FiniteStateMachine().has_final_states()
False

>>> from sage.all import *
>>> FiniteStateMachine().has_final_states()
False
```

**has_initial_state(state)**

Return whether state is one of the initial states of the finite state machine.

INPUT:

- state can be a FSMState or a label.

OUTPUT:

True or False.

EXAMPLES:

```sage
F = FiniteStateMachine([('A', 'A')], initial_states=['A'])
sage: F.has_initial_state('A')
True

>>> from sage.all import *
>>> F = FiniteStateMachine([('A', 'A')], initial_states=['A'])
>>> F.has_initial_state('A')
True
```

**has_initial_states()**

Return whether the finite state machine has an initial state.

OUTPUT:
True or False.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: FiniteStateMachine().has_initial_states()
False
```

```python
>>> from sage.all import *
>>> FiniteStateMachine().has_initial_states()
False
```

**has_state**(state)

Return whether state is one of the states of the finite state machine.

**INPUT:**

- state can be a FSMState or a label of a state.

**OUTPUT:**

True or False.

**EXAMPLES:**

```python
sage: FiniteStateMachine().has_state('A')
False
```

```python
>>> from sage.all import *
>>> FiniteStateMachine().has_state('A')
False
```

**has_transition**(transition)

Return whether transition is one of the transitions of the finite state machine.

**INPUT:**

- transition has to be a FSMTransition.

**OUTPUT:**

True or False.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'A', 0, 1)
sage: FiniteStateMachine().has_transition(t)
False
sage: FiniteStateMachine().has_transition(('A', 'A', 0, 1))
Traceback (most recent call last):
  ...
TypeError: Transition is not an instance of FSMTransition.
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>>
t = FSMTransition('A', 'A', Integer(0), Integer(1))
>>> FiniteStateMachine().has_transition(t)
False
>>> FiniteStateMachine().has_transition(('A', 'A', Integer(0), Integer(1)))
Traceback (most recent call last):
  ...
TypeError: Transition is not an instance of FSMTransition.
```
**induced_subFiniteStateMachine** *(states)*

Return a sub-finite-state-machine of the finite state machine induced by the given states.

**INPUT:**

- states – a list (or an iterator) of states (either labels or instances of `FSMState`) of the sub-finite-state-machine.

**OUTPUT:**

A new finite state machine. It consists of deep copies of the given states and (deep copies) of all transitions of `self` between these states.

**EXAMPLES:**

```python
sage: FSM = FiniteStateMachine([(0, 1, 0), (0, 2, 0),
                                  (1, 2, 0), (2, 0, 0)])

sage: sub_FSM = FSM.induced_sub FiniteStateMachine([0, 1])

sage: sub_FSM.states()
[0, 1]

sage: sub_FSM.transitions()
[Transition from 0 to 1: 0|-

sage: FSM.induced_subFiniteStateMachine([3])
Traceback (most recent call last):
... ValueError: 3 is not a state of this finite state machine.
```

```python
>>> from sage.all import *

>>> FSM = FiniteStateMachine([(Integer(0), Integer(1), Integer(0)),
                             (Integer(0), Integer(2), Integer(0)),
                             (Integer(1), Integer(2), Integer(0)),
                             (Integer(2), Integer(0), Integer(0))])

>>> sub_FSM = FSM.induced_subFiniteStateMachine([Integer(0), Integer(1)])

>>> sub_FSM.states()
[0, 1]

>>> sub_FSM.transitions()
[Transition from 0 to 1: 0|-

>>> FSM.induced_subFiniteStateMachine([Integer(3)])
Traceback (most recent call last):
... ValueError: 3 is not a state of this finite state machine.
```

**initial_states** *( )*

Return a list of all initial states.

**OUTPUT:**

A list of all initial states.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)

sage: B = FSMState('B')

sage: F = FiniteStateMachine([(A, B, 1, 0)])

sage: F.initial_states()
['A']
```

1556 Chapter 5. Comprehensive Module List
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_initial=True)
>>> B = FSMState('B')
>>> F = FiniteStateMachine([(A, B, Integer(1), Integer(0))])
>>> F.initial_states()
['A']

input_alphabet = None
A list of letters representing the input alphabet of the finite state machine.

It can be set by the parameter input_alphabet when initializing a finite state machine, see FiniteStateMachine.

It can also be set by the method determine_alphabets().

See also:
FiniteStateMachine, determine_alphabets(), output_alphabet.

input_projection()
Return an automaton where the output of each transition of self is deleted.

OUTPUT:
An automaton.

EXAMPLES:

>>> F = FiniteStateMachine([(A, B, 0, 1), (A, A, 1, 1), ...
                 (B, B, 1, 0)])
>>> G = F.input_projection()
>>> G.transitions()
[Transition from A to B: 0|-
Transition from A to A: 1|-
Transition from B to B: 1|-]

intersection(other)

is_Markov_chain(is_zero=None)
Checks whether self is a Markov chain where the transition probabilities are modeled as input labels.

INPUT:

• is_zero – by default (is_zero=None), checking for zero is simply done by is_zero(). This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below.

OUTPUT:
True or False.
on_duplicate_transition must be duplicate_transition_add_input(), the sum of the input weights of the transitions leaving a state must add up to 1 and the sum of initial probabilities must add up to 1 (or all be None).

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....:     [1, 0, 1/2, 0], [1, 1, 1/2, 1]],
                   ....:     on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4), Integer(0)],
                   ....:     [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
                   ....:     [Integer(1), Integer(0), Integer(1)/Integer(2), Integer(0)],
                   ....:     [Integer(1), Integer(1), Integer(1)/Integer(2), Integer(1)]],
                   ....:     on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
True
```

on_duplicate_transition must be duplicate_transition_add_input():

```python
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....:     [1, 0, 1/2, 0], [1, 1, 1/2, 1]])
sage: F.is_Markov_chain()
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4), Integer(0)],
                   ....:     [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
                   ....:     [Integer(1), Integer(0), Integer(1)/Integer(2), Integer(0)],
                   ....:     [Integer(1), Integer(1), Integer(1)/Integer(2), Integer(1)]],
                   ....:     on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
```

False

Sum of input labels of the transitions leaving states must be 1:

```python
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   ....:     [1, 0, 1/2, 0]],
                   ....:     on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4), Integer(0)],
                   ....:     [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
                   ....:     [Integer(1), Integer(0), Integer(1)/Integer(2), Integer(0)],
                   ....:     [Integer(1), Integer(1), Integer(1)/Integer(2), Integer(1)]],
                   ....:     on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
```

False

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4), Integer(0)],
                   ....:     [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
                   ....:     [Integer(1), Integer(0), Integer(1)/Integer(2), Integer(0)],
                   ....:     [Integer(1), Integer(1), Integer(1)/Integer(2), Integer(1)]],
                   ....:     on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
```

False
The initial probabilities of all states must be `None` or they must sum up to 1. The initial probabilities of all states have to be set in the latter case:

```python
sage: F = Transducer([[0, 0, 1/4, 0], [0, 1, 3/4, 1],
                   [1, 0, 1, 0],
                   on_duplicate_transition=duplicate_transition_add_input)
sage: F.is_Markov_chain()
True
sage: F.state(0).initial_probability = 1/4
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 7
sage: F.is_Markov_chain()
False
sage: F.state(1).initial_probability = 3/4
sage: F.is_Markov_chain()
True
```

If the probabilities are variables in the symbolic ring, `assume()` will do the trick:

```python
# needs sage.symbolic
sage: var('p q')
p, q
sage: F = Transducer([[0, 0, p, 1], [0, 0, q, 0]],
                   on_duplicate_transition=duplicate_transition_add_input)
sage: assume(p + q == 1)
sage: (p + q - 1).is_zero()
True
sage: F.is_Markov_chain()
True
sage: forget()
sage: del p, q
```

```python
>>> from sage.all import *
>>> F = Transducer([[Integer(0), Integer(0), Integer(1)/Integer(4),
                   Integer(0)], [Integer(0), Integer(1), Integer(3)/Integer(4), Integer(1)],
                   [Integer(1), Integer(0), Integer(1), Integer(0)],
                   on_duplicate_transition=duplicate_transition_add_input)
>>> F.is_Markov_chain()
True
>>> F.state(Integer(0)).initial_probability = Integer(1)/Integer(4)
>>> F.is_Markov_chain()
False
>>> F.state(Integer(1)).initial_probability = Integer(7)
>>> F.is_Markov_chain()
False
>>> F.state(Integer(1)).initial_probability = Integer(3)/Integer(4)
>>> F.is_Markov_chain()
True
```
If the probabilities are variables in some polynomial ring, the parameter `is_zero` can be used:

```python
sage: R.<p, q> = PolynomialRing(QQ)
sage: def is_zero_polynomial(polynomial):
    return polynomial in (p + q - Integer(1))*R
sage: F = Transducer([(0, 0, p, 1), (0, 0, q, 0)],
    on_duplicate_transition=duplicate_transition_add_input)
sage: F.state(0).initial_probability = p + q
sage: F.is_Markov_chain()  # needs sage.libs.singular
False
```

### is_complete(){}

Return whether the finite state machine is complete.

**OUTPUT:**

True or False

A finite state machine is considered to be complete if each transition has an input label of length one and for each pair \((q, a)\) where \(q\) is a state and \(a\) is an element of the input alphabet, there is exactly one transition from \(q\) with input label \(a\).

**EXAMPLES:**

```python
sage: fsm = FiniteStateMachine([(0, 0, 0, 0),
    (0, 1, 1, 1),
    (1, 1, 0, 0)],
    determine_alphabets=False)
sage: fsm.is_complete()
Traceback (most recent call last):
  ... ValueError: No input alphabet is given. Try calling determine_alphabets().
```
sage: fsm.input_alphabet = [0, 1]
sage: fsm.is_complete()
False
sage: fsm.add_transition((1, 1, 1, 1))
Transition from 1 to 1: 1|1
sage: fsm.is_complete()
True
sage: fsm.add_transition((0, 0, 1, 0))
Transition from 0 to 0: 1|0
sage: fsm.is_complete()
False

>>> from sage.all import *

>>> fsm = FiniteStateMachine([((Integer(0), Integer(0), Integer(0)), ...
                                 →Integer(0)), ...
                                 →Integer(1)), ...
                                 →Integer(0)), ...
                                 determine_alphabets=False)

>>> fsm.is_complete()
Traceback (most recent call last):
... ValueError: No input alphabet is given. Try calling determine_alphabets().

>>> fsm.input_alphabet = [Integer(0), Integer(1)]

>>> fsm.is_complete()

is_connected()

is_deterministic()

Return whether the finite finite state machine is deterministic.

OUTPUT:

True or False

A finite state machine is considered to be deterministic if each transition has input label of length one and for each pair \((q, a)\) where \(q\) is a state and \(a\) is an element of the input alphabet, there is at most one transition from \(q\) with input label \(a\). Furthermore, the finite state may not have more than one initial state.

EXAMPLES:

sage: fsm = FiniteStateMachine()
sage: fsm.add_transition(('A', 'B', 0, []))
Transition from 'A' to 'B': 0|
sage: fsm.is_deterministic()
True
sage: fsm.add_transition(('A', 'C', 0, []))
Transition from 'A' to 'C': 0|-
sage: fsm.is_deterministic()
False
sage: fsm.add_transition(('A', 'B', [0,1], []))
Transition from 'A' to 'B': 0,1|-
sage: fsm.is_deterministic()
False

>>> from sage.all import *
>>> from sage.all import *
>>> fsm = FiniteStateMachine()
>>> fsm.add_transition(('A', 'B', Integer(0), []))
Transition from 'A' to 'B': 0|-
>>> fsm.is_deterministic()
True
>>> fsm.add_transition(('A', 'C', Integer(0), []))
Transition from 'A' to 'C': 0|-
>>> fsm.is_deterministic()
False
>>> fsm.add_transition(('A', 'B', [Integer(0),Integer(1)], []))
Transition from 'A' to 'B': 0,1|-
>>> fsm.is_deterministic()
False

Check that Issue #18556 is fixed:
sage: Automaton().is_deterministic()
True
sage: Automaton(initial_states=[0]).is_deterministic()
True
sage: Automaton(initial_states=[0, 1]).is_deterministic()
False

>>> from sage.all import *
>>> from sage.all import *
>>> Automaton().is_deterministic()
True
>>> Automaton(initial_states=[Integer(0)]).is_deterministic()
True
>>> Automaton(initial_states=[Integer(0), Integer(1)]).is_deterministic()
False

is_monochromatic()
Check whether the colors of all states are equal.

OUTPUT:
True or False

EXAMPLES:
sage: G = transducers.GrayCode()
sage: [s.color for s in G.iter_states()]
[None, None, None]
sage: G.is_monochromatic()
True
sage: G.state(1).color = 'blue'
sage: G.is_monochromatic()
False
```python
>>> from sage.all import *
>>> G = transducers.GrayCode()
>>> [s.color for s in G.iter_states()]
[None, None, None]
>>> G.is_monochromatic()
True
>>> G.state(Integer(1)).color = 'blue'
>>> G.is_monochromatic()
False
```

**iter_final_states()**

Return an iterator of the final states.

**OUTPUT:**

An iterator over all initial states.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_final=True)
sage: B = FSMState('B', is_initial=True)
sage: C = FSMState('C', is_final=True)
sage: F = FiniteStateMachine([(A, B), (A, C)])
sage: [s.label() for s in F.iter_final_states()]
['A', 'C']
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_final=True)
>>> B = FSMState('B', is_initial=True)
>>> C = FSMState('C', is_final=True)
>>> F = FiniteStateMachine([(A, B), (A, C)])
>>> [s.label() for s in F.iter_final_states()]
['A', 'C']
```

**iter_initial_states()**

Return an iterator of the initial states.

**OUTPUT:**

An iterator over all initial states.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A', is_initial=True)
sage: B = FSMState('B')
sage: F = FiniteStateMachine([(A, B, 1, 0)])
sage: [s.label() for s in F.iter_initial_states()]
['A']
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMState
>>> A = FSMState('A', is_initial=True)
>>> B = FSMState('B')
>>> F = FiniteStateMachine([(A, B, Integer(1), Integer(0))])
>>> [s.label() for s in F.iter_initial_states()]
['A']
```
**iter_process** *(input_tape=None, initial_state=None, process_iterator_class=None, iterator_type=None, automatic_output_type=False, **kwargs)*

This function returns an iterator for processing the input. See `process()` (which runs this iterator until the end) for more information.

INPUT:

- **iterator_type** – If None (default), then an instance of `FSMProcessIterator` is returned. If this is 'simple' only an iterator over one output is returned (an exception is raised if this is not the case, i.e., if the process has branched).

See `process()` for a description of the other parameters.

OUTPUT:

An iterator.

EXAMPLES:

We can use `iter_process()` to deal with infinite words:

```python
sage: inverter = Transducer({'A': [('A', 0, 1), ('A', 1, 0)]},
....:     initial_states=['A'], final_states=['A'])

sage: # needs sage.combinat
sage: words.FibonacciWord()
word: 0100101001001010010100100101001001010010...

sage: it = inverter.iter_process(
....:     words.FibonacciWord(), iterator_type='simple')

sage: Words([0,1])(it)
word: 10110101101101101101101101101101101101101...
```

This can also be done by:

```python
>>> from sage.all import *

>>> inverter = Transducer({'A': [('A', Integer(0), Integer(1)), ('A', ...->Integer(1), Integer(0)))]},
....:     initial_states=['A'], final_states=['A'])

>>> # needs sage.combinat

>>> words.FibonacciWord()
word: 0100101001001010010100100101001001010010...

>>> it = inverter.iter_process(
....:     words.FibonacciWord(), iterator_type='simple')

>>> Words([Integer(0),Integer(1)])(it)
word: 10110101101101101101101101101101101101101...
```

```python
sage: inverter.iter_process(words.FibonacciWord(),
....:     iterator_type='simple',
....:     automatic_output_type=True)
word: 10110101101101101101101101101101101101101...
```

```python
>>> from sage.all import *

>>> inverter.iter_process(words.FibonacciWord(),
....:     iterator_type='simple',
....:     automatic_output_type=True)
word: 10110101101101101101101101101101101101101...
```
or even simpler by:

```python
sage: inverter(words.FibonacciWord())  # needs sage.combinat
word: 101101101101101101101101101101101...
```

To see what is going on, we use `iter_process()` without arguments:

```python
sage: from itertools import islice
sage: it = inverter.iter_process(words.FibonacciWord())
```

```python
>>> from sage.all import *

>>> inverter(words.FibonacciWord())  # needs sage.combinat
word: 101101101101101101101101101101101...
```

The following show the difference between using the 'simple'-option and not using it. With this option, we have

```python
sage: it = inverter.iter_process(input_tape=[0, 1, 1], iterator_type='simple')
```

```python
sage: for i, o in enumerate(it):
....:     print('step $s$: output $s$' % (i, o))
```

(continues on next page)
step 0: output 1
step 1: output 0
step 2: output 0

```python
>>> from sage.all import *
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1),
                                            Integer(1)],
                               iterator_type='simple')
>>> for i, o in enumerate(it):
...     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 0
step 2: output 0
```

So `iter_process()` is a generator expression which gives a new output letter in each step (and not more). In many cases this is sufficient.

Doing the same without the 'simple'-option does not give the output directly; it has to be extracted first.

On the other hand, additional information is presented:

```python
sage: it = inverter.iter_process(input_tape=[0, 1, 1])
sage: for current in it:
....:     print(current)
process (1 branch)
  + at state 'A'
  --- tape at 1, [[1]]
process (1 branch)
  + at state 'A'
  --- tape at 2, [[1, 0]]
process (1 branch)
  + at state 'A'
  --- tape at 3, [[1, 0, 0]]
process (0 branches)
sage: it.result()
[Branch(accept=True, state='A', output=[1, 0, 0])]
```

```python
>>> from sage.all import *
>>> it = inverter.iter_process(input_tape=[Integer(0), Integer(1),
                                            Integer(1)])
>>> for current in it:
...     print(current)
process (1 branch)
  + at state 'A'
  --- tape at 1, [[1]]
process (1 branch)
  + at state 'A'
  --- tape at 2, [[1, 0]]
process (1 branch)
  + at state 'A'
  --- tape at 3, [[1, 0, 0]]
process (0 branches)
>>> it.result()
[Branch(accept=True, state='A', output=[1, 0, 0])]
```

One can see the growing of the output (the list of lists at the end of each entry).

Even if the transducer has transitions with empty or multiletter output, the simple iterator returns one new
output letter in each step:

```
sage: T = Transducer([(0, 0, 0, []),
            ...: (0, 0, 1, [1]),
            ...: (0, 0, 2, [2, 2])],
            ...: initial_states=[0])
sage: it = T.iter_process(input_tape=[0, 1, 2, 0, 1, 2],
            ...: iterator_type='simple')
sage: for i, o in enumerate(it):
            ...:     print('step %s: output %s' % (i, o))
step 0: output 1
step 1: output 2
step 2: output 2
step 3: output 1
step 4: output 2
step 5: output 2
```

See also:

`FiniteStateMachine.process()`, `Automaton.process()`, `Transducer.process()`, `__call__()`, `FSMProcessIterator`

`iter_states()`

Return an iterator of the states.

OUTPUT:

An iterator of the states of the finite state machine.

EXAMPLES:

```
sage: FSM = Automaton([(1, 2, 1), (2, 2, 0)])
sage: [s.label() for s in FSM.iter_states()]
['1', '2']
```

```
>>> from sage.all import *
>>> FSM = Automaton([('1', '2', Integer(1)), ('2', '2', Integer(0))])
>>> [s.label() for s in FSM.iter_states()]
['1', '2']
```
**iter_transitions** *(from_state=None)*

Return an iterator of all transitions.

**INPUT:**

- `from_state` – (default: None) If `from_state` is given, then a list of transitions starting there is given.

**OUTPUT:**

An iterator of all transitions.

**EXAMPLES:**

```python
sage: FSM = Automaton([(1, 2, 1), (2, 2, 0)])
sage: [(t.from_state.label(), t.to_state.label())
    for t in FSM.iter_transitions(1)]
[(1, 2)]
sage: [(t.from_state.label(), t.to_state.label())
    for t in FSM.iter_transitions(2)]
[(2, 2)]
sage: [(t.from_state.label(), t.to_state.label())
    for t in FSM.iter_transitions()]
[(1, 2), (2, 2)]
```

**kleene_star**

Compute the Kleene closure of this finite state machine.

**OUTPUT:**

A `FiniteStateMachine` of the same type as this finite state machine.

Assume that this finite state machine is an automaton recognizing the language $\mathcal{L}$. Then the Kleene star recognizes the language $\mathcal{L}^* = \{w_1...w_n \mid n \geq 0, w_j \in \mathcal{L} \text{ for all } j\}$.

Assume that this finite state machine is a transducer realizing a function $f$ on some alphabet $\mathcal{L}$. Then the Kleene star realizes a function $g$ on $\mathcal{L}^*$ with $g(w_1...w_n) = f(w_1)...f(w_n)$.

**EXAMPLES:**

Kleene star of an automaton:

```python
sage: A = automata.Word([0, 1])
sage: B = A.kleene_star()
sage: B.transitions()
[Transition from 0 to 1: 0|-,
 Transition from 2 to 0: -|-,
 Transition from 1 to 2: 1|-]
sage: from sage.combinat.finite_state_machine import *
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> A = automata.Word([Integer(0), Integer(1)])
>>> B = A.kleene_star()
>>> B.transitions()
[Transition from 0 to 1: 0|-, Transition from 2 to 0: -|-, Transition from 1 to 2: 1|-]
>>> from sage.combinat.finite_state_machine import (...
... is_Automaton, is_Transducer)
>>> isinstance(B, Automaton)
True
>>> [w for w in ([], [Integer(0), Integer(1)], [Integer(0), Integer(1),...
... Integer(0)], [Integer(0), Integer(1), Integer(0), Integer(1)], [Integer(0),...
... Integer(1), Integer(1)])
... if B(w)]
[[], [0, 1], [0, 1, 0, 1]]
```

Kleene star of a transducer:

```python
sage: T = Transducer([(0, 1, 0, 1), (0, 1, 1, 0)],
... initial_states=[0],
... final_states=[1])
```

```python
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), Integer(1)),...
... -> (Integer(0), Integer(1), Integer(1), Integer(0))],
... initial_states=[Integer(0)],
... final_states=[Integer(1)])
```

5.1. Comprehensive Module List
Transition from 0 to 1: 1|0,
Transition from 1 to 0: -|--

```python
>>> isinstance(S, Transducer)
True
>>> for w in ([], [Integer(0)], [Integer(1)], [Integer(0), Integer(0)],...
...
>> print("/{} /").format(w, S.process(w))
[ ] (True, 0, [1])
[0] [(True, 0, [1]), (True, 1, [1])]
[1] [(True, 0, [0]), (True, 1, [0])]
[0, 0] [(True, 0, [1, 1]), (True, 1, [1, 1])]
[0, 1] [(True, 0, [1, 0]), (True, 1, [1, 0])]
```

Final output words are taken into account:

```python
sage: T = Transducer([(0, 1, 0, 1)],
....:   initial_states=[0],
....:   final_states=[1])
sage: T.state(1).final_word_out = 2
sage: S = T.kleene_star()
sage: sorted(S.process([0, 0]))
[(True, 0, [1, 2, 1, 2]), (True, 1, [1, 2, 1, 2])]
```

Final output words may lead to undesirable situations if initial states and final states coincide:

```python
sage: T = Transducer(initial_states=[0], final_states=[0])
sage: T.state(0).final_word_out = 1
sage: T([])
[1]
sage: S = T.kleene_star()
sage: S([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input), but output is written.
```

```python
>>> from sage.all import *

>>> T = Transducer([Integer(0), Integer(1), Integer(0), Integer(1)],
....:   initial_states=[Integer(0)],
....:   final_states=[Integer(1)])
>>> T.state(Integer(1)).final_word_out = Integer(2)
>>> S = T.kleene_star()
>>> sorted(S.process([Integer(0), Integer(0)]))
[(True, 0, [1, 2, 1, 2]), (True, 1, [1, 2, 1, 2])]
```

```python
>>> from sage.all import *

>>> T = Transducer(initial_states=[Integer(0)], final_states=[Integer(0)])
>>> T.state(Integer(0)).final_word_out = Integer(1)
>>> T([])
[1]
>>> S = T.kleene_star()
>>> S([])
Traceback (most recent call last):
...
RuntimeError: State 0 is in an epsilon cycle (no input), but output is written.
```
**language** (*max_length=None, **kwargs*)

Return all words that can be written by this transducer.

**INPUT:**

- `max_length` – an integer or `None` (default). Only output words which come from inputs of length at most `max_length` will be considered. If `None`, then this iterates over all possible words without length restrictions.

- `kwargs` – will be passed on to the `process iterator`. See `process()` for a description.

**OUTPUT:**

An iterator.

**EXAMPLES:**

```python
sage: NAF = Transducer([('I', 0, 0, None), ('I', 1, 1, None),
    ... (0, 0, 0, 0), (0, 1, 1, 0),
    ... (1, 0, 0, 1), (1, 2, 1, -1),
    ... initial_states=['I'], final_states=[0],
    ... input_alphabet=[0, 1])

sage: sorted(NAF.language(4),
    ... key=lambda o: (ZZ(o, base=2), len(o)))
[[], [0], [0, 0], [0, 0, 0],
[1], [1, 0], [1, 0, 0],
[-1, 0, 1],
[0, 0, 1],
[1, 0, 1]]
```
sage: next(iterator)
[0, 0]
sage: next(iterator)
[0, 1]

```python
>>> from sage.all import *
>>> iterator = NAF.language()
```

```python
>>> next(iterator)
[]
>>> next(iterator)
[0]
>>> next(iterator)
[1]
>>> next(iterator)
[0, 0]
>>> next(iterator)
[0, 1]
```

See also:

Automaton.language(), process().

latex_options (coordinates=None, format_state_label=None, format_letter=None, format_transition_label=None, loop_where=None, initial_where=None, accepting_style=None, accepting_distance=None, accepting_where=None, accepting_show_empty=None)

Set options for LaTeX output via latex() and therefore view().

INPUT:

- coordinates—a dictionary or a function mapping labels of states to pairs interpreted as coordinates. If no coordinates are given, states placed equidistantly on a circle of radius 3. See also set_coordinates().

- format_state_label—a function mapping labels of states to a string suitable for typesetting in LaTeX's mathematics mode. If not given, latex() is used.

- format_letter—a function mapping letters of the input and output alphabets to a string suitable for typesetting in LaTeX's mathematics mode. If not given, default_format_transition_label() uses latex().

- format_transition_label—a function mapping words over the input and output alphabets to a string suitable for typesetting in LaTeX's mathematics mode. If not given, default_format_transition_label() is used.

- loop_where—a dictionary or a function mapping labels of initial states to one of 'above', 'left', 'below', 'right'. If not given, 'above' is used.

- initial_where—a dictionary or a function mapping labels of initial states to one of 'above', 'left', 'below', 'right'. If not given, TikZ' default (currently 'left') is used.

- accepting_style—one of 'accepting by double' and 'accepting by arrow'. If not given, 'accepting by double' is used unless there are non-empty final output words.

- accepting_distance—a string giving a LaTeX length used for the length of the arrow leading from a final state. If not given, TikZ' default (currently '3ex') is used unless there are non-empty final output words, in which case '7ex' is used.
• accepting_where – a dictionary or a function mapping labels of final states to one of 'above', 'left', 'below', 'right'. If not given, TikZ’ default (currently 'right') is used. If the final state has a final output word, it is also possible to give an angle in degrees.

• accepting_show_empty – if True the arrow of an empty final output word is labeled as well. Note that this implicitly implies accepting_style='accepting by arrow'. If not given, the default False is used.

OUTPUT:
Nothing.

As TikZ (cf. the Wikipedia article PGF/TikZ) is used to typeset the graphics, the syntax is oriented on TikZ’ syntax.

This is a convenience function collecting all options for LaTeX output. All of its functionality can also be achieved by directly setting the attributes

• coordinates, format_label, loop_where, initial_where, and accepting_where of FSMState (here, format_label is a callable without arguments, everything else is a specific value);

• format_label of FSMTransition (format_label is a callable without arguments);

• format_state_label, format_letter, format_transition_label, accepting_style, accepting_distance, and accepting_show_empty of FiniteStateMachine.

This function, however, also (somewhat) checks its input and serves to collect documentation on all these options.

The function can be called several times, only those arguments which are not None are taken into account. By the same means, it can be combined with directly setting some attributes as outlined above.

EXAMPLES:
See also the section on \textit{LaTeX output} in the introductory examples of this module.

\begin{verbatim}

5.1. Comprehensive Module List
\textbf{markov\_chain\_simplification()}

Consider \texttt{self} as Markov chain with probabilities as input labels and simplify it.

\textbf{INPUT:}

Nothing.

\textbf{OUTPUT:}

Simplified version of \texttt{self}.

\textbf{EXAMPLES:}

\begin{verbatim}
\sage: \textbf{from sage.combinat.finite_state_machine import duplicate_transition_add_input}
\sage: T = Transducer([[1, 2, 1/4, 0], [1, -2, 1/4, 0], [1, -2, 1/2, 0],
                    [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
                    [-2, 2, 1/4, 1], [2, 3, 1/2, 2], [-2, 3, 1/2, 2]],
                   initial_states=[1],
                   final_states=[3],
                   on_duplicate_transition=duplicate_transition_add_input)
\sage: T1 = T.markov_chain_simplification()
\sage: sorted(T1.transitions())
[Transition from ((1,),) to ((2, -2),): 1/2|1,
 Transition from ((2, -2),) to ((2, -2),): 1/2|2,
 Transition from ((2, -2),) to ((3,),): 1/2|2]
\end{verbatim}

\begin{verbatim}
>>> \textbf{from sage.all import *}
>>> \textbf{from sage.combinat.finite_state_machine import duplicate_transition_add_input}
>>> T = Transducer([[Integer(1), Integer(2), Integer(1)/Integer(4),
                   Integer(0)],
                   [Integer(1), -Integer(2), Integer(1)/Integer(4), Integer(0)],
                   [Integer(1), -Integer(2), Integer(1)/Integer(2), Integer(0)],
                   [Integer(2), Integer(2), Integer(1)/Integer(4), Integer(1)],
                   [-Integer(2), Integer(2), Integer(1)/Integer(4), Integer(1)],
                   [-Integer(2), -Integer(2), Integer(1)/Integer(4), Integer(1)],
                   [-Integer(2), -Integer(2), Integer(1)/Integer(2), Integer(2)],
                   [Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)],
                   [-Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)],
                   [-Integer(2), Integer(3), Integer(1)/Integer(4), Integer(1)],
                   [-Integer(2), Integer(3), Integer(1)/Integer(4), Integer(1)],
                   [-Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)],
                   [Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)],
                   [Integer(2), Integer(3), Integer(1)/Integer(4), Integer(1)],
                   [Integer(2), Integer(3), Integer(1)/Integer(4), Integer(1)],
                   [Integer(2), Integer(3), Integer(1)/Integer(2), Integer(2)]],
                  initial_states=[Integer(1)],
                  final_states=[Integer(3)],
                  on_duplicate_transition=duplicate_transition_add_input)
>>> T1 = T.markov_chain_simplification()
>>> sorted(T1.transitions())
[Transition from ((1,),) to ((2, -2),): 1/2|0,
 Transition from ((2, -2),) to ((2, -2),): 1/2|1,
 Transition from ((2, -2),) to ((3,),): 1/2|2]
\end{verbatim}

\textbf{merged\_transitions()}

Merges transitions which have the same \texttt{from\_state}, \texttt{to\_state} and \texttt{word\_out} while adding their \texttt{word\_in}.

\textbf{INPUT:}
Nothing.

OUTPUT:

A finite state machine with merged transitions. If no mergers occur, return `self`.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: T = Transducer([[1, 2, 1/4, 1], [1, -2, 1/4, 1], [1, -2, 1/2, 1],
                   [2, 2, 1/4, 1], [2, -2, 1/4, 1], [-2, -2, 1/4, 1],
                   [-2, 2, 1/4, 1], [2, 3, 1/2, 1], [-2, 3, 1/2, 1]],
                   on_duplicate_transition=duplicate_transition_add_input)
```

```python
sage: T1 = T.merged_transitions()
sage: T1 is T
False
sage: sorted(T1.transitions())
[Transition from -2 to -2: 1/4|1,
 Transition from -2 to 2: 1/4|1,
 Transition from -2 to 3: 1/2|1,
 Transition from 1 to 2: 1/4|1,
 Transition from 1 to -2: 3/4|1,
 Transition from 2 to -2: 1/4|1,
 Transition from 2 to 2: 1/4|1,
 Transition from 2 to 3: 1/2|1]
```

Applying the function again does not change the result:

```python
sage: T2 = T1.merged_transitions()
sage: T2 is T1
True
```

5.1. Comprehensive Module List
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> T2 = T1.merged_transitions()
>>> T2 is T1
True
```

`moments_waiting_time` *(test=\langle class 'bool'\rangle, is_zero=None, expectation_only=False)*

If this finite state machine acts as a Markov chain, return the expectation and variance of the number of steps until first writing `True`.

**INPUT:**

- `test` – (default: `bool`) a callable deciding whether an output label is to be considered `True`. By default, the standard conversion to boolean is used.
- `is_zero` – (default: `None`) a callable deciding whether an expression for a probability is zero. By default, checking for zero is simply done by `is_zero()`. This parameter can be used to provide a more sophisticated check for zero, e.g. in the case of symbolic probabilities, see the examples below.
- `expectation_only` – (default: `False`) if set, the variance is not computed (in order to save time). By default, the variance is computed.

**OUTPUT:**

A dictionary (if `expectation_only=False`) consisting of

- expectation.
- variance.

Otherwise, just the expectation is returned (no dictionary for `expectation_only=True`).

Expectation and variance of the number of steps until first writing `True` (as determined by the parameter `test`).

**ALGORITHM:**

Relies on a (classical and easy) probabilistic argument, cf. [FGT1992], Eqns. (6) and (7).

For the variance, see [FHP2015], Section 2.

**EXAMPLES:**

1. The simplest example is to wait for the first 1 in a 0-1-string where both digits appear with probability 1/2. In fact, the waiting time equals \( k \) if and only if the string starts with \( 0^{k-1}1 \). This event occurs with probability \( 2^{-k} \). Therefore, the expected waiting time and the variance are \( \sum_{k\geq1} k2^{-k} = 2 \) and \( \sum_{k\geq1}(k-2)^22^{-k} = 2 \):

```python
sage: var('k')
# needs sage.symbolic
k
sage: sum(k * 2^(-k), k, 1, infinity)
# needs sage.symbolic
2
sage: sum((k-2)^2 * 2^(-k), k, 1, infinity)
# needs sage.symbolic
2
```
We now compute the same expectation and variance by using a Markov chain:

```python
sage: from sage.combinat.finite_state_machine import (....: duplicate_transition_add_input)
....: T = Transducer(
....:     [(Integer(0), Integer(0), Integer(1)/Integer(2), Integer(0)),
....:      on_duplicate_transition=duplicate_transition_add_input,
....:      initial_states=[Integer(0)],
....:      final States=[Integer(0)])
sage: T.moments_waiting_time()
{'expectation': 2, 'variance': 2}
sage: T.moments_waiting_time(expectation_only=True)
2
```
2. Make sure that the transducer is actually a Markov chain. Although this is checked by the code, unexpected behaviour may still occur if the transducer looks like a Markov chain. In the following example, we 'forget' to assign probabilities, but due to a coincidence, all 'probabilities' add up to one. Nevertheless, 0 is never written, so the expectation is 1.

```python
sage: T = Transducer([(0, 0, 0, 0), (0, 0, 1, 1)],
                   on_duplicate_transition=duplicate_transition_add_input,
                   initial_states=[0],
                   final_states=[0])
sage: T.moments_waiting_time()
{'expectation': 1, 'variance': 0}
```

3. If True is never written, the moments are $+\infty$:

```python
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), Integer(0)),
                  (Integer(0), Integer(0), Integer(1), Integer(1))],
                  on_duplicate_transition=duplicate_transition_add_input,
                  initial_states=[Integer(0)],
                  final_states=[Integer(0)])
>>> T.moments_waiting_time()
{'expectation': +Infinity, 'variance': +Infinity}
```

4. Let $h$ and $r$ be positive integers. We consider random strings of letters $1, \ldots, r$ where the letter $j$ occurs with probability $p_j$. Let $B$ be the random variable giving the first position of a block of $h$ consecutive identical letters. Then

$$E(B) = \frac{1}{\sum_{i=1}^{r} p_i^{-1} + \cdots + p_i^{-h}},$$

$$V(B) = \frac{\sum_{i=1}^{r} \left( p_i + p_i^h - 2h p_i^h (1 - p_i) (1 - p_i^h)^2 \right)}{\left(\sum_{i=1}^{r} p_i^{-1} + \cdots + p_i^{-h}\right)^2}.$$  

cf. [S1986], p. 62, or [FHP2015], Theorem 1. We now verify this with a transducer approach.
```python
def test(h, r):
    R = PolynomialRing(QQ, names=['p_%d' % j for j in range(r)])
p = R.gens()
def is_zero(polynomial):
    return polynomial in (sum(p) - 1) * R
theory_expectation = 1/(sum(1/sum(p[j]**(-i) for i in range(1, h+1)) for j in range(r)))
theory_variance = sum((p[i] + p[i]**h)/(1 - p[i]**h) - 2*h*p[i]**h * (1 - p[i])/(1 - p[i]**h)**2 for i in range(r))
alphabet = list(range(r))
counters = [transducers.CountSubblockOccurrences([j]*h, alphabet) for j in alphabet]
all_counter = counters[0].cartesian_product(counters[1:])
adder = transducers.add(input_alphabet=[0, 1], number_of_operands=r)
probabilities = Transducer([(0, 0, p[j], j) for j in alphabet], initial_states=[0], final_states=[0], on_duplicate_transition=duplicate_transition_add_input)
chain = adder(all_counter(probabilities))
result = chain.moments_waiting_time(is_zero=is_zero)
return is_zero((result['expectation'] - theory_expectation).numerator()) and is_zero((result['variance'] - theory_variance).numerator())
```
5. Consider the alphabet \{0, \ldots, r - 1\}, some 1 \leq j \leq r and some 1 \leq h \geq 1. For some probabilities \(p_0, \ldots, p_{r-1}\), we consider infinite words where the letters occur independently with the given probabilities. The random variable \(B_j\) is the first position \(n\) such that there exist \(j\) of the \(r\) letters having an \(h\)-run. The expectation of \(B_j\) is given in [FHP2015], Theorem 2. Here, we verify this result by using transducers:

```sage
# needs sage.libs.singular
sage: def test(h, r, j):
...... R = PolynomialRing(
...... QQ,
...... names=['p_%d' % i for i in range(r)])
...... p = R.gens()
...... def is_zero(polynomial):
...... return polynomial in {sum(p) - 1} * R
...... alphabet = list(range(r))
...... counters = [
...... transducers.Wait([0, 1])
...... transducers.CountSubblockOccurrences([i]*h, alphabet))
...... for i in alphabet]
```

(continues on next page)
all_counter = counters[0].cartesian_product(counters[1:])
adder = transducers.add(input_alphabet=[0, 1], number_of_operands=r)
threshold = transducers.map(f=lambda x: x >= j, input_alphabet=srange(r+1))
probabilities = Transducer([(0, 0, p[i], i) for i in alphabet], initial_states=[0], final_states=[0], on_duplicate_transition=duplicate_transition_add_input)
chain = threshold(adder(all_counter(probabilities)))
result = chain.moments_waiting_time(is_zero=is_zero, expectation_only=True)
R_v = PolynomialRing(QQ, names=['p_%d' % i for i in range(r)])
v = R_v.gens()
S = 1/(1 - sum(v[i]/(1+v[i]) for i in range(r)))
alpha = [(p[i] - p[i]^h)/(1 - p[i]) for i in range(r)]
gamma = [p[i]/(1 - p[i]) for i in range(r)]
alphabet_set = set(alphabet)
expectation = 0
for q in range(j):
    for M in Subsets(alphabet_set, q):

            summand = summand.subs(
                {v[i]: gamma[i]}) - summand.
        for i in alphabet_set - set(M):
            summand = summand.subs(
                {v[i]: alpha[i]})
        expectation += summand
return is_zero((result - expectation).numerator())

>>> test(Integer(2), Integer(3), Integer(2))
True

REFERENCES:

number_of_words (variable=None, base_ring=None)

Return the number of successful input words of given length.

INPUT:

- variable – a symbol denoting the length of the words, by default $n$. 

1586 Chapter 5. Comprehensive Module List
• base_ring – Ring (default: $\mathbb{Q}$) in which to compute the eigenvalues.

OUTPUT:

A symbolic expression.

EXAMPLES:

```
sage: NAFpm = Automaton([(0, 0, 0), (0, 1, 1), ...
....: (0, 1, -1), (1, 0, 0)], ...
....: initial_states=[0], ...
....: final_states=[0, 1])
sage: N = NAFpm.number_of_words(); N
\# needs sage.symbolic
4/3*2^n - 1/3*(-1)^n
sage: all(len(list(NAFpm.language(s))) == N.subs(n=s) ...
....: for s in srange(1, 6))
True

>>> from sage.all import *
>>> NAFpm = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),...
....: Integer(1), Integer(1)), ...
....: (Integer(0), Integer(1), -Integer(1)), (Integer(1),...
....: Integer(0), Integer(0))], ...
....: initial_states=[Integer(0)], ...
....: final_states=[Integer(0), Integer(1)])
>>> N = NAFpm.number_of_words(); N
\# needs sage.symbolic
4/3*2^n - 1/3*(-1)^n
>>> all(len(list(NAFpm.language(s))) == N.subs(n=s) ...
....: for s in srange(Integer(1), Integer(6)))
True
```

An example with non-rational eigenvalues. By default, eigenvalues are elements of the field of algebraic numbers.

```
sage: NAFp = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 0)], ...
....: initial_states=[0], ...
....: final_states=[0, 1])
sage: N = NAFp.number_of_words(); N
\# needs sage.rings.number_field sage.symbolic
1.70820393249937*1.618033988749895^n - 0.1708203932499369*(-0.618033988749895)?n
sage: all(len(list(NAFp.language(s))) == N.subs(n=s) ...
....: for s in srange(Integer(1), Integer(6)))
True
```

```
>>> from sage.all import *
>>> NAFp = Automaton([(Integer(0), Integer(0), Integer(0)), (Integer(0),...
....: Integer(1), Integer(1)), (Integer(1), Integer(0), Integer(0))], ...
....: initial_states=[Integer(0)], ...
....: final_states=[Integer(0), Integer(1)])
(continues on next page)
We specify a suitable base_ring to obtain a radical expression. To do so, we first compute the characteristic polynomial and then construct a number field generated by its roots.

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field sage.symbolic
>>> M = NAFp.adjacency_matrix(entry=lambda t: 1)
>>> M.characteristic_polynomial()
x^2 - x - 1
>>> R = NumberField(x**Integer(2)-x-Integer(1), embedding=golden_ratio)
>>> N = NAFp.number_of_words(base_ring=R); N
```

In this special case, we might also use the constant golden_ratio:

```python
>>> from sage.all import *
>>> # needs sage.rings.number_field sage.symbolic
>>> R.<phi> = NumberField(x^2-x-1, embedding=golden_ratio)
>>> N = NAFp.number_of_words(base_ring=R); N
```

(continues on next page)
The adjacency matrix of the following example is a Jordan matrix of size 3 to the eigenvalue 4:

```python
sage: J3 = Automaton([(0, 1, -1), (1, 2, -1)],
                   initial_states=[0],
                   final_states=[0, 1, 2])
```

```python
sage: for i in range(3):
    ... for j in range(4):
    ...     new_transition = J3.add_transition(i, i, j)
```

```python
sage: J3.adjacency_matrix(entry=lambda t: 1)
```

\[
\begin{bmatrix}
4 & 1 & 0 \\
0 & 4 & 1 \\
0 & 0 & 4 \\
\end{bmatrix}
\]

```python
sage: N = J3.number_of_words(); N
```

\[\frac{1}{2}4^{n-2}(n-1)n + 4^{n-1}n + 4^n\]

```python
sage: all(len(list(J3.language(s))) == N.subs(n=s) for s in range(1, 6))
```

True

Here is an automaton without cycles, so with eigenvalue 0.

```python
sage: A = Automaton([(j, j+1, 0) for j in range(3)],
                   initial_states=[0],
                   final_states=list(range(3)))
```

(continues on next page)
sage: A.number_of_words()  # needs sage.symbolic
\frac{1}{2} \cdot 0^{n-2} \cdot (n-1) \cdot n + 0^{n-1} \cdot n + 0^n

```python
>>> from sage.all import *
>>> A = Automaton([({j}, j+Integer(1), Integer(0)) for j in range(Integer(3))],
...    initial_states=[Integer(0)],
...    final_states=list(range(Integer(3))))
>>> A.number_of_words()  # needs sage.symbolic
\frac{1}{2} \cdot 0^{n-2} \cdot (n-1) \cdot n + 0^{n-1} \cdot n + 0^n
```

**on_duplicate_transition (old_transition, new_transition)**

Which function to call when a duplicate transition is inserted.

It can be set by the parameter `on_duplicate_transition` when initializing a finite state machine, see `FiniteStateMachine`.

See also:

`FiniteStateMachine`, `is_Markov_chain()`, `markov_chain_simplification()`.

**output_alphabet = None**

A list of letters representing the output alphabet of the finite state machine.

It can be set by the parameter `output_alphabet` when initializing a finite state machine, see `FiniteStateMachine`.

It can also be set by the method `determine_alphabets()`.

See also:

`FiniteStateMachine`, `determine_alphabets()`, `input_alphabet`.

**output_projection()**

Return a automaton where the input of each transition of self is deleted and the new input is the original output.

**OUTPUT:**

An automaton.

**EXAMPLES:**

```python
sage: F = FiniteStateMachine([[('A', 'B', 0, 1), ('A', 'A', 1, 1), ...
  ('B', 'B', 1, 0))]
sage: G = F.output_projection()
sage: G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

```python
>>> from sage.all import *
>>> F = FiniteStateMachine([(('A', 'B', Integer(0), Integer(1)), ('A', 'A',
  Integer(1)), Integer(1)), Integer(1), Integer(1)),
  ('B', 'B', Integer(1), Integer(0))])
>>> G = F.output_projection()
>>> G.transitions()
[Transition from 'A' to 'B': 1|-,
...
(continues on next page)```
Final output words are also considered correctly:

```
sage: H = Transducer([(A, B, 0, 1), (A, A, 1, 1), ...
                      (B, B, 1, 0), (A, ('final', 0), 0, 0)],
                      final_states=['A', 'B'])
sage: H.state('B').final_word_out = 2
sage: J = H.output_projection()
sage: J.states()
['A', 'B', ('final', 0), ('final', 1)]
sage: J.transitions()
[Transition from A to B: 1|-,
 Transition from A to A: 1|-,
 Transition from A to ('final', 0): 0|-,
 Transition from B to B: 0|-,
 Transition from B to ('final', 1): 2|-]
sage: J.final_states()
['A', ('final', 1)]
```

```
>>> from sage.all import *
>>> H = Transducer([(A, B, Integer(0), Integer(1)), (A, A, Integer(1),
... Integer(1)), ...
... (B, B, Integer(1), Integer(0)), (A, ('final', ...
... Integer(0), Integer(0)), (A, ('final',...
... Integer(0)), Integer(0), Integer(0))],
... final_states=['A', 'B'])
>>> H.state('B').final_word_out = Integer(2)
>>> J = H.output_projection()
>>> J.states()
['A', 'B', ('final', 0), ('final', 1)]
>>> J.transitions()
[Transition from A to B: 1|-,
 Transition from A to A: 1|-,
 Transition from A to ('final', 0): 0|-,
 Transition from B to B: 0|-,
 Transition from B to ('final', 1): 2|-]
>>> J.final_states()
['A', ('final', 1)]
```

```
plot()
```
Plots a graph of the finite state machine with labeled vertices and labeled edges.

INPUT:

Nothing.

OUTPUT:

A plot of the graph of the finite state machine.

```
predecessors (state, valid_input=None)
```
Lists all predecessors of a state.

INPUT:

- state – the state from which the predecessors should be listed.
• valid_input - If valid_input is a list, then we only consider transitions whose input labels are contained in valid_input. state has to be a FSMState (not a label of a state). If input labels of length larger than 1 are used, then valid_input has to be a list of lists.

OUTPUT:
A list of states.

EXAMPLES:

```
sage: A = Transducer([('I', 'A', 'a', 'b'), ('I', 'B', 'b', 'c'),
                      ('I', 'C', 'c', 'a'), ('A', 'F', 'b', 'a'),
                      ('B', 'F', ['c', 'b'], 'b'), ('C', 'F', 'a', 'c')],
                      initial_states=['I'], final_states=['F'])

sage: A.predecessors(A.state('A'))
['A', 'I']

sage: A.predecessors(A.state('F'), valid_input=['b', 'a'])
['C', 'A', 'I']

sage: A.predecessors(A.state('F'), valid_input=[['c', 'b'], 'a'])
['C', 'B']
```

```
>>> from sage.all import *

>>> A = Transducer([('I', 'A', 'a', 'b'), ('I', 'B', 'b', 'c'),
                   ('I', 'C', 'c', 'a'), ('A', 'F', 'b', 'a'),
                   ('B', 'F', ['c', 'b'], 'b'), ('C', 'F', 'a', 'c')],
                   initial_states=['I'], final_states=['F'])

>>> A.predecessors(A.state('A'))
['A', 'I']

>>> A.predecessors(A.state('F'), valid_input=['b', 'a'])
['C', 'A', 'I']

>>> A.predecessors(A.state('F'), valid_input=[['c', 'b'], 'a'])
['C', 'B']
```

prepone_output()

For all paths, shift the output of the path from one transition to the earliest possible preceding transition of the path.

INPUT:
Nothing.

OUTPUT:
Nothing.

Apply the following to each state s (except initial states) of the finite state machine as often as possible:

If the letter a is a prefix of the output label of all transitions from s (including the final output of s), then remove it from all these labels and append it to all output labels of all transitions leading to s.

We assume that the states have no output labels, but final outputs are allowed.

EXAMPLES:

```
sage: A = Transducer([('A', 'B', 1, 1),
                    ('B', 'B', 0, 0),
                    ('B', 'C', 1, 0)],
                    initial_states=['A'], final_states=['C'])

sage: A.prepone_output()

sage: A.transitions()
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

>>> from sage.all import *
>>> A = Transducer([(A, B, Integer(1), Integer(1)),
...                  (B, B, Integer(0), Integer(0)),
...                  (B, C, Integer(1), Integer(0))],
...                initial_states=['A'],
...                final_states=['C'])

>>> A.prepone_output()

>>> A.transitions()

>>> from sage.all import *

>>> A = Transducer([(A, B, Integer(0), Integer(1)),
...                  (B, C, Integer(1), [Integer(1), Integer(1)]),
...                  (B, C, Integer(0), Integer(1))],
...                initial_states=['A'],
...                final_states=['C'])

>>> A.prepone_output()

If initial states are not labeled as such, unexpected results may be obtained:

>>> from sage.all import *

>>> A = Transducer([(['A', 'B', 0, 1]),
...                  ('B', 'C', 1, [1, 1]),
...                  ('B', 'C', 0, 1)],
...                initial_states=['A'],
...                final_states=['C'])

>>> A.prepone_output()

>>> A.transitions()

>>> from sage.all import *

>>> B = Transducer([(Integer(0), Integer(1), Integer(0), Integer(0))])

>>> B.prepone_output()

(continues on next page)
verbose 0 (...: finite_state_machine.py, prepone_output)

All transitions leaving state 0 have an output label with prefix 0. However, there is no inbound transition and it is not an initial state. This routine (possibly called by simplification) therefore erased this prefix from all outbound transitions.

```python
>>> C.transitions()
[Transition from 0 to 1: 0|-
```

Also the final output of final states can be changed:

```python
sage: T = Transducer([[‘A’, ‘B’, 0, 1],
                      [‘B’, ‘C’, 1, [1, 1]],
                      [‘B’, ‘C’, 0, 1],
                      initial_states=[‘A’],
                      final_states=[‘B’])
sage: T.state(‘B’).final_word_out = [1]
sage: T.prepone_output()
[Transition from ‘A’ to ‘B’: 0|1,1, Transition from ‘B’ to ‘C’: 1|1, Transition from ‘B’ to ‘C’: 0|-]
sage: T.state(‘B’).final_word_out
[]
```

```python
>>> from sage.all import *
```

```python
sage: S = Transducer([[‘A’, ‘B’, 0, 1],
                      [‘B’, ‘C’, 1, [1, 1]],
                      [‘B’, ‘C’, 0, 1],
                      initial_states=[‘A’],
                      final_states=[‘B’])
sage: S.state(‘B’).final_word_out = [0]
sage: S.prepone_output()
sage: S.transitions()
[Transition from ‘A’ to ‘B’: 0|1, Transition from ‘B’ to ‘C’: 1|1, Transition from ‘B’ to ‘C’: 0|1]
sage: S.state(‘B’).final_word_out
[0]
```

```python
>>> from sage.all import *
```

```python
>>>
```
..., ('B', 'C', Integer(1), [Integer(1), Integer(1)]),
..., ('B', 'C', Integer(0), Integer(1)),
..., initial_states=['A'],
..., final_states=['B'])
>>> S.state('B').final_word_out = [Integer(0)]
>>> S.prepone_output()
>>> S.transitions()
[Transition from 'A' to 'B': 0|1,
 Transition from 'B' to 'C': 1|0|1,
 Transition from 'B' to 'C': 0|1]
>>> S.state('B').final_word_out
[0]
Output labels do not have to be hashable:

```
sage: C = Transducer([(0, 1, 0, []),
                   (1, 0, 0, [vector([0, 0]), 0]),
                   (1, 1, 1, [vector([0, 0]), 1]),
                   (0, 0, 1, 0)],
... initial_states=[0])
sage: C.prepone_output()
sage: sorted(C.transitions())
[Transition from 0 to 1: 0|(0, 0),
 Transition from 0 to 0: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 1: 1|1,(0, 0)]
```

```
>>> from sage.all import *
>>> C = Transducer([(Integer(0), Integer(1), Integer(0), []),
                   (Integer(1), Integer(0), Integer(0), [vector([Integer(0), Integer(0)]), Integer(0)]),
                   (Integer(1), Integer(1), Integer(1), [vector([Integer(0), Integer(0)]), Integer(0)]),
                   (Integer(0), Integer(0), Integer(1), Integer(0))],
... initial_states=[Integer(0)])
>>> C.prepone_output()
>>> sorted(C.transitions())
[Transition from 0 to 1: 0|(0, 0),
 Transition from 0 to 0: 1|0,
 Transition from 1 to 0: 0|0,
 Transition from 1 to 1: 1|1,(0, 0)]
```

```
process(*args, **kwargs)
Return whether the finite state machine accepts the input, the state where the computation stops and which
output is generated.
INPUT:

• input_tape – the input tape can be a list or an iterable with entries from the input alphabet. If we
  are working with a multi-tape machine (see parameter use_multitape_input and notes below),
  then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the
  input alphabet.

• initial_state or initial_states – the initial state(s) in which the machine starts. Either
  specify a single one with initial_state or a list of them with initial_states. If both are
given, initial_state will be appended to initial_states. If neither is specified, the initial
states of the finite state machine are taken.

- list_of_outputs – (default: None) a boolean or None. If True, then the outputs are given
  in list form (even if we have no or only one single output). If False, then the result is never a list
  (an exception is raised if the result cannot be returned). If list_of_outputs=None, the method
determines automatically what to do (e.g. if a non-deterministic machine returns more than one path,
then the output is returned in list form).

- only_accepted – (default: False) a boolean. If set, then the first argument in the output is guar-
  anteed to be True (if the output is a list, then the first argument of each element will be True).

- always_include_output – if set (not by default), always include the output. This is inconsequential
  for a FiniteStateMachine, but can be used in derived classes where the output is suppressed
  by default, cf. Automaton.process().

- format_output – a function that translates the written output (which is in form of a list) to something
  more readable. By default (None) identity is used here.

- check_epsilon_transitions – (default: True) a boolean. If False, then epsilon transitions
  are not taken into consideration during process.

- write_final_word_out – (default: True) a boolean specifying whether the final output words
  should be written or not.

- use_multitape_input – (default: False) a boolean. If True, then the multi-tape mode of the
  process iterator is activated. See also the notes below for multi-tape machines.

- process_all_prefixes_of_input – (default: False) a boolean. If True, then each prefix
  of the input word is processed (instead of processing the whole input word at once). Consequently, there
  is an output generated for each of these prefixes.

- process_iterator_class – (default: None) a class inherited from FSMProcessIterator.
  If None, then FSMProcessIterator is taken. An instance of this class is created and is used during
  the processing.

- automatic_output_type – (default: False) a boolean. If set and the input has a parent, then
  the output will have the same parent. If the input does not have a parent, then the output will be of the
  same type as the input.

OUTPUT:

A triple (or a list of triples, cf. parameter list_of_outputs), where

- the first entry is True if the input string is accepted,

- the second gives the reached state after processing the input tape (This is a state with label None if the
  input could not be processed, i.e., if at one point no transition to go on could be found.), and

- the third gives a list of the output labels written during processing (in the case the finite state machine
  runs as transducer).

Note that in the case the finite state machine is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To
decide which way to go, it uses the input words of the outgoing transitions and compares them to the input
tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input
label equals the input letter of the tape. The output label of the transition, if present, is written on the output
tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine),
all possibilities are followed. This is done by splitting the process into several branches, one for each of the
possible outgoing transitions.
The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of \( k \)-tuples of letters. Moreover, the input tape has to consist of \( k \) tracks, i.e., be a list or tuple of \( k \) iterators, one for each track.

**Warning:** Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

**EXAMPLES:**

```python
sage: binary_inverter = FiniteStateMachine({A: [(A, 0, 1), (A, 1, 0)]},
                                             initial_states=['A'],
                                             final_states=['A'])

>>> binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

```python
>>> from sage.all import *

>>> binary_inverter = FiniteStateMachine({A: [(A, Integer(0), Integer(1)),
                                             ('A', Integer(1), Integer(0))]},
                                             initial_states=['A'],
                                             final_states=[
                                             'A'])

>>> binary_inverter.process([Integer(0), Integer(1), Integer(0), Integer(0),
                                             Integer(1), Integer(1)])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Alternatively, we can invoke this function by:

```python
sage: binary_inverter([0, 1, 0, 0, 1, 1])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

```python
>>> from sage.all import *

>>> binary_inverter([Integer(0), Integer(1), Integer(0), Integer(0),
                                             Integer(1), Integer(1)])
(True, 'A', [1, 0, 1, 1, 0, 0])
```

Below we construct a finite state machine which tests if an input is a non-adjacent form, i.e., no two neighboring letters are both nonzero (see also the example on non-adjacent forms in the documentation of the module `Finite state machines, automata, transducers`):

```python
sage: NAF = FiniteStateMachine(

      \{\_\': [\_('\', 0), (1, 1)], 1: [\_('\', 0)]},
      initial_states=[\_'\'],
      final_states=[\_'\', 1])

sage: \[NAF.process(w)[0] for w in [[0], [0, 1], [1, 1], [0, 1, 0, 1],
                                             [0, 1, 1, 1, 0], [1, 0, 0, 1, 1]]\]

[True, True, False, True, False, False]
```

```python
>>> from sage.all import *

>>> NAF = FiniteStateMachine(

      ... \{'\_\': [\_('\', Integer(0)), (Integer(1), Integer(1))], Integer(1): [\_'\%
```
... initial_states=["0", "1", Integer(1)]

```python
>>> [TAF.process(w) for w in [[Integer(0)], [Integer(0),
    ... Integer(1)], [Integer(1), Integer(0)], [Integer(0), Integer(1), Integer(0),
    ... Integer(1)],
    ... [Integer(0), Integer(1), Integer(1), Integer(1), Integer(0), Integer(1), Integer(1)]]
[True, True, False, True, False, False]
```

Working only with the first component (i.e., returning whether accepted or not) usually corresponds to using the more specialized class `Automaton`.

Non-deterministic finite state machines can be handled as well.

```python
sage: T = Transducer([(0, 1, 0, 0), (0, 2, 0, 0)],
    ... initial_states=[0])
sage: T.process([0])
[(False, 1, [0]), (False, 2, [0])]
```

Here is another non-deterministic finite state machine. Note that we use `format_output` (see `FSMProcessIterator`) to convert the written outputs (all characters) to strings.

```python
sage: T = Transducer([(0, 1, [0, 0], 'a'), (0, 2, [0, 0, 1], 'b'),
    ... (0, 1, 1, 'c'), (1, 0, [], 'd'),
    ... (1, 1, 1, 'e')],
    ... initial_states=[0], final_states=[0, 1])
sage: T.process([0], format_output=lambda o: ''.join(o))
(False, None, None)
sage: T.process([0, 0], format_output=lambda o: ''.join(o))
[(True, 0, 'ad'), (True, 0, 'a')]
sage: T.process([1], format_output=lambda o: ''.join(o))
[(True, 0, 'cd'), (True, 1, 'c')]
sage: T.process([1, 1], format_output=lambda o: ''.join(o))
[(True, 0, 'cdcd'), (True, 0, 'ced'),
  (True, 1, 'cdc'), (True, 1, 'ce')]
sage: T.process([0, 0, 1], format_output=lambda o: ''.join(o))
[(False, 2, 'b'),
  (True, 0, 'adcd'),
  (True, 0, 'aed'),
  (True, 1, 'adc'),
  (True, 1, 'ae')]
sage: T.process([0, 0, 1], format_output=lambda o: ''.join(o),
    ... only_accepted=True)
[(True, 0, 'adcd'), (True, 0, 'aed'),
  (True, 1, 'adc'), (True, 1, 'ae')]
```

```python
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(1), [Integer(0), Integer(0)], 'a'),
    ... (Integer(0), Integer(2), [Integer(0), Integer(0), Integer(1)], 'b'),
    ... (Integer(0), Integer(1), [Integer(0), Integer(0), Integer(1), Integer(0)], 'c'),
    ... (Integer(0), Integer(2), [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1)], 'd'),
    ... (Integer(0), Integer(1), [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0)], 'e')],
    ... initial_states=[Integer(0)], final_states=[0, 1])
```

(continues on next page)
A simple example of a multi-tape finite state machine is the following: It writes the length of the first tape many letters a and then the length of the second tapemanyl...
Return a new finite state machine whose states are \(d\)-tuples of states of the original finite state machines.

**INPUT:**

- **other** – a finite state machine (for \(d = 2\)) or a list (or iterable) of \(d - 1\) finite state machines.
- **function** has to accept \(d\) transitions from \(A_j\) to \(B_j\) for \(j \in \{1, \ldots, d\}\) and returns a pair \((\text{word}_\text{in}, \text{word}_\text{out})\) which is the label of the transition \(A = (A_1, \ldots, A_d)\) to \(B = (B_1, \ldots, B_d)\). If there is no transition from \(A\) to \(B\), then **function** should raise a **LookupError**.
- **new_input_alphabet** (optional) – the new input alphabet as a list.
- **only_accessible_components** – If True (default), then the result is piped through **accessible_components()**. If no **new_input_alphabet** is given, it is determined by **determine_alphabets()**.
- **final_function** – A function mapping \(d\) final states of the original finite state machines to the final output of the corresponding state in the new finite state machine. By default, the final output is the empty word if both final outputs of the constituent states are empty; otherwise, a **ValueError** is raised.
- **new_class** – Class of the new finite state machine. By default (None), the class of self is used.

**OUTPUT:**

A finite state machine whose states are \(d\)-tuples of states of the original finite state machines. A state is initial or final if all constituent states are initial or final, respectively.

The labels of the transitions are defined by **function**.

The final output of a final state is determined by calling **final_function** on the constituent states.

The color of a new state is the tuple of colors of the constituent states of **self** and **other**. However, if all constituent states have color None, then the state has color None, too.

**EXAMPLES:**

```python
sage: F = Automaton([('A', 'B', 1), ('A', 'A', 0), ('B', 'A', 2)],
......:     initial_states=['A'], final_states=['B'],
......:     determine_alphabets=True)

sage: G = Automaton([(1, 1, 1)], initial_states=[1], final_states=[1])

sage: def addition(transition1, transition2):
......:     return (transition1.word_in[0] + transition2.word_in[0],
......:             None)

sage: H = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_accessible_components=False)

sage: H.transitions()
[Transition from ('A', 1) to ('B', 1): 2|-,
 Transition from ('A', 1) to ('A', 1): 1|-,
 Transition from ('B', 1) to ('A', 1): 3|-]

sage: [s.color for s in H.iter_states()]
[None, None]

sage: H1 = F.product_FiniteStateMachine(G, addition, [0, 1, 2, 3], only_accessible_components=False)

sage: H1.states()[0].label()[0] is F.states()[0]
True

sage: H1.states()[0].label()[1] is G.states()[0]
True

>>> from sage.all import *

```

(continues on next page)
determine_alphabets=True)

>>> G = Automaton([(Integer(1), Integer(1), Integer(1))], initial_→states=[Integer(1)], final_states=[Integer(1)])

>>> def addition(transition1, transition2):
... return (transition1.word_in[Integer(0)] + transition2.word_→in[Integer(0)],
... None)

>>> H = F.product_FiniteStateMachine(G, addition, [Integer(0), Integer(1), Integer(2), Integer(3)], only_accessible_components=False)

>>> H.transitions()
[Transition from ('A', 1) to ('B', 1): 2|-
, Transition from ('A', 1) to ('A', 1): 1|-
, Transition from ('B', 1) to ('A', 1): 3|-
]

>>> [s.color for s in H.iter_states()]
[None, None]

>>> H1 = F.product_FiniteStateMachine(G, addition, [Integer(0), Integer(1), Integer(2), Integer(3)], only_accessible_components=False)

>>> H1.states()[Integer(0)].label()[Integer(0)] is F.states()[Integer(0)]
True

>>> H1.states()[Integer(0)].label()[Integer(1)] is G.states()[Integer(0)]
True

sage: F = Automaton([(0,1,1/4), (0,0,3/4), (1,1,3/4), (1,0,1/4)], initial_states=[0] )

sage: G = Automaton([(0,0,1), (1,1,3/4), (1,0,1/4)], initial_states=[0] )

sage: H = F.product_FiniteStateMachine(lambda t1,t2: (t1.word_in[0]*t2.word_in[0], None), only_accessible_components=False)

sage: H.states()
[(0, 0), (1, 0), (0, 1), (1, 1)]

>>> from sage.all import *

>>> F = Automaton([(Integer(0),Integer(1),Integer(1)/Integer(4)), (Integer(0), Integer(0),Integer(3)/Integer(4)), (Integer(1),Integer(1),Integer(3)/Integer(4)), (Integer(1),Integer(0),Integer(1)/Integer(4))], initial_states=[Integer(0)] )

>>> G = Automaton([(Integer(0),Integer(0),Integer(1)), (Integer(1),Integer(1),Integer(3)/Integer(4)), (Integer(1),Integer(0),Integer(1)/Integer(4))], initial_states=[Integer(0)] )

>>> H = F.product_FiniteStateMachine(lambda t1,t2: (t1.word_in[Integer(0)]*t2.word_in[Integer(0)], None))

>>> H.states()
[(0, 0), (1, 0)]
>>> from sage.all import *

>>> F = Automaton([(Integer(0), Integer(1), Integer(1)/Integer(4)), (Integer(0),
                Integer(0), Integer(3)/Integer(4)), (Integer(1), Integer(1), Integer(3)/
                Integer(4)), (Integer(1), Integer(0), Integer(1)/Integer(4))],
                initial_states=[Integer(0)] )
>>> G = Automaton([(Integer(0), Integer(0), Integer(1)), (Integer(1), Integer(1),
                Integer(3)/Integer(4)), (Integer(1), Integer(0), Integer(1)/Integer(4))],
                initial_states=[Integer(0)] )
>>> H = F.product_FiniteStateMachine(G, lambda t1, t2: (t1.word_in[Integer(0)]*t2.
                word_in[Integer(0)], None), only_accessible_components=False)
>>> H.states()
[(0, 0), (1, 0), (0, 1), (1, 1)]

Also final output words are considered according to the function final_function:

sage: F = Transducer([(0, 1, 0, 1), (1, 1, 1, 1), (1, 1, 0, 1)],
                   final_states=[1])

sage: F.state(1).final_word_out = 1

sage: G = Transducer([(0, 0, 0, 1), (0, 0, 1, 0)], final_states=[0])

sage: G.state(0).final_word_out = 1

sage: def minus(t1, t2):
...     return (t1.word_in[0] - t2.word_in[0], t1.word_out[0] - t2.word_out[0])

sage: H = F.product_FiniteStateMachine(G, minus)
Traceback (most recent call last):
  ... ValueError: A final function must be given.

sage: def plus(s1, s2):
...     return s1.final_word_out[0] + s2.final_word_out[0]

sage: H = F.product_FiniteStateMachine(G, minus, final_function=plus)

sage: H.final_states()
[(1, 0)]

sage: H.final_states()[0].final_word_out[2]

>>> from sage.all import *

>>> F = Transducer([(0, 1, 0, 1), (1, 1, 1, 1), (1, 1, 0, 1)],
                   final_states=[1])

>>> F.state(1).final_word_out = 1

>>> G = Transducer([(0, 0, 0, 1), (0, 0, 1, 0)], final_states=[0])

>>> G.state(0).final_word_out = 1

>>> def minus(t1, t2):
...     return (t1.word_in[Integer(0)] - t2.word_in[Integer(0)], t1.word_out[Integer(0)] - t2.word_out[Integer(0)])

>>> H = F.product_FiniteStateMachine(G, minus)
Traceback (most recent call last):
  ... ValueError: A final function must be given.

>>> def plus(s1, s2):
...     return s1.final_word_out[Integer(0)] + s2.final_word_out[Integer(0)]

(continues on next page)
Products of more than two finite state machines are also possible:

```python
sage: def plus(s1, s2, s3):
    if s1.word_in == s2.word_in == s3.word_in:
        return (s1.word_in,
                sum(s.word_out[Integer(0)] for s in (s1, s2, s3)))
    else:
        raise LookupError
sage: T0 = transducers.CountSubblockOccurrences([Integer(0), Integer(0)], [Integer(0), Integer(1), Integer(2)])
```

```python
sage: T1 = transducers.CountSubblockOccurrences([Integer(1), Integer(1)], [Integer(0), Integer(1), Integer(2)])
```

```python
sage: T2 = transducers.CountSubblockOccurrences([Integer(2), Integer(2)], [Integer(0), Integer(1), Integer(2)])
```

```python
sage: T = T0.product_FiniteStateMachine([T1, T2], plus)
```

```python
sage: T.transitions()
[Transition from ((), (), ()) to ((0,), (), ()): 0|0,
 Transition from ((), (), ()) to ((), (1,), ()): 1|0,
 Transition from ((), (), ()) to ((), (), (2,)): 2|0,

    Integer(0), Integer(1), Integer(2), Integer(2)])
[0, 1, 0, 1, 0, 1, 0, 0, 0, 1]
```

other can also be an iterable:

```python
sage: T == T0.product_FiniteStateMachine(iter([T1, T2]), plus)
True
```

projection (what='input')

Return an Automaton which transition labels are the projection of the transition labels of the input.

INPUT:

- what -(default: input) either input or output.

OUTPUT:

An automaton.

EXAMPLES:

```python
sage: F = FiniteStateMachine([(A, B, 0, 1), (A, A, 1, 1),
                      (B, B, 1, 0)])
sage: G = F.projection(what='output')
sage: G.transitions()
[Transition from A to B: 1|-,
 Transition from A to A: 1|-,
 Transition from B to B: 0|-
```

```python
from sage.all import *
>>> F = FiniteStateMachine([['A', 'B', 0, 1], ('A', 'A', 1, 1),
                      ('B', 'B', 0, 1)])
>>> G = F.projection(what='output')
>>> G.transitions()
[Transition from 'A' to 'B': 1|-,
 Transition from 'A' to 'A': 1|-,
 Transition from 'B' to 'B': 0|-]
```

quotient (classes)

Construct the quotient with respect to the equivalence classes.

INPUT:

- classes is a list of equivalence classes of states.

OUTPUT:
A finite state machine.

The labels of the new states are tuples of states of the self, corresponding to classes.

Assume that \( c \) is a class, and \( a \) and \( b \) are states in \( c \). Then there is a bijection \( \varphi \) between the transitions from \( a \) and the transitions from \( b \) with the following properties: if \( \varphi(t_a) = t_b \), then

- \( t_a.\text{word}_\text{in} = t_b.\text{word}_\text{in} \),
- \( t_a.\text{word}_\text{out} = t_b.\text{word}_\text{out} \), and
- \( t_a \) and \( t_b \) lead to some equivalent states \( a' \) and \( b' \).

Non-initial states may be merged with initial states, the resulting state is an initial state.

All states in a class must have the same \( \text{is}_\text{final} \), \( \text{final_word}_\text{out} \) and \( \text{word}_\text{out} \) values.

EXAMPLES:

```python
sage: fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
                               ("B", "C", 0, 0), ("B", "C", 1, 1),
                               ("C", "D", 0, 1), ("C", "D", 1, 0),
                               ("D", "A", 0, 0), ("D", "A", 1, 1)])

sage: fsmq = fsm.quotient([fsm.state("A"), fsm.state("C")],
                        [fsm.state("B"), fsm.state("D")])

sage: fsmq.transitions()
[Transition from (A, C) to (B, D): 0|1,
  Transition from (A, C) to (B, D): 1|0,
  Transition from (B, D) to (A, C): 0|0,
  Transition from (B, D) to (A, C): 1|1]

sage: fsmq.relabeled().transitions()
[Transition from 0 to 1: 0|1,
  Transition from 0 to 1: 1|0,
  Transition from 1 to 0: 0|0,
  Transition from 1 to 0: 1|1]

sage: fsmq1 = fsm.quotient(fsm.equivalence_classes())

sage: fsmq1 == fsmq
True

sage: fsm.q = fsm.quotient([fsm.state("A"), fsm.state("B"), fsm.state("C"), fsm.
  └ state("D"))])

Traceback (most recent call last):
  ...: AssertionError: Transitions of state 'A' and 'B' are incompatible.
```

```python
>>> from sage.all import *

>>> fsm = FiniteStateMachine([("A", "B", 0, 1), ("A", "B", 1, 0),
  └ integer(1), integer(0)),
  └ integer(1), integer(0)),
  └ integer(1), integer(0)),
  └ integer(1), integer(0))])

>>> fsmq = fsm.quotient([fsm.state("A"), fsm.state("C")],
  └ [fsm.state("B"), fsm.state("D")])

>>> fsmq.transitions()
```

Traceback (most recent call last):
  ...  AssertionError: Transitions of state 'A' and 'B' are incompatible.
```

**relabeled** *(memo=None, labels=None)*

Return a deep copy of the finite state machine, but the states are relabeled.

**INPUT:**
- *memo* — (default: None) a dictionary storing already processed elements.
- *labels* — (default: None) a dictionary or callable mapping old labels to new labels. If None, then the new labels are integers starting with 0.

**OUTPUT:**
A new finite state machine.

**EXAMPLES:**

```python
sage: FSM1 = FiniteStateMachine([("A", "B"), ("B", "C"), ("C", "A")])
sage: FSM1.states()
['A', 'B', 'C']
sage: FSM2 = FSM1.relabeled()
sage: FSM2.states()
[0, 1, 2]
sage: FSM3 = FSM1.relabeled(labels={"A": 'a', 'B': 'b', 'C': 'c'})
sage: FSM3.states()
['a', 'b', 'c']
sage: FSM4 = FSM2.relabeled(labels=lambda x: 2*x)
sage: FSM4.states()
[0, 2, 4]
```

```python
>>> from sage.all import *
>>> FSM1 = FiniteStateMachine([("A", "B"), ("B", "C"), ("C", "A")])
>>> FSM1.states()
['A', 'B', 'C']
>>> FSM2 = FSM1.relabeled()
>>> FSM2.states()
[0, 1, 2]
```
FSM3 \(=\) FSM1.relabelled(labels={'A': 'a', 'B': 'b', 'C': 'c'})

FSM3.states()
['a', 'b', 'c']

FSM4 \(=\) FSM2.relabelled(labels=lambda x: Integer(2)*x)

FSM4.states()
[0, 2, 4]

**remove_epsilon_transitions()**

**set_coordinates (coordinates, default=True)**

Set coordinates of the states for the LaTeX representation by a dictionary or a function mapping labels to coordinates.

**INPUT:**

- coordinates – a dictionary or a function mapping labels of states to pairs interpreted as coordinates.
- default – If True, then states not given by coordinates get a default position on a circle of radius 3.

**OUTPUT:**

Nothing.

**EXAMPLES:**

```python
sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
```

```python
sage: F.set_coordinates({0: (0, 0), 1: (2, 0), 2: (1, 1)})
```

```python
sage: F.state(0).coordinates
(0, 0)
```

We can also use a function to determine the coordinates:

```python
sage: F = Automaton([[0, 1, 1], [1, 2, 2], [2, 0, 0]])
```

```python
sage: F.set_coordinates(lambda l: (l, 3/(l+1)))
```

```python
sage: F.state(2).coordinates
(2, 1)
```

**split_transitions()**

Return a new transducer, where all transitions in self with input labels consisting of more than one letter are replaced by a path of the corresponding length.
A new transducer.

EXAMPLES:

```python
sage: A = Transducer([('A', 'B', [1, 2, 3], 0)],
                  initial_states=['A'], final_states=['B'])
sage: A.split_transitions().states()
[('A', ()), ('B', ()),
 ('A', (1,)), ('A', (1, 2))]
```

```python
>>> from sage.all import *
>>> A = Transducer([('A', 'B', [Integer(1), Integer(2), Integer(3)],
                  Integer(0))],
                  initial_states=['A'], final_states=['B'])
>>> A.split_transitions().states()
[('A', ()), ('B', ()),
 ('A', (1,)), ('A', (1, 2))]
```

```
state (state)
Return the state of the finite state machine.

INPUT:

- state – If `state` is not an instance of `FSMState`, then it is assumed that it is the label of a state.

OUTPUT:

The state of the finite state machine corresponding to `state`.

If no state is found, then a `LookupError` is thrown.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import FSMState
sage: A = FSMState('A')
sage: FSM = FiniteStateMachine([('A', 'B'), ('C', A)])
sage: FSM.state('A') == A
True
sage: FSM.state('xyz')
Traceback (most recent call last):
... LookupError: No state with label xyz found.
```
```
states ()
Return the states of the finite state machine.

OUTPUT:

The states of the finite state machine as list.
```
EXAMPLES:

```python
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: FSM.states()
['1', '2']
>>> from sage.all import *
>>> FSM = Automaton([('1', '2', Integer(1)), ('2', '2', Integer(0))])
>>> FSM.states()
['1', '2']
```

**transition** *(transition)*

Return the transition of the finite state machine.

**INPUT:**

- transition – If transition is not an instance of `FSMTransition`, then it is assumed that it is a tuple (from_state, to_state, word_in, word_out).

**OUTPUT:**

The transition of the finite state machine corresponding to transition.

If no transition is found, then a `LookupError` is thrown.

**EXAMPLES:**

```python
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: t = FSMTransition('A', 'B', 0)
sage: F = FiniteStateMachine([t])
sage: F.transition(('A', 'B', 0))
Transition from 'A' to 'B': 0|--
```

```python
>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import FSMTransition
>>> t = FSMTransition('A', 'B', Integer(0))
>>> F = FiniteStateMachine([t])
>>> F.transition(('A', 'B', Integer(0)))
Transition from 'A' to 'B': 0|--
```

**transitions** *(from_state=None)*

Return a list of all transitions.

**INPUT:**

- from_state – (default: None) If from_state is given, then a list of transitions starting there is given.

**OUTPUT:**

A list of all transitions.

**EXAMPLES:**

```python
sage: FSM = Automaton([('1', '2', 1), ('2', '2', 0)])
sage: FSM.transitions()
```
transposition (reverse_output_labels=True)

Return a new finite state machine, where all transitions of the input finite state machine are reversed.

INPUT:

- reverse_output_labels – a boolean (default: True): whether to reverse output labels.

OUTPUT:

A new finite state machine.

EXAMPLES:

A new finite state machine.
... initial_states=[Integer(0)],
... final_states=[Integer(1)])
>>> A([Integer(1), Integer(0)])
True
>>> A.transposition()([Integer(0), Integer(1)])
True

sage: T = Transducer(((0, 1, [1, 0], [1, 0]),
....: initial_states=[0],
....: final_states=[1])
sage: T([1, 0])
[1, 0]
sage: T.transposition()([0, 1])
[0, 1]
sage: T.transposition(reverse_output_labels=False)([0, 1])
[1, 0]

>>> from sage.all import *

>>> T = Transducer(((Integer(0), Integer(1), [Integer(1), Integer(0)],
˓→[Integer(0), Integer(0)]),
....: initial_states=[Integer(0)],
....: final_states=[Integer(1)])
>>> T([Integer(1), Integer(0)])
[1, 0]
>>> T.transposition()([Integer(0), Integer(1)])
[0, 1]
>>> T.transposition(reverse_output_labels=False)([Integer(0), Integer(1)])
[1, 0]

**with_final_word_out** (letters, allow_non_final=True)

Constructs a new finite state machine with final output words for all states by implicitly reading trailing letters until a final state is reached.

**INPUT:**
- **letters** – either an element of the input alphabet or a list of such elements. This is repeated cyclically when needed.
- **allow_non_final** – a boolean (default: True) which indicates whether we allow that some states may be non-final in the resulting finite state machine. I.e., if False then each state has to have a path to a final state with input label matching letters.

**OUTPUT:**
A finite state machine.

The inplace version of this function is *construct_final_word_out*().

Suppose for the moment a single element letter as input for letters. This is equivalent to letters = [letter]. We will discuss the general case below.

Let word_in be a word over the input alphabet and assume that the original finite state machine transforms word_in to word_out reaching a possibly non-final state s. Let further k be the minimum number of letters letter such that there is a path from s to some final state f whose input label consists of k copies of letter and whose output label is path_word_out. Then the state s of the resulting finite state machine is a final state with final output path_word_out + f.final_word_out. Therefore, the new finite state machine transforms word_in to word_out + path_word_out + f.final_word_out.
This is e.g. useful for finite state machines operating on digit expansions: there, it is sometimes required to read a sufficient number of trailing zeros (at the most significant positions) in order to reach a final state and to flush all carries. In this case, this method constructs an essentially equivalent finite state machine in the sense that it not longer requires adding sufficiently many trailing zeros. However, it is the responsibility of the user to make sure that if adding trailing zeros to the input anyway, the output is equivalent.

If letters consists of more than one letter, then it is assumed that (not necessarily complete) cycles of letters are appended as trailing input.

example on Gray code

EXAMPLES:

1. A simple transducer transforming 00 blocks to 01 blocks:

```
sage: T = Transducer([(0, 1, 0, 0), (1, 0, 0, 1)],
....:     initial_states=[0],
....:     final_states=[0])
sage: T.process([0, 0, 0])
(False, 1, [0, 1, 0])
sage: T.process([0, 0, 0, 0])
(True, 0, [0, 1, 0, 1])
sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
....:     print("{} {}\n").format(f, f.final_word_out))
0 []
1 [1]
sage: F.process([0, 0, 0])
(True, 1, [0, 1, 0, 1])
sage: F.process([0, 0, 0, 0])
(True, 0, [0, 1, 0, 1])
```

2. A more realistic example: Addition of 1 in binary. We construct a transition function transforming the input to its binary expansion:

```
sage: def binary_transition(carry, input):
....:     value = carry + input
....:     if value.mod(2) == 0:
....:         pass
....:     else:
....:         return carry + input
```

(continues on next page)
from sage.all import *
def binary_transition(carry, input):
    value = carry + input
    if value % 2 == 0:
        return (value // 2, 0)
    else:
        return ((value - 1) // 2, 1)

T = Transducer(binary_transition,
                input_alphabet=[0, 1],
                initial_states=[1],
                final_states=[0])

T.process([1, 1, 1])
(False, 1, [0, 0, 0])

T.process([Integer(1), Integer(1), Integer(1)])
(True, 0, [0, 0, 0, 1])

all(ZZ(T(k.bits() + [0]), base=2) == k + 1 for k in srange(16))
True

T.process([Integer(1), Integer(1), Integer(1), Integer(0)])
(True, 0, [0, 0, 0, 1])

all(ZZ(T(k.bits() + [Integer(0)]), base=Integer(2)) == k + Integer(1) for k in srange(Integer(16)))
True

However, most of the time, we produce superfluous trailing zeros:
Combinatorics, Release 10.4

sage: T(11.bits()+[0])
[0, 0, 1, 1, 0]

```python
>>> from sage.all import *
>>> T(Integer(11).bits()+[Integer(0)])
[0, 0, 1, 1, 0]
```

We now use this method:

```python
sage: F = T.with_final_word_out(0)
sage: for f in F.iter_final_states():
    print("{} {}", format(f, f.final_word_out))
1 [1]
0 []
```

```python
>>> from sage.all import *
>>> F = T.with_final_word_out(Integer(0))
>>> for f in F.iter_final_states():
    print("{} {}", format(f, f.final_word_out))
1 [1]
0 []
```

The same tests as above, but we do not have to pad with trailing zeros anymore:

```python
sage: F.process([1, 1, 1])
(True, 1, [0, 0, 0, 1])
sage: all(ZZ(F(k.bits()), base=2) == k + 1
....:     for k in srange(16))
True
```

```python
>>> from sage.all import *
>>> F.process([Integer(1), Integer(1), Integer(1)])
(True, 1, [0, 0, 0, 1])
>>> all(ZZ(F(k.bits()), base=Integer(2)) == k + Integer(1)
...     for k in srange(Integer(16)))
True
```

No more trailing zero in the output:

```python
sage: F(11.bits())
[0, 0, 1, 1]
sage: all(F(k.bits())[-1] == 1
....:     for k in srange(16))
True
```

```python
>>> from sage.all import *
>>> F(Integer(11).bits())
[0, 0, 1, 1]
>>> all(F(k.bits())[-Integer(1)] == Integer(1)
...     for k in srange(Integer(16)))
True
```

3. Here is an example, where we allow trailing repeated 10:

```python
sage: T = Transducer([(0, 1, 0, 'a'),
....:     (1, 2, 1, 'b'),
(continues on next page)
(continued from previous page)

```python
sage: F = T.with_final_word_out([1, 0])
sage: for f in F.iter_final_states():
    print(str(f) + ' ' + ''.join(f.final_word_out))
```
```
0 1 bc
```

```
>>> from sage.all import *
```
```
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), 'a'),
                   (Integer(1), Integer(2), Integer(1), 'b'),
                   (Integer(2), Integer(0), Integer(0), 'c')],
                   initial_states=[Integer(0)],
                   final_states=[Integer(0)])
>>> F = T.with_final_word_out([Integer(1), Integer(0)])
>>> for f in F.iter_final_states():
    print(str(f) + ' ' + ''.join(f.final_word_out))
```
```
0 1 bc
```

Trying this with trailing repeated 01 does not produce a final_word_out for state 1, but for state 2:

```
sage: F = T.with_final_word_out([0, 1])
sage: for f in F.iter_final_states():
    print(str(f) + ' ' + ''.join(f.final_word_out))
```
```
0 2 c
```

```
>>> from sage.all import *
```
```
>>> F = T.with_final_word_out([Integer(0), Integer(1)])
>>> for f in F.iter_final_states():
    print(str(f) + ' ' + ''.join(f.final_word_out))
```
```
0 2 c
```

4. Here another example with a more-letter trailing input:

```
sage: T = Transducer([(0, 1, 0, 'a'),
                   (1, 2, 0, 'b'), (1, 2, 1, 'b'),
                   (2, 3, 0, 'c'), (2, 0, 1, 'e'),
                   (3, 1, 0, 'd'), (3, 1, 1, 'd')],
                   initial_states=[0],
                   final_states=[0],
                   with_final_word_out=[0, 0, 1, 1])
```
```
sage: for f in T.iter_final_states():
    print(str(f) + ' ' + ''.join(f.final_word_out))
```
```
0 1 bcdbcdbe
2 cdbe
3 dbe
```

```
>>> from sage.all import *
```
```
>>> T = Transducer([(Integer(0), Integer(1), Integer(0), 'a'),
                   (Integer(1), Integer(2), Integer(1), 'b'),
                   (Integer(2), Integer(0), Integer(0), 'c')],
                   initial_states=[Integer(0)],
                   final_states=[Integer(0)])
```

**class** `sage.combinat.finite_state_machine.Transducer` *(data=None, initial_states=None, final_states=None, input_alphabet=None, output_alphabet=None, determine_alphabets=None, with_final_word_out=None, store_states_dict=True, on_duplicate_transition=None)*

Bases: `FiniteStateMachine`

This creates a transducer, which is a finite state machine, whose transitions have input and output labels.

A transducer has additional features like creating a simplified transducer.

See class `FiniteStateMachine` for more information.

**EXAMPLES:**

We can create a transducer performing the addition of 1 (for numbers given in binary and read from right to left) in the following way:

```python
sage: T = Transducer([(C, C, 1, 0), (C, N, 0, 1),
...                    (N, N, 0, 0), (N, N, 1, 1)],
...                  initial_states=['C'], final_states=['N'])
```

```python
sage: T
Transducer with 2 states
sage: T([0])
[1]
sage: T([1,1,0])
[0, 0, 1]
sage: ZZ(T(15.digits(base=2)+[0]), base=2)
16
```

```python
>>> from sage.all import *
>>> T = Transducer([('C', 'C', Integer(1), Integer(0)), ('C', 'N', Integer(0),
...                 Integer(1)),
...                ('N', 'N', Integer(0), Integer(0)), ('N', 'N', Integer(1),
...                Integer(1))],
...                initial_states=['C'], final_states=['N'])
```

(continues on next page)
Transducer with 2 states
>>> T([Integer(0)])
[1]
>>> T([Integer(1), Integer(1), Integer(0)])
[0, 0, 1]
>>> ZZ(T(Integer(15).digits(base=Integer(2)) + [Integer(0)]), base=Integer(2))
16

Note that we have padded the binary input sequence by a 0 so that the transducer can reach its final state.

cartesian_product (other, only_accessibile_components=True)

Return a new transducer which can simultaneously process an input with the machines self and other where the output labels are $d$-tuples of the original output labels.

INPUT:

- other – a finite state machine (if $d = 2$) or a list (or other iterable) of $d - 1$ finite state machines
- only_accessibile_components – If True (default), then the result is piped through accessible_components(). If no new_input_alphabet is given, it is determined by determine_alphabets().

OUTPUT:

A transducer which can simultaneously process an input with self and the machine(s) in other.

The set of states of the new transducer is the Cartesian product of the set of states of self and other.

Let $(A_j, B_j, a_j, b_j)$ for $j \in \{1, \ldots, d\}$ be transitions in the machines self and in other. Then there is a transition $((A_1, \ldots, A_d), (B_1, \ldots, B_d), a, (b_1, \ldots, b_d))$ in the new transducer if $a_1 = \cdots = a_d = a$.

EXAMPLES:

```python
sage: transducer1 = Transducer([('A', 'A', 0, 0),
...: ('A', 'A', 1, 1)],
...: initial_states=['A'],
...: final_states=['A'],
...: determine_alphabets=True)

sage: transducer2 = Transducer([([0, 1, 0], ['b', 'c'])),
...: (0, 0, 1, 'b'),
...: (1, 1, 0, 'a')],
...: initial_states=[0],
...: final_states=[1],
...: determine_alphabets=True)

sage: result = transducer1.cartesian_product(transducer2)
sage: result
Transducer with 2 states

sage: result.transitions()
[Transition from ('A', 0) to ('A', 1): 0|(0, 'b'), (None, 'c')],
Transition from ('A', 0) to ('A', 0): 1|(1, 'b')],
Transition from ('A', 1) to ('A', 1): 0|(0, 'a')]

sage: result([1, 0, 0])
[(1, 'b'), (0, 'b'), (None, 'c'), (0, 'a')]

sage: (transducer1([1, 0, 0]), transducer2([1, 0, 0]))
([1, 0, 0], ['b', 'b', 'c', 'a'])
```

```python
>>> from sage.all import *
>>> transducer1 = Transducer([[('A', 'A', Integer(0), Integer(0))],
...: ('A', 'A', Integer(1), Integer(1))],
...: initial_states=['A'],
...: final_states=['A'],
...: determine_alphabets=True)
```

(continues on next page)
... initial_states=[A],
... final_states=[A],
... determine_alphabets=True)
>>> transducer2 = Transducer([(Integer(0), Integer(1), Integer(0), ['b', 'c →'])],
... (Integer(0), Integer(0), Integer(1), 'b'),
... (Integer(1), Integer(1), Integer(0), 'a')],
... initial_states=[Integer(0)],
... final_states=[Integer(1)],
... determine_alphabets=True)
>>> result = transducer1.cartesian_product(transducer2)
>>> result
Transducer with 2 states
>>> result.transitions()
[Transition from ('A', 0) to ('A', 1): 0|(0, b),(None, c),
 Transition from ('A', 0) to ('A', 0): 1|(1, b),
 Transition from ('A', 1) to ('A', 1): 0|(0, a)]
>>> result([Integer(1), Integer(0), Integer(0)])
[(1, b), (0, b), (None, c), (0, a)]
>>> (transducer1([Integer(1), Integer(0), Integer(0)]),
  transducer2([Integer(1), Integer(0), Integer(0)]))
([(1, 0, 0), ['b', 'b', 'c', 'a'])

Also final output words are correctly processed:

sage: transducer1.state('A').final_word_out = 2
sage: result = transducer1.cartesian_product(transducer2)
sage: result.final_states()[0].final_word_out
[(2, None)]

>>> from sage.all import *

>>> result = transducer1.state('A').final_word_out = Integer(2)

>>> result = transducer1.cartesian_product(transducer2)
>>> result.final_states()[Integer(0)].final_word_out
[(2, None)]

The following transducer counts the number of 11 blocks minus the number of 10 blocks over the alphabet [0, 1].

sage: count_11 = transducers.CountSubblockOccurrences(...: [1, 1],
.....: input_alphabet=[0, 1])
sage: count_10 = transducers.CountSubblockOccurrences(...: [1, 0],
.....: input_alphabet=[0, 1])
sage: count_11x10 = count_11.cartesian_product(count_10)
sage: difference = transducers.sub([0, 1])(count_11x10)
sage: T = difference.simplification().relabeled()
sage: T.initial_states()
[1]
sage: sorted(T.transitions())
[Transition from 0 to 1: 0|-1,
 Transition from 0 to 0: 1|1,
 Transition from 1 to 1: 0|0,
 Transition from 1 to 0: 1|0]
If `other` is an automaton, then `cartesian_product()` returns `self` where the input is restricted to the input accepted by `other`.

For example, if the transducer transforms the standard binary expansion into the non-adjacent form and the automaton recognizes the binary expansion without adjacent ones, then the Cartesian product of these two is a transducer which does not change the input (except for changing a to `(a, None)` and ignoring a leading 0).

```python
sage: NAF = Transducer([(0, 1, 0, None),
                     (0, 2, 1, None),
                     (1, 1, 0, 0),
                     (1, 2, 1, 0),
                     (2, 1, 0, 1),
                     (2, 3, 1, -1),
                     (3, 2, 0, 0),
                     (3, 3, 1, 0)],
                     initial_states=[0],
                     final_states=[1],
                     determine_alphabets=True)

sage: aut11 = Automaton([(0, 0, 0), (0, 1, 1), (1, 0, 0)],
                     initial_states=[0],
                     final_states=[0, 1],
                     determine_alphabets=True)

sage: res = NAF.cartesian_product(aut11)

sage: res([1, 0, 0, 1, 0, 1, 0])
[(1, None), (0, None), (0, None), (1, None), (0, None), (1, None)]
```
```python
>>> from sage.all import *
>>> NAF = Transducer([(Integer(0), Integer(1), Integer(0), None),  
                  (Integer(0), Integer(2), Integer(1), None),  
                  (Integer(1), Integer(1), Integer(0), Integer(0)),  
                  (Integer(1), Integer(2), Integer(1), Integer(0)),  
                  (Integer(2), Integer(1), Integer(0), Integer(1)),  
                  (Integer(2), Integer(3), Integer(1), -Integer(1)),  
                  (Integer(3), Integer(2), Integer(0), Integer(0)),  
                  (Integer(3), Integer(3), Integer(1), Integer(0))],  
                  initial_states=[Integer(0)],  
                  final_states=[Integer(1)],  
                  determine_alphabets=True)

>>> aut11 = Automaton([(Integer(0), Integer(0), Integer(0)),  
                      (Integer(0), Integer(1), Integer(0)),  
                      (Integer(1), Integer(0), Integer(0))],  
                      initial_states=[Integer(0)],  
                      final_states=[Integer(0), Integer(1)],  
                      determine_alphabets=True)

>>> res = NAF.cartesian_product(aut11)

>>> res([Integer(1), Integer(0), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0), Integer(1), Integer(0)])
[(1, None), (0, None), (0, None), (1, None), (0, None), (1, None)]

This is obvious because if the standard binary expansion does not have adjacent ones, then it is the same as the non-adjacent form.

Be aware that `cartesian_product()` is not commutative.

```
sage: aut11.cartesian_product(NAF)

intersection (other, only_accessible_components=True)

Return a new transducer which accepts an input if it is accepted by both given
finite state machines producing the same output.

INPUT:

• other – a transducer

• only_accessible_components – If True (default), then the result is piped through accessible_components(). If no new_input_alphabet is given, it is determined by determine_alphabets().
OUTPUT:

A new transducer which computes the intersection (see below) of the languages of self and other.

The set of states of the transducer is the Cartesian product of the set of states of both given transducers. There is a transition \((A, B, C, D, a, b)\) in the new transducer if there are transitions \((A, C, a, b)\) and \((B, D, a, b)\) in the old transducers.

EXAMPLES:

```python
sage: transducer1 = Transducer(
    (1, 2, 1, 0),
    (2, 2, 1, 0),
    (2, 2, 0, 1),
    initial_states=[1],
    final_states=[2],
)

sage: transducer2 = Transducer(
    (A, A, 1, 0),
    (A, B, 0, 0),
    (B, B, 0, 1),
    (B, A, 1, 1),
    initial_states=[A],
    final_states=[B],
)

sage: res = transducer1.intersection(transducer2)
sage: res.transitions()
[Transition from (1, A) to (2, A): 1|0,
 Transition from (2, A) to (2, A): 1|0]
```

In general, transducers are not closed under intersection. But for transducer which do not have epsilon-transitions, the intersection is well defined (cf. [BaWo2012]). However, in the next example the intersection of the two transducers is not well defined. The intersection of the languages consists of \((a^n, b^n c^n)\). This set is not recognizable by a finite transducer.

```python
sage: t1 = Transducer(
    (0, 0, 'a', 'b'),
    (0, 1, None, 'c'),
    (1, 1, None, 'c'),
    initial_states=[0],
    final_states=[0, 1],
)

sage: t2 = Transducer(
    (A, A, None, 'b'),
    (A, 'B', 'a', 'c'),
    (B, 'B', 'a', 'c'),
    initial_states=['A'],
    final_states=['A', 'B'],
)
```

(continues on next page)
sage: t2.intersection(t1)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input or output) was found.

```python
>>> from sage.all import *

                   ..., (Integer(0), Integer(1), None, 'c'),
                   ..., (Integer(1), Integer(1), None, 'c')],
                   initial_states=[Integer(0)],
                   final_states=[Integer(0), Integer(1)])

>>> t2 = Transducer([(A, A, None, 'b'),
                   ..., (A, B, 'a', 'c'),
                   ..., (B, B, 'a', 'c')],
                   initial_states=['A'],
                   final_states=['A', 'B'])

>>> t2.intersection(t1)
Traceback (most recent call last):
...
ValueError: An epsilon-transition (with empty input or output) was found.
```

REFERENCES:

process(*args, **kwargs)

Return whether the transducer accepts the input, the state where the computation stops and which output is generated.

INPUT:

- **input_tape** – the input tape can be a list or an iterable with entries from the input alphabet. If we are working with a multi-tape machine (see parameter use_multitape_input and notes below), then the tape is a list or tuple of tracks, each of which can be a list or an iterable with entries from the input alphabet.

- **initial_state** or **initial_states** – the initial state(s) in which the machine starts. Either specify a single one with initial_state or a list of them with initial_states. If both are given, initial_state will be appended to initial_states. If neither is specified, the initial states of the finite state machine are taken.

- **list_of_outputs** – (default: None) a boolean or None. If True, then the outputs are given in list form (even if we have no or only one single output). If False, then the result is never a list (an exception is raised if the result cannot be returned). If list_of_outputs=None the method determines automatically what to do (e.g. if a non-deterministic machine returns more than one path, then the output is returned in list form).

- **only_accepted** – (default: False) a boolean. If set, then the first argument in the output is guaranteed to be True (if the output is a list, then the first argument of each element will be True).

- **full_output** – (default: True) a boolean. If set, then the full output is given, otherwise only the generated output (the third entry below only). If the input is not accepted, a ValueError is raised.

- **always_include_output** – if set (not by default), always include the output. This is inconsequential for a Transducer, but can be used in other classes derived from FiniteStateMachine where the output is suppressed by default, cf. Automaton.process().

- **format_output** – a function that translates the written output (which is in form of a list) to something more readable. By default (None) identity is used here.
• `check_epsilon_transitions` – (default: True) a boolean. If False, then epsilon transitions are not taken into consideration during process.

• `write_final_word_out` – (default: True) a boolean specifying whether the final output words should be written or not.

• `use_multitape_input` – (default: False) a boolean. If True, then the multi-tape mode of the process iterator is activated. See also the notes below for multi-tape machines.

• `process_all_prefixes_of_input` – (default: False) a boolean. If True, then each prefix of the input word is processed (instead of processing the whole input word at once). Consequently, there is an output generated for each of these prefixes.

• `process_iterator_class` – (default: None) a class inherited from `FSMProcessIterator`. If None, then `FSMProcessIterator` is taken. An instance of this class is created and is used during the processing.

• `automatic_output_type` – (default: False) a boolean. If set and the input has a parent, then the output will have the same parent. If the input does not have a parent, then the output will be of the same type as the input.

OUTPUT:

The full output is a triple (or a list of triples, cf. parameter `list_of_outputs`), where

• the first entry is True if the input string is accepted,

• the second gives the reached state after processing the input tape (This is a state with label `None` if the input could not be processed, i.e., if at one point no transition to go on could be found.), and

• the third gives a list of the output labels written during processing.

If `full_output` is False, then only the third entry is returned.

Note that in the case the transducer is not deterministic, all possible paths are taken into account.

This function uses an iterator which, in its simplest form, goes from one state to another in each step. To decide which way to go, it uses the input words of the outgoing transitions and compares them to the input tape. More precisely, in each step, the iterator takes an outgoing transition of the current state, whose input label equals the input letter of the tape. The output label of the transition, if present, is written on the output tape.

If the choice of the outgoing transition is not unique (i.e., we have a non-deterministic finite state machine), all possibilities are followed. This is done by splitting the process into several branches, one for each of the possible outgoing transitions.

The process (iteration) stops if all branches are finished, i.e., for no branch, there is any transition whose input word coincides with the processed input tape. This can simply happen when the entire tape was read.

Also see `__call__()` for a version of `process()` with shortened output.

Internally this function creates and works with an instance of `FSMProcessIterator`. This iterator can also be obtained with `iter_process()`.

If working with multi-tape finite state machines, all input words of transitions are words of $k$-tuples of letters. Moreover, the input tape has to consist of $k$ tracks, i.e., be a list or tuple of $k$ iterators, one for each track.

Warning: Working with multi-tape finite state machines is still experimental and can lead to wrong outputs.

EXAMPLES:
sage: binary_inverter = Transducer({\textquoteleft\textasciitilde}{A}: \{[\textquoteleft\textasciitilde}{A}, 0, 1, \{\textquoteleft\textasciitilde}{A}, 1, 0\}\},
....:
initial_states=[\textquoteleft\textasciitilde}{A}], final_states=[\textquoteleft\textasciitilde}{A}])
sage: binary_inverter.process([0, 1, 0, 0, 1, 1])
(True, \textquoteleft\textasciitilde}{A}, [1, 0, 1, 1, 0, 0])

If we are only interested in the output, we can also use:

sage: binary_inverter([0, 1, 0, 0, 1, 1])
[1, 0, 1, 1, 0, 0]

This can also be used with words as input:

sage: # needs sage.combinat
sage: W = Words([0, 1]); W
Finite and infinite words over \{0, 1\}
sage: w = W([0, 1, 0, 0, 1, 1]); w
word: 010011
sage: binary_inverter(w)
word: 101100

In this case it is automatically determined that the output is a word. The call above is equivalent to:

sage: binary_inverter.process(w,
# needs sage.combinat
....:
full_output=False,
....:
list_of_outputs=False,
....:
automatic_output_type=True)
word: 101100

(continues on next page)
The following transducer transforms $0^n1$ to $1^n2$:

```python
sage: T = Transducer([(0, 0, 0, 1), (0, 1, 1, 2)])
sage: T.state(0).is_initial = True
sage: T.state(1).is_final = True
```

We can see the different possibilities of the output by:

```python
sage: [T.process(w) for w in [[1], [0, 1], [0, 0, 1], [0, 1, 1], ...
    ....:    [0], [0, 0], [2, 0], [0, 1, 2]]
  [(True, 1, [2]), (True, 1, [1, 2]),
  (False, None, None),
  (False, 0, [1]), (False, 0, [1, 1]),
  (False, None, None), (False, None, None)]
```

If we just want a condensed output, we use:

```python
sage: [T.process(w, full_output=False) ...
    ....:    for w in [[1], [0, 1], [0, 0, 1]]
  [[2], [1, 2], [1, 1, 2]]
sage: T.process([0], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```python
>>> from sage.all import *
>>> T = Transducer([(Integer(0), Integer(0), Integer(0), Integer(1)), ...
    ...    (Integer(0), Integer(1), Integer(1), Integer(2))])
>>> T.state(Integer(0)).is_initial = True
>>> T.state(Integer(1)).is_final = True
```

```python
>>> from sage.all import *
>>> [T.process(w) for w in [[Integer(1)], [Integer(0), Integer(1)], ...
    ...    [Integer(0), Integer(0), Integer(1)], [Integer(0), Integer(1), Integer(1)], ...
    ...    [Integer(2), Integer(0)], [Integer(0), Integer(1), Integer(2)]]]
  [(True, 1, [2]), (True, 1, [1, 2]),
  (False, None, None),
  (False, 0, [1]), (False, 0, [1, 1]),
  (False, None, None), (False, None, None)]
```

```python
>>> from sage.all import *
>>> [T.process(w, full_output=False) ...
    ...    for w in [[Integer(1)], [Integer(0), Integer(1)], [Integer(0), ...
    ...    Integer(0), Integer(1)]]]
  [[2], [1, 2], [1, 1, 2]]
>>> T.process([Integer(0)], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

(continues on next page)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.

```python
>>> T.process([Integer(0), Integer(1), Integer(2)], full_output=False)
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

It is equivalent to:

```python
sage: [T(w) for w in [[1], [0, 1], [0, 0, 1]]
[[2], [1, 2], [1, 1, 2]]
sage: T([0])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([0, 1, 2])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

```python
>>> from sage.all import *

sage: [T(w) for w in [[Integer(1)], [Integer(0), Integer(1)], [Integer(0),
    Integer(0), Integer(1)]]
[[2], [1, 2], [1, 1, 2]]
sage: T([Integer(0)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([Integer(0), Integer(1), Integer(2)])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
```

A cycle with empty input and empty output is correctly processed:

```python
sage: T = Transducer([(0, 1, None, None), (1, 0, None, None)],
    initial_states=[0], final_states=[1])
sage: T.process([])
[(False, 0, []), (True, 1, [])]
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([0])
[(False, 0, ['r']), (True, 1, ['r'])]
```

```python
>>> from sage.all import *

sage: T = Transducer([(Integer(0), Integer(1),
    None, None), (Integer(1), None, None)],
    initial_states=[Integer(0)], final_states=[Integer(1)])
>>> T.process([])
[(False, 0, []), (True, 1, [])]
>>> _ = T.add_transition(-Integer(1), Integer(0), Integer(0), 'r')
>>> T.state(-Integer(1)).is_initial = True
>>> T.state(Integer(0)).is_initial = False
>>> T.process([Integer(0)])
```

(continues on next page)
If there is a cycle with empty input but non-empty output, the possible outputs would be an infinite set:

```python
sage: T = Transducer([(0, 1, None, 'z'), (1, 0, None, None)],
                  initial_states=[0], final_states=[1])
```

```python
sage: T.process([])
Traceback (most recent call last):
  ...:
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

```python
>>> from sage.all import *

>>> T = Transducer([(Integer(0), Integer(1), None, 'z'), (Integer(1), Integer(0), None, None)],
                  initial_states=[Integer(0)], final_states=[Integer(1)])

>>> T.process([])
Traceback (most recent call last):
  ...:
RuntimeError: State 0 is in an epsilon cycle (no input),
but output is written.
```

But if this cycle with empty input and non-empty output is not reached, the correct output is produced:

```python
sage: _ = T.add_transition(-1, 0, 0, 'r')
sage: T.state(-1).is_initial = True
sage: T.state(0).is_initial = False
sage: T.process([])
(False, -1, [])
```

```python
>>> from sage.all import *

>>> _ = T.add_transition(-Integer(1), Integer(0), Integer(0), 'r')

>>> T.state(-Integer(1)).is_initial = True

>>> T.state(Integer(0)).is_initial = False

>>> T.process([])
(False, -1, [])
```

If we set `check_epsilon_transitions=False`, then no transitions with empty input are considered anymore. Thus cycles with empty input are no problem anymore:

```python
sage: T.process([], check_epsilon_transitions=False)
(False, 0, ['r'])
```

```python
>>> from sage.all import *

>>> T.process([Integer(0)], check_epsilon_transitions=False)
(False, 0, ['r'])
```
A simple example of a multi-tape transducer is the following: It writes the length of the first tape many letters \(a\) and then the length of the second tape many letters \(b\):

```
sage: M = Transducer([(0, 0, (1, None), 'a'),
                     (1, 1, (None, 1), 'b')],
                     initial_states=[0],
                     final_states=[1])
```

```
sage: M.process(([1, 1], [1]), use_multitape_input=True)
(True, 1, ['a', 'a', 'b'])
```

See also:

- `FiniteStateMachine.process()`, `Automaton.process()`, `iter_process()`, `__call__`, `FSMProcessIterator`

`simplification()`

Return a simplified transducer.

OUTPUT:

A new transducer.

This function simplifies a transducer by Moore’s algorithm, first moving common output labels of transitions leaving a state to output labels of transitions entering the state (cf. `prepone_output()`).

The resulting transducer implements the same function as the original transducer.

EXAMPLES:

```
sage: fsm = Transducer([("A", "B", 0, 1),
                      ("A", "B", 1, 0),
                      ("B", "C", 0, 1),
                      ("B", "C", 1, 0),
                      ("C", "D", 0, 1),
                      ("C", "D", 1, 0),
                      ("D", "A", 0, 1),
                      ("D", "A", 1, 1)])

sage: fsms = fsm.simplification()
sage: fsms
Transducer with 2 states

sage: fsms.transitions()
[Transition from ('B', 'D') to ('A', 'C'): 0|0,
 Transition from ('B', 'D') to ('A', 'C'): 1|1,
 Transition from ('A', 'C') to ('B', 'D'): 0|1,
 Transition from ('A', 'C') to ('B', 'D'): 1|0]

sage: fsms.relabeled().transitions()
[Transition from 0 to 1: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```
```python
>>> from sage.all import *
>>> fsm = Transducer([("A", "B", Integer(0), Integer(1)), ("A", "B", Integer(1), Integer(0)), ("B", "C", Integer(0), Integer(0)), ("B", "C", Integer(1), Integer(1)), ("C", "D", Integer(0), Integer(1)), ("C", "D", Integer(1), Integer(0)), ("D", "A", Integer(0), Integer(0)), ("D", "A", Integer(1), Integer(1))])
>>> fsms = fsm.simplification()
>>> fsms
Transducer with 2 states
>>> fsms.transitions()
[Transition from (B, D) to (A, C): 0|0,
 Transition from (B, D) to (A, C): 1|1,
 Transition from (A, C) to (B, D): 0|1,
 Transition from (A, C) to (B, D): 1|0]
>>> fsms.relabeled().transitions()
[Transition from 0 to 1: 0|0,
 Transition from 0 to 1: 1|1,
 Transition from 1 to 0: 0|1,
 Transition from 1 to 0: 1|0]
```

```python
sage: fsm = Transducer([("A", "A", 0, 0),
                      ("A", "B", 1, 1),
                      ("A", "C", 1, -1),
                      ("B", "A", 2, 0),
                      ("C", "A", 2, 0)])

sage: fsm_simplified = fsm.simplification()
```

```python
sage: fsm_simplified
Transducer with 2 states
```

```python
sage: fsm_simplified.transitions()
[Transition from (A,) to (A,): 0|0,
 Transition from (A,) to (B, C): 1|1,0,
 Transition from (A,) to (B, C): 1|-1,0,
 Transition from (B, C) to (A,): 2|-
]
```

```python
>>> from sage.all import *
>>> fsm = Transducer([("A", "A", Integer(0), Integer(0)),
                      ("A", "B", Integer(1), Integer(1)),
                      ("A", "C", Integer(1), -Integer(1)),
                      ("B", "A", Integer(2), Integer(0)),
                      ("C", "A", Integer(2), Integer(0))])

>>> fsm_simplified = fsm.simplification()
```

```python
>>> fsm_simplified
Transducer with 2 states
```

```python
>>> fsm_simplified.transitions()
[Transition from (A,) to (A,): 0|0,
 Transition from (A,) to (B, C): 1|1,0,
 Transition from (A,) to (B, C): 1|-1,0,
 Transition from (B, C) to (A,): 2|-]
```

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_add_input
sage: T = Transducer([("A", "A", 1/2, 0),
                   ("A", "B", 1/4, 1),
                   ("A", "C", 1/8, -1),
                   ("B", "A", 1/2, 0),
                   ("C", "A", 1/2, 0)])
```

(continues on next page)
Illustrating the use of colors in order to avoid identification of states:

```python
sage: T = Transducer([[0,0,0,0], [0,1,1,1],
                   [1,0,0,0], [1,1,1,1]],
                   initial_states=[0],
                   final_states=[0,1])
sage: sorted(T.simplification().transitions())
[Transition from (0, 1) to (0, 1): 0|0,
 Transition from (0, 1) to (0, 1): 1|1]
sage: T.state(0).color = 0
sage: T.state(0).color = 1
```

```python
>>> from sage.all import *
>>> T = Transducer([[Integer(0),Integer(0),Integer(0),Integer(0)],
                   [Integer(0),Integer(1),Integer(1),Integer(1)],
                   [Integer(1),Integer(0),Integer(0),Integer(0)],
                   [Integer(1),Integer(1),Integer(1),Integer(1)]],
                   initial_states=[Integer(0)],
                   final_states=[Integer(0),Integer(1)])
>>> sorted(T.simplification().transitions())
[Transition from (0, 1) to (0, 1): 0|0,
 Transition from (0, 1) to (0, 1): 1|1]
```

(continues on next page)
sage.combinat.finite_state_machine.duplicate_transition_add_input (old_transition, new_transition)

Alternative function for handling duplicate transitions in finite state machines. This implementation adds the input label of the new transition to the input label of the old transition. This is intended for the case where a Markov chain is modelled by a finite state machine using the input labels as transition probabilities.

See the documentation of the on_duplicate_transition parameter of FiniteStateMachine.

INPUT:

• old_transition – A transition in a finite state machine.

• new_transition – A transition, identical to old_transition, which is to be inserted into the finite state machine.

OUTPUT:

A transition whose input weight is the sum of the input weights of old_transition and new_transition.

EXAMPLES:

```python
>>> from sage.combinat.finite_state_machine import duplicate_transition_add_input
>>> from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_add_input(FSMTransition('a', 'a', 1/2),
   FSM Transition('a', 'a', 1/2))
Transition from 'a' to 'a': 1|-
```

Input labels must be lists of length 1:

```python
sage: duplicate_transition_add_input(FSMTransition('a', 'a', [1, 1]),
   FSM Transition('a', 'a', [1, 1]))
Traceback (most recent call last):
  ...
TypeError: Trying to use duplicate_transition_add_input on
"Transition from 'a' to 'a': 1,1|" and
"Transition from 'a' to 'a': 1,1|",
but input words are assumed to be lists of length 1
```

```python
>>> from sage.all import *
>>> duplicate_transition_add_input(FSMTransition('a', 'a', [Integer(1),
   Integer(1)]),
   FSM Transition('a', 'a', [Integer(1),
   Integer(1)]))
```

(continues on next page)
Traceback (most recent call last):
...
TypeError: Trying to use duplicate_transition_add_input on
"Transition from 'a' to 'a': 1,1|" and
"Transition from 'a' to 'a': 1,1|-",
but input words are assumed to be lists of length 1

sage.combinat.finite_state_machine.duplicate_transition_ignore(old_transition, new_transition)

Default function for handling duplicate transitions in finite state machines. This implementation ignores the occurrence.

See the documentation of the on_duplicate_transition parameter of FiniteStateMachine.

INPUT:

- old_transition – A transition in a finite state machine.
- new_transition – A transition, identical to old_transition, which is to be inserted into the finite state machine.

OUTPUT:

The same transition, unchanged.

EXAMPLES:

```python
sage: from sage.combinat.finite_state_machine import duplicate_transition_ignore
sage: FSMTransition(0, 0, 1)
sage: duplicate_transition_ignore(FSMTransition(0, 0, 1), FSMTransition(0, 0, 1))
Transition from 0 to 0: 1|-```

sage.combinat.finite_state_machine.duplicate_transition_raise_error(old_transition, new_transition)

Alternative function for handling duplicate transitions in finite state machines.

This implementation raises a ValueError.

See the documentation of the on_duplicate_transition parameter of FiniteStateMachine.

INPUT:

- old_transition – A transition in a finite state machine.
- new_transition – A transition, identical to old_transition, which is to be inserted into the finite state machine.

OUTPUT:

Nothing. A ValueError is raised.

EXAMPLES:
sage: from sage.combinat.finite_state_machine import duplicate_transition_raise_error
sage: from sage.combinat.finite_state_machine import FSMTransition
sage: duplicate_transition_raise_error(FSMTransition(0, 0, 1),
        ...:      FSMTransition(0, 0, 1))
Traceback (most recent call last):
  ...:
ValueError: Attempting to re-insert transition Transition from 0 to 0: 1|

We can test other properties of the elements than the elements themselves. In the following example, we check whether all tuples have the same lengths:

sage.combinat.finite_state_machine.equal(iterator)

Checks whether all elements of iterator are equal.

INPUT:

• iterator – an iterator of the elements to check

OUTPUT:

True or False.

This implements https://stackoverflow.com/a/3844832/1052778.

EXAMPLES:

sage: from sage.combinat.finite_state_machine import equal
sage: equal([0, 0, 0])
True
sage: equal([0, 1, 0])
False
sage: equal([])
True
sage: equal(iter([None, None]))
True

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import equal
>>> equal([[Integer(0), Integer(0), Integer(0)]]
True
>>> equal([[Integer(0), Integer(1), Integer(0)]]
False
>>> equal([])
True
>>> equal(iter([None, None]))
True

We can test other properties of the elements than the elements themselves. In the following example, we check whether all tuples have the same lengths:
sage: equal(len(x) for x in [(1, 2), (2, 3), (3, 1)])
True
sage: equal(len(x) for x in [(1, 2), (1, 2, 3), (3, 1)])
False

>>> from sage.all import *
>>> equal(len(x) for x in [(Integer(1), Integer(2)), (Integer(2), Integer(3)), ... →(Integer(3), Integer(1))])
True
>>> equal(len(x) for x in [(Integer(1), Integer(2)), (Integer(1), Integer(2), ... →Integer(3)), (Integer(3), Integer(1))])
False

sage.combinat.finite_state_machine.full_group_by(l, key=None)

Group iterable l by values of key.

INPUT:

- iterable l
- key function key

OUTPUT:

A list of pairs (k, elements) such that key(e)=k for all e in elements.

This is similar to itertools.groupby() except that lists are returned instead of iterables and no prior sorting is required.

We do not require

- that the keys are sortable (in contrast to the approach via sorted() and itertools.groupby()) and
- that the keys are hashable (in contrast to the implementation proposed in https://stackoverflow.com/a/15250161).

However, it is required

- that distinct keys have distinct str-representations.

The implementation is inspired by https://stackoverflow.com/a/15250161, but non-hashable keys are allowed.

EXAMPLES:

```python
sage: # needs sage.symbolic
sage: from sage.combinat.finite_state_machine import full_group_by
sage: t = [2/x, 1/x, 2/x]
sage: r = full_group_by([0, 1, 2], key=lambda i: t[i])
sage: sorted(r, key=lambda p: p[1])
[(2/x, [0, 2]), (1/x, [1])]
sage: from itertools import groupby
sage: for k, elements in groupby(sorted([0, 1, 2], ...: key=lambda i:t[i]), ...: key=lambda i:t[i]):
...:     print("{} {}").format(k, list(elements))
2/x [0]
1/x [1]
2/x [2]
```
Note that the behavior is different from `itertools.groupby()` because neither $1/x < 2/x$ nor $2/x < 1/x$ does hold.

Here, the result $r$ has been sorted in order to guarantee a consistent order for the doctest suite.

sage.combinat.finite_state_machine.is_Automaton($FSM$)
Tests whether or not $FSM$ inherits from Automaton.

sage.combinat.finite_state_machine.is_FSMProcessIterator($PI$)
Tests whether or not $PI$ inherits from FSMProcessIterator.

sage.combinat.finite_state_machine.is_FSMState($S$)
Tests whether or not $S$ inherits from FSMState.

sage.combinat.finite_state_machine.is_FSMTransition($T$)
Tests whether or not $T$ inherits from FSMTransition.

sage.combinat.finite_state_machine.is_FiniteStateMachine($FSM$)
Tests whether or not $FSM$ inherits from FiniteStateMachine.

sage.combinat.finite_state_machine.is_Transducer($FSM$)
Tests whether or not $FSM$ inherits from Transducer.

sage.combinat.finite_state_machine.setup_latex_preamble()
This function adds the package tikz with support for automata to the preamble of Latex so that the finite state machines can be drawn nicely.

See the section on LaTeX output in the introductory examples of this module.

sage.combinat.finite_state_machine.startswith($list_\_, prefix$)
Determine whether list starts with the given prefix.

INPUT:

- $list_\_$ – list
- prefix – list representing the prefix

OUTPUT:

True or False.

Similar to `str.startswith()`.

EXAMPLES:
sage: from sage.combinat.finite_state_machine import startswith
sage: startswith([1, 2, 3], [1, 2])
True
sage: startswith([1], [1, 2])
False
sage: startswith([1, 3, 2], [1, 2])
False

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import startswith
>>> startswith([Integer(1), Integer(2), Integer(3)], [Integer(1), Integer(2)])
True
>>> startswith([Integer(1)], [Integer(1), Integer(2)])
False
>>> startswith([Integer(1), Integer(3), Integer(2)], [Integer(1), Integer(2)])
False

sage.combinat.finite_state_machine.tupleofwords_to_wordoftuples(tupleofwords)
Transposes a tuple of words over the alphabet to a word of tuples.

INPUT:

• tupleofwords – a tuple of a list of letters.

OUTPUT:

A list of tuples.

Missing letters in the words are padded with the letter None (from the empty word).

EXAMPLES:

sage: from sage.combinat.finite_state_machine import (....:
....: tupleofwords_to_wordoftuples)
sage: tupleofwords_to_wordoftuples(....:
....: ([1, 2], [3, 4, 5, 6], [7]))
[(1, 3, 7), (2, 4, None), (None, 5, None), (None, 6, None)]

>>> from sage.all import *
>>> from sage.combinat.finite_state_machine import (....:
....: tupleofwords_to_wordoftuples)
>>> tupleofwords_to_wordoftuples(....:
....: ([Integer(1), Integer(2)], [Integer(3), Integer(4), Integer(5),...
....: Integer(6)], [Integer(7)]))
[(1, 3, 7), (2, 4, None), (None, 5, None), (None, 6, None)]

sage.combinat.finite_state_machine.wordoftuples_to_tupleofwords(wordoftuples)
Transposes a word of tuples to a tuple of words over the alphabet.

INPUT:

• wordoftuples – a list of tuples of letters.

OUTPUT:

A tuple of lists.

Letters None (empty word) are removed from each word in the output.

EXAMPLES:
5.1.109 Common Automata and Transducers (Finite State Machines Generators)

Automata and Transducers in Sage can be built through the automata and transducers objects, respectively. It contains generators for common finite state machines. For example,

```python
sage: I = transducers.Identity([0, 1, 2])
```

generates an identity transducer on the alphabet \{0, 1, 2\}.

To construct automata and transducers manually, you can use the classes Automaton and Transducer, respectively. See Finite state machines, automata, transducers for more details and a lot of examples.

**Automata**

- **AnyLetter()**: Return an automaton recognizing any letter.
- **AnyWord()**: Return an automaton recognizing any word.
- **EmptyWord()**: Return an automaton recognizing the empty word.
- **Word()**: Return an automaton recognizing the given word.
- **ContainsWord()**: Return an automaton recognizing words containing the given word.

**Transducers**

- **Identity()**: Returns a transducer realizing the identity map.
- **abs()**: Returns a transducer realizing absolute value.
- **map()**: Returns a transducer realizing a function.
- **operator()**: Returns a transducer realizing a binary operation.
- **all()**: Returns a transducer realizing logical and.
- **any()**: Returns a transducer realizing logical or.
- **add()**: Returns a transducer realizing addition.
- **sub()**: Returns a transducer realizing subtraction.
- **CountSubblockOccurrences()**: Returns a transducer counting the occurrences of a subblock.
- **Wait()**: Returns a transducer writing \( \text{False} \) until first (or k-th) true input is read.
- **weight()**: Returns a transducer realizing the Hamming weight.
- **GrayCode()**: Returns a transducer realizing binary Gray code.
- **Recursion()**: Returns a transducer defined by recursions.

Functions and methods

class sage.combinat.finite_state_machine_generators.AutomatonGenerators
    Bases: object

A collection of constructors for several common automata.

A list of all automata in this database is available via tab completion. Type “automata.” and then hit tab to see which automata are available.

The automata currently in this class include:

• AnyLetter()
• AnyWord()
• EmptyWord()
• Word()
• ContainsWord()

**AnyLetter** *(input_alphabet)*

Return an automaton recognizing any letter of the given input alphabet.

**INPUT:**

• input_alphabet – a list, the input alphabet

**OUTPUT:**

An *Automaton*.

**EXAMPLES:**

```
sage: A = automata.AnyLetter([0, 1])
sage: A([])
False
sage: A([0])
```

(continues on next page)
True
sage: A([1])
True
sage: A([0, 0])
False

>>> from sage.all import *
>>> A = automata.AnyLetter([Integer(0), Integer(1)])
>>> A([])
False
>>> A([Integer(0)])
True
>>> A([Integer(1)])
True
>>> A([Integer(0), Integer(0)])
False

See also:

*AnyWord()*

**AnyWord** *(input_alphabet)*

Return an automaton recognizing any word of the given input alphabet.

**INPUT:**

- input_alphabet – a list, the input alphabet

**OUTPUT:**

An *Automaton*.

**EXAMPLES:**

sage: A = automata.AnyWord([0, 1])

sage: A([0])
True
sage: A([1])
True
sage: A([0, 1])
True
sage: A([0, 2])
False

>>> from sage.all import *
>>> A = automata.AnyWord([Integer(0), Integer(1)])

>>> A([Integer(0)])
True
>>> A([Integer(1)])
True
>>> A([Integer(0), Integer(1)])
True
>>> A([Integer(0), Integer(2)])
False

This is equivalent to taking the *kleene_star()* of *AnyLetter()* and minimizing the result. This method immediately gives a minimized version:
sage: B = automata.AnyLetter([0, 1]).kleene_star().minimization().relabeled()

sage: B == A
True

>>> from sage.all import *

>>> B = automata.AnyLetter([Integer(0), Integer(1)]).kleene_star().
  →minimization().relabeled()

>>> B == A
True

See also:

ContainsWord(word, input_alphabet)

Return an automaton recognizing the words containing the given word as a factor.

INPUT:

• word – a list (or other iterable) of letters, the word we are looking for.
• input_alphabet – a list or other iterable, the input alphabet.

OUTPUT:
An Automaton.

EXAMPLES:

sage: A = automata.ContainsWord([0, 1, 0, 1, 1],
    ....: input_alphabet=[0, 1]

sage: A([1, 0, 1, 0, 1, 0, 1, 1, 0, 0])
True

sage: A([1, 0, 1, 0, 1, 0, 1, 0])
False

>>> from sage.all import *

>>> A = automata.ContainsWord([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)],
    ...: input_alphabet=[Integer(0), Integer(1)])

>>> A([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0),
    ...: Integer(1), Integer(1), Integer(0), Integer(0)])
True

>>> A([Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0), Integer(1), Integer(0)])
False

This is equivalent to taking the concatenation of AnyWord(), Word() and AnyWord() and minimizing the result. This method immediately gives a minimized version:

sage: B = (automata.AnyWord([0, 1]) *
    ....: automata.Word([0, 1, 0, 1, 1], [0, 1]) *
    ....: automata.AnyWord([0, 1])).minimization()

sage: B.isEquivalent(A)
True

>>> from sage.all import *

>>> B = (automata.AnyWord([Integer(0), Integer(1)]) *

See also:

*CountSubblockOccurrences(), AnyWord(), Word().*

EmptyWord(input_alphabet=None)

Return an automaton recognizing the empty word.

**INPUT:**

* input_alphabet – (default: None) an iterable or None.

**OUTPUT:**

An Automaton.

**EXAMPLES:**

```python
sage: A = automata.EmptyWord()
sage: A([])
True
sage: A([0])
False
```

```python
>>> from sage.all import *
```

```python
>>> A = automata.EmptyWord()
>>> A([[]])
True
>>> A([Integer(0)])
False
```

See also:

*AnyLetter(), AnyWord().*

Word(word, input_alphabet=None)

Return an automaton recognizing the given word.

**INPUT:**

* word – an iterable.

* input_alphabet – a list or None. If None, then the letters occurring in the word are used.

**OUTPUT:**

An Automaton.

**EXAMPLES:**

```python
sage: A = automata.Word([0])
sage: A.transitions()
[Transition from 0 to 1: 0|-
```
```python
sage: A.transitions()
[Transition from 0 to 1: 0|-
Transition from 1 to 2: 1|-
Transition from 2 to 3: 0|-
```

```python
sage: [A(w) for w in ([], [0], [0, 1], [0, 1, 1], [0, 1, 0])]
[False, False, False, False, True]
```

```python
>>> from sage.all import *
```

```python
>>> A = automata.Word([Integer(0)])
```

```python
>>> A.transitions()
[Transition from 0 to 1: 0|-
```

```python
>>> [A(w) for w in ([], [Integer(0)], [Integer(1)])]
[False, True, False]
```

```python
>>> A = automata.Word([Integer(0), Integer(1), Integer(0)])
```

```python
>>> A.transitions()
[Transition from 0 to 1: 0|-
Transition from 1 to 2: 1|-
Transition from 2 to 3: 0|-
```

```python
>>> [A(w) for w in ([], [Integer(0)], [Integer(0), Integer(1)], [Integer(0), Integer(1), Integer(1)], [Integer(0), Integer(1), Integer(0)])]
[False, False, False, False, True]
```

If the input alphabet is not given, it is derived from the given word.

```python
sage: A.input_alphabet
[0, 1]
```

```python
sage: A = automata.Word([0, 1, 0], input_alphabet=[0, 1, 2])
```

```python
sage: A.input_alphabet
[0, 1, 2]
```

```python
>>> from sage.all import *
```

```python
>>> A.input_alphabet
[0, 1]
```

```python
>>> A = automata.Word([Integer(0), Integer(1), Integer(0)], input_alphabet=[Integer(0), Integer(1), Integer(2)])
```

```python
>>> A.input_alphabet
[0, 1, 2]
```

See also:

- AnyWord()
- ContainsWord().

**class** `sage.combinat.finite_state_machine_generators.TransducerGenerators`

**Bases**: object

A collection of constructors for several common transducers.

A list of all transducers in this database is available via tab completion. Type “transducers.” and then hit tab to see which transducers are available.

The transducers currently in this class include:

- Identity()
- abs()
- operator()
- all()
• `any()`
• `add()`
• `sub()`
• `CountSubblockOccurrences()`
• `Wait()`
• `GrayCode()`
• `Recursion()`

**CountSubblockOccurrences** *(block, input_alphabet)*

Returns a transducer counting the number of (possibly overlapping) occurrences of a block in the input.

**INPUT:**

- `block` – a list (or other iterable) of letters.
- `input_alphabet` – a list or other iterable.

**OUTPUT:**

A transducer counting (in unary) the number of occurrences of the given block in the input. Overlapping occurrences are counted several times.

Denoting the block by \(b_0 \ldots b_{k-1}\), the input word by \(i_0 \ldots i_L\) and the output word by \(o_0 \ldots o_L\), we have \(o_j = 1\) if and only if \(i_{j-k+1} \ldots i_j = b_0 \ldots b_{k-1}\). Otherwise, \(o_j = 0\).

**EXAMPLES:**

1. Counting the number of 10 blocks over the alphabet [0, 1]:

```sage
sage: T = transducers.CountSubblockOccurrences(
    ... : [1, 0],
    ... : [0, 1])
sage: sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]
sage: T.input_alphabet
[0, 1]
sage: T.output_alphabet
[0, 1]
sage: T.initial_states()
[()]
sage: T.final_states()
[(), (1,)]
```

```python
>>> from sage.all import *

>>> T = transducers.CountSubblockOccurrences(
...     [Integer(1), Integer(0)],
...     [Integer(0), Integer(1)])

>>> sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|1,
 Transition from (1,) to (1,): 1|0]

>>> T.input_alphabet
[0, 1]
```
>>> T.output_alphabet
[0, 1]
>>> T.initial_states()
[]
>>> T.final_states()
[(), (1,)]

Check some sequence:

```python
sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 1, 0, 0, 1]
```

```python
>>> from sage.all import *

>>> T([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)])
[0, 0, 1, 0, 0, 1]
```

2. Counting the number of 11 blocks over the alphabet [0, 1]:

```python
sage: T = transducers.CountSubblockOccurrences(
    ....: [1, 1],
    ....: [0, 1])

sage: sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
```

```python
>>> from sage.all import *

>>> T = transducers.CountSubblockOccurrences(
    ...
    [Integer(1), Integer(1)],
    ...
    [Integer(0), Integer(1)])

>>> sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
```

Check some sequence:

```python
sage: T([0, 1, 0, 1, 1, 0])
[0, 0, 0, 0, 1, 0]
```

```python
>>> from sage.all import *

>>> T([Integer(0), Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)])
[0, 0, 0, 0, 1, 0]
```

3. Counting the number of 1010 blocks over the alphabet [0, 1, 2]:

```python
sage: T = transducers.CountSubblockOccurrences(
    ....: [1, 0, 1, 0],
    ....: [0, 1, 2])

sage: sorted(T.transitions())
[Transition from () to (): 0|0,
 Transition from () to (1,): 1|0,
 Transition from (1,) to (): 0|0,
 Transition from (1,) to (1,): 1|1]
```

(continues on next page)
Transition from (0) to (1,): 1|0,
Transition from (0) to (): 2|0,
Transition from (1,0) to (1,0): 0|0,
Transition from (1,0) to (1,): 1|0,
Transition from (1,0) to (): 2|0,
Transition from (1,0,1) to (1,0): 0|0,
Transition from (1,0,1) to (1,): 1|0,
Transition from (1,0,1) to (): 2|0,
Transition from (1,0,1) to (1,0,1): 1|0,
Transition from (1,0,1) to (): 2|0.

sage: input = [0, 1, 0, 1, 0, 1, 0, 0, 1, 0, 1, 0, 2]
sage: output = [0, 0, 0, 0, 1, 0, 1, 0, 0, 0, 0, 1, 0]

sage: T(input) == output
True

See also:
ContainsWord()

GrayCode()

Returns a transducer converting the standard binary expansion to Gray code.

INPUT:
Nothing.

OUTPUT:
A transducer.

Cf. the Wikipedia article Gray_code for a description of the Gray code.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: G = transducers.GrayCode()
sage: G
Transducer with 3 states
sage: for v in srange(10):
    ....:     print("{} {}").format(v, G(v.digits(base=2)))
0 []
1 [1]
2 [1, 1]
3 [0, 1]
4 [0, 1, 1]
5 [1, 1, 1]
6 [1, 0, 1]
7 [0, 0, 1]
8 [0, 0, 1, 1]
9 [1, 0, 1, 1]
```

```python
>>> from sage.all import *
>>> G = transducers.GrayCode()
>>> G
Transducer with 3 states
>>> for v in srange(Integer(10)):
    ...     print("{} {}").format(v, G(v.digits(base=Integer(2))))
0 []
1 [1]
2 [1, 1]
3 [0, 1]
4 [0, 1, 1]
5 [1, 1, 1]
6 [1, 0, 1]
7 [0, 0, 1]
8 [0, 0, 1, 1]
9 [1, 0, 1, 1]
```

In the example *Gray Code* in the documentation of the *Finite state machines, automata, transducers* module, the Gray code transducer is derived from the algorithm converting the binary expansion to the Gray code. The result is the same as the one given here.

**Identity** (*input_alphabet*)

Returns the identity transducer realizing the identity map.

**INPUT:**

- *input_alphabet* – a list or other iterable.

**OUTPUT:**

A transducer mapping each word over *input_alphabet* to itself.

**EXAMPLES:**

```python
sage: T = transducers.Identity([0, 1])
sage: sorted(T.transitions())
[Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T.input_alphabet
```

(continues on next page)
Recursion (recursions, base, function=None, var=None, input_alphabet=None, word_function=None, is_zero=None, output_rings=[Integer Ring, Rational Field])

Return a transducer realizing the given recursion when reading the digit expansion with base base.

**INPUT:**

- **recursions** — list or iterable of equations. Each equation has either the form
  - \( f(base^K \cdot n + r) = f(base^k \cdot n + s) + t \) for some integers \( 0 \leq k < K, r \) and some \( t \)—valid for all \( n \) such that the arguments on both sides are non-negative—
  or the form
  - \( f(r) = t \) for some integer \( r \) and some \( t \).

  Alternatively, an equation may be replaced by a transducers.RecursionRule with the attributes \( K, r, k, s, t \) as above or a tuple \( (r, t) \). Note that \( t \) must be a list in this case.

- **base** — base of the digit expansion.

- **function** — symbolic function \( f \) occurring in the recursions.

- **var** — symbolic variable.

- **input_alphabet** — (default: None) a list of digits to be used as the input alphabet. If None and the base is an integer, input_alphabet is chosen to be \( \text{range}(base\text{.abs}()) \).

- **word_function** — (default: None) a symbolic function. If not None, word_function \( (arg1, \ldots, argn) \) in a symbolic recurrence relation is interpreted as a transition with output \( [arg1, \ldots, argn] \). This could not be entered in a symbolic recurrence relation because lists do not coerce into the SymbolicRing.

- **is_zero** — (default: None) a callable. The recursion relations are only well-posed if there is no cycle with non-zero output and input consisting of zeros. This parameter is used to determine whether the output of such a cycle is non-zero. By default, the output must evaluate to False as a boolean.

- **output_rings** — (default: [ZZ, QQ]) a list of rings. The output labels are converted into the first ring of the list in which they are contained. If they are not contained in any ring, they remain in whatever
ring they are after parsing the recursions, typically the symbolic ring.

**OUTPUT:**

A transducer $T$.

The transducer is constructed such that $T(\text{expansion}) = f(n)$ if expansion is the digit expansion of $n$ to the base $\text{base}$ with the given input alphabet as set of digits. Here, the $+$ on the right hand side of the recurrence relation is interpreted as the concatenation of words.

The formal equations and initial conditions in the recursion have to be selected such that $f$ is uniquely defined.

**EXAMPLES:**

- The following example computes the Hamming weight of the ternary expansion of integers.

```
sage: # needs sage.symbolic
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([
    ...: f(3*n + 1) == f(n) + 1,
    ...: f(3*n + 2) == f(n) + 1,
    ...: f(3*n) == f(n),
    ...: f(0) == 0],
    ...: 3, f, n)
sage: T.transitions()  # Transition from (0, 0) to (0, 0): 0|-,  
                     # Transition from (0, 0) to (0, 0): 1|1,  
                     # Transition from (0, 0) to (0, 0): 2|1
```

To illustrate what this transducer does, we consider the example of $n = 601$:

```
sage: ternary_expansion = 601.digits(base=3)
sage: ternary_expansion
[1, 2, 0, 1, 1, 2]
sage: weight_sequence = T(ternary_expansion)
sage: weight_sequence
[1, 1, 1, 1, 1]
sage: sum(weight_sequence)
5
```
Note that the digit zero does not show up in the output because the equation $f(3n) = f(n)$ means that no output is added to $f(n)$.

- The following example computes the Hamming weight of the non-adjacent form, cf. the Wikipedia article Non-adjacent_form.
Transition from (1, 1) to (1, 0): 1|1,
Transition from (1, 0) to (1, 1): 0|-
Transition from (1, 0) to (1, 0): 1|-

\[
\text{[(s.label(), s.final_word_out)}
\text{ for s in T.iter_final_states()]}\]
\[
\text{[((0, 0), [])},
\text{((1, 1), [1])},
\text{((1, 0), [1])}\]

As we are interested in the weight only, we also output 1 for numbers congruent to 3 mod 4. The actual expansion is computed in the next example.

Consider the example of 29 = (100\bar{1}01)_2 (as usual, the digit −1 is denoted by \bar{1} and digits are written from the most significant digit at the left to the least significant digit at the right; for the transducer, we have to give the digits in the reverse order):

\[
\text{\sage{NAF = [1, 0, -1, 0, 0, 1]}\}
\text{\sage{ZZ(NAF, base=2)} 29}
\text{\sage{binary_expansion = 29.digits(base=2)}
\text{\sage{binary_expansion} [1, 0, 1, 1, 1]
\text{\sage{T(binary_expansion)}
\text{\# needs sage.symbolic}
\text{[1, 1, 1]
\text{\sage{sum(T(binary_expansion))}
\text{\# needs sage.symbolic}
3}
\]

Indeed, the given non-adjacent form has three non-zero digits.

- The following example computes the non-adjacent form from the binary expansion, cf. the Wikipedia article Non-adjacent_form. In contrast to the previous example, we actually compute the expansion, not only the weight.

We have to write the output 0 when converting an even number. This cannot be encoded directly by an equation in the symbolic ring, because \( f(2n) == f(n) + 0 \) would be equivalent to \( f(2n) == f(n) \) and an empty output would be written. Therefore, we wrap the output in the symbolic function \( w \) and use the parameter \text{word_function} to announce this.

Similarly, we use \( w(-1, 0) \) to write an output word of length 2 in one iteration. Finally, we write \( f(0) == w() \) to write an empty word upon completion.
Moreover, there is a cycle with output \([0]\) which—from the point of view of this method—is a contradicting recursion. We override this by the parameter \(\text{is\_zero}\).

```python
sage: # needs sage.symbolic
sage: var('n')
n
sage: function('f w')(f, w)

sage: T = transducers.Recursion([
....:     f(2*n) == f(n) + w(0),
....:     f(4*n + 1) == f(n) + w(1, 0),
....:     f(4*n - 1) == f(n) + w(-1, 0),
....:     f(0) == w(),
....:     2, f, n,
....:     word_function=w,
....:     is_zero=lambda x: sum(x).is_zero()]

sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,0,
 Transition from (1, 1) to (1, 0): 1|-1,0,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]

sage: for s in T.iter_states():
......:     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(1, 1) [1, 0]
(1, 0) [1, 0]

>>> from sage.all import *
>>> # needs sage.symbolic
>>> var('n')
n
>>> function('f w')(f, w)

>>> T = transducers.Recursion([
...     f(Integer(2)*n) == f(n) + w(Integer(0)),
...     f(Integer(4)*n + Integer(1)) == f(n) + w(Integer(1), Integer(0)),
...     f(Integer(4)*n - Integer(1)) == f(n) + w(-Integer(1),
...     Integer(0)),
...     f(Integer(0)) == w(),
...     Integer(2), f, n,
...     word_function=w,
...     is_zero=lambda x: sum(x).is_zero()]

>>> T.transitions()
[Transition from (0, 0) to (0, 0): 0|0,
 Transition from (0, 0) to (1, 1): 1|-,
 Transition from (1, 1) to (0, 0): 0|1,0,
 Transition from (1, 1) to (1, 0): 1|-1,0,
 Transition from (1, 0) to (1, 1): 0|-,
 Transition from (1, 0) to (1, 0): 1|0]

>>> for s in T.iter_states():
......:     print("{} {}".format(s, s.final_word_out))
(0, 0) []
(1, 1) [1, 0]
(1, 0) [1, 0]
```

We again consider the example of \(n = 29\):
sage: T(29.digits(base=2))  # needs sage.symbolic
[1, 0, -1, 0, 0, 1, 0]

>>> from sage.all import *

>>> T(Integer(29).digits(base=Integer(2))) # needs sage.symbolic
[1, 0, -1, 0, 0, 1, 0]

The same transducer can also be entered by bypassing the symbolic equations:

sage: R = transducers.RecursionRule
sage: TR = transducers.Recursion(['
....:
    R(K=1, r=0, k=0, s=0, t=[0]),
....:
    R(K=2, r=1, k=0, s=0, t=[1, 0]),
....:
    R(K=2, r=-1, k=0, s=0, t=[-1, 0]),
....:
    (0, [])],
....:
    2,
....:
    is_zero=lambda x: sum(x).is_zero())

sage: TR == T # needs sage.symbolic
True

>>> from sage.all import *

>>> R = transducers.RecursionRule

>>> TR = transducers.Recursion(['
...
    R(K=Integer(1), r=Integer(0), k=Integer(0), s=Integer(0), t=[Integer(0)]),
...
    R(K=Integer(2), r=Integer(1), k=Integer(0), s=Integer(0), t=[Integer(1), Integer(0)]),
...
    R(K=Integer(2), r=-Integer(1), k=Integer(0), s=Integer(0), t=[-Integer(1), Integer(0)]),
...
    (Integer(0), []],
    Integer(2),
    is_zero=lambda x: sum(x).is_zero())

>>> TR == T # needs sage.symbolic
True

• Here is an artificial example where some of the s are negative:

sage: # needs sage.symbolic
sage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion(['
....:
    f(2*n + 1) == f(n-1) + 1,
....:
    f(2*n) == f(n),
....:
    f(1) == 1,
....:
    f(0) == 0, 2, f, n)

sage: T.transitions()
[Transition from (0, 0) to (0, 0): 0|-, Transition from (0, 0) to (1, 1): 1|-,
Transition from (1, 1) to (-1, 1): 0|1, Transition from (1, 1) to (0, 0): 1|1,
Transition from (-1, 1) to (-1, 2): 0|-,
Combinatorics, Release 10.4

Transition from (-1, 1) to (1, 2): 1|-,
Transition from (-1, 2) to (-1, 1): 0|1,
Transition from (-1, 2) to (0, 0): 1|1,
Transition from (1, 2) to (-1, 2): 0|1,
Transition from (1, 2) to (1, 2): 1|1

```
sage: [(s.label(), s.final_word_out) ....: for s in T.iter_final_states()]
[((0, 0), []),
 ((1, 1), [1]),
((-1, 1), [0]),
((-1, 2), [0]),
((1, 2), [1])]```

```
>>> from sage.all import *
>>>
>>> # needs sage.symbolic
>>> function('f')
f
>>> var('n')
n
>>> T = transducers.Recursion([ ....: f(4*n) == f(2*n),
....: f(4*n+2) == f(2*n+1)+1,
....: f(16*n+1) == f(8*n+1),
....: f(16*n+5) == f(4*n+1)+2,
....: f(16*n+11) == f(4*n+3)+2,
....: f(16*n+15) == f(2*n+2)+1,
....: f(1) == 2, f(0) == 0
....: + [f(16*n+jj) == f(2*n+1)+2 for jj in [3,7,9,13]],
....: 2, f, n]
```

Transition from (3, 3) to (3, 2): 1|2,
Transition from (7, 3) to (1, 1): 0|2,
Transition from (7, 3) to (2, 1): 1|1,
Transition from (2, 1) to (1, 1): 0|1,
Transition from (2, 1) to (2, 1): 1|−

```python
>>> for s in T.iter_states():
...    print("{} {}".format(s, s.final_word_out))
(0, 0) []
(0, 1) [1]
(1, 1) [2]
(1, 2) [2]
(3, 2) [2, 2]
(1, 3) [2]
(5, 3) [2, 2]
(3, 3) [2, 2]
(7, 3) [2, 2]
(2, 1) [1, 2]
```

```
>>> list(sum(T(n.bits())) for n in srange(Integer(1), Integer(21)))
[2, 3, 4, 3, 4, 5, 4, 3, 4, 5, 6, 5, 4, 5, 4, 3, 4, 5, 6, 5]
```

- We now demonstrate the use of the `output_rings` parameter. If no `output_rings` are specified, the output labels are converted into ZZ:

```python
tsage: # needs sage.symbolic
tsage: function('f')
f
sage: var('n')
n
sage: T = transducers.Recursion([  
....:     f(2*n + 1) == f(n) + 1,
....:     f(2*n) == f(n),
....:     f(0) == 2],
....:     2, f, n)

sage: for t in T.transitions():
....:     print([x.parent() for x in t.word_out])
[]
[Integer Ring]
sage: [x.parent() for x in T.states()[0].final_word_out]
[Integer Ring]
```

```python
>>> from sage.all import *
>>> # needs sage.symbolic
>>> function('f')
```
In contrast, if `output_rings` is set to the empty list, the results are not converted:

```python
sage: T = transducers.Recursion([# _
 ˓→ needs sage.symbolic
 ˓→ : f(2*n + 1) == f(n) + 1,
 ˓→ : f(2*n) == f(n),
 ˓→ : f(0) == 2],
 ˓→ : 2, f, n, output_rings=[])
```

```python
sage: for t in T.transitions():  # _
 ˓→ needs sage.symbolic
 ˓→ : print([x.parent() for x in t.word_out])
[]
[Sage Ring]
```

```python
sage: [x.parent() for x in T.states()[0].final_word_out]  # _
˓→ : needs sage.symbolic
[Sage Ring]
```

Finally, we use a somewhat questionable conversion:

```python
sage: T = transducers.Recursion([# _
 ˓→ needs sage.symbolic
 ˓→ ... f(Integer(2)*n + Integer(1)) == f(n) + Integer(1),
 ˓→ ... f(Integer(2)*n) == f(n),
 ˓→ ... f(Integer(0)) == Integer(2)],
 ˓→ ... Integer(2), f, n)
```

```python
>>> for t in T.transitions():  # _
 ˓→ needs sage.symbolic
 ˓→ ... print([x.parent() for x in t.word_out])
[]
[Symbolic Ring]
```

```python
>>> [x.parent() for x in T.states()[0].final_word_out]  # _
˓→ # needs sage.symbolic
[Symbolic Ring]
```

(continues on next page)
Todo: Extend the method to

- non-integral bases,
- higher dimensions.

ALGORITHM:

See [HKP2015], Section 6. However, there are also recursion transitions for states of level < $\kappa$ if the recursion rules allow such a transition. Furthermore, the intermediate step of a non-deterministic transducer is left out by implicitly using recursion transitions. The well-posedness is checked in a truncated version of the recursion digraph.

class RecursionRule($K, r, s, t$)

Bases: tuple

- $K$
  
  Alias for field number 0

- $k$
  
  Alias for field number 2

- $r$
  
  Alias for field number 1

- $s$
  
  Alias for field number 3

- $t$
  
  Alias for field number 4

Wait($\text{input\_alphabet, threshold=1}$)

Writes False until reading the threshold-th occurrence of a true input letter; then writes True.

INPUT:

- $\text{input\_alphabet}$ – a list or other iterable.
• threshold – a positive integer specifying how many occurrences of True inputs are waited for.

OUTPUT:
A transducer writing False until the threshold-th true (Python's standard conversion to boolean is used to convert the actual input to boolean) input is read. Subsequently, the transducer writes True.

EXAMPLES:

```python
sage: T = transducers.Wait([0, 1])
sage: T([0, 0, 1, 0, 1, 0])
[False, False, True, True, True, True]
sage: T2 = transducers.Wait([0, 1], threshold=2)
sage: T2([0, 0, 1, 0, 1, 0])
[False, False, False, False, True, True]
```

```python
>>> from sage.all import *

>>> T = transducers.Wait([Integer(0), Integer(1)])
>>> T([-1, -1, 0, 1])
[1, 1, 0, 1]
```

abs(input_alphabet)

Returns a transducer which realizes the letter-wise absolute value of an input word over the given input alphabet.

INPUT:

• input_alphabet – a list or other iterable.

OUTPUT:

A transducer mapping \(i_0 \ldots i_k\) to \(|i_0| \ldots |i_k|\).

EXAMPLES:

The following transducer realizes letter-wise absolute value:

```python
sage: T = transducers.abs([-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([-1, -1, 0, 1])
[1, 1, 0, 1]
```

```python
>>> from sage.all import *

>>> T = transducers.abs([-Integer(1), Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 1|1]
```

(continues on next page)
add \((\text{input\_alphabet, number\_of\_operands}=2)\)

Returns a transducer which realizes addition on pairs over the given input alphabet.

**INPUT:**

- \(\text{input\_alphabet}\) – a list or other iterable.
- \(\text{number\_of\_operands}\) – (default: 2) it specifies the number of input arguments the operator takes.

**OUTPUT:**

A transducer mapping an input word \((i_{01}, \ldots, i_{0d}) \ldots (i_{k1}, \ldots, i_{kd})\) to the word \((i_{01} + \cdots + i_{0d}) \ldots (i_{k1} + \cdots + i_{kd})\).

The input alphabet of the generated transducer is the Cartesian product of \(\text{number\_of\_operands}\) copies of \(\text{input\_alphabet}\).

**EXAMPLES:**

The following transducer realizes letter-wise addition:

```python
>>> T = transducers.add([0, 1])
>>> T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
>>> T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, 1, 1, 2]
```

```python
>>> from sage.all import *
>>> T = transducers.add([Integer(0), Integer(1)])
>>> T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
>>> T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(Integer(0), Integer(0)), (Integer(0), Integer(1)), (Integer(1), Integer(0)), (Integer(1), Integer(1))])
[0, 1, 1, 2]
```
More than two operands can also be handled:

```python
sage: T3 = transducers.add([0, 1], number_of_operands=3)
sage: T3.input_alphabet
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1)]
sage: T3([(0, 0, 0), (0, 1, 0), (0, 1, 1), (1, 1, 1)])
[0, 1, 2, 3]
```

```python
>>> from sage.all import *

>>> T3 = transducers.add([Integer(0), Integer(1)], number_of_operands=Integer(3))

``` all ```(input_alphabet, number_of_operands=2)

Returns a transducer which realizes logical and over the given input alphabet.

**INPUT:**

- `input_alphabet` – a list or other iterable.
- `number_of_operands` – (default: 2) specifies the number of input arguments for the and operation.

**OUTPUT:**

A transducer mapping an input word \((i_0, \ldots, i_{d})\)\(\ldots\)\((i_k, \ldots, i_{kd})\) to the word \((i_0 \land \ldots \land i_{d})\)\(\ldots\)\((i_k \land \ldots \land i_{kd})\).

The input alphabet of the generated transducer is the Cartesian product of `number_of_operands` copies of `input_alphabet`.

**EXAMPLES:**

The following transducer realizes letter-wise logical and:

```python
sage: T = transducers.all([False, True])
sage: T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|False,
 Transition from 0 to 0: (True, False)|False,
 Transition from 0 to 0: (True, True)|True]
sage: T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(False, False), (False, True), (True, False), (True, True)])
[False, False, False, True]
```

```python
>>> from sage.all import *

```
Combinatorics, Release 10.4

Transition from 0 to 0: (False, True)|False,
Transition from 0 to 0: (True, False)|False,
Transition from 0 to 0: (True, True)|True

```python
>>> T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]
>>> T.initial_states()
[0]
>>> T.final_states()
[0]
>>> T([(False, False), (False, True), (True, False), (True, True)])
[False, False, False, True]
```

More than two operands and other input alphabets (with conversion to boolean) are also possible:

```python
sage: T3 = transducers.all([0, 1], number_of_operands=3)
sage: T3([(0, 0, 0), (1, 0, 0), (1, 1, 1)])
[False, False, True]
```

```python
>>> from sage.all import *
```
Combinatorics, Release 10.4

sage: T([[False, False], (False, True), (True, False), (True, True)])
[False, True, True, True]

>>> from sage.all import *

>>> T = transducers.any([[False, True]])

>>> T.transitions()
[Transition from 0 to 0: (False, False)|False,
 Transition from 0 to 0: (False, True)|True,
 Transition from 0 to 0: (True, False)|True,
 Transition from 0 to 0: (True, True)|True]

>>> T.input_alphabet
[(False, False), (False, True), (True, False), (True, True)]

>>> T.initial_states()
[0]

>>> T.final_states()
[0]

>>> T([[False, False], (False, True), (True, False), (True, True)])
[False, True, True, True]

More than two operands and other input alphabets (with conversion to boolean) are also possible:

sage: T3 = transducers.any([0, 1], number_of_operands=3)
sage: T3([[0, 0, 0], (1, 0, 0), (1, 1, 1)])
[False, True, True]

>>> from sage.all import *

>>> T3 = transducers.any([Integer(0), Integer(1)], number_of_operands=Integer(3))

>>> T3([[Integer(0), Integer(0), Integer(0)], (Integer(1), Integer(0), Integer(0)), (Integer(1), Integer(1), Integer(1))])
[False, True, True]

map(f, input_alphabet)

Return a transducer which realizes a function on the alphabet.

INPUT:

• f – function to realize.
• input_alphabet – a list or other iterable.

OUTPUT:

A transducer mapping an input letter \(x\) to \(f(x)\).

EXAMPLES:

The following binary transducer realizes component-wise absolute value (this transducer is also available as \texttt{abs()}):

sage: T = transducers.map(abs, [-1, 0, 1])
sage: T.transitions()
[Transition from 0 to 0: -1\rightarrow 1,
 Transition from 0 to 0: 0\rightarrow 0,
 Transition from 0 to 0: 1\rightarrow 1]
sage: T.input_alphabet
[-1, 0, 1]
sage: T.initial_states()
(continues on next page)
See also:

Automaton.with_output().

operator (operator, input_alphabet, number_of_operands=2)

Returns a transducer which realizes an operation on tuples over the given input alphabet.

INPUT:

- operator – operator to realize. It is a function which takes number_of_operands input arguments (each out of input_alphabet).
- input_alphabet – a list or other iterable.
- number_of_operands – (default: 2) it specifies the number of input arguments the operator takes.

OUTPUT:

A transducer mapping an input letter \((i_1, \ldots, i_n)\) to \(\text{operator}(i_1, \ldots, i_n)\). Here, \(n\) equals number_of_operands.

The input alphabet of the generated transducer is the Cartesian product of number_of_operands copies of input_alphabet.

EXAMPLES:

The following binary transducer realizes component-wise addition (this transducer is also available as add()):

```python
sage: import operator
sage: T = transducers.operator(operator.add, [0, 1])
sage: T.transitions()
[Transition from 0 to 0: (0, 0)|0,
 Transition from 0 to 0: (0, 1)|1,
 Transition from 0 to 0: (1, 0)|1,
 Transition from 0 to 0: (1, 1)|2]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
```
Note that for a unary operator the input letters of the new transducer are tuples of length 1:

```
sage: T = transducers.operator(abs,
.....:       [-1, 0, 1],
.....:       number_of_operands=1)
sage: T([-1, 1, 0])
Traceback (most recent call last):
...
ValueError: Invalid input sequence.
sage: T([(-1,), (1,), (0,)])
[1, 1, 0]
```

Compare this with the transducer generated by `map()`:

```
sage: T = transducers.map(abs,
.....:       [-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```
```python
>>> from sage.all import *

>>> T = transducers.map(abs,
...                      [-Integer(1), Integer(0), Integer(1)])

>>> T([-Integer(1), Integer(1), Integer(0)])
[1, 1, 0]

In fact, this transducer is also available as `abs()`:

```sage`
T = transducers.abs([-1, 0, 1])
sage: T([-1, 1, 0])
[1, 1, 0]
```

```python
>>> from sage.all import *

>>> T = transducers.abs([-Integer(1), Integer(0), Integer(1)])

>>> T([-Integer(1), Integer(1), Integer(0)])
[1, 1, 0]

```

```
sub(input_alphabet)
```
Returns a transducer which realizes subtraction on pairs over the given input alphabet.

**INPUT:**

- `input_alphabet` – a list or other iterable.

**OUTPUT:**

A transducer mapping an input word \((i_0, i'_0)\ldots(i_k, i'_k)\) to the word \((i_0 - i'_0)\ldots(i_k - i'_k)\).

The input alphabet of the generated transducer is the Cartesian product of two copies of `input_alphabet`.

**EXAMPLES:**

The following transducer realizes letter-wise subtraction:

```sage`
T = transducers.sub([0, 1])
sage: T.transitions()
[(Transition from 0 to 0: (0, 0)|0,
  Transition from 0 to 0: (0, 1)|-1,
  Transition from 0 to 0: (1, 0)|1,
  Transition from 0 to 0: (1, 1)|0]
sage: T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]
sage: T.initial_states()
[0]
sage: T.final_states()
[0]
sage: T([(0, 0), (0, 1), (1, 0), (1, 1)])
[0, -1, 1, 0]
```

```python
>>> from sage.all import *

>>> T = transducers.sub([Integer(0), Integer(1)])

>>> T.transitions()
[(Transition from 0 to 0: (0, 0)|0,
  Transition from 0 to 0: (0, 1)|-1,
  Transition from 0 to 0: (1, 0)|1,
  Transition from 0 to 0: (1, 1)|0]

>>> T.input_alphabet
[(0, 0), (0, 1), (1, 0), (1, 1)]

```
weight \((input\_alphabet, zero=0)\)

Returns a transducer which realizes the Hamming weight of the input over the given input alphabet.

**INPUT:**

- `input_alphabet` – a list or other iterable.
- `zero` – the zero symbol in the alphabet used

**OUTPUT:**

A transducer mapping \(i_0 \ldots i_k\) to \((i_0 \neq 0) \ldots (i_k \neq 0)\).

The Hamming weight is defined as the number of non-zero digits in the input sequence over the alphabet `input_alphabet` (see Wikipedia article Hamming_weight). The output sequence of the transducer is a unary encoding of the Hamming weight. Thus the sum of the output sequence is the Hamming weight of the input.

**EXAMPLES:**

```python
sage: W = transducers.weight([-1, 0, 2])
sage: W.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 2|1]
sage: unary_weight = W([-1, 0, 0, 2, -1])
sage: unary_weight
[1, 0, 0, 1, 1]
sage: weight = add(unary_weight)
sage: weight
3
```

```python
>>> from sage.all import *
>>> W = transducers.weight([-Integer(1), Integer(0), Integer(2)])
>>> W.transitions()
[Transition from 0 to 0: -1|1,
 Transition from 0 to 0: 0|0,
 Transition from 0 to 0: 2|1]
>>> unary_weight = W([-Integer(1), Integer(0), Integer(0), Integer(2), -Integer(1)])
>>> unary_weight
[1, 0, 0, 1, 1]
>>> weight = add(unary_weight)
>>> weight
3
```

Also the joint Hamming weight can be computed:

```python
sage: v1 = vector([-1, 0])
sage: v0 = vector([0, 0])
sage: W = transducers.weight([v1, v0])
```

(continues on next page)
sage: unary_weight = W([v1, v0, v1, v0])
sage: add(unary_weight)
2

>>> from sage.all import *
>>> v1 = vector([-Integer(1), Integer(0)])
>>> v0 = vector([Integer(0), Integer(0)])
>>> W = transducers.weight([v1, v0])
>>> unary_weight = W([v1, v0, v1, v0])
>>> add(unary_weight)
2

For the input alphabet \([-1, 0, 1]\) the weight transducer is the same as the absolute value transducer abs():

sage: W = transducers.weight([-1, 0, 1])
sage: A = transducers.abs([-1, 0, 1])
sage: W == A
True

>>> from sage.all import *
>>> W = transducers.weight([-Integer(1), Integer(0), Integer(1)])
>>> A = transducers.abs([-Integer(1), Integer(0), Integer(1)])
>>> W == A
True

For other input alphabets, we can specify the zero symbol:

sage: W = transducers.weight(['a', 'b'], zero='a')
sage: add(W(['a', 'b', 'b']))
2

>>> from sage.all import *
>>> W = transducers.weight(['a', 'b'], zero='a')
>>> add(W(['a', 'b', 'b']))
2

5.1.110 Free Quasi-symmetric functions

AUTHORS:

• Frédéric Chapoton, Darij Grinberg (2017)

class sage.combinat.fqsym.FQSymBases(base)
    Bases: Category_realization_of_parent

    The category of graded bases of FQSym indexed by permutations.

class ElementMethods
    Bases: object

    omega_involution()
        Return the image of the element \(self\) of FQSym under the omega involution.

        The \(\omega\) involution is defined as the linear map FQSym \(\rightarrow\) FQSym that sends each basis element \(F_w\) of the F-basis of FQSym to the basis element \(F_{\omega w_0}\), where \(w_0\) is the longest word (i.e., \(w_0(i) = n+1-i\))
in the symmetric group $S_n$ that contains $u$. The $\omega$ involution is a graded algebra automorphism and a coalgebra anti-automorphism of $FQSym$. Every permutation $u \in S_n$ satisfies

$$\omega(F_u) = F_{u_0u}, \quad \omega(G_u) = G_{u_0u},$$

where standard notations for classical bases of $FQSym$ are being used (that is, $F$ for the F-basis, and $G$ for the G-basis). In other words, writing permutations in one-line notation, we have

$$\omega(F(u_1, u_2, \ldots, u_n)) = F(u_n, u_{n-1}, \ldots, u_1), \quad \omega(G(u_1, u_2, \ldots, u_n)) = G(n+1-u_1, n+1-u_2, \ldots, n+1-u_n).$$

If we also consider the $\omega$ involution ($\omega$-involution()) of the quasisymmetric functions (by slight abuse of notation), and if we let $\pi$ be the canonical projection $FQSym \rightarrow QSym$, then $\pi \circ \omega = \omega \circ \pi$.

Additionally, consider the $\psi$ involution ($\psi$-involution()) of the noncommutative symmetric functions, and if we let $\iota$ be the canonical inclusion $NSym \rightarrow FQSym$, then $\omega \circ \iota = \iota \circ \psi$.

**Todo:** Duality?

**See also:**

psi_involution(), star_involution()

**EXAMPLES:**

```python
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].omega_involution()
F[1, 3, 2]
sage: (3*F[[1]] - 4*F[[[]]] + 5*F[[1,2]]).omega_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
sage: G = FQSym.G()
sage: G[[2,3,1]].omega_involution()
G[2, 1, 3]
sage: M = FQSym.M()
sage: M[[2,3,1]].omega_involution()
-M[1, 2, 3] - M[2, 1, 3] - M[3, 1, 2]
```

```python
>>> from sage.all import *

>>> FQSym = algebras.FQSym(ZZ)
>>> F = FQSym.F()
>>> F[[Integer(2),Integer(3),Integer(1)]].omega_involution()
F[1, 3, 2]
>>> (Integer(3)*F[[Integer(1)]] - Integer(4)*F[[[]]] +
    -Integer(5)*F[[Integer(1),Integer(2)]]).omega_involution()
-4*F[] + 3*F[1] + 5*F[2, 1]
>>> G = FQSym.G()
>>> G[[Integer(2),Integer(3),Integer(1)]].omega_involution()
G[2, 1, 3]
>>> M = FQSym.M()
>>> M[[Integer(2),Integer(3),Integer(1)]].omega_involution()
-M[1, 2, 3] - M[2, 1, 3] - M[3, 1, 2]
```

The omega involution is an algebra homomorphism:
The omega involution intertwines the antipode and the inverse of the antipode:

```python
sage: all( F(I).antipode().omega_involution().antipode() == F(I).omega_involution() for I in Permutations(4) )
True
```

Testing the $\pi \circ \omega = \omega \circ \pi$ relation noticed above:

```python
sage: all( M[I].omega_involution().to_qsym() == M[I].to_qsym().omega_involution() for I in Permutations(4) )
True
```

Testing the $\omega \circ \iota = \iota \circ \psi$ relation:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].psi_involution().to_fqsym() == S[I].to_fqsym().omega_involution() for I in Compositions(4) )
True
```

```python
from sage.all import *
```
psi_involution()

Return the image of the element self of $FQSym$ under the psi involution.

The $\psi$ involution is defined as the linear map $FQSym \to FQSym$ that sends each basis element $F_u$ of the $F$-basis of $FQSym$ to the basis element $F_{w_0u}$, where $w_0$ is the longest word (i.e., $w_0(i) = n+1-i$) in the symmetric group $S_n$ that contains $u$. The $\psi$ involution is a graded coalgebra automorphism and an algebra anti-automorphism of $FQSym$. Every permutation $u \in S_n$ satisfies

$$\psi(F_u) = F_{w_0u}, \quad \psi(G_u) = G_{w_0u},$$

where standard notations for classical bases of $FQSym$ are being used (that is, $F$ for the $F$-basis, and $G$ for the $G$-basis). In other words, writing permutations in one-line notation, we have

$$\psi(F_{(u_1, u_2, \ldots, u_n)}) = F_{(n+1-u_1, n+1-u_2, \ldots, n+1-u_n)}, \quad \psi(G_{(u_1, u_2, \ldots, u_n)}) = G_{(u_n, u_{n-1}, \ldots, u_1)}.$$
The \( \psi \) involution intertwines the antipode and the inverse of the antipode:

```
sage: all( F(I).antipode().psi_involution().antipode() == F(I).psi_involution() for I in Permutations(4) )
True
```

Testing the \( \pi \circ \psi = \psi \circ \pi \) relation above:

```
sage: all( M[I].psi_involution().to_qsym() == M[I].to_qsym().psi_involution() for I in Permutations(4) )
True
```

Testing the \( \psi \circ \omega = \omega \circ \psi \) relation:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].omega_involution().to_fqsym() == S[I].to_fqsym().psi_involution() for I in Compositions(4) )
True
```

Todo: Check further commutative squares.

```
star_involution()
```

Return the image of the element \( \text{self} \) of \( FQSym \) under the star involution.

The star involution is defined as the linear map \( FQSym \to FQSym \) that sends each basis element \( F_u \) of the F-basis of \( FQSym \) to the basis element \( F_{w_0w_0w_0} \), where \( w_0 \) is the longest word (i.e., \( w_0(i) = 1672 \) Chapter 5. Comprehensive Module List
in the symmetric group $S_n$ that contains $u$. The star involution is a graded Hopf algebra anti-automorphism of $FQSym$. It is denoted by $f \mapsto f^*$. Every permutation $u \in S_n$ satisfies

$$
(F_u)^* = F_{(n+1-i_n, n+1-i_{n-1}, \ldots, n+1-i_1)} \quad \text{and} \quad (G_u)^* = G_{(n+1-i_n, n+1-i_{n-1}, \ldots, n+1-i_1)} \quad \text{and} \quad (M_u)^* = M_{(n+1-i_n, n+1-i_{n-1}, \ldots, n+1-i_1)}
$$

where standard notations for classical bases of $FQSym$ are being used (that is, $F$ for the F-basis, $G$ for the G-basis, and $M$ for the Monomial basis). In other words, writing permutations in one-line notation, we have

$$
(F_{(u_1, u_2, \ldots, u_n)})^* = F_{(n+1-u_n, n+1-u_{n-1}, \ldots, n+1-u_1)} \quad \text{and} \quad (G_{(u_1, u_2, \ldots, u_n)})^* = G_{(n+1-u_n, n+1-u_{n-1}, \ldots, n+1-u_1)} \quad \text{and} \quad (M_{(u_1, u_2, \ldots, u_n)})^* = M_{(n+1-u_n, n+1-u_{n-1}, \ldots, n+1-u_1)}
$$

Let us denote the star involution by $(*)$ as well.

If we also denote by $(*)$ the star involution of of the quasisymmetric functions $(\text{star involution})$ and if we let $\pi : FQSym \to QSym$ be the canonical projection then $\pi \circ (\star) = (\star) \circ \pi$. Similar for the noncommutative symmetric functions $(\text{star involution})$ with $\pi : NSym \to FQSym$ being the canonical inclusion and the word quasisymmetric functions $(\text{star involution})$ with $\pi : FQSym \to WQSym$ the canonical inclusion.

Todo: Duality?

See also: $\text{omega_involution()}, \text{psi_involution()}$

EXAMPLES:

```python
sage: FQSym = algebras.FQSym(ZZ)
sage: F = FQSym.F()
sage: F[[2,3,1]].star_involution()
F[3, 1, 2]
sage: (3*F[[1]] - 4*F[[[]]] + 5*F[[1,2]]).star_involution()
-4*F[[]] + 3*F[1] + 5*F[1, 2]
sage: G = FQSym.G()
sage: G[[2,3,1]].star_involution()
G[3, 1, 2]
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
```

```python
>>> from sage.all import *
>>> FQSym = algebras.FQSym(ZZ)
>>> F = FQSym.F()
>>> F[[Integer(2),Integer(3),Integer(1)]].star_involution()
F[3, 1, 2]
>>> (Integer(3)*F[[Integer(1)]], Integer(4)*F[[[]]] +
   Integer(5)*F[[Integer(1),Integer(2)]]).star_involution()
-4*F[[]] + 3*F[1] + 5*F[1, 2]
>>> G = FQSym.G()
>>> G[[Integer(2),Integer(3),Integer(1)]].star_involution()
G[3, 1, 2]
>>> M = FQSym.M()
>>> M[[Integer(2),Integer(3),Integer(1)]].star_involution()
M[3, 1, 2]
```
The star involution commutes with the antipode:

```python
sage: all( F(I).antipode().star_involution()
...:     == F(I).star_involution().antipode()
...:     for I in Permutations(4) )
True

>>> from sage.all import *
>>> all( F(I).antipode().star_involution()
...:     == F(I).star_involution().antipode()
...:     for I in Permutations(Integer(4)) )
True
```

Testing the $\pi \circ (*) = (*) \circ \pi$ relation:

```python
sage: all( M[I].star_involution().to_qsym()
...:     == M[I].to_qsym().star_involution()
...:     for I in Permutations(4) )
True

>>> from sage.all import *
>>> all( M[I].star_involution().to_qsym()
...:     == M[I].to_qsym().star_involution()
...:     for I in Permutations(Integer(4)) )
True
```

Similar for $NSym$:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: all( S[I].star_involution().to_fqsym() == S[I].to_fqsym().star_involution()
...:     for I in Compositions(4) )
True

>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> all( S[I].star_involution().to_fqsym() == S[I].to_fqsym().star_involution()
...:     for I in Compositions(Integer(4)) )
True
```

Similar for $WQSym$:

```python
sage: WQSym = algebras.WQSym(ZZ)
sage: all( F(I).to_wqsym().star_involution()
...:     == F(I).star_involution().to_wqsym()
...:     for I in Permutations(4) )
True

>>> from sage.all import *
>>> WQSym = algebras.WQSym(ZZ)
>>> all( F(I).to_wqsym().star_involution()
...:     == F(I).star_involution().to_wqsym()
...:     for I in Permutations(Integer(4)) )
True
```
Todo: Check further commutative squares.

to_qsym()

Return the image of self under the canonical projection $FQSym \to QS\text{ym}$.

The canonical projection $FQSym \to QS\text{ym}$ is a surjective homomorphism of Hopf algebras. It sends a basis element $F_w$ of $FQSym$ to the basis element $F_{\text{Comp } w}$ of the fundamental basis of $QS\text{ym}$, where $\text{Comp } w$ stands for the descent composition ($\text{sage.combinat.permutation.Permutation.descents_composition()}$) of the permutation $w$.

See also:

*QuasiSymmetricFunctions* for a definition of $QS\text{ym}$.

EXAMPLES:

```sage
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_qsym()
F[2, 1]
sage: G[2, 3, 1].to_qsym()
F[1, 2]
sage: F = algebras.FQSym(QQ).F()
sage: F[2, 3, 1].to_qsym()
F[2, 1]
sage: (F[2, 3, 1] + F[1, 3, 2] + F[1, 2, 3]).to_qsym()
sage: F2 = algebras.FQSym(GF(2)).F()
sage: F2[2, 3, 1].to_qsym()
F[2, 1]
sage: (F2[2, 3, 1] + F2[1, 3, 2] + F2[1, 2, 3]).to_qsym()
F[3]
```

```python
>>> from sage.all import *
>>> G = algebras.FQSym(QQ).G()
>>> x = G[Integer(1), Integer(3), Integer(2)]
>>> x.to_qsym()
F[2, 1]
>>> G[Integer(2), Integer(3), Integer(1)].to_qsym()
F[1, 2]
>>> F = algebras.FQSym(QQ).F()
>>> F[Integer(2), Integer(3), Integer(1)].to_qsym()
F[2, 1]
>>> (F[Integer(2), Integer(3), Integer(1)] + F[Integer(1), Integer(3),
     Integer(2)] + F[Integer(1), Integer(2), Integer(3)]).to_qsym()
>>> F2 = algebras.FQSym(GF(Integer(2))).F()
>>> F2[Integer(2), Integer(3), Integer(1)].to_qsym()
F[2, 1]
>>> (F2[Integer(2), Integer(3), Integer(1)] + F2[Integer(1), Integer(3),
     Integer(2)] + F2[Integer(1), Integer(2), Integer(3)]).to_qsym()
F[3]
```

to_symmetric_group_algebra($n$=None)

Return the element of a symmetric group algebra corresponding to the element self of $FQSym$.

INPUT:
• \(n\) – integer (default: the maximal degree of \(self\)); the rank of the target symmetric group algebra

**EXAMPLES:**

```
sage: A = algebras.FQSym(QQ).G()
sage: x = A([1,3,2,4]) + 5/2 * A([2,3,4,1])
sage: x.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[4, 1, 2, 3]
```

```
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).G()
>>> x = A([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/
˓→Integer(2) * A([Integer(2),Integer(3),Integer(4),Integer(1)])
>>> x.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[4, 1, 2, 3]
```

to_wqsym()

Return the image of \(self\) under the canonical inclusion map \(FQSym \to WQSym\).

The canonical inclusion map \(FQSym \to WQSym\) is an injective homomorphism of Hopf algebras. It sends a basis element \(G_w\) of \(FQSym\) to the sum of basis elements \(M_u\) of \(WQSym\), where \(u\) ranges over all packed words whose standardization is \(w\).

See also:

*WordQuasiSymmetricFunctions* for a definition of \(WQSym\).

**EXAMPLES:**

```
sage: G = algebras.FQSym(QQ).G()
sage: x = G[1, 3, 2]
sage: x.to_wqsym()
M[{1}, {3}, {2}] + M[{1, 3}, {2}]
```

```
>>> from sage.all import *
>>> G = algebras.FQSym(QQ).G()
>>> x = G[Integer(1), Integer(3), Integer(2)].to_wqsym()
M[{1}, {3}, {2}] + M[{1, 3}, {2}]
```

```
sage: F = algebras.FQSym(QQ).F()
sage: F[3, 1, 2].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
```

```
>>> from sage.all import *
>>> F = algebras.FQSym(QQ).F()
>>> F[Integer(3), Integer(1), Integer(2)].to_wqsym()
M[{3}, {1}, {2}] + M[{3}, {1, 2}]
```

class ParentMethods

Bases: object

**basis**(degree=None)

The basis elements (optionally: of the specified degree).
OUTPUT: Family

EXAMPLES:

```python
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G()
sage: G.basis()
Lazy family (Term map from Standard permutations to Free Quasi-symmetric\n→functions over Rational Field in the G basis(i))(i in Standard\n→permutations)
sage: G.basis().keys()
Standard permutations
sage: G.basis(degree=3).keys()
Standard permutations of 3
sage: G.basis(degree=3).list()
[\text{G}[1, 2, 3], \text{G}[1, 3, 2], \text{G}[2, 1, 3], \text{G}[2, 3, 1], \text{G}[3, 1, 2], \text{G}[3, 2, 1]]
```

```python
>>> from sage.all import *

>>> FQSym = algebras.FQSym(QQ)

>>> G = FQSym.G()

>>> G.basis()
Lazy family (Term map from Standard permutations to Free Quasi-symmetric\n→functions over Rational Field in the G basis(i))(i in Standard\n→permutations)

>>> G.basis().keys()
Standard permutations

>>> G.basis(degree=Integer(3)).keys()
Standard permutations of 3

>>> G.basis(degree=Integer(3)).list()
[\text{G}[1, 2, 3], \text{G}[1, 3, 2], \text{G}[2, 1, 3], \text{G}[2, 3, 1], \text{G}[3, 1, 2], \text{G}[3, 2, 1]]
```

### from_symmetric_group_algebra(x)

Return the element of \( F_{\text{QSym}} \) corresponding to the element \( x \) of a symmetric group algebra.

EXAMPLES:

```python
sage: A = algebras.FQSym(QQ).F()
sage: SGA4 = SymmetricGroupAlgebra(QQ, Integer(4))
sage: x = SGA4([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/2 * SGA4([Integer(1),Integer(2),Integer(4),Integer(3)])
sage: A.from_symmetric_group_algebra(x)
5/2*\text{F}[1, 2, 4, 3] + \text{F}[1, 3, 2, 4]

sage: A.from_symmetric_group_algebra(SGA4.zero())
0
```

```python
>>> from sage.all import *

>>> A = algebras.FQSym(QQ).F()

>>> SGA4 = SymmetricGroupAlgebra(QQ, Integer(4))

>>> x = SGA4([Integer(1),Integer(3),Integer(2),Integer(4)]) + Integer(5)/2 * SGA4([Integer(1),Integer(2),Integer(4),Integer(3)])

>>> A.from_symmetric_group_algebra(x)
5/2*\text{F}[1, 2, 4, 3] + \text{F}[1, 3, 2, 4]

>>> A.from_symmetric_group_algebra(SGA4.zero())
0
```

### is_commutative()

Return whether this \( F_{\text{QSym}} \) is commutative.

EXAMPLES:
```python
sage: F = algebras.FQSym(ZZ).F()
sage: F.is_commutative()
False

>>> from sage.all import *

>>> F = algebras.FQSym(ZZ).F()

>>> F.is_commutative()
False
```

**is_field** *(proof=True)*

Return whether this $\mathcal{F}Q\mathcal{S}ym$ is a field.

**EXAMPLES:**

```python
sage: F = algebras.FQSym(QQ).F()
sage: F.is_field()
False

>>> from sage.all import *

>>> F = algebras.FQSym(QQ).F()

>>> F.is_field()
False
```

**one_basis()**

Return the index of the unit.

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ).F()
sage: A.one_basis()
[]

>>> from sage.all import *

>>> A = algebras.FQSym(QQ).F()

>>> A.one_basis()
[]
```

**prec()**

Return the $\prec$ product.

On the $F$-basis of $\mathcal{F}Q\mathcal{S}ym$, this product is determined by $F_x \prec F_y = \sum F_z$, where the sum ranges over all $z$ in the shifted shuffle of $x$ and $y$ with the additional condition that the first letter of the result comes from $x$.

The usual symbol for this operation is $\prec$.

**See also:**

*product(), succ*

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ).F()
sage: x = A([2,1])
sage: A.prec(x, x)
sage: y = A([2,1,3])

(continues on next page)```
sage: A.prec(x, y)

sage: A.prec(y, x)

>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = A([Integer(2), Integer(1)])
>>> A.prec(x, x)

>>> y = A([Integer(2), Integer(1), Integer(3)])
>>> A.prec(x, y)

>>> A.prec(y, x)

prec_by_coercion(x, y)

Return $x \prec y$, computed using coercion to the F-basis.

See prec() for the definition of the objects involved.

EXAMPLES:

sage: G = algebras.FQSym(ZZ).G()
sage: a = G([Integer(1)])
sage: b = G([Integer(2), Integer(3), Integer(1)])
sage: G.prec(a, b) + G.succ(a, b) == a * b  # indirect doctest
True

>>> from sage.all import *
>>> a = G([Integer(1)])
>>> b = G([Integer(2), Integer(3), Integer(1)])
>>> G.prec(a, b) + G.succ(a, b) == a * b  # indirect doctest
True

some_elements()

Return some elements of the free quasi-symmetric functions.

EXAMPLES:

sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.some_elements()

sage: G = A.G()
sage: G.some_elements()

sage: M = A.M()
sage: M.some_elements()
[M[], M[1], M[1, 2] + 2*M[2, 1], M[1] + M[1, 2] + 2*M[2, 1]]
from sage.all import *
A = algebras.FQSym(QQ)
F = A.F()
F.some_elements()
[F[], F[1], F[1, 2] + F[2, 1], F[] + F[1, 2] + F[2, 1]]
G = A.G()
G.some_elements()
[G[], G[1], G[1, 2] + G[2, 1], G[] + G[1, 2] + G[2, 1]]
M = A.M()
M.some_elements()
[M[], M[1], M[1, 2] + 2*F[2, 1], M[] + M[1, 2] + 2*M[2, 1]]

succ()

Return the $\succ$ product.

On the F-basis of \texttt{FQSym}, this product is determined by $F_x \succ F_y = \sum F_z$, where the sum ranges over all $z$ in the shifted shuffle of $x$ and $y$ with the additional condition that the first letter of the result comes from $y$.

The usual symbol for this operation is $\succ$.

See also:

\texttt{product()}, \texttt{prec()}

EXAMPLES:

\begin{verbatim}
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1])
sage: A.succ(x, x)
F[2, 1]
sage: y = A([3,1,2])
sage: A.succ(x, y)
F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
sage: A.succ(y, x)
F[4, 3, 1, 2]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).F()
>>> x = A([Integer(1)])
>>> A.succ(x, x)
F[2, 1]
>>> y = A([Integer(3),Integer(1),Integer(2)])
>>> A.succ(x, y)
F[4, 1, 2, 3] + F[4, 2, 1, 3] + F[4, 2, 3, 1]
>>> A.succ(y, x)
F[4, 3, 1, 2]
\end{verbatim}

succ_by_coercion(x, y)

Return $x \succ y$, computed using coercion to the F-basis.

See \texttt{succ()} for the definition of the objects involved.

EXAMPLES:

\begin{verbatim}
sage: G = algebras.FQSym(ZZ).G()
sage: G.succ(G([1]), G([2, 3, 1])) # indirect doctest
\end{verbatim}
**super_categories()**

The super categories of self.

**EXAMPLES:**

```python
sage: from sage.combinat.fqsym import FQSymBases
sage: FQSym = algebras.FQSym(ZZ)
sage: bases = FQSymBases(FQSym)
sage: bases.super_categories()
[Category of realizations of Free Quasi-symmetric functions over Integer Ring,
 Join of Category of realizations of Hopf algebras over Integer Ring
 and Category of graded algebras over Integer Ring
 and Category of graded coalgebras over Integer Ring,
 Category of graded connected Hopf algebras with basis over Integer Ring]
```

**class sage.combinat.fqsym.FQSymBasis_abstract**(alg)

Bases: `CombinatorialFreeModule, BindableClass`

Abstract base class for bases of FQSym.

This must define two attributes:

- `_prefix` - the basis prefix
- `_basis_name` - the name of the basis and must match one of the names that the basis can be constructed from FQSym

**an_element()**

Return an element of self.

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ)
sage: F = A.F()
sage: F.an_element()
sage: G = A.G()
sage: G.an_element()
sage: M = A.M()
sage: M.an_element()
M[1] + 2*M[1, 2] + 4*M[2, 1]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> A = algebras.FQSym(QQ)
>>> F = A.F()
>>> F.an_element()
>>> G = A.G()
>>> G.an_element()
>>> M = A.M()
>>> M.an_element()
M[1] + 2*M[1, 2] + 4*M[2, 1]
```

```python
class sage.combinat.fqsym.FreeQuasisymmetricFunctions(R)

Bases: UniqueRepresentation, Parent

The free quasi-symmetric functions.

The Hopf algebra \( FQSym \) of free quasi-symmetric functions over a commutative ring \( R \) is the free \( R \)-module with basis indexed by all permutations (i.e., the indexing set is the disjoint union of all symmetric groups). Its product is determined by the shifted shuffles of two permutations, whereas its coproduct is given by splitting a permutation (regarded as a word) into two (at every possible point) and standardizing the two pieces. This Hopf algebra was introduced in [MR]. See [GriRei18] (Chapter 8) for a treatment using modern notations.

In more detail: For each \( n \geq 0 \), consider the symmetric group \( S_n \). Let \( S \) be the disjoint union of the \( S_n \) over all \( n \geq 0 \). Then, \( FQSym \) is the free \( R \)-module with basis \( \{ F_w \} \) for \( w \in S \). This \( R \)-module is graded, with the \( n \)-th graded component being spanned by all \( F_w \) for \( w \in S_n \). A multiplication is defined on \( FQSym \) as follows: For any two permutations \( u \in S_k \) and \( v \in S_l \), we set

\[
F_u F_v = \sum F_w,
\]

where the sum is over all shuffles of \( u \) with \( v[k] \). Here, the permutations \( u \) and \( v \) are regarded as words (by writing them in one-line notation), and \( v[k] \) means the word obtained from \( v \) by increasing each letter by \( k \) (for example, \( (1, 4, 2, 3)[5] = (6, 9, 7, 8) \)); and the shuffles \( w \) are translated back into permutations. This defines an associative multiplication on \( FQSym \); its unity is \( F_e \), where \( e \) is the identity permutation in \( S_0 \).

In Section 1.3 of [AguSot05], Aguiar and Sottile construct a different basis of \( FQSym \). Their basis, called the monomial basis and denoted by \( \{ M_u \} \), is also indexed by permutations. It is connected to the above F-basis by the relation

\[
F_u = \sum M_v,
\]

where the sum ranges over all permutations \( v \) such that each inversion of \( u \) is an inversion of \( v \). (An inversion of a permutation \( w \) means a pair \( (i, j) \) of positions satisfying \( i < j \) and \( w(i) > w(j) \).) The above relation yields a unitriangular change-of-basis matrix, and thus can be used to compute the \( M_u \) by Mobius inversion.

Another classical basis of \( FQSym \) is \( \{ G_w \} \), where \( G_w = F_{w^{-1}} \). This is just a relabeling of the basis \( \{ F_w \} \), but is a more natural choice from some viewpoints.

The algebra \( FQSym \) is often identified with (“realized as”) a subring of the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in \( R(x_1, x_2, x_3, \ldots) \) of bounded degree). Namely, consider words over the alphabet \( \{ 1, 2, 3, \ldots \} \); every noncommutative power series is an infinite \( R \)-linear combination of these words. Consider the \( R \)-linear map that sends each \( G_u \) to the sum of all words whose standardization (also known as “standard permutation”; see standard_permutation()) is \( u \). This map is an injective \( R \)-algebra homomorphism, and thus embeds \( FQSym \) into the latter ring.

As an associative algebra, \( FQSym \) has the richer structure of a dendriform algebra. This means that the associative product \( * \) is decomposed as a sum of two binary operations

\[
x y = x \triangleright y + x \lhd y
\]
that satisfy the axioms:

\[(x \succ y) \prec z = x \succ (y \prec z),\]
\[(x \prec y) \prec z = x \prec (y \prec z),\]
\[(xy) \succ z = x \succ (y \succ z).\]

These two binary operations are defined similarly to the (associative) product above: We set

\[F_u \prec F_v = \sum F_w,\]

where the sum is now over all shuffles of \(u\) with \(v[k]\) whose first letter is taken from \(u\) (rather than from \(v[k]\)). Similarly,

\[F_u \succ F_v = \sum F_w,\]

where the sum is over all remaining shuffles of \(u\) with \(v[k]\).

**Todo:** Decide what \(1 \prec 1\) and \(1 \succ 1\) are.

**Note:** The usual binary operator * is used for the associative product.

**EXAMPLES:**

```
sage: F = algebras.FQSym(ZZ).F()
sage: x,y,z = F([1]), F([1,2]), F([1,3,2])
sage: (x * y) * z
F[1, 2, 3, 4, 6, 5] + ...
```

```
>>> from sage.all import *
>>> F = algebras.FQSym(ZZ).F()
>>> x,y,z = F([Integer(1)]), F([Integer(1),Integer(2)]), F([Integer(1),Integer(3),
˓→Integer(2)]))
>>> (x * y) * z
F[1, 2, 3, 4, 6, 5] + ...
```

The product of \(FQSym\) is associative:

```
sage: x * (y * z) == (x * y) * z
True
```

```
>>> from sage.all import *
>>> x * (y * z) == (x * y) * z
True
```

The associative product decomposes into two parts:

```
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

```
>>> from sage.all import *
>>> x * y == F.prec(x, y) + F.succ(x, y)
True
```
The axioms of a dendriform algebra hold:

```python
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

\( \mathbb{F}_{\mathbb{Q}Sym} \) is also known as the Malvenuto-Reutenauer algebra:

```python
sage: algebras.MalvenutoReutenauer(ZZ)
Free Quasi-symmetric functions over Integer Ring
```

REFERENCES:

- [MR]
- [LR1998]
- [GriRei18]

class \textbf{F} (\textit{alg})

Bases: \textit{FQSymBasis\_abstract}

The F-basis of \( \mathbb{F}_{\mathbb{Q}Sym} \).

This is the basis \( (F_w) \), with \( w \) ranging over all permutations. See the documentation of \textit{FreeQuasisymmetricFunctions} for details.

EXAMPLES:

```python
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.F()
Free Quasi-symmetric functions over Rational Field in the F basis
```

class \textbf{Element}

Bases: \textit{IndexedFreeModuleElement}

**to\_symmetric\_group\_algebra** \((n=\text{None})\)

Return the element of a symmetric group algebra corresponding to the element \textit{self} of \( \mathbb{F}_{\mathbb{Q}Sym} \).

INPUT:
• \( n \) – integer (default: the maximal degree of \( \text{self} \)); the rank of the target symmetric group algebra

EXAMPLES:

```python
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1,3,2,4]) + 5/2 * A([1,2,4,3])
sage: x.to_symmetric_group_algebra()
5/2*[1, 2, 4, 3] + [1, 3, 2, 4]
sage: x.to_symmetric_group_algebra(n=7)
5/2*[1, 2, 4, 3, 5, 6, 7] + [1, 3, 2, 4, 5, 6, 7]
sage: a = A.zero().to_symmetric_group_algebra(); a
0
sage: parent(a)
Symmetric group algebra of order 0 over Rational Field
sage: y = A([1,3,2,4]) + 5/2 * A([2,1])
sage: y.to_symmetric_group_algebra()
[1, 3, 2, 4] + 5/2*[2, 1, 3, 4]
sage: y.to_symmetric_group_algebra(6)
[1, 3, 2, 4, 5, 6] + 5/2*[2, 1, 3, 4, 5, 6]
```

**coproduct_on_basis** (x)

Return the coproduct of \( F_\sigma \) for \( \sigma \) a permutation (here, \( \sigma = \infty \)).

EXAMPLES:

```python
sage: A = algebras.FQSym(QQ).F()
sage: x = A([1])
sage: ascii_art(A.coproduct(A.one())) # indirect doctest
1 # 1
sage: ascii_art(A.coproduct(x)) # indirect doctest
1 # F + F # 1
   [1]   [1]
sage: A = algebras.FQSym(QQ).F()
sage: x, y, z = A([1]), A([2,1]), A([3,2,1])
sage: A.coproduct(z)
```

(continues on next page)
>>> from sage.all import *

>>> A = algebras.FQSym(QQ).F()

>>> x = A([Integer(1)])

>>> ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

>>> ascii_art(A.coproduct(x))  # indirect doctest
1 # F + F # 1

[1] [1]

>>> A = algebras.FQSym(QQ).F()

>>> x, y, z = A([Integer(1)]), A([Integer(2), Integer(1)]), A([Integer(3), Integer(2), Integer(1)])

>>> A.coproduct(z)

### degree_on_basis(t)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the $n$ for which the permutation belongs to $S_n$).

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

```
>>> from sage.all import *

>>> A = algebras.FQSym(QQ).F()

>>> u = Permutation([Integer(2), Integer(1)])

>>> A.degree_on_basis(u)
2
```

### prec_product_on_basis(x, y)

Return the $≺$ product of two permutations.

This is the shifted shuffle of $x$ and $y$ with the additional condition that the first letter of the result comes from $x$.

The usual symbol for this operation is $≺$.

See also:

product_on_basis(), succ_product_on_basis()

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([1,2])
sage: A.prec_product_on_basis(x, x)
F[1, 2, 3, 4] + F[1, 3, 2, 4] + F[1, 3, 4, 2]

```
product_on_basis \( (x, y) \)

Return the * associative product of two permutations.

This is the shifted shuffle of \( x \) and \( y \).

See also:

succ_product_on_basis(), prec_product_on_basis()

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([Integer(1)])
sage: A.product_on_basis(x, x)
F[1, 2] + F[2, 1]
```

succ_product_on_basis \( (x, y) \)

Return the \( \succ \) product of two permutations.

This is the shifted shuffle of \( x \) and \( y \) with the additional condition that the first letter of the result comes from \( y \).

The usual symbol for this operation is \( \succ \).

See also:

• product_on_basis(), prec_product_on_basis()

EXAMPLES:

```
sage: A = algebras.FQSym(QQ).F()
sage: x = Permutation([Integer(1), Integer(2)])
sage: A.prec_product_on_basis(x, x)
F[1, 2, 3, 4] + F[1, 3, 2, 4] + F[1, 3, 4, 2]
sage: y = Permutation([[]])
sage: A.prec_product_on_basis(x, y) == A(x)
True
sage: A.prec_product_on_basis(y, x) == Integer(0)
True
```
class G(alg)
Bases: FQSymBasis_abstract

The G-basis of FQSym.

This is the basis \((G_w)\), with \(w\) ranging over all permutations. See the documentation of FreeQuasisymmetricFunctions for details.

EXAMPLES:

```python
sage: FQSym = algebras.FQSym(QQ)
sage: G = FQSym.G(); G
Free Quasi-symmetric functions over Rational Field in the G basis
sage: G([3, 1, 2]).coproduct()
sage: G([3, 1, 2]) * G([2, 1])
+ G[5, 3, 4, 2, 1]
```

```python
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> G = FQSym.G(); G
Free Quasi-symmetric functions over Rational Field in the G basis

```
**Combinatorics, Release 10.4**

**EXAMPLES:**

```python
sage: A = algebras.FQSym(QQ).G()
sage: u = Permutation([2,1])
sage: A.degree_on_basis(u)
2
```

```python
>>> from sage.all import *
>>> A = algebras.FQSym(QQ).G()
>>> u = Permutation([Integer(2),Integer(1)])
>>> A.degree_on_basis(u)
2
```

```python
class M(alg):
    Bases: FQSymBasis_abstract

    The M-basis of FQSym.

    This is the Monomial basis (M_w), with w ranging over all permutations. See the documentation of FQSym for details.

    EXAMPLES:

```python
sage: FQSym = algebras.FQSym(QQ)
sage: M = FQSym.M(); M
Free Quasi-symmetric functions over Rational Field in the Monomial basis
sage: M([3, 1, 2]).coproduct()
sage: M([3, 2, 1]).coproduct()
sage: M([1, 2]) * M([1])
```

```python
>>> from sage.all import *
>>> FQSym = algebras.FQSym(QQ)
>>> M = FQSym.M(); M
Free Quasi-symmetric functions over Rational Field in the Monomial basis
>>> M([Integer(3), Integer(1), Integer(2)]).coproduct()
>>> M([Integer(3), Integer(2), Integer(1)]).coproduct()
>>> M([Integer(1), Integer(2)]) * M([Integer(1)])
```

class Element
    Bases: IndexedFreeModuleElement

    star_involution()

    Return the image of the element self of FQSym under the star involution.

    See FQSymBases.ElementMethods.star_involution() for a definition of the involution and for examples.

5.1. Comprehensive Module List
See also:

omega_involution(), psi_involution()

EXAMPLES:

```
sage: FQSym = algebras.FQSym(ZZ)
sage: M = FQSym.M()
sage: M[[2,3,1]].star_involution()
M[3, 1, 2]
sage: M[[1]].star_involution()
M[]
```

```python
>>> from sage.all import *
>>> FQSym = algebras.FQSym(ZZ)
>>> M = FQSym.M()
```

\[ \text{coproduct_on_basis}(x) \]

Return the coproduct of \( M_\sigma \) for \( \sigma \) a permutation (here, \( \sigma \) is \( x \)).

This uses Theorem 3.1 in [AguSot05].

EXAMPLES:

```
sage: M = algebras.FQSym(QQ).M()
sage: x = M([1])
sage: ascii_art(M.coproduct(M.one()))
# indirect doctest
1 # 1
sage: ascii_art(M.coproduct(x))
# indirect doctest
1 # M + M # 1
[1] [1]
sage: M.coproduct(M([2, 1, 3]))
M[] # M[2, 1, 3] + M[2, 1, 3] # M[]
sage: M.coproduct(M([2, 3, 1]))
sage: M.coproduct(M([3, 2, 1]))
sage: M.coproduct(M([3, 4, 2, 1]))
```

```python
>>> from sage.all import *
>>> M = algebras.FQSym(QQ).M()
>>> x = M([Integer(1)])
>>> ascii_art(M.coproduct(M.one()))
# indirect doctest
1 # 1
>>> ascii_art(M.coproduct(x))
# indirect doctest
1 # M + M # 1
[1] [1]
```
degree_on_basis(t)

Return the degree of a permutation in the algebra of free quasi-symmetric functions.

This is the size of the permutation (i.e., the \( n \) for which the permutation belongs to \( S_n \)).

EXAMPLES:

```python
sage: A = algebras.FQSym(QQ).M()
sage: u = Permutation([2, 1])
sage: A.degree_on_basis(u)
2
```

a_realization()

Return a particular realization of self (the F-basis).

EXAMPLES:

```python
sage: FQSym = algebras.FQSym(QQ)
sage: FQSym.a_realization()
Free Quasi-symmetric functions over Rational Field in the F basis
```

```python
from sage.all import *
A = algebras.FQSym(QQ).M()
u = Permutation([Integer(2), Integer(1)])
A.degree_on_basis(u)
2
```
5.1.111 Free modules

class sage.combinat.free_module.CartesianProductWithFlattening (flatten)

Bases: object

A class for Cartesian product constructor, with partial flattening

class sage.combinat.free_module.CombinatorialFreeModule (R, basis_keys=None,
    element_class=None, category=None, prefix=None, names=None, **kwds)

Bases: UniqueRepresentation, Module, IndexedGenerators

Class for free modules with a named basis

INPUT:

- R – base ring
- basis_keys – list, tuple, family, set, etc. defining the indexing set for the basis of this module
- element_class – the class of which elements of this module should be instances (default: None, in which case the elements are instances of IndexedFreeModuleElement)
- category – the category in which this module lies (optional, default None, in which case use the “category of modules with basis” over the base ring $R$); this should be a subcategory of ModulesWithBasis

For the options controlling the printing of elements, see IndexedGenerators.

Note: These print options may also be accessed and modified using the print_options() method, after the module has been defined.

EXAMPLES:

We construct a free module whose basis is indexed by the letters a, b, c:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'])
sage: F
Free module generated by {'a', 'b', 'c'} over Rational Field
```

>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a','b','c'])
>>> F
Free module generated by {'a', 'b', 'c'} over Rational Field

Its basis is a family, indexed by a, b, c:

```
sage: e = F.basis()
sage: e
Finite family {'a': B['a'], 'b': B['b'], 'c': B['c']}
```

>>> from sage.all import *
>>> e = F.basis()
>>> e
Finite family {'a': B['a'], 'b': B['b'], 'c': B['c']}
Let us construct some elements, and compute with them:

```python
sage: e['a']
B['a']
sage: 2*e['a']
2*B['a']
sage: e['a'] + 3*e['b']
B['a'] + 3*B['b']
```

Some uses of `sage.categories.commutative_additive_semigroups.CommutativeAdditiveSemigroups.ParentMethods.summation()` and `sum()`:

```python
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.summation(F.monomial(1), F.monomial(3))
sage: F = CombinatorialFreeModule(QQ, [1,2,3,4])
sage: F.sum(F.monomial(i) for i in [1,2,3])
```

Note that free modules with a given basis and parameters are unique:

```python
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
```
The identity of the constructed free module depends on the order of the basis and on the other parameters, like the prefix. Note that \texttt{CombinatorialFreeModule} is a \texttt{UniqueRepresentation}. Hence, two combinatorial free modules evaluate equal if and only if they are identical:

```python
sage: F1 = CombinatorialFreeModule(QQ, (1,2,3,4))
sage: F1 is F
True
sage: F1 = CombinatorialFreeModule(QQ, [4,3,2,1])
sage: F1 == F
False
sage: F2 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F2 == F
False
```

Because of this, if you create a free module with certain parameters and then modify its prefix or other print options, this affects all modules which were defined using the same parameters.

```python
sage: F2.print_options(prefix='x')
sage: F2.prefix()
'x'
sage: F3 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F')
sage: F3 is F2  # F3 was defined just like F2
True
sage: F3.prefix()
'x'
sage: F4 = CombinatorialFreeModule(QQ, [1,2,3,4], prefix='F', bracket=\texttt{True})
sage: F4 == F2  # F4 was NOT defined just like F2
False
sage: F4.prefix()
'F'
sage: F2.print_options(prefix='F')  # reset for following doctests
```

```python
>>> from sage.all import *
>>> F2.print_options(prefix='x')
>>> F2.prefix()
'x'
>>> F3 = CombinatorialFreeModule(QQ, [Integer(1),Integer(2),Integer(3),
Integer(4)])
>>> F3
```
The constructed module is in the category of modules with basis over the base ring:

```
sage: CombinatorialFreeModule(QQ, Partitions()).category()  #...

Category of vector spaces with basis over Rational Field
```

If furthermore the index set is finite (i.e. in the category `Sets().Finite()`), then the module is declared as being finite dimensional:

```
sage: CombinatorialFreeModule(QQ, [1,2,3,4]).category()  #...

Category of finite dimensional vector spaces with basis over Rational Field
```

```
sage: CombinatorialFreeModule(QQ, Partitions(3), ...

Category of finite dimensional algebras with basis over Rational Field
```

See `sage.categories.examples.algebras_with_basis` and `sage.categories.examples.hopf_algebras_with_basis` for illustrations of the use of the category keyword, and see `sage.combinat.root_system.weight_space.WeightSpace` for an example of the use of `element_class`.

Customizing print and LaTeX representations of elements:

```
sage: F = CombinatorialFreeModule(QQ, ['a','b'], prefix='x')
sage: original_print_options = F.print_options()
sage: sorted(original_print_options.items())
[('bracket', None), ('iterate_key', False), ...
```

(continues on next page)
Combinatorics, Release 10.4

sage: e = F.basis()
sage: e['a'] - 3 * e['b']
\(x\{a\} - 3x\{b\}\)

sage: F.print_options(prefix='x', scalar_mult=' ', bracket='()')
sage: e['a'] - 3 * e['b']
\(x(a) - 3 x(b)\)

sage: latex(e['a'] - 3 * e['b'])
\(x_{a} - 3 x_{b}\)

sage: F.print_options(latex_prefix=y)

sage: latex(e['a'] - 3 * e['b'])
\(y_{a} - 3 y_{b}\)

sage: F.print_options(sorting_reverse=True)

sage: e['a'] - 3 * e['b']

sage: F.print_options(**original_print_options) # reset print options

sage: e = F.basis()

sage: e[(1,2)] - 3 * e[(3,4)]
\(B\{(1, 2)\} - 3*B\{(3, 4)\}\)

sage: F.print_options(bracket=[', '])
sage: e[(1,2)] - 3 * e[(3,4)]
\(B_{(1, 2)} - 3*B_{(3, 4)}\)

sage: F.print_options(prefix='', bracket=False)
sage: e[(1,2)] - 3 * e[(3,4)]
\((1, 2) - 3*(3, 4)\)

>>> from sage.all import *

>>> F = CombinatorialFreeModule(QQ, ['a', 'b'], prefix='x')

>>> original_print_options = F.print_options()

>>> sorted(original_print_options.items())

[(bracket, None),
 (iterate_key, False),
 (latex_bracket, False), (latex_names, None),
 (latex_prefix, None), (latex_scalar_mult, None),
 (names, None), (prefix, 'x'),
 (scalar_mult, '**'),
 (sorting_key, <function ...<lambda> at ...>),
 (sorting_reverse, False), (string_quotes, True),
 (tensor_symbol, None)]

>>> e = F.basis()

>>> e['a'] - Integer(3) * e['b']

(continues on next page)
\[ x[a] - 3x[b] \]

```python
>>> F.print_options(prefix='x', scalar_mult=', bracket=')
>>> e['a'] - Integer(3) * e['b']
x(a) - 3 x(b)
>>> latex(e['a'] - Integer(3) * e['b'])
x_{a} - 3 x_{b}
```

```python
>>> F.print_options(latex_prefix='y')
>>> latex(e['a'] - Integer(3) * e['b'])
y_{a} - 3 y_{b}
```

```python
>>> F.print_options(sorting_reverse=True)
>>> e['a'] - Integer(3) * e['b']
-3 x(b) + x(a)
>>> F.print_options(**original_print_options)  # reset print options
```

```python
>>> F = CombinatorialFreeModule(QQ, [(Integer(1),Integer(2)), (Integer(3), Integer(4))])
>>> e = F.basis()
>>> e[(Integer(1),Integer(2))] - Integer(3) * e[(Integer(3),Integer(4))]
B_{(1, 2)} - 3*B_{(3, 4)}
```

```python
>>> F.print_options(bracket=['{', '}'])
>>> e[(Integer(1),Integer(2))] - Integer(3) * e[(Integer(3),Integer(4))]
B_{(1, 2)} - 3*B_{(3, 4)}
```

```python
>>> F.print_options(prefix=' ', bracket=False)
>>> e[(Integer(1),Integer(2))] - Integer(3) * e[(Integer(3),Integer(4))]
(1, 2) - 3*(3, 4)
```

**CartesianProduct**

alias of *CombinatorialFreeModule_CartesianProduct*

**Element**

alias of *IndexedFreeModuleElement*

**Tensor**

alias of *CombinatorialFreeModule_Tensor*

**change_ring** (*R*)

Return the base change of *self* to *R*.

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(ZZ, ['a','b','c']); F
Free module generated by {a', b', c'} over Integer Ring
sage: F_QQ = F.change_ring(QQ); F_QQ
Free module generated by {a', b', c'} over Rational Field
sage: F_QQ.change_ring(ZZ) == F
True
sage: T = F.tensor(F); T
Free module generated by {a', b', c'} over Integer Ring
# Free module generated by {a', b', c'} over Integer Ring
sage: T.change_ring(QQ)
Free module generated by {a', b', c'} over Rational Field
```

(continues on next page)
# Free module generated by \{a, b, c\} over Rational Field

```python
sage: G = CombinatorialFreeModule(ZZ, ['x', 'y']); G
Free module generated by \{'x', 'y'\} over Integer Ring
``` 

```python
sage: T = F.cartesian_product(G); T
Free module generated by \{'a', 'b', 'c'\} over Integer Ring
(+) Free module generated by \{'x', 'y'\} over Integer Ring
sage: T.change_ring(QQ)
Free module generated by \{'a', 'b', 'c'\} over Rational Field
(+) Free module generated by \{'x', 'y'\} over Rational Field
``` 

```python
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, ['a,b,c']); F
Free module generated by \{'a', 'b', 'c'\} over Integer Ring
``` 

```python
>>> F_QQ = F.change_ring(QQ); F_QQ
Free module generated by \{'a', 'b', 'c'\} over Rational Field
``` 

```python
>>> F_QQ.change_ring(ZZ) == F
True
``` 

```python
>>> T = F.tensor(F); T
Free module generated by \{'a', 'b', 'c'\} over Integer Ring
# Free module generated by \{'a', 'b', 'c'\} over Integer Ring
>>> T.change_ring(QQ)
Free module generated by \{'a', 'b', 'c'\} over Rational Field
# Free module generated by \{'a', 'b', 'c'\} over Rational Field
``` 

```python
>>> G = CombinatorialFreeModule(ZZ, ['x', 'y']); G
Free module generated by \{'x', 'y'\} over Integer Ring
``` 

```python
>>> T = F.cartesian_product(G); T
Free module generated by \{'a', 'b', 'c'\} over Integer Ring
(+) Free module generated by \{'x', 'y'\} over Integer Ring
``` 

```python
>>> T.change_ring(QQ)
Free module generated by \{'a', 'b', 'c'\} over Rational Field
(+) Free module generated by \{'x', 'y'\} over Rational Field
``` 

### construction()

The construction functor and base ring for self.

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(QQ, ['a','b','c'],
                                 category=AlgebrasWithBasis(QQ))
sage: F.construction()
(VectorFunctor, Rational Field)
``` 

```python
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a','b','c'],
                                 category=AlgebrasWithBasis(QQ))
>>> F.construction()
(VectorFunctor, Rational Field)
``` 

### dimension()

Return the dimension of the free module (which is given by the number of elements in the basis).

**EXAMPLES:**
```python
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()
3
sage: F.basis().keys().cardinality()
3
```

Rank is available as a synonym:

```python
sage: F.rank()
3
```

```python
>>> from sage.all import *

>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])

>>> F.rank()
3
```

```python
sage: s = SymmetricFunctions(QQ).schur()
# needs sage.combinat
sage: s.dimension()
# needs sage.combinat
+Infinity
```

```python
>>> from sage.all import *

>>> s = SymmetricFunctions(QQ).schur()
# needs sage.combinat
>>> s.dimension()
# needs sage.combinat
+Infinity
```

**element_class()**

The (default) class for the elements of this parent

Overrides `Parent.element_class()` to force the construction of Python class. This is currently needed to inherit really all the features from categories, and in particular the initialization of `_mul_` in `Magmas.ParentMethods.__init_extra__()`.}

**EXAMPLES:**

```python
sage: # needs sage.combinat
sage: A = Algebras(QQ).WithBasis().example(); A
An example of an algebra with basis:
the free algebra on the generators ('a', 'b', 'c') over Rational Field
sage: A.element_class.mro()
[<class 'sage.categories.examples.algebras_with_basis.FreeAlgebra_with_
  category.element_class'>,
  <class 'sage.modules.with_basis.indexed_element.IndexedFreeModuleElement'>,
  ...
]  ```
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: a, b, c = A.algebra_generators()
sage: a * b
B[a*b]
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> A = Algebras(QQ).WithBasis().example(); A
An example of an algebra with basis:
the free algebra on the generators ('a', 'b', 'c') over Rational Field

```

```python
>>> A.element_class.mro()
[<class 'sage.categories.examples.algebras_with_basis.FreeAlgebra_with_
\rightarrow category.element_class'>,
 <class 'sage.modules.with_basis.indexed_element.IndexedFreeModuleElement'>,
 ...
```

```python
>>> a, b, c = A.algebra_generators()
>>> a * b
B[a*b]
```

```python
from_vector (vector, order=None, coerc=True)

Build an element of self from a (sparse) vector.

See also:

```
get_order(), CombinatorialFreeModule.Element._vector_
```

EXAMPLES:

```python
sage: # needs sage.combinat
sage: QS3 = SymmetricGroupAlgebra(QQ, 3)
sage: b = QS3.from_vector(vector((2, 0, 0, 0, 0, 4))); b
2*[[1, 2, 3]] + 4*[[3, 2, 1]]
sage: a = 2*QS3([1, 2, 3]) + 4*QS3([3, 2, 1])
sage: a == b
True
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> QS3 = SymmetricGroupAlgebra(QQ, Integer(3))

```

```python
>>> a = Integer(2)*QS3([Integer(1),Integer(2),Integer(3)]) +
>>> Integer(4)*QS3([Integer(3),Integer(2),Integer(1)])
>>> a == b
True
```

```python
get_order()

Return the order of the elements in the basis.

EXAMPLES:

```python
sage: # needs sage.combinat
sage: QS2 = SymmetricGroupAlgebra(QQ,2)
```
>>> from sage.all import *
>>> QS2 = SymmetricGroupAlgebra(QQ,Integer(2))
˓→ # needs sage.combinat
>>> QS2.get_order()  # note: order changed on 2009-03-13
˓→ needs sage.combinat
[[[2, 1], [1, 2]]]

get_order_key()

Return a comparison key on the basis indices that is compatible with the current term order.

EXAMPLES:

```python
sage: A = FiniteDimensionalAlgebrasWithBasis(QQ).example()
sage: A.set_order(['x', 'y', 'a', 'b'])
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['x', 'y', 'a', 'b']
sage: A.set_order(list(reversed(A.basis().keys())))
sage: Akey = A.get_order_key()
sage: sorted(A.basis().keys(), key=Akey)
['b', 'a', 'y', 'x']
```

is_exact()

Return True if elements of self have exact representations, which is true of self if and only if it is true of self.basis().keys() and self.base_ring().

EXAMPLES:

```python
sage: GroupAlgebra(GL(3, GF(7))).is_exact()  # needs sage.groups sage.rings.finite_rings
True
sage: GroupAlgebra(GL(3, GF(7)), RR).is_exact()  # needs sage.groups sage.rings.finite_rings
False
sage: GroupAlgebra(GL(3, pAdicRing(7))).is_exact()  # not implemented, needs sage.groups sage.rings.padics
False
```

(continues on next page)
linear_combination(iter_of_elements_coeff, factor_on_left=True)

Return the linear combination $\lambda_1 v_1 + \cdots + \lambda_k v_k$ (resp. the linear combination $v_1 \lambda_1 + \cdots + v_k \lambda_k$) where iter_of_elements_coeff iterates through the sequence $((v_1, \lambda_1), ..., (v_k, \lambda_k))$.

**INPUT:**

- iter_of_elements_coeff – iterator of pairs (element, coeff) with element in self and coeff in self.base_ring()
- factor_on_left – (optional) if True, the coefficients are multiplied from the left if False, the coefficients are multiplied from the right

**EXAMPLES:**

```
sage: F = CombinatorialFreeModule(QQ, [1,2])
sage: f = F.an_element(); f
sage: F.linear_combination( (f,i) for i in range(5) )
```

monomial()

Return the basis element indexed by i.

**INPUT:**

- i – an element of the index set

**EXAMPLES:**

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.monomial('a')
B['a']
```

F.monomial is in fact (almost) a map:

```
sage: F.monomial
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} over Rational Field
```
Term map from {'a', 'b', 'c'} to Free module generated by {'a', 'b', 'c'} → over Rational Field

**rank()**

Return the dimension of the free module (which is given by the number of elements in the basis).

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.dimension()
3
sage: F.basis().cardinality()
3
sage: F.basis().keys().cardinality()
3
```

>>> from sage.all import *

```python
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.dimension()
3
>>> F.basis().cardinality()
3
>>> F.basis().keys().cardinality()
3
```

Rank is available as a synonym:

```python
sage: F.rank()
3
```

```python
>>> from sage.all import *

```
Warning: Many cached methods depend on this order, in particular for constructing subspaces and quotients. Changing the order after some computations have been cached does not invalidate the cache, and is likely to introduce inconsistencies.

EXAMPLES:

```python
sage: # needs sage.combinat	sage: QS2 = SymmetricGroupAlgebra(QQ,2)	sage: b = list(QS2.basis().keys())	sage: b.reverse()	sage: QS2.set_order(b)	sage: QS2.get_order()
[[2, 1], [1, 2]]
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> QS2 = SymmetricGroupAlgebra(QQ,Integer(2))
>>> b = list(QS2.basis().keys())
>>> b.reverse()
>>> QS2.set_order(b)
>>> QS2.get_order()
[[2, 1], [1, 2]]
```

**sum(iter_of_elements)**

Return the sum of all elements in `iter_of_elements`.

Overrides method inherited from commutative additive monoid as it is much faster on dicts directly.

INPUT:

- `iter_of_elements` – iterator of elements of `self`

EXAMPLES:

```python
sage: F = CombinatorialFreeModule(QQ,[1,2])
sage: f = F.an_element(); f
sage: F.sum( f for _ in range(5) )
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> F = CombinatorialFreeModule(QQ,[Integer(1),Integer(2)])
>>> f = F.an_element(); f
>>> F.sum( f for _ in range(Integer(5)) )
```

**sum_of_terms(terms, distinct=False)**

Construct a sum of terms of `self`.

INPUT:

- `terms` – a list (or iterable) of pairs (index, coeff)
- `distinct` – (default: False) whether the indices are guaranteed to be distinct

EXAMPLES:
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.sum_of_terms([(a,2), (c,3)])
2*B[a] + 3*B[c]

>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.sum_of_terms(['a', Integer(2)], ('c',Integer(3)))
2*B[a] + 3*B[c]

If distinct is True, then the construction is optimized:

sage: F.sum_of_terms(['a',2], ('c',3), distinct = True)
2*B[a] + 3*B[c]

>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.sum_of_terms(['a',Integer(2)], ('c',Integer(3)), distinct = True)
2*B[a] + 3*B[c]

Warning: Use distinct=True only if you are sure that the indices are indeed distinct:

sage: F.sum_of_terms(['a',2], ('a',3), distinct = True)
3*B[a]

>>> from sage.all import *
>>> F.sum_of_terms(['a',Integer(2)], ('a',Integer(3)), distinct = True)
3*B[a]

Extreme case:

sage: F.sum_of_terms([])
0

>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.sum_of_terms([])
0

**term**(index, coeff=None)

Construct a term in self.

INPUT:

- index – the index of a basis element
- coeff – an element of the coefficient ring (default: one)

EXAMPLES:

sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.term('a',3)
3*B[a]

5.1. Comprehensive Module List
Design: should this do coercion on the coefficient ring?

```
zero()
```

EXAMPLES:

```
sage: F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
sage: F.zero()
0
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(QQ, ['a', 'b', 'c'])
>>> F.term('a',Integer(3))
3*B['a']
>>> F.term('a')
B['a']
```

```
class sage.combinat.free_module.CombinatorialFreeModule_CartesianProduct (modules, **options)
```

Bases: `CombinatorialFreeModule`

An implementation of Cartesian products of modules with basis

EXAMPLES:

We construct two free modules, assign them short names, and construct their Cartesian product:

```
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: H = CombinatorialFreeModule(ZZ, [4,7]); H.rename("H")
sage: S = cartesian_product([F, G])
sage: S
F (+) G
```

```
>>> from sage.all import *
>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename("F")
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename("G")
>>> H = CombinatorialFreeModule(ZZ, [Integer(4),Integer(7)]); H.rename("H")
```

```
>>> S = cartesian_product([F, G])
```

```
>>> S.basis()
Lazy family (Term map
from Disjoint union of Family {{4, 5}, {4, 6}}
to F (+) G(i))_{i in Disjoint union of Family {{4, 5}, {4, 6}}}'''
```

Note that the indices of the basis elements of F and G intersect non trivially. This is handled by forcing the union to be disjoint:
We now compute the Cartesian product of elements of free modules:

```python
sage: f = F.monomial(4) + 2*F.monomial(5)
sage: g = 2*G.monomial(4) + G.monomial(6)
sage: h = H.monomial(4) + H.monomial(7)
sage: cartesian_product([f, g])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)]
sage: cartesian_product([f, g, h])
B[(0, 4)] + 2*B[(0, 5)] + 2*B[(1, 4)] + B[(1, 6)] + B[(2, 4)] + B[(2, 7)]
sage: cartesian_product([f, g, h]).parent()
F (+) G (+) H
```

TODO: choose an appropriate semantic for Cartesian products of Cartesian products (associativity?):

```python
S = cartesian_product([cartesian_product([F, G]), H])  # todo: not implemented
```

**class Element**

**Bases:** IndexedFreeModuleElement

**cartesian_embedding(i)**

Return the natural embedding morphism of the i-th Cartesian factor (summand) of self into self.

**INPUT:**

- i – an integer

**EXAMPLES:**

```python
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
5
```

(continues on next page)
sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True

sage: from sage.all import *

sage: F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename("F")

sage: G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename("G")

sage: S = cartesian_product([F, G])

sage: phi = S.cartesian_embedding(Integer(0))

sage: phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(5)))
B[(0, 4)] + 2*B[(0, 5)]

sage: phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(6))).parent() == S
True

---

**cartesian_factors()**

Return the factors of the Cartesian product.

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")

sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")

sage: S = cartesian_product([F, G])

sage: S.cartesian_factors()
(F, G)
```

```python
>>> from sage.all import *

>>> F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")

>>> G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")

>>> S = cartesian_product([F, G])

>>> S.cartesian_factors()
(F, G)
```

---

**cartesian_projection(i)**

Return the natural projection onto the i-th Cartesian factor (summand) of self.

**INPUT:**

- i – an integer

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")

sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")

sage: S = cartesian_product([F, G])

sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))

sage: S.cartesian_projection(0)(x)

sage: S.cartesian_projection(1)(x)
3*B[6]

sage: S.cartesian_projection(0)(x).parent() == F
True

sage: S.cartesian_projection(1)(x).parent() == G
True
```
```python
>>> from sage.all import *

>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename("F")
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename("G")
>>> S = cartesian_product([F, G])

>>> x = S.monomial((Integer(0),Integer(4))) + Integer(2) * S.monomial((Integer(0),Integer(5))) + Integer(3) * S.monomial((Integer(1), Integer(6)))

>>> S.cartesian_projection(Integer(0))(x)

>>> S.cartesian_projection(Integer(1))(x)
3*B[6]

>>> S.cartesian_projection(Integer(0))(x).parent() == F
True

>>> S.cartesian_projection(Integer(1))(x).parent() == G
True
```

**summand_embedding**(i)

Return the natural embedding morphism of the i-th Cartesian factor (summand) of self into self.

**INPUT:**

- i – an integer

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: phi = S.cartesian_embedding(0)
sage: phi(F.monomial(4) + 2 * F.monomial(5))
B[(0, 4)] + 2*B[(0, 5)]

sage: phi(F.monomial(4) + 2 * F.monomial(6)).parent() == S
True
```

```python
>>> from sage.all import *

>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename("F")
>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename("G")
>>> S = cartesian_product([F, G])

>>> phi = S.cartesian_embedding(Integer(0))

>>> phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(5)))
B[(0, 4)] + 2*B[(0, 5)]

>>> phi(F.monomial(Integer(4)) + Integer(2) * F.monomial(Integer(6))).parent() == S
True
```

**summand_projection**(i)

Return the natural projection onto the i-th Cartesian factor (summand) of self.

**INPUT:**

- i – an integer

**EXAMPLES:**

```python
sage: F = CombinatorialFreeModule(ZZ, [4,5]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [4,6]); G.rename("G")
sage: S = cartesian_product([F, G])
sage: x = S.monomial((0,4)) + 2 * S.monomial((0,5)) + 3 * S.monomial((1,6))

(continues on next page)
```
Combinatorics, Release 10.4

sage: S.cartesian_projection(0)(x)
sage: S.cartesian_projection(1)(x)
3*B[6]
sage: S.cartesian_projection(0)(x).parent() == F
True
sage: S.cartesian_projection(1)(x).parent() == G
True

>>> from sage.all import *

>>> F = CombinatorialFreeModule(ZZ, [Integer(4),Integer(5)]); F.rename("F")

>>> G = CombinatorialFreeModule(ZZ, [Integer(4),Integer(6)]); G.rename("G")

>>> S = cartesian_product([F, G])

>>> x = S.monomial((Integer(0),Integer(4))) + Integer(2) * S.monomial((Integer(0),Integer(5))) + Integer(3) * S.monomial((Integer(1),Integer(6)))

>>> S.cartesian_projection(Integer(0))(x)

>>> S.cartesian_projection(Integer(1))(x).parent() == G
True

class sage.combinat.free_module.CombinatorialFreeModule_Tensor(modules, **options) Base:sage.combinat.free_module.CombinatorialFreeModule

Tensor Product of Free Modules

EXAMPLES:

We construct two free modules, assign them short names, and construct their tensor product:

sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.rename("G")
sage: T = tensor([F, G]); T
F # G

sage: T.category()
Category of tensor products of
  finite dimensional modules with basis over Integer Ring

sage: T.construction() # todo: not implemented
[tensor, ]

>>> from sage.all import *

>>> F = CombinatorialFreeModule(ZZ, [Integer(1),Integer(2)]); F.rename("F")

>>> G = CombinatorialFreeModule(ZZ, [Integer(3),Integer(4)]); G.rename("G")

>>> T = tensor([F, G]); T
F # G

>>> T.category()
Category of tensor products of
  finite dimensional modules with basis over Integer Ring

(continues on next page)
>>> T.construction()  # todo: not implemented
[tensor, ]

T is a free module, with same base ring as F and G:

```
sage: T.base_ring()
Integer Ring
```

```
>>> from sage.all import *

>>> T.base_ring()
Integer Ring
```

The basis of T is indexed by tuples of basis indices of F and G:

```
sage: T.basis().keys()
Image of Cartesian product of {1, 2}, {3, 4} by The map <class 'tuple'> from Cartesian product of {1, 2}, {3, 4}

sage: T.basis().keys().list()
[(1, 3), (1, 4), (2, 3), (2, 4)]
```

```
>>> from sage.all import *

>>> T.basis().keys()
Image of Cartesian product of {1, 2}, {3, 4} by The map <class 'tuple'> from Cartesian product of {1, 2}, {3, 4}

>>> T.basis().keys().list()
[(1, 3), (1, 4), (2, 3), (2, 4)]
```

FIXME: Should elements of a CartesianProduct be tuples (making them hashable)?

Here are the basis elements themselves:

```
sage: T.basis().cardinality()
4
sage: list(T.basis())
```

```
>>> from sage.all import *

>>> T.basis().cardinality()
4

>>> list(T.basis())
```

The tensor product is associative and flattens sub tensor products:

```
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename("H")

sage: tensor([F, tensor([G, H])])
F # G # H

sage: tensor([tensor([F, G]), H])
F # G # H

sage: tensor([F, G, H])
F # G # H
```

```
>>> from sage.all import *

>>> H = CombinatorialFreeModule(ZZ, [Integer(5),Integer(6)]); H.rename("H")

>>> tensor([F, tensor([G, H])])
```

(continues on next page)
We now compute the tensor product of elements of free modules:

```
sage: f = F.monomial(1) + 2 * F.monomial(2)
sage: g = 2*G.monomial(3) + G.monomial(4)
sage: h = H.monomial(5) + H.monomial(6)
sage: tensor([f, g])
```

```
```

Again, the tensor product is associative on elements:

```
sage: tensor([f, tensor([g, h])]) == tensor([f, g, h])
```

```
True
```

```
sage: tensor([tensor([f, g]), h]) == tensor([f, g, h])
```

```
True
```

Note further that the tensor product spaces need not preexist:

```
sage: t = tensor([f, g, h])
sage: t.parent()
```

```
F # G # H
```

```
sage: from sage.all import *
sage: t = tensor([f, g, h])
sage: t.parent()
```

```
F # G # H
```

---

**tensor_constructor** *(modules)*

**INPUT:**

- modules - a tuple \((F_1, \ldots, F_n)\) of free modules whose tensor product is self

Returns the canonical multilinear morphism from \(F_1 \times \cdots \times F_n\) to \(F_1 \otimes \cdots \otimes F_n\)

**EXAMPLES:**

```
sage: F = CombinatorialFreeModule(ZZ, [1,2]); F.rename("F")
sage: G = CombinatorialFreeModule(ZZ, [3,4]); G.rename("G")
```
sage: H = CombinatorialFreeModule(ZZ, [5,6]); H.rename("H")

sage: f = F.monomial(1) + 2*F.monomial(2)
sage: g = 2*G.monomial(3) + G.monomial(4)
sage: h = H.monomial(5) + H.monomial(6)
sage: FG = tensor([F, G])
sage: phi_fg = FG.tensor_constructor((F, G))
sage: phi_fg(f, g)

sage: FGH = tensor([F, G, H])
sage: phi_fgh = FGH.tensor_constructor((F, G, H))
sage: phi_fgh(f, g, h)

sage: phi_fg_h = FGH.tensor_constructor((FG, H))
sage: phi_fg_h(phi_fg(f, g), h)

>>> from sage.all import *

>>> F = CombinatorialFreeModule(ZZ, [Integer(1),Integer(2)]); F.rename("F")
>>> G = CombinatorialFreeModule(ZZ, [Integer(3),Integer(4)]); G.rename("G")
>>> H = CombinatorialFreeModule(ZZ, [Integer(5),Integer(6)]); H.rename("H")

>>> f = F.monomial(Integer(1)) + Integer(2)*F.monomial(Integer(2))
>>> g = Integer(2)*G.monomial(Integer(3)) + G.monomial(Integer(4))
>>> h = H.monomial(Integer(5)) + H.monomial(Integer(6))

>>> FG = tensor([F, G])
>>> phi_fg = FG.tensor_constructor((F, G))
>>> phi_fg(f, g)

>>> FGH = tensor([F, G, H])
>>> phi_fgh = FGH.tensor_constructor((F, G, H))
>>> phi_fgh(f, g, h)

>>> phi_fg_h = FGH.tensor_constructor((FG, H))
>>> phi_fg_h(phi_fg(f, g), h)

tensor_factors()

Return the tensor factors of this tensor product.

EXAMPLES:

sage: F = CombinatorialFreeModule(ZZ, [1,2])
sage: F.rename("F")
5.1.112 Free Dendriform Algebras

AUTHORS:
Frédéric Chapoton (2017)

class sage.combinat.free_dendriform_algebra.DendriformFunctor (vars)

    Bases: ConstructionFunctor

    A constructor for dendriform algebras.

    EXAMPLES:

        sage: P = algebras.FreeDendriform(ZZ, 'x,y')
        sage: x,y = P.gens()
        sage: F = P.construction()[0]; F
        Dendriform[x,y]
        sage: A = GF(5)['a,b']
        sage: a, b = A.gens()
        sage: F(A)
        Free Dendriform algebra on 2 generators ['x', 'y']
        over Multivariate Polynomial Ring in a, b over Finite Field of size 5
        sage: f = A.hom([a+b,a-b],A)
        sage: F(f)
        Generic endomorphism of Free Dendriform algebra on 2 generators ['x', 'y']
        over Multivariate Polynomial Ring in a, b over Finite Field of size 5
        sage: F(f)(a * F(A)(x))
        (a+b)*B[x[., .]]
A = GF(Integer(5))['a,b']
a, b = A.gens()
F(A)
Free Dendriform algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5
f = A.hom([a+b,a-b],A)
F(f)
Generic endomorphism of Free Dendriform algebra on 2 generators ['x', 'y']
over Multivariate Polynomial Ring in a, b over Finite Field of size 5
F(f)(a * F(A)(x))
(a+b)*B[x[.., .]]

merge (other)
Merge self with another construction functor, or return None.

EXAMPLES:
sage: F = sage.combinat.free_dendriform_algebra.DendriformFunctor(['x','y'])
sage: G = sage.combinat.free_dendriform_algebra.DendriformFunctor(['t'])
sage: F.merge(G)
Dendriform[x,y,t]
sage: F.merge(F)
Dendriform[x,y]

>>> from sage.all import *
>>> R = algebras.FreeDendriform(ZZ, x,y,z)
>>> x,y,z = R.gens()
>>> Integer(1)/Integer(2) * x
1/2*B[x[.., .]]

Now some actual use cases:

sage: R = algebras.FreeDendriform(ZZ, 'x,y,z')
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[.., .]]
sage: parent(1/2 * x)
Free Dendriform algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreeDendriform(QQ, 'zt')
sage: z,t = S.gens()
sage: x + t
B[t[.., .]] + B[x[.., .]]
sage: parent(x + t)
Free Dendriform algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field
The free dendriform algebra.  

Dendriform algebras are associative algebras, where the associative product \( \ast \) is decomposed as a sum of two binary operations

\[
x \ast y = x \succ y + x \prec y
\]

that satisfy the axioms:

\[
(x \succ y) \prec z = x \succ (y \prec z),
\]

\[
(x \prec y) \prec z = x \prec (y \ast z).
\]

\[
(x \ast y) \succ z = x \succ (y \succ z).
\]

The free Dendriform algebra on a given set \( E \) has an explicit description using (planar) binary trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite binary trees endowed with a map from their vertices to \( E \). In this basis, the associative product of two (decorated) binary trees \( S \ast T \) is the sum over all possible ways of identifying (glueing) the rightmost path in \( S \) and the leftmost path in \( T \).

The decomposition of the associative product as the sum of two binary operations \( \succ \) and \( \prec \) is made by separating the terms according to the origin of the root vertex. For \( x \succ y \), one keeps the terms where the root vertex comes from \( y \), whereas for \( x \prec y \) one keeps the terms where the root vertex comes from \( x \).

The free dendriform algebra can also be considered as the free algebra over the Dendriform operad.

**Note:** The usual binary operator \( \ast \) is used for the associative product.

**EXAMPLES:**

```python
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
```

```python
sage: x,y,z = F.gens()
```

```python
sage: (x * y) * z
```

```python
B[x[., y[., z[., .]]]] + B[x[., z[y[., .], .]]] + B[y[x[., .], z[., .]]] + B[z[x[., y[., .]], .]] + B[z[y[x[., .], .], .]]
```
The free dendriform algebra is associative:

```python
sage: x * (y * z) == (x * y) * z
True
```

The associative product decomposes in two parts:

```python
sage: x * y == F.prec(x, y) + F.succ(x, y)
True
```

The axioms hold:

```python
sage: F.prec(F.succ(x, y), z) == F.succ(x, F.prec(y, z))
True
sage: F.prec(F.prec(x, y), z) == F.prec(x, y * z)
True
sage: F.succ(x * y, z) == F.succ(x, F.succ(y, z))
True
```

When there is only one generator, unlabelled trees are used instead:

```python
sage: F1 = algebras.FreeDendriform(QQ)
sage: w = F1.gen(0); w
B[., .]
sage: w * w * w
B[[., ., .]] + B[., [., .], .] + B[[., .], [., .]]
```

(continues on next page)
The set $E$ can be infinite:

```sage
sage: F = algebras.FreeDendriform(QQ, ZZ)
sage: w = F.gen(1); w
B[1[., .]]
sage: x = F.gen(2); x
B[-1[., .]]
sage: w*x
B[-1[1[., .], .]] + B[1[., -1[., .]]]
```

REFERENCES:

- [LR1998]

**algebra_generators()**

Return the generators of this algebra.

These are the binary trees with just one vertex.

**EXAMPLES:**

```sage
sage: A = algebras.FreeDendriform(ZZ, 'fgh'); A
Free Dendriform algebra on 3 generators ['f', 'g', 'h'] over Integer Ring
sage: list(A.algebra_generators())
[B[f[., .]], B[g[., .]], B[h[., .]]]
sage: A = algebras.FreeDendriform(QQ, ['x1','x2']); A
Free Dendriform algebra on 3 generators ['x1', 'x2'] over Integer Ring
sage: list(A.algebra_generators())
[B[x1[., .]], B[x2[., .]]]
```

**an_element()**

Return an element of self.

**EXAMPLES:**
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.an_element()
B[\llbracket ., . \rrbracket] + 2*B[\llbracket ., x[., .] \rrbracket] + 2*B[x[\llbracket ., . \rrbracket], .]

>>> from sage.all import *

>>> A = algebras.FreeDendriform(QQ, 'xy')
>>> A.an_element()
B[\llbracket ., . \rrbracket] + 2*B[\llbracket ., x[., .] \rrbracket] + 2*B[x[\llbracket ., . \rrbracket], .]

change_ring(R)
Return the free dendriform algebra in the same variables over $R$.

INPUT:
• $R$ – a ring

EXAMPLES:
sage: A = algebras.FreeDendriform(ZZ, fgh)
sage: A.change_ring(QQ)
Free Dendriform algebra on 3 generators ['f', 'g', 'h'] over Rational Field

construction()
Return a pair $(F, R)$, where $F$ is a `DendriformFunctor` and $R$ is a ring, such that $F(R)$ returns self.

EXAMPLES:
sage: P = algebras.FreeDendriform(ZZ, x,y)
sage: x,y = P.gens()
sage: F, R = P.construction()
sage: F
Dendriform[\llbracket x, y \rrbracket]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free Dendriform algebra on 2 generators ['x', 'y'] over Rational Field

>>> from sage.all import *

>>> P = algebras.FreeDendriform(ZZ, 'x,y')
>>> x,y = P.gens()
>>> F, R = P.construction()
>>> F
Dendriform[\llbracket x, y \rrbracket]
>>> R
Integer Ring
>>> F(ZZ) is P
True

(continues on next page)
coproduct_on_basis (x)

Return the coproduct of a binary tree.

EXAMPLES:

```python
sage: A = algebras.FreeDendriform(QQ)
sage: x = A.gen(0)
sage: ascii_art(A.coproduct(A.one()))  # indirect doctest
1 # 1

sage: ascii_art(A.coproduct(x))  # indirect doctest
1 # B + B # 1

sage: A = algebras.FreeDendriform(QQ, 'xyz')
sage: x, y, z = A.gens()
sage: w = A.under(z, A.over(x, y))
sage: A.coproduct(z)
B[..] # B[z[.., .]] + B[z[.., .]] # B[..]
sage: A.coproduct(w)
B[..] # B[x[z[., .], y[., .]]] + B[x[., .]] # B[z[.., y[., .]]] + B[x[., y[., .]]] # B[z[.., .]] + B[x[., y[., .]]] # B[z[.., .]] + B[x[z[., .], .]] # B[y[., .]] + B[x[z[.., .], y[.., .]]] # B[..]
```

degree_on_basis (t)

Return the degree of a binary tree in the free Dendriform algebra.

This is the number of vertices.

EXAMPLES:

```python
sage: A = algebras.FreeDendriform(QQ, 'x')
sage: RT = A.basis().keys()
sage: u = RT([], '@')
```

(continues on next page)
sage: A.degree_on_basis(u.over(u))
2

```python
from sage.all import *

A = algebras.FreeDendriform(QQ,'θ')
RT = A.basis().keys()
u = RT([], 'θ')
A.degree_on_basis(u.over(u))
2
```

**gen** (*i*)

Return the *i*-th generator of the algebra.

**INPUT:**

- *i* – an integer

**EXAMPLES:**

```python
sage: F = algebras.FreeDendriform(ZZ, 'xyz')
sage: F.gen(0)
B[x[., .]]
sage: F.gen(4)
Traceback (most recent call last):
  ... IndexError: argument i (= 4) must be between 0 and 2
```

```python
from sage.all import *

F = algebras.FreeDendriform(ZZ, 'xyz')
F.gen(Integer(0))
B[x[., .]]
F.gen(Integer(4))
Traceback (most recent call last):
  ... IndexError: argument i (= 4) must be between 0 and 2
```

**gens**()

Return the generators of *self* (as an algebra).

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(ZZ, 'fgh')
sage: A.gens()
(B[f[., .]], B[g[., .]], B[h[., .]])
```

```python
from sage.all import *

A = algebras.FreeDendriform(ZZ, 'fgh')
A.gens()
(B[f[., .]], B[g[., .]], B[h[., .]])
```

**one_basis**()

Return the index of the unit.

**EXAMPLES:**
over()  
Return the over product.

The over product $x/y$ is the binary tree obtained by grafting the root of $y$ at the rightmost leaf of $x$.

The usual symbol for this operation is $/$.  

See also:  
product(), succ(), prec(), under()  

EXAMPLES:

given

sage: A = algebras.FreeDendriform(QQ)  
sage: RT = A.basis().keys()  
sage: x = A.gen(0)  
sage: A.over(x, x)  
B[[., [., .]]]

prec()  
Return the $≺$ dendriform product.

This is the sum over all possible ways to identify the rightmost path in $x$ and the leftmost path in $y$, with the additional condition that the root vertex of the result comes from $x$.

The usual symbol for this operation is $≺$.  

See also:  
product(), succ(), over(), under()  

EXAMPLES:

given

sage: A = algebras.FreeDendriform(QQ)  
sage: RT = A.basis().keys()  
sage: x = A.gen(Integer(0))  
sage: A.prec(x, x)  
B[[., [., .]]]
prec_product_on_basis \( (x, y) \)

Return the \( \prec \) dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in \( x \) and the leftmost path in \( y \), with the additional condition that the root vertex of the result comes from \( x \).

The usual symbol for this operation is \( \prec \).

See also:

* product_on_basis(), succ_product_on_basis()

EXAMPLES:

```python
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.prec_product_on_basis(x, x)
B[[., [., .]]]
```

product_on_basis \( (x, y) \)

Return the \( \ast \) associative dendriform product of two trees.

This is the sum over all possible ways of identifying the rightmost path in \( x \) and the leftmost path in \( y \). Every term corresponds to a shuffle of the vertices on the rightmost path in \( x \) and the vertices on the leftmost path in \( y \).

See also:

* succ_product_on_basis(), prec_product_on_basis()

EXAMPLES:

```python
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.product_on_basis(x, x)
B[[., [., .]]] + B[[[., .], .]]
```
some_elements()

Return some elements of the free dendriform algebra.

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: A.some_elements()
[B[.],
 B[[.], .],
 B[[., [., .]]] + B[[[., .], .]],
 B[.] + B[[., [., .]]] + B[[[., .], .]]]
```

With several generators:

```
sage: A = algebras.FreeDendriform(QQ, 'xy')
sage: A.some_elements()
[B[.],
 B[x[.], .],
 B[x[., x[., .]]] + B[x[x[., .], .]],
 B[.] + B[x[., x[., .]]] + B[x[x[., .], .]]]
```

succ()

Return the $>$-dendriform product.

This is the sum over all possible ways of identifying the rightmost path in $x$ and the leftmost path in $y$, with the additional condition that the root vertex of the result comes from $y$.

The usual symbol for this operation is $>$. 

See also:

product(), prec(), over(), under()

EXAMPLES:

```
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
```
sage: A.succ(x, x)
B[[[., .], .]]

```python
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.succ(x, x)
B[[[., .], .]]
```

**succ_product_on_basis** (*x, y*)

Return the \(\succ\) dendriform product of two trees.

This is the sum over all possible ways to identify the rightmost path in \(x\) and the leftmost path in \(y\), with the additional condition that the root vertex of the result comes from \(y\).

The usual symbol for this operation is \(\succ\).

See also:

• *product_on_basis()*, *prec_product_on_basis()*

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = RT([])
sage: A.succ_product_on Basis(x, x)
B[[[., .], .]]
```

```python
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = RT([])
>>> A.succ_product_on_basis(x, x)
B[[[., .], .]]
```

**under**

Return the under product.

The over product \(x \setminus y\) is the binary tree obtained by grafting the root of \(x\) at the leftmost leaf of \(y\).

The usual symbol for this operation is \(\setminus\).

See also:

*product(), succ(), prec(), over()*

**EXAMPLES:**

```python
sage: A = algebras.FreeDendriform(QQ)
sage: RT = A.basis().keys()
sage: x = A.gen(0)
sage: A.under(x, x)
B[[[., .], .]]
```
```python
>>> from sage.all import *
>>> A = algebras.FreeDendriform(QQ)
>>> RT = A.basis().keys()
>>> x = A.gen(Integer(0))
>>> A.under(x, x)
B[[[., .], .]]
```

### variable_names()

Return the names of the variables.

**EXAMPLES:**

```python
sage: R = algebras.FreeDendriform(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}
```

### 5.1.113 Free Pre-Lie Algebras

**AUTHORS:**

- Florent Hivert, Frédéric Chapoton (2011)

```python
class sage.combinat.free_prelie_algebra.FreePreLieAlgebra(R, names=None)
```

The free pre-Lie algebra.

Pre-Lie algebras are non-associative algebras, where the product \( \ast \) satisfies

\[
(x \ast y) \ast z - x \ast (y \ast z) = (x \ast z) \ast y - x \ast (z \ast y).
\]

We use here the convention where the associator

\[
(x, y, z) := (x \ast y) \ast z - x \ast (y \ast z)
\]

is symmetric in its two rightmost arguments. This is sometimes called a right pre-Lie algebra.

They have appeared in numerical analysis and deformation theory.

The free Pre-Lie algebra on a given set \( E \) has an explicit description using rooted trees, just as the free associative algebra can be described using words. The underlying vector space has a basis indexed by finite rooted trees endowed with a map from their vertices to \( E \). In this basis, the product of two (decorated) rooted trees \( S \ast T \) is the sum over vertices of \( S \) of the rooted tree obtained by adding one edge from the root of \( T \) to the given vertex of \( S \). The root of these trees is taken to be the root of \( S \). The free pre-Lie algebra can also be considered as the free algebra over the PreLie operad.

**Warning:** The usual binary operator \( \ast \) can be used for the pre-Lie product. Beware that it but must be parenthesized properly, as the pre-Lie product is not associative. By default, a multiple product will be taken with left parentheses.

**EXAMPLES:**
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = F.gens()
sage: (x * y) * z
B[x[y[[]]], z[[]]] + B[x[y[], z[]]]
sage: (x * y) * z - x * (y * z) == (x * z) * y - x * (z * y)
True

The free pre-Lie algebra is non-associative:

sage: x * (y * z) == (x * y) * z
False

The default product is with left parentheses:

sage: x * y * z == (x * y) * z
True
sage: x * y * z * x == ((x * y) * z) * x
True

The NAP product as defined in [Liv2006] is also implemented on the same vector space:

sage: N = F.nap_product
sage: N(x*y,z*z)
B[x[y[], z[z[]]]]

When None is given as input, unlabelled trees are used instead:

sage: F1 = algebras.FreePreLie(QQ, None)
sage: w = F1.gen(0); w
B[[]]
sage: w * w * w * w
B[[][]][] + B[[][], [[]]] + 3*B[[], [[]]] + B[[]][, ], [[]]]

5.1. Comprehensive Module List
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> F1 = algebras.FreePreLie(QQ, None)
>>> w = F1.gen(Integer(0)); w
B[[]]
>>> w * w * w * w
B[[][]][[]] + B[[], [[]]] + 3*B[[], [[], []]] + B[[], [], []]

However, it is equally possible to use labelled trees instead:

```sage
F1 = algebras.FreePreLie(QQ, 'q')
w = F1.gen(0); w
B[q[]]
w * w * w * w
B[q[q[q[[]]]]] + B[q[q[[]], q[[]]]] + 3*B[q[q[[]], q[[]], q[[]]]] + B[q[q[[]], q[[]], q[[]], q[[]]]]
```
sage: F = algebras.FreePreLie(QQ, 'abc')
sage: a, b, c = F.gens()
sage: (a*b + b*c).lift()
B[#[a[b[]]]] + B[#[b[c[]]]]

>>> from sage.all import *
>>> F = algebras.FreePreLie(QQ, 'abc')
>>> a, b, c = F.gens()
>>> (a*b + b*c).lift()
B[#[a[b[]]]] + B[#[b[c[]]]]

Note: Variables names can be None, a list of strings, a string or an integer. When None is given, unlabelled rooted trees are used. When a single string is given, each letter is taken as a variable. See sage.combinat.words.alphabet.build_alphabet().

Warning: Beware that the underlying combinatorial free module is based either on RootedTrees or on LabelledRootedTrees, with no restriction on the labellings. This means that all code calling the basis() method would not give meaningful results, since basis() returns many “chaff” elements that do not belong to the algebra.

REFERENCES:
• [ChLi]
• [Liv2006]

class Element
    Bases: IndexedFreeModuleElement

    lift()
        Lift element to the Grossman-Larson algebra.

    EXAMPLES:

sage: F = algebras.FreePreLie(QQ, 'abc')
sage: elt = F.an_element().lift(); elt
B[#[a[a[a[a]]]]] + B[#[a[a[]], a[a[]]]]
sage: parent(elt)
Grossman-Larson Hopf algebra on 3 generators ['a', 'b', 'c'] over Rational Field

>>> from sage.all import *
>>> F = algebras.FreePreLie(QQ, 'abc')
>>> elt = F.an_element().lift(); elt
B[#[a[a[a[a]]]]] + B[#[a[a[]], a[a[]]]]
>>> parent(elt)
Grossman-Larson Hopf algebra on 3 generators ['a', 'b', 'c'] over Rational Field

valuation()
    Return the valuation of self.

    EXAMPLES:
algebra_generators()  
Return the generators of this algebra.  
These are the rooted trees with just one vertex.  
EXAMPLES:

```python
sage: A = algebras.FreePreLie(ZZ, 'fg').gens()
sage: list(A.algebra_generators())
[B[f[]], B[g[]], B[h[]]]
```

an_element()
Return an element of self.

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, 'xy')
sage: A.an_element()
B[[[[], [], []]]] + B[[[[], [], []]]]
```

**bracket_on_basis** *(x, y)*

Return the Lie bracket of two trees.

This is the commutator \([x, y] = x \ast y - y \ast x\) of the pre-Lie product.

See also:

* `pre_Lie_product_on_basis()`

EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: y = RT([x])
sage: A.bracket_on_basis(x, y)
-B[[[[], [[[]]]]]] + B[[[[], [[[]]]]]] - B[[[[], []]]] - B[[[[], []]]]
```

**change_ring** *(R)*

Return the free pre-Lie algebra in the same variables over \(R\).

INPUT:

- \(R\) – a ring

EXAMPLES:

```
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.change_ring(QQ)
Free PreLie algebra on 3 generators ['f', 'g', 'h'] over Rational Field
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, 'xy')
>>> A.an_element()
B[[[[], [], []]]] + B[[[[], [], []]]]
```
**construction()**

Return a pair \((F, R)\), where \(F\) is a **PreLieFunctor** and \(R\) is a ring, such that \(F(R)\) returns **self**.

**EXAMPLES:**

```
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x, y = P.gens()
sage: F, R = P.construction()
sage: F
PreLie[x,y]
sage: R
Integer Ring
sage: F(ZZ) is P
True
sage: F(QQ)
Free PreLie algebra on 2 generators ['x', 'y'] over Rational Field
```

**corolla\((x, y, n, N)\)**

Return the corolla obtained with \(x\) as root and \(y\) as leaves.

**INPUT:**

- \(x, y\) – two elements
- \(n\) – integer; width of the corolla
- \(N\) – integer; truncation order (up to order \(N\) included)

**OUTPUT:**

the sum over all possible ways to graft \(n\) copies of \(y\) on top of \(x\) (with at most \(N\) vertices in total)

This operation can be defined by induction starting from the pre-Lie product.

**EXAMPLES:**

```
sage: A = algebras.FreePreLie(QQ)
sage: a = A.gen(0)
sage: b = A.corolla(a,a,1,4); b
B[[[]]]
sage: A.corolla(b,b,2,7)
B[[[[[]], [[]]]]] + 2*B[[[[[], [[]]]]]] + B[[][]], [[], [], []])
sage: A = algebras.FreePreLie(QQ, 'x')
sage: a = A.gen(0)
sage: b = A.corolla(a,a,1,4)
```

(continues on next page)
sage: A = algebras.FreePreLie(QQ, 'ab')
sage: a, b = A.gens()
sage: A.corolla(a,b,1,4)
B[a[b[]]]
sage: A.corolla(b,a,3,4)
B[b[a[], a[], a[]]]
sage: A.corolla(a+b,a+b,2,4)
B[a[a[], a[]]] + 2*B[a[a[], b[]]] + B[a[b[], a[]]] + B[b[a[], a[]]] + 2*B[b[a[], b[]]] + B[b[b[], b[]]]
• $i$ – an integer

EXAMPLES:

```python
sage: F = algebras.FreePreLie(ZZ, 'xyz')
sage: F.gen(0)
B[x[]]
sage: F.gen(4)
Traceback (most recent call last):
  ... IndexError: argument i (= 4) must be between 0 and 2
```

```python
>>> from sage.all import *

>>> F = algebras.FreePreLie(ZZ, 'xyz')

>>> F.gen(Integer(0))
B[x[]]

>>> F.gen(Integer(4))
Traceback (most recent call last):
  ... IndexError: argument i (= 4) must be between 0 and 2
```

gens()
Return the generators of self (as an algebra).

EXAMPLES:

```python
sage: A = algebras.FreePreLie(ZZ, 'fgh')
sage: A.gens()
(B[f[]], B[g[]], B[h[]])
```

```python
>>> from sage.all import *

>>> A = algebras.FreePreLie(ZZ, 'fgh')

>>> A.gens()
(B[f[]], B[g[]], B[h[]])
```

group_product($x$, $y$, $n$, $N=10$)
Return the truncated group product of $x$ and $y$.

This is a weighted sum of all corollas with up to $n$ leaves, with $x$ as root and $y$ as leaves.

The result is computed up to order $N$ (included).

When considered with infinitely many terms and infinite precision, this is an analogue of the Baker-Campbell-Hausdorff formula: it defines an associative product on the completed free pre-Lie algebra.

INPUT:

• $x$, $y$ – two elements
• $n$ – integer; the maximal width of corollas
• $N$ – integer (default: 10); truncation order

EXAMPLES:

In the free pre-Lie algebra with one generator:
In the free pre-Lie algebra with several generators:

```python
sage: PL = algebras.FreePreLie(QQ,
                            None)
sage: a, b = PL.gens()
sage: PL.group_product(a, b, 3, 10)
B[[]] + B[[0[]]] + 1/2*B[[0[], 0[]]] + 1/6*B[[0[], 0[], 0[]]]
```
EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([[]])])
sage: A.nap_product_on_basis(x, x)
B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([[]])])
>>> A.nap_product_on_basis(x, x)
B[[[], [[]]]]
```

**preLie_product()**
Return the pre-Lie product.

See also:

**pre_Lie_product_on_basis()**
EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = A(RT([RT([[]])]))
sage: A.pre_Lie_product(x, x)
B[[[][]]] + B[[[], [[]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = A(RT([RT([[]])]))
>>> A.pre_Lie_product(x, x)
B[[[][]]] + B[[[], [[]]]]
```

**pre_Lie_product_on_basis(x, y)**
Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of \( y \) over a vertex of \( x \). The root of the resulting trees is the root of \( x \).

See also:

**pre_Lie_product()**
EXAMPLES:

```
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([[]])])
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[[]]]]]
```

```
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, None)
>>> RT = A.basis().keys()
>>> x = RT([RT([[]])])
>>> A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[[]]]]]
```

(continues on next page)
**product_on_basis** \((x, y)\)

Return the pre-Lie product of two trees.

This is the sum over all graftings of the root of \(y\) over a vertex of \(x\). The root of the resulting trees is the root of \(x\).

See also:

- **pre_Lie_product**

**EXAMPLES:**

```python
sage: A = algebras.FreePreLie(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], [[]]]]
```

```python
>>> from sage.all import *
```
```python
>>> from sage.all import *
>>> A = algebras.FreePreLie(QQ, 'xy')
>>> A.some_elements()
[B[x[]],
 B[x[x[]]],
 B[x(x[x[x[]]])] + B[x[x[]], x[x[]]]],
 B[x(x[x[]])] + B[x[x[]], x[]]],
 B[x(x[[]])] + B[x[[]], y[]]]]
```

**variable_names()**

Return the names of the variables.

**EXAMPLES:**

```python
sage: R = algebras.FreePreLie(QQ, 'xy')
sage: R.variable_names()
{'x', 'y'}
sage: R = algebras.FreePreLie(QQ, None)
sage: R.variable_names()
{'o'}
```

```python
>>> from sage.all import *
>>> R = algebras.FreePreLie(QQ, 'xy')
>>> R.variable_names()
{'x', 'y'}
>>> R = algebras.FreePreLie(QQ, None)
>>> R.variable_names()
{'o'}
```

**class sage.combinat.free_prelie_algebra.PreLieFunctor**(vars)

Bases: ConstructionFunctor

A constructor for pre-Lie algebras.

**EXAMPLES:**

```python
sage: P = algebras.FreePreLie(ZZ, 'x,y')
sage: x,y = P.gens()
sage: F = P.construction()[0]; F
PreLie[x,y]
sage: A = GF(5)['a,b']
sage: a, b = A.gens()
sage: F(A)
Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in a, b over Finite Field of size 5
sage: f = A.hom([a+b,a-b],A)
sage: F(f)
Generic endomorphism of Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in a, b over Finite Field of size 5
```

```python
sage: F(f)(a * F(A)(x))
(a+b)*B[x[]]
```
>>> from sage.all import *
>>> P = algebras.FreePreLie(ZZ, 'x,y')
>>> x,y = P.gens()
>>> F = P.construction()[Integer(0)]; F
PreLie[x,y]

>>> A = GF(Integer(5))[a,b]
>>> a, b = A.gens()
>>> F(A)
Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in a, b over Finite Field of size 5

>>> f = A.hom([a+b,a-b],A)
>>> F(f)
Generic endomorphism of Free PreLie algebra on 2 generators ['x', 'y'] over Multivariate Polynomial Ring in a, b over Finite Field of size 5

>>> F(f)(a * F(A)(x))
(a+b)*B[x[]]

merge (other)

Merge self with another construction functor, or return None.

EXAMPLES:

```python
sage: F = sage.combinat.free_prelie_algebra.PreLieFunctor(['x','y'])
sage: G = sage.combinat.free_prelie_algebra.PreLieFunctor(['t'])
sage: F.merge(G)
PreLie[x,y,t]
sage: F.merge(F)
PreLie[x,y]
```

Now some actual use cases:

```python
sage: R = algebras.FreePreLie(ZZ, 'xyz')
sage: x,y,z = R.gens()
sage: 1/2 * x
1/2*B[x[]]
sage: parent(1/2 * x)
Free PreLie algebra on 3 generators ['x', 'y', 'z'] over Rational Field

sage: S = algebras.FreePreLie(QQ, 'zt')
sage: z,t = S.gens()
sage: x + t
B[t[]] + B[x[]]
sage: parent(x + t)
Free PreLie algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> R = algebras.FreePreLie(ZZ, 'xyz')
>>> x, y, z = R.gens()
>>> Integer(1)/Integer(2) * x
1/2*B[x[]]
>>> parent(Integer(1)/Integer(2) * x)
Free PreLie algebra on 3 generators ['x', 'y', 'z'] over Rational Field
>>> S = algebras.FreePreLie(QQ, 'zt')
>>> z, t = S.gens()
>>> x + t
B[t[]] + B[x[]]
>>> parent(x + t)
Free PreLie algebra on 4 generators ['z', 't', 'x', 'y'] over Rational Field
```

\[ \text{rank} = 9 \]

```
sage.combinat.free_prelie_algebra.corolla_gen(tx, list_ty, labels=True)
Yield the terms in the corolla with given bottom tree and top trees.
These are the possible terms in the simultaneous grafting of the top trees on vertices of the bottom tree.

INPUT:
- \( tx \) – a tree
- \( \text{list}_\text{ty} \) – a list of trees

EXAMPLES:
```
sage: from sage.combinat.free_prelie_algebra import corolla_gen
sage: a = algebras.FreePreLie(QQ).gen(0)
sage: ta = a.support()[0]
sage: list(corolla_gen(ta, [ta], False))
[[[]]]
sage: a, b = algebras.FreePreLie(QQ, 'ab').gens()
sage: ta = a.support()[0]
sage: tb = b.support()[0]
sage: ab = (a*b).support()[0]
sage: list(corolla_gen(ta, [tb]))
[a[b[]]]
sage: list(corolla_gen(ab, [ab, ta]))
[a[a[]], b[a[]]], a[a[b[]]], b[a[]], a[a[b[]]], b[a[b[]]], a[a[b[a[b[]]]]], b[a[b[a[b[]]]]]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.free_prelie_algebra import corolla_gen
>>> a = algebras.FreePreLie(QQ).gen(Integer(0))
>>> ta = a.support()[Integer(0)]
>>> list(corolla_gen(ta, [ta], False))
[[[]]]
```

```python
>>> a, b = algebras.FreePreLie(QQ, 'ab').gens()
>>> ta = a.support()[Integer(0)]
>>> tb = b.support()[Integer(0)]
>>> ab = (a*b).support()[Integer(0)]
```
(continues on next page)
sage.combinat.free_prelie_algebra.tree_from_sortkey(ch, labels=True)

Transform a list of (valence, label) into a tree and a remainder.

This is like an inverse of the sort_key method.

INPUT:

- ch—a list of pairs (integer, label)
- labels—(default True) whether to use labelled trees

OUTPUT:

a pair (tree, remainder of the input)

EXAMPLES:

sage: from sage.combinat.free_prelie_algebra import tree_from_sortkey
sage: a = algebras.FreePreLie(QQ).gen(0)
sage: t = (a*a*a*a).support()
sage: all(tree_from_sortkey(u.sort_key(), False)[0] == u for u in t) # doctest: +EXACT
True

sage: a, b = algebras.FreePreLie(QQ, 'ab').gens()
sage: t = (a*b*a*b).support()
sage: all(tree_from_sortkey(u.sort_key())[0] == u for u in t) # doctest: +EXACT
True

>>> from sage.all import *
>>> from sage.combinat.free_prelie_algebra import tree_from_sortkey
>>> a = algebras.FreePreLie(QQ).gen(Integer(0))
>>> t = (a*a*a*a).support()
>>> all(tree_from_sortkey(u.sort_key(), False)[Integer(0)] == u for u in t) # doctest: +EXACT
True

>>> a, b = algebras.FreePreLie(QQ, 'ab').gens()
>>> t = (a*b*a*b).support()
>>> all(tree_from_sortkey(u.sort_key())[Integer(0)] == u for u in t) # doctest: +EXACT
True

5.1. Comprehensive Module List 1741
5.1.114 Fully packed loops

AUTHORS:

- Vincent Knight, James Campbell, Kevin Dilks, Emily Gunawan (2015): Initial version
- Vincent Delecroix (2017): cleaning and enhanced plotting function

```
class sage.combinat.fully_packed_loop.FullyPackedLoop(parent, generator)
```

A class for fully packed loops.

A fully packed loop is a collection of non-intersecting lattice paths on a square grid such that every vertex is part of some path, and the paths are either closed internal loops or have endpoints corresponding to alternate points on the boundary [Pro2001]. They are known to be in bijection with alternating sign matrices.

See also:

* AlternatingSignMatrix

To each fully packed loop, we assign a link pattern, which is the non-crossing matching attained by seeing which points on the boundary are connected by open paths in the fully packed loop.

We can create a fully packed loop using the corresponding alternating sign matrix and also extract the link pattern:

```
sage: A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern() 
[(1, 4), (2, 3), (5, 6)]
sage: fpl  
+ + + +
| | + |
+ + + +
| |
+ + + +
| |
+ + + +
| |

sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fplb = FullyPackedLoop(B)
sage: fplb.link_pattern()
[(1, 6), (2, 5), (3, 4)]
sage: fplb  
+ + + +
| |
+ + + +
| |
+ + + +
| |
+ + + +
| |
```
The class also has a plot method:

```python
sage: fpl.plot()
```

```
Graphics object consisting of 3 graphics primitives
```

which gives:

Note that we can also create a fully packed loop from a six vertex model configuration:

```python
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: S
```

```
^ ^ ^
-> # -> # -> # <--
```
```python
>>> from sage.all import *
>>> S = SixVertexModel(Integer(3), boundary_conditions='ice').from_alternating_sign_matrix(A)
>>> fpl = FullyPackedLoop(S)
>>> fpl
```

(continues on next page)
Once we have a fully packed loop we can obtain the corresponding alternating sign matrix:

```
sage: fpl.to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

Here are some more examples using bigger ASMs:

```
sage: A = AlternatingSignMatrix([[0,1,0,0],[0,0,1,0],[1,-1,0,1],[0,1,0,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5), (7, 8)]
sage: fpl
```

```
sage: m = AlternatingSignMatrix([[0,0,1,0,0,0],
....: [1,0,-1,0,1,0],
....: [0,0,0,1,0,0],
....: [0,1,0,0,-1,1],
....: [0,0,0,0,1,0],
....: [0,0,1,0,0,0]])
sage: fpl = FullyPackedLoop(m)
sage: fpl.link_pattern()
[(4, 12), (2, 7), (3, 4), (5, 6), (8, 9), (10, 11)]
sage: fpl
```

(continues on next page)
sage: m = AlternatingSignMatrix([[0,1,0,0,0,0,0],
....: [1,-1,0,1,0,0,0],
....: [0,0,0,0,1,0,0],
....: [0,1,0,0,-1,1,0],
....: [0,0,0,0,1,0,0],
....: [0,0,1,0,-1,0,1],
....: [0,0,0,0,1,0,0]])

sage: fpl = FullyPackedLoop(m)
sage: fpl.link_pattern()
[(1, 2), (3, 4), (5, 6), (7, 8), (9, 14), (10, 11), (12, 13)]

>>> rotated_ncp=[]
>>> for (a,b) in ncp:
...     for i in range(Integer(11)):
...         a,b=a%Integer(12)+Integer(1),b%Integer(12)+Integer(1);
...     rotated_ncp.append((a,b))
>>> PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) == PerfectMatching(rotated_ncp)
True

More examples:

We can initiate a fully packed loop using an alternating sign matrix:

```
sage: A = AlternatingSignMatrix([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl
```
We can also input a matrix:

```
sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
```

```
sage: FullyPackedLoop([[0, 0, 1], [0, 1, 0], [1, 0, 0]]) ==\n....: FullyPackedLoops(3)([[0, 0, 1], [0, 1, 0], [1, 0, 0]])
True
```
Otherwise we initiate a fully packed loop using a six vertex model:

```python
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl

| | | + + -- |
| | | |
| | | |
+ + -- + |

sage: FullyPackedLoops(3)(S) == FullyPackedLoop(S)
True

sage: fpl.six_vertex_model().to_alternating_sign_matrix()
[0 0 1]
[0 1 0]
[1 0 0]
```

```python
>>> from sage.all import *
>>> S = SixVertexModel(Integer(3), boundary_conditions='ice').from_alternating_sign_matrix(A)
>>> fpl = FullyPackedLoop(S)
>>> fpl

| | | + + -- |
| | | |
| | | |
+ + -- + |
```
We can also input the matrix associated to a six vertex model:

```
sage: SixVertexModel(2)([[3,1],[5,3]])
```

```
^ ^
| |
--> # <- # <--
| ^
V |
--> # -> # <--
| |
V V
```

```
sage: FullyPackedLoop([[3,1],[5,3]])
```

```
|
|
+ + --
|
|
-- + +
|
```

```
sage: FullyPackedLoops(2)([[3,1],[5,3]]) == FullyPackedLoop([[3,1],[5,3]])
True
```
Note that the matrix corresponding to a six vertex model without the ice boundary condition is not allowed:

```sage
sage: SixVertexModel(2)([[3,1],[5,5]])
```

```
| | --> # <- # <--
| ^  V  V
| V  V
```

```sage
sage: FullyPackedLoop([[3,1],[5,5]])
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```sage
sage: FullyPackedLoops(2)([[3,1],[5,5]])
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```>>> from sage.all import *
```

```>>> SixVertexModel(Integer(2))([[Integer(3),Integer(1)],[Integer(5),Integer(5)]]))
```

```
| | --> # <- # <--
| ^  V  V
| V  V
```

```>>> FullyPackedLoop([[Integer(3),Integer(1)],[Integer(5),Integer(5)]]))
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```>>> FullyPackedLoops(Integer(2))([[Integer(3),Integer(1)],[Integer(5),
˓→Integer(5)]]))
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

Note that if anything else is used to generate the fully packed loop an error will occur:

```sage
sage: fpl = FullyPackedLoop(5)
```

Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix

```sage
sage: fpl = FullyPackedLoop((1, 2, 3))
```

Traceback (most recent call last):
ValueError: the alternating sign matrices must be square

```
sage: SVM = SixVertexModel(3)[0]
sage: FullyPackedLoop(SVM)
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix
```

```
>>> from sage.all import *
>>> fpl = FullyPackedLoop(Integer(5))
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix
```

```
>>> fpl = FullyPackedLoop((Integer(1), Integer(2), Integer(3)))
Traceback (most recent call last):
...
ValueError: the alternating sign matrices must be square
```

```
>>> SVM = SixVertexModel(Integer(3))[Integer(0)]
>>> FullyPackedLoop(SVM)
Traceback (most recent call last):
...
ValueError: invalid alternating sign matrix
```

gyration()

Return the fully packed loop obtained by applying gyration to the alternating sign matrix in bijection with self.

Gyration was first defined in [Wie2000] as an action on fully-packed loops.

EXAMPLES:

```
sage: A = AlternatingSignMatrix([[1, 0, 0],[0, 1, 0],[0, 0, 1]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.gyration().to_alternating_sign_matrix()  
[0 0 1]
[0 1 0]
[1 0 0]
sage: asm = AlternatingSignMatrix([[0, 0, 1],[1, 0, 0],[0, 1, 0]])
sage: f = FullyPackedLoop(asm)
sage: f.gyration().to_alternating_sign_matrix()  
[0 1 0]
[0 0 1]
[1 0 0]
```

```
>>> from sage.all import *
>>> A = AlternatingSignMatrix([[Integer(1), Integer(0), Integer(0)],
    →[Integer(0), Integer(1), Integer(0)],[Integer(0), Integer(0), Integer(1)]]
>>> fpl = FullyPackedLoop(A)
```
link_pattern()

Return a link pattern corresponding to a fully packed loop.

Here we define a link pattern $LP$ to be a partition of the list $[1, \ldots, 2k]$ into 2-element sets (such a partition is also known as a perfect matching) such that the following non-crossing condition holds: Let the numbers $1, \ldots, 2k$ be written on the perimeter of a circle. For every 2-element set $(a, b)$ of the partition $LP$, draw an arc linking the two numbers $a$ and $b$. We say that $LP$ is non-crossing if every arc can be drawn so that no two arcs intersect.

Since every endpoint of a fully packed loop $fpl$ is connected to a different endpoint, there is a natural surjection from the fully packed loops on an $n \times n$ grid onto the link patterns on the list $[1, \ldots, 2n]$. The pairs of connected endpoints of a fully packed loop $fpl$ correspond to the 2-element tuples of the corresponding link pattern.

See also:

PerfectMatching

Note: by convention, we choose the top left vertex to be even. See [Pro2001] and [Str2015].

EXAMPLES:

We can extract the underlying link pattern (a non-crossing partition) from a fully packed loop:

```
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.link_pattern()
[(1, 2), (3, 6), (4, 5)]
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
sage: fpl.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```
Gyration on an alternating sign matrix/fully packed loop $fpl$ corresponds to a rotation (i.e. $a$ becomes $a-1 \mod 2n$) of the link pattern corresponding to $fpl$:

```python
>>> fpl.link_pattern()
[(1, 6), (2, 5), (3, 4)]
```

```
sage: ASMs = AlternatingSignMatrices(3).list()
sage: ncp = FullyPackedLoop(ASMs[1]).link_pattern()
sage: rotated_ncp = []
sage: for (a, b) in ncp:
    ...:     for i in range(5):
    ...:         a, b = a % 6 + 1, b % 6 + 1;
    ...:         rotated_ncp.append((a, b))
sage: PerfectMatching(ASMs[1].gyration().to_fully_packed_loop().link_pattern()) == \n    ...:     PerfectMatching(rotated_ncp)
True
```
```
sage: for (a, b) in ncp:
    ...:     for i in range(5):
    ...:         a, b = a % 6 + 1, b % 6 + 1;
    ...:         rotated_ncp.append((a, b))
sage: PerfectMatching(ASMs[0].gyration().to_fully_packed_loop().link_pattern()) == \n    ...:     PerfectMatching(rotated_ncp)
True
```
```
sage: mat = AlternatingSignMatrix([[0, 0, 0, 1, 0, 0, 0, 0],
    ...:     [0, 0, -1, 0, 0, 0, 0, 0],
    ...:     [0, 0, 0, 0, 1, 0, 0, 0],
    ...:     [0, 0, 1, 0, 0, 0, 0, 0],
    ...:     [0, 0, 0, 0, 0, 1, 0, 0],

...                                Integer(0), Integer(0), Integer(1)],
...                               [Integer(0), Integer(1), Integer(0), Integer(0),
...                                Integer(0), Integer(0), Integer(1)]])

>>> fpl = FullyPackedLoop(mat)

>>> ncp = fpl.link_pattern()

>>> rotated_ncp = []
```

(continues on next page)
>>> for (a,b) in ncp:
...  for i in range(Integer(11)):
...    a,b=\(a \mod 12 + 1\), b\( \mod 12 + 1\);
...  rotated_ncp.append((a,b))

>>> PerfectMatching(mat.gyration().to_fully_packed_loop().link_pattern()) == PerfectMatching(rotated_ncp)
True

The result of "plot" command:

plot(link=True, loop=True, loop_fill=False, **options)

Return a graphical object of the Fully Packed Loop.

Each option can be specified separately for links (the curves that join boundary points) and the loops. In order to do so, you need to prefix its name with either 'link_' or 'loop_'. As an example, setting color='red' will color both links and loops in red while setting link_color='red' will only apply the color option for the links.

INPUT:

- link, loop – (boolean, default True) whether to plot the links or the loops
- color, link_color, loop_color – (optional, a string or a RGB triple)
- colors, link_colors, loop_colors – (optional, list) a list of colors
- color_map, link_color_map, loop_color_map – (string, optional) a name of a matplotlib colormap for the link or the loop
- link_color_randomize – (boolean, default False) when link_colors or link_color_map is specified it randomizes its order. Setting this option to True makes it unlikely to have two neighboring links with the same color.
- loop_fill – (boolean, optional) whether to fill the interior of the loops

EXAMPLES:

To plot the fully packed loop associated to the following alternating sign matrix

\[
\begin{pmatrix}
0 & 1 & 1 \\
1 & -1 & 1 \\
0 & 1 & 0
\end{pmatrix}
\]

simply do:

sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: fpl = FullyPackedLoop(A)
sage: fpl.plot()

The resulting graphics is as follows

You can also have the three links in different colors with:
You can plot the 42 fully packed loops of size $4 \times 4$ using:

```sage
g = [fpl.plot(link_color_map='winter', loop_color='black')
    for fpl in FullyPackedLoops(4)]
graphics_array(g, 7, 6)
```

Here is an example of a $20 \times 20$ fully packed loop:
six_vertex_model()

Return the underlying six vertex model configuration.

EXAMPLES:

```python
sage: B = AlternatingSignMatrix([[1, 0, 0], [0, 1, 0], [0, 0, 1]])
sage: fpl = FullyPackedLoop(B)
```
sage: fpl
+ + -- +
| |
-- + + + --
| |
+ -- + +
| |
sage: fpl.six_vertex_model()

--> # -> # <- # <--
| | ^
V V |
--> # -> # -> # <--
| | |
V V V

to_alternating_sign_matrix()
Return the alternating sign matrix corresponding to this class.
See also:

**AlternatingSignMatrix**

**EXAMPLES:**

```python
sage: A = AlternatingSignMatrix([[0, 1, 0], [1, -1, 1], [0, 1, 0]])
sage: S = SixVertexModel(3, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
sage: A = AlternatingSignMatrix([[0,1,0],[0,0,1],[1,-1,0],[0,1,0]])
sage: S = SixVertexModel(4, boundary_conditions='ice').from_alternating_sign_matrix(A)
sage: fpl = FullyPackedLoop(S)
sage: fpl.to_alternating_sign_matrix()
[ 0 1 0 0]
[ 0 0 1 0]
[ 1 -1 0 1]
[ 0 1 0 0]
```

```python
>>> from sage.all import *

>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0)],
                             [Integer(1), -Integer(1), Integer(1)],
                             [Integer(0), Integer(1), Integer(0)]])

>>> S = SixVertexModel(Integer(3), boundary_conditions='ice').from_alternating_sign_matrix(A)

>>> fpl = FullyPackedLoop(S)

>>> fpl.to_alternating_sign_matrix()
[ 0 1 0]
[ 1 -1 1]
[ 0 1 0]
```

```python
>>> A = AlternatingSignMatrix([[Integer(0), Integer(1), Integer(0), Integer(0)],
                             [Integer(0), Integer(0), Integer(1), Integer(0)],
                             [Integer(1), -Integer(1), Integer(0), Integer(1)],
                             [Integer(0), Integer(1), Integer(0), Integer(0)]])

>>> S = SixVertexModel(Integer(4), boundary_conditions='ice').from_alternating_sign_matrix(A)

>>> fpl = FullyPackedLoop(S)

>>> fpl.to_alternating_sign_matrix()
[ 0 1 0 0]
[ 0 0 1 0]
[ 1 -1 0 1]
[ 0 1 0 0]
```

class `sage.combinat.fully_packed_loop.FullyPackedLoops(n)`

**Bases:** `Parent`, `UniqueRepresentation`

Class of all fully packed loops on an $n \times n$ grid.

They are known to be in bijection with alternating sign matrices.

**See also:**

**AlternatingSignMatrices**

**INPUT:**

- $n$ – the number of row (and column) or grid
EXAMPLES:

This will create an instance to manipulate the fully packed loops of size 3:

```
sage: FPLs = FullyPackedLoops(3)
sage: FPLs
Fully packed loops on a 3x3 grid
sage: FPLs.cardinality()
7
```

When using the square ice model, it is known that the number of configurations is equal to the number of alternating sign matrices:

```
sage: M = FullyPackedLoops(1)
sage: len(M)
1
sage: M = FullyPackedLoops(4)
sage: len(M)
42
```

```
>>> from sage.all import *

>>> FPLs = FullyPackedLoops(Integer(3))

>>> FPLs
Fully packed loops on a 3x3 grid

>>> FPLs.cardinality()
7
```

```
>>> from sage.all import *

>>> M = FullyPackedLoops(Integer(1))

>>> len(M)
1

>>> M = FullyPackedLoops(Integer(4))

>>> len(M)
42
```

```
....:   == FullyPackedLoops(n).cardinality() for n in range(1, 7))

True
```

```
>>> from sage.all import *

>>> M = FullyPackedLoops(Integer(1))

>>> len(M)
1

>>> M = FullyPackedLoops(Integer(4))

>>> len(M)
42
```

```
....:   == FullyPackedLoops(n).cardinality() for n in range(Integer(1),...

Integer(7)))

True
```

Element

alias of `FullyPackedLoop`

cardinality()

Return the cardinality of self.

The number of fully packed loops on $n \times n$ grid

\[
\prod_{k=0}^{n-1} \frac{(3k + 1)!}{(n+k)!} = \frac{1!4!7!10!\cdots(3n-2)!}{n!(n+1)!(n+2)!(n+3)!\cdots(2n-1)!}.
\]

EXAMPLES:

```
sage: [AlternatingSignMatrices(n).cardinality() for n in range(10)]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460]
```
```python
>>> from sage.all import *

>>> [AlternatingSignMatrices(n).cardinality() for n in range(Integer(10))]
[1, 1, 2, 7, 42, 429, 7436, 218348, 10850216, 911835460]
```

size()

Return the size of the matrices in self.

## 5.1.115 Gelfand-Tsetlin Patterns

**AUTHORS:**

**REFERENCES:**

```python
class sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPattern
    Bases: ClonableArray

A Gelfand-Tsetlin (sometimes written as Gelfand-Zetlin or Gelfand-Cetlin) pattern. They were originally defined in [GC50].

A Gelfand-Tsetlin pattern is a triangular array:

\[
\begin{array}{ccccccc}
    a_{1,1} & a_{1,2} & a_{1,3} & \cdots & a_{1,n} \\
    a_{2,2} & a_{2,3} & \cdots & a_{2,n} \\
    a_{3,3} & \cdots & a_{3,n} \\
    \vdots \\
    a_{n,n}
\end{array}
\]

such that \(a_{i,j} \geq a_{i+1,j+1} \geq a_{i,j+1}\).

Gelfand-Tsetlin patterns are in bijection with semistandard Young tableaux by the following algorithm. Let \(G\) be a Gelfand-Tsetlin pattern with \(\lambda^{(k)}\) being the \((n-k+1)\)-st row (note that this is a partition). The definition of \(G\) implies

\[
\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},
\]

where \(\lambda^{(0)}\) is the empty partition, and each skew shape \(\lambda^{(k)}/\lambda^{(k-1)}\) is a horizontal strip. Thus define \(T(G)\) by inserting \(k\) into the squares of the skew shape \(\lambda^{(k)}/\lambda^{(k-1)}\), for \(k = 1, \ldots, n\).

To each entry in a Gelfand-Tsetlin pattern, one may attach a decoration of a circle or a box (or both or neither). These decorations appear in the study of Weyl group multiple Dirichlet series, and are implemented here following the exposition in [BBF].

**Note:** We use the “right-hand” rule for determining circled and boxed entries.

**Warning:** The entries in Sage are 0-based and are thought of as flushed to the left in a matrix. In other words, the coordinates of entries in the Gelfand-Tsetlin patterns are thought of as the matrix:

\[
\begin{bmatrix}
g_{0,0} & g_{0,1} & g_{0,2} & \cdots & g_{0,n-2} & g_{n-1,n-1} \\
g_{1,0} & g_{1,1} & g_{1,2} & \cdots & g_{1,n-2} \\
g_{2,0} & g_{2,1} & g_{2,2} & \cdots \\
\vdots & \vdots & \vdots \\
g_{n-2,0} & g_{n-2,1} \\
g_{n-1,0}
\end{bmatrix}
\]
However, in the discussions, we will be using the standard numbering system.

EXAMPLES:

```python
g = GelfandTsetlinPattern([[3, 2, 1], [2, 1], [1]]); g
[[3, 2, 1], [2, 1], [1]]
g.pp()
3 2 1
2 1
1

```  

```python
g = GelfandTsetlinPattern([[7, 7, 4, 0], [7, 7, 3], [7, 5], [5]]); g.pp()
7 7 4 0
7 7 3
7 5
5

```  

```python
g.to_tableau().pp()
1 1 1 1 1 2 2
2 2 2 2 2 3 3
3 3 3 4

```  

```python
from sage.all import *
G = GelfandTsetlinPattern([[Integer(3), Integer(2), Integer(1)], [Integer(2),
Integer(1)]]); G
[[3, 2, 1], [2, 1], [1]]
G.pp()
3 2 1
2 1
1

```  

```python
G = GelfandTsetlinPattern([[Integer(7), Integer(7), Integer(4), Integer(0)],
Integer(7)], [Integer(7)], [Integer(3)], [Integer(7)], [Integer(5)], [Integer(5)]); G
G.pp()
7 7 4 0
7 7 3
7 5
5

```  

```python
G.to_tableau().pp()
1 1 1 1 1 2 2
2 2 2 2 2 3 3
3 3 3 4

```  

**Tokuyama_coefficient** *(name='t')*

Return the Tokuyama coefficient attached to self.

Following the exposition of [BBF], Tokuyama’s formula asserts

\[
\sum_{\mathcal{G}} (t + 1)^{s(G)} \mu(G) z_1^{d_{n+1}} z_2^{d_n - d_{n+1}} \cdots z_{n+1}^{d_1 - d_2} z_{n+1}^{d_2 - d_3} \cdots z_1^{d_2 - d_3} = s_\lambda(z_1, \ldots, z_{n+1}) \prod_{i < j} (z_j + tz_i),
\]

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row \( \lambda + \rho \), with \( \lambda \) a partition with at most \( n + 1 \) parts and \( \rho = (n, n - 1, \ldots, 1, 0) \), and \( s_\lambda \) is a Schur function.

**INPUT:**

- **name** — (Default: ‘t’) An alternative name for the variable \( t \).

**EXAMPLES:**
```python
sage: P = GelfandTsetlinPattern([[3,2,1],[2,2],[2]])
sage: P.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[2]])
sage: G.Tokuyama_coefficient()
t^2 + t
sage: G = GelfandTsetlinPattern([[2,1,0],[1,1],[1]])
sage: G.Tokuyama_coefficient()
0
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.Tokuyama_coefficient()
t^8 + 3*t^7 + 3*t^6 + t^5

>>> from sage.all import *
>>> P = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(2),
˓→Integer(2)],[Integer(2)]]))
>>> P.Tokuyama_coefficient()
0
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
˓→Integer(1)],[Integer(2)]]))
>>> G.Tokuyama_coefficient()
t^2 + t
>>> G = GelfandTsetlinPattern([[Integer(2),Integer(1),Integer(0)],[Integer(1),
˓→Integer(1)],[Integer(1)]]))
>>> G.Tokuyama_coefficient()
0
>>> G = GelfandTsetlinPattern([[Integer(5),Integer(3),Integer(2),Integer(1),
˓→Integer(0)],[Integer(4),Integer(3),Integer(2),Integer(0)],[Integer(4),
˓→Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(3)]]))
>>> G.Tokuyama_coefficient()
t^8 + 3*t^7 + 3*t^6 + t^5
```

**bender_knuth_involution(i)**

Return the image of self under the i-th Bender-Knuth involution.

If the triangle self has size n then this is defined for 0 < i < n.

The entries of self can take values in any ordered ring. Usually, this will be the integers but can also be the rationals or the real numbers.

This implements the construction of the Bender-Knuth involution using toggling due to Berenstein-Kirillov.

This agrees with the Bender-Knuth involution on semistandard tableaux.

**EXAMPLES:**

```python
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.bender_knuth_involution(2)
[[5, 3, 2, 1, 0], [4, 3, 2, 0, [4, 2, 1], [3, 1]], [3]]

sage: G = GelfandTsetlinPattern([[3,2,0],[2.2,0],[2]])
sage: G.bender_knuth_involution(2)
[[3, 2, 0], [2.80000000000000, 2], [2]

>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(5),Integer(3),Integer(2),Integer(1),
˓→Integer(0)],[Integer(4),Integer(3),Integer(2),Integer(0)],[Integer(4),
˓→Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(3)]]))
```
boxed_entries()

Return the position of the boxed entries of self.

Using the right-hand rule, an entry $a_{i,j}$ is boxed if $a_{i,j} = a_{i-1,j-1}$; i.e., $a_{i,j}$ has the same value as its neighbor to the northwest.

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.boxed_entries()
((1, 1),)
```

check()

Check that this is a valid Gelfand-Tsetlin pattern.

EXAMPLES:

```python
sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1]]).check()
```

circled_entries()

Return the circled entries of self.

Using the right-hand rule, an entry $a_{i,j}$ is circled if $a_{i,j} = a_{i-1,j+1}$; i.e., $a_{i,j}$ has the same value as its neighbor to the northeast.

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.circled_entries()
((1, 1), (2, 0))
```
is_strict()

Return True if self is a strict Gelfand-Tsetlin pattern.

A Gelfand-Tsetlin pattern is said to be strict if every row is strictly decreasing.

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[7,3,1],[6,2],[4]]).is_strict()
True
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]]).is_strict()
True
sage: G = GelfandTsetlinPattern([[6,0,0],[3,0],[2]]).is_strict()
False
```

number_of_boxes()

Return the number of boxed entries. See boxed_entries().

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_boxes()
1
```

number_of_circles()

Return the number of boxed entries. See circled_entries().

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_circles()
2
```

number_of_special_entries()

Return the number of special entries. See special_entries().

```python
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.number_of_special_entries()
2
```

From sage.all import *

```python
>>> G = GelfandTsetlinPattern([[Integer(7),Integer(3),Integer(1)],[Integer(6), Integer(2)],[Integer(4)]]).is_strict()
True
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3), Integer(1)],[Integer(1)]]).is_strict()
True
>>> G = GelfandTsetlinPattern([[Integer(6),Integer(0),Integer(0)],[Integer(3), Integer(0)],[Integer(2)]]).is_strict()
False
```
EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.number_of_special_entries()
1

>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(4),Integer(2),Integer(1)],[Integer(4),
˓→Integer(1)],[Integer(2)])
>>> G.number_of_special_entries()
1
```

`pp()`
Pretty print self.

EXAMPLES:

```python
sage: G = GelfandTsetlinPatterns()
sage: G([[3,2,1],[2,1],[1])).pp()
   3 2 1
   2 1
   1

>>> from sage.all import *
>>> G = GelfandTsetlinPatterns()
>>> G([[Integer(3),Integer(2),Integer(1)],[Integer(2),Integer(1)],
˓→[Integer(1)])].pp()
   3 2 1
   2 1
   1
```

`row_sums()`
Return the list of row sums.

For a Gelfand-Tsetlin pattern $G$, the $i$-th row sum $d_i$ is

$$d_i = d_i(G) = \sum_{j=i}^{n} a_{i,j}.$$  

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[5,3,2,1,0],[4,3,2,0],[4,2,1],[3,2],[3]])
sage: G.row_sums()
[11, 9, 7, 5, 3]
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[2]])
sage: G.row_sums()
[6, 4, 2]

>>> from sage.all import *
>>> G = GelfandTsetlinPattern([[Integer(5),Integer(3),Integer(2),Integer(1),
˓→Integer(0)],[Integer(4),Integer(3),Integer(2),Integer(0)],[Integer(4),
˓→Integer(2),Integer(1)],[Integer(3),Integer(2)],[Integer(3)])
>>> G.row_sums()
[11, 9, 7, 5, 3]
>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)],[Integer(3),
˓→Integer(1)],[Integer(2)])
>>> G.row_sums()
[6, 4, 2]
```
special_entries()

Return the special entries.

An entry $a_{i,j}$ is special if $a_{i-1,j-1} > a_{i,j} > a_{i-1,j}$, that is to say, the entry is neither boxed nor circled and is not in the first row. The name was coined by [Tok88].

EXAMPLES:

```
sage: G = GelfandTsetlinPattern([[3,2,1],[3,1],[1]])
sage: G.special_entries()
()
sage: G = GelfandTsetlinPattern([[4,2,1],[4,1],[2]])
sage: G.special_entries()
((2, 0),)
```

```
>>> from sage.all import *

>>> G = GelfandTsetlinPattern([[Integer(3),Integer(2),Integer(1)], [Integer(3), Integer(1)], [Integer(1)]]))
>>> G.special_entries()
()
>>> G = GelfandTsetlinPattern([[Integer(4),Integer(2),Integer(1)], [Integer(4), Integer(1)], [Integer(2)]]))
>>> G.special_entries()
((2, 0),)
```

to_tableau()

Return self as a semistandard Young tableau.

The conversion from a Gelfand-Tsetlin pattern to a semistandard Young tableaux is as follows. Let $G$ be a Gelfand-Tsetlin pattern with $\lambda^{(k)}$ being the $(n-k+1)$-st row (note that this is a partition). The definition of $G$ implies

$$
\lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(n)},
$$

where $\lambda^{(0)}$ is the empty partition, and each skew shape $\lambda^{(k)}/\lambda^{(k-1)}$ is a horizontal strip. Thus define $T(G)$ by inserting $k$ into the squares of the skew shape $\lambda^{(k)}/\lambda^{(k-1)}$, for $k = 1, \ldots, n$.

EXAMPLES:

```
sage: G = GelfandTsetlinPatterns()
sage: elt = G([[3,2,1],[2,1],[1]})
sage: T = elt.to_tableau(); T
[[1, 2, 3], [2, 3], [3]]
sage: T.pp()
 1 2 3
 2 3
 3
sage: G(T) == elt
True
```

```
>>> from sage.all import *

>>> G = GelfandTsetlinPatterns()

>>> elt = G([[Integer(3),Integer(2),Integer(1)], [Integer(2),Integer(1)],
\textcolor{red}{\rightarrow} [Integer(1)]]))

>>> T = elt.to_tableau(); T
[[1, 2, 3], [2, 3], [3]]
>>> T.pp()
 1 2 3
```

(continues on next page)
weight()

Return the weight of self.

Define the weight of \( G \) to be the content of the tableau to which \( G \) corresponds under the bijection between Gelfand-Tsetlin patterns and semistandard tableaux. More precisely,

\[
\text{wt}(G) = (d_n, d_{n-1} - d_n, \ldots, d_1 - d_2),
\]

where the \( d_i \) are the row sums.

EXAMPLES:

```python
sage: G = GelfandTsetlinPattern([[2,1,0],[1,0],[1]])
sage: G.weight()
(1, 0, 2)
sage: G = GelfandTsetlinPattern([[4,2,1],[3,1],[2]])
sage: G.weight()
(2, 2, 3)
```

```python
>>> from sage.all import *
```

```python
>>> G = GelfandTsetlinPattern([[Integer(2),Integer(1),Integer(0)],[Integer(1),-Integer(0)],[Integer(1)]]))
>>> G.weight()
(1, 0, 2)
```

```python
>>> G = GelfandTsetlinPattern([[Integer(4),Integer(2),Integer(1)],[Integer(3),-Integer(1)],[Integer(2)]]))
>>> G.weight()
(2, 2, 3)
```
sage: g = GelfandTsetlinPatterns(4, 5)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()

>>> from sage.all import *
>>> g = GelfandTsetlinPatterns(Integer(4), Integer(5))
>>> x = g.random_element()
>>> x in g
True
>>> len(x)
4
>>> all(y in range(Integer(5)+Integer(1)) for z in x for y in z)
True
>>> x.check()

sage: g = GelfandTsetlinPatterns(4, 5, strict=True)
sage: x = g.random_element()
sage: x in g
True
sage: len(x)
4
sage: all(y in range(5+1) for z in x for y in z)
True
sage: x.check()
sage: x.is_strict()
True

>>> from sage.all import *
>>> g = GelfandTsetlinPatterns(Integer(4), Integer(5), strict=True)
>>> x = g.random_element()
>>> x in g
True
>>> len(x)
4
>>> all(y in range(Integer(5)+Integer(1)) for z in x for y in z)
True
>>> x.check()
>>> x.is_strict()
True

class sage.combinat.gelfand_tsetlin_patterns.GelfandTsetlinPatternsTopRow(top_row, strict)

Bases: GelfandTsetlinPatterns

Gelfand-Tsetlin patterns with a fixed top row.

Tokuyama_formula(name='t')

    Return the Tokuyama formula of self.
Following the exposition of [BBF], Tokuyama’s formula asserts

$$\sum_{G} (t + 1)^{s(G)} p(G) \frac{d_{n+1}}{z_1} \frac{d_n - d_{n+1}}{z_2} \cdots \frac{d_1 - d_2}{z_{n+1}} = s_{\lambda}(z_1, \ldots, z_{n+1}) \prod_{i<j}(z_j + tz_i),$$

where the sum is over all strict Gelfand-Tsetlin patterns with fixed top row $\lambda + \rho$, with $\lambda$ a partition with at most $n + 1$ parts and $\rho = (n, n-1, \ldots, 1, 0)$, and $s_{\lambda}$ is a Schur function.

INPUT:

- **name** – (Default: 't') An alternative name for the variable $t$.

EXAMPLES:

```
sage: GT = GelfandTsetlinPatterns(top_row=[2,1,0], strict=True)
sage: GT.Tokuyama_formula()
t^3*x1^2*x2 + t^2*x1*x2^2 + t^2*x1^2*x3 + t^2*x1*x2*x3 + t*x1*x2*x3 + t*x2^2*x3 + t*x1*x3^2 + x2*x3^2
```

```
sage: GT = GelfandTsetlinPatterns(top_row=[3,2,1], strict=True)
sage: GT.Tokuyama_formula()
t^3*x1^3*x2^2*x3 + t^2*x1^2*x2^3*x3 + t^2*x1^3*x2*x3^2 + t^2*x1^2*x2^2*x3^2 + t*x1^2*x2^2*x3^2 + t*x1*x2^3*x3^2 + t*x1^2*x2*x3^3 + x1*x2^2*x3^3
```

```
sage: GT = GelfandTsetlinPatterns(top_row=[1,1,1], strict=True)
sage: GT.Tokuyama_formula()
0
```

```
>>> from sage.all import *
>>> GT = GelfandTsetlinPatterns(top_row=[2,1,0], strict=True)
>>> GT.Tokuyama_formula()
t^3*x1^2*x2 + t^2*x1*x2^2 + t^2*x1^2*x3 + t^2*x1*x2*x3 + t*x1*x2*x3 + t*x2^2*x3 + t*x1*x3^2 + x2*x3^2
```

```
>>> GT = GelfandTsetlinPatterns(top_row=[3,2,1], strict=True)
>>> GT.Tokuyama_formula()
t^3*x1^3*x2^2*x3 + t^2*x1^2*x2^3*x3 + t^2*x1^3*x2*x3^2 + t^2*x1^2*x2^2*x3^2 + t*x1^2*x2^2*x3^2 + t*x1*x2^3*x3^2 + t*x1^2*x2*x3^3 + x1*x2^2*x3^3
```

```
>>> GT = GelfandTsetlinPatterns(top_row=[1,1,1], strict=True)
>>> GT.Tokuyama_formula()
0
```

random_element()

Return a uniformly random Gelfand-Tsetlin pattern with specified top row.

EXAMPLES:

```
sage: g = GelfandTsetlinPatterns(top_row = [4, 3, 1, 1])
sage: x = g.random_element()
sage: x in g
True
sage: x[0] == [4, 3, 1, 1]
True
sage: x.check()
```

```
sage: g = GelfandTsetlinPatterns(top_row=[4, 3, 2, 1], strict=True)
sage: x = g.random_element()
sage: x in g
True
```

(continues on next page)
sage: x[0] == [4, 3, 2, 1]
True
sage: x.is_strict()
True
sage: x.check()

>>> from sage.all import *

>>> g = GelfandTsetlinPatterns(top_row = [Integer(4), Integer(3), Integer(1),
Integer(1)])
>>> x = g.random_element()
>>> x in g
True
>>> x[Integer(0)] == [Integer(4), Integer(3), Integer(1), Integer(1)]
True
>>> x.is_strict()
True
>>> x.check()

>>> g = GelfandTsetlinPatterns(top_row=[Integer(4), Integer(3), Integer(2),
Integer(1)], strict=True)
>>> x = g.random_element()
>>> x in g
True
>>> x[Integer(0)] == [Integer(4), Integer(3), Integer(2), Integer(1)]
True
>>> x.is_strict()
True
>>> x.check()

\section*{top_row()}

Return the top row of self.

\section*{EXAMPLES:}

sage: G = GelfandTsetlinPatterns(top_row=[4,4,3,1])
sage: G.top_row()
(4, 4, 3, 1)

5.1.116 Paths in Directed Acyclic Graphs

\texttt{sage.combinat.graph_path.GraphPaths} \texttt{(g, source=None, target=None)}

Return the combinatorial class of paths in the directed acyclic graph \texttt{g}.

\section*{EXAMPLES:}

\texttt{sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)}

\texttt{>>> from sage.all import *}
\texttt{>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],...}

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

\[
\begin{align*}
&\text{Integer}(2):[\text{Integer}(3),\text{Integer}(4)],
&\text{Integer}(3):[\text{Integer}(4)],
&\text{Integer}(4):[\text{Integer}(5),\text{Integer}(5)],
\end{align*}
\]

If source and target are not given, then the returned class contains all paths (including trivial paths containing only one vertex).

\[
sage: p = \text{GraphPaths}(G) ; p
\]
Paths in Multi-digraph on 5 vertices
\[
sage: p.\text{cardinality}()
37
\]
\[
sage: path = p.\text{random_element}()
\]
\[
sage: \text{all}(\text{G}.\text{has_edge}(*\text{path}[i:i+2]) \text{ for } i \text{ in } \text{range}(\text{len}(\text{path}) -1))
\]
True

\[
>>> \text{from sage.all import } *
\]
\[
>>> p = \text{GraphPaths}(G) ; p
\]
Paths in Multi-digraph on 5 vertices
\[
>>> p.\text{cardinality}()
37
\]
\[
>>> path = p.\text{random_element}()
\]
\[
>>> \text{all}(\text{G}.\text{has_edge}(*\text{path}[i:i+\text{Integer}(2)]) \text{ for } i \text{ in } \text{range}(\text{len}(\text{path}) -\text{Integer}(1)))
\]
True

If the source is specified, then the returned class contains all of the paths starting at the vertex source (including the trivial path).

\[
sage: p = \text{GraphPaths}(G, \text{source=3}) ; p
\]
Paths in Multi-digraph on 5 vertices starting at 3
\[
sage: p.\text{list}()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
\]

\[
>>> \text{from sage.all import } *
\]
\[
>>> p = \text{GraphPaths}(G, \text{source=3}) ; p
\]
Paths in Multi-digraph on 5 vertices starting at 3
\[
>>> p.\text{list}()
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]
\]

If the target is specified, then the returned class contains all of the paths ending at the vertex target (including the trivial path).

\[
sage: p = \text{GraphPaths}(G, \text{target=3}) ; p
\]
Paths in Multi-digraph on 5 vertices ending at 3
\[
sage: p.\text{cardinality}()
5
\]
\[
sage: p.\text{list}()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
\]

\[
>>> \text{from sage.all import } *
\]
\[
>>> p = \text{GraphPaths}(G, \text{target=3}) ; p
\]
Paths in Multi-digraph on 5 vertices ending at 3
\[
>>> p.\text{cardinality}()
5
\]
\[
>>> p.\text{list}()
[[3], [1, 3], [2, 3], [1, 2, 3], [1, 2, 3]]
\]

If both the target and source are specified, then the returned class contains all of the paths from source to target.

5.1. Comprehensive Module List 1777
sage: p = GraphPaths(G, source=1, target=3); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
sage: p.cardinality()
3
sage: p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]

>>> from sage.all import *
>>> p = GraphPaths(G, source=Integer(1), target=Integer(3)); p
Paths in Multi-digraph on 5 vertices starting at 1 and ending at 3
>>> p.cardinality()
3
>>> p.list()
[[1, 2, 3], [1, 2, 3], [1, 3]]

Note that G must be a directed acyclic graph.

sage: G = DiGraph({1:[2,2,3,5], 2:[3,4], 3:[4], 4:[2,5,7], 5:[6]}, multiedges=True)
sage: GraphPaths(G)
Traceback (most recent call last):

>>> GraphPaths(G)
Traceback (most recent call last):
...
TypeError: g must be a directed acyclic graph

list()

Return a list of the paths of self.

EXAMPLES:
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: len(GraphPaths(G).list())
37

from sage.all import *

G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
             Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
             Integer(4):[Integer(5),Integer(5)]}, multiedges=True)

len(GraphPaths(G).list())
37

class sage.combinat.graph_path.GraphPaths_common
    Bases: object

    incoming_edges(v)
    Return a list of v's incoming edges.
    EXAMPLES:

    sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.incoming_edges(2)
[(1, 2, None), (1, 2, None)]

    >>> from sage.all import *
    >>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
                   Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
                   Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
    >>> p = GraphPaths(G)
    >>> p.incoming_edges(Integer(2))
    [(1, 2, None), (1, 2, None)]

    incoming_paths(v)
    Return a list of paths that end at v.
    EXAMPLES:

    sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.incoming_paths(2)
[[2], [1, 2], [1, 2]]

    >>> from sage.all import *
    >>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
                   Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
                   Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
    >>> gp = GraphPaths(G)
    >>> gp.incoming_paths(Integer(2))
    [[2], [1, 2], [1, 2]]

    outgoing_edges(v)
    Return a list of v's outgoing edges.
    EXAMPLES:
Combinatorics, Release 10.4

```python
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G)
sage: p.outgoing_edges(2)
[(2, 3, None), (2, 4, None)]

>>> from sage.all import *

G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
             Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
             Integer(4):[Integer(5),Integer(5)]}, multiedges=True)

>>> p = GraphPaths(G)

p.outgoing_edges(Integer(2))
[(2, 3, None), (2, 4, None)]
```

### outgoing_paths(v)

Return a list of the paths that start at v.

**EXAMPLES:**

```python
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)

sage: gp = GraphPaths(G)

sage: gp.outgoing_paths(3)
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]

sage: gp.outgoing_paths(2)
[[2], [2, 3], [2, 3, 4], [2, 3, 4, 5], [2, 3, 4, 5], [2, 4], [2, 4, 5], [2, 4, 5]]

>>> from sage.all import *

G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
             Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
             Integer(4):[Integer(5),Integer(5)]}, multiedges=True)

>>> gp = GraphPaths(G)

>>> gp.outgoing_paths(Integer(3))
[[3], [3, 4], [3, 4, 5], [3, 4, 5]]

>>> gp.outgoing_paths(Integer(2))
[[2], [2, 3], [2, 3, 4], [2, 3, 4, 5], [2, 3, 4, 5], [2, 4], [2, 4, 5], [2, 4, 5]]
```

### paths()

Return a list of all the paths of self.

**EXAMPLES:**

```python
sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)

sage: gp = GraphPaths(G)
(continues on next page)
```
sage: len(gp.paths())
37

>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
    →Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
    →Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> len(gp.paths())
37

paths_from_source_to_target (source, target)
Return a list of paths from source to target.

EXAMPLES:

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: gp = GraphPaths(G)
sage: gp.paths_from_source_to_target(2,4)
[[2, 3, 4], [2, 4]]

>>> from sage.all import *
>>>
G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
    →Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
    →Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> gp = GraphPaths(G)
>>> gp.paths_from_source_to_target(Integer(2),Integer(4))
[[2, 3, 4], [2, 4]]

class sage.combinat.graph_path.GraphPaths_s (g, source)
Bases: Parent, GraphPaths_common
list ()

EXAMPLES:

sage: G = DiGraph({1:[2,2,3], 2:[3,4], 3:[4], 4:[5,5]}, multiedges=True)
sage: p = GraphPaths(G, 4)
sage: p.list()
[[4], [4, 5], [4, 5]]

>>> from sage.all import *
>>> G = DiGraph({Integer(1):[Integer(2),Integer(2),Integer(3)],
    →Integer(2):[Integer(3),Integer(4)], Integer(3):[Integer(4)],
    →Integer(4):[Integer(5),Integer(5)]}, multiedges=True)
>>> p = GraphPaths(G, Integer(4))
>>> p.list()

 [1, 2, 3, 4]]

5.1.117 Gray codes

Functions

sage.combinat.gray_codes.combinations(n, t)

Iterator through the switches of the revolving door algorithm.

The revolving door algorithm is a way to generate all combinations of a set (i.e. the subset of given cardinality) in such way that two consecutive subsets differ by one element. At each step, the iterator output a pair \((i, j)\) where the item \(i\) has to be removed and \(j\) has to be added.

The ground set is always \(\{0, 1, \ldots, n - 1\}\). Note that \(n\) can be infinity in that algorithm.

See [Knu2011] Section 7.2.1.3, “Generating All Combinations”.

INPUT:
- \( n \) – (integer or \( \text{Infinity} \)) – size of the ground set
- \( t \) – (integer) – size of the subsets

**EXAMPLES:**

```python
sage: from sage.combinat.gray_codes import combinations
sage: b = [1, 1, 1, 0, 0]
sage: for i, j in combinations(5, 3):
    ....:     b[i] = 0; b[j] = 1
    ....:     print(b)
[1, 0, 1, 1, 0]
[0, 1, 1, 1, 0]
[1, 1, 0, 1, 0]
[1, 0, 0, 1, 1]
[0, 1, 0, 1, 1]
[0, 0, 1, 1, 1]
[1, 0, 1, 0, 1]
[0, 1, 1, 0, 1]
[1, 1, 0, 0, 1]

sage: s = set([0, 1])
sage: for i, j in combinations(4, 2):
    ....:     s.remove(i)
    ....:     s.add(j)
    ....:     print(sorted(s))
[1, 2]
[0, 2]
[2, 3]
[1, 3]
[0, 3]
```

```python
>>> from sage.all import *
>>> from sage.combinat.gray_codes import combinations

>>> b = [Integer(1), Integer(1), Integer(1), Integer(0), Integer(0)]
>>> for i, j in combinations(Integer(5), Integer(3)):
...     b[i] = Integer(0); b[j] = Integer(1)
...     print(b)
[1, 0, 1, 1, 0]
[0, 1, 1, 1, 0]
[1, 1, 0, 1, 0]
[1, 0, 0, 1, 1]
[0, 1, 0, 1, 1]
[0, 0, 1, 1, 1]
[1, 0, 1, 0, 1]
[0, 1, 1, 0, 1]
[1, 1, 0, 0, 1]

>>> s = set([Integer(0), Integer(1)])
>>> for i, j in combinations(Integer(4), Integer(2)):
...     s.remove(i)
...     s.add(j)
...     print(sorted(s))
[1, 2]
[0, 2]
[2, 3]
[1, 3]
[0, 3]
```
Note that $n$ can be infinity:

```python
sage: c = combinations(Infinity, 4)
sage: s = set([0, 1, 2, 3])
sage: for _ in range(10):
    ....:    i, j = next(c)
    ....:    s.remove(i); s.add(j)
    ....:    print(sorted(s))
[0, 1, 3, 4]
[1, 2, 3, 4]
[0, 2, 3, 4]
[0, 1, 2, 4]
[0, 1, 4, 5]
[1, 2, 4, 5]
[0, 2, 4, 5]
[2, 3, 4, 5]
[1, 3, 4, 5]
[0, 3, 4, 5]
sage: for _ in range(1000):
    ....:    i, j = next(c)
    ....:    s.remove(i); s.add(j)
sage: sorted(s)
[0, 4, 13, 14]
```

```python
>>> from sage.all import *
>>> c = combinations(Infinity, Integer(4))
>>> s = set([Integer(0), Integer(1), Integer(2), Integer(3)])
>>> for _ in range(Integer(10)):
    ...    i, j = next(c)
    ...    s.remove(i); s.add(j)
    ...    print(sorted(s))
[0, 1, 3, 4]
[1, 2, 3, 4]
[0, 2, 3, 4]
[0, 1, 2, 4]
[0, 1, 4, 5]
[1, 2, 4, 5]
[0, 2, 4, 5]
[2, 3, 4, 5]
[1, 3, 4, 5]
[0, 3, 4, 5]
>>> for _ in range(Integer(1000)):
    ...    i, j = next(c)
    ...    s.remove(i); s.add(j)
>>> sorted(s)
[0, 4, 13, 14]
```

`sage.combinat.gray_codes.product(m)`

Iterator over the switch for the iteration of the product $[m_0] \times [m_1] \times \cdots \times [m_k]$.

The iterator return at each step a pair $(p, i)$ which corresponds to the modification to perform to get the next element. More precisely, one has to apply the increment $i$ at the position $p$. By construction, the increment is either $+1$ or $-1$.

This is algorithm H in [Knu2011] Section 7.2.1.1, “Generating All $n$-Tuples”: loopless reflected mixed-radix Gray generation.

**INPUT:**
• \( m \) – a list or tuple of positive integers that correspond to the size of the sets in the product

**EXAMPLES:**

```python
sage: from sage.combinat.gray_codes import product
sage: l = [0,0,0]

sage: for p, i in product([3,3,3]):
    ....:     l[p] += i
    ....:     print(l)

[1, 0, 0]
[2, 0, 0]
[2, 1, 0]
[1, 1, 0]
[0, 1, 0]
[0, 2, 0]

5.1.118 Growth diagrams and dual graded graphs

AUTHORS:

- Martin Rubey (2016-09): Initial version
- Martin Rubey (2017-09): generalize, more rules, improve documentation
- Travis Scrimshaw (2017-09): switch to rule-based framework

Todo:

- provide examples for the P and Q-symbol in the skew case
- implement a method providing a visualization of the growth diagram with all labels, perhaps as LaTeX code
- when shape is given, check that it is compatible with filling or labels
- optimize rules, mainly for RuleRSK and RuleBurge
- implement backward rules for GrowthDiagram.rules.Domino
- implement backward rule from [LLMSSZ2013], [LS2007]
- make semistandard extension generic
- accommodate dual filtered graphs
A guided tour

Growth diagrams, invented by Sergey Fomin [Fom1994], [Fom1995], provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with non-negative integer entries and pairs of semi-standard Young tableaux of the same shape.

The main fact is that many correspondences similar to RSK can be defined by providing a pair of so-called local rules: a ‘forward’ rule, whose input are three vertices $y$, $t$ and $x$ of a certain directed graph (in the case of Robinson-Schensted: the directed graph corresponding to Young’s lattice) and an integer (in the case of Robinson-Schensted: 0 or 1), and whose output is a fourth vertex $z$. This rule should be invertible in the following sense: there is a so-called ‘backward’ rule that recovers the integer and $t$ given $y$, $z$ and $x$.

As an example, the growth rules for the classical RSK correspondence are provided by $\text{RuleRSK}$. To produce a growth diagram, pass the desired rule and a permutation to $\text{GrowthDiagram}$:

```sage
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: w = [2,3,6,1,4,5]; G = GrowthDiagram(RuleRSK, w); G
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 0 1 0
0 0 0 0 0 1
0 0 1 0 0 0
```

The forward rule just mentioned assigns 49 partitions to the corners of each of the 36 cells of this matrix (i.e., 49 the vertices of a $(6 + 1) \times (6 + 1)$ grid graph), with the exception of the corners on the left and top boundary, which are initialized with the empty partition. More precisely, for each cell, the $\text{forward_rule()}$ computes the partition $z$ labelling the lower right corner, given the content $c$ of a cell and the other three partitions:

```
t --- x
| c |
y --- z
```

**Warning:** Note that a growth diagram is printed with matrix coordinates, the origin being in the top-left corner. Therefore, the growth is from the top left to the bottom right!

The partitions along the boundary opposite of the origin, reading from the bottom left to the top right, are obtained by using the method $\text{out_labels()}$:

```sage
sage: G.out_labels()
[[],
 [1],
 [2],
 [3],
```
However, in the case of a rectangular filling, it is more practical to split this sequence of labels in two. Interpreting the sequence of partitions along the right boundary as a standard Young tableau, we then obtain the so-called \( P\text{-symbol}() \), the partitions along the bottom boundary yield the so-called \( Q\text{-symbol}() \). These coincide with the output of the classical \( RSK() \) insertion algorithm:

```python
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 3 4 5 1 2 3 6 ]
[ 2 6 , 4 5 ]
sage: ascii_art(RSK(w))
[ 1 3 4 5 1 2 3 6 ]
[ 2 6 , 4 5 ]
```

The filling can be recovered knowing the partitions labelling the corners of the bottom and the right boundary alone, by repeatedly applying the `backward_rule()`. Therefore, to initialize a `GrowthDiagram`, we can provide these labels instead of the filling:

```python
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 0 1 0
```

(continues on next page)
Invocation

In general, growth diagrams are defined for $0 - 1$-fillings of arbitrary skew shapes. In the case of the Robinson-Schensted-Knuth correspondence, even arbitrary non-negative integers are allowed. In other cases, entries may be either zero or an $r$-th root of unity - for example, RuleDomino insertion is defined for signed permutations, that is, $r = 2$. Traditionally, words and permutations are also used to specify a filling in special cases.

To accommodate all this, the filling may be passed in various ways. The most general possibility is to pass a dictionary of coordinates to (signed) entries, where zeros can be omitted. In this case, when the parameter shape is not explicitly specified, it is assumed to be the minimal rectangle containing the origin and all coordinates with non-zero entries.

For example, consider the following generalized permutation:

\[
\begin{array}{cccccc}
1 & 2 & 2 & 2 & 4 & 4 \\
4 & 2 & 3 & 3 & 2 & 3 \\
\end{array}
\]

that we encode as the dictionary:

```
\documentclass{article}
\usepackage{amsmath, amsthm, amssymb, graphicx}
\begin{document}
\section{Combinatorics, Release 10.4}

\begin{verbatim}
>>> from sage.all import *

>>> GrowthDiagram(RuleRSK, labels=G.out_labels())
\end{verbatim}
```

```
\begin{verbatim}
0 0 0 1 0 0
1 0 0 0 0 0
0 1 0 0 0 0
0 0 0 1 0
0 0 0 0 0 1
0 0 1 0 0 0
\end{verbatim}
```

```
\begin{verbatim}
0 1 0 0 0 0
1 0 0 0 0 0
0 0 0 1 0
0 0 0 0 0 1
0 0 1 0 0 0
\end{verbatim}
```

```
\begin{verbatim}
>>> from sage.all import *

>>> GrowthDiagram(RuleRSK, P)
\end{verbatim}
```

```
\begin{verbatim}
0 0 0 0
0 1 0 1
0 2 0 1
1 0 0 0
\end{verbatim}
```

Alternative, we could create the same growth diagram using a matrix.
Let us also mention that one can pass the arguments specifying a growth diagram directly to the rule:

```sage
sage: RuleRSK(P)
0 0 0 0
0 1 0 1
0 2 0 1
1 0 0 0
```

In contrast to the classical insertion algorithms, growth diagrams immediately generalize to fillings whose shape is an arbitrary skew partition:

```sage
sage: GrowthDiagram(RuleRSK, [3,1,2], shape=SkewPartition([[3,3,2],[1,1]]))
. 1 0
. 0 1
1 0
```

As an important example, consider the Stanley-Sundaram correspondence between oscillating tableaux and (partial) perfect matchings. Perfect matchings of \(\{1, \ldots, 2r\}\) are in bijection with \(0−1\)-fillings of a triangular shape with \(2r−1\) rows, such that for each \(k\) there is either exactly one non-zero entry in row \(k\) or exactly one non-zero entry in column \(2r−k\). Explicitly, if \((i, j)\) is a pair in the perfect matching, the entry in column \(i−1\) and row \(2r−j\) equals 1. For example:

```sage
sage: m = [[1,5],[3,4],[2,7],[6,8]]
sage: G = RuleRSK({(i-1, 8-j): 1 for i,j in m}, shape=[7,6,5,4,3,2,1]); G
0 0 0 0 1 0
0 1 0 0 0 0
0 0 0 0 0
1 0 0 0
0 0 1
0 0
0
```

(continues on next page)
The partitions labelling the bottom-right corners along the boundary opposite of the origin then form a so-called oscillating tableau - the remaining partitions along the bottom-right boundary are redundant:

```python
sage: G.out_labels()[1::2]
[[1], [1, 1], [2, 1], [1, 1], [1], [1, 1], [1]]
```

Another great advantage of growth diagrams is that we immediately have access to a skew version of the correspondence, by providing different initialization for the labels on the side of the origin. We reproduce the original example of Bruce Sagan and Richard Stanley, see also Tom Roby's thesis [Rob1991]:

```python
sage: w = {(1-1,4-1): 1, (2-1,2-1): 1, (4-1,3-1): 1}
sage: T = SkewTableau([None, None], [None, 5], [1])
sage: U = SkewTableau([None, None], [None, 3], [5])
sage: labels = T.to_chain()[:-1] + U.to_chain()[1:]
sage: G = GrowthDiagram(RuleRSK, filling=w, shape=[5,5,5,5,5], labels=labels); G
```

```plaintext
0 0 0 0 0
0 1 0 0 0
0 0 0 1 0
1 0 0 0 0
0 0 0 0 0
```

```python
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ . . 2 3 . . 1 4 ]
[ . . . . ]
[ . 4 . 2 ]
[ 1 3 ]
[ 5 , 5 ]
```

```python
>>> from sage.all import *

>>> w = {(Integer(1)-Integer(1),Integer(4)-Integer(1)): Integer(1), (Integer(2)-Integer(1),Integer(2)-Integer(1)): Integer(1), (Integer(4)-Integer(1),Integer(3)-Integer(1)): Integer(1)}

>>> T = SkewTableau([None, None], [None, Integer(5)], [Integer(1)])

>>> U = SkewTableau([None, None], [None, Integer(3)], [Integer(5)])

>>> labels = T.to_chain()[:-1] + U.to_chain()[1:]

>>> G = GrowthDiagram(RuleRSK, filling=w, shape=[Integer(5),Integer(5),Integer(5),Integer(5),Integer(5)], labels=labels); G

>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[ . . 2 3 . . 1 4 ]
[ . . . . ]
[ . 4 . 2 ]
[ 1 3 ]
[ 5 , 5 ]
```

1792 Chapter 5. Comprehensive Module List
Similarly, there is a correspondence for skew oscillating tableau. Let us conclude by reproducing Example 4.2.6 from [Rob1991]. The oscillating tableau, as given, is:

\[
\begin{align*}
\text{sage: } o &= \left[ \left[ 2,1 \right], \left[ 2,2 \right], \left[ 3,2 \right], \left[ 4,2 \right], \left[ 4,1 \right], \left[ 3,1,1 \right], \left[ 3,1 \right], \left[ 3,2 \right], \left[ 3,1 \right], \left[ 2,1 \right] \right] \\
\text{sage: } o &= \left[ \left[ \text{Integer}(2) \right], \left[ \text{Integer}(1) \right] \right], \left[ \text{Integer}(2) \right], \left[ \text{Integer}(2) \right], \left[ \text{Integer}(3) \right], \left[ \text{Integer}(2) \right], \\
&\quad \left[ \text{Integer}(4) \right], \left[ \text{Integer}(2) \right], \left[ \text{Integer}(4) \right], \left[ \text{Integer}(1) \right], \left[ \text{Integer}(4) \right], \left[ \text{Integer}(1) \right], \\
&\quad \left[ \text{Integer}(3) \right], \left[ \text{Integer}(1) \right], \left[ \text{Integer}(1) \right], \left[ \text{Integer}(3) \right], \left[ \text{Integer}(1) \right], \\
&\quad \left[ \text{Integer}(3) \right], \left[ \text{Integer}(1) \right] \right] \\
\end{align*}
\]

From this, we have to construct the list of labels of the corners along the bottom-right boundary. The labels with odd indices are given by the oscillating tableau, the other labels are obtained by taking the smaller of the two neighbouring partitions:

\[
\begin{align*}
\text{sage: } l &= \left[ o[i//2] \text{ if } \text{is_even}(i) \text{ else } \min(o[(i-1)//2],o[(i+1)//2]) \right] \\
\text{sage: } la &= \text{list(range(len(o)-2, 0, -1))} \\
\text{sage: } G &= \text{RuleRSK(labels=l[1:-1], shape=la)}; G \\
\text{sage: } l &= \left[ o[i//Integer(2)] \text{ if } \text{is_even}(i) \text{ else } \min(o[(i-Integer(1))//Integer(2)],o[(i+Integer(1))//Integer(2)]) \right] \\
\text{sage: } la &= \text{list(range(len(o)-Integer(2), Integer(0), -Integer(1)))} \\
\text{sage: } G &= \text{RuleRSK(labels=l[Integer(1):-Integer(1)], shape=la)}; G
\end{align*}
\]

The skew tableaux can now be read off the partitions labelling the left and the top boundary. These can be accessed using the method `in_labels()`:

\[
\begin{align*}
\text{sage: } \text{ascii_art(SkewTableau(chain=G.in_labels()[-2:]),}) \\
&\quad \text{ascii_art(SkewTableau(chain=G.in_labels()[-2:-1]),}) \\
\end{align*}
\]

(continues on next page)
Rules currently available

As mentioned at the beginning, the Robinson-Schensted-Knuth correspondence is just a special case of growth diagrams. In particular, we have implemented the following local rules:

- RSK (RuleRSK).
- A variation of RSK originally due to Burge (RuleBurge).
- A correspondence producing binary words originally due to Viennot (RuleBinaryWord).
- A correspondence producing domino tableaux (RuleDomino) originally due to Barbasch and Vogan.
- A correspondence for shifted shapes (RuleShiftedShapes), where the original insertion algorithm is due to Sagan and Worley, and Haiman.
- The Sylvester correspondence, producing binary trees (RuleSylvester).
- The Young-Fibonacci correspondence (RuleYoungFibonacci).
- LLMS insertion (RuleLLMS).

Background

At the heart of Fomin’s framework is the notion of dual graded graphs. This is a pair of digraphs $P, Q$ (multiple edges being allowed) on the same set of vertices $V$, that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \to \mathbb{N}$, such that for any edge $(v, w)$ of $P$ and also of $Q$ we have $\rho(w) = \rho(v) + 1$,
- there is a vertex 0 with rank zero, and
- there is a positive integer $r$ such that $DU = UD + rI$ on the free $\mathbb{Z}$-module $\mathbb{Z}[V]$, where $D$ is the down operator of $Q$, assigning to each vertex the formal sum of its predecessors, $U$ is the up operator of $P$, assigning to each vertex the formal sum of its successors, and $I$ is the identity operator.

Note that the condition $DU = UD + rI$ is symmetric with respect to the interchange of the graphs $P$ and $Q$, because the up operator of a graph is the transpose of its down operator.

For example, taking for both $P$ and $Q$ to be Young’s lattice and $r = 1$, we obtain the dual graded graphs for classical Schensted insertion.

Given such a pair of graphs, there is a bijection between the $r$-colored permutations on $k$ letters and pairs $(p, q)$, where $p$ is a path in $P$ from zero to a vertex of rank $k$ and $q$ is a path in $Q$ from zero to the same vertex.

It turns out that - in principle - this bijection can always be described by so-called local forward and backward rules, see [Fom1995] for a detailed description. Knowing at least the forward rules, or the backward rules, you can implement your own growth diagram class.
Implementing your own growth diagrams

The class `GrowthDiagram` is written so that it is easy to implement growth diagrams you come across in your research. Moreover, the class tolerates some deviations from Fomin’s definitions. For example, although the general Robinson-Schensted-Knuth correspondence between integer matrices and semistandard tableaux is, strictly speaking, not a growth on dual graded graphs, it is supported by our framework.

For illustration, let us implement a growth diagram class with the backward rule only. Suppose that the vertices of the graph are the non-negative integers, the rank is given by the integer itself, and the backward rule is \((y, z, x) \mapsto (\min(x, y), 0)\) if \(y = z\) or \(x = z\) and \((y, z, x) \mapsto (\min(x, y), 1)\) otherwise.

We first need to import the base class for a rule:

```python
from sage.combinat.growth import Rule
```

```python
from sage.all import *
```

```python
from sage.combinat.growth import Rule
```

Next, we implement the backward rule and the rank function and provide the bottom element `zero` of the graph. For more information, see `Rule`.

```python
class RulePascal(Rule):
    zero = 0
    def rank(self, v):
        return v
    def backward_rule(self, y, z, x):
        return (min(x, y), 0 if y==z or x==z else 1)
```

```python
from sage.all import *
```

```python
class RulePascal(Rule):
    zero = Integer(0)
    def rank(self, v):
        return v
    def backward_rule(self, y, z, x):
        return (min(x, y), Integer(0) if y==z or x==z else Integer(1))
```

We can now compute the filling corresponding to a sequence of labels as follows:

```python
GrowthDiagram(RulePascal(), labels=[0,1,2,1,2,1,0])
```

```python
1 0 0
0 0 1
0 1
```

```python
GrowthDiagram(RulePascal(), labels=[Integer(0),Integer(1),Integer(2),Integer(1),
                                        Integer(2),Integer(1),Integer(0)])
```

```python
1 0 0
0 0 1
0 1
```

Of course, since we have not provided the forward rule, we cannot compute the labels belonging to a filling:

```python
GrowthDiagram(RulePascal(), [3,1,2])
```

Traceback (most recent call last):
...
AttributeError: 'RulePascal' object has no attribute 'forward_rule'...
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> GrowthDiagram(RulePascal(), [Integer(3), Integer(1), Integer(2)])
Traceback (most recent call last):
...
AttributeError: 'RulePascal' object has no attribute 'forward_rule'
```

We now re-implement the rule where we provide the dual graded graphs:

```python
sage: class RulePascal(Rule):
    ...
    zero = 0
    ...
    def rank(self, v):
        return v
    ...
    def backward_rule(self, y, z, x):
        return (min(x, y), 0 if y==z or x==z else 1)
    ...
    def vertices(self, n):
        return [n]
    ...
    def is_P_edge(self, v, w):
        return w == v + 1
    ...
    def is_Q_edge(self, v, w):
        return w == v + 1
```

Are they really dual?

```python
sage: RulePascal()._check_duality(3)
Traceback (most recent call last):
...
ValueError: D U - U D differs from 1 I for vertex 3:
D U = [3]
U D + 1 I = [3, 3]
```

```python
>>> from sage.all import *
>>> RulePascal()._check_duality(Integer(3))
Traceback (most recent call last):
...
ValueError: D U - U D differs from 1 I for vertex 3:
D U = [3]
U D + 1 I = [3, 3]
```

With our current definition, duality fails - in fact, there are no dual graded graphs on the integers without multiple edges. Consequently, also the backward rule cannot work as `backward_rule` requires additional information (the edge labels as arguments).

Let us thus continue with the example from Section 4.7 of [Fom1995] instead, which defines dual graded graphs with multiple edges on the integers. The color `self.zero_edge`, which defaults to 0 is reserved for degenerate edges, but may be abused for the unique edge if one of the graphs has no multiple edges. For greater clarity in this example we set it to `None`:

```python
sage: class RulePascal(Rule):
    ....:     zero = 0
    ....:     has_multiple_edges = True
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
>>> class RulePascal(Rule):
... zero = Integer(0)
... has_multiple_edges = True
... zero_edge = None
... def rank(self, v): return v
... def vertices(self, n): return [n]
... def is_P_edge(self, v, w): return [0] if w == v + 1 else []
... def is_Q_edge(self, v, w): return list(range(w)) if w == v+1 else []
```

We verify these are 1 dual at level 5:

```python
sage: RulePascal()._check_duality(5)
```

Finally, let us provide the backward rule. The arguments of the rule are vertices together with the edge labels now, specifying the path from the lower left to the upper right of the cell. The horizontal edges come from $Q$, whereas the vertical edges come from $P$.

Thus, the definition in Section 4.7 of [Fom1995] translates as follows:

```python
sage: class RulePascal(Rule):
... zero = 0
... has_multiple_edges = True
... zero_edge = None
... def rank(self, v): return v
... def vertices(self, n): return [n]
... def is_P_edge(self, v, w): return [Integer(0)] if w == v + Integer(1) else []
... def is_Q_edge(self, v, w): return list(range(w)) if w == v+Integer(1) else []
... def backward_rule(self, y, g, z, h, x):
... if g is None:
... return (0, x, None, 0)
... if h is None:
... return (None, y, g, 0)
... if g == 0:
... return (None, y, None, 1)
... else:
... return (0, x-1, g-1, 0)
```

(continues on next page)
def backward_rule(self, y, g, z, h, x):
    if g is None:
        return (Integer(0), x, None, Integer(0))
    if h is None:
        return (None, y, g, Integer(0))
    if g == Integer(0):
        return (None, y, None, Integer(1))
    else:
        return (Integer(0), x-Integer(1), g-Integer(1), Integer(0))

The labels are now alternating between vertices and edge-colors:

sage: GrowthDiagram(RulePascal(), labels=[0,0,1,0,2,0,1,0,0])
1 0
0 1

sage: GrowthDiagram(RulePascal(), labels=[0,0,1,1,2,0,1,0,0])
0 1
1 0

>>> from sage.all import *

>>> GrowthDiagram(RulePascal(), labels=[Integer(0),Integer(0),Integer(1),Integer(0),
 →Integer(2),Integer(0),Integer(1),Integer(0),Integer(0)])
1 0
0 1

>>> GrowthDiagram(RulePascal(), labels=[Integer(0),Integer(0),Integer(1),Integer(1),
 →Integer(2),Integer(0),Integer(1),Integer(0),Integer(0)])
0 1
1 0

class sage.combinat.growth.GrowthDiagram (rule, filling=None, shape=None, labels=None)

Bases: SageObject

A generalized Schensted growth diagram in the sense of Fomin.

Growth diagrams were introduced by Sergey Fomin [Fom1994], [Fom1995] and provide a vast generalization of the Robinson-Schensted-Knuth (RSK) correspondence between matrices with non-negative integer entries and pairs of semistandard Young tableaux of the same shape.

A growth diagram is based on the notion of dual graded graphs, a pair of digraphs $P,Q$ (multiple edges being allowed) on the same set of vertices $V$, that satisfy the following conditions:

- the graphs are graded, that is, there is a function $\rho : V \to \mathbb{N}$, such that for any edge $(v, w)$ of $P$ and also of $Q$ we have $\rho(w) = \rho(v) + 1$.
- there is a vertex $0$ with rank zero, and
- there is a positive integer $r$ such that $DU = UD + rI$ on the free $\mathbb{Z}$-module $\mathbb{Z}[V]$, where $D$ is the down operator of $Q$, assigning to each vertex the formal sum of its predecessors, $U$ is the up operator of $P$, assigning to each vertex the formal sum of its successors, and $I$ is the identity operator.

Growth diagrams are defined by providing a pair of local rules: a ‘forward’ rule, whose input are three vertices $y, t$ and $x$ of the dual graded graphs and an integer, and whose output is a fourth vertex $z$. This rule should be invertible in the following sense: there is a so-called ‘backward’ rule that recovers the integer and $t$ given $y, z$ and $x$.

All implemented growth diagram rules are available by GrowthDiagram.rules.<tab>. The current list is:

- RuleRSK – RSK
• **RuleBurge** – a variation of RSK originally due to Burge

• **RuleBinaryWord** – a correspondence producing binary words originally due to Viennot

• **RuleDomino** – a correspondence producing domino tableaux originally due to Barbasch and Vogan

• **RuleShiftedShapes** – a correspondence for shifted shapes, where the original insertion algorithm is due to Sagan and Worley, and Haiman.

• **RuleSylvester** – the Sylvester correspondence, producing binary trees

• **RuleYoungFibonacci** – the Young-Fibonacci correspondence

• **RuleLLMS** – LLMS insertion

**INPUT:**

- **rule** – *Rule*; the growth diagram rule
- **filling** – (optional) a dictionary whose keys are coordinates and values are integers, a list of lists of integers, or a word with integer values; if a word, then negative letters but without repetitions are allowed and interpreted as coloured permutations
- **shape** – (optional) a (possibly skew) partition
- **labels** – (optional) a list that specifies a path whose length in the half-perimeter of the shape; more details given below

If **filling** is not given, then the growth diagram is determined by applying the backward rule to **labels** decorating the boundary opposite of the origin of the **shape**. In this case, **labels** are interpreted as labelling the boundary opposite of the origin.

Otherwise, **shape** is inferred from **filling** or **labels** if possible and **labels** is set to **rule.zero** if not specified. Here, **labels** are labelling the boundary on the side of the origin.

For **labels**, if **rule.has_multiple_edges** is True, then the elements should be of the form $(v_1, e_1, \ldots, e_{n-1}, v_n)$, where $n$ is the half-perimeter of **shape**, and $(v_i, e_i, v_i)$ is an edge in the dual graded graph for all $i$. Otherwise, it is a list of $n$ vertices.

**Note:** Coordinates are of the form (col, row) where the origin is in the upper left, to be consistent with permutation matrices and skew tableaux (in English convention). This is different from Fomin’s convention, who uses a Cartesian coordinate system.

Conventions are chosen such that for permutations, the same growth diagram is constructed when passing the permutation matrix instead.

**EXAMPLES:**

We create a growth diagram using the forward RSK rule and a permutation:

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: pi = Permutation([4, 1, 2, 3])
sage: G = GrowthDiagram(RuleRSK, pi); G
GrowthDiagram(RuleRSK, Permutation([4, 1, 2, 3]))

sage: G.out_labels()
[[0, 1, 0, 0]
 [0, 1, 1, 1]
 [0, 2, 1, 1]
 [1, 0, 0, 0]

sage: G.out_labels()
[[[], [1], [1, 1], [2, 1], [3, 1], [3], [2], [1], []]]
```
```
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> pi = Permutation([Integer(4), Integer(1), Integer(2), Integer(3)])
>>> G = GrowthDiagram(RuleRSK, pi); G
0 1 0 0
0 0 1 0
0 0 0 1
1 0 0 0
>>> G.out_labels()
[[], [1], [1, 1], [2, 1], [3, 1], [3], [2], [1], []]
```

Passing the permutation matrix instead gives the same result:

```
sage: G = GrowthDiagram(RuleRSK, pi.to_matrix())
#...
˓→ needs sage.modules
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
#...
˓→ needs sage.modules
[ 1 2 3 1 3 4 ]
[ 4 , 2 ]
```

We give the same example but using a skew shape:

```
sage: shape = SkewPartition([[4,4,4,2],[1,1]])
sage: G = GrowthDiagram(RuleRSK, pi, shape=shape); G
 . 1 0 0
 . 0 1 0
0 0 0 1
1 0
sage: G.out_labels()
[[], [1], [1, 1], [1], [2], [3], [2], [1], []]
```

We construct a growth diagram using the backwards RSK rule by specifying the labels:

```
sage: GrowthDiagram(RuleRSK, labels=G.out_labels())
0 1 0 0
0 0 1 0
0 0 0 1
1 0
```
P_chain()

Return the labels along the vertical boundary of a rectangular growth diagram.

EXAMPLES:

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [4, 1, 2, 3])
sage: G.P_chain()
[word: , word: 1, word: 11, word: 111, word: 1011]
```

Check that Issue #25631 is fixed:

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).P_chain()
[word: ]
```

Q_chain()

Return the labels along the horizontal boundary of a rectangular growth diagram.

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 2 1 3 3 ]
[ 2 , 2 ]
```
EXAMPLES:

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: G = GrowthDiagram(BinaryWord, [[0,1,0,0], [0,0,1,0], [0,0,0,1], [1,0,0,1]])
sage: G.Q_chain()
[word: , word: 1, word: 10, word: 101, word: 1011]
```

```python
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> G = GrowthDiagram(BinaryWord, [[Integer(0),Integer(1),Integer(0), Integer(0)], [Integer(0),Integer(0),Integer(1),Integer(0)], [Integer(0), Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0),Integer(0), Integer(0)]])
>>> G.Q_chain()
[word: , word: 1, word: 10, word: 101, word: 1011]
```

Check that Issue #25631 is fixed:

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord(filling = {}).Q_chain()
[word: ]
```

```python
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord(filling = {}).Q_chain()
[word: ]
```

Q_symbol()  
Return the labels along the horizontal boundary of a rectangular growth diagram as a generalized standard tableau.

EXAMPLES:

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 2 1 3 3 ]
[ 2 , 2 ]
```

```python
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0),Integer(2)]]
>>> ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 2 1 3 3 ]
[ 2 , 2 ]
```

conjugate()  
Return the conjugate growth diagram of self.

This is the growth diagram with the filling reflected over the main diagonal.

The sequence of labels along the boundary on the side of the origin is the reversal of the corresponding sequence of the original growth diagram.

When the filling is a permutation, the conjugate filling corresponds to its inverse.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.conjugate()
sage: (Gc.P_symbol(), Gc.Q_symbol()) == (G.Q_symbol(), G.P_symbol())
True

>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],
    →[Integer(1),Integer(0),Integer(2)]])
>>> Gc = G.conjugate()
>>> (Gc.P_symbol(), Gc.Q_symbol()) == (G.Q_symbol(), G.P_symbol())
True
```

**filling()**

Return the filling of the diagram as a dictionary.

**EXAMPLES:**

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: G.filling()
{(0, 1): 1, (1, 0): 1, (2, 1): 2}

>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, [[Integer(0),Integer(1),Integer(0)],
    →[Integer(1),Integer(0),Integer(2)]])
>>> G.filling()
{(0, 1): 1, (1, 0): 1, (2, 1): 2}
```

**half_perimeter()**

Return half the perimeter of the shape of the growth diagram.

**in_labels()**

Return the labels along the boundary on the side of the origin.

**EXAMPLES:**

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, labels=[[2,2],[3,2],[3,3],[3,2]]); G
1 0
sage: G.in_labels()
[[2, 2], [2, 2], [2, 2], [3, 2]]

>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = GrowthDiagram(RuleRSK, labels=[[Integer(2),Integer(2)],[Integer(3),
    →Integer(2)],[Integer(3),Integer(3)],[Integer(3),Integer(2)]]); G
1 0
>>> G.in_labels()
[[2, 2], [2, 2], [2, 2], [3, 2]]
```

**is_rectangular()**

Return True if the shape of the growth diagram is rectangular.

**EXAMPLES:**
The rotate() function allows for 180-degree rotation of the growth diagram. This can be useful for visualizing the diagram from different perspectives. For RSK growth diagrams and rectangular fillings, this corresponds to the evacuation of the $P$- and $Q$-symbols.

**Examples:**

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = GrowthDiagram(RuleRSK, [[0,1,0], [1,0,2]])
sage: Gc = G.rotate()
sage: ascii_art([Gc.P_symbol(), Gc.Q_symbol()])
[ 1 1 1 1 1 2 ]
[ 2 , 3 ]
sage: ascii_art([Tableau(t).evacuation() for t in [G.P_symbol(), G.Q_symbol()]])
[ 1 1 1 1 1 2 ]
[ 2 , 3 ]
```
rules
alias of Rules

shape()
Return the shape of the growth diagram as a skew partition.

Warning: In the literature the label on the corner opposite of the origin of a rectangular filling is often called the shape of the filling. This method returns the shape of the region instead.

EXAMPLES:

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [1]).shape()
[1] / []

from sage.all import *

>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> GrowthDiagram(RuleRSK, [Integer(1)]).shape()
[1] / []

to_biword()
Return the filling as a biword, if the shape is rectangular.

EXAMPLES:

sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: P = Tableau([[1,2,2],[2]])
sage: Q = Tableau([[1,3,3],[2]])
sage: bw = RSK_inverse(P, Q); bw
[[1, 2, 2, 2], [2, 1, 2, 2]]
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-1]+P.to_chain()[::-1])
→ G
0 1 0
1 0 2

sage: P = SemistandardTableau([[1, 1, 2], [2]])
sage: Q = SemistandardTableau([[1, 2, 2], [2]])
sage: G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-1]+P.to_chain()[::-1])
→ G
0 2
1 1
sage: G.to_biword()
([(1, 2, 2, 2), [2, 1, 1, 2])
sage: RSK([1, 2, 2, 2], [2, 1, 1, 2])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]

```python
>>> from sage.all import *

>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> P = Tableau([[Integer(1), Integer(2), Integer(2)], [Integer(2)]]
>>> Q = Tableau([[Integer(1), Integer(3), Integer(3)], [Integer(2)]]
>>> bw = RSK_inverse(P, Q); bw
[[[1, 2, 3, 3], [2, 1, 2, 2]]

>>> G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-Integer(1)]+P.to_
    →chain()[:-Integer(1)]); G
0 1 0
1 0 2

>>> P = SemistandardTableau([[Integer(1), Integer(1), Integer(2)],
    →[Integer(2)]]
>>> Q = SemistandardTableau([[Integer(1), Integer(2), Integer(2)],
    →[Integer(2)]]
>>> G = GrowthDiagram(RuleRSK, labels=Q.to_chain()[:-Integer(1)]+P.to_
    →chain()[:-Integer(1)]); G
0 2
1 1

>>> G.to_biword()
([[1, 2, 2, 2], [2, 1, 1, 2]])

>>> RSK([Integer(1), Integer(2), Integer(2), Integer(2)], [Integer(2),
    →Integer(1), Integer(1), Integer(2)])
[[[1, 1, 2], [2]], [[1, 2, 2], [2]]]
```
**Bases:** UniqueRepresentation

Generic base class for a rule for a growth diagram.

Subclasses may provide the following attributes:

- **zero** – the zero element of the vertices of the graphs
- **r** – (default: 1) the parameter in the equation $DU - UD = rI$
- **has_multiple_edges** – (default: False) if the dual graded graph has multiple edges and therefore edges are triples consisting of two vertices and a label.
- **zero_edge** – (default: 0) the zero label of the edges of the graphs used for degenerate edges. It is allowed to use this label also for other edges.

Subclasses may provide the following methods:

- **normalize_vertex** – a function that converts its input to a vertex.
- **vertices** – a function that takes a non-negative integer as input and returns the list of vertices on this rank.
- **rank** – the rank function of the dual graded graphs.
- **forward_rule** – a function with input $(y, t, x, content)$ or $(y, e, t, f, x, content)$ if `has_multiple_edges` is True. $(y, e, t)$ is an edge in the graph $P$, $(t, f, x)$ an edge in the graph $Q$. It should return the fourth vertex $z$, or, if `has_multiple_edges` is True, the path $(g, z, h)$ from $y$ to $x$.
- **backward_rule** – a function with input $(y, z, x)$ or $(y, g, z, h, x)$ if `has_multiple_edges` is True. $(y, g, z)$ is an edge in the graph $Q$, $(z, h, x)$ an edge in the graph $P$. It should return the fourth vertex and the content $(t, content)$, or, if `has_multiple_edges` is True, the path from $y$ to $x$ and the content as $(e, t, f, content)$.
- **is_P_edge, is_Q_edge** – functions that take two vertices as arguments and return True or False, or, if multiple edges are allowed, the list of edge labels of the edges from the first vertex to the second in the respective graded graph. These are only used for checking user input and providing the dual graded graph, and are therefore not mandatory.

Note that the class `GrowthDiagram` is able to use partially implemented subclasses just fine. Suppose that `MyRule` is such a subclass. Then:

- `GrowthDiagram(MyRule, my_filling)` requires only an implementation of `forward_rule`, `zero` and possibly `has_multiple_edges`.
- `GrowthDiagram(MyRule, labels=my_labels, shape=my_shape)` requires only an implementation of `backward_rule` and possibly `has_multiple_edges`, provided that the labels `my_labels` are given as needed by `backward_rule`.
- `GrowthDiagram(MyRule, labels=my_labels)` additionally needs an implementation of `rank` to deduce the shape.

In particular, this allows to implement rules which do not quite fit Fomin’s notion of dual graded graphs. An example would be Bloom and Saracino’s variant of the RSK correspondence [BS2012], where a backward rule is not available.

Similarly:

- `MyRule.P_graph` only requires an implementation of `vertices`, `is_P_edge` and possibly `has_multiple_edges` is required, mutatis mutandis for `MyRule.Q_graph`.
- `MyRule._check_duality` requires `P_graph` and `Q_graph`.

In particular, this allows to work with dual graded graphs without local rules.
P_graph \( (n) \)

Return the first \( n \) levels of the first dual graded graph.

The non-degenerate edges in the vertical direction come from this graph.

EXAMPLES:

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.P_graph(3)
Finite poset containing 8 elements
```

Q_graph \( (n) \)

Return the first \( n \) levels of the second dual graded graph.

The non-degenerate edges in the horizontal direction come from this graph.

EXAMPLES:

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: Q = Domino.Q_graph(3); Q
Finite poset containing 8 elements
sage: Q.upper_covers(Partition([1,1]))
[[1, 1, 1, 1], [3, 1], [2, 2]]
```

has_multiple_edges = False

normalize_vertex \( (v) \)

Return \( v \) as a vertex of the dual graded graph.

This is a default implementation, returning its argument.

EXAMPLES:

```python
sage: from sage.combinat.growth import Rule
sage: Rule().normalize_vertex("hello") == "hello"
True
```

\( r = 1 \)
The vertices of the dual graded graph are binary words:

sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]

Note that, instead of passing the rule to `GrowthDiagram`, we can also use call the rule to create growth diagrams. For example:

sage: BinaryWord([2,4,1,3]).P_chain()
[word: , word: 1, word: 10, word: 101, word: 1101]
sage: BinaryWord([2,4,1,3]).Q_chain()
[word: , word: 1, word: 11, word: 110, word: 1101]

The Kleitman Greene invariant is the descent word, encoded by the positions of the zeros:

sage: pi = Permutation([4,1,8,3,6,5,2,7,9])
sage: G = BinaryWord(pi); G
0 1 0 0 0 0 0 0 0
0 0 0 0 0 0 1 0 0
0 0 0 1 0 0 0 0 0
1 0 0 0 0 0 0 0 0
0 0 0 0 0 1 0 0 0
0 0 0 0 1 0 0 0 0
0 0 0 0 0 0 0 1 0
0 0 1 0 0 0 0 0 0

(continues on next page)
backward_rule(y, z, x)

Return the content and the input shape.

• y, z, x – three binary words from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:

A pair (t, content) consisting of the shape of the fourth word and the content of the cell according to Viennot's bijection [Vie1983].

forward_rule(y, t, x, content)

Return the output shape given three shapes and the content.

INPUT:

• y, t, x – three binary words from a cell in a growth diagram, labelled as:

```
t x
y
```

• content – 0 or 1; the content of the cell

OUTPUT:

The fourth binary word z according to Viennot's bijection [Vie1983].

EXAMPLES:

```
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.forward_rule([], [], [], 1)
word: 1
```
sage: BinaryWord.forward_rule([1], [1], [1], 1)
word: 11

>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.forward_rule([], [], [], Integer(1))
word: 1
>>> BinaryWord.forward_rule([Integer(1)], [Integer(1)], [Integer(1)],...
    → Integer(1))
word: 11

if $x \neq y$ append last letter of $x$ to $y$:

sage: BinaryWord.forward_rule([1,0], [1], [1,1], 0)
word: 101

>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> v = BinaryWord.vertices(Integer(2))[Integer(1)]; v
word: 11
>>> [w for w in BinaryWord.vertices(Integer(3)) if BinaryWord.is_P_edge(v, w)]
[word: 101, word: 110, word: 111]

if $x == y \neq t$ append 0 to $y$:

sage: BinaryWord.forward_rule([1,1], [1], [1,1], 0)
word: 110

>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> v = BinaryWord.vertices(Integer(2))[Integer(1)]; v
word: 11
>>> BinaryWord.is_P_edge(v, w)

is_P_edge$(v, w)$

Return whether $(v, w)$ is a $P$-edge of self.

$(v, w)$ is an edge if $v$ is obtained from $w$ by deleting a letter.

EXAMPLES:

sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> v = BinaryWord.vertices(2)[1]; v
word: 11
>>> [w for w in BinaryWord.vertices(3) if BinaryWord.is_P_edge(v, w)]
[word: 101, word: 110, word: 111]
>>> [w for w in BinaryWord.vertices(4) if BinaryWord.is_P_edge(v, w)]
[]

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> [w for w in BinaryWord.vertices(Integer(4)) if BinaryWord.is_P_edge(v, w)]
[]
```

**is_Q_edge** *(v, w)*

Return whether *(v, w)* is a *Q*-edge of self.

*(w, v)* is an edge if *w* is obtained from *v* by appending a letter.

**EXAMPLES:**

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: v = BinaryWord.vertices(2)[0]; v
word: 10
sage: [w for w in BinaryWord.vertices(3) if BinaryWord.is_Q_edge(v, w)]
[word: 100, word: 101]
sage: [w for w in BinaryWord.vertices(4) if BinaryWord.is_Q_edge(v, w)]
[]
```

```python
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> v = BinaryWord.vertices(Integer(2))[Integer(0)]; v
word: 10
>>> [w for w in BinaryWord.vertices(Integer(3)) if BinaryWord.is_Q_edge(v, w)]
[word: 100, word: 101]
>>> [w for w in BinaryWord.vertices(Integer(4)) if BinaryWord.is_Q_edge(v, w)]
[]
```

**normalize_vertex** *(v)*

Return *v* as a binary word.

**EXAMPLES:**

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.normalize_vertex([0,1]).parent()
Finite words over {0, 1}
```

```python
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.normalize_vertex([Integer(0),Integer(1)]).parent()
Finite words over {0, 1}
```

**rank** *(v)*

Return the rank of *v*: number of letters of the word.

**EXAMPLES:**

```python
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.rank(BinaryWord.vertices(3)[0])
3
```

```python
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.rank(BinaryWord.vertices(Integer(3))[Integer(0)])
3
```
vertices$(n)$

Return the vertices of the dual graded graph on level $n$.

EXAMPLES:

```sage
sage: BinaryWord = GrowthDiagram.rules.BinaryWord()
sage: BinaryWord.vertices(3)
[word: 100, word: 101, word: 110, word: 111]
```

```python
>>> from sage.all import *
>>> BinaryWord = GrowthDiagram.rules.BinaryWord()
>>> BinaryWord.vertices(Integer(3))
[word: 100, word: 101, word: 110, word: 111]
```

The vertices of the dual graded graph are integer partitions:

```sage
sage: Burge = GrowthDiagram.rules.Burge()
sage: GrowthDiagram(Burge, labels=[[],[1,1,1],[2,1,1,1],[2,1,1],[2,1],[1,1],[]])
```

```python
>>> from sage.all import *
>>> Burge = GrowthDiagram.rules.Burge()
>>> GrowthDiagram(Burge, labels=[[],[Integer(1),Integer(1),Integer(1)],
  ➔[Integer(2),Integer(1),Integer(1),Integer(1)],[Integer(2),Integer(1),
  ➔Integer(1)],[Integer(2),Integer(1)],[Integer(1),Integer(1)],[]])
```

The local rules implemented provide Burge's correspondence between matrices with non-negative integer entries and pairs of semistandard tableaux, the $P_{\text{symbol}}()$ and the $Q_{\text{symbol}}()$. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams. For example:

```sage
sage: m = matrix([[2,0,0,1,0],[1,1,0,0,0],[0,0,0,0,3]])
sage: G = Burge(m); G
```

(continues on next page)
For rectangular fillings, the Kleitman-Greene invariant is the shape of the $P_{\text{symbol}}()$. Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the transpose of the partition $(\mu_1, \ldots, \mu_n)$, where $\mu_1 + \cdots + \mu_i$ is the maximal sum of entries in a collection of $i$ pairwise disjoint sequences of cells with weakly decreasing row indices and weakly increasing column indices.

**backward_rule** ($y, z, x$)

Return the content and the input shape.

See [Kra2006] ($B^40) - (B^42)$. (In the arXiv version of the article there is a typo: in the computation of carry in ($B^42), \rho$ must be replaced by $\lambda$).

**INPUT:**

- $y, z, x$ – three partitions from a cell in a growth diagram, labelled as:

```plaintext
  x
 y z
```

**OUTPUT:**

A pair $(t, \text{content})$ consisting of the shape of the fourth partition according to the Burge correspondence and the content of the cell.

**EXAMPLES:**

```python
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.backward_rule([1,1,1],[2,1,1,1],[2,1,1])
([1, 1], 0)
```

(continues on next page)
Burge.backward_rule([Integer(1), Integer(1), Integer(1)], [Integer(2), → Integer(1), Integer(1), Integer(1)], [Integer(2), Integer(1), Integer(1), Integer(1)])[([1, 1], 0)

**forward_rule** *(y, t, x, content)*

Return the output shape given three shapes and the content.

See [Kra2006] \((F^40) - (F^42)\).

**INPUT:**

- y, t, x – three from a cell in a growth diagram, labelled as:

  t x
  y

- content – a non-negative integer; the content of the cell

**OUTPUT:**

The fourth partition according to the Burge correspondence.

**EXAMPLES:**

```python
sage: Burge = GrowthDiagram.rules.Burge()
sage: Burge.forward_rule([2, 1], [2, 1], [2, 1], 1)
[3, 1]
sage: Burge.forward_rule([1], [], [2], 2)
[2, 1, 1, 1]
```

**class** `sage.combinat.growth.RuleDomino`

**Bases:** `Rule`

A rule modelling domino insertion.

**EXAMPLES:**

```python
sage: Domino = GrowthDiagram.rules.Domino()
sage: GrowthDiagram(Domino, [[1, 0, 0], [0, 0, 1], [0, -1, 0]])
1 0 0
0 0 1
0 -1 0

>>> from sage.all import *

>>> Domino = GrowthDiagram.rules.Domino()

>>> GrowthDiagram(Domino, [[Integer(1), Integer(0), Integer(0)], [Integer(0), → Integer(0), Integer(1)], [Integer(0), -Integer(1), Integer(0)]]))
1 0 0
```
The vertices of the dual graded graph are integer partitions whose Ferrers diagram can be tiled with dominoes:

```
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

Instead of passing the rule to `GrowthDiagram`, we can also call the rule to create growth diagrams. For example, let us check Figure 3 in [Lam2004]:

```
sage: G = Domino([[0,0,0,-1],[0,0,1,0],[-1,0,0,0],[0,1,0,0]]); G

0 0 0 -1
0 0 1 0
-1 0 0 0
0 1 0 0

sage: ascii_art([G.P_symbol(), G.Q_symbol()])
[ 1 2 4 1 2 2 ]
[ 1 2 4 1 3 3 ]
[ 3 3 , 4 4 ]
```

The spin of a domino tableau is half the number of vertical dominoes:

```
sage: def spin(T):
    ... return sum(2*len(set(row)) - len(row) for row in T)/4
```

According to [Lam2004], the number of negative entries in the signed permutation equals the sum of the spins of the two associated tableaux:

```
sage: pi = [3,-1,2,4,-5]
sage: G = Domino(pi)
sage: list(G.filling().values()).count(-1) == spin(G.P_symbol()) + spin(G.Q_symbol())
```
Negating all signs transposes all the partitions:

\[
\text{sage: } \text{G.P}\_\text{symbol}() == \text{Domino}([-e \text{ for } e \text{ in } \text{pi}]).\text{P}\_\text{symbol}().\text{conjugate}()
\]

\[
\text{True}
\]

### P\_symbol (P\_chain)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

**EXAMPLES:**

\[
\text{sage: } \text{Domino} = \text{GrowthDiagram.rules.Domino}()
\]

\[
\text{sage: } \text{G} = \text{Domino}([[0,1,0],[0,0,-1],[1,0,0]])
\]

\[
\text{sage: } \text{G.P}\_\text{symbol}().\text{pp}()
\]

\[
1 \\
2 3 \\
2 3
\]

### Q\_symbol (P\_chain)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) domino tableau.

**EXAMPLES:**

\[
\text{sage: } \text{Domino} = \text{GrowthDiagram.rules.Domino}()
\]

\[
\text{sage: } \text{G} = \text{Domino}([[\text{Integer}(0),\text{Integer}(1),\text{Integer}(0)],[\text{Integer}(0),\text{Integer}(0),-\text{Integer}(1)],[\text{Integer}(1),\text{Integer}(0),\text{Integer}(0)]])
\]

\[
\text{sage: } \text{G.P}\_\text{symbol}().\text{pp}()
\]

\[
1 \\
2 3 \\
2 3
\]

(continues on next page)
forward_rule (y, t, x, content)

Return the output shape given three shapes and the content.
See [Lam2004] Section 3.1.

INPUT:

• y, t, x – three partitions from a cell in a growth diagram, labelled as:

  t
  x
  y

• content = −1, 0 or 1; the content of the cell

OUTPUT:
The fourth partition according to domino insertion.

EXAMPLES:

sage: Domino = GrowthDiagram.rules.Domino()

>>> from sage.all import *

from sage.all import *

Domino = GrowthDiagram.rules.Domino()

Rule 1:

sage: Domino.forward_rule([], [], [], 1)

[2]

sage: Domino.forward_rule([1, 1], [1, 1], [1, 1], 1)

[3, 1]

>>> from sage.all import *

from sage.all import *

Domino.forward_rule([], [], [], Integer(1))

[2]

Domino.forward_rule([Integer(1), Integer(1)], [Integer(1), Integer(1)],
  [Integer(1), Integer(1)], Integer(1))

[3, 1]

Rule 2:

sage: Domino.forward_rule([1, 1], [1, 1], [1, 1], -1)

[1, 1, 1, 1]

>>> from sage.all import *

from sage.all import *

Domino.forward_rule([Integer(1), Integer(1)], [Integer(1), Integer(1)],
  [Integer(1), Integer(1)], -Integer(1))

[1, 1, 1, 1]

Rule 3:
```python
sage: Domino.forward_rule([1,1], [1,1], [2,2], 0)
[2, 2]

>>> from sage.all import *

>>> Domino.forward_rule([Integer(1),Integer(1)], [Integer(1),Integer(1)], → [Integer(2),Integer(2)], Integer(0))
[2, 2]

Rule 4:

```python
sage: Domino.forward_rule([2,2,2], [2,2], [3,3], 0)
[3, 3, 2]
sage: Domino.forward_rule([2], [], [1,1], 0)
[2, 2]
sage: Domino.forward_rule([1,1], [], [2], 0)
[2, 2]
sage: Domino.forward_rule([2], [], [2], 0)
[2, 2]
sage: Domino.forward_rule([4], [2], [4], 0)
[4, 2]
sage: Domino.forward_rule([1,1,1,1], [1,1], [1,1,1,1], 0)
[2, 2, 1, 1]
sage: Domino.forward_rule([2,1,1], [2], → [4], Integer(0))
[4, 1, 1]

>>> from sage.all import *

>>> Domino.forward_rule([Integer(2),Integer(2),Integer(2)], [Integer(2), → Integer(2)], [Integer(3),Integer(3)], Integer(0))
[3, 3, 2]

>>> Domino.forward_rule([Integer(2)], [], [Integer(1),Integer(1)], Integer(0))
[2, 2]
```

is_P_edge(v, w)
Return whether \((v, w)\) is a \(P\)-edge of self.

\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a domino.

EXAMPLES:

```plaintext
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
*** *

sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[ *** ]
[ * ]
[ ***** *** * ]
[ * , ***, * ]
sage: [w for w in Domino.vertices(4) if Domino.is_P_edge(v, w)]
[]
```

```

```plaintext
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> v = Domino.vertices(Integer(2))[Integer(1)]; ascii_art(v)
*** *

>>> ascii_art([w for w in Domino.vertices(Integer(3)) if Domino.is_P_edge(v, w)])
[ *** ]
[ * ]
[ ***** *** * ]
[ * , ***, * ]

>>> [w for w in Domino.vertices(Integer(4)) if Domino.is_P_edge(v, w)]
[]
```

is_Q_edge \((v, w)\)

Return whether \((v, w)\) is a \(P\)-edge of self.

\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a domino.

EXAMPLES:

```plaintext
sage: Domino = GrowthDiagram.rules.Domino()
sage: v = Domino.vertices(2)[1]; ascii_art(v)
*** *

sage: ascii_art([w for w in Domino.vertices(3) if Domino.is_P_edge(v, w)])
[ *** ]
[ * ]
[ ***** *** * ]
[ * , ***, * ]
sage: [w for w in Domino.vertices(4) if Domino.is_P_edge(v, w)]
[]
```

```

```plaintext
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> v = Domino.vertices(Integer(2))[Integer(1)]; ascii_art(v)
*** *

>>> ascii_art([w for w in Domino.vertices(Integer(3)) if Domino.is_P_edge(v, w)])
[ *** ]
[ * ]
[ ***** *** * ]
[ * , ***, * ]
```
normalize_vertex(v)
Return v as a partition.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.normalize_vertex([3,1]).parent()
Partitions
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

r = 2
rank(v)
Return the rank of v.
The rank of a vertex is half the size of the partition, which equals the number of dominoes in any filling.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.rank(Domino.vertices(3)[0])
3
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.rank(Domino.vertices(Integer(3))[Integer(0)])
3
```

vertices(n)
Return the vertices of the dual graded graph on level n.

EXAMPLES:

```
sage: Domino = GrowthDiagram.rules.Domino()
sage: Domino.vertices(2)
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

```
>>> from sage.all import *
>>> Domino = GrowthDiagram.rules.Domino()
>>> Domino.vertices(Integer(2))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

zero = []
class sage.combinat.growth.RuleLLMS(k)

Bases: Rule

A rule modelling the Schensted correspondence for affine permutations.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: GrowthDiagram(LLMS3, [3,1,2])
```

```
0 1 0
0 0 1
1 0 0
```

```python
>>> from sage.all import *

>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))

>>> GrowthDiagram(LLMS3, [Integer(3),Integer(1),Integer(2)])
```

```
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are Cores:

```python
sage: LLMS3.vertices(4)
```

```
3-Cores of length 4
```

```python
>>> from sage.all import *

>>> LLMS3.vertices(Integer(4))
```

```
3-Cores of length 4
```

Let us check example of Figure 1 in [LS2007]. Note that, instead of passing the rule to GrowthDiagram, we can also call the rule to create growth diagrams:

```python
sage: G = LLMS3([4,1,2,6,3,5]); G
```

```
0 1 0 0 0 0
0 0 1 0 0 0
0 0 0 0 1 0
1 0 0 0 0 0
0 0 0 0 0 1
0 0 0 1 0 0
```

```python
>>> from sage.all import *

>>> G = LLMS3([Integer(4),Integer(1),Integer(2),Integer(6),Integer(3),Integer(5)]); G
```

```
0 1 0 0 0 0
0 0 1 0 0 0
0 0 0 0 1 0
1 0 0 0 0 0
0 0 0 0 0 1
0 0 0 1 0 0
```

The P_symbol() is a StrongTableau:

```python
sage: G.P_symbol().pp()
```

```
-1 -2 -3 -5
3 5
-4 -6
5
6
```
The \texttt{Q\_symbol()} is a \texttt{WeakTableau}:

\begin{verbatim}
sage: G.Q_symbol().pp()
sage: G.P_symbol().pp()
\end{verbatim}

Let us also check Example 6.2 in [LLMSSZ2013]:

\begin{verbatim}
sage: G = LLMS3([4,1,3,2])
sage: G = LLMS3([Integer(4),Integer(1),Integer(3),Integer(2)])
\end{verbatim}

\texttt{P\_symbol} (\texttt{P\_chain})

Return the labels along the vertical boundary of a rectangular growth diagram as a skew \texttt{StrongTableau}.

\textbf{EXAMPLES:}

\begin{verbatim}
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
\end{verbatim}
sage: G.P_symbol().pp()
-1 -2
-3 -4

```python
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> G = LLMS4([Integer(3),Integer(4),Integer(1),Integer(2)])
>>> G.P_symbol().pp()
-1 -2
-3 -4
```

**Q_symbol** *(Q_chain)*

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew \textit{WeakTableau}.

**EXAMPLES:**

```python
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: G = LLMS4([3,4,1,2])
sage: G.Q_symbol().pp()
1 2
3 4
```

```python
>>> from sage.all import *
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))
>>> G = LLMS4([Integer(3),Integer(4),Integer(1),Integer(2)])
>>> G.Q_symbol().pp()
1 2
3 4
```

**forward_rule** *(y, e, t, f, x, content)*

Return the output path given two incident edges and the content.

See [LS2007] Section 3.4 and [LLMSSZ2013] Section 6.3.

**INPUT:**

- \(y, e, t, f, x\) – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

  \[
  \begin{array}{c}
  t \\
  f \\
  x \\
  e \\
  y \\
  \end{array}
  \]

- **content** – 0 or 1; the content of the cell

**OUTPUT:**

The two colors and the fourth partition \(g, z, h\) according to LLMS insertion.

**EXAMPLES:**

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: Z = LLMS3.zero
sage: LLMS3.forward_rule(Z, None, Z, None, Z, 0)
(None, [], None)
sage: LLMS3.forward_rule(Z, None, Z, None, Z, 1)
```

(continues on next page)
sage: Y = Core([3,1,1], 3)
sage: LLMS3.forward_rule(Y, None, None, Y, 1)
(Non  e, [4, 2, 1, 1], 3)

>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS4 = GrowthDiagram.rules.LLMS(Integer(4))

>>> Z = LLMS3.zero
>>> LLMS3.forward_rule(Z, None, None, Z, Integer(0))
(Non  e, [], None)

>>> LLMS3.forward_rule(Z, None, None, Z, Integer(1))
(Non  e, [1], 0)

>>> Y = Core([Integer(3),Integer(1),Integer(1)], Integer(3))

>>> LLMS3.forward_rule(Y, None, None, Y, Integer(1))
(Non  e, [4, 2, 1, 1], 3)

if x != y:

sage: Y = Core([1,1], 3); T = Core([1], 3); X = Core([2], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(Non  e, [2, 1, 1], -1)

sage: Y = Core([2], 4); T = Core([1], 4); X = Core([1,1], 4)
sage: LLMS4.forward_rule(Y, 1, T, None, X, 0)
(Non  e, [2, 1, 1], 1)

sage: Y = Core([2,1,1], 3); T = Core([2], 3); X = Core([3,1], 3)
sage: LLMS3.forward_rule(Y, -1, T, None, X, 0)
(Non  e, [3, 1, 1], -2)

(None, [1, 1], -1)

>>> Y = Core([Integer(1)], Integer(4)); T = Core([Integer(1), Integer(1)], Integer(4)); X = Core([Integer(2), Integer(1)], Integer(4))
>>> LLMS4.forward_rule(Y, Integer(1), T, None, X, Integer(0))
(None, [2, 2], 0)

has_multiple_edges = True

is_P_edge(v, w)

Return whether (v, w) is a $P$-edge of self.

For two k-cores $v$ and $w$ containing $v$, there are as many edges as there are components in the skew partition $w/v$. These components are ribbons, and therefore contain a unique cell with maximal content. We index the edge with this content.

EXAMPLES:

>>> LLMS4 = GrowthDiagram.rules.LLMS(4)
>>> v = LLMS4.vertices(2)[0]; v
[2]

>>> [(w, LLMS4.is_P_edge(v, w)) for w in LLMS4.vertices(3)]
[[[3], [2], [[2, 1], [-1]], [[1, 1, 1], []]]]

>>> all(LLMS4.is_P_edge(v, w) == [] for w in LLMS4.vertices(4))
True

is_Q_edge(v, w)

Return whether (v, w) is a $Q$-edge of self.
(v, w) is an edge if w is a weak cover of v, see weak_cover().

EXAMPLES:

```python
sage: LLMS4 = GrowthDiagram.rules.LLMS(4)
sage: v = LLMS4.vertices(3)[1]; v
[2, 1]
sage: [w for w in LLMS4.vertices(4) if len(LLMS4.is_Q_edge(v, w)) > 0]
[[2, 2], [3, 1, 1]]
sage: all(LLMS4.is_Q_edge(v, w) == [] for w in LLMS4.vertices(5))
True
```

normalize_vertex(v)

Convert v to a k-core.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.normalize_vertex([3, 1]).parent()
3-Cores of length 3
```

rank(v)

Return the rank of v: the length of the core.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.rank(LLMS3.vertices(3)[0])
3
```

vertices(n)

Return the vertices of the dual graded graph on level n.

EXAMPLES:

```python
sage: LLMS3 = GrowthDiagram.rules.LLMS(3)
sage: LLMS3.vertices(2)
3-Cores of length 2
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> LLMS3 = GrowthDiagram.rules.LLMS(Integer(3))
>>> LLMS3.vertices(Integer(2))
3-Cores of length 2
```

```python
zero_edge = None
class sage.combinat.growth.RulePartitions
    Bases: Rule

A rule for growth diagrams on Young's lattice on integer partitions graded by size.

**P_symbol** (*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a (skew) tableau.

**EXAMPLES:**

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.P_symbol().pp()
1 2 2
2
```

```python
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = RuleRSK([[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0), Integer(2)]])
>>> G.P_symbol().pp()
1 2 2
2
```

**Q_symbol** (*Q_chain*)

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

**EXAMPLES:**

```python
sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: G = RuleRSK([[0,1,0], [1,0,2]])
sage: G.Q_symbol().pp()
1 3 3
2
```

```python
>>> from sage.all import *
>>> RuleRSK = GrowthDiagram.rules.RSK()
>>> G = RuleRSK([[Integer(0),Integer(1),Integer(0)], [Integer(1),Integer(0), Integer(2)]])
>>> G.Q_symbol().pp()
1 3 3
2
```

**normalize_vertex** (*v*)

Return *v* as a partition.

**EXAMPLES:**

```python
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.normalize_vertex([3,1]).parent()
Partitions
```
```python
from sage.all import *
RSK = GrowthDiagram.rules.RSK()
RSK.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions
```

### rank(v)

Return the rank of v: the size of the partition.

**EXAMPLES:**

```python
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.rank(RSK.vertices(3)[0])
3
```

### vertices(n)

Return the vertices of the dual graded graph on level n.

**EXAMPLES:**

```python
sage: RSK = GrowthDiagram.rules.RSK()
sage: RSK.vertices(3)
Partitions of the integer 3
```

```python
zero = []
```

```python
class sage.combinat.growth.RuleRSK
    Bases: RulePartitions

    A rule modelling Robinson-Schensted-Knuth insertion.

    **EXAMPLES:**

    ```python
    sage: RuleRSK = GrowthDiagram.rules.RSK()
sage: GrowthDiagram(RuleRSK, [3,2,1,2,3])
    0 0 1 0 0
    0 1 0 1 0
    1 0 0 0 1
    ```
    ```python
    >>> from sage.all import *
    >>> RuleRSK = GrowthDiagram.rules.RSK()
    >>> GrowthDiagram(RuleRSK, [Integer(3),Integer(2),Integer(1),Integer(2), Integer(3)])
    0 0 1 0 0
    0 1 0 1 0
    1 0 0 0 1
    ```

    The vertices of the dual graded graph are integer partitions:
```
The local rules implemented provide the RSK correspondence between matrices with non-negative integer entries and pairs of semistandard tableaux, the \texttt{P\_symbol()} and the \texttt{Q\_symbol()}. For permutations, it reduces to classical Schensted insertion.

Instead of passing the rule to \texttt{GrowthDiagram}, we can also call the rule to create growth diagrams. For example:

\begin{verbatim}
sage: m = matrix([[0,0,0,0,1], [1,1,0,2,0], [0,3,0,0,0]])
sage: G = RuleRSK(m); G
0 0 0 0 1
1 1 0 2 0
0 3 0 0 0

sage: ascii_art([G.P\_symbol(), G.Q\_symbol()])
[ 1 2 2 2 3 1 2 2 2 2 ]
[ 2 3 4 4 1 1 1 1 1 1 ]
[ 3 3 3 3 3 3 3 3 3 3 ]
\end{verbatim}

For rectangular fillings, the Kleitman-Greene invariant is the shape of the \texttt{P\_symbol()} (or the \texttt{Q\_symbol()}). Put differently, it is the partition labelling the lower right corner of the filling (recall that we are using matrix coordinates). It can be computed alternatively as the partition \((\mu_1, \ldots, \mu_n)\), where \(\mu_1 + \cdots + \mu_i\) is the maximal sum of entries in a collection of \(i\) pairwise disjoint sequences of cells with weakly increasing coordinates.

For rectangular fillings, we could also use the (faster) implementation provided via \texttt{RSK()}. Because the of the coordinate conventions in \texttt{RSK()}, we have to transpose matrices:

\begin{verbatim}
sage: [G.P\_symbol(), G.Q\_symbol()] == RSK(m.transpose())
True

sage: n = 5; l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
sage: all([G.P\_symbol(), G.Q\_symbol()] == RSK(pi) for pi, G in l)
True

sage: n = 5; l = [(w, RuleRSK(w)) for w in Words([1,2,3], 5)]
sage: all([G.P\_symbol(), G.Q\_symbol()] == RSK(pi) for pi, G in l)
True
\end{verbatim}
```python
from sage.all import *

[G.P_symbol(), G.Q_symbol()] == RSK(m.transpose())
True

n = Integer(5);
l = [(pi, RuleRSK(pi)) for pi in Permutations(n)]
all([G.P_symbol(), G.Q_symbol()]==RSK(pi) for pi, G in l)
True

n = Integer(5);
l = [(w, RuleRSK(w)) for w in Words([Integer(1), Integer(2), Integer(3)], Integer(5))]
all([G.P_symbol(), G.Q_symbol()]==RSK(pi) for pi, G in l)
True
```

**backward_rule** *(y, z, x)*  
Return the content and the input shape.

See [Kra2006] $(B^{10}) - (B^{12})$.

**INPUT:**

• y, z, x – three partitions from a cell in a growth diagram, labelled as:

```
x
y
z
```

**OUTPUT:**

A pair *(t, content)* consisting of the shape of the fourth word according to the Robinson-Schensted-Knuth correspondence and the content of the cell.

**forward_rule** *(y, t, x, content)*  
Return the output shape given three shapes and the content.

See [Kra2006] $(F^{10}) - (F^{12})$.

**INPUT:**

• y, t, x – three partitions from a cell in a growth diagram, labelled as:

```
t
x
y
```

• content – a non-negative integer; the content of the cell

**OUTPUT:**

The fourth partition according to the Robinson-Schensted-Knuth correspondence.

**EXAMPLES:**

```python
RuleRSK = GrowthDiagram.rules.RSK()
RuleRSK.forward_rule([2,1],[2,1],[2,1],1)
[3, 1]
RuleRSK.forward_rule([1],[],[2],2)
[4, 1]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

→[Integer(2),Integer(1)],Integer(1))
[3, 1]

>>> RuleRSK.forward_rule([Integer(1)],[],[Integer(2)],Integer(2))
[4, 1]

class sage.combinat.growth.RuleShiftedShapes

Bases: Rule

A class modelling the Schensted correspondence for shifted shapes.

This agrees with Sagan [Sag1987] and Worley's [Wor1984], and Haiman's [Hai1989] insertion algorithms, see Proposition 4.5.2 of [Fom1995].

EXAMPLES:

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: GrowthDiagram(Shifted, [3,1,2])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are shifted shapes:

```python
sage: Shifted.vertices(3)
```

```python
sage: Shifted.vertices(Integer(3))
```

Let us check the example just before Corollary 3.2 in [Sag1987]. Note that, instead of passing the rule to GrowthDiagram, we can also call the rule to create growth diagrams:

```python
sage: G = Shifted([2,6,5,1,7,4,3])
sage: G.P_chain()
```

```python
sage: G.Q_chain()
```

```python
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
```

```python
>>> GrowthDiagram(Shifted, [Integer(3),Integer(1),Integer(2)])
0 1 0
0 0 1
1 0 0
```

```python
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
```

```python
>>> GrowthDiagram(Shifted, [Integer(3),Integer(1),Integer(2)])
0 1 0
0 0 1
1 0 0
```
**P_symbol** (*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a shifted tableau.

EXAMPLES:

Check the example just before Corollary 3.2 in [Sag1987]:

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2, 6, 5, 1, 7, 4, 3])
sage: G.P_symbol().pp()
1 2 3 6 7
4 5
```

Check the example just before Corollary 8.2 in [SS1990]:

```python
sage: T = ShiftedPrimedTableau([[4], [1], [5]], skew=[3, 1])
sage: T.pp()
. . . 4
. . 1
. . 5
sage: U = ShiftedPrimedTableau([[1], [3.5], [5]], skew=[3, 1])
sage: U.pp()
. . . 1
. . 4
. . 5
```

(continues on next page)
\[\text{\texttt{Q\_symbol}(Q\_chain)}\]

Return the labels along the horizontal boundary of a rectangular growth diagram as a skew tableau.

**EXAMPLES:**

Check the example just before Corollary 3.2 in [Sag1987]:

```python
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: G = Shifted([2, 6, 5, 1, 7, 4, 3])
sage: G.Q_symbol().pp()
1 2 4' 5 7' 3 6'
```

Check the example just before Corollary 8.2 in [SS1990]:

```python
sage: T = ShiftedPrimedTableau([[4], [1], [5]], skew=[3, 1])
sage: T.pp()
... 4
... 1
... 5
sage: U = ShiftedPrimedTableau([[1], [3.5], [5]], skew=[3, 1])
sage: U.pp()
... 1
... 4'
... 5
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: labels = [mu if is_even(i) else 0 ...
    for i, mu in enumerate(T.to_chain()[:-1]) + U.to_chain()[1:]]
sage: G = Shifted({(1, 2): 1, (2, 1): 1}, shape=[5, 5, 5, 5, 5], labels=labels)
sage: G.Q_symbol().pp()
... 2
... 1 4'
... 3 5'
```

```python
>>> from sage.all import *
>>> T = ShiftedPrimedTableau([[Integer(4)], [Integer(1)], [Integer(5)]], ...
    skew=[Integer(3), Integer(1)])
>>> T.pp()
... 4
```
backward_rule(y, g, z, h, x)

Return the input path and the content given two incident edges.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- y, g, z, h, x – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

\[
\begin{align*}
x \\
h \\
y \quad g \quad z
\end{align*}
\]

OUTPUT:

A tuple \((e, t, f, \text{content})\) consisting of the shape \(t\) of the fourth word, the colours of the incident edges and the content of the cell according to Sagan - Worley insertion.

EXAMPLES:

```plaintext
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.backward_rule([], 1, [1], 0, [])
(0, [], 0, 1)
sage: Shifted.backward_rule([1], 2, [2], 0, [1])
(0, [1], 0, 1)
```

```
if x != y:
```
```python
sage: Shifted.backward_rule([3], 1, [3, 1], 0, [2,1])
(0, [2], 1, 0)
sage: Shifted.backward_rule([2,1], 2, [3, 1], 0, [3])
(0, [2], 2, 0)

>>> from sage.all import *

>>> Shifted.backward_rule([Integer(3)], Integer(1), [Integer(3), Integer(1)],
 вещественно Integer(0), [Integer(2),Integer(1)])
(0, [2], 1, 0)
>>> Shifted.backward_rule([Integer(2),Integer(1)], Integer(2), [Integer(3), вещество Integer(1)], Integer(0), [Integer(3)])
(0, [2], 2, 0)

if x == y != t:

sage: Shifted.backward_rule([3], 1, [3, 1], 0, [3])
(0, [2], 2, 0)
sage: Shifted.backward_rule([3,1], 2, [3, 2], 0, [3,1])
(0, [2, 1], 2, 0)
sage: Shifted.backward_rule([2,1], 3, [3, 1], 0, [2,1])
(0, [2], 1, 0)
sage: Shifted.backward_rule([3], 3, [4], 0, вещественно [Integer(3)])
(0, [2], 3, 0)
```

forward_rule(y, e, t, f, x, content)

Return the output path given two incident edges and the content.

See [Fom1995] Lemma 4.5.1, page 38.

INPUT:

- y, e, t, f, x – a path of three partitions and two colors from a cell in a growth diagram, labelled as:

  t f x
e
Y
• content = 0 or 1; the content of the cell

OUTPUT:

The two colors and the fourth partition $g$, $z$, $h$ according to Sagan-Worley insertion.

EXAMPLES:

```
sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: Shifted.forward_rule([], 0, [], 0, [], 1)
(1, [1], 0)
sage: Shifted.forward_rule([1], 0, [1], 0, [1], 1)
(2, [2], 0)
```

```python
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.forward_rule([], Integer(0), [], Integer(0), [], Integer(1))
(1, [1], 0)
>>> Shifted.forward_rule([Integer(1)], Integer(0), [Integer(1)], Integer(0), [Integer(1)], Integer(1))
(2, [2], 0)
```

```
if x != y:

```
sage: Shifted.forward_rule([3], 0, [2], 1, [2,1], 0)
(1, [3, 1], 0)
sage: Shifted.forward_rule([2,1], 0, [2], 2, [3], 0)
(2, [3, 1], 0)
```

```python
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(1), [Integer(1)], Integer(0))
(1, [3, 1], 0)
>>> Shifted.forward_rule([Integer(2),Integer(1)], Integer(0), [Integer(2)], Integer(1), [Integer(3)], Integer(0))
(2, [3, 1], 0)
```

```
if x == y != t:

```
sage: Shifted.forward_rule([3], 0, [2], 2, [3], 0)
(1, [3, 1], 0)
sage: Shifted.forward_rule([3,1], 0, [2,1], 2, [3,1], 0)
(2, [3, 1], 0)
sage: Shifted.forward_rule([2,1], 0, [2], 1, [2,1], 0)
(3, [3, 1], 0)
sage: Shifted.forward_rule([3], 0, [2], 3, [3], 0)
(3, [4], 0)
```

```python
>>> from sage.all import *
>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.forward_rule([Integer(3)], Integer(0), [Integer(2)], Integer(2), [Integer(3)], Integer(0))
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

(3, [4], 0)

has_multiple_edges = True

is_P_edge(v, w)
Return whether (v, w) is a P-edge of self.
(v, w) is an edge if w contains v.

EXAMPLES:

sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(2)[0]; v
[2]
sage: [w for w in Shifted.vertices(3) if Shifted.is_P_edge(v, w)]
[[3], [2, 1]]

>>> from sage.all import *

is_Q_edge(v, w)
Return whether (v, w) is a Q-edge of self.
(v, w) is an edge if w is obtained from v by adding a cell. It is a black (color 1) edge, if the cell is on the diagonal, otherwise it can be blue or red (color 2 or 3).

EXAMPLES:

sage: Shifted = GrowthDiagram.rules.ShiftedShapes()
sage: v = Shifted.vertices(Integer(2))[Integer(0)]; v
[2]
sage: [[w, Shifted.is_Q_edge(v, w)] for w in Shifted.vertices(Integer(3)) if Shifted.is_P_edge(v, w)]
[[[3], [2, 1]]]

>>> all(Shifted.is_Q_edge(v, w) == [] for w in Shifted.vertices(Integer(4)))
True

>>> from sage.all import *

(continues on next page)
normalize_vertex(v)
    Return v as a partition.

EXAMPLES:

>>> from sage.all import *

>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.normalize_vertex([Integer(3),Integer(1)]).parent()
Partitions

rank(v)
    Return the rank of v: the size of the shifted partition.

EXAMPLES:

>>> from sage.all import *

>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.rank(Shifted.vertices(Integer(3))[Integer(0)])
3

vertices(n)
    Return the vertices of the dual graded graph on level n.

EXAMPLES:

>>> from sage.all import *

>>> Shifted = GrowthDiagram.rules.ShiftedShapes()
>>> Shifted.vertices(Integer(3))
Partitions of the integer 3 satisfying constraints max_slope=-1
The vertices of the dual graded graph are BinaryTrees:

```
sage: Sylvester.vertices(3)
Binary trees of size 3
```

The P_graph() is also known as the bracket tree, the Q_graph() is the lattice of finite order ideals of the infinite binary tree, see Example 2.4.6 in [Fom1994].

For a permutation, the P_symbol() is the binary search tree, the Q_symbol() is the increasing tree corresponding to the inverse permutation. Note that, instead of passing the rule to GrowthDiagram, we can also call the rule to create growth diagrams. From [Nze2007]:

```
sage: pi = Permutation([3,5,1,4,2,6]); G = Sylvester(pi); G
0 0 1 0 0 0
0 0 0 1 0
1 0 0 0 0
0 0 0 1 0
0 1 0 0 0
0 0 0 0 1
sage: ascii_art(G.P_symbol())
__3__
/ \  
1 5  
/ \  
2 4 6
sage: ascii_art(G.Q_symbol())
__1__
/ \  
3 2  
/ \  
5 4 6
sage: all(Sylvester(pi).P_symbol() == pi.binary_search_tree() 
....:     for pi in Permutations(5))
True
sage: all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree() 
....:     for pi in Permutations(5))
True
```
>>> from sage.all import *
>>> pi = Permutation([Integer(3), Integer(5), Integer(1), Integer(4), Integer(2), Integer(6)]); G = Sylvester(pi); G
0 0 1 0 0 0
0 0 0 0 1 0
1 0 0 0 0 0
0 0 0 1 0 0
0 1 0 0 0 0
0 0 0 0 0 1

>>> ascii_art(G.P_symbol())
__3__
/ \  \
1  5 \\
/ \  \
2  4 6

>>> ascii_art(G.Q_symbol())
__1__
/ \  \
3  2 \\
/ \  \
5  4 6

>>> all(Sylvester(pi).P_symbol() == pi.binary_search_tree() for pi in Permutations(Integer(5)))
True

>>> all(Sylvester(pi).Q_symbol() == pi.inverse().increasing_tree() for pi in Permutations(Integer(5)))
True

**P_symbol** (*P_chain*)

Return the labels along the vertical boundary of a rectangular growth diagram as a labelled binary tree.

For permutations, this coincides with the binary search tree.

**EXAMPLES:**

```sage
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: pi = Permutation([2,4,3,1])
sage: ascii_art(Sylvester(pi).P_symbol())
_2_
/ \ 
1  4
/  
3
sage: Sylvester(pi).P_symbol() == pi.binary_search_tree()
True
```

```sage
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> pi = Permutation([Integer(2), Integer(4), Integer(3), Integer(1)])
>>> ascii_art(Sylvester(pi).P_symbol())
_2_
/ \ 
1  4
/  
3
```

(continues on next page)
We can also do the skew version:

```python
>>> from sage.all import *

>>> B = BinaryTree; E = B(); N = B([])
>>> ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,N,E,E,E,N]).P_symbol())

```

```
     _1_
    /   \
   None 3
    /   \
   2
```

```
>>> from sage.all import *

```
```sage
B = BinaryTree(); E = B(); N = B([])

ascii_art(Sylvester([3,2], shape=[3,3,3], labels=[N,N,E,E,E,N]).Q_symbol())

backward_rule(y, z, x)

Return the output shape given three shapes and the content.

See [Nze2007], page 9.

INPUT:

- y, z, x – three binary trees from a cell in a growth diagram, labelled as:

```
x
y z
```

OUTPUT:

A pair (t, content) consisting of the shape of the fourth binary tree t and the content of the cell.

EXAMPLES:

```sage
E = B(); N = B([])
R = B([None, []]); T = B([[], []])

ascii_art(Sylvester.backward_rule(E, E, E))
( , 0 )

ascii_art(Sylvester.backward_rule(N, N, N))
( o, 0 )
```

forward_rule(y, t, x, content)

Return the output shape given three shapes and the content.
```
See [Nze2007], page 9.

INPUT:

• $y, t, x$ – three binary trees from a cell in a growth diagram, labelled as:

```
  t x
  y
```

• content = 0 or 1; the content of the cell

OUTPUT:

The fourth binary tree $z$.

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()

sage: B = BinaryTree; E = B(); N = B([]); L = B([[]], None)

sage: R = B([None, []]); T = B([], [])

sage: ascii_art(Sylvester.forward_rule(E, E, E, Integer(1)))

sage: ascii_art(Sylvester.forward_rule(N, N, N, Integer(1)))

sage: ascii_art(Sylvester.forward_rule(L, L, L, Integer(1)))

sage: ascii_art(Sylvester.forward_rule(R, R, R, Integer(1)))

>>> from sage.all import *

>>> Sylvester = GrowthDiagram.rules.Sylvester()

>>> B = BinaryTree; E = B(); N = B([]); L = B([[]], None)

>>> R = B([None, []]); T = B([], [])

>>> ascii_art(Sylvester.forward_rule(E, E, E, Integer(1)))

>>> ascii_art(Sylvester.forward_rule(N, N, N, Integer(1)))

>>> ascii_art(Sylvester.forward_rule(L, L, L, Integer(1)))

>>> ascii_art(Sylvester.forward_rule(R, R, R, Integer(1)))
```
If \( y \neq x \), obtain \( z \) from \( y \) adding a node such that deleting the right most gives \( x \):

```
>>> from sage.all import *
>>> ascii_art(Sylvester.forward_rule(R, N, L, 0))
.o
/ \
.o .o
```

```
>>> ascii_art(Sylvester.forward_rule(L, N, R, 0))
.o
/ 
.o
```

If \( y == x \neq t \), obtain \( z \) from \( x \) by adding a node as left child to the right most node:

```
>>> ascii_art(Sylvester.forward_rule(N, E, N, 0))
.o
/ 
```

```
>>> ascii_art(Sylvester.forward_rule(T, L, T, 0))
._o_
/ \ 
.o .o
/ 
```

```
>>> ascii_art(Sylvester.forward_rule(L, N, L, 0))
.o
/ 
```

```
>>> ascii_art(Sylvester.forward_rule(R, N, R, 0))
.o
\ 
```

(continues on next page)
is_P_edge\((v, w)\)

Return whether \((v, w)\) is a 𝑃-edge of self.

\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting its right-most node.

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
   /
  /
sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_P_edge(v, w)])
[[ o , o ]
[ / \ / ]
[ o o o ]
[   /   ]
[   o   ]
sage: [w for w in Sylvester.vertices(4) if Sylvester.is_P_edge(v, w)]
[]
```
is_Q_edge(v, w)

Return whether \((v, w)\) is a \(Q\)-edge of self.
\((v, w)\) is an edge if \(v\) is a sub-tree of \(w\) with one node less.

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: v = Sylvester.vertices(2)[1]; ascii_art(v)
    o
    /
   / o
sage: ascii_art([w for w in Sylvester.vertices(3) if Sylvester.is_Q_edge(v, w)])
[ o , o, o ]
[ / \ / / ]
[ o o , o ]
[ \ / ]
[ o o ]
```

normalize_vertex(v)

Return \(v\) as a binary tree.

EXAMPLES:

```python
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```

```python
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.normalize_vertex([[],[]]).parent()
Binary trees
```
rank \((v)\)
Return the rank of \(v\): the number of nodes of the tree.

EXAMPLES:
```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.rank(Sylvester.vertices(3)[0])
3
```
```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.rank(Sylvester.vertices(Integer(3))[Integer(0)])
3
```

vertices \((n)\)
Return the vertices of the dual graded graph on level \(n\).

EXAMPLES:
```
sage: Sylvester = GrowthDiagram.rules.Sylvester()
sage: Sylvester.vertices(3)
Binary trees of size 3
```
```
>>> from sage.all import *
>>> Sylvester = GrowthDiagram.rules.Sylvester()
>>> Sylvester.vertices(Integer(3))
Binary trees of size 3
```

zero = .

class sage.combinat.growth.RuleYoungFibonacci
Bases: Rule
A rule modelling a Schensted-like correspondence for Young-Fibonacci-tableaux.

EXAMPLES:
```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: GrowthDiagram(YF, [3,1,2])
0 1 0
0 0 1
1 0 0
```
```
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> GrowthDiagram(YF, [Integer(3),Integer(1),Integer(2)])
0 1 0
0 0 1
1 0 0
```

The vertices of the dual graded graph are Fibonacci words - compositions into parts of size at most two:
```
sage: YF.vertices(4)
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```
```
>>> from sage.all import *
>>> YF.vertices(Integer(4))
[word: 22, word: 211, word: 121, word: 112, word: 1111]
```
Note that, instead of passing the rule to `GrowthDiagram`, we can also use call the rule to create growth diagrams. For example:

```sage
g = YF([2, 3, 7, 4, 1, 6, 5]); g
0 0 0 0 1 0 0
1 0 0 0 0 0 0
0 1 0 0 0 0 0
0 0 0 1 0 0 0
0 0 0 0 0 0 1
0 0 0 0 0 1 0
0 0 1 0 0 0 0
```

The Kleitman Greene invariant is: take the last letter and the largest letter of the permutation and remove them. If they coincide write 1, otherwise write 2:

```sage
g.P_chain()[-1]
word: 21211
>>> from sage.all import *
>>> g.P_chain()[-Integer(1)]
word: 21211
```

**backward_rule** *(y, z, x)*

Return the content and the input shape.

See [Fom1995] Lemma 4.4.1, page 35.

- y, z, x – three Fibonacci words from a cell in a growth diagram, labelled as:

```
x
y z
```

**OUTPUT:**

A pair *(t, content)* consisting of the shape of the fourth word and the content of the cell.

**forward_rule** *(y, t, x, content)*

Return the output shape given three shapes and the content.

See [Fom1995] Lemma 4.4.1, page 35.

**INPUT:**

- y, t, x – three Fibonacci words from a cell in a growth diagram, labelled as:

```
t x
y
```

- content – 0 or 1; the content of the cell
OUTPUT:

The fourth Fibonacci word.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.forward_rule([], [], [], 1)
word: 1
sage: YF.forward_rule([1], [1], [1], 1)
word: 11
sage: YF.forward_rule([1,2], [1], [1,1], 0)
word: 21
sage: YF.forward_rule([1,1], [1], [1,1], 0)
word: 21

>>> from sage.all import *

>>> YF = GrowthDiagram.rules.YoungFibonacci()

>>> YF.forward_rule([], [], [], Integer(1))
word: 1

>>> YF.forward_rule([Integer(1)], [Integer(1)], [Integer(1)], Integer(1))
word: 11

>>> YF.forward_rule([Integer(1),Integer(2)], [Integer(1)], [Integer(1), Integer(0)])
word: 21

>>> YF.forward_rule([Integer(1),Integer(1)], [Integer(1)], [Integer(1), Integer(0)])
word: 21

is_P_edge(v, w)

Return whether (v, w) is a \( P \)-edge of self.

(v, w) is an edge if \( v \) is obtained from \( w \) by deleting a 1 or replacing the left-most 2 by a 1.

EXAMPLES:

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()

sage: v = YF.vertices(5)[5]; v
word: 1121

sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]

sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]

>>> from sage.all import *

>>> YF = GrowthDiagram.rules.YoungFibonacci()

>>> v = YF.vertices(Integer(5))[Integer(5)]; v
word: 1121

>>> [w for w in YF.vertices(Integer(6)) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
```

(continues on next page)
is_P_edge \((v, w)\)
Return whether \((v, w)\) is a \(P\)-edge of self.
\((v, w)\) is an edge if \(v\) is obtained from \(w\) by deleting a 1 or replacing the left-most 2 by a 1.

EXAMPLES:
```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: v = YF.vertices(5)[5]; v
word: 1121
sage: [w for w in YF.vertices(6) if YF.is_P_edge(v, w)]
[word: 2121, word: 11121]
sage: [w for w in YF.vertices(7) if YF.is_P_edge(v, w)]
[]
```

normalize_vertex \((v)\)
Return \(v\) as a word with letters 1 and 2.

EXAMPLES:
```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.normalize_vertex([1,2,1]).parent()
Finite words over \{1, 2\}
```

rank \((v)\)
Return the rank of \(v\): the size of the corresponding composition.

EXAMPLES:
```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.rank(YF.vertices(3)[0])
3
```

```
vertices\((n)\)

Return the vertices of the dual graded graph on level \(n\).

**EXAMPLES:**

```
sage: YF = GrowthDiagram.rules.YoungFibonacci()
sage: YF.vertices(3)
[word: 21, word: 12, word: 111]
```

```python
>>> from sage.all import *
>>> YF = GrowthDiagram.rules.YoungFibonacci()
>>> YF.vertices(Integer(3))
[word: 21, word: 12, word: 111]
```

```
zero = word:
```

### 5.1.119 Grossman-Larson Hopf Algebras

**AUTHORS:**

- Frédéric Chapoton (2017)

```python
class sage.combinat.grossman_larson_algebras.GrossmanLarsonAlgebra\((R, \,\text{names}=\text{None})\)
    Bases: CombinatorialFreeModule

```
The Grossman-Larson Hopf Algebras are Hopf algebras with a basis indexed by forests of decorated rooted trees. They are the universal enveloping algebras of free pre-Lie algebras, seen as Lie algebras.

The Grossman-Larson Hopf algebra on a given set $E$ has an explicit description using rooted forests. The underlying vector space has a basis indexed by finite rooted forests endowed with a map from their vertices to $E$ (called the “labeling”). In this basis, the product of two (decorated) rooted forests $S \ast T$ is a sum over all maps from the set of roots of $T$ to the union of a singleton $\{\#\}$ and the set of vertices of $S$. Given such a map, one defines a new forest as follows. Starting from the disjoint union of all rooted trees of $S$ and $T$, one adds an edge from every root of $T$ to its image when this image is not the fake vertex labelled $\#$. The coproduct sends a rooted forest $T$ to the sum of all tensors $T_1 \otimes T_2$ obtained by splitting the connected components of $T$ into two subsets and letting $T_1$ be the forest formed by the first subset and $T_2$ the forest formed by the second. This yields a connected graded Hopf algebra (the degree of a forest is its number of vertices).

See [Pana2002] (Section 2) and [GroLar1]. (Note that both references use rooted trees rather than rooted forests, so think of each rooted forest grafted onto a new root. Also, the product is reversed, so they are defining the opposite algebra structure.)

**Warning:** For technical reasons, instead of using forests as labels for the basis, we use rooted trees. Their root vertex should be considered as a fake vertex. This fake root vertex is labelled $'\#' when labels are present.

**EXAMPLES:**

```python
sage: G = algebras.GrossmanLarson(QQ, 'xy')
sage: x, y = G.single_vertex_all()
sage: ascii_art(x*y)
B + B
  #   #_
|   / /
| x  x y
| |
| y

sage: ascii_art(x*x*x)
B + B + 3*B + B
  #   #   #_   ___
| | | | | | | | | |
| x  x_  x  x  x  x
| | | |
| x  x  x  x
| |
| x
```

```python
>>> from sage.all import *
>>> G = algebras.GrossmanLarson(QQ, 'xy')
>>> x, y = G.single_vertex_all()
>>> ascii_art(x*y)
B + B
  #   #_
|   / /
| x  x y
| |
| y

>>> ascii_art(x*x*x)
B + B + 3*B + B
```
The Grossman-Larson algebra is associative:

```python
sage: z = x * y
sage: x * (y * z) == (x * y) * z
True
```

```python
>>> from sage.all import *
>>> z = x * y
>>> x * (y * z) == (x * y) * z
True
```

It is not commutative:

```python
sage: x * y == y * x
False
```

```python
>>> from sage.all import *
>>> x * y == y * x
False
```

When `None` is given as input, unlabelled forests are used instead; this corresponds to a 1-element set $E$:

```python
sage: G = algebras.GrossmanLarson(QQ, None)
sage: x = G.single_vertex_all()[0]
sage: ascii_art(x*x)
B + B
  o  o_
   |
  o  o
   |

>>> from sage.all import *
>>> G = algebras.GrossmanLarson(QQ, None)
>>> x = G.single_vertex_all()[Integer(0)]
>>> ascii_art(x*x)
B + B
  o  o_
   |
  o  o
   |
```

**Note:** Variables names can be `None`, a list of strings, a string or an integer. When `None` is given, unlabelled rooted forests are used. When a single string is given, each letter is taken as a variable. See `sage.combinat.words.alphabet.build_alphabet()`.
**Warning:** Beware that the underlying combinatorial free module is based either on `RootedTrees` or on `LabelledRootedTrees`, with no restriction on the labellings. This means that all code calling the `basis()` method would not give meaningful results, since `basis()` returns many “chaff” elements that do not belong to the algebra.

REFERENCES:
- [Pana2002]
- [GroLar1]

`an_element()`

Return an element of `self`.

EXAMPLES:
```
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: A.an_element()
B[#[x[]]] + 2*B[#[x[x[]]]] + 2*B[#[x[], x[]]]
```

`antipode_on_basis(x)`

Return the antipode of a forest.

EXAMPLES:
```
sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: G.antipode(x)  # indirect doctest
-B[#[0[]]]
sage: G.antipode(y*x)  # indirect doctest
B[#[0[1[]]]] + B[#[0[], 1[]]]
```

`change_ring(R)`

Return the Grossman-Larson algebra in the same variables over `R`.

INPUT:
- `R` – a ring

EXAMPLES:
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.change_ring(QQ)
Grossman–Larson Hopf algebra on 3 generators ['f', 'g', 'h']
over Rational Field

>>> from sage.all import *

sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.change_ring(QQ)
Grossman–Larson Hopf algebra on 3 generators ['f', 'g', 'h']
over Rational Field

coproduct_on_basis(x)

Return the coproduct of a forest.

EXAMPLES:

sage: G = algebras.GrossmanLarson(QQ,2)
sage: x, y = G.single_vertex_all()
sage: ascii_art(G.coproduct(x))  # indirect doctest
1 # B + B # 1
   #   |
|    |
0 0

sage: Delta_xy = G.coproduct(y*x)
sage: ascii_art(Delta_xy)  # random indirect doctest
1 # B + 1 # B + B # B + B # 1 + B # B + B # 1
   #_ # # # #_ # # #
/ / |
0 1 1 0 1 0 1 0 1 0 1
   | |
0 0 0

sage: G = algebras.GrossmanLarson(QQ,Integer(2))
sage: x, y = G.single_vertex_all()
sage: ascii_art(G.coproduct(x))  # indirect doctest
1 # B + B # 1
   #   |
|    |
0 0

sage: Delta_xy = G.coproduct(y*x)
sage: ascii_art(Delta_xy)  # random indirect doctest
1 # B + 1 # B + B # B + B # 1 + B # B + B # 1
   #_ # # # #_ # # #
/ / |
0 1 1 0 1 0 1 0 1 0 1
   | |
0 0 0

counit_on_basis(x)

Return the counit on a basis element.

This is zero unless the forest x is empty.

EXAMPLES:
```python
sage: A = algebras.GrossmanLarson(QQ, 'xy')
sage: RT = A.basis().keys()
sage: x = RT([RT([[]], 'x')], '#')
sage: A.counit_on_basis(x)
0
sage: A.counit_on_basis(RT([[]], '#'))
1
```

```python
def degree_on_basis(t):
    """Return the degree of a rooted forest in the Grossman-Larson algebra."
    This is the total number of vertices of the forest.
    EXAMPLES:

    sage: A = algebras.GrossmanLarson(QQ, '@')
sage: A.degree_on_basis(RT([[]]))
1
```

```python
def one_basis():
    """Return the empty rooted forest."
    EXAMPLES:

    sage: A = algebras.GrossmanLarson(QQ, 'ab')
sage: A.one_basis()
[]
sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.one_basis()
[]
```

>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'xy')
>>> RT = A.basis().keys()
>>> x = RT([RT([[]], 'x')], '#')
>>> A.counit_on_basis(x)
0
>>> A.counit_on_basis(RT([[]], '#'))
1
```
**product_on_basis** \((x, y)\)

Return the product of two forests \(x\) and \(y\).

This is the sum over all possible ways for the components of the forest \(y\) to either fall side-by-side with components of \(x\) or be grafted on a vertex of \(x\).

**EXAMPLES:**

```python
sage: A = algebras.GrossmanLarson(QQ, None)
sage: RT = A.basis().keys()
sage: x = RT([RT([])])
sage: A.product_on_basis(x, x)
B[[[[[]]]]] + B[[[], []]]
```

Check that the product is the correct one:

```python
sage: A = algebras.GrossmanLarson(QQ, 'uv')
sage: RT = A.basis().keys()
sage: Tu = RT([RT([],u)],#)
sage: Tv = RT([RT([],v)],#)
sage: A.product_on_basis(Tu, Tv)
B[#[u[[]]]] + B[#[u[], v[]]]
```

**single_vertex** \((i)\)

Return the \(i\)-th rooted forest with one vertex.

This is the rooted forest with just one vertex, labelled by the \(i\)-th element of the label list.

See also:

**single_vertex_all()**.

**INPUT:**

- \(i\) – a nonnegative integer

**EXAMPLES:**

```python
sage: F = algebras.GrossmanLarson(ZZ, 'xyz')
sage: F.single_vertex(0)
B[#[x[[]]]]
sage: F.single_vertex(4)
Traceback (most recent call last):
(continues on next page)```
... IndexError: argument i (= 4) must be between 0 and 2

```python
>>> from sage.all import *

>>> F = algebras.GrossmanLarson(ZZ, 'xyz')
>>> F.single_vertex(Integer(0))
B[#[x[]]]

>>> F.single_vertex(Integer(4))
Traceback (most recent call last):
  ... IndexError: argument i (= 4) must be between 0 and 2
```

**single_vertex_all()**

Return the rooted forests with one vertex in self.

They freely generate the Lie algebra of primitive elements as a pre-Lie algebra.

**See also:**

*single_vertex()*.  

**EXAMPLES:**

```
sage: A = algebras.GrossmanLarson(ZZ, 'fgh')
sage: A.single_vertex_all()
(B[#[f[]]], B[#[g[]]], B[#[h[]]])

sage: A = algebras.GrossmanLarson(QQ, ['x1','x2'])
sage: A.single_vertex_all()
(B[#[x1[]]], B[#[x2[]]])

sage: A = algebras.GrossmanLarson(ZZ, None)
sage: A.single_vertex_all()
(B[[]],)
```

```python
>>> from sage.all import *

>>> A = algebras.GrossmanLarson(ZZ, 'fgh')

>>> A.single_vertex_all()
(B[#[f[]]], B[#[g[]]], B[#[h[]]])

>>> A = algebras.GrossmanLarson(QQ, ['x1','x2'])

>>> A.single_vertex_all()
(B[#[x1[]]], B[#[x2[]]])

>>> A = algebras.GrossmanLarson(ZZ, None)

>>> A.single_vertex_all()
(B[[]],)
```

**some_elements()**

**EXAMPLES:**

```
sage: A = algebras.GrossmanLarson(QQ, None)
sage: A.some_elements()
```

(continues on next page)
With several generators:

```python
>>> from sage.all import *
>>> A = algebras.GrossmanLarson(QQ, 'xy')
>>> A.some_elements()
[B[#[x[]]], B[#[]] + B[#[x[]]] + B[#[]], B[#[x[]]] + 3*B[#[x[]]] + B[#[]], B[#[x[]]] + 3*B[#[x[]]] + B[#[]]]
```

**variable_names()**

Return the names of the variables.

This returns the set $E$ (as a family).

**EXAMPLES:**

```python
>>> R = algebras.GrossmanLarson(QQ, 'xy')
>>> R.variable_names()
{'x', 'y'}

>>> R = algebras.GrossmanLarson(QQ, ['a','b'])
>>> R.variable_names()
{'a', 'b'}

>>> R = algebras.GrossmanLarson(QQ, 2)
>>> R.variable_names()
{0, 1}

>>> R = algebras.GrossmanLarson(QQ, None)
>>> R.variable_names()
{'0'}
```
5.1. Comprehensive Module List

5.1.120 Hall Polynomials

sage.combinat.hall_polynomial.hall_polynomial(nu, mu, la=None)

Return the (classical) Hall polynomial \( P_{\nu,\lambda}^{\mu} \) (where \( \nu, \mu \) and \( \lambda \) are the inputs \( nu, mu \) and \( la \)).

Let \( \nu, \mu, \lambda \) be partitions. The Hall polynomial \( P_{\nu,\lambda}^{\mu}(q) \) (in the indeterminate \( q \)) is defined as follows: Specialize \( q \) to a prime power, and consider the category of \( \mathbb{F}_q \)-vector spaces with a distinguished nilpotent endomorphism. The morphisms in this category shall be the linear maps commuting with the distinguished endomorphisms. The type of an object in this category will be the Jordan type of the distinguished endomorphism; this is a partition. Now, if \( N \) is any fixed object of type \( \nu \) in this category, then the polynomial \( P_{\nu,\lambda}^{\mu}(q) \) specialized at the prime power \( q \) counts the number of subobjects \( L \) of \( N \) having type \( \lambda \) such that the quotient object \( N/L \) has type \( \mu \). This determines the values of the polynomial \( P_{\nu,\lambda}^{\mu} \) at infinitely many points (namely, at all prime powers), and hence \( P_{\nu,\lambda}^{\mu} \) is uniquely determined. The degree of this polynomial is at most \( n(\nu) - n(\lambda) - n(\mu) \), where \( n(\kappa) = \sum_i (i - 1)\kappa_i \) for every partition \( \kappa \). (If this is negative, then the polynomial is zero.)

These are the structure coefficients of the (classical) Hall algebra.

If \( |\nu| \neq |\mu| + |\lambda| \), then we have \( P_{\nu,\lambda}^{\mu} = 0 \). More generally, if the Littlewood-Richardson coefficient \( c_{\nu,\lambda}^{\mu} \) vanishes, then \( P_{\nu,\lambda}^{\mu} = 0 \).

The Hall polynomials satisfy the symmetry property \( P_{\nu,\lambda}^{\mu} = P_{\lambda,\mu}^{\nu} \).

ALGORITHM:
If \( \lambda = (1^r) \) and \( |\nu| = |\mu| + |\lambda| \), then we compute \( P_{\nu,\lambda}^{\mu} \) as follows (cf. Example 2.4 in [Sch2006]):

First, write \( \nu = (1^{i_1}, 2^{i_2}, \ldots, n^{i_n}) \), and define a sequence \( r = r_0 \geq r_1 \geq \cdots \geq r_n \) such that

\[
\mu = (1^{i_1-r_0+2r_1-r_2}, 2^{i_2-r_1+2r_2-r_3}, \ldots, (n-1)^{i_{n-1}-r_{n-2}+2r_{n-1}-r_n}, n^{i_n-r_{n-1}+r_n}).
\]

Thus if \( \mu = (1^{m_1}, \ldots, n^{m_n}) \), we have the following system of equations:

\[
m_1 = l_1 - r + 2r_1 - r_2,
m_2 = l_2 - r_1 + 2r_2 - r_3,
\vdots
m_{n-1} = l_{n-1} - r_{n-2} + 2r_{n-1} - r_n,
m_n = l_n - r_{n-1} + r_n
\]

and solving for \( r_i \) and back substituting we obtain the equations:

\[
 r_n = r_{n-1} + m_n - l_n,
 r_{n-1} = r_{n-2} + m_{n-1} - l_{n-1} + m_n - l_n,
\vdots
 r_1 = r + \sum_{k=1}^{n} (m_k - l_k),
\]
or in general we have the recursive equation:

\[ r_i = r_{i-1} + \sum_{k=i}^{n} (m_k - l_k). \]

This, combined with the condition that \( r_0 = r \), determines the \( r_i \) uniquely (recursively). Next we define

\[ t = (r_{n-2} - r_{n-1})(l_n - l_{n-1}) + (r_{n-3} - r_{n-2})(l_{n-1} + l_n - r_{n-2}) + \cdots + (r_0 - r_1)(l_2 + \cdots + l_n - r_1), \]

and with these notations we have

\[ P_{\mu, \nu}^{\nu} = q^t \left( \frac{l_n}{r_{n-1}} \right)_q \left( \frac{l_{n-1}}{r_{n-2} - r_{n-1}} \right)_q \cdots \left( \frac{l_1}{r_0 - r_1} \right)_q. \]

To compute \( P_{\mu, \lambda}^{\nu} \) in general, we compute the product \( I_{\mu}I_{\lambda} \) in the Hall algebra and return the coefficient of \( I_{\nu} \).

**EXAMPLES:**

```python
sage: from sage.combinat.hall_polynomial import hall_polynomial
sage: hall_polynomial([1,1],[1],[1])
q + 1
sage: hall_polynomial([2],[1],[1])
1
sage: hall_polynomial([2,1],[2],[1])
q
sage: hall_polynomial([2,2,1],[2,1],[1])
q^2 + q
sage: hall_polynomial([3,2,2,1],[3,2],[2,1])
q^6 + q^5
sage: hall_polynomial([4,2,1,1],[3,1,1],[2,1])
q^6 + q^5
sage: hall_polynomial([4,2],[2,1],[2,1], 0)
1
```

```bash
>>> from sage.all import *
>>> from sage.combinat.hall_polynomial import hall_polynomial
>>> hall_polynomial([Integer(1),Integer(1)],[Integer(1)],[Integer(1)])
q + 1
>>> hall_polynomial([Integer(2)],[Integer(1)],[Integer(1)])
1
>>> hall_polynomial([Integer(2),Integer(1)],[Integer(2)],[Integer(1)])
q
>>> hall_polynomial([Integer(2),Integer(2),Integer(1)],[Integer(2),Integer(1)],[Integer(1)])
q^2 + q
>>> hall_polynomial([Integer(2),Integer(2),Integer(2),Integer(1)],[Integer(2),Integer(1)],[Integer(1)])
q^4 + q^3 + q^2
>>> hall_polynomial([Integer(3),Integer(2),Integer(2),Integer(1)],[Integer(3),Integer(2),Integer(1)],[Integer(1)])
q^6 + q^5
>>> hall_polynomial([Integer(4),Integer(2),Integer(1),Integer(1)],[Integer(3),Integer(2),Integer(1)],[Integer(0)])
1
```
5.1.121 The Hillman-Grassl correspondence

This module implements weak reverse plane partitions and four correspondences on them: the Hillman-Grassl correspondence and its inverse, as well as the Sulzgruber correspondence and its inverse (the Pak correspondence).

Fix a partition $\lambda$ (see `Partition()`). We draw all partitions and tableaux in English notation.

A $\lambda$-array will mean a tableau of shape $\lambda$ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape $\lambda$ (short: $\lambda$-rpp) will mean a $\lambda$-array whose entries weakly increase along each row and weakly increase along each column. (The name "weak reverse plane partition" comes from Stanley in [EnumComb2] Section 7.22; other authors – such as Pak [Sulzgr2017], or Hillman and Grassl in [HilGra1976] – just call it a reverse plane partition.)

The Hillman-Grassl correspondence is a bijection from the set of $\lambda$-arrays to the set of $\lambda$-rpps. For its definition, see `hillman_grassl()`; for its inverse, see `hillman_grassl_inverse()`.

The Sulzgruber correspondence $\Phi_\lambda$ and the Pak correspondence $\xi_\lambda$ are two further mutually inverse bijections between the set of $\lambda$-arrays and the set of $\lambda$-rpps. They appear (sometimes with different definitions, but defining the same maps) in [Pak2002], [Hopkins2017] and [Sulzgr2017]. For their definitions, see `sulzgruber_correspondence()` and `pak_correspondence()`.

EXAMPLES:

We construct a $\lambda$-rpp for $\lambda = (3, 3, 1)$ (note that $\lambda$ needs not be specified explicitly):

```python
sage: p = WeakReversePlanePartition([[0, 1, 3], [2, 4, 4], [3]])
sage: p.parent()
Weak Reverse Plane Partitions
```

This is the example in Section 7.22 of [EnumComb2].

Next, we apply the inverse of the Hillman-Grassl correspondence to it:

```python
sage: HGp = p.hillman_grassl_inverse(); HGp
[[1, 2, 0], [1, 0, 1], [1]]
sage: HGp.parent()
Tableaux
```

This is a $\lambda$-array, encoded as a tableau. We can recover our original $\lambda$-rpp from it using the Hillman-Grassl correspondence:

```python
sage: HGp.hillman_grassl() == p
True
```
We can also apply the Pak correspondence to our rpp:

```
>>> from sage.all import *
>>> Pp = p.pak_correspondence(); Pp
[[2, 0, 1], [0, 2, 0], [1]]
```

This is undone by the Sulzgruber correspondence:

```
>>> from sage.all import *
>>> Pp = Pp.sulzgruber_correspondence() == p
True
```

These four correspondences can also be accessed as standalone functions (`hillman_grassl_inverse()`, `hillman_grassl()`, `pak_correspondence()` and `sulzgruber_correspondence()`) that transform lists of lists into lists of lists; this may be more efficient. For example, the above computation of HGp can also be obtained as follows:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: HGp_bare = hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
sage: HGp_bare
[[1, 2, 0], [1, 0, 1], [1]]
sage: isinstance(HGp_bare, list)
True
```

class sage.combinat.hillman_grassl.WeakReversePlanePartition (parent, t)

Bases: Tableau

A weak reverse plane partition (short: rpp).

A weak reverse plane partition is a tableau with nonnegative entries that are weakly increasing in each row and weakly increasing in each column.

EXAMPLES:

```python
sage: x = WeakReversePlanePartition([[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]); x
[[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]
sage: x.pp()
0 1 1
0 1 3
1 2 2
1 2 3
2
sage: x.shape()
[3, 3, 3, 3, 1]
```

```python
>>> from sage.all import *

>>> x = WeakReversePlanePartition([[Integer(0), Integer(1), Integer(1)], [Integer(0), Integer(1), Integer(3)], [Integer(1), Integer(2), Integer(2)], [Integer(1), Integer(2), Integer(3)], [Integer(2)]]); x
[[0, 1, 1], [0, 1, 3], [1, 2, 2], [1, 2, 3], [2]]

>>> x.pp()
0 1 1
0 1 3
1 2 2
1 2 3
2

>>> x.shape()
[3, 3, 3, 3, 1]
```

calculate

Return the conjugate of self.

EXAMPLES:

```python
sage: c = WeakReversePlanePartition([[1,1],[1,3],[2]]).conjugate(); c
[[1, 1, 2], [1, 3]]
sage: c.parent()
Weak Reverse Plane Partitions

>>> from sage.all import *

>>> c = WeakReversePlanePartition([[Integer(1), Integer(1)], [Integer(1), Integer(3)], [Integer(2)]]).conjugate(); c
[[1, 1, 2], [1, 3]]

>>> c.parent()
Weak Reverse Plane Partitions
```
Return the image of the \( \lambda \)-rpp \texttt{self} under the inverse of the Hillman-Grassl correspondence (as a \texttt{Tableau}).

Fix a partition \( \lambda \) (see \texttt{Partition()}). We draw all partitions and tableaux in English notation.

A \( \lambda \)-array will mean a tableau of shape \( \lambda \) whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape \( \lambda \) (short: \( \lambda \)-rpp) will mean a \( \lambda \)-array whose entries weakly increase along each row and weakly increase along each column.

The inverse \( H^{-1} \) of the Hillman-Grassl correspondence (see \texttt{hillman_grassl()}) sends a \( \lambda \)-rpp \( \pi \) to a \( \lambda \)-array \( H^{-1}(\pi) \) constructed recursively as follows:

- If all entries of \( \pi \) are 0, then \( H^{-1}(\pi) = \pi \).
- Otherwise, let \( s \) be the index of the leftmost column of \( \pi \) containing a nonzero entry. Write the \( \lambda \)-array \( M \) as \((m_{i,j})\).

- Define a sequence \(( (i_1,j_1), (i_2,j_2), \ldots, (i_n,j_n) ) \) of boxes in the diagram of \( \lambda \) (actually a lattice path made of northward and eastward steps) as follows: Let \((i_1,j_1)\) be the bottommost box in the \( s \)-th column of \( \pi \). If \((i_k,j_k)\) is defined for some \( k \geq 1 \), then \((i_{k+1},j_{k+1})\) is constructed as follows: If \( q_{i_k-1,j_k} \) is well-defined and equals \( q_{i_k,j_k} \), then we set \((i_{k+1},j_{k+1}) = (i_k-1,j_k)\). Otherwise, we set \((i_{k+1},j_{k+1}) = (i_k,j_k+1)\) if this is still a box of \( \lambda \). Otherwise, the sequence ends here.

- Let \( \pi' \) be the \( \lambda \)-rpp obtained from \( \pi \) by subtracting 1 from the \((i_k,j_k)\)-th entry of \( \pi \) for each \( k \in \{1,2,\ldots,n\} \).

- Let \( N' \) be the image \( H^{-1}(\pi') \) (which is already constructed by recursion). Then, \( H^{-1}(\pi) \) is obtained from \( N' \) by adding 1 to the \((i_n,s)\)-th entry of \( N' \).

This construction appears in \cite{HilGra1976} Section 6 (where \( \lambda \)-arrays are re-encoded as sequences of “hook number multiplicities”) and \cite{EnumComb2} Section 7.22.

See also:

- \texttt{hillman_grassl_inverse()} for the inverse of the Hillman-Grassl correspondence as a standalone function.
- \texttt{hillman_grassl()} for the inverse map.

**EXAMPLES:**

```python
sage: a = WeakReversePlanePartition([[2, 2, 4], [2, 3, 4], [3, 5]])
```

```python
sage: a.hillman_grassl_inverse()
[[1, 1, 1], [0, 2, 0], [1, 1]]
```

```python
sage: b = WeakReversePlanePartition([[1, 1, 2, 2], [1, 1, 2, 2], [2, 2, 3, 3],
                                 [1, 0, 1, 0], [0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 0, 1]])
```

```python
sage: B = b.hillman_grassl_inverse(); B
[[1, 0, 1, 0], [0, 1, 0, 1], [1, 0, 1, 0], [0, 1, 0, 1]]
```

```python
sage: a.parent(), B.parent()
(Weak Reverse Plane Partitions, Tableaux)
```

```python
>>> from sage.all import *
```

```python
>>> a = WeakReversePlanePartition([[Integer(2), Integer(2), Integer(4)],
                                 [Integer(2), Integer(3), Integer(4)], [Integer(3), Integer(5)]])
```

```python
>>> a.hillman_grassl_inverse()
[[2, 1, 1], [0, 2, 0], [1, 1]]
```

```python
>>> b = WeakReversePlanePartition([[Integer(1), Integer(1), Integer(2),
                                 Integer(2)], [Integer(1), Integer(1), Integer(2), Integer(2)], [Integer(2),
                                 Integer(2), Integer(2), Integer(1)]])
```

(continues on next page)
Applying the inverse of the Hillman-Grassl correspondence to the transpose of a $\lambda$-rpp $M$ yields the same result as applying it to $M$ and then transposing the result ([Gans1981] Corollary 3.4):

```python
def aic == a.conjugate().hillman_grassl_inverse()
True
```

The Pak correspondence is the map $\xi_{\lambda}$ from [Sulzgr2017] Section 7, and is the map $\xi_{\lambda}$ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence ($\text{sulzgruber_correspondence()}$).

The following description of the Pak correspondence follows [Hopkins2017] (which denotes it by $\text{RSK}^{-1}$):

Fix a partition $\lambda$ (see $\text{Partition()}$). We draw all partitions and tableaux in English notation.

A $\lambda$-array will mean a tableau of shape $\lambda$ whose entries are nonnegative integers. (No conditions on the order of these entries are made. Note that 0 is allowed.)

A weak reverse plane partition of shape $\lambda$ (short: $\lambda$-rpp) will mean a $\lambda$-array whose entries weakly increase along each row and weakly increase along each column.

We shall also use the following notation: If $(u, v)$ is a cell of $\lambda$, and if $\pi$ is a $\lambda$-rpp, then:

- the lower bound of $\pi$ at $(u, v)$ (denoted by $\pi_{< (u,v)}$) is defined to be $\max\{\pi_{u-1,v}, \pi_{u,v-1}\}$ (where $\pi_{0,v}$ and $\pi_{u,0}$ are understood to mean 0).
- the upper bound of $\pi$ at $(u, v)$ (denoted by $\pi_{> (u,v)}$) is defined to be $\min\{\pi_{u+1,v}, \pi_{u,v+1}\}$ (where $\pi_{i,j}$ is understood to mean $+\infty$ if $(i,j)$ is not in $\lambda$; thus, the upper bound at a corner cell is $+\infty$).
- toggling $\pi$ at $(u, v)$ means replacing the entry $\pi_{u,v}$ of $\pi$ at $(u, v)$ by $\pi_{< (u,v)} + \pi_{> (u,v)} - \pi_{u,v}$ (this is well-defined as long as $(u, v)$ is not a corner of $\lambda$).

Note that every $\lambda$-rpp $\pi$ and every cell $(u,v)$ of $\lambda$ satisfy $\pi_{< (u,v)} \leq \pi_{u,v} \leq \pi_{> (u,v)}$. Note that toggling a $\lambda$-rpp (at a cell that is not a corner) always results in a $\lambda$-rpp. Also, toggling is an involution.

Note also that the lower bound of $\pi$ at $(u, v)$ is defined (and finite) even when $(u, v)$ is not a cell of $\lambda$, as long as both $(u - 1, v)$ and $(u, v - 1)$ are cells of $\lambda$.

The Pak correspondence $\Phi_{\lambda}$ sends a $\lambda$-array $M = (m_{i,j})$ to a $\lambda$-rpp $\Phi_{\lambda}(M)$. It is defined by recursion on $\lambda$ (that is, we assume that $\Phi_{\mu}$ is already defined for every partition $\mu$ smaller than $\lambda$), and its definition proceeds as follows:
• If $\lambda = \emptyset$, then $\Phi_\lambda$ is the obvious bijection sending the only $\emptyset$-array to the only $\emptyset$-rpp.

• Pick any corner $c = (i, j)$ of $\lambda$, and let $\mu$ be the result of removing this corner $c$ from the partition $\lambda$. (The exact choice of $c$ is immaterial.)

• Let $M'$ be what remains of $M$ when the corner cell $c$ is removed.

• Let $\pi' = \Phi_\mu(M')$.

• For each positive integer $k$ such that $(i - k, j - k)$ is a cell of $\lambda$, toggle $\pi'$ at $(i - k, j - k)$. (All these togglings commute, so the order in which they are made is immaterial.)

• Extend the $\mu$-rpp $\pi'$ to a $\lambda$-rpp $\pi$ by adding the cell $c$ and writing the number $m_{i,j} - \pi'_{<i,j}$ into this cell.

• Set $\Phi_\lambda(M) = \pi$.

See also:

pak_correspondence() for the Pak correspondence as a standalone function.

sulzgruber_correspondence() for the inverse map.

EXAMPLES:

```python
sage: a = WeakReversePlanePartition([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
sage: A = a.pak_correspondence(); A
[[1, 0, 2], [0, 2, 0], [1, 1, 0]]
sage: a.parent(), A.parent()  # (Weak Reverse Plane Partitions, Tableaux)
```

Applying the Pak correspondence to the transpose of a $\lambda$-rpp $M$ yields the same result as applying it to $M$ and then transposing the result:

```python
sage: a = WeakReversePlanePartition([[1,3,5],[2,4]])
sage: acc = a.pak_correspondence().conjugate()
sage: acc == a.conjugate().pak_correspondence()
True
```

```python
>>> from sage.all import *

>>> a = WeakReversePlanePartition([[Integer(1), Integer(3), Integer(5)],
   [Integer(2), Integer(4)]])

>>> acc = a.pak_correspondence().conjugate()

>>> acc == a.conjugate().pak_correspondence()
True
```

class sage.combinat.hillman_grassl.WeakReversePlanePartitions

Bases: Tableaux

The set of all weak reverse plane partitions.

Element

alias of WeakReversePlanePartition
an_element()

Returns a particular element of the class.

sage.combinat.hillman_grassl.hillman_grassl(M)

Return the image of the $\lambda$-array $M$ under the Hillman-Grassl correspondence.

The Hillman-Grassl correspondence is a bijection between the tableaux with nonnegative entries (otherwise arbitrary) and the weak reverse plane partitions with nonnegative entries. This bijection preserves the shape of the tableau. See hillman_grassl.

See hillman_grassl() for a description of this map.

See also:

hillman_grassl_inverse()

EXAMPLES:

sage: from sage.combinat.hillman_grassl import hillman_grassl
sage: hillman_grassl([[2, 1, 1], [0, 2, 0], [1, 1]])
[[2, 2, 4], [2, 3, 4], [3, 5]]

sage: hillman_grassl([[1, 2, 0], [1, 0, 1], [1]])
[[0, 1, 3], [2, 4, 4], [3]]

sage: hillman_grassl([])
[]

sage: hillman_grassl([[3, 1, 2]])
[[3, 4, 6]]

sage: hillman_grassl([[2, 2, 0], [1, 1, 1], [1]])
[[1, 2, 4], [3, 5, 5], [4]]

sage: hillman_grassl([[1, 1, 1, 1]]*3)
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]

>>> from sage.all import *
>>> from sage.combinat.hillman_grassl import hillman_grassl

>>> hillman_grassl([[2, 1, 1], [0, 2, 0], [1, 1]])
[[2, 2, 4], [2, 3, 4], [3, 5]]

>>> hillman_grassl([[1, 2, 0], [1, 0, 1], [1]])
[[0, 1, 3], [2, 4, 4], [3]]

>>> hillman_grassl([])
[]

>>> hillman_grassl([[3, 1, 2]])
[[3, 4, 6]]

>>> hillman_grassl([[2, 2, 0], [1, 1, 1], [1]])
[[1, 2, 4], [3, 5, 5], [4]]

>>> hillman_grassl([[1, 1, 1, 1]]*3)
[[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]]

sage.combinat.hillman_grassl.hillman_grassl_inverse(M)

Return the image of the $\lambda$-rpp $M$ under the inverse of the Hillman-Grassl correspondence.

See hillman_grassl.

See hillman_grassl_inverse() for a description of this map.

See also:

hillman_grassl()
EXAMPLES:

```
sage: from sage.combinat.hillman_grassl import hillman_grassl_inverse
sage: hillman_grassl_inverse([[2, 2, 4], [2, 3, 4], [3, 5]])
[[2, 1, 1], [0, 2, 0], [1, 1]]
sage: hillman_grassl_inverse([[0, 1, 3], [2, 4, 4], [3]])
[[1, 2, 0], [1, 0, 1], [1]]
```

Applying the inverse of the Hillman-Grassl correspondence to the transpose of a $\lambda$-rpp $M$ yields the same result as applying it to $M$ and then transposing the result ([Gans1981] Corollary 3.4):

```
sage: hillman_grassl_inverse([[1, 3, 5], [2, 4]])
[[1, 2, 2], [1, 1]]
sage: hillman_grassl_inverse([[1, 2], [3, 4], [5]])
[[1, 1], [2, 1], [2]]
sage: hillman_grassl_inverse([[1, 2, 3], [1, 2, 3], [2, 4, 4]])
[[1, 2, 0], [0, 1, 1], [1, 0, 1]]
sage: hillman_grassl_inverse([[1, 2, 3, 4], [2, 3, 4, 5], [3, 4, 5, 6]])
[[1, 1, 1, 1], [1, 1, 1, 1], [1, 1, 1, 1]]
```

```
sage.combinat.hillman_grassl.pak_correspondence (M, copy=True)
```

Return the image of a $\lambda$-rpp $M$ under the Pak correspondence.

The Pak correspondence is the map $\xi_\lambda$ from [Sulzgr2017] Section 7, and is the map $\xi_\lambda$ from [Pak2002] Section 4. It is the inverse of the Sulzgruber correspondence (sulzgruber_correspondence()).

See pak_correspondence() for a description of this map.

INPUT:

- `copy` (default: True) – boolean; if set to False, the algorithm will mutate the input (but be more efficient)

EXAMPLES:
The Pak correspondence can actually be extended (by the same definition) to “rpps” of nonnegative reals rather than nonnegative integers. This implementation supports this:

```
sage: pak_correspondence([[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]])
[[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]]
```

sage.combinat.hillman_grassl.sulzgruber_correspondence(M)

Return the image of a $\lambda$-array $M$ under the Sulzgruber correspondence.

The Sulzgruber correspondence is the map $\Phi_\lambda$ from [Sulzgr2017] Section 7, and is the map $\zeta_\lambda^{-1}$ from [Pak2002] Section 5. It is denoted by $\mathcal{RSK}$ in [Hopkins2017]. It is the inverse of the Pak correspondence (pak_correspondence()).

See sulzgruber_correspondence() for a description of this map.

EXAMPLES:
The Sulzgruber correspondence can actually be extended (by the same definition) to arrays of nonnegative reals rather than nonnegative integers. This implementation supports this:

```
sage: sulzgruber_correspondence([[1/2, 0, 1], [0, 1, 0], [1/2, 1/2]])
[[0, 1, 3/2], [1/2, 3/2, 3/2], [1, 2]]
```

`sage.combinat.hillman_grassl.transpose(M)`

Return the transpose of a \( \lambda \)-array.

The transpose of a \( \lambda \)-array \((m_{i,j})\) is the \( \lambda^t \)-array \((m_{j,i})\) (where \( \lambda^t \) is the conjugate of the partition \( \lambda \)).

**EXAMPLES:**

```
sage: from sage.combinat.hillman_grassl import transpose
sage: transpose([[1, 2, 3], [4, 5]])
[[1, 4], [2, 5], [3]]
sage: transpose([[5, 0, 3], [4, 1, 0], [7]])
[[5, 4, 7], [0, 1], [3, 0]]
```
5.1.122 Enumerated set of lists of integers with constraints: base classes

- **IntegerListsBackend**: base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.
- **Envelope**: a utility class for upper (lower) envelope of a function under constraints.

```python
class sage.combinat.integer_lists.base.Envelope
Bases: object
The (currently approximated) upper (lower) envelope of a function under the specified constraints.

INPUT:
- `f` - a function, list, or tuple; if `f` is a list, it is considered as the function `f(i)=f[i]`, completed for larger `i` with `f(i)=max_part`.
- `min_part, max_part, min_slope, max_slope, ...` as for `IntegerListsLex` (please consult for details).
- `sign` - (+1 or -1) multiply the input values with `sign` and multiply the output with `sign`. Setting this to -1 can be used to implement a lower envelope.

The upper envelope `U(f)` of `f` is the (pointwise) largest function which is bounded above by `f` and satisfies the `max_part` and `max_slope` conditions. Furthermore, for `i, i+1 < min_length`, the upper envelope also satisfies the `min_slope` condition.

Upon computing `U(f)(i)`, all the previous values for `j ≤ i` are computed and cached; in particular `f(i)` will be computed at most once for each `i`.

Todo:
- This class is a good candidate for Cythonization, especially to get the critical path in `__call__` super fast.
- To get full envelopes, we would want both the `min_slope` and `max_slope` conditions to always be satisfied. This is only properly defined for the restriction of `f` to a finite interval `0, ..., k`, and depends on `k`.
- This is the core “data structure” of `IntegerListsLex`. Improving the lookahead there essentially depends on having functions with a good complexity to compute the area below an envelope; and in particular how it evolves when increasing the length.

EXAMPLES:
```python
sage: from sage.combinat.integer_lists import Envelope

>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
```

Trivial upper and lower envelopes:
Combinatorics, Release 10.4

```python
sage: f = Envelope([3,2,2])
sage: [f(i) for i in range(10)]
[3, 2, 2, inf, inf, inf, inf, inf, inf, inf]
sage: f = Envelope([3,2,2], sign=-1)
sage: [f(i) for i in range(10)]
[3, 2, 2, 0, 0, 0, 0, 0, 0, 0]
```

```python
>>> from sage.all import *

```python
sage: f = Envelope(
 Integer(3), Integer(2), Integer(2)
), sign=Integer(-1),
min_part=Integer(2), min_slope=Integer(-1))

```python
sage: [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

A more interesting lower envelope:

```python
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

Currently, adding max_slope has no effect:

```python
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

unless min_length is large enough:

```python
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,...
               min_length=2)
sage: [f(i) for i in range(10)]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]
```

```python
sage: f = Envelope([4,1,5,3,5], sign=-1, min_part=2, min_slope=-1, max_slope=0,...
               min_length=4)
sage: [f(i) for i in range(10)]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]
```

1874 Chapter 5. Comprehensive Module List
```python
>>> from sage.all import *

>>> f = Envelope([Integer(4), Integer(1), Integer(5), Integer(3), Integer(5)],
                sign=Integer(1), min_part=Integer(2), min_slope=Integer(1),
                max_slope=Integer(0), min_length=Integer(2))

>>> [f(i) for i in range(Integer(10))]
[4, 3, 5, 4, 5, 4, 3, 2, 2, 2]

>>> f = Envelope([Integer(4), Integer(1), Integer(5), Integer(3), Integer(5)],
                sign=Integer(1), min_part=Integer(2), min_slope=Integer(1),
                max_slope=Integer(0), min_length=Integer(4))

>>> [f(i) for i in range(Integer(10))]
[5, 5, 5, 4, 5, 4, 3, 2, 2, 2]

>>> f = Envelope([Integer(4), Integer(1), Integer(5), Integer(3), Integer(5)],
                sign=Integer(1), min_part=Integer(2), min_slope=Integer(1),
                max_slope=Integer(0), min_length=Integer(5))

>>> [f(i) for i in range(Integer(10))]
[5, 5, 5, 5, 5, 4, 3, 2, 2, 2]

An non trivial upper envelope:

```sage`
f = Envelope([9, 1, 5, 4], max_part=7, max_slope=2)
sage:
[f(i) for i in range(10)]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

```python
>>> from sage.all import *

>>> f = Envelope([Integer(9), Integer(1), Integer(5), Integer(4)],
                max_part=Integer(7), max_slope=Integer(2))

>>> [f(i) for i in range(Integer(10))]
[7, 1, 3, 4, 6, 7, 7, 7, 7, 7]
```

adapt\((m,j)\)

Return this envelope adapted to an additional local constraint.

**INPUT:**

- \(m\) – a nonnegative integer (starting value)
- \(j\) – a nonnegative integer (position)

This method adapts this envelope to the additional local constraint imposed by having a part \(m\) at position \(j\). Namely, this returns a function which computes, for any \(i > j\), the minimum of the ceiling function and the value restriction given by the slope conditions.

**EXAMPLES:**

```python
sage: from sage.combinat.integer_lists import Envelope
sage: f = Envelope(3)
sage: g = f.adapt(1,1)
sage: g is f
True
sage: [g(i) for i in range(10)]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

sage: f = Envelope(3, max_slope=1)
sage: g = f.adapt(1,1)
sage: [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]
```
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope

f = Envelope(Integer(3))
g = f.adapt(Integer(1), Integer(1))
g is f
True

>>> [g(i) for i in range(Integer(10))]
[3, 3, 3, 3, 3, 3, 3, 3, 3, 3]

f = Envelope(Integer(3), max_slope=Integer(1))
g = f.adapt(Integer(1), Integer(1))

>>> [g(i) for i in range(Integer(10))]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

Note that, in both cases above, the adapted envelope is only guaranteed to be valid for \( i > j \)! This is to leave potential room in the future for sharing similar adapted envelopes:

>>> g = f.adapt(0, 0)
>>> [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

>>> g = f.adapt(2, 2)
>>> [g(i) for i in range(10)]
[0, 1, 2, 3, 3, 3, 3, 3, 3, 3]

Now with a lower envelope:

>>> f = Envelope(1, sign=-1, min_slope=-1)
>>> g = f.adapt(Integer(2), Integer(2))

>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]

>>> g = f.adapt(Integer(2), Integer(2))

>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]

(continues on next page)
\begin{verbatim}
>>> g = f.adapt(Integer(1),Integer(3))
>>> [g(i) for i in range(Integer(10))]
[4, 3, 2, 1, 1, 1, 1, 1, 1, 1]
\end{verbatim}

**limit()**

Return a bound on the limit of \texttt{self}.

**OUTPUT:** a nonnegative integer or $\infty$

This returns some upper bound for the accumulation points of this upper envelope. For a lower envelope, a lower bound is returned instead.

In particular this gives a bound for the value of \texttt{self} at \texttt{i} for \texttt{i} large enough. Special case: for a lower envelope, and when the limit is $\infty$, the envelope is guaranteed to tend to $\infty$ instead.

When \texttt{s=\texttt{self.limit_start()}} is finite, this bound is guaranteed to be valid for \texttt{i} \geq \texttt{s}.

Sometimes it’s better to have a loose bound that starts early; sometimes the converse holds. At this point which specific bound and starting point is returned is not set in stone, in order to leave room for later optimizations.

**EXAMPLES:**

\begin{verbatim}
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit()
inf
sage: Envelope([4,1,5], max_part=2).limit()
2
sage: Envelope([4,1,5], max_slope=0).limit()
1
sage: Envelope(lambda x: 3, max_part=2).limit()
2
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> Envelope([Integer(4),Integer(1),Integer(5)]).limit()
inf
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_part=Integer(2)).limit()
2
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_slope=Integer(0)).limit()
1
>>> Envelope(lambda x: Integer(3), max_part=Integer(2)).limit()
2
\end{verbatim}

Lower envelopes:

\begin{verbatim}
sage: Envelope(lambda x: 3, min_part=2, sign=-1).limit()
2
sage: Envelope([4,1,5], min_slope=0, sign=-1).limit()
5
sage: Envelope([4,1,5], sign=-1).limit()
0
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> Envelope(lambda x: Integer(3), min_part=Integer(2), sign=Integer(1)).limit()
2
>>> Envelope([Integer(4),Integer(1),Integer(5)], min_slope=Integer(0), sign=-Integer(1)).limit()
2
\end{verbatim}

(continues on next page)
See also:

\texttt{limit_start()}

\texttt{limit_start()}

Return from which \( i \) on the bound returned by \texttt{limit} holds.

See also:

\texttt{limit()} for the precise specifications.

\textbf{EXAMPLES:}

```python
sage: from sage.combinat.integer_lists import Envelope
sage: Envelope([4,1,5]).limit_start()
3
sage: Envelope([4,1,5], sign=-1).limit_start()
3
sage: Envelope([4,1,5], max_part=2).limit_start()
3
sage: Envelope(4).limit_start()
0
sage: Envelope(4, sign=-1).limit_start()
0
sage: Envelope(\lambda x: 3).limit_start() == Infinity
True
sage: Envelope(\lambda x: 3, max_part=2).limit_start() == Infinity
True
sage: Envelope(\lambda x: 3, sign=-1, min_part=2).limit_start() == Infinity
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.integer_lists import Envelope
>>> Envelope([Integer(4),Integer(1),Integer(5)]).limit_start()
3
>>> Envelope([Integer(4),Integer(1),Integer(5)], sign=Integer(1)).limit_start()
3
>>> Envelope([Integer(4),Integer(1),Integer(5)], max_part=Integer(2)).limit_start()
3
>>> Envelope(Integer(4)).limit_start()
0
>>> Envelope(Integer(4), sign=Integer(1)).limit_start()
0
>>> Envelope(\lambda x: Integer(3)).limit_start() == Infinity
True
```
(continued from previous page)

```python
>>> Envelope(lambda x: Integer(3), max_part=Integer(2)).limit_start() == -Infinity
True

>>> Envelope(lambda x: Integer(3), sign=-Integer(1), min_part=Integer(2)).
→ limit_start() == Infinity
True
```

**class** `sage.combinat.integer_lists.base.IntegerListsBackend`

**Bases:** `object`

Base class for the Cython back-end of an enumerated set of lists of integers with specified constraints.

This base implements the basic operations, including checking for containment using `_contains()`, but not iteration. For iteration, subclass this class and implement an `_iter()` method.

**EXAMPLES:**

```python
sage: from sage.combinat.integer_lists.base import IntegerListsBackend
sage: L = IntegerListsBackend(6, max_slope=-1)
sage: L._contains([3,2,1])
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.integer_lists.base import IntegerListsBackend
>>> L = IntegerListsBackend(Integer(6), max_slope=-Integer(1))
>>> L._contains([Integer(3),Integer(2),Integer(1)])
True
```

### ceiling

### floor

### max_length

### max_part

### max_slope

### max_sum

### min_length

### min_part

### min_slope

### min_sum
5.1.123 Enumerated set of lists of integers with constraints: front-end

- **IntegerLists**: class which models an enumerated set of lists of integers with certain constraints. This is a Python front-end where all user-accessible functionality should be implemented.

```python
class sage.combinat.integer_lists.lists.IntegerList
    Bases: ClonableArray

Element class for IntegerLists.

check()
    Check to make sure this is a valid element in its IntegerLists parent.

EXAMPLES:

sage: C = IntegerListsLex(4)
sage: C([4]).check()
True
sage: C([5]).check()
False
```

```python
>>> from sage.all import *
>>> C = IntegerListsLex(Integer(4))
>>> C([Integer(4)]).check()
True
>>> C([Integer(5)]).check()
False
```

```python
class sage.combinat.integer_lists.lists.IntegerLists(*args, **kwds)
    Bases: Parent

Enumerated set of lists of integers with constraints.

Currently, this is simply an abstract base class which should not be used by itself. See IntegerListsLex for a class which can be used by end users.

IntegerLists is just a Python front-end, acting as a Parent, supporting element classes and so on. The attribute .backend which is an instance of sage.combinat.integer_lists.base.IntegerListsBackend is the Cython back-end which implements all operations such as iteration.

The front-end (i.e. this class) and the back-end are supposed to be orthogonal: there is no imposed correspondence between front-ends and back-ends.

For example, the set of partitions of 5 and the set of weakly decreasing sequences which sum to 5 might be implemented by the same back-end, but they will be presented to the user by a different front-end.

EXAMPLES:

```python
sage: from sage.combinat.integer_lists import IntegerLists
sage: L = IntegerLists(5)
sage: L
Integer lists of sum 5 satisfying certain constraints
sage: IntegerListsLex(2, length=3, name="A given name")
A given name
```

```python
>>> from sage.all import *

5.1.124 Enumerated set of lists of integers with constraints, in inverse lexicographic order

- `IntegerListsLex`: the enumerated set of lists of nonnegative integers with specified constraints, in inverse lexicographic order.
- `IntegerListsBackend_invlex`: Cython back-end for `IntegerListsLex`.

HISTORY:
This generic tool was originally written by Hivert and Thiery in MuPAD-Combinat in 2000 and ported over to Sage by Mike Hansen in 2007. It was then completely rewritten in 2015 by Gillespie, Schilling, and Thiery, with the help of many, to deal with limitations and lack of robustness w.r.t. input.

class sage.combinat.integer_lists.invlex.IntegerListsBackend_invlex
  Bases: IntegerListsBackend
  
  Cython back-end of a set of lists of integers with specified constraints enumerated in inverse lexicographic order.

check

class sage.combinat.integer_lists.invlex.IntegerListsLex(*args, **kwds)
  Bases: IntegerLists
  
  Lists of nonnegative integers with constraints, in inverse lexicographic order.

  An integer list is a list \( l \) of nonnegative integers, its parts. The slope (at position \( i \)) is the difference \( l[i+1] - l[i] \) between two consecutive parts.

  This class allows to construct the set \( S \) of all integer lists \( l \) satisfying specified bounds on the sum, the length, the slope, and the individual parts, enumerated in inverse lexicographic order, that is from largest to smallest in lexicographic order. Note that, to admit such an enumeration, \( S \) is almost necessarily finite (see On finiteness and inverse lexicographic enumeration).

  The main purpose is to provide a generic iteration engine for all the enumerated sets like Partitions, Compositions, IntegerVectors. It can also be used to generate many other combinatorial objects like Dyck paths, Motzkin paths, etc. Mathematically speaking, this is a special case of set of integral points of a polytope (or union thereof, when the length is not fixed).

INPUT:
- \( \text{min\_sum} \) – a nonnegative integer (default: 0): a lower bound on \( \text{sum}(l) \).
- \( \text{max\_sum} \) – a nonnegative integer or \( \infty \) (default: \( \infty \)): an upper bound on \( \text{sum}(l) \).
- \( n \) – a nonnegative integer (optional): if specified, this overrides \( \text{min}_\text{sum} \) and \( \text{max}_\text{sum} \).
- \( \text{min}_\text{length} \) – a nonnegative integer (default: 0): a lower bound on \( \text{len}(l) \).
- \( \text{max}_\text{length} \) – a nonnegative integer or \( \infty \) (default: \( \infty \)): an upper bound on \( \text{len}(l) \).
- \( \text{length} \) – an integer (optional); overrides \( \text{min}_\text{length} \) and \( \text{max}_\text{length} \) if specified;
- \( \text{min}_\text{part} \) – a nonnegative integer: a lower bounds on all parts: \( \text{min}_\text{part} \leq l[i] \) for \( 0 \leq i < \text{len}(l) \).
- \( \text{floor} \) – a list of nonnegative integers or a function: lower bounds on the individual parts \( l[i] \).
  If \( \text{floor} \) is a list of integers, then \( \text{floor} \leq l[i] \) for \( 0 \leq i < \text{min} (\text{len}(l)), \text{len}(\text{floor}) \). Similarly, if \( \text{floor} \) is a function, then \( \text{floor}(i) \leq l[i] \) for \( 0 \leq i < \text{len}(l) \).
- \( \text{max}_\text{part} \) – a nonnegative integer or \( \infty \): an upper bound on all parts: \( l[i] \leq \text{max}_\text{part} \) for \( 0 \leq i < \text{len}(l) \).
- \( \text{ceiling} \) – upper bounds on the individual parts \( l[i] \); this takes the same type of input as \( \text{floor} \), except that \( \infty \) is allowed in addition to integers, and the default value is \( \infty \).
- \( \text{min}_\text{slope} \) – an integer or \( -\infty \) (default: \( -\infty \)): a lower bound on the slope between consecutive parts: \( \text{min}_\text{slope} \leq l[i+1]-l[i] \) for \( 0 \leq i < \text{len}(l)-1 \)
- \( \text{max}_\text{slope} \) – an integer or \( +\infty \) (default: \( +\infty \)): an upper bound on the slope between consecutive parts: \( l[i+1]-l[i] \leq \text{max}_\text{slope} \) for \( 0 \leq i < \text{len}(l)-1 \)
- \( \text{category} \) – a category (default: \( \text{FiniteEnumeratedSets} \))
- \( \text{check} \) – boolean (default: True): whether to display the warnings raised when functions are given as input to \( \text{floor} \) or \( \text{ceiling} \) and the errors raised when there is no proper enumeration.
- \( \text{name} \) – a string or None (default: None) if set, this will be passed down to Parent.rename() to specify the name of \( \text{self} \). It is recommended to use rename method directly because this feature may become deprecated.
- \( \text{element}_\text{constructor} \) – a function (or callable) that creates elements of \( \text{self} \) from a list. See also Parent.
- \( \text{element}_\text{class} \) – a class for the elements of \( \text{self} \) (default: \( \text{ClonableArray} \)). This merely sets the attribute \( \text{self}.\text{Element} \). See the examples for details.

**Note:** When several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is enumerated (and therefore counted). The others are still considered valid. See the examples below.

This feature is questionable. It is recommended not to rely on it, as it may eventually be discontinued.

**EXAMPLES:**

We create the enumerated set of all lists of nonnegative integers of length 3 and sum 2:

```python
sage: C = IntegerListsLex(2, length=3)
sage: C
Integer lists of sum 2 satisfying certain constraints
sage: C.cardinality()
6
sage: [p for p in C]
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
sage: [2, 0, 0] in C
True
```
One can specify lower and upper bounds on each part:

```python
sage: list(IntegerListsLex(5, length=3, floor=[1, 2, 0], ceiling=[3, 2, 3]))
[[3, 2, 0], [2, 2, 1], [1, 2, 2]]
```

When the length is fixed as above, one can also use \texttt{IntegerVectors}:

```python
sage: IntegerVectors(2,3).list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2]]
```

Using the slope condition, one can generate integer partitions (but see \texttt{Partitions}):

```python
sage: list(IntegerListsLex(4, max_slope=0))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```
The following is the list of all partitions of 7 with parts at least 2:

```
sage: list(IntegerListsLex(7, max_slope=0, min_part=2))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

```
>>> from sage.all import *

>>> list(IntegerListsLex(Integer(7), max_slope=Integer(0), min_part=Integer(2)))
[[7], [5, 2], [4, 3], [3, 2, 2]]
```

### Floor and ceiling conditions

Next we list all partitions of 5 of length at most 3 which are bounded below by \([2,1,1]\):

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, floor=[2,1,1]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *

>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), max_length=Integer(3), floor=[Integer(2),Integer(1),Integer(1)]))
[[5], [4, 1], [3, 2], [3, 1, 1], [2, 2, 1]]
```

Note that \([5]\) is considered valid, because the floor constraints only apply to existing positions in the list. To obtain instead the partitions containing \([2,1,1]\), one needs to use `min_length` or `length`:

```
sage: list(IntegerListsLex(5, max_slope=0, length=3, floor=[2,1,1]))
[[3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *

>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), length=Integer(3), floor=[Integer(2),Integer(1),Integer(1)]))
[[3, 1, 1], [2, 2, 1]]
```

Here is the list of all partitions of 5 which are contained in \([3,2,2]\):

```
sage: list(IntegerListsLex(5, max_slope=0, max_length=3, ceiling=[3,2,2]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

```
>>> from sage.all import *

>>> list(IntegerListsLex(Integer(5), max_slope=Integer(0), max_length=Integer(3), ceiling=[Integer(3),Integer(2),Integer(2)]))
[[3, 2], [3, 1, 1], [2, 2, 1]]
```

This is the list of all compositions of 4 (but see `Compositions`):

```
sage: list(IntegerListsLex(4, min_part=1))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

```
>>> from sage.all import *

>>> list(IntegerListsLex(Integer(4), min_part=Integer(1)))
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]
```

This is the list of all integer vectors of sum 4 and length 3:
Combinatorics, Release 10.4

sage: list(IntegerListsLex(4, length=3))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]

>>> from sage.all import *
>>> list(IntegerListsLex(Integer(4), length=Integer(3)))
[[4, 0, 0], [3, 1, 0], [3, 0, 1], [2, 2, 0], [2, 1, 1],
 [2, 0, 2], [1, 3, 0], [1, 2, 1], [1, 1, 2], [1, 0, 3],
 [0, 4, 0], [0, 3, 1], [0, 2, 2], [0, 1, 3], [0, 0, 4]]

For whatever it is worth, the floor and min_part constraints can be combined:

sage: L = IntegerListsLex(5, floor=[2,0,2], min_part=1)
sage: L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]

>>> from sage.all import *
>>> L = IntegerListsLex(Integer(5), floor=[Integer(2),Integer(0),Integer(2)], min_part=Integer(1))
>>> L.list()
[[5], [4, 1], [3, 2], [2, 3], [2, 1, 2]]

This is achieved by updating the floor upon constructing L:

sage: [L.floor(i) for i in range(5)]
[2, 1, 2, 1, 1]

>>> from sage.all import *
>>> [L.floor(i) for i in range(Integer(5))]
[2, 1, 2, 1, 1]

Similarly, the ceiling and max_part constraints can be combined:

sage: L = IntegerListsLex(4, ceiling=[2,3,1], max_part=2, length=3)
sage: L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]

sage: [L.ceiling(i) for i in range(5)]
[2, 2, 1, 2, 2]

>>> from sage.all import *
>>> L = IntegerListsLex(Integer(4), ceiling=[Integer(2),Integer(3),Integer(1)], max_part=Integer(2), length=Integer(3))
>>> L.list()
[[2, 2, 0], [2, 1, 1], [1, 2, 1]]

This can be used to generate Motzkin words (see Wikipedia article Motzkin_number):

```
sage: def motzkin_words(n):
....:     return IntegerListsLex(length=n+1, min_slope=-1, max_slope=1,
....:                                 ceiling=[0]+[+oo for i in range(n-1)]+[0])
sage: motzkin_words(4).list()
[[0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 1, 1, 0],
 [0, 1, 2, 1, 0],
 [0, 1, 1, 1, 0]]
```

(continues on next page)
On finiteness and inverse lexicographic enumeration

The set of all lists of integers cannot be enumerated in inverse lexicographic order, since there is no largest list (take \([n]\) for \(n\) as large as desired):

```sage
sage: IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

```
>>> from sage.all import *

>>> IntegerListsLex().first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

Here is a variant which could be enumerated in lexicographic order but not in inverse lexicographic order:

```sage
sage: L = IntegerListsLex(length=2, ceiling=[Infinity, 0], floor=[0,1])
sage: for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m
```

```
>>> from sage.all import *

>>> L = IntegerListsLex(length=Integer(2), ceiling=[Infinity, Integer(0)],
˓→floor=[Integer(0),Integer(1)])

>>> for l in L: print(l)
Traceback (most recent call last):
...
ValueError: infinite upper bound for values of m
```

Even when the sum is specified, it is not necessarily possible to enumerate all elements in inverse lexicographic order. In the following example, the list \([1, 1, 1]\) will never appear in the enumeration:

```sage
sage: IntegerListsLex(3).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

```
>>> from sage.all import *

>>> IntegerListsLex(Integer(3)).first()
Traceback (most recent call last):
...
ValueError: could not prove that the specified constraints yield a finite set
```

If one wants to proceed anyway, one can sign a waiver by setting `check=False` (again, be warned that some valid lists may never appear):

```sage
sage: L = IntegerListsLex(3, check=False)
sage: it = iter(L)
```

(continues on next page)
In fact, being inverse lexicographically enumerable is almost equivalent to being finite. The only infinity that can occur would be from a tail of numbers $0, 1$ as in the previous example, where the $1$ moves further and further to the right. If there is any list that is inverse lexicographically smaller than such a configuration, the iterator would not reach it and hence would not be considered iterable. Given that the infinite cases are very specific, at this point only the finite cases are supported (without signing the waiver).

The finiteness detection is not complete yet, so some finite cases may not be supported either, at least not without disabling the checks. Practical examples of such are welcome.

### On trailing zeroes, and their caveats

As mentioned above, when several lists satisfying the constraints differ only by trailing zeroes, only the shortest one is listed:

```plaintext
sage: L = IntegerListsLex(max_length=4, max_part=1)
sage: L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

```plaintext
sage: L = IntegerListsLex(max_length=4, max_part=1)

>>> L = IntegerListsLex(max_length=Integer(4), max_part=Integer(1))
>>> L.list()
[[1, 1, 1, 1],
 [1, 1, 1],
 [1, 1, 0, 1],
 [1, 1],
 [1, 0, 1, 1],
 [1, 0, 1],
 [1, 0, 0, 1],
 [1],
 [0, 1, 1, 1],
 [0, 1, 1],
 [0, 1, 0, 1],
 [0, 1],
 [0, 0, 1, 1],
 [0, 0, 1],
 [0, 0, 0, 1],
 []]
```

(continues on next page)
and counted:

```python
sage: L.cardinality()
16
```

```python
>>> from sage.all import *

```

```python
>>> L.cardinality()
16
```

Still, the others are considered as elements of \( L \):

```python
sage: L = IntegerListsLex(4, min_length=3, max_length=4)
sage: L.list()
[...,[2, 2, 0],...]
sage: [2, 2, 0] in L  # in L.list()
True
sage: [2, 2, 0, 0] in L  # not in L.list() !
True
sage: [2, 2, 0, 0, 0] in L
False
```

```python
>>> from sage.all import *

```

```python
>>> L = IntegerListsLex(Integer(4), min_length=Integer(3), max_length=Integer(4))

```

```python
>>> L.list()
[...,[2, 2, 0],...]

```

```python
>>> [Integer(2), Integer(2), Integer(0)] in L  # in L.list()
True

```

```python
>>> [Integer(2), Integer(2), Integer(0), Integer(0)] in L  # not in L.list()!
True

```

```python
>>> [Integer(2), Integer(2), Integer(0), Integer(0), Integer(0)] in L
False
```

### Specifying functions as input for the floor or ceiling

We construct all lists of sum 4 and length 4 such that \( l[i] \leq i \):

```python
sage: list(IntegerListsLex(4, length=4, ceiling=lambda i: i, check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```

```python
>>> from sage.all import *

```

```python
>>> list(IntegerListsLex(Integer(4), length=Integer(4), ceiling=lambda i, _ → check=False))
[[0, 1, 2, 1], [0, 1, 1, 2], [0, 1, 0, 3], [0, 0, 2, 2], [0, 0, 1, 3]]
```
Warning: When passing a function as `floor` or `ceiling`, it may become undecidable to detect improper inverse lexicographic enumeration. For example, the following example has a finite enumeration:

```python
sage: L = IntegerListsLex(3, floor=lambda i: 1 if i>=2 else 0, check=False)
sage: L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
 [0, 0, 1, 2],
 [0, 0, 1, 1, 1]]
```

```python
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(1) if i>Integer(2) else Integer(0), check=False)
>>> L.list()
[[3],
 [2, 1],
 [2, 0, 1],
 [1, 2],
 [1, 1, 1],
 [1, 0, 2],
 [1, 0, 1, 1],
 [0, 3],
 [0, 2, 1],
 [0, 1, 2],
 [0, 1, 1, 1],
 [0, 0, 3],
 [0, 0, 2, 1],
 [0, 0, 1, 2],
 [0, 0, 1, 1, 1]]
```

but one cannot decide whether the following has an improper inverse lexicographic enumeration without computing the floor all the way to `Infinity`:

```python
sage: L = IntegerListsLex(3, floor=lambda i: 0, check=False)
sage: it = iter(L)
sage: [next(it) for i in range(6)]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

```python
>>> from sage.all import *
>>> L = IntegerListsLex(Integer(3), floor=lambda i: Integer(0), check=False)
>>> it = iter(L)
>>> [next(it) for i in range(Integer(6))]
[[3], [2, 1], [2, 0, 1], [2, 0, 0, 1], [2, 0, 0, 0, 1], [2, 0, 0, 0, 0, 1]]
```

Hence a warning is raised when a function is specified as input, unless the waiver is signed by setting `check=False`:
A function has been given as input of the floor=[] or ceiling=[] arguments of IntegerListsLex. Please see the documentation for the caveats. If you know what you are doing, you can set check=False to skip this warning.

Similarly, the algorithm may need to search forever for a solution when the ceiling is ultimately zero:

Tip: using disjoint union enumerated sets for additional flexibility

Sometimes, specifying a range for the sum or the length may be too restrictive. One would want instead to specify a list, or iterable \( L \), of acceptable values. This is easy to achieve using a disjoint union of enumerated sets. Here we want to accept the values \( n = 0, 2, 3 \):

(continues on next page)
The price to pay is that the enumeration order is now *graded lexicographic* instead of lexicographic: first choose the value according to the order specified by \( L \), and use lexicographic order within each value. Here is we reverse \( L \):

```
from sage.all import *

C = DisjointUnionEnumeratedSets(Family([Integer(3),Integer(2),Integer(0)],
...     lambda n: IntegerListsLex(n, length=Integer(2))),
...     lambda n: IntegerListsLex(n, length=Integer(2))))
C
```

```
Disjoint union of Finite family
{3: Integer lists of sum 3 satisfying certain constraints,
  2: Integer lists of sum 2 satisfying certain constraints,
  0: Integer lists of sum 0 satisfying certain constraints}
```

```
C.list()
[[3, 0], [2, 1], [1, 2], [0, 3],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```

Note that if a given value appears several times, the corresponding elements will be enumerated several times, which may, or not, be what one wants:

```
from sage.all import *

C = DisjointUnionEnumeratedSets(Family([Integer(2),Integer(2)],
...     lambda n: IntegerListsLex(n, length=Integer(2)))
...     lambda n: IntegerListsLex(n, length=Integer(2))))
C
```

```
Disjoint union of Finite family
{2: Integer lists of sum 2 satisfying certain constraints,
  0: Integer lists of sum 0 satisfying certain constraints}
```

```
C.list()
[[2, 0], [1, 1], [0, 2],
 [0, 0]]
```

Here is a variant where we specify acceptable values for the length:

```
from sage.all import *

C = DisjointUnionEnumeratedSets(Family([Integer(0),Integer(1),Integer(3)],
...     lambda 1: IntegerListsLex(2, length=1))
...     lambda 1: IntegerListsLex(Integer(2), length=1))
C
```

```
Disjoint union of Finite family
{0: Integer lists of sum 0 satisfying certain constraints,
  1: Integer lists of sum 1 satisfying certain constraints,
  3: Integer lists of sum 3 satisfying certain constraints}
```

```
C.list()
[[2, 0, 0], [1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1], [0, 0, 2],
 [2, 0], [1, 1], [0, 2],
 [0, 0]]
```
This technique can also be useful to obtain a proper enumeration on infinite sets by using a graded lexicographic enumeration:

```
sage: C = DisjointUnionEnumeratedSets(Family(NN,
.....: lambda n: IntegerListsLex(n, length=2)))
sage: C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
sage: it = iter(C)
sage: [next(it) for i in range(10)]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

```
>>> from sage.all import *
>>> C = DisjointUnionEnumeratedSets(Family(NN,
... lambda n: IntegerListsLex(n, length=Integer(2))))
>>> C
Disjoint union of Lazy family (<lambda>(i))_{i in Non negative integer semiring}
>>> it = iter(C)
>>> [next(it) for i in range(Integer(10))]
[[0, 0],
 [1, 0], [0, 1],
 [2, 0], [1, 1], [0, 2],
 [3, 0], [2, 1], [1, 2], [0, 3]]
```

Specifying how to construct elements

This is the list of all monomials of degree 4 which divide the monomial $x^3y^1z^2$ (a monomial being identified with its exponent vector):

```
sage: R.<x,y,z> = QQ[]
sage: m = [3,1,2]
sage: def term(exponents):
.....: return x^exponents[0] * y^exponents[1] * z^exponents[2]
sage: list( IntegerListsLex(4, length=len(m), ceiling=m, element_
˓→constructor=term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

```
>>> from sage.all import *
>>> R = QQ['x, y, z']; (x, y, z,) = R._first_ngens(3)
>>> m = [Integer(3),Integer(1),Integer(2)]
>>> def term(exponents):
... return x**exponents[Integer(0)] * y**exponents[Integer(1)] *␣
˓→z**exponents[Integer(2)]
>>> list( IntegerListsLex(Integer(4), length=len(m), ceiling=m, element_
˓→constructor=term) )
[x^3*y, x^3*z, x^2*y*z, x^2*z^2, x*y*z^2]
```

Note the use of the `element_constructor` option to specify how to construct elements from a plain list.
A variant is to specify a class for the elements. With the default element constructor, this class should take as input the parent `self` and a list.

**Warning:** The protocol for specifying the element class and constructor is subject to changes.

**ALGORITHM:**

The iteration algorithm uses a depth first search through the prefix tree of the list of integers (see also *Lexicographic generation of lists of integers*). While doing so, it does some lookahead heuristics to attempt to cut dead branches.

In most practical use cases, most dead branches are cut. Then, roughly speaking, the time needed to iterate through all the elements of $S$ is proportional to the number of elements, where the proportion factor is controlled by the length $l$ of the longest element of $S$. In addition, the memory usage is also controlled by $l$, which is to say negligible in practice.

Still, there remains much room for efficiency improvements; see Issue #18055, Issue #18056.

**Note:** The generation algorithm could in principle be extended to deal with non-constant slope constraints and with negative parts.

**TESTS from comments on Issue #17979**

Comment 191:

```python
sage: list(IntegerListsLex(1, min_length=2, min_slope=0, max_slope=0))
[]
```

```python
>>> from sage.all import *
>>> list(IntegerListsLex(Integer(1), min_length=Integer(2), min_slope=Integer(0), max_slope=Integer(0)))
[]
```

Comment 240:

```python
sage: L = IntegerListsLex(min_length=2, max_part=0)
sage: L.list()
[[0, 0]]
```

```python
>>> from sage.all import *
>>> L = IntegerListsLex(min_length=Integer(2), max_part=Integer(0))
>>> L.list()
[[0, 0]]
```
**Tests on the element constructor feature and mutability**

Internally, the iterator works on a single list that is mutated along the way. Therefore, you need to make sure that the `element_constructor` actually copies its input. This example shows what can go wrong:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=lambda x: x)
sage: list(P)
[[], [1], [1]]
```

However, specifying `list()` as constructor solves this problem:

```
sage: P = IntegerListsLex(n=3, max_slope=0, min_part=1, element_constructor=list)
sage: list(P)
[[3], [2, 1], [1, 1, 1]]
```

Same, step by step:

```
sage: it = iter(P)
sage: a = next(it); a
[3]
sage: b = next(it); b
[2, 1]
sage: a
[3]
sage: a is b
False
```

Tests from MuPAD-Combinat:

```
sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0,0,2,0,0,1],
     ceiling=[3,2,3,2,1,2]).cardinality()
83
```
sage: IntegerListsLex(7, min_length=2, max_length=6, floor=[0, 0, 2, 0, 1, 1],
                   ceiling=[3, 2, 3, 2, 1, 2]).cardinality()
53
sage: IntegerListsLex(5, min_length=2, max_length=6, floor=[0, 0, 2, 0, 0, 0],
                   ceiling=[2, 2, 2, 2, 2, 2]).cardinality()
30
sage: IntegerListsLex(5, min_length=2, max_length=6, floor=[0, 0, 1, 1, 0, 0],

    → ceiling=[Integer(3), Integer(1), Integer(2), Integer(3), Integer(2),
               Integer(2)]).cardinality()
0
```

This used to hang (see comment 389 and fix in `Envelope.__init__`):

```python
sage: IntegerListsLex(7, max_part=Integer(0), ceiling=lambda i:i, check=False).list() []

>>> from sage.all import *

>>> IntegerListsLex(Integer(7), max_part=Integer(0), ceiling=lambda i:i, 
    → check=False).list() []
```
backend_class
alias of IntegerListsBackend_invlex

class sage.combinat.integer_lists.invlex.IntegerListsLexIter(backend)
Bases: object

Iterator class for IntegerListsLex.

Let \( T \) be the prefix tree of all lists of nonnegative integers that satisfy all constraints except possibly for \( \text{min\_length} \) and \( \text{min\_sum} \); let the children of a list be sorted decreasingly according to their last part.

The iterator is based on a depth-first search exploration of a subtree of this tree, trying to cut branches that do not contain a valid list. Each call of \text{next} iterates through the nodes of this tree until it finds a valid list to return.

Here are the attributes describing the current state of the iterator, and their invariants:

- `backend` – the \text{IntegerListsBackend} object this is iterating on;
- `_current_list` – the list corresponding to the current node of the tree;
- `_j` – the index of the last element of `_current_list`: \( \text{self.}_j == \text{len(self.}_current_list) - 1; \)
- `_current_sum` – the sum of the parts of `_current_list`;
- `_search_ranges` – a list of same length as `_current_list`: the range for each part.

Furthermore, we assume that there is no obvious contradiction in the constraints:

- \( \text{self.backend.min\_length} \leq \text{self.backend.max\_length} \);
- \( \text{self.backend.min\_slope} \leq \text{self.backend.max\_slope} \) unless \( \text{self.backend.}\text{min\_length} \leq 1 \).

Along this iteration, \text{next} switches between the following states:

- **LOOKAHEAD**: determine whether the current list could be a prefix of a valid list;
- **PUSH**: go deeper into the prefix tree by appending the largest possible part to the current list;
- **ME**: check whether the current list is valid and if yes return it
- **DECREASE**: decrease the last part;
- **POP**: pop the last part of the current list;
- **STOP**: the iteration is finished.

The attribute `_next_state` contains the next state \text{next} should enter in.

### 5.1.125 Counting, generating, and manipulating non-negative integer matrices

Counting, generating, and manipulating non-negative integer matrices with prescribed row sums and column sums.

**AUTHORS:**

- Franco Saliola

\text{class sage.combinat.integer_matrices.IntegerMatrices}(row_sums, column_sums)

Bases: UniqueRepresentation, Parent

The class of non-negative integer matrices with prescribed row sums and column sums.
An integer matrix $m$ with column sums $c := (c_1, ..., c_k)$ and row sums $l := (l_1, ..., l_n)$ where $c_1 + ... + c_k$ is equal to $l_1 + ... + l_n$, is a $n \times k$ matrix $m = (m_{i,j})$ such that $m_{1,j} + \cdots + m_{n,j} = c_j$, for all $j$ and $m_{i,1} + \cdots + m_{i,k} = l_i$, for all $i$.

EXAMPLES:

There are 6 integer matrices with row sums $[3, 2, 2]$ and column sums $[2, 5]$:

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
```
This method computes the cardinality using symmetric functions. Below are the same examples, but computed by generating the actual matrices:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: len(IntegerMatrices([2,5], [3,2,2]).list())
6
sage: len(IntegerMatrices([1,1,1,1,1], [1,1,1,1,1]).list())
120
sage: len(IntegerMatrices([2,2,2,2], [2,2,2,2]).list())
282
sage: len(IntegerMatrices([4], [3]).list())
0
sage: len(IntegerMatrices([0], [0]).list())
1
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
```

```
column_sums()
```

The column sums of the integer matrices in self.

OUTPUT:

• Composition

EXAMPLES:

```
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3,2,2], [2,5])
sage: IM.column_sums()
[2, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.integer_matrices import IntegerMatrices
```
```python
>>> IM = IntegerMatrices([Integer(3), Integer(2), Integer(2)], [Integer(2), Integer(5)])
>>> IM.column_sums()
[2, 5]
```

**row_sums()**

The row sums of the integer matrices in self.

**OUTPUT:**

- Composition

**EXAMPLES:**

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3, 2, 2], [2, 5])
sage: IM.row_sums()
[3, 2, 2]
```

**to_composition(x)**

The composition corresponding to the integer matrix.

This is the composition obtained by reading the entries of the matrix from left to right along each row, and reading the rows from top to bottom, ignore zeros.

**INPUT:**

- \( x \) – matrix

**EXAMPLES:**

```python
sage: from sage.combinat.integer_matrices import IntegerMatrices
sage: IM = IntegerMatrices([3, 2, 2], [2, 5]); IM
Non-negative integer matrices with row sums [3, 2, 2] and column sums [2, 5]
sage: IM.list()
[[2, 1], [1, 2], [1, 2], [0, 3], [0, 3], [0, 3], [0, 2], [1, 1], [0, 2], [2, 0], [1, 1], [0, 2], [0, 2], [0, 2], [1, 1], [0, 2], [1, 1], [2, 0]]
sage: for m in IM: print(IM.to_composition(m))
[2, 1, 2, 2]
[1, 2, 1, 1, 2]
[1, 2, 2, 1, 1]
[3, 2, 2]
[3, 1, 1, 1, 1]
[3, 2, 2]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> IM = IntegerMatrices(\([\text{Integer}(3), \text{Integer}(2), \text{Integer}(2)], \text{[Integer}(2), \text{Integer}(5)]\)); IM
Non-negative integer matrices with row sums \([3, 2, 2]\) and column sums \([2, 5]\)
```  

```python
>>> IM.list()
\[
\begin{bmatrix}
2 & 1 \\ 0 & 2 \\
1 & 2 \\
0 & 2 \\
\end{bmatrix},
\begin{bmatrix}
1 & 2 \\ 1 & 1 \\
0 & 2 \\
1 & 1 \\
\end{bmatrix},
\begin{bmatrix}
1 & 2 \\ 0 & 2 \\
1 & 1 \\
2 & 0 \\
\end{bmatrix}
\]
```  

```python
>>> for m in IM: print(IM.to_composition(m))
\[
\begin{bmatrix}
2, 1, 2, 2 \\
1, 2, 1, 1, 2 \\
1, 2, 2, 1, 1 \\
3, 2, 2 \\
\end{bmatrix}
```  

```python
sage.combinat.integer_matrices.integer_matrices_generator(row_sums, column_sums)
```

Recursively generate the integer matrices with the prescribed row sums and column sums.

**INPUT:**

- `row_sums` – list or tuple
- `column_sums` – list or tuple

**OUTPUT:**

- an iterator producing a list of lists

**EXAMPLES:**

```python
sage: from sage.combinat.integer_matrices import integer_matrices_generator
sage: iter = integer_matrices_generator([3,2,2], [2,5]); iter
<generator object ...integer_matrices_generator at ...>
```

```python
sage: for m in iter: print(m)
```

```python
>>> from sage.all import *
```

```python
>>> from sage.combinat.integer_matrices import integer_matrices_generator
```

```python
>>> iter = integer_matrices_generator([\text{Integer}(3), \text{Integer}(2), \text{Integer}(2)], \text{[Integer}(2), \text{Integer}(5)]); iter
<generator object ...integer_matrices_generator at ...>
```

```python
>>> for m in iter: print(m)
```

5.1. Comprehensive Module List 1903
5.1.126 (Non-negative) Integer vectors

AUTHORS:

• Mike Hansen (2007) - original module
• Nathann Cohen, David Joyner (2009-2010) - Gale-Ryser stuff
• Nathann Cohen, David Joyner (2011) - Gale-Ryser bugfix
• Travis Scrimshaw (2012-05-12) - Updated doc-strings to tell the user of that the class’s name is a misnomer (that they only contains non-negative entries).
• Federico Poloni (2013) - specialized rank()
• Travis Scrimshaw (2013-02-04) - Refactored to use ClonableIntArray

class sage.combinat.integer_vector.IntegerVector

Bases: ClonableArray

An integer vector.

c check ()

Check to make sure this is a valid integer vector by making sure all entries are non-negative.

EXAMPLES:

sage: IV = IntegerVectors()
sage: elt = IV([1,2,1])
sage: elt.check()

>>> from sage.all import *
>>> IV = IntegerVectors()
>>> elt = IV([Integer(1),Integer(2),Integer(1)])
>>> elt.check()

Check Issue #34510:

sage: IV3 = IntegerVectors(n=3)
sage: IV3([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
sage: IVk3 = IntegerVectors(k=3)
sage: IVk3([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints
sage: IV33 = IntegerVectors(n=3, k=3)
sage: IV33([2,2])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints

>>> from sage.all import *
>>> IV3 = IntegerVectors(n=Integer(3))
>>> IV3([Integer(2),Integer(2)])
Traceback (most recent call last):
...
ValueError: [2, 2] doesn't satisfy correct constraints

(continues on next page)
Combinatorics, Release 10.4

```
>>> IVk3 = IntegerVectors(k=Integer(3))
>>> IVk3([[Integer(2), Integer(2)]]
Traceback (most recent call last):
... ValueError: [2, 2] doesn't satisfy correct constraints
```

```
>>> IV33 = IntegerVectors(n=Integer(3), k=Integer(3))
>>> IV33([[Integer(2), Integer(2)]]
Traceback (most recent call last):
... ValueError: [2, 2] doesn't satisfy correct constraints
```

`specht_module`(base_ring=None)

Return the Specht module corresponding to self.

EXAMPLES:

```
sage: SM = IntegerVectors()([[2,0,1,0,2]]).specht_module(QQ); SM
# needs sage.combinat sage.modules
Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
sage: s = SymmetricFunctions(QQ).s()
# needs sage.combinat sage.modules
sage: s(SM.frobenius_image())
# needs sage.combinat sage.modules
s[2, 2, 1]
```

```
>>> from sage.all import *
```

```
>>> SM = IntegerVectors()([[Integer(2), Integer(0), Integer(1), Integer(0),
Integer(2)]]).specht_module(QQ); SM
# needs sage.combinat sage.modules
Specht module of [(0, 0), (0, 1), (2, 0), (4, 0), (4, 1)] over Rational Field
>>> s = SymmetricFunctions(QQ).s()
# needs sage.combinat sage.modules
>>> s(SM.frobenius_image())
# needs sage.combinat sage.modules
s[2, 2, 1]
```

`specht_module_dimension`(base_ring=None)

Return the dimension of the Specht module corresponding to self.

INPUT:

- `BR` – (default: `QQ`) the base ring

EXAMPLES:

```
sage: IntegerVectors()([[2,0,1,0,2]]).specht_module_dimension()
# needs sage.combinat sage.modules
5
sage: IntegerVectors()([[2,0,1,0,2]]).specht_module_dimension(GF(2))
# needs sage.combinat sage.modules sage.rings.finite_rings
5
```

```
>>> from sage.all import *
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> IntegerVectors()([Integer(2),Integer(0),Integer(1),Integer(0),
→Integer(2)]).specht_module_dimension(GF(Integer(2)))
# needs sage.
→combinat sage.modules sage.rings.finite_rings
```

trim()

Remove trailing zeros from the integer vector.

EXAMPLES:

```python
sage: IV = IntegerVectors()
sage: IV([5,3,5,1,0,0]).trim()
[5, 3, 5, 1]
sage: IV([5,0,5,1,0]).trim()
[5, 0, 5, 1]
sage: IV([4,3,3]).trim()
[4, 3, 3]
sage: IV([0,0,0]).trim()
[]
sage: IV = IntegerVectors(k=4)
sage: v = IV([4,3,2,0]).trim(); v
[4, 3, 2]
sage: v.parent()
Integer vectors
```

```python
>>> from sage.all import *
>>> IV = IntegerVectors()
>>> IV([Integer(5),Integer(3),Integer(5),Integer(1),Integer(0),Integer(0)]).trim()
[5, 3, 5, 1]
>>> IV([Integer(5),Integer(0),Integer(5),Integer(1),Integer(0)]).trim()
[5, 0, 5, 1]
>>> IV([Integer(4),Integer(3),Integer(3)]).trim()
[4, 3, 3]
>>> IV([Integer(0),Integer(0),Integer(0)]).trim()
[]
>>> IV = IntegerVectors(k=Integer(4))
>>> v = IV([Integer(4),Integer(3),Integer(2),Integer(0)]).trim(); v
[4, 3, 2]
>>> v.parent()
Integer vectors
```

class sage.combinat.integer_vector.IntegerVectors(category=None)

Bases: Parent

The class of (non-negative) integer vectors.

INPUT:

- n – if set to an integer, returns the combinatorial class of integer vectors whose sum is \( n \); if set to None (default), no such constraint is defined
- k – the length of the vectors; set to None (default) if you do not want such a constraint
Note: The entries are non-negative integers.

EXAMPLES:

If \( n \) is not specified, it returns the class of all integer vectors:

```sage
sage: IntegerVectors()
Integer vectors
sage: [] in IntegerVectors()
True
sage: [1,2,1] in IntegerVectors()
True
sage: [1, 0, 0] in IntegerVectors()
True
```

Entries are non-negative:

```sage
sage: [-1, 2] in IntegerVectors()
False
```

If \( n \) is specified, then it returns the class of all integer vectors which sum to \( n \):

```sage
sage: IV3 = IntegerVectors(3); IV3
Integer vectors that sum to 3
```

Note that trailing zeros are ignored so that \([3, 0]\) does not show up in the following list (since \([3]\) does):

```sage
sage: IntegerVectors(3, max_length=2).list()
[[3], [2, 1], [1, 2], [0, 3]]
```

If \( n \) and \( k \) are both specified, then it returns the class of integer vectors that sum to \( n \) and are of length \( k \):
Combinatorics, Release 10.4

```python
sage: IV53 = IntegerVectors(5,3); IV53
Integer vectors of length 3 that sum to 5
sage: IV53.cardinality()
21
sage: IV53.first()
[5, 0, 0]
sage: IV53.last()
[0, 0, 5]
sage: IV53.random_element().parent() is IV53
True

>>> from sage.all import *
>>> IV53 = IntegerVectors(Integer(5),Integer(3)); IV53
Integer vectors of length 3 that sum to 5
>>> IV53.cardinality()
21
>>> IV53.first()
[5, 0, 0]
>>> IV53.last()
[0, 0, 5]
>>> IV53.random_element().parent() is IV53
True

Further examples:

```python
sage: IntegerVectors(-1, 0, min_part=1).list()
[]
sage: IntegerVectors(-1, 2, min_part=1).list()
[]
sage: IntegerVectors(0, 0, min_part=1).list()
[]
sage: IntegerVectors(3, 0, min_part=1).list()
[]
sage: IntegerVectors(0, 1, min_part=1).list()
[]
sage: IntegerVectors(2, 2, min_part=1).list()
[[1, 1]]
sage: IntegerVectors(2, 3, min_part=1).list()
[]
sage: IntegerVectors(4, 2, min_part=1).list()
[[3, 1], [2, 2], [1, 3]]
```

```python
>>> from sage.all import *
>>> IntegerVectors(-Integer(1), Integer(0), min_part=Integer(1)).list()
[]
>>> IntegerVectors(-Integer(1), Integer(2), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(0), Integer(0), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(3), Integer(0), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(0), Integer(1), min_part=Integer(1)).list()
[]
>>> IntegerVectors(Integer(2), Integer(2), min_part=Integer(1)).list()
[[1, 1]]
>>> IntegerVectors(Integer(2), Integer(3), min_part=Integer(1)).list()
[]
```

(continues on next page)
>>> IntegerVectors(Integer(4), Integer(2), min_part=Integer(1)).list()
[[3, 1], [2, 2], [1, 3]]

sage: IntegerVectors(0, 3, outer=[0,0,0]).list()
[[0, 0, 0]]
sage: IntegerVectors(1, 3, outer=[0,0,0]).list()
[]
sage: IntegerVectors(2, 3, outer=[0,2,0]).list()
[[0, 2, 0]]

sage: IntegerVectors(2, 3, outer=[1,2,1]).list()
[[1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1]]
sage: IntegerVectors(2, 3, outer=[1,1,1]).list()
[[1, 1, 0], [1, 0, 1]]
sage: IntegerVectors(2, 5, outer=[1,1,1,1,1]).list()
[[1, 1, 0, 0, 0], [1, 0, 1, 0, 0], [1, 0, 0, 1, 0], [1, 0, 0, 0, 1], [0, 1, 1, 0, 0], [0, 1, 0, 1, 0], [0, 1, 0, 0, 1], [0, 0, 1, 1, 0], [0, 0, 1, 0, 1], [0, 0, 0, 1, 1]]

>>> from sage.all import *

>>> IntegerVectors(Integer(0), Integer(3), outer=[Integer(0),Integer(0), Integer(0)]).list()
[[0, 0, 0]]

>>> IntegerVectors(Integer(1), Integer(3), outer=[Integer(0),Integer(0), Integer(0)]).list()
[]

>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(0),Integer(2), Integer(0)]).list()
[[0, 2, 0]]

>>> IntegerVectors(Integer(2), Integer(3), outer=[Integer(1),Integer(2), Integer(1)]).list()
[[1, 1, 0], [1, 0, 1], [0, 2, 0], [0, 1, 1]]

>>> IntegerVectors(Integer(2), Integer(5), outer=[Integer(1),Integer(1), Integer(1), Integer(1), Integer(1)]).list()
[[1, 1, 0, 0, 0], [1, 0, 1, 0, 0], [1, 0, 0, 1, 0], [1, 0, 0, 0, 1], [0, 1, 1, 0, 0], [0, 1, 0, 1, 0], [0, 1, 0, 0, 1], [0, 0, 1, 1, 0], [0, 0, 1, 0, 1], [0, 0, 0, 1, 1]]

sage: iv = [ IntegerVectors(n,k) for n in range(-2, 7) for k in range(7) ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True
sage: essai = [[1,1,1], [2,5,6], [6,5,2]]
sage: iv = [ IntegerVectors(x[0], x[1], max_part = x[2]-1) for x in essai ]
sage: all(map(lambda x: x.cardinality() == len(x.list()), iv))
True

>>> from sage.all import *
>>> iv = [ IntegerVectors(n,k) for n in range(Integer(-2), Integer(7)) for k in range(Integer(7)) ]
>>> all(map(lambda x: x.cardinality() == len(x.list()), iv))
True

>>> essai = [[Integer(1),Integer(1),Integer(1)], [Integer(2),Integer(5),Integer(6)], [Integer(6),Integer(5),Integer(2)]]
>>> iv = [ IntegerVectors(x[Integer(0)], x[Integer(1)], max_part = x[Integer(2)]-Integer(1)) for x in essai ]
>>> all(map(lambda x: x.cardinality() == len(x.list()), iv))
True

An example showing the same output by using IntegerListsLex:

sage: IntegerVectors(4, max_length=2).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
sage: list(IntegerListsLex(4, max_length=2))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]

>>> from sage.all import *
>>> IntegerVectors(Integer(4), max_length=Integer(2)).list()
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]
>>> list(IntegerListsLex(Integer(4), max_length=Integer(2)))
[[4], [3, 1], [2, 2], [1, 3], [0, 4]]

See also:

sage.combinat.integer_lists.invlex.IntegerListsLex

Element

alias of IntegerVector

class sage.combinat.integer_vector.IntegerVectorsConstraints(n=None, k=None, **constraints)

Bases: IntegerVectors

Class of integer vectors subject to various constraints.

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: IntegerVectors(3, 3, min_part=1).cardinality()
1
sage: IntegerVectors(5, 3, min_part=1).cardinality()
6
sage: IntegerVectors(13, 4, max_part=4).cardinality()
20
sage: IntegerVectors(k=4, max_part=3).cardinality()
256
sage: IntegerVectors(k=3, min_part=2, max_part=4).cardinality()
27
sage: IntegerVectors(13, 4, min_part=2, max_part=4).cardinality()
16

>>> from sage.all import *
>>> IntegerVectors(Integer(3), Integer(3), min_part=Integer(1)).cardinality()
1
>>> IntegerVectors(Integer(5), Integer(3), min_part=Integer(1)).cardinality()
6
>>> IntegerVectors(Integer(13), Integer(4), max_part=Integer(4)).cardinality()
20
>>> IntegerVectors(k=Integer(4), max_part=Integer(3)).cardinality()
256
>>> IntegerVectors(k=Integer(3), min_part=Integer(2), max_part=Integer(4)).cardinality()
27
>>> IntegerVectors(Integer(13), Integer(4), min_part=Integer(2), max_part=Integer(4)).cardinality()
16

class sage.combinat.integer_vector.IntegerVectors_all
   Bases: UniqueRepresentation, IntegerVectors
   Class of all integer vectors.

class sage.combinat.integer_vector.IntegerVectors_k(k)
   Bases: UniqueRepresentation, IntegerVectors
   Integer vectors of length k.

cardinality()
   Return the cardinality of self.

   EXAMPLES:

sage: IntegerVectors(k=0).cardinality()
1
sage: IntegerVectors(k=10).cardinality()
+Infinity

>>> from sage.all import *
>>> IntegerVectors(k=Integer(0)).cardinality()
1
>>> IntegerVectors(k=Integer(10)).cardinality()
+Infinity

rank(x)
   Return the rank of a given element.

   INPUT:
   • x – a list with len(x) == k

   EXAMPLES:
sage: IntegerVectors(k=5).rank([0,0,0,0,0])
0
sage: IntegerVectors(k=5).rank([1,1,0,0,0])
7

>>> from sage.all import *

sage: IntegerVectors(k=Integer(5)).rank([Integer(0),Integer(0),Integer(0),Integer(0),Integer(0)])
0
sage: IntegerVectors(k=Integer(5)).rank([Integer(1),Integer(1),Integer(0),Integer(0),Integer(0)])
7

unrank(x)
Return the element at given rank x.

INPUT:

• x – an integer such that x < self.cardinality()

EXAMPLES:

sage: IntegerVectors(k=5).unrank(10)
[1, 0, 0, 0, 1]
sage: IntegerVectors(k=5).unrank(15)
[0, 0, 2, 0, 0]
sage: IntegerVectors(k=0).unrank(0)
[]

sage: IntegerVectors(k=Integer(5)).unrank(Integer(10))
[1, 0, 0, 0, 1]

class sage.combinat.integer_vector.IntegerVectors_n(n)
Bases: UniqueRepresentation, IntegerVectors

Integer vectors that sum to n.

cardinality()
Return the cardinality of self.

EXAMPLES:

sage: IntegerVectors(n=0).cardinality()
1
sage: IntegerVectors(n=10).cardinality()
+Infinity

sage: IntegerVectors(n=Integer(0)).cardinality()
1
sage: IntegerVectors(n=Integer(10)).cardinality()
+Infinity
\textbf{rank} (x)

Return the rank of a given element.

**INPUT:**

- \( x \) – a list with \( \sum(x) == n \)

**EXAMPLES:**

```sage
sage: IntegerVectors(n=5).rank([5,0])
1
sage: IntegerVectors(n=5).rank([3,2])
3
```

```python
>>> from sage.all import *

>>> IntegerVectors(n=Integer(5)).rank([Integer(5),Integer(0)])
1
>>> IntegerVectors(n=Integer(5)).rank([Integer(3),Integer(2)])
3
```

\textbf{unrank} (x)

Return the element at given rank x.

**INPUT:**

- \( x \) – an integer.

**EXAMPLES:**

```sage
sage: IntegerVectors(n=5).unrank(2)
[4, 1]
sage: IntegerVectors(n=10).unrank(10)
[1, 9]
```

```python
>>> from sage.all import *

>>> IntegerVectors(n=Integer(5)).unrank(Integer(2))
[4, 1]
>>> IntegerVectors(n=Integer(10)).unrank(Integer(10))
[1, 9]
```

class \texttt{sage.combinat.integer_vector.IntegerVectors\_nk} (n, k)

**Bases:** \texttt{UniqueRepresentation, IntegerVectors}

Integer vectors of length \( k \) that sum to \( n \).

**AUTHORS:**

- Martin Albrecht
- Mike Hansen

\textbf{cardinality} ()

Return the cardinality of \texttt{self}.

**EXAMPLES:**

```sage
sage: IntegerVectors(3,5).cardinality()
35
sage: IntegerVectors(99, 3).cardinality()
5050
```

(continues on next page)
sage: IntegerVectors(10^9 - 1, 3).cardinality()
500000000500000000

>>> from sage.all import *

>>> IntegerVectors(Integer(3),Integer(5)).cardinality()
35

>>> IntegerVectors(Integer(99), Integer(3)).cardinality()
5050

>>> IntegerVectors(Integer(10)**Integer(9) - Integer(1), Integer(3)).
   → cardinality()
500000000500000000

**rank** (x)
Return the rank of a given element.

**INPUT:**
• x – a list with \( \text{sum}(x) == n \) and \( \text{len}(x) == k \)

**unrank** (x)
Return the element at given rank x.

**INPUT:**
• x – an integer such that \( x < \text{self.cardinality()} \)

**EXAMPLES:**

sage: IntegerVectors(4,5).unrank(30)
[1, 0, 1, 0, 2]
sage: IntegerVectors(2,3).unrank(5)
[0, 0, 2]

>>> from sage.all import *

>>> IntegerVectors(Integer(4),Integer(5)).unrank(Integer(30))
[1, 0, 1, 0, 2]

>>> IntegerVectors(Integer(2),Integer(3)).unrank(Integer(5))
[0, 0, 2]

**class** `sage.combinat.integer_vector.IntegerVectors_nnondescents(n, comp)`

Bases: `UniqueRepresentation, IntegerVectors`

Integer vectors graded by two parameters.

The grading parameters on the integer vector \( v \) are:
• \( n \) – the sum of the parts of \( v \),
• \( c \) – the non descents composition of \( v \).

In other words: the length of \( v \) equals \( c_1 + \cdots + c_k \), and \( v \) is decreasing in the consecutive blocs of length \( c_1, \ldots, c_k \).

**INPUT:**
• \( n \) – the positive integer \( n \)
• \( \text{comp} \) – the composition \( c \)

Those are the integer vectors of sum \( n \) that are lexicographically maximal (for the natural left-to-right reading) in their orbit by the Young subgroup \( S_{c_1} \times \cdots \times S_{c_k} \). In particular, they form a set of orbit representative of integer vectors with respect to this Young subgroup.
Returns the binary matrix given by the Gale-Ryser theorem.

The Gale Ryser theorem asserts that if $p_1, p_2$ are two partitions of $n$ of respective lengths $k_1, k_2$, then there is a binary $k_1 \times k_2$ matrix $M$ such that $p_1$ is the vector of row sums and $p_2$ is the vector of column sums of $M$, if and only if the conjugate of $p_2$ dominates $p_1$.

**INPUT:**

- $p_1, p_2$ – list of integers representing the vectors of row/column sums
- `algorithm` – two possible string values:
  - `'ryser'` implements the construction due to Ryser [Ryser63].
  - `'gale'` (default) implements the construction due to Gale [Gale57].
- `solver` – (default: `None`) Specify a Mixed Integer Linear Programming (MILP) solver to be used. If set to `None`, the default one is used. For more information on MILP solvers and which default solver is used, see the method `solve` of the class `MixedIntegerLinearProgram`.
- `integrality_tolerance` – parameter for use with MILP solvers over an inexact base ring; see `MixedIntegerLinearProgram.get_values()`.

**OUTPUT:**

A binary matrix if it exists, `None` otherwise.

**Gale’s Algorithm:**

(Gale [Gale57]): A matrix satisfying the constraints of its sums can be defined as the solution of the following Linear Program, which Sage knows how to solve.

\[
\forall i \sum_{j=1}^{k_2} b_{i,j} = p_{1,j} \\
\forall i \sum_{j=1}^{k_1} b_{j,i} = p_{2,j}
\]

$b_{i,j}$ is a binary variable

**Ryser’s Algorithm:**

(Ryser [Ryser63]): The construction of an $m \times n$ matrix $A = A_{r,s}$, due to Ryser, is described as follows. The construction works if and only if have $s \leq r^*$. 

- Construct the $m \times n$ matrix $B$ from $r$ by defining the $i$-th row of $B$ to be the vector whose first $r_i$ entries are 1, and the remainder are 0’s, $1 \leq i \leq m$. This maximal matrix $B$ with row sum $r$ and ones left justified has column sum $r^*$.
- Shift the last 1 in certain rows of $B$ to column $n$ in order to achieve the sum $s_n$. Call this $B$ again.
  - The 1’s in column $n$ are to appear in those rows in which $A$ has the largest row sums, giving preference to the bottom-most positions in case of ties.
  - Note: When this step automatically “fixes” other columns, one must skip ahead to the first column index with a wrong sum in the step below.
- Proceed inductively to construct columns $n - 1, \ldots, 2, 1$. Note: when performing the induction on step $k$, we consider the row sums of the first $k$ columns.
- Set $A = B$. Return $A$. 

5.1. Comprehensive Module List 1915
EXAMPLES:

Computing the matrix for \( p_1 = p_2 = 2 + 2 + 1 \):

```
sage: # needs sage.combinat sage.modules
sage: from sage.combinat.integer_vector import gale_ryser_theorem
sage: p1 = [2,2,1]
 sage: p2 = [2,2,1]
 sage: print(gale_ryser_theorem(p1, p2)) # not tested
 [1 1 0]
 [1 0 1]
 [0 1 0]
 sage: A = gale_ryser_theorem(p1, p2)
 sage: rs = [sum(x) for x in A.rows()]
 sage: cs = [sum(x) for x in A.columns()]
 sage: p1 == rs; p2 == cs
 True
 True
```

Or for a non-square matrix with \( p_1 = 3 + 3 + 2 + 1 \) and \( p_2 = 3 + 2 + 1 + 1 + 1 \), using Ryser’s algorithm:

```
>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> from sage.combinat.integer_vector import gale_ryser_theorem
>>> p1 = [Integer(2),Integer(2),Integer(1)]
 >>> p2 = [Integer(2),Integer(2),Integer(1)]
 >>> print(gale_ryser_theorem(p1, p2)) # not tested
 [1 1 0]
 [1 0 1]
 [0 1 0]
 >>> A = gale_ryser_theorem(p1, p2)
 >>> rs = [sum(x) for x in A.rows()]
 >>> cs = [sum(x) for x in A.columns()]
 >>> p1 == rs; p2 == cs
 True
 True
```

(continues on next page)
sage: p1 = [3,3,2,1]
sage: p2 = [3,2,2,1,1]
sage: print(gale_ryser_theorem(p1, p2, algorithm="gale"))  # not tested
[1 1 1 0 0]
[1 1 0 1 0]
[1 0 1 0 0]
[0 0 0 1 0]

>>> from sage.all import *
>>> # needs sage.combinat sage.modules
>>> from sage.combinat.integer_vector import gale_ryser_theorem
>>> p1 = [Integer(3),Integer(3),Integer(1),Integer(1)]
>>> p2 = [Integer(3),Integer(3),Integer(1),Integer(1)]

REFERENCES:
sage.combinat.integer_vector.integer_vectors_nk_fast_iter(n, k)
A fast iterator for integer vectors of $n$ of length $k$ which yields Python lists filled with Sage Integers.

EXAMPLES:

sage: from sage.combinat.integer_vector import integer_vectors_nk_fast_iter
sage: list(integer_vectors_nk_fast_iter(3, 2))
[[3, 0], [2, 1], [1, 2], [0, 3]]

sage: list(integer_vectors_nk_fast_iter(2, 2))
[[2, 0], [1, 1], [0, 2]]

sage: list(integer_vectors_nk_fast_iter(1, 2))
[[1, 0], [0, 1]]

We check some corner cases:

sage: list(integer_vectors_nk_fast_iter(5, 1))
[[5]]

sage: list(integer_vectors_nk_fast_iter(1, 1))
[[1]]

sage: list(integer_vectors_nk_fast_iter(2, 0))
(continues on next page)
Tests whether the given sequences satisfy the condition of the Gale-Ryser theorem.

Given a binary matrix $B$ of dimension $n \times m$, the vector of row sums is defined as the vector whose $i^{th}$ component is equal to the sum of the $i^{th}$ row in $A$. The vector of column sums is defined similarly.

If, given a binary matrix, these two vectors are easy to compute, the Gale-Ryser theorem lets us decide whether, given two non-negative vectors $r, s$, there exists a binary matrix whose row/column sums vectors are $r$ and $s$.

This function answers accordingly.

INPUT:

- $r, s$ – lists of non-negative integers.

ALGORITHM:

Without loss of generality, we can assume that:

- The two given sequences do not contain any 0 (which would correspond to an empty column/row)
- The two given sequences are ordered in decreasing order (reordering the sequence of row (resp. column) sums amounts to reordering the rows (resp. columns) themselves in the matrix, which does not alter the columns (resp. rows) sums).

We can then assume that $r$ and $s$ are partitions (see the corresponding class $\texttt{Partition}$).

If $r^*$ denote the conjugate of $r$, the Gale-Ryser theorem asserts that a binary Matrix satisfying the constraints exists if and only if $s \leq r^*$, where $\leq$ denotes the domination order on partitions.

EXAMPLES:
REMerk: In the literature, what we are calling a Gale-Ryser sequence sometimes goes by the (rather
generic-sounding) term “realizable sequence”.

Given a list l, return a function that takes in a value i and return l[i]. If default is not None, then the function
will return the default value for out of range i’s.

Examples:

```python
sage: f = sage.combinat.integer_vector.list2func([1, 2, 3])
sage: f(0)
1
sage: f(1)
2
sage: f(2)
3
sage: f(3)
Traceback (most recent call last):
  ... IndexError: list index out of range
```

```python
>>> from sage.all import *
>>> f = sage.combinat.integer_vector.list2func([Integer(1), Integer(2), Integer(3)])
>>> f(Integer(0))
1
>>> f(Integer(1))
2
>>> f(Integer(2))
3
>>> f(Integer(3))
Traceback (most recent call last):
  ... IndexError: list index out of range
```

```python
sage: f = sage.combinat.integer_vector.list2func([1, 2, 3], 0)
sage: f(2)
3
sage: f(3)
0
```

5.1.127 Weighted Integer Vectors

AUTHORS:
• Mike Hansen (2007): initial version, ported from MuPAD-Combinat
• Nicolas M. Thiery (2010-10-30): WeightedIntegerVectors(weights) + cleanup

class sage.combinat.integer_vector_weighted.WeightIntegerVectors (n, weight)
Bases: Parent, UniqueRepresentation
The class of integer vectors of $n$ weighted by weight, that is, the nonnegative integer vectors $(v_1, \ldots, v_\ell)$ satisfying $\sum_{i=1}^\ell v_i w_i = n$ where $\ell$ is length(weight) and $w_i$ is weight[i].

INPUT:
• $n$ – a non negative integer (optional)
• weight – a tuple (or list or iterable) of positive integers

EXAMPLES:

sage: WeightedIntegerVectors(8, [1,1,2])
Integer vectors of 8 weighted by [1, 1, 2]
sage: WeightedIntegerVectors(8, [1,1,2]).first()
[0, 0, 4]
sage: WeightedIntegerVectors(8, [1,1,2]).last()
[8, 0, 0]
sage: WeightedIntegerVectors(8, [1,1,2]).cardinality()
25
sage: w = WeightedIntegerVectors(8, [1,1,2]).random_element()
sage: w.parent() is WeightedIntegerVectors(8, [1,1,2])
True

sage: WeightedIntegerVectors([1,1,2])
Integer vectors weighted by [1, 1, 2]
sage: WeightedIntegerVectors([1,1,2]).cardinality()
+Infinity
sage: WeightedIntegerVectors([1,1,2]).first()
[0, 0, 0]

from sage.all import *

>>> from sage.all import *
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)])
Integer vectors of 8 weighted by [1, 1, 2]
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).first()
[0, 0, 4]
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).last()
[8, 0, 0]
>>> WeightedIntegerVectors(Integer(8), [Integer(1),Integer(1),Integer(2)]).cardinality()
Todo: Should the order of the arguments \( n \) and \( \text{weight} \) be exchanged to simplify the logic?

Element

alias of \texttt{IntegerVector}

class \texttt{sage.combinat.integer_vector_weighted.WeightedIntegerVectors\_all}(\texttt{weight})

Bases: \texttt{DisjointUnionEnumeratedSets}

Set of weighted integer vectors.

EXAMPLES:

```python
sage: W = WeightedIntegerVectors([3,1,1,2,1]); W
Integer vectors weighted by [3, 1, 1, 2, 1]
sage: W.cardinality()
+Infinity
sage: W12 = W.graded_component(12)  
sage: W12.an_element()  
[4, 0, 0, 0, 0]
sage: W12.last()  
[0, 12, 0, 0, 0]
sage: W12.cardinality()  
441
sage: for w in W12: print(w)  
[4, 0, 0, 0, 0]
[3, 0, 0, 1, 1]
[3, 0, 1, 1, 0]
...
[0, 11, 1, 0, 0]
[0, 12, 0, 0, 0]
```

```python
>>> from sage.all import *  
```
>>> W12 = WeightedIntegerVectors([2,3,2,1])
>>> W12.cardinality()
441

\[
\begin{align*}
& [4, 0, 0, 0, 0] \\
& [3, 0, 0, 1, 1] \\
& [3, 0, 1, 1, 0] \\
& \ldots \\
& [0, 11, 1, 0, 0] \\
& [0, 12, 0, 0, 0]
\end{align*}
\]

grading\((x)\)

EXAMPLES:

```python
sage: C = WeightedIntegerVectors([2,1,3])
sage: C.grading((2,1,1))
8
```

```python
>>> from sage.all import *
>>> C = WeightedIntegerVectors([Integer(2),Integer(1),Integer(3)])
>>> C.grading((Integer(2),Integer(1),Integer(1)))
8
```

subset\((size=None)\)

EXAMPLES:

```python
sage: C = WeightedIntegerVectors([2,1,3])
sage: C.subset(4)
Integer vectors of 4 weighted by [2, 1, 3]
```

```python
>>> from sage.all import *
>>> C = WeightedIntegerVectors([Integer(2),Integer(1),Integer(3)])
>>> C.subset(Integer(4))
Integer vectors of 4 weighted by [2, 1, 3]
```

`sage.combinat.integer_vector_weighted.iterator_fast\((n, l)\)`

Iterate over all \( l \) weighted integer vectors with total weight \( n \).

INPUT:

- \( n \) – an integer
- \( l \) – the weights in weakly decreasing order

EXAMPLES:

```python
sage: from sage.combinat.integer_vector_weighted import iterator_fast
sage: list(iterator_fast(3, [2,1,1]))
[[1, 1, 0], [1, 0, 1], [0, 3, 0], [0, 2, 1], [0, 1, 2], [0, 0, 3]]
sage: list(iterator_fast(2, [2]))
[[1]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.integer_vector_weighted import iterator_fast
```
Test that Issue #20491 is fixed:

```python
sage: type(list(iterator_fast(2, [2]))[0][0])
<class 'sage.rings.integer.Integer'>
```

5.1.128 Integer vectors modulo the action of a permutation group

AUTHORS:

- Nicolas Borie (2010-2012) - original module
- Jukka Kohonen (2023) - fast cardinality method, Issue #36787, Issue #36681

class sage.combinat.integer_vectors_mod_permgroup.IntegerVectorsModPermutationGroup

Bases: UniqueRepresentation

Return an enumerated set containing integer vectors which are maximal in their orbit under the action of the permutation group G for the lexicographic order.

In Sage, a permutation group G is viewed as a subgroup of the symmetric group S_n of degree n and n is said to be the degree of G. Any integer vector v is said to be canonical if it is maximal in its orbit under the action of G. v is canonical if and only if

\[ v = \max_{\text{lex order}} \{ g \cdot v \mid g \in G \} \]

The action of G is on position. This means for example that the simple transposition \( s_1 = (1, 2) \) swaps the first and the second entries of any integer vector \( v = [a_1, a_2, a_3, \ldots, a_n] \)

\[ s_1 \cdot v = [a_2, a_1, a_3, \ldots, a_n] \]

This function returns a parent which contains, from each orbit orbit under the action of the permutation group G, a single canonical vector. The canonical vector is the one that is maximal within the orbit according to lexicographic order.

INPUT:

- G - a permutation group
- sum - (default: None) - a nonnegative integer
- max_part - (default: None) - a nonnegative integer setting the maximum value for every element
- sgs - (default: None) - a strong generating system of the group G. If you do not provide it, it will be calculated at the creation of the parent

OUTPUT:
• If `sum` and `max_part` are None, it returns the infinite enumerated set of all integer vectors (lists of integers) maximal in their orbit for the lexicographic order. Exceptionally, if the domain of $G$ is empty, the result is a finite enumerated set that contains one element, namely the empty vector.

• If `sum` is an integer, it returns a finite enumerated set containing all integer vectors maximal in their orbit for the lexicographic order and whose entries sum to `sum`.

EXAMPLES:

Here is the set enumerating integer vectors modulo the action of the cyclic group of 3 elements:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3)]))
sage: I.category()
Category of infinite enumerated quotients of sets
sage: I.cardinality()
+Infinity
sage: I.list()
Traceback (most recent call last):
  ...  
NotImplementedError: cannot list an infinite set
sage: p = iter(I)
sage: for i in range(10): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

```python
>>> from sage.all import *

>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([(Integer(1), Integer(2), Integer(3))]))

>>> I.category()
Category of infinite enumerated quotients of sets

>>> I.cardinality()
+Infinity

>>> I.list()
Traceback (most recent call last):
  ...  
NotImplementedError: cannot list an infinite set

>>> p = iter(I)

>>> for i in range(Integer(10)): next(p)
[0, 0, 0]
[1, 0, 0]
[2, 0, 0]
[1, 1, 0]
[3, 0, 0]
[2, 1, 0]
[2, 0, 1]
[1, 1, 1]
[4, 0, 0]
[3, 1, 0]
```

The method `is_canonical()` tests if an integer vector is maximal in its orbit. This method is also used in the containment test:
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: I.is_canonical([5,2,0,4])
True
sage: I.is_canonical([5,0,6,4])
False
sage: I.is_canonical([1,1,1,1])
True
sage: [2,3,1,0] in I
True
sage: [5,0,5,0] in I
True
sage: 'Bla' in I
False
sage: I.is_canonical('bla')
Traceback (most recent call last):
  ... AssertionError: bla should be a list or an integer vector

>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([(Integer(1),
           →Integer(2),Integer(3),Integer(4))]))
>>> I.is_canonical([Integer(5),Integer(2),Integer(0),Integer(4)])
True
>>> I.is_canonical([Integer(5),Integer(0),Integer(6),Integer(4)])
False
>>> I.is_canonical([Integer(1),Integer(1),Integer(1),Integer(1)])
True
>>> [Integer(2),Integer(3),Integer(1),Integer(0)] in I
False
>>> [Integer(5),Integer(0),Integer(5),Integer(0)] in I
True
>>> 'Bla' in I
False
>>> I.is_canonical('bla')
Traceback (most recent call last):
  ... AssertionError: bla should be a list or an integer vector

If you give a value to the extra argument sum, the set returned will be a finite set containing only canonical vectors whose entries sum to sum:

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3)]), sum=6)
sage: I.cardinality()
10
sage: I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
  [4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]
sage: I.category()
Join of Category of finite enumerated sets
    and Category of subquotients of finite sets
    and Category of quotients of sets

>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([(Integer(1),
           →Integer(2),Integer(3))]), sum=Integer(6))
>>> I.cardinality()
10
(continues on next page)
I.list()
[[6, 0, 0], [5, 1, 0], [5, 0, 1], [4, 2, 0], [4, 1, 1],
[4, 0, 2], [3, 3, 0], [3, 2, 1], [3, 1, 2], [2, 2, 2]]

I.category()
Join of Category of finite enumerated sets
and Category of subquotients of finite sets
and Category of quotients of sets

To get the orbit of any integer vector \( v \) under the action of the group, use the method \( \text{orbit()} \): we convert the returned set of vectors into a list in increasing lexicographic order, to get a reproducible test:

```
sage: sorted(I.orbit([6,0,0]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
sage: sorted(I.orbit([5,1,0]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
sage: I.orbit([2,2,2])
{(2, 2, 2)}
```

Even without constraints, for an empty domain the result is a singleton set:

```
sage: G = PermutationGroup([], domain=[])
sage: sgs = tuple(tuple(s) for s in G.strong_generating_system())
sage: list(IntegerVectorsModPermutationGroup(G, sgs=sgs))
[[]]
```

```
>>> from sage.all import *
>>> sorted(I.orbit([Integer(6),Integer(0),Integer(0)]))
[[0, 0, 6], [0, 6, 0], [6, 0, 0]]
>>> sorted(I.orbit([Integer(5),Integer(1),Integer(0)]))
[[0, 5, 1], [1, 0, 5], [5, 1, 0]]
>>> I.orbit([Integer(2),Integer(2),Integer(2)])
{(2, 2, 2)}
```

Warning: Because of Issue #36527, permutation groups that have different domains but similar generators can be erroneously treated as the same group. This will silently produce erroneous results. To avoid this issue, compute a strong generating system for the group as:

```
s = tuple(tuple(s) for s in G.strong_generating_system())
```

and provide it as the optional \( sgs \) argument to the constructor.

A Sage permutation group is viewed as a subgroup of the symmetric group \( S_n \) for a certain \( n \). This group has a natural action by position on vectors of length \( n \). This class implements a set which keeps a single vector for each
orbit. We say that a vector is canonical if it is the maximum in its orbit under the action of the permutation group for the lexicographic order.

EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]])); I
Integer vectors of length 4 enumerated up to the action of
Permutation Group with generators [(1,2,3,4)]
sage: I.cardinality()
+Infinity
sage: TestSuite(I).run()
sage: it = iter(I)
sage: [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0],
 [1, 0, 0, 0],
 [2, 0, 0, 0],
 [1, 1, 0, 0],
 [1, 0, 1, 0]]
sage: x = next(it); x
[3, 0, 0, 0]
sage: I.first()
[0, 0, 0, 0]
```

```python
>>> from sage.all import *

>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]])); I
Integer vectors of length 4 enumerated up to the action of
Permutation Group with generators [(1,2,3,4)]

>>> I.cardinality()
+Infinity

>>> TestSuite(I).run()

>>> it = iter(I)

>>> [next(it), next(it), next(it), next(it), next(it)]
[[0, 0, 0, 0],
 [1, 0, 0, 0],
 [2, 0, 0, 0],
 [1, 1, 0, 0],
 [1, 0, 1, 0]]

>>> x = next(it); x
[3, 0, 0, 0]

>>> I.first()
[0, 0, 0, 0]
```

class Element

Bases: ClonableIntArray

Element class for the set of integer vectors of given sum enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent appearing in the method `check()`.

`check()`

Checks that `self` verify the invariants needed for living in `self.parent()`.

EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]))
sage: v = I.an_element()
```
sage: v.check()
sage: w = I([0,4,0,0], check=False); w
[0, 4, 0, 0]
sage: w.check()
Traceback (most recent call last):
...AssertionError

ambient()
Return the ambient space from which self is a quotient.

EXAMPLES:
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: S.ambient()
Integer vectors of length 4

children(x)
Returns the list of children of the element x. This method is required to build the tree structure of self which inherits from the class RecursivelyEnumeratedSet_forest.

EXAMPLES:
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: I.children(I([2,1,0,0], check=False))
[[2, 2, 0, 0], [2, 1, 1, 0], [2, 1, 0, 1]]

is_canonical(v, check=True)
Returns True if the integer list v is maximal in its orbit under the action of the permutation group given to define self. Such integer vectors are said to be canonical. A vector v is canonical if and only if

\[ v = \max_{\text{lex order}} \{ g \cdot v | g \in G \} \]
EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))
sage: I.is_canonical([4, 3, 2, 1])
True
sage: I.is_canonical([4, 0, 0, 1])
True
sage: I.is_canonical([4, 0, 3, 3])
True
sage: I.is_canonical([4, 0, 4, 4])
False
```

```python
>>> from sage.all import *

>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([(1, 2, 3, 4)]))

>>> I.is_canonical([4, 3, 0, 1])
True
```

```python
from sage.all import *

S = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))

v = S([4, 3, 0, 1]); v
[4, 3, 0, 1]

sage: type(v)
<class 'list'>
```

```python
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))

>>> v = S([4, 3, 0, 1]); v
[4, 3, 0, 1]

sage: type(v)
<class 'list'>
```

lift (elt)

Lift the element elt inside the ambient space from which self is a quotient.

EXAMPLES:

```python
S = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))

v = S.lift(S([4, 3, 0, 1])); v
[4, 3, 0, 1]

sage: type(v)
<class 'list'>
```

```python
>>> from sage.all import *

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))

>>> v = S.lift(S([4, 3, 0, 1])); v
[4, 3, 0, 1]

sage: type(v)
<class 'list'>
```

orbit (v)

Returns the orbit of the integer vector v under the action of the permutation group defining self. The result is a set.

EXAMPLES:

In order to get reproducible doctests, we convert the returned sets into lists in increasing lexicographic order:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))

sage: sorted(I.orbit([2, 0, 0, 0]))
[[0, 0, 0, 2], [0, 2, 0, 0], [2, 0, 0, 0], [2, 2, 0, 0]]

sage: sorted(I.orbit([2, 1, 0, 0]))
[[0, 0, 2, 1], [0, 2, 1, 0], [1, 0, 0, 2], [2, 1, 0, 0]]

sage: sorted(I.orbit([2, 0, 1, 0]))

(continues on next page)
```
Combinatorics, Release 10.4

(continued from previous page)

```
[[0, 1, 0, 2], [0, 2, 0, 1], [1, 0, 2, 0], [2, 0, 1, 0]]
sage: sorted(I.orbit([2, 0, 2, 0]))
[[0, 2, 0, 2], [2, 0, 2, 0]]
sage: I.orbit([1, 1, 1, 1])
{[1, 1, 1, 1]}
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))
```

```
permutation_group()

Returns the permutation group given to define self.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))
sage: I.permutation_group()
Permutation Group with generators [(1,2,3,4)]
```

```
>>> from sage.all import *
>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))
```

```
retract(elt)

Return the canonical representative of the orbit of the integer elt under the action of the permutation group defining self.

If the element elt is already maximal in its orbit for the lexicographic order, elt is thus the good representative for its orbit.

EXAMPLES:

```
sage: [0, 0, 0, 0] in IntegerVectors(0, 4)
True
sage: [1, 0, 0, 0] in IntegerVectors(1, 4)
True
sage: [0, 1, 0, 0] in IntegerVectors(1, 4)
True
sage: [1, 0, 1, 0] in IntegerVectors(2, 4)
True
sage: [0, 1, 0, 1] in IntegerVectors(2, 4)
True
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1, 2, 3, 4]]))
sage: S.retract([0, 0, 0, 0])
```

(continues on next page)
[0, 0, 0, 0]
sage: S.retract([1, 0, 0, 0])
[1, 0, 0, 0]
sage: S.retract([0, 1, 0, 0])
[1, 0, 0, 0]
sage: S.retract([1, 0, 1, 0])
[1, 0, 1, 0]
sage: S.retract([0, 1, 0, 1])
[1, 0, 1, 0]

>>> from sage.all import *
>>> [Integer(0),Integer(0),Integer(0),Integer(0)] in IntegerVectors(Integer(0),Integer(4))
True
>>> [Integer(1),Integer(0),Integer(0),Integer(0)] in IntegerVectors(Integer(1),Integer(4))
True
>>> [Integer(0),Integer(1),Integer(0),Integer(0)] in IntegerVectors(Integer(1),Integer(4))
True
>>> [Integer(1),Integer(0),Integer(1),Integer(0)] in IntegerVectors(Integer(2),Integer(4))
True
>>> [Integer(0),Integer(1),Integer(0),Integer(1)] in IntegerVectors(Integer(2),Integer(4))
True
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))

roots()
Returns the root of generation of self. This method is required to build the tree structure of self which inherits from the class RecursivelyEnumeratedSet_forest.

EXAMPLES:

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: I.roots()
[[0, 0, 0, 0]]
Returns the subset of \texttt{self} containing integer vectors whose entries sum to \texttt{sum}.

**EXAMPLES:**

```python
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))

sage: S.subset(4)
Integer vectors of length 4 and of sum 4 enumerated up to the action of Permutation Group with generators [(1,2,3,4)]
```

```python
>>> from sage.all import *

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([(Integer(1),
    →Integer(2),Integer(3),Integer(4)]))

>>> S.subset(Integer(4))
Integer vectors of length 4 and of sum 4 enumerated up to the action of Permutation Group with generators [(1,2,3,4)]
```

```python
class sage.combinat.integer_vectors_mod_permgroup.IntegerVectorsModPermutationGroup_with_constraints(G, d, max_part, sgs=None): Bases: UniqueRepresentation, RecursivelyEnumeratedSet_forest

This class models finite enumerated sets of integer vectors with constraint enumerated up to the action of a permutation group. Integer vectors are enumerated modulo the action of the permutation group. To implement that, we keep a single integer vector by orbit under the action of the permutation group. Elements chosen are vectors maximal in their orbit for the lexicographic order.

For more information see \texttt{IntegerVectorsModPermutationGroup}.

**EXAMPLES:**

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]),
    ...: max_part=1)

sage: I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0], [1, 1, 1, 1]]

sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]),
    ...: sum=6, max_part=4)

sage: I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0], [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2], [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```

```python
>>> from sage.all import *

>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([(Integer(1),
    →Integer(2),Integer(3),Integer(4)])),
    ... max_part=Integer(1))

>>> I.list()
[[0, 0, 0, 0], [1, 0, 0, 0], [1, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 0], [1, 1, 1, 1]]

>>> I = IntegerVectorsModPermutationGroup(PermutationGroup([(Integer(1),
    →Integer(2),Integer(3),Integer(4)])),
    ... sum=Integer(6), max_part=Integer(4))

>>> I.list()
[[4, 2, 0, 0], [4, 1, 1, 0], [4, 1, 0, 1], [4, 0, 2, 0], [4, 0, 1, 1], [3, 3, 0, 0], [3, 2, 1, 0], [3, 2, 0, 1], [3, 1, 2, 0], [3, 1, 1, 1], [3, 1, 0, 2], [3, 0, 3, 0], [3, 0, 2, 1], [3, 0, 1, 2], [2, 2, 2, 0], [2, 2, 1, 1], [2, 1, 2, 1]]
```
Here is the enumeration of unlabeled graphs over 5 vertices:

```
sage: G = IntegerVectorsModPermutationGroup(TransitiveGroup(10,12), max_part=1)
sage: G.cardinality()
34
```

```python
>>> from sage.all import *

>>> G = IntegerVectorsModPermutationGroup(TransitiveGroup(Integer(10), Integer(12)), max_part=Integer(1))
>>> G.cardinality()
34
```

```
class Element
    Bases: ClonableIntArray

Element class for the set of integer vectors with constraints enumerated modulo the action of a permutation group. These vectors are clonable lists of integers which must satisfy conditions coming from the parent as in the method check().

    check()
        Check that self meets the constraints of being an element of self.parent().

        EXAMPLES:

```
```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]),-→6)
sage: S.ambient()
Integer vectors that sum to 6
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→6, max_part=12)
sage: S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→max_part=12)
sage: S.ambient()
Integer vectors with constraints: max_part=12

>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1), ˓→Integer(2),Integer(3),Integer(4)]],[Integer(6)])
>>> S.ambient()
Integer vectors that sum to 6
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1), ˓→Integer(2),Integer(3),Integer(4)]],[Integer(6), max_part=Integer(12)])
>>> S.ambient()
Integer vectors that sum to 6 with constraints: max_part=12
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1), ˓→Integer(2),Integer(3),Integer(4)]],[max_part=Integer(12)])
>>> S.ambient()
Integer vectors with constraints: max_part=12

an_element()

Return an element of self.

Raises an EmptySetError when self is empty.

EXAMPLES:

sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→sum=0, max_part=1)
sage: S.an_element()
[0, 0, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→sum=1, max_part=1)
sage: S.an_element()
[1, 0, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→sum=2, max_part=1)
sage: S.an_element()
[1, 1, 0, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→sum=3, max_part=1)
sage: S.an_element()
[1, 1, 1, 0]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→sum=4, max_part=1)
sage: S.an_element()
[1, 1, 1, 1]
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), ˓→(continues on next page)
sage: S.an_element()
Traceback (most recent call last):
...
EmptySetError

>>> from sage.all import *

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    --> Integer(2), Integer(3), Integer(4)]]),
    ...
    sum=Integer(0), max_part=Integer(1))

>>> S.an_element()
[0, 0, 0, 0]

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    --> Integer(2), Integer(3), Integer(4)]]),
    ...
    sum=Integer(1), max_part=Integer(1))

>>> S.an_element()
[1, 0, 0, 0]

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    --> Integer(2), Integer(3), Integer(4)]]),
    ...
    sum=Integer(2), max_part=Integer(1))

>>> S.an_element()
[1, 1, 0, 0]

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    --> Integer(2), Integer(3), Integer(4)]]),
    ...
    sum=Integer(3), max_part=Integer(1))

>>> S.an_element()
[1, 1, 1, 0]

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    --> Integer(2), Integer(3), Integer(4)]]),
    ...
    sum=Integer(4), max_part=Integer(1))

>>> S.an_element()
[1, 1, 1, 1]

>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    --> Integer(2), Integer(3), Integer(4)]]),
    ...
    sum=Integer(5), max_part=Integer(1))

>>> S.an_element()
Traceback (most recent call last):
...
EmptySetError

cardinality()

Return the number of integer vectors in the set.

The algorithm utilises Cycle Index Theorem, allowing for a faster than a plain enumeration computation.

EXAMPLES:

With a trivial group all vectors are canonical:

sage: G = PermutationGroup([], domain=[1,2,3])
sage: IntegerVectorsModPermutationGroup(G, 5).cardinality()
21
sage: IntegerVectors(5, 3).cardinality()
21

>>> from sage.all import *

>>> G = PermutationGroup([], domain=[Integer(1),Integer(2),Integer(3)])
With two interchangeable elements, the smaller one ranges from zero to \( \text{sum}/2 \):

```python
sage: G = PermutationGroup([(1,2)])
sage: IntegerVectorsModPermutationGroup(G, 1000).cardinality()
501
```

Binary vectors up to full symmetry are first some ones and then some zeros:

```python
sage: G = SymmetricGroup(10)
sage: I = IntegerVectorsModPermutationGroup(G, max_part=1)
sage: I.cardinality()
11
```

Binary vectors of constant weight, up to PGL(2,17), which is 3-transitive, but not 4-transitive:

```python
sage: G=PGL(2,17)
sage: I = IntegerVectorsModPermutationGroup(G, sum=3, max_part=1)
sage: I.cardinality()
1
```

```python
>>> from sage.all import *
```

```python
G=PGL(Integer(2),Integer(17))

>>> I = IntegerVectorsModPermutationGroup(G, sum=Integer(3), max_part=Integer(1))
>>> I.cardinality()
1
>>> I = IntegerVectorsModPermutationGroup(G, sum=Integer(4), max_part=Integer(1))
>>> I.cardinality()
3
```

```python
children(x)
```

Return the list of children of the element \( x \).

This method is required to build the tree structure of \( \text{self} \) which inherits from the class `RecursiveLyEnumeratedSet_forest`.

EXAMPLES:
is canonical \((v, \text{check=True})\)

Return True if the integer list \(v\) is maximal in its orbit under the action of the permutation group given to define self. Such integer vectors are said to be canonical. A vector \(v\) is canonical if and only if

\[
v = \max_{\text{lex order}} \{g \cdot v \mid g \in G\}
\]

EXAMPLES:

```python
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[(1,2,3,4)]]), max_part=3)
```

```python
sage: I.is_canonical([3,0,0,0])
True
sage: I.is_canonical([1,0,2,0])
False
sage: I.is_canonical([2,0,1,0])
True
```
>>> from sage.all import *
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    Integer(2), Integer(3), Integer(4)]],
    max_part=Integer(1))
>>> v = S.lift([[Integer(1), Integer(0), Integer(1), Integer(0)]]); v
[1, 0, 1, 0]
>>> v in IntegerVectors(Integer(2), Integer(4), max_part=Integer(1))
True
>>> S = IntegerVectorsModPermutationGroup(PermutationGroup([[Integer(1),
    Integer(2), Integer(3), Integer(4)]],
    sum=Integer(6))
>>> v = S.lift(S.list()[Integer(5)]); v
[4, 1, 1, 0]
>>> v in IntegerVectors(n=Integer(6))
True

orbit (v)
Return the orbit of the vector v under the action of the permutation group defining self. The result is a set.

INPUT:

• v – an element of self or any list of length the degree of the permutation group.

EXAMPLES:

We convert the result in a list in increasing lexicographic order, to get a reproducible doctest:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), 4)
sage: I.orbit([1,1,1,1])
{(1, 1, 1, 1)}
sage: sorted(I.orbit([3,0,0,1]))
[[0, 0, 1, 3], [0, 1, 3, 0], [1, 3, 0, 0], [3, 0, 0, 1]]
```

permutation_group ()
Return the permutation group given to define self.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), 4)
sage: I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), 5)
sage: I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([[1,2,3,4]]), 5)
sage: I.permutation_group()
Permutation Group with generators [(1,2,3)]
```

5.1. Comprehensive Module List
retract (elt)

Return the canonical representative of the orbit of the integer elt under the action of the permutation group defining self.

If the element elt is already maximal in its orbits for the lexicographic order, elt is thus the good representative for its orbit.

EXAMPLES:

```
sage: S = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]),
      sum=2, max_part=1)
sage: S.retract([1,1,0,0])
[1, 1, 0, 0]
sage: S.retract([1,0,1,0])
[1, 0, 1, 0]
sage: S.retract([1,0,0,1])
[1, 1, 0, 0]
sage: S.retract([0,1,1,0])
[1, 1, 0, 0]
sage: S.retract([0,1,0,1])
[1, 0, 1, 0]
sage: S.retract([0,0,1,1])
[1, 1, 0, 0]
```

roots ()

Return the root of generation of self.

This method is required to build the tree structure of self which inherits from the class RecursivelyEnumeratedSet_forest.

EXAMPLES:

```
sage: I = IntegerVectorsModPermutationGroup(PermutationGroup([(1,2,3,4)]))
sage: I.roots()
[[0, 0, 0, 0]]
```

```
5.1.129 Tamari Interval-posets

This module implements Tamari interval-posets: combinatorial objects which represent intervals of the Tamari order. They have been introduced in [CP2015] and allow for many combinatorial operations on Tamari intervals. In particular, they are linked to DyckWords and BinaryTrees. An introduction into Tamari interval-posets is given in Chapter 7 of [Pons2013].

The Tamari lattice can be defined as a lattice structure on either of several classes of Catalan objects, especially binary trees and Dyck paths [Tam1962] [HT1972] [Sta-EC2]. An interval can be seen as a pair of comparable elements. The number of intervals has been given in [Cha2008].

AUTHORS:
- Viviane Pons 2014: initial implementation
- Frédéric Chapoton 2014: review
- Darij Grinberg 2014: review
- Travis Scrimshaw 2014: review

sage.combinat.interval_posets.TIP
alias of TamariIntervalPoset

class sage.combinat.interval_posets.TamariIntervalPoset(parent, size, relations=None, check=True)

Bases: Element

The class of Tamari interval-posets.

An interval-poset is a labelled poset of size \( n \), with labels 1, 2, ..., \( n \), satisfying the following conditions:

- if \( a < c \) (as integers) and \( a \) precedes \( c \) in the poset, then, for all \( b \) such that \( a < b < c \), \( b \) precedes \( c \),
- if \( a < c \) (as integers) and \( c \) precedes \( a \) in the poset, then, for all \( b \) such that \( a < b < c \), \( b \) precedes \( a \).

We use the word “precedes” here to distinguish the poset order and the natural order on numbers. “Precedes” means “is smaller than with respect to the poset structure”; this does not imply a covering relation.

Interval-posets of size \( n \) are in bijection with intervals of the Tamari lattice of binary trees of size \( n \). Specifically, if \( P \) is an interval-poset of size \( n \), then the set of linear extensions of \( P \) (as permutations in \( S_n \)) is an interval in the right weak order (see permutohedron_lequal()), and in fact the preimage of an interval in the Tamari lattice (of binary trees of size \( n \)) under the operation which sends a permutation to its right-to-left binary search tree (binary_search_tree() with the left_to_right variable set to False) without its labelling.

INPUT:

- `size` – an integer, the size of the interval-posets (number of vertices)
- `relations` – a list (or tuple) of pairs \((a, b)\) (themselves lists or tuples), each representing a relation of the form ‘\(a\) precedes \(b\)’ in the poset.
- `check` – (default: True) whether to check the interval-poset condition or not.

Warning: The `relations` input can be a list or tuple, but not an iterator (nor should its entries be iterators).

NOTATION:

Here and in the following, the signs `<` and `>` always refer to the natural ordering on integers, whereas the word “precedes” refers to the order of the interval-poset. “Minimal” and “maximal” refer to the natural ordering on integers.
The increasing relations of an interval-poset $P$ mean the pairs $(a, b)$ of elements of $P$ such that $a < b$ as integers and $a$ precedes $b$ in $P$. The initial forest of $P$ is the poset obtained by imposing (only) the increasing relations on the ground set of $P$. It is a sub-interval poset of $P$, and is a forest with its roots on top. This forest is usually given the structure of a planar forest by ordering brother nodes by their labels; it then has the property that if its nodes are traversed in post-order (see `post_order_traversal()`), and traverse the trees of the forest from left to right as well), then the labels encountered are $1, 2, \ldots, n$ in this order.

The decreasing relations of an interval-poset $P$ mean the pairs $(a, b)$ of elements of $P$ such that $b < a$ as integers and $a$ precedes $b$ in $P$. The final forest of $P$ is the poset obtained by imposing (only) the decreasing relations on the ground set of $P$. It is a sub-interval poset of $P$, and is a forest with its roots on top. This forest is usually given the structure of a planar forest by ordering brother nodes by their labels; it then has the property that if its nodes are traversed in pre-order (see `pre_order_traversal()`), and traverse the trees of the forest from left to right as well), then the labels encountered are $1, 2, \ldots, n$ in this order.

EXAMPLES:

```python
sage: TamariIntervalPoset(0, [])
The Tamari interval of size 0 induced by relations []
sage: TamariIntervalPoset(3, [])
The Tamari interval of size 3 induced by relations []
sage: TamariIntervalPoset(3, [(1, 2)])
The Tamari interval of size 3 induced by relations [(1, 2)]
sage: TamariIntervalPoset(3, [(1, 2), (2, 3)])
The Tamari interval of size 3 induced by relations [(1, 2), (2, 3)]
```

(continues on next page)
The Tamari interval of size 3 induced by relations \([(1, 2), (2, 3)]\)

```
>>> TamariIntervalPoset(Integer(3),\[(Integer(1),Integer(2)), (Integer(2),
→ Integer(3))\])
```

The Tamari interval of size 3 induced by relations \([(1, 2), (2, 3)]\)

```
>>> TamariIntervalPoset(Integer(3),\[(Integer(1),Integer(2)), (Integer(3),
→ Integer(2))\])
```

The Tamari interval of size 3 induced by relations \([(1, 2), (3, 2)]\)

```
>>> TamariIntervalPoset(Integer(3),\[\{(Integer(1),Integer(2)), (Integer(2),
→ Integer(3))\}\])
```

The Tamari interval of size 3 induced by relations \([(1, 2), (2, 3)]\)

```
>>> TamariIntervalPoset(Integer(3),\[\{(Integer(1),Integer(2)), (Integer(2),
→ Integer(3))\}, \{(Integer(1),Integer(3))\}\])
```

The Tamari interval of size 3 induced by relations \([(1, 2), (2, 3)]\)

```
>>> TamariIntervalPoset(Integer(3),\[\{(Integer(3),Integer(4))\}\])
```

Traceback (most recent call last):
...
ValueError: the relations do not correspond to the size of the poset

```
>>> TamariIntervalPoset(Integer(2),\[(Integer(2),Integer(1)), (Integer(1),
→ Integer(2))\])
```

Traceback (most recent call last):
...
ValueError: The graph is not directed acyclic

```
>>> TamariIntervalPoset(Integer(3),\{(Integer(1),Integer(3))\})
```

Traceback (most recent call last):
...
ValueError: this does not satisfy the Tamari interval-poset condition

It is also possible to transform a poset directly into an interval-poset:

```
sage: TIP = TamariIntervalPosets()
sage: p = Poset(([1,2,3], [(1,2)]))
sage: TIP(p)
```

The Tamari interval of size 3 induced by relations \([(1, 2)]\)

```
sage: TIP(Poset({1: []}))
```

The Tamari interval of size 1 induced by relations []

```
sage: TIP(Poset({}))
```

The Tamari interval of size 0 induced by relations []

```
>>> from sage.all import *
>>> TIP = TamariIntervalPosets()
>>> p = Poset({(Integer(1),Integer(2),Integer(3)): \[(Integer(1),Integer(2))]\})
```

```
>>> TIP(p)
```

The Tamari interval of size 3 induced by relations \([(1, 2)]\)

```
>>> TIP(Poset({Integer(1): []}))
```

The Tamari interval of size 1 induced by relations []

```
>>> TIP(Poset({}))
```

The Tamari interval of size 0 induced by relations []

```
binary_trees()
```

Return an iterator on all the binary trees in the interval represented by `self`.

See also:

```
interval_cardinality()
```

5.1. Comprehensive Module List
EXAMPLES:

```
sage: list(TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).binary_trees())
[[[., [[., .], .]], .]],
[[[., [[., .], .]], .]],
[[[., .], [[., .], .]], .]]
sage: set(TamariIntervalPoset(4,[]).binary_trees()) == set(BinaryTrees(4))
True

>>> from sage.all import *

>>> list(TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))]).binary_trees())
[[., [[., .], [., .]]],
[[., [[., .], [., .]]], .]]

>>> set(TamariIntervalPoset(Integer(4),[]).binary_trees()) == set(BinaryTrees(Integer(4)))
True
```

**complement()**

Return the complement of the interval-poset self.

If \( P \) is a Tamari interval-poset of size \( n \), then the complement of \( P \) is defined as the interval-poset \( Q \) whose base set is \( [n] = \{1, 2, \ldots, n\} \) (just as for \( P \)), but whose order relation has \( a \) precede \( b \) if and only if \( n+1-a \) precedes \( n+1-b \) in \( P \).

In terms of the Tamari lattice, the complement is the symmetric of self. It is formed from the left-right symmetrization of the binary trees of the interval (switching left and right subtrees, see `left_right_symmetry()`). In particular, initial intervals are sent to final intervals and vice-versa.

EXAMPLES:

```
sage: TamariIntervalPoset(3, [(2,1), (3,1)]).complement() # The Tamari interval of size 3 induced by relations [(1,3), (2,3)]
sage: TamariIntervalPoset(0, []).complement() # The Tamari interval of size 0 induced by relations []
sage: ip = TamariIntervalPoset(4, [(1,2), (2,4), (3,4)])
```

(continues on next page)
The Tamari interval of size 0 induced by relations []
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)),
   (Integer(2), Integer(4)), (Integer(3), Integer(4))])
>>> ip.complement() == TamariIntervalPoset(Integer(4), [(Integer(2),
   Integer(1)), (Integer(3), Integer(1)), (Integer(4), Integer(3))])
True
>>> ip.lower_binary_tree() == ip.complement().upper_binary_tree().left_right_
   symmetry()
True
>>> ip.upper_binary_tree() == ip.complement().lower_binary_tree().left_right_
   symmetry()
True
>>> ip.is_initial_interval()
True
>>> ip.complement().is_final_interval()
True

contains_binary_tree (binary_tree)

Return whether the interval represented by self contains the binary tree binary_tree.

INPUT:
• binary_tree – a binary tree

See also:
contains_dyck_word()

EXAMPLES:

sage: ip = TamariIntervalPoset(4, [(2,4), (3,4), (2,1), (3,1)])
sage: ip.contains_binary_tree(BinaryTree([[None, [None, []], None]]))
True
sage: ip.contains_binary_tree(BinaryTree([[], [[], None], None]))
False
sage: ip.contains_binary_tree(ip.lower_binary_tree())
True
sage: ip.contains_binary_tree(ip.upper_binary_tree())
True
sage: all(ip.contains_binary_tree(bt) for bt in ip.binary_trees())
True

>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2), Integer(4)), (Integer(3),
   Integer(4)), (Integer(2), Integer(1)), (Integer(3), Integer(1))])
>>> ip.contains_binary_tree(BinaryTree([[None, [None, []], None]]))
True
>>> ip.contains_binary_tree(BinaryTree([[], [[], None], None]))
False
>>> ip.contains_binary_tree(ip.lower_binary_tree())
True
>>> ip.contains_binary_tree(ip.upper_binary_tree())
True

(continues on next page)
contains_dyck_word(dyck_word)

Return whether the interval represented by self contains the Dyck word dyck_word.

INPUT:

• dyck_word – a Dyck word

See also:

contains_binary_tree()

data\combinatorics\polytopes\lattice\ TamariIntervalPoset.py

EXAMPLES:

```python
sage: # needs sage.combinat
sage: ip = TamariIntervalPoset(4, [(2,4),(3,4),(2,1),(3,1)])
sage: ip.contains_dyck_word(DyckWord([1,1,1,0,0,0,1,0]))
True
sage: ip.contains_dyck_word(DyckWord([1,1,0,1,0,1,0,0]))
True
sage: ip.contains_dyck_word(DyckWord([1,0,1,1,0,1,0,0]))
False
sage: ip.contains_dyck_word(ip.lower_dyck_word())
True
sage: ip.contains_dyck_word(ip.upper_dyck_word())
True
sage: all(ip.contains_dyck_word(bt) for bt in ip.dyck_words())
True
```

contains_interval(other)

Return whether the interval represented by other is contained in self as an interval of the Tamari lattice.

In terms of interval-posets, it means that all relations of self are relations of other.

INPUT:

• other – an interval-poset
EXAMPLES:

```python
from sage.all import *

ip1 = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)), (Integer(2), Integer(3))])

ip2 = TamariIntervalPoset(Integer(4), [(Integer(2), Integer(3))])

ip2.contains_interval(ip1)
True

ip2.contains_interval(ip3)
False

ip4 = TamariIntervalPoset(Integer(3), [(Integer(2), Integer(3))])

ip2.contains_interval(ip4)
False
```

cubical_coordinates()

Return the cubical coordinates of self.

This provides a fast and natural way to order the set of interval-posets of a given size.

EXAMPLES:

```python
ip = TamariIntervalPoset(4, [(1, 2), (2, 3)])

ip.cubical_coordinates()
(-1, -2, 0)
```

REFERENCES:

- [Com2019]

decomposition_to_triple()

Decompose an interval-poset into a triple (left, right, r).

For the inverse method, see `TamariIntervalPosets.recomposition_from_triple()`.

OUTPUT:

a triple (left, right, r) where left and right are interval-posets and r (an integer) is the parameter of the decomposition.

EXAMPLES:
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7),
....: (3,2), (5,4), (6,4), (8,7)])
sage: tip.decomposition_to_triple()
(The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)],
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3), (2)]
sage: tip == TamariIntervalPosets.recomposition_from_triple(*tip.decomposition_to_triple())
True

REFERENCES:

• [CP2015]

decreasing_children(v)

Return the children of v in the final forest of self.

INPUT:

• v – an integer representing a vertex of self (between 1 and size)

OUTPUT:

The list of all children of v in the final forest of self, in increasing order.

EXAMPLES:
sage: ip = TamariIntervalPoset(6, [(3,2), (4,3), (5,2), (6,5), (1,2), (3,5), (4,5)]);
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),
→(6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.decreasing_children(2)
[3, 5]
sage: ip.decreasing_children(3)
[4]
sage: ip.decreasing_children(1)
[]

>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3),Integer(2)), (Integer(4),
→Integer(3)), (Integer(5),Integer(2)), (Integer(6),Integer(5)), (Integer(1),
→Integer(2)), (Integer(3),Integer(5)), (Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),
→(6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.decreasing_children(Integer(2))
[3, 5]
decreasing_cover_relations()

Return the cover relations of the final forest of self.

This is the poset formed by keeping only the relations of the form \( a \) precedes \( b \) with \( a > b \).

The final forest of \( self \) is a forest with its roots being on top. It is also called the decreasing poset of \( self \).

**Warning:** This method computes the cover relations of the final forest. This is not identical with the cover relations of \( self \) which happen to be decreasing!

See also:

* final_forest()

EXAMPLES:

```python
sage: TamariIntervalPoset(4, [(2, 1), (3, 2), (3, 4), (4, 2)]).decreasing_cover_relations()
[(4, 2), (3, 2), (2, 1)]
```

```python
sage: TamariIntervalPoset(4, [(2, 1), (4, 3), (2, 3)]).decreasing_cover_relations()
[(4, 3), (2, 1)]
```

```python
sage: TamariIntervalPoset(3, [(2, 1), (3, 1), (3, 2)]).decreasing_cover_relations()
[(3, 2), (2, 1)]
```

```python
>>> from sage.all import *
```

```python
>>> TamariIntervalPoset(Integer(4), [(Integer(2), Integer(1)), (Integer(3), Integer(2)), (Integer(3), Integer(4)), (Integer(4), Integer(2))]).decreasing_cover_relations()
[(4, 2), (3, 2), (2, 1)]
```

```python
>>> TamariIntervalPoset(Integer(4), [(Integer(2), Integer(1)), (Integer(4), Integer(3)), (Integer(2), Integer(3))]).decreasing_cover_relations()
[(4, 3), (2, 1)]
```

```python
>>> TamariIntervalPoset(Integer(3), [(Integer(2), Integer(1)), (Integer(3), Integer(1)), (Integer(3), Integer(2))]).decreasing_cover_relations()
[(3, 2), (2, 1)]
```

decreasing_parent(v)

Return the vertex parent of \( v \) in the final forest of \( self \).

This is the highest (as integer!) vertex \( a < v \) such that \( v \) precedes \( a \). If there is no such vertex (that is, \( v \) is a decreasing root), then None is returned.

**INPUT:**

- \( v \) – an integer representing a vertex of \( self \) (between 1 and size)

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(6, [(3, 2), (4, 3), (5, 2), (6, 5), (1, 2), (3, 5), (4, 5)])
```

The Tamari interval of size 6 induced by relations \{ (1, 2), (3, 5), (4, 5), ... \}
\[(6, 5), (5, 2), (4, 3), (3, 2)\]

```python
sage: ip.decreasing_parent(4)
3
sage: ip.decreasing_parent(3)
2
sage: ip.decreasing_parent(5)
2
sage: ip.decreasing_parent(2) is None
True
```

```python
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
cripcion(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
.descripcion(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
.descripcion(6), (5, 2), (4, 3), (3, 2)]
>>> ip.decreasing_parent(Integer(4))
3
>>> ip.decreasing_parent(Integer(3))
2
>>> ip.decreasing_parent(Integer(5))
2
>>> ip.decreasing_parent(Integer(2)) is None
True
```

decreasing_roots()

Return the root vertices of the final forest of self.

These are the vertices \( b \) such that there is no \( a < b \) with \( b \) preceding \( a \).

OUTPUT:

The list of all roots of the final forest of self, in increasing order.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(6,[(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]);
>>> ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
.descripcion(6), (5, 2), (4, 3), (3, 2)]
```

```python
sage: ip.decreasing_roots()
[1, 2]
```

```python
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6),[(Integer(3),Integer(2)),(Integer(4),
.descripcion(3)),(Integer(5),Integer(2)),(Integer(6),Integer(5)),(Integer(1),
.descripcion(2)),(Integer(3),Integer(5)),(Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),␣
.descripcion(6), (5, 2), (4, 3), (3, 2)]
```

```python
>>> ip.decreasing_roots()
[1, 2]
```

dyck_words()

Return an iterator on all the Dyck words in the interval represented by self.
EXAMPLES:

```python
sage: list(TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)]).dyck_words()) # needs sage.combinat
[[], [1, 1, 1, 0, 0, 1, 0, 0], [1, 1, 1, 0, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 0, 1, 0, 0, 1, 0]]
```

```python
sage: set(TamariIntervalPoset(4,[]).dyck_words()) == set(DyckWords(4)) # needs sage.combinat
True
```

```python
>>> from sage.all import *

>>> list(TamariIntervalPoset(Integer(4),[(Integer(2),Integer(4)),(Integer(3),Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))]).dyck_words()) # needs sage.combinat
[[], [1, 1, 1, 0, 0, 1, 0, 0], [1, 1, 1, 0, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 0, 1, 0, 0, 1, 0]]

>>> set(TamariIntervalPoset(Integer(4),[]).dyck_words()) == set(DyckWords(Integer(4))) # needs sage.combinat
True
```

```python
factor()  
Return the unique decomposition as a list of connected components.
```

```python
sage: factor(TamariIntervalPoset(2,[])) # indirect doctest
[The Tamari interval of size 1 induced by relations [], The Tamari interval of size 1 induced by relations []]
```

```python
>>> from sage.all import *

>>> factor(TamariIntervalPoset(Integer(2),[])) # indirect doctest
[The Tamari interval of size 1 induced by relations [], The Tamari interval of size 1 induced by relations []]
```

See also:

`is_connected()`

```python
final_forest()  
Return the final forest of self, i.e., the interval-poset formed with only the decreasing relations of self.
```

See also:

`initial_forest()`

EXAMPLES:

```python
sage: TamariIntervalPoset(4,[(2,1),(3,2),(3,4),(4,2)]).final_forest()  
The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)]
```

```python
sage: ip = TamariIntervalPoset(3,[(2,1),(3,1)])

sage: ip.final_forest() == ip
True
```
ge \((e1, e2)\)

Return whether \(e2\) precedes or equals \(e1\) in \(self\).

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1,2), (2,3)])
sage: ip.ge(2,1)
True
sage: ip.ge(3,1)
True
sage: ip.ge(3,2)
True
sage: ip.ge(4,3)
False
sage: ip.ge(1,1)
True
```

grafting_tree()

Return the grafting tree of the interval-poset.

For the inverse method, see `TamariIntervalPosets.from_grafting_tree()`.

EXAMPLES:

```python
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4), (6,4), (8,7)])
sage: tip.grafting_tree()
2[1[0[., .], 0[., .]], 0[., 1[0[., .], 0[., .]]]]
sage: tip == TamariIntervalPosets.from_grafting_tree(tip.grafting_tree())
True
```
Combinatorics, Release 10.4

(continued from previous page)

... (Integer(3), Integer(2)), (Integer(5),
    Integer(4)), (Integer(6), Integer(4)), (Integer(8), Integer(7))]
>>> tip.grafting_tree()
2[[[0[., .], 0[., .]], 0[., 1[0[., .], 0[., .]]]],
>>> tip == TamariIntervalPosets.from_grafting_tree(tip.grafting_tree())
True

REFERENCES:

- [Pons2018]

gt (el, e2)

Return whether e2 strictly precedes e1 in self.

EXAMPLES:

sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 3)])
sage: ip.gt(2, 1)
True
sage: ip.gt(3, 1)
True
sage: ip.gt(3, 2)
True
sage: ip.gt(4, 3)
False
sage: ip.gt(1, 1)
False

>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)),
    Integer(2), Integer(3)])
>>> ip.gt(Integer(2), Integer(1))
True
>>> ip.gt(Integer(3), Integer(1))
True
>>> ip.gt(Integer(3), Integer(2))
True
>>> ip.gt(Integer(4), Integer(3))
False
>>> ip.gt(Integer(1), Integer(1))
False

increasing_children (v)

Return the children of v in the initial forest of self.

INPUT:

- v – an integer representing a vertex of self (between 1 and size)

OUTPUT:

The list of all children of v in the initial forest of self, in decreasing order.

EXAMPLES:

sage: ip = TamariIntervalPoset(6, [(3, 2), (4, 3), (5, 2), (6, 5), (1, 2), (3, 5), (4, 5)])
    → ip
The Tamari interval of size 6 induced by relations 
(continues on next page)
Combinatorics, Release 10.4

Space in parentheses indicate relations.

\[ (6, 5), (5, 2), (4, 3), (3, 2) \]

sage: ip.increasing_children(2)
[1]
sage: ip.increasing_children(5)
[4, 3]
sage: ip.increasing_children(1)
[]

>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3), Integer(2)), (Integer(4),
        Integer(3)), (Integer(5), Integer(2)), (Integer(6), Integer(5)), (Integer(1),
        Integer(2)), (Integer(3), Integer(5)), (Integer(4), Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5),
        (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.increasing_children(Integer(2))
[1]
>>> ip.increasing_children(Integer(5))
[4, 3]
>>> ip.increasing_children(Integer(1))
[]

increasing_cover_relations()

Return the cover relations of the initial forest of self.

This is the poset formed by keeping only the relations of the form \( a \) precedes \( b \) with \( a < b \).

The initial forest of self is a forest with its roots being on top. It is also called the increasing poset of self.

Warning: This method computes the cover relations of the initial forest. This is not identical with the
cover relations of self which happen to be increasing!

See also:

initial_forest()

EXAMPLES:

sage: TamariIntervalPoset(4, [(1, 2), (3, 2), (2, 4), (3, 4)]).increasing_cover_relations()
[(1, 2), (2, 4), (3, 4)]
sage: TamariIntervalPoset(3, [(1, 2), (1, 3), (2, 3)]).increasing_cover_relations()
[(1, 2), (2, 3)]

>>> from sage.all import *
>>> TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)), (Integer(3),
        Integer(2)), (Integer(2), Integer(4)), (Integer(3), Integer(4))]).increasing_cove
        r_relations()
[(1, 2), (2, 4), (3, 4)]
>>> TamariIntervalPoset(Integer(3), [(Integer(1), Integer(2)), (Integer(1),
        Integer(3)), (Integer(2), Integer(3))]).increasing_cover_relations()
[(1, 2), (2, 3)]

increasing_parent(v)

Return the vertex parent of v in the initial forest of self.
This is the lowest (as integer!) vertex \( b > v \) such that \( v \) precedes \( b \). If there is no such vertex (that is, \( v \) is an increasing root), then \( \text{None} \) is returned.

**INPUT:**

- \( v \) – an integer representing a vertex of \( \text{self} \) (between 1 and \( \text{size} \))

**EXAMPLES:**

```sage
def ip = TamariIntervalPoset(6, [(3, 2), (4, 3), (5, 2), (6, 5), (1, 2), (3, 5), (4, 5)]);
\`
\`
```

returns the root vertices of the initial forest of \( \text{self} \).

These are the vertices \( a \) of \( \text{self} \) such that there is no \( b > a \) with \( a \) precedes \( b \).

**OUTPUT:**

The list of all roots of the initial forest of \( \text{self} \), in decreasing order.

**EXAMPLES:**

```sage
def ip = TamariIntervalPoset(6, [(3, 2), (4, 3), (5, 2), (6, 5), (1, 2), (3, 5), (4, 5)]);
\`
```

(continues on next page)
The Tamari interval of size 6 induced by relations $[(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]$

>>> ip.increasing_roots()
[6, 5, 2]

>>> ip.initial_forest().increasing_roots()
[6, 5, 2]

**initial_forest()**

Return the initial forest of self, i.e., the interval-poset formed from only the increasing relations of self.

See also:

**final_forest()**

**EXAMPLES:**

```python
sage: TamariIntervalPoset(4, [(1, 2), (3, 2), (2, 4), (3, 4)]).initial_forest()
The Tamari interval of size 4 induced by relations [(1, 2), (2, 4), (3, 4)]
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 3)])
sage: ip.initial_forest() == ip
True
```

```python
>>> from sage.all import *

>>> TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)), (Integer(2), Integer(3))]).initial_forest()
The Tamari interval of size 4 induced by relations [(1, 2), (2, 4), (3, 4)]
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)), (Integer(2), Integer(3))])
>>> ip.initial_forest() == ip
True
```

**insertion(i)**

Return the Tamari insertion of an integer $i$ into the interval-poset self. If $P$ is a Tamari interval-poset of size $n$ and $i$ is an integer with $1 \leq i \leq n + 1$, then the Tamari insertion of $i$ into $P$ is defined as the Tamari interval-poset of size $n + 1$ which corresponds to the interval $[C_1, C_2]$ on the Tamari lattice, where the binary trees $C_1$ and $C_2$ are defined as follows: We write the interval-poset $P$ as $[B_1, B_2]$ for two binary trees $B_1$ and $B_2$. We label the vertices of each of these two trees with the integers $1, 2, \ldots, i-1, i+1, i+2, \ldots, n+1$ in such a way that the trees are binary search trees (this labelling is unique). Then, we insert $i$ into each of these trees (in the way as explained in binary_search_insert()). The shapes of the resulting two trees are denoted $C_1$ and $C_2$.

An alternative way to construct the insertion of $i$ into $P$ is by relabeling each vertex $u$ of $P$ satisfying $u \geq i$ (as integers) as $u + 1$, and then adding a vertex $i$ which should precede $i-1$ and $i+1$.

**Todo:** To study this, it would be more natural to define interval-posets on arbitrary ordered sets rather than just on $\{1, 2, \ldots, n\}$.

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(4, [(2, 3), (4, 3)]); ip
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)]
```
sage: ip.insertion(1)
The Tamari interval of size 5 induced by relations [(1, 2), (3, 4), (5, 4)]

sage: ip.insertion(2)
The Tamari interval of size 5 induced by relations [(2, 3), (3, 4), (5, 4), \rightarrow (2, 1)]

sage: ip.insertion(3)
The Tamari interval of size 5 induced by relations [(2, 4), (3, 4), (5, 4), \rightarrow (3, 2)]

sage: ip.insertion(4)
The Tamari interval of size 5 induced by relations [(2, 3), (4, 5), (5, 3), \rightarrow (4, 3)]

sage: ip.insertion(5)
The Tamari interval of size 5 induced by relations [(2, 3), (5, 4), (4, 3)]

sage: ip = TamariIntervalPoset(0, [])
sage: ip.insertion(1)
The Tamari interval of size 1 induced by relations []

sage: ip = TamariIntervalPoset(1, [])
sage: ip.insertion(1)
The Tamari interval of size 2 induced by relations [(1, 2)]

sage: ip.insertion(2)
The Tamari interval of size 2 induced by relations [(2, 1)]

>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2), Integer(3)), \rightarrow (Integer(4), Integer(3))]); ip
The Tamari interval of size 4 induced by relations [(2, 3), (4, 3)]

>>> ip.insertion(Integer(1))
The Tamari interval of size 5 induced by relations [(1, 2), (3, 4), (5, 4)]

>>> ip.insertion(Integer(2))
The Tamari interval of size 5 induced by relations [(2, 3), (3, 4), (5, 4), \rightarrow (2, 1)]

>>> ip.insertion(Integer(3))
The Tamari interval of size 5 induced by relations [(2, 4), (3, 4), (5, 4), \rightarrow (3, 2)]

>>> ip.insertion(Integer(4))
The Tamari interval of size 5 induced by relations [(2, 3), (4, 5), (5, 3), \rightarrow (4, 3)]

>>> ip.insertion(Integer(5))
The Tamari interval of size 5 induced by relations [(2, 3), (5, 4), (4, 3)]

>>> ip = TamariIntervalPoset(Integer(0), [])

>>> ip.insertion(Integer(1))
The Tamari interval of size 1 induced by relations []

>>> ip = TamariIntervalPoset(Integer(1), [])

>>> ip.insertion(Integer(1))
The Tamari interval of size 2 induced by relations [(1, 2)]

>>> ip.insertion(Integer(2))
The Tamari interval of size 2 induced by relations [(2, 1)]

intersection (other)

Return the interval-poset formed by combining the relations from both self and other. It corresponds to the intersection of the two corresponding intervals of the Tamari lattice.

INPUT:

5.1. Comprehensive Module List 1957
**EXAMPLES:**

```python
sage: ip1 = TamariIntervalPoset(4, [(1, 2), (2, 3)])
sage: ip2 = TamariIntervalPoset(4, [(4, 3)])
sage: ip1.intersection(ip2)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3), (4, 3)]
sage: ip3 = TamariIntervalPoset(4, [(2, 1)])
sage: ip1.intersection(ip3)
Traceback (most recent call last):
  ... ValueError: this intersection is empty, it does not correspond to an interval-poset
sage: ip4 = TamariIntervalPoset(3, [(2, 3)])
sage: ip2.intersection(ip4)
Traceback (most recent call last):
  ... ValueError: intersections are only possible on interval-posets of the same size
```

**interval_cardinality()**

Return the cardinality of the interval, i.e., the number of elements (binary trees or Dyck words) in the interval represented by `self`.

Not to be confused with `size()` which is the number of vertices.

**See also:**

`binary_trees()`

**EXAMPLES:**

```python
sage: TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)]).interval_cardinality() 4
sage: TamariIntervalPoset(4, []).interval_cardinality() 14
sage: TamariIntervalPoset(4, [(1, 2), (2, 3), (3, 4)]).interval_cardinality() 1
```
is_connected()  
Return whether self is a connected Tamari interval.  
This means that the Hasse diagram is connected.  
This condition is invariant under complementation.

See also:  
is_indecomposable(), factor()  

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_connected()])
8
```

is_dexter()  
Return whether self is a dexter Tamari interval.  
This is defined by an exclusion pattern in the Hasse diagram. See the code for the exact description.  
This condition is not invariant under complementation.

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_dexter()])
12
```

is_exceptional()  
Return whether self is an exceptional Tamari interval.  
This is defined by exclusion of a simple pattern in the Hasse diagram, namely there is no configuration \( y \leftarrow x \rightarrow z \) with \( 1 \leq y < x < z \leq n \).  
This condition is invariant under complementation.

EXAMPLES:

```python
sage: len([T for T in TamariIntervalPosets(3) if T.is_exceptional()])
12
```
**is_final_interval()**

Return if `self` corresponds to a final interval of the Tamari lattice.

This means that its upper end is the largest element of the lattice. It consists of checking that `self` does not contain any increasing relations.

See also:

**is_initial_interval()**

**EXAMPLES:**

```
sage: ip = TamariIntervalPoset(4, [(4, 3), (3, 1), (2, 1)])
sage: ip.is_final_interval()
True
sage: ip.upper_dyck_word()  # needs sage.combinat
[1, 1, 1, 1, 0, 0, 0, 0]
sage: ip = TamariIntervalPoset(4, [(4, 3), (3, 1), (2, 1), (2, 3)])
sage: ip.is_final_interval()
False
sage: ip.upper_dyck_word()  # needs sage.combinat
[1, 0, 1, 1, 0, 0, 0, 0]
sage: all(dw.tamari_interval(DyckWord([1, 1, 1, 0, 0, 0]))  # needs sage.combinat
    ...:   for dw in DyckWords(3))
True
```

**is_indecomposable()**

Return whether `self` is an indecomposable Tamari interval.
This is the terminology of [Cha2008].
This means that the upper binary tree has an empty left subtree.
This condition is not invariant under complementation.

**See also:**

*is_connected()*

**EXAMPLES:**

```python
sage: len([T for T in TamariIntervalPosets(3)
.....:   if T.is_indecomposable()])
8
```

```python
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3))
...   if T.is_indecomposable()])
8
```

**is_ininitely_modern()**

Return whether self is an infinitely-modern Tamari interval.
This is defined by the exclusion of the configuration $i \rightarrow i + 1$ and $j + 1 \rightarrow j$ with $i < j$.
This condition is invariant under complementation.

**See also:**

*is_new(), is_modern()*

**EXAMPLES:**

```python
sage: len([T for T in TamariIntervalPosets(3)
.....:   if T.is_ininitely_modern()])
12
```

```python
>>> from sage.all import *
>>> len([T for T in TamariIntervalPosets(Integer(3))
...   if T.is_ininitely_modern()])
12
```

**REFERENCES:**

- [Rog2018]

**is_initial_interval()**

Return if self corresponds to an initial interval of the Tamari lattice.
This means that its lower end is the smallest element of the lattice. It consists of checking that self does not contain any decreasing relations.

**See also:**

*is_final_interval()*

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 4), (3, 4)])
sage: ip.is_initial_interval()
True
```
is_linear_extension (perm)
Return whether the permutation perm is a linear extension of self.

INPUT:

• perm – a permutation of the size of self

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1, 2), (2, 3), (4, 3)])
sage: ip.is_linear_extension([1, 4, 2, 3])
True
sage: ip.is_linear_extension(Permutation([1, 4, 2, 3]))
True
sage: ip.is_linear_extension(Permutation([1, 4, 3, 2]))
False
```
is_linear_extension()

Return whether self is a linear extension.

is_linear_extension([1, 4, 2, 3])
True

is_linear_extension(Permutation([1, 4, 2, 3]))
True

is_linear_extension(Permutation([1, 4, 3, 2]))
False

is_modern()

Return whether self is a modern Tamari interval.

is_modern()

is_new()

Return whether self is a new Tamari interval.

is_new()
Combinatorics, Release 10.4

12

```python
>>> TIP3 = TamariIntervalPosets(Integer(3))
>>> len([u for u in TIP3 if u.is_new()])
3
```

**is_simple()**

Return whether `self` is a simple Tamari interval.

Here 'simple' means that the interval contains a unique binary tree.

These intervals define the simple modules over the incidence algebras of the Tamari lattices.

See also:

`is_final_interval()`, `is_initial_interval()`

**EXAMPLES:**

```python
sage: TIP4 = TamariIntervalPosets(4)
sage: len([u for u in TIP4 if u.is_simple()])
14
sage: TIP3 = TamariIntervalPosets(3)
sage: len([u for u in TIP3 if u.is_simple()])
5
```

```python
>>> from sage.all import *
```

```python
>>> TIP4 = TamariIntervalPosets(Integer(4))
>>> len([u for u in TIP4 if u.is_simple()])
14
>>> TIP3 = TamariIntervalPosets(Integer(3))
>>> len([u for u in TIP3 if u.is_simple()])
5
```

**is_synchronized()**

Return whether `self` is a synchronized Tamari interval.

This means that the upper and lower binary trees have the same canopy. This condition is invariant under complementation.

This has been considered in [FPR2015]. The numbers of synchronized intervals are given by the sequence OEIS sequence A000139.

**EXAMPLES:**

```python
sage: len([T for T in TamariIntervalPosets(3) ....: if T.is_synchronized()])
6
```

```python
>>> from sage.all import *
```

```python
>>> len([T for T in TamariIntervalPosets(Integer(3)) ....: if T.is_synchronized()])
6
```

**latex_options()**

Return the latex options for use in the `_latex_` function as a dictionary.
The default values are set using the options.

- \texttt{tikz\_scale} – (default: 1) scale for use with the tikz package
- \texttt{line\_width} – (default: 1) value representing the line width (additionally scaled by \texttt{tikz\_scale})
- \texttt{color\_decreasing} – (default: 'red') the color for decreasing relations
- \texttt{color\_increasing} – (default: 'blue') the color for increasing relations
- \texttt{hspace} – (default: 1) the difference between horizontal coordinates of adjacent vertices
- \texttt{vspace} – (default: 1) the difference between vertical coordinates of adjacent vertices

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(2,4),(3,4),(2,1),(3,1)])
sage: ip.latex_options()['color\_decreasing']
'\textcolor{red}{'
sage: ip.latex_options()['hspace']
1
```

>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2),Integer(4)), (Integer(3),
→ Integer(4)), (Integer(2),Integer(1)), (Integer(3),Integer(1))])
>>> ip.latex_options()['color\_decreasing']
'\textcolor{red}{'
>>> ip.latex_options()['hspace']
1
```

le \((e1, e2)\)

Return whether \(e1\) precedes or equals \(e2\) in self.

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(1,2),(2,3)])
sage: ip.le(1,2)
True
sage: ip.le(1,3)
True
sage: ip.le(2,3)
True
sage: ip.le(3,4)
False
sage: ip.le(1,1)
True
```

>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1),Integer(2)), (Integer(2),
→ Integer(3))])
>>> ip.le(Integer(1),Integer(2))
True
>>> ip.le(Integer(1),Integer(3))
True
>>> ip.le(Integer(2),Integer(3))
True
>>> ip.le(Integer(3),Integer(4))
False
>>> ip.le(Integer(3),Integer(1))
True
```
left_branch_involution()

Return the image of self by the left-branch involution.

OUTPUT: an interval-poset

See also:

rise_contact_involution()

EXAMPLES:

sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4), (6,4), (8,7)])
sage: t = tip.left_branch_involution(); t
The Tamari interval of size 8 induced by relations [(1, 6), (2, 6), (3, 5), (4, 5), (5, 6), (6, 8), (7, 8), (7, 6), (4, 3), (3, 1), (2, 1)]
sage: t.left_branch_involution() == tip
True

REFERENCES:

• [Pons2018]

linear_extensions()

Return an iterator on the permutations which are linear extensions of self.

They form an interval of the right weak order (also called the right permutohedron order – see permutohedron_lequal() for a definition).

EXAMPLES:

sage: ip = TamariIntervalPoset(3, [(1,2),(3,2)])
sage: list(ip.linear_extensions())
[[3, 1, 2], [1, 3, 2]]
sage: ip = TamariIntervalPoset(4, [(1,2),(2,3),(4,3)])
sage: list(ip.linear_extensions())
[[4, 1, 2, 3], [1, 2, 4, 3], [1, 4, 2, 3]]
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1), Integer(2)), (Integer(2), Integer(3)), (Integer(4), Integer(3))])
>>> list(ip.linear_extensions()) # needs sage.modules sage.rings.finite_rings
[[4, 1, 2, 3], [1, 2, 4, 3], [1, 4, 2, 3]]
```

**lower_binary_tree()**

Return the lowest binary tree in the interval of the Tamari lattice represented by `self`.

This is a binary tree. It is the shape of the unique binary search tree whose left-branch ordered forest (i.e., the result of applying `to_ordered_tree_left_branch()` and cutting off the root) is the final forest of `self`.

See also:

* `lower_dyck_word()`

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(6, [(3,2), (4,3), (5,2), (6,5), (1,2), (4,5)]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.lower_binary_tree()
[[., .], [[., .], [., .]]]
sage: ff = TamariIntervalPosets.final_forest(ip.lower_binary_tree())
sage: ff == ip.final_forest()
True
sage: ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(), ...
True
```

```python
>>> from sage.all import *
```

```python
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3), Integer(2)), (Integer(4), Integer(3)), (Integer(5), Integer(2)), (Integer(6), Integer(5)), (Integer(1), Integer(2)), (Integer(4), Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
```

```python
>>> ip.lower_binary_tree()
[[., .], [[., .], [., .]]]
```

```python
>>> ff = TamariIntervalPosets.final_forest(ip.lower_binary_tree())
>>> ff == ip.final_forest()
True
```

```python
>>> ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(), ...
True
```

**lowercontained_intervals()**

If `self` represents the interval \([t_1, t_2]\) of the Tamari lattice, return an iterator on all intervals \([t_1, t]\) with \(t \leq t_2\) for the Tamari lattice.

In terms of interval-posets, it corresponds to adding all possible relations of the form \(n\) precedes \(m\) with \(n < m\).

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(4, [(2,4), (3,4), (2,1), (3,1)])
sage: list(ip.lower_contained_intervals())
```

(continues on next page)
The Tamari interval of size 4 induced by relations
[(2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
[(1, 4), (2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
[(2, 3), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
[(1, 4), (2, 3), (3, 4), (3, 1), (2, 1)]

sage: ip = TamariIntervalPoset(4, [])
sage: len(list(ip.lower_contained_intervals()))
14

lower_contains_interval (other)
Return whether the interval represented by other is contained in self as an interval of the Tamari lattice and if they share the same lower bound.

As interval-posets, it means that other contains the relations of self plus some extra increasing relations.

INPUT:
• other – an interval-poset

EXAMPLES:
sage: ip1 = TamariIntervalPoset(4, [(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4, [(4,3)])
sage: ip2.lower_contains_interval(ip1)
True
sage: ip2.contains_interval(ip1) and ip2.lower_binary_tree() == ip1.lower_binary_tree()
True
sage: ip3 = TamariIntervalPoset(4, [(4,3),(2,1)])
sage: ip2.contains_interval(ip3)
True
sage: ip2.lower_binary_tree() == ip3.lower_binary_tree()
False
sage: ip2.lower_contains_interval(ip3)
False

>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2),Integer(4)), (Integer(3),
˓→Integer(4)), (Integer(2),Integer(1)), (Integer(3),Integer(1))])
>>> list(ip.lower_contained_intervals())
[The Tamari interval of size 4 induced by relations
[(2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
[(1, 4), (2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
[(2, 3), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
[(1, 4), (2, 3), (3, 4), (3, 1), (2, 1)]]
>>> ip = TamariIntervalPoset(Integer(4), [])
>>> len(list(ip.lower_contained_intervals()))
14
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> ip2 = TamariIntervalPoset(Integer(4), [(Integer(4), Integer(3))])
>>> ip2.lower_contains_interval(ip1)
True
>>> ip2.contains_interval(ip1) and ip2.lower_binary_tree() == ip1.lower_binary_tree()
True
>>> ip3 = TamariIntervalPoset(Integer(4), [(Integer(4), Integer(3)), (Integer(2), Integer(1))])
>>> ip2.contains_interval(ip3)
True
>>> ip2.lower_binary_tree() == ip3.lower_binary_tree()
False
>>> ip2.lower_contains_interval(ip3)
False
```

### lower_dyck_word()

Return the lowest Dyck word in the interval of the Tamari lattice represented by `self`.

#### See also:

`lower_binary_tree()`

#### EXAMPLES:

```python
sage: # needs sage.combinat
sage: ip = TamariIntervalPoset(6, [(3, 2), (4, 3), (5, 2), (6, 5), (1, 2), (4, 5)]); ip
The Tamari interval of size 6 induced by relations
[(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.lower_dyck_word()
[1, 0, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
sage: ldw_ff = TamariIntervalPosets.final_forest(ip.lower_dyck_word())
sage: ldw_ff == ip.final_forest()
True
sage: ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(), ...: ip.upper_dyck_word())
True
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3), Integer(2)), (Integer(4),
Integer(3)), (Integer(5), Integer(2)), (Integer(6), Integer(5)), (Integer(1),
Integer(2)), (Integer(4), Integer(5))]); ip
The Tamari interval of size 6 induced by relations
[(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
>>> ip.lower_dyck_word()
[1, 0, 1, 1, 1, 0, 0, 1, 1, 0, 0, 0]
>>> ldw_ff = TamariIntervalPosets.final_forest(ip.lower_dyck_word())
>>> ldw_ff == ip.final_forest()
True
>>> ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(), ...
: ip.upper_dyck_word())
True
```

### lt(e1, e2)

Return whether `e1` strictly precedes `e2` in `self`.

#### EXAMPLES:
Combinatorics, Release 10.4

```python
sage: ip = TamariIntervalPoset(4, [(1,2), (2,3)])
sage: ip.lt(1,2)  # True
sage: ip.lt(1,3)  # True
sage: ip.lt(2,3)  # True
sage: ip.lt(3,4)  # False
sage: ip.lt(1,1)  # False

>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1),Integer(2)), (Integer(2), Integer(3))])

>>> ip.lt(Integer(1),Integer(2))  # True
>>> ip.lt(Integer(1),Integer(3))  # True
>>> ip.lt(Integer(2),Integer(3))  # True
>>> ip.lt(Integer(3),Integer(4))  # False
>>> ip.lt(Integer(1),Integer(1))  # False
```

**max_linear_extension()**

Return the maximal permutation for the right weak order which is a linear extension of self.

This is also the maximal permutation in the sylvester class of self.upper_binary_tree() and is a 132-avoiding permutation.

The right weak order is also known as the right permutohedron order. See permutohedron_lequal() for its definition.

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(4, [(1,2), (2,3), (4,3)])
sage: ip.max_linear_extension()  # [4, 1, 2, 3]

sage: ip = TamariIntervalPoset(6, [(3,2), (4,3), (5,2), (6,5), (1,2), (4,5)]); ip
    The Tamari interval of size 6 induced by relations [(1, 2), (4, 5), (6, 5), ...
       (5, 2), (4, 3), (3, 2)]
sage: ip.max_linear_extension()  # [6, 4, 5, 3, 1, 2]

sage: ip = TamariIntervalPoset(0, []); ip
    The Tamari interval of size 0 induced by relations []
sage: ip.max_linear_extension()  # []

sage: ip = TamariIntervalPoset(5, [(1,4), (2,4), (3,4), (5,4)]); ip
    The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4), ...
       (5, 4)]
sage: ip.max_linear_extension()  # [5, 3, 2, 1, 4]
```

```python
>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1),Integer(2)), (Integer(2), ...
```
Combinatorics, Release 10.4

maximal_chain_binary_trees()

Return an iterator on the binary trees forming a longest chain of self (regarding self as an interval of the Tamari lattice).

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)])
sage: list(ip.maximal_chain_binary_trees())
[[[., [[., .], .]], .], [[., [[., .], .]], .], [[., [[., .], .]], .], [[., [[., .], .]], .]]
sage: ip = TamariIntervalPoset(4, [])
sage: list(ip.maximal_chain_binary_trees())
[[[., [[., .], .]], .], [[., [[., .], .]], .], [[., [[., .], .]], .], [[., [[., .], .]], .]]
```

maximal_chain_dyck_words()

.. raw:: html

   <div class="ebook-chapter-section" id="comprehensive-module-list">

   5.1. Comprehensive Module List

   1971

```
Return an iterator on the Dyck words forming a longest chain of self (regarding self as an interval of the Tamari lattice).

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)])
sage: list(ip.maximal_chain_dyck_words())
[[1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0]]
sage: ip = TamariIntervalPoset(4, [])
sage: list(ip.maximal_chain_dyck_words())
[[1, 0, 1, 0, 1, 0, 1, 0], [1, 1, 0, 0, 1, 0, 1, 0], [1, 1, 0, 1, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0], [1, 1, 1, 0, 1, 0, 0, 0], [1, 1, 1, 1, 0, 0, 0, 0]]
```

```python
>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2), Integer(4)), (Integer(3), Integer(4)), (Integer(2), Integer(1)), (Integer(3), Integer(1))])

>>> list(ip.maximal_chain_dyck_words())
[[1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0]]
```

```python
>>> ip = TamariIntervalPoset(Integer(4), [])

>>> list(ip.maximal_chain_dyck_words())
[[1, 0, 1, 0, 1, 0, 1, 0], [1, 1, 0, 0, 1, 0, 1, 0], [1, 1, 0, 1, 0, 0, 1, 0], [1, 1, 0, 1, 0, 1, 0, 0], [1, 1, 1, 0, 0, 1, 0, 0], [1, 1, 1, 0, 1, 0, 0, 0], [1, 1, 1, 1, 0, 0, 0, 0]]
```

maximal_chain_tamari_intervals()

Return an iterator on the upper contained intervals of one longest chain of the Tamari interval represented by self.

If self represents the interval \([T_1, T_2]\) of the Tamari lattice, this returns intervals \([T', T_2]\) with \(T'\) following one longest chain between \(T_1\) and \(T_2\).

To obtain a longest chain, we use the Tamari inversions of self. The elements of the chain are obtained by adding one by one the relations \((b, a)\) from each Tamari inversion \((a, b)\) to self, where the Tamari inversions are taken in lexicographic order.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)])
sage: list(ip.maximal_chain_tamari_intervals())
[The Tamari interval of size 4 induced by relations
 (2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
 (2, 4), (3, 4), (4, 1), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations
```
Combinatorics, Release 10.4

(continued from previous page)

```python
[(2, 4), (3, 4), (4, 1), (3, 2), (2, 1)]
sage: ip = TamariIntervalPoset(4, [])
sage: list(ip.maximal_chain_tamari_intervals())

[The Tamari interval of size 4 induced by relations [],
The Tamari interval of size 4 induced by relations [(2, 1)],
The Tamari interval of size 4 induced by relations [(3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 1), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 1), (3, 2), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 3), (3, 2), (2, 1)],
```

>>> from sage.all import *

```python
>>> ip = TamariIntervalPoset(Integer(4), [(Integer(2),Integer(4)),(Integer(3),
˓→Integer(4)),(Integer(2),Integer(1)),(Integer(3),Integer(1))])
>>> list(ip.maximal_chain_tamari_intervals())

[The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (4, 1), (3, 1), (2, 1)],
The Tamari interval of size 4 induced by relations [(2, 4), (3, 4), (4, 1), (3, 2), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 1), (3, 2), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 2), (3, 2), (2, 1)],
The Tamari interval of size 4 induced by relations [(4, 3), (3, 2), (2, 1)]
```

```python
>>> ip = TamariIntervalPoset(Integer(4), [])
>>> list(ip.maximal_chain_tamari_intervals())

[The Tamari interval of size 4 induced by relations [],
The Tamari interval of size 4 induced by relations [(2, 1)],
The Tamari interval of size 4 induced by relations [(3, 1), (2, 1)],

The Tamari interval of size 4 induced by relations [(4, 3), (3, 2), (2, 1)],
```

min_linear_extension()

Return the minimal permutation for the right weak order which is a linear extension of self.

This is also the minimal permutation in the sylvester class of self.lower_binary_tree() and is a
312-avoiding permutation.

The right weak order is also known as the right permutohedron order. See permutohedron_lequal() for its definition.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1,2),(2,3),(4,3)])
sage: ip.min_linear_extension()

[1, 2, 3, 4]
sage: ip = TamariIntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(4,5)])
sage: ip.min_linear_extension()

[1, 4, 3, 6, 5, 2]
sage: ip = TamariIntervalPoset(0, [])
sage: ip.min_linear_extension()

[]
sage: ip = TamariIntervalPoset(5, [(1, 4), (2, 4), (3, 4), (5, 4)])
```

The Tamari interval of size 5 induced by relations [(1, 4), (2, 4), (3, 4), (4, 5)]

```python
sage: ip.min_linear_extension()

[1, 2, 3, 5, 4]
```

5.1. Comprehensive Module List
new_decomposition()  

Return the decomposition of the interval-poset into new interval-posets.

Every interval-poset has a unique decomposition as a planar tree of new interval-posets, as explained in [Cha2008]. This function computes the terms of this decomposition, but not the planar tree.

For the number of terms, you can use instead the method number_of_new_components().

OUTPUT:

a list of new interval-posets.

See also:

number_of_new_components(), is_new()

EXAMPLES:

sage: ex = TamariIntervalPosets(4)[11]
sage: ex.number_of_new_components()  
3
sage: ex.new_decomposition()  
# needs sage.combinat

[The Tamari interval of size 1 induced by relations []],
The Tamari interval of size 2 induced by relations [],
The Tamari interval of size 1 induced by relations []]

number_of_new_components()
Return the number of terms in the decomposition in new interval-posets.

Every interval-poset has a unique decomposition as a planar tree of new interval-posets, as explained in [Cha2008]. This function just computes the number of terms, not the planar tree nor the terms themselves.

See also:

is_new(), new_decomposition()

EXAMPLES:

```python
sage: TIP4 = TamariIntervalPosets(4)
sage: nb = [u.number_of_new_components() for u in TIP4]
sage: [nb.count(i) for i in range(1, 5)]
[12, 21, 21, 14]
```

number_of_tamari_inversions()

Return the number of Tamari inversions of self.

This is also the length the longest chain of the Tamari interval represented by self.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4,[(2,4),(3,4),(2,1),(3,1)])
sage: ip.number_of_tamari_inversions()
2
sage: ip = TamariIntervalPoset(4,[])
6
sage: ip = TamariIntervalPoset(3,[])
3
```

plot(**kws)

Return a picture.

The picture represents the Hasse diagram, where the covers are colored in blue if they are increasing and in red if they are decreasing.

This uses the same coordinates as the latex view.
EXAMPLES:

```python
sage: ti = TamariIntervalPosets(4)[2]
sage: ti.plot()  # needs sage.plot
Graphics object consisting of 6 graphics primitives
```

```python
from sage.all import *

sage: ti = TamariIntervalPosets(Integer(4))[Integer(2)]

sage: ti.plot()  # needs sage.plot
```

```python
poset()
```

Return self as a labelled poset.

An interval-poset is indeed constructed from a labelled poset which is stored internally. This method allows to access the poset and all the associated methods.

EXAMPLES:

```python
sage: ip = TamariIntervalPoset(4, [(1,2),(3,2),(2,4),(3,4)])
sage: pos = ip.poset(); pos
Finite poset containing 4 elements

sage: pos.maximal_chains()
[[3, 2, 4], [1, 2, 4]]

sage: pos.maximal_elements()
[4]

sage: pos.is_lattice()
False
```

```python
from sage.all import *

sage: ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(3),
                                          Integer(2)),(Integer(2),Integer(4)),(Integer(3),
                                          Integer(4))])

sage: pos = ip.poset(); pos
Finite poset containing 4 elements

sage: pos.maximal_chains()
[[3, 2, 4], [1, 2, 4]]

sage: pos.maximal_elements()
[4]

sage: pos.is_lattice()
False
```

```python
rise_contact_involution()
```

Return the image of self by the rise-contact involution.

OUTPUT: an interval-poset

This is defined by conjugating the complement involution by the left-branch involution.

See also:

`left_branch_involution()`, `complement()`

EXAMPLES:

```python
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7),
                                      (3,2), (5,4), (6,4), (8,7)])
sage: t = tip.rise_contact_involution(); t
```

(continues on next page)
The Tamari interval of size 8 induced by relations 
\[
\{(2, 8), (3, 8), (4, 5), (5, 7), (6, 7), (7, 8), (8, 1), (7, 2), (6, 2), (5, 3), (4, 3), (3, 2), (2, 1)\}
\]
\[
\text{sage: } t.\text{rise_contact_involution()} == \text{tip}
\]
True
\[
\text{sage: } (\text{tip.\text{lower_dyck_word().number_of_touch_points()}})
\]
\[
\text{# needs sage.combinat}
\]
True
\[
\text{sage: } \text{tip.number_of_tamari_inversions()} == t.\text{number_of_tamari_inversions()}
\]
True

REFERENCES:

• [Pons2018]

set\_latex\_options (D)

Set the latex options for use in the \_latex\_ function.

The default values are set in the \_init\_ function.

- tikz_scale – (default: 1) scale for use with the tikz package
- line_width – (default: 1 * tikz_scale) value representing the line width
- color_decreasing – (default: red) the color for decreasing relations
- color_increasing – (default: blue) the color for increasing relations
- hspace – (default: 1) the difference between horizontal coordinates of adjacent vertices
- vspace – (default: 1) the difference between vertical coordinates of adjacent vertices

INPUT:

- D – a dictionary with a list of latex parameters to change

EXAMPLES:

\[
\text{sage: } \text{ip = TamariIntervalPoset(4,[[2,4],[3,4],[2,1],[3,1]])}
\]
\[
\text{sage: } \text{ip.\text{latex_options()}["color_decreasing"]}
\]
'\text{red}'
To change the default options for all interval-posets, use the parent's latex options:

```sage
ip = TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)])
ip2 = TamariIntervalPoset(4, [(1, 2), (2, 3)])
print(ip.latex_options()['color_decreasing']) # red
print(ip2.latex_options()['color_decreasing']) # red
TamariIntervalPosets.options(latex_color_decreasing='green')
print(ip.latex_options()['color_decreasing']) # green
print(ip2.latex_options()['color_decreasing']) # green
```

Next we set a local latex option and show the global option does not override it:

```sage
ip = TamariIntervalPoset(4, [(2, 4), (3, 4), (2, 1), (3, 1)])
print(ip.latex_options()['color_decreasing']) # red
TamariIntervalPosets.options(latex_color_decreasing='blue')
print(ip.latex_options()['color_decreasing']) # red
```

(continues on next page)
sage: ip2.latex_options()['color_decreasing']
'blue'
sage: TamariIntervalPosets.options._reset()

>>> from sage.all import *
>>> ip.set_latex_options({"color_decreasing": 'black'})
>>> ip.latex_options()['color_decreasing']
'black'
>>> TamariIntervalPosets.options(latex_color_decreasing='blue')
>>> ip.latex_options()['color_decreasing']
'black'
>>> ip2.latex_options()['color_decreasing']
'blue'
>>> TamariIntervalPosets.options._reset()

size()

Return the size (number of vertices) of the interval-poset.

EXAMPLES:

sage: TamariIntervalPoset(3,[(2,1),(3,1)]).size()
3

>>> from sage.all import *

>>> TamariIntervalPoset(Integer(3),[(Integer(2),Integer(1)),(Integer(3),Integer(1)))].size()
3

sub_poset(start, end)

Return the renormalized subposet of self consisting solely of integers from start (inclusive) to end (not inclusive).

“Renormalized” means that these integers are relabelled 1, 2, . . . , k in the obvious way (i.e., by subtracting start − 1).

INPUT:

• start – an integer, the starting vertex (inclusive)
• end – an integer, the ending vertex (not inclusive)

EXAMPLES:

sage: ip = TamariIntervalPoset(6, [(3,2),(4,3),(5,2),(6,5),(1,2),(3,5),(4,5)]); ip
The Tamari interval of size 6 induced by relations
[(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
sage: ip.subposet(1,3)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: ip.subposet(1,4)
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]
sage: ip.subposet(1,5)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
sage: ip.subposet(1,7) == ip
True
sage: ip.subposet(1,1)
The Tamari interval of size 0 induced by relations []
>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3), Integer(2)), (Integer(4), Integer(3)), (Integer(5), Integer(2)), (Integer(6), Integer(5)), (Integer(1), Integer(2)), (Integer(3), Integer(5)), (Integer(4), Integer(5))]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

>>> ip.subposet(Integer(1), Integer(3))
The Tamari interval of size 2 induced by relations [(1, 2)]

>>> ip.subposet(Integer(1), Integer(4))
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]

>>> ip.subposet(Integer(1), Integer(5))
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]

>>> ip.subposet(Integer(1), Integer(7)) == ip
True

>>> ip.subposet(Integer(1), Integer(1))
The Tamari interval of size 0 induced by relations []

subposet (start, end)

Return the renormalized subposet of self consisting solely of integers from start (inclusive) to end (not inclusive).

“Renormalized” means that these integers are relabelled 1, 2, . . . , k in the obvious way (i.e., by subtracting start − 1).

INPUT:

• start – an integer, the starting vertex (inclusive)
• end – an integer, the ending vertex (not inclusive)

EXAMPLES:

sage: ip = TamariIntervalPoset(6, [(3,2), (4,3), (5,2), (6,5), (1,2), (3,5), (4,5)]); ip
The Tamari interval of size 6 induced by relations [(1, 2), (3, 5), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

sage: ip.subposet(1,3)
The Tamari interval of size 2 induced by relations [(1, 2)]

sage: ip.subposet(1,4)
The Tamari interval of size 3 induced by relations [(1, 2), (3, 2)]

sage: ip.subposet(1,5)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]

sage: ip.subposet(1,7) == ip
True

sage: ip.subposet(1,1)
The Tamari interval of size 0 induced by relations []

(continues on next page)
The Tamari interval of size 4 induced by relations [(1, 2), (4, 3), (3, 2)]
>>> ip.subposet(Integer(1), Integer(7)) == ip
True
>>> ip.subposet(Integer(1), Integer(1))
The Tamari interval of size 0 induced by relations []

tamari_inversions()
Return the Tamari inversions of self.
A Tamari inversion is a pair of vertices \((a, b)\) with \(a < b\) such that:
- the decreasing parent of \(b\) is strictly smaller than \(a\) (or does not exist), and
- the increasing parent of \(a\) is strictly bigger than \(b\) (or does not exist).

“Smaller” and “bigger” refer to the numerical values of the elements, not to the poset order.
This method returns the list of all Tamari inversions in lexicographic order.
The number of Tamari inversions is the length of the longest chain of the Tamari interval represented by self.
Indeed, when an interval consists of just one binary tree, it has no inversion. One can also prove that if a Tamari interval \(I = [T_1', T_2']\) is a proper subset of a Tamari interval \(I = [T_1, T_2]\), then the inversion number of \(I'\) is strictly lower than the inversion number of \(I\). And finally, by adding the relation \((b, a)\) to the interval-poset where \((a, b)\) is the first inversion of \(I\) in lexicographic order, one reduces the inversion number by exactly 1.

See also:
tamari_inversions_iter(), number_of_tamari_inversions()

EXAMPLES:

sage: ip = TamariIntervalPoset(3,[])
sage: ip.tamari_inversions()
[(1, 2), (1, 3), (2, 3)]
sage: ip = TamariIntervalPoset(3,[(2,1)])
sage: ip.tamari_inversions()

        for bt in BinaryTrees(Integer(4)))  
True

tamari_inversions_iter()
Iterate over the Tamari inversions of self, in lexicographic order.

See tamari_inversions() for the definition of the terms involved.

EXAMPLES:

sage: T = TamariIntervalPoset(5, [[1,2],[3,4],[3,2],[5,2],[4,2]])
sage: list(T.tamari_inversions_iter())
[(4, 5)]

sage: T = TamariIntervalPoset(8, [(2, 7), (3, 7), (4, 7), (5, 7), (6, 7),
˓→(8, 7), (6, 4), (5, 4), (4, 3), (3, 2)])

sage: list(T.tamari_inversions_iter())
[(1, 2), (1, 7), (5, 6)]

sage: T = TamariIntervalPoset(1, [])
sage: list(T.tamari_inversions_iter())
[]

sage: T = TamariIntervalPoset(0, [])
\texttt{sage: list(T.tamari_inversions_iter())}
\[

\textbf{upper\textunderscore binary\textunderscore tree()} \hfill \text{Return the highest binary tree in the interval of the Tamari lattice represented by self.}

This is a binary tree. It is the shape of the unique binary search tree whose right-branch ordered forest (i.e., the result of applying to\textunderscore ordered\textunderscore tree\textunderscore right\textunderscore branch() and cutting off the root) is the initial forest of self.

\textbf{See also:}

\textbf{upper\textunderscore dyck\textunderscore word()}

\textbf{EXAMPLES:}

\texttt{sage: ip = TamariIntervalPoset(6, [(3, 2), (4, 3), (5, 2), (6, 5), (1, 2), (4, 5)]); ip}
The Tamari interval of size 6 induced by relations

\]
\texttt{sage: ip == TamariIntervalPosets.from\textunderscore binary\textunderscore trees(ip.lower\textunderscore binary\textunderscore tree(), ip.\textunderscore upper\textunderscore binary\textunderscore tree())}
\[
True
\]

\texttt{>>> from sage.all import *}
\texttt{>>> ip = TamariIntervalPoset(Integer(6), [[Integer(3), Integer(2)], (Integer(4), Integer(3)), (Integer(5), Integer(2)), (Integer(6), Integer(5)), (Integer(1), Integer(2)), (Integer(4), Integer(5))]); ip}

(continues on next page)
The Tamari interval of size 6 induced by relations
[(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

```python
>>> ip.upper_binary_tree()
[[., .], [., [., .]], [., .]]

>>> TamariIntervalPosets.initial_forest(ip.upper_binary_tree()) == ip.initial_forest()
True
```

```
>>> ip == TamariIntervalPosets.from_binary_trees(ip.lower_binary_tree(), ip.upper_binary_tree())
True
```

**upper_contains_interval (other)**

Return whether the interval represented by other is contained in self as an interval of the Tamari lattice and if they share the same upper bound.

As interval-posets, it means that other contains the relations of self plus some extra decreasing relations.

**INPUT:**

- other – an interval-poset

**EXAMPLES:**

```python
sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: ip2.upper_contains_interval(ip1)
True
sage: ip2.contains_interval(ip1) and ip2.upper_binary_tree() == ip1.upper_binary_tree()
True
```

```python
sage: ip3 = TamariIntervalPoset(4,[(1,2),(2,3),(3,4)])
sage: ip2.upper_contains_interval(ip3)
False
sage: ip2.contains_interval(ip3)
True
```

```python
>>> from sage.all import *
>>> ip1 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2), Integer(3)),(Integer(4),Integer(3))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2), Integer(3))])
>>> ip2.upper_contains_interval(ip1)
True
>>> ip2.contains_interval(ip1) and ip2.upper_binary_tree() == ip1.upper_binary_tree()
True
```

```python
>>> ip3 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2), Integer(3)),(Integer(3),Integer(4))])
>>> ip2.upper_contains_interval(ip3)
False
```

```python
>>> ip2.contains_interval(ip3)
True
```

```python
>>> ip2.upper_binary_tree() == ip3.upper_binary_tree()
False
```
upper_dyck_word()

Return the highest Dyck word in the interval of the Tamari lattice represented by self.

See also:

upper_binary_tree()

EXAMPLES:

```python
sage: # needs sage.combinat
sage: ip = TamariIntervalPoset(6, [(3,2), (4,3), (5,2), (6,5), (1,2), (4,5)]); ip
The Tamari interval of size 6 induced by relations
[(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

sage: ip.upper_dyck_word()
[1, 0, 1, 1, 1, 0, 1, 1, 0, 0, 0, 0]

sage: udw_if = TamariIntervalPosets.initial_forest(ip.upper_dyck_word())

sage: udw_if == ip.initial_forest()
True

sage: ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),
.....: ip.upper_dyck_word())
True
```

```python
>>> from sage.all import *

>>> # needs sage.combinat

>>> ip = TamariIntervalPoset(Integer(6), [(Integer(3),Integer(2)), (Integer(4), Integer(3)), (Integer(5),Integer(2)), (Integer(6),Integer(5)), (Integer(1), Integer(2)), (Integer(4),Integer(5))]); ip
The Tamari interval of size 6 induced by relations
[(1, 2), (4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

>>> ip.upper_dyck_word()
[1, 0, 1, 1, 1, 0, 1, 1, 0, 0, 0, 0]

>>> udw_if = TamariIntervalPosets.initial_forest(ip.upper_dyck_word())

>>> udw_if == ip.initial_forest()
True

>>> ip == TamariIntervalPosets.from_dyck_words(ip.lower_dyck_word(),
.....: ip.upper_dyck_word())
True
```

class sage.combinat.interval_posets.TamariIntervalPosets

Factory for interval-posets.

INPUT:

• size – (optional) an integer

OUTPUT:

• the set of all interval-posets (of the given size if specified)

EXAMPLES:

```python
sage: TamariIntervalPosets()
Interval-posets

sage: TamariIntervalPosets(2)
Interval-posets of size 2
```
Note: This is a factory class whose constructor returns instances of subclasses.

static check_poset(poset)
Check if the given poset poset is an interval-poset, that is, if it satisfies the following properties:

- Its labels are exactly $1, \ldots, n$ where $n$ is its size.
- If $a < c$ (as numbers) and $a$ precedes $c$, then $b$ precedes $c$ for all $b$ such that $a < b < c$.
- If $a < c$ (as numbers) and $c$ precedes $a$, then $b$ precedes $a$ for all $b$ such that $a < b < c$.

INPUT:

- poset – a finite labeled poset

EXAMPLES:

sage: p = Poset(([1,2,3],[[1,2],[2,3]]))
sage: TamariIntervalPosets.check_poset(p)
True
sage: p = Poset(([2,3],[[2,3]])
sage: TamariIntervalPosets.check_poset(p)
False
sage: p = Poset(([1,2,3],[[3,1]])
sage: TamariIntervalPosets.check_poset(p)
False
sage: p = Poset(([1,2,3],[[1,3]])
sage: TamariIntervalPosets.check_poset(p)
False

static final_forest(element)
Return the final forest of a binary tree, an interval-poset or a Dyck word.

A final forest is an interval-poset corresponding to a final interval of the Tamari lattice, i.e., containing only decreasing relations.
It can be constructed from a binary tree by its binary search tree labeling with the rule: \( b \) precedes \( a \) in the final forest iff \( b \) is in the right subtree of \( a \) in the binary search tree.

**INPUT:**

- element — a binary tree, a Dyck word or an interval-poset

**EXAMPLES:**

```python
sage: ip = TamariIntervalPoset(4, [(1,2), (2,3), (4,3)])
sage: TamariIntervalPosets.final_forest(ip)
The Tamari interval of size 4 induced by relations [(4, 3)]
```

From binary trees:

```python
sage: bt = BinaryTree(); bt
.sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 0 induced by relations []
sage: bt = BinaryTree([]); bt
[., .]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 1 induced by relations []
sage: bt = BinaryTree([[],None]); bt
[., [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations [(2, 1)]
sage: bt = BinaryTree([[],[]]); bt
[., [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 3 induced by relations [(3, 2)]
sage: bt = BinaryTree([[],[None,[]],[]]); bt
[., [., [., .]], [., .]]
sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

```python
>>> from sage.all import *

>>> ip = TamariIntervalPoset(Integer(4), [(Integer(1),Integer(2)), (Integer(2),
   Integer(3)), (Integer(4),Integer(3))])
>>> TamariIntervalPosets.final_forest(ip)
The Tamari interval of size 4 induced by relations [(4, 3)]
```

```python
sage: bt = BinaryTree(); bt
.sage: TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 0 induced by relations []

>>> bt = BinaryTree([]); bt
[., .]

>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 1 induced by relations []

>>> bt = BinaryTree([[],None]); bt
[., [., .]]

>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations [(2, 1)]

>>> bt = BinaryTree([[],[]]); bt
[., [., .]]

>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 3 induced by relations [(3, 2)]

>>> bt = BinaryTree([[],[None,[]],[]]); bt
[., [., [., .]], [., .]]

>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

(continues on next page)
The Tamari interval of size 2 induced by relations []
```python
>>> bt = BinaryTree([None,[]]); bt
[., [., .]]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 2 induced by relations [(2, 1)]
>>> bt = BinaryTree([[[]],[]]); bt
[[., [], .], [., .]]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 3 induced by relations [(3, 2)]
>>> bt = BinaryTree([[None,[[],None]],[[]]]); bt
[[., [[., .], .]], [., .]]
>>> TamariIntervalPosets.final_forest(bt)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

From Dyck words:
```python
sage: # needs sage.combinat
dsage: dw = DyckWord([1,0])
dsage: TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 1 induced by relations []
dsage: dw = DyckWord([1,1,0,1,0,0,1,1,0,0])
dsage: TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

```python
>>> from sage.all import *
>>> # needs sage.combinat
>>> dw = DyckWord([Integer(1),Integer(0)])
>>> TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 1 induced by relations []
>>> dw = DyckWord([Integer(1),Integer(1),Integer(0),Integer(1),Integer(1),Integer(0),Integer(0),Integer(1),Integer(1),Integer(0),Integer(0),Integer(0)])
>>> TamariIntervalPosets.final_forest(dw)
The Tamari interval of size 5 induced by relations [(5, 4), (3, 1), (2, 1)]
```

`static from_binary_trees (tree1, tree2)`
Return the interval-poset corresponding to the interval `[tree1, tree2]` of the Tamari lattice.

Raise an exception if `tree1` is not `≤` `tree2` in the Tamari lattice.

INPUT:
- `tree1` – a binary tree
- `tree2` – a binary tree greater or equal than `tree1` for the Tamari lattice

EXAMPLES:
```python
sage: tree1 = BinaryTree([[],[None]])
sage: tree2 = BinaryTree([None,[]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 2 induced by relations []
sage: TamariIntervalPosets.from_binary_trees(tree1,tree1)
The Tamari interval of size 2 induced by relations []
sage: TamariIntervalPosets.from_binary_trees(tree1,tree2)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: TamariIntervalPosets.from_binary_trees(tree2,tree2)
The Tamari interval of size 2 induced by relations [(2, 1)]
sage: tree1 = BinaryTree([[],[[None,[]],[None]]])
sage: tree2 = BinaryTree([None,[[None,[]],[None]]])
```
The Tamari interval of size 6 induced by relations 
\[(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)\]

```
sage: tree3 = BinaryTree([[None, [None, [[]]], [None, [[]]]]])
sage: TamariIntervalPosets.from_binary_trees(tree1,tree3)
Traceback (most recent call last):
... ValueError: the two binary trees are not comparable on the Tamari lattice
sage: TamariIntervalPosets.from_binary_trees(tree1,BinaryTree())
Traceback (most recent call last):
... ValueError: the two binary trees are not comparable on the Tamari lattice
```

\[ \text{static from_dyck_words} \ (dw1, dw2) \]

Return the interval-poset corresponding to the interval \([dw1, dw2]\) of the Tamari lattice.

Raise an exception if the two Dyck words \(dw1\) and \(dw2\) do not satisfy \(dw1 \leq dw2\) in the Tamari lattice.

**INPUT:**

- \(dw1\) – a Dyck word
- \(dw2\) – a Dyck word greater or equal than \(dw1\) for the Tamari lattice

**EXAMPLES:**

```
sage: # needs sage.combinat
sage: dw1 = DyckWord([1,0,1,0])
sage: dw2 = DyckWord([1,1,0,0])
sage: TamariIntervalPosets.from_dyck_words(dw1, dw2)
The Tamari interval of size 2 induced by relations []
```
sage: TamariIntervalPosets.from_dyck_words(dw1, dw1)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: TamariIntervalPosets.from_dyck_words(dw2, dw2)
The Tamari interval of size 2 induced by relations [(2, 1)]

sage: # needs sage.combinat
dw1 = DyckWord([1,0,1,1,0,1,0,0,1,1,0,0,0])
dw2 = DyckWord([1,1,1,0,1,1,0,0,0,0,0,0])

sage: TamariIntervalPosets.from_dyck_words(dw1, dw2)
The Tamari interval of size 6 induced by relations [(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]
dw3 = DyckWord([1,1,0,1,1,0,0,0,0,0])

sage: TamariIntervalPosets.from_dyck_words(dw1, dw3)
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice

sage: TamariIntervalPosets.from_dyck_words(dw1, DyckWord([1, 0]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice

>>> from sage.all import *
>>> # needs sage.combinat

>>> dw1 = DyckWord([Integer(1), Integer(0), Integer(1), Integer(1),
                   Integer(0), Integer(0), Integer(1), Integer(1),
                   Integer(0)])
dw2 = DyckWord([Integer(1), Integer(1), Integer(1), Integer(0),
                   Integer(1), Integer(1), Integer(0), Integer(0),
                   Integer(0)])

>>> TamariIntervalPosets.from_dyck_words(dw1, dw2)
The Tamari interval of size 6 induced by relations [(4, 5), (6, 5), (5, 2), (4, 3), (3, 2)]

>>> dw3 = DyckWord([Integer(1), Integer(1), Integer(1), Integer(0),
                   Integer(1), Integer(1), Integer(0), Integer(0),
                   Integer(0)])

>>> TamariIntervalPosets.from_dyck_words(dw1, dw3)
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice

>>> TamariIntervalPosets.from_dyck_words(dw1, DyckWord([Integer(1),
                                                      Integer(0)]))
Traceback (most recent call last):
...
ValueError: the two Dyck words are not comparable on the Tamari lattice

static from_grafting_tree(tree)

Return an interval-poset from a grafting tree.
For the inverse method, see `TamariIntervalPoset.grafting_tree()`.

EXAMPLES:

```python
sage: tip = TamariIntervalPoset(8, [(1,2), (2,4), (3,4), (6,7), (3,2), (5,4),
                                 (6,4), (8,7)])
sage: t = tip.grafting_tree()
sage: TamariIntervalPosets.from_grafting_tree(t) == tip
True

>>> from sage.all import *
>>> tip = TamariIntervalPoset(Integer(8), [(Integer(1),Integer(2)),
                                         (Integer(2),Integer(4)), (Integer(3),Integer(4)),
                                         (Integer(6),Integer(7)),
                                         (Integer(3),Integer(2)), (Integer(5),Integer(4)),
                                         (Integer(6),Integer(4)), (Integer(8),Integer(7))])
>>> t = tip.grafting_tree()
>>> TamariIntervalPosets.from_grafting_tree(t) == tip
True
```

REFERENCES:

- [Pons2018]

static from_minimal_schnyder_wood(graph)
Returns a Tamari interval built from a minimal Schnyder wood.

This is an implementation of Bernardi and Bonichon's bijection [BeBo2009].

INPUT:

a minimal Schnyder wood, given as a graph with colored and oriented edges, without the three exterior
unoriented edges

The three boundary vertices must be -1, -2 and -3.

One assumes moreover that the embedding around -1 is the list of neighbors of -1 and not just a cyclic
permutation of that.

Beware that the embedding convention used here is the opposite of the one used by the plot method.

OUTPUT:

a Tamari interval-poset

EXAMPLES:

A small example:

```python
sage: TIP = TamariIntervalPosets
sage: G = DiGraph([(0,-1,0),(0,-2,1),(0,-3,2)], format='list_of_edges')
sage: G.set_embedding({-1:[0],-2:[0],-3:[0],0:[-1,-2,-3]})
sage: TIP.from_minimal_schnyder_wood(G)  
```

The Tamari interval of size 1 induced by relations []

```python
>>> from sage.all import *
>>> TIP = TamariIntervalPosets
>>> G = DiGraph([(Integer(0),-Integer(1),Integer(0)),(Integer(0),-Integer(2),
                                         -Integer(1)),(Integer(0),-Integer(3),Integer(2))],
                                         format='list_of_edges')
>>> G.set_embedding((-Integer(1):[Integer(0)],-Integer(2):[Integer(0)],-
                                         -Integer(3):[Integer(0)],Integer(0):[-Integer(1),-Integer(2),-Integer(3)]))
```
An example from page 14 of [BeBo2009]:

```python
sage: c0 = [(0,-1),(1,0),(2,0),(4,3),(3,-1),(5,3)]
```

```python
sage: c1 = [(5,-2),(3,-2),(4,5),(1,3),(2,3),(0,3)]
```

```python
sage: c2 = [(0,-3),(1,-3),(3,-3),(4,3),(5,-3),(2,1)]
```

```python
sage: ed = [(u,v,0) for u,v in c0]
sage: ed += [(u,v,1) for u,v in c1]
sage: ed += [(u,v,2) for u,v in c2]
sage: G = DiGraph(ed, format=list_of_edges)
sage: embed = {-1:[3,0],-2:[5,3],-3:[0,1,3,4,5]}
sage: data_emb = [[3,2,1,-3,-1],[2,3,-3,0],[3,1,0]]
sage: data_emb += [[-2,5,4,-3,1,2,0,-1],[5,-3,3],[-2,-3,4,3]]
sage: for k in range(6):
    ...:    embed[k] = data_emb[k]
sage: G.set_embedding(embed)
```

```python
sage: TIP.from_minimal_schnyder_wood(G)
```

The Tamari interval of size 1 induced by relations []

An example from page 18 of [BeBo2009]:

```python
from sage.all import *
```

```python
c0 = [(Integer(0),-Integer(1)),(Integer(1),Integer(0)),(Integer(2),-Integer(0)),(Integer(4),Integer(3)),(Integer(3),-Integer(1)),(Integer(5),-Integer(3)),(Integer(2),-Integer(1))]
```

```python
c1 = [(Integer(5),-Integer(2)),(Integer(3),-Integer(2)),(Integer(4),Integer(5)),(Integer(1),Integer(3)),(Integer(2),Integer(3)),(Integer(0),-Integer(3))]
```

```python
c2 = [(Integer(0),-Integer(3)),(Integer(1),-Integer(3)),(Integer(3),-Integer(3)),(Integer(4),-Integer(3)),(Integer(5),-Integer(3)),(Integer(2),-Integer(1))]
```

```python
ed = [(u,v,Integer(0)) for u,v in c0]
ed += [(u,v,Integer(1)) for u,v in c1]
ed += [(u,v,Integer(2)) for u,v in c2]
```

```python
G = DiGraph(ed, format='list_of_edges')
```

```python
embed = {-Integer(1):[Integer(3),Integer(0)],[Integer(2),Integer(5)],[Integer(3),Integer(1)]}
data_emb = [[1,Integer(4),Integer(3)]]
data_emb += [[-2,5,4,-3,1,2,0,-1],[5,-3,3],[-2,-3,4,3]]
```

```python
for k in range(Integer(6)):
    ...:    embed[k] = data_emb[k]
```

```python
G.set_embedding(embed)
```

```python
TIP.from_minimal_schnyder_wood(G)
```

The Tamari interval of size 6 induced by relations [(1, 4), (2, 4), (3, 4), (5, 6), (6, 4), (5, 4), (3, 1), (2, 1)]
The Tamari interval of size 6 induced by relations
[(1, 3), (2, 3), (4, 5), (5, 3), (4, 3), (2, 1)]
Anothersmallexample:
sage: c0 = [(0,-1),(1,0),(2,-1),(3,2),(4,2),(5,-1)]
sage: c1 = [(5,-2),(2,-2),(4,-2),(3,4),(1,2),(0,2)]
sage: c2 = [(0,-3),(1,-3),(3,-3),(4,-3),(2,-3),(5,2)]
sage: ed = [(u,v,0) for u,v in c0]
sage: ed += [(u,v,1) for u,v in c1]
sage: ed += [(u,v,2) for u,v in c2]
sage: G = DiGraph(ed, format=list_of_edges)

Another small example:

sage: G = DiGraph(ed, format='list_of_edges')
static initial_forest (element)

Return the initial forest of a binary tree, an interval-poset or a Dyck word.

An initial forest is an interval-poset corresponding to an initial interval of the Tamari lattice, i.e., containing only increasing relations.

It can be constructed from a binary tree by its binary search tree labeling with the rule: $a$ precedes $b$ in the initial forest iff $a$ is in the left subtree of $b$ in the binary search tree.

INPUT:

* element – a binary tree, a Dyck word or an interval-poset

EXAMPLES:

```
sage: ip = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: TamariIntervalPosets.initial_forest(ip)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3)]
```

```
>>> from sage.all import *
>>> ip = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
                        Integer(3)),(Integer(4),Integer(3))])
>>> TamariIntervalPosets.initial_forest(ip)
The Tamari interval of size 4 induced by relations [(1, 2), (2, 3)]
```
```python
sage: bt = BinaryTree(); bt
.sage:
.sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 0 induced by relations []
sage: bt = BinaryTree([[]]); bt
[., .]
sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 1 induced by relations []
sage: bt = BinaryTree([[],None]); bt
[[., .], .]
sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations [(1, 2)]
sage: bt = BinaryTree([[],[]]); bt
[., [., .]]
sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations []
sage: bt = BinaryTree([[],[]]); bt
[., [., .]]
sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 3 induced by relations []
sage: bt = BinaryTree([[],[],None]); bt
[[[., [., .]], .]], [., .]]
sage: TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 5 induced by relations [(1, 4), (2, 3), (3, 4)]
```

```python
from sage.all import *

>>> bt = BinaryTree(); bt
.sage.all
>>>
>>> TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 0 induced by relations []
>>> bt = BinaryTree([[]]); bt
[., .]
>>> TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 1 induced by relations []
>>> bt = BinaryTree([[],None]); bt
[[., .], .]
>>> TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations [(1, 2)]
>>> bt = BinaryTree([[],[]]); bt
[., [., .]]
>>> TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 2 induced by relations []
>>> bt = BinaryTree([[],[]]); bt
[., [., .]]
>>> TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 3 induced by relations []
>>> bt = BinaryTree([[],[],None]); bt
[[[., [., .]], .]], [., .]]
>>> TamariIntervalPosets.initial_forest(bt)
The Tamari interval of size 5 induced by relations [(1, 4), (2, 3), (3, 4)]
```

from Dyck words:

```python
sage: # needs sage.combinat
dw = DyckWord([1,0])
sage: TamariIntervalPosets.initial_forest(dw)
The Tamari interval of size 1 induced by relations []
```

(continues on next page)
sage: dw = DyckWord([1,1,0,1,0,0,1,1,0,0])
sage: TamariIntervalPosets.initial_forest(dw)
The Tamari interval of size 5 induced by relations [(1, 4), (2, 3), (3, 4)]

>>> from sage.all import *
>>> # needs sage.combinat
>>> dw = DyckWord([Integer(1),Integer(0)])
>>> TamariIntervalPosets.initial_forest(dw)
The Tamari interval of size 1 induced by relations []

le (el1, el2)

Poset structure on the set of interval-posets.
The comparison is first by size, then using the cubical coordinates.

See also: cubical_coordinates()

INPUT:

• el1 – an interval-poset
• el2 – an interval-poset

EXAMPLES:

sage: ip1 = TamariIntervalPoset(4,[(1,2),(2,3),(4,3)])
sage: ip2 = TamariIntervalPoset(4,[(1,2),(2,3)])
sage: TamariIntervalPosets().le(ip1,ip2)
False
sage: TamariIntervalPosets().le(ip2,ip1)
True

>>> from sage.all import *
>>> ip1 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2)),(Integer(2),
→Integer(3)),(Integer(4),Integer(3))])
>>> ip2 = TamariIntervalPoset(Integer(4),[(Integer(1),Integer(2))])
>>> TamariIntervalPosets().le(ip1,ip2)
False
>>> TamariIntervalPosets().le(ip2,ip1)
True

options = Current options for TamariIntervalPosets -

static recomposition_from_triple (left, right, r)

Recompose an interval-poset from a triple (left, right, r).

For the inverse method, see TamariIntervalPoset.decomposition_to_triple().

INPUT:
• left – an interval-poset
• right – an interval-poset
• r – the parameter of the decomposition, an integer

OUTPUT: an interval-poset

EXAMPLES:

```python
sage: T1 = TamariIntervalPoset(3, [(1, 2), (3, 2)])
sage: T2 = TamariIntervalPoset(4, [(2, 3), (4, 3)])
sage: TamariIntervalPosets.recomposition_from_triple(T1, T2, 2)
The Tamari interval of size 8 induced by relations [(1, 2), (2, 4), (3, 4), (6, 7), (8, 7), (6, 4), (5, 4), (3, 2)]
```

REFERENCES:

• [Pons2018]

```python
class sage.combinat.interval_posets.TamariIntervalPosets_all
```

```python
class sage.combinat.interval_posets.TamariIntervalPosets_size(size)
```

5.1. Comprehensive Module List
The formula was given in [Cha2008]:
\[
\frac{2(4n+1)!}{(n+1)!(3n+2)!} = \frac{2}{n(n+1)} \binom{4n+1}{n-1}.
\]

EXAMPLES:

```
sage: [TamariIntervalPosets(i).cardinality() for i in range(6)]
[1, 1, 3, 13, 68, 399]
```

```
>>> from sage.all import *
>>> [TamariIntervalPosets(i).cardinality() for i in range(Integer(6))]
[1, 1, 3, 13, 68, 399]
```

element_class()

random_element()

Return a random Tamari interval of fixed size.

This is obtained by first creating a random rooted planar triangulation, then computing its unique minimal Schnyder wood, then applying a bijection of Bernardi and Bonichon [BeBo2009]. Because the random rooted planar triangulation is chosen uniformly at random, the Tamari interval is also chosen according to the uniform distribution.

EXAMPLES:

```
sage: # needs sage.combinat
sage: T = TamariIntervalPosets(4).random_element()
sage: T.parent()
Interval-posets
sage: u = T.lower_dyck_word(); u  # random
[1, 1, 0, 1, 0, 0, 1, 0]
sage: v = T.lower_dyck_word(); v  # random
[1, 1, 0, 1, 0, 0, 1, 0]
sage: len(u)
8
```

```
>>> from sage.all import *
>>> # needs sage.combinat
>>> T = TamariIntervalPosets(Integer(4)).random_element()
>>> T.parent()
Interval-posets
>>> u = T.lower_dyck_word(); u  # random
[1, 1, 0, 1, 0, 0, 1, 0]
>>> v = T.lower_dyck_word(); v  # random
[1, 1, 0, 1, 0, 0, 1, 0]
>>> len(u)
8
```
There are two types of $k$-tableaux: strong $k$-tableaux and weak $k$-tableaux. Standard weak $k$-tableaux correspond to saturated chains in the weak order, whereas standard strong $k$-tableaux correspond to saturated chains in the strong Bruhat order. For semistandard tableaux, the notion of weak and strong horizontal strip is necessary. More information can be found in [LLMS2006].

**See also:**

`sage.combinat.k_tableau.StrongTableau()`, `sage.combinat.k_tableau.WeakTableau()`

Authors:

• Anne Schilling and Mike Zabrocki (2013): initial version

• Avi Dalal and Nate Gallup (2013): implementation of $k$-charge

```python
class sage.combinat.k_tableau.StrongTableau (parent, T):
  Bases: ClonableList
  A (standard) strong $k$-tableau is a (saturated) chain in Bruhat order.
  Combinatorially, it is a sequence of embedded $k+1$-cores (subject to some conditions) together with a set of markings.

  A strong cover in terms of cores corresponds to certain translated ribbons. A marking corresponds to the choice of one of the translated ribbons, which is indicated by marking the head (southeast most cell in French notation) of the chosen ribbon. For more information, see [LLMS2006] and [LLMSSZ2013].

  In Sage, a strong $k$-tableau is created by specifying $k$, a standard strong tableau together with its markings, and a weight $\mu$. Here the standard tableau is represented by a sequence of $k+1$-cores

  \[ \lambda^{(0)} \subseteq \lambda^{(1)} \subseteq \cdots \subseteq \lambda^{(m)} \]

  where each of the $\lambda^{(i)}$ is a $k+1$-core. The standard tableau is a filling of the diagram for the core $\lambda^{(m)}/\lambda^{(0)}$ where a strong cover is represented by letters $\pm i$ in the skew shape $\lambda^{(i)}/\lambda^{(i-1)}$. Each skew $(k+1)$-core $\lambda^{(i)}/\lambda^{(i-1)}$ is a ribbon or multiple copies of the same ribbon which are separated by $k+1$ diagonals. Precisely one of the copies of the ribbons will be marked in the largest diagonal of the connected component (the 'head' of the ribbon). The marked cells are indicated by negative signs.

  The strong tableau is stored as a standard strong marked tableau (referred to as the standard part of the strong tableau) and a vector representing the weight.

  EXAMPLES:
```
```
```python
sage: StrongTableau([[-1, -2, -3], [3]], 2, [3])
[[-1, -1, -1], [1]]
sage: StrongTableau([[[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, 1]])
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
```
```
```python
>>> from sage.all import *
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]],
    - Integer(2), [Integer(3)])
[[-1, -1, -1], [1]]
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(4), -Integer(7)], [-Integer(3),
    - Integer(6), -Integer(8), Integer(8)], [Integer(4), Integer(7)], [-Integer(5),
    - Integer(8)]], 3, [Integer(2), Integer(2), Integer(3), Integer(1)])
[[-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]]
```
```
```
```
```python
Alternatively, the strong $k$-tableau can also be entered directly in semistandard format and then the standard tableau and the weight are computed and stored:
sage: T = StrongTableau(\([-1, -1, -1], [1]\], 2); T
\([-1, -1, -1], [1]\]
sage: T.to_standard_list()
\([-1, -2, -3], [3]\]
sage: T.weight()
(3,)
sage: T = StrongTableau(\([-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]\], 3);
\([-1, -1, -2, -3], [-2, 3, -3, 4], [2, 3], [-3, -4]\]
sage: T.to_standard_list()
\([-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]\]
sage: T.weight()
(2, 2, 3, 1)

\[\text{cell_of_highest_head}(v)\]

Return the cell of the highest head of label \(v\) in the standard part of \(self\).

Return the cell where the head of the ribbon in the highest row is located in the underlying standard tableau. If there is no cell with entry \(v\) then the cell returned is \((0, r)\) where \(r\) is the length of the first row.

This cell is calculated by iterating through the diagonals of the tableau.

INPUT:

- \(v\) – an integer indicating the label in the standard tableau

OUTPUT:

- a pair of integers indicating the coordinates of the head of the highest ribbon with label \(v\)

EXAMPLES:

sage: T = StrongTableau(\([-1, 2, -3], [-2, 3], [3]\], 1)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(0, 0), (1, 0), (2, 0), (0, 3)]
sage: T = StrongTableau([\[None, None, -3, 4], [3, -4]\], 2)
sage: [T.cell_of_highest_head(v) for v in range(1,5)]
[(1, 0), (1, 1), (0, 4), (0, 4)]
cell_of_marked_head(v)

Return location of marked head labeled by v in the standard part of self.

Return the coordinates of the v-th marked cell in the strong standard tableau self. If there is no mark, then the value returned is (0, r) where r is the length of the first row.

**INPUT:**
- v – an integer representing the label in the standard tableau

**OUTPUT:**
- a pair of the coordinates of the marked cell with entry v

**EXAMPLES:**

```plaintext
sage: T = StrongTableau([[None, None, -Integer(3), Integer(4)], [Integer(3), -Integer(4)], Integer(2)])
sage: [T.cell_of_marked_head(i) for i in range(1,7)]
[(1, 0), (1, 1), (0, 4), (0, 4)]
```

```plaintext
t = StrongTableau([[Integer(3), -Integer(4)], Integer(2)])
t = StrongTableau([[None, None, -Integer(3), Integer(4)], [Integer(3), -Integer(4)], Integer(2)])
t = StrongTableau([[None, None, -Integer(3), Integer(4)], [Integer(3), -Integer(4)], Integer(2)])

```
cells_of_heads(v)

Return a list of cells of the heads with label v in the standard part of self.

A list of cells which are heads of the ribbons with label v in the standard part of the tableau self. If there is no cell labelled by v then return the empty list.

INPUT:

• v – an integer label

OUTPUT:

• a list of pairs of integers of the coordinates of the heads of the ribbons with label v

EXAMPLES:
cells_of_marked_ribbon(v)

Return a list of all cells the marked ribbon labeled by v in the standard part of self.

Return the list of coordinates of the cells which are in the marked ribbon with label v in the standard part of the tableau. Note that the result is independent of the weight of the tableau.

The cells are listed from largest content (where the mark is located) to the smallest. Hence, the first entry in this list will be the marked cell.

INPUT:

• v – the entry of the standard tableau

OUTPUT:

• a list of pairs representing the coordinates of the cells of the marked ribbon

EXAMPLES:

sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3, 3, 3]], 4)
sage: T.cells_of_heads(1)

[[-1, -2, -3, -4, 6], [4, -6], [-5]]

>>> T.cells_of_marked_ribbon(Integer(1))
[(0, 0)]
```

check()  
Check that self is a valid strong \(k\)-tableau.

This function verifies that the outer and inner shape of the parent class is equal to the outer and inner shape of the tableau, that the tableau portion of self is a valid standard tableau, that the marks are placed correctly and that the size and weight agree.

EXAMPLES:

```python
sage: T = StrongTableau([[-1, -1, -2], [2]], 2)
sage: T.check()
sage: T = StrongTableau([[None, None, -1, -2, 4], [2, -4], [-3]], 3)
sage: T.check()
```

```python
>>> from sage.all import *

>>> T = StrongTableau([[-Integer(1), -Integer(1), -Integer(2)], [Integer(2)]], Integer(2))
>>> T.check()
```

content_of_highest_head(\(v\))  
Return the diagonal of the highest head of the cells labeled \(v\) in the standard part of self.
Return the content of the cell of the head in the highest row of all ribbons labeled by \( v \) of the underlying standard tableau. If there is no cell with entry \( v \) then the value returned is the length of the first row.

**INPUT:**
- \( v \) – an integer representing the label in the standard tableau

**OUTPUT:**
- an integer representing the content of the head of the highest ribbon with label \( v \)

**EXAMPLES:**

```python
sage: StrongTableau([[-1,2,-3],[-2,3],[3]], 1).content_of_highest_head(v)
for v in range(1,6))
[0, -1, -2, 3]
```

**content_of_marked_head** 
Return the diagonal of the marked label \( v \) in the standard part of \( self \).

Return the content (the \( j - i \) coordinate of the cell) of the \( v \)-th marked cell in the strong standard tableau \( self \). If there is no mark, then the value returned is the size of first row.

**INPUT:**
- \( v \) – an integer representing the label in the standard tableau

**OUTPUT:**
- an integer representing the residue of the location of the mark

**EXAMPLES:**

```python
sage: StrongTableau([[1, -3, 4, -5], [-2], [-4]], 3).content_of_marked_head(i)
for i in range(1,7])
[0, 1, 2, 3, 4]
sage: T = StrongTableau([[None, None, -1, -2], [-1, -2], [1, 2],
[-3], [3], [3], [3]], 4)
sage: T.content_of_marked_head(i) for i in range(1,7])
[-2, 2, -1, 3, -4, 4]
```

**contents_of_heads** 
A list of contents of the cells which are heads of the ribbons with label \( v \).
If there is no cell labelled by \( v \) then return the empty list.

**INPUT:**
- \( v \) – an integer label

**OUTPUT:**
- a list of integers of the content of the heads of the ribbons with label \( v \)

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                   → [-3], [3], [3], [3]], 4)
sage: T.contents_of_heads(1)
[-2]
sage: T.contents_of_heads(2)
[-3, 2]
sage: T.contents_of_heads(3)
[-1]
sage: T.contents_of_heads(4)
[-2, 3]
sage: T.contents_of_heads(5)
[-4]
sage: T.contents_of_heads(6)
[]
```

```python
>>> from sage.all import *

>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],
                   → [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)],
                   → [Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))

>>> T.contents_of_heads(Integer(1))
[-2]

>>> T.contents_of_heads(Integer(2))
[-3, 2]

>>> T.contents_of_heads(Integer(3))
[-1]

>>> T.contents_of_heads(Integer(4))
[-2, 3]

>>> T.contents_of_heads(Integer(5))
[-4]

>>> T.contents_of_heads(Integer(6))
[]
```

**entries_by_content** \((\text{diag})\)

Return the entries on the diagonal of \( \text{self} \).

Return the entries in the tableau that are in the cells \((i, j)\) with \( j - i \) equal to \text{diag} (that is, with content equal to \text{diag}).

**INPUT:**
- \( \text{diag} \) – an integer indicating the diagonal

**OUTPUT:**
- a list (perhaps empty) of labels on the diagonal \text{diag}

**EXAMPLES:**
```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]], 4)
sage: T.entries_by_content(0)
[]
sage: T.entries_by_content(1)
[]
sage: T.entries_by_content(2)
[-1]
sage: T.entries_by_content(-2)
[-1, 2]
```

```python
>>> from sage.all import *

>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],
                      [-Integer(1), -Integer(2)], [Integer(1), Integer(2)],
                      [-Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))

>>> T.entries_by_content(Integer(0))
[]
```

### entries_by_content_standard(diag)

Return the entries on the diagonal of the standard part of self.

Return the entries in the tableau that are in the cells \((i, j)\) with \(j - i\) equal to \(\text{diag}\) (that is, with content equal to \(\text{diag}\)) in the standard tableau.

**INPUT:**

- \(\text{diag}\) – an integer indicating the diagonal

**OUTPUT:**

- a list (perhaps empty) of labels on the diagonal \(\text{diag}\)

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                      [-3], [3], [3], [3]], 4)
sage: T.entries_by_content_standard(0)
[]
sage: T.entries_by_content_standard(1)
[]
sage: T.entries_by_content_standard(2)
[-2]
sage: T.entries_by_content_standard(-2)
[-1, 4]
```

```python
>>> from sage.all import *

>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None],
                      [-Integer(1), -Integer(2)], [Integer(1), Integer(2)],
                      [-Integer(3)], [Integer(3)], [Integer(3)]], Integer(4))

>>> T.entries_by_content_standard(Integer(0))
[]
```

(continues on next page)
follows_tableau()

Return a list of strong marked tableaux with length one longer than self.

Return list of all strong tableaux obtained from self by extending to a core which follows the shape of self in the strong order.

OUTPUT:

• a list of strong tableaux which follow self in strong order

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1])
sage: T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5],
 [-1, -1, -2, -3, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5],
 [-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5], [5]]
```

```
sage: StrongTableau([[-Integer(1),-Integer(2)],[[-Integer(3),Integer(6),-Integer(6),Integer(8)], [Integer(4),Integer(7)], [-Integer(5),-Integer(9)]}, Integer(3), [Integer(2),Integer(2),Integer(3),-Integer(1)])
>>> T.follows_tableau()
[[[-1, -1, -2, -3, 5, 5, -5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5]],
 [-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [-5],
 [-1, -1, -2, -3, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], [5], [5]]
```

height_of_ribbon(v)

The number of rows occupied by one of the ribbons with label v.

The number of rows occupied by the marked ribbon with label v (and by consequence the number of rows occupied by any ribbon with the same label) in the standard part of self.

INPUT:

• v – the label of the standard marked tableau

OUTPUT:

• a non-negative integer representing the number of rows occupied by the ribbon which is marked
EXAMPLES:

```python
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]], 3)
sage: T.to_standard_list()
[[[-1, -2, -3, -4, 6], [4, -6], [-5]]
sage: T.height_of_ribbon(1)
1
sage: T.height_of_ribbon(4)
1
sage: T = StrongTableau([[None, None, -1, -2],[None, 3, 4, -5],[-1, 3],[-4, 5]], 3)
sage: T.height_of_ribbon(3)
2
sage: T.height_of_ribbon(6)
0
```

```python
>>> from sage.all import *
>>> T = StrongTableau([[None, None, 1, -2],[None, 3, 4, -5],[-1, 3],[-4, 5]], 3)
>>> T.to_standard_list()
[[[-1, -2, -3, -4, 6], [4, -6], [-5]]
>>> T.height_of_ribbon(Integer(1))
1
>>> T.height_of_ribbon(Integer(4))
1
>>> T = StrongTableau([[None, None, Integer(1),-Integer(2)],[None, -Integer(3),-Integer(4),-Integer(5)],[Integer(1),Integer(3)],[Integer(4),Integer(5)],[Integer(3)]]
>>> T.height_of_ribbon(Integer(3))
2
>>> T.height_of_ribbon(Integer(6))
0
```

**inner_shape()**

Return the inner shape of *self*.

If *self* is a strong skew tableau, then this method returns the inner shape (the shape of the cells labelled with None). If *self* is not skew, then the inner shape is empty.

**OUTPUT:**

- a \((k+1)\)-core

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -1, -2],[None, None, -1, -2],[1, 2],[-3], [3], [3], [3]], Integer(4)).inner_shape()
[2, 2]
sage: T = StrongTableau([[None, None, -1, -2, -4, -7],[-3, 6, -6, 8],[4, 7],[-5, 8]], 3, [2,2,3,1]).inner_shape()
[]
```

```python
>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(1), -Integer(2)],[None, None, -Integer(1), -Integer(2)],[Integer(1), Integer(2)], [-Integer(3)],[Integer(3)],[Integer(3)],[Integer(4)]]
>>> T.height_of_ribbon(Integer(1))
[2, 2]
>>> T = StrongTableau([[-Integer(1), -Integer(2), -Integer(4), -Integer(7)], [-Integer(3), Integer(6), -Integer(6), Integer(8)],[Integer(4), Integer(7)],[Integer(3)]], 3, [2,3,1,2,3,4]).inner_shape()
[2, 2]
```

(continues on next page)
intermediate_shapes()

Return the intermediate shapes of self.

A (skew) tableau with letters 1, 2, ..., \( \ell \) can be viewed as a sequence of shapes, where the \( i \)-th shape is given by the shape of the subtableau on letters 1, 2, ..., \( i \).

The output is the list of these shapes. The marked cells are ignored so to recover the strong tableau one would need the intermediate shapes and the content_of_marked_head() for each pair of adjacent shapes in the list.

OUTPUT:

- a list of lists of integers representing \( k + 1 \)-cores

EXAMPLES:

```
sage: T = StrongTableau([[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1])
sage: T.intermediate_shapes()
[[], [2], [3, 1, 1], [4, 3, 2, 1], [4, 4, 2, 2]]
sage: T = StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2],
                      -> [-3], [3], [3], [3]], 4)
sage: T.intermediate_shapes()
[[2, 2], [3, 2, 1, 1], [4, 2, 2, 2], [4, 2, 2, 2, 1, 1, 1, 1]]
```

is_column_strict_with_weight(\( \mu \))

Test if self is a column strict tableau with respect to the weight \( \mu \).

INPUT:

- \( \mu \) – a vector of weights

OUTPUT:

- a boolean, True means the underlying column strict strong marked tableau is valid

EXAMPLES:

```
sage: StrongTableau([[-1, -2, -3], [3]], 2).is_column_strict_with_weight([3])
True
sage: StrongTableau([[-1, -2, 3], [-3]], 2).is_column_strict_with_weight([3])
False
```
left_action(tij)
Action of transposition tij on self by adding marked ribbons.

Computes the left action of the transposition tij on the tableau. If tij acting on the element of the affine Grassmannian raises the length by 1, then this function will add a cell to the standard tableau.

INPUT:
• tij – a transposition represented as a pair (i, j).

OUTPUT:
• self after it has been modified by the action of the transposition tij

EXAMPLES:

```python
code_snippet
```
number_of_connected_components(v)
Number of connected components of ribbons with label v in the standard part.

The number of connected components is calculated by finding the number of cells with label v in the standard part of the tableau and dividing by the number of cells in the ribbon.

INPUT:
• v – the label of the standard marked tableau

OUTPUT:
• a non-negative integer representing the number of connected components

EXAMPLES:

```sage
sage: T = StrongTableau([[-1, -1, -2, -2, 3], [2, -3], [-3]], 3)
sage: T.to_standard_list()
[[1, -1, -2, -3, 6], [4, -6], [-5]]
sage: T.number_of_connected_components(1)
1
sage: T.number_of_connected_components(4)
2
sage: T = StrongTableau([[-1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3)
sage: T.number_of_connected_components(6)
1
sage: T.number_of_connected_components(9)
0
```

outer_shape()
Return the outer shape of self.

This method returns the outer shape of self as viewed as a Core. The outer shape of a strong tableau is always a $(k + 1)$-core.
OUTPUT:

• a \((k+1)\)-core

EXAMPLES:

```
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-2, 3], [3], [3], [3]], 4).outer_shape()
[4, 2, 2, 1, 1, 1, 1]
sage: StrongTableau([[\(\ldots\), -1, -2, -4, -7], [-3, 6, -6, 8], [4, 7], [-5, -8]], 3, [2, 2, 3, 1]).outer_shape()
[4, 4, 2, 2]
```

```
>>> from sage.all import *

>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).outer_shape()
[4, 2, 2, 1, 1, 1, 1]

>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(4), -Integer(7)], [-Integer(3), Integer(6), -Integer(6), Integer(8)], [Integer(4), Integer(7)], [-Integer(5), -Integer(8)]], Integer(3), [Integer(2), Integer(2), Integer(3), Integer(1)]).outer_shape()
[4, 4, 2, 2]
```

```
PP()

Print the strong tableau self in pretty print format.

EXAMPLES:

```
sage: T = StrongTableau([[-1, -2, -3], [3]], 3)
sage: T.pp()
-1 -2
```

```
sage: Tableaux.options(convention="French")
sage: T.pp()
3
3
3
3
```
```
sage: Tableaux.options(convention="English")
```
"
```python
>>> from sage.all import *

>>> T = StrongTableau([[[-1,-2,-4,-7], [-3,3,6,-6,8], [4,7], [-5,-8]], Integer(3), [2,2,3,1]])

>>> T.pp()
-1 -1 -2 -3
-2 3 -3 4
 2 3
-3 -4

>>> T = StrongTableau([[None, None, -1, -2], [None, None, -1, -2, 1, 2, 3, 3, 3], Integer(4)])

>>> T.pp()
  .  .  -1 -2
  .  .
-1 -2
 1 2
-3
 3
 3

>>> Tableaux.options(convention="French")

>>> T.pp()
 3
 3
 3
 1 2
-1 -2
  .  .
  .  .  -1 -2

>>> Tableaux.options(convention="English")
```

**restrict** *(r)*

Restrict the standard part of the tableau to the labels 1, 2, ..., *r*.

Return the tableau consisting of the labels of the standard part of *self* restricted to the labels of 1 through *r*. The result is another *StrongTableau* object.

**INPUT:**

- *r* – an integer

**OUTPUT:**

- A strong tableau

**EXAMPLES:**

```python
sage: T = StrongTableau([[None, None, -4, 5, -5], [None, None, -1, -3], [-2], [2], [3]], 4, weight=[1,1,1,1,1])
sage: T.restrict(3)
[[None, None], [None, None], [-1, -3], [-2], [2], [3]]
sage: TT = T.restrict(0)
sage: TT
[[None, None], [None, None]]
sage: TT == StrongTableau([ [None, None], [None, None] ], 4 )
True
```

(continues on next page)
sage: T.restrict(5) == T
True

>>> from sage.all import *
>>> T = StrongTableau([[None, None, -Integer(4), Integer(5), -Integer(5)],-
    →[None, None, [-Integer(1), -Integer(3)], [-Integer(2)], [Integer(2)],-
    →[Integer(2)], [Integer(3)], Integer(4), weight=[Integer(1),Integer(1),-
    →Integer(1),Integer(1),Integer(1)]})
>>> T.restrict(Integer(3))
[[None, None], [None, None], [-1, -3], [-2], [2], [2], [3]]
>>> TT = T.restrict(Integer(0))
>>> TT
[[None, None], [None, None]]
>>> TT == StrongTableau( [[None, None], [None, None]], Integer(4) )
True
>>> T.restrict(Integer(5)) == T
True

ribbons_above_marked(v)

Number of ribbons of label \(v\) higher than the marked ribbon in the standard part.

Return the number of copies of the ribbon with label \(v\) in the standard part of \(self\) which are in a higher row than the marked ribbon. Note that the result is independent of the weight of the tableau.

INPUT:

• \(v\) – the entry of the standard tableau

OUTPUT:

• an integer representing the number of copies of the ribbon above the marked ribbon

EXAMPLES:

sage: T = StrongTableau([[None, None, -Integer(4), Integer(5), -Integer(5)],-
    →[None, None, [-Integer(1), -Integer(3)], [-Integer(2)], [Integer(2)],-
    →[Integer(2)], [Integer(3)], Integer(4), weight=[Integer(1),Integer(1),-
    →Integer(1),Integer(1),Integer(1)]})
sage: T.ribbons_above_marked(4)
1
sage: T.ribbons_above_marked(6)
0
sage: T.ribbons_above_marked(9)
0
sage: StrongTableau([[None, None, -Integer(4), Integer(5), -Integer(5)],-
    →[None, None, [-Integer(1), -Integer(3)], [-Integer(2)], [Integer(2)],-
    →[Integer(2)], [Integer(3)], Integer(4), weight=[Integer(1),Integer(1),-
    →Integer(1),Integer(1),Integer(1)]})
(continues on next page)
set_weight \( \mu \)

Sets a new weight \( \mu \) for \( \text{self} \).

This method first tests if the underlying standard tableau is column-strict with respect to the weight \( \mu \). If it is, then it changes the weight and returns the tableau; otherwise it raises an error.

**INPUT:**

- \( \mu \) – a list of non-negative integers representing the new weight

**EXAMPLES:**

```python
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [3] )
[[[-1, -1, -1], [1]]
sage: StrongTableau( [[-1, -2, -3], [3]], 2 ).set_weight( [0,3] )
[[[-2, -2, -2], [2]]
sage: StrongTableau( [[-1, -2, 3], [-3]], 2 ).set_weight( [2, 0, 1] )
[[[-1, -1, 3], [-3]]
Traceback (most recent call last):
... ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with respect to the partition [3]
```

shape()

Return the shape of \( \text{self} \).

If \( \text{self} \) is a skew tableau then return a pair of \( k + 1 \)-cores consisting of the outer and the inner shape. If \( \text{self} \) is strong tableau with no inner shape then return a \( k + 1 \)-core.

**INPUT:**

- \( \text{form} \) – optional argument to indicate ‘inner’, ‘outer’ or ‘skew’ (default: ‘outer’)

**OUTPUT:**

- a \( k + 1 \)-core or a pair of \( k + 1 \)-cores if form is not ‘inner’ or ‘outer’

**EXAMPLES:**

```python
>>> from sage.all import *
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]]).shape()
([-Integer(1), -Integer(2), Integer(3)], [Integer(3)])
>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3)], [Integer(3)]]).shape(form='inner')
([Integer(0), Integer(3)], [Integer(3)])
>>> StrongTableau( [[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]]).shape(form='outer')
([[-1, -1, 3], [-3]], [[Integer(2), Integer(0), Integer(1)]]
>>> StrongTableau( [[-Integer(1), -Integer(2), Integer(3)], [-Integer(3)]]).shape(form='skew')
([[-1, -1, 3], [-3]], [[Integer(3)]]
Traceback (most recent call last):
... ValueError: [[-1, -2, 3], [-3]] is not a semistandard strong tableau with respect to the partition [3]
```
sage: T = StrongTableau([[None, None, -1, -2], [None, None, [-3], [3], [3], [3]], 4])
sage: T.shape()
([4, 2, 2, 2, 1, 1, 1, 1], [2, 2])
sage: type(StrongTableau([[None, None, -2], [-2]], 2).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>

size()

Return the size of the strong tableau.

The size of the strong tableau is the sum of the entries in the weight(). It will also be equal to the length of the outer shape (as a $k+1$-core) minus the length of the inner shape.

See also:
sage.combinat.core.Core.length()

OUTPUT:

* a non-negative integer

EXAMPLES:

sage: StrongTableau([[None, None, -1, -2, -3, 4], [-4], [-5]], 3).size() 5
sage: StrongTableau([[None, None, -1, 2], [-2], [-3]], 3).size() 3

spin()

Return the spin statistic of the tableau self.

The spin is an integer statistic on a strong marked tableau. It is the sum of $(h-1)r$ plus the number of connected components above the marked one where $h$ is the height of the marked ribbon and $r$ is the number of connected components.
See also:

\texttt{height\_of\_ribbon()}, \texttt{number\_of\_connected\_components()}, \texttt{ribbons\_above\_marked()}

The $k$-Schur functions with a parameter $t$ can be defined as

$$s^{(k)}_\lambda[X; t] = \sum_T t^{\text{spin}(T)} m_{\text{weight}(T)}[X]$$

where the sum is over all column strict marked strong $k$-tableaux of shape $\lambda$ and partition content.

OUTPUT:

- an integer value representing the spin.

EXAMPLES:

```python
sage: StrongTableau([[[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3, [2,2,3,1]).spin()
sage: StrongTableau([[[-1,-2,-4,-7],[-3,6,-6,8],[4,7],[-5,-8]], 3, [2,2,3,1]).spin()
sage: StrongTableau([[None,None,-1,3],[-2,3,-3,4],[2,3],[-3,-4]], 3).spin()
sage: ks3 = SymmetricFunctions(QQ['t'].fraction_field()).kschur(3)
sage: t = ks3.realization_of().t
sage: m = ks3.ambient().realization_of().m()
sage: myks221 = sum(sum(t**T.spin() for T in StrongTableaux(3,[3,2,1], weight=mu))*m(mu) for mu in Partitions(5, max_part=3))
sage: myks221 == m(ks3[2,2,1])
True
sage: h = ks3.ambient().realization_of().h()
sage: Core([4,4,2,2],4).to_bounded_partition()
[2, 2, 2, 2]
sage: ks3[2,2,2,2].lift().scalar(h[3,3,2]) == sum( t**T.spin() for T in StrongTableaux([4,4,2,2], weight=[3,3,2]) )
True
```

```python
>> from sage.all import *
>> StrongTableau([[[-Integer(1),-Integer(2),Integer(5),Integer(6)],[-Integer(3),-Integer(4),-Integer(7),Integer(8)],[-Integer(5),-Integer(6)],[Integer(7),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(1)]).spin()
1
>> StrongTableau([[[-Integer(1),-Integer(2),-Integer(4),-Integer(7)],[-Integer(3),Integer(6),-Integer(6),Integer(8)],[4,Integer(4),Integer(7)],[-Integer(5),-Integer(8)]], Integer(3), [Integer(2),Integer(2),Integer(3),-Integer(1)]).spin()
2
>> StrongTableau([[None,None,-Integer(1),-Integer(3)],[-Integer(2),-Integer(3),-Integer(3),Integer(4)],[Integer(2),Integer(3)],-Integer(4)]), Integer(3).spin()
2
>> ks3 = SymmetricFunctions(QQ['t'].fraction_field()).kschur(Integer(3))
>> t = ks3.realization_of().t
>> m = ks3.ambient().realization_of().m()
>> myks221 = sum(sum(t**T.spin() for T in StrongTableaux(Integer(3), weight=mu))*m(mu) for mu in...
```

(continues on next page)
spin_of_ribbon(v)

Return the spin of the ribbon with label v in the standard part of self.

The spin of a ribbon is an integer statistic. It is the sum of \((h - 1)r\) plus the number of connected components above the marked one where \(h\) is the height of the marked ribbon and \(r\) is the number of connected components.

See also:

height_of_ribbon(), number_of_connected_components(), ribbons_above_marked()

INPUT:

- v – a label of the standard part of the tableau

OUTPUT:

- an integer value representing the spin of the ribbon with label v.

EXAMPLES:

```python
sage: T = StrongTableau([[-1,-2,5,6],[-3,-4,-7,8],[-5,-6],[7,-8]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,9)]
[0, 0, 0, 0, 0, 0, 0, 0]
sage: T = StrongTableau([[None,None,-1,-3],[-2,3,-3,4],[2,3],[-3,-4]], 3)
sage: [T.spin_of_ribbon(v) for v in range(1,7)]
[0, 0, 0, 0, 0, 0]

>>> from sage.all import *

>>> T = StrongTableau([[-Integer(1),-Integer(2),Integer(5),Integer(6)],[-Integer(3),-Integer(4),-Integer(7),Integer(8)],[-Integer(9)],[-Integer(8)],[Integer(7)]]
>>> [T.spin_of_ribbon(v) for v in range(Integer(1),Integer(9))]}

[0, 0, 0, 0, 0, 0, 0, 0, 0]
>>> T = StrongTableau([[-None,None,-Integer(1),-Integer(3)],[-Integer(2),-Integer(3),-Integer(3),Integer(4)],[Integer(2),Integer(3)],[-Integer(3),-Integer(4)],Integer(3))
>>> [T.spin_of_ribbon(v) for v in range(Integer(1),Integer(7))]}

[0, 0, 0, 0, 0, 0, 0]
```

to_list()

Return the marked column strict (possibly skew) tableau as a list of lists.

OUTPUT:

- a list of lists of integers or None
EXAMPLES:

```
sage: StrongTableau([[[-1, -2, -3, 4], [-4], [-5]], 3], 3).set_weight([2, 1, 1, 1]).to_list()
[[[-1, -1, -2, 3], [-3], [-4]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], 4], 3).to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
sage: StrongTableau([[[-1, -2, -3, 4], [-4], [-5]], 3, [3, 1, 1]].to_list()
[[[-1, -1, -1, 2], [-2], [-3]]
```

```
>>> from sage.all import *

>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(5)], Integer(3)].set_weight([Integer(2), Integer(1), Integer(1), Integer(1)]).to_list()
[[-1, -1, -2, 3], [-3], [-4]]
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], Integer(4)].to_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
```

```
>>> StrongTableau([[[-1, -2, -3, 4], [-4], [-5]], 3, [3, 1, 1]].to_list()
[[[-1, -1, -1, 2], [-2], [-3]]
```

```
>>> from sage.all import *

>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3)].set_weight([Integer(2), Integer(1), Integer(1), Integer(1)]).to_list()
[[-1, -1, -2, 3], [-3], [-4]]
>>> StrongTableau([[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], Integer(4)].to_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3), Integer(3), Integer(3), Integer(1)].to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> from sage.all import *

>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3), Integer(3), Integer(3), Integer(1)].to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3), Integer(3), Integer(3), Integer(1)].to_standard_tableau()
```

```
>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3), Integer(3), Integer(3), Integer(1)].to_standard_tableau()
```

```
```

to_standard_list()

Return the underlying standard strong tableau as a list of lists.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part.

OUTPUT:

• a list of lists of integers or None

EXAMPLES:

```
sage: StrongTableau([[[-1, -2, -3, 4], [-4], [-5]], 3, [3, 1, 1]].to_standard_list()
[[[-1, -2, -3, 4], [-4], [-5]]
sage: StrongTableau([[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], 4], 3).to_standard_list()
[[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]]
```

```
>>> from sage.all import *

>>> StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3), Integer(3), Integer(3), Integer(1)].to_standard_list()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```
```

to_standard_tableau()

Return the underlying standard strong tableau as a StrongTableau object.

Internally, for a strong tableau the standard strong tableau and its weight is stored separately. This method returns the underlying standard part as a StrongTableau.
OUTPUT:

- a strong tableau with standard weight

EXAMPLES:

```sage
T = StrongTableau([[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
sage: T.to_standard_tableau()
[[-1, -2, -3, 4], [-4], [-5]]
sage: T.to_standard_tableau() == T.to_standard_list()
False
sage: StrongTableau([None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3]), 4).to_standard_tableau()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

```sage
from sage.all import *

T = StrongTableau([[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)]], Integer(3), [Integer(3),Integer(1),Integer(1)])
sage: T.to_standard_tableau()
[[1, 2, 3, [-1, -2, -3, 4], [-4], [-5]]
sage: T.to_standard_tableau() == T.to_standard_list()
False
sage: StrongTableau([None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3]), 4).to_standard_tableau()
[[None, None, -2, -4], [None, None], [-1, -3], [2, 4], [-5], [5], [5], [5]]
```

**to_transposition_sequence()**

Return a list of transpositions corresponding to **self**.

Given a strong column strict tableau **self** returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

OUTPUT:

- a list of pairs of values \([i, j]\) representing the transpositions \(t_{ij}\)

EXAMPLES:

```sage
T = StrongTableau([[-1, -1, -1], [1]], 2)
sage: T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
sage: T = StrongTableau([[-1, -1, 2], [-2]], 2)
sage: T.to_transposition_sequence()
[[1, 2], [0, 1]]
sage: T = StrongTableau([None, -1, 2, -3], [-2, 3], 2)
sage: T.to_transposition_sequence()
[[3, 4], [-1, 0], [1, 2]]
```

```sage
from sage.all import *

T = StrongTableau([[-Integer(1), -Integer(2), -Integer(1)], [Integer(1)]], Integer(2))
sage: T.to_transposition_sequence()
[[2, 3], [1, 2], [0, 1]]
sage: T = StrongTableau([[-Integer(1), -Integer(1), Integer(2)], [-Integer(2)]], Integer(2))
sage: T.to_transposition_sequence()
[[1, 2], [0, 1]]
sage: T = StrongTableau([None, -Integer(1), Integer(2), -Integer(3)], [-
```

(continues on next page)
to_unmarked_list()

Return the tableau as a list of lists with markings removed.

Return the list of lists of the rows of the tableau where the markings have been removed.

OUTPUT:

• a list of lists of integers or None

EXAMPLES:

```sage
t = StrongTableau( [[-1, -2, -3, 4], [-4], [-5]], 3, [3,1,1])
t.to_unmarked_list()
```

```sage
tt = t.set_weight([2,1,1])
tt.to_unmarked_list()
```

```sage
tt = StrongTableau( [[None, None, -1, -2], [None, None], [-1, -2], [1, 2], [-3], [3], [3], [3]], 4).to_unmarked_list()
```

```sage
from sage.all import *
t = StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)]], Integer(3), [Integer(3), Integer(3), Integer(1), -Integer(1)])
t.to_unmarked_list()
```

```sage
TT = T.set_weight([Integer(2), Integer(1), Integer(1), Integer(1)])
TT.to_unmarked_list()
```

```sage
TT = StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], [Integer(3)], Integer(4)]).to_unmarked_list()
```

```sage
tt = StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], [Integer(3)], Integer(4)]).to_unmarked_standard_list()
```

```sage
from sage.all import *
t = StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)]], Integer(3), [Integer(3), Integer(1)])
t.to_unmarked_standard_list()
```

```sage
TT = T.set_weight([Integer(2), Integer(1), Integer(1), Integer(1)])
TT.to_unmarked_standard_list()
```

```sage
TT = StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], [Integer(3)], Integer(4)]).to_unmarked_standard_list()
```

```sage
from sage.all import *
t = StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)]], Integer(3), [Integer(3), Integer(1)])
t.to_unmarked_standard_list()
```
>>> from sage.all import *

>>> StrongTableau( [[-Integer(1), -Integer(2), -Integer(3), Integer(4)], [-Integer(4)], [-Integer(5)], Integer(3), [Integer(3), Integer(1), -Integer(1)]]).to_unmarked_standard_list()
[[1, 2, 3, 4], [4], [5]]

>>> StrongTableau( [[None, None, -Integer(1), -Integer(2)], [None, None], [-Integer(1), -Integer(2)], [Integer(1), Integer(2)], [-Integer(3)], [Integer(3)], [Integer(3)]], Integer(4)).to_unmarked_standard_list()
[[None, None, 2, 4], [None, None], [1, 3], [2, 4], [5], [5], [5], [5]]

weight()

Return the weight of the tableau.

The weight is a list of non-negative integers indicating the number of 1s, number of 2s, number of 3s, etc.

OUTPUT:

• a list of non-negative integers

EXAMPLES:

sage: T = StrongTableau([[1, -2, -3, 4], [-4], [-5]], 3); T.weight()
(1, 1, 1, 1)

sage: T.set_weight([3,1,1]).weight()
(3, 1, 1)

sage: StrongTableau([[1,1,1,-2,3],[-2,3,-3,4],[2,3],[-3,-4]], 3).weight()
(2, 2, 3, 1)

class sage.combinat.k_tableau.StrongTableaux(k, shape, weight)

Bases: UniqueRepresentation, Parent

Element

alias of StrongTableau

classmethod add_marking(unmarkedT, marking, k, weight)

Add markings to a partially marked strong tableau.

Given a partially marked standard tableau and a list of cells where the marks should be placed along with a weight, return the semi-standard marked strong tableau. The marking should complete the marking so that the result is a strong standard marked tableau.

INPUT:

• unmarkedT – a list of lists which is a partially marked strong k-tableau
• marking – a list of pairs of coordinates where cells are to be marked
• k – a positive integer
• weight – a tuple of the weight of the output tableau

OUTPUT:
• a StrongTableau object

EXAMPLES:

```
sage: StrongTableaux.add_marking([[None, 1, 2], [2]], [(0,1), (1,0)], 2, [1,1])
[[None, -1, 2], [-2]]
sage: StrongTableaux.add_marking([[None, 1, 2], [2]], [(0,1), (1,0)], 2, [2])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -1, 2], [-2]] do not agree.
sage: StrongTableaux.add_marking([[None, 1, 2], [2]], [(0,1), (0,2)], 2, [2])
[[None, -1, -1], [1]]
```

```
>> from sage.all import *
>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)], [Integer(2)]],
   -> [(Integer(0),Integer(1)), (Integer(1),Integer(0))], Integer(2), [Integer(1),
   -> Integer(1)])
[[None, -1, 2], [-2]]
>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)], [Integer(2)]],
   -> [(Integer(0),Integer(1)), (Integer(1),Integer(0))], Integer(2),
   -> [Integer(2)])
Traceback (most recent call last):
...
ValueError: The weight=(2,) and the markings on the standard tableau=[[None, -1, 2], [-2]] do not agree.
>> StrongTableaux.add_marking([[None,Integer(1),Integer(2)], [Integer(2)]],
   -> [(Integer(0),Integer(1)), (Integer(0),Integer(2))], Integer(2),
   -> [Integer(2)])
[[None, -1, -1], [1]]
```

```
an_element()
Return the first generated element of the class of StrongTableaux.

EXAMPLES:

sage: ST = StrongTableaux(3, [3], weight=[3])
sage: ST.an_element()
[-1, -1, -1]
```

```
>>> from sage.all import *
>>> ST = StrongTableaux(Integer(3), [Integer(3)], weight=[Integer(3)])
>>> ST.an_element()
[-1, -1, -1]
```

```
classmethod cells_head_dictionary(T)
Return a dictionary with the locations of the heads of all markings.

Return a dictionary of values and lists of cells where the heads with the values are located in a strong standard unmarked tableau T.

INPUT:
• T – a strong standard unmarked tableau as a list of lists

OUTPUT:
```
```
• a dictionary with keys the entries in the tableau and values are the coordinates of the heads with those entries

EXAMPLES:

```python
sage: StrongTableaux.cells_head_dictionary([[1,2,4,7],[3,6,6,8],[4,7],[5,8]])
{(1: [(0, 0)],
  2: [(0, 1)],
  3: [(1, 0)],
  4: [(2, 0), (0, 2)],
  5: [(3, 0)],
  6: [(1, 2)],
  7: [(2, 1), (0, 3)],
  8: [(3, 1), (1, 3)]
}sage: StrongTableaux.cells_head_dictionary([[None, 2, 2, 4, 5, 6, 6, 6],
                                           [None, 3, 6, 6, 6], [1, 4]])
{(1: [(2, 0)],
  2: [(0, 2)],
  3: [(1, 1)],
  4: [(2, 1), (0, 3)],
  5: [(0, 4)],
  6: [(1, 4), (0, 7)]
}>> from sage.all import *
>> StrongTableaux.cells_head_dictionary([[Integer(1),Integer(2),Integer(4),
                                           Integer(7)], [Integer(3),Integer(6),Integer(8)], [Integer(4),
                                           Integer(7)], [Integer(5),Integer(8)]])
{(1: [(0, 0)],
  2: [(0, 1)],
  3: [(1, 0)],
  4: [(2, 0), (0, 2)],
  5: [(3, 0)],
  6: [(1, 2)],
  7: [(2, 1), (0, 3)],
  8: [(3, 1), (1, 3)]
}>> StrongTableaux.cells_head_dictionary([[None, Integer(2), Integer(2),
                                           Integer(4), Integer(5), Integer(6), Integer(6), Integer(6)],
                                           [None, Integer(3), Integer(6), Integer(6), Integer(6)],
                                           [None, Integer(3), Integer(6), Integer(6), Integer(6)],
                                           [Integer(1), Integer(4)]])
{(1: [(2, 0)],
  2: [(0, 2)],
  3: [(1, 1)],
  4: [(2, 1), (0, 3)],
  5: [(0, 4)],
  6: [(1, 4), (0, 7)]
)
```

```python

classmethod follows_tableau_unsigned_standard(Tlist, k)

Return a list of strong tableaux one longer in length than Tlist.

Return list of all standard strong tableaux obtained from Tlist by extending to a core which follows the shape of Tlist in the strong order. It does not put the markings on the last entry that it adds but it does keep the markings on all entries smaller. The objects returned are not StrongTableau objects (and cannot be) because the last entry will not properly marked.

INPUT:

• Tlist – a filling of a \( k + 1 \)-core as a list of lists
• k – an integer

OUTPUT:

```
• a list of strong tableaux which follow $T$ in strong order

EXAMPLES:

```
sage: StrongTableaux.follows_tableau_unsigned_standard([[-1, -1, -2, -3], [-2, → 3, -3, 4], [2, 3], [-3, -4]], 3)
[[[-1, -1, -2, -3, 5, 5, 5], [-2, 3, -3, 4], [2, 3, 5], [-3, -4], 5]],
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], 4],
[[None, -1, -2, -3], [4, [4], 4]]]
```

```
sage: StrongTableaux.follows_tableau_unsigned_standard([[None, -1], [-2, -3]], 3)
[[[None, -1], 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], 4],
[[None, -1], [4, [4], 4]]
```

```
>>> from sage.all import *

>> from sage.all import *

>> StrongTableaux.follows_tableau_unsigned_standard([[None, -1], [-2, -3]], 3)
[[[None, -1, 4, 4, 4], [-2, -3]], [[None, -1, 4], [-2, -3], 4],
[[None, -1, -2, -3], [4, [4], 4]]
```

```
inner_shape()
```

Return the inner shape of the class of strong tableaux.

OUTPUT:

• a $k + 1$-core

EXAMPLES:

```
sage: StrongTableaux( 2, [3,1] ).inner_shape()
[[]]
sage: type(StrongTableaux( 2, [3,1] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).inner_shape()
[1]
```

```
>>> from sage.all import *

>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).inner_shape()
[[[]]]
```

```
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

```
>> from sage.all import *

>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).inner_shape()
[[[]]]
```

```
>>> type(StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).inner_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
```

```
classmethod marked_CST_to_transposition_sequence($T$, $k$)
```

Return a list of transpositions corresponding to $T$.

Given a strong column strict tableau $T$ returns the list of transpositions which when applied to the left of an empty tableau gives the corresponding strong standard tableau.

INPUT:

• $T$ – a non-empty column strict tableau as a list of lists
• $k$ – a positive integer

OUTPUT:

• a list of pairs of values $[i, j]$ representing the transpositions $t_{ij}$

EXAMPLES:

```python
sage: CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
sage: CST_to_trans([[-1, -1, -1], [1]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([], 2)
[]
sage: CST_to_trans([[-2, -2, -2], [2]], 2)
[[2, 3], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -2, -2, -2], [-2, 2], [2]], 3)
[[4, 5], [3, 4], [2, 3], [1, 2], [-1, 0], [0, 1]]
sage: CST_to_trans([[-1, -2, -5, 5, -5, 5, -5], [-3, -4, 5, 5], [5]], 3)
[[5, 7], [3, 5], [2, 3], [0, 1], [-1, 0], [1, 2], [0, 1]]
sage: CST_to_trans([[-1, -2, -3, 4, -7], [-4, -6], [-5, 6]], 3)
[[4, 5], [-1, 1], [-2, -1], [-1, 0], [2, 3], [1, 2], [0, 1]]
```

```python
>>> from sage.all import *
>>> CST_to_trans = StrongTableaux.marked_CST_to_transposition_sequence
>>> CST_to_trans([[-Integer(1), -Integer(1), -Integer(1)], [Integer(1)]], Integer(2))
[[2, 3], [1, 2], [0, 1]]
>>> CST_to_trans([], Integer(2))
[]
>>> CST_to_trans([[-Integer(2), -Integer(2), -Integer(2)], [Integer(2)]], Integer(2))
[[2, 3], [1, 2], [0, 1]]
```

#### `classmethod marked_given_unmarked_and_weight_iterator(unmarkedT, k, weight)`

An iterator generating strong marked tableaux from an unmarked strong tableau.

Iterator which lists all marked tableaux of weight `weight` such that the standard unmarked part of the tableau is equal to `unmarkedT`.

INPUT:

• `unmarkedT` – a list of lists representing a strong unmarked tableau

• $k$ – a positive integer

• `weight` – a list of non-negative integers indicating the weight

OUTPUT:

• an iterator that returns `StrongTableau` objects
EXAMPLES:

```
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
                         →[3]], 2, [3])
sage: list(ST)
[[[-1, -1, -1], [1]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
                         →[3]], 2, [0,3])
sage: list(ST)
[[[-2, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
                         →[3]], 2, [1,2])
sage: list(ST)
[[[-1, -2, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[1,2,3],
                         →[3]], 2, [2,1])
sage: list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,
                         →None, 1, 2, 4], [2, 4], [3]], 3, [3,1])
sage: list(ST)
[]
sage: ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,
                         →None, 1, 2, 4], [2, 4], [3]], 3, [2,2])
sage: list(ST)
[[[None, None, -1, -1, 2], [1, -2]],
  [[None, None, -1, -1, -2], [1, 2], [-2]]]
```

```
>>> from sage.all import *
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[Integer(1),Integer(2),Integer(3)], [Integer(3)]], Integer(2),
                                           →[Integer(3)])
>>> list(ST)
[[[-1, -1, -1], [1]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[Integer(1),Integer(2),Integer(3)], [Integer(3)]], Integer(2),
                                           →[Integer(0),Integer(3)])
>>> list(ST)
[[[-2, -2, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[Integer(1),Integer(2),Integer(3)], [Integer(3)]], Integer(2),
                                           →[Integer(1),Integer(2)])
>>> list(ST)
[[[-1, -2, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[Integer(1),Integer(2),Integer(3)], [Integer(3)]], Integer(2),
                                           →[Integer(2),Integer(1)])
>>> list(ST)
[[[-1, -1, 2], [-2]], [[-1, -1, -2], [2]]]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,
                                           →None, Integer(1), Integer(2), Integer(4)], [2, 4], [3]], 3, [Integer(3),Integer(1)])
>>> list(ST)
[]
>>> ST = StrongTableaux.marked_given_unmarked_and_weight_iterator([[None,
                                           →None, Integer(1), Integer(2), Integer(4)], [2, 4], [3]], 3, [Integer(2),Integer(2)])
>>> list(ST)
```
options = Current options for Tableaux - ascii_art: repr - convention: English - display: list - latex: diagram

outer_shape()

Return the outer shape of the class of strong tableaux.

OUTPUT:

• a $k+1$-core

EXAMPLES:

```sage
sage: StrongTableaux( 2, [3,1] ).outer_shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).outer_shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).outer_shape()
[2, 1]
```

shape()

Return the shape of self.

If the self has an inner shape return a pair consisting of an inner and an outer shape. If the inner shape is empty then return only the outer shape.

OUTPUT:

• a $k+1$-core or a pair of $k+1$-cores

EXAMPLES:

```sage
sage: StrongTableaux( 2, [3,1] ).shape()
[3, 1]
sage: type(StrongTableaux( 2, [3,1] ).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
sage: StrongTableaux( 4, [[2,1], [1]] ).shape()
([[2, 1], [1]])
```

```python
>>> from sage.all import *

>>> StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).shape()
[[2, 1], [1]]
>>> type(StrongTableaux( Integer(2), [Integer(3),Integer(1)] ).shape())
<class 'sage.combinat.core.Cores_length_with_category.element_class'>
>>> StrongTableaux( Integer(4), [[Integer(2),Integer(1)], [Integer(1)]] ).shape()

(2, 1, 1)
```
class method standard_marked_iterator \((k, size, outer\_shape=None, inner\_shape=[])\)

An iterator for generating standard strong marked tableaux.

An iterator which generates all standard marked \(k\)-tableaux of a given size which are contained in outer\_shape and contain the inner\_shape. If outer\_shape is None then there is no restriction on the shape of the tableaux which are created.

**INPUT:**

- \(k\) – a positive integer
- size – a positive integer
- outer\_shape – a list which is a \(k+1\)-core (default: None)
- inner\_shape – a list which is a \(k+1\)-core (default: [])

**OUTPUT:**

- an iterator which returns the standard marked tableaux with size cells and that are contained in outer\_shape and contain inner\_shape

**EXAMPLES:**

```python
sage: list(StrongTableaux.standard_marked_iterator(2, 3))
[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, 2], [-2], [3]]
sage: list(StrongTableaux.standard_marked_iterator(2, 1, inner\_shape=[1,1]))
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None], [1]]]
sage: len(list(StrongTableaux.standard_marked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_marked_iterator(4,6)))
140
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, inner\_shape=[2,2])))
200
sage: len(list(StrongTableaux.standard_marked_iterator(4,4, outer\_shape=[5,2,2,2], inner\_shape=[2,2])))
24
```

```python
>>> from sage.all import *
>>> list(StrongTableaux.standard_marked_iterator(Integer(2), Integer(3)))
[[[-1, -2, 3], [-3]], [[-1, -2, -3], [3]], [[-1, -2], [-3], [3]], [[-1, 3, 2], [-2], [3]]
>>> list(StrongTableaux.standard_marked_iterator(Integer(2), Integer(1), inner\_shape=[Integer(1),Integer(1)])
[[[None, 1, -1], [None]], [[None, 1], [None], [-1]], [[None, -1], [None], [1]]]
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4))))
10
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(6))))
140
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4, inner\_shape=[Integer(2),Integer(2)])))
200
>>> len(list(StrongTableaux.standard_marked_iterator(Integer(4),Integer(4, outer\_shape=[Integer(5),Integer(2),Integer(2),Integer(1)], inner\_shape=[Integer(2),Integer(2)])))
24
```
classmethod standard_unmarked_iterator \((k, \text{size}, \text{outer_shape}=\text{None}, \text{inner_shape}=[])\)

An iterator for standard unmarked strong tableaux.

An iterator which generates all unmarked tableaux of a given size which are contained in outer_shape and which contain the inner_shape.

These are built recursively by building all standard marked strong tableaux of size size - 1 and adding all possible covers.

If outer_shape is None then there is no restriction on the shape of the tableaux which are created.

INPUT:

- \(k, \text{size}\) – positive integers
- \text{outer_shape} – a list representing a \(k+1\)-core (default: None)
- \text{inner_shape} – a list representing a \(k+1\)-core (default: [])

OUTPUT:

- an iterator which lists all standard strong unmarked tableaux with size cells and which are contained in outer_shape and contain inner_shape

EXAMPLES:

```
sage: list(StrongTableaux.standard_unmarked_iterator(2, 3))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
sage: list(StrongTableaux.standard_unmarked_iterator(2, 1, inner_shape=[1,1]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4)))
10
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,6)))
98
sage: len(list(StrongTableaux.standard_unmarked_iterator(4,4, inner_shape=[2, 2, 1], inner_shape=[2,2])))
92
```

```bash
>>> from sage.all import *
>>> list(StrongTableaux.standard_unmarked_iterator(Integer(2), Integer(3)))
[[[1, 2, 3], [3]], [[1, 2], [3], [3]], [[1, 3, 3], [2]], [[1, 3], [2], [3]]]
>>> list(StrongTableaux.standard_unmarked_iterator(Integer(2), Integer(1), inner_shape=[Integer(1),Integer(1)]))
[[[None, 1, 1], [None]], [[None, 1], [None], [1]]]
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4), inner_shape=[Integer(4), Integer(4)])))
10
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4), inner_shape=[Integer(6)])))
98
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4), Integer(4), inner_shape=[Integer(2),Integer(2)])))
92
>>> len(list(StrongTableaux.standard_unmarked_iterator(Integer(4), Integer(4), outer_shape=[Integer(5),Integer(2),Integer(2),Integer(1)], inner_shape=[Integer(2),Integer(2)])))
10
```
class method \texttt{transpositions\_to\_standard\_strong}(\texttt{transeq}, k, emptyTableau=[]) 

Return a strong tableau corresponding to a sequence of transpositions.

This method returns the action by left multiplication on the empty strong tableau by transpositions specified by \texttt{transeq}.

INPUT:

• \texttt{transeq} – a sequence of transpositions \(t_{ij}\) (a list of pairs).

• \texttt{emptyTableau} – (default: []) an empty list or a skew strong tableau possibly consisting of None entries

OUTPUT:

• a \texttt{StrongTableau} object

EXAMPLES:

\begin{verbatim}
sage: StrongTableaux.transpositions_to_standard_strong([[0,1]], 2)
[[1]]
sage: StrongTableaux.transpositions_to_standard_strong([[-2,-1], [2,3]], 2, ...
        -> [[None, None]])
[[None, None, -1, [1], [-2]]]
sage: StrongTableaux.transpositions_to_standard_strong([[2, 3], [1, 2], [0, ...
        -> 1]], 2)
[[1, -2, -3], [3]]
sage: StrongTableaux.transpositions_to_standard_strong([[-1, 0], [1, 2], [0, ...
        -> 1]], 2)
[[1, -2, 3], [-3]]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> StrongTableaux.transpositions_to_standard_strong([[Integer(0), ...
        -> Integer(1)]], Integer(2))
[[1]]

>>> StrongTableaux.transpositions_to_standard_strong([[-Integer(2), ...
        -> Integer(1)], [Integer(2), Integer(3)]], Integer(2), [[None, None]])
[[None, None, -1, [1], [-2]]]

>>> StrongTableaux.transpositions_to_standard_strong([[Integer(2), ...
        -> Integer(3)], [Integer(1), Integer(2)], [Integer(0), Integer(1)]],...
        -> Integer(2))
[[1, -2, -3], [3]]

>>> StrongTableaux.transpositions_to_standard_strong([[-Integer(1), ...
        -> Integer(0)], [Integer(1), Integer(2)], [Integer(0), Integer(1)]],...
        -> Integer(2))
[[1, -2, 3], [-3]]

>>> StrongTableaux.transpositions_to_standard_strong([[Integer(3), ...
        -> Integer(4)], [-Integer(1), Integer(0)], [Integer(1), Integer(2)]],...
        -> Integer(2), [[None]])

[[None, None, -1, 2, -3], [-2, 3]]
\end{verbatim}

\texttt{sage.combinat.k\_tableau.WeakTableau}(t, k, inner\_shape=[], representation='core')

This is the dispatcher method for the element class of weak \(k\)-tableaux.

Standard weak \(k\)-tableaux correspond to saturated chains in the weak order. There are three formulations of weak tableaux, one in terms of cores, one in terms of \(k\)-bounded partitions, and one in terms of factorizations of affine
Grassmannian elements. For semistandard weak $k$-tableaux, all letters of the same value have to satisfy the conditions of a horizontal strip. In the affine Grassmannian formulation this means that all factors are cyclically decreasing elements. For more information, see for example [LLMSSZ2013].

INPUT:

- $t$ – a weak $k$-tableau in the specified representation:
  - for the ‘core’ representation $t$ is a list of lists where each subtableaux should have a $k + 1$-core shape; None is allowed as an entry for skew weak $k$-tableaux
  - for the ‘bounded’ representation $t$ is a list of lists where each subtableaux should have a $k$-bounded shape; None is allowed as an entry for skew weak $k$-tableaux
  - for the ‘factorized_permutation’ representation $t$ is either a list of cyclically decreasing Weyl group elements or a list of reduced words of cyclically decreasing Weyl group elements; to indicate a skew tableau in this representation, inner_shape should be the inner shape as a $(k + 1)$-core

- $k$ – positive integer

- inner_shape – this entry is only relevant for the ‘factorized_permutation’ representation and specifies the inner shape in case the tableau is skew (default: [])

- representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

EXAMPLES:

Here is an example of a weak 3-tableau in core representation:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t.weight()
(2, 2, 2)
sage: type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

And now we give a skew weak 3-tableau in core representation:

```python
sage: ts = WeakTableau([[None, 1, 2, 3], [None, 2], [1]], 3)
sage: ts.shape()
([5, 2, 1], [1, 1])
sage: ts.weight()
(2, 2)
sage: type(ts)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

```python
>>> from sage.all import *

>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)], ...
[Integer(2), Integer(3), [Integer(3)]]], Integer(3))

>>> t.shape()
[5, 2, 1]

>>> t.weight()
(2, 2)

>>> type(t)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
```

```python
>>> from sage.all import *

>>> ts = WeakTableau([[None, Integer(1), Integer(2), Integer(2), Integer(3)]...
[None, Integer(2), [Integer(1)]]], Integer(3))
```

(continues on next page)
Next we create the analogue of the first example in bounded representation:

```python
sage: tb = WeakTableau([[1,1,2], [2,3], [3]], 3, representation="bounded")
sage: tb.shape()
[3, 2, 1]
sage: tb.weight()
(2, 2, 2)
sage: type(tb)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: tb.to_core_tableau()
[[1, 1, 2, 2, 3], [2, 3], [3]]
sage: t == tb.to_core_tableau()
True
```

And the analogue of the skew example in bounded representation:

```python
sage: tbs = WeakTableau([[None, 1, 2], [None, 2], [1]], 3, representation = "bounded")
sage: tbs.shape()
([3, 2, 1], [1, 1])
sage: tbs.weight()
(2, 2)
sage: tbs.to_core_tableau()
[[None, 1, 1, 2, 2], [None, 2], [1]]
sage: ts.to_bounded_tableau() == tbs
True
```
Finally we do the same examples for the factorized permutation representation:

\[
\texttt{from sage.all import *}\n\]
\[
\texttt{tf = WeakTableau([[Integer(2),Integer(0)],\}}\n\texttt{[Integer(3),Integer(2)],\}}\n\texttt{[Integer(1),\}}\n\texttt{Integer(0)]], Integer(3), representation = "factorized_\}
\texttt{ permutation")}\n\]
\[
\texttt{tf.shape()}\n\]
\[
\texttt{[5, 2, 1]}\n\]
\[
\texttt{tf.weight()}\n\]
\[
\texttt{(2, 2, 2)}\n\]
\[
\texttt{type(tf)}\n\]
\[
<\texttt{class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.\}
\texttt{element_class'>}\n\]
\[
\texttt{tf.to_core_tableau()} \equiv \texttt{t}\n\]
\[
\texttt{True}\n\]
\[
\texttt{tfs = WeakTableau([[Integer(0),Integer(3)],\}}\n\texttt{[Integer(2),Integer(1)]],\}}\n\texttt{Integer(3), inner_shape = [1,1], representation = \}
\texttt{"factorized_permutation'})}\n\]
\[
\texttt{tfs.shape()}\n\]
\[
\texttt{([5, 2, 1], [1, 1])}\n\]
\[
\texttt{tfs.weight()}\n\]
\[
\texttt{(2, 2)}\n\]
\[
\texttt{type(tfs)}\n\]
\[
<\texttt{class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.\}
\texttt{element_class'>}\n\]
\[
\texttt{tfs.to_core_tableau()}}\n\]
\[
\texttt{[None, 1, 1, 2, 2], [None, 2], [1]}\n\]

Another way to pass from one representation to another is as follows:
To test whether a given semistandard tableau is a weak \(k\)-tableau in the bounded representation, one can ask:

```python
def test_weak_tableau_k_representation():
    # Test cases
    tableau1 = Tableau([[1,1,2],[2,3],[3]])
    print(tableau1.is_k_tableau(3))  # True
    tableau2 = SkewTableau([[[None, 1, 2], [None, 2]], [1]])
    print(tableau2.is_k_tableau(3))  # True
    tableau3 = SkewTableau([[[None, 1, 1], [None, 2]], [2]])
    print(tableau3.is_k_tableau(3))  # False

def test_weak_tableau_k_representation():
    # Test cases
    tableau1 = Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3)]]).is_k_tableau(Integer(3))
    print(tableau1)  # True
    tableau2 = SkewTableau([[[None, Integer(1), Integer(2)], [None, Integer(2)]], [Integer(1)]]).is_k_tableau(Integer(3))
    print(tableau2)  # True
    tableau3 = SkewTableau([[[None, Integer(1), Integer(1)], [None, Integer(2)]], [Integer(2)]]).is_k_tableau(Integer(3))
    print(tableau3)  # False
```

---

**class sage.combinat.k_tableau.WeakTableau_abstract**

**Bases:** `ClonableList`

Abstract class for the various element classes of `WeakTableau`.

**intermediate_shapes()**

Return the intermediate shapes of `self`.

A (skew) tableau with letters 1, 2, ..., \(\ell\) can be viewed as a sequence of shapes, where the \(i\)-th shape is given by the shape of the subtableau on letters 1, 2, ..., \(i\). The output is the list of these shapes.

**EXAMPLES:**

```python
def example_intermediate_shapes():
    # Example
    tableau = WeakTableau([[1, 1, 2], [2, 3], [3]], 3)
    print(tableau.intermediate_shapes())  # [[], [2], [4, 1], [5, 2, 1]]
def example_intermediate_shapes():
    # Example
    tableau = Tableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),Integer(3)],[Integer(3)]]).intermediate_shapes()
    print(tableau)  # [[], [2], [4, 1], [5, 2, 1]]
```

(continues on next page)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

sage: t = WeakTableau([[1, 1, 1], [2, 2], [3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[1], [3], [3, 2], [3, 2, 1]]

sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

sage: t = WeakTableau([[0], [3], [2], [3]], Integer(3), inner_shape = [2], representation = 'factorized_permutation')
sage: t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.intermediate_shapes()
[[1], [2], [4, 1], [5, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)], [Integer(1), Integer(4)], Integer(3)]), Integer(3))
>>> t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3)], [Integer(2)], [Integer(3)]], Integer(3), representation = 'bounded')
>>> t.intermediate_shapes()
[[1], [3], [3, 2], [3, 2, 1]]

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4), Integer(3)]], Integer(3), representation = 'bounded')
>>> t.intermediate_shapes()
[[2], [3], [3, 1], [3, 1, 1], [3, 2, 1]]

>>> t = WeakTableau([[Integer(0)], [Integer(3)], [Integer(2)], [Integer(3)]], Integer(3), inner_shape = [Integer(2)], representation = 'factorized_permutation')
>>> t.intermediate_shapes()
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]

PP()
Return a pretty print string of the tableau.

EXAMPLES:

sage: t = WeakTableau([[None, 1, 1, 2, 2], [None, 2], [1]], 3)
sage: t.pp()
. 1 1 2 2
 . 2
1

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.pp()
[s2*s0, s3*s2]
```

```python
>>> from sage.all import *

>>> t = WeakTableau([[None, Integer(1), Integer(1), Integer(2), Integer(2), Integer(2), Integer(2)],
                   [None, Integer(2)], [Integer(1)], Integer(3))

>>> t.pp()
1 1 2 2
2
1
```

```python
>>> t = WeakTableau([[Integer(2),Integer(0)], [Integer(3),Integer(2)], Integer(3), inner_shape = [Integer(2)], representation = 'factorized_permutation'))

>>> t.pp()
[s2*s0, s3*s2]
```

**representation**(representation='core')
Return the analogue of self in the specified representation.

**INPUT:**

- representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.parent()._representation
'core'
sage: t.representation(bounded)
[[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]]
sage: t.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: tb = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4,
                    representation = 'bounded')
sage: tb.parent()._representation
'bounded'
sage: tb.representation('core') == t
True
sage: tb.representation('factorized_permutation')
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]
sage: tp = WeakTableau([[0], [3,1], [2,1], [0,4], [3,0], [4,2], [1,0]], 4,
                    representation = 'factorized_permutation')
sage: tp.parent()._representation
'factorized_permutation'
sage: tp.representation('core') == t
True
sage: tp.representation('bounded') == tb
True
```

(continues on next page)
shape()

Return the shape of self.

When the tableau is straight, the outer shape is returned. When the tableau is skew, the tuple of the outer and inner shape is returned.

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape()
[5, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape()
([5, 2, 1], [2])
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape()
[3, 2, 1]
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.shape()
([3, 2, 1], [2])
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
```
size()

Return the size of the shape of self.

In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

See also:
sage.combinat.core.Core.length()

EXAMPLES:

```python
sage: t = WeakTableau([[None, None, 1], [Integer(2), Integer(4)]], Integer(3), representation = 'factorized_permutation')
sage: t.shape()
([3, 2, 1], [2])
```
weight()

Return the weight of self.

The weight is a tuple whose $i$-th entry is the number of labels $i$ in the bounded representation of self.

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.weight()
(1, 1, 1)
sage: t = WeakTableau([[None, 2, 3], [3]], 2)
sage: t.weight()
(0, 1, 1)
sage: t = WeakTableau([[1, 1, 1], [2, 2], [3]], 3, representation = 'bounded')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation = 'bounded')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.weight()
(1, 1, 1)
sage: t = WeakTableau([[2], [0, 3], [2, 1, 0]], 3, representation = 'factorized_permutation')
sage: t.weight()
(3, 2, 1)
sage: t = WeakTableau([[2, 0], [3, 2], [1, 0]], 3, representation = 'factorized_permutation')
sage: t.weight()
(2, 2, 2)
sage: t = WeakTableau([[2, 0], [3, 2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.weight()
(3, 2, 1)
```
from sage.all import *

>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),
                  Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))

>>> t.weight()
(2, 2, 2)

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],
                  [Integer(1), Integer(4)], [Integer(2)]], Integer(3))

>>> t.weight()
(1, 1, 1, 1)

>>> t = WeakTableau([[None, Integer(2), Integer(3)],[Integer(3)]], Integer(2))

>>> t.weight()
(0, 1, 1)

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(1)],[Integer(2),
                  Integer(2)],[Integer(3)]], Integer(3), representation = 'bounded')

>>> t.weight()
(3, 2, 1)

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],[Integer(2),
                  Integer(3)],[Integer(3)]], Integer(3), representation = 'bounded')

>>> t.weight()
(2, 2, 2)

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],
                  [Integer(3)]]), Integer(3), representation = 'bounded')

>>> t.weight()
(1, 1, 1, 1)

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
                  [Integer(1),Integer(0)]], Integer(3), representation = 'factorized_permutation')

>>> t.weight()
(3, 2, 1)

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
                  [Integer(1),Integer(0)]], Integer(3), representation = 'factorized_permutation')

>>> t.weight()
(2, 2, 2)

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],
                  [Integer(3)], inner_shape = [Integer(2)], representation = 'factorized_permutation')

>>> t.weight()
(2, 2)

class sage.combinat.k_tableau.WeakTableau_bounded(parent, t):

    Bases: WeakTableau_abstract

    A (skew) weak k-tableau represented in terms of k-bounded partitions.

    check()

    Check that self is a valid weak k-tableau.

    EXAMPLES:

    sage: t = WeakTableau([[1,1],[2]], 2, representation = 'bounded')
    sage: t.check()
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.check()

>>> from sage.all import *
>>> t = WeakTableau([[Integer(1),Integer(1)], [Integer(2)]], Integer(2),
representation = 'bounded')
>>> t.check()

>>> t = WeakTableau([[None, None, Integer(1)], [Integer(2), Integer(4)],
[Integer(3)]], Integer(3), representation = 'bounded')

classmethod from_core_tableau(t, k)
Construct weak \( k \)-bounded tableau from \( k \)-core tableau.

EXAMPLES:

sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: WeakTableau_bounded.from_core_tableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
[[1, 1, 2], [2, 3], [3]]

sage: WeakTableau_bounded.from_core_tableau([[None, None, 2, 3, 4], [1, 4],
[2]], 2)
[[None, None, 3], [1, 4], [2]]

sage: WeakTableau_bounded.from_core_tableau([[None, Integer(2), Integer(3)],
[Integer(3)]], Integer(2))
[[None, 2], [3]]

k_charge(algorithm='I')
Return the \( k \)-charge of self.

INPUT:

- `algorithm` – (default: “I”) if “I”, computes \( k \)-charge using the \( I \) algorithm, otherwise uses the \( J \)-algorithm

OUTPUT:

- a nonnegative integer

For the definition of \( k \)-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].
Combinatorics, Release 10.4

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2], [2, 3], [3]], 3, representation = 'bounded')
sage: t.k_charge()
2
sage: t = WeakTableau([[1, 3, 5], [2, 6], [4]], 3, representation = 'bounded')
sage: t.k_charge()
8
sage: t = WeakTableau([[1, 1, 2, 4], [2, 3, 5], [3, 4], [5, 6], [6], [7]], 4, representation = bounded)
sage: t.k_charge()
12
```

```python
>>> from sage.all import *

>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3), representation = bounded)
```

```python
shape_bounded()  

Return the shape of self as \( k \)-bounded partition. 

When the tableau is straight, the outer shape is returned as a \( k \)-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as \( k \)-bounded partitions.

EXAMPLES:

```python
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_bounded()
[3, 2, 1]
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

```python
>>> from sage.all import *

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)], [Integer(2)], [Integer(3)]], Integer(3), representation = 'bounded')
```

```python
shape_core()  

```
Return the shape of `self` as \((k + 1)\)-core.

When the tableau is straight, the outer shape is returned as a \((k + 1)\)-core. When the tableau is skew, the tuple of the outer and inner shape is returned as \((k + 1)\)-cores.

**EXAMPLES:**

```
sage: t = WeakTableau([[1,1,1],[2,2],[3]], 3, representation = 'bounded')
sage: t.shape_core()
[5, 2, 1]
```

```
sage: t = WeakTableau([[None, None, 1], [2, 4], [3]], 3, representation = 'bounded')
sage: t.shape_core()
([5, 2, 1], [2])
```

**to_core_tableau()**

Return the weak \(k\)-tableau `self` where the shape of each restricted tableau is a \((k + 1)\)-core.

**EXAMPLES:**

```
sage: t = WeakTableau([[1,1,2,4],[2,3,5],[3,4],[5,6],[6],[7]], 4, representation = 'bounded')
sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>
sage: t = WeakTableau([], 4, representation = 'bounded')
sage: t.to_core_tableau()
[]
```

```
sage: from sage.combinat.k_tableau import WeakTableau_bounded
sage: t = WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
[[1, 1, 2], [2, 3], [3]]
sage: t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True
```

```
sage: t = WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),3)
True
```
```python
>>> from sage.all import *

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2),Integer(4)],
                   [Integer(2),Integer(3),Integer(5)],[Integer(3),Integer(4)],
                   [Integer(5),[Integer(6),[Integer(7)]]], Integer(4), representation =
                   'bounded')

>>> c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]

>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>

>>> t = WeakTableau([], Integer(4), representation = 'bounded')

>>> t.to_core_tableau()
[]

>>> from sage.combinat.k_tableau import WeakTableau_bounded

>>> t = WeakTableau([[Integer(1),Integer(1),Integer(2)],
                   [Integer(2)],
                   [Integer(3)]]), Integer(3), representation = 'bounded')

>>> WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
[[1, 1, 2], [2, 4], [3]]

>>> t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
True

>>> t = WeakTableau([[None, None, 1, 2, 4], [2, 4], [3]]), Integer(3), representation = 'bounded')

>>> t.to_core_tableau()
[[None, None, 1, 2, 4], [2, 4], [3]]

>>> t == WeakTableau_bounded.from_core_tableau(t.to_core_tableau(),Integer(3))
True
```

```python
class sage.combinat.k_tableau.WeakTableau_core(parent, t)
Bases: WeakTableau_abstract

A (skew) weak \( k \)-tableau represented in terms of \((k+1)\)-cores.

def check()
    Check that self is a valid weak \( k \)-tableau.

    EXAMPLES:

    sage: t = WeakTableau([[1, 1, 2], [2]], 2)
    sage: t.check()
    sage: t = WeakTableau([[None, None, 1, 2, 4], [2, 4], [3]], 3)
    sage: t.check()
```

dictionary_of_coordinates_at_residues(v)

Return a dictionary assigning to all residues of self with label \( v \) a list of cells with the given residue.

INPUT:

- \( v \) – a label of a cell in self
```
OUTPUT:

- dictionary assigning coordinates in self to residues

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.dictionary_of_coordinates_at_residues(3)
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}

sage: t = WeakTableau([[None, None, 1, 1, 4], [1, 4], [3]], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}

sage: t = WeakTableau([], 3)
sage: t.dictionary_of_coordinates_at_residues(1)
{}
```

```python
>>> from sage.all import *

>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2),
    \rightarrow Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(3))
{0: [(0, 4), (1, 1)], 2: [(2, 0)]}

>>> t = WeakTableau([[None, None, Integer(1), Integer(1), Integer(4)],
    \rightarrow [Integer(1), Integer(4)], [Integer(3)]], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(1))
{2: [(0, 2)], 3: [(0, 3), (1, 0)]}

>>> t = WeakTableau([], Integer(3))
>>> t.dictionary_of_coordinates_at_residues(Integer(1))
{}
```

**k_charge** *(algorithm='I')*

Return the $k$-charge of self.

INPUT:

- **algorithm** – (default: “I”) if “I”, computes $k$-charge using the $I$ algorithm, otherwise uses the $J$-algorithm

OUTPUT:

- a nonnegative integer

For the definition of $k$-charge and the various algorithms to compute it see Section 3.3 of [LLMSSZ2013].

See also:

- *k_charge_I() and k_charge_J()*

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge()
2

sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge()
8

sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
```
k_charge_I()

Return the $k$-charge of self using the $I$-algorithm.

For the definition of $k$-charge and the $I$-algorithm see Section 3.3 of [LLMSSZ2013].

OUTPUT:

- a nonnegative integer

See also:

$k_charge()$ and $k_charge_J()$

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_I()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_I()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.k_charge_I()
12
```
k\_charge\_J()  
Return the $k$-charge of self using the $J$-algorithm.

For the definition of $k$-charge and the $J$-algorithm see Section 3.3 of [LLMSSZ2013].

OUTPUT:
- a nonnegative integer

See also:
- $k\_charge()$ and $k\_charge\_I()$

EXAMPLES:

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.k_charge_J()
2
sage: t = WeakTableau([[1, 3, 4, 5, 6], [2, 6], [4]], 3)
sage: t.k_charge_J()
8
sage: t = WeakTableau([[1, 1, 2, 3, 4, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.k_charge_J()
12
```

```python
>>> from sage.all import *
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)], [Integer(3)]], Integer(3))
>>> t.k_charge_J()
2
>>> t = WeakTableau([[Integer(1), Integer(3), Integer(4), Integer(5), Integer(6)], [Integer(2), Integer(6)], [Integer(4)]], Integer(3))
>>> t.k_charge_J()
8
>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(3), Integer(4), Integer(4), Integer(5), Integer(5), Integer(6)], [Integer(2), Integer(3), Integer(5), Integer(5), Integer(6)], [Integer(3), Integer(4), Integer(7)], [Integer(5), Integer(6)], [Integer(6)], [Integer(7)]], Integer(4))
>>> t.k_charge_J()
12
```

list\_of\_standard\_cells()  
Return a list of lists of the coordinates of the standard cells of self.

INPUT:
- self - a weak $k$-tableau in core representation with partition weight

OUTPUT:
- a list of lists of coordinates
**Warning:** This method currently only works for straight weak tableaux with partition weight.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.list_of_standard_cells()
[[0, 1, 0, 2, 0], [0, 0, 2, 1, 1]]
sage: t = WeakTableau([[1, 1, 2, 3], [2, 3], [3]], 5)
sage: t.list_of_standard_cells()
[[0, 1, 2], [0, 0, 3], [0, 0, 4]]
sage: t = WeakTableau([[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4)
sage: t.list_of_standard_cells()
[[0, 1, 2, 0, 0, 3, 0, 0, 4, 0, 0, 5, 0, 0, 6, 0, 0, 7], [0, 0, 2, 1, 1, 2, 1, 2, 3, 1]]
```
shape_bounded()

Return the shape of self as a $k$-bounded partition.

When the tableau is straight, the outer shape is returned as a $k$-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as $k$-bounded partitions.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape_bounded()
[3, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of self as a $(k+1)$-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: t.shape_core()
[5, 2, 1]
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: t.shape_core()
([5, 2, 1], [2])
```
Combinatorics, Release 10.4

(continued from previous page)

>>> t = WeakTableau([[[None, None, Integer(2), Integer(3), Integer(4)],...
    ...
>>> t.shape_core()
[[5, 2, 1], [2]]

**to_bounded_tableau()**

Return the bounded representation of the weak $k$-tableau `self`. Each restricted subtableau of the output is a $k$-bounded partition.

**EXAMPLES:**

```python
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: c = t.to_bounded_tableau(); c
[[1, 1, 2], [2, 3], [3]]
sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_bounded_with_category.element_class'>
sage: t = WeakTableau([[[None, None, 2, 3, 4], [1, 4], [2]], 3]
sage: t.to_bounded_tableau()
[[None, None, 3], [1, 4], [2]]
sage: t.to_bounded_tableau().to_core_tableau() == t
True
```

```python
>>> from sage.all import *

```(continues on next page)
sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]
sage: c._inner_shape
[2]
sage: c.to_core_tableau() == t
True

>>> from sage.all import *

>>> t = WeakTableau([[Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)],
                   [Integer(2), Integer(3)], [Integer(3)]], Integer(3))

>>> c = t.to_factorized_permutation_tableau(); c
[s2*s0, s3*s2, s1*s0]

>>> type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_factorized_permutation_with_category.element_class'>

>>> c.to_core_tableau() == t
True

>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],
                   [Integer(1), Integer(4)], [Integer(2)]], Integer(3))

>>> c = t.to_factorized_permutation_tableau(); c
[s0, s3, s2, s3]

>>> c._inner_shape
[2]

>>> c.to_core_tableau() == t
True

class sage.combinat.k_tableau.WeakTableau_factorized_permutation(parent, t)

Bases: WeakTableau_abstract

A weak (skew) $k$-tableau represented in terms of factorizations of affine permutations into cyclically decreasing elements.

check()

Check that self is a valid weak $k$-tableau.

EXAMPLES:

sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.check()

>>> from sage.all import *

>>> t = WeakTableau([[Integer(2)],[Integer(0),Integer(3)],[Integer(2),
                   Integer(1),Integer(0)]], Integer(3), representation = 'factorized_permutation')

>>> t.check()

classmethod from_core_tableau(t, k)

Construct weak factorized affine permutation tableau from a $k$-core tableau.

EXAMPLES:

sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.from_core_tableau([[1, 1, 2, 2, 3],
... (continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

\[ \rightarrow [2, 3], [3] \]
\[ s_2 s_0, s_3 s_2, s_1 s_0 \]
\[ \text{sage: WeakTableau\_factorized\_permutation\_from\_core\_tableau([[1, 1, 2, 3, 4, 4,} \]
\[ \rightarrow 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]], 4) \]
\[ [s_0, s_3 s_1, s_2 s_1, s_0 s_4, s_3 s_0, s_4 s_2, s_1 s_0] \]
\[ \text{sage: WeakTableau\_factorized\_permutation\_from\_core\_tableau([[None, i, 1, 2,} \]
\[ \rightarrow 2], [None, 2], [1]], 3) \]
\[ [s_0 s_3, s_2 s_1] \]

\[ \text{from sage.all import *} \]
\[ \text{from sage.combinat.k\_tableau import WeakTableau\_factorized\_permutation} \]
\[ \text{from WeakTableau\_factorized\_permutation\_from\_core\_tableau([[Integer(1),} \]
\[ \rightarrow Integer(2), Integer(2), Integer(3)], [Integer(2), Integer(3)],} \]
\[ \rightarrow [Integer(3)]], Integer(3)) \]
\[ [s_2 s_0, s_3 s_2, s_1 s_0] \]
\[ \text{WeakTableau\_factorized\_permutation\_from\_core\_tableau([[Integer(1),} \]
\[ \rightarrow Integer(2), Integer(3), Integer(4), Integer(4), Integer(5),} \]
\[ \rightarrow Integer(5), Integer(6)], [Integer(2), Integer(3), Integer(5), Integer(5),} \]
\[ \rightarrow Integer(6)], [Integer(3), Integer(4), Integer(7)], [Integer(5), Integer(6)],} \]
\[ \rightarrow [Integer(6)], [Integer(7)]], Integer(4)) \]
\[ [s_0, s_3 s_1, s_2 s_1, s_0 s_4, s_3 s_0, s_4 s_2, s_1 s_0] \]
\[ \text{WeakTableau\_factorized\_permutation\_from\_core\_tableau([[None, Integer(1),} \]
\[ \rightarrow Integer(1), Integer(2), Integer(2)], [None, Integer(2)], [Integer(1)],} \]
\[ \rightarrow Integer(3)) \]
\[ [s_0 s_3, s_2 s_1] \]

**k\_charge (algorithm='I')**

Return the $k$-charge of self.

OUTPUT:

- a nonnegative integer

EXAMPLES:

\[ \text{sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized\_} \]
\[ \rightarrow \text{permutation')} \]
\[ \text{sage: t.k\_charge()} \]
\[ 2 \]
\[ \text{sage: t = WeakTableau([[0],[3],[2],[1],[3],[0]], 3, representation =} \]
\[ \rightarrow 'factorized\_permutation') \]
\[ \text{sage: t.k\_charge()} \]
\[ 8 \]
\[ \text{sage: t = WeakTableau([[0],[3,1],[2,1],[0,4],[3,0],[4,2],[1,0]], 4,} \]
\[ \rightarrow \text{representation = 'factorized\_permutation'}) \]
\[ \text{sage: t.k\_charge()} \]
\[ 12 \]

\[ \text{from sage.all import *} \]
\[ \text{from WeakTableau\_factorized\_permutation\_from\_core\_tableau([[Integer(2),} \]
\[ \rightarrow Integer(0)], [Integer(3), Integer(2)],} \]
\[ \rightarrow [Integer(1), Integer(0)]], Integer(3), representation = 'factorized\_} \]
\[ \rightarrow \text{permutation') \]
\[ \text{t.k\_charge()} \]
\[ 2 \]
\[ \text{t = WeakTableau([[Integer(0)], [Integer(3)], [Integer(2)],} \]
\[ \rightarrow [Integer(1)], [Integer(3)], [Integer(0)]], Integer(3), representation = 'factorized\_} \]
\[ \rightarrow \text{permutation'}) \]
shape_bounded()

Return the shape of self as a \( k \)-bounded partition.

When the tableau is straight, the outer shape is returned as a \( k \)-bounded partition. When the tableau is skew, the tuple of the outer and inner shape is returned as \( k \)-bounded partitions.

EXAMPLES:

```python
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.shape_bounded()
[3, 2, 1]

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.shape_bounded()
([3, 2, 1], [2])
```

shape_core()

Return the shape of self as a \( (k + 1) \)-core.

When the tableau is straight, the outer shape is returned as a core. When the tableau is skew, the tuple of the outer and inner shape is returned as cores.

EXAMPLES:

```python
sage: t = WeakTableau([[2],[0,3],[2,1,0]], 3, representation = 'factorized_permutation')
sage: t.shape_core()
[5, 2, 1]

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')
sage: t.shape()
([5, 2, 1], [2])
```
Combinatorics, Release 10.4

>>> from sage.all import *
>>> t = WeakTableau([[Integer(2)], [Integer(0), Integer(3)], [Integer(2),
\rightarrow Integer(1), Integer(0)]], Integer(3), representation = 'factorized_
\rightarrow permutation')
>>> t.shape_core()
[5, 2, 1]

>>> t = WeakTableau([[Integer(2), Integer(0)], [Integer(3), Integer(2)]],
\rightarrow Integer(3), inner_shape = [Integer(2)], representation = 'factorized_
\rightarrow permutation')
>>> t.shape()
([5, 2, 1], [2])

static straighten_input(t, k)
Straightens input.

INPUT:

• t – a list of reduced words or a list of elements in the Weyl group of type A_{k}^{(1)}

• k – a positive integer

EXAMPLES:

sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: WeakTableau_factorized_permutation.straighten_input([[2, 0], [3, 2], [1, 0]],
\rightarrow 3)
(s2*s0, s3*s2, s1*s0)

sage: W = WeylGroup(['A', 4, 1])

sage: WeakTableau_factorized_permutation.straighten_input([[W.an_element(), W.
\rightarrow an_element()]], 4)
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)

>>> from sage.all import *
>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation

>>> WeakTableau_factorized_permutation.straighten_input([[Integer(2),
\rightarrow Integer(0)], [Integer(3), Integer(2)]], Integer(3), inner_shape = [Integer(2)],
\rightarrow representation = 'factorized_permutation')

>>> W = WeylGroup(['A', Integer(4), Integer(1)])

>>> WeakTableau_factorized_permutation.straighten_input([[W.an_element(), W.an_
\rightarrow element()]], Integer(4))
(s0*s1*s2*s3*s4, s0*s1*s2*s3*s4)

to_core_tableau()
Return the weak k-tableau self where the shape of each restricted tableau is a (k+1)-core.

EXAMPLES:

sage: t = WeakTableau([[0], [3, 1], [2, 1], [0, 4], [3, 0], [4, 2], [1, 0]], 4,
\rightarrow representation = 'factorized_permutation'); t
[s0, s3*s1, s2*s1, s0*s4, s3*s0, s4*s2, s1*s0]

sage: c = t.to_core_tableau(); c
[[1, 1, 2, 3, 4, 4, 5, 5, 6], [2, 3, 5, 5, 6], [3, 4, 7], [5, 6], [6], [7]]

sage: type(c)
<class 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'
\rightarrow 'sage.combinat.k_tableau.WeakTableaux_core_with_category.element_class'>

sage: t = WeakTableau([], 4, representation = 'factorized_permutation'); t
[1]

(continues on next page)
sage: t.to_core_tableau()
[]

sage: from sage.combinat.k_tableau import WeakTableau_factorized_permutation
sage: t = WeakTableau([[2,0],[3,2],[1,0]], 3, representation = 'factorized_permutation')

sage: WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)
[s2*s0, s3*s2, s1*s0]

sage: t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), 3)  
True

sage: t = WeakTableau([[2,0],[3,2]], 3, inner_shape = [2], representation = 'factorized_permutation')

sage: t.to_core_tableau()
[[None, None, 1, 1, 2], [1, 2], [2]]

>>> t.to_core_tableau()
[]

>>> from sage.combinat.k_tableau import WeakTableau_factorized_permutation

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)],
Integer(1),Integer(0)]], Integer(3), representation = 'factorized_permutation')

>>> WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(),
Integer(3))
[s2*s0, s3*s2, s1*s0]

>>> t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), Integer(3))  
True

>>> t = WeakTableau([[Integer(2),Integer(0)],[Integer(3),Integer(2)]],
Integer(3), inner_shape = [Integer(2)], representation = 'factorized_permutation')

>>> t.to_core_tableau()
[[None, None, 1, 1, 2], [1, 2], [2]]

>>> t == WeakTableau_factorized_permutation.from_core_tableau(t.to_core_tableau(), Integer(3))  
True
Combinatorics, Release 10.4

sage.combinat.k_tableau.WeakTableaux \( (k, \text{shape}, \text{weight}, \text{representation}='\text{core}') \)

This is the dispatcher method for the parent class of weak \( k \)-tableaux.

**INPUT:**

- \( k \) – positive integer
- \( \text{shape} \) – shape of the weak \( k \)-tableaux; for the ‘core’ and ‘factorized_permutation’ representation, the shape is inputted as a \( (k+1) \)-core; for the ‘bounded’ representation, the shape is inputted as a \( k \)-bounded partition; for skew tableaux, the shape is inputted as a tuple of the outer and inner shape
- \( \text{weight} \) – the weight of the weak \( k \)-tableaux as a list or tuple
- \( \text{representation} \) – 'core', 'bounded', or 'factorized_permutation' (default: 'core')

**EXAMPLES:**

```
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1])
sage: T.list()
[[[1, 3, 4, 5, 6], [2, 6], [4]],
 [[1, 2, 4, 5, 6], [3, 6], [4]],
 [[1, 2, 3, 4, 6], [4, 6], [5]],
 [[1, 2, 3, 4, 5], [4, 5], [6]]]
sage: T.cardinality()
4

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])
sage: T.list()
[[None, None, 2, 3, 4], [1, 4], [2]],
 [[None, None, 1, 2, 4], [2, 4], [3]],
 [[None, None, 1, 2, 3], [2, 3], [4]]]

sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.list()
[[[1, 3, 5], [2, 6], [4]],
 [[1, 2, 5], [3, 6], [4]],
 [[1, 2, 3], [4, 6], [5]],
 [[1, 2, 3], [4, 5], [6]]]

sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[None, None, 3], [1, 4], [2]],
 [[None, None, 1], [2, 4], [3]],
 [[None, None, 1], [2, 3], [4]]]

sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1], representation = 'factorized_permutation')
sage: T.list()

class sage.combinat.k_tableau.WeakTableaux_abstract
Bases: UniqueRepresentation, Parent

Abstract class for the various parent classes of WeakTableaux.

representation (representation='core')

    Return the analogue of self in the specified representation.

    INPUT:
• representation – ‘core’, ‘bounded’, or ‘factorized_permutation’ (default: ‘core’)

EXAMPLES:

```python
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T._representation
'core'
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)
sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T._representation
'bounded'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)
sage: T.representation('bounded') == T
True
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation') == T
False
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1], representation = 'factorized_permutation')
sage: T._representation
'factorized_permutation'
sage: T.representation('core')
Core weak 3-Tableaux of (skew) core shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)
sage: T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)
sage: T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)

>>> from sage.all import *

>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(1)],...
            [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])

>>> T._representation
'core'

>>> T.representation('bounded')
Bounded weak 3-Tableaux of (skew) 3-bounded shape [3, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)

>>> T.representation('factorized_permutation')
Factorized permutation (skew) weak 3-Tableaux of shape [5, 2, 1] and weight (1, 1, 1, 1, 1, 1, 1)

>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(2),Integer(1)],...
            [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)])
>>> T._representation
'factorized_permutation'
```

(continues on next page)
shape ()

Return the shape of the tableaux of self.

When self is the class of straight tableaux, the outer shape is returned. When self is the class of skew tableaux, the tuple of the outer and inner shape is returned.

Note that in the 'core' and 'factorized_permutation' representation, the shapes are \((k+1)\)-cores. In the 'bounded' representation, the shapes are \(k\)-bounded partitions.

If the user wants to access the skew shape (even if the inner shape is empty), please use \(self._shape\).

EXAMPLES:

```python
sage: T = WeakTableaux(3, [5,2,2], [2,2,2,1])
sage: T.shape()
[5, 2, 2]
sage: T._shape
([5, 2, 2], [])
sage: T = WeakTableaux(3, [[5,2,2], [1]], [2,1,2,1])
sage: T.shape()
([[5, 2, 2], [1]])
sage: T = WeakTableaux(3, [3,2,2], [2,2,2,1], representation = 'bounded')
sage: T.shape()
[3, 2, 2]
```
```python
sage: T._shape
([3, 2, 2], [])
sage: T = WeakTableaux(3, [[3, 2, 2], [1]], [2, 1, 1, 1], representation = 'bounded')
sage: T.shape()
([3, 2, 2], [1])
sage: T = WeakTableaux(3, [4, 1], [2, 2], representation = 'factorized_permutation')
sage: T.shape()
([4, 1], [])
sage: T = WeakTableaux(4, [[6, 2, 1], [2]], [2, 1, 1, 1], representation = 'factorized_permutation')
sage: T.shape()
([6, 2, 1], [2])
```

```python
>>> from sage.all import *

>>> T = WeakTableaux(Integer(3), [Integer(5), Integer(2), Integer(2)], Integer(2), Integer(2), Integer(1))

>>> T.shape()
([5, 2, 2], [1])

>>> T = WeakTableaux(Integer(3), [Integer(3), Integer(2), Integer(2)], Integer(2), Integer(2), Integer(1), Integer(1))

>>> T.shape()
([3, 2, 2], [1])
```

```
>>> T = WeakTableaux(Integer(3), [Integer(3), Integer(2), Integer(2)], [Integer(2), Integer(2), Integer(2), Integer(2), Integer(1)], representation = 'bounded')

>>> T.shape()
([3, 2, 2], [1])
```

```
>>> T = WeakTableaux(Integer(4), [Integer(6), Integer(2), Integer(1)], [Integer(2), Integer(2), Integer(1), Integer(1), Integer(1)], representation = 'factorized_permutation')

>>> T.shape()
([6, 2, 1], [2])
```
In the bounded representation, the size of the shape is the number of boxes in the outer shape minus the number of boxes in the inner shape. For the core and factorized permutation representation, the size is the length of the outer shape minus the length of the inner shape.

**EXAMPLES:**

```python
sage: T = WeakTableaux(3, [5,2,1], [1,1,1,1,1,1])
sage: T.size()
6
sage: T = WeakTableaux(3, [3,2,1], [1,1,1,1,1,1], representation = 'bounded')
sage: T.size()
6
sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], 'factorized_permutation')
sage: T.size()
5
```

```python
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(5),Integer(2),Integer(1)],
                   [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)]
>>> T.size()
6
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(2),Integer(1)],
                   [Integer(1),Integer(1),Integer(1),Integer(1),Integer(1),Integer(1)],
                   representation = 'bounded')
>>> T.size()
6
>>> T = WeakTableaux(Integer(4), [[Integer(6),Integer(2),Integer(1)],
                                [Integer(2)]], [Integer(2),Integer(1),Integer(1),Integer(1),Integer(1)], 'factorized_permutation')
>>> T.size()
5
```

class `sage.combinat.k_tableau.WeakTableaux_bounded`(k, shape, weight)

The class of (skew) weak \(k\)-tableaux in the bounded representation of shape \(shape\) (as \(k\)-bounded partition or tuple of \(k\)-bounded partitions in the skew case) and weight \(weight\).

**INPUT:**

- \(k\) – positive integer
- \(shape\) – the shape of the \(k\)-tableaux represented as a \(k\)-bounded partition; if the tableaux are skew, the shape is a tuple of the outer and inner shape each represented as a \(k\)-bounded partition
- \(weight\) – the weight of the \(k\)-tableaux

**EXAMPLES:**

```python
sage: T = WeakTableaux(3, [3,1], [2,2], representation = 'bounded')
sage: T.list()
[[[1, 1, 2], [2]]]
sage: T = WeakTableaux(3, [[3,2,1], [2]], [1,1,1,1], representation = 'bounded')
sage: T.list()
[[[None, None, 3], [1, 4], [2]],
 [[None, None, 1], [2, 4], [3]],
 [[None, None, 1], [2, 3], [4]]]
```
>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(3),Integer(1)], [Integer(2),Integer(2)],
      representation = 'bounded')
>>> T.list()
[[[1, 1, 2], [2]]]

>>> T = WeakTableaux(Integer(3), [[Integer(3),Integer(2),Integer(1)],
      [Integer(2)]], [Integer(1),Integer(1),Integer(1),Integer(1)],
      representation = 'bounded')
>>> T.list()
[[[None, None, 3], [1, 4], [2]],
 [[None, None, 1], [2, 4], [3]],
 [[None, None, 1], [2, 3], [4]]]

Element
     alias of WeakTableau_bounded

class sage.combinat.k_tableau.WeakTableaux_core (k, shape, weight)
     Bases: WeakTableaux_abstract
     The class of (skew) weak k-tableaux in the core representation of shape shape (as k+1-core) and weight weight.
     INPUT:
     • k – positive integer
     • shape – the shape of the k-tableaux represented as a (k + 1)-core; if the tableaux are skew, the shape is a
tuple of the outer and inner shape (both as (k + 1)-cores)
     • weight – the weight of the k-tableaux
     EXAMPLES:

sage: T = WeakTableaux(3, [4,1], [2,2])
sage: T.list()
[[[1, 1, 2, 2], [2]]]

sage: T = WeakTableaux(3, [[5,2,1], [2]], [1,1,1,1])
sage: T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
 [[None, None, 1, 2, 4], [2, 4], [3]],
 [[None, None, 1, 2, 3], [2, 3], [4]]]

>>> from sage.all import *
>>> T = WeakTableaux(Integer(3), [Integer(4),Integer(1)], [Integer(2),Integer(2)])
>>> T.list()
[[[1, 1, 2, 2], [2]]]

>>> T = WeakTableaux(Integer(3), [[Integer(5),Integer(2),Integer(1)],
      [Integer(2)]], [Integer(1),Integer(1),Integer(1),Integer(1)])
>>> T.list()
[[[None, None, 2, 3, 4], [1, 4], [2]],
 [[None, None, 1, 2, 4], [2, 4], [3]],
 [[None, None, 1, 2, 3], [2, 3], [4]]]

Element
     alias of WeakTableau_core
**circular_distance**(cr, r)
Return the shortest counterclockwise distance between cr and r modulo k + 1.

**INPUT:**
- cr, r – nonnegative integers between 0 and k

**OUTPUT:**
- a positive integer

**EXAMPLES:**

```python
sage: T = WeakTableaux(10, [], [])
sage: T.circular_distance(8, 6)
2
sage: T.circular_distance(8, 8)
0
sage: T.circular_distance(8, 9)
10
```

```python
>>> from sage.all import *

>>> T = WeakTableaux(Integer(10), [], [])

>>> T.circular_distance(Integer(8), Integer(6))
2

>>> T.circular_distance(Integer(8), Integer(8))
0

>>> T.circular_distance(Integer(8), Integer(9))
10
```

**diag**(c, ha)
Return the number of diagonals strictly between cells c and ha of the same residue as c.

**INPUT:**
- c – a cell in the lattice
- ha – another cell in the lattice with bigger row and smaller column than c

**OUTPUT:**
- a nonnegative integer

**EXAMPLES:**

```python
sage: T = WeakTableaux(4, [5,2,2], [2,2,2,1])
sage: T.diag((1,2),(4,0))
0
```

```python
>>> from sage.all import *

>>> T = WeakTableaux(Integer(4), [Integer(5),Integer(2),Integer(2)],
...                   [Integer(2),Integer(2),Integer(2),Integer(1)])

>>> T.diag((Integer(1),Integer(2)),(Integer(4),Integer(0)))
0
```

class sage.combinat.k_tableau.WeakTableaux_factorized_permutation(k, shape, weight)
Bases: WeakTableaux_abstract

The class of (skew) weak k-tableaux in the factorized permutation representation of shape shape (as k + 1-core or tuple of (k + 1)-cores in the skew case) and weight weight.

**INPUT:**
• $k$ – positive integer

• shape – the shape of the $k$-tableaux represented as a $(k+1)$-core; in the skew case the shape is a tuple of the outer and inner shape both as $(k+1)$-cores

• weight – the weight of the $k$-tableaux

EXAMPLES:

```python
sage: T = WeakTableaux(3, [4,1], [2,2], representation = 'factorized_permutation')
sage: T.list()
[[s3*s2, s1*s0]]

sage: T = WeakTableaux(4, [[6,2,1], [2]], [2,1,1,1], representation = 'factorized_permutation')
sage: T.list()
[[s0, s4, s3, s4*s2], [s0, s3, s4, s3*s2], [s3, s0, s4, s3*s2]]
```

Element

alias of `WeakTableau_factorized_permutation`

`sage.combinat.k_tableau.intermediate_shapes(t)`

Return the intermediate shapes of tableau $t$.

A (skew) tableau with letters $1, 2, \ldots, \ell$ can be viewed as a sequence of shapes, where the $i$-th shape is given by the shape of the subtableau on letters $1, 2, \ldots, i$. The output is the list of these shapes.

OUTPUT:

• a list of lists representing partitions

EXAMPLES:

```python
sage: from sage.combinat.k_tableau import intermediate_shapes
sage: t = WeakTableau([[1, 1, 2, 2, 3], [2, 3], [3]], 3)
sage: intermediate_shapes(t)
[[], [2], [4, 3], [5, 2, 1]]

sage: t = WeakTableau([[None, None, 2, 3, 4], [1, 4], [2]], 3)
sage: intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```python
>>> from sage.all import *

>>> from sage.combinat.k_tableau import intermediate_shapes

>>> t = WeakTableau([Integer(1), Integer(1), Integer(2), Integer(2), Integer(3)], Integer(3))

>>> intermediate_shapes(t)  # (continues on next page)
```
\[
\begin{bmatrix}
[], [2], [4, 1], [5, 2, 1]
\end{bmatrix}
\]

```python
>>> t = WeakTableau([[None, None, Integer(2), Integer(3), Integer(4)],
                   [Integer(1), Integer(4)], [Integer(2)]], Integer(3))
```

```python
>>> intermediate_shapes(t)
[[2], [2, 1], [3, 1, 1], [4, 1, 1], [5, 2, 1]]
```

```python
sage.combinat.k_tableau.nabs(v)
```
Return the absolute value of \( v \) or None.

INPUT:

- \( v \) – either an integer or None

OUTPUT:

- either a non-negative integer or None

EXAMPLES:

```python
sage: from sage.combinat.k_tableau import nabs
sage: nabs(None)
```

```python
sage: nabs(-3)
3
```

```python
sage: nabs(None)
```

```python
>>> from sage.all import *
>>> from sage.combinat.k_tableau import nabs
```

```python
>>> nabs(None)
3
```

```python
>>> nabs(-Integer(3))
3
```

### 5.1.131 Kazhdan-Lusztig Polynomials

**AUTHORS:**

- Daniel Bump (2008): initial version
- Alan J.X. Guo (2014-03-18): \( R_{\tilde{t}}() \) method.

**class** `sage.combinat.kazhdan_lusztig.KazhdanLusztigPolynomial(W, q, trace=False)`

Bases: `UniqueRepresentation`, `SageObject`

A Kazhdan-Lusztig polynomial.

INPUT:

- \( W \) – a Weyl Group
- \( q \) – an indeterminate

OPTIONAL:

- \( \text{trace} \) – if True, then this displays the trace: the intermediate results. This is instructive and fun.

The parent of \( q \) may be a `PolynomialRing` or a `LaurentPolynomialRing`.

**EXAMPLES:**
A faster implementation (using the optional package Coxeter 3) is given by:

\[
P(x, y)
\]

Return the Kazhdan-Lusztig \( P \) polynomial.

If the rank is large, this runs slowly at first but speeds up as you do repeated calculations due to the caching.

INPUT:

- \( x, y \) – elements of the underlying Coxeter group

See also:

kazhdan_lusztig_polynomial for a faster implementation using Fokko Ducloux’s Coxeter3 C++ library.

EXAMPLES:
\textbf{R}(x, y)\\
Return the Kazhdan-Lusztig R polynomial.
\textbf{INPUT:}\\
\begin{itemize}
  \item x, y \text{ – elements of the underlying Coxeter group}
\end{itemize}
\textbf{EXAMPLES:}

```
sage: R.<q>=QQ[]
sage: W = WeylGroup("A2", prefix="s")
sage: [s1,s2]=W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2 - 2*q + 1, q - 1, q - 1, 0]
```

\textbf{\tilde{R}}(x, y)\\
Return the Kazhdan-Lusztig \(\tilde{R}\) polynomial.
\textbf{INPUT:}\\
\begin{itemize}
  \item x, y \text{ – elements of the underlying Coxeter group}
\end{itemize}
\textbf{EXAMPLES:}

```
sage: R.<q>=QQ[]
sage: W = WeylGroup("A2", prefix="s")
sage: [s1,s2]=W.simple_reflections()
sage: KL = KazhdanLusztigPolynomial(W, q)
sage: [KL.R_tilde(x,s2*s1) for x in [1,s1,s2,s1*s2]]
[q^2, q, q, 0]
```

---

5.1. Comprehensive Module List 2069
5.1.132 Key polynomials

Key polynomials (also known as type A Demazure characters) are defined by applying the divided difference operator $\pi_\sigma$, where $\sigma$ is a permutation, to a monomial corresponding to an integer partition $\mu \vdash n$.

See also:

For Demazure characters in other types, see

- `sage.combinat.root_system.weyl_characters.WeylCharacterRing.demazure_character()`

AUTHORS:

- Trevor K. Karn (2022-08-17): initial version

```python
class sage.combinat.key_polynomial.KeyPolynomial
    Bases: IndexedFreeModuleElement

A key polynomial.

Key polynomials are polynomials that form a basis for a polynomial ring and are indexed by weak compositions.

Elements should be created by first creating the basis `KeyPolynomialBasis` and passing a list representing
the indexing composition.

EXAMPLES:

```sage
k = KeyPolynomials(QQ)
f = k([4,3,2,1]) + k([1,2,3,4]); f
k[1, 2, 3, 4] + k[4, 3, 2, 1]
```

```python
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)]) + k([Integer(1),
-  Integer(2),Integer(3),Integer(4)]); f
k[1, 2, 3, 4] + k[4, 3, 2, 1]
```

`divided_difference(w)`

Apply the divided difference operator $\partial_w$ to self.

The convention is to apply from left to right so if $w = [w_1, w_2, \ldots, w_m]$ then we apply $\partial_{w_2 \cdots w_m} \circ \partial_{w_1}$

EXAMPLES:

```sage
k = KeyPolynomials(QQ)
k([3,2,1]).divided_difference(2)
k[3, 1, 1]
k([3,2,1]).divided_difference([2,3])
k[3, 1, 1]
k = KeyPolynomials(QQ, 4)
k([3,2,1,0]).divided_difference(2)
k[3, 1, 1, 0]
```
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).divided_difference(Integer(2))
k[3, 1, 1]
>>> k([Integer(3),Integer(2),Integer(1)]).divided_difference([Integer(2),
-→Integer(3)])
k[3, 1]

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k([Integer(3),Integer(2),Integer(1),Integer(0)]).divided_difference(Integer(2))
k[3, 1, 1, 0]

**expand()**

Return self written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

**EXAMPLES:**

```python
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4
sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2 + z_2*z_1^2*z_0^3
```

```python
>>> from sage.all import *

>>> k = KeyPolynomials(QQ)

>>> f = k([Integer(4),Integer(3),Integer(2),Integer(1)])

>>> f.expand()
z_3*z_2^2*z_1^3*z_0^4

>>> f = k([Integer(1),Integer(2),Integer(3)])

>>> f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0 + 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2 + z_2*z_1^2*z_0^3
```

**isobaric_divided_difference**(w)

Apply the operator \(\pi_w\) to self.

w may be either a Permutation or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if \(w = [w_1, w_2, \ldots, w_m]\) then we apply \(\pi_{w_2 \cdots w_m} \circ \pi_{w_1}\)

**EXAMPLES:**

```python
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
```
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]

sage: k([3, 2, 1, 0]).pi(2).pi(2)
k[3, 1, 2]
sage: (-k([3, 2, 1, 0]) + 4*k([3, 1, 2, 0])).pi(2)
3*k[3, 1, 2]

sage: k = KeyPolynomials(QQ, 4)
sage: k([3, 2, 1, 0]).pi(2)
k[3, 1, 2, 0]
sage: k([3, 2, 1, 0]).pi([2, 1])
k[1, 3, 2, 0]
sage: f = k([3, 2, 1, 0]) + k([3, 2, 1, 1])
sage: f.pi(2)
k[3, 1, 2, 0] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]
Apply the operator $\pi_w$ to self.

$w$ may be either a $\text{Permutation}$ or a list of indices of simple transpositions (1-based).

The convention is to apply from left to right so if $w = [w_1, w_2, \ldots, w_m]$ then we apply $\pi_{w_2} \cdots \pi_{w_m} \circ \pi_{w_1}$

**EXAMPLES:**

```python
sage: k = KeyPolynomials(QQ)
sage: k([3,2,1]).pi(2)
k[3, 1, 2]
sage: k([3,2,1]).pi([2,1])
k[1, 3, 2]
sage: k([3,2,1]).pi(Permutation([3,2,1]))
k[1, 2, 3]
sage: f = k([3,2,1]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[]
sage: k([3,2,1,0]).pi(2).pi(2)
k[3, 1, 2]
sage: (-k([3,2,1,0]) + 4*k([3,1,2,0])).pi(2)
3*k[3, 1, 2]
sage: k = KeyPolynomials(QQ, 4)
sage: k([3,2,1,0]).pi(2)
k[3, 1, 2, 0]
sage: k([3,2,1,0]).pi([2,1])
k[1, 3, 2, 0]
sage: k([3,2,1,0]).pi(Permutation([3,2,1,4]))
k[1, 2, 3, 0]
sage: f = k([3,2,1,0]) + k([3,2,1,1])
sage: f.pi(2)
k[3, 1, 2, 0] + k[3, 1, 2, 1]
sage: k.one().pi(1)
k[0, 0, 0, 0]
```

```python
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Integer(2))
k[3, 1, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi([Integer(2),Integer(1)])
k[1, 3, 2]
>>> k([Integer(3),Integer(2),Integer(1)]).pi(Permutation([Integer(3),Integer(2),Integer(1)]))
k[1, 2, 3]
>>> f = k([Integer(3),Integer(2),Integer(1)]) + k([Integer(3),Integer(2),Integer(1)])
```
```python
>>> f.pi(Integer(2))
k[3, 1, 2] + k[3, 1, 2, 1]

>>> k.one().pi(Integer(1))
k[]

>>> k([Integer(3), Integer(2), Integer(1), Integer(0)]).pi(Integer(2)).
    ~pi(Integer(2))
k[3, 1, 2]

>>> (-k([Integer(3), Integer(2), Integer(1), Integer(0)])) ~
    Integer(4)*k([Integer(3), Integer(1), Integer(2), Integer(0)]))
    .pi(Integer(2))
3*k[3, 1, 2]

>>> k = KeyPolynomials(QQ, Integer(4))

>>> k([Integer(3), Integer(2), Integer(1), Integer(0)]).pi(Integer(2))

>>> f = k([Integer(4), Integer(3), Integer(2), Integer(1)])
>>> f.expand()
z_3*z_2^2*z_1^3*z_0^4

>>> f = k([Integer(1), Integer(2), Integer(3)])
>>> f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0 +
   z_2*z_1^2*z_0^3

>>> from sage.all import *

>>> k = KeyPolynomials(QQ)

>>> f = k([Integer(4), Integer(3), Integer(2), Integer(1)])
>>> f.expand()
z_3*z_2^2*z_1^3*z_0^4

>>> f = k([Integer(1), Integer(2), Integer(3)])
>>> f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0 +
   z_2*z_1^2*z_0^3
```

```
class sage.combinat.key_polynomial.KeyPolynomialBasis(R=None, k=None, poly_ring=None)
```

---

**to_polynomial()**

Return `self` written in the monomial basis (i.e., as an element in the corresponding polynomial ring).

**EXAMPLES:**

```
sage: k = KeyPolynomials(QQ)
sage: f = k([4,3,2,1])
sage: f.expand()
z_3*z_2^2*z_1^3*z_0^4

sage: f = k([1,2,3])
sage: f.expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^2*z_1^3*z_0 +
   z_2*z_1^2*z_0^3
```

---

**class sage.combinat.key_polynomial.KeyPolynomialBasis** *(R=None, k=None, poly_ring=None)*
Bases: `CombinatorialFreeModule`

The key polynomial basis for a polynomial ring.

For a full definition, see `SymmetricFunctions.com`. Key polynomials are indexed by weak compositions with no trailing zeros, and $\sigma$ is the permutation of shortest length which sorts the indexing composition into a partition.

**EXAMPLES:**

Key polynomials are a basis, indexed by (weak) compositions, for polynomial rings:

```python
sage: k = KeyPolynomials(QQ)
sage: k([3,0,1,2])
k[3, 0, 1, 2]
sage: k([3,0,1,2])/2
1/2*k[3, 0, 1, 2]
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
sage: K = KeyPolynomials(GF(5)); K
Key polynomial basis over Finite Field of size 5
sage: 2*K([3,0,1,2])
2*k[3, 0, 1, 2]
sage: 5*(K([3,0,1,2]) + K([3,1,1]))
0
```

We can expand them in the standard monomial basis:

```python
sage: k([3,0,1,2]).expand()
z_3^2*z_2^2*z_1*z_0^3 + z_3^2*z_2^2*z_1^2*z_0^3 + z_3^2*z_2^2*z_0^3 + 2*z_3*z_2^2*z_1*z_0^3 + z_3*z_2^2*z_1^2*z_0^3 + 2*z_3*z_2^2*z_0^3 + z_2*z_1^2*z_0^3
sage: k([0,0,2]).expand()
z_2^2 + z_2*z_1 + z_2*z_0 + z_1^2 + z_1*z_0 + z_0^2
```

(continues on next page)
If we have a polynomial, we can express it in the key basis:

```sage
k([10,9,1])*z[0] + k([10,9,1])
k[10, 9, 1] + k[10, 9, 1]
```

Since the ring of key polynomials may be regarded as a different choice of basis for a polynomial ring, it forms an algebra, so we have multiplication:

```sage
k([10,5,2])*k([1,1,1])
k[11, 6, 3]
```

We can also multiply by polynomials in the monomial basis:

```sage
k([10,9,1])*z[0]
k[11, 9, 1]
```

(continues on next page)
When the sorting permutation is the longest element, the key polynomial agrees with the Schur polynomial:

```
sage: s = SymmetricFunctions(QQ).schur()
sage: k([1,2,3]).expand()
z_2^3*z_1^2*z_0 + z_2^3*z_1*z_0^2 + z_2^3*z_1^3*z_0
+ 2*z_2^2*z_1^2*z_0^2 + z_2^2*z_1*z_0^3 + z_2*z_1^3*z_0^2
+ z_2*z_1^2*z_0^3
sage: s[3,2,1].expand(3)
x0^3*x1^2*x2 + x0^2*x1^3*x2 + x0^3*x1*x2^2 + 2*x0^2*x1^2*x2^2
+ x0^2*x1^3*x2^2 + x0^2*x1*x2^3 + x0*x1^2*x2^3
```

The polynomial expansions can be computed using crystals and expressed in terms of the key basis:

```
sage: T = crystals.Tableaux(['A',3],shape=[2,1])
sage: f = T.demazure_character([3,2,1])
sage: k.from_polynomial(f)
k[1, 0, 0, 2]
```

The default behavior is to work in a polynomial ring with infinitely many variables. One can work in a specified number of variables:

```
sage: k = KeyPolynomials(QQ, 4)
sage: k[[3,0,1,2]].expand()
z_0^3*z_1^2*z_2 + z_0^3*z_1*z_2^2 + z_0^3*z_1^3*z_2
+ 2*z_0^2*z_1^2*z_2 + z_0^2*z_1*z_3 + z_0^2*z_2^2*z_3 + z_0^2*z_1*z_3^2 + z_0^2*z_2*z_3^2
sage: k[[0,0,2,0]].expand()
z_0^2 + z_0^3*z_1 + z_1^2 + z_0*z_2 + z_1*z_2 + z_2^2
sage: k[[0,0,2,0]].expand().parent()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```
Combinatorics, Release 10.4

\[
z_0^3z_1^2z_2 + z_0^3z_1z_2^2 + z_0^3z_1^2z_3 + 2z_0^3z_1z_2z_3 + z_0^3z_2^2z_3 + z_0^3z_1z_3^2 + z_0^3z_2z_3^2
\]

\[
>>> k([Integer(0),Integer(0),Integer(2),Integer(0)]).expand()
\]
\[
z_0^2 + z_0z_1 + z_1^2 + z_0z_2 + z_1z_2 + z_2^2
\]

\[
>>> k([Integer(0),Integer(0),Integer(2),Integer(0)]).expand().parent()
\]
\[
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
\]

If working in a specified number of variables, the length of the indexing composition must be the same as the number of variables:

\[
sage: k([0,0,2])
\]

Traceback (most recent call last):
...
TypeError: do not know how to make x (= [0, 0, 2]) an element of self (=Key polynomial basis over Rational Field)

\[
>>> from sage.all import *
\]

\[
>>> k([Integer(0),Integer(0),Integer(2)])
\]

Traceback (most recent call last):
...
TypeError: do not know how to make x (= [0, 0, 2]) an element of self (=Key polynomial basis over Rational Field)

One can also work in a specified polynomial ring:

\[
sage: k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
\]

\[
sage: k([0,2,0,0])
\]

k[0, 2, 0, 0]

\[
sage: k([4,0,0,0]).expand()
\]

x0^4

\[
>>> from sage.all import *
\]

\[
>>> k = KeyPolynomials(QQ['x0', 'x1', 'x2', 'x3'])
\]

\[
>>> k([Integer(0),Integer(2),Integer(0),Integer(0)])
\]

k[0, 2, 0, 0]

\[
>>> k([Integer(4),Integer(0),Integer(0),Integer(0)]).expand()
\]

x0^4

If one wishes to use a polynomial ring as coefficients for the key polynomials, pass the keyword argument `poly_coeffs=True`:

\[
sage: k = KeyPolynomials(QQ['q'], poly_coeffs=True)
\]

\[
sage: R = k.base_ring(); R
\]

Univariate Polynomial Ring in q over Rational Field

\[
sage: R.inject_variables()
\]

Defining q

\[
sage: (q^2 + q + 1)*k([0,2,2,0,3,2])
\]

\[
(q^2+q+1)*k[0, 2, 2, 0, 3, 2]
\]

\[
>>> from sage.all import *
\]

\[
>>> k = KeyPolynomials(QQ['q'], poly_coeffs=True)
\]

\[
>>> R = k.base_ring(); R
\]

Univariate Polynomial Ring in q over Rational Field

(continues on next page)
Element

alias of KeyPolynomial

degree_on_basis(alpha)

Return the degree of the basis element indexed by alpha.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: k.degree_on_basis([2, 1, 0, 2])
5
```

```python
sage: k = KeyPolynomials(QQ, 5)
sage: k.degree_on_basis([2, 1, 0, 2, 0])
5
```

from_polynomial(f)

Expand a polynomial in terms of the key basis.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: z = k.poly_gens(); z
z_0
sage: k.from_polynomial(p)
k[4, 1, 2, 1]
```

```python
sage: all(k(c) == k.from_polynomial(k(c).expand()) for c in IntegerVectors(n=5, k=4))
True
```

```python
sage: T = crystals.Tableaux(['A', 4], shape=[4, 2, 1, 1])
sage: k.from_polynomial(T.demazure_character([2]))
k[4, 1, 2, 1]
```

```python
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> z = k.poly_gens(); z
z_0
```
from_combinatorics import *

k = KeyPolynomials(ZZ)
k = KeyPolynomials(GF(7), 4)

one_basis()

Return the basis element indexing the identity.

EXAMPLES:
```python
sage: k = KeyPolynomials(QQ)
sage: k.one_basis()
[]
sage: k = KeyPolynomials(QQ, 4)
sage: k.one_basis()
[0, 0, 0, 0]

>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.one_basis()
[]
>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.one_basis()
[0, 0, 0, 0]
```

**poly_gens()**

Return the polynomial generators for the polynomial ring associated to `self`.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: k.poly_gens()
z_*
sage: k = KeyPolynomials(QQ, 4)
sage: k.poly_gens()
(z_0, z_1, z_2, z_3)
```

```python
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.poly_gens()
z_*
>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.poly_gens()
(z_0, z_1, z_2, z_3)
```

**polynomial_ring()**

Return the polynomial ring associated to `self`.

EXAMPLES:

```python
sage: k = KeyPolynomials(QQ)
sage: k.polynomial_ring()
Infinite polynomial ring in z over Rational Field
sage: k = KeyPolynomials(QQ, 4)
sage: k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field
```

```python
>>> from sage.all import *
>>> k = KeyPolynomials(QQ)
>>> k.polynomial_ring()
Infinite polynomial ring in z over Rational Field
```

(continues on next page)
Combinatorics, Release 10.4

>>> k = KeyPolynomials(QQ, Integer(4))
>>> k.polynomial_ring()
Multivariate Polynomial Ring in z_0, z_1, z_2, z_3 over Rational Field

sage.combinat.key_polynomial.divided_difference(f, i)

Apply the i-th divided difference operator to the polynomial f.

EXAMPLES:

```
sage: from sage.combinat.key_polynomial import divided_difference
divided_difference(f, 3)
sage: divided_difference(f, 3)
z_3^2*z_1 + z_3*z_2*z_1 + z_2^2*z_1
```

```
sage: k = KeyPolynomials(QQ, 4)
sage: z = k.poly_gens()
sage: divided_difference(f, 3)
z_1*z_2^2 + z_1*z_2*z_3 + z_1*z_3^2
```

```
sage: k = KeyPolynomials(QQ)
sage: R = k.polynomial_ring(); R
Infinite polynomial ring in z over Rational Field
sage: z = R.gen()
sage: divided_difference(z[1]*z[2]^3, 2)
-z_2^2*z_1 - z_2*z_1^2
```

```
sage: k = KeyPolynomials(QQ, 5)
sage: z = k.polynomial_ring().gens()
sage: divided_difference(z[1]*z[2]^3, 2)
-z_1^2*z_2 - z_1*z_2^2
```

```
sage: from sage.all import *
sage: from sage.combinat.key_polynomial import divided_difference
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import divided_difference
```

(continues on previous page)
sage.combinat.key_polynomial.isobaric_divided_difference(f, w)

Apply the isobaric divided difference operator $\pi_w$ to the polynomial $f$.

$w$ may be either a single index or a list of indices of simple transpositions.

**Warning:** The simple transpositions should be applied from left to right.

**EXAMPLES:**

```python
sage: from sage.combinat.key_polynomial import isobaric_divided_difference as idd
sage: R.<z> = InfinitePolynomialRing(GF(3))

>>> idd(z[1]^4*z[2]^2*z[4], 4)
0

>>> idd(z[1]^4*z[2]^2*z[3]*z[4], 3)
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[1]^4*z[2]^2*z[3]*z[4], [3, 4])
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4 + z_4*z_3^2*z_2^2*z_1^4

>>> idd(z[1]^4*z[2]^2*z[3]*z[4], [4, 3])
z_4*z_3^2*z_2*z_1^4 + z_4*z_3*z_2^2*z_1^4

>>> idd(z[1]^2*z[2], [3, 2])
```

(continues on next page)
\[ z_3^2 z_2 + z_3 z_2^2 z_1 + z_3 z_1^2 + z_2^2 z_1 + z_2 z_1^2 \]

```python
>>> from sage.all import *
>>> from sage.combinat.key_polynomial import isobaric_divided_difference as idd
>>> R = InfinitePolynomialRing(GF(Integer(3)), names=('z',)); (z,) = R._first_ngens(1)
>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(4)], Integer(4))
0
>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]**Integer(3)*z[Integer(4)], Integer(3))
z_4^2 z_3 z_2 z_1 + z_4 z_3^2 z_2^2 z_1^4
>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]**Integer(3)*z[Integer(4)], [Integer(3), Integer(4)])
z_4^4 z_3^2 z_2^2 z_1^4 + z_4 z_3 z_2^2 z_1^4 + z_4 z_3 z_2 z_1^4
>>> idd(z[Integer(1)]**Integer(4)*z[Integer(2)]**Integer(2)*z[Integer(3)]**Integer(3)*z[Integer(4)], [Integer(4), Integer(3)])
z_4^4 z_3^2 z_2^2 z_1^4 + z_4 z_3 z_2^2 z_1^4
>>> idd(z[Integer(1)]**Integer(2)*z[Integer(2)], [Integer(3), Integer(2)])
z_3^2 z_2^2 + z_3 z_2 z_1 + z_3 z_1^2 + z_2^2 z_1 + z_2 z_1^2
```

`sage.combinat.key_polynomial.sorting_word(alpha)`

Get a reduced word for the permutation which sorts `alpha` into a partition.

The result is a list `l = [i0, i1, i2, ...]` where each `ij` is a positive integer such that it applies the simple transposition \((ij, ij+1)\). The transpositions are applied starting with `i0`, then `i1` is applied, followed by `i2`, and so on. See `sage.combinat.permutation.Permutation.reduced_words()` for the convention used.

EXAMPLES:

```python
sage: IV = IntegerVectors()
sage: from sage.combinat.key_polynomial import sorting_word
sage: list(sorting_word(IV([2,3,2]))[0])
[1]
sage: sorting_word(IV([2,3,2]))[1]
[3, 2, 2]
sage: list(sorting_word(IV([5,6,7]))[0])

5.1.133 Knutson-Tao Puzzles

This module implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable: the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

Acknowledgements

This code was written during Sage Days 45 at ICERM with Franco Saliola, Anne Schilling, and Avinash Dalal in discussions with Allen Knutson. The code was tested afterwards by Liz Beazley and Ed Richmond.

Todo: Functionality to add:

- plotter will not plot edge labels higher than 2; e.g. in BK puzzles, the labels are 1,…, n and so in 3-step examples, none of the edge labels with 3 appear
- we should also have a 3-step puzzle pieces constructor, taken from p22 of arXiv math/0610538
- implement the bijection from puzzles to tableaux; see for example R. Vakil, A geometric Littlewood-Richardson rule, arXiv math/0302294 or K. Purbhoo, Puzzles, Tableaux and Mosaics, arXiv 0705.1184.

sage.combinat.knutson_tao_puzzles.BK_pieces(max_letter)

The puzzle pieces used in computing the Belkale-Kumar coefficients for any partial flag variety in type A.

There are two types of puzzle pieces:

- a triangle, with each edge labeled with the same letter;
- a rhombus, with edges labeled \( i, j, i, j \) in clockwise order with \( i > j \).

Each of these is rotated by 60 degrees, but not reflected.

We model the rhombus pieces as two triangles: a delta piece north-west label \( i \), north-east label \( j \) and south label \( i(j) \); and a nabla piece with south-east label \( i \), south-west label \( j \) and north label \( i(j) \).

INPUT:

- max_letter – positive integer specifying the number of steps in the partial flag variety, equivalently, the number of elements in the alphabet for the edge labels. The smallest label is 1.
REFERENCES:
EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import BK_pieces
sage: BK_pieces(3)
Nablas : [1/1/1, 1/2(1)/2, 1/3(1)/3, 2(1)/2/1, 2\1/2/1, 2\2/2, 2\3(2)/3, 3(1)/3/
\rightarrow1, 3\2/3/2, 3\1/3/1, 3\2/3(2), 3\3/3]
Deltas : [1/1/1, 1/2\2/1, 1/3\3(1), 2(1)/1/1, 2/2\1/1, 2/2/2, 2/3\3(2), 3(1)/1/
\rightarrow3, 3\2/2/3, 3\3(1)/1, 3\3(2)/2, 3\3/3]
```

```python
class sage.combinat.knutson_tao_puzzles.DeltaPiece(south, north_west, north_east)

Bases: PuzzlePiece

Delta Piece takes as input three labels, inputted as strings. They label the South, Northwest and Northeast edges, respectively.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: DeltaPiece('a','b','c')
b/a\c
```

```python
clockwise_rotation()

Rotate the Delta piece by 120 degree clockwise.

OUTPUT:

- Delta piece

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','2','3')
sage: delta.clockwise_rotation()
1/3\2
```

```python
edges()

Return the tuple of edge names.

```
EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: delta.edges() ('south', 'north_west', 'north_east')
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece

>>> delta = DeltaPiece('1', '2', '3')
```

```python
half_turn_rotation()
```

Rotate the Delta piece by 180 degree.

OUTPUT:

- Nabla piece

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1', '2', '3')
```

```python
3\1/2
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece

>>> delta = DeltaPiece('1', '2', '3')
```

```python
3\1/2
```

```python
sage.combinat.knutson_tao_puzzles.HT_grassmannian_pieces()
```

Define the puzzle pieces used in computing the torus-equivariant cohomology of the Grassmannian.

REFERENCES:

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
sage: HT_grassmannian_pieces()
```

```python
Nablas : [0/0\0, 0/10/1, 0/1/10, 10/1/0, 1\0/10, 1\1/1, 1\T0|1/0]
```

```python
Deltas : [0/0\0, 0/1/10, 0/T0|1\1, 1/10/0, 1/1/1, 10/0/1]
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import HT_grassmannian_pieces
```

```python
>>> HT_grassmannian_pieces()
```

```python
Nablas : [0/0\0, 0/10/1, 0/1/10, 10/1/0, 1\0/10, 1\1/1, 1\T0|1/0]
```

```python
Deltas : [0/0\0, 0/1/10, 0/T0|1\1, 1/10/0, 1/1/1, 10/0/1]
```

```python
sage.combinat.knutson_tao_puzzles.HT_two_step_pieces()
```

Define the puzzle pieces used in computing the equivariant two step puzzle pieces.

For the puzzle pieces, see Figure 26 on page 22 of [CoskunVakil06].

sage.combinat.knutson_tao_puzzles.K_grassmannian_pieces()

Define the puzzle pieces used in computing the K-theory of the Grassmannian.

REFERENCES:

EXAMPLES:

>>> from sage.combinat.knutson_tao_puzzles import K_grassmannian_pieces
>>> K_grassmannian_pieces()
Nablas : [0\0/0, 0/10/1, 0\K/1, 10/1/0, 1\0/0, 1\1/1, K\1/0]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1, K/K\K]

class sage.combinat.knutson_tao_puzzles.KnutsonTaoPuzzleSolver(puzzle_pieces)

Return puzzle solver function used to create all puzzles with given boundary conditions.

This class implements a generic algorithm to solve Knutson-Tao puzzles. An instance of this class will be callable:
the arguments are the labels of north-east and north-west sides of the puzzle boundary; the output is the list of the fillings of the puzzle with the specified pieces.

INPUT:

- puzzle_pieces – takes either a collection of puzzle pieces or a string indicating a pre-programmed collection of puzzle pieces:
- H – cohomology of the Grassmannian
- HT – equivariant cohomology of the Grassmannian
- K – K-theory
- H2step – cohomology of the 2-step Grassmannian
- HT2step – equivariant cohomology of the 2-step Grassmannian
- BK – Belkale-Kumar puzzle pieces
- max_letter – (default: None) None or a positive integer. This is only required only for Belkale-Kumar puzzles.
EXAMPLES:

Each puzzle piece is an edge-labelled triangle oriented in such a way that it has a south edge (called a \textit{delta} piece) or a north edge (called a \textit{nabla} piece). For example, the puzzle pieces corresponding to the cohomology of the Grassmannian are the following:

```
sage: from sage.combinat.knutson_tao_puzzles import H_grassmannian_pieces
sage: H_grassmannian_pieces()
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

In the string representation, the nabla pieces are depicted as $c\a/b$, where $a$ is the label of the north edge, $b$ is the label of the south-east edge, $c$ is the label of the south-west edge. A similar string representation exists for the delta pieces.

To create a puzzle solver, one specifies a collection of puzzle pieces:

```
sage: KnutsonTaoPuzzleSolver(H_grassmannian_pieces())
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The following shorthand to create the above puzzle solver is also supported:

```
sage: KnutsonTaoPuzzleSolver('H')
Knutson-Tao puzzle solver with pieces:
Nablas : [0\0/0, 0\10/1, 10\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The solver will compute all fillings of the puzzle with the given puzzle pieces. The user specifies the labels of north-east and north-west sides of the puzzle boundary and the output is a list of the fillings of the puzzle with the specified pieces. For example, there is one solution to the puzzle whose north-west and north-east edges are both labeled '0':

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: ps('0', '0')
[[{(1, 1): 0/0\0}]]
```
There are two solutions to the puzzle whose north-west and north-east edges are both labeled ‘0101’:

```
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: len(solns)
2
sage: solns.sort(key=str)
sage: solns
[(1, 1): 0/0\0,
  (1, 2): 1/\0 0\/1,
  (1, 3): 0/\0 0\/0,
  (1, 4): 1/\0 0\/1,
  (2, 2): 1/1\1,
  (2, 3): 0/\10 1\/1,
  (2, 4): 1/\1 10\/0,
  (3, 3): 1/1\1,
  (3, 4): 0/\0 1\/10,
  (4, 4): 10/0\1),
(1, 1): 0/1\10,
  (1, 2): 1/\1 10\/0,
  (1, 3): 0/\0 1\/10,
  (1, 4): 1/\0 0\/1,
  (2, 2): 0/0\0,
  (2, 3): 10/\1 0\/0,
  (2, 4): 1/\1 1\/1,
  (3, 3): 0/0\0,
  (3, 4): 1/\0 0\/1,
  (4, 4): 1/1\1)]```

(continues on next page)
The pieces in a puzzle filling are indexed by pairs of non-negative integers \((i, j)\) with \(1 \leq i \leq j \leq n\), where \(n\) is the length of the word labelling the triangle edge. The pieces indexed by \((i, i)\) are the triangles along the south edge of the puzzle.

\[
\begin{array}{c}
(3, 4): 1/0 0/1, \\
(4, 4): 1/1/1/
\end{array}
\]

The pieces indexed by \((i, j)\) for \(j > i\) are a pair consisting of a delta piece and nabla piece glued together along the south edge and north edge, respectively (these pairs are called rhombi).

\[
\begin{array}{c}
sage: f = solns[0] \\
sage: [f[i, i] for i in range(1, 5)] \\
[0/0/0, 1/1/1, 1/1/1, 10/0/1]
\end{array}
\]

There are various methods and options to display puzzle solutions. A single puzzle can be displayed using the plot method of the puzzle:

\[
\begin{array}{c}
sage: ps = KnutsonTaoPuzzleSolver("H") \\
sage: puzzle = ps(('0101', '1001'))[0] \\
sage: puzzle.plot() # not tested \\
sage: puzzle.plot(style='fill') # not tested \\
sage: puzzle.plot(style='edges') # not tested
\end{array}
\]

To plot several puzzle solutions, use the plot method of the puzzle solver:

\[
\begin{array}{c}
sage: ps = KnutsonTaoPuzzleSolver('K') \\
sage: solns = ps(('0101', '0101')) \\
sage: ps.plot(solns) # not tested
\end{array}
\]
The code can also generate a PDF of a puzzle (using LaTeX and \texttt{tikz}):

```python
sage: latex.extra_preamble(r'\usepackage{tikz}')
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: solns = ps('0101', '0101')
sage: view(solns[0], viewer='pdf')  # not tested
```

Below are examples of using each of the currently supported puzzles.

Cohomology of the Grassmannian:

```python
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[[(1, 1): 0/0\0, (1, 2): 1/\0 0\1, (1, 3): 0/\0 0\0, (1, 4): 1/\0 0\1, (2, 2): 1/1\1, (2, 3): 0/\10 1\1, (2, 4): 1/\1 10/0, (3, 3): 1/1\1, (3, 4): 0/\0 1\10, (4, 4): 10/0\1}, {(1, 1): 0/1\10, (1, 2): 1/\1 10/0, (1, 3): 0/\0 1\10, (1, 4): 1/\0 0\1, (2, 2): 0/0\0, (2, 3): 10/\1 0\0, (2, 4): 1/\1 1\1, (3, 3): 0/0\0, (3, 4): 1/\0 0\1, (4, 4): 1/1\1}]
```

```python
>>> from sage.all import *

```
Equivariant puzzles:

```
sage: ps = KnutsonTaoPuzzleSolver("HT")
sage: solns = ps('0101', '0101')
sage: sorted(solns, key=str)
[[{(1, 1): 0/0\0,
  (1, 2): 1\0 0\1,
  (1, 3): 0\0 0\0,
  (1, 4): 1\0 0\1,
  (2, 2): 1/1\1,
  (2, 3): 0\1 1\0,
  (2, 4): 1\1 1\1,
  (3, 3): 0/0\0,
  (3, 4): 1\0 0\1,
  (4, 4): 1/1\1}],
[(1, 1): 0/0\0,
  (1, 2): 1\0 0\1,
  (1, 3): 0\0 0\0,
  (1, 4): 1\0 0\1,
  (2, 2): 1/1\1,
  (2, 3): 0\1 1\0,
  (2, 4): 1\1 1\1,
  (3, 3): 0/0\0,
  (3, 4): 1\0 0\1,
  (4, 4): 1/1\1}]}
```
(continued from previous page)

\[(1, 4): 1/\backslash0 0/\backslash1, \\
(2, 2): 1/1/\backslash1, \\
(2, 3): 0/\backslash10 1/\backslash1, \\
(2, 4): 1/\backslash1 10/\backslash0, \\
(3, 3): 1/1/\backslash1, \\

Belkale-Kumar puzzles (the following example is Figure 2 of [KnutsonPurbhoo10]):

```python
sage: ps = KnutsonTaoPuzzleSolver('BK', 3)

sage: solns = ps(12132, 23112)

sage: len(solns)
1

sage: solns[0].south_labels()
(3, 2, 1, 2, 1)

sage: solns
[{(1, 1): 1/3\3(1),
  (1, 2): 2/\3(2) 3(1)\1,
  (1, 3): 1/\3(1) 3(2)\2,
  (1, 4): 3/\3 3(1)\1,
  (1, 5): 2/\2 3(1)\3(2),
  (2, 2): 1/2\2(1),
  (2, 3): 2/\2 2(1)\1,
  (2, 4): 1/\2(1) 2\2,
  (2, 5): 3(2)\3 2(1)\1,
  (3, 3): 1/1\1,
  (3, 4): 2/\1 1\2,
  (3, 5): 1/\1 1\1,
  (4, 4): 2/2\2,
  (4, 5): 1/\1 2\2(1),
  (5, 5): 2(1)/1\2}]
```

>>> from sage.all import *

```python
>>> ps = KnutsonTaoPuzzleSolver('BR', Integer(3))

>>> solns = ps('12132', '23112')

>>> len(solns)
1

>>> solns[Integer(0)].south_labels()
('3', '2', '1', '2', '1')

```python
>>> solns
[(1, 1): 1/3\3(1),
  (1, 2): 2/\3(2) 3(1)\1,
  (1, 3): 1/\3(1) 3(2)\2,

  (1, 5): 2/\2 3(1)\3(2),
  (2, 2): 1/2\2(1),
  (2, 3): 2/\2 2(1)\1,
  (2, 4): 1/\2(1) 2\2,
  (2, 5): 3(2)\3 2(1)\1,
  (3, 3): 1/1\1,
  (3, 4): 2/\1 1\2,
  (3, 5): 1/\1 1\1,
  (4, 4): 2/2\2,
  (4, 5): 1/\1 2\2(1),
  (5, 5): 2(1)/1\2}]
```
(1, 3): 1/3(1) 3(2)\2,  
(1, 4): 3/3 3(1)\1,  
(1, 5): 2/2 3\3(2),  
(2, 2): 1/2\2(1),  
(2, 3): 2/\2 2(1)\1,  
(2, 4): 1/\2(1) 2/\2,  
(2, 5): 3(2)/\3 2(1)\1,  
(3, 3): 1/1,  
(3, 4): 2/1 1/2,  
(3, 5): 1/1 1/1,  
(4, 4): 2/2\2,  
(4, 5): 1/1 2/2(1),  
(5, 5): 2(1)/1\2]

plot (puzzles)
Return plot of puzzles.

INPUT:

• puzzles – list of puzzles

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('K')

sage: solns = ps('0101', '0101')

sage: ps.plot(solns)  # not tested

>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver('K')

>>> solns = ps('0101', '0101')

>>> ps.plot(solns)  # not tested

puzzle_pieces()
The puzzle pieces used for filling in the puzzles.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver('H')

sage: ps.puzzle_pieces()

Nablas : [0\0/0, 0/10/1, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/1\0, 1/1/1, 10/0/1]

>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver

>>> ps = KnutsonTaoPuzzleSolver('H')

>>> ps.puzzle_pieces()

Nablas : [0\0/0, 0/10/1, 1\1/0, 1\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/1\0, 1/1/1, 10/0/1]

solutions (lambda, mu, algorithm='strips')
Compute cohomology structure coefficients from puzzles.

INPUT:
- pieces – puzzle pieces to be used
- \( \lambda, \mu \) – edge labels of puzzle for northwest and northeast side
- \( \nu \) – (default: None) If \( \nu \) is not specified a dictionary is returned with the structure coefficients corresponding to all south labels; if \( \nu \) is given, only the coefficients with the specified label is returned.

OUTPUT: dictionary

EXAMPLES:

Note: In order to standardize the output of the following examples, we output a sorted list of items from the dictionary instead of the dictionary itself.

Grassmannian cohomology:

```sage
sage: ps = KnutsonTaoPuzzleSolver('H')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[((0, 1, 1, 0), 1), ((1, 0, 0, 1), 1)]
sage: ps.structure_constants('001001', '001010', '010100')
```

Equivariant cohomology:

```sage
sage: ps = KnutsonTaoPuzzleSolver('HT')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[((0, 1, 0, 1), y2 - y3), ((0, 1, 1, 0), 1), ((1, 0, 0, 1), 1)]
```

K-theory:

```sage
sage: ps = KnutsonTaoPuzzleSolver('K')
sage: cp = ps.structure_constants('0101', '0101')
sage: sorted(cp.items(), key=str)
[((0, 1, 1, 0), 1), ((1, 0, 0, 1), 1), ((1, 0, 1, 0), -1)]
```

(continues on next page)
Combinatorics, Release 10.4

>>> sorted(cp.items(), key=str)
[(('0', '1', '1', '0'), 1), (('1', '0', '0', '1'), 1), (('1', '0', '1', '0'), (-1))]

Two-step:

```python
sage: ps = KnutsonTaoPuzzleSolver('H2step')
sage: cp = ps.structure_constants('01122', '01122')
sage: sorted(cp.items(), key=str)
[((0, 1, 1, 0, 1), 1), ((1, 0, 0, 1, 1), 1)]
```

```python
sage: cp = ps.structure_constants('01201', '01021')
sage: sorted(cp.items(), key=str)
[((0, 2, 1, 1, 0), 1), ((1, 2, 0, 0, 1), 1), ((2, 0, 1, 0, 1), 1)]
```

```python
>>> from sage.all import *
```

```python
ps = KnutsonTaoPuzzleSolver('H2step')
```

```python
>>> cp = ps.structure_constants('01122', '01122')
>>> sorted(cp.items(), key=str)
[((0, 1, 1, 2, 2), 1)]
```

```python
>>> cp = ps.structure_constants('01201', '01021')
>>> sorted(cp.items(), key=str)
[((0, 2, 1, 1, 0), 1), ((1, 2, 0, 0, 1), 1), ((2, 0, 1, 0, 1), 1)]
```

Two-step equivariant:

```python
sage: ps = KnutsonTaoPuzzleSolver('HT2step')
sage: cp = ps.structure_constants('10212', '12012')
sage: sorted(cp.items(), key=str)
[((1, 2, 0, 1, 2), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 ((1, 2, 0, 2, 1), y1 - y3),
 ((1, 2, 1, 0, 2), y2 - y4),
 ((1, 2, 1, 2, 0), 1),
 ((1, 2, 2, 0, 1), 1),
 ((2, 1, 0, 1, 2), y1 - y3),
 ((2, 1, 1, 0, 2), 1)]
```

```python
>>> from sage.all import *
```

```python
ps = KnutsonTaoPuzzleSolver('HT2step')
```

```python
>>> cp = ps.structure_constants('10212', '12012')
>>> sorted(cp.items(), key=str)
[((1, 2, 0, 1, 2), y1*y2 - y2*y3 - y1*y4 + y3*y4),
 ((1, 2, 0, 2, 1), y1 - y3),
 ((1, 2, 1, 0, 2), y2 - y4),
 ((1, 2, 1, 2, 0), 1),
 ((1, 2, 2, 0, 1), 1),
 ((2, 1, 0, 1, 2), y1 - y3),
 ((2, 1, 1, 0, 2), 1)]
```

```python
class sage.combinat.knutson_tao_puzzles.NablaPiece(north, south_east, south_west)
Bases: PuzzlePiece
```

Nabla Piece takes as input three labels, inputted as strings. They label the North, Southeast and Southwest edges, respectively.
EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: NablaPiece('a', 'b', 'c')
c\a/b
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> NablaPiece('a', 'b', 'c')
c\a/b
```

clockwise_rotation()

Rotate the Nabla piece by 120 degree clockwise.

OUTPUT:

- Nabla piece

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1', '2', '3')
sage: nabla.clockwise_rotation()
2\3/1
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1', '2', '3')
>>> nabla.clockwise_rotation()
2\3/1
```

dalles

Return the tuple of edge names.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1', '2', '3')
sage: nabla.edges()
('north', 'south_east', 'south_west')
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nabla = NablaPiece('1', '2', '3')
>>> nabla.edges()
('north', 'south_east', 'south_west')
```

half_turn_rotation()

Rotate the Nabla piece by 180 degree.

OUTPUT:

- Delta piece

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import NablaPiece
sage: nabla = NablaPiece('1', '2', '3')
```

(continues on next page)
```python
sage: nbla.half_turn_rotation()
2/1\3
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import NablaPiece
>>> nbla = NablaPiece('1','2','3')
>>> nbla.half_turn_rotation()
2/1\3
```

class sage.combinat.knutson_tao_puzzles.PuzzleFilling(north_west_labels,
north_east_labels)

Bases: object

Create partial puzzles and provides methods to build puzzles from them.

**add_piece** *(piece)*

Add piece to partial puzzle.

**EXAMPLES:**

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: piece = DeltaPiece('0','1','0')
```

```python
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: P.add_piece(piece); P
{(1, 4): 1/0\0}
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>>
>>> piece = DeltaPiece('0','1','0')
>>> pieces = [piece,piece]
>>> P.add_pieces(pieces)
>>> P
{{(1, 4): 1/0\0, (2, 4): 1/0\0}}
```

**add_pieces** *(pieces)*

Add piece to partial puzzle.

**INPUT:**

- **pieces**—tuple of pieces

**EXAMPLES:**

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
sage: P = PuzzleFilling('0101','0101'); P
{}
sage: piece = DeltaPiece('0','1','0')
sage: pieces = [piece,piece]
sage: P.add_pieces(pieces)
sage: P
{(1, 4): 1/0\0, (2, 4): 1/0\0}
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
>>> P = PuzzleFilling('0101','0101'); P
```
{} >>> piece = DeltaPiece('0', '1', '0') >>> pieces = [piece, piece] >>> P.add_pieces(pieces) >>> P {(1, 4): 1/0, (2, 4): 1/0}

contribution()

Return equivariant contributions from self in polynomial ring.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("HT")

>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver

>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
```

```python
>>> sorted([p.contribution() for p in puzzles], key=str)

```

```python
[1, y1 - y3]
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
```

```python
>>> sorted([p.contribution() for p in puzzles], key=str)

```

```python
[1, y1 - y3]
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
```

```python
>>> piece = DeltaPiece('0', '1', '0')
```

```python
>>> P = PuzzleFilling('0101', '0101'); P
```

```python
>>> PP = P.copy()
```

```python
>>> P.add_piece(piece); P
```

```python
{(1, 4): 1/0}
```

```python
>>> PP
```

```python
{}
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, PuzzleFilling
```

```python
>>> piece = DeltaPiece('0', '1', '0')
```

```python
>>> P = PuzzleFilling('0101', '0101'); P
```

```python
>>> PP = P.copy()
```

```python
>>> P.add_piece(piece); P
```

```python
{(1, 4): 1/0}
```

```python
>>> PP
```

```python
{}
```

is_completed()

Whether partial puzzle is complete (completely filled) or not.

EXAMPLES:
Combinatorics, Release 10.4

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_completed()
False

sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.is_completed()
True

is_in_south_edge()
Check whether kink coordinates of partial puzzle is in south corner.
EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.is_in_south_edge()
False

kink_coordinates()
Provide the coordinates of the kinks.
The kink coordinates are the coordinates up to which the puzzle has already been built. The kink starts in the
north corner and then moves down the diagonals as the puzzles is built.
EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.kink_coordinates()
(1, 4)
P = PuzzleFilling('0101','0101')

P
{}

P.kink_coordinates()
(1, 4)

north_east_label_of_kink()
Return north east label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_east_label_of_kink()
'0'
```

north_west_label_of_kink()
Return north-west label of kink.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzleFilling
sage: P = PuzzleFilling('0101','0101')
sage: P.north_west_label_of_kink()
'1'
```

plot (labels=True, style='fill')
Plot completed puzzle.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: puzzle = ps('0101','1001')[0]
sage: puzzle.plot()  #not tested
sage: puzzle.plot(style='fill')  #not tested
sage: puzzle.plot(style='edges')  #not tested
```

(continues on next page)
puzzle.plot(style='fill')  # not tested
puzzle.plot(style='edges')  # not tested

south_labels()

Return south labels for completed puzzle.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
sage: ps = KnutsonTaoPuzzleSolver("H")
sage: ps('0101','1001')[0].south_labels()
(1, 0, 1, 0)
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import KnutsonTaoPuzzleSolver
>>> ps = KnutsonTaoPuzzleSolver("H")
>>> ps('0101','1001')[Integer(0)].south_labels()
(1, 0, 1, 0)
```

class sage.combinat.knutson_tao_puzzles.PuzzlePiece

Bases: object

Abstract class for puzzle pieces.

This abstract class contains information on how to test equality of puzzle pieces, and sets color and plotting options.

border()

Return the border of self.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece("a","b","c")
sage: sorted(delta.border())
['a', 'b', 'c']
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece("a","b","c")
>>> sorted(delta.border())
['a', 'b', 'c']
```

color()

Return the color of self.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece("a","b","c")
sage: delta.color()
'white'
sage: delta = DeltaPiece("0","0","0")
sage: delta.color()
'red'
sage: delta = DeltaPiece("1","1","1")
```

(continues on next page)
sage: delta.color()
'blue'
sage: delta = DeltaPiece('2','2','2')
sage: delta.color()
'green'
sage: delta = DeltaPiece('2','K','2')
sage: delta.color()
'orange'
sage: delta = DeltaPiece('2','T1/2','2')
sage: delta.color()
'yellow'

>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece

edge_color(edge)

Color of the specified edge of self (to be used when plotting the piece).

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('1','0','10')
sage: delta.edge_color(south)
'blue'
sage: delta.edge_color(north_west)
'red'
sage: delta.edge_color(north_east)
'white'

>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece

5.1. Comprehensive Module List
edge_label

Return the edge label of edge.

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece
sage: delta = DeltaPiece('2', 'K', '2')
sage: delta.edge_label('south')
'2'
sage: delta.edge_label('north_east')
'2'
sage: delta.edge_label('north_west')
'K'
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece
>>> delta = DeltaPiece('2', 'K', '2')
>>> delta.edge_label('south')
'2'
>>> delta.edge_label('north_east')
'2'
>>> delta.edge_label('north_west')
'K'
```

class sage.combinat.knutson_tao_puzzles.PuzzlePieces (forbidden_border_labels=None)

Bases: object

Construct a valid set of puzzle pieces.

This class constructs the set of valid puzzle pieces. It can take a list of forbidden border labels as input. These labels are forbidden from appearing on the south edge of a puzzle filling. The user can add valid nbla or delta pieces and specify which rotations of these pieces are legal. For example, rotations=0 does not add any additional pieces (only the piece itself), rotations=60 adds six pieces (the pieces and its rotations by 60, 120, 180, 240, 300), etc..

EXAMPLES:

```
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
sage: forbidden_border_labels = ['10']
sage: pieces = PuzzlePieces(forbidden_border_labels)
sage: pieces.add_piece(NablaPiece('0', '0', '0'), rotations=60)
sage: pieces.add_piece(NablaPiece('1', '1', '1'), rotations=60)
sage: pieces.add_piece(NablaPiece('1', '0', '10'), rotations=60)
sage: pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 10\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

```
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, NablaPiece
>>> forbidden_border_labels = ['10']
>>> pieces = PuzzlePieces(forbidden_border_labels)
>>> pieces.add_piece(NablaPiece('0', '0', '0'), rotations=Integer(60))
>>> pieces.add_piece(NablaPiece('1', '1', '1'), rotations=Integer(60))
>>> pieces.add_piece(NablaPiece('1', '0', '10'), rotations=Integer(60))
>>> pieces
Nablas : [0\0/0, 0\10/1, 10\1/0, 10\0/10, 1\1/1]
Deltas : [0/0\0, 0/1\10, 1/10\0, 1/1\1, 10/0\1]
```

The user can obtain the list of valid rhombi pieces as follows:
add_T_piece(label1, label2)
Add a nabla and delta piece with label1 and label2.
This method adds a nabla piece with edges label2T"label1" | label2 / label1. and a delta piece with edges label1 /T"label1" | label2. It also adds T"label1" | label2 to the forbidden list.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_T_piece(1,3)
sage: pieces
Nablas : [3/T1|3]
Deltas : [1/T1|3]
sage: pieces._forbidden_border_labels
['T1|3']
```

add_forbidden_label(label)
Add forbidden border labels.

**INPUT:**
- label – string specifying a new forbidden label

**EXAMPLES:**

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces
sage: pieces = PuzzlePieces()
sage: pieces.add_forbidden_label(1)
sage: pieces._forbidden_border_labels
[1]
sage: pieces.add_forbidden_label(2)
sage: pieces._forbidden_border_labels
[1, 2]
```
add_piece (piece, rotations=120)

Add piece to the list of pieces.

INPUT:

- piece – a nabra piece or a delta piece
- rotations – (default: 120) 0, 60, 120, 180

The user can add valid nabra or delta pieces and specify which rotations of these pieces are legal. For example, rotations=0 does not add any additional pieces (only the piece itself), rotations=60 adds six pieces (namely three delta and three nabra pieces), while rotations=120 adds only delta or nabra (depending on which piece self is). rotations=180 adds the piece and its 180 degree rotation, i.e. one delta and one nabra piece.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: delta = DeltaPiece('a', 'b', 'c')
```

```python
sage: pieces = PuzzlePieces()
sage: pieces
Nablas : []
Deltas : []
sage: pieces.add_piece(delta)
sage: pieces
Nablas : []
Deltas : [a/c\b, b/a\c, c/b\a]
```

```python
sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta, rotations=0)
sage: pieces
Nablas : []
Deltas : [b/a\c]
```

```python
sage: pieces = PuzzlePieces()
sage: pieces.add_piece(delta, rotations=60)
sage: pieces
Nablas : [a\b/c, b\c/a, c\a/b]
Deltas : [a/c\b, b/a\c, c/b\a]
```
Deltas : [a/c\b, b/a\c, c/b\a]

>>> pieces = PuzzlePieces()
>>> pieces.add_piece(delta, rotations=Integer(0))
>>> pieces
Nablas : []
Deltas : [b/a\c]

>>> pieces = PuzzlePieces()
>>> pieces.add_piece(delta, rotations=Integer(60))
>>> pieces
Nablas : [a\b/c, b\c/a, c\a/b]
Deltas : [a/c\b, b/a\c, c/b\a]

boundary_deltas()
Return deltas with south edges not in the forbidden list.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces(['a'])
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.boundary_deltas()], key=str)
[a/c\b, c/b\a]

delta_pieces()
Return the delta pieces as a set.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.delta_pieces()], key=str)
[a/c\b, b/a\c, c/b\a]

nabla_pieces()
Return the nabla pieces as a set.

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a', 'b', 'c')
>>> pieces.add_piece(delta, rotations=Integer(60))
>>> sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```python
sage: from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
sage: pieces = PuzzlePieces()
sage: delta = DeltaPiece('a', 'b', 'c')
sage: pieces.add_piece(delta, rotations=60)
sage: sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```python
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import PuzzlePieces, DeltaPiece
>>> pieces = PuzzlePieces()
>>> delta = DeltaPiece('a', 'b', 'c')
>>> pieces.add_piece(delta, rotations=Integer(60))
>>> sorted([p for p in pieces.nabla_pieces()], key=str)
[a\b/c, b\c/a, c\a/b]
```

```python
class sage.combinat.knutson_tao_puzzles.RhombusPiece(north_piece, south_piece)

Bases: PuzzlePiece

Class of rhombi pieces.

To construct a rhombus piece we input a delta and a nabla piece. The delta and nabla pieces are joined along the south and north edge, respectively.

EXAMPLES:

```python
sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: nabla = NablaPiece('4', '5', '6')
sage: RhombusPiece(delta, nabla)
```

2/\3 6/\5
>>> from sage.all import *
>>> from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    → RhombusPiece
>>> delta = DeltaPiece('1', '2', '3')
>>> nabla = NablaPiece('4', '5', '6')
>>> RhombusPiece(delta, nabla) 2/1\3 6/\5

edges()

Return the tuple of edge names.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    → RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: nabla = NablaPiece('4', '5', '6')
sage: RhombusPiece(delta, nabla).edges() ('north_west', 'north_east', 'south_east', 'south_west')

north_piece()

Return the north piece.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    → RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: nabla = NablaPiece('4', '5', '6')
sage: r = RhombusPiece(delta, nabla)
sage: r.north_piece() 2/1\3

south_piece()

Return the south piece.

EXAMPLES:

sage: from sage.combinat.knutson_tao_puzzles import DeltaPiece, NablaPiece,
    → RhombusPiece
sage: delta = DeltaPiece('1', '2', '3')
sage: nabla = NablaPiece('4', '5', '6')
sage: r = RhombusPiece(delta, nabla)
sage: r.south_piece() 2/1\3

(continues on next page)
5.1.134 Combinatorics on matrices

- Dancing Links internal ppx code
- Dancing links C++ wrapper
- Hadamard matrices
- Latin Squares

5.1.135 Dancing Links internal ppx code

EXAMPLES:

```python
defaultrange = range(0, 6)
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0, 1, 2], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: x = dlx_solver(rows)
sage: x
Dancing links solver for 6 columns and 6 rows
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0), Integer(1), Integer(2)], [Integer(3), Integer(4), Integer(5)], ...
  [Integer(0), Integer(1)], [Integer(2), Integer(3), Integer(4), Integer(5)], ...
  [Integer(0)], [Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)]]
>>> x = dlx_solver(rows)
>>> x
Dancing links solver for 6 columns and 6 rows
```

The number of solutions:

```python
sage: x.number_of_solutions()
3
```

```python
>>> from sage.all import *
>>> x.number_of_solutions()
3
```

Iterate over the solutions:
Combinatorics, Release 10.4

\begin{verbatim}
sage: sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]

>>> from sage.all import *
>>> sorted(map(sorted, x.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]

All solutions (computed in parallel):

sage: sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]

>>> from sage.all import *
>>> sorted(map(sorted, x.all_solutions()))
[[0, 1], [2, 3], [4, 5]]

Return the first solution found when the computation is done in parallel:

sage: sorted(x.one_solution(ncpus=2)) # random
[0, 1]

>>> from sage.all import *
>>> sorted(x.one_solution(ncpus=Integer(2))) # random
[0, 1]

Find all solutions using some specific rows:

sage: x_using_row_2 = x.restrict([2])
sage: x_using_row_2
Dancing links solver for 7 columns and 6 rows
sage: sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]

>>> from sage.all import *
>>> x_using_row_2 = x.restrict([Integer(2)])
>>> x_using_row_2
Dancing links solver for 7 columns and 6 rows
>>> sorted(map(sorted, x_using_row_2.solutions_iterator()))
[[2, 3]]

The two basic methods that are wrapped in this class are search which returns 1 if a solution is found or 0 otherwise and get_solution which return the current solution:

sage: x = dlx_solver(rows)
sage: x.search()
1
sage: x.get_solution()
[0, 1]
sage: x.search()
1
sage: x.get_solution()
[2, 3]
sage: x.search()
1
sage: x.get_solution()

(continues on next page)
\end{verbatim}

5.1. Comprehensive Module List 2121
There is also a method reinitialize to reinitialize the algorithm:

```python
sage: x.reinitialize()
sage: x.search()
1
sage: x.get_solution()
[0, 1]
```
list of solutions

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0, 1, 2], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]

sage: d = dlx_solver(rows)

sage: S = d.all_solutions()

sage: sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]

sage: from sage.all import *

sage: from sage.combinat.matrices.dancing_links import dlx_solver

sage: rows = [[Integer(0), Integer(1), Integer(2)], [Integer(3), Integer(4, 5)], [Integer(0), Integer(1)], [Integer(2), Integer(3), Integer(4), Integer(5)], [Integer(0)], [Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)]]

sage: d = dlx_solver(rows)

sage: S = d.all_solutions()

sage: sorted(sorted(s) for s in S)
[[0, 1], [2, 3], [4, 5]]

sage: S = Subsets(range(4))

sage: rows = map(list, S)

sage: dlx = dlx_solver(rows)

sage: dlx
Dancing links solver for 4 columns and 16 rows

sage: dlx.number_of_solutions()
15

sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=2))
[[1, 2, 3, 4], [1, 2, 10], [1, 3, 9], [1, 4, 8], [1, 14], [2, 3, 7], [2, 4, 6], [2, 13], [3, 4, 5], [3, 12], [4, 11], [5, 10], [6, 9], [7, 8], [15]]
```

The number of CPUs can be specified as input:

```python
sage: S = Subsets(range(4))

sage: rows = map(list, S)

sage: dlx = dlx_solver(rows)

sage: dlx
Dancing links solver for 4 columns and 16 rows

sage: dlx.number_of_solutions()
15

sage: sorted(sorted(s) for s in dlx.all_solutions(ncpus=2))
[[1, 2, 3, 4], [1, 2, 10], [1, 3, 9], [1, 4, 8], [1, 14], [2, 3, 7], [2, 4, 6], [2, 13], [3, 4, 5], [3, 12], [4, 11], [5, 10], [6, 9], [7, 8], [15]]
```

(continues on next page)
If \texttt{ncpus} = 1, the computation is not done in parallel:

\begin{verbatim}
>>> from sage.all import *

>>> sorted(sorted(s) for s in dlx.all_solutions(ncpus=Integer(1))
[[[1, 2, 3, 4],
  [1, 2, 10],
  [1, 3, 9],
  [1, 4, 8],
  [1, 14],
  [2, 3, 7],
  [2, 4, 6],
  [2, 13],
  [3, 4, 5],
  [3, 12],
  [4, 11],
  [5, 10],
  [6, 9],
  [7, 8],
  [15]]

get_solution()

Return the current solution.

After a new solution is found using the method \texttt{search()} this method return the rows that make up the current solution.
\end{verbatim}
ncols()

Return the number of columns.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.ncols()
6
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0), Integer(1), Integer(2)], [Integer(1), Integer(2)],
[-][Integer(0)], [Integer(3), Integer(4), Integer(5)]
>>> dlx = dlx_solver(rows)
>>> dlx.ncols()
6
```

nrows()

Return the number of rows.

EXAMPLES:

```
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [1,2], [0], [3,4,5]]
sage: dlx = dlx_solver(rows)
sage: dlx.nrows()
4
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0), Integer(1), Integer(2)], [Integer(1), Integer(2)],
[-][Integer(0)], [Integer(3), Integer(4), Integer(5)]
>>> dlx = dlx_solver(rows)
>>> dlx.nrows()
4
```

number_of_solutions (ncpus=None, column=None)

Return the number of distinct solutions.

INPUT:

- ncpus – integer (default: None), maximal number of subprocesses to use at the same time. If ncpus>1 the dancing links problem is split into independent subproblems to allow parallel computation. If None, it detects the number of effective CPUs in the system using sage.parallel.ncpus.ncpus().

- column – integer (default: None), the column used to split the problem, if None a random column is chosen (this argument is ignored if ncpus is 1)

OUTPUT:

integer

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows += [[0,2]]
sage: rows += [[1]]
sage: rows += [[3]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions()
2
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]
...
>>> rows += [[Integer(0),Integer(2)]
...
>>> rows += [[Integer(1)]
...
>>> rows += [[Integer(3)]
...
>>> x = dlx_solver(rows)
>>> x.number_of_solutions()
2
```

The number of CPUs can be specified as input:

```python
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: x = dlx_solver(rows)
sage: x.number_of_solutions(ncpus=2, column=3)
3
```

```python
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)],
...
>>> rows += [[Integer(0),Integer(2)]
...
>>> rows += [[Integer(1)]
...
>>> rows += [[Integer(3)]
...
>>> x = dlx_solver(rows)
>>> x.number_of_solutions(ncpus=Integer(2), column=Integer(3))
3
```

```python
sage: S = Subsets(range(5))
sage: rows = map(list, S)
sage: d = dlx_solver(rows)
sage: d.number_of_solutions()
52
```

```python
>>> from sage.all import *
>>> S = Subsets(range(Integer(5)))
>>> rows = map(list, S)
>>> d = dlx_solver(rows)
>>> d.number_of_solutions()
52
```

**one_solution (ncpus=None, column=None)**

Return the first solution found.

This method allows parallel computations which might be useful for some kind of problems when it is very hard just to find one solution.

**INPUT:**

- `ncpus` – integer (default: None), maximal number of subprocesses to use at the same time. If None,
it detects the number of effective CPUs in the system using `sage.parallel.ncpus.ncpus()`.
If `ncpus=1`, the first solution is searched serially.

- `column` – integer (default: None), the column used to split the problem (see `restrict()`). If None, a random column is chosen. This argument is ignored if `ncpus=1`.

**OUTPUT:**

list of rows or None if no solution is found

**Note:** For some case, increasing the number of cpus makes it faster. For other instances, `ncpus=1` is faster. It all depends on problem which is considered.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
dsage: d = dlx_solver(rows)
dsage: solutions = [[0,1], [2,3], [4,5]]
dsage: sorted(d.one_solution()) in solutions
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4), ...
>>> Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4), ...
>>> Integer(5)], [Integer(0), [Integer(1),Integer(2),Integer(3),Integer(4), ...
>>> Integer(5)]]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)], ...
>>> [Integer(4),Integer(5)]]
>>> sorted(d.one_solution()) in solutions
True
```

The number of CPUs can be specified as input:

```python
sage: sorted(d.one_solution(ncpus=Integer(2))) in solutions
True
```

The column used to split the problem for parallel computations can be given:

```python
>>> from sage.all import *
>>> sorted(d.one_solution(ncpus=Integer(2), column=Integer(4))) in solutions
True
```

When no solution is found:

```python
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
```
sage: d.one_solution() is None
True

```python
>>> from sage.all import *
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(2),Integer(3),
   →Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3)]
>>> d = dlx_solver(rows)
>>> d.one_solution() is None
True
```

one_solution_using_milp_solver (solver=None, integrality_tolerance=0.001)

Return a solution found using a MILP solver.

INPUT:

* solver – string or None (default: None), possible values include 'GLPK', 'GLPK/exact', 'Coin', 'Cplex', 'Gurobi', 'CVXOPT', 'PPL', 'InteractiveLP'.

OUTPUT:
list of rows or None if no solution is found

Note: When comparing the time taken by method one_solution, have in mind that one_solution_using_milp_solver first creates (and caches) the MILP solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_milp_solver() in solutions
# needs sage.numerical.mip
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver

>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),
   →Integer(5)], [Integer(0),Integer(1)], [Integer(2),Integer(3),Integer(4),
   →Integer(5)], [Integer(0)], [Integer(1),Integer(2),Integer(3),Integer(4),
   →Integer(5)]
>>> d = dlx_solver(rows)
>>> solutions = [[Integer(0),Integer(1)], [Integer(2),Integer(3)],...
   →[Integer(4),Integer(5)]]
>>> d.one_solution_using_milp_solver() in solutions
# needs sage.numerical.mip
True
```

Using optional solvers:

```python
sage: # optional - gurobi sage_numerical_backends_gurobi, needs sage.
   →numerical.mip
sage: s = d.one_solution_using_milp_solver('gurobi')
sage: s in solutions
True
```
```python
>>> from sage.all import *
>>> # optional - gurobi sage_numerical_backends_gurobi, needs sage.numerical.mip
>>> s = d.one_solution_using_milp_solver('gurobi')
>>> s in solutions
True
```

When no solution is found:

```python
sage: rows = [[0,1,2], [2,3,4,5], [0,1,2,3]]
sage: d = dlx_solver(rows)
sage: d.one_solution_using_milp_solver() is None # needs sage.numerical.mip
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]]
>>> d = dlx_solver(rows)
>>> d.one_solution_using_milp_solver() is None # needs sage.numerical.mip
True
```

### one_solution_using_sat_solver (solver=None)

Return a solution found using a SAT solver.

**INPUT:**

- solver - string or None (default: None), possible values include 'picosat', 'cryptominisat', 'LP', 'glucose', 'glucose-syrup'.

**OUTPUT:**

list of rows or None if no solution is found

**Note:** When comparing the time taken by method one_solution, have in mind that one_solution_using_sat_solver first creates the SAT solver instance from the dancing links solver. This copy of data may take many seconds depending on the size of the problem.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: solutions = [[0,1], [2,3], [4,5]]
sage: d.one_solution_using_sat_solver() in solutions # needs sage.sat
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(3),Integer(4),Integer(5)], [Integer(0),Integer(1),Integer(2),Integer(3),Integer(4),Integer(5)]]
>>> d = dlx_solver(rows)
```

(continues on next page)
Using optional solvers:

```python
>>> from sage.all import *
```
>>> Integer(5)], [Integer(0)], [Integer(1), Integer(2), Integer(3), Integer(4),
>>> Integer(5)])
>>> x = dlx_solver(rows)
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]

Reinitialization of the algorithm:

sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None

>>> from sage.all import *
>>> x.reinitialize()
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
>>> x.get_solution() if x.search() else None
[4, 5]

Reinitialization works after solutions are exhausted:

sage: x.reinitialize()
sage: x.get_solution() if x.search() else None
[0, 1]
sage: x.get_solution() if x.search() else None
[2, 3]
sage: x.get_solution() if x.search() else None
[4, 5]
sage: x.get_solution() if x.search() else None

>>> from sage.all import *
>>> x.reinitialize()
>>> x.get_solution() if x.search() else None
[0, 1]
>>> x.get_solution() if x.search() else None
[2, 3]
>>> x.get_solution() if x.search() else None
[4, 5]

restrict (indices)

Return a dancing links solver solving the subcase which uses some given rows.

For every row that is wanted in the solution, we add a new column to the row to make sure it is in the solution.

INPUT:
• indices – list, row indices to be found in the solution

OUTPUT:

dancing links solver

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0, 1, 2], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [Integer(0), Integer(1), Integer(2), Integer(3), Integer(4), Integer(5), Integer(0), Integer(1), Integer(2), Integer(3), Integer(4), Integer(5)]
>>> d = dlx_solver(rows)
>>> d
Dancing links solver for 6 columns and 6 rows
>>> sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3]]
```

To impose that the 0th row is part of the solution, the rows of the new problem are:

```python
sage: d_using_0 = d.restrict([0])
sage: d_using_0
Dancing links solver for 7 columns and 6 rows
sage: d_using_0.rows()
[[0, 1, 2, 6], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

After restriction the subproblem has one more columns and the same number of rows as the original one:

```python
sage: d.restrict([1]).rows()
[[0, 1, 2], [3, 4, 5, 6], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d.restrict([2]).rows()
[[0, 1, 2], [3, 4, 5], [0, 1, 6], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
```

This method allows to find solutions where the 0th row is part of a solution:
Some other examples:

```python
sage: sorted(map(sorted, d.restrict([1]).solutions_iterator()))
[[0, 1]]
sage: sorted(map(sorted, d.restrict([2]).solutions_iterator()))
[[2, 3]]
sage: sorted(map(sorted, d.restrict([3]).solutions_iterator()))
[[2, 3]]
```

Here there are no solution using both 0th and 3rd row:

```python
sage: list(d.restrict([0,3]).solutions_iterator())
[]
```

**rows()**

Return the list of rows.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
dsage: rows = [[0,1,2], [1,2], [0]]
dsage: x = dlx_solver(rows)
dsage: x.rows()
[[0, 1, 2], [1, 2], [0]]
```

**search()**

Search for a new solution.

Return 1 if a new solution is found and 0 otherwise. To recover the solution, use the method `get_solution()`.
EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> print(x.search())
1
>>> print(x.get_solution())
[3, 0]
```

`solutions_iterator()`

Return an iterator of the solutions.

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [3,4,5], [0,1], [2,3,4,5], [0], [1,2,3,4,5]]
sage: d = dlx_solver(rows)
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)],
          [Integer(3),Integer(4), ..., Integer(5)]
          [Integer(0),Integer(1)],
          [Integer(2),Integer(3),Integer(4), ...
          Integer(5)],
          [Integer(0), [Integer(1),Integer(2),Integer(3),Integer(4), ...
          Integer(5)]
          >>> d = dlx_solver(rows)
          >>> sorted(map(sorted, d.solutions_iterator()))
          [[0, 1], [2, 3], [4, 5]]
```

`split(column)`

Return a dict of independent solvers.

For each i-th row containing a 1 in the `column`, the dict associates the solver giving all solution using the i-th row.

This is used for parallel computations.

INPUT:

- `column` – integer, the column used to split the problem into independent subproblems

OUTPUT:
dict where keys are row numbers and values are dlx solvers

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0, 1, 2], [3, 4, 5], [0, 1], [2, 3, 4, 5], [0], [1, 2, 3, 4, 5]]
sage: d = dlx_solver(rows)
sage: d
Dancing links solver for 6 columns and 6 rows
sage: sorted(map(sorted, d.solutions_iterator()))
[[0, 1], [2, 3], [4, 5]]
```

After the split each subproblem has one more column and the same number of rows as the original problem:

```python
sage: D = d.split(0)
sage: D
{0: Dancing links solver for 7 columns and 6 rows,
  2: Dancing links solver for 7 columns and 6 rows,
  4: Dancing links solver for 7 columns and 6 rows}
```

The (disjoint) union of the solutions of the subproblems is equal to the set of solutions shown above:

```python
sage: for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

```python
>>> from sage.all import *
>>> D = d.split(Integer(0))
>>> D
{0: Dancing links solver for 7 columns and 6 rows,
  2: Dancing links solver for 7 columns and 6 rows,
  4: Dancing links solver for 7 columns and 6 rows}
```

```python
>>> for x in D.values(): sorted(map(sorted, x.solutions_iterator()))
[[0, 1]]
[[2, 3]]
[[4, 5]]
```

```python
to_milp(solver=None)
```
Return the mixed integer linear program (MILP) representing an equivalent problem.

See also sage.numerical.mip.MixedIntegerLinearProgram.

INPUT:
Combinatorics, Release 10.4

- solver - string or None (default: None), possible values include 'GLPK', 'GLPK/exact',
  'Coin', 'CPLEX', 'Gurobi', 'CVXOPT', 'PPL', 'InteractiveLP'.

OUTPUT:
- MixedIntegerLinearProgram instance
- MIPVariable with binary components

EXAMPLES:
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: d = dlx_solver(rows)
sage: p, x = d.to_milp()
# needs sage.numerical.mip
sage: p
# needs sage.numerical.mip
Boolean Program (no objective, 4 variables, ... constraints)
sage: x
# needs sage.numerical.mip
MIPVariable with 4 binary components

In the reduction, the boolean variable x_i is True if and only if the i-th row is in the solution:
sage: p.show()
# needs sage.numerical.mip
Maximization:

Constraints:
- one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
- one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
- one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
- one 1 in 3-th column: 1.0 <= x_3 <= 1.0

Variables:
- x_0 is a boolean variable (min=0.0, max=1.0)
- x_1 is a boolean variable (min=0.0, max=1.0)
- x_2 is a boolean variable (min=0.0, max=1.0)
- x_3 is a boolean variable (min=0.0, max=1.0)

(continues on next page)
Constraints:...
one 1 in 0-th column: 1.0 <= x_0 + x_1 <= 1.0
one 1 in 1-th column: 1.0 <= x_0 + x_2 <= 1.0
one 1 in 2-th column: 1.0 <= x_0 + x_1 <= 1.0
one 1 in 3-th column: 1.0 <= x_3 <= 1.0
Variables:
x_0 is a boolean variable (min=0.0, max=1.0)
x_1 is a boolean variable (min=0.0, max=1.0)
x_2 is a boolean variable (min=0.0, max=1.0)
x_3 is a boolean variable (min=0.0, max=1.0)

Using some optional MILP solvers:

```python
sage: d.to_milp('gurobi')  # optional - gurobi sage_numerical_backends_gurobi, needs sage.numerical.mip
(Boolean Program (no objective, 4 variables, 4 constraints), MIPVariable with 4 binary components)
```

```python
>>> from sage.all import *
>>> d.to_milp('gurobi')  # optional - gurobi sage_numerical_backends_gurobi, needs sage.numerical.mip
(Boolean Program (no objective, 4 variables, 4 constraints), MIPVariable with 4 binary components)
```

```
to_sat_solver (solver=None)
```

Return the SAT solver solving an equivalent problem.

Note that row index \( i \) in the dancing links solver corresponds to the boolean variable index \( +1 \) for the SAT solver to avoid the variable index 0.

See also `sage.sat.solvers.satsolver`.

INPUT:

* solver — string or None (default: None), possible values include 'picosat', 'cryptominisat', 'LP', 'glucose', 'glucose-syrup'.

OUTPUT:

SAT solver instance

EXAMPLES:

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2], [0,2], [1], [3]]
sage: x = dlx_solver(rows)
sage: s = x.to_sat_solver()  # needs sage.sat
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)], [Integer(0),Integer(2)], [Integer(1)], [Integer(3)]]
>>> x = dlx_solver(rows)
>>> s = x.to_sat_solver()  # needs sage.sat
```
Using some optional SAT solvers:

```python
sage: x.to_sat_solver('cryptominisat')  # optional - pycryptosat  #
              # needs sage.sat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

```python
>>> from sage.all import *
>>> x.to_sat_solver('cryptominisat')  # optional - pycryptosat  #
              # needs sage.sat
CryptoMiniSat solver: 4 variables, 7 clauses.
```

```

sage.combinat.matrices.dancing_links.dlx_solver(rows)
```

Internal-use wrapper for the dancing links C++ code.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.dancing_links import dlx_solver
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: x = dlx_solver(rows)
sage: print(x.search())
1
sage: print(x.get_solution())
[3, 0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.dancing_links import dlx_solver
>>> rows = [[Integer(0),Integer(1),Integer(2)]]
>>> rows+= [[Integer(0),Integer(2)]]
>>> rows+= [[Integer(1)]]
>>> rows+= [[Integer(3)]]
>>> x = dlx_solver(rows)
>>> print(x.search())
1
```

```

sage.combinat.matrices.dancing_links.make_dlxwrapper(s)
```

Create a dlx wrapper from a Python string s.

This was historically used in unpickling and is kept for backwards compatibility. We expect s to be `dumps(rows)` where rows is the list of rows used to instantiate the object.
5.1.136 Dancing links C++ wrapper

`sage.combinat.matrices.dlxcpp.AllExactCovers(M)`

Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

**EXAMPLES:** No exact covers:

```python
sage: M = Matrix([[1,1,0],[1,0,1],[0,1,1]])
# needs sage.modules
sage: [cover for cover in AllExactCovers(M)]
# needs sage.modules
[]
```

Two exact covers:

```python
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]])
# needs sage.modules
sage: [cover for cover in AllExactCovers(M)]
# needs sage.modules
[((1, 1, 0), (0, 0, 1)), ((1, 0, 1), (0, 1, 0))]
```

`sage.combinat.matrices.dlxcpp.DLXCPP(rows)`

Solves the Exact Cover problem by using the Dancing Links algorithm described by Knuth.

Consider a matrix M with entries of 0 and 1, and compute a subset of the rows of this matrix which sum to the vector of all 1’s.

The dancing links algorithm works particularly well for sparse matrices, so the input is a list of lists of the form:

```
[ [i_11, i_12, ..., i_1r]
 ..., [i_m1, i_m2, ..., i_ms]
]
```

where M[j][i_jk] = 1.

The first example below corresponds to the matrix:

```
1110
1010
```
which is exactly covered by:

\[
\begin{array}{c}
1110 \\
0001
\end{array}
\]

and

\[
\begin{array}{c}
1010 \\
0100 \\
0001
\end{array}
\]

If soln is a solution given by DLXCPP(rows) then

\[\text{[ rows[soln[0]], rows[soln[1]], \ldots rows[soln[len(soln)-1]] ]}\]

is an exact cover.

Solutions are given as a list.

EXAMPLES:

```python
sage: rows = [[0,1,2]]
sage: rows+= [[0,2]]
sage: rows+= [[1]]
sage: rows+= [[3]]
sage: [x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

```
from sage.all import *
```

```
rows = [[Integer(0),Integer(1),Integer(2)]]
rows+= [[Integer(0),Integer(2)]]
rows+= [[Integer(1)]]
rows+= [[Integer(3)]]
[ x for x in DLXCPP(rows)]
[[3, 0], [3, 1, 2]]
```

sage.combinat.matrices.dlxcpp.\texttt{OneExactCover}(M)

Solves the exact cover problem on the matrix M (treated as a dense binary matrix).

EXAMPLES:

```python
sage: # needs sage.modules
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0]]) # no exact covers
sage: print(OneExactCover(M))
None
sage: M = Matrix([[1,1,0],[1,0,1],[0,0,1],[0,1,0],[0,1,0]]) # two exact covers
sage: OneExactCover(M)
[(1, 1, 0), (0, 0, 1)]
```

```
from sage.all import *
```

```
# needs sage.modules
>>> M = Matrix([[Integer(1),Integer(1),Integer(0)],[Integer(1),Integer(0),
\rightarrow Integer(1)], [Integer(0),Integer(1),Integer(1)]])) # no exact covers
>>> print(OneExactCover(M))
```
None

```python
>>> M = Matrix([[Integer(1), Integer(1), Integer(0)],
              [Integer(1), Integer(0), Integer(1)],
              [Integer(0), Integer(0), Integer(1)],
              [Integer(0), Integer(1), Integer(0)]]) # two exact covers
```

### 5.1.137 Hadamard matrices

A Hadamard matrix is an $n \times n$ matrix $H$ whose entries are either $+1$ or $-1$ and whose rows are mutually orthogonal. For example, the matrix $H_2$ defined by

\[
\begin{pmatrix}
1 & 1 \\
1 & -1
\end{pmatrix}
\]

is a Hadamard matrix. An $n \times n$ matrix $H$ whose entries are either $+1$ or $-1$ is a Hadamard matrix if and only if:

(a) $|\text{det}(H)| = n^{n/2}$ or

(b) $H \cdot H^t = n \cdot I_n$, where $I_n$ is the identity matrix.

In general, the tensor product of an $m \times m$ Hadamard matrix and an $n \times n$ Hadamard matrix is an $(mn) \times (mn)$ matrix. In particular, if there is an $n \times n$ Hadamard matrix then there is a $(2n) \times (2n)$ Hadamard matrix (since one may tensor with $H_2$). This particular case is sometimes called the Sylvester construction.

The Hadamard conjecture (possibly due to Paley) states that a Hadamard matrix of order $n$ exists if and only if $n = 1, 2$ or $n$ is a multiple of 4.

The module below implements constructions of Hadamard and skew Hadamard matrices for all known orders $\leq 1200$, plus some more greater than 1200. It also allows you to pull a Hadamard matrix from the database at [SloaHada].

The following code will test that a construction for all known orders $\leq 4k$ is implemented. The assertion above can be verified by setting $k=300$ (note that it will take a long time to run):

```python
sage: from sage.combinat.matrices.hadamard_matrix import (hadamard_matrix,
                                                         skew_hadamard_matrix, is_hadamard_matrix,
                                                         is_skew_hadamard_matrix)

sage: k = 20
sage: unknown_hadamard = [668, 716, 892, 1132]

sage: unknown_skew_hadamard = [356, 404, 428, 476, 596, 612, 668, 708, 712, 716, 764, 772, 804, 808, 820, 836, 856, 892, 900, 916, 932, 940, 952, 980, 996, 1004, 1012, 1028, 1036, 1044, 1060, 1076, 1100, 1108, 1132, 1140, 1148, 1156, 1180, 1192, 1196]

sage: for n in range(1, k+1):
    if 4*n not in unknown_hadamard:
        H = hadamard_matrix(4*n, check=False)
        assert is_hadamard_matrix(H)
    if 4*n not in unknown_skew_hadamard:
        H = skew_hadamard_matrix(4*n, check=False)
        assert is_skew_hadamard_matrix(H)
```

}(continues on next page)
```python
>>> k = Integer(20)
>>> unknown_hadamard = [Integer(668), Integer(716), Integer(892), Integer(1132)]
>>> unknown_skew_hadamard = [Integer(356), Integer(404), Integer(428), Integer(476),...
Integer(596), Integer(612), Integer(668), Integer(708), Integer(712), Integer(716),...
Integer(764), Integer(772), Integer(804), Integer(808),...
Integer(820), Integer(836), Integer(856), Integer(892), Integer(900), Integer(916),...
Integer(932), Integer(940), Integer(952), Integer(980),...
Integer(996), Integer(1004), Integer(1012), Integer(1028), Integer(1036),...
Integer(1044), Integer(1060), Integer(1076),...
Integer(1100), Integer(1108), Integer(1132), Integer(1140), Integer(1148),...
Integer(1156), Integer(1180), Integer(1192),...
Integer(1196)]
>>> for n in range(Integer(1), k+Integer(1)):
...    if Integer(4)*n not in unknown_hadamard:
...        H = hadamard_matrix(Integer(4)*n, check=False)
...        assert is_hadamard_matrix(H)
...    if Integer(4)*n not in unknown_skew_hadamard:
...        H = skew_hadamard_matrix(Integer(4)*n, check=False)
...        assert is_skew_hadamard_matrix(H)
```

AUTHORS:
- David Joyner (2009-05-17): initial version
- Matteo Cati (2023-03-18): implemented more constructions for Hadamard and skew Hadamard matrices, to cover all known orders up to 1200.

sage.combinat.matrices.hadamard_matrix.GS_skew_hadamard_smallcases(n, existence=False, check=True)

Data for Williamson-Goethals-Seidel construction of skew Hadamard matrices

Here we keep the data for this construction. Namely, it needs 4 circulant matrices with extra properties, as described in sage.combinat.matrices.hadamard_matrix.williamson_goethals_seidel_skew_hadamard_matrix(). Matrices are taken from:

- n = 36, 52: [GS70s]
- n = 92: [Wall71]
- n = 188: [Djo2008a]
- n = 236: [FKS2004]
- n = 276: [Djo2023a]

Additional data is obtained from skew supplementary difference sets contained in sage.combinat.designs.difference_family.skew_supplementary_difference_set(), using the construction described in [Djo1992a].

INPUT:
Combinatorics, Release 10.4

• \( n \) – integer; the order of the matrix
• \( \text{existence} \) – boolean (default: True); if True, only check that we can do the construction
• \( \text{check} \) – boolean (default: False); if True, check the result

\[
\text{RSHCD}_{324} (\epsilon)
\]

Return a size 324x324 Regular Symmetric Hadamard Matrix with Constant Diagonal.

We build the matrix \( M \) for the case \( n = 324 \), \( \epsilon = 1 \) directly from JankoKharaghaniTonchevGraph and for the case \( \epsilon = -1 \) from the “twist” \( M' \) of \( M \), using Lemma 11 in [HX2010]. Namely, it turns out that the matrix

\[
M' = \begin{pmatrix}
M_{12} & M_{11} \\
M_{11}^T & M_{21}
\end{pmatrix}, \quad M = \begin{pmatrix}
M_{11} & M_{12} \\
M_{21} & M_{22}
\end{pmatrix},
\]

and the \( M_{ij} \) are 162x162-blocks, also RSHCD. Its diagonal blocks having zero row sums, as needed by [loc.cit.]. Interestingly, the corresponding \((324, 152, 70, 72)\)-strongly regular graph has a vertex-transitive automorphism group of order 2592, twice the order of the (intransitive) automorphism group of the graph corresponding to \( M \). Cf. [CP2016].

INPUT:
• \( \epsilon = -1 \) or +1; the value of \( \epsilon \)

REFERENCE:
• [CP2016]

\[
\text{amicable_hadamard_matrices} (n, \text{existence}=\text{False}, \text{check}=\text{True})
\]

Construct amicable Hadamard matrices of order \( n \) using the available methods.

INPUT:
• \( n \) – positive integer; the order of the amicable Hadamard matrices
• \( \text{existence} \) – boolean (default: False); if True, only return whether amicable Hadamard matrices of order \( n \) can be constructed
• \( \text{check} \) – boolean (default: True); if True, check that the matrices are amicable Hadamard matrices before returning them

OUTPUT:
If \text{existence} is true, the function returns a boolean representing whether amicable Hadamard matrices of order \( n \) can be constructed. If \text{existence} is false, returns two amicable Hadamard matrices, or raises an error if the matrices cannot be constructed.

EXAMPLES:

\[
\begin{align*}
\text{sage: } & \text{from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices} \\
\text{sage: } & \text{amicable_hadamard_matrices}(2) \\
& \{ \\
& [ 1 1] [ 1 1] \\
& [-1 1], [ 1 -1] \\
\}
\]

\[
\begin{align*}
\text{>>> from sage.all import *} \\
\text{>>> from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices} \\
\text{>>> amicable_hadamard_matrices(Integer(2))} \\
& \{ \\
\}
\]

(continues on next page)
If `existence` is `true`, the function returns a boolean:

```python
sage: amicable_hadamard_matrices(16, existence=True)
False
```

```python
>>> from sage.all import *
>>> amicable_hadamard_matrices(Integer(16), existence=True)
False
```

`sage.combinat.matrices.hadamard_matrix.amicable_hadamard_matrices_wallis(n, check=True)`

Construct amicable Hadamard matrices of order \( n = q + 1 \) where \( q \) is a prime power.

If \( q \) is a prime power \( \equiv 3 \mod 4 \), then amicable Hadamard matrices of order \( q+1 \) can be constructed as described in [Wal1970b].

**INPUT:**

- \( n \) – integer; the order of the matrices to be constructed
- `check` – boolean (default: `True`); if `True`, check that the resulting matrices are amicable Hadamard before returning them

**OUTPUT:**

The function returns two amicable Hadamard matrices, or raises an error if such matrices cannot be created using this construction.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import amicable_hadamard_matrices_wallis
sage: M, N = amicable_hadamard_matrices_wallis(28)
```

```python
>>> M, N = amicable_hadamard_matrices_wallis(Integer(28))
```

`sage.combinat.matrices.hadamard_matrix.are_amicable_hadamard_matrices(M, N, verbose=False)`

Check if \( M \) and \( N \) are amicable Hadamard matrices.

Two matrices \( M \) and \( N \) of order \( n \) are called amicable if they satisfy the following conditions (see [Seb2017]):

- \( M \) is a skew Hadamard matrix
- \( N \) is a symmetric Hadamard matrix
- \( M N^T = N M^T \)

**INPUT:**

- \( M \) – a square matrix
- \( N \) – a square matrix
• verbose – boolean (default False); whether to be verbose when the matrices are not amicable Hadamard matrices

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_matrices
sage: M = matrix([[1, 1], [-1, 1]])
sage: N = matrix([[1, 1], [1, -1]])
sage: are_amicable_hadamard_matrices(M, N)
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_matrices
>>>
>>> M = matrix([[Integer(1), Integer(1)], [-Integer(1), Integer(1)]])
>>> N = matrix([[Integer(1), Integer(1)], [Integer(1), -Integer(1)]])
>>> are_amicable_hadamard_matrices(M, N)
True
```

If verbose is true, the function will be verbose when returning False:

```python
sage: N = matrix([[1, 1], [1, 1]])
sage: are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import are_amicable_hadamard_matrices
>>>
>>> N = matrix([[Integer(1), Integer(1)], [Integer(1), Integer(1)]])
>>> are_amicable_hadamard_matrices(M, N, verbose=True)
The second matrix is not Hadamard
False
```

sage.combinat.matrices.hadamard_matrix.construction_four_symbol_delta_code_I(X, Y, Z, W)

Construct 4-symbol $\delta$ code of length $2n + 1$.

The 4-symbol $\delta$ code is constructed from sequences $X, Y, Z, W$ of length $n + 1, n + 1, n, n$ satisfying for all $s > 0$:

$$N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0$$

where $N_A(s)$ is the nonperiodic correlation function:

$$N_A(s) = \sum_{i=1}^{n-s} a_i a_{i+s}$$

The construction (detailed in [Tur1974]) is as follows:

$$T_1 = X; Z$$
$$T_2 = X; -Z$$
$$T_3 = Y; W$$
$$T_4 = Y; -W$$

INPUT:
Combinatorics, Release 10.4

• \( X \) – list; the first sequence (length \( n + 1 \))
• \( Y \) – list; the second sequence (length \( n + 1 \))
• \( Z \) – list; the third sequence (length \( n \))
• \( W \) – list; the fourth sequence (length \( n \))

OUTPUT:
A tuple containing the 4-symbol \( \delta \) code of length \( 2n + 1 \).

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_delta_code_I
sage: construction_four_symbol_delta_code_I([1, 1], [1, -1], [1], [1])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_delta_code_I
>>> construction_four_symbol_delta_code_I([Integer(1), Integer(1)], [Integer(1), -Integer(1)], [Integer(1)], [Integer(1)])
([1, 1, 1], [1, 1, -1], [1, -1, 1], [1, -1, -1])
```

sage.combinat.matrices.hadamard_matrix.constructors_four_symbol_delta_code_II(\( X \), \( Y \), \( Z \), \( W \))

Construct 4-symbol \( \delta \) code of length \( 4n + 3 \).

The 4-symbol \( \delta \) code is constructed from sequences \( X, Y, Z, W \) of length \( n + 1, n + 1, n, n \) satisfying for all \( s > 0 \):

\[
N_X(s) + N_Y(s) + N_Z(s) + N_W(s) = 0
\]

where \( N_A(s) \) is the nonperiodic correlation function:

\[
N_A(s) = \sum_{i=1}^{n-s} a_ia_{i+s}
\]

The construction (detailed in [Tur1974]) is as follows (writing \( A/B \) to mean \( A \) alternated with \( B \)):

\[
\begin{align*}
T_1 &= X/Z; Y/W; 1 \\
T_2 &= X/Z; Y/-W; -1 \\
T_3 &= X/Z; -Y/-W; 1 \\
T_4 &= X/Z; -Y/W; -1
\end{align*}
\]

INPUT:
• \( X \) – list; the first sequence (length \( n + 1 \))
• \( Y \) – list; the second sequence (length \( n + 1 \))
• \( Z \) – list; the third sequence (length \( n \))
• \( W \) – list; the fourth sequence (length \( n \))
OUTPUT:
A tuple containing the four 4-symbol $\delta$ code of length $4n + 3$.

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_delta_code_II
sage: construction_four_symbol_delta_code_II([1, 1], [1, -1], [1], [1])
([1, 1, 1, 1, 1, -1, 1],
 [1, 1, 1, -1, -1, 1, 1],
 [1, 1, 1, -1, 1, 1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import construction_four_symbol_delta_code_II
>>> construction_four_symbol_delta_code_II([Integer(1), Integer(1)], [Integer(1), -Integer(1)], [Integer(1)], [Integer(1)])
([1, 1, 1, 1, 1, -1, 1],
 [1, 1, 1, -1, -1, 1, 1],
 [1, 1, 1, -1, 1, 1, -1])
```

```
sage.combinat.matrices.hadamard_matrix.four_symbol_delta_code_smallcases(n, existence=False)
```
Return the 4-symbol $\delta$ code of length $n$ if available.

The 4-symbol $\delta$ codes are constructed using `construction_four_symbol_delta_code_I()` or `construction_four_symbol_delta_code_II()`. The base sequences used are taken from [Tur1974].

INPUT:

- $n$ – integer; the length of the desired 4-symbol $\delta$ code
- existence – boolean (default: False); if True, only check if the sequences are available

EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import four_symbol_delta_code_smallcases
sage: four_symbol_delta_code_smallcases(3)
([1, -1, 1], [1, -1, -1], [1, 1, 1], [1, 1, -1])
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import four_symbol_delta_code_smallcases
>>> four_symbol_delta_code_smallcases(Integer(3))
([1, -1, 1], [1, -1, -1], [1, 1, 1], [1, 1, -1])
```

```
sage.combinat.matrices.hadamard_matrix.hadamard_matrix(n, existence=False, check=True, construction_name=False)
```
This function is available as hadamard_matrix(...) and matrix.hadamard(...).

Tries to construct a Hadamard matrix using the available methods.
Currently all orders $\leq 1200$ for which a construction is known are implemented. For $n > 1200$, only some orders are available.

**INPUT:**

- $n$ – integer; dimension of the matrix
- **existence** – boolean (default: False); whether to build the matrix or merely query if a construction is available in Sage. When set to True, the function returns:
  - **True** – meaning that Sage knows how to build the matrix
  - **Unknown** – meaning that Sage does not know how to build the matrix, although the matrix may exist (see `sage.misc.unknown`).
  - **False** – meaning that the matrix does not exist.
- **check** – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed.
- **construction_name** – boolean (default: False); if it is True, existence is True, and a matrix exists, output the construction name. It has no effect if existence is set to False.

**EXAMPLES:**

```python
sage: hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: hadamard_matrix(1)
[1]
sage: hadamard_matrix(2)
[ 1 1]
[ 1 -1]
sage: hadamard_matrix(8) # random
[ 1 1 1 1 1 1 1 1]
[ 1 -1 1 -1 1 -1 1 -1]
[ 1 -1 -1 1 -1 1 -1 1]
[ 1 1 1 -1 -1 -1 -1 -1]
[ 1 -1 1 -1 -1 1 -1 1]
[ 1 1 -1 -1 -1 1 -1 1]
[ 1 -1 -1 1 1 -1 1 -1]
[ 1 1 1 1 1 1 1 1]
sage: hadamard_matrix(8).det() == 8^4
True
```

```python
>>> from sage.all import *
>>> hadamard_matrix(Integer(12)).det()
2985984
>>> Integer(12)**Integer(6)
2985984
>>> hadamard_matrix(Integer(1))
[1]
>>> hadamard_matrix(Integer(2))
[ 1 1]
[ 1 -1]
>>> hadamard_matrix(Integer(8)) # random
[ 1 1 1 1 1 1 1 1]
[ 1 -1 1 -1 1 -1 1 -1]
[ 1 1 -1 -1 1 1 -1 1]
(continues on next page)
```
We note that \texttt{hadamard_matrix()} returns a normalised Hadamard matrix (the entries in the first row and column are all +1)

```python
to find how the matrix is obtained, use \texttt{construction\_name}
```

```
sage: matrix.hadamard(476, existence=True, construction_name=True)
'cooper-wallis small cases: 476'
```
Construct a Hadamard matrix of order 156.

The matrix is created using the construction detailed in [BH1965]. This uses four circulant matrices of size $13 \times 13$, which are composed into a $156 \times 156$ block matrix.

Create a Hadamard matrix using the contruction detailed in [CW1972].

Given four circulant matrices $X_1, X_2, X_3, X_4$ of order $n$ with entries $(0, 1, -1)$ such that the entrywise product of two distinct matrices is always equal to 0 and that $\sum_{i=1}^{n} X_i X_i^\top = nI_n$ holds, and four matrices $A, B, C, D$ of order $m$ with elements $(1, -1)$ such that $MN^\top = NM^\top$ for all distinct $M, N$ and $AA^\top + BB^\top + CC^\top + DD^\top = 4mI_n$ holds, we construct a Hadamard matrix of order $4nm$.

**INPUT:**

- $x1$ – list or vector; the first row of the circulant matrix $X_1$
- $x2$ – list or vector; the first row of the circulant matrix $X_2$
- $x3$ – list or vector; the first row of the circulant matrix $X_3$
- $x4$ – list or vector; the first row of the circulant matrix $X_4$
- $A$ – the matrix described above
- $B$ – the matrix described above
- $C$ – the matrix described above
- $D$ – the matrix described above
- $check$ – boolean (default: True); if True, check that the resulting matrix is Hadamard before returing it.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_wallis_construction
sage: from sage.combinat.t_sequences import T_sequences_smallcases
sage: seqs = T_sequences_smallcases(19)
sage: hadamard_matrix_cooper_wallis_construction(seqs[0], seqs[1], seqs[2], seqs[3], matrix([1]), matrix([1]), matrix([1]), matrix([1]))
76 x 76 dense matrix over Integer Ring...
```
Construct Hadamard matrices using the Cooper-Wallis construction for some small values of \( n \).

This function calls the function `hadamard_matrix_cooper_wallis_construction()` with the appropriate arguments. It constructs the matrices \( X_1, X_2, X_3, X_4 \) using either T-matrices or the T-sequences from `sage.combinat.t_sequences.T_sequences_smallcases()`. The matrices \( A, B, C, D \) are taken from `williamson_type_quadruples_smallcases()`.

Data for T-matrices of order 67 is taken from [Saw1985].

**INPUT:**

- \( n \) – integer; the order of the matrix to be constructed
- `check` – boolean (default: True); if True, check that the matrix is a Hadamard matrix before returning
- `existence` – boolean (default: False); if True, only check if the matrix exists.

**OUTPUT:**

If `existence=False`, returns the Hadamard matrix of order \( n \). It raises an error if no data is available to construct the matrix of the given order. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**See also:**

`hadamard_matrix_cooper_wallis_construction()`

**EXAMPLES:**

By default, the function returns the Hadamard matrix

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_cooper_wallis_smallcases
sage: hadamard_matrix_cooper_wallis_smallcases(28)
28 x 28 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns a boolean

```python
sage: hadamard_matrix_cooper_wallis_smallcases(20, existence=True)
True
```
Construction of Hadamard matrices from supplementary difference sets.

Given four SDS with parameters $4 - \{n_1, n_2, n_3, n_4; \lambda\}$ with $n_1 + n_2 + n_3 + n_4 = n + \lambda$ we can construct four (-1,+1) sequences $a_i = (a_{i,0}, \ldots, a_{i,n-1})$ where $a_{i,j} = -1$ iff $j \in S_j$. These will be the first rows of four circulant matrices $A_1, A_2, A_3, A_4$ which, when plugged into the Goethals-Seidel array, create a Hadamard matrix of order $4n$ (see [Djo1994b]).

The supplementary difference sets are taken from `sage.combinat.designs.difference_family.supplementary_difference_set()`.

INPUT:

- $n$ – integer; the order of the matrix to be constructed
- check – boolean (default: True); if True, check that the matrix is a Hadamard before returning
- existence – boolean (default: False); if True, only check if the matrix exists

OUTPUT:

If `existence=False`, returns the Hadamard matrix of order $n$. It raises an error if no data is available to construct the matrix of the given order, or if $n$ is not a multiple of 4. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

EXAMPLES:

By default, the function returns the Hadamard matrix

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_from_sds
sage: hadamard_matrix_from_sds(148)
148 x 148 dense matrix over Integer Ring...
```

If `existence` is set to True, the function returns a boolean

```python
sage: hadamard_matrix_from_sds(764, existence=True)
True
```

Construct Hadamard matrix using the Miyamoto construction.
If \( q = n/4 \) is a prime power, and there exists a Hadamard matrix of order \( q - 1 \), then a Hadamard matrix of order \( n \) can be constructed (see [Miy1991]).

**INPUT:**
- \( n \) – integer; the order of the matrix to be constructed
- \( \text{check} \) – boolean (default: True); if True, check that the matrix is a Hadamard before returning
- \( \text{existence} \) – boolean (default: False); if True, only check if the matrix exists

**OUTPUT:**
If \( \text{existence}=\text{False} \), returns the Hadamard matrix of order \( n \). It raises an error if no data is available to construct the matrix of the given order, or if \( n \) does not satisfy the constraints. If \( \text{existence}=\text{True} \), returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**
By default the function returns the Hadamard matrix

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_miyamoto_construction
sage: hadamard_matrix_miyamoto_construction(20)
20 x 20 dense matrix over Integer Ring...
```

If \( \text{existence} \) is set to \( \text{True} \), the function returns a boolean

```python
sage: hadamard_matrix_miyamoto_construction(36, existence=True)
True
```

sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyI \((n, \text{normalize}=\text{True})\)
Implement the Paley type I construction.

The Paley type I case corresponds to the case \( p = n - 1 \equiv 3 \mod 4 \) for a prime power \( p \) (see [Hora]).

**INPUT:**
- \( n \) – the matrix size
- \( \text{normalize} \) – boolean (default: True); whether to normalize the result

**EXAMPLES:**
We note that this method by default returns a normalised Hadamard matrix

```python
sage: hadamard_matrix_paleyI(4)
[ 1  1  1  1]
[ 1 -1  1 -1]
[ 1 -1 -1  1]
[ 1  1 -1 -1]
```
Otherwise, it returns a skew Hadamard matrix $H$, i.e. $H = S + I$, with $S = -S^T$

```
sage: M = hadamard_matrix_paleyI(4, normalize=False); M
[1 1 1 1]
[-1 1 1 -1]
[-1 -1 1 -1]
[-1 -1 -1 1]
sage: S = M - identity_matrix(4); -S == S.T
True
```

`sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(n)`
Implement the Paley type II construction.

The Paley type II case corresponds to the case $p = n/2 - 1 \equiv 1 \mod 4$ for a prime power $p$ (see [Hora]).

**EXAMPLES:**

```
sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(12).det()
2985984
sage: 12^6
2985984
```

```
sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(Integer(12)).det()
2985984
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_paleyI
>>> hadamard_matrix_paleyI(Integer(4))
[1 1 1 1]
[1 -1 1 -1]
[1 -1 -1 1]
[1 1 -1 -1]
```

We note that the method returns a normalised Hadamard matrix

```
sage: sage.combinat.matrices.hadamard_matrix.hadamard_matrix_paleyII(12)
[1 1 1 1 1 1 1 1 1 1 1 1]
[1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
[1 -1 1 1 -1 -1 -1 -1 1 1 -1 -1]
[1 1 -1 1 -1 -1 -1 -1 -1 1 1 -1]
[1 -1 1 -1 -1 -1 1 1 1 -1 -1 -1]
[1 1 -1 -1 -1 -1 -1 1 1 1 -1 -1]
[1 -1 -1 1 -1 -1 -1 -1 1 1 1 -1]
[1 1 1 -1 -1 -1 -1 -1 -1 -1 1 1]
(continues on next page)
Create a Hadamard matrix of order $n$ using the Spence construction.

This construction (detailed in [Spe1975]), uses supplementary difference sets implemented in `sage.combinat.designs.difference_family.supplementary_difference_set_from_rel_diff_set()` to create the desired matrix.

**INPUT:**

- $n$ – integer; the order of the matrix to be constructed
- `existence` – boolean (default: False); if True, only check if the matrix exists
- `check` – boolean (default: True); if True, check that the matrix is a Hadamard matrix before returning

**OUTPUT:**

If `existence=True`, returns a boolean representing whether the Hadamard matrix can be constructed. Otherwise, returns the Hadamard matrix, or raises an error if it cannot be constructed.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_spence_construction
sage: hadamard_matrix_spence_construction(36)
```

36 x 36 dense matrix over Integer Ring...
```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_spence_construction
>>> hadamard_matrix_spence_construction(Integer(36))
36 x 36 dense matrix over Integer Ring...
```

If `existence` is `True`, the function returns a boolean.

```python
sage: hadamard_matrix_spence_construction(52, existence=True)
True
```

```python
>>> from sage.all import *
>>> hadamard_matrix_spence_construction(Integer(52), existence=True)
True
```

```python
sage.combinat.matrices.hadamard_matrix.hadamard_matrix_turyn_type(a, b, c, d, e1, e2, e3, e4, check=True)
```

Construction of Turyń type Hadamard matrix.

Given \( n \times n \) circulant matrices \( A, B, C, D \) with 1,-1 entries, satisfying \( AA^T + BB^T + CC^T + DD^T = 4nI \), and a set of Baumert-Hall units of order \( 4t \), one can construct a Hadamard matrix of order \( 4tn \) as detailed by Turyń in [Tur1974].

**INPUT:**
- \( a \) – 1,-1 list; the 1st row of \( A \)
- \( b \) – 1,-1 list; the 1st row of \( B \)
- \( d \) – 1,-1 list; the 1st row of \( C \)
- \( c \) – 1,-1 list; the 1st row of \( D \)
- \( e1 \) – Matrix; the first Baumert-Hall unit
- \( e2 \) – Matrix; the second Baumert-Hall unit
- \( e3 \) – Matrix; the third Baumert-Hall unit
- \( e4 \) – Matrix; the fourth Baumert-Hall unit
- \( check \) – boolean (default: `True`); whether to check that the output is a Hadamard matrix before returning it

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_turyn_type, _get_baumert_hall_units
sage: A, B, C, D = _get_baumert_hall_units(28)
sage: hadamard_matrix_turyn_type([1], [1], [1], [1], A, B, C, D)
28 x 28 dense matrix over Integer Ring...
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_turyn_type, _get_baumert_hall_units
>>> A, B, C, D = _get_baumert_hall_units(Integer(28))
>>> hadamard_matrix_turyn_type([Integer(1)], [Integer(1)], [Integer(1)], [Integer(1)], Integer(28), A, B, C, D)
28 x 28 dense matrix over Integer Ring...
```
Construction of Williamson type Hadamard matrix.

Given $n \times n$ circulant matrices $A, B, C, D$ with 1,-1 entries, and satisfying $AA^T + BB^T + CC^T + DD^T = 4nI$, one can construct a Hadamard matrix of order $4n$, cf. [Ha83].

**INPUT:**
- $a$ = (1,-1) list; the 1st row of $A$
- $b$ = (1,-1) list; the 1st row of $B$
- $c$ = (1,-1) list; the 1st row of $C$
- $d$ = (1,-1) list; the 1st row of $D$
- check = boolean (default: True); whether to check that the output is a Hadamard matrix before returning it

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_williamson_type
sage: a = [ 1, 1, 1]
sage: b = [ 1, -1, -1]
sage: c = [ 1, -1, -1]
sage: d = [ 1, -1, -1]
sage: M = hadamard_matrix_williamson_type(a,b,c,d,check=True)
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import hadamard_matrix_williamson_type
>>> a = [ Integer(1), Integer( 1), Integer(1)]
>>> b = [ Integer(1), -Integer(1), -Integer(1)]
>>> c = [ Integer(1), -Integer(1), -Integer(1)]
>>> d = [ Integer(1), -Integer(1), -Integer(1)]
>>> M = hadamard_matrix_williamson_type(a,b,c,d,check=True)
```

**sage.combinat.matrices.hadamard_matrix.hadamard_matrix_www(url_file, comments=False)**

Pull file from Sloane's database and return the corresponding Hadamard matrix as a Sage matrix.

You must input a filename of the form “had.n.xxx.txt” as described on the webpage http://neilsloane.com/hadamard/, where “xxx” could be empty or a number of some characters.

If comments=True then the “Automorphism…” line of the had.n.xxx.txt file is printed if it exists. Otherwise nothing is done.

**EXAMPLES:**

```python
sage: hadamard_matrix_www("had.4.txt")             # optional - internet
[ 1 1 1 1]
[ 1 -1 1 -1]
[ 1 1 -1 -1]
[ 1 -1 -1 1]
```

```python
sage: hadamard_matrix_www("had.16.2.txt", comments=True)  # optional - internet
Automorphism group has order = 49152 = 2^14 * 3
[ 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1 1]
[ 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1 1 -1]
[ 1 1 -1 -1 1 1 -1 -1 1 -1 1 -1 1 -1 1 -1]
```

(continues on next page)

\end{bmatrix}
\]

sage.combinat.matrices.hadamard_matrix.is_hadamard_matrix(M, normalized=False, skew=False, verbose=False)

Test if \( M \) is a Hadamard matrix.

**INPUT:**

- \( M \) – a matrix

- `normalized` – boolean (default: `False`); whether to test if \( M \) is a normalized Hadamard matrix, i.e. has its first row/column filled with +1

- `skew` – boolean (default: `False`); whether to test if \( M \) is a skew Hadamard matrix, i.e. \( M = S + I \) for \( -S = S^\top \), and \( I \) the identity matrix

- `verbose` – boolean (default: `False`); whether to be verbose when the matrix is not Hadamard

**EXAMPLES:**
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: h = matrix.hadamard(12)
sage: is_hadamard_matrix(h)
True
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: h = skew_hadamard_matrix(12)
sage: is_hadamard_matrix(h, skew=True)
True
sage: h = matrix.hadamard(12)
sage: h[0,0] = 2
sage: is_hadamard_matrix(h,verbose=True)
The matrix does not only contain +1 and -1 entries, e.g. 2 False
sage: h = matrix.hadamard(12)
sage: for i in range(12):
...:    h[i,2] = -h[i,2]
sage: is_hadamard_matrix(h,verbose=True,normalized=True)
The matrix is not normalized False

sage.combinat.matrices.hadamard_matrix.is_skew_hadamard_matrix(M, normalized=False, verbose=False)

Test if M is a skew Hadamard matrix.
this is a wrapper around the function is_hadamard_matrix()

INPUT:
- M - a matrix
- normalized - boolean (default: False); whether to test if M is a skew-normalized Hadamard matrix, i.e. has its first row filled with +1
- verbose - boolean (default: False); whether to be verbose when the matrix is not skew Hadamard

EXAMPLES:
sage: from sage.combinat.matrices.hadamard_matrix import is_skew_hadamard_matrix, skew_hadamard_matrix
sage: h = matrix.hadamard(12)
sage: is_skew_hadamard_matrix(h, verbose=True)
The matrix is not skew
False
sage: h = skew_hadamard_matrix(12)
sage: is_skew_hadamard_matrix(h)
True
sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard
sage: h = normalise_hadamard(skew_hadamard_matrix(12), skew=True)
sage: is_skew_hadamard_matrix(h, verbose=True, normalized=True)
True

>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import is_skew_hadamard_matrix, skew_hadamard_matrix
>>> h = matrix.hadamard(Integer(12))
>>> is_skew_hadamard_matrix(h, verbose=True)
The matrix is not skew
False
>>> h = skew_hadamard_matrix(Integer(12))
>>> is_skew_hadamard_matrix(h)
True
>>> from sage.combinat.matrices.hadamard_matrix import normalise_hadamard
>>> h = normalise_hadamard(skew_hadamard_matrix(Integer(12)), skew=True)
>>> is_skew_hadamard_matrix(h, verbose=True, normalized=True)
True

sage.combinat.matrices.hadamard_matrix.normalise_hadamard(H, skew=False)
Return the normalised Hadamard matrix corresponding to H.

The normalised Hadamard matrix corresponding to a Hadamard matrix H is a matrix whose every entry in the first row and column is +1.

If skew is True, the matrix returned will be skew-normal: a skew Hadamard matrix with first row of all +1.

EXAMPLES:

sage: from sage.combinat.matrices.hadamard_matrix import normalise_hadamard, is_hadamard_matrix, skew_hadamard_matrix
sage: H = normalise_hadamard(hadamard_matrix(4))
sage: H == hadamard_matrix(4)
True
sage: H = normalise_hadamard(skew_hadamard_matrix(20, skew_normalize=False), skew=True)

(continues on next page)
If `skew` is True but the Hadamard matrix is not skew, the matrix returned will not be normalized:

```python
sage: H = normalise_hadamard(hadamard_matrix(92), skew=True)
sage: is_hadamard_matrix(H, normalized=True)
False
```

Return a Regular Symmetric Hadamard Matrix with Constant Diagonal.

A Hadamard matrix is said to be regular if its rows all sum to the same value.

For \( \epsilon \in \{-1, +1\} \), we say that \( M \) is a \( (n, \epsilon) \) \(-RSHCD\) if \( M \) is a regular symmetric Hadamard matrix with constant diagonal \( \delta \in \{-1, +1\} \) and row sums all equal to \( \delta \epsilon \sqrt{n} \). For more information, see [HX2010] or 10.5.1 in [BH2012]. For the case \( n = 324 \), see \texttt{RSHCD\_324()} and [CP2016].

**INPUT:**

- \( n \) – integer; side of the matrix
- \( \epsilon \) = \(-1\) or \(+1\); the value of \( \epsilon \)

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import regular_symmetric_hadamard_matrix_with_constant_diagonal
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4,1)
[ 1  1  1 -1]
[ 1  1 -1  1]
[ 1 -1  1  1]
[-1  1  1  1]
```

```python
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(4,-1)
[ 1 -1 -1 -1]
[-1  1 -1 -1]
[-1 -1  1 -1]
[-1 -1 -1  1]
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import regular_symmetric_hadamard_matrix_with_constant_diagonal

>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(4), Integer(1))
[ 1  1  1 -1]
[ 1  1 -1  1]
[ 1 -1  1  1]
[-1 -1  1  1]
```
Combinatorics, Release 10.4

(continued from previous page)

>>> regular_symmetric_hadamard_matrix_with_constant_diagonal(Integer(4),-
Integer(1))
[ 1 -1 -1 -1]
[-1 1 -1 -1]
[-1 -1 1 -1]
[-1 -1 -1 1]

Other hardcoded values:

sage: for n,e in [(36,1),(36,-1),(100,1),(100,-1),(196, 1)]:
# long time
....:
print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,->
-e)))
36 x 36 dense matrix over Integer Ring
36 x 36 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
100 x 100 dense matrix over Integer Ring
196 x 196 dense matrix over Integer Ring

sage: for n,e in [(324,1),(324,-1)]:
# not tested - long time, tested in RSHCD_324
....:
print(repr(regular_symmetric_hadamard_matrix_with_constant_diagonal(n,->
-e)))
324 x 324 dense matrix over Integer Ring
324 x 324 dense matrix over Integer Ring

>>> from sage.all import *

From two close prime powers:

sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(64,-1)
64 x 64 dense matrix over Integer Ring (use the '.str()' method to see the␣
entries)

>>> from sage.all import *

From a prime power and a conference matrix:

sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(676,1)  # long time
676 x 676 dense matrix over Integer Ring (use the '.str()' method to see the␣
entries)
Recursive construction:

```python
sage: regular_symmetric_hadamard_matrix_with_constant_diagonal(144,-1)
144 x 144 dense matrix over Integer Ring (use the '.str()' method to see the entries)
```

REFERENCE:
- [BH2012]
- [HX2010]

sage.combinat.matrices.hadamard_matrix.rshcd_from_close_prime_powers(n)

Return a $(n^2, 1)$-RSHCD when $n - 1$ and $n + 1$ are odd prime powers and $n = 0 \pmod{4}$.

The construction implemented here appears in Theorem 4.3 from [GS1970].

Note that the authors of [SWW1972] claim in Corollary 5.12 (page 342) to have proved the same result without the $n = 0 \pmod{4}$ restriction with a very similar construction. So far, however, I (Nathann Cohen) have not been able to make it work.

INPUT:
- $n$ – an integer congruent to 0 (mod 4)

See also:
- `regular_symmetric_hadamard_matrix_with_constant_diagonal`

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import rshcd_from_close_prime_powers
sage: rshcd_from_close_prime_powers(4)
[-1 -1 1 -1 1 -1 -1 1 -1 -1 1 -1 1 -1 1 -1]
[-1 -1 1 1 -1 1 -1 -1 1 -1 -1 1 -1 1 -1 1 -1]

REFERENCE:

• [SWW1972]

sage.combinat.matrices.hadamard_matrix.rshcd_from_prime_power_and_conference_matrix(n)

Return a \((n - 1)^2, 1\)-RSHCD if \(n\) is prime power, and symmetric \((n - 1)\)-conference matrix exists.

The construction implemented here is Theorem 16 (and Corollary 17) from [WW1972].

In [SWW1972] this construction (Theorem 5.15 and Corollary 5.16) is reproduced with a typo. Note that [WW1972] refers to [Sz1969] for the construction, provided by `szekeres_difference_set_pair()`, of complementary difference sets, and the latter has a typo.

From a `symmetric_conference_matrix()`, we only need the Seidel adjacency matrix of the underlying strongly regular conference (i.e., Paley type) graph, which we construct directly.

INPUT:

• \(n\) – an integer

See also:

`regular_symmetric_hadamard_matrix_with_constant_diagonal()`

EXAMPLES:

A 36x36 example

```python
sage: from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_and_conference_matrix
sage: from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
sage: H = rshcd_from_prime_power_and_conference_matrix(7); H
36 x 36 dense matrix over Integer Ring (use the '.str()' method to see the_
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: H == H.T and is_hadamard_matrix(H) and H.diagonal() == [1]*36 and
    list(sum(H)) == [6]*36
True
```

Bigger examples, only provided by this construction

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_and_conference_matrix
>>> from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
>>>
H = rshcd_from_prime_power_and_conference_matrix(Integer(7)); H
36 x 36 dense matrix over Integer Ring (use the '.str()' method to see the
  entries)
H == H.T and is_hadamard_matrix(H) and H.diagonal() ==
    [Integer(1)]*Integer(36) and list(sum(H)) == [Integer(6)]*Integer(36)
True
```

In this example the conference matrix is not Paley, as 45 is not a prime power

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import rshcd_from_prime_power_and_conference_matrix
>>> from sage.combinat.matrices.hadamard_matrix import is_hadamard_matrix
>>>
H = rshcd_from_prime_power_and_conference_matrix(Integer(47)); H
# not tested (long time)
H == H.T and is_hadamard_matrix(H)
# not tested (long time)
H.diagonal() == [Integer(1)]*Integer(676) and list(sum(H)) ==
    [Integer(26)]*Integer(676)
# not tested (long time)
```

REFERENCE:

• [WW1972]
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix(n, existence=False,
    skew_normalize=True, check=True, construction_name=False)

Tries to construct a skew Hadamard matrix.

A Hadamard matrix $H$ is called skew if $H = S - I$, for $I$ the identity matrix and $-S = S^T$. Currently all orders $\leq 1200$ for which a construction is known are implemented. For $n > 1200$, only some orders are available.

INPUT:

• $n$ – integer; dimension of the matrix

5.1. Comprehensive Module List 2165
• existence – boolean (default: False); whether to build the matrix or merely query if a construction is available in Sage. When set to True, the function returns:
  - True – meaning that Sage knows how to build the matrix
  - Unknown – meaning that Sage does not know how to build the matrix, but that the design may exist (see sage.misc.unknown).
  - False – meaning that the matrix does not exist.

• skew_normalize – boolean (default: True); whether to make the 1st row all-one, and adjust the 1st column accordingly

• check – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed

• construction_name – boolean (default: False); if it is True, existence is True, and a matrix exists, output the construction name. It has no effect if existence is set to False.

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
sage: skew_hadamard_matrix(12).det()
2985984
sage: 12^6
2985984
sage: skew_hadamard_matrix(1)
[1]
sage: skew_hadamard_matrix(2)
[ 1  1]
[-1  1]
sage: skew_hadamard_matrix(196, existence=True, construction_name=True)
'Williamson-Goethals-Seidel: 196'
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix
>>> skew_hadamard_matrix(Integer(12)).det()
2985984
>>> Integer(12)**Integer(6)
2985984
>>> skew_hadamard_matrix(Integer(1))
[1]
>>> skew_hadamard_matrix(Integer(2))
[ 1  1]
[-1  1]
>>> skew_hadamard_matrix(Integer(196), existence=True, construction_name=True)
'Williamson-Goethals-Seidel: 196'
```

REFERENCES:
• [Ha83]

Construct a skew Hadamard matrix of order \( n = 4(m + 1) \) from complementary difference sets.

If \( A, B \) are complementary difference sets over a group of order \( 2m + 1 \), then they can be used to construct a skew Hadamard matrix, as described in [BS1969].
The complementary difference sets are constructed using the function `sage.combinat.designs.difference_family.complementary_difference_sets()`.

**INPUT:**
- `n` – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: False); if True, only return whether the skew Hadamard matrix can be constructed
- `check` – boolean (default: True); if True, check that the result is a skew Hadamard matrix before returning it

**OUTPUT:**
If `existence=False`, returns the skew Hadamard matrix of order `n`. It raises an error if `n` does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**

```sage
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_complementary_difference_sets
sage: skew_hadamard_matrix_from_complementary_difference_sets(20)
20 x 20 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_from_complementary_difference_sets(52, existence=True)
True
```

Construct skew Hadamard matrix from good matrices.

Given good matrices $A$, $B$, $C$, $D$ ($A$ circulant, $B, C, D$ back-circulant) they can be used to construct a skew Hadamard matrix using the following block matrix (as described in [Sze1988]):

$$
\begin{pmatrix}
A & B & C & D \\
-B & A & D & -C \\
-C & -D & A & B \\
-D & C & -B & A \\
\end{pmatrix}
$$

**INPUT:**
- `a` – (1,-1) list; the 1st row of $A$
- `b` – (1,-1) list; the 1st row of $B$
- `c` – (1,-1) list; the 1st row of $C$
- `d` – (1,-1) list; the 1st row of $D$
• check – boolean (default: True); if True, check that the matrix is a skew Hadamard matrix before returning it

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_good_matrices
sage: a, b, c, d = ([1, 1, 1, -1, -1], [1, -1, 1, 1, -1], [1, -1, 1, -1, -1], [1, -1, -1, -1, -1])
sage: skew_hadamard_matrix_from_good_matrices(a, b, c, d)
20 x 20 dense matrix over Integer Ring...
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_good_matrices
>>> a, b, c, d = (Integer(1), Integer(1), Integer(1), -Integer(1), -Integer(1),
                -Integer(1), -Integer(1), -Integer(1),
                -Integer(1), -Integer(1), -Integer(1), -Integer(1))
>>> skew_hadamard_matrix_from_good_matrices(a, b, c, d)
20 x 20 dense matrix over Integer Ring...
```

sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_from_good_matrices_smallcases(n, existence=False, check=True)

Construct skew Hadamard matrices from good matrices for some small values of \( n = 4m \), with \( m \) odd.

The function stores good matrices of odd orders \( \leq 31 \), taken from [Sze1988]. These are used to create skew Hadamard matrices of order \( 4m \), \( 1 \leq m \leq 31 \) (\( m \) odd), using the function `skew_hadamard_matrix_from_good_matrices()`.

ALGORITHM:

Given four sequences (stored in `E_sequences`) of length \( m \), they can be used to construct four \( E - sequences \) of length \( n = 2m + 1 \), as follows:

\[
\begin{align*}
a &= 1, a_0, a_1, \ldots, a_m, -a_m, -a_{m-1}, \ldots, -a_0 \\
b &= 1, b_0, b_1, \ldots, b_m, b_m, b_{m-1}, \ldots, b_0 \\
c &= 1, c_0, c_1, \ldots, c_m, c_m, c_{m-1}, \ldots, c_0 \\
d &= 1, d_0, d_1, \ldots, d_m, d_m, d_{m-1}, \ldots, d_0
\end{align*}
\]

These E-sequences will be the first rows of the four good matrices needed to construct a skew Hadamard matrix of order \( 4n \).

INPUT:

• \( n \) – integer; the order of the skew Hadamard matrix to be constructed
• \( existence \) – boolean (default: False); If True, only return whether the Hadamard matrix can be constructed
• \( check \) – boolean (default: True); if True, check that the matrix is a Hadamard matrix before returning it

OUTPUT:

If `existence=False`, returns the skew Hadamard matrix of order \( n \). It raises an error if no data is available to construct the matrix of the given order. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.
EXAMPLES:

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_good_matrices_smallcases
sage: skew_hadamard_matrix_from_good_matrices_smallcases(20)
20 x 20 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_from_good_matrices_smallcases(20, existence=True)
True
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_good_matrices_smallcases
>>> skew_hadamard_matrix_from_good_matrices_smallcases(Integer(20))
20 x 20 dense matrix over Integer Ring...
>>> skew_hadamard_matrix_from_good_matrices_smallcases(Integer(20), existence=True)
True
```

```
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_from_orthogonal_design(n, existence=False, check=True)
```

Construct skew Hadamard matrices of order $mn(n-1)$ if suitable orthogonal designs exist.

In [Seb1978] it is proved that if amicable Hadamard matrices of order $n$ and an orthogonal design of type $(1, m, mn-m-1)$ in order $mn$ exist, then a skew Hadamard matrix of order $mn(n-1)$ can be constructed. The paper uses amicable orthogonal designs instead of amicable Hadamard matrices, but the two are equivalent (see [Seb2017]).

Amicable Hadamard matrices are constructed using `amicable_hadamard_matrices()`, and the orthogonal designs are constructed using the Goethals-Seidel array, with data taken from [Seb2017].

**INPUT:**

- $n$ – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: False); if True, only return whether the skew Hadamard matrix can be constructed
- `check` – boolean (default: True); if True, check that the result is a skew Hadamard matrix before returning it

**OUTPUT:**

If `existence=False`, returns the skew Hadamard matrix of order $n$. It raises an error if a construction for order $n$ is not yet implemented, or if $n$ does not satisfy the constraint. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**

```
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_orthogonal_design
sage: skew_hadamard_matrix_from_orthogonal_design(756)
756 x 756 dense matrix over Integer Ring...
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_from_orthogonal_design
>>> skew_hadamard_matrix_from_orthogonal_design(Integer(756))
756 x 756 dense matrix over Integer Ring...
```
If `existence` is True, the function returns a boolean:

```python
sage: skew_hadamard_matrix_from_orthogonal_design(200, existence=True)
False
```

```python
>>> from sage.all import *
>>> skew_hadamard_matrix_from_orthogonal_design(Integer(200), existence=True)
False
```

```python
sage.combinat.matrices.hadamard_matrix.skew_hadamard_matrix_spence_1975(n, existence=False, check=True)
```

Construct a skew Hadamard matrix of order $n = 4(1 + q + q^2)$ using the Spence construction. If $n = 4(1 + q + q^2)$ where $q$ is a prime power such that either $1 + q + q^2$ is a prime congruent to $3, 5, 7$ mod $8$ or $3 + 2q + 2q^2$ is a prime power, then a skew Hadamard matrix of order $n$ can be constructed using the Goethals Seidel array. The four matrices $A, B, C, D$ plugged into the GS-array are created using complementary difference sets of order $1 + q + q^2$ (which exist if $q$ satisfies the conditions above), and a cyclic planar difference set with parameters $(1 + q^2 + q^4, 1 + q^2, 1)$. These are constructed by the functions `sage.combinat.designs.difference_family.complementary_difference_sets()` and `sage.combinat.designs.difference_family.difference_family()`.

For more details, see [Spe1975b].

**INPUT:**

- $n$ – positive integer; the order of the matrix to be constructed
- `existence` – boolean (default: False); if True, only return whether the Hadamard matrix can be constructed
- `check` – boolean (default: True); check that the result is a skew Hadamard matrix before returning it

**OUTPUT:**

If `existence=False`, returns the skew Hadamard matrix of order $n$. It raises an error if $n$ does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_spence_1975
sage: skew_hadamard_matrix_spence_1975(52)
52 x 52 dense matrix over Integer Ring...
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_spence_1975
>>> skew_hadamard_matrix_spence_1975(Integer(52))
52 x 52 dense matrix over Integer Ring...
```

If `existence` is True, the function returns a boolean:

```python
sage: skew_hadamard_matrix_spence_1975(52, existence=True)
True
```
Construct skew Hadamard matrix of order $n$ using Spence construction.

This function will construct skew Hadamard matrix of order $n = 2(q + 1)$ where $q$ is a prime power with $q \equiv 5 \pmod{8}$. The construction is taken from [Spe1977], and the relative difference sets are constructed using \texttt{sage.combinat.designs.difference_family.relative_difference_set_from_homomorphism()}.

**INPUT:**
- $n$ – positive integer
- \texttt{check} – boolean (default: True); if True, check that the resulting matrix is Hadamard before returning it

**OUTPUT:**
If $n$ satisfies the requirements described above, the function returns a $n \times n$ Hadamard matrix. Otherwise, an exception is raised.

**EXAMPLES:**

```
>>> from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_spence_construction
>>> skew_hadamard_matrix_spence_construction(28)
28 x 28 dense matrix over Integer Ring...
```

Construct a skew Hadamard matrix of order $n = 2(q + 1)$ where $q = p^t$ is a prime power with $p \equiv 5 \pmod{8}$ and $t \equiv 2 \pmod{4}$.

Assuming $n$ satisfies the conditions above, it is possible to construct two supplementary difference sets $A, B$ (see [Whi1971]), and these can be used to construct a skew Hadamard matrix, as described in [BS1969].

**INPUT:**
- $n$ – positive integer; the order of the matrix to be constructed
- \texttt{existence} – boolean (default: False); If True, only return whether the Hadamard matrix can be constructed
- \texttt{check} – boolean (default: True); if True, check that the result is a skew Hadamard matrix before returning it

**OUTPUT:**
If `existence=False`, returns the skew Hadamard matrix of order \( n \). It raises an error if \( n \) does not satisfy the required conditions. If `existence=True`, returns a boolean representing whether the matrix can be constructed or not.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import skew_hadamard_matrix_whiteman_construction
sage: skew_hadamard_matrix_whiteman_construction(52)
52 x 52 dense matrix over Integer Ring...
sage: skew_hadamard_matrix_whiteman_construction(52, existence=True)
True
```

**Note:** A more general version of this construction is `skew_hadamard_matrix_from_complementary_difference_sets()`.

```python
sage.combinat.matrices.hadamard_matrix.symmetric_conference_matrix(n, check=True)
```

Tries to construct a symmetric conference matrix

A conference matrix is an \( n \times n \) matrix \( C \) with 0s on the main diagonal and 1s and -1s elsewhere, satisfying \( CC^T = (n-1)I \). If \( C = C^T \) then \( n \equiv 2 \mod 4 \) and \( C \) is Seidel adjacency matrix of a graph, whose descendent graphs are strongly regular graphs with parameters \((n-1,(n-2)/2,(n-6)/4,(n-2)/4)\), see Sec.10.4 of [BH2012]. Thus we build \( C \) from the Seidel adjacency matrix of the latter by adding row and column of 1s.

**INPUT:**

- \( n \) – integer; dimension of the matrix
- `check` – boolean (default: True); whether to check that output is correct before returning it. As this is expected to be useless (but we are cautious guys), you may want to disable it whenever you want speed

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix
sage: C = symmetric_conference_matrix(10); C
[ 0 1 1 1 1 1 1 1 1 1]
[ 1 0 -1 -1 1 1 1 1 -1 1]
[ 1 -1 0 -1 1 1 -1 -1 1 1]
[ 1 1 -1 1 0 -1 -1 1 -1 1]
[ 1 1 1 -1 0 -1 -1 1 1 1]
[ 1 -1 1 1 0 -1 1 1 -1 1]
[ 1 1 1 -1 1 0 -1 1 1 1]
[ 1 1 1 1 1 1 -1 1 1 1]
[ 1 1 1 1 -1 1 1 -1 1 1]
[ 1 1 -1 1 1 1 1 -1 1 1]
sage: C^2 == 9*identity_matrix(10) and C == C.T
True
```
```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix

>>> C = symmetric_conference_matrix(Integer(10)); C

[ [0 1 1 1 1 1 1 1 1 1]
 [1 0 -1 -1 1 1 1 1 -1 -1]

 [1 -1 1 1 1 -1 1 -1 -1 0] ]

```

```python
>>> C**Integer(2) == Integer(9)*identity_matrix(Integer(10)) and C == C.T

True
```

```python
sage.combinat.matrices.hadamard_matrix.symmetric_conference_matrix_paley(n)

Construct a symmetric conference matrix of order n.

A conference matrix is an \( n \times n \) matrix \( C \) with 0s on the main diagonal and 1s and -1s elsewhere, satisfying \( CC^T = (n - 1)I \). This construction assumes that \( q = n - 1 \) is a prime power, with \( q \equiv 1 \) mod 4. See [Hora] or [Lon2013].

These matrices are used in `hadamard_matrix_paleyII()`.

**INPUT:**

- \( n \) – integer; the order of the symmetric conference matrix to construct

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import symmetric_conference_matrix_paley

sage: symmetric_conference_matrix_paley(6)

[ [0 1 1 1 1 1]
 [1 0 1 -1 -1 1]
 [1 1 0 1 -1 -1]
 [1 -1 0 1 -1 1]
 [1 1 -1 1 0 1]
 [1 -1 -1 1 0 1] ]

sage: symmetric_conference_matrix_paley(Integer(6))

```

```python
sage.combinat.matrices.hadamard_matrix.szekeres_difference_set_pair(m, check=True)

Construct Szekeres \((2m + 1, m, 1)\)-cyclic difference family

Let \( 4m + 3 \) be a prime power. Theorem 3 in [Sz1969] contains a construction of a pair of complementary difference sets \( A, B \) in the subgroup \( G \) of the quadratic residues in \( F_{4m+3}^* \). Namely \( |A| = |B| = m, a \in A \) whenever

```
Combinatorics, Release 10.4

\(a - 1 \in G, b \in B\) whenever \(b + 1 \in G\). See also Theorem 2.6 in [SWW1972] (there the formula for \(B\) is correct, as opposed to (4.2) in [Sz1969], where the sign before 1 is wrong.

In modern terminology, for \(m > 1\) the sets \(A\) and \(B\) form a difference family with parameters \((2m + 1, m, 1)\). I.e. each non-identity \(g \in G\) can be expressed uniquely as \(xy^{-1}\) for \(x, y \in A\) or \(x, y \in B\). Other, specific to this construction, properties of \(A\) and \(B\) are: for \(a \in A\) one has \(a^{-1}\) not in \(A\), whereas for \(b \in B\) one has \(b^{-1}\) in \(B\).

**INPUT:**
- \(m\) – integer; dimension of the matrix
- check – boolean (default: True); whether to check \(A\) and \(B\) for correctness

**EXAMPLES:**

```
sage: from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_pair
sage: G,A,B=szekeres_difference_set_pair(6)
sage: G,A,B=szekeres_difference_set_pair(7)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import szekeres_difference_set_pair
>>> G,A,B=szekeres_difference_set_pair(Integer(6))
>>> G,A,B=szekeres_difference_set_pair(Integer(7))
```

**REFERENCE:**
- [Sz1969]

Construct a Hadamard matrix of order \(n\) from available 4-symbol \(\delta\) codes and Williamson quadruples.

The function looks for Baumert-Hall units and Williamson type matrices from four_symbol_delta_code_smallcases() and williamson_type_quadruples_smallcases() and use them to construct a Hadamard matrix with the Turyn construction defined in hadamard_matrix_turyn_type().

**INPUT:**
- \(n\) – integer; the order of the matrix to be constructed
- existence – boolean (default: False): if True, only check if the matrix exists
- check – boolean (default: True): if True, check that the matrix is a Hadamard matrix before returning

**EXAMPLES:**

```
sage: from sage.combinat.matrices.hadamard_matrix import turyn_type_hadamard_matrix_smallcases
sage: turyn_type_hadamard_matrix_smallcases(28, existence=True)
True
sage: turyn_type_hadamard_matrix_smallcases(28)
28 x 28 dense matrix over Integer Ring...
```
sage.combinat.matrices.hadamard_matrix.typeI_matrix_difference_set \((G, A)\)

(1,-1)-incidence type I matrix of a difference set \(A\) in \(G\)

Let \(A\) be a difference set in a group \(G\) of order \(n\). Return \(n \times n\) matrix \(M\) with \(M_{ij} = 1\) if \(A_iA_j^{-1} \in A\), and \(M_{ij} = -1\) otherwise.

**EXAMPLES:**

```
sage: from sage.combinat.matrices.hadamard_matrix import typeI_matrix_difference_set
sage: G,A,B=szekeres_difference_set_pair(2)
sage: typeI_matrix_difference_set(G,A)
[-1 1 -1 -1 1]
[-1 -1 -1 1 1]
[ 1 1 -1 -1 -1]
[ 1 -1 1 -1 -1]
[-1 -1 1 1 -1]
```

Williamson-Goethals-Seidel construction of a skew Hadamard matrix

Given \(n \times n\) (anti)circulant matrices \(A, B, C, D\) with 1,-1 entries, and satisfying \(A + A^T = 2I, AA^T + BB^T + CC^T + DD^T = 4nI\), one can construct a skew Hadamard matrix of order \(4n\), cf. [GS70s].

**INPUT:**

- \(a\) – 1,-1 list; the 1st row of \(A\)
- \(b\) – 1,-1 list; the 1st row of \(B\)
- \(d\) – 1,-1 list; the 1st row of \(C\)
- \(c\) – 1,-1 list; the 1st row of \(D\)
• check – boolean (default: True); if True, check that the resulting matrix is skew Hadamard before returning it

EXAMPLES:

```python
sage: from sage.combinat.matrices.hadamard_matrix import williamson_goethals_seidel_skew_hadamard_matrix as WGS
sage: a = [1, 1, 1, -1, 1, -1, 1, -1, -1]
sage: b = [1, -1, 1, 1, -1, -1, 1, 1, -1]
sage: c = [-1, -1] + [1]*6 + [-1]
sage: d = [1, 1, 1, -1, 1, 1, -1, 1, 1]
sage: M = WGS(a,b,c,d,check=True)
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.hadamard_matrix import williamson_goethals_seidel_skew_hadamard_matrix as WGS
>>> a = [Integer(1), Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), -Integer(1)]
>>> b = [Integer(1), -Integer(1), Integer(1), Integer(1), -Integer(1), -Integer(1), Integer(1), Integer(1), -Integer(1)]
>>> c = [-Integer(1), -Integer(1)] + [Integer(1)]*6 + [-Integer(1)]
>>> d = [Integer(1), Integer(1), Integer(1), -Integer(1), Integer(1), -Integer(1), Integer(1), Integer(1), Integer(1)]
>>> M = WGS(a,b,c,d,check=True)
```

sage.combinat.matrices.hadamard_matrix.williamson_hadamard_matrix_smallcases(n, existence=False, check=True)

Construct Williamson type Hadamard matrices for some small values of n.

This function uses the data contained in sage.combinat.matrices.hadamard_matrix.williamson_type_quadruples_smallcases() to create Hadamard matrices of the Williamson type, using the construction from sage.combinat.matrices.hadamard_matrix.hadamard_matrix_williamson_type().

INPUT:

• n – integer; the order of the matrix
• existence – boolean (default: False); if True, only check that we can do the construction
• check – boolean (default: True); if True check the result

sage.combinat.matrices.hadamard_matrix.williamson_type_quadruples_smallcases(n, existence=False)

Quadruples of matrices that can be used to construct Williamson type Hadamard matrices.

This function contains for some values of n, four n x n matrices used in the Williamson construction of Hadamard matrices. Namely, the function returns the first row of 4 n x n cir-
culant matrices with the properties described in `sage.combinat.matrices.hadamard_matrix.
hadamard_matrix_williamson_type()`. The matrices for \( n = 3, 5, \ldots, 29, 37, 43 \) are given in [Ha83].

The matrices for \( n = 31, 33, 39, 41, 45, 49, 51, 55, 57, 61, 63 \) are given in [Lon2013].

**INPUT:**

- \( n \) – integer; the order of the matrices to be returned
- \( \text{existence} \) – boolean (default: False); if True, only check that we have the quadruple

**OUTPUT:**

If \( \text{existence} \) is false, returns a tuple containing four vectors, each being the first line of one of the four matrices. It raises an error if no such matrices are available. If \( \text{existence} \) is true, returns a boolean representing whether the matrices are available or not.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.hadamard_matrix import williamson_type_quadruples_smallcases
sage: williamson_type_quadruples_smallcases(29)
((1, 1, 1, -1, -1, -1, 1, 1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1),
(1, -1, 1, -1, -1, -1, 1, 1, -1, -1, 1, -1, 1, -1, 1, 1, 1, 1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1),
(1, 1, 1, 1, -1, 1, 1, -1, 1, -1, -1, -1, 1, 1, 1, 1, 1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1),
(1, 1, -1, -1, 1, -1, -1, 1, -1, 1, 1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1, -1, 1, -1, -1, -1, -1, 1))

```python
sage: williamson_type_quadruples_smallcases(43, existence=True)
True
```

5.1.138 Latin Squares

A **latin square** of order \( n \) is an \( n \times n \) array such that each symbol \( s \in \{0, 1, \ldots, n-1\} \) appears precisely once in each row, and precisely once in each column. A **partial latin square** of order \( n \) is an \( n \times n \) array such that each symbol \( s \in \{0, 1, \ldots, n-1\} \) appears at most once in each row, and at most once in each column. Empty cells are denoted by \(-1\). A latin square \( L \) is a **completion** of a partial latin square \( P \) if \( P \subseteq L \). If \( P \) completes to just \( L \) then \( P \) has **unique completion**.

A **latin bitrade** \((T_1, T_2)\) is a pair of partial latin squares such that:

1. \( \{(i, j) \mid (i, j, k) \in T_1 \text{ for some } k\} = \{(i, j) \mid (i, j, k') \in T_2 \text{ for some } k'\} \);
2. for each \((i, j, k) \in T_1\) and \((i, j, k') \in T_2, k \neq k'\);

3. the symbols appearing in row \(i\) of \(T_1\) are the same as those of row \(i\) of \(T_2\); the symbols appearing in column \(j\) of \(T_1\) are the same as those of column \(j\) of \(T_2\).

Intuitively speaking, a bitrade gives the difference between two latin squares, so if \((T_1, T_2)\) is a bitrade for the pair of latin squares \((L_1, L_2)\), then \(L_1 = (L_2 \setminus T_1) \cup T_2\) and \(L_2 = (L_1 \setminus T_2) \cup T_1\).

This file contains

1. LatinSquare class definition;
2. some named latin squares (back circulant, forward circulant, abelian 2-group);
3. methods \texttt{is\_partial\_latin\_square()} and \texttt{is\_latin\_square()} to test if a \texttt{LatinSquare} object satisfies the definition of a latin square or partial latin square, respectively;
4. tests for completion and unique completion (these use the C++ implementation of Knuth’s dancing links algorithm to solve the problem as a instance of 0 – 1 matrix exact cover);
5. functions for calculating the \(\tau_i\) representation of a bitrade and the genus of the associated hypermap embedding;
6. Markov chain of Jacobson and Matthews (1996) for generating latin squares uniformly at random (provides a generator interface);
7. a few examples of \(\tau_i\) representations of bitrades constructed from the action of a group on itself by right multiplication, functions for converting to a pair of \texttt{LatinSquare} objects.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(5)
sage: B
[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
sage: B.is_latin_square()
True
sage: B[0, 1] = 0
sage: B.is_latin_square()

-1 & 1 & 0 \\
1 & 3 & 2 \\
2 & 0 & -1
\end{array}
\]

>>> T2

\[
\begin{array}{ccc}
1 & -1 & 0 \\
-1 & 0 & 2 \\
2 & 1 & 3 \\
0 & 3 & 1
\end{array}
\]

>>> T1.nr_filled_cells()
12

>>> genus(T1, T2)
1

Todo:

1. Latin squares with symbols from a ring instead of the integers \{0, 1, \ldots, n-1\}.

2. Isotopism testing of latin squares and bitrades via graph isomorphism (nauty?).

3. Combinatorial constructions for bitrades.

AUTHORS:

- Carlo Hamalainen (2008-03-23): initial version

**class** sage.combinat.matrices.latin.LatinSquare(*args)

Bases: object

Latin squares.

This class implements a latin square of order n with rows and columns indexed by the set 0, 1, ..., n-1 and symbols from the same set. The underlying latin square is a matrix(ZZ, n, n). If L is a latin square, then the cell at row r, column c is empty if and only if L[r, c] < 0. In this way we allow partial latin squares and can speak of completions to latin squares, etc.

There are two ways to declare a latin square:

Empty latin square of order n:
**Combinatorics, Release 10.4**

```python
sage: n = 3
sage: L = LatinSquare(n)
sage: L
[-1 -1 -1]
[-1 -1 -1]
[-1 -1 -1]
```

```python
from sage.all import *

n = Integer(3)
L = LatinSquare(n)
L
```

Latin square from a matrix:

```python
sage: M = matrix(ZZ, [[0, 1], [2, 3]])
sage: LatinSquare(M)
[0 1]
[2 3]
```

```python
from sage.all import *

M = matrix(ZZ, [[Integer(0), Integer(1)], [Integer(2), Integer(3)]])
LatinSquare(M)
```

**actual_row_col_sym_sizes()**

Bitrades sometimes end up in partial latin squares with unused rows, columns, or symbols. This function works out the actual number of used rows, columns, and symbols.

**Warning:** We assume that the unused rows/columns occur in the lower right of self, and that the used symbols are in the range \( \{0, 1, \ldots, m\} \) (no holes in that list).

**EXAMPLES:**

```python
from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0,0] = B[2,1] = -1
sage: B
[-1  1 -1]
[ 1  2 -1]
[ 2 -1 -1]
sage: B.actual_row_col_sym_sizes()
(3, 2, 2)
```

```python
from sage.all import *
from sage.combinat.matrices.latin import *

B = back_circulant(Integer(3))
B[Integer(0),Integer(2)] = B[Integer(1),Integer(2)] = B[Integer(2), Integer(1)] = -Integer(1)
```

(continues on next page)
apply_isotopism(row_perm, col_perm, sym_perm)

An isotopism is a permutation of the rows, columns, and symbols of a partial latin square self. Use isotopism() to convert a tuple (indexed from 0) to a Permutation object.

EXAMPLES:
```python
sage: from sage.combinat.matrices.latin import *

sage: B = back_circulant(5)

sage: B

[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]

sage: alpha = isotopism((0,1,2,3,4))

sage: beta = isotopism((1,0,2,3,4))

sage: gamma = isotopism((2,1,0,3,4))

sage: B.apply_isotopism(alpha, beta, gamma)

[3 4 2 0 1]
[0 2 3 1 4]
[1 3 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
```

clear_cells()

Mark every cell in self as being empty.

EXAMPLES:
sage: A = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))
sage: A.clear_cells()
sage: A
[-1 -1]
[-1 -1]

```
>>> from sage.all import *
>>> A = LatinSquare(matrix(ZZ, [[Integer(0), Integer(1)], [Integer(2), Integer(3)]]))
>>> A.clear_cells()
>>> A
[-1 -1]
[-1 -1]
```

column(x)

Return column x of the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).column(0)
(0, 1, 2)
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(3)).column(Integer(0))
(0, 1, 2)
```

contained_in(Q)

Return True if self is a subset of Q?

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: P = elementary_abelian_2group(2)
sage: P[0, 0] = -1
sage: P.contained_in(elementary_abelian_2group(2))
True
sage: back_circulant(4).contained_in(elementary_abelian_2group(Integer(2)))
False
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> P = elementary_abelian_2group(Integer(2))
>>> P[Integer(0), Integer(0)] = -Integer(1)
>>> P.contained_in(elementary_abelian_2group(Integer(2)))
True
>>> back_circulant(Integer(4)).contained_in(elementary_abelian_2group(Integer(2)))
False
```

disjoint_mate_dlxcpp_rows_and_map(allow_subtrade)

Internal function for find_disjoint_mates.

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: B.disjoint_mate_dlxcpp_rows_and_map(allow_subtrade = True)

dlxcpp_has_unique_completion()

Check if the partial latin square self of order n can be embedded in precisely one latin square of order n.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2).dlxcpp_has_unique_completion()
True
sage: P = LatinSquare(2)
sage: P.dlxcpp_has_unique_completion()
False
sage: P[0, 0] = 0
sage: P.dlxcpp_has_unique_completion()
True

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(2)).dlxcpp_has_unique_completion()
Combinatorics, Release 10.4

(continued from previous page)

True
>>> P = LatinSquare(Integer(2))
>>> P.dlxcpp_has_unique_completion()
False
>>> P[Integer(0), Integer(0)] = Integer(0)
>>> P.dlxcpp_has_unique_completion()
True

dumps()

Since the latin square class does not hold any other private variables we just call dumps on self.square:

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(2) == loads(dumps(back_circulant(2)))
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *

>>> back_circulant(Integer(2)) == loads(dumps(back_circulant(Integer(2))))
True
```

filled_cells_map()

Number the filled cells of self with integers from \{1, 2, 3, \ldots\}.

INPUT:

- self – partial latin square self (empty cells have negative values)

OUTPUT:

A dictionary cells_map where \(\text{cells_map}[(i,j)] = m\) means that \((i,j)\) is the \(m\)-th filled cell in \(P\), while \(\text{cells_map}[m] = (i,j)\).

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: D = T1.filled_cells_map()
sage: {i: v for i, v in D.items() if i in ZZ}
{1: (0, 0),
 2: (0, 2),
 3: (0, 3),
 4: (1, 1),
 5: (1, 2),
 6: (1, 3),
 7: (2, 0),
 8: (2, 1),
 9: (2, 2),
10: (3, 0),
11: (3, 1),
12: (3, 3)}
sage: {i: v for i, v in D.items() if not i in ZZ}
{(0, 0): 1,
 (0, 2): 2,
 (0, 3): 3,
 (1, 1): 4,
(continues on next page)
```
(1, 2): 5,
(1, 3): 6,
(2, 0): 7,
(2, 1): 8,
(2, 2): 9,
(3, 0): 10,
(3, 1): 11,
(3, 3): 12}

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> (a, b, c, G) = alternating_group_bitrade_generators(Integer(1))
>>> (T1, T2) = bitrade_from_group(a, b, c, G)
>>> D = T1.filled_cells_map()
>>> {i: v for i,v in D.items() if i in ZZ}
{(0, 0): 1,
 (0, 1): 2,
 (0, 3): 3,
 (1, 1): 4,
 (1, 2): 5,
 (1, 3): 6,
 (2, 0): 7,
 (2, 1): 8,
 (2, 2): 9,
 (3, 0): 10,
 (3, 1): 11,
 (3, 3): 12}

find_disjoint_mates (nr_to_find=None, allow_subtrade=False)

Warning: If allow_subtrade is True then we may return a partial latin square that is not disjoint to self. In that case, use bitrade(P, Q) to get an actual bitrade.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(4)
sage: g = B.find_disjoint_mates(allow_subtrade = True)
sage: B1 = next(g)
sage: B0, B1 = bitrade(B, B1)
sage: assert is_bitrade(B0, B1)
\textbf{sage: print (B0)}
\begin{verbatim}
[-1 1 2 -1]
[-1 2 -1 0]
[-1 -1 -1 -1]
[-1 0 1 2]
\end{verbatim}
\textbf{sage: print (B1)}
\begin{verbatim}
[-1 2 1 -1]
[-1 0 -1 2]
[-1 -1 -1 -1]
[-1 1 2 0]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B = back_circulant(Integer(4))
>>> g = B.find_disjoint_mates(allow_subtrade = True)
>>> B1 = next (g)
>>> B0, B1 = bitrade (B, B1)
>>> assert is_bitrade (B0, B1)
>>> print (B0)
\begin{verbatim}
[-1 1 2 -1]
[-1 2 -1 0]
[-1 -1 -1 -1]
[-1 0 1 2]
\end{verbatim}
>>> print (B1)
\begin{verbatim}
[-1 2 1 -1]
[-1 0 -1 2]
[-1 -1 -1 -1]
[-1 1 2 0]
\end{verbatim}
\end{verbatim}

\textbf{gcs()}

A greedy critical set of a latin square self is found by successively removing elements in a row-wise (bottom-up) manner, checking for unique completion at each step.

\textbf{EXAMPLES:}

\begin{verbatim}
\textbf{sage: from sage.combinat.matrices.latin import *}
\textbf{sage: A = elementary_abelian_2group(3)}
\textbf{sage: G = A.gcs()}
\textbf{sage: A}
\begin{verbatim}
[0 1 2 3 4 5 6 7]
[1 0 3 2 5 4 7 6]
[2 3 0 1 6 7 4 5]
[3 2 1 0 7 6 5 4]
[4 5 6 7 0 1 2 3]
[5 4 7 6 1 0 3 2]
[6 7 4 5 2 3 0 1]
[7 6 5 4 3 2 1 0]
\end{verbatim}
\textbf{sage: G}
\begin{verbatim}
[ 0 1 2 3 4 5 6 -1]
[ 1 0 3 2 5 4 -1 -1]
[ 2 3 0 1 6 -1 4 -1]
[ 3 2 1 0 -1 -1 -1 -1]
[ 4 5 6 -1 0 1 2 -1]
[ 5 4 -1 -1 1 0 -1 -1]
[ 6 -1 4 -1 2 -1 0 -1]
[-1 -1 -1 -1 -1 -1 -1 -1]
\end{verbatim}
\end{verbatim}
is_completable()

Return True if the partial latin square can be completed to a latin square.

EXAMPLES:
The following partial latin square has no completion because there is nowhere that we can place the symbol 0 in the third row:

```
sage: B = LatinSquare(3)
... from sage.all import *
... B = LatinSquare(Integer(3))

sage: B[0, 0] = 0
sage: B[1, 1] = 0
sage: B[2, 2] = 1
... from sage.all import *
... B[Integer(0), Integer(0)] = Integer(0)
... B[Integer(1), Integer(1)] = Integer(0)
... B[Integer(2), Integer(2)] = Integer(1)

sage: B
[ 0 -1 -1]
[-1 0 -1]
[-1 -1 1]
... from sage.all import *
... B
[ 0 -1 -1]
[-1 0 -1]
[-1 -1 1]
```
```python
sage: B.is_completable()
False

>>> from sage.all import *

>>> B.is_completable()
False

sage: B[2, 2] = 0
sage: B.is_completable()
True

>>> from sage.all import *

>>> B[Integer(2), Integer(2)] = Integer(0)

>>> B.is_completable()
True
```

### is_empty_column(c)

Check if column c of the partial latin square self is empty.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *

sage: L = back_circulant(4)

sage: L.is_empty_column(0)
False

sage: L[0,0] = L[1,0] = L[2,0] = L[3,0] = -1

sage: L.is_empty_column(0)
True
```

```python
>>> from sage.all import *

>>> from sage.combinat.matrices.latin import *

>>> L = back_circulant(Integer(4))

>>> L.is_empty_column(Integer(0))
False

>>> L[Integer(0), Integer(0)] = L[Integer(1), Integer(0)] = L[Integer(2), Integer(0)] = L[Integer(3), Integer(0)] = -Integer(1)

>>> L.is_empty_column(Integer(0))
True
```

### is_empty_row(r)

Check if row r of the partial latin square self is empty.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *

sage: L = back_circulant(4)

sage: L.is_empty_row(0)
False

sage: L[0,0] = L[0,1] = L[0,2] = L[0,3] = -1

sage: L.is_empty_row(0)
True
```

```python
>>> from sage.all import *

>>> from sage.combinat.matrices.latin import *

>>> L = back_circulant(Integer(4))

(continues on next page)
```
is_latin_square()

self is a latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears exactly once in each row, and exactly once in each column.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(4).is_latin_square()
True
```

```python
sage: from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> elementary_abelian_2group(Integer(4)).is_latin_square()
True
```

```python
sage: forward_circulant(7).is_latin_square()
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>>
>>> forward_circulant(Integer(7)).is_latin_square()
True
```

is_partial_latin_square()

self is a partial latin square if it is an n by n matrix, and each symbol in [0, 1, ..., n-1] appears at most once in each row, and at most once in each column.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: LatinSquare(4).is_partial_latin_square()
True
```

```python
sage: back_circulant(3).gcs().is_partial_latin_square()
True
```

```python
sage: back_circulant(6).is_partial_latin_square()
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> LatinSquare(Integer(4)).is_partial_latin_square()
True
```

```python
>>> back_circulant(Integer(3)).gcs().is_partial_latin_square()
True
```

```python
>>> back_circulant(Integer(6)).is_partial_latin_square()
True
```

is_uniquely_completable()

Return True if the partial latin square self has exactly one completion to a latin square. This is just a wrapper for the current best-known algorithm, Dancing Links by Knuth. See dancing_links.spyx
EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(4).gcs().is_uniquely_completable()
True
```

```
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(4)).gcs().is_uniquely_completable()
True
```

```
sage: G = elementary_abelian_2group(3).gcs()
sage: G.is_uniquely_completable()
True
```

```
>>> from sage.all import *

>>> G = elementary_abelian_2group(Integer(3)).gcs()

>>> G.is_uniquely_completable()
True
```

```
sage: G[0, 0] = -1
sage: G.is_uniquely_completable()
False
```

```
>>> from sage.all import *

>>> G[Integer(0), Integer(0)] = -Integer(1)

>>> G.is_uniquely_completable()
False
```

latex()

Return \LaTeX\ code for the latin square.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: print(back_circulant(3).latex())
\begin{array}{|c|c|c|}
\hline 0 & 1 & 2 \\
\hline 1 & 2 & 0 \\
\hline 2 & 0 & 1 \\
\hline
\end{array}
```

```
>>> from sage.all import *

>>> from sage.combinat.matrices.latin import *

>>> print(back_circulant(Integer(3)).latex())
\begin{array}{|c|c|c|}
\hline 0 & 1 & 2 \\
\hline 1 & 2 & 0 \\
\hline 2 & 0 & 1 \\
\hline
\end{array}
```

list()

Convert the latin square into a list, in a row-wise manner.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(3).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> back_circulant(Integer(3)).list()
[0, 1, 2, 1, 2, 0, 2, 0, 1]
```

**ncols()**

Number of columns in the latin square.

**EXAMPLES:**

```python
sage: LatinSquare(3).ncols()
sage: LatinSquare(Integer(3)).ncols()
3
```

**nr_distinct_symbols()**

Return the number of distinct symbols in the partial latin square self.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5).nr_distinct_symbols()
sage: L = LatinSquare(10)
sage: L.nr_distinct_symbols()
sage: L[0, 0] = 0
sage: L[0, 1] = 1
sage: L.nr_distinct_symbols()
2
```

**nr_filled_cells()**

Return the number of filled cells (i.e. cells with a positive value) in the partial latin square self.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: L[Integer(0), Integer(0)] = Integer(0)
sage: L[Integer(0), Integer(1)] = Integer(1)
sage: L.nr_distinct_symbols()
2
```

(continues on next page)
```python
LatinSquare(matrix([[Integer(0), -Integer(1)], [-Integer(1), Integer(0)]])).nr_filled_cells()
2
```

### nrows()
Number of rows in the latin square.

**EXAMPLES:**

```python
sage: LatinSquare(3).nrows()
3
```

```python
>>> from sage.all import *
>>> LatinSquare(Integer(3)).nrows()
3
```

### permissable_values(r, c)
Find all values that do not appear in row r and column c of the latin square self. If self[r, c] is filled then we return the empty list.

**INPUT:**

- `self` – `LatinSquare`
- `r` – int; row of the latin square
- `c` – int; column of the latin square

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: L = back_circulant(5)
sage: L[0, 0] = -1
sage: L.permissable_values(0, 0)
[0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = back_circulant(Integer(5))
>>> L[Integer(0), Integer(0)] = -Integer(1)
>>> L.permissable_values(Integer(0), Integer(0))
[0]
```

### random_empty_cell()
Find an empty cell of self, uniformly at random.

**INPUT:**

- `self` – `LatinSquare`

**OUTPUT:**

- `[r, c]` – cell such that `self[r, c]` is empty, or returns `None` if `self` is a (full) latin square

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: P = back_circulant(2)
sage: P[1, 1] = -1
```
sage: P.random_empty_cell()
[1, 1]

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> P = back_circulant(Integer(2))
>>> P[Integer(1),Integer(1)] = -Integer(1)
>>> P.random_empty_cell()
[1, 1]

row(x)
Return row x of the latin square.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *

sage: back_circulant(3).row(0)
(0, 1, 2)

sage: back_circulant(Integer(3)).row(Integer(0))
(0, 1, 2)

set_immutable()
A latin square is immutable if the underlying matrix is immutable.

EXAMPLES:

sage: L = LatinSquare(matrix(ZZ, [[0, 1], [2, 3]]))

sage: L.set_immutable()

sage: {L : 0}  # this would fail without set_immutable()
{{0 1}
 [2 3]: 0}

sage: L = LatinSquare(matrix(ZZ, [[Integer(0), Integer(1)], [Integer(2), Integer(3)]]))

sage: L.set_immutable()

sage: {L : Integer(0)}  # this would fail without set_immutable()
{{0 1}
 [2 3]: 0}

top_left_empty_cell()
Return the least [r, c] such that self[r, c] is an empty cell. If all cells are filled then we return None.

INPUT:

• self – LatinSquare

EXAMPLES:

sage: from sage.combinat.matrices.latin import *

sage: B = back_circulant(5)

sage: B[3, 4] = -1

sage: B.top_left_empty_cell()
[3, 4]
vals_in_col(c)
Return a dictionary with key e if and only if column c of self has the symbol e.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_col(0)
{0: True, 1: True, 2: True}
```

vals_in_row(r)
Return a dictionary with key e if and only if row r of self has the symbol e.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: B = back_circulant(3)
sage: B[0, 0] = -1
sage: back_circulant(3).vals_in_row(0)
{0: True, 1: True, 2: True}
```

sage.combinat.matrices.latin.LatinSquare_generator(L_start, check Assertions=False)
Generator for a sequence of uniformly distributed latin squares, given L_start as the initial latin square.

This code implements the Markov chain algorithm of Jacobson and Matthews (1996), see below for the BibTex entry. This generator will never throw the StopIteration exception, so it provides an infinite sequence of latin squares.

EXAMPLES:

Use the back circulant latin square of order 4 as the initial square and print the next two latin squares given by the Markov chain:

```python
sage: from sage.combinat.matrices.latin import *
sage: g = LatinSquare_generator(back_circulant(4))
```
sage: next(g).is_latin_square()
True

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *

>>>

REFERENCES:
sage.combinat.matrices.latin.alternating_group_bitrade_generators(m)
Construct generators a, b, c for the alternating group on 3m+1 points, such that a*b*c = 1.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *

sage: a, b, c, G = alternating_group_bitrade_generators(1)
sage: (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])
sage: a*b*c
()

>>> from sage.all import *

>>> (a, b, c, G) = alternating_group_bitrade_generators(Integer(1))

>>> (a, b, c, G)
((1,2,3), (1,4,2), (2,4,3), Permutation Group with generators [(1,2,3), (1,4,2)])

>>> a*b*c
()

sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1 3 1]
[-1 1 0 2]
[ 1 3 2 -1]
[ 2 0 -1 3]
sage: T2
[ 1 -1 0 3]
[-1 0 2 1]
[ 2 1 3 -1]
[ 0 3 -1 2]

>>> from sage.all import *

>>> (T1, T2) = bitrade_from_group(a, b, c, G)

>>> T1
[ 0 -1 3 1]
[-1 1 0 2]
[ 1 3 2 -1]
[ 2 0 -1 3]

>>> T2
[ 1 -1 0 3]
[-1 0 2 1]
[ 2 1 3 -1]
[ 0 3 -1 2]
The back-circulant latin square of order n is the Cayley table for \((\mathbb{Z}_n, +)\), the integers under addition modulo \(n\).

**INPUT:**

- \(n\) – int; order of the latin square.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: back_circulant(5)

[0 1 2 3 4]
[1 2 3 4 0]
[2 3 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
```

Find the unique \((x, c, e)\) in \(T_2\) such that \((r, c, e)\) is in \(T_1\).

**INPUT:**

- \(rce\) – tuple (or list) \((r, c, e)\) in \(T_1\)
- \(T_1, T_2\) – latin bitrade

**OUTPUT:** \((x, c, e)\) in \(T_2\).

**EXAMPLES:**

```python
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5)  # identity
sage: z = isotopism(5)  # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
```

```python
sage: beta1([0, 0, 0], T1, T2)
(1, 0, 0)
```

(continues on next page)
sage.combinat.matrices.latin.beta2(rce, T1, T2)

Find the unique \((r, x, e)\) in \(T2\) such that \((r, c, e)\) is in \(T1\).

**INPUT:**
- \(rce\) – tuple (or list) \((r, c, e)\) in \(T1\)
- \(T1, T2\) – latin bitrade

**OUTPUT:**
- \((r, x, e)\) in \(T2\).

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta2([0, 0, 0], T1, T2)
(0, 1, 0)
```

sage.combinat.matrices.latin.beta3(rce, T1, T2)

Find the unique \((r, c, x)\) in \(T2\) such that \((r, c, e)\) is in \(T1\).

**INPUT:**
- \(rce\) – tuple (or list) \((r, c, e)\) in \(T1\)
- \(T1, T2\) – latin bitrade

**OUTPUT:**
- \((r, c, x)\) in \(T2\).

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5) # identity
sage: z = isotopism(5) # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True
sage: beta3([0, 0, 0], T1, T2)
(0, 1, 0)
```
Form the bitrade \((Q_1, Q_2)\) from \((T_1, T_2)\) by setting empty the cells \((r, c)\) such that \(T_1[r, c] == T_2[r, c]\).

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: B1 = back_circulant(5)
sage: alpha = isotopism((0,1,2,3,4))
sage: beta = isotopism((1,0,2,3,4))
sage: gamma = isotopism((2,1,0,3,4))
sage: B2 = B1.apply_isotopism(alpha, beta, gamma)
sage: T1, T2 = bitrade(B1, B2)
sage: T1
[ 0 1 -1 3 4]
[ 1 -1 -1 4 0]
[ 2 -1 4 0 1]
[ 3 4 0 1 2]
[ 4 0 1 2 3]
sage: T2
[3 4 -1 0 1]
[0 -1 1 1 4]
[1 -1 0 4 2]
[4 0 1 2 3]
[2 1 4 3 0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> B1 = back_circulant(Integer(5))
>>> alpha = isotopism((Integer(0),Integer(1),Integer(2),Integer(3),Integer(4)))
>>> beta = isotopism((Integer(1),Integer(0),Integer(2),Integer(3),Integer(4)))
>>> gamma = isotopism((Integer(2),Integer(1),Integer(0),Integer(3),Integer(4)))
>>> B2 = B1.apply_isotopism(alpha, beta, gamma)
>>> T1, T2 = bitrade(B1, B2)
>>> T1
[0 1 -1 3 4]
[1 -1 -1 4 0]
[2 -1 4 0 1]
[3 4 0 1 2]
[4 0 1 2 3]
(continues on next page)
```
sage.combinat.matrices.latin.bitrade_from_group \((a, b, c, G)\)

Given group elements \(a, b, c\) in \(G\) such that \(abc = 1\) and the subgroups \(a, b, c\) intersect (pairwise) only in the identity, construct a bitrade \((T_1, T_2)\) where rows, columns, and symbols correspond to cosets of \(a, b,\) and \(c\), respectively.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: T1
[ 0 -1 3 1]
[-1 1 0 2]
[ 1 3 2 -1]
[ 2 0 -1 3]
sage: T2
[ 1 -1 0 3]
[-1 0 2 1]
[ 2 1 3 -1]
[ 0 3 -1 2]
```

```
>>> from sage.combinat.matrices.latin import *
>>> (a, b, c, G) = alternating_group_bitrade_generators(Integer(1))
```

```python
>>> (T1, T2) = bitrade_from_group(a, b, c, G)
```

```python
sage.combinat.matrices.latin.cells_map_as_square \((cells\_map, n)\)

Return a LatinSquare with cells numbered from 1, 2, … to given the dictionary \(cells\_map\).

**Note:** The value \(n\) should be the maximum of the number of rows and columns of the original partial latin square

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
```

(continues on next page)
There are 12 filled cells in T:

```
sage: cells_map_as_square(T1.filled_cells_map(), max(T1.nrows(), T1.ncols()))
[ 1  2 -1  3]
[ 4  5  6 -1]
[ 7  8  9 -1]
[10 11 12 -1]
```

```
sage.combinat.matrices.latin.check_bitrade_generators(a, b, c)
```

Three group elements $a$, $b$, $c$ will generate a bitrade if $a\cdot b\cdot c = 1$ and the subgroups $a$, $b$, $c$ intersect (pairwise) in just the identity.

**EXAMPLES:**

```
sage: from sage.combinat.matrices.latin import *
sage: a, b, c, G = p3_group_bitrade_generators(3)
sage: check_bitrade_generators(a, b, c)
True
sage: check_bitrade_generators(a, b, libgap(gap(())))
False
```

```
sage.combinat.matrices.latin.coin()
```

Simulate a fair coin (returns True or False) using ZZ.random_element(2).

**EXAMPLES:**
sage: from sage.combinat.matrices.latin import coin
sage: x = coin()
sage: x == 0 or x == 1
True

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import coin
>>>
x = coin()
>>> x == Integer(0) or x == Integer(1)
True

sage.combinat.matrices.latin.column_containing_sym(L, r, x)
Given an improper latin square L with L[r, c1] = L[r, c2] = x, return c1 or c2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: L = matrix([[1, 0, 2, 3], [0, 2, 3, 0], [2, 3, 0, 1], [3, 0, 1, 2]])
sage: L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
sage: c = column_containing_sym(L, 1, 0)
sage: c == 0 or c == 3
True

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> L = matrix([[Integer(1), Integer(0), Integer(2), Integer(3)],
              [Integer(0), Integer(2), Integer(3), Integer(0)],
              [Integer(2), Integer(3), Integer(0), Integer(1)],
              [Integer(3), Integer(0), Integer(1), Integer(2)]])
>>> L
[1 0 2 3]
[0 2 3 0]
[2 3 0 1]
[3 0 1 2]
>>> c = column_containing_sym(L, Integer(1), Integer(0))
>>> c == Integer(0) or c == Integer(3)
True

sage.combinat.matrices.latin.direct_product(L1, L2, L3, L4)
The 'direct product' of four latin squares L1, L2, L3, L4 of order n is the latin square of order 2n consisting of

<table>
<thead>
<tr>
<th>L1</th>
<th>L2</th>
</tr>
</thead>
<tbody>
<tr>
<td>L3</td>
<td>L4</td>
</tr>
</tbody>
</table>

where the subsquares L2 and L3 have entries offset by n.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: direct_product(back_circulant(4), back_circulant(4), elementary_abelian_
\begin{verbatim}
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *

>>> direct_product(back_circulant(Integer(4)), back_circulant(Integer(4)),
                   elementary_abelian_2group(Integer(2)), elementary_abelian_2group(Integer(2)))

sage.combinat.matrices.latin.dlxcpp_find_completions(P, nr_to_find=None)

Return a list of all latin squares \(L\) of the same order as \(P\) such that \(P\) is contained in \(L\). The optional parameter \(nr\_to\_find\) limits the number of latin squares that are found.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_find_completions(LatinSquare(2))

\[
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}
\end{verbatim}

\begin{verbatim}
sage: dlxcpp_find_completions(LatinSquare(Integer(2)))

\[
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}
\end{verbatim}

\begin{verbatim}
sage: dlxcpp_find_completions(LatinSquare(2), 1)

\[
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}
\end{verbatim}

\begin{verbatim}
sage: dlxcpp_find_completions(LatinSquare(Integer(2)), Integer(1))

\[
\begin{bmatrix}
0 & 1 \\
1 & 0
\end{bmatrix}
\end{verbatim}
\end{verbatim}

sage.combinat.matrices.latin.dlxcpp_rows_and_map(P)

Internal function for \texttt{dlxcpp\_find\_completions}. Given a partial latin square \(P\) we construct a list of rows of a 0-1 matrix \(M\) such that an exact cover of \(M\) corresponds to a completion of \(P\) to a latin square.

EXAMPLES:
\end{verbatim}
sage: from sage.combinat.matrices.latin import *
sage: dlxcpp_rows_and_map(LatinSquare(2))
([[0, 4, 8],
  [1, 5, 8],
  [2, 4, 9],
  [3, 5, 9],
  [0, 6, 10],
  [1, 7, 10],
  [2, 6, 11],
  [3, 7, 11]],
  {(0, 4, 8): (0, 0, 0),
   (0, 6, 10): (1, 0, 0),
   (1, 5, 8): (0, 0, 1),
   (1, 7, 10): (1, 0, 1),
   (2, 4, 9): (0, 1, 0),
   (2, 6, 11): (1, 1, 0),
   (3, 5, 9): (0, 1, 1),
   (3, 7, 11): (1, 1, 1)})

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> dlxcpp_rows_and_map(LatinSquare(Integer(2)))
([[0, 4, 8],
  [1, 5, 8],
  [2, 4, 9],
  [3, 5, 9],
  [0, 6, 10],
  [1, 7, 10],
  [2, 6, 11],
  [3, 7, 11]],
  {(0, 4, 8): (0, 0, 0),
   (0, 6, 10): (1, 0, 0),
   (1, 5, 8): (0, 0, 1),
   (1, 7, 10): (1, 0, 1),
   (2, 4, 9): (0, 1, 0),
   (2, 6, 11): (1, 1, 0),
   (3, 5, 9): (0, 1, 1),
   (3, 7, 11): (1, 1, 1)})

sage.combinat.matrices.latin.elementary_abelian_2group(s)

Return the latin square based on the Cayley table for the elementary abelian 2-group of order 2s.

INPUT:

  • s – int; order of the latin square will be 2s.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: elementary_abelian_2group(3)

1 3 2 4 5 6 7
[0 1 5 3 4 2 6]

1 2 5 4 6 7 3
[0 1 0 5 2 7 4]

0 1 2 6 7 4 5
[0 1 5 3 4 2 6]

5 4 7 6 1 0 3 2
[4 5 6 7 0 1 2 3]

5 4 7 6 1 0 3 2
[4 5 6 7 0 1 2 3]

6 7 4 5 2 3 0 1
[6 7 4 5 2 3 0 1]

7 6 5 4 3 2 1 0
Combinatorics, Release 10.4

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> elementary_abelian_2group(Integer(3))

[[0 1 2 3 4 5 6 7]
 [1 0 3 2 5 4 7 6]
 [2 3 0 1 6 7 4 5]
 [3 2 1 0 7 6 5 4]
 [4 5 6 7 0 1 2 3]
 [5 4 7 6 1 0 3 2]
 [6 7 4 5 2 3 0 1]
 [7 6 5 4 3 2 1 0]]
```

`sage.combinat.matrices.latin.forward_circulant(n)`

The forward-circulant Latin square of order n is the Cayley table for the operation \( r + c = (n - c + r) \mod n \).

**INPUT:**

- \( n \) – int; order of the Latin square.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *
sage: forward_circulant(5)

[[0 4 3 2 1]
 [1 0 4 3 2]
 [2 1 0 4 3]
 [3 2 1 0 4]
 [4 3 2 1 0]]
```

`sage.combinat.matrices.latin.genus(T1, T2)`

Return the genus of hypermap embedding associated with the bitrade \((T1, T2)\).

Informally, we compute the \([\tau_1, \tau_2, \tau_3]\) permutation representation of the bitrade. Each cycle of \(\tau_1, \tau_2, \) and \(\tau_3\) gives a rotation scheme for a black, white, and star vertex (respectively). The genus then comes from Euler's formula.

For more details see Carlo Hamalainen: *Partitioning 3-homogeneous Latin bitrades*. To appear in Geometriae Dedicata, available at arXiv 0710.0938

**EXAMPLES:**

```python
sage: (a, b, c, G) = alternating_group_bitrade_generators(1)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
1
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)
sage: genus(T1, T2)
3
```
```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> (a, b, c, G) = alternating_group_bitrade_generators(Integer(1))
>>> (T1, T2) = bitrade_from_group(a, b, c, G)
>>> genus(T1, T2)
1
>>> (a, b, c, G) = pq_group_bitrade_generators(Integer(3), Integer(7))
>>> (T1, T2) = bitrade_from_group(a, b, c, G)
>>> genus(T1, T2)
3
```

sage.combinat.matrices.latin.group_to_LatinSquare(G)

Construct a latin square on the symbols [0, 1, ..., n-1] for a group with an n by n Cayley table.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import group_to_LatinSquare

sage: group_to_LatinSquare(DihedralGroup(2))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import group_to_LatinSquare

>>> group_to_LatinSquare(DihedralGroup(Integer(2)))
[0 1 2 3]
[1 0 3 2]
[2 3 0 1]
[3 2 1 0]
```

```python
sage: G = libgap.Group(PermutationGroupElement((1,2,3)))

sage: group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

```python
>>> from sage.all import *
>>> G = libgap.Group(PermutationGroupElement((Integer(1),Integer(2),Integer(3))))

>>> group_to_LatinSquare(G)
[0 1 2]
[1 2 0]
[2 0 1]
```

sage.combinat.matrices.latin.is_bitrade(T1, T2)

Combinatorially, a pair (T1, T2) of partial latin squares is a bitrade if they are disjoint, have the same shape, and have row and column balance. For definitions of each of these terms see the relevant function in this file.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *

sage: T1 = back_circulant(5)
sage: x = isotopism( (0,1,2,3,4) )
sage: y = isotopism(5) # identity
```
sage: z = isotopism(5)  # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_bitrade(T1, T2)
True

The partial latin squares T1 and T2 are disjoint if T1[r, c] \neq T2[r, c] or T1[r, c] == T2[r, c] == -1 for each cell [r, c].

EXAMPLES:

sage: from sage.combinat.matrices.latin import is_disjoint, back_circulant,
˓→isotopism
sage: is_disjoint(back_circulant(2), back_circulant(2))
False

sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5)  # identity
sage: z = isotopism(5)  # identity
sage: T2 = T1.apply_isotopism(x, y, z)
sage: is_disjoint(T1, T2)
True

sage.combinat.matrices.latin.is_primary_bitrade(a, b, c, G)
A bitrade generated from elements a, b, c is primary if a, b, c = G.

EXAMPLES:
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = p3_group_bitrade_generators(5)
is_primary_bitrade(a, b, c, G)
True

>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *
>>> (a, b, c, G) = p3_group_bitrade_generators(Integer(5))
is_primary_bitrade(a, b, c, G)
True

sage.combinat.matrices.latin.is_row_and_col_balanced(T1, T2)
Partial latin squares T1 and T2 are balanced if the symbols appearing in row r of T1 are the same as the symbols appearing in row r of T2, for each r, and if the same condition holds on columns.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
sage: T1 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
sage: T2 = matrix([[0,1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
is_row_and_col_balanced(T1, T2)
True

sage: T2 = matrix([[0,3,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1], [-1,-1,-1,-1]])
is_row_and_col_balanced(T1, T2)
False

sage.combinat.matrices.latin.is_same_shape(T1, T2)
Two partial latin squares T1, T2 have the same shape if T1[r, c] = 0 if and only if T2[r, c] = 0.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *
is_same_shape(elementary_abelian_2group(2), back_circulant(4))
True

sage: is_same_shape(LatinSquare(5), LatinSquare(5))
True

sage: is_same_shape(forward_circulant(5), LatinSquare(5))
False
```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *

is_same_shape(elementary_abelian_2group(Integer(2)), back_circulant(Integer(4)))
True

is_same_shape(LatinSquare(Integer(5)), LatinSquare(Integer(5)))
True

is_same_shape(forward_circulant(Integer(5)), LatinSquare(Integer(5)))
False
```

`sage.combinat.matrices.latin.isotopism(p)`

Return a Permutation object that represents an isotopism (for rows, columns or symbols of a partial latin square).

Technically, all this function does is take as input a representation of a permutation of $0, \ldots, n - 1$ and return a `Permutation` object defined on $1, \ldots, n$.

For a definition of isotopism, see the wikipedia section on isotopism.

**INPUT:**

According to the type of input (see examples below):

- an integer $n$ – the function returns the identity on $1, \ldots, n$.
- a string representing a permutation in disjoint cycles notation, e.g. $(0, 1, 2)(3, 4, 5)$ – the corresponding permutation is returned, shifted by 1 to act on $1, \ldots, n$.
- list/tuple of tuples – assumes disjoint cycle notation, see previous entry.
- a list of integers – the function adds 1 to each member of the list, and returns the corresponding permutation.
- a `PermutationGroupElement p` – returns a permutation describing $p$ without any shift.

**EXAMPLES:**

```python
sage: from sage.combinat.matrices.latin import *

sage: isotopism(5)  # identity on 5 points
[1, 2, 3, 4, 5]

sage: G = PermutationGroup(['(1,2,3)(4,5)'])

sage: g = G.gen(0)

sage: isotopism(g)
[2, 3, 1, 5, 4]

sage: isotopism([0, 3, 2, 1])  # 0 goes to 0, 1 goes to 3, etc.
[1, 4, 3, 2]
```
>>> from sage.all import *
>>> isotopism([Integer(0),Integer(3),Integer(2),Integer(1)])  # 0 goes to 0, 1...
   → goes to 3, etc.
[1, 4, 3, 2]

sage: isotopism( (0,1,2) )  # single cycle, presented as a tuple
[2, 3, 1]

>>> from sage.all import *
>>> isotopism( (Integer(0),Integer(1),Integer(2)) )  # single cycle, presented as a tuple
[2, 3, 1]

sage: x = isotopism( ((0,1,2), (3,4)) )  # tuple of cycles
sage: x
[2, 3, 1, 5, 4]

sage: x.to_cycles()
[(1, 2, 3), (4, 5)]

sage.combinat.matrices.latin.next_conjugate(L)
Permute L[r, c] = e to the conjugate L[c, e] = r.

We assume that L is an n by n matrix and has values in the range 0, 1, ..., n-1.

EXAMPLES:

sage: from sage.combinat.matrices.latin import *

sage: L = back_circulant(6)

sage: L

sage: next_conjugate(L)

sage: L == next_conjugate(next_conjugate(next_conjugate(L)))
True

(continues on next page)
sage.combinat.matrices.latin.p3_group_bitrade_generators(p)
Generators for a group of order p3 where p is a prime.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: p3_group_bitrade_generators(3)
((2,6,7)(3,8,9),
 (1,2,3)(4,7,8)(5,6,9),
 (1,9,2)(3,7,4)(5,8,6),
Permutation Group with generators [(2,6,7)(3,8,9), (1,2,3)(4,7,8)(5,6,9)])
```

sage.combinat.matrices.latin.pq_group_bitrade_generators(p, q)
Generators for a group of order pq where p and q are primes such that (q % p) == 1.

EXAMPLES:

```
sage: from sage.combinat.matrices.latin import *
sage: pq_group_bitrade_generators(3,7)
((2,3,5)(4,7,6), (1,2,3,4,5,6,7), (1,4,2)(3,5,6), Permutation Group with generators [(2,3,5)(4,7,6), (1,2,3,4,5,6,7)])
```

sage.combinat.matrices.latin.row_containing_sym(L, c, x)
Given an improper latin square L with L[r1, c] = L[r2, c] = x, return r1 or r2 with equal probability. This is an internal function and should only be used in LatinSquare_generator().
EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: L = matrix([(0, 1, 0, 3), (3, 0, 2, 1), (1, 0, 3, 2), (2, 3, 1, 0)])
sage: L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]
sage: c = row_containing_sym(L, 1, 0)
sage: c == 1 or c == 2
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *

>>> L = matrix([[Integer(0), Integer(1), Integer(0), Integer(3)), (Integer(3),
\rightarrow Integer(0), Integer(2), Integer(1)), (Integer(1), Integer(0), Integer(3),
\rightarrow Integer(2)), (Integer(2), Integer(3), Integer(1), Integer(0))])

>>> L
[0 1 0 3]
[3 0 2 1]
[1 0 3 2]
[2 3 1 0]

>>> c = row_containing_sym(L, Integer(1), Integer(0))
>>> c == Integer(1) or c == Integer(2)
True
```

**sage.combinat.matrices.latin.taul(T1, T2, cells_map)**

The definition of $\tau_1$ is

$$
\tau_1 : T1 \to T1 \quad \tau_1 = \beta_2^{-1}\beta_3
$$

where the composition is left to right and $\beta_i : T2 \to T1$ changes just the $i^{th}$ coordinate of a triple.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: T1 = back_circulant(5)
sage: x = isotopism((0,1,2,3,4))
sage: y = isotopism(5)  # identity
sage: z = isotopism(5)  # identity
sage: T2 = T1.apply_isotopism(x, y, z)

sage: is_bitrade(T1, T2)
True

sage: (cells_map, t1, t2, t3) = tau123(T1, T2)

sage: t1 = tau1(T1, T2, cells_map)
sage: t1
[2, 3, 4, 5, 1, 7, 8, 9, 10, 6, 12, 13, 14, 15, 11, 17, 18, 19, 20, 16, 22, 23, \rightarrow 24, 25, 21]
sage: t1.to_cycles()
[(1, 2, 3, 4, 5), (6, 7, 8, 9, 10), (11, 12, 13, 14, 15), (16, 17, 18, 19, 20), \rightarrow (21, 22, 23, 24, 25)]
```

```python
>>> from sage.all import *
>>> from sage.combinat.matrices.latin import *

>>> T1 = back_circulant(Integer(5))
(continues on next page)
sage.combinat.matrices.latin.tau123(T1, T2)
Compute the tau_i representation for a bitrade (T1, T2).

See the functions tau1, tau2, and tau3 for the mathematical definitions.

OUTPUT:

• (cells_map, t1, t2, t3)

where cells_map is a map to/from the filled cells of T1, and t1, t2, t3 are the tau1, tau2, tau3 permutations.

EXAMPLES:

```python
sage: from sage.combinat.matrices.latin import *
sage: (a, b, c, G) = pq_group_bitrade_generators(3, 7)
sage: (T1, T2) = bitrade_from_group(a, b, c, G)

[ 1 2 3 -1 -1 -1 -1]
[ 4 5 6 -1 -1 -1 -1]
[ 7 8 9 -1 -1 -1 -1]
[10 11 12 -1 -1 -1 -1]
[13 14 15 -1 -1 -1 -1]
[16 17 18 -1 -1 -1 -1]
[19 20 21 -1 -1 -1 -1]
```

```python
t1
[3, 1, 2, 6, 4, 5, 9, 7, 8, 12, 10, 11, 15, 13, 14, 18, 16, 17, 21, 19, 20]
```

```python
t2
[4, 8, 15, 7, 11, 18, 10, 14, 21, 13, 17, 3, 16, 20, 6, 19, 2, 9, 1, 5, 12]
```

```python
t3
[20, 18, 10, 2, 21, 13, 5, 3, 16, 8, 6, 19, 11, 9, 1, 14, 12, 4, 17, 15, 7]
```

```python
sage: t1.to_cycles()
[(1, 3, 2), (4, 6, 5), (7, 9, 8), (10, 12, 11), (13, 15, 14), (16, 18, 17), (19, ...
→ 21, 20)]
```

```python
sage: t2.to_cycles()
[(1, 4, 7, 10, 13, 16, 19), (2, 8, 14, 20, 5, 11, 17), (3, 15, 6, 18, 9, 21, 12)]
```

```python
sage: t3.to_cycles()
[(1, 20, 15), (2, 18, 4), (3, 10, 8), (5, 21, 7), (6, 13, 11), (9, 16, 14), (12, ...
→ 19, 17)]
```

The product $t_1 \ast t_2 \ast t_3$ is the identity, i.e. it fixes every point:

```python
sage: len((t1*t2*t3).fixed_points()) == T1.nr_filled_cells()
True
```

```python
sage: from sage.all import *
```

EXAMPLES:

sage.combinat.matrices.latin.tau3(T1, T2, cells_map)
The definition of $\tau_3$ is
\[
\tau_3 : T1 \to T1 \\
\tau_3 = \beta_1^{-1} \beta_2
\]
where the composition is left to right and $\beta_i : T2 \to T1$ changes just the $i^{th}$ coordinate of a triple.

```

### 5.1.139 Miscellaneous

**class** `sage.combinat.misc.DoublyLinkedList(l)`

**Bases:** object

A doubly linked list class that provides constant time hiding and unhiding of entries.

Note that this list’s indexing is 1-based.

**EXAMPLES:**

### Sage examples

```python
sage: dll = sage.combinat.misc.DoublyLinkedList([1,2,3]); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(1); dll
Doubly linked list of [1, 2, 3]: [2, 3]
sage: dll.unhide(1); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
sage: dll.hide(2); dll
Doubly linked list of [1, 2, 3]: [1, 3]
sage: dll.unhide(2); dll
Doubly linked list of [1, 2, 3]: [1, 2, 3]
```

```python
sage: dll = sage.combinat.misc.DoublyLinkedList([Integer(1),Integer(2),Integer(3)]);

>>> from sage.all import *

>>> dll = sage.combinat.misc.DoublyLinkedList([Integer(1),Integer(2),Integer(3)]);

```

```python
head()
```
This class wraps functions with a yield statement (generators) by an object that can be iterated over. For example,

EXAMPLES:

```
sage: def f():
    yield 'a'; yield 'b'

>>> from sage.all import *
>>> def f():
    yield 'a'; yield 'b'

This does not work:

```
sage: for z in f: print(z)
Traceback (most recent call last):
  ...TypeError: 'function' object is not iterable
```

Use IterableFunctionCall if you want something like the above to work:

```
sage: from sage.combinat.misc import IterableFunctionCall
sage: g = IterableFunctionCall(f)
sage: for z in g: print(z)
a
b
```

If your function takes arguments, just put them after the function name. You needn’t enclose them in a tuple or anything, just put them there:

```
sage: def f(n, m):
    yield 'a' * n; yield 'b' * m; yield 'foo'
sage: g = IterableFunctionCall(f, 2, 3)
sage: for z in g: print(z)
a
b
foo
```
```python
>>> from sage.all import *
>>> def f(n, m): yield 'a' * n; yield 'b' * m; yield 'foo'
>>> g = IterableFunctionCall(f, Integer(2), Integer(3))

>>> for z in g: print(z)
aa
bbb
foo
```

```python
sage.combinat.misc.check_integer_list_constraints(l, **kwargs)
```

EXAMPLES:

```python
sage: from sage.combinat.misc import check_integer_list_constraints
sage: cilc = check_integer_list_constraints
sage: l = [[2,1,3],[1,2],[3,3],[4,1,1]]
sage: cilc(l, min_part=2)
[[3, 3]]
sage: cilc(l, max_part=2)
[[1, 2]]
sage: cilc(l, length=2)
[[1, 2], [3, 3]]
sage: cilc(l, max_length=2)
[[1, 2], [3, 3]]
sage: cilc(l, min_length=3)
[[2, 1, 3], [4, 1, 1]]
sage: cilc(l, max_slope=0)
[[3, 3], [4, 1, 1]]
sage: cilc(l, min_slope=1)
[[1, 2]]
sage: cilc(l, outer=[2,2])
[[1, 2]]
sage: cilc(l, inner=[2,2])
[[3, 3]]
```
```python
sage: cilc([1,2,3], length=3, singleton=True)
[1, 2, 3]
sage: cilc([1,2,3], length=2, singleton=True) is None
True

>>> from sage.all import *

>>> cilc([Integer(1),Integer(2),Integer(3)], length=Integer(3), singleton=True)
[1, 2, 3]
>>> cilc([Integer(1),Integer(2),Integer(3)], length=Integer(2), singleton=True) is None
True
```

`sage.combinat.misc.umbral_operation(poly)`

Returns the umbral operation ↓ applied to poly.

The umbral operation replaces each instance of $x_i^a$ with $x_i \cdot (x_i - 1) \cdots (x_i - a + 1)$.

**EXAMPLES:**

```python
sage: P = PolynomialRing(QQ, 2, 'x')
sage: x = P.gens()
sage: from sage.combinat.misc import umbral_operation
sage: umbral_operation(x[0]**3) == x[0]*(x[0]-1)*(x[0]-2)
True
sage: umbral_operation(x[0]*x[1])
x0*x1
sage: umbral_operation(x[0]+x[1])
x0 + x1
sage: umbral_operation(x[0]**2*x[1]**2) == x[0]*(x[0]-1)*x[1]*(x[1]-1)
True

>>> from sage.all import *

>>> P = PolynomialRing(QQ, Integer(2), 'x')

>>> x = P.gens()

>>> from sage.combinat.misc import umbral_operation

>>> umbral_operation(x[Integer(0)]**Integer(3)) == x[Integer(0)]*(x[Integer(0)]-Integer(1))*(x[Integer(0)]-Integer(2))
True
```

5.1. Comprehensive Module List 2225
5.1.140 Ordered Multiset Partitions into Sets and the Minimaj Crystal

This module provides element and parent classes for ordered multiset partitions. It also implements the minimaj crystal of Benkart et al. [BCHOPSY2017]. (See MinimajCrystal.)

AUTHORS:
- Aaron Lauve (2018): initial implementation. First draft of minimaj crystal code provided by Anne Schilling.

REFERENCES:
- [BCHOPSY2017]
- [HRW2015]
- [HRS2016]
- [LM2018]

EXAMPLES:
An ordered multiset partition into sets of the multiset \{\{1, 3, 5\}\}:

\[
\texttt{sage: OrderedMultisetPartitionIntoSets([\{5, 3\}, \{1, 3\}])}
\]

\[
\{3, 5\}, \{1, 3\}
\]

Ordered multiset partitions into sets of the multiset \{\{1, 3, 5\}\}:

\[
\texttt{sage: OrderedMultisetPartitionsIntoSets([1,1,3]).list()}
\]

\[
\{\{1\}, \{1\}, \{3\}\}, \{\{1\}, \{1,3\}\}, \{\{1\}, \{3\}, \{1\}\}, \{\{3\}, \{1\}, \{1\}\}
\]

Ordered multiset partitions into sets of the integer 4:

\[
\texttt{sage: OrderedMultisetPartitionsIntoSets(4).list()}
\]

\[
\{\{4\}\}, \{\{1,3\}\}, \{\{3\}, \{1\}\}, \{\{1,2\}, \{1\}\}, \{\{2\}, \{2\}\}, \{\{2\}, \{1\}, \{1\}\}, \{\{1\}, \{3\}\}, \{\{1\}, \{1,2\}\}, \{\{1\}, \{2\}, \{1\}\}, \{\{1\}, \{2\}, \{2\}\}, \{\{1\}, \{1\}, \{1\}, \{1\}\}
\]

Ordered multiset partitions into sets on the alphabet \{1, 4\} of order 3:

\[
\texttt{sage: OrderedMultisetPartitionsIntoSets([1,4], 3).list()}
\]

\[
\{\{1,4\}, \{1\}\}, \{\{1,4\}, \{4\}\}, \{\{1\}, \{1,4\}\}, \{\{4\}, \{1,4\}\}, \{\{1\}, \{1\}, \{1\}\}, \{\{1\}, \{4\}, \{4\}\}, \{\{1\}, \{4\}, \{1\}\}, \{\{4\}, \{4\}, \{1\}\}, \{\{4\}, \{1\}, \{4\}\}, \{\{4\}, \{1\}, \{1\}\}
\]
Crystal of ordered multiset partitions into sets on the alphabet \{1, 2, 3\} with 4 letters divided into 2 blocks:

```
sage: crystals.Minimaj(3, 4, 2).list()               # needs sage.modules
[[(2, 3, 1), (1,)], [(2, 3), (1, 2)], [(2, 3), (1, 3)], [(2, 1), (1, 2)],
 [(3, 1), (1, 2)], [(3, 1), (1, 3)], [(3, 1, 2), (2,)], [(3, 1), (1, 3)],
 [(3, 2), (2, 3)], [(2, 1), (1, 3)], [(2,), (1, 2, 3)], [(3,), (1, 2, 3)],
 [(1,), (1, 2, 3)], [(1), (1, 2, 3)], [(1, 2), (2, 3)], [(1, 2, 3), (3,)]]
```

```
crystals.Minimaj(3, 5, 2).list()                    # needs sage.modules
[[(2, 3, 1), (1,)], [(2, 3), (1, 2)], [(2, 3), (1, 3)], [(2, 1), (1, 2)],
 [(3, 1), (1, 2)], [(3, 1, 2), (2,)], [(3, 1), (1, 3)], [(3, 1), (1, 3)],
 [(3, 2), (2, 3)], [(2, 1), (1, 3)], [(2,), (1, 2, 3)], [(3,), (1, 2, 3)],
 [(1,), (1, 2, 3)], [(1, 2), (2, 3)], [(1, 2, 3), (3,)]]
```

class `sage.combinat.multiset_partition_into_sets_ordered.MinimajCrystal(n, ell, k)`
Bases: `UniqueRepresentation, Parent`

Crystal of ordered multiset partitions into sets with \(\ell\) letters from alphabet \{1, 2, \ldots, n\} divided into \(k\) blocks. Elements are represented in the minimaj ordering of blocks as in Benkart et al. [BCHOPSY2017].

**Note:** Elements are not stored internally as ordered multiset partitions into sets, but as certain (pairs of) words stemming from the minimaj bijection \(\phi\) of [BCHOPSY2017]. See `sage.combinat.multiset_partition_into_sets_ordered.MinimajCrystal.Element` for further details.

**AUTHORS:**
- Anne Schilling (2018): initial draft
- Aaron Lauve (2018): changed to use `Letters` crystal for elements

**EXAMPLES:**

```
sage: list(crystals.Minimaj(2,3,2))              # needs sage.modules
[[(2, 1), (1,}], [(2,), (1, 2)], [(1,), (1, 2)], [(1, 2), (2,)]]
```

```
sage: b = crystals.Minimaj(3, 5, 2).an_element(); b  # needs sage.modules
((2, 3, 1), (1, 2))
sage: b.f(2)                                      # needs sage.modules
((2, 3, 1), (1, 3))
sage: b.e(2)                                      # needs sage.modules
((2, 3, 1), (1, 3))
```

5.1. Comprehensive Module List
```python
>>> from sage.all import *

>>> list(crystals.Minimaj(Integer(2), Integer(3), Integer(2)))    # needs sage.modules
[[(2, 1), (1,)], [(2,), (1, 2)], [(1,), (1, 2)], [(1, 2), (2,)]]

>>> b = crystals.Minimaj(Integer(3), Integer(5), Integer(2)).an_element(); b     # needs sage.modules
((2, 3, 1), (1, 2))

>>> b.f(Integer(2))     # needs sage.modules
((2, 3, 1), (1, 3))

>>> b.e(Integer(2))     # needs sage.modules
((2, 3, 1), (1, 3))
```

class Element

Bases: ElementWrapper

An element of a Minimaj crystal.

**Note:** Minimaj elements $b$ are stored internally as pairs $(w, \text{breaks})$, where:

- $w$ is a word of length `self.parent().ell` over the letters 1 up to `self.parent().n`;
- `breaks` is a list of de-concatenation points to turn $w$ into a list of row words of (skew-)tableaux that represent $b$ under the minimaj bijection $\varphi$ of [BCHOPSY2017].

The pair $(w, \text{breaks})$ may be recovered via `b.value`.

### e($i$)

Return $e_i$ on `self`.

**EXAMPLES:**

```python
sage: B = crystals.Minimaj(4,3,2)                      # needs sage.modules
sage: b = B([[2,3],[3]]); b                             # needs sage.modules
((2, 3), (3,))

sage: [b.e(i) for i in range(1,4)]                      # needs sage.modules
[((1, 3), (3,)), ((2,), (2, 3)), None]
```

### f($i$)

Return $f_i$ on `self`.

**EXAMPLES:**

```python
>>> from sage.all import *

>>> B = crystals.Minimaj(Integer(4),Integer(3),Integer(2)) # needs sage.modules

>>> b = B([[Integer(2),Integer(3)], [Integer(3)]]); b # needs sage.modules
((2, 3), (3,))

>>> [b.e(i) for i in range(Integer(1),Integer(4))] # needs sage.modules
[((1, 3), (3,)), ((2,), (2, 3)), None]
```
to_tableaux_words()

Return the image of the ordered multiset partition into sets self under the minimaj bijection $\phi$ of [BCHOPSY2017].

EXAMPLES:

```python
sage: B = crystals.Minimaj(4,5,3)
sage: b = B.an_element(); b
((2, 3, 1), (1,), (1,))
sage: b.to_tableaux_words()
[[1], [3], [2, 1, 1]]
sage: b = B([[1,3,4], [3], [3]]); b
((4, 1, 3), (3,), (3,))
sage: b.to_tableaux_words()
[[3, 1], [], [4, 3, 3]]
```

from_tableau(t)

Return the bijection $\phi^{-1}$ of [BCHOPSY2017] applied to t.

INPUT:

- t – a sequence of column tableaux and a ribbon tableau

EXAMPLES:
sage: # needs sage.modules
sage: B = crystals.Minimaj(3, 6, 3)
sage: b = B.an_element(); b
((3, 1, 2), (2, 1), (1,))
sage: t = b.to_tableaux_words(); t
[[1], [2, 1], [], [3, 2, 1]]
sage: B.from_tableau(t)
((3, 1, 2), (2, 1), (1,))
sage: B.from_tableau(t) == b
True

val(q='q')
Return the Val polynomial corresponding to self.

EXAMPLES:
Verifying Example 4.5 from [BCHOPY2017]:

sage: B = crystals.Minimaj(3, 4, 2)  # for AVal_{4,1}^{(3)}A

sage: B.val()  # needs sage.modules
(q^2+q+1)*s[2, 1, 1] + q*s[2, 2]

Bases: ClonableArray

Ordered Multiset Partition into sets

An ordered multiset partition into sets $c$ of a multiset $X$ is a list $[c_1, \ldots, c_r]$ of nonempty subsets of $X$ (note: not sub-multisets), called the blocks of $c$, whose multi-union is $X$.

EXAMPLES:
The simplest way to create an ordered multiset partition into sets is by specifying its blocks as a list or tuple:
sage: OrderedMultisetPartitionIntoSets([[3],[2,1]])

sage: OrderedMultisetPartitionIntoSets(((3,), (1,2)))

sage: OrderedMultisetPartitionIntoSets([set([i]) for i in range(2,5)])

>>> from sage.all import *

>>> OrderedMultisetPartitionIntoSets(([Integer(3)], [Integer(2),Integer(1)]))

>>> OrderedMultisetPartitionIntoSets(((Integer(3),), (Integer(1),Integer(2))))

>>> OrderedMultisetPartitionIntoSets([set([i]) for i in range(Integer(2), Integer(5))])

REFERENCES:

- [HRW2015]
- [HRS2016]
- [LM2018]

check()

Check that we are a valid ordered multiset partition into sets.

EXAMPLES:

sage: c = OrderedMultisetPartitionsIntoSets(4)([[1], [1,2]])
sage: c.check()

sage: OMPs = OrderedMultisetPartitionsIntoSets()
sage: c = OMPs([[1], [1], ['a']])
sage: c.check()

>>> from sage.all import *

>>> c = OrderedMultisetPartitionsIntoSets(Integer(4))([[Integer(1)], ...

>>> c.check()

>>> OMPs = OrderedMultisetPartitionsIntoSets()

>>> c = OMPs([[Integer(1)], [Integer(1)], ['a']])

>>> c.check()

deconcatenate (k=2)

Return the list of k-deconcatenations of self.

A k-tuple \((C_1, \ldots, C_k)\) of ordered multiset partitions into sets represents a k-deconcatenation of an ordered multiset partition into sets \(C\) if \(C_1 + \cdots + C_k = C\).

Note: This is not to be confused with self.split_blocks(), which splits each block of self before making \(k\)-tuples of ordered multiset partitions into sets.

EXAMPLES:
sage: OrderedMultisetPartitionIntoSets([[7,1],[3,4,5]]).deconcatenate()
[[[7,7], [3,4,5]], [[7]], [[7], [3,4,5]]]
sage: OrderedMultisetPartitionIntoSets([['b','c'],['a']]).deconcatenate()
[[[['b','c'], ('a')]], [[('b','c')]], [['a']]], (['b','c'], ('a'))]
sage: OrderedMultisetPartitionIntoSets([['a','b','c']]).deconcatenate(3)
[[[['a','b','c']]], [], []]

>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(7),Integer(1)], [Integer(3), Integer(4), Integer(5)]]).deconcatenate()
[[[Integer(7), (3,4,5)], [], [[Integer(7)], [3,4,5]]], (['b','c'], ('a'))]
>>> OrderedMultisetPartitionIntoSets([['b','c'],['a']]).deconcatenate()
[[[['b','c'], ('a')]], [[('b','c')]], [['a']]], (['b','c'], ('a'))]
>>> OrderedMultisetPartitionIntoSets([['a','b','c']]).deconcatenate(Integer(3))
[[[['a','b','c']]], [], []]

fatten(grouping)

Return the ordered multiset partition into sets fatter than self, obtained by grouping together consecutive parts according to grouping (whenever this does not violate the strictness condition).

INPUT:

• grouping—a composition (or list) whose sum is the length of self

EXAMPLES:

Let us start with the composition:

sage: C = OrderedMultisetPartitionIntoSets([[4,1,5], [2], [7,1]]); C
[{1,4,5}, {2}, {1,7}]

>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(4),Integer(1),Integer(5)],[Integer(2)], [Integer(7),Integer(1)]]); C
[{1,4,5}, {2}, {1,7}]

With grouping equal to (1,1,1), C is left unchanged:

sage: C.fatten([1,1,1])
[{1,4,5}, {2}, {1,7}]

>>> from sage.all import *
>>> C.fatten([Integer(1),Integer(1),Integer(1)])
[{1,4,5}, {2}, {1,7}]

With grouping equal to (2,1) or (1,2), a union of consecutive parts is achieved:

sage: C.fatten([2,1])
[{1,2,4,5}, {1,7}]
sage: C.fatten([1,2])
[{1,4,5}, {1,2,7}]
However, the grouping $([3])$ will throw an error, as 1 cannot appear twice in any block of C:

```
>> from sage.all import *
>> C.fatten(Composition([3]))
Traceback (most recent call last):
...
ValueError: [{1,4,5,2,1,7}] is not a valid ordered multiset partition into...
˓→sets
```

fatter()

Return the set of ordered multiset partitions into sets which are fatter than self.

An ordered multiset partition into sets $A$ is fatter than another $B$ if, reading left-to-right, every block of $A$ is the union of some consecutive blocks of $B$.

EXAMPLES:

```
 sage: C = OrderedMultisetPartitionIntoSets([{{1,4,5}, {2}, {1,7}}]).fatter()
sage: len(C)
3
 sage: sorted(C)
[[{1,4,5}, {2}, {1,7}], [{1,4,5}, {1,2,7}], [{1,2,4,5}, {1,7}]]
 sage: sorted(OrderedMultisetPartitionIntoSets([['a','b'],['c'],['a']]).fatter())
[[], [['a','b'], ['c'], ['a']], [['a','b'], {'a','c'}], [{'a','b','c'}, {'a'}]]
```

Some extreme cases:

```
 sage: list(OrderedMultisetPartitionIntoSets([['a','b','c']]).fatter())
[['a','b','c']]
 sage: list(OrderedMultisetPartitionIntoSets([]).fatter())
[[]]
 sage: A = OrderedMultisetPartitionIntoSets([[[1], [2], [3], [4]]])
sage: B = OrderedMultisetPartitionIntoSets([[[1,2,3,4]]])
```

(continues on next page)
Combinatorics, Release 10.4

sage: A.fatter().issubset(B.finer())
True

>>> from sage.all import *
>>> list(OrderedMultisetPartitionIntoSets([['a', 'b', 'c']]).fatter())
[[['a', 'b', 'c']]]
>>> list(OrderedMultisetPartitionIntoSets([]).fatter())
[[]]

A = OrderedMultisetPartitionIntoSets([Integer(1)], [Integer(2)], ...
      [Integer(3)], [Integer(4)])
B = OrderedMultisetPartitionIntoSets([Integer(1), Integer(2), Integer(3), ...
      Integer(4)])

>>> A.fatter().issubset(B.finer())
True

finer (strong=False)

Return the set of ordered multiset partitions into sets that are finer than self.

An ordered multiset partition into sets $A$ is finer than another $B$ if, reading left-to-right, every block of $B$ is the union of some consecutive blocks of $A$.

If optional argument strong is set to True, then return only those $A$ whose blocks are deconcatenations of blocks of $B$. (Here, we view blocks of $B$ as sorted lists instead of sets.)

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[3, 2]]).finer()
sage: len(C)
3

sage: sorted(C, key=str)
[[[2, 3]], [[2], [3]], [[[3], [2]]]]

sage: O = OrderedMultisetPartitionsIntoSets([1, 1, a, b])

sage: o = O([{1}, {a, b}, {1}])

sage: sorted(o.finer(), key=str)
[[{1}, {a, b}, {1}], [{1}, {a}, {b}, {1}], [{1}, {b}, {a}, {1}]]

sage: o.finer() & o.fatter() == set([o])
True

is_finer (co)

Return True if the ordered multiset partition into sets self is finer than the composition \(co\); otherwise,
return False.

EXAMPLES:

```python
sage: OrderedMultisetPartitionIntoSets([[4], [1], [2]]).is_finer([[1], [4], [2]])
True
sage: OrderedMultisetPartitionIntoSets([[1], [4], [2]]).is_finer([[1], [4], [2]])
True
sage: OrderedMultisetPartitionIntoSets([[1, 4], [1], [1]]).is_finer([[1, 4], [2]])
False
```

```python
>>> from sage.all import *

>>> OrderedMultisetPartitionIntoSets([[Integer(4)], [Integer(1)], [Integer(2)]]).is_finer([[Integer(1), Integer(4)], [Integer(2)]])
True
>>> OrderedMultisetPartitionIntoSets([[Integer(1)], [Integer(4)], [Integer(2)]]).is_finer([[Integer(1), Integer(4)], [Integer(2)]])
True
>>> OrderedMultisetPartitionIntoSets([[Integer(1), Integer(4)], [Integer(1)], [Integer(1)]].is_finer([[Integer(1), Integer(4)], [Integer(2)]])
False
```

length()

Return the number of blocks of self.

EXAMPLES:

```python
sage: OrderedMultisetPartitionIntoSets([[7, 1], [3]]).length()
2
```

```python
>>> from sage.all import *

>>> OrderedMultisetPartitionIntoSets([[Integer(7), Integer(1)], [Integer(3)]]).length()
2
```

letters()

Return the set of distinct elements occurring within the blocks of self.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
{k(3), k(4), k(1), k(2), k(1, 2, 3, 7)}
sage: C.letters()
frozenset({1, 2, 3, 4, 7})
```

```python
>>> from sage.all import *

>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4), Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3), Integer(7)]]); C
{k(1, 3, 4), k(2), k(1, 2, 3, 7)}
>>> C.letters()
frozenset({1, 2, 3, 4, 7})
```

major_index()

Return the major index of self.

The major index is a statistic on ordered multiset partitions into sets, which we define here via an example.
1. Sort each block in the list `self` in descending order to create a word \( w \), keeping track of the original separation into blocks:

\[
\text{in: } [(3,4,5), (2,3,4), (1), (4,5)] \\
\text{out: } [5,4,3, 4,3,2, 1, 5,4]
\]

2. Create a sequence \( v = (v_0, v_1, v_2, \ldots) \) of length `self.order()+1`, built recursively by:

1. \( v_0 = 0 \)
2. \( v_j = v_{j-1} + \delta(j) \), where \( \delta(j) = 1 \) if \( j \) is the index of an end of a block, and zero otherwise.

\[
\text{in: } [5,4,3, 4,3,2, 1, 5,4] \\
\text{out: } (0, 0,0,1, 1,1,2, 3, 3,4)
\]

3. Compute \( \sum_j v_j \), restricted to descent positions in \( w \), i.e., sum over those \( j \) with \( w_j > w_{j+1} \):

\[
\text{in: } w: [5, 4, 3, 4, 3, 2, 1, 5, 4] \\
v: (0 0, 0, 1, 1, 1, 2, 3, 3, 4) \\
maj := 0 +0 +1 +1 +2 +3 = 7
\]

REFERENCES:

- [HRW2015]

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[1,5,7], [2,4], [5,6], [4,6,8], [1,3], [1,2,3]])
sage: C.major_index()
sage: C.major_index()
27
```

```
sage: C = OrderedMultisetPartitionIntoSets([[3,4,5], [2,3,4], [1], [4,5]])
sage: C.major_index()
sage: C.major_index()
7
```

```
>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(1),Integer(5),Integer(7)], [Integer(2),Integer(4)], [Integer(5),Integer(6)], [Integer(4),Integer(6), Integer(8)], [Integer(1),Integer(3)], [Integer(1),Integer(2),Integer(3)]])
>>> C.major_index()
27
```

```
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3),Integer(4),Integer(5)], [Integer(2),Integer(3),Integer(4)], [Integer(1)], [Integer(1), Integer(4),Integer(5)]])
>>> C.major_index()
7
```

\( \text{max_letter()} \)

Return the maximum letter appearing in `self.letters()` of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]])
sage: C.max_letter()
7
```

```
sage: D = OrderedMultisetPartitionIntoSets([['a','b','c'],['a','b'],['a'],['b','c','f'],['c','d']])
sage: D.max_letter()
'f'
```

(continues on next page)
sage: C = OrderedMultisetPartitionIntoSets([])
sage: C.max_letter()

>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4),
  →Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3),
  →Integer(7)]])
>>> C.max_letter()
7
>>> D = OrderedMultisetPartitionIntoSets(['a','b','c'],['a','b'],['a'],['b',
  →'c','f'],['c','d'])
>>> D.max_letter()
'f'
>>> C = OrderedMultisetPartitionIntoSets([])
>>> C.max_letter()

minimaj()

Return the minimaj statistic on ordered multiset partitions into sets.

We define minimaj via an example:

1. Sort the block in self as prescribed by self.minimaj_word(), keeping track of the original separation into blocks:

   in:  [(1,5,7), (2,4), {5,6}, {4,6,8}, {1,3}, {1,2,3}]
   out:  ( 5,7,1 / 2,4 / 5,6 / 4,6,8 / 3,1 / 1,2,3 )

2. Record the indices where descents in this word occur:

   word:  (5, 7, 1 / 2, 4 / 5, 6 / 4, 6, 8 / 3, 1 / 1, 2, 3)
   indices:  1 2 3 4 5 6 7 8 9 10 11 12 13 14 15
   descents:  { 2, 7, 10, 11 }

3. Compute the sum of the descents:

   minimaj = 2 + 7 + 10 + 11 = 30

REFERENCES:

• [HRW2015]

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[1,5,7], (2,4), {5,6}, {4,6,8},
  →{1,3}, {1,2,3}])
sage: C, C.minimaj_word()

(sage: C, C.minimaj_word())

(continues on next page)
minimaj_blocks()

Return the minimaj ordering on blocks of self.

We define the ordering via the example below.

Sort the blocks \([B_1, ..., B_k]\) of self from right to left via:

1. Sort the last block \(B_k\) in increasing order, call it the word \(W_k\).
2. If blocks \(B_{i+1}, ..., B_k\) have been converted to words \(W_{i+1}, ..., W_k\), use the letters in \(B_i\) to make the unique word \(W_i = (u, v)\) that has a factorization \(W_i = (u, v)\) satisfying:
   • letters of \(u\) and \(v\) appear in increasing order, with \(v\) possibly empty;
   • letters in \(vu\) appear in increasing order;
   • \(v[\cdot] - 1\) is the largest letter \(a \in B_i\) satisfying \(a <= W_{i+1}[0]\).

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([['b', 'd'], ['a', 'b', 'c'], ['b']])
sage: C, C.minimaj_word()
(('[b', 'd'], ['a', 'b', 'c'], ['b']), (d, b, c, a, b, b))
sage: C.minimaj()
4

>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([Integer(1), Integer(5), Integer(7)],
     Integer(2), Integer(4), {Integer(5), Integer(6)}, {Integer(4), Integer(6),
     Integer(8)}, {Integer(1), Integer(3)}, {Integer(1), Integer(2), Integer(3)})
>>> C, C.minimaj_word()
([1, 5, 7], {2, 4}, {5, 6}, {4, 6, 8}, {1, 3}, {1, 2, 3}),
(5, 7, 1, 2, 4, 5, 6, 4, 6, 8, 3, 1, 1, 2, 3))
>>> C.minimaj()
30
```

minimaj_blocks()

Return the minimaj ordering on blocks of self.

We define the ordering via the example below.

Sort the blocks \([B_1, ..., B_k]\) of self from right to left via:

1. Sort the last block \(B_k\) in increasing order, call it the word \(W_k\).
2. If blocks \(B_{i+1}, ..., B_k\) have been converted to words \(W_{i+1}, ..., W_k\), use the letters in \(B_i\) to make the unique word \(W_i = (u, v)\) that has a factorization \(W_i = (u, v)\) satisfying:
   • letters of \(u\) and \(v\) appear in increasing order, with \(v\) possibly empty;
   • letters in \(vu\) appear in increasing order;
   • \(v[\cdot] - 1\) is the largest letter \(a \in B_i\) satisfying \(a <= W_{i+1}[0]\).

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([['b', 'd'], ['a', 'b', 'c'], ['b']])
sage: C, C.minimaj_word()
(('[b', 'd'], ['a', 'b', 'c'], ['b']), (d, b, c, a, b, b))
sage: C.minimaj()
4

>>> from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([Integer(1), Integer(5), Integer(7)],
     Integer(2), Integer(4), {Integer(5), Integer(6)}, {Integer(4), Integer(6),
     Integer(8)}, {Integer(1), Integer(3)}, {Integer(1), Integer(2), Integer(3)})
>>> C, C.minimaj_word()
([1, 5, 7], {2, 4}, {5, 6}, {4, 6, 8}, {1, 3}, {1, 2, 3}),
(5, 7, 1, 2, 4, 5, 6, 4, 6, 8, 3, 1, 1, 2, 3))
```
from sage.all import *

OrderedMultisetPartitionIntoSets([[Integer(1), Integer(5), Integer(7)], ...
→ [Integer(2), Integer(4)], [Integer(5), Integer(6), [Integer(4), Integer(6), ...
→ Integer(5)], [Integer(3), Integer(3)], [Integer(1), Integer(2), Integer(3)]])
[(1, 5, 7), (2, 4), {5, 6}, {4, 6, 8}, {1, 3}, {1, 2, 3}]

_.minimaj_blocks()
((5, 7, 1), (2, 4), (5, 6), (4, 6, 8), (3, 1), (1, 2, 3))

OrderedMultisetPartitionIntoSets([]).minimaj_blocks()

minimaj_word()

Return an ordering of self._multiset derived from the minimaj ordering on blocks of self.

See also:

OrderedMultisetPartitionIntoSets.minimaj_blocks().

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[2, 1], [1, 2, 3], [1, 2], [3], [1]]);
C
[{1,2}, {1,2,3}, {1,2}, {3}, {1}]
sage: C.minimaj_blocks()
((1, 2), (2, 3, 1), (1, 2), (3,), (1,))
sage: C.minimaj_word()
(1, 2, 2, 3, 1, 1, 2, 3, 1)

sage: from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(2), Integer(1)], ...
→ [Integer(1), Integer(2)], [Integer(1), Integer(2)], [Integer(3)], ...
→ Integer(1)])); C
C
[(1, 2), (2, 3, 1), (1, 2), (3,), (1,)]
>>> C.minimaj_blocks()
((1, 2), (2, 3, 1), (1, 2), (3,), (1,))
>>> C.minimaj_word()
(1, 2, 2, 3, 1, 1, 2, 3, 1)

multiset (as_dict=False)

Return the multiset corresponding to self.

INPUT:

- as_dict – (default: False) whether to return the multiset as a tuple of a dict of multiplicities

EXAMPLES:

sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
C
[(1, 3, 4), {2}, {1, 2, 3, 7}]
sage: C.multiset()
(1, 2, 2, 3, 3, 4, 7)
sage: C.multiset(as_dict=True)
{1: 2, 2: 2, 3: 3, 4: 1, 7: 1}
sage: OrderedMultisetPartitionIntoSets([]).multiset() == {}
True

sage: from sage.all import *
>>> C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4), ...
→ Integer(1)], [Integer(2)], [Integer(1), Integer(2), Integer(3)], ...
(continues on next page)
order()

Return the total number of elements in all blocks of self.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[{1, 3, 4}, {2}, {1, 2, 3, 7}]
sage: C.order()
8
sage: C.order() == sum(C.weight().values())
True
sage: C.order() == sum(k for k in C.shape_from_cardinality())
True
```

reversal()

Return the reverse ordered multiset partition into sets of self.

Given an ordered multiset partition into sets \((B_1, B_2, \ldots, B_k)\), its reversal is defined to be the ordered multiset partition into sets \((B_k, \ldots, B_2, B_1)\).

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[Integer(3), Integer(4), Integer(1)], [1, 3], [2, 3, 4]]); C
[{1, 3, 4}, {2}, {1, 2, 3, 7}]
sage: C.reversal()
[{2, 3, 4}, {1, 3}, {1}]
```

`(continues on previous page)`
shape_from_cardinality()

Return a composition that records the cardinality of each block of self.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[[1, 3, 4], [2], [1, 2, 3, 7]]
sage: C.shape_from_cardinality()
[3, 1, 4]
sage: OrderedMultisetPartitionIntoSets([]).shape_from_cardinality() == Composition([])
True
```

shape_from_size()

Return a composition that records the sum of entries of each block of self.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4, 1], [2], [1, 2, 3, 7]]); C
[[1, 3, 4], [2], [1, 2, 3, 7]]
sage: C.shape_from_size()
[8, 2, 13]
```

shuffle_product (other, overlap=False)

Return the shuffles (with multiplicity) of blocks of self with blocks of other.

In case optional argument overlap is True, instead return the allowable overlapping shuffles. An overlapping shuffle $C$ is allowable if, whenever one of its blocks $c$ comes from the union $c = a \cup b$ of a block of self and a block of other, then this union is disjoint.

See also:

Composition.shuffle_product()

EXAMPLES:

```python
```
size()

Return the size of self (that is, the sum of all integers in all blocks) if self is a list of subsets of positive integers.

Else, return None.

EXAMPLES:

```python
sage: C = OrderedMultisetPartitionIntoSets([[3, 4], [2], [1, 2, 3, 7]]); C
{(3, 4), (2), (1, 2, 3, 7)}
sage: C.size()
23
sage: C.size() == sum(k for k in C.shape_from_size())
True
sage: OrderedMultisetPartitionIntoSets([[7, 1], [3]]).size()
11
```

(continues on next page)
split_blocks \((k=2)\)

Return a dictionary representing the \(k\)-splittings of \texttt{self}.

A \(k\)-tuple \((A_1, \ldots, A_k)\) of ordered multiset partitions into sets represents a \(k\)-splitting of an ordered multiset partition into sets \(A = [b_1, \ldots, b_r]\) if one can express each block \(b_i\) as an (ordered) disjoint union of sets \(b_i = b_{i1} \sqcup \cdots \sqcup b_{ik}\) (some possibly empty) so that each \(A_j\) is the ordered multiset partition into sets corresponding to the list \([b_{i1}', b_{i2}', \ldots, b_{ik}']\), excising empty sets appearing therein.

This operation represents the coproduct in Hopf algebra of ordered multiset partitions into sets in its natural basis [LM2018].

**EXAMPLES:**

```python
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).split_blocks()

{([1], [2], [3,4]): 2, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```

```python
>>> OrderedMultisetPartitionIntoSets([[Integer(3)]]).split_blocks()

{([1], [2], [3,4]): 1, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```

```python
>>> OrderedMultisetPartitionIntoSets([[1],[2],[3],[4]]).split_blocks()

{([1], [2], [3,4]): 1, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```

```python
>>> OrderedMultisetPartitionIntoSets([[1],[2],[3],[4]]).split_blocks(3)

{([1], [2], [3,4]): 1, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```

```python
>>> OrderedMultisetPartitionIntoSets([[1],[2],[3],[4]]).split_blocks(4)

{([1], [2], [3,4]): 1, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```

```python
>>> OrderedMultisetPartitionIntoSets([[1],[2],[3],[4]]).split_blocks(5)

{([1], [2], [3,4]): 1, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```

```python
>>> from sage.all import *
>>> OrderedMultisetPartitionIntoSets([[Integer(1),Integer(2)],[Integer(3),Integer(4)]]).split_blocks()

{([1], [2], [3,4]): 2, ([1], [4], [2,3]): 1, ([2], [1], [3,4]): 1, ([2], [4], [1,3]): 1, ([3], [1], [2,4]): 1, ([3], [4], [1,2]): 1, ([4], [1], [2,3]): 1, ([4], [2], [1,3]): 1, ([4], [3], [1,2]): 1}
```
Combinatorics, Release 10.4

([3,4], \{1,2\}), \\
([3], \{1,2\}, \{4\}), \\
([4], \{1,2\}, \{3\})
\end{align*}$$

```python
>>> sorted(OrderedMultisetPartitionIntoSets([[Integer(1),Integer(2)]]).split_˓→blocks(Integer(3)), key=str)
[[[1], [], [[1,2]]], [[[1], [[1,2]]], [], [[1]]], [[[1,2], [[1]]], [], [], [], [], [], []]
>>> OrderedMultisetPartitionIntoSets([[Integer(4),Integer(4)]]).split_˓→blocks()
[[[[], [[4]], [[4]]]], 1, [[[4]], [[4]]], 2, [[[4]], [[4]]], 1]
```

to_tableaux_words()

Return a sequence of lists corresponding to row words of (skew-)tableaux.

**OUTPUT:**

The minimaj bijection $\phi$ of [BCHOPSY2017] applied to `self`.

**Todo:** Implement option for mapping to sequence of (skew-)tableaux?

**EXAMPLES:**

```python
sage: co = ((1,2,4),(4,5),(3), (4,6,1),(2,3,1),(1),(2,5))
sage: OrderedMultisetPartitionIntoSets(co).to_tableaux_words()
[[5, 1], [3, 1], [6], [5, 4, 2], [1, 4, 3, 4, 2, 1, 2]]
```

```python
>>> from sage.all import *
>>> co = ((Integer(1),Integer(2),Integer(4)),(Integer(4),Integer(5)),
˓→(Integer(3),), (Integer(4),Integer(6),Integer(1)),(Integer(2),Integer(3),
˓→Integer(1)),(Integer(1)),(Integer(2),Integer(5)))
>>> OrderedMultisetPartitionIntoSets(co).to_tableaux_words()
[[5, 1], [3, 1], [6], [5, 4, 2], [1, 4, 3, 4, 2, 1, 2]]
```

**weight (as_weak_comp=False)**

Return a dictionary, with keys being the letters in `self.letters()` and values being their (positive) frequency.

Alternatively, if `as_weak_comp` is `True`, count the number of instances $n_i$ for each distinct positive integer $i$ across all blocks of `self`. Return as a list $[n_1, n_2, n_3, ..., n_k]$, where $k$ is the max letter appearing in `self.letters()`.

**EXAMPLES:**

```python
sage: c = OrderedMultisetPartitionIntoSets([[6,1],[1,3],[1,3,6]])
sage: c.weight()
{1: 3, 3: 2, 6: 2}
sage: c.weight(as_weak_comp=True)
[3, 0, 2, 0, 0, 2]
```

```python
>>> from sage.all import *
>>> c = OrderedMultisetPartitionIntoSets([[Integer(6),Integer(1)],[Integer(1),
˓→(continues on next page)```

\[
\text{class \ sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets}
\]

Bases: \text{UniqueRepresentation}, \text{Parent}

Ordered Multiset Partitions into Sets.

An ordered multiset partition into sets \(c\) of a multiset \(X\) is a list of nonempty subsets (not multisets), called the blocks of \(c\), whose multi-union is \(X\).

The number of blocks of \(c\) is called its length. The order of \(c\) is the cardinality of the multiset \(X\). If, additionally, \(X\) is a multiset of positive integers, then the size of \(c\) is the sum of all elements of \(X\).

The user may wish to focus on ordered multiset partitions into sets of a given size, or over a given alphabet. Hence, this class allows a variety of arguments as input.

INPUT:

Expects one or two arguments, with different behaviors resulting:

- One Argument:
  - \(X\) – a dictionary or list or tuple (representing a multiset for \(c\)), or an integer (representing the size of \(c\))

- Two Arguments:
  - \(A\) – a list (representing allowable letters within blocks of \(c\)), or a positive integer (representing the maximal allowable letter)
  - \(n\) – a nonnegative integer (the total number of letters within \(c\))

Optional keyword arguments are as follows: (See corresponding methods in see \text{OrderedMultisetPartitionIntoSets} for more details.)

- \text{weight=X} (list or dictionary \(X\)) specifies the multiset for \(c\)
- \text{size=n} (integer \(n\)) specifies the size of \(c\)
- \text{alphabet=A} (iterable \(A\)) specifies allowable elements for the blocks of \(c\)
- \text{length=k} (integer \(k\)) specifies the number of blocks in the partition
- \text{min_length=k} (integer \(k\)) specifies minimum number of blocks in the partition
- \text{max_length=k} (integer \(k\)) specifies maximum number of blocks in the partition
- \text{order=n} (integer \(n\)) specifies the cardinality of the multiset that \(c\) partitions
- \text{min_order=n} (integer \(n\)) specifies minimum number of elements in the partition
- \text{max_order=n} (integer \(n\)) specifies maximum number of elements in the partition

EXAMPLES:

Passing one argument to \text{OrderedMultisetPartitionsIntoSets}:

There are 5 ordered multiset partitions into sets of the multiset \(
\{1, 1, 4\}\):

5.1. Comprehensive Module List 2245
Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets([1, 1, 4]).list()
[[[1], [1], [4]], [[1], [1, 4]], [[1], [4], [1]], [[1, 4], [1]], [[4], [1], [1]]]
```

By chance, there are also 5 ordered multiset partitions into sets of the integer 3:

```
sage: OrderedMultisetPartitionsIntoSets(3).cardinality()
5
```

Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets(3).list()
[[[3]], [[1, 2]], [[2], [1]], [[1], [2]], [[1], [1], [1]]]
```

Passing two arguments to `OrderedMultisetPartitionsIntoSets`:

There are also 5 ordered multiset partitions into sets of order 2 over the alphabet \{1, 4\}:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).cardinality()
5
```

Here is the list of them:

```
sage: OrderedMultisetPartitionsIntoSets([1, 4], 2).list()
[[[1, 4]], [[1], [1]], [[1], [4]], [[4], [1]], [[4], [4]]]
```
If no arguments are passed to `OrderedMultisetPartitionsIntoSets`, then the code returns all ordered multiset partitions into sets:

```
sage: OrderedMultisetPartitionsIntoSets()
Ordered Multiset Partitions into Sets
sage: [] in OrderedMultisetPartitionsIntoSets()
True
sage: [[2,3], [1]] in OrderedMultisetPartitionsIntoSets()
True
sage: [['a','b'], ['a']] in OrderedMultisetPartitionsIntoSets()
True
sage: [[-2,3], [3]] in OrderedMultisetPartitionsIntoSets()
True
sage: [[2], [3,3]] in OrderedMultisetPartitionsIntoSets()
False
```
OrderedMultisetPartitionsIntoSets(Integer(5))

False

Optional keyword arguments

Passing keyword arguments that are incompatible with required requirements results in an error; otherwise, the collection of ordered multiset partitions into sets is restricted accordingly:

The weight keyword:

This is used to specify which multiset $X$ is to be considered, if this multiset was not passed as one of the required arguments for `OrderedMultisetPartitionsIntoSets`. In principle, it is a dictionary, but weak compositions are also allowed. For example, the ordered multiset partitions into sets of integer 4 are listed by weight below:

```
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,0,0,1])
Ordered Multiset Partitions into Sets of integer 4 with constraint: weight={4: 1}
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,0,0,1]).list()
[[[4]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[1,0,1]).list()
[[[1], [3]], [[1,3]], [[3], [1]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,2]).list()
[[[2], [2]]]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[0,1,1]).list()
[]
sage: OrderedMultisetPartitionsIntoSets(4, weight=[2,1]).list()
[[[1], [1], [2]], [[1], [1,2]], [[1], [2], [1]], [[1,2], [1]], [[2], [1], [1]]]
sage: O1 = OrderedMultisetPartitionsIntoSets(weight={2:0,1})
sage: O2 = OrderedMultisetPartitionsIntoSets(weight={1:2, 3:1})
sage: O1 == O2
True
sage: OrderedMultisetPartitionsIntoSets(4, weight=[4]).list()
[[[1], [1], [1], [1]]]
```

```
>> from sage.all import *
>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(0),
-> Integer(0),Integer(1)])
Ordered Multiset Partitions into Sets of integer 4 with constraint: weight={4: 1}
>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(0),
-> Integer(0),Integer(1)]).list()
[[[4]]]
>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(1),Integer(0),
-> Integer(1)]).list()
[[[1], [3]], [[1,3]], [[3], [1]]]
>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(2)]).list()
[[[2], [2]]]
>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(0),Integer(1),
-> Integer(1)]).list()
[]
>> OrderedMultisetPartitionsIntoSets(Integer(4), weight=[Integer(2),Integer(1)]).list()
[[[1], [1], [2]], [[1], [1,2]], [[1], [2], [1]], [[1,2], [1]], [[2], [1], [1]]]
>> O1 = OrderedMultisetPartitionsIntoSets(weight=[Integer(2),Integer(0),
-> Integer(1)])
```

(continues on next page)
The `size` keyword:

This is used to constrain the sum of entries across all blocks of the ordered multiset partition into sets. (This size is not pre-determined when alphabet $A$ and order $d$ are passed as required arguments.) For example, the ordered multiset partitions into sets of order 3 over the alphabet $\{1, 2, 4\}$ that have size equal to 5 are as follows:

```sage
OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs([1,2,4], 3, size=5).list()
[[[1,2], {2}], [[2], {1,2}], [[2], {2}, {1}],
 [[2], {1}, {2}], [[1], {2}, {2}]]
```

The `alphabet` option:

This is used to constrain which integers appear across all blocks of the ordered multiset partition into sets. For example, the ordered multiset partitions into sets of integer 4 are listed for different choices of alphabet below. Note that alphabet is allowed to be an integer or an iterable:

```sage
OMPs = OrderedMultisetPartitionsIntoSets
sage: OMPs(4, alphabet=3).list()
[[{1,3}], {{3}}, {{1}},
 [[{1,2}], {{1}}, [{1}, {3}],
 [[{2}], {{1}}, {{1}}, {3}],
 [{1}, {1,2}], {{1}, {2}, {1}},
 [[{1}, {1}], {1}], {{1}, {1}, {1}},]

sage: OMPs(4, alphabet=3) == OMPs(4, alphabet=[1,2,3])
True
sage: OMPs(4, alphabet=[3]).list()
[]
sage: OMPs(4, alphabet=[1,2,3]).list()
[[{1,3}], {{3}}, {{1}}, [{1}, {1}, {1}]]
sage: OMPs(4, alphabet=[2]).list()
[[{2}], {2}]]
sage: OMPs(4, alphabet=1,2).list()
[[{1,2}, {1}], [{2}, {2}], [{2}, {1}, {1}], [{1}, {1,2}],
 [{1}, {2}, {1}], [{1}, {1}, {2}], [{1}, {1}, {1}, {1}]]
sage: OMPs(4, alphabet=4).list() == OMPs(4).list()
True
```

```sage
from sage.all import *
```

```sage
OMPs = OrderedMultisetPartitionsIntoSets
```

```sage
OMPs(Integer(4), alphabet=Integer(3)).list()
[[{1,3}], {{3}}, {{1}},
 [[{1,2}], {{1}}, [{2}, {2}]],
```

(continues on next page)
The `length`, `min_length`, and `max_length` options:

These are used to constrain the number of blocks within the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 of length exactly 2, at least 2, and at most 2 are given by:

```python
sage: OrderedMultisetPartitionsIntoSets(4, length=2).list()
[[[3], [1]], [[1, 2], [1]], [[2], [2]], [[1], [3]], [[1], [1, 2]]]
sage: OrderedMultisetPartitionsIntoSets(4, min_length=3).list()
[[[2], [1], [1]], [[1, 2], [1]], [[1], [1, 2]], [[1], [1, 1], [1]]]
sage: OrderedMultisetPartitionsIntoSets(4, max_length=2).list()
[[[4]], [[1, 3]], [[3], [1]], [[1, 2], [1]], [[2], [2]], [[1], [3]],
[[1], [1, 2]]]
```

The `order`, `min_order`, and `max_order` options:

These are used to constrain the number of elements across all blocks of the ordered multiset partitions into sets. For example, the ordered multiset partitions into sets of integer 4 by order below:

```python
>>> OrderedMultisetPartitionsIntoSets(4, order=1).list()
[[[4]]]
sage: OrderedMultisetPartitionsIntoSets(4, order=2).list()
[[[1, 3]], [[3], [1]], [[2], [2]], [[1], [3]]]
sage: OrderedMultisetPartitionsIntoSets(4, order=3).list()
[[[1, 2], [1]], [[1], [2], [1]], [[1], [1, 2]], [[1], [2], [1]],
[[1], [1], [2]]]
sage: OrderedMultisetPartitionsIntoSets(4, order=4).list()
[[[1], [1], [1], [1]]]
```

```python
>>> from sage.all import *
```

```python
>>> OrderedMultisetPartitionsIntoSets(Integer(4), order=Integer(1)).list()
(continues on next page)```
Also, here is a use of `max_order`, giving the ordered multiset partitions into sets of integer 4 with order 1 or 2:

```
sage: OrderedMultisetPartitionsIntoSets(4, max_order=2).list()
[[[4]], [[1,3]], [[3], [1]], [[2], [2]], [[1], [3]]]
```

Element alias of `OrderedMultisetPartitionIntoSets` subset

Return a subset of all ordered multiset partitions into sets.

INPUT:

- `size`—an integer representing a slice of all ordered multiset partitions into sets

The slice alluded to above is taken with respect to length, or to order, or to size, depending on the constraints of `self`.

EXAMPLES:

```
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1})
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset \{2, 3, 5\} with
Constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets(weight={2:2, 3:1, 5:1}, min_length=2)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of multiset \{2, 3, 5\} with
Constraint: length=2
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5])
sage: C.subset(3)
Ordered Multiset Partitions into Sets of order 3 over alphabet \{2, 3, 5\}
sage: C = OrderedMultisetPartitionsIntoSets(order=5)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of integer 3 with constraint: order=5
sage: C = OrderedMultisetPartitionsIntoSets(alphabet=[2,3,5], order=5, length=3)
sage: C.subset(3)
Ordered Multiset Partitions into Sets of order 3 over alphabet \{2, 3, 5\} with
Constraint: length=3
sage: C = OrderedMultisetPartitionsIntoSets()
sage: C.subset(3)
Ordered Multiset Partitions into Sets of integer 3
sage: C.subset(3) == OrderedMultisetPartitionsIntoSets(3)
True
```
```python
>>> from sage.all import *

>>> C = OrderedMultisetPartitionsIntoSets(weight={Integer(2):Integer(2),
    Integer(3):Integer(1), Integer(5):Integer(1)})

>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with
    constraint: length=3

>>> C = OrderedMultisetPartitionsIntoSets(weight={Integer(2):Integer(2),
    Integer(3):Integer(1), Integer(5):Integer(1)}, min_length=Integer(2))

>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of multiset {{2, 2, 3, 5}} with
    constraint: length=3

>>> C = OrderedMultisetPartitionsIntoSets(alphabet=[Integer(2),Integer(3),
    Integer(5)])

>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5}

>>> C = OrderedMultisetPartitionsIntoSets(order=Integer(5))

>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of integer 3 with constraint: order=5

>>> C = OrderedMultisetPartitionsIntoSets(alphabet=[Integer(2),Integer(3),
    Integer(5)], order=Integer(5), length=Integer(3))

>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of order 3 over alphabet {2, 3, 5} with
    constraint: length=3

>>> C = OrderedMultisetPartitionsIntoSets()

>>> C.subset(Integer(3))
Ordered Multiset Partitions into Sets of integer 3

>>> C.subset(Integer(3)) == OrderedMultisetPartitionsIntoSets(Integer(3))
True
```

class `sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_X`

Bases: `OrderedMultisetPartitionsIntoSets`

Class of ordered multiset partitions into sets of a fixed multiset $X$.

**cardinality()**

Return the number of ordered partitions of multiset $X$.

**random_element()**

Return a random element of self.

This method does not return elements of self with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random permutation $p$ of the multiset;
- create blocks of an OMP fat by breaking $p$ after non-ascents;
- take a random element of fat.finer().

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[[1], [1,3]]

sage: OrderedMultisetPartitionsIntoSets([1,1,3]).random_element()  # random
[[3], [1], [1]]

sage: OMP = OrderedMultisetPartitionsIntoSets([1,1,3,3])

sage: d = {}

sage: for _ in range(1000):
```

(continues on next page)
....:   x = OMP.random_element()
....:   d[x] = d.get(x, 0) + 1
\sage: d.values()  # random
[102, 25, 76, 24, 66, 88, 327, 27, 83, 83, 239, 72, 88]

\>>> from sage.all import *
\>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3)]).
   \rightarrow random_element()  # random
[\{1\}, \{1,3\}]
\>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3)]).
   \rightarrow random_element()  # random
[\{3\}, \{1\}, \{1\}]
\>>> OMP = OrderedMultisetPartitionsIntoSets([Integer(1),Integer(1),Integer(3),
   \rightarrow Integer(3)])
\>>> d = {}
\>>> for _ in range(Integer(1000)):
   ...   x = OMP.random_element()
   ...   d[x] = d.get(x, Integer(0)) + Integer(1)
\>>> d.values()  # random
[102, 25, 76, 24, 66, 88, 327, 27, 83, 83, 239, 72, 88]

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets

Bases: OrderedMultisetPartitionsIntoSets

Class of ordered multiset partitions into sets of a fixed multiset \(X\) satisfying constraints.

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets

Bases: OrderedMultisetPartitionsIntoSets

All ordered multiset partitions into sets (with or without constraints).

EXAMPLES:

\sage: C = OrderedMultisetPartitionsIntoSets(); C
Ordered Multiset Partitions into Sets
\sage: [[1],[1,'a']] in C
True
\sage: OrderedMultisetPartitionsIntoSets(weight=[2,0,1], length=2)
Ordered Multiset Partitions into Sets of multiset \{1, 1, 3\} with constraint:
 \rightarrow length=2

\>>> from sage.all import *
\>>> C = OrderedMultisetPartitionsIntoSets(); C
Ordered Multiset Partitions into Sets
\>>> [[Integer(1)],[Integer(1),'a']] in C
True
\>>> OrderedMultisetPartitionsIntoSets(weight=[Integer(2),Integer(0),Integer(1)],...
   \rightarrow length=Integer(2))
Ordered Multiset Partitions into Sets of multiset \{1, 1, 3\} with constraint:
\(\rightarrow\) length=2

```python
class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets(A, d):
    # Bases: OrderedMultisetPartitionsIntoSets
    Class of ordered multiset partitions into sets of specified order \(d\) over a fixed alphabet \(A\).

cardinality()

    Return the number of ordered partitions of order \(self._order\) on alphabet \(self._alphabet\).

class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_alph_d_constraints(A, d, **constraints):
```

EXAMPIES:

```python
sage: OrderedMultisetPartitionsIntoSets([1,4], 3).random_element()  # random
[[4], [1,4]]
sage: OrderedMultisetPartitionsIntoSets([1,3], 4).random_element()  # random
[[1,3], [1], [3]]
sage: OMP = OrderedMultisetPartitionsIntoSets([2,3,4], 2)
sage: d = {}
sage: for _ in range(1200):
    ... x = OMP.random_element()
    ... d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[192, 68, 73, 61, 69, 60, 77, 204, 210, 66, 53, 67]
```

```python
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(4)], Integer(3)).
  random_element()  # random
[[4], [1,4]]
>>> OrderedMultisetPartitionsIntoSets([Integer(1),Integer(3)], Integer(4)).
  random_element()  # random
[[1,3], [1], [3]]
>>> OMP = OrderedMultisetPartitionsIntoSets([Integer(2),Integer(3),
  Integer(4)], Integer(2))
>>> d = {}
>>> for _ in range(Integer(1200)):
    ... x = OMP.random_element()
    ... d[x] = d.get(x, Integer(0)) + Integer(1)
>>> d.values()  # random
[192, 68, 73, 61, 69, 60, 77, 204, 210, 66, 53, 67]
```
**Bases:** `OrderedMultisetPartitionsIntoSets`

Class of ordered multiset partitions into sets of specified order \( d \) over a fixed alphabet \( A \) satisfying constraints.

```python
class sage.combinat.multiset_partition_into_sets_ordered.OrderedMultisetPartitionsIntoSets_n(n)
```

Ordered multiset partitions into sets of a fixed integer \( n \).

**cardinality()**

Return the number of elements in self.

**random_element()**

Return a random element of self.

This method does not return elements of self with uniform probability, but it does cover all elements. The scheme is as follows:

- produce a random composition \( C \);
- choose a random partition of \( c \) into distinct parts for each \( c \) in \( C \).

**EXAMPLES:**

```python
sage: OrderedMultisetPartitionsIntoSets(5).random_element()  # random
[\{1, 2\}, \{1\}, \{1\}]

sage: OrderedMultisetPartitionsIntoSets(5).random_element()  # random
[\{2\}, \{1, 2\}]

sage: OMP = OrderedMultisetPartitionsIntoSets(5)
sage: d = {}
sage: for _ in range(1100):
    x = OMP.random_element()
    d[x] = d.get(x, 0) + 1
sage: d.values()  # random
[72, 73, 162, 78, 135, 75, 109, 65, 135, 134, 62]
```

```python
>>> from sage.all import *
>>> OrderedMultisetPartitionsIntoSets(Integer(5)).random_element()  # random
[\{1, 2\}, \{1\}, \{1\}]

>>> OrderedMultisetPartitionsIntoSets(Integer(5)).random_element()  # random
[\{2\}, \{1, 2\}]

>>> OMP = OrderedMultisetPartitionsIntoSets(Integer(5))
>>> d = {}
>>> for _ in range(Integer(1100)):
    x = OMP.random_element()
    d[x] = d.get(x, Integer(0)) + Integer(1)
>>> d.values()  # random
[72, 73, 162, 78, 135, 75, 109, 65, 135, 134, 62]
```

```
```

**Bases:** `OrderedMultisetPartitionsIntoSets`

Class of ordered multiset partitions into sets of a fixed integer \( n \) satisfying constraints.
5.1.141 Non-commutative symmetric functions and quasi-symmetric functions

- Introduction to Quasisymmetric Functions
- Non-Commutative Symmetric Functions (NCSF)
- Quasi-Symmetric Functions (QSym)
- Generic code for bases

5.1.142 Common combinatorial tools

REFERENCES:

sage.combinat.ncsf_qsym.combinatorics.coeff_dab(I, J)

Return the number of standard composition tableaux of shape \( I \) with descent composition \( J \).

INPUT:
- \( I, J \) – compositions

OUTPUT: integer

EXAMPLES:

sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
sage: coeff_dab(Composition([2,1]),Composition([2,1]))
1
sage: coeff_dab(Composition([1,1,2]),Composition([1,2,1]))
0

>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import coeff_dab
>>> coeff_dab(Composition([Integer(2),Integer(1)]),Composition([Integer(2), ...
1
>>> coeff_dab(Composition([Integer(1),Integer(2)]),Composition([Integer(2),Integer(1)]))
0

sage.combinat.ncsf_qsym.combinatorics.coeff_ell(J, I)

Returns the coefficient \( \ell_{J,I} \) as defined in [NCSF].

INPUT:
- \( J \) – a composition
- \( I \) – a composition refining \( J \)

OUTPUT: integer

EXAMPLES:

sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_ell
sage: coeff_ell(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_ell(Composition([2,1]), Composition([3]))
2
sage.combinat.ncsf_qsym.combinatorics\texttt{.coeff\_lp(J, I)}

Returns the coefficient $l_{p_{J,I}}$ as defined in [NCSF].

**INPUT:**

- $J$ – a composition
- $I$ – a composition refining $J$

**OUTPUT:** integer

**EXAMPLES:**

```python
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_lp
sage: coeff_lp(Composition([1,1,1]), Composition([2,1]))
1
sage: coeff_lp(Composition([2,1]), Composition([3]))
1
```

sage.combinat.ncsf_qsym.combinatorics\texttt{.coeff\_pi(J, I)}

Returns the coefficient $\pi_{J,I}$ as defined in [NCSF].

**INPUT:**

- $J$ – a composition
- $I$ – a composition refining $J$

**OUTPUT:** integer

**EXAMPLES:**

```python
sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_pi
sage: coeff_pi(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_pi(Composition([2,1]), Composition([3]))
6
```

(continues on next page)
sage.combinat.ncsf_qsym.combinatorics.coeff_sp(J, I)

Returns the coefficient $sp_J, I$ as defined in [NCSF].

INPUT:

• $J$ – a composition
• $I$ – a composition refining $J$

OUTPUT: integer

EXAMPLES:

sage: from sage.combinat.ncsf_qsym.combinatorics import coeff_sp
sage: coeff_sp(Composition([1,1,1]), Composition([2,1]))
2
sage: coeff_sp(Composition([2,1]), Composition([3]))
4

sage.combinat.ncsf_qsym.combinatorics.compositions_order(n)

Return the compositions of $n$ ordered as defined in [QSCHUR].

Let $S(\gamma)$ return the composition $\gamma$ after sorting. For compositions $\alpha$ and $\beta$, we order $\alpha \triangleright \beta$ if

1) $S(\alpha) > S(\beta)$ lexicographically, or

2) $S(\alpha) = S(\beta)$ and $\alpha > \beta$ lexicographically.

INPUT:

• $n$ – a positive integer

OUTPUT:

• A list of the compositions of $n$ sorted into decreasing order by $\triangleright$

EXAMPLES:

sage: from sage.combinat.ncsf_qsym.combinatorics import compositions_order
sage: compositions_order(3)
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: compositions_order(4)
[[4], [3, 1], [1, 3], [2, 2], [2, 1, 1], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

(continues on next page)
sage.combinat.ncsf_qsym.combinatorics.m_to_s_stat(R, I, K)

Return the coefficient of the complete non-commutative symmetric function $S^K$ in the expansion of the monomial non-commutative symmetric function $M^I$ with respect to the complete basis over the ring $R$. This is the coefficient in formula (36) of Tevlin’s paper [Tev2007].

INPUT:

• $R$ – A ring, supposed to be a $\mathbb{Q}$-algebra
• $I, K$ – compositions

OUTPUT:

• The coefficient of $S^K$ in the expansion of $M^I$ in the complete basis of the non-commutative symmetric functions over $R$.

EXAMPLES:

```python
sage: from sage.combinat.ncsf_qsym.combinatorics import m_to_s_stat
sage: m_to_s_stat(QQ, Composition([2,1]), Composition([1,1,1]))
-1
sage: m_to_s_stat(QQ, Composition([3]), Composition([1,2]))
-2
sage: m_to_s_stat(QQ, Composition([2,1,2]), Composition([2,1,2]))
8/3
```

sage.combinat.ncsf_qsym.combinatorics.number_of_SSRCT(shape_comp)

The number of semi-standard reverse composition tableaux.

The dual quasisymmetric-Schur functions satisfy a left Pieri rule where $S_n dQs_{\gamma}$ is a sum over dual quasisymmetric-Schur functions indexed by compositions which contain the composition $\gamma$. The definition of an SSRCT comes from this rule. The number of SSRCT of content $\beta$ and shape $\alpha$ is equal to the number of SSRCT of content $(\beta_2, \ldots, \beta_{\ell})$ and shape $\gamma$ where $dQs_{\alpha}$ appears in the expansion of $S_{\beta_1} dQs_{\gamma}$.

In sage the recording tableau for these objects are called CompositionTableaux.

INPUT:

• content_comp, shape_comp – compositions

OUTPUT:

• An integer

EXAMPLES:
```
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
sage: number_of_SSRCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_SSRCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_SSRCT(Composition([1,1,2,2]), Composition([3,3]))
2
sage: all(CompositionTableaux(be).cardinality() == sum(number_of_SSRCT(al,be)*binomial(4,len(al))
....:     for al in Compositions(4))
....:     for be in Compositions(4))
True
```

```
>> from sage.all import *
>> from sage.combinat.ncsf_qsym.combinatorics import number_of_SSRCT
>> number_of_SSRCT(Composition([Integer(3),Integer(1)]), Composition([Integer(1),
˓→Integer(3)]))
0
>> number_of_SSRCT(Composition([Integer(1),Integer(2),Integer(1)]),...
˓→Composition([Integer(1),Integer(3)]))
1
>> number_of_SSRCT(Composition([Integer(1),Integer(1),Integer(2),Integer(2)]),...
˓→Composition([Integer(3),Integer(3)]))
2
>> all(CompositionTableaux(be).cardinality() == sum(number_of_SSRCT(al,be)*binomial(Integer(4),len(al))
....:     for al in Compositions(Integer(4))
....:     for be in Compositions(Integer(4)))
True
```

`sage.combinat.ncsf_qsym.combinatorics.number_of_fCT(shape_comp)`

Return the number of Immaculate tableaux of shape `shape_comp` and content `content_comp`.

See [BBSSZ2012], Definition 3.9, for the notion of an immaculate tableau.

**INPUT:**
- `content_comp`, `shape_comp` – compositions

**OUTPUT:**
- An integer

**EXAMPLES:**
```
sage: from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
sage: number_of_fCT(Composition([3,1]), Composition([1,3]))
0
sage: number_of_fCT(Composition([1,2,1]), Composition([1,3]))
1
sage: number_of_fCT(Composition([1,1,3,1]), Composition([2,1,3]))
2
```

```
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.combinatorics import number_of_fCT
>>> number_of_fCT(Composition([Integer(3),Integer(1)]), Composition([Integer(1),
˓→Integer(3)]))
0
```
(continues on next page)
5.1.143 Generic code for bases

This is a collection of code that is shared by bases of noncommutative symmetric functions and quasisymmetric functions.

AUTHORS:

• Jason Bandlow
• Franco Saliola
• Chris Berg

```python
class sage.combinat.ncsf_qsym.generic_basis_code.AlgebraMorphism(domain, on_generators, position=0, codomain=None, category=None, anti=False)
```

Bases: `ModuleMorphismByLinearity`

A class for algebra morphism defined on a free algebra from the image of the generators

```python
class sage.combinat.ncsf_qsym.generic_basis_code.BasesOfQSymOrNCSF(parent_with_realization)
```

Bases: `Category_realization_of_parent`

class ElementMethods

Bases: object

```python
def degree()
    The maximum of the degrees of the homogeneous summands.

    See also:
    homogeneous_degree()

    EXAMPLES:
```

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: (x, y) = (S[2], S[3])
sage: x.degree()
2
sage: (x^3 + 4*y^2).degree()
6
sage: ((1 + x)^3).degree()
6
```

```python
>>> from sage.all import *
```

```python
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> (x, y) = (S[Integer(2)], S[Integer(3)])
```
degree_negation()

Return the image of self under the degree negation automorphism of the parent of self.

The degree negation is the automorphism which scales every homogeneous element of degree \( k \) by \((-1)^k\) (for all \( k \)).

Calling degree_negation(self) is equivalent to calling self.parent().degree_negation(self).

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: f = 2*S[2,1] + 4*S[1,1] - 5*S[1,2] - 3*S[]
sage: f.degree_negation()
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dualImmaculate()
sage: f.degree_negation()
```

```python
>>> from sage.all import *

>>> NSym = NonCommutativeSymmetricFunctions(ZZ)

>>> S = NSym.S()

>>> f = Integer(2)*S[Integer(2),Integer(1)] + Integer(4)*S[Integer(1),
-Integer(1)] - Integer(5)*S[Integer(1),Integer(2)] - Integer(3)*S[]

>>> f.degree_negation()
-3*S[] + 4*S[1, 1] + 5*S[1, 2] - 2*S[2, 1]
```
Todo: Generalize this to all graded vector spaces?

duality_pairing(y)
The duality pairing between elements of $NSym$ and elements of $QSym$.
The complete basis is dual to the monomial basis with respect to this pairing.

INPUT:
• $y$ – an element of the dual Hopf algebra of self

OUTPUT:
• The result of pairing self with $y$.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R[1,1,2].duality_pairing(F[1,1,2])
1
sage: R[1,2,1].duality_pairing(F[1,1,2])
0
```

```
>>> from sage.all import *

>>> R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R[Integer(1),Integer(1),Integer(2)].duality_pairing(F[Integer(1),
→Integer(1),Integer(2)])
1
>>> R[Integer(1),Integer(2),Integer(1)].duality_pairing(F[Integer(1),
→Integer(1),Integer(2)])
0
```

```
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L[1,2].duality_pairing(F[1,2])
0
sage: L[1,1,1].duality_pairing(F[1,2])
1
```

```
>>> from sage.all import *

>>> L = NonCommutativeSymmetricFunctions(QQ).Elementary()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> L[Integer(1),Integer(2)].duality_pairing(F[Integer(1),
→Integer(1),Integer(2)])
0
>>> L[Integer(1),Integer(1),Integer(1)].duality_pairing(F[Integer(1),
→Integer(2)])
1
```

5.1. Comprehensive Module List 2263
skew_by \((y, \text{side}='left')\)

The operation which is dual to multiplication by \(y\), where \(y\) is an element of the dual space of \(self\).

This is calculated through the coproduct of \(self\) and the expansion of \(y\) in the dual basis.

**INPUT:**

- \(y\) – an element of the dual Hopf algebra of \(self\)
- \(\text{side}=(\text{Default='left'})\) Either 'left' or 'right'

**OUTPUT:**

- The result of skewing \(self\) by \(y\), on the side \(\text{side}\)

**EXAMPLES:**

Skewing an element of NCSF by an element of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R([2,2,2]).skew_by(F[1,1])
sage: R([2,2,2]).skew_by(F[2])
```

Skewing an element of QSym by an element of NCSF:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F[3,2].skew_by(R[1,1])
0
sage: F[3,2].skew_by(R[1,1], side='right')
0
sage: F[3,2].skew_by(S[1,1,1], side='right')
F[2]
sage: F[3,2].skew_by(S[1,2], side='right')
F[2]
sage: F[3,2].skew_by(S[2,1], side='right')
0
sage: F[3,2].skew_by(S[1,1,1])
F[2]
sage: F[3,2].skew_by(S[1,1])
F[1, 2]
sage: F[3,2].skew_by(S[1])
F[2, 2]
```

```
class ParentMethods

Bases: object

alternating_sum_of_compositions(n)

Alternating sum over compositions of \( n \).

Note that this differs from the method `alternating_sum_of_finer_compositions()` because the coefficient of the composition \( 1^n \) is positive. This method is used in the expansion of the elementary generators into the complete generators and vice versa.
INPUT:
• \textit{n} – a positive integer

OUTPUT:
• The expansion of the complete generator indexed by \textit{n} into the elementary basis.

EXAMPLES:

\begin{verbatim}
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.alternating_sum_of_compositions(0)
L[]
sage: L.alternating_sum_of_compositions(1)
L[1]
sage: L.alternating_sum_of_compositions(2)
L[1, 1] - L[2]
sage: L.alternating_sum_of_compositions(3)
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.alternating_sum_of_compositions(3)
\end{verbatim}

\textbf{alternating_sum_of_fatter_compositions}(\textit{composition})

Return the alternating sum of fatter compositions in a basis of the non-commutative symmetric functions.

INPUT:
• \textit{composition} – a composition

OUTPUT:
• The alternating sum of the compositions fatter than \textit{composition}, in the basis self. The alternation is upon the length of the compositions, and is normalized so that \textit{composition} has coefficient 1.

EXAMPLES:

\begin{verbatim}
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_fatter_compositions(Composition([2,2,1]))
sage: elementary.alternating_sum_of_fatter_compositions(Composition([1,2]))
L[1, 2] - L[3]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> L = NonCommutativeSymmetricFunctions(QQ).L()

>>> L.alternating_sum_of_compositions(Integer(0))
L[]

>>> L.alternating_sum_of_compositions(Integer(1))
L[1]

>>> L.alternating_sum_of_compositions(Integer(2))
L[1, 1] - L[2]

>>> L.alternating_sum_of_compositions(Integer(3))

>>> S = NonCommutativeSymmetricFunctions(QQ).S()

>>> S.alternating_sum_of_compositions(Integer(3))
\end{verbatim}

\textbf{alternating_sum_of_fatter_compositions}(\textit{composition})

Return the alternating sum of fatter compositions in a basis of the non-commutative symmetric functions.

INPUT:
• \textit{composition} – a composition

OUTPUT:
• The alternating sum of the compositions fatter than \textit{composition}, in the basis self. The alternation is upon the length of the compositions, and is normalized so that \textit{composition} has coefficient 1.

EXAMPLES:

\begin{verbatim}
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_fatter_compositions(Composition([2,2,
˓→1]))
sage: elementary.alternating_sum_of_fatter_compositions(Composition([1,
˓→2]))
L[1, 2] - L[3]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> NCSF=NonCommutativeSymmetricFunctions(QQ)

>>> elementary = NCSF.elementary()
\end{verbatim}
elementary.alternating_sum_of_fatter_compositions(Composition([Integer(2), Integer(2), Integer(1)]))

alternating_sum_of_finer_compositions (composition, conjugate=False)

Return the alternating sum of finer compositions in a basis of the non-commutative symmetric functions.

INPUT:
• composition – a composition
• conjugate – (default: False) a boolean

OUTPUT:
• The alternating sum of the compositions finer than composition, in the basis self. The alternation is upon the length of the compositions, and is normalized so that composition has coefficient 1. If the variable conjugate is set to True, then the conjugate of composition is used instead of composition.

EXAMPLES:
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.alternating_sum_of_finer_compositions(Composition([2, 2, 1]))
L[1, 1, 1, 1] - L[1, 1, 2, 1] - L[2, 1, 1, 1] + L[2, 2, 1]
sage: elementary.alternating_sum_of_finer_compositions(Composition([1, 2]))
-L[1, 1, 1] + L[1, 2]

counit_on_basis (I)

The counit is defined by sending all elements of positive degree to zero.

EXAMPLES:
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.counit_on_basis([1, 3])
0
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.counit_on_basis([1, 3])
0

>>> from sage.all import *

5.1. Comprehensive Module List
degree_negation\( (element) \)

Return the image of \( element \) under the degree negation automorphism of \( self \).

The degree negation is the automorphism which scales every homogeneous element of degree \( k \) by \((-1)^k\) (for all \( k \)).

INPUT:

- \( element \) – element of \( self \)

EXAMPLES:

\[
\text{sage: } NSym = \text{NonCommutativeSymmetricFunctions}(\mathbb{Z})
\text{sage: } S = NSym.S()
\text{sage: } f = 2 \ast S[2,1] + 4 \ast S[1,1] - 5 \ast S[1,2] - 3 \ast S[]
\text{sage: } S.\text{degree_negation}(f)
-3 \ast S[] + 4 \ast S[1,1] + 5 \ast S[1,2] - 2 \ast S[2,1]
\text{sage: } QSym = \text{QuasiSymmetricFunctions}(\mathbb{Q})
\text{sage: } dI = QSym.dualImmaculate()
\text{sage: } f = -3 \ast dI[2,1] + 4 \ast dI[2] + 2 \ast dI[1]
\text{sage: } dI.\text{degree_negation}(f)
-2 \ast dI[1] + 4 \ast dI[2] + 3 \ast dI[2,1]
\]

Todo: Generalize this to all graded vector spaces?

degree_on_basis\( (I) \)

Return the degree of the basis element indexed by \( I \).

INPUT:

- \( I \) – a composition

OUTPUT:

- The degree of the non-commutative symmetric function basis element of \( self \) indexed by \( I \). By definition, this is the size of the composition \( I \).

EXAMPLES:

\[
\text{sage: } R = \text{NonCommutativeSymmetricFunctions}(\mathbb{Q}).\text{ribbon()}
\text{sage: } R.\text{degree_on_basis}(\text{Composition}([2,3]))
\]
duality_pairing \((x, y)\)

The duality pairing between elements of \(NSym\) and elements of \(QSym\).

This is a default implementation that uses \self.realizations_of().a_realization() and its dual basis.

**INPUT:**
- \(x\) – an element of \self
- \(y\) – an element in the dual basis of \self

**OUTPUT:**
- The result of pairing the function \(x\) from \self with the function \(y\) from the dual basis of \self

**EXAMPLES:**

```
sage: R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing(R[1,1,2], F[1,1,2])
1
sage: R.duality_pairing(R[1,2,1], F[1,1,2])
0
sage: F.duality_pairing(F[1,2,1], R[1,1,2])
0
```

```
>>> from sage.all import *

>>> R = NonCommutativeSymmetricFunctions(QQ).Ribbon()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> R.duality_pairing(R[Integer(1),Integer(1),Integer(2)], F[Integer(1),
Integer(1),Integer(2)])
1
>>> R.duality_pairing(R[Integer(1),Integer(2),Integer(1)], F[Integer(1),
Integer(1),Integer(2)])
0
>>> F.duality_pairing(F[Integer(1),Integer(2),Integer(1)], R[Integer(1),
Integer(1),Integer(2)])
0
```

```
sage: S = NonCommutativeSymmetricFunctions(QQ).Complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing(S[1,1,2], M[1,1,2])
```

(continues on next page)
duality_pairing(x, y)

The duality pairing between elements of NSym and elements of QSym.

This is a default implementation that uses self.realizations_of().a_realization() and its dual basis.

INPUT:

- x – an element of self
- y – an element in the dual basis of self

OUTPUT:

- The result of pairing the function x from self with the function y from the dual basis of self

EXAMPLES:
sage: L = NonCommutativeSymmetricFunctions(QQ).Elementary()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: L.duality_pairing_by_coercion(L[1,2], F[1,2])
0
sage: F.duality_pairing_by_coercion(F[1,2], L[1,2])
0
sage: L.duality_pairing_by_coercion(L[1,1,1], F[1,2])
1
sage: F.duality_pairing_by_coercion(F[1,2], L[1,1,1])
1

```
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).Elementary()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> L.duality_pairing_by_coercion(L[Integer(1),Integer(2)], F[Integer(1),
˓→Integer(2)])
0
>>> F.duality_pairing_by_coercion(F[Integer(1),Integer(2)], L[Integer(1),
˓→Integer(2)])
0
>>> L.duality_pairing_by_coercion(L[Integer(1),Integer(1),Integer(1)],...
˓→F[Integer(1),Integer(2)])
1
>>> F.duality_pairing_by_coercion(F[Integer(1),Integer(2)], L[Integer(1),
˓→Integer(1),Integer(1)])
```

\begin{verbatim}
duality_pairing_matrix(basis, degree)
\end{verbatim}

The matrix of scalar products between elements of NSym and elements of QSym.

INPUT:
\begin{itemize}
\item basis – A basis of the dual Hopf algebra
\item degree – a non-negative integer
\end{itemize}

OUTPUT:
\begin{itemize}
\item The matrix of scalar products between the basis self and the basis basis
      in degree degree.
\end{itemize}

EXAMPLES:

The ribbon basis of NCSF is dual to the fundamental basis of QSym:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: R.duality_pairing_matrix(F, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: F.duality_pairing_matrix(R, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

```
The complete basis of NCSF is dual to the monomial basis of QSym:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: S.duality_pairing_matrix(M, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
sage: M.duality_pairing_matrix(S, 3)
[1 0 0 0]
[0 1 0 0]
[0 0 1 0]
[0 0 0 1]
```

The matrix between the ribbon basis of NCSF and the monomial basis of QSym:

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: R.duality_pairing_matrix(M, 3)
[ 1 -1 -1  1]
[ 0  1  0 -1]
[ 0  0  1 -1]
[ 0  0  0  1]
sage: M.duality_pairing_matrix(R, 3)
[ 1  0  0  0]
[-1  1  0  0]
[-1  0  1  0]
[ 1 -1 -1  1]
```
The matrix between the complete basis of NCSF and the fundamental basis of QSym:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.duality_pairing_matrix(F, 3)
[1 1 1 1]
[0 1 0 1]
[0 0 1 1]
[0 0 0 1]
```

A base case test:

```
sage: R.duality_pairing_matrix(M, 0)
[1]
```

```
one_basis()
```

Return the empty composition.

OUTPUT:
- The empty composition.

EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.
˓Elementary_with_category'>
sage: parent(L).one_basis()
[]
```
>>> from sage.all import *

>>> L = NonCommutativeSymmetricFunctions(QQ).L()

>>> parent(L)
<class 'sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions.
˓Elementary_with_category'>

>>> parent(L).one_basis()
[

skew (x, y, side='left')

Return a function x in self skewed by a function y in the Hopf dual of self.

INPUT:

• x – a non-commutative or quasi-symmetric function; it is an element of self
• y – a quasi-symmetric or non-commutative symmetric function; it is an element of the dual algebra of self
• side – (default: 'left') either 'left' or 'right'

OUTPUT:

• The result of skewing the element x by the Hopf algebra element y (either from the left or from the right, as determined by side), written in the basis self.

EXAMPLES:

sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: S.skew(S[2,2,2], F[1,1])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1]
sage: S.skew(S[2,2,2], F[2])
S[1, 1, 2] + S[1, 2, 1] + S[2, 1, 1] + 3*S[2, 2]

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()

sage: R.skew(R[2,2,2], F[1,1])
˓→R[4]

sage: R.skew(R[2,2,2], F[2])
˓→R[4]

sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()

sage: R.skew(R[2,2,2], F[1,1])
˓→R[4]

sage: R.skew(R[2,2,2], F[2])
˓→R[4]
```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.skew(M[3,2], S[2])
0
sage: M.skew(M[3,2], S[2], side='right')
M[3]
sage: M.skew(M[3,2], S[3])
M[2]
sage: M.skew(M[3,2], S[3], side='right')
0
```

```python
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> M = QuasiSymmetricFunctions(QQ).M()
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(2)])
0
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(2)], side='right')
M[3]
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(3)])
M[2]
>>> M.skew(M[Integer(3),Integer(2)], S[Integer(3)], side='right')
0
```

**sum_of_fatter_compositions** (*composition*)

Return the sum of all fatter compositions.

**INPUT:**
- *composition* – a composition

**OUTPUT:**
- The sum of all basis elements which are indexed by compositions fatter (coarser?) than *composition*.

**EXAMPLES:**

```python
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_fatter_compositions(Composition([2,1]))
L[2, 1] + L[3]
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_fatter_compositions(Composition([1,3]))
R[1, 3] + R[4]
```

```python
>>> from sage.all import *
>>> L = NonCommutativeSymmetricFunctions(QQ).L()
>>> L.sum_of_fatter_compositions(Composition([Integer(2),Integer(1)]))
L[2, 1] + L[3]
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> R.sum_of_fatter_compositions(Composition([Integer(1),Integer(3)]))
R[1, 3] + R[4]
```

**sum_of_finer_compositions** (*composition*)

Return the sum of all finer compositions.

**INPUT:**
- *composition* – a composition

**OUTPUT:**
- The sum of all basis elements which are indexed by compositions finer than *composition*.  

5.1. Comprehensive Module List 2275
EXAMPLES:

```
sage: L = NonCommutativeSymmetricFunctions(QQ).L()
sage: L.sum_of_finer_compositions(Composition([2,1]))
L[1, 1, 1] + L[2, 1]
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.sum_of_finer_compositions(Composition([1,3]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

```
>>> from sage.all import *

>>> L = NonCommutativeSymmetricFunctions(QQ).L()
>>> L.sum_of_finer_compositions(Composition([Integer(2),Integer(1)]))
L[1, 1, 1] + L[2, 1]
```

```
>>> R = NonCommutativeSymmetricFunctions(QQ).R()
>>> R.sum_of_finer_compositions(Composition([Integer(1),Integer(3)]))
R[1, 1, 1, 1] + R[1, 1, 2] + R[1, 2, 1] + R[1, 3]
```

\[\text{sum_of_partition_rearrangements}(\text{par})\]

Return the sum of all basis elements indexed by compositions which can be sorted to obtain a given partition.

**INPUT:**
- \text{par} – a partition

**OUTPUT:**
- The sum of all self basis elements indexed by compositions which are permutations of \text{par} (without multiplicity).

**EXAMPLES:**

```
sage: NCSF=NonCommutativeSymmetricFunctions(QQ)
sage: elementary = NCSF.elementary()
sage: elementary.sum_of_partition_rearrangements(Partition([2,2,1]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
sage: elementary.sum_of_partition_rearrangements(Partition([3,2,1]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2, 1]
```

```
>>> from sage.all import *

>>> NCSF=NonCommutativeSymmetricFunctions(QQ)

>>> elementary = NCSF.elementary()

>>> elementary.sum_of_partition_rearrangements(Partition([Integer(2),Integer(1)]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
```

```
>>> elementary.sum_of_partition_rearrangements(Partition([Integer(3),Integer(2),Integer(1)]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2, 1]
```

```
>>> elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

```
>>> from sage.all import *

>>> NCSF=NonCommutativeSymmetricFunctions(QQ)

>>> elementary = NCSF.elementary()

>>> elementary.sum_of_partition_rearrangements(Partition([Integer(2),Integer(2),Integer(1)]))
L[1, 2, 2] + L[2, 1, 2] + L[2, 2, 1]
```

```
>>> elementary.sum_of_partition_rearrangements(Partition([Integer(3),Integer(2),Integer(1)]))
L[1, 2, 3] + L[1, 3, 2] + L[2, 1, 3] + L[2, 3, 1] + L[3, 1, 2] + L[3, 2, 1]
```

```
>>> elementary.sum_of_partition_rearrangements(Partition([]))
L[]
```

\[\text{super_categories}()\]

\texttt{class sage.combinat.ncsf_qsym.generic_basis_code.GradedModulesWithInternalProduct(base, name=\text{None})}\n
\texttt{Bases: Category\_over\_base\_ring}\n
Constructs the class of modules with internal product. This is used to give an internal product structure to the non-commutative symmetric functions.

EXAMPLES:

```
sage: from sage.combinat.ncsf_qsym.generic_basis_code import
        GradedModulesWithInternalProduct
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: R in GradedModulesWithInternalProduct(QQ)
True
```

```python
>>> from sage.all import *
>>> from sage.combinat.ncsf_qsym.generic_basis_code import
        GradedModulesWithInternalProduct
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> R in GradedModulesWithInternalProduct(QQ)
True
```

class ElementMethods

Bases: object

`internal_product`(other)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions $f$ and $g$ and any quasi-symmetric function $h$ satisfy

$$\langle f \ast g, h \rangle = \sum_i \langle f, h_i' \rangle \langle g, h_i'' \rangle,$$

where we write $\Delta^\times(h_i)$ as $\sum_i h_i' \otimes h_i''$. Here, $f \ast g$ denotes the internal product of the non-commutative symmetric functions $f$ and $g$.

If $f$ and $g$ are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f \ast g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If $I$ and $J$ are two compositions of lengths $p$ and $q$, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions $S^I$ and $S^J$ have internal product

$$S^I \ast S^J = \sum S^{\text{comp} M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbb{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is $I$ (that is, the sum of the entries of the $r$-th row is the $r$-th part of $I$ for all $r$) and whose column sum vector is $J$ (that is, the sum of all entries of the $s$-th row is the $s$-th part of $J$ for all $s$). Here, for any $M \in \mathbb{N}^{p \times q}$, we denote by $\text{comp} M$ the composition obtained by reading the entries of the matrix $M$ in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let $I$ and $J$ be two compositions of lengths $p$ and $q$, respectively, having the same size $|I| = |J|$. We denote by $\Psi^K$ the element of the Psi basis corresponding to any composition $K$.

- If $p > q$, then $\Psi^I \ast \Psi^J$ is plainly 0.

5.1. Comprehensive Module List
• Assume that \( p = q \). Let \( \tilde{\delta}_{I,J} \) denote the integer 1 if the compositions \( I \) and \( J \) are permutations of each other, and the integer 0 otherwise. For every positive integer \( i \), let \( m_i \) denote the number of parts of \( I \) equal to \( i \). Then, \( \Psi^I \ast \Psi^J \) equals \( \tilde{\delta}_{I,J} \prod_{i>0} i^{m_i} \Psi^I \).

• Now assume that \( p < q \). Write the composition \( I \) as \( I = (i_1, i_2, \ldots, i_p) \). For every nonempty composition \( K = (k_1, k_2, \ldots, k_s) \), denote by \( \Gamma_K \) the non-commutative symmetric function \( k_1 \cdots \left[ \Psi_{k_1}, \Psi_{k_2} \right] \cdots \left[ \Psi_{k_s} \right] \). For any subset \( A \) of \( \{1, 2, \ldots, q\} \), let \( J_A \) be the composition obtained from \( J \) by removing the \( r \)-th parts for all \( r \notin A \) (while keeping the \( r \)-th parts for all \( r \in A \) in order). Then, \( \Psi^I \ast \Psi^J \) equals the sum of \( \Gamma_{J_A} \Gamma_{K_{k_1}} \cdots \Gamma_{K_{k_s}} \) over all ordered set partitions \( (K_1, K_2, \ldots, K_p) \) of \( \{1, 2, \ldots, q\} \) into \( p \) parts such that each \( 1 \leq k \leq p \) satisfies \( |J_{K_k}| = i_k \). (See \texttt{OrderedSetPartition()} for the meaning of “ordered set partition”.)

Aliases for \texttt{internal_product()} are \texttt{itensor()} and \texttt{kronecker_product()}

**INPUT:**
- \texttt{other} – another non-commutative symmetric function

**OUTPUT:**
- The result of taking the internal product of \texttt{self} with \texttt{other}.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```python
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()
sage: def tensor_incorp(f, g, h):
    # computes \sum_i \left< f, h_i \right> \left< g, h_i \right>
    result = h.base_ring().zero()
    h_parent = h.parent()
    for partition_pair, coeff in h.internal_coproduct().monomial_coefficients().items():
        result += coeff * f.duality_pairing(h_parent[partition_pair[0]]) * g.duality_pairing(h_parent[partition_pair[1]])
    return result
sage: def testall(n):
    ....:     return all( all( tensor_incorp(S[u], S[v], M[w]) == (S[u].itensor(S[v])).duality_pairing(M[w])
```

(continues on next page)
The internal product on the algebra of non-commutative symmetric functions commutes with the canonical commutative projection on the symmetric functions:

```python
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()

sage: e = SymmetricFunctions(ZZ).e()

sage: def int_pr_of_S_in_e(I, J):
...:    return (S[I].internal_product(S[J])).to_symmetric_function()

sage: all( all( int_pr_of_S_in_e(J, I) == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_function())
...:     for I in Compositions(3) )
...:     for J in Compositions(3) )
True
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
... == S[I].to_symmetric_function().internal_product(S[J].to_symmetric_function())
... for I in Compositions(Integer(3)) )
... for J in Compositions(Integer(3)) )
True
```

**itensor**(other)

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasi-symmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions $f$ and $g$ and any quasi-symmetric function $h$ satisfy

$$
\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle,
$$

where we write $\Delta^\times(h)$ as $\sum_i h'_i \otimes h''_i$. Here, $f \ast g$ denotes the internal product of the non-commutative symmetric functions $f$ and $g$.

If $f$ and $g$ are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f \ast g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If $I$ and $J$ are two compositions of lengths $p$ and $q$, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions $S^I$ and $S^J$ have internal product

$$
S^I \ast S^J = \sum S^{\text{comp} M},
$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbb{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is $I$ (that is, the sum of the entries of the $r$-th row is the $r$-th part of $I$ for all $r$) and whose column sum vector is $J$ (that is, the sum of all entries of the $s$-th row is the $s$-th part of $J$ for all $s$). Here, for any $M \in \mathbb{N}^{p \times q}$, we denote by $\text{comp} M$ the composition obtained by reading the entries of the matrix $M$ in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let $I$ and $J$ be two compositions of lengths $p$ and $q$, respectively, having the same size $|I| = |J|$. We denote by $\Psi^K$ the element of the Psi basis corresponding to any composition $K$.

- If $p > q$, then $\Psi^I \ast \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\delta_{I,J}$ denote the integer 1 if the compositions $I$ and $J$ are permutations of each other, and the integer 0 otherwise. For every positive integer $i$, let $m_i$ denote the number of parts of $I$ equal to $i$. Then, $\Psi^I \ast \Psi^J$ equals $\delta_{I,J} \prod_{i = 0}^m m_i! \Psi^I$.
- Now assume that $p < q$. Write the composition $I$ as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_p)$, denote by $\Gamma_K$ the non-commutative symmetric function $k_1 \cdots \left(\Psi_{k_1}, \Psi_{k_2}, \ldots, \Psi_{k_p}\right)$. For any subset $A$ of $\{1, 2, \ldots, q\}$, let $J_A$ be the composition obtained from $J$ by removing the $r$-th parts for all $r \not\in A$ (while keeping the $r$-th parts for all $r \in A$ in order). Then, $\Psi^I \ast \Psi^J$ equals the sum of $\Gamma_{J_{K_1}} \Gamma_{J_{K_2}} \cdots \Gamma_{J_{K_p}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into $p$ parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See `OrderedSetPartition()` for the meaning of “ordered set partition”).

Aliases for `internal_product()` are `itensor()` and `kronecker_product()`.

**INPUT:**

- other – another non-commutative symmetric function

**OUTPUT:**
• The result of taking the internal product of \texttt{self} with \texttt{other}.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: x = S.an_element(); x
2*S[] + 2*S[1] + 3*S[1, 1]
sage: x.internal_product(S[2])
3*S[1, 1]
sage: x.internal_product(S[1])
2*S[1]
sage: S[1,2].internal_product(S[1,2])
S[1, 1, 1] + S[1, 2]
```

Let us check the duality between the inner product and the inner coproduct in degree 4:

```python
sage: M = QuasiSymmetricFunctions(FiniteField(29)).M()
sage: S = NonCommutativeSymmetricFunctions(FiniteField(29)).S()

Return the internal product of two non-commutative symmetric functions.

The internal product on the algebra of non-commutative symmetric functions is adjoint to the internal coproduct on the algebra of quasisymmetric functions with respect to the duality pairing between these two algebras. This means, explicitly, that any two non-commutative symmetric functions $f$ and $g$ and any quasi-symmetric function $h$ satisfy

$$\langle f \ast g, h \rangle = \sum_i \langle f, h'_i \rangle \langle g, h''_i \rangle,$$
where we write $\Delta^\times(h)$ as $\sum h'_i \otimes h''_i$. Here, $f \ast g$ denotes the internal product of the non-commutative symmetric functions $f$ and $g$.

If $f$ and $g$ are two homogeneous elements of $NSym$ having distinct degrees, then the internal product $f \ast g$ is zero.

Explicit formulas can be given for internal products of elements of the complete and the Psi bases. First, the formula for the Complete basis ([NCSF1] Proposition 5.1): If $I$ and $J$ are two compositions of lengths $p$ and $q$, respectively, then the corresponding Complete homogeneous non-commutative symmetric functions $S^I$ and $S^J$ have internal product

$$S^I \ast S^J = \sum S^{\text{comp } M},$$

where the sum ranges over all $p \times q$-matrices $M \in \mathbb{N}^{p \times q}$ (with nonnegative integers as entries) whose row sum vector is $I$ (that is, the sum of the entries of the $r$-th row is the $r$-th part of $I$ for all $r$) and whose column sum vector is $J$ (that is, the sum of all entries of the $s$-th row is the $s$-th part of $J$ for all $s$). Here, for any $M \in \mathbb{N}^{p \times q}$, we denote by comp $M$ the composition obtained by reading the entries of the matrix $M$ in the usual order (row by row, proceeding left to right in each row, traversing the rows from top to bottom).

The formula on the Psi basis ([NCSF2] Lemma 3.10) is more complicated. Let $I$ and $J$ be two compositions of lengths $p$ and $q$, respectively, having the same size $|I| = |J|$. We denote by $\Psi^K$ the element of the Psi basis corresponding to any composition $K$.

- If $p > q$, then $\Psi^I \ast \Psi^J$ is plainly 0.
- Assume that $p = q$. Let $\delta_{I,J}$ denote the integer 1 if the compositions $I$ and $J$ are permutations of each other, and the integer 0 otherwise. For every positive integer $i$, let $m_i$ denote the number of parts of $I$ equal to $i$. Then, $\Psi^I \ast \Psi^J$ equals $\delta_{I,J} \prod_{i \geq 1} \lambda_i m_i ! \Psi^I$.
- Now assume that $p < q$. Write the composition $I$ as $I = (i_1, i_2, \ldots, i_p)$. For every nonempty composition $K = (k_1, k_2, \ldots, k_s)$, denote by $\Gamma_k$ the non-commutative symmetric function $\prod_k [\Psi_{k_1}, \Psi_{k_2}, \ldots, \Psi_{k_s}]$. For any subset $A$ of $\{1, 2, \ldots, q\}$, let $J_A$ be the composition obtained from $J$ by removing the $r$-th parts for all $r \notin A$ (while keeping the $r$-th parts for all $r \in A$ in order). Then, $\Psi^I \ast \Psi^J$ equals the sum of $\Gamma_{K_{k_1}} \Gamma_{K_{k_2}} \cdots \Gamma_{K_{k_s}}$ over all ordered set partitions $(K_1, K_2, \ldots, K_p)$ of $\{1, 2, \ldots, q\}$ into $p$ parts such that each $1 \leq k \leq p$ satisfies $|J_{K_k}| = i_k$. (See OrderedSetPartition() for the meaning of “ordered set partition”.)

Aliases for internal_product() are itensor() and kronecker_product().

internal_product_on_basis(I, J)
The internal product of the two basis elements indexed by I and J (optional)

INPUT:
  • I, J – compositions indexing two elements of the basis of self

Returns the internal product of the corresponding basis elements. If this method is implemented, the
internal product is defined from it by linearity.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2], [1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2], [2,1])
0
**itensor()**

The bilinear product inherited from the isomorphism with the descent algebra.

This is constructed by extending the method `internal_product_on_basis()` bilinearly, if available, or using the method `internal_product_by_coercion()`.

**OUTPUT:**

- The internal product map of the algebra the non-commutative symmetric functions.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
Generic endomorphism of Non-Commutative Symmetric Functions over the Rational Field in the Complete basis

sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
```

```python
>>> from sage.all import *
```
The internal product map of the algebra the non-commutative symmetric functions.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product
Generic endomorphism of Non-Commutative Symmetric Functions over the
→Rational Field in the Complete basis
sage: S.internal_product(S[2,2], S[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product(S[2,2], S[1,2])
0
```
INPUT:
• left – an element of the non-commutative symmetric functions
• right – an element of the non-commutative symmetric functions

OUTPUT:
• The internal product of left and right.

EXAMPLES:

```
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.internal_product_by_coercion(S[2,1], S[3])
S[2, 1]
sage: S.internal_product_by_coercion(S[2,1], S[4])
0
```

```
>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S/internal_product_by_coercion(S[Integer(2),Integer(1)],
˓→S[Integer(3)])
S[2, 1]
>>> S.internal_product_by_coercion(S[Integer(2),Integer(1)],
˓→S[Integer(4)])
0
```

```

5.1.144 Non-Commutative Symmetric Functions

```
class sage.combinat.ncsf_qsym.ncsf.NonCommutativeSymmetricFunctions(R)
    Bases: UniqueRepresentation, Parent

The abstract algebra of non-commutative symmetric functions.

We construct the abstract algebra of non-commutative symmetric functions over the rational numbers:
```
```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
sage: S = NCSF.complete()
sage: R = NCSF.ribbon()
sage: S[2,1]*R[1,2]
S[2, 1, 2] - S[2, 1, 3]
```
NCSF is the unique free (non-commutative!) graded connected algebra with one generator in each degree:

```python
sage: NCSF.category()
Join of Category of Hopf algebras over Rational Field
    and Category of graded algebras over Rational Field
    and Category of monoids with realizations
    and Category of graded coalgebras over Rational Field
    and Category of coalgebras over Rational Field with realizations
    and Category of cocommutative coalgebras over Rational Field
sage: [S[i].degree() for i in range(10)]
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
```

We use the Sage standard renaming idiom to get shorter outputs:

```python
sage: NCSF.rename("NCSF")
sage: NCSF
NCSF
```

NCSF has many representations as a concrete algebra. Each of them has a distinguished basis, and its elements are expanded in this basis. Here is the $\Psi$ ($\Psi$) representation:

```python
sage: Psi = NCSF.Psi()
sage: Psi
NCSF in the Psi basis
```

```python
sage: from sage.all import *
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
sage: S = NCSF.complete()
sage: R = NCSF.ribbon()
sage: S[Integer(2),Integer(1)]*R[Integer(1),Integer(2)]
S[2, 1, 1, 2] - S[2, 1, 3]
```
Elements of $\Psi$ are linear combinations of basis elements indexed by compositions:

```
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

The basis itself is accessible through:

```
sage: Psi.basis()
Lazy family (Term map from Compositions of non-negative integers...
```

To construct an element one can therefore do:

```
sage: Psi.basis()[Composition([2, 1, 3])]
Psi[2, 1, 3]
```

As this is rather cumbersome, the following abuses of notation are allowed:

```
sage: Psi[Composition([2, 1, 3])]
Psi[2, 1, 3]
sage: Psi[[2, 1, 3]]
Psi[2, 1, 3]
sage: Psi[2, 1, 3]
Psi[2, 1, 3]
```

or even:

```
sage: Psi[{i for i in [2, 1, 3]}]
Psi[2, 1, 3]
```
Unfortunately, due to a limitation in Python syntax, one cannot use:

```python
sage: Psi[]  # not implemented

>>> from sage.all import *
>>> Psi[]  # not implemented
```

Instead, you can use:

```python
sage: Psi[[ ] ]
Psi[]

>>> from sage.all import *
>>> Psi[[ ] ]
Psi[]
```

Now, we can construct linear combinations of basis elements:

```python

>>> from sage.all import *
>>> Psi[Integer(2),Integer(1),Integer(3)] + Integer(2) * (Psi[Integer(4)] +
˓→Psi[Integer(2),Integer(1)])
```

**Algebra structure**

To start with, \( \Psi \) is a graded algebra, the grading being induced by the size of compositions. The one is the basis element indexed by the empty composition:

```python
sage: Psi.one()
Psi[]
sage: S.one()
S[]
sage: R.one()
R[]

>>> from sage.all import *
>>> Psi.one()
Psi[]
>>> S.one()
S[]
>>> R.one()
R[]
```

As we have seen above, the \( \Psi \) basis is multiplicative; that is multiplication is induced by linearity from the concatenation of compositions:

```python
sage: Psi[1,3] * Psi[2,1]
Psi[1, 3, 2, 1]
sage: (Psi.one() + 2 * Psi[1,3]) * Psi[2, 4]
2*Psi[1, 3, 2, 4] + Psi[2, 4]
```
>>> from sage.all import *
>>> Psi[Integer(1),Integer(3)] * Psi[Integer(2),Integer(1)]
Psi[1, 3, 2, 1]
>>> (Psi.one() + Integer(2) * Psi[Integer(1),Integer(3)]) * Psi[Integer(2),␣
˓→Integer(4)]
2*Psi[1, 3, 2, 4] + Psi[2, 4]

Hopf algebra structure

Psi is further endowed with a coalgebra structure. The coproduct is an algebra morphism, and therefore determined by its values on the generators; those are primitive:

```python
sage: Psi[1].coproduct()
Psi[] # Psi[1] + Psi[1] # Psi[]
sage: Psi[2].coproduct()
```

The coproduct, being cocommutative on the generators, is cocommutative everywhere:

```python
sage: Psi[1,2].coproduct()
```

The algebra and coalgebra structures on Psi combine to form a bialgebra structure, which cooperates with the grading to form a connected graded bialgebra. Thus, as any connected graded bialgebra, Psi is a Hopf algebra. Over \(\mathbb{Q}\) (or any other \(\mathbb{Q}\)-algebra), this Hopf algebra \(\Psi\) is isomorphic to the tensor algebra of its space of primitive elements.

The antipode is an anti-algebra morphism; in the \(\Psi\) basis, it sends the generators to their opposites and changes their sign if they are of odd degree:

```python
sage: Psi[3].antipode()
-Psi[3]
sage: Psi[1,3,2].antipode()
-Psi[2, 3, 1]
sage: Psi[1,3,2].coproduct().apply_multilinear_morphism(lambda be,ga:
˓→Psi(be)*Psi(ga).antipode())
0
```

```python
>>> from sage.all import *
>>> Psi[Integer(3)].antipode()
-Psi[3]
>>> Psi[Integer(1),Integer(3),Integer(2)].antipode()
-Psi[2, 3, 1]
>>> Psi[Integer(1),Integer(3),Integer(2)].coproduct().apply_multilinear_␣
˓→(continues on next page)"
→ morphism(...lambda be,ga: Psi(be)*Psi(ga).antipode())

The counit is defined by sending all elements of positive degree to zero:

```
sage: S[3].degree(), S[3,1,2].degree(), S.one().degree()
(3, 6, 0)
sage: S[3].counit()
0
sage: S[3,1,2].counit()
0
sage: S.one().counit()
1
7
7
```
Concrete representations

NCSF admits the concrete realizations defined in [NCSF1]:

```python
sage: Phi = NCSF.Phi()
sage: Psi = NCSF.Psi()
sage: ribbon = NCSF.ribbon()
sage: complete = NCSF.complete()
sage: elementary = NCSF.elementary()
```

To change from one basis to another, one simply does:

```python
>>> from sage.all import *

>>> Phi = NCSF.Phi()

>>> Psi = NCSF.Psi()

>>> ribbon = NCSF.ribbon()

>>> complete = NCSF.complete()

>>> elementary = NCSF.elementary()
```

In general, one can mix up different bases in computations:

```python
sage: Phi(Psi[1])
Phi[1]

sage: Phi(Psi[3])
-1/4*Phi[1, 2] + 1/4*Phi[2, 1] + Phi[3]
```

Some of the changes of basis are easy to guess:

```python
sage: ribbon(complete[1,3,2])
```

This is the sum of all fatter compositions. Using the usual Möbius function for the boolean lattice, the inverse change of basis is given by the alternating sum of all fatter compositions:

```python
sage: complete(ribbon[1,3,2])
```
The analogue of the elementary basis is the sum over all finer compositions than the ‘complement’ of the composition in the ribbon basis:

```
sage: Composition([1,3,2]).complement()  
[2, 1, 2, 1]

sage: ribbon(elementary([1,3,2]))  
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1] + R[2, 1, 2, 1]
```

By Möbius inversion on the composition poset, the ribbon basis element corresponding to a composition $I$ is then the alternating sum over all compositions fatter than the complement composition of $I$ in the elementary basis:

```
sage: elementary(ribbon[2,1,2,1])  
```

By Möbius inversion on the composition poset, the ribbon basis element corresponding to a composition $I$ is then the alternating sum over all compositions fatter than the complement composition of $I$ in the elementary basis:

```
sage: Composition([Integer(1),Integer(3),Integer(2)]).complement()  
[2, 1, 2, 1]

sage: ribbon(elementary([Integer(1),Integer(3),Integer(2)]))  
R[1, 1, 1, 1, 1, 1] + R[1, 1, 1, 2, 1] + R[2, 1, 1, 1, 1] + R[2, 1, 2, 1]
```

The $\Phi$ (Phi) and $\Psi$ bases are computed by changing to and from the Complete basis. The expansion of $\Psi$ basis is given in Proposition 4.5 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{\pi_u(J,I)} \Psi^J$$

and

$$\Psi^I = \sum_{J \geq I} (-1)^{\ell(J)-\ell(I)} lp(J,I) S^J$$

where the coefficients $\pi_u(J,I)$ and $lp(J,I)$ are coefficients in the methods `coeff_pi()` and `coeff_lp()` respectively. For example:

```
sage: Psi(complete[Integer(3)])  
1/6*Psi[1, 1, 1] + 1/3*Psi[1, 2] + 1/6*Psi[2, 1] + 1/3*Psi[3]

sage: complete(Psi[3])  
```

The $\Phi$ basis is another analogue of the power sum basis from the algebra of symmetric functions and the expansion in the Complete basis is given in Proposition 4.9 of [NCSF1] by the formulae

$$S^I = \sum_{J \geq I} \frac{1}{sp(J,I)} \Phi^J$$
and

\[ \Phi^I = \sum_{J \geq I} (-1)^{\ell(J) - \ell(I)} \prod_{i \in I} l(J, I) S^J \]

where the coefficients \( sp(J, I) \) and \( l(J, I) \) are coefficients in the methods \texttt{coeff_sp()} and \texttt{coeff_ell()} respectively. For example:

```sage
>>> from sage.all import *
>>> Phi(complete[3])
1/6*Phi[1, 1, 1] + 1/4*Phi[1, 2] + 1/4*Phi[2, 1] + 1/3*Phi[3]
>>> complete(Phi[3])
```

Here is how to fetch the conversion morphisms:

```sage
sage: f = complete.coerce_map_from(elementary); f
Generic morphism:
    From: NCSF in the Elementary basis
    To:   NCSF in the Complete basis
sage: g = elementary.coerce_map_from(complete); g
Generic morphism:
    From: NCSF in the Complete basis
    To:   NCSF in the Elementary basis
sage: f.category()
Category of homsets of unital magmas and right modules over Rational Field and
    left modules over Rational Field
sage: f(elementary[1,2,2])
S[1, 1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
sage: g(complete[1,2,2])
L[1, 1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
sage: h = f*g; h
Composite map:
    From: NCSF in the Complete basis
    To:   NCSF in the Complete basis
    Defn:  Generic morphism:
        From: NCSF in the Complete basis
        To:   NCSF in the Elementary basis
        then
        Generic morphism:
            From: NCSF in the Elementary basis
            To:   NCSF in the Complete basis
sage: h(complete[1,3,2])
S[1, 3, 2]
```

(continues on next page)
From: NCSF in the Complete basis
To: NCSF in the Elementary basis

```python
>>> f.category()
Category of homsets of unital magmas and right modules over Rational Field and
left modules over Rational Field
>>> f(elementary[Integer(1),Integer(2),Integer(2)])
S[1, 1, 1, 1] - S[1, 1, 1, 2] - S[1, 2, 1, 1] + S[1, 2, 2]
```

```python
>>> g(complete[Integer(1),Integer(2),Integer(2)])
L[1, 1, 1, 1] - L[1, 1, 1, 2] - L[1, 2, 1, 1] + L[1, 2, 2]
```

```python
h = f*g; h
Composite map:
From: NCSF in the Complete basis
To: NCSF in the Complete basis
Defn: Generic morphism:
  From: NCSF in the Complete basis
  To: NCSF in the Elementary basis
  then
  Generic morphism:
  From: NCSF in the Elementary basis
  To: NCSF in the Complete basis

>>> h(complete[Integer(1),Integer(3),Integer(2)])
S[1, 3, 2]
```

### Additional concrete representations

NCSF has some additional bases which appear in the literature:

```python
sage: Monomial = NCSF.Monomial()
sage: Immaculate = NCSF.Immaculate()
sage: dualQuasisymmetric_Schur = NCSF.dualQuasisymmetric_Schur()

>>> from sage.all import *

```

The `Monomial` basis was introduced in [Tev2007] and the `Immaculate` basis was introduced in [BBSSZ2012]. The `Quasisymmetric_Schur` were defined in [QSCHUR] and the dual basis is implemented here as `dualQuasisymmetric_Schur`. Refer to the documentation for the use and definition of these bases.

### Todo:

- implement fundamental, forgotten, and simple (coming from the simple modules of HS_n) bases.

We revert back to the original name from our custom short name NCSF:

```python
sage: NCSF
NCSF
sage: NCSF.rename()
sage: NCSF
Non-Commutative Symmetric Functions over the Rational Field
```
class Bases (parent_with_realization)

Bases: Category_realization_of_parent

Category of bases of non-commutative symmetric functions.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.Bases()
Category of bases of Non-Commutative Symmetric Functions over the Rational Field
sage: R = N.Ribbon()
sage: R in N.Bases()
True

class ElementMethods

Bases: object

bernstein_creation_operator(n)

Return the image of self under the n-th Bernstein creation operator.

Let n be an integer. The n-th Bernstein creation operator $\mathbb{B}_n$ is defined as the endomorphism of the space $NSym$ of noncommutative symmetric functions which sends every $f$ to

$$\sum_{i \geq 0} (-1)^i H_{n+i}^i F_{i1}^i,$$

where usual notations are in place (the letter $H$ stands for the complete basis of $NSym$, the letter $F$ stands for the fundamental basis of the algebra $QSym$ of quasisymmetric functions, and $F_{i1}^i$ means skewing ($\text{skew_by()}$) by $F_{i1}$). Notice that $F_{i1}$ is nothing other than the elementary symmetric function $e_i$.

This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions (bernstein_creation_operator()), and studied further in [BBSSZ2012], mainly in the context of immaculate functions (Immaculate). In fact, if $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ is an $m$-tuple of integers, then

$$\mathbb{B}_n I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)} = I_{(n, \alpha_1, \alpha_2, \ldots, \alpha_m)},$$

where $I_{(\alpha_1, \alpha_2, \ldots, \alpha_m)}$ is the immaculate function associated to the $m$-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_m)$ (see immaculate_function()).
EXAMPLES:

We get the immaculate functions by repeated application of Bernstein creation operators:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: I = NSym.I()
sage: S = NSym.S()
sage: def immaculate_by_bernstein(xs):
    # immaculate function corresponding to integer
    # tuple `xs`, computed by iterated application
    # of Bernstein creation operators.
    res = S.one()
    for i in reversed(xs):
        res = res.bernstein_creation_operator(i)
    return res
sage: import itertools
sage: all( immaculate_by_bernstein(p) == I.immaculate_function(p)
    for p in itertools.product(range(-1, 3), repeat=3))
True
```

Some examples:

```
sage: S[3,2].bernstein_creation_operator(-2)
S[2, 1]
sage: S[3,2].bernstein_creation_operator(-1)
S[1, 2, 1] - S[2, 2] - S[3, 1]
sage: S[3,2].bernstein_creation_operator(0)
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
sage: S[3,2].bernstein_creation_operator(1)
sage: S[3,2].bernstein_creation_operator(2)
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> I = NSym.I()
>>> S = NSym.S()
>>> def immaculate_by_bernstein(xs):
...     # immaculate function corresponding to integer
...     # tuple `xs`, computed by iterated application
...     # of Bernstein creation operators.
...     res = S.one()
...     for i in reversed(xs):
...         res = res.bernstein_creation_operator(i)
...     return res
>>> import itertools
>>> all( immaculate_by_bernstein(p) == I.immaculate_function(p)
...     for p in itertools.product(range(-Integer(1), Integer(3)), repeat=Integer(3)))
True
```

```python
>>> from sage.all import *
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(2))
S[2, 1]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(-Integer(1))
S[1, 2, 1] - S[2, 2] - S[3, 1]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(0)
-S[1, 2, 2] - S[1, 3, 1] + S[2, 2, 1] + S[3, 2]
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(1)
>>> S[Integer(3),Integer(2)].bernstein_creation_operator(2)
```

(continues on next page)
\[
\]

\[
\]

\[
\chi()
\]
Return the commutative image of a non-commutative symmetric function.

\section{OUTPUT:}
\begin{itemize}
  \item The commutative image of \texttt{self}. This will be a symmetric function.
\end{itemize}

\section{EXAMPLES:}
\begin{verbatim}
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
\end{verbatim}

\section{expand (n, alphabet='x')} Expand the noncommutative symmetric function into an element of a free algebra in \( n \) indeterminates of an alphabet, which by default is \( 'x' \).

\section{INPUT:}
\begin{itemize}
  \item \( n \) – a nonnegative integer; the number of variables in the expansion
  \item \( \text{alphabet} \) – (default: \( 'x' \)); the alphabet in which \texttt{self} is to be expanded
\end{itemize}

\section{OUTPUT:}
\begin{itemize}
  \item An expansion of \texttt{self} into the \( n \) variables specified by \texttt{alphabet}.
\end{itemize}

\section{EXAMPLES:}
\begin{verbatim}
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[3].expand(3)
x0^3 + x0^2*x1 + x0^2*x2 + x0*x1^2 + x0*x1*x2  
  + x0*x2^2 + x1^3 + x1^2*x2 + x1*x2^2 + x2^3
sage: L = NSym.L()
sage: L[3].expand(3)
x2*x1*x0
sage: L[2].expand(3)
x1*x0 + x2*x0 + x2*x1
sage: L[3].expand(4)
x2*x1*x0 + x3*x1*x0 + x3*x2*x0 + x3*x2*x1
\end{verbatim}
One can use a different set of variables by adding an optional argument `alphabet=...`:

```python
sage: L[3].expand(4, alphabet="y")
y2*y1*y0 + y3*y1*y0 + y3*y2*y0 + y3*y2*y1
```

```
Todo: So far this is only implemented on the elementary basis, and everything else goes through coercion. Maybe it is worth shortcutting some of the other bases?
```

```python
left_padded_kronecker_product(x)
```

Return the left-padded Kronecker product of `self` and `x` in the basis of `self`.

The left-padded Kronecker product is a bilinear map mapping two non-commutative symmetric functions to another, not necessarily preserving degree. It can be defined as follows: Let $\ast$ denote the internal product (`internal_product()`) on the space of non-commutative symmetric functions. For any composition $I$, let $S^I$ denote the complete homogeneous symmetric function indexed by $I$. For any compositions $\alpha$, $\beta$, $\gamma$, let $g_{\alpha,\beta}^\gamma$ denote the coefficient of $S^\gamma$ in the internal product $S^\alpha \ast S^\beta$. For every composition $I = (i_1, i_2, \ldots, i_k)$ and every integer $n > |I|$, define the ‘$n$-completion of $I$’ to be the composition $(n - |I|, i_1, i_2, \ldots, i_k)$; this $n$-completion is denoted by $I[n]$. Then, for any compositions $\alpha$ and $\beta$ and every integer $n > |\alpha| + |\beta|$, we can write the internal
product \( S^\alpha[n] \ast S^\beta[n] \) in the form

\[
S^\alpha[n] \ast S^\beta[n] = \sum_\gamma g_{\alpha[n],\beta[n]}^{\gamma[n]} S^\gamma[n]
\]

with \( \gamma \) ranging over all compositions. The coefficients \( g_{\alpha[n],\beta[n]}^{\gamma[n]} \) are independent on \( n \). These coefficients \( g_{\alpha[n],\beta[n]}^{\gamma[n]} \) are denoted by \( \bar{g}_{\alpha,\beta}^{\gamma} \), and the non-commutative symmetric function

\[
\sum_\gamma \bar{g}_{\alpha,\beta}^{\gamma}[n] S^\gamma
\]

is said to be the left-padded Kronecker product of \( S^\alpha \) and \( S^\beta \). By bilinearity, this extends to a definition of a left-padded Kronecker product of any two non-commutative symmetric functions.

The left-padded Kronecker product on the non-commutative symmetric functions lifts the left-padded Kronecker product on the symmetric functions. More precisely: Let \( \pi \) denote the canonical projection (\texttt{to_symmetric_function()}\) from the non-commutative symmetric functions to the symmetric functions. Then, any two non-commutative symmetric functions \( f \) and \( g \) satisfy

\[
\pi(f \ast g) = \pi(f) \pi(g),
\]

where the \( \pi \) on the left-hand side denotes the left-padded Kronecker product on the non-commutative symmetric functions, and the \( \pi \) on the right-hand side denotes the left-padded Kronecker product on the symmetric functions.

**INPUT:**
- \( x \) – element of the ring of non-commutative symmetric functions over the same base ring as \texttt{self}

**OUTPUT:**
- the left-padded Kronecker product of \texttt{self} with \( x \) (an element of the ring of non-commutative symmetric functions in the same basis as \texttt{self})

**AUTHORS:**
- Darij Grinberg (15 Mar 2014)

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: S[2,1].left_padded_kronecker_product(S[3])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1] + S[2, 1, 1] + S[2, 2, 1] + ...
\rightarrow S[3, 2, 1]
sage: S[2,1].left_padded_kronecker_product(S[1])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1]
sage: S[1,1].left_padded_kronecker_product(S[2])
S[1, 1] + 2*S[1, 1, 1] + S[2, 1, 1]
sage: S[1,1].left_padded_kronecker_product(S[2,1])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1, 1]
sage: S[1].left_padded_kronecker_product(S[3])
S[1, 2] + S[2, 1, 1] + S[3, 2]
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> S = NSym.S()
>>> S[Integer(2),Integer(1)].left_padded_kronecker_product(S[Integer(3)])
S[1, 1, 1] + S[1, 2, 1] + S[2, 1] + S[2, 1, 1] + S[2, 2, 1] + ...
```
(continues on next page)
Taking the left-padded Kronecker product with $1 = S$ is the identity map on the ring of non-commutative symmetric functions:

```python
sage: all( S[Composition([i])].left_padded_kronecker_product(S[lam])
        == S[lam].left_padded_kronecker_product(S[Composition([i])])
        == S[lam]
        for i in range(4) for lam in Compositions(i) )
True
```

Here is a rule for the left-padded Kronecker product of $S_1$ (this is the same as $S^{(1)}$) with any complete homogeneous function: Let $I$ be a composition. Then, the left-padded Kronecker product of $S_1$ and $S^I$ is $\sum_K a_K S^K$, where the sum runs over all compositions $K$, and the coefficient $a_K$ is defined as the number of ways to obtain $K$ from $I$ by one of the following two operations:

- Insert a 1 at the end of $I$.
- Subtract 1 from one of the entries of $I$ (and remove the entry if it thus becomes 0), and insert a 1 at the end of $I$.

We check this for compositions of size $\leq 4$:

```python
sage: def mults1(I):
    ...
    res = S[I[:1]] + [1]
    ...
    for k in range(len(I)):
        ...
        I2 = I[:]
        ...
        if I2[k] == 1:
            ...
            I2 = I2[:k] + I2[k+1:]
        ...
        else:
            ...
            I2[k] -= 1
        ...
        res += S[I2 + [1]]
    ...
    return res
sage: all( mults1(I) == S[I].left_padded_kronecker_product(S[1])
        for i in range(5) for I in Compositions(i) )
True
```
A similar rule can be made for the left-padded Kronecker product of any complete homogeneous function with $S_1$: Let $I$ be a composition. Then, the left-padded Kronecker product of $S^I$ and $S_1$ is $\sum_K b_K S^K$, where the sum runs over all compositions $K$, and the coefficient $b_K$ is defined as the number of ways to obtain $K$ from $I$ by one of the following two operations:

- Insert a 1 at the front of $I$.
- Subtract 1 from one of the entries of $I$ (and remove the entry if it thus becomes 0), and insert a 1 right after this entry.

We check this for compositions of size $\leq 4$:

Checking the $\pi(f \cdot g) = \pi(f) \cdot \pi(g)$ equality:
omega_involution()

Return the image of the noncommutative symmetric function self under the omega involution.

The omega involution is defined as the algebra antimorphism \( NCSF \rightarrow NCSF \) which, for every positive integer \( n \), sends the \( n \)-th complete non-commutative symmetric function \( S_n \) to the \( n \)-th elementary non-commutative symmetric function \( \Lambda_n \). This omega involution is denoted by \( \omega \).

It can be shown that every composition \( I \) satisfies

\[
\omega(S^I) = \Lambda^{I^r}, \quad \omega(\Lambda^I) = S^{I^r}, \quad \omega(R_I) = R_{I^t}, \quad \omega(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^{I^r}, \quad \omega(\Psi^I) = (-1)^{|I| - \ell(I)} \Psi^{I^r},
\]

where \( I^r \) denotes the reversed composition of \( I \), and \( I^t \) denotes the conjugate composition of \( I \), and \( \ell(I) \) denotes the length of the composition \( I \), and standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( R \) for the ribbon basis, \( \Phi \) for that of the power-sums of the second kind, and \( \Psi \) for that of the power-sums of the first kind). More generally, if \( f \) is a homogeneous element of \( NCSF \) of degree \( n \), then

\[
\omega(f) = (-1)^n S(f),
\]

where \( S \) denotes the antipode of \( NCSF \).

The omega involution \( \omega \) is an involution and a coalgebra automorphism of \( NCSF \). It is an automorphism of the graded vector space \( NCSF \). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions (\( \text{to_symmetric_function()} \)), then \( \pi(\omega(f)) = \omega(\pi(f)) \) for every \( f \in NCSF \), where the \( \omega \) on the right hand side denotes the omega automorphism of \( Sym \).
The omega involution on $\text{NCSF}$ is adjoint to the omega involution on $\text{QSym}$ by the standard adjunction between $\text{NCSF}$ and $\text{QSym}$.

The omega involution has been denoted by $\omega$ in [LMvW13], section 3.6. See [NCSF1], section 3.1 for the properties of this map.

See also:

omega involution of $\text{QSym}$, psi involution of $\text{NCSF}$, star involution of $\text{NCSF}$.

EXAMPLED:

```sage
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)

L[3, 1]
>>> L((S[Integer(9),Integer(1)] - S[Integer(8),Integer(2)] +
Integer(2)*S[Integer(6),Integer(4)] - Integer(3)*S[Integer(3)] +
Integer(4)*S[[[]]].omega_involution())
# long time
>>> L((S[Integer(3),Integer(3)] - Integer(2)*S[Integer(2)]).omega_involution())
```

(continues on next page)
Testing the $\pi(\omega(f)) = \omega(\pi(f))$ relation noticed above:

```
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).omega_involution().to_symmetric_function()
     ....: == R(I).to_symmetric_function().omega_involution()
     ....: for I in Compositions(4) )
True
```

The omega involution on $\mathcal{QSym}$ is adjoint to the omega involution on $\mathcal{NSym}$ with respect to the duality pairing:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).omega_involution().duality_pairing(S(J))
     ....: == M(I).duality_pairing(S(J).omega_involution())
     ....: for I in Compositions(2) )
     ....: for J in Compositions(3) )
True
```

(continues on next page)
psi_involution()

Return the image of the noncommutative symmetric function self under the involution ψ.

The involution ψ is defined as the linear map \( NCSF \to NCSF \) which, for every composition \( I \), sends the complete noncommutative symmetric function \( S^I \) to the elementary noncommutative symmetric function \( \Lambda^I \). It can be shown that every composition \( I \) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)}\Phi^I
\]

where \( I^c \) denotes the complement of the composition \( I \), and \( \ell(I) \) denotes the length of \( I \), and where standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( \Phi \) for the basis of the power sums of the second kind, and \( R \) for the ribbon basis).

The map \( \psi \) is an involution and a graded Hopf algebra automorphism of \( NCSF \). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions \( \text{to_symmetric_function()} \), then \( \pi(\psi(f)) = \omega(\pi(f)) \) for every \( f \in NCSF \), where the \( \omega \) on the right hand side denotes the omega automorphism of \( Sym \).

The involution \( \psi \) of \( NCSF \) is adjoint to the involution \( \psi \) of \( QSym \) by the standard adjunction between \( NCSF \) and \( QSym \).

The involution \( \psi \) has been denoted by \( \psi \) in [LMvW13], section 3.6.

See also:

psi involution of QSym, star involution of NCSF.

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: R = NSym.R()
sage: R[3,2].psi_involution()
R[1, 1, 2, 1]
sage: R[6,3].psi_involution()
R[1, 1, 1, 1, 2, 1, 1]
4*R[[], 1, 1, 1, 1] - 2*R[1, 2, 1, 1] + R[1, 1, 1, 1, 2, 1, 1]
-2*R[1, 1, 1, 1, 1, 1, 1, 1, 1, 1, 1] + R[1, 1, 1, 1, 1, 1, 1, 1, 1]
sage: R([2,1,1]).psi_involution()
R[1, 3]
sage: S = NSym.S()
sage: S([2,1]).psi_involution()
S[1, 1, 1, 1] - S[2, 1]
sage: S.zero().psi_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).psi_involution()
-Phi[2, 1]
sage: Phi([3,1]).psi_involution()
Phi[3, 1]
```
```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> R = NSym.R()
>>> R[Integer(3),Integer(2)].psi_involution()
R[1, 1, 2, 1]
>>> R[Integer(6),Integer(3)].psi_involution()
R[1, 1, 1, 2, 1, 1]
>>> (R[Integer(9),Integer(1)] - R[Integer(8),Integer(2)] +
   R[Integer(2),Integer(4)] - R[Integer(3),Integer(3)]) .psi_involution()
4*R[1] - 3*R[1, 1, 1] + R[1, 1, 1, 1, 1, 1, 1, 1, 2] - R[1, 1, 1, 1, 1, 1, 1, 1, 1, 1]
>>> (R[Integer(3),Integer(3)] - Integer(2)*R[Integer(2)]).psi_involution()
-2*R[1, 1] + R[1, 1, 2, 1, 1]
>>> R([Integer(2),Integer(1),Integer(1)]).psi_involution()
R[1, 3]
>>> S = NSym.S()
>>> S([Integer(2),Integer(1)]).psi_involution()
S[1, 1, 1] - S[2, 1]
>>> S.zero().psi_involution()
0
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NSym.Phi()
>>> Phi([Integer(2),Integer(1)]).psi_involution()
-Phi[2, 1]
>>> Phi([Integer(3),Integer(1)]).psi_involution()
1/2*Phi[1, 2, 1] - 1/2*Phi[2, 1, 1] + Phi[3, 1]

The Psi basis doesn't behave as nicely:

```sage```
Psi = NSym.Psi()
Psi([2,1]).psi_involution()
-Psi[2, 1]
Psi([3,1]).psi_involution()
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

```python
>>> from sage.all import *
>>> Psi = NSym.Psi()
>>> Psi([Integer(2),Integer(1)]).psi_involution()
-Psi[2, 1]
>>> Psi([Integer(3),Integer(1)]).psi_involution()
1/2*Psi[1, 2, 1] - 1/2*Psi[2, 1, 1] + Psi[3, 1]
```

The involution \( \psi \) commutes with the antipode:

```sage```
all( R(I).psi_involution().antipode() == R(I).antipode().psi_involution() for I in Compositions(4) )
```

```python
>>> all( R(I).psi_involution().antipode() == R(I).antipode().psi_involution() for I in Compositions(Integer(4)) )
```

True
```
Testing the $\pi(\psi(f)) = \omega(\pi(f))$ relation noticed above:

```sage
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).psi_involution().to_symmetric_function() == R(I).to_symmetric_function().omega() for I in Compositions(4) )
True
```

The involution $\psi$ of $QS\!ym$ is adjoint to the involution $\psi$ of $NSym$ with respect to the duality pairing:

```sage
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).psi_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).psi_involution()) for J in Compositions(3) ) for I in Compositions(Integer(2)) )
True
```
graded component) corresponds to the automorphism of the descent algebra given by \( x \mapsto \omega_n x \omega_n \),
where \( \omega_n \) is the permutation \( (n, n - 1, \ldots, 1) \in S_n \) (written here in one-line notation). If \( \pi \) denotes the projection from \( \text{NCSF} \) to the ring of symmetric functions (\text{to_symmetric_function()}), then \( \pi(f^*) = \pi(f) \) for every \( f \in \text{NCSF} \).

The star involution on \( \text{NCSF} \) is adjoint to the star involution on \( \text{QSym} \) by the standard adjunction between \( \text{NCSF} \) and \( \text{QSym} \).

The star involution has been denoted by \( \rho \) in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

* star involution of \( \text{QSym} \),
* psi involution of \( \text{NCSF} \).

**EXAMPLES:**

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].star_involution()
S[2, 3]
sage: S[6,3].star_involution()
S[3, 6]
sage: (S[3,3] - 2*S[2]).star_involution()
sage: S([4,2]).star_involution()
S[2, 4]
sage: R = NSym.R()
sage: R([4,2]).star_involution()
R[2, 4]
sage: R.zero().star_involution()
0
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi([2,1]).star_involution()
Phi[1, 2]
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> S[Integer(3),Integer(2)].star_involution()
S[2, 3]
>>> S[Integer(6),Integer(3)].star_involution()
S[3, 6]
>>> (S[Integer(9),Integer(1)] - S[Integer(8),Integer(2)] +
   Integer(2)*S[Integer(6),Integer(4)] - Integer(3)*S[Integer(3)] +
   Integer(4)*S[]).star_involution()
>>> (S[Integer(3),Integer(3)] - Integer(2)*S[Integer(2)]).star_involution()
>>> S([Integer(4),Integer(2)]).star_involution()
S[2, 4]
>>> R = NSym.R()
>>> R([Integer(4),Integer(2)]).star_involution()
R[2, 4]
>>> R.zero().star_involution()
```

(continues on next page)
The \( \Psi \) basis doesn't behave as nicely:

\[
\begin{align*}
\text{sage: } & \Psi = \text{NSym}.\Psi() \\
\text{sage: } & \Psi([2,1]).\text{star-involution()} \\
\text{sage: } & \Psi([3,1]).\text{star-involution()} \\
\end{align*}
\]

\[
\begin{align*}
& 1/2*\Psi[1, 1, 2] - 1/2*\Psi[1, 2, 1] + \Psi[1, 3] \\
\end{align*}
\]

The star involution commutes with the antipode:

\[
\begin{align*}
\text{sage: } & \text{all}( \text{R(I).star-involution().antipode()} \\
& \qquad \qquad == \text{R(I).antipode().star-involution()} \\
& \qquad \qquad \text{for } I \text{ in Compositions(4) } ) \\
\text{True} \\
\end{align*}
\]

Checking the relation with the descent algebra described above:

\[
\begin{align*}
\text{sage: } & \text{def descent_test(n):} \\
& \quad \text{DA = DescentAlgebra(QQ, n)} \\
& \quad \text{NSym = NonCommutativeSymmetricFunctions(QQ)} \\
& \quad \text{S = NSym.S()} \\
& \quad \text{DAD = DA.D()} \\
& \quad \text{w_n = DAD(set(range(1, n)))} \\
& \quad \text{for I in Compositions(n):} \\
& \quad \quad \text{if not (S[I].star-involution() == w_n * S[I].to_descent_algebra(n) * w_n):} \\
& \quad \quad \quad \text{return False} \\
& \quad \quad \text{return True} \\
\text{sage: } & \text{all( descent_test(i) for i in range(4) )} \\
\text{True} \\
\text{sage: } & \text{all( descent_test(i) for i in range(6) )} \ # \text{long time} \\
\text{True} \\
\end{align*}
\]
Testing the $\pi(f^*) = \pi(f)$ relation noticed above:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: R = NSym.R()
sage: all( R(I).star_involution().to_symmetric_function() == R(I).to_symmetric_function() for I in Compositions(4) )
True
```

```python
>>> from sage.all import *

>>> R = NSym.R()

>>> all( R(I).star_involution().to_symmetric_function() == R(I).to_symmetric_function() for I in Compositions(Integer(4)) )
True
```

The star involution on $QSym$ is adjoint to the star involution on $NSym$ with respect to the duality pairing:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( M(I).star_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).star_involution()) for I in Compositions(2) )
True
```

```python
>>> from sage.all import *

>>> QSym = QuasiSymmetricFunctions(QQ)

>>> M = QSym.M()

>>> NSym = NonCommutativeSymmetricFunctions(QQ)

>>> S = NSym.S()

>>> all( M(I).star_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).star_involution()) for I in Compositions(Integer(2)) )
True
```

```python
... NSym = NonCommutativeSymmetricFunctions(QQ)
... S = NSym.S()
... DAD = DA.D()
... w_n = DAD(set(range(Integer(1), n)))
... for I in Compositions(n):
...     if not (S[I].star_involution() == w_n * S[I].to_descent_algebra(n) * w_n):
...         return False
... return True

>>> all( descent_test(i) for i in range(Integer(4)) )
True

>>> all( descent_test(i) for i in range(Integer(6)) )
# long time
True
```

The star involution on $QSym$ is adjoint to the star involution on $NSym$ with respect to the duality pairing:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: all( all( M(I).star_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).star_involution()) for I in Compositions(2) )
True
```

```python
>>> from sage.all import *

>>> QSym = QuasiSymmetricFunctions(QQ)

>>> M = QSym.M()

>>> NSym = NonCommutativeSymmetricFunctions(QQ)

>>> S = NSym.S()

>>> all( all( M(I).star_involution().duality_pairing(S(J)) == M(I).duality_pairing(S(J).star_involution()) for I in Compositions(Integer(2)) )
True
```

```python
... to_descent_algebra(n=None)
```
Return the image of the $n$-th degree homogeneous component of `self` in the descent algebra of $S_n$ over the same base ring as `self`.

This is based upon the canonical isomorphism from the $n$-th degree homogeneous component of the algebra of noncommutative symmetric functions to the descent algebra of $S_n$. This isomorphism maps the inner product of noncommutative symmetric functions either to the product in the descent algebra of $S_n$ or to its opposite (depending on how the latter is defined).

If $n$ is not specified, it will be taken to be the highest homogeneous component of `self`.

**OUTPUT:**
- The image of the $n$-th homogeneous component of `self` under the isomorphism into the descent algebra of $S_n$ over the same base ring as `self`.

**EXAMPLES:**

```python
sage: S = NonCommutativeSymmetricFunctions(ZZ).S()
sage: S[2,1].to_descent_algebra(3)
B[2, 1]
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(4)
-3*B[1, 1, 2] + B[1, 2, 1]
sage: S[2,1].to_descent_algebra(2)
0
sage: S[2,1].to_descent_algebra()
B[2, 1]
sage: S.zero().to_descent_algebra().parent()
Descent algebra of 0 over Integer Ring in the subset basis
sage: (S[1,2,1] - 3 * S[1,1,2]).to_descent_algebra(1)
0
```

To return the image of the non-commutative symmetric function `self` under the morphism $\iota : NSym \to FQS\text{Sym}$. This morphism is the injective algebra homomorphism $NSym \to FQS\text{Sym}$ that sends each Complete generator $S_n$ to $F_{[1,2,\ldots,n]}$. It is the inclusion map, if we regard both $NSym$ and $FQS\text{Sym}$ as rings of noncommutative power series.

**See also:**

*FreeQuasisymmetricFunctions* for a definition of $FQS\text{Sym}$.  

**EXAMPLES:**
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x.to_fqsym()
2*F[[]] + 2*F[1] + 3*F[1, 2]
sage: R[2,1].to_fqsym()
F[1, 3, 2] + F[3, 1, 2]
sage: x = R.an_element(); x
2*R[[]] + 2*R[1] + 3*R[1, 1]
sage: x.to_fqsym()

sage: y = N.Ph()[1,2]
sage: y.to_fqsym()

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fqsym()
F[1, 2]
sage: S[1,2].to_fqsym()
F[1, 2, 3] + F[2, 1, 3] + F[2, 3, 1]
sage: S[1,2,1].to_fqsym()
to_fsym()  

Return the image of \( self \) under the natural map to \( FSym \).

There is an injective Hopf algebra morphism from \( NSym \) to \( FSym \) (see \textit{FreeSymmetricFunctions}), which maps the ribbon \( R_\alpha \) indexed by a composition \( \alpha \) to the sum of all tableaux whose descent composition is \( \alpha \). If we regard \( NSym \) as a Hopf subalgebra of \( FQSym \) via the morphism \( \iota : NSym \rightarrow FQSym \) (implemented as \textit{to_fqsym()}), then this injective morphism is just the inclusion map.

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x.to_fsym()
sage: R[2,1].to_fsym()
G[12|3]
sage: R[1,2].to_fsym()
G[13|2]
sage: R[2,1,2].to_fsym()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_fsym()
sage: y = N.Phi()[1,2]
sage: y.to_fsym()
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S[2].to_fsym()
G[12]
sage: S[2,1].to_fsym()
G[12|3] + G[123]
```

```bash
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> x = Integer(2)*R[] + Integer(2)*R[Integer(1)] +
...      Integer(3)*R[Integer(2)]
>>> x.to_fsym()
>>> R[Integer(2),Integer(1)].to_fsym()
G[12|3]
>>> R[Integer(1),Integer(2)].to_fsym()
G[13|2]
>>> R[Integer(2),Integer(1),Integer(2)].to_fsym()
>>> x = R.an_element(); x
```
\[
2 \ast R[1] + 2 \ast R[1, 1] + 3 \ast R[1, 1, 1]
\]
```python
>>> x.to_fsym()
2*G[] + 2*G[1] + 3*G[1,1]
```
```python
>>> y = N.Ph[i][Integer(1),Integer(2)]
>>> y.to_fsym()
```
```python
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S[Integer(2)].to_fsym()
G[12]
```
```python
>>> S[Integer(2),Integer(1)].to_fsym()
G[12|3] + G[123]
```
```
to_ncsym()
Return the image of self under the injective algebra homomorphism \( \kappa : NSym \to NCSym \) that fixes the symmetric functions.

As usual, \( NCSym \) denotes the ring of symmetric functions in non-commuting variables. Let \( S_n \) denote a generator of the complete basis. The algebra homomorphism \( \kappa : NSym \to NCSym \) is defined by

\[
S_n \mapsto \sum_{A^{\vdash [n]}} \frac{\lambda(A) \lambda(A)^t}{n!} m_A.
\]

It has the property that the canonical maps \( \chi : NCSym \to Sym \) and \( \rho : NSym \to Sym \) satisfy \( \chi \circ \kappa = \rho \).

Note: A remark in [BRRZ08] makes it clear that the embedding of \( NSym \) into \( NCSym \) that preserves the projection into the symmetric functions is not unique. While this seems to be a natural embedding, any free set of algebraic generators of \( NSym \) can be sent to a set of free elements in \( NCSym \) to form another embedding.

See also:
NonCommutativeSymmetricFunctions for a definition of \( NCSym \).

EXAMPLES:
```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S[2].to_ncsym()
1/2*m{{1}, {2}} + m{{1, 2}}
sage: S[1,2,1].to_ncsym()
1/2*m{{1}, {2}, {3}, {4}} + 1/2*m{{1}, {2}, {3, 4}} + m{{1}, {2, 3}, ...
```
```python
+ m{{1}, {2, 3, 4}} + 1/2*m{{1}, {2, 4}, {3}, {4}}
+ 1/2*m{{1}, {2, 3}, {4}} + m{{1, 2, 3}, {4}} + m{{1, 2, 4}, {3}} + 1/2*m{{1, 3}, {4}}
+ 1/2*m{{1, 3}, {2}, {4}} + m{{1, 3, 4}, {2}}
```
```
sage: S[1,2].to_ncsym()
1/2*m{{1}, {2}, {3}} + m{{1}, {2, 3}} + 1/2*m{{1}, {2, 3}} + m{{1, 2}, {3}}
```
```

+ 1/2*m({1, 2}, {3, 4}) + m({1, 2, 3, 4})

>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()

S[Integer(2)].to_ncsym()
1/2*m({1, 2}) + m({1, 2})

S[Integer(1),Integer(2)].to_ncsym()
1/2*m({1, 2}, {3}) + 1/2*m({1, 2}, {3, 4})
+ 1/2*m({1, 2}, {3, 4}) + m({1, 2, 3, 4})
\[ + \frac{1}{2} m\{1\}, \{2, 4\}, \{3\} - \frac{1}{4} m\{1, 2\}, \{3, 4\} - \frac{1}{4} m\{1, 2, 3\}, \{4\} \\
+ m\{1, 2, 3, 4\} + \frac{1}{2} m\{1, 2, 4\}, \{3\} + \frac{1}{2} m\{1, 3\}, \{2, 4\} - \frac{1}{4} m\{1, 3, 4\}, \{2\} - \frac{1}{4} m\{1, 4\}, \{2, 3\} \]

**to_symmetric_function()**

Return the commutative image of a non-commutative symmetric function.

**OUTPUT:**

• The commutative image of *self*. This will be a symmetric function.

**EXAMPLES:**

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: R = N.ribbon()
sage: x = R.an_element(); x
2*R[] + 2*R[1] + 3*R[1, 1]
sage: x.to_symmetric_function()
2*s[] + 2*s[1] + 3*s[1, 1]
sage: y = N.Phi()[1,3]
sage: y.to_symmetric_function()
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

**to_symmetric_group_algebra()**

Return the image of a non-commutative symmetric function into the symmetric group algebra where the ribbon basis element indexed by a composition is associated with the sum of all permutations which have descent set equal to said composition. In compliance with the anti-isomorphism between the descent algebra and the non-commutative symmetric functions, we index descent positions by the reversed composition.

**OUTPUT:**

• The image of *self* under the embedding of the \(n\)-th degree homogeneous component of the non-commutative symmetric functions in the symmetric group algebra of \(S_n\). This can behave unexpectedly when *self* is not homogeneous.

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R[2,1].to_symmetric_group_algebra()
[1, 3, 2] + [2, 3, 1]
sage: R([]).to_symmetric_group_algebra()
[]
```

```python
>>> from sage.all import *

>>> R = NonCommutativeSymmetricFunctions(QQ).R()

>>> R[Integer(2),Integer(1)].to_symmetric_group_algebra()

```

(continues on next page)
verschiebung (n)

Return the image of the noncommutative symmetric function self under the n-th Verschiebung operator.

The n-th Verschiebung operator \( V_n \) is defined to be the map from the \( \mathbf{k} \)-algebra of noncommutative symmetric functions to itself that sends the complete function \( S^I \) indexed by a composition \( I = (i_1, i_2, \ldots, i_k) \) to \( S^{(i_1/n,n,\ldots,n_i/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \), and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n}\Lambda_{r/n}, \quad V_n(\Psi_r) = n\Psi_{r/n}, \quad V_n(\Phi_r) = n\Phi_{r/n}
\]

(where \( S_r \) denotes the \( r \)-th complete non-commutative symmetric function, \( \Lambda_r \) denotes the \( r \)-th elementary non-commutative symmetric function, \( \Psi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the first kind, and \( \Phi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The n-th Verschiebung operator is also called the n-th Verschiebung endomorphism.

It is a lift of the n-th Verschiebung operator on the ring of symmetric functions (\( \text{verschiebung}() \)) to the ring of noncommutative symmetric functions.

The action of the n-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \( I \) of size \( n\ell \) satisfies

\[
V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n},
\]

where \( J \) denotes the meet of the compositions \( I \) and \( (n, n, \ldots, n) \), where \( \ell(I) \) is the length of \( I \), and \( \ell(J) \) is the length of \( J \), and \( |I|/n \) times

where \( J/n \) denotes the composition obtained by dividing every entry of \( J \) by \( n \). For a composition \( I \) of size not divisible by \( n \), we have \( V_n(R_I) = 0 \).

See also:

adams_operator method of QSym, verschiebung method of Sym

INPUT:

• \( n \) – a positive integer

OUTPUT:

The result of applying the n-th Verschiebung operator (on the ring of noncommutative symmetric functions) to \( \text{self} \).

EXAMPLES:

```sage
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: S[3,2].verschiebung(2)
0
sage: S[6,4].verschiebung(2)
S[3, 2]
```
sage: (S[3, 3] - 2*S[2]).verschiebung(3) S[1, 1]
sage: S([4, 2]).verschiebung(1)
S[4, 2]
sage: R = NSym.R()
sage: R([4, 2]).verschiebung(2)
R[2, 1]

>>> from sage.all import *
>>>
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> S[Integer(3), Integer(2)].verschiebung(Integer(2))
0
>>> S[Integer(6), Integer(4)].verschiebung(Integer(2))
S[3, 2]

Being Hopf algebra endomorphisms, the Verschiebung operators commute with the antipode:

sage: all( R(I).verschiebung(2).antipode()
....:     == R(I).antipode().verschiebung(2)
....:     for I in Compositions(4) )
True

They lift the Verschiebung operators of the ring of symmetric functions:

sage: all( S(I).verschiebung(2).to_symmetric_function()
....:     == S(I).to_symmetric_function().verschiebung(2)
....:     for I in Compositions(4) )
True
The Frobenius operators on $QSym$ are adjoint to the Verschiebung operators on $NSym$ with respect to the duality pairing:

```plaintext
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: all( all( M(I).adams_operator(3).duality_pairing(S(J))
......: == M(I).duality_pairing(S(J).verschiebung(3))
......: for I in Compositions(2) )
......: for J in Compositions(3) )
True
```

```plaintext
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> M = QSym.M()
>>> all( all( M(I).adams_operator(Integer(3)).duality_pairing(S(J))
.....: == M(I).duality_pairing(S(J).verschiebung(Integer(3)))
.....: for I in Compositions(Integer(2)) )
.....: for J in Compositions(Integer(3)) )
True
```

```python
class ParentMethods
    Bases: object

    immaculate_function(xs)
        Return the immaculate function corresponding to the integer vector xs, written in the basis self. If $\alpha$ is any integer vector – i.e., an element of $\mathbb{Z}^m$ for some $m \in \mathbb{N}$ –, the immaculate function corresponding to $\alpha$ is a non-commutative symmetric function denoted by $S_\alpha$. One way to define this function is by setting
        
        $$S_\alpha = \sum_{\sigma \in S_m} (-1)^\sigma S_{\alpha_1+\sigma(1)-1}S_{\alpha_2+\sigma(2)-2}\cdots S_{\alpha_m+\sigma(m)-m},$$
        
        where $\alpha$ is written in the form $(\alpha_1, \alpha_2, \ldots, \alpha_m)$, and where $S$ stands for the complete basis (Complete).

        The immaculate function $S_\alpha$ first appeared in [BBSSZ2012] (where it was defined differently, but the definition we gave above appeared as Theorem 3.27). The immaculate functions $S_\alpha$ for $\alpha$ running over all compositions (i.e., finite sequences of positive integers) form a basis of $NCSF$. This is the immaculate basis (Immaculate).

        INPUT:
        * xs – list (or tuple or any iterable – possibly a composition) of integers

        OUTPUT:

        The immaculate function $S_{\alpha}$ written in the basis self.

        EXAMPLES:

        Let us first check that, for $xs$ a composition, we get the same as the result of self.
        realization_of().I() [xs]:
        ```
        sage: def test_comp(xs):
......:     NSym = NonCommutativeSymmetricFunctions(QQ)
......:     I = NSym.I()
......:     return I[xs] == I.immaculate_function(xs)
        sage: def test_allcomp(n):
......:     return all( test_comp(c) for c in Compositions(n) )
        ```
```
```
Now some examples of non-composition immaculate functions:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: I = NSym.I()
sage: I.immaculate_function([0, 1])
0
sage: I.immaculate_function([0, 2])
-I[1, 1]
sage: I.immaculate_function([-1, 1])
-I[]
sage: I.immaculate_function([2, -1])
0
sage: I.immaculate_function([2, 0])
I[2]
sage: I.immaculate_function([2, 0, 1])
0
sage: I.immaculate_function([1, 0, 2])
-I[1, 1, 1]
sage: I.immaculate_function([2, 0, 2])
-I[2, 1, 1]
sage: I.immaculate_function([0, 2, 0, 2])
I[1, 1, 1, 1] + I[1, 2, 1]
sage: I.immaculate_function([2, 0, 2, 0, 2])
I[2, 1, 1, 1, 1] + I[2, 1, 2, 1]
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> I = NSym.I()
>>> I.immaculate_function([Integer(0), Integer(1)])
0
>>> I.immaculate_function([Integer(0), Integer(2)])
-I[1, 1]
>>> I.immaculate_function([-Integer(1), Integer(1)])
-I[]
```

(continues on next page)
to_symmetric_function()
Morphism to the algebra of symmetric functions.
This is constructed by extending the computation on the basis or by coercion to the complete basis.

OUTPUT:
• The module morphism from the basis self to the symmetric functions which corresponds to
taking a commutative image.

EXAMPLES:

```sage
>>> from sage.all import *
```

```sage
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> R = N.ribbon()
>>> x = R.an_element(); x
2*R[0] + 2*R[1] + 3*R[1, 1]
>>> R.to_symmetric_function(x)
2*s[0] + 2*s[1] + 3*s[1, 1]
```

```sage
>>> nM = N.Monomial()
```

```sage
>>> nM.to_symmetric_function(nM[3,1])
```

to_symmetric_function_on_basis(I)
The image of the basis element indexed by I under the map to the symmetric functions.
This default implementation does a change of basis and computes the image in the complete basis.

INPUT:
• I – a composition

OUTPUT:
• The image of the non-commutative basis element of self indexed by the composition I under
the map from non-commutative symmetric functions to the symmetric functions. This will be a
symmetric function.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: I = N.Immaculate()
sage: I.to_symmetric_function(I[1,3])
-h[2, 2] + h[3, 1]
sage: I.to_symmetric_function(I[1,2])
0
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_basis([3,1,2]) == Phi.to_symmetric_function(Phi[3,1,2])
True
sage: Phi.to_symmetric_function_on_basis([])
h[]
```

```python
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> I = N.Immaculate()
>>> I.to_symmetric_function(I[Integer(1),Integer(3)])
-h[2, 2] + h[3, 1]
>>> I.to_symmetric_function(I[Integer(1),Integer(2)])
0
>>> Phi = N.Phi()
>>> Phi.to_symmetric_function_on_basis([Integer(3),Integer(1), Integer(2)]) == Phi.to_symmetric_function(Phi[Integer(3),Integer(1), Integer(2)])
True
>>> Phi.to_symmetric_function_on_basis([])
h[]
```

```
super_categories()

Return the super categories of the category of bases of the non-commutative symmetric functions.

OUTPUT:
• list

class Complete(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Complete basis.

The Complete basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((S^f)_f\). It is a multiplicative basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function \(S_n\) for every nonnegative integer \(n\) by the power series identity

\[
\sum_{k \geq 0} t^k S_k = \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1},
\]

with \(\Lambda_0\) denoting 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(S^{(i_1,i_2,\ldots,i_k)} = S_{i_1} S_{i_2} \cdots S_{i_k}\).

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: S = NCSF.Complete(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```
```
sage: S.an_element()
2*S[] + 2*S[1] + 3*S[1, 1]

The following are aliases for this basis:

sage: NCSF.complete()
Non-Commutative Symmetric Functions over the Rational Field in the Complete\n→basis
sage: NCSF.S()
Non-Commutative Symmetric Functions over the Rational Field in the Complete\n→basis

class Element

Bases: IndexedFreeModuleElement

An element in the Complete basis.

psi_involution()

Return the image of the noncommutative symmetric function self under the involution ψ.

The involution ψ is defined as the linear map \( NCSF \rightarrow NCSF \) which, for every composition \( I \), sends the complete noncommutative symmetric function \( S^I \) to the elementary noncommutative symmetric function \( \Lambda^I \). It can be shown that every composition \( I \) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{\|I\| - \ell(I)} \Phi^I
\]

where \( I^c \) denotes the complement of the composition \( I \), and \( \ell(I) \) denotes the length of \( I \), and where standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( \Phi \) for the basis of the power sums of the second kind, and \( R \) for the ribbon basis).

The map \( \psi \) is an involution and a graded Hopf algebra automorphism of \( NCSF \). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions (\( to_symmetric_function() \)), then \( \pi(\psi(f)) = \omega(\pi(f)) \) for every \( f \in NCSF \), where the \( \omega \) on the right hand side denotes the omega automorphism of \( Sym \).

The involution \( \psi \) of \( NCSF \) is adjoint to the involution \( \psi \) of \( QSym \) by the standard adjunction between \( NCSF \) and \( QSym \).

The involution \( \psi \) has been denoted by \( \psi \) in [LMvW13], section 3.6.
See also:

\textit{psi involution of NCSF}, \textit{psi involution of QSym}, \textit{star involution of NCSF}.

\section*{EXAMPLES:}

\begin{verbatim}
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: S[3,1].psi_involution()
S[1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]
sage: L(S[3,1].psi_involution())
L[3, 1]
sage: S[].psi_involution()
S[]
sage: S[1,1].psi_involution()
S[1, 1]
sage: (S[2,1] - 2*S[2]).psi_involution()
\end{verbatim}

The implementation at hand is tailored to the complete basis. It is equivalent to the generic implementation via the ribbon basis:

\begin{verbatim}
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> S = NSym.S()
>>> L = NSym.L()
>>> S[Integer(3),Integer(1)].psi_involution()
S[1, 1, 1] - S[1, 2, 1] - S[2, 1, 1] + S[3, 1]
>>> L(S[Integer(3),Integer(1)].psi_involution())
L[3, 1]
>>> S[].psi_involution()
S[]
>>> S[Integer(1),Integer(1)].psi_involution()
S[1, 1]
>>> (S[Integer(2),Integer(1)] - Integer(2)*S[Integer(2)]).psi_involution()
\end{verbatim}

\section*{dual ()}

Return the dual basis to the complete basis of non-commutative symmetric functions. This is the Monomial basis of quasi-symmetric functions.

\section*{OUTPUT:}

- The Monomial basis of quasi-symmetric functions.

\section*{EXAMPLES:}

\begin{verbatim}
sage: R = NSym.R()
sage: all( R(S[I].psi_involution()) == R(S[I]).psi_involution() ....: for I in Compositions(4) )
True
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> R = NSym.R()
>>> all( R(S[I].psi_involution()) == R(S[I]).psi_involution() ....: for I in Compositions(Integer(4)) )
True
\end{verbatim}
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis

>>> from sage.all import *

>>> S = NonCommutativeSymmetricFunctions(QQ).S()

>>> S.dual()
Quasisymmetric functions over the Rational Field in the Monomial basis

internal_product_on_basis(I, J)

The internal product of two non-commutative symmetric complete functions.

See internal_product() for a thorough documentation of this operation.

INPUT:

• I, J – compositions

OUTPUT:

• The internal product of the complete non-commutative symmetric function basis elements indexed by I and J, expressed in the complete basis.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.internal_product_on_basis([2,2],[1,2,1])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]
sage: S.internal_product_on_basis([2,2],[1,2])
0

>>> from sage.all import *

>>> N = NonCommutativeSymmetricFunctions(QQ)

>>> S = N.complete()

>>> S.internal_product_on_basis([Integer(2),Integer(2)],[Integer(1),
˓→Integer(2),Integer(1)])
2*S[1, 1, 1, 1] + S[1, 1, 2] + S[2, 1, 1]

>>> S.internal_product_on_basis([Integer(2),Integer(2)],[Integer(1),
˓→Integer(2)])
0

to_symmetric_function()

Morphism to the algebra of symmetric functions.

This is constructed by extending the computation on the complete basis.

OUTPUT:

• The module morphism from the basis self to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[3,1,2])
h[3, 2, 1]
sage: S.to_symmetric_function(S[[]])
h[[]]
to\_symmetric\_function\_on\_basis(I)

The commutative image of a complete element

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element and the output is in the complete basis of the symmetric functions.

INPUT:

• I – a composition

OUTPUT:

• The commutative image of the complete basis element indexed by \(I\). The result is the complete symmetric function indexed by the partition obtained by sorting \(I\).

EXAMPLES:

```python
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> S.to_symmetric_function(S[Integer(3),Integer(1),Integer(2)])
\h[3, 2, 1]
>>> S.to_symmetric_function(S[[]])
\h[]
```

class Elementary(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Elementary basis.

The Elementary basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((\Lambda^I)_I\). It is a multiplicative basis, and is obtained from the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions through the formula \(\Lambda^{(i_1,i_2,\ldots,i_k)} = \Lambda_{i_1} \Lambda_{i_2} \cdots \Lambda_{i_k}\) for every composition \((i_1,i_2,\ldots,i_k)\).

EXAMPLES:

```python
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> L = NCSF.Elementary(); L
Non-Commutative Symmetric Functions over the Rational Field in the Elementary→basis
>>> L.an_element()
```
The following are aliases for this basis:

```
sage: NCSF.elementary()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary...
  →basis
sage: NCSF.L()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary...
  →basis
```

```python
>>> from sage.all import *
```

```python
NCSF.elementary()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary...
  →basis
```

```python
NCSF.L()
Non-Commutative Symmetric Functions over the Rational Field in the Elementary...
  →basis
```

```python
class Element
    Bases:
    IndexedFreeModuleElement

    psi_involution()

    Return the image of the noncommutative symmetric function self under the involution \( \psi \).

    The involution \( \psi \) is defined as the linear map \( NCSF \to NCSF \) which, for every composition \( I \), sends the complete noncommutative symmetric function \( S^I \) to the elementary noncommutative symmetric function \( \Lambda^I \). It can be shown that every composition \( I \) satisfies

    \[
    \psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
    \]

    where \( I^c \) denotes the complement of the composition \( I \), and \( \ell(I) \) denotes the length of \( I \), and where standard notations for classical bases of \( NCSF \) are being used (\( S \) for the complete basis, \( \Lambda \) for the elementary basis, \( \Phi \) for the basis of the power sums of the second kind, and \( R \) for the ribbon basis). The map \( \psi \) is an involution and a graded Hopf algebra automorphism of \( NCSF \). If \( \pi \) denotes the projection from \( NCSF \) to the ring of symmetric functions (\( to_symmetric_function() \)), then \( \pi(\psi(f)) = \omega(\pi(f)) \) for every \( f \in NCSF \), where the \( \omega \) on the right hand side denotes the omega automorphism of \( Sym \).

    The involution \( \psi \) of \( NCSF \) is adjoint to the involution \( \psi \) of \( QSym \) by the standard adjunction between \( NCSF \) and \( QSym \).

    The involution \( \psi \) has been denoted by \( \psi \) in \cite{LMvW13}, section 3.6.

    See also:

    \( \psi \) involution of \( NCSF \), \( \psi \) involution of \( QSym \), \( \star \) involution of \( NCSF \).
```

```python
EXAMPLES:
```
```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: S = NSym.S()
sage: L = NSym.L()
sage: L[3,1].psi_involution()
L[1, 1, 1, 1] - L[1, 2, 1] - L[2, 1, 1] + L[3, 1]
```

(continues on next page)
The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the ribbon basis:

```
sage: R = NSym.R()
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution() 
....:   for I in Compositions(3) )
True
sage: all( R(L[I].psi_involution()) == R(L[I]).psi_involution() 
....:   for I in Compositions(Integer(3)) )
True
```

The star involution is defined as the algebra antihomomorphism $NCSF \to NCSF$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in NCSF$ under this star involution, it can be shown that every composition $I$ satisfies

$$
(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R_i^* = R_{i^r}, \quad (\Phi^I)^* = \Phi^{I^r},
$$

where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for...
that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see $\text{to_descent_algebra}()$), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions ($\text{to_symmetric_function}()$), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

$\text{star involution of NCSF, psi involution of NCSF, star involution of QSym}$.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L[3,3,2,3].star_involution()
L[3, 2, 3, 3]
sage: L[6,3,3].star_involution()
L[3, 3, 6]
sage: (L[3,3] - 2*L[2]).star_involution()
sage: L([4,1]).star_involution()
L[1, 4]
```

```
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> L = NSym.L()
>>> L[Integer(3),Integer(3),Integer(2),Integer(3)].star_involution()
L[3, 2, 3, 3]
>>> L[Integer(6),Integer(3),Integer(3)].star_involution()
L[3, 3, 6]
>>> (L[Integer(1),Integer(9),Integer(1)] - L[Integer(8),Integer(2)] +...
Integer(2)*L[Integer(6),Integer(4)] - Integer(3)*L[Integer(3)] +...
Integer(4)*L[]).star_involution()
>>> (L[Integer(3),Integer(3)] - Integer(2)*L[Integer(2)]).star_involution()
>>> L([Integer(4),Integer(1)]).star_involution()
L[1, 4]
```

The implementation at hand is tailored to the elementary basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
sage: all( S(L[I].star_involution()) == S(L[I]).star_involution() )
(continues on next page)
verschiebung \((n)\)

Return the image of the noncommutative symmetric function \(\text{self}\) under the \(n\)-th Verschiebung operator.

The \(n\)-th Verschiebung operator \(V_n\) is defined to be the map from the \(k\)-algebra of noncommutative symmetric functions to itself that sends the complete function \(S^I\) indexed by a composition \(I = (i_1, i_2, \ldots, i_k)\) to \(S^{(i_1/n, i_2/n, \ldots, i_k/n)}\) if all of the numbers \(i_1, i_2, \ldots, i_k\) are divisible by \(n\), and to \(0\) otherwise. This operator \(V_n\) is a Hopf algebra endomorphism. For every positive integer \(r\) with \(n \mid r\), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}
\]

(where \(S_r\) denotes the \(r\)-th complete non-commutative symmetric function, \(\Lambda_r\) denotes the \(r\)-th elementary non-commutative symmetric function, \(\Psi_r\) denotes the \(r\)-th power-sum non-commutative symmetric function of the first kind, and \(\Phi_r\) denotes the \(r\)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \(r\) with \(n \nmid r\), it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The \(n\)-th Verschiebung operator is also called the \(n\)-th Verschiebung endomorphism.

It is a lift of the \(n\)-th Verschiebung operator on the ring of symmetric functions (\text{verschiebung()}\) to the ring of noncommutative symmetric functions.

The action of the \(n\)-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \(I\) of size \(n\ell\) satisfies

\[
V_n(R_I) = (-1)^{\ell(I) - \ell(J)} \cdot R_{J/n},
\]

where \(J\) denotes the meet of the compositions \(I\) and \((n, n, \ldots, n)\), where \(\ell(I)\) is the length of \(I\), and \(\ell(J)\) is the length of \(J\), \(|I|/n\) times

where \(J/n\) denotes the composition obtained by dividing every entry of \(J\) by \(n\). For a composition \(I\) of size not divisible by \(n\), we have \(V_n(R_I) = 0\).

See also:

\text{verschiebung method of NCSF, adams_operator method of QSym, verschiebung method of Sym}

INPUT:

• \(n\) – a positive integer

OUTPUT:

The result of applying the \(n\)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to \(\text{self}\).

EXAMPLES:
```python
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: L = NSym.L()
sage: L([4, 2]).verschiebung(2)
-L[2, 1]
sage: L([2, 4]).verschiebung(2)
-L[1, 2]
sage: L([6]).verschiebung(2)
-L[3]
sage: L([2, 1]).verschiebung(3)
0
sage: L([3]).verschiebung(2)
0
sage: L([]).verschiebung(2)
L[]
sage: L([5, 1]).verschiebung(3)
0
sage: L([5, 1]).verschiebung(6)
0
sage: L([5, 1]).verschiebung(2)
0
sage: L([1, 2, 3, 1]).verschiebung(7)
0
sage: L([1, 2, 3, 1]).verschiebung(5)
0
```

(continues on next page)
I

alias of \texttt{Immaculate}

\begin{classdef}
\texttt{Immaculate} (\texttt{NCSF})
\texttt{Bases: CombinatorialFreeModule, BindableClass}

\end{classdef}

The immaculate basis of the non-commutative symmetric functions.

The immaculate basis first appears in Berg, Bergeron, Saliola, Serrano and Zabrocki’s [BBSSZ2012]. It can be described as the family \((\mathcal{S}_\alpha)\), where \(\alpha\) runs over all compositions, and \(\mathcal{S}_\alpha\) denotes the immaculate function corresponding to \(\alpha\) (see \texttt{immaculate_function()}).

If \(\alpha\) is a composition \((\alpha_1, \alpha_2, \ldots, \alpha_m)\), then
\[
\mathcal{S}_\alpha = \sum_{\sigma \in \mathcal{S}_m} (-1)^\sigma S_{\alpha_1 + \sigma(1) - 1} S_{\alpha_2 + \sigma(2) - 2} \cdots S_{\alpha_m + \sigma(m) - m}.
\]

\textbf{Warning:} This \texttt{basis} contains only the immaculate functions indexed by compositions (i.e., finite sequences of positive integers). To obtain the remaining immaculate functions (sensu lato), use the \texttt{immaculate_function()} method. Calling the immaculate basis with a list which is not a composition will currently return garbage!

\begin{exmp}
\begin{verbatim}
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: I = NCSF.I()
sage: I([1,3,2])*I([1])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
sage: I([1,1])*I([1,3,2])
sage: I([1,3])*I([1,1])
I[1, 3, 1, 1] + I[1, 4, 1] + I[2, 3, 1] + I[2, 4]
sage: I([3,1])*I([2,1])
sage: R = NCSF.ribbon()
sage: R(I(R([2,1,3])))
R[2, 1, 3]
\end{verbatim}
\end{exmp}

\begin{verbatim}
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> I = NCSF.I()
>>> I([Integer(1),Integer(3),Integer(2)])*I([Integer(1)])
I[1, 3, 2, 1] + I[1, 3, 3] + I[1, 4, 2] + I[2, 3, 2]
>>> I([Integer(1)])*I([Integer(1),Integer(3),Integer(2)])
>>> I([Integer(1),Integer(3)])*I([Integer(1),Integer(1)])
\end{verbatim}
\end{exmp}
class Element

    Bases: IndexedFreeModuleElement

An element in the Immaculate basis.

bernstein_creation_operator(n)

    Return the image of self under the n-th Bernstein creation operator.

    Let n be an integer. The n-th Bernstein creation operator B_n is defined as the endomorphism of the space NSym of noncommutative symmetric functions given by

    \[ B_n I(\alpha_1, \alpha_2, \ldots, \alpha_m) = I(n, \alpha_1, \alpha_2, \ldots, \alpha_m), \]

    where I(\alpha_1, \alpha_2, \ldots, \alpha_m) is the immaculate function associated to the m-tuple (\alpha_1, \alpha_2, \ldots, \alpha_m) \in \mathbb{Z}^m.

    This has been introduced in [BBSSZ2012], section 3.1, in analogy to the Bernstein creation operators on the symmetric functions.

    For more information on the n-th Bernstein creation operator, see bernstein_creation_operator().

EXAMPLES:

    sage: NSym = NonCommutativeSymmetricFunctions(QQ)
    sage: I = NSym.I()
    sage: b = I[1,3,2,1]
    sage: b.bernstein_creation_operator(3)
    I[3, 1, 3, 2, 1]
    sage: b.bernstein_creation_operator(5)
    I[5, 1, 3, 2, 1]
    sage: elt = b + 3*I[4,1,2]
    sage: elt.bernstein_creation_operator(1)
    I[1, 1, 3, 2, 1] + 3*I[1, 4, 1, 2]

We check that this agrees with the definition on the Complete basis:
\begin{verbatim}
sage: S = NSym.S()
sage: S(elt).bernstein_creation_operator(1) == S(elt.bernstein_creation_operator(1))
True

>>> from sage.all import *
>>> S = NSym.S()

>>> S(elt).bernstein_creation_operator(Integer(1)) == S(elt.bernstein_creation_operator(Integer(1)))
True

Check on non-positive values of \( n \):

sage: I[2,2,2].bernstein_creation_operator(-1)
I[1, 1, 1, 2] + I[1, 1, 2, 1] + I[1, 2, 1, 1] - I[1, 2, 2]
sage: I[2,3,2].bernstein_creation_operator(0)
-I[1, 1, 3, 2] - I[1, 2, 2, 2] - I[1, 2, 3, 1] + I[2, 3, 2]

>>> from sage.all import *

>>> I[Integer(2),Integer(2),Integer(2)].bernstein_creation_operator(-Integer(1))
I[1, 1, 1, 2] + I[1, 1, 2, 1] + I[1, 2, 1, 1] - I[1, 2, 2]

>>> I[Integer(2),Integer(3),Integer(2)].bernstein_creation_operator(Integer(0))
-I[1, 1, 3, 2] - I[1, 2, 2, 2] - I[1, 2, 3, 1] + I[2, 3, 2]
\end{verbatim}

dual()

Return the dual basis to the Immaculate basis of NCSF.

The basis returned is the dualImmaculate basis of QSym.

OUTPUT:
• The dualImmaculate basis of the quasi-symmetric functions.

EXAMPLES:

\begin{verbatim}
sage: I = NonCommutativeSymmetricFunctions(QQ).Immaculate()
sage: I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate basis

>>> from sage.all import *

>>> I = NonCommutativeSymmetricFunctions(QQ).Immaculate()

>>> I.dual()
Quasisymmetric functions over the Rational Field in the dualImmaculate basis
\end{verbatim}

\textbf{L}

alias of \texttt{Elementary}

class Monomial\,(NCSF)

Bases: \texttt{CombinatorialFreeModule}, \texttt{BindableClass}

The monomial basis defined in Tevlin’s paper [Tev2007].

The monomial basis is well-defined only when the base ring is a Q-algebra. It is the basis denoted by \((M')_l\) in [Tev2007].
class MultiplicativeBases(parent_with_realization)

Bases: Category_realization_of_parent

Category of multiplicative bases of non-commutative symmetric functions.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBases()
Category of multiplicative bases of Non-Commutative Symmetric Functions over...
→ the Rational Field

From sage.all import *
N = NonCommutativeSymmetricFunctions(QQ)
N.MultiplicativeBases()
Category of multiplicative bases of Non-Commutative Symmetric Functions over...
→ the Rational Field

The complete basis is a multiplicative basis, but the ribbon basis is not:

sage: N.Complete() in N.MultiplicativeBases()
True
sage: N.Ribbon() in N.MultiplicativeBases()
False

From sage.all import *
N.Complete() in N.MultiplicativeBases()
True
N.Ribbon() in N.MultiplicativeBases()
False

class ParentMethods

Bases: object

algebra_generators()

Return the algebra generators of a given multiplicative basis of non-commutative symmetric functions.

OUTPUT:
• The family of generators of the multiplicative basis self.

EXAMPLES:

sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: f = Psi.algebra_generators()
sage: f
Lazy family (<lambda>(i))_{i in Positive integers}
sage: f[1], f[2], f[3]
(Psi[1], Psi[2], Psi[3])

From sage.all import *
Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
f = Psi.algebra_generators()
f
Lazy family (<lambda>(i))_{i in Positive integers}
f[1], f[2], f[3]
(Psi[1], Psi[2], Psi[3])

5.1. Comprehensive Module List 2339
**algebra_morphism** (*on_generators*, **keywords**)

Given a map defined on the generators of the multiplicative basis *self*, return the algebra morphism that extends this map to the whole algebra of non-commutative symmetric functions.

**INPUT:**
- *on_generators* – a function defined on the index set of the generators (that is, on the positive integers)
- *anti* – a boolean; defaults to False
- *category* – a category; defaults to None

**OUTPUT:**
- The algebra morphism of *self* which is defined by *on_generators* in the basis *self*. When *anti* is set to True, an algebra anti-morphism is computed instead of an algebra morphism.

**EXAMPLES:**

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi()
sage: double = lambda i: Psi[i,i]
sage: f = Psi.algebra_morphism(double, codomain = Psi)
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the...
→Rational Field in the Psi basis
sage: f(2*Psi[] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] + 3*Psi[1, 1, 3, 3, 2, 2] + Psi[2, 2, 4, 4]
sage: f.category()
Category of endsets of unital magmas and right modules over Rational...
→Field and left modules over Rational Field
```

When extra properties about the morphism are known, one can specify the category of which it is a morphism:

```python
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> Psi = NCSF.Psi()
>>> double = lambda i: Psi[i,i]
>>> f = Psi.algebra_morphism(double, codomain = Psi, category =...
→GradedHopfAlgebrasWithBasis(QQ))
>>> f
Generic endomorphism of Non-Commutative Symmetric Functions over the...
→Rational Field in the Psi basis
>>> f(Integer(2)*Psi[] + Integer(3) * Psi[1,Integer(1),Integer(3),
→Integer(2)] + Psi[Integer(2),Integer(4)])
2*Psi[] + 3*Psi[1, 1, 3, 3, 2, 2] + Psi[2, 2, 4, 4]
>>> f.category()
Category of endsets of unital magmas and right modules over Rational...
→Field and left modules over Rational Field
```

```python
sage: negate = lambda i: -Psi[i]
sage: f = Psi.algebra_morphism(negate, codomain = Psi, category =...
→GradedHopfAlgebrasWithBasis(QQ))
sage: f
Generic endomorphism of Non-Commutative Symmetric Functions over the...
→Rational Field in the Psi basis
sage: f(2*Psi[] + 3 * Psi[1,3,2] + Psi[2,4] )
2*Psi[] - 3*Psi[1, 1, 3, 2] + Psi[2, 2, 4, 4]
sage: f.category()
Category of endsets of Hopf algebras over Rational Field and graded...
→modules over Rational Field
```
antipode()

Return the antipode morphism on the basis self.

The antipode of $NSym$ is closely related to the omega involution; see omega_involution() for the latter.

OUTPUT:

• The antipode module map from non-commutative symmetric functions on basis self.

EXAMPLES:

sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the_˓→Rational Field in the Complete basis

>>> from sage.all import *
>>> S = NonCommutativeSymmetricFunctions(QQ).S()
>>> S.antipode
Generic endomorphism of Non-Commutative Symmetric Functions over the_˓→Rational Field in the Complete basis

5.1. Comprehensive Module List 2341
coproduct()

Return the coproduct morphism in the basis self.

OUTPUT:
• The coproduct module map from non-commutative symmetric functions on basis self.

EXAMPLES:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.coproduct
Generic morphism:
    From: Non-Commutative Symmetric Functions over the Rational Field in
    the Complete basis
    To:   Non-Commutative Symmetric Functions over the Rational Field in
    the Complete basis
```

product_on_basis(composition1, composition2)

Return the product of two basis elements from the multiplicative basis. Multiplication is just concatenation on compositions.

INPUT:
• composition1, composition2 – integer compositions

OUTPUT:
• The product of the two non-commutative symmetric functions indexed by composition1 and composition2 in the multiplicative basis self. This will be again a non-commutative symmetric function.

EXAMPLES:

```python
sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
sage: Psi[3,1,2] * Psi[4,2] == Psi[3,1,2,4,2]
True
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: S.product_on_basis(Composition([2,1]), Composition([1,2]))
S[2, 1, 1, 2]
```

to_symmetric_function()

Morphism to the algebra of symmetric functions.
This is constructed by extending the algebra morphism by the image of the generators.

OUTPUT:
• The module morphism from the basis \texttt{self} to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: S = N.complete()
sage: S.to_symmetric_function(S[1,3])
h[3, 1]
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function(Phi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function(Psi[1,3])
h[1, 1, 1, 1] - 3*h[2, 1, 1] + 3*h[3, 1]
```

```python
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> S = N.complete()
>>> S.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
>>> Phi = N.Phi()
>>> Phi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
>>> Psi = N.Psi()
>>> Psi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
```

\texttt{to\_symmetric\_function\_on\_generators}(i)

Morphism of the generators to symmetric functions.

This is constructed by coercion to the complete basis and applying the morphism.

OUTPUT:
• The module morphism from the basis \texttt{self} to the symmetric functions which corresponds to taking a commutative image.

EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = N.Phi()
sage: Phi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: Phi.to_symmetric_function_on_generators(0)
h[]
sage: Psi = N.Psi()
sage: Psi.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 3*h[2, 1] + 3*h[3]
sage: L = N.elementary()
sage: L.to_symmetric_function_on_generators(3)
h[1, 1, 1] - 2*h[2, 1] + h[3]
```

```python
>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = N.Phi()
>>> Phi.to_symmetric_function_on_generators(Integer(3))
```
super_categories()
Return the super categories of the category of multiplicative bases of the non-commutative symmetric
functions.
OUTPUT:
• list
class MultiplicativeBasesOnGroupLikeElements (parent_with_realization)
Bases: Category_realization_of_parent
Category of multiplicative bases on grouplike elements of non-commutative symmetric functions.
Here, a “multiplicative basis on grouplike elements” means a multiplicative basis whose generators
\((f_1, f_2, f_3, \ldots)\)
satisfy
\[
\Delta(f_i) = \sum_{j=0}^{i} f_j \otimes f_{i-j}
\]
with \(f_0 = 1\). (In other words, the generators are to form a divided power sequence in the sense of a coalgebra.)
This does not mean that the generators are grouplike, but means that the element \(1 + f_1 + f_2 + f_3 + \cdots\)
in the completion of the ring of non-commutative symmetric functions with respect to the grading is grouplike.
EXAMPLES:

```python
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative␣
˓→Symmetric Functions over the Rational Field

>>> from sage.all import *
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> N.MultiplicativeBasesOnGroupLikeElements()
Category of multiplicative bases on group like elements of Non-Commutative␣
˓→Symmetric Functions over the Rational Field
```

The complete basis is a multiplicative basis, but the ribbon basis is not:

```python
sage: N.Complete() in N.MultiplicativeBasesOnGroupLikeElements()
True
sage: N.Ribbon() in N.MultiplicativeBasesOnGroupLikeElements()
False
```
class ParentMethods

    Bases: object

antipode_on_basis(composition)

    Return the application of the antipode to a basis element.

    INPUT:
    • composition – a composition

    OUTPUT:
    • The image of the basis element indexed by composition under the antipode map.

    EXAMPLES:

    sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
    sage: S.antipode_on_basis(Composition([2,1]))
    -S[1, 1, 1] + S[1, 2]
    sage: S[1].antipode() # indirect doctest
    -S[1]
    sage: S[2].antipode() # indirect doctest
    S[1, 1] - S[2]
    sage: S[3].antipode() # indirect doctest
    -S[1, 1, 1] + S[1, 2] + S[2, 1] - S[3]
    sage: S[2, 3].coproduct().apply_multilinear_morphism(lambda be, ga: S(be)*S(ga).antipode())
    0
    sage: S[2, 3].coproduct().apply_multilinear_morphism(lambda be, ga: S(be).antipode()*S(ga))
    0

    >>> from sage.all import *
    >>> S = NonCommutativeSymmetricFunctions(QQ).complete()
    >>> S.antipode_on_basis(Composition([Integer(2),Integer(1)]))
    -S[1, 1, 1] + S[1, 2]
    >>> S[Integer(1)].antipode() # indirect doctest
    -S[1]
    >>> S[Integer(2)].antipode() # indirect doctest
    S[1, 1] - S[2]
    >>> S[Integer(3)].antipode() # indirect doctest
    -S[1, 1, 1] + S[1, 2] + S[2, 1] - S[3]
    >>> S[Integer(2),Integer(1)].coproduct().apply_multilinear_morphism(lambda be, ga: S(be)*S(ga).antipode())
    0
    >>> S[Integer(2),Integer(1)].coproduct().apply_multilinear_morphism(lambda be, ga: S(be).antipode()*S(ga))
    0

coproduct_on_generators(i)

    Return the image of the $i^{th}$ generator of the algebra under the coproduct.

    INPUT:
    • $i$ – a positive integer

    OUTPUT:
    • The result of applying the coproduct to the $i^{th}$ generator of self.

    EXAMPLES:

    sage: S = NonCommutativeSymmetricFunctions(QQ).complete()
    sage: S.coproduct_on_generators(3)

5.1. Comprehensive Module List
from sage.all import *
S = NonCommutativeSymmetricFunctions(QQ).complete()
S.coproduct_on_generators(Integer(3))

super_categories()

Return the super categories of the category of multiplicative bases of group-like elements of the
non-commutative symmetric functions.

OUTPUT:

• list

class MultiplicativeBasesOnPrimitiveElements (parent_with_realization)

Bases: Category_realization_of_parent

Category of multiplicative bases of the non-commutative symmetric functions whose generators are primitive elements.

An element $x$ of a bialgebra is primitive if $\Delta(x) = x \otimes 1 + 1 \otimes x$, where $\Delta$ is the coproduct of the bialgebra.

Given a multiplicative basis and knowing the coproducts and antipodes of its generators, one can compute the
coproduct and the antipode of any element, since they are respectively algebra morphisms and anti-morphisms.
See antipode_on_generators() and coproduct_on_generators().

Todo: this could be generalized to any free algebra.

EXAMPLES:

sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: N.MultiplicativeBasesOnPrimitiveElements()
Category of multiplicative bases on primitive elements of Non-Commutative…”

The Phi and Psi bases are multiplicative bases whose generators are primitive elements, but the complete and
ribbon bases are not:

class ParentMethods
    Bases: object

    antipode_on_generators(i)
    Return the image of a generator of a primitive basis of the non-commutative symmetric functions
    under the antipode map.
    
    INPUT:
    • i – a positive integer
    
    OUTPUT:
    • The image of the i-th generator of the multiplicative basis self under the antipode of the algebra
    of non-commutative symmetric functions.

    EXAMPLES:

    sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
    sage: Psi.antipode_on_generators(2)
    -Psi[2]

    >>> from sage.all import *
    >>> Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
    >>> Psi.antipode_on_generators(Integer(2))
    -Psi[2]

    coproduct_on_generators(i)
    Return the image of the i-th generator of the multiplicative basis self under the coproduct.
    
    INPUT:
    • i – a positive integer
    
    OUTPUT:
    • The result of applying the coproduct to the i-th generator of self.

    EXAMPLES:

    sage: Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
    sage: Psi.coproduct_on_generators(3)

    >>> from sage.all import *
    >>> Psi = NonCommutativeSymmetricFunctions(QQ).Psi()
    >>> Psi.coproduct_on_generators(Integer(3))

    super_categories()
    Return the super categories of the category of multiplicative bases of primitive elements of the
    non-commutative symmetric functions.
    
    OUTPUT:
    • list

class Phi(NCSF)
    Bases: CombinatorialFreeModule, BindableClass

5.1. Comprehensive Module List
The Hopf algebra of non-commutative symmetric functions in the Phi basis.

The Phi basis is defined in Definition 3.4 of \([NCSF1]\), where it is denoted by \((\Phi^I)_I\). It is a multiplicative basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions by the following relation: Define a non-commutative symmetric function \(\Phi^n\) for every positive integer \(n\) by the power series identity

\[
\sum_{k \geq 1} t^k \frac{1}{k} \Phi_k = -\log \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right),
\]

with \(\Lambda_0\) denoting 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(\Phi^{(i_1, i_2, \ldots, i_k)} = \Phi_{i_1} \Phi_{i_2} \cdots \Phi_{i_k}\).

The Phi basis is well-defined only when the base ring is a \(\mathbb{Q}\)-algebra. The elements of the Phi basis are known as the “power-sum non-commutative symmetric functions of the second kind”.

The generators \(\Phi_n\) are related to the (first) Eulerian idempotents in the descent algebras of the symmetric groups (see \([NCSF1]\), 5.4 for details).

**EXAMPLES:**

```
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
sage: Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

```
>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NCSF.Phi(); Phi
Non-Commutative Symmetric Functions over the Rational Field in the Phi basis
>>> Phi.an_element()
2*Phi[] + 2*Phi[1] + 3*Phi[1, 1]
```

class Element

Bases: `IndexedFreeModuleElement`

```
psi_involution()
Return the image of the noncommutative symmetric function \(\text{self}\) under the involution \(\psi\).

The involution \(\psi\) is defined as the linear map \(NCSF \rightarrow NCSF\) which, for every composition \(I\), sends the complete noncommutative symmetric function \(S^I\) to the elementary noncommutative symmetric function \(\Lambda^I\). It can be shown that every composition \(I\) satisfies

\[
\psi(R_I) = R_{I^c}, \quad \psi(S^I) = \Lambda^I, \quad \psi(\Lambda^I) = S^I, \quad \psi(\Phi^I) = (-1)^{|I| - \ell(I)} \Phi^I
\]

where \(I^c\) denotes the complement of the composition \(I\), and \(\ell(I)\) denotes the length of \(I\), and where standard notations for classical bases of \(NCSF\) are being used (\(S\) for the complete basis, \(\Lambda\) for the elementary basis, \(\Phi\) for the basis of the power sums of the second kind, and \(R\) for the ribbon basis).

The map \(\psi\) is an involution and a graded Hopf algebra automorphism of \(NCSF\). If \(\pi\) denotes the projection from \(NCSF\) to the ring of symmetric functions (\(\text{to_symmetric_function()}\)), then \(\pi(\psi(f)) = \omega(\pi(f))\) for every \(f \in NCSF\), where the \(\omega\) on the right hand side denotes the omega automorphism of \(Sym\).

The involution \(\psi\) of \(NCSF\) is adjoint to the involution \(\psi\) of \(QSym\) by the standard adjunction between \(NCSF\) and \(QSym\).

The involution \(\psi\) has been denoted by \(\psi\) in \([LMvW13]\), section 3.6.
See also:

*psi involution of NCSF*, *psi involution of QSym*, *star involution of NCSF*.

**EXAMPLES:**

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,2].psi_involution()  # -Phi[3, 2]
sage: Phi[2,2].psi_involution()  # Phi[2, 2]
sage: Phi[[[]]].psi_involution() # Phi[

sage: Phi(0).psi_involution()  # 0
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NSym.Phi()
>>> Phi[3,2].psi_involution()  # -Phi[3, 2]
>>> Phi[2,2].psi_involution()  # Phi[2, 2]
>>> Phi[[[]]].psi_involution() # Phi[

>>> Phi(0).psi_involution()  # 0
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the ribbon basis:

```python
sage: R = NSym.R()
sage: all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution() 
      ....: for I in Compositions(4) )
True
```

```python
>>> from sage.all import *
>>> R = NSym.R()

>>> all( R(Phi[I].psi_involution()) == R(Phi[I]).psi_involution() 
      ... for I in Compositions(Integer(4)) )
True
```

**star_involution()**

Return the image of the noncommutative symmetric function self under the star involution.

The star involution is defined as the algebra antihomomorphism \( NCSF \rightarrow NCSF \) which, for every positive integer \( n \), sends the \( n \)-th complete non-commutative symmetric function \( S_n \) to \( S_n \).

Denoting by \( f^* \) the image of an element \( f \in NCSF \) under this star involution, it can be shown that every composition \( I \) satisfies

\[
(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R^I_j = R^{I^r}_j, \quad (\Phi^I)^* = \Phi^{I^r},
\]
where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $NCSF$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $NCSF$. It is an automorphism of the graded vector space $NCSF$. Under the canonical isomorphism between the $n$-th graded component of $NCSF$ and the descent algebra of the symmetric group $S_n$ (see `to_descent_algebra()`), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $NCSF$ to the ring of symmetric functions (`to_symmetric_function()`), then $\pi(f^*) = \pi(f)$ for every $f \in NCSF$.

The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

- star involution of NCSF
- psi involution of NCSF
- star involution of QSym.

EXAMPLES:

```python
sage: NSym = NonCommutativeSymmetricFunctions(QQ)
sage: Phi = NSym.Phi()
sage: Phi[3,1,1,4].star_involution()
 Phi[4, 1, 1, 3]
sage: Phi[4,2,1].star_involution()
 Phi[1, 2, 4]
sage: (Phi[3,3] + 3*Phi[1]).star_involution()
 3*Phi[1] + Phi[3, 3]
sage: Phi[[2,1]].star_involution()
 Phi[1, 2]
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(QQ)
>>> Phi = NSym.Phi()
>>> Phi[3,1,1,4].star_involution()
 Phi[4, 1, 1, 3]
>>> Phi[4,2,1].star_involution()
 Phi[1, 2, 4]
>>> (Phi[3,3] + 3*Phi[1]).star_involution()
 3*Phi[1] + Phi[3, 3]
>>> Phi[[2,1]].star_involution()
 Phi[1, 2]
```

The implementation at hand is tailored to the Phi basis. It is equivalent to the generic implementation via the complete basis:
verschiebung \((n)\)

Return the image of the noncommutative symmetric function \(self\) under the \(n\)-th Verschiebung operator.

The \(n\)-th Verschiebung operator \(V_n\) is defined to be the map from the \(k\)-algebra of noncommutative symmetric functions to itself that sends the complete function \(S^I\) indexed by a composition \(I = (i_1, i_2, \ldots, i_k)\) to \(S^{(i_1/n, i_2/n, \ldots, i_k/n)}\) if all of the numbers \(i_1, i_2, \ldots, i_k\) are divisible by \(n\), and to 0 otherwise. This operator \(V_n\) is a Hopf algebra endomorphism. For every positive integer \(r\) with \(n \mid r\), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-n/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}
\]

(where \(S_r\) denotes the \(r\)-th complete non-commutative symmetric function, \(\Lambda_r\) denotes the \(r\)-th elementary non-commutative symmetric function, \(\Psi_r\) denotes the \(r\)-th power-sum non-commutative symmetric function of the first kind, and \(\Phi_r\) denotes the \(r\)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \(r\) with \(n \nmid r\), it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The \(n\)-th Verschiebung operator is also called the \(n\)-th Verschiebung endomorphism.

It is a lift of the \(n\)-th Verschiebung operator on the ring of symmetric functions \((\text{verschiebung}(n))\) to the ring of noncommutative symmetric functions.

The action of the \(n\)-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition \(I\) of size \(n\ell\) satisfies

\[
V_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n},
\]

where \(J\) denotes the meet of the compositions \(I\) and \((n, n, \ldots, n)\), where \(\ell(I)\) is the length of \(I\), and \(|I|/n\) times

where \(J/n\) denotes the composition obtained by dividing every entry of \(J\) by \(n\). For a composition \(I\) of size not divisible by \(n\), we have \(V_n(R_I) = 0\).

See also:

\texttt{verschiebung method of NCSF, adams\_operator method of QSym, verschiebung method of Sym}

INPUT:

- \(n\) – a positive integer

OUTPUT:

The result of applying the \(n\)-th Verschiebung operator (on the ring of noncommutative symmetric functions) to \(self\).

EXAMPLES:
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: Phi = NSym.Phi()
sage: Phi([4,2]).verschiebung(2)

>>> Phi([Integer(1), Integer(2), Integer(3), Integer(1)]).verschiebung(Integer(5))
(continues on next page)
class Psi(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the Psi basis.

The Psi basis is defined in Definition 3.4 of [NCSF1], where it is denoted by \((\Psi^I)_I\). It is a multiplicative
basis, and is connected to the elementary generators \(\Lambda_i\) of the ring of non-commutative symmetric functions
by the following relation: Define a non-commutative symmetric function \(\Psi_n\) for every positive integer \(n\) by
the power series identity

\[
\frac{d}{dt} \sigma(t) = \sigma(t) \cdot \left( \sum_{k \geq 1} t^{k-1} \Psi_k \right),
\]

where

\[
\sigma(t) = \left( \sum_{k \geq 0} (-t)^k \Lambda_k \right)^{-1}
\]

and where \(\Lambda_0\) denotes 1. For every composition \((i_1, i_2, \ldots, i_k)\), we have \(\Psi^{(i_1, i_2, \ldots, i_k)} = \Psi_{i_1} \Psi_{i_2} \cdots \Psi_{i_k}\).

The \(\Psi\)-basis is a basis only when the base ring is a \(\mathbb{Q}\)-algebra (although the \(\Psi^I\) can be defined over any base
ring). The elements of the \(\Psi\)-basis are known as the “power-sum non-commutative symmetric functions of
the first kind”. The generators \(\Psi_n\) correspond to the Dynkin (quasi-)idempotents in the descent algebras of
the symmetric groups (see [NCSF1], 5.2 for details).

Another (equivalent) definition of \(\Psi_n\) is

\[
\Psi_n = \sum_{i=0}^{n-1} (-1)^i R_{1^i, n-i},
\]

where \(R\) denotes the ribbon basis of \(NCSF\), and where \(1^i\) stands for \(i\) repetitions of the integer 1.

EXAMPLES:

```python
sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = NCSF.Psi(); Psi
Non-Commutative Symmetric Functions over the Rational Field in the Psi basis
sage: Psi.an_element()
2*Psi[] + 2*Psi[1] + 3*Psi[1, 1]
```

Checking the equivalent definition of \(\Psi_n\):
sage: def test_psi(n):
....:     NCSF = NonCommutativeSymmetricFunctions(ZZ)
....:     R = NCSF.R()
....:     Psi = NCSF.Psi()
....:     a = R.sum([-1 ** i * R[[1]*i + [n-i]]
....:                 for i in range(n)])
....:     return a == R(Psi[n])

sage: test_psi(2)
True
sage: test_psi(3)
True
sage: test_psi(4)
True

>>> from sage.all import *

>>> def test_psi(n):
...     NCSF = NonCommutativeSymmetricFunctions(ZZ)
...     R = NCSF.R()
...     Psi = NCSF.Psi()
...     a = R.sum([-Integer(1) ** i * R[[Integer(1)]*i + [n-i]]
...                 for i in range(n)])
...     return a == R(Psi[n])

>>> test_psi(Integer(2))
True
>>> test_psi(Integer(3))
True
>>> test_psi(Integer(4))
True

class Element

    Bases: IndexedFreeModuleElement

    verschiebung(n)

    Return the image of the noncommutative symmetric function self under the n-th Verschiebung operator.

    The n-th Verschiebung operator \( V_n \) is defined to be the map from the \( k \)-algebra of noncommutative symmetric functions to itself that sends the complete function \( S^f \) indexed by a composition \( f = (i_1, i_2, \ldots, i_k) \) to \( S^{(i_1/n, i_2/n, \ldots, i_k/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \), and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(S_r) = S_r/n, \quad V_n(\Lambda_r) = (-1)^{r-n} n^{r/n} \Lambda_r/n, \quad V_n(\Psi_r) = n \Psi_r/n, \quad V_n(\Phi_r) = n \Phi_r/n
\]

(where \( S_r \) denotes the \( r \)-th complete non-commutative symmetric function, \( \Lambda_r \) denotes the \( r \)-th elementary non-commutative symmetric function, \( \Psi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the first kind, and \( \Phi_r \) denotes the \( r \)-th power-sum non-commutative symmetric function of the second kind). For every positive integer \( r \) with \( n \nmid r \), it satisfies

\[
V_n(S_r) = V_n(\Lambda_r) = V_n(\Psi_r) = V_n(\Phi_r) = 0.
\]

The \( n \)-th Verschiebung operator is also called the \( n \)-th Verschiebung endomorphism.

It is a lift of the \( n \)-th Verschiebung operator on the ring of symmetric functions \( \text{verschiebung()} \) to the ring of noncommutative symmetric functions.
The action of the $n$-th Verschiebung operator can also be described on the ribbon Schur functions. Namely, every composition $I$ of size $n\ell$ satisfies
\[ V_n(R_I) = (-1)^{\ell(I)-\ell(J)} \cdot R_{J/n}, \]
where $J$ denotes the meet of the compositions $I$ and $(n, n, \ldots, n)$, where $\ell(I)$ is the length of $I$, and where $J/n$ denotes the composition obtained by dividing every entry of $J$ by $n$. For a composition $I$ of size not divisible by $n$, we have $V_n(R_I) = 0$.

See also:

verschiebung method of NCSF, adams_operator method of QSym, verschiebung method of Sym

INPUT:

• $n$ – a positive integer

OUTPUT:

The result of applying the $n$-th Verschiebung operator (on the ring of noncommutative symmetric functions) to self.

EXAMPLES:

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
sage: Psi = NSym.Psi()
sage: Psi([4,2]).verschiebung(2) 4*Psi[2, 1]
sage: Psi([2,4]).verschiebung(2) 4*Psi[1, 2]

sage: Psi([5, 1]).verschiebung(3) 0
sage: Psi([5, 1]).verschiebung(6) 0
sage: Psi([5, 1]).verschiebung(2) 0
sage: Psi([1, 2, 3, 1]).verschiebung(7) 0
sage: Psi([7]).verschiebung(7) 7*Psi[1]
sage: Psi([1, 2, 3, 1]).verschiebung(5) 0
```

```python
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> Psi = NSym.Psi()
>>> Psi([Integer(4),Integer(2)]).verschiebung(Integer(2))
4*Psi[2, 1]
```
internal_product_on_basis_by_bracketing(I, J)

The internal product of two elements of the Psi basis.

See internal_product() for a thorough documentation of this operation.

This is an implementation using [NCSF2] Lemma 3.10. It is fast when the length of $I$ is small, but can get very slow otherwise. Therefore it is not being used by default for internally multiplying Psi functions.

INPUT:
• $I, J$ – compositions

OUTPUT:
• The internal product of the elements of the Psi basis of $NSym$ indexed by $I$ and $J$, expressed in the Psi basis.

AUTHORS:
• Travis Scrimshaw, 29 Mar 2014

EXAMPLES:

```
sage: N = NonCommutativeSymmetricFunctions(QQ)
sage: Psi = N.Psi()
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1],[2,1,1])
4*Psi[1, 2, 1]
sage: Psi.internal_product_on_basis_by_bracketing([2,1,1],[1,2,1])
4*Psi[2, 1, 1]
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [1,1,1,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([3,1], [1,2,1])
-Psi[1, 2, 1] + Psi[2, 1, 1]
```
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: Psi.internal_product_on_basis_by_bracketing([1,2,1], [3,1])
0
sage: Psi.internal_product_on_basis_by_bracketing([2,2],[1,2])
0
sage: Psi.internal_product_on_basis_by_bracketing([4], [1,2,1])
-Psi[1, 1, 2] + 2*Psi[1, 2, 1] - Psi[2, 1, 1]
```

>>> from sage.all import *

```python
>>> N = NonCommutativeSymmetricFunctions(QQ)
>>> Psi = N.Psi()
>>> Psi.internal_product_on_basis_by_bracketing([Integer(2),Integer(2)],
   ...  [Integer(1),Integer(2),Integer(1)])
0
>>> Psi.internal_product_on_basis_by_bracketing([Integer(1),Integer(2),
   ...  Integer(1)], [Integer(2),Integer(1),Integer(1)])
4*Psi[1, 2, 1]
>>> Psi.internal_product_on_basis_by_bracketing([Integer(2),Integer(1),
   ...  Integer(1)], [Integer(1),Integer(2),Integer(1)])
4*Psi[2, 1, 1]
>>> Psi.internal_product_on_basis_by_bracketing([Integer(1),Integer(2),
   ...  Integer(1)], [Integer(1),Integer(1),Integer(1)])
0
```

R

alias of `Ribbon`

class Ribbon(NCSF)

| Bases: `CombinatorialFreeModule, BindableClass`

The Hopf algebra of non-commutative symmetric functions in the Ribbon basis.

The Ribbon basis is defined in Definition 3.12 of [NCSF1], where it is denoted by \((R_I)_I\). It is connected to the complete basis of the ring of non-commutative symmetric functions by the following relation: For every composition \(I\), we have

\[
R_I = \sum_J (-1)^{\ell(I)-\ell(J)} S^J,
\]

where the sum is over all compositions \(J\) which are coarser than \(I\) and \(\ell(I)\) denotes the length of \(I\). (See the proof of Proposition 4.13 in [NCSF1].)

The elements of the Ribbon basis are commonly referred to as the ribbon Schur functions.

EXAMPLES:
The following are aliases for this basis:

```python
sage: NCSF.ribbon()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon→basis
```

```python
sage: NCSF.R()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon→basis
```

**class Element**

Bases: `IndexedFreeModuleElement`

**star_involution()**

Return the image of the noncommutative symmetric function `self` under the star involution.

The star involution is defined as the algebra antihomomorphism $\text{NCSF} \rightarrow \text{NCSF}$ which, for every positive integer $n$, sends the $n$-th complete non-commutative symmetric function $S_n$ to $S_n$. Denoting by $f^*$ the image of an element $f \in \text{NCSF}$ under this star involution, it can be shown that every composition $I$ satisfies

$$(S^I)^* = S^{I^r}, \quad (\Lambda^I)^* = \Lambda^{I^r}, \quad R^I_j = R_{I^r}, \quad (\Phi^I)^* = \Phi^{I^r},$$

where $I^r$ denotes the reversed composition of $I$, and standard notations for classical bases of $\text{NCSF}$ are being used ($S$ for the complete basis, $\Lambda$ for the elementary basis, $R$ for the ribbon basis, and $\Phi$ for that of the power-sums of the second kind). The star involution is an involution and a coalgebra automorphism of $\text{NCSF}$. It is an automorphism of the graded vector space $\text{NCSF}$. Under the canonical isomorphism between the $n$-th graded component of $\text{NCSF}$ and the descent algebra of the symmetric group $S_n$ (see `to_descent_algebra()`), the star involution (restricted to the $n$-th graded component) corresponds to the automorphism of the descent algebra given by $x \mapsto \omega_n x \omega_n$, where $\omega_n$ is the permutation $(n, n-1, \ldots, 1) \in S_n$ (written here in one-line notation). If $\pi$ denotes the projection from $\text{NCSF}$ to the ring of symmetric functions (to_symmetric_function()), then $\pi(f^*) = \pi(f)$ for every $f \in \text{NCSF}$. 

2358 Chapter 5. Comprehensive Module List
The star involution on $NCSF$ is adjoint to the star involution on $QSym$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6. See [NCSF2], section 2.3 for the properties of this map.

See also:

\textit{star involution of NCSF, star involution of QSym, psi involution of NCSF.}

**EXAMPLES:**

```
sage: NSym = NonCommutativeSymmetricFunctions(ZZ)
```
```
sage: R = NSym.R()
```
```
sage: R[3,1,4,2].star_involution()
R[2, 4, 1, 3]
```
```
sage: R[4,1,2].star_involution()
R[2, 1, 4]
```
```
```
```
sage: (R[3,3] - 21*R[1]).star_involution()
-21*R[1] + R[3, 3]
```
```
sage: R([14,1]).star_involution()
R[1, 14]
```

The implementation at hand is tailored to the ribbon basis. It is equivalent to the generic implementation via the complete basis:

```
sage: S = NSym.S()
```
```
sage: all( S(R[I].star_involution()) == S(R[I]).star_involution()
.... for I in Compositions(4) )
True
```

\textit{verschiebung ($n$)}

Return the image of the noncommutative symmetric function \texttt{self} under the $n$-th Verschiebung
The \( n \)-th Verschiebung operator \( V_n \) is defined to be the map from the \( k \)-algebra of noncommutative symmetric functions to itself that sends the complete function \( S_I \) indexed by a composition \( I = (i_1, i_2, \ldots, i_k) \) to \( S_{(i_1/n, i_2/n, \ldots, i_k/n)} \) if all of the numbers \( i_1, i_2, \ldots, i_k \) are divisible by \( n \), and to 0 otherwise. This operator \( V_n \) is a Hopf algebra endomorphism. For every positive integer \( r \) with \( n \mid r \), it satisfies

\[
V_n(S_r) = S_{r/n}, \quad V_n(\Lambda_r) = (-1)^{r-r/n} \Lambda_{r/n}, \quad V_n(\Psi_r) = n \Psi_{r/n}, \quad V_n(\Phi_r) = n \Phi_{r/n}
\]

(continued on next page)
\begin{verbatim}
>>> from sage.all import *
>>> NSym = NonCommutativeSymmetricFunctions(ZZ)
>>> R = NSym.R()
>>> R([4,2]).verschiebung(2)
-R[2, 1]
>>> R([2,1]).verschiebung(3)
-R[1]
>>> R([3]).verschiebung(2)
0
>>> R([]).verschiebung(2)
R[]
>>> R([5,1]).verschiebung(2)
-R[3]
>>> R([1,2,3,1]).verschiebung(7)
-R[1]
>>> R([1,2,3,1]).verschiebung(5)
0
\end{verbatim}

antipode_on_basis \texttt{(composition)}

Return the application of the antipode to a basis element of the ribbon basis self.

INPUT:

\begin{itemize}
\item composition \texttt{--} a composition
\end{itemize}

OUTPUT:

\begin{itemize}
\item The image of the basis element indexed by composition under the antipode map.
\end{itemize}

EXAMPLES:

\begin{verbatim}
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.antipode_on_basis(Composition([2,1]))
-R[2, 1]
sage: R[3,1].antipode() # indirect doctest
R[2, 1, 1]
sage: R[].antipode() # indirect doctest
R[]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> R = NonCommutativeSymmetricFunctions(QQ).ribbon()
\end{verbatim}
We check that the implementation of the antipode at hand does not contradict the generic one:

```python
sage: S = NonCommutativeSymmetricFunctions(QQ).S()
sage: all( S(R[I].antipode()) == S(R[I]).antipode()
....:   for I in Compositions(4) )
True
```

The `dual()` method returns the dual basis to the ribbon basis of the non-commutative symmetric functions. This is the Fundamental basis of the quasi-symmetric functions.

**OUTPUT:**
- The fundamental basis of the quasi-symmetric functions.

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R.dual()
Quasisymmetric functions over the Rational Field in the Fundamental basis
```

The `product_on_basis(I,J)` method returns the product of two ribbon basis elements of the non-commutative symmetric functions.

**INPUT:**
- I, J – compositions

**OUTPUT:**
- The product of the ribbon functions indexed by I and J.

**EXAMPLES:**

```python
sage: R = NonCommutativeSymmetricFunctions(QQ).ribbon()
sage: R[1,2,1] * R[3,1]
R[1, 2, 1, 3, 1] + R[1, 2, 4, 1]
```
to_symmetric_function_on_basis()

Return the commutative image of a ribbon basis element of the non-commutative symmetric functions.

INPUT:
• I — a composition

OUTPUT:
• The commutative image of the ribbon basis element indexed by I. This will be expressed as a symmetric function in the Schur basis.

EXAMPLES:

```
sage: R = NonCommutativeSymmetricFunctions(QQ).R()
sage: R.to_symmetric_function_on_basis(Composition([3,1,1]))
s[3, 1, 1]
sage: R.to_symmetric_function_on_basis(Composition([4,2,1]))
s[4, 2, 1] + s[5, 1, 1] + s[5, 2]
sage: R.to_symmetric_function_on_basis(Composition([]))
s[]
```

S
alias of Complete

ZL
alias of Zassenhaus_left

ZR
alias of Zassenhaus_right

class Zassenhaus_left(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the left Zassenhaus basis.

This basis is the left-version of the basis defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with $Z_n$ defined as the element of $NCSF$, satisfying the equation

$$ \sigma_1 = \cdots \exp(Z_n) \cdots \exp(Z_2) \exp(Z_1), $$

where

$$ \sigma_1 = \sum_{n \geq 0} S_n. $$
It can be recursively computed by the formula
\[
S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)!m_2(\lambda)!m_3(\lambda)! \cdots} Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots
\]
for all \( n \geq 0 \).

**class Zassenhaus_right (NCSF)**

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of non-commutative symmetric functions in the right Zassenhaus basis.

This basis is defined in Section 2.5.1 of [HLNT09]. It is multiplicative, with \( Z_n \) defined as the element of \( NCSF_n \) satisfying the equation
\[
\sigma_1 = \exp(Z_1) \exp(Z_2) \exp(Z_3) \cdots \exp(Z_n) \cdots
\]
where
\[
\sigma_1 = \sum_{n \geq 0} S_n.
\]

It can be recursively computed by the formula
\[
S_n = \sum_{\lambda \vdash n} \frac{1}{m_1(\lambda)!m_2(\lambda)!m_3(\lambda)! \cdots} Z_{\lambda_1} Z_{\lambda_2} Z_{\lambda_3} \cdots
\]
for all \( n \geq 0 \).

Note that there is a variant (called the “noncommutative power sum symmetric functions of the third kind”) in Definition 5.26 of [NCSF2] that satisfies:
\[
\sigma_1 = \exp(Z_1) \exp(Z_2/2) \exp(Z_3/3) \cdots \exp(Z_n/n) \cdots.
\]

**a_realization()**

Gives a realization of the algebra of non-commutative symmetric functions. This particular realization is the complete basis of non-commutative symmetric functions.

**OUTPUT:**
- The realization of the non-commutative symmetric functions in the complete basis.

**EXAMPLES:**
```
sage: NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete___
˓→basis
```

```
>>> from sage.all import *
>>> NonCommutativeSymmetricFunctions(ZZ).a_realization()
Non-Commutative Symmetric Functions over the Integer Ring in the Complete___
˓→basis
```

**complete**
- alias of *Complete*

**dQs**
- alias of *dualQuasisymmetric_Schur*
dYQS

alias of dualYoungQuasisymmetric_Schur
dual()

Return the dual to the non-commutative symmetric functions.

OUTPUT:

• The dual of the non-commutative symmetric functions over a ring. This is the algebra of quasi-symmetric functions over the ring.

EXAMPLES:

sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: NCSF.dual()
Quasisymmetric functions over the Rational Field

>>> from sage.all import *
>>> NCSF = NonCommutativeSymmetricFunctions(QQ)
>>> NCSF.dual()
Quasisymmetric functions over the Rational Field

class dualQuasisymmetric_Schur(NCSF)

Bases: CombinatorialFreeModule, BindableClass

The basis of NCSF dual to the Quasisymmetric-Schur basis of QSym.

The Quasisymmetric_Schur functions are defined in [QSCHUR] (see also Definition 5.1.1 of [LMvW13]). The dual basis in the algebra of non-commutative symmetric functions is defined by the following formula:

$$ R_{\alpha} = \sum_{T} dQS_{\text{shape}(T)}, $$

where the sum is over all standard composition tableaux with descent composition equal to \( \alpha \). The Quasisymmetric_Schur basis \( QS_{\alpha} \) has the property that

$$ s_{\lambda} = \sum_{\text{sort}(\alpha) = \lambda} QS_{\alpha}. $$

As a consequence the commutative image of a dual Quasisymmetric-Schur element in the algebra of symmetric functions (the map defined in the method to_symmetric_function()) is equal to the Schur function indexed by the decreasing sort of the indexing composition.

See also:

CompositionTableaux, CompositionTableau.

EXAMPLES:

sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dQS = NCSF.d QS()
sage: dQS([1,3,2])*dQS([1])
dQS[1, 2, 4] + dQS[1, 3, 2, 1] + dQS[1, 3, 3] + dQS[2, 2, 2]
sage: dQS([1])*dQS([1,3,2])
dQS[1, 1, 3, 2] + dQS[1, 3, 3] + dQS[2, 4, 2] + dQS[2, 3, 2]
sage: dQS([1,3])*dQS([1,1])
sage: dQS([3,1])*dQS([2,1])

(continues on next page)
sage: dQS([1, 1]).coproduct()
sage: dQS([3, 3]).coproduct().monomial_coefficients()[\(\text{Composition}([1, 2])\)]
\(-1\)
sage: S = NCSF.complete()
sage: S(dQS([1, 3, 1]))
sage: S(dQS([1, 3, 1]))
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dQS([2, 1, 3])).to_symmetric_function())
s[3, 2, 1]

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the Quasisymmetric_Schur basis of QSym.

OUTPUT:
• the Quasisymmetric-Schur basis of the quasi-symmetric functions

EXAMPLES:
sage: dQS=NonCommutativeSymmetricFunctions(QQ).dualQuasisymmetric_Schur()
sage: dQS.dual()
Quasisymmetric functions over the Rational Field in the Quasisymmetric Schur basis
sage: dQS.duality_pairing_matrix(dQS.dual(), 3)

(continues on next page)
from sage.all import *

dQS = NonCommutativeSymmetricFunctions(QQ).dualQuasisymmetric_Schur()
dQS.dual()
Quasisymmetric functions over the Rational Field in the Quasisymmetric Schur basis
dQS.duality_pairing_matrix(dQS.dual(), Integer(3))

\[
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

to_symmetric_function_on_basis(I)
The commutative image of a dual quasi-symmetric Schur element
The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:
• I - a composition

OUTPUT:
• The commutative image of the dual quasi-Schur basis element indexed by I. The result is the Schur symmetric function indexed by the partition obtained by sorting I.

EXAMPLES:

sage: dQS = NonCommutativeSymmetricFunctions(QQ).dQS()
sage: dQS.to_symmetric_function_on_basis([2, 1, 3])
s[3, 2, 1]
sage: dQS.to_symmetric_function_on_basis([])
s[]

class dualYoungQuasisymmetric_Schur(NCSF)
Bases: CombinatorialFreeModule, BindableClass
The basis of NCSF dual to the Young Quasisymmetric-Schur basis of QSym.

The YoungQuasisymmetric_Schur functions are given in Definition 5.2.1 of [LMvW13]. The dual basis in the algebra of non-commutative symmetric functions are related by an involution reversing the indexing composition of the complete expansion of a quasi-Schur basis element. This basis has many of the same properties as the Quasisymmetric Schur basis and is related to that basis by an algebraic transformation.

EXAMPLES:

sage: NCSF = NonCommutativeSymmetricFunctions(QQ)
sage: dYQS = NCSF.dYQS()
sage: dYQS([1, 3, 2]) * dYQS([1])
sage: dYQS([1]) * dYQS([1, 3, 2])
sage: dYQS([1, 3]) * dYQS([1, 1])
sage: dYQS([3, 1]) * dYQS([2, 1])
sage: dYQS([1, 1]).coproduct()
sage: dYQS([3, 3]).coproduct().monomial_coefficients()[(Composition([1, 2]),
Composition([2, 1]))] 1
sage: S = NCSF.complete()
sage: dYQS(S[1, 3, 1])
sage: S(dYQS[1, 3, 1])
sage: s = SymmetricFunctions(QQ).s()
sage: s(S(dYQS([2, 1, 3])).to_symmetric_function())
s[3, 2, 1]

The dual basis to the dual Quasisymmetric-Schur basis of NCSF.

The basis returned is the Quasisymmetric_Schur basis of QSym.
OUTPUT:
- the Young Quasisymmetric-Schur basis of quasi-symmetric functions

EXAMPLES:

```sage
dYQS=NonCommutativeSymmetricFunctions(QQ).dualYoungQuasisymmetricSchur()
sage: dYQS.dual()
Quasisymmetric functions over the Rational Field in the Young Quasisymmetric Schur basis
sage: dYQS.duality_pairing_matrix(dYQS.dual(),3)
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
```

```python
>>> from sage.all import *
>>> dYQS=NonCommutativeSymmetricFunctions(QQ).dualYoungQuasisymmetricSchur()
>>> dYQS.dual()
Quasisymmetric functions over the Rational Field in the Young Quasisymmetric Schur basis
>>> dYQS.duality_pairing_matrix(dYQS.dual(),Integer(3))
\begin{bmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{bmatrix}
```

to_symmetric_function_on_basis()

The commutative image of a dual Young quasi-symmetric Schur element.

The commutative image of a basis element is obtained by sorting the indexing composition of the basis element.

INPUT:
- \( I \) - a composition

OUTPUT:
- The commutative image of the dual Young quasi-Schur basis element indexed by \( I \). The result is the Schur symmetric function indexed by the partition obtained by sorting \( I \).

EXAMPLES:

```sage
dYQS=NonCommutativeSymmetricFunctions(QQ).dYQS()
sage: dYQS.to_symmetric_function_on_basis([2,1,3])
s[3, 2, 1]
sage: dYQS.to_symmetric_function_on_basis([])
s[]
```

```python
>>> from sage.all import *
>>> dYQS=NonCommutativeSymmetricFunctions(QQ).dYQS()
>>> dYQS.to_symmetric_function_on_basis([Integer(2),Integer(1),Integer(3)])
s[3, 2, 1]
>>> dYQS.to_symmetric_function_on_basis([])
s[]
```

class sage.combinat.ncsf_qsym.qsym.QuasiSymmetricFunctions(R)
Bases: UniqueRepresentation, Parent

The Hopf algebra of quasisymmetric functions.

Let $R$ be a commutative ring with unity. The $R$-algebra of quasi-symmetric functions may be realized as an $R$-subalgebra of the ring of power series in countably many variables $R[[x_1, x_2, x_3, \ldots]]$. It consists of those formal power series $p$ which are degree-bounded (i.e., the degrees of all monomials occurring with nonzero coefficient in $p$ are bounded from above, although the bound can depend on $p$) and satisfy the following condition: For every tuple $(a_1, a_2, \ldots, a_m)$ of positive integers, the coefficient of the monomial $x_1^{a_1}x_2^{a_2} \cdots x_m^{a_m}$ in $p$ is the same for all strictly increasing sequences $(i_1 < i_2 < \cdots < i_m)$ of positive integers. (In other words, the coefficient of a monomial in $p$ depends only on the sequence of nonzero exponents in the monomial. If “sequence” were to be replaced by “multiset” here, we would obtain the definition of a symmetric function.)

The $R$-algebra of quasi-symmetric functions is commonly called $QSym_R$ or occasionally just $QSym$ (when $R$ is clear from the context or $Z$ or $Q$). It is graded by the total degree of the power series. Its homogeneous elements of degree $k$ form a free $R$-submodule of rank equal to the number of compositions of $k$ (that is, $2^{k-1}$ if $k \geq 1$, else 1).

The two classical bases of $QSym$, the monomial basis $(M_I)_I$ and the fundamental basis $(F_I)_I$, are indexed by compositions $I = (I_1, I_2, \cdots, I_\ell)$ and defined by the formulas:

$$M_I = \sum_{1 \leq i_1 < i_2 < \cdots < i_\ell} x_1^{I_1}x_2^{I_2} \cdots x_\ell^{I_\ell}$$

and

$$F_I = \sum_{(j_1, j_2, \ldots, j_n)} x_{j_1}x_{j_2} \cdots x_{j_n}$$

where in the second equation the sum runs over all weakly increasing $n$-tuples $(j_1, j_2, \ldots, j_n)$ of positive integers (where $n$ is the size of $I$) which increase strictly from $j_r$ to $j_{r+1}$ if $r$ is a descent of the composition $I$.

These bases are related by the formula
\[ F_I = \sum_{J \leq I} M_J \]

where the inequality \( J \leq I \) indicates that \( J \) is finer than \( I \).

The \( R \)-algebra of quasi-symmetric functions is a Hopf algebra, with the coproduct satisfying

\[ \Delta M_I = \sum_{k=0}^\ell M_{(I_1, I_2, \ldots, I_k)} \otimes M_{(I_{k+1}, I_{k+2}, \ldots, I_\ell)} \]

for every composition \( I = (I_1, I_2, \ldots, I_\ell) \).

It is possible to define an \( R \)-algebra of quasi-symmetric functions in a finite number of variables as well (but it is not a bialgebra). These quasi-symmetric functions are actual polynomials then, not just power series.

Chapter 5 of [GriRei18] and Section 11 of [HazWitt1] are devoted to quasi-symmetric functions, as are Malvenuto’s thesis [Mal1993] and part of Chapter 7 of [Sta-EC2].

The implementation of the quasi-symmetric function Hopf algebra

We realize the \( R \)-algebra of quasi-symmetric functions in Sage as a graded Hopf algebra with basis elements indexed by compositions:

```sage
QSym = QuasiSymmetricFunctions(QQ)
QSym.category()
```

The most standard two bases for this \( R \)-algebra are the monomial and fundamental bases, and are accessible by the \( M() \) and \( F() \) methods:

```sage
M = QSym.M()
F = QSym.F()
```

```sage
M(F[2,1,2])
M[1, 1, 1, 1, 1] + M[1, 1, 1, 2] + M[2, 1, 1, 1] + M[2, 1, 2]
```

```sage
F(M[2,1,2])
F[1, 1, 1, 1, 1] - F[1, 1, 1, 2] - F[2, 1, 1, 1] + F[2, 1, 2]
```
The product on this space is commutative and is inherited from the product on the realization within the ring of power series:

```
sage: M[3]*M[1,1] == M[1,1]*M[3]
True
sage: M[3]*M[1,1]
sage: F[3]*F[1,1]
sage: M[3]*F[2]
sage: F[2]*M[3]
```

There is a coproduct on QSym as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The coproduct is not co-commutative:

```
sage: M[1,3,1].coproduct()
```

```
>>> from sage.all import *

>>> M[Integer(1),Integer(3),Integer(1)].coproduct()
```

```
>>> from sage.all import *

>>> M[Integer(1),Integer(3),Integer(1)].coproduct()
```

```
>>> from sage.all import *

>>> M[Integer(1),Integer(3),Integer(1)].coproduct()
```
The duality pairing with non-commutative symmetric functions

These two operations endow the quasi-symmetric functions $\text{QSym}$ with the structure of a Hopf algebra. It is the graded dual Hopf algebra of the non-commutative symmetric functions $\text{NCSF}$. Under this duality, the Monomial basis of $\text{QSym}$ is dual to the Complete basis of $\text{NCSF}$, and the Fundamental basis of $\text{QSym}$ is dual to the Ribbon basis of $\text{NCSF}$ (see [MR]).

```python
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1
sage: M.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: F.duality_pairing_matrix( S, degree=4 )
[1 0 0 0 0 0 0 0]
[1 1 0 0 0 0 0 0]
[1 0 1 0 0 0 0 0]
[1 1 1 1 0 0 0 0]
[1 0 0 1 0 0 0 0]
[1 1 0 1 1 0 0 0]
[1 0 1 0 1 0 1 0]
[1 1 1 1 1 1 1 1]
sage: NCSF = M.realization_of().dual()
sage: R = NCSF.Ribbon()
sage: F.duality_pairing_matrix( R, degree=4 )
[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: M.duality_pairing_matrix( R, degree=4 )
[ 1 0 0 0 0 0 0 0]
[-1 1 0 0 0 0 0 0]
[-1 0 1 0 0 0 0 0]
[ 1 -1 -1 1 0 0 0 0]
[-1 0 0 0 1 0 0 0]
[-1 1 0 -1 0 1 0]
[-1 -1 0 0 -1 1 0]
[ 1 0 -1 0 -1 0 1]
[ 1 1 1 -1 1 -1 -1 1]
```

```python
>>> from sage.all import *

>>> S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
>>> M[Integer(1),Integer(3),Integer(1)].duality_pairing( S[Integer(1),Integer(3),
   →Integer(1)] )
1
>>> M.duality_pairing_matrix( S, degree=Integer(4) )
```

(continues on next page)
Let $H$ and $G$ be elements of $QSym$, and $h$ an element of $NCSF$. Then, if we represent the duality pairing with the mathematical notation $\langle \cdot, \cdot \rangle$,

$$[H,G,h] = [H \otimes G, \Delta(h)].$$

For example, the coefficient of $M[2,1,4,1]$ in $M[1,3] \ast M[2,1,1]$ may be computed with the duality pairing:

```python
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I] * M[J]).duality_pairing(S[2,1,4,1])
1
```

And the coefficient of $S[1,3] \# S[2,1,1]$ in $S[2,1,4,1].\coprod$ is equal to this result:
Combinatorics, Release 10.4

\[ S[2,1,4,1].coproduct() \]
\[ S[] \oplus S[2, 1, 4, 1] + ... + S[1, 3] \oplus S[2, 1, 1] + ... + S[4, 1] \oplus S[2, 1] \]

\[ \text{from sage.all import } \]
\[ \text{from sage.all import } \]

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

\[ X = S[2,1,4,1].coproduct() \]
\[ \text{def linear_morphism}(x, y):
\]
\[ \quad \text{return } x.duality_pairing(M[1,3]) \ast y.duality_pairing(M[2,1,1]) \]
\[ \text{X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)} \]

Similarly, if \( H \) is an element of \( \text{QSym} \) and \( g \) and \( h \) are elements of \( \text{NCSF} \), then

\[ [H, gh] = [\Delta(H), g \otimes h]. \]

For example, the coefficient of \( R[2,3,1] \) in \( R[2,1] \ast R[2,1] \) is computed with the duality pairing by the following command:

\[ \text{sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])} \]

\[ \text{sage: R[2,1]*R[2,1]} \]
\[ R[2, 1, 2, 1] + R[2, 3, 1] \]

This coefficient should then be equal to the coefficient of \( F[2,1] \) in \( F[2,3,1].coproduct() \):

\[ \text{sage: F[2,3,1].coproduct()} \]
\[ F[] \oplus F[2, 3, 1] + ... + F[2, 1] \oplus F[2, 1] + ... + F[2, 3, 1] \oplus F[] \]

This can also be computed by the duality pairing on the tensor space, as above:
The operation dual to multiplication by a non-commutative symmetric function

Let $g \in NCSF$ and consider the linear endomorphism of $NCSF$ defined by left (respectively, right) multiplication by $g$. Since there is a duality between $QSym$ and $NCSF$, this linear transformation induces an operator $g^\perp$ on $QSym$ satisfying

$$[g^\perp(H), h] = [H, gh].$$

for any non-commutative symmetric function $h$.

This is implemented by the method `skew_by()`. Explicitly, if $H$ is a quasi-symmetric function and $g$ a non-commutative symmetric function, then $H.skew_by(g)$ and $H.skew_by(g, side='right')$ are expressions that satisfy, for any non-commutative symmetric function $h$, the following equalities:

$$H.skew_by(g).duality_pairing(h) \equiv H.duality_pairing(g*h)$$
$$H.skew_by(g, side='right').duality_pairing(h) \equiv H.duality_pairing(h*g)$$

For example, $M[J].skew_by(S[I])$ is 0 unless the composition $J$ begins with $I$ and $M[J].skew_by(S[I], side='right')$ is 0 unless the composition $J$ ends with $I$. For example:

sage: M[3,2,2].skew_by(S[3])
M[2, 2]
sage: M[3,2,2].skew_by(S[2])
0
sage: M[3,2,2].coproduct().apply_multilinear_morphism(lambda x,y: x.duality_pairing(S[3])*y)
M[2, 2]
sage: M[3,2,2].skew_by(S[3], side='right')
0
sage: M[3,2,2].skew_by(S[2], side='right')
M[3, 2]

(continues on next page)
The counit

The counit is defined by sending all elements of positive degree to zero:

```
sage: M[3].degree(), M[3,1,2].degree(), M.one().degree()
(3, 6, 0)
sage: M[3].counit()
0
sage: M[3,1,2].counit()
0
sage: M.one().counit()
1
7
7
```

The antipode

The antipode sends the Fundamental basis element indexed by the composition $I$ to $(-1)^{|I|}$ times the Fundamental basis element indexed by the conjugate composition to $I$ (where $|I|$ stands for the size of $I$, that is, the sum of all entries of $I$).

```
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
```

(continues on next page)
The antipodes of the Monomial quasisymmetric functions can also be computed easily: Every composition $I$ satisfies

$$\omega(M_I) = (-1)^{\ell(I)} \sum M_J,$$

where the sum ranges over all compositions $J$ of $|I|$ which are coarser than the reversed composition $I^r$ of $I$. Here, $\ell(I)$ denotes the length of the composition $I$ (that is, the number of its parts).

We demonstrate here the defining relation of the antipode:

The relation with symmetric functions

The quasi-symmetric functions are a ring which contain the symmetric functions as a subring. The Monomial quasi-symmetric functions are related to the monomial symmetric functions by

$$m_{\lambda} = \sum_{\text{sort}(I) = \lambda} M_I$$

(continues on next page)
The expansion of the Schur function in terms of the Fundamental quasi-symmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

It is also possible to convert a symmetric function to a quasi-symmetric function:

It is possible to experiment with the quasi-symmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.
Combinatorics, Release 10.4

```
sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSym = QuasiSymmetricFunctions(R)
sage: Ft = QSym.F()
sage: Ft(Qp[2,2])
```

```
>>> from sage.all import *
>>> R = QQ['t']
>>> Qp = SymmetricFunctions(R).hall_littlewood().Qp()
>>> QSym = QuasiSymmetricFunctions(R)
>>> Ft = QSym.F()
>>> Ft(Qp[Integer(2),Integer(2)])
```

```
sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

```
>>> from sage.all import *
>>> K = QQ['q','t'].fraction_field()
>>> Ht = SymmetricFunctions(K).macdonald().Ht()
>>> Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
>>> Fqt(Ht[Integer(2),Integer(1)])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of \( F \) is not equal to the base ring of \( Ht \):

```
sage: F(Ht[2,1])
Traceback (most recent call last):
  ...TypeError: do not know how to make x (= McdHt[2, 1]) an element of self_.
  (=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

```
>>> from sage.all import *
>>> F(Ht[Integer(2),Integer(1)])
Traceback (most recent call last):
  ...TypeError: do not know how to make x (= McdHt[2, 1]) an element of self_.
  (=Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

The map to the ring of polynomials

The quasi-symmetric functions can be seen as an inverse limit of a subring of a polynomial ring as the number of variables increases. Indeed, there exists a projection from the quasi-symmetric functions onto the polynomial ring \( R[x_1, x_2, \ldots, x_n] \). This projection is defined by sending the variables \( x_{n+1}, x_{n+2}, \ldots \) to 0, while the remaining \( n \) variables remain fixed. Note that this projection sends \( M_I \) to 0 if the length of the composition \( I \) is higher than \( n \).
```
sage: M[1,3,1].expand(2)
0

>>> from sage.all import *

>>> M[Integer(1),Integer(3),Integer(1)].expand(Integer(4))
x0*x1^3*x2 + x0*x1^3*x3 + x0*x2^3*x3 + x1*x2^3*x3

>>> F[Integer(1),Integer(3),Integer(1)].expand(Integer(4))
x0*x1^3*x2 + x0*x1^3*x3 + x0*x1^2*x2*x3 + x0*x1*x2^2*x3 + x0*x2^3*x3 + x1*x2^3*x3

>>> M[Integer(1),Integer(3),Integer(1)].expand(Integer(2))
0
```

class Bases (parent_with_realization)

Bases: Category_realization_of_parent

Category of bases of quasi-symmetric functions.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.Bases()
Category of bases of Quasisymmetric functions over the Rational Field

>>> from sage.all import *

>>> QSym = QuasiSymmetricFunctions(QQ)

>>> QSym.Bases()
Category of bases of Quasisymmetric functions over the Rational Field
```

class ElementMethods

Bases: object

Methods common to all elements of QuasiSymmetricFunctions.

```
adams_operator (n)

Return the image of the quasi-symmetric function self under the n-th Adams operator.

The n-th Adams operator \( f_n \) is defined to be the map from the \( R \)-algebra of quasi-symmetric functions to itself that sends every symmetric function \( P(x_1, x_2, x_3, \ldots) \) to \( P(x_1^n, x_2^n, x_3^n, \ldots) \). This operator \( f_n \) is a Hopf algebra endomorphism, and satisfies

\[
f_n M_{(i_1, i_2, i_3, \ldots)} = M_{(ni_1, ni_2, ni_3, \ldots)}
\]

for every composition \( (i_1, i_2, i_3, \ldots) \) (where \( M \) means the monomial basis).

The n-th Adams operator is also called the n-th Frobenius endomorphism. It is not related to the Frobenius map which connects the ring of symmetric functions with the representation theory of the symmetric group.

The n-th Adams operator is the n-th Adams operator of the \( \Lambda \)-ring of quasi-symmetric functions over the integers.

The restriction of the n-th Adams operator to the subring formed by all symmetric functions is, not unexpectedly, the n-th Adams operator of the ring of symmetric functions.

See also:

Symmetric functions plethysm

INPUT:

- \( n \) – a positive integer

5.1. Comprehensive Module List 2381
OUTPUT:

The result of applying the \(n\)-th Adams operator (on the ring of quasi-symmetric functions) to \(self\).

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M[3,2].adams_operator(2)
M[6, 4]
sage: (M[2,1] - 2*M[3]).adams_operator(4)
sage: M([]).adams_operator(3)
M[]
sage: F[1,1].adams_operator(2)
F[1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
```

```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> M = QSym.M()
>>> F = QSym.F()
>>> M[Integer(3),Integer(2)].adams_operator(Integer(2))
M[6, 4]
>>> (M[Integer(2),Integer(1)] - Integer(2)*M[Integer(3)]).adams_operator(Integer(4))
>>> M([]).adams_operator(Integer(3))
M[]
>>> F[Integer(1),Integer(1)].adams_operator(Integer(2))
F[1, 1, 1] - F[1, 1, 2] - F[2, 1, 1] + F[2, 2]
```

The Adams endomorphisms are multiplicative:

```python
sage: all( all( M(I).adams_operator(3) * M(J).adams_operator(3)
.....: == (M(I) * M(J)).adams_operator(3)
.....: for I in Compositions(3) )
.....: for J in Compositions(2) )
True
```

```
>>> from sage.all import *
>>> all( M(I).adams_operator(Integer(3)) * M(J).adams_operator(Integer(3))
... == (M(I) * M(J)).adams_operator(Integer(3))
... for I in Compositions(Integer(3))
... for J in Compositions(Integer(2))
True
```

Being Hopf algebra endomorphisms, the Adams operators commute with the antipode:

```python
sage: all( M(I).adams_operator(4).antipode()
.....: == M(I).antipode().adams_operator(4)
.....: for I in Compositions(3) )
True
```

```
>>> from sage.all import *
>>> all( M(I).adams_operator(Integer(4)).antipode()
... for I in Compositions(3) )
(continues on next page)```
The restriction of the Adams operators to the subring of symmetric functions are the Adams operators of the latter:

```python
sage: e = SymmetricFunctions(ZZ).e()
sage: all( M(e(lam)).adams_operator(3) == M(e(lam).adams_operator(3))
       for lam in Partitions(3) )
True
```

\[ \text{dendriform\_leq}(other) \]

Return the result of applying the dendriform smaller-or-equal operation to the two quasi-symmetric functions \( \text{self} \) and \( \text{other} \).

The dendriform smaller-or-equal operation is a binary operation, denoted by \( \preceq \) and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by \( \preceq \) and written infix as well) on the ring of formal power series \( R[[x_1, x_2, x_3, \ldots]] \), which is defined as follows: If \( m \) and \( n \) are two monomials in \( x_1, x_2, x_3, \ldots \), then we let \( m \preceq n \) be the product \( mn \) if the smallest positive integer \( i \) for which \( x_i \) occurs in \( m \) is smaller or equal to the smallest positive integer \( j \) for which \( x_j \) occurs in \( n \) (this is understood to be false when \( m = 1 \) and \( n \neq 1 \), and true when \( n = 1 \), and we let \( m \preceq n \) be 0 otherwise. Having thus defined \( \preceq \) on monomials, we extend \( \preceq \) to a binary operation on \( R[[x_1, x_2, x_3, \ldots]] \) by requiring it to be continuous (in both inputs) and \( R \)-bilinear. It is easily seen that \( QSym \preceq QSym \subseteq QSym \), so that \( \preceq \) restricts to a binary operation on \( QSym \).

This operation \( \preceq \) is related to the dendriform smaller relation \( \prec \) (\text{dendriform\_less}()). Namely, if we define a binary operation \( \succ \) on \( QSym \) by \( a \succ b = b \prec a \), then \( (QSym, \preceq, \succ) \) is a dendriform \( R \)-algebra. Thus, any \( a, b \in QSym \) satisfy \( a \preceq b = ab - b \prec a \).

See also:

\[ \text{dendriform\_less}() \]

INPUT:

- \text{other} – a quasi-symmetric function over the same base ring as \text{self}.

OUTPUT:

The quasi-symmetric function \( \text{self} \preceq \text{other} \), written in the basis of \text{self}.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_leq(M[1, 2])
sage: F = QSym.F()
```
Return the result of applying the dendriform smaller operation to the two quasi-symmetric functions `self` and `other`.

The dendriform smaller operation is a binary operation, denoted by ≺ and written infix, on the ring of quasi-symmetric functions. It can be defined as a restriction of a binary operation (denoted by ≺ and written infix as well) on the ring of formal power series $R[[x_1, x_2, x_3, \ldots]]$, which is defined as follows: If $m$ and $n$ are two monomials in $x_1, x_2, x_3, \ldots$, then we let $m \prec n$ be the product $mn$ if the smallest positive integer $i$ for which $x_i$ occurs in $m$ is smaller than the smallest positive integer $j$ for which $x_j$ occurs in $n$ (this is understood to be false when $m = 1$, and true when $m \neq 1$ and $n = 1$), and we let $m \prec n$ be 0 otherwise. Having thus defined $\prec$ on monomials, we extend $\prec$ to a binary operation on $R[[x_1, x_2, x_3, \ldots]]$ by requiring it to be continuous (in both inputs) and $R$-bilinear. It is easily seen that $QSym \prec QSym \subseteq QSym$, so that $\prec$ restricts to a binary operation on $QSym$.

**See also:**

`dendriform_leq()`

**INPUT:**
- `other` – a quasi-symmetric function over the same base ring as `self`

**OUTPUT:**

The quasi-symmetric function `self \prec other`, written in the basis of `self`.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: M[2, 1].dendriform_less(M[1, 2])
```

```
>>> F = QSym.F()
>>> F[Integer(2), Integer(1)].dendriform_less(F[Integer(1), ...
    ← Integer(2)])
```

The operation $\prec$ can be used to recursively construct the dual immaculate basis: For every positive integer $m$ and every composition $I$, the dual immaculate function $dI_{[m, I]}$ of the composition $[m, I]$ (this composition is $I$ with $m$ prepended to it) is $F_{[m]} \prec dI_I$.

```
sage: dI = QSym.dI()
sage: dI(F[2]).dendriform_less(dI[1, 2])
dI[2, 1, 2]
```

```
>>> from sage.all import *
>>> dI = QSym.dI()
>>> dI(F[Integer(2)]).dendriform_less(dI[Integer(1), Integer(2)])
dI[2, 1, 2]
```

We check with the identity element:

```
sage: M.one().dendriform_less(M[1,2])
0
sage: M[1,2].dendriform_less(M.one())
M[1, 2]
```

```
>>> from sage.all import *
>>> M[Integer(1),Integer(2)].dendriform_less(M[Integer(1),Integer(2)])
0
```

The operation $\prec$ is not symmetric, nor if $a \prec b \neq 0$, then $b \prec a = 0$ (as it would be for a single monomial):

```
sage: M[1,2,1].dendriform_less(M[1,2])
M[1, 1, 2, 1, 2] + 2 \cdot M[1, 1, 2, 2, 1] + M[1, 1, 2, 3] + M[1, 2, 1, 2, 1] + M[1, 2, 1, 3] + M[1, 2, 2, 2] + M[1, 3, 1, 2] + M[1, 3, 2, 1] + M[1, 3, 3]
```

```
>>> from sage.all import *
>>> M[Integer(1),Integer(2),Integer(1)].dendriform_less(M[Integer(1), ...
    ← Integer(2)])
M[1, 1, 2, 1, 2] + 2 \cdot M[1, 1, 2, 2, 1] + M[1, 1, 2, 3] + M[1, 2, 1, 2, 1] + M[1, 2, 1, 3] + M[1, 2, 2, 2] + M[1, 3, 1, 2] + M[1, 3, 2, 1]
```

(continues on next page)
(continued from previous page)

\[ M[1, 1, 2, 1, 2] + 2*M[1, 1, 2, 2, 1] + M[1, 1, 2, 3] + M[1, 1, 4, 1] + M[1, 2, 1, 2, 1] + M[1, 3, 2, 1] \]

\[ \text{expand}(n, \text{alphabet}='x') \]

Expand the quasi-symmetric function into \( n \) variables in an alphabet, which by default is 'x'.

**INPUT:**
- \( n \) – A nonnegative integer; the number of variables in the expansion
- \( \text{alphabet} = \) (default: 'x'); the alphabet in which \( \text{self} \) is to be expanded

**OUTPUT:**
- An expansion of \( \text{self} \) into the \( n \) variables specified by \( \text{alphabet} \).

**EXAMPLES:**

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(3)
x0^3 + x0^2*x1 + x0*x1^2 + x1^3 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + x2^3
```

```
>>> from sage.all import *

>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> F[Integer(3)].expand(Integer(3))
x0^3 + x0^2*x1 + x0*x1^2 + x1^3 + x0^2*x2 + x0*x1*x2 + x1^2*x2 + x0*x2^2 + x1*x2^2 + x2^3
```

One can use a different set of variable by adding an optional argument \( \text{alphabet}=... \)

```
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[3].expand(2,alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
```

```
>>> from sage.all import *

>>> F = QuasiSymmetricFunctions(QQ).Fundamental()

>>> F[Integer(3)].expand(Integer(1),alphabet='y')
y0^3 + y0^2*y1 + y0*y1^2 + y1^3
```

```
frobenius(*args, **kwds)
```

*Deprecated:* Use \( \text{adams_operator()} \) instead. See Issue #36396 for details.

**internal_coproduct()**

Return the inner coproduct of \( \text{self} \) in the basis of \( \text{self} \).

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the \( R \)-algebra of quasi-symmetric functions) is an \( R \)-algebra homomorphism \( \Delta^* \) from the \( R \)-algebra of quasi-symmetric functions to the tensor square (over \( R \)) of quasi-symmetric functions. It can be defined in the following two ways:

1. If \( I \) is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \( I \). If \( A \) is a \((0, I)\)-matrix, then \( \text{row}(A) \) will denote the vector of row sums of \( A \) (regarded as a composition), and \( \text{column}(A) \) will denote the vector of column sums of \( A \) (regarded as a composition).
For every composition $I$, the internal coproduct $\Delta^\times (M_I)$ of the $I$-th monomial quasisymmetric function $M_I$ is the sum
\[
\sum_{A \text{ is a } (0,1)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
\]

See Section 11.39 of [HazWitt1].

2. For every permutation $w$, let $C(w)$ denote the descent composition of $w$. Then, for any composition $I$ of size $n$, the internal coproduct $\Delta^\times (F_I)$ of the $I$-th fundamental quasisymmetric function $F_I$ is the sum
\[
\sum_{\sigma \in S_n, \tau \in S_n, \tau \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},
\]
where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1]. The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method `kronecker_coproduct()` is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0, [2,1])$-matrices are
\[
\begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \quad \begin{bmatrix} 2 & 1 \\ 0 & 1 \end{bmatrix}, \quad \text{and} \quad \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}
\]
so
\[
\Delta^\times (M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_5 + M_{21} \otimes M_{21} + M_{21} \otimes M_{21}.
\]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```sage
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Further examples:

```sage
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])]) ....: for i in range(1, 4) )
True
```

```sage
click: M([1, 2]).internal_coproduct()
```
The definition of $\Delta^x(M_I)$ in terms of $(0,I)$-matrices is not suitable for computation in cases where the length of $I$ is large, but we can use it as a doctest. Here is a naive implementation:

```python
sage: def naive_internal_coproduct_on_M(I):
    # INPUT: composition $I$
    # (not quasi-symmetric function)
    # OUTPUT: interior coproduct of $M_I$
    M = QuasiSymmetricFunctions(ZZ).M()
    M2 = M.tensor(M)
    res = M2.zero()
    l = len(I)
    n = I.size()
    for S in Subsets(range(l**2), l):
        M_list = sorted(S)
        row_M = [sum([I[M_list.index(l * i + j)]
                        for j in range(l)])
                        for i in range(l)]
        for j in range(l):
            col_M = [sum([I[M_list.index(l * i + j)]
                            for i in range(l)])
                            for j in range(l)]
            if 0 in row_M:
                first_zero = row_M.index(0)
                row_M = row_M[:first_zero]
                if sum(row_M) != n:
                    continue
            if 0 in col_M:
                first_zero = col_M.index(0)
                col_M = col_M[:first_zero]
                if sum(col_M) != n:
                    continue
            res += tensor([M(Compositions(n)(row_M)),
                            M(Compositions(n)(col_M))])
    return res

sage: all( naive_internal_coproduct_on_M(I) == M(I).internal_coproduct()
        for I in Compositions(3) )
True
```
... n = I.size()
... for S in Subsets(range(l**Integer(2)), l):
...     M_list = sorted(S)
...     row_M = [sum([I[M_list.index(l * i + j)]
...         for j in range(l) if
...         l * i + j in S])
...         for i in range(l)]
...     col_M = [sum([I[M_list.index(l * i + j)]
...         for i in range(l) if
...         l * i + j in S])
...         for j in range(l)]
...     if Integer(0) in row_M:
...         first_zero = row_M.index(Integer(0))
...         row_M = row_M[:first_zero]
...         if sum(row_M) != n:
...             continue
...     if Integer(0) in col_M:
...         first_zero = col_M.index(Integer(0))
...         col_M = col_M[:first_zero]
...         if sum(col_M) != n:
...             continue
...     res += tensor([M(Compositions(n)(row_M)),
...                     M(Compositions(n)(col_M))])
... return res

>>> all( naive_internal_coproduct_on_M(I)
...     == M(I).internal_coproduct()
...     for I in Compositions(Integer(3)) )
True

Todo: Implement this directly on the monomial basis maybe? The \((0, I)\)-matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above “further examples” should be moved to the \(M\)-method.

**is_symmetric()**

Return True if self is an element of the symmetric functions.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

OUTPUT:

- True if self is symmetric. False if self is not symmetric.

EXAMPLES:

```sage
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).is_symmetric()  
False
sage: (F[1, 1, 1, 2] + F[1, 1, 3] + F[1, 3, 1] + F[2, 1, 1, 1] + F[3, 1, 1, 1]).is_symmetric()
True
sage: F([]).is_symmetric()
True
```

```python
>>> from sage.all import *
```
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> F = QSym.Fundamental()
>>> (F[Integer(3),Integer(2)] + F[Integer(2),Integer(3)]).is_symmetric()
False
>>> (F[Integer(1), Integer(1), Integer(1), Integer(2)] + F[Integer(1), Integer(3), Integer(1), Integer(1)] + F[Integer(2), Integer(1), Integer(1), Integer(1)] + F[Integer(3), Integer(1), Integer(1)]).is_symmetric()
True
>>> F([]).is_symmetric()
True

**kronecker_coproduct()**

Return the inner coproduct of *self* in the basis of *self*.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the *R*-algebra of quasi-symmetric functions) is an *R*-algebra homomorphism \( \Delta^\times \) from the *R*-algebra of quasi-symmetric functions to the tensor square (over \( R \)) of quasi-symmetric functions. It can be defined in the following two ways:

1. If \( I \) is a composition, then a \((0, I)\)-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is \( I \). If \( A \) is a \((0, I)\)-matrix, then \( \text{row}(A) \) will denote the vector of row sums of \( A \) (regarded as a composition), and \( \text{column}(A) \) will denote the vector of column sums of \( A \) (regarded as a composition).

For every composition \( I \), the internal coproduct \( \Delta^\times (M_I) \) of the \( I \)-th monomial quasisymmetric function \( M_I \) is the sum

\[
\sum_{A \text{ is a } (0, I)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.
\]

See Section 11.39 of [HazWitt1].

2. For every permutation \( w \), let \( C(w) \) denote the descent composition of \( w \). Then, for any composition \( I \) of size \( n \), the internal coproduct \( \Delta^\times (F_I) \) of the \( I \)-th fundamental quasisymmetric function \( F_I \) is the sum

\[
\sum_{\sigma \in S_n, \tau \circ \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},
\]

where \( \pi \) is any permutation in \( S_n \) having descent composition \( I \) and where permutations act from the left and multiply accordingly, so \( \tau \circ \sigma \) means first applying \( \sigma \) and then \( \tau \). See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the \( R \)-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method **kronecker_coproduct()** is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of \( M_{21} \) (which is short for \( M_{[2, 1]} \)). The \((0, [2, 1])\)-matrices are

\[
\begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 1 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}
\]
so

\[ \Delta^X(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}. \]

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```python
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Further examples:

```python
sage: all( M([i]).internal_coproduct() == tensor([M([i]), M([i])])
    for i in range(1, 4) )
True
sage: M([1, 2]).internal_coproduct()
```

The definition of \( \Delta^X(M_I) \) in terms of \((0, I)\)-matrices is not suitable for computation in cases where the length of \( I \) is large, but we can use it as a doctest. Here is a naive implementation:

```python
def naive_internal_coproduct_on_M(I):
    # INPUT: composition I
    # (not quasi-symmetric function)
    # OUTPUT: interior coproduct of M_I
    M = QuasiSymmetricFunctions(ZZ).M()
    M2 = M.tensor(M)
    res = M2.zero()
    l = len(I)
    n = I.size()
    for S in Subsets(range(l**2), l):
        M_list = sorted(S)
        row_M = [sum([I[M_list.index(l * i + j)]
            for j in range(l) if l * i + j in S])
            for i in range(l)]
        col_M = [sum([I[M_list.index(l * i + j)]
            for i in range(l) if l * i + j in S])
            for j in range(l)]
```

(continues on next page)
....:     if 0 in row_M:
....:         first_zero = row_M.index(0)
....:         row_M = row_M[:first_zero]
....:         if sum(row_M) != n:
....:             continue
....:     if 0 in col_M:
....:         first_zero = col_M.index(0)
....:         col_M = col_M[:first_zero]
....:         if sum(col_M) != n:
....:             continue
....:     res += tensor([M(Compositions(n)(row_M)),
....:                     M(Compositions(n)(col_M))])
....: return res

sage: all( naive_internal_coproduct_on_M(I) == M(I).internal_coproduct() for I in Compositions(3) )
True
Todo: Implement this directly on the monomial basis maybe? The \((0, I)\)‐matrices are a pain to generate from their definition, but maybe there is a good algorithm. If so, the above “further examples” should be moved to the M‐method.

**omega_involution()**

Return the image of the quasisymmetric function `self` under the omega involution.

The omega involution is defined as the linear map \( QS_{sym} \rightarrow QS_{sym} \) which, for every composition \( I \), sends the fundamental quasisymmetric function \( F_I \) to \( F_{I^t} \), where \( I^t \) denotes the conjugate \((\text{conjugate}())\) of the composition \( I \). This map is commonly denoted by \( \omega \). It is an algebra homomorphism and a coalgebra antihomomorphism; it also is an involution and an automorphism of the graded vector space \( QS_{sym} \). Also, every composition \( I \) satisfies

\[
\omega(M_I) = (-1)^{|I| - \ell(I)} \sum M_J,
\]

where the sum ranges over all compositions \( J \) of \(|I|\) which are coarser than the reversed composition \( I^r \) of \( I \). Here, \( \ell(I) \) denotes the length of the composition \( I \) (that is, the number of parts of \( I \)).

If \( f \) is a homogeneous element of \( NCSF \) of degree \( n \), then

\[
\omega(f) = (-1)^n S(f),
\]

where \( S \) denotes the antipode of \( QS_{sym} \).

The restriction of \( \omega \) to the ring of symmetric functions (which is a subring of \( QS_{sym} \)) is precisely the omega involution \((\text{omega}())\) of said ring.

The omega involution on \( QS_{sym} \) is adjoint to the omega involution on \( NCSF \) by the standard adjunction between \( NCSF \) and \( QS_{sym} \).

The omega involution has been denoted by \( \omega \) in [LMvW13], section 3.6.

See also:

omega involution on NCSF, psi involution on QSym, star involution on QSym.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,2].omega_involution()
F[1, 2, 1, 1]
sage: F[6,3].omega_involution()
F[1, 1, 2, 1, 1, 1, 1]
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: (F[3,3] - 2*F[2]).omega_involution()
-2*F[1, 1] + F[1, 1, 2, 1, 1]
sage: F([2,1,1]).omega_involution()
F[3, 1]
sage: M = QSym.M()
sage: M([2,1]).omega_involution()
-M[1, 2] - M[3]
sage: M.zero().omega_involution()
0
```
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F()
>>> F[Integer(3),Integer(2)].omega_involution()
F[1, 2, 1, 1]
>>> F[Integer(6),Integer(3)].omega_involution()
F[1, 1, 2, 1, 1, 1]
>>> (F[Integer(9),Integer(1)] - F[Integer(8),Integer(2)] +
   Integer(2)*F[Integer(2),Integer(4)] - Integer(3)*F[Integer(3)])
Integer(4)*F[[1]].omega_involution()
F[2, 1, 1, 1, 1, 1, 1, 1, 1]
>>> (F[Integer(3),Integer(3)] - Integer(2)*F[Integer(2)]).omega_involution()
-2*F[1, 1] + F[1, 2, 1, 1, 1, 1, 1, 1, 1]
>>> F((Integer(2),Integer(1),Integer(1))).omega_involution()
F[3, 1]
>>> M = QSym.M()
>>> M((Integer(2),Integer(1))).omega_involution()
-M[1, 2] - M[3]
>>> M.zero().omega_involution()
0

Testing the fact that the restriction of $\omega$ to $Sym$ is the omega automorphism of $Sym$:

```python
sage: Sym = SymmetricFunctions(ZZ)
sage: e = Sym.e()
sage: all( F(e[lam]).omega_involution() == F(e[lam].omega())
   for lam in Partitions(4) )
True
```

```python
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(ZZ)
>>> F = QSym.F()
>>> F((Integer(2),Integer(1),Integer(1))).omega_involution()
F[3, 1]
```

```
...
True
```

**psi_involution()**

Return the image of the quasisymmetric function `self` under the involution $\psi$.

The involution $\psi$ is defined as the linear map $QSym \to QSym$ which, for every composition $I$, sends the fundamental quasisymmetric function $F_I$ to $F_{I^c}$, where $I^c$ denotes the complement of the composition $I$. The map $\psi$ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution $\psi$ of $QSym$ is adjoint to the involution $\psi$ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

`psi involution on NCSF`, `star involution on QSym`.

**EXAMPLES:**
The involution $\psi$ commutes with the antipode:

```
sage: all( F(I).psi_involution().antipode() == F(I).antipode().psi_involution() for I in Compositions(4) )
True
```

Testing the fact that the restriction of $\psi$ to $\text{Sym}$ is the omega automorphism of $\text{Sym}$:
star_involution()

Return the image of the quasisymmetric function self under the star involution.

The star involution is defined as the linear map $QSym \rightarrow QSym$ which, for every composition $I$, sends the monomial quasisymmetric function $M_I$ to $M_{I^r}$. Here, if $I$ is a composition, we denote by $I^r$ the reversed composition of $I$. Denoting by $f^*$ the image of an element $f \in QSym$ under the star involution, it can be shown that every composition $I$ satisfies

$$(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},$$

where $F_I$ denotes the fundamental quasisymmetric function corresponding to the composition $I$.

The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of $QSym$. It also is an automorphism of the graded vector space $QSym$, and is the identity on the subspace $Sym$ of $QSym$. It is adjoint to the star involution on $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The star involution has been denoted by $\rho$ in [LMvW13], section 3.6.

See also:

star involution on NCSF.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].star_involution()
M[2, 3]
sage: M[6,3].star_involution()
M[3, 6]
sage: (M[3,3] - 2*M[2]).star_involution()
sage: M([4,2]).star_involution()
M[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0
```
The star involution commutes with the antipode:

```python
sage: all( M(I).star_involution().antipode() == M(I).antipode().star_involution() for I in Compositions(4) )
True
```

The star involution is the identity on Sym:

```python
sage: Sym = SymmetricFunctions(ZZ)
```

```python
sage: all( M(e(lam)).star_involution() == M(e(lam)) for lam in Partitions(4) )
True
```

**to_symmetric_function()**

Convert a quasi-symmetric function to a symmetric function.

OUTPUT:

- If self is a symmetric function, then return the expansion in the monomial basis. Otherwise raise an error.

EXAMPLES:
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.Fundamental()
sage: (F[3,2] + F[2,3]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
sage: m = SymmetricFunctions(QQ).m()
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,1,1]).to_symmetric_function()
6*m[1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]

>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> F = QSym.Fundamental()
>>> (F[Integer(3),Integer(2)] + F[Integer(2),Integer(3)]).to_symmetric_function()
Traceback (most recent call last):
...
ValueError: F[2, 3] + F[3, 2] is not a symmetric function
>>> m = SymmetricFunctions(QQ).m()
>>> s = SymmetricFunctions(QQ).s()
>>> F(s[Integer(3),Integer(1),Integer(1)]).to_symmetric_function()
6*m[1, 1, 1, 1] + 3*m[2, 1, 1, 1] + m[2, 2, 1] + m[3, 1, 1]

class ParentMethods

Bases: object

Methods common to all bases of QuasiSymmetricFunctions.

Eulerian(n, j, k=None)

Return the Eulerian (quasi)symmetric function \( Q_{n,j} \) in terms of self.

INPUT:

- \( n \) – the value \( n \) or a partition
- \( j \) – the number of excedances
- \( k \) – (optional) if specified, determines the number of fixed points of the permutation

EXAMPLES:

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()

sage: M.Eulerian(3, 1)

sage: M.Eulerian(4, 1, 2)

sage: QS = QSym.QS()

sage: QS.Eulerian(4, 2)

sage: QS.Eulerian([2, 2, 1], 2)
from polynomial \((f, \text{check=True})\)

The quasi-symmetric function expanded in this basis corresponding to the quasi-symmetric polynomial \(f\).

This is a default implementation that computes the expansion in the Monomial basis and converts to this basis.

**INPUT:**
- \(f\) – a polynomial in finitely many variables over the same base ring as \(self\). It is assumed that this polynomial is quasi-symmetric.
- \(\text{check}\) – boolean (default: True), checks whether the polynomial is indeed quasi-symmetric.

**OUTPUT:**
- quasi-symmetric function

**EXAMPLES:**

```python
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> M = QSym.M()
>>> M.Eulerian(Integer(3), Integer(1))
>>> M.Eulerian(Integer(4), Integer(1), Integer(2))
>>> QS = QSym.QS()
>>> QS.Eulerian(Integer(4), Integer(2))
>>> QS.Eulerian([Integer(2), Integer(2), Integer(1)], Integer(2))
>>> dI = QSym.dI()
>>> dI.Eulerian(Integer(5), Integer(2))
```

```python
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> P = PolynomialRing(QQ, x, Integer(3))
>>> x = P.gens()
>>> f = x[0] + x[1] + x[2]
>>> M.from_polynomial(f)
M[1]
>>> F.from_polynomial(f)
F[1]
>>> f = x[0]**2+x[1]**2+x[2]**2
>>> M.from_polynomial(f)
M[2]
>>> F.from_polynomial(f)
-F[1, 1] + F[2]
```

```python
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
>>> F = QuasiSymmetricFunctions(QQ).Fundamental()
>>> P = PolynomialRing(QQ, 'x', Integer(3))
```
If the polynomial is not quasi-symmetric, an error is raised:

```
>>> from sage.all import *
>>> f = x[Integer(0)]**Integer(2)+x[Integer(1)]
>>> M.from_polynomial(f)
Traceback (most recent call last):
...  
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
```

```
>>> F.from_polynomial(f)
Traceback (most recent call last):
...
ValueError: x0^2 + x1 is not a quasi-symmetric polynomial
```

The Hopf algebra of quasi-symmetric functions in the Essential basis.

The Essential quasi-symmetric functions are defined by

\[ E_I = \sum_{J \geq I} M_J = \sum_{i_1 \leq \cdots \leq i_k} x_{i_1}^{I_1} \cdots x_{i_k}^{I_k}, \]

where \( I = (I_1, \ldots, I_k) \).
**Note:** Our convention of \( \leq \) and \( \geq \) of compositions is opposite that of [Hoff2015].

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: E = QSym.E()
sage: M = QSym.M()
sage: E(M[2,2])
```

```python
sage: s = SymmetricFunctions(QQ).s()
sage: E(s[3,2])
5*E[1, 1, 1, 1] - 2*E[1, 1, 1, 2] - 2*E[1, 1, 2, 1] - 2*E[1, 2, 1, 1] + E[2, 1, 2] + E[2, 2, 1]
```

```python
sage: (1 + E[1])^3
```

```python
sage: E[1,2,1].coproduct()
```

The following is an alias for this basis:

```python
sage: QSym.Essential()
Quasisymmetric functions over the Rational Field in the Essential basis
```

```python
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> E = QSym.E()
>>> M = QSym.M()
>>> E(M[Integer(2),Integer(2)])
>>> s = SymmetricFunctions(QQ).s()
>>> E(s[Integer(3),Integer(2)])
5*E[1, 1, 1, 1] - 2*E[1, 1, 1, 2] - 2*E[1, 1, 2, 1] - 2*E[1, 2, 1, 1] + E[2, 1, 2] + E[2, 2, 1]
```

```python
>>> (Integer(1) + E[Integer(1)])^Integer(3)
>>> E[Integer(1),Integer(2),Integer(1)].coproduct()
```

**antipode_on_basis**(compo)

Return the result of the antipode applied to a quasi-symmetric Essential basis element.

**INPUT:**
- compo – composition

**OUTPUT:**
- The result of the antipode applied to the composition compo, expressed in the Essential basis.

**EXAMPLES:**

**5.1. Comprehensive Module List** 2401
\textbf{coproduct\_on\_basis (compo)}

Return the coproduct of a Essential basis element.

Combinatorial rule: deconcatenation.

INPUT:
• \texttt{compo} – composition

OUTPUT:
• The coproduct applied to the Essential quasi-symmetric function indexed by \texttt{compo}, expressed in the Essential basis.

EXAMPLES:

\begin{verbatim}
sage: E = QuasiSymmetricFunctions(QQ).Essential()
sage: E[[4, 2, 3]].coproduct()
sage: E.coproduct_on_basis(Composition([]))
E[] # E[]
\end{verbatim}

\textbf{product\_on\_basis (I, J)}

The product on Essential basis elements.

The product of the basis elements indexed by two compositions \(I\) and \(J\) is the sum of the basis elements indexed by compositions \(K\) in the stuffle product (also called the overlapping shuffle product) of \(I\) and \(J\) with a coefficient of \((-1)^{\ell(I) + \ell(J) - \ell(K)}\), where \(\ell(C)\) is the length of the composition \(C\).

INPUT:
• \(I, J\) – compositions

OUTPUT:
• The product of the Essential quasi-symmetric functions indexed by \(I\) and \(J\), expressed in the Essential basis.

EXAMPLES:

\begin{verbatim}
sage: E = QuasiSymmetricFunctions(QQ).E()
sage: c1 = Composition([2])
sage: c2 = Composition([1, 3])
sage: E.product_on_basis(c1, c2)
\end{verbatim}
\[ \text{sage: } E.\text{product_on_basis}(c1, \text{Composition([])}) \]
\[ E[2] \]
\[ \text{sage: } E.\text{product_on_basis}(c1, \text{Composition([3])}) \]

```python
>>> from sage.all import *
>>> E = QuasiSymmetricFunctions(QQ).E()
>>> c1 = Composition([Integer(2)])
>>> c2 = Composition([Integer(1), Integer(3)])
>>> E.\text{product_on_basis}(c1, c2)
E[2]
>>> E.\text{product_on_basis}(c1, Composition([Integer(3)]))
```

**F**

alias of **Fundamental**

**class Fundamental(QSym)**

Bases: **CombinatorialFreeModule**, BindableClass

The Hopf algebra of quasi-symmetric functions in the Fundamental basis.

**EXAMPLES:**

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(M[2,2])
F[1, 1, 1] - F[1, 2] - F[2, 1] + F[2, 2]
```

```python
sage: s = SymmetricFunctions(QQ).s()
sage: F(s[3,2])
```

```python
sage: (1+F[1])**3
```

```python
sage: F[Integer(1),Integer(2)]**Integer(3)
```

```python
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> F = QSym.F()
>>> M = QSym.M()
>>> F(M[2,2])
F[1, 1, 1] - F[1, 2] - F[2, 1] + F[2, 2]
```

```python
>>> s = SymmetricFunctions(QQ).s()
>>> F(s[3,2])
```

```python
>>> (1+F[1])**3
```

```python
>>> F[Integer(1),Integer(2)]**Integer(3)
```

The following is an alias for this basis:
sage: QSym.Fundamental()
Quasisymmetric functions over the Rational Field in the Fundamental basis

>>> from sage.all import *

>>> QSym.Fundamental()
Quasisymmetric functions over the Rational Field in the Fundamental basis

class Element

    Bases: IndexedFreeModuleElement

    internal_coproduct()

    Return the inner coproduct of self in the Fundamental basis.

    The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the $R$-algebra of quasi-symmetric functions) is an $R$-algebra homomorphism $\Delta^\times$ from the $R$-algebra of quasi-symmetric functions to the tensor square (over $R$) of quasi-symmetric functions. It can be defined in the following two ways:

1. If $I$ is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is $I$. If $A$ is a $(0, I)$-matrix, then row($A$) will denote the vector of row sums of $A$ (regarded as a composition), and column($A$) will denote the vector of column sums of $A$ (regarded as a composition).

For every composition $I$, the internal coproduct $\Delta^\times(M_I)$ of the $I$-th monomial quasi-symmetric function $M_I$ is the sum

$$\sum_{A \text{ is a } (0, I)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.$$ 

See Section 11.39 of [HazWitt1].

2. For every permutation $w$, let $C(w)$ denote the descent composition of $w$. Then, for any composition $I$ of size $n$, the internal coproduct $\Delta^\times(F_I)$ of the $I$-th fundamental quasi-symmetric function $F_I$ is the sum

$$\sum_{\sigma, \tau \in S_n, \tau \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},$$

where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method kronecker_coproduct() is a synonym of this one.

EXAMPLES:

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0, [2,1])$-matrices are

$$\begin{bmatrix} 2 & 1 \\ 1 & 0 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 0 \end{bmatrix}$$

so

$$\Delta^\times(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$
This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```python
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

Some examples on the Fundamental basis:

```python
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
sage: F([2]).internal_coproduct()
sage: F([3]).internal_coproduct()
```

kronecker_coproduct ()

Return the inner coproduct of self in the Fundamental basis.

The inner coproduct (also known as the Kronecker coproduct, or as the second comultiplication on the $R$-algebra of quasi-symmetric functions) is an $R$-algebra homomorphism $\Delta^\times$ from the $R$-algebra of quasi-symmetric functions to the tensor square (over $R$) of quasi-symmetric functions. It can be defined in the following two ways:

1. If $I$ is a composition, then a $(0, I)$-matrix will mean a matrix whose entries are nonnegative integers such that no row and no column of this matrix is zero, and such that if all the non-zero entries of the matrix are read (row by row, starting at the topmost row, reading every row from left to right), then the reading word obtained is $I$. If $A$ is a $(0, I)$-matrix, then row($A$) will denote the vector of row sums of $A$ (regarded as a composition), and column($A$) will denote the vector of column sums of $A$ (regarded as a composition).

   For every composition $I$, the internal coproduct $\Delta^\times(M_I)$ of the $I$-th monomial quasisymmetric
function $M_I$ is the sum

$$\sum_{A \text{ is a } (0, I)-\text{matrix}} M_{\text{row}(A)} \otimes M_{\text{column}(A)}.$$ 

See Section 11.39 of [HazWitt1].

2. For every permutation $w$, let $C(w)$ denote the descent composition of $w$. Then, for any composition $I$ of size $n$, the internal coproduct $\Delta^X(F_I)$ of the $I$-th fundamental quasisymmetric function $F_I$ is the sum

$$\sum_{\sigma \in S_n, \tau \in S_n, \tau \sigma = \pi} F_{C(\sigma)} \otimes F_{C(\tau)},$$

where $\pi$ is any permutation in $S_n$ having descent composition $I$ and where permutations act from the left and multiply accordingly, so $\tau \sigma$ means first applying $\sigma$ and then $\tau$. See Theorem 4.23 in [Mal1993], but beware of the notations which are apparently different from those in [HazWitt1].

The restriction of the internal coproduct to the $R$-algebra of symmetric functions is the well-known internal coproduct on the symmetric functions.

The method \texttt{kroncker_coproduct()} is a synonym of this one.

**EXAMPLES:**

Let us compute the internal coproduct of $M_{21}$ (which is short for $M_{[2,1]}$). The $(0, [2, 1])$-matrices are

$$\begin{bmatrix} 2 & 1 \\ 1 & 1 \end{bmatrix}, \begin{bmatrix} 2 & 0 \\ 0 & 1 \end{bmatrix}, \text{ and } \begin{bmatrix} 0 & 2 \\ 1 & 1 \end{bmatrix}$$

so

$$\Delta^X(M_{21}) = M_3 \otimes M_{21} + M_{21} \otimes M_3 + M_{21} \otimes M_{21} + M_{21} \otimes M_{12}.$$ 

This is confirmed by the following Sage computation (incidentally demonstrating the non-cocommutativity of the internal coproduct):

```sage
sage: M = QuasiSymmetricFunctions(ZZ).M()
sage: a = M([2,1])
sage: a.internal_coproduct()
```

```python
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(ZZ).M()
>>> a = M([Integer(2),Integer(1)])
>>> a.internal_coproduct()
```

Some examples on the Fundamental basis:

```sage
sage: F = QuasiSymmetricFunctions(ZZ).F()
sage: F([1,1]).internal_coproduct()
sage: F([2]).internal_coproduct()
sage: F([3]).internal_coproduct()
sage: F([1,2]).internal_coproduct()
```

```python
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(ZZ).F()
>>> F([1,1]).internal_coproduct()
>>> F([2]).internal_coproduct()
>>> F([3]).internal_coproduct()
>>> F([1,2]).internal_coproduct()
```
\begin{verbatim}
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(ZZ).F()
>>> F([Integer(1),Integer(1)]).internal_coproduct()
>>> F([Integer(2)]).internal_coproduct()

\end{verbatim}

\begin{verbatim}

5.1. Comprehensive Module List
2407

\end{verbatim}

**star_involution()**

Return the image of the quasisymmetric function \texttt{self} under the star involution.

The star involution is defined as the linear map \(QSym \rightarrow QSym\) which, for every composition \(I\), sends the monomial quasisymmetric function \(M_I\) to \(M_{I^r}\). Here, if \(I\) is a composition, we denote by \(I^r\) the reversed composition of \(I\). Denoting by \(f^*\) the image of an element \(f \in QSym\) under the star involution, it can be shown that every composition \(I\) satisfies

\[(M_I)^* = M_{I^r}, \quad (F_I)^* = F_{I^r},\]

where \(F_I\) denotes the fundamental quasisymmetric function corresponding to the composition \(I\).

The star involution is an involution, an algebra automorphism and a coalgebra anti-automorphism of \(QSym\). It also is an automorphism of the graded vector space \(QSym\), and is the identity on the subspace \(Sym\) of \(QSym\). It is adjoint to the star involution on \(NCSF\) by the standard adjunction between \(NCSF\) and \(QSym\).

The star involution has been denoted by \(\rho\) in [LMvW13], section 3.6.

See also:

*star involution on QSym*, *star involution on NCSF*.

**EXAMPLES:**

\begin{verbatim}
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: F = QSym.F()
sage: F[3,1].star_involution()
F[1, 3]
sage: F[5,3].star_involution()
F[3, 5]
sage: F([4,2]).star_involution()
F[2, 4]
sage: dI = QSym.dI()
sage: dI([1,2]).star_involution()
-dI[1, 2] + dI[2, 1]
sage: dI.zero().star_involution()
0

(continues on next page)
\end{verbatim}
Eulerian \((n, j, k=None)\)

Return the Eulerian (quasi)symmetric function \(Q_{n,j}\) (with \(n\) either an integer or a partition) defined in [SW2010] in terms of the fundamental quasisymmetric functions. Or, if the optional argument \(k\) is specified, return the function \(Q_{n,j,k}\) defined ibidem.

If \(n\) and \(j\) are nonnegative integers, then the Eulerian quasisymmetric function \(Q_{n,j}\) is defined as

\[
Q_{n,j} := \sum_{\sigma} F_{\text{Dex}(\sigma)},
\]

where we sum over all permutations \(\sigma \in S_n\) such that the number of excedances of \(\sigma\) is \(j\), and where \(\text{Dex}(\sigma)\) is a composition of \(n\) defined as follows: Let \(S\) be the set of all \(i \in \{1, 2, \ldots, n-1\}\) such that either \(\sigma_i > \sigma_{i+1} > i+1\) or \(i \geq \sigma_i > \sigma_{i+1} > i+1 > \sigma_i\). Then, \(\text{Dex}(\sigma)\) is set to be the composition of \(n\) whose descent set is \(S\).

Here, an excedance of a permutation \(\sigma \in S_n\) means an element \(i \in \{1, 2, \ldots, n-1\}\) satisfying \(\sigma_i > i\).

Similarly, we can define a quasisymmetric function \(Q_{\lambda,j}\) for every partition \(\lambda\) and every nonnegative integer \(j\). This differs from \(Q_{n,j}\) only in that the sum is restricted to all permutations \(\sigma \in S_n\) whose cycle type is \(\lambda\) (where \(n = |\lambda|\), and where we still require the number of excedances to be \(j\)). The method at hand allows computing these functions by passing \(\lambda\) as the \(n\) parameter.

Analogously we can define a quasisymmetric function \(Q_{n,j,k}\) for any nonnegative integers \(n, j\) and \(k\) by restricting the sum to all permutations \(\sigma \in S_n\) that have exactly \(k\) fixed points (and \(j\) excedances). This can be obtained by specifying the optional \(k\) argument in this method.

All three versions of Eulerian quasisymmetric functions (\(Q_{n,j}, Q_{\lambda,j}\) and \(Q_{n,j,k}\)) are actually symmetric functions. See Eulerian().

**INPUT:**
- \(n\) – the nonnegative integer \(n\) or a partition
- \(j\) – the number of excedances
- \(k\) – (optional) if specified, determines the number of fixed points of the permutations which are being summed over

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.Eulerian(3, 1)
```
\[ \text{sage: } F.\text{Eulerian}(4, 2) \]
\[ \text{sage: } F.\text{Eulerian}(5, 2) \]
\[ \text{sage: } F.\text{Eulerian}(4, 0) \]
\[ F[4] \]
\[ \text{sage: } F.\text{Eulerian}(4, 3) \]
\[ F[4] \]
\[ \text{sage: } F.\text{Eulerian}(4, 1, 2) \]
\[ \text{sage: } F.\text{Eulerian}(\text{Partition([2, 2, 1])}, 2) \]
\[ \text{sage: } F.\text{Eulerian}(0, 0) \]
\[ F[4] \]
\[ \text{sage: } F.\text{Eulerian}(0, 1) \]
\[ 0 \]
\[ \text{sage: } F.\text{Eulerian}(1, 0) \]
\[ F[1] \]
\[ \text{sage: } F.\text{Eulerian}(1, 1) \]
\[ 0 \]

```python
>>> from sage.all import *
>>> F = QuasiSymmetricFunctions(QQ).F()
>>> F.\text{Eulerian}(Integer(3), Integer(1))
>>> F.\text{Eulerian}(Integer(4), Integer(2))
>>> F.\text{Eulerian}(Integer(4), Integer(0))
F[4]
>>> F.\text{Eulerian}(Integer(4), Integer(3))
F[4]
>>> F.\text{Eulerian}(Integer(4), Integer(1), Integer(2))
>>> F.\text{Eulerian}(\text{Partition([Integer(2), Integer(2), Integer(1)])}, Integer(2))
>>> F.\text{Eulerian}(Integer(0), Integer(0))
F[]
>>> F.\text{Eulerian}(Integer(0), Integer(1))
0
>>> F.\text{Eulerian}(Integer(1), Integer(0))
F[1]
>>> F.\text{Eulerian}(Integer(1), Integer(1))
0
```

\( \text{antipode_on_basis} \) (compo)
Return the antipode to a Fundamental quasi-symmetric basis element.

**INPUT:**
- `compo` – composition

**OUTPUT:**
- The result of the antipode applied to the quasi-symmetric Fundamental basis element indexed by `compo`.

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.antipode_on_basis(Composition([2,1]))
-F[2, 1]
```

**coproduct_on_basis** (`compo`)

Return the coproduct to a Fundamental quasi-symmetric basis element.

Combinatorial rule: quasi-deconcatenation.

**INPUT:**
- `compo` – composition

**OUTPUT:**
- The application of the coproduct to the Fundamental quasi-symmetric function indexed by the composition `compo`.

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).Fundamental()
sage: F[4].coproduct()
sage: F[2,1,3].coproduct()
```

**dual**

Return the dual basis to the Fundamental basis. This is the ribbon basis of the non-commutative symmetric functions.

**OUTPUT:**
- The ribbon basis of the non-commutative symmetric functions.

**EXAMPLES:**

```python
sage: F = QuasiSymmetricFunctions(QQ).F()
sage: F.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Ribbon...
→basis
```
```python
>>> from sage.all import *

```
The product on Hazewinkel Lambda basis elements.

The product of the basis elements indexed by two compositions \( I \) and \( J \) is the basis element obtained by concatenating the Lyndon factorizations of the words \( I \) and \( J \), then reordering the Lyndon factors in nonincreasing order, and finally concatenating them in this order (giving a new composition).

**INPUT:**
- \( I, J \) – compositions

**OUTPUT:**
- The product of the Hazewinkel Lambda quasi-symmetric functions indexed by \( I \) and \( J \), expressed in the Hazewinkel Lambda basis.

**EXAMPLES:**

```python
sage: HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
sage: c1 = Composition([1, 2, 1])
sage: c2 = Composition([2, 1, 3, 2])
sage: HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
sage: HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
sage: HWL.product_on_basis(Composition([]), Composition([]))
HWL[]
```

```python
>>> from sage.all import *
>>> HWL = QuasiSymmetricFunctions(QQ).HazewinkelLambda()
>>> c1 = Composition([Integer(1), Integer(2), Integer(1)])
>>> c2 = Composition([Integer(2), Integer(1), Integer(3), Integer(2)])
>>> HWL.product_on_basis(c1, c2)
HWL[2, 1, 3, 2, 1, 2, 1]
>>> HWL.product_on_basis(c1, Composition([]))
HWL[1, 2, 1]
>>> HWL.product_on_basis(Composition([]), Composition([]))
HWL[]
```
M

alias of Monomial
class Monomial(QSym)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of quasi-symmetric function in the Monomial basis.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: M = QSym.M()
sage: F = QSym.F()
sage: M(F[2,2])
sage: m = SymmetricFunctions(QQ).m()
sage: M(m[3,1,1])
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: (1+M[1])**3
sage: M[1,2,1].coproduct()
```
**expand** (*n, alphabet='x'*)

Expand the quasi-symmetric function written in the monomial basis in *n* variables.

**INPUT:**
- *n* – an integer
- alphabet – (default: 'x') a string

**OUTPUT:**
- The quasi-symmetric function *self* expressed in the *n* variables described by *alphabet*.

**Todo:** accept an *alphabet* as input

**EXAMPLES:**

```sage```
M = QuasiSymmetricFunctions(QQ).Monomial()
M[4,2].expand(3)
x0^4*x1^2 + x0^4*x2^2 + x1^4*x2^2
```

```sage```
M[Integer(4),Integer(2)].expand(Integer(3))
x0^4*x1^2 + x0^4*x2^2 + x1^4*x2^2
```

One can use a different set of variables by using the optional argument *alphabet*:

```sage```
M = QuasiSymmetricFunctions(QQ).Monomial()
M[2,1,1].expand(4,alphabet='y')
y0^2*y1*y2 + y0^2*y1*y3 + y0^2*y2*y3 + y1^2*y2*y3
```

**is_symmetric** ()

Determine if a quasi-symmetric function, written in the Monomial basis, is symmetric.

This is being tested by looking at the expansion in the Monomial basis and checking if the coefficients are the same if the indexing compositions are permutations of each other.

**OUTPUT:**
- True if *self* is an element of the symmetric functions and False otherwise.

**EXAMPLES:**

```sage```
QSym = QuasiSymmetricFunctions(QQ)
M = QSym.Monomial()
(M[3,2] + M[2,3] + M[4,1]).is_symmetric()  # False
(M[3,2] + M[2,3]).is_symmetric()  # True
(M[1,2,1] + M[1,1,2]).is_symmetric()  # False
(M[1,2,1] + M[1,1,2] + M[2,1,1]).is_symmetric()  # True
```

```sage```
QSym = QuasiSymmetricFunctions(QQ)
```
psi_involution()

Return the image of the quasisymmetric function self under the involution $\psi$.

The involution $\psi$ is defined as the linear map $QSym \to QSym$ which, for every composition $I$, sends the fundamental quasisymmetric function $F_{I}$ to $F_{I^c}$, where $I^c$ denotes the complement of the composition $I$. The map $\psi$ is an involution and a graded Hopf algebra automorphism of $QSym$. Its restriction to the ring of symmetric functions coincides with the omega automorphism of the latter ring.

The involution $\psi$ of $QSym$ is adjoint to the involution $\phi$ of $NCSF$ by the standard adjunction between $NCSF$ and $QSym$.

The involution $\psi$ has been denoted by $\psi$ in [LMvW13], section 3.6.

See also:

psi involution on QSym, psi involution on NCSF, star involution on QSym.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(ZZ)
sage: M = QSym.M()
sage: M[3,2].psi_involution()
sage: M[3,1].psi_involution()
sage: M[3,1,1].psi_involution()
sage: M[1,1,1].psi_involution()
sage: M[[]].psi_involution()
M[]
sage: M[0].psi_involution()
0
```
Combinatorics, Release 10.4

\[
\begin{align*}
\text{>>> } & M[\text{Integer}(3), \text{Integer}(1), \text{Integer}(1)].\psi\text{\textunderscore involution()} \\
\text{>>> } & M[\text{Integer}(1), \text{Integer}(1), \text{Integer}(1)].\psi\text{\textunderscore involution()} \\
\text{>>> } & M[\text{[]}].\psi\text{\textunderscore involution()} \\
M[\text{[]}] \\
\text{>>> } & (\text{Integer}(2) \ast M[\text{[]}] - M[\text{Integer}(3), \text{Integer}(1)] + \ldots \\
\text{>>> } & \text{Integer}(4) \ast M[\text{Integer}(2)]).\psi\text{\textunderscore involution()} \\
\end{align*}
\]

This particular implementation is tailored to the monomial basis. It is semantically equivalent to the generic implementation it overshadows:

\[
\begin{align*}
\text{sage: } & F = \text{QSym.F()} \\
\text{sage: } & \text{all( } F(M[I].\psi\text{\textunderscore involution()} ) == F(M[I]).\psi\text{\textunderscore involution()} \\
\text{......: } & \text{ for } I \text{ in Compositions(3) } ) \\
& \text{True} \\
\text{sage: } & F = \text{QSym.F()} \\
\text{sage: } & \text{all( } F(M[I].\psi\text{\textunderscore involution()} ) == F(M[I]).\psi\text{\textunderscore involution()} \\
\text{......: } & \text{ for } I \text{ in Compositions(4) } ) \\
& \text{True}
\end{align*}
\]

\[
\begin{align*}
\text{>>> from sage.all import *} \\
\text{>>> } & F = \text{QSym.F()} \\
\text{>>> } & \text{all( } F(M[I].\psi\text{\textunderscore involution()} ) == F(M[I]).\psi\text{\textunderscore involution()} \\
\text{...: } & \text{ for } I \text{ in Compositions(Integer(3)) } ) \\
& \text{True} \\
\text{>>> } & F = \text{QSym.F()} \\
\text{>>> } & \text{all( } F(M[I].\psi\text{\textunderscore involution()} ) == F(M[I]).\psi\text{\textunderscore involution()} \\
\text{...: } & \text{ for } I \text{ in Compositions(Integer(4)) } ) \\
& \text{True}
\end{align*}
\]

\textbf{to\_symmetric\_function()}

Take a quasi-symmetric function, expressed in the monomial basis, and return its symmetric realization, when possible, expressed in the monomial basis of symmetric functions.

\textbf{OUTPUT:}

- If self is a symmetric function, then the expansion in the monomial basis of the symmetric functions is returned. Otherwise an error is raised.

\textbf{EXAMPLES:}

\[
\begin{align*}
\text{sage: } & \text{QSym} = \text{QuasiSymmetricFunctions(QQ)} \\
\text{sage: } & M = \text{QSym.Monomial()} \\
\text{sage: } & (M[3,2] + M[2,3] + M[4,1]).\text{to\_symmetric\_function()} \\
\text{Traceback (most recent call last):} \\
\text{...}
\text{ValueError: } M[2, 3] + M[3, 2] + M[4, 1] \text{ is not a symmetric function} \\
\text{sage: } & (M[3,2] + M[2,3] + 2 \ast M[4,1] + 2 \ast M[1,4]).\text{to\_symmetric\_function()} \\
& m[3, 2] + 2 \ast m[4, 1] \\
\text{sage: } & m = \text{SymmetricFunctions(QQ).m()} \\
\text{sage: } & M(m[3,1,1]).\text{to\_symmetric\_function()}
\end{align*}
\]

0

antipode_on_basis (compo)

Return the result of the antipode applied to a quasi-symmetric Monomial basis element.

INPUT:

• compo – composition

OUTPUT:

• The result of the antipode applied to the composition compo, expressed in the Monomial basis.

EXAMPLES:

sage: M = QuasiSymmetricFunctions(QQ).M()

sage: M.antipode_on_basis(Composition([2,1]))

M[1, 2] + M[3]

sage: M.antipode_on_basis(Composition([[]]))

M[]

>>> from sage.all import *

>>> M = QuasiSymmetricFunctions(QQ).M()

>>> M.antipode_on_basis(Composition([Integer(2),Integer(1)]))

M[1, 2] + M[3]

>>> M.antipode_on_basis(Composition([[]]))

M[]

coproduct_on_basis (compo)

Return the coproduct of a Monomial basis element.

Combinatorial rule: deconcatenation.

INPUT:

• compo – composition

OUTPUT:

• The coproduct applied to the Monomial quasi-symmetric function indexed by compo, expressed in the Monomial basis.
EXAMPLES:

```python
sage: M = QuasiSymmetricFunctions(QQ).Monomial()
sage: M[4,2,3].coproduct()
sage: M.coproduct_on_basis(Composition([]))
M[] # M[]
```

`dual()`

Return the dual basis to the Monomial basis. This is the complete basis of the non-commutative symmetric functions.

OUTPUT:

- The complete basis of the non-commutative symmetric functions.

EXAMPLES:

```python
sage: M = QuasiSymmetricFunctions(QQ).M()
sage: M.dual()
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
```

`lambda_of_monomial(I, n)`

Return the image of the monomial quasi-symmetric function $M_I$ under the lambda-map $\lambda^n$, expanded in the monomial basis.

The ring of quasi-symmetric functions over the integers, QSym$_\mathbb{Z}$ (and more generally, the ring of quasi-symmetric functions over any binomial ring) becomes a $\lambda$-ring (with the $\lambda$-structure inherited from the ring of formal power series, so that $\lambda^i(x_j)$ is $x_j$ if $i = 1$ and 0 if $i > 1$).

The Adams operations of this $\lambda$-ring are the Adams endomorphisms $f_n$ (see `adams_operator()` for their definition). Using these endomorphisms, the $\lambda$-operations can be explicitly computed via the formula

$$\exp\left(-\sum_{n=1}^{\infty} \frac{1}{n} f_n(x)t^n\right) = \sum_{j=0}^{\infty} (-1)^j \lambda^j(x)t^j$$

in the ring of formal power series in a variable $t$ over the ring of quasi-symmetric functions. In particular, every composition $I = (I_1, I_2, \cdots, I_k)$ satisfies

$$\exp\left(-\sum_{n=1}^{\infty} \frac{1}{n} M_{(n_1,n_2,\cdots,n_k)}t^n\right) = \sum_{j=0}^{\infty} (-1)^j \lambda^j(M_I)t^j$$

(corrected version of Remark 2.4 in [Haz2004]).
The quasi-symmetric functions $\lambda^n(M_I)$ with $n$ ranging over the positive integers and $I$ ranging over the reduced Lyndon compositions (i.e., compositions which are Lyndon words and have the gcd of their entries equal to 1) form a set of free polynomial generators for QSym. See [GriRei18], Chapter 6, for the proof, and [Haz2004] for a major part of it.

**INPUT:**
- $I$ – composition
- $n$ – nonnegative integer

**OUTPUT:**
The quasi-symmetric function $\lambda^n(M_I)$, expanded in the monomial basis over the ground ring of `self`.

**EXAMPLES:**

```sage
M = QuasiSymmetricFunctions(CyclotomicField()).Monomial()
M.lambda_of_monomial([1, 2], 2)
M.lambda_of_monomial([1, 1, 2], 2)
3*M[1, 1, 1] + M[1, 1, 2] + M[1, 2, 1] + M[2, 1, 1]
```

The map $\lambda^0$ sends everything to 1:

```sage
M = QuasiSymmetricFunctions(ZZ).Monomial()
all( M.lambda_of_monomial(I, 0) == M.one() for I in Compositions(3) )
True
```
The map $\lambda^1$ is the identity map:

```python
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(ZZ).Monomial()
... all( M.lambda_of_monomial(I, Integer(0)) == M.one() 
    ... for I in Compositions(Integer(3)) )
True
```

The product on basis elements.

The product of the basis elements indexed by two compositions $I$ and $J$ is the sum of the basis elements indexed by compositions in the shuffle product (also called the overlapping shuffle product) of $I$ and $J$.

INPUT:

- $I, J$ – compositions

OUTPUT:

- The product of the Monomial quasi-symmetric functions indexed by $I$ and $J$, expressed in the Monomial basis.

EXAMPLES:

```python
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
... all( M.lambda_of_monomial(I, Integer(1)) == M(I) 
    ... for I in Compositions(Integer(3)) )
True
```

```
product_on_basis(I, J)
```

The product on Monomial basis elements.

The product of the basis elements indexed by two compositions $I$ and $J$ is the sum of the basis elements indexed by compositions in the shovel product (also called the overlapping shovel product) of $I$ and $J$.

INPUT:

- $I, J$ – compositions

OUTPUT:

- The product of the Monomial quasi-symmetric functions indexed by $I$ and $J$, expressed in the Monomial basis.

EXAMPLES:

```python
>>> from sage.all import *
>>> M = QuasiSymmetricFunctions(QQ).Monomial()
... all( M.lambda_of_monomial(I, 1) == M(I) 
    ... for I in Compositions(3) )
True
```

```
product_on_basis(I, J)
```

The product on Monomial basis elements.

The product of the basis elements indexed by two compositions $I$ and $J$ is the sum of the basis elements indexed by compositions in the shovel product (also called the overlapping shovel product) of $I$ and $J$.

INPUT:

- $I, J$ – compositions

OUTPUT:

- The product of the Monomial quasi-symmetric functions indexed by $I$ and $J$, expressed in the Monomial basis.

EXAMPLES:
from sage.all import *
M = QuasiSymmetricFunctions(QQ).Monomial()
c1 = Composition([Integer(2)])
c2 = Composition([Integer(1), Integer(3)])
M.product_on_basis(c1, c2)
M.product_on_basis(c1, Composition([]))
M[2]

QS

alias of Quasisymmetric_Schur
class Quasisymmetric_Schur (QSym)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of quasi-symmetric function in the Quasisymmetric Schur basis.
The basis of Quasisymmetric Schur functions is defined in [QSCHUR] and in Definition 5.1.1 of [LMvW13].
Don’t mistake them for the completely unrelated quasi-Schur functions of [NCSF1]!

EXAMPLES:

sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QS = QSym.QS()
sage: F = QSym.F()
sage: M = QSym.M()
sage: F(QS[1,2])
F[1, 2]
sage: M(QS[1,2])
M[1, 1, 1] + M[1, 2]
sage: s = SymmetricFunctions(QQ).s()
sage: QS(s[2,1,1])
QS[1, 1, 2] + QS[1, 2, 1] + QS[2, 1, 1]

dual()  
The dual basis to the Quasisymmetric Schur basis.
The dual basis to the Quasisymmetric Schur basis is implemented as dual.

OUTPUT:
• the dual Quasisymmetric Schur basis of the non-commutative symmetric functions

EXAMPLES:

sage: QS = QuasiSymmetricFunctions(QQ).Quasisymmetric_Schur()
sage: QS.dual()
Non-Commutative Symmetric Functions over the Rational Field in the dual Quasisymmetric-Schur basis

```python
>>> from sage.all import *
>>> QS = QuasiSymmetricFunctions(QQ).Quasisymmetric_Schur()
>>> QS.dual()
Non-Commutative Symmetric Functions over the Rational Field in the dual Quasisymmetric-Schur basis
```

YQS

alias of **Young_Quasisymmetric_Schur**

class **Young_Quasisymmetric_Schur**(*QSym*)

Bases: **CombinatorialFreeModule**, **BindableClass**

The Hopf algebra of quasi-symmetric functions in the Young Quasisymmetric Schur basis.

The basis of Young Quasisymmetric Schur functions is from Definition 5.2.1 of [LMvW13].

This basis is related to the Quasisymmetric Schur basis `QS` by `QS(alphareversed()) == YQS(alphastar_involution())`.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: YQS = QSym.YQS()
sage: F = QSym.F()
sage: QS = QSym.QS()
sage: F(YQS[1,2])
F[1, 2]
sage: all(QS(alphareversed()) == YQS(alphastar_involution()) for al in Compositions(5))
True
sage: s = SymmetricFunctions(QQ).s()
sage: YQS(s[2,1,1])
YQS[1, 1, 2] + YQS[1, 2, 1] + YQS[2, 1, 1]
```

```python
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> YQS = QSym.YQS()
>>> F = QSym.F()
>>> QS = QSym.QS()
>>> F(YQS[Integer(1),Integer(2)])
F[1, 2]
>>> all(QS(alphareversed()) == YQS(alphastar_involution()) for al in Compositions(Integer(5)))
True
>>> s = SymmetricFunctions(QQ).s()
>>> YQS(s[Integer(2),Integer(1),Integer(1)])
YQS[1, 1, 2] + YQS[1, 2, 1] + YQS[2, 1, 1]
```

**a_realization()**

Return the realization of the Monomial basis of the ring of quasi-symmetric functions.

**OUTPUT:**

- The Monomial basis of quasi-symmetric functions.
EXAMPLES:

```python
sage: QuasiSymmetricFunctions(QQ).a_realization()
Quasisymmetric functions over the Rational Field in the Monomial basis

from sage.all import *

QuasiSymmetricFunctions(QQ).a_realization()
Quasisymmetric functions over the Rational Field in the Monomial basis
```

dI

alias of `dualImmaculate`

dual()

Return the dual Hopf algebra of the quasi-symmetric functions, which is the non-commutative symmetric functions.

OUTPUT:

- The non-commutative symmetric functions.

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.dual()
Non-Commutative Symmetric Functions over the Rational Field
```

class `dualImmaculate`(QSym)

Bases: `CombinatorialFreeModule`, `BindableClass`

The dual immaculate basis of the quasi-symmetric functions.

This basis first appears in [BBSSZ2012].

EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: dI = QSym.dI()
sage: dI([1,3,2])*dI([1])  # long time (6s on sage.math, 2013)
dI[1, 1, 3, 2] + dI[2, 3, 2]
sage: dI([1,3])*dI([1,1])
sage: dI([3,1])*dI([2,1])  # long time (7s on sage.math, 2013)
sage: F = QSym.F()
sage: dI(F([1,3,1]))
-dI[1, 1, 1, 2] + dI[1, 1, 2, 1] - dI[1, 2, 2] + dI[1, 3, 1]
sage: F(dI(F([2,1,3])))
F[2, 1, 3]
```
from sage.all import *

QSym = QuasiSymmetricFunctions(QQ)

dI = QSym.dI()

dI([Integer(1), Integer(3), Integer(2)])*dI([Integer(1)])  # long time (6s on sage.math, 2013)
dI[1, 1, 3, 2] + dI[2, 3, 2]

F = QSym.F()

F(dI(F([Integer(1), Integer(3), Integer(1)])))
-2*dI[1, 1, 1, 2] + dI[1, 1, 2, 1] - dI[1, 2, 2] + dI[1, 3, 1]

from_polynomial(f, check=True)

Return the quasi-symmetric function in the Monomial basis corresponding to the quasi-symmetric polynomial f.

INPUT:

• f – a polynomial in finitely many variables over the same base ring as self. It is assumed that this polynomial is quasi-symmetric.

• check – boolean (default: True), checks whether the polynomial is indeed quasi-symmetric.

OUTPUT:

• quasi-symmetric function in the Monomial basis

EXAMPLES:

sage: P = PolynomialRing(QQ, 'x', 3)
sage: x = P.gens()
sage: f = x[0] + x[1] + x[2]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.from_polynomial(f)

M[1]

sage: P = PolynomialRing(QQ, 'x', Integer(3))
sage: x = P.gens()
sage: f = x[Integer(0)] + x[Integer(1)] + x[Integer(2)]
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.from_polynomial(f)

M[1]

Beware of setting check=False:

sage: f = x[0] + 2*x[1] + x[2]
sage: QSym.from_polynomial(f, check=True)
Traceback (most recent call last):
...
ValueError: x0 + 2*x1 + x2 is not a quasi-symmetric polynomial
To expand the quasi-symmetric function in a basis other than the Monomial basis, the following shorthands are provided:

```python
sage: M = QSym.Monomial()
sage: f = x[0]**2+x[1]**2+x[2]**2
sage: g = M.from_polynomial(f); g
M[2]
sage: F = QSym.Fundamental()
sage: F(g) -F[1, 1] + F[2]
sage: F.from_polynomial(f) -F[1, 1] + F[2]
```

```python
>>> from sage.all import *
>>> M = QSym.Monomial()
>>> f = x[Integer(0)]**Integer(2)+x[Integer(1)]**Integer(2)+x[Integer(2)]**Integer(2)
>>> g = M.from_polynomial(f); g
M[2]
>>> F = QSym.Fundamental()
>>> F(g) -F[1, 1] + F[2]
>>> F.from_polynomial(f) -F[1, 1] + F[2]
```

### class phi(QSym)

Bases: `CombinatorialFreeModule`, `BindableClass`

The Hopf algebra of quasi-symmetric functions in the \( \phi \) basis.

The \( \phi \) basis is defined as a rescaled Hopf dual of the \( \Phi \) basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

\[
(\phi_I, \Phi_J) = z_I \delta_{I,J},
\]

where \( z_I = 1^{m_1}m_1!2^{m_2}m_2! \cdots \) with \( m_i \) being the multiplicity of \( i \) in the composition \( I \). Therefore, we call these the *quasi-symmetric power sums of the second kind*.

Using the duality, we can directly define the \( \phi \) basis by

\[
\phi_I = \sum_{J \succ I} z_I/sp_{I,J}M_J,
\]

where \( sp_{I,J} \) is as defined in [NCSF].

The \( \phi \)-basis is well-defined only when the base ring is a \( \mathbb{Q} \)-algebra.
EXAMPLES:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: phi = QSym.phi(); phi
Quasisymmetric functions over the Rational Field in the phi basis
sage: phi.an_element()
2*phi[] + 2*phi[1] + 3*phi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[2,2,1])
phi[1, 2, 2] + phi[2, 1, 2] + phi[2, 2, 1]
sage: all(sum(phi(list(al)) for al in Permutations(la))==phi(p(la)) for la in Partitions(6))
True

sage: p = SymmetricFunctions(QQ).p()
sage: phi(p[3,2,2])
phi[2, 2, 3] + phi[2, 3, 2] + phi[3, 2, 2]
```

Checking the equivalent definition of $\phi_n$:

```python
sage: def test_phi(n):
    phi = QuasiSymmetricFunctions(QQ).phi()
    Phi = NonCommutativeSymmetricFunctions(QQ).Phi()
    M = matrix([[phi[I].duality_pairing(Phi[J])
                 for I in Compositions(n)]
                 for J in Compositions(n)])
    def z(J):
        return J.to_partition().centralizer_size()
    return M == matrix.diagonal([z(I) for I in Compositions(n)])
sage: all(test_phi(k) for k in range(1,5))
True
```

```python
>>> from sage.all import *
>>> def test_phi(n):
...     phi = QuasiSymmetricFunctions(QQ).phi()
...     Phi = NonCommutativeSymmetricFunctions(QQ).Phi()
...     M = matrix([[phi[I].duality_pairing(Phi[J])
...                 for I in Compositions(n)]
...                 for J in Compositions(n)])
...     def z(J):
...         return J.to_partition().centralizer_size()
...     return M == matrix.diagonal([z(I) for I in Compositions(n)])
>>> all(test_phi(k) for k in range(Integer(1),Integer(5)))
True
```
class psi(QSym)

Bases: CombinatorialFreeModule, BindableClass

The Hopf algebra of quasi-symmetric functions in the $\psi$ basis.

The $\psi$ basis is defined as a rescaled Hopf dual of the $\Psi$ basis of the non-commutative symmetric functions (see Section 3.1 of [BDHMN2017]), where the pairing is

$$(\psi_I, \Psi_J) = z_I \delta_{I,J},$$

where $z_I = 1^{m_1}m_2!m_2\cdots$ with $m_i$ being the multiplicity of $i$ in the composition $I$. Therefore, we call these the quasi-symmetric power sums of the first kind.

Using the duality, we can directly define the $\psi$ basis by

$$\psi_I = \sum_{J \succ I} z_I / \pi_{I,J} M_J,$$

where $\pi_{I,J}$ is as defined in [NCSF].

The $\psi$-basis is well-defined only when the base ring is a $\mathbb{Q}$-algebra.

EXAMPLES:

```
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: psi = QSym.psi(); psi
Quasisymmetric functions over the Rational Field in the psi basis
sage: psi.an_element()
2*psi[] + 2*psi[1] + 3*psi[1, 1]
sage: p = SymmetricFunctions(QQ).p()
sage: psi(p[2, 2, 1])
psi[1, 2, 2] + psi[2, 1, 2] + psi[2, 2, 1]
```

Checking the equivalent definition of $\psi_n$:
5.1.146 Introduction to Quasisymmetric Functions

In this document we briefly explain the quasisymmetric function bases and related functionality in Sage. We assume the reader is familiar with the package `SymmetricFunctions`.

Quasisymmetric functions, denoted $\mathcal{QSym}$, form a subring of the power series ring in countably many variables. $\mathcal{QSym}$ contains the symmetric functions. These functions first arose in the theory of $P$-partitions. The initial ideas in this field are attributed to MacMahon, Knuth, Kreweras, Glânfrwd Thomas, Stanley. In 1984, Gessel formalized the study of quasisymmetric functions and introduced the basis of fundamental quasisymmetric functions [Ges]. In 1995, Gelfand, Krob, Lascoux, Leclerc, Retakh, and Thibon showed that the ring of quasisymmetric functions is Hopf dual to the non-commutative symmetric functions [NCSF]. Many results have built on these.

One advantage of working in $\mathcal{QSym}$ is that many interesting families of symmetric functions have explicit expansions in fundamental quasisymmetric functions such as Schur functions [Ges], Macdonald polynomials [HHL05], and plethysm of Schur functions [LW12].

For more background see Wikipedia article Quasisymmetric_function.

To begin, initialize the ring. Below we chose to use the rational numbers $\mathbb{Q}$. Other options include the integers $\mathbb{Z}$ and $\mathbb{C}$:

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym
Quasisymmetric functions over the Rational Field
sage: QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision
sage: QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

```python
>>> from sage.all import *
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym
Quasisymmetric functions over the Rational Field
```
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> QSym = QuasiSymmetricFunctions(CC); QSym
Quasisymmetric functions over the Complex Field with 53 bits of precision

>>> QSym = QuasiSymmetricFunctions(ZZ); QSym
Quasisymmetric functions over the Integer Ring
```

All bases of $QSym$ are indexed by compositions e.g. $[3, 1, 1, 4]$. The convention is to use capital letters for bases of $QSym$ and lowercase letters for bases of the symmetric functions $Sym$. Next set up names for the known bases by running `inject_shorthands()`. As with symmetric functions, you do not need to run this command and you could assign these bases other names.

```python
sage: QSym = QuasiSymmetricFunctions(QQ)
sage: QSym.inject_shorthands()
Defining M as shorthand for Quasisymmetric functions over the Rational Field in the
   → Monomial basis
Defining F as shorthand for Quasisymmetric functions over the Rational Field in the
   → Fundamental basis
Defining E as shorthand for Quasisymmetric functions over the Rational Field in the
   → Essential basis
Defining dI as shorthand for Quasisymmetric functions over the Rational Field in the
   → dualImmaculate basis
Defining QS as shorthand for Quasisymmetric functions over the Rational Field in the
   → Quasisymmetric Schur basis
Defining YQS as shorthand for Quasisymmetric functions over the Rational Field in the
   → Young Quasisymmetric Schur basis
Defining phi as shorthand for Quasisymmetric functions over the Rational Field in the
   → phi basis
Defining psi as shorthand for Quasisymmetric functions over the Rational Field in the
   → psi basis
```

```python
>>> from sage.all import *
```

```python
>>> QSym = QuasiSymmetricFunctions(QQ)
>>> QSym.inject_shorthands()
Defining M as shorthand for Quasisymmetric functions over the Rational Field in the
   → Monomial basis
Defining F as shorthand for Quasisymmetric functions over the Rational Field in the
   → Fundamental basis
Defining E as shorthand for Quasisymmetric functions over the Rational Field in the
   → Essential basis
Defining dI as shorthand for Quasisymmetric functions over the Rational Field in the
   → dualImmaculate basis
Defining QS as shorthand for Quasisymmetric functions over the Rational Field in the
   → Quasisymmetric Schur basis
Defining YQS as shorthand for Quasisymmetric functions over the Rational Field in the
   → Young Quasisymmetric Schur basis
Defining phi as shorthand for Quasisymmetric functions over the Rational Field in the
   → phi basis
Defining psi as shorthand for Quasisymmetric functions over the Rational Field in the
   → psi basis
```

Now one can start constructing quasisymmetric functions.

**Note:** It is best to use variables other than $M$ and $F$.  

5.1. Comprehensive Module List

2429
Combinatorics, Release 10.4

```sage
sage: x = M[2,1] + M[1,2]
sage: x
M[1, 2] + M[2, 1]
sage: y = 3*M[1,2] + M[3]^2; y
sage: F[3,1,3] + 7*F[2,1]
7*F[2, 1] + F[3, 1, 3]
```

```sage
>>> from sage.all import *

sage: x = M[Integer(2),Integer(1)] + M[Integer(1),Integer(2)]
sage: x
M[1, 2] + M[2, 1]

sage: y = Integer(3)*M[Integer(1),Integer(2)] + M[Integer(3)]**Integer(2); y

sage: F[Integer(3),Integer(1),Integer(3)] + Integer(7)*F[Integer(2),Integer(1)]
7*F[2, 1] + F[3, 1, 3]

sage: Integer(3)*F[Integer(2),Integer(1),Integer(2)] + F[Integer(3)]**Integer(2)
```

To convert from one basis to another is easy:

```sage
sage: z = M[1,2,1]
sage: z
M[1, 2, 1]

sage: F(z)
-F[1, 1, 1, 1] + F[1, 2, 1]

sage: M(F(z))
M[1, 2, 1]
```

```sage
>>> from sage.all import *

sage: z = M[Integer(1),Integer(2),Integer(1)]

sage: z
M[1, 2, 1]

sage: F(z)
-F[1, 1, 1, 1] + F[1, 2, 1]

sage: M(F(z))
M[1, 2, 1]
```

To expand in variables, one can specify a finite size alphabet $x_1, x_2, \ldots, x_m$:
sage: y = M[1,2,1]
sage: y.expand(4)
x0*x1^2*x2 + x0*x1^2*x3 + x0*x2^2*x3 + x1*x2^2*x3

>>> from sage.all import *
>>> y = M[Integer(1),Integer(2),Integer(1)]
>>> y.expand(Integer(4))
x0*x1^2*x2 + x0*x1^2*x3 + x0*x2^2*x3 + x1*x2^2*x3

The usual methods on free modules are available such as coefficients, degrees, and the support:

sage: z = 3*M[1,2]+M[3]^2; z
sage: z.coefficient([1,2])
3
sage: z.degree()
6

sage: sorted(z.coefficients())
[1, 2, 3]
sage: sorted(z.monomials(), key=lambda x: tuple(x.support()))
[M[1, 2], M[3, 3], M[6]]
sage: z.monomial_coefficients()
{(1, 2): 3, (3, 3): 2, (6): 1}

>>> from sage.all import *
>>> z = Integer(3)*M[Integer(1),Integer(2)]+M[Integer(3)**Integer(2)]; z

>>> z.coefficient([Integer(1),Integer(2)])
3

>>> z.degree()
6

>>> sorted(z.coefficients())
[1, 2, 3]

>>> sorted(z.monomials(), key=lambda x: tuple(x.support()))
[M[1, 2], M[3, 3], M[6]]

>>> z.monomial_coefficients()
{(1, 2): 3, (3, 3): 2, (6): 1}

As with the symmetric functions package, the quasisymmetric function 1 has several instantiations. However, the most obvious way to write 1 leads to an error (this is due to the semantics of python):

sage: M[[]]
M[]
sage: M.one()
M[]
sage: M(1)
M[]

(continues on next page)
**Working with symmetric functions**

The quasisymmetric functions are a ring which contains the symmetric functions as a subring. The Monomial quasisymmetric functions are related to the monomial symmetric functions by $m_\lambda = \sum_{\text{sort}(\epsilon) = \lambda} M_\epsilon$, where $\text{sort}(\epsilon)$ means the partition obtained by sorting the composition $\epsilon$:

```
sage: SymmetricFunctions(QQ).inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary→basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten→basis
Defining h as shorthand for Symmetric Functions over Rational Field in the→homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial→basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum→basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis

sage: m[2,1]
m[2, 1]
sage: M(m[2,1])
M[1, 2] + M[2, 1]
sage: M(s[2,1])
2*M[1, 1, 1] + M[1, 2] + M[2, 1]
```

```python
>>> from sage.all import *

>>> SymmetricFunctions(QQ).inject_shorthands()
Defining e as shorthand for Symmetric Functions over Rational Field in the elementary→basis
Defining f as shorthand for Symmetric Functions over Rational Field in the forgotten→basis
Defining h as shorthand for Symmetric Functions over Rational Field in the→homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial→basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum→basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis
```
homogeneous basis
Defining m as shorthand for Symmetric Functions over Rational Field in the monomial basis
Defining p as shorthand for Symmetric Functions over Rational Field in the powersum basis
Defining s as shorthand for Symmetric Functions over Rational Field in the Schur basis

```python
>>> m[Integer(2),Integer(1)]
m[2, 1]
```

```python
>>> M(m[Integer(2),Integer(1)])
M[1, 2] + M[2, 1]
```

```python
>>> M(s[Integer(2),Integer(1)])
2*M[1, 1, 1] + M[1, 2] + M[2, 1]
```

There are methods to test if an expression $f$ in the quasisymmetric functions is a symmetric function:

```python
sage: f = M[1,1,2] + M[1,2,1]
sage: f.is_symmetric()
False
sage: f = M[3,1] + M[1,3]
sage: f.is_symmetric()
True
```

```python
>>> from sage.all import *
```

```python
>>> f.is_symmetric()
False
>>> f.is_symmetric()
True
```

If $f$ is symmetric, there are methods to convert $f$ to an expression in the symmetric functions:

```python
sage: f.to_symmetric_function()
m[3, 1]
```

```python
>>> from sage.all import *
```

```python
>>> f.to_symmetric_function()
m[3, 1]
```

The expansion of the Schur function in terms of the Fundamental quasisymmetric functions is due to [Ges]. There is one term in the expansion for each standard tableau of shape equal to the partition indexing the Schur function.

```python
sage: f.is_symmetric()
True
```

```python
sage: f.to_symmetric_function()
5*m[1, 1, 1, 1] + 3*m[2, 1, 1, 1] + 2*m[2, 2, 1] + m[3, 1, 1] + m[3, 2]
sage: s(f.to_symmetric_function())
s[3, 2]
```

```python
>>> from sage.all import *
```

```python
>>> f = F[Integer(3),Integer(2)] + F[Integer(2),Integer(2),Integer(1)] + F[Integer(2), Integer(3)] + F[Integer(1),Integer(3),Integer(1)] + F[Integer(1),Integer(2), Integer(2)]
(continues on next page)
It is also possible to convert any symmetric function to the quasisymmetric function expansion in any known basis. The converse is not true:

```python
sage: M( m[3,1,1] )
M[1, 1, 3] + M[1, 3, 1] + M[3, 1, 1]
sage: F( s[2,2,1] )
F[1, 1, 2, 1] + F[1, 2, 1, 1] + F[1, 2, 2] + F[2, 1, 2] + F[2, 2, 1]

sage: s(M[2,1])
Traceback (most recent call last):
...: TypeError: do not know how to make x (= M[2, 1]) an element of self
```

It is possible to experiment with the quasisymmetric function expansion of other bases, but it is important that the base ring be the same for both algebras.

```python
sage: R = QQ['t']
sage: Qp = SymmetricFunctions(R).hall_littlewood().Qp()
sage: QSym = QuasiSymmetricFunctions(R)
sage: Ft = QSym.F()
sage: Ft( Qp[2,2] )
```

```python
sage: K = QQ['q','t'].fraction_field()
sage: Ht = SymmetricFunctions(K).macdonald().Ht()
sage: Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()
sage: Fqt(Ht[2,1])
q*t*F[1, 2, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```
```python
>>> from sage.all import *

>>> K = QQ['q','t'].fraction_field()
>>> Ht = SymmetricFunctions(K).macdonald().Ht()

>>> Fqt = QuasiSymmetricFunctions(Ht.base_ring()).F()

>>> Fqt(Ht[Integer(2),Integer(1)])
q*t*F[1, 1, 1] + (q+t)*F[1, 2] + (q+t)*F[2, 1] + F[3]
```

The following will raise an error because the base ring of $F$ is not equal to the base ring of $Ht$:

```python
sage: F(Ht[2,1])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self...
˓→(Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

```python
>>> from sage.all import *

>>> F(Ht[Integer(2),Integer(1)])
Traceback (most recent call last):
...
TypeError: do not know how to make x (= McdHt[2, 1]) an element of self...
˓→(Quasisymmetric functions over the Rational Field in the Fundamental basis)
```

**QSym is a Hopf algebra**

The product on $QSym$ is commutative and is inherited from the product by the realization within the polynomial ring:

```python
sage: M[3]*M[1,1] == M[1,1]*M[3]
True

sage: M[3]*M[1,1]

sage: F[3]*F[1,1]

sage: M[3]*F[2]

sage: F[2]*M[3]
```

```python
>>> from sage.all import *

>>> M[Integer(3)]*M[Integer(1),Integer(1)] == M[Integer(1),Integer(1)]*M[Integer(3)]
True

>>> M[Integer(3)]*M[Integer(1),Integer(1)]

>>> F[Integer(3)]*F[Integer(1),Integer(1)]

>>> M[Integer(3)]*F[Integer(2)]

>>> F[Integer(2)]*M[Integer(3)]
```

There is a coproduct on this ring as well, which in the Monomial basis acts by cutting the composition into a left half and a right half. The co-product is non-co-commutative:
The Duality Pairing with Non-Commutative Symmetric Functions

These two operations endow $QS\ym$ with the structure of a Hopf algebra. It is the dual Hopf algebra of the non-commutative symmetric functions $N\CSF$. Under this duality, the Monomial basis of $QS\ym$ is dual to the Complete basis of $N\CSF$, and the Fundamental basis of $QS\ym$ is dual to the Ribbon basis of $N\CSF$ (see [MR]):

```python
sage: S = M.dual(); S
Non-Commutative Symmetric Functions over the Rational Field in the Complete basis
sage: M[1,3,1].duality_pairing( S[1,3,1] )
1
sage: M.duality_pairing_matrix( S, degree=4 )

[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: F.duality_pairing_matrix( S, degree=4 )

[1 0 0 0 0 0 0 0]
[0 1 0 0 0 0 0 0]
[0 0 1 0 0 0 0 0]
[0 0 0 1 0 0 0 0]
[0 0 0 0 1 0 0 0]
[0 0 0 0 0 1 0 0]
[0 0 0 0 0 0 1 0]
[0 0 0 0 0 0 0 1]
sage: NCSF = M.realization_of().dual()
sage: R = NCSF.Ribbon()
sage: F.duality_pairing_matrix( R, degree=4 )

[1 0 0 0 0 0 0 0]
[1 1 0 0 0 0 0 0]
[1 0 1 0 0 0 0 0]
[1 1 1 1 0 0 0 0]
[1 0 0 1 0 0 0 0]
[1 1 0 0 1 0 0 0]
[1 0 1 0 1 0 0 0]
[1 1 1 1 1 1 1 1]
sage: M.duality_pairing_matrix( R, degree=4 )

[ 1 0 0 0 0 0 0 0]
[-1 1 0 0 0 0 0 0]
```
Let $H$ and $G$ be elements of $QSym$ and $h$ an element of $NCSF$. Then if we represent the duality pairing with the mathematical notation $[\cdot, \cdot]$, we have:

$$[H \cdot G, h] = [H \otimes G, \Delta(h)].$$

For example, the coefficient of $M[2,1,4,1]$ in $M[1,3] \ast M[2,1,1]$ may be computed with the duality pairing.
Combinatorics, Release 10.4

```
sage: I, J = Composition([1,3]), Composition([2,1,1])
sage: (M[I]*M[J]).duality_pairing(S[2,1,4,1])
1
```

And the coefficient of $S[1, 3] \# S[2, 1, 1]$ in $S[2, 1, 4, 1].coproduct()$ is equal to this result:

```
sage: S[2,1,4,1].coproduct()
```

The duality pairing on the tensor space is another way of getting this coefficient, but currently the method `duality_pairing()` is not defined on the tensor squared space. However, we can extend this functionality by applying a linear morphism to the terms in the coproduct, as follows:

```
sage: X = S[2,1,4,1].coproduct()
sage: def linear_morphism(x, y):
....:     return x.duality_pairing(M[1,3]) * y.duality_pairing(M[2,1,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
1
```

Similarly, if $H$ is an element of $QSym$ and $g$ and $h$ are elements of $NCSF$, then

$$[H, g \cdot h] = [\Delta(H), g \otimes h].$$

For example, the coefficient of $R[2, 3, 1]$ in $R[2, 1] * R[2, 1]$ is computed with the duality pairing by the following command:

```
sage: (R[2,1]*R[2,1]).duality_pairing(F[2,3,1])
1
```

```
sage: R[2,1]*R[2,1]
R[2, 1, 2, 1] + R[2, 3, 1]
```
This coefficient should then be equal to the coefficient of \( F[2, 1] \# F[2, 1] \) in \( F[2, 3, 1].\text{coproduct}() \):

```python
sage: F[2,3,1].coproduct()
```

\[
F[] \# F[2, 3, 1] + \ldots + F[2, 1] \# F[2, 1] + \ldots + F[2, 3, 1] \# F[]
\]

```python
>>> from sage.all import *

>>> F[Integer(2),Integer(3),Integer(1)].coproduct()
```

This can also be computed by the duality pairing on the tensor space, as above:

```python
sage: X = F[2,3,1].coproduct()
sage: def linear_morphism(x, y):
    ... return x.duality_pairing(R[2,1]) * y.duality_pairing(R[2,1])
sage: X.apply_multilinear_morphism(linear_morphism, codomain=ZZ)
```

```
1
```

The Operation Adjoint to Multiplication by a Non-Commutative Symmetric Function

Let \( g \in NCSF \) and consider the linear endomorphism of \( NCSF \) defined by left (respectively, right) multiplication by \( g \). Since there is a duality between \( QSym \) and \( NCSF \), this linear transformation induces an operator \( g^\perp \) on \( QSym \) satisfying

\[
[g^\perp(H), h] = [H, g \cdot h].
\]

for any non-commutative symmetric function \( h \).

This is implemented by the method `skew_by()`. Explicitly, if \( H \) is a quasisymmetric function and \( g \) a non-commutative symmetric function, then \( H.skew_by(g) \) and \( H.skew_by(g, \text{side='right'} \) are expressions that satisfy, for any non-commutative symmetric function \( h \), the following identities:

\[
H.skew_by(g).duality_pairing(h) == H.duality_pairing(g*h)
H.skew_by(g, side='right').duality_pairing(h) == H.duality_pairing(h*g)
\]

For example, \( M[J].skew_by(S[I]) \) is 0 unless the composition \( J \) begins with \( I \) and \( M(J).skew_by(S(I), \text{side='right'} \) is 0 unless the composition \( J \) ends with \( I \):

```python
sage: M[3,2,2].skew_by(S[3])
```

\( M[2, 2] \)

```python
sage: M[3,2,2].skew_by(S[2])
```

0

```python
sage: M[3,2,2].coproduct().apply_multilinear_morphism( lambda x,y: x.duality_pairing(S[3])*y )
```

\( M[2, 2] \)

```python
sage: M[3,2,2].skew_by(S[3], side='right')
```

0

```python
sage: M[3,2,2].skew_by(S[2], side='right')
```

\( M[3, 2] \)
The antipode

The antipode sends the Fundamental basis element indexed by the composition $I$ to $-1$ to the size of $I$ times the Fundamental basis element indexed by the conjugate composition to $I$:

```python
sage: F[3,2,2].antipode()
-F[1, 2, 2, 1, 1]
sage: Composition([3,2,2]).conjugate()
[1, 2, 2, 1, 1]
sage: M[3,2,2].antipode()
```

We demonstrate here the defining relation of the antipode:

```python
sage: X = F[3,2,2].coproduct()
sage: X.apply_multilinear_morphism(lambda x,y: x*y.antipode())
0
sage: X.apply_multilinear_morphism(lambda x,y: x.antipode()*y)
0
```

5.1.148 Bases for NCSym

**Authors:**
- Travis Scrimshaw (08-04-2013): Initial version

```python
class sage.combinat.ncsym.bases.MultiplicativeNCSymBases( parent_with_realization ):
    Bases: Category_realization_of_parent
    
    Category of multiplicative bases of symmetric functions in non-commuting variables.

    A multiplicative basis is one for which \( b_A b_B = b_{A|B} \) where \( A|B \) is the pipe() operation on set partitions.

    EXAMPLES:
```

```python
sage: from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: MultiplicativeNCSymBases(NCSym)
```

```python
>>> from sage.all import *
>>> from sage.combinat.ncsym.bases import MultiplicativeNCSymBases
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> MultiplicativeNCSymBases(NCSym)
```

```python
class ElementMethods:
    Bases: object

class ParentMethods:
    Bases: object

    product_on_basis(A, B)
    
    The product on basis elements.
    
    The product on a multiplicative basis is given by \( b_A \cdot b_B = b_{A|B} \).
    
    The bases \( \{e, h, x, cp, p, chi, rho\} \) are all multiplicative.

    INPUT:
    - \( A, B \) -- set partitions

    OUTPUT:
    - an element in the basis self

    EXAMPLES:
```
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).p()
sage: chi = SymmetricFunctionsNonCommutingVariables(QQ).chi()
sage: rho = SymmetricFunctionsNonCommutingVariables(QQ).rho()
sage: A = SetPartition([[1], [2, 3]])
sage: B = SetPartition([[1], [3], [2, 4]])
sage: e.product_on_basis(A, B)
e{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: h.product_on_basis(A, B)
h{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: x.product_on_basis(A, B)
x{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: cp.product_on_basis(A, B)
cp{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: p.product_on_basis(A, B)
p{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: chi.product_on_basis(A, B)
chi{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: rho.product_on_basis(A, B)
rho{{1}, {2, 3}, {4}, {5, 7}, {6}}
sage: e.product_on_basis(A, B) == e(h(e(A))*h(e(B)))
True
sage: h.product_on_basis(A, B) == h(x(h(A))*x(h(B)))
True
sage: x.product_on_basis(A, B) == x(h(x(A))*h(x(B)))
True
sage: cp.product_on_basis(A, B) == cp(p(cp(A))*p(cp(B)))
True
sage: p.product_on_basis(A, B) == p(e(p(A))*e(p(B)))
True

>>> from sage.all import *
>>> e = SymmetricFunctionsNonCommutingVariables(QQ).e()

x{{1}, {2, 3}, {4}, {5, 7}, {6}}
>>> cp.product_on_basis(A, B)
cp{{1}, {2, 3}, {4}, {5, 7}, {6}}
>>> p.product_on_basis(A, B)
p{{1}, {2, 3}, {4}, {5, 7}, {6}}
>>> chi.product_on_basis(A, B)
chi{{1}, {2, 3}, {4}, {5, 7}, {6}}
(continues on next page)
super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

• a list of categories

class sage.combinat.ncsym.bases.NCSymBases(parent_with_realization)

Bases: Category_realization_of_parent

Category of bases of symmetric functions in non-commuting variables.

EXAMPLES:

sage: from sage.combinat.ncsym.bases import NCSymBases
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: NCSymBases(NCSym)
Category of bases of symmetric functions in non-commuting variables over the
˓→Rational Field

class ElementMethods

Bases: object

expand(n, alphabet='x')

Expand the symmetric function into n non-commuting variables in an alphabet, which by default is 'x'. This computation is completed by coercing the element self into the monomial basis and computing the expansion in the alphabet there.

INPUT:

• n – the number of variables in the expansion
• alphabet – (default: 'x') the alphabet in which self is to be expanded

OUTPUT:

• an expansion of self into the n non-commuting variables specified by alphabet

EXAMPLES:

```python
>>> rho.product_on_basis(A, B)
rho({1}, {2, 3}, {4}, {5, 7}, {6})
>>> e.product_on_basis(A, B) == e(h(e(A))*h(e(B)))
True
>>> h.product_on_basis(A, B) == h(x(h(A))*x(h(B)))
True
>>> x.product_on_basis(A, B) == x(h(x(A))*h(x(B)))
True
>>> cp.product_on_basis(A, B) == cp(p(cp(A))*p(cp(B)))
True
>>> p.product_on_basis(A, B) == p(e(p(A))*e(p(B)))
True
```
Combinatorics, Release 10.4

```python
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].expand(3)
2*x0^3 + x0^2*x1 + x0^2*x2 + 2*x0*x1*x0 + x0*x1*x2 + 2*x0*x2*x0 + x0*x2*x1 + x0*x2^2 + x1*x0^2 + 2*x1*x0*x1 + x1*x0*x2 + x1^2*x0 + 2*x1^3 + x1^2*x2 + x1*x2*x0 + 2*x1*x2*x1 + x1*x2^2 + x2*x0^2 + x2*x0*x1 + x2*x1*x0 + x2*x1^2 + 2*x2*x1*x2 + x2^2*x0 + x2^2*x1 + 2*x2^3
```

```python
data: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1,3],[2]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 3}, {2}} + x{{1, 3}, {2}} # x{{1}, {2}, {3}} + x{{1, 3}, {2}} # x{{1, 3}, {2}}
```

```python
>>> from sage.all import *
>>> x = SymmetricFunctionsNonCommutingVariables(QQ).x()
>>> x[[1], [2]].omega()
x{{1}, {2}}
```

### internal_coproduct()

Return the internal coproduct of self.

The internal coproduct is defined on the power sum basis as

\[ P_A \mapsto P_A \otimes P_A \]

and the map is extended linearly.

**OUTPUT:**

- an element of the tensor square of the basis of self

**EXAMPLES:**

```python
sage: x = SymmetricFunctionsNonCommutingVariables(QQ).x()
sage: x[[1], [2]].internal_coproduct()
x{{1}, {2}, {3}} # x{{1, 3}, {2}} + x{{1, 3}, {2}} # x{{1}, {2}, {3}} + x{{1, 3}, {2}} # x{{1, 3}, {2}}
```

```python
>>> from sage.all import *
>>> x = SymmetricFunctionsNonCommutingVariables(QQ).x()
>>> x[[1], [2]].omega()
x{{1}, {2}}
```

### omega()

Return the involution \( \omega \) applied to self.

The involution \( \omega \) is defined by

\[ e_A \mapsto h_A \]
and the result is extended linearly.

OUTPUT:

• an element in the same basis as self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: m[[1,3],[2]].omega()
-2*m{{1, 2, 3}} - m{{1, 3}, {2}}
sage: p = NCSym.p()
sage: p[[1,3],[2]].omega()
-p{{1, 3}, {2}}
sage: cp = NCSym.cp()
sage: cp[[1,3],[2]].omega()
-2*cp{{1, 2, 3}} - cp{{1, 3}, {2}}
sage: x = NCSym.x()
sage: x[[1,3],[2]].omega()
-2*x{{1}, {2}, {3}} - x{{1, 3}, {2}}
```

```python
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> m[[1,3],[2]].omega()
-2*m{{1, 2, 3}} - m{{1, 3}, {2}}
>>> p = NCSym.p()
>>> p[[1,3],[2]].omega()
-p{{1, 3}, {2}}
>>> cp = NCSym.cp()
>>> cp[[1,3],[2]].omega()
-2*cp{{1, 2, 3}} - cp{{1, 3}, {2}}
>>> x = NCSym.x()
>>> x[[1,3],[2]].omega()
-2*x{{1}, {2}, {3}} - x{{1, 3}, {2}}
```

to_symmetric_function()

Compute the projection of an element of symmetric function in non-commuting variables to the symmetric functions.

The projection of a monomial symmetric function in non-commuting variables indexed by the set partition \( A \) is defined as

\[
m_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!
\]

where \( \lambda(A) \) is the partition associated with \( A \) by taking the sizes of the parts and \( n_i(\mu) \) is the multiplicity of \( i \) in \( \mu \). For other bases this map is extended linearly.

OUTPUT:

• an element of the symmetric functions in the monomial basis

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
```
Combinatorics, Release 10.4

```python
sage: cp[[1,3],[2]].to_symmetric_function()
m[2, 1]
sage: x[[1,3],[2]].to_symmetric_function()
-6*m[1, 1, 1] - 2*m[2, 1]
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
sage: p[[1,3],[2]].to_symmetric_function()
p[2, 1]
```

```python
from sage.all import *

NCSym = SymmetricFunctionsNonCommutingVariables(QQ)

e = NCSym.e()
h = NCSym.h()
p = NCSym.p()
cp = NCSym.cp()
x = NCSym.x()

cp[[1,3],[2]].to_symmetric_function()
m[2, 1]
x[[1,3],[2]].to_symmetric_function()
-6*m[1, 1, 1] - 2*m[2, 1]
e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
h[[1,3],[2]].to_symmetric_function()
2*h[2, 1]
p[[1,3],[2]].to_symmetric_function()
p[2, 1]
```

to_wqsym()

Return the image of self under the canonical inclusion map $NCSym \to WQSym$.

The canonical inclusion map $NCSym \to WQSym$ is an injective homomorphism of algebras. It sends a basis element $m_A$ of $NCSym$ to the sum of basis elements $M_P$ of $WQSym$, where $P$ ranges over all ordered set partitions that become $A$ when the ordering is forgotten. This map is denoted by $\theta$ in [BZ05] (17).

See also:

WordQuasiSymmetricFunctions for a definition of $WQSym$.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: cp = NCSym.cp()
sage: x = NCSym.x()
sage: m = NCSym.m()
sage: m[[1,3],[2]].to_wqsym()
M[[1, 3], {2}] + M[{}, {1, 3}]
sage: x[[1,3],[2]].to_wqsym()

class ParentMethods
Bases: object

from_symmetric_function(f)
Return the image of the symmetric function f in self.

This is performed by converting to the monomial basis and extending the method sum_of_partitions() linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also:
to_symmetric_function()

INPUT:
• f – a symmetric function

OUTPUT:
• an element of self

EXAMPLES:
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: Sym = SymmetricFunctions(QQ)
sage: e = NCSym.e()
sage: elem = Sym.e()
sage: elt = e.from_symmetric_function(elem[2,1,1]); elt
1/12*e{{1}, {2}, {3, 4}} + 1/12*e{{1}, {2, 3}, {4}} + 1/12*e{{1}, {2, 4},
    {3}}
+ 1/12*e{{1, 2}, {3}, {4}} + 1/12*e{{1, 3}, {2}, {4}} + 1/12*e{{1, 4},
    {2}, {3}}
sage: elem(elt.to_symmetric_function())
e[2, 1, 1]
sage: e.from_symmetric_function(elem[4])
1/24*e{{1, 2, 3, 4}}
sage: p = NCSym.p()
sage: pow = Sym.p()
sage: elt = p.from_symmetric_function(pow[2,1,1]); elt
1/6*p{{1}, {2}, {3, 4}} + 1/6*p{{1}, {2, 3}, {4}} + 1/6*p{{1}, {2, 4}, {3}}
+ 1/6*p{{1, 2}, {3}, {4}} + 1/6*p{{1, 3}, {2}, {4}} + 1/6*p{{1, 4}, {2},
˓→ {3}}

sage: pow(elt.to_symmetric_function())
p[2, 1, 1]

sage: p.from_symmetric_function(pow[4])
p{{1, 2, 3, 4}}

sage: h = NCSym.h()
sage: comp = Sym.complete()
sage: elt = h.from_symmetric_function(comp[2,1,1]); elt
1/12*h{{1}, {2}, {3, 4}} + 1/12*h{{1}, {2, 3}, {4}} + 1/12*h{{1}, {2, 4},
˓→ {3}}
+ 1/12*h{{1, 2}, {3}, {4}} + 1/12*h{{1, 3}, {2}, {4}} + 1/12*h{{1, 4},
˓→ {2}, {3}}

sage: comp(elt.to_symmetric_function())
h[2, 1, 1]

sage: h.from_symmetric_function(comp[4])
1/24*h{{1, 2, 3, 4}}

>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> Sym = SymmetricFunctions(QQ)
>>> e = NCSym.e()
>>> elem = Sym.e()

>>> elt = e.from_symmetric_function(elem[2,1,1]); elt
1/12*e{{1}, {2}, {3, 4}} + 1/12*e{{1}, {2, 3}, {4}} + 1/12*e{{1}, {2, 4},
˓→ {3}}
+ 1/12*e{{1, 2}, {3}, {4}} + 1/12*e{{1, 3}, {2}, {4}} + 1/12*e{{1, 4},
˓→ {2}, {3}}

>>> elem(elt.to_symmetric_function())

>>> e.from_symmetric_function(elem[4])
1/24*e{{1, 2, 3, 4}}

>>> p = NCSym.p()

>>> pow = Sym.p()

>>> elt = p.from_symmetric_function(pow[2,1,1]); elt
1/6*p{{1}, {2}, {3, 4}} + 1/6*p{{1}, {2, 3}, {4}} + 1/6*p{{1}, {2, 4},
˓→ {3}}
+ 1/6*p{{1, 2}, {3}, {4}} + 1/6*p{{1, 3}, {2}, {4}} + 1/6*p{{1, 4}, {2},
˓→ {3}}

>>> pow(elt.to_symmetric_function())
p[2, 1, 1]

>>> p.from_symmetric_function(pow[4])
p{{1, 2, 3, 4}}

>>> h = NCSym.h()

>>> comp = Sym.complete()

>>> elt = h.from_symmetric_function(comp[2,1,1]); elt
1/12*h{{1}, {2}, {3, 4}} + 1/12*h{{1}, {2, 3}, {4}} + 1/12*h{{1}, {2, 4},
˓→ {3}}
+ 1/12*h{{1, 2}, {3}, {4}} + 1/12*h{{1, 3}, {2}, {4}} + 1/12*h{{1, 4},
˓→ {2}, {3}}}
internal_coproduct()

Compute the internal coproduct of self.

If internal_coproduct_on_basis() is available, construct the internal coproduct morphism from self to self ⊗ self by extending it by linearity. Otherwise, this uses internal_coproduct_by_coercion(), if available.

OUTPUT:
• an element of the tensor squared of self

EXAMPLES:

sage: cp = SymmetricFunctionsNonCommutingVariables(QQ).cp()
sage: cp(internal_coproduct(cp[[1,3],[2]] - 2*cp[[1]]))
-2*cp({1}) # cp({1}) + cp({1, 2, 3}) # cp({1, 3}, {2}) + cp({1, 3}, {2})
    -# cp({1, 2, 3})
    + cp({1, 3}, {2}) # cp({1, 3}, {2})

internal_coproduct_by_coercion(x)

Return the internal coproduct by coercing the element to the powersum basis.

INPUT:
• x – an element of self

OUTPUT:
• an element of the tensor squared of self

EXAMPLES:

sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: h[[1,3],[2]].internal_coproduct()
2*h({1}, {2}, {3}) # h({1}, {2}, {3}) - h({1}, {2}, {3}) # h({1, 3}, {2})
    - h({1, 3}, {2}) # h({1}, {2}, {3}) + h({1, 3}, {2}) # h({1, 3}, {2})

internal_coproduct_on_basis(i)

The internal coproduct of the algebra on the basis (optional).

INPUT:
• i – the indices of an element of the basis of self
OUTPUT:
- an element of the tensor squared of self

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.internal_coproduct_on_basis(SetPartition([[1,2]]))
m{{1, 2}} # m{{1, 2}}
```

```
>>> from sage.all import *
>>> m = SymmetricFunctionsNonCommutingVariables(QQ).m()
>>> m.internal_coproduct_on_basis(SetPartition([[Integer(1),Integer(2)]]))
m{{1, 2}} # m{{1, 2}}
```

**primitive** *(A, i=1)*

Return the primitive associated to A in self.

See also:

**primitive()**

INPUT:
- A – a set partition
- i – a positive integer

OUTPUT:
- an element of self

EXAMPLES:

```python
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: elt = e.primitive(SetPartition([[1,3], [2]])); elt
e{{1, 2}, {3}} - e{{1, 3}, {2}}
sage: elt.coproduct()
e{} # e{{1, 2}, {3}} - e{} # e{{1, 3}, {2}} + e{{1, 2}, {3}} # e{} - e{{1, 2}, {3}} # e{}
```

```
>>> from sage.all import *
>>> e = SymmetricFunctionsNonCommutingVariables(QQ).e()
>>> elt = e.primitive(SetPartition([[Integer(1),Integer(3)],
                                              [Integer(2)]])); elt
e{{1, 2}, {3}} - e{{1, 3}, {2}}
```

**super_categories()**

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:
- a list of categories

**class** `sage.combinat.ncsym.bases.NCSymBasis_abstract` *(R, basis_keys=None, element_class=None, category=None, prefix=None, names=None, **kwds)*

**Bases:** `CombinatorialFreeModule`, `BindableClass`

Abstract base class for a basis of `NCSym` or its dual.
class sage.combinat.ncsym.bases.NCSymDualBases(parent_with_realization)

Bases: Category_realization_of_parent

Category of bases of dual symmetric functions in non-commuting variables.

EXAMPLES:

```python
sage: from sage.combinat.ncsym.bases import NCSymDualBases
sage: DNCSym = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymDualBases(DNCSym)
Category of bases of dual symmetric functions in non-commuting variables over the
  Rational Field
```

super_categories()

Return the super categories of bases of the Hopf dual of the symmetric functions in non-commuting variables.

OUTPUT:

• a list of categories

class sage.combinat.ncsym.bases.NCSymOrNCSymDualBases(parent_with_realization)

Bases: Category_realization_of_parent

Base category for the category of bases of symmetric functions in non-commuting variables or its Hopf dual for the common code.

class ElementMethods

Bases: object

duality_pairing(other)

Compute the pairing between self and an element other of the dual.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: elt = m[[1,3],[2]] - 3*m[[1,2],[3]]
sage: elt.duality_pairing(w[[1,3],[2]])
1
sage: elt.duality_pairing(w[[1,2],[3]])
-3
sage: elt.duality_pairing(w[[1,2]])
0
sage: e = NCSym.e()
sage: w[[1,3],[2]].duality_pairing(e[[1,3],[2]])
0
```

```python
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> w = m.dual_basis()
```

(continues on next page)
elt = m[[Integer(1),Integer(3)],[Integer(2)]] - \Integer(3)*m[[Integer(1),Integer(2)],[Integer(3)]]

elt.duality_pairing(w[[Integer(1),Integer(3)],[Integer(2)]]))
1

elt.duality_pairing(w[[Integer(1),Integer(2)],[Integer(3)]]))
-3

elt.duality_pairing(w[[Integer(1),Integer(2)]]))
0

e = NCSym.e()
w[[Integer(1),Integer(3)],[Integer(2)]]).duality_pairing(e[[Integer(1),
-\Integer(3)],[Integer(2)]])
0

class ParentMethods

Bases: object
counit_on_basis(A)
The counit is defined by sending all elements of positive degree to zero.

INPUT:
• A – a set partition

OUTPUT:
• either the 0 or the 1 of the base ring of self

EXAMPLES:
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: m.counit_on_basis(SetPartition([]))
1
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.counit_on_basis(SetPartition([[1,3], [2]]))
0
sage: w.counit_on_basis(SetPartition([]))
1

duality_pairing(x,y)
Compute the pairing between an element of self and an element of the dual.

Carry out this computation by converting x to the m basis and y to the w basis.

INPUT:
• x – an element of symmetric functions in non-commuting variables
• $y$ – an element of the dual of symmetric functions in non-commuting variables

OUTPUT:
• an element of the base ring of self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()
sage: w = NCSym.m().dual_basis()
sage: matrix([[h(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartitions(3)])
[6 2 2 2 1]
[2 2 1 1 1]
[2 1 2 1 1]
[2 1 1 2 1]
[1 1 1 1 1]
sage: (h[[1, 2], [3]] + 3*h[[1, 3], [2]]).duality_pairing(2*w[[1, 3], [2]] +
+w[[1, 2, 3]] + 2*w[[1, 2], [3]])
32
```
```python
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> w = NCSym.dual().w()
>>> m.duality_pairing_matrix(w, Integer(3))

[[1 0 0 0 0]
 [0 1 0 0 0]
 [0 0 1 0 0]
 [0 0 0 1 0]
 [0 0 0 0 1]]

Similarly for some of the other basis of \(NCSym\) and the \(w\) basis:

```python
sage: e = NCSym.e()
sage: e.duality_pairing_matrix(w, 3)

[[0 0 0 0 1]
 [0 0 1 1 1]
 [0 1 0 1 1]
 [0 1 1 0 1]
 [1 1 1 1 1]]

sage: p = NCSym.p()
sage: p.duality_pairing_matrix(w, 3)

[[1 0 0 0 0]
 [1 1 0 0 0]
 [1 0 1 0 0]
 [1 0 0 1 0]
 [1 1 1 1 1]]

sage: cp = NCSym.cp()
sage: cp.duality_pairing_matrix(w, 3)

[[1 0 0 0 0]
 [1 1 0 0 0]
 [0 0 1 0 0]
 [1 0 0 1 0]
 [1 1 1 1 1]]

sage: x = NCSym.x()
sage: w.duality_pairing_matrix(x, 3)

[[ 0 0 0 0 1]
 [ 1 0 -1 -1 1]
 [ 1 -1 0 -1 1]
 [ 1 -1 -1 0 1]
 [ 2 -1 -1 -1 1]]
```

```
>>> from sage.all import *
>>> e = NCSym.e()
>>> e.duality_pairing_matrix(w, Integer(3))

[[0 0 0 0 1]
 [0 0 1 1 1]
 [0 1 0 1 1]
 [0 1 1 0 1]
 [1 1 1 1 1]]

>>> p = NCSym.p()
>>> p.duality_pairing_matrix(w, Integer(3))

[[1 0 0 0 0]
 [1 1 0 0 0]
 [1 0 1 0 0]
 [1 0 0 1 0]
 [1 1 1 1 1]]
```

(continues on next page)
A base case test:

```python
sage: m.duality_pairing_matrix(w, 0)
[1]
```

```
from sage.all import *
```

```
m = SymmetricFunctionsNonCommutingVariables(QQ).m()
m.basis(){}
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.basis(){}
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.basis(){}
```

super_categories()

Return the super categories of bases of (the Hopf dual of) the symmetric functions in non-commuting variables.

OUTPUT:

• a list of categories
5.1.149 Dual Symmetric Functions in Non-Commuting Variables

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

```python
class sage.combinat.ncsym.dual.SymmetricFunctionsNonCommutingVariablesDual(R):
   Bases: UniqueRepresentation, Parent

The Hopf dual to the symmetric functions in non-commuting variables.
See Section 2.3 of [BZ05] for a study.

a_realization()  
Return the realization of the w basis of self.
```

```
EXAMPLES:
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual().a_realization()
Dual symmetric functions in non-commuting variables over the Rational Field
  → in the w basis

>>> from sage.all import *

>>> SymmetricFunctionsNonCommutingVariables(QQ).dual().a_realization()
Dual symmetric functions in non-commuting variables over the Rational Field
  → in the w basis
```

dual()  
Return the dual Hopf algebra of the dual symmetric functions in non-commuting variables.

```
EXAMPLES:
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: NCSymD.dual()
Symmetric functions in non-commuting variables over the Rational Field

>>> from sage.all import *

>>> NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
>>> NCSymD.dual()
Symmetric functions in non-commuting variables over the Rational Field
```

class w(NCSymD)
Bases: NCSymBasis_abstract

The dual Hopf algebra of symmetric functions in non-commuting variables in the w basis.

```
EXAMPLES:
sage: NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
sage: w = NCSymD.w()

>>> from sage.all import *

>>> NCSymD = SymmetricFunctionsNonCommutingVariables(QQ).dual()
>>> w = NCSymD.w()
```

We have the embedding $\chi^*$ of $Sym$ into $NCSym^*$ available as a coercion:
Combinatorics, Release 10.4

```python
sage: h = SymmetricFunctions(QQ).h()
sage: w(h[2,1])
w({1}, (2, 3)) + w({1, 2}, (3)) + w({1, 3}, (2))
```

Similarly we can pull back when we are in the image of $\chi^*$:

```python
sage: elt = 3*(w[[1],[2,3]] + w[[1,2],[3]] + w[[1,3],[2]])
sage: h(elt)
3*h[2, 1]
```

class Element
Bases: IndexedFreeModuleElement

An element in the $w$ basis.

```python
expand(n, letter='x')
```

Expand self written in the $w$ basis in $n^2$ commuting variables which satisfy the relation $x_{ij}x_{ik} = 0$ for all $i, j, k$.

The expansion of an element of the $w$ basis is given by equations (26) and (55) in [HNT06].

INPUT:
• $n$ – an integer
• letter – (default: 'x') a string

OUTPUT:
• The symmetric function of self expressed in the $n*n$ non-commuting variables described by letter.

REFERENCES:

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1,3],[2]].expand(4)
x02*x11*x20 + x03*x11*x30 + x03*x22*x30 + x13*x22*x31
```

```python
>>> from sage.all import *
```

```python
sage: elt = Integer(3)*(w[[Integer(1),[Integer(2),Integer(3)]] + w[[Integer(1),-Integer(2)],[Integer(3)]] + w[[Integer(1),Integer(3)],[Integer(2)]]])
>>> h(elt)
3*h[2, 1]
```

One can use a different set of variable by using the optional argument letter:

```python
sage: w[[1,3],[2]].expand(3, letter='y')
y02*y11*y20
```
is_symmetric()
Determine if a \( NC\Sym^* \) function, expressed in the \( w \) basis, is symmetric.
A function \( f \) in the \( w \) basis is a symmetric function if it is in the image of \( \chi^* \). That is to say we have
\[
    f = \sum_{\lambda} \sum_{\lambda(\lambda) = \lambda} \prod_{i} m_i(\mu)! \ c_{\lambda} \ w_A
\]
where the second sum is over all set partitions \( A \) whose shape \( \lambda(A) \) is equal to \( \lambda \) and \( m_i(\mu) \) is the multiplicity of \( i \) in the partition \( \mu \).

OUTPUT:
- True if \( \lambda(A) = \lambda(B) \) implies the coefficients of \( w_A \) and \( w_B \) are equal, False otherwise.

EXAMPLES:
```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1])
sage: elt.is_symmetric()
True
sage: elt -= 3*w.sum_of_partitions([1,1])
sage: elt.is_symmetric()
True
sage: w = SymmetricFunctionsNonCommutingVariables(ZZ).dual().w()
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.is_symmetric()
False
sage: elt = w[[1,3],[2]]
sage: elt.is_symmetric()
False
sage: elt = w[[1],[2,3]] + w[[1,2],[3]] + 2*w[[1,3],[2]]
sage: elt.is_symmetric()
False
```
```python
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> elt = w.sum_of_partitions([Integer(2),Integer(1),Integer(1)])
>>> elt.is_symmetric()
True
>>> elt -= Integer(3)*w.sum_of_partitions([Integer(1),Integer(1),Integer(1)])
>>> elt.is_symmetric()
True
>>> w = SymmetricFunctionsNonCommutingVariables(ZZ).dual().w()
>>> elt = w.sum_of_partitions([Integer(2),Integer(1),Integer(1)]) / Integer(2)
>>> elt.is_symmetric()
False
>>> elt = w[[Integer(1),Integer(3)],[Integer(2)]]
>>> elt.is_symmetric()
False
>>> elt = w[[Integer(1)],[Integer(2),Integer(3)]] + w[[Integer(1),
    →Integer(2)],[Integer(3)]] + Integer(2)*w[[Integer(1),Integer(3)],
    →[Integer(2)]]
```
(continues on next page)
elt.is_symmetric()
False

**to_symmetric_function()**

Take a function in the \( w \) basis, and return its symmetric realization, when possible, expressed in the homogeneous basis of symmetric functions.

**OUTPUT:**
- If `self` is a symmetric function, then the expansion in the homogeneous basis of the symmetric functions is returned. Otherwise an error is raised.

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: elt = w[[1], [2, 3]] + w[[1, 2], [3]] + w[[1, 3], [2]]
sage: elt.to_symmetric_function()
\( h_{2,1} \)
sage: elt = w.sum_of_partitions([2,1,1]) / 2
sage: elt.to_symmetric_function()
\( \frac{1}{2} h_{2,1,1} \)
```

**antipode_on_basis** (\( A \))

Return the antipode applied to the basis element indexed by \( A \).

**INPUT:**
- \( A \) – a set partition

**OUTPUT:**
- an element in the basis `self`

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.antipode_on_basis(SetPartition([[1], [2, 3]]))
-3*\( w_{(1)}, (2), (3) \) + \( w_{(1, 2)}, (3) \) + \( w_{(1, 3)}, (2) \)
sage: F = w[[1, 3], [5], [2, 4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x, y: x.antipode()*y)
0
```

```python
>>> from sage.all import *
```

```python
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
```

```python
>>> w.antipode_on_basis(SetPartition([[Integer(1)], [Integer(2), Integer(3)]]))
-3*w(1), (2), (3) + w(1, 2), (3) + w(1, 3), (2)
```

```python
>>> F = w[[Integer(1), Integer(3)], [Integer(5)], [Integer(2), Integer(4)]].coproduct()
```

```python
>>> F.apply_multilinear_morphism(lambda x, y: x.antipode()*y)
0
```
coproduct_on_basis(A)

Return the coproduct of a \( w \) basis element.

The coproduct on the basis element \( w_A \) is the sum over tensor product terms \( w_B \otimes w_C \) where \( B \) is the restriction of \( A \) to \( \{1, 2, \ldots, k\} \) and \( C \) is the restriction of \( A \) to \( \{k + 1, k + 2, \ldots, n\} \).

INPUT:
- \( A \) – a set partition

OUTPUT:
- The coproduct applied to the \( w \) dual symmetric function in non-commuting variables indexed by \( A \) expressed in the \( w \) basis.

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w[[1], [2,3]].coproduct()
\w{} \# \w{1, \{2\}} + \w{\{1\}} \# \w{} + \w{\{1\}} \# \w{\{1\}, \{2\}} + \w{\{1\}, \{2\}} \# \w{}
sage: w.coproduct_on_basis(SetPartition([[]]))
\w{} \# \w{}
```

dual_basis()

Return the dual basis to the \( w \) basis.

The dual basis to the \( w \) basis is the monomial basis of the symmetric functions in non-commuting variables.

OUTPUT:
- the monomial basis of the symmetric functions in non-commuting variables

EXAMPLES:

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.dual_basis()
Symmetric functions in non-commuting variables over the Rational Field in...
˓→the monomial basis
```

duality_pairing(x, y)

Compute the pairing between an element of \( \text{self} \) and an element of the dual.

INPUT:
- \( x \) – an element of the dual of symmetric functions in non-commuting variables
- \( y \) – an element of the symmetric functions in non-commuting variables

OUTPUT:
- an element of the base ring of \( \text{self} \)
EXAMPLES:

```python
sage: DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
sage: w = DNCSym.w()
sage: m = w.dual_basis()
sage: matrix([[w(A).duality_pairing(m(B)) for A in SetPartitions(3)] for B in SetPartitions(3))
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
sage: (w[[1,2],[3]] + 3*w[[1,3],[2]]).duality_pairing(2*m[[1,3],[2]] + m[[1,2,3]] + 2*m[[1,2],[3]])
8
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()
sage: matrix([[w(A).duality_pairing(h(B)) for A in SetPartitions(3)] for B in SetPartitions(3))
\begin{bmatrix}
6 & 2 & 2 & 2 & 1 \\
2 & 2 & 1 & 1 & 1 \\
2 & 1 & 2 & 1 & 1 \\
2 & 1 & 1 & 2 & 1 \\
1 & 1 & 1 & 1 & 1
\end{bmatrix}
sage: (2*w[[1,3],[2]] + w[[1,2,3]] + 2*w[[1,2],[3]]).duality_pairing(h[[1,2],[3]] + 3*h[[1,3],[2]])
32
```

```python
>>> from sage.all import *
>>> DNCSym = SymmetricFunctionsNonCommutingVariablesDual(QQ)
>>> w = DNCSym.w()
>>> m = w.dual_basis()
>>> matrix([[w(A).duality_pairing(m(B)) for A in SetPartitions(Integer(3)))] for B in SetPartitions(Integer(3))])
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 \\
0 & 0 & 0 & 0 & 1
\end{bmatrix}
>>> (w[[Integer(1),Integer(2)],[Integer(3)]] + Integer(3)*w[[Integer(1),
Integer(2)],[Integer(3)]]).duality_pairing(Integer(2)*m[[Integer(1),
Integer(3)],[Integer(2)]] + m[[Integer(1),Integer(2),Integer(3)]] +
Integer(2)*m[[Integer(1),Integer(2)],[Integer(3)]]))
8
>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()
>>> matrix([[w(A).duality_pairing(h(B)) for A in SetPartitions(Integer(3)))] for B in SetPartitions(Integer(3))])
\begin{bmatrix}
6 & 2 & 2 & 2 & 1 \\
2 & 2 & 1 & 1 & 1 \\
2 & 1 & 2 & 1 & 1 \\
2 & 1 & 1 & 2 & 1 \\
1 & 1 & 1 & 1 & 1
\end{bmatrix}
>>> (Integer(2)*w[[Integer(1),Integer(2)],[Integer(3)]] + Integer(3)*w[[Integer(1),
Integer(2)],[Integer(3)]] + Integer(2)*w[[Integer(1),Integer(2),
Integer(3)]]).duality_pairing(h[[Integer(1),Integer(2)],[Integer(3)]] +
Integer(3)*h[[Integer(1),Integer(3)],Integer(2)])
32
```

\(\text{product_on_basis}(A, B)\)
The product on \( w \) basis elements.

The product on the \( w \) is the dual to the coproduct on the \( m \) basis. On the basis \( w \) it is defined as

\[
W_A W_B = \sum_{S \subseteq [n]} W_{A \uparrow S \cup B \uparrow S^c}
\]

where the sum is over all possible subsets \( S \) of \([n]\) such that \(|S| = |A|\) with a term indexed the union of \( A \uparrow S \) and \( B \uparrow S^c \). The notation \( A \uparrow S \) represents the unique set partition of the set \( S \) such that the standardization is \( A \). This product is commutative.

**INPUT:**
- \( A, B \) – set partitions

**OUTPUT:**
- an element of the \( w \) basis

**EXAMPLES:**

```python
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1, 2, 3]])
sage: w.product_on_basis(A, B)
w{{1}, {2, 3}, {4, 5, 6}} + w{{1}, {2, 3, 4}, {5, 6}}
+ w{{1}, {2, 3, 5}, {4, 6}} + w{{1}, {2, 3, 6}, {4, 5}}
+ w{{1}, {2, 4}, {3, 5, 6}} + w{{1}, {2, 4, 5}, {3, 6}}
+ w{{1}, {2, 4, 6}, {3, 5}} + w{{1}, {2, 5}, {3, 4, 6}}
+ w{{1}, {2, 5, 6}, {3, 4}} + w{{1}, {2, 6}, {3, 4, 5}}
+ w{{1}, {2, 4}, {3}, {5, 6}} + w{{1}, {2, 5}, {3}, {4, 6}}
+ w{{1}, {2, 5}, {3}, {4, 6}} + w{{1}, {2, 6}, {3}, {4, 5}}
+ w{{1}, {2}, {3}, {4, 5, 6}} + w{{1}, {2}, {3, 4}, {5, 6}}
+ w{{1}, {2}, {3}, {4}, {5}} + w{{1}, {2}, {3}, {4}, {5}}
+ w{{1}, {2}, {3, 4}, {5}, {6}} + w{{1}, {2}, {3, 4}, {5}, {6}}
+ w{{1}, {2}, {3}, {4}, {5}} + w{{1}, {2}, {3}, {4}, {5}}
+ w{{1}, {2}, {3}, {4}, {5}} + w{{1}, {2}, {3}, {4}, {5}}
+ w{{1}, {2}, {3}, {4}, {5}} + w{{1}, {2}, {3}, {4}, {5}}
```

```python
>>> from sage.all import *
>>> w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
>>> A = SetPartition([[Integer(1)], [Integer(2),Integer(3)]]
>>> B = SetPartition([[Integer(1), Integer(2), Integer(3)]])
>>> w.product_on_basis(A, B)
w{{1}, {2, 3}, {4, 5, 6}} + w{{1}, {2, 3, 4}, {5, 6}}
+ w{{1}, {2, 3, 5}, {4, 6}} + w{{1}, {2, 3, 6}, {4, 5}}
+ w{{1}, {2, 4}, {3, 5, 6}} + w{{1}, {2, 4, 5}, {3, 6}}
+ w{{1}, {2, 4, 6}, {3, 5}} + w{{1}, {2, 5}, {3, 4, 6}}
+ w{{1}, {2, 5, 6}, {3, 4}} + w{{1}, {2, 6}, {3, 4, 5}}
+ w{{1}, {2, 4}, {3}, {5, 6}} + w{{1}, {2, 5}, {3}, {4, 6}}
+ w{{1}, {2, 5}, {3}, {4, 6}} + w{{1}, {2, 6}, {3}, {4, 5}}
+ w{{1}, {2, 4}, {3}, {5, 6}} + w{{1}, {2, 5}, {3}, {4, 6}}
+ w{{1}, {2, 5}, {3}, {4, 6}} + w{{1}, {2, 6}, {3}, {4, 5}}
+ w{{1}, {2, 4}, {3}, {5, 6}} + w{{1}, {2, 5}, {3}, {4, 6}}
+ w{{1}, {2, 5}, {3}, {4, 6}} + w{{1}, {2, 6}, {3}, {4, 5}}
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
+ w{{1}, {2, 4}, {3}, {5}} + w{{1}, {2, 5}, {3}, {4}}
```

```w.product_on_basis(A, SetPartition([]))
w{{1}, {2, 3}}
```

**sum_of_partitions** *(la)*

Return the sum over all set partitions whose shape is la, scaled by \( \prod_i m_i! \) where \( m_i \) is the multiplicity of \( i \) in la.

**INPUT:**

* la – an integer partition

**OUTPUT:**

* an element of self

**EXAMPLES:**

```
sage: w = SymmetricFunctionsNonCommutingVariables(QQ).dual().w()
sage: w.sum_of_partitions([2,1,1])
2*w{{1}, {2}, {3, 4}} + 2*w{{1}, {2, 3}, {4}} + 2*w{{1}, {2, 4}, {3}}
+ 2*w{{1, 2}, {3}, {4}} + 2*w{{1, 3}, {2}, {4}} + 2*w{{1, 4}, {2}, {3}}
```

```from sage.all import *
```
5.1.150 Symmetric Functions in Non-Commuting Variables

AUTHORS:

- Travis Scrimshaw (08-04-2013): Initial version

class sage.combinat.ncsym.ncsym.SymmetricFunctionsNonCommutingVariables(R)
Bases: UniqueRepresentation, Parent

Symmetric functions in non-commutative variables.

The ring of symmetric functions in non-commutative variables, which is not to be confused with the non-commutative symmetric functions, is the ring of all bounded-degree noncommutative power series in countably many indeterminates (i.e., elements in $R((x_1, x_2, x_3, \ldots))$ of bounded degree) which are invariant with respect to the action of the symmetric group $S_\infty$ on the indices of the indeterminates. It can be regarded as a direct limit over all $n \to \infty$ of rings of $S_n$-invariant polynomials in $n$ non-commuting variables (that is, $S_n$-invariant elements of $R(x_1, x_2, \ldots, x_n)$).

This ring is implemented as a Hopf algebra whose basis elements are indexed by set partitions.

Let $A = \{A_1, A_2, \ldots, A_r\}$ be a set partition of the integers $[k] := \{1, 2, \ldots, k\}$. This partition $A$ determines an equivalence relation $\sim_A$ on $[k]$, which has $c \sim_A d$ if and only if $c$ and $d$ are in the same part $A_j$ of $A$. The monomial basis element $m_A$ indexed by $A$ is the sum of monomials $x_{i_1}x_{i_2}\cdots x_{i_k}$ such that $i_c = i_d$ if and only if $c \sim_A d$.

The $k$-th graded component of the ring of symmetric functions in non-commutative variables has its dimension equal to the number of set partitions of $[k]$. (If we work, instead, with finitely many -- say, $n$ -- variables, then its dimension is equal to the number of set partitions of $[k]$ where the number of parts is at most $n$.)

Note: All set partitions are considered standard (i.e., set partitions of $[n]$ for some $n$) unless otherwise stated.

REFERENCES:

EXAMPLES:

We begin by first creating the ring of $NC\text{Sym}$ and the bases that are analogues of the usual symmetric functions:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: p = NCSym.p()
sage: m
Symmetric functions in non-commuting variables over the Rational Field in the
˓→monomial basis
```

```
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> m = NCSym.m()
>>> e = NCSym.e()
>>> h = NCSym.h()
>>> p = NCSym.p()
>>> m
Symmetric functions in non-commuting variables over the Rational Field in the
˓→monomial basis
```

The basis is indexed by set partitions, so we create a few elements and convert them between these bases:
There is also a shorthand for creating elements. We note that we must use `p([])` to create the empty set partition due to python's syntax.

```python
sage: elt = m(SetPartition([[1,3],[2]])) - 2*m(SetPartition([[1],[2]])); elt
-2*m{(1), (2)} + m{(1, 3), (2)}
sage: elt
-2*e{(1), (2)} + 2*e{(1, 2), (3)} - 1/2*e{(1, 2, 3)} - 1/2*e{(1, 3), (2)}
sage: e(elt)
1/2*e{(1), (2)} - 2*e{(1, 2), (3)} + 1/2*e{(1, 2), (3)} + 2*h{(1, 2)}
+ 1/2*h{(1, 2), (3)} - 1/2*h{(1, 2, 3)} + 3/2*h{(1, 3), (2)}
sage: h(elt)
-4*h{(1), (2)} - 2*h{(1, 2), (3)} + 2*h{(1, 2, 3)}
+ 1/2*h{(1, 2, 3)} - 1/2*h{(1, 3), (2)}
sage: p(elt)
-2*p{(1), (2)} + 2*p{(1, 2), (3)} - p{(1, 2, 3)} + p{(1, 3), (2)}
sage: m(p(elt))
-2*m{(1), (2)} + m{(1, 3), (2)}
```
There is also a natural projection to the usual symmetric functions by letting the variables commute. This projection map preserves the product and coproduct structure. We check that Theorem 2.1 of [RS06] holds:
2*e[2, 1]
>>> elth.to_symmetric_function()
4*h[2, 2]
>>> Sh(m(elth).to_symmetric_function())
4*h[2, 2]
>>> eltp.to_symmetric_function()
>>> Sp(e(eltp).to_symmetric_function())

a_realization()
Return the realization of the powersum basis of self.

OUTPUT:
• The powersum basis of symmetric functions in non-commuting variables.

EXAMPLES:

```python
sage: SymmetricFunctionsNonCommutingVariables(QQ).a_realization()
Symmetric functions in non-commuting variables over the Rational Field in the
cpy basis
```

chi
alias of `supercharacter`

class coarse_powersum(NCSym)
Bases: NCSymBasis_abstract
The Hopf algebra of symmetric functions in non-commuting variables in the cp basis.
This basis was defined in [BZ05] as

\[
\text{cp}_A = \sum_{A \leq B} m_B,
\]

where we sum over all strict coarsenings of the set partition A. An alternative description of this basis was
given in [BT13] as

\[
\text{cp}_A = \sum_{A \subset B} m_B,
\]

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition A.

Note: In [BZ05], this basis was denoted by q. In [BT13], this basis was called the powersum basis and
denoted by p. However it is a coarser basis than the usual powersum basis in the sense that it does not yield
the usual powersum basis of the symmetric function under the natural map of letting the variables commute.

EXAMPLES:
```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: cp = NCSym.cp()
sage: cp[[1, 3], [2, 4]]*cp[[1, 2, 3]]
cp{(1, 3), (2, 4), (5, 6, 7)}
sage: cp[[1, 2], [3]].internal_coproduct()
cp{(1, 2), (3)} @ cp{(1, 2), (3)}
sage: ps = SymmetricFunctions(NCSym.base_ring()).p()
sage: ps(cp[[1, 3], [2]].to_symmetric_function())
sage: ps(cp[[1, 2], [3]].to_symmetric_function())
p[2, 1]
```

```python
>>> from sage.all import *

>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)

>>> cp = NCSym.cp()

>>> cp[[Integer(1),Integer(3)],[Integer(2),Integer(4)]]*cp[[Integer(1),

- Integer(2),Integer(3)]]
cp{(1, 3), (2, 4), (5, 6, 7)}

>>> cp[[Integer(1),Integer(2)],[Integer(3)]].internal_coproduct()
cp{(1, 2), (3)} @ cp{(1, 2), (3)}

>>> ps = SymmetricFunctions(NCSym.base_ring()).p()

>>> ps(cp[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function())

>>> ps(cp[[Integer(1),Integer(2)],[Integer(3)]].to_symmetric_function())
p[2, 1]
```

cp
alias of coarse_powersum
class deformed_coarse_powersum(NCSym, q=2)
    Bases: NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the ρ basis.

This basis was defined in [BT13] as a q-deformation of the cp basis:

\[ \rho_A = \sum_{A \subseteq B} \frac{1}{q^{\text{set partitions of } A \to B}} m_B, \]

where we sum over all set partitions whose arcs are a subset of the arcs of the set partition A.

INPUT:

- q – (default: 2) the parameter q

EXAMPLES:

```python
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: rho = NCSym.rho(q)
```

We construct Example 3.1 in [BT13]:
sage: rnode = lambda A: sorted([a[1] for a in A.arcs()], reverse=True)
sage: dimv = lambda A: sorted([a[1]-a[0] for a in A.arcs()], reverse=True)
sage: S = sorted(lst, key=lambda A: (dimv(A), rnode(A)))
sage: m = NCSym.m()

matrix([[m(rho[A])[B] for B in S] for A in S])

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 & 1 \\
0 & 1 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 1 & 0 & 1 & 1 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 & 1/q \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
\end{bmatrix}
\]

Return the deformation parameter \( q \) of \( \text{self} \).

EXAMPLES:

sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: rho = NCSym.rho(5)
sage: rho.q()
5

sage: R = QQ['q'].fraction_field()

(continues on next page)
dual()

Return the dual Hopf algebra of the symmetric functions in non-commuting variables.

EXAMPLES:

```
sage: SymmetricFunctionsNonCommutingVariables(QQ).dual()
Dual symmetric functions in non-commuting variables over the Rational Field
```

e
alias of elementary
class elementary(NCSym)

Bases: NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the elementary basis.

EXAMPLES:

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
```

class Element

Bases: IndexedFreeModuleElement

An element in the elementary basis of NCSym.

omega()

Return the involution \( \omega \) applied to self.

The involution \( \omega \) on \( NCSym \) is defined by \( \omega(e_A) = h_A \).
OUTPUT:
• an element in the basis self

EXAMPLES:
```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: e = NCSym.e()
sage: h = NCSym.h()
sage: elt = e[[1,3],[2]].omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
sage: elt.omega()
e{{1, 3}, {2}}
sage: h(elt)
h{{1, 3}, {2}}
```

```python
>>> from sage.all import *
>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
>>> e = NCSym.e()
>>> h = NCSym.h()
>>> elt = e[[Integer(1),Integer(3)],[Integer(2)]] .omega(); elt
2*e{{1}, {2}, {3}} - e{{1, 3}, {2}}
>>> elt.omega()
e{{1, 3}, {2}}
>>> h(elt)
h{{1, 3}, {2}}
```

to_symmetric_function()
The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the e basis, and return the projection of expressed in the elementary basis of symmetric functions.

The map $\chi: NCSym \rightarrow Sym$ is given by

$$e_A \mapsto e_{\lambda(A)} \prod_i \lambda(A)_i!$$

where $\lambda(A)$ is the partition associated with $A$ by taking the sizes of the parts.

OUTPUT:
• An element of the symmetric functions in the elementary basis

EXAMPLES:
```python
sage: e = SymmetricFunctionsNonCommutingVariables(QQ).e()
sage: e[[1,3],[2]].to_symmetric_function()
2*e[2, 1]
sage: e[[1],[3],[2]].to_symmetric_function()
e[1, 1, 1]
```

```python
>>> from sage.all import *
>>> e = SymmetricFunctionsNonCommutingVariables(QQ).e()
>>> e[[Integer(1),Integer(3)],[Integer(2)]].to_symmetric_function()
2*e[2, 1]
>>> e[[Integer(1)],[Integer(3)],[Integer(2)]].to_symmetric_function()
e[1, 1, 1]
```

h

alias of homogeneous
class homogeneous (NCSym)

Bases: NCSymBasis_abstract

The Hopf algebra of symmetric functions in non-commuting variables in the homogeneous basis.

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()

h([[1,3],[2,4]]) * h([[1,2],[3]])

h([[1,3],[2,4]], {2, 4}, {5, 6, 7})

h([[1,2]].coproduct())

h() h((1, 2)) + 2*h({1}) # h({1}) + h({1, 2}) # h()
```

>>> from sage.all import *

```python
NCSym = SymmetricFunctionsNonCommutingVariables(QQ)

h = NCSym.h()

h([[Integer(1),Integer(3)],[Integer(2),Integer(4)]] * h([[Integer(1),
                                                        Integer(2),Integer(3)]]

h({1, 3}, {2, 4}, {5, 6, 7})

h([[Integer(1),Integer(3)],[Integer(2)]]).coproduct()

h() # h((1, 2)) + 2*h({1}) # h({1}) + h({1, 2}) # h()
```

class Element

Bases: IndexedFreeModuleElement

An element in the homogeneous basis of NCSym.

omega()

Return the involution \( \omega \) applied to self.

The involution \( \omega \) on NCSym is defined by \( \omega(h_A) = e_A \).

OUTPUT:

- an element in the basis self

EXAMPLES:

```python
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: h = NCSym.h()

elt = h([[1,3],[2]]).omega(); elt

2*h({1}, {2}, {3}) - h({1, 3}, {2})

elt.omega()

h({1, 3}, {2})

e(elt)
e({1, 3}, {2})
```

```python
from sage.all import *

NCSym = SymmetricFunctionsNonCommutingVariables(QQ)

h = NCSym.h()

e = NCSym.e()

elt = h([[Integer(1),Integer(3)],[Integer(2)]]).omega(); elt

2*h({1}, {2}, {3}) - h({1, 3}, {2})

elt.omega()

h({1, 3}, {2})

e(elt)
e({1, 3}, {2})
```
to_symmetric_function()  
The projection of self to the symmetric functions.  

Take a symmetric function in non-commuting variables expressed in the h basis, and return the projection of expressed in the complete basis of symmetric functions.  
The map $\chi: NCsym \rightarrow Sym$ is given by  

$$h_A \mapsto h_{\lambda(A)} \prod_{i} \lambda_i(A)!$$  

where $\lambda(A)$ is the partition associated with $A$ by taking the sizes of the parts.  

**OUTPUT:**  
- An element of the symmetric functions in the complete basis  

**EXAMPLES:**

```python  
sage: h = SymmetricFunctionsNonCommutingVariables(QQ).h()  
sage: h[[1,3],[2]].to_symmetric_function()  
2*h[2, 1]  
sage: h[[1],[3],[2]].to_symmetric_function()  
h[1, 1, 1]  
```

```python  
>>> from sage.all import *  

>>> h = SymmetricFunctionsNonCommutingVariables(QQ).h()

h[1, 1, 1]  
```

m  
alias of monomial  

**class monomial (NCSym)**  
Bases: NCSymBasis_abstract  
The Hopf algebra of symmetric functions in non-commuting variables in the monomial basis.  

**EXAMPLES:**

```python  
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)  
sage: m = NCSym.m()  
sage: m[[1,3],[2]]*m[[1,2]]  
m{{1, 3}, {2}, {4, 5}} + m{{1, 3}, {2, 4, 5}} + m{{1, 3, 4, 5}, {2}}  
sage: m[[1,3],[2]].coproduct()  
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3}, {2}} # m{}  
```

```python  
>>> from sage.all import *  

>>> NCSym = SymmetricFunctionsNonCommutingVariables(QQ)  

>>> m = NCSym.m()  

>>> m[[Integer(1),Integer(3)],[Integer(2)]]*m[[Integer(1),Integer(2)]]  
m{{1, 3}, {2}, {4, 5}} + m{{1, 3}, {2, 4, 5}} + m{{1, 3, 4, 5}, {2}}  

>>> m[[Integer(1)],[Integer(3)],[Integer(2)]] .coproduct()  
m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3}, {2}} # m{}  
```
class Element
Bases: IndexedFreeModuleElement

An element in the monomial basis of $NCSym$.

expand($n$, alphabet='x')

Expand self written in the monomial basis in $n$ non-commuting variables.

INPUT:
• $n$ – an integer
• alphabet – (default: 'x') a string

OUTPUT:
• The symmetric function of self expressed in the $n$ non-commuting variables described by alphabet.

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].expand(4)
x0*x1*x0 + x0*x2*x0 + x0*x3*x0 + x1*x0*x1 + x1*x2*x1 + x1*x3*x1 + x2*x0*x2 + x2*x1*x2 + x2*x3*x2 + x3*x0*x3 + x3*x1*x3 + x3*x2*x3
```

One can use a different set of variables by using the optional argument alphabet:

```python
sage: m[[1],[2,3]].expand(3,alphabet='y')
y0*y1^2 + y0*y2^2 + y1*y0^2 + y1*y2^2 + y2*y0^2 + y2*y1^2
```

to_symmetric_function()

The projection of self to the symmetric functions.

Take a symmetric function in non-commuting variables expressed in the $m$ basis, and return the projection of expressed in the monomial basis of symmetric functions.

The map $\chi: NCSym \rightarrow Sym$ is defined by

$$m_A \mapsto m_{\lambda(A)} \prod_i n_i(\lambda(A))!$$

where $\lambda(A)$ is the partition associated with $A$ by taking the sizes of the parts and $n_i(\mu)$ is the multiplicity of $i$ in $\mu$.

OUTPUT:
• an element of the symmetric functions in the monomial basis

EXAMPLES:

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m[[1,3],[2]].to_symmetric_function()
(continues on next page)
coproduct_on_basis(A)

Return the coproduct of a monomial basis element.

INPUT:
- A – a set partition

OUTPUT:
- The coproduct applied to the monomial symmetric function in non-commuting variables indexed by A expressed in the monomial basis.

EXAMPLES:

```python
>>> from sage.all import *

>>> m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
>>> m[[Integer(1), Integer(3)], [Integer(2)]].coproduct()
 m{} # m{{1, 3}, {2}} + m{{1}} # m{{1, 2}} + m{{1, 2}} # m{{1}} + m{{1, 3}, {2}} # m{}

>>> m.coproduct_on_basis(SetPartition([]))
m{} # m{}

>>> m.coproduct_on_basis(SetPartition([[Integer(1), Integer(2), Integer(3)]]))
m{} # m{{1, 2, 3}} + m{{1, 2, 3}} # m{}

>>> m[[Integer(1), Integer(5)], [Integer(2), Integer(4)], [Integer(3), Integer(7)], [Integer(6)]].coproduct()
m{} # m{{1, 5}, {2, 4}, {3, 7}, {6}} + 2*m{{1, 2}} # m{{1, 3}, {2, 5}, {4}} + m{{1, 2}} # m{{1, 3}, {2}} + 2*m{{1, 3}, {2}} # m{{1, 3}, {2}, {5}} + m{{1, 3}, {2}, {5}} # m{{1, 2}} + m{{1, 4}, {2, 3}} # m{{1, 5}, {2, 4}, {3, 6}} # m{{1, 5}, {2, 4}, {3, 6}} # m{{1, 5}, {2, 4}, {3, 6}} # m{}
```
Combinatorics, Release 10.4

(continued from previous page)

\[ + 2 \cdot m\{(1, 2), (3)\} \cdot m\{(1, 3), (2, 4)\} + m\{(1, 3), (2)\} \cdot m\{(1, 4), (2, \rightarrow 3)\} + 2 \cdot m\{(1, 3), (2, 4)\} \cdot m\{(1, 2), (3)\} + 2 \cdot m\{(1, 3), (2, 5), (4)\} \cdot m\{(1, \rightarrow 2)\} + m\{(1, 4), (2, 3)\} \cdot m\{(1, 3), (2)\} + m\{(1, 4), (2, 3), (5)\} \cdot m\{(1, 2)\} + m\{(1, 5), (2, 4), (3, 6)\} \cdot m\{(1)\} + m\{(1, 5), (2, 4), (3, 7), (6)\} \cdot m \rightarrow \{} \]

\textbf{dual\_basis()} \\
Return the dual basis to the monomial basis.

\textbf{OUTPUT:} \\
• the \texttt{w} basis of the dual Hopf algebra

\textbf{EXAMPLES:}

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.dual_basis()
Dual symmetric functions in non-commuting variables over the Rational Field in the w basis
```

\textbf{duality\_pairing}(x, y) \\
Compute the pairing between an element of \texttt{self} and an element of the dual.

\textbf{INPUT:} \\
• \texttt{x} – an element of symmetric functions in non-commuting variables \\
• \texttt{y} – an element of the dual of symmetric functions in non-commuting variables

\textbf{OUTPUT:} \\
• an element of the base ring of \texttt{self}

\textbf{EXAMPLES:}

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: m = NCSym.m()
sage: w = m.dual_basis()
sage: matrix([[m(A).duality_pairing(w(B)) for A in SetPartitions(3)] for B in SetPartitions(3)])
[1 0 0 0 0]
[0 1 0 0 0]
[0 0 1 0 0]
[0 0 0 1 0]
[0 0 0 0 1]
sage: (m[[1,2],[3]] + 3*m[[1,3],[2]]).duality_pairing(2*w[[1,3],[2]] + 2*w[[1,2],[3]] + 2*w[[1,2],[3]])
8
```

```
from symmetric_function(f)

Return the image of the symmetric function f in self.

This is performed by converting to the monomial basis and extending the method sum_of_partitions() linearly. This is a linear map from the symmetric functions to the symmetric functions in non-commuting variables that does not preserve the product or coproduct structure of the Hopf algebra.

See also:

to_symmetric_function()

INPUT:

• f – an element of the symmetric functions

OUTPUT:

• An element of the \( m \) basis

EXAMPLES:

\[
\begin{align*}
\text{sage: } m &= \text{SymmetricFunctionsNonCommutingVariables(QQ).m()} \\
\text{sage: } \text{elt} &= m.\text{from_symmetric_function(mon[2,1,1])}; \text{elt} \\
&= 1/12*m\{(1), \{2\}, \{3, 4\}\} + 1/12*m\{(1), \{2, 3\}, \{4\}\} + 1/12*m\{(1), \{2, 4\}, \rightarrow\{3\}\} \\
&\quad + 1/12*m\{(1, 2), \{3\}, \{4\}\} + 1/12*m\{(1, 3), \{2\}, \{4\}\} + 1/12*m\{(1, 4), \rightarrow\{2\}, \{3\}\} \\
\text{sage: } \text{elt}.\text{to_symmetric_function()} \\
&= m[2, 1, 1] \\
\text{sage: } e &= \text{SymmetricFunctionsNonCommutingVariables(QQ).e()} \\
\text{sage: } \text{elm} &= e.m.\text{from_symmetric_function(elm[4])} \\
&= 1/24*e\{(1, 2, 3, 4)\} \\
\text{sage: } h &= \text{SymmetricFunctionsNonCommutingVariables(QQ).h()} \\
\text{sage: } \text{hom} &= h.m.\text{from_symmetric_function(hom[4])} \\
&= 1/24*h\{(1, 2, 3, 4)\} \\
\text{sage: } p &= \text{SymmetricFunctionsNonCommutingVariables(QQ).p()} \\
\text{sage: } \text{pow} &= p.m.\text{from_symmetric_function(pow[4])} \\
&= p\{(1, 2, 3, 4)\} \\
\text{sage: } \text{p(m.from_symmetric_function(pow[2,1])} \\
&= 1/3*p\{(1, \{2, 3\}\} + 1/3*p\{(1, 2), \{3\}\} + 1/3*p\{(1, 3), \{2\}\} \\
\text{sage: } \text{p([[1,2]])p([[1]])} \\
&= p\{(1, 2), \{3\}\} \\
\end{align*}
\]

from sage.all import *

m = SymmetricFunctionsNonCommutingVariables(QQ).m()
Combinatorics, Release 10.4

>>> mon = SymmetricFunctions(QQ).m()
>>> elt = m.from_symmetric_function(mon[Integer(2),Integer(1),
→Integer(1)])
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4},
→3})
+ 1/12*m{{1, 2}, {3}, {4}} + 1/12*m{{1, 3}, {2}, {4}} + 1/12*m{{1, 4},
→2}, {3})
>>> elt.to_symmetric_function()
1/12*m{{1}, {2}, {3, 4}} + 1/12*m{{1}, {2, 3}, {4}} + 1/12*m{{1}, {2, 4},

→{2}, {3}}

Check that \( \chi \circ \tilde{\chi} \) is the identity on \( Sym \):

sage: all(m.from_symmetric_function(pow(la)).to_symmetric_function() ==
→pow(la)
....: for la in Partitions(4))
True

internal_coproduct_on_basis \( (A) \)

Return the internal coproduct of a monomial basis element.

The internal coproduct is defined by

\[
\Delta^\otimes(m_A) = \sum_{B \land C = A} m_B \otimes m_C
\]

where we sum over all pairs of set partitions \( B \) and \( C \) whose infimum is \( A \).

INPUT:
• \( A \) – a set partition

OUTPUT:
• an element of the tensor square of the \( m \) basis

EXAMPLES:

sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: m.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
The product on monomial basis elements.

The product of the basis elements indexed by two set partitions $A$ and $B$ is the sum of the basis elements indexed by set partitions $C$ such that $C \wedge (|n||k|) = |A||B|$ where $n = |A|$ and $k = |B|$. Here $A \wedge B$ is the infimum of $A$ and $B$ and $A|B$ is the `SetPartition.pipe()` operation. Equivalently we can describe all $C$ as matchings between the parts of $A$ and $B$ where if $a \in A$ is matched with $b \in B$, we take $a \cup b$ instead of $a$ and $b$ in $C$.

**INPUT:**
- $A, B$ – set partitions

**OUTPUT:**
- an element of the $m$ basis

**EXAMPLES:**

```python
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).monomial()
sage: A = SetPartition([[1], [2,3]])
sage: B = SetPartition([[1], [3], [2,4]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5, 7}, {6}} + m{{1}, {2, 3, 4}, {5, 7}, {6}} + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}} + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}} + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}} + m{{1}, {2, 3, 5, 7}, {4}, {6}} + m{{1}, {2, 3, 6}, {4}, {5, 7}}
sage: B = SetPartition([[1], [2]])
sage: m.product_on_basis(A, B)
m{{1}, {2, 3}, {4}, {5}} + m{{1}, {2, 3, 4}, {5}} + m{{1}, {2, 3, 5}, {4}} + m{{1}, {2, 3, 6}, {4}} + m{{1}, {2, 3, 5}, {4}} + m{{1}, {2, 3, 6}, {4}} + m{{1}, {2, 3, 5}, {4}} + m{{1}, {2, 3, 6}, {4}}
sage: m.product_on_basis(A, SetPartition([]))
m{{1}, {2, 3}}
```

(continues on next page)
+ m\{{1, 6\}, \{2, 3, 5, 7\}, \{4\}}
>>> B = SetPartition([[Integer(1)],[Integer(2)]]))
>>> m.product_on_basis(A, B)
m\{{1\}, \{2, 3\}, \{4\}, \{5\}} + m\{{1\}, \{2, 3, 4\}, \{5\}}
+ m\{{1\}, \{2, 3, 5\}, \{4\}} + m\{{1, 4\}, \{2, 3\}, \{5\}} + m\{{1, 4\}, \{2, 3, 5\}}
+ m\{{1, 5\}, \{2, 3\}, \{4\}} + m\{{1, 5\}, \{2, 3, 4\}}

>>> m.product_on_basis(A, SetPartition([]))
m\{{1\}, \{2, 3\}}

\textbf{sum\_of\_partitions}(\textit{la})

Return the sum over all set partitions whose shape is \textit{la} with a fixed coefficient \textit{C} defined below.

Fix a partition \(\lambda\), we define \(\lambda! := \prod\lambda_i!\) and \(\lambda^i := \prod m_i!\). Recall that \(|\lambda| = \sum\lambda_i\) and \(m_i\) is the number of parts of length \(i\) of \(\lambda\). Thus we defined the coefficient as

\[C := \frac{\lambda! \lambda^i}{|\lambda|!}\]

Hence we can define a lift \(\overline{\chi}\) from \(\text{Sym}\) to \(NCSym\) by

\[m_\lambda \mapsto C \sum_A m_A\]

where the sum is over all set partitions whose shape is \(\lambda\).

\textbf{INPUT:}
- \(\textit{la}\) – an integer partition

\textbf{OUTPUT:}
- an element of the \textit{m} basis

\textbf{EXAMPLES:}

```
sage: m = SymmetricFunctionsNonCommutingVariables(QQ).m()
sage: m.sum_of_partitions(Partition([2,1,1]))
1/12*m\{{1\}, \{2\}, \{3, 4\}} + 1/12*m\{{1\}, \{2, 3\}, \{4\}} + 1/12*m\{{1\}, \{2, 4\}, \rightarrow\{3\}}
+ 1/12*m\{{1\}, \{2\}, \{3\}, \{4\}} + 1/12*m\{{1\}, \{2, 3\}, \{4\}} + 1/12*m\{{1, 4\}, \rightarrow\{2\}, \{3\}}
```
where we sum over all coarsenings of the set partition $A$. If we allow our variables to commute, then $p_A$ goes to the usual powersum symmetric function $p_\lambda$ whose (integer) partition $\lambda$ is the shape of $A$.

**EXAMPLES:**

```
sage: NCSym = SymmetricFunctionsNonCommutingVariables(QQ)
sage: p = NCSym.p()
sage: x = p.an_element()**2; x
4*p{} + 8*p{{1}} + 4*p{{1}, {2}} + 6*p{{1}, {2, 3}}
+ 12*p{{1, 2}} + 6*p{{1, 2}, {3}} + 9*p{{1, 2}, {3, 4}}
sage: x.to_symmetric_function()
4*p{} + 8*p{{1}} + 4*p{{1, 1}} + 12*p{{2}} + 12*p{{2, 1}} + 9*p{{2, 2}}
```
antipode_on_basis \( (A) \)

Return the result of the antipode applied to a powersum basis element.

Let \( A \) be a set partition. The antipode given in [LM2011] is

\[
S(p_A) = \sum_{\gamma} (-1)^{\ell(\gamma)} p_{\gamma[A]}
\]

where we sum over all ordered set partitions (i.e. set compositions) of \( [\ell(A)] \) and

\[
\gamma[A] = A_{\gamma_1}^1 \cdots A_{\gamma_{\ell(A)}}^l
\]

is the action of \( \gamma \) on \( A \) defined in \( \text{SetPartition.ordered_set_partition_action()} \).

INPUT:
• \( A \) – a set partition

OUTPUT:
• an element in the basis \( self \)

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.antipode_on_basis(SetPartition([[1], [2,3]]))
p{{1, 2}, {3}}
sage: p.antipode_on_basis(SetPartition([[]])
p{}
sage: F = p[[1,3],[5],[2,4]].coproduct()
sage: F.apply_multilinear_morphism(lambda x,y: x.antipode()*y)

0
```

coproduct_on_basis \( (A) \)

Return the coproduct of a monomial basis element.

INPUT:
• \( A \) – a set partition

OUTPUT:
• The coproduct applied to the monomial symmetric function in non-commuting variables indexed by \( A \) expressed in the monomial basis.

EXAMPLES:

```
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p[[1, 3], [2]].coproduct()
p() + p({1}, {2}) + p({1}) + p({1, 2}) + p({1}) + p({1}) + p({1, 3}, {2})
sage: p.coproduct_on_basis(SetPartition([[1]]))
p() + p({1}) + p({1}) + p()
sage: p.coproduct_on_basis(SetPartition([[]])
p()
```
from sage.all import *

p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
p[([Integer(1), Integer(3)], [Integer(2)]).coproduct()
p{} # p{1, 3}, (2) + p{1} # p{1, 2} + p{1, 2} # p{} + p{3, 1}, (2) # p{}
p.coproduct_on_basis(SetPartition([[Integer(1)]]))
p{} # p{1} + p{1} # p{}
p.coproduct_on_basis(SetPartition([]))
p{} # p{}

internal_coproduct_on_basis(A)

Return the internal coproduct of a powersum basis element.

The internal coproduct is defined by

\[ \Delta^\otimes(p_A) = p_A \otimes p_A \]

INPUT:
- \( A \) – a set partition

OUTPUT:
- an element of the tensor square of \( self \)

EXAMPLES:
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: p.internal_coproduct_on_basis(SetPartition([[1,3],[2]]))
p{{1, 3}, {2}} # p{{1, 3}, {2}}

>> from sage.all import *
>> p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
>> p.internal_coproduct_on_basis(SetPartition([[Integer(1),Integer(3)],
[Integer(2)]]))
p{{1, 3}, {2}} # p{{1, 3}, {2}}

primitive(A, i=1)

Return the primitive associated to \( A \) in \( self \).

Fix some \( i \in S \). Let \( A \) be an atomic set partition of \( S \), then the primitive \( p(A) \) given in [LM2011] is

\[ p(A) = \sum_\gamma (-1)^{\ell(\gamma)} p_{\gamma[A]} \]

where we sum over all ordered set partitions of \( [\ell(A)] \) such that \( i \in \gamma_1 \) and \( \gamma[A] \) is the action of \( \gamma \) on \( A \) defined in \( SetPartition.ordered_set_partition_action() \). If \( A \) is not atomic, then \( p(A) = 0 \).

See also:
SetPartition.is_atomic()

INPUT:
- \( A \) – a set partition
- \( i \) – (default: 1) index in the base set for \( A \) specifying which set of primitives this belongs to

OUTPUT:
- an element in the basis \( self \)

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
sage: elt = p.primitive(SetPartition([[1,3], [2]]))
-p({1, 2}, {3}) + p({1, 3}, {2})
sage: elt.coproduct()
-p{} # p{{1, 2}, {3}} + p{} # p{{1, 3}, {2}} - p{{1, 2}, {3}} # p{} + p{
    (1, 3), (2)} # p{}
sage: p.primitive(SetPartition([[1], [2,3]]))
0
sage: p.primitive(SetPartition([]))
p{}
```

```python
>>> from sage.all import *
>>> p = SymmetricFunctionsNonCommutingVariables(QQ).powersum()
>>> elt = p.primitive(SetPartition([[Integer(1),Integer(3)],
                          [Integer(2)]])); elt
-p({1, 2}, {3}) + p({1, 3}, {2})
>>> elt.coproduct()
-p{} # p{{1, 2}, {3}} + p{} # p{{1, 3}, {2}} - p{{1, 2}, {3}} # p{} + p{
                          (1, 3), (2)} # p{}
>>> p.primitive(SetPartition([[Integer(1)], [Integer(2),Integer(3)]]))
0
>>> p.primitive(SetPartition([]))
p{}
```

**rho**

alias of **deformed_coarse_powersum**

**class supercharacter** *(NCSym, q=2)*

Bases: **NCSymBasis_abstract**

The Hopf algebra of symmetric functions in non-commuting variables in the supercharacter \( \chi \) basis.

This basis was defined in [BT13] as a \( q \)-deformation of the supercharacter basis.

\[
\chi_A = \sum_B \chi_A(B)m_B,
\]

where we sum over all set partitions \( A \) and \( \chi_A(B) \) is the evaluation of the supercharacter \( \chi_A \) on the superclass \( \mu_B \).

**Note:** The supercharacters considered in [BT13] are coarser than those considered by Aguiar et. al.

**INPUT:**

- \( q \) – (default: 2) the parameter \( q \)

**EXAMPLES:**

```python
sage: R = QQ['q'].fraction_field()
sage: q = R.gen()
sage: NCSym = SymmetricFunctionsNonCommutingVariables(R)
sage: chi = NCSym.chi(q)
sage: chi[[1,3],[2]]*chi[[1,2]]
chi{[1, 3], [2]}*chi{[1, 2]}
chi{[1, 3], [2], [4, 5]}
sage: chi[[1,3],[2]].coproduct()
(continues on next page)
```

2484 Chapter 5. Comprehensive Module List
(3*q-2)*chi\{(1, 2)\} \# chi\{(1)\} + chi\{(1, 3), \{2\}\} \# chi\{}

sage: chi2 = NCSym.chi()
sage: chi(chi2[[1,2],[3]])
((-q+2)/q)*chi\{(1), \{2\}, \{3\}\} + 2/q*chi\{(1, 2), \{3\}\}

sage: chi2
Symmetric functions in non-commuting variables over the Fraction Field of Univariate Polynomial Ring in q over Rational Field in the supercharacter basis with parameter q=2

>>> from sage.all import *
>>> R = QQ['q'].fraction_field()

>>> NCSym = SymmetricFunctionsNonCommutingVariables(R)
>>> chi = NCSym.chi(q)
>>> chi.q() == q
True

(continues on next page)
True

alias of \texttt{x_basis}

\textbf{class \texttt{x_basis}(NCSym)}

Bases: \texttt{NCSymBasis\_abstract}

The Hopf algebra of symmetric functions in non-commuting variables in the \texttt{x} basis.

This basis is defined in \cite{BHRZ06} by the formula:

\[ x_A = \sum_{B \leq A} \mu(B, A) p_B \]

and has the following properties:

\[ x_A x_B = x_{A|B}, \quad \Delta^\otimes(x_C) = \sum_{A \vee B = C} x_A \otimes x_B. \]

\textbf{EXCEPTIONS:}

\begin{verbatim}
    sage: x = NCSym.x()
    sage: x[[1,2],[3]][1,2] * x[[1,2],[3]][1,2]
    x{{1, 2}, {3}} # x{{1, 2}, {3}} + x{{1, 2}, {3}} # x{{1, 2}, {3}} +
    x{{1, 2}, {3}} # x{{1, 2}, {3}}

>>> sage.combinat.ncsym.ncsym.matchings(A, B)

Iterate through all matchings of the sets \( A \) and \( B \).

\textbf{EXCEPTIONS:}

\begin{verbatim}
    sage: list(matchings([1, 2, 3, -1, -2]), [1, 2, 3, -1, -2]), [1, 2, 3, -1, -2])
    [[[1], [2], [3], [-1], [-2]],
     [[1], [2], [3, -1], [-2]],

sage.combinat.ncsym.ncsym.nesting(la, nu)

Return the nesting number of la inside of nu.

If we consider a set partition A as a set of arcs \( i - j \) where \( i \) and \( j \) are in the same part of \( A \). Define

\[
\text{nst}_\lambda^\nu = \# \{i < j < k < l \mid i - l \in \nu, j - k \in \lambda\},
\]

and this corresponds to the number of arcs of \( \lambda \) strictly contained inside of \( \nu \).

EXAMPLES:

```python
sage: from sage.combinat.ncsym.ncsym import nesting
sage: nu = SetPartition([[Integer(1), Integer(4)], [Integer(2)], [Integer(3)]]))
```

```python
sage: mu = SetPartition([[Integer(1), Integer(4)], [Integer(2), Integer(3)]]))
```

```python
sage: nesting(set(mu).difference(nu), nu)
```

```python
1
```

```python
sage: A = SetPartition([[Integer(1), [Integer(2), Integer(3), Integer(4)]], [Integer(5)]])
```

```python
sage: nesting(A, B)
```

```python
1
```

>>> from sage.all import *
>>> from sage.combinat.ncsym.ncsym import nesting
>>> nu = SetPartition([[Integer(1), Integer(2), Integer(4)], [Integer(2), Integer(3)]])
>>> mu = SetPartition([[Integer(1), Integer(4)], [Integer(2), Integer(3), Integer(4)]])
>>> nesting(set(mu).difference(nu), nu)

1

>>> A = SetPartition([[Integer(1), Integer(2), Integer(4)], [Integer(3), Integer(5)]])
>>> B = SetPartition([[Integer(1), Integer(4)], [Integer(2), Integer(5)]])
```
\[ \text{sage: } \text{lst} = \text{list(SetPartitions}(4)) \]
\[ \text{sage: } d = {} \]
\[ \text{sage: } \text{for } i, \text{nu} \text{ in enumerate(lst):} \]

\]
5.1.151 Necklaces

The algorithm used in this file comes from

```
sage.combinat.necklace.Necklaces(content)
```

Return the set of necklaces with evaluation content.

A necklace is a list of integers that such that the list is the smallest lexicographic representative of all the cyclic shifts of the list.

See also:

*LyndonWords*

**INPUT:**

- **content** – a list or tuple of non-negative integers

**EXAMPLES:**

```
sage: Necklaces([2,1,1])
Necklaces with evaluation [2, 1, 1]
sage: Necklaces([2,1,1]).cardinality()
3
sage: Necklaces([2,1,1]).first()
[1, 1, 2, 3]
sage: Necklaces([2,1,1]).last()
[1, 2, 1, 3]
sage: Necklaces([2,1,1]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
sage: Necklaces([0,2,1,1]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
sage: Necklaces([2,0,1,1]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

```python
>>> from sage.all import *
>>> Necklaces([Integer(2),Integer(1),Integer(1)])
Necklaces with evaluation [2, 1, 1]
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).cardinality()
3
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).first()
[1, 1, 2, 3]
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).last()
[1, 2, 1, 3]
>>> Necklaces([Integer(2),Integer(1),Integer(1)]).list()
[[1, 1, 2, 3], [1, 1, 3, 2], [1, 2, 1, 3]]
>>> Necklaces([Integer(0),Integer(2),Integer(1),Integer(1)]).list()
[[2, 2, 3, 4], [2, 2, 4, 3], [2, 3, 2, 4]]
>>> Necklaces([Integer(2),Integer(0),Integer(1),Integer(1)]).list()
[[1, 1, 3, 4], [1, 1, 4, 3], [1, 3, 1, 4]]
```

```
class sage.combinat.necklace.Necklaces_evaluation(content)
```

**Bases:** UniqueRepresentation, Parent

Necklaces with a fixed evaluation (content).

**INPUT:**
**content** – a list or tuple of non-negative integers

**cardinality()**

Return the number of integer necklaces with the evaluation content.

The formula for the number of necklaces of content $\alpha$ a composition of $n$ is:

$$\sum_{d|\gcd(\alpha)} \phi(d) \left(\frac{n}{d}\right)^{\frac{\alpha_1}{d}, \ldots, \frac{\alpha_\ell}{d}},$$

where $\phi(d)$ is the Euler $\phi$ function.

**EXAMPLES:**

```
sage: Necklaces([]).cardinality()
0
sage: Necklaces([2,2]).cardinality()
2
sage: Necklaces([2,3,2]).cardinality()
30
sage: Necklaces([0,3,2]).cardinality()
2
```

Check to make sure that the count matches up with the number of necklace words generated.

```
sage: comps = [[], [2,2], [3,2,7], [4,2], [0,4,2], [2,0,4]] + Compositions(4).list()
sage: ns = [Necklaces(comp) for comp in comps]
sage: all(n.cardinality() == len(n.list()) for n in ns) # needs sage.libs.pari
True
```

**content()**

Return the content (or evaluation) of the necklaces.

**EXAMPLES:**

```
sage: N = Necklaces([2,2,2])
sage: N.content()
[2, 2, 2]
```
5.1.152 Non-Decreasing Parking Functions

A non-decreasing parking function of size $n$ is a non-decreasing function $f$ from $\{1, \ldots, n\}$ to itself such that for all $i$, one has $f(i) \leq i$.

The number of non-decreasing parking functions of size $n$ is the $n$-th Catalan number.

The set of non-decreasing parking functions of size $n$ is in bijection with the set of Dyck words of size $n$.

AUTHORS:

• Florent Hivert (2009-04)
• Christian Stump (2012-11) added pretty printing

class sage.combinat.non_decreasing_parking_function.NonDecreasingParkingFunction(lst)
Bases: Element

A non decreasing parking function of size $n$ is a non-decreasing function $f$ from $\{1, \ldots, n\}$ to itself such that for all $i$, one has $f(i) \leq i$.

EXAMPLES:

```python
sage: NonDecreasingParkingFunction([])
[]
sage: NonDecreasingParkingFunction([1])
[1]
sage: NonDecreasingParkingFunction([2])
Traceback (most recent call last):
  ... ValueError: [2] is not a non-decreasing parking function
sage: NonDecreasingParkingFunction([1,2])
[1, 2]
sage: NonDecreasingParkingFunction([1,1,2])
[1, 1, 2]
sage: NonDecreasingParkingFunction([1,1,4])
Traceback (most recent call last):
  ... ValueError: [1, 1, 4] is not a non-decreasing parking function
```
classmethod from_dyck_word(dw)

Bijection from Dyck words. It is the inverse of the bijection to_dyck_word(). You can find there the mathematical definition.

EXAMPLES:

```python
def from_dyck_word(dw):
    pass
```

grade()

Return the length of self.

EXAMPLES:

```python
def grade(self):
    return len(self)
```

to_dyck_word()

Implement the bijection to Dyck words, which is defined as follows.

```python
def to_dyck_word()
    return DyckWord()
```
The corresponding Dyck word [1,1,0,1,0,0,1,1,0,0,0] is then read off from the sequence of horizontal and vertical steps. The converse bijection is from_dyck_word().

**EXAMPLES:**

```python
sage: NonDecreasingParkingFunction([1, 1, 2, 4, 5, 5]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 0]
sage: NonDecreasingParkingFunction([]).to_dyck_word()
[]
sage: NonDecreasingParkingFunction([1, 1, 1]).to_dyck_word()
[1, 1, 1, 0, 0, 0]
sage: NonDecreasingParkingFunction([1, 2, 3]).to_dyck_word()
[1, 0, 1, 0, 1, 0]
sage: NonDecreasingParkingFunction([1, 1, 3, 3, 4, 6, 6]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

```python
>>> from sage.all import *

>>> NonDecreasingParkingFunction([Integer(1), Integer(1), Integer(2), Integer(4),
˓→Integer(5), Integer(5)]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0, 1, 1, 0, 0]
```

```python
>>> NonDecreasingParkingFunction([Integer(1), Integer(1), Integer(2), Integer(3)]).to_dyck_word()
[1, 1, 1, 0, 0, 0]
```

```python
>>> NonDecreasingParkingFunction([Integer(1), Integer(1), Integer(3), Integer(3),
˓→Integer(4), Integer(6), Integer(6)]).to_dyck_word()
[1, 1, 0, 0, 1, 1, 0, 1, 0, 0, 1, 1, 0, 0]
```

sage.combinat.non_decreasing_parking_function. NonDecreasingParkingFunctions (n=None)

Return the set of Non-Decreasing Parking Functions.

A non-decreasing parking function of size $n$ is a non-decreasing function $f$ from \{1, \ldots, n\} to itself such that for all $i$, one has $f(i) \leq i$.

**EXAMPLES:**

Here are all the non-decreasing parking functions of size 5:

```python
sage: NonDecreasingParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
```

```python
>>> from sage.all import *

>>> NonDecreasingParkingFunctions(Integer(3)).list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
```

If no size is specified, then NonDecreasingParkingFunctions returns the set of all non-decreasing parking functions.
sage: PF = NonDecreasingParkingFunctions(); PF

class sage.combinat.non_decreasing_parking_function.
NonDecreasingParkingFunctions_all

Bases: UniqueRepresentation, Parent

graded_component(n)

Return the graded component.

EXAMPLES:

```
sage: P = NonDecreasingParkingFunctions()
sage: P.graded_component(4) == NonDecreasingParkingFunctions(4)
True
```

```
from sage.all import *

>>> P = NonDecreasingParkingFunctions()
>>> P.graded_component(Integer(4)) == NonDecreasingParkingFunctions(Integer(4))
True
```

class sage.combinat.non_decreasing_parking_function. NonDecreasingParkingFunctions_n(n)

Bases: UniqueRepresentation, Parent

The combinatorial class of non-decreasing parking functions of size n.

A non-decreasing parking function of size n is a non-decreasing function f from \{1, \ldots, n\} to itself such that for all i, one has \( f(i) \leq i \).

The number of non-decreasing parking functions of size n is the n-th Catalan number.

EXAMPLES:

```
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
sage: PF = NonDecreasingParkingFunctions(4)
sage: PF.list()
[[1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 1, 3], [1, 1, 1, 4], [1, 1, 2, 2], [1, 1, 2, 3], [1, 1, 2, 4], [1, 1, 3, 3], [1, 1, 3, 4], [1, 2, 2, 2], [1, 2, 2, 3], [1, 2, 2, 4], [1, 2, 3, 3], [1, 2, 3, 4], [1, 3, 3, 3], [1, 3, 3, 4], [1, 3, 4, 4], [1, 4, 4, 4]]
sage: [ NonDecreasingParkingFunctions(i).cardinality() for i in range(10) ]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

5.1. Comprehensive Module List
```python
>>> from sage.all import *
>>> PF = NonDecreasingParkingFunctions(Integer(3))
>>> PF.list()
[[1, 1, 1], [1, 1, 2], [1, 1, 3], [1, 2, 2], [1, 2, 3]]
>>> PF = NonDecreasingParkingFunctions(Integer(4))
>>> PF.list()
[[1, 1, 1, 1], [1, 1, 1, 2], [1, 1, 1, 3], [1, 1, 1, 4], [1, 1, 2, 2], [1, 1, 2, 3], [1, 1, 2, 4], [1, 1, 3, 3], [1, 1, 3, 4], [1, 2, 2, 2], [1, 2, 2, 3], [1, 2, 2, 4], [1, 2, 3, 3], [1, 2, 3, 4]]
>>> [NonDecreasingParkingFunctions(i).cardinality() for i in range(Integer(10))]
[1, 1, 2, 5, 14, 42, 132, 429, 1430, 4862]
```

**Warning:** The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

**AUTHORS:**

- Florent Hivert

**Element**

alias of `NonDecreasingParkingFunction`

**cardinality()**

Return the number of non-decreasing parking functions of size \( n \).

This number is the \( n \)-th Catalan number.

**EXAMPLES:**

```
sage: PF = NonDecreasingParkingFunctions(0)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(1)
sage: PF.cardinality()
1
sage: PF = NonDecreasingParkingFunctions(3)
sage: PF.cardinality()
5
sage: PF = NonDecreasingParkingFunctions(5)
sage: PF.cardinality()
42
```
one()

Return the unit of this monoid.

This is the non-decreasing parking function [1, 2, ..., n].

EXAMPLES:

```
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
sage: e = ndpf.one()
sage: x * e == x == e * x
True
```

random_element()

Return a random parking function of the given size.

EXAMPLES:

```
sage: ndpf = NonDecreasingParkingFunctions(5)
sage: x = ndpf.random_element(); x  # random
[1, 2, 2, 4, 5]
sage: x in ndpf
True
```

sage.combinat.non_decreasing_parking_function.is_a(x, n=None)

Check whether a list is a non-decreasing parking function.

If a size $n$ is specified, checks if a list is a non-decreasing parking function of size $n$.

5.1.153 $\nu$-Dyck Words

A class of the $\nu$-Dyck word, see [PRV2017] for details.

AUTHORS:

* Aram Dermenjian (2020-09-26)

This file is based off the class `DyckWords` written by Mike Hansen, Dan Drake, Florent Hivert, Christian Stump, Mike Zabrocki, Jean–Baptiste Priez and Travis Scrimshaw

```
class sage.combinat.nu_dyck_word.NuDyckWord(parent, dw, latex_options=None)
    Bases: CombinatorialElement
```

A $\nu$-Dyck word.
Given a lattice path $\nu$ in the $\mathbb{Z}^2$ grid starting at the origin $(0, 0)$ consisting of North $N = (0, 1)$ and East $E = (1, 0)$ steps, a $\nu$-Dyck path is a lattice path in the $\mathbb{Z}^2$ grid starting at the origin $(0, 0)$ and ending at the same coordinate as $\nu$ such that it is weakly above $\nu$. A $\nu$-Dyck word is the representation of a $\nu$-Dyck path where a North step is represented by a 1 and an East step is represented by a 0.

**INPUT:**
- $k_1$ – A path for the $\nu$-Dyck word
- $k_2$ – A path for $\nu$

**EXAMPLES:**

```python
sage: dw = NuDyckWord([1,0,1,0],[1,0,0,1]); dw
[1, 0, 1, 0]
sage: print(dw)
NENE
sage: dw.height()
2
sage: dw = NuDyckWord('1010',[1,0,0,1]); dw
[1, 0, 1, 0]
sage: dw = NuDyckWord('NENE',[1,0,0,1]); dw
[1, 0, 1, 0]
sage: NuDyckWord([1,0,1,0],[1,0,0,1]).pretty_print()
__
|\ x
| . 
| .
```

```python
sage: from sage.combinat.nu_dyck_word import update_ndw_symbols
sage: update_ndw_symbols(0,1)
sage: dw = NuDyckWord([Integer(1),Integer(0),Integer(1),Integer(0)],[Integer(1),
˓→Integer(0),Integer(0),Integer(1)]); dw
[1, 0, 1, 0]
sage: print(dw)
NENE
sage: dw.height()
2
sage: dw = NuDyckWord('1010',[Integer(1),Integer(0),Integer(0),Integer(1)]); dw
[1, 0, 1, 0]
sage: dw = NuDyckWord('NENE',[Integer(1),Integer(0),Integer(0),Integer(1)]); dw
[1, 0, 1, 0]
sage: NuDyckWord([Integer(1),Integer(0),Integer(1),Integer(0)],[Integer(1),
˓→Integer(0),Integer(0),Integer(1)]).pretty_print()
```

(continues on next page)
can_mutate \(i\)

Return True/False based off if mutable at height \(i\).

Can only mutate if an east step is followed by a north step at height \(i\).

OUTPUT:

Whether we can mutate at height of \(i\).

EXAMPLES:

```sage
NDW = NuDyckWord('10010100', '00000111')
sage: NDW.can_mutate(1)
False
can: NDW.can_mutate(3)
5
```
**heights()**

Return the heights of each point on \texttt{self}.

We view the Dyck word as a Dyck path from \((0,0)\) to \((x,y)\) in the first quadrant by letting 1’s represent steps in the direction \((0,1)\) and 0’s represent steps in the direction \((1,0)\).

The heights is the sequence of the \(y\)-coordinates of all \(x + y\) lattice points along the path.

**EXAMPLES:**

```python
sage: NuDyckWord('010', '010').heights()
[0, 0, 1, 1]
sage: NuDyckWord('110100', '101010').heights()
[0, 1, 2, 3, 3, 3]
```

**horizontal_distance()**

Return a list of how far each point is from \(\nu\).

**EXAMPLES:**

```python
sage: NDW = NuDyckWord('10010100', '00000111')
sage: NDW.horizontal_distance()
[5, 5, 4, 3, 2, 2, 1, 0]
sage: NDW = NuDyckWord('10010100', '00001011')
sage: NDW.horizontal_distance()
[4, 5, 4, 3, 3, 2, 2, 1, 0]
sage: NDW = NuDyckWord('10010100', '0010010101')
sage: NDW.horizontal_distance()
[2, 4, 3, 2, 3, 3, 2, 1, 0]
```

**latex_options()**

Return the latex options for use in the \_latex\_ function as a dictionary.

The default values are set using the options.

- \texttt{color} – (default: 'black') the line color.
- \texttt{line width} – (default: \(2^{\text{\texttt{tikz_scale}}}\)) value representing the line width.
- \texttt{nu_options} – (default: \{'rounded corners=1, color=red, line width=1\'}\) str to indicate what the \texttt{tikz} options should be for path of \(\nu\).
- \texttt{points color} – (default: 'black') str to indicate color points should be drawn with.
• `show_grid` – (default: True) boolean value to indicate if grid should be shown.

• `show_nu` – (default: True) boolean value to indicate if \( \nu \) should be shown.

• `show_points` – (default: False) boolean value to indicate if points should be shown on path.

• `tikz_scale` – (default: 1) scale for use with the tikz package.

EXAMPLES:

```python
sage: NDW = NuDyckWord('010','010')
sage: NDW.latex_options()
{'color': black,
 'line width': 2,
 'nu_options': rounded corners=1, color=red, line width=1,
 'points_color': black,
 'show_grid': True,
 'show_nu': True,
 'show_points': False,
 'tikz_scale': 1}
```

Todo: This should probably be merged into NuDyckWord.options.

```python
>>> from sage.all import *
>>> NDW = NuDyckWord('010','010')
>>> NDW.latex_options()
{'color': black,
 'line width': 2,
 'nu_options': rounded corners=1, color=red, line width=1,
 'points_color': black,
 'show_grid': True,
 'show_nu': True,
 'show_points': False,
 'tikz_scale': 1}
```

**length()**

Return the length of self.

The length is the total number of steps.

EXAMPLES:

```python
sage: NDW = NuDyckWord('10011001000','00100101001')
sage: NDW.length()
11
```

```python
>>> from sage.all import *
>>> NDW = NuDyckWord('10011001000','00100101001')
>>> NDW.length()
11
```

mutate \((i)\)

Return a new \( \nu \)-Dyck Word if possible.

If at height \( i \) we have an east step \( E \) meeting a north step \( N \) then we calculate all horizontal distances from this point until we find the first point that has the same horizontal distance to \( \nu \). We let

• \( d \) is everything up until \( EN \) (not including \( EN \))
• f be everything between N and the point with the same horizontal distance (including N)
• g is everything after f

See also:

can_mutate()

EXAMPLES:

```sage
NDW = NuDyckWord('10010100', '00000111')
NDW.mutate(1)
NDW.mutate(3)
[1, 0, 0, 1, 1, 0, 0, 0]
```

```python

 (16, 17))]
Display a NuDyckWord as a lattice path in the $\mathbb{Z}^2$ grid.

If the style is “N-E”, then a cell below the diagonal is indicated by a period, whereas a cell below the path but above the diagonal is indicated by an x. If a list of labels is included, they are displayed along the vertical edges of the Dyck path.

**INPUT:**

- **style** – (default: None) can either be:
  - None to use the option default
  - “N-E” to show self as a path of north and east steps, or
- **labelling** – (if style is “N-E”) a list of labels assigned to the up steps in self.
- **underpath** – (if style is “N-E”, default: True) If True, an x to show the boxes between $\nu$ and the $\nu$-Dyck Path.

**EXAMPLES:**

```sage
for ND in NuDyckWords('101010'): ND.pretty_print()
```
| x . . |
| . . . |

```python

\[ . \]
\[ \texttt{NuDyckWord().pretty_print()} \]

5.1. Comprehensive Module List 2509
set_latex_options($D$)

Set the latex options for use in the _latex_ function.

The default values are set in the __init__ function.

• color – (default: black) the line color.
• line width – (default: 2$x$ tikz_scale) value representing the line width.
• nu_options – (default: 'rounded corners=1, color=red, line width=1') str to indicate what the tikz options should be for path of $\nu$.
• points_color – (default: 'black') str to indicate color points should be drawn with.
• show_grid – (default: True) boolean value to indicate if grid should be shown.
• show_nu – (default: True) boolean value to indicate if $\nu$ should be shown.
• show_points – (default: False) boolean value to indicate if points should be shown on path.
• tikz_scale – (default: 1) scale for use with the tikz package.

INPUT:

• $D$ – a dictionary with a list of latex parameters to change

EXAMPLES:

```python
sage: NDW = NuDyckWord('010','010')
sage: NDW.set_latex_options({'tikz_scale':2})
sage: NDW.set_latex_options({'color':'blue','show_points':True})
```

Todo: This should probably be merged into NuDyckWord.options.

width()

Return the width of self.

The width is the number of east steps.

EXAMPLES:

```python
sage: NuDyckWord('110111001101001000110111100011000','...
....: '101010101010101010101010101010101').width()
16
```

```python
>>> from sage.all import *
>>> NuDyckWord('110111001101001000110111100011000','...
....: '101010101010101010101010101010101').width()
16
```
widths()

Return the widths of each point on self.

We view the Dyck word as a Dyck path from \((0, 0)\) to \((x, y)\) in the first quadrant by letting 1’s represent steps in the direction \((0, 1)\) and 0’s represent steps in the direction \((1, 0)\).

The widths is the sequence of the \(x\)-coordinates of all \(x + y\) lattice points along the path.

EXAMPLES:

```
sage: NuDyckWord('010', '010').widths()
[0, 1, 1, 2]
sage: NuDyckWord('110100', '101010').widths()
[0, 0, 0, 1, 1, 2, 3]
```

```
>>> from sage.all import *

>>> NuDyckWord('010', '010').widths()
[0, 1, 1, 2]
>>> NuDyckWord('110100', '101010').widths()
[0, 0, 0, 1, 1, 2, 3]
```

class sage.combinat.nu_dyck_word.NuDyckWords(nu=())

Bases: Parent

\(\nu\)-Dyck words.

Given a lattice path \(\nu\) in the \(\mathbb{Z}^2\) grid starting at the origin \((0, 0)\) consisting of North \(N = (0, 1)\) and East \(E = (1, 0)\) steps, a \(\nu\)-Dyck path is a lattice path in the \(\mathbb{Z}^2\) grid starting at the origin \((0, 0)\) and ending at the same coordinate as \(\nu\) such that it is weakly above \(\nu\). A \(\nu\)-Dyck word is the representation of a \(\nu\)-Dyck path where a North step is represented by a 1 and an East step is represented by a 0.

INPUT:

- \(\nu\) – the base lattice path.

EXAMPLES:

```
sage: NDW = NuDyckWords('1010'); NDW
[1, 0, 1, 0] Dyck words
sage: [1,0,1,0] in NDW
True
sage: [1,1,0,0] in NDW
True
sage: [1,0,0,1] in NDW
False
sage: [0,1,0,1] in NDW
False
sage: NDW.cardinality()
2
```

```
>>> from sage.all import *

>>> NDW = NuDyckWords('1010'); NDW
[1, 0, 1, 0] Dyck words
>>> [Integer(1),Integer(0),Integer(1),Integer(0)] in NDW
True
>>> [Integer(1),Integer(1),Integer(0),Integer(0)] in NDW
True
>>> [Integer(1),Integer(1),Integer(0),Integer(1)] in NDW
False
```

(continues on next page)
Element
  alias of NuDyckWord
cardinality()
  Return the number of ν-Dyck words.
  EXAMPLES:
  sage: NDW = NuDyckWords('101010'); NDW.cardinality()
  5
  sage: NDW = NuDyckWords('1010010'); NDW.cardinality()
  7
  sage: NDW = NuDyckWords('100100100'); NDW.cardinality()
  12

options = Current options for NuDyckWords - ascii_art: pretty_output -
diagram_style: grid - display: list - latex_color: black -
latex_line_width_scalar: 2 - latex_nu_options: rounded corners=1,
color=red, line width=1 - latex_points_color: black - latex_show_grid:
True - latex_show_nu: True - latex_show_points: False - latex_tikz_scale:
1

sage.combinat.nu_dyck_word.path_weakly_above_other(path, other)
  Test if path is weakly above other.
  A path P is weakly above another path Q if P and Q are the same length and if any
prefix of length n of Q contains more North steps than the prefix of length n of P.
  INPUT:
  • path – The path to verify is weakly above the other path.
  • other – The other path to verify is weakly below the path.
  OUTPUT:
  bool
  EXAMPLES:
  sage: from sage.combinat.nu_dyck_word import path_weakly_above_other
  sage: path_weakly_above_other('1001', '0110')
  False
  sage: path_weakly_above_other('1001', '0101')
  True
sage: path_weakly_above_other('1111', '0101')
False
sage: path_weakly_above_other('111100', '0101')
False

```python
>>> from sage.all import *
>>> from sage.combinat.nu_dyck_word import path_weakly_above_other
>>> path_weakly_above_other('1001', '0110')
False
>>> path_weakly_above_other('1001', '0101')
True
>>> path_weakly_above_other('1111', '0101')
False
>>> path_weakly_above_other('111100', '0101')
False
```

```python
sage.combinat.nu_dyck_word.replace_dyck_char(x)
A map sending an opening character ('1', 'N', and '(') to ndw_open_symbol, a closing character ('0', 'E', and ')') to ndw_close_symbol, and raising an error on any input other than one of the opening or closing characters.

This is the inverse map of replace_dyck_symbol().

INPUT:
• x – string; a '1', '0', 'N', 'E', '(' or ')' 

OUTPUT:
• If x is an opening character, replace x with the constant ndw_open_symbol.
• If x is a closing character, replace x with the constant ndw_close_symbol.
• Raise a ValueError if x is neither an opening nor a closing character.

See also:
replace_dyck_symbol()

EXAMPLES:
```
sage.combinat.nu_dyck_word.replace_dyck_symbol(x, open_char='N', close_char='E')

A map sending ndw_open_symbol to open_char and ndw_close_symbol to close_char, and raising an error on any input other than ndw_open_symbol and ndw_close_symbol. The values of the constants ndw_open_symbol and ndw_close_symbol are subject to change.

This is the inverse map of replace_dyck_char().

INPUT:
• x – either ndw_open_symbol or ndw_close_symbol.
• open_char – str (optional) default 'N'
• close_char – str (optional) default 'E'

OUTPUT:
• If x is ndw_open_symbol, replace x with open_char.
• If x is ndw_close_symbol, replace x with close_char.
• If x is neither ndw_open_symbol nor ndw_close_symbol, a ValueError is raised.

See also:
replace_dyck_char()

EXAMPLES:

```python
sage: from sage.combinat.nu_dyck_word import replace_dyck_symbol
sage: replace_dyck_symbol(1)
'N'
sage: replace_dyck_symbol(0)
'E'
sage: replace_dyck_symbol(3)
Traceback (most recent call last):
... ValueError
```

```python
>>> from sage.all import *
>>> from sage.combinat.nu_dyck_word import replace_dyck_symbol
>>> replace_dyck_symbol(Integer(1))
'N'
>>> replace_dyck_symbol(Integer(0))
'E'
>>> replace_dyck_symbol(Integer(3))
Traceback (most recent call last):
...
ValueError
```

sage.combinat.nu_dyck_word.to_word_path(word)

Convert input into a word path over an appropriate alphabet.

Helper function.

INPUT:
• word – word to convert to wordpath
OUTPUT:

- A `FiniteWordPath_north_east` object.

EXAMPLES:

```python
def from_sage.combinat.nu_dyck_word import to_word_path
def wp = to_word_path('NEENENEN'); wp
Path: 10010101
def from_sage.combinat.words.paths import FiniteWordPath_north_east
def isinstance(wp,FiniteWordPath_north_east)
True
def to_word_path('1001')
Path: 1001
def to_word_path([0,1,0,0,1,0])
Path: 010010
```

```python
def from_sage.all import *
def from_sage.combinat.nu_dyck_word import to_word_path
def wp = to_word_path('NEENENEN'); wp
Path: 10010101
def from_sage.combinat.words.paths import FiniteWordPath_north_east
def isinstance(wp,FiniteWordPath_north_east)
True
def to_word_path('1001')
Path: 1001
def to_word_path([Integer(0),Integer(1),Integer(0),Integer(0),Integer(1),
                   Integer(0)])
Path: 010010
```

`sage.combinat.nu_dyck_word.update_ndw_symbols(os,cs)`

A way to alter the open and close symbols from sage.

INPUT:

- `os` – the open symbol
- `cs` – the close symbol

EXAMPLES:

```python
def from_sage.combinat.nu_dyck_word import update_ndw_symbols

def update_ndw_symbols(0,1)

def dw = NuDyckWord('0101001','0110010'); dw
[0, 1, 0, 1, 0, 0, 1]
def dw = NuDyckWord('1010110','1001101'); dw
Traceback (most recent call last):
...
ValueError: invalid nu-Dyck word
def update_ndw_symbols(1,0)
```

```python
def from_sage.all import *
def from_sage.combinat.nu_dyck_word import update_ndw_symbols
def update_ndw_symbols(Integer(0),Integer(1))
def dw = NuDyckWord('0101001','0110010'); dw
[0, 1, 0, 1, 0, 0, 1]
def dw = NuDyckWord('1010110','1001101'); dw
```

(continues on next page)
5.1.154 $\nu$-Tamari lattice

A class of the $\nu$-Tamari lattice, and $(\delta, \nu)$-Tamari lattice (or alt $\nu$-Tamari lattices), see [PRV2017] and [CC2023] for details.

These lattices depend on a parameter $\nu$ where $\nu$ is a path of North and East steps. The alt $\nu$-Tamari lattice depends on an additional parameter $\delta$, which is an increment vector with respect to $\nu$.

The elements are $nu$-Dyck paths which are weakly above $\nu$.

To use the provided functionality, you should import $\nu$-Tamari lattices by typing:

```sage
from sage.combinat.nu_tamari_lattice import NuTamariLattice, AltNuTamariLattice
```

Then,

```sage
NuTamariLattice([1,1,1,0,0,1,1,0])
```
Finite lattice containing 6 elements

```sage
NuTamariLattice([0,0,0,1,1,0,0,1])
```
Finite lattice containing 40 elements

```sage
AltNuTamariLattice([0,0,0,1,1,0,0,1])
```
Finite lattice containing 40 elements

```sage
AltNuTamariLattice([0,0,0,1,1,0,0,1], [0,1,0])
```
Finite lattice containing 40 elements

The classical Tamari lattices and the Generalized Tamari lattices are special cases of this construction and are also available with this poset:

```sage
NuTamariLattice([1,0,1,0,1,0])
```
Finite lattice containing 5 elements

```sage
NuTamariLattice([1,0,0,1,0,0,1,0,0])
```
Finite lattice containing 12 elements
>>> from sage.all import *
>>> NuTamariLattice([Integer(1),Integer(0),Integer(1),Integer(0),Integer(1),
                  Integer(0)])
Finite lattice containing 5 elements

>>> NuTamariLattice([Integer(1),Integer(0),Integer(0),Integer(1),Integer(0),
                  Integer(0),Integer(1),Integer(0),Integer(0)])
Finite lattice containing 12 elements

See also:

For more detailed information see NuTamariLattice() and AltNuTamariLattice(). For more information on the standard Tamari lattice see sage.combinat.tamari_lattices.TamariLattice(), sage.combinat.tamari_lattices.GeneralizedTamariLattice()

AUTHORS:

• Aram Dermenjian (2020-09-26): initial version
• Clément Chenevière (2024-02-01): added the alt \(\nu\)-Tamari lattices

sage.combinat.nu_tamari_lattice.AltNuTamariLattice(nu, delta=None)

Return the \((\delta, \nu)\)-Tamari lattice (or alt \(\nu\)-Tamari lattice).

For more information, see [CC2023].

The path \(\nu\) is a path of North steps (represented as 1 s) and East steps (represented as 0 s).

The vector \(\delta = (\delta_1, \ldots, \delta_n)\) is an increment vector with respect to the path \(\nu\), that is to say \(\delta_i \leq \nu_i\), where \(\nu_i\) is the number of 0 s following the \(i\)-th 1 of \(\nu\). If not provided, \(\delta\) is set by default to produce the classical \(\nu\)-Tamari lattice.

INPUT:

• \(\nu\) – a list of 0s and 1s or a string of 0s and 1s.
• \(\delta\) – a list of nonnegative integers.

OUTPUT:

• a finite lattice

EXAMPLES:

sage: from sage.combinat.nu_tamari_lattice import AltNuTamariLattice,
    NuTamariLattice
sage: AltNuTamariLattice('01001', [0, 0])
Finite lattice containing 7 elements
sage: AltNuTamariLattice('01001', [1, 0])
Finite lattice containing 7 elements
sage: AltNuTamariLattice('01001') == AltNuTamariLattice('01001', [2, 0])
True
sage: nu = '00100100101'; P = AltNuTamariLattice(nu); Q = NuTamariLattice(nu); P == Q
True

(continues on next page)
```
>>> AltNuTamariLattice('01001', [Integer(1), Integer(0)])
Finite lattice containing 7 elements
>>> AltNuTamariLattice('01001') == AltNuTamariLattice('01001', [Integer(2),
-Integer(0)])
True
>>> nu = '00100100101'; P = AltNuTamariLattice(nu); Q = NuTamariLattice(nu); P ==
-Q
True

REFERENCES:

• [PRV2017]
• [CC2023]

sage.combinat.nu_tamari_lattice.NuTamariLattice(nu)
Return the \( \nu \)-Tamari lattice.

INPUT:

• \( \nu \) – a list of 0s and 1s or a string of 0s and 1s.

OUTPUT:

a finite lattice

The elements of the lattice are \textit{nu-Dyck paths} weakly above \( \nu \).

The usual Tamari lattice is the special case where \( \nu = (NE)^h \) where \( h \) is the height.

Other special cases give the \( m \)-Tamari lattices studied in [BMFPR].

EXAMPLES:

```
```
Perform a covering move in the $(\delta, \nu)$-Tamari lattice (or alt $\nu$-Tamari lattice, see [CC2023]).

The letter at position $k$ is a North step of the $\nu$-Dyck word $p$, and must be preceded by an East step.

The vector $\delta = (\delta_1, \ldots, \delta_n)$ is an increment vector with respect to the path $\nu$, that is to say $\delta_i \leq \nu_i$, where $\nu_i$ is the number of East steps following the $i$-th North step of $\nu$.

**INPUT:**
- $p$ – a $\nu$-Dyck word
- $k$ – an integer between 0 and $p$.length()-1
- $\delta$ – a list of nonnegative integers of length $p$.height()

**OUTPUT:**
- a $\nu$-Dyck word

**EXAMPLES:**

```python
sage: from sage.combinat.nu_tamari_lattice import delta_swap
sage: delta_swap(NuDyckWord('0101', '0101'), 3, delta = [1, 0])
[0, 1, 1, 0]
sage: delta_swap(NuDyckWord('1001110100', '0100010111'), 3, [3, 1, 0, 0, 0])
[1, 0, 1, 1, 0, 0, 1, 0, 0]
sage: delta_swap(NuDyckWord('1010010000', '0100100011'), 2, [2, 3, 0, 1])
[1, 1, 0, 0, 1, 0, 0, 1, 0, 0]
```

```python
>>> from sage.all import *
>>> from sage.combinat.nu_tamari_lattice import delta_swap
>>> delta_swap(NuDyckWord('0101', '0101'), Integer(3), delta = [Integer(1), Integer(0)])
[0, 1, 1, 0]
>>> delta_swap(NuDyckWord('1001110100', '0100010111'), Integer(3), [Integer(3), Integer(1), Integer(0), Integer(0), Integer(0)])
[1, 0, 1, 1, 0, 0, 1, 0, 0]
>>> delta_swap(NuDyckWord('1010010000', '0100100011'), Integer(2), [Integer(2), Integer(1)])
[1, 1, 0, 0, 1, 0, 1, 0, 0]
>>> delta_swap(NuDyckWord('1010010000', '0100100011'), Integer(2), [Integer(1), Integer(0), Integer(0)])
[1, 1, 0, 0, 1, 0, 1, 0, 0]
```

## 5.1.155 Ordered Rooted Trees

**AUTHORS:**
- Florent Hivert (2010-2011): initial revision
- Frédéric Chapoton (2010): contributed some methods

```python
class sage.combinat.ordered_tree.LabelledOrderedTree (parent, children, label=None, check=True)
Bases: AbstractLabelledClonableTree, OrderedTree
Labelled ordered trees.
```
A labelled ordered tree is an ordered tree with a label attached at each node.

INPUT:

- *children* – a list or tuple or more generally any iterable of trees or object convertible to trees
- *label* – any Sage object (default: None)

EXAMPLES:

```python
sage: x = LabelledOrderedTree([], label = 3); x
3[

sage: LabelledOrderedTree([x, x, x], label = 2)
2[3[], 3[], 3[]]

sage: LabelledOrderedTree((x, x, x), label = 2)
2[3[], 3[], 3[]]

sage: LabelledOrderedTree([[],[[], []]], label = 3)
3[None[], None[None[], None[]]]

>>> from sage.all import *

>>> x = LabelledOrderedTree([], label=Integer(3)); x
3[

>>> LabelledOrderedTree([x, x, x], label=Integer(2))
2[3[], 3[], 3[]]

>>> LabelledOrderedTree((x, x, x), label=Integer(2))
2[3[], 3[], 3[]]

>>> LabelledOrderedTree([[],[[], []]], label=Integer(3))
3[None[], None[None[], None[]]]

left_right_symmetry()

Return the symmetric tree of self.

The symmetric tree \( s(T) \) of a labelled ordered tree \( T \) is defined as follows: If \( T \) is a labelled ordered tree with children \( C_1, C_2, \ldots, C_k \) (listed from left to right), then the symmetric tree \( s(T) \) of \( T \) is a labelled ordered tree with children \( s(C_k), s(C_{k-1}), \ldots, s(C_1) \) (from left to right), and with the same root label as \( T \).

Note: If you have a subclass of `LabelledOrderedTree()` which also inherits from another subclass of `OrderedTree()` which does not come with a labelling, then (depending on the method resolution order) it might happen that this method gets overridden by an implementation from that other subclass, and thus forgets about the labels. In this case you need to manually override this method on your subclass.

EXAMPLES:

```python
sage: L2 = LabelledOrderedTree([], label=2)

sage: L3 = LabelledOrderedTree([], label=3)

sage: T23 = LabelledOrderedTree([L2, L3], label=4)

sage: T23.left_right_symmetry()
4[3[], 2[]]

sage: T223 = LabelledOrderedTree([L2, T23], label=17)

sage: T223.left_right_symmetry()
17[4[3[], 2[]], 2[]]

sage: T223.left_right_symmetry().left_right_symmetry() == T223
True

>>> from sage.all import *

>>> L2 = LabelledOrderedTree([], label=Integer(2))

>>> L3 = LabelledOrderedTree([], label=Integer(3))
```

(continues on next page)
>>> T23 = LabelledOrderedTree([L2, L3], label=Integer(4))
>>> T23.left_right_symmetry()
4[3[[], 2[]]]
>>> T223 = LabelledOrderedTree([L2, T23], label=Integer(17))
>>> T223.left_right_symmetry()
17[4[3[[], 2[]]], 2[[]]]
>>> T223.left_right_symmetry().left_right_symmetry() == T223
True

sort_key()

Return a tuple of nonnegative integers encoding the labelled tree self.

The first entry of the tuple is a pair consisting of the number of children of the root and the label of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right.

This tuple characterizes the labelled tree uniquely, and can be used to sort the labelled ordered trees provided that the labels belong to a type which is totally ordered.

Warning: This method overrides OrderedTree.sort_key() and returns a result different from what the latter would return, as it wants to encode the whole labelled tree including its labelling rather than just the unlabelled tree. Therefore, be careful with using this method on subclasses of LabelledOrderedTree; under some circumstances they could inherit it from another superclass instead of from OrderedTree, which would cause the method to forget the labelling. See the docstring of OrderedTree.sort_key().

EXAMPLES:

```python
sage: L2 = LabelledOrderedTree([], label=2)
sage: L3 = LabelledOrderedTree([], label=3)
sage: T23 = LabelledOrderedTree([L2, L3], label=4)
sage: T23.sort_key()
((2, 4), (0, 2), (0, 3))
sage: T32 = LabelledOrderedTree([L3, L2], label=5)
sage: T32.sort_key()
((2, 5), (0, 3), (0, 2))
sage: T23322 = LabelledOrderedTree([T23, T32, L2], label=14)
sage: T23322.sort_key()
((3, 14), (2, 4), (0, 2), (0, 3), (2, 5), (0, 3), (0, 2), (0, 2))
```
This is a parent stub to serve as a factory class for trees with various label constraints.

EXAMPLES:

```
>>> from sage.all import *

>>> LOT = LabelledOrderedTrees(); LOT
Labelled ordered trees
>>> x = LOT([[]], label = 3); x
3[]
>>> x.parent() is LOT
True
>>> y = LOT([x, x, x], label = 2); y
2[3[], 3[], 3[]]
>>> y.parent() is LOT
True
```

Element

alias of `LabelledOrderedTree`

cardinality()

Return the cardinality of `self`.

EXAMPLES:

```
>>> LabelledOrderedTrees().cardinality()
+Infinity
```

```
>>> from sage.all import *

>>> LabelledOrderedTrees().cardinality()
+Infinity
```

labelled_trees()

Return the set of labelled trees associated to `self`.

This is precisely `self`, because `self` already is the set of labelled ordered trees.

EXAMPLES:

```
>>> LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
```

```
>>> LOT = LabelledOrderedTrees()
>>> x = LOT([[]], label = 3)
>>> y = LOT([x, x, x], label = 2)
>>> y.canonical_labelling()
1[2[], 3[], 4[]]
```
>>> from sage.all import *
>>> LabelledOrderedTrees().labelled_trees()
Labelled ordered trees
>>> LOT = LabelledOrderedTrees()
>>> x = LOT([], label = Integer(3))
>>> y = LOT([x, x, x], label = Integer(2))
>>> y.canonical_labelling()
1[2[], 3[], 4[]]

unlabelled_trees()

Return the set of unlabelled trees associated to self.

This is the set of ordered trees, since self is the set of labelled ordered trees.

EXAMPLES:

sage: LabelledOrderedTrees().unlabelled_trees()
Ordered trees

class sage.combinat.ordered_tree.OrderedTree (parent=None, children=None, check=True)

Bases: AbstractClonableTree, ClonableList

The class of (ordered rooted) trees.

An ordered tree is constructed from a node, called the root, on which one has grafted a possibly empty list of trees. There is a total order on the children of a node which is given by the order of the elements in the list. Note that there is no empty ordered tree (so the smallest ordered tree consists of just one node).

INPUT:

One can create a tree from any list (or more generally iterable) of trees or objects convertible to a tree. Alternatively a string is also accepted. The syntax is the same as for printing: children are grouped by square brackets.

EXAMPLES:

sage: x = OrderedTree([])
sage: x1 = OrderedTree([x,x])
sage: x2 = OrderedTree([[[],[]]])
sage: x1 == x2
True
sage: tt1 = OrderedTree([x,x1,x2])
sage: tt2 = OrderedTree([[[],[[],[]],x2]])
sage: tt1 == tt2
True
sage: OrderedTree([]) == OrderedTree()
True

>>> from sage.all import *
>>> x = OrderedTree([])
>>> x1 = OrderedTree([x,x])
>>> x2 = OrderedTree([[[],[]]])
>>> x1 == x2
True
Combinatorics, Release 10.4

```python
>>> tt1 = OrderedTree([x, x1, x2])
>>> tt2 = OrderedTree([[], [[]], []], x2)
>>> tt1 == tt2
True

>>> OrderedTree([]) == OrderedTree()
True

is_empty()
Return if self is the empty tree.
For ordered trees, this always returns False.

Note: this is different from bool(t) which returns whether t has some child or not.

EXAMPLES:
```
sage: t = OrderedTrees(4)([[[]]], [[]])
sage: t.is_empty()
False
sage: bool(t)
True
```

left_right_symmetry()
Return the symmetric tree of self.
The symmetric tree $s(T)$ of an ordered tree $T$ is defined as follows: If $T$ is an ordered tree with children $C_1, C_2, \ldots, C_k$ (listed from left to right), then the symmetric tree $s(T)$ of $T$ is the ordered tree with children $s(C_k), s(C_{k-1}), \ldots, s(C_1)$ (from left to right).

EXAMPLES:
```
sage: T = OrderedTree([[], [[]]])
sage: T.left_right_symmetry()
[[[]], []]
sage: T = OrderedTree([[], [[], []]], [[], [[]])
sage: T.left_right_symmetry()
[[[[], []]], [[], []], [[], []]]
```

```
normalize\( (inplace=False) \)

Return the normalized tree of \( \text{self} \).

INPUT:

- \( \text{inplace} \) – boolean, (default \( \text{False} \)) if \( \text{True} \), then \( \text{self} \) is modified and nothing returned. Otherwise the normalized tree is returned.

The normalization of an ordered tree \( t \) is an ordered tree \( s \) which has the property that \( t \) and \( s \) are isomorphic as unordered rooted trees, and that if two ordered trees \( t \) and \( t' \) are isomorphic as unordered rooted trees, then the normalizations of \( t \) and \( t' \) are identical. In other words, normalization is a map from the set of ordered trees to itself which picks a representative from every equivalence class with respect to the relation of “being isomorphic as unordered trees”, and maps every ordered tree to the representative chosen from its class.

This map proceeds recursively by first normalizing every subtree, and then sorting the subtrees according to the value of the \( \text{sort_key()} \) method.

Consider the quotient map \( \pi \) that sends a planar rooted tree to the associated unordered rooted tree. Normalization is the composite \( s \circ \pi \), where \( s \) is a section of \( \pi \).

EXAMPLES:

```python
sage: OT = OrderedTree
sage: ta = OT([[[]], [[]]])
sage: tb = OT([[[[]], []]])
sage: ta.normalize() == tb.normalize()
True
sage: ta == tb
False
```

```python
>>> from sage.all import *
>>> OT = OrderedTree
>>> ta = OT([[[]], [[]]])
>>> tb = OT([[[[]], []]])
>>> ta.normalize(inplace=True); ta
[[[]], [[]]]
>>> tb.normalize(inplace=True); tb
[[[]], [[]]]
```

An example with inplace normalization:

```python
sage: OT = OrderedTree
sage: ta = OT([[[]], [[]]])
sage: tb = OT([[[[]], []]])
sage: ta.normalize(inplace=True); ta
[[[]], [[]]]
sage: tb.normalize(inplace=True); tb
[[[]], [[]]]
```
plot()

Plot the tree self.

Warning: For a labelled tree, this will fail unless all labels are distinct. For unlabelled trees, some arbitrary labels are chosen. Use \_latex\_(), view, \_ascii\_art\_() or pretty\_print for more faithful representations of the data of the tree.

EXAMPLES:

\begin{verbatim}
sage: p = OrderedTree([[[]],[],[]])
sage: ascii_art(p)
  _o__
 / / /
 o o o
 |
 |

sage: p.plot()
# needs sage.plot
Graphics object consisting of 10 graphics primitives
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> p = OrderedTree([[[]],[],[]])
>>> ascii_art(p)
  _o__
 / / /
 o o o
 |
 |

>>> p.plot()
# needs sage.plot
Graphics object consisting of 10 graphics primitives
\end{verbatim}

Now a labelled example:

\begin{verbatim}
sage: g = OrderedTree([[],[[[]],[[]]]]).canonical_labelling()
sage: ascii_art(g)
  _1__
 / / /
2 3 5
 | 4

sage: g.plot()
# needs sage.plot
Graphics object consisting of 10 graphics primitives
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> g = OrderedTree([[],[[[]],[[]]]]).canonical_labelling()
>>> ascii_art(g)
  _1__
 / / /
2 3 5
 | 4

>>> g.plot()
# ...
\end{verbatim}

(continues on next page)
5.1. Comprehensive Module List
sort_key()

Return a tuple of nonnegative integers encoding the ordered tree self.

The first entry of the tuple is the number of children of the root. Then the rest of the tuple is the concatenation of the tuples associated to these children (we view the children of a tree as trees themselves) from left to right. This tuple characterizes the tree uniquely, and can be used to sort the ordered trees.

Note: By default, this method does not encode any extra structure that self might have—e.g., if you were to define a class EdgeColoredOrderedTree which implements edge-colored trees and which inherits from OrderedTree, then the sort_key() method it would inherit would forget about the colors of the edges (and thus would not characterize edge-colored trees uniquely). If you want to preserve extra data, you need to override this method or use a new method. For instance, on the LabelledOrderedTree subclass, this method is overridden by a slightly different method, which encodes not only the numbers of children of the nodes of self, but also their labels. Be careful with using overridden methods, however: If you have (say) a class BalancedTree which inherits from OrderedTree and which encodes balanced trees, and if you have another class BalancedLabelledOrderedTree which inherits both from BalancedOrderedTree and from LabelledOrderedTree, then (depending on the MRO) the default sort_key() method on BalancedLabelledOrderedTree (unless manually overridden) will be taken either from BalancedTree or from LabelledOrderedTree, and in the former case will
ignore the labelling!

EXAMPLES:

```python
sage: RT = OrderedTree
sage: RT([[[],[]]]).sort_key()
(2, 0, 1, 0)
sage: RT([[[]],[[]]]).sort_key()
(2, 1, 0, 0)
```

```python
>>> from sage.all import *
>>> RT = OrderedTree
>>> RT([[[],[]]]).sort_key()
(2, 0, 1, 0)
>>> RT([[[]],[[]]]).sort_key()
(2, 1, 0, 0)
```

`to_binary_tree_left_branch()`

Return a binary tree of size $n - 1$ (where $n$ is the size of $t$, and where $t$ is `self`) obtained from $t$ by the following recursive rule:

- if $x$ is the left brother of $y$ in $t$, then $x$ becomes the left child of $y$;
- if $x$ is the last child of $y$ in $t$, then $x$ becomes the right child of $y$,

and removing the root of $t$.

EXAMPLES:

```python
sage: T = OrderedTree([[[]],[[]]])
sage: T.to_binary_tree_left_branch()
[[[., .], .], .]
sage: T = OrderedTree([[[]],[[]],[[]],[[]]]))
sage: T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [., .]]]
```

```python
>>> from sage.all import *
>>> T = OrderedTree([[[]],[[]]])
>>> T.to_binary_tree_left_branch()
[[[., .], .], .]
>>> T = OrderedTree([[[]],[[]],[[]],[[]]])
>>> T.to_binary_tree_left_branch()
[[[., .], [[., .], .]], [[., .], [., .]]]
```

`to_binary_tree_right_branch()`

Return a binary tree of size $n - 1$ (where $n$ is the size of $t$, and where $t$ is `self`) obtained from $t$ by the following recursive rule:

- if $x$ is the right brother of $y$ in $t$, then `x` becomes the right child of $y$;
- if $x$ is the first child of $y$ in $t$, then $x$ becomes the left child of $y$,

and removing the root of $t$.

EXAMPLES:

```python
sage: T = OrderedTree([[[]],[[]]])
sage: T.to_binary_tree_right_branch()
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
[., [., .]]
sage: T = OrderedTree([[], [[], []], [[], []]])
sage: T.to_binary_tree_right_branch()
[., [., [., .]], [., [., .]], .]
```

```
>>> from sage.all import *
>>> T = OrderedTree([[],[ ]])
>>> T.to_binary_tree_right_branch()
[., [., .]]

>>> T = OrderedTree([[], [[], []], [[], []]])
>>> T.to_binary_tree_right_branch()
[., [., [., .]], [., [., .]], .]
```

to_dyck_word()

Return the Dyck path corresponding to self where the maximal height of the Dyck path is the depth of self.

EXAMPLES:

```
sage: T = OrderedTree([[],[]])
sage: T.to_dyck_word()
[1, 0, 1, 0]
sage: T = OrderedTree([[],[]])
sage: T.to_dyck_word()
[1, 0, 1, 1, 0, 0]

>>> from sage.all import *
>>> T = OrderedTree([[],[]])
>>> T.to_dyck_word()
[1, 0, 1, 0]

>>> T = OrderedTree([[],[]])
>>> T.to_dyck_word()
[1, 0, 1, 1, 0, 0]
```

to_parallelogram_polyomino(bijection=None)

Return a polyomino parallelogram.

INPUT:

- bijection – (default: 'Boussicault-Socci') is the name of the bijection to use. Possible values are 'Boussicault-Socci', 'via dyck and Delest-Viennot'.

EXAMPLES:

```
```

2530 Chapter 5. Comprehensive Module List
```python
sage: T = OrderedTree([[[]], [[[]], [[]]]], [], [[[]], [[]]], [], []

sage: T.to_parallelogram_polyomino(bijection='Boussicault-Socci')
[[0, 0, 0, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1],
 [1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 0]]

sage: T = OrderedTree([[]])

sage: T.to_parallelogram_polyomino()
[[1], [1]]

sage: T = OrderedTree([[]])

sage: T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]

sage: T = OrderedTree([[], []])

sage: T.to_parallelogram_polyomino()
[[0, 1, 1], [1, 1, 0]]

sage: T = OrderedTree([[]])

sage: T.to_parallelogram_polyomino()
[[0, 0, 1], [1, 0, 0]]

>>> from sage.all import *

>>> T = OrderedTree([[[]], [[[]], [[]]]], [], [[[]], [[]]], [], []

>>> T.to_parallelogram_polyomino(bijection='Boussicault-Socci')
[[0, 0, 0, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 1],
 [1, 1, 1, 1, 1, 0, 1, 1, 1, 1, 0, 1, 1, 0]]

>>> T = OrderedTree([[]])

>>> T.to_parallelogram_polyomino()
[[1], [1]]

>>> T = OrderedTree([[]])

>>> T.to_parallelogram_polyomino()
[[0, 1], [1, 0]]

>>> T = OrderedTree([[], []])

>>> T.to_parallelogram_polyomino()
[[0, 1, 1], [1, 1, 0]]

>>> T = OrderedTree([[]])

>>> T.to_parallelogram_polyomino()
[[0, 0, 1], [1, 0, 0]]
```

**to_poset (root_to_leaf=False)**

Return the poset obtained by interpreting the tree as a Hasse diagram. The default orientation is from leaves to root but you can pass root_to_leaf=True to obtain the inverse orientation.

**INPUT:**

- root_to_leaf - boolean, true if the poset orientation should be from root to leaves. It is false by default.

**EXAMPLES:**

```python
sage: t = OrderedTree([])
sage: t.to_poset()
Finite poset containing 1 elements
sage: p = OrderedTree([[], []]).to_poset()
sage: p.height(), p.width()  #...
needs networkx
(3, 3)
```
```python
from sage.all import *
t = OrderedTree([])
t.to_poset()
```

Finite poset containing 1 elements
```python
p = OrderedTree([[]], []).to_poset()
p.height(), p.width() # needs networkx
(3, 3)
```

If the tree is labelled, we use its labelling to label the poset. Otherwise, we use the poset canonical labelling:
```python
t = OrderedTree([[], []]).canonical_labelling().to_poset()
t.height(), t.width() # needs networkx
(3, 3)
```

```python
t = OrderedTree([[], []]).canonical_labelling().to_poset()
t.height(), t.width() # needs networkx
(3, 3)
```

to_undirected_graph()

Return the undirected graph obtained from the tree nodes and edges.
The graph is endowed with an embedding, so that it will be displayed correctly.

EXAMPLES:
```python
t = OrderedTree([])
t.to_undirected_graph()
```

Graph on 1 vertex
```python
t = OrderedTree([[], []])
t.to_undirected_graph()
```

Graph on 5 vertices

If the tree is labelled, we use its labelling to label the graph. This will fail if the labels are not all distinct. Otherwise, we use the graph canonical labelling which means that two different trees can have the same graph.

EXAMPLES:
```python
t = OrderedTree([[], []])
t.canonical_labelling().to_undirected_graph()
```

Graph on 5 vertices

```python
t = OrderedTree([[], []])
t.canonical_labelling().to_undirected_graph()
```

Graph on 5 vertices
class sage.combinat.ordered_tree.OrderedTrees

Bases: UniqueRepresentation, Parent

Factory for ordered trees

INPUT:

- size – (optional) an integer

OUTPUT:

- the set of all ordered trees (of the given size if specified)

EXAMPLES:

```
sage: OrderedTrees()
Ordered trees
sage: OrderedTrees(2)
Ordered trees of size 2
```

```
>>> from sage.all import *
>>> OrderedTrees()
Ordered trees
>>> OrderedTrees(Integer(2))
Ordered trees of size 2
```

Note: this is a factory class whose constructor returns instances of subclasses.

Note: the fact that OrderedTrees is a class instead of a simple callable is an implementation detail. It could be changed in the future and one should not rely on it.

leaf()

Return a leaf tree with self as parent

EXAMPLES:

```
sage: OrderedTrees().leaf()
[]
```

```
>>> from sage.all import *
>>> OrderedTrees().leaf()
[]
```

class sage.combinat.ordered_tree.OrderedTrees_all

Bases: DisjointUnionEnumeratedSets, OrderedTrees

The set of all ordered trees.

EXAMPLES:

```
sage: OT = OrderedTrees(); OT
Ordered trees
sage: OT.cardinality()
+Infinity
```
from sage.all import *

OT = OrderedTrees(); OT
Ordered trees

OT.cardinality() +Infinity

Element

alias of OrderedTree

labelled_trees()

Return the set of labelled trees associated to self

EXAMPLES:

sage: OrderedTrees().labelled_trees()
Labelled ordered trees

unlabelled_trees()

Return the set of unlabelled trees associated to self

EXAMPLES:

sage: OrderedTrees().unlabelled_trees()
Ordered trees

class sage.combinat.ordered_tree.OrderedTrees_size(size)

Bases: OrderedTrees

The enumerated sets of binary trees of a given size

EXAMPLES:

sage: S = OrderedTrees(3); S
Ordered trees of size 3
sage: S.cardinality()
2
sage: S.list()
[[[[], []], [[]]]]

>>> from sage.all import *
>>> S = OrderedTrees(Integer(3)); S
Ordered trees of size 3
>>> S.cardinality()
2
>>> S.list()
[[[[], []], [[]]]]
cardinality()

The cardinality of self
This is a Catalan number.

element_class()

The class of the element of self

EXAMPLES:

```
sage: from sage.combinat.OrderedTree import OrderedTrees_size, OrderedTrees_all
sage: S = OrderedTrees_size(3)
sage: S.element_class is OrderedTrees().element_class
True
sage: S.first().__class__ == OrderedTrees_all().first().__class__
True
```

random_element()

Return a random OrderedTree with uniform probability.

This method generates a random DyckWord and then uses a bijection between Dyck words and ordered trees.

EXAMPLES:

```
sage: OrderedTrees(5).random_element()  # random
[[[], [[]], []]]
sage: OrderedTrees(0).random_element()
Traceback (most recent call last):
...
EmptySetError: there are no ordered trees of size 0
sage: OrderedTrees(1).random_element()  # random
[]
```

```
5.1.156 Output functions

These are the output functions for latexing and ascii/unicode art versions of partitions and tableaux.

AUTHORS:

- Mike Hansen (?): initial version
- Travis Scrimshaw (2020-08): Added support for ascii/unicode art

\begin{verbatim}
sage.combinat.output.ascii_art_table(data, use_unicode=False, convention='English')
\end{verbatim}

Return an ascii art table of data.

EXAMPLES:

\begin{verbatim}
sage: from sage.combinat.output import ascii_art_table

sage: data = [[None, None, 1], [2, 2], [3, 4, 5], [None, None, 10], [], [6]]
sage: print(ascii_art_table(data))
+----+
| 1 |
+---+---+----+
| 2 | 2 |
+---+---+----+
| 3 | 4 | 5 |
+---+---+----+
| 10 |
+----+

sage: print(ascii_art_table(data, use_unicode=True))
┌────┐
│ 1 │
│ 2 │
├───┼───┼────┐
│ 3 │ 4 │ 5 │
└───┼───┼────┘
│ 10 │
└────┘

sage: data = [[1, None, 2], [None, 2]]
sage: print(ascii_art_table(data))
+---+ +---+
| 1 | | 2 |
+---+---+---+

sage: print(ascii_art_table(data, use_unicode=True))
┌───┐ ┌───┐
│ 1 │ │ 2 │
│ 2 │
└───┘
\end{verbatim}

(continues on next page)
```python
>>> from sage.all import *
>>> from sage.combinat.output import ascii_art_table

>>> data = [[None, None, Integer(1)], [Integer(2), Integer(2)], [Integer(3), Integer(4), Integer(5)], [None, None, Integer(10)], [], [Integer(6)]
>>> print(ascii_art_table(data))
+----+
| 1 |
+---+---+----+
| 2 | 2 |
+---+---+----+
| 3 | 4 | 5 |
+---+---+----+
| 10 |
+----+

>>> from sage.combinat.output import ascii_art_table_russian
>>> print(ascii_art_table_russian(data, use_unicode=True))

```

sage.combinat.output.ascii_art_table_russian(data, use_unicode=False, compact=False)

Return an ascii art table of data for the Russian convention.

EXAMPLES:
```python
>>> from sage.combinat.output import ascii_art_table_russian
>>> data = [[None, None, Integer(1)], [Integer(2), Integer(2)], [Integer(3), Integer(4), Integer(5)], [None, None, Integer(10)], [], [Integer(6)]]
>>> print(ascii_art_table_russian(data))
/ \ / \ /
\ 6 \ 10 / \ / \ \
\ / \ X 5 / \ / \ / \\
\ / \ / 4 X / \ / \\
\ / \ / \ / \ / \
\ 3 \ 2 \ 1 / \ / \
\ / \ / \ / \
\ 2 / \\

>>> print(ascii_art_table_russian(data, use_unicode=True))
╱ ╲ ╱ ╲
╱ ╲ ╱ ╲
╲ 6 ╳ 10 ╳
╱ ╲ ╱ ╲
╲ ╳ 5 ╳
╱ ╲ ╱
╲ 4 ╳
╱ ╲
╲ 3 ╳ 2 ╳ 1 ╳
╱ ╲ ╱ ╲ ╲
╱ ╲ ╱ ╲
╲ 2 ╳
╱ ╲
╲ 1 ╳

>>> data = [[Integer(1), None, Integer(2)], [None, Integer(2)]]
>>> print(ascii_art_table_russian(data))
/ \ \
\ 2 \ 2 / \ / \
\ / \ X / \
\ / \ 1 / \\

>>> print(ascii_art_table_russian(data, use_unicode=True))
╱ ╲
╱ 2 ╳ 2 ╳
╱ ╲
╱ X
╱发扬
```

`sage.combinat.output.box_exists(tab, i, j)`
Return True if tab[i][j] exists and is not None; in particular this allows for tab[i][j] to be '' or 0.

INPUT:
- tab – a list of lists
- i – first coordinate
- j – second coordinate

`sage.combinat.output.tex_from_array(array, with_lines=True)`

Return a latex string for a two dimensional array of partition, composition or skew composition shape

INPUT:
- array – a list of list
- with_lines – a boolean (default: True)
  Whether to draw a line to separate the entries in the array.

Empty rows are allowed; however, such rows should be given as [None] rather than [].

The array is drawn using either the English or French convention following `Tableaux.options()`.

See also:
`tex_from_array_tuple()`

EXAMPLES:

```python
sage: from sage.combinat.output import tex_from_array
sage: print(tex_from_array([[1,2,3],[4,5]]))
\\begin{array}\cline{1-3}
\lr{1}&\lr{2}&\lr{3}\\\cline{1-3}
\lr{4}&\lr{5}\\\cline{1-2}
\end{array}
```

```python
sage: print(tex_from_array([[1,2,3],[4,5]], with_lines=False))
\\begin{array}\lr{1}&\lr{2}&\lr{3}\\\lr{4}&\lr{5}\\\end{array}
```

```python
sage: print(tex_from_array([[1,2,3],[4,5,6,7],[8]]))
\\begin{array}\cline{1-3}
\lr{1}&\lr{2}&\lr{3}\\\cline{1-4}
\lr{4}&\lr{5}&\lr{6}&\lr{7}\\\cline{1-4}
\lr{8}\\\cline{1-1}
\end{array}
```

```python
sage: print(tex_from_array([[1,2,3],[4,5,6,7],[8]], with_lines=False))
\\begin{array}\lr{1}&\lr{2}&\lr{3}\\\end{array}
```

\end{array}$}
```
sage.combinat.output.tex_from_array_tuple(a_tuple, with_lines=True)

Return a latex string for a tuple of two dimensional array of partition, composition or skew composition shape.

INPUT:

- a_tuple – a tuple of lists of lists
- with_lines – a boolean (default: True) Whether to draw lines to separate the entries in the components of a_tuple.

See also:

tex_from_array() for the description of each array

EXAMPLES:
sage: from sage.combinat.output import tex_from_array_tuple
sage: print(tex_from_array_tuple([[1,2,3],[4,5]],[],[[None,6,7],[None,8],[9]]))
\begin{array}{*{3}c|}

(continues on next page)
sage.combinat.output.tex_from_skew_array(array, with_lines=False, align='b')

This function creates latex code for a “skew composition” array. That is, for a two dimensional array in which each row can begin with an arbitrary number of None’s and the remaining entries could, in principle, be anything but probably should be strings or integers of similar width. A row consisting completely of None’s is allowed.

INPUT:

- array – The array
- with_lines – (Default: False) If True lines are drawn, if False they are not
- align – (Default: ’b’) Determines the alignment on the latex array environments

EXAMPLES:

```python
sage: array=[[None, 2,3,4],[None,None],[5,6,7,8]]
sage: print(sage.combinat.output.tex_from_skew_array(array))
\begin{array}{*{4}c}
&\ll{2}&\ll{3}&\ll{4}\\
&\\n\ll{5}&\ll{6}\ll{7}&\ll{8}\\
\end{array}
```

```
array=[[None, Integer(2),Integer(3),Integer(4)],[None,None],[Integer(5),
-Integer(6),Integer(7),Integer(8)]]
>>> print(sage.combinat.output.tex_from_skew_array(array))
\begin{array}{*{4}c}
&\ll{2}&\ll{3}&\ll{4}\\
&\\n\ll{5}\ll{6}\ll{7}\ll{8}\\
\end{array}
```

5.1.157 Parallelogram Polyominoes

The goal of this module is to give some tools to manipulate the parallelogram polyominoes.

```python
class sage.combinat.parallelogram_polyomino.LocalOptions(name='', **options)

Bases: object
```

This class allow to add local options to an object. LocalOptions is like a dictionary, it has keys and values that represent options and the values associated to the option. This is useful to decorate an object with some optional informations.

LocalOptions should be used as follow.

INPUT:

- name – The name of the LocalOptions
- <options>=dict(...) – dictionary specifying an option
The options are specified by keyword arguments with their values being a dictionary which describes the option. The allowed/expected keys in the dictionary are:

- checker – a function for checking whether a particular value for the option is valid
- default – the default value of the option
- values – a dictionary of the legal values for this option (this automatically defines the corresponding checker); this dictionary gives the possible options, as keys, together with a brief description of them

```python
sage: from sage.combinat.parallelogram_polyomino import LocalOptions

sage: o = LocalOptions(
    ...:   'Name Example',
    ...:   delim=dict(
    ...:       default='b',
    ...:       values={'b':'the option b', 'p':'the option p'})
    ...:)

sage: class Ex:
    ...:   options=o
    ...:   def _repr_b(self):
    ...:       return "b"
    ...:   def _repr_p(self):
    ...:       return "p"
    ...:   def __repr__(self):
    ...:       return self.options._dispatch(self, '_repr_', 'delim')

sage: e = Ex(); e
b

sage: e.options(delim='p'); e
p
```

This class is temporary, in the future, this class should be integrated into sage.structure.global_options.py. We should split global_option in two classes LocalOptions and GlobalOptions.

```python
>>> from sage.all import *
>>> from sage.combinat.parallelogram_polyomino import LocalOptions

>>> o = LocalOptions(
...    'Name Example',
...    delim=dict(
...        default='b',
...        values={'b':'the option b', 'p':'the option p'})
...)

>>> class Ex:
...    options=o
...    def _repr_b(self):
...       return "b"
...    def _repr_p(self):
...       return "p"
...    def __repr__(self):
...       return self.options._dispatch(self, '_repr_', 'delim')

>>> e = Ex(); e
b

>>> e.options(delim='p'); e
p
```

**keys()**

Return the list of the options in self.

**EXAMPLES:**
class sage.combinat.parallelogram_polyomino.ParallelogramPolyomino(parent, value, check=True)

Bases: ClonableList

Parallelogram Polyominoes.

A parallelogram polyomino is a finite connected union of cells whose boundary can be decomposed in two paths,
Combinatorics, Release 10.4

the upper and the lower paths, which are comprised of north and east unit steps and meet only at their starting and final points.

Parallelogram Polyominoes can be defined with those two paths.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp
[[0, 1], [1, 0]]
```

```python
>>> from sage.all import *

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
   →Integer(0)]])
>>> pp
[[0, 1], [1, 0]]
```

area()

Return the area of the parallelogram polyomino. The area of a parallelogram polyomino is the number of cells of the parallelogram polyomino.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....: [0, 0, 1, 0, 1, 1, 0, 1, 0, 1, 1],
    ....: [0, 1, 0, 1, 0, 1, 0, 1, 0, 1, 0]
    ....: )

sage: pp.area()
13

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])

sage: pp.area()
1

sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp.area()
0
```

```python
>>> from sage.all import *

>>> pp = ParallelogramPolyomino(
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...
   ...

>>> pp.area()
13

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
   →Integer(0)]])

>>> pp.area()
1

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]]

(continues on next page)
bounce \( (direction=1) \)

Return the bounce of the parallelogram polyomino.

Let \( p \) be the bounce path of the parallelogram polyomino (\( bounce_path() \)). The bounce is defined by:

\[
\text{sum}((1 + \text{floor}(i/2)) \times p[i] \text{ for } i \text{ in range}(\text{len}(p)))
\]

INPUT:

- \( \text{direction} \) – the initial direction of the bounce path (see \( \text{bounce_path}() \) for the definition).

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]
    ....: )
sage: pp.bounce(direction=1)
6
sage: pp.bounce(direction=0)
7

sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 1, 1, 1, 0, 0, 1, 1],
    ....:     [1, 1, 1, 0, 1, 1, 0, 0, 0]
    ....: )
sage: pp.bounce(direction=1)
12
sage: pp.bounce(direction=0)
10

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])

sage: pp.bounce(direction=1)
1
sage: pp.bounce(direction=0)
1

sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp.bounce(direction=1)
0
sage: pp.bounce(direction=0)
0

>>> from sage.all import *
```

(continues on next page)
bou**n**ce_path (**direction**=1)

Return the bounce path of the parallelogram polyomino.

The bounce path is a path with two steps (1, 0) and (0, 1).

If ‘direction’ is 1 (resp. 0), the bounce path is the path starting at position (h=1, w=0) (resp. (h=0, w=1)) with initial direction, the vector (0, 1) (resp. (1, 0)), and turning each time the path crosses the perimeter of the parallelogram polyomino.

The path is coded by a list of integers. Each integer represents the size of the path between two turnings.

You can visualize the two bounce paths by using the following commands.

**INPUT:**

- **direction** – the initial direction of the bounce path (see above for the definition).

**EXAMPLES:**

```sage
>>> PP = ParallelogramPolyomino(
...   ...
...   [Integer(0), Integer(0), Integer(1), Integer(1), Integer(1), _
...     Integer(0), Integer(0), Integer(1), Integer(1), _
...     Integer(1), Integer(1), Integer(1), Integer(0), Integer(1), _
...     Integer(1), Integer(0), Integer(0), Integer(0)]
...   )
...)
>>> PP.bounce_path(direction=Integer(1))
[2, 2, 1]
>>> PP.bounce_path(direction=Integer(0))
[2, 1, 1]
```
sage: PP.bounce_path(direction=1)
[3, 1, 2, 2]
sage: PP.bounce_path(direction=0)
[2, 4, 2]

sage: PP = ParallelogramPolyomino(  ....:    [[0, 0, 1, 0, 1, 1], [1, 1, 0, 0, 1, 0]]  ....: )
sage: PP.set_options(  ....:    drawing_components=dict(  ....:      diagram = True  ....:      , bounce_0 = True  ....:      , bounce_1 = True  ....:    )  ....: )
sage: view(PP) # not tested

sage: PP = ParallelogramPolyomino([[0, 0], [1, 1]])
sage: PP.bounce_path(direction=1)
[1]
sage: PP.bounce_path(direction=0)
[1]
sage: PP = ParallelogramPolyomino([[1], [1]])
sage: PP.bounce_path(direction=1)
[]
sage: PP.bounce_path(direction=0)
[]
box_is_node (pos)

Return True if the box contains a node in the context of the Aval-Boussicault bijection between parallelogram polyomino and binary tree.

A box is a node if there is no cell on the top of the box in the same column or on the left of the box in the same row.

INPUT:

- pos – the [x,y] coordinate of the box.

OUTPUT:

A boolean

EXAMPLES:

sage: pp = ParallelogramPolyomino(
    ....:   [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
    ....: )
sage: pp.set_options(display='drawing')
sage: pp

[[1 1 0]
 [1 1 1]
 [0 1 1]
 [0 1 1]
 [0 1 1]]
sage: pp.box_is_node([2, 1])
True
sage: pp.box_is_node([2, 0])
False
sage: pp.box_is_node([1, 1])
False
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...    [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0), Integer(0),
      Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(1),
      Integer(0), Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]
...    )
>>> pp.set_options(display='drawing')
>>> pp

[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 1 1]

>>> pp.box_is_root([Integer(2),Integer(1)])
True
>>> pp.box_is_root([Integer(2),Integer(0)])
False
>>> pp.box_is_root([Integer(1),Integer(1)])
False

\textbf{box\_is\_root} (box)

Return \texttt{True} if the box contains the root of the tree: it is the top-left box of the parallelogram polyomino.

**INPUT:**

- \texttt{box} – the x,y coordinate of the cell.

**EXAMPLES:**

\begin{verbatim}
  sage: pp = ParallelogramPolyomino(
  ...    [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
  ...    )
  sage: pp.box_is_root([0, 0])
  True
  sage: pp.box_is_root([0, 1])
  False
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...    [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0), Integer(0),
      Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(1),
      Integer(0), Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]
...    )
>>> pp.box_is_root([Integer(0), Integer(0)])
True
>>> pp.box_is_root([Integer(0), Integer(1)])
False
\end{verbatim}

\textbf{cell\_is\_inside} (w, h)

Determine whether the cell at a given position is inside the parallelogram polyomino.

**INPUT:**

- \texttt{w} – The x coordinate of the box position.
- \texttt{h} – The y coordinate of the box position.

**OUTPUT:**

Return 0 if there is no cell at the given position, return 1 if there is a cell.
EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
    ....:     [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
    ....: )
sage: pp.cell_is_inside(0, 0)
1
sage: pp.cell_is_inside(1, 0)
1
sage: pp.cell_is_inside(0, 1)
0
sage: pp.cell_is_inside(3, 0)
0
sage: pp.cell_is_inside(pp.width()-1, pp.height()-1)
1
sage: pp.cell_is_inside(pp.width(), pp.height()-1)
0
sage: pp.cell_is_inside(pp.width()-1, pp.height())
0
```

```python
>>> from sage.all import *
```

```python
>>> pp = ParallelogramPolyomino(
    ...:     [Integer(0), Integer(1), Integer(0), Integer(0), Integer(1),...
    ...:      Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)],
    ...:     [Integer(1), Integer(1), Integer(1), Integer(0), Integer(1),...
    ...:      Integer(0), Integer(0), Integer(1), Integer(1), Integer(0)]
    ...: )

>>> pp.cell_is_inside(Integer(0), Integer(0))
1
>>> pp.cell_is_inside(Integer(1), Integer(0))
1
>>> pp.cell_is_inside(Integer(0), Integer(1))
0
>>> pp.cell_is_inside(Integer(3), Integer(0))
0
>>> pp.cell_is_inside(pp.width()-Integer(1), pp.height()-Integer(1))
1
>>> pp.cell_is_inside(pp.width(), pp.height()-Integer(1))
0
>>> pp.cell_is_inside(pp.width()-Integer(1), pp.height())
0
```

**check()**

This method raises an error if the internal data of the class does not represent a parallelogram polyomino.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:     [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....: )
```

(continues on next page)
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp = ParallelogramPolyomino(  
....:     # indirect doctest
....:     [[1, 0], [0, 1]]
....: )
Traceback (most recent call last):
...

>>> from sage.all import *

>>> pp = ParallelogramPolyomino(  
...     [  
...         [Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),
...             Integer(1), Integer(0), Integer(1), Integer(0),
...             Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),
...             Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),
...             Integer(1), Integer(0), Integer(1), Integer(0), Integer(0)]
...     ]
... )

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
...     Integer(0)]])
degree_convexity()  
Return the degree convexity of a parallelogram polyomino.

A convex polyomino is said to be k-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most k changes of direction. The degree of convexity of a convex polyomino P is the smallest integer k such that P is k-convex.

If the parallelogram polyomino is empty, the function return -1.

EXAMPLES:
sage: pp = ParallelogramPolyomino(
    ...:     [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ...:     [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ...: )
sage: pp.degree_convexity()
3

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.degree_convexity()
0

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.degree_convexity()
-1

>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
    ...:     [0, 1, 0, 0, 1, 1],
    ...:     [1, 1, 1, 0, 0, 0]
    ...: )
>>> pp.degree_convexity()
3
>>> pp = ParallelogramPolyomino([[0, 1], [1, 0]])
>>> pp.degree_convexity()
0
>>> pp = ParallelogramPolyomino([[1], [1]])
>>> pp.degree_convexity()
-1

static from_dyck_word(dyck, bijection=None)
Convert a Dyck word to parallelogram polyomino.

INPUT:

- dyck – a Dyck word
- bijection – string or None (default: None) the bijection to use. See to_dyck_word() for more details.

OUTPUT:

A parallelogram polyomino.

EXAMPLES:

sage: dyck = DyckWord([1, 1, 0, 1, 1, 0, 1, 0, 0, 0])
sage: ParallelogramPolyomino.from_dyck_word(dyck)
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
sage: ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot')
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
sage: ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot-beta')
[[0, 0, 1, 0, 1, 1], [1, 1, 1, 0, 0, 0]]

>> from sage.all import *
>> dyck = DyckWord([Integer(1), Integer(1), Integer(1), Integer(0), Integer(1), ...
                    Integer(1), Integer(0), Integer(1), Integer(0), Integer(0)])
>> ParallelogramPolyomino.from_dyck_word(dyck)
[[0, 1, 0, 1, 0, 1], [1, 1, 1, 0, 0, 0]]
>> ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot')
[[0, 1, 0, 0, 1, 1], [1, 1, 1, 0, 0, 0]]
>> ParallelogramPolyomino.from_dyck_word(dyck, bijection='Delest-Viennot-beta')
[[0, 0, 1, 0, 1, 1], [1, 1, 1, 0, 0, 0]]

geometry()
Return a pair \([h, w]\) containing the height and the width of the parallelogram polyomino.

EXAMPLES:

```sage
sage: pp = ParallelogramPolyomino(....: [[0, 1, 1, 1, 1], [1, 1, 1, 1, 0]])
sage: pp.geometry()
[1, 4]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.geometry()
[1, 1]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.geometry()
[0, 1]
```

```sage
>> from sage.all import *
>> pp = ParallelogramPolyomino(...
    [[Integer(0), Integer(1), Integer(1), Integer(1), Integer(1)],
    ... [Integer(1), Integer(1), Integer(1), Integer(1), Integer(0)]
    ... ]
>> pp.geometry()
[1, 4]
>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),...
    Integer(0)]])
>> pp.geometry()
[1, 1]
>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]]
>> pp.geometry()
[0, 1]
```

get_BS_nodes()
Return the list of cells containing node of the left and right planar tree in the Boussicault-Socci bijection.

EXAMPLES:
```python
sage: pp = ParallelogramPolyomino(
    ....: [[0, 0, 1, 0, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]],
    ....: )

sage: pp.set_options(display='drawing')

sage: pp

[[1 1 0], [1 1 1], [0 1 1], [0 1 1], [0 1 1]]

sage: sorted(pp.get_BS_nodes())

[[0, 1], [1, 0], [1, 2], [2, 1], [3, 1], [4, 1]]

>>> from sage.all import *

>>> pp = ParallelogramPolyomino(
    ...
    [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),
      Integer(0), Integer(0), Integer(1), Integer(1)],
     ...
     Integer(0), Integer(0), Integer(0), Integer(1),
     ...
     Integer(0), Integer(0), Integer(0), Integer(0), Integer(0)]]
    ...
)

>>> pp.set_options(display='drawing')

>>> pp

[[1 1 0], [1 1 1], [0 1 1], [0 1 1], [0 1 1]]

>>> sorted(pp.get_BS_nodes())

[[0, 1], [1, 0], [1, 2], [2, 1], [3, 1], [4, 1]]
```

You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red)

```python
sage: pp.set_options(drawing_components=dict(tree=True))

sage: view(pp)  # not tested
```

```python
>>> from sage.all import *

>>> pp.set_options(drawing_components=dict(tree=True))

>>> view(pp)  # not tested
```

**get_array()**

Return an array of 0s and 1s such that the 1s represent the boxes of the parallelogram polyomino.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....: [
    ....:     [0, 0, 0, 0, 1, 0, 1, 0, 1],
    ....:     [1, 0, 0, 0, 1, 1, 0, 0, 0]
    ....: ]
    ....: )

sage: matrix(pp.get_array())

[[1 0 0]
 [1 0 0]
 [1 1 1]
 [0 1 1]]
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
[0 0 1]
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_array()
[[1]]
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.get_array()
[]
```

```python
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(...
... [Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),
- Integer(0), Integer(1), Integer(0), Integer(1)],
... [Integer(1), Integer(0), Integer(0), Integer(0), Integer(1),
- Integer(1), Integer(0), Integer(0), Integer(0)]
... ]
...
) >>> matrix(pp.get_array())
[1 0 0]
[1 0 0]
[1 1 1]
[0 1 1]
[0 0 1]

```python
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
- Integer(0)]]))
```python
>>> pp.get_array()
[[1]]
```python
>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
```python
>>> pp.get_array()
[]
```

### `get_left_BS_nodes()`

Return the list of cells containing node of the left planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

**OUTPUT:**

A list of [row,column] position of cells.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
.....: [[0, 0, 1, 0, 0, 1, 1], [1, 1, 0, 1, 0, 0, 0, 0]]
.....: )
sage: pp.set_options(display='drawing')
sage: pp
[1 1 0]
[1 1 1]
[0 1 1]
[0 1 1]
[0 0 1]
sage: sorted(pp.get_left_BS_nodes())
```
You can draw the point inside the parallelogram polyomino by typing (the left nodes are in blue, and the right node are in red):

```sage
tp.set_options(drawing_components=dict(tree=True))
view(pp) # not tested
```
This function starts from a cell inside a parallelogram polyomino and a direction.

If \( direction \) is equal to 0, the function selects the column associated with the y-coordinate of \( \text{box_position} \) and then returns the topmost cell of the column that is on the top of \( \text{box_position} \) (the cell of \( \text{box_position} \) is included).

If \( direction \) is equal to 1, the function selects the row associated with the x-coordinate of \( \text{box_position} \) and then returns the leftmost cell of the row that is on the left of \( \text{box_position} \) (the cell of \( \text{box_position} \) is included).

This function updates the entry of \( \text{nb_crossed_nodes} \). The function increases the entry of \( \text{nb_crossed_nodes} \) by the number of boxes that is a node (see \( \text{box_is_node} \)) located on the top if \( direction \) is 0 (resp. on the left if \( direction \) is 1) of \( \text{box_position} \) (cell at \( \text{box_position} \) is excluded).

**INPUT:**

- \( \text{box_position} \) – the position of the starting cell.
- \( \text{direction} \) – the direction (0 or 1).
- \( \text{nb_crossed_nodes} \) – \( [0] \) (default) a list containing just one integer.

**OUTPUT:**

A [row, column] position of the cell.

**EXAMPLES:**

```sage
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 0, 1, 0, 0, 0, 1, 1], [1, 0, 1, 1, 0, 0, 0, 0]]
    ....: )
sage: matrix(pp.get_array())
[[1 0 0]
 [1 1 1]
 [0 1 1]
 [0 1 1]]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 0, l)
[1, 2]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 2], 1, l)
[3, 1]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([1, 2], 0, l)
[1, 2]
sage: l
[0]
sage: l = [0]
sage: pp.get_node_position_from_box([1, 2], 1, l)
[1, 0]
sage: l
[1]
sage: l = [0]
sage: pp.get_node_position_from_box([3, 1], 0, l)
[3, 1]
```
from sage.all import *

pp = ParallelogramPolyomino(...
   [[Integer(0), Integer(0), Integer(1), Integer(0), Integer(0),
   Integer(0), Integer(1), Integer(1)],
   [Integer(1), Integer(0), Integer(1), Integer(1), Integer(1),
   Integer(0), Integer(0), Integer(0), Integer(0), Integer(0)]
...
)

matrix(pp.get_array())

l = [Integer(0)]

>>> pp.get_node_position_from_box([Integer(3), Integer(2)], Integer(0), l)
[1, 2]

>>> pp.get_node_position_from_box([Integer(3), Integer(2)], Integer(1), l)
[3, 1]

>>> pp.get_node_position_from_box([Integer(1), Integer(2)], Integer(0), l)
[1, 2]

>>> pp.get_node_position_from_box([Integer(1), Integer(2)], Integer(1), l)
[1, 0]

get_options()

Return all the options of the object.

EXAMPLES:
```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_options()
Current options for ParallelogramPolyominoes_size
- display: 'list'
- drawing_components: {'bounce_0': False,
  'bounce_1': False,
  'bounce_values': False,
  'diagram': True,
  'tree': False}
- latex: 'drawing'
- tikz_options: {'color_bounce_0': 'red',
  'color_bounce_1': 'blue',
  'color_line': 'black',
  'color_point': 'black',
  'line_size': 1,
  'mirror': None,
  'point_size': 3.5,
  'rotation': 0,
  'scale': 1,
  'translation': [0, 0]}
```

```python
>>> from sage.all import *

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1), Integer(0)]]

>>> pp.get_options()
Current options for ParallelogramPolyominoes_size
- display: 'list'
- drawing_components: {'bounce_0': False,
  'bounce_1': False,
  'bounce_values': False,
  'diagram': True,
  'tree': False}
- latex: 'drawing'
- tikz_options: {'color_bounce_0': 'red',
  'color_bounce_1': 'blue',
  'color_line': 'black',
  'color_point': 'black',
  'line_size': 1,
  'mirror': None,
  'point_size': 3.5,
  'rotation': 0,
  'scale': 1,
  'translation': [0, 0]}
```

**get_right_BS_nodes()**

Return the list of cells containing node of the right planar tree in the Boussicault-Socci bijection between parallelogram polyominoes and pair of ordered trees.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino([ [0, 0, 1, 0, 0, 0, 1, 1],
.....: [1, 1, 0, 1, 0, 0, 0, 0]]

sage: pp.set_options(display='drawing')
sage: pp
[[1 1 0]
 [1 1 1]
```
You can draw the point inside the parallelogram polyomino by typing, (the left nodes are in blue, and the right node are in red)

```python
sage: pp.set_options(drawing_components=dict(tree=True))
sage: view(pp) # not tested
```
>>> from sage.all import *
>>> pp.set_options(drawing_components=dict(tree=True))
>>> view(pp) # not tested

get_tikz_options()
Return all the tikz options permitting to draw the parallelogram polyomino.

See LocalOption to have more informations about the modification of those options.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.get_tikz_options()
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

```python
>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1), Integer(0)]])
>>> pp.get_tikz_options()
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

height()
Return the height of the parallelogram polyomino.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([...
.....:     [0, 1, 0, 0, 1, 0, 1, 1, 1, 1, 0, 0, 0, 1, 1, 1, 0],
.....:     [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]
.....:     ]
.....: }
.....: )
sage: pp.height()
4
```

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.height()
1
```

(continues on next page)
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.height()
0

```python
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [Integer(0), Integer(1), Integer(0), Integer(0), Integer(1),
...     Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),
...     Integer(1), Integer(1), Integer(1), Integer(0), Integer(1)],
...     [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),
...     Integer(0), Integer(1), Integer(1), Integer(1), Integer(0)])
>>> pp.height()
4
```
is_flat()  
Return whether the two bounce paths join together in the rightmost cell of the bottom row of \( P \).

EXAMPLES:

```
sage: pp = ParallelogramPolyomino(
    ....:     [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:     [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....: )
sage: pp.is_flat()
False
```

```
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.is_flat()
True
```

```
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.is_flat()
True
```

```
>>> from sage.all import *
```

```
>>> pp = ParallelogramPolyomino(
    ...     [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ...     [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ... )
>>> pp.is_flat()
False
```

```
>>> pp = ParallelogramPolyomino([[0, 1], [1, 0]])
>>> pp.is_flat()
True
```

```
>>> pp = ParallelogramPolyomino([[1], [1]])
>>> pp.is_flat()
True
```
**is_k_directed**($k$)

Return whether the Polyomino Parallelogram is $k$-directed.

A convex polyomino is said to be $k$-convex if every pair of its cells can be connected by a monotone path (path with south and east steps) with at most $k$ changes of direction.

The degree of convexity of a convex polyomino $P$ is the smallest integer $k$ such that $P$ is $k$-convex.

**INPUT:**

- $k$ – A non negative integer.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ...: [0, 0, 0, 1, 0, 1, 0, 1, 1],
    ...: [1, 0, 1, 1, 0, 0, 1, 0, 0]
    ...: )
```

```python
sage: pp.is_k_directed(3)
True
```

```python
sage: pp.is_k_directed(4)
True
```

```python
sage: pp.is_k_directed(5)
True
```

```python
sage: pp.is_k_directed(0)
False
```

```python
sage: pp.is_k_directed(1)
False
```

```python
sage: pp.is_k_directed(2)
False
```

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
```

```python
sage: pp.is_k_directed(0)
True
```

```python
sage: pp.is_k_directed(1)
True
```

```python
sage: pp = ParallelogramPolyomino([[1], [1]])
```

```python
sage: pp.is_k_directed(0)
True
```

```python
sage: pp.is_k_directed(1)
True
```

```python
>>> from sage.all import *
```

```python
>>> pp = ParallelogramPolyomino(
...    [Integer(0), Integer(0), Integer(0), Integer(1), Integer(1), Integer(0), ...
...    Integer(1), Integer(0), Integer(1), Integer(1), Integer(1)],
...    [Integer(1), Integer(0), Integer(1), Integer(1), Integer(0), ...
...    Integer(0), Integer(1), Integer(0), Integer(0)]
...    )
```

```python
>>> pp.is_k_directed(Integer(3))
True
```

```python
>>> pp.is_k_directed(Integer(4))
True
```

```python
>>> pp.is_k_directed(Integer(5))
```

(continues on next page)
True
>>> pp.is_k_directed(Integer(0))
False
>>> pp.is_k_directed(Integer(1))
False
>>> pp.is_k_directed(Integer(2))
False

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1), Integer(0)]])
>>> pp.is_k_directed(Integer(0))
True
>>> pp.is_k_directed(Integer(1))
True

lower_heights()
Return the list of heights associated to each vertical step of the parallelogram polyomino’s lower path.

OUTPUT:
A list of integers.

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_heights()
[1]
sage: ParallelogramPolyomino(
    ....: [[0, 0, 1, 1, 0, 1, 1, 1],
    ....:  [1, 0, 1, 1, 0, 1, 1, 0]]).lower_heights()
[2, 2, 3, 3, 3]
```

```
>>> from sage.all import *
```
```
>>> ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1), Integer(0)]]).lower_heights()
[1]
```
```
>>> ParallelogramPolyomino(
    ....: [[Integer(0), Integer(0), Integer(1), Integer(1), Integer(0),
    ....:  Integer(1), Integer(1), Integer(1)],
    ....:  [Integer(1), Integer(0), Integer(1),
    ....:  Integer(1), Integer(0), Integer(1), Integer(1), Integer(0)]])
```
```
    ....: ).lower_heights()
    ....: [2, 2, 3, 3, 3]
```

lower_path()
Get the lower path of the parallelogram polyomino.

EXAMPLES:

```
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
```

(continues on next page)
sage: pp.lower_path()
[0, 0, 1, 0, 1, 1]

>>> from sage.all import *
>>> lower_path = [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)]
>>> upper_path = [Integer(1), Integer(1), Integer(0), Integer(1), Integer(0), Integer(0)]
>>> pp = ParallelogramPolyomino([lower_path, upper_path])
>>> pp.lower_path()
[0, 0, 1, 0, 1, 1]

lower_widths()

Return the list of widths associated to each horizontal step of the parallelogram polyomino's lower path.

OUTPUT:

A list of integers.

EXAMPLES:

sage: ParallelogramPolyomino([[0, 1], [1, 0]]).lower_widths()
[0]

plot()

Return a plot of self.

EXAMPLES:

sage: pp = ParallelogramPolyomino([[0,1],[1,0]])
sage: pp.plot()  # needs sage.plot
Graphics object consisting of 4 graphics primitives
sage: pp.set_options(
    drawing_components=dict(
        diagram=True,
        bounce_0=True,
        bounce_1=True,
        bounce_values=0,
    )
)
sage: pp.plot()  # needs sage.plot
needs sage.plot
Graphics object consisting of 7 graphics primitives

>>> from sage.all import *
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
-Integer(0)]])
>>> pp.plot()
needs sage.plot
Graphics object consisting of 4 graphics primitives

>>> pp.set_options(
...    drawing_components=dict(
...        diagram=True,
...        bounce_0=True,
...        bounce_1=True,
...        bounce_values=Integer(0),
...    )
...)
>>> pp.plot()  
needs sage.plot
Graphics object consisting of 7 graphics primitives

reflect()

Return the parallelogram polyomino obtained by switching rows and columns.

EXAMPLES:

sage: pp = ParallelogramPolyomino([[0, 0, 0, 0, 1, 1, 0, 1, 0, 1],
[1, 0, 1, 0, 0, 1, 1, 0, 0, 0]])

sage: pp.heights(), pp.upper_heights()
(\([4, 3, 2, 3]) (\([0, 1, 3, 3])

sage: pp = pp.reflect()

sage: pp.widths(), pp.lower_widths()
(\([4, 3, 2, 3]) (\([0, 1, 3, 3])

sage: pp = ParallelogramPolyomino([[0, 0, 0, 1, 1], [1, 0, 0, 1, 0]])

sage: ascii_art(pp)
*
**

sage: ascii_art(pp反映())
***
*

>>> from sage.all import *

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(0), Integer(0),
-Integer(1), Integer(1), Integer(0), Integer(1), Integer(0),
-Integer(1), Integer(1), Integer(0), Integer(0), Integer(0),
-Integer(1), Integer(1), Integer(0), Integer(0), Integer(0),
-Integer(1), Integer(1), Integer(0), Integer(0), Integer(0)]])

>>> pp.heights(), pp.upper_heights()
(\([4, 3, 2, 3]) (\([0, 1, 3, 3])

>>> pp = pp.reflect()

>>> pp.widths(), pp.lower_widths()
(\([4, 3, 2, 3]) (\([0, 1, 3, 3])

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(0), Integer(0),
-Integer(1), Integer(1)], [Integer(1), Integer(0), Integer(0),
-Integer(1), Integer(1), [Integer(1), Integer(0), Integer(0),
-Integer(1), Integer(1), Integer(1), Integer(0), Integer(0), Integer(0), Integer(0)]])

(continues on next page)
rotate()
Return the parallelogram polyomino obtained by rotation of 180 degrees.

EXAMPLES:

```python
>>> from sage.all import *

>>> pp = ParallelogramPolyomino([[0,0,0,1,1], [1,0,0,1,0]])
>>> ascii_art(pp)
* *
**

>>> ascii_art(pp.reflect())
***
* *
```

set_options(*get_value, **set_value)
Set new options to the object. See LocalOptions for more info.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino([...:
....: [0, 0, 0, 1, 0, 1, 0, 1],
....: [1, 0, 0, 0, 1, 1, 0, 0, 0]
....: ]
....: )

sage: pp
[[0, 0, 0, 0, 1, 0, 1, 0, 1], [1, 0, 0, 0, 1, 1, 0, 0, 0]]

sage: pp.set_options(display='drawing')
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: view(PP)  # not tested
sage: pp.set_options(
....:     drawing_components=dict(
....:         diagram = True,
....:         bounce_0 = True,
....:         bounce_1 = True,
....:     )
....:)
sage: view(PP)  # not tested
```

```python
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
...     [[0, 0, 0, 0, 1, 0, 1, 0, 1], [1, 0, 0, 0, 1, 1, 0, 0, 0]]
... )
```

```
size()

Return the size of the parallelogram polyomino.

The size of a parallelogram polyomino is its half-perimeter.

EXAMPLES:
```
```
sage: pp = ParallelogramPolyomino(
....:     [[0, 0, 0, 0, 1, 0, 1, 1], [1, 0, 0, 0, 1, 1, 0, 0]]
....: )
sage: pp.size()
8
```
Combinatorics, Release 10.4

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.size()
2

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.size()
1

>>> from sage.all import *

>>> pp = ParallelogramPolyomino(
... [[Integer(0), Integer(0), Integer(0), Integer(0), Integer(1),
...   Integer(0), Integer(1), Integer(1)],
...  [Integer(1), Integer(0), Integer(0), Integer(0), Integer(1),
...   Integer(1), Integer(1), Integer(1), Integer(0), Integer(0)]
... )

>>> pp.size()
8

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
...   Integer(0)]])

>>> pp.size()
2

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]]

>>> pp.size()
1

to_binary_tree(bijection=None)
Convert to a binary tree.

INPUT:

• bijection – string or None (default:None) The name of bijection to use for the conversion.
  The possible values are None or 'Aval-Boussicault'. The None value is equivalent to
  'Aval-Boussicault'.

EXAMPLES:

sage: pp = ParallelogramPolyomino(
....: [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
....: [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
....: )

sage: pp.to_binary_tree()
[[., [[., .], [[., .], .]]], [[., .], .]]

sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.to_binary_tree()
[., .]

sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.to_binary_tree()
.

>>> from sage.all import *

>>> pp = ParallelogramPolyomino( (continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

... [Integer(0), Integer(0), Integer(1), Integer(0), Integer(1),
\rightarrow Integer(0), Integer(1), Integer(0), Integer(1), Integer(1)],
... [Integer(1), Integer(1), Integer(0), Integer(1), Integer(1),
\rightarrow Integer(0), Integer(0), Integer(0), Integer(1), Integer(0)]
...

>>> pp.to_binary_tree()
[[., [., .]], [[., [., .]], .]], [[., .], .]]

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)],
\rightarrow Integer(0)])
>>> pp.to_binary_tree()
[., .]

>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]])
>>> pp.to_binary_tree()

\begin{verbatim}
to_dyck_word \(\text{bijection} = \text{None}\)
\end{verbatim}

Convert to a Dyck word.

INPUT:

- \text{bijection} – string or None (default: None) The name of the bijection. If it is set to None then the 'Delest-Viennot' bijection is used. Expected values are None, 'Delest-Viennot', or 'Delest-Viennot-beta'.

OUTPUT:

a Dyck word

EXAMPLES:

\begin{verbatim}
sage: pp = ParallelogramPolyomino([[0, 1, 0, 1, 1, 0, 0, 0]])
sage: pp.to_dyck_word()
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]
sage: pp.to_dyck_word(bijection='Delest-Viennot')
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]
sage: pp.to_dyck_word(bijection='Delest-Viennot-beta')
[1, 0, 1, 1, 1, 0, 1, 0, 0, 0]
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1), Integer(0),\rightarrow Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1), Integer(1),\rightarrow Integer(0), Integer(0), Integer(0)]])
>>> pp.to_dyck_word()
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]

>>> pp.to_dyck_word(bijection='Delest-Viennot')
[1, 1, 0, 1, 1, 0, 1, 0, 0, 0]

>>> pp.to_dyck_word(bijection='Delest-Viennot-beta')
[1, 0, 1, 1, 1, 0, 1, 0, 0, 0]
\end{verbatim}

\begin{verbatim}
to_ordered_tree \(\text{bijection} = \text{None}\)
\end{verbatim}

Return an ordered tree from the parallelogram polyomino.
Different bijections can be specified.

The bijection 'via dyck and Delest-Viennot' is the composition of _to_dyck_delest_viennot() and the classical bijection between dyck paths and ordered trees.

The bijection between Dyck Word and ordered trees is described in [DerZak1980] (See page 12 and 13 and Figure 3.1).

The bijection 'Boussicault-Socci' is described in [BRS2015].

**INPUT:**

- **bijection** – string or None (default: None) The name of bijection to use for the conversion. The possible value are None, 'Boussicault-Socci' or 'via dyck and Delest-Viennot'.

  The None value is equivalent to the 'Boussicault-Socci' value.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....:    [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
    ....:    [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
    ....:)

sage: pp.to_ordered_tree()
[[[[]], [[]]]]

sage: pp = ParallelogramPolyomino([0, 1], [1, 0])

sage: pp.to_ordered_tree()
[]

sage: pp = ParallelogramPolyomino(
    ....:    [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
    ....:    [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
    ....:)

sage: pp.to_ordered_tree('via dyck and Delest-Viennot')
[[[[]], [[]]], [], [[]]]
```

```python
>>> from sage.all import *

>>> pp = ParallelogramPolyomino(
    ...
    [0, 0, 1, 0, 1, 0, 1, 0, 1, 1],
    ...
    [1, 1, 0, 1, 1, 0, 0, 0, 1, 0]
    ...
)

>>> pp.to_ordered_tree()
[[[[]], [[]]]]

>>> pp = ParallelogramPolyomino([0, 1], [1, 0])

>>> pp.to_ordered_tree()
[]
```

(continues on next page)

```
[[[]]

```
sage: pp.set_options(
    ....:     drawing_components=dict(
    ....:         diagram=True,
    ....:         tree=True,
    ....:         bounce_0=True,
    ....:         bounce_1=True
    ....:     )
    ....: )

sage: print(pp.to_tikz())

\filldraw[color=black] (2.500000, 5.500000) circle (3.5pt);

(continues on next page)
upper_heights()

Return the list of heights associated to each vertical step of the parallelogram polyomino's upper path.

OUTPUT:

A list of integers.

EXAMPLES:

```
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).upper_heights()
[0]
sage: ParallelogramPolyomino(
    ....:   [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
    ....: ).upper_heights()
[0, 1, 1, 2, 2]
```

upper_path()

Get the upper path of the parallelogram polyomino.

EXAMPLES:

```
sage: lower_path = [0, 0, 1, 0, 1, 1]
sage: upper_path = [1, 1, 0, 1, 0, 0]
sage: pp = ParallelogramPolyomino([lower_path, upper_path])
sage: pp.upper_path()
[1, 1, 0, 1, 0, 0]
```

upper_widths()

Return the list of widths associated to each horizontal step of the parallelogram polyomino's upper path.

OUTPUT:

A list of integers.
EXAMPLES:

```python
sage: ParallelogramPolyomino([[0, 1], [1, 0]]).upper_widths()
[1]
sage: ParallelogramPolyomino(
    ....:     [[0, 0, 1, 1, 0, 1, 1, 1], [1, 0, 1, 1, 0, 1, 1, 0]]
    ....: ).upper_widths()
[1, 3, 5]
```

```python
>>> from sage.all import *

>>> ParallelogramPolyomino([[0, 1], [1, 0]]).upper_widths()
[1]
```

### width()

Return the width of the parallelogram polyomino.

EXAMPLES:

```python
sage: pp = ParallelogramPolyomino(
    ....:     [[0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
    ....:      [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]]
    ....: )
sage: pp.width()
6
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])

sage: pp.width()
1
sage: pp = ParallelogramPolyomino([[1], [1]])

sage: pp.width()
1
```

```python
>>> from sage.all import *

>>> pp = ParallelogramPolyomino(
    ....:     [[0, 1, 0, 0, 1, 1, 0, 1, 1, 1],
    ....:      [1, 1, 1, 0, 1, 0, 0, 1, 1, 0]]
    ....: )

>>> pp.width()
6
```

```python
>>>
```
```
>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]]))
>>> pp.widths()
1

**widths()**

Return a list of the widths of the parallelogram polyomino.

Namely, the parallelogram polyomino is split row by row and the method returns the list containing the sizes of the rows.

**EXAMPLES:**

```python
sage: pp = ParallelogramPolyomino(
    ....:[0, 0, 0, 1, 0, 1, 0, 1, 1],
    ....:[1, 0, 1, 1, 0, 0, 1, 0, 0]
    ....:)
sage: pp.widths()
[1, 3, 3, 3, 2]
```

```python
sage: pp = ParallelogramPolyomino([[0, 1], [1, 0]])
sage: pp.widths()
[1]
```

```python
sage: pp = ParallelogramPolyomino([[1], [1]])
sage: pp.widths()
[]
```

```python
>>> from sage.all import *
>>> pp = ParallelogramPolyomino(
    ...:[Integer(0), Integer(0), Integer(0), Integer(1), Integer(0),
       Integer(1), Integer(0), Integer(1), Integer(1)],
    ...:[Integer(1), Integer(0), Integer(1), Integer(1), Integer(0),
       Integer(0), Integer(1), Integer(0), Integer(0)]
    ...:)
>>> pp.widths()
[1, 3, 3, 3, 2]
```

```python
>>> pp = ParallelogramPolyomino([[Integer(0), Integer(1)], [Integer(1),
       Integer(0)]]))
>>> pp.widths()
[1]
```

```python
>>> pp = ParallelogramPolyomino([[Integer(1)], [Integer(1)]]))
>>> pp.widths()
[]
```

`sage.combinat.parallelogram_polyomino.ParallelogramPolyominoes(size=None, policy=None)`

Return a family of parallelogram polyominoes enumerated with the parameter constraints.

**INPUT:**
• **size** – integer (default: None), the size of the parallelogram polyominoes contained in the family. If set to None, the family returned contains all the parallelogram polyominoes.

**EXAMPLES:**

```python
sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[[0, 0, 1, 1], [1, 0, 1, 0]],
 [[[0, 0, 1, 1], [1, 1, 0, 0]],
 [[[0, 1, 0, 1], [1, 1, 0, 0]],
 [[[0, 1, 1, 1], [1, 1, 1, 0]]]

sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()
+Infinity

sage: PPS = ParallelogramPolyominoes(size=None)
sage: PPS
Parallelogram polyominoes
sage: PPS.cardinality()
+Infinity
```

```bash
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(size=Integer(4))
>>> PPS
Parallelogram polyominoes of size 4
>>> sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[[0, 0, 1, 1], [1, 0, 1, 0]],
 [[[0, 0, 1, 1], [1, 1, 0, 0]],
 [[[0, 1, 0, 1], [1, 1, 0, 0]],
 [[[0, 1, 1, 1], [1, 1, 1, 0]]]

>>> PPS = ParallelogramPolyominoes()
>>> PPS
Parallelogram polyominoes
>>> PPS.cardinality()
+Infinity

>>> PPS = ParallelogramPolyominoes(size=None)
>>> PPS
Parallelogram polyominoes
>>> PPS.cardinality()
+Infinity
```

class sage.combinat.parallelgram_polyomino.ParallelogramPolyominoesFactory

Bases: SetFactory

The parallelogram polyominoes factory.

**EXAMPLES:**
sage: PPS = ParallelogramPolyominoes(size=4)
sage: PPS
Parallelogram polyominoes of size 4

sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes

sage: PPS.cardinality()
+Infinity

>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(size=Integer(4))
>>> PPS
Parallelogram polyominoes of size 4

>>> sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]

>>> PPS = ParallelogramPolyominoes()
>>> PPS
Parallelogram polyominoes

>>> PPS.cardinality()
+Infinity

sage.combinat.parallelogram_polyomino.ParallelogramPolyominoesOptions =
Current options for ParallelogramPolyominoes_size - display: 'list' -
drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex: 'drawing' - tikz_options:
{'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}

This global option contains all the data needed by the Parallelogram classes to draw, display in ASCII, compile in latex a parallelogram polyomino.

The available options are:

- **tikz_options**: this option configure all the information useful to generate TIKZ code. For example, color, line size, etc...

- **drawing_components**: this option is used to explain to the system which component of the drawing you want to draw. For example, you can ask to draw some elements of the following list: - the diagram, - the tree inside the parallelogram polyomino, - the bounce paths inside the parallelogram polyomino, - the value of the bounce on each square of a bounce path.

- **display**: this option is used to configure the ASCII display. The available options are: - list: (this is the default value) is used to represent PP as a list containing the upper and lower path. - drawing: this value is used to explain we want to display an array with the PP drawn inside (with connected 1).
• latex : Same as display. The default is “drawing”.

See `ParallelogramPolyomino.get_options()` for more details and for an user use of options.

**EXAMPLES:**

```python
sage: from sage.combinat.parallelogram_polyomino import (....:   ParallelogramPolyominoesOptions....: )
sage: opt = ParallelogramPolyominoesOptions['tikz_options']
sage: opt
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

**>>> from sage.all import ***

**>>> from sage.combinat.parallelogram_polyomino import (....:   ParallelogramPolyominoesOptions....: )**

**>>> opt = ParallelogramPolyominoesOptions['tikz_options']**

**>>> opt**

```python
{'color_bounce_0': 'red',
 'color_bounce_1': 'blue',
 'color_line': 'black',
 'color_point': 'black',
 'line_size': 1,
 'mirror': None,
 'point_size': 3.5,
 'rotation': 0,
 'scale': 1,
 'translation': [0, 0]}
```

**class sage.combinat.parallelogram_polyomino.ParallelogramPolyominoes_all(policy)**

**Bases:** `ParentWithSetFactory`, `DisjointUnionEnumeratedSets`

This class enumerates all the parallelogram polyominoes.

**EXAMPLES:**

```python
sage: PPS = ParallelogramPolyominoes()
sage: PPS
Parallelogram polyominoes
```

**>>> from sage.all import ***

**>>> PPS = ParallelogramPolyominoes()**

**>>> PPS**

Parallelogram polyominoes

**check_element (el, check)**

Check if a given element `el` is in the set of parallelogram polyominoes.

**EXAMPLES:**
sage: PPS = ParallelogramPolyominoes()

```python
>>> from sage.all import *

>>> PPS = ParallelogramPolyominoes()

ParallelogramPolyomino(# indirect doctest
[[0, 1, 1], [1, 1, 0]]
) in PPS
True
```

**get_options()**

Return all the options associated with the set of parallelogram polyominoes.

**EXAMPLES:**

```python
sage: PPS = ParallelogramPolyominoes()

>>> options = PPS.get_options()

Current options for ParallelogramPolyominoes_size
- display: 'list'
```

```python
options = Current options for ParallelogramPolyominoes_size - display: 'list'
- drawing_components: {'bounce_0': False, 'bounce_1': False, 'bounce_values': False, 'diagram': True, 'tree': False} - latex:
- drawing - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1, 'translation': [0, 0]}
```

The options for ParallelogramPolyominoes.

**set_options(**get_value, **set_value)**

Set new options to the object.

**EXAMPLES:**

```python
sage: PPS = ParallelogramPolyominoes()

>>> PPS.set_options(

```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
sage: pp = next(iter(PPS))
sage: view(pp) # not tested
```

```python
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes()
>>> PPS.set_options(
...   drawing_components=dict(
...     diagram = True,
...     bounce_0 = True,
...     bounce_1 = True,
...   )
... )
>>> pp = next(iter(PPS))
>>> view(pp) # not tested
```

class sage.combinat.parallelgram_polyomino.ParallelogramPolyominoes_size(size, policy)

Bases: ParentWithSetFactory, UniqueRepresentation

The parallelogram polyominoes of size $n$.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes(4)
sage: PPS
Parallelogram polyominoes of size 4
sage: sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]
```

```python
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(Integer(4))
>>> PPS
Parallelogram polyominoes of size 4
>>> sorted(PPS)
[[[0, 0, 0, 1], [1, 0, 0, 0]],
 [[0, 0, 1, 1], [1, 0, 1, 0]],
 [[0, 0, 1, 1], [1, 1, 0, 0]],
 [[0, 1, 0, 1], [1, 1, 0, 0]],
 [[0, 1, 1, 1], [1, 1, 1, 0]]]
```

an_element()

Return an element of a parallelogram polyomino of a given size.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes(4)
sage: PPS.an_element() in PPS
True
```

```python
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(Integer(4))
```
Combinatorics

>>> PPS.an_element() in PPS
True

**cardinality()**

Return the number of parallelogram polyominoes.

The number of parallelogram polyominoes of size \( n \) is given by the Catalan number \( c_{n-1} \).

**EXAMPLES:**

```sage
sage: ParallelogramPolyominoes(1).cardinality()
1
sage: ParallelogramPolyominoes(2).cardinality()
1
sage: ParallelogramPolyominoes(3).cardinality()
2
sage: ParallelogramPolyominoes(4).cardinality()
5
```

```sage
sage: all(ParallelogramPolyominoes(i).cardinality() == len(list(ParallelogramPolyominoes(i))) for i in range(1,7))
True
```

```sage
>>> from sage.all import *
```

```sage
>>> PPS = ParallelogramPolyominoes(Integer(3))
>>> PPS.an_element() in PPS
True
```

**check_element (el, check)**

Check is a given element \( el \) is in the set of parallelogram polyominoes of a fixed size.

**EXAMPLES:**

```sage
sage: PPS = ParallelogramPolyominoes(3)
sage: ParallelogramPolyomino(  # indirect doctest
    [[0, 1, 1], [1, 1, 0]])
in PPS
True
```

```sage
>>> from sage.all import *
```

```sage
>>> PPS = ParallelogramPolyominoes(Integer(3))
```
ParallelogramPolyomino(
... [[Integer(0), Integer(1), Integer(1)], [Integer(1), Integer(1),
→Integer(0)]],
... ) in PPS
True

get_options()

Return all the options associated with all the elements of the set of parallelogram polyominoes with a fixed size.

EXAMPLES:

```python
sage: pps = ParallelogramPolyominoes(5)
sage: pps.get_options()
Current options for ParallelogramPolyominoes_size
- display: 'list'
...
```

```python
>>> from sage.all import *
>>> pps = ParallelogramPolyominoes(Integer(5))
>>> pps.get_options()
Current options for ParallelogramPolyominoes_size
- display: 'list'
...
```

```python
options = Current options for ParallelogramPolyominoes_size - display:
'list' - drawing_components: {'bounce_0': False, 'bounce_1': False,
'bounce_values': False, 'diagram': True, 'tree': False} - latex:
drawing - tikz_options: {'color_bounce_0': 'red', 'color_bounce_1':
'blue', 'color_line': 'black', 'color_point': 'black', 'line_size': 1,
'mirror': None, 'point_size': 3.5, 'rotation': 0, 'scale': 1,
'translation': [0, 0]}
```

The options for ParallelogramPolyominoes.

set_options(*get_value, **set_value)

Set new options to the object.

EXAMPLES:

```python
sage: PPS = ParallelogramPolyominoes(3)
sage: PPS.set_options(
..... drawing_components=dict(
..... diagram = True,
..... bounce_0 = True,
..... bounce_1 = True,
..... )
..... )
sage: pp = PPS[0]
sage: view(pp) # not tested
```

```python
>>> from sage.all import *
>>> PPS = ParallelogramPolyominoes(Integer(3))
>>> PPS.set_options(
... drawing_components=dict(
... diagram = True,
... )
... )
```

(continues on next page)
... bounce_0 = True,
... bounce_1 = True,
... }

```python
>>> pp = PPS[Integer(0)]
>>> view(pp) # not tested
```

```python
size()
```

Return the size of the parallelogram polyominoes generated by this parent.

**EXAMPLES:**

```python
sage: ParallelogramPolyominoes(0).size()
0
sage: ParallelogramPolyominoes(1).size()
1
sage: ParallelogramPolyominoes(5).size()
5
```

```python
>>> from sage.all import *
>>> ParallelogramPolyominoes(Integer(0)).size()
0
>>> ParallelogramPolyominoes(Integer(1)).size()
1
>>> ParallelogramPolyominoes(Integer(5)).size()
5
```

sage.combinat.parallelogram_polyomino.default_tikz_options =
{ 'color_bounce_0': 'red', 'color_bounce_1': 'blue', 'color_line': 'black',
'color_point': 'black', 'line_size': 1, 'mirror': None, 'point_size': 3.5,
'rotation': 0, 'scale': 1, 'translation': [0, 0]}

This is the default TIKZ options.

This option is used to configure element of a drawing to allow TIKZ code generation.

## 5.1.158 Parking Functions

**INFORMALLY** (reference [Beck]):

Imagine a one-way cul-de-sac with \( n \) parking spots. We will give the first parking spot the number 1, the next one number 2, etc., down to the last one, number \( n \). Initially they are all free, but there are \( n \) cars approaching the street, and they would all like to park there. To make life interesting, every car has a parking preference, and we record the preferences in a sequence; For example, if \( n = 3 \), the sequence \((2, 1, 1)\) means that the first car would like to park at spot number 2, the second car prefers parking spot number 1, and the last car would also like to park at number 1. The street is very narrow, so there is no way to back up. Now each car enters the street and approaches its preferred parking spot; if it is free, it parks there, and if not, it moves down the street to the first available spot. We call a sequence a parking function (of length \( n \)) if all cars end up finding a parking spot. For example, the sequence \((2, 1, 1)\) is a parking sequence (of length 3), whereas the sequence \((2, 3, 2)\) is not.

**FORMALLY:**

A parking function of size \( n \) is a sequence \((a_1, \ldots, a_n)\) of positive integers such that if \( b_1 \leq b_2 \leq \cdots \leq b_n \) is the increasing rearrangement of \(a_1, \ldots, a_n\), then \( b_i \leq i \).

A parking function of size \( n \) is a pair \((L, D)\) of two sequences \(L\) and \(D\) where \(L\) is a permutation and \(D\) is an area sequence of a Dyck path of size \( n \) such that \( D[i] \geq 0, D[i+1] \leq D[i] + 1 \) and if \( D[i+1] = D[i] + 1 \) then \( L[i+1] > L[i] \).
The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n+1)^{n-1}$.

class sage.combinat.parking_functions.ParkingFunction (parent, lst)
    Bases: ClonableArray

A Parking Function.

A parking function of size $n$ is a sequence $(a_1, \ldots, a_n)$ of positive integers such that if $b_1 \leq b_2 \leq \cdots \leq b_n$ is the increasing rearrangement of $a_1, \ldots, a_n$, then $b_i \leq i$.

A parking function of size $n$ is a pair $(L, D)$ of two sequences $L$ and $D$ where $L$ is a permutation and $D$ is an area sequence of a Dyck Path of size $n$ such that $D[i] \geq 0$, $D[i+1] \leq D[i] + 1$ and if $D[i+1] = D[i] + 1$ then $L[i+1] > L[i]$.

The number of parking functions of size $n$ is equal to the number of rooted forests on $n$ vertices and is equal to $(n+1)^{n-1}$.

INPUT:
- $pf$ – (default: None) a list whose increasing rearrangement satisfies $b_i \leq i$
- $labelling$ – (default: None) a labelling of the Dyck path
- $area_sequence$ – (default: None) an area sequence of a Dyck path
- $labelled_dyck_word$ – (default: None) a Dyck word with 1’s replaced by labelling

OUTPUT:
A parking function

EXAMPLES:
```

\textbf{area()}

Return the area of the labelled Dyck path corresponding to the parking function.

\textbf{OUTPUT:}

- the sum of squares under and over the main diagonal of the Dyck Path, corresponding to the parking function

\textbf{EXAMPLES:}

\[ \texttt{sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])} \]
\[ \texttt{sage: PF.area()} \]
6

\[ \texttt{>>> from sage.all import *} \]
\[ \texttt{>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2), Integer(2), Integer(1), Integer(5)])} \]
\[ \texttt{>>> PF.area()} \]
6
cars_permutation()

Return the sequence of cars that take parking spots 1 through n and corresponding to the parking function.

For example, cars_permutation(PF) = [2, 4, 5, 6, 3, 1, 7] means that car 2 takes spots 1, car 4 takes spot 2, ..., car 1 takes spot 6 and car 7 takes spot 7.

OUTPUT:

- the permutation of cars corresponding to the parking function and which is the same size as parking function

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.cars_permutation()
[2, 4, 5, 6, 3, 1, 7]

sage: ParkingFunction([3,1,1,4]).cars_permutation()
[2, 3, 1, 4]

sage: ParkingFunction([4,1,1,1]).cars_permutation()
[2, 3, 4, 1]

sage: ParkingFunction([2,1,4,1]).cars_permutation()
[2, 1, 4, 3]

characteristic_quasisymmetric_function (q=None, R=Fraction Field of Multivariate Polynomial Ring in q, t over Rational Field)
Return the characteristic quasisymmetric function of self.

The characteristic function of the Parking Function is the sum over all permutation labellings of the Dyck path $q^{\text{diw}(PF)}F_{\text{ides}(PF)}$ where $\text{ides}(PF)$ (ides_composition()) is the descent composition of diagonal reading word of the parking function.

INPUT:

- $q$ – (default: $q = R('q')$) a parameter for the generating function power
- $R$ – (default: $R = QQ['q','t'].fraction_field()$) the base ring to do the calculations over

OUTPUT:

- an element of the quasisymmetric functions over the ring $R$

EXAMPLES:

```python
sage: # needs sage.modules
sage: R = QQ['q','t'].fraction_field()
sage: (q,t) = R.gens()
sage: cqf = sum(t**PF.area() * PF.characteristic_quasisymmetric_function() for PF in ParkingFunctions(3)); cqf
(q^3+q^2*t+q*t^2+t^3+q*t)*F[1, 1, 1] + (q^2+q*t+t^2+q+t)*F[1, 2] + (q^2+q*t+t^2+q+t)*F[2, 1] + F[3]
sage: s = SymmetricFunctions(R).s()
sage: s(cqf.to_symmetric_function())
(q^3+q^2*t+q*t^2+t^3+q*t)*s[1, 1, 1] + (q^2+q*t+t^2+q+t)*s[2, 1] + s[3]
sage: s(cqf.to_symmetric_function()).nabla(power=-1)
s[1, 1, 1]
```
check()

Check that self is a valid parking function.

EXAMPLES:

```python
sage: PF = ParkingFunction([1, 1, 2, 2, 5, 6])
sage: PF.check()

>>> from sage.all import *
>>> PF = ParkingFunction([Integer(1), Integer(1), Integer(2), Integer(2),
... Integer(5), Integer(6)])
>>> PF.check()
```

diagonal_composition()

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, `touch_composition(PF) = [4, 3]` means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

OUTPUT:

- the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]

>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
... Integer(2), Integer(1), Integer(5)])
>>> PF.touch_composition()
[4, 3]

sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]

>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).touch_composition()
[2, 1, 1]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).touch_composition()
```
diagonal_reading_word()

Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

OUTPUT:

- returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

EXAMPLES:

```sage
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
```

```sage
>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
 Integer(2), Integer(1), Integer(5)])
>>> PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
```

```sage
sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 4, 3, 1]).diagonal_reading_word()
[4, 2, 3, 1]
```

```sage
>>> from sage.all import *

>>> ParkingFunction([Integer(1), Integer(1), Integer(1)]).diagonal_reading_...
[3, 2, 1]
```

```sage
>>> ParkingFunction([Integer(1), Integer(2), Integer(3)]).diagonal_reading_...
[3, 2, 1]
```

(continues on next page)
diagonal_word()

Return a diagonal word of the labelled Dyck path corresponding to parking function (see [Hag08] p. 75).

**OUTPUT:**

- returns a word, read diagonally from NE to SW of the pretty print of the labelled Dyck path that corresponds to self and the same size as self

**EXAMPLES:**

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.diagonal_reading_word()
[5, 1, 7, 4, 6, 3, 2]
```

```python
from sage.all import *
PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2), Integer(2), Integer(1), Integer(5)])
PF.diagonal_reading_word()
```

```python
sage: ParkingFunction([1, 1, 1]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 2, 3]).diagonal_reading_word()
[3, 2, 1]
sage: ParkingFunction([1, 1, 3, 4]).diagonal_reading_word()
[2, 4, 3, 1]
```
\textbf{dinv()}

Return the number of inversions of a labelled Dyck path corresponding to the parking function (see [Hag08] p. 74).

Same as the cardinality of \texttt{dinversion_pairs()}.

\textbf{OUTPUT}:

\begin{itemize}
  \item the number of dinversion pairs
\end{itemize}

\textbf{EXAMPLES}:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinv()
6

>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
\texttt{\rightarrow} Integer(2), Integer(1), Integer(5)])

>>> PF.dinv()
6

sage: ParkingFunction([3,1,1,4]).dinv()
3
sage: ParkingFunction([4,1,1,1]).dinv()
1
sage: ParkingFunction([2,1,4,1]).dinv()
2

\textbf{dinversion_pairs()}

Return the descent inversion pairs of a labelled Dyck path corresponding to the parking function.

\textbf{OUTPUT}:

\begin{itemize}
  \item the primary and secondary diversion pairs
\end{itemize}

\textbf{EXAMPLES}:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]

>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),\texttt{\rightarrow} Integer(2), Integer(1), Integer(5)])

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> PF.dinversion_pairs()
[(0, 4), (1, 5), (2, 5), (1, 4), (2, 4), (3, 6)]
```

```python
sage: ParkingFunction([3,1,1,4]).dinversion_pairs()
[(0, 3), (2, 3), (1, 2)]
```

```python
sage: ParkingFunction([4,1,1,1]).dinversion_pairs()
[(1, 3)]
```

```python
sage: ParkingFunction([2,1,4,1]).dinversion_pairs()
[(0, 3), (1, 3)]
```

```python
>>> from sage.all import *
```

```python
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).dinversion_pairs()
[(0, 3), (2, 3), (1, 2)]
```

```python
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).dinversion_pairs()
[(1, 3)]
```

```python
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).dinversion_pairs()
[(0, 3), (1, 3)]
```

```
grade()
Return the length of the parking function.

EXAMPLES:

```
sage: PF = ParkingFunction([1, 1, 2, 2, 5, 6])
sage: PF.grade()
6
```

```
>>> from sage.all import *
```

```
>>> PF = ParkingFunction([Integer(1), Integer(1), Integer(2), Integer(2),
Integer(5), Integer(6)])
```

```
>>> PF.grade()
6
```

```
ides()
Return the descents() sequence of the inverse of the diagonal_reading_word() of self.

Warning: Here we use the standard convention that descent labels start at 1. This behaviour has been changed in Issue #20555.

For example, `ides(PF) = [2, 3, 4, 6]` means that descents are at the 2nd, 3rd, 4th and 6th positions in the inverse of the `diagonal_reading_word()` of the parking function (see [GXZ] p. 2).

OUTPUT:

- the descents sequence of the inverse of the `diagonal_reading_word()` of the parking function

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides()
[2, 3, 4, 6]
```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                         Integer(2), Integer(1), Integer(5)])
>>> PF.ides()
[2, 3, 4, 6]

sage: ParkingFunction([3,1,1,4]).ides()
[2]
sage: ParkingFunction([4,1,1,1]).ides()
[2, 3]
sage: ParkingFunction([4,3,1,1]).ides()
[3]

>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).ides()
[2]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).ides()
[2, 3]
>>> ParkingFunction([Integer(4),Integer(3),Integer(1),Integer(1)]).ides()
[3]

ides_composition()

Return the descents_composition() of the inverse of the diagonal_reading_word() of corresponding parking function.

For example, \texttt{ides_composition(PF) = [4, 2, 1]} means that the descents of the inverse of the permutation \texttt{diagonal_reading_word()} of the parking function with word \texttt{PF} are at the 4th and 6th positions.

OUTPUT:

- the descents composition of the inverse of the \texttt{diagonal_reading_word()} of the parking function

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.ides_composition()
[2, 1, 1, 2, 1]

>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                         Integer(2), Integer(1), Integer(5)])
>>> PF.ides_composition()
[2, 1, 1, 2, 1]

sage: ParkingFunction([3,1,1,4]).ides_composition()
[2, 2]
sage: ParkingFunction([4,1,1,1]).ides_composition()
[2, 1, 1]
sage: ParkingFunction([4,3,1,1]).ides_composition()
[3, 1]

>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).ides_composition()
[2, 2]

(continues on next page)
Jump

Return the sum of the differences between the parked and preferred parking spots.

See [Shin] p. 18.

OUTPUT:

• the sum of the differences between the parked and preferred parking spots

EXAMPLES:

```sage
df = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
df.jump()
6
```

```sage
df = ParkingFunction([3,1,1,4])
df.jump()
1
```

```sage
df = ParkingFunction([4,1,1,1])
df.jump()
3
```

```sage
df = ParkingFunction([2,1,4,1])
df.jump()
2
```

Jump_list

Return the displacements of cars that correspond to the parking function.

For example, jump_list (PF) = [0, 0, 0, 0, 1, 3, 2] means that car 1 through 4 parked in their preferred spots, car 5 had to park one spot farther (jumped or was displaced by one spot), car 6 had to jump 3 spots, and car 7 had to jump two spots.

OUTPUT:

• the displacements sequence of parked cars which corresponds to the parking function and which is the same size as parking function

EXAMPLES:
**sage:** PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
**sage:** PF.jump_list()
[0, 0, 0, 0, 1, 3, 2]

```python
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                        Integer(2), Integer(1), Integer(5)])
>>> PF.jump_list()
[0, 0, 0, 1, 3, 2]
```

**sage:** ParkingFunction([3,1,1,4]).jump_list()
[0, 0, 1, 0]
**sage:** ParkingFunction([4,1,1,1]).jump_list()
[0, 0, 1, 2]
**sage:** ParkingFunction([2,1,4,1]).jump_list()
[0, 0, 0, 2]

```python
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).jump_list()
[0, 0, 1, 0]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).jump_list()
[0, 0, 1, 2]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).jump_list()
[0, 0, 0, 2]
```

**luck()**

Return the number of cars that parked in their preferred parking spots (see [Shin] p. 33).

**OUTPUT:**

- the number of cars that parked in their preferred parking spots

**EXAMPLES:**

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.luck()
4
```

```python
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                        Integer(2), Integer(1), Integer(5)])
>>> PF.luck()
4
```

```python
sage: ParkingFunction([3,1,1,4]).luck()
3
sage: ParkingFunction([4,1,1,1]).luck()
2
sage: ParkingFunction([2,1,4,1]).luck()
3
```

```python
>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).luck()
3
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).luck()
2
```

(continues on next page)
lucky_cars()

Return the cars that can park in their preferred spots. For example, lucky_cars(PF) = [1, 2, 7] means that cars 1, 2 and 7 parked in their preferred spots and all the other cars did not.

OUTPUT:

• the cars that can park in their preferred spots

EXAMPLES:

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.lucky_cars()
[1, 2, 3, 4]
```

```sage
PF = ParkingFunction([3, 1, 1, 4])
sage: PF.lucky_cars()
[1, 2, 4]
```

```sage
PF = ParkingFunction([4, 1, 1, 1])
sage: PF.lucky_cars()
[1, 2]
```

```sage
PF = ParkingFunction([2, 1, 4, 1])
sage: PF.lucky_cars()
[1, 2, 3]
```

parking_permutation()

Return the sequence of parking spots that are taken by cars 1 through 𝑛 and corresponding to the parking function.

For example, parking_permutation(PF) = [6, 1, 5, 2, 3, 4, 7] means that spot 6 is taken by car 1, spot 1 by car 2, spot 5 by car 3, spot 2 is taken by car 4, spot 3 is taken by car 5, spot 4 is taken by car 6 and spot 7 is taken by car 7.

OUTPUT:

• the permutation of parking spots that corresponds to the parking function and which is the same size as parking function

EXAMPLES:
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]

>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
→Integer(2), Integer(1), Integer(5)])
>>> PF.parking_permutation()
[6, 1, 5, 2, 3, 4, 7]

sage: ParkingFunction([3,1,1,4]).parking_permutation()
[3, 1, 2, 4]

sage: ParkingFunction([4,1,1,1]).parking_permutation()
[4, 1, 2, 3]

sage: ParkingFunction([2,1,4,1]).parking_permutation()
[2, 1, 4, 3]

>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).parking_permutation()
[3, 1, 2, 4]

>>>

pretty_print (underpath=True)
Displays a parking function as a lattice path consisting of a Dyck path and a labelling with the labels displayed along the edges of the Dyck path.

INPUT:

• underpath – if the length of the parking function is less than or equal to 9 then display the labels under the path if underpath is True otherwise display them to the right of the path (default: True)

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print()
___
|1x
|7x .
____|3 . .
|5x x . .
_|4x . . .
|6x . . . .
|2 . . . .

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.pretty_print(underpath = False)
___
| x 1
| x . 7
____| . . 3
| x x . . 5

(continues on next page)
>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
    →Integer(2), Integer(1), Integer(5)])

>>> PF.pretty_print()

___
|    |1x
|    |7x .
|____|3 . .
|5x x . .
|____|4x . . .
|6x . . . .
|2 . . . .

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
    →Integer(2), Integer(1), Integer(5)])

primary_dinversion_pairs()

Return the primary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

OUTPUT:

• the pairs $i, j$ such that $i < j$, and $i^{th}$ area = $j^{th}$ area, and $i^{th}$ label < $j^{th}$ label

EXAMPLES:

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]

>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2), Integer(2), Integer(1), Integer(5)])
>>> PF.primary_dinversion_pairs()
[(0, 4), (1, 5), (2, 5)]

sage: ParkingFunction([3, 1, 1, 4]).primary_dinversion_pairs()
[(0, 3), (2, 3)]

sage: ParkingFunction([4, 1, 1, 1]).primary_dinversion_pairs()
[]

sage: ParkingFunction([2, 1, 4, 1]).primary_dinversion_pairs()
[(0, 3)]

>>> from sage.all import *
>>> ParkingFunction([Integer(3), Integer(1), Integer(1), Integer(4)]).primary_dinversion_pairs()
[(0, 3), (2, 3)]

>>> ParkingFunction([Integer(4), Integer(1), Integer(1), Integer(1)]).primary_dinversion_pairs()
[]

>>> ParkingFunction([Integer(2), Integer(1), Integer(4), Integer(1)]).primary_dinversion_pairs()
`secondary_dinversion_pairs()`

Return the secondary descent inversion pairs of a labelled Dyck path corresponding to the parking function.

**OUTPUT:**

- the pairs \((i, j)\) such that \(i < j\), and \(i^{th}\) area = \(j^{th}\) area + 1, and \(i^{th}\) label > \(j^{th}\) label

**EXAMPLES:**

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.secondary_dinversion_pairs()
[(1, 4), (2, 4), (3, 6)]
```

```sage
PF = ParkingFunction([3, 1, 1, 4])
sage: PF.secondary_dinversion_pairs()
[(1, 2)]
```

```sage
PF = ParkingFunction([4, 1, 1, 1])
sage: PF.secondary_dinversion_pairs()
[(1, 3)]
```

```sage
PF = ParkingFunction([2, 1, 4, 1])
sage: PF.secondary_dinversion_pairs()
[(1, 3)]
```

`to_NonDecreasingParkingFunction()`

Return the non-decreasing parking function which underlies the parking function.

**OUTPUT:**

- a sorted parking function

**See also:**

`NonDecreasingParkingFunction()`

**EXAMPLES:**

```sage
PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]
```
```python
>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                        Integer(2), Integer(1), Integer(5)])

>>> PF.to_NonDecreasingParkingFunction()
[1, 1, 2, 2, 5, 5, 6]

sage: ParkingFunction([3,1,1,4]).to_NonDecreasingParkingFunction()
[1, 1, 3, 4]

sage: ParkingFunction([4,1,1,1]).to_NonDecreasingParkingFunction()
[1, 1, 1, 4]

sage: ParkingFunction([2,1,4,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]

sage: ParkingFunction([4,1,2,1]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]

>>> from sage.all import *

>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_NonDecreasingParkingFunction()
[1, 1, 3, 4]

>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_NonDecreasingParkingFunction()
[1, 1, 1, 4]

>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]

>>> ParkingFunction([Integer(4),Integer(1),Integer(2),Integer(1)]).to_NonDecreasingParkingFunction()
[1, 1, 2, 4]
```

to_area_sequence()

Return the area sequence of the support Dyck path of the parking function.

OUTPUT:

- the area sequence of the Dyck path

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_area_sequence()
[0, 1, 1, 2, 0, 1, 1]

>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                        Integer(2), Integer(1), Integer(5)])

>>> PF.to_area_sequence()
[0, 1, 1, 2, 0, 1, 1]

sage: ParkingFunction([3,1,1,4]).to_area_sequence()
[0, 1, 0, 0]

sage: ParkingFunction([4,1,1,1]).to_area_sequence()
[0, 1, 2, 0]

sage: ParkingFunction([2,1,4,1]).to_area_sequence()
[0, 1, 1, 0]

sage: ParkingFunction([2,1,4,1]).to_area_sequence()
[0, 1, 1, 0]
```
from sage.all import *

ParkingFunction([Integer(3), Integer(1), Integer(1), Integer(4)]).to_area_sequence()
[0, 1, 0, 0]

ParkingFunction([Integer(4), Integer(1), Integer(1), Integer(1)]).to_area_sequence()
[0, 1, 2, 0]

ParkingFunction([Integer(2), Integer(1), Integer(4), Integer(1)]).to_area_sequence()
[0, 1, 1, 0]

to_dyck_word()
Return the support Dyck word of the parking function.

OUTPUT:

• the Dyck word of the corresponding parking function

See also:

DyckWord()

EXAMPLES:
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0]

sage: ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                        Integer(2), Integer(1), Integer(5)]).to_dyck_word()
[1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0]

sage: ParkingFunction([3,1,1,4]).to_dyck_word()
[1, 1, 0, 0, 1, 0, 1, 0]

sage: ParkingFunction([4,1,1,1]).to_dyck_word()
[1, 1, 1, 0, 0, 0, 1, 0]

sage: ParkingFunction([2,1,4,1]).to_dyck_word()
[1, 1, 0, 1, 0, 0, 1, 0]

to_labelled_dyck_word()
Return the labelled Dyck word corresponding to the parking function.

This is a representation of the parking function as a list where the entries of 1 in the Dyck word are replaced with the corresponding label.

OUTPUT:
• the labelled Dyck word of the corresponding parking function which is twice the size of parking function word

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]

>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2), Integer(2), Integer(1), Integer(5)])
>>> PF.to_labelled_dyck_word()
[2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]

sage: ParkingFunction([3,1,1,4]).to_labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]

sage: ParkingFunction([4,1,1,1]).to_labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]

sage: ParkingFunction([2,1,4,1]).to_labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]

>>> from sage.all import *

>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).to_labelled_dyck_word()
[2, 3, 0, 0, 1, 0, 4, 0]

>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).to_labelled_dyck_word()
[2, 3, 4, 0, 0, 0, 1, 0]

>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).to_labelled_dyck_word()
[2, 4, 0, 1, 0, 0, 3, 0]
```

to_labelling_area_sequence_pair()

Return a pair consisting of a labelling and an area sequence of a Dyck path which corresponds to the given parking function.

OUTPUT:

• returns a pair \((L, D)\) where \(L\) is a labelling and \(D\) is the area sequence of the underlying Dyck path

EXAMPLES:

```
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])

>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2), Integer(2), Integer(1), Integer(5)])

>>> PF.to_labelling_area_sequence_pair()
([2, 6, 4, 5, 3, 7, 1], [0, 1, 1, 2, 0, 1, 1])

sage: ParkingFunction([1, 1, 1]).to_labelled_area_sequence_pair()
([1, 2, 3], [0, 1, 2])

sage: ParkingFunction([1, 2, 3]).to_labelled_area_sequence_pair()
([1, 2, 3], [0, 0, 0])
```

(continues on next page)
to_labelling_dyck_word_pair()

Return the pair \((L, D)\) where \(L\) is a labelling and \(D\) is the Dyck word of the parking function.

OUTPUT:

- the pair \((L, D)\), where \(L\) is the labelling and \(D\) is the Dyck word of the parking function

See also:

DyckWord()

EXAMPLES:

```python
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_dyck_word_pair()
([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0])
```

```python
>>> from sage.all import *

>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
Integer(2), Integer(1), Integer(5)])

>>> PF.to_labelling_dyck_word_pair()
([2, 6, 4, 5, 3, 7, 1], [1, 1, 0, 1, 1, 0, 0, 0, 1, 1, 0, 1, 0, 0])
```

```python
sage: ParkingFunction([3,1,1,4]).to_labelling_dyck_word_pair()
([2, 3, 1, 4], [1, 1, 0, 1, 0, 1, 0, 0])

sage: ParkingFunction([4,1,1,1]).to_labelling_dyck_word_pair()
([2, 3, 4, 1], [1, 1, 0, 0, 0, 1, 0, 0])

sage: ParkingFunction([2,1,4,1]).to_labelling_dyck_word_pair()
([2, 4, 1, 3], [1, 1, 1, 0, 0, 0, 1, 0])
```

```python
>>> from sage.all import *

>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(1),Integer(4)])
.to_labelling_dyck_word_pair()
([2, 3, 1, 4], [1, 1, 0, 0, 1, 0, 1, 0])

>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1),Integer(1)])
.to_labelling_dyck_word_pair()
([2, 3, 4, 1], [1, 1, 1, 0, 0, 0, 1, 0])
```

(continues on next page)
to_labelling_permutation()

Return the labelling of the support Dyck path of the parking function.

OUTPUT:

• the labelling of the Dyck path

EXAMPLES:

```sage
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.to_labelling_permutation()
[2, 6, 4, 5, 3, 7, 1]
```

```sage
sage: ParkingFunction([3,1,1,4]).to_labelling_permutation()
[2, 3, 1, 4]
```

```sage
sage: ParkingFunction([4,1,1,1]).to_labelling_permutation()
[2, 3, 4, 1]
```

```sage
sage: ParkingFunction([2,1,4,1]).to_labelling_permutation()
[2, 4, 1, 3]
```

```sage
sage: ParkingFunction([3,1,1,4]).to_labelling_permutation()
[2, 3, 1, 4]
```

```sage
sage: ParkingFunction([4,1,1,1]).to_labelling_permutation()
[2, 3, 4, 1]
```

```sage
sage: ParkingFunction([2,1,4,1]).to_labelling_permutation()
[2, 4, 1, 3]
```

touch_composition()

Return the composition of the labelled Dyck path corresponding to the parking function.

For example, touch_composition(PF) = [4, 3] means that the first touch is four diagonal units from the starting point, and the second is three units further (see [GXZ] p. 2).

OUTPUT:

• the length between the corresponding touch points which of the labelled Dyck path that corresponds to the parking function

EXAMPLES:

```sage
sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_composition()
[4, 3]
```
>>> from sage.all import *
>>> PF = ParkingFunction([Integer(6), Integer(1), Integer(5), Integer(2),
                        Integer(2), Integer(1), Integer(5)])
>>> PF.touch_composition()
[4, 3]

sage: ParkingFunction([3,1,1,4]).touch_composition()
[2, 1, 1]
sage: ParkingFunction([4,1,1,1]).touch_composition()
[3, 1]
sage: ParkingFunction([2,1,4,1]).touch_composition()
[3, 1]

>>> from sage.all import *
>>> ParkingFunction([Integer(3),Integer(1),Integer(1),Integer(4)]).touch_composition()
[2, 1, 1]
>>> ParkingFunction([Integer(4),Integer(1),Integer(1),Integer(1)]).touch_composition()
[3, 1]
>>> ParkingFunction([Integer(2),Integer(1),Integer(4),Integer(1)]).touch_composition()
[3, 1]

\textbf{touch_points()} \newline

Return the sequence of touch points which corresponds to the labelled Dyck path after initial step.

For example, \texttt{touch_points(PF) = [4, 7]} means that after the initial step, the path touches the main diagonal at points \((4, 4)\) and \((7, 7)\).

\textbf{OUTPUT:}

\begin{itemize}
\item the sequence of touch points after the initial step of the labelled Dyck path that corresponds to the parking function
\end{itemize}

\textbf{EXAMPLES:}

sage: PF = ParkingFunction([6, 1, 5, 2, 2, 1, 5])
sage: PF.touch_points()
[4, 7]

\textbf{(continues on next page)}
class sage.combinat.parking_functions.ParkingFunctions

Bases: UniqueRepresentation, Parent

Return the combinatorial class of Parking Functions.

A parking function of size \( n \) is a sequence \((a_1, \ldots, a_n)\) of positive integers such that if \( b_1 \leq b_2 \leq \cdots \leq b_n \) is the increasing rearrangement of \( a_1, \ldots, a_n \), then \( b_i \leq i \).

A parking function of size \( n \) is a pair \((L, D)\) of two sequences \( L \) and \( D \) where \( L \) is a permutation and \( D \) is an area sequence of a Dyck Path of size \( n \) such that \( D[i] \geq 0, D[i + 1] \leq D[i] + 1 \) and if \( D[i + 1] = D[i] + 1 \) then \( L[i + 1] > L[i] \).

The number of parking functions of size \( n \) is equal to the number of rooted forests on \( n \) vertices and is equal to \((n + 1)^{n-1}\).

**EXAMPLES:**

Here are all parking functions of size 3:

```
sage: from sage.combinat.parking_functions import ParkingFunctions
sage: ParkingFunctions(3).list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [2, 1, 1], [1, 1, 3], [1, 3, 1],
 [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1], [1, 2, 3], [1, 3, 2],
 [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]
```

If no size is specified, then ParkingFunctions returns the combinatorial class of all parking functions.

```
sage: PF = ParkingFunctions(); PF
Parking functions
sage: [] in PF
True
sage: [1] in PF
True
sage: [2] in PF
False
sage: [1,3,1] in PF
True
sage: [1,4,1] in PF
False
```
If the size $n$ is specified, then ParkingFunctions returns the combinatorial class of all parking functions of size $n$. 

```python
sage: PF3 = ParkingFunctions(3); PF3
Parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,3,1] in PF3
True
sage: [1,4,1] in PF3
False
```

```python
sage: PF3 = ParkingFunctions(Integer(3)); PF3
Parking functions of size 3
sage: [] in PF3
False
sage: [1] in PF3
False
sage: [1,3,1] in PF3
True
sage: [1,4,1] in PF3
False
```

(continues on next page)
False
>>> [Integer(1)] in PF3
False
>>> [Integer(1), Integer(3), Integer(1)] in PF3
True
>>> [Integer(1), Integer(4), Integer(1)] in PF3
False

class sage.combinat.parking_functions.ParkingFunctions_all
Bases: ParkingFunctions
Element
    alias of ParkingFunction

graded_component(n)
    Return the graded component.

    EXAMPLES:

sage: PF = ParkingFunctions()
sage: PF.graded_component(4) == ParkingFunctions(4)
True
sage: it = iter(ParkingFunctions()) # indirect doctest
sage: [next(it) for i in range(8)]
[[], [1], [1, 1], [1, 2], [2, 1], [1, 1, 1], [1, 1, 2], [1, 2, 1]]

>>> from sage.all import *
>>> PF = ParkingFunctions()
>>> PF.graded_component(Integer(4)) == ParkingFunctions(Integer(4))
True
>>> it = iter(ParkingFunctions(Integer(4))) # indirect doctest
>>> [next(it) for i in range(Integer(8))]
[[], [1], [1, 1], [1, 2], [2, 1], [1, 1, 1], [1, 1, 2], [1, 2, 1]]

class sage.combinat.parking_functions.ParkingFunctions_n(n)
Bases: ParkingFunctions

The combinatorial class of parking functions of size n.

A parking function of size n is a sequence \((a_1, \ldots, a_n)\) of positive integers such that if \(b_1 \leq b_2 \leq \cdots \leq b_n\) is the increasing rearrangement of \(a_1, \ldots, a_n\), then \(b_i \leq i\).

A parking function of size n is a pair \((L, D)\) of two sequences \(L\) and \(D\) where \(L\) is a permutation and \(D\) is an area sequence of a Dyck Path of size \(n\) such that \(D[i] \geq 0\), \(D[i+1] \leq D[i] + 1\) and if \(D[i+1] = D[i] + 1\) then \(L[i+1] > L[i]\).

The number of parking functions of size \(n\) is equal to the number of rooted forests on \(n\) vertices and is equal to \((n+1)^{n-1}\).

EXAMPLES:

sage: PF = ParkingFunctions(3)
sage: PF.list()
[[1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 2, 1], [1, 1, 3], [1, 1, 3], [1, 3, 1], [1, 3, 1], [2, 1, 2], [2, 1, 2], [2, 2, 1], [2, 2, 1], [1, 2, 3], [1, 3, 2], [2, 1, 3], [2, 3, 1], [3, 1, 2], [3, 2, 1]]

(continues on next page)
sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]

```
>>> from sage.all import *
>>> PF = ParkingFunctions(Integer(3))
>>> PF.list()
[[[1, 1, 1], [1, 1, 2], [1, 2, 1], [1, 1, 3],
  [1, 3, 1], [3, 1, 1], [1, 2, 2], [2, 1, 2], [2, 2, 1],
  [1, 2, 3], [1, 3, 2], [2, 1, 3], [3, 1, 2], [3, 2, 1]]

Warning: The precise order in which the parking function are generated or listed is not fixed, and may change in the future.

Element

alias of ParkingFunction
cardinality()

Return the number of parking functions of size n.

The cardinality is equal to \((n + 1)^{n-1}\).

EXAMPLES:

sage: [ParkingFunctions(i).cardinality() for i in range(6)]
[1, 1, 3, 16, 125, 1296]

random_element()

Return a random parking function of size n.

The algorithm uses a circular parking space with \(n + 1\) spots. Then all \(n\) cars can park and there remains one empty spot. Spots are then renumbered so that the empty spot is 0.

The probability distribution is uniform on the set of \((n + 1)^{n-1}\) parking functions of size \(n\).

EXAMPLES:

sage: pf = ParkingFunctions(8)
sage: a = pf.random_element(); a  # random
[5, 7, 2, 4, 2, 5, 1, 3]
sage: a in pf
True

```
sage.combinat.parking_functions.from_labelled_dyck_word(LDW)

Return the parking function corresponding to the labelled Dyck word.

INPUT:

• LDW – labelled Dyck word

OUTPUT:

• the parking function corresponding to the labelled Dyck word that is half the size of LDW

EXAMPLES:

```python
sage: from sage.combinat.parking_functions import from_labelled_dyck_word
sage: LDW = [2, 6, 0, 4, 5, 0, 0, 0, 3, 7, 0, 1, 0, 0]
sage: from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]
```

```
>>> from sage.all import *
>>> from sage.combinat.parking_functions import from_labelled_dyck_word
>>> LDW = [Integer(2), Integer(6), Integer(0), Integer(4), Integer(5), Integer(0),
        Integer(0), Integer(0), Integer(3), Integer(7), Integer(0), Integer(1),
        Integer(0), Integer(0)]
>>> from_labelled_dyck_word(LDW)
[6, 1, 5, 2, 2, 1, 5]
```

```python
sage: from_labelled_dyck_word([2, 3, 0, 0, 1, 0, 4, 0])
[3, 1, 1, 4]
sage: from_labelled_dyck_word([2, 3, 4, 0, 0, 0, 1, 0])
[4, 1, 1]
sage: from_labelled_dyck_word([2, 4, 0, 1, 0, 0, 3, 0])
[2, 1, 4, 1]
```

sage.combinat.parking_functions.from_labelling_and_area_sequence(L, D)

Return the parking function corresponding to the labelling area sequence pair.

INPUT:

• L – a labelling permutation
• D – an area sequence for a Dyck word

OUTPUT:

• the parking function corresponding the labelling permutation L and D an area sequence of the corresponding Dyck path

EXAMPLES:
```python
sage: from sage.combinat.parking_functions import from_labelling_and_area_sequence
sage: from_labelling_and_area_sequence([2, 6, 4, 5, 3, 7, 1], [0, 1, 2, 0, 1, ...
   ...1])
[6, 1, 5, 2, 2, 1, 5]
```

```python
>>> from sage.all import *

>>> from sage.combinat.parking_functions import from_labelling_and_area_sequence

>>> from_labelling_and_area_sequence([Integer(2), Integer(6), Integer(4), ...
   ...Integer(5), Integer(3), Integer(7), Integer(1)], [Integer(0), Integer(1),...
   ...Integer(1), Integer(2), Integer(0), Integer(1), Integer(1)])
[6, 1, 5, 2, 2, 1, 5]
```

```python
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 2])
[1, 1, 1]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 0, 0])
[1, 2, 3]
sage: from_labelling_and_area_sequence([1, 2, 3], [0, 1, 1])
[1, 1, 2]
```

```python
sage: from_labelling_and_area_sequence([Integer(1), Integer(2), Integer(3)], [Integer(0), Integer(1), Integer(2)])
[1, 1, 1]
sage: from_labelling_and_area_sequence([Integer(1), Integer(2), Integer(4), Integer(3)], [Integer(0), Integer(1), Integer(2), Integer(1)])
[1, 1, 3, 1]
```

```python
sage.combinat.parking_functions.is_a(x, n=None)
Check whether a list is a parking function.
If a size n is specified, checks if a list is a parking function of size n.
```

### 5.1.159 Catalog of Path Tableaux

The path_tableaux object may be used to access examples of various path tableau objects currently implemented in Sage. Using tab-completion on this object is an easy way to discover and quickly create the path tableaux that are available (as listed here).

Let `<tab>` indicate pressing the Tab key. So begin by typing `path_tableaux.<tab>` to see the currently implemented path tableaux.

- `CylindricalDiagram`
- `DyckPath`
- `DyckPaths`
- `FriezePattern`
5.1.160 Dyck Paths

This is an implementation of the abstract base class `sage.combinat.path_tableaux.path_tableau.PathTableau`. This is the simplest implementation of a path tableau and is included to provide a convenient test case and for pedagogical purposes.

In this implementation we have sequences of nonnegative integers. These are required to be the heights Dyck words (except that we do not require the sequence to start or end at height zero). These are in bijection with skew standard tableaux with at most two rows. Sequences which start and end at height zero are in bijection with noncrossing perfect matchings.

AUTHORS:

- Bruce Westbury (2018): initial version

```python
class sage.combinat.path_tableaux.dyck_path.DyckPath(parent, ot, check=True)

Bases: PathTableau

An instance is the sequence of nonnegative integers given by the heights of a Dyck word.

INPUT:

- a sequence of nonnegative integers
- a two row standard skew tableau
- a Dyck word
- a noncrossing perfect matching

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1,0])
[0, 1, 2, 1, 0]

sage: w = DyckWord([1,1,0,0])
sage: path_tableaux.DyckPath(w)
[0, 1, 2, 1, 0]

sage: p = PerfectMatching([(1,2), (3,4)])
sage: path_tableaux.DyckPath(p)
[0, 1, 0, 1, 0]

sage: t = Tableau([[1,2,4],[3,5,6]])
sage: path_tableaux.DyckPath(t)
[0, 1, 2, 1, 2, 1, 0]

sage: st = SkewTableau([[None, 1,4],[2,3]])
sage: path_tableaux.DyckPath(st)
[1, 2, 1, 0, 1]

```
\[
(0, 1, 2, 1, 0)
\]

```python
>>> w = DyckWord([Integer(1), Integer(1), Integer(0), Integer(0)])
>>> path_tableaux.DyckPath(w)
[0, 1, 2, 1, 0]
```

```python
>>> p = PerfectMatching([(Integer(1), Integer(2)), (Integer(3), Integer(4))])
>>> path_tableaux.DyckPath(p)
[0, 1, 0, 1, 0]
```

```python
>>> t = Tableau([[Integer(1), Integer(2), Integer(4)], [Integer(3), Integer(5), Integer(6)]])
>>> path_tableaux.DyckPath(t)
[0, 1, 2, 1, 2, 1, 0]
```

```python
>>> st = SkewTableau([[None, Integer(1), Integer(4)], [Integer(2), Integer(3)]])
>>> path_tableaux.DyckPath(st)
[1, 2, 1, 0, 1]
```

Here we illustrate the slogan that promotion = rotation:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 3), (1, 2), (4, 5)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 1), (2, 5), (3, 4)]
sage: t = t.promotion()
sage: t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
```

```python
>>> from sage.all import *
```

```python
>>> t = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3), Integer(2), Integer(1), Integer(0)])
>>> t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
```

```python
>>> t = t.promotion()
```

```python
>>> t = t.promotion()
```

```python
>>> t = t.promotion()
```

```python
>>> t = t.promotion()
```

```python
>>> t = t.promotion()
```

```python
>>> t = t.promotion()
```

```python
>>> t.to_perfect_matching()
[(0, 5), (1, 4), (2, 3)]
```

```python
check ()
Check that self is a valid path.
```

5.1. Comprehensive Module List
EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,0,-1,0]) # indirect doctest
Traceback (most recent call last):
  ...  
ValueError: [0, 1, 0, -1, 0] has a negative entry
```

```python
sage: path_tableaux.DyckPath([0,1,3,1,0]) # indirect doctest
Traceback (most recent call last):
  ...  
ValueError: [0, 1, 3, 1, 0] is not a Dyck path
```

```python
>>> from sage.all import *

>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(0),-Integer(1),
  → Integer(0)]) # indirect doctest
Traceback (most recent call last):
  ...  
ValueError: [0, 1, 0, -1, 0] has a negative entry

>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(3),Integer(1),
  → Integer(0)]) # indirect doctest
Traceback (most recent call last):
  ...  
ValueError: [0, 1, 3, 1, 0] is not a Dyck path
```

descents()

Return the descent set of self.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1,2,1,0,1,0]).descents()
{3, 6}
```

```python
>>> from sage.all import *

>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
  → Integer(2),Integer(1),Integer(0),Integer(1),Integer(0)]).descents()
{3, 6}
```

is_skew()

Return True if self is skew and False if not.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([0,1,2,1]).is_skew()
False
```

```python
sage: path_tableaux.DyckPath([1,0,1,2,1]).is_skew()
True
```

```python
>>> from sage.all import *

>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1)]).is_ ¬skew()
False

>>> path_tableaux.DyckPath([Integer(1),Integer(0),Integer(1),Integer(2),
  → Integer(1)]).is_skew()
True
```
local_rule(i)

This has input a list of objects. This method first takes the list of objects of length three consisting of the 
(i − 1)-st, i-th and (i + 1)-term and applies the rule. It then replaces the i-th object by the object returned 
by the rule.

EXAMPLES:

sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]

>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
                  →Integer(2),Integer(1),Integer(0)])
>>> t.local_rule(Integer(3))
[0, 1, 2, 1, 2, 1, 0]

to_DyckWord()

Converts self to a Dyck word.

EXAMPLES:

sage: c = path_tableaux.DyckPath([0,1,2,1,0])
sage: c.to_DyckWord()
[1, 1, 0, 0]

>>> from sage.all import *
>>> c = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
                  →Integer(2),Integer(1),Integer(0)])
>>> c.to_DyckWord()
[1, 1, 0, 0]

to_perfect_matching()

Return the perfect matching associated to self.

EXAMPLES:

sage: path_tableaux.DyckPath([0,1,2,1,2,1,0,1,0]).to_perfect_matching()
[(0, 5), (1, 2), (3, 4), (6, 7)]

>>> from sage.all import *
>>> path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(1),
                  →Integer(2),Integer(1),Integer(0),Integer(1),Integer(0)]).to_perfect_
                  →matching()
[(0, 5), (1, 2), (3, 4), (6, 7)]

to_tableau()

Return the skew tableau associated to self.

EXAMPLES:

sage: T = path_tableaux.DyckPath([0,1,2,3,2,3])
sage: T.to_tableau()
[[[1, 2, 3], [4]]

sage: U = path_tableaux.DyckPath([2,3,2,3])
sage: U.to_tableau()
[[None, None, 1, 3], [2]]

```python
>>> from sage.all import *

>>> T = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
                               Integer(2),Integer(3)])

>>> T.to_tableau()
[[1, 2, 3, 5], [4]]

>>> U = path_tableaux.DyckPath([Integer(2),Integer(3),Integer(2),Integer(3)])

>>> U.to_tableau()
[[None, None, 1, 3], [2]]
```

to_word()

Return the word in the alphabet \{0, 1\} associated to self.

EXAMPLES:

```python
sage: path_tableaux.DyckPath([1,0,1,2,1]).to_word()
[0, 1, 1, 0]
```

```python
>>> from sage.all import *

>>> path_tableaux.DyckPath([Integer(1),Integer(0),Integer(1),Integer(2),
                           Integer(1)]).to_word()
[0, 1, 1, 0]
```

class `sage.combinat.path_tableaux.dyck_path.DyckPaths`

Bases: `PathTableaux`

The parent class for DyckPath.

Element

alias of `DyckPath`

5.1.161 Frieze Patterns

This implements the original frieze patterns due to Conway and Coxeter. Such a frieze pattern is considered as a sequence of nonnegative integers following [CoCo1] and [CoCo2] using `sage.combinat.path_tableaux.path_tableau`.

AUTHORS:

- Bruce Westbury (2019): initial version

class `sage.combinat.path_tableaux.frieze.FriezePattern`

Bases: `PathTableau`

A frieze pattern.

We encode a frieze pattern as a sequence in a fixed ground field.

INPUT:

- `fp` – a sequence of elements of `field`
- `field` – (default: `QQ`) the ground field

EXAMPLES:
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 1, 2, 3, 1, 0]
[ , 0, 1, 1, 3, 5, 2, 1, 0]
[ , , 0, 1, 4, 7, 3, 2, 1, 0]
[ , , , 0, 1, 2, 1, 1, 1, 1, 0]
[ , , , , 0, 1, 2, 3, 4, 1, 0]
[ , , , , , 0, 1, 3, 5, 7, 2, 1, 0]
[ , , , , , , 0, 1, 2, 3, 1, 1, 1, 0]
[ , , , , , , , 0, 1, 2, 1, 2, 3, 1, 0]

sage: TestSuite(t).run()

sage: t = path_tableaux.FriezePattern([1,2,7,5,3,7,4,1])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[ , 0, 1, 4, 3, 2, 5, 3, 1, 1, 0]
[ , , 0, 1, 1, 1, 3, 2, 1, 2, 1, 0]
[ , , , 0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[ , , , , 0, 1, 4, 3, 2, 5, 3, 1, 1, 0]
[ , , , , , 0, 1, 1, 1, 3, 2, 1, 2, 1, 0]
[ , , , , , , 0, 1, 2, 7, 5, 3, 7, 4, 1, 0]
[ , , , , , , , 0, 1, 4, 3, 2, 5, 3, 1, 1, 0]
[ , , , , , , , , 0, 1, 1, 1, 3, 2, 1, 2, 1, 0]
[ , , , , , , , , , 0, 1, 2, 7, 5, 3, 7, 4, 1, 0]

sage: TestSuite(t).run()

sage: t = path_tableaux.FriezePattern([1,3,4,5,1])
sage: path_tableaux.CylindricalDiagram(t)
[ 0, 1, 3, 4, 5, 1, 0]
[ , 0, 1, 5/3, 7/3, 2/3, 1, 0]
[ , , 0, 1, 2, 1, 3, 1, 0]

[ , , , , 0, 1, sqrt2, 3, 2*sqrt2, 5, 3*sqrt2, ...
 → 1, 0]
[ , , , , 0, 1, sqrt2, 3, 2*sqrt2, 5, 3*sqrt2, ...
 → 1, 0]
[ , , , , 0, 1, sqrt2, 3, 2*sqrt2, 5, 3*sqrt2, ...
 → 1, 0]
>>> TestSuite(t).run()
```

`change_ring(R)`

Return `self` as a frieze pattern with coefficients in `R`.

This assumes that there is a canonical coerce map from the base ring of `self` to `R`.

EXAMPLES:

```python
sage: fp = path_tableaux.FriezePattern([1,2,7,5,3,7,4,1])
sage: fp.change_ring(RealField())
# needs sage.rings.real_mpfr
[0.000000000000000, 1.00000000000000, ... 4.00000000000000, 1.00000000000000, 0.000000000000000]
sage: fp.change_ring(GF(7))
Traceback (most recent call last):
... TypeError: no base extension defined
```

```python
>>> from sage.all import *
>>> fp = path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(7), Integer(5),Integer(3),Integer(7),Integer(4),Integer(1)])
>>> fp.change_ring(RealField())
# needs sage.rings.real_mpfr
[0.000000000000000, 1.00000000000000, ...]
```
Check that `self` is a valid frieze pattern.

**is_integral()**

Return `True` if all entries of the frieze pattern are positive integers.

**EXAMPLES:**

```python
sage: path_tableaux.FriezePattern([1, 2, 7, 5, 3, 7, 4, 1]).is_integral()
True
sage: path_tableaux.FriezePattern([1, 3, 4, 5, 1]).is_integral()
False
```

**is_positive()**

Return `True` if all elements of `self` are positive.

This implies that all entries of `CylindricalDiagram(self)` are positive.

**Warning:** There are orders on all fields. These may not be ordered fields as they may not be compatible with the field operations. This method is intended to be used with ordered fields only.

**EXAMPLES:**

```python
sage: path_tableaux.FriezePattern([1, 2, 7, 5, 3, 7, 4, 1]).is_positive()
True
sage: path_tableaux.FriezePattern([-3, 4, 5, 1]).is_positive()
False
sage: x = polygen(ZZ, 'x')
sage: K.<sqrt3> = NumberField(x^2 - 3)  # needs sage.rings.number_field
sage: path_tableaux.FriezePattern([1, sqrt3, 1], K).is_positive()  # needs sage.rings.number_field
True
```

```python
>>> from sage.all import *
```
\begin{verbatim}
path_tableaux.FriezePattern([Integer(1),-Integer(3),Integer(4),Integer(5),
                           -Integer(1)]).is_positive()
False

x = polygen(ZZ, 'x')
K = NumberField(x**Integer(2) - Integer(3), names=('sqrt3',)); (sqrt3,)
  = K._first_ngens(1) # needs sage.rings.number_field
path_tableaux.FriezePattern([Integer(1),sqrt3,Integer(1)], K).is_positive()
# needs sage.rings.number_field
True
\end{verbatim}

**is_skew()**

Return True if self is skew and False if not.

**EXAMPLES:**

\begin{verbatim}
sage: path_tableaux.FriezePattern([1,2,1,2,3,1]).is_skew()
False
tsage: path_tableaux.FriezePattern([2,2,1,2,3,1]).is_skew()
True
\end{verbatim}

\begin{verbatim}
from sage.all import *
path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),Integer(2),
                             -Integer(3),Integer(1)]).is_skew()
False
path_tableaux.FriezePattern([Integer(2),Integer(2),Integer(1),Integer(2),
                             -Integer(3),Integer(1)]).is_skew()
True
\end{verbatim}

**local_rule(i)**

Return the i-th local rule on self.

This interprets self as a list of objects. This method first takes the list of objects of length three consisting of the \((i - 1)\)-st, \(i\)-th and \((i + 1)\)-term and applies the rule. It then replaces the \(i\)-th object by the object returned by the rule.

**EXAMPLES:**

\begin{verbatim}
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: t.local_rule(3)
[1, 2, 5, 2, 3, 1]
sage: t = path_tableaux.FriezePattern([1,2,1,2,3,1])
sage: t.local_rule(0)
Traceback (most recent call last):
...
ValueError: 0 is not a valid integer
\end{verbatim}

\begin{verbatim}
from sage.all import *
path_tableaux.FriezePattern([Integer(1),Integer(2),Integer(1),
                             Integer(2),Integer(3),Integer(1)]).is_skew()
False
path_tableaux.FriezePattern([Integer(2),Integer(2),Integer(1),Integer(2),
                             -Integer(3),Integer(1)]).is_skew()
True
\end{verbatim}
```python
>>> t.local_rule(Integer(3))
[1, 2, 5, 2, 3, 1]
```

```python
>>> t = path_tableaux.FriezePattern([Integer(1), Integer(2), Integer(1), 
                                  -Integer(2), Integer(3), Integer(1)])
>>> t.local_rule(Integer(0))
Traceback (most recent call last):
... 
ValueError: 0 is not a valid integer
```

```
plot (model='UHP')

Plot the frieze as an ideal hyperbolic polygon.

This is only defined up to isometry of the hyperbolic plane.

We are identifying the boundary of the hyperbolic plane with the real projective line.

The option model must be one of

- 'UHP' – (default) for the upper half plane model
- 'PD' – for the Poincare disk model
- 'KM' – for the Klein model

The hyperboloid model is not an option as this does not implement boundary points.

EXAMPLES:
```
TypeError: '>' not supported between instances of 'NotANumber' and 'Pi'
sage: t.plot(model='KM')
Graphics object consisting of 18 graphics primitives

>>> from sage.all import *
>>> # needs sage.plot sage.symbolic
>>> t = path_tableaux.FriezePattern([Integer(1), Integer(2), Integer(7),
Integer(5), Integer(3), Integer(7), Integer(4), Integer(1)])
>>> t.plot()
Graphics object consisting of 18 graphics primitives
>>> t.plot(model='UHP')
Graphics object consisting of 18 graphics primitives
>>> t.plot(model='PD')
Traceback (most recent call last):
... 
TypeError: '>' not supported between instances of 'NotANumber' and 'Pi'

triangulation()

Plot a regular polygon with some diagonals.

If self is positive and integral then this will be a triangulation.

EXAMPLES:

sage: path_tableaux.FriezePattern([1,2,7,5,3,7,4,1]).triangulation() #...
needs sage.plot sage.symbolic
Graphics object consisting of 25 graphics primitives

sage: path_tableaux.FriezePattern([1,2,1/7,5,3]).triangulation() #...
needs sage.plot sage.symbolic
Graphics object consisting of 12 graphics primitives
sage: x = polygen(ZZ, 'x')
sage: K.<sqrt2> = NumberField(x^2 - 2)  # needs sage.rings.number_field
sage: path_tableaux.FriezePattern([1, sqrt2, 1, sqrt2, 3, 2*sqrt2, 5, 3*sqrt2, 1]), # needs sage.plot sage.rings.number_field sage.symbolic
....:   field=K).triangulation()
Graphics object consisting of 24 graphics primitives

>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1), Integer(2), Integer(7), Integer(5), Integer(3), Integer(7), Integer(4), Integer(1)]).triangulation()  # needs sage.plot sage.symbolic
Graphics object consisting of 25 graphics primitives

>>> x = polygen(ZZ, 'x')
>>> K = NumberField(x**Integer(2) - Integer(2), names=('sqrt2',)); (sqrt2,) = K._first_ngens(1)  # needs sage.rings.number_field
>>> path_tableaux.FriezePattern([Integer(1), sqrt2, Integer(1), sqrt2, Integer(3), Integer(2)*sqrt2, Integer(5), Integer(3)*sqrt2, Integer(1)]),  # needs sage.plot sage.rings.number_field sage.symbolic
....:   field=K).triangulation()
Graphics object consisting of 24 graphics primitives

width()

Return the width of self.

If the first and last terms of self are 1 then this is the length of self plus two and otherwise is undefined.

EXAMPLES:

sage: path_tableaux.FriezePattern([1, 2, 1, 2, 3, 1]).width()
8
sage: path_tableaux.FriezePattern([1, 2, 1, 2, 3, 4]).width() is None
True

>>> from sage.all import *
>>> path_tableaux.FriezePattern([Integer(1), Integer(2), Integer(1), Integer(2), Integer(3), Integer(1)]).width()
8
>>> path_tableaux.FriezePattern([Integer(1), Integer(2), Integer(1), Integer(2), Integer(3), Integer(4)]).width() is None
True

class sage.combinat.path_tableaux.frieze.FriezePatterns(field)
Bases: PathTableaux

The set of all frieze patterns.

EXAMPLES:

5.1. Comprehensive Module List
Element alias of \textit{FriezePattern}

5.1.162 Path Tableaux

This is an abstract base class for using local rules to construct rectification and the action of the cactus group [Wes2017].

This is a construction of the Henriques-Kamnitzer construction of the action of the cactus group on tensor powers of a crystal. This is also a generalisation of the Fomin growth rules, which are a version of the operations on standard tableaux which were previously constructed using jeu de taquin.

The basic operations are rectification, evacuation and promotion. Rectification of standard skew tableaux agrees with the rectification by jeu de taquin as does evacuation. Promotion agrees with promotion by jeu de taquin on rectangular tableaux but in general they are different.

class \texttt{sage.combinat.path_tableaux.path_tableau.CylindricalDiagram}(T)

Bases: \texttt{SageObject}

Cylindrical growth diagrams.

EXAMPLES:

\begin{verbatim}
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: path_tableaux.CylindricalDiagram(t)
[0, 1, 2, 3, 2, 1, 0]
[ , 0, 1, 2, 1, 0, 1, 0]
[ , , 0, 1, 0, 1, 2, 1, 0]
[ , , , 0, 1, 2, 3, 2, 1, 0]
[ , , , , 0, 1, 2, 1, 0, 1, 0]
[ , , , , , 0, 1, 0, 1, 2, 1, 0]
[ , , , , , , 0, 1, 2, 3, 2, 1, 0]
\end{verbatim}
```python
>>> from sage.all import *

>>> t = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3), Integer(2), Integer(1), Integer(0)])

>>> path_tableaux.CylindricalDiagram(t)

[0, 1, 2, 3, 2, 1, 0]
[ , 0, 1, 2, 1, 0, 1, 0]
[ , , 0, 1, 0, 1, 2, 1, 0]
[ , , , 0, 1, 2, 3, 2, 1, 0]
[ , , , , 0, 1, 0, 1, 2, 1, 0]
[ , , , , , 0, 1, 2, 3, 2, 1, 0]
[ , , , , , , 0, 1, 2, 3, 2, 1, 0]

pp()

A pretty print utility method.

EXAMPLES:

sage: t = path_tableaux.DyckPath([0, 1, 2, 3, 2, 1, 0])
sage: path_tableaux.CylindricalDiagram(t).pp()

0 1 2 3 2 1 0
 0 1 2 1 0 1 0
   0 1 0 1 2 1 0
      0 1 2 3 2 1 0
         0 1 2 1 0 1 0
            0 1 0 1 2 1 0
               0 1 2 3 2 1 0

sage: t = path_tableaux.FriezePattern([1, 3, 4, 5, 1])
sage: path_tableaux.CylindricalDiagram(t).pp()

0 1 3 4 5 1 0
 0 1 5/3 7/3 2/3 1 0
   0 1 2 1 3 1 0
      0 1 1 4 5/3 1 0
         0 1 5 7/3 2 1 0
            0 1 2/3 1 1 1 0
               0 1 3 4 5 1 0

>>> from sage.all import *

>>> t = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3), Integer(2), Integer(1), Integer(0)])

>>> path_tableaux.CylindricalDiagram(t).pp()

0 1 2 3 2 1 0
 0 1 2 1 0 1 0
   0 1 0 1 2 1 0
      0 1 2 3 2 1 0
         0 1 2 1 0 1 0
            0 1 0 1 2 1 0
               0 1 2 3 2 1 0

>>> t = path_tableaux.FriezePattern([Integer(1), Integer(3), Integer(4), Integer(5), Integer(1)])

>>> path_tableaux.CylindricalDiagram(t).pp()

0 1 3 4 5 1 0
 0 1 5/3 7/3 2/3 1 0
   0 1 2 1 3 1 0
      0 1 1 4 5/3 1 0
         0 1 5 7/3 2 1 0
            0 1 3 4 5 1 0
```

(continues on next page)
class sage.combinat.path_tableaux.path_tableau.PathTableau

Bases: ClonableArray

This is the abstract base class for a path tableau.

cactus (i, j)

Return the action of the generator \( s_{i,j} \) of the cactus group on self.

INPUT:

- \( i \) – a positive integer
- \( j \) – a positive integer weakly greater than \( i \)

EXAMPLES:

```
sage: t = path_tableaux.DyckPath([0, 1, 2, 3, 2, 1, 0])
sage: t.cactus(1, 5)
[0, 1, 2, 1, 0, 1, 0]
sage: t.cactus(1, 7) == t.evacuation()
True
sage: t.cactus(1, 7).cactus(1, 6) == t.promotion()
True
```

```
>>> from sage.all import *

>>> t = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3), Integer(2), Integer(1), Integer(0)])

>>> t.cactus(Integer(1), Integer(5))
[0, 1, 2, 1, 0, 1, 0]

>>> t.cactus(Integer(1), Integer(6))
[0, 1, 2, 1, 0, 1, 0]

>>> t.cactus(Integer(1), Integer(7)) == t.evacuation()
True

>>> t.cactus(Integer(1), Integer(7)).cactus(Integer(1), Integer(6)) == t.promotion()
True
```

commutor (other, verbose=False)

Return the commutor of self with other.

If verbose=True then the function will print the rectangle.

EXAMPLES:

```
sage: t1 = path_tableaux.DyckPath([0, 1, 2, 3, 2, 1, 0])
sage: t2 = path_tableaux.DyckPath([0, 1, 2, 1, 0])
sage: t1.commutor(t2)
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
sage: t1.commutor(t2, verbose=True)
```
```python
>>> from sage.all import *

>>> t1 = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3),
                               Integer(2), Integer(1), Integer(0)]

>>> t2 = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(1),
                               Integer(0)]

>>> t1.commutor(t2)
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])

>>> t1.commutor(t2, verbose=True)
[0, 1, 2, 1, 0]
[1, 2, 3, 2, 1]
[2, 3, 4, 3, 2]
[3, 4, 5, 4, 3]
[2, 3, 4, 3, 2]
[1, 2, 3, 2, 1]
[0, 1, 2, 1, 0]
([0, 1, 2, 1, 0], [0, 1, 2, 3, 2, 1, 0])
```

dual_equivalence_graph()  

Return the graph with vertices the orbit of self and edges given by the action of the cactus group generators.  

In most implementations the generators $s_i, s_{i+1}$ will act as the identity operators. The usual dual equivalence graphs are given by replacing the label $i, i+2$ by $i$ and removing edges with other labels.

EXAMPLES:

```python
sage: s = path_tableaux.DyckPath([0, 1, 2, 3, 2, 3, 2, 1, 0])
sage: s.dual_equivalence_graph().edges(sort=True)  # needs sage.graphs
```

(continues on next page)
Combinatorics, Release 10.4

(continued from previous page)

```python
>>> from sage.all import *
```

```python
s = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3),
                           Integer(2), Integer(1), Integer(0)])
```

```python
s.dual_equivalence_graph().adjacency_matrix()
```

```python
[0 1 1 1 0 1 0 1 1 0 0 0 0 0]
[0 1 0 1 1 1 1 0 1 0 0 1 1 0]
[0 1 1 0 0 1 1 1 1 1 0 1 1 0]
[0 1 0 1 1 1 0 1 0 1 0 1 1 1]
[0 1 1 0 0 0 1 1 1 1 1 0 1 1]
[0 1 0 1 1 0 1 1 1 1 1 0 1 1]
[0 1 0 1 1 1 1 0 1 1 1 1 0 0 0]
[0 1 0 1 1 1 0 0 1 1 1 0 1 1 1]
[0 1 1 0 0 1 1 1 1 1 1 0 1 1 0]
[0 1 0 1 1 0 1 1 1 1 1 0 1 1 0]
[0 1 0 0 1 0 1 0 0 1 1 1 0 1 1]
[0 1 0 1 1 1 1 0 1 1 1 1 1 1 0]
[0 0 0 0 1 0 1 0 0 1 1 1 1 0 0]
```

```python
s = path_tableaux.DyckPath([Integer(0), Integer(1), Integer(2), Integer(3),
                           Integer(2), Integer(1), Integer(0)])
```

```python
t.evacuation()
```

```python
[0, 1, 2, 3, 2, 1, 0]
```
Return the final shape of self.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.final_shape()
0

>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
    →Integer(2),Integer(1),Integer(0)])
>>> t.final_shape()
0
```

initial_shape()

Return the initial shape of self.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.initial_shape()
0

>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
    →Integer(2),Integer(1),Integer(0)])
>>> t.initial_shape()
0
```

local_rule(i)

This is the abstract local rule defined in any coboundary category.

This has input a list of objects. This method first takes the list of objects of length three consisting of the

\((i - 1)\)-st, \(i\)-th and \((i + 1)\)-term and applies the rule. It then replaces the \(i\)-th object by the object returned
by the rule.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.local_rule(3)
[0, 1, 2, 1, 2, 1, 0]

>>> from sage.all import *
>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
    →Integer(2),Integer(1),Integer(0)])
>>> t.local_rule(Integer(3))
[0, 1, 2, 1, 2, 1, 0]
```

orbit()

Return the orbit of self under the action of the cactus group.

EXAMPLES:

```python
sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.orbit()
{[0, 1, 0, 1, 0, 1, 0],
 [0, 1, 0, 1, 2, 1, 0],
 ..., [0, 1, 0, 2, 0, 2, 0],
 [0, 1, 0, 2, 2, 2, 0],
 [0, 1, 0, 2, 2, 1, 0],
 [0, 1, 0, 2, 1, 2, 0],
 [0, 1, 0, 1, 2, 2, 0],
 [0, 1, 0, 1, 1, 2, 0],
 [0, 1, 0, 1, 0, 2, 0]}
```
from sage.all import *

>>> t = path_tableaux.DyckPath([Integer(0),Integer(1),Integer(2),Integer(3),
   →Integer(2),Integer(1),Integer(0)])

>>> t.orbit()
{[0, 1, 0, 1, 0, 1, 0],
 [0, 1, 0, 1, 2, 1, 0],
 [0, 1, 2, 1, 0, 1, 0],
 [0, 1, 2, 1, 2, 1, 0],
 [0, 1, 2, 3, 2, 1, 0]}

promotion()
Return the promotion operator applied to self.

EXAMPLES:

sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.promotion()
[0, 1, 2, 1, 0, 1, 0]

size()
Return the size or length of self.

EXAMPLES:

sage: t = path_tableaux.DyckPath([0,1,2,3,2,1,0])
sage: t.size()
7

class sage.combinat.path_tableaux.path_tableau.PathTableaux
   Bases: UniqueRepresentation, Parent

The abstract parent class for PathTableau.
5.1.163 Semistandard Tableaux

This is an implementation of the abstract base class `sage.combinat.path_tableaux.path_tableau.PathTableau`. This implementation is for semistandard tableaux, represented as a chain of partitions (essentially, the Gelfand-Tsetlin pattern). This generalises the jeu de taquin operations of rectification, promotion, evacuation from standard tableaux to semistandard tableaux. The local rule is the Bender-Knuth involution.

**EXAMPLES:**

```python
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1], ....: [3,3,2,1], [4,3,3,1,0]])
sage: pt.promotion()
[(), (2,), (3, 1), (3, 2, 1), (4, 3, 1, 0), (4, 3, 3, 1, 0)]
sage: pt.evacuation()
[(), (2,), (4, 0), (4, 2, 0), (4, 3, 1, 0), (4, 3, 3, 1, 0)]

sage: pt2 = path_tableaux.SemistandardPathTableau([3,2], [3,3,1], ....: [3,3,2,1], [4,3,3,1,0])
sage: pt1 = path_tableaux.SemistandardPathTableau([3], [3,2])
sage: pt1.commutor(pt2, verbose=True)
[(3, 2), (3, 3, 1), (3, 3, 2, 1), (4, 3, 3, 1, 0)]
[(3,), (3, 2), (3, 2, 2), (4, 3, 2, 0)]
[(), (2,), (2, 2), (4, 2, 0)]
```

```python
sage: st = SkewTableau([[None, None, None, 4, 4, 5, 6, 7], ....: [None, 4, 5, 8, 8, 9], [None, 6, 7, 10], [None, 8, 8, 11], ....: [None], [4]])
sage: pt = path_tableaux.SemistandardPathTableau(st)
sage: bk = [sk.bender_knuth_involution(i+1) for i in range(10)]
sage: lr = [pt.local_rule(i+1) for i in range(10)]
sage: [r.to_tableau() for r in lr] == bk
True
```

```python
>>> from sage.all import *

\]

\[
\text{Bases: PathTableau}
\]
An instance is a sequence of lists. Usually the entries will be non-negative integers in which case this is the chain of partitions of a (skew) semistandard tableau. In general the entries are elements of an ordered abelian group; each list is weakly decreasing and successive lists are interleaved.

**INPUT:**

Can be any of the following

- a sequence of partitions
- a sequence of lists/tuples
- a semistandard tableau
- a semistandard skew tableau
- a Gelfand-Tsetlin pattern

**EXAMPLES:**

```python
sage: path_tableaux.SemistandardPathTableau([[], [2], [2,1]])
[(), (2,), (2, 1)]

sage: gt = GelfandTsetlinPattern([[2,1], [2]])
sage: path_tableaux.SemistandardPathTableau(gt)
[(), (2,), (2, 1)]

sage: st = SemistandardTableau([[1,1], [2]])
sage: path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

sage: st = SkewTableau([[1,1], [2]])
sage: path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

sage: st = SkewTableau([[None,1,1], [2]])
sage: path_tableaux.SemistandardPathTableau(st)
[(1,), (3, 0), (3, 1, 0)]

sage: path_tableaux.SemistandardPathTableau([[], [5/2], [7/2,2]])
[(), (5/2,), (7/2, 2)]

sage: path_tableaux.SemistandardPathTableau([[], [2.5], [3.5,2]])
[(), (2.50000000000000,), (3.50000000000000, 2)]

>>> from sage.all import *

>>> path_tableaux.SemistandardPathTableau([[], [Integer(2)], [Integer(2),
  →Integer(1)]])
[(), (2,), (2, 1)]

>>> gt = GelfandTsetlinPattern([[Integer(2),Integer(1)], [Integer(2)])

>>> path_tableaux.SemistandardPathTableau(gt)
[(), (2,), (2, 1)]

>>> st = SemistandardTableau([[Integer(1),Integer(1)], [Integer(2)]])

>>> path_tableaux.SemistandardPathTableau(st)
[(), (2,), (2, 1)]

>>> st = SkewTableau([[Integer(1),Integer(1)], [Integer(2)])

>>> path_tableaux.SemistandardPathTableau(st)
```

(continues on next page)
check()  
Check that self is a valid path.

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [3], [2,2]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: [(), (3,), (2, 2)] does not satisfy the required inequalities in row 1
```

```
sage: path_tableaux.SemistandardPathTableau([[], [3/2], [2,5/2]])  # indirect doctest
Traceback (most recent call last):
...
ValueError: [(), (3/2,), (2, 5/2)] does not satisfy the required inequalities in row 1
```

is_integral()  
Return True if all entries are non-negative integers.

EXAMPLES:

```
sage: path_tableaux.SemistandardPathTableau([[], [3], [3,2]]).is_integral()  
True
```

```
sage: path_tableaux.SemistandardPathTableau([[], [5/2], [7/2,2]]).is_  
(continues on next page)
integral()
False
sage: path_tableaux.SemistandardPathTableau([[], [3], [3,-2]]).is_integral()
False

>>> from sage.all import *
>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
˓→Integer(2)]]).is_integral()
True
>>> path_tableaux.SemistandardPathTableau([[], [Integer(5)/Integer(2)],
˓→[Integer(7)/Integer(2),Integer(2)]]).is_integral()
False
>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
˓→Integer(2)]]).is_integral()
False

is_skew()
Return True if self is skew.

EXAMPLES:

sage: path_tableaux.SemistandardPathTableau([[], [2]]).is_skew()
False
sage: path_tableaux.SemistandardPathTableau([[], [2,1]]).is_skew()
True

local_rule(i)
This is the Bender-Knuth involution.

This is implemented by toggling the entries of the i-th list. The allowed range for i is 0 < i < len(self)-1 so any row except the first and last can be changed.

EXAMPLES:

sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2],
˓→[3,3,1], [3,3,2,1]])
sage: pt.local_rule(1)
[(), (2,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
sage: pt.local_rule(2)
[(), (3,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]
sage: pt.local_rule(3)
[(), (3,), (3, 2), (3, 2, 2), (3, 3, 2, 1)]

>>> from sage.all import *
>>> pt = path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
˓→Integer(2)],
˓→[Integer(3),Integer(3),Integer(1)], [Integer(3),Integer(3),Integer(2),Integer(1)]]
>>> pt.local_rule(Integer(1))
[(), (2,), (3, 2), (3, 3, 1), (3, 3, 2, 1)]

(continues on next page)
>> pt.local_rule(Integer(2))
[(0, (3,)), (3, (2,)), (3, (3, 1), (3, 3, 2, 1))]

>> pt.local_rule(Integer(3))
[(0, (3,)), (3, (2,)), (3, (3, 2, 1), (3, 3, 2, 1))]

**rectify** *(inner=None, verbose=False)*

Rectify self.

This gives the usual rectification of a skew standard tableau and gives a generalisation to skew semistandard tableaux. The usual construction uses jeu de taquin but here we use the Bender-Knuth involutions.

**EXAMPLES:**

```python
sage: st = SkewTableau([[None, None, None, 4], [None, None, 1, 6], ...: [None, None, 5], [2, 3]])

sage: path_tableaux.SemistandardPathTableau(st).rectify()
[(1), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0, 0)]

sage: path_tableaux.SemistandardPathTableau(st).rectify(verbos=True)
[(3, 2, 2), (3, 3, 2, 0), (3, 3, 2, 1, 0), (3, 3, 2, 2, 0, 0),
 (4, 3, 2, 2, 0, 0, 0), (4, 3, 3, 2, 0, 0, 0, 0), (4, 4, 3, 2, 0, 0, 0, 0, 0)]

sage: path_tableaux.SemistandardPathTableau(st).rectify()
[(1), (1, 1), (2, 1, 0), (3, 1, 0, 0), (3, 2, 0, 0, 0), (4, 2, 0, 0, 0, 0)]

sage: path_tableaux.SemistandardPathTableau(st).rectify(verbos=True)
[(3, 2, 2), (3, 3, 2, 0), (3, 3, 2, 1, 0), (3, 3, 2, 2, 0, 0),
 (4, 3, 2, 2, 0, 0, 0), (4, 3, 3, 2, 0, 0, 0, 0), (4, 4, 3, 2, 0, 0, 0, 0, 0)]
```

**size()**

Return the size or length of *self*.

**EXAMPLES:**

```python
sage: path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1], [3,3,2,1]]).size()
5
```
Combinatorics, Release 10.4

```python
>>> from sage.all import *

>>> path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
   →Integer(2)], [Integer(3),Integer(3),Integer(1)], [Integer(3),Integer(3),
   →Integer(2),Integer(1)])].size()
5

to_pattern()
Convert self to a Gelfand-Tsetlin pattern.

EXAMPLES:

```
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1],
   ....: [3,3,2,1], [4,3,3,1]])
sage: pt.to_pattern()
[[4, 3, 3, 1, 0], [3, 3, 2, 1], [3, 3, 1], [3, 2], [3]]
```

```python
>>> from sage.all import *

>>> pt = path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
   →Integer(2)], [Integer(3),Integer(3),Integer(1),
   ...: [Integer(3),Integer(3),Integer(2),Integer(1)], [Integer(4),Integer(3),
   Integer(3),Integer(1)])]

>>> pt.to_pattern()
[[4, 3, 3, 1, 0], [3, 3, 2, 1], [3, 3, 1], [3, 2], [3]]
```
to_tableau()
Convert self to a SemistandardTableau.
The SemistandardSkewTableau is not implemented so this returns a SkewTableau

EXAMPLES:

```
sage: pt = path_tableaux.SemistandardPathTableau([[], [3], [3,2], [3,3,1],
   ....: [3,3,2,1], [4,3,3,1,0]])
sage: pt.to_tableau()
[[1, 1, 1, 5], [2, 2, 3], [3, 4, 5], [4]]
```

```python
>>> from sage.all import *

>>> pt = path_tableaux.SemistandardPathTableau([[], [Integer(3)], [Integer(3),
   →Integer(2)], [Integer(3),Integer(3),Integer(1),
   ...: [Integer(3),Integer(3),Integer(2),Integer(1)], [Integer(4),Integer(3),
   Integer(3),Integer(1),
   →Integer(0)])]

>>> pt.to_tableau()
[[1, 1, 1, 5], [2, 2, 3], [3, 4, 5], [4]]
```

class sage.combinat.path_tableaux.semistandard.SemistandardPathTableaux

Bases: PathTableaux

The parent class for SemistandardPathTableau.

Element

  alias of SemistandardPathTableau
```
5.1.164 Plane Partitions

AUTHORS:

• Jang Soo Kim (2016): Initial implementation
• Jessica Striker (2016): Added additional methods
• Kevin Dilks (2021): Added symmetry classes

class sage.combinat.plane_partition.PlanePartition(parent, pp, check=True)
    Bases: ClonableArray

A plane partition.

A plane partition is a stack of cubes in the positive orthant.

INPUT:

• PP – a list of lists which represents a tableau
• box_size – (optional) a list \([A, B, C]\) of 3 positive integers, where \(A, B, C\) are the lengths of the box in the \(x\)-axis, \(y\)-axis, \(z\)-axis, respectively; if this is not given, it is determined by the smallest box bounding \(PP\)

OUTPUT:

The plane partition whose tableau representation is \(PP\).

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP
Plane partition [[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

```python
>>> from sage.all import *
...
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
               ...,[Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP
Plane partition [[4, 3, 3, 1], [2, 1, 1], [1, 1]]
```

bounding_box()

Return the smallest box \((a, b, c)\) that \(self\) is contained in.

EXAMPLES:

```python
sage: PP = PlanePartition([[5,2,1,1], [2,2], [2]])
sage: PP.bounding_box()
(3, 4, 5)
```

```python
>>> from sage.all import *
...
>>> PP = PlanePartition([[Integer(5),Integer(2),Integer(1),Integer(1)],
               ...,[Integer(2),Integer(2)], [Integer(2)]])
>>> PP.bounding_box()
(3, 4, 5)
```

cells()

Return the list of cells inside \(self\).

Each cell is a tuple.

EXAMPLES:
Combinatorics, Release 10.4

sage: PP = PlanePartition([[3,1],[2]])
sage: PP.cells()
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 0), (1, 0, 0), (1, 0, 1)]

>>> from sage.all import *

>>> PP = PlanePartition([[Integer(3),Integer(1)],[Integer(2)]]))

>>> PP.cells()
[(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 0), (1, 0, 0), (1, 0, 1)]

check()

Check to see that self is a valid plane partition.

EXAMPLES:

sage: a = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: a.check()

sage: b = PlanePartition([[1,2],[1]])
Traceback (most recent call last):
  ... ValueError: not weakly decreasing along rows

sage: c = PlanePartition([[1,1],[2]])
Traceback (most recent call last):
  ... ValueError: not weakly decreasing along columns

sage: d = PlanePartition([[2,-1],[-2]])
Traceback (most recent call last):
  ... ValueError: entries not all nonnegative

sage: e = PlanePartition([[3/2,1],[RealNumber(.5)])
Traceback (most recent call last):
  ... ValueError: entries not all integers

complement(tableau_only=False)

Return the complement of self.
If the parent of \texttt{self} consists only of partitions inside a given box, then the complement is taken in this box. Otherwise, the complement is taken in the smallest box containing the plane partition. The empty plane partition with no box specified is its own complement.

If \texttt{tableau_only} is set to \texttt{True}, then only the tableau consisting of the projection of boxes size onto the $xy$-plane is returned instead of a \texttt{PlanePartition}. This output will not have empty trailing rows or trailing zeros removed.

**EXAMPLES:**

```python
sage: PP = PlanePartition([[4,3,3,1], [2,1,1], [1,1]])
sage: PP.complement()
Plane partition [[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1]]
sage: PP.complement(True)
[[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]
```

```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4), Integer(3), Integer(3), Integer(1)],
                      [Integer(2), Integer(1), Integer(1), Integer(1)],
                      [Integer(1), Integer(1), Integer(1), Integer(1)]])
>>> PP.complement()
Plane partition [[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1]]
>>> PP.complement(True)
[[4, 4, 3, 3], [4, 3, 3, 2], [3, 1, 1, 0]]
```

\texttt{contains(PP)}

Return \texttt{True} if \texttt{PP} is a plane partition that fits inside \texttt{self}.

Specifically, \texttt{self} contains \texttt{PP} if, for all $i, j$, the height of \texttt{PP} at $ij$ is less than or equal to the height of \texttt{self} at $ij$.

**EXAMPLES:**

```python
sage: P1 = PlanePartition([[5,4,3], [3,2,2], [1]])
sage: P2 = PlanePartition([[3,2], [1,1], [0,0], [0,0]])
sage: P3 = PlanePartition([[5,5,5], [2,1,0]])
sage: P1.contains(P2)
True
sage: P2.contains(P1)
False
sage: P1.contains(P3)
False
```

```python
>>> from sage.all import *
>>> P1 = PlanePartition([[Integer(5), Integer(4), Integer(3)],
                      [Integer(3), Integer(2), Integer(2)],
                      [Integer(1)]])
>>> P2 = PlanePartition([[Integer(3), Integer(2)],
                      [Integer(1), Integer(1), Integer(1)],
                      [Integer(0), Integer(0), Integer(0)]])
>>> P3 = PlanePartition([[Integer(5), Integer(5), Integer(5)],
                      [Integer(2), Integer(1), Integer(0)]])
>>> P1.contains(P2)
True
>>> P2.contains(P1)
False
>>> P1.contains(P3)
False
```

(continues on next page)
cyclically_rotate(preserve_parent=False)

Return the cyclic rotation of self.

By default, if the parent of self consists of plane partitions inside an a \times b \times c box, the result will have a parent consisting of partitions inside a c \times a \times b box, unless the optional parameter preserve_parent is set to True. Enabling this setting may give an element that is not an element of its parent.

EXAMPLES:

```python
sage: PlanePartition([[3,2,1],[2,2],[2]]).cyclically_rotate()
Plane partition [[3, 3, 1], [2, 2], [1]]
sage: PP = PlanePartition([[4,1],[1],[1]])
sage: PP.cyclically_rotate()
Plane partition [[3, 1, 1, 1], [1]]
sage: PP == PP.cyclically_rotate().cyclically_rotate().cyclically_rotate()
True
```

is_CSPP()

Return whether self is a cyclically symmetric plane partition.

A plane partition is cyclically symmetric if its x, y, and z tableaux are all equal.

EXAMPLES:
Combinatorics, Release 10.4

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSPP()
False
sage: PP = PlanePartition([[3,2,2],[3,1,0],[1,1,0]])
sage: PP.is_CSPP()
True
```

```python
>>> from sage.all import *

>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
                      [Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_CSPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(2),Integer(2)],[Integer(3),
                      Integer(2),Integer(1)],[Integer(1),Integer(1),Integer(0)]])
>>> PP.is_CSPP()
True
```

**is_CSSCPP()**

Return whether self is a cyclically symmetric and self-complementary plane partition.

**EXAMPLES:**

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSSCPP()
False
sage: PP = PlanePartition([[4,4,4,1],[3,3,2,1],[3,2,1,1],[3,0,0,0]])
sage: PP.is_CSSCPP()
True
```

```python
>>> from sage.all import *

>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
                      [Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_CSSCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(4),Integer(1)],
                      [Integer(3),Integer(3),Integer(2),Integer(1)],[Integer(3),Integer(0),Integer(0),Integer(0)]])
>>> PP.is_CSSCPP()
True
```

**is_CSTCPP()**

Return whether self is a cyclically symmetric and transpose-complementary plane partition.

**EXAMPLES:**

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSTCPP()
False
sage: PP = PlanePartition([[4,4,4,1],[3,3,2,1],[3,2,1,1],[3,0,0,0]])
sage: PP.is_CSTCPP()
True
```

```python
>>> from sage.all import *

>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
                      [Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]])
>>> PP.is_CSTCPP()
False
>>> PP = PlanePartition([[Integer(4),Integer(4),Integer(4),Integer(1)],
                      [Integer(3),Integer(3),Integer(2),Integer(1)],[Integer(3),Integer(0),Integer(0),Integer(0)]])
```
is_CSTCPP()

Return whether self is a self-complementary plane partition.

Note that the complement of a plane partition (and thus the property of being self-complementary) is dependent on the choice of a box that it is contained in. If no parent/bounding box is specified, the box is taken to be the smallest box that contains the plane partition.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_CSTCPP()
False
```

is_SCPP()

Return whether self is a self-complementary plane partition.

A plane partition is symmetric if the corresponding tableau is symmetric about the diagonal.

EXAMPLES:

```python
sage: PP = PlanePartition([[3,3,2],[3,3,2],[2,2,2]])
sage: PP.is_SCPP()
True
```

is_SPP()

Return whether self is a symmetric plane partition.

A plane partition is symmetric if the corresponding tableau is symmetric about the diagonal.

EXAMPLES:

```python
sage: PP = PlanePartition([[3,2,1],[2,0,0]])
```
is_SSCPP()

Return whether self is a symmetric, self-complementary plane partition.

EXAMPLES:

```python
sage: PP = PlanePartition([[4, 3, 1], [2, 1, 1], [1, 1]])
sage: PP.is_SSCPP()
False
sage: PP = PlanePartition([[4, 3, 2], [3, 2, 1], [3, 2, 1], [2, 1, 0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[2, 1], [1, 0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4, 3, 2], [3, 2, 1], [2, 1, 0]])
sage: PP.is_SSCPP()
True
sage: PP = PlanePartition([[4, 2, 2], [2, 2, 2], [2, 2, 2], [2, 2, 2]])
```
sage: PP.is_SSCPP()
True

>>> from sage.all import *
>>>
PP = PlanePartition(
[[Integer(4),Integer(3),Integer(3),Integer(1)],
 →[Integer(2),Integer(1),Integer(1),[Integer(1),Integer(1)]]])
>>>
PP.is_SSCPP()
False
>>>
PP = PlanePartition(
[[Integer(4),Integer(3),Integer(3),Integer(2)],
 →[Integer(3),Integer(2),Integer(2),Integer(1)],[Integer(3),Integer(2),
 →Integer(2),Integer(1)],[Integer(2),Integer(1)],[Integer(1),Integer(0)]])
>>>
PP.is_SSCPP()
True
>>>
PP = PlanePartition(
[[Integer(4),Integer(2),Integer(2),Integer(2)],[Integer(2),Integer(2),
 →Integer(2),Integer(2)],
 →[Integer(2),Integer(2),Integer(2),Integer(0)],[Integer(2),Integer(2),
 →Integer(2),Integer(0)],[Integer(2),Integer(0),Integer(0)]])
>>>
PP.is_SSCPP()
True

is_TCPP()

Return whether self is a transpose-complementary plane partition.

EXAMPLES:

sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])

sage: PP.is_TCPP()
False

sage: PP = PlanePartition([[4,4,3,2],[4,4,2,1],[4,2,0,0],[2,0,0,0]])

sage: PP.is_TCPP()
True

>>> from sage.all import *
>>>
PP = PlanePartition(
[[Integer(4),Integer(4),Integer(3),Integer(2)],
 →[Integer(4),Integer(4),Integer(2),Integer(2)],[Integer(4),Integer(2),
 →Integer(2),Integer(2)],
 →[Integer(2),Integer(2),Integer(2),Integer(0)],[Integer(2),Integer(0),Integer(0)]])
>>>
PP.is_TCPP()
True

is_TSPP()

Return whether self is a totally symmetric plane partition.

A plane partition is totally symmetric if it is both symmetric and cyclically symmetric.

EXAMPLES:
Combinatorics, Release 10.4

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSSCPP()
False
sage: PP = PlanePartition([[3,3,3],[3,3,2],[3,2,1]])
sage: PP.is_TSSCPP()
True

>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
[Integer(2),Integer(1),Integer(1),Integer(1)],[Integer(1),Integer(1),Integer(1)]])
>>> PP.is_TSSCPP()
False
>>> PP = PlanePartition([[Integer(3),Integer(3),Integer(3)],[Integer(3),
[Integer(2),Integer(2),Integer(2)],[Integer(3),Integer(2),Integer(1),
[Integer(2),Integer(1),Integer(0),Integer(0)]])
>>> PP.is_TSSCPP()
True
```

### is_TSSCPP()

Return whether `self` is a totally symmetric self-complementary plane partition.

**EXAMPLES:**

```
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.is_TSSCPP()
False
sage: PP = PlanePartition([[4,4,3,2],[4,3,2,1],[3,2,1,0],[2,1,0,0]])
sage: PP.is_TSSCPP()
True
```

### maximal_boxes()

Return the coordinates of the maximal boxes of `self`.

The maximal boxes of a plane partitions are the boxes that can be removed from a plane partition and still yield a valid plane partition.

**EXAMPLES:**

```
sage: sorted(PlanePartition([[3,2,1],[2,2],[2]]).maximal_boxes())
[[0, 0, 2], [0, 2, 0], [1, 1, 1], [2, 0, 1]]
sage: sorted(PlanePartition([[2,1],[1],[1]]).maximal_boxes())
[[0, 0, 1], [0, 1, 0], [2, 0, 0]]
```

```python
>>> from sage.all import *
>>> sorted(PlanePartition([[Integer(3),Integer(2),Integer(1)],[Integer(2),
[Integer(2)],[Integer(2)]]).maximal_boxes())
(continues on next page)
```
number_of_boxes()

Return the number of boxes in the plane partition.

EXAMPLES:

```python
sage: PP = PlanePartition([[3,1],[2]])
sage: PP.number_of_boxes()
6
```

```
from sage.all import *
PP = PlanePartition([[Integer(3),Integer(1)], [Integer(2)]])
PP.number_of_boxes()
6
```

plot(show_box=False, colors=None)

Return a plot of self.

INPUT:

- `show_box` – boolean (default: False); if True, also shows the visible tiles on the $xy$-, $yz$-, $zx$-planes
- `colors` – (default: ["white", "lightgray", "darkgray"])) list [A, B, C] of 3 strings representing colors

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot()
```

```
needs sage.plot
Graphics object consisting of 27 graphics primitives
```

```python
from sage.all import *
PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
                     [Integer(2),Integer(1),Integer(1)], [Integer(1),Integer(1)]])
PP.plot()  #...
```

```
needs sage.plot
Graphics object consisting of 27 graphics primitives
```

plot3d(colors=None)

Return a 3D-plot of self.

INPUT:

- `colors` – (default: ["white", "lightgray", "darkgray"])) list [A, B, C] of 3 strings representing colors

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.plot3d()
```

```
#...
```

```
needs sage.plot
Graphics3d Object
```
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4), Integer(3), Integer(3), Integer(1)],
                      [Integer(2), Integer(1), Integer(1), Integer(1)],
                      [Integer(1), Integer(1), Integer(1), Integer(1)]]
>>> PP.plot3d()
# needs sage.plot
Graphics3d Object

pp (show_box=False)

Return a pretty print of the plane partition.

INPUT:

- show_box – boolean (default: False); if True, also shows the visible tiles on the xy-, yz-, zx-planes

OUTPUT:

A pretty print of the plane partition.

EXAMPLES:

sage: PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]]).pp()

```
    /
   /\ 
  /  \ 
 /_____/ 
```

sage: PlanePartition([[4, 3, 3, 1], [2, 1, 1], [1, 1]]).pp(True)

```
   ______
  /_______
 /_______/
 /_______/
 /_______/
```

(continues on next page)
to_orderIdeal()

Return the order ideal corresponding to self.

Todo: As many families of symmetric plane partitions are in bijection with order ideals in an associated poset, this function could feasibly have options to send symmetric plane partitions to the associated order ideal in that poset, instead.

EXAMPLES:

```sage
PlanePartition([[3, 2, 1], [2, 2], [2]]).to_orderIdeal()  # needs sage.graphs sage.modules
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (0, 1, 1), (0, 2, 0),
 (1, 0, 0), (1, 0, 1), (1, 1, 0), (1, 1, 1), (2, 0, 0), (2, 0, 1)]
```

```sage
PlanePartition([[2, 1], [1], [1]]).to_orderIdeal()  # needs sage.graphs sage.modules
[(0, 0, 0), (0, 0, 1), (0, 1, 0), (1, 0, 0), (2, 0, 0)]
```

```sage
from sage.all import *
from sage.all import *
```
EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.transpose()
Plane partition [[4, 2, 1], [3, 1, 1], [3, 1], [1]]
sage: PP.transpose(True)
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]

sage: PPP = PlanePartitions([1, 2, 3])
sage: PP = PPP([[1, 1]])
sage: PT = PP.transpose(); PT
Plane partition [[1], [1]]
sage: PT.parent()
Plane partitions inside a 2 x 1 x 3 box
```

```python
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
                      [Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]]
>>> PP.transpose()
Plane partition [[4, 2, 1], [3, 1, 1], [3, 1], [1]]
>>> PP.transpose(True)
[[4, 2, 1], [3, 1, 1], [3, 1, 0], [1, 0, 0]]

>>> PPP = PlanePartitions([Integer(1), Integer(2), Integer(3)])
>>> PP = PPP([[Integer(1), Integer(1)])
>>> PT = PP.transpose(); PT
Plane partition [[1], [1]]
>>> PT.parent()
Plane partitions inside a 2 x 1 x 3 box
```

**x_tableau**

Return the projection of self in the x direction.

If `tableau` is set to False, then only the list of lists consisting of the projection of boxes size onto the yz-plane is returned instead of a `Tableau` object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
```

```python
>>> from sage.all import *
>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
                      [Integer(2),Integer(1),Integer(1)],[Integer(1),Integer(1)]]
>>> PP.x_tableau()
[[3, 2, 1, 1], [3, 1, 1, 0], [2, 1, 1, 0], [1, 0, 0, 0]]
```

**y_tableau**

Return the projection of self in the y direction.

If `tableau` is set to False, then only the list of lists consisting of the projection of boxes size onto the xz-plane is returned instead of a `Tableau` object. This output will not have empty trailing rows or trailing zeros removed.

EXAMPLES:
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])
sage: PP.y_tableau()
[[4, 3, 2], [3, 1, 0], [3, 0, 0], [1, 0, 0]]

```python
>>> from sage.all import *

>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
    →[Integer(2),Integer(1),Integer(1),Integer(1)],[Integer(1),Integer(1)]])

>>> PP.y_tableau()
[[4, 3, 2], [3, 1, 0], [3, 0, 0], [1, 0, 0]]
```

**z_tableau** *(tableau=True)*

Return the projection of self in the z direction.

If tableau is set to False, then only the list of lists consisting of the projection of boxes size onto the \(xy\)-plane is returned instead of a Tableau object. This output will not have empty trailing rows or trailing zeros removed.

**EXAMPLES:**

```python
sage: PP = PlanePartition([[4,3,3,1],[2,1,1],[1,1]])

sage: PP.z_tableau()
[[4, 3, 3, 1], [2, 1, 1, 0], [1, 1, 0, 0]]
```

```python
>>> from sage.all import *

>>> PP = PlanePartition([[Integer(4),Integer(3),Integer(3),Integer(1)],
    →[Integer(2),Integer(1),Integer(1),Integer(1)],[Integer(1),Integer(1)]])

>>> PP.z_tableau()
[[4, 3, 3, 1], [2, 1, 1, 0], [1, 1, 0, 0]]
```

**class** `sage.combinat.plane_partition.PlanePartitions` *(box_size=None, symmetry=None, category=None)*

**Bases:** `UniqueRepresentation, Parent`

Plane partitions.

`PlanePartitions()` returns the class of all plane partitions.

`PlanePartitions(n)` return the class of all plane partitions with precisely \(n\) boxes.

`PlanePartitions([a, b, c])` returns the class of plane partitions that fit inside an \(a \times b \times c\) box.

`PlanePartitions([a, b, c])` has the optional keyword `symmetry`, which restricts the plane partitions inside a box of the specified size satisfying certain symmetry conditions.

- `symmetry='SPP'` gives the class of symmetric plane partitions, which is all plane partitions fixed under reflection across the diagonal. Requires that \(a = b\).
- `symmetry='CSPP'` gives the class of cyclic plane partitions, which is all plane partitions fixed under cyclic rotation of coordinates. Requires that \(a = b = c\).
- `symmetry='TSPP'` gives the class of totally symmetric plane partitions, which is all plane partitions fixed under any interchanging of coordinates. Requires that \(a = b = c\).
- `symmetry='SCPP'` gives the class of self-complementary plane partitions, which is all plane partitions that are equal to their own complement in the specified box. Requires at least one of \(a, b, c\) be even.
- `symmetry='TCPP'` gives the class of transpose complement plane partitions, which is all plane partitions whose complement in the box of the specified size is equal to their transpose. Requires \(a = b\) and at least one of \(a, b, c\) be even.
Combinatorics, Release 10.4

- symmetry='SSCPP' gives the class of symmetric self-complementary plane partitions, which is all plane partitions that are both symmetric and self-complementary. Requires $a = b$ and at least one of $a, b, c$ be even.

- symmetry='CSTCPP' gives the class of cyclically symmetric transpose complement plane partitions, which is all plane partitions that are both symmetric and equal to the transpose of their complement. Requires $a = b = c$.

- symmetry='CSSCPP' gives the class of cyclically symmetric self-complementary plane partitions, which is all plane partitions that are both cyclically symmetric and self-complementary. Requires $a = b = c$ and all $a, b, c$ be even.

- symmetry='TSSCPP' gives the class of totally symmetric self-complementary plane partitions, which is all plane partitions that are totally symmetric and also self-complementary. Requires $a = b = c$ and all $a, b, c$ be even.

EXAMPLES:

If no arguments are passed, then the class of all plane partitions is returned:

```
sage: PlanePartitions()
Plane partitions
sage: [[2,1],[1]] in PlanePartitions()
True
```

```
>>> from sage.all import *
>>> PlanePartitions()
Plane partitions
>>> [[Integer(2),Integer(1)], [Integer(1)]] in PlanePartitions()
True
```

If an integer $n$ is passed, then the class of plane partitions of $n$ is returned:

```
sage: PlanePartitions(3)
Plane partitions of size 3
sage: PlanePartitions(3).list()
[Plane partition [[3]],
 Plane partition [[2, 1]],
 Plane partition [[1, 1, 1]],
 Plane partition [[2], [1]],
 Plane partition [[1, 1], [1]],
 Plane partition [[1], [1], [1]]]
```

```
>>> from sage.all import *
>>> PlanePartitions(Integer(3))
Plane partitions of size 3
>>> PlanePartitions(Integer(3)).list()
[Plane partition [[3]],
 Plane partition [[2, 1]],
 Plane partition [[1, 1, 1]],
 Plane partition [[2], [1]],
 Plane partition [[1, 1], [1]],
 Plane partition [[1], [1], [1]]]
```

If a three-element tuple or list $[a, b, c]$ is passed, then the class of all plane partitions that fit inside and $a \times b \times c$ box is returned:
If an additional keyword `symmetry` is passed along with a three-element tuple or list \([a, b, c]\), then the class of all plane partitions that fit inside an \(a \times b \times c\) box with the specified symmetry is returned:

```
sage: PlanePartitions([2,2,2], symmetry='CSPP')
Cyclically symmetric plane partitions inside a 2 x 2 x 2 box
sage: [[2,1],[1]] in PlanePartitions([2,2,2], symmetry='CSPP')
True
```

- `PlanePartitions_CSTCPP`
- `PlanePartitions_CSSCPP`
- `PlanePartitions_TSSCPP`

Element

alias of `PlanePartition`
box()

Return the size of the box of the plane partition of self is contained in.

EXAMPLES:

```python
sage: P = PlanePartitions([4,3,5])
sage: P.box()
(4, 3, 5)
sage: PP = PlanePartitions()
sage: PP.box() is None
True
```

>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(3),Integer(5)])
>>> P.box()
(4, 3, 5)
>>> PP = PlanePartitions()
>>> PP.box() is None
True

symmetry()

Return the symmetry class of self.

EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,2], symmetry=SPP)
sage: PP.symmetry()
'SPP'
sage: PP = PlanePartitions()
sage: PP.symmetry() is None
True
```

>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry=SPP)
>>> PP.symmetry()
'SPP'
>>> PP = PlanePartitions()
>>> PP.symmetry() is None
True

class sage.combinat.plane_partition.PlanePartitions_CSPP(box_size)

Bases: PlanePartitions

Plane partitions that fit inside a box of a specified size that are cyclically symmetric.

cardinality()

Return the cardinality of self.

The number of cyclically symmetric plane partitions inside an $a \times a \times a$ box is equal to

$$\left( \prod_{i=1}^{a} \frac{3i-1}{3i-2} \right) \left( \prod_{1 \leq i < j \leq a} \frac{i+j+a-1}{2i+j-1} \right).$$

EXAMPLES:
sage: P = PlanePartitions([4,4,4], symmetry='CSPP')
sage: P.cardinality()
132

```python
>>> from sage.all import *

>>> P = PlanePartitions([Integer(4),Integer(4),Integer(4)], symmetry='CSPP')

```

**from_antichain** *(acl)*

Return the cyclically symmetric plane partition corresponding to an antichain in the poset given in `to_poset()`.

**EXAMPLES:**

```python
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: A = [(0, 2, 2), (1, 1, 1)]
sage: PP.from_antichain(A)
Plane partition [[3, 3, 3], [3, 2, 1], [3, 1, 1]]
```

```python
>>> from sage.all import *

```

```python
>>> P = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')

```

```python
>>> A = [(Integer(0), Integer(2), Integer(2)), (Integer(1), Integer(1), Integer(1))]

```

```python
>>> PP.from_antichain(A)
Plane partition [[3, 3, 3], [3, 2, 1], [3, 1, 1]]
```

**from_order_ideal** *(I)*

Return the cyclically symmetric plane partition corresponding to an order ideal in the poset given in `to_poset()`.

**EXAMPLES:**

```python
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: I = [(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 1), (0, 1, 2),
       ..., (1, 0, 2), (0, 2, 2), (1, 1, 1), (1, 1, 2), (1, 2, 2)]
sage: PP.from_order_ideal(I)  # needs sage.graphs
Plane partition [[3, 3, 3], [3, 3, 3], [3, 3, 2]]
```

```python
>>> from sage.all import *

```

```python
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')

```

```python
>>> I = [(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(0), Integer(1)),
      ..., (Integer(1), Integer(0), Integer(2)), (Integer(0), Integer(2), Integer(2))]

```

```python
>>> PP.from_order_ideal(I)  # needs sage.graphs
Plane partition [[3, 3, 3], [3, 3, 3], [3, 3, 2]]
```

**random_element**

Return a uniformly random element of `self`.

**ALGORITHM:**

5.1. Comprehensive Module List 2675
This uses the `random_order_ideal()` method and the natural bijection between cyclically symmetric plane partitions and order ideals in an associated poset.

**EXAMPLES:**

```python
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: PP.random_element()  # random
Plane partition [[3, 2, 2], [3, 1], [1, 1]]
```

```python
>>> from sage.all import *

>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')
>>> PP.random_element()  # random
Plane partition [[3, 2, 2], [3, 1], [1, 1]]
```

to_poset()

Return a partially ordered set whose order ideals are in bijection with cyclically symmetric plane partitions.

**EXAMPLES:**

```python
sage: PP = PlanePartitions([3,3,3], symmetry='CSPP')
sage: PP.to_poset()  # needs sage.graphs
Finite poset containing 11 elements

sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  # needs sage.graphs
True
```

```python
>>> from sage.all import *

>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(3)], symmetry='CSPP')

>>> PP.to_poset()  # needs sage.graphs
Finite poset containing 11 elements

>>> PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  # needs sage.graphs
True
```

class `sage.combinat.plane_partition.PlanePartitions_CSSCPP(box_size)`

**Bases:** `PlanePartitions`

Plane partitions that fit inside a box of a specified size that are cyclically symmetric self-complementary.

**cardinality()**

Return the cardinality of `self`.

The number of cyclically symmetric self-complementary plane partitions inside a $2a \times 2a \times 2a$ box is equal to

$$\left(\prod_{i=0}^{a-1} \frac{(3i+1)!}{(a+i)!}\right)^2.$$ 

**EXAMPLES:**

```python
sage: P = PlanePartitions([6,6,6], symmetry='CSSCPP')
sage: P.cardinality()
49
```
```python
>>> from sage.all import *
>>> P = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='CSSCPP')
>>> P.cardinality()
49
```

**class sage.combinat.plane_partition.PlanePartitions_CSTCPP**(box_size)

**Bases:** PlanePartitions

Plane partitions that fit inside a box of a specified size that are cyclically symmetric and transpose-complement.

**cardinality()**

Return the cardinality of self.

The number of cyclically symmetric transpose complement plane partitions inside a $2a \times 2a \times 2a$ box is equal to

$$\prod_{i=0}^{a-1} \frac{(3i + 1)(6i)! (2i)!}{(4i + 1)(4i)!}.$$

**EXAMPLES:**
```python
sage: P = PlanePartitions([6,6,6], symmetry='CSTCPP')
sage: P.cardinality()
11
```

```python
>>> from sage.all import *
>>> P = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='CSTCPP')
>>> P.cardinality()
11
```

**class sage.combinat.plane_partition.PlanePartitions_SCPP**(box_size)

**Bases:** PlanePartitions

Plane partitions that fit inside a box of a specified size that are self-complementary.

**cardinality()**

Return the cardinality of self.

The number of self complementary plane partitions inside a $2a \times 2b \times 2c$ box is equal to

$$\left( \prod_{i=1}^{r} \prod_{j=1}^{b} \frac{i + j + c - 1}{i + j - 1} \right)^2.$$

The number of self complementary plane partitions inside a $(2a + 1) \times 2b \times 2c$ box is equal to

$$\left( \prod_{i=1}^{a} \prod_{j=1}^{b} \frac{i + j + c - 1}{i + j - 1} \right) \left( \prod_{i=1}^{a+1} \prod_{j=1}^{b} \frac{i + j + c - 1}{i + j - 1} \right).$$

The number of self complementary plane partitions inside an $(2a + 1) \times (2b + 1) \times 2c$ box is equal to

$$\left( \prod_{i=1}^{a+1} \prod_{j=1}^{b} \frac{i + j + c - 1}{i + j - 1} \right) \left( \prod_{i=1}^{a+1} \prod_{j=1}^{b+1} \frac{i + j + c - 1}{i + j - 1} \right).$$

**EXAMPLES:**
```python
>>> from sage.all import *
>>> P = PlanePartitions([Integer(6),Integer(6),Integer(6)], symmetry='SCPP')
>>> P.cardinality()
11
```
```python
sage: P = PlanePartitions([4,4,4], symmetry='SCPP')
sage: P.cardinality()
400
sage: P = PlanePartitions([5,4,4], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([4,5,4], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([4,4,5], symmetry='SCPP')
sage: P.cardinality()
1000
sage: P = PlanePartitions([5,5,4], symmetry='SCPP')
sage: P.cardinality()
2500
sage: P = PlanePartitions([5,4,5], symmetry='SCPP')
sage: P.cardinality()
2500
sage: P = PlanePartitions([4,5,5], symmetry='SCPP')
sage: P.cardinality()
2500
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
400
>>> P = PlanePartitions([Integer(5),Integer(4),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
1000
>>> P = PlanePartitions([Integer(4),Integer(5),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
1000
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(5)], symmetry='SCPP')
>>> P.cardinality()
1000
>>> P = PlanePartitions([Integer(5),Integer(5),Integer(4)], symmetry='SCPP')
>>> P.cardinality()
2500
>>> P = PlanePartitions([Integer(5),Integer(4),Integer(5)], symmetry='SCPP')
>>> P.cardinality()
2500
>>> P = PlanePartitions([Integer(4),Integer(5),Integer(5)], symmetry='SCPP')
>>> P.cardinality()
2500
```

```python
class sage.combinat.plane_partition.PlanePartitions_SPP(box_size)
    Bases: PlanePartitions

    Plane partitions that fit inside a box of a specified size that are symmetric.

    cardinality()
        Return the cardinality of self.
```
The number of symmetric plane partitions inside an $a \times a \times b$ box is equal to

$$\left(\prod_{i=1}^{a} \frac{2i+b-1}{2i-1}\right) \left(\prod_{1 \leq i < j \leq a} \frac{i+j+b-1}{i+j-1}\right).$$

EXAMPLES:

```python
sage: P = PlanePartitions([3,3,2], symmetry='SPP')
sage: P.cardinality()
35
```

```python
>>> from sage.all import *
>>> P = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> P.cardinality()
35
```

**from_antichain(A)**

Return the symmetric plane partition corresponding to an antichain in the poset given in `to_poset()`.

EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: A = [(2, 2, 0), (1, 0, 1), (1, 1, 0)]
sage: PP.from_antichain(A)
Plane partition [[2, 2, 1], [2, 1, 1], [1, 1, 1]]
```

```python
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> A = [(Integer(2), Integer(2), Integer(0)), (Integer(1), Integer(0),... →Integer(1)), (Integer(1), Integer(1), Integer(0))]
>>> PP.from_antichain(A)
Plane partition [[2, 2, 1], [2, 1, 1], [1, 1, 1]]
```

**from_order_ideal(I)**

Return the symmetric plane partition corresponding to an order ideal in the poset given in `to_poset()`.

EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: I = [(0, 0, 0), (1, 0, 0), (1, 1, 0), (2, 0, 0)]
sage: PP.from_order_ideal(I) # needs sage.graphs
Plane partition [[1, 1, 1], [1, 1], [1]]
```

```python
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> I = [(Integer(0), Integer(0), Integer(0)), (Integer(1), Integer(0),... →Integer(0)), (Integer(1), Integer(1), Integer(0)), (Integer(2), Integer(0),... →Integer(0))]
>>> PP.from_order_ideal(I) # needs sage.graphs
Plane partition [[1, 1, 1], [1, 1], [1]]
```

**random_element()**

Return a uniformly random element of `self`.

ALGORITHM:
This uses the `random_order_ideal()` method and the natural bijection between symmetric plane partitions and order ideals in an associated poset.

EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.random_element()  # random
Plane partition [[2, 2, 2], [2, 2], [2]]
```

```python
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> PP.random_element()  # random
Plane partition [[2, 2, 2], [2, 2], [2]]
```

to_poset()

Return a poset whose order ideals are in bijection with symmetric plane partitions.

EXAMPLES:

```python
sage: PP = PlanePartitions([3,3,2], symmetry='SPP')
sage: PP.to_poset()  # needs sage.graphs
Finite poset containing 12 elements
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  # needs sage.graphs sage.modules sage.rings.finite_rings
True
```

```python
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SPP')
>>> PP.to_poset()  # needs sage.graphs
Finite poset containing 12 elements
>>> PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  # needs sage.graphs sage.modules sage.rings.finite_rings
True
```

class sage.combinat.plane_partition.PlanePartitions_SSCPP(box_size)

Bases: `PlanePartitions`

Plane partitions that fit inside a box of a specified size that are symmetric self-complementary.

cardinality()

Return the cardinality of self.

The number of symmetric self-complementary plane partitions inside a $2a \times 2a \times 2b$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{a} \frac{i + j + b - 1}{i + j - 1}.$$  

The number of symmetric self-complementary plane partitions inside a $(2a + 1) \times (2a + 1) \times 2b$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{a+1} \frac{i + j + b - 1}{i + j - 1}.$$  

EXAMPLES:
sage: P = PlanePartitions([4,4,2], symmetry='SSCPP')
sage: P.cardinality()
6
sage: Q = PlanePartitions([3,3,2], symmetry='SSCPP')
sage: Q.cardinality()
3

>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(2)], symmetry='SSCPP')
>>> P.cardinality()
6
>>> Q = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='SSCPP')
>>> Q.cardinality()
3

class sage.combinat.plane_partition.PlanePartitions_TCPP(box_size)
    Bases: PlanePartitions
    Plane partitions that fit inside a box of a specified size that are transpose-complement.

cardinality()
    Return the cardinality of self.
    The number of transpose complement plane partitions inside an $a \times a \times 2b$ box is equal to
    $$\left(\frac{b+1}{a-1}\right) \prod_{1 \leq i,j \leq a-2} \frac{i+j+2b-1}{i+j-1}.$$  

EXAMPLES:

sage: P = PlanePartitions([3,3,2], symmetry='TCP')
sage: P.cardinality()
5

>>> from sage.all import *
>>> P = PlanePartitions([Integer(3),Integer(3),Integer(2)], symmetry='TCP')
>>> P.cardinality()
5

class sage.combinat.plane_partition.PlanePartitions_TSPP(box_size)
    Bases: PlanePartitions
    Plane partitions that fit inside a box of a specified size that are totally symmetric.

cardinality()
    Return the cardinality of self.
    The number of totally symmetric plane partitions inside an $a \times a \times a$ box is equal to
    $$\prod_{1 \leq i,j \leq a} \frac{i+j+a-1}{i+2j-2}.$$  

EXAMPLES:

sage: P = PlanePartitions([4,4,4], symmetry='TSP')
sage: P.cardinality()
66
from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(4),Integer(4)], symmetry='TSP')
>>> P.cardinality()
66

from_antichain(acl)
Return the totally symmetric plane partition corresponding to an antichain in the poset given in to_poset().

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='TSP')
sage: A = [(0, 0, 2), (0, 1, 1)]
sage: PP.from_antichain(A)
Plane partition [[3, 2, 1], [2, 1], [1]]
```

from_order_ideal(I)
Return the totally symmetric plane partition corresponding to an order ideal in the poset given in to_poset().

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='TSP')
sage: I = [(0, 0, 0), (0, 0, 1), (0, 0, 2), (0, 1, 1)]
sage: PP.from_order_ideal(I)
# needs sage.graphs
Plane partition [[3, 2, 1], [2, 1], [1]]
```

to_poset()
Return a poset whose order ideals are in bijection with totally symmetric plane partitions.

EXAMPLES:

```
sage: PP = PlanePartitions([3,3,3], symmetry='TSP')
sage: PP.to_poset()  # needs sage.graphs
Finite poset containing 10 elements
sage: (PP.to_poset().order_ideals_lattice().cardinality()  # needs sage.graphs sage.modules sage.rings.finite_rings
....: == PP.cardinality())
True
```
```python
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(3), Integer(3), Integer(3)], symmetry='TSPP')
>>> PP.to_poset()
needs sage.graphs
Finite poset containing 10 elements
>>> (PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality())
True
```

```python
class sage.combinat.plane_partition.PlanePartitions_TSSCPP(box_size)
Bases: PlanePartitions

Plane partitions that fit inside a box of a specified size that are totally symmetric self-complementary.

cardinality()

Return the cardinality of self.

The number of totally symmetric self-complementary plane partitions inside a $2a \times 2a \times 2a$ box is equal to

\[
\prod_{i=0}^{a-1} \frac{(3i+1)!}{(a+i)!}.
\]

EXAMPLES:

```python
sage: P = PlanePartitions([6, 6, 6], symmetry='TSSCPP')
sage: P.cardinality()
7
```

```python
>>> from sage.all import *
>>> PP = PlanePartitions([Integer(6), Integer(6), Integer(6)], symmetry='TSSCPP')
>>> A = [(Integer(0), Integer(0), Integer(1)), (Integer(1), Integer(0), Integer(0))]
>>> PP.from_antichain(A)
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 4, 3, 1], [6, 5, 4, 3, 2, 1],
[5, 4, 3, 2, 1], [5, 3, 2, 1, 1], [3, 1, 1]]
```

from_antichain(ad)

Return the totally symmetric self-complementary plane partition corresponding to an antichain in the poset given in to_poset().

EXAMPLES:

```python
sage: PP = PlanePartitions([6, 6, 6], symmetry='TSSCPP')
sage: A = [(0, 0, 1), (1, 1, 0)]
sage: PP.from_antichain(A)
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 4, 3, 1], [6, 5, 4, 3, 2, 1],
[5, 4, 3, 2, 1], [5, 3, 2, 1, 1], [3, 1, 1]]
```
```
from_order_ideal(I)

Return the totally symmetric self-complementary plane partition corresponding to an order ideal in the poset given in to_poset().

EXAMPLES:

```python
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')  # needs sage.graphs
sage: I = [(0, 0, 0), (0, 1, 0), (1, 1, 0)]
```

```python
sage: PP.from_order_ideal(I)  # needs sage.graphs
Plane partition [[6, 6, 6, 5, 5, 3], [6, 5, 5, 3, 3, 1], [6, 5, 5, 3, 3, 1], [5, 3, 3, 1, 1], [5, 3, 3, 1, 1], [3, 1, 1]]
```

to_poset()

Return a poset whose order ideals are in bijection with totally symmetric self-complementary plane partitions.

EXAMPLES:

```python
sage: PP = PlanePartitions([6,6,6], symmetry='TSSCPP')
```

```python
sage: PP.to_poset()  # needs sage.graphs sage.modules
Finite poset containing 4 elements
```

```python
sage: PP.to_poset().order_ideals_lattice().cardinality() == PP.cardinality()  # needs sage.graphs sage.modules
True
```

class sage.combinat.plane_partition.PlanePartitions_all

Bases: PlanePartitions, DisjointUnionEnumeratedSets

All plane partitions.

an_element()

Return a particular element of the class.

class sage.combinat.plane_partition.PlanePartitions_box(box_size)

Bases: PlanePartitions
All plane partitions that fit inside a box of a specified size.

By convention, a plane partition in an $a \times b \times c$ box will have at most $a$ rows, of lengths at most $b$, with entries at most $c$.

**cardinality()**

Return the cardinality of *self*.

The number of plane partitions inside an $a \times b \times c$ box is equal to

$$\prod_{i=1}^{a} \prod_{j=1}^{b} \prod_{k=1}^{c} \frac{i+j+k-1}{i+j+k-2}$$

**EXAMPLES:**

```python
sage: P = PlanePartitions([4,3,5])
sage: P.cardinality()
116424
```

```python
>>> from sage.all import *
>>> P = PlanePartitions([Integer(4),Integer(3),Integer(5)])
>>> P.cardinality()
116424
```

**from_antichain(A)**

Return the plane partition corresponding to an antichain in the poset given in `to_poset()`.

**EXAMPLES:**

```python
sage: A = [(1,0,1), (0,1,1), (1,1,0)]
sage: PlanePartitions([2,2,2]).from_antichain(A)
Plane partition [[2, 2], [2, 1]]
```

```python
>>> from sage.all import *
>>> A = [(Integer(1),Integer(0),Integer(1)), (Integer(0),Integer(1),
˓→Integer(0)), (Integer(1),Integer(1),Integer(0))]
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)]).from_antichain(A)
Plane partition [[2, 2], [2, 1]]
```

**from_order_ideal(I)**

Return the plane partition corresponding to an order ideal in the poset given in `to_poset()`.

**EXAMPLES:**

```python
sage: I = [(1, 0, 0), (1, 0, 1), (1, 1, 0),
˓→(0, 1, 0), (0, 0, 0), (0, 0, 1), (0, 1, 1)]
```

```python
>>> from sage.all import *
>>> I = [(Integer(1), Integer(0), Integer(0)), (Integer(1), Integer(0),
˓→Integer(1)), (Integer(1), Integer(1), Integer(0)), (Integer(0), Integer(0),
˓→Integer(0)), ...
˓→(Integer(0), Integer(0), Integer(0)), (Integer(0), Integer(0),
˓→Integer(1)), (Integer(0), Integer(1), Integer(1))]
>>> PlanePartitions([Integer(2),Integer(2),Integer(2)]).from_order_ideal(I)
```

(continues on next page)
random_element()

Return a uniformly random plane partition inside a box.

ALGORITHM:

This uses the random_order_ideal() method and the natural bijection with plane partitions.

EXAMPLES:

```python
sage: P = PlanePartitions([4,3,5])
sage: P.random_element()  # random
[4, 3, 3], [4], [2]
```

```python
>>> from sage.all import *

>>> P = PlanePartitions([Integer(4),Integer(3),Integer(5)])

>>> P.random_element()  # random
[4, 3, 3], [4], [2]
```

to_poset()

Return the product of three chains poset, whose order ideals are naturally in bijection with plane partitions inside a box.

EXAMPLES:

```python
sage: PlanePartitions([2,2,2]).to_poset()  # needs sage.graphs sage.modules
Finite lattice containing 8 elements
```

```python
>>> from sage.all import *

>>> PlanePartitions([Integer(2),Integer(2),Integer(2)]).to_poset()  # needs sage.graphs sage.modules
Finite lattice containing 8 elements
```

class sage.combinat.plane_partition.PlanePartitions_n(n)

Bases: PlanePartitions

Plane partitions with a fixed number of boxes.

cardinality()

Return the number of plane partitions with \( n \) boxes.

Calculated using the recurrence relation

\[
PL(n) = \sum_{k=1}^{n} PL(n - k)\sigma_2(k),
\]

where \( \sigma_k(n) \) is the sum of the \( k \)-th powers of divisors of \( n \).

EXAMPLES:

```python
sage: P = PlanePartitions(17)
sage: P.cardinality()
18334
```
>>> from sage.all import *
>>> P = PlanePartitions(Integer(17))
>>> P.cardinality()
18334

5.1.165 Integer partitions

A partition \( p \) of a nonnegative integer \( n \) is a non-increasing list of positive integers (the \( \text{parts} \) of the partition) with total sum \( n \).

A partition can be depicted by a diagram made of rows of cells, where the number of cells in the \( i^{th} \) row starting from the top is the \( i^{th} \) part of the partition.

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition \([5, 3, 1]\) are \([0, 4], [1, 2], [2, 0]\).

For display options, see \texttt{Partitions.options}.

\textbf{Note:}

- Boxes is a synonym for cells. All methods will use ‘cell’ and ‘cells’ instead of ‘box’ and ‘boxes’.
- Partitions are 0 based with coordinates in the form of (row-index, column-index).
- If given coordinates of the form \((r, c)\), then use Python’s \*-operator.
- Throughout this documentation, for a partition \( \lambda \) we will denote its conjugate partition by \( \lambda' \). For more on conjugate partitions, see \texttt{Partition.conjugate()}.
- The comparisons on partitions use lexicographic order.

\textbf{Note:} We use the convention that lexicographic ordering is read from left-to-right. That is to say \([1, 3, 7]\) is smaller than \([2, 3, 4]\).

\textbf{AUTHORS:}

- Mike Hansen (2007): initial version
- Dan Drake (2009-03-28): deprecate RestrictedPartitions and implement Partitions\_parts\_in
- Travis Scrimshaw (2012-01-12): Implemented latex function to Partition\_class
- Travis Scrimshaw (2012-05-09): Fixed Partitions(-1).list() infinite recursion loop by saying Partitions\_n is the empty set.
- Travis Scrimshaw (2012-05-11): Fixed bug in inner where if the length was longer than the length of the inner partition, it would include 0’s.
- Andrew Mathas (2012-06-01): Removed deprecated functions and added compatibility with the PartitionTuple classes. See Issue #13072
- Travis Scrimshaw (2012-10-12): Added options. Made \texttt{Partition\_class} to the element \texttt{Partition}. \texttt{Partitions*} are now all in the category framework except \texttt{PartitionsRestricted} (which will eventually be removed). Cleaned up documentation.
- Matthew Lancellotti (2018-09-14): Added a bunch of “k” methods to Partition.
EXAMPLES:

There are 5 partitions of the integer 4:

```python
sage: Partitions(4).cardinality()  # needs sage.libs.flint
5
sage: Partitions(4).list()
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

We can use the method `.first()` to get the ‘first’ partition of a number:

```python
sage: Partitions(4).first()
[4]
```

Using the method `.next(p)`, we can calculate the ‘next’ partition after `p`. When we are at the last partition, `None` will be returned:

```python
sage: Partitions(4).next([4])
[3, 1]
sage: Partitions(4).next([1,1,1,1])
is None
True
```

We can use `iter` to get an object which iterates over the partitions one by one to save memory. Note that when we do something like `for part in Partitions(4)` this iterator is used in the background:

```python
sage: g = iter(Partitions(4))
sage: next(g)
[4]
sage: next(g)
[3, 1]
sage: next(g)
[2, 2]
sage: for p in Partitions(4): print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]
```
>>> from sage.all import *

>>> g = iter(Partitions(Integer(4)))
>>> next(g)
[4]
>>> next(g)
[3, 1]
>>> next(g)
[2, 2]

>>> for p in Partitions(Integer(4)): print(p)
[4]
[3, 1]
[2, 2]
[2, 1, 1]
[1, 1, 1, 1]

We can add constraints to the type of partitions we want. For example, to get all of the partitions of $4$ of length 2, we'd do the following:

```
sage: Partitions(4, length=2).list()
[[3, 1], [2, 2]]
```

Here is the list of partitions of length at least 2 and the list of ones with length at most 2:

```
sage: Partitions(4, min_length=2).list()
[[3, 1], [2, 2], [2, 1, 1], [1, 1, 1, 1]]
sage: Partitions(4, max_length=2).list()
[[4], [3, 1], [2, 2]]
```

The options min_part and max_part can be used to set constraints on the sizes of all parts. Using max_part, we can select partitions having only 'small' entries. The following is the list of the partitions of $4$ with parts at most 2:

```
sage: Partitions(4, max_part=2).list()
[[2, 2], [2, 1, 1], [1, 1, 1, 1]]
```

The min_part options is complementary to max_part and selects partitions having only 'large' parts. Here is the list of all partitions of $4$ with each part at least 2:

```
sage: Partitions(4, min_part=2).list()
[[4], [2, 2]]
```

5.1. Comprehensive Module List
The options `inner` and `outer` can be used to set part-by-part constraints. This is the list of partitions of 4 with [3, 1, 1] as an outer bound (that is, partitions of 4 contained in the partition [3, 1, 1]):

```
sage: Partitions(4, outer=[3,1,1]).list()
[[3, 1], [2, 1, 1]]
```

outer sets `max_length` to the length of its argument. Moreover, the parts of `outer` may be infinite to clear constraints on specific parts. Here is the list of the partitions of 4 of length at most 3 such that the second and third part are 1 when they exist:

```
sage: Partitions(4, outer=[oo,1,1]).list()
[[4], [3, 1], [2, 1, 1]]
```

Finally, here are the partitions of 4 with [1,1,1] as an inner bound (i.e., the partitions of 4 containing the partition [1,1,1]). Note that `inner` sets `min_length` to the length of its argument:

```
sage: Partitions(4, inner=[1,1,1]).list()
[[2, 1, 1], [1, 1, 1, 1]]
```

The options `min_slope` and `max_slope` can be used to set constraints on the slope, that is on the difference \(p[i+1] - p[i]\) of two consecutive parts. Here is the list of the strictly decreasing partitions of 4:

```
sage: Partitions(4, max_slope=-1).list()
[[4], [3, 1]]
```

The constraints can be combined together in all reasonable ways. Here are all the partitions of 11 of length between 2 and 4 such that the difference between two consecutive parts is between \(-3\) and \(-1\):

```
sage: Partitions(11,min_slope=-3,max_slope=-1,min_length=2,max_length=4).list()
[[7, 4], [6, 5], [6, 4, 1], [6, 3, 2], [5, 4, 2], [5, 3, 2, 1]]
```
Partition objects can also be created individually with `Partition`:

```python
sage: Partition([2, 1])
[2, 1]
```

```python
>>> from sage.all import *

>>> Partition([Integer(2), Integer(1)])
[2, 1]
```

Once we have a partition object, then there are a variety of methods that we can use. For example, we can get the conjugate of a partition. Geometrically, the conjugate of a partition is the reflection of that partition through its main diagonal. Of course, this operation is an involution:

```python
sage: Partition([4, 1]).conjugate()
[2, 1, 1, 1]
sage: Partition([4, 1]).conjugate().conjugate()
[4, 1]
```

```python
>>> from sage.all import *

>>> Partition([Integer(4), Integer(1)]).conjugate()
[2, 1, 1, 1]

>>> Partition([Integer(4), Integer(1)]).conjugate().conjugate()
[4, 1]
```

If we create a partition with extra zeros at the end, they will be dropped:

```python
sage: Partition([4, 1, 0, 0])
[4, 1]
sage: Partition([0])
[]
sage: Partition([0, 0])
[]
```

```python
>>> from sage.all import *

>>> p = Partition([Integer(4), Integer(1), Integer(0), Integer(0)])

>>> p.get_part(Integer(0))
5

>>> p.get_part(Integer(10))
0
```

The idea of a partition being followed by infinitely many parts of size 0 is consistent with the `get_part` method:
We can go back and forth between the standard and the exponential notations of a partition. The exponential notation can be padded with extra zeros:

```python
sage: Partition([6, 4, 4, 2, 1]).to_exp()
[1, 1, 0, 2, 0, 1]
sage: Partition(exp=[1, 1, 0, 2, 0, 1])
[6, 4, 4, 2, 1]
sage: Partition([6, 4, 4, 2, 1]).to_exp(5)
[1, 1, 0, 2, 0, 1]
sage: Partition([6, 4, 4, 2, 1]).to_exp(7)
[1, 1, 0, 2, 0, 1, 0]
sage: Partition([6, 4, 4, 2, 1]).to_exp(10)
[1, 1, 0, 2, 0, 1, 0, 0, 0, 0]
```

We can get the (zero-based!) coordinates of the corners of a partition:

```python
sage: Partition([4, 3, 1]).corners()
[(0, 3), (1, 2), (2, 0)]
```

We can compute the core and quotient of a partition and build the partition back up from them:

```python
sage: Partition([6, 3, 2, 2]).core(3)
[2, 1, 1]
sage: Partition([7, 7, 5, 3, 3, 3, 1]).quotient(3)
([2], [1], [2, 2, 2])
sage: p = Partition([11, 5, 5, 3, 2, 2, 2])
sage: p.core(3)
[]
sage: p.quotient(3)
([2, 1], [4], [1, 1, 1])
sage: Partition(core=[], quotient=([2, 1], [4], [1, 1, 1]))
[11, 5, 5, 3, 2, 2, 2]
```

(continues on next page)
We can compute the $0 - 1$ sequence and go back and forth:

```
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: all(Partitions().from_zero_one(mu.zero_one_sequence()) ==
    mu for n in range(5) for mu in Partitions(n))
True
```

We can compute the Frobenius coordinates and go back and forth:

```
sage: Partition([7,3,1]).frobenius_coordinates()
([6, 1], [2, 0])
sage: Partition(frobenius_coordinates=([6,1],[2,0]))
[7, 3, 1]
sage: all(mu ==
    Partition(frobenius_coordinates=mu.frobenius_coordinates())
    for n in range(12) for mu in Partitions(n))
True
```

We use the lexicographic ordering:

```
sage: pl = Partition([4,1,1])
sage: ql = Partitions()([3,3])
sage: pl > ql
True
```

(continues on next page)
sage: pl > ql
True

>>> from sage.all import *
>>> pl = Partition([Integer(4),Integer(1),Integer(1)])
>>> ql = Partitions()([Integer(3),Integer(3)])
>>> pl > ql
True
>>> PL = Partitions()
>>> pl = PL([Integer(4),Integer(1),Integer(1)])
>>> ql = PL([Integer(3),Integer(3)])
>>> pl > ql
True

class sage.combinat.partition.OrderedPartitions(n, k)

Bases: Partitions

The class of ordered partitions of n. If k is specified, then this contains only the ordered partitions of length k.

An ordered partition of a nonnegative integer n means a list of positive integers whose sum is n. This is the same as a composition of n.

Note: It is recommended that you use Compositions() instead as OrderedPartitions() wraps GAP.

EXAMPLES:

sage: OrderedPartitions(3)
Ordered partitions of 3
sage: OrderedPartitions(3).list()  # needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2)
Ordered partitions of 3 of length 2
sage: OrderedPartitions(3,2).list()  # needs sage.libs.gap
[[2, 1], [1, 2]]
sage: OrderedPartitions(10, k=2).list()  # needs sage.libs.gap
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]
sage: OrderedPartitions(4).list()  # needs sage.libs.gap
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

>>> from sage.all import *
>>> OrderedPartitions(Integer(3))
Ordered partitions of 3
>>> OrderedPartitions(Integer(3)).list()  # needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
>>> OrderedPartitions(Integer(3),Integer(2))
Ordered partitions of 3 of length 2
>>> OrderedPartitions(Integer(3),Integer(2)).list()  # needs sage.libs.gap
[[2, 1], [1, 2]]

(continues on next page)
OrderedPartitions(Integer(10), k=Integer(2)).list() → # needs sage.libs.gap
[[9, 1], [8, 2], [7, 3], [6, 4], [5, 5], [4, 6], [3, 7], [2, 8], [1, 9]]

OrderedPartitions(Integer(4)).list() → # needs sage.libs.gap
[[4], [3, 1], [2, 2], [2, 1, 1], [1, 3], [1, 2, 1], [1, 1, 2], [1, 1, 1, 1]]

cardinality()

Return the cardinality of self.

EXAMPLES:

sage: OrderedPartitions(3).cardinality() 4
sage: OrderedPartitions(3,2).cardinality() 2
sage: OrderedPartitions(10,2).cardinality() 9
sage: OrderedPartitions(15).cardinality() 16384

list()

Return a list of partitions in self.

EXAMPLES:

sage: OrderedPartitions(3).list() # needs sage.libs.gap
[[3], [2, 1], [1, 2], [1, 1, 1]]
sage: OrderedPartitions(3,2).list() # needs sage.libs.gap
[[2, 1], [1, 2]]

class sage.combinat.partition.Particle (parent, mu)

Bases: CombinatorialElement
A partition $p$ of a nonnegative integer $n$ is a non-increasing list of positive integers (the parts of the partition) with total sum $n$.

A partition is often represented as a diagram consisting of cells, or boxes, placed in rows on top of each other such that the number of cells in the $i^{th}$ row, reading from top to bottom, is the $i^{th}$ part of the partition. The rows are left-justified (and become shorter and shorter the farther down one goes). This diagram is called the Young diagram of the partition, or more precisely its Young diagram in English notation. (French and Russian notations are variations on this representation.)

The coordinate system related to a partition applies from the top to the bottom and from left to right. So, the corners of the partition $[5, 3, 1]$ are $[[0,4], [1,2], [2,0]]$.

For display options, see `Partitions.options()`.

**Note:** Partitions are 0 based with coordinates in the form of (row-index, column-index). For example consider the partition $\mu=\text{Partition}([4,3,2,2])$, the first part is $\mu[0]$ (which is 4), the second is $\mu[1]$, and so on, and the upper-left cell in English convention is $(0, 0)$.

A partition can be specified in one of the following ways:

- a list (the default)
- using exponential notation
- by Frobenius coordinates
- specifying its 0 − 1 sequence
- specifying the core and the quotient

See the examples below.

**EXAMPLES:**

Creating partitions though parents:

```sage
sage: mu = Partitions(8)([3,2,1,1,1]); mu
[3, 2, 1, 1, 1]
sage: nu = Partition([3,2,1,1,1]); nu
[3, 2, 1, 1, 1]
sage: mu == nu
True
sage: mu is nu
False
sage: mu in Partitions()
True
sage: mu.parent()
Partitions of the integer 8
sage: mu.size()
8
sage: mu.category()
Category of elements of Partitions of the integer 8
sage: mu.parent()
Partitions
sage: nu.category()
Category of elements of Partitions
sage: mu[0]
3
sage: mu[1]
2
```
sage: mu[2]  
1  

sage: mu.pp()  
***  
**  
*  
*  

sage: mu.removable_cells()  
[(0, 2), (1, 1), (4, 0)]  

sage: mu.down_list()  
[[2, 2, 1, 1], [3, 1, 1, 1], [3, 2, 1, 1]]  

sage: mu.addable_cells()  
[(0, 3), (1, 2), (2, 1), (5, 0)]  

sage: mu.up_list()  
[[4, 2, 1, 1, 1], [3, 3, 1, 1, 1], [3, 2, 2, 1, 1], [3, 2, 1, 1, 1, 1]]  

sage: mu.conjugate()  
[5, 2, 1]  

sage: mu.dominates(nu)  
True  

sage: nu.dominates(mu)  
True  

>>> from sage.all import *  

>>> mu = Partitions(Integer(8))([Integer(3),Integer(2),Integer(1),Integer(1),  
˓→Integer(1)]); mu  
[3, 2, 1, 1, 1]  

>>> nu = Partition([Integer(3),Integer(2),Integer(1),Integer(1),Integer(1)]); nu  
[3, 2, 1, 1, 1]  

>>> mu == nu  
True  

>>> mu is nu  
False  

>>> mu in Partitions()  
True  

>>> mu.parent()  
Partitions of the integer 8  

>>> mu.size()  
8  

>>> mu.category()  
Category of elements of Partitions of the integer 8  

>>> nu.parent()  
Partitions  

>>> nu.category()  
Category of elements of Partitions  

>>> mu[Integer(0)]  
3  

>>> mu[Integer(1)]  
2  

>>> mu[Integer(2)]  
1  

>>> mu.pp()  
***  
**

(continues on next page)
Creating partitions using \texttt{Partition}:

\begin{verbatim}
sage: Partition([3,2,1])
[3, 2, 1]
sage: Partition(exp=[2,1,1])
[3, 2, 1, 1]
sage: Partition(core=[2,1], quotient=[[2,1],[3],[1,1,1]])
[11, 5, 5, 3, 2, 2, 2]
sage: Partition(frobenius_coordinates=(3,2),(4,0))
[4, 4, 1, 1, 1]
sage: Partitions().from_zero_one([1, 1, 1, 1, 0, 1, 0])
[5, 4]
sage: [2,1] in Partitions()
True
sage: [2,1,0] in Partitions()
True
sage: Partition([1,2,3])
Traceback (most recent call last):
...
ValueError: [1, 2, 3] is not an element of Partitions
\end{verbatim}

\begin{verbatim}
>>> from sage.all import *

>>> Partition([Integer(3),Integer(2),Integer(1)])
[3, 2, 1]
>>> Partition(exp=[Integer(2),Integer(1),Integer(1)])
[3, 2, 1, 1]
>>> Partition(core=[Integer(2),Integer(1)], quotient=[[Integer(2),Integer(1)],
[Integer(3)],[Integer(1),Integer(1),Integer(1)]])
[11, 5, 5, 3, 2, 2, 2]
>>> Partition(frobenius_coordinates=[[Integer(3),Integer(2)],
[Integer(4),
[Integer(0)]])
[4, 4, 1, 1, 1]
>>> Partitions().from_zero_one([Integer(1), Integer(1), Integer(1), Integer(1),
[Integer(0), Integer(1), Integer(0)])
[5, 4]
>>> [Integer(2),Integer(1)] in Partitions()
True
>>> [Integer(2),Integer(1),Integer(0)] in Partitions()
True
>>> Partition([Integer(1),Integer(2),Integer(3)])
\end{verbatim}
Traceback (most recent call last):
...
ValueError: [1, 2, 3] is not an element of Partitions

Sage ignores trailing zeros at the end of partitions:

```python
sage: Partition([3,2,1,0])
[3, 2, 1]
sage: Partitions()([3,2,1,0])
[3, 2, 1]
sage: Partitions(6)([3,2,1,0])
[3, 2, 1]
```

```python
>> from sage.all import *
>> Partition([Integer(3),Integer(2),Integer(1),Integer(0)])
[3, 2, 1]
>> Partitions()([Integer(3),Integer(2),Integer(1),Integer(0)])
[3, 2, 1]
>> Partitions(Integer(6))([Integer(3),Integer(2),Integer(1),Integer(0)])
[3, 2, 1]
```

**add_cell** (*i*, *j=None*)

Return a partition corresponding to *self* with a cell added in row *i*. (This does not change *self*.)

**EXAMPLES:**

```python
sage: Partition([3, 2, 1, 1]).add_cell(0)
[4, 2, 1, 1]
sage: cell = [4, 0]; Partition([3, 2, 1, 1]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

```python
>> from sage.all import *
>> Partition([Integer(3), Integer(2), Integer(1), Integer(1)]).add_cell(Integer(0))
[4, 2, 1, 1]
>> cell = [Integer(4), Integer(0)]; Partition([Integer(3), Integer(2), Integer(1), Integer(1)]).add_cell(*cell)
[3, 2, 1, 1, 1]
```

**add_horizontal_border_strip** (*k*)

Return a list of all the partitions that can be obtained by adding a horizontal border strip of length *k* to *self*.

**EXAMPLES:**

```python
sage: Partition([]).add_horizontal_border_strip(0)
[[1]]
sage: Partition([3, 2, 1]).add_horizontal_border_strip(0)
[[3, 2, 1]]
sage: Partition([]).add_horizontal_border_strip(2)
[[2]]
sage: Partition([2, 2]).add_horizontal_border_strip(2)
[[4, 2], [3, 2, 1], [2, 2, 2]]
sage: Partition([3, 2, 2]).add_horizontal_border_strip(2)
[[5, 2, 2], [4, 3, 2], [4, 2, 2, 1], [3, 3, 2, 1], [3, 2, 2, 1]]
```
```python
>>> from sage.all import *

>>> Partition([]).add_horizontal_border_strip(Integer(0))
[[
]]

>>> Partition([Integer(3), Integer(2), Integer(1)]).add_horizontal_border_strip(Integer(0))
[[3, 2, 1]]

>>> Partition([]).add_horizontal_border_strip(Integer(2))
[[2]]

>>> Partition([Integer(2), Integer(2)]).add_horizontal_border_strip(Integer(2))
[[4, 2], [3, 2, 1], [2, 2, 2]]

>>> Partition([Integer(3), Integer(2), Integer(2)]).add_horizontal_border_strip(Integer(2))
[[5, 2, 2], [4, 3, 2], [4, 2, 2, 1], [3, 3, 2, 1], [3, 2, 2, 2]]
```

### addable_cells()

Return a list of the outside corners of the partition self.

An outside corner (also called a cocorner) of a partition \( \lambda \) is a cell on \( \mathbb{Z}^2 \) which does not belong to the Young diagram of \( \lambda \) but can be added to this Young diagram to still form a straight-shape Young diagram.

The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0.

**Note:** These are called “outer corners” in [Sag2001].

**EXAMPLES:**

```python
>>> from sage.all import *

>>> Partition([]).add_horizontal_border_strip(Integer(0))
[[
]]

>>> Partition([3, 2, 1]).add_horizontal_border_strip(Integer(0))
[[3, 2, 1]]

>>> Partition([]).add_horizontal_border_strip(Integer(2))
[[1, 1]]

>>> Partition([2, 2]).add_horizontal_border_strip(Integer(2))
[[3, 3], [3, 2, 1], [2, 2, 1, 1]]

>>> Partition([3, 2, 2]).add_horizontal_border_strip(Integer(2))
[[4, 3, 2], [4, 2, 2, 1], [3, 3, 3], [3, 3, 2, 1], [3, 2, 2, 1, 1]]
```
\texttt{addable\_cells\_residue}(i, l) \\
Return a list of the outside corners of the partition \texttt{self} having l-residue \(i\). \\

An outside corner (also called a cocorner) of a partition \(\lambda\) is a cell on \(\mathbb{Z}^2\) which does not belong to the Young diagram of \(\lambda\) but can be added to this Young diagram to still form a straight-shape Young diagram. See \texttt{residue()} for the definition of the l-residue. \\
The entries of the list returned are pairs of the form \((i, j)\), where \(i\) and \(j\) are the coordinates of the respective corner. The coordinates are counted from 0. \\

\textbf{EXAMPLES:}

\begin{verbatim}
\texttt{sage: Partition([3,2,1]).outside\_corners\_residue(0, 3)}
[(0, 3), (3, 0)]
\texttt{sage: Partition([3,2,1]).outside\_corners\_residue(1, 3)}
[(1, 2)]
\texttt{sage: Partition([3,2,1]).outside\_corners\_residue(2, 3)}
[(2, 1)]
\end{verbatim}

\texttt{arm\_cells}(i, j) \\
Return the list of the cells of the arm of cell \((i, j)\) in \texttt{self}. \\
The arm of cell \(c = (i, j)\) is the boxes that appear to the right of \(c\). \\
The cell coordinates are zero-based, i. e., the northwesternmost cell is \((0, 0)\). \\

\textbf{INPUT:}

\begin{verbatim}
\texttt{>>> from sage.all import *}
\texttt{>>> Partition([Integer(3),Integer(2),Integer(1)]).outside\_corners\_residue(Integer(0), Integer(3))}
[(0, 3), (3, 0)]
\texttt{>>> Partition([Integer(3),Integer(2),Integer(1)]).outside\_corners\_residue(Integer(1), Integer(3))}
[(1, 2)]
\texttt{>>> Partition([Integer(3),Integer(2),Integer(1)]).outside\_corners\_residue(Integer(2), Integer(3))}
[(2, 1)]
\end{verbatim}
• i, j – two integers

OUTPUT:
A list of pairs of integers

EXAMPLES:

```python
given = Partition([4, 4, 3, 1]).arm_cells(1, 1)
[(1, 2), (1, 3)]

given = Partition([]).arm_cells(0, 0)
Traceback (most recent call last):
...
ValueError: the cell is not in the diagram
```
arm_lengths (flat=False)

Return a tableau of shape self where each cell is filled with its arm length.

The optional boolean parameter flat provides the option of returning a flat list.

EXAMPLES:

```
sage: Partition([2,2,1]).arm_lengths()
[[1, 0], [1, 0], [0]]
sage: Partition([2,2,1]).arm_lengths(flat=True)
[1, 0, 1, 0, 0]
sage: Partition([3,3]).arm_lengths()
[[2, 1, 0], [2, 1, 0]]
sage: Partition([3,3]).arm_lengths(flat=True)
[2, 1, 0, 2, 1, 0]
```

arms_legs_coeff (i, j)

This is a statistic on a cell $c = (i, j)$ in the diagram of partition $p$ given by

$$
\frac{1 - q^a \cdot t^{\ell+1}}{1 - q^{a+1} \cdot t^\ell}
$$

where $a$ is the arm length of $c$ and $\ell$ is the leg length of $c$.

The coordinates $i$ and $j$ of the cell are understood to be 0-based, so that $(0, 0)$ is the northwesternmost cell (in English notation).

EXAMPLES:

```
sage: Partition([3,2,1]).arms_legs_coeff(1,1)
(-t + 1)/(-q + 1)
sage: Partition([3,2,1]).arms_legs_coeff(0,0)
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
sage: Partition([3,2,1]).arms_legs_coeff(*[0,0])
(-q^2*t^3 + 1)/(-q^3*t^2 + 1)
```

(continues on next page)
(-t + 1)/(-q + 1)

>>> Partition([Integer(3),Integer(2),Integer(1)]).arms_legs_coeff(Integer(0), →Integer(0))

(-q^2*t^3 + 1)/(-q^3*t^2 + 1)

>>> Partition([Integer(3),Integer(2),Integer(1)]).arms_legs_ →coeff(*[Integer(0),Integer(0)])

(-q^2*t^3 + 1)/(-q^3*t^2 + 1)

atom()

Return a list of the standard tableaux of size self.size() whose atom is equal to self.

EXAMPLES:

sage: Partition([2,1]).atom()
[[[1, 2], [3]]]
sage: Partition([3,2,1]).atom()
[[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]]

>>> from sage.all import *

>>> Partition([Integer(2),Integer(1)]).atom()
[[[1, 2], [3]]]

>>> Partition([Integer(3),Integer(2),Integer(1)]).atom()
[[[1, 2, 3, 6], [4, 5]], [[1, 2, 3], [4, 5], [6]]]

attacking_pairs()

Return a list of the attacking pairs of the Young diagram of self.

A pair of cells (c, d) of a Young diagram (in English notation) is said to be attacking if one of the following conditions holds:

1. c and d lie in the same row with c strictly to the west of d.
2. c is in the row immediately to the south of d, and c lies strictly east of d.

This particular method returns each pair (c, d) as a tuple, where each of c and d is given as a tuple (i, j) with i and j zero-based (so i = 0 means that the cell lies in the topmost row).

EXAMPLES:

sage: p = Partition([3, 2])
sage: p.attacking_pairs()
[((0, 0), (0, 1)),
 (0, 0), (0, 2)),
 (0, 1), (0, 2)),
 (1, 0), (1, 1)),
 (1, 1), (0, 0)])
sage: Partition([]).attacking_pairs()
[]

>>> from sage.all import *

>>> p = Partition([Integer(3), Integer(2)])

>>> p.attacking_pairs()
[((0, 0), (0, 1)),
 (0, 0), (0, 2)),
 (0, 1), (0, 2)),
 (1, 0), (1, 1)),
 (1, 1), (0, 0))]
Partition(\[\]).attacking_pairs()
\[
\]
\textbf{aut} \ (t=0, \ q=0)

Return the size of the centralizer of any permutation of cycle type \texttt{self}.

If \(m_i\) is the multiplicity of \(i\) as a part of \(p\), this is given by

\[
\prod_i m_i! i^{m_i}.
\]

Including the optional parameters \(t\) and \(q\) gives the \(q, t\) analog, which is the former product times

\[
\prod_{i=1}^{\text{length}(p)} \frac{1 - q^{p_i}}{1 - t^{p_i}}.
\]

See Section 1.3, p. 24, in [Ke1991].

\textbf{EXAMPLES}:

\begin{verbatim}
>>> Partition([2,2,1]).centralizer_size()
8
>>> Partition([2,2,2]).centralizer_size()
48
>>> Partition([2,2,1]).centralizer_size(q=2, t=3)
9/16
>>> Partition([ ]).centralizer_size()
1
>>> Partition([ ]).centralizer_size(q=2, t=4)
1
>>> from sage.all import *

>>> Partition([Integer(2),Integer(2),Integer(1)]).centralizer_size()
8
>>> Partition([Integer(2),Integer(2),Integer(2)]).centralizer_size()
48
>>> Partition([Integer(2),Integer(2),Integer(2)]).centralizer_size(q=Integer(2), t=Integer(3))
9/16
>>> Partition([ ]).centralizer_size()
1
>>> Partition([ ]).centralizer_size(q=Integer(2), t=Integer(4))
1
\end{verbatim}

\textbf{beta_numbers} \ (\textit{length}=None)

Return the set of beta numbers corresponding to \texttt{self}.

The optional argument \texttt{length} specifies the length of the beta set (which must be at least the length of \texttt{self}).

For more on beta numbers, see \textit{frobenius_coordinates}().

\textbf{EXAMPLES}:

\begin{verbatim}
sage: Partition([4,3,2]).beta_numbers()
[6, 4, 2]
sage: Partition([4,3,2]).beta_numbers(5)

\end{verbatim}
block \((e, \text{multicharge}=(0,))\)

Return a dictionary \(\beta\) that determines the block associated to the partition \(\text{self}\) and the \(\text{quantum_characteristic()}\) \(e\).

INPUT:

- \(e\) – the quantum characteristic

- \(\text{multicharge}\) – the multicharge (default \((0,)\))

OUTPUT:

- A dictionary giving the multiplicities of the residues in the partition tuple \(\text{self}\)

In more detail, the value \(\text{beta}[i]\) is equal to the number of nodes of residue \(i\). This corresponds to the positive root

\[
\sum_{i \in I} \beta_i \alpha_i \in Q^+,
\]

an element of the positive root lattice of the corresponding Kac-Moody algebra. See [DJM1998] and [BK2009] for more details.

This is a useful statistics because two Specht modules for a Hecke algebra of type \(A\) belong to the same block if and only if they correspond to same element \(\beta\) of the root lattice, given above.
We return a dictionary because when the quantum characteristic is 0, the Cartan type is $A_\infty$, in which case the simple roots are indexed by the integers.

**EXAMPLES:**

```python
sage: Partition([4,3,2]).block(0)
{-2: 1, -1: 2, 0: 2, 1: 2, 2: 1, 3: 1}
sage: Partition([4,3,2]).block(2)
{0: 4, 1: 5}
sage: Partition([4,3,2]).block(2, multicharge=(1,))
{0: 5, 1: 4}
sage: Partition([4,3,2]).block(3)
{0: 3, 1: 3, 2: 3}
sage: Partition([4,3,2]).block(4)
{0: 2, 1: 2, 2: 2, 3: 3}
```

```python
>>> from sage.all import *

>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(0))
{-2: 1, -1: 2, 0: 2, 1: 2, 2: 1, 3: 1}

>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(2))
{0: 4, 1: 5}

>>> Partition([Integer(4),Integer(3),Integer(2)]).block(Integer(2), multicharge=(Integer(1),))
{0: 5, 1: 4}
